`LIKE` performs case-insensitive substring matches if the collation for the expression and pattern is case-insensitive. For case-sensitive matches, declare either argument to use a binary collation using `COLLATE` , or coerce either of them to a `BINARY` string using `CAST` . Use `SHOW COLLATION` to get a list of available collations. Collations ending in `_bin` are case-sensitive.

Numeric arguments are coerced to binary strings.

The `_` wildcard matches a single character, not byte. It will only match a multi-byte character if it is valid in the expression's character set. For example, `_` will match `_utf8"€"` , but it will not match `_latin1"€"` because the Euro sign is not a valid latin1 character. If necessary, use `CONVERT` to use the expression in a different character set.

If you need to match the characters `_` or `%` , you must escape them. By default, you can prefix the wildcard characters the backslash character `\` to escape them. The backslash is used both to encode special characters like newlines when a string is parsed as well as to escape wildcards in a pattern after parsing. Thus, to match an actual backslash, you sometimes need to double-escape it as `"\ \ \ \"` .

To avoid difficulties with the backslash character, you can change the wildcard escape character using `ESCAPE` in a `LIKE` expression. The argument to `ESCAPE` must be a single-character string.

Examples

Select the days that begin with "T":

```
CREATE TABLE t1 (d VARCHAR(16));
INSERT INTO t1 VALUES
  ("Monday"), ("Tuesday"), ("Wednesday"),
  ("Thursday"), ("Friday"), ("Saturday"), ("Sunday");
SELECT * FROM t1 WHERE d LIKE "T%";
```

```
SELECT * FROM t1 WHERE d LIKE "T%";
+-----------+
| d         |
+-----------+
| Tuesday   |
| Thursday  |
+-----------+
```

Select the days that contain the substring "es":

```
SELECT * FROM t1 WHERE d LIKE "%es%";
```

```
SELECT * FROM t1 WHERE d LIKE "%es%";
+-----------+
| d         |
+-----------+
| Tuesday   |
| Wednesday |
+-----------+
```

Select the six-character day names:

```
SELECT * FROM t1 WHERE d like "___day";
```

```
SELECT * FROM t1 WHERE d like "___day";
+---------+
| d       |
+---------+
| Monday  |
| Friday  |
| Sunday  |
+---------+
```

With the default collations, `LIKE` is case-insensitive:

```
SELECT * FROM t1 where d like "t%";
```

```
SELECT * FROM t1 where d like "t%";
+----------+
| d        |
+----------+
| Tuesday  |
| Thursday |
+----------+
```

Use `COLLATE` to specify a binary collation, forcing case-sensitive matches:

```
SELECT * FROM t1 WHERE d like "t%" COLLATE latin1_bin;
```

```
SELECT * FROM t1 WHERE d like "t%" COLLATE latin1_bin;
Empty set (0.00 sec)
```

You can include functions and operators in the expression to match. Select dates based on their day name:

```
CREATE TABLE t2 (d DATETIME);
INSERT INTO t2 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
SELECT * FROM t2 WHERE DAYNAME(d) LIKE "T%";
```

```
SELECT * FROM t2 WHERE DAYNAME(d) LIKE "T%";
+------------------+
| d                |
+------------------+
| 2007-01-30 21:31 |
| 2011-04-21 12:34 |
| 2004-10-07 11:19 |
+------------------+
3 rows in set, 7 warnings (0.00 sec)
```

Optimizing LIKE

- MariaDB can use indexes for LIKE on string columns in the case where the LIKE doesn't start with `%` or `_`.
- Starting from MariaDB 10.0, one can set the optimizer_use_condition_selectivity variable to 5. If this is done, then the optimizer will read optimizer_selectivity_sampling_limit rows to calculate the selectivity of the LIKE expression before starting to calculate the query plan. This can help speed up some LIKE queries by providing the optimizer with more information about your data.

1.1.1.4.2.4.4 LOAD_FILE

1.2.2.31 LOCATE

Syntax

```
LOCATE(substr,str), LOCATE(substr,str,pos)
```

Description

The first syntax returns the position of the first occurrence of substring `substr` in string `str`. The second syntax returns the position of the first occurrence of substring `substr` in string `str`, starting at position `pos`. Returns 0 if `substr` is not in `str`.

`LOCATE()` performs a case-insensitive search.

If any argument is `NULL`, returns `NULL`.

INSTR() is the same as the two-argument form of `LOCATE()`, except that the order of the arguments is reversed.

Examples

```
SELECT LOCATE('bar', 'foobarbar');
+----------------------------+
| LOCATE('bar', 'foobarbar') |
+----------------------------+
|                          4 |
+----------------------------+

SELECT LOCATE('My', 'Maria');
+-----------------------+
| LOCATE('My', 'Maria') |
+-----------------------+
|                     0 |
+-----------------------+

SELECT LOCATE('bar', 'foobarbar', 5);
+-------------------------------+
| LOCATE('bar', 'foobarbar', 5) |
+-------------------------------+
|                             7 |
+-------------------------------+
```

1.2.2.32 LOWER

Syntax

```
LOWER(str)
LCASE(str)
```

Contents

Description

Returns the string `str` with all characters changed to lowercase according to the current character set mapping. The default is latin1 (cp1252 West European).

`LCASE` is a synonym for `LOWER`

Examples

```
 SELECT LOWER('QUADRATICALLY');
+------------------------+
| LOWER('QUADRATICALLY') |
+------------------------+
| quadratically          |
+------------------------+
```

`LOWER()` (and `UPPER()`) are ineffective when applied to binary strings (`BINARY`, `VARBINARY`, `BLOB`). To perform lettercase conversion, CONVERT the string to a non-binary string:

```
SET @str = BINARY 'North Carolina';

SELECT LOWER(@str), LOWER(CONVERT(@str USING latin1));
+----------------+-----------------------------------+
| LOWER(@str)    | LOWER(CONVERT(@str USING latin1)) |
+----------------+-----------------------------------+
| North Carolina | north carolina                    |
+----------------+-----------------------------------+
```

1.2.2.33 LPAD

Syntax

```
LPAD(str, len [,padstr])
```

Contents

Description

Returns the string `str`, left-padded with the string `padstr` to a length of `len` characters. If `str` is longer than `len`, the return value is shortened to `len` characters. If `padstr` is omitted, the LPAD function pads spaces.

Prior to MariaDB 10.3.1, the `padstr` parameter was mandatory.

Returns NULL if given a NULL argument. If the result is empty (zero length), returns either an empty string or, from MariaDB 10.3.6 with SQL_MODE=Oracle, NULL.

The Oracle mode version of the function can be accessed outside of Oracle mode by using `LPAD_ORACLE` as the function name.

Examples

```
SELECT LPAD('hello',10,'.');
+----------------------+
| LPAD('hello',10,'.') |
+----------------------+
| .....hello           |
+----------------------+

SELECT LPAD('hello',2,'.');
+--------------------+
| LPAD('hello',2,'.') |
+--------------------+
| he                 |
+--------------------+
```

From MariaDB 10.3.1, with the pad string defaulting to space.

```
SELECT LPAD('hello',10);
+------------------+
| LPAD('hello',10) |
+------------------+
|      hello       |
+------------------+
```

Oracle mode version from MariaDB 10.3.6:

```
SELECT LPAD('',0),LPAD_ORACLE('',0);
+-----------+-------------------+
| LPAD('',0) | LPAD_ORACLE('',0) |
+-----------+-------------------+
|           | NULL              |
+-----------+-------------------+
```

1.2.2.34 LTRIM

Syntax

```
LTRIM(str)
```

Contents

Description

Returns the string `str` with leading space characters removed.

Returns NULL if given a NULL argument. If the result is empty, returns either an empty string, or, from MariaDB 10.3.6 with SQL_MODE=Oracle, NULL.

The Oracle mode version of the function can be accessed outside of Oracle mode by using `LTRIM_ORACLE` as the function name.

Examples

```
SELECT QUOTE(LTRIM('   MariaDB   '));
+-------------------------------+
| QUOTE(LTRIM('   MariaDB   ')) |
+-------------------------------+
| 'MariaDB   '                  |
+-------------------------------+
```

Oracle mode version from MariaDB 10.3.6:

```
SELECT LTRIM(''),LTRIM_ORACLE('');
+-----------+-----------------+
| LTRIM('') | LTRIM_ORACLE('') |
+-----------+-----------------+
|           | NULL            |
+-----------+-----------------+
```

1.2.2.35 MAKE_SET

Syntax

```
MAKE_SET(bits,str1,str2,...)
```

Description

Returns a set value (a string containing substrings separated by "," characters) consisting of the strings that have the corresponding bit in bits set. *str1* corresponds to bit 0, *str2* to bit 1, and so on. NULL values in *str1*, *str2*, ... are not appended to the result.

Examples

```
SELECT MAKE_SET(1,'a','b','c');
+------------------------+
| MAKE_SET(1,'a','b','c') |
+------------------------+
| a                      |
+------------------------+

SELECT MAKE_SET(1 | 4,'hello','nice','world');
+-------------------------------------+
| MAKE_SET(1 | 4,'hello','nice','world') |
+-------------------------------------+
| hello,world                         |
+-------------------------------------+

SELECT MAKE_SET(1 | 4,'hello','nice',NULL,'world');
+-----------------------------------------+
| MAKE_SET(1 | 4,'hello','nice',NULL,'world') |
+-----------------------------------------+
| hello                                   |
+-----------------------------------------+

SELECT QUOTE(MAKE_SET(0,'a','b','c'));
+--------------------------------+
| QUOTE(MAKE_SET(0,'a','b','c')) |
+--------------------------------+
| ''                             |
+--------------------------------+
```

1.2.2.36 MATCH AGAINST

Syntax

```
MATCH (col1,col2,...) AGAINST (expr [search_modifier])
```

Description

A special construct used to perform a fulltext search on a fulltext index.

See Fulltext Index Overview for a full description, and Full-text Indexes for more articles on the topic.

Examples

```
CREATE TABLE ft_myisam(copy TEXT,FULLTEXT(copy)) ENGINE=MyISAM;

INSERT INTO ft_myisam(copy) VALUES ('Once upon a time'), ('There was a wicked witch'),
 ('Who ate everybody up');

SELECT * FROM ft_myisam WHERE MATCH(copy) AGAINST('wicked');
+--------------------------+
| copy                     |
+--------------------------+
| There was a wicked witch |
+--------------------------+
```

```
SELECT id, body, MATCH (title,body) AGAINST
    ('Security implications of running MySQL as root'
    IN NATURAL LANGUAGE MODE) AS score
    FROM articles WHERE MATCH (title,body) AGAINST
    ('Security implications of running MySQL as root'
    IN NATURAL LANGUAGE MODE);
+----+-------------------------------------+-----------------+
| id | body                                | score           |
+----+-------------------------------------+-----------------+
|  4 | 1. Never run mysqld as root. 2. ... | 1.5219271183014 |
|  6 | When configured properly, MySQL ... | 1.3114095926285 |
+----+-------------------------------------+-----------------+
```

3.3.3.3.2 Full-Text Index Stopwords

1.2.2.38 MID

Syntax

```
MID(str,pos,len)
```

Description

MID(str,pos,len) is a synonym for SUBSTRING(str,pos,len).

Examples

```
SELECT MID('abcd',4,1);
+-----------------+
| MID('abcd',4,1) |
+-----------------+
| d               |
+-----------------+

SELECT MID('abcd',2,2);
+-----------------+
| MID('abcd',2,2) |
+-----------------+
| bc              |
+-----------------+
```

A negative starting position:

```
SELECT MID('abcd',-2,4);
+------------------+
| MID('abcd',-2,4) |
+------------------+
| cd               |
+------------------+
```

1.2.2.39 NATURAL_SORT_KEY

MariaDB starting with 10.7.0

NATURAL_SORT_KEY was added in MariaDB 10.7.0.

Syntax

```
NATURAL_SORT_KEY(str)
```

Contents

Description

The `NATURAL_SORT_KEY` function is used for sorting that is closer to natural sorting. Strings are sorted in alphabetical order, while numbers are treated in a way such that, for example, `10` is greater than `2`, whereas in other forms of sorting, `2` would be greater than `10`, just like `z` is greater than `ya`.

There are multiple natural sort implementations, differing in the way they handle leading zeroes, fractions, i18n, negatives, decimals and so on.

MariaDB's implementation ignores leading zeroes when performing the sort.

You can use also use `NATURAL_SORT_KEY` with generated columns. The value is not stored permanently in the table. When using a generated column, the virtual column must be longer than the base column to cater for embedded numbers in the string and MDEV-24582.

Examples

Strings and Numbers

```
CREATE TABLE t1 (c TEXT);

INSERT INTO t1 VALUES ('b1'),('a2'),('a11'),('a1');

SELECT c FROM t1;
+------+
| c    |
+------+
| b1   |
| a2   |
| a11  |
| a1   |
+------+

SELECT c FROM t1 ORDER BY c;
+------+
| c    |
+------+
| a1   |
| a11  |
| a2   |
| b1   |
+------+
```

Unsorted, regular sort and natural sort:

```
TRUNCATE t1;

INSERT INTO t1 VALUES
  ('5.5.31'),('10.7.0'),('10.2.1'),
  ('10.1.22'),('10.3.32'),('10.2.12');

SELECT c FROM t1;
+---------+
| c       |
+---------+
| 5.5.31  |
| 10.7.0  |
| 10.2.1  |
| 10.1.22 |
| 10.3.32 |
| 10.2.12 |
+---------+

SELECT c FROM t1 ORDER BY c;
+---------+
| c       |
+---------+
| 10.1.22 |
| 10.2.1  |
| 10.2.12 |
| 10.3.32 |
| 10.7.0  |
| 5.5.31  |
+---------+

SELECT c FROM t1 ORDER BY NATURAL_SORT_KEY(c);
+---------+
| c       |
+---------+
| 5.5.31  |
| 10.1.22 |
| 10.2.1  |
| 10.2.12 |
| 10.3.32 |
| 10.7.0  |
+---------+
```

IPs

Sorting IPs, unsorted, regular sort and natural sort::

```
TRUNCATE t1;

INSERT INTO t1 VALUES
  ('192.167.3.1'),('192.167.1.12'),('100.200.300.400'),
  ('100.50.60.70'),('100.8.9.9'),('127.0.0.1'),('0.0.0.0');

SELECT c FROM t1;
+-----------------+
| c               |
+-----------------+
| 192.167.3.1     |
| 192.167.1.12    |
| 100.200.300.400 |
| 100.50.60.70    |
| 100.8.9.9       |
| 127.0.0.1       |
| 0.0.0.0         |
+-----------------+

SELECT c FROM t1 ORDER BY c;
+-----------------+
| c               |
+-----------------+
| 0.0.0.0         |
| 100.200.300.400 |
| 100.50.60.70    |
| 100.8.9.9       |
| 127.0.0.1       |
| 192.167.1.12    |
| 192.167.3.1     |
+-----------------+

SELECT c FROM t1 ORDER BY NATURAL_SORT_KEY(c);
+-----------------+
| c               |
+-----------------+
| 0.0.0.0         |
| 100.8.9.9       |
| 100.50.60.70    |
| 100.200.300.400 |
| 127.0.0.1       |
| 192.167.1.12    |
| 192.167.3.1     |
+-----------------+
```

Generated Columns

Using with a generated column:

```
CREATE TABLE t(c VARCHAR(3), k VARCHAR(4) AS (NATURAL_SORT_KEY(c)) INVISIBLE);

INSERT INTO t(c) VALUES ('b1'),('a2'),('a11'),('a10');

SELECT * FROM t ORDER by k;
+------+
| c    |
+------+
| a2   |
| a10  |
| a11  |
| b1   |
+------+
```

Note that if the virtual column is not longer, results may not be as expected:

```
CREATE TABLE t2(c VARCHAR(3), k VARCHAR(3) AS (NATURAL_SORT_KEY(c)) INVISIBLE);

INSERT INTO t2(c) VALUES ('b1'),('a2'),('a11'),('a10');

SELECT * FROM t2 ORDER by k;
+------+
| c    |
+------+
| a2   |
| a11  |
| a10  |
| b1   |
+------+
```

Leading Zeroes

Ignoring leading zeroes can lead to undesirable results in certain contexts. For example:

```
CREATE TABLE t3 (a VARCHAR(4));

INSERT INTO t3 VALUES
  ('a1'), ('a001'), ('a10'), ('a001'), ('a10'),
  ('a01'), ('a01'), ('a01b'), ('a01b'), ('a1');

SELECT a FROM t3 ORDER BY a;
+------+
| a    |
+------+
| a001 |
| a001 |
| a01  |
| a01  |
| a01b |
| a01b |
| a1   |
| a1   |
| a10  |
| a10  |
+------+
10 rows in set (0.000 sec)

SELECT a FROM t3 ORDER BY NATURAL_SORT_KEY(a);
+------+
| a    |
+------+
| a1   |
| a01  |
| a01  |
| a001 |
| a001 |
| a1   |
| a01b |
| a01b |
| a10  |
| a10  |
+------+
```

This may not be what we were hoping for in a 'natural' sort. A workaround is to sort by both NATURAL_SORT_KEY and regular sort.

```
SELECT a FROM t3 ORDER BY NATURAL_SORT_KEY(a), a;
+------+
| a    |
+------+
| a001 |
| a001 |
| a01  |
| a01  |
| a1   |
| a1   |
| a01b |
| a01b |
| a10  |
| a10  |
+------+
```

1.2.2.40 NOT LIKE

Syntax

```
expr NOT LIKE pat [ESCAPE 'escape_char']
```

Description

This is the same as NOT (expr LIKE pat [ESCAPE 'escape_char']).

1.2.2.1.3 NOT REGEXP

1.2.2.42 OCTET_LENGTH

Syntax

```
OCTET_LENGTH(str)
```

Description

`OCTET_LENGTH()` returns the length of the given string, in octets (bytes). This is a synonym for LENGTHB(), and, when Oracle mode from MariaDB 10.3 is not set, a synonym for LENGTH().

A multi-byte character counts as multiple bytes. This means that for a string containing five two-byte characters, `OCTET_LENGTH()` returns 10, whereas CHAR_LENGTH() returns 5.

If `str` is not a string value, it is converted into a string. If `str` is `NULL`, the function returns `NULL`.

Examples

When Oracle mode from MariaDB 10.3 is not set:

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');
+-------------------+--------------+---------------+--------------------+
| CHAR_LENGTH('π')  | LENGTH('π')  | LENGTHB('π')  | OCTET_LENGTH('π')  |
+-------------------+--------------+---------------+--------------------+
|                 1 |            2 |             2 |                  2 |
+-------------------+--------------+---------------+--------------------+
```

In Oracle mode from MariaDB 10.3:

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');
+------------------+--------------+---------------+--------------------+
| CHAR_LENGTH('π') | LENGTH('π')  | LENGTHB('π')  | OCTET_LENGTH('π')  |
+------------------+--------------+---------------+--------------------+
|                1 |            1 |             2 |                  2 |
+------------------+--------------+---------------+--------------------+
```

1.2.2.43 ORD

Syntax

```
ORD(str)
```

Description

If the leftmost character of the string `str` is a multi-byte character, returns the code for that character, calculated from the numeric values of its constituent bytes using this formula:

```
  (1st byte code)
+ (2nd byte code x 256)
+ (3rd byte code x 256 x 256) ...
```

If the leftmost character is not a multi-byte character, ORD() returns the same value as the ASCII() function.

Examples

```
SELECT ORD('2');
+----------+
| ORD('2') |
+----------+
|       50 |
+----------+
```

1.2.2.44 POSITION

Syntax

```
POSITION(substr IN str)
```

Description

POSITION(substr IN str) is a synonym for LOCATE(substr,str).

It's part of ODBC 3.0.

1.2.2.45 QUOTE

Syntax

```
QUOTE(str)
```

Description

Quotes a string to produce a result that can be used as a properly escaped data value in an SQL statement. The string is returned enclosed by single quotes and with each instance of single quote (" ' "), backslash (" \ "), `ASCII NUL`, and Control-Z preceded by a backslash. If the argument is `NULL`, the return value is the word " `NULL` " without enclosing single quotes.

Examples

```
SELECT QUOTE("Don't!");
+-----------------+
| QUOTE("Don't!") |
+-----------------+
| 'Don\'t!'       |
+-----------------+

SELECT QUOTE(NULL);
+-------------+
| QUOTE(NULL) |
+-------------+
| NULL        |
+-------------+
```

1.2.2.46 REPEAT Function

Syntax

```
REPEAT(str,count)
```

Description

Returns a string consisting of the string `str` repeated `count` times. If `count` is less than 1, returns an empty string. Returns NULL if `str` or `count` are NULL.

Examples

```
SELECT QUOTE(REPEAT('MariaDB ',4));
+-----------------------------------+
| QUOTE(REPEAT('MariaDB ',4))       |
+-----------------------------------+
| 'MariaDB MariaDB MariaDB MariaDB ' |
+-----------------------------------+
```

1.2.2.47 REPLACE Function

Syntax

```
REPLACE(str,from_str,to_str)
```

Description

Returns the string `str` with all occurrences of the string `from_str` replaced by the string `to_str`. REPLACE() performs a case-sensitive match when searching for `from_str`.

Examples

```
SELECT REPLACE('www.mariadb.org', 'w', 'Ww');
+--------------------------------------+
| REPLACE('www.mariadb.org', 'w', 'Ww') |
+--------------------------------------+
| WwWwWw.mariadb.org                   |
+--------------------------------------+
```

1.2.2.48 REVERSE

Syntax

```
REVERSE(str)
```

Description

Returns the string `str` with the order of the characters reversed.

Examples

```
SELECT REVERSE('desserts');
+---------------------+
| REVERSE('desserts') |
+---------------------+
| stressed            |
+---------------------+
```

1.2.2.49 RIGHT

Syntax

```
RIGHT(str,len)
```

Description

Returns the rightmost *`len`* characters from the string *`str`*, or NULL if any argument is NULL.

Examples

```
SELECT RIGHT('MariaDB', 2);
+---------------------+
| RIGHT('MariaDB', 2) |
+---------------------+
| DB                  |
+---------------------+
```

1.2.2.50 RPAD

Syntax

```
RPAD(str, len [, padstr])
```

Contents

Description

Returns the string `str`, right-padded with the string `padstr` to a length of `len` characters. If `str` is longer than `len`, the return value is shortened to `len` characters. If `padstr` is omitted, the RPAD function pads spaces.

Prior to MariaDB 10.3.1, the `padstr` parameter was mandatory.

Returns NULL if given a NULL argument. If the result is empty (a length of zero), returns either an empty string, or, from MariaDB 10.3.6 with SQL_MODE=Oracle, NULL.

The Oracle mode version of the function can be accessed outside of Oracle mode by using `RPAD_ORACLE` as the function name.

Examples

```
SELECT RPAD('hello',10,'.');
+----------------------+
| RPAD('hello',10,'.') |
+----------------------+
| hello.....           |
+----------------------+

SELECT RPAD('hello',2,'.');
+---------------------+
| RPAD('hello',2,'.') |
+---------------------+
| he                  |
+---------------------+
```

From MariaDB 10.3.1, with the pad string defaulting to space.

```
SELECT RPAD('hello',30);
+--------------------------------+
| RPAD('hello',30)               |
+--------------------------------+
| hello                          |
+--------------------------------+
```

Oracle mode version from MariaDB 10.3.6:

```
SELECT RPAD('',0),RPAD_ORACLE('',0);
+------------+-------------------+
| RPAD('',0) | RPAD_ORACLE('',0) |
+------------+-------------------+
|            | NULL              |
+------------+-------------------+
```

1.2.2.51 RTRIM

Syntax

```
RTRIM(str)
```

Contents

Description

Returns the string `str` with trailing space characters removed.

Returns NULL if given a NULL argument. If the result is empty, returns either an empty string, or, from MariaDB 10.3.6 with SQL_MODE=Oracle, NULL.

The Oracle mode version of the function can be accessed outside of Oracle mode by using `RTRIM_ORACLE` as the function name.

Examples

```
SELECT QUOTE(RTRIM('MariaDB    '));
+-----------------------------+
| QUOTE(RTRIM('MariaDB    ')) |
+-----------------------------+
| 'MariaDB'                   |
+-----------------------------+
```

Oracle mode version from MariaDB 10.3.6:

```
SELECT RTRIM(''),RTRIM_ORACLE('');
+-----------+------------------+
| RTRIM('') | RTRIM_ORACLE('') |
+-----------+------------------+
|           | NULL             |
+-----------+------------------+
```

1.2.2.52 SFORMAT

MariaDB starting with 10.7.0
SFORMAT was added in MariaDB 10.7.0.

Description

The `SFORMAT` function takes an input string and a formatting specification and returns the string formatted using the rules the user passed in the specification.

It uses the fmtlib library for Python-like (as well as Rust, C++20, etc) string formatting.

Only fmtlib 7.0.0+ is supported.

There is no native support for temporal and decimal values:

- TIME_RESULT is handled as STRING_RESULT
- DECIMAL_RESULT as REAL_RESULT

Examples

```
SELECT SFORMAT("The answer is {}.", 42);
+---------------------------------+
| SFORMAT("The answer is {}.", 42) |
+---------------------------------+
| The answer is 42.               |
+---------------------------------+

CREATE TABLE test_sformat(mdb_release char(6), mdev int, feature char(20));

INSERT INTO test_sformat VALUES('10.7.0', 25015, 'Python style sformat'),
  ('10.7.0', 4958, 'UUID');

SELECT * FROM test_sformat;
+-------------+-------+----------------------+
| mdb_release | mdev  | feature              |
+-------------+-------+----------------------+
| 10.7.0      | 25015 | Python style sformat |
| 10.7.0      |  4958 | UUID                 |
+-------------+-------+----------------------+

SELECT SFORMAT('MariaDB Server {} has a preview for MDEV-{} which is about {}',
  mdb_release, mdev, feature) AS 'Preview Release Examples'
  FROM test_sformat;
+-----------------------------------------------------------------------------------------+
| Preview Release Examples                                                                |
+-----------------------------------------------------------------------------------------+
| MariaDB Server 10.7.0 has a preview for MDEV-25015 which is about Python style sformat |
| MariaDB Server 10.7.0 has a preview for MDEV-4958 which is about UUID                   |
+-----------------------------------------------------------------------------------------+
```

1.2.2.53 SOUNDEX

Syntax

```
SOUNDEX(str)
```

Description

Returns a soundex string from *str*. Two strings that sound almost the same should have identical soundex strings. A standard soundex string is four characters long, but the `SOUNDEX()` function returns an arbitrarily long string. You can use `SUBSTRING()` on the result to get a standard soundex string. All non-alphabetic characters in *str* are ignored. All international alphabetic characters outside the A-Z range are treated as vowels.

Important: When using SOUNDEX(), you should be aware of the following details:

- This function, as currently implemented, is intended to work well with strings that are in the English language only. Strings in other languages may not produce reasonable results.
- This function implements the original Soundex algorithm, not the more popular enhanced version (also described by D. Knuth). The difference is that original version discards vowels first and duplicates second, whereas the enhanced version discards duplicates first and vowels second.

Examples

```
SOUNDEX('Hello');
+------------------+
| SOUNDEX('Hello') |
+------------------+
| H400             |
+------------------+
```

```
SELECT SOUNDEX('MariaDB');
+--------------------+
| SOUNDEX('MariaDB') |
+--------------------+
| M631               |
+--------------------+
```

```
SELECT SOUNDEX('Knowledgebase');
+--------------------------+
| SOUNDEX('Knowledgebase') |
+--------------------------+
| K543212                  |
+--------------------------+
```

```
SELECT givenname, surname FROM users WHERE SOUNDEX(givenname) = SOUNDEX("robert");
+-----------+---------+
| givenname | surname |
+-----------+---------+
| Roberto   | Castro  |
+-----------+---------+
```

1.2.2.54 SOUNDS LIKE

Syntax

```
expr1 SOUNDS LIKE expr2
```

Description

This is the same as `SOUNDEX(expr1) = SOUNDEX(expr2)`.

Example

```
SELECT givenname, surname FROM users WHERE givenname SOUNDS LIKE "robert";
+-----------+---------+
| givenname | surname |
+-----------+---------+
| Roberto   | Castro  |
+-----------+---------+
```

1.2.2.55 SPACE

Syntax

```
SPACE(N)
```

Description

Returns a string consisting of *N* space characters. If `N` is NULL, returns NULL.

Examples

```
SELECT QUOTE(SPACE(6));
+-----------------+
| QUOTE(SPACE(6)) |
+-----------------+
| '      '        |
+-----------------+
```

1.2.2.56 STRCMP

Syntax

```
STRCMP(expr1,expr2)
```

Description

`STRCMP()` returns `0` if the strings are the same, `-1` if the first argument is smaller than the second according to the current sort order, and `1` if the strings are otherwise not the same. Returns `NULL` is either argument is `NULL`.

Examples

```
SELECT STRCMP('text', 'text2');
+-------------------------+
| STRCMP('text', 'text2') |
+-------------------------+
|                      -1 |
+-------------------------+

SELECT STRCMP('text2', 'text');
+-------------------------+
| STRCMP('text2', 'text') |
+-------------------------+
|                       1 |
+-------------------------+

SELECT STRCMP('text', 'text');
+-----------------------+
| STRCMP('text', 'text') |
+-----------------------+
|                     0 |
+-----------------------+
```

1.2.2.57 SUBSTR

Description

`SUBSTR()` is a synonym for `SUBSTRING()`.

1.2.2.58 SUBSTRING

Syntax

```
SUBSTRING(str,pos),
SUBSTRING(str FROM pos),
SUBSTRING(str,pos,len),
SUBSTRING(str FROM pos FOR len)

SUBSTR(str,pos),
SUBSTR(str FROM pos),
SUBSTR(str,pos,len),
SUBSTR(str FROM pos FOR len)
```

Contents

Description

The forms without a *len* argument return a substring from string *str* starting at position *pos*.

The forms with a *len* argument return a substring *len* characters long from string *str*, starting at position *pos*.

The forms that use *FROM* are standard SQL syntax.

It is also possible to use a negative value for *pos*. In this case, the beginning of the substring is *pos* characters from the end of the string, rather than the beginning. A negative value may be used for *pos* in any of the forms of this function.

By default, the position of the first character in the string from which the substring is to be extracted is reckoned as 1. For Oracle-compatibility, from MariaDB 10.3.3, when sql_mode is set to 'oracle', position zero is treated as position 1 (although the first character is still reckoned as 1).

If any argument is `NULL`, returns `NULL`.

Examples

```
SELECT SUBSTRING('Knowledgebase',5);
+-----------------------------+
| SUBSTRING('Knowledgebase',5) |
+-----------------------------+
| ledgebase                   |
+-----------------------------+

SELECT SUBSTRING('MariaDB' FROM 6);
+----------------------------+
| SUBSTRING('MariaDB' FROM 6) |
+----------------------------+
| DB                         |
+----------------------------+

SELECT SUBSTRING('Knowledgebase',3,7);
+-------------------------------+
| SUBSTRING('Knowledgebase',3,7) |
+-------------------------------+
| owledge                       |
+-------------------------------+

SELECT SUBSTRING('Knowledgebase', -4);
+--------------------------------+
| SUBSTRING('Knowledgebase', -4) |
+--------------------------------+
| base                           |
+--------------------------------+

SELECT SUBSTRING('Knowledgebase', -8, 4);
+-----------------------------------+
| SUBSTRING('Knowledgebase', -8, 4) |
+-----------------------------------+
| edge                              |
+-----------------------------------+

SELECT SUBSTRING('Knowledgebase' FROM -8 FOR 4);
+-----------------------------------------+
| SUBSTRING('Knowledgebase' FROM -8 FOR 4) |
+-----------------------------------------+
| edge                                    |
+-----------------------------------------+
```

Oracle mode from MariaDB 10.3.3:

```
SELECT SUBSTR('abc',0,3);
+------------------+
| SUBSTR('abc',0,3) |
+------------------+
|                  |
+------------------+

SELECT SUBSTR('abc',1,2);
+------------------+
| SUBSTR('abc',1,2) |
+------------------+
| ab               |
+------------------+

SET sql_mode='oracle';

SELECT SUBSTR('abc',0,3);
+------------------+
| SUBSTR('abc',0,3) |
+------------------+
| abc              |
+------------------+

SELECT SUBSTR('abc',1,2);
+------------------+
| SUBSTR('abc',1,2) |
+------------------+
| ab               |
+------------------+
```

1.2.2.59 SUBSTRING_INDEX

Syntax

```
SUBSTRING_INDEX(str,delim,count)
```

Contents

Description

Returns the substring from string *str* before count occurrences of the delimiter *delim*. If *count* is positive, everything to the left of the final delimiter (counting from the left) is returned. If *count* is negative, everything to the right of the final delimiter (counting from the right) is returned. SUBSTRING_INDEX() performs a case-sensitive match when searching for *delim*.

If any argument is NULL, returns NULL.

For example

```
SUBSTRING_INDEX('www.mariadb.org', '.', 2)
```

means "Return all of the characters up to the 2nd occurrence of ."

Examples

```
SELECT SUBSTRING_INDEX('www.mariadb.org', '.', 2);
+--------------------------------------------+
| SUBSTRING_INDEX('www.mariadb.org', '.', 2) |
+--------------------------------------------+
| www.mariadb                                |
+--------------------------------------------+

SELECT SUBSTRING_INDEX('www.mariadb.org', '.', -2);
+---------------------------------------------+
| SUBSTRING_INDEX('www.mariadb.org', '.', -2) |
+---------------------------------------------+
| mariadb.org                                 |
+---------------------------------------------+
```

1.2.2.60 TO_BASE64

Syntax

```
TO_BASE64(str)
```

Description

Converts the string argument `str` to its base-64 encoded form, returning the result as a character string in the connection character set and collation.

The argument `str` will be converted to string first if it is not a string. A NULL argument will return a NULL result.

The reverse function, FROM_BASE64(), decodes an encoded base-64 string.

There are a numerous different methods to base-64 encode a string. The following are used by MariaDB and MySQL:

- Alphabet value 64 is encoded as '+'.
- Alphabet value 63 is encoded as '/'.
- Encoding output is made up of groups of four printable characters, with each three bytes of data encoded using four characters. If the final group is not complete, it is padded with '=' characters to make up a length of four.
- To divide long output, a newline is added after every 76 characters.
- Decoding will recognize and ignore newlines, carriage returns, tabs, and spaces.

Examples

```
SELECT TO_BASE64('Maria');
+--------------------+
| TO_BASE64('Maria') |
+--------------------+
| TWFyaWE=           |
+--------------------+
```

1.2.2.61 TO_CHAR

MariaDB starting with 10.6.1

The TO_CHAR function was introduced in MariaDB 10.6.1 to enhance Oracle compatibility.

Syntax

```
TO_CHAR(expr[, fmt])
```

Contents

Description

The `TO_CHAR` function converts an *expr* of type date, datetime, time or timestamp to a string. The optional *fmt* argument supports YYYY/YYY/YY/RRRR/RR/MM/MON/MONTH/MI/DD/DY/HH/HH12/HH24/SS and special characters. The default value is "YYYY-MM-DD HH24:MI:SS".

In Oracle, TO_CHAR can also be used to convert numbers to strings, but this is not supported in MariaDB and will give an error.

Examples

```
SELECT TO_CHAR('1980-01-11 04:50:39', 'YYYY-MM-DD');
+-------------------------------------------+
| TO_CHAR('1980-01-11 04:50:39', 'YYYY-MM-DD') |
+-------------------------------------------+
| 1980-01-11                                |
+-------------------------------------------+

SELECT TO_CHAR('1980-01-11 04:50:39', 'HH24-MI-SS');
+-------------------------------------------+
| TO_CHAR('1980-01-11 04:50:39', 'HH24-MI-SS') |
+-------------------------------------------+
| 04-50-39                                  |
+-------------------------------------------+

SELECT TO_CHAR('00-01-01 00:00:00', 'YY-MM-DD HH24:MI:SS');
+-----------------------------------------------------+
| TO_CHAR('00-01-01 00:00:00', 'YY-MM-DD HH24:MI:SS') |
+-----------------------------------------------------+
| 00-01-01 00:00:00                                   |
+-----------------------------------------------------+

SELECT TO_CHAR('99-12-31 23:59:59', 'YY-MM-DD HH24:MI:SS');
+-----------------------------------------------------+
| TO_CHAR('99-12-31 23:59:59', 'YY-MM-DD HH24:MI:SS') |
+-----------------------------------------------------+
| 99-12-31 23:59:59                                   |
+-----------------------------------------------------+

SELECT TO_CHAR('9999-12-31 23:59:59', 'YY-MM-DD HH24:MI:SS');
+-----------------------------------------------------+
| TO_CHAR('9999-12-31 23:59:59', 'YY-MM-DD HH24:MI:SS') |
+-----------------------------------------------------+
| 99-12-31 23:59:59                                    |
+-----------------------------------------------------+

SELECT TO_CHAR('21-01-03 08:30:00', 'Y-MONTH-DY HH:MI:SS');
+-----------------------------------------------------+
| TO_CHAR('21-01-03 08:30:00', 'Y-MONTH-DY HH:MI:SS') |
+-----------------------------------------------------+
| 1-January  -Sun 08:30:00                            |
+-----------------------------------------------------+
```

1.2.2.62 TRIM

Syntax

```
TRIM([{BOTH | LEADING | TRAILING} [remstr] FROM] str), TRIM([remstr FROM] str)
```

From MariaDB 10.3.6

```
TRIM_ORACLE([{BOTH | LEADING | TRAILING} [remstr] FROM] str), TRIM([remstr FROM] str)
```

Contents

Description

Returns the string `str` with all `remstr` prefixes or suffixes removed. If none of the specifiers `BOTH`, `LEADING`, or `TRAILING` is given, `BOTH` is assumed. `remstr` is optional and, if not specified, spaces are removed.

Returns NULL if given a NULL argument. If the result is empty, returns either an empty string, or, from MariaDB 10.3.6 with SQL_MODE=Oracle, NULL. `SQL_MODE=Oracle` is not set by default.

The Oracle mode version of the function can be accessed in any mode by using `TRIM_ORACLE` as the function name.

Examples

```
SELECT TRIM('  bar   ')\G
*************************** 1. row ***************************
TRIM('  bar   '): bar

SELECT TRIM(LEADING 'x' FROM 'xxxbarxxx')\G
*************************** 1. row ***************************
TRIM(LEADING 'x' FROM 'xxxbarxxx'): barxxx

SELECT TRIM(BOTH 'x' FROM 'xxxbarxxx')\G
*************************** 1. row ***************************
TRIM(BOTH 'x' FROM 'xxxbarxxx'): bar

SELECT TRIM(TRAILING 'xyz' FROM 'barxxyz')\G
*************************** 1. row ***************************
TRIM(TRAILING 'xyz' FROM 'barxxyz'): barx
```

From MariaDB 10.3.6, with SQL_MODE=Oracle not set:

```
SELECT TRIM(''),TRIM_ORACLE('');
+----------+-----------------+
| TRIM('') | TRIM_ORACLE('') |
+----------+-----------------+
|          | NULL            |
+----------+-----------------+
```

From MariaDB 10.3.6, with SQL_MODE=Oracle set:

```
SELECT TRIM(''),TRIM_ORACLE('');
+----------+-----------------+
| TRIM('') | TRIM_ORACLE('') |
+----------+-----------------+
| NULL     | NULL            |
+----------+-----------------+
```

1.2.2.63 TRIM_ORACLE

MariaDB starting with 10.3.6

`TRIM_ORACLE` is a synonym for the Oracle mode version of the TRIM function, and is available in all modes.

1.2.2.64 UCASE

Syntax

```
UCASE(str)
```

Description

`UCASE()` is a synonym for `UPPER()`.

1.2.2.65 UNCOMPRESS

Syntax

```
UNCOMPRESS(string_to_uncompress)
```

Description

Uncompresses a string compressed by the `COMPRESS()` function. If the argument is not a compressed value, the result is `NULL`. This function requires MariaDB to have been compiled with a compression library such as zlib. Otherwise, the return value is always `NULL`. The have_compress server system variable indicates whether a compression library is present.

Examples

```
SELECT UNCOMPRESS(COMPRESS('a string'));
+----------------------------------+
| UNCOMPRESS(COMPRESS('a string')) |
+----------------------------------+
| a string                         |
+----------------------------------+

SELECT UNCOMPRESS('a string');
+------------------------+
| UNCOMPRESS('a string') |
+------------------------+
| NULL                   |
+------------------------+
```

1.2.2.66 UNCOMPRESSED_LENGTH

Syntax

```
UNCOMPRESSED_LENGTH(compressed_string)
```

Description

Returns the length that the compressed string had before being compressed with `COMPRESS()`.

`UNCOMPRESSED_LENGTH()` returns `NULL` or an incorrect result if the string is not compressed.

Until MariaDB 10.3.1, returns `MYSQL_TYPE_LONGLONG`, or bigint(10), in all cases. From MariaDB 10.3.1, returns `MYSQL_TYPE_LONG`, or int(10), when the result would fit within 32-bits.

Examples

```
SELECT UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a',30)));
+-----------------------------------------------+
| UNCOMPRESSED_LENGTH(COMPRESS(REPEAT('a',30))) |
+-----------------------------------------------+
|                                            30 |
+-----------------------------------------------+
```

1.2.2.67 UNHEX

Syntax

```
UNHEX(str)
```

Description

Performs the inverse operation of HEX(str). That is, it interprets each pair of hexadecimal digits in the argument as a number and converts it to the character represented by the number. The resulting characters are returned as a binary string.

If `str` is `NULL`, `UNHEX()` returns `NULL`.

Examples

```
SELECT HEX('MariaDB');
+----------------+
| HEX('MariaDB') |
+----------------+
| 4D617269614442 |
+----------------+

SELECT UNHEX('4D617269614442');
+-------------------------+
| UNHEX('4D617269614442') |
+-------------------------+
| MariaDB                 |
+-------------------------+

SELECT 0x4D617269614442;
+------------------+
| 0x4D617269614442 |
+------------------+
| MariaDB          |
+------------------+

SELECT UNHEX(HEX('string'));
+----------------------+
| UNHEX(HEX('string')) |
+----------------------+
| string               |
+----------------------+

SELECT HEX(UNHEX('1267'));
+--------------------+
| HEX(UNHEX('1267')) |
+--------------------+
| 1267               |
+--------------------+
```

1.2.2.68 UPDATEXML

Syntax

```
UpdateXML(xml_target, xpath_expr, new_xml)
```

Description

This function replaces a single portion of a given fragment of XML markup `xml_target` with a new XML fragment `new_xml`, and then returns the changed XML. The portion of `xml_target` that is replaced matches an XPath expression `xpath_expr` supplied by the user. If no expression matching `xpath_expr` is found, or if multiple matches are found, the function returns the original `xml_target` XML fragment. All three arguments should be strings.

Examples

```
SELECT
    UpdateXML('<a><b>ccc</b><d></d></a>', '/a', '<e>fff</e>') AS val1,
    UpdateXML('<a><b>ccc</b><d></d></a>', '/b', '<e>fff</e>') AS val2,
    UpdateXML('<a><b>ccc</b><d></d></a>', '//b', '<e>fff</e>') AS val3,
    UpdateXML('<a><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val4,
    UpdateXML('<a><d></d><b>ccc</b><d></d></a>', '/a/d', '<e>fff</e>') AS val5
    \G
*************************** 1. row ***************************
val1: <e>fff</e>
val2: <a><b>ccc</b><d></d></a>
val3: <a><e>fff</e><d></d></a>
val4: <a><b>ccc</b><e>fff</e></a>
val5: <a><d></d><b>ccc</b><d></d></a>
1 row in set (0.00 sec)
```

1.2.2.69 UPPER

Syntax

```
UPPER(str)
UCASE(str)
```

Description

Returns the string `str` with all characters changed to uppercase according to the current character set mapping. The default is latin1 (cp1252 West European).

`UCASE` is a synonym.

```
SELECT UPPER(surname), givenname FROM users ORDER BY surname;
+----------------+------------+
| UPPER(surname) | givenname  |
+----------------+------------+
| ABEL           | Jacinto    |
| CASTRO         | Robert     |
| COSTA          | Phestos    |
| MOSCHELLA      | Hippolytos |
+----------------+------------+
```

`UPPER()` is ineffective when applied to binary strings (BINARY, VARBINARY, BLOB). The description of LOWER() shows how to perform lettercase conversion of binary strings.

Prior to MariaDB 11.3, the query optimizer did not handle queries of the format `UCASE(varchar_col)=...`. An optimizer_switch option, `sargable_casefold=ON`, was added in MariaDB 11.3.0 to handle this case. (MDEV-31496)

1.2.2.70 WEIGHT_STRING

Syntax

```
WEIGHT_STRING(str [AS {CHAR|BINARY}(N)] [LEVEL levels] [flags])
  levels: N [ASC|DESC|REVERSE] [, N [ASC|DESC|REVERSE]] ...
```

Description

Returns a binary string representing the string's sorting and comparison value. A string with a lower result means that for sorting purposes the string appears before a string with a higher result.

WEIGHT_STRING() is particularly useful when adding new collations, for testing purposes.

If `str` is a non-binary string (CHAR, VARCHAR or TEXT), WEIGHT_STRING returns the string's collation weight. If `str` is a binary string (BINARY, VARBINARY or BLOB), the return value is simply the input value, since the weight for each byte in a binary string is the byte value.

WEIGHT_STRING() returns NULL if given a NULL input.

The optional AS clause permits casting the input string to a binary or non-binary string, as well as to a particular length.

AS BINARY(N) measures the length in bytes rather than characters, and right pads with 0x00 bytes to the desired length.

AS CHAR(N) measures the length in characters, and right pads with spaces to the desired length.

N has a minimum value of 1, and if it is less than the length of the input string, the string is truncated without warning.

The optional LEVEL clause specifies that the return value should contain weights for specific collation levels. The `levels` specifier can either be a single integer, a comma-separated list of integers, or a range of integers separated by a dash (whitespace is ignored). Integers can range from 1 to a maximum of 6, dependent on the collation, and need to be listed in ascending order.

If the LEVEL clause is no provided, a default of 1 to the maximum for the collation is assumed.

If the LEVEL is specified without using a range, an optional modifier is permitted.

`ASC`, the default, returns the weights without any modification.

`DESC` returns bitwise-inverted weights.

`REVERSE` returns the weights in reverse order.

Examples

The examples below use the HEX() function to represent non-printable results in hexadecimal format.

```
SELECT HEX(WEIGHT_STRING('x'));
+-------------------------+
| HEX(WEIGHT_STRING('x')) |
+-------------------------+
| 0058                    |
+-------------------------+

SELECT HEX(WEIGHT_STRING('x' AS BINARY(4)));
+--------------------------------------+
| HEX(WEIGHT_STRING('x' AS BINARY(4))) |
+--------------------------------------+
| 78000000                             |
+--------------------------------------+

SELECT HEX(WEIGHT_STRING('x' AS CHAR(4)));
+-----------------------------------+
| HEX(WEIGHT_STRING('x' AS CHAR(4))) |
+-----------------------------------+
| 0058002000200020                  |
+-----------------------------------+

SELECT HEX(WEIGHT_STRING(0xaa22ee LEVEL 1));
+--------------------------------------+
| HEX(WEIGHT_STRING(0xaa22ee LEVEL 1)) |
+--------------------------------------+
| AA22EE                               |
+--------------------------------------+

SELECT HEX(WEIGHT_STRING(0xaa22ee LEVEL 1 DESC));
+-----------------------------------------+
| HEX(WEIGHT_STRING(0xaa22ee LEVEL 1 DESC)) |
+-----------------------------------------+
| 55DD11                                  |
+-----------------------------------------+

SELECT HEX(WEIGHT_STRING(0xaa22ee LEVEL 1 REVERSE));
+-------------------------------------------+
| HEX(WEIGHT_STRING(0xaa22ee LEVEL 1 REVERSE)) |
+-------------------------------------------+
| EE22AA                                    |
+-------------------------------------------+
```

1.2.2.71 Type Conversion

Contents

Implicit type conversion takes place when MariaDB is using operands or different types, in order to make the operands compatible.

It is best practice not to rely upon implicit conversion; rather use CAST to explicitly convert types.

Rules for Conversion on Comparison

- If either argument is NULL, the result of the comparison is NULL unless the NULL-safe <=> equality comparison operator is used.
- If both arguments are integers, they are compared as integers.
- If both arguments are strings, they are compared as strings.
- If one argument is decimal and the other argument is decimal or integer, they are compared as decimals.
- If one argument is decimal and the other argument is a floating point, they are compared as floating point values.
- If one argument is string and the other argument is integer, they are compared as decimals. This conversion was added in MariaDB 10.3.36. Prior to 10.3.36, this combination was compared as floating point values, which did not always work well for huge 64-bit integers because of a possible precision loss on conversion to double.
- If a hexadecimal argument is not compared to a number, it is treated as a binary string.
- If a constant is compared to a TIMESTAMP or DATETIME, the constant is converted to a timestamp, unless used as an argument to the IN function.

- In other cases, arguments are compared as floating point, or real, numbers.

Note that if a string column is being compared with a numeric value, MariaDB will not use the index on the column, as there are numerous alternatives that may evaluate as equal (see examples below).

Comparison Examples

Converting a string to a number:

```
SELECT 15+'15';
+---------+
| 15+'15' |
+---------+
|      30 |
+---------+
```

Converting a number to a string:

```
SELECT CONCAT(15,'15');
+-----------------+
| CONCAT(15,'15') |
+-----------------+
| 1515            |
+-----------------+
```

Floating point number errors:

```
SELECT '9746718491924563214' = 9746718491924563213;
+-------------------------------------------+
| '9746718491924563214' = 9746718491924563213 |
+-------------------------------------------+
|                                         1 |
+-------------------------------------------+
```

Numeric equivalence with strings:

```
SELECT '5' = 5;
+---------+
| '5' = 5 |
+---------+
|       1 |
+---------+

SELECT '   5' = 5;
+------------+
| '   5' = 5 |
+------------+
|          1 |
+------------+

SELECT '   5  ' = 5;
+--------------+
| '   5  ' = 5 |
+--------------+
|            1 |
+--------------+
1 row in set, 1 warning (0.000 sec)

SHOW WARNINGS;
+-------+------+-------------------------------------------+
| Level | Code | Message                                   |
+-------+------+-------------------------------------------+
| Note  | 1292 | Truncated incorrect DOUBLE value: '   5  ' |
+-------+------+-------------------------------------------+
```

As a result of the above, MariaDB cannot use the index when comparing a string with a numeric value in the example below:

```
CREATE TABLE t (a VARCHAR(10), b VARCHAR(10), INDEX idx_a (a));

INSERT INTO t VALUES
  ('1', '1'), ('2', '2'), ('3', '3'),
  ('4', '4'), ('5', '5'), ('1', '5');

EXPLAIN SELECT * FROM t WHERE a = '3' \G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: t
         type: ref
possible_keys: idx_a
          key: idx_a
      key_len: 13
          ref: const
         rows: 1
        Extra: Using index condition

EXPLAIN SELECT * FROM t WHERE a = 3 \G
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: t
         type: ALL
possible_keys: idx_a
          key: NULL
      key_len: NULL
          ref: NULL
         rows: 6
        Extra: Using where
```

Rules for Conversion on Dyadic Arithmetic Operations

Implicit type conversion also takes place on dyadic arithmetic operations (+,-,*,/). MariaDB chooses the minimum data type that is guaranteed to fit the result and converts both arguments to the result data type.

For addition (+), subtraction (-) and multiplication (*), the result data type is chosen as follows:

- If either of the arguments is an approximate number (float, double), the result is double.
- If either of the arguments is a string (char, varchar, text), the result is double.
- If either of the arguments is a decimal number, the result is decimal.
- If either of the arguments is of a temporal type with a non-zero fractional second precision (time(N), datetime(N), timestamp(N)), the result is decimal.
- If either of the arguments is of a temporal type with a zero fractional second precision (time(0), date, datetime(0), timestamp(0)), the result may vary between int, int unsigned, bigint or bigint unsigned, depending on the exact data type combination.
- If both arguments are integer numbers (tinyint, smallint, mediumint, bigint), the result may vary between int, int unsigned, bigint or bigint unsigned, depending of the exact data types and their signs.

For division (/), the result data type is chosen as follows:

- If either of the arguments is an approximate number (float, double), the result is double.
- If either of the arguments is a string (char, varchar, text), the result is double.
- Otherwise, the result is decimal.

Arithmetic Examples

Note, the above rules mean that when an argument of a temporal data type appears in addition or subtraction, it's treated as a number by default.

```
SELECT TIME'10:20:30' + 1;
+--------------------+
| TIME'10:20:30' + 1 |
+--------------------+
|             102031 |
+--------------------+
```

In order to do temporal addition or subtraction instead, use the DATE_ADD() or DATE_SUB() functions, or an INTERVAL expression as the second argument:

```
SELECT TIME'10:20:30' + INTERVAL 1 SECOND;
+-----------------------------------+
| TIME'10:20:30' + INTERVAL 1 SECOND |
+-----------------------------------+
| 10:20:31                          |
+-----------------------------------+
```

```
SELECT "2.2" + 3;
+-----------+
| "2.2" + 3 |
+-----------+
|       5.2 |
+-----------+

SELECT 2.2 + 3;
+---------+
| 2.2 + 3 |
+---------+
| 5.2     |
+---------+

SELECT 2.2 / 3;
+---------+
| 2.2 / 3 |
+---------+
| 0.73333 |
+---------+

SELECT "2.2" / 3;
+--------------------+
| "2.2" / 3          |
+--------------------+
| 0.7333333333333334 |
+--------------------+
```

1.2.3 Date & Time Functions

Functions for handling date and time, e.g. TIME, DATE, DAYNAME etc.

Microseconds in MariaDB

Microseconds have been supported since MariaDB 5.3.

Date and Time Units

Date or time units

ADD_MONTHS

Adds a number of months to a date.

ADDDATE

Add days or another interval to a date.

ADDTIME

Adds a time to a time or datetime.

CONVERT_TZ

Converts a datetime from one time zone to another.

CURDATE

Returns the current date.

CURRENT_DATE

Synonym for CURDATE().

CURRENT_TIME

Synonym for CURTIME().

CURRENT_TIMESTAMP
Synonym for NOW().

CURTIME
Returns the current time.

DATE FUNCTION
Extracts the date portion of a datetime.

DATEDIFF
Difference in days between two date/time values.

DATE_ADD
Date arithmetic - addition.

DATE_FORMAT
Formats the date value according to the format string.

DATE_SUB
Date arithmetic - subtraction.

DAY
Synonym for DAYOFMONTH().

DAYNAME
Return the name of the weekday.

DAYOFMONTH
Returns the day of the month.

DAYOFWEEK
Returns the day of the week index.

DAYOFYEAR
Returns the day of the year.

EXTRACT
Extracts a portion of the date.

FORMAT_PICO_TIME
Given a time in picoseconds, returns a human-readable time value and unit indicator.

FROM_DAYS
Returns a date given a day.

FROM_UNIXTIME
Returns a datetime from a Unix timestamp.

GET_FORMAT
Returns a format string.

HOUR
Returns the hour.

LAST_DAY
Returns the last day of the month.

LOCALTIME
Synonym for NOW().

LOCALTIMESTAMP
Synonym for NOW().

MAKEDATE

Returns a date given a year and day.

MAKETIME

Returns a time.

MICROSECOND

Returns microseconds from a date or datetime.

MINUTE

Returns a minute from 0 to 59.

MONTH

Returns a month from 1 to 12.

MONTHNAME

Returns the full name of the month.

NOW

Returns the current date and time.

PERIOD_ADD

Add months to a period.

PERIOD_DIFF

Number of months between two periods.

QUARTER

Returns year quarter from 1 to 4.

SECOND

Returns the second of a time.

SEC_TO_TIME

Converts a second to a time.

STR_TO_DATE

Converts a string to date.

SUBDATE

Subtract a date unit or number of days.

SUBTIME

Subtracts a time from a date/time.

SYSDATE

Returns the current date and time.

TIME Function

Extracts the time.

TIMEDIFF

Returns the difference between two date/times.

TIMESTAMP FUNCTION

Return the datetime, or add a time to a date/time.

TIMESTAMPADD

Add interval to a date or datetime.

TIMESTAMPDIFF

Difference between two datetimes.

TIME_FORMAT
Formats the time value according to the format string.

TIME_TO_SEC
Returns the time argument, converted to seconds.

TO_DAYS
Number of days since year 0.

TO_SECONDS
Number of seconds since year 0.

UNIX_TIMESTAMP
Returns a Unix timestamp.

UTC_DATE
Returns the current UTC date.

UTC_TIME
Returns the current UTC time.

UTC_TIMESTAMP
Returns the current UTC date and time.

WEEK
Returns the week number.

WEEKDAY
Returns the weekday index.

WEEKOFYEAR
Returns the calendar week of the date as a number in the range from 1 to 53.

YEAR
Returns the year for the given date.

YEARWEEK
Returns year and week for a date.

There are 6 related questions.

1.2.3.1 Microseconds in MariaDB

Contents

The TIME, DATETIME, and TIMESTAMP types, along with the temporal functions, CAST and dynamic columns, support microseconds. The datetime precision of a column can be specified when creating the table with CREATE TABLE, for example:

```
CREATE TABLE example(
  col_microsec DATETIME(6),
  col_millisec TIME(3)
);
```

Generally, the precision can be specified for any `TIME`, `DATETIME`, or `TIMESTAMP` column, in parentheses, after the type name. The datetime precision specifies number of digits after the decimal dot and can be any integer number from 0 to 6. If no precision is specified it is assumed to be 0, for backward compatibility reasons.

A datetime precision can be specified wherever a type name is used. For example:

- when declaring arguments of stored routines.

- when specifying a return type of a stored function.
- when declaring variables.
- in a `CAST` function:

```
create function example(x datetime(5)) returns time(4)
begin
  declare y timestamp(6);
  return cast(x as time(2));
end;
```

`%f` is used as the formatting option for microseconds in the STR_TO_DATE, DATE_FORMAT and FROM_UNIXTIME functions, for example:

```
SELECT STR_TO_DATE('20200809 020917076','%Y%m%d %H%i%s%f');
+-------------------------------------------------------+
| STR_TO_DATE('20200809 020917076','%Y%m%d %H%i%s%f') |
+-------------------------------------------------------+
| 2020-08-09 02:09:17.076000                            |
+-------------------------------------------------------+
```

Additional Information

- when comparing anything to a temporal value (`DATETIME` , `TIME` , `DATE` , or `TIMESTAMP`), both values are compared as temporal values, not as strings.
- The INFORMATION_SCHEMA.COLUMNS table has a new column `DATETIME_PRECISION`
- NOW(), CURTIME(), UTC_TIMESTAMP(), UTC_TIME(), CURRENT_TIME(), CURRENT_TIMESTAMP(), LOCALTIME() and LOCALTIMESTAMP() now accept datetime precision as an optional argument. For example:

```
SELECT CURTIME(4);
--> 10:11:12.3456
```

- TIME_TO_SEC() and UNIX_TIMESTAMP() preserve microseconds of the argument. These functions will return a decimal number if the result non-zero datetime precision and an integer otherwise (for backward compatibility).

```
SELECT TIME_TO_SEC('10:10:10.12345');
--> 36610.12345
```

- Current versions of this patch fix a bug in the following optimization: in certain queries with `DISTINCT` MariaDB can ignore this clause if it can prove that all result rows are unique anyway, for example, when a primary key is compared with a constant. Sometimes this optimization was applied incorrectly, though — for example, when comparing a string with a date constant. This is now fixed.
- `DATE_ADD()` and `DATE_SUB()` functions can now take a `TIME` expression as an argument (not just `DATETIME` as before).

```
SELECT TIME('10:10:10') + INTERVAL 100 MICROSECOND;
--> 10:10:10.000100
```

- The `event_time` field in the mysql.general_log table and the `start_time` , `query_time` , and `lock_time` fields in the mysql.slow_log table now store values with microsecond precision.
- This patch fixed a bug when comparing a temporal value using the `BETWEEN` operator and one of the operands is `NULL` .
- The old syntax `TIMESTAMP(N)` , where `N` is the display width, is no longer supported. It was deprecated in MySQL 4.1.0 (released on 2003-04-03).
- when a `DATETIME` value is compared to a `TIME` value, the latter is treated as a full datetime with a zero date part, similar to comparing `DATE` to a `DATETIME` , or to comparing `DECIMAL` numbers. Earlier versions of MariaDB used to compare only the time part of both operands in such a case.
- In MariaDB, an extra column `TIME_MS` has been added to the `INFORMATION_SCHEMA.PROCESSLIST` table, as well as to the output of `SHOW FULL PROCESSLIST` .

Note: When you convert a temporal value to a value with a smaller precision, it will be truncated, not rounded. This is done to guarantee that the date part is not changed. For example:

```
SELECT CAST('2009-12-31 23:59:59.998877' as DATETIME(3));
-> 2009-12-31 23:59:59.998
```

MySQL 5.6 Microseconds

MySQL 5.6 introduced microseconds using a slightly different implementation to MariaDB 5.3. Since MariaDB 10.1, MariaDB has defaulted to the MySQL format, by means of the --mysql56-temporal-format variable. The MySQL version requires slightly more storage but has some advantages in permitting the eventual support of negative dates, and in replication.

1.2.3.2 Date and Time Units

The `INTERVAL` keyword can be used to add or subtract a time interval of time to a `DATETIME`, `DATE` or `TIME` value.

The syntax is:

```
INTERVAL time_quantity time_unit
```

For example, the `SECOND` unit is used below by the `DATE_ADD()` function:

```
SELECT '2008-12-31 23:59:59' + INTERVAL 1 SECOND;
+---------------------------------------+
| '2008-12-31 23:59:59' + INTERVAL 1 SECOND |
+---------------------------------------+
| 2009-01-01 00:00:00                   |
+---------------------------------------+
```

The following units are valid:

Unit	Description
`MICROSECOND`	Microseconds
`SECOND`	Seconds
`MINUTE`	Minutes
`HOUR`	Hours
`DAY`	Days
`WEEK`	Weeks
`MONTH`	Months
`QUARTER`	Quarters
`YEAR`	Years
`SECOND_MICROSECOND`	Seconds.Microseconds
`MINUTE_MICROSECOND`	Minutes.Seconds.Microseconds
`MINUTE_SECOND`	Minutes.Seconds
`HOUR_MICROSECOND`	Hours.Minutes.Seconds.Microseconds
`HOUR_SECOND`	Hours.Minutes.Seconds
`HOUR_MINUTE`	Hours.Minutes
`DAY_MICROSECOND`	Days Hours.Minutes.Seconds.Microseconds
`DAY_SECOND`	Days Hours.Minutes.Seconds
`DAY_MINUTE`	Days Hours.Minutes
`DAY_HOUR`	Days Hours
`YEAR_MONTH`	Years-Months

The time units containing an underscore are composite; that is, they consist of multiple base time units. For base time units, `time_quantity` is an integer number. For composite units, the quantity must be expressed as a string with multiple integer numbers separated by any punctuation character.

Example of composite units:

```
INTERVAL '2:2' YEAR_MONTH
INTERVAL '1:30:30' HOUR_SECOND
INTERVAL '1!30!30' HOUR_SECOND -- same as above
```

Time units can be used in the following contexts:

- after a `+` or a `-` operator;
- with the following `DATE` or `TIME` functions: `ADDDATE()`, `SUBDATE()`, `DATE_ADD()`, `DATE_SUB()`, `TIMESTAMPADD()`, `TIMESTAMPDIFF()`, `EXTRACT()`;
- in the `ON SCHEDULE` clause of `CREATE EVENT` and `ALTER EVENT`.
- when defining a partitioning `BY SYSTEM_TIME`

1.2.3.3 ADD_MONTHS

MariaDB starting with 10.6.1

The ADD_MONTHS function was introduced in MariaDB 10.6.1 to enhance Oracle compatibility. Similar functionality can be achieved with the DATE_ADD function.

Syntax

```
ADD_MONTHS(date, months)
```

Contents

Description

`ADD_MONTHS` adds an integer *months* to a given *date* (DATE, DATETIME or TIMESTAMP), returning the resulting date.

months can be positive or negative.

The resulting day component will remain the same as that specified in *date*, unless the resulting month has fewer days than the day component of the given date, in which case the day will be the last day of the resulting month.

Returns NULL if given an invalid date, or a NULL argument.

Examples

```
SELECT ADD_MONTHS('2012-01-31', 2);
+-----------------------------+
| ADD_MONTHS('2012-01-31', 2) |
+-----------------------------+
| 2012-03-31                  |
+-----------------------------+

SELECT ADD_MONTHS('2012-01-31', -5);
+-----------------------------+
| ADD_MONTHS('2012-01-31', -5) |
+-----------------------------+
| 2011-08-31                   |
+-----------------------------+

SELECT ADD_MONTHS('2011-01-31', 1);
+-----------------------------+
| ADD_MONTHS('2011-01-31', 1) |
+-----------------------------+
| 2011-02-28                  |
+-----------------------------+

SELECT ADD_MONTHS('2012-01-31', 1);
+-----------------------------+
| ADD_MONTHS('2012-01-31', 1) |
+-----------------------------+
| 2012-02-29                  |
+-----------------------------+

SELECT ADD_MONTHS('2012-01-31', 2);
+-----------------------------+
| ADD_MONTHS('2012-01-31', 2) |
+-----------------------------+
| 2012-03-31                  |
+-----------------------------+

SELECT ADD_MONTHS('2012-01-31', 3);
+-----------------------------+
| ADD_MONTHS('2012-01-31', 3) |
+-----------------------------+
| 2012-04-30                  |
+-----------------------------+
```

1.2.3.4 ADDDATE

Syntax

```
ADDDATE(date,INTERVAL expr unit), ADDDATE(expr,days)
```

Description

When invoked with the `INTERVAL` form of the second argument, `ADDDATE()` is a synonym for `DATE_ADD()`. The related function `SUBDATE()` is a synonym for `DATE_SUB()`. For information on the `INTERVAL` unit argument, see the discussion for `DATE_ADD()`.

When invoked with the days form of the second argument, MariaDB treats it as an integer number of days to be added to *expr*.

Examples

```
SELECT DATE_ADD('2008-01-02', INTERVAL 31 DAY);
+----------------------------------------+
| DATE_ADD('2008-01-02', INTERVAL 31 DAY) |
+----------------------------------------+
| 2008-02-02                             |
+----------------------------------------+

SELECT ADDDATE('2008-01-02', INTERVAL 31 DAY);
+----------------------------------------+
| ADDDATE('2008-01-02', INTERVAL 31 DAY) |
+----------------------------------------+
| 2008-02-02                             |
+----------------------------------------+
```

```
SELECT ADDDATE('2008-01-02', 31);
+---------------------------+
| ADDDATE('2008-01-02', 31) |
+---------------------------+
| 2008-02-02                |
+---------------------------+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT d, ADDDATE(d, 10) from t1;
+---------------------+---------------------+
| d                   | ADDDATE(d, 10)      |
+---------------------+---------------------+
| 2007-01-30 21:31:07 | 2007-02-09 21:31:07 |
| 1983-10-15 06:42:51 | 1983-10-25 06:42:51 |
| 2011-04-21 12:34:56 | 2011-05-01 12:34:56 |
| 2011-10-30 06:31:41 | 2011-11-09 06:31:41 |
| 2011-01-30 14:03:25 | 2011-02-09 14:03:25 |
| 2004-10-07 11:19:34 | 2004-10-17 11:19:34 |
+---------------------+---------------------+

SELECT d, ADDDATE(d, INTERVAL 10 HOUR) from t1;
+---------------------+-----------------------------+
| d                   | ADDDATE(d, INTERVAL 10 HOUR) |
+---------------------+-----------------------------+
| 2007-01-30 21:31:07 | 2007-01-31 07:31:07         |
| 1983-10-15 06:42:51 | 1983-10-15 16:42:51         |
| 2011-04-21 12:34:56 | 2011-04-21 22:34:56         |
| 2011-10-30 06:31:41 | 2011-10-30 16:31:41         |
| 2011-01-30 14:03:25 | 2011-01-31 00:03:25         |
| 2004-10-07 11:19:34 | 2004-10-07 21:19:34         |
+---------------------+-----------------------------+
```

1.2.3.5 ADDTIME

Syntax

```
ADDTIME(expr1,expr2)
```

Description

`ADDTIME()` adds *expr2* to *expr1* and returns the result. *expr1* is a time or datetime expression, and *expr2* is a time expression.

Examples

```
SELECT ADDTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002');
+----------------------------------------------------------+
| ADDTIME('2007-12-31 23:59:59.999999', '1 1:1:1.000002') |
+----------------------------------------------------------+
| 2008-01-02 01:01:01.000001                               |
+----------------------------------------------------------+

SELECT ADDTIME('01:00:00.999999', '02:00:00.999998');
+---------------------------------------------+
| ADDTIME('01:00:00.999999', '02:00:00.999998') |
+---------------------------------------------+
| 03:00:01.999997                             |
+---------------------------------------------+
```

1.2.3.6 CONVERT_TZ

Syntax

```
CONVERT_TZ(dt,from_tz,to_tz)
```

Description

CONVERT_TZ() converts a datetime value *dt* from the time zone given by *from_tz* to the time zone given by *to_tz* and returns the resulting value.

In order to use named time zones, such as GMT, MET or Africa/Johannesburg, the time_zone tables must be loaded (see mysql_tzinfo_to_sql).

No conversion will take place if the value falls outside of the supported TIMESTAMP range ('1970-01-01 00:00:01' to '2038-01-19 05:14:07' UTC) when converted from *from_tz* to UTC.

This function returns NULL if the arguments are invalid (or named time zones have not been loaded).

See time zones for more information.

Examples

```
SELECT CONVERT_TZ('2016-01-01 12:00:00','+00:00','+10:00');
+-----------------------------------------------------+
| CONVERT_TZ('2016-01-01 12:00:00','+00:00','+10:00') |
+-----------------------------------------------------+
| 2016-01-01 22:00:00                                 |
+-----------------------------------------------------+
```

Using named time zones (with the time zone tables loaded):

```
SELECT CONVERT_TZ('2016-01-01 12:00:00','GMT','Africa/Johannesburg');
+------------------------------------------------------------+
| CONVERT_TZ('2016-01-01 12:00:00','GMT','Africa/Johannesburg') |
+------------------------------------------------------------+
| 2016-01-01 14:00:00                                        |
+------------------------------------------------------------+
```

The value is out of the TIMESTAMP range, so no conversion takes place:

```
SELECT CONVERT_TZ('1969-12-31 22:00:00','+00:00','+10:00');
+-----------------------------------------------------+
| CONVERT_TZ('1969-12-31 22:00:00','+00:00','+10:00') |
+-----------------------------------------------------+
| 1969-12-31 22:00:00                                 |
+-----------------------------------------------------+
```

1.2.3.7 CURDATE

Syntax

```
CURDATE()
CURRENT_DATE
CURRENT_DATE()
```

Description

`CURDATE` returns the current date as a value in 'YYYY-MM-DD' or YYYYMMDD format, depending on whether the function is used in a string or numeric context.

`CURRENT_DATE` and `CURRENT_DATE()` are synonyms.

Examples

```
SELECT CURDATE();
+------------+
| CURDATE()  |
+------------+
| 2019-03-05 |
+------------+
```

In a numeric context (note this is not performing date calculations):

```
SELECT CURDATE() +0;
+--------------+
| CURDATE() +0 |
+--------------+
|     20190305 |
+--------------+
```

Data calculation:

```
SELECT CURDATE() - INTERVAL 5 DAY;
+----------------------------+
| CURDATE() - INTERVAL 5 DAY |
+----------------------------+
| 2019-02-28                 |
+----------------------------+
```

1.2.3.8 CURRENT_DATE

Syntax

```
CURRENT_DATE, CURRENT_DATE()
```

Description

`CURRENT_DATE` and `CURRENT_DATE()` are synonyms for CURDATE().

1.2.3.9 CURRENT_TIME

Syntax

```
CURRENT_TIME
CURRENT_TIME([precision])
```

Description

`CURRENT_TIME` and `CURRENT_TIME()` are synonyms for `CURTIME()` .

1.2.3.10 CURRENT_TIMESTAMP

Syntax

```
CURRENT_TIMESTAMP
CURRENT_TIMESTAMP([precision])
```

Description

`CURRENT_TIMESTAMP` and `CURRENT_TIMESTAMP()` are synonyms for `NOW()` .

1.2.3.11 CURTIME

Syntax

```
CURTIME([precision])
```

Description

Returns the current time as a value in 'HH:MM:SS' or HHMMSS.uuuuuu format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone.

The optional *precision* determines the microsecond precision. See Microseconds in MariaDB.

Examples

```
SELECT CURTIME();
+-----------+
| CURTIME() |
+-----------+
| 12:45:39  |
+-----------+

SELECT CURTIME() + 0;
+---------------+
| CURTIME() + 0 |
+---------------+
| 124545.000000 |
+---------------+
```

With precision:

```
SELECT CURTIME(2);
+-------------+
| CURTIME(2)  |
+-------------+
| 09:49:08.09 |
+-------------+
```

1.2.3.12 DATE FUNCTION

Syntax

```
DATE(expr)
```

Description

Extracts the date part of the date or datetime expression *expr*. Returns NULL and throws a warning when passed an invalid date.

Examples

```
SELECT DATE('2013-07-18 12:21:32');
+----------------------------+
| DATE('2013-07-18 12:21:32') |
+----------------------------+
| 2013-07-18                 |
+----------------------------+
```

1.2.3.13 DATEDIFF

Syntax

```
DATEDIFF(expr1,expr2)
```

Description

`DATEDIFF()` returns (*expr1* – *expr2*) expressed as a value in days from one date to the other. *expr1* and *expr2* are date or date-and-time expressions. Only the date parts of the values are used in the calculation.

Examples

```
SELECT DATEDIFF('2007-12-31 23:59:59','2007-12-30');
+-----------------------------------------------+
| DATEDIFF('2007-12-31 23:59:59','2007-12-30') |
+-----------------------------------------------+
|                                             1 |
+-----------------------------------------------+

SELECT DATEDIFF('2010-11-30 23:59:59','2010-12-31');
+-----------------------------------------------+
| DATEDIFF('2010-11-30 23:59:59','2010-12-31') |
+-----------------------------------------------+
|                                           -31 |
+-----------------------------------------------+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT NOW();
+---------------------+
| NOW()               |
+---------------------+
| 2011-05-23 10:56:05 |
+---------------------+

SELECT d, DATEDIFF(NOW(),d) FROM t1;
+---------------------+-------------------+
| d                   | DATEDIFF(NOW(),d) |
+---------------------+-------------------+
| 2007-01-30 21:31:07 |              1574 |
| 1983-10-15 06:42:51 |             10082 |
| 2011-04-21 12:34:56 |                32 |
| 2011-10-30 06:31:41 |              -160 |
| 2011-01-30 14:03:25 |               113 |
| 2004-10-07 11:19:34 |              2419 |
+---------------------+-------------------+
```

1.2.3.14 DATE_ADD

Syntax

```
DATE_ADD(date,INTERVAL expr unit)
```

Contents

Description

Performs date arithmetic. The *date* argument specifies the starting date or datetime value. *expr* is an expression specifying the interval value to be added or subtracted from the starting date. *expr* is a string; it may start with a " - " for negative intervals. *unit* is a keyword indicating the units in which the expression should be interpreted. See Date and Time Units for a complete list of permitted units.

Examples

```
SELECT '2008-12-31 23:59:59' + INTERVAL 1 SECOND;
+-----------------------------------------+
| '2008-12-31 23:59:59' + INTERVAL 1 SECOND |
+-----------------------------------------+
| 2009-01-01 00:00:00                     |
+-----------------------------------------+
```

```
SELECT INTERVAL 1 DAY + '2008-12-31';
+-------------------------------+
| INTERVAL 1 DAY + '2008-12-31' |
+-------------------------------+
| 2009-01-01                    |
+-------------------------------+
```

```
SELECT '2005-01-01' - INTERVAL 1 SECOND;
+---------------------------------+
| '2005-01-01' - INTERVAL 1 SECOND |
+---------------------------------+
| 2004-12-31 23:59:59              |
+---------------------------------+
```

```
SELECT DATE_ADD('2000-12-31 23:59:59', INTERVAL 1 SECOND);
+-----------------------------------------------------+
| DATE_ADD('2000-12-31 23:59:59', INTERVAL 1 SECOND) |
+-----------------------------------------------------+
| 2001-01-01 00:00:00                                 |
+-----------------------------------------------------+
```

```
SELECT DATE_ADD('2010-12-31 23:59:59', INTERVAL 1 DAY);
+------------------------------------------------+
| DATE_ADD('2010-12-31 23:59:59', INTERVAL 1 DAY) |
+------------------------------------------------+
| 2011-01-01 23:59:59                             |
+------------------------------------------------+
```

```
SELECT DATE_ADD('2100-12-31 23:59:59', INTERVAL '1:1' MINUTE_SECOND);
+-------------------------------------------------------------+
| DATE_ADD('2100-12-31 23:59:59', INTERVAL '1:1' MINUTE_SECOND) |
+-------------------------------------------------------------+
| 2101-01-01 00:01:00                                          |
+-------------------------------------------------------------+
```

```
SELECT DATE_ADD('1900-01-01 00:00:00', INTERVAL '-1 10' DAY_HOUR);
+-----------------------------------------------------------+
| DATE_ADD('1900-01-01 00:00:00', INTERVAL '-1 10' DAY_HOUR) |
+-----------------------------------------------------------+
| 1899-12-30 14:00:00                                        |
+-----------------------------------------------------------+
```

```
SELECT DATE_ADD('1992-12-31 23:59:59.000002', INTERVAL '1.999999' SECOND_MICROSECOND);
+-----------------------------------------------------------------------------+
| DATE_ADD('1992-12-31 23:59:59.000002', INTERVAL '1.999999' SECOND_MICROSECOND) |
+-----------------------------------------------------------------------------+
| 1993-01-01 00:00:01.000001                                                   |
+-----------------------------------------------------------------------------+
```

1.2.3.15 DATE_FORMAT

Syntax

```
DATE_FORMAT(date, format[, locale])
```

Contents

Description

Formats the date value according to the format string.

The language used for the names is controlled by the value of the lc_time_names system variable. See server locale for more on the supported locales.

The options that can be used by DATE_FORMAT(), as well as its inverse STR_TO_DATE() and the FROM_UNIXTIME()

function, are:

Option	Description
`%a`	Short weekday name in current locale (Variable lc_time_names).
`%b`	Short form month name in current locale. For locale en_US this is one of: Jan,Feb,Mar,Apr,May,Jun,Jul,Aug,Sep,Oct,Nov or Dec.
`%c`	Month with 1 or 2 digits.
`%D`	Day with English suffix 'th', 'nd', 'st' or 'rd''. (1st, 2nd, 3rd...).
`%d`	Day with 2 digits.
`%e`	Day with 1 or 2 digits.
`%f`	Microseconds 6 digits.
`%H`	Hour with 2 digits between 00-23.
`%h`	Hour with 2 digits between 01-12.
`%I`	Hour with 2 digits between 01-12.
`%i`	Minute with 2 digits.
`%j`	Day of the year (001-366)
`%k`	Hour with 1 digits between 0-23.
`%l`	Hour with 1 digits between 1-12.
`%M`	Full month name in current locale (Variable lc_time_names).
`%m`	Month with 2 digits.
`%p`	AM/PM according to current locale (Variable lc_time_names).
`%r`	Time in 12 hour format, followed by AM/PM. Short for '%I:%i:%S %p'.
`%S`	Seconds with 2 digits.
`%s`	Seconds with 2 digits.
`%T`	Time in 24 hour format. Short for '%H:%i:%S'.
`%U`	Week number (00-53), when first day of the week is Sunday.
`%u`	Week number (00-53), when first day of the week is Monday.
`%V`	Week number (01-53), when first day of the week is Sunday. Used with %X.
`%v`	Week number (01-53), when first day of the week is Monday. Used with %x.
`%W`	Full weekday name in current locale (Variable lc_time_names).
`%w`	Day of the week. 0 = Sunday, 6 = Saturday.
`%X`	Year with 4 digits when first day of the week is Sunday. Used with %V.
`%x`	Year with 4 digits when first day of the week is Monday. Used with %v.
`%Y`	Year with 4 digits.
`%y`	Year with 2 digits.
`%Z`	Timezone abbreviation. From MariaDB 11.3.0.
`%z`	Numeric timezone +hhmm or -hhmm presenting the hour and minute offset from UTC. From MariaDB 11.3.0.
`%#`	For str_to_date(), skip all numbers.
`%.`	For str_to_date(), skip all punctation characters.
`%@`	For str_to_date(), skip all alpha characters.
`%%`	A literal `%` character.

To get a date in one of the standard formats, `GET_FORMAT()` can be used.

Examples

```
SELECT DATE_FORMAT('2009-10-04 22:23:00', '%W %M %Y');
+-----------------------------------------------+
| DATE_FORMAT('2009-10-04 22:23:00', '%W %M %Y') |
+-----------------------------------------------+
| Sunday October 2009                           |
+-----------------------------------------------+

SELECT DATE_FORMAT('2007-10-04 22:23:00', '%H:%i:%s');
+-----------------------------------------------+
| DATE_FORMAT('2007-10-04 22:23:00', '%H:%i:%s') |
+-----------------------------------------------+
| 22:23:00                                      |
+-----------------------------------------------+

SELECT DATE_FORMAT('1900-10-04 22:23:00', '%D %y %a %d %m %b %j');
+------------------------------------------------------------+
| DATE_FORMAT('1900-10-04 22:23:00', '%D %y %a %d %m %b %j') |
+------------------------------------------------------------+
| 4th 00 Thu 04 10 Oct 277                                   |
+------------------------------------------------------------+

SELECT DATE_FORMAT('1997-10-04 22:23:00', '%H %k %I %r %T %S %w');
+------------------------------------------------------------+
| DATE_FORMAT('1997-10-04 22:23:00', '%H %k %I %r %T %S %w') |
+------------------------------------------------------------+
| 22 22 10 10:23:00 PM 22:23:00 00 6                         |
+------------------------------------------------------------+

SELECT DATE_FORMAT('1999-01-01', '%X %V');
+-----------------------------------+
| DATE_FORMAT('1999-01-01', '%X %V') |
+-----------------------------------+
| 1998 52                           |
+-----------------------------------+

SELECT DATE_FORMAT('2006-06-00', '%d');
+---------------------------------+
| DATE_FORMAT('2006-06-00', '%d') |
+---------------------------------+
| 00                              |
+---------------------------------+
```

Optionally, the locale can be explicitly specified as the third DATE_FORMAT() argument. Doing so makes the function independent from the session settings, and the three argument version of DATE_FORMAT() can be used in virtual indexed and persistent generated-columns:

```
SELECT DATE_FORMAT('2006-01-01', '%W', 'el_GR');
+-----------------------------------------+
| DATE_FORMAT('2006-01-01', '%W', 'el_GR') |
+-----------------------------------------+
| Κυριακή                                 |
+-----------------------------------------+
```

From MariaDB 11.3, the timezone information:

```
SELECT DATE_FORMAT(NOW(), '%W %d %M %Y %H:%i:%s %Z %z');
+-------------------------------------------------+
| DATE_FORMAT(NOW(), '%W %d %M %Y %H:%i:%s %Z %z') |
+-------------------------------------------------+
| Wednesday 20 September 2023 15:00:23 SAST +0200  |
+-------------------------------------------------+
```

1.2.3.16 DATE_SUB

Syntax

```
DATE_SUB(date,INTERVAL expr unit)
```

Description

Performs date arithmetic. The *date* argument specifies the starting date or datetime value. *expr* is an expression specifying the interval value to be added or subtracted from the starting date. *expr* is a string; it may start with a " - " for negative intervals. *unit* is a keyword indicating the units in which the expression should be interpreted. See Date and Time Units for a complete list of permitted units.

See also `DATE_ADD()` .

Examples

```
SELECT DATE_SUB('1998-01-02', INTERVAL 31 DAY);
+-----------------------------------------+
| DATE_SUB('1998-01-02', INTERVAL 31 DAY) |
+-----------------------------------------+
| 1997-12-02                              |
+-----------------------------------------+
```

```
SELECT DATE_SUB('2005-01-01 00:00:00', INTERVAL '1 1:1:1' DAY_SECOND);
+-----------------------------------------------------------------+
| DATE_SUB('2005-01-01 00:00:00', INTERVAL '1 1:1:1' DAY_SECOND) |
+-----------------------------------------------------------------+
| 2004-12-30 22:58:59                                             |
+-----------------------------------------------------------------+
```

1.2.3.17 DAY

Syntax

```
DAY(date)
```

Description

`DAY()` is a synonym for `DAYOFMONTH()` .

1.2.3.18 DAYNAME

Syntax

```
DAYNAME(date)
```

Description

Returns the name of the weekday for date. The language used for the name is controlled by the value of the lc_time_names system variable. See server locale for more on the supported locales.

Examples

```
SELECT DAYNAME('2007-02-03');
+-----------------------+
| DAYNAME('2007-02-03') |
+-----------------------+
| Saturday              |
+-----------------------+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT d, DAYNAME(d) FROM t1;
+---------------------+------------+
| d                   | DAYNAME(d) |
+---------------------+------------+
| 2007-01-30 21:31:07 | Tuesday    |
| 1983-10-15 06:42:51 | Saturday   |
| 2011-04-21 12:34:56 | Thursday   |
| 2011-10-30 06:31:41 | Sunday     |
| 2011-01-30 14:03:25 | Sunday     |
| 2004-10-07 11:19:34 | Thursday   |
+---------------------+------------+
```

Changing the locale:

```
SET lc_time_names = 'fr_CA';

SELECT DAYNAME('2013-04-01');
+-----------------------+
| DAYNAME('2013-04-01') |
+-----------------------+
| lundi                 |
+-----------------------+
```

1.2.3.19 DAYOFMONTH

Syntax

```
DAYOFMONTH(date)
```

Description

Returns the day of the month for date, in the range `1` to `31`, or `0` for dates such as `'0000-00-00'` or `'2008-00-00'` which have a zero day part.

DAY() is a synonym.

Examples

```
SELECT DAYOFMONTH('2007-02-03');
+--------------------------+
| DAYOFMONTH('2007-02-03') |
+--------------------------+
|                        3 |
+--------------------------+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT d FROM t1 where DAYOFMONTH(d) = 30;
+---------------------+
| d                   |
+---------------------+
| 2007-01-30 21:31:07 |
| 2011-10-30 06:31:41 |
| 2011-01-30 14:03:25 |
+---------------------+
```

1.2.3.20 DAYOFWEEK

Syntax

```
DAYOFWEEK(date)
```

Description

Returns the day of the week index for the date (1 = Sunday, 2 = Monday, ..., 7 = Saturday). These index values correspond to the ODBC standard.

This contrasts with `WEEKDAY()` which follows a different index numbering (`0` = Monday, `1` = Tuesday, ... `6` = Sunday).

Examples

```
SELECT DAYOFWEEK('2007-02-03');
+--------------------------+
| DAYOFWEEK('2007-02-03') |
+--------------------------+
|                        7 |
+--------------------------+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT d, DAYNAME(d), DAYOFWEEK(d), WEEKDAY(d) from t1;
+---------------------+------------+--------------+------------+
| d                   | DAYNAME(d) | DAYOFWEEK(d) | WEEKDAY(d) |
+---------------------+------------+--------------+------------+
| 2007-01-30 21:31:07 | Tuesday    |            3 |          1 |
| 1983-10-15 06:42:51 | Saturday   |            7 |          5 |
| 2011-04-21 12:34:56 | Thursday   |            5 |          3 |
| 2011-10-30 06:31:41 | Sunday     |            1 |          6 |
| 2011-01-30 14:03:25 | Sunday     |            1 |          6 |
| 2004-10-07 11:19:34 | Thursday   |            5 |          3 |
+---------------------+------------+--------------+------------+
```

1.2.3.21 DAYOFYEAR

Syntax

```
DAYOFYEAR(date)
```

Description

Returns the day of the year for date, in the range 1 to 366.

Examples

```
SELECT DAYOFYEAR('2018-02-16');
+-------------------------+
| DAYOFYEAR('2018-02-16') |
+-------------------------+
|                      47 |
+-------------------------+
```

1.2.3.22 EXTRACT

Syntax

```
EXTRACT(unit FROM date)
```

Contents

Description

The EXTRACT() function extracts the required unit from the date. See Date and Time Units for a complete list of permitted units.

In MariaDB 10.0.7 and MariaDB 5.5.35, `EXTRACT (HOUR FROM ...)` was changed to return a value from 0 to 23, adhering to the SQL standard. Until MariaDB 10.0.6 and MariaDB 5.5.34, and in all versions of MySQL at least as of MySQL 5.7, it could return a value > 23. HOUR() is not a standard function, so continues to adhere to the old behaviour inherited from MySQL.

Examples

```
SELECT EXTRACT(YEAR FROM '2009-07-02');
+---------------------------------+
| EXTRACT(YEAR FROM '2009-07-02') |
+---------------------------------+
|                            2009 |
+---------------------------------+

SELECT EXTRACT(YEAR_MONTH FROM '2009-07-02 01:02:03');
+-----------------------------------------------+
| EXTRACT(YEAR_MONTH FROM '2009-07-02 01:02:03') |
+-----------------------------------------------+
|                                        200907 |
+-----------------------------------------------+

SELECT EXTRACT(DAY_MINUTE FROM '2009-07-02 01:02:03');
+-----------------------------------------------+
| EXTRACT(DAY_MINUTE FROM '2009-07-02 01:02:03') |
+-----------------------------------------------+
|                                         20102 |
+-----------------------------------------------+

SELECT EXTRACT(MICROSECOND FROM '2003-01-02 10:30:00.000123');
+-------------------------------------------------------+
| EXTRACT(MICROSECOND FROM '2003-01-02 10:30:00.000123') |
+-------------------------------------------------------+
|                                                   123 |
+-------------------------------------------------------+
```

From MariaDB 10.0.7 and MariaDB 5.5.35, `EXTRACT (HOUR FROM...)` returns a value from 0 to 23, as per the SQL standard. `HOUR` is not a standard function, so continues to adhere to the old behaviour inherited from MySQL.

```
SELECT EXTRACT(HOUR FROM '26:30:00'), HOUR('26:30:00');
+--------------------------------+------------------+
| EXTRACT(HOUR FROM '26:30:00') | HOUR('26:30:00') |
+--------------------------------+------------------+
|                              2 |               26 |
+--------------------------------+------------------+
```

1.2.3.23 FORMAT_PICO_TIME

MariaDB starting with 11.0.2
Introduced in MariaDB 11.0.2

Syntax

```
FORMAT_PICO_TIME(time_val)
```

Contents

Description

Given a time in picoseconds, returns a human-readable time value and unit indicator. Resulting unit is dependent on the length of the argument, and can be:

- ps - picoseconds
- ns - nanoseconds
- us - microseconds
- ms - milliseconds
- s - seconds
- min - minutes
- h - hours

- d - days

With the exception of results under one nanosecond, which are not rounded and are represented as whole numbers, the result is rounded to 2 decimal places, with a minimum of 3 significant digits.

Returns NULL if the argument is NULL.

This function is very similar to the Sys Schema FORMAT_TIME function, but with the following differences:

- Represents minutes as `min` rather than `m`.
- Does not represent weeks.

Examples

```
SELECT
    FORMAT_PICO_TIME(43) AS ps,
    FORMAT_PICO_TIME(4321) AS ns,
    FORMAT_PICO_TIME(43211234) AS us,
    FORMAT_PICO_TIME(432112344321) AS ms,
    FORMAT_PICO_TIME(43211234432123) AS s,
    FORMAT_PICO_TIME(432112344321234) AS m,
    FORMAT_PICO_TIME(4321123443212345) AS h,
    FORMAT_PICO_TIME(432112344321234545) AS d;
+--------+---------+----------+-----------+---------+----------+--------+--------+
| ps     | ns      | us       | ms        | s       | m        | h      | d      |
+--------+---------+----------+-----------+---------+----------+--------+--------+
|  43 ps | 4.32 ns | 43.21 us | 432.11 ms | 43.21 s | 7.20 min | 1.20 h | 5.00 d |
+--------+---------+----------+-----------+---------+----------+--------+--------+
```

1.2.3.24 FROM_DAYS

Syntax

```
FROM_DAYS(N)
```

Description

Given a day number N, returns a DATE value. The day count is based on the number of days from the start of the standard calendar (0000-00-00).

The function is not designed for use with dates before the advent of the Gregorian calendar in October 1582. Results will not be reliable since it doesn't account for the lost days when the calendar changed from the Julian calendar.

This is the converse of the TO_DAYS() function.

Examples

```
SELECT FROM_DAYS(730669);
+-------------------+
| FROM_DAYS(730669) |
+-------------------+
| 2000-07-03        |
+-------------------+
```

1.2.3.25 FROM_UNIXTIME

Syntax

```
FROM_UNIXTIME(unix_timestamp), FROM_UNIXTIME(unix_timestamp,format)
```

Contents

Description

Returns a representation of the unix_timestamp argument as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS.uuuuuu format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone. unix_timestamp is an internal timestamp value such as is produced by the UNIX_TIMESTAMP() function.

If format is given, the result is formatted according to the format string, which is used the same way as listed in the entry for the DATE_FORMAT() function.

Timestamps in MariaDB have a maximum value of 2147483647, equivalent to 2038-01-19 05:14:07. This is due to the underlying 32-bit limitation. Using the function on a timestamp beyond this will result in NULL being returned. Use DATETIME as a storage type if you require dates beyond this.

The options that can be used by FROM_UNIXTIME(), as well as DATE_FORMAT() and STR_TO_DATE(), are:

Option	Description
`%a`	Short weekday name in current locale (Variable lc_time_names).
`%b`	Short form month name in current locale. For locale en_US this is one of: Jan,Feb,Mar,Apr,May,Jun,Jul,Aug,Sep,Oct,Nov or Dec.
`%c`	Month with 1 or 2 digits.
`%D`	Day with English suffix 'th', 'nd', 'st' or 'rd''. (1st, 2nd, 3rd...).
`%d`	Day with 2 digits.
`%e`	Day with 1 or 2 digits.
`%f`	Microseconds 6 digits.
`%H`	Hour with 2 digits between 00-23.
`%h`	Hour with 2 digits between 01-12.
`%I`	Hour with 2 digits between 01-12.
`%i`	Minute with 2 digits.
`%j`	Day of the year (001-366)
`%k`	Hour with 1 digits between 0-23.
`%l`	Hour with 1 digits between 1-12.
`%M`	Full month name in current locale (Variable lc_time_names).
`%m`	Month with 2 digits.
`%p`	AM/PM according to current locale (Variable lc_time_names).
`%r`	Time in 12 hour format, followed by AM/PM. Short for '%I:%i:%S %p'.
`%S`	Seconds with 2 digits.
`%s`	Seconds with 2 digits.
`%T`	Time in 24 hour format. Short for '%H:%i:%S'.
`%U`	Week number (00-53), when first day of the week is Sunday.
`%u`	Week number (00-53), when first day of the week is Monday.
`%V`	Week number (01-53), when first day of the week is Sunday. Used with %X.
`%v`	Week number (01-53), when first day of the week is Monday. Used with %x.
`%W`	Full weekday name in current locale (Variable lc_time_names).

%w	Day of the week. 0 = Sunday, 6 = Saturday.
%X	Year with 4 digits when first day of the week is Sunday. Used with %V.
%x	Year with 4 digits when first day of the week is Sunday. Used with %v.
%Y	Year with 4 digits.
%y	Year with 2 digits.
%#	For str_to_date(), skip all numbers.
%.	For str_to_date(), skip all punctation characters.
%@	For str_to_date(), skip all alpha characters.
%%	A literal % character.

Performance Considerations

If your session time zone is set to `SYSTEM` (the default), `FROM_UNIXTIME()` will call the OS function to convert the data using the system time zone. At least on Linux, the corresponding function (`localtime_r`) uses a global mutex inside glibc that can cause contention under high concurrent load.

Set your time zone to a named time zone to avoid this issue. See mysql time zone tables for details on how to do this.

Examples

```
SELECT FROM_UNIXTIME(1196440219);
+---------------------------+
| FROM_UNIXTIME(1196440219) |
+---------------------------+
| 2007-11-30 11:30:19       |
+---------------------------+

SELECT FROM_UNIXTIME(1196440219) + 0;
+------------------------------+
| FROM_UNIXTIME(1196440219) + 0 |
+------------------------------+
|         20071130113019.000000 |
+------------------------------+

SELECT FROM_UNIXTIME(UNIX_TIMESTAMP(), '%Y %D %M %h:%i:%s %x');
+-----------------------------------------------------------+
| FROM_UNIXTIME(UNIX_TIMESTAMP(), '%Y %D %M %h:%i:%s %x') |
+-----------------------------------------------------------+
| 2010 27th March 01:03:47 2010                             |
+-----------------------------------------------------------+
```

1.2.3.26 GET_FORMAT

Syntax

```
GET_FORMAT({DATE|DATETIME|TIME}, {'EUR'|'USA'|'JIS'|'ISO'|'INTERNAL'})
```

Description

Returns a format string. This function is useful in combination with the DATE_FORMAT() and the STR_TO_DATE() functions.

Possible result formats are:

Function Call	Result Format
GET_FORMAT(DATE,'EUR')	'%d.%m.%Y'

GET_FORMAT(DATE,'USA')	'%m.%d.%Y'
GET_FORMAT(DATE,'JIS')	'%Y-%m-%d'
GET_FORMAT(DATE,'ISO')	'%Y-%m-%d'
GET_FORMAT(DATE,'INTERNAL')	'%Y%m%d'
GET_FORMAT(DATETIME,'EUR')	'%Y-%m-%d %H.%i.%s'
GET_FORMAT(DATETIME,'USA')	'%Y-%m-%d %H.%i.%s'
GET_FORMAT(DATETIME,'JIS')	'%Y-%m-%d %H:%i:%s'
GET_FORMAT(DATETIME,'ISO')	'%Y-%m-%d %H:%i:%s'
GET_FORMAT(DATETIME,'INTERNAL')	'%Y%m%d%H%i%s'
GET_FORMAT(TIME,'EUR')	'%H.%i.%s'
GET_FORMAT(TIME,'USA')	'%h:%i:%s %p'
GET_FORMAT(TIME,'JIS')	'%H:%i:%s'
GET_FORMAT(TIME,'ISO')	'%H:%i:%s'
GET_FORMAT(TIME,'INTERNAL')	'%H%i%s'

Examples

Obtaining the string matching to the standard European date format:

```
SELECT GET_FORMAT(DATE, 'EUR');
+--------------------------+
| GET_FORMAT(DATE, 'EUR') |
+--------------------------+
| %d.%m.%Y                 |
+--------------------------+
```

Using the same string to format a date:

```
SELECT DATE_FORMAT('2003-10-03',GET_FORMAT(DATE,'EUR'));
+-----------------------------------------------+
| DATE_FORMAT('2003-10-03',GET_FORMAT(DATE,'EUR')) |
+-----------------------------------------------+
| 03.10.2003                                    |
+-----------------------------------------------+

SELECT STR_TO_DATE('10.31.2003',GET_FORMAT(DATE,'USA'));
+-----------------------------------------------+
| STR_TO_DATE('10.31.2003',GET_FORMAT(DATE,'USA')) |
+-----------------------------------------------+
| 2003-10-31                                    |
+-----------------------------------------------+
```

1.2.3.27 HOUR

Syntax

```
HOUR(time)
```

Description

Returns the hour for time. The range of the return value is 0 to 23 for time-of-day values. However, the range of `TIME` values actually is much larger, so HOUR can return values greater than 23.

The return value is always positive, even if a negative `TIME` value is provided.

Examples

```
SELECT HOUR('10:05:03');
+------------------+
| HOUR('10:05:03') |
+------------------+
|               10 |
+------------------+

SELECT HOUR('272:59:59');
+--------------------+
| HOUR('272:59:59') |
+--------------------+
|                272 |
+--------------------+
```

Difference between `EXTRACT (HOUR FROM ...)` (>= MariaDB 10.0.7 and MariaDB 5.5.35) and `HOUR`:

```
SELECT EXTRACT(HOUR FROM '26:30:00'), HOUR('26:30:00');
+--------------------------------+------------------+
| EXTRACT(HOUR FROM '26:30:00') | HOUR('26:30:00') |
+--------------------------------+------------------+
|                              2 |               26 |
+--------------------------------+------------------+
```

1.2.3.28 LAST_DAY

Syntax

```
LAST_DAY(date)
```

Description

Takes a date or datetime value and returns the corresponding value for the last day of the month. Returns NULL if the argument is invalid.

Examples

```
SELECT LAST_DAY('2003-02-05');
+-----------------------+
| LAST_DAY('2003-02-05') |
+-----------------------+
| 2003-02-28            |
+-----------------------+

SELECT LAST_DAY('2004-02-05');
+-----------------------+
| LAST_DAY('2004-02-05') |
+-----------------------+
| 2004-02-29            |
+-----------------------+

SELECT LAST_DAY('2004-01-01 01:01:01');
+--------------------------------+
| LAST_DAY('2004-01-01 01:01:01') |
+--------------------------------+
| 2004-01-31                     |
+--------------------------------+

SELECT LAST_DAY('2003-03-32');
+-----------------------+
| LAST_DAY('2003-03-32') |
+-----------------------+
| NULL                  |
+-----------------------+
1 row in set, 1 warning (0.00 sec)

Warning (Code 1292): Incorrect datetime value: '2003-03-32'
```

1.2.3.29 LOCALTIME

Syntax

```
LOCALTIME
LOCALTIME([precision])
```

Description

`LOCALTIME` and `LOCALTIME()` are synonyms for `NOW()`.

1.2.3.30 LOCALTIMESTAMP

Syntax

```
LOCALTIMESTAMP
LOCALTIMESTAMP([precision])
```

Description

`LOCALTIMESTAMP` and `LOCALTIMESTAMP()` are synonyms for `NOW()`.

1.2.3.31 MAKEDATE

Syntax

```
MAKEDATE(year,dayofyear)
```

Description

Returns a date, given `year` and `day-of-year values`. `dayofyear` must be greater than 0 or the result is NULL.

Examples

```
SELECT MAKEDATE(2011,31), MAKEDATE(2011,32);
+-------------------+-------------------+
| MAKEDATE(2011,31) | MAKEDATE(2011,32) |
+-------------------+-------------------+
| 2011-01-31        | 2011-02-01        |
+-------------------+-------------------+

SELECT MAKEDATE(2011,365), MAKEDATE(2014,365);
+--------------------+--------------------+
| MAKEDATE(2011,365) | MAKEDATE(2014,365) |
+--------------------+--------------------+
| 2011-12-31         | 2014-12-31         |
+--------------------+--------------------+

SELECT MAKEDATE(2011,0);
+------------------+
| MAKEDATE(2011,0) |
+------------------+
| NULL             |
+------------------+
```

1.2.3.32 MAKETIME

Syntax

```
MAKETIME(hour,minute,second)
```

Description

Returns a time value calculated from the `hour`, `minute`, and `second` arguments.

If `minute` or `second` are out of the range 0 to 60, NULL is returned. The `hour` can be in the range -838 to 838, outside of which the value is truncated with a warning.

Examples

```
SELECT MAKETIME(13,57,33);
+--------------------+
| MAKETIME(13,57,33) |
+--------------------+
| 13:57:33           |
+--------------------+

SELECT MAKETIME(-13,57,33);
+---------------------+
| MAKETIME(-13,57,33) |
+---------------------+
| -13:57:33           |
+---------------------+

SELECT MAKETIME(13,67,33);
+--------------------+
| MAKETIME(13,67,33) |
+--------------------+
| NULL               |
+--------------------+

SELECT MAKETIME(-1000,57,33);
+-----------------------+
| MAKETIME(-1000,57,33) |
+-----------------------+
| -838:59:59            |
+-----------------------+
1 row in set, 1 warning (0.00 sec)

SHOW WARNINGS;
+---------+------+-----------------------------------------------+
| Level   | Code | Message                                       |
+---------+------+-----------------------------------------------+
| Warning | 1292 | Truncated incorrect time value: '-1000:57:33' |
+---------+------+-----------------------------------------------+
```

1.2.3.33 MICROSECOND

Syntax

```
MICROSECOND(expr)
```

Contents

Description

Returns the microseconds from the time or datetime expression *expr* as a number in the range from 0 to 999999.

If *expr* is a time with no microseconds, zero is returned, while if *expr* is a date with no time, zero with a warning is returned.

Examples

```
SELECT MICROSECOND('12:00:00.123456');
+-------------------------------+
| MICROSECOND('12:00:00.123456') |
+-------------------------------+
|                         123456 |
+-------------------------------+

SELECT MICROSECOND('2009-12-31 23:59:59.000010');
+----------------------------------------+
| MICROSECOND('2009-12-31 23:59:59.000010') |
+----------------------------------------+
|                                     10 |
+----------------------------------------+

SELECT MICROSECOND('2013-08-07 12:13:14');
+-----------------------------------+
| MICROSECOND('2013-08-07 12:13:14') |
+-----------------------------------+
|                                 0 |
+-----------------------------------+

SELECT MICROSECOND('2013-08-07');
+---------------------------+
| MICROSECOND('2013-08-07') |
+---------------------------+
|                         0 |
+---------------------------+
1 row in set, 1 warning (0.00 sec)

SHOW WARNINGS;
+---------+------+-----------------------------------------------+
| Level   | Code | Message                                       |
+---------+------+-----------------------------------------------+
| Warning | 1292 | Truncated incorrect time value: '2013-08-07' |
+---------+------+-----------------------------------------------+
```

1.2.3.34 MINUTE

Syntax

```
MINUTE(time)
```

Description

Returns the minute for *time*, in the range 0 to 59.

Examples

```
SELECT MINUTE('2013-08-03 11:04:03');
+-------------------------------+
| MINUTE('2013-08-03 11:04:03') |
+-------------------------------+
|                             4 |
+-------------------------------+

 SELECT MINUTE ('23:12:50');
+---------------------+
| MINUTE ('23:12:50') |
+---------------------+
|                  12 |
+---------------------+
```

1.2.3.35 MONTH

Syntax

```
MONTH(date)
```

Description

Returns the month for `date` in the range 1 to 12 for January to December, or 0 for dates such as '0000-00-00' or '2008-00-00' that have a zero month part.

Examples

```
SELECT MONTH('2019-01-03');
+---------------------+
| MONTH('2019-01-03') |
+---------------------+
|                   1 |
+---------------------+

SELECT MONTH('2019-00-03');
+---------------------+
| MONTH('2019-00-03') |
+---------------------+
|                   0 |
+---------------------+
```

1.2.3.36 MONTHNAME

Syntax

```
MONTHNAME(date)
```

Description

Returns the full name of the month for date. The language used for the name is controlled by the value of the lc_time_names system variable. See server locale for more on the supported locales.

Examples

```
SELECT MONTHNAME('2019-02-03');
+--------------------------+
| MONTHNAME('2019-02-03') |
+--------------------------+
| February                 |
+--------------------------+
```

Changing the locale:

```
SET lc_time_names = 'fr_CA';

SELECT MONTHNAME('2019-05-21');
+--------------------------+
| MONTHNAME('2019-05-21') |
+--------------------------+
| mai                      |
+--------------------------+
```

1.2.3.37 NOW

Syntax

```
NOW([precision])
CURRENT_TIMESTAMP
CURRENT_TIMESTAMP([precision])
LOCALTIME, LOCALTIME([precision])
LOCALTIMESTAMP
LOCALTIMESTAMP([precision])
```

Contents

Description

Returns the current date and time as a value in `'YYYY-MM-DD HH:MM:SS'` or `YYYYMMDDHHMMSS.uuuuuu` format, depending on whether the function is used in a string or numeric context. The value is expressed in the current time zone.

The optional *precision* determines the microsecond precision. See Microseconds in MariaDB.

`NOW()` (or its synonyms) can be used as the default value for TIMESTAMP columns as well as, since MariaDB 10.0.1, DATETIME columns. Before MariaDB 10.0.1, it was only possible for a single TIMESTAMP column per table to contain the CURRENT_TIMESTAMP as its default.

When displayed in the INFORMATION_SCHEMA.COLUMNS table, a default CURRENT TIMESTAMP is displayed as `CURRENT_TIMESTAMP` up until MariaDB 10.2.2, and as `current_timestamp()` from MariaDB 10.2.3, due to to MariaDB 10.2 accepting expressions in the DEFAULT clause.

Changing the timestamp system variable with a SET `timestamp` statement affects the value returned by NOW(), but not by SYSDATE().

Examples

```
SELECT NOW();
+---------------------+
| NOW()               |
+---------------------+
| 2010-03-27 13:13:25 |
+---------------------+

SELECT NOW() + 0;
+-----------------------+
| NOW() + 0             |
+-----------------------+
| 20100327131329.000000 |
+-----------------------+
```

With precision:

```
SELECT CURRENT_TIMESTAMP(2);
+------------------------+
| CURRENT_TIMESTAMP(2)   |
+------------------------+
| 2018-07-10 09:47:26.24 |
+------------------------+
```

Used as a default TIMESTAMP:

```
CREATE TABLE t (createdTS TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP);
```

From MariaDB 10.2.2:

```
SELECT * FROM INFORMATION_SCHEMA.COLUMNS WHERE TABLE_SCHEMA='test'
  AND COLUMN_NAME LIKE '%ts%'\G
*************************** 1. row ***************************
           TABLE_CATALOG: def
            TABLE_SCHEMA: test
              TABLE_NAME: t
             COLUMN_NAME: ts
        ORDINAL_POSITION: 1
          COLUMN_DEFAULT: current_timestamp()
...
```

<= MariaDB 10.2.1

```
SELECT * FROM INFORMATION_SCHEMA.COLUMNS WHERE TABLE_SCHEMA='test'
  AND COLUMN_NAME LIKE '%ts%'\G
*************************** 1. row ***************************
           TABLE_CATALOG: def
            TABLE_SCHEMA: test
              TABLE_NAME: t
             COLUMN_NAME: createdTS
        ORDINAL_POSITION: 1
          COLUMN_DEFAULT: CURRENT_TIMESTAMP
...
```

1.2.3.38 PERIOD_ADD

Syntax

```
PERIOD_ADD(P,N)
```

Description

Adds `N` months to period `P`. `P` is in the format YYMM or YYYYMM, and is not a date value. If `P` contains a two-digit year, values from 00 to 69 are converted to from 2000 to 2069, while values from 70 are converted to 1970 upwards.

Returns a value in the format YYYYMM.

Examples

```
SELECT PERIOD_ADD(200801,2);
+----------------------+
| PERIOD_ADD(200801,2) |
+----------------------+
|               200803 |
+----------------------+

SELECT PERIOD_ADD(6910,2);
+--------------------+
| PERIOD_ADD(6910,2) |
+--------------------+
|             206912 |
+--------------------+

SELECT PERIOD_ADD(7010,2);
+--------------------+
| PERIOD_ADD(7010,2) |
+--------------------+
|             197012 |
+--------------------+
```

1.2.3.39 PERIOD_DIFF

Syntax

```
PERIOD_DIFF(P1,P2)
```

Description

Returns the number of months between periods P1 and P2. P1 and P2 can be in the format `YYMM` or `YYYYMM`, and are not date values.

If P1 or P2 contains a two-digit year, values from 00 to 69 are converted to from 2000 to 2069, while values from 70 are converted to 1970 upwards.

Examples

```
SELECT PERIOD_DIFF(200802,200703);
+----------------------------+
| PERIOD_DIFF(200802,200703) |
+----------------------------+
|                         11 |
+----------------------------+

SELECT PERIOD_DIFF(6902,6803);
+------------------------+
| PERIOD_DIFF(6902,6803) |
+------------------------+
|                     11 |
+------------------------+

SELECT PERIOD_DIFF(7002,6803);
+------------------------+
| PERIOD_DIFF(7002,6803) |
+------------------------+
|                  -1177 |
+------------------------+
```

1.2.3.40 QUARTER

Syntax

```
QUARTER(date)
```

Description

Returns the quarter of the year for `date`, in the range 1 to 4. Returns 0 if month contains a zero value, or `NULL` if the given value is not otherwise a valid date (zero values are accepted).

Examples

```
SELECT QUARTER('2008-04-01');
+-----------------------+
| QUARTER('2008-04-01') |
+-----------------------+
|                     2 |
+-----------------------+

SELECT QUARTER('2019-00-01');
+-----------------------+
| QUARTER('2019-00-01') |
+-----------------------+
|                     0 |
+-----------------------+
```

1.2.3.41 SECOND

Syntax

```
SECOND(time)
```

Description

Returns the second for a given `time` (which can include microseconds), in the range 0 to 59, or `NULL` if not given a valid time value.

Examples

```
SELECT SECOND('10:05:03');
+--------------------+
| SECOND('10:05:03') |
+--------------------+
|                  3 |
+--------------------+

SELECT SECOND('10:05:01.999999');
+---------------------------+
| SECOND('10:05:01.999999') |
+---------------------------+
|                         1 |
+---------------------------+
```

1.2.3.42 SEC_TO_TIME

Syntax

```
SEC_TO_TIME(seconds)
```

Description

Returns the seconds argument, converted to hours, minutes, and seconds, as a TIME value. The range of the result is constrained to that of the TIME data type. A warning occurs if the argument corresponds to a value outside that range.

The time will be returned in the format `hh:mm:ss`, or `hhmmss` if used in a numeric calculation.

Examples

```
SELECT SEC_TO_TIME(12414);
+--------------------+
| SEC_TO_TIME(12414) |
+--------------------+
| 03:26:54           |
+--------------------+

SELECT SEC_TO_TIME(12414)+0;
+----------------------+
| SEC_TO_TIME(12414)+0 |
+----------------------+
|                32654 |
+----------------------+

SELECT SEC_TO_TIME(9999999);
+----------------------+
| SEC_TO_TIME(9999999) |
+----------------------+
| 838:59:59            |
+----------------------+
1 row in set, 1 warning (0.00 sec)

SHOW WARNINGS;
+---------+------+-----------------------------------------+
| Level   | Code | Message                                 |
+---------+------+-----------------------------------------+
| Warning | 1292 | Truncated incorrect time value: '9999999' |
+---------+------+-----------------------------------------+
```

1.2.3.43 STR_TO_DATE

Syntax

```
STR_TO_DATE(str,format)
```

Contents

Description

This is the inverse of the DATE_FORMAT() function. It takes a string `str` and a format string `format`. `STR_TO_DATE()` returns a `DATETIME` value if the format string contains both date and time parts, or a `DATE` or `TIME` value if the string contains only date or time parts.

The date, time, or datetime values contained in `str` should be given in the format indicated by format. If str contains an illegal date, time, or datetime value, `STR_TO_DATE()` returns `NULL`. An illegal value also produces a warning.

Under specific SQL_MODE settings an error may also be generated if the `str` isn't a valid date:

- ALLOW_INVALID_DATES
- NO_ZERO_DATE
- NO_ZERO_IN_DATE

The options that can be used by STR_TO_DATE(), as well as its inverse DATE_FORMAT() and the FROM_UNIXTIME() function, are:

Option	Description
%a	Short weekday name in current locale (Variable lc_time_names).
%b	Short form month name in current locale. For locale en_US this is one of: Jan,Feb,Mar,Apr,May,Jun,Jul,Aug,Sep,Oct,Nov or Dec.
%c	Month with 1 or 2 digits.

%D	Day with English suffix 'th', 'nd', 'st' or 'rd''. (1st, 2nd, 3rd...).
%d	Day with 2 digits.
%e	Day with 1 or 2 digits.
%f	Microseconds 6 digits.
%H	Hour with 2 digits between 00-23.
%h	Hour with 2 digits between 01-12.
%I	Hour with 2 digits between 01-12.
%i	Minute with 2 digits.
%j	Day of the year (001-366)
%k	Hour with 1 digits between 0-23.
%l	Hour with 1 digits between 1-12.
%M	Full month name in current locale (Variable lc_time_names).
%m	Month with 2 digits.
%p	AM/PM according to current locale (Variable lc_time_names).
%r	Time in 12 hour format, followed by AM/PM. Short for '%I:%i:%S %p'.
%S	Seconds with 2 digits.
%s	Seconds with 2 digits.
%T	Time in 24 hour format. Short for '%H:%i:%S'.
%U	Week number (00-53), when first day of the week is Sunday.
%u	Week number (00-53), when first day of the week is Monday.
%V	Week number (01-53), when first day of the week is Sunday. Used with %X.
%v	Week number (01-53), when first day of the week is Monday. Used with %x.
%W	Full weekday name in current locale (Variable lc_time_names).
%w	Day of the week. 0 = Sunday, 6 = Saturday.
%X	Year with 4 digits when first day of the week is Sunday. Used with %V.
%x	Year with 4 digits when first day of the week is Monday. Used with %v.
%Y	Year with 4 digits.
%y	Year with 2 digits.
%#	For str_to_date(), skip all numbers.
%.	For str_to_date(), skip all punctation characters.
%@	For str_to_date(), skip all alpha characters.
%%	A literal % character.

Examples

```
SELECT STR_TO_DATE('Wednesday, June 2, 2014', '%W, %M %e, %Y');
+-----------------------------------------------------+
| STR_TO_DATE('Wednesday, June 2, 2014', '%W, %M %e, %Y') |
+-----------------------------------------------------+
| 2014-06-02                                          |
+-----------------------------------------------------+

SELECT STR_TO_DATE('Wednesday23423, June 2, 2014', '%W, %M %e, %Y');
+-------------------------------------------------------------+
| STR_TO_DATE('Wednesday23423, June 2, 2014', '%W, %M %e, %Y') |
+-------------------------------------------------------------+
| NULL                                                        |
+-------------------------------------------------------------+
1 row in set, 1 warning (0.00 sec)

SHOW WARNINGS;
+---------+------+-----------------------------------------------------------------------------------------
| Level   | Code | Message
+---------+------+-----------------------------------------------------------------------------------------
| Warning | 1411 | Incorrect datetime value: 'Wednesday23423, June 2, 2014' for function str_to_d
+---------+------+-----------------------------------------------------------------------------------------

SELECT STR_TO_DATE('Wednesday23423, June 2, 2014', '%W%#, %M %e, %Y');
+-------------------------------------------------------------+
| STR_TO_DATE('Wednesday23423, June 2, 2014', '%W%#, %M %e, %Y') |
+-------------------------------------------------------------+
| 2014-06-02                                                  |
+-------------------------------------------------------------+
```

1.2.3.44 SUBDATE

Syntax

```
SUBDATE(date,INTERVAL expr unit), SUBDATE(expr,days)
```

Description

When invoked with the `INTERVAL` form of the second argument, `SUBDATE()` is a synonym for `DATE_SUB()`. See Date and Time Units for a complete list of permitted units.

The second form allows the use of an integer value for days. In such cases, it is interpreted as the number of days to be subtracted from the date or datetime expression expr.

Examples

```
SELECT DATE_SUB('2008-01-02', INTERVAL 31 DAY);
+----------------------------------------+
| DATE_SUB('2008-01-02', INTERVAL 31 DAY) |
+----------------------------------------+
| 2007-12-02                             |
+----------------------------------------+

SELECT SUBDATE('2008-01-02', INTERVAL 31 DAY);
+----------------------------------------+
| SUBDATE('2008-01-02', INTERVAL 31 DAY) |
+----------------------------------------+
| 2007-12-02                             |
+----------------------------------------+
```

```
SELECT SUBDATE('2008-01-02 12:00:00', 31);
+-----------------------------------+
| SUBDATE('2008-01-02 12:00:00', 31) |
+-----------------------------------+
| 2007-12-02 12:00:00                |
+-----------------------------------+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT d, SUBDATE(d, 10) from t1;
+---------------------+---------------------+
| d                   | SUBDATE(d, 10)      |
+---------------------+---------------------+
| 2007-01-30 21:31:07 | 2007-01-20 21:31:07 |
| 1983-10-15 06:42:51 | 1983-10-05 06:42:51 |
| 2011-04-21 12:34:56 | 2011-04-11 12:34:56 |
| 2011-10-30 06:31:41 | 2011-10-20 06:31:41 |
| 2011-01-30 14:03:25 | 2011-01-20 14:03:25 |
| 2004-10-07 11:19:34 | 2004-09-27 11:19:34 |
+---------------------+---------------------+

SELECT d, SUBDATE(d, INTERVAL 10 MINUTE) from t1;
+---------------------+-------------------------------+
| d                   | SUBDATE(d, INTERVAL 10 MINUTE) |
+---------------------+-------------------------------+
| 2007-01-30 21:31:07 | 2007-01-30 21:21:07            |
| 1983-10-15 06:42:51 | 1983-10-15 06:32:51            |
| 2011-04-21 12:34:56 | 2011-04-21 12:24:56            |
| 2011-10-30 06:31:41 | 2011-10-30 06:21:41            |
| 2011-01-30 14:03:25 | 2011-01-30 13:53:25            |
| 2004-10-07 11:19:34 | 2004-10-07 11:09:34            |
+---------------------+-------------------------------+
```

1.2.3.45 SUBTIME

Syntax

```
SUBTIME(expr1,expr2)
```

Description

SUBTIME() returns `expr1 - expr2` expressed as a value in the same format as `expr1`. `expr1` is a time or datetime expression, and expr2 is a time expression.

Examples

```
SELECT SUBTIME('2007-12-31 23:59:59.999999','1 1:1:1.000002');
+-----------------------------------------------------------+
| SUBTIME('2007-12-31 23:59:59.999999','1 1:1:1.000002') |
+-----------------------------------------------------------+
| 2007-12-30 22:58:58.999997                                |
+-----------------------------------------------------------+

SELECT SUBTIME('01:00:00.999999', '02:00:00.999998');
+---------------------------------------------+
| SUBTIME('01:00:00.999999', '02:00:00.999998') |
+---------------------------------------------+
| -00:59:59.999999                            |
+---------------------------------------------+
```

1.2.3.46 SYSDATE

Syntax

```
SYSDATE([precision])
```

Contents

Description

Returns the current date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS.uuuuuu format, depending on whether the function is used in a string or numeric context.

The optional *precision* determines the microsecond precision. See Microseconds in MariaDB.

SYSDATE() returns the time at which it executes. This differs from the behavior for NOW(), which returns a constant time that indicates the time at which the statement began to execute. (Within a stored routine or trigger, NOW() returns the time at which the routine or triggering statement began to execute.)

In addition, changing the timestamp system variable with a SET `timestamp` statement affects the value returned by NOW() but not by SYSDATE(). This means that timestamp settings in the binary log have no effect on invocations of SYSDATE().

Because SYSDATE() can return different values even within the same statement, and is not affected by SET TIMESTAMP, it is non-deterministic and therefore unsafe for replication if statement-based binary logging is used. If that is a problem, you can use row-based logging, or start the server with the mysqld option --sysdate-is-now to cause SYSDATE() to be an alias for NOW(). The non-deterministic nature of SYSDATE() also means that indexes cannot be used for evaluating expressions that refer to it, and that statements using the SYSDATE() function are unsafe for statement-based replication.

Examples

Difference between NOW() and SYSDATE():

```
SELECT NOW(), SLEEP(2), NOW();
+---------------------+----------+---------------------+
| NOW()               | SLEEP(2) | NOW()               |
+---------------------+----------+---------------------+
| 2010-03-27 13:23:40 |        0 | 2010-03-27 13:23:40 |
+---------------------+----------+---------------------+

SELECT SYSDATE(), SLEEP(2), SYSDATE();
+---------------------+----------+---------------------+
| SYSDATE()           | SLEEP(2) | SYSDATE()           |
+---------------------+----------+---------------------+
| 2010-03-27 13:23:52 |        0 | 2010-03-27 13:23:54 |
+---------------------+----------+---------------------+
```

With precision:

```
SELECT SYSDATE(4);
+--------------------------+
| SYSDATE(4)               |
+--------------------------+
| 2018-07-10 10:17:13.1689 |
+--------------------------+
```

1.2.3.47 TIME Function

Syntax

```
TIME(expr)
```

Description

Extracts the time part of the time or datetime expression `expr` and returns it as a string.

Examples

```
SELECT TIME('2003-12-31 01:02:03');
+-----------------------------+
| TIME('2003-12-31 01:02:03') |
+-----------------------------+
| 01:02:03                    |
+-----------------------------+

SELECT TIME('2003-12-31 01:02:03.000123');
+--------------------------------------+
| TIME('2003-12-31 01:02:03.000123') |
+--------------------------------------+
| 01:02:03.000123                      |
+--------------------------------------+
```

1.2.3.48 TIMEDIFF

Syntax

```
TIMEDIFF(expr1,expr2)
```

Description

TIMEDIFF() returns `expr1 - expr2` expressed as a time value. `expr1` and `expr2` are time or date-and-time expressions, but both must be of the same type.

Examples

```
SELECT TIMEDIFF('2000:01:01 00:00:00', '2000:01:01 00:00:00.000001');
+----------------------------------------------------------------+
| TIMEDIFF('2000:01:01 00:00:00', '2000:01:01 00:00:00.000001') |
+----------------------------------------------------------------+
| -00:00:00.000001                                               |
+----------------------------------------------------------------+

SELECT TIMEDIFF('2008-12-31 23:59:59.000001', '2008-12-30 01:01:01.000002');
+----------------------------------------------------------------------+
| TIMEDIFF('2008-12-31 23:59:59.000001', '2008-12-30 01:01:01.000002') |
+----------------------------------------------------------------------+
| 46:58:57.999999                                                      |
+----------------------------------------------------------------------+
```

1.2.3.49 TIMESTAMP FUNCTION

Syntax

```
TIMESTAMP(expr), TIMESTAMP(expr1,expr2)
```

Description

With a single argument, this function returns the date or datetime expression `expr` as a datetime value. With two arguments, it adds the time expression `expr2` to the date or datetime expression `expr1` and returns the result as a datetime value.

Examples

```
SELECT TIMESTAMP('2003-12-31');
+-------------------------+
| TIMESTAMP('2003-12-31') |
+-------------------------+
| 2003-12-31 00:00:00     |
+-------------------------+

SELECT TIMESTAMP('2003-12-31 12:00:00','6:30:00');
+-----------------------------------------+
| TIMESTAMP('2003-12-31 12:00:00','6:30:00') |
+-----------------------------------------+
| 2003-12-31 18:30:00                     |
+-----------------------------------------+
```

1.2.3.50 TIMESTAMPADD

Syntax

```
TIMESTAMPADD(unit,interval,datetime_expr)
```

Description

Adds the integer expression interval to the date or datetime expression datetime_expr. The unit for interval is given by the unit argument, which should be one of the following values: MICROSECOND, SECOND, MINUTE, HOUR, DAY, WEEK, MONTH, QUARTER, or YEAR.

The unit value may be specified using one of keywords as shown, or with a prefix of SQL_TSI_. For example, DAY and SQL_TSI_DAY both are legal.

Before MariaDB 5.5, FRAC_SECOND was permitted as a synonym for MICROSECOND.

Examples

```
SELECT TIMESTAMPADD(MINUTE,1,'2003-01-02');
+-------------------------------------+
| TIMESTAMPADD(MINUTE,1,'2003-01-02') |
+-------------------------------------+
| 2003-01-02 00:01:00                 |
+-------------------------------------+

SELECT TIMESTAMPADD(WEEK,1,'2003-01-02');
+----------------------------------+
| TIMESTAMPADD(WEEK,1,'2003-01-02') |
+----------------------------------+
| 2003-01-09                       |
+----------------------------------+
```

1.2.3.51 TIMESTAMPDIFF

Syntax

```
TIMESTAMPDIFF(unit,datetime_expr1,datetime_expr2)
```

Description

Returns `datetime_expr2 - datetime_expr1`, where `datetime_expr1` and `datetime_expr2` are date or datetime expressions. One expression may be a date and the other a datetime; a date value is treated as a datetime having the time part '00:00:00' where necessary. The unit for the result (an integer) is given by the unit argument. The legal values for unit are the same as those listed in the description of the TIMESTAMPADD() function, i.e MICROSECOND, SECOND, MINUTE, HOUR, DAY, WEEK, MONTH, QUARTER, or YEAR.

`TIMESTAMPDIFF` can also be used to calculate age.

Examples

```
SELECT TIMESTAMPDIFF(MONTH,'2003-02-01','2003-05-01');
+----------------------------------------------+
| TIMESTAMPDIFF(MONTH,'2003-02-01','2003-05-01') |
+----------------------------------------------+
|                                            3 |
+----------------------------------------------+

SELECT TIMESTAMPDIFF(YEAR,'2002-05-01','2001-01-01');
+---------------------------------------------+
| TIMESTAMPDIFF(YEAR,'2002-05-01','2001-01-01') |
+---------------------------------------------+
|                                          -1 |
+---------------------------------------------+

SELECT TIMESTAMPDIFF(MINUTE,'2003-02-01','2003-05-01 12:05:55');
+-----------------------------------------------------------+
| TIMESTAMPDIFF(MINUTE,'2003-02-01','2003-05-01 12:05:55') |
+-----------------------------------------------------------+
|                                                    128885 |
+-----------------------------------------------------------+
```

Calculating age:

```
SELECT CURDATE();
+------------+
| CURDATE()  |
+------------+
| 2019-05-27 |
+------------+

SELECT TIMESTAMPDIFF(YEAR, '1971-06-06', CURDATE()) AS age;
+------+
| age  |
+------+
|   47 |
+------+

SELECT TIMESTAMPDIFF(YEAR, '1971-05-06', CURDATE()) AS age;
+------+
| age  |
+------+
|   48 |
+------+
```

Age as of 2014-08-02:

```
SELECT name, date_of_birth, TIMESTAMPDIFF(YEAR,date_of_birth,'2014-08-02') AS age
  FROM student_details;
+---------+---------------+------+
| name    | date_of_birth | age  |
+---------+---------------+------+
| Chun    | 1993-12-31    |   20 |
| Esben   | 1946-01-01    |   68 |
| Kaolin  | 1996-07-16    |   18 |
| Tatiana | 1988-04-13    |   26 |
+---------+---------------+------+
```

1.2.3.52 TIME_FORMAT

Syntax

```
TIME_FORMAT(time,format)
```

Description

This is used like the DATE_FORMAT() function, but the format string may contain format specifiers only for hours, minutes, and seconds. Other specifiers produce a NULL value or 0.

Examples

```
SELECT TIME_FORMAT('100:00:00', '%H %k %h %I %l');
+----------------------------------------+
| TIME_FORMAT('100:00:00', '%H %k %h %I %l') |
+----------------------------------------+
| 100 100 04 04 4                        |
+----------------------------------------+
```

1.2.3.53 TIME_TO_SEC

Syntax

```
TIME_TO_SEC(time)
```

Description

Returns the time argument, converted to seconds.

The value returned by `TIME_TO_SEC` is of type `DOUBLE`. Before MariaDB 5.3 (and MySQL 5.6), the type was `INT`. The returned value preserves microseconds of the argument. See also Microseconds in MariaDB.

Examples

```
SELECT TIME_TO_SEC('22:23:00');
+-------------------------+
| TIME_TO_SEC('22:23:00') |
+-------------------------+
|                   80580 |
+-------------------------+
```

```
SELECT TIME_TO_SEC('00:39:38');
+-------------------------+
| TIME_TO_SEC('00:39:38') |
+-------------------------+
|                    2378 |
+-------------------------+
```

```
SELECT TIME_TO_SEC('09:12:55.2355');
+-------------------------------+
| TIME_TO_SEC('09:12:55.2355') |
+-------------------------------+
|                   33175.2355 |
+-------------------------------+
1 row in set (0.000 sec)
```

1.2.3.54 TO_DAYS

Syntax

```
TO_DAYS(date)
```

Description

Given a date `date`, returns the number of days since the start of the current calendar (0000-00-00).

The function is not designed for use with dates before the advent of the Gregorian calendar in October 1582. Results will not be reliable since it doesn't account for the lost days when the calendar changed from the Julian calendar.

This is the converse of the FROM_DAYS() function.

Examples

```
SELECT TO_DAYS('2007-10-07');
+-----------------------+
| TO_DAYS('2007-10-07') |
+-----------------------+
|                733321 |
+-----------------------+

SELECT TO_DAYS('0000-01-01');
+-----------------------+
| TO_DAYS('0000-01-01') |
+-----------------------+
|                     1 |
+-----------------------+

SELECT TO_DAYS(950501);
+-----------------+
| TO_DAYS(950501) |
+-----------------+
|          728779 |
+-----------------+
```

1.2.3.55 TO_SECONDS

Syntax

```
TO_SECONDS(expr)
```

Description

Returns the number of seconds from year 0 till `expr`, or NULL if `expr` is not a valid date or datetime.

Examples

```
SELECT TO_SECONDS('2013-06-13');
+--------------------------+
| TO_SECONDS('2013-06-13') |
+--------------------------+
|              63538300800 |
+--------------------------+

SELECT TO_SECONDS('2013-06-13 21:45:13');
+-----------------------------------+
| TO_SECONDS('2013-06-13 21:45:13') |
+-----------------------------------+
|                       63538379113 |
+-----------------------------------+

SELECT TO_SECONDS(NOW());
+-------------------+
| TO_SECONDS(NOW()) |
+-------------------+
|       63543530875 |
+-------------------+

SELECT TO_SECONDS(20130513);
+----------------------+
| TO_SECONDS(20130513) |
+----------------------+
|          63535622400 |
+----------------------+
1 row in set (0.00 sec)

SELECT TO_SECONDS(130513);
+--------------------+
| TO_SECONDS(130513) |
+--------------------+
|        63535622400 |
+--------------------+
```

1.2.3.56 UNIX_TIMESTAMP

Contents

Syntax

```
UNIX_TIMESTAMP()
UNIX_TIMESTAMP(date)
```

Description

If called with no argument, returns a Unix timestamp (seconds since '1970-01-01 00:00:00' UTC) as an unsigned integer. If `UNIX_TIMESTAMP()` is called with a date argument, it returns the value of the argument as seconds since '1970-01-01 00:00:00' UTC. date may be a `DATE` string, a `DATETIME` string, a `TIMESTAMP`, or a number in the format YYMMDD or YYYYMMDD. The server interprets date as a value in the current time zone and converts it to an internal value in UTC. Clients can set their time zone as described in time zones.

The inverse function of `UNIX_TIMESTAMP()` is `FROM_UNIXTIME()`

`UNIX_TIMESTAMP()` supports microseconds.

Timestamps in MariaDB have a maximum value of 2147483647, equivalent to 2038-01-19 05:14:07. This is due to the underlying 32-bit limitation. Using the function on a date beyond this will result in NULL being returned. Use DATETIME as a storage type if you require dates beyond this.

Error Handling

Returns NULL for wrong arguments to `UNIX_TIMESTAMP()`. In MySQL and MariaDB before 5.3 wrong arguments to `UNIX_TIMESTAMP()` returned 0.

Compatibility

As you can see in the examples above, UNIX_TIMESTAMP(constant-date-string) returns a timestamp with 6 decimals while MariaDB 5.2 and before returns it without decimals. This can cause a problem if you are using UNIX_TIMESTAMP() as a partitioning function. You can fix this by using FLOOR(UNIX_TIMESTAMP(..)) or changing the date string to a date number, like 20080101000000.

Examples

```
SELECT UNIX_TIMESTAMP();
+------------------+
| UNIX_TIMESTAMP() |
+------------------+
|       1269711082 |
+------------------+

SELECT UNIX_TIMESTAMP('2007-11-30 10:30:19');
+---------------------------------------+
| UNIX_TIMESTAMP('2007-11-30 10:30:19') |
+---------------------------------------+
|                   1196436619.000000 |
+---------------------------------------+

SELECT UNIX_TIMESTAMP("2007-11-30 10:30:19.123456");
+-----------------------------------------------+
| unix_timestamp("2007-11-30 10:30:19.123456") |
+-----------------------------------------------+
|                          1196411419.123456 |
+-----------------------------------------------+

SELECT FROM_UNIXTIME(UNIX_TIMESTAMP('2007-11-30 10:30:19'));
+-------------------------------------------------------+
| FROM_UNIXTIME(UNIX_TIMESTAMP('2007-11-30 10:30:19')) |
+-------------------------------------------------------+
| 2007-11-30 10:30:19.000000                            |
+-------------------------------------------------------+

SELECT FROM_UNIXTIME(FLOOR(UNIX_TIMESTAMP('2007-11-30 10:30:19')));
+-------------------------------------------------------------+
| FROM_UNIXTIME(FLOOR(UNIX_TIMESTAMP('2007-11-30 10:30:19'))) |
+-------------------------------------------------------------+
| 2007-11-30 10:30:19                                         |
+-------------------------------------------------------------+
```

1.2.3.57 UTC_DATE

Syntax

```
UTC_DATE, UTC_DATE()
```

Description

Returns the current UTC date as a value in 'YYYY-MM-DD' or YYYYMMDD format, depending on whether the function is used in a string or numeric context.

Examples

```
SELECT UTC_DATE(), UTC_DATE() + 0;
+------------+----------------+
| UTC_DATE() | UTC_DATE() + 0 |
+------------+----------------+
| 2010-03-27 |       20100327 |
+------------+----------------+
```

1.2.3.58 UTC_TIME

Syntax

```
UTC_TIME
UTC_TIME([precision])
```

Description

Returns the current UTC time as a value in 'HH:MM:SS' or HHMMSS.uuuuuu format, depending on whether the function is used in a string or numeric context.

The optional *precision* determines the microsecond precision. See Microseconds in MariaDB.

Examples

```
SELECT UTC_TIME(), UTC_TIME() + 0;
+------------+----------------+
| UTC_TIME() | UTC_TIME() + 0 |
+------------+----------------+
| 17:32:34   |  173234.000000 |
+------------+----------------+
```

With precision:

```
SELECT UTC_TIME(5);
+----------------+
| UTC_TIME(5)    |
+----------------+
| 07:52:50.78369 |
+----------------+
```

1.2.3.59 UTC_TIMESTAMP

Syntax

```
UTC_TIMESTAMP
UTC_TIMESTAMP([precision])
```

Description

Returns the current UTC date and time as a value in 'YYYY-MM-DD HH:MM:SS' or YYYYMMDDHHMMSS.uuuuuu format, depending on whether the function is used in a string or numeric context.

The optional *precision* determines the microsecond precision. See Microseconds in MariaDB.

Examples

```
SELECT UTC_TIMESTAMP(), UTC_TIMESTAMP() + 0;
+---------------------+----------------------+
| UTC_TIMESTAMP()     | UTC_TIMESTAMP() + 0  |
+---------------------+----------------------+
| 2010-03-27 17:33:16 | 20100327173316.000000 |
+---------------------+----------------------+
```

With precision:

```
SELECT UTC_TIMESTAMP(4);
+--------------------------+
| UTC_TIMESTAMP(4)         |
+--------------------------+
| 2018-07-10 07:51:09.1019 |
+--------------------------+
```

1.2.3.60 WEEK

Syntax

```
WEEK(date[,mode])
```

Description

This function returns the week number for `date`. The two-argument form of `WEEK()` allows you to specify whether the week starts on Sunday or Monday and whether the return value should be in the range from 0 to 53 or from 1 to 53. If the `mode` argument is omitted, the value of the default_week_format system variable is used.

Modes

Mode	1st day of week	Range	Week 1 is the 1st week with
0	Sunday	0-53	a Sunday in this year
1	Monday	0-53	more than 3 days this year
2	Sunday	1-53	a Sunday in this year
3	Monday	1-53	more than 3 days this year
4	Sunday	0-53	more than 3 days this year
5	Monday	0-53	a Monday in this year
6	Sunday	1-53	more than 3 days this year
7	Monday	1-53	a Monday in this year

With the mode value of 3, which means 'more than 3 days this year', weeks are numbered according to ISO 8601:1988.

Examples

```
SELECT WEEK('2008-02-20');
+--------------------+
| WEEK('2008-02-20') |
+--------------------+
|                  7 |
+--------------------+

SELECT WEEK('2008-02-20',0);
+----------------------+
| WEEK('2008-02-20',0) |
+----------------------+
|                    7 |
+----------------------+

SELECT WEEK('2008-02-20',1);
+----------------------+
| WEEK('2008-02-20',1) |
+----------------------+
|                    8 |
+----------------------+

SELECT WEEK('2008-12-31',0);
+----------------------+
| WEEK('2008-12-31',0) |
+----------------------+
|                   52 |
+----------------------+

SELECT WEEK('2008-12-31',1);
+----------------------+
| WEEK('2008-12-31',1) |
+----------------------+
|                   53 |
+----------------------+

 SELECT WEEK('2019-12-30',3);
+----------------------+
| WEEK('2019-12-30',3) |
+----------------------+
|                    1 |
+----------------------+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT d, WEEK(d,0), WEEK(d,1) from t1;
+---------------------+-----------+-----------+
| d                   | WEEK(d,0) | WEEK(d,1) |
+---------------------+-----------+-----------+
| 2007-01-30 21:31:07 |         4 |         5 |
| 1983-10-15 06:42:51 |        41 |        41 |
| 2011-04-21 12:34:56 |        16 |        16 |
| 2011-10-30 06:31:41 |        44 |        43 |
| 2011-01-30 14:03:25 |         5 |         4 |
| 2004-10-07 11:19:34 |        40 |        41 |
+---------------------+-----------+-----------+
```

1.2.3.61 WEEKDAY

Syntax

```
WEEKDAY(date)
```

Description

Returns the weekday index for `date` (`0` = Monday, `1` = Tuesday, ... `6` = Sunday).

This contrasts with `DAYOFWEEK()` which follows the ODBC standard (`1` = Sunday, `2` = Monday, ..., `7` = Saturday).

Examples

```
SELECT WEEKDAY('2008-02-03 22:23:00');
+--------------------------------+
| WEEKDAY('2008-02-03 22:23:00') |
+--------------------------------+
|                              6 |
+--------------------------------+

SELECT WEEKDAY('2007-11-06');
+-----------------------+
| WEEKDAY('2007-11-06') |
+-----------------------+
|                     1 |
+-----------------------+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT d FROM t1 where WEEKDAY(d) = 6;
+---------------------+
| d                   |
+---------------------+
| 2011-10-30 06:31:41 |
| 2011-01-30 14:03:25 |
+---------------------+
```

1.2.3.62 WEEKOFYEAR

Syntax

```
WEEKOFYEAR(date)
```

Description

Returns the calendar week of the date as a number in the range from 1 to 53. `WEEKOFYEAR()` is a compatibility function that is equivalent to `WEEK(date,3)` .

Examples

```
SELECT WEEKOFYEAR('2008-02-20');
+--------------------------+
| WEEKOFYEAR('2008-02-20') |
+--------------------------+
|                        8 |
+--------------------------+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
 select * from t1;
+---------------------+
| d                   |
+---------------------+
| 2007-01-30 21:31:07 |
| 1983-10-15 06:42:51 |
| 2011-04-21 12:34:56 |
| 2011-10-30 06:31:41 |
| 2011-01-30 14:03:25 |
| 2004-10-07 11:19:34 |
+---------------------+
```

```
SELECT d, WEEKOFYEAR(d), WEEK(d,3) from t1;
+---------------------+---------------+-----------+
| d                   | WEEKOFYEAR(d) | WEEK(d,3) |
+---------------------+---------------+-----------+
| 2007-01-30 21:31:07 |             5 |         5 |
| 1983-10-15 06:42:51 |            41 |        41 |
| 2011-04-21 12:34:56 |            16 |        16 |
| 2011-10-30 06:31:41 |            43 |        43 |
| 2011-01-30 14:03:25 |             4 |         4 |
| 2004-10-07 11:19:34 |            41 |        41 |
+---------------------+---------------+-----------+
```

1.2.3.63 YEAR

Syntax

```
YEAR(date)
```

Description

Returns the year for the given date, in the range 1000 to 9999, or 0 for the "zero" date.

Examples

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT * FROM t1;
+---------------------+
| d                   |
+---------------------+
| 2007-01-30 21:31:07 |
| 1983-10-15 06:42:51 |
| 2011-04-21 12:34:56 |
| 2011-10-30 06:31:41 |
| 2011-01-30 14:03:25 |
| 2004-10-07 11:19:34 |
+---------------------+

SELECT * FROM t1 WHERE YEAR(d) = 2011;
+---------------------+
| d                   |
+---------------------+
| 2011-04-21 12:34:56 |
| 2011-10-30 06:31:41 |
| 2011-01-30 14:03:25 |
+---------------------+
```

```
SELECT YEAR('1987-01-01');
+--------------------+
| YEAR('1987-01-01') |
+--------------------+
|               1987 |
+--------------------+
```

1.2.3.64 YEARWEEK

Syntax

```
YEARWEEK(date), YEARWEEK(date,mode)
```

Description

Returns year and week for a date. The mode argument works exactly like the mode argument to WEEK(). The year in the result may be different from the year in the date argument for the first and the last week of the year.

Examples

```
SELECT YEARWEEK('1987-01-01');
+------------------------+
| YEARWEEK('1987-01-01') |
+------------------------+
|                 198652 |
+------------------------+
```

```
CREATE TABLE t1 (d DATETIME);
INSERT INTO t1 VALUES
    ("2007-01-30 21:31:07"),
    ("1983-10-15 06:42:51"),
    ("2011-04-21 12:34:56"),
    ("2011-10-30 06:31:41"),
    ("2011-01-30 14:03:25"),
    ("2004-10-07 11:19:34");
```

```
SELECT * FROM t1;
+---------------------+
| d                   |
+---------------------+
| 2007-01-30 21:31:07 |
| 1983-10-15 06:42:51 |
| 2011-04-21 12:34:56 |
| 2011-10-30 06:31:41 |
| 2011-01-30 14:03:25 |
| 2004-10-07 11:19:34 |
+---------------------+
6 rows in set (0.02 sec)
```

```
SELECT YEARWEEK(d) FROM t1 WHERE YEAR(d) = 2011;
+-------------+
| YEARWEEK(d) |
+-------------+
|      201116 |
|      201144 |
|      201105 |
+-------------+
3 rows in set (0.03 sec)
```

1.2.4 Aggregate Functions

The following functions (also called aggregate functions) can be used with the GROUP BY clause:

Stored Aggregate Functions

Custom aggregate functions.

AVG

Returns the average value.

BIT_AND

Bitwise AND.

BIT_OR

Bitwise OR.

BIT_XOR

Bitwise XOR.

COUNT

Returns count of non-null values.

COUNT DISTINCT

Returns count of number of different non-NULL values.

GROUP_CONCAT

Returns string with concatenated values from a group.

JSON_ARRAYAGG

Returns a JSON array containing an element for each value in a given set of JSON or SQL values.

JSON_OBJECTAGG

Returns a JSON object containing key-value pairs.

MAX

Returns the maximum value.

MIN

Returns the minimum value.

STD
Population standard deviation.

STDDEV
Population standard deviation.

STDDEV_POP
Returns the population standard deviation.

STDDEV_SAMP
Standard deviation.

SUM
Sum total.

VARIANCE
Population standard variance.

VAR_POP
Population standard variance.

VAR_SAMP
Returns the sample variance.

1.2.4.1 Stored Aggregate Functions

MariaDB starting with 10.3.3
The ability to create stored aggregate functions was added in MariaDB 10.3.3.

Contents

Aggregate functions are functions that are computed over a sequence of rows and return one result for the sequence of rows.

Creating a custom aggregate function is done using the CREATE FUNCTION statement with two main differences:

- The addition of the AGGREGATE keyword, so `CREATE AGGREGATE FUNCTION`
- The `FETCH GROUP NEXT ROW` instruction inside the loop
- Oracle PL/SQL compatibility using SQL/PL is provided

Standard Syntax

```
CREATE AGGREGATE FUNCTION function_name (parameters) RETURNS return_type
BEGIN
      All types of declarations
      DECLARE CONTINUE HANDLER FOR NOT FOUND RETURN return_val;
      LOOP
           FETCH GROUP NEXT ROW; // fetches next row from table
           other instructions
      END LOOP;
END
```

Stored aggregate functions were a 2016 Google Summer of Code project by Varun Gupta.

Using SQL/PL

```
SET sql_mode=Oracle;
DELIMITER //

CREATE AGGREGATE FUNCTION function_name (parameters) RETURN return_type
   declarations
BEGIN
   LOOP
      FETCH GROUP NEXT ROW; -- fetches next row from table
      -- other instructions

   END LOOP;
EXCEPTION
   WHEN NO_DATA_FOUND THEN
      RETURN return_val;
END //

DELIMITER ;
```

Examples

First a simplified example:

```
CREATE TABLE marks(stud_id INT, grade_count INT);

INSERT INTO marks VALUES (1,6), (2,4), (3,7), (4,5), (5,8);

SELECT * FROM marks;
+---------+-------------+
| stud_id | grade_count |
+---------+-------------+
|       1 |           6 |
|       2 |           4 |
|       3 |           7 |
|       4 |           5 |
|       5 |           8 |
+---------+-------------+

DELIMITER //
CREATE AGGREGATE FUNCTION IF NOT EXISTS aggregate_count(x INT) RETURNS INT
BEGIN
 DECLARE count_students INT DEFAULT 0;
 DECLARE CONTINUE HANDLER FOR NOT FOUND
 RETURN count_students;
      LOOP
          FETCH GROUP NEXT ROW;
          IF x  THEN
            SET count_students = count_students+1;
          END IF;
      END LOOP;
END //
DELIMITER ;
```

A non-trivial example that cannot easily be rewritten using existing functions:

```
DELIMITER //
CREATE AGGREGATE FUNCTION medi_int(x INT) RETURNS DOUBLE
BEGIN
  DECLARE CONTINUE HANDLER FOR NOT FOUND
    BEGIN
      DECLARE res DOUBLE;
      DECLARE cnt INT DEFAULT (SELECT COUNT(*) FROM tt);
      DECLARE lim INT DEFAULT (cnt-1) DIV 2;
      IF cnt % 2 = 0 THEN
        SET res = (SELECT AVG(a) FROM (SELECT a FROM tt ORDER BY a LIMIT lim,2) ttt);
      ELSE
        SET res = (SELECT a FROM tt ORDER BY a LIMIT lim,1);
      END IF;
      DROP TEMPORARY TABLE tt;
      RETURN res;
    END;
  CREATE TEMPORARY TABLE tt (a INT);
  LOOP
    FETCH GROUP NEXT ROW;
    INSERT INTO tt VALUES (x);
  END LOOP;
END //
DELIMITER ;
```

SQL/PL Example

This uses the same marks table as created above.

```
SET sql_mode=Oracle;
DELIMITER //

CREATE AGGREGATE FUNCTION aggregate_count(x INT) RETURN INT AS count_students INT DEFAULT 0;
BEGIN
   LOOP
      FETCH GROUP NEXT ROW;
      IF x  THEN
        SET count_students := count_students+1;
      END IF;
   END LOOP;
EXCEPTION
   WHEN NO_DATA_FOUND THEN
      RETURN count_students;
END aggregate_count //
DELIMITER ;

SELECT aggregate_count(stud_id) FROM marks;
```

1.2.4.2 AVG

Syntax

```
AVG([DISTINCT] expr)
```

Contents

Description

Returns the average value of expr. The DISTINCT option can be used to return the average of the distinct values of expr. NULL values are ignored. It is an aggregate function, and so can be used with the GROUP BY clause.

AVG() returns NULL if there were no matching rows.

AVG() can be used as a window function.

Examples

```
CREATE TABLE sales (sales_value INT);

INSERT INTO sales VALUES(10),(20),(20),(40);

SELECT AVG(sales_value) FROM sales;
+------------------+
| AVG(sales_value) |
+------------------+
|          22.5000 |
+------------------+

SELECT AVG(DISTINCT(sales_value)) FROM sales;
+----------------------------+
| AVG(DISTINCT(sales_value)) |
+----------------------------+
|                    23.3333 |
+----------------------------+
```

Commonly, AVG() is used with a GROUP BY clause:

```
CREATE TABLE student (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student VALUES
  ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
  ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
  ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
  ('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);

SELECT name, AVG(score) FROM student GROUP BY name;
+---------+------------+
| name    | AVG(score) |
+---------+------------+
| Chun    |    74.0000 |
| Esben   |    37.0000 |
| Kaolin  |    72.0000 |
| Tatiana |    85.0000 |
+---------+------------+
```

Be careful to avoid this common mistake, not grouping correctly and returning mismatched data:

```
SELECT name,test,AVG(score) FROM student;
+------+------+------------+
| name | test | MIN(score) |
+------+------+------------+
| Chun | SQL  |         31 |
+------+------+------------+
```

As a window function:

```
CREATE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);

SELECT name, test, score, AVG(score) OVER (PARTITION BY test)
    AS average_by_test FROM student_test;
+---------+--------+-------+-----------------+
| name    | test   | score | average_by_test |
+---------+--------+-------+-----------------+
| Chun    | SQL    |    75 |         65.2500 |
| Chun    | Tuning |    73 |         68.7500 |
| Esben   | SQL    |    43 |         65.2500 |
| Esben   | Tuning |    31 |         68.7500 |
| Kaolin  | SQL    |    56 |         65.2500 |
| Kaolin  | Tuning |    88 |         68.7500 |
| Tatiana | SQL    |    87 |         65.2500 |
| Tatiana | Tuning |    83 |         68.7500 |
+---------+--------+-------+-----------------+
```

1.2.4.3 BIT_AND

Syntax

```
BIT_AND(expr) [over_clause]
```

Description

Returns the bitwise AND of all bits in *expr*. The calculation is performed with 64-bit (BIGINT) precision. It is an aggregate function, and so can be used with the GROUP BY clause.

If no rows match, `BIT_AND` will return a value with all bits set to 1. NULL values have no effect on the result unless all results are NULL, which is treated as no match.

`BIT_AND` can be used as a window function with the addition of the *over_clause*.

Examples

```
CREATE TABLE vals (x INT);

INSERT INTO vals VALUES(111),(110),(100);

SELECT BIT_AND(x), BIT_OR(x), BIT_XOR(x) FROM vals;
+------------+-----------+------------+
| BIT_AND(x) | BIT_OR(x) | BIT_XOR(x) |
+------------+-----------+------------+
|        100 |       111 |        101 |
+------------+-----------+------------+
```

As an aggregate function:

```
CREATE TABLE vals2 (category VARCHAR(1), x INT);

INSERT INTO vals2 VALUES
  ('a',111),('a',110),('a',100),
  ('b','000'),('b',001),('b',011);

SELECT category, BIT_AND(x), BIT_OR(x), BIT_XOR(x)
  FROM vals GROUP BY category;
+----------+------------+-----------+------------+
| category | BIT_AND(x) | BIT_OR(x) | BIT_XOR(x) |
+----------+------------+-----------+------------+
| a        |        100 |       111 |        101 |
| b        |          0 |        11 |         10 |
+----------+------------+-----------+------------+
```

No match:

```
SELECT BIT_AND(NULL);
+----------------------+
| BIT_AND(NULL)        |
+----------------------+
| 18446744073709551615 |
+----------------------+
```

1.2.4.4 BIT_OR

Syntax

```
BIT_OR(expr) [over_clause]
```

Contents

Description

Returns the bitwise OR of all bits in `expr`. The calculation is performed with 64-bit (BIGINT) precision. It is an aggregate function, and so can be used with the GROUP BY clause.

If no rows match, `BIT_OR` will return a value with all bits set to `0`. NULL values have no effect on the result unless all results are NULL, which is treated as no match.

`BIT_OR` can be used as a window function with the addition of the *over_clause*.

Examples

```
CREATE TABLE vals (x INT);

INSERT INTO vals VALUES(111),(110),(100);

SELECT BIT_AND(x), BIT_OR(x), BIT_XOR(x) FROM vals;
+------------+-----------+------------+
| BIT_AND(x) | BIT_OR(x) | BIT_XOR(x) |
+------------+-----------+------------+
|        100 |       111 |        101 |
+------------+-----------+------------+
```

As an aggregate function:

```
CREATE TABLE vals2 (category VARCHAR(1), x INT);

INSERT INTO vals2 VALUES
  ('a',111),('a',110),('a',100),
  ('b','000'),('b',001),('b',011);

SELECT category, BIT_AND(x), BIT_OR(x), BIT_XOR(x)
  FROM vals GROUP BY category;
+----------+------------+-----------+------------+
| category | BIT_AND(x) | BIT_OR(x) | BIT_XOR(x) |
+----------+------------+-----------+------------+
| a        |        100 |       111 |        101 |
| b        |          0 |        11 |         10 |
+----------+------------+-----------+------------+
```

No match:

```
SELECT BIT_OR(NULL);
+--------------+
| BIT_OR(NULL) |
+--------------+
|            0 |
+--------------+
```

1.2.4.5 BIT_XOR

Syntax

```
BIT_XOR(expr) [over_clause]
```

Contents

Description

Returns the bitwise XOR of all bits in `expr`. The calculation is performed with 64-bit (BIGINT) precision. It is an aggregate function, and so can be used with the GROUP BY clause.

If no rows match, `BIT_XOR` will return a value with all bits set to `0`. NULL values have no effect on the result unless all results are NULL, which is treated as no match.

`BIT_XOR` can be used as a window function with the addition of the *over_clause*.

Examples

```
CREATE TABLE vals (x INT);

INSERT INTO vals VALUES(111),(110),(100);

SELECT BIT_AND(x), BIT_OR(x), BIT_XOR(x) FROM vals;
+------------+-----------+------------+
| BIT_AND(x) | BIT_OR(x) | BIT_XOR(x) |
+------------+-----------+------------+
|        100 |       111 |        101 |
+------------+-----------+------------+
```

As an aggregate function:

```
CREATE TABLE vals2 (category VARCHAR(1), x INT);

INSERT INTO vals2 VALUES
  ('a',111),('a',110),('a',100),
  ('b','000'),('b',001),('b',011);

SELECT category, BIT_AND(x), BIT_OR(x), BIT_XOR(x)
  FROM vals GROUP BY category;
+----------+------------+-----------+------------+
| category | BIT_AND(x) | BIT_OR(x) | BIT_XOR(x) |
+----------+------------+-----------+------------+
| a        |        100 |       111 |        101 |
| b        |          0 |        11 |         10 |
+----------+------------+-----------+------------+
```

No match:

```
SELECT BIT_XOR(NULL);
+---------------+
| BIT_XOR(NULL) |
+---------------+
|             0 |
+---------------+
```

1.2.4.6 COUNT

Syntax

```
COUNT(expr)
```

Contents

Description

Returns a count of the number of non-NULL values of expr in the rows retrieved by a SELECT statement. The result is a BIGINT value. It is an aggregate function, and so can be used with the GROUP BY clause.

COUNT(*) counts the total number of rows in a table.

COUNT() returns 0 if there were no matching rows.

COUNT() can be used as a window function.

Examples

```
CREATE TABLE student (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student VALUES
  ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
  ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
  ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
  ('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);

SELECT COUNT(*) FROM student;
+----------+
| COUNT(*) |
+----------+
|        8 |
+----------+
```

COUNT(DISTINCT) example:

```
SELECT COUNT(DISTINCT (name)) FROM student;
+------------------------+
| COUNT(DISTINCT (name)) |
+------------------------+
|                      4 |
+------------------------+
```

As a window function

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, COUNT(score) OVER (PARTITION BY name)
    AS tests_written FROM student_test;
+---------+--------+-------+---------------+
| name    | test   | score | tests_written |
+---------+--------+-------+---------------+
| Chun    | SQL    |    75 |             2 |
| Chun    | Tuning |    73 |             2 |
| Esben   | SQL    |    43 |             2 |
| Esben   | Tuning |    31 |             2 |
| Kaolin  | SQL    |    56 |             2 |
| Kaolin  | Tuning |    88 |             2 |
| Tatiana | SQL    |    87 |             1 |
+---------+--------+-------+---------------+
```

1.2.4.7 COUNT DISTINCT

Syntax

```
COUNT(DISTINCT expr,[expr...])
```

Contents

Description

Returns a count of the number of different non-NULL values.

COUNT(DISTINCT) returns 0 if there were no matching rows.

Although, from MariaDB 10.2.0, COUNT can be used as a window function, COUNT DISTINCT cannot be.

Examples

```
CREATE TABLE student (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student VALUES
  ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
  ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
  ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
  ('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);

SELECT COUNT(*) FROM student;
+----------+
| COUNT(*) |
+----------+
|        8 |
+----------+

SELECT COUNT(DISTINCT (name)) FROM student;
+------------------------+
| COUNT(DISTINCT (name)) |
+------------------------+
|                      4 |
+------------------------+
```

1.2.4.8 GROUP_CONCAT

Syntax

```
GROUP_CONCAT(expr)
```

Contents

Description

This function returns a string result with the concatenated non-NULL values from a group. It returns NULL if there are no non-NULL values.

The maximum returned length in bytes is determined by the group_concat_max_len server system variable, which defaults to 1M (>= MariaDB 10.2.4) or 1K (<= MariaDB 10.2.3).

If group_concat_max_len <= 512, the return type is VARBINARY or VARCHAR; otherwise, the return type is BLOB or TEXT. The choice between binary or non-binary types depends from the input.

The full syntax is as follows:

```
GROUP_CONCAT([DISTINCT] expr [,expr ...]
             [ORDER BY {unsigned_integer | col_name | expr}
                 [ASC | DESC] [,col_name ...]]
             [SEPARATOR str_val]
             [LIMIT {[offset,] row_count | row_count OFFSET offset}])
```

`DISTINCT` eliminates duplicate values from the output string.

ORDER BY determines the order of returned values.

`SEPARATOR` specifies a separator between the values. The default separator is a comma (`,`). It is possible to avoid using a separator by specifying an empty string.

LIMIT

MariaDB starting with 10.3.3

Until MariaDB 10.3.2, it was not possible to use the LIMIT clause with `GROUP_CONCAT` . This restriction was lifted in MariaDB 10.3.3.

Examples

```
SELECT student_name,
       GROUP_CONCAT(test_score)
       FROM student
       GROUP BY student_name;
```

Get a readable list of MariaDB users from the mysql.user table:

```
SELECT GROUP_CONCAT(DISTINCT User ORDER BY User SEPARATOR '\n')
   FROM mysql.user;
```

In the former example, `DISTINCT` is used because the same user may occur more than once. The new line (`\n`) used as a `SEPARATOR` makes the results easier to read.

Get a readable list of hosts from which each user can connect:

```
SELECT User, GROUP_CONCAT(Host ORDER BY Host SEPARATOR ', ')
   FROM mysql.user GROUP BY User ORDER BY User;
```

The former example shows the difference between the `GROUP_CONCAT` 's ORDER BY (which sorts the concatenated hosts), and the `SELECT` 's ORDER BY (which sorts the rows).

From MariaDB 10.3.3, LIMIT can be used with `GROUP_CONCAT` , so, for example, given the following table:

```
CREATE TABLE d (dd DATE, cc INT);

INSERT INTO d VALUES ('2017-01-01',1);
INSERT INTO d VALUES ('2017-01-02',2);
INSERT INTO d VALUES ('2017-01-04',3);
```

the following query:

```
SELECT SUBSTRING_INDEX(GROUP_CONCAT(CONCAT_WS(":",dd,cc) ORDER BY cc DESC),",",1) FROM d;
+-----------------------------------------------------------------------------+
| SUBSTRING_INDEX(GROUP_CONCAT(CONCAT_WS(":",dd,cc) ORDER BY cc DESC),",",1) |
+-----------------------------------------------------------------------------+
| 2017-01-04:3                                                                |
+-----------------------------------------------------------------------------+
```

can be more simply rewritten as:

```
SELECT GROUP_CONCAT(CONCAT_WS(":",dd,cc) ORDER BY cc DESC LIMIT 1) FROM d;
+-----------------------------------------------------------+
| GROUP_CONCAT(CONCAT_WS(":",dd,cc) ORDER BY cc DESC LIMIT 1) |
+-----------------------------------------------------------+
| 2017-01-04:3                                              |
+-----------------------------------------------------------+
```

1.2.4.9 JSON_ARRAYAGG

MariaDB starting with 10.5.0

JSON_ARRAYAGG was added in MariaDB 10.5.0.

Syntax

```
JSON_ARRAYAGG(column_or_expression)
```

Description

`JSON_ARRAYAGG` returns a JSON array containing an element for each value in a given set of JSON or SQL values. It acts

on a column or an expression that evaluates to a single value.

The maximum returned length in bytes is determined by the group_concat_max_len server system variable.

Returns NULL in the case of an error, or if the result contains no rows.

`JSON_ARRAYAGG` cannot currently be used as a window function.

The full syntax is as follows:

```
JSON_ARRAYAGG([DISTINCT] expr [,expr ...]
             [ORDER BY {unsigned_integer | col_name | expr}
                 [ASC | DESC] [,col_name ...]]
             [LIMIT {[offset,] row_count | row_count OFFSET offset}])
```

Examples

```
CREATE TABLE t1 (a INT, b INT);

INSERT INTO t1 VALUES (1, 1),(2, 1), (1, 1),(2, 1), (3, 2),(2, 2),(2, 2),(2, 2);

SELECT JSON_ARRAYAGG(a), JSON_ARRAYAGG(b) FROM t1;
+-------------------+-------------------+
| JSON_ARRAYAGG(a)  | JSON_ARRAYAGG(b)  |
+-------------------+-------------------+
| [1,2,1,2,3,2,2,2] | [1,1,1,1,2,2,2,2] |
+-------------------+-------------------+

SELECT JSON_ARRAYAGG(a), JSON_ARRAYAGG(b) FROM t1 GROUP BY b;
+-----------------+-----------------+
| JSON_ARRAYAGG(a) | JSON_ARRAYAGG(b) |
+-----------------+-----------------+
| [1,2,1,2]       | [1,1,1,1]       |
| [3,2,2,2]       | [2,2,2,2]       |
+-----------------+-----------------+
```

1.2.4.10 JSON_OBJECTAGG

MariaDB starting with 10.5.0

JSON_OBJECTAGG was added in MariaDB 10.5.0.

Syntax

```
JSON_OBJECTAGG(key, value)
```

Description

`JSON_OBJECTAGG` returns a JSON object containing key-value pairs. It takes two expressions that evaluate to a single value, or two column names, as arguments, the first used as a key, and the second as a value.

The maximum returned length in bytes is determined by the group_concat_max_len server system variable.

Returns NULL in the case of an error, or if the result contains no rows.

`JSON_OBJECTAGG` cannot currently be used as a window function.

Examples

```
select * from t1;
+------+-------+
| a    | b     |
+------+-------+
|    1 | Hello |
|    1 | World |
|    2 | This  |
+------+-------+

SELECT JSON_OBJECTAGG(a, b) FROM t1;
+--------------------------------------+
| JSON_OBJECTAGG(a, b)                 |
+--------------------------------------+
| {"1":"Hello", "1":"World", "2":"This"} |
+--------------------------------------+
```

1.2.4.11 MAX

Syntax

```
MAX([DISTINCT] expr)
```

Contents

Description

Returns the largest, or maximum, value of *expr*. `MAX()` can also take a string argument in which case it returns the maximum string value. The `DISTINCT` keyword can be used to find the maximum of the distinct values of *expr*, however, this produces the same result as omitting `DISTINCT`.

Note that SET and ENUM fields are currently compared by their string value rather than their relative position in the set, so MAX() may produce a different highest result than ORDER BY DESC.

It is an aggregate function, and so can be used with the GROUP BY clause.

MAX() can be used as a window function.

`MAX()` returns `NULL` if there were no matching rows.

Examples

```
CREATE TABLE student (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student VALUES
  ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
  ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
  ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
  ('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);

SELECT name, MAX(score) FROM student GROUP BY name;
+---------+------------+
| name    | MAX(score) |
+---------+------------+
| Chun    |         75 |
| Esben   |         43 |
| Kaolin  |         88 |
| Tatiana |         87 |
+---------+------------+
```

MAX string:

```
SELECT MAX(name) FROM student;
+-----------+
| MAX(name) |
+-----------+
| Tatiana   |
+-----------+
```

Be careful to avoid this common mistake, not grouping correctly and returning mismatched data:

```
SELECT name,test,MAX(SCORE) FROM student;
+------+------+------------+
| name | test | MAX(SCORE) |
+------+------+------------+
| Chun | SQL  |         88 |
+------+------+------------+
```

Difference between ORDER BY DESC and MAX():

```
CREATE TABLE student2(name CHAR(10),grade ENUM('b','c','a'));

INSERT INTO student2 VALUES('Chun','b'),('Esben','c'),('Kaolin','a');

SELECT MAX(grade) FROM student2;
+------------+
| MAX(grade) |
+------------+
| c          |
+------------+

SELECT grade FROM student2 ORDER BY grade DESC LIMIT 1;
+-------+
| grade |
+-------+
| a     |
+-------+
```

As a window function:

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);
INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, MAX(score)
  OVER (PARTITION BY name) AS highest_score FROM student_test;
+---------+--------+-------+---------------+
| name    | test   | score | highest_score |
+---------+--------+-------+---------------+
| Chun    | SQL    |    75 |            75 |
| Chun    | Tuning |    73 |            75 |
| Esben   | SQL    |    43 |            43 |
| Esben   | Tuning |    31 |            43 |
| Kaolin  | SQL    |    56 |            88 |
| Kaolin  | Tuning |    88 |            88 |
| Tatiana | SQL    |    87 |            87 |
+---------+--------+-------+---------------+
```

1.2.4.12 MIN

Syntax

```
MIN([DISTINCT] expr)
```

Contents

Description

Returns the minimum value of *expr*. MIN() may take a string argument, in which case it returns the minimum string value. The DISTINCT keyword can be used to find the minimum of the distinct values of *expr*, however, this produces the same result as omitting DISTINCT.

Note that SET and ENUM fields are currently compared by their string value rather than their relative position in the set, so MIN() may produce a different lowest result than ORDER BY ASC.

It is an aggregate function, and so can be used with the GROUP BY clause.

MIN() can be used as a window function.

MIN() returns NULL if there were no matching rows.

Examples

```
CREATE TABLE student (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student VALUES
  ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
  ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
  ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
  ('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);

SELECT name, MIN(score) FROM student GROUP BY name;
+---------+------------+
| name    | MIN(score) |
+---------+------------+
| Chun    |         73 |
| Esben   |         31 |
| Kaolin  |         56 |
| Tatiana |         83 |
+---------+------------+
```

MIN() with a string:

```
SELECT MIN(name) FROM student;
+-----------+
| MIN(name) |
+-----------+
| Chun      |
+-----------+
```

Be careful to avoid this common mistake, not grouping correctly and returning mismatched data:

```
SELECT name,test,MIN(score) FROM student;
+------+------+------------+
| name | test | MIN(score) |
+------+------+------------+
| Chun | SQL  |         31 |
+------+------+------------+
```

Difference between ORDER BY ASC and MIN():

```
CREATE TABLE student2(name CHAR(10),grade ENUM('b','c','a'));

INSERT INTO student2 VALUES('Chun','b'),('Esben','c'),('Kaolin','a');

SELECT MIN(grade) FROM student2;
+------------+
| MIN(grade) |
+------------+
| a          |
+------------+

SELECT grade FROM student2 ORDER BY grade ASC LIMIT 1;
+-------+
| grade |
+-------+
| b     |
+-------+
```

As a window function:

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);
INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, MIN(score)
  OVER (PARTITION BY name) AS lowest_score FROM student_test;
+---------+--------+-------+--------------+
| name    | test   | score | lowest_score |
+---------+--------+-------+--------------+
| Chun    | SQL    |    75 |           73 |
| Chun    | Tuning |    73 |           73 |
| Esben   | SQL    |    43 |           31 |
| Esben   | Tuning |    31 |           31 |
| Kaolin  | SQL    |    56 |           56 |
| Kaolin  | Tuning |    88 |           56 |
| Tatiana | SQL    |    87 |           87 |
+---------+--------+-------+--------------+
```

1.2.4.13 STD

Syntax

```
STD(expr)
```

Description

Returns the population standard deviation of `expr`. This is an extension to standard SQL. The standard SQL function `STDDEV_POP()` can be used instead.

It is an aggregate function, and so can be used with the GROUP BY clause.

STD() can be used as a window function.

This function returns `NULL` if there were no matching rows.

Examples

As an aggregate function:

```
CREATE OR REPLACE TABLE stats (category VARCHAR(2), x INT);

INSERT INTO stats VALUES
  ('a',1),('a',2),('a',3),
  ('b',11),('b',12),('b',20),('b',30),('b',60);

SELECT category, STDDEV_POP(x), STDDEV_SAMP(x), VAR_POP(x)
  FROM stats GROUP BY category;
+----------+--------------+---------------+------------+
| category | STDDEV_POP(x) | STDDEV_SAMP(x) | VAR_POP(x) |
+----------+--------------+---------------+------------+
| a        |       0.8165 |        1.0000 |     0.6667 |
| b        |      18.0400 |       20.1693 |   325.4400 |
+----------+--------------+---------------+------------+
```

As a window function:

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, STDDEV_POP(score)
  OVER (PARTITION BY test) AS stddev_results FROM student_test;
+---------+--------+-------+----------------+
| name    | test   | score | stddev_results |
+---------+--------+-------+----------------+
| Chun    | SQL    |    75 |        16.9466 |
| Chun    | Tuning |    73 |        24.1247 |
| Esben   | SQL    |    43 |        16.9466 |
| Esben   | Tuning |    31 |        24.1247 |
| Kaolin  | SQL    |    56 |        16.9466 |
| Kaolin  | Tuning |    88 |        24.1247 |
| Tatiana | SQL    |    87 |        16.9466 |
+---------+--------+-------+----------------+
```

1.2.4.14 STDDEV

Syntax

```
STDDEV(expr)
```

Contents

Description

Returns the population standard deviation of `expr`. This function is provided for compatibility with Oracle. The standard SQL function `STDDEV_POP()` can be used instead.

It is an aggregate function, and so can be used with the GROUP BY clause.

STDDEV() can be used as a window function.

This function returns `NULL` if there were no matching rows.

Examples

As an aggregate function:

```
CREATE OR REPLACE TABLE stats (category VARCHAR(2), x INT);

INSERT INTO stats VALUES
  ('a',1),('a',2),('a',3),
  ('b',11),('b',12),('b',20),('b',30),('b',60);

SELECT category, STDDEV_POP(x), STDDEV_SAMP(x), VAR_POP(x)
  FROM stats GROUP BY category;
+----------+---------------+----------------+------------+
| category | STDDEV_POP(x) | STDDEV_SAMP(x) | VAR_POP(x) |
+----------+---------------+----------------+------------+
| a        |        0.8165 |         1.0000 |     0.6667 |
| b        |       18.0400 |        20.1693 |   325.4400 |
+----------+---------------+----------------+------------+
```

As a window function:

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, STDDEV_POP(score)
  OVER (PARTITION BY test) AS stddev_results FROM student_test;
+---------+--------+-------+----------------+
| name    | test   | score | stddev_results |
+---------+--------+-------+----------------+
| Chun    | SQL    |    75 |        16.9466 |
| Chun    | Tuning |    73 |        24.1247 |
| Esben   | SQL    |    43 |        16.9466 |
| Esben   | Tuning |    31 |        24.1247 |
| Kaolin  | SQL    |    56 |        16.9466 |
| Kaolin  | Tuning |    88 |        24.1247 |
| Tatiana | SQL    |    87 |        16.9466 |
+---------+--------+-------+----------------+
```

1.2.4.15 STDDEV_POP

Syntax

```
STDDEV_POP(expr)
```

Contents

Description

Returns the population standard deviation of *expr* (the square root of `VAR_POP()`). You can also use `STD()` or `STDDEV()`, which are equivalent but not standard SQL.

It is an aggregate function, and so can be used with the GROUP BY clause.

STDDEV_POP() can be used as a window function.

STDDEV_POP() returns `NULL` if there were no matching rows.

Examples

As an aggregate function:

```
CREATE OR REPLACE TABLE stats (category VARCHAR(2), x INT);

INSERT INTO stats VALUES
  ('a',1),('a',2),('a',3),
  ('b',11),('b',12),('b',20),('b',30),('b',60);

SELECT category, STDDEV_POP(x), STDDEV_SAMP(x), VAR_POP(x)
  FROM stats GROUP BY category;
+----------+--------------+---------------+------------+
| category | STDDEV_POP(x) | STDDEV_SAMP(x) | VAR_POP(x) |
+----------+--------------+---------------+------------+
| a        |       0.8165 |        1.0000 |     0.6667 |
| b        |      18.0400 |       20.1693 |   325.4400 |
+----------+--------------+---------------+------------+
```

As a window function:

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, STDDEV_POP(score)
  OVER (PARTITION BY test) AS stddev_results FROM student_test;
+---------+--------+-------+----------------+
| name    | test   | score | stddev_results |
+---------+--------+-------+----------------+
| Chun    | SQL    |    75 |        16.9466 |
| Chun    | Tuning |    73 |        24.1247 |
| Esben   | SQL    |    43 |        16.9466 |
| Esben   | Tuning |    31 |        24.1247 |
| Kaolin  | SQL    |    56 |        16.9466 |
| Kaolin  | Tuning |    88 |        24.1247 |
| Tatiana | SQL    |    87 |        16.9466 |
+---------+--------+-------+----------------+
```

1.2.4.16 STDDEV_SAMP

Syntax

```
STDDEV_SAMP(expr)
```

Description

Returns the sample standard deviation of `expr` (the square root of VAR_SAMP()).

It is an aggregate function, and so can be used with the GROUP BY clause.

STDDEV_SAMP() can be used as a window function.

STDDEV_SAMP() returns `NULL` if there were no matching rows.

1.2.4.17 SUM

Syntax

```
SUM([DISTINCT] expr)
```

Contents

Description

Returns the sum of `expr`. If the return set has no rows, `SUM()` returns `NULL`. The `DISTINCT` keyword can be used to sum only the distinct values of `expr`.

SUM() can be used as a window function, although not with the DISTINCT specifier.

Examples

```
CREATE TABLE sales (sales_value INT);
INSERT INTO sales VALUES(10),(20),(20),(40);

SELECT SUM(sales_value) FROM sales;
+------------------+
| SUM(sales_value) |
+------------------+
|               90 |
+------------------+

SELECT SUM(DISTINCT(sales_value)) FROM sales;
+----------------------------+
| SUM(DISTINCT(sales_value)) |
+----------------------------+
|                         70 |
+----------------------------+
```

Commonly, SUM is used with a GROUP BY clause:

```
CREATE TABLE sales (name CHAR(10), month CHAR(10), units INT);

INSERT INTO sales VALUES
  ('Chun', 'Jan', 75), ('Chun', 'Feb', 73),
  ('Esben', 'Jan', 43), ('Esben', 'Feb', 31),
  ('Kaolin', 'Jan', 56), ('Kaolin', 'Feb', 88),
  ('Tatiana', 'Jan', 87), ('Tatiana', 'Feb', 83);

SELECT name, SUM(units) FROM sales GROUP BY name;
+---------+------------+
| name    | SUM(units) |
+---------+------------+
| Chun    |        148 |
| Esben   |         74 |
| Kaolin  |        144 |
| Tatiana |        170 |
+---------+------------+
```

The GROUP BY clause is required when using an aggregate function along with regular column data, otherwise the result will be a mismatch, as in the following common type of mistake:

```
SELECT name,SUM(units) FROM sales
;+------+------------+
| name | SUM(units) |
+------+------------+
| Chun |        536 |
+------+------------+
```

As a window function:

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);
INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, SUM(score) OVER (PARTITION BY name) AS total_score FROM student_test;
+---------+--------+-------+-------------+
| name    | test   | score | total_score |
+---------+--------+-------+-------------+
| Chun    | SQL    |    75 |         148 |
| Chun    | Tuning |    73 |         148 |
| Esben   | SQL    |    43 |          74 |
| Esben   | Tuning |    31 |          74 |
| Kaolin  | SQL    |    56 |         144 |
| Kaolin  | Tuning |    88 |         144 |
| Tatiana | SQL    |    87 |          87 |
+---------+--------+-------+-------------+
```

1.2.4.18 VARIANCE

Syntax

```
VARIANCE(expr)
```

Contents

Description

Returns the population standard variance of `expr`. This is an extension to standard SQL. The standard SQL function VAR_POP() can be used instead.

Variance is calculated by

- working out the mean for the set
- for each number, subtracting the mean and squaring the result
- calculate the average of the resulting differences

It is an aggregate function, and so can be used with the GROUP BY clause.

VARIANCE() can be used as a window function.

VARIANCE() returns `NULL` if there were no matching rows.

Examples

```
CREATE TABLE v(i tinyint);

INSERT INTO v VALUES(101),(99);

SELECT VARIANCE(i) FROM v;
+-------------+
| VARIANCE(i) |
+-------------+
|      1.0000 |
+-------------+

INSERT INTO v VALUES(120),(80);

SELECT VARIANCE(i) FROM v;
+-------------+
| VARIANCE(i) |
+-------------+
|    200.5000 |
+-------------+
```

As an aggregate function:

```
CREATE OR REPLACE TABLE stats (category VARCHAR(2), x INT);

INSERT INTO stats VALUES
  ('a',1),('a',2),('a',3),
  ('b',11),('b',12),('b',20),('b',30),('b',60);

SELECT category, STDDEV_POP(x), STDDEV_SAMP(x), VAR_POP(x)
  FROM stats GROUP BY category;
+----------+---------------+----------------+-------------+
| category | STDDEV_POP(x) | STDDEV_SAMP(x) | VAR_POP(x) |
+----------+---------------+----------------+-------------+
| a        |        0.8165 |         1.0000 |      0.6667 |
| b        |       18.0400 |        20.1693 |    325.4400 |
+----------+---------------+----------------+-------------+
```

As a window function:

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, VAR_POP(score)
  OVER (PARTITION BY test) AS variance_results FROM student_test;
+---------+--------+-------+------------------+
| name    | test   | score | variance_results |
+---------+--------+-------+------------------+
| Chun    | SQL    |    75 |         287.1875 |
| Chun    | Tuning |    73 |         582.0000 |
| Esben   | SQL    |    43 |         287.1875 |
| Esben   | Tuning |    31 |         582.0000 |
| Kaolin  | SQL    |    56 |         287.1875 |
| Kaolin  | Tuning |    88 |         582.0000 |
| Tatiana | SQL    |    87 |         287.1875 |
+---------+--------+-------+------------------+
```

1.2.4.19 VAR_POP

Syntax

```
VAR_POP(expr)
```

Contents

Description

Returns the population standard variance of `expr`. It considers rows as the whole population, not as a sample, so it has the number of rows as the denominator. You can also use VARIANCE(), which is equivalent but is not standard SQL.

Variance is calculated by

- working out the mean for the set
- for each number, subtracting the mean and squaring the result
- calculate the average of the resulting differences

It is an aggregate function, and so can be used with the GROUP BY clause.

VAR_POP() can be used as a window function.

VAR_POP() returns `NULL` if there were no matching rows.

Examples

```
CREATE TABLE v(i tinyint);

INSERT INTO v VALUES(101),(99);

SELECT VAR_POP(i) FROM v;
+------------+
| VAR_POP(i) |
+------------+
|     1.0000 |
+------------+

INSERT INTO v VALUES(120),(80);

SELECT VAR_POP(i) FROM v;
+------------+
| VAR_POP(i) |
+------------+
|   200.5000 |
+------------+
```

As an aggregate function:

```
CREATE OR REPLACE TABLE stats (category VARCHAR(2), x INT);

INSERT INTO stats VALUES
  ('a',1),('a',2),('a',3),
  ('b',11),('b',12),('b',20),('b',30),('b',60);

SELECT category, STDDEV_POP(x), STDDEV_SAMP(x), VAR_POP(x)
  FROM stats GROUP BY category;
+----------+---------------+----------------+------------+
| category | STDDEV_POP(x) | STDDEV_SAMP(x) | VAR_POP(x) |
+----------+---------------+----------------+------------+
| a        |        0.8165 |         1.0000 |     0.6667 |
| b        |       18.0400 |        20.1693 |   325.4400 |
+----------+---------------+----------------+------------+
```

As a window function:

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, VAR_POP(score)
  OVER (PARTITION BY test) AS variance_results FROM student_test;
+---------+--------+-------+------------------+
| name    | test   | score | variance_results |
+---------+--------+-------+------------------+
| Chun    | SQL    |    75 |         287.1875 |
| Esben   | SQL    |    43 |         287.1875 |
| Kaolin  | SQL    |    56 |         287.1875 |
| Tatiana | SQL    |    87 |         287.1875 |
| Chun    | Tuning |    73 |         582.0000 |
| Esben   | Tuning |    31 |         582.0000 |
| Kaolin  | Tuning |    88 |         582.0000 |
+---------+--------+-------+------------------+
```

1.2.4.20 VAR_SAMP

Syntax

```
VAR_SAMP(expr)
```

Contents

Description

Returns the sample variance of *expr*. That is, the denominator is the number of rows minus one.

It is an aggregate function, and so can be used with the GROUP BY clause.

VAR_SAMP() can be used as a window function.

VAR_SAMP() returns `NULL` if there were no matching rows.

Examples

As an aggregate function:

```
CREATE OR REPLACE TABLE stats (category VARCHAR(2), x INT);

INSERT INTO stats VALUES
  ('a',1),('a',2),('a',3),
  ('b',11),('b',12),('b',20),('b',30),('b',60);

SELECT category, STDDEV_POP(x), STDDEV_SAMP(x), VAR_POP(x)
  FROM stats GROUP BY category;
+----------+---------------+---------------+------------+
| category | STDDEV_POP(x) | STDDEV_SAMP(x) | VAR_POP(x) |
+----------+---------------+---------------+------------+
| a        |        0.8165 |         1.0000 |     0.6667 |
| b        |       18.0400 |        20.1693 |   325.4400 |
+----------+---------------+---------------+------------+
```

As a window function:

```
CREATE OR REPLACE TABLE student_test (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, VAR_SAMP(score)
  OVER (PARTITION BY test) AS variance_results FROM student_test;
+---------+--------+-------+------------------+
| name    | test   | score | variance_results |
+---------+--------+-------+------------------+
| Chun    | SQL    |    75 |         382.9167 |
| Chun    | Tuning |    73 |         873.0000 |
| Esben   | SQL    |    43 |         382.9167 |
| Esben   | Tuning |    31 |         873.0000 |
| Kaolin  | SQL    |    56 |         382.9167 |
| Kaolin  | Tuning |    88 |         873.0000 |
| Tatiana | SQL    |    87 |         382.9167 |
+---------+--------+-------+------------------+
```

1.2.5 Numeric Functions

Functions dealing with numerals, including ABS, CEIL, DIV, EXP, PI, SIN, etc.

Addition Operator (+)

Addition.

Subtraction Operator (-)

Subtraction and unary minus.

Division Operator (/)

Division.

Multiplication Operator (*)

Multiplication.

Modulo Operator (%)

Modulo operator. Returns the remainder of N divided by M.

DIV

Integer division.

ABS

Returns an absolute value.

ACOS

Returns an arc cosine.

ASIN

Returns the arc sine.

ATAN

Returns the arc tangent.

ATAN2

Returns the arc tangent of two variables.

CEIL

Synonym for CEILING().

CEILING

Returns the smallest integer not less than X.

CONV
Converts numbers between different number bases.

COS
Returns the cosine.

COT
Returns the cotangent.

CRC32
Computes a cyclic redundancy check (CRC) value.

CRC32C
Computes a cyclic redundancy check (CRC) value using the Castagnoli polynomial.

DEGREES
Converts from radians to degrees.

EXP
e raised to the power of the argument.

FLOOR
Largest integer value not greater than the argument.

GREATEST
Returns the largest argument.

LEAST
Returns the smallest argument.

LN
Returns natural logarithm.

LOG
Returns the natural logarithm.

LOG10
Returns the base-10 logarithm.

LOG2
Returns the base-2 logarithm.

MOD
Modulo operation. Remainder of N divided by M.

OCT
Returns octal value.

PI
Returns the value of π (pi).

POW
Returns X raised to the power of Y.

POWER
Synonym for POW().

RADIANS
Converts from degrees to radians.

RAND
Random floating-point value.

ROUND

Rounds a number.

SIGN

Returns 1, 0 or -1.

SIN

Returns the sine.

SQRT

Square root.

TAN

Returns the tangent.

TRUNCATE

The TRUNCATE function truncates a number to a specified number of decimal places.

1.1.5.1.1 Addition Operator (+)

1.1.5.1.7 Subtraction Operator (-)

1.1.5.1.3 Division Operator (/)

1.1.5.1.6 Multiplication Operator (*)

1.1.5.1.5 Modulo Operator (%)

1.2.5.6 DIV

Syntax

```
DIV
```

Description

Integer division. Similar to FLOOR(), but is safe with BIGINT values. Incorrect results may occur for non-integer operands that exceed BIGINT range.

If the `ERROR_ON_DIVISION_BY_ZERO` SQL_MODE is used, a division by zero produces an error. Otherwise, it returns NULL.

The remainder of a division can be obtained using the MOD operator.

Examples

```
SELECT 300 DIV 7;
+-----------+
| 300 DIV 7 |
+-----------+
|        42 |
+-----------+

SELECT 300 DIV 0;
+-----------+
| 300 DIV 0 |
+-----------+
|      NULL |
+-----------+
```

1.2.5.7 ABS

Syntax

```
ABS(X)
```

Contents

Description

Returns the absolute (non-negative) value of `X`. If `X` is not a number, it is converted to a numeric type.

Examples

```
SELECT ABS(42);
+---------+
| ABS(42) |
+---------+
|      42 |
+---------+

SELECT ABS(-42);
+----------+
| ABS(-42) |
+----------+
|       42 |
+----------+

SELECT ABS(DATE '1994-01-01');
+------------------------+
| ABS(DATE '1994-01-01') |
+------------------------+
|               19940101 |
+------------------------+
```

1.2.5.8 ACOS

Syntax

```
ACOS(X)
```

Contents

Description

Returns the arc cosine of `X`, that is, the value whose cosine is `X`. Returns `NULL` if `X` is not in the range `-1` to `1`.

Examples

```
SELECT ACOS(1);
+---------+
| ACOS(1) |
+---------+
|       0 |
+---------+

SELECT ACOS(1.0001);
+--------------+
| ACOS(1.0001) |
+--------------+
|         NULL |
+--------------+

SELECT ACOS(0);
+-----------------+
| ACOS(0)         |
+-----------------+
| 1.5707963267949 |
+-----------------+

SELECT ACOS(0.234);
+------------------+
| ACOS(0.234)      |
+------------------+
| 1.33460644244679 |
+------------------+
```

1.2.5.9 ASIN

Syntax

```
ASIN(X)
```

Contents

Description

Returns the arc sine of X, that is, the value whose sine is X. Returns NULL if X is not in the range -1 to 1.

Examples

```
SELECT ASIN(0.2);
+--------------------+
| ASIN(0.2)          |
+--------------------+
| 0.2013579207903308 |
+--------------------+

SELECT ASIN('foo');
+-------------+
| ASIN('foo') |
+-------------+
|           0 |
+-------------+

SHOW WARNINGS;
+---------+------+----------------------------------------+
| Level   | Code | Message                                |
+---------+------+----------------------------------------+
| Warning | 1292 | Truncated incorrect DOUBLE value: 'foo' |
+---------+------+----------------------------------------+
```

1.2.5.10 ATAN

Syntax

```
ATAN(X)
```

Contents

Description

Returns the arc tangent of X, that is, the value whose tangent is X.

Examples

```
SELECT ATAN(2);
+--------------------+
| ATAN(2)            |
+--------------------+
| 1.1071487177940904 |
+--------------------+

SELECT ATAN(-2);
+---------------------+
| ATAN(-2)            |
+---------------------+
| -1.1071487177940904 |
+---------------------+
```

1.2.5.11 ATAN2

Syntax

```
ATAN(Y,X), ATAN2(Y,X)
```

Description

Returns the arc tangent of the two variables X and Y. It is similar to calculating the arc tangent of Y / X, except that the signs of both arguments are used to determine the quadrant of the result.

Examples

```
SELECT ATAN(-2,2);
+---------------------+
| ATAN(-2,2)          |
+---------------------+
| -0.7853981633974483 |
+---------------------+

SELECT ATAN2(PI(),0);
+--------------------+
| ATAN2(PI(),0)      |
+--------------------+
| 1.5707963267948966 |
+--------------------+
```

1.2.5.12 CEIL

Syntax

```
CEIL(X)
```

Description

CEIL() is a synonym for CEILING().

1.2.5.13 CEILING

Syntax

```
CEILING(X)
```

Description

Returns the smallest integer value not less than X.

Examples

```
SELECT CEILING(1.23);
+---------------+
| CEILING(1.23) |
+---------------+
|             2 |
+---------------+

SELECT CEILING(-1.23);
+----------------+
| CEILING(-1.23) |
+----------------+
|             -1 |
+----------------+
```

1.2.5.14 CONV

Syntax

```
CONV(N,from_base,to_base)
```

Description

Converts numbers between different number bases. Returns a string representation of the number `N`, converted from base `from_base` to base `to_base`.

Returns `NULL` if any argument is `NULL`, or if the second or third argument are not in the allowed range.

The argument `N` is interpreted as an integer, but may be specified as an integer or a string. The minimum base is 2 and the maximum base is 36. If `to_base` is a negative number, `N` is regarded as a signed number. Otherwise, `N` is treated as unsigned. `CONV()` works with 64-bit precision.

Some shortcuts for this function are also available: `BIN()`, `OCT()`, `HEX()`, `UNHEX()`. Also, MariaDB allows binary literal values and hexadecimal literal values.

Examples

```
SELECT CONV('a',16,2);
+----------------+
| CONV('a',16,2) |
+----------------+
| 1010           |
+----------------+

SELECT CONV('6E',18,8);
+-----------------+
| CONV('6E',18,8) |
+-----------------+
| 172             |
+-----------------+

SELECT CONV(-17,10,-18);
+------------------+
| CONV(-17,10,-18) |
+------------------+
| -H               |
+------------------+

SELECT CONV(12+'10'+'10'+0xa,10,10);
+-------------------------------+
| CONV(12+'10'+'10'+0xa,10,10) |
+-------------------------------+
| 42                            |
+-------------------------------+
```

1.2.5.15 COS

Syntax

```
COS(X)
```

Description

Returns the cosine of X, where X is given in radians.

Examples

```
SELECT COS(PI());
+-----------+
| COS(PI()) |
+-----------+
|        -1 |
+-----------+
```

1.2.5.16 COT

Syntax

```
COT(X)
```

Description

Returns the cotangent of X.

Examples

```
SELECT COT(42);
+--------------------+
| COT(42)            |
+--------------------+
| 0.4364167060752729 |
+--------------------+

SELECT COT(12);
+---------------------+
| COT(12)             |
+---------------------+
| -1.5726734063976893 |
+---------------------+

SELECT COT(0);
ERROR 1690 (22003): DOUBLE value is out of range in 'cot(0)'
```

1.2.5.17 CRC32

Syntax

<= MariaDB 10.7

```
CRC32(expr)
```

From MariaDB 10.8

```
CRC32([par,]expr)
```

Description

Computes a cyclic redundancy check (CRC) value and returns a 32-bit unsigned value. The result is NULL if the argument is NULL. The argument is expected to be a string and (if possible) is treated as one if it is not.

Uses the ISO 3309 polynomial that used by zlib and many others. MariaDB 10.8 introduced the CRC32C() function, which uses the alternate Castagnoli polynomia.

MariaDB starting with 10.8

Often, CRC is computed in pieces. To facilitate this, MariaDB 10.8.0 introduced an optional parameter:

CRC32('MariaDB')=CRC32(CRC32('Maria'),'DB').

Examples

```
SELECT CRC32('MariaDB');
+------------------+
| CRC32('MariaDB') |
+------------------+
|       4227209140 |
+------------------+

SELECT CRC32('mariadb');
+------------------+
| CRC32('mariadb') |
+------------------+
|       2594253378 |
+------------------+
```

From MariaDB 10.8.0

```
SELECT CRC32(CRC32('Maria'),'DB');
+----------------------------+
| CRC32(CRC32('Maria'),'DB') |
+----------------------------+
|                 4227209140 |
+----------------------------+
```

1.2.5.18 CRC32C

MariaDB starting with 10.8

Introduced in MariaDB 10.8.0 to compute a cyclic redundancy check (CRC) value using the Castagnoli polynomial.

Syntax

```
CRC32C([par,]expr)
```

Description

MariaDB has always included a native unary function CRC32() that computes the CRC-32 of a string using the ISO 3309 polynomial that used by zlib and many others.

InnoDB and MyRocks use a different polynomial, which was implemented in SSE4.2 instructions that were introduced in the Intel Nehalem microarchitecture. This is commonly called CRC-32C (Castagnoli).

The CRC32C function uses the Castagnoli polynomial.

This allows `SELECT…INTO DUMPFILE` to be used for the creation of files with valid checksums, such as a logically empty InnoDB redo log file `ib_logfile0` corresponding to a particular log sequence number.

The optional parameter allows the checksum to be computed in pieces:
CRC32C('MariaDB')=CRC32C(CRC32C('Maria'),'DB').

Examples

```
SELECT CRC32C('MariaDB');
+-------------------+
| CRC32C('MariaDB') |
+-------------------+
|         809606978 |
+-------------------+

SELECT CRC32C(CRC32C('Maria'),'DB');
+------------------------------+
| CRC32C(CRC32C('Maria'),'DB') |
+------------------------------+
|                    809606978 |
+------------------------------+
```

1.2.5.19 DEGREES

Syntax

```
DEGREES(X)
```

Description

Returns the argument *X*, converted from radians to degrees.

This is the converse of the RADIANS() function.

Examples

```
SELECT DEGREES(PI());
+---------------+
| DEGREES(PI()) |
+---------------+
|           180 |
+---------------+

SELECT DEGREES(PI() / 2);
+-------------------+
| DEGREES(PI() / 2) |
+-------------------+
|                90 |
+-------------------+

SELECT DEGREES(45);
+-----------------+
| DEGREES(45)     |
+-----------------+
| 2578.3100780887 |
+-----------------+
```

1.2.5.20 EXP

Syntax

```
EXP(X)
```

Description

Returns the value of e (the base of natural logarithms) raised to the power of X. The inverse of this function is LOG() (using a single argument only) or LN().

If `X` is `NULL`, this function returns `NULL`.

Examples

```
SELECT EXP(2);
+------------------+
| EXP(2)           |
+------------------+
| 7.38905609893065 |
+------------------+

SELECT EXP(-2);
+--------------------+
| EXP(-2)            |
+--------------------+
| 0.1353352832366127 |
+--------------------+

SELECT EXP(0);
+--------+
| EXP(0) |
+--------+
|      1 |
+--------+

SELECT EXP(NULL);
+-----------+
| EXP(NULL) |
+-----------+
|      NULL |
+-----------+
```

1.2.5.21 FLOOR

Syntax

```
FLOOR(X)
```

Description

Returns the largest integer value not greater than X.

Examples

```
SELECT FLOOR(1.23);
+-------------+
| FLOOR(1.23) |
+-------------+
|           1 |
+-------------+

SELECT FLOOR(-1.23);
+--------------+
| FLOOR(-1.23) |
+--------------+
|           -2 |
+--------------+
```

1.1.5.4.10 GREATEST

1.1.5.4.18 LEAST

1.2.5.24 LN

Syntax

```
LN(X)
```

Description

Returns the natural logarithm of X; that is, the base-e logarithm of X. If X is less than or equal to 0, or `NULL`, then NULL is returned.

The inverse of this function is `EXP()`.

Examples

```
SELECT LN(2);
+-------------------+
| LN(2)             |
+-------------------+
| 0.693147180559945 |
+-------------------+

SELECT LN(-2);
+--------+
| LN(-2) |
+--------+
|   NULL |
+--------+
```

1.2.5.25 LOG

Syntax

```
LOG(X), LOG(B,X)
```

Description

If called with one parameter, this function returns the natural logarithm of X. If X is less than or equal to 0, then NULL is returned.

If called with two parameters, it returns the logarithm of X to the base B. If B is <= 1 or X <= 0, the function returns NULL.

If any argument is `NULL`, the function returns `NULL`.

The inverse of this function (when called with a single argument) is the EXP() function.

Examples

LOG(X):

```
SELECT LOG(2);
+-------------------+
| LOG(2)            |
+-------------------+
| 0.693147180559945 |
+-------------------+

SELECT LOG(-2);
+---------+
| LOG(-2) |
+---------+
|    NULL |
+---------+
```

LOG(B,X)

```
SELECT LOG(2,16);
+-----------+
| LOG(2,16) |
+-----------+
|         4 |
+-----------+

SELECT LOG(3,27);
+-----------+
| LOG(3,27) |
+-----------+
|         3 |
+-----------+

SELECT LOG(3,1);
+----------+
| LOG(3,1) |
+----------+
|        0 |
+----------+

SELECT LOG(3,0);
+----------+
| LOG(3,0) |
+----------+
|     NULL |
+----------+
```

1.2.5.26 LOG10

Syntax

```
LOG10(X)
```

Description

Returns the base-10 logarithm of X.

Examples

```
SELECT LOG10(2);
+-------------------+
| LOG10(2)          |
+-------------------+
| 0.301029995663981 |
+-------------------+

SELECT LOG10(100);
+------------+
| LOG10(100) |
+------------+
|          2 |
+------------+

SELECT LOG10(-100);
+-------------+
| LOG10(-100) |
+-------------+
|        NULL |
+-------------+
```

1.2.5.27 LOG2

Syntax

```
LOG2(X)
```

Description

Returns the base-2 logarithm of X.

Examples

```
SELECT LOG2(4398046511104);
+----------------------+
| LOG2(4398046511104) |
+----------------------+
|                   42 |
+----------------------+

SELECT LOG2(65536);
+-------------+
| LOG2(65536) |
+-------------+
|          16 |
+-------------+

SELECT LOG2(-100);
+------------+
| LOG2(-100) |
+------------+
|       NULL |
+------------+
```

1.2.5.28 MOD

Syntax

```
MOD(N,M), N % M, N MOD M
```

Description

Modulo operation. Returns the remainder of N divided by M. See also Modulo Operator.

If the `ERROR_ON_DIVISION_BY_ZERO` SQL_MODE is used, any number modulus zero produces an error. Otherwise, it returns NULL.

The integer part of a division can be obtained using DIV.

Examples

```
SELECT 1042 % 50;
+-----------+
| 1042 % 50 |
+-----------+
|        42 |
+-----------+

SELECT MOD(234, 10);
+--------------+
| MOD(234, 10) |
+--------------+
|            4 |
+--------------+

SELECT 253 % 7;
+---------+
| 253 % 7 |
+---------+
|       1 |
+---------+

SELECT MOD(29,9);
+-----------+
| MOD(29,9) |
+-----------+
|         2 |
+-----------+

SELECT 29 MOD 9;
+----------+
| 29 MOD 9 |
+----------+
|        2 |
+----------+
```

1.2.5.29 OCT

Syntax

```
OCT(N)
```

Contents

Description

Returns a string representation of the octal value of N, where N is a longlong (BIGINT) number. This is equivalent to CONV(N,10,8). Returns NULL if N is NULL.

Examples

```
SELECT OCT(34);
+---------+
| OCT(34) |
+---------+
| 42      |
+---------+

SELECT OCT(12);
+---------+
| OCT(12) |
+---------+
| 14      |
+---------+
```

1.2.5.30 PI

Syntax

```
PI()
```

Description

Returns the value of π (pi). The default number of decimal places displayed is six, but MariaDB uses the full double-precision value internally.

Examples

```
SELECT PI();
+----------+
| PI()     |
+----------+
| 3.141593 |
+----------+

SELECT PI()+0.00000000000000000000;
+---------------------------------+
| PI()+0.00000000000000000000 |
+---------------------------------+
|      3.141592653589793115980 |
+---------------------------------+
```

1.2.5.31 POW

Syntax

```
POW(X,Y)
```

Description

Returns the value of X raised to the power of Y.

POWER() is a synonym.

Examples

```
SELECT POW(2,3);
+----------+
| POW(2,3) |
+----------+
|        8 |
+----------+

SELECT POW(2,-2);
+-----------+
| POW(2,-2) |
+-----------+
|      0.25 |
+-----------+
```

1.2.5.32 POWER

Syntax

```
POWER(X,Y)
```

Description

This is a synonym for POW(), which returns the value of X raised to the power of Y.

1.2.5.33 RADIANS

Syntax

```
RADIANS(X)
```

Description

Returns the argument X, converted from degrees to radians. Note that π radians equals 180 degrees.

This is the converse of the DEGREES() function.

Examples

```
SELECT RADIANS(45);
+-------------------+
| RADIANS(45)       |
+-------------------+
| 0.785398163397448 |
+-------------------+

SELECT RADIANS(90);
+------------------+
| RADIANS(90)      |
+------------------+
| 1.5707963267949 |
+------------------+

SELECT RADIANS(PI());
+--------------------+
| RADIANS(PI())      |
+--------------------+
| 0.0548311355616075 |
+--------------------+

SELECT RADIANS(180);
+-------------------+
| RADIANS(180)      |
+-------------------+
| 3.14159265358979 |
+-------------------+
```

1.2.5.34 RAND

Contents

Syntax

```
RAND(), RAND(N)
```

Description

Returns a random `DOUBLE` precision floating point value v in the range 0 <= v < 1.0. If a constant integer argument N is specified, it is used as the seed value, which produces a repeatable sequence of column values. In the example below, note that the sequences of values produced by RAND(3) is the same both places where it occurs.

In a WHERE clause, RAND() is evaluated each time the WHERE is executed.

Statements using the RAND() function are not safe for statement-based replication.

Practical uses

The expression to get a random integer from a given range is the following:

```
FLOOR(min_value + RAND() * (max_value - min_value +1))
```

RAND() is often used to read random rows from a table, as follows:

```
SELECT * FROM my_table ORDER BY RAND() LIMIT 10;
```

Note, however, that this technique should never be used on a large table as it will be extremely slow. MariaDB will read all rows in the table, generate a random value for each of them, order them, and finally will apply the LIMIT clause.

Examples

```
CREATE TABLE t (i INT);

INSERT INTO t VALUES(1),(2),(3);

SELECT i, RAND() FROM t;
+------+------------------+
| i    | RAND()           |
+------+------------------+
|    1 | 0.255651095188829 |
|    2 | 0.833920199269355 |
|    3 |  0.40264774151393 |
+------+------------------+

SELECT i, RAND(3) FROM t;
+------+------------------+
| i    | RAND(3)          |
+------+------------------+
|    1 |  0.90576975597606 |
|    2 | 0.373079058130345 |
|    3 | 0.148086053457191 |
+------+------------------+

SELECT i, RAND() FROM t;
+------+------------------+
| i    | RAND()           |
+------+------------------+
|    1 | 0.511478140495232 |
|    2 | 0.349447508668012 |
|    3 | 0.212803152588013 |
+------+------------------+
```

Using the same seed, the same sequence will be returned:

```
SELECT i, RAND(3) FROM t;
+------+------------------+
| i    | RAND(3)          |
+------+------------------+
|    1 |  0.90576975597606 |
|    2 | 0.373079058130345 |
|    3 | 0.148086053457191 |
+------+------------------+
```

Generating a random number from 5 to 15:

```
SELECT FLOOR(5 + (RAND() * 11));
```

1.2.5.35 ROUND

Syntax

```
ROUND(X), ROUND(X,D)
```

Description

Rounds the argument `X` to `D` decimal places. `D` defaults to `0` if not specified. `D` can be negative to cause `D` digits left of the decimal point of the value `X` to become zero.

The rounding algorithm depends on the data type of `X`:

- for floating point types (FLOAT, DOUBLE) the C libraries rounding function is used, so the behavior *may* differ between operating systems
- for fixed point types (DECIMAL, DEC/NUMBER/FIXED) the "round half up" rule is used, meaning that e.g. a value ending in exactly .5 is always rounded up.

Examples

```
SELECT ROUND(-1.23);
+--------------+
| ROUND(-1.23) |
+--------------+
|           -1 |
+--------------+

SELECT ROUND(-1.58);
+--------------+
| ROUND(-1.58) |
+--------------+
|           -2 |
+--------------+

SELECT ROUND(1.58);
+-------------+
| ROUND(1.58) |
+-------------+
|           2 |
+-------------+

SELECT ROUND(1.298, 1);
+-----------------+
| ROUND(1.298, 1) |
+-----------------+
|             1.3 |
+-----------------+

SELECT ROUND(1.298, 0);
+-----------------+
| ROUND(1.298, 0) |
+-----------------+
|               1 |
+-----------------+

SELECT ROUND(23.298, -1);
+-------------------+
| ROUND(23.298, -1) |
+-------------------+
|                20 |
+-------------------+
```

1.2.5.36 SIGN

Syntax

```
SIGN(X)
```

Description

Returns the sign of the argument as -1, 0, or 1, depending on whether X is negative, zero, or positive.

Examples

```
SELECT SIGN(-32);
+-----------+
| SIGN(-32) |
+-----------+
|        -1 |
+-----------+

SELECT SIGN(0);
+---------+
| SIGN(0) |
+---------+
|       0 |
+---------+

SELECT SIGN(234);
+-----------+
| SIGN(234) |
+-----------+
|         1 |
+-----------+
```

1.2.5.37 SIN

Syntax

```
SIN(X)
```

Description

Returns the sine of X, where X is given in radians.

Examples

```
SELECT SIN(1.5707963267948966);
+--------------------------+
| SIN(1.5707963267948966) |
+--------------------------+
|                        1 |
+--------------------------+

SELECT SIN(PI());
+----------------------+
| SIN(PI())            |
+----------------------+
| 1.22460635382238e-16 |
+----------------------+

SELECT ROUND(SIN(PI()));
+------------------+
| ROUND(SIN(PI())) |
+------------------+
|                0 |
+------------------+
```

1.2.5.38 SQRT

Syntax

```
SQRT(X)
```

Description

Returns the square root of X. If X is negative, NULL is returned.

Examples

```
SELECT SQRT(4);
+---------+
| SQRT(4) |
+---------+
|       2 |
+---------+

SELECT SQRT(20);
+------------------+
| SQRT(20)         |
+------------------+
| 4.47213595499958 |
+------------------+

SELECT SQRT(-16);
+-----------+
| SQRT(-16) |
+-----------+
|      NULL |
+-----------+

SELECT SQRT(1764);
+------------+
| SQRT(1764) |
+------------+
|         42 |
+------------+
```

1.2.5.39 TAN

Syntax

```
TAN(X)
```

Description

Returns the tangent of X, where X is given in radians.

Examples

```
SELECT TAN(0.7853981633974483);
+--------------------------+
| TAN(0.7853981633974483) |
+--------------------------+
|       0.9999999999999999 |
+--------------------------+

SELECT TAN(PI());
+-----------------------+
| TAN(PI())             |
+-----------------------+
| -1.22460635382238e-16 |
+-----------------------+

SELECT TAN(PI()+1);
+-----------------+
| TAN(PI()+1)     |
+-----------------+
| 1.5574077246549 |
+-----------------+

SELECT TAN(RADIANS(PI()));
+--------------------+
| TAN(RADIANS(PI())) |
+--------------------+
| 0.0548861508080033 |
+--------------------+
```

1.2.5.40 TRUNCATE

This page documents the TRUNCATE function. See TRUNCATE TABLE for the DDL statement.

Syntax

```
TRUNCATE(X,D)
```

Contents

Description

Returns the number X, truncated to D decimal places. If D is 0, the result has no decimal point or fractional part. D can be negative to cause D digits left of the decimal point of the value X to become zero.

Examples

```
SELECT TRUNCATE(1.223,1);
+-------------------+
| TRUNCATE(1.223,1) |
+-------------------+
|               1.2 |
+-------------------+

SELECT TRUNCATE(1.999,1);
+-------------------+
| TRUNCATE(1.999,1) |
+-------------------+
|               1.9 |
+-------------------+

SELECT TRUNCATE(1.999,0);
+-------------------+
| TRUNCATE(1.999,0) |
+-------------------+
|                 1 |
+-------------------+

SELECT TRUNCATE(-1.999,1);
+--------------------+
| TRUNCATE(-1.999,1) |
+--------------------+
|               -1.9 |
+--------------------+

SELECT TRUNCATE(122,-2);
+------------------+
| TRUNCATE(122,-2) |
+------------------+
|              100 |
+------------------+

SELECT TRUNCATE(10.28*100,0);
+------------------------+
| TRUNCATE(10.28*100,0) |
+------------------------+
|                   1028 |
+------------------------+
```

1.2.6 Control Flow Functions

Built-In functions for assessing data to determine what results to return.

CASE OPERATOR

Returns the result where value=compare_value or for the first condition that is true.

DECODE

Decrypts a string encoded with ENCODE(), or, in Oracle mode, matches expressions.

DECODE_ORACLE

Synonym for the Oracle mode version of DECODE().

IF Function

If expr1 is TRUE, returns expr2; otherwise it returns expr3.

IFNULL

Check whether an expression is NULL.

NULLIF

Returns NULL if expr1 = expr2.

NVL

Synonym for IFNULL.

NVL2

Returns a value based on whether a specified expression is NULL or not.

There are 1 related questions.

1.2.6.1 CASE OPERATOR

Syntax

```
CASE value WHEN [compare_value] THEN result [WHEN [compare_value] THEN
result ...] [ELSE result] END

CASE WHEN [condition] THEN result [WHEN [condition] THEN result ...]
[ELSE result] END
```

Contents

Description

The first version returns the result where value=compare_value. The second version returns the result for the first condition that is true. If there was no matching result value, the result after ELSE is returned, or NULL if there is no ELSE part.

There is also a CASE statement, which differs from the CASE operator described here.

Examples

```
SELECT CASE 1 WHEN 1 THEN 'one' WHEN 2 THEN 'two' ELSE 'more' END;
+-------------------------------------------------------------+
| CASE 1 WHEN 1 THEN 'one' WHEN 2 THEN 'two' ELSE 'more' END |
+-------------------------------------------------------------+
| one                                                         |
+-------------------------------------------------------------+

SELECT CASE WHEN 1>0 THEN 'true' ELSE 'false' END;
+---------------------------------------+
| CASE WHEN 1>0 THEN 'true' ELSE 'false' END |
+---------------------------------------+
| true                                  |
+---------------------------------------+

SELECT CASE BINARY 'B' WHEN 'a' THEN 1 WHEN 'b' THEN 2 END;
+-----------------------------------------------------+
| CASE BINARY 'B' WHEN 'a' THEN 1 WHEN 'b' THEN 2 END |
+-----------------------------------------------------+
|                                                NULL |
+-----------------------------------------------------+
```

1.2.6.2 DECODE

Syntax

```
DECODE(crypt_str,pass_str)
```

In Oracle mode from MariaDB 10.3.2:

```
DECODE(expr, search_expr, result_expr [, search_expr2, result_expr2 ...] [default_expr])
```

In all modes from MariaDB 10.3.2:

```
DECODE_ORACLE(expr, search_expr, result_expr [, search_expr2, result_expr2 ...] [default_expr])
```

Description

In the default mode, `DECODE` decrypts the encrypted string *crypt_str* using *pass_str* as the password. *crypt_str* should be a string returned from ENCODE(). The resulting string will be the original string only if *pass_str* is the same.

In Oracle mode from MariaDB 10.3.2, `DECODE` compares *expr* to the search expressions, in order. If it finds a match, the corresponding result expression is returned. If no matches are found, the default expression is returned, or NULL if no default is provided.

NULLs are treated as equivalent.

`DECODE_ORACLE` is a synonym for the Oracle-mode version of the function, and is available in all modes.

Examples

From MariaDB 10.3.2:

```
SELECT DECODE_ORACLE(2+1,3*1,'found1',3*2,'found2','default');
+-----------------------------------------------------------+
| DECODE_ORACLE(2+1,3*1,'found1',3*2,'found2','default') |
+-----------------------------------------------------------+
| found1                                                    |
+-----------------------------------------------------------+

SELECT DECODE_ORACLE(2+4,3*1,'found1',3*2,'found2','default');
+-----------------------------------------------------------+
| DECODE_ORACLE(2+4,3*1,'found1',3*2,'found2','default') |
+-----------------------------------------------------------+
| found2                                                    |
+-----------------------------------------------------------+

SELECT DECODE_ORACLE(2+2,3*1,'found1',3*2,'found2','default');
+-----------------------------------------------------------+
| DECODE_ORACLE(2+2,3*1,'found1',3*2,'found2','default') |
+-----------------------------------------------------------+
| default                                                   |
+-----------------------------------------------------------+
```

Nulls are treated as equivalent:

```
SELECT DECODE_ORACLE(NULL,NULL,'Nulls are equivalent','Nulls are not equivalent');
+-----------------------------------------------------------------------------+
| DECODE_ORACLE(NULL,NULL,'Nulls are equivalent','Nulls are not equivalent') |
+-----------------------------------------------------------------------------+
| Nulls are equivalent                                                        |
+-----------------------------------------------------------------------------+
```

1.2.6.3 DECODE_ORACLE

MariaDB starting with 10.3.2

`DECODE_ORACLE` is a synonym for the Oracle mode version of the DECODE function, and is available in all modes.

1.2.6.4 IF Function

Syntax

```
IF(expr1,expr2,expr3)
```

Contents

Description

If `expr1` is `TRUE` (`expr1 <> 0` and `expr1 <> NULL`) then `IF()` returns `expr2` ; otherwise it returns `expr3` . `IF()` returns a numeric or string value, depending on the context in which it is used.

Note: There is also an IF statement which differs from the `IF()` function described here.

Examples

```
SELECT IF(1>2,2,3);
+-------------+
| IF(1>2,2,3) |
+-------------+
|           3 |
+-------------+
```

```
SELECT IF(1<2,'yes','no');
+--------------------+
| IF(1<2,'yes','no') |
+--------------------+
| yes                |
+--------------------+
```

```
SELECT IF(STRCMP('test','test1'),'no','yes');
+---------------------------------------+
| IF(STRCMP('test','test1'),'no','yes') |
+---------------------------------------+
| no                                    |
+---------------------------------------+
```

1.2.6.5 IFNULL

Syntax

```
IFNULL(expr1,expr2)
NVL(expr1,expr2)
```

Contents

Description

If *`expr1`* is not NULL, IFNULL() returns *`expr1`* ; otherwise it returns *`expr2`* . IFNULL() returns a numeric or string value, depending on the context in which it is used.

From MariaDB 10.3, NVL() is an alias for IFNULL().

Examples

```
SELECT IFNULL(1,0);
+-------------+
| IFNULL(1,0) |
+-------------+
|           1 |
+-------------+

SELECT IFNULL(NULL,10);
+-----------------+
| IFNULL(NULL,10) |
+-----------------+
|              10 |
+-----------------+

SELECT IFNULL(1/0,10);
+----------------+
| IFNULL(1/0,10) |
+----------------+
|        10.0000 |
+----------------+

SELECT IFNULL(1/0,'yes');
+-------------------+
| IFNULL(1/0,'yes') |
+-------------------+
| yes               |
+-------------------+
```

1.2.6.6 NULLIF

Syntax

```
NULLIF(expr1,expr2)
```

Contents

Description

Returns NULL if expr1 = expr2 is true, otherwise returns expr1. This is the same as CASE WHEN expr1 = expr2 THEN NULL ELSE expr1 END.

Examples

```
SELECT NULLIF(1,1);
+-------------+
| NULLIF(1,1) |
+-------------+
|        NULL |
+-------------+

SELECT NULLIF(1,2);
+-------------+
| NULLIF(1,2) |
+-------------+
|           1 |
+-------------+
```

1.2.6.7 NVL

MariaDB starting with 10.3

From MariaDB 10.3, NVL is a synonym for IFNULL.

1.2.6.8 NVL2

MariaDB starting with 10.3

The NLV2 function was introduced in MariaDB 10.3.0.

Syntax

```
NVL2(expr1,expr2,expr3)
```

Contents

Description

The `NVL2` function returns a value based on whether a specified expression is NULL or not. If *expr1* is not NULL, then NVL2 returns *expr2*. If *expr1* is NULL, then NVL2 returns *expr3*.

Examples

```
SELECT NVL2(NULL,1,2);
+----------------+
| NVL2(NULL,1,2) |
+----------------+
|              2 |
+----------------+

SELECT NVL2('x',1,2);
+---------------+
| NVL2('x',1,2) |
+---------------+
|             1 |
+---------------+
```

1.2.7 Pseudo Columns

MariaDB has pseudo columns that can be used for different purposes.

_rowid

_rowid is an alias for the primary key column

1.2.7.1 _rowid

Syntax

_rowid

Description

The `_rowid` pseudo column is mapped to the primary key in the related table. This can be used as a replacement of the `rowid` pseudo column in other databases. Another usage is to simplify sql queries as one doesn't have to know the name of the primary key.

Examples

```
create table t1 (a int primary key, b varchar(80));
insert into t1 values (1,"one"),(2,"two");
select * from t1 where _rowid=1;
```

```
+---+------+
| a | b    |
+---+------+
| 1 | one  |
+---+------+
```

```
update t1 set b="three" where _rowid=2;
select * from t1 where _rowid>=1 and _rowid<=10;
```

```
+---+-------+
| a | b     |
+---+-------+
| 1 | one   |
| 2 | three |
+---+-------+
```

1.2.8 Secondary Functions

These are commonly used functions, but they are not primary functions.

Bit Functions and Operators

Operators for comparison and setting of values, and related functions.

Encryption, Hashing and Compression Functions

Functions used for encryption, hashing and compression.

Information Functions

Functions which return information on the server, the user, or a given query.

Miscellaneous Functions

Functions for very singular and specific needs.

1.2.8.1 Bit Functions and Operators

Operators for comparison and setting of values, and related functions. They all return a result of the `BIGINT UNSIGNED` type

Operator Precedence

Precedence of SQL operators

&

Bitwise AND

<<

Left shift

>>

Shift right

BIT_COUNT

Returns the number of set bits

^

Bitwise XOR

|

Bitwise OR

~

Bitwise NOT

Parentheses

Parentheses modify the precedence of other operators in an expression

TRUE FALSE

TRUE and FALSE evaluate to 1 and 0

1.1.5.6 Operator Precedence

1.2.8.1.2 &

Syntax

```
&
```

Description

Bitwise AND. Converts the values to binary and compares bits. Only if both the corresponding bits are 1 is the resulting bit also 1.

See also bitwise OR.

Examples

```
SELECT 2&1;
+-----+
| 2&1 |
+-----+
|   0 |
+-----+

SELECT 3&1;
+-----+
| 3&1 |
+-----+
|   1 |
+-----+

SELECT 29 & 15;
+---------+
| 29 & 15 |
+---------+
|      13 |
+---------+
```

1.2.8.1.3 <<

Syntax

```
value1 << value2
```

Description

Converts a longlong (BIGINT) number (*value1*) to binary and shifts *value2* units to the left.

Examples

```
SELECT 1 << 2;
+--------+
| 1 << 2 |
+--------+
|      4 |
+--------+
```

1.2.8.1.4 >>

Syntax

```
value1 >> value2
```

Description

Converts a longlong (BIGINT) number (*value1*) to binary and shifts *value2* units to the right.

Examples

```
SELECT 4 >> 2;
+--------+
| 4 >> 2 |
+--------+
|      1 |
+--------+
```

1.2.8.1.5 BIT_COUNT

Syntax

```
BIT_COUNT(N)
```

Description

Returns the number of bits that are set in the argument N.

Examples

```
SELECT BIT_COUNT(29), BIT_COUNT(b'101010');
+---------------+----------------------+
| BIT_COUNT(29) | BIT_COUNT(b'101010') |
+---------------+----------------------+
|             4 |                    3 |
+---------------+----------------------+
```

1.2.8.1.6 ^

Syntax

```
^
```

Description

Bitwise XOR. Converts the values to binary and compares bits. If one (and only one) of the corresponding bits is 1 is the resulting bit also 1.

Examples

```
SELECT 1 ^ 1;
+-------+
| 1 ^ 1 |
+-------+
|     0 |
+-------+

SELECT 1 ^ 0;
+-------+
| 1 ^ 0 |
+-------+
|     1 |
+-------+

SELECT 11 ^ 3;
+--------+
| 11 ^ 3 |
+--------+
|      8 |
+--------+
```

1.2.8.1.7 |

Syntax

```
|
```

Description

Bitwise OR. Converts the values to binary and compares bits. If either of the corresponding bits has a value of 1, the resulting bit is also 1.

See also bitwise AND.

Examples

```
SELECT 2|1;
+-----+
| 2|1 |
+-----+
|   3 |
+-----+

SELECT 29 | 15;
+---------+
| 29 | 15 |
+---------+
|      31 |
+---------+
```

1.2.8.1.8 ~

Syntax

```
~
```

Description

Bitwise NOT. Converts the value to 4 bytes binary and inverts all bits.

Examples

```
SELECT 3 & ~1;
+--------+
| 3 & ~1 |
+--------+
|      2 |
+--------+

SELECT 5 & ~1;
+--------+
| 5 & ~1 |
+--------+
|      4 |
+--------+
```

1.2.8.1.9 Parentheses

Parentheses are sometimes called precedence operators - this means that they can be used to change the other operator's precedence in an expression. The expressions that are written between parentheses are computed before the expressions that are written outside. Parentheses must always contain an expression (that is, they cannot be empty), and can be nested.

For example, the following expressions could return different results:

- `NOT a OR b`
- `NOT (a OR b)`

In the first case, `NOT` applies to `a`, so if `a` is `FALSE` or `b` is `TRUE`, the expression returns `TRUE`. In the second case, `NOT` applies to the result of `a OR b`, so if at least one of `a` or `b` is `TRUE`, the expression is `TRUE`.

When the precedence of operators is not intuitive, you can use parentheses to make it immediately clear for whoever reads the statement.

The precedence of the `NOT` operator can also be affected by the `HIGH_NOT_PRECEDENCE` SQL_MODE flag.

Other uses

Parentheses must always be used to enclose subqueries.

Parentheses can also be used in a `JOIN` statement between multiple tables to determine which tables must be joined first.

Also, parentheses are used to enclose the list of parameters to be passed to built-in functions, user-defined functions and stored routines. However, when no parameter is passed to a stored procedure, parentheses are optional. For builtin functions and user-defined functions, spaces are not allowed between the function name and the open parenthesis, unless the `IGNORE_SPACE` SQL_MODE is set. For stored routines (and for functions if `IGNORE_SPACE` is set) spaces are allowed before the open parenthesis, including tab characters and new line characters.

Syntax errors

If there are more open parentheses than closed parentheses, the error usually looks like this:

```
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
corresponds to your MariaDB server version for the right syntax to use near '' a
t line 1
```

Note the empty string.

If there are more closed parentheses than open parentheses, the error usually looks like this:

```
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
corresponds to your MariaDB server version for the right syntax to use near ')'
at line 1
```

Note the quoted closed parenthesis.

1.2.8.1.10 TRUE FALSE

Description

The constants TRUE and FALSE evaluate to 1 and 0, respectively. The constant names can be written in any lettercase.

Examples

```
SELECT TRUE, true, FALSE, false;
+------+------+-------+-------+
| TRUE | TRUE | FALSE | FALSE |
+------+------+-------+-------+
|    1 |    1 |     0 |     0 |
+------+------+-------+-------+
```

1.2.8.2 Encryption, Hashing and Compression Functions

Encryption, hashing and compression functions, such as ENCRYPT, DECRYPT, COMPRESS, PASSWORD etc.

AES_DECRYPT

Decryption data encrypted with AES_ENCRYPT.

AES_ENCRYPT

Encrypts a string with the AES algorithm.

COMPRESS

Returns a binary, compressed string.

DECODE

Decrypts a string encoded with ENCODE(), or, in Oracle mode, matches expressions.

DES_DECRYPT

Decrypts a string encrypted with DES_ENCRYPT().

DES_ENCRYPT

Encrypts a string using the Triple-DES algorithm.

ENCODE

Encrypts a string.

ENCRYPT

Encrypts a string with Unix crypt().

KDF

Key derivation function

MD5
MD5 checksum.

OLD_PASSWORD
Pre MySQL 4.1 password implementation.

PASSWORD
Calculates a password string.

RANDOM_BYTES
Generates a binary string of random bytes.

SHA1
Calculates an SHA-1 checksum.

SHA2
Calculates an SHA-2 checksum.

UNCOMPRESS
Uncompresses string compressed with COMPRESS().

UNCOMPRESSED_LENGTH
Returns length of a string before being compressed with COMPRESS().

There are 1 related questions.

1.2.8.2.1 AES_DECRYPT

Syntax

```
AES_DECRYPT(crypt_str,key_str)
```

From MariaDB 11.2.0

```
AES_ENCRYPT(crypt_str, key_str, [, iv [, mode]])
```

Description

This function allows decryption of data using the official AES (Advanced Encryption Standard) algorithm. For more information, see the description of AES_ENCRYPT().

MariaDB starting with 11.2

From MariaDB 11.2, the function supports an initialization vector, and control of the block encryption mode. The default mode is specified by the block_encryption_mode system variable, which can be changed when calling the function with a mode. *mode* is aes-{128,192,256}-{ecb,cbc,ctr} for example: "AES-128-cbc".

For modes that require it, the initialization_vector *iv* should be 16 bytes (it can be longer, but the extra bytes are ignored). A shorter *iv*, where one is required, results in the function returning NULL. Calling RANDOM_BYTES(16) will generate a random series of bytes that can be used for the *iv*.

Examples

From MariaDB 11.2.0:

```
SELECT HEX(AES_ENCRYPT('foo', 'bar', '0123456789abcdef', 'aes-128-ctr')) AS x;
+--------+
| x      |
+--------+
| C57C4B |
+--------+

SELECT AES_DECRYPT(x'C57C4B', 'bar', '0123456789abcdef', 'aes-128-ctr');
+-----------------------------------------------------------------+
| AES_DECRYPT(x'C57C4B', 'bar', '0123456789abcdef', 'aes-128-ctr') |
+-----------------------------------------------------------------+
| foo                                                             |
+-----------------------------------------------------------------+
```

1.2.8.2.2 AES_ENCRYPT

Syntax

```
AES_ENCRYPT(str,key_str)
```

From MariaDB 11.2.0

```
AES_ENCRYPT(str, key, [, iv [, mode]])
```

Description

`AES_ENCRYPT()` and AES_DECRYPT() allow encryption and decryption of data using the official AES (Advanced Encryption Standard) algorithm, previously known as "Rijndael." Encoding with a 128-bit key length is used (from MariaDB 11.2.0, this is the default, and can be changed). 128 bits is much faster and is secure enough for most purposes.

`AES_ENCRYPT()` encrypts a string *`str`* using the key *`key_str`*, and returns a binary string.

`AES_DECRYPT()` decrypts the encrypted string and returns the original string.

The input arguments may be any length. If either argument is NULL, the result of this function is also `NULL`.

Because AES is a block-level algorithm, padding is used to encode uneven length strings and so the result string length may be calculated using this formula:

```
16 x (trunc(string_length / 16) + 1)
```

If `AES_DECRYPT()` detects invalid data or incorrect padding, it returns `NULL`. However, it is possible for `AES_DECRYPT()` to return a non-`NULL` value (possibly garbage) if the input data or the key is invalid.

MariaDB starting with 11.2

From MariaDB 11.2, the function supports an initialization vector, and control of the block encryption mode. The default mode is specified by the block_encryption_mode system variable, which can be changed when calling the function with a mode. *mode* is aes-{128,192,256}-{ecb,cbc,ctr} for example: "AES-128-cbc".

AES_ENCRYPT(str, key) can no longer be used in persistent virtual columns (and the like).

Examples

```
INSERT INTO t VALUES (AES_ENCRYPT('text',SHA2('password',512)));
```

From MariaDB 11.2.0:

```
SELECT HEX(AES_ENCRYPT('foo', 'bar', '0123456789abcdef', 'aes-256-cbc')) AS x;
+----------------------------------+
| x                                |
+----------------------------------+
| 42A3EB91E6DFC40A900D278F99E0726E |
+----------------------------------+
```

1.2.8.2.3 COMPRESS

Syntax

```
COMPRESS(string_to_compress)
```

Description

Compresses a string and returns the result as a binary string. This function requires MariaDB to have been compiled with a compression library such as zlib. Otherwise, the return value is always `NULL`. The compressed string can be uncompressed with `UNCOMPRESS()`.

The have_compress server system variable indicates whether a compression library is present.

Examples

```
SELECT LENGTH(COMPRESS(REPEAT('a',1000)));
+-----------------------------------+
| LENGTH(COMPRESS(REPEAT('a',1000))) |
+-----------------------------------+
|                                21 |
+-----------------------------------+

SELECT LENGTH(COMPRESS(''));
+----------------------+
| LENGTH(COMPRESS('')) |
+----------------------+
|                    0 |
+----------------------+

SELECT LENGTH(COMPRESS('a'));
+-----------------------+
| LENGTH(COMPRESS('a')) |
+-----------------------+
|                    13 |
+-----------------------+

SELECT LENGTH(COMPRESS(REPEAT('a',16)));
+---------------------------------+
| LENGTH(COMPRESS(REPEAT('a',16))) |
+---------------------------------+
|                              15 |
+---------------------------------+
```

1.2.6.2 DECODE

1.2.8.2.5 DES_DECRYPT

DES_DECRYPT has been deprecated from MariaDB 10.10.0, and will be removed in a future release.

Syntax

```
DES_DECRYPT(crypt_str[,key_str])
```

Description

Decrypts a string encrypted with `DES_ENCRYPT()`. If an error occurs, this function returns `NULL`.

This function works only if MariaDB has been configured with TLS support.

If no `key_str` argument is given, `DES_DECRYPT()` examines the first byte of the encrypted string to determine the DES key number that was used to encrypt the original string, and then reads the key from the DES key file to decrypt the message. For this to work, the user must have the SUPER privilege. The key file can be specified with the `--des-key-file` server option.

If you pass this function a `key_str` argument, that string is used as the key for decrypting the message.

If the `crypt_str` argument does not appear to be an encrypted string, MariaDB returns the given crypt_str.

1.2.8.2.6 DES_ENCRYPT

DES_ENCRYPT has been deprecated from MariaDB 10.10.0, and will be removed in a future release.

Syntax

```
DES_ENCRYPT(str[,{key_num|key_str}])
```

Description

Encrypts the string with the given key using the Triple-DES algorithm.

This function works only if MariaDB has been configured with TLS support.

The encryption key to use is chosen based on the second argument to `DES_ENCRYPT()`, if one was given. With no argument, the first key from the DES key file is used. With a *`key_num`* argument, the given key number (0-9) from the DES key file is used. With a *`key_str`* argument, the given key string is used to encrypt *`str`*.

The key file can be specified with the `--des-key-file` server option.

The return string is a binary string where the first character is `CHAR(128 | key_num)`. If an error occurs, `DES_ENCRYPT()` returns `NULL`.

The 128 is added to make it easier to recognize an encrypted key. If you use a string key, *`key_num`* is 127.

The string length for the result is given by this formula:

```
new_len = orig_len + (8 - (orig_len % 8)) + 1
```

Each line in the DES key file has the following format:

```
key_num des_key_str
```

Each *`key_num`* value must be a number in the range from 0 to 9. Lines in the file may be in any order. *`des_key_str`* is the string that is used to encrypt the message. There should be at least one space between the number and the key. The first key is the default key that is used if you do not specify any key argument to `DES_ENCRYPT()`.

You can tell MariaDB to read new key values from the key file with the FLUSH DES_KEY_FILE statement. This requires the RELOAD privilege.

One benefit of having a set of default keys is that it gives applications a way to check for the existence of encrypted column values, without giving the end user the right to decrypt those values.

Examples

```
SELECT customer_address FROM customer_table
   WHERE crypted_credit_card = DES_ENCRYPT('credit_card_number');
```

1.2.8.2.7 ENCODE

Syntax

```
ENCODE(str,pass_str)
```

Description

ENCODE is not considered cryptographically secure, and should not be used for password encryption.

Encrypt `str` using `pass_str` as the password. To decrypt the result, use `DECODE()`.

The result is a binary string of the same length as `str`.

The strength of the encryption is based on how good the random generator is.

It is not recommended to rely on the encryption performed by the ENCODE function. Using a salt value (changed when a password is updated) will improve matters somewhat, but for storing passwords, consider a more cryptographically secure function, such as SHA2().

Examples

```
ENCODE('not so secret text', CONCAT('random_salt','password'))
```

1.2.8.2.8 ENCRYPT

Syntax

```
ENCRYPT(str[,salt])
```

Description

Encrypts a string using the Unix crypt() system call, returning an encrypted binary string. The `salt` argument should be a string with at least two characters or the returned result will be NULL. If no salt argument is given, a random value of sufficient length is used.

It is not recommended to use ENCRYPT() with utf16, utf32 or ucs2 multi-byte character sets because the crypt() system call expects a string terminated with a zero byte.

Note that the underlying crypt() system call may have some limitations, such as ignoring all but the first eight characters.

If the have_crypt system variable is set to `NO` (because the crypt() system call is not available), the ENCRYPT function will always return NULL.

Examples

```
SELECT ENCRYPT('encrypt me');
+----------------------+
| ENCRYPT('encrypt me') |
+----------------------+
| 4I5BsEx0lqTDk         |
+----------------------+
```

1.2.8.2.9 KDF

MariaDB starting with 11.3

KDF() is a key derivation function introduced in MariaDB 11.3.0.

Syntax

```
KDF(key_str, salt [, {info | iterations} [, kdf_name [, width ]]])
```

Description

`KDF` is a key derivation function, similar to OpenSSL's EVP_KDF_derive(), useful for generating good encryption keys for AES_ENCRYPT.

- *kdf_name* is "hkdf" or "pbkdf2_hmac" (default)
- *width* (in bits) can be any number divisible by 8, by default it's taken from @@block_encryption_mode
- *iterations* must be positive, and is 1000 by default

Note that OpenSSL 1.0 doesn't support HKDF, so in this case NULL is returned. This OpenSSL version is still used in SLES 12 and CentOS 7.

Examples

```
select hex(kdf('foo', 'bar', 'infa', 'hkdf'));
+----------------------------------------+
| hex(kdf('foo', 'bar', 'infa', 'hkdf')) |
+----------------------------------------+
| 612875F859CFB4EE0DFEFF9F2A18E836       |
+----------------------------------------+
```

1.2.8.2.10 MD5

Syntax

```
MD5(str)
```

Description

Calculates an MD5 128-bit checksum for the string.

The return value is a 32-hex digit string, and as of MariaDB 5.5, is a nonbinary string in the connection character set and collation, determined by the values of the character_set_connection and collation_connection system variables. Before 5.5, the return value was a binary string.

NULL is returned if the argument was NULL.

Examples

```
SELECT MD5('testing');
+----------------------------------+
| MD5('testing')                   |
+----------------------------------+
| ae2b1fca515949e5d54fb22b8ed95575 |
+----------------------------------+
```

1.2.8.2.11 OLD_PASSWORD

Syntax

```
OLD_PASSWORD(str)
```

Contents

Description

`OLD_PASSWORD()` was added to MySQL when the implementation of PASSWORD() was changed to improve security. `OLD_PASSWORD()` returns the value of the old (pre-MySQL 4.1) implementation of PASSWORD() as a string, and is intended to permit you to reset passwords for any pre-4.1 clients that need to connect to a more recent MySQL server version, or any version of MariaDB, without locking them out.

As of MariaDB 5.5, the return value is a nonbinary string in the connection character set and collation, determined by the values of the character_set_connection and collation_connection system variables. Before 5.5, the return value was a binary string.

The return value is 16 bytes in length, or NULL if the argument was NULL.

1.2.8.2.12 PASSWORD

Syntax

```
PASSWORD(str)
```

Contents

Description

> The PASSWORD() function is used for hashing passwords for use in authentication by the MariaDB server. It is not intended for use in other applications.

Calculates and returns a hashed password string from the plaintext password *str*. Returns an empty string (>= MariaDB 10.0.4) if the argument was NULL.

The return value is a nonbinary string in the connection character set and collation, determined by the values of the character_set_connection and collation_connection system variables.

This is the function that is used for hashing MariaDB passwords for storage in the Password column of the user table (see privileges), usually used with the SET PASSWORD statement. It is not intended for use in other applications.

Until MariaDB 10.3, the return value is 41-bytes in length, and the first character is always '*'. From MariaDB 10.4, the function takes into account the authentication plugin where applicable (A CREATE USER or SET PASSWORD statement). For example, when used in conjunction with a user authenticated by the ed25519 plugin, the statement will create a longer hash:

```
CREATE USER edtest@localhost IDENTIFIED VIA ed25519 USING PASSWORD('secret');

CREATE USER edtest2@localhost IDENTIFIED BY 'secret';

SELECT CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv)) FROM mysql.global_priv
  WHERE user LIKE 'edtest%'\G
*************************** 1. row ***************************
CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv)): edtest@localhost => {
...
    "plugin": "ed25519",
    "authentication_string": "ZIgUREUg5PVgQ6LskhXmO+eZLS0nC8be6HPjYWR4YJY",
...
}
*************************** 2. row ***************************
CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv)): edtest2@localhost => {
...
    "plugin": "mysql_native_password",
    "authentication_string": "*14E65567ABDB5135D0CFD9A70B3032C179A49EE7",
...
}
```

The behavior of this function is affected by the value of the old_passwords system variable. If this is set to `1` (`0` is default), MariaDB reverts to using the mysql_old_password authentication plugin by default for newly created users and passwords.

Examples

```
SELECT PASSWORD('notagoodpwd');
+-------------------------------------------+
| PASSWORD('notagoodpwd')                   |
+-------------------------------------------+
| *3A70EE9FC6594F88CE9E959CD51C5A1C002DC937 |
+-------------------------------------------+
```

```
SET PASSWORD FOR 'bob'@'%.loc.gov' = PASSWORD('newpass');
```

1.2.8.2.13 RANDOM_BYTES

MariaDB starting with 10.10.0

The RANDOM_BYTES function generates a binary string of random bytes. It was added in MariaDB 10.10.0.

Syntax

```
RANDOM_BYTES(length)
```

Description

Given a *length* from 1 to 1024, generates a binary string of *length* consisting of random bytes generated by the SSL library's random number generator.

See the RAND_bytes() function documentation of your SSL library for information on the random number generator. In the case of OpenSSL, a cryptographically secure pseudo random generator (CSPRNG) is used.

Statements containing the RANDOM_BYTES function are unsafe for statement-based replication.

An error occurs if *length* is outside the range 1 to 1024.

1.2.8.2.14 SHA1

Syntax

Syntax

```
SHA1(str), SHA(str)
```

Description

Calculates an SHA-1 160-bit checksum for the string *str*, as described in RFC 3174 (Secure Hash Algorithm).

The value is returned as a string of 40 hex digits, or NULL if the argument was NULL. As of MariaDB 5.5, the return value is a nonbinary string in the connection character set and collation, determined by the values of the character_set_connection and collation_connection system variables. Before 5.5, the return value was a binary string.

Examples

```
SELECT SHA1('some boring text');
+------------------------------------------+
| SHA1('some boring text')                 |
+------------------------------------------+
| af969fc2085b1bb6d31e517d5c456def5cdd7093 |
+------------------------------------------+
```

1.2.8.2.15 SHA2

Syntax

```
SHA2(str,hash_len)
```

Description

Given a string *str*, calculates an SHA-2 checksum, which is considered more cryptographically secure than its SHA-1 equivalent. The SHA-2 family includes SHA-224, SHA-256, SHA-384, and SHA-512, and the *hash_len* must correspond to one of these, i.e. 224, 256, 384 or 512. 0 is equivalent to 256.

The return value is a nonbinary string in the connection character set and collation, determined by the values of the character_set_connection and collation_connection system variables.

NULL is returned if the hash length is not valid, or the string *str* is NULL.

SHA2 will only work if MariaDB was has been configured with TLS support.

Examples

```
SELECT SHA2('Maria',224);
+----------------------------------------------------------+
| SHA2('Maria',224)                                        |
+----------------------------------------------------------+
| 6cc67add32286412efcab9d0e1675a43a5c2ef3cec8879f81516ff83 |
+----------------------------------------------------------+

SELECT SHA2('Maria',256);
+------------------------------------------------------------------+
| SHA2('Maria',256)                                                |
+------------------------------------------------------------------+
| 9ff18ebe7449349f358e3af0b57cf7a032c1c6b2272cb2656ff85eb112232f16 |
+------------------------------------------------------------------+

SELECT SHA2('Maria',0);
+------------------------------------------------------------------+
| SHA2('Maria',0)                                                  |
+------------------------------------------------------------------+
| 9ff18ebe7449349f358e3af0b57cf7a032c1c6b2272cb2656ff85eb112232f16 |
+------------------------------------------------------------------+
```

1.2.2.65 UNCOMPRESS

1.2.2.66 UNCOMPRESSED_LENGTH

1.2.8.3 Information Functions

General information functions, including BENCHMARK, CHARSET, DATABASE, USER, VERSION, etc.

BENCHMARK

Executes an expression repeatedly.

BINLOG_GTID_POS

Returns a string representation of the corresponding GTID position.

CHARSET

Returns the character set.

COERCIBILITY

Returns the collation coercibility value.

COLLATION

Collation of the string argument.

CONNECTION_ID

Connection ID.

CURRENT_ROLE

Current role name.

CURRENT_USER

Username/host that authenticated the current client.

DATABASE

Current default database.

DECODE_HISTOGRAM

Returns comma separated numerics corresponding to a probability distribution.

DEFAULT

Returns column default.

FOUND_ROWS

Number of (potentially) returned rows.

LAST_INSERT_ID

Last inserted auto_increment value.

LAST_VALUE

Returns the last value in a list or set of values.

PROCEDURE ANALYSE

Suggests optimal data types for each column.

ROWNUM

Function that returns the number of accepted rows so far.

ROW_COUNT

Number of rows affected by previous statement.

SCHEMA

Synonym for DATABASE().

SESSION_USER
Synonym for USER().

SYSTEM_USER
Synonym for USER().

USER
Current user/host.

VERSION
MariaDB server version.

There are 1 related questions.

1.2.8.3.1 BENCHMARK

Syntax

```
BENCHMARK(count,expr)
```

Description

The BENCHMARK() function executes the expression `expr` repeatedly `count` times. It may be used to time how quickly MariaDB processes the expression. The result value is always 0. The intended use is from within the mariadb client, which reports query execution times.

Examples

```
SELECT BENCHMARK(1000000,ENCODE('hello','goodbye'));
+----------------------------------------------+
| BENCHMARK(1000000,ENCODE('hello','goodbye')) |
+----------------------------------------------+
|                                            0 |
+----------------------------------------------+
1 row in set (0.21 sec)
```

1.2.8.3.2 BINLOG_GTID_POS

Syntax

```
BINLOG_GTID_POS(binlog_filename,binlog_offset)
```

Description

The BINLOG_GTID_POS() function takes as input an old-style binary log position in the form of a file name and a file offset. It looks up the position in the current binlog, and returns a string representation of the corresponding GTID position. If the position is not found in the current binlog, NULL is returned.

Examples

```
SELECT BINLOG_GTID_POS("master-bin.000001", 600);
```

1.2.8.3.3 CHARSET

Syntax

```
CHARSET(str)
```

Description

Returns the character set of the string argument. If `str` is not a string, it is considered as a binary string (so the function returns 'binary'). This applies to `NULL`, too. The return value is a string in the utf8 character set.

Examples

```
SELECT CHARSET('abc');
+----------------+
| CHARSET('abc') |
+----------------+
| latin1         |
+----------------+

SELECT CHARSET(CONVERT('abc' USING utf8));
+-----------------------------------+
| CHARSET(CONVERT('abc' USING utf8)) |
+-----------------------------------+
| utf8                              |
+-----------------------------------+

SELECT CHARSET(USER());
+-----------------+
| CHARSET(USER()) |
+-----------------+
| utf8            |
+-----------------+
```

1.2.8.3.4 COERCIBILITY

Syntax

```
COERCIBILITY(str)
```

Description

Returns the collation coercibility value of the string argument. Coercibility defines what will be converted to what in case of collation conflict, with an expression with higher coercibility being converted to the collation of an expression with lower coercibility.

Coercibility	Description	Example
0	Explicit	Value using a COLLATE clause
1	No collation	Concatenated strings using different collations
2	Implicit	A string data type column value, CAST to a string data type
3	System constant	DATABASE(), USER() return value
4	Coercible	Literal string
5	Numeric	Numeric and temporal values
6	Ignorable	NULL or derived from NULL

Examples

```
SELECT COERCIBILITY('abc' COLLATE latin1_swedish_ci);
+-------------------------------------------------+
| COERCIBILITY('abc' COLLATE latin1_swedish_ci) |
+-------------------------------------------------+
|                                               0 |
+-------------------------------------------------+

SELECT COERCIBILITY(CAST(1 AS CHAR));
+--------------------------------+
| COERCIBILITY(CAST(1 AS CHAR)) |
+--------------------------------+
|                              2 |
+--------------------------------+

SELECT COERCIBILITY(USER());
+----------------------+
| COERCIBILITY(USER()) |
+----------------------+
|                    3 |
+----------------------+

SELECT COERCIBILITY('abc');
+---------------------+
| COERCIBILITY('abc') |
+---------------------+
|                   4 |
+---------------------+

SELECT COERCIBILITY(1);
+-----------------+
| COERCIBILITY(1) |
+-----------------+
|               5 |
+-----------------+

SELECT COERCIBILITY(NULL);
+--------------------+
| COERCIBILITY(NULL) |
+--------------------+
|                  6 |
+--------------------+
```

1.2.8.3.5 COLLATION

Syntax

```
COLLATION(str)
```

Contents

Description

Returns the collation of the string argument. If `str` is not a string, it is considered as a binary string (so the function returns 'binary'). This applies to `NULL`, too. The return value is a string in the utf8 character set.

See Character Sets and Collations.

Examples

```
SELECT COLLATION('abc');
+------------------+
| COLLATION('abc')  |
+------------------+
| latin1_swedish_ci |
+------------------+

SELECT COLLATION(_utf8'abc');
+----------------------+
| COLLATION(_utf8'abc') |
+----------------------+
| utf8_general_ci       |
+----------------------+
```

1.2.8.3.6 CONNECTION_ID

Syntax

```
CONNECTION_ID()
```

Description

Returns the connection ID for the connection. Every connection (including events) has an ID that is unique among the set of currently connected clients.

Until MariaDB 10.3.1, returns `MYSQL_TYPE_LONGLONG`, or bigint(10), in all cases. From MariaDB 10.3.1, returns `MYSQL_TYPE_LONG`, or int(10), when the result would fit within 32-bits.

Examples

```
SELECT CONNECTION_ID();
+-----------------+
| CONNECTION_ID() |
+-----------------+
|               3 |
+-----------------+
```

1.2.8.3.7 CURRENT_ROLE

Syntax

```
CURRENT_ROLE, CURRENT_ROLE()
```

Description

Returns the current role name. This determines your access privileges. The return value is a string in the utf8 character set.

If there is no current role, NULL is returned.

The output of `SELECT CURRENT_ROLE` is equivalent to the contents of the ENABLED_ROLES Information Schema table.

USER() returns the combination of user and host used to login. CURRENT_USER() returns the account used to determine current connection's privileges.

Statements using the `CURRENT_ROLE` function are not safe for statement-based replication.

Examples

```
SELECT CURRENT_ROLE;
+--------------+
| CURRENT_ROLE |
+--------------+
| NULL         |
+--------------+

SET ROLE staff;

SELECT CURRENT_ROLE;
+--------------+
| CURRENT_ROLE |
+--------------+
| staff        |
+--------------+
```

1.2.8.3.8 CURRENT_USER

Syntax

```
CURRENT_USER, CURRENT_USER()
```

Description

Returns the user name and host name combination for the MariaDB account that the server used to authenticate the current client. This account determines your access privileges. The return value is a string in the utf8 character set.

The value of `CURRENT_USER()` can differ from the value of USER(). CURRENT_ROLE() returns the current active role.

Statements using the `CURRENT_USER` function are not safe for statement-based replication.

Examples

```
shell> mysql --user="anonymous"

select user(),current_user();
+---------------------+----------------+
| user()              | current_user() |
+---------------------+----------------+
| anonymous@localhost | @localhost     |
+---------------------+----------------+
```

When calling `CURRENT_USER()` in a stored procedure, it returns the owner of the stored procedure, as defined with `DEFINER`.

1.2.8.3.9 DATABASE

Syntax

```
DATABASE()
SCHEMA()
```

Description

Returns the default (current) database name as a string in the utf8 character set. If there is no default database, DATABASE() returns NULL. Within a stored routine, the default database is the database that the routine is associated with, which is not necessarily the same as the database that is the default in the calling context.

SCHEMA() is a synonym for DATABASE().

To select a default database, the USE statement can be run. Another way to set the default database is specifying its name at mariadb command line client startup.

Examples

```
SELECT DATABASE();
+------------+
| DATABASE() |
+------------+
| NULL       |
+------------+

USE test;
Database changed

SELECT DATABASE();
+------------+
| DATABASE() |
+------------+
| test       |
+------------+
```

1.2.8.3.10 DECODE_HISTOGRAM

Syntax

```
DECODE_HISTOGRAM(hist_type,histogram)
```

Description

Returns a string of comma separated numeric values corresponding to a probability distribution represented by the histogram of type `hist_type` (`SINGLE_PREC_HB` or `DOUBLE_PREC_HB`). The `hist_type` and `histogram` would be commonly used from the mysql.column_stats table.

See Histogram Based Statistics for details.

Examples

```
CREATE TABLE origin (
  i INT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  v INT UNSIGNED NOT NULL
);

INSERT INTO origin(v) VALUES
  (1),(2),(3),(4),(5),(10),(20),
  (30),(40),(50),(60),(70),(80),
  (90),(100),(200),(400),(800);

SET histogram_size=10,histogram_type=SINGLE_PREC_HB;

ANALYZE TABLE origin PERSISTENT FOR ALL;
+-------------+---------+----------+-----------------------------------------+
| Table       | Op      | Msg_type | Msg_text                                |
+-------------+---------+----------+-----------------------------------------+
| test.origin | analyze | status   | Engine-independent statistics collected |
| test.origin | analyze | status   | OK                                      |
+-------------+---------+----------+-----------------------------------------+

```

1.2.8.3.11 DEFAULT

Syntax

```
DEFAULT(col_name)
```

Description

Returns the default value for a table column. If the column has no default value (and is not NULLABLE - NULLABLE fields have a NULL default), an error is returned.

For integer columns using AUTO_INCREMENT, `0` is returned.

When using `DEFAULT` as a value to set in an INSERT or UPDATE statement, you can use the bare keyword `DEFAULT` without the parentheses and argument to refer to the column in context. You can only use `DEFAULT` as a bare keyword if you are using it alone without a surrounding expression or function.

Examples

Select only non-default values for a column:

```
SELECT i FROM t WHERE i != DEFAULT(i);
```

Update values to be one greater than the default value:

```
UPDATE t SET i = DEFAULT(i)+1 WHERE i < 100;
```

When referring to the default value exactly in `UPDATE` or `INSERT`, you can omit the argument:

```
INSERT INTO t (i) VALUES (DEFAULT);
UPDATE t SET i = DEFAULT WHERE i < 100;
```

```
CREATE OR REPLACE TABLE t (
  i INT NOT NULL AUTO_INCREMENT,
  j INT NOT NULL,
  k INT DEFAULT 3,
  l INT NOT NULL DEFAULT 4,
  m INT,
  PRIMARY KEY (i)
);

DESC t;
+-------+---------+------+-----+---------+----------------+
| Field | Type    | Null | Key | Default | Extra          |
+-------+---------+------+-----+---------+----------------+
| i     | int(11) | NO   | PRI | NULL    | auto_increment |
| j     | int(11) | NO   |     | NULL    |                |
| k     | int(11) | YES  |     | 3       |                |
| l     | int(11) | NO   |     | 4       |                |
| m     | int(11) | YES  |     | NULL    |                |
+-------+---------+------+-----+---------+----------------+

INSERT INTO t (j) VALUES (1);
INSERT INTO t (j,m) VALUES (2,2);
INSERT INTO t (j,l,m) VALUES (3,3,3);

SELECT * FROM t;
+---+---+------+---+------+
| i | j | k    | l | m    |

| i | j | k    | l | m    |
+---+---+------+---+------+
| 1 | 1 |    3 | 4 | NULL |
+---+---+------+---+------+
```

1.2.8.3.12 FOUND_ROWS

Syntax

```
FOUND_ROWS()
```

Description

A SELECT statement may include a LIMIT clause to restrict the number of rows the server returns to the client. In some cases, it is desirable to know how many rows the statement would have returned without the LIMIT, but without running the statement again. To obtain this row count, include a SQL_CALC_FOUND_ROWS option in the SELECT statement, and then invoke FOUND_ROWS() afterwards.

You can also use FOUND_ROWS() to obtain the number of rows returned by a SELECT which does not contain a LIMIT clause. In this case you don't need to use the SQL_CALC_FOUND_ROWS option. This can be useful for example in a stored procedure.

Also, this function works with some other statements which return a resultset, including SHOW, DESC and HELP. For DELETE ... RETURNING you should use ROW_COUNT(). It also works as a prepared statement, or after executing a prepared statement.

Statements which don't return any results don't affect FOUND_ROWS() - the previous value will still be returned.

Warning: When used after a CALL statement, this function returns the number of rows selected by the last query in the procedure, not by the whole procedure.

Statements using the FOUND_ROWS() function are not safe for statement-based replication.

Examples

```
SHOW ENGINES\G
*************************** 1. row ***************************
      Engine: CSV
     Support: YES
     Comment: Stores tables as CSV files

          XA: NO
  Savepoints: NO
8 rows in set (0.000 sec)

SELECT FOUND_ROWS();
+--------------+
| FOUND_ROWS() |
+--------------+
|            8 |
+--------------+

SELECT SQL_CALC_FOUND_ROWS * FROM tbl_name WHERE id > 100 LIMIT 10;

SELECT FOUND_ROWS();
+--------------+
| FOUND_ROWS() |
+--------------+
|           23 |
+--------------+
```

1.2.8.3.13 LAST_INSERT_ID

Syntax

```
LAST_INSERT_ID(), LAST_INSERT_ID(expr)
```

Contents

Description

LAST_INSERT_ID() (no arguments) returns the first automatically generated value successfully inserted for an AUTO_INCREMENT column as a result of the most recently executed INSERT statement. The value of LAST_INSERT_ID() remains unchanged if no rows are successfully inserted.

If one gives an argument to LAST_INSERT_ID(), then it will return the value of the expression and the next call to LAST_INSERT_ID() will return the same value. The value will also be sent to the client and can be accessed by the mysql_insert_id function.

For example, after inserting a row that generates an AUTO_INCREMENT value, you can get the value like this:

```
SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|                9 |
+------------------+
```

You can also use LAST_INSERT_ID() to delete the last inserted row:

```
DELETE FROM product WHERE id = LAST_INSERT_ID();
```

If no rows were successfully inserted, LAST_INSERT_ID() returns 0.

The value of LAST_INSERT_ID() will be consistent across all versions if all rows in the INSERT or UPDATE statement were successful.

The currently executing statement does not affect the value of LAST_INSERT_ID(). Suppose that you generate an AUTO_INCREMENT value with one statement, and then refer to LAST_INSERT_ID() in a multiple-row INSERT statement that inserts rows into a table with its own AUTO_INCREMENT column. The value of LAST_INSERT_ID() will remain stable in the second statement; its value for the second and later rows is not affected by the earlier row insertions. (However, if you mix references to LAST_INSERT_ID() and LAST_INSERT_ID(expr), the effect is undefined.)

If the previous statement returned an error, the value of LAST_INSERT_ID() is undefined. For transactional tables, if the statement is rolled back due to an error, the value of LAST_INSERT_ID() is left undefined. For manual ROLLBACK, the value of LAST_INSERT_ID() is not restored to that before the transaction; it remains as it was at the point of the ROLLBACK.

Within the body of a stored routine (procedure or function) or a trigger, the value of LAST_INSERT_ID() changes the same way as for statements executed outside the body of these kinds of objects. The effect of a stored routine or trigger upon the value of LAST_INSERT_ID() that is seen by following statements depends on the kind of routine:

- If a stored procedure executes statements that change the value of LAST_INSERT_ID(), the new value will be seen by statements that follow the procedure call.
- For stored functions and triggers that change the value, the value is restored when the function or trigger ends, so following statements will not see a changed value.

Examples

```
CREATE TABLE t (
  id INTEGER UNSIGNED AUTO_INCREMENT PRIMARY KEY,
  f VARCHAR(1))
ENGINE = InnoDB;

INSERT INTO t(f) VALUES('a');

SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|                1 |
+------------------+

INSERT INTO t(f) VALUES('b');

INSERT INTO t(f) VALUES('c');

SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|                3 |
+------------------+

INSERT INTO t(f) VALUES('d'),('e');

SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|                4 |
+------------------+
```

```
SELECT * FROM t;
+----+------+
| id | f    |
+----+------+
|  1 | a    |
|  2 | b    |
|  3 | c    |
|  4 | d    |
|  5 | e    |
+----+------+

SELECT LAST_INSERT_ID(12);
+--------------------+
| LAST_INSERT_ID(12) |
+--------------------+
|                 12 |
+--------------------+

SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|               12 |
+------------------+

INSERT INTO t(f) VALUES('f');

SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|                6 |
+------------------+

SELECT * FROM t;
+----+------+
| id | f    |
+----+------+
|  1 | a    |
|  2 | b    |
|  3 | c    |
|  4 | d    |
|  5 | e    |
|  6 | f    |
+----+------+

SELECT LAST_INSERT_ID(12);
+--------------------+
| LAST_INSERT_ID(12) |
+--------------------+
|                 12 |
+--------------------+

INSERT INTO t(f) VALUES('g');

SELECT * FROM t;
+----+------+
| id | f    |
+----+------+
|  1 | a    |
|  2 | b    |
|  3 | c    |
|  4 | d    |
|  5 | e    |
|  6 | f    |
|  7 | g    |
+----+------+
```

1.2.8.3.14 LAST_VALUE

Syntax

```
LAST_VALUE(expr,[expr,...])
```

```
LAST_VALUE(expr) OVER (
  [ PARTITION BY partition_expression ]
  [ ORDER BY order_list ]
)
```

Contents

Description

`LAST_VALUE()` evaluates all expressions and returns the last.

This is useful together with setting user variables to a value with @var:=expr, for example when you want to get data of rows updated/deleted without having to do two queries against the table.

LAST_VALUE can be used as a window function.

Returns NULL if no last value exists.

Examples

```
CREATE TABLE t1 (a int, b int);
INSERT INTO t1 VALUES(1,10),(2,20);
DELETE FROM t1 WHERE a=1 AND last_value(@a:=a,@b:=b,1);
SELECT @a,@b;
+------+------+
| @a   | @b   |
+------+------+
|    1 |   10 |
+------+------+
```

As a window function:

```
CREATE TABLE t1 (
  pk int primary key,
  a int,
  b int,
  c char(10),
  d decimal(10, 3),
  e real
);

INSERT INTO t1 VALUES
( 1, 0, 1,    'one',    0.1,  0.001),
( 2, 0, 2,    'two',    0.2,  0.002),
( 3, 0, 3,    'three',  0.3,  0.003),
( 4, 1, 2,    'three',  0.4,  0.004),
( 5, 1, 1,    'two',    0.5,  0.005),
( 6, 1, 1,    'one',    0.6,  0.006),
( 7, 2, NULL, 'n_one',  0.5,  0.007),
( 8, 2, 1,    'n_two',  NULL, 0.008),
( 9, 2, 2,    NULL,     0.7,  0.009),
(10, 2, 0,    'n_four', 0.8,  0.010),
(11, 2, 10,   NULL,     0.9,  NULL);

SELECT pk, FIRST_VALUE(pk) OVER (ORDER BY pk) AS first_asc,
           LAST_VALUE(pk) OVER (ORDER BY pk) AS last_asc,
           FIRST_VALUE(pk) OVER (ORDER BY pk DESC) AS first_desc,
           LAST_VALUE(pk) OVER (ORDER BY pk DESC) AS last_desc
FROM t1
ORDER BY pk DESC;

+----+-----------+----------+------------+-----------+
| pk | first_asc | last_asc | first_desc | last_desc |

```

1.2.8.3.15 PROCEDURE ANALYSE

Syntax

```
analyse([max_elements[,max_memory]])
```

Description

This procedure is defined in the sql/sql_analyse.cc file. It examines the result from a query and returns an analysis of the results that suggests optimal data types for each column. To obtain this analysis, append PROCEDURE ANALYSE to the end of a SELECT statement:

```
SELECT ... FROM ... WHERE ... PROCEDURE ANALYSE([max_elements,[max_memory]])
```

For example:

```
SELECT col1, col2 FROM table1 PROCEDURE ANALYSE(10, 2000);
```

The results show some statistics for the values returned by the query, and propose an optimal data type for the columns. This can be helpful for checking your existing tables, or after importing new data. You may need to try different settings for the arguments so that PROCEDURE ANALYSE() does not suggest the ENUM data type when it is not appropriate.

The arguments are optional and are used as follows:

- max_elements (default 256) is the maximum number of distinct values that analyse notices per column. This is used by analyse to check whether the optimal data type should be of type ENUM; if there are more than max_elements distinct values, then ENUM is not a suggested type.
- max_memory (default 8192) is the maximum amount of memory that analyse should allocate per column while trying to find all distinct values.

1.2.8.3.16 ROWNUM

MariaDB starting with 10.6.1

From MariaDB 10.6.1, the `ROWNUM()` function is supported.

Contents

Syntax

```
ROWNUM()
```

In Oracle mode one can just use `ROWNUM`, without the parentheses.

Description

`ROWNUM()` returns the current number of accepted rows in the current context. It main purpose is to emulate the `ROWNUM` pseudo column in Oracle. For MariaDB native applications, we recommend the usage of LIMIT, as it is easier to use and gives more predictable results than the usage of `ROWNUM()`.

The main difference between using `LIMIT` and `ROWNUM()` to limit the rows in the result is that `LIMIT` works on the result set while `ROWNUM` works on the number of accepted rows (before any `ORDER` or `GROUP BY` clauses).

The following queries will return the same results:

```
SELECT * from t1 LIMIT 10;
SELECT * from t1 WHERE ROWNUM() <= 10;
```

While the following may return different results based on in which orders the rows are found:

```
SELECT * from t1 ORDER BY a LIMIT 10;
SELECT * from t1 ORDER BY a WHERE ROWNUM() <= 10;
```

The recommended way to use `ROWNUM` to limit the number of returned rows and get predictable results is to have the query in a subquery and test for `ROWNUM()` in the outer query:

```
SELECT * FROM (select * from t1 ORDER BY a) WHERE ROWNUM() <= 10;
```

`ROWNUM()` can be used in the following contexts:

- SELECT
- INSERT
- UPDATE
- DELETE
- LOAD DATA INFILE

Used in other contexts, `ROWNUM()` will return 0.

Examples

```
INSERT INTO t1 VALUES (1,ROWNUM()),(2,ROWNUM()),(3,ROWNUM());

INSERT INTO t1 VALUES (1),(2) returning a, ROWNUM();

UPDATE t1 SET row_num_column=ROWNUM();

DELETE FROM t1 WHERE a < 10 AND ROWNUM() < 2;

LOAD DATA INFILE 'filename' into table t1 fields terminated by ','
  lines terminated by "\r\n" (a,b) set c=ROWNUM();
```

Optimizations

In many cases where `ROWNUM()` is used, MariaDB will use the same optimizations it uses with LIMIT.

`LIMIT` optimization is possible when using `ROWNUM` in the following manner:

- When one is in a top level `WHERE` clause comparing `ROWNUM()` with a numerical constant using any of the following expressions:
  - `ROWNUM()` < number
  - `ROWNUM()` <= number
  - `ROWNUM()` = 1 `ROWNUM()` can be also be the right argument to the comparison function.

In the above cases, `LIMIT` optimization can be done in the following cases:

- For the current sub query when the ROWNUM comparison is done on the top level:

```
SELECT * from t1 WHERE ROWNUM() <= 2 AND t1.a > 0
```

- For an inner sub query, when the upper level has only a `ROWNUM()` comparison in the `WHERE` clause:

```
SELECT * from (select * from t1) as t WHERE ROWNUM() <= 2
```

Other Changes Related to ROWNUM

When `ROWNUM()` is used anywhere in a query, the optimization to ignore `ORDER BY` in subqueries are disabled.

This was done to get the following common Oracle query to work as expected:

```
 select * from (select * from t1 order by a desc) as t where rownum() <= 2;
```

By default MariaDB ignores any `ORDER BY` in subqueries both because the SQL standard defines results sets in subqueries to be un-ordered and because of performance reasons (especially when using views in subqueries). See MDEV-3926 "Wrong result with GROUP BY ... WITH ROLLUP" for a discussion of this topic.

Other Considerations

While MariaDB tries to emulate Oracle's usage of `ROWNUM()` as closely as possible, there are cases where the result is different:

- When the optimizer finds rows in a different order (because of different storage methods or optimization). This may also happen in Oracle if one adds or deletes an index, in which case the rows may be found in a different order.

Note that usage of `ROWNUM()` in functions or stored procedures will use their own context, not the caller's context.

1.2.8.3.17 ROW_COUNT

Syntax

```
ROW_COUNT()
```

Description

ROW_COUNT() returns the number of rows updated, inserted or deleted by the preceding statement. This is the same as the row count that the mariadb client displays and the value from the mysql_affected_rows() C API function.

Generally:

- For statements which return a result set (such as SELECT, SHOW, DESC or HELP), returns -1, even when the result set is empty. This is also true for administrative statements, such as OPTIMIZE.
- For DML statements other than SELECT and for ALTER TABLE, returns the number of affected rows.
- For DDL statements (including TRUNCATE) and for other statements which don't return any result set (such as USE, DO, SIGNAL or DEALLOCATE PREPARE), returns 0.

For UPDATE, affected rows is by default the number of rows that were actually changed. If the CLIENT_FOUND_ROWS flag to mysql_real_connect() is specified when connecting to mysqld, affected rows is instead the number of rows matched by the WHERE clause.

For REPLACE, deleted rows are also counted. So, if REPLACE deletes a row and adds a new row, ROW_COUNT() returns 2.

For INSERT ... ON DUPLICATE KEY, updated rows are counted twice. So, if INSERT adds a new rows and modifies another row, ROW_COUNT() returns 3.

ROW_COUNT() does not take into account rows that are not directly deleted/updated by the last statement. This means that rows deleted by foreign keys or triggers are not counted.

Warning: You can use ROW_COUNT() with prepared statements, but you need to call it after EXECUTE, not after DEALLOCATE PREPARE, because the row count for allocate prepare is always 0.

Warning: When used after a CALL statement, this function returns the number of rows affected by the last statement in the procedure, not by the whole procedure.

Warning: After INSERT DELAYED, ROW_COUNT() returns the number of the rows you tried to insert, not the number of the successful writes.

This information can also be found in the diagnostics area.

Statements using the ROW_COUNT() function are not safe for statement-based replication.

Examples

```
CREATE TABLE t (A INT);

INSERT INTO t VALUES(1),(2),(3);

SELECT ROW_COUNT();
+-------------+
| ROW_COUNT() |
+-------------+
|           3 |
+-------------+

DELETE FROM t WHERE A IN(1,2);

SELECT ROW_COUNT();
+-------------+
| ROW_COUNT() |
+-------------+
|           2 |
+-------------+
```

Example with prepared statements:

```
SET @q = 'INSERT INTO t VALUES(1),(2),(3);';

PREPARE stmt FROM @q;

EXECUTE stmt;
Query OK, 3 rows affected (0.39 sec)
Records: 3  Duplicates: 0  Warnings: 0

SELECT ROW_COUNT();
+-------------+
| ROW_COUNT() |
+-------------+
|           3 |
+-------------+
```

1.2.8.3.18 SCHEMA

Syntax

```
SCHEMA()
```

Description

This function is a synonym for DATABASE().

1.2.8.3.19 SESSION_USER

Syntax

```
SESSION_USER()
```

Description

SESSION_USER() is a synonym for USER().

1.2.8.3.20 SYSTEM_USER

Syntax

```
SYSTEM_USER()
```

Description

SYSTEM_USER() is a synonym for USER().

1.2.8.3.21 USER

Syntax

```
USER()
```

Description

Returns the current MariaDB user name and host name, given when authenticating to MariaDB, as a string in the utf8 character set.

Note that the value of USER() may differ from the value of CURRENT_USER(), which is the user used to authenticate the current client. `CURRENT_ROLE()` returns the current active role.

`SYSTEM_USER()` and `SESSION_USER` are synonyms for `USER()` .

Statements using the `USER()` function or one of its synonyms are not safe for statement level replication.

Examples

```
shell> mysql --user="anonymous"

SELECT USER(),CURRENT_USER();
+---------------------+----------------+
| USER()              | CURRENT_USER() |
+---------------------+----------------+
| anonymous@localhost | @localhost     |
+---------------------+----------------+
```

To select only the IP address, use SUBSTRING_INDEX(),

```
SELECT SUBSTRING_INDEX(USER(), '@', -1);
+---------------------------------+
| SUBSTRING_INDEX(USER(), '@', -1) |
+---------------------------------+
| 192.168.0.101                   |
+---------------------------------+
```

1.2.8.3.22 VERSION

Syntax

```
VERSION()
```

Description

Returns a string that indicates the MariaDB server version. The string uses the utf8 character set.

Examples

```
SELECT VERSION();
+----------------+
| VERSION()      |
+----------------+
| 10.4.7-MariaDB |
+----------------+
```

The `VERSION()` string may have one or more of the following suffixes:

Suffix	Description
-embedded	The server is an embedded server (libmariadbd).
-log	General logging, slow logging or binary (replication) logging is enabled.
-debug	The server is compiled for debugging.
-valgrind	The server is compiled to be instrumented with valgrind.

Changing the Version String

Some old legacy code may break because they are parsing the `VERSION` string and expecting a MySQL string or a simple version string like Joomla til API17, see MDEV-7780.

One can fool these applications by setting the version string from the command line or the my.cnf files with --version=....

1.2.8.4 Miscellaneous Functions

Miscellaneous functions include DEFAULT, GET_LOCK, SLEEP, UUID, etc.

GET_LOCK
Obtain LOCK.

INET6_ATON
Given an IPv6 or IPv4 network address, returns a VARBINARY numeric value.

INET6_NTOA
Given an IPv6 or IPv4 network address, returns the address as a nonbinary string.

INET_ATON
Returns numeric value of IPv4 address.

INET_NTOA
Returns dotted-quad representation of IPv4 address.

IS_FREE_LOCK
Checks whether lock is free to use.

IS_IPV4
Whether or not an expression is a valid IPv4 address.

IS_IPV4_COMPAT
Whether or not an IPv6 address is IPv4-compatible.

IS_IPV4_MAPPED
Whether an IPv6 address is a valid IPv4-mapped address.

IS_IPV6
Whether or not an expression is a valid IPv6 address.

IS_USED_LOCK
Check if lock is in use.

MASTER_GTID_WAIT
Wait until slave reaches the GTID position.

MASTER_POS_WAIT
Blocks until the replica has applied all specified updates.

NAME_CONST
Returns the given value.

RELEASE_ALL_LOCKS
Releases all named locks held by the current session.

RELEASE_LOCK
Releases lock obtained with GET_LOCK().

SLEEP
Pauses for the given number of seconds.

SYS_GUID
Returns a globally unique identifier (GUID).

UUID
Returns a Universal Unique Identifier.

UUID_SHORT
Return short universal identifier.

VALUES / VALUE
Refer to columns in INSERT ... ON DUPLICATE KEY UPDATE.

There are 1 related questions.

1.2.8.4.1 GET_LOCK

Syntax

```
GET_LOCK(str,timeout)
```

Contents

Description

Tries to obtain a lock with a name given by the string `str`, using a timeout of `timeout` seconds. Returns `1` if the lock was obtained successfully, `0` if the attempt timed out (for example, because another client has previously locked the name), or `NULL` if an error occurred (such as running out of memory or the thread was killed with mariadb-admin kill).

A lock is released with RELEASE_LOCK(), when the connection terminates (either normally or abnormally). A connection can hold multiple locks at the same time, so a lock that is no longer needed needs to be explicitly released.

The IS_FREE_LOCK function returns whether a specified lock a free or not, and the IS_USED_LOCK whether the function is in use or not.

Locks obtained with `GET_LOCK()` do not interact with transactions. That is, committing a transaction does not release any such locks obtained during the transaction.

It is also possible to recursively set the same lock. If a lock with the same name is set `n` times, it needs to be released `n` times as well.

`str` is case insensitive for `GET_LOCK()` and related functions. If `str` is an empty string or `NULL`, `GET_LOCK()` returns `NULL` and does nothing. `timeout` supports microseconds.

If the metadata_lock_info plugin is installed, locks acquired with this function are visible in the Information Schema METADATA_LOCK_INFO table.

This function can be used to implement application locks or to simulate record locks. Names are locked on a server-wide basis. If a name has been locked by one client, `GET_LOCK()` blocks any request by another client for a lock with the same name. This allows clients that agree on a given lock name to use the name to perform cooperative advisory locking. But be aware that it also allows a client that is not among the set of cooperating clients to lock a name, either inadvertently or deliberately, and thus prevent any of the cooperating clients from locking that name. One way to reduce the likelihood of this is to use lock names that are database-specific or application-specific. For example, use lock names of the form `db_name.str` or `app_name.str`.

Statements using the `GET_LOCK` function are not safe for statement-based replication.

The patch to permit multiple locks was contributed by Konstantin "Kostja" Osipov (MDEV-3917).

Examples

```
SELECT GET_LOCK('lock1',10);
+----------------------+
| GET_LOCK('lock1',10) |
+----------------------+
|                    1 |
+----------------------+

SELECT IS_FREE_LOCK('lock1'), IS_USED_LOCK('lock1');
+----------------------+----------------------+
| IS_FREE_LOCK('lock1') | IS_USED_LOCK('lock1') |
+----------------------+----------------------+
|                    0 |                   46 |
+----------------------+----------------------+

SELECT IS_FREE_LOCK('lock2'), IS_USED_LOCK('lock2');
+----------------------+----------------------+
| IS_FREE_LOCK('lock2') | IS_USED_LOCK('lock2') |
+----------------------+----------------------+
|                    1 |                 NULL |
+----------------------+----------------------+
```

Multiple locks can be held:

```
SELECT GET_LOCK('lock2',10);
+----------------------+
| GET_LOCK('lock2',10) |
+----------------------+
|                    1 |
+----------------------+

SELECT IS_FREE_LOCK('lock1'), IS_FREE_LOCK('lock2');
+----------------------+----------------------+
| IS_FREE_LOCK('lock1') | IS_FREE_LOCK('lock2') |
+----------------------+----------------------+
|                    0 |                    0 |
+----------------------+----------------------+

SELECT RELEASE_LOCK('lock1'), RELEASE_LOCK('lock2');
+----------------------+----------------------+
| RELEASE_LOCK('lock1') | RELEASE_LOCK('lock2') |
+----------------------+----------------------+
|                    1 |                    1 |
+----------------------+----------------------+
```

It is possible to hold the same lock recursively. This example is viewed using the metadata_lock_info plugin:

```
SELECT GET_LOCK('lock3',10);
+----------------------+
| GET_LOCK('lock3',10) |
+----------------------+
|                    1 |
+----------------------+

SELECT GET_LOCK('lock3',10);
+----------------------+
| GET_LOCK('lock3',10) |
+----------------------+
|                    1 |
+----------------------+

SELECT * FROM INFORMATION_SCHEMA.METADATA_LOCK_INFO;
+-----------+---------------------+---------------+-----------+--------------+------------+
| THREAD_ID | LOCK_MODE           | LOCK_DURATION | LOCK_TYPE | TABLE_SCHEMA | TABLE_NAME |
+-----------+---------------------+---------------+-----------+--------------+------------+
|        46 | MDL_SHARED_NO_WRITE | NULL          | User lock | lock3        |            |
+-----------+---------------------+---------------+-----------+--------------+------------+

SELECT RELEASE_LOCK('lock3');
+----------------------+
| RELEASE_LOCK('lock3') |
+----------------------+
|                    1 |
+----------------------+

SELECT * FROM INFORMATION_SCHEMA.METADATA_LOCK_INFO;
+-----------+---------------------+---------------+-----------+--------------+------------+
| THREAD_ID | LOCK_MODE           | LOCK_DURATION | LOCK_TYPE | TABLE_SCHEMA | TABLE_NAME |
+-----------+---------------------+---------------+-----------+--------------+------------+
|        46 | MDL_SHARED_NO_WRITE | NULL          | User lock | lock3        |            |
+-----------+---------------------+---------------+-----------+--------------+------------+

SELECT RELEASE_LOCK('lock3');
+----------------------+
| RELEASE_LOCK('lock3') |
+----------------------+
|                    1 |
+----------------------+

SELECT * FROM INFORMATION_SCHEMA.METADATA_LOCK_INFO;
Empty set (0.000 sec)
```

Timeout example: Connection 1:

```
SELECT GET_LOCK('lock4',10);
+----------------------+
| GET_LOCK('lock4',10) |
+----------------------+
|                    1 |
+----------------------+
```

Connection 2:

```
SELECT GET_LOCK('lock4',10);
```

After 10 seconds...

```
+----------------------+
| GET_LOCK('lock4',10) |
+----------------------+
|                    0 |
+----------------------+
```

Deadlocks are automatically detected and resolved. Connection 1:

```
SELECT GET_LOCK('lock5',10);
+----------------------+
| GET_LOCK('lock5',10) |
+----------------------+
|                    1 |
+----------------------+
```

Connection 2:

```
SELECT GET_LOCK('lock6',10);
+----------------------+
| GET_LOCK('lock6',10) |
+----------------------+
|                    1 |
+----------------------+
```

Connection 1:

```
SELECT GET_LOCK('lock6',10);
+----------------------+
| GET_LOCK('lock6',10) |
+----------------------+
|                    0 |
+----------------------+
```

Connection 2:

```
SELECT GET_LOCK('lock5',10);
ERROR 1213 (40001): Deadlock found when trying to get lock; try restarting transaction
```

1.2.8.4.2 INET6_ATON

Syntax

```
INET6_ATON(expr)
```

Description

Given an IPv6 or IPv4 network address as a string, returns a binary string that represents the numeric value of the address.

No trailing zone ID's or traling network masks are permitted. For IPv4 addresses, or IPv6 addresses with IPv4 address

parts, no classful addresses or trailing port numbers are permitted and octal numbers are not supported.

The returned binary string will be VARBINARY(16) or VARBINARY(4) for IPv6 and IPv4 addresses respectively.

Returns NULL if the argument is not understood.

MariaDB starting with 10.5.0

From MariaDB 10.5.0, `INET6_ATON` can take INET6 as an argument.

Examples

```
SELECT HEX(INET6_ATON('10.0.1.1'));
+----------------------------+
| HEX(INET6_ATON('10.0.1.1')) |
+----------------------------+
| 0A000101                   |
+----------------------------+

SELECT HEX(INET6_ATON('48f3::d432:1431:ba23:846f'));
+--------------------------------------------+
| HEX(INET6_ATON('48f3::d432:1431:ba23:846f')) |
+--------------------------------------------+
| 48F3000000000000D4321431BA23846F           |
+--------------------------------------------+
```

1.2.8.4.3 INET6_NTOA

Contents

1. Syntax
2. Description
3. Examples

Syntax

```
INET6_NTOA(expr)
```

Description

Given an IPv6 or IPv4 network address as a numeric binary string, returns the address as a nonbinary string in the connection character set.

The return string is lowercase, and is platform independent, since it does not use functions specific to the operating system. It has a maximum length of 39 characters.

Returns NULL if the argument is not understood.

Examples

```
SELECT INET6_NTOA(UNHEX('0A000101'));
+-------------------------------+
| INET6_NTOA(UNHEX('0A000101')) |
+-------------------------------+
| 10.0.1.1                      |
+-------------------------------+

SELECT INET6_NTOA(UNHEX('48F3000000000000D4321431BA23846F'));
+-----------------------------------------------------+
| INET6_NTOA(UNHEX('48F3000000000000D4321431BA23846F')) |
+-----------------------------------------------------+
| 48f3::d432:1431:ba23:846f                           |
+-----------------------------------------------------+
```

1.2.8.4.4 INET_ATON

Syntax

```
INET_ATON(expr)
```

Description

Given the dotted-quad representation of an IPv4 network address as a string, returns an integer that represents the numeric value of the address. Addresses may be 4- or 8-byte addresses.

Returns NULL if the argument is not understood.

Examples

```
SELECT INET_ATON('192.168.1.1');
+--------------------------+
| INET_ATON('192.168.1.1') |
+--------------------------+
|               3232235777 |
+--------------------------+
```

This is calculated as follows: 192 x 256^3 + 168 x 256^2 + 1 x 256 + 1

1.2.8.4.5 INET_NTOA

Syntax

```
INET_NTOA(expr)
```

Description

Given a numeric IPv4 network address in network byte order (4 or 8 byte), returns the dotted-quad representation of the address as a string.

Examples

```
SELECT INET_NTOA(3232235777);
+-----------------------+
| INET_NTOA(3232235777) |
+-----------------------+
| 192.168.1.1           |
+-----------------------+
```

192.168.1.1 corresponds to 3232235777 since 192 x 256^3 + 168 x 256^2 + 1 x 256 + 1 = 3232235777

1.2.8.4.6 IS_FREE_LOCK

Syntax

```
IS_FREE_LOCK(str)
```

Description

Checks whether the lock named `str` is free to use (that is, not locked). Returns `1` if the lock is free (no one is using the lock), `0` if the lock is in use, and `NULL` if an error occurs (such as an incorrect argument, like an empty string or `NULL`). `str` is case insensitive.

If the metadata_lock_info plugin is installed, the Information Schema metadata_lock_info table contains information about locks of this kind (as well as metadata locks).

Statements using the `IS_FREE_LOCK` function are not safe for statement-based replication.

1.2.8.4.7 IS_IPV4

Syntax

```
IS_IPV4(expr)
```

Description

If the expression is a valid IPv4 address, returns 1, otherwise returns 0.

IS_IPV4() is stricter than INET_ATON(), but as strict as INET6_ATON(), in determining the validity of an IPv4 address. This implies that if IS_IPV4 returns 1, the same expression will always return a non-NULL result when passed to INET_ATON(), but that the reverse may not apply.

Examples

```
SELECT IS_IPV4('1110.0.1.1');
+-----------------------+
| IS_IPV4('1110.0.1.1') |
+-----------------------+
|                     0 |
+-----------------------+

SELECT IS_IPV4('48f3::d432:1431:ba23:846f');
+--------------------------------------+
| IS_IPV4('48f3::d432:1431:ba23:846f') |
+--------------------------------------+
|                                    0 |
+--------------------------------------+
```

1.2.8.4.8 IS_IPV4_COMPAT

Syntax

```
IS_IPV4_COMPAT(expr)
```

Description

Returns 1 if a given numeric binary string IPv6 address, such as returned by INET6_ATON(), is IPv4-compatible, otherwise returns 0.

MariaDB starting with 10.5.0

From MariaDB 10.5.0, when the argument is not INET6, automatic implicit CAST to INET6 is applied. As a consequence, `IS_IPV4_COMPAT` now understands arguments in both text representation and binary(16)

representation. Before MariaDB 10.5.0, the function understood only binary(16) representation.

Examples

```
SELECT IS_IPV4_COMPAT(INET6_ATON('::10.0.1.1'));
+---------------------------------------+
| IS_IPV4_COMPAT(INET6_ATON('::10.0.1.1')) |
+---------------------------------------+
|                                     1 |
+---------------------------------------+

SELECT IS_IPV4_COMPAT(INET6_ATON('::48f3::d432:1431:ba23:846f'));
+-----------------------------------------------------------+
| IS_IPV4_COMPAT(INET6_ATON('::48f3::d432:1431:ba23:846f')) |
+-----------------------------------------------------------+
|                                                         0 |
+-----------------------------------------------------------+
```

1.2.8.4.9 IS_IPV4_MAPPED

Syntax

```
IS_IPV4_MAPPED(expr)
```

Description

Returns 1 if a given a numeric binary string IPv6 address, such as returned by INET6_ATON(), is a valid IPv4-mapped address, otherwise returns 0.

MariaDB starting with 10.5.0

From MariaDB 10.5.0, when the argument is not INET6, automatic implicit CAST to INET6 is applied. As a consequence, `IS_IPV4_MAPPED` now understands arguments in both text representation and binary(16) representation. Before MariaDB 10.5.0, the function understood only binary(16) representation.

Examples

```
SELECT IS_IPV4_MAPPED(INET6_ATON('::10.0.1.1'));
+---------------------------------------+
| IS_IPV4_MAPPED(INET6_ATON('::10.0.1.1')) |
+---------------------------------------+
|                                     0 |
+---------------------------------------+

SELECT IS_IPV4_MAPPED(INET6_ATON('::ffff:10.0.1.1'));
+-----------------------------------------------+
| IS_IPV4_MAPPED(INET6_ATON('::ffff:10.0.1.1')) |
+-----------------------------------------------+
|                                             1 |
+-----------------------------------------------+
```

1.2.8.4.10 IS_IPV6

Syntax

```
IS_IPV6(expr)
```

Description

Returns 1 if the expression is a valid IPv6 address specified as a string, otherwise returns 0. Does not consider IPv4 addresses to be valid IPv6 addresses.

Examples

```
 SELECT IS_IPV6('48f3::d432:1431:ba23:846f');
+--------------------------------------+
| IS_IPV6('48f3::d432:1431:ba23:846f') |
+--------------------------------------+
|                                    1 |
+--------------------------------------+
1 row in set (0.02 sec)

SELECT IS_IPV6('10.0.1.1');
+----------------------+
| IS_IPV6('10.0.1.1') |
+----------------------+
|                    0 |
+----------------------+
```

1.2.8.4.11 IS_USED_LOCK

Syntax

```
IS_USED_LOCK(str)
```

Contents

Description

Checks whether the lock named `str` is in use (that is, locked). If so, it returns the connection identifier of the client that holds the lock. Otherwise, it returns `NULL`. `str` is case insensitive.

If the metadata_lock_info plugin is installed, the Information Schema metadata_lock_info table contains information about locks of this kind (as well as metadata locks).

Statements using the `IS_USED_LOCK` function are not safe for statement-based replication.

1.2.8.4.12 MASTER_GTID_WAIT

Syntax

```
MASTER_GTID_WAIT(gtid-list[, timeout)
```

Description

This function takes a string containing a comma-separated list of global transaction id's (similar to the value of, for example, gtid_binlog_pos). It waits until the value of gtid_slave_pos has the same or higher seq_no within all replication domains specified in the gtid-list; in other words, it waits until the slave has reached the specified GTID position.

An optional second argument gives a timeout in seconds. If the timeout expires before the specified GTID position is reached, then the function returns -1. Passing NULL or a negative number for the timeout means no timeout, and the function will wait indefinitely.

If the wait completes without a timeout, 0 is returned. Passing NULL for the gtid-list makes the function return NULL immediately, without waiting.

The gtid-list may be the empty string, in which case MASTER_GTID_WAIT() returns immediately. If the gtid-list contains fewer domains than gtid_slave_pos, then only those domains are waited upon. If gtid-list contains a domain that is not present in @@gtid_slave_pos, then MASTER_GTID_WAIT() will wait until an event containing such domain_id arrives on the slave (or until timed out or killed).

MASTER_GTID_WAIT() can be useful to ensure that a slave has caught up to a master. Simply take the value of gtid_binlog_pos on the master, and use it in a MASTER_GTID_WAIT() call on the slave; when the call completes, the slave will have caught up with that master position.

MASTER_GTID_WAIT() can also be used in client applications together with the last_gtid session variable. This is useful in a read-scaleout replication setup, where the application writes to a single master but divides the reads out to a number of slaves to distribute the load. In such a setup, there is a risk that an application could first do an update on the master, and then a bit later do a read on a slave, and if the slave is not fast enough, the data read from the slave might not include the update just made, possibly confusing the application and/or the end-user. One way to avoid this is to request the value of last_gtid on the master just after the update. Then before doing the read on the slave, do a MASTER_GTID_WAIT() on the value obtained from the master; this will ensure that the read is not performed until the slave has replicated sufficiently far for the update to have become visible.

Note that MASTER_GTID_WAIT() can be used even if the slave is configured not to use GTID for connections (CHANGE MASTER TO master_use_gtid=no). This is because from MariaDB 10, GTIDs are always logged on the master server, and always recorded on the slave servers.

Differences to MASTER_POS_WAIT()

- MASTER_GTID_WAIT() is global; it waits for any master connection to reach the specified GTID position. MASTER_POS_WAIT() works only against a specific connection. This also means that while MASTER_POS_WAIT() aborts if its master connection is terminated with STOP SLAVE or due to an error, MASTER_GTID_WAIT() continues to wait while slaves are stopped.
- MASTER_GTID_WAIT() can take its timeout as a floating-point value, so a timeout in fractional seconds is supported, eg. MASTER_GTID_WAIT("0-1-100", 0.5). (The minimum wait is one microsecond, 0.000001 seconds).
- MASTER_GTID_WAIT() allows one to specify a timeout of zero in order to do a non-blocking check to see if the slaves have progressed to a specific GTID position (MASTER_POS_WAIT() takes a zero timeout as meaning an infinite wait). To do an infinite MASTER_GTID_WAIT(), specify a negative timeout, or omit the timeout argument.
- MASTER_GTID_WAIT() does not return the number of events executed since the wait started, nor does it return NULL if a slave thread is stopped. It always returns either 0 for successful wait completed, or -1 for timeout reached (or NULL if the specified gtid-pos is NULL).

Since MASTER_GTID_WAIT() looks only at the seq_no part of the GTIDs, not the server_id, care is needed if a slave becomes diverged from another server so that two different GTIDs with the same seq_no (in the same domain) arrive at the same server. This situation is in any case best avoided; setting gtid_strict_mode is recommended, as this will prevent any such out-of-order sequence numbers from ever being replicated on a slave.

1.2.8.4.13 MASTER_POS_WAIT

Syntax

```
MASTER_POS_WAIT(log_name,log_pos[,timeout,["connection_name"]])
```

Description

This function is useful in replication for controlling primary/replica synchronization. It blocks until the replica has read and applied all updates up to the specified position (`log_name,log_pos`) in the primary log. The return value is the number of log events the replica had to wait for to advance to the specified position. The function returns NULL if the replica SQL thread is not started, the replica's primary information is not initialized, the arguments are incorrect, or an error occurs. It returns -1 if the timeout has been exceeded. If the replica SQL thread stops while `MASTER_POS_WAIT()` is waiting, the function returns NULL. If the replica is past the specified position, the function returns immediately.

If a `timeout` value is specified, `MASTER_POS_WAIT()` stops waiting when `timeout` seconds have elapsed. `timeout` must be greater than 0; a zero or negative `timeout` means no `timeout` .

The `connection_name` is used when you are using multi-source-replication. If you don't specify it, it's set to the value of the default_master_connection system variable.

Statements using the MASTER_POS_WAIT() function are not safe for statement-based replication.

1.2.8.4.14 NAME_CONST

Syntax

```
NAME_CONST(name,value)
```

Description

Returns the given value. When used to produce a result set column, `NAME_CONST()` causes the column to have the given name. The arguments should be constants.

This function is used internally when replicating stored procedures. It makes little sense to use it explicitly in SQL statements, and it was not supposed to be used like that.

```
SELECT NAME_CONST('myname', 14);
+--------+
| myname |
+--------+
|     14 |
+--------+
```

1.2.8.4.15 RELEASE_ALL_LOCKS

MariaDB until 10.5.2

RELEASE_ALL_LOCKS was added in MariaDB 10.5.2.

Syntax

```
RELEASE_ALL_LOCKS()
```

Contents

Description

Releases all named locks held by the current session. Returns the number of locks released, or `0` if none were held.

Statements using the `RELEASE_ALL_LOCKS` function are not safe for statement-based replication.

Examples

```
SELECT RELEASE_ALL_LOCKS();
+---------------------+
| RELEASE_ALL_LOCKS() |
+---------------------+
|                   0 |
+---------------------+

SELECT GET_LOCK('lock1',10);
+----------------------+
| GET_LOCK('lock1',10) |
+----------------------+
|                    1 |
+----------------------+

SELECT RELEASE_ALL_LOCKS();
+---------------------+
| RELEASE_ALL_LOCKS() |
+---------------------+
|                   1 |
+---------------------+
```

1.2.8.4.16 RELEASE_LOCK

Syntax

```
RELEASE_LOCK(str)
```

Contents

Description

Releases the lock named by the string `str` that was obtained with GET_LOCK(). Returns 1 if the lock was released, 0 if the lock was not established by this thread (in which case the lock is not released), and `NULL` if the named lock did not exist. The lock does not exist if it was never obtained by a call to `GET_LOCK()` or if it has previously been released.

`str` is case insensitive. If `str` is an empty string or `NULL`, `RELEASE_LOCK()` returns `NULL` and does nothing.

Statements using the `RELEASE_LOCK` function are not safe for statement-based replication.

The DO statement is convenient to use with `RELEASE_LOCK()`.

Examples

Connection1:

```
SELECT GET_LOCK('lock1',10);
+----------------------+
| GET_LOCK('lock1',10) |
+----------------------+
|                    1 |
+----------------------+
```

Connection 2:

```
SELECT GET_LOCK('lock2',10);
+----------------------+
| GET_LOCK('lock2',10) |
+----------------------+
|                    1 |
+----------------------+
```

Connection 1:

```
SELECT RELEASE_LOCK('lock1'), RELEASE_LOCK('lock2'), RELEASE_LOCK('lock3');
+----------------------+----------------------+----------------------+
| RELEASE_LOCK('lock1') | RELEASE_LOCK('lock2') | RELEASE_LOCK('lock3') |
+----------------------+----------------------+----------------------+
|                    1 |                    0 |                 NULL |
+----------------------+----------------------+----------------------+
```

It is possible to hold the same lock recursively. This example is viewed using the metadata_lock_info plugin:

```
SELECT GET_LOCK('lock3',10);
+---------------------+
| GET_LOCK('lock3',10) |
+---------------------+
|                   1 |
+---------------------+

SELECT GET_LOCK('lock3',10);
+---------------------+
| GET_LOCK('lock3',10) |
+---------------------+
|                   1 |
+---------------------+

SELECT * FROM INFORMATION_SCHEMA.METADATA_LOCK_INFO;
+-----------+---------------------+---------------+-----------+--------------+------------+
| THREAD_ID | LOCK_MODE           | LOCK_DURATION | LOCK_TYPE | TABLE_SCHEMA | TABLE_NAME |
+-----------+---------------------+---------------+-----------+--------------+------------+
|        46 | MDL_SHARED_NO_WRITE | NULL          | User lock | lock3        |            |
+-----------+---------------------+---------------+-----------+--------------+------------+

SELECT RELEASE_LOCK('lock3');
+----------------------+
| RELEASE_LOCK('lock3') |
+----------------------+
|                    1 |
+----------------------+

SELECT * FROM INFORMATION_SCHEMA.METADATA_LOCK_INFO;
+-----------+---------------------+---------------+-----------+--------------+------------+
| THREAD_ID | LOCK_MODE           | LOCK_DURATION | LOCK_TYPE | TABLE_SCHEMA | TABLE_NAME |
+-----------+---------------------+---------------+-----------+--------------+------------+
|        46 | MDL_SHARED_NO_WRITE | NULL          | User lock | lock3        |            |
+-----------+---------------------+---------------+-----------+--------------+------------+

SELECT RELEASE_LOCK('lock3');
+----------------------+
| RELEASE_LOCK('lock3') |
+----------------------+
|                    1 |
+----------------------+

SELECT * FROM INFORMATION_SCHEMA.METADATA_LOCK_INFO;
Empty set (0.000 sec)
```

1.2.8.4.17 SLEEP

Syntax

```
SLEEP(duration)
```

Description

Sleeps (pauses) for the number of seconds given by the duration argument, then returns `0`. If `SLEEP()` is interrupted, it returns `1`. The duration may have a fractional part given in microseconds.

Statements using the SLEEP() function are not safe for statement-based replication.

Example

```
SELECT SLEEP(5.5);
+------------+
| SLEEP(5.5) |
+------------+
|          0 |
+------------+
1 row in set (5.50 sec)
```

1.2.8.4.18 SYS_GUID

MariaDB starting with 10.6.1

The SYS_GUID function was introduced in MariaDB 10.6.1 to enhance Oracle compatibility. Similar functionality can be achieved with the UUID function.

Syntax

```
SYS_GUID()
```

Description

Returns a 16-byte globally unique identifier (GUID), similar to the UUID function, but without the `-` character.

Example

```
SELECT SYS_GUID();
+----------------------------------+
| SYS_GUID()                       |
+----------------------------------+
| 2C574E45BA2811EBB265F859713E4BE4 |
+----------------------------------+
```

1.2.8.4.19 UUID

Syntax

```
UUID()
```

Contents

Description

Returns a Universally Unique Identifier (UUID).

A UUID is designed as a number that is globally unique in space and time. Two calls to `UUID()` are expected to generate two different values, even if these calls are performed on two separate computers that are not connected to each other.

UUID() results are intended to be unique, but cannot always be relied upon to be unpredictable and unguessable.

A UUID is a 128-bit number represented by a utf8 string of five hexadecimal numbers in `aaaaaaaa-bbbb-cccc-dddd-eeeeeeeeeeee` format:

- The first three numbers are generated from a timestamp.
- The fourth number preserves temporal uniqueness in case the timestamp value loses monotonicity (for example, due to daylight saving time).
- The fifth number is an IEEE 802 node number that provides spatial uniqueness. A random number is substituted if the latter is not available (for example, because the host computer has no Ethernet card, or we do not know how to find the hardware address of an interface on your operating system). In this case, spatial uniqueness cannot be guaranteed. Nevertheless, a collision should have very low probability.

Currently, the MAC address of an interface is taken into account only on FreeBSD and Linux. On other operating systems, MariaDB uses a randomly generated 48-bit number.

Statements using the UUID() function are not safe for statement-based replication.

The results are generated according to the "DCE 1.1:Remote Procedure Call" (Appendix A) CAE (Common Applications Environment) Specifications published by The Open Group in October 1997 (Document Number C706).

Examples

```
SELECT UUID();
+--------------------------------------+
| UUID()                               |
+--------------------------------------+
| cd41294a-afb0-11df-bc9b-00241dd75637 |
+--------------------------------------+
```

1.2.8.4.20 UUID_SHORT

Syntax

```
UUID_SHORT()
```

Contents

Description

Returns a "short" universally unique identifier as a 64-bit unsigned integer (rather than a string-form 128-bit identifier as returned by the UUID() function).

The value of `UUID_SHORT()` is guaranteed to be unique if the following conditions hold:

- The server_id of the current host is unique among your set of master and slave servers
- `server_id` is between 0 and 255
- You don't set back your system time for your server between mysqld restarts
- You do not invoke `UUID_SHORT()` on average more than 16 million times per second between mysqld restarts

The UUID_SHORT() return value is constructed this way:

```
  (server_id & 255) << 56
+ (server_startup_time_in_seconds << 24)
+ incremented_variable++;
```

Statements using the UUID_SHORT() function are not safe for statement-based replication.

Examples

```
SELECT UUID_SHORT();
+-------------------+
| UUID_SHORT()      |
+-------------------+
| 21517162376069120 |
+-------------------+
```

```
create table t1 (a bigint unsigned default(uuid_short()) primary key);
insert into t1 values(),();
select * from t1;
+-------------------+
| a                 |
+-------------------+
| 98113699159474176 |
| 98113699159474177 |
+-------------------+
```

1.2.8.4.21 VALUES / VALUE

Syntax

MariaDB starting with 10.3.3

```
VALUE(col_name)
```

MariaDB until 10.3.2

```
VALUES(col_name)
```

Description

In an INSERT ... ON DUPLICATE KEY UPDATE statement, you can use the `VALUES(col_name)` function in the UPDATE clause to refer to column values from the INSERT portion of the statement. In other words, `VALUES(col_name)` in the `UPDATE` clause refers to the value of col_name that would be inserted, had no duplicate-key conflict occurred. This function is especially useful in multiple-row inserts.

The `VALUES()` function is meaningful only in `INSERT ... ON DUPLICATE KEY UPDATE` statements and returns `NULL` otherwise.

In MariaDB 10.3.3 this function was renamed to `VALUE()`, because it's incompatible with the standard Table Value Constructors syntax, implemented in MariaDB 10.3.3.

The `VALUES()` function can still be used even from MariaDB 10.3.3, but only in `INSERT ... ON DUPLICATE KEY UPDATE` statements; it's a syntax error otherwise.

Examples

MariaDB starting with 10.3.3

```
INSERT INTO t (a,b,c) VALUES (1,2,3),(4,5,6)
    ON DUPLICATE KEY UPDATE c=VALUE(a)+VALUE(b);
```

MariaDB until 10.3.2

```
INSERT INTO t (a,b,c) VALUES (1,2,3),(4,5,6)
    ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

1.2.9 Special Functions

There are many commonly used built-in functions. These are lesser used function for specific needs.

Dynamic Columns Functions
Functions for storing key/value pairs of data within a column.

Galera Functions
Built-in functions related to Galera.

Geographic Functions
Geographic, as well as geometric functions.

JSON Functions
Built-in functions related to JSON.

SEQUENCE Functions
Functions that can be used on SEQUENCEs.

Spider Functions
User-defined functions available with the Spider storage engine.

Window Functions
Window functions for performing calculations on a set of rows related to the current row.

1.2.2.2 Dynamic Columns Functions

1.2.9.2 Galera Functions

The following functions are for use with Galera.

WSREP_LAST_SEEN_GTID
Returns the Global Transaction ID of the most recent write transaction observed by the client.

WSREP_LAST_WRITTEN_GTID
Returns the Global Transaction ID of the most recent write transaction performed by the client.

WSREP_SYNC_WAIT_UPTO_GTID
Blocks the client until the transaction specified by the given GTID is applied and committed.

1.2.9.2.1 WSREP_LAST_SEEN_GTID

MariaDB starting with 10.4.2
WSREP_LAST_SEEN_GTID was added as part of Galera 4 in MariaDB 10.4.2.

Syntax

```
WSREP_LAST_SEEN_GTID()
```

Description

Returns the Global Transaction ID of the most recent write transaction observed by the client.

The result can be useful to determine the transaction to provide to WSREP_SYNC_WAIT_UPTO_GTID for waiting and unblocking purposes.

1.2.9.2.2 WSREP_LAST_WRITTEN_GTID

MariaDB starting with 10.4.2

MariaDB starting with 10.4.2
WSREP_LAST_WRITTEN_GTID was added as part of Galera 4 in MariaDB 10.4.2.

Syntax

```
WSREP_LAST_WRITTEN_GTID()
```

Description

Returns the Global Transaction ID of the most recent write transaction performed by the client.

1.2.9.2.3 WSREP_SYNC_WAIT_UPTO_GTID

MariaDB starting with 10.4.2
WSREP_SYNC_WAIT_UPTO_GTID was added as part of Galera 4 in MariaDB 10.4.2.

Syntax

```
WSREP_SYNC_WAIT_UPTO_GTID(gtid[,timeout])
```

Description

Blocks the client until the transaction specified by the given Global Transaction ID is applied and committed by the node.

The optional *timeout* argument can be used to specify a block timeout in seconds. If not provided, the timeout will be indefinite.

Returns the node that applied and committed the Global Transaction ID, `ER_LOCAL_WAIT_TIMEOUT` if the function is timed out before this, or `ER_WRONG_ARGUMENTS` if the function is given an invalid GTID.

The result from WSREP_LAST_SEEN_GTID can be useful to determine the transaction to provide to WSREP_SYNC_WAIT_UPTO_GTID for waiting and unblocking purposes.

1.2.9.3 Geographic Functions

Geographic and geometry functions. See Geographic Features for a full discussion of MariaDB's spatial extensions.

WKB
Well-Known Binary format for geometric data

WKT
Well-Known Text geometry representation

There are 2 related questions.

1.2.9.3.1 Geometry Constructors

Geometry constructors

BUFFER
Synonym for ST_BUFFER.

CONVEXHULL
Synonym for ST_CONVEXHULL.

GEOMETRYCOLLECTION
Constructs a WKB GeometryCollection.

LINESTRING
Constructs a WKB LineString value from a number of WKB Point arguments.

MULTILINESTRING
Constructs a MultiLineString value.

MULTIPOINT
Constructs a WKB MultiPoint value.

MULTIPOLYGON
Constructs a WKB MultiPolygon.

POINT
Constructs a WKB Point.

PointOnSurface
Synonym for ST_PointOnSurface.

POLYGON
Constructs a WKB Polygon value from a number of WKB LineString arguments.

ST_BUFFER
A new geometry with a buffer added to the original geometry.

ST_CONVEXHULL
The minimum convex geometry enclosing all geometries within the set.

ST_INTERSECTION
The intersection, or shared portion, of two geometries.

ST_POINTONSURFACE
Returns a POINT guaranteed to intersect a surface.

ST_SYMDIFFERENCE
Portions of two geometries that don't intersect.

ST_UNION
Union of two geometries.

1.2.9.3.1.1 BUFFER

A synonym for ST_BUFFER.

1.2.9.3.1.2 CONVEXHULL

A synonym for ST_CONVEXHULL.

1.2.9.3.1.3 GEOMETRYCOLLECTION

Syntax

```
GeometryCollection(g1,g2,...)
```

Description

Constructs a WKB GeometryCollection. If any argument is not a well-formed WKB representation of a geometry, the return value is `NULL` .

Examples

```
CREATE TABLE gis_geometrycollection  (g GEOMETRYCOLLECTION);
SHOW FIELDS FROM gis_geometrycollection;
INSERT INTO gis_geometrycollection VALUES
    (GeomCollFromText('GEOMETRYCOLLECTION(POINT(0 0), LINESTRING(0 0,10 10))')),
    (GeometryFromWKB(AsWKB(GeometryCollection(Point(44, 6), LineString(Point(3, 6), Point(7, 9))))),
    (GeomFromText('GeometryCollection()')),
    (GeomFromText('GeometryCollection EMPTY'));
```

1.2.9.3.1.4 LINESTRING

Syntax

```
LineString(pt1,pt2,...)
```

Description

Constructs a WKB LineString value from a number of WKB Point arguments. If any argument is not a WKB Point, the return value is `NULL` . If the number of Point arguments is less than two, the return value is `NULL` .

Examples

```
SET @ls = 'LineString(1 1,2 2,3 3)';

SELECT AsText(EndPoint(GeomFromText(@ls)));
+-----------------------------------+
| AsText(EndPoint(GeomFromText(@ls))) |
+-----------------------------------+
| POINT(3 3)                        |
+-----------------------------------+

CREATE TABLE gis_line  (g LINESTRING);
INSERT INTO gis_line VALUES
    (LineFromText('LINESTRING(0 0,0 10,10 0)')),
    (LineStringFromText('LINESTRING(10 10,20 10,20 20,10 20,10 10)')),
    (LineStringFromWKB(AsWKB(LineString(Point(10, 10), Point(40, 10)))));
```

1.2.9.3.1.5 MULTILINESTRING

Syntax

```
MultiLineString(ls1,ls2,...)
```

Description

Constructs a WKB MultiLineString value using WKB LineString arguments. If any argument is not a WKB LineString, the return value is `NULL` .

Example

```
CREATE TABLE gis_multi_line (g MULTILINESTRING);
INSERT INTO gis_multi_line VALUES
 (MultiLineStringFromText('MULTILINESTRING((10 48,10 21,10 0),(16 0,16 23,16 48))')),
 (MLineFromText('MULTILINESTRING((10 48,10 21,10 0))')),
 (MLineFromWKB(AsWKB(MultiLineString(LineString(Point(1, 2),
    Point(3, 5)), LineString(Point(2, 5),Point(5, 8),Point(21, 7))))));
```

1.2.9.3.1.6 MULTIPOINT

Syntax

```
MultiPoint(pt1,pt2,...)
```

Description

Constructs a WKB MultiPoint value using WKB Point arguments. If any argument is not a WKB Point, the return value is `NULL` .

Examples

```
SET @g = ST_GEOMFROMTEXT('MultiPoint( 1 1, 2 2, 5 3, 7 2, 9 3, 8 4, 6 6, 6 9, 4 9, 1 5 )');

CREATE TABLE gis_multi_point (g MULTIPOINT);
INSERT INTO gis_multi_point VALUES
    (MultiPointFromText('MULTIPOINT(0 0,10 10,10 20,20 20)')),
    (MPointFromText('MULTIPOINT(1 1,11 11,11 21,21 21)')),
    (MPointFromWKB(AsWKB(MultiPoint(Point(3, 6), Point(4, 10)))));
```

1.2.9.3.1.7 MULTIPOLYGON

Syntax

```
MultiPolygon(poly1,poly2,...)
```

Description

Constructs a WKB MultiPolygon value from a set of WKB Polygon arguments. If any argument is not a WKB Polygon, the return value is `NULL`.

Example

```
CREATE TABLE gis_multi_polygon  (g MULTIPOLYGON);
INSERT INTO gis_multi_polygon VALUES
    (MultiPolygonFromText('MULTIPOLYGON(((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48
6,52 18)),
     ((59 18,67 18,67 13,59 13,59 18)))')),
    (MPolyFromText('MULTIPOLYGON(((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48 6,52 18)),
        ((59 18,67 18,67 13,59 13,59 18)))')),
    (MPolyFromWKB(AsWKB(MultiPolygon(Polygon(LineString(
       Point(0, 3), Point(3, 3), Point(3, 0), Point(0, 3)))))));
```

1.2.9.3.1.8 POINT

Syntax

```
Point(x,y)
```

Description

Constructs a WKB Point using the given coordinates.

Examples

```
SET @g = ST_GEOMFROMTEXT('Point(1 1)');

CREATE TABLE gis_point  (g POINT);
INSERT INTO gis_point VALUES
    (PointFromText('POINT(10 10)')),
    (PointFromText('POINT(20 10)')),
    (PointFromText('POINT(20 20)')),
    (PointFromWKB(AsWKB(PointFromText('POINT(10 20)'))));
```

1.2.9.3.1.9 PointOnSurface

A synonym for ST_PointOnSurface.

1.2.9.3.1.10 POLYGON

Syntax

```
Polygon(ls1,ls2,...)
```

Description

Constructs a WKB Polygon value from a number of WKB LineString arguments. If any argument does not represent the WKB of a LinearRing (that is, not a closed and simple LineString) the return value is `NULL`.

Note that according to the OpenGIS standard, a POLYGON should have exactly one ExteriorRing and all other rings should lie within that ExteriorRing and thus be the InteriorRings. Practically, however, some systems, including MariaDB's, permit polygons to have several 'ExteriorRings'. In the case of there being multiple, non-overlapping exterior rings ST_NUMINTERIORRINGS() will return 1.

Examples

```
SET @g = ST_GEOMFROMTEXT('POLYGON((1 1,1 5,4 9,6 9,9 3,7 2,1 1))');

CREATE TABLE gis_polygon    (g POLYGON);
INSERT INTO gis_polygon VALUES
    (PolygonFromText('POLYGON((10 10,20 10,20 20,10 20,10 10))')),
    (PolyFromText('POLYGON((0 0,50 0,50 50,0 50,0 0), (10 10,20 10,20 20,10 20,10 10))')),
    (PolyFromWKB(AsWKB(Polygon(LineString(Point(0, 0), Point(30, 0), Point(30, 30), Point(0, 0))
```

Non-overlapping 'polygon':

```
SELECT ST_NumInteriorRings(ST_PolyFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),
  (-1 -1,-5 -1,-5 -5,-1 -5,-1 -1))')) AS NumInteriorRings;
+------------------+
| NumInteriorRings |
+------------------+
|                1 |
+------------------+
```

1.2.9.3.1.11 ST_BUFFER

Syntax

```
ST_BUFFER(g1,r)
BUFFER(g1,r)
```

Description

Returns a geometry that represents all points whose distance from geometry *g1* is less than or equal to distance, or radius, *r*.

Uses for this function could include creating for example a new geometry representing a buffer zone around an island.

BUFFER() is a synonym.

Examples

Determining whether a point is within a buffer zone:

```
SET @g1 = ST_GEOMFROMTEXT('POLYGON((10 10, 10 20, 20 20, 20 10, 10 10))');

SET @g2 = ST_GEOMFROMTEXT('POINT(8 8)');

SELECT ST_WITHIN(@g2,ST_BUFFER(@g1,5));
+--------------------------------+
| ST_WITHIN(@g2,ST_BUFFER(@g1,5)) |
+--------------------------------+
|                              1 |
+--------------------------------+

SELECT ST_WITHIN(@g2,ST_BUFFER(@g1,1));
+--------------------------------+
| ST_WITHIN(@g2,ST_BUFFER(@g1,1)) |
+--------------------------------+
|                              0 |
+--------------------------------+
```

1.2.9.3.1.12 ST_CONVEXHULL

MariaDB starting with 10.1.2
ST_ConvexHull() was introduced in MariaDB 10.1.2

Syntax

```
ST_ConvexHull(g)
ConvexHull(g)
```

Description

Given a geometry, returns a geometry that is the minimum convex geometry enclosing all geometries within the set. Returns NULL if the geometry value is NULL or an empty value.

ST_ConvexHull() and ConvexHull() are synonyms.

Examples

The ConvexHull of a single point is simply the single point:

```
SET @g = ST_GEOMFROMTEXT('Point(0 0)');

SELECT ST_ASTEXT(ST_CONVEXHULL(@g));
+------------------------------+
| ST_ASTEXT(ST_CONVEXHULL(@g)) |
+------------------------------+
| POINT(0 0)                   |
+------------------------------+
```

```
SET @g = ST_GEOMFROMTEXT('MultiPoint(0 0, 1 2, 2 3)');

SELECT ST_ASTEXT(ST_CONVEXHULL(@g));
+------------------------------+
| ST_ASTEXT(ST_CONVEXHULL(@g)) |
+------------------------------+
| POLYGON((0 0,1 2,2 3,0 0))   |
+------------------------------+
```

```
SET @g = ST_GEOMFROMTEXT('MultiPoint( 1 1, 2 2, 5 3, 7 2, 9 3, 8 4, 6 6, 6 9, 4 9, 1 5 )');

SELECT ST_ASTEXT(ST_CONVEXHULL(@g));
+--------------------------------------+
| ST_ASTEXT(ST_CONVEXHULL(@g))         |
+--------------------------------------+
| POLYGON((1 1,1 5,4 9,6 9,9 3,7 2,1 1)) |
+--------------------------------------+
```

1.2.9.3.1.13 ST_INTERSECTION

Syntax

```
ST_INTERSECTION(g1,g2)
```

Description

Returns a geometry that is the intersection, or shared portion, of geometry *g1* and geometry *g2*.

Examples

```
SET @g1 = ST_GEOMFROMTEXT('POINT(2 1)');

SET @g2 = ST_GEOMFROMTEXT('LINESTRING(2 1, 0 2)');

SELECT ASTEXT(ST_INTERSECTION(@g1,@g2));
+---------------------------------+
| ASTEXT(ST_INTERSECTION(@g1,@g2)) |
+---------------------------------+
| POINT(2 1)                      |
+---------------------------------+
```

1.2.9.3.1.14 ST_POINTONSURFACE

MariaDB starting with 10.1.2

ST_POINTONSURFACE() was introduced in MariaDB 10.1.2

Syntax

```
ST_PointOnSurface(g)
PointOnSurface(g)
```

Description

Given a geometry, returns a POINT guaranteed to intersect a surface. However, see MDEV-7514.

ST_PointOnSurface() and PointOnSurface() are synonyms.

1.2.9.3.1.15 ST_SYMDIFFERENCE

Syntax

```
ST_SYMDIFFERENCE(g1,g2)
```

Description

Returns a geometry that represents the portions of geometry `g1` and geometry `g2` that don't intersect.

Examples

```
SET @g1 = ST_GEOMFROMTEXT('LINESTRING(10 20, 10 40)');

SET @g2 = ST_GEOMFROMTEXT('LINESTRING(10 15, 10 25)');

SELECT ASTEXT(ST_SYMDIFFERENCE(@g1,@g2));
+-------------------------------------------+
| ASTEXT(ST_SYMDIFFERENCE(@g1,@g2))         |
+-------------------------------------------+
| MULTILINESTRING((10 15,10 20),(10 25,10 40)) |
+-------------------------------------------+

SET @g2 = ST_GeomFromText('LINESTRING(10 20, 10 41)');

SELECT ASTEXT(ST_SYMDIFFERENCE(@g1,@g2));
+-----------------------------------+
| ASTEXT(ST_SYMDIFFERENCE(@g1,@g2)) |
+-----------------------------------+
| LINESTRING(10 40,10 41)           |
+-----------------------------------+
```

1.2.9.3.1.16 ST_UNION

Syntax

```
ST_UNION(g1,g2)
```

Description

Returns a geometry that is the union of the geometry `g1` and geometry `g2` .

Examples

```
SET @g1 = GEOMFROMTEXT('POINT (0 2)');

SET @g2 = GEOMFROMTEXT('POINT (2 0)');

SELECT ASTEXT(ST_UNION(@g1,@g2));
+---------------------------+
| ASTEXT(ST_UNION(@g1,@g2)) |
+---------------------------+
| MULTIPOINT(2 0,0 2)       |
+---------------------------+
```

```
SET @g1 = GEOMFROMTEXT('POLYGON((0 0,0 3,3 3,3 0,0 0))');

SET @g2 = GEOMFROMTEXT('POLYGON((2 2,4 2,4 4,2 4,2 2))');

SELECT ASTEXT(ST_UNION(@g1,@g2));
+-------------------------------------------+
| ASTEXT(ST_UNION(@g1,@g2))                 |
+-------------------------------------------+
| POLYGON((0 0,0 3,2 3,2 4,4 4,4 2,3 2,3 0,0 0)) |
+-------------------------------------------+
```

1.2.9.3.2 Geometry Properties

Geometry properties

BOUNDARY
Synonym for ST_BOUNDARY.

DIMENSION
Synonym for ST_DIMENSION.

ENVELOPE
Synonym for ST_ENVELOPE.

GeometryN
Synonym for ST_GeometryN.

GeometryType
Synonym for ST_GeometryType.

IsClosed
Synonym for ST_IsClosed.

IsEmpty
Synonym for ST_IsEmpty.

IsRing
Synonym for ST_IsRing.

IsSimple
Synonym for ST_IsSimple.

NumGeometries
Synonym for ST_NumGeometries.

SRID
Synonym for ST_SRID.

ST_BOUNDARY
Returns a geometry that is the closure of a combinatorial boundary.

ST_DIMENSION
Inherent dimension of a geometry value.

ST_ENVELOPE
Returns the Minimum Bounding Rectangle for a geometry value.

ST_GEOMETRYN
Returns the N-th geometry in a GeometryCollection.

ST_GEOMETRYTYPE
Returns name of the geometry type of which a given geometry instance is a member.

ST_ISCLOSED
Returns true if a given LINESTRING's start and end points are the same.

ST_ISEMPTY
Indicated validity of geometry value.

ST_IsRing
Returns true if a given LINESTRING is both ST_IsClosed and ST_IsSimple.

ST_IsSimple
Returns true if the given Geometry has no anomalous geometric points.

ST_NUMGEOMETRIES
Number of geometries in a GeometryCollection.

ST_RELATE
Returns true if two geometries are related

ST_SRID
Returns a Spatial Reference System ID.

1.2.9.3.2.1 BOUNDARY

A synonym for ST_BOUNDARY.

1.2.9.3.2.2 DIMENSION

A synonym for ST_DIMENSION.

1.2.9.3.2.3 ENVELOPE

A synonym for ST_ENVELOPE.

1.2.9.3.2.4 GeometryN

A synonym for ST_GeometryN.

1.2.9.3.2.5 GeometryType

A synonym for ST_GeometryType.

1.2.9.3.2.6 IsClosed

A synonym for ST_IsClosed.

1.2.9.3.2.7 IsEmpty

A synonym for ST_IsEmpty.

1.2.9.3.2.8 IsRing

A synonym for ST_IsRing.

1.2.9.3.2.9 IsSimple

A synonym for ST_IsSImple.

1.2.9.3.2.10 NumGeometries

A synonym for ST_NumGeometries.

1.2.9.3.2.11 SRID

A synonym for ST_SRID.

1.2.9.3.2.12 ST_BOUNDARY

MariaDB starting with 10.1.2
The ST_BOUNDARY function was introduced in MariaDB 10.1.2

Syntax

```
ST_BOUNDARY(g)
BOUNDARY(g)
```

Description

Returns a geometry that is the closure of the combinatorial boundary of the geometry value `g`.

BOUNDARY() is a synonym.

Examples

```
SELECT ST_AsText(ST_Boundary(ST_GeomFromText('LINESTRING(3 3,0 0, -3 3)')));
+-----------------------------------------------------------------------+
| ST_AsText(ST_Boundary(ST_GeomFromText('LINESTRING(3 3,0 0, -3 3)'))) |
+-----------------------------------------------------------------------+
| MULTIPOINT(3 3,-3 3)                                                  |
+-----------------------------------------------------------------------+

SELECT ST_AsText(ST_Boundary(ST_GeomFromText('POLYGON((3 3,0 0, -3 3, 3 3))')));
+--------------------------------------------------------------------------+
| ST_AsText(ST_Boundary(ST_GeomFromText('POLYGON((3 3,0 0, -3 3, 3 3))'))) |
+--------------------------------------------------------------------------+
| LINESTRING(3 3,0 0,-3 3,3 3)                                             |
+--------------------------------------------------------------------------+
```

1.2.9.3.2.13 ST_DIMENSION

Syntax

```
ST_Dimension(g)
Dimension(g)
```

Description

Returns the inherent dimension of the geometry value `g`. The result can be

Dimension	Definition
-1	empty geometry
0	geometry with no length or area
1	geometry with no area but nonzero length
2	geometry with nonzero area

`ST_Dimension()` and `Dimension()` are synonyms.

Examples

```
SELECT Dimension(GeomFromText('LineString(1 1,2 2)'));
+-----------------------------------------------+
| Dimension(GeomFromText('LineString(1 1,2 2)')) |
+-----------------------------------------------+
|                                             1 |
+-----------------------------------------------+
```

1.2.9.3.2.14 ST_ENVELOPE

Syntax

```
ST_ENVELOPE(g)
ENVELOPE(g)
```

Description

Returns the Minimum Bounding Rectangle (MBR) for the geometry value `g`. The result is returned as a Polygon value.

The polygon is defined by the corner points of the bounding box:

```
POLYGON((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

`ST_ENVELOPE()` and `ENVELOPE()` are synonyms.

Examples

```
SELECT AsText(ST_ENVELOPE(GeomFromText('LineString(1 1,4 4)')));
+-------------------------------------------------------------+
| AsText(ST_ENVELOPE(GeomFromText('LineString(1 1,4 4)'))) |
+-------------------------------------------------------------+
| POLYGON((1 1,4 1,4 4,1 4,1 1))                              |
+-------------------------------------------------------------+
```

1.2.9.3.2.15 ST_GEOMETRYN

Syntax

```
ST_GeometryN(gc,N)
GeometryN(gc,N)
```

Description

Returns the N-th geometry in the GeometryCollection `gc`. Geometries are numbered beginning with 1.

`ST_GeometryN()` and `GeometryN()` are synonyms.

Example

```
SET @gc = 'GeometryCollection(Point(1 1),LineString(12 14, 9 11))';

SELECT AsText(GeometryN(GeomFromText(@gc),1));
+--------------------------------------+
| AsText(GeometryN(GeomFromText(@gc),1)) |
+--------------------------------------+
| POINT(1 1)                           |
+--------------------------------------+
```

1.2.9.3.2.16 ST_GEOMETRYTYPE

Syntax

```
ST_GeometryType(g)
GeometryType(g)
```

Description

Returns as a string the name of the geometry type of which the geometry instance `g` is a member. The name corresponds to one of the instantiable Geometry subclasses.

`ST_GeometryType()` and `GeometryType()` are synonyms.

Examples

```
SELECT GeometryType(GeomFromText('POINT(1 1)'));
+---------------------------------------+
| GeometryType(GeomFromText('POINT(1 1)')) |
+---------------------------------------+
| POINT                                 |
+---------------------------------------+
```

1.2.9.3.2.17 ST_ISCLOSED

Syntax

```
ST_IsClosed(g)
IsClosed(g)
```

Description

Returns 1 if a given LINESTRING's start and end points are the same, or 0 if they are not the same. Before MariaDB 10.1.5, returns NULL if not given a LINESTRING. After MariaDB 10.1.5, returns -1.

`ST_IsClosed()` and `IsClosed()` are synonyms.

Examples

```
SET @ls = 'LineString(0 0, 0 4, 4 4, 0 0)';
SELECT ST_ISCLOSED(GEOMFROMTEXT(@ls));
+--------------------------------+
| ST_ISCLOSED(GEOMFROMTEXT(@ls)) |
+--------------------------------+
|                              1 |
+--------------------------------+

SET @ls = 'LineString(0 0, 0 4, 4 4, 0 1)';
SELECT ST_ISCLOSED(GEOMFROMTEXT(@ls));
+--------------------------------+
| ST_ISCLOSED(GEOMFROMTEXT(@ls)) |
+--------------------------------+
|                              0 |
+--------------------------------+
```

1.2.9.3.2.18 ST_ISEMPTY

Syntax

```
ST_IsEmpty(g)
IsEmpty(g)
```

Description

IsEmpty is a function defined by the OpenGIS specification, but is not fully implemented by MariaDB or MySQL.

Since MariaDB and MySQL do not support GIS EMPTY values such as POINT EMPTY, as implemented it simply returns `1` if the geometry value `g` is invalid, `0` if it is valid, and `NULL` if the argument is `NULL`.

`ST_IsEmpty()` and `IsEmpty()` are synonyms.

1.2.9.3.2.19 ST_IsRing

MariaDB starting with 10.1.2

The ST_IsRing function was introduced in MariaDB 10.1.2

Syntax

```
ST_IsRing(g)
IsRing(g)
```

Description

Returns true if a given LINESTRING is a ring, that is, both ST_IsClosed and ST_IsSimple. A simple curve does not pass through the same point more than once. However, see MDEV-7510.

`St_IsRing()` and `IsRing()` are synonyms.

1.2.9.3.2.20 ST_IsSimple

Syntax

```
ST_IsSimple(g)
IsSimple(g)
```

Description

Returns true if the given Geometry has no anomalous geometric points, false if it does, or NULL if given a NULL value.

ST_IsSimple() and IsSimple() are synonyms.

Examples

A POINT is always simple.

```
SET @g = 'Point(1 2)';

SELECT ST_ISSIMPLE(GEOMFROMTEXT(@g));
+------------------------------+
| ST_ISSIMPLE(GEOMFROMTEXT(@g)) |
+------------------------------+
|                            1 |
+------------------------------+
```

1.2.9.3.2.21 ST_NUMGEOMETRIES

Syntax

```
ST_NumGeometries(gc)
NumGeometries(gc)
```

Description

Returns the number of geometries in the GeometryCollection `gc`.

`ST_NumGeometries()` and `NumGeometries()` are synonyms.

Example

```
SET @gc = 'GeometryCollection(Point(1 1),LineString(2 2, 3 3))';

SELECT NUMGEOMETRIES(GeomFromText(@gc));
+----------------------------------+
| NUMGEOMETRIES(GeomFromText(@gc)) |
+----------------------------------+
|                                2 |
+----------------------------------+
```

1.2.9.3.2.22 ST_RELATE

MariaDB starting with 10.1.2

The ST_RELATE() function was introduced in MariaDB 10.1.2

Syntax

```
ST_Relate(g1, g2, i)
```

Description

Returns true if Geometry `g1` is spatially related to Geometry `g2` by testing for intersections between the interior, boundary and exterior of the two geometries as specified by the values in intersection matrix pattern `i`.

1.2.9.3.2.23 ST_SRID

Syntax

```
ST_SRID(g)
SRID(g)
```

Description

Returns an integer indicating the Spatial Reference System ID for the geometry value g.

In MariaDB, the SRID value is just an integer associated with the geometry value. All calculations are done assuming Euclidean (planar) geometry.

`ST_SRID()` and `SRID()` are synonyms.

Examples

```
SELECT SRID(GeomFromText('LineString(1 1,2 2)',101));
+-----------------------------------------------+
| SRID(GeomFromText('LineString(1 1,2 2)',101)) |
+-----------------------------------------------+
|                                           101 |
+-----------------------------------------------+
```

1.2.9.3.3 Geometry Relations

Geometry relations

CONTAINS

Whether one geometry contains another.

CROSSES

Whether two geometries spatially cross

DISJOINT

Whether the two elements do not intersect.

EQUALS

Indicates whether two geometries are spatially equal.

INTERSECTS

Indicates whether two geometries spatially intersect.

OVERLAPS

Indicates whether two elements spatially overlap.

ST_CONTAINS

Whether one geometry is contained by another.

ST_CROSSES

Whether two geometries spatially cross.

ST_DIFFERENCE

Point set difference.

ST_DISJOINT

Whether one geometry is spatially disjoint from another.

ST_DISTANCE

The distance between two geometries.

ST_DISTANCE_SPHERE

Spherical distance between two geometries (point or multipoint) on a sphere.

ST_EQUALS

Whether two geometries are spatoially equal.

ST_INTERSECTS

Whether two geometries spatially intersect.

ST_LENGTH

Length of a LineString value.

ST_OVERLAPS

Whether two geometries overlap.

ST_TOUCHES

Whether one geometry g1 spatially touches another.

ST_WITHIN

Whether one geometry is within another.

TOUCHES

Whether two geometries spatially touch.

WITHIN

Indicate whether a geographic element is spacially within another.

1.2.9.3.3.1 CONTAINS

Syntax

```
Contains(g1,g2)
```

Description

Returns `1` or `0` to indicate whether a geometry `g1` completely contains geometry `g2` . CONTAINS() is based on the original MySQL implementation and uses object bounding rectangles, while ST_CONTAINS() uses object shapes.

This tests the opposite relationship to Within().

1.2.9.3.3.2 CROSSES

Syntax

```
Crosses(g1,g2)
```

Description

Returns `1` if `g1` spatially crosses `g2` . Returns `NULL` if `g1` is a Polygon or a MultiPolygon, or if `g2` is a Point or a MultiPoint. Otherwise, returns `0` .

The term spatially crosses denotes a spatial relation between two given geometries that has the following properties:

- The two geometries intersect
- Their intersection results in a geometry that has a dimension that is one less than the maximum dimension of the two given geometries
- Their intersection is not equal to either of the two given geometries

CROSSES() is based on the original MySQL implementation, and uses object bounding rectangles, while ST_CROSSES() uses object shapes.

1.2.9.3.3.3 DISJOINT

Syntax

```
Disjoint(g1,g2)
```

Description

Returns `1` or `0` to indicate whether `g1` is spatially disjoint from (does not intersect) `g2` .

DISJOINT() tests the opposite relationship to INTERSECTS().

DISJOINT() is based on the original MySQL implementation and uses object bounding rectangles, while ST_DISJOINT() uses object shapes.

1.2.9.3.3.4 EQUALS

Syntax

```
Equals(g1,g2)
```

From MariaDB 10.2.3:

```
MBREQUALS(g1,g2)
```

Description

Returns `1` or `0` to indicate whether *g1* is spatially equal to *g2*.

EQUALS() is based on the original MySQL implementation and uses object bounding rectangles, while ST_EQUALS() uses object shapes.

From MariaDB 10.2.3, `MBREQUALS` is a synonym for `Equals`.

1.2.9.3.3.5 INTERSECTS

Syntax

```
INTERSECTS(g1,g2)
```

Description

Returns `1` or `0` to indicate whether geometry *g1* spatially intersects geometry *g2*.

INTERSECTS() is based on the original MySQL implementation and uses object bounding rectangles, while ST_INTERSECTS() uses object shapes.

INTERSECTS() tests the opposite relationship to DISJOINT().

1.2.9.3.3.6 OVERLAPS

Syntax

```
OVERLAPS(g1,g2)
```

Description

Returns `1` or `0` to indicate whether `g1` spatially overlaps `g2`. The term spatially overlaps is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

OVERLAPS() is based on the original MySQL implementation and uses object bounding rectangles, while ST_OVERLAPS() uses object shapes.

1.2.9.3.3.7 ST_CONTAINS

Syntax

```
ST_CONTAINS(g1,g2)
```

Description

Returns `1` or `0` to indicate whether a geometry `g1` completely contains geometry `g2`.

ST_CONTAINS() uses object shapes, while CONTAINS(), based on the original MySQL implementation, uses object bounding rectangles.

ST_CONTAINS tests the opposite relationship to ST_WITHIN().

Examples

```
SET @g1 = ST_GEOMFROMTEXT('POLYGON((175 150, 20 40, 50 60, 125 100, 175 150))');

SET @g2 = ST_GEOMFROMTEXT('POINT(174 149)');

SELECT ST_CONTAINS(@g1,@g2);
+----------------------+
| ST_CONTAINS(@g1,@g2) |
+----------------------+
|                    1 |
+----------------------+

SET @g2 = ST_GEOMFROMTEXT('POINT(175 151)');

SELECT ST_CONTAINS(@g1,@g2);
+----------------------+
| ST_CONTAINS(@g1,@g2) |
+----------------------+
|                    0 |
+----------------------+
```

1.2.9.3.3.8 ST_CROSSES

Syntax

```
ST_CROSSES(g1,g2)
```

Description

Returns `1` if geometry *`g1`* spatially crosses geometry *`g2`*. Returns `NULL` if `g1` is a Polygon or a MultiPolygon, or if `g2` is a Point or a MultiPoint. Otherwise, returns `0`.

The term spatially crosses denotes a spatial relation between two given geometries that has the following properties:

- The two geometries intersect
- Their intersection results in a geometry that has a dimension that is one less than the maximum dimension of the two given geometries
- Their intersection is not equal to either of the two given geometries

ST_CROSSES() uses object shapes, while CROSSES(), based on the original MySQL implementation, uses object bounding rectangles.

Examples

```
SET @g1 = ST_GEOMFROMTEXT('LINESTRING(174 149, 176 151)');

SET @g2 = ST_GEOMFROMTEXT('POLYGON((175 150, 20 40, 50 60, 125 100, 175 150))');

SELECT ST_CROSSES(@g1,@g2);
+---------------------+
| ST_CROSSES(@g1,@g2) |
+---------------------+
|                   1 |
+---------------------+

SET @g1 = ST_GEOMFROMTEXT('LINESTRING(176 149, 176 151)');

SELECT ST_CROSSES(@g1,@g2);
+---------------------+
| ST_CROSSES(@g1,@g2) |
+---------------------+
|                   0 |
+---------------------+
```

1.2.9.3.3.9 ST_DIFFERENCE

Syntax

```
ST_DIFFERENCE(g1,g2)
```

Description

Returns a geometry representing the point set difference of the given geometry values.

Example

```
SET @g1 = POINT(10,10), @g2 = POINT(20,20);

SELECT ST_AsText(ST_Difference(@g1, @g2));
+-----------------------------------+
| ST_AsText(ST_Difference(@g1, @g2)) |
+-----------------------------------+
| POINT(10 10)                      |
+-----------------------------------+
```

1.2.9.3.3.10 ST_DISJOINT

Syntax

```
ST_DISJOINT(g1,g2)
```

Description

Returns `1` or `0` to indicate whether geometry *`g1`* is spatially disjoint from (does not intersect with) geometry *`g2`*.

ST_DISJOINT() uses object shapes, while DISJOINT(), based on the original MySQL implementation, uses object bounding rectangles.

ST_DISJOINT() tests the opposite relationship to ST_INTERSECTS().

Examples

```
SET @g1 = ST_GEOMFROMTEXT('POINT(0 0)');

SET @g2 = ST_GEOMFROMTEXT('LINESTRING(2 0, 0 2)');

SELECT ST_DISJOINT(@g1,@g2);
+----------------------+
| ST_DISJOINT(@g1,@g2) |
+----------------------+
|                    1 |
+----------------------+

SET @g2 = ST_GEOMFROMTEXT('LINESTRING(0 0, 0 2)');

SELECT ST_DISJOINT(@g1,@g2);
+----------------------+
| ST_DISJOINT(@g1,@g2) |
+----------------------+
|                    0 |
+----------------------+
```

1.2.9.3.3.11 ST_DISTANCE

Syntax

```
ST_DISTANCE(g1,g2)
```

Description

Returns the distance between two geometries, or null if not given valid inputs.

Example

```
SELECT ST_Distance(POINT(1,2),POINT(2,2));
+-----------------------------------+
| ST_Distance(POINT(1,2),POINT(2,2)) |
+-----------------------------------+
|                                 1 |
+-----------------------------------+
```

1.2.9.3.3.12 ST_DISTANCE_SPHERE

MariaDB starting with 10.2.38

`ST_DISTANCE_SPHERE` was introduced in MariaDB 10.2.38, MariaDB 10.3.29, MariaDB 10.4.19 and MariaDB 10.5.10.

Syntax

```
ST_DISTANCE_SPHERE(g1,g2,[r])
```

Description

Returns the spherical distance between two geometries (point or multipoint) on a sphere with the optional radius *r* (default is the Earth radius if *r* is not specified), or NULL if not given valid inputs.

Example

```
set @zenica   = ST_GeomFromText('POINT(17.907743 44.203438)');
set @sarajevo = ST_GeomFromText('POINT(18.413076 43.856258)');
SELECT ST_Distance_Sphere(@zenica, @sarajevo);
55878.59337591705
```

1.2.9.3.3.13 ST_EQUALS

Syntax

```
ST_EQUALS(g1,g2)
```

Description

Returns `1` or `0` to indicate whether geometry *`g1`* is spatially equal to geometry *`g2`*.

ST_EQUALS() uses object shapes, while EQUALS(), based on the original MySQL implementation, uses object bounding rectangles.

Examples

```
SET @g1 = ST_GEOMFROMTEXT('LINESTRING(174 149, 176 151)');

SET @g2 = ST_GEOMFROMTEXT('LINESTRING(176 151, 174 149)');

SELECT ST_EQUALS(@g1,@g2);
+--------------------+
| ST_EQUALS(@g1,@g2) |
+--------------------+
|                  1 |
+--------------------+
```

```
SET @g1 = ST_GEOMFROMTEXT('POINT(0 2)');

SET @g1 = ST_GEOMFROMTEXT('POINT(2 0)');

SELECT ST_EQUALS(@g1,@g2);
+--------------------+
| ST_EQUALS(@g1,@g2) |
+--------------------+
|                  0 |
+--------------------+
```

1.2.9.3.3.14 ST_INTERSECTS

Syntax

```
ST_INTERSECTS(g1,g2)
```

Description

Returns `1` or `0` to indicate whether geometry *`g1`* spatially intersects geometry *`g2`*.

ST_INTERSECTS() uses object shapes, while INTERSECTS(), based on the original MySQL implementation, uses object bounding rectangles.

ST_INTERSECTS() tests the opposite relationship to ST_DISJOINT().

Examples

```
SET @g1 = ST_GEOMFROMTEXT('POINT(0 0)');

SET @g2 = ST_GEOMFROMTEXT('LINESTRING(0 0, 0 2)');

SELECT ST_INTERSECTS(@g1,@g2);
+------------------------+
| ST_INTERSECTS(@g1,@g2) |
+------------------------+
|                      1 |
+------------------------+
```

```
SET @g2 = ST_GEOMFROMTEXT('LINESTRING(2 0, 0 2)');

SELECT ST_INTERSECTS(@g1,@g2);
+------------------------+
| ST_INTERSECTS(@g1,@g2) |
+------------------------+
|                      0 |
+------------------------+
```

1.2.9.3.3.15 ST_LENGTH

Syntax

```
ST_LENGTH(ls)
```

Description

Returns as a double-precision number the length of the LineString value `ls` in its associated spatial reference.

Examples

```
SET @ls = 'LineString(1 1,2 2,3 3)';

SELECT ST_LENGTH(ST_GeomFromText(@ls));
+---------------------------------+
| ST_LENGTH(ST_GeomFromText(@ls)) |
+---------------------------------+
|                2.82842712474619 |
+---------------------------------+
```

1.2.9.3.3.16 ST_OVERLAPS

Syntax

```
ST_OVERLAPS(g1,g2)
```

Description

Returns `1` or `0` to indicate whether geometry `g1` spatially overlaps geometry `g2`.

The term spatially overlaps is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

ST_OVERLAPS() uses object shapes, while OVERLAPS(), based on the original MySQL implementation, uses object

bounding rectangles.

1.2.9.3.3.17 ST_TOUCHES

Syntax

```
ST_TOUCHES(g1,g2)
```

Description

Returns `1` or `0` to indicate whether geometry `g1` spatially touches geometry `g2`. Two geometries spatially touch if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

ST_TOUCHES() uses object shapes, while TOUCHES(), based on the original MySQL implementation, uses object bounding rectangles.

Examples

```
SET @g1 = ST_GEOMFROMTEXT('POINT(2 0)');

SET @g2 = ST_GEOMFROMTEXT('LINESTRING(2 0, 0 2)');

SELECT ST_TOUCHES(@g1,@g2);
+---------------------+
| ST_TOUCHES(@g1,@g2) |
+---------------------+
|                   1 |
+---------------------+

SET @g1 = ST_GEOMFROMTEXT('POINT(2 1)');

SELECT ST_TOUCHES(@g1,@g2);
+---------------------+
| ST_TOUCHES(@g1,@g2) |
+---------------------+
|                   0 |
+---------------------+
```

1.2.9.3.3.18 ST_WITHIN

Syntax

```
ST_WITHIN(g1,g2)
```

Description

Returns `1` or `0` to indicate whether geometry `g1` is spatially within geometry `g2`.

This tests the opposite relationship as `ST_CONTAINS()`.

ST_WITHIN() uses object shapes, while WITHIN(), based on the original MySQL implementation, uses object bounding rectangles.

Examples

```
SET @g1 = ST_GEOMFROMTEXT('POINT(174 149)');

SET @g2 = ST_GEOMFROMTEXT('POLYGON((175 150, 20 40, 50 60, 125 100, 175 150))');

SELECT ST_WITHIN(@g1,@g2);
+--------------------+
| ST_WITHIN(@g1,@g2) |
+--------------------+
|                  1 |
+--------------------+

SET @g1 = ST_GEOMFROMTEXT('POINT(176 151)');

SELECT ST_WITHIN(@g1,@g2);
+--------------------+
| ST_WITHIN(@g1,@g2) |
+--------------------+
|                  0 |
+--------------------+
```

1.2.9.3.3.19 TOUCHES

Syntax

```
Touches(g1,g2)
```

Description

Returns `1` or `0` to indicate whether `g1` spatially touches `g2`. Two geometries spatially touch if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

TOUCHES() is based on the original MySQL implementation and uses object bounding rectangles, while ST_TOUCHES() uses object shapes.

1.2.9.3.3.20 WITHIN

Syntax

```
Within(g1,g2)
```

Description

Returns `1` or `0` to indicate whether `g1` is spatially within `g2`. This tests the opposite relationship as `Contains()`.

WITHIN() is based on the original MySQL implementation, and uses object bounding rectangles, while ST_WITHIN() uses object shapes.

Examples

```
SET @g1 = GEOMFROMTEXT('POINT(174 149)');
SET @g2 = GEOMFROMTEXT('POINT(176 151)');
SET @g3 = GEOMFROMTEXT('POLYGON((175 150, 20 40, 50 60, 125 100, 175 150))');

SELECT within(@g1,@g3);
+-----------------+
| within(@g1,@g3) |
+-----------------+
|               1 |
+-----------------+

SELECT within(@g2,@g3);
+-----------------+
| within(@g2,@g3) |
+-----------------+
|               0 |
+-----------------+
```

1.2.9.3.4 LineString Properties

LineString properties

ENDPOINT

Synonym for ST_ENDPOINT.

GLENGTH

Length of a LineString value.

NumPoints

Synonym for ST_NumPoints.

PointN

Synonym for PointN.

STARTPOINT

Synonym for ST_StartPoint.

ST_ENDPOINT

Returns the endpoint of a LineString.

ST_NUMPOINTS

Returns the number of Point objects in a LineString.

ST_POINTN

Returns the N-th Point in the LineString.

ST_STARTPOINT

Returns the start point of a LineString

1.2.9.3.4.1 ENDPOINT

A synonym for ST_ENDPOINT.

1.2.9.3.4.2 GLENGTH

Syntax

```
GLength(ls)
```

Description

Returns as a double-precision number the length of the LineString value `ls` in its associated spatial reference.

Examples

```
SET @ls = 'LineString(1 1,2 2,3 3)';

SELECT GLength(GeomFromText(@ls));
+----------------------------+
| GLength(GeomFromText(@ls)) |
+----------------------------+
|          2.82842712474619 |
+----------------------------+
```

1.2.9.3.4.3 NumPoints

A synonym for ST_NumPoints.

1.2.9.3.4.4 PointN

A synonym for ST_PointN.

1.2.9.3.4.5 STARTPOINT

A synonym for ST_STARTPOINT.

1.2.9.3.4.6 ST_ENDPOINT

Syntax

```
ST_EndPoint(ls)
EndPoint(ls)
```

Description

Returns the Point that is the endpoint of the LineString value `ls` .

`ST_EndPoint()` and `EndPoint()` are synonyms.

Examples

```
SET @ls = 'LineString(1 1,2 2,3 3)';

SELECT AsText(EndPoint(GeomFromText(@ls)));
+-------------------------------------+
| AsText(EndPoint(GeomFromText(@ls))) |
+-------------------------------------+
| POINT(3 3)                          |
+-------------------------------------+
```

1.2.9.3.4.7 ST_NUMPOINTS

Syntax

```
ST_NumPoints(ls)
NumPoints(ls)
```

Description

Returns the number of Point objects in the LineString value `ls` .

`ST_NumPoints()` and `NumPoints()` are synonyms.

Examples

```
SET @ls = 'LineString(1 1,2 2,3 3)';

SELECT NumPoints(GeomFromText(@ls));
+------------------------------+
| NumPoints(GeomFromText(@ls)) |
+------------------------------+
|                            3 |
+------------------------------+
```

1.2.9.3.4.8 ST_POINTN

Syntax

```
ST_PointN(ls,N)
PointN(ls,N)
```

Description

Returns the N-th Point in the LineString value `ls` . Points are numbered beginning with `1` .

`ST_PointN()` and `PointN()` are synonyms.

Examples

```
SET @ls = 'LineString(1 1,2 2,3 3)';

SELECT AsText(PointN(GeomFromText(@ls),2));
+-------------------------------------+
| AsText(PointN(GeomFromText(@ls),2)) |
+-------------------------------------+
| POINT(2 2)                          |
+-------------------------------------+
```

1.2.9.3.4.9 ST_STARTPOINT

Syntax

```
ST_StartPoint(ls)
StartPoint(ls)
```

Description

Returns the Point that is the start point of the LineString value `ls` .

`ST_StartPoint()` and `StartPoint()` are synonyms.

Examples

```
SET @ls = 'LineString(1 1,2 2,3 3)';

SELECT AsText(StartPoint(GeomFromText(@ls)));
+--------------------------------------+
| AsText(StartPoint(GeomFromText(@ls))) |
+--------------------------------------+
| POINT(1 1)                           |
+--------------------------------------+
```

1.2.9.3.5 MBR (Minimum Bounding Rectangle)

MBR Definition

Minimum Bounding Rectangle.

MBRContains

Indicates one Minimum Bounding Rectangle contains another.

MBRDisjoint

Indicates whether the Minimum Bounding Rectangles of two geometries are disjoint.

MBREqual

Whether the Minimum Bounding Rectangles of two geometries are the same.

MBRIntersects

Indicates whether the Minimum Bounding Rectangles of the two geometries intersect.

MBROverlaps

Whether the Minimum Bounding Rectangles of two geometries overlap.

MBRTouches

Whether the Minimum Bounding Rectangles of two geometries touch.

MBRWithin

Indicates whether one Minimum Bounding Rectangle is within another

1.2.9.3.5.1 MBR Definition

Description

The MBR (Minimum Bounding Rectangle), or Envelope is the bounding geometry, formed by the minimum and maximum (X,Y) coordinates:

Examples

```
((MINX MINY, MAXX MINY, MAXX MAXY, MINX MAXY, MINX MINY))
```

1.2.9.3.5.2 MBRContains

Syntax

```
MBRContains(g1,g2)
```

Description

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangle of g1 contains the Minimum Bounding Rectangle of g2. This tests the opposite relationship as MBRWithin().

Examples

```
SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');

SET @g2 = GeomFromText('Point(1 1)');

SELECT MBRContains(@g1,@g2), MBRContains(@g2,@g1);
+----------------------+----------------------+
| MBRContains(@g1,@g2) | MBRContains(@g2,@g1) |
+----------------------+----------------------+
|                    1 |                    0 |
+----------------------+----------------------+
```

1.2.9.3.5.3 MBRDisjoint

Syntax

```
MBRDisjoint(g1,g2)
```

Description

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries g1 and g2 are disjoint. Two geometries are disjoint if they do not intersect, that is touch or overlap.

Examples

```
SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((4 4,4 7,7 7,7 4,4 4))');
SELECTmbrdisjoint(@g1,@g2);
+----------------------+
| mbrdisjoint(@g1,@g2) |
+----------------------+
|                    1 |
+----------------------+

SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((3 3,3 6,6 6,6 3,3 3))');
SELECT mbrdisjoint(@g1,@g2);
+----------------------+
| mbrdisjoint(@g1,@g2) |
+----------------------+
|                    0 |
+----------------------+
```

1.2.9.3.5.4 MBREqual

Syntax

```
MBREqual(g1,g2)
```

Description

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries g1 and g2 are the same.

Examples

```
SET @g1=GEOMFROMTEXT('LINESTRING(0 0, 1 2)');
SET @g2=GEOMFROMTEXT('POLYGON((0 0, 0 2, 1 2, 1 0, 0 0))');
SELECT MbrEqual(@g1,@g2);
+-------------------+
| MbrEqual(@g1,@g2) |
+-------------------+
|                 1 |
+-------------------+

SET @g1=GEOMFROMTEXT('LINESTRING(0 0, 1 3)');
SET @g2=GEOMFROMTEXT('POLYGON((0 0, 0 2, 1 4, 1 0, 0 0))');
SELECT MbrEqual(@g1,@g2);
+-------------------+
| MbrEqual(@g1,@g2) |
+-------------------+
|                 0 |
+-------------------+
```

1.2.9.3.5.5 MBRIntersects

Syntax

```
MBRIntersects(g1,g2)
```

Description

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries g1 and g2 intersect.

Examples

```
SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((3 3,3 6,6 6,6 3,3 3))');
SELECT mbrintersects(@g1,@g2);
+------------------------+
| mbrintersects(@g1,@g2) |
+------------------------+
|                      1 |
+------------------------+

SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((4 4,4 7,7 7,7 4,4 4))');
SELECT mbrintersects(@g1,@g2);
+------------------------+
| mbrintersects(@g1,@g2) |
+------------------------+
|                      0 |
+------------------------+
```

1.2.9.3.5.6 MBROverlaps

Syntax

```
MBROverlaps(g1,g2)
```

Description

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries `g1` and `g2` overlap. The term spatially overlaps is used if two geometries intersect and their intersection results in a geometry of the same dimension but not equal to either of the given geometries.

Examples

```
SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((4 4,4 7,7 7,7 4,4 4))');
SELECT mbroverlaps(@g1,@g2);
+----------------------+
| mbroverlaps(@g1,@g2) |
+----------------------+
|                    0 |
+----------------------+

SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((3 3,3 6,6 6,6 3,3 3))');
SELECT mbroverlaps(@g1,@g2);
+----------------------+
| mbroverlaps(@g1,@g2) |
+----------------------+
|                    0 |
+----------------------+

SET @g1 = GeomFromText('Polygon((0 0,0 4,4 4,4 0,0 0))');
SET @g2 = GeomFromText('Polygon((3 3,3 6,6 6,6 3,3 3))');
SELECT mbroverlaps(@g1,@g2);
+----------------------+
| mbroverlaps(@g1,@g2) |
+----------------------+
|                    1 |
+----------------------+
```

1.2.9.3.5.7 MBRTouches

Syntax

```
MBRTouches(g1,g2)
```

Description

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangles of the two geometries `g1` and `g2` touch. Two geometries spatially touch if the interiors of the geometries do not intersect, but the boundary of one of the geometries intersects either the boundary or the interior of the other.

Examples

```
SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((4 4,4 7,7 7,7 4,4 4))');
SELECT mbrtouches(@g1,@g2);
+---------------------+
| mbrtouches(@g1,@g2) |
+---------------------+
|                   0 |
+---------------------+

SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((3 3,3 6,6 6,6 3,3 3))');
SELECT mbrtouches(@g1,@g2);
+---------------------+
| mbrtouches(@g1,@g2) |
+---------------------+
|                   1 |
+---------------------+

SET @g1 = GeomFromText('Polygon((0 0,0 4,4 4,4 0,0 0))');
SET @g2 = GeomFromText('Polygon((3 3,3 6,6 6,6 3,3 3))');
SELECT mbrtouches(@g1,@g2);
+---------------------+
| mbrtouches(@g1,@g2) |
+---------------------+
|                   0 |
+---------------------+
```

1.2.9.3.5.8 MBRWithin

Syntax

```
MBRWithin(g1,g2)
```

Description

Returns 1 or 0 to indicate whether the Minimum Bounding Rectangle of g1 is within the Minimum Bounding Rectangle of g2. This tests the opposite relationship as MBRContains().

Examples

```
SET @g1 = GeomFromText('Polygon((0 0,0 3,3 3,3 0,0 0))');
SET @g2 = GeomFromText('Polygon((0 0,0 5,5 5,5 0,0 0))');
SELECT MBRWithin(@g1,@g2), MBRWithin(@g2,@g1);
+--------------------+--------------------+
| MBRWithin(@g1,@g2) | MBRWithin(@g2,@g1) |
+--------------------+--------------------+
|                  1 |                  0 |
+--------------------+--------------------+
```

1.2.9.3.6 Point Properties

Point properties

ST_X

X-coordinate value for a point.

ST_Y

Y-coordinate for a point.

X

Synonym for ST_X.

Y

Synonym for ST_Y.

1.2.9.3.6.1 ST_X

Syntax

```
ST_X(p)
X(p)
```

Description

Returns the X-coordinate value for the point `p` as a double-precision number.

`ST_X()` and `X()` are synonyms.

Examples

```
SET @pt = 'Point(56.7 53.34)';

SELECT X(GeomFromText(@pt));
+----------------------+
| X(GeomFromText(@pt)) |
+----------------------+
|                 56.7 |
+----------------------+
```

1.2.9.3.6.2 ST_Y

Syntax

```
ST_Y(p)
Y(p)
```

Description

Returns the Y-coordinate value for the point p as a double-precision number.

`ST_Y()` and `Y()` are synonyms.

Examples

```
SET @pt = 'Point(56.7 53.34)';

SELECT Y(GeomFromText(@pt));
+----------------------+
| Y(GeomFromText(@pt)) |
+----------------------+
|                53.34 |
+----------------------+
```

1.2.9.3.6.3 X

A synonym for ST_X.

1.2.9.3.6.4 Y

A synonym for ST_Y.

1.2.9.3.7 Polygon Properties

Polygon properties

AREA

Synonym for ST_AREA.

CENTROID

Synonym for ST_CENTROID.

ExteriorRing

Synonym for ST_ExteriorRing.

InteriorRingN

Synonym for ST_InteriorRingN.

NumInteriorRings

Synonym for NumInteriorRings.

ST_AREA

Area of a Polygon.

ST_CENTROID

The mathematical centroid (geometric center) for a MultiPolygon.

ST_ExteriorRing

Returns the exterior ring of a Polygon as a LineString.

ST_InteriorRingN

Returns the N-th interior ring for a Polygon.

ST_NumInteriorRings

Number of interior rings in a Polygon.

1.2.9.3.7.1 AREA

A synonym for ST_AREA.

1.2.9.3.7.2 CENTROID

A synonym for ST_CENTROID.

1.2.9.3.7.3 ExteriorRing

A synonym for ST_ExteriorRing.

1.2.9.3.7.4 InteriorRingN

A synonym for ST_InteriorRingN.

1.2.9.3.7.5 NumInteriorRings

A synonym for ST_NumInteriorRings.

1.2.9.3.7.6 ST_AREA

Syntax

```
ST_Area(poly)
Area(poly)
```

Description

Returns as a double-precision number the area of the Polygon value `poly`, as measured in its spatial reference system.

`ST_Area()` and `Area()` are synonyms.

Examples

```
SET @poly = 'Polygon((0 0,0 3,3 0,0 0),(1 1,1 2,2 1,1 1))';

SELECT Area(GeomFromText(@poly));
+---------------------------+
| Area(GeomFromText(@poly)) |
+---------------------------+
|                         4 |
+---------------------------+
```

1.2.9.3.7.7 ST_CENTROID

Syntax

```
ST_Centroid(mpoly)
Centroid(mpoly)
```

Description

Returns a point reflecting the mathematical centroid (geometric center) for the MultiPolygon *mpoly*. The resulting point will not necessarily be on the MultiPolygon.

`ST_Centroid()` and `Centroid()` are synonyms.

Examples

```
SET @poly = ST_GeomFromText('POLYGON((0 0,20 0,20 20,0 20,0 0))');
SELECT ST_AsText(ST_Centroid(@poly)) AS center;
+--------------+
| center       |
+--------------+
| POINT(10 10) |
+--------------+
```

1.2.9.3.7.8 ST_ExteriorRing

Syntax

```
ST_ExteriorRing(poly)
ExteriorRing(poly)
```

Description

Returns the exterior ring of the Polygon value `poly` as a LineString.

`ST_ExteriorRing()` and `ExteriorRing()` are synonyms.

Examples

```
SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';

SELECT AsText(ExteriorRing(GeomFromText(@poly)));
+------------------------------------------+
| AsText(ExteriorRing(GeomFromText(@poly))) |
+------------------------------------------+
| LINESTRING(0 0,0 3,3 3,3 0,0 0)           |
+------------------------------------------+
```

1.2.9.3.7.9 ST_InteriorRingN

Syntax

```
ST_InteriorRingN(poly,N)
InteriorRingN(poly,N)
```

Description

Returns the N-th interior ring for the Polygon value `poly` as a LineString. Rings are numbered beginning with 1.

`ST_InteriorRingN()` and `InteriorRingN()` are synonyms.

Examples

```
SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';

SELECT AsText(InteriorRingN(GeomFromText(@poly),1));
+---------------------------------------------+
| AsText(InteriorRingN(GeomFromText(@poly),1)) |
+---------------------------------------------+
| LINESTRING(1 1,1 2,2 2,2 1,1 1)              |
+---------------------------------------------+
```

1.2.9.3.7.10 ST_NumInteriorRings

Syntax

```
ST_NumInteriorRings(poly)
NumInteriorRings(poly)
```

Description

Returns an integer containing the number of interior rings in the Polygon value `poly`.

Note that according the the OpenGIS standard, a POLYGON should have exactly one ExteriorRing and all other rings should lie within that ExteriorRing and thus be the InteriorRings. Practically, however, some systems, including MariaDB's, permit polygons to have several 'ExteriorRings'. In the case of there being multiple, non-overlapping exterior rings ST_NumInteriorRings() will return `1`.

`ST_NumInteriorRings()` and `NumInteriorRings()` are synonyms.

Examples

```
SET @poly = 'Polygon((0 0,0 3,3 3,3 0,0 0),(1 1,1 2,2 2,2 1,1 1))';

SELECT NumInteriorRings(GeomFromText(@poly));
+---------------------------------------+
| NumInteriorRings(GeomFromText(@poly)) |
+---------------------------------------+
|                                     1 |
+---------------------------------------+
```

Non-overlapping 'polygon':

```
SELECT ST_NumInteriorRings(ST_PolyFromText('POLYGON((0 0,10 0,10 10,0 10,0 0),
  (-1 -1,-5 -1,-5 -5,-1 -5,-1 -1))')) AS NumInteriorRings;
+------------------+
| NumInteriorRings |
+------------------+
|                1 |
+------------------+
```

1.2.9.3.8 WKB

WKB stands for Well-Known Binary, a standard representation for geometric values.

Well-Known Binary (WKB) Format

Well-Known Binary format for representing geometric data.

AsBinary

Synonym for ST_AsBinary.

AsWKB

Synonym for ST_AsBinary.

MLineFromWKB

Constructs a MULTILINESTRING.

MPointFromWKB

Constructs a MULTIPOINT value using its WKB representation and SRID.

MPolyFromWKB

Constructs a MULTIPOLYGON value using its WKB representation and SRID.

GeomCollFromWKB

Synonym for ST_GeomCollFromWKB.

GeometryCollectionFromWKB

Synonym for ST_GeomCollFromWKB.

GeometryFromWKB

Synonym for ST_GeomFromWKB.

GeomFromWKB

Synonym for ST_GeomFromWKB.

LineFromWKB

Synonym for ST_LineFromWKB.

LineStringFromWKB

Synonym for ST_LineFromWKB.

MultiLineStringFromWKB
A synonym for MLineFromWKB.

MultiPointFromWKB
Synonym for MPointFromWKB.

MultiPolygonFromWKB
Synonym for MPolyFromWKB.

PointFromWKB
Synonym for PointFromWKB.

PolyFromWKB
Synonym for ST_PolyFromWKB.

PolygonFromWKB
Synonym for ST_PolyFromWKB.

ST_AsBinary
Converts a value to its WKB representation.

ST_AsWKB
Synonym for ST_AsBinary.

ST_GeomCollFromWKB
Constructs a GEOMETRYCOLLECTION value from a WKB.

ST_GeometryCollectionFromWKB
Synonym for ST_GeomCollFromWKB.

ST_GeometryFromWKB
Synonym for ST_GeomFromWKB.

ST_GeomFromWKB
Constructs a geometry value using its WKB representation and SRID.

ST_LineFromWKB
Constructs a LINESTRING using its WKB and SRID.

ST_LineStringFromWKB
Synonym for ST_LineFromWKB.

ST_PointFromWKB
Constructs POINT using its WKB and SRID.

ST_PolyFromWKB
Constructs POLYGON value using its WKB representation and SRID.

ST_PolygonFromWKB
Synonym for ST_PolyFromWKB.

1.2.9.3.8.1 Well-Known Binary (WKB) Format

WKB stands for Well-Known Binary, a format for representing geographical and geometrical data.

WKB uses 1-byte unsigned integers, 4-byte unsigned integers, and 8-byte double-precision numbers.

- The first byte indicates the byte order. 00 for big endian, or 01 for little endian.
- The next 4 bytes indicate the geometry type. Values from 1 to 7 indicate whether the type is Point, LineString, Polygon, MultiPoint, MultiLineString, MultiPolygon, or GeometryCollection respectively.
- The 8-byte floats represent the co-ordinates.

Take the following example, a sequence of 21 bytes each represented by two hex digits:

```
000000000140000000000000004010000000000000
```

- It's big endian
  - 00**00000000140000000000000004010000000000000**
- It's a POINT
  - 00**00000001**40000000000000004010000000000000
- The X co-ordinate is 2.0
  - 00000000001**40000000000000000**4010000000000000
- The Y-co-ordinate is 4.0
  - 00000000014000000000000000**4010000000000000**

1.2.9.3.8.2 AsBinary

A synonym for ST_AsBinary().

1.2.9.3.8.3 AsWKB

A synonym for ST_AsBinary().

1.2.9.3.8.4 MLineFromWKB

Syntax

```
MLineFromWKB(wkb[,srid])
MultiLineStringFromWKB(wkb[,srid])
```

Description

Constructs a MULTILINESTRING value using its WKB representation and SRID.

`MLineFromWKB()` and `MultiLineStringFromWKB()` are synonyms.

Examples

```
SET @g = ST_AsBinary(MLineFromText('MULTILINESTRING((10 48,10 21,10 0),(16 0,16 23,16 48))'));

SELECT ST_AsText(MLineFromWKB(@g));
+-----------------------------------------------------+
| ST_AsText(MLineFromWKB(@g))                         |
+-----------------------------------------------------+
| MULTILINESTRING((10 48,10 21,10 0),(16 0,16 23,16 48)) |
+-----------------------------------------------------+
```

1.2.9.3.8.5 MPointFromWKB

Syntax

```
MPointFromWKB(wkb[,srid])
MultiPointFromWKB(wkb[,srid])
```

Description

Constructs a MULTIPOINT value using its WKB representation and SRID.

`MPointFromWKB()` and `MultiPointFromWKB()` are synonyms.

Examples

```
SET @g = ST_AsBinary(MPointFromText('MultiPoint( 1 1, 2 2, 5 3, 7 2, 9 3, 8 4, 6 6, 6 9, 4 9, 1 5

SELECT ST_AsText(MPointFromWKB(@g));
+-------------------------------------------------+
| ST_AsText(MPointFromWKB(@g))                    |
+-------------------------------------------------+
| MULTIPOINT(1 1,2 2,5 3,7 2,9 3,8 4,6 6,6 9,4 9,1 5) |
+-------------------------------------------------+
```

1.2.9.3.8.6 MPolyFromWKB

Syntax

```
MPolyFromWKB(wkb[,srid])
MultiPolygonFromWKB(wkb[,srid])
```

Description

Constructs a MULTIPOLYGON value using its WKB representation and SRID.

`MPolyFromWKB()` and `MultiPolygonFromWKB()` are synonyms.

Examples

```
SET @g = ST_AsBinary(MPointFromText('MULTIPOLYGON(((28 26,28 0,84 0,84 42,28 26),(52 18,66
23,73 9,48 6,52 18)),((59 18,67 18,67 13,59 13,59 18)))'));

SELECT ST_AsText(MPolyFromWKB(@g))\G
*************************** 1. row ***************************
ST_AsText(MPolyFromWKB(@g)): MULTIPOLYGON(((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48
6,52 18)),((59 18,67 18,67 13,59 13,59 18)))
```

1.2.9.3.8.7 GeomCollFromWKB

A synonym for ST_GeomCollFromWKB.

1.2.9.3.8.8 GeometryCollectionFromWKB

A synonym for ST_GeomCollFromWKB.

1.2.9.3.8.9 GeometryFromWKB

A synonym for ST_GeomFromWKB.

1.2.9.3.8.10 GeomFromWKB

A synonym for ST_GeomFromWKB.

1.2.9.3.8.11 LineFromWKB

A synonym for ST_LineFromWKB.

1.2.9.3.8.12 LineStringFromWKB

A synonym for ST_LineFromWKB.

1.2.9.3.8.13 MultiLineStringFromWKB

A synonym for MLineFromWKB().

1.2.9.3.8.14 MultiPointFromWKB

A synonym for MPointFromWKB.

1.2.9.3.8.15 MultiPolygonFromWKB

Synonym for MPolyFromWKB.

1.2.9.3.8.16 PointFromWKB

A synonym for ST_PointFromWKB.

1.2.9.3.8.17 PolyFromWKB

A synonym for ST_PolyFromWKB.

1.2.9.3.8.18 PolygonFromWKB

A synonym for ST_PolyFromWKB.

1.2.9.3.8.19 ST_AsBinary

Syntax

```
ST_AsBinary(g)
AsBinary(g)
ST_AsWKB(g)
AsWKB(g)
```

Description

Converts a value in internal geometry format to its WKB representation and returns the binary result.

`ST_AsBinary()`, `AsBinary()`, `ST_AsWKB()` and `AsWKB()` are synonyms,

Examples

```
SET @poly = ST_GeomFromText('POLYGON((0 0,0 1,1 1,1 0,0 0))');
SELECT ST_AsBinary(@poly);

SELECT ST_AsText(ST_GeomFromWKB(ST_AsWKB(@poly)));
+-------------------------------------------+
| ST_AsText(ST_GeomFromWKB(ST_AsWKB(@poly))) |
+-------------------------------------------+
| POLYGON((0 0,0 1,1 1,1 0,0 0))             |
+-------------------------------------------+
```

1.2.9.3.8.20 ST_AsWKB

A synonym for ST_AsBinary().

1.2.9.3.8.21 ST_GeomCollFromWKB

Syntax

```
ST_GeomCollFromWKB(wkb[,srid])
ST_GeometryCollectionFromWKB(wkb[,srid])
GeomCollFromWKB(wkb[,srid])
GeometryCollectionFromWKB(wkb[,srid])
```

Description

Constructs a GEOMETRYCOLLECTION value using its WKB representation and SRID.

`ST_GeomCollFromWKB()`, `ST_GeometryCollectionFromWKB()`, `GeomCollFromWKB()` and `GeometryCollectionFromWKB()` are synonyms.

Examples

```
SET @g = ST_AsBinary(ST_GeomFromText('GEOMETRYCOLLECTION(
   POLYGON((5 5,10 5,10 10,5 5)),POINT(10 10))'));

SELECT ST_AsText(ST_GeomCollFromWKB(@g));
+-----------------------------------------------------------------+
| ST_AsText(ST_GeomCollFromWKB(@g))                               |
+-----------------------------------------------------------------+
| GEOMETRYCOLLECTION(POLYGON((5 5,10 5,10 10,5 5)),POINT(10 10)) |
+-----------------------------------------------------------------+
```

1.2.9.3.8.22 ST_GeometryCollectionFromWKB

A synonym for ST_GeomCollFromWKB.

1.2.9.3.8.23 ST_GeometryFromWKB

A synonym for ST_GeomFromWKB.

1.2.9.3.8.24 ST_GeomFromWKB

Syntax

```
ST_GeomFromWKB(wkb[,srid])
ST_GeometryFromWKB(wkb[,srid])
GeomFromWKB(wkb[,srid])
GeometryFromWKB(wkb[,srid])
```

Description

Constructs a geometry value of any type using its WKB representation and SRID.

`ST_GeomFromWKB()`, `ST_GeometryFromWKB()`, `GeomFromWKB()` and `GeometryFromWKB()` are synonyms.

Examples

```
SET @g = ST_AsBinary(ST_LineFromText('LINESTRING(0 4, 4 6)'));

SELECT ST_AsText(ST_GeomFromWKB(@g));
+------------------------------+
| ST_AsText(ST_GeomFromWKB(@g)) |
+------------------------------+
| LINESTRING(0 4,4 6)          |
+------------------------------+
```

1.2.9.3.8.25 ST_LineFromWKB

Syntax

```
ST_LineFromWKB(wkb[,srid])
LineFromWKB(wkb[,srid])
ST_LineStringFromWKB(wkb[,srid])
LineStringFromWKB(wkb[,srid])
```

Description

Constructs a LINESTRING value using its WKB representation and SRID.

`ST_LineFromWKB()`, `LineFromWKB()`, `ST_LineStringFromWKB()`, and `LineStringFromWKB()` are synonyms.

Examples

```
SET @g = ST_AsBinary(ST_LineFromText('LineString(0 4,4 6)'));

SELECT ST_AsText(ST_LineFromWKB(@g)) AS l;
+---------------------+
| l                   |
+---------------------+
| LINESTRING(0 4,4 6) |
+---------------------+
```

1.2.9.3.8.26 ST_LineStringFromWKB

A synonym for ST_LineFromWKB.

1.2.9.3.8.27 ST_PointFromWKB

Syntax

```
ST_PointFromWKB(wkb[,srid])
PointFromWKB(wkb[,srid])
```

Description

Constructs a POINT value using its WKB representation and SRID.

`ST_PointFromWKB()` and `PointFromWKB()` are synonyms.

Examples

```
SET @g = ST_AsBinary(ST_PointFromText('POINT(0 4)'));

SELECT ST_AsText(ST_PointFromWKB(@g)) AS p;
+------------+
| p          |
+------------+
| POINT(0 4) |
+------------+
```

1.2.9.3.8.28 ST_PolyFromWKB

Syntax

```
ST_PolyFromWKB(wkb[,srid])
ST_PolygonFromWKB(wkb[,srid])
PolyFromWKB(wkb[,srid])
PolygonFromWKB(wkb[,srid])
```

Description

Constructs a POLYGON value using its WKB representation and SRID.

`ST_PolyFromWKB()`, `ST_PolygonFromWKB()`, `PolyFromWKB()` and `PolygonFromWKB()` are synonyms.

Examples

```
SET @g = ST_AsBinary(ST_PolyFromText('POLYGON((1 1,1 5,4 9,6 9,9 3,7 2,1 1))'));

SELECT ST_AsText(ST_PolyFromWKB(@g)) AS p;
+--------------------------------------+
| p                                    |
+--------------------------------------+
| POLYGON((1 1,1 5,4 9,6 9,9 3,7 2,1 1)) |
+--------------------------------------+
```

1.2.9.3.8.29 ST_PolygonFromWKB

A synonym for ST_PolyFromWKB.

1.2.9.3.9 WKT

The Well-Known Text (WKT) representation of Geometry is designed to exchange geometry data in ASCII form. This section has articles on WKT in MariaDB.

WKT Definition
Well-Known Text for exchanging geometry data in ASCII form.

AsText
Synonym for ST_AsText.

AsWKT
Synonym for ST_AsText.

GeomCollFromText
Synonym for ST_GeomCollFromText.

GeometryCollectionFromText
Synonym for ST_GeomCollFromText.

GeometryFromText
Synonym for ST_GeomFromText.

GeomFromText
Synonym for ST_GeomFromText.

LineFromText
Synonym for ST_LineFromText.

LineStringFromText
Synonym for ST_LineFromText.

MLineFromText
Constructs MULTILINESTRING using its WKT representation and SRID.

MPointFromText
Constructs a MULTIPOINT value using its WKT and SRID.

MPolyFromText
Constructs a MULTIPOLYGON value.

MultiLineStringFromText
Synonym for MLineFromText.

MultiPointFromText
Synonym for MPointFromText.

MultiPolygonFromText
Synonym for MPolyFromText.

PointFromText
Synonym for ST_PointFromText.

PolyFromText
Synonym for ST_PolyFromText.

PolygonFromText
Synonym for ST_PolyFromText.

ST_AsText
Converts a value to its WKT-Definition.

ST_ASWKT
Synonym for ST_ASTEXT().

ST_GeomCollFromText
Constructs a GEOMETRYCOLLECTION value.

ST_GeometryCollectionFromText
Synonym for ST_GeomCollFromText.

ST_GeometryFromText
Synonym for ST_GeomFromText.

ST_GeomFromText
Constructs a geometry value using its WKT and SRID.

ST_LineFromText
Creates a linestring value.

ST_LineStringFromText
Synonym for ST_LineFromText.

ST_PointFromText
Constructs a POINT value.

ST_PolyFromText
Constructs a POLYGON value.

ST_PolygonFromText
Synonym for ST_PolyFromText.

1.2.9.3.9.1 WKT Definition

Description

The Well-Known Text (WKT) representation of Geometry is designed to exchange geometry data in ASCII form. Examples of the basic geometry types include:

Geometry Types
POINT
LINESTRING
POLYGON
MULTIPOINT
MULTILINESTRING
MULTIPOLYGON
GEOMETRYCOLLECTION
GEOMETRY

1.2.9.3.9.2 AsText

A synonym for ST_AsText().

1.2.9.3.9.3 AsWKT

A synonym for ST_AsText().

1.2.9.3.9.4 GeomCollFromText

A synonym for ST_GeomCollFromText.

1.2.9.3.9.5 GeometryCollectionFromText

A synonym for ST_GeomCollFromText.

1.2.9.3.9.6 GeometryFromText

A synonym for ST_GeomFromText.

1.2.9.3.9.7 GeomFromText

A synonym for ST_GeomFromText.

1.2.9.3.9.8 LineFromText

A synonym for ST_LineFromText.

1.2.9.3.9.9 LineStringFromText

A synonym for ST_LineFromText.

1.2.9.3.9.10 MLineFromText

Syntax

```
MLineFromText(wkt[,srid])
MultiLineStringFromText(wkt[,srid])
```

Description

Constructs a MULTILINESTRING value using its WKT representation and SRID.

`MLineFromText()` and `MultiLineStringFromText()` are synonyms.

Examples

```
CREATE TABLE gis_multi_line (g MULTILINESTRING);
SHOW FIELDS FROM gis_multi_line;
INSERT INTO gis_multi_line VALUES
    (MultiLineStringFromText('MULTILINESTRING((10 48,10 21,10 0),(16 0,16 23,16 48))')),
    (MLineFromText('MULTILINESTRING((10 48,10 21,10 0))')),
    (MLineFromWKB(AsWKB(MultiLineString(
      LineString(Point(1, 2), Point(3, 5)),
      LineString(Point(2, 5), Point(5, 8), Point(21, 7))))));
```

1.2.9.3.9.11 MPointFromText

Syntax

```
MPointFromText(wkt[,srid])
MultiPointFromText(wkt[,srid])
```

Description

Constructs a MULTIPOINT value using its WKT representation and SRID.

`MPointFromText()` and `MultiPointFromText()` are synonyms.

Examples

```
CREATE TABLE gis_multi_point (g MULTIPOINT);
SHOW FIELDS FROM gis_multi_point;
INSERT INTO gis_multi_point VALUES
    (MultiPointFromText('MULTIPOINT(0 0,10 10,10 20,20 20)')),
    (MPointFromText('MULTIPOINT(1 1,11 11,11 21,21 21)')),
    (MPointFromWKB(AsWKB(MultiPoint(Point(3, 6), Point(4, 10)))));
```

1.2.9.3.9.12 MPolyFromText

Syntax

```
MPolyFromText(wkt[,srid])
MultiPolygonFromText(wkt[,srid])
```

Description

Constructs a MULTIPOLYGON value using its WKT representation and SRID.

`MPolyFromText()` and `MultiPolygonFromText()` are synonyms.

Examples

```
CREATE TABLE gis_multi_polygon  (g MULTIPOLYGON);
SHOW FIELDS FROM gis_multi_polygon;
INSERT INTO gis_multi_polygon VALUES
    (MultiPolygonFromText('MULTIPOLYGON(
       ((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48 6,52 18)),
       ((59 18,67 18,67 13,59 13,59 18)))')),
    (MPolyFromText('MULTIPOLYGON(
       ((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48 6,52 18)),
       ((59 18,67 18,67 13,59 13,59 18)))')),
    (MPolyFromWKB(AsWKB(MultiPolygon(Polygon(
       LineString(Point(0, 3), Point(3, 3), Point(3, 0), Point(0, 3)))))));
```

1.2.9.3.9.13 MultiLineStringFromText

A synonym for MLineFromText.

1.2.9.3.9.14 MultiPointFromText

A synonym for MPointFromText.

1.2.9.3.9.15 MultiPolygonFromText

A synonym for MPolyFromText.

1.2.9.3.9.16 PointFromText

A synonym for ST_PointFromText.

1.2.9.3.9.17 PolyFromText

A synonym for ST_PolyFromText.

1.2.9.3.9.18 PolygonFromText

A synonym for ST_PolyFromText.

1.2.9.3.9.19 ST_AsText

Syntax

```
ST_AsText(g)
AsText(g)
ST_AsWKT(g)
AsWKT(g)
```

Description

Converts a value in internal geometry format to its WKT representation and returns the string result.

`ST_AsText()`, `AsText()`, `ST_AsWKT()` and `AsWKT()` are all synonyms.

Examples

```
SET @g = 'LineString(1 1,4 4,6 6)';

SELECT ST_AsText(ST_GeomFromText(@g));
+--------------------------------+
| ST_AsText(ST_GeomFromText(@g)) |
+--------------------------------+
| LINESTRING(1 1,4 4,6 6)        |
+--------------------------------+
```

1.2.9.3.9.20 ST_ASWKT

A synonym for ST_ASTEXT().

1.2.9.3.9.21 ST_GeomCollFromText

Syntax

```
ST_GeomCollFromText(wkt[,srid])
ST_GeometryCollectionFromText(wkt[,srid])
GeomCollFromText(wkt[,srid])
GeometryCollectionFromText(wkt[,srid])
```

Description

Constructs a GEOMETRYCOLLECTION value using its WKT representation and SRID.

`ST_GeomCollFromText()`, `ST_GeometryCollectionFromText()`, `GeomCollFromText()` and `GeometryCollectionFromText()` are all synonyms.

Example

```
CREATE TABLE gis_geometrycollection  (g GEOMETRYCOLLECTION);
SHOW FIELDS FROM gis_geometrycollection;
INSERT INTO gis_geometrycollection VALUES
    (GeomCollFromText('GEOMETRYCOLLECTION(POINT(0 0), LINESTRING(0 0,10 10))')),
    (GeometryFromWKB(AsWKB(GeometryCollection(Point(44, 6), LineString(Point(3, 6), Point(7, 9))))),
    (GeomFromText('GeometryCollection()')),
    (GeomFromText('GeometryCollection EMPTY'));
```

1.2.9.3.9.22 ST_GeometryCollectionFromText

A synonym for ST_GeomCollFromText.

1.2.9.3.9.23 ST_GeometryFromText

A synonym for ST_GeomFromText.

1.2.9.3.9.24 ST_GeomFromText

Syntax

```
ST_GeomFromText(wkt[,srid])
ST_GeometryFromText(wkt[,srid])
GeomFromText(wkt[,srid])
GeometryFromText(wkt[,srid])
```

Description

Constructs a geometry value of any type using its WKT representation and SRID.

`GeomFromText()`, `GeometryFromText()`, `ST_GeomFromText()` and `ST_GeometryFromText()` are all synonyms.

Example

```
SET @g = ST_GEOMFROMTEXT('POLYGON((1 1,1 5,4 9,6 9,9 3,7 2,1 1))');
```

1.2.9.3.9.25 ST_LineFromText

Syntax

```
ST_LineFromText(wkt[,srid])
ST_LineStringFromText(wkt[,srid])
LineFromText(wkt[,srid])
LineStringFromText(wkt[,srid])
```

Description

Constructs a LINESTRING value using its WKT representation and SRID.

`ST_LineFromText()`, `ST_LineStringFromText()`, `ST_LineFromText()` and `ST_LineStringFromText()` are all synonyms.

Examples

```
CREATE TABLE gis_line  (g LINESTRING);
SHOW FIELDS FROM gis_line;
INSERT INTO gis_line VALUES
    (LineFromText('LINESTRING(0 0,0 10,10 0)')),
    (LineStringFromText('LINESTRING(10 10,20 10,20 20,10 20,10 10)')),
    (LineStringFromWKB(AsWKB(LineString(Point(10, 10), Point(40, 10)))));
```

1.2.9.3.9.26 ST_LineStringFromText

A synonym for ST_LineFromText.

1.2.9.3.9.27 ST_PointFromText

Syntax

```
ST_PointFromText(wkt[,srid])
PointFromText(wkt[,srid])
```

Description

Constructs a POINT value using its WKT representation and SRID.

`ST_PointFromText()` and `PointFromText()` are synonyms.

Examples

```
CREATE TABLE gis_point  (g POINT);
SHOW FIELDS FROM gis_point;
INSERT INTO gis_point VALUES
    (PointFromText('POINT(10 10)')),
    (PointFromText('POINT(20 10)')),
    (PointFromText('POINT(20 20)')),
    (PointFromWKB(AsWKB(PointFromText('POINT(10 20)'))));
```

1.2.9.3.9.28 ST_PolyFromText

Syntax

```
ST_PolyFromText(wkt[,srid])
ST_PolygonFromText(wkt[,srid])
PolyFromText(wkt[,srid])
PolygonFromText(wkt[,srid])
```

Description

Constructs a POLYGON value using its WKT representation and SRID.

`ST_PolyFromText()`, `ST_PolygonFromText()`, `PolyFromText()` and `ST_PolygonFromText()` are all synonyms.

Examples

```
CREATE TABLE gis_polygon   (g POLYGON);
INSERT INTO gis_polygon VALUES
    (PolygonFromText('POLYGON((10 10,20 10,20 20,10 20,10 10))')),
    (PolyFromText('POLYGON((0 0,50 0,50 50,0 50,0 0), (10 10,20 10,20 20,10 20,10 10))'));
```

1.2.9.3.9.29 ST_PolygonFromText

A synonym for ST_PolyFromText.

1.2.9.4 JSON Functions

Functions relating to JSON, such as JSON_VALUE, JSON_ARRAY etc.

Differences between JSON_QUERY and JSON_VALUE

Comparison between and examples with JSON_QUERY and JSON_VALUE.

JSONPath Expressions

MariaDB JSONPath description and definition.

JSON_ARRAY

Returns a JSON array containing the listed values.

JSON_ARRAYAGG

Returns a JSON array containing an element for each value in a given set of JSON or SQL values.

JSON_ARRAY_APPEND

Appends values to the end of the given arrays within a JSON document.

JSON_ARRAY_INSERT

Inserts a value into a JSON document.

JSON_ARRAY_INTERSECT

Finds intersection between two arrays.

JSON_COMPACT

Removes all unnecessary spaces so the json document is as short as possible.

JSON_CONTAINS

Whether a value is found in a given JSON document or at a specified path within the document.

JSON_CONTAINS_PATH

Indicates whether the given JSON document contains data at the specified path or paths.

JSON_DEPTH

Maximum depth of a JSON document.

JSON_DETAILED

Represents JSON in the most understandable way emphasizing nested structures.

JSON_EQUALS

Checks if there is equality between two json objects.

JSON_EXISTS

Determines whether a specified JSON value exists in the given data.

JSON_EXTRACT

Extracts data from a JSON document.

JSON_INSERT

Inserts data into a JSON document.

JSON_KEYS

Returns keys from top-level value of a JSON object or top-level keys from the path.

JSON_LENGTH

Returns the length of a JSON document, or the length of a value within the document.

JSON_LOOSE

Adds spaces to a JSON document to make it look more readable.

JSON_MERGE

Merges the given JSON documents.

JSON_MERGE_PATCH

RFC 7396-compliant merge of the given JSON documents.

JSON_MERGE_PRESERVE

Synonym for JSON_MERGE.

JSON_NORMALIZE

Recursively sorts keys and removes spaces, allowing comparison of json documents for equality.

JSON_OBJECT

Returns a JSON object containing the given key/value pairs.

JSON_OBJECT_FILTER_KEYS

Returns keys from the object that are present in the array.

JSON_OBJECT_TO_ARRAY

Converts JSON objects to JSON array where each item represents each key-value pair from object.

JSON_OBJECTAGG

Returns a JSON object containing key-value pairs.

JSON_OVERLAPS

Returns true if two json documents have at least one key-value pair or array element in common.

JSON_PRETTY

Alias for JSON_DETAILED.

JSON_QUERY

Given a JSON document, returns an object or array specified by the path.

JSON_QUOTE

Quotes a string as a JSON value.

JSON_REMOVE

Removes data from a JSON document.

JSON_REPLACE

Replaces existing values in a JSON document.

JSON_SCHEMA_VALID

JSON schema validation.

JSON_SEARCH

Returns the path to the given string within a JSON document.

JSON_SET

Updates or inserts data into a JSON document.

JSON_TABLE

Given data from a JSON document, returns a representation of it as a relational table.

JSON_TYPE

Returns the type of a JSON value.

JSON_UNQUOTE

Unquotes a JSON value, returning a string.

JSON_VALID

Whether a value is a valid JSON document or not.

JSON_VALUE

Given a JSON document, returns the specified scalar.

There are 6 related questions.

1.2.9.4.1 Differences between JSON_QUERY and JSON_VALUE

The primary difference between the two functions is that *JSON_QUERY* returns an object or an array, while *JSON_VALUE* returns a scalar.

Take the following JSON document as an example

```
SET @json='{ "x": [0,1], "y": "[0,1]", "z": "Monty" }';
```

Note that data member "x" is an array, and data members "y" and "z" are strings. The following examples demonstrate the differences between the two functions.

```
SELECT JSON_QUERY(@json,'$'), JSON_VALUE(@json,'$');
+-----------------------------------------+-----------------------+
| JSON_QUERY(@json,'$')                   | JSON_VALUE(@json,'$') |
+-----------------------------------------+-----------------------+
| { "x": [0,1], "y": "[0,1]", "z": "Monty" } | NULL                  |
+-----------------------------------------+-----------------------+

SELECT JSON_QUERY(@json,'$.x'), JSON_VALUE(@json,'$.x');
+-------------------------+-------------------------+
| JSON_QUERY(@json,'$.x') | JSON_VALUE(@json,'$.x') |
+-------------------------+-------------------------+
| [0,1]                   | NULL                    |
+-------------------------+-------------------------+

SELECT JSON_QUERY(@json,'$.y'), JSON_VALUE(@json,'$.y');
+-------------------------+-------------------------+
| JSON_QUERY(@json,'$.y') | JSON_VALUE(@json,'$.y') |
+-------------------------+-------------------------+
| NULL                    | [0,1]                   |
+-------------------------+-------------------------+

SELECT JSON_QUERY(@json,'$.z'), JSON_VALUE(@json,'$.z');
+-------------------------+-------------------------+
| JSON_QUERY(@json,'$.z') | JSON_VALUE(@json,'$.z') |
+-------------------------+-------------------------+
| NULL                    | Monty                   |
+-------------------------+-------------------------+

SELECT JSON_QUERY(@json,'$.x[0]'), JSON_VALUE(@json,'$.x[0]');
+----------------------------+----------------------------+
| JSON_QUERY(@json,'$.x[0]') | JSON_VALUE(@json,'$.x[0]') |
+----------------------------+----------------------------+
| NULL                       | 0                          |
+----------------------------+----------------------------+
```

1.2.9.4.2 JSONPath Expressions

Contents

A number of JSON functions accept JSON Path expressions. MariaDB defines this path as follows:

JSON Path Syntax

```
path : ['lax'] '$' [step]*
```

The path starts with an optional *path mode*. At the moment, MariaDB supports only the "lax" mode, which is also the mode that is used when it is not explicitly specified.

The `$` symbol represents the context item. The search always starts from the context item; because of that, the path always starts with `$`.

Then, it is followed by zero or more steps, which select element(s) in the JSON document. A step may be one of the following:

- Object member selector
- Array element selector
- Wildcard selector

Object Member Selector

To select member(s) in a JSON object, one can use one of the following:

- `.memberName` selects the value of the member with name memberName.
- `."memberName"` - the same as above but allows one to select a member with a name that's not a valid identifier (that is, has space, dot, and/or other characters)
- `.*` - selects the values of all members of the object.

If the current item is an array (instead of an object), nothing will be selected.

Array Element Selector

To select elements of an array, one can use one of the following:

- `[N]` selects element number N in the array. The elements are counted from zero.
- `[*]` selects all elements in the array.

If the current item is an object (instead of an array), nothing will be selected.

Starting from MariaDB server 10.9, JSON path also supports negative index in array, 'last' keyword and range notation ('to' keyword) for accessing array elements. Negative index starts from -1.

- `[-N]` selects n th element from end.
- `[last-N]` selects n th element from the last element.
- `[M to N]` selects range of elements starting from index M to N.

Example:

```
SET @json='{
            "A": [0,
                  [1, 2, 3],
                  [4, 5, 6],
                  "seven",
                   0.8,
                   true,
                   false,
                   "eleven",
                  [12, [13, 14], {"key1":"value1"},[15]],
                  true],
            "B": {"C": 1},
            "D": 2
           }';
SELECT JSON_EXTRACT(@json, '$.A[-8][1]');
+---------------------------------------------------+
| JSON_EXTRACT(@json, '$.A[-8][1]')                 |
+---------------------------------------------------+
| 5                                                 |
+---------------------------------------------------+

SELECT JSON_EXTRACT(@json, '$.A[last-7][1]');
+-----------------------------------------------+
| SELECT JSON_EXTRACT(@json, '$.A[last-7][1]'); |
+-----------------------------------------------+
| 5                                             |
+-----------------------------------------------+

SET @json= '[
             [1, {"key1": "value1"}, 3],
             [false, 5, 6],
             [7, 8, [9, {"key2": 2}, 11]],
             [15, 1.34, [14], ["string1", [16, {"key1":[1,2,3,[4,5,6]]}, 18]]],
             [19, 20],
             21, 22
            ]';

SELECT JSON_EXTRACT(@json, '$[0 to 3][2]');
+-----------------------------------------------+
| JSON_EXTRACT(@json, '$[0 to 3][2]')           |
+-----------------------------------------------+
| [3, 6, [9, {"key2": 2}, 11], [14]]            |
+-----------------------------------------------+
```

This will produce output for first index of eighth from last element of a two dimensional array.

Note: In range notation, when M > N (when M,N are greater than or equal to 0) or (size of array - M or size of array - N when M, N are less than 0), then it is treated as an impossible range and NULL is returned.

```
SET @json= '[1, 2, 3, 4, 5]';
SELECT JSON_EXTRACT(@json, '$[4 to 2]');
+----------------------------------+
| JSON_EXTRACT(@json, '$[4 to 2]') |
+----------------------------------+
| NULL                             |
+----------------------------------+
```

Wildcard

The wildcard step, `**`, recursively selects all child elements of the current element. Both array elements and object members are selected.

The wildcard step must not be the last step in the JSONPath expression. It must be followed by an array or object member selector step.

For example:

```
select json_extract(@json_doc, '$**.price');
```

will select all object members in the document that are named `price`, while

```
select json_extract(@json_doc, '$**[2]');
```

will select the second element in each of the arrays present in the document.

Compatibility

MariaDB's JSONPath syntax supports a subset of JSON Path's definition in the SQL Standard. The most notable things not supported are the `strict` mode and filters.

MariaDB's JSONPath is close to MySQL's JSONPath. The wildcard step (`**`) is a non-standard extension that has the same meaning as in MySQL. The difference between MariaDB and MySQL's JSONPath is: MySQL doesn't allow one to specify the mode explicitly (but uses `lax` mode implicitly).

1.2.9.4.3 JSON_ARRAY

Syntax

```
JSON_ARRAY([value[, value2] ...])
```

Description

Returns a JSON array containing the listed values. The list can be empty.

Example

```
SELECT Json_Array(56, 3.1416, 'My name is "Foo"', NULL);
+--------------------------------------------------+
| Json_Array(56, 3.1416, 'My name is "Foo"', NULL) |
+--------------------------------------------------+
| [56, 3.1416, "My name is \"Foo\"", null]         |
+--------------------------------------------------+
```

1.2.9.4.4 JSON_ARRAYAGG

1.2.9.4.5 JSON_ARRAY_APPEND

Syntax

```
JSON_ARRAY_APPEND(json_doc, path, value[, path, value] ...)
```

Description

Appends values to the end of the specified arrays within a JSON document, returning the result, or NULL if any of the arguments are NULL.

Evaluation is performed from left to right, with the resulting document from the previous pair becoming the new value against which the next pair is evaluated.

If the `json_doc` is not a valid JSON document, or if any of the paths are not valid, or contain a `*` or `**` wildcard, an error is returned.

Examples

```
SET @json = '[1, 2, [3, 4]]';

SELECT JSON_ARRAY_APPEND(@json, '$[0]', 5)
+-------------------------------------+
| JSON_ARRAY_APPEND(@json, '$[0]', 5) |
+-------------------------------------+
| [[1, 5], 2, [3, 4]]                 |
+-------------------------------------+

SELECT JSON_ARRAY_APPEND(@json, '$[1]', 6);
+-------------------------------------+
| JSON_ARRAY_APPEND(@json, '$[1]', 6) |
+-------------------------------------+
| [1, [2, 6], [3, 4]]                 |
+-------------------------------------+

SELECT JSON_ARRAY_APPEND(@json, '$[1]', 6, '$[2]', 7);
+-----------------------------------------------+
| JSON_ARRAY_APPEND(@json, '$[1]', 6, '$[2]', 7) |
+-----------------------------------------------+
| [1, [2, 6], [3, 4, 7]]                        |
+-----------------------------------------------+

SELECT JSON_ARRAY_APPEND(@json, '$', 5);
+----------------------------------+
| JSON_ARRAY_APPEND(@json, '$', 5) |
+----------------------------------+
| [1, 2, [3, 4], 5]                |
+----------------------------------+

SET @json = '{"A": 1, "B": [2], "C": [3, 4]}';

SELECT JSON_ARRAY_APPEND(@json, '$.B', 5);
+-----------------------------------+
| JSON_ARRAY_APPEND(@json, '$.B', 5) |
+-----------------------------------+
| {"A": 1, "B": [2, 5], "C": [3, 4]} |
+-----------------------------------+
```

1.2.9.4.6 JSON_ARRAY_INSERT

Syntax

```
JSON_ARRAY_INSERT(json_doc, path, value[, path, value] ...)
```

Description

Inserts a value into a JSON document, returning the modified document, or NULL if any of the arguments are NULL.

Evaluation is performed from left to right, with the resulting document from the previous pair becoming the new value against which the next pair is evaluated.

If the `json_doc` is not a valid JSON document, or if any of the paths are not valid, or contain a `*` or `**` wildcard, an error is returned.

Examples

```
SET @json = '[1, 2, [3, 4]]';

SELECT JSON_ARRAY_INSERT(@json, '$[0]', 5);
+-----------------------------------+
| JSON_ARRAY_INSERT(@json, '$[0]', 5) |
+-----------------------------------+
| [5, 1, 2, [3, 4]]                 |
+-----------------------------------+

SELECT JSON_ARRAY_INSERT(@json, '$[1]', 6);
+-----------------------------------+
| JSON_ARRAY_INSERT(@json, '$[1]', 6) |
+-----------------------------------+
| [1, 6, 2, [3, 4]]                 |
+-----------------------------------+

SELECT JSON_ARRAY_INSERT(@json, '$[1]', 6, '$[2]', 7);
+-----------------------------------------------+
| JSON_ARRAY_INSERT(@json, '$[1]', 6, '$[2]', 7) |
+-----------------------------------------------+
| [1, 6, 7, 2, [3, 4]]                          |
+-----------------------------------------------+
```

1.2.9.4.7 JSON_ARRAY_INTERSECT

MariaDB starting with 11.2.0

JSON_ARRAY_INTERSECT was added in MariaDB 11.2.0.

Syntax

```
JSON_ARRAY_INTERSECT(arr1, arr2)
```

Description

Finds intersection between two json arrays and returns an array of items found in both array.

Examples

```
SET @json1= '[1,2,3]';
SET @json2= '[1,2,4]';

SELECT json_array_intersect(@json1, @json2);
+-------------------------------------+
| json_array_intersect(@json1, @json2) |
+-------------------------------------+
| [1, 2]                              |
+-------------------------------------+
```

1.2.9.4.8 JSON_COMPACT

Syntax

```
JSON_COMPACT(json_doc)
```

Contents

Description

Removes all unnecessary spaces so the json document is as short as possible.

Example

```
SET @j = '{ "A": 1, "B": [2, 3]}';

SELECT JSON_COMPACT(@j), @j;
+------------------+-----------------------+
| JSON_COMPACT(@j)  | @j                    |
+------------------+-----------------------+
| {"A":1,"B":[2,3]} | { "A": 1, "B": [2, 3]} |
+------------------+-----------------------+
```

1.2.9.4.9 JSON_CONTAINS

Syntax

```
JSON_CONTAINS(json_doc, val[, path])
```

Description

Returns whether or not the specified value is found in the given JSON document or, optionally, at the specified path within the document. Returns `1` if it does, `0` if not and NULL if any of the arguments are null. An error occurs if the document or path is not valid, or contains the `*` or `**` wildcards.

Examples

```
SET @json = '{"A": 0, "B": {"C": 1}, "D": 2}';

SELECT JSON_CONTAINS(@json, '2', '$.A');
+---------------------------------+
| JSON_CONTAINS(@json, '2', '$.A') |
+---------------------------------+
|                               0 |
+---------------------------------+

SELECT JSON_CONTAINS(@json, '2', '$.D');
+---------------------------------+
| JSON_CONTAINS(@json, '2', '$.D') |
+---------------------------------+
|                               1 |
+---------------------------------+

SELECT JSON_CONTAINS(@json, '{"C": 1}', '$.A');
+-------------------------------------+
| JSON_CONTAINS(@json, '{"C": 1}', '$.A') |
+-------------------------------------+
|                                   0 |
+-------------------------------------+

SELECT JSON_CONTAINS(@json, '{"C": 1}', '$.B');
+-------------------------------------+
| JSON_CONTAINS(@json, '{"C": 1}', '$.B') |
+-------------------------------------+
|                                   1 |
+-------------------------------------+
```

1.2.9.4.10 JSON_CONTAINS_PATH

Syntax

```
JSON_CONTAINS_PATH(json_doc, return_arg, path[, path] ...)
```

Description

Indicates whether the given JSON document contains data at the specified path or paths. Returns `1` if it does, `0` if not and NULL if any of the arguments are null.

The *return_arg* can be `one` or `all`:

- `one` - Returns `1` if at least one path exists within the JSON document.
- `all` - Returns `1` only if all paths exist within the JSON document.

Examples

```
SET @json = '{"A": 1, "B": [2], "C": [3, 4]}';

SELECT JSON_CONTAINS_PATH(@json, 'one', '$.A', '$.D');
+-----------------------------------------------+
| JSON_CONTAINS_PATH(@json, 'one', '$.A', '$.D') |
+-----------------------------------------------+
|                                             1 |
+-----------------------------------------------+
1 row in set (0.00 sec)

SELECT JSON_CONTAINS_PATH(@json, 'all', '$.A', '$.D');
+-----------------------------------------------+
| JSON_CONTAINS_PATH(@json, 'all', '$.A', '$.D') |
+-----------------------------------------------+
|                                             0 |
+-----------------------------------------------+
```

1.2.9.4.11 JSON_DEPTH

Syntax

```
JSON_DEPTH(json_doc)
```

Description

Returns the maximum depth of the given JSON document, or NULL if the argument is null. An error will occur if the argument is an invalid JSON document.

- Scalar values or empty arrays or objects have a depth of 1.
- Arrays or objects that are not empty but contain only elements or member values of depth 1 will have a depth of 2.
- In other cases, the depth will be greater than 2.

Examples

```
SELECT JSON_DEPTH('[]'), JSON_DEPTH('true'), JSON_DEPTH('{}');
+------------------+-------------------+------------------+
| JSON_DEPTH('[]') | JSON_DEPTH('true') | JSON_DEPTH('{}') |
+------------------+-------------------+------------------+
|                1 |                 1 |                1 |
+------------------+-------------------+------------------+

SELECT JSON_DEPTH('[1, 2, 3]'), JSON_DEPTH('[[], {}, []]');
+-------------------------+----------------------------+
| JSON_DEPTH('[1, 2, 3]') | JSON_DEPTH('[[], {}, []]') |
+-------------------------+----------------------------+
|                       2 |                          2 |
+-------------------------+----------------------------+

SELECT JSON_DEPTH('[1, 2, [3, 4, 5, 6], 7]');
+---------------------------------------+
| JSON_DEPTH('[1, 2, [3, 4, 5, 6], 7]') |
+---------------------------------------+
|                                     3 |
+---------------------------------------+
```

1.2.9.4.12 JSON_DETAILED

Syntax

```
JSON_DETAILED(json_doc[, tab_size])
JSON_PRETTY(json_doc[, tab_size])
```

Contents

Description

Represents JSON in the most understandable way emphasizing nested structures.

`JSON_PRETTY` was added as an alias for `JSON_DETAILED` in MariaDB 10.10.3, MariaDB 10.9.5, MariaDB 10.8.7, MariaDB 10.7.8, MariaDB 10.6.12, MariaDB 10.5.19 and MariaDB 10.4.28.

Example

```
SET @j = '{ "A":1,"B":[2,3]}';

SELECT @j;
+--------------------+
| @j                 |
+--------------------+
| { "A":1,"B":[2,3]} |
+--------------------+

SELECT JSON_DETAILED(@j);
+------------------------------------------------------------+
| JSON_DETAILED(@j)                                          |
+------------------------------------------------------------+
| {
    "A": 1,
    "B":
    [
        2,
        3
    ]
} |
+------------------------------------------------------------+
```

1.2.9.4.13 JSON_EQUALS

MariaDB starting with 10.7.0
JSON_EQUALS was added in MariaDB 10.7.0

Syntax

```
JSON_EQUALS(json1, json2)
```

Description

Checks if there is equality between two json objects. Returns `1` if it there is, `0` if not, or NULL if any of the arguments are null.

Examples

```
SELECT JSON_EQUALS('{"a"   :[1, 2, 3],"b":[4]}', '{"b":[4],"a":[1, 2, 3.0]}');
+-----------------------------------------------------------------------+
| JSON_EQUALS('{"a"   :[1, 2, 3],"b":[4]}', '{"b":[4],"a":[1, 2, 3.0]}') |
+-----------------------------------------------------------------------+
|                                                                     1 |
+-----------------------------------------------------------------------+

SELECT JSON_EQUALS('{"a":[1, 2, 3]}', '{"a":[1, 2, 3.01]}');
+-------------------------------------------------------+
| JSON_EQUALS('{"a":[1, 2, 3]}', '{"a":[1, 2, 3.01]}') |
+-------------------------------------------------------+
|                                                     0 |
+-------------------------------------------------------+
```

1.2.9.4.14 JSON_EXISTS

Syntax

Description

Determines whether a specified JSON value exists in the given data. Returns `1` if found, `0` if not, or `NULL` if any of the inputs were NULL.

Examples

```
SELECT JSON_EXISTS('{"key1":"xxxx", "key2":[1, 2, 3]}', "$.key2");
+-----------------------------------------------------------+
| JSON_EXISTS('{"key1":"xxxx", "key2":[1, 2, 3]}', "$.key2") |
+-----------------------------------------------------------+
|                                                         1 |
+-----------------------------------------------------------+

SELECT JSON_EXISTS('{"key1":"xxxx", "key2":[1, 2, 3]}', "$.key3");
+-----------------------------------------------------------+
| JSON_EXISTS('{"key1":"xxxx", "key2":[1, 2, 3]}', "$.key3") |
+-----------------------------------------------------------+
|                                                         0 |
+-----------------------------------------------------------+

SELECT JSON_EXISTS('{"key1":"xxxx", "key2":[1, 2, 3]}', "$.key2[1]");
+-------------------------------------------------------------+
| JSON_EXISTS('{"key1":"xxxx", "key2":[1, 2, 3]}', "$.key2[1]") |
+-------------------------------------------------------------+
|                                                           1 |
+-------------------------------------------------------------+

SELECT JSON_EXISTS('{"key1":"xxxx", "key2":[1, 2, 3]}', "$.key2[10]");
+--------------------------------------------------------------+
| JSON_EXISTS('{"key1":"xxxx", "key2":[1, 2, 3]}', "$.key2[10]") |
+--------------------------------------------------------------+
|                                                            0 |
+--------------------------------------------------------------+
```

1.2.9.4.15 JSON_EXTRACT

Contents

Syntax

```
JSON_EXTRACT(json_doc, path[, path] ...)
```

Description

Extracts data from a JSON document. The extracted data is selected from the parts matching the path arguments. Returns all matched values; either as a single matched value, or, if the arguments could return multiple values, a result autowrapped as an array in the matching order.

Returns NULL if no paths match or if any of the arguments are NULL.

An error will occur if any path argument is not a valid path, or if the json_doc argument is not a valid JSON document.

The path expression be a JSONPath expression as supported by MariaDB

Examples

```
SET @json = '[1, 2, [3, 4]]';

SELECT JSON_EXTRACT(@json, '$[1]');
+----------------------------+
| JSON_EXTRACT(@json, '$[1]') |
+----------------------------+
| 2                          |
+----------------------------+

SELECT JSON_EXTRACT(@json, '$[2]');
+----------------------------+
| JSON_EXTRACT(@json, '$[2]') |
+----------------------------+
| [3, 4]                     |
+----------------------------+

SELECT JSON_EXTRACT(@json, '$[2][1]');
+-------------------------------+
| JSON_EXTRACT(@json, '$[2][1]') |
+-------------------------------+
| 4                             |
+-------------------------------+
```

1.2.9.4.16 JSON_INSERT

Syntax

```
JSON_INSERT(json_doc, path, val[, path, val] ...)
```

Contents

Description

Inserts data into a JSON document, returning the resulting document or NULL if either of the *json_doc* or *path* arguments are null.

An error will occur if the JSON document is invalid, or if any of the paths are invalid or contain a `*` or `**` wildcard.

JSON_INSERT can only insert data while JSON_REPLACE can only update. JSON_SET can update or insert data.

Examples

```
SET @json = '{ "A": 0, "B": [1, 2]}';

SELECT JSON_INSERT(@json, '$.C', '[3, 4]');
+-------------------------------------+
| JSON_INSERT(@json, '$.C', '[3, 4]')  |
+-------------------------------------+
| { "A": 0, "B": [1, 2], "C":"[3, 4]"} |
+-------------------------------------+
```

1.2.9.4.17 JSON_KEYS

Syntax

```
JSON_KEYS(json_doc[, path])
```

Description

Returns the keys as a JSON array from the top-level value of a JSON object or, if the optional path argument is provided, the top-level keys from the path.

Excludes keys from nested sub-objects in the top level value. The resulting array will be empty if the selected object is empty.

Returns NULL if any of the arguments are null, a given path does not locate an object, or if the json_doc argument is not an object.

An error will occur if JSON document is invalid, the path is invalid or if the path contains a `*` or `**` wildcard.

Examples

```
SELECT JSON_KEYS('{"A": 1, "B": {"C": 2}}');
+-------------------------------------+
| JSON_KEYS('{"A": 1, "B": {"C": 2}}') |
+-------------------------------------+
| ["A", "B"]                          |
+-------------------------------------+

SELECT JSON_KEYS('{"A": 1, "B": 2, "C": {"D": 3}}', '$.C');
+-----------------------------------------------------+
| JSON_KEYS('{"A": 1, "B": 2, "C": {"D": 3}}', '$.C') |
+-----------------------------------------------------+
| ["D"]                                               |
+-----------------------------------------------------+
```

1.2.9.4.18 JSON_LENGTH

Syntax

```
JSON_LENGTH(json_doc[, path])
```

Description

Returns the length of a JSON document, or, if the optional path argument is given, the length of the value within the document specified by the path.

Returns NULL if any of the arguments argument are null or the path argument does not identify a value in the document.

An error will occur if the JSON document is invalid, the path is invalid or if the path contains a `*` or `**` wildcard.

Length will be determined as follow:

- A scalar's length is always 1.
- If an array, the number of elements in the array.
- If an object, the number of members in the object.

The length of nested arrays or objects are not counted.

Examples

```
```

1.2.9.4.19 JSON_LOOSE

Syntax

```
JSON_LOOSE(json_doc)
```

Description

Adds spaces to a JSON document to make it look more readable.

Example

```
SET @j = '{ "A":1,"B":[2,3]}';

SELECT JSON_LOOSE(@j), @j;
+----------------------+--------------------+
| JSON_LOOSE(@j)       | @j                 |
+----------------------+--------------------+
| {"A": 1, "B": [2, 3]} | { "A":1,"B":[2,3]} |
+----------------------+--------------------+
```

1.2.9.4.20 JSON_MERGE

Syntax

```
JSON_MERGE(json_doc, json_doc[, json_doc] ...)
```

Description

Merges the given JSON documents.

Returns the merged result,or NULL if any argument is NULL.

An error occurs if any of the arguments are not valid JSON documents.

`JSON_MERGE` has been deprecated since MariaDB 10.2.25, MariaDB 10.3.16 and MariaDB 10.4.5. JSON_MERGE_PATCH is an RFC 7396-compliant replacement, and JSON_MERGE_PRESERVE is a synonym.

Example

```
SET @json1 = '[1, 2]';
SET @json2 = '[3, 4]';

SELECT JSON_MERGE(@json1,@json2);
+---------------------------+
| JSON_MERGE(@json1,@json2) |
+---------------------------+
| [1, 2, 3, 4]              |
+---------------------------+
```

1.2.9.4.21 JSON_MERGE_PATCH

Syntax

```
JSON_MERGE_PATCH(json_doc, json_doc[, json_doc] ...)
```

Description

Merges the given JSON documents, returning the merged result, or NULL if any argument is NULL.

`JSON_MERGE_PATCH` is an RFC 7396-compliant replacement for JSON_MERGE, which has been deprecated.

Unlike JSON_MERGE_PRESERVE, members with duplicate keys are not preserved.

Example

```
SET @json1 = '[1, 2]';
SET @json2 = '[2, 3]';
SELECT JSON_MERGE_PATCH(@json1,@json2),JSON_MERGE_PRESERVE(@json1,@json2);
+--------------------------------+-----------------------------------+
| JSON_MERGE_PATCH(@json1,@json2) | JSON_MERGE_PRESERVE(@json1,@json2) |
+--------------------------------+-----------------------------------+
| [2, 3]                         | [1, 2, 2, 3]                      |
+--------------------------------+-----------------------------------+
```

1.2.9.4.22 JSON_MERGE_PRESERVE

Syntax

```
JSON_MERGE_PRESERVE(json_doc, json_doc[, json_doc] ...)
```

Description

Merges the given JSON documents, returning the merged result, or NULL if any argument is NULL.

`JSON_MERGE_PRESERVE` was introduced as a synonym for JSON_MERGE, which has been deprecated.

Unlike JSON_MERGE_PATCH, members with duplicate keys are preserved.

Example

```
SET @json1 = '[1, 2]';
SET @json2 = '[2, 3]';
SELECT JSON_MERGE_PATCH(@json1,@json2),JSON_MERGE_PRESERVE(@json1,@json2);
+--------------------------------+-----------------------------------+
| JSON_MERGE_PATCH(@json1,@json2) | JSON_MERGE_PRESERVE(@json1,@json2) |
+--------------------------------+-----------------------------------+
| [2, 3]                         | [1, 2, 2, 3]                      |
+--------------------------------+-----------------------------------+
```

1.2.9.4.23 JSON_NORMALIZE

MariaDB starting with 10.7.0

JSON_NORMALIZE was added in MariaDB 10.7.0.

Syntax

```
JSON_NORMALIZE(json)
```

Description

Recursively sorts keys and removes spaces, allowing comparison of json documents for equality.

Examples

We may wish our application to use the database to enforce a unique constraint on the JSON contents, and we can do so using the JSON_NORMALIZE function in combination with a unique key.

For example, if we have a table with a JSON column:

```
CREATE TABLE t1 (
 id BIGINT UNSIGNED NOT NULL AUTO_INCREMENT,
 val JSON,
 /* other columns here */
 PRIMARY KEY (id)
);
```

Add a unique constraint using JSON_NORMALIZE like this:

```
ALTER TABLE t1
   ADD COLUMN jnorm JSON AS (JSON_NORMALIZE(val)) VIRTUAL,
   ADD UNIQUE KEY (jnorm);
```

We can test this by first inserting a row as normal:

```
INSERT INTO t1 (val) VALUES ('{"name":"alice","color":"blue"}');
```

And then seeing what happens with a different string which would produce the same JSON object:

```
INSERT INTO t1 (val) VALUES ('{ "color": "blue", "name": "alice" }');
ERROR 1062 (23000): Duplicate entry '{"color":"blue","name":"alice"}' for key 'jnorm'
```

1.2.9.4.24 JSON_OBJECT

Syntax

```
JSON_OBJECT([key, value[, key, value] ...])
```

Description

Returns a JSON object containing the given key/value pairs. The key/value list can be empty.

An error will occur if there are an odd number of arguments, or any key name is NULL.

Example

```
SELECT JSON_OBJECT("id", 1, "name", "Monty");
+---------------------------------------+
| JSON_OBJECT("id", 1, "name", "Monty") |
+---------------------------------------+
| {"id": 1, "name": "Monty"}            |
+---------------------------------------+
```

1.2.9.4.25 JSON_OBJECT_FILTER_KEYS

MariaDB starting with 11.2.0

JSON_OBJECT_FILTER_KEYS was added in MariaDB 11.2.0.

Syntax

```
JSON_OBJECT_FILTER_KEYS(obj, array_keys)
```

Description

`JSON_OBJECT_FILTER_KEYS` returns a JSON object with keys from the object that are also present in the array as string. It is used when one wants to get key-value pair such that the keys are common but the values may not be common.

Example

```
SET @obj1= '{ "a": 1, "b": 2, "c": 3}';
SET @obj2= '{"b" : 10, "c": 20, "d": 30}';
SELECT JSON_OBJECT_FILTER_KEYS (@obj1, JSON_ARRAY_INTERSECT(JSON_KEYS(@obj1), JSON_KEYS(@obj2)));
+-----------------------------------------------------------------------------------------+
| JSON_OBJECT_FILTER_KEYS (@obj1, JSON_ARRAY_INTERSECT(JSON_KEYS(@obj1), JSON_KEYS(@obj2))) |
+-----------------------------------------------------------------------------------------+
| {"b": 2, "c": 3}                                                                        |
+-----------------------------------------------------------------------------------------+
```

1.2.9.4.26 JSON_OBJECT_TO_ARRAY

MariaDB starting with 11.2.0
JSON_OBJECT_TO_ARRAY was added in MariaDB 11.2.0.

Syntax

```
JSON_OBJECT_TO_ARRAY(Obj)
```

Description

It is used to convert all JSON objects found in a JSON document to JSON arrays where each item in the outer array represents a single key-value pair from the object. It is used when we want not just common keys, but also common values. It can be used in conjunction with JSON_ARRAY_INTERSECT().

Examples

```
SET @obj1= '{ "a": [1, 2, 3], "b": { "key1":"val1", "key2": {"key3":"val3"} }}';

SELECT JSON_OBJECT_TO_ARRAY(@obj1);
+-----------------------------------------------------------------------+
| JSON_OBJECT_TO_ARRAY(@obj1)                                           |
+-----------------------------------------------------------------------+
| [["a", [1, 2, 3]], ["b", {"key1": "val1", "key2": {"key3": "val3"}}]] |
+-----------------------------------------------------------------------+
```

1.2.4.10 JSON_OBJECTAGG

1.2.9.4.28 JSON_OVERLAPS

MariaDB starting with 10.9
JSON_OVERLAPS was added in MariaDB 10.9.

Syntax

```
JSON_OVERLAPS(json_doc1, json_doc2)
```

Description

JSON_OVERLAPS() compares two json documents and returns true if they have at least one common key-value pair between two objects, array element common between two arrays, or array element common with scalar if one of the arguments is a scalar and other is an array. If two json documents are scalars, it returns true if they have same type and

value.

If none of the above conditions are satisfied then it returns false.

Examples

```
SELECT JSON_OVERLAPS('false', 'false');
+---------------------------------+
| JSON_OVERLAPS('false', 'false') |
+---------------------------------+
| 1                               |
+---------------------------------+

SELECT JSON_OVERLAPS('true', '["abc", 1, 2, true, false]');
+-----------------------------------------------------+
| JSON_OVERLAPS('true','["abc", 1, 2, true, false]') |
+-----------------------------------------------------+
| 1                                                   |
+-----------------------------------------------------+

SELECT JSON_OVERLAPS('{"A": 1, "B": {"C":2}}', '{"A": 2, "B": {"C":2}}') AS is_overlap;
+---------------------+
| is_overlap          |
+---------------------+
| 1                   |
+---------------------+
```

Partial match is considered as no-match.

Examples

```
SELECT JSON_OVERLAPS('[1, 2, true, false, null]', '[3, 4, [1]]') AS is_overlap;
+---------------------- +
| is_overlap           |
+----------------------+
| 0                    |
+----------------------+
```

1.2.9.4.29 JSON_PRETTY

`JSON_PRETTY` was added as an alias for JSON_DETAILED in MariaDB 10.10.3, MariaDB 10.9.5, MariaDB 10.8.7, MariaDB 10.7.8, MariaDB 10.6.12, MariaDB 10.5.19 and MariaDB 10.4.28.

1.2.9.4.30 JSON_QUERY

Syntax

```
JSON_QUERY(json_doc, path)
```

Description

Given a JSON document, returns an object or array specified by the path. Returns NULL if not given a valid JSON document, or if there is no match.

Examples

```
select json_query('{"key1":{"a":1, "b":[1,2]}}', '$.key1');
+-----------------------------------------------------+
| json_query('{"key1":{"a":1, "b":[1,2]}}', '$.key1') |
+-----------------------------------------------------+
| {"a":1, "b":[1,2]}                                  |
+-----------------------------------------------------+

select json_query('{"key1":123, "key1": [1,2,3]}', '$.key1');
+-----------------------------------------------------+
| json_query('{"key1":123, "key1": [1,2,3]}', '$.key1') |
+-----------------------------------------------------+
| [1,2,3]                                             |
+-----------------------------------------------------+
```

1.2.9.4.31 JSON_QUOTE

Syntax

```
JSON_QUOTE(json_value)
```

Description

Quotes a string as a JSON value, usually for producing valid JSON string literals for inclusion in JSON documents. Wraps the string with double quote characters and escapes interior quotes and other special characters, returning a utf8mb4 string.

Returns NULL if the argument is NULL.

Examples

```
SELECT JSON_QUOTE('A'), JSON_QUOTE("B"), JSON_QUOTE('"C"');
+-----------------+-----------------+-------------------+
| JSON_QUOTE('A') | JSON_QUOTE("B") | JSON_QUOTE('"C"') |
+-----------------+-----------------+-------------------+
| "A"             | "B"             | "\"C\""           |
+-----------------+-----------------+-------------------+
```

1.2.9.4.32 JSON_REMOVE

Syntax

```
JSON_REMOVE(json_doc, path[, path] ...)
```

Contents

Description

Removes data from a JSON document returning the result, or NULL if any of the arguments are null. If the element does not exist in the document, no changes are made.

The function returns NULL and throws a warning if the JSON document is invalid, the path is invalid, contains a range, or contains a `*` or `**` wildcard.

Path arguments are evaluated from left to right, with the result from the earlier evaluation being used as the value for the next.

Examples

```
SELECT JSON_REMOVE('{"A": 1, "B": 2, "C": {"D": 3}}', '$.C');
+-----------------------------------------------------+
| JSON_REMOVE('{"A": 1, "B": 2, "C": {"D": 3}}', '$.C') |
+-----------------------------------------------------+
| {"A": 1, "B": 2}                                    |
+-----------------------------------------------------+

SELECT JSON_REMOVE('["A", "B", ["C", "D"], "E"]', '$[1]');
+-------------------------------------------------+
| JSON_REMOVE('["A", "B", ["C", "D"], "E"]', '$[1]') |
+-------------------------------------------------+
| ["A", ["C", "D"], "E"]                          |
+-------------------------------------------------+
```

1.2.9.4.33 JSON_REPLACE

Syntax

```
JSON_REPLACE(json_doc, path, val[, path, val] ...)
```

Contents

Description

Replaces existing values in a JSON document, returning the result, or NULL if any of the arguments are NULL.

An error will occur if the JSON document is invalid, the path is invalid or if the path contains a `*` or `**` wildcard.

Paths and values are evaluated from left to right, with the result from the earlier evaluation being used as the value for the next.

JSON_REPLACE can only update data, while JSON_INSERT can only insert. JSON_SET can update or insert data.

Examples

```
SELECT JSON_REPLACE('{ "A": 1, "B": [2, 3]}', '$.B[1]', 4);
+-----------------------------------------------------+
| JSON_REPLACE('{ "A": 1, "B": [2, 3]}', '$.B[1]', 4) |
+-----------------------------------------------------+
| { "A": 1, "B": [2, 4]}                              |
+-----------------------------------------------------+
```

1.2.9.4.34 JSON_SCHEMA_VALID

MariaDB starting with 11.1

`JSON_SCHEMA_VALID` was introduced in MariaDB 11.1.

Syntax

```
JSON_SCHEMA_VALID(schema, json);
```

Contents

Description

`JSON_SCHEMA_VALID` allows MariaDB to support JSON schema validation. If a given json is valid against a schema it returns true. When JSON does not validate against the schema, it does not return a message about which keyword it failed against and only returns false.

The function supports JSON Schema Draft 2020 with a few exceptions:

- External resources are not supported
- Hyper schema keywords are not supported
- Formats like date, email etc are treated as annotations.

Examples

To create validation rules for json field

```
CREATE TABLE obj_table(val_obj JSON CHECK(JSON_SCHEMA_VALID('{
  "type":"object",
    "properties": {
      "number1":{
        "type":"number",
        "maximum":5,
        "const":4
      },
      "string1":{
        "type":"string",
        "maxLength":5,
        "minLength":3
      },
    "object1":{
      "type":"object",
       "properties":{
         "key1": {"type":"string"},
         "key2":{"type":"array"},
         "key3":{"type":"number", "minimum":3}
       },
       "dependentRequired": { "key1":["key3"] }
     }
  },
  "required":["number1","object1"]
  }', val_obj)));

INSERT INTO obj_table VALUES(
  '{"number1":4, "string1":"abcd",
  "object1":{"key1":"val1", "key2":[1,2,3, "string1"], "key3":4}}'
);

INSERT INTO obj_table VALUES(
  '{"number1":3, "string1":"abcd",
  "object1":{"key1":"val1", "key2":[1,2,3, "string1"], "key3":4}}'
);
ERROR 4025 (23000): CONSTRAINT `obj_table.val_obj` failed for `test`.`obj_table`

SELECT * FROM obj_table;
+-----------------------------------------------------------------------------------------------------------+
| val_obj                                                                                                   |
+-----------------------------------------------------------------------------------------------------------+
| {"number1":4, "string1":"abcd", "object1":{"key1":"val1", "key2":[1,2,3, "string1"], "key3":4}}           |
+-----------------------------------------------------------------------------------------------------------+

SET @schema= '{
  "properties" : {
    "number1":{ "maximum":10 },
    "string1" : { "maxLength": 3}
  }
}';

SELECT JSON_SCHEMA_VALID(@schema, '{ "number1":25, "string1":"ab" }');
+-----------------------------------------------------------------+
| JSON_SCHEMA_VALID(@schema, '{ "number1":25, "string1":"ab" }') |
+-----------------------------------------------------------------+
|                                                               0 |
+-----------------------------------------------------------------+

SELECT JSON_SCHEMA_VALID(@schema, '{ "number1":10, "string1":"ab" }');
+-----------------------------------------------------------------+
| JSON_SCHEMA_VALID(@schema, '{ "number1":10, "string1":"ab" }') |
+-----------------------------------------------------------------+
|                                                               1 |
+-----------------------------------------------------------------+
```

1.2.9.4.35 JSON_SEARCH

Syntax

```
JSON_SEARCH(json_doc, return_arg, search_str[, escape_char[, path] ...])
```

Description

Returns the path to the given string within a JSON document, or NULL if any of *json_doc*, *search_str* or a path argument is NULL; if the search string is not found, or if no path exists within the document.

A warning will occur if the JSON document is not valid, any of the path arguments are not valid, if *return_arg* is neither *one* nor *all*, or if the escape character is not a constant. NULL will be returned.

return_arg can be one of two values:

- `'one` : Terminates after finding the first match, so will return one path string. If there is more than one match, it is undefined which is considered first.
- `all` : Returns all matching path strings, without duplicates. Multiple strings are autowrapped as an array. The order is undefined.

Examples

```
SET @json = '["A", [{"B": "1"}], {"C":"AB"}, {"D":"BC"}]';

SELECT JSON_SEARCH(@json, 'one', 'AB');
+--------------------------------+
| JSON_SEARCH(@json, 'one', 'AB') |
+--------------------------------+
| "$[2].C"                       |
+--------------------------------+
```

1.2.9.4.36 JSON_SET

Syntax

```
JSON_SET(json_doc, path, val[, path, val] ...)
```

Description

Updates or inserts data into a JSON document, returning the result, or NULL if any of the arguments are NULL or the optional path fails to find an object.

An error will occur if the JSON document is invalid, the path is invalid or if the path contains a * or **wildcard.**

JSON_SET can update or insert data, while JSON_REPLACE can only update, and JSON_INSERT only insert.

Examples

```
SELECT JSON_SET(Priv, '$.locked', 'true') FROM mysql.global_priv
```

1.2.9.4.37 JSON_TABLE

MariaDB starting with 10.6.0

JSON_TABLE was added in MariaDB 10.6.0.

JSON_TABLE is a table function that converts JSON data into a relational form.

Syntax

```
JSON_TABLE(json_doc,
          context_path COLUMNS (column_list)
) [AS] alias
```

```
column_list:
    column[, column][, ...]
```

```
column:
    name FOR ORDINALITY
    |  name type PATH path_str [on_empty] [on_error]
    |  name type EXISTS PATH path_str
    |  NESTED PATH path_str COLUMNS (column_list)
```

```
on_empty:
    {NULL | DEFAULT string | ERROR} ON EMPTY
```

```
on_error:
    {NULL | DEFAULT string | ERROR} ON ERROR
```

Contents

Description

JSON_TABLE can be used in contexts where a table reference can be used; in the FROM clause of a SELECT statement, and in multi-table UPDATE/DELETE statements.

`json_doc` is the JSON document to extract data from. In the simplest case, it is a string literal containing JSON. In more complex cases it can be an arbitrary expression returning JSON. The expression may have references to columns of other tables. However, one can only refer to tables that precede this JSON_TABLE invocation. For RIGHT JOIN, it is assumed that its outer side precedes the inner. All tables in outer selects are also considered preceding.

`context_path` is a JSON Path expression pointing to a collection of nodes in `json_doc` that will be used as the source of rows.

The `COLUMNS` clause declares the names and types of the columns that JSON_TABLE returns, as well as how the values of the columns are produced.

Column Definitions

The following types of columns are supported:

Path Columns

```
name type PATH path_str [on_empty] [on_error]
```

Locates the JSON node pointed to by `path_str` and returns its value. The path_str is evaluated using the current row source node as the context node.

```
set @json='
[
  {"name":"Laptop", "color":"black", "price":"1000"},
  {"name":"Jeans",  "color":"blue"}
]';

select * from json_table(@json, '$[*]'
  columns(
   name  varchar(10) path '$.name',
   color varchar(10) path '$.color',
   price decimal(8,2) path '$.price' )
) as jt;
+--------+-------+---------+
| name   | color | price   |
+--------+-------+---------+
| Laptop | black | 1000.00 |
| Jeans  | blue  |    NULL |
+--------+-------+---------+
```

The `on_empty` and `on_error` clauses specify the actions to be performed when the value was not found or there was an error condition. See the ON EMPTY and ON ERROR clauses section for details.

ORDINALITY Columns

```
name FOR ORDINALITY
```

Counts the rows, starting from 1.

Example:

```
set @json='
[
  {"name":"Laptop", "color":"black"},
  {"name":"Jeans",  "color":"blue"}
]';

select * from json_table(@json, '$[*]'
  columns(
   id for ordinality,
   name  varchar(10) path '$.name')
) as jt;
+------+--------+
| id   | name   |
+------+--------+
|    1 | Laptop |
|    2 | Jeans  |
+------+--------+
```

EXISTS PATH Columns

```
name type EXISTS PATH path_str
```

Checks whether the node pointed to by `value_path` exists. The `value_path` is evaluated using the current row source node as the context node.

```
set @json='
[
  {"name":"Laptop", "color":"black", "price":1000},
  {"name":"Jeans",  "color":"blue"}
]';

select * from json_table(@json, '$[*]'
  columns(
   name  varchar(10) path '$.name',
   has_price integer exists path '$.price')
) as jt;
+--------+-----------+
| name   | has_price |
+--------+-----------+
| Laptop |         1 |
| Jeans  |         0 |
+--------+-----------+
```

NESTED PATHs

NESTED PATH converts nested JSON structures into multiple rows.

```
NESTED PATH path COLUMNS (column_list)
```

It finds the sequence of JSON nodes pointed to by `path` and uses it to produce rows. For each found node, a row is generated with column values as specified by the NESTED PATH's COLUMNS clause. If `path` finds no nodes, only one row is generated with all columns having NULL values.

For example, consider a JSON document that contains an array of items, and each item, in turn, is expected to have an array of its available sizes:

```
set @json='
[
  {"name":"Jeans",  "sizes": [32, 34, 36]},
  {"name":"T-Shirt", "sizes":["Medium", "Large"]},
  {"name":"Cellphone"}
]';
```

NESTED PATH allows one to produce a separate row for each size each item has:

```
select * from json_table(@json, '$[*]'
  columns(
    name  varchar(10) path '$.name',
    nested path '$.sizes[*]' columns (
      size varchar(32) path '$'
    )
  )
) as jt;
+-----------+--------+
| name      | size   |
+-----------+--------+
| Jeans     | 32     |
| Jeans     | 34     |
| Jeans     | 36     |
| T-Shirt   | Medium |
| T-Shirt   | Large  |
| Cellphone | NULL   |
+-----------+--------+
```

NESTED PATH clauses can be nested within one another. They can also be located next to each other. In that case, the nested path clauses will produce records one at a time. The ones that are not producing records will have all columns set to NULL.

Example:

```
set @json='
[
  {"name":"Jeans",  "sizes": [32, 34, 36], "colors":["black", "blue"]}
]';

select * from json_table(@json, '$[*]'
  columns(
    name  varchar(10) path '$.name',
    nested path '$.sizes[*]' columns (
      size varchar(32) path '$'
    ),
    nested path '$.colors[*]' columns (
      color varchar(32) path '$'
    )
  )
) as jt;

+-------+------+-------+
| name  | size | color |
+-------+------+-------+
| Jeans | 32   | NULL  |
| Jeans | 34   | NULL  |
| Jeans | 36   | NULL  |
| Jeans | NULL | black |
| Jeans | NULL | blue  |
+-------+------+-------+
```

ON EMPTY and ON ERROR Clauses

The ON EMPTY clause specifies what will be done when the element specified by the search path is missing in the JSON document.

```
on_empty:
    {NULL | DEFAULT string | ERROR} ON EMPTY
```

When `ON EMPTY` clause is not present, `NULL ON EMPTY` is implied.

```
on_error:
    {NULL | DEFAULT string | ERROR} ON ERROR
```

The ON ERROR clause specifies what should be done if a JSON structure error occurs when trying to extract the value pointed to by the path expression. A JSON structure error here occurs only when one attempts to convert a JSON non-scalar (array or object) into a scalar value. When the `ON ERROR` clause is not present, `NULL ON ERROR` is implied.

Note: A datatype conversion error (e.g. attempt to store a non-integer value into an integer field, or a varchar column being truncated) is not considered a JSON error and so will not trigger the `ON ERROR` behavior. It will produce warnings, in the same way as CAST(value AS datatype) would.

Replication

In the current code, evaluation of JSON_TABLE is deterministic, that is, for a given input string JSON_TABLE will always produce the same set of rows in the same order. However, one can think of JSON documents that one can consider identical which will produce different output. In order to be future-proof and withstand changes like:

- sorting JSON object members by name (like MySQL does)
- changing the way duplicate object members are handled the function is marked as unsafe for statement-based replication.

Extracting a Subdocument into a Column

MariaDB starting with 10.6.9

Prior to MariaDB 10.6.9, JSON_TABLE did not allow one to extract a JSON "subdocument" into a JSON column.

```
SELECT * FROM JSON_TABLE('{"foo": [1,2,3,4]}','$' columns( jscol json path '$.foo') ) AS T;
+--------+
| jscol |
+--------+
| NULL  |
+--------+
```

This is supported from MariaDB 10.6.9:

```
SELECT * FROM JSON_TABLE('{"foo": [1,2,3,4]}','$' columns( jscol json path '$.foo') ) AS T;
+-----------+
| jscol     |
+-----------+
| [1,2,3,4] |
+-----------+
```

1.2.9.4.38 JSON_TYPE

Syntax

```
JSON_TYPE(json_val)
```

Description

Returns the type of a JSON value (as a string), or NULL if the argument is null.

An error will occur if the argument is an invalid JSON value.

The following is a complete list of the possible return types:

Return type	Value	Example
ARRAY	JSON array	[1, 2, {"key": "value"}]
OBJECT	JSON object	{"key":"value"}
BOOLEAN	JSON true/false literals	true, false
DOUBLE	A number with at least one floating point decimal.	1.2
INTEGER	A number without a floating point decimal.	1
NULL	JSON null literal (this is returned as a string, not to be confused with the SQL NULL value!)	null
STRING	JSON String	"a sample string"

Examples

```
SELECT JSON_TYPE('{"A": 1, "B": 2, "C": 3}');
+---------------------------------------+
| JSON_TYPE('{"A": 1, "B": 2, "C": 3}') |
+---------------------------------------+
| OBJECT                                |
+---------------------------------------+
```

1.2.9.4.39 JSON_UNQUOTE

Syntax

```
JSON_UNQUOTE(val)
```

Description

Unquotes a JSON value, returning a string, or NULL if the argument is null.

An error will occur if the given value begins and ends with double quotes and is an invalid JSON string literal.

If the given value is not a JSON string, value is passed through unmodified.

Certain character sequences have special meanings within a string. Usually, a backslash is ignored, but the escape sequences in the table below are recognised by MariaDB, unless the SQL Mode is set to NO_BACKSLASH_ESCAPES SQL.

Escape sequence	Character
`\"`	Double quote (")
`\b`	Backslash
`\f`	Formfeed
`\n`	Newline (linefeed)
`\r`	Carriage return
`\t`	Tab
`\\`	Backslash (\)
`\uXXXX`	UTF-8 bytes for Unicode value XXXX

Examples

```
SELECT JSON_UNQUOTE('"Monty"');
+-------------------------+
| JSON_UNQUOTE('"Monty"') |
+-------------------------+
| Monty                   |
+-------------------------+
```

With the default SQL Mode:

```
SELECT JSON_UNQUOTE('Si\bng\ting');
+-----------------------------+
| JSON_UNQUOTE('Si\bng\ting') |
+-----------------------------+
| Sng ing                     |
+-----------------------------+
```

Setting NO_BACKSLASH_ESCAPES:

```
SET @@sql_mode = 'NO_BACKSLASH_ESCAPES';

SELECT JSON_UNQUOTE('Si\bng\ting');
+-----------------------------+
| JSON_UNQUOTE('Si\bng\ting') |
+-----------------------------+
| Si\bng\ting                 |
+-----------------------------+
```

1.2.9.4.40 JSON_VALID

Syntax

```
JSON_VALID(value)
```

Contents

Description

Indicates whether the given value is a valid JSON document or not. Returns `1` if valid, `0` if not, and NULL if the argument is NULL.

From MariaDB 10.4.3, the JSON_VALID function is automatically used as a CHECK constraint for the JSON data type alias in order to ensure that a valid json document is inserted.

Examples

```
SELECT JSON_VALID('{"id": 1, "name": "Monty"}');
+---------------------------------------+
| JSON_VALID('{"id": 1, "name": "Monty"}') |
+---------------------------------------+
|                                     1 |
+---------------------------------------+

SELECT JSON_VALID('{"id": 1, "name": "Monty", "oddfield"}');
+-----------------------------------------------------+
| JSON_VALID('{"id": 1, "name": "Monty", "oddfield"}') |
+-----------------------------------------------------+
|                                                   0 |
+-----------------------------------------------------+
```

1.2.9.4.41 JSON_VALUE

Syntax

```
JSON_VALUE(json_doc, path)
```

Description

Given a JSON document, returns the scalar specified by the path. Returns NULL if not given a valid JSON document, or if there is no match.

Examples

```
select json_value('{"key1":123}', '$.key1');
+--------------------------------------+
| json_value('{"key1":123}', '$.key1') |
+--------------------------------------+
| 123                                  |
+--------------------------------------+

select json_value('{"key1": [1,2,3], "key1":123}', '$.key1');
+-----------------------------------------------------+
| json_value('{"key1": [1,2,3], "key1":123}', '$.key1') |
+-----------------------------------------------------+
| 123                                                 |
+-----------------------------------------------------+
```

In the SET statement below, two escape characters are needed, as a single escape character would be applied by the SQL parser in the SET statement, and the escaped character would not form part of the saved value.

```
SET @json = '{"key1":"60\\" Table", "key2":"1"}';

SELECT JSON_VALUE(@json,'$.key1') AS Name , json_value(@json,'$.key2') as ID;
+-----------+------+
| Name      | ID   |
+-----------+------+
| 60" Table | 1    |
+-----------+------+
```

1.1.6.6 SEQUENCE Functions

1.2.9.6 Spider Functions

The following UDFs are available with the Spider Storage Engine.

SPIDER_BG_DIRECT_SQL

Background SQL execution

SPIDER_COPY_TABLES

Copy table data

SPIDER_DIRECT_SQL

Execute SQL on the remote server

SPIDER_FLUSH_TABLE_MON_CACHE

Refreshing Spider monitoring server information

1.2.9.6.1 SPIDER_BG_DIRECT_SQL

Syntax

```
SPIDER_BG_DIRECT_SQL('sql', 'tmp_table_list', 'parameters')
```

Description

Executes the given SQL statement in the background on the remote server, as defined in the parameters listing. If the query returns a result-set, it sttores the results in the given temporary table. When the given SQL statement executes successfully, this function returns the number of called UDF's. It returns `0` when the given SQL statement fails.

This function is a UDF installed with the Spider storage engine.

Examples

```
SELECT SPIDER_BG_DIRECT_SQL('SELECT * FROM example_table',  '',
   'srv "node1", port "8607"') AS "Direct Query";
+--------------+
| Direct Query |
+--------------+
|            1 |
+--------------+
```

Parameters

`error_rw_mode`

- **Description:** Returns empty results on network error.
  - `0` : Return error on getting network error.
  - `1` : Return 0 records on getting network error.

- **Default Table Value:** `0`
- **DSN Parameter Name:** `erwm`

1.2.9.6.2 SPIDER_COPY_TABLES

Syntax

```
SPIDER_COPY_TABLES(spider_table_name,
  source_link_id, destination_link_id_list [,parameters])
```

Description

A UDF installed with the Spider Storage Engine, this function copies table data from `source_link_id` to `destination_link_id_list`. The service does not need to be stopped in order to copy.

If the Spider table is partitioned, the name must be of the format `table_name#P#partition_name`. The partition name can be viewed in the `mysql.spider_tables` table, for example:

```
SELECT table_name FROM mysql.spider_tables;
+-------------+
| table_name  |
+-------------+
| spt_a#P#pt1 |
| spt_a#P#pt2 |
| spt_a#P#pt3 |
+-------------+
```

Returns `1` if the data was copied successfully, or `0` if copying the data failed.

1.2.9.6.3 SPIDER_DIRECT_SQL

Syntax

```
SPIDER_DIRECT_SQL('sql', 'tmp_table_list', 'parameters')
```

Description

A UDF installed with the Spider Storage Engine, this function is used to execute the SQL string `sql` on the remote server, as defined in `parameters`. If any resultsets are returned, they are stored in the `tmp_table_list`.

The function returns `1` if the SQL executes successfully, or `0` if it fails.

Examples

```
SELECT SPIDER_DIRECT_SQL('SELECT * FROM s', '', 'srv "node1", port "8607"');
+---------------------------------------------------------------------------+
| SPIDER_DIRECT_SQL('SELECT * FROM s', '', 'srv "node1", port "8607"') |
+---------------------------------------------------------------------------+
|                                                                         1 |
+---------------------------------------------------------------------------+
```

1.2.9.6.4 SPIDER_FLUSH_TABLE_MON_CACHE

Syntax

```
SPIDER_FLUSH_TABLE_MON_CACHE()
```

Description

A UDF installed with the Spider Storage Engine, this function is used for refreshing monitoring server information. It returns a value of `1`.

Examples

```
SELECT SPIDER_FLUSH_TABLE_MON_CACHE();
+--------------------------------+
| SPIDER_FLUSH_TABLE_MON_CACHE() |
+--------------------------------+
|                              1 |
+--------------------------------+
```

1.2.9.7 Window Functions

Window functions perform calculations across a set of rows related to the current row.

Window Functions Overview

Window functions perform calculations across a set of rows related to the current row.

AVG

Returns the average value.

BIT_AND

Bitwise AND.

BIT_OR

Bitwise OR.

BIT_XOR

Bitwise XOR.

COUNT

Returns count of non-null values.

CUME_DIST

Window function that returns the cumulative distribution of a given row.

DENSE_RANK

Rank of a given row with identical values receiving the same result, no skipping.

FIRST_VALUE

Returns the first result from an ordered set.

JSON_ARRAYAGG

Returns a JSON array containing an element for each value in a given set of JSON or SQL values.

JSON_OBJECTAGG

Returns a JSON object containing key-value pairs.

LAG

Accesses data from a previous row in the same result set without the need for a self-join.

LAST_VALUE

Returns the last value in a list or set of values.

LEAD

Accesses data from a following row in the same result set without the need for a self-join.

MAX
Returns the maximum value.

MEDIAN
Window function that returns the median value of a range of values.

MIN
Returns the minimum value.

NTH_VALUE
Returns the value evaluated at the specified row number of the window frame.

NTILE
Returns an integer indicating which group a given row falls into.

PERCENT_RANK
Window function that returns the relative percent rank of a given row.

PERCENTILE_CONT
Continuous percentile.

PERCENTILE_DISC
Discrete percentile.

RANK
Rank of a given row with identical values receiving the same result.

ROW_NUMBER
Row number of a given row with identical values receiving a different result.

STD
Population standard deviation.

STDDEV
Population standard deviation.

STDDEV_POP
Returns the population standard deviation.

STDDEV_SAMP
Standard deviation.

SUM
Sum total.

VAR_POP
Population standard variance.

VAR_SAMP
Returns the sample variance.

VARIANCE
Population standard variance.

Aggregate Functions as Window Functions
It is possible to use aggregate functions as window functions.

ColumnStore Window Functions
Summary of window function use with the ColumnStore engine

Window Frames
Some window functions operate on window frames.

1.2.9.7.1 Window Functions Overview

Contents

Introduction

Window functions allow calculations to be performed across a set of rows related to the current row.

Syntax

```
function (expression) OVER (
  [ PARTITION BY expression_list ]
  [ ORDER BY order_list [ frame_clause ] ] )

function:
  A valid window function

expression_list:
  expression | column_name [, expr_list ]

order_list:
  expression | column_name [ ASC | DESC ]
  [, ... ]

frame_clause:
  {ROWS | RANGE} {frame_border | BETWEEN frame_border AND frame_border}

frame_border:
  | UNBOUNDED PRECEDING
  | UNBOUNDED FOLLOWING
  | CURRENT ROW
  | expr PRECEDING
  | expr FOLLOWING
```

Description

In some ways, window functions are similar to aggregate functions in that they perform calculations across a set of rows. However, unlike aggregate functions, the output is not grouped into a single row.

Non-aggregate window functions include

- CUME_DIST
- DENSE_RANK
- FIRST_VALUE
- LAG
- LAST_VALUE
- LEAD
- MEDIAN
- NTH_VALUE
- NTILE
- PERCENT_RANK
- PERCENTILE_CONT
- PERCENTILE_DISC
- RANK, ROW_NUMBER

Aggregate functions that can also be used as window functions include

- AVG
- BIT_AND
- BIT_OR
- BIT_XOR
- COUNT

- MAX
- MIN
- STD
- STDDEV
- STDDEV_POP
- STDDEV_SAMP
- SUM
- VAR_POP
- VAR_SAMP
- VARIANCE

Window function queries are characterised by the OVER keyword, following which the set of rows used for the calculation is specified. By default, the set of rows used for the calculation (the "window) is the entire dataset, which can be ordered with the ORDER BY clause. The PARTITION BY clause is used to reduce the window to a particular group within the dataset.

For example, given the following data:

```
CREATE TABLE student (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student VALUES
  ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
  ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
  ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
  ('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);
```

the following two queries return the average partitioned by test and by name respectively:

```
SELECT name, test, score, AVG(score) OVER (PARTITION BY test)
  AS average_by_test FROM student;
+---------+--------+-------+-----------------+
| name    | test   | score | average_by_test |
+---------+--------+-------+-----------------+
| Chun    | SQL    |    75 |         65.2500 |
| Chun    | Tuning |    73 |         68.7500 |
| Esben   | SQL    |    43 |         65.2500 |
| Esben   | Tuning |    31 |         68.7500 |
| Kaolin  | SQL    |    56 |         65.2500 |
| Kaolin  | Tuning |    88 |         68.7500 |
| Tatiana | SQL    |    87 |         65.2500 |
| Tatiana | Tuning |    83 |         68.7500 |
+---------+--------+-------+-----------------+

SELECT name, test, score, AVG(score) OVER (PARTITION BY name)
  AS average_by_name FROM student;
+---------+--------+-------+-----------------+
| name    | test   | score | average_by_name |
+---------+--------+-------+-----------------+
| Chun    | SQL    |    75 |         74.0000 |
| Chun    | Tuning |    73 |         74.0000 |
| Esben   | SQL    |    43 |         37.0000 |
| Esben   | Tuning |    31 |         37.0000 |
| Kaolin  | SQL    |    56 |         72.0000 |
| Kaolin  | Tuning |    88 |         72.0000 |
| Tatiana | SQL    |    87 |         85.0000 |
| Tatiana | Tuning |    83 |         85.0000 |
+---------+--------+-------+-----------------+
```

It is also possible to specify which rows to include for the window function (for example, the current row and all preceding rows). See Window Frames for more details.

Scope

Window functions were introduced in SQL:2003, and their definition was expanded in subsequent versions of the standard. The last expansion was in the latest version of the standard, SQL:2011.

Most database products support a subset of the standard, they implement some functions defined as late as in SQL:2011, and at the same time leave some parts of SQL:2008 unimplemented.

MariaDB:

- Supports ROWS and RANGE-type frames

    - All kinds of frame bounds are supported, including `RANGE PRECEDING|FOLLOWING n` frame bounds (unlike PostgreSQL or MS SQL Server)
    - Does not yet support DATE[TIME] datatype and arithmetic for RANGE-type frames (MDEV-9727)
- Does not support GROUPS-type frames (it seems that no popular database supports it, either)
- Does not support frame exclusion (no other database seems to support it, either) (MDEV-9724)
- Does not support explicit `NULLS FIRST` or `NULLS LAST` .
- Does not support nested navigation in window functions (this is `VALUE_OF(expr AT row_marker [, default_value)` syntax)
- The following window functions are supported:
    - "Streamable" window functions: ROW_NUMBER, RANK, DENSE_RANK,
    - Window functions that can be streamed once the number of rows in partition is known: PERCENT_RANK, CUME_DIST, NTILE
- Aggregate functions that are currently supported as window functions are: COUNT, SUM, AVG, BIT_OR, BIT_AND, BIT_XOR.
- Aggregate functions with the `DISTINCT` specifier (e.g. `COUNT( DISTINCT x)`) are not supported as window functions.

Links

- MDEV-6115 is the main jira task for window functions development. Other tasks are are attached as sub-tasks
- bb-10.2-mdev9543 is the feature tree for window functions. Development is ongoing, and this tree has the newest changes.
- Testcases are in `mysql-test/t/win*.test`

Examples

Given the following sample data:

```
CREATE TABLE users (
  email VARCHAR(30),
  first_name VARCHAR(30),
  last_name VARCHAR(30),
  account_type VARCHAR(30)
);

INSERT INTO users VALUES
  ('admin@boss.org', 'Admin', 'Boss', 'admin'),
  ('bob.carlsen@foo.bar', 'Bob', 'Carlsen', 'regular'),
  ('eddie.stevens@data.org', 'Eddie', 'Stevens', 'regular'),
  ('john.smith@xyz.org', 'John', 'Smith', 'regular'),
  ('root@boss.org', 'Root', 'Chief', 'admin')
```

First, let's order the records by email alphabetically, giving each an ascending *rnum* value starting with 1. This will make use of the ROW_NUMBER window function:

```
SELECT row_number() OVER (ORDER BY email) AS rnum,
    email, first_name, last_name, account_type
FROM users ORDER BY email;
+------+-------------------------+------------+-----------+--------------+
| rnum | email                   | first_name | last_name | account_type |
+------+-------------------------+------------+-----------+--------------+
|    1 | admin@boss.org          | Admin      | Boss      | admin        |
|    2 | bob.carlsen@foo.bar     | Bob        | Carlsen   | regular      |
|    3 | eddie.stevens@data.org  | Eddie      | Stevens   | regular      |
|    4 | john.smith@xyz.org      | John       | Smith     | regular      |
|    5 | root@boss.org           | Root       | Chief     | admin        |
+------+-------------------------+------------+-----------+--------------
```

We can generate separate sequences based on account type, using the PARTITION BY clause:

```
SELECT row_number() OVER (PARTITION BY account_type ORDER BY email) AS rnum,
  email, first_name, last_name, account_type
FROM users ORDER BY account_type,email;
+------+-----------------------+------------+-----------+--------------+
| rnum | email                 | first_name | last_name | account_type |
+------+-----------------------+------------+-----------+--------------+
|    1 | admin@boss.org        | Admin      | Boss      | admin        |
|    2 | root@boss.org         | Root       | Chief     | admin        |
|    1 | bob.carlsen@foo.bar   | Bob        | Carlsen   | regular      |
|    2 | eddie.stevens@data.org | Eddie      | Stevens   | regular      |
|    3 | john.smith@xyz.org    | John       | Smith     | regular      |
+------+-----------------------+------------+-----------+--------------+
```

Given the following structure and data, we want to find the top 5 salaries from each department.

```
CREATE TABLE employee_salaries (dept VARCHAR(20), name VARCHAR(20), salary INT(11));

INSERT INTO employee_salaries VALUES
('Engineering', 'Dharma', 3500),
('Engineering', 'Binh', 3000),
('Engineering', 'Adalynn', 2800),
('Engineering', 'Samuel', 2500),
('Engineering', 'Cveta', 2200),
('Engineering', 'Ebele', 1800),
('Sales', 'Carbry', 500),
('Sales', 'Clytemnestra', 400),
('Sales', 'Juraj', 300),
('Sales', 'Kalpana', 300),
('Sales', 'Svantepolk', 250),
('Sales', 'Angelo', 200);
```

We could do this without using window functions, as follows:

```
select dept, name, salary
from employee_salaries as t1
where (select count(t2.salary)
       from employee_salaries as t2
       where t1.name != t2.name and
             t1.dept = t2.dept and
             t2.salary > t1.salary) < 5
order by dept, salary desc;

+-------------+--------------+--------+
| dept        | name         | salary |
+-------------+--------------+--------+
| Engineering | Dharma       |   3500 |
| Engineering | Binh         |   3000 |
| Engineering | Adalynn      |   2800 |
| Engineering | Samuel       |   2500 |
| Engineering | Cveta        |   2200 |
| Sales       | Carbry       |    500 |
| Sales       | Clytemnestra |    400 |
| Sales       | Juraj        |    300 |
| Sales       | Kalpana      |    300 |
| Sales       | Svantepolk   |    250 |
+-------------+--------------+--------+
```

This has a number of disadvantages:

- if there is no index, the query could take a long time if the employee_salary_table is large
- Adding and maintaining indexes adds overhead, and even with indexes on *dept* and *salary*, each subquery execution adds overhead by performing a lookup through the index.

Let's try achieve the same with window functions. First, generate a rank for all employees, using the RANK function.

```
select rank() over (partition by dept order by salary desc) as ranking,
    dept, name, salary
    from employee_salaries
    order by dept, ranking;
+---------+-------------+--------------+--------+
| ranking | dept        | name         | salary |
+---------+-------------+--------------+--------+
|       1 | Engineering | Dharma       |   3500 |
|       2 | Engineering | Binh         |   3000 |
|       3 | Engineering | Adalynn      |   2800 |
|       4 | Engineering | Samuel       |   2500 |
|       5 | Engineering | Cveta        |   2200 |
|       6 | Engineering | Ebele        |   1800 |
|       1 | Sales       | Carbry       |    500 |
|       2 | Sales       | Clytemnestra |    400 |
|       3 | Sales       | Juraj        |    300 |
|       3 | Sales       | Kalpana      |    300 |
|       5 | Sales       | Svantepolk   |    250 |
|       6 | Sales       | Angelo       |    200 |
+---------+-------------+--------------+--------+
```

Each department has a separate sequence of ranks due to the *PARTITION BY* clause. This particular sequence of values for *rank()* is given by the *ORDER BY* clause inside the window function's *OVER* clause. Finally, to get our results in a readable format we order the data by *dept* and the newly generated *ranking* column.

Now, we need to reduce the results to find only the top 5 per department. Here is a common mistake:

```
select
rank() over (partition by dept order by salary desc) as ranking,
dept, name, salary
from employee_salaries
where ranking <= 5
order by dept, ranking;

ERROR 1054 (42S22): Unknown column 'ranking' in 'where clause'
```

Trying to filter only the first 5 values per department by putting a where clause in the statement does not work, due to the way window functions are computed. The computation of window functions happens after all WHERE, GROUP BY and HAVING clauses have been completed, right before ORDER BY, so the WHERE clause has no idea that the ranking column exists. It is only present after we have filtered and grouped all the rows.

To counteract this problem, we need to wrap our query into a derived table. We can then attach a where clause to it:

```
select *from (select rank() over (partition by dept order by salary desc) as ranking,
  dept, name, salary
from employee_salaries) as salary_ranks
where (salary_ranks.ranking <= 5)
  order by dept, ranking;
+---------+-------------+--------------+--------+
| ranking | dept        | name         | salary |
+---------+-------------+--------------+--------+
|       1 | Engineering | Dharma       |   3500 |
|       2 | Engineering | Binh         |   3000 |
|       3 | Engineering | Adalynn      |   2800 |
|       4 | Engineering | Samuel       |   2500 |
|       5 | Engineering | Cveta        |   2200 |
|       1 | Sales       | Carbry       |    500 |
|       2 | Sales       | Clytemnestra |    400 |
|       3 | Sales       | Juraj        |    300 |
|       3 | Sales       | Kalpana      |    300 |
|       5 | Sales       | Svantepolk   |    250 |
+---------+-------------+--------------+--------+
```

1.2.4.2 AVG

1.2.4.3 BIT_AND

1.2.4.4 BIT_OR

1.2.4.5 BIT_XOR

1.2.4.6 COUNT

1.2.9.7.7 CUME_DIST

Contents

Syntax

```
CUME_DIST() OVER (
  [ PARTITION BY partition_expression ]
  [ ORDER BY order_list ]
)
```

Description

CUME_DIST() is a window function that returns the cumulative distribution of a given row. The following formula is used to calculate the value:

```
(number of rows <= current row) / (total rows)
```

Examples

```
create table t1 (
  pk int primary key,
  a int,
  b int
);

insert into t1 values
( 1 , 0, 10),
( 2 , 0, 10),
( 3 , 1, 10),
( 4 , 1, 10),
( 8 , 2, 10),
( 5 , 2, 20),
( 6 , 2, 20),
( 7 , 2, 20),
( 9 , 4, 20),
(10 , 4, 20);

select pk, a, b,
    rank() over (order by a) as rank,
    percent_rank() over (order by a) as pct_rank,
    cume_dist() over (order by a) as cume_dist
from t1;
+----+------+------+------+--------------+--------------+
| pk | a    | b    | rank | pct_rank     | cume_dist    |
+----+------+------+------+--------------+--------------+
|  1 |    0 |   10 |    1 | 0.0000000000 | 0.2000000000 |
|  2 |    0 |   10 |    1 | 0.0000000000 | 0.2000000000 |
|  3 |    1 |   10 |    3 | 0.2222222222 | 0.4000000000 |
|  4 |    1 |   10 |    3 | 0.2222222222 | 0.4000000000 |
|  5 |    2 |   20 |    5 | 0.4444444444 | 0.8000000000 |
|  6 |    2 |   20 |    5 | 0.4444444444 | 0.8000000000 |
|  7 |    2 |   20 |    5 | 0.4444444444 | 0.8000000000 |
|  8 |    2 |   10 |    5 | 0.4444444444 | 0.8000000000 |
|  9 |    4 |   20 |    9 | 0.8888888889 | 1.0000000000 |
| 10 |    4 |   20 |    9 | 0.8888888889 | 1.0000000000 |
+----+------+------+------+--------------+--------------+
```

```
select pk, a, b,
       percent_rank() over (order by pk) as pct_rank,
       cume_dist() over (order by pk) as cume_dist
from t1 order by pk;
+----+------+------+--------------+--------------+
| pk | a    | b    | pct_rank     | cume_dist    |
+----+------+------+--------------+--------------+
|  1 |    0 |   10 | 0.0000000000 | 0.1000000000 |
|  2 |    0 |   10 | 0.1111111111 | 0.2000000000 |
|  3 |    1 |   10 | 0.2222222222 | 0.3000000000 |
|  4 |    1 |   10 | 0.3333333333 | 0.4000000000 |
|  5 |    2 |   20 | 0.4444444444 | 0.5000000000 |
|  6 |    2 |   20 | 0.5555555556 | 0.6000000000 |
|  7 |    2 |   20 | 0.6666666667 | 0.7000000000 |
|  8 |    2 |   10 | 0.7777777778 | 0.8000000000 |
|  9 |    4 |   20 | 0.8888888889 | 0.9000000000 |
| 10 |    4 |   20 | 1.0000000000 | 1.0000000000 |
+----+------+------+--------------+--------------+

select pk, a, b,
        percent_rank() over (partition by a order by a) as pct_rank,
        cume_dist() over (partition by a order by a) as cume_dist
from t1;
+----+------+------+--------------+--------------+
| pk | a    | b    | pct_rank     | cume_dist    |
+----+------+------+--------------+--------------+
|  1 |    0 |   10 | 0.0000000000 | 1.0000000000 |
|  2 |    0 |   10 | 0.0000000000 | 1.0000000000 |
|  3 |    1 |   10 | 0.0000000000 | 1.0000000000 |
|  4 |    1 |   10 | 0.0000000000 | 1.0000000000 |
|  5 |    2 |   20 | 0.0000000000 | 1.0000000000 |
|  6 |    2 |   20 | 0.0000000000 | 1.0000000000 |
|  7 |    2 |   20 | 0.0000000000 | 1.0000000000 |
|  8 |    2 |   10 | 0.0000000000 | 1.0000000000 |
|  9 |    4 |   20 | 0.0000000000 | 1.0000000000 |
| 10 |    4 |   20 | 0.0000000000 | 1.0000000000 |
+----+------+------+--------------+--------------+
```

1.2.9.7.8 DENSE_RANK

Contents

Syntax

```
DENSE_RANK() OVER (
  [ PARTITION BY partition_expression ]
  [ ORDER BY order_list ]
)
```

Description

DENSE_RANK() is a window function that displays the number of a given row, starting at one and following the ORDER BY sequence of the window function, with identical values receiving the same result. Unlike the RANK() function, there are no skipped values if the preceding results are identical. It is also similar to the ROW_NUMBER() function except that in that function, identical values will receive a different row number for each result.

Examples

The distinction between DENSE_RANK(), RANK() and ROW_NUMBER():

```
CREATE TABLE student(course VARCHAR(10), mark int, name varchar(10));

INSERT INTO student VALUES
  ('Maths', 60, 'Thulile'),
  ('Maths', 60, 'Pritha'),
  ('Maths', 70, 'Voitto'),
  ('Maths', 55, 'Chun'),
  ('Biology', 60, 'Bilal'),
   ('Biology', 70, 'Roger');

SELECT
  RANK() OVER (PARTITION BY course ORDER BY mark DESC) AS rank,
  DENSE_RANK() OVER (PARTITION BY course ORDER BY mark DESC) AS dense_rank,
  ROW_NUMBER() OVER (PARTITION BY course ORDER BY mark DESC) AS row_num,
  course, mark, name
FROM student ORDER BY course, mark DESC;
+------+------------+---------+---------+------+---------+
| rank | dense_rank | row_num | course  | mark | name    |
+------+------------+---------+---------+------+---------+
|    1 |          1 |       1 | Biology |   70 | Roger   |
|    2 |          2 |       2 | Biology |   60 | Bilal   |
|    1 |          1 |       1 | Maths   |   70 | Voitto  |
|    2 |          2 |       2 | Maths   |   60 | Thulile |
|    2 |          2 |       3 | Maths   |   60 | Pritha  |

1.2.9.7.9 FIRST_VALUE

Contents

Syntax

```
FIRST_VALUE(expr) OVER (
  [ PARTITION BY partition_expression ]
  [ ORDER BY order_list ]
)
```

Description

`FIRST_VALUE` returns the first result from an ordered set, or NULL if no such result exists.

Examples

```
CREATE TABLE t1 (
  pk int primary key,
  a int,
  b int,
  c char(10),
  d decimal(10, 3),
  e real
);

INSERT INTO t1 VALUES
( 1, 0, 1,    'one',    0.1,  0.001),
( 2, 0, 2,    'two',    0.2,  0.002),
( 3, 0, 3,    'three',  0.3,  0.003),
( 4, 1, 2,    'three',  0.4,  0.004),
( 5, 1, 1,    'two',    0.5,  0.005),
( 6, 1, 1,    'one',    0.6,  0.006),
( 7, 2, NULL, 'n_one',  0.5,  0.007),
( 8, 2, 1,    'n_two',  NULL, 0.008),
( 9, 2, 2,    NULL,     0.7,  0.009),
(10, 2, 0,    'n_four', 0.8,  0.010),
(11, 2, 10,   NULL,     0.9,  NULL);

SELECT pk, FIRST_VALUE(pk) OVER (ORDER BY pk) AS first_asc,

1.2.4.9 JSON_ARRAYAGG

1.2.4.10 JSON_OBJECTAGG

1.2.9.7.12 LAG

Contents

Syntax

```
LAG (expr[, offset]) OVER (
  [ PARTITION BY partition_expression ]
  < ORDER BY order_list >
)
```

Description

The *LAG* function accesses data from a previous row according to the ORDER BY clause without the need for a self-join. The specific row is determined by the *offset* (default *1*), which specifies the number of rows behind the current row to use. An offset of *0* is the current row.

Examples

```
CREATE TABLE t1 (pk int primary key, a int, b int, c char(10), d decimal(10, 3), e real);

INSERT INTO t1 VALUES
 ( 1, 0, 1,    'one',    0.1,  0.001),
 ( 2, 0, 2,    'two',    0.2,  0.002),
 ( 3, 0, 3,    'three',  0.3,  0.003),
 ( 4, 1, 2,    'three',  0.4,  0.004),
 ( 5, 1, 1,    'two',    0.5,  0.005),
 ( 6, 1, 1,    'one',    0.6,  0.006),
 ( 7, 2, NULL, 'n_one',  0.5,  0.007),
 ( 8, 2, 1,    'n_two',  NULL, 0.008),
 ( 9, 2, 2,    NULL,     0.7,  0.009),
 (10, 2, 0,    'n_four', 0.8,  0.010),
 (11, 2, 10,   NULL,     0.9,  NULL);

SELECT pk, LAG(pk) OVER (ORDER BY pk) AS l,

+----+------+------+------+------+------+------+
```

1.2.8.3.14 LAST_VALUE

1.2.9.7.14 LEAD

Contents

Syntax

```
LEAD (expr[, offset]) OVER (
  [ PARTITION BY partition_expression ]
  [ ORDER BY order_list ]
)
```

Description

The *LEAD* function accesses data from a following row in the same result set without the need for a self-join. The specific row is determined by the *offset* (default *1*), which specifies the number of rows ahead the current row to use. An offset of *0* is the current row.

Example

```
CREATE TABLE t1 (pk int primary key, a int, b int, c char(10), d decimal(10, 3), e real);

INSERT INTO t1 VALUES
 ( 1, 0, 1,    'one',    0.1,  0.001),
 ( 2, 0, 2,    'two',    0.2,  0.002),
 ( 3, 0, 3,    'three',  0.3,  0.003),
 ( 4, 1, 2,    'three',  0.4,  0.004),
 ( 5, 1, 1,    'two',    0.5,  0.005),
 ( 6, 1, 1,    'one',    0.6,  0.006),
 ( 7, 2, NULL, 'n_one',  0.5,  0.007),
 ( 8, 2, 1,    'n_two',  NULL, 0.008),
 ( 9, 2, 2,    NULL,     0.7,  0.009),
 (10, 2, 0,    'n_four', 0.8,  0.010),
 (11, 2, 10,   NULL,     0.9,  NULL);

SELECT pk, LEAD(pk) OVER (ORDER BY pk) AS l,

```

1.2.4.11 MAX

1.2.9.7.16 MEDIAN

Contents

Syntax

```
MEDIAN(median expression) OVER (
  [ PARTITION BY partition_expression ]
)
```

Description

MEDIAN() is a window function that returns the median value of a range of values.

It is a specific case of PERCENTILE_CONT, with an argument of 0.5 and the ORDER BY column the one in `MEDIAN` 's argument.

```
MEDIAN(<median-arg>) OVER ( [ PARTITION BY partition_expression] )
```

Is equivalent to:

```
PERCENTILE_CONT(0.5) WITHIN
  GROUP (ORDER BY <median-arg>) OVER ( [ PARTITION BY partition_expression ])
```

Examples

```
CREATE TABLE book_rating (name CHAR(30), star_rating TINYINT);

INSERT INTO book_rating VALUES ('Lord of the Ladybirds', 5);
INSERT INTO book_rating VALUES ('Lord of the Ladybirds', 3);
INSERT INTO book_rating VALUES ('Lady of the Flies', 1);
INSERT INTO book_rating VALUES ('Lady of the Flies', 2);
INSERT INTO book_rating VALUES ('Lady of the Flies', 5);

SELECT name, median(star_rating) OVER (PARTITION BY name) FROM book_rating;
+----------------------+-----------------------------------------------+
| name                 | median(star_rating) OVER (PARTITION BY name)  |
+----------------------+-----------------------------------------------+
| Lord of the Ladybirds |                                  4.0000000000 |
| Lord of the Ladybirds |                                  4.0000000000 |
| Lady of the Flies     |                                  2.0000000000 |
| Lady of the Flies     |                                  2.0000000000 |
| Lady of the Flies     |                                  2.0000000000 |
+----------------------+-----------------------------------------------+
```

1.2.4.12 MIN

1.2.9.7.18 NTH_VALUE

Syntax

```
NTH_VALUE (expr[, num_row]) OVER (
  [ PARTITION BY partition_expression ]
  [ ORDER BY order_list ]
)
```

Contents

Description

The `NTH_VALUE` function returns the value evaluated at row number `num_row` of the window frame, starting from 1, or NULL if the row does not exist.

1.2.9.7.19 NTILE

Contents

Syntax

```
NTILE (expr) OVER (
  [ PARTITION BY partition_expression ]
  [ ORDER BY order_list ]
)
```

Description

NTILE() is a window function that returns an integer indicating which group a given row falls into. The number of groups is specified in the argument (*expr*), starting at one. Ordered rows in the partition are divided into the specified number of groups with as equal a size as possible.

Examples

```
create table t1 (
    pk int primary key,
    a int,
    b int
  );

insert into t1 values
    (11 , 0, 10),
    (12 , 0, 10),
    (13 , 1, 10),
    (14 , 1, 10),
    (18 , 2, 10),
    (15 , 2, 20),
    (16 , 2, 20),
    (17 , 2, 20),
    (19 , 4, 20),
    (20 , 4, 20);

select pk, a, b,
    ntile(1) over (order by pk)
  from t1;
+----+------+------+-----------------------------+
| pk | a    | b    | ntile(1) over (order by pk) |
+----+------+------+-----------------------------+
| 11 |    0 |   10 |                           1 |
| 12 |    0 |   10 |                           1 |

```

1.2.9.7.20 PERCENT_RANK

Contents

Syntax

```
PERCENT_RANK() OVER (
  [ PARTITION BY partition_expression ]
  [ ORDER BY order_list ]
)
```

Description

PERCENT_RANK() is a window function that returns the relative percent rank of a given row. The following formula is used to calculate the percent rank:

```
(rank - 1) / (number of rows in the window or partition - 1)
```

Examples

```
create table t1 (
  pk int primary key,
  a int,
  b int
);

insert into t1 values
( 1 , 0, 10),
( 2 , 0, 10),
( 3 , 1, 10),
( 4 , 1, 10),
( 8 , 2, 10),
( 5 , 2, 20),
( 6 , 2, 20),
( 7 , 2, 20),
( 9 , 4, 20),
(10 , 4, 20);

select pk, a, b,
    rank() over (order by a) as rank,
    percent_rank() over (order by a) as pct_rank,
    cume_dist() over (order by a) as cume_dist
from t1;
+----+------+------+------+--------------+--------------+
| pk | a    | b    | rank | pct_rank     | cume_dist    |
+----+------+------+------+--------------+--------------+
|  1 |    0 |   10 |    1 | 0.0000000000 | 0.2000000000 |
|  2 |    0 |   10 |    1 | 0.0000000000 | 0.2000000000 |
|  3 |    1 |   10 |    3 | 0.2222222222 | 0.4000000000 |
|  4 |    1 |   10 |    3 | 0.2222222222 | 0.4000000000 |
|  5 |    2 |   20 |    5 | 0.4444444444 | 0.8000000000 |
|  6 |    2 |   20 |    5 | 0.4444444444 | 0.8000000000 |
|  7 |    2 |   20 |    5 | 0.4444444444 | 0.8000000000 |
|  8 |    2 |   10 |    5 | 0.4444444444 | 0.8000000000 |

1.2.9.7.21 PERCENTILE_CONT

MariaDB starting with 10.3.3

The PERCENTILE_CONT() window function was first introduced with in MariaDB 10.3.3.

Contents

Syntax

Description

`PERCENTILE_CONT()` (standing for continuous percentile) is a window function which returns a value which corresponds to the given fraction in the sort order. If required, it will interpolate between adjacent input items.

Essentially, the following process is followed to find the value to return:

- Get the number of rows in the partition, denoted by N
- RN = p*(N-1), where p denotes the argument to the PERCENTILE_CONT function
- calculate the FRN(floor row number) and CRN(column row number for the group(FRN= floor(RN) and CRN = ceil(RN))
- look up rows FRN and CRN
- If (CRN = FRN = RN) then the result is (value of expression from row at RN)
- Otherwise the result is
- (CRN - RN) * (value of expression for row at FRN) +
- (RN - FRN) * (value of expression for row at CRN)

The MEDIAN function is a specific case of `PERCENTILE_CONT`, equivalent to `PERCENTILE_CONT(0.5)`.

Examples

```
CREATE TABLE book_rating (name CHAR(30), star_rating TINYINT);

INSERT INTO book_rating VALUES ('Lord of the Ladybirds', 5);
INSERT INTO book_rating VALUES ('Lord of the Ladybirds', 3);
INSERT INTO book_rating VALUES ('Lady of the Flies', 1);
INSERT INTO book_rating VALUES ('Lady of the Flies', 2);
INSERT INTO book_rating VALUES ('Lady of the Flies', 5);

SELECT name, PERCENTILE_CONT(0.5) WITHIN GROUP (ORDER BY star_rating)
  OVER (PARTITION BY name) AS pc
  FROM book_rating;
+----------------------+--------------+
| name                 | pc           |
+----------------------+--------------+
| Lord of the Ladybirds | 4.0000000000 |
| Lord of the Ladybirds | 4.0000000000 |
| Lady of the Flies     | 2.0000000000 |
| Lady of the Flies     | 2.0000000000 |
| Lady of the Flies     | 2.0000000000 |
+----------------------+--------------+

SELECT name, PERCENTILE_CONT(1) WITHIN GROUP (ORDER BY star_rating)
  OVER (PARTITION BY name) AS pc
  FROM book_rating;
+----------------------+--------------+
| name                 | pc           |
+----------------------+--------------+
| Lord of the Ladybirds | 5.0000000000 |
| Lord of the Ladybirds | 5.0000000000 |
| Lady of the Flies     | 5.0000000000 |
| Lady of the Flies     | 5.0000000000 |
| Lady of the Flies     | 5.0000000000 |
+----------------------+--------------+

SELECT name, PERCENTILE_CONT(0) WITHIN GROUP (ORDER BY star_rating)
  OVER (PARTITION BY name) AS pc
  FROM book_rating;
+----------------------+--------------+
| name                 | pc           |
+----------------------+--------------+
| Lord of the Ladybirds | 3.0000000000 |
| Lord of the Ladybirds | 3.0000000000 |
| Lady of the Flies     | 1.0000000000 |
| Lady of the Flies     | 1.0000000000 |
| Lady of the Flies     | 1.0000000000 |
+----------------------+--------------+

SELECT name, PERCENTILE_CONT(0.6) WITHIN GROUP (ORDER BY star_rating)
  OVER (PARTITION BY name) AS pc
  FROM book_rating;
+----------------------+--------------+
| name                 | pc           |
+----------------------+--------------+
| Lord of the Ladybirds | 4.2000000000 |
| Lord of the Ladybirds | 4.2000000000 |
| Lady of the Flies     | 2.6000000000 |
| Lady of the Flies     | 2.6000000000 |
| Lady of the Flies     | 2.6000000000 |
+----------------------+--------------+
```

1.2.9.7.22 PERCENTILE_DISC

MariaDB starting with 10.3.3

The PERCENTILE_DISC() window function was first introduced with in MariaDB 10.3.3.

Syntax

Contents

Description

`PERCENTILE_DISC()` (standing for discrete percentile) is a window function which returns the first value in the set whose ordered position is the same or more than the specified fraction.

Essentially, the following process is followed to find the value to return:

- Get the number of rows in the partition.
- Walk through the partition, in order, until finding the the first row with `CUME_DIST()` >= function_argument.

Examples

```
CREATE TABLE book_rating (name CHAR(30), star_rating TINYINT);

INSERT INTO book_rating VALUES ('Lord of the Ladybirds', 5);
INSERT INTO book_rating VALUES ('Lord of the Ladybirds', 3);
INSERT INTO book_rating VALUES ('Lady of the Flies', 1);
INSERT INTO book_rating VALUES ('Lady of the Flies', 2);
INSERT INTO book_rating VALUES ('Lady of the Flies', 5);

SELECT name, PERCENTILE_DISC(0.5) WITHIN GROUP (ORDER BY star_rating)
  OVER (PARTITION BY name) AS pc FROM book_rating;
+----------------------+------+
| name                 | pc   |
+----------------------+------+
| Lord of the Ladybirds |    3 |
| Lord of the Ladybirds |    3 |
| Lady of the Flies     |    2 |
| Lady of the Flies     |    2 |
| Lady of the Flies     |    2 |
+----------------------+------+
5 rows in set (0.000 sec)

SELECT name, PERCENTILE_DISC(0) WITHIN GROUP (ORDER BY star_rating)
 OVER (PARTITION BY name) AS pc FROM book_rating;
+----------------------+------+
| name                 | pc   |
+----------------------+------+
| Lord of the Ladybirds |    3 |
| Lord of the Ladybirds |    3 |
| Lady of the Flies     |    1 |
| Lady of the Flies     |    1 |
| Lady of the Flies     |    1 |
+----------------------+------+
5 rows in set (0.000 sec)

SELECT name, PERCENTILE_DISC(1) WITHIN GROUP (ORDER BY star_rating)
  OVER (PARTITION BY name) AS pc FROM book_rating;
+----------------------+------+
| name                 | pc   |
+----------------------+------+
| Lord of the Ladybirds |    5 |
| Lord of the Ladybirds |    5 |
| Lady of the Flies     |    5 |
| Lady of the Flies     |    5 |
| Lady of the Flies     |    5 |
+----------------------+------+
5 rows in set (0.000 sec)

SELECT name, PERCENTILE_DISC(0.6) WITHIN GROUP (ORDER BY star_rating)
  OVER (PARTITION BY name) AS pc FROM book_rating;
+----------------------+------+
| name                 | pc   |
+----------------------+------+
| Lord of the Ladybirds |    5 |
| Lord of the Ladybirds |    5 |
| Lady of the Flies     |    2 |
| Lady of the Flies     |    2 |
| Lady of the Flies     |    2 |
+----------------------+------
```

1.2.9.7.23 RANK

Contents

Syntax

```
RANK() OVER (
  [ PARTITION BY partition_expression ]
  [ ORDER BY order_list ]
)
```

Description

RANK() is a window function that displays the number of a given row, starting at one and following the ORDER BY sequence of the window function, with identical values receiving the same result. It is similar to the ROW_NUMBER() function except that in that function, identical values will receive a different row number for each result.

Examples

The distinction between DENSE_RANK(), RANK() and ROW_NUMBER():

```
CREATE TABLE student(course VARCHAR(10), mark int, name varchar(10));

INSERT INTO student VALUES
  ('Maths', 60, 'Thulile'),
  ('Maths', 60, 'Pritha'),
  ('Maths', 70, 'Voitto'),
  ('Maths', 55, 'Chun'),
  ('Biology', 60, 'Bilal'),
   ('Biology', 70, 'Roger');

SELECT
  RANK() OVER (PARTITION BY course ORDER BY mark DESC) AS rank,
  DENSE_RANK() OVER (PARTITION BY course ORDER BY mark DESC) AS dense_rank,
  ROW_NUMBER() OVER (PARTITION BY course ORDER BY mark DESC) AS row_num,
  course, mark, name
FROM student ORDER BY course, mark DESC;
+------+------------+---------+---------+------+---------+
| rank | dense_rank | row_num | course  | mark | name    |
+------+------------+---------+---------+------+---------+
|    1 |          1 |       1 | Biology |   70 | Roger   |
|    2 |          2 |       2 | Biology |   60 | Bilal   |
|    1 |          1 |       1 | Maths   |   70 | Voitto  |
|    2 |          2 |       2 | Maths   |   60 | Thulile |
|    2 |          2 |       3 | Maths   |   60 | Pritha  |
|    4 |          3 |       4 | Maths   |   55 | Chun    |
+------+------------+---------+---------+------+---------+
```

1.2.9.7.24 ROW_NUMBER

Contents

Syntax

```
ROW_NUMBER() OVER (
  [ PARTITION BY partition_expression ]
  [ ORDER BY order_list ]
)
```

Description

ROW_NUMBER() is a window function that displays the number of a given row, starting at one and following the ORDER BY sequence of the window function, with identical values receiving different row numbers. It is similar to the RANK() and DENSE_RANK() functions except that in that function, identical values will receive the same rank for each result.

Examples

The distinction between DENSE_RANK(), RANK() and ROW_NUMBER():

```
CREATE TABLE student(course VARCHAR(10), mark int, name varchar(10));

INSERT INTO student VALUES
  ('Maths', 60, 'Thulile'),
  ('Maths', 60, 'Pritha'),
  ('Maths', 70, 'Voitto'),
  ('Maths', 55, 'Chun'),
  ('Biology', 60, 'Bilal'),
   ('Biology', 70, 'Roger');

SELECT
  RANK() OVER (PARTITION BY course ORDER BY mark DESC) AS rank,
  DENSE_RANK() OVER (PARTITION BY course ORDER BY mark DESC) AS dense_rank,
  ROW_NUMBER() OVER (PARTITION BY course ORDER BY mark DESC) AS row_num,
  course, mark, name
FROM student ORDER BY course, mark DESC;
+------+------------+---------+---------+------+---------+
| rank | dense_rank | row_num | course  | mark | name    |
+------+------------+---------+---------+------+---------+
|    1 |          1 |       1 | Biology |   70 | Roger   |
|    2 |          2 |       2 | Biology |   60 | Bilal   |
|    1 |          1 |       1 | Maths   |   70 | Voitto  |
|    2 |          2 |       2 | Maths   |   60 | Thulile |
|    2 |          2 |       3 | Maths   |   60 | Pritha  |
|    4 |          3 |       4 | Maths   |   55 | Chun    |
+------+------------+---------+---------+------+---------+
```

1.2.4.13 STD

1.2.4.14 STDDEV

1.2.4.15 STDDEV_POP

1.2.4.16 STDDEV_SAMP

1.2.4.17 SUM

1.2.4.18 VARIANCE

1.2.4.19 VAR_POP

1.2.4.20 VAR_SAMP

1.2.9.7.33 Aggregate Functions as Window Functions

It is possible to use aggregate functions as window functions. An aggregate function used as a window function must have the `OVER` clause. For example, here's COUNT() used as a window function:

```
select COUNT(*) over  (order by column) from table;
```

MariaDB currently allows these aggregate functions to be used as window functions:

- AVG
- BIT_AND
- BIT_OR

- BIT_XOR
- COUNT
- JSON_ARRAYAGG
- JSON_OBJECTAGG
- MAX
- MIN
- STD
- STDDEV
- STDDEV_POP
- STDDEV_SAMP
- SUM
- VAR_POP
- VAR_SAMP
- VARIANCE

1.2.9.7.34 ColumnStore Window Functions

Introduction

MariaDB ColumnStore provides support for window functions broadly following the SQL 2003 specification. A window function allows for calculations relating to a window of data surrounding the current row in a result set. This capability provides for simplified queries in support of common business questions such as cumulative totals, rolling averages, and top 10 lists.

Aggregate functions are utilized for window functions however differ in behavior from a group by query because the rows remain ungrouped. This provides support for cumulative sums and rolling averages, for example.

Two key concepts for window functions are Partition and Frame:

- A Partition is a group of rows, or window, that have the same value for a specific column, for example a Partition can be created over a time period such as a quarter or lookup values.
- The Frame for each row is a subset of the row's Partition. The frame typically is dynamic allowing for a sliding frame of rows within the Partition. The Frame determines the range of rows for the windowing function. A Frame could be defined as the last X rows and next Y rows all the way up to the entire Partition.

Window functions are applied after joins, group by, and having clauses are calculated.

Syntax

A window function is applied in the select clause using the following syntax:

```
function_name ([expression [, expression ... ]]) OVER ( window_definition )
```

where *window_definition* is defined as:

```
[ PARTITION BY expression [, ...] ]
[ ORDER BY expression [ ASC | DESC ] [ NULLS { FIRST | LAST } ] [, ...] ]
[ frame_clause ]
```

PARTITION BY:

- Divides the window result set into groups based on one or more *expressions*.
- An expression may be a constant, column, and non window function expressions.
- A query is not limited to a single partition by clause. Different partition clauses can be used across different window function applications.
- The partition by columns do not need to be in the select list but do need to be available from the query result set.
- If there is no PARTITION BY clause, all rows of the result set define the group.

ORDER BY

- Defines the ordering of values within the partition.
- Can be ordered by multiple keys which may be a constant, column or non window function expression.
- The order by columns do not need to be in the select list but need to be available from the query result set.
- Use of a select column alias from the query is not supported.
- ASC (default) and DESC options allow for ordering ascending or descending.
- NULLS FIRST and NULL_LAST options specify whether null values come first or last in the ordering sequence. NULLS_FIRST is the default for ASC order, and NULLS_LAST is the default for DESC order.

and the optional *frame_clause* is defined as:

```
{ RANGE | ROWS } frame_start
{ RANGE | ROWS } BETWEEN frame_start AND frame_end
```

and the optional *frame_start* and *frame_end* are defined as (value being a numeric expression):

```
UNBOUNDED PRECEDING
value PRECEDING
CURRENT ROW
value FOLLOWING
UNBOUNDED FOLLOWING
```

RANGE/ROWS:

- Defines the windowing clause for calculating the set of rows that the function applies to for calculating a given rows window function result.
- Requires an ORDER BY clause to define the row order for the window.
- ROWS specify the window in physical units, i.e. result set rows and must be a constant or expression evaluating to a positive numeric value.
- RANGE specifies the window as a logical offset. If the the expression evaluates to a numeric value then the ORDER BY expression must be a numeric or DATE type. If the expression evaluates to an interval value then the ORDER BY expression must be a DATE data type.
- UNBOUNDED PRECEDING indicates the window starts at the first row of the partition.
- UNBOUNDED FOLLOWING indicates the window ends at the last row of the partition.
- CURRENT ROW specifies the window start or ends at the current row or value.
- If omitted, the default is ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW.

Supported Functions

Function	Description
AVG()	The average of all input values.
COUNT()	Number of input rows.
CUME_DIST()	Calculates the cumulative distribution, or relative rank, of the current row to other rows in the same partition. Number of peer or preceding rows / number of rows in partition.
DENSE_RANK()	Ranks items in a group leaving no gaps in ranking sequence when there are ties.
FIRST_VALUE()	The value evaluated at the row that is the first row of the window frame (counting from 1); null if no such row.
LAG()	The value evaluated at the row that is offset rows before the current row within the partition; if there is no such row, instead return default. Both offset and default are evaluated with respect to the current row. If omitted, offset defaults to 1 and default to null. LAG provides access to more than one row of a table at the same time without a self-join. Given a series of rows returned from a query and a position of the cursor, LAG provides access to a row at a given physical offset prior to that position.
LAST_VALUE()	The value evaluated at the row that is the last row of the window frame (counting from 1); null if no such row.
LEAD()	Provides access to a row at a given physical offset beyond that position. Returns value evaluated at the row that is offset rows after the current row within the partition; if there is no such row, instead return default. Both offset and default are evaluated with respect to the current row. If omitted, offset defaults to 1 and default to null.
MAX()	Maximum value of expression across all input values.
MEDIAN()	An inverse distribution function that assumes a continuous distribution model. It takes a numeric or datetime value and returns the middle value or an interpolated value that would be the middle value once the values are sorted. Nulls are ignored in the calculation.
MIN()	Minimum value of expression across all input values.
NTH_VALUE()	The value evaluated at the row that is the nth row of the window frame (counting from 1); null if no such row.

NTILE()	Divides an ordered data set into a number of buckets indicated by expr and assigns the appropriate bucket number to each row. The buckets are numbered 1 through expr. The expr value must resolve to a positive constant for each partition. Integer ranging from 1 to the argument value, dividing the partition as equally as possible.
PERCENT_RANK()	relative rank of the current row: (rank - 1) / (total rows - 1).
PERCENTILE_CONT()	An inverse distribution function that assumes a continuous distribution model. It takes a percentile value and a sort specification, and returns an interpolated value that would fall into that percentile value with respect to the sort specification. Nulls are ignored in the calculation.
PERCENTILE_DISC()	An inverse distribution function that assumes a discrete distribution model. It takes a percentile value and a sort specification and returns an element from the set. Nulls are ignored in the calculation.
RANK()	rank of the current row with gaps; same as row_number of its first peer.
ROW_NUMBER()	number of the current row within its partition, counting from 1
STDDEV() STDDEV_POP()	Computes the population standard deviation and returns the square root of the population variance.
STDDEV_SAMP()	Computes the cumulative sample standard deviation and returns the square root of the sample variance.
SUM()	Sum of expression across all input values.
VARIANCE() VAR_POP()	Population variance of the input values (square of the population standard deviation).
VAR_SAMP()	Sample variance of the input values (square of the sample standard deviation).

Examples

Example Schema

The examples are all based on the following simplified sales opportunity table:

```
create table opportunities (
id int,
accountName varchar(20),
name varchar(128),
owner varchar(7),
amount decimal(10,2),
closeDate date,
stageName varchar(11)
) engine=columnstore;
```

Some example values are (thanks to https://www.mockaroo.com for sample data generation):

id	accountName	name	owner	amount	closeDate	stageName
1	Browseblab	Multi-lateral executive function	Bob	26444.86	2016-10-20	Negotiating
2	Mita	Organic demand-driven benchmark	Maria	477878.41	2016-11-28	ClosedWon
3	Miboo	De-engineered hybrid groupware	Olivier	80181.78	2017-01-05	ClosedWon
4	Youbridge	Enterprise-wide bottom-line Graphic Interface	Chris	946245.29	2016-07-02	ClosedWon
5	Skyba	Reverse-engineered fresh-thinking standardization	Maria	696241.82	2017-02-17	Negotiating
6	Eayo	Fundamental well-modulated artificial intelligence	Bob	765605.52	2016-08-27	Prospecting
7	Yotz	Extended secondary infrastructure	Chris	319624.20	2017-01-06	ClosedLost
8	Oloo	Configurable web-enabled data-warehouse	Chris	321016.26	2017-03-08	ClosedLost
9	Kaymbo	Multi-lateral web-enabled definition	Bob	690881.01	2017-01-02	Developing
10	Rhyloo	Public-key coherent infrastructure	Chris	965477.74	2016-11-07	Prospecting

The schema, sample data, and queries are available as an attachment to this article.

Cumulative Sum and Running Max Example

Window functions can be used to achieve cumulative / running calculations on a detail report. In this case a won opportunity report for a 7 day period adds columns to show the accumulated won amount as well as the current highest opportunity amount in preceding rows.

```
select owner,
accountName,
CloseDate,
amount,
sum(amount) over (order by CloseDate rows between unbounded preceding and current row) cumeWon,

max(amount) over (order by CloseDate rows between unbounded preceding and current row) runningM
ax
from opportunities
where stageName='ClosedWon'
and closeDate >= '2016-10-02' and closeDate <= '2016-10-09'
order by CloseDate;
```

with example results:

owner	accountName	CloseDate	amount	cumeWon	runningMax
Bill	Babbleopia	2016-10-02	437636.47	437636.47	437636.47
Bill	Thoughtworks	2016-10-04	146086.51	583722.98	437636.47
Olivier	Devpulse	2016-10-05	834235.93	1417958.91	834235.93
Chris	Linkbridge	2016-10-07	539977.45	2458738.65	834235.93
Olivier	Trupe	2016-10-07	500802.29	1918761.20	834235.93

Chris	Avamm	2016-10-09	699566.86	4015560.38	857254.87

Partitioned Cumulative Sum and Running Max Example

The above example can be partitioned, so that the window functions are over a particular field grouping such as owner and accumulate within that grouping. This is achieved by adding the syntax "partition by <columns>" in the window function clause.

```
select owner,
accountName,
CloseDate,
amount,
sum(amount) over (partition by owner order by CloseDate rows between unbounded preceding and cu
rrent row) cumeWon,
max(amount) over (partition by owner order by CloseDate rows between unbounded preceding and cu
rrent row) runningMax
from opportunities
where stageName='ClosedWon'
and closeDate >= '2016-10-02' and closeDate <= '2016-10-09'
order by owner, CloseDate;
```

with example results:

owner	accountName	CloseDate	amount	cumeWon	runningMax
Bill	Babbleopia	2016-10-02	437636.47	437636.47	437636.47
Bill	Thoughtworks	2016-10-04	146086.51	583722.98	437636.47
Bill	Latz	2016-10-08	857254.87	1440977.85	857254.87
Chris	Linkbridge	2016-10-07	539977.45	539977.45	539977.45
Chris	Avamm	2016-10-09	699566.86	1239544.31	699566.86
Olivier	Devpulse	2016-10-05	834235.93	834235.93	834235.93
Olivier	Trupe	2016-10-07	500802.29	1335038.22	834235.93

Ranking / Top Results

The rank window function allows for ranking or assigning a numeric order value based on the window function definition.

Using the Rank() function will result in the same value for ties / equal values and the next rank value skipped. The Dense_Rank() function behaves similarly except the next consecutive number is used after a tie rather than skipped. The Row_Number() function will provide a unique ordering value. The example query shows the Rank() function being applied to rank sales reps by the number of opportunities for Q4 2016.

```
select owner,
wonCount,
rank() over (order by wonCount desc) rank
from (
  select owner,
  count(*) wonCount
  from opportunities
  where stageName='ClosedWon'
  and closeDate >= '2016-10-01' and closeDate < '2016-12-31'
  group by owner
) t
order by rank;
```

with example results (note the query is technically incorrect by using closeDate < '2016-12-31' however this creates a tie scenario for illustrative purposes):

owner	wonCount	rank
Bill	19	1
Chris	15	2
Maria	14	3
Bob	14	3
Olivier	10	5

If the dense_rank function is used the rank values would be 1,2,3,3,4 and for the row_number function the values would be 1,2,3,4,5.

First and Last Values

The first_value and last_value functions allow determining the first and last values of a given range. Combined with a group by this allows summarizing opening and closing values. The example shows a more complex case where detailed information is presented for first and last opportunity by quarter.

```
select a.year,
a.quarter,
f.accountName firstAccountName,
f.owner firstOwner,
f.amount firstAmount,
l.accountName lastAccountName,
l.owner lastOwner,
l.amount lastAmount
from (
  select year,
  quarter,
  min(firstId) firstId,
  min(lastId) lastId
  from (
    select year(closeDate) year,
    quarter(closeDate) quarter,
    first_value(id) over (partition by year(closeDate), quarter(closeDate) order by closeDate r
ows between unbounded preceding and current row) firstId,
    last_value(id) over (partition by year(closeDate), quarter(closeDate) order by closeDate ro
ws between current row and unbounded following) lastId
    from opportunities  where stageName='ClosedWon'
  ) t
  group by year, quarter order by year,quarter
) a
join opportunities f on a.firstId = f.id
join opportunities l on a.lastId = l.id
order by year, quarter;
```

with example results:

year	quarter	firstAccountName	firstOwner	firstAmount	lastAccountName	lastOwner	lastAmount

2016	3	Skidoo	Bill	523295.07	Skipstorm	Bill	151420.86
2016	4	Skimia	Chris	961513.59	Avamm	Maria	112493.65
2017	1	Yombu	Bob	536875.51	Skaboo	Chris	270273.08

Prior and Next Example

Sometimes it useful to understand the previous and next values in the context of a given row. The lag and lead window functions provide this capability. By default the offset is one providing the prior or next value but can also be provided to get a larger offset. The example query is a report of opportunities by account name showing the opportunity amount, and the prior and next opportunity amount for that account by close date.

```
select accountName,
closeDate,
amount currentOppAmount,
lag(amount) over (partition by accountName order by closeDate) priorAmount, lead(amount) over (
partition by accountName order by closeDate) nextAmount
from opportunities
order by accountName, closeDate
limit 9;
```

with example results:

accountName	closeDate	currentOppAmount	priorAmount	nextAmount
Abata	2016-09-10	645098.45	NULL	161086.82
Abata	2016-10-14	161086.82	645098.45	350235.75
Abata	2016-12-18	350235.75	161086.82	878595.89
Abata	2016-12-31	878595.89	350235.75	922322.39
Abata	2017-01-21	922322.39	878595.89	NULL
Abatz	2016-10-19	795424.15	NULL	NULL
Agimba	2016-07-09	288974.84	NULL	914461.49
Agimba	2016-09-07	914461.49	288974.84	176645.52
Agimba	2016-09-20	176645.52	914461.49	NULL

Quartiles Example

The NTile window function allows for breaking up a data set into portions assigned a numeric value to each portion of the range. NTile(4) breaks the data up into quartiles (4 sets). The example query produces a report of all opportunities summarizing the quartile boundaries of amount values.

```
select t.quartile,
min(t.amount) min,
max(t.amount) max
from (
  select amount,
  ntile(4) over (order by amount asc) quartile
  from opportunities
  where closeDate >= '2016-10-01' and closeDate <= '2016-12-31'
  ) t
group by quartile
order by quartile;
```

With example results:

quartile	min	max
1	6337.15	287634.01
2	288796.14	539977.45
3	540070.04	748727.51
4	753670.77	998864.47

Percentile Example

The percentile functions have a slightly different syntax from other window functions as can be seen in the example below. These functions can be only applied against numeric values. The argument to the function is the percentile to evaluate. Following 'within group' is the sort expression which indicates the sort column and optionally order. Finally after 'over' is an optional partition by clause, for no partition clause use 'over ()'. The example below utilizes the value 0.5 to calculate the median opportunity amount in the rows. The values differ sometimes because percentile_cont will return the average of the 2 middle rows for an even data set while percentile_desc returns the first encountered in the sort.

```
select owner,
accountName,
CloseDate,
amount,
percentile_cont(0.5) within group (order by amount) over (partition by owner) pct_cont,
percentile_disc(0.5) within group (order by amount) over (partition by owner) pct_disc
from opportunities
where stageName='ClosedWon'
and closeDate >= '2016-10-02' and closeDate <= '2016-10-09'
order by owner, CloseDate;
```

With example results:

owner	accountName	CloseDate	amount	pct_cont	pct_disc
Bill	Babbleopia	2016-10-02	437636.47	437636.4700000000	437636.47
Bill	Thoughtworks	2016-10-04	146086.51	437636.4700000000	437636.47
Bill	Latz	2016-10-08	857254.87	437636.4700000000	437636.47

Chris	Avamm	2016-10-09	699566.86	619772.1550000000	539977.45
Olivier	Devpulse	2016-10-05	834235.93	667519.1100000000	500802.29
Olivier	Trupe	2016-10-07	500802.29	667519.1100000000	500802.29

1.2.9.7.35 Window Frames

Syntax

```
frame_clause:
  {ROWS | RANGE} {frame_border | BETWEEN frame_border AND frame_border}

frame_border:
  | UNBOUNDED PRECEDING
  | UNBOUNDED FOLLOWING
  | CURRENT ROW
  | expr PRECEDING
  | expr FOLLOWING
```

Description

A basic overview of window functions is described in Window Functions Overview. Window frames expand this functionality by allowing the function to include a specified a number of rows around the current row.

These include:

- All rows before the current row (UNBOUNDED PRECEDING), for example `RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW`
- All rows after the current row (UNBOUNDED FOLLOWING), for example `RANGE BETWEEN CURRENT ROW AND UNBOUNDED FOLLOWING`
- A set number of rows before the current row (expr PRECEDING) for example `RANGE BETWEEN 6 PRECEDING AND CURRENT ROW`
- A set number of rows after the current row (expr PRECEDING AND expr FOLLOWING) for example `RANGE BETWEEN CURRENT ROW AND 2 FOLLOWING`
- A specified number of rows both before and after the current row, for example `RANGE BETWEEN 6 PRECEDING AND`

```
    3 FOLLOWING
```

The following functions operate on window frames:

- AVG
- BIT_AND
- BIT_OR
- BIT_XOR
- COUNT
- LEAD
- MAX
- MIN
- NTILE
- STD
- STDDEV
- STDDEV_POP
- STDDEV_SAMP
- SUM
- VAR_POP
- VAR_SAMP
- VARIANCE

Window frames are determined by the *frame_clause* in the window function request.

Take the following example:

```
CREATE TABLE `student_test` (
  name char(10),
  test char(10),
  score tinyint(4)
);

INSERT INTO student_test VALUES
    ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
    ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
    ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
    ('Tatiana', 'SQL', 87);

SELECT name, test, score, SUM(score)
  OVER () AS total_score
  FROM student_test;
+---------+--------+-------+-------------+
| name    | test   | score | total_score |
+---------+--------+-------+-------------+
| Chun    | SQL    |    75 |         453 |
| Chun    | Tuning |    73 |         453 |
| Esben   | SQL    |    43 |         453 |
| Esben   | Tuning |    31 |         453 |
| Kaolin  | SQL    |    56 |         453 |
| Kaolin  | Tuning |    88 |         453 |
| Tatiana | SQL    |    87 |         453 |
+---------+--------+-------+-------------+
```

By not specifying an OVER clause, the SUM function is run over the entire dataset. However, if we specify an ORDER BY condition based on score (and order the entire result in the same way for clarity), the following result is returned:

```
SELECT name, test, score, SUM(score)
  OVER (ORDER BY score) AS total_score
  FROM student_test ORDER BY score;
+---------+--------+-------+-------------+
| name    | test   | score | total_score |
+---------+--------+-------+-------------+
| Esben   | Tuning |    31 |          31 |
| Esben   | SQL    |    43 |          74 |
| Kaolin  | SQL    |    56 |         130 |
| Chun    | Tuning |    73 |         203 |
| Chun    | SQL    |    75 |         278 |
| Tatiana | SQL    |    87 |         365 |
| Kaolin  | Tuning |    88 |         453 |
+---------+--------+-------+-------------+
```

The total_score column represents a running total of the current row, and all previous rows. The window frame in this

example expands as the function proceeds.

The above query makes use of the default to define the window frame. It could be written explicitly as follows:

```
SELECT name, test, score, SUM(score)
  OVER (ORDER BY score RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW) AS total_score
  FROM student_test ORDER BY score;
+---------+--------+-------+-------------+
| name    | test   | score | total_score |
+---------+--------+-------+-------------+
| Esben   | Tuning |    31 |          31 |
| Esben   | SQL    |    43 |          74 |
| Kaolin  | SQL    |    56 |         130 |
| Chun    | Tuning |    73 |         203 |
| Chun    | SQL    |    75 |         278 |
| Tatiana | SQL    |    87 |         365 |
| Kaolin  | Tuning |    88 |         453 |
+---------+--------+-------+-------------+
```

Let's look at some alternatives:

Firstly, applying the window function to the current row and all following rows can be done with the use of UNBOUNDED FOLLOWING:

```
SELECT name, test, score, SUM(score)
  OVER (ORDER BY score RANGE BETWEEN CURRENT ROW AND UNBOUNDED FOLLOWING) AS total_score
  FROM student_test ORDER BY score;
+---------+--------+-------+-------------+
| name    | test   | score | total_score |
+---------+--------+-------+-------------+
| Esben   | Tuning |    31 |         453 |
| Esben   | SQL    |    43 |         422 |
| Kaolin  | SQL    |    56 |         379 |
| Chun    | Tuning |    73 |         323 |
| Chun    | SQL    |    75 |         250 |
| Tatiana | SQL    |    87 |         175 |
| Kaolin  | Tuning |    88 |          88 |
+---------+--------+-------+-------------+
```

It's possible to specify a number of rows, rather than the entire unbounded following or preceding set. The following example takes the current row, as well as the previous row:

```
SELECT name, test, score, SUM(score)
  OVER (ORDER BY score ROWS BETWEEN 1 PRECEDING AND CURRENT ROW) AS total_score
  FROM student_test ORDER BY score;
+---------+--------+-------+-------------+
| name    | test   | score | total_score |
+---------+--------+-------+-------------+
| Esben   | Tuning |    31 |          31 |
| Esben   | SQL    |    43 |          74 |
| Kaolin  | SQL    |    56 |          99 |
| Chun    | Tuning |    73 |         129 |
| Chun    | SQL    |    75 |         148 |
| Tatiana | SQL    |    87 |         162 |
| Kaolin  | Tuning |    88 |         175 |
+---------+--------+-------+-------------+
```

The current row and the following row:

```
SELECT name, test, score, SUM(score)
  OVER (ORDER BY score ROWS BETWEEN 1 PRECEDING AND 1 FOLLOWING) AS total_score
  FROM student_test ORDER BY score;
+---------+--------+-------+-------------+
| name    | test   | score | total_score |
+---------+--------+-------+-------------+
| Esben   | Tuning |    31 |          74 |
| Esben   | SQL    |    43 |         130 |
| Kaolin  | SQL    |    56 |         172 |
| Chun    | Tuning |    73 |         204 |
| Chun    | SQL    |    75 |         235 |
| Tatiana | SQL    |    87 |         250 |
| Kaolin  | Tuning |    88 |         175 |
+---------+--------+-------+-------------+
```

1.3 Clients & Utilities

mariadb Client

The mariadb command-line client.

Aria Clients and Utilities

Clients and utilities for working with Aria tables

Backup, Restore and Import Clients

Clients for taking backups or importing/restoring data

Graphical and Enhanced Clients

Incomplete list of graphical clients

MyISAM Clients and Utilities

Clients and utilities for working with MyISAM tables

dbdeployer

Installing and testing multiple MariaDB versions in isolation.

dbForge Studio for MySQL/MariaDB

IDE for the development, management, and administration of MariaDB & MySQL databases.

EXPLAIN Analyzer

The EXPLAIN Analyzer is no longer active. The EXPLAIN Analyzer was an onlin...

EXPLAIN Analyzer API

The online EXPLAIN Analyzer tool has an open API to allow client applicatio...

innochecksum

Tool for printing checksums for InnoDB files.

msql2mysql

Description Initially, the MySQL C API was developed to be very similar to ...

my_print_defaults

Displays the options from option groups of option files

mariadb-binlog

mariadb-binlog utility for processing binary log files.

mariadb-stress-test

Perl script that performs stress-testing of the MariaDB server

mariadb-test

Testing utility

perror

Display descriptions for system or storage engine error codes

replace Utility

The replace utility program changes strings in place infiles or on the standard input

resolveip

Resolves IP addresses to host names and vice versa

resolve_stack_dump

Resolve numeric stack strace dump into symbols

xtstat

Used to monitor all internal activity of PBXT

mariadb-access

Tool for checking access privileges.

mariadb-admin

Admin tool for monitoring, creating/dropping databases, stopping MariaDB etc.

mariadb-check

Tool for checking, repairing, analyzing and optimizing tables.

mariadb-conv

Character set conversion utility for MariaDB.

mariadb-convert-table-format

Convert tables to use a particular storage engine by default.

mariadb-dumpslow

Display data from the slow query log.

mariadb-embedded

mariadb client statically linked to libmariadbd, the embedded server.

mariadb-find-rows

Read files containing SQL statements and extract statements that match a pattern.

mariadb-fix-extensions

Converts the extensions for MyISAM (or ISAM) table files to their canonical forms.

mariadb-install-db

Tool for creating the system tables in the mysql database.

mariadb-plugin

Tool for enabling or disabling plugins.

mariadb-report

Creates a friendly report of important MariaDB status values.

mariadb-secure-installation

Improve the security of a MariaDB installation.

mariadb-setpermission

Helps add users or databases or change passwords in MariaDB.

mariadb-show

Shows database structure.

mariadb-slap

Tool for load-testing MariaDB.

mariadb-tzinfo-to-sql

Load time zones into the time zone tables.

mariadb-upgrade

Update to the latest MariaDB Server version.

mariadb-waitpid

Terminate processes.

Legacy Clients and Utilities

Removed, deprecated or unmaintained MariaDB clients and utilities.

There are 8 related questions.

1.3.1 mariadb Client

The mariadb command-line client.

Previously, the client was called `mysql` which, from MariaDB 10.5, is still a symlink.

mariadb Command-Line Client

mariadb is a simple SQL shell with GNU readline capabilities.

Delimiters

How to change the delimiter for the mariadb client.

mysql Command-line Client

Symlink or old name for mariadb, the command-line client.

There are 4 related questions.

1.3.2 mariadb Command-Line Client

mariadb is a simple SQL shell (with GNU readline capabilities).

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb` is a symlink to `mysql`, the command-line client.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadb` is the name of the command-line client, with `mysql` a symlink.

About the mariadb Command-Line Client

mariadb supports interactive and non-interactive use. When used interactively, query results are presented in an ASCII-table format. When used non-interactively (for example, as a filter), the result is presented in tab-separated format. The output format can be changed using command options.

If you have problems due to insufficient memory for large result sets, use the `--quick` option. This forces mariadb to retrieve results from the server a row at a time rather than retrieving the entire result set and buffering it in memory before displaying it. This is done by returning the result set using the `mysql_use_result()` C API function in the client/server library rather than `mysql_store_result()`.

Using mariadb is very easy. Invoke it from the prompt of your command interpreter as follows:

```
mariadb db_name
```

Or:

```
mariadb --user=user_name --password=your_password db_name
```

Then type an SQL statement, end it with “;”, \g, or \G and press Enter.

Typing Control-C causes mariadb to attempt to kill the current statement. If this cannot be done, or Control-C is typed again before the statement is killed, mariadb exits.

You can execute SQL statements in a script file (batch file) like this:

```
mariadb db_name < script.sql > output.tab
```

Using mariadb

The command to use `mariadb` and the general syntax is:

```
mariadb <options>
```

Options

`mariadb` supports the following options:

`-?, --help`

Display help and exit.

`-I, --help`

Synonym for `-?`

`--abort-source-on-error`

Abort 'source filename' operations in case of errors.

`--auto-rehash`

Enable automatic rehashing. This option is on by default, which enables database, table, and column name completion. Use `--disable-auto-rehash`, `--no-auto-rehash` or `skip-auto-rehash` to disable rehashing. That causes mariadb to start faster, but you must issue the rehash command if you want to use name completion. To complete a name, enter the first part and press Tab. If the name is unambiguous, mariadb completes it. Otherwise, you can press Tab again to see the possible names that begin with what you have typed so far. Completion does not occur if there is no default database.

`-A, --no-auto-rehash`

No automatic rehashing. One has to use 'rehash' to get table and field completion. This gives a quicker start of mariadb and disables rehashing on reconnect.

`--auto-vertical-output`

Automatically switch to vertical output mode if the result is wider than the terminal width.

`-B, --batch`

Print results using tab as the column separator, with each row on a new line. With this option, mariadb does not use the history file. Batch mode results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the `--raw` option. (Enables `--silent`.)

`--binary-mode`

By default, ASCII '\0' is disallowed and '\r\n' is translated to '\n'. This switch turns off both features, and also turns off parsing of all client commands except \C and DELIMITER, in non-interactive mode (for input piped to mariadb or loaded using the 'source' command). This is necessary when processing output from mariadb-binlog that may contain blobs.

`--character-sets-dir=name`

Directory for character set files.

`--column-names`

Write column names in results. (Defaults to on; use `--skip-column-names` to disable.)

`--column-type-info`

Display column type information.

`-c, --comments`

Preserve comments. Send comments to the server. The default is `--skip-comments` (discard comments), enable with `--comments`.

`-C, --compress`

Compress all information sent between the client and the server if both support compression.

`--connect-expired-password`

Notify the server that this client is prepared to handle expired password sandbox mode even if `--batch` was specified. From MariaDB 10.4.3.

`--connect-timeout=num`

Number of seconds before connection timeout. Defaults to zero.

`-D, --database=name`

Database to use.

`-# [options], --debug[=options]`

On debugging builds, write a debugging log. A typical debug_options string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mysql.trace`.

`--debug-check`

Check memory and open file usage at exit.

`-T, --debug-info`

Print some debug info at exit.

`--default-auth=plugin`

Default authentication client-side plugin to use.

`--default-character-set=name`

Set the default character set. A common issue that can occur when the operating system uses utf8 or another multibyte character set is that output from the mariadb client is formatted incorrectly, due to the fact that the MariaDB client uses the latin1 character set by default. You can usually fix such issues by using this option to force the client to use the system character set instead. If set to `auto` the character set is taken from the client environment (`LC_CTYPE` on Unix).

`--defaults-extra-file=file`

Read this file after the global files are read. Must be given as the first option.

`--defaults-file=file`

Only read default options from the given *file*. Must be given as the first option.

`--defaults-group-suffix=suffix`

In addition to the given groups, also read groups with this suffix.

`--delimiter=name`

Delimiter to be used. The default is the semicolon character (";").

`--enable-cleartext-plugin`

Obsolete option. Exists only for MySQL compatibility. From MariaDB 10.3.36.

`-e, --execute=name`

Execute statement and quit. Disables `--force` and history file. The default output format is like that produced with `--batch`.

`-f, --force`

Continue even if we get an SQL error. Sets `--abort-source-on-error` to 0.

`-h, --host=name`

Connect to host.

`-H, --html`

Produce HTML output.

`-U, --i-am-a-dummy`

Synonym for option `--safe-updates`, `-U`.

`-i, --ignore-spaces`

Ignore space after function names. Allows one to have spaces (including tab characters and new line characters) between function name and '('. The drawback is that this causes built in functions to become reserved words.

`--init-command=str`

SQL Command to execute when connecting to the MariaDB server. Will automatically be re-executed when reconnecting.

`--line-numbers`

Write line numbers for errors. (Defaults to on; use `--skip-line-numbers` to disable.)

`--local-infile`

Enable or disable LOCAL capability for LOAD DATA INFILE. With no value, the option enables LOCAL. The option may be given as `--local-infile=0` or `--local-infile=1` to explicitly disable or enable LOCAL. Enabling LOCAL has no effect if the server does not also support it.

`--max-allowed-packet=num`

The maximum packet length to send to or receive from server. The default is 16MB, the maximum 1GB.

`--max-join-size=num`

Automatic limit for rows in a join when using `--safe-updates`. Default is 1000000.

`-G, --named-commands`

Enable named commands. Named commands mean mariadb's internal commands (see below) . When enabled, the named commands can be used from any line of the query, otherwise only from the first line, before an enter. Long-format commands are allowed, not just short-format commands. For example, `quit` and `\q` are both recognized. Disable with `--disable-named-commands`. This option is disabled by default.

`--net-buffer-length=num`

The buffer size for TCP/IP and socket communication. Default is 16KB.

`-b, --no-beep`

Turn off beep on error.

`--no-defaults`

Don't read default options from any option file. Must be given as the first option.

`-o, --one-database`

Ignore statements except those those that occur while the default database is the one named on the command line. This filtering is limited, and based only on USE statements. This is useful for skipping updates to other databases in the binary log.

`--pager[=name]`

Pager to use to display results (Unix only). If you don't supply an option, the default pager is taken from your ENV variable PAGER. Valid pagers are *less*, *more*, *cat [> filename]*, etc. See interactive help (\h) also. This option does not work in batch mode. Disable with `--disable-pager`. This option is disabled by default.

`-p, --password[=name]`

Password to use when connecting to server. If you use the short option form (-p), you cannot have a space between the

option and the password. If you omit the password value following the `--password` or `-p` option on the command line, mariadb prompts for one. Specifying a password on the command line should be considered insecure. You can use an option file to avoid giving the password on the command line.

`--plugin-dir=name`

Directory for client-side plugins.

`-P, --port=num`

Port number to use for connection or 0 for default to, in order of preference, my.cnf, $MYSQL_TCP_PORT, /etc/services, built-in default (3306).

`--print-defaults`

Print the program argument list and exit. Must be given as the first option.

`--progress-reports`

Get progress reports for long running commands (such as ALTER TABLE). (Defaults to on; use `--skip-progress-reports` to disable.)

`--prompt=name`

Set the mariadb prompt to this value. See prompt command for options.

`--protocol=name`

The protocol to use for connection (tcp, socket, pipe, memory).

`-q, --quick`

Don't cache result, print it row by row. This may slow down the server if the output is suspended. Doesn't use history file.

`-r, --raw`

For tabular output, the “boxing” around columns enables one column value to be distinguished from another. For nontabular output (such as is produced in batch mode or when the `--batch` or `--silent` option is given), special characters are escaped in the output so they can be identified easily. Newline, tab, NUL, and backslash are written as `\n`, `\t`, `\0`, and . The `--raw` option disables this character escaping.

`--reconnect`

Reconnect if the connection is lost. This option is enabled by default. Disable with `--disable-reconnect` or `skip-reconnect`.

`-U, --safe-updates`

Allow only those UPDATE and DELETE statements that specify which rows to modify by using key values. If you have set this option in an option file, you can override it by using `--safe-updates` on the command line. See using the --safe-updates option for more.

`--secure-auth`

Refuse client connecting to server if it uses old (pre-MySQL4.1.1) protocol. Defaults to false.

`--select-limit=num`

Automatic limit for SELECT when using --safe-updates. Default 1000.

`--server-arg=name`

Send embedded server this as a parameter.

`--shared-memory-base-name=name`

Shared-memory name to use for Windows connections using shared memory to a local server (started with the --shared-memory option). Case-sensitive.

`--show-warnings`

Show warnings after every statement. Applies to interactive and batch mode.

`--sigint-ignore`

Ignore SIGINT signals (usually CTRL-C).

`-s, --silent`

Be more silent. This option can be given multiple times to produce less and less output. This option results in nontabular output format and escaping of special characters. Escaping may be disabled by using raw mode; see the description for the `--raw` option.

`--skip-auto-rehash`

Disable automatic rehashing. See `--auto-rehash`.

`-N, --skip-column-names`

Don't write column names in results. See `--column-names`.

`--skip-comments`

Discard comments. Set by default, see `--comments` to enable.

`-L, --skip-line-numbers`

Don't write line number for errors. See `--line-numbers`.

`--skip-progress-reports`

Disables getting progress reports for long running commands. See `--progress-reports`.

`--skip-reconnect`

Don't reconnect if the connection is lost. See `--reconnect`.

`-S, --socket=name`

For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.

`--ssl`

Enables TLS. TLS is also enabled even without setting this option when certain other TLS options are set. The `--ssl` option does not enable verifying the server certificate by default. In order to verify the server certificate, the user must specify the `--ssl-verify-server-cert` option. Set by default from MariaDB 10.10.

`--ssl-ca=name`

Defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option implies the `--ssl` option.

`--ssl-capath=name`

Defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the `openssl rehash` command. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option is only supported if the client was built with

OpenSSL or yaSSL. If the client was built with GnuTLS or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms. This option implies the `--ssl` option.

`--ssl-cert=name`

Defines a path to the X509 certificate file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.

`--ssl-cipher=name`

List of permitted ciphers or cipher suites to use for TLS. This option implies the `--ssl` option.

`--ssl-crl=name`

Defines a path to a PEM file that should contain one or more revoked X509 certificates to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL or Schannel. If the client was built with yaSSL or GnuTLS, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

`--ssl-crlpath=name`

Defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the `openssl rehash` command. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL. If the client was built with yaSSL, GnuTLS, or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

`--ssl-key=name`

Defines a path to a private key file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.

`--ssl-verify-server-cert`

Enables server certificate verification. Prior to MariaDB 11.3, this option is disabled by default, otherwise enabled. Use `--disable-ssl` or `--disable-ssl-verify-server-cert` to revert to the pre-11.3 behavior.

`-t, --table`

Display output in table format. This is the default for interactive use, but can be used to produce table output in batch mode.

`--tee=name`

Append everything into outfile. See interactive help (\h) also. Does not work in batch mode. Disable with `--disable-tee`. This option is disabled by default.

`--tls-version=name`

This option accepts a comma-separated list of TLS protocol versions. A TLS protocol version will only be enabled if it is present in this list. All other TLS protocol versions will not be permitted. See Secure Connections Overview: TLS Protocol Versions for more information. This option was added in MariaDB 10.4.6.

`--tls-fp=name`

Server certificate fingerprint (implies --ssl). Added in MariaDB 11.3.0.

`--tls-fplist=name`

File with accepted server certificate fingerprints, one per line (implies --ssl). Added in MariaDB 11.3.0.

`-n, --unbuffered`

Flush buffer after each query.

`-u, --user=name`

User for login if not current user.

`-v, --verbose`

Write more. (-v -v -v gives the table output format).

`-V, --version`

Output version information and exit.

`-E, --vertical`

Print the output of a query (rows) vertically. Use the `\G` delimiter to apply to a particular statement if this option is not enabled.

`-w, --wait`

If the connection cannot be established, wait and retry instead of aborting.

`-X, --xml`

Produce XML output. See the mariadb-dump --xml option for more.

Option Files

In addition to reading options from the command-line, `mariadb` can also read options from option files. If an unknown option is provided to `mariadb` in an option file, then it is ignored.

The following options relate to how MariaDB command-line tools handles option files. They must be given as the first argument on the command-line:

Option	Description
`--print-defaults`	Print the program argument list and exit.
`--no-defaults`	Don't read default options from any option file.
`--defaults-file=#`	Only read default options from the given file #.
`--defaults-extra-file=#`	Read this file after the global files are read.
`--defaults-group-suffix=#`	In addition to the default option groups, also read option groups with this suffix.

`mariadb` is linked with MariaDB Connector/C. However, MariaDB Connector/C does not yet handle the parsing of option files for this client. That is still performed by the server option file parsing code. See MDEV-19035 for more information.

Option Groups

`mariadb` reads options from the following option groups from option files:

Group	Description
`[mysql]`	Options read by `mysql`, which includes both MariaDB Server and MySQL Server.
`[mariadb-client]`	Options read by `mariadb`. Available starting with MariaDB 10.4.6.
`[client]`	Options read by all MariaDB and MySQL client programs, which includes both MariaDB and MySQL clients. For example, `mysqldump`.
`[client-server]`	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
`[client-mariadb]`	Options read by all MariaDB client programs.

How to Specify Which Protocol to Use When Connecting to the Server

You can force which protocol to be used to connect to the `mariadbd` server by giving the `protocol` option one of the following values: `tcp`, `socket`, `pipe` or `memory`.

If `protocol` is not specified, before MariaDB 10.6.1, command line connection properties that do not force protocol are ignored.

From MariaDB 10.6.1, a connection property specified via the command line (e.g. `--port=3306`) will force its type. The protocol that matches the respective connection property is used, e.g. a TCP/IP connection is created when `--port` is specified.

If multiple or no connection properties are specified via the command-line, then the following happens:

Linux/Unix

- If `hostname` is not specified or `hostname` is `localhost`, then Unix sockets are used.
- In other cases (`hostname` is given and it's not `localhost`) then a TCP/IP connection through the `port` option is used.

Note that `localhost` is a special value. Using 127.0.0.1 is not the same thing. The latter will connect to the mariadbd server through TCP/IP.

Windows

- If `shared-memory-base-name` is specified and `hostname` is not specified or `hostname` is `localhost`, then the connection will happen through shared memory.
- If `shared-memory-base-name` is not specified and `hostname` is not specified or `hostname` is `localhost`, then the connection will happen through windows named pipes.
- Named pipes will also be used if the `libmysql` / `libmariadb` client library detects that the client doesn't support TCP/IP.
- In other cases then a TCP/IP connection through the `port` option is used.

How to Test Which Protocol is Used

The `status` command shows you information about which protocol is used:

```
shell> mariadb test

Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 10
Server version: 10.2.2-MariaDB-valgrind-max-debug Source distribution

Copyright (c) 2000, 2016, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [test]> status;
--------------
mysql  Ver 15.1 Distrib 10.0.25-MariaDB, for Linux (x86_64) using readline 5.2

Connection id:          10
Current database:       test
Current user:           monty@localhost
...
Connection:             Localhost via UNIX socket
...
UNIX socket:            /tmp/mysql-dbug.sock
```

mariadb Commands

There are also a number of commands that can be run inside the client. Note that all text commands must be first on line and end with ';'

Command	Description

`?`, `\?`	Synonym for `help'.
`clear`, `\c`	Clear the current input statement.
`connect`, `\r`	Reconnect to the server. Optional arguments are db and host.
`delimiter`, `\d`	Set statement delimiter.
`edit`, `\e`	Edit command with $EDITOR.
`ego`, `\G`	Send command to mariadb server, display result vertically.
`exit`, `\q`	Exit mariadb. Same as quit.
`go`, `\g`	Send command to mariadb server.
`help`, `\h`	Display this help.
`nopager`, `\n`	Disable pager, print to stdout.
`notee`, `\t`	Don't write into outfile.
`pager`, `\P`	Set PAGER [to_pager]. Print the query results via PAGER.
`print`, `\p`	Print current command.
`prompt`, `\R`	Change your mariadb prompt. See prompt command for options.
`quit`, `\q`	Quit mariadb.
`rehash`, `\#`	Rebuild completion hash.
`source`, `\.`	Execute an SQL script file. Takes a file name as an argument.
`status`, `\s`	Get status information from the server.
`system`, `\!`	Execute a system shell command. Only works in Unix-like systems.
`tee`, `\T`	Set outfile [to_outfile]. Append everything into given outfile.
`use`, `\u`	Use another database. Takes database name as argument.
`charset`, `\C`	Switch to another charset. Might be needed for processing binlog with multi-byte charsets.
`warnings`, `\W`	Show warnings after every statement.
`nowarning`, `\w`	Don't show warnings after every statement.

The mysql_history File

On Unix, the mariadb client writes a record of executed statements to a history file. By default, this file is named `.mysql_history` and is created in your home directory. To specify a different file, set the value of the MYSQL_HISTFILE environment variable.

The .mysql_history file should be protected with a restrictive access mode because sensitive information might be written to it, such as the text of SQL statements that contain passwords.

If you do not want to maintain a history file, first remove .mysql_history if it exists, and then use either of the following techniques:

- Set the MYSQL_HISTFILE variable to /dev/null. To cause this setting to take effect each time you log in, put the setting in one of your shell's startup files.
- Create .mysql_history as a symbolic link to /dev/null:

```
shell> ln -s /dev/null $HOME/.mysql_history
```

You need do this only once.

prompt Command

The prompt command reconfigures the default prompt `\N [\d]>`. The string for defining the prompt can contain the following special sequences.

Option	Description

`\c`	A counter that increments for each statement you issue.
`\D`	The full current date.
`\d`	The default database.
`\h`	The server host.
`\l`	The current delimiter.
`\m`	Minutes of the current time.
`\n`	A newline character.
`\O`	The current month in three-letter format (Jan, Feb, ...).
`\o`	The current month in numeric format.
`\P`	am/pm.
`\p`	The current TCP/IP port or socket file.
`\R`	The current time, in 24-hour military time (0–23).
`\r`	The current time, standard 12-hour time (1–12).
`\S`	Semicolon.
`\s`	Seconds of the current time.
`\t`	A tab character.
`\U`	Your full user_name@host_name account name.
`\u`	Your user name.
`\v`	The server version.
`\w`	The current day of the week in three-letter format (Mon, Tue, ...).
`\Y`	The current year, four digits.
`\y`	The current year, two digits.
`\_`	A space.
`\ `	A space (a space follows the backslash).
`\'`	Single quote.
`\"`	Double quote.
`\ \`	A literal “\” backslash character.
`\x`	x, for any “x” not listed above.

mariadb Tips

This section describes some techniques that can help you use **`mariadb`** more effectively.

Displaying Query Results Vertically

Some query results are much more readable when displayed vertically, instead of in the usual horizontal table format. Queries can be displayed vertically by terminating the query with \G instead of a semicolon. For example, longer text values that include newlines often are much easier to read with vertical output:

```
mariadb> SELECT * FROM mails WHERE LENGTH(txt) < 300 LIMIT 300,1\G
*************************** 1. row ***************************
  msg_nro: 3068
     date: 2000-03-01 23:29:50
time_zone: +0200
mail_from: Monty
    reply: monty@no.spam.com
  mail_to: "Thimble Smith" <tim@no.spam.com>
      sbj: UTF-8
      txt: >>>>> "Thimble" == Thimble Smith writes:
Thimble> Hi.  I think this is a good idea.  Is anyone familiar
Thimble> with UTF-8 or Unicode? Otherwise, I´ll put this on my
Thimble> TODO list and see what happens.
Yes, please do that.
Regards,
Monty
    file: inbox-jani-1
    hash: 190402944
1 row in set (0.09 sec)
```

Using the --safe-updates Option

For beginners, a useful startup option is `--safe-updates` (or `--i-am-a-dummy`, which has the same effect). It is helpful for cases when you might have issued a `DELETE FROM tbl_name` statement but forgotten the `WHERE` clause. Normally, such a statement deletes all rows from the table. With `--safe-updates`, you can delete rows only by specifying the key values that identify them. This helps prevent accidents.

When you use the `--safe-updates` option, mariadb issues the following statement when it connects to the MariaDB server:

```
SET sql_safe_updates=1, sql_select_limit=1000, sql_max_join_size=1000000;
```

The SET statement has the following effects:

- You are not allowed to execute an UPDATE or DELETE statement unless you specify a key constraint in the WHERE clause or provide a LIMIT clause (or both). For example:

```
UPDATE tbl_name SET not_key_column=val WHERE key_column=val;
UPDATE tbl_name SET not_key_column=val LIMIT 1;
```

- The server limits all large `SELECT` results to 1,000 rows unless the statement includes a `LIMIT` clause.
- The server aborts multiple-table `SELECT` statements that probably need to examine more than 1,000,000 row combinations.

To specify limits different from 1,000 and 1,000,000, you can override the defaults by using the `--select_limit` and `--max_join_size` options:

```
mariadb --safe-updates --select_limit=500 --max_join_size=10000
```

Disabling mariadb Auto-Reconnect

If the mariadb client loses its connection to the server while sending a statement, it immediately and automatically tries to reconnect once to the server and send the statement again. However, even if mariadb succeeds in reconnecting, your first connection has ended and all your previous session objects and settings are lost: temporary tables, the autocommit mode, and user-defined and session variables. Also, any current transaction rolls back. This behavior may be dangerous for you, as in the following example where the server was shut down and restarted between the first and second statements without you knowing it:

```
mariadb> SET @a=1;
Query OK, 0 rows affected (0.05 sec)
mariadb> INSERT INTO t VALUES(@a);
ERROR 2006: MySQL server has gone away
No connection. Trying to reconnect...
Connection id:    1
Current database: test
Query OK, 1 row affected (1.30 sec)
mariadb> SELECT * FROM t;
+------+
| a    |
+------+
| NULL |
+------+
```

The @a user variable has been lost with the connection, and after the reconnection it is undefined. If it is important to have mariadb terminate with an error if the connection has been lost, you can start the mariadb client with the `--skip-reconnect` option.

1.3.3 Delimiters

The default delimiter in the mariadb client is the semicolon.

When creating stored programs from the command-line, it is likely you will need to differentiate between the regular delimiter and a delimiter inside a BEGIN END block. To understand better, consider the following example:

```
CREATE FUNCTION FortyTwo() RETURNS TINYINT DETERMINISTIC
BEGIN
 DECLARE x TINYINT;
 SET x = 42;
 RETURN x;
END;
```

If you enter the above line by line, the mariadb client will treat the first semicolon, at the end of the `DECLARE x TINYINT` line, as the end of the statement. Since that's only a partial definition, it will throw a syntax error, as follows:

```
CREATE FUNCTION FortyTwo() RETURNS TINYINT DETERMINISTIC
BEGIN
DECLARE x TINYINT;
ERROR 1064 (42000): You have an error in your SQL syntax;
check the manual that corresponds to your MariaDB server version
 for the right syntax to use near '' at line 3
```

The solution is to specify a distinct delimiter for the duration of the process, using the DELIMITER command. The delimiter can be any set of characters you choose, but it needs to be a distinctive set of characters that won't cause further confusion. `//` is a common choice, and used throughout the Knowledge Base.

Here's how the function could be successfully entered from the mariadb client with the new delimiter.

```
DELIMITER //

CREATE FUNCTION FortyTwo() RETURNS TINYINT DETERMINISTIC
BEGIN
  DECLARE x TINYINT;
  SET x = 42;
  RETURN x;
END

//

DELIMITER ;
```

At the end, the delimiter is restored to the default semicolon. The `\g` and `\G` delimiters can always be used, even when a custom delimiter is specified.

1.3.4 mysql Command-line Client

mysql is a simple SQL shell (with GNU readline capabilities).

MariaDB starting with 10.4.6

From MariaDB 10.4.6, mariadb is a symlink to `mysql`.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, mariadb is the name of the script, with `mysql` a symlink.

See mariadb for details.

1.3.5 Aria Clients and Utilities

Clients and utilities for working with the Aria storage engine

aria_chk

Used for checking, repairing, optimizing and sorting Aria tables.

aria_pack

Tool for compressing Aria tables.

aria_read_log

Tool for displaying and applying log records from an Aria transaction log.

aria_s3_copy

Copies an Aria table to and from S3.

There are 4 related questions.

1.3.5.1 aria_chk

Contents

`aria_chk` is used to check, repair, optimize, sort and get information about Aria tables.

With the MariaDB server you can use CHECK TABLE, REPAIR TABLE and OPTIMIZE TABLE to do similar things.

Note: `aria_chk` should not be used when MariaDB is running. MariaDB assumes that no one is changing the tables it's using!

Usage:

```
aria_chk [OPTIONS] aria_tables[.MAI]
```

Aria table information is stored in 2 files: the `.MAI` file contains base table information and the index and the `.MAD` file contains the data. `aria_chk` takes one or more `.MAI` files as arguments.

The following groups are read from the my.cnf files:

- `[maria_chk]`
- `[aria_chk]`

Options and Variables

Global Options

The following options to handle option files may be given as the first argument:

Option	Description
`--print-defaults`	Print the program argument list and exit.
`--no-defaults`	Don't read default options from any option file.
`--defaults-file=#`	Only read default options from the given file #.
`--defaults-extra-file=#`	Read this file after the global files are read.

Main Arguments

Option	Description
`-#`, `--debug=...`	Output debug log. Often this is 'd:t:o,filename'.
`-H`, `--HELP`	Display this help and exit.
`-?`, `--help`	Display this help and exit.
`--datadir=path`	Path for control file (and logs if `--logdir` not used).
`--ignore-control-file`	Don't open the control file. Only use this if you are sure the tables are not used by another program
`--logdir=path`	Path for log files.
`--require-control-file`	Abort if we can't find/read the maria_log_control file
`-s`, `--silent`	Only print errors. One can use two -s to make aria_chk very silent.
`-t`, `--tmpdir=path`	Path for temporary files. Multiple paths can be specified, separated by colon (:) on Unix or semicolon (;) on Windows. They will be used in a round-robin fashion.
`-v`, `--verbose`	Print more information. This can be used with `--description` and `--check`. Use many -v for more verbosity.
`-V`, `--version`	Print version and exit.
`-w`, `--wait`	Wait if table is locked.

Check Options (--check is the Default Action for aria_chk):

Option	Description
`-c`, `--check`	Check table for errors.
`-e`, `--extend-check`	Check the table VERY throughly. Only use this in extreme cases as aria_chk should normally be able to find out if the table is ok even without this switch.
`-F`, `--fast`	Check only tables that haven't been closed properly.
`-C`, `--check-only-changed`	Check only tables that have changed since last check.
`-f`, `--force`	Restart with '`-r`' if there are any errors in the table. States will be updated as with '`--update-state`'.
`-i`, `--information`	Print statistics information about table that is checked.

`-m`, `--medium-check`	Faster than extend-check, and finds 99.99% of all errors. Should be good enough for most cases.
`-U`, `--update-state`	Mark tables as crashed if any errors were found and clean if check didn't find any errors but table was marked as 'not clean' before. This allows one to get rid of warnings like 'table not properly closed'. If table was updated, update also the timestamp for when the check was made. This option is on by default! Use `--skip-update-state` to disable.
`-T`, `--read-only`	Don't mark table as checked.

Recover (Repair) Options (When Using '--recover' or '--safe-recover'):

Option	Description
`-B`, `--backup`	Make a backup of the .MAD file as 'filename-time.BAK'.
`--correct-checksum`	Correct checksum information for table.
`-D`, `--data-file-length=#`	Max length of data file (when recreating data file when it's full).
`-e`, `--extend-check`	Try to recover every possible row from the data file Normally this will also find a lot of garbage rows; Don't use this option if you are not totally desperate.
`-f`, `--force`	Overwrite old temporary files.
`-k`, `--keys-used=#`	Tell MARIA to update only some specific keys. # is a bit mask of which keys to use. This can be used to get faster inserts.
`--max-record-length=#`	Skip rows bigger than this if aria_chk can't allocate memory to hold it.
`-r`, `--recover`	Can fix almost anything except unique keys that aren't unique.
`-n`, `--sort-recover`	Forces recovering with sorting even if the temporary file would be very big.
`-p`, `--parallel-recover`	Uses the same technique as '-r' and '-n', but creates all the keys in parallel, in different threads.
`-o`, `--safe-recover`	Uses old recovery method; Slower than '-r' but can handle a couple of cases where '-r' reports that it can't fix the data file.
`--transaction-log`	Log repair command to transaction log. This is needed if one wants to use the maria_read_log to repeat the repair.
`--character-sets-dir=...`	Directory where character sets are.
`--set-collation=name`	Change the collation used by the index.
`-q`, `--quick`	Faster repair by not modifying the data file. One can give a second '`-q`' to force aria_chk to modify the original datafile in case of duplicate keys. NOTE: Tables where the data file is currupted can't be fixed with this option.
`-u`, `--unpack`	Unpack file packed with aria_pack.

Other Options

Option	Description
`-a`, `--analyze`	Analyze distribution of keys. Will make some joins in MariaDB faster. You can check the calculated distribution by using '`--description --verbose table_name`'.

`--stats_method=name`	Specifies how index statistics collection code should treat NULLs. Possible values of name are "nulls_unequal" (default for 4.1/5.0), "nulls_equal" (emulate 4.0), and "nulls_ignored".
`-d, --description`	Prints some information about table.
`-A, --set-auto-increment[=value]`	Force auto_increment to start at this or higher value If no value is given, then sets the next auto_increment value to the highest used value for the auto key + 1.
`-S, --sort-index`	Sort index blocks. This speeds up 'read-next' in applications.
`-R, --sort-records=#`	Sort records according to an index. This makes your data much more localized and may speed up things (It may be VERY slow to do a sort the first time!).
`-b, --block-search=#`	Find a record, a block at given offset belongs to.
`-z, --zerofill`	Remove transaction id's from the data and index files and fills empty space in the data and index files with zeroes. Zerofilling makes it possible to move the table from one system to another without the server having to do an automatic zerofill. It also allows one to compress the tables better if one want to archive them.
`--zerofill-keep-lsn`	Like `--zerofill` but does not zero out LSN of data/index pages.

Variables

Option	Description
`page_buffer_size`	Size of page buffer. Used by `--safe-repair`
`read_buffer_size`	Read buffer size for sequential reads during scanning
`write_buffer_size`	Write buffer size for sequential writes during repair of fixed size or dynamic size rows
`sort_buffer_size`	Size of sort buffer. Used by `--recover`
`sort_key_blocks`	Internal buffer for sorting keys; Don't touch :)

Usage

One main usage of `aria_chk` is when you want to do a fast check of all Aria tables in your system. This is faster than doing it in MariaDB as you can allocate all free memory to the buffers.

Assuming you have a bit more than 2G free memory.

The following commands, run in the MariaDB data directory, check all your tables and repairs only those that have an error:

```
aria_chk --check --sort_order --force --sort_buffer_size=1G */*.MAI
```

If you want to optimize all your tables: (The `--zerofill` is used here to fill up empty space with `\0` which can speed up compressed backups).

```
aria_chk --analyze --sort-index --page_buffer_size=1G --zerofill */*.MAI
```

In case you have a serious problem and have to use `--safe-recover`:

```
aria_chk --safe-recover --zerofill --page_buffer_size=2G */*.MAI
```

1.3.5.2 aria_pack

Contents

aria_pack is a tool for compressing Aria tables. The resulting table are read-only, and usually about 40% to 70% smaller.

aria_pack is run as follows

```
aria_pack [options] file_name [file_name2...]
```

The file name is the .MAI index file. The extension can be omitted, although keeping it permits wildcards, such as

```
aria_pack *.MAI
```

to compress all the files.

aria_pack compresses each column separately, and, when the resulting data is read, only the individual rows and columns required need to be decompressed, allowing for quicker reading.

Once a table has been packed, use aria_chk -rq (the quick and recover options) to rebuild its indexes.

Options

The following variables can be set while passed as commandline options to aria_pack, or set in the [ariapack] section in your my.cnf file.

Option	Description
-b, --backup	Make a backup of the table as table_name.OLD.
--character-sets-dir=name	Directory where character sets are.
-h, --datadir	Path for control file (and logs if `--logdir` not used). From MariaDB 10.5.3
-#, --debug[=name]	Output debug log. Often this is 'd:t:o,filename'.
-?, --help	Display help and exit.
-f, --force	Force packing of table even if it gets bigger or if tempfile exists.
--ignore-control-file	Ignore the control file. From MariaDB 10.5.3.
-j, --join=name	Join all given tables into 'new_table_name'. All tables MUST have identical layouts.
--require-control-file	Abort if cannot find control file. From MariaDB 10.5.3.
-s, --silent	Only write output when an error occurs.
-t, --test	Don't pack table, only test packing it.
-T, --tmpdir=name	Use temporary directory to store temporary table.
-v, --verbose	Write info about progress and packing result. Use many -v for more verbosity!
-V, --version	Output version information and exit.
-w, --wait	Wait and retry if table is in use.

Unpacking

To unpack a table compressed with aria_pack, use the aria_chk -u option.

Example

```
> aria_pack /my/data/test/posts
Compressing /my/data/test/posts.MAD: (1690 records)
- Calculating statistics
- Compressing file
37.71%
> aria_chk -rq --ignore-control-file /my/data/test/posts
- check record delete-chain
- recovering (with keycache) Aria-table '/my/data/test/posts'
Data records: 1690
State updated
```

1.3.5.3 aria_read_log

aria_read_log is a tool for displaying and applying log records from an Aria transaction log.

Note: Aria is compiled without -DIDENTICAL_PAGES_AFTER_RECOVERY which means that the table files are not byte-to-byte identical to files created during normal execution. This should be ok, except for test scripts that try to compare files before and after recovery.

Usage:

```
aria_read_log OPTIONS
```

You need to use one of `-d` or `-a` .

Options

The following variables can be set while passed as commandline options to aria_read_log, or set in the `[aria_read_log]` section in your my.cnf file.

Option	Description
-a, --apply	Apply log to tables: modifies tables! you should make a backup first! Displays a lot of information if not run with --silent.
--character-sets-dir=name	Directory where character sets are.
-c, --check	if --display-only, check if record is fully readable (for debugging).
-?, --help	Display help and exit.
-d, --display-only	Display brief info read from records' header.
-e, --end-lsn=#	Stop applying at this lsn. If end-lsn is used, UNDO:s will not be applied
-h, --aria-log-dir-path=name	Path to the directory where to store transactional log
-P, --page-buffer-size=#	The size of the buffer used for index blocks for Aria tables.
-l, --print-log-control-file	Print the content of the aria_log_control_file. From MariaDB 10.4.1.
-o, --start-from-lsn=#	Start reading log from this lsn.
-C, --start-from-checkpoint	Start applying from last checkpoint.
-s, --silent	Print less information during apply/undo phase.
-T, --tables-to-redo=name	List of comma-separated tables that we should apply REDO on. Use this if you only want to recover some tables.
-t, --tmpdir=name	Path for temporary files. Multiple paths can be specified, separated by colon (:)
--translog-buffer-size=#	The size of the buffer used for transaction log for Aria tables.
-u, --undo	Apply UNDO records to tables. (disable with --disable-undo) (Defaults to on; use --skip-undo to disable.)
-v, --verbose	Print more information during apply/undo phase.
-V, --version	Print version and exit.

5.3.16.4 aria_s3_copy

1.3.6 Backup, Restore and Import Clients

Clients for taking backups or importing/restoring data

Mariabackup

Physical backups, supports Data-at-Rest and InnoDB compression.

mariadb-dump

Dump a database or a collection of databases in a portable format.

mariadb-hotcopy

Fast backup program on local machine. Deprecated.

mariadb-import

Loads tables from text files in various formats.

Backup/Restore + Data Export/Import via dbForge Studio

The fastest and easiest way to perform these operations with MariaDB databases.

There are 5 related questions.

2.3.4 Mariabackup

1.3.6.2 mariadb-dump

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-dump` is a symlink to `mysqldump`, the backup tool.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadb-dump` is the name of the tool, with `mysqldump` a symlink.

MariaDB starting with 11.0.1

From MariaDB 11.0.1, `mysqldump` (the symlink) is deprecated and removed from the `mariadb` Docker Official Image.

The `mariadb-dump` client (originally called `mysqldump`)is a backup program originally written by Igor Romanenko. It can be used to dump a database or a collection of databases for backup or transfer to another database server (not necessarily MariaDB or MySQL). The dump typically contains SQL statements to create the table, populate it, or both. However, `mariadb-dump` can also be used to generate files in CSV, other delimited text, or XML format.

If you are doing a backup on the server and your tables all are MyISAM tables, consider using mariadb-hotcopy instead because it can accomplish faster backups and faster restores.

mariadb-dump dumps triggers along with tables, as these are part of the table definition. However, stored procedures, views, and events are not, and need extra parameters to be recreated explicitly (for example, `--routines` and `--events`). Procedures and functions are however also part of the system tables (for example mysql.proc).

`mariadb-dump` supports the enhancements for START TRANSACTION WITH CONSISTENT SNAPSHOT.

Performance

mariadb-dump doesn't usually consume much CPU resources on modern hardware as by default it uses a single thread. This method is good for a heavily loaded server.

Disk input/outputs per second (IOPS), can however increase for multiple reasons. When you back-up on the same device as the database, this produces unnecessary random IOPS. The dump is done sequentially, on a per table basis, causing a full-table scan and many buffer page misses on tables that are not fully cached in memory.

It's recommended that you back-up from a network location to remove disk IOPS on the database server, but it is vital to use a separate network card to keep network bandwidth available for regular traffic.

Although mariadb-dump will by default preserve your resources for regular spindle disks and low-core hardware, this doesn't mean that concurrent dumps cannot benefit from hardware architecture like SAN, flash storage, low write workload. The back-up time would benefit from a tool such as MyDumper.

Usage

There are four general ways to invoke `mariadb-dump`:

```
shell> mariadb-dump [options] db_name [tbl_name ...]
shell> mariadb-dump [options] --databases db_name ...
shell> mariadb-dump [options] --all-databases
shell> mariadb-dump [options] --system=[option_list]
```

If you do not name any tables following db_name or if you use the `--databases` or `--all-databases` option, entire databases are dumped.

`mariadb-dump` does not dump the INFORMATION_SCHEMA (or PERFORMANCE_SCHEMA, if enabled) database by default. MariaDB dumps the `INFORMATION_SCHEMA` if you name it explicitly on the command line, although currently you must also use the `--skip-lock-tables` option.

To see a list of the options your version of `mariadb-dump` supports, execute `mariadb-dump --help`.

Row by Row vs. Buffering

`mariadb-dump` can retrieve and dump table contents row by row, or it can retrieve the entire content from a table and buffer it in memory before dumping it. Buffering in memory can be a problem if you are dumping large tables. To dump tables row by row, use the `--quick` option (or `--opt`, which enables `--quick`). The `--opt` option (and hence `--quick`) is enabled by default, so to enable memory buffering, use `--skip-quick`.

mariadb-dump and the mysql.transaction_registry_table

`mariadb-dump` includes logic to cater for the mysql.transaction_registry table. `mysqldump` from an earlier MariaDB release cannot be used on MariaDB 10.3 and beyond.

mariadb-dump and Old Versions of MySQL

If you are using a recent version of `mariadb-dump` to generate a dump to be reloaded into a very old MySQL server, you should not use the `--opt` or `--extended-insert` option. Use `--skip-opt` instead.

Options

`mariadb-dump` supports the following options:

Option	Description
`--all`	Deprecated. Use `--create-options` instead.
`-A`, `--all-databases`	Dump all the databases. This will be same as `--databases` with all databases selected.
`-Y`, `--all-tablespaces`	Dump all the tablespaces.
`-y`, `--no-tablespaces`	Do not dump any tablespace information.
`--add-drop-database`	Add a DROP DATABASE before each create. Typically used in conjunction with the `--all-databases` or `--databases` option because no CREATE DATABASE statements are written unless one of those options is specified.
`--add-drop-table`	Add a DROP TABLE before each create.
`--add-drop-trigger`	Add a DROP TRIGGER statement before each CREATE TRIGGER. From MariaDB 10.2.6.
`--add-locks`	Add locks around INSERT statements, which results in faster inserts when the dump file is reloaded. Use `--skip-add-locks` to disable.
`--allow-keywords`	Allow creation of column names that are keywords. This works by prefixing each column name with the table name.
`--apply-slave-statements`	Adds STOP SLAVE prior to CHANGE MASTER and START SLAVE to bottom of dump.
`--as-of`	Dump system versioned table as of specified timestamp. From MariaDB 10.7.0.
`--character-sets-dir=name`	Directory for character set files.
`-i`, `--comments`	Write additional information in the dump file such as program version, server version, and host. Disable with `--skip-comments`.
`--compact`	Give less verbose output (useful for debugging). Disables structure comments and header/footer constructs. Enables the `--skip-add-drop-table`, `--skip-add-locks`, `--skip-comments`, `--skip-disable-keys`, and `--skip-set-charset` options.
`--compatible=name`	Change the dump to be compatible with a given mode. By default tables are dumped in a format optimized for MariaDB and MySQL. Legal modes are: `ansi`, `mysql323`, `mysql40`, `postgresql`, `oracle`, `mssql`, `db2`, `maxdb`, `no_key_options`, `no_table_options`, and `no_field_options`. One can use several modes separated by commas. This option does not guarantee compatibility with other servers. It only enables those SQL mode values that are currently available for making dump output more compatible. For example, `--compatible=oracle` does not map data types to Oracle types or use Oracle comment syntax.

`-c , --complete-insert`	Use complete INSERT statements that include column names.
`-C , --compress`	Use compression in server/client protocol. Both client and server must support compression for this to work.
`--copy-s3-tables`	By default S3 tables are ignored. With this option set, the result file will contain a CREATE statement for a similar Aria table, followed by the table data and ending with an `ALTER TABLE xxx ENGINE=S3` . From MariaDB 10.5.0.
`-a , --create-options`	Include all MariaDB and/or MySQL specific create options in `CREATE TABLE` statements. Use `--skip-create-options` to disable.
`-B , --databases`	Dump several databases. Normally, `mariadb-dump` treats the first name argument on the command line as a database name and following names as table names. With this option, it treats all name arguments as database names. CREATE DATABASE and USE statements are included in the output before each new database.
`-#, --debug[=#]`	If using a debug version of MariaDB, write a debugging log. A typical debug_options string is ´d:t:o,file_name´. The default value is ´d:t:o,/tmp/mysqldump.trace´. If using a non-debug version, `mariadb-dump` will catch this and exit.
`--debug-check`	Check memory and open file usage at exit.
`--debug-info`	Print some debug info at exit.
`--default-auth=name`	Default authentication client-side plugin to use.
`--default-character-set=name`	Set the default character set to *name*. If no character set is specified *mariadb-dump* uses utf8mb4.
`--defaults-extra-file=name`	Read the file *name* after the global files are read. Must be given as the first argument.
`--defaults-file=name`	Only read default options from the given file *name*. Must be given as the first argument.
`--defaults-group-suffix=str`	Also read groups with a suffix of *str*. For example, since *mariadb-dump* normally reads the [client] and [mariadb-dump] (or [mysqldump]) groups, --defaults-group-suffix=x would cause it to also read the groups [mariadb-dump_x] (or [mysqldump_x]) and [client_x].
`--delayed-insert`	Insert rows with INSERT DELAYED instead of INSERT.
`--delete-master-logs`	On a primary replication server, delete the binary logs by sending a PURGE BINARY LOGS statement to the server after performing the dump operation. This option automatically enables `--master-data` .
`-K , --disable-keys`	`'/*!40000 ALTER TABLE tb_name DISABLE KEYS */;` and `'/*!40000 ALTER TABLE tb_name ENABLE KEYS */;` will be put in the output. This makes loading the dump file faster because the indexes are created after all rows are inserted. This option is effective only for non-unique indexes of MyISAM tables. Disable with `--skip-disable-keys` .
`--dump-date`	If the `--comments` option and this option are given, `mariadb-dump` produces a comment at the end of the dump of the following form: `-- Dump completed on DATE` However, the date causes dump files taken at different times to appear to be different, even if the data are otherwise identical. `--dump-date` and `--skip-dump-date` control whether the date is added to the comment. The default is `--dump-date` (include the date in the comment). `--skip-dump-date` suppresses date printing.
`-H , --dump-history`	Dump tables with history. From MariaDB 10.11.0. Until this option, `mariadb-dump` could not read historical rows from versioned tables, and so historical data would not be backed up.
`--dump-slave[=value]`	Used for producing a dump file from a replica server that can be used to set up another replica server with the same primary. Causes the binary log position and filename of the primary to be appended to the dumped data output. Setting the value to `1` (the default) will print it as a CHANGE MASTER command in the dumped data output; if set to `2` , that command will be prefixed with a comment symbol. This option will turn `--lock-all-tables` on, unless `--single-transaction` is specified too (in which case a global read lock is only taken a short time at the beginning of the dump - don't forget to read about `--single-transaction` below). In all cases any action on logs will happen at the exact moment of the dump. Option automatically turns `--lock-tables` off. Using this option causes mariadb-dump to stop the replica SQL thread before beginning the dump, and restart it again after completion.
`-E, --events`	Include Event Scheduler events for the dumped databases in the output.
`-e , --extended-insert`	Use multiple-row INSERT syntax that include several `VALUES` lists. This results in a smaller dump file and speeds up inserts when the file is reloaded. Defaults to on; use `--skip-extended-insert` to disable.
`--fields-terminated-by=name`	Fields in the output file are terminated by the given string. Used with the `--tab` option and has the same meaning as the corresponding `FIELDS` clause for LOAD DATA INFILE.
`--fields-enclosed-by=name`	Fields in the output file are enclosed by the given character. Used with the `--tab` option and has the same meaning as the corresponding `FIELDS` clause for LOAD DATA INFILE.
`--fields-optionally-enclosed-by=name`	Fields in the output file are optionally enclosed by the given character. Used with the `--tab` option and has the same meaning as the corresponding `FIELDS` clause for LOAD DATA INFILE.
`--fields-escaped-by=name`	Fields in the output file are escaped by the given character. Used with the `--tab` option and has the same meaning as the corresponding `FIELDS` clause for LOAD DATA INFILE.
`--first-slave`	Removed in MariaDB 5.5. Use `--lock-all-tables` instead.
`-F , --flush-logs`	Flush the MariaDB server log files before starting the dump. This option requires the `RELOAD` privilege. If you use this option in combination with the `--databases=` or `--all-databases` option, the logs are flushed for each database dumped. The exception is when using `--lock-all-tables` or `--master-data` : In this case, the logs are flushed only once, corresponding to the moment all tables are locked. If you want your dump and the log flush to happen at the same exact moment, you should use `--flush-logs` together with either `--lock-all-tables` or `--master-data` .
`--flush-privileges`	Send a FLUSH PRIVILEGES statement to the server after dumping the mysql database. This option should be used any time the dump contains the mysql database and any other database that depends on the data in the mysql database for proper restoration.
`-f , --force`	Continue even if an SQL error occurs during a table dump. One use for this option is to cause *mariadb-dump* to continue executing even when it encounters a view that has become invalid because the definition refers to a table that has been dropped. Without `--force` in this example, `mariadb-dump` exits with an error message. With `--force` , *mariadb-dump* prints the error message, but it also writes an SQL comment containing the view definition to the dump output and continues executing.

`--gtid`	Used together with `--master-data` and `--dump-slave` to more conveniently set up a new GTID replica. It causes those options to output SQL statements that configure the replica to use the global transaction ID to connect to the primary instead of old-style filename/offset positions. The old-style positions are still included in comments when `--gtid` is used; likewise the GTID position is included in comments even if `--gtid` is not used.
`-?` , `--help`	Display a help message and exit.
`--hex-blob`	Dump binary strings in hexadecimal format (for example, `´abc´` becomes `0x616263`). The affected data types are BINARY, VARBINARY, the BLOB types, and BIT.
`-h name` , `--host=name`	Connect to and dump data from the MariaDB or MySQL server on the given host. The default host is `localhost` .
`--ignore-database=name`	Do not dump the specified database. To specify more than one database to ignore, use the directive multiple times, once for each database. Only takes effect when used together with `--all-databases` or `-A` . Added in MariaDB 10.3.7.
`--ignore-table=name`	Do not dump the specified table. To specify more than one table to ignore, use the directive multiple times, once for each table. Each table must be specified with both database and table names, e.g., `--ignore-table=database.table` . This option also can be used to ignore views.
`--ignore-table-data=name`	Do not dump the specified table data (only the structure). To specify more than one table to ignore, use the directive multiple times, once for each table. Each table must be specified with both database and table names. From MariaDB 10.1.46, MariaDB 10.2.33, MariaDB 10.3.24, MariaDB 10.4.14 and MariaDB 10.5.3. See also `--no-data` .
`--include-master-host-port`	Add the `MASTER_HOST` and `MASTER_PORT` options for the CHANGE MASTER TO statement when using the `--dump-slave` option for a replica dump.
`--insert-ignore`	Insert rows with `INSERT IGNORE` instead of `INSERT` .
`--lines-terminated-by=name`	Lines in the output file are terminated by the given string. This option is used with the `--tab` option and has the same meaning as the corresponding `LINES` clause for LOAD DATA INFILE.
`-x` , `--lock-all-tables`	Lock all tables across all databases. This is achieved by acquiring a global read lock for the duration of the whole dump by executing FLUSH TABLES WITH READ LOCK. This option automatically turns off `--single-transaction` and `--lock-tables` .
`-l` , `--lock-tables`	For each dumped database, lock all tables to be dumped before dumping them. The tables are locked with `READ LOCAL` to allow concurrent inserts in the case of MyISAM tables. For transactional tables such as InnoDB, `--single-transaction` is a much better option than `--lock-tables` because it does not need to lock the tables at all. Because `--lock-tables` locks tables for each database separately, this option does not guarantee that the tables in the dump file are logically consistent between databases. Tables in different databases may be dumped in completely different states. Use `--skip-lock-tables` to disable.
`--log-error=name`	Log warnings and errors by appending them to the named file. The default is to do no logging.
`--log-queries`	When restoring the dump, the server will, if logging is turned on, log the queries to the general and slow query log. Defaults to on; use --skip-log-queries to disable. Added in MariaDB 10.1.1.
`--master-data[=#]`	Causes the binary log position and filename to be appended to the output, useful for dumping a primary replication server to produce a dump file that can be used to set up another server as a replica of the primary. These are the primary server coordinates from which the replica should start replicating after you load the dump file into the replica. If the option is set to 1 (the default), will print it as a CHANGE MASTER command; if set to 2, that command will be prefixed with a comment symbol. This `--master-data` option will turn `--lock-all-tables` on, unless `--single-transaction` is specified too. Before MariaDB 5.3 this would take a global read lock for a short time at the beginning of the dump - see Enhancements for START TRANSACTION WITH CONSISTENT SNAPSHOT and the `--single-transaction` option below). In all cases, any action on logs will happen at the exact moment of the dump. This option automatically turns `--lock-tables` off. In all cases, any action on logs happens at the exact moment of the dump. It is also possible to set up a replica by dumping an existing replica of the primary. To do this, use the following procedure on the existing replica: 1. Stop the replica's SQL thread and get its current status: `mariadb> STOP SLAVE SQL_THREAD;` `mariadb> SHOW SLAVE STATUS;` 2. From the output of the SHOW SLAVE STATUS statement, the binary log coordinates of the primary server from which the new replica should start replicating are the values of the Relay_Master_Log_File and Exec_Master_Log_Pos fields. Denote those values as file_name and file_pos. 2. Dump the replica server: `shell> mariadb-dump --master-data=2 --all-databases > dumpfile` 3. Restart the replica: `mariadb> START SLAVE;` 4. On the new replica, load the dump file: `shell> mariadb < dumpfile` 5. On the new replica, set the replication coordinates to those of the primary server obtained earlier: `mariadb> CHANGE MASTER TO MASTER_LOG_FILE = ´file_name´, MASTER_LOG_POS = file_pos;` The `CHANGE MASTER` TO statement might also need other parameters, such as MASTER_HOST to point the replica to the correct primary server host. Add any such parameters as necessary.
`--max-allowed-packet=#`	The maximum packet length to send to or receive from server. The maximum is 1GB.
`--max-statement-time=#`	Sets the maximum time any statement can run before being timed out by the server. (Default value is 0 (no limit))
`--net-buffer-length=#`	The initial buffer size for client/server TCP/IP and socket communication. This can be used to limit the size of rows in the dump. When creating multiple-row `INSERT` statements (as with the `--extended-insert` or `--opt` option), `mariadb-dump` creates rows up to `net_buffer_length` length.
`--no-autocommit`	Enclose the INSERT statements for each dumped table within SET autocommit = 0 and COMMIT statements.
`-n` , `--no-create-db`	This option suppresses the CREATE DATABASE ... IF EXISTS statement that normally is output for each dumped database if `--all-databases` or `--databases` is given.

`-t , --no-create-info`	Do not write CREATE TABLE statements which re-create each dumped table.
`-d , --no-data`	Do not write any table row information (that is, do not dump table contents). This is useful if you want to dump only the CREATE TABLE statement for the table (for example, to create an empty copy of the table by loading the dump file). See also --ignore-table-data .
`--no-data-med`	Do not dump rows for engines that manage external data (i.e.MRG_MyISAM, MRG_ISAM, CONNECT, OQGRAPH, Spider, VP, Federated). This option is enabled by default. If you want to dump data for these engines, then you would need to set `--no-data-med=0` .
`--no-defaults`	Don't read default options from any option file. Must be given as the first argument.
`-N , --no-set-names`	Suppress the `SET NAMES` statement. This has the same effect as `--skip-set-charset` .
`--opt`	This option is shorthand. It is the same as specifying `--add-drop-table` , `--add-locks` , `--create-options` , `--quick` , `--extended-insert` , `--lock-tables` , `--set-charset` , and `--disable-keys` . Enabled by default, disable with `--skip-opt` . It should give you a fast dump operation and produce a dump file that can be reloaded into a MariaDB server quickly. The `--opt` option is enabled by default. Use `--skip-opt` to disable it. See the discussion at the beginning of this section for information about selectively enabling or disabling a subset of the options affected by `--opt` .
`--order-by-primary`	Sorts each table's rows by primary key, or first unique key, if such a key exists. This is useful when dumping a MyISAM table to be loaded into an InnoDB table, but will make the dump itself take considerably longer.
`--order-by-size`	Dump each table according to their size, smallest first. Useful when using `--single-transaction` on tables which get truncated/altered often. The assumption here is that smaller tables get truncated more often, and by dumping those first, this reduces the chance that a `--single-transaction` dump will fail with with 'Table definition has changed, please retry transaction'. From MariaDB 10.9.1.
`-p[passwd] , --password[=passwd`	The password to use when connecting to the server. If you use the short option form (`-p`), you cannot have a space between the option and the password. If you omit the password value following the `--password` or `-p` option on the command line, *mariadb-dump* prompts for one. Specifying a password on the command line should be considered insecure. You can use an option file to avoid giving the password on the command line.
`-W , --pipe`	On Windows, connect to the server via a named pipe. This option applies only if the server supports named-pipe connections.
`--plugin-dir`	Directory for client-side plugins.
`-P num , --port=num`	The TCP/IP port number to use for the connection.
`--print-defaults`	Print the program argument list and exit. Must be given as the first argument.
`--protocol=name`	The connection protocol to use for connecting to the server (TCP, SOCKET, PIPE, MEMORY). It is useful when the other connection parameters normally would cause a protocol to be used other than the one you want.
`-q , --quick`	This option is useful for dumping large tables. It forces *mariadb-dump* to retrieve rows for a table from the server a row at a time and to then dump the results directly to stdout rather than retrieving the entire row set and buffering it in memory before writing it out. Defaults to on, use `--skip-quick` to disable.
`-Q , --quote-names`	Quote identifiers (such as database, table, and column names) within backtick (`` ` ``) characters. If the `ANSI_QUOTES` SQL mode is enabled, identifiers are quoted within (`"`) characters. This option is enabled by default. It can be disabled with `--skip-quote-names` , but this option should be given after any option such as `--compatible` that may enable `--quote-names` .
`--replace`	Use REPLACE INTO statements instead of INSERT INTO statements.
`-r , --result-file=name`	Direct output to a given file. This option should be used on Windows to prevent newline `"\n"` characters from being converted to `"\r\n"` carriage return/newline sequences. The result file is created and its previous contents overwritten, even if an error occurs while generating the dump.
`-R , --routines`	Include stored routines (procedures and functions) for the dumped databases in the output. Use of this option requires the `SELECT` privilege for the mysql.proc table. The output generated using `--routines` contains CREATE PROCEDURE and CREATE FUNCTION statements to re-create the routines. However, these statements do not include attributes such as the routine creation and modification timestamps. This means that when the routines are reloaded, they will be created with the timestamps equal to the reload time. If you require routines to be re-created with their original timestamp attributes, do not use `--routines` . Instead, dump and reload the contents of the mysql.proc table directly, using a MariaDB account which has appropriate privileges for the mysql database.
`set-charset`	Add `'SET NAMES default_character_set'` to the output in order to set the character set. Enabled by default; suppress with `--skip-set-charset` .
`-O, --set-variable=name`	Change the value of a variable. Please note that this option is deprecated; you can set variables directly with `--variable-name=value` .
`--shared-memory-base-name`	Shared-memory name to use for Windows connections using shared memory to a local server (started with the `--shared-memory` option). Case-sensitive. Defaults to `MYSQL` .

`--single-transaction`	This option sends a START TRANSACTION SQL statement to the server before dumping data. It is useful only with transactional tables such as InnoDB, because then it dumps the consistent state of the database at the time when `BEGIN` was issued without blocking any applications. When using this option, you should keep in mind that only InnoDB tables are dumped in a consistent state. The single-transaction feature depends not only on the engine being transactional and capable of REPEATABLE-READ, but also on START TRANSACTION WITH CONSISTENT SNAPSHOT. The dump is **not** guaranteed to be consistent for other storage engines. For example, any TokuDB, MyISAM or MEMORY tables dumped while using this option may still change state. While a `--single-transaction` dump is in process, to ensure a valid dump file (correct table contents and binary log coordinates), no other connection should use the following statements: ALTER TABLE, CREATE TABLE, DROP TABLE, RENAME TABLE, or TRUNCATE TABLE. A consistent read is not isolated from those statements, so use of them on a table to be dumped can cause the `SELECT` (performed by *mariadb-dump* to retrieve the table contents) to obtain incorrect contents or fail. The `--single-transaction` option and the `--lock-tables` option are mutually exclusive because LOCK TABLES causes any pending transactions to be committed implicitly. So this option automatically turns off `--lock-tables` To dump large tables, you should combine the `--single-transaction` option with `--quick`.
`--skip-add-locks`	Disable the `--add-locks` option.
`--skip-comments`	Disable the `--comments` option.
`--skip-disable-keys`	Disable the `--disable-keys` option.
`--skip-extended-insert`	Disable the `--extended-insert` option.
`--skip-opt`	Disable the `--opt` option (disables `--add-drop-table`, `--add-locks`, `--create-options`, `--quick`, `--extended-insert`, `--lock-tables`, `--set-charset`, and `--disable-keys`).
`--skip-quick`	Disable the `--quick` option.
`--skip-quote-name`	Disable the `--quote-names` option.
`--skip-set-charset`	Disable the `--set-charset` option.
`--skip-triggers`	Disable the `--triggers` option.
`--skip-tz-utc`	Disable the `--tz-utc` option.
`-S name`, `--socket=name`	For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.
`--ssl`	Enables TLS. TLS is also enabled even without setting this option when certain other TLS options are set. Starting with MariaDB 10.2, the `--ssl` option will not enable verifying the server certificate by default. In order to verify the server certificate, the user must specify the `--ssl-verify-server-cert` option.
`--ssl-ca=name`	Defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option implies the `--ssl` option.
`--ssl-capath=name`	Defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the `openssl rehash` command. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option is only supported if the client was built with OpenSSL or yaSSL. If the client was built with GnuTLS or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms. This option implies the `--ssl` option.
`--ssl-cert=name`	Defines a path to the X509 certificate file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.
`--ssl-cipher=name`	List of permitted ciphers or cipher suites to use for TLS. This option implies the `--ssl` option.
`--ssl-crl=name`	Defines a path to a PEM file that should contain one or more revoked X509 certificates to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL or Schannel. If the client was built with yaSSL or GnuTLS, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
`--ssl-crlpath=name`	Defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the `openssl rehash` command. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL. If the client was built with yaSSL, GnuTLS, or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
`--ssl-key=name`	Defines a path to a private key file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.
`--ssl-verify-server-cert`	Enables server certificate verification. This option is disabled by default.
`--system=option[,option]`	Dump the database's system tables in a logical form. With this option, the mysql database tables are dumped as CREATE USER, CREATE SERVER and other forms of logical portable SQL statements. The option values here are from the set of `all`, `users`, `plugins`, `udfs`, `servers`, `stats`, `timezones`. From MariaDB 10.2.37, MariaDB 10.3.28, MariaDB 10.4.18 and MariaDB 10.5.9.

`-T`, `--tab=name`	Produce tab-separated text-format data files. With this option, for each dumped table `mariadb-dump` will create a `tbl_name.sql` file containing the `CREATE TABLE` statement that creates the table, and a `tbl_name.txt` file containing the table's data. The option value is the directory in which to write the files. **Note:** *This option can only be used when* mariadb-dump/ is run on the same machine as the mysqld server. You must have the `FILE` privilege, and the server must have permission to write files in the directory that you specify. *By default, the `.txt` data files are formatted using tab characters between column values and a newline at the end of each line. The format can be specified explicitly using the `--fields-xxx` and `--lines-terminated-by` options.* *Column values are converted to the character set specified by the `--default-character-set` option.*
`--tables`	This option overrides the `--databases` (`-B`) option. *mariadb-dump* regards all name arguments following the option as table names.
`--tls-version=name`	This option accepts a comma-separated list of TLS protocol versions. A TLS protocol version will only be enabled if it is present in this list. All other TLS protocol versions will not be permitted. See Secure Connections Overview: TLS Protocol Versions for more information. This option was added in MariaDB 10.4.6.
`--triggers`	Include triggers for each dumped table in the output. This option is enabled by default; disable it with `--skip-triggers`.
`--tz-utc`	This option enables TIMESTAMP columns to be dumped and reloaded between servers in different time zones. *mariadb-dump* sets its connection time zone to UTC and adds `SET TIME_ZONE='+00:00'` to the dump file. Without this option, TIMESTAMP columns are dumped and reloaded in the time zones local to the source and destination servers, which can cause the values to change if the servers are in different time zones. `--tz-utc` also protects against changes due to daylight saving time. `--tz-utc` is enabled by default. To disable it, use `--skip-tz-utc`.
`-u name`, `--user=name`	The MariaDB user name to use when connecting to the server.
`-v`, `--verbose`	Verbose mode. Print more information about what the program is doing during various stages.
`-V`, `--version`	Output version information and exit.
`-w cond`, `--where=cond`	Dump only rows selected by the given `WHERE` condition *cond*. Quotes around the condition are mandatory if it contains spaces or other characters that are special to your command interpreter. Examples: `--where="user='jimf'"` `-w"userid>1"` `-w"userid<1"`
`-X`, `--xml`	Dump a database as well formed XML.

Group Options

Some `mariadb-dump` options are shorthand for groups of other options:

- Use of `--opt` is the same as specifying `--add-drop-table`, `--add-locks`, `--create-options`, `--disable-keys`, `--extended-insert`, `--lock-tables`, `--quick`, and `--set-charset`. All of the options that `--opt` stands for also are on by default because `--opt` is on by default.
- Use of `--compact` is the same as specifying `--skip-add-drop-table`, `--skip-add-locks`, `--skip-comments`, `--skip-disable-keys`, and `--skip-set-charset` options.

To reverse the effect of a group option, uses its `--skip-xxx` form (`--skip-opt` or `--skip-compact`). It is also possible to select only part of the effect of a group option by following it with options that enable or disable specific features. Here are some examples:

- To select the effect of `--opt` except for some features, use the `--skip` option for each feature. To disable extended inserts and memory buffering, use `--opt --skip-extended-insert --skip-quick`. (Actually, `--skip-extended-insert --skip-quick` is sufficient because `--opt` is on by default.)
- To reverse `--opt` for all features except index disabling and table locking, use `--skip-opt --disable-keys --lock-tables`.

When you selectively enable or disable the effect of a group option, order is important because options are processed first to last. For example, `--disable-keys --lock-tables --skip-opt` would not have the intended effect; it is the same as `--skip-opt` by itself.

Special Characters in Option Values

Some options, like `--lines-terminated-by`, accept a string. The string can be quoted, if necessary. For example, on Unix systems this is the option to enclose fields within double quotes:

```
--fields-enclosed-by='"'
```

An alternative to specify the hexadecimal value of a character. For example, the following syntax works on any platform:

```
--fields-enclosed-by=0x22
```

Option Files

In addition to reading options from the command-line, `mariadb-dump` can also read options from option files. If an unknown option is provided to `mariadb-dump` in an option file, then it is ignored.

The following options relate to how MariaDB command-line tools handles option files. They must be given as the first argument on the command-line:

Option	Description
`--print-defaults`	Print the program argument list and exit.
`--no-defaults`	Don't read default options from any option file.
`--defaults-file=#`	Only read default options from the given file #.
`--defaults-extra-file=#`	Read this file after the global files are read.
`--defaults-group-suffix=#`	In addition to the default option groups, also read option groups with this suffix.

`mariadb-dump` is linked with MariaDB Connector/C. However, MariaDB Connector/C does not yet handle the parsing of option files for this client. That is still performed by the server option file parsing code. See MDEV-19035 for more information.

Option Groups

`mariadb-dump` reads options from the following option groups from option files:

Group	Description
`[mysqldump]`	Options read by *mariadb-dump*, which includes both MariaDB Server and MySQL Server.
`[mariadb-dump]`	Options read by *mariadb-dump*. Available starting with MariaDB 10.4.6.
`[client]`	Options read by all MariaDB and MySQL client programs, which includes both MariaDB and MySQL clients. For example, `mysqldump` .
`[client-server]`	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
`[client-mariadb]`	Options read by all MariaDB client programs.

NULL, ´NULL´, and Empty Values in XML

For a column named `column_name` , the `NULL` value, an empty string, and the string value `´NULL´` are distinguished from one another in the output generated by this option as follows.

Value	XML Representation
NULL (unknown value)	`<field name="column_name" xsi:nil="true" />`
´´ (empty string)	`<field name="column_name"></field>`
´NULL´ (string value)	`<field name="column_name">NULL</field>`

The output from the mariadb client when run using the `--xml` option also follows the preceding rules.

XML output from mariadb-dump includes the XML namespace, as shown here :

```
shell> mariadb-dump --xml -u root world City
<?xml version="1.0"?>
<mariadb-dump xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<database name="world">
<table_structure name="City">
<field Field="ID" Type="int(11)" Null="NO" Key="PRI" Extra="auto_increment" />
<field Field="Name" Type="char(35)" Null="NO" Key="" Default="" Extra="" />
<field Field="CountryCode" Type="char(3)" Null="NO" Key="" Default="" Extra="" />
<field Field="District" Type="char(20)" Null="NO" Key="" Default="" Extra="" />
<field Field="Population" Type="int(11)" Null="NO" Key="" Default="0" Extra="" />
<key Table="City" Non_unique="0" Key_name="PRIMARY" Seq_in_index="1" Column_name="ID"
Collation="A" Cardinality="4079" Null="" Index_type="BTREE" Comment="" />
<options Name="City" Engine="MyISAM" Version="10" Row_format="Fixed" Rows="4079"
Avg_row_length="67" Data_length="273293" Max_data_length="18858823439613951"
Index_length="43008" Data_free="0" Auto_increment="4080"
Create_time="2007-03-31 01:47:01" Update_time="2007-03-31 01:47:02"
Collation="latin1_swedish_ci" Create_options="" Comment="" />
</table_structure>
<table_data name="City">
<row>
<field name="ID">1</field>
<field name="Name">Kabul</field>
<field name="CountryCode">AFG</field>
<field name="District">Kabol</field>
<field name="Population">1780000</field>
</row>
...
<row>
<field name="ID">4079</field>
<field name="Name">Rafah</field>
<field name="CountryCode">PSE</field>
<field name="District">Rafah</field>
<field name="Population">92020</field>
</row>
</table_data>
</database>
</mariadb-dump>
```

Restoring

To restore a backup created with mariadb-dump, use the mariadb client to import the dump, for example:

```
mariadb db_name < backup-file.sql
```

Variables

You can also set the following variables (`--variable-name=value`) and boolean options `{FALSE|TRUE}` by using:

Name	Default Values
all	TRUE
all-databases	FALSE
all-tablespaces	FALSE
no-tablespaces	FALSE
add-drop-database	FALSE
add-drop-table	TRUE
add-drop-trigger	FALSE
add-locks	TRUE
allow-keywords	FALSE

tz-utc	TRUE
user	*(No default value)*
verbose	FALSE
where	*(No default value)*
plugin-dir	*(No default value)*
default-auth	*(No default value)*

Examples

A common use of `mariadb-dump` is for making a backup of an entire database:

```
shell> mariadb-dump db_name > backup-file.sql
```

You can load the dump file back into the server like this:

```
shell> mariadb db_name < backup-file.sql
```

Or like this:

```
shell> mariadb -e "source /path-to-backup/backup-file.sql" db_name
```

`mariadb-dump` is also very useful for populating databases by copying data from one MariaDB server to another:

```
shell> mariadb-dump --opt db_name | mariadb --host=remote_host -C db_name
```

It is possible to dump several databases with one command:

```
shell> mariadb-dump --databases db_name1 [db_name2 ...] > my_databases.sql
```

To dump all databases, use the `--all-databases` option:

```
shell> mariadb-dump --all-databases > all_databases.sql
```

For InnoDB tables, `mariadb-dump` provides a way of making an online backup:

```
shell> mariadb-dump --all-databases --single-transaction all_databases.sql
```

This backup acquires a global read lock on all tables (using `FLUSH TABLES WITH READ LOCK`) at the beginning of the dump. As soon as this lock has been acquired, the binary log coordinates are read and the lock is released. If long updating statements are running when the FLUSH statement is issued, the MariaDB server may get stalled until those statements finish. After that, the dump becomes lock free and does not disturb reads and writes on the tables. If the update statements that the MariaDB server receives are short (in terms of execution time), the initial lock period should not be noticeable, even with many updates.

For point-in-time recovery (also known as "roll-forward," when you need to restore an old backup and replay the changes that happened since that backup), it is often useful to rotate the binary log or at least know the binary log coordinates to which the dump corresponds:

```
shell> mariadb-dump --all-databases --master-data=2 > all_databases.sql
```

Or:

```
shell> mariadb-dump --all-databases --flush-logs --master-data=2 > all_databases.sql
```

The `--master-data` and `--single-transaction` options can be used simultaneously, which provides a convenient way to make an online backup suitable for use prior to point-in-time recovery if tables are stored using the InnoDB storage engine.

1.3.6.3 mariadb-hotcopy

mariadb-hotcopy is deprecated and may be removed in a future release.

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-hotcopy` is a symlink to `mysqlhotcopy`, the deprecated backup script.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadb-hotcopy` is the name of the script, with `mysqlhotcopy` a symlink .

`mariadb-hotcopy` is a Perl script that was originally written (as `mysqlhotcopy`) and contributed by Tim Bunce. It uses FLUSH TABLES, LOCK TABLES, and cp or scp to make a database backup. It is a fast way to make a backup of the database or single tables, but it can be run only on the same machine where the database directories are located. `mariadb-hotcopy` > works only for backing up MyISAM and ARCHIVE tables. It runs on Unix and NetWare.

To use `mariadb-hotcopy`, you must have read access to the files for the tables that you are backing up, the SELECT privilege for those tables, the RELOAD privilege (to be able to execute FLUSH TABLES), and the LOCK TABLES privilege (to be able to lock the tables).

```
shell> mariadb-hotcopy db_name [/path/to/new_directory]
shell> mariadb-hotcopy db_name_1 ... db_name_n /path/to/new_directory
```

Back up tables in the given database that match a regular expression:

```
shell> mariadb-hotcopy db_name./regex/
```

The regular expression for the table name can be negated by prefixing it with a tilde (" `~` "):

```
shell> mariadb-hotcopy db_name./~regex/
```

`mariadb-hotcopy` supports the following options, which can be specified on the command line or in the [`mariadb-`

`hotcopy`] and [`client`] option file groups.

Option	Description
`--help`, `-?`	Display a help message and exit.
`--addtodest`	Do not rename target directory (if it exists); merely add files to it.
`--allowold`	Do not abort if a target exists; rename it by adding an _old suffix.
`--checkpoint=db_name.tbl_name`	Insert checkpoint entries into the specified database `db_name` and table `tbl_name`.
`--chroot=path`	Base directory of the chroot jail in which mysqld operates. The path value should match that of the `--chroot` option given to mysqld.
`--debug`	Enable debug output.
`--dryrun`, `-n`	Report actions without performing them.
`--flushlog`	Flush logs after all tables are locked.
`--host=host_name`, `-h host_name`	The host name of the local host to use for making a TCP/IP connection to the local server. By default, the connection is made to localhost using a Unix socket file.
`--keepold`	Do not delete previous (renamed) target when done.
`--method=command`	The method for copying files (cp or scp). The default is cp.
`--noindices`	Do not include full index files for MyISAM tables in the backup. This makes the backup smaller and faster. The indexes for reloaded tables can be reconstructed later with myisamchk -rq.
`--old-server`	Connect to old MySQL-server (before v5.5) which doesn't have FLUSH TABLES WITH READ LOCK fully implemented.
`--password=password`, `-ppassword`	The password to use when connecting to the server. The password value is not optional for this option, unlike for other MariaDB programs. Specifying a password on the command line should be considered insecure. You can use an option file to avoid giving the password on the command line.
`--port=port_num`, `-P port_num`	The TCP/IP port number to use when connecting to the local server.
`--quiet`, `-q`	Be silent except for errors.
`--record_log_pos=db_name.tbl_name`	Record master and slave status in the specified database db_name and table tbl_name.
`--regexp=expr`	Copy all databases with names that match the given regular expression.
`--resetmaster`	Reset the binary log after locking all the tables.
`--resetslave`	Reset the master.info file after locking all the tables.
`--socket=path`, `-S path`	The Unix socket file to use for connections to localhost.
`--suffix=str`	The suffix to use for names of copied databases.
`--tmpdir=path`	The temporary directory. The default is /tmp.
`--user=username`, `-u username`	The MariaDB username to use when connecting to the server.

Use perldoc for additional `mariadb-hotcopy` documentation, including information about the structure of the tables needed for the `--checkpoint` and `--record_log_pos` options:

```
shell> perldoc mariadb-hotcopy
```

1.3.6.4 mariadb-import

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-import` is a symlink to `mysqlimport`, the old name of tool for loading tables from text files in various formats.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadb-import` is the name of the script, with `mysqlimport` a symlink .

`mariadb-import` loads tables from text files in various formats. The base name of the text file must be the name of the table that should be used. If one uses sockets to connect to the MariaDB server, the server will open and read the text file directly. In other cases the client will open the text file. The SQL command LOAD DATA INFILE is used to import the rows.

Using mariadb-import

The command to use `mariadb-import` and the general syntax is:

```
mariadb-import [OPTIONS] database textfile1 [textfile2 ...]
```

Options

`mariadb-import` supports the following options:

variable	Description
`--character-sets-dir=name`	Directory for character set files.
`-c cols , --columns=cols`	Use only these columns to import the data to. Give the column names in a comma separated list. This is same as giving columns to LOAD DATA INFILE.
`-C , --compress`	Use compression in server/client protocol.
`-# [options] , --debug[=options]`	Output debug log. Often this is `d:t:o,filename` . The default is `d:t:o` .
`--debug-check`	Check memory and open file usage at exit.
`--debug-info`	Print some debug info at exit.
`--default-auth=plugin`	Default authentication client-side plugin to use.
`--default-character-set=name`	Set the default character set.
`--defaults-extra-file=name`	Read this file after the global files are read. Must be given as the first option.
`--defaults-file=name`	Only read default options from the given file *name* Must be given as the first option.
`--defaults-group-suffix=name`	In addition to the given groups, also read groups with this suffix.
`-d , --delete`	First delete all rows from table.
`--fields-terminated-by=name`	Fields in the input file are terminated by the given string.
`--fields-enclosed-by=name`	Fields in the import file are enclosed by the given character.
`--fields-optionally-enclosed-by=name`	Fields in the input file are optionally enclosed by the given character.
`--fields-escaped-by=name`	Fields in the input file are escaped by the given character.
`-f , --force`	Continue even if we get an SQL error.
`-? , --help`	Displays this help and exits.

`-h name , --host=name`	Connect to host.
`-i , --ignore`	If duplicate unique key was found, keep old row.
`k , --ignore-foreign-keys`	Disable foreign key checks while importing the data. From MariaDB 10.3.16, MariaDB 10.2.25 and MariaDB 10.1.41.
`--ignore-lines=n`	Ignore first *n* lines of data infile.
`--lines-terminated-by=name`	Lines in the input file are terminated by the given string.
`-L , --local`	Read all files through the client.
`-l , --lock-tables`	Lock all tables for write (this disables threads).
`--low-priority`	Use LOW_PRIORITY when updating the table.
`--no-defaults`	Don't read default options from any option file. Must be given as the first option.
`-p[passwd] , --password[=passwd]`	Password to use when connecting to server. If password is not given it's asked from the terminal. Specifying a password on the command line should be considered insecure. You can use an option file to avoid giving the password on the command line.
`--pipe , -W`	On Windows, connect to the server via a named pipe. This option applies only if the server supports named-pipe connections.
`--plugin-dir`	Directory for client-side plugins.
`-P num , --port=num`	Port number to use for connection or 0 for default to, in order of preference, my.cnf, the MYSQL_TCP_PORT environment variable, /etc/services, built-in default (3306).
`--print-defaults`	Print the program argument list and exit. Must be given as the first option.
`--protocol=name`	The protocol to use for connection (tcp, socket, pipe, memory).
`-r , --replace`	If duplicate unique key was found, replace old row.
`--shared-memory-base-name`	Shared-memory name to use for Windows connections using shared memory to a local server (started with the `--shared-memory` option). Case-sensitive.
`-s , --silent`	Silent mode. Produce output only when errors occur.
`-S , --socket=name`	For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.
`--ssl`	Enables TLS. TLS is also enabled even without setting this option when certain other TLS options are set. Starting with MariaDB 10.2, the `--ssl` option will not enable verifying the server certificate by default. In order to verify the server certificate, the user must specify the `--ssl-verify-server-cert` option.
`--ssl-ca=name`	Defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option implies the `--ssl` option.
`--ssl-capath=name`	Defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the `openssl rehash` command. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option is only supported if the client was built with OpenSSL or yaSSL. If the client was built with GnuTLS or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms. This option implies the `--ssl` option.
`--ssl-cert=name`	Defines a path to the X509 certificate file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.
`--ssl-cipher=name`	List of permitted ciphers or cipher suites to use for TLS. This option implies the `--ssl` option.

`--ssl-crl=name`	Defines a path to a PEM file that should contain one or more revoked X509 certificates to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL or Schannel. If the client was built with yaSSL or GnuTLS, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
`--ssl-crlpath=name`	Defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the `openssl rehash` command. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL. If the client was built with yaSSL, GnuTLS, or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
`--ssl-key=name`	Defines a path to a private key file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.
`--ssl-verify-server-cert`	Enables server certificate verification. This option is disabled by default.
`--tls-version=name`	This option accepts a comma-separated list of TLS protocol versions. A TLS protocol version will only be enabled if it is present in this list. All other TLS protocol versions will not be permitted. See Secure Connections Overview: TLS Protocol Versions for more information. This option was added in MariaDB 10.4.6.
`--use-threads=num`	Load files in parallel. The argument is the number of threads to use for loading data.
`-u name`, `--user=name`	User for login if not current user.
`-v`, `--verbose`	Print info about the various stages.
`-V`, `--version`	Output version information and exit.

Option Files

In addition to reading options from the command-line, `mariadb-import` can also read options from option files. If an unknown option is provided to `mariadb-import` in an option file, then it is ignored.

The following options relate to how MariaDB command-line tools handles option files. They must be given as the first argument on the command-line:

Option	Description
`--print-defaults`	Print the program argument list and exit.
`--no-defaults`	Don't read default options from any option file.
`--defaults-file=#`	Only read default options from the given file #.
`--defaults-extra-file=#`	Read this file after the global files are read.

In MariaDB 10.2 and later, `mariadb-import` is linked with MariaDB Connector/C. Therefore, it may be helpful to see Configuring MariaDB Connector/C with Option Files for more information on how MariaDB Connector/C handles option files.

Option Groups

`mariadb-import` reads options from the following option groups from option files:

Group	Description
`[mysqlimport]`	Options read by `mysqlimport`, which includes both MariaDB Server and MySQL Server.
`[mariadb-import]`	Options read by `mysqlimport`. Available starting with MariaDB 10.4.6.
`[client]`	Options read by all MariaDB and MySQL client programs, which includes both MariaDB and MySQL clients. For example, `mysqldump`.

`[client-server]`	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
`[client-mariadb]`	Options read by all MariaDB client programs.

Default Values

Variables (`--variable-name=value`) and boolean options `{FALSE | TRUE}`	Value (after reading options)
`character-sets-dir`	*(No default value)*
`default-character-set`	latin1
`columns`	*(No default value)*
`compress`	FALSE
`debug-check`	FALSE
`debug-info`	FALSE
`delete`	FALSE
`fields-terminated-by`	*(No default value)*
`fields-enclosed-by`	*(No default value)*
`fields-optionally-enclosed-by`	*(No default value)*
`fields-escaped-by`	*(No default value)*
`force`	FALSE
`host`	*(No default value)*
`ignore`	FALSE
`ignore-lines`	0
`lines-terminated-by`	*(No default value)*
`local`	FALSE
`lock-tables`	FALSE
`low-priority`	FALSE
`port`	3306
`replace`	FALSE
`silent`	FALSE
`socket`	/var/run/mysqld/mysqld.sock
`ssl`	FALSE
`ssl-ca`	*(No default value)*
`ssl-capath`	*(No default value)*
`ssl-cert`	*(No default value)*
`ssl-cipher`	*(No default value)*
`ssl-key`	*(No default value)*
`ssl-verify-server-cert`	FALSE
`use-threads`	0
`user`	*(No default value)*
`verbose`	FALSE

1.3.7 Graphical and Enhanced Clients

This list is incomplete - most MySQL tools will work with MariaDB. See also a list of projects that officially work with MariaDB.

dbForge Studio for MariaDB
Universal GUI Tool for Management & Administration, Development for MariaDB and MySQL

dbForge Edge
dbForge Edge is a versatile software solution designed to meet the needs of...

DBeaver
Free convenient cross-platform and cross-database Java GUI client

ERBuilder Data Modeler
A data modeling tool for multiple databases platforms including MariaDB, MySQL, and more ...

SQLyog: Community Edition
SQLyog Community Edition

HeidiSQL
Windows GUI client for MariaDB and MySQL.

Navicat
Graphical front-end for MariaDB

Querious
Mac OS X tool for database administration

TablePlus
A modern, native GUI client for multiple databases

Database Workbench
Database development environment for multiple database systems including MySQL and MariaDB

Luna Modeler
Luna Modeler is a database design tool for MariaDB. Draw ER diagrams, visua...

SQL Diagnostic Manager & SQLyog
Graphical MariaDB manager and monitor

mycli
Command line interface with auto-completion and syntax highlighting

ocelotgui
Linux client for MySQL and MariaDB

phpMyAdmin
Web-based MariaDB administration tool

Sequel Pro
Database management tool running on Mac

SQLTool Pro Database Editor
Android SQL client

dbForge Data Compare
A tool for MariaDB & MySQL data comparison and synchronization of data betw...

dbForge Data Generator
A tool for generation of large volumes of meaningful test table data.

dbForge Documenter for MariaDB and MySQL
dbForge Documenter is a useful tool for MariaDB and MySQL database for the ...

dbForge Fusion: MySQL & MariaDB Plugin for VS

Visual Studio plugin designed to simplify database development and management.

dbForge Query Builder for MySQL & MariaDB

A tool for visual query creation without code typing.

dbForge Schema Compare for MariaDB & MySQL

A tool for comparison and synchronization of DDL differences between database objects.

DbSchema

Mariadb Diagram Designer & Admin GUI Tool

Improved SQL Document Parser Performance in Updated dbForge Tools for MySQL and MariaDB

Devart has upgraded dbForge Tools for MySQL and MariaDB with improved SQL d...

OmniDB

Browser-based IDE for MariaDB Administration

TOAD Edge

Windows GUI for MySQL. SQL Syntax Check. Freeware (Basic Features) & Payware (Extended Features).

TOAD for MySQL

Windows GUI for MySQL. Compatible with MariaDB. Freeware. SQL syntax check.

SQLPro Studio

SQLPro Studio is a fully native database client for macOS and iOS.

SB Data Generator

A tool to generate and populate selected tables or entire databases with realistic test data.

Beekeeper Studio

Open source and free GUI with a focus on usability. Mac, Linux, and Windows

LibreOffice Base

An open source RDBMS front-end tool to create and manage various databases

Valentina Studio

Free, advanced MariaDB GUI native on macOS, Windows & Linux, with advanced commercial version

DbVisualizer

Cross-platform universal database tool supporting MariaDB, PostgreSQL, MySQL and more

KS DB Merge Tools for MySQL and MariaDB

Windows GUI to compare and synchronize MySQL and MariaDB schema and data, freemium

1.3.8 MyISAM Clients and Utilities

Clients and utilities for working with the MyISAM storage engine

myisamchk

Utility for checking, repairing and optimizing MyISAM tables.

Memory and Disk Use With myisamchk

myisamchk's performance can be dramatically enhanced for larger tables

myisamchk Table Information

myisamchk can be used to obtain information about MyISAM tables

myisamlog

Process the MyISAM log

myisampack

Tool for compressing MyISAM tables

myisam_ftdump

A tool for displaying information on MyISAM FULLTEXT indexes.

1.3.8.1 myisamchk

Contents

myisamchk is a commandline tool for checking, repairing and optimizing non-partitioned MyISAM tables.

myisamchk is run from the commandline as follows:

```
myisamchk [OPTIONS] tables[.MYI]
```

The full list of options are listed below. One or more MyISAM tables can be specified. MyISAM tables have an associated .MYI index file, and the table name can either be specified with or without the .MYI extension. Referencing it with the extension allows you to use wildcards, so it's possible to run myisamchk on *all* the MyISAM tables in the database with `*.MYI`.

The path to the files must also be specified if they're not in the current directory.

> myisamchk should not be run while anyone is accessing any of the affected tables. It is also best to make a backup before running.

With no options, myisamchk simply checks your table as the default operation.

The following options can be set while passed as commandline options to myisamchk, or set with a [myisamchk] section in your my.cnf file.

General Options

Option	Description
-H, --HELP	Display help and exit. Options are presented in a single list.
-?, --help	Display help and exit. Options are grouped by type of operation.
-debug=options, -# options	Write a debugging log. A typical debug_options string is ´d:t:o,file_name´. The default is ´d:t:o,/tmp/myisamchk.trace´. (Available in debug builds only)
-t path, --tmpdir=path	Path for temporary files. Multiple paths can be specified, separated by colon (:) on Unix and semicolon (;) on Windows. They will be used in a round-robin fashion. If not set, the TMPDIR environment variable is used.
-s, --silent	Only print errors. One can use two -s (-ss) to make myisamchk very silent.
-v, --verbose	Print more information. This can be used with --description and --check. Use many -v for more verbosity.
-V, --version	Print version and exit.
-w, --wait	If table is locked, wait instead of returning an error.
--print-defaults	Print the program argument list and exit.
--no-defaults	Don't read default options from any option file.

--defaults-file=filename	Only read default options from the given file *filename*, which can be the full path, or the path relative to the current directory.
--defaults-extra-file=filename	Read the file *filename*, which can be the full path, or the path relative to the current directory, after the global files are read.
--defaults-group-suffix=str	Also read groups with a suffix of *str*. For example, `--defaults-group-suffix=x` would read the groups [myisamchk] and [myisamchk_x]

The following variables can also be set by using *--var_name=value*, for example *--ft_min_word_len=5*

Variable	Default Value
decode_bits	9
ft_max_word_len	version-dependent
ft_min_word_len	4
ft_stopword_file	built-in list
key_buffer_size	1044480
key_cache_block_size	1024
myisam_block_size	1024
myisam_sort_buffer_size	134216704
myisam_sort_key_blocks	16
read_buffer_size	262136
sort_buffer_size	134216704
sort_key_blocks	16
stats_method	nulls_unequal
write_buffer_size	262136

Checking Tables

If no option is provided, myisamchk will perform a check table. It is possible to check MyISAM tables without shutting down or restricting access to the server by using CHECK TABLE instead.

The following check options are available:

Option	Description
-c, --check	Check table for errors. This is the default operation if you specify no option that selects an operation type explicitly.
-e, --extend-check	Check the table VERY throughly. Only use this in extreme cases as it may be slow, and myisamchk should normally be able to find out if the table has errors even without this switch. Increasing the *key_buffer_size* can help speed the process up.
-F, --fast	Check only tables that haven't been closed properly.
-C, --check-only-changed	Check only tables that have changed since last check.
-f, --force	Restart with '-r' (recover) if there are any errors in the table. States will be updated as with '--update-state'.
-i, --information	Print statistics information about the table that is checked.
-m, --medium-check	Faster than *extend-check*, but only finds 99.99% of all errors. Should be good enough for most cases.
-U --update-state	Mark tables as crashed if you find any errors. This should be used to get the full benefit of the *--check-only-changed* option, but you shouldn´t use this option if the mysqld server is using the table and you are running it with external locking disabled.

-T, --read-only	Don't mark table as checked. This is useful if you use myisamchk to check a table that is in use by some other application that does not use locking, such as mysqld when run with external locking disabled.

Repairing Tables

It is also possible to repair MyISAM tables by using REPAIR TABLE.

The following repair options are available, and are applicable when using '-r' or '-o':

Option	Description
-B, --backup	Make a backup of the .MYD file as 'filename-time.BAK'.
--correct-checksum	Correct the checksum information for table.
-D len, --data-file-length=#	Max length of data file (when recreating data file when it's full).
-e, --extend-check	Try to recover every possible row from the data file. Normally this will also find a lot of garbage rows; Don't use this option if you are not totally desperate.
-f, --force	Overwrite old temporary files. Add another --force to avoid 'myisam_sort_buffer_size is too small' errors. In this case we will attempt to do the repair with the given myisam_sort_buffer_size and dynamically allocate as many management buffers as needed.
-k val, --keys-used=#	Specify which keys to update. The value is a bit mask of which keys to use. Each binary bit corresponds to a table index, with the first index being bit 0. *0* disables all index updates, useful for faster inserts. Deactivated indexes can be reactivated by using *myisamchk -r*.
--create-missing-keys	Create missing keys. This assumes that the data file is correct and that the number of rows stored in the index file is correct. Enables *--quick*
--max-record-length=#	Skip rows larger than this if myisamchk can't allocate memory to hold them.
-r, --recover	Can fix almost anything except unique keys that aren't unique (a rare occurrence). Usually this is the best option to try first. Increase *myisam_sort_buffer_size* for better performance.
-n, --sort-recover	Forces recovering with sorting even if the temporary file would be very large.
-p, --parallel-recover	Uses the same technique as '-r' and '-n', but creates all the keys in parallel, in different threads.
-o, --safe-recover	Uses old recovery method; Slower than '-r' but uses less disk space and can handle a couple of cases where '-r' reports that it can't fix the data file. Increase *key_buffer_size* for better performance.
--character-sets-dir=directory_name	Directory where the character sets are installed.
--set-collation=name	Change the collation (and by implication, the character set) used by the index.
-q, --quick	Faster repair by not modifying the data file. One can give a second '-q' to force myisamchk to modify the original datafile in case of duplicate keys. NOTE: Tables where the data file is corrupted can't be fixed with this option.
-u, --unpack	Unpack file packed with myisampack.

Other Actions

Option	Description
-a, --analyze	Analyze distribution of keys. Will make some joins faster as the join optimizer can better choose the order in which to join the tables and which indexes to use. You can check the calculated distribution by using '--description --verbose table_name' or SHOW INDEX FROM table_name.
--stats_method=name	Specifies how index statistics collection code should treat NULLs. Possible values of *name* are "nulls_unequal" (default), "nulls_equal" (emulate MySQL 4.0 behavior), and "nulls_ignored".
-d, --description	Print some descriptive information about the table. Specifying the *--verbose* option once or twice produces additional information.

-A [value], --set-auto-increment[=value]	Force auto_increment to start at this or higher value. If no value is given, then sets the next auto_increment value to the highest used value for the auto key + 1.
-S, --sort-index	Sort the index tree blocks in high-low order. This optimizes seeks and makes table scans that use indexes faster.
-R index_num, --sort-records=#	Sort records according to the given index (as specified by the index number). This makes your data much more localized and may speed up range-based SELECTs and ORDER BYs using this index. It may be VERY slow to do a sort the first time! To see the index numbers, SHOW INDEX displays table indexes in the same order that myisamchk sees them. The first index is 1.
-b offset, --block-search=offset	Find the record to which a block at the given *offset* belongs.

For more, see Memory and Disk Use With myisamchk.

Examples

Check all the MyISAM tables in the current directory:

```
myisamchk *.MYI
```

If you are not in the database directory, you can check all the tables there by specifying the path to the directory:

```
myisamchk /path/to/database_dir/*.MYI
```

Check all tables in all databases by specifying a wildcard with the path to the MariaDB data directory:

```
myisamchk /path/to/datadir/*/*.MYI
```

The recommended way to quickly check all MyISAM tables:

```
myisamchk --silent --fast /path/to/datadir/*/*.MYI
```

Check all MyISAM tables and repair any that are corrupted:

```
myisamchk --silent --force --fast --update-state \
  --key_buffer_size=64M --sort_buffer_size=64M \
  --read_buffer_size=1M --write_buffer_size=1M \
  /path/to/datadir/*/*.MYI
```

1.3.8.2 Memory and Disk Use With myisamchk

myisamchk's performance can be dramatically enhanced for larger tables by making sure that its memory-related variables are set to an optimum level.

By default, myisamchk will use very little memory (about 3MB is allocated), but can temporarily use a lot of disk space. If disk space is a limitation when repairing, the *--safe-recover* option should be used instead of *--recover*. However, if TMPDIR points to a memory file system, an out of memory error can easily be caused, as myisamchk places temporary files in TMPDIR. The *--tmpdir=path* option should be used in this case to specify a directory on disk.

myisamchk has the following requirements for disk space:

- When repairing, space for twice the size of the data file, available in the same directory as the original file. This is for the original file as well as a copy. This space is not required if the *--quick* option is used, in which case only the index file is re-created.
- Disk space in the temporary directory (TMPDIR or the *tmpdir=path* option) is needed for sorting if the *--recover* or *--sort-recover* options are used when not using *--safe-recover*). The space required will be approximately *(largest_key + row_pointer_length) * number_of_rows * 2*. To get information about the length of the keys as well as the row pointer length, use *myisamchk -dv table_name*.
- Space for a new index file to replace the existing one. The old index is first truncated, so unless the old index file is not present or is smaller for some reason, no significant extra space will be needed.

There are a number of system variables that are useful to adjust when running myisamchk. They will increase memory usage, and since some are per-session variables, you don't want to increase the general value, but you can either pass an

increased value to myisamchk as a commandline option, or with a [myisamchk] section in your my.cnf file.

- sort_buffer_size. By default this is 4M, but it's very useful to increase to make myisamchk sorting much faster. Since the server won't be running when you run myisamchk, you can increase substantially. 16M is usually a minimum, but values such as 256M are not uncommon if memory is available.
- key_buffer_size (which particularly helps with the *--extend-check* and *--safe-recover* options.
- read_buffer_size
- write_buffer_size

For example, if you have more than 512MB available to allocate to the process, the following settings could be used:

```
myisamchk
  --myisam_sort_buffer_size=256M
  --key_buffer_size=512M
  --read_buffer_size=64M
  --write_buffer_size=64M
...
```

1.3.8.3 myisamchk Table Information

Contents

myisamchk can be used to obtain information about MyISAM tables, particularly with the *-d*, *-e*, *-i* and *-v* options.

Common options for gathering information include:

- myisamchk -d
- myisamchk -dv
- myisamchk -dvv
- myisamchk -ei
- myisamchk -eiv

The *-d* option returns a short description of the table and its keys. Running the option while the table is being updated, and with external locking disabled, may result in an error, but no damage will be done to the table. Each extra *v* adds more output. *-e* checks the table thoroughly (but slowly), and the *-i* options adds statistical information,

-dvv output

The following table describes the output from the running myisamchk with the *-dvv* option:

Heading	Description
MyISAM file	Name and path of the MyISAM index file (without the extension)
Record format	Storage format. One of *packed* (dynamic), *fixed* or *compressed*.
Chararacter set	Default character set for the table.
File-version	Always 1.
Creation time	Time the data file was created
Recover time	Most recent time the file was reconstructed.
Status	Table status. One or more of *analyzed*, *changed*, *crashed*, *open*, *optimized keys* and *sorted index pages*.
Auto increment key	Index number of the table's auto-increment column. Not shown if no auto-increment column exists.
Last value	Most recently generated auto-increment value. Not shown if no auto-increment column exists.
Data records	Number of records in the table.
Deleted blocks	Number of deleted blocks that are still reserving space. Use OPTIMIZE TABLE to defragment.

Datafile parts	For dynamic tables, the number of data blocks. If the table is optimized, this will match the number of data records.
Deleted data	Number of bytes of unreclaimed deleted data, Use OPTIMIZE TABLE to reclaim the space.
Datafile pointer	Size in bytes of the data file pointer. The size of the data file pointer, in bytes.
Keyfile pointer	Size in bytes of the index file pointer.
Max datafile length	Maximum length, in bytes, that the data file could become.
Max keyfile length	Maximum length, in bytes, that the index file could become.
Recordlength	Space, in bytes, that each row takes.
table description	Description of all indexes in the table, followed by all columns
Key	Index number, starting with one. If not shown, the index is part of a multiple-column index.
Start	Where the index part starts in the row.
Len	Length of the index or index part. The length of a multiple-column index is the sum of the component lengths. Indexes of string columns will be shorter than the full column length if only a string prefix is indexed.
Index	Whether an index value is unique or not. Either *multip.* or *unique*.
Type	Data type of the index of index part.
Rec/key	Record of the number of rows per value for the index or index part. Used by the optimizer to calculate query plans. Can be updated with myisamchk-a. If not present, defaults to *30*.
Root	Root index block address.
Blocksize	Index block size, in bytes.
Field	Column number, starting with one. The first line will contain the position and number of bytes used to store NULL flags, if any (see *Nullpos* and *Nullbit*, below).
Start	Column's byte position within the table row.
Length	Column length, in bytes.
Nullpos	Byte containing the flag for NULL values. Empty if column cannot be NULL.
Nullbit	Bit containing the flag for NULL values. Empty if column cannot be NULL.
Type	Data type - see the table below for a list of possible values.
Huff tree	Only present for packed tables, contains the Huffman tree number associated with the column.
Bits	Only present for packed tables, contains the number of bits used in the Huffman tree.

Data type	Description
constant	All rows contain the same value.
no endspace	No endspace is stored.
no endspace, not_always	No endspace is stored, and endspace compression is not always performed for all values.
no endspace, no empty	No endspace is stored, no empty values are stored.
table-lookup	Column was converted to an ENUM.
zerofill(N)	Most significant *N* bytes of the value are not stored, as they are always zero.
no zeros	Zeros are not stored.
always zero	Zero values are stored with one bit.

-eiv output

The following table describes the output from the running myisamchk with the *-eiv* option:

Heading	Description
Data records	Number of records in the table.
Deleted blocks	Number of deleted blocks that are still reserving space. Use OPTIMIZE TABLE to defragment.
Key	Index number, starting with one.
Keyblocks used	Percentage of the keyblocks that are used. Percentages will be higher for optimized tables.
Packed	Percentage space saved from packing key values with a common suffix.
Max levels	Depth of the b-tree index for the key. Larger tables and longer key values result in higher values.
Records	Number of records in the table.
M.recordlength	Average row length. For fixed rows, will be the actual length of each row.
Packed	Percentage saving from stripping spaces from the end of strings.
Recordspace used	Percentage of the data file used.
Empty space	Percentage of the data file unused.
Blocks/Record	Average number of blocks per record. Values higher than one indicate fragmentation. Use OPTIMIZE TABLE to defragment.
Recordblocks	Number of used blocks. Will match the number of rows for fixed or optimized tables.
Deleteblocks	Number of deleted blocks
Recorddata	Used bytes in the data file.
Deleted data	Unused bytes in the data file.
Lost space	Total bytes lost, such as when a row is updated to a shorter length.
Linkdata	Sum of the bytes used for pointers linking disconnected blocks. Each is four to seven bytes in size.

Examples

```
myisamchk -d /var/lib/mysql/test/posts

MyISAM file:         /var/lib/mysql/test/posts
Record format:       Compressed
Character set:       utf8mb4_unicode_ci (224)
Data records:                1680  Deleted blocks:                0
Recordlength:                2758
Using only keys '0' of 5 possibly keys

table description:
Key Start Len Index   Type
1   1     8   unique  ulonglong
2   2265  80  multip. varchar prefix
    63    80          varchar
    17    5           binary
    1     8           ulonglong
3   1231  8   multip. ulonglong
4   9     8   multip. ulonglong
5   387   764 multip. ? prefix
```

```
myisamchk -dvv /var/lib/mysql/test/posts

MyISAM file:         /var/lib/mysql/test/posts
Record format:       Compressed
Character set:       utf8mb4_unicode_ci (224)
File-version:        1
Creation time:       2015-08-10 16:26:54
Recover time:        2015-08-10 16:26:54
Status:              checked,analyzed,optimized keys
Auto increment key:              1  Last value:                  1811
Checksum:               2299272165
Data records:                 1680  Deleted blocks:                 0
Datafile parts:               1680  Deleted data:                   0
Datafile pointer (bytes):        6  Keyfile pointer (bytes):        6

```

1.3.8.4 myisamlog

`myisamlog` processes and returns the contents of a MyISAM log file.

Invoke `myisamlog` like this:

```
shell> myisamlog [options] [log_file [tbl_name] ...]
shell> isamlog [options] [log_file [tbl_name] ...]
```

The default operation is update (`-u`). If a recovery is done (`-r`), all writes and possibly updates and deletes are done and errors are only counted. The default log file name is `myisam.log` for `myisamlog` and `isam.log` for `isamlog` if no `log_file` argument is given. If tables are named on the command line, only those tables are updated.

`myisamlog` supports the following options:

Option	Description
`-?` , `-I`	Display a help message and exit.
`-c N`	Execute only `N` commands.
`-f N`	Specify the maximum number of open files.
`-i`	Display extra information before exiting.
`-o offset`	Specify the starting offset.
`-p N`	Remove `N` components from path.
`-r`	Perform a recovery operation.
`-R record_pos_file record_pos`	Specify record position file and record position.

`-u`	Displays update operations.
`-v`	Verbose mode. Print more output about what the program does. This option can be given multiple times (*-vv*, *-vvv*) to produce more and more output.
`-w write_file`	Specify the write file.
`-V`	Display version information.

1.3.8.5 myisampack

Contents

`myisampack` is a tool for compressing MyISAM tables. The resulting tables are read-only, and usually about 40% to 70% smaller. It is run as follows:

```
myisampack [options] file_name [file_name2...]
```

The `file_name` is the `.MYI` index file. The extension can be omitted, although keeping it permits wildcards, such as:

```
myisampack *.MYI
```

...to compress all the files.

`myisampack` compresses each column separately, and, when the resulting data is read, only the individual rows and columns required need to be decompressed, allowing for quicker reading.

Once a table has been packed, use `myisamchk -rq` (the quick and recover options) to rebuild its indexes.

`myisampack` does not support partitioned tables.

> Do not run myisampack if the tables could be updated during the operation, and skip_external_locking has been set.

Options

The following variables can be set while passed as commandline options to `myisampack`, or set with a `[myisampack]` section in your my.cnf file.

Option	Description
`-b`, `--backup`	Make a backup of the table as `table_name.OLD`.
`--character-sets-dir=name`	Directory where character sets are.
`-#`, `--debug[=name]`	Output debug log. Often this is `'d:t:o,filename'`.
`-f`, `--force`	Force packing of table even if it gets bigger or if tempfile exists.
`-j`, `--join=name`	Join all given tables into `'new_table_name'`. All tables **must** have identical layouts.
`-?`, `--help`	Display help and exit.
`-s`, `--silent`	Only write output when an error occurs
`-T`, `--tmpdir=name`	Use temporary directory to store temporary table.
`-t`, `--test`	Don't pack table, only test packing it.
`-v`, `--verbose`	Write info about progress and packing result. Use multiple `-v` flags for more verbosity.
`-V`, `--version`	Output version information and exit.
`-w`, `--wait`	Wait and retry if table is in use.

Uncompressing

To uncompress a table compressed with `myisampack`, use the `myisamchk -u` option.

Examples

```
> myisampack /var/lib/mysql/test/posts
Compressing /var/lib/mysql/test/posts.MYD: (1680 records)
- Calculating statistics
- Compressing file
37.71%
> myisamchk -rq /var/lib/mysql/test/posts
- check record delete-chain
- recovering (with sort) MyISAM-table '/var/lib/mysql/test/posts'
Data records: 1680
- Fixing index 1
- Fixing index 2
```

1.3.8.6 myisam_ftdump

myisam_ftdump is a utility for displaying information about MyISAM FULLTEXT indexes. It will scan and dump the entire index, and can be a lengthy process.

If the server is running, make sure you run a FLUSH TABLES statement first.

Usage

```
myisam_ftdump <table_name> <index_num>
```

The table_name can be specified with or without the .MYI index extension.

The index number refers to the number of the index when the table was defined, starting at zero. For example, take the following table definition:

```
CREATE TABLE IF NOT EXISTS `employees_example` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `first_name` varchar(30) NOT NULL,
  `last_name` varchar(40) NOT NULL,
  `position` varchar(25) NOT NULL,
  `home_address` varchar(50) NOT NULL,
  `home_phone` varchar(12) NOT NULL,
  `employee_code` varchar(25) NOT NULL,
  `bio` text NOT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `employee_code` (`employee_code`),
  FULLTEXT (`bio`)
) ENGINE=MyISAM;
```

The fulltext index will be `2`. The primary key is index `0`, and the unique key index `1`.

You can use *myisam_ftdump* to generate a list of index entries in order of frequency of occurrence as follows:

```
myisam_ftdump -c mytexttable 1 | sort -r
```

Options

Option	Description
-h, --help	Display help and exit.
-?, --help	Synonym for -h.
-c, --count	Calculate per-word stats (counts and global weights).
-d, --dump	Dump index (incl. data offsets and word weights).
-l, --length	Report length distribution.

-s, --stats	Report global stats.
-v, --verbose	Be verbose.

1.3.9 dbdeployer

dbdeployer is a tool for installing multiple versions of MariaDB and/or MySQL in isolation from each other. It is primarily used for easily testing different server versions. It is written in Go, and is a replacement for MySQL Sandbox.

Visit https://www.dbdeployer.com for details on how to install and use it.

1.3.10 EXPLAIN Analyzer

> The EXPLAIN Analyzer is no longer active.

The EXPLAIN Analyzer was an online tool for analyzing and optionally sharing the output of both EXPLAIN and `EXPLAIN EXTENDED`.

Using the Analyzer

Using the analyzer is very simple.

1. In the mariadb client, run `EXPLAIN` on a query and copy the output. For example:

```
EXPLAIN SELECT * FROM t1 INNER JOIN t2 INNER JOIN t3 WHERE t1.a=t2.a AND t2.a=t3.a;
+------+-------------+-------+------+---------------+------+---------+------+------+---------
---------------------------------------------+
| id   | select_type | table | type | possible_keys | key  | key_len | ref  | rows | Extra
|
+------+-------------+-------+------+---------------+------+---------+------+------+---------
---------------------------------------------+
|    1 | SIMPLE      | t1    | ALL  | NULL          | NULL | NULL    | NULL |    3 |
|
|    1 | SIMPLE      | t2    | ALL  | NULL          | NULL | NULL    | NULL |    3 | Using
where; Using join buffer (flat, BNL join)        |
|    1 | SIMPLE      | t3    | ALL  | NULL          | NULL | NULL    | NULL |    3 | Using
where; Using join buffer (incremental, BNL join) |
+------+-------------+-------+------+---------------+------+---------+------+------+---------
---------------------------------------------+
3 rows in set (0.00 sec)
```

2. Paste the output into the `EXPLAIN` Analyzer input box and click the "Analyze Explain" button.
3. The formatted `EXPLAIN` will be shown. You can now click on various part to get more information about them.

Some Notes:

- As you can see in the example above, you don't need to chop off the query line or the command prompt.
- To save the EXPLAIN, so you can share it, or just for future reference, click the "Save Explain for analysis and sharing" button and then click the "Analyze Explain" button. You will be given a link which leads to your saved `EXPLAIN`. For example, the above explain can be viewed here: https://mariadb.org/explain_analyzer/analyze/
- Some of the elements in the formatted `EXPLAIN` are clickable. Clicking on them will show pop-up help related to that element.

Clients which integrate with the Explain Analyzer

The Analyzer has an API that client programs can use to send EXPLAINs. If you are a client application developer, see the EXPLAIN Analyzer API page for details.

The following clients have support for the EXPLAIN Analyzer built in:

HeidiSQL

HeidiSQL has a button when viewing a query that sends the query to the explain analyzer.

1.3.11 EXPLAIN Analyzer API

The online EXPLAIN Analyzer tool has an open API to allow client applications to send it EXPLAINs.

Sending EXPLAINs to the EXPLAIN Analyzer

To send an EXPLAIN to the EXPLAIN Analyzer, simply POST or GET to the following address:

```
mariadb.org/explain_analyzer/api/1/?raw_explain=EXPLAIN&client=CLIENT
```

Replace "EXPLAIN" with the output of the EXPLAIN command and "CLIENT" with the name of your client.

Client Banner

If you like, you can have a banner promoting your client appear at the bottom of the page. Once you've added support for the EXPLAIN Analyzer to your client application, just send a logo, the name of your client, and what you want the name and logo to link to to bryan AT montyprogram DOT com

1.3.12 innochecksum

Contents

innochecksum is a tool for printing checksums for InnoDB files.

Usage

```
innochecksum [options] file_name
```

Description

It reads an InnoDB tablespace file, calculates the checksum for each page, compares the calculated checksum to the stored checksum, and reports mismatches, which indicate damaged pages. It was originally developed to speed up verifying the integrity of tablespace files after power outages but can also be used after file copies. Because checksum mismatches will cause InnoDB to deliberately shut down a running server, it can be preferable to use innochecksum rather than waiting for a server in production usage to encounter the damaged pages.

Multiple filenames can be specified by a wildcard on non-Windows systems only.

innochecksum works with compressed pages, and also includes options to analyze leaf pages to estimate how fragmented an index is and how much benefit can be gained from defragmentation.

> innochecksum cannot be used on tablespace files that the server already has open. For such files, you should use CHECK TABLE to check tables within the tablespace. If checksum mismatches are found, you would normally restore the tablespace from backup or start the server and attempt to use mariadb-dump to make a backup of the tables within the tablespace.

Options

innochecksum supports the following options. For options that refer to page numbers, the numbers are zero-based.

Option	Description
-a, --allow-mismatches=#	Maximum checksum mismatch allowed before innochecksum terminates. Defaults to 0, which terminates on the first mismatch.
-c, --count	Print a count of the number of pages in the file.

-e num, --end-page=#	End at this page number (0-based).
-?, --help	Displays help and exits.
-I, --info	Synonym for --help.
-f, --leaf	Examine leaf index pages. Until MariaDB 10.2.4, the short code was `-l`, but this was changed to avoid confusion with the `--log` option.
-l fn, --log=fn	Log output to the specified filename `fn`.
-m num, --merge=#	Leaf page count if merge given number of consecutive pages.
-n, --no-check	Ignore the checksum verification. Until MariaDB 10.6, must be used with the `--write` option.
-p num, --page=#	Check only this page number (0-based).
-D, --page-type-dump=name	Dump the page type info for each page in a tablespace.
-S, --page-type-summary	Display a count of each page type in a tablespace
-i, --per-page-details	Print out per-page detail information.
-u, --skip-corrupt	Skip corrupt pages.
-s num, --start-page=#	Start at this page number (0-based).
-C, --strict-check=name	Specify the strict checksum algorithm. One of: `crc32`, `innodb`, `none`. If not specified, validates against `innodb`, `crc32` and `none`. `full_crc32` is not supported. See also innodb_checksum_algorithm. Removed in MariaDB 10.6.0
-v, --verbose	Verbose mode; print a progress indicator every five seconds.
-V, --version	Displays version information and exits.
-w, --write=name	Rewrite the checksum algorithm. One of crc32, innodb, none. An exclusive lock is obtained during use. Use in conjunction with the `-no-check` option to rewrite an invalid checksum. Removed in MariaDB 10.6.0

Examples

Rewriting a crc32 checksum to replace an invalid checksum:

```
innochecksum --no-check --write crc32 tablename.ibd
```

A count of each page type:

```
innochecksum --page-type-summary data/mysql/gtid_slave_pos.ibd

File::data/mysql/gtid_slave_pos.ibd
================PAGE TYPE SUMMARY==============
#PAGE_COUNT PAGE_TYPE
===============================================
       1 Index page
       0 Undo log page
       1 Inode page
       0 Insert buffer free list page
       2 Freshly allocated page
       1 Insert buffer bitmap
       0 System page
       0 Transaction system page
       1 File Space Header
       0 Extent descriptor page
       0 BLOB page
       0 Compressed BLOB page
       0 Page compressed page
       0 Page compressed encrypted page
       0 Other type of page

===============================================
Additional information:
Undo page type: 0 insert, 0 update, 0 other
Undo page state: 0 active, 0 cached, 0 to_free, 0 to_purge, 0 prepared, 0 other

index_id page_data_bytes_histgram(empty,...,oversized)
24  1 0 0 0 0 0 0 0 0 0 0 0
```

1.3.13 msql2mysql

Description

Initially, the MySQL C API was developed to be very similar to that of the mSQL database system.

Because of this, mSQL programs often can be converted relatively easily for use with MySQL by changing the names of their C API functions.

The `msql2mysql` utility performs the conversion of mSQL C API function calls to their MySQL equivalents.

Warning: `msql2mysql` converts the input file in place, so make a copy of the original before converting it.

Example

```
shell> cp client-prog.c client-prog.c.orig
shell> msql2mysql client-prog.c
client-prog.c converted
```

After conversion, examine `client-prog.c` and make any necessary post-conversion revisions.

`msql2mysql` uses the `replace` utility to make the function name substitutions.

1.3.14 my_print_defaults

`my_print_defaults` displays the options from option groups of option files. It is useful to see which options a particular tool will use.

Output is one option per line, displayed in the form in which they would be specified on the command line.

Usage

```
my_print_defaults [OPTIONS] [groups]
```

Options

Option	Description
`-c , --config-file=name`	Deprecated, please use --defaults-file instead. Name of config file to read; if no extension is given, default extension (e.g., .ini or .cnf) will be added.
`-# , --debug[=#]`	In debug versions, write a debugging log. A typical debug_options string is `d:t:o,file_name` . The default is `d:t:o,/tmp/my_print_defaults.trace` .
`-c, --defaults-file=name`	Like --config-file, except: if first option, then read this file only, do not read global or per-user config files; should be the first option. Removed in MariaDB 10.8.0.
`-e , --defaults-extra-file=name`	Read this file after the global config file and before the config file in the users home directory; should be the first option. Removed in MariaDB 10.8.0.
`-g , --defaults-group-suffix=name`	In addition to the given groups, read also groups with this suffix. Removed in MariaDB 10.8.0.
`-e , --extra-file=name`	Deprecated. Synonym for --defaults-extra-file.
`--mysqld`	Read the same set of groups that the mysqld binary does.
`-n , --no-defaults`	Return an empty string (useful for scripts).
`? , --help`	Display this help message and exit.
`-v , --verbose`	Increase the output level.
`-V , --version`	Output version information and exit.

Examples

```
my_print_defaults --defaults-file=example.cnf client client-server mysql
```

mariadb-check reads from the [mariadb-check] and [client] sections, so the following would display the mariadb-check options.

```
my_print_defaults mariadb-check client
```

1.3.15 mysqladmin

mysqladmin is an administration program for the mysqld daemon.

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-admin` is a symlink to `mysqladmin` .

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadb-admin` is the name of the script, with `mysqladmin` a symlink .

See mariadb-admin for details.

1.3.16 mariadb-binlog

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-binlog` is a symlink to `mysqlbinlog` .

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadb-binlog` is the name of the tool, with `mysqlbinlog` a symlink .

`mariadb-binlog` is a utility included with MariaDB for processing binary log and relay log files.

The MariaDB server's binary log is a set of files containing "events" which represent modifications to the contents of a MariaDB database. These events are written in a binary (i.e. non-human-readable) format. The mariadb-binlog utility is used to view these events in plain text.

Using mariadb-binlog

Viewing the binary log with mariadb-binlog.

mariadb-binlog Options

Options supported by mariadb-binlog.

Annotate_rows_log_event

Annotate_rows events accompany row events and describe the query which caused the row event.

mysqlbinlog

Symlink or old name for mariadb-binlog.

There are 3 related questions.

1.3.16.1 Using mariadb-binlog

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-binlog` is a symlink to `mysqlbinlog`.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadb-binlog` is the name of the tool, with `mysqlbinlog` a symlink.

The MariaDB server's binary log is a set of files containing "events" which represent modifications to the contents of a MariaDB database. These events are written in a binary (i.e. non-human-readable) format. The *mariadb-binlog* utility is used to view these events in plain text.

Run mariadb-binlog from a command-line like this:

```
shell> mariadb-binlog [options] log_file ...
```

See mariadb-binlog Options for details on the available options.

As an example, here is how you could display the contents of a binary log file named "mariadb-bin.000152":

```
shell> mariadb-binlog mariadb-bin.000152
```

The logging format is determined by the value of the binlog_format system variable. If you are using statement-based logging, the output includes the SQL statement, the ID of the server the statement was executed on, a timestamp, and how much time the statement took to execute. If you are using row-based logging the output of an event will not include an SQL statement but will instead output how individual rows were changed.

The output from mariadb-binlog can be used as input to the mariadb client to redo the statements contained in a binary log. This is useful for recovering after a server crash. Here is an example:

```
shell> mariadb-binlog binlog-filenames | mysql -u root -p
```

If you would like to view and possibly edit the file before applying it to your database, use the '-r' flag to redirect the output to a file:

```
shell> mariadb-binlog -r filename binlog-filenames
```

You can then open the file and view it and delete any statements you don't want executed (such as an accidental DROP DATABASE). Once you are satisfied with the contents you can execute it with:

```
shell> mariadb -u root -p < filename
```

Be careful to process multiple log files in a single connection, especially if one or more of them have any `CREATE TEMPORARY TABLE ...` statements. Temporary tables are dropped when the mariadb client terminates, so if you are processing multiple log files one at a time (i.e. multiple connections) and one log file creates a temporary table and then a subsequent log file refers to the table you will get an 'unknown table' error.

To execute multiple logfiles using a single connection, list them all on the mariadb-binlog command line:

```
shell> mariadb-binlog mariadb-bin.000001 mariadb-bin.000002 | mariadb -u root -p
```

If you need to manually edit the binlogs before executing them, combine them all into a single file before processing. Here is an example:

```
shell> mariadb-binlog mariadb-bin.000001 > /tmp/mariadb-bin.sql
shell> mariadb-binlog mariadb-bin.000002 >> /tmp/mariadb-bin.sql
shell> # make any edits
shell> mysql -u root -p -e "source /tmp/mariadb-bin.sql"
```

1.3.16.2 mariadb-binlog Options

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-binlog` is a symlink to `mysqlbinlog`.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadb-binlog` is the name of the tool, with `mysqlbinlog` a symlink.

Contents

mariadb-binlog is a utility included with MariaDB for processing binary log and relay log files.

Options

The following options are supported by mariadb-binlog. They can be specified on the command line or in option files:

Option	default value	Description	Introduced
`-?`, `--help`		Display a help statement.	
`--base64-output=name` (>= MariaDB 10.6.1, MariaDB 10.5.11)	`auto`	Determine when the output statements should be base64-encoded BINLOG statements. Options (case-insensitive) include `auto`, `unspec`, `never` and `decode-rows`. `never` neither prints base64 encodings nor verbose event data, and will exit on error if a row-based event is found. This option is useful for binlogs that are entirely statement based. `decode-rows` decodes row events into commented SQL statements if the `--verbose` option is also given. It can enhance the debugging experience with large binary log files, as the raw data will be omitted. Unlike *never*, *mariadb-binlog* will not exit with an error if a row event is found. `auto` (synonymous with *unspec*) outputs base64 encoded entries for row-based and format description events; it should be used when ROW-format events are processed for re-executing on the MariaDB server. This behavior is presumed, such that `auto` is the default value when no option specification is provided. The other option values are intended only for debugging or testing purposes because they may produce output that does not include all events in executable form.	
`--base64-output[=name]` (<= MariaDB 10.6.0, MariaDB 10.5.10)	*(No default Value)*	Determine when the output statements should be base64-encoded BINLOG statements. Options (case-insensitive) include `auto`, `unspec`, `always` (deprecated), `never` and `decode-rows`. `never` disables it and works only for binlogs without row-based events; `decode-rows` decodes row events into commented SQL statements if the `--verbose` option is also given; Unlike *never*, *mariadb-binlog* does not exit with an error if a row event is found `auto` or `unspec`, the default, prints base64 only when necessary (i.e., for row-based events and format description events), and is the only safe behavior if you intend to use the output of mariadb-binlog to re-execute binary log file contents. The other option values are intended only for debugging or testing purposes because they may produce output that does not include all events in executable form.; `always` prints base64 whenever possible, and is for debugging only and should not be used in a production system. If this option is not given, the default is `auto`; if it is given with no argument, `always` is used.	
`--binlog-row-event-max-size=val`	4294967040 (4GB)	The maximum size in bytes of a row-based binary log event. Should be a multiple of 256. Minimum 256, maximum 18446744073709547520.	

`--character-sets-dir=name`	*(No default value)*	Directory where the character sets are.	
`-d , --database=name`	*(No default value)*	Output entries from the binary log (local log only) that occur while *name* has been selected as the default database by USE. Only one database can be specified. The effects depend on whether the statement-based or row-based logging format is in use. For statement-based logging, the server will only log statements where the default database is *name*. The default database is set with the USE statement. For row-based logging, the server will log any updates to any tables in the named database, irrespective of the current database. Ignored in `--raw` mode.	
`-# [options] , --debug[=options]`	`d:t:o,/tmp/mariadb-binlog.trace`	In a debug build, write a debugging log. A typical debug options string is `d:t:o,file_name` .	
`--debug-check`	FALSE	Print some debug info at exit..	
`--debug-info`	FALSE	Print some debug info and memory and CPU info at exit.	
`--default-auth=name`		Default authentication client-side plugin to use.	
`--defaults-extra-file=name`		Read the file *name*, which can be the full path, or the path relative to the current directory, after the global files are read.	
`--defaults-file=name`		Only read default options from the given file name , which can be the full path, or the path relative to the current directory.	
`--defaults-group-suffix=str`		Also read groups with a suffix of *str*. For example, since *mariadb-binlog* normally reads the [client] and [mysqlbinlog] groups, `--defaults-group-suffix=x` would cause it to also read the groups [mysqlbinlog_x] and [client_x].	
`-D , --disable-log-bin`	FALSE	Disable binary log. This is useful, if you enabled `--to-last-log` and are sending the output to the same MariaDB server. This way you could avoid an endless loop. You would also like to use it when restoring after a crash to avoid duplication of the statements you already have. NOTE: you will need a SUPER privilege to use this option.	
`--do-domain-ids=name`	*(No default value)*	A list of positive integers, separated by commas, that form a whitelist of domain ids. Any log event with a GTID that originates from a domain id specified in this list is displayed. Cannot be used with `--ignore-domain-ids` . When used with `--ignore-server-ids` or `--do-server-ids` , the result is the intersection between the two datasets	MariaDB 10.9.0
`--do-server-ids=name`	*(No default value)*	A list of positive integers, separated by commas, that form a whitelist of server ids. Any log event originating from a server id specified in this list is displayed. Cannot be used with `--ignore-server-ids` . When used with `--ignore-domain-ids` or `do-domain-ids` , the result is the intersection between the two datasets. Alias for `--server-id` .	MariaDB 10.9.0
`-B , --flashback`	FALSE	Support flashback mode.	MariaDB 10.2.4
`-F , --force-if-open`	TRUE	Force if binlog was not closed properly. Defaults to ON; use `--skip-force-if-open` to disable.	
`-f , --force-read`	FALSE	If *mariadb-binlog* reads a binary log event that it does not recognize, it prints a warning, ignores the event, and continues. Without this option, mariadb-binlog stops if it reads such an event.	
`--gtid-strict-mode`	TRUE	Process binlog according to gtid-strict-mode specification. The start, stop positions are verified to satisfy start < stop comparison condition. Sequence numbers of any gtid domain must comprise monotically growing sequence, Defaults to on; use `--skip-gtid-strict-mode` to disable.	MariaDB 10.8.0
`-H , --hexdump`	FALSE	Augment output with hexadecimal and ASCII event dump.	
`-h , --host=name`	*(No default value)*	Get the binlog from the MariaDB server on the given host.	
`--ignore-domain-ids=name`	*(No default value)*	A list of positive integers, separated by commas, that form a blacklist of domain ids. Any log event with a GTID that originates from a domain id specified in this list is hidden. Cannot be used with `--do-domain-ids` . When used with `--ignore-server-ids` or `--do-server-ids` , the result is the intersection between the two datasets.	MariaDB 10.9.0
`--ignore-server-ids=name`	*(No default value)*	A list of positive integers, separated by commas, that form a blacklist of server ids. Any log event originating from a server id specified in this list is hidden. Cannot be used with `--do-server-ids` . When used with `--ignore-domain-ids` or `--do-domain-ids` , the result is the intersection between the two datasets.	MariaDB 10.9.0
`-l path , --local-load=path`	*(No default value)*	Prepare local temporary files for LOAD DATA INFILE in the specified directory. The temporary files are not automatically removed.	
`--no-defaults`		Don't read default options from any option file	
`-o value , --offset=value`	0	Skip the first *value* entries in the log.	
`--open_files_limit=#`	64	Reserve file descriptors for usage by *mariadb-binlog*.	
`-p[passwd] , --password[=passwd]`	*(No default value)*	Password to connect to the remote server. The password can be omitted allow it be entered from the prompt, or an option file can be used to avoid the security risk of passing a password on the commandline.	
`--plugin-dir=dir_name ,`		Directory for client-side plugins.	
`-P num , --port=num`	0	Port number to use for connection or 0 for default to, in order of preference, my.cnf, $MYSQL_TCP_PORT, /etc/services, built-in default (3306).	

`--position=#`	4	Removed in MariaDB 5.5. Use `--start-position` instead.	
`--print-defaults`		Print the program argument list from all option files and exit.	
`--print-row-count`	TRUE	Print row counts for each row events. (Defaults to on; use `--skip-print-row-count` to disable.)	MariaDB 10.3
`--print-row-event-positions`	TRUE	Print row event positions. Defaults to on; use `--skip-print-row-event-positions` to disable.)	MariaDB 10.3
`print-table-metadata`		Print metadata stored in Table_map_log_event.	MariaDB 10.5.0
`--protocol=name`	*(No default value)*	The protocol of the connection (tcp,socket,pipe,memory).	
`--raw`		Requires -R. Output raw binlog data instead of SQL statements. Output files named after server logs.	MariaDB 10.2.0
`-R`, `--read-from-remote-server`	FALSE	Read binary logs from a remote MariaDB server rather than reading a local log file. Any connection parameter options are ignored unless this option is given as well. These options are `--host`, `--password`, `--port`, `--protocol`, `--socket`, and `--user`. This option requires that the remote server be running. It works only for binary log files on the remote server, not relay log files.	
`-r name`, `--result-file=name`	*(No default value)*	Direct output to a given file. With --raw this is a prefix for the file names.	
`--rewrite-db=name`	*(No default value)*	Updates to a database with a different name than the original. Example: `rewrite-db='from->to'` For events that are binlogged as statements, rewriting the database constitutes changing a statement's default database from `db1` to `db2`. There is no statement analysis or rewrite of any kind, that is, if one specifies "`db1.tbl`" in the statement explicitly, that occurrence won't be changed to "`db2.tbl`". Row-based events are rewritten correctly to use the new database name. Filtering (e.g. with `--database=name`) happens *before* the database rewrites have been performed. If you use this option on the command line and "`>`" has a special meaning to your command interpreter, quote the value (e.g. `--rewrite-db="oldname->newname"`).	
`--server-id=idnum`	0	Extract only binlog entries created by the server having the given id. From MariaDB 10.9.0, alias for --do-server-ids.	
`--set-charset=character_set`	*(No default value)*	Add '`SET NAMES character_set`' to the output to specify the character set to be used for processing log files.	
`--shared-memory-base-name=name`	MYSQL	Shared-memory name to use for Windows connections using shared memory to a local server (started with the `--shared-memory` option). Case-sensitive.	
`-s`, `--short-form`	FALSE	Just show regular queries: no extra info and no row-based events. This is for testing only, and should not be used in production systems. If you want to suppress base64-output, consider using `--base64-output=never` instead.	
`--skip-annotate-row-events`		Skip all Annotate_rows events in the mariadb-binlog output (by default, mariadb-binlog prints Annotate_rows events, if the binary log does contain them).	
`-S`, `--socket=name`	*(No default value)*	For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.	
`--ssl`	`FALSE`	Enables TLS. TLS is also enabled even without setting this option when certain other TLS options are set. Starting with MariaDB 10.2, the `--ssl` option will not enable verifying the server certificate by default. In order to verify the server certificate, the user must specify the `--ssl-verify-server-cert` option.	
`--ssl-ca=name`		Defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option implies the `--ssl` option.	
`--ssl-capath=name`		Defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the `openssl rehash` command. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option is only supported if the client was built with OpenSSL or yaSSL. If the client was built with GnuTLS or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms. This option implies the `--ssl` option.	
`--ssl-cert=name`		Defines a path to the X509 certificate file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.	
`--ssl-cipher=name`		List of permitted ciphers or cipher suites to use for TLS. This option implies the `--ssl` option.	

`--ssl-crl=name`		Defines a path to a PEM file that should contain one or more revoked X509 certificates to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL or Schannel. If the client was built with yaSSL or GnuTLS, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.	
`--ssl-crlpath=name`		Defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the `openssl rehash` command. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL. If the client was built with yaSSL, GnuTLS, or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.	
`--ssl-key=name`		Defines a path to a private key file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.	
`--ssl-verify-server-cert`	`FALSE`	Enables server certificate verification. This option is disabled by default.	
`--start-datetime=datetime`	*(No default value)*	Start reading the binlog at first event having a datetime equal to or later than the argument; the argument must be a date and time in the local time zone, in any format accepted by the MariaDB server for DATETIME and TIMESTAMP types, for example: 2014-12-25 11:25:56 (you should probably use quotes for your shell to set it properly). This option is useful for point-in-time recovery.	
`-j pos`, `--start-position=pos`	4	Start reading the binlog at this position. Type can either be a positive integer or, from MariaDB 10.8.0, a GTID list. When using a positive integer, the value only applies to the first binlog passed on the command line. In GTID mode, multiple GTIDs can be passed as a comma separated list, where each must have a unique domain id. The list represents the gtid binlog state that the client (another "replica" server) is aware of. Therefore, each GTID is exclusive; only events after a given sequence number will be printed to allow users to receive events after their current state.	
`--stop-datetime=name`	*(No default value)*	Stop reading the binlog at first event having a datetime equal or posterior to the argument; the argument must be a date and time in the local time zone, in any format accepted by the MariaDB server for DATETIME and TIMESTAMP types, for example: 2014-12-25 11:25:56 (you should probably use quotes for your shell to set it properly). Ignored in `--raw` mode.	
`--stop-never`		Wait for more data from the server instead of stopping at the end of the last log. Implies `--to-last-log`.	MariaDB 10.2.0
`--stop-never-slave-server-id`		The slave server_id used for `--read-from-remote-server --stop-never`.	MariaDB 10.2.0
`--stop-position=pos`	18446744073709551615	Stop reading the binlog at this position. Type can either be a positive integer or, from MariaDB 10.8, a GTID list. When using a positive integer, the value only applies to the last binlog passed on the command line. In GTID mode, multiple GTIDs can be passed as a comma separated list, where each must have a unique domain id. Each GTID is inclusive; only events up to the given sequence numbers are printed. Ignored in `--raw` mode.	
`-T`, `--table`		List entries for just this table (affects only row events).	MariaDB 10.2.4
`--tls-version=name`	TLSv1.1,TLSv1.2,TLSv1.3	This option accepts a comma-separated list of TLS protocol versions. A TLS protocol version will only be enabled if it is present in this list. All other TLS protocol versions will not be permitted. See Secure Connections Overview: TLS Protocol Versions for more information.	MariaDB 10.4.6
`-t`, `--to-last-log`	FALSE	Requires `-R` or `--read-from-remote-server`. Will not stop at the end of the requested binlog but rather continue printing until the end of the last binlog of the MariaDB server. If you send the output to the same MariaDB server, that may lead to an endless loop.	
`-u`, `--user=username`	*(No default value)*	Connect to the remote server as username.	
`-v`, `--verbose`		Reconstruct SQL statements out of row events. -v -v adds comments on column data types	
`-V`, `--version`		Print version and exit.	
`--verify-binlog-checksum`		Verify binlog event checksums when reading a binlog file.	

Option Files

In addition to reading options from the command-line, `mariadb-binlog` can also read options from option files. If an unknown option is provided to `mariadb-binlog` in an option file, then it is ignored.

The following options relate to how MariaDB command-line tools handles option files. They must be given as the first argument on the command-line:

Option	Description

`--print-defaults`	Print the program argument list and exit.
`--no-defaults`	Don't read default options from any option file.
`--defaults-file=#`	Only read default options from the given file #.
`--defaults-extra-file=#`	Read this file after the global files are read.
`--defaults-group-suffix=#`	In addition to the default option groups, also read option groups with this suffix.

In MariaDB 10.2 and later, `mariadb-binlog` is linked with MariaDB Connector/C. However, MariaDB Connector/C does not yet handle the parsing of option files for this client. That is still performed by the server option file parsing code. See MDEV-19035 for more information.

Option Groups

`mariadb-binlog` reads options from the following option groups from option files:

Group	Description
`[mysqlbinlog]`	Options read by `mariadb-binlog`, which includes both MariaDB Server and MySQL Server.
`[mariadb-binlog]`	Options read by `mariadb-binlog`. Available starting with MariaDB 10.4.6.
`[client]`	Options read by all MariaDB and MySQL client programs, which includes both MariaDB and MySQL clients. For example, `mysqldump`.
`[client-server]`	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
`[client-mariadb]`	Options read by all MariaDB client programs.

`mariadb-binlog` is linked with MariaDB Connector/C. However, MariaDB Connector/C does not yet handle the parsing of option files for this client. That is still performed by the server option file parsing code. See MDEV-19035 for more information.

1.3.16.3 Annotate_rows_log_event

The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Contents

`Annotate_rows` events accompany `row` events and describe the query which caused the row event.

Until MariaDB 10.2.4, the binlog event type `Annotate_rows_log_event` was off by default (so as not to change the binary log format and to allow one to replicate MariaDB 5.3 to MySQL/MariaDB 5.1). You can enable this with `--binlog-annotate-row-events`.

In the binary log, each `Annotate_rows` event precedes the corresponding Table map event or the first of the Table map events, if there are more than one (e.g. in a case of multi-delete or insert delayed).

`Annotate_rows` Example

```
master> DROP DATABASE IF EXISTS test;
master> CREATE DATABASE test;
master> USE test;
```

```
master> CREATE TABLE t1(a int);
master> INSERT INTO t1 VALUES (1), (2), (3);
master> CREATE TABLE t2(a int);
master> INSERT INTO t2 VALUES (1), (2), (3);
master> CREATE TABLE t3(a int);
master> INSERT DELAYED INTO t3 VALUES (1), (2), (3);
master> DELETE t1, t2 FROM t1 INNER JOIN t2 INNER JOIN t3
    ->        WHERE t1.a=t2.a AND t2.a=t3.a;

Options Related to Annotate_rows_log_event

The following options have been added to control the behavior of `Annotate_rows_log_event`:

Master Option: `--binlog-annotate-row-events`

This option tells the master to write `Annotate_rows` events to the binary log. See binlog_annotate_row_events for a detailed description of the variable.

Session values allow you to annotate only some selected statements:

```
...
SET SESSION binlog_annotate_row_events=ON;
... statements to be annotated ...
SET SESSION binlog_annotate_row_events=OFF;
... statements not to be annotated ...
```

Slave Option: `--replicate-annotate-row-events`

This option tells the slave to reproduce `Annotate_row` events received from the master in its own binary log (sensible only when used in tandem with the `log-slave-updates` option).

See replicate_annotate_row_events for a detailed description of the variable.

mariadb-binlog Option: `--skip-annotate-row-events`

This option tells mariadb-binlog to skip all `Annotate_row` events in its output (by default, mariadb-binlog prints `Annotate_row` events, if the binary log contains them).

Example of mariadb-binlog Output

```
...> mariadb-binlog.exe -vv -R --user=root --port=3306 --host=localhost master-bin.000001

1.3.16.4 mysqlbinlog

MariaDB starting with 10.4.6

From MariaDB 10.4.6, mariadb-binlog is a symlink to `mysqlbinlog`.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, mariadb-binlog is the name of the tool, with `mysqlbinlog` a symlink.

See mariadb-binlog for details.

1.3.17 mariadb-stress-test

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-stress-test` is a symlink to `mysql-stress-test`, the script for assisting with adding users or databases or changing passwords in MariaDB.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mysql-stress-test` is the symlink, and `mariadb-stress-test` the binary name.

Contents

mariadb-stress-test.pl is a Perl script that performs stress-testing of the MariaDB server. It requires a version of Perl that has been built with threads support.

Syntax

```
mariadb-stress-test.pl [options]
```

Options

Option	Description
`--help`	Display a help message and exit.
`--abort-on-error=N`	Causes the program to abort if an error with severity less than or equal to N was encountered. Set to 1 to abort on any error.
`--check-tests-file`	Periodically check the file that lists the tests to be run. If it has been modified, reread the file. This can be useful if you update the list of tests to be run during a stress test.
`--cleanup`	Force cleanup of the working directory.
`--log-error-details`	Log error details in the global error log file.
`--loop-count=N`	In sequential test mode, the number of loops to execute before exiting.
`--mysqltest=path`	The path name to the mysqltest program.
`--server-database=db_name`	The database to use for the tests. The default is test.
`--server-host=host_name`	he host name of the local host to use for making a TCP/IP connection to the local server. By default, the connection is made to localhost using a Unix socket file.
`--server-logs-dir=path`	This option is required. path is the directory where all client session logs will be stored. Usually this is the shared directory that is associated with the server used for testing.
`--server-password=password`	The password to use when connecting to the server.
`--server-port=port_num`	The TCP/IP port number to use for connecting to the server. The default is 3306.
`--server-socket=file_name`	For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use. The default is `/tmp/mysql.sock`.
`--server-user=user_name`	The MariaDB user name to use when connecting to the server. The default is root.
`--sleep-time=N`	The delay in seconds between test executions.
`--stress-basedir=path`	This option is required and specified the path is the working directory for the test run. It is used as the temporary location for result tracking during testing.
`--stress-datadir=path`	The directory of data files to be used during testing. The default location is the data directory under the location given by the `--stress-suite-basedir` option.
`--stress-init-file[=path]`	*file_name* is the location of the file that contains the list of tests to be run once to initialize the database for the testing. If missing, the default file is `stress_init.txt` in the test suite directory.

`--stress-mode=mode`	This option indicates the test order in stress-test mode. The mode value is either `random` to select tests in random order or `seq` to run tests in each thread in the order specified in the test list file. The default mode is `random`.
`--stress-suite-basedir=path`	This option is required and specifies the directory that has the *t* and *r* subdirectories containing the test case and result files. This directory is also the default location of the `stress-test.txt` file that contains the list of tests. (A different location can be specified with the `--stress-tests-file` option.)
`--stress-tests-file[=file_name]`	Use this option to run the stress tests. *file_name* is the location of the file that contains the list of tests. If omitted, the default file is `stress-test.txt` in the stress suite directory. (See `--stress-suite-basedir`.)
`--suite=suite_name`	Run the named test suite. The default name is `main` (the regular test suite located in the `mysql-test` directory).
`--test-count=N`	The number of tests to execute before exiting.
`--test-duration=N`	The duration of stress testing in seconds.
`--threads=N`	The number of threads. The default is 1.
`--verbose`	Verbose mode. Print more information about what the program does

1.3.18 mariadb-test

MariaDB uses **mariadb-test** to test functionality. It is an all-in-one test framework, doing unit, regression, and conformance testing. The framework was inherited from MySQL, but is greatly enhanced, optimized, and extended in MariaDB.

mariadb-test Overview

Overview of mariadb-test.

1.3.18.1 mariadb-test Overview

Contents

The Basics

At its core, mariadb-test is very simple. The client program `mariadb-test` executes a *test file* and compares the produced output with the *result file*. If the files match, the test is passed; otherwise the test has failed. This approach can be used to test any SQL statement, as well as other executables (with the `exec` command).

The complete process of testing is governed and monitored by the *mariadb-test-run.pl* driver script, or *mtr* for short (for convenience, `mtr` is created as a symbolic link to `mariadb-test-run.pl`). The mtr script is responsible for preparing the test environment, creating a list of all tests to run, running them, and producing the report at the end. It can run many tests in parallel, execute tests in an order which minimizes server restarts (as they are slow), run tests in a debugger or under valgrind or strace, and so on.

Test files are located in *suites*. A *suite* is a directory which contains test files, result files, and optional configuration files. The mtr looks for suites in the `mariadb-test/suite` directory, and in the `mariadb-test` subdirectories of plugins and storage engine directories. For example, the following are all valid suite paths:

```
mariadb-test/suite/rpl
```

```
mariadb-test/suite/handler
```

```
storage/example/mariadb-test/demo
```

```
plugin/auth_pam/mariadb-test/pam
```

In almost all cases, the suite directory name is the suite name. A notable historical exception is the *main* suite, which is located directly in the `mariadb-test` directory.

Test files have a `.test` extension and can be placed directly in the suite directory (for example, `mariadb-test/suite/handler/interface.test`) or in the `t` subdirectory (e.g. `mariadb-test/suite/rpl/t/rpl_alter.test` or `mariadb-test/t/grant.test`). Similarly, result files have the `.result` extension and can be placed either in the suite directory or in the `r` subdirectory.

A test file can include other files (with the `source` command). These included files can have any name and may be placed anywhere, but customarily they have a `.inc` extension and are located either in the suite directory or in the `inc` or `include` subdirectories (for example, `mariadb-test/suite/handler/init.inc` or `mariadb-test/include/start_slave.inc`).

Other files which affect testing, while not being tests themselves, are:

- `disabled.def`
- `suite.opt`
- other `*.opt` files
- `my.cnf`
- other `*.cnf` files
- `combinations`
- other `*.combinations` files
- `suite.pm`
- `*.sh` files
- `*.require` files
- `*.rdiff` files
- `valgrind.supp`

See Auxiliary files for details on these.

Overlays

In addition to regular suite directories, mtr supports *overlays*. An *overlay* is a directory with the same name as an existing suite, but which is located in a storage engine or plugin directory. For example, `storage/myisam/mariadb-test/rpl` could be a *myisam* overlay of the *rpl* suite in `mariadb-test/suite/rpl`. And `plugin/daemon_example/mariadb-test/demo` could be a *daemon_example* overlay of the *demo* suite in `storage/example/mariadb-test/demo`. As a special exception, an overlay of the main suite, should be called `main`, as in `storage/pbxt/mariadb-test/main`.

An overlay is like a second transparent layer in a graphics editor. It can obscure, extend, or modify the background image. Also, one may notice that an overlay is very close to a *UnionFS*, but implemented in perl inside mtr.

An overlay can replace almost any file in the overlaid suite, or add new files. For example, if some overlay of the main suite contains a `include/have_innodb.inc` file, then all tests that include it will see and use the overlaid version. Or, an overlay can create a `t/create.opt` file (even though the main suite does not have such a file), and `create.test` will be executed with the specified additional options.

But adding an overlay never affects how the original suite is executed. That is, mtr always executes the original suite as if no overlay was present. And then, additionally, it executes a combined "union" of the overlay and the original suite. When doing that, mtr takes care to avoid re-executing tests that are not changed in the overlay. For example, creating `t/create.opt` in the overlay of the main suite will only cause `create.test` to be executed in the overlay. But creating `suite.opt` affects all tests — and it will cause all tests to be re-executed with the new options.

Combinations

In certain cases it makes sense to run a specific test or a group of tests several times with different server settings. This can be done using so-called *combinations*. Combinations are groups of settings that are used alternatively. A combinations file defines these alternatives using `my.cnf` syntax, for example

```
[row]
binlog-format=row

[stmt]
binlog-format=statement

[mix]
binlog-format=mixed
```

And all tests where this combinations file applies will be run three times: once for the combination called "row", and `--binlog-format=row` on the server command line, once for the "stmt" combination, and once for the "mix" combination.

More than one combinations file may be applicable to a given test file. In this case, mtr will run the test for all possible combinations of the given combinations. A test that uses replication (three combinations as above) and innodb (two combinations - innodb and xtradb), will be run six times.

Sample Output

Typical mtr output looks like this

```
==========================================================================
TEST                                   WORKER RESULT   TIME (ms) or COMMENT
--------------------------------------------------------------------------
rpl.rpl_row_find_row_debug                [ skipped ]  Requires debug build
main-pbxt.connect                         [ skipped ]  No PBXT engine
main-pbxt.mysqlbinlog_row                 [ disabled ]  test expects a non-transactional engine
rpl.rpl_savepoint 'mix,xtradb'            w2 [ pass ]    238
rpl.rpl_stm_innodb 'innodb_plugin,row'    w1 [ skipped ]  Neither MIXED nor STATEMENT binlog form
binlog.binlog_sf 'stmt'                   w2 [ pass ]      7
unit.dbug                                 w2 [ pass ]      1
maria.small_blocksize                     w1 [ pass ]     23
sys_vars.autocommit_func3 'innodb_plugin' w1 [ pass ]      5
sys_vars.autocommit_func3 'xtradb'        w1 [ pass ]      6
main.ipv6                                 w1 [ pass ]    131
...
```

Every test is printed as "suitename.testname", and a suite name may include an overlay name (like in `main-pbxt`). After the test name, mtr prints combinations that were applied to this test, if any.

A similar syntax can be used on the mtr command line to specify what tests to run:

`$ ./mtr innodb`	search for *innodb* test in every suite from the default list, and run all that was found.
`$ ./mtr main.innodb`	run the *innodb* test from the *main* suite
`$ ./mtr main-pbxt.innodb`	run the *innodb* test from the *pbxt* overlay of the *main* suite
`$ ./mtr main-.innodb`	run the *innodb* test from the *main* suite and all its overlays.
`$ ./mtr main.innodb,xtradb`	run the *innodb* test from the *main* suite, only in the *xtradb* combination

Plugin Support

The mtr driver has special support for MariaDB plugins.

First, on startup it copies or symlinks all dynamically-built plugins into `var/plugins`. This allows one to have many plugins loaded at the same time. For example, one can load Federated and InnoDB engines together. Also, mtr creates environment variables for every plugin with the corresponding plugin name. For example, if the InnoDB engine was built, `$HA_INNODB_SO` will be set to `ha_innodb.so` (or `ha_innodb.dll` on Windows). And the test can safely use the corresponding environment variable on all platforms to refer to a plugin file; it will always have the correct platform-dependent extension.

Second, when combining server command-line options (which may come from many different sources) into one long list before starting `mariadbd`, mtr treats `--plugin-load` specially. Normal server semantics is to use the latest value of any particular option on the command line. If one starts the server with, for example, `--port=2000 --port=3000`, the server will use the last value for the port, that is 3000. To allow different `.opt` files to require different plugins, mtr goes through the assembled server command line, and joins all `--plugin-load` options into one. Additionally it removes all empty `--plugin-load` options. For example, suppose a test is affected by three `.opt` files which contain, respectively:

```
--plugin-load=$HA_INNODB_SO
```

```
--plugin-load=$AUTH_PAM_SO
```

```
--plugin-load=$HA_EXAMPLE_SO
```

...and, let's assume the Example engine was not built (`$HA_EXAMPLE_SO` is empty). Then the server will get:

```
--plugin-load=ha_innodb.so:auth_pam.so
```

instead of

```
--plugin-load=ha_innodb.so --plugin-load=auth_pam.so --plugin-load=
```

Third, to allow plugin sources to be simply copied into the `plugin/` or `storage/` directories, and still not affect existing tests (even if new plugins are statically linked into the server), mtr automatically disables all optional plugins on server startup. A plugin is optional if it can be disabled with the corresponding `--skip-XXX` server command-line option. Mandatory plugins, like MyISAM or MEMORY, do not have `--skip-XXX` options (e.g. there is no `--skip-myisam` option). This mtr behavior means that no plugin, statically or dynamically built, has any effect on the server unless it was explicitly enabled. A convenient way to enable a given plugin *XXX* for specific tests is to create a `have_XXX.opt` file which contains the necessary command-line options, and a `have_XXX.inc` file which checks whether a plugin was loaded. Then any test that needs this plugin can source the `have_XXX.inc` file and have the plugin loaded automatically.

mtr communication procedure

`mtr` is first creating the server socket (`master`).

After that, `workers` are created using `fork()` .

For each worker `run_worker()` function is called, which is executing the following:

- creates a new socket to connect to `server_port` obtained from the `master`
- initiate communication with the `master` using `START` command
- `master` sends first test from list of tests supplied by the user and immediately sends command `TESTCASE` to the `worker`
- `worker` gets command `TESTCASE` and processes test case, by calling `run_testcase()` function which

starts(/restarts if needed) the server and sends `TESTRESULT` (in case of restart `WARNINGS` command is issued to the `master` in case some warnings/error logs are found)
- `master` accepts `TESTRESULT` command and run `mtr_report_test()` function which check does the test fail and also generates the new command `TESTCASE` if some new test case exist
- If there is no other test case `master` sends `BYE` command which gets accepted by the `worker` which is properly closing the connection.

1.3.18.2 mariadb-test Auxiliary Files

Contents

The mariadb-test framework utilizes many other files that affect the testing process, in addition to test and result files.

`disabled.def` file

This file can be used to disable certain tests temporarily. For example, if one test fails and you are working on that, you may want to push the changeset that disables the test into the test suite so that other tests won't be disturbed by this failure.

The file contains test names and a comment (that should explain why the test was disabled), separated by a colon. Lines that start with a hash sign (`#`) are ignored. A typical `disabled.def` may look like this (note that a hash sign in the middle of a line does not start a comment):

```
# List of disabled tests
# test name : comment
rpl_redirect : Fails due to bug#49978
events_time_zone  : need to fix the timing
```

During testing, mtr will print disabled tests like this:

```
...
rpl.rpl_redirect              [ disabled ]  Fails due to bug#49978
rpl.events_time_zone          [ disabled ]  need to fix the timing
...
```

This file should be located in the suite directory.

`suite.opt` file

This file lists server options that will be added to the `mariadbd` command line for every test of this suite. It can refer to environment variables with the `$NAME` syntax. Shell meta-characters should be quoted. For example

```
--plugin-load=$AUTH_PAM_SO
--max-connections=40 --net_read_timeout=5
"--replicate-rewrite-db=test->rewrite"
```

Note that options may be put either on one line or on separate lines. It is a good idea to start an option name with the `--loose-` prefix if the server may or may not recognize the option depending on the configuration. An unknown option in the `.opt` file will stop the server from starting, and the test will be aborted.

This file should be located in the suite directory.

other `*.opt` files

For every test or include file `somefile.test` or `somefile.inc`, mtr will look for `somefile.opt`, `somefile-master.opt` and `somefile-slave.opt`. These files have exactly the same syntax as the `suite.opt` above. Options from these files will also be added to the server command line (all servers started for this test, only master, or only slave respectively) for all affected tests, for example, for all tests that include `somefile.inc` directly or indirectly.

A typical usage example is `include/have_blackhole.inc` and `include/have_blackhole.opt`. The latter contains the necessary command-line options to load the Blackhole storage engine, while the former verifies that the engine was really loaded. Any test that needs the Blackhole engine needs only to start from `source include/have_blackhole.inc;` and the engine will be automatically loaded for the test.

`my.cnf` file

This is not the `my.cnf` file that tests from this suite will use, but rather a *template* of it. It will be converted later to an actual `my.cnf`. If a suite contains no `my.cnf` template, a default template, — `include/default_my.cnf` — will be used. Or `suite/rpl/my.cnf` if the test includes `master-slave.inc` (it's one of the few bits of the old MySQL `mysql-test-run` magic that we have not removed yet). Typically a suite template will not contain a complete server configuration, but rather start from

```
!include include/default_my.cnf
```

and then add the necessary modifications.

The syntax of `my.cnf` template is the same of a normal `my.cnf` file, with a few extensions and assumptions. They are:

- For any group with the name `[mysqld.N]`, where **N** is a number, mtr will start one `mysqld` process. Usually one needs to have only `[mysqld.1]` group, and `[mysqld.2]` group for replication tests.
- There can be groups with non-standard names (`[foo]`, `[bar]`, whatever), not used by `mysqld`. The `suite.pm` files (see below) may use them somehow.
- Values can refer to each other using the syntax `@groupname.optionname` — these references be expanded as needed. For example

  ```
  [mysqld.2]
  master-port= @mysqld.1.port
  ```

  it sets the value of the `master-port` in the `[mysqld.2]` group to the value of `port` in the `[mysqld.1]` group.
- An option name may start with a hash sign `#`. In the resulting `my.cnf` it will look like a comment, but it still can be referred to. For example:

```
[example]
#location = localhost:@mysqld.1.port
bar = server:@example.#location/data
```

- There is the `[ENV]` group. It sets values for the environment variables. For example

  ```
  [ENV]
  MASTER_MYPORT = @mysqld.1.port
  ```

  Also, one can refer to values of environment variables via this group:

  ```
  [mysqld.1]
  user = @ENV.LOGNAME
  ```

- There is the `[OPT]` group. It allows to invoke functions and generate values. Currently it contains only one option — `@OPT.port`. Every time this option is referred to in some other group in the `my.cnf` template, a new unique port number is generated. It will not match any other port number used by this test run. For example

  ```
  [ENV]
  SPHINXSEARCH_PORT = @OPT.port
  ```

This file should be located in the suite directory.

other `*.cnf` files

For every test file `somefile.test` (but for not included files) mtr will look for `somefile.cnf` file. If such a file exists, it will be used as a template instead of suite `my.cnf` or a default `include/default_my.cnf` templates.

`combinations` file

The `combinations` file defines few sets of alternative configurations, and every test in this suite will be run many times - once for every configuration. This can be used, for example, to run all replication tests in the *rpl* suite for all three binlog format modes (row, statement, and mixed). A corresponding `combinations` file would look as following:

```
[row]
binlog-format=row

[stmt]
binlog-format=statement

[mix]
binlog-format=mixed
```

It uses `my.cnf` file syntax, with groups (where group names define combination names) and options. But, despite the similarity, it is not a `my.cnf` template, and it cannot use the templating extentions. Instead, options from the `combinations` file are added to the server command line. In this regard, combination file is closer to `suite.opt` file. And just like it, combination file can use environment variables using the `$NAME` syntax.

Not all tests will necessarily run for all combinations. A particular test may require to be run only in one specific combination. For example, in replication, if a test can only be run with the row binlog format, it will have `--binlog-format=row` in one of the `.opt` files. In this case, mtr will notice that server command line already has an option that matches one of the combinations, and will skip all other combinations for this particular test.

The `combinations` file should be located in the suite directory.

other `*.combinations` files

Just like with the `*.opt` files, mtr will use `somefile.combinations` file for any `somefile.test` and `somefile.inc` that is used in testing. These files have exactly the same format as a suite `combinations` file.

This can cause many combination files affecting one test file (if a test includes two `.inc` files, and both of them have corresponding `.combinations` files). In this case, mtr will run the test for all combinations of combinations from both files. In MariaDB 5.5, for example, `rpl_init.inc` adds combinations for row/statement/mixed, and `have_innodb.inc` adds combinations for innodb/xtradb. Thus any replication test that uses innodb will be run six times.

`suite.pm` file

This (optional) file is a perl module. It must declare a package that inherits from `My::Suite`.

This file must normally end with `bless {}` — that is it must return an object of that class. It can also return a string — in this case all tests in the suite will be skipped, with this string being printed as a reason (for example "PBXT engine was not compiled").

A suite class can define the following methods:

- `config_files()`
- `is_default()`
- `list_cases()`
- `servers()`
- `skip_combinations()`
- `start_test()`

A `config_files()` method returns a list of additional config files (besides `my.cnf`), that this suite needs to be created.

For every file it specifies a function that will create it, when given a `My::Config` object. For example:

```
sub config_files {(
    'config.ini' => \&write_ini,
    'new.conf'   => \&do_new
)}
```

A `servers()` method returns a list of processes that needs to be started for this suite. A process is specified as a [regex, hash] pair. The regular expression must match a section in the `my.cnf` template (for example, `qr/mysqld\./` corresponds to all `mysqld` processes), the hash contains these options:

`SORT`	a number. Processes are started in the order of increasing `SORT` values (and stopped in the reverse order). `mysqld` has number 300.
`START`	a function to start a process. It takes two arguments, `My::Config::Group` and `My::Test`. If `START` is undefined a process will not be started.
`WAIT`	a function to wait for the process to be started. It takes `My::Config::Group` as an argument. Internally mtr first invokes `START` for all processes, then `WAIT` for all started processes.

```
sub servers {(
    qr/^foo$/ => { SORT => 200,  # start foo before mysqld
                   START => \&start_foo,
                   WAIT => \&wait_foo }
)}
```

See the *sphinx* suite for a working example.

A `list_cases()` method returns a complete list of tests for this suite. By default it will be the list of files that have `.test` extension, but without the extension. This list will be filtered by mtr, subject to different mtr options (`--big-test`, `--start-from`, etc), the suite object does not have to do it.

A `start_test()` method starts one test process, by default it will be `mariadb-test`. See the *unit* suite for a working example of `list_cases()` and `start_test()` methods.

A `skip_combinations()` method returns a hash that maps file names (where combinations are defined) to a list of combinations that should be skipped. As a special case, it can disable a complete file by using a string instead of a hash. For example

```
sub skip_combinations {(
    'combinations' => [ 'mix', 'rpl' ],
    'inc/many.combinations' => [ 'a', 'bb', 'c' ],
    'windows.inc' => "Not on windows",
)}
```

The last line will cause all tests of this suite that include `windows.inc` to be skipped with the reason being "Not on windows".

An `is_default()` method returns 1 if this particular suite should be run by default, when the `mariadb-test-run.pl` script is run without explicitly specified test suites or test cases.

`*.sh` files

For every test file `sometest.test` mtr looks for `sometest-master.sh` and `sometest-slave.sh`. If either of these files is found, it will be run before the test itself.

`*.require` files

These files are obsolete. Do not use them anymore. If you need to skip a test use the `skip` command instead.

`*.rdiff` files

These files also define what the test result should be. But unlike `*.result` files, they contain a patch that should be applied to one result file to create a new result file. This is very useful when a result of some test in one combination differs slightly from the result of the same test, but in another combination. Or when a result of a test in an overlay differs from the test result in the overlayed suite.

It is quite difficult to edit `.rdiff` files to update them after the test file has changed. But luckily, it is never needed. When a test fails, mtr creates a `.reject` file. Having it, one can create `.rdiff` file as easy as (for example)

```
diff -u main/foo.result main/foo.reject > main/foo,comb.rdiff
or
diff -u main/foo.result main/foo,comb.reject > main/foo,comb.rdiff
```

Some example:

```
diff -u main/innodb_ext_key.result main/innodb_ext_key,off.reject >
main/innodb_ext_key,off.rdiff

diff -u suite/sys_vars/r/sysvars_server_notembedded.result
suite/sys_vars/r/sysvars_server_notembedded,32bit.reject >
suite/sys_vars/r/sysvars_server_notembedded,32bit.rdiff
```

Note: This will also add a timestamp in the .rdiff file, so if you are submitting a patch you could remove it manually. If the same .rdiff file is used for multiple combinations, then it would be good to omit in the header that would identify the combination, to allow git to pack the repository better. Example:

```
--- testname.result
+++ testname.reject
```

Because a combination can be part of the `.result` or `.rdiff` file name, mtr has to look in many different places for a test result. For example, consider a test `foo.test` in the combination pair `aa,bb`, that is run in the overlay *rty* of the suite *qwe*, in other words, for the test that mtr prints as

```
qwe-rty.foo 'aa,bb'                      [ pass ]
```

For this test a result can be in

- either `.rdiff` or `.result` file
- either in the overlay "`rty/`" or in the overlayed suite "`qwe/`"
- with or without combinations in the file name ("`,a`", "`,b`", "`,a,b`", or nothing)

which means any of the following 15 file names can be used:

1. `rty/r/foo,aa,bb.result`
2. `rty/r/foo,aa,bb.rdiff`
3. `qwe/r/foo,aa,bb.result`
4. `qwe/r/foo,aa,bb.rdiff`
5. `rty/r/foo,aa.result`
6. `rty/r/foo,aa.rdiff`
7. `qwe/r/foo,aa.result`
8. `qwe/r/foo,aa.rdiff`
9. `rty/r/foo,bb.result`
10. `rty/r/foo,bb.rdiff`
11. `qwe/r/foo,bb.result`
12. `qwe/r/foo,bb.rdiff`
13. `rty/r/foo.result`
14. `rty/r/foo.rdiff`
15. `qwe/r/foo.result`

They are listed, precisely, in the order of preference, and mtr will walk that list from top to bottom and the first file that is found will be used.

If this found file is a `.rdiff`, mtr continues walking down the list until the first `.result` file is found. A `.rdiff` is applied to that `.result`.

`valgrind.supp` file

This file defines valgrind suppressions, and it is used when mtr is started with a `--valgrind` option.

1.3.18.3 mariadb-test-run.pl Options

Contents

Syntax

```
./mariadb-test-run.pl [ OPTIONS ] [ TESTCASE ]
```

Where the test case can be specified as: `testcase[.test]` Runs the test case named 'testcase' from all suits

```
path-to-testcase
[suite.]testcase[,combination]
```

Examples

`alias main.alias` 'main' is the name of the suite for the 't' directory.

```
rpl.rpl_invoked_features,mix,xtradb_plugin
suite/rpl/t/rpl.rpl_invoked_features
```

Options

Options to Control What Engine/Variation to Run

Option	Description
`--embedded-server`	Use the embedded server, i.e. no mysqld daemons.
`--ps-protocol`	Use the binary protocol between client and server.
`--cursor-protocol`	Use the cursor protocol between client and server (implies `--ps-protocol`).
`--view-protocol`	Create a view to execute all non updating queries.
`--sp-protocol`	Create a stored procedure to execute all queries.
`--compress`	Use the compressed protocol between client and server if both support it.
`--ssl`	If mariadb-test-run.pl is started with the `--ssl` option, it sets up a secure connection for all test cases. In this case, if mysqld does not support TLS, mariadb-test-run.pl exits with an error message: `Couldn´t find support for SSL`.
`--skip-ssl`	Dont start server with support for TLS connections.
`--vs-config`	Visual Studio configuration used to create executables (default: MTR_VS_CONFIG environment variable).
`--parallel=num`	How many parallel tests should be run. Default is `1`, use `--parallel=auto` for auto-setting of *num*.

`--defaults-file=<config template>`	Use fixed config template for all tests.
`--defaults_extra_file=<config template>`	Extra config template to add to all generated configs.
`--combination=<opt>`	Extra options to pass to mysqld. The value should consist of one or more comma-separated mysqld options. This option is similar to `--mysqld` but should be given two or more times. mariadb-test-run.pl executes multiple test runs, using the options for each instance of `--combination` in successive runs. If `--combination` is given only once, it has no effect. For test runs specific to a given test suite, an alternative to the use of `--combination` is to create a combinations file in the suite directory. The file should contain a section of options for each test run.
`--dry-run`	Don't run any tests, print the list of tests that were selected for execution.

Options to Control Directories to Use

Option	Description
`--tmpdir=DIR`	The directory where temporary files are stored (default: ./var/tmp). The environment variable MYSQL_TMP_DIR will be set to the path for this directory, whether it has the default value or has been set explicitly. This may be referred to in tests.
`--vardir=DIR`	The directory where files generated from the test run is stored (default: ./var). Specifying a ramdisk or tmpfs will speed up tests. The environment variable MYSQLTEST_VARDIR will be set to the path for this directory, whether it has the default value or has been set explicitly. This may be referred to in tests.
`--mem`	Run testsuite in "memory" using tmpfs or ramdisk. This can decrease test times significantly, in particular if you would otherwise be running over a remote file system. Attempts to find a suitable location using a builtin list of standard locations for tmpfs (/dev/shm). The option can also be set using environment variable MTR_MEM=[DIR]. If DIR is given, it is added to the beginning of the list of locations to search, so it takes precedence over any built-in locations. Once you have run tests with --mem within a mariadb-testdirectory, a soflink var will have been set up to the temporary directory, and this will be re-used the next time, until the soflink is deleted. Thus, you do not have to repeat the `--mem` option next time.
`--client-bindir=PATH`	Path to the directory where client binaries are located.
`--client-libdir=PATH`	Path to the directory where client libraries are located.

Options to Control What Test Suites or Cases to Run

Option	Description
`--force`	Normally, mariadb-test-run.pl exits if a test case fails. `--force` causes execution to continue regardless of test case failure.
`--with-ndbcluster-only`	Run only tests that include "ndb" in the filename.
`--skip-ndb[cluster]`	Skip all tests that need cluster. Default.
`--do-test=PREFIX or REGEX`	Run test cases with names prefixed with PREFIX or which fulfil the REGEX. For example, `--do-test=testa` matches tests that begin with *testa*, `--do-test=main.testa` matches tests in the main test suite that begin with *testa*, and `--do-test=main.*testa` matches test names that contain *main* followed by *testa* with anything in between. In the latter case, the pattern match is not anchored to the beginning of the test name, so it also matches names such as *xmainytestz*.
`--skip-test=PREFIX or REGEX`	Skip test cases with names prefixed with PREFIX or which fulfil the REGEX. See `-do-test` for examples.
`--start-from=PREFIX`	Sorts the list of names of the test cases to be run, and then starts with the test prefixed with PREFIX, where the prefix may be *suite.testname* or just *testname*.

`--suite[s]=NAME1,..,NAMEN`	Comma separated list of suite names to run. The default, as of MariaDB 10.4.5, is: "main-, archive-, binlog-, binlog_encryption-, csv-, compat/oracle-, encryption-, federated-, funcs_1-, funcs_2-, gcol-, handler-, heap-, innodb-, innodb_fts-, innodb_gis-, innodb_zip-, json-, maria-, mariabackup-, multi_source-, optimizer_unfixed_bugs-, parts-, perfschema-, plugins-, roles-, rpl-, sys_vars-, sql_sequence-, unit-, vcol-, versioning-,period-".
`--skip-rpl`	Skip the replication test cases.
`--big-test`	Allow tests marked as "big" to run. Tests can be thus marked by including the line `--source include/big_test.inc`, and they will only be run if this option is given, or if the environment variable BIG_TEST is set to 1. Repeat this option twice to run only "big" tests. This is typically used for tests that take a very long to run, or that use many resources, so that they are not suitable for running as part of a normal test suite run
`--staging-run`	Run a limited number of tests (no slow tests). Used for running staging trees with valgrind.
`--enable-disabled`	Ignore any *disabled.def* file, and also run tests marked as disabled. Success or failure of those tests will be reported the same way as other tests.
`--print-testcases`	Don't run the tests but print details about all the selected tests, in the order they would be run.
`--skip-test-list=FILE`	Skip the tests listed in FILE. Each line in the file is an entry and should be formatted as: <TESTNAME> : <COMMENT>

Options That Specify Ports

Option	Description
`--[mtr-]port-base=num`	Base for port numbers. Ports from this number to number+9 are reserved. Should be divisible by 10; if not it will be rounded down. May be set with environment variable MTR_PORT_BASE. If this value is set and is not "auto", it overrides build-thread.
`--[mtr-]build-thread=num`	Specify unique number to calculate port number(s) from. Can be set in environment variable MTR_BUILD_THREAD. Set MTR_BUILD_THREAD="auto" to automatically acquire a build thread id that is unique to current host. The more logical `--port-base` is supported as an alternative.

Options For Test Case Authoring

Option	Description
`--record TESTNAME`	(Re)generate the result file for TESTNAME.
`--check-testcases`	Check testcases for side-effects. This is done by checking system state before and after each test case; if there is any difference, a warning to that effect will be written, but the test case will not be marked as failed because of it. This check is enabled by default. Use `--nocheck-testcases` to disable.
`mark-progress`	Log line number and elapsed time to <testname>.progress

Options That Pass On Options

Option	Description
`--mysqld=ARGS`	Specify additional arguments to "mysqld"
`--mysqltest=ARGS`	Specify additional arguments to "mariadb-test". Use additional `--mysqld-env` options to set more than one variable.

Options to Run Test On Running Server

Option	Description

`extern option=value`	Use an already running server. The option/value pair is what is needed by the mariadb client to connect to the server. Each `--extern` option can only take one option/value pair as an argument, so you need to repeat `--extern` for each pair needed. Example: `./mariadb-test-run.pl --extern socket=var/tmp/mysqld.1.sock alias` . Note: If a test case has an .opt file that requires the server to be restarted with specific options, the file will not be used. The test case likely will fail as a result.

Options For Debugging the Product

In `mariadb-test-run.pl` there is a concept of a "debugger". A "debugger" is a tool that `mariadb-test-run.pl` will execute instead of `mariadbd` . This tool will then start `mariadbd` and can control its execution as it wants. The following "debuggers" are supported:

name	Description
`gdb`	GNU debugger
`ddd`	GUI frontend for gdb
`dbx`	https://en.wikipedia.org/wiki/Dbx_(debugger)
`devenv`	Visual Studio debugger
`windbg`	https://en.wikipedia.org/wiki/WinDbg
`lldb`	Debugger from LLVM project
`valgrind`	Detects memory management problems and more
`strace`	syscall tracer
`rr`	"record and replay" — record the program execution and then replay it forward, backward, or in any other direction

Every "debugger" from the list above supports the following set of options (replace XXX below with a debugger name)

Option	Description
`--XXX`	Start `mariadbd` process under a debugger
`--client-XXX`	Start `mariadb-test` process under a debugger
`--boot-XXX`	Before running tests `mariadb-test-run` executes `mariadbd` to bootstrap, prepare the datadir. This options causes this bootstrapping `mariadbd` process to be run under a debugger.
`--manual-XXX`	Don't start anything, instead print the command that the user needs to run to start `mariadbd` under a debugger. Then wait.

Every option from the above accepts an optional argument. It can be used to specify additional command line options to pass to the tool. Or additional commands that the tool will run on startup. Or both. Commands are separated from each other and from options with a semicolon. For example:

```
./mtr 1st --strace
./mtr 1st --client-rr=--chaos
./mtr 1st --manual-gdb='b mysql_parse;r'
./mtr 1st --boot-gdb='--quiet --tui;b mysql_parse;r'
```

Misc Debugging Related Options

Option	Description
`--debug`	Dump trace output for all servers and client programs.
`--debug-common`	Same as `--debug` , but sets the 'd' debug flags to "query,info,error,enter,exit"

`--debug-server`	Use debug version of server, but without turning on tracing.
`--max-save-core`	Limit the number of core files saved (to avoid filling up disks for heavily crashing server). Defaults to 5, set to 0 for no limit. Set its default with MTR_MAX_SAVE_CORE.
`--max-save-datadir`	Limit the number of datadir saved (to avoid filling up disks for heavily crashing server). Defaults to 20, set to 0 for no limit. Set its default with MTR_MAX_SAVE_DATDIR.
`--max-test-fail`	Limit the number of test failurs before aborting the current test run. Defaults to 10, set to 0 for no limit. Set its default with MTR_MAX_TEST_FAIL.

Misc Options

Option	Description
`--user=USER`	User for connecting to mysqld (default: root)
`--comment=STR`	Write STR to the output within lines filled with #, as a form of banner.
`--timer`	Show test case execution time. Use `no-timer` to disable.
`--verbose`	More verbose output(use multiple times for even more)
`--verbose-restart`	Write when and why servers are restarted between test cases.
`--start`	Only initialize and start the servers, using the startup settings for the first specified test case Example: `./mariadb-test-run.pl --start alias & start-dirty` Only start the servers (without initialization) for the first specified test case
`--start-and-exit`	Same as `--start` , but *mariadb-test-run* terminates and leaves just the server running.
`--start-dirty`	This is similar to `--start` , but will skip the database initialization phase and assume that database files are already available. Usually this means you must have run another test first.
`--user-args`	In combination with start* and no test name, drops arguments to mysqld except those specified with `--mysqld` (if any).
`--wait-all`	If `--start` or `--start-dirty` option is used, wait for all servers to exit before finishing the process. Otherwise, it will terminate if one (of several) servers is restarted.
`--fast`	Do not perform controlled shutdown when servers need to be restarted or at the end of the test run. This is equivalent to using `--shutdown-timeout=0` .
`--force-restart`	Always restart servers between tests.
`--parallel=N`	Run tests in N parallel threads (default 1) Use parallel=auto for auto-setting of N.
`--repeat=N`	Run each test N number of times.
`--retry=N`	If a test fails, it is retried up to a maximum of N runs (default 1). Retries are also limited by the maximum number of failures before stopping, set with the `--retry-failure` option. This option has no effect unless `--force` is also used; without it, test execution will terminate after the first failure. The `--retry` and `--retry-failure` options do not affect how many times a test repeated with `--repeat` may fail in total, as each repetition is considered a new test case, which may in turn be retried if it fails.
`--retry-failure=N`	When using the --retry option to retry failed tests, stop when N failures have occured (default 2). Setting it to 0 or 1 effectively turns off retries.
`--reorder`	Reorder tests to get fewer server restarts. This is the default behavior. There is no guarantee that a particular set of tests will always end up in the same order. Use `-no-reorder` to disable.
`--help`	Display help text.
`--testcase-timeout=MINUTES`	Max test case run time in minutes (default 15).

`--suite-timeout=MINUTES`	Max test suite run time in minutes (default 360).
`--shutdown-timeout=SECONDS`	Max number of seconds to wait for server shutdown before killing servers (default 10).
`--warnings`	Scan the log files for warnings and report any suspicious ones; if any are found, the test will be marked as failed. Use `--nowarnings` to turn off.
`--stop-file=file`	If this file is detected, mariadb-test will not start new tests until the file is removed (also MTR_STOP_FILE environment variable).
`--stop-keep-alive=sec`	Works with `--stop-file`, print messages every *sec* seconds when mariadb-test is waiting to remove the file (for buildbot) (also MTR_STOP_KEEP_ALIVE environment variable).
`--sleep=SECONDS`	Passed to mariadb-test; will be used as fixed sleep time.
`--debug-sync-timeout=NUM`	Set default timeout for WAIT_FOR debug sync actions. Disable facility with NUM=0.
`--gcov`	Collect coverage information after the test. The result is a dgcov file per source and header file and a `last_changes.dgcov` file in the vardir with the coverage for the uncommitted changes if any (or the last commit).
`--gprof`	Collect profiling information using the gprof profiling tool.
`--experimental=<file>`	Specify a file that contains a list of test cases that should be displayed with the [exp-fail] code rather than [fail] if they fail. For an example of a file that might be specified via this option, see *mariadb-test/collections/default.experimental*.
`--report-features`	First run a "test" that reports MariaDB features, displaying the output of SHOW ENGINES and SHOW VARIABLES. This can be used to verify that binaries are built with all required features.
`--timestamp`	Print timestamp before each test report line, showing when the test ended.
`--timediff`	Used with `--timestamp`, also print time passed since the previous test started.
`--max-connections=N`	Maximum number of simultaneous server connections that may be used per test. Default is 128. Minimum is 8, maximum is 5120. Corresponds to the same option for mariadb-test.
`--default-myisam`	Set default storage engine to MyISAM for non-innodb tests. This is needed after switching default storage engine to InnoDB.
`--report-times`	Report how much time has been spent on different phases of test execution.
`--stress=ARGS`	Run stress test, providing options to mysql-stress-test.pl. Options are separated by comma.
`xml-report=<file>`	Output jUnit xml file of the results. From MariaDB 10.1.45, MariaDB 10.2.32, MariaDB 10.3.23, MariaDB 10.4.13, MariaDB 10.5.3
`tail-lines=N`	Number of lines of the result to include in a failure report. From MariaDB 10.3.4.

1.3.18.4 Pausing mariadb-test-run.pl

Contents

Sometimes you need to work when your computer is busy running mariadb-test-run.pl. The mariadb-test-run.pl script allows you to stop it temporarily so you can use your computer and then restart the tests when you're ready.

There are two ways to enable this:

1. **Command-line:** The `--stop-file` and `--stop-keep-alive` options.
2. **Environment Variables:** If you are calling mariadb-test-run.pl indirectly (i.e from a script or program such as buildbot) you can set `MTR_STOP_FILE` and `MTR_STOP_KEEP_ALIVE`.

Keep Alive

If you plan on using this feature with other programs, such as buildbot, you should set the

<code>MTR_STOP_KEEP_ALIVE</code> environment variable or the <code>--stop-keep-alive</code> command-line option with a value in seconds. This will make the script print messages to whatever program is calling mariadb-test-run.pl at the interval you set to prevent timeouts.

If you are calling mariadb-test-run.pl directly, you do not need to specify a timeout.

The mariadb-test-run Stop File

The stop file is a temporary file that you create on your system when you want to pause the execution of mariadb-test-run. When enabled via the command-line or environment variable options, mariadb-test-run will periodically check for the existence of the file and if it exists it will stop until the file is no longer present.

Examples

Command-line:

```
mariadb-test-run.pl --stop-file="/path/to/stop/file" --stop-keep-alive=120
```

Environment Variables:

```
export MTR_STOP_FILE="/path/to/stop/file"
export MTR_STOP_KEEP_ALIVE=120
mariadb-test-run.pl
```

1.3.18.5 mariadb-test and mariadb-test-embedded

Contents

The `mariadb-test` program runs a test case against a MariaDB or MySQL server and optionally compares the output with a result file. This program reads input written in a special test language. Typically, you invoke *mariadb-test* via `mariadb-test-run.pl` rather than invoking it directly.

`mariadb-test_embedded` is similar but is built with support for the `libmariadbd` embedded server.

Features of mariadb-test:

- Can send SQL statements to the server for execution
- Can execute external shell commands
- Can test whether the result from an SQL statement or shell command is as expected
- Can connect to one or more standalone mariadbd servers and switch between connections
- Can connect to an embedded server (libmariadbd), if MariaDB is compiled with support for libmariadbd. (In this case, the executable is named mariadb-test_embedded rather than mariadb-test.)

By default, mariadb-test reads the test case on the standard input. To run mariadb-test this way, you normally invoke it like this:

```
shell> mariadb-test **[options] [db_name]** < //test_file//
```

You can also name the test case file with a `--test-file=file_name` option.

The exit value from mariadb-test is 0 for success, 1 for failure, and 62 if it skips the test case (for example, if after checking some preconditions it decides not to run the test).

Options

mariadb-test supports the following options:

Option	Description
`--help , -?`	Display a help message and exit.
`--basedir=dir , -b dir`	The base directory for tests.

`--character-sets-dir=path`	The directory where character sets are installed.
`--compress`, `-C`	Compress all information sent between the client and the server if both support compression.
`--connect-timeout=N`	This can be used to set the MYSQL_OPT_CONNECT_TIMEOUT parameter of mysql_options to change the number of seconds before an unsuccessful connection attempt times out.
`--continue-on-error`	Continue test even if we got an error. This is mostly useful when testing a storage engine to see what from a test file it can execute, or to find all syntax errors in a newly created big test file
`--cursor-protocol`	Use cursors for prepared statements.
`--database=db_name`, `-D db_name`	The default database to use.
`--debug[=debug_options]`, `-#[debug_options]`	Write a debugging log if MariaDB is built with debugging support. The default debug_options value is `d:t:S:i:O,/tmp/mysqltest.trace` on Unix and `d:t:i:O,\mysqld.trace` on Windows.
`--debug-check`	Print some debugging information when the program exits.
`--debug-info`	Print debugging information and memory and CPU usage statistics when the program exits.
`--host=host_name`, `-h host_name`	Connect to the server on the given host.
`--logdir=dir_name`	The directory to use for log files.
`--mark-progress`	Write the line number and elapsed time to *test_file.progress*.
`--max-connect-retries=num`	The maximum number of connection attempts when connecting to server.
`--max-connections=num`	The maximum number of simultaneous server connections per client (that is, per test). If not set, the maximum is 128. Minimum allowed limit is 8, maximum is 5120.
`--no-defaults`	Do not read default options from any option files. If used, this must be the first option.
`--non-blocking-api`	Use the non-blocking client API for communication.
`--overlay-dir=name`	Overlay directory.
`--password[=password]`, `-p[password]`	The password to use when connecting to the server. If you use the short option form (-p), you cannot have a space between the option and the password. If you omit the password value following the `--password` or `-p` option on the command line, you are prompted for one.
`plugin-dir`	Directory for client-side plugins.
`--port=port_num`, `-P port_num`	The TCP/IP port number to use for the connection, or 0 for default to, in order of preference, my.cnf, $MYSQL_TCP_PORT, /etc/services, built-in default (3306).
`--prologue=name`	Include the contents of the given file before processing the contents of the test file. The included file should have the same format as other *mariadb-test* test files. This option has the same effect as putting a --source file_name command as the first line of the test file.
`--protocol=name`	The protocol to use for connection (tcp, socket, pipe, memory).
`--ps-protocol`	Use the prepared-statement protocol for communication.
`--quiet`	Suppress all normal output. This is a synonym for `--silent`.
`--record`, `-r`	Record the output that results from running the test file into the file named by the `--result-file` option, if that option is given. It is an error to use this option without also using `--result-file`.

`--result-file=file_name`, `-R file_name`	This option specifies the file for test case expected results. `--result-file`, together with `--record`, determines how mariadb-test treats the test actual and expected results for a test case: If the test produces no results, mariadb-test exits with an error message to that effect, unless `--result-file` is given and the named file is an empty file. Otherwise, if `--result-file` is not given, mariadb-test sends test results to the standard output. With `--result-file` but not `--record`, mariadb-test reads the expected results from the given file and compares them with the actual results. If the results do not match, mariadb-test writes a reject file in the same directory as the result file, outputs a diff of the two files, and exits with an error. With both `--result-file` and `--record`, mariadb-test updates the given file by writing the actual test results to it.
`--result-format-version=#`	Version of the result file format to use.
`--server-arg=value`, `-A value`	Pass the argument as an argument to the embedded server. For example, `--server-arg=--tmpdir=/tmp` or `--server-arg=--core`. Up to 64 arguments can be given.
`--server-file=file_name`, `-F file_name`	Read arguments for the embedded server from the given file. The file should contain one argument per line.
`--shared-memory-base-name`	Shared-memory name to use for Windows connections using shared memory to a local server (started with the `--shared-memory` option). Case-sensitive.
`--silent`, `-s`	Suppress all normal output.
`--sleep=num`, `-T num`	Cause all sleep commands in the test case file to sleep num seconds. This option does not affect real_sleep commands. An option value of 0 can be used, which effectively disables sleep commands in the test case.
`--socket=path`, `-S path`	The socket file to use when connecting to localhost (which is the default host).
`--sp-protocol`	Execute DML statements within a stored procedure. For every DML statement, mariadb-test creates and invokes a stored procedure that executes the statement rather than executing the statement directly.
`--ssl`	Enable TLS for secure connection (automatically enabled with other flags). Disable with `--skip-ssl`.
`--ssl-ca=name`	CA file in PEM format (check OpenSSL docs, implies `--ssl`).
`--ssl-capath=name`	CA directory (check OpenSSL docs, implies `--ssl`).
`--ssl-cert=name`	X509 cert in PEM format (implies `--ssl`).
`--ssl-cipher=name`	SSL cipher to use (implies `--ssl`).
`--ssl-key=name`	X509 key in PEM format (implies `--ssl`).
`--ssl-crl=name`	Certificate revocation list (implies `--ssl`).
`--ssl-crlpath=name`	Certificate revocation list path (implies `--ssl`).
`--ssl-verify-server-cert`	Verify server's "Common Name" in its cert against hostname used when connecting. This option is disabled by default.
`--suite-dir=name`	Suite directory.
`--tail-lines=nn`	Specify how many lines of the result to include in the output if the test fails because an SQL statement fails. The default is 0, meaning no lines of result printed.
`--test-file=file_name`, `-x file_name`	Read test input from this file. The default is to read from the standard input.

`--timer-file=file_name`, `-m file_name`	If given, the number of microseconds spent running the test will be written to this file. This is used by mariadb-test-run.pl for its reporting.
`--tmpdir=dir_name`, `-t dir_name`	The temporary directory where socket files are created.
`--user=user_name`, `-u user_name`	The user name to use when connecting to the server.
`--verbose`, `-v`	Verbose mode. Print out more information about what the program does.
`--version`, `-V`	Display version information and exit.
`--view-protocol`	Every SELECT statement is wrapped inside a view.
`--wait-longer-for-timeouts`	Wait longer for timeouts. Useful when running under valgrind.

1.3.18.6 New Features for mysqltest in MariaDB

Note that not all MariaDB-enhancements are listed on this page. See mariadb-test and mariadb-test-embedded for a full set of options.

Startup Option --connect-timeout

```
--connect-timeout=N
```

This can be used to set the MYSQL_OPT_CONNECT_TIMEOUT parameter of mysql_options, to change the number of seconds before an unsuccessful connection attempt times out.

Test Commands for Handling Warnings During Prepare Statements

- `enable_prepare_warnings;`
- `disable_prepare_warnings;`

Normally, when running with the prepared statement protocol with warnings enabled and executing a statement that returns a result set (like SELECT), warnings that occur during the execute phase are shown, but warnings that occur during the prepare phase are "not" shown. The reason for this is that some warnings are returned both during prepare and execute; if both copies of warnings were shown, then test cases would show different number of warnings between prepared statement execution and normal execution (where there is no prepare phase).

The `enable_prepare_warnings` command changes this so that warnings from both the prepare and execute phase are shown, regardless of whether the statement produces a result set in the execute phase. The `disable_prepare_warnings` command reverts to the default behaviour.

These commands only have effect when running with the prepared statement protocol (--ps-protocol) *and* with warnings enabled (enable_warnings). Furthermore, they only have effects for statements that return a result set (as for statements without result sets, warnings from are always shown when warnings are enabled).

The `replace_regex` command supports paired delimiters (like in perl, etc). If the first non-space character in the `replace_regex` argument is one of `(`, `[`, `{`, `<`, then the pattern should end with `)`, `]`, `}`, `>` accordingly. The replacement string can use its own pair of delimiters, not necessarily the same as the pattern. If the first non-space character in the `replace_regex` argument is not one of the above, then it should also separate the pattern and the replacement string and it should end the replacement string. Backslash can be used to escape the current terminating character as usual. The examples below demonstrate valid usage of `replace_regex`:

```
--replace_regex (/some/path)</another/path>
--replace_regex !/foo/bar!foobar!
--replace_regex {pat\}tern}/replace\/ment/i
```

1.3.18.7 Debugging MariaDB With a Debugger

Contents

If you have MariaDB compiled for debugging you can both use it in a debugger, like ddd or gdb, and get comprehensive trace files of the execution of MariaDB. The trace files allow you to both see the flow of the code and to see the differences in execution by by comparing two trace files.

Core dumps are also much easier to investigate if they come from a debug binary.

Note that a binary compiled for debugging and tracing is about 10-20% slower than a normal binary. If you just compile a binary for debugging (option `-g` with gcc) the speed difference compared to a normal binary is negligible.

Checking That MariaDB is Compiled For Debugging

Execute:

```
mariadbd --debug --help
```

If you are using MariaDB before 10.5, then you should use `mysqld` instead of `mariadbd`!

If you get an error `unknown option '--debug`, then MariaDB is not compiled for debugging and tracing.

Building MariaDB for Debugging Starting from 5.5

On Unix you need to pass `-DCMAKE_BUILD_TYPE=Debug` to cmake to compile with debug information.

Building MariaDB 5.3 and Older

Here is how you compile with debug on older versions:

Use the scripts in the BUILD directory that will compile MariaDB with most common debug options and plugins, for example:

```
./BUILD/compile-pentium64-debug-max
```

For the most common configurations there exists a fine-tuned script in the BUILD directory.

If you want to use valgrind, a very good memory instrumentation tool and memory overrun checker, you should use

```
./BUILD/compile-pentium64-valgrind-max
```

Some recommended debugging scripts for Intel/AMD are:

```
BUILD/compile-pentium64-debug-max
BUILD/compile-pentium64-valgrind-max
```

This is an example of how to compile MariaDB for debugging in your home directory with MariaDB 5.2.9 as an example:

```
cd ~
mkdir mariadb
cd mariadb
tar xvf mariadb-5.2.9.tar.gz
ln -s mariadb-5.2.9 current
cd current
./BUILD/compile-pentium64-debug-max
```

The last command will produce a debug version of `sql/mysqld`.

Debugging MariaDB From the Source Directory

Creating the MariaDB Database Directory

The following example creates the MariaDB databases in `/data`.

```
./scripts/mariadb-install-db --srcdir=. --datadir=/data
```

Running MariaDB in a Debugger

The following example is using `ddd`, an excellent graphical debugger in Linux. If you don't have `ddd` installed, you can use `gdb` instead.

```
cd sql
ddd ./mariadbd &
```

In `ddd` or `gdb`

```
run --datadir=/data --language=./share/english --gdb
```

You can set the options in your /.my.cnf file so as not to have to repeat them on the `run` line.

If you run `mysqld` with `--debug`, you will get a trace file in /tmp/mysqld.trace that shows what is happening.

Note that you can have different options in the configuration file for each MariaDB version (like having a specific language directory).

Debugging MariaDB Server with mariadb-test-run

If you get a crash while running `mariadb-test-run` you can debug this in a debugger by using one of the following options:

```
mariadb-test-run --gdb failing-test-name
```

or if you prefer the `ddd` debugger:

```
mariadb-test-run --ddd failing-test-name
```

Sample .my.cnf file to Make Debugging Easier

```
[client-server]
socket=/tmp/mysql-dbug.sock
port=3307

[mariadb]
datadir=/my/data
loose-innodb_file_per_table
server_id= 1
log-basename=master
loose-debug-mutex-deadlock-detector
max-connections=20
lc-messages=en_us

[mariadb-10.0]
lc-messages-dir=/my/maria-10.0/sql/share

[mariadb-10.1]
lc-messages-dir=/my/maria-10.1/sql/share

[mariadb-10.2]
lc-messages-dir=/my/maria-10.2/sql/share

[mariadb-10.3]
lc-messages-dir=/my/maria-10.3/sql/share
```

The above `.my.cnf` file:

- Uses an explicit socket for both client and server.
- Assumes the server source is in /my/maria-xxx. You should change this to point to where your sources are located.
- Has a unique patch for each MariaDB version so that one doesn't have to specify --lc-messages-dir or --language even if one switches between debugging different MariaDB versions.

1.3.18.8 The Debug Sync Facility

Contents

The Debug Sync Facility allows placement of synchronization points in the server code by using the DEBUG_SYNC macro:

```
open_tables(...)

DEBUG_SYNC(thd, "after_open_tables");

lock_tables(...)
```

When activated, a sync point can

- Emit a signal and/or
- Wait for a signal

Nomenclature	Description
signal	A value of a global variable that persists until overwritten by a new signal. The global variable can also be seen as a "signal post" or "flag mast". Then the signal is what is attached to the "signal post" or "flag mast".
emit a signal	Assign the value (the signal) to the global variable ("set a flag") and broadcast a global condition to wake those waiting for a signal.
wait for a signal	Loop over waiting for the global condition until the global value matches the wait-for signal.

By default, all sync points are inactive. They do nothing (except to burn a couple of CPU cycles for checking if they are active).

A sync point becomes active when an action is requested for it. To do so, put a line like this in the test case file:

```
SET DEBUG_SYNC= 'after_open_tables SIGNAL opened WAIT_FOR flushed';
```

This activates the sync point `'after_open_tables'`. It requests it to emit the signal `'opened'` and wait for another thread to emit the signal `'flushed'` when the thread's execution runs through the sync point.

For every sync point there can be one action per thread only. Every thread can request multiple actions, but only one per sync point. In other words, a thread can activate multiple sync points.

Here is an example how to activate and use the sync points:

```
--connection conn1
SET DEBUG_SYNC= 'after_open_tables SIGNAL opened WAIT_FOR flushed';
send INSERT INTO t1 VALUES(1);
    --connection conn2
    SET DEBUG_SYNC= 'now WAIT_FOR opened';
    SET DEBUG_SYNC= 'after_abort_locks SIGNAL flushed';
    FLUSH TABLE t1;
```

When `conn1` runs through the `INSERT` statement, it hits the sync point `'after_open_tables'`. It notices that it is active and executes its action. It emits the signal `'opened'` and waits for another thread to emit the signal `'flushed'`.

`conn2` waits immediately at the special sync point `'now'` for another thread to emit the `'opened'` signal.

A signal remains in effect until it is overwritten. If `conn1` signals `'opened'` before `conn2` reaches `'now'`, `conn2` will still find the `'opened'` signal. It does not wait in this case.

When `conn2` reaches `'after_abort_locks'`, it signals `'flushed'`, which lets `conn1` awake.

Normally the activation of a sync point is cleared when it has been executed. Sometimes it is necessary to keep the sync point active for another execution. You can add an execute count to the action:

```
SET DEBUG_SYNC= 'name SIGNAL sig EXECUTE 3';
```

This sets the signal point's activation counter to 3. Each execution decrements the counter. After the third execution the sync point becomes inactive.

One of the primary goals of this facility is to eliminate sleeps from the test suite. In most cases it should be possible to rewrite test cases so that they do not need to sleep. (But this facility cannot synchronize multiple processes.) However, to support test development, and as a last resort, sync point waiting times out. There is a default timeout, but it can be overridden:

```
SET DEBUG_SYNC= 'name WAIT_FOR sig TIMEOUT 10 EXECUTE 2';
```

`TIMEOUT 0` is special: If the signal is not present, the wait times out immediately.

When a wait timed out (even on `TIMEOUT 0`), a warning is generated so that it shows up in the test result.

You can throw an error message and kill the query when a synchronization point is hit a certain number of times:

```
SET DEBUG_SYNC= 'name HIT_LIMIT 3';
```

Or combine it with signal and/or wait:

```
SET DEBUG_SYNC= 'name SIGNAL sig EXECUTE 2 HIT_LIMIT 3';
```

Here the first two hits emit the signal, the third hit returns the error message and kills the query.

For cases where you are not sure that an action is taken and thus cleared in any case, you can force to clear (deactivate) a sync point:

```
SET DEBUG_SYNC= 'name CLEAR';
```

If you want to clear all actions and clear the global signal, use:

```
SET DEBUG_SYNC= 'RESET';
```

This is the only way to reset the global signal to an empty string.

For testing of the facility itself you can execute a sync point just as if it had been hit:

```
SET DEBUG_SYNC= 'name TEST';
```

Formal Syntax

The string to "assign" to the DEBUG_SYNC variable can contain:

```
RESET |
<sync point name> TEST |
<sync point name> CLEAR |
<sync point name> {{SIGNAL <signal name> |
                   WAIT_FOR <signal name> [TIMEOUT <seconds>]}
                   [EXECUTE <count>] &| HIT_LIMIT <count>}
```

Here '&|' means 'and/or'. This means that one of the sections separated by '&|' must be present or both of them.

Activation/Deactivation

With a MariaDB for debug build, it can be enabled by a mysqld command line option:

```
 --debug-sync-timeout[=default_wait_timeout_value_in_seconds]
```

`'default_wait_timeout_value_in_seconds'` is the default timeout for the `WAIT_FOR` action. If set to zero, the facility

stays disabled.

The facility is enabled by default in the test suite, but can be disabled with:

```
mariadb-test-run.pl ... --debug-sync-timeout=0 ...
```

Likewise the default wait timeout can be set:

```
mariadb-test-run.pl ... --debug-sync-timeout=10 ...
```

The command line option influences the readable value of the debug_sync system variable.

- If the facility is not compiled in, the system variable does not exist.
- If `--debug-sync-timeout=0` the value of the variable reads as `"OFF"`.
- Otherwise the value reads as `"ON - current signal: "` followed by the current signal string, which can be empty.

The readable variable value is the same, regardless if read as a global or session value.

Setting the debug_sync system variable requires the `'SUPER'` privilege. You can never read back the string that you assigned to the variable, unless you assign the value that the variable already has. But that would give a parse error. A syntactically correct string is parsed into a debug sync action and stored apart from the variable value.

Implementation

Pseudo code for a sync point:

```
#define DEBUG_SYNC(thd, sync_point_name)
        if (unlikely(opt_debug_sync_timeout))
          debug_sync(thd, STRING_WITH_LEN(sync_point_name))
```

The sync point performs a binary search in a sorted array of actions for this thread.

The `SET DEBUG_SYNC` statement adds a requested action to the array or overwrites an existing action for the same sync point. When it adds a new action, the array is sorted again.

A typical synchronization pattern

There are quite a few places in MariaDB and MySQL where we use a synchronization pattern like this:

```
mysql_mutex_lock(&mutex);
thd->enter_cond(&condition_variable, &mutex, new_message);
#if defined(ENABLE_DEBUG_SYNC)
if (!thd->killed && !end_of_wait_condition)
   DEBUG_SYNC(thd, "sync_point_name");
#endif
while (!thd->killed && !end_of_wait_condition)
  mysql_cond_wait(&condition_variable, &mutex);
thd->exit_cond(old_message);
```

Here are some explanations:

`thd->enter_cond()` is used to register the condition variable and the mutex in `thd->mysys_var`. This is done to allow the thread to be interrupted (killed) from its sleep. Another thread can find the condition variable to signal and mutex to use for synchronization in this thread's `THD::mysys_var`.

`thd->enter_cond()` requires the mutex to be acquired in advance.

`thd->exit_cond()` unregisters the condition variable and mutex and releases the mutex.

If you want to have a Debug Sync point with the wait, please place it behind `enter_cond()`. Only then you can safely decide, if the wait will be taken. Also you will have `THD::proc_info` correct when the sync point emits a signal. `DEBUG_SYNC` sets its own proc_info, but restores the previous one before releasing its internal mutex. As soon as another thread sees the signal, it does also see the proc_info from before entering the sync point. In this case it will be "new_message", which is associated with the wait that is to be synchronized.

In the example above, the wait condition is repeated before the sync point. This is done to skip the sync point, if no wait takes place. The sync point is before the loop (not inside the loop) to have it hit once only. It is possible that the condition variable is signaled multiple times without the wait condition to be true.

A bit off-topic: At some places, the loop is taken around the whole synchronization pattern:

```
while (!thd->killed && !end_of_wait_condition)
{
  mysql_mutex_lock(&mutex);
  thd->enter_cond(&condition_variable, &mutex, new_message);
  if (!thd->killed [&& !end_of_wait_condition])
  {
    [DEBUG_SYNC(thd, "sync_point_name");]
    mysql_cond_wait(&condition_variable, &mutex);
  }
  thd->exit_cond(old_message);
}
```

Note that it is important to repeat the test for thd->killed after `enter_cond()` . Otherwise the killing thread may kill this thread after it tested `thd->killed` in the loop condition and before it registered the condition variable and mutex in `enter_cond()` . In this case, the killing thread does not know that this thread is going to wait on a condition variable. It would just set `THD::killed` . But if we would not test it again, we would go asleep though we are killed. If the killing thread would kill us when we are after the second test, but still before sleeping, we hold the mutex, which is registered in mysys_var. The killing thread would try to acquire the mutex before signaling the condition variable. Since the mutex is only released implicitly in `mysql_cond_wait()` , the signaling happens at the right place. We have a safe synchronization.

Co-work with the DBUG facility

When running the MariaDB test suite with the `--debug-dbug` command line option, the Debug Sync Facility writes trace messages to the DBUG trace. The following shell commands proved very useful in extracting relevant information:

```
egrep 'query:|debug_sync_exec:' mysql-test/var/log/mysqld.1.trace
```

It shows all executed SQL statements and all actions executed by synchronization points.

Sometimes it is also useful to see, which synchronization points have been run through (hit) with or without executing actions. Then add `"|debug_sync_point:"` to the egrep pattern.

Synchronizing DEBUG_SYNC Actions

Tests may need additional synchronization mechanisms between `DEBUG_SYNC` actions, because certain combinations of actions can result in lost signals. More specifically, once a `SIGNAL` action is issued, it is stored in a global variable for any waiting threads to determine if they are depending on that signal for continuing. However, if a subsequent action overwrites that variable before a waiting thread is able to check against it, the original signal is lost. Examples of actions which would change the variable state are another `SIGNAL` or a `RESET` . Therefore, before issuing these commands, the test writer should verify the previous signal has been acknowledged. The following code snippets show an example of a problematic pattern and a potential solution.

```
SET DEBUG_SYNC='now SIGNAL sig';
SET DEBUG_SYNC='RESET'; # Problematic because sig can be cleared before a waiting thread can
acknowledge it
```

```
SET DEBUG_SYNC='now SIGNAL sig';

# Don't issue the RESET until we have proven the waiting thread has received the signal
let $wait_condition= select count(*)=0 from information_schema.processlist where state like
"debug sync point%";
source include/wait_condition.inc;

SET DEBUG_SYNC='RESET'; # Now this is safe
```

1.3.18.9 Code Coverage with dgcov

Contents

The dgcov tool helps you check the coverage for new code. The dgcov.pl script is part of the mariadb-test framework (and any packages that include mariadb-test).

Overview

The dgcov program runs gcov for code coverage analysis, aggregates the coverage data, and (optionally) reports coverage only for those lines that are changed by the commit(s). Commits are specified in the `git diff` format.

If no commits are specified, the default is to work on all uncommitted changes, if any, otherwise on the last commit (in other words, on `git diff HEAD` or `git diff HEAD^`).

It's recommended that a developer runs dgcov on their new code before pushing it into a MariaDB repository.

Usage

```
./dgcov.pl --help
./dgcov.pl [options] [<commit> [<commit>]]
```

Options and Variables

Short Option	Long Option	Description
`-h`	`--help`	Print help and exit
`-v`	`--verbose`	Show commands run.
`-p`	`--purge`	Delete all test coverage information, to prepare for a new coverage test.
`-o`	`--only-gcov`	Stop after running gcov, don't run git
`-s`	`--skip-gcov`	Do not run gcov, assume .gcov files are already in place
`-g`	`--generate`	Create .dgcov files for all source files

How to Prepare the Code for dgcov

Prior to running this tool, MariaDB should be built with

```
  cmake -DENABLE_GCOV=ON
```

and the testsuite should be run. dgcov will report the coverage for all lines modified in the specified commits.

Output

Output .dgcov files have a conventional gcov format: lines not covered are prefixed with `#####` , lines without generated code are prefixed with `-` , and other lines are prefixed with the number of times they were executed. See `info gcov` for more information.

The patch-like coverage for commits uses gcov format (as above) for lines, changed in these commits, and no prefix at all for lines that were not changed.

Examples

Checking the coverage for all unpushed commits:

```
dgcov.pl @{u} HEAD
```

Checking the coverate for all uncommitted changes:

```
dgcov.pl HEAD
```

Checking the coverage for a specific commit 1234567:

```
dgcov.pl 1234567^ 1234567
```

mariadb-test-run can invoke dgcov automatically:

```
./mtr --gcov
```

in the latter case the coverate for the uncommitted changes (or the last commit) will be not printed to the stdout, but will be put into `var/last_changes.dgcov` file.

Caveats

Note that to be able to run gcov with the mariadb-test framework you need to have gcc version 4.8 or newer.

References

- dgcov was created by Kristian Nielsen and was first announced here.
- dgcov was re-implemented to aggregate the data and to work for git and cmake by Sergei Golubchik.

1.3.18.10 Installing MinIO for Usage With mariadb-test-run

When testing the S3 storage engine with the s3 test suite, mariadb-test-run needs access to Amazon S3 compatible storage.

The easiest way to achieve this is to install MinIO, an open source S3 compatible storage.

Here is a shell script that you can use to install MinIO with the right credentials for mariadb-test-run. This should work on most Linux systems as the binaries are statically linked. You can alternatively download MinIO binaries directly from here.

```
# Where to install the MinIO binaries and where to store the data
install=/my/local/minio
data=/tmp/shared

# Get the MinIO binaries. You can skip this test if you already have MinIO installed.
mkdir -p $install
wget https://dl.min.io/server/minio/release/linux-amd64/minio -O $install/minio
wget https://dl.min.io/client/mc/release/linux-amd64/mc -O $install/mc
chmod a+x $install/minio $install/mc

# Setup MinIO for usage with mariadb-test-run
MINIO_ACCESS_KEY=minio MINIO_SECRET_KEY=minioadmin $install/minio server $data 2>&1 &
$install/mc config host add local http://127.0.0.1:9000 minio minioadmin
$install/mc mb --ignore-existing local/storage-engine
```

Now you can run the S3 test suite:

```
cd "mysql-source-dir"/mariadb-test
./mariadb-test-run --suite=s3
```

If there is an issue while running the test suite, you can see the files created by MinIO with:

```
$install/mc ls -r local/storage-engine
```

or

```
ls $data/storage-engine
```

If you want to use MinIO with different credentials or you want to run the test against another S3 storage you ave to update the update the following files:

```
mariadb-test/suite/s3/my.cnf
mariadb-test/suite/s3/slave.cnf
```

1.3.19 perror

Contents

perror is a utility that displays descriptions for system or storage engine error codes.

See MariaDB Error Codes for a full list of MariaDB error codes, and Operating System Error Codes for a list of Linux and Windows error codes.

Usage

```
perror [OPTIONS] [ERRORCODE [ERRORCODE...]]
```

If you need to describe a negative error code, use `--` before the first error code to end the options.

Options

Option	Description
`-?`, `--help`	Display help and exit.
`-I`, `--info`	Synonym for `--help`.
`-s`, `--silent`	Only print the error message.
`-v`, `--verbose`	Print error code and message (default). (Defaults to on; use `--skip-verbose` to disable.)
`-V`, `--version`	Displays version information and exits.

Examples

System error code:

```
shell> perror 96
OS error code  96:  Protocol family not supported
```

MariaDB/MySQL error code:

```
shell> perror 1005 1006
MySQL error code 1005 (ER_CANT_CREATE_TABLE): Can't create table %`s.%`s (errno: %M)
MySQL error code 1006 (ER_CANT_CREATE_DB): Can't create database '%-.192s' (errno: %M)
```

```
shell> perror --silent 1979
You are not owner of query %lu
```

1.3.20 replace Utility

Description

The replace utility program changes strings in place in files or on the standard input. Invoke replace in one of the following ways:

```
shell> replace from to [from to] ... -- file_name [file_name] ...
shell> replace from to [from to] ... < file_name
```

" `from` " represents a string to look for and " `to` " represents its replacement. There can be one or more pairs of strings.

A from-string can contain these special characters:

Character	Description
`\^`	Match start of line.
`\$`	Match end of line.
`\b`	Match space-character, start of line or end of line. For an end `\b` the next replace starts looking at the end space-character. A `\b` alone in a string matches only a space-character

Use the `--` option to indicate where the string-replacement list ends and the file names begin. Any file named on the command line is modified in place, so you may want to make a copy of the original before converting it. `replace` prints a message indicating which of the input files it actually modifies.

If the `--` option is not given, replace reads standard input and writes to standard output.

replace uses a finite state machine to match longer strings first. It can be used to swap strings. For example, the following command swaps "a" and "b" in the given files, /file1 *and* file2*:*

```
shell> replace a b b a -- file1 file2 ...
```

The replace program is used by msql2mysql.

Options

`replace` supports the following options.

Option	Description
`-?, -I`	Display a help message and exit.
`-#debug_options`	Enable debugging.
`-s`	Silent mode. Print less information about what the program does.
`-v`	Verbose mode. Print more information about what the program does.
`-V`	Display version information and exit.

1.3.21 resolveip

Contents

resolveip is a utility for resolving IP addresses to host names and vice versa.

Usage

```
resolveip [OPTIONS] hostname or IP-address
```

Options

Option	Description
`-?, --help`	Display help and exit.

`-I`, `--info`	Synonym for `--help`.
`-s`, `--silent#`	Be more silent.
`-V`, `--version`	Display version information and exit.

Examples

```
shell> resolveip mariadb.org
IP address of mariadb.org is 166.78.144.191
```

```
resolveip 166.78.144.191
Host name of 166.78.144.191 is mariadb.org
```

1.3.22 resolve_stack_dump

resolve_stack_dump is a tool that resolves numeric stack strace dumps into symbols.

Usage

```
resolve_stack_dump [OPTIONS] symbols-file [numeric-dump-file]
```

The symbols-file should include the output from: `nm --numeric-sort mysqld`. The numeric-dump-file should contain a numeric stack trace from mysqld. If the numeric-dump-file is not given, the stack trace is read from stdin.

Options

Option	Description
`-h`, `--help`	Display this help and exit.
`-V`, `--version`	Output version information and exit.
`-s`, `--symbols-file=name`	Use specified symbols file.
`-n`, `--numeric-dump-file=name`	Read the dump from specified file.

1.3.23 xtstat

Contents

`xtstat` can be used to monitor all internal activity of PBXT.

`xtstat` polls the `INFORMATION_SCHEMA.PBXT_STATISTICS` table. The poll interval can be set using the `--delay` option, and is 1 second by default.

For most statistics, `xtstat` will display the difference in values between the current and previous polls. For example, if bytes written current value is 1000, and on the previous call it was 800, then `xtstat` will display 200. This means that 200 bytes were written to disk in the intervening period.

Using `xtstat`

Invoke xtstat as follows:

```
$ xtstat [ options ]
```

For example, to poll every 10 seconds:

```
xtstat -D10
```

Note that statistic counters are never reset, even if a rollback occurs. For example, if an `UPDATE` statement is rolled back, `xtstat` will still indicate that one write statement (see stat-write below) was executed.

If MariaDB shuts down or crashes, `xtstat` will attempt to reconnect. `xtstat` can be terminated any time using the `CTRL-C` key cimbination.

Before PBXT has recovered, not all statistics are available. In particular, the statistics relating to PBXT background threads are not available (including the `sweep` and `chkpnt` statistics).

Command line options

`xtstat` options are as follows:

Option	Description
`-?, --help`	Prints help text.
`-h, --host=value`	Connect to host.
`-u, --user=value`	User for login if not current user.
`-p, --password[=value]`	Password to use when connecting to server. If password is not given it's asked from the tty.
`-d, --database=value`	Database to be used (`pbxt` or `information_schema` required), default is `information_schema`
`-P, --port=value`	Port number to use for connection.
`-S, --socket=value`	Socket file to use for connection.
`-D, --delay=value`	Delay in seconds between polls of the database.
`--protocol=value`	Connection protocol to use: `default/tcp/socket/pipe/memory`
`--display=value`	Columns to display: use short names separated by `|` (the pipe character), partial match allowed. Use `--display=all` to display all columns available.

Connection options will also be taken from the MySQL config file if available.

Size indicators

Values displayed by `xtstat` are either a time in milliseconds, a value in bytes, or a counter. If these values are too large to be displayed then the value is rounded and a size indicator is added.

The following size indicators are used:

- `K` : Kilobytes *(1,024 bytes)*
- `M` : Megabytes *(1,048,576 bytes)*
- `G` : Gigabytes *(1,073,741,024 bytes)*
- `T` : Terabytes *(1,099,511,627,776 bytes)*
- `t` : thousands *(1,000s)*
- `m` : millions *(1,000,000s)*
- `b` : billions *(1,000,000,000s)*

Statistics

The following is a list of the statistics displayed by `xtstat` . Each statistic as a two-part display name. The first part is the

category and the second part is the type.

You can select categories and types for display, as you require. For example `--display=read` will display all read activity, `--display=xact|stat` will display transaction and statement activity.

Note, for diagnostics it is best to capture all statistics. The reason is because you never now where a problem might turn up, so without certain statistics you may not be able to identify the problem.

Display name	Name	Description
`time-curr`	Current Time	The current time in seconds
`time-msec`	Time Since Last Call	Time passed in milliseconds since last statistics call
`xact-commt`	Commit Count	Number of transactions committed
`xact-rollb`	Rollback Count	Number of transactions rolled back
`xact-waits`	Wait for Xact Count	Number of times waited for another transaction
`xact-dirty`	Dirty Xact Count	Number of transactions still to be cleaned up. This also includes all the currently running transactions. Cleanup means that the Sweeper thread must still scan the transcation and collect/mark any "garbage" left by the transaction. Garbage is, for example, versions of rows that are no longer visiable by any transaction.
`stat-read`	Read Statements	Number of SELECT statements
`stat-write`	Write Statements	Number of UPDATE/INSERT/DELETE statements
`rec-in`	Record Bytes Read	Bytes read from the record/row files
`rec-out`	Record Bytes Written	Bytes written to the record/row files. This data is transfered from the transaction logs to the handle data (xtd) and the row index files (xtr).
`rec-syncs/ms`	Record File Flushes	2 values separated by a '/': the number of flushes to data handle (.xtd) and row index (.xtr) files and the time taken in milliseconds to perform the flush operations.
`rec-hits`	Record Cache Hits	Hits when accessing the record cache. The record cache caches the data handle (.xtd) and row index (.xtr) files.
`rec-miss`	Record Cache Misses	Misses when accessing the record cache
`rec-frees`	Record Cache Frees	Number of record cache pages freed
`rec-%use`	Record Cache Usage	Percentage of record cache in use. This value is displayed by xtstat as a percentage of the total cache available, but the value returned by PBXT_STATISTICS table is in bytes used.
`ind-in`	Index Bytes Read	Bytes read from the index files
`ind-out`	Index Bytes Written	Bytes written to the index files. This data is transfered from the index log files (ilog) to the index files (xti), during a consistent flush of the index.
`ind-syncs/ms`	Index File Flushes	2 values separated by a '/': the number of flushes to index files and the time taken for the flush operations in milliseconds.
`ind-hits`	Index Cache Hits	Hits when accessing the index cache
`ind-miss`	Index Cache Misses	Misses when accessing the index cache
`ind-%use`	Index Cache Usage	Percentage of index cache used. This value is displayed by xtstat as a percentage of the total cache available, but the value returned by PBXT_STATISTICS table is in bytes used.
`ilog-in`	Index Log Bytes In	Bytes read from the index log files
`ilog-out`	Index Log Bytes Out	Bytes written to the index log files. This data is transfered from the index cache in main memory to the index log files (ilog) during a consistent flush of the index.
`ilog-syncs/ms`	Index Log File Syncs	2 values separated by a '/': the number of flushes to index log files and the time taken for the flush operations in milliseconds
`xlog-in`	Xact Log Bytes In	Bytes read from the transaction log files
`xlog-out`	Xact Log Bytes Out	Bytes written to the transaction log files. This is data transfered from the transaction log buffer (pbxt_transaction_buffer_size) to the transaction log files (.xlog). This transfer occurs on commit or when the transaction log buffer is full.
`xlog-syncs`	Xact Log File Syncs	Number of flushes to transaction log files

`xlog-msec`	Xact Log Sync Time	The time in milliseconds to flush transaction log files
`xlog-hits`	Xact Log Cache Hits	Hits when accessing the transaction log cache
`xlog-miss`	Xact Log Cache Misses	Misses when accessing the transaction log cache
`xlog-%use`	Xact Log Cache Usage	Percentage of transaction log cache used. This value is displayed by xtstat as a percentage of the total cache available, but the value returned by PBXT_STATISTICS table is in bytes used.
`data-in`	Data Log Bytes In	Bytes read from the data log files
`data-out`	Data Log Bytes Out	Bytes written to the data log files. This data is transfered from the data log buffer (pbxt_log_buffer_size) to the data log files (.dlog), when the buffer is full, or on commit.
`data-syncs`	Data Log File Syncs	Number of flushes to data log files
`data-msec`	Data Log Sync Time	The time in milliseconds spent flushing data log files
`to-chkpt`	Bytes to Checkpoint	Bytes written to the transaction log since the last checkpoint
`to-write`	Log Bytes to Write	Bytes written to the transaction log, still to be written to the database
`to-sweep`	Log Bytes to Sweep	Bytes written to the transaction log, still to be read by the Sweeper thread
`sweep-waits`	Sweeper Wait on Xact	Attempts to cleanup a transaction
`scan-index`	Index Scan Count	Number of index scans
`scan-table`	Table Scan Count	Number of table scans
`row-sel`	Select Row Count	Number of rows selected
`row-ins`	Insert Row Count	Number of rows inserted
`row-upd`	Update Row Count	Number of rows updated
`row-del`	Delete Row Count	Number of rows deleted

More Information

Documentation on this page is based on the xtstat documentation on the PrimeBase website.

Paul McCullagh's presentation from the 2010 User's Conference has some usage examples:
http://www.primebase.org/download/pbxt-uc-2010.pdf

1.3.24 mariadb-access

`mariadb-access` is a tool for checking access privileges, developed by Yves Carlier.

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-access` is a symlink to `mysqlaccess`.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadb-access` is the name of the tool, with `mysqlaccess` a symlink.

Contents

It checks the access privileges for a host name, user name, and database combination. Note that mariadb-access checks access using only the user, db, and host tables. It does not check table, column, or routine privileges specified in the tables_priv, columns_priv, or procs_priv tables.

Usage

```
mariadb-access [host [user [db]]] OPTIONS
```

If your MariaDB distribution is installed in some non-standard location, you must change the location where *mariadb-access* expects to find the mariadb client. Edit the *mariadb-access* script at approximately line 18. Search for a line that looks like this: <<code> $MYSQL = ´/usr/local/bin/mariadb; # path to mariadb executable <</code>> Change the path to reflect the location where *mariadb* actually is stored on your system. If you do not do this, a *Broken pipe error* will occur when you run *mariadb-access*.

Options

Option	Description
`-?, --help`	Displayhelp and exit.
`-v, --version`	Display version.
`-u username, --user=username`	Username for logging in to the db.
`-p[password], --password[=password]`	Password to use for user. If ommitted, `mariadb-access` prompts for one.
`-h hostname, --host=hostname`	Name or IP of the host.
`-d dbname, --db=dbname`	Name of the database.
`-U username, --superuser=username`	Connect as superuser.
`-P password, --spassword=password`	Password for superuser.
`-H server, --rhost=server`	Remote server to connect to.
`--old_server`	Connect to a very old MySQL servers (before version 3.21) that does not know how to handle full WHERE clauses.
`-b, --brief`	Single-line tabular report.
`-t, --table`	Report in table-format.
`--relnotes`	Print release-notes.
`--plan`	Print suggestions/ideas for future releases.
`--howto`	Some examples of how to run `mariadb-access'.
`--debug=N`	Enter debug level N (0..3).
`--copy`	Reload temporary grant-tables from original ones.
`--preview`	Show differences in privileges after making changes in (temporary) grant-tables.
`--commit`	Copy grant-rules from temporary tables to grant-tables (the grant tables must be flushed after, for example with mariadb-admin reload).
`--rollback`	Undo the last changes to the grant-tables.

Note

At least the user (`-u`) and the database (`-d`) must be given, even with wildcards. If no host is provided, `localhost' is assumed. Wildcards (*,?,%,_) are allowed for *host*, *user* and *db*, but be sure to escape them from your shell!! (ie type * or '*')

1.3.25 mariadb-admin

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-admin` is a symlink to `mysqladmin`, the administration program for the mysqld daemon.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadb-admin` is the name of the administration program for the mysqld daemon, with

`mysqladmin` a symlink .

Contents

`mariadb-admin` is an administration program for the mysqld daemon. It can be used to:

- Monitor what the MariaDB clients are doing (processlist)
- Get usage statistics and variables from the MariaDB server
- Create/drop databases
- Flush (reset) logs, statistics and tables
- Kill running queries.
- Stop the server (shutdown)
- Start/stop replicas
- Check if the server is alive (ping)

Using mariadb-admin

The command to use `mariadb-admin` and the general syntax is:

```
mariadb-admin [options] command [command-arg] [command [command-arg]] ...
```

Options

`mariadb-admin` supports the following options:

Option	Description
`--character-sets-dir=name`	Directory where the character set files are located.
`-C , --compress`	Compress all information sent between the client and the server if both support compression.
`--connect_timeout=val`	Maximum time in seconds before connection timeout. The default value is 43200 (12 hours).
`-c val , --count=val`	Number of iterations to make. This works with `-i` (`--sleep`) only.
`--debug[=debug_options] , -# [debug_options]`	Write a debugging log. A typical debug_options string is `d:t:o,file_name` . The default is `d:t:o,/tmp/mysqladmin.trace` .
`--debug-check`	Check memory and open file usage at exit.
`--debug-info`	Print debugging information and memory and CPU usage statistics when the program exits.
`--default-auth=plugin`	Default authentication client-side plugin to use.
`--default-character-set=name`	Set the default character set.
`-f , --force`	Don't ask for confirmation on drop database; with multiple commands, continue even if an error occurs.
`-? , --help`	Display this help and exit.
`-h name , --host=name`	Hostname to connect to.
`-l , --local`	Suppress the SQL command(s) from being written to the binary log by enabling sql_log_bin=0 for the session, or, from MariaDB 10.2.7 and MariaDB 10.1.24, for flush commands only, using `FLUSH LOCAL` rather than `SET sql_log_bin=0` , so the privilege requirement is RELOAD rather than SUPER.

`-b , --no-beep`	Turn off beep on error.
`-p[password] , --password[=password]`	Password to use when connecting to server. If password is not given it's asked from the terminal.
`--pipe , -W`	On Windows, connect to the server via a named pipe. This option applies only if the server supports named-pipe connections.
`-P portnum , --port=portnum`	Port number to use for connection, or 0 for default to, in order of preference, my.cnf, $MYSQL_TCP_PORT, /etc/services, built-in default (3306).
`--protocol=name`	The protocol to use for connection (tcp, socket, pipe, memory).
`-r , --relative`	Show difference between current and previous values when used with `-i` . Currently only works with extended-status.
`-O value , --set-variable=vaue`	Change the value of a variable. Please note that this option is deprecated; you can set variables directly with `--variable-name=value` .
`--shutdown_timeout=val`	Maximum number of seconds to wait for server shutdown. The default value is 3600 (1 hour).
`-s , --silent`	Silently exit if one can't connect to server.
`-i delay , --sleep=delay`	Execute commands repeatedly, sleeping for *delay* seconds in between. The `--count` option determines the number of iterations. If `--count` is not given, *mariadb-admin* executes commands indefinitely until interrupted.
`-S name , --socket=name`	For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.
`--ssl`	Enables TLS. TLS is also enabled even without setting this option when certain other TLS options are set. The `--ssl` option will not enable verifying the server certificate by default. In order to verify the server certificate, the user must specify the `--ssl-verify-server-cert` option.
`--ssl-ca=name`	Defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option implies the `--ssl` option.
`--ssl-capath=name`	Defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the `openssl rehash` command. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option is only supported if the client was built with OpenSSL or yaSSL. If the client was built with GnuTLS or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms. This option implies the `--ssl` option.
`--ssl-cert=name`	Defines a path to the X509 certificate file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.
`--ssl-cipher=name`	List of permitted ciphers or cipher suites to use for TLS. This option implies the `--ssl` option.
`--ssl-crl=name`	Defines a path to a PEM file that should contain one or more revoked X509 certificates to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL or Schannel. If the client was built with yaSSL or GnuTLS, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

`--ssl-crlpath=name`	Defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the `openssl rehash` command. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL. If the client was built with yaSSL, GnuTLS, or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
`--ssl-key=name`	Defines a path to a private key file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.
`--ssl-verify-server-cert`	Enables server certificate verification. This option is disabled by default.
`--tls-version=name`	This option accepts a comma-separated list of TLS protocol versions. A TLS protocol version will only be enabled if it is present in this list. All other TLS protocol versions will not be permitted. See Secure Connections Overview: TLS Protocol Versions for more information.
`-u`, `--user=name`	User for login if not current user.
`-v`, `--verbose`	Write more information.
`-V`, `--version`	Output version information and exit.
`-E`, `--vertical`	Print output vertically. Is similar to ' `--relative` ', but prints output vertically.
`-w[count]`, `--wait[=count]`	If the connection cannot be established, wait and retry instead of aborting. If a *count* value is given, it indicates the number of times to retry. The default is one time.
`--wait-for-all-slaves`	Wait for the last binlog event to be sent to all connected replicas before shutting down. This option is off by default.

Option Files

In addition to reading options from the command-line, `mariadb-admin` can also read options from option files. If an unknown option is provided to `mariadb-admin` in an option file, then it is ignored.

The following options relate to how MariaDB command-line tools handles option files. They must be given as the first argument on the command-line:

Option	Description
`--print-defaults`	Print the program argument list and exit.
`--no-defaults`	Don't read default options from any option file.
`--defaults-file=#`	Only read default options from the given file #.
`--defaults-extra-file=#`	Read this file after the global files are read.
`--defaults-group-suffix=#`	In addition to the default option groups, also read option groups with this suffix.

`mariadb-admin` is linked with MariaDB Connector/C. However, MariaDB Connector/C does not yet handle the parsing of option files for this client. That is still performed by the server option file parsing code. See MDEV-19035 for more information.

Option Groups

`mariadb-admin` reads options from the following option groups from option files:

Group	Description
`[mysqladmin]`	Options read by `mysqladmin`, which includes both MariaDB Server and MySQL Server.
`[mariadb-admin]`	Options read by `mariadb-admin`. Available starting with MariaDB 10.4.6.
`[client]`	Options read by all MariaDB and MySQL client programs, which includes both MariaDB and MySQL clients. For example, `mysqldump`.

`[client-server]`	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
`[client-mariadb]`	Options read by all MariaDB client programs.

mariadb-admin Variables

Variables can be set with `--variable-name=value`.

Variables and boolean options	Value
`count`	`0`
`debug-check`	`FALSE`
`debug-info`	`FALSE`
`force`	`FALSE`
`compress`	`FALSE`
`character-sets-dir`	*(No default value)*
`default-character-set`	*(No default value)*
`host`	*(No default value)*
`no-beep`	`FALSE`
`port`	`3306`
`relative`	`FALSE`
`socket`	`/var/run/mysqld/mysqld.sock`
`sleep`	`0`
`ssl`	`FALSE`
`ssl-ca`	*(No default value)*
`ssl-capath`	*(No default value)*
`ssl-cert`	*(No default value)*
`ssl-cipher`	*(No default value)*
`ssl-key`	*(No default value)*
`ssl-verify-server-cert`	`FALSE`
`user`	*(No default value)*
`verbose`	`FALSE`
`vertical`	`FALSE`
`connect_timeout`	`43200`
`shutdown_timeout`	`3600`

mariadb-admin Commands

```
mariadb-admin [options] command [command-arg] [command [command-arg]] ...
```

Command is one or more of the following. Commands may be shortened to a unique prefix.

Command	Description
`create databasename`	Create a new database.
`debug`	Instruct server to write debug information to log.

`drop databasename`	Delete a database and all its tables.
`extended-status`	Return all status variables and their values.
`flush-all-statistics`	Flush all statistics tables
`flush-all-status`	Flush status and statistics.
`flush-binary-log`	Flush binary log.
`flush-client-statistics`	Flush client statistics.
`flush-engine-log`	Flush engine log.
`flush-error-log`	Flush error log.
`flush-general-log`	Flush general query log.
`flush-hosts`	Flush all cached hosts.
`flush-index-statistics`	Flush index statistics.
`flush-logs`	Flush all logs.
`flush-privileges`	Reload grant tables (same as reload).
`flush-relay-log`	Flush relay log.
`flush-slow-log`	Flush slow query log.
`flush-ssl`	Flush SSL certificates. Added in MariaDB 10.6.0.
`flush-status`	Clear status variables.
`flush-table-statistics`	Clear table statistics.
`flush-tables`	Flush all tables.
`flush-threads`	Flush the thread cache.
`flush-user-resources`	Flush user resources.
`flush-user-statistics`	Flush user statistics.
`kill id,id,...`	Kill mysql threads.
`password new-password`	Change old password to new-password. The new password can be passed on the commandline as the next argument (for example, `mariadb-admin password "new_password"`, or can be omitted (as long as no other command follows), in which case the user will be prompted for a password. If the password contains special characters, it needs to be enclosed in quotation marks. In Windows, the quotes can only be double quotes, as single quotes are assumed to be part of the password. If the server was started with the --skip-grant-tables option, changing the password in this way will have no effect.

`old-password new-password`	Change old password to new-password using the old pre-MySQL 4.1 format.
`ping`	Check if mysqld is alive. Return status is 0 if the server is running (even in the case of an error such as access denied), 1 if it is not.
`processlist`	Show list of active threads in server, equivalent to SHOW PROCESSLIST. With `--verbose`, equivalent to SHOW FULL PROCESSLIST.
`reload`	Reload grant tables.
`refresh`	Flush all tables and close and open log files.
`shutdown`	Take server down by executing the SHUTDOWN command on the server. If connected to a local server using a Unix socket file, mariadb-admin waits until the server's process ID file has been removed to ensure that the server has stopped properly. See also the `--wait-for-all-slaves` option.
`status`	Gives a short status message from the server.
`start-all-slaves`	Start all replicas.
`start-slave`	Start replication on a replica server.
`stop-all-slaves`	Stop all replicas.
`stop-slave`	Stop replication on a replica server.
`variables`	Prints variables available.
`version`	Returns version as well as status info from the server.

The shutdown Command and the --wait-for-all-slaves Option

The `--wait-for-all-slaves` option was first added in MariaDB 10.4.4. When a primary server is shutdown and it goes through the normal shutdown process, the primary kills client threads in random order. By default, the primary also considers its binary log dump threads to be regular client threads. As a consequence, the binary log dump threads can be killed while client threads still exist, and this means that data can be written on the primary during a normal shutdown that won't be replicated. This is true even if semi-synchronous replication is being used.

In MariaDB 10.4 and later, this problem can be solved by shutting down the server with the mariadb-admin utility and by providing the `--wait-for-all-slaves` option to the utility and by executing the `shutdown` command with the utility. For example:

```
mariadb-admin --wait-for-all-slaves shutdown
```

When the `--wait-for-all-slaves` option is provided, the server only kills its binary log dump threads after all client threads have been killed, and it only completes the shutdown after the last binary log has been sent to all connected replicas.

See Replication Threads: Binary Log Dump Threads and the Shutdown Process for more information.

Examples

Quick check of what the server is doing:

```
shell> mariadb-admin status
Uptime: 8023 Threads: 1 Questions: 14 Slow queries: 0 Opens: 15 Flush tables: 1 Open tables: 8
Queries per second avg: 0.1
shell> mariadb-admin processlist
+----+-------+-----------+----+---------+------+-------+------------------+
| Id | User | Host | db | Command | Time | State | Info |
+----+-------+-----------+----+---------+------+-------+------------------+
....
+----+-------+-----------+----+---------+------+-------+------------------+
```

More extensive information of what is happening 'just now' changing (great for troubleshooting a slow server):

```
shell> mariadb-admin --relative --sleep=1 extended-status | grep -v " 0 "
```

Check the variables for a running server:

```
shell> mariadb-admin variables | grep datadir
| datadir | /my/data/ |
```

Using a shortened prefix for the `version` command:

```
shell> mariadb-admin ver
mariadb-admin from 11.1.0-preview-MariaDB, client 9.1 for linux-systemd (x86_64)
Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Server version  11.1.0-preview-MariaDB
Protocol version 10
Connection  localhost via TCP/IP
TCP port  11100
Uptime:   3 min 21 sec

Threads: 1  Questions: 1  Slow queries: 0  Opens: 17  Open tables: 10  Queries per second avg:
0.004
```

Other Ways To Stop mysqld (Unix)

If you get the error:

```
mariadb-admin: shutdown failed; error: 'Access denied; you need (at least one of) the SHUTDOWN
privilege(s) for this operation'
```

It means that you didn't use `mariadb-admin` with a user that has the SUPER or SHUTDOWN privilege.

If you don't know the user password, you can still take the mysqld process down with a system `kill` command:

```
kill -SIGTERM pid-of-mysqld-process
```

The above is identical to `mariadb-admin shutdown` .

On windows you should use:

```
NET STOP MySQL
```

You can use the SHUTDOWN command from any client.

1.3.26 mariadb-check

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-check` is a symlink to `mysqlcheck` , the tool for checking, repairing, analyzing and optimizing tables.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadb-check` is the name of the tool, with `mysqlcheck` a symlink .

Contents

`mariadb-check` is a maintenance tool that allows you to check, repair, analyze and optimize multiple tables from the command line.

It is essentially a commandline interface to the CHECK TABLE, REPAIR TABLE, ANALYZE TABLE and OPTIMIZE TABLE commands, and so, unlike myisamchk and aria_chk, requires the server to be running.

This tool does not work with partitioned tables.

Using mariadb-check

```
./client/mariadb-check [OPTIONS] database [tables]
```

OR

```
./client/mariadb-check [OPTIONS] --databases DB1 [DB2 DB3...]
```

OR

```
./client/mariadb-check [OPTIONS] --all-databases
```

`mariadb-check` can be used to CHECK (-c, -m, -C), REPAIR (-r), ANALYZE (-a), or OPTIMIZE (-o) tables. Some of the options (like -e or -q) can be used at the same time. Not all options are supported by all storage engines.

The -c, -r, -a and -o options are exclusive to each other.

The option `--check` will be used by default, if no other options were specified. You can change the default behavior by making a symbolic link to the binary, or copying it somewhere with another name, the alternatives are:

`mysqlrepair`	The default option will be `-r` (`--repair`)
`mysqlanalyze`	The default option will be `-a` (`--analyze`)
`mysqloptimize`	The default option will be `-o` (`--optimize`)

Options

`mariadb-check` supports the following options:

Option	Description
`-A` , `--all-databases`	Check all the databases. This is the same as `--databases` with all databases selected.
`-1` , `--all-in-1`	Instead of issuing one query for each table, use one query per database, naming all tables in the database in a comma-separated list.
`-a` , `--analyze`	Analyze given tables.
`--auto-repair`	If a checked table is corrupted, automatically fix it. Repairing will be done after all tables have been checked.
`--character-sets-dir=name`	Directory where character set files are installed.
`-c` , `--check`	Check table for errors.
`-C` , `--check-only-changed`	Check only tables that have changed since last check or haven't been closed properly.
`-g` , `--check-upgrade`	Check tables for version-dependent changes. May be used with `--auto-repair` to correct tables requiring version-dependent updates. Automatically enables the `--fix-db-names` and `--fix-table-names` options. Used when upgrading
`--compress`	Compress all information sent between the client and server if both support compression.
`-B` , `--databases`	Check several databases. Note that normally *mariadb-check* treats the first argument as a database name, and following arguments as table names. With this option, no tables are given, and all name arguments are regarded as database names.

`-# , --debug[=name]`	Output debug log. Often this is 'd:t:o,filename'.
`--debug-check`	Check memory and open file usage at exit.
`--debug-info`	Print some debug info at exit.
`--default-auth=plugin`	Default authentication client-side plugin to use.
`--default-character-set=name`	Set the default character set.
`-e , --extended`	If you are using this option with `--check` , it will ensure that the table is 100 percent consistent, but will take a long time. If you are using this option with `--repair` , it will force using the old, slow, repair with keycache method, instead of the much faster repair by sorting.
`-F , --fast`	Check only tables that haven't been closed properly.
`--fix-db-names`	Convert database names to the format used since MySQL 5.1. Only database names that contain special characters are affected. Used when upgrading from an old MySQL version.
`--fix-table-names`	Convert table names (including views) to the format used since MySQL 5.1. Only table names that contain special characters are affected. Used when upgrading from an old MySQL version.
`--flush`	Flush each table after check. This is useful if you don't want to have the checked tables take up space in the caches after the check.
`-f , --force`	Continue even if we get an SQL error.
`-? , --help`	Display this help message and exit.
`-h name , --host=name`	Connect to the given host.
`-m , --medium-check`	Faster than extended-check, but only finds 99.99 percent of all errors. Should be good enough for most cases.
`-o , --optimize`	Optimize tables.
`-p , --password[=name]`	Password to use when connecting to the server. If you use the short option form (`-p`), you cannot have a space between the option and the password. If you omit the password value following the `--password` or `-p` option on the command line, mariadb-check prompts for one. Specifying a password on the command line should be considered insecure. You can use an option file to avoid giving the password on the command line.
`-Z , --persistent`	When using ANALYZE TABLE (`--analyze`), uses the PERSISTENT FOR ALL option, which forces Engine-independent Statistics for this table to be updated. Added in MariaDB 10.1.10
`-W , --pipe`	On Windows, connect to the server via a named pipe. This option applies only if the server supports named-pipe connections.
`--plugin-dir`	Directory for client-side plugins.
`-P num , --port=num`	Port number to use for connection or 0 for default to, in order of preference, my.cnf, $MYSQL_TCP_PORT, /etc/services, built-in default (3306).
`--process-tables`	Perform the requested operation (check, repair, analyze, optimize) on tables. Enabled by default. Use `--skip-process-tables` to disable.
`--process-views[=val]`	Perform the requested operation (only CHECK VIEW or REPAIR VIEW). Possible values are NO, YES (correct the checksum, if necessary, add the mariadb-version field), UPGRADE_FROM_MYSQL (same as YES and toggle the algorithm MERGE<->TEMPTABLE.
`--protocol=name`	The connection protocol (tcp, socket, pipe, memory) to use for connecting to the server. Useful when other connection parameters would cause a protocol to be used other than the one you want.
`-q , --quick`	If you are using this option with CHECK TABLE, it prevents the check from scanning the rows to check for wrong links. This is the fastest check. If you are using this option with REPAIR TABLE, it will try to repair only the index tree. This is the fastest repair method for a table.
`-r , --repair`	Can fix almost anything except unique keys that aren't unique.

`--shared-memory-base-name`	Shared-memory name to use for Windows connections using shared memory to a local server (started with the `--shared-memory` option). Case-sensitive.
`-s`, `--silent`	Print only error messages.
`--skip-database`	Don't process the database (case-sensitive) specified as argument.
`-S name`, `--socket=name`	For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.
`--ssl`	Enables TLS. TLS is also enabled even without setting this option when certain other TLS options are set. Starting with MariaDB 10.2, the `--ssl` option will not enable verifying the server certificate by default. In order to verify the server certificate, the user must specify the `--ssl-verify-server-cert` option.
`--ssl-ca=name`	Defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option implies the `--ssl` option.
`--ssl-capath=name`	Defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option is only supported if the client was built with OpenSSL or yaSSL. If the client was built with GnuTLS or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms. This option implies the `--ssl` option.
`--ssl-cert=name`	Defines a path to the X509 certificate file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.
`--ssl-cipher=name`	List of permitted ciphers or cipher suites to use for TLS. This option implies the `--ssl` option.
`--ssl-crl=name`	Defines a path to a PEM file that should contain one or more revoked X509 certificates to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL or Schannel. If the client was built with yaSSL or GnuTLS, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
`--ssl-crlpath=name`	Defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL. If the client was built with yaSSL, GnuTLS, or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
`--ssl-key=name`	Defines a path to a private key file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.
`--ssl-verify-server-cert`	Enables server certificate verification. This option is disabled by default.
`--tables`	Overrides the `--databases` or `-B` option such that all name arguments following the option are regarded as table names.
`--use-frm`	For repair operations on MyISAM tables, get table structure from .frm file, so the table can be repaired even if the .MYI header is corrupted.
`-u`, `--user=name`	User for login if not current user.
`-v`, `--verbose`	Print info about the various stages. You can give this option several times to get even more information. See mariadb-check and verbose, below.
`-V`, `--version`	Output version information and exit.

`--write-binlog`	Write ANALYZE, OPTIMIZE and REPAIR TABLE commands to the binary log. Enabled by default; use `--skip-write-binlog` when commands should not be sent to replication slaves.

Option Files

In addition to reading options from the command-line, `mariadb-check` can also read options from option files. If an unknown option is provided to `mariadb-check` in an option file, then it is ignored.

The following options relate to how MariaDB command-line tools handles option files. They must be given as the first argument on the command-line:

Option	Description
`--print-defaults`	Print the program argument list and exit.
`--no-defaults`	Don't read default options from any option file.
`--defaults-file=#`	Only read default options from the given file #.
`--defaults-extra-file=#`	Read this file after the global files are read.
`--defaults-group-suffix=#`	In addition to the default option groups, also read option groups with this suffix.

`mariadb-check` is linked with MariaDB Connector/C. However, MariaDB Connector/C does not yet handle the parsing of option files for this client. That is still performed by the server option file parsing code. See MDEV-19035 for more information.

Option Groups

`mariadb-check` reads options from the following option groups from option files:

Group	Description
`[mysqlcheck]`	Options read by `mysqlcheck`, which includes both MariaDB Server and MySQL Server.
`[mariadb-check]`	Options read by `mariadb-check`. Available starting with MariaDB 10.4.6.
`[client]`	Options read by all MariaDB and MySQL client programs, which includes both MariaDB and MySQL clients. For example, `mysqldump`.
`[client-server]`	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
`[client-mariadb]`	Options read by all MariaDB client programs.

Notes

Default Values

To see the default values for the options and also to see the arguments you get from configuration files you can do:

```
./client/mariadb-check --print-defaults
./client/mariadb-check --help
```

mariadb-check and auto-repair

When running `mariadb-check` with `--auto-repair` (as done by mariadb-upgrade), `mariadb-check` will first check all tables and then in a separate phase repair those that failed the check.

mariadb-check and all-databases

`mariadb-check --all-databases` will ignore the internal log tables general_log and slow_log as these can't be checked, repaired or optimized.

mariadb-check and verbose

Using one `--verbose` option will give you more information about what mariadb-check is doing.

Using two `--verbose` options will also give you connection information.

If you use three `--verbose` options you will also get, on stdout, all ALTER, RENAME, and CHECK commands that mariadb-check executes.

1.3.27 mariadb-conv

MariaDB starting with 10.5.1

`mariadb-conv` is a character set conversion utility for MariaDB and was added in MariaDB 10.5.1.

Contents

Usage

```
mariadb-conv [OPTION...] [FILE...]
```

Options

`mariadb-conv` supports the following options:

Option	Description
-f, --from=name	Specifies the encoding of the input.
-t, --to=name	Specifies the encoding of the output.
-c, --continue	Silently ignore conversion errors.
--delimiter=name	Treat the specified characters as delimiters.

By default, `mariadb-conv` exits whenever it encounters any conversion problems, for example:

- the input byte sequence is not valid in the source character set
- the character cannot be converted to the target character set

The `-c` option makes `mariadb-conv` ignore such errors and use the question mark '?' to replace bytes in bad input sequences, or unconvertable characters.

The `--delimiter=...` option makes `mariadb-conv` treat the specified characters as delimiters rather than data to convert, so the input is treated as a combination of:

- data chunks, which are converted according to the `-f` and `-t` options.
- delimiters, which are not converted and are copied from the input to the output as is.

Examples

Converts the file `file.latin1.txt` from `latin1` to `utf8`.

```
mariadb-conv -f latin1 -t utf8 file.latin1.txt
```

Convert the file `file.latin1.txt` from `latin1` to `utf8`, reading the input data from stdin.

```
mariadb-conv -f latin1 -t utf8 < file.latin1.txt
```

Using mariadb-conv in a pipe:

```
echo test | ./mariadb-conv -f utf8 -t ucs2 >file.ucs2.txt
```

As a side effect, mariadb-conv can be used to list MariaDB data directories in a human readable form. Suppose you create the following tables:

```
SET NAMES utf8;
CREATE OR REPLACE TABLE t1 (a INT);
CREATE OR REPLACE TABLE ß (a INT);
CREATE OR REPLACE TABLE абв (a INT);
CREATE OR REPLACE TABLE 桌子 (a INT);
```

The above makes the server create the following files in the MariaDB data directory:

```
@1j.frm
@1j.ibd
@684c@5b50.frm
@684c@5b50.ibd
@g0@h0@i0.frm
@g0@h0@i0.ibd
t1.frm
t1.ibd
```

It's not precisely clear which file stores which table, because MariaDB uses a special table-name-to-file-name encoding.

This command on Linux (assuming an utf-8 console) can print the table list in a readable way::

```
ls | mariadb-conv -f filename -t utf8 --delimiter=".\n"

ß.frm
ß.ibd
桌子.frm
桌子.ibd
абв.frm
абв.ibd
t1.frm
t1.ibd
```

Note, the `--delimiter=".\n"` option is needed to make `mariadb-conv` treat the dot character (delimiting the encoded table name from the file extension) and the new line character (delimiting separate lines) as delimiters rather than as the data to convert (otherwise the conversion would fail).

Windows users can use the following command to list the data directory in the ANSI text console:

```
dir /b | mariadb-conv -c -f filename -t cp850 --delimiter=".\r\n"
```

Note:

- The `-t` options assume a Western machine.
- The `-c` option is needed to ignore conversion errors for Cyrillic and CJK characters.
- `--delimiter=` additionally needs the carriage return character \r

1.3.28 mariadb-convert-table-format

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-convert-table-format` is a symlink to `mysql_convert_table_format`, the tool for converting the tables in a database to use a particular storage engine.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadb-convert-table-format` is the name of the tool, with `mysql_convert_table_format` a symlink .

Usage

```
mariadb-convert-table-format [options] db_name
```

Contents
1. Usage
2. Description
3. Options

Description

`mariadb-convert-table-format` converts the tables in a database to use a particular storage engine (MyISAM by default).

`mariadb-convert-table-format` is written in Perl and requires that the DBI and DBD::mysql Perl modules be installed

Invoke `mariadb-convert-table-format` like this:

```
shell> mariadb-convert-table-format [options]db_name
```

The `db_name` argument indicates the database containing the tables to be converted.

Options

`mariadb-convert-table-format` supports the options described in the following list:

Option	Description
-?, --help	Display help and exit.
-e, --engine=ENGINE	Specify the storage engine that the tables should be converted to use. The default is MyISAM if this option is not given.
-f, --force	Continue even if errors occur.
-h, --host=host_name	Connect to the MariaDB server on the given host. Default localhost.
-p, --password=password	The password to use when connecting to the server. Note that the password value is not optional for this option, unlike for other client programs. Specifying the password on the command-line is generally considered insecure.
-P, --port=port_num	The TCP/IP port number to use for the connection.
-S, --socket=path	For connections to localhost, the Unix socket file to use.
-u, --user=user_name	The MariaDB user name to use when connecting to the server.
-v, --verbose	Verbose mode. Print more information about what the program does.
-V, --version	Display version information and exit.

1.3.29 mariadb-dumpslow

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-dumpslow` is a symlink to `mysqldumpslow` , the tool for examining the slow query log.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadb-dumpslow` is the name of the tool, with `mysqldumpslow` a symlink .

`mariadb-dumpslow` is a tool to examine the slow query log.

It parses the slow query log files, printing a summary result. Normally, mariadb-dumpslow groups queries that are similar except for the particular values of number and string data values. It “abstracts” these values to N and ´S´ when displaying summary output. The `-a` and `-n` options can be used to modify value abstracting behavior.

Usage

```
mariadb-dumpslow [ options... ] [ logs... ]
```

Options

Option	Description
`-a`	Don't abstract all numbers to N and strings to 'S'
`-d`, `--debug`	Debug
`-g PATTERN`	Grep: only consider statements that include this string
`--help`	Display help
`-h HOSTNAME`	Hostname of db server for *-slow.log filename (can be wildcard), default is '*', i.e. match all
`-i NAME`	Name of server instance (if using mysql.server startup script)
`-l`	Don't subtract lock time from total time
`-n NUM`	Abstract numbers with at least *NUM* digits within names
`-r`	Reverse the sort order (largest last instead of first)
`-s ORDER`	What to sort by (aa, ae, al, ar, at, a, c, e, l, r, t). `at` is default. `aa` average rows affected `ae` aggregated number of rows examined `al` average lock time `ar` average rows sent `at` average query time `a` rows affected `c` count `e` rows examined `l` lock time `r` rows sent `t` query time
`-t NUM`	Just show the top *NUM* queries.
`-v`, `--verbose`	Verbose mode.

1.3.30 mariadb-embedded

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-embedded` is a symlink to `mysql_embedded`, the embedded server.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadb-embedded` is the name of the tool, with `mysql_embedded` a symlink.

`mariadb-embedded` is a mariadb client statically linked to libmariadbd, the embedded server. Upon execution, an embedded MariaDB server is instantiated and you can execute statements just as you would using the normal mariadb client, using the same options.

Do not run *mariadb-embedded* using the same database as a running MariaDB server!

Examples

```
sudo mariadb-embedded -e 'select user, host, password from mysql.user where user="root"'
+------+-----------+-------------------------------------------+
| user | host      | password                                  |
+------+-----------+-------------------------------------------+
| root | localhost | *196BDEDE2AE4F84CA44C47D54D78478C7E2BD7B7 |
| root | db1       | *196BDEDE2AE4F84CA44C47D54D78478C7E2BD7B7 |
| root | 127.0.0.1 | *196BDEDE2AE4F84CA44C47D54D78478C7E2BD7B7 |
| root | ::1       | *196BDEDE2AE4F84CA44C47D54D78478C7E2BD7B7 |
+------+-----------+-------------------------------------------+
```

Sending options with `--server-arg`:

```
sudo mariadb-embedded --server-arg='--skip-innodb'
  --server-arg='--default-storage-engine=myisam'
  --server-arg='--log-error=/tmp/mysql.err'
  -e 'select user, host, password from mysql.user where user="root"'
+------+-----------+-------------------------------------------+
| user | host      | password                                  |
+------+-----------+-------------------------------------------+
| root | localhost | *196BDEDE2AE4F84CA44C47D54D78478C7E2BD7B7 |
| root | db1       | *196BDEDE2AE4F84CA44C47D54D78478C7E2BD7B7 |
| root | 127.0.0.1 | *196BDEDE2AE4F84CA44C47D54D78478C7E2BD7B7 |
| root | ::1       | *196BDEDE2AE4F84CA44C47D54D78478C7E2BD7B7 |
+------+-----------+-------------------------------------------+
```

1.3.31 mariadb-find-rows

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-find-rows` is a symlink to `mysql_find_rows`, the tool for reading files containing SQL statements and extracting statements that match a given regular expression or that contain USE db_name or SET statements.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadb-find-rows` is the name of the tool, with `mysql_find_rows` a symlink.

Contents

`mariadb-find-rows` reads files containing SQL statements and extracts statements that match a given regular expression or that contain USE db_name or SET statements. The utility was written for use with update log files (as used prior to MySQL 5.0) and as such expects statements to be terminated with semicolon (;) characters. It may be useful with other files that contain SQL statements as long as statements are terminated with semicolons.

Usage

```
mariadb-find-rows [options] [file_name ...]
```

Each file_name argument should be the name of file containing SQL statements. If no file names are given, *mariadb-find-rows* reads the standard input.

Options

mariadb-find-rows supports the following options:

Option	Description
`--help`, `--Information`	Display help and exit.
`--regexp=pattern`	Display queries that match the pattern.
`--rows=N`	Quit after displaying N queries.

`--skip-use-db`	Do not include USE db_name statements in the output.
`--start_row=N`	Start output from this row (first row is 1).

Examples

```
mariadb-find-rows --regexp=problem_table --rows=20 < update.log
mariadb-find-rows --regexp=problem_table  update-log.1 update-log.2
```

1.3.32 mariadb-fix-extensions

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-fix-extensions` is a symlink to `mysql_fix_extensions`, the tool for converting the extensions for MyISAM (or ISAM) table files to their canonical forms.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mysql_fix_extensions` is the symlink, and `mariadb-fix-extensions` the binary name.

`mariadb-fix-extensions` converts the extensions for MyISAM (or ISAM) table files to their canonical forms.

It looks for files with extensions matching any lettercase variant of `.frm`, `.myd`, `.myi`, `.isd`, and `.ism` and renames them to have extensions of `.frm`, `.MYD`, `.MYI`, `.ISD`, and `.ISM`, respectively. This can be useful after transferring the files from a system with case-insensitive file names (such as Windows) to a system with case-sensitive file names.

Invoke mariadb-fix-extensions as follows, where data_dir is the path name to the MariaDB data directory.

```
mariadb-fix-extensions data_dir
```

1.3.33 mariadb-install-db

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-install-db` is a symlink to `mysql_install_db`. the tool for initializing the MariaDB data directory and creating the system tables

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mysql_install_db` is the symlink, and `mariadb-install-db` the binary name.

This page is for the `mariadb-install-db` script for Linux/Unix only

For the Windows specific tool of similar name and purpose see mysql_install_db.exe.

The Windows version shares the common theme (creating system tables), yet has a lot of functionality specific to Windows systems, for example creating a Windows service. The Windows version does *not* share command line parameters with the Unix shell script.

Contents

`mariadb-install-db` initializes the MariaDB data directory and creates the system tables in the mysql database, if they do not exist. MariaDB uses these tables to manage privileges, roles, and plugins. It also uses them to provide the data for the help command in the mariadb client.

`mariadb-install-db` works by starting MariaDB Server's `mysqld` process in --bootstrap mode and sending commands to create the system tables and their content.

Using mariadb-install-db

To invoke `mariadb-install-db`, use the following syntax:

```
$ mariadb-install-db [options]
```

Because the MariaDB server, `mysqld`, needs to access the data directory when it runs later, you should either run `mariadb-install-db` from the same account that will be used for running `mysqld` or run it as root and use the `--user` option to indicate the user name that `mysqld` will run as. It might be necessary to specify other options such as `--basedir` or `--datadir` if `mariadb-install-db` does not use the correct locations for the installation directory or data directory. For example:

```
$ scripts/mariadb-install-db --user=mysql \
   --basedir=/opt/mysql/mysql \
   --datadir=/opt/mysql/mysql/data
```

Options

`mariadb-install-db` supports the following options:

Option	Description
`--auth-root-authentication-method={normal | socket}`	If set to `normal`, it creates a `root@localhost` account that authenticates with the `mysql_native_password` authentication plugin and that has no initial password set, which can be insecure. If set to `socket`, it creates a `root@localhost` account that authenticates with the `unix_socket` authentication plugin. Set to `socket` by default from MariaDB 10.4 (see Authentication from MariaDB 10.4), or `normal` by default in earlier versions. Available since MariaDB 10.1.
`--auth-root-socket-user=USER`	Used with `--auth-root-authentication-method=socket`. It specifies the name of the second account to create with `SUPER` privileges in addition to `root`, as well as of the system account allowed to access it. Defaults to the value of `--user`.
`--basedir=path`	The path to the MariaDB installation directory.
`--builddir=path`	If using `--srcdir` with out-of-directory builds, you will need to set this to the location of the build directory where built files reside.
`--catalogs=["list"]`	Initialize MariaDB for catalogs. Argument is a list, separated with space, of the catalogs to create. The def catalog is created automatically. Added in MariaDB 11.3.
`--catalog-user=user`	User when adding catalogs to running server. Added in MariaDB 11.3.

`--catalog-password[=password]`	Password for catalog-user. Added in MariaDB 11.3.
`--catalog-client-arg=arg`	Other arguments to 'mariadb' when adding new catalogs. Added in MariaDB 11.3.
`--cross-bootstrap`	For internal use. Used when building the MariaDB system tables on a different host than the target.
`--datadir=path`, `--ldata=path`	The path to the MariaDB data directory.
`--debug=path`	Write commands to-be executed in 'path'. Added in MariaDB 11.3.
`--defaults-extra-file=name`	Read this file after the global files are read. Must be given as the first option.
`--defaults-file=name`	Only read default options from the given file *name* Must be given as the first option.
`--defaults-group-suffix=name`	In addition to the given groups, read also groups with this suffix. From MariaDB 10.1.31, MariaDB 10.2.13 and MariaDB 10.3.5.
`--force`	Causes `mariadb-install-db` to run even if DNS does not work. In that case, grant table entries that normally use host names will use IP addresses.
`--no-defaults`	Don't read default options from any option file. Must be given as the first option.
`--print-defaults`	Print the program argument list and exit. Must be given as the first option.
`--rpm`	For internal use. This option is used by RPM files during the MariaDB installation process.
`--skip-name-resolve`	Uses IP addresses rather than host names when creating grant table entries. This option can be useful if your DNS does not work.
`--skip-test-db`	Don't install the test database
`--srcdir=path`	For internal use. The path to the MariaDB source directory. This option uses the compiled binaries and support files within the source tree, useful for if you don't want to install MariaDB yet and just want to create the system tables. The directory under which `mariadb-install-db` looks for support files such as the error message file and the file for populating the help tables.
`--user=user_name`	The login user name to use for running `mysqld`. Files and directories created by `mysqld` will be owned by this user. You must be `root` to use this option. By default, `mysqld` runs using your current login name and files and directories that it creates will be owned by you.
`--verbose`	Verbose mode. Print more information about what the program does.
`--windows`	For internal use. This option is used for creating Windows distributions.

Option Files

In addition to reading options from the command-line, `mariadb-install-db` can also read options from option files. If an unknown option is provided to `mariadb-install-db` in an option file, then it is ignored.

The following options relate to how MariaDB command-line tools handles option files. They must be given as the first argument on the command-line:

Option	Description
`--print-defaults`	Print the program argument list and exit.
`--no-defaults`	Don't read default options from any option file.
`--defaults-file=#`	Only read default options from the given file #.
`--defaults-extra-file=#`	Read this file after the global files are read.
`--defaults-group-suffix=#`	In addition to the default option groups, also read option groups with this suffix.

Option Groups

`mariadb-install-db` reads options from the following option groups from option files:

Group	Description
`[mysql_install_db]`	Options read by `mysqld_safe`, which includes both MariaDB Server and MySQL Server.

`mariadb-install-db` also reads options from the following server option groups from option files:

Group	Description
`[mysqld]`	Options read by `mysqld`, which includes both MariaDB Server and MySQL Server.
`[server]`	Options read by MariaDB Server.
`[mysqld-X.Y]`	Options read by a specific version of `mysqld`, which includes both MariaDB Server and MySQL Server. For example, `[mysqld-5.5]`.
`[mariadb]`	Options read by MariaDB Server.
`[mariadb-X.Y]`	Options read by a specific version of MariaDB Server.
`[client-server]`	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
`[galera]`	Options read by a galera-capable MariaDB Server. Available on systems compiled with Galera support.

Installing System Tables

Installing System Tables From a Source Tree

If you have just compiled MariaDB from source, and if you want to use `mariadb-install-db` from your source tree, then that can be done without having to actually install MariaDB. This is very useful if you want to test your changes to MariaDB without disturbing any existing installations of MariaDB.

To do so, you would have to provide the `--srcdir` option. For example:

```
./scripts/mariadb-install-db --srcdir=. --datadir=path-to-temporary-data-dir
```

Installing System Tables From a Binary Tarball

If you install a binary tarball package in a non standard path, like your home directory, and if you already have a MariaDB / MySQL package installed, then you may get conflicts with the default `/etc/my.cnf`. This often results in permissions errors.

One possible solution is to use the `--no-defaults` option, so that it does not read any option files. For example:

```
./scripts/mariadb-install-db --no-defaults --basedir=. --datadir=data
```

Another possible solution is to use the `defaults-file` option, so that you can specify your own option file. For example:

```
./scripts/mariadb-install-db --defaults-file=~/.my.cnf
```

User Accounts Created by Default

MariaDB starting with 10.4

In MariaDB 10.4 and later, `mariadb-install-db` sets `--auth-root-authentication-method=socket` by default. When this is set, the default `root@localhost` user account is created with the ability to use two authentication plugins:

- First, it is configured to try to use the unix_socket authentication plugin. This allows the the `root@localhost` user to login without a password via the local Unix socket file defined by the socket system variable, as long as the login is attempted from a process owned by the operating system `root` user account.
- Second, if authentication fails with the unix_socket authentication plugin, then it is configured to try to use the mysql_native_password authentication plugin.

The definition of the default `root@localhost` user account is:

```
CREATE USER 'root'@'localhost' IDENTIFIED VIA unix_socket
  OR mysql_native_password USING 'invalid';
GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' WITH GRANT OPTION;
GRANT PROXY ON ''@'%' TO 'root'@'localhost' WITH GRANT OPTION;
```

Since `mariadb-install-db` sets `--auth-root-authentication-method=socket` by default, the following additional user accounts are **not** created by default:

- `root@127.0.0.1`
- `root@::1`
- `root@${current_hostname}`

However, an additional user account that is defined by the `--auth-root-socket-user` option is created. If this option is not set, then the value defaults to the value of the `--user` option. On most systems, the `--user` option will use the value of `mysql` by default, so this additional user account would be called `mysql@localhost`.

The definition of this `mysql@localhost` user account is similar to the `root@localhost` user account:

```
CREATE USER 'mysql'@'localhost' IDENTIFIED VIA unix_socket
  OR mysql_native_password USING 'invalid';
GRANT ALL PRIVILEGES ON *.* TO 'mysql'@'localhost' WITH GRANT OPTION;
```

An invalid password is initially set for both of these user accounts. This means that before a password can be used to authenticate as either of these user accounts, the accounts must first be given a valid password by executing the `SET PASSWORD` statement.

For example, here is an example of setting the password for the `root@localhost` user account immediately after installation:

```
$ sudo yum install MariaDB-server
$ sudo systemctl start mariadb
$ sudo mariadb
...
MariaDB> SET PASSWORD = PASSWORD('XH4VmT3_jt');
```

You may notice in the above example that the mariadb command-line client is executed via sudo. This allows the `root@localhost` user account to successfully authenticate via the unix_socket authentication plugin.

MariaDB until 10.3

In MariaDB 10.3 and before, `mariadb-install-db` sets `--auth-root-authentication-method=normal` by default. When this is set, the following default accounts are created with no password:

- `root@localhost`
- `root@127.0.0.1`
- `root@::1`
- `root@${current_hostname}`

The definition of the default `root@localhost` user account is:

```
CREATE USER 'root'@'localhost';
GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' WITH GRANT OPTION;
GRANT PROXY ON ''@'%' TO 'root'@'localhost' WITH GRANT OPTION;
```

The definition of the other default `root` accounts is similar.

A password should be set for these user accounts immediately after installation. This can be done either by executing the SET PASSWORD statement or by running mysql_secure_installation.

For example, here is an example of setting the password for the `root@localhost` user account immediately after installation:

```
$ sudo yum install MariaDB-server
$ sudo systemctl start mariadb
$ mysql -u root
...
MariaDB> SET PASSWORD = PASSWORD('XH4VmT3_jt');
```

Since `mariadb-install-db` sets `--auth-root-authentication-method=normal` by default, the `--auth-root-socket-user` option is ignored by default.

Troubleshooting Issues

Checking the Error Log

If `mariadb-install-db` fails, you should examine the error log in the data directory, which is the directory specified with `--datadir` option. This should provide a clue about what went wrong.

Testing With mysqld

You can also test that this is not a general fault of MariaDB Server by trying to start the `mysqld` process. The -skip-grant-tables option will tell it to ignore the system tables. Enabling the general query log can help you determine what queries are being run on the server. For example:

```
mysqld --skip-grant-tables --general-log
```

At this point, you can use the mariadb client to connect to the mysql database and look at the system tables. For example:

```
$ /usr/local/mysql/bin/mysql -u root mysql
MariaDB [mysql]> show tables
```

Using a Server Compiled With --disable-grant-options

The following only apply in the exceptional case that you are using a mysqld server which is configured with the `--disable-grant-options` option:

`mariadb-install-db` needs to invoke `mysqld` with the `--bootstrap` and `--skip-grant-tables` options. A MariaDB configured with the `--disable-grant-options` option has `--bootstrap` and `--skip-grant-tables` disabled. To handle this case, set the `MYSQLD_BOOTSTRAP` environment variable to the full path name of a mysqld server that is configured without `--disable-grant-options`. `mariadb-install-db` will use that server.

The test and test_% Databases

When calling the `mariadb-install-db` script, a new folder called `test` is created in the data directory. It only has the single `db.opt` file, which sets the client options `default-character-set` and `default-collation` only.

If you run `mysql` as an anonymous user, `mysql -u''@localhost`, and look for the grants and databases you are able to work with, you will get the following:

```
SELECT current_user;
+--------------+
| current_user |
+--------------+
| @localhost   |
+--------------+

SHOW GRANTS FOR current_user;
+---------------------------------------+
| Grants for @localhost                 |
+---------------------------------------+
| GRANT USAGE ON *.* TO ``@`localhost` |
+---------------------------------------+

SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| test               |
+--------------------+
```

Shown are the `information_schema` as well as `test` databases that are built in databases. But looking from SHOW GRANTS appears to be a paradox; how can the current user see something if they don't have privileges for that?

Let's go a step further.
Now, use the `root` / `unix` user, which has all rights, in order to create a new database with the prefix `test_`, something

like:

```
CREATE DATABASE test_electricity;
```

With the above change, a new directory will be created in the data directory.
Now login again with the anonymous user and run SHOW DATABASES:

```
SHOW DATABASES
+--------------------+
| Database           |
+--------------------+
| information_schema |
| test               |
| test_electricity   |
+--------------------+
```

Again we are able to see the newly created database, without any rights? We have an anonymous user that has no privileges, but still can see the `test` and `test_electricity` databases.
Where does this come from?

Login with the `root` / `unix` user to find out all privileges that the anonymous user has:

```
SELECT * FROM mysql.user WHERE user='' AND host='localhost'\G
*************************** 1. row ***************************
                  Host: localhost
                  User:
              Password:
           Select_priv: N
           Insert_priv: N
           Update_priv: N
           Delete_priv: N
           Create_priv: N
             Drop_priv: N
           Reload_priv: N
         Shutdown_priv: N
          Process_priv: N
             File_priv: N
            Grant_priv: N
       References_priv: N
            Index_priv: N
            Alter_priv: N
          Show_db_priv: N
            Super_priv: N
 Create_tmp_table_priv: N
      Lock_tables_priv: N
          Execute_priv: N
       Repl_slave_priv: N
      Repl_client_priv: N
      Create_view_priv: N
        Show_view_priv: N
   Create_routine_priv: N
    Alter_routine_priv: N
      Create_user_priv: N
            Event_priv: N
          Trigger_priv: N
Create_tablespace_priv: N
   Delete_history_priv: N
              ssl_type:
            ssl_cipher:
           x509_issuer:
          x509_subject:
         max_questions: 0
           max_updates: 0
       max_connections: 0
  max_user_connections: 0
                plugin:
 authentication_string:
      password_expired: N
               is_role: N
          default_role:
    max_statement_time: 0.000000
```

As seen above from the mysql.user table, the anonymous user doesn't have any global privileges. Still, the anonymous user can see databases, so there must be a way so that anonymous user can see the `test` and `test_electricity` databases.

Let's check for grants on the database level. That information can be found in the mysql.db table. Looking at the `mysql.db` table, it already contains 2 rows created when the `mariadb-install-db` script was invoked.

The anonymous user has database privileges (without `grant`, `alter_routine` and `execute`) on `test` and `test_%` databases:

```
SELECT * FROM mysql.db\G
*************************** 1. row ***************************
                 Host: %
                   Db: test
                 User:
          Select_priv: Y
          Insert_priv: Y
          Update_priv: Y
          Delete_priv: Y
          Create_priv: Y
            Drop_priv: Y
           Grant_priv: N
      References_priv: Y
           Index_priv: Y
           Alter_priv: Y
Create_tmp_table_priv: Y
     Lock_tables_priv: Y
     Create_view_priv: Y
       Show_view_priv: Y
  Create_routine_priv: Y
   Alter_routine_priv: N
         Execute_priv: N
           Event_priv: Y
         Trigger_priv: Y
  Delete_history_priv: Y
*************************** 2. row ***************************
                 Host: %
                   Db: test\_%
                 User:
          Select_priv: Y
          Insert_priv: Y
          Update_priv: Y
          Delete_priv: Y
          Create_priv: Y
            Drop_priv: Y
           Grant_priv: N
      References_priv: Y
           Index_priv: Y
           Alter_priv: Y
Create_tmp_table_priv: Y
     Lock_tables_priv: Y
     Create_view_priv: Y
       Show_view_priv: Y
  Create_routine_priv: Y
   Alter_routine_priv: N
         Execute_priv: N
           Event_priv: Y
         Trigger_priv: Y
  Delete_history_priv: Y
```

The first row is reserved for explicit usage for the `test` database, which is automatically created with `mariadb-install-db` .

Since database `test_electricity` satisfies the `test_%` pattern where `test_` is a prefix, we can understand why the user has the right to work with the newly-created database.

As long as records in `mysql.db` for the anonymous user exists, each new user created will have the privileges for the `test` and `test_%` databases.

Other databases privileges **are not automatically granted** for the newly created user. We have to grant privileges, which will be visible in `mysql.db` table.

Not Creating the test Database and Anonymous User

If you run `mariadb-install-db` with the `--skip-test-db` option, no `test` database will be created, which we can see as follows:

```
SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| mysql              |
| performance_schema |
+--------------------+

SELECT * FROM mysql.db;
Empty set (0.001 sec)
```

Also, no anonymous user is created (only `unix` / `mariadb.sys` / `root` users):

```
SELECT user,host FROM mysql.user;
+-------------+-----------+
| User        | Host      |
+-------------+-----------+
| anel        | localhost |
| mariadb.sys | localhost |
| root        | localhost |
+-------------+-----------+
```

1.3.34 mariadb-plugin

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-plugin` is a symlink to `mysql_plugin`, the tool for enabling or disabling plugins.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mysql_plugin` is the symlink, and `mariadb-plugin` the binary name.

Contents

`mariadb-plugin` is a tool for enabling or disabling plugins.

It is a commandline alternative to the INSTALL PLUGIN and UNINSTALL PLUGIN statements, and the `--plugin-load` option to mysqld.

`mariadb-plugin` must be run while the server is offline, and works by adding or removing rows from the mysql.plugin table.

`mariadb-plugin` basically has two use cases:

- adding a plugin even before the first real server startup
- removing a plugin that crashes the server on startup

For the install use case, adding a plugin-load-add entry to `my.cnf` or in a separate include option file, is probably a better alternative. In case of a plugin loaded via a `mysql.plugin` crashing the server, uninstalling the plugin with the help of `mariadb-plugin` can be the only viable action though.

Usage

```
mariadb-plugin [options] <plugin> ENABLE|DISABLE
```

`mariadb-plugin` expects to find a configuration file that indicates how to configure the plugins. The configuration file is by default the same name as the plugin, with a `.ini` extension. For example:

```
mariadb-plugin crazyplugins ENABLE
```

Here, `mariadb-plugin` will look for a file called `crazyplugins.ini`

```
crazyplugins
crazyplugin1
crazyplugin2
crazyplugin3
```

The first line should contain the name of the library object file, with no extension. The other lines list the names of the components. Each value should be on a separate line, and the `#` character at the start of the line indicates a comment.

Options

The following options can be specified on the command line, while some can be specified in the `[mysqld]` group of any option file. For options specified in a `[mysqld]` group, only the `--basedir`, `--datadir`, and `--plugin-dir` options can be used - the rest are ignored.

Option	Description
`-b`, `--basedir=name`	The base directory for the server.
`-d`, `--datadir=name`	The data directory for the server.
`-?`, `--help`	Display help and exit.
`-f`, `--my-print-defaults=name`	Path to `my_print_defaults` executable. Example: `/source/temp11/extra`
`-m`, `--mysqld=name`	Path to `mysqld` executable. Example: `/sbin/temp1/mysql/bin`
`-n`, `--no-defaults`	Do not read values from configuration file.
`-p`, `--plugin-dir=name`	The plugin directory for the server.
`-i`, `--plugin-ini=name`	Read plugin information from configuration file specified instead of from `<plugin-dir>/<plugin_name>.ini`.
`-P`, `--print-defaults`	Show default values from configuration file.
`-v`, `--verbose`	More verbose output; you can use this multiple times to get even more verbose output.
`-V`, `--version`	Output version information and exit.

1.3.35 mariadb-report

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-report` is a symlink to `mysqlreport`, the binary for showing the value of important status variables.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadb-report` is the name of the binary, with `mysqlreport` a symlink.

Contents

`mariadb-report` makes a friendly report of important MariaDB status values. Actually, it makes a friendly report of nearly every status value from SHOW STATUS. Unlike SHOW STATUS which simply dumps over 100 values to the screen in one long list, mariadb-report interprets and formats the values and presents the basic values and many more inferred values in a human-readable format. Numerous example reports are available in the archive of the old hackmysql.com/mysqlreport, archived here.

The benefit of mariadb-report is that it allows you to very quickly see a wide array of performance indicators for your MariaDB server which would otherwise need to be calculated by hand from all the various SHOW STATUS values. For example, the Index Read Ratio is an important value but it's not present in SHOW STATUS; it's an inferred value (the ratio of Key_reads to Key_read_requests).

This documentation outlines all the command line options in mariadb-report, most of which control which reports are printed. This document does not address how to interpret these reports; that topic is covered in the document Guide To Understanding mysqlreport, archived here.

Usage

```
mariadb-report [options]
```

mariadb-report options

Technically, command line options are in the form `--option`, but `-option` works too. All options can be abbreviated if the abbreviation is unique. For example, option `--host` can be abbreviated to `--ho` but not `--h` because `--h` is ambiguous: it could mean `--host` or `--help`.

Option	Description
`--all`	Equivalent to `--dtq --dms --com 3 --sas --qcache`. (Notice `--tab` is not invoked by `--all`.)
`--com N`	Print top N number of non-DMS Com_ status values in descending order (after DMS in Questions report). If N is not given, default is 3. Such non-DMS Com_ values include Com_change_db, Com_show_tables, Com_rollback, etc.
`--dms`	Print Data Manipulation Statements (DMS) report (under DMS in Questions report). DMS are those from the Data Manipulation section. mariadb-report considers only SELECT, INSERT, REPLACE, UPDATE, and DELETE. Each DMS is listed in descending order by count.
`--dtq`	Print Distribution of Total Queries (DTQ) report (under Total in Questions report). Queries (or Questions) can be divided into four main areas: DMS (see `--dms`), Com_ (see `--com`), COM_QUIT (see COM_QUIT and Questions, archived here), and Unknown. `--dtq` lists the number of queries in each of these areas in descending order.
`--email ADDRESS`	After printing the report to screen, email the report to ADDRESS. This option requires sendmail in /usr/sbin/, therefore it does not work on Windows. /usr/sbin/sendmail can be a sym link to qmail, for example, or any MTA that emulates sendmail's -t command line option and operation. The FROM: field is "mariadb-report", SUBJECT: is "MySQL status report".
`--flush-status`	Execute a FLUSH STATUS after generating the reports. If you do not have permissions in MariaDB to do this an error from DBD::mysql::st will be printed after the reports.
`--help`	Output help information and exit.
`--host ADDRESS`	Host address.
`--infile FILE`	Instead of getting SHOW STATUS values from MariaDB, read values from FILE. FILE is often a copy of the output of SHOW STATUS including formatting characters (+, -). *mariadb-report* expects FILE to have the format " value number " where value is only alpha and underscore characters (A-Z and _) and number is a positive integer. Anything before, between, or after value and number is ignored. *mariadb-report* also needs the following MariaDB server variables: version, table_cache, max_connections, key_buffer_size, query_cache_size. These values can be specified in INFILE in the format "name = value" where name is one of the aforementioned server variables and value is a positive integer with or without a trailing M and possible periods (for version). For example, to specify an 18M key_buffer_size: key_buffer_size = 18M. Or, a 256 table_cache: table_cache = 256. The M implies Megabytes not million, so 18M means 18,874,368 not 18,000,000. If these server variables are not specified the following defaults are used (respectively) which may cause strange values to be reported: 0.0.0, 64, 100, 8M, 0.
`--no-mycnf`	Makes mariadb-report not read /.my.cnf which it does by default otherwise. `--user` and `--password` always override values from /.my.cnf.
`--outfile FILE`	After printing the report to screen, print the report to FILE too. Internally, mariadb-report always writes the report to a temp file first: `/tmp/mysqlreport.PID` on *nix, `c:sqlreport.PID` on Windows (PID is the script's process ID). Then it prints the temp file to screen. Then if `--outfile` is specified, the temp file is copied to OUTFILE. After `--email` (above), the temp file is deleted.
`--password`	As of version 2.3 `--password` can take the password on the command line like `--password FOO`. Using `--password` alone without giving a password on the command line causes mariadb-report to prompt for a password.
`--port PORT`	Port number.
`--qcache`	Print Query Cache report.

`--sas`	Print report for Select_ and Sort_ status values (after Questions report). See MySQL Select and Sort Status Variables, archived here.
`--socket SOCKET`	For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.
`--tab`	Print Threads, Aborted, and Bytes status reports (after Created temp report). The Threads report reports on all Threads_ status values.
`--user USERNAME`	Username.

1.3.36 mariadb-secure-installation

Note that many of the reasons for the existence of this script no longer apply (and therefore the guidelines in many online tutorials. In particular, from MariaDB 10.4, Unix socket authentication is applied by default, and there is usually no need to create a root password. See Authentication from MariaDB 10.4.

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-secure-installation` is a symlink to mysql_secure_installation, the script for enabling you to improve the security of your MariaDB installation.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mysql_secure_installation` is the symlink, and `mariadb-secure-installation` the binary name.

Contents

Description

`mariadb-secure-installation` is a shell script available on Unix systems, and enables you to improve the security of your MariaDB installation in the following ways:

- You can set a password for root accounts.
- You can remove root accounts that are accessible from outside the local host.
- You can remove anonymous-user accounts.
- You can remove the test database, which by default can be accessed by anonymous users.

`mariadb-secure-installation` can be invoked without arguments:

```
shell> mariadb-secure-installation
```

The script will prompt you to determine which actions to perform.

```
Example:
localhost:# mariadb-secure-installation

NOTE: RUNNING ALL PARTS OF THIS SCRIPT IS RECOMMENDED FOR ALL MariaDB
      SERVERS IN PRODUCTION USE!  PLEASE READ EACH STEP CAREFULLY!

In order to log into MariaDB to secure it, we'll need the current
password for the root user.  If you've just installed MariaDB, and
you haven't set the root password yet, the password will be blank,
so you should just press enter here.

Enter current password for root (enter for none):
OK, successfully used password, moving on...

Setting the root password ensures that nobody can log into the MariaDB
root user without the proper authorisation.

You already have a root password set, so you can safely answer 'n'.

Change the root password? [Y/n] n
 ... skipping.

By default, a MariaDB installation has an anonymous user, allowing anyone
to log into MariaDB without having to have a user account created for
them.  This is intended only for testing, and to make the installation
go a bit smoother.  You should remove them before moving into a
production environment.

Remove anonymous users? [Y/n] y
 ... Success!

Normally, root should only be allowed to connect from 'localhost'.  This
ensures that someone cannot guess at the root password from the network.

Disallow root login remotely? [Y/n] y
 ... Success!

By default, MariaDB comes with a database named 'test' that anyone can
access.  This is also intended only for testing, and should be removed
before moving into a production environment.

Remove test database and access to it? [Y/n] y
 - Dropping test database...
 ... Success!
 - Removing privileges on test database...
 ... Success!

Reloading the privilege tables will ensure that all changes made so far
will take effect immediately.

Reload privilege tables now? [Y/n] y
 ... Success!

Cleaning up...

All done!  If you've completed all of the above steps, your MariaDB
installation should now be secure.

Thanks for using MariaDB!
```

Options

`mariadb-secure-installation` accepts some options:

Option	Description
`--basedir=dir`	Base directory.

`--no-defaults`	Don't read default options from any option file.
`--defaults-file=#`	Only read default options from the given file #.
`--defaults-extra-file=#`	Read this file after the global files are read.

Other unrecognized options will be passed on to the server.

Option Files

In addition to reading options from the command-line, `mariadb-secure-installation` can also read options from option files. If an unknown option is provided to `mariadb-secure-installation` in an option file, then it is ignored.

The following options relate to how MariaDB command-line tools handles option files. They must be given as the first argument on the command-line:

Option	Description
`--no-defaults`	Don't read default options from any option file.
`--defaults-file=#`	Only read default options from the given file #.
`--defaults-extra-file=#`	Read this file after the global files are read.
`--defaults-group-suffix=#`	In addition to the default option groups, also read option groups with this suffix.

Option Groups

`mariadb-secure-installation` reads options from the following option groups from option files:

Group	Description
`[client]`	Options read by all MariaDB and MySQL client programs, which includes both MariaDB and MySQL clients. For example, `mysqldump`.
`[client-server]`	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
`[client-mariadb]`	Options read by all MariaDB client programs.

Use With Galera Cluster

This script is not 100% safe for use with Galera Cluster as it directly manipulates the mysql.user/mysql.global_priv table, which is not transported by Galera to the other nodes.

You should run this script on the first node in the cluster before adding more nodes.

If you want to run this after the cluster is up and running you should find alternative ways.

Anyone can vote for this to be fixed at https://jira.mariadb.org/browse/MDEV-10112.

1.3.37 mariadb-setpermission

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-setpermission` is a symlink to `mysql_setpermission`, the script for assisting with adding users or databases or changing passwords in MariaDB.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mysql_setpermission` is the symlink, and `mariadb-setpermission` the binary name.

Contents

Syntax

```
mariadb-setpermission [options]
```

Description

mariadb-setpermission is a Perl script that was originally written and contributed by Luuk de Boer. It requires the DBI and DBD::mysql Perl modules to be installed. *mariadb-setpermission* can help you add users or databases or change passwords in MariaDB.

It interactively sets permissions in the MariaDB grant tables, but does not check permissions which have already been set in MariaDB. So if you can't connect to MariaDB using the permission you just added, take a look at the permissions which have already been set in MariaDB.

The account used when you connect determines which permissions you have when attempting to modify existing permissions in the grant tables.

mariadb-setpermission also reads options from the [client] and [perl] groups in the .my.cnf file in your home directory, if the file exists.

The following options are available:

Options

Option	Description
`--help`	Display a help message and exit.
`--host=host_name`	Connect to the MariaDB server on the given host.
`--password=password`	The password to use when connecting to the server. Note that the password value is not optional for this option, unlike for other MariaDB programs *Specifying a password on the command line should be considered insecure. You can use an option file to avoid giving the password on the command line.*
`--port=port_num`	The TCP/IP port number to use for the connection.
`--socket=path`	For connections to localhost, the Unix socket file to use.
`--user=user_name`	The MariaDB user name to use when connecting to the server.

Example

```
./mariadb-setpermission --user=msandbox --password=msandbox --host=127.0.0.1 --port=11200
##########################################################################
## Welcome to the permission setter 1.4 for MariaDB.
## made by Luuk de Boer
##########################################################################
What would you like to do:
  1. Set password for an existing user.
  2. Create a database + user privilege for that database
     and host combination (user can only do SELECT)
  3. Create/append user privilege for an existing database
     and host combination (user can only do SELECT)
  4. Create/append broader user privileges for an existing
     database and host combination
     (user can do SELECT,INSERT,UPDATE,DELETE)
  5. Create/append quite extended user privileges for an
     existing database and host combination (user can do
     SELECT,INSERT,UPDATE,DELETE,CREATE,DROP,INDEX,
     LOCK TABLES,CREATE TEMPORARY TABLES)
  6. Create/append full privileges for an existing database
     and host combination (user has FULL privilege)
  7. Remove all privileges for for an existing database and
     host combination.
     (user will have all permission fields set to N)
  0. exit this program
```

1.3.38 mariadb-show

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-show` is a symlink to `mysqlshow`, the script showing the structure of a MariaDB database.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mysqlshow` is the symlink, and `mariadb-show` the binary name.

Contents

Shows the structure of a MariaDB database (databases, tables, columns and indexes). You can also use SHOW DATABASES, SHOW TABLES, SHOW COLUMNS, SHOW INDEX and SHOW TABLE STATUS, as well as the Information Schema tables (TABLES, COLUMNS, STATISTICS), to get similar functionality.

Using mariadb-show

```
mariadb-show [OPTIONS] [database [table [column]]]
```

The output displays only the names of those databases, tables, or columns for which you have some privileges.

If no database is given then all matching databases are shown. If no table is given, then all matching tables in database are shown. If no column is given, then all matching columns and column types in table are shown.

If the last argument contains a shell or SQL wildcard (*,?,% or _) then only what's matched by the wildcard is shown. If a database name contains any underscores, those should be escaped with a backslash (some Unix shells require two) to get a list of the proper tables or columns. “*” and “?” characters are converted into SQL “%” and “_” wildcard characters. This might cause some confusion when you try to display the columns for a table with a “_” in the name, because in this case, mariadb-show shows you only the table names that match the pattern. This is easily fixed by adding an extra “%” last on the command line as a separate argument.

Options

`mariadb-show` supports the following options:

Option	Description
`-c name, --character-sets-dir=name`	Directory for character set files.
`-C, --compress`	Use compression in server/client protocol if both support it.
`--count`	Show number of rows per table (may be slow for non-MyISAM tables).
`-# [name], --debug[=name]`	Output debug log. Typical is `d:t:o,filename`, the default is `d:t:o`.
`--debug-check`	Check memory and open file usage at exit.
`--debug-info`	Print some debug info at exit.
`--default-auth=name`	Default authentication client-side plugin to use.
`--default-character-set=name`	Set the default character set.
`--defaults-extra-file=name`	Read the file *name* after the global files are read. Must be given as the first option.

`--defaults-file=name`	Only read default options from the given file *name*. Must be given as the first option.
`--defaults-group-suffix=suffix`	In addition to the given groups, also read groups with this suffix.
`-?, --help`	Display help and exit.
`-h name, --host=name`	Connect to the MariaDB server on the given host.
`-k, --keys`	Show indexes for table.
`--no-defaults`	Don't read default options from any option file. Must be given as the first option.
`-p[password], --password[=password]`	Password to use when connecting to server. If password is not given, it's solicited on the command line. Specifying a password on the command line should be considered insecure. You can use an option file to avoid giving the password on the command line.
`-W, --pipe`	On Windows, connect to the server via a named pipe. This option applies only if the server supports named-pipe connections.
`--plugin-dir=name`	Directory for client-side plugins.
`-P num, --port=num`	Port number to use for connection or 0 for default to, in order of preference, my.cnf, $MYSQL_TCP_PORT, /etc/services, built-in default (3306).
`--print-defaults`	Print the program argument list and exit. Must be given as the first option.
`--protocol=name`	The protocol to use for connection (tcp, socket, pipe, memory).
`--shared-memory-base-name=name`	On Windows, the shared-memory name to use, for connections made using shared memory to a local server. The default value is `MYSQL`. The shared-memory name is case sensitive. The server must be started with the `--shared-memory` option to enable shared-memory connections.
`-t, --show-table-type`	Show table type column, as in SHOW FULL TABLES. The type is BASE TABLE or VIEW.
`-S name, --socket=name`	For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.
`--ssl`	Enables TLS. TLS is also enabled even without setting this option when certain other TLS options are set. Starting with MariaDB 10.2, the `--ssl` option will not enable verifying the server certificate by default. In order to verify the server certificate, the user must specify the `--ssl-verify-server-cert` option.
`--ssl-ca=name`	Defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option implies the `--ssl` option.
`--ssl-capath=name`	Defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the `openssl rehash` command. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option is only supported if the client was built with OpenSSL. If the client was built with yaSSL, GnuTLS, or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms. This option implies the `--ssl` option.
`--ssl-cert=name`	Defines a path to the X509 certificate file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.
`--ssl-cipher=name`	List of permitted ciphers or cipher suites to use for TLS. This option implies the `--ssl` option.
`--ssl-key=name`	Defines a path to a private key file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.

`--ssl-crl=name`	Defines a path to a PEM file that should contain one or more revoked X509 certificates to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL or Schannel. If the client was built with yaSSL or GnuTLS, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms. This option implies the `--ssl` option.
`--ssl-crlpath=name`	Defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the `openssl rehash` command. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL. If the client was built with yaSSL, GnuTLS, or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms. This option implies the `--ssl` option.
`--ssl-verify-server-cert`	Enables (or disables) server certificate verification. This option is disabled by default.
`-i , --status`	Shows a lot of extra information about each table. See the INFORMATION_SCHEMA.TABLES table for more details on the returned information.
`--tls-version=name`	This option accepts a comma-separated list of TLS protocol versions. A TLS protocol version will only be enabled if it is present in this list. All other TLS protocol versions will not be permitted. See Secure Connections Overview: TLS Protocol Versions for more information. This option was added in MariaDB 10.4.6.
`-u , --user=name`	User for login if not current user.
`-v , --verbose`	More verbose output; you can use this multiple times to get even more verbose output.
`-V , --version`	Output version information and exit.

Option Files

In addition to reading options from the command-line, `mariadb-show` can also read options from option files. If an unknown option is provided to `mariadb-show` in an option file, then it is ignored.

The following options relate to how MariaDB command-line tools handles option files. They must be given as the first argument on the command-line:

Option	Description
`--print-defaults`	Print the program argument list and exit.
`--no-defaults`	Don't read default options from any option file.
`--defaults-file=#`	Only read default options from the given file #.
`--defaults-extra-file=#`	Read this file after the global files are read.
`--defaults-group-suffix=#`	In addition to the default option groups, also read option groups with this suffix.

In MariaDB 10.2 and later, `mariadb-show` is linked with MariaDB Connector/C. However, MariaDB Connector/C does not yet handle the parsing of option files for this client. That is still performed by the server option file parsing code. See MDEV-19035 for more information.

Option Groups

`mariadb-show` reads options from the following option groups from option files:

Group	Description
`[mysqlshow]`	Options read by `mysqlshow`, which includes both MariaDB Server and MySQL Server.
`[mariadb-show]`	Options read by `mariadb-show`. Available starting with MariaDB 10.4.6.
`[client]`	Options read by all MariaDB and MySQL client programs, which includes both MariaDB and MySQL clients. For example, `mysqldump`.

`[client-server]`	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
`[client-mariadb]`	Options read by all MariaDB client programs.

Examples

Getting a list of databases:

```
bin/mariadb-show
+--------------------+
|     Databases      |
+--------------------+
| information_schema |
| test               |
+--------------------+
```

Getting a list of tables in the `test` database:

```
bin/mariadb-show test
Database: test
+---------+
| Tables  |
+---------+
| author  |
| book    |
| city    |
| country |
+---------+
```

Getting a list of columns in the `test.book` table:

```
bin/mariadb-show test book
Database: test  Table: book
+-----------+-----------------------+--------------------+------+-----+---------+-------------
---+---------------------------------+---------+
| Field     | Type                  | Collation          | Null | Key | Default | Extra
| Privileges                      | Comment |
+-----------+-----------------------+--------------------+------+-----+---------+-------------
---+---------------------------------+---------+
| id        | mediumint(8) unsigned |                    | NO   | PRI |         |
auto_increment | select,insert,update,references |         |
| title     | varchar(200)          | latin1_swedish_ci | NO   |     |         |
| select,insert,update,references |         |
| author_id | smallint(5) unsigned  |                    | NO   | MUL |         |
| select,insert,update,references |         |
+-----------+-----------------------+--------------------+------+-----+---------+-------------
---+---------------------------------+---------+
```

1.3.39 mariadb-slap

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-slap` is a symlink to `mysqlslap`, the tool for load-testing MariaDB.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mysqlslap` is the symlink, and `mariadb-slap` the binary name.

Contents

`mariadb-slap` is a tool for load-testing MariaDB. It allows you to emulate multiple concurrent connections, and run a set of queries multiple times.

It returns a benchmark including the following information:

- Average number of seconds to run all queries
- Minimum number of seconds to run all queries
- Maximum number of seconds to run all queries
- Number of clients running queries
- Average number of queries per client

Using mariadb-slap

The command to use `mariadb-slap` and the general syntax is:

```
mariadb-slap [options]
```

Options

`mariadb-slap` supports the following options:

Option	Description
`-a`, `--auto-generate-sql`	Generate SQL statements automatically when they are not supplied in files or via command options.
`--auto-generate-sql-add-autoincrement`	Add an AUTO_INCREMENT column to auto-generated tables.
`--auto-generate-sql-execute-number=num`	Specify how many queries to generate automatically.
`--auto-generate-sql-guid-primary`	Add GUID based primary keys to auto-generated tables.
`--auto-generate-sql-load-type=name`	Specify the test load type. The allowable values are `read` (scan tables), `write` (insert into tables), `key` (read primary keys), `update` (update primary keys), or `mixed` (half inserts, half scanning selects). The default is mixed.
`--auto-generate-sql-secondary-indexes=num`	Number of secondary indexes to add to auto-generated tables. By default, none are added.
`--auto-generate-sql-unique-query-number=num`	Number of unique queries to generate for automatic tests. For example, if you run a key test that performs 1000 selects, you can use this option with a value of 1000 to run 1000 unique queries, or with a value of 50 to perform 50 different selects. The default is 10.
`--auto-generate-sql-unique-write-number=num`	Number of unique queries to generate for `auto-generate-sql-write-number`.
`--auto-generate-sql-write-number=num`	Number of row inserts to perform for each thread. The default is 100.
`--commit=num`	Number of statements to execute before committing. The default is 0.
`-C`, `--compress`	Use compression in server/client protocol if both support it.
`-c name`, `--concurrency=name`	Number of clients to simulate for query to run.

`--create=name`	File or string containing the statement to use for creating the table.
`--create-schema=name`	Schema to run tests in.
`--csv[=name]`	Generate comma-delimited output to named file or to standard output if no file is named.
`-# , --debug[=options]`	For debug builds, write a debugging log. A typical debug_options string is `d:t:o,file_name`. The default is `d:t:o,/tmp/mariadb-slap.trace`.
`--debug-check`	Check memory and open file usage at exit.
`-T, --debug-info`	Print some debug info at exit.
`--default-auth=name`	Default authentication client-side plugin to use.
`--defaults-extra-file=name`	Read this file after the global files are read. Must be given as the first option.
`--defaults-file=name`	Only read default options from the given file *name* Must be given as the first option.
`-F name , --delimiter=name`	Delimiter to use in SQL statements supplied in file or command line.
`--detach=num`	Detach (close and reopen) connections after the specified number of requests. The default is 0 (connections are not detached).
`-e name , --engine=name`	Comma separated list of storage engines to use for creating the table. The test is run for each engine. You can also specify an option for an engine after a #:#, for example `memory:max_row=2300`.
`-? , --help`	Display help and exit.
`-h name , --host=name`	Connect to the MariaDB server on the given host.
`--init-command=name`	SQL Command to execute when connecting to the MariaDB server. Will automatically be re-executed when reconnecting. Added in MariaDB 5.5.34.
`-i num , --iterations=num`	Number of times to run the tests.
`--no-defaults`	Don't read default options from any option file. Must be given as the first option.
`--no-drop`	Do not drop any schema created during the test after the test is complete.
`-x name , --number-char-cols=name`	Number of VARCHAR columns to create in table if specifying `--auto-generate-sql`.
`-y name , --number-int-cols=name`	Number of INT columns to create in table if specifying `--auto-generate-sql`.
`--number-of-queries=num`	Limit each client to approximately this number of queries. Query counting takes into account the statement delimiter. For example, if you invoke as follows, `mariadb-slap --delimiter=";" --number-of-queries=10 --query="use test;insert into t values(null)"`, the #;# delimiter is recognized so that each instance of the query string counts as two queries. As a result, 5 rows (not 10) are inserted.
`--only-print`	Do not connect to the databases, but instead print out what would have been done.
`-p[password] , --password[=password]`	Password to use when connecting to server. If password is not given it's asked from the command line. Specifying a password on the command line should be considered insecure. You can use an option file to avoid giving the password on the command line.
`-W , --pipe`	On Windows, connect to the server via a named pipe. This option applies only if the server supports named-pipe connections.
`--plugin-dir=name`	Directory for client-side plugins.
`-P num , --port=num`	Port number to use for connection.

`--post-query=name`	Query to run or file containing query to execute after tests have completed. This execution is not counted for timing purposes.
`--post-system=name`	system() string to execute after tests have completed. This execution is not counted for timing purposes.
`--pre-query=name`	Query to run or file containing query to execute before running tests. This execution is not counted for timing purposes.
`--pre-system=name`	system() string to execute before running tests. This execution is not counted for timing purposes.
`--print-defaults`	Print the program argument list and exit. Must be given as the first option.
`--protocol=name`	The protocol to use for connection (tcp, socket, pipe, memory).
`-q name , --query=name`	Query to run or file containing query to run.
`--shared-memory-base-name`	Shared-memory name to use for Windows connections using shared memory to a local server (started with the `--shared-memory` option). Case-sensitive.
`-s , --silent`	Run program in silent mode - no output.
`-S , --socket=name`	For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.
`--ssl`	Enables TLS. TLS is also enabled even without setting this option when certain other TLS options are set. The `--ssl` option will not enable verifying the server certificate by default. In order to verify the server certificate, the user must specify the `--ssl-verify-server-cert` option.
`--ssl-ca=name`	Defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option implies the `--ssl` option.
`--ssl-capath=name`	Defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the `openssl rehash` command. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option is only supported if the client was built with OpenSSL or yaSSL. If the client was built with GnuTLS or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms. This option implies the `--ssl` option.
`--ssl-cert=name`	Defines a path to the X509 certificate file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.
`--ssl-cipher=name`	List of permitted ciphers or cipher suites to use for TLS. This option implies the `--ssl` option.
`--ssl-crl=name`	Defines a path to a PEM file that should contain one or more revoked X509 certificates to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL or Schannel. If the client was built with yaSSL or GnuTLS, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
`--ssl-crlpath=name`	Defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the `openssl rehash` command. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL. If the client was built with yaSSL, GnuTLS, or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
`--ssl-key=name`	Defines a path to a private key file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.
`--ssl-verify-server-cert`	Enables server certificate verification. This option is disabled by default.
`-u , --user=name`	User for login if not current user.

`-v , --verbose`	More verbose output; you can use this multiple times to get even more verbose output.
`-V , --version`	Output version information and exit.

Option Files

In addition to reading options from the command-line, `mariadb-slap` can also read options from option files. If an unknown option is provided to `mariadb-slap` in an option file, then it is ignored.

The following options relate to how MariaDB command-line tools handles option files. They must be given as the first argument on the command-line:

Option	Description
`--print-defaults`	Print the program argument list and exit.
`--no-defaults`	Don't read default options from any option file.
`--defaults-file=#`	Only read default options from the given file #.
`--defaults-extra-file=#`	Read this file after the global files are read.
`--defaults-group-suffix=#`	In addition to the default option groups, also read option groups with this suffix.

`mariadb-slap` is linked with MariaDB Connector/C. However, MariaDB Connector/C does not yet handle the parsing of option files for this client. That is still performed by the server option file parsing code. See MDEV-19035 for more information.

Option Groups

`mariadb-slap` reads options from the following option groups from option files:

Group	Description
`[mysqlslap]`	Options read by `mariadb-slap`, which includes both MariaDB Server and MySQL Server.
`[mariadb-slap]`	Options read by `mariadb-slap`. Available starting with MariaDB 10.4.6.
`[client]`	Options read by all MariaDB and MySQL client programs, which includes both MariaDB and MySQL clients. For example, `mysqldump`.
`[client-server]`	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
`[client-mariadb]`	Options read by all MariaDB client programs.

Examples

Create a table with data, and then query it with 40 simultaneous connections 100 times each.

```
mariadb-slap
 --delimiter=";"
 --create="CREATE TABLE t (a int);INSERT INTO t VALUES (5)"
 --query="SELECT * FROM t"
 --concurrency=40
 --iterations=100

Benchmark
 Average number of seconds to run all queries: 0.010 seconds
 Minimum number of seconds to run all queries: 0.009 seconds
 Maximum number of seconds to run all queries: 0.020 seconds
 Number of clients running queries: 40
 Average number of queries per client: 1
```

Using files to store the create and query SQL. Each file can contain multiple statements separated by the specified delimiter.

```
mariadb-slap
 --create=define.sql
 --query=query.sql
 --concurrency=10
 --iterations=20
 --delimiter=";"

Benchmark
 Average number of seconds to run all queries: 0.002 seconds
 Minimum number of seconds to run all queries: 0.002 seconds
 Maximum number of seconds to run all queries: 0.004 seconds
 Number of clients running queries: 10
 Average number of queries per client: 1
```

1.3.40 mariadb-tzinfo-to-sql

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-tzinfo-to-sql` is a symlink to `mysql_tzinfo_to_sql`, the tool for loading time zones on systems that have a zoneinfo database.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mysql_tzinfo_to_sql` is the symlink, and `mariadb-tzinfo-to-sql` the binary name.

`mariadb-tzinfo-to-sql` is a utility used to load time zones on systems that have a zoneinfo database to load the time zone tables (time_zone, time_zone_leap_second, time_zone_name, time_zone_transition and time_zone_transition_type) into the mysql database.

Most Linux, Mac OS X, FreeBSD and Solaris systems will have a zoneinfo database - Windows does not. The database is commonly found in the /usr/share/zoneinfo directory, or, on Solaris, the /usr/share/lib/zoneinfo directory.

Usage

`mariadb-tzinfo-to-sql` can be called in several ways. The output is usually passed straight to the mariadb client for direct loading in the mysql database.

```
shell> mariadb-tzinfo-to-sql timezone_dir
shell> mariadb-tzinfo-to-sql timezone_file timezone_name
shell> mariadb-tzinfo-to-sql --leap timezone_file
```

Examples

Most commonly, the whole directory is passed:

```
shell>mariadb-tzinfo-to-sql /usr/share/zoneinfo | mariadb -u root mysql
```

Load a single time zone file, `timezone_file`, corresponding to the time zone called `timezone_name`.

```
shell> mariadb-tzinfo-to-sql timezone_file timezone_name | mariadb -u root mysql
```

A separate command for each time zone and time zone file the server needs is required.

To account for leap seconds, use:

```
shell> mariadb-tzinfo-to-sql --leap timezone_file | mariadb -u root mysql
```

After populating the time zone tables, you should usually restart the server so that the new time zone data is correctly loaded.

1.3.41 mariadb-upgrade

`mariadb-upgrade` is a tool that checks and updates your tables to the latest version.

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-upgrade` is a symlink to `mysql_upgrade`, the tool that checks and updates your tables to the latest version.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mysql_upgrade` is the symlink, and `mariadb-upgrade` the binary name.

MariaDB starting with 10.4.23

Starting from `mysql_upgrade` / `mariadb-upgrade` 2.0, the user running the upgrade tool must have write access to `datadir/mysql_upgrade_info`, so that the tool can write the current MariaDB version into the file. `mysql-upgrade` was updated in MariaDB 10.2.42, MariaDB 10.3.33, MariaDB 10.4.23, MariaDB 10.5.14, MariaDB 10.6.6, MariaDB 10.7.2 and newer.

Contents

You should run `mariadb-upgrade` after upgrading from one major MySQL/MariaDB release to another, such as from MySQL 5.0 to MariaDB 10.4 or MariaDB 10.4 to MariaDB 10.5. You also have to use `mariadb-upgrade` after a direct "horizontal" migration, for example from MySQL 5.5.40 to MariaDB 5.5.40. It's also safe to run `mariadb-upgrade` for minor upgrades, as if there are no incompatibilities nothing is changed.

It needs to be run as a user with write access to the data directory.

`mariadb-upgrade` is run after starting the new MariaDB server. Running it before you shut down the old version will not hurt anything and will allow you to make sure it works and figure out authentication for it ahead of time.

It is recommended to make a backup of all the databases before running `mariadb-upgrade`.

In most cases, `mariadb-upgrade` should just take a few seconds. The main work of `mariadb-upgrade` is to:

- Update the system tables in the `mysql` database to the latest version (normally just add new fields to a few tables).
- Check that all tables are up to date (runs CHECK TABLE table_name FOR UPGRADE). For tables that are not up to date, runs ALTER TABLE table_name FORCE on the table to update it. A table is not up to date if:
  - The table uses an index for which there has been a collation change (rare)
  - A format change in the storage engine requires an update (very rare)

Using mariadb-upgrade

```
mariadb-upgrade [--force] [--user=# --password=#
  --host=hostname --port=# --socket=#
  --protocol=tcp|socket|pipe|memory
  --verbose] [OTHER_OPTIONS]
```

`mariadb-upgrade` is mainly a framework to call mariadb-check. `mariadb-upgrade` works by doing the following operations:

```
# Find out path to datadir
echo "show show variables like 'datadir'" | mysql
mariadb-check --no-defaults --check-upgrade --auto-repair --databases mysql
mysql_fix_privilege_tables
mariadb-check --no-defaults --all-databases --fix-db-names --fix-table-names
mariadb-check --no-defaults --check-upgrade --all-databases --auto-repair
```

The connect options given to `mariadb-upgrade` are passed along to mariadb-check and mysql.

The `mysql_fix_privilege_tables` script is not actually called; it's included as part of `mariadb-upgrade`

If you have a problem with `mariadb-upgrade` try run it in very verbose mode:

```
mariadb-upgrade --verbose --verbose other-options
```

`mariadb-upgrade` also saves the MariaDB version number in a file named `mysql_upgrade_info` in the data directory. This is used to quickly check whether all tables have been checked for this release so that table-checking can be skipped. For this reason, `mariadb-upgrade` needs to be run as a user with write access to the data directory. To ignore this file and perform the check regardless, use the `--force` option.

Options

`mariadb-upgrade` supports the following options:

Option	Description	Version
`-?, --help`	Display this help message and exit.	
`--basedir=path`	Old option accepted for backward compatibility but ignored.	
`--character-sets-dir=path`	Old option accepted for backward compatibility but ignored.	
`check-if-upgrade-is-needed`	Do a quick check if upgrade is needed. Returns 0 if yes, 1 if no.	2.0
`--compress=name`	Old option accepted for backward compatibility but ignored.	
`--datadir=name`	Old option accepted for backward compatibility but ignored.	
`-# [name], --debug[=name]`	For debug builds, output debug log.	
`--debug-check`	Check memory and open file usage at exit.	
`-T, --debug-info`	Print some debug info at exit.	
`--default-character-set=name`	Old option accepted for backward compatibility but ignored.	
`-f, --force`	Force execution of mariadb-check even if `mariadb-upgrade` has already been executed for the current version of MariaDB. Ignores `mysql_upgrade_info`.	
`-h, --host=name`	Connect to MariaDB on the given host.	
`-p, --password[=name]`	Password to use when connecting to server. If password is not given, it's solicited on the command line (which should be considered insecure). You can use an option file to avoid giving the password on the command line.	
`-P, --port=name`	Port number to use for connection or 0 for default to, in order of preference, my.cnf, the MYSQL_TCP_PORT environment variable, /etc/services, built-in default (3306).	
`--protocol=name`	The protocol to use for connection (tcp, socket, pipe, memory).	
`--silent`	Print less information.	
`-S, --socket=name`	For connections to localhost, the Unix socket file to use, or, on Windows, the name of the named pipe to use.	
`--ssl`	Enables TLS. TLS is also enabled even without setting this option when certain other TLS options are set. Starting with MariaDB 10.2, the `--ssl` option will not enable verifying the server certificate by default. In order to verify the server certificate, the user must specify the `--ssl-verify-server-cert` option.	
`--ssl-ca=name`	Defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option implies the `--ssl` option.	

`--ssl-capath=name`	Defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command. See Secure Connections Overview: Certificate Authorities (CAs) for more information. This option is only supported if the client was built with OpenSSL or yaSSL. If the client was built with GnuTLS or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms. This option implies the `--ssl` option.	
`--ssl-cert=name`	Defines a path to the X509 certificate file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.	
`--ssl-cipher=name`	List of permitted ciphers or cipher suites to use for TLS. This option implies the `--ssl` option.	
`--ssl-crl=name`	Defines a path to a PEM file that should contain one or more revoked X509 certificates to use for TLS. This option requires that you use the absolute path, not a relative path. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL or Schannel. If the client was built with yaSSL or GnuTLS, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.	
`--ssl-crlpath=name`	Defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command. See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information. This option is only supported if the client was built with OpenSSL. If the client was built with yaSSL, GnuTLS, or Schannel, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.	
`--ssl-key=name`	Defines a path to a private key file to use for TLS. This option requires that you use the absolute path, not a relative path. This option implies the `--ssl` option.	
`--ssl-verify-server-cert`	Enables server certificate verification. This option is disabled by default.	
`-t, --tmpdir=name`	Directory for temporary files.	
`-s, --upgrade-system-tables`	Only upgrade the system tables in the mysql database. Tables in other databases are not checked or touched.	
`-u, --user=name`	User for login if not current user.	
`-v, --verbose`	Display more output about the process, using it twice will print connection arguments; using it 3 times will print out all CHECK, RENAME and ALTER TABLE commands used during the check phase; using it 4 times will also write out all mariadb-check commands used.	
`-V, --version`	Output version information and exit.	
`-k, --version-check`	Run this program only if its 'server version' matches the version of the server to which it's connecting check. Note: the 'server version' of the program is the version of the MariaDB server with which it was built/distributed. (Defaults to on; use `--skip-version-check` to disable.)	
`--write-binlog`	All commands including those run by mariadb-check are written to the binary log. Disabled by default. Before MariaDB 10.0.6 and MariaDB 5.5.34, this was enabled by default, and `--skip-write-binlog` should be used when commands should not be sent to replication slaves.	

mariadb-upgrade 2.0

`mariadb-upgrate/mysql_upgrade 2.0` was introduced in MariaDB 10.2.42, MariaDB 10.3.33, MariaDB 10.4.23, MariaDB 10.5.14, MariaDB 10.6.6, MariaDB 10.7.2.

Previously the tool first ran the upgrade process and then created the `datadir/mysql_upgrade_info` file. If the file could

not be created because of permissions (`mariadb-upgrade` did not have rights to create the file), `mariadb-upgrad` gave an error, but this was often ignored. One effect of not being able to create the `mysql_upgrade_info` file was that every new `mariadb-upgrade` run would have to do a full upgrade check, which can take a while if there are a lot of tables.

`mariadb-upgrade` 2.0 fixes the following issues:

- The `datadir/mysql_upgrade_info` is now created at the start of the upgrade process and locked. This ensures that two `mariadb-upgrade` processes cannot be run in parallel, which can cause deadlocks (MDEV-27068). One side-effect of this is that `mariadb-upgrade` has to have write access to `datadir` , which means it has to be run as as the user that installed MariaDB, normally 'mysql' or 'root' .
- One can use `mariadb-upgrade --force --force` to force the upgrade to be run, even if there was no version change or if one doesn't have write access to `datadir` . Note that if this option is used, the next `mariadb-upgrade` run will assume that there is a major version change and the upgrade must be done (again).
- The upgrade will only be done if there is a major server version change (10.4.X -> 10.5.X). This will avoid unnecessary upgrades.
- New option added: `--check-if-upgrade-is-needed` . If this is used, `mariadb-upgrade` will return 0 if there has been a major version change and one should run `mariadb-upgrade` . If not upgrade is need, 1 will be returned.
- `--verbose` writes more information, including from which version to which version the upgrade will be done.
- Better messages when there is no need to run `mariadb-upgrade` .

Option Files

In addition to reading options from the command-line, `mariadb-upgrade` can also read options from option files. If an unknown option is provided to `mariadb-upgrade` in an option file, then it is ignored.

The following options relate to how MariaDB command-line tools handles option files. They must be given as the first argument on the command-line:

Option	Description
`--print-defaults`	Print the program argument list and exit.
`--no-defaults`	Don't read default options from any option file.
`--defaults-file=#`	Only read default options from the given file #.
`--defaults-extra-file=#`	Read this file after the global files are read.
`--defaults-group-suffix=#`	In addition to the default option groups, also read option groups with this suffix.

In MariaDB 10.2 and later, `mariadb-upgrade` is linked with MariaDB Connector/C . However, MariaDB Connector/C does not yet handle the parsing of option files for this client. That is still performed by the server option file parsing code. See MDEV-19035 for more information.

Option Groups

`mariadb-upgrade` reads options from the following option groups from option files:

Group	Description
`[mysql_upgrade]`	Options read by `mariadb-upgrade` , which includes both MariaDB Server and MySQL Server.
`[mariadb-upgrade]`	Options read by `mariadb-upgrade` . Available starting with MariaDB 10.4.6.
`[client]`	Options read by all MariaDB and MySQL client programs, which includes both MariaDB and MySQL clients. For example, `mysqldump` .
`[client-server]`	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
`[client-mariadb]`	Options read by all MariaDB client programs.

Differences Between mysql_upgrade in MariaDB and MySQL

This is as of MariaDB 5.1.50 :

- MariaDB will convert long table names properly.

- MariaDB will convert InnoDB tables (no need to do a dump/restore or `ALTER TABLE`).
- MariaDB will convert old archive tables to the new 5.1 format.
- "mysql_upgrade --verbose" will run "mariadb-check --verbose" so that you get more information of what is happening. Running with 3 times --verbose will in MariaDB 10.0 print out all CHECK, RENAME and ALTER TABLE commands executed.
- The mysql.event table is upgraded live; no need to restart the server to use events if the event table has changed (MariaDB 10.0.22 and MariaDB 10.1.9).
- More descriptive output.

Speeding Up mariadb-upgrade

- If you are sure that all your tables are up to date with the current version, then you can run `mariadb-upgrade --upgrade-system-tables`, which will only fix your system tables in the mysql database to be compatible with the latest version.

The main reason to run `mariadb-upgrade` on all your tables is to allow it to check that:

- There has not been any change in table formats between versions.
  - This has not happened since MariaDB 5.1.
- If some of the tables are using an index for which we have changed sort order.
  - This has not happened since MariaDB 5.5.

If you are 100% sure this applies to you, you can just run `mariadb-upgrade` with the `--upgrade-system-tables` option.

Symptoms of Not Having Run mariadb-upgrade When It Was Needed

- Errors in the error log that some system tables don't have all needed columns.
- Updates or searches may not find the record they are attempting to update or search for.
- CHECKSUM TABLE may report the wrong checksum for MyISAM or Aria tables.
- The error message "Cannot load from mysql.proc. The table is probably corrupted."

To fix issues like this, run `mariadb-upgrade`, mariadb-check, CHECK TABLE and if needed REPAIR TABLE on the wrong table.

Other Uses

- `mariadb-upgrade` will re-create any missing tables in the mysql database. It will not touch any data in existing tables.

1.3.42 mariadb-waitpid

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-waitpid` is a symlink to `mysql_waitpid`, the utility for terminating processes.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mysql_waitpid` is the symlink, and `mariadb-waitpid` the binary name.From MariaDB 10.5.2, `mysql_waitpid` is the symlink, and `mariadb-waitpid` the binary name.

`mysql_pid` is a utility for terminating processes. It runs on Unix-like systems, making use of the `kill()` system call.

Usage

```
mariadb-waitpid [options] pid time
```

Description

`mariadb-waitpid` sends signal 0 to the process *pid* and waits up to *time* seconds for the process to terminate. *pid* and *time* must be positive integers.

Returns 0 if the process terminates in time, or does not exist, and 1 otherwise.

Signal 1 is used if the kill() system call cannot handle signal 0

Options

Option	Description
`-?`, `--help`	Display help and exit
`-I`, `--help`	Synonym for -?
`-v`, `--verbose`	Be more verbose. Give a warning, if kill can't handle signal 0
`-V`, `--version`	Print version information and exit

1.3.43 Legacy Clients and Utilities

Category for removed, deprecated or unmaintained MariaDB clients and utilities.

Percona XtraBackup

Open source tool for performing hot backups of MariaDB, MySQL and Percona Server databases.

MySQL Sandbox

Installing multiple MariaDB versions in isolation.

mysqlaccess

Symlink or old name for mariadb-access.

mysqladmin

Old name or symlink for mariadb-admin.

mysqlcheck

Symlink or old name for mariadb-check.

mysqldump

Symlink or old name for mariadb-dump.

mysqldumpslow

Symlink or old name for mariadb-dumpslow.

mysqlhotcopy

Symlink or old name for mariadb-hotcopy.

mysqlimport

Symlink or old name for mariadb-import.

mysqlreport

Symlink or old name for mariadb-report.

mysqlshow

Symlink or old name for mariadb-show.

mysqlslap

Symlink or old name for mariadb-slap.

mysql_convert_table_format

Symlink or old name for mariadb-convert-table-format.

mysql_embedded

Symlink or old name for mariadb-embedded.

mysql_find_rows

Symlink or old name for mariadb-find-rows.

mysql_fix_extensions

Symlink or old name for mariadb-fix-extensions.

mysql_install_db

Symlink or old name for mariadb-install-db.

mysql_plugin

Symlink or old name for mariadb-plugin.

mysql_secure_installation

Symlink or old name for mariadb-secure-installation.

mysql_setpermission

Symlink or old name for mariadb_setpermission.

mysql_tzinfo_to_sql

Symlink or old name for mariadb-tzinfo-to-sql.

mysql_upgrade

Symlink or old name for mariadb-upgrade.

mysql_waitpid

Symlink or old name for mariadb-waitpid.

mysql_zap

Kill processes that match a pattern.

1.3.43.1 mysqlaccess

`mysqlaccess` is a tool for checking access privileges, developed by Yves Carlier.

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-access` is a symlink to `mysqlaccess`.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadb-access` is the name of the tool, with `mysqlaccess` a symlink.

Contents

See mariadb-access for details.

1.3.43.2 mysqldump

mysqldump is used to dump a database or a collection of databases for backup or transfer to another database server.

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-dump` is a symlink to `mysqldump`.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadb-dump` is the name of the command-line client, with `mysqldump` a symlink.

MariaDB starting with 11.0.1

From MariaDB 11.0.1, `mysqldump` (the symlink) is deprecated and removed from the `mariadb` Docker Official Image. Use `mariadb-dump` instead.

See mariadb-dump for details.

1.3.43.3 mysqldumpslow

`mysqldumpslow` is a tool to examine the slow query log.

MariaDB starting with 10.4.6
From MariaDB 10.4.6, mariadb-dumpslow is a symlink to `mysqldumpslow`.

MariaDB starting with 10.5.2
From MariaDB 10.5.2, mariadb-dumpslow is the name of the tool, with `mysqldumpslow` a symlink.

Contents

See mariadb-dumpslow for details.

1.1.1.2.1.10

1.3.43.5 mysql_convert_table_format

`mysql-convert-table-format` converts the tables in a database to use a particular storage engine (MyISAM by default).

MariaDB starting with 10.4.6
From MariaDB 10.4.6, mariadb-convert-table-format is a symlink to `mysql_convert_table_format`.

MariaDB starting with 10.5.2
From MariaDB 10.5.2, mariadb-convert-table-format is the name of the tool, with `mysql_convert_table_format` a symlink.

See mariadb-convert-table-format for details.

1.3.43.6 mysql_embedded

MariaDB starting with 10.4.6
From MariaDB 10.4.6, mariadb-embedded is a symlink to `mysql_embedded`.

MariaDB starting with 10.5.2
From MariaDB 10.5.2, mariadb-embedded is the name of the tool, with `mysql_embedded` a symlink.

See mariadb-embedded for details.

1.3.43.7 mysql_find_rows

`mysql_find_rows` reads files containing SQL statements and extracts statements that match a given regular expression or that contain USE db_name or SET statements.

MariaDB starting with 10.4.6
From MariaDB 10.4.6, mariadb-find-rows is a symlink to `mysql_find_rows`.

MariaDB starting with 10.5.2
From MariaDB 10.5.2, mariadb-find-rows is the name of the binary, with `mysql_find_rows` a symlink.

See mariadb-find-rows for details.

1.3.43.8 mysql_fix_extensions

MariaDB starting with 10.4.6
From MariaDB 10.4.6, mariadb-fix-extensions is a symlink to `mysql_fix_extensions`.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mysql_fix_extensions` is the symlink, and mariadb-fix-extensions the binary name.

See mariadb-fix-extensions for details.

1.3.43.9 mysqlhotcopy

mysqlhotcopy is deprecated and may be removed in a future release.

`mysqlhotcopy` uses FLUSH TABLES, LOCK TABLES, and cp or scp to make a database backup.

MariaDB starting with 10.4.6

From MariaDB 10.4.6, mariadb-hotcopy is a symlink to `mysqlhotcopy` .

MariaDB starting with 10.5.2

From MariaDB 10.5.2, mariadb-hotcopy is the name of the script, with `mysqlhotcopy` a symlink .

See mariadb-hotcopy for details.

1.3.43.10 mysqlimport

mysqlimport is used to load tables from text files in various formats

MariaDB starting with 10.4.6

From MariaDB 10.4.6, mariadb-import is a symlink to `mysqlimport` .

MariaDB starting with 10.5.2

From MariaDB 10.5.2, mariadb-import is the name of the script, with `mysqlimport` a symlink .

See mariadb-import for details.

1.3.43.11 mysql_install_db

`mariadb-install-db` initializes the MariaDB data directory and creates the system tables in the mysql database.

MariaDB starting with 10.4.6

From MariaDB 10.4.6, mariadb-install-db is a symlink to `mysql_install_db` .

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mysql_install_db` is the symlink, and mariadb-install-db the binary name.

See mariadb-install-db for details.

1.3.43.12 mysql_plugin

`mysql_plugin` is a tool for enabling or disabling plugins.

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-plugin` is a symlink to `mysql_plugin` .

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mysql_plugin` is the symlink, and `mariadb-plugin` the binary name.

See mariadb-plugin for details.

1.3.43.13 mysqlreport

`mysqlreport` makes a friendly report of important MariaDB status values.

MariaDB starting with 10.4.6
From MariaDB 10.4.6, mariadb-report is a symlink to `mysqlreport`.

MariaDB starting with 10.5.2
From MariaDB 10.5.2, `mysqlreport` is the symlink, and mariadb-report the binary name.

See mariadb-report for details.

1.3.43.14 mysql_secure_installation

Note that many of the reasons for the existence of this script no longer apply. In particular, from MariaDB 10.4, Unix socket authentication is applied by default, and there is usually no need to create a root password. See Authentication from MariaDB 10.4.

MariaDB starting with 10.4.6
From MariaDB 10.4.6, mariadb-secure-installation is a symlink to `mysql_secure_installation`.

MariaDB starting with 10.5.2
From MariaDB 10.5.2, `mysql_secure_installation` is the symlink, and mariadb-secure-installation the binary name.

See mariadb-secure-installation for details.

1.3.43.15 mysql_setpermission

MariaDB starting with 10.4.6
From MariaDB 10.4.6, mariadb-setpermission is a symlink to `mysql_setpermission`.

MariaDB starting with 10.5.2
From MariaDB 10.5.2, `mysql_setpermission` is the symlink, and mariadb-setpermission the binary name.

See mariadb-setpermission for details.

1.3.43.16 mysqlshow

Shows the structure of a MariaDB database (databases, tables, columns and indexes).

MariaDB starting with 10.4.6
From MariaDB 10.4.6, mariadb-show is a symlink to `mysqlshow`.

MariaDB starting with 10.5.2
From MariaDB 10.5.2, `mysqlshow` is the symlink, and mariadb-show the binary name.

See mariadb-show for details.

1.3.43.17 mysqlslap

`mysqlslap` is a tool for load-testing MariaDB. It allows you to emulate multiple concurrent connections, and run a set of queries multiple times.

MariaDB starting with 10.4.6
From MariaDB 10.4.6, mariadb-slap is a symlink to `mysqlslap`.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mysqlslap` is the symlink, and mariadb-slap the binary name.

See mariadb-slap for details.

1.3.43.18 mysql_tzinfo_to_sql

MariaDB starting with 10.4.6

From MariaDB 10.4.6, mariadb-tzinfo-to-sql is a symlink to `mysql_tzinfo_to_sql`.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mysql_tzinfo_to_sql` is the symlink, and mariadb-tzinfo-to-sql the binary name.

See mariadb-tzinfo-to-sql for details.

1.3.43.19 mysql_upgrade

`mariadb-upgrade/mysql_upgrade` is a tool that checks and updates your tables to the latest version.

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-upgrade` is a symlink to `mysql_upgrade`.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mysql_upgrade` is the symlink, and `mariadb-upgrade` the binary name.

See mariadb-upgrade for details.

1.3.43.20 mysql_waitpid

`mysql_pid` is a utility for terminating processes. It runs on Unix-like systems, making use of the `kill()` system call.

MariaDB starting with 10.4.6

From MariaDB 10.4.6, mariadb-waitpid is a symlink to `mysql_waitpid`.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mysql_waitpid` is the symlink, and mariadb-waitpid the binary name.

Contents

See mariadb-waitpid for details.

2 MariaDB Administration

There are many tasks that database administrators (DBAs) have to perform. This section of the MariaDB Documentation provides information on how to do these tasks.

Getting, Installing, and Upgrading MariaDB

Getting, installing, and upgrading MariaDB Server and related software.

User & Server Security

Creating users, granting privileges, and encryption.

Backing Up and Restoring Databases

Tools and methods for backing up and restoring databases.

Server Monitoring & Logs

Monitoring MariaDB Server and enabling and using logs.

Partitioning Tables
Splitting huge tables into multiple table files.

MariaDB Audit Plugin
Logging user activity with the MariaDB Audit Plugin.

Variables and Modes
Server variables and SQL modes.

Copying Tables Between Different MariaDB Databases and MariaDB Servers
Copy table files.

2.1 Getting, Installing, and Upgrading MariaDB

Where to Download MariaDB
Downloading tarballs, binaries, packages, and the source code for MariaDB.

MariaDB Binary Packages
Instructions on installing MariaDB binaries and packages.

Upgrading MariaDB
Upgrading from an earlier version, or from MySQL

2.1.1 Where to Download MariaDB

Contents

The Latest Packages

Tarballs, binaries (Linux, Solaris, and Windows), and packages for some Linux distributions are available at mariadb.com/downloads/ or mariadb.org/download/ (which also contains a PDF version of the MariaDB Server documentation).

We hope that interested community package maintainers will step forward, as others already have, to build packages for their distributions. We ask for strict adherence to your packaging system's best practices and invite you to create a bug report if our project impedes this in any way.

Instructions how to install the packages can be found here.

Distributions Which Include MariaDB

- Most distributions already include MariaDB. See Distributions Which Include MariaDB.

Pre-Release Binaries

Binaries from our Buildbot system (see also the Buildbot page), are available at http://hasky.askmonty.org/archive. They are not suitable for use in production systems but may be of use for debugging.

Once at the above URL you will need to click on the MariaDB tree you are interested in, and then the build. The build number corresponds to the `tarbuildnum` variable in Buildbot.

For example, if you were interested in the bsd9-64 build of the MariaDB 5.5 tree, revision 3497, the `tarbuildnum` is listed in the "Build Properties" table of the Buildbot build report. In this case, the value is "2434".

Getting the Source

You can find all the source code at https://github.com/MariaDB/server

To retrieve the code, the Git source control software offers the path of least resistance. If you are unfamiliar with git, please refer to the git documentation for an understanding of version control with git.

For instructions on creating a local branch of MariaDB, see the Getting the MariaDB Source Code page.

See the Generic Build Instructions page for general instructions on compiling MariaDB from the source. The source page has links to platform and distribution-specific information, including information on how we build the release packages.

2.1.2 MariaDB Binary Packages

This section contains information on and installation instructions for MariaDB binaries and packages.

Installing MariaDB RPM Files

Information and instructions on using the RPM packages and the related repositories.

Installing MariaDB .deb Files
Installing MariaDB .deb Files.

Installing MariaDB MSI Packages on Windows
MSI packages are available for both x86 (32 bit) and x64 (64 bit) processor architectures

Installing MariaDB Server PKG packages on macOS
MariaDB Server does not currently provide a .pkg installer for macOS

Installing MariaDB Binary Tarballs
Installing MariaDB binary tarballs, systemd, and glibc-2.14.

2.1.2.1.1 About the MariaDB RPM Files

Contents

Available RPM Packages

The available RPM packages depend on the specific MariaDB release series.

Available RPM Packages in MariaDB 10.4

MariaDB starting with 10.4

From MariaDB 10.4, the following RPMs are available:

Package Name	Description
`galera-4`	The WSREP provider for Galera 4.
`MariaDB-backup`	Mariabackup
`MariaDB-backup-debuginfo`	Debuginfo for Mariabackup
`MariaDB-client`	Client tools like mariadb CLI, mariadb-dump, and others.
`MariaDB-client-debuginfo`	Debuginfo for client tools like `mariadb` CLI, `mariadb-dump` , and others.
`MariaDB-common`	Character set files and `/etc/my.cnf`
`MariaDB-common-debuginfo`	Debuginfo for character set files and `/etc/my.cnf`
`MariaDB-compat`	Old shared client libraries, may be needed by old MariaDB or MySQL clients
`MariaDB-connect-engine`	The `CONNECT` storage engine.
`MariaDB-connect-engine-debuginfo`	Debuginfo for the `CONNECT` storage engine.

`MariaDB-cracklib-password-check`	The `cracklib_password_check` password validation plugin.
`MariaDB-cracklib-password-check`	Debuginfo for the `cracklib_password_check` password validation plugin.
`MariaDB-devel`	Development headers and static libraries.
`MariaDB-devel-debuginfo`	Debuginfo for development headers and static libraries.
`MariaDB-gssapi-server`	The `gssapi` authentication plugin.
`MariaDB-gssapi-server-debuginfo`	Debuginfo for the `gssapi` authentication plugin.
`MariaDB-rocksdb-engine`	The MyRocks storage engine.
`MariaDB-rocksdb-engine-debuginfo`	Debuginfo for the MyRocks storage engine.
`MariaDB-server`	The server and server tools, like myisamchk and mariadb-hotcopy are here.
`MariaDB-server-compat`	Symbolic links from old MySQL tool names to MariaDB, like `mysqladmin` -> `mariadb-admin` or `mysql` -> `mariadb` . Good to have if you are using MySQL tool names in your scripts.
`MariaDB-server-debuginfo`	Debuginfo for the server and server tools, like myisamchk and mariadb-hotcopy are here.
`MariaDB-shared`	Dynamic client libraries.
`MariaDB-shared-debuginfo`	Debuginfo for dynamic client libraries.
`MariaDB-test`	`mysql-client-test` executable, and **mysql-test** framework with the tests.
`MariaDB-test-debuginfo`	Debuginfo for `mysql-client-test` executable, and **mysql-test** framework with the tests.
`MariaDB-tokudb-engine`	The TokuDB storage engine.
`MariaDB-tokudb-engine-debuginfo`	Debuginfo for the TokuDB storage engine.

Available RPM Packages in MariaDB 10.2 and MariaDB 10.3

MariaDB starting with 10.2

In MariaDB 10.2 and MariaDB 10.3, the following RPMs are available:

Package Name	Description
`galera`	The WSREP provider for Galera 3.
`MariaDB-backup`	Mariabackup
`MariaDB-backup-debuginfo`	Debuginfo for Mariabackup
`MariaDB-client`	Client tools like `mysql` CLI, `mysqldump` , and others.
`MariaDB-client-debuginfo`	Debuginfo for client tools like `mysql` CLI, `mariadb-dump` , and others.
`MariaDB-common`	Character set files and `/etc/my.cnf`
`MariaDB-common-debuginfo`	Debuginfo for character set files and `/etc/my.cnf`

`MariaDB-compat`	Old shared client libraries, may be needed by old MariaDB or MySQL clients
`MariaDB-connect-engine`	The `CONNECT` storage engine.
`MariaDB-connect-engine-debuginfo`	Debuginfo for the `CONNECT` storage engine.
`MariaDB-cracklib-password-check`	The `cracklib_password_check` password validation plugin.
`MariaDB-cracklib-password-check`	Debuginfo for the `cracklib_password_check` password validation plugin.
`MariaDB-devel`	Development headers and static libraries.
`MariaDB-devel-debuginfo`	Debuginfo for development headers and static libraries.
`MariaDB-gssapi-server`	The `gssapi` authentication plugin.
`MariaDB-gssapi-server-debuginfo`	Debuginfo for the `gssapi` authentication plugin.
`MariaDB-rocksdb-engine`	The MyRocks storage engine.
`MariaDB-rocksdb-engine-debuginfo`	Debuginfo for the MyRocks storage engine.
`MariaDB-server`	The server and server tools, like myisamchk and mariadb-hotcopy are here.
`MariaDB-server-debuginfo`	Debuginfo for the server and server tools, like myisamchk and mariadb-hotcopy are here.
`MariaDB-shared`	Dynamic client libraries.
`MariaDB-shared-debuginfo`	Debuginfo for dynamic client libraries.
`MariaDB-test`	`mysql-client-test` executable, and **mysql-test** framework with the tests.
`MariaDB-test-debuginfo`	Debuginfo for `mysql-client-test` executable, and **mysql-test** framework with the tests.
`MariaDB-tokudb-engine`	The TokuDB storage engine.
`MariaDB-tokudb-engine-debuginfo`	Debuginfo for the TokuDB storage engine.

Installing RPM Packages

Preferably, you should install MariaDB RPM packages using the package manager of your Linux distribution, for example **`yum`** or **`zypper`**. But you can also use the lower-level **`rpm`** tool.

Actions Performed by RPM Packages

Users and Groups Created

When the `MariaDB-server` RPM package is installed, it will create a user and group named `mysql`, if it does not already exist.

2.1.2.1.2 Installing MariaDB with yum/dnf

On RHEL, CentOS, Fedora, and other similar Linux RPM based distributions, these provide MariaDB packages. These are supported by those distributions. If you have a particular need for a later version than what is in the distribution, then MariaDB provides repositories for them.

Using repositories rather than installing RPM allows for an ease of update when a new release is made. It is highly recommended to install the relevant RPM packages from MariaDB's repository using yum or dnf. Centos 7 still uses `yum`, most others use `dnf`, and SUSE/openSUSE use `zypper`.

This page walks you through the simple installation steps using `dnf` and `yum`.

Contents

Adding the MariaDB YUM repository

We currently have YUM/DNF repositories for the following Linux distributions, and for the versions that are in standard (not extended) support:

- Red Hat Enterprise Linux (RHEL)
- CentOS
- Fedora
- openSUSE
- SUSE

Using the MariaDB Package Repository Setup Script

If you want to install MariaDB with `yum`, then you can configure `yum` to install from MariaDB Corporation's MariaDB Package Repository by using the MariaDB Package Repository setup script.

MariaDB Corporation provides a MariaDB Package Repository for several Linux distributions that use `yum` to manage packages. This repository contains software packages related to MariaDB Server, including the server itself, clients and utilities, client libraries, plugins, and Mariabackup. The MariaDB Package Repository setup script automatically configures your system to install packages from the MariaDB Package Repository.

To use the script, execute the following command:

```
curl -sS https://downloads.mariadb.com/MariaDB/mariadb_repo_setup | sudo bash
```

Note that this script also configures a repository for MariaDB MaxScale and a repository for MariaDB Tools, which currently only contains Percona XtraBackup and its dependencies.

See MariaDB Package Repository Setup and Usage for more information.

Using the MariaDB Repository Configuration Tool

If you want to install MariaDB with `yum`, then you can configure `yum` to install from MariaDB Foundation's MariaDB Repository by using the MariaDB Repository Configuration Tool.

The MariaDB Foundation provides a MariaDB repository for several Linux distributions that use `yum` to manage packages. This repository contains software packages related to MariaDB Server, including the server itself, clients and utilities, client libraries, plugins, and Mariabackup. The MariaDB Repository Configuration Tool can easily generate the appropriate configuration file to add the repository for your distribution.

Once you have the appropriate repository configuration section for your distribution, add it to a file named `MariaDB.repo` under `/etc/yum.repos.d/`.

For example, if you wanted to use the repository to install MariaDB 10.6 on RHEL (any version), then you could use the following `yum` repository configuration in `/etc/yum.repos.d/MariaDB.repo`:

```
[mariadb]
name = MariaDB
baseurl = https://rpm.mariadb.org/10.6/rhel/$releasever/$basearch
gpgkey= https://rpm.mariadb.org/RPM-GPG-KEY-MariaDB
gpgcheck=1
```

The example file above includes a `gpgkey` line to automatically fetch the GPG public key that is used to verify the digital signatures of the packages in our repositories. This allows the the `yum`, `dnf`, and `rpm` utilities to verify the integrity of the packages that they install.

Pinning the MariaDB Repository to a Specific Minor Release

If you wish to pin the `yum` repository to a specific minor release, or if you would like to do a `yum downgrade` to a specific minor release, then you can create a `yum` repository configuration with a `baseurl` option set to that specific minor release.

The MariaDB Foundation archives repositories all releases is at the following URL:

- http://archive.mariadb.org/

Note this isn't configured as a highly available server. For that purpose please use the main mirrors.

For example, if you wanted to pin your repository to MariaDB 10.3.34 on CentOS 7, then you could use the following `yum` repository configuration in `/etc/yum.repos.d/MariaDB.repo`:

```
[mariadb]
name = MariaDB-10.3.34
baseurl= http://archive.mariadb.org/mariadb-10.3.34/yum/centos/$releasever/$basearch
gpgkey= https://archive.mariadb.org/PublicKey
gpgcheck=1
```

Note that if you change an existing repository configuration, then you may need to execute the following:

```
sudo yum clean all
```

Updating the MariaDB YUM repository to a New Major Release

MariaDB's `yum` repository can be updated to a new major release. How this is done depends on how you originally configured the repository.

Updating the Major Release with the MariaDB Package Repository Setup Script

If you configured `yum` to install from MariaDB Corporation's MariaDB Package Repository by using the MariaDB Package Repository setup script, then you can update the major release that the repository uses by running the script again.

Updating the Major Release with the MariaDB Repository Configuration Tool

If you configured `yum` to install from MariaDB Foundation's MariaDB Repository by using the MariaDB Repository Configuration Tool, then you can update the major release that the repository uses by updating the `yum` repository configuration file in-place. For example, if you wanted to change the repository from MariaDB 10.6 to MariaDB 10.11, and if the repository configuration file was at `/etc/yum.repos.d/MariaDB.repo`, then you could execute the following:

```
sudo sed -i 's/10.6/10.11/' /etc/yum.repos.d/MariaDB.repo
```

After that, the repository should refer to MariaDB 10.11.

If the `yum` repository is pinned to a specific minor release, then the above `sed` command can result in an invalid repository configuration. In that case, the recommended options are:

- Edit the `MariaDB.repo` repository file manually.
- Or delete the `MariaDB.repo` repository file, and then install the repository of the new version with the more robust

MariaDB Package Repository setup script.

Importing the MariaDB GPG Public Key

Before MariaDB can be installed, you also have to import the GPG public key that is used to verify the digital signatures of the packages in our repositories. This allows the `yum`, `dnf` and `rpm` utilities to verify the integrity of the packages that they install.

The id of our GPG public key is:

- short form: `0xC74CD1D8`
- long form: `0xF1656F24C74CD1D8`
- full fingerprint: `177F 4010 FE56 CA33 3630 0305 F165 6F24 C74C D1D8`

`yum` should prompt you to import the GPG public key the first time that you install a package from MariaDB's repository. However, if you like, the rpm utility can be used to manually import this key instead. For example:

```
sudo rpm --import https://supplychain.mariadb.com/MariaDB-Server-GPG-KEY
```

Once the GPG public key is imported, you are ready to install packages from the repository.

Old Key

For releases before 2023 an older SHA1 based GPG key was used.

The id of this older GPG public key was `0xcbcb082a1bb943db`. The short form was `0x1BB943DB`. The full key fingerprint was:

```
1993 69E5 404B D5FC 7D2F E43B CBCB 082A 1BB9 43DB
```

Installing MariaDB Packages with YUM/DNF

After the `dnf` / `yum` repository is configured, you can install MariaDB by executing the dnf or yum command. The specific command that you would use would depend on which specific packages that you want to install.

Installing the Most Common Packages

MariaDB starting with 10.4

In MariaDB 10.4 and later, to Install the most common packages, execute the following command:

```
sudo dnf install MariaDB-server galera-4 MariaDB-client MariaDB-shared MariaDB-backup MariaDB
```

MariaDB until 10.3

In MariaDB 10.3 and before, to Install the most common packages, execute the following command:

```
sudo yum install MariaDB-server galera MariaDB-client MariaDB-shared MariaDB-backup MariaDB-c
```

Installing MariaDB Server

To Install MariaDB Server, execute the following command:

```
sudo dnf install MariaDB-server
```

Installing MariaDB Galera Cluster with YUM

The process to install MariaDB Galera Cluster with the MariaDB `yum` repository is practically the same as installing standard MariaDB Server.

In MariaDB 10.4 and later, you also need to install the `galera-4` package to obtain the Galera 4 wsrep provider library.

In MariaDB 10.3 and before, you also need to install the `galera` package to obtain the Galera 3 wsrep provider library.

MariaDB starting with 10.4

In MariaDB 10.4 and later, to install MariaDB Galera Cluster, you could execute the following command:

```
sudo yum install MariaDB-server MariaDB-client galera-4
```

MariaDB until 10.3

In MariaDB 10.3 and before, to install MariaDB Galera Cluster, you could execute the following command:

```
sudo yum install MariaDB-server MariaDB-client galera
```

If you haven't yet imported the MariaDB GPG public key, then `yum` will prompt you to import it after it downloads the packages, but before it prompts you to install them.

See MariaDB Galera Cluster for more information on MariaDB Galera Cluster.

Installing MariaDB Clients and Client Libraries with YUM

In MariaDB 10.2 and later, MariaDB Connector/C has been included as the client library (statically linked). However, the package name for the client library has not been changed.

To Install the clients and client libraries, execute the following command:

```
sudo yum install MariaDB-client MariaDB-shared
```

If you want compile your own programs against MariaDB Connector/C, execute the following command:

```
sudo yum install MariaDB-devel
```

Installing Mariabackup with YUM

To install Mariabackup, execute the following command:

```
sudo yum install MariaDB-backup
```

Installing Plugins with YUM

Some plugins may also need to be installed.

For example, to install the cracklib_password_check password validation plugin, execute the following command:

```
sudo yum install MariaDB-cracklib-password-check
```

Installing Debug Info Packages with YUM

MariaDB starting with 5.5.64

The MariaDB `yum` repository first added debuginfo packages in MariaDB 5.5.64, MariaDB 10.1.39, MariaDB 10.2.23, MariaDB 10.3.14, and MariaDB 10.4.4.

The MariaDB `yum` repository also contains debuginfo packages. These package may be needed when debugging a problem.

Installing Debug Info for the Most Common Packages with YUM

To install debuginfo for the most common packages, execute the following command:

```
sudo yum install MariaDB-server-debuginfo MariaDB-client-debuginfo MariaDB-shared-debuginfo
MariaDB-backup-debuginfo MariaDB-common-debuginfo
```

All packages have their debuginfo by appending `-debuginfo` to the package name.

Installing Debug Info for MariaDB Server with YUM

To install debuginfo for MariaDB Server, execute the following command:

```
sudo yum install MariaDB-server-debuginfo
```

Installing Older Versions from the Repository

The MariaDB `yum` repository contains the last few versions of MariaDB. To show what versions are available, use the following command:

```
yum list --showduplicates MariaDB-server
```

In the output you will see the available versions. For example:

```
$ yum list --showduplicates MariaDB-server
Loaded plugins: fastestmirror
Loading mirror speeds from cached hostfile
 * base: centos.mirrors.ovh.net
 * extras: centos.mirrors.ovh.net
 * updates: centos.mirrors.ovh.net
Available Packages
MariaDB-server.x86_64   10.3.10-1.el7.centos    mariadb
MariaDB-server.x86_64   10.3.11-1.el7.centos    mariadb
MariaDB-server.x86_64   10.3.12-1.el7.centos    mariadb
mariadb-server.x86_64   1:5.5.60-1.el7_5         base
```

The MariaDB `yum` repository in this example contains MariaDB 10.3.10, MariaDB 10.3.11, and MariaDB 10.3.12. The CentOS base `yum` repository also contains MariaDB 5.5.60.

To install an older version of a package instead of the latest version we just need to specify the package name, a dash, and then the version number. And we only need to specify enough of the version number for it to be unique from the other available versions.

However, when installing an older version of a package, if `yum` has to install dependencies, then it will automatically choose to install the latest versions of those packages. To ensure that all MariaDB packages are on the same version in this scenario, it is necessary to specify them all.

The packages that the MariaDB-server package depend on are: MariaDB-client, MariaDB-shared, and MariaDB-common. Therefore, to install MariaDB 10.3.11 from this `yum` repository, we would do the following:

```
sudo yum install MariaDB-server-10.3.11 MariaDB-client-10.3.11 MariaDB-shared-10.3.11 MariaDB-
backup-10.3.11 MariaDB-common-10.3.11
```

The rest of the install and setup process is as normal.

After Installation

After the installation is complete, you can start MariaDB.

If you are using MariaDB Galera Cluster, then keep in mind that the first node will have to be bootstrapped.

2.1.2.1.3 Installing MariaDB with zypper

On SLES, OpenSUSE, and other similar Linux distributions, it is highly recommended to install the relevant RPM packages from MariaDB's repository using `zypper` .

This page walks you through the simple installation steps using `zypper` .

Contents

Adding the MariaDB ZYpp repository

We currently have ZYpp repositories for the following Linux distributions:

- SUSE Linux Enterprise Server (SLES) 12
- SUSE Linux Enterprise Server (SLES) 15
- OpenSUSE 15
- OpenSUSE 42

Using the MariaDB Package Repository Setup Script

If you want to install MariaDB with `zypper`, then you can configure `zypper` to install from MariaDB Corporation's MariaDB Package Repository by using the MariaDB Package Repository setup script.

MariaDB Corporation provides a MariaDB Package Repository for several Linux distributions that use `zypper` to manage packages. This repository contains software packages related to MariaDB Server, including the server itself, clients and utilities, client libraries, plugins, and Mariabackup. The MariaDB Package Repository setup script automatically configures your system to install packages from the MariaDB Package Repository.

To use the script, execute the following command:

```
curl -sS https://downloads.mariadb.com/MariaDB/mariadb_repo_setup | sudo bash
```

Note that this script also configures a repository for MariaDB MaxScale and a repository for MariaDB Tools, which currently only contains Percona XtraBackup and its dependencies.

See MariaDB Package Repository Setup and Usage for more information.

Using the MariaDB Repository Configuration Tool

If you want to install MariaDB with `zypper`, then you can configure `zypper` to install from MariaDB Foundation's MariaDB Repository by using the MariaDB Repository Configuration Tool.

The MariaDB Foundation provides a MariaDB repository for several Linux distributions that use `zypper` to manage packages. This repository contains software packages related to MariaDB Server, including the server itself, clients and utilities, client libraries, plugins, and Mariabackup. The MariaDB Repository Configuration Tool can easily generate the appropriate commands to add the repository for your distribution.

For example, if you wanted to use the repository to install MariaDB 10.3 on SLES 15, then you could use the following commands to add the MariaDB `zypper` repository:

```
sudo zypper addrepo --gpgcheck --refresh https://yum.mariadb.org/10.3/sles/15/x86_64 mariadb
sudo zypper --gpg-auto-import-keys refresh
```

Pinning the MariaDB Repository to a Specific Minor Release

If you wish to pin the `zypper` repository to a specific minor release, or if you would like to downgrade to a specific minor release, then you can create a `zypper` repository with the URL hard-coded to that specific minor release.

The MariaDB Foundation archives repositories of old minor releases at the following URL:

- http://archive.mariadb.org/

So if you can't find the repository of a specific minor release at `yum.mariadb.org`, then it would be a good idea to check the archive.

For example, if you wanted to pin your repository to MariaDB 10.3.14 on SLES 15, then you could use the following commands to add the MariaDB `zypper` repository:

```
sudo zypper removerepo mariadb
sudo zypper addrepo --gpgcheck --refresh https://yum.mariadb.org/10.3.14/sles/15/x86_64 mariadb
```

Updating the MariaDB ZYpp repository to a New Major Release

MariaDB's `zypper` repository can be updated to a new major release. How this is done depends on how you originally configured the repository.

Updating the Major Release with the MariaDB Package Repository Setup Script

If you configured `zypper` to install from MariaDB Corporation's MariaDB Package Repository by using the MariaDB Package Repository setup script, then you can update the major release that the repository uses by running the script again.

Updating the Major Release with the MariaDB Repository Configuration Tool

If you configured `zypper` to install from MariaDB Foundation's MariaDB Repository by using the MariaDB Repository Configuration Tool, then you can update the major release that the repository uses by removing the repository for the old version and adding the repository for the new version.

First, you can remove the repository for the old version by executing the following command:

```
sudo zypper removerepo mariadb
```

After that, you can add the repository for the new version. For example, if you wanted to use the repository to install MariaDB 10.3 on SLES 15, then you could use the following commands to add the MariaDB `zypper` repository:

```
sudo zypper addrepo --gpgcheck --refresh https://yum.mariadb.org/10.3/sles/15/x86_64 mariadb
sudo zypper --gpg-auto-import-keys refresh
```

After that, the repository should refer to MariaDB 10.3.

Importing the MariaDB GPG Public Key

Before MariaDB can be installed, you also have to import the GPG public key that is used to verify the digital signatures of the packages in our repositories. This allows the the `zypper` and `rpm` utilities to verify the integrity of the packages that they install.

The id of our GPG public key is `0xcbcb082a1bb943db`. The short form of the id is `0x1BB943DB`. The full key fingerprint is:

```
1993 69E5 404B D5FC 7D2F E43B CBCB 082A 1BB9 43DB
```

The `rpm` utility can be used to import this key. For example:

```
sudo rpm --import https://yum.mariadb.org/RPM-GPG-KEY-MariaDB
```

Once the GPG public key is imported, you are ready to install packages from the repository.

Installing MariaDB Packages with ZYpp

After the `zypper` repository is configured, you can install MariaDB by executing the `zypper` command. The specific command that you would use would depend on which specific packages that you want to install.

Installing the Most Common Packages with ZYpp

MariaDB starting with 10.4

In MariaDB 10.4 and later, to Install the most common packages, execute the following command:

```
sudo zypper install MariaDB-server galera-4 MariaDB-client MariaDB-shared MariaDB-backup
MariaDB-common
```

MariaDB until 10.3

In MariaDB 10.3 and before, to Install the most common packages, execute the following command:

```
sudo zypper install MariaDB-server galera MariaDB-client MariaDB-shared MariaDB-backup
MariaDB-common
```

Installing MariaDB Server with ZYpp

To Install MariaDB Server, execute the following command:

```
sudo zypper install MariaDB-server
```

Installing MariaDB Galera Cluster with ZYpp

The process to install MariaDB Galera Cluster with the MariaDB `zypper` repository is practically the same as installing standard MariaDB Server.

In MariaDB 10.1 and later, Galera Cluster support has been included in the standard MariaDB Server packages, so you will need to install the `MariaDB-server` package, as you normally would.

In MariaDB 10.4 and later, you also need to install the `galera-4` package to obtain the Galera 4 wsrep provider library.

In MariaDB 10.3 and before, you also need to install the `galera` package to obtain the Galera 3 wsrep provider library.

MariaDB starting with 10.4

In MariaDB 10.4 and later, to install MariaDB Galera Cluster, you could execute the following command:

```
sudo zypper install MariaDB-server MariaDB-client galera-4
```

MariaDB until 10.3

In MariaDB 10.3 and before, to install MariaDB Galera Cluster, you could execute the following command:

```
sudo zypper install MariaDB-server MariaDB-client galera
```

If you haven't yet imported the MariaDB GPG public key, then `zypper` will prompt you to import it after it downloads the packages, but before it prompts you to install them.

See MariaDB Galera Cluster for more information on MariaDB Galera Cluster.

Installing MariaDB Clients and Client Libraries with ZYpp

In MariaDB 10.2 and later, MariaDB Connector/C has been included as the client library. However, the package name for

the client library has not been changed.

To Install the clients and client libraries, execute the following command:

```
sudo zypper install MariaDB-client MariaDB-shared
```

Installing Mariabackup with ZYpp

To install Mariabackup, execute the following command:

```
sudo zypper install MariaDB-backup
```

Installing Plugins with ZYpp

Some plugins may also need to be installed.

For example, to install the `cracklib_password_check` password validation plugin, execute the following command:

```
sudo zypper install MariaDB-cracklib-password-check
```

Installing Debug Info Packages with ZYpp

MariaDB starting with 5.5.64

The MariaDB `zypper` repository first added `debuginfo` packages in MariaDB 5.5.64, MariaDB 10.1.39, MariaDB 10.2.23, MariaDB 10.3.14, and MariaDB 10.4.4.

The MariaDB `zypper` repository also contains `debuginfo` packages. These package may be needed when debugging a problem.

Installing Debug Info for the Most Common Packages with ZYpp

To install debuginfo for the most common packages, execute the following command:

```
sudo zypper install MariaDB-server-debuginfo MariaDB-client-debuginfo MariaDB-shared-debuginfo
MariaDB-backup-debuginfo MariaDB-common-debuginfo
```

Installing Debug Info for MariaDB Server with ZYpp

To install `debuginfo` for MariaDB Server, execute the following command:

```
sudo zypper install MariaDB-server-debuginfo
```

Installing Debug Info for MariaDB Clients and Client Libraries with ZYpp

In MariaDB 10.2 and later, MariaDB Connector/C has been included as the client library. However, the package name for the client library has not been changed.

To install `debuginfo` for the clients and client libraries, execute the following command:

```
sudo zypper install MariaDB-client-debuginfo MariaDB-shared-debuginfo
```

Installing Debug Info for Mariabackup with ZYpp

To install `debuginfo` for Mariabackup, execute the following command:

```
sudo zypper install MariaDB-backup-debuginfo
```

Installing Debug Info for Plugins with ZYpp

For some plugins, `debuginfo` may also need to be installed.

For example, to install `debuginfo` for the `cracklib_password_check` password validation plugin, execute the following command:

```
sudo zypper install MariaDB-cracklib-password-check-debuginfo
```

Installing Older Versions from the Repository

The MariaDB `zypper` repository contains the last few versions of MariaDB. To show what versions are available, use the following command:

```
zypper search --details MariaDB-server
```

In the output you will see the available versions.

To install an older version of a package instead of the latest version we just need to specify the package name, a dash, and then the version number. And we only need to specify enough of the version number for it to be unique from the other available versions.

However, when installing an older version of a package, if `zypper` has to install dependencies, then it will automatically choose to install the latest versions of those packages. To ensure that all MariaDB packages are on the same version in this scenario, it is necessary to specify them all.

The packages that the MariaDB-server package depend on are: MariaDB-client, MariaDB-shared, and MariaDB-common. Therefore, to install MariaDB 10.3.14 from this `zypper` repository, we would do the following:

```
sudo zypper install MariaDB-server-10.3.14 MariaDB-client-10.3.14 MariaDB-shared-10.3.14
MariaDB-backup-10.3.14 MariaDB-common-10.3.14
```

The rest of the install and setup process is as normal.

After Installation

After the installation is complete, you can start MariaDB.

If you are using MariaDB Galera Cluster, then keep in mind that the first node will have to be bootstrapped.

2.1.2.1.4 Installing MariaDB With the rpm Tool

This article describes how to download the RPM files and install them using the `rpm` command.

It is highly recommended to Install MariaDB with yum where possible.

Navigate to https://mariadb.org/download/ and choose the desired database version and then select the RPMs that match your Linux distribution and architecture.

Clicking those links takes you to a local mirror. Choose the rpms link and download the desired packages. The packages will be similar to the following:

```
MariaDB-client-5.2.5-99.el5.x86_64.rpm
MariaDB-debuginfo-5.2.5-99.el5.x86_64.rpm
MariaDB-devel-5.2.5-99.el5.x86_64.rpm
MariaDB-server-5.2.5-99.el5.x86_64.rpm
MariaDB-shared-5.2.5-99.el5.x86_64.rpm
MariaDB-test-5.2.5-99.el5.x86_64.rpm
```

For a standard server installation you will need to download at least the *client*, *shared*, and *server* RPM files. See About the MariaDB RPM Files for more information about what is included in each RPM package.

After downloading the MariaDB RPM files, you might want to check their signatures. See Checking MariaDB RPM Package Signatures for more information about checking signatures.

```
rpm --checksig $(find . -name '*.rpm')
```

Prior to installing MariaDB, be aware that it will conflict with an existing installation of MySQL. To check whether MySQL is already installed, issue the command:

```
rpm -qa 'mysql*'
```

If necessary, you can remove found MySQL packages before installing MariaDB.

To install MariaDB, use the command:

```
rpm -ivh MariaDB-*
```

You should see output such as the following:

```
Preparing...                ########################################### [100%]
   1:MariaDB-shared         ########################################### [ 14%]
   2:MariaDB-client         ########################################### [ 29%]
   3:MariaDB-client         ########################################### [ 43%]
   4:MariaDB-debuginfo      ########################################### [ 57%]
   5:MariaDB-devel          ########################################### [ 71%]
   6:MariaDB-server         ########################################### [ 86%]

PLEASE REMEMBER TO SET A PASSWORD FOR THE MariaDB root USER !
To do so, start the server, then issue the following commands:

/usr/bin/mariadb-admin -u root password 'new-password'
/usr/bin/mariadb-admin -u root -h hostname password 'new-password'

Alternatively you can run:
/usr/bin/mysql_secure_installation

which will also give you the option of removing the test
databases and anonymous user created by default.  This is
strongly recommended for production servers.

See the MySQL manual for more instructions.

Please report any problems with the /usr/bin/mysqlbug script!

The latest information about MariaDB is available at http://www.askmonty.org/.
You can find additional information about the MySQL part at:
http://dev.mysql.com
Support MariaDB development by buying support/new features from
Monty Program Ab. You can contact us about this at sales@askmonty.org.
Alternatively consider joining our community based development effort:
http://askmonty.org/wiki/index.php/MariaDB#How_can_I_participate_in_the_development_of_MariaDB

Starting MySQL....[  OK  ]
Giving mysqld 2 seconds to start
   7:MariaDB-test           ########################################### [100%]
```

Be sure to follow the instructions given in the preceding output and create a password for the root user either by using mariadb-admin or by running the /usr/bin/mysql_secure_installation script.

Installing the MariaDB RPM files installs the MySQL tools in the `/usr/bin` directory. You can confirm that MariaDB has been installed by using the mariadb client program. Issuing the command `mariadb` should give you the MariaDB cursor.

2.1.2.1.5 Checking MariaDB RPM Package Signatures

MariaDB RPM packages since MariaDB 5.1.55 are signed.

The key we use has an id of `1BB943DB` and the key fingerprint is:

```
1993 69E5 404B D5FC 7D2F E43B CBCB 082A 1BB9 43DB
```

To check the signature you first need to import the public part of the key like so:

```
gpg --keyserver hkp://pgp.mit.edu --recv-keys 1BB943DB
```

Next you need to let pgp know about the key like so:

```
gpg --export --armour 1BB943DB > mariadb-signing-key.asc
sudo rpm --import mariadb-signing-key.asc
```

You can check to see if the key was imported with:

```
rpm -qa gpg-pubkey*
```

Once the key is imported, you can check the signature of the MariaDB RPM files by running the something like the following in your download directory:

```
rpm --checksig $(find . -name '*.rpm')
```

The output of the above will look something like this (make sure gpg shows up on each OK line):

```
me@desktop:~$ rpm --checksig $(find . -name '*.rpm')
./kvm-rpm-centos5-amd64/rpms/MariaDB-test-5.1.55-98.el5.x86_64.rpm: (sha1) dsa sha1 md5 gpg OK
./kvm-rpm-centos5-amd64/rpms/MariaDB-server-5.1.55-98.el5.x86_64.rpm: (sha1) dsa sha1 md5 gpg OK
./kvm-rpm-centos5-amd64/rpms/MariaDB-client-5.1.55-98.el5.x86_64.rpm: (sha1) dsa sha1 md5 gpg OK
./kvm-rpm-centos5-amd64/rpms/MariaDB-shared-5.1.55-98.el5.x86_64.rpm: (sha1) dsa sha1 md5 gpg OK
./kvm-rpm-centos5-amd64/rpms/MariaDB-devel-5.1.55-98.el5.x86_64.rpm: (sha1) dsa sha1 md5 gpg OK
./kvm-rpm-centos5-amd64/rpms/MariaDB-debuginfo-5.1.55-98.el5.x86_64.rpm: (sha1) dsa sha1 md5 gpg
./kvm-rpm-centos5-amd64/srpms/MariaDB-5.1.55-98.el5.src.rpm: (sha1) dsa sha1 md5 gpg OK
```

2.1.2.1.6 Troubleshooting MariaDB Installs on Red Hat/CentOS

The following article is about different issues people have encountered when installing MariaDB on Red Hat / CentOS.

It is highly recommended to install with yum where possible.

In Red Hat / CentOS it is also possible to install a RPM or a tar ball. The RPM is the preferred version, except if you want to install many versions of MariaDB or install MariaDB in a non standard location.

Replacing MySQL

If you removed an MySQL RPM to install MariaDB, note that the MySQL RPM on uninstall renames /etc/my.cnf to /etc/my.cnf.rpmsave.

After installing MariaDB you should do the following to restore your configuration options:

```
mv /etc/my.cnf.rpmsave /etc/my.cnf
```

Unsupported configuration options

If you are using any of the following options in your /etc/my.cnf or other my.cnf file you should remove them. This is also true for MySQL 5.1 or newer:

```
skip-bdb
```

2.1.2.1.7 MariaDB for DirectAdmin Using RPMs

If you are using DirectAdmin and you encounter any issues with Installing MariaDB with YUM, then the directions below may help. The process is very straightforward.

Note: Installing with YUM is preferable to installing the MariaDB RPM packages manually, so only do this if you are having issues such as:

```
Starting httpd:
  httpd:
    Syntax error on line 18 of /etc/httpd/conf/httpd.conf:
    Syntax error on line 1 of /etc/httpd/conf/extra/httpd-phpmodules.conf:
      Cannot load /usr/lib/apache/libphp5.so into server:
        libmysqlclient.so.18: cannot open shared object file: No such file or directory
```

Or:

```
Starting httpd:
  httpd:
    Syntax error on line 18 of /etc/httpd/conf/httpd.conf:
    Syntax error on line 1 of /etc/httpd/conf/extra/httpd-phpmodules.conf:
      Cannot load /usr/lib/apache/libphp5.so into server:
        /usr/lib/apache/libphp5.so: undefined symbol: client_errors
```

RPM Installation

To install the RPMs, there is a quick and easy guide to Installing MariaDB with the RPM Tool. Follow the instructions there.

Necessary Edits

We do not want DirectAdmin's custombuild to remove/overwrite our MariaDB installation whenever an update is performed. To rectify this, disable automatic MySQL installation.

Edit `/usr/local/directadmin/custombuild/options.conf`

Change:

```
mysql_inst=yes
```

To:

```
mysql_inst=no
```

Note: When MariaDB is installed manually (i.e. not using YUM), updates are not automatic. You will need to update the RPMs yourself.

2.1.2.1.8 MariaDB Installation (Version 10.1.21) via RPMs on CentOS 7

Here are the detailed steps for installing MariaDB (version 10.1.21) via RPMs on CentOS 7.

The RPM's needed for the installation are all available on the MariaDB website and are given below:

- jemalloc-3.6.0-1.el7.x86_64.rpm
- MariaDB-10.1.21-centos7-x86_64-client.rpm
- MariaDB-10.1.21-centos7-x86_64-compat.rpm
- galera-25.3.19-1.rhel7.el7.centos.x86_64.rpm
- jemalloc-devel-3.6.0-1.el7.x86_64.rpm
- MariaDB-10.1.21-centos7-x86_64-common.rpm
- MariaDB-10.1.21-centos7-x86_64-server.rpm

Step by step installation:

- 1) First install all of the dependencies needed. Its easy to do this via YUM packages: yum install rsync nmap lsof perl-DBI nc
- 2) rpm -ivh jemalloc-3.6.0-1.el7.x86_64.rpm
- 3) rpm -ivh jemalloc-devel-3.6.0-1.el7.x86_64.rpm
- 4) rpm -ivh MariaDB-10.1.21-centos7-x86_64-common.rpm MariaDB-10.1.21-centos7-x86_64-compat.rpm MariaDB-10.1.21-centos7-x86_64-client.rpm galera-25.3.19-1.rhel7.el7.centos.x86_64.rpm MariaDB-10.1.21-centos7-x86_64-server.rpm

While installing MariaDB-10.1.21-centos7-x86_64-common.rpm there might be a conflict with older MariaDB packages. we need to remove them and install the original rpm again.

Here is the error message for dependencies:

```
# rpm -ivh MariaDB-10.1.21-centos7-x86_64-common.rpm
warning: MariaDB-10.1.21-centos7-x86_64-common.rpm: Header V4 DSA/SHA1 Signature, key ID
1bb943db: NOKEY
error: Failed dependencies:
 mariadb-libs < 1:10.1.21-1.el7.centos conflicts with MariaDB-common-10.1.21-
1.el7.centos.x86_64
```

Solution: search for this package:

```
# rpm -qa | grep mariadb-libs
mariadb-libs-5.5.52-1.el7.x86_64
```

Remove this package:

```
# rpm -ev --nodeps mariadb-libs-5.5.52-1.el7.x86_64
Preparing packages...
mariadb-libs-1:5.5.52-1.el7.x86_64
```

While installing the Galera package there might be a conflict in installation for a dependency package. Here is the error message:

```
[root@centos-2 /]# rpm -ivh galera-25.3.19-1.rhel7.el7.centos.x86_64.rpm
error: Failed dependencies:
 libboost_program_options.so.1.53.0()(64bit) is needed by galera-25.3.19-
1.rhel7.el7.centos.x86_64

The dependencies for Galera package is: libboost_program_options.so.1.53.0
```

Solution:

```
yum install boost-devel.x86_64
```

Another warning message while installing Galera package is as shown below:

```
warning: galera-25.3.19-1.rhel7.el7.centos.x86_64.rpm: Header V4 DSA/SHA1 Signature, key ID
1bb943db: NOKEY
```

The solution for this is to import the key:

```
#rpm --import http://yum.mariadb.org/RPM-GPG-KEY-MariaDB
```

After step 4, the installation will be completed. The last step will be to run mysql_secure_installation to secure the production server by dis allowing remote login for root, creating root password and removing the test database.

- 5) mysql_secure_installation

2.1.2.1.9 Why Source RPMs (SRPMs) Aren't Packaged For Some Platforms

MariaDB source RPMs (SRPMs) are not packaged on all platforms for which MariaDB RPMs are packaged.

The reason is that MariaDB's build process relies heavily on `cmake` for a lot of things. In this specific case, MariaDB's build process relies on CMake CPack Package Generators to build RPMs. The specific package generator that it uses to build RPMs is called `CPackRPM`.

Support for source RPMs in `CPackRPM` became usable with MariaDB's build system starting from around cmake 3.10. This means that we do not produce source RPMs on platforms where the installed `cmake` version is older than that.

See also Building MariaDB from a Source RPM.

2.1.2.1.10 Building MariaDB from a Source RPM

For some distributions you can build MariaDB from a source RPM. (See also Why Source RPMs (SRPMs) Aren't Packaged For Some Platforms).

You can build it as follows:

using dnf

On RHEL8 you might need to start with:

```
sudo dnf config-manager --set-enabled codeready-builder-beta-for-rhel-8-x86_64-rpms
```

Then, on all dnf distributions:

```
sudo dnf install rpm-build perl-generators
dnf download --source MariaDB
sudo dnf builddep MariaDB-*.src.rpm
rpmbuild --rebuild MariaDB-*.src.rpm
```

using yum

```
sudo yum install rpm-build yum-utils
yumdownloader --source MariaDB
sudo yum-builddep MariaDB-*.src.rpm
rpmbuild --rebuild MariaDB-*.src.rpm
```

using zypper

```
sudo zypper in rpm-build
sudo zypper si MariaDB
sudo rpmbuild -bb /usr/src/packages/SPECS/MariaDB.spec
```

Or (to avoid building as root):

```
sudo zypper in rpm-build
sudo zypper si -d MariaDB
zypper --pkg-cache-dir=`pwd` si --download-only MariaDB
rpmbuild --rebuild mariadb/srpms/MariaDB-*.src.rpm
```

2.1.2.2 Installing MariaDB .deb Files

Contents

Installing MariaDB with APT

On Debian, Ubuntu, and other similar Linux distributions, it is highly recommended to install the relevant `.deb` packages from MariaDB's repository using `apt`, `aptitude`, Ubuntu Software Center, Synaptic Package Manager, or another package manager.

This page walks you through the simple installation steps using `apt`.

Adding the MariaDB APT repository

We currently have APT repositories for the following Linux distributions:

- Debian 10 (Buster)
- Debian 11 (Bullseye)
- Debian 12 (Bookworm)
- Debian Unstable (Sid)
- Ubuntu 18.04 LTS (Bionic)
- Ubuntu 20.04 LTS (Focal)
- Ubuntu 22.04 (Jammy)
- Ubuntu 22.10 (Kinetic)
- Ubuntu 23.04 (Lunar)

Using the MariaDB Package Repository Setup Script

If you want to install MariaDB with `apt`, then you can configure `apt` to install from MariaDB Corporation's MariaDB Package Repository by using the MariaDB Package Repository setup script.

MariaDB Corporation provides a MariaDB Package Repository for several Linux distributions that use `apt` to manage packages. This repository contains software packages related to MariaDB Server, including the server itself, clients and utilities, client libraries, plugins, and Mariabackup. The MariaDB Package Repository setup script automatically configures your system to install packages from the MariaDB Package Repository.

To use the script, execute the following command:

```
curl -sS https://downloads.mariadb.com/MariaDB/mariadb_repo_setup | sudo bash
```

Note that this script also configures a repository for MariaDB MaxScale and a repository for MariaDB Tools, which currently only contains Percona XtraBackup and its dependencies.

See MariaDB Package Repository Setup and Usage for more information.

Using the MariaDB Repository Configuration Tool

If you want to install MariaDB with `apt`, then you can configure `apt` to install from MariaDB Foundation's MariaDB Repository by using the MariaDB Repository Configuration Tool.

The MariaDB Foundation provides a MariaDB repository for several Linux distributions that use `apt-get` to manage packages. This repository contains software packages related to MariaDB Server, including the server itself, clients and utilities, client libraries, plugins, and Mariabackup. The MariaDB Repository Configuration Tool can easily generate the appropriate commands to add the repository for your distribution.

There are several ways to add the repository.

Executing add-apt-repository

One way to add an `apt` repository is by using the `add-apt-repository` command. This command will add the repository configuration to `/etc/apt/sources.list`.

For example, if you wanted to use the repository to install MariaDB 10.3 on Ubuntu 18.04 LTS (Bionic), then you could use the following commands to add the MariaDB `apt` repository:

```
sudo apt-get install software-properties-common
sudo add-apt-repository 'deb [arch=amd64,arm64,ppc64el]
http://sfo1.mirrors.digitalocean.com/mariadb/repo/10.3/ubuntu bionic main'
```

And then you would have to update the package cache by executing the following command:

```
sudo apt update
```

Creating a Source List File

Another way to add an `apt` repository is by creating a source list file in `/etc/apt/sources.list.d/`.

For example, if you wanted to use the repository to install MariaDB 10.3 on Ubuntu 18.04 LTS (Bionic), then you could create the `MariaDB.list` file in `/etc/apt/sources.list.d/` with the following contents to add the MariaDB `apt` repository:

```
# MariaDB 10.3 repository list - created 2019-01-27 09:50 UTC
# http://downloads.mariadb.org/mariadb/repositories/
deb [arch=amd64,arm64,ppc64el] http://sfo1.mirrors.digitalocean.com/mariadb/repo/10.3/ubuntu
bionic main
deb-src http://sfo1.mirrors.digitalocean.com/mariadb/repo/10.3/ubuntu bionic main
```

And then you would have to update the package cache by executing the following command:

```
sudo apt update
```

Using Ubuntu Software Center

Another way to add an `apt` repository is by using Ubuntu Software Center.

You can do this by going to the **Software Sources** window. This window can be opened either by navigating to **Edit** > **Software Sources** or by navigating to **System** > **Administration** > **Software Sources**.

Once the **Software Sources** window is open, go to the **Other Software** tab, and click the **Add** button. At that point, you can input the repository information provided by the MariaDB Repository Configuration Tool.

See here for more information.

Using Synaptic Package Manager

Another way to add an `apt` repository is by using Synaptic Package Manager.

You can do this by going to the **Software Sources** window. This window can be opened either by navigating to **System** > **Administrator** > **Software Sources** or by navigating to **Settings** > **Repositories**.

Once the **Software Sources** window is open, go to the **Other Software** tab, and click the **Add** button. At that point, you can

input the repository information provided by the MariaDB Repository Configuration Tool.

See here for more information.

Pinning the MariaDB Repository to a Specific Minor Release

If you wish to pin the `apt` repository to a specific minor release, or if you would like to downgrade to a specific minor release, then you can create a `apt` repository with the URL hard-coded to that specific minor release.

The MariaDB Foundation archives repositories of old minor releases at the following URL:

- http://archive.mariadb.org/

Archives are only of the distros and architectures supported at the time of release. For example MariaDB 10.0.38 is exists for Ubuntu `precise`, `trusty`, `xenial`, `wily`, and `yakkety` obtained looking in https://archive.mariadb.org/mariadb-10.0.38/repo/ubuntu/dists.

For example, if you wanted to pin your repository to MariaDB 10.5.9 on Ubuntu 20.04 LTS (Focal), then you would have to first remove any existing MariaDB repository source list file from `/etc/apt/sources.list.d/`. And then you could use the following commands to add the MariaDB `apt-get` repository:

```
sudo add-apt-repository 'deb [arch=amd64,arm64,ppc64el,s390x]
http://archive.mariadb.org/mariadb-10.5.9/repo/ubuntu/ focal main main/debug'
```

Ensure you have the signing key installed.

Ubuntu Xenial and older will need:

```
sudo apt-get install -y apt-transport-https
```

And then you would have to update the package cache by executing the following command:

```
sudo apt update
```

Updating the MariaDB APT repository to a New Major Release

MariaDB's `apt` repository can be updated to a new major release. How this is done depends on how you originally configured the repository.

Updating the Major Release with the MariaDB Package Repository Setup Script

If you configured `apt` to install from MariaDB Corporation's MariaDB Package Repository by using the MariaDB Package Repository setup script, then you can update the major release that the repository uses by running the script again.

Updating the Major Release with the MariaDB Repository Configuration Tool

If you configured `apt` to install from MariaDB Foundation's MariaDB Repository by using the MariaDB Repository Configuration Tool, then you can update the major release in various ways, depending on how you originally added the repository.

Updating a Repository with add-apt-repository

If you added the `apt` repository by using the `add-apt-repository` command, then you can update the major release that the repository uses by using the the `add-apt-repository` command again.

First, look for the repository string for the old version in `/etc/apt/sources.list`.

And then, you can remove the repository for the old version by executing the `add-apt-repository` command and providing the `--remove` option. For example, if you wanted to remove a MariaDB 10.2 repository, then you could do so by executing something like the following:

```
sudo add-apt-repository --remove 'deb [arch=amd64,arm64,ppc64el]
http://sfo1.mirrors.digitalocean.com/mariadb/repo/10.2/ubuntu bionic main'
```

After that, you can add the repository for the new version with the `add-apt-repository` command. For example, if you wanted to use the repository to install MariaDB 10.3 on Ubuntu 18.04 LTS (Bionic), then you could use the following commands to add the MariaDB `apt` repository:

```
sudo apt-get install software-properties-common
sudo add-apt-repository 'deb [arch=amd64,arm64,ppc64el]
http://sfo1.mirrors.digitalocean.com/mariadb/repo/10.3/ubuntu bionic main'
```

And then you would have to update the package cache by executing the following command:

```
sudo apt update
```

After that, the repository should refer to MariaDB 10.3.

Updating a Source List File

If you added the `apt` repository by creating a source list file in `/etc/apt/sources.list.d/`, then you can update the major release that the repository uses by updating the source list file in-place. For example, if you wanted to change the repository from MariaDB 10.2 to MariaDB 10.3, and if the source list file was at `/etc/apt/sources.list.d/MariaDB.list`, then you could execute the following:

```
sudo sed -i 's/10.2/10.3/' /etc/apt/sources.list.d/MariaDB.list
```

And then you would have to update the package cache by executing the following command:

```
sudo apt update
```

After that, the repository should refer to MariaDB 10.3.

Importing the MariaDB GPG Public Key

Before MariaDB can be installed, you also have to import the GPG public key that is used to verify the digital signatures of the packages in our repositories. This allows the `apt` utility to verify the integrity of the packages that it installs.

- Prior to Debian 9 (Stretch), and Debian Unstable (Sid), and Ubuntu 16.04 LTS (Xenial), the id of our GPG public key is `0xcbcb082a1bb943db`. The full key fingerprint is:

```
1993 69E5 404B D5FC 7D2F E43B CBCB 082A 1BB9 43DB
```

The `apt-key` utility can be used to import this key. For example:

```
sudo apt-key adv --recv-keys --keyserver hkp://keyserver.ubuntu.com:80 0xcbcb082a1bb943db
```

- Starting with Debian 9 (Stretch) and Ubuntu 16.04 LTS (Xenial), the id of our GPG public key is `0xF1656F24C74CD1D8`. The full key fingerprint is:

```
177F 4010 FE56 CA33 3630  0305 F165 6F24 C74C D1D8
```

The `apt-key` utility can be used to import this key. For example:

```
sudo apt-key adv --recv-keys --keyserver hkp://keyserver.ubuntu.com:80 0xF1656F24C74CD1D8
```

Starting with Debian 9 (Stretch), the `dirmngr` package needs to be installed before the GPG public key can be imported. To install it, execute: `sudo apt install dirmngr`

If you are unsure which GPG public key you need, then it is perfectly safe to import both keys.

The command used to import the GPG public key is the same on both Debian and Ubuntu. For example:

```
$ sudo apt-key adv --recv-keys --keyserver hkp://keyserver.ubuntu.com:80 0xcbcb082a1bb943db
Executing: gpg --ignore-time-conflict --no-options --no-default-keyring --secret-keyring
/tmp/tmp.ASyOPV87XC --trustdb-name /etc/apt/trustdb.gpg --keyring /etc/apt/trusted.gpg --
primary-keyring /etc/apt/trusted.gpg --recv-keys --keyserver hkp://keyserver.ubuntu.com:80
0xcbcb082a1bb943db
gpg: requesting key 1BB943DB from hkp server keyserver.ubuntu.com
gpg: key 1BB943DB: "MariaDB Package Signing Key <package-signing-key@mariadb.org>" imported
gpg: no ultimately trusted keys found
gpg: Total number processed: 1
gpg:               imported: 1
```

Once the GPG public key is imported, you are ready to install packages from the repository.

Installing MariaDB Packages with APT

After the `apt` repository is configured, you can install MariaDB by executing the `apt-get` command. The specific command that you would use would depend on which specific packages that you want to install.

Installing the Most Common Packages with APT

To Install the most common packages, first you would have to update the package cache by executing the following command:

```
sudo apt update
```

MariaDB starting with 10.4

In MariaDB 10.4 and later, to Install the most common packages, execute the following command:

```
sudo apt-get install mariadb-server galera-4 mariadb-client libmariadb3 mariadb-backup mariadb
```

MariaDB 10.2 - 10.3

In MariaDB 10.2 and MariaDB 10.3, to Install the most common packages, execute the following command:

```
sudo apt-get install mariadb-server galera mariadb-client libmariadb3 mariadb-backup mariadb-
```

Installing MariaDB Server with APT

To Install MariaDB Server, first you would have to update the package cache by executing the following command:

```
sudo apt update
```

Then, execute the following command:

```
sudo apt-get install mariadb-server
```

Installing MariaDB Galera Cluster with APT

The process to install MariaDB Galera Cluster with the MariaDB `apt-get` repository is practically the same as installing standard MariaDB Server.

In MariaDB 10.1 and later, Galera Cluster support has been included in the standard MariaDB Server packages, so you will need to install the `mariadb-server` package, as you normally would.

In MariaDB 10.4 and later, you also need to install the `galera-4` package to obtain the Galera 4 wsrep provider library.

In MariaDB 10.3 and before, you also need to install the `galera-3` package to obtain the Galera 3 wsrep provider library.

To install MariaDB Galera Cluster, first you would have to update the package cache by executing the following command:

```
sudo apt update
```

MariaDB starting with 10.4

In MariaDB 10.4 and later, to install MariaDB Galera Cluster, you could execute the following command:

```
sudo apt-get install mariadb-server mariadb-client galera-4
```

MariaDB until 10.3

In MariaDB 10.3 and before, to install MariaDB Galera Cluster, you could execute the following command:

```
sudo apt-get install mariadb-server mariadb-client galera-3
```

MariaDB Galera Cluster also has a separate package that can be installed on arbitrator nodes. In MariaDB 10.4 and later, the package is called `galera-arbitrator-4`. In MariaDB 10.3 and before, the package is called `galera-arbitrator-3`. This package should be installed on whatever node you want to serve as the arbitrator. It can either run on a separate server that is not acting as a cluster node, which is the recommended configuration, or it can run on a server that is also acting as an existing cluster node.

MariaDB starting with 10.4

In MariaDB 10.4 and later, to install the arbitrator package, you could execute the following command:

```
sudo apt-get install galera-arbitrator-4
```

MariaDB until 10.3

In MariaDB 10.3 and before, to install the arbitrator package, you could execute the following command:

```
sudo apt-get install galera-arbitrator-3
```

See MariaDB Galera Cluster for more information on MariaDB Galera Cluster.

Installing MariaDB Clients and Client Libraries with APT

In MariaDB 10.2 and later, MariaDB Connector/C has been included as the client library.

To Install the clients and client libraries, first you would have to update the package cache by executing the following command:

```
sudo apt update
```

Then, in MariaDB 10.2 and later, execute the following command:

```
sudo apt-get install mariadb-client libmariadb3
```

Installing Mariabackup with APT

To install Mariabackup, first you would have to update the package cache by executing the following command:

```
sudo apt update
```

Then, execute the following command:

```
sudo apt-get install mariadb-backup
```

Installing Plugins with APT

Some plugins may also need to be installed.

For example, to install the `cracklib_password_check` password validation plugin, first you would have to update the package cache by executing the following command:

```
sudo apt update
```

Then, execute the following command:

```
sudo apt-get install mariadb-cracklib-password-check
```

Installing Older Versions from the Repository

The MariaDB `apt` repository contains the last few versions of MariaDB. To show what versions are available, use the `apt-cache` command:

```
sudo apt-cache showpkg mariadb-server
```

In the output you will see the available versions.

To install an older version of a package instead of the latest version we just need to specify the package name, an equal sign, and then the version number.

However, when installing an older version of a package, if `apt-get` has to install dependencies, then it will automatically choose to install the latest versions of those packages. To ensure that all MariaDB packages are on the same version in this scenario, it is necessary to specify them all. Therefore, to install MariaDB 10.3.14 from this `apt` repository, we would do the following:

```
sudo apt-get install mariadb-server=10.3.14-1 mariadb-client=10.3.14-1 libmariadb3=10.3.14-1
mariadb-backup=10.3.14-1 mariadb-common=10.3.14-1
```

The rest of the install and setup process is as normal.

Installing MariaDB with dpkg

While it is not recommended, it is possible to download and install the `.deb` packages manually. However, it is generally recommended to use a package manager like `apt-get`.

A tarball that contains the `.deb` packages can be downloaded from the following URL:

- https://downloads.mariadb.com

For example, to install the MariaDB 10.4.8 `.deb` packages on Ubuntu 18.04 LTS (Bionic), you could execute the following:

```
sudo apt-get update
sudo apt-get install libdbi-perl libdbd-mysql-perl psmisc libaio1 socat
wget https://downloads.mariadb.com/MariaDB/mariadb-10.4.8/repo/ubuntu/mariadb-10.4.8-ubuntu-
bionic-amd64-debs.tar
tar -xvf mariadb-10.4.8-ubuntu-bionic-amd64-debs.tar
cd mariadb-10.4.8-ubuntu-bionic-amd64-debs/
sudo dpkg --install ./mariadb-common*.deb \
   ./mysql-common*.deb \
   ./mariadb-client*.deb \
   ./libmariadb3*.deb \
   ./libmysqlclient18*.deb
sudo dpkg --install ./mariadb-server*.deb \
   ./mariadb-backup*.deb \
   ./galera-4*.deb
```

After Installation

After the installation is complete, you can start MariaDB.

If you are using MariaDB Galera Cluster, then keep in mind that the first node will have to be bootstrapped.

Available DEB Packages

The available DEB packages depend on the specific MariaDB release series.

Available DEB Packages in MariaDB 10.4

MariaDB starting with 10.4

In MariaDB 10.4, the following DEBs are available:

Package Name	Description

galera-4	The WSREP provider for Galera 4.
libmariadb3	Dynamic client libraries.
libmariadb-dev	Development headers and static libraries.
libmariadbclient18	Virtual package to satisfy external depends
libmysqlclient18	Virtual package to satisfy external depends
mariadb-backup	Mariabackup
mariadb-client	Client tools like mariadb CLI, mariadb-dump, and others.
mariadb-client-core	Core client tools
mariadb-common	Character set files and /etc/my.cnf
mariadb-plugin-connect	The CONNECT storage engine.
mariadb-plugin-cracklib-password-check	The cracklib_password_check password validation plugin.
mariadb-plugin-gssapi-client	The client-side component of the gssapi authentication plugin.
mariadb-plugin-gssapi-server	The server-side component of the gssapi authentication plugin.
mariadb-plugin-rocksdb	The MyRocks storage engine.
mariadb-plugin-spider	The SPIDER storage engine.
mariadb-plugin-tokudb	The TokuDB storage engine.
mariadb-server	The server and server tools, like myisamchk and mariadb-hotcopy are here.
mariadb-server-core	The core server.
mariadb-test	mysql-client-test executable, and **mysql-test** framework with the tests.
mariadb-test-data	MariaDB database regression test suite - data files

Available DEB Packages in MariaDB 10.2 and MariaDB 10.3

MariaDB starting with 10.2

In MariaDB 10.2 and MariaDB 10.3, the following DEBs are available:

Package Name	Description
galera	The WSREP provider for Galera 3.
libmariadb3	Dynamic client libraries.
libmariadb-dev	Development headers and static libraries.
libmariadbclient18	Virtual package to satisfy external depends
libmysqlclient18	Virtual package to satisfy external depends
mariadb-backup	Mariabackup
mariadb-client	Client tools like mariadb CLI, mariadb-dump, and others.
mariadb-client-core	Core client tools
mariadb-common	Character set files and /etc/my.cnf
mariadb-plugin-connect	The CONNECT storage engine.
mariadb-plugin-cracklib-password-check	The cracklib_password_check password validation plugin.
mariadb-plugin-gssapi-client	The client-side component of the gssapi authentication plugin.
mariadb-plugin-gssapi-server	The server-side component of the gssapi authentication plugin.
mariadb-plugin-rocksdb	The MyRocks storage engine.

`mariadb-plugin-spider`	The `SPIDER` storage engine.
`mariadb-plugin-tokudb`	The TokuDB storage engine.
`mariadb-server`	The server and server tools, like myisamchk and mariadb-hotcopy are here.
`mariadb-server-core`	The core server.
`mariadb-test`	`mysql-client-test` executable, and **mysql-test** framework with the tests.
`mariadb-test-data`	MariaDB database regression test suite - data files

Actions Performed by DEB Packages

Users and Groups Created

When the `mariadb-server` DEB package is installed, it will create a user and group named `mysql`, if they do not already exist.

2.1.2.3 Installing MariaDB MSI Packages on Windows

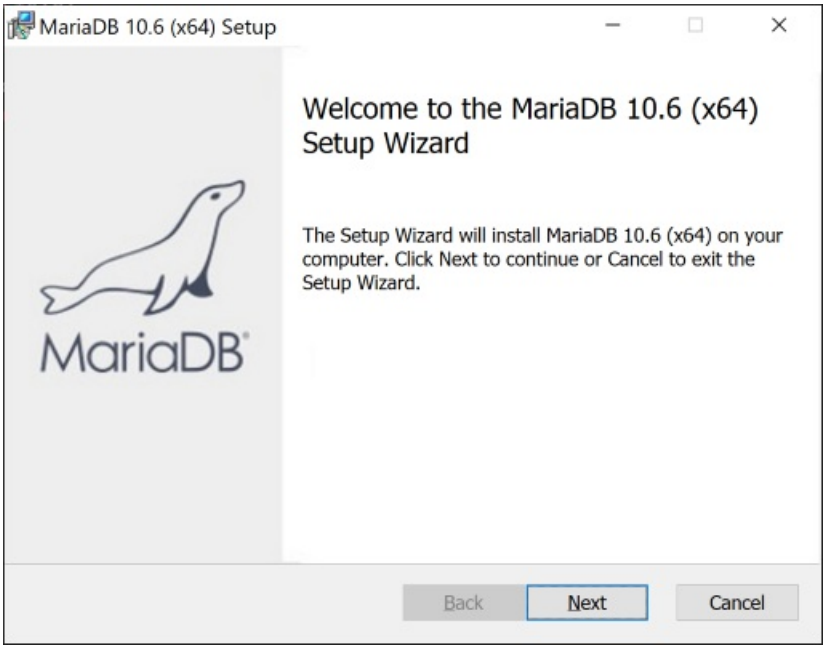
MSI packages is available for x64 (64 bit) processor architectures and, in some older releases only, for x86 (32 bit). We'll use screenshots from an x64 installation below (the 32 bit installer is very similar).

Contents

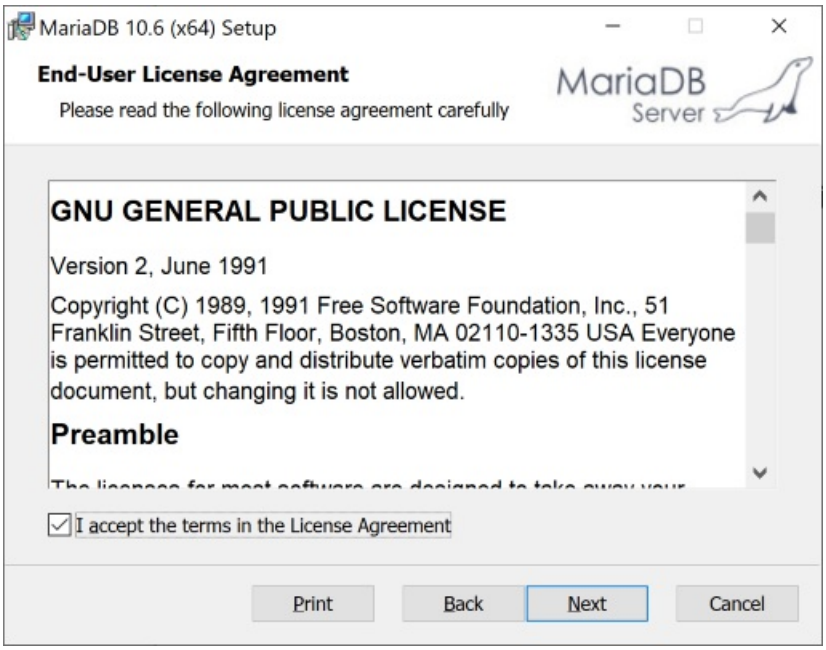
Installation UI

This is the typical mode of installation. To start the installer, just click on the mariadb-<major>.<minor>.<patch>.msi

Welcome

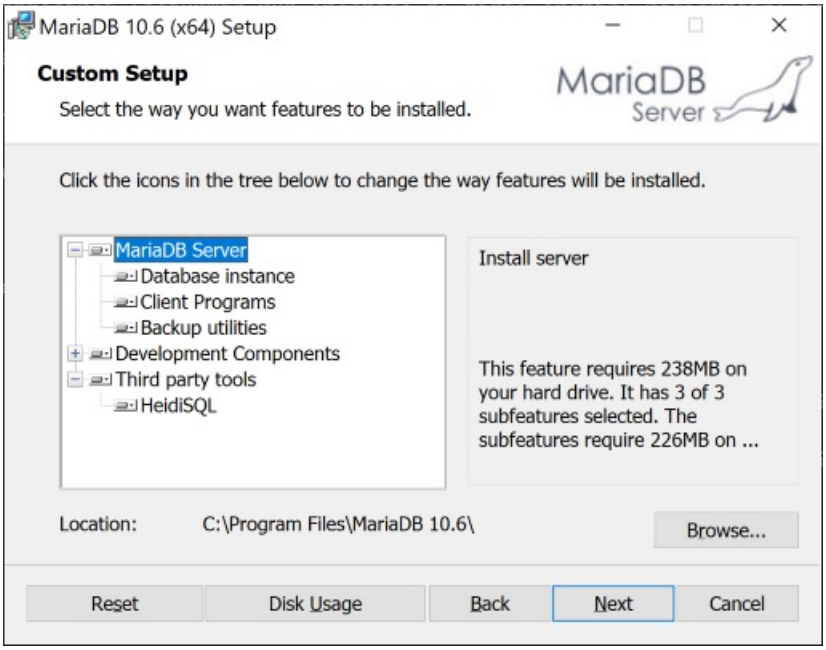


License Agreement



Click on "I accept the terms"

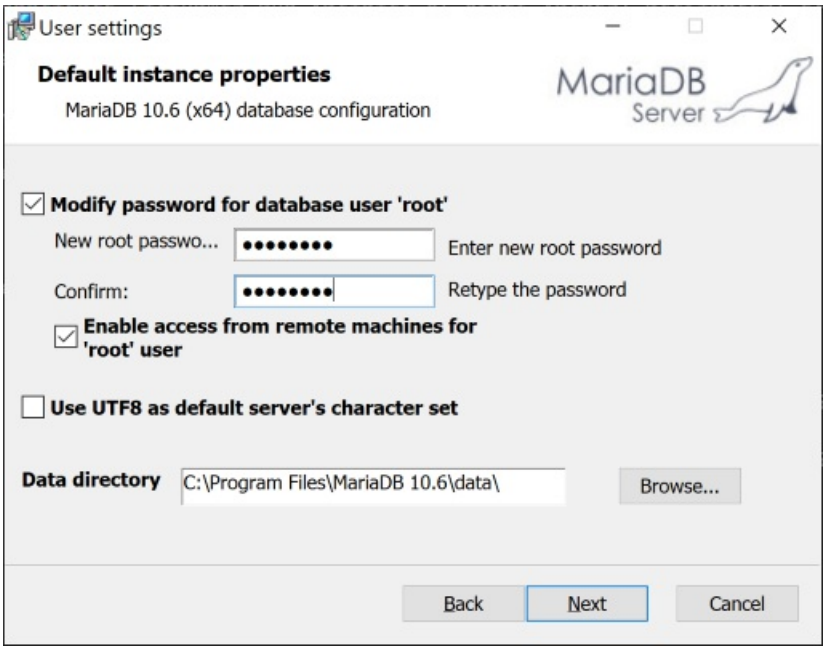
Custom Setup



Here, you can choose what features to install. By default, all features are installed with the exception of the debug symbols. If the "Database instance" feature is selected, the installer will create a database instance, by default running as a service. In this case the installer will present additional dialogs to control various database properties. Note that you do not necessarily have to create an instance at this stage. For example, if you already have MySQL or MariaDB databases running as services, you can just upgrade them during the installation. Also, you can create additional database instances after the installation, with the `mysql_install_db.exe` utility.

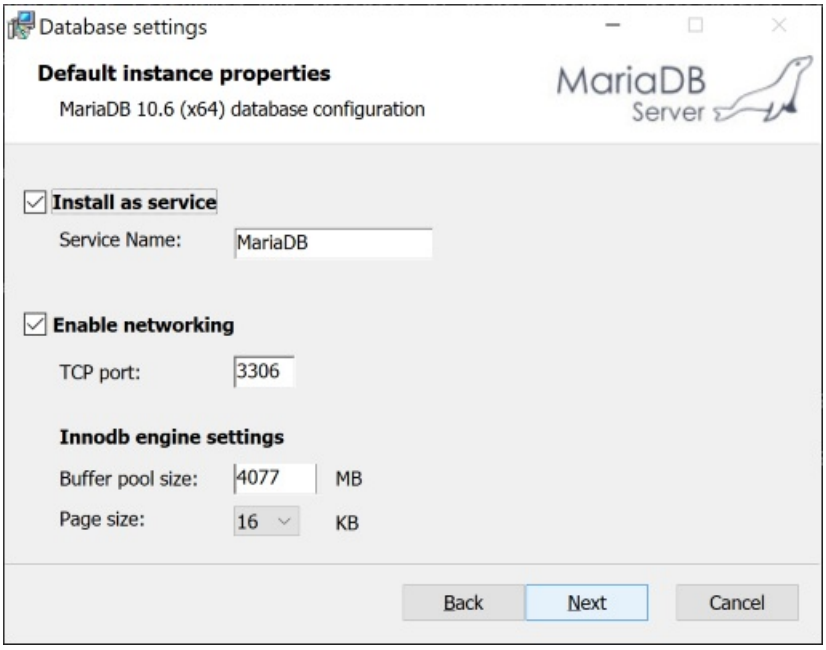
NOTE: By default, if you install a database instance, the data directory will be in the "data" folder under the installation root. To change the data directory location, select "Database instance" in the feature tree, and use the "Browse" button to point to another place.

Database Authentication/Security Related Properties



This dialog is shown if you selected the "Database instance" feature. Here, you can set the password for the "root" database user and specify whether root can access database from remote machines. The "Create anonymous account" setting allows for anonymous (non-authenticated) users. It is off by default and it is not recommended to change this setting.

Other Database Properties



- Install as service

  Defines whether the database should be run as a service. If it should be run as a service, then it also defines the service name. It is recommended to run your database instance as a service as it greatly simplifies database management. In MariaDB 10.4 and later, the default service name used by the MSI installer is "MariaDB". In 10.3 and before, the default service name used by the MSI installer is "MySQL". Note that the default service name for the `--install` and `--install-manual` options for `mysqld.exe` is "MySQL" in all versions of MariaDB.

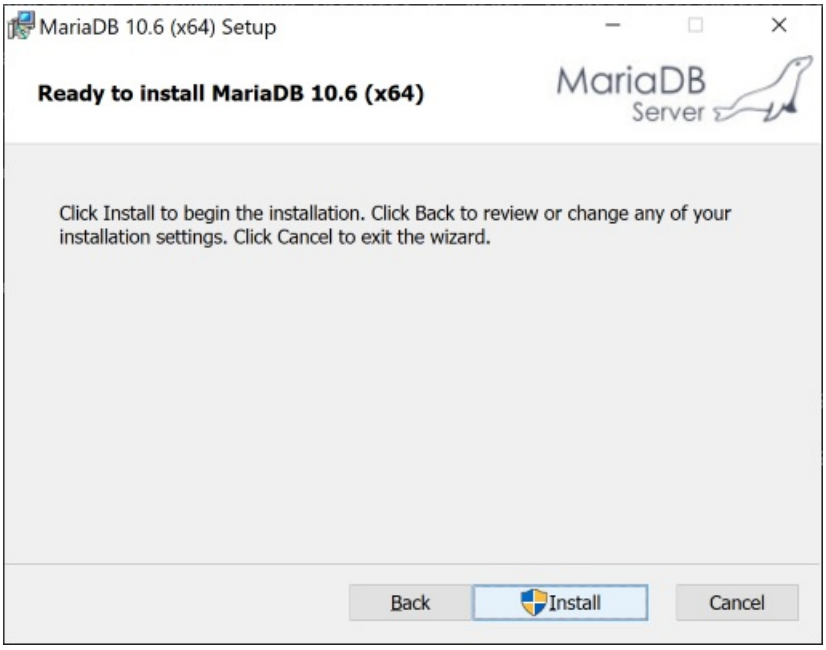
- Enable Networking

  Whether to enable TCP/IP (recommended) and which port MariaDB should listen to. If security is a concern, you can change the bind-address parameter post-installation to bind to only local addresses. If the "Enable networking" checkbox is deselected, the database will use named pipes for communication.

- InnoDB engine settings

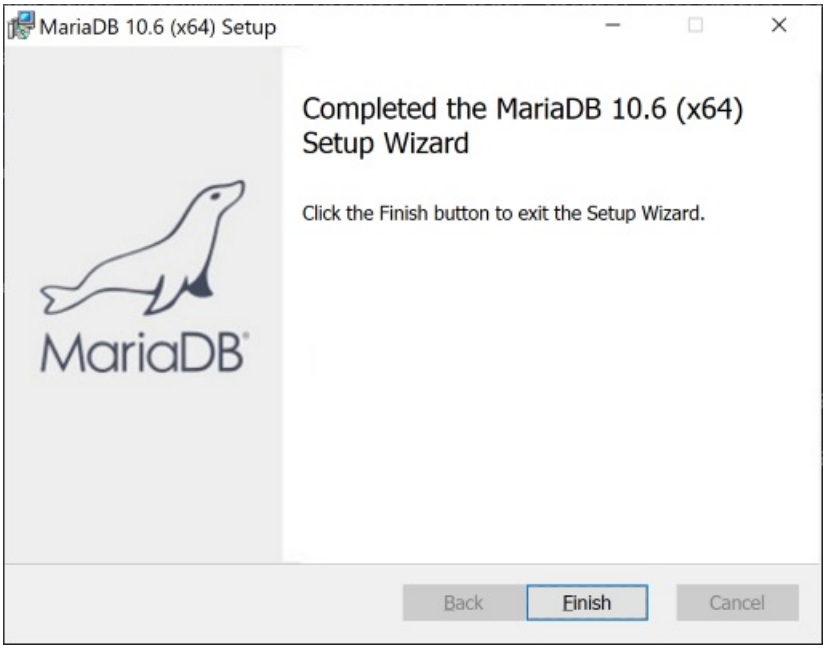
  Defines the InnoDB buffer pool size, and the InnoDB page size. The default buffer pool size is 12.5% of RAM, and depending on your requirements you can give InnoDB more (up to 70-80% RAM). 32 bit versions of MariaDB have restrictions on maximum buffer pool size, which is approximately 1GB, due to virtual address space limitations for 32bit processes. A 16k page size is suitable for most situations. See the innodb_page_size system variable for details on other settings.

Ready to Install



At this point, all installation settings are collected. Click on the "Install" button.

End

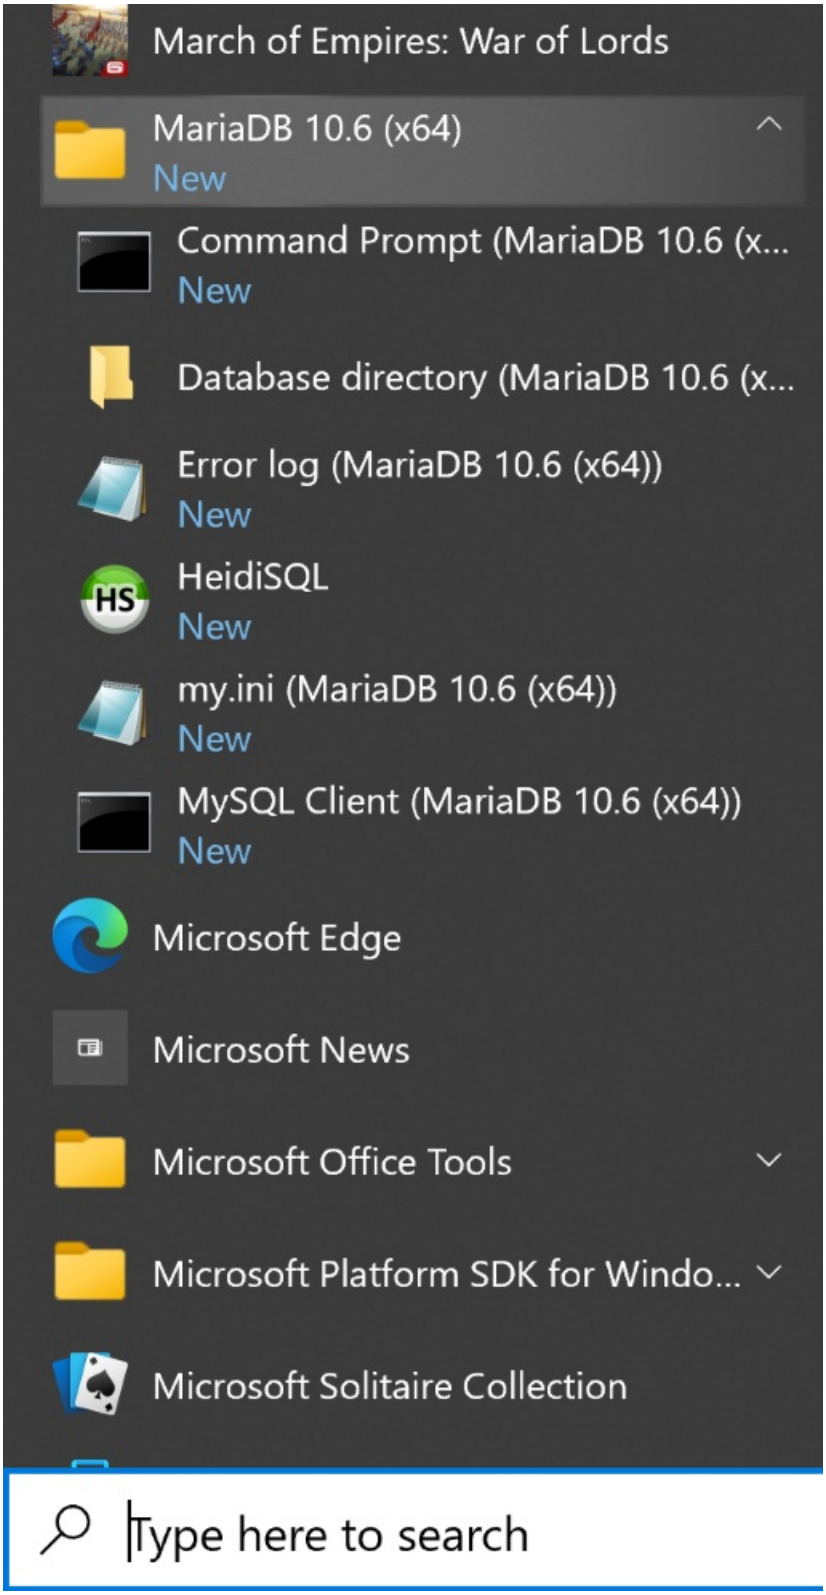


Installation is finished now. If you have upgradable instances of MariaDB/MySQL, running as services, this dialog will present a "Do you want to upgrade existing instances" checkbox (if selected, it launches the Upgrade Wizard post-installation).

If you installed a database instance as service, the service will be running already.

New Entries in Start Menu

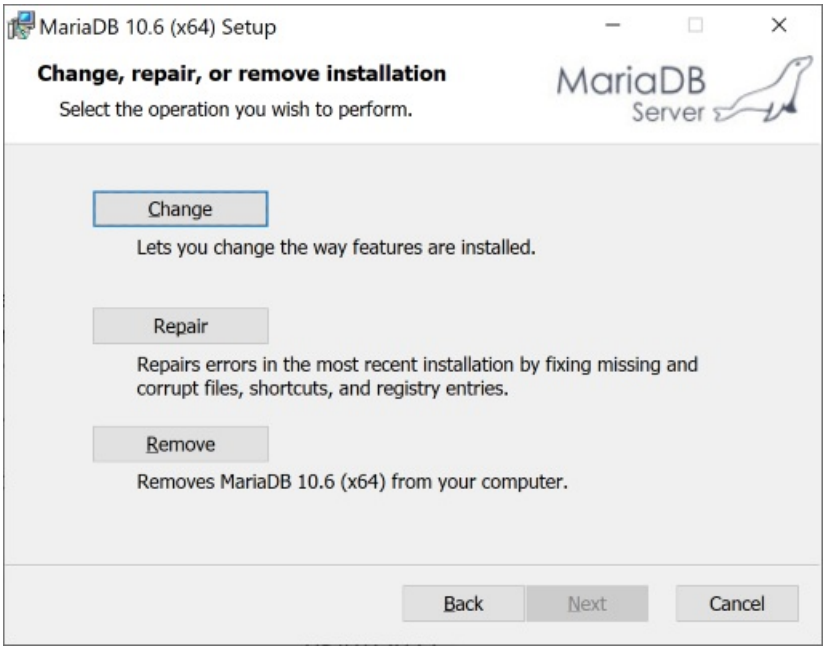
Installation will add some entries in the Start Menu:



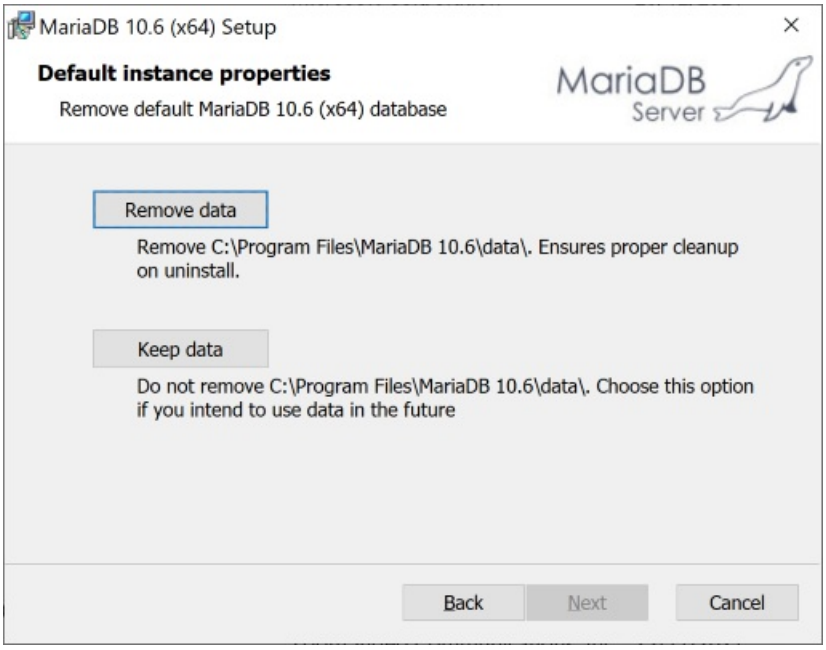
- MariaDB Client - Starts command line client mysql.exe
- Command Prompt - Starts a command prompt. Environment is set such that "bin" directory of the installation is included into PATH environment variable, i.e you can use this command prompt to issue MariaDB commands (mysqldadmin, mysql etc...)
- Database directory - Opens the data directory in Explorer.
- Error log - Opens the database error log in Notepad.
- my.ini - Opens the database configuration file my.ini in Notepad.
- Upgrade Wizard - Starts the Wizard to upgrade an existing MariaDB/MySQL database instance to this MariaDB version.

Uninstall UI

In the Explorer applet "Programs and Features" (or "Add/Remove programs" on older Windows), find the entry for MariaDB, choose Uninstall/Change and click on the "Remove" button in the dialog below.



If you installed a database instance, you will need to decide if you want to remove or keep the data in the database directory.



Silent Installation

The MSI installer supports silent installations as well. In its simplest form silent installation with all defaults can be performed from an elevated command prompt like this:

```
msiexec /i path-to-package.msi /qn
```

Note: the installation is silent due to msiexe.exe's /qn switch (no user interface), if you omit the switch, the installation will have the full UI.

Properties

Silent installations also support installation properties (a property would correspond for example to checked/unchecked state of a checkbox in the UI, user password, etc). With properties the command line to install the MSI package would look like this:

```
msiexec /i path-to-package.msi [PROPERTY_1=VALUE_1 ... PROPERTY_N=VALUE_N] /qn
```

The MSI installer package requires property names to be all capitals and contain only English letters. By convention, for a boolean property, an empty value means "false" and a non-empty is "true".

MariaDB installation supports the following properties:

Property name	Default value	Description
INSTALLDIR	%ProgramFiles%\MariaDB <version>\	Installation root
PORT	3306	--port parameter for the server
ALLOWREMOTEROOTACCESS		Allow remote access for root user
BUFFERPOOLSIZE	RAM/8	Bufferpoolsize for innodb
CLEANUPDATA	1	Remove the data directory (uninstall only)
DATADIR	INSTALLDIR\data	Location of the data directory
DEFAULTUSER		Allow anonymous users
PASSWORD		Password of the root user
SERVICENAME		Name of the Windows service. A service is not created if this value is empty.
SKIPNETWORKING		Skip networking
STDCONFIG	1	Corresponds to "optimize for transactions" in the GUI, default engine innodb, strict sql mode
UTF8		if set, adds character-set-server=utf8 to my.ini file
PAGESIZE	16K	page size for innodb

Features

Feature is a Windows installer term for a unit of installation. Features can be selected and deselected in the UI in the feature tree in the "Custom Setup" dialog.

Silent installation supports adding features with the special property `ADDLOCAL=Feature_1,..,Feature_N` and removing features with `REMOVE=Feature_1,..., Feature_N`

Features in the MariaDB installer:

Feature id	Installed by default?	Description
DBInstance	yes	Install database instance
Client	yes	Command line client programs
MYSQLSERVER	yes	Install server
SharedLibraries	yes	Install client shared library
DEVEL	yes	install C/C++ header files and client libraries
HeidiSQL	yes	Installs HeidiSQL

Silent Installation Examples

All examples here require running as administrator (and elevated command line in Vista and later)

- Install default features, database instance as service, non-default datadir and port

```
msiexec /i path-to-package.msi SERVICENAME=MySQL DATADIR=C:\mariadb5.2\data PORT=3307 /qn
```

- Install service, add debug symbols, do not add development components (client libraries and headers)

```
msiexec /i path-to-package.msi SERVICENAME=MySQL ADDLOCAL=DEBUGSYMBOLS REMOVE=DEVEL /qn
```

Silent Uninstall

To uninstall silently, use the `REMOVE=ALL` property with msiexec:

```
msiexec /i path-to-package.msi REMOVE=ALL /qn
```

To keep the data directory during an uninstall, you will need to pass an additional parameter:

```
msiexec /i path-to-package.msi REMOVE=ALL CLEANUPDATA="" /qn
```

Installation Logs

If you encounter a bug in the installer, the installer logs should be used for diagnosis. Please attach verbose logs to the bug reports you create. To create a verbose installer log, start the installer from the command line with the `/l*v` switch, like so:

```
  msiexec.exe /i path-to-package.msi  /l*v path-to-logfile.txt
```

Running 32 and 64 Bit Distributions on the Same Machine

It is possible to install 32 and 64 bit packages on the same Windows x64.

Apart from testing, an example where this feature can be useful is a development scenario, where users want to run a 64 bit server and develop both 32 and 64 bit client components. In this case the full 64 bit package can be installed, including a database instance plus development-related features (headers and libraries) from the 32 bit package.

2.1.2.4 Installing MariaDB Server PKG packages on macOS

MariaDB Server does not currently provide a `.pkg` installer for macOS. For information about how to install MariaDB Server on macOS using Homebrew, see Installing MariaDB Server on macOS Using Homebrew.

2.1.2.5 Installing MariaDB Binary Tarballs

Contents

MariaDB Binary tarballs are named following the pattern: mariadb-VERSION-OS.tar.gz. Be sure to download the correct version for your machine.

Note: Some older binary tarballs are marked *'(GLIBC_2.14)'* or *'(requires GLIBC_2.14+)'*. These binaries are built the same as the others, but on a newer build host, and they require GLIBC 2.14 or higher. Use the other binaries for machines with older versions of GLIBC installed. Run `ldd --version` to see which version is running on your distribution.

Others are marked *'systemd'*, which are for systems with `systemd` and GLIBC 2.19 or higher.

To install the binaries, unpack the distribution into the directory of your choice and run the `mariadb-install-db` script.

In the example below we install MariaDB in the `/usr/local/mysql` directory (this is the default location for MariaDB for many platforms). However any other directory should work too.

We install the binary with a symlink to the original name. This is done so that you can easily change MariaDB versions just by moving the symlink to point to another directory.

Ensure You Use the Correct my.cnf Files

MariaDB searches for the configuration files ' `/etc/my.cnf` ' (on some systems ' `/etc/mysql/my.cnf` ') and ' `~/.my.cnf` '. If you have an old `my.cnf` file (maybe from a system installation of MariaDB or MySQL) you need to take care that you don't accidentally use the old one with your new binary .tar installation.

The normal solution for this is to ignore the `my.cnf` file in `/etc` when you use the programs in the tar file.

This is done by creating your own .my.cnf file in your home directory and telling mariadb-install-db, mysqld_safe and possibly mysql (the command-line client utility) to **only** use this one with the option '`--defaults-file=~/.my.cnf`'. Note that this has to be first option for the above commands!

Installing MariaDB as root in /usr/local/mysql

If you have root access to the system, you probably want to install MariaDB under the user and group 'mysql' (to keep compatibility with MySQL installations):

```
groupadd mysql
useradd -g mysql mysql
cd /usr/local
tar -zxvpf /path-to/mariadb-VERSION-OS.tar.gz
ln -s mariadb-VERSION-OS mysql
cd mysql
./scripts/mariadb-install-db --user=mysql
chown -R root .
chown -R mysql data
```

The symlinking with `ln -s` is recommended as it makes it easy to install many MariaDB version at the same time (for easy testing, upgrading, downgrading etc).

If you are installing MariaDB to replace MySQL, then you can leave out the call to `mariadb-install-db`. Instead shut down MySQL. MariaDB should find the path to the data directory from your old `/etc/my.cnf` file (path may vary depending on your system).

To start mysqld you should now do:

```
./bin/mysqld_safe --user=mysql &
or
./bin/mysqld_safe --defaults-file=~/.my.cnf --user=mysql &
```

To test connection, modify your $PATH so you can invoke client such as mysql, mysqldump, etc.

```
export PATH=$PATH:/usr/local/mysql/bin/
```

You may want to modify your .bashrc or .bash_profile to make it permanent.

Installing MariaDB as Not root in Any Directory

Below, change /usr/local to the directory of your choice.

```
cd /usr/local
gunzip < /path-to/mariadb-VERSION-OS.tar.gz | tar xf -
ln -s mariadb-VERSION-OS mysql
cd mysql
./scripts/mariadb-install-db --defaults-file=~/.my.cnf
```

If you have problems with the above gunzip command line, you can instead, if you have gnu tar, do:

```
tar xfz /path-to/mariadb-VERSION-OS.tar.gz
```

To start mysqld you should now do:

```
./bin/mysqld_safe --defaults-file=~/.my.cnf &
```

Auto Start of mysqld

You can get mysqld (the MariaDB server) to autostart by copying the file `mysql.server` file to the right place.

```
cp support-files/mysql.server /etc/init.d/mysql.server
```

The exact place depends on your system. The `mysql.server` file contains instructions of how to use and fine tune it.

For systemd installation the mariadb.service file will need to be copied from the support-files/systemd folder to the /usr/lib/systemd/system/ folder.

```
cp support-files/systemd/mariadb.service /usr/lib/systemd/system/mariadb.service
```

Note that by default the /usr/ directory is write protected by systemd though, so when having the data directory in /usr/local/mysql/data as per the instructions above you also need to make that directory writable. You can do so by adding an extra service include file:

```
mkdir /etc/systemd/system/mariadb.service.d/

cat > /etc/systemd/system/mariadb.service.d/datadir.conf <<EOF
[Service]
ReadWritePaths=/usr/local/mysql/data
EOF

systemctl daemon-reload
```

After this you can start and stop the service using

```
systemctl start mariadb.service
```

and

```
systemctl stop mariadb.service
```

respectively.

Please refer to the systemd page for further information.

Post Installation

After this, remember to set proper passwords for all accounts accessible from untrusted sources, to avoid exposing the host to security risks!

Also consider using the mysql.server to start MariaDB automatically when your system boots.

On systems using systemd you can instead enable automatic startup during system boot with

```
systemctl enable mariadb.service
```

instead.

Our MariaDB binaries are similar to the Generic binaries available for the MySQL binary distribution. So for more options on using these binaries, the MySQL 5.5 manual entry on installing generic binaries can be consulted.

For details on the exact steps used to build the binaries, see the compiling MariaDB section of the KB.

2.1.2.6 Installing MariaDB Server on macOS Using Homebrew

Contents

MariaDB Server is available for installation on macOS (formerly Mac OS X) via the Homebrew package manager.

MariaDB Server is available as a Homebrew "bottle", a pre-compiled package. This means you can install it without having to build from source yourself. This saves time.

After installing Homebrew, MariaDB Server can be installed with this command:

```
brew install mariadb
```

After installation, start MariaDB Server:

```
mysql.server start
```

To auto-start MariaDB Server, use Homebrew's services functionality, which configures auto-start with the launchctl utility from launchd:

```
brew services start mariadb
```

After MariaDB Server is started, you can log in as your user:

```
mysql
```

Or log in as root:

```
sudo mysql -u root
```

Upgrading MariaDB

First you may need to update your brew installation:

```
brew update
```

Then, to upgrade MariaDB Server:

```
brew upgrade mariadb
```

Building MariaDB Server from source

In addition to the "bottled" MariaDB Server package available from Homebrew, you can use Homebrew to build MariaDB from source. This is useful if you want to use a different version of the server or enable some different capabilities that are not included in the bottle package.

Two components not included in the bottle package are the CONNECT and OQGRAPH engines, because they have non-standard dependencies. To build MariaDB Server with these engines, you must first install `boost` and `judy`. Follow these steps to install the dependencies and build the server:

```
brew install boost judy
brew install mariadb --build-from-source
```

You can also use Homebrew to build and install a pre-release version of MariaDB Server. Use this command to build and install a "development" version of MariaDB Server:

```
brew install mariadb --devel
```

Other resources

- mariadb.rb on github
- MariaDB Server on macOS: Does it even make sense to try? (video)

2.1.2.7 Installing MariaDB Windows ZIP Packages

Users need to run mysql_install_db.exe, without parameters to create a data directory, e.g

```
C:\zip_unpack\directory> bin\mysqld_install_db.exe
```

Then you can start server like this

```
C:\zip_unpack\directory> bin\mysqld.exe --console
```

For very old distributions (10.3 and earlier), a prebuilt data directory is already provided.

If you like to customize the server instance (data directory, install as service etc), please refer to mysql_install_db.exe documentation

2.1.2.8.1 Get, Build and Test Latest MariaDB the Lazy Way

The intention of this documentation is show all the steps of getting, building and testing the latest MariaDB server (10.5 at time of writing) from GitHub. Each stage links to the full documentation for that step if you need to find out more.

Install all tools needed to build MariaDB

OpenSuse

```
sudo zypper install git gcc gcc-c++ make bison ncurses ncurses-devel zlib-devel libevent-devel
cmake openssl
```

Debian

```
apt install -y build-essential bison
apt build-dep mariadb-server
```

Set Up git

Fetch and checkout the MariaDB source to a subdirectory of the current directory

```
git clone https://github.com/MariaDB/server.git mariadb
cd mariadb
git checkout 10.5
```

Build It

The following command builds a server the same way that is used for building releases. Use `cmake . -DCMAKE_BUILD_TYPE=Debug` to build for debugging.

```
cmake . -DBUILD_CONFIG=mysql_release && make -j8
```

Check the Server (If You Want To)

```
cd mysql-test
./mtr --parallel=8 --force
```

Install the Default Databases

```
./scripts/mariadb-install-db --srcdir=.
```

(Older MariaDB version use mysql_install_db)

Install the Server (If needed)

You can also run and test mariadb directly from the build directory, in which case you can skip the rest of the steps below.

```
make install
```

Start the Server

Start the server in it's own terminal window for testing. Note that the directory depends on your system!

```
/usr/sbin/mysqld
```

2.1.2.8.2 MariaDB Source Code

Checking out the Source with Git

The MariaDB source is hosted on GitHub: https://github.com/MariaDB/server

If you want a source tarball for a specific released MariaDB version, you can find it at http://downloads.mariadb.org.

At any given time, developers will be working on their own branches locally or on GitHub, with the main MariaDB branches receiving pushes less often.

The main MariaDB branches are:

- 11.3
- 11.2
- 11.1
- 11.0
- 10.11
- 10.10
- 10.6
- 10.5
- 10.4

Source repositories for the MariaDB Connectors are:

- MariaDB Connector/C
- MariaDB Connector/J
- MariaDB Connector/Node.js
- MariaDB Connector/ODBC
- MariaDB Connector/Python

See the Using git page for instructions on how to use git to check out the source code and switch between the various branches.

2.1.2.8.3 Build Environment Setup for Linux

Contents

Required Tools

The following is a list of tools that are required for building MariaDB on Linux and Mac OS X. Most, if not all, of these will exist as packages in your distribution's package repositories, so check there first. See Building MariaDB on Ubuntu, Building MariaDB on CentOS, and Building MariaDB on Gentoo pages for specific requirements for those platforms.

- git
- gzip
- GNU tar
- gcc/g++ 4.8.5 or later, recommend above 9 or clang/clang++
- GNU make 3.75 or later or Ninja
- bison (3.0)
- libncurses
- zlib-dev
- libevent-dev
- cmake above 2.8.7 though preferably above 3.3
- gnutls or openssl
- jemalloc (optional)
- snappy (compression library, optional)
- valgrind (only needed if running mysql-test-run --valgrind)
- libcurl (only needed if you want to use the S3 storage engine)
- libxml2-devel
- boost
- libaio-devel
- systemd-devel
- pcre2-devel (optiona, will be automatically downloaded and installed if not on the system)
- ccache ; Will speed up builds if you are going to use the scripts in the BUILD directory.

You can install these programs individually through your package manager.

In addition, some package managers support the use a build dependency command. When using this command, the package manager retrieves a list of build dependencies and install them for you, making it much easier to get started on the compile. The actual option varies, depending on the distribution you use.

On Ubuntu and Debian you can use the `build-dep` command.

```
# apt build-dep mariadb-server
```

Fedora uses the `builddep` command with DNF.

```
# dnf builddep mariadb-server
```

If building on Centos 7, use the building MariaDB on Centos instructions.

With openSUSE and SUSE, you can use the source-install command.

```
# zypper source-install -d mariadb
```

Each of these commands works off of the release of MariaDB provided in the official software repositories of the given distribution. In some instances and especially in older versions of Linux, MariaDB may not be available in the official repositories. In these cases you can use the MariaDB repositories as an alternative.

Bear in mind, the release of MariaDB provided by your distribution may not be the same as the version you are trying to install. Additionally, the package managers don't always retrieve all of the packages you need to compile MariaDB. There may be some missed or unlisted in the process. When this is the case, CMake fails during checks with an error message telling you what's missing.

Note: On Debian-based distributions, you may receive a *"You must put some 'source' URIs in your sources.list"* error. To avoid this, ensure that /etc/apt/sources.list contains the source repositories.

For example, for Debian buster:

```
deb http://ftp.debian.org/debian buster main contrib
deb http://security.debian.org buster/updates main contrib
deb-src http://ftp.debian.org/debian buster main contrib
deb-src  http://security.debian.org buster/updates main contrib
```

Refer to the documentation for your Linux distribution for how to do this on your system.

After editing the sources.list, do:

```
sudo apt update
```

...and then the above mentioned `build-dep` command.

Note: On openSUSE the source package repository may be disabled. The following command will enable it:

```
sudo zypper mr -er repo-source
```

After enabling it, you will be able to run the zypper command to install the build dependencies.

You should now have your build environment set up and can proceed to Getting the MariaDB Source Code and then using the Generic Build Instructions to build MariadB (or following the steps for your Linux distribution or Creating a MariaDB Binary Tarball).

2.1.2.8.4 Generic Build Instructions

Contents

The instructions on this page will help you compile MariaDB from source. Links to more complete instructions for specific platforms can be found on the source page.

First, get a copy of the MariaDB source.

Next, prepare your system to be able to compile the source.

If you don't want to run MariaDB as yourself, then you should create a `mysql` user. The example below uses this user.

Using cmake

MariaDB 5.5 and above is compiled using *cmake*.

It is recommended to create a build directory **beside** your source directory

```
mkdir build-mariadb
cd build-mariadb
```

NOTE If you have built MariaDB in the past and have recently updated the repository, you should perform a complete cleanup of old artifacts (such as cmake configured files). In the base repository run:

```
git clean -xffd && git submodule foreach --recursive git clean -xffd
```

You can configure your build simply by running *cmake* without any special options, like

```
cmake ../server
```

where `server` is where you installed MariaDB. If you are building in the source directory, just omit `../server`.

If you want it to be configured exactly as a normal MariaDB server release is built, use

```
cmake ../server -DBUILD_CONFIG=mysql_release
```

This will configure the build to generate binary tarballs similar to release tarballs from downloads.mariadb.org. Unfortunately this doesn't work on old platforms, like OpenSuse Leap 15.0, because MariaDB binary tarballs are built to minimize external dependencies, and that needs static libraries that might not be provided by the platform by default, and would need to be installed manually.

To do a build suitable for debugging use:

```
cmake ../server -DCMAKE_BUILD_TYPE=Debug
```

By default, MariaDB is compiled with the `-Werror` flag, which causes compiling to abort if there is a compiler warning. You can disable that by configuring with `-DMYSQL_MAINTAINER_MODE=OFF`.

```
cmake ../server -DCMAKE_BUILD_TYPE=Debug -DMYSQL_MAINTAINER_MODE=OFF.
```

All *cmake* configuration options for MariaDB can be displayed with:

```
cmake ../server -LH
```

To build and install MariaDB after running *cmake* use

```
cmake --build .
sudo cmake --install .
```

If the commands above fail, you can enable more compilation information by doing:

```
cmake --build . --verbose
```

If you want to generate a binary tarball, run

```
cpack
```

Using BUILD Scripts

There are also `BUILD` scripts for the most common systems for those that doesn't want to dig into cmake options. These are optimized for in source builds.

The scripts are of type 'compile-#cpu#-how_to_build'. Some common scripts-are

Script	Description
compile-pentium64	Compile an optimized binary optimized for 64 bit pentium (works also for amd64)
compile-pentium-debug	Compile a debug binary optimized for 64 bit pentium
compile-pentium-valgrind-max	Compile a debug binary that can be used with valgrind to find wrong memory accesses and memory leaks. Should be used if one want's to run the `mysql-test-run` test suite with the `--valgrind` option

Some common suffixes used for the scripts:

Suffix	Description
`32`	Compile for 32 bit cpu's
`64`	Compile for 64 bit cpu's
`-max`	Enable (almost) all features and plugins that MariaDB supports
`-gprof`	binary is compiled with profiling (gcc --pg)
`-gcov`	binary is compiled with code coverage (gcc -fprofile-arcs -ftest-coverage)

`-valgrind`	The binary is compiled for debugging and optimized to be used with valgrind.
`-debug`	The binary is compiled with all symbols (gcc -g) and the `DBUG` log system is enabled.

All `BUILD` scripts support the following options:

Suffix	Description
-h, --help	Show this help message.
-n, --just-print	Don't actually run any commands; just print them.
-c, --just-configure	Stop after running configure. Combined with --just-print shows configure options.
--extra-configs=xxx	Add this to configure options
--extra-flags=xxx	Add this C and CXX flags
--extra-cflags=xxx	Add this to C flags
--extra-cxxflags=xxx	Add this to CXX flags
--verbose	Print out full compile lines
--with-debug=full	Build with full debug(no optimizations, keep call stack).

A typical compilation used by a developer would be:

```
shell> ./BUILD/compile-pentium64-debug
```

This configures the source for debugging and runs make. The server binary will be `sql/mariadbd` or `sql/mysqld`.

Starting MariaDB for the First Time

After installing MariaDB (using `sudo make install`), but prior to starting MariaDB for the first time, one should:

1. ensure the directory where you installed MariaDB is owned by the mysql user (if the user doesn't exist, you'll need to create it)
2. run the mariadb-install-db script to generate the needed system tables

Here is an example:

```
# The following assumes that the 'mysql' user exists and that we installed MariaDB
# in /usr/local/mysql
chown -R mysql /usr/local/mysql/
cd /usr/local/mysql/
scripts/mariadb-install-db --user=mysql
/usr/local/mysql/bin/mysqld_safe --user=mysql &
```

Testing MariaDB

If you want to test your compiled MariaDB, you can do either of:

Run unit tests:

```
cmake --build . --target test
```

Or run mtr tests:

```
mysql-test/mysql-test-run --force
```

Each of the above are run from the build directory. There is no need to ' `make install` / `cmake --install .` ' MariaDB prior to running them.

NOTE: If you are doing more extensive testing or debugging of MariaDB (like with real application data and workloads) you may want to start and run MariaDB directly from the source directory instead of installing it with ' `sudo make install` '. If so, see Running MariaDB from the Source Directory.

Increasing Version Number or Tagging a Version

If you have made code changes and want to increase the version number or tag our version with a specific tag you can do this by editing the `VERSION` file. Tags are shown when running the ' `mysqld --version` ' command.

Non-ascii Symbols

MariaDB builds with `readline` ; using an alternative such as `Editline` may result in problems with non-ascii symbols.

Post-install Tasks

- Installing system tables (mariadb-install-db)
- Starting and Stopping MariaDB Automatically

2.1.2.8.5 Compiling MariaDB with Extra Modules/Options

Compiling MariaDB with Vanilla XtraDB

Sometimes, one needs to have MariaDB compiled with Vanilla XtraDB. This pag...

Specifying Which Plugins to Build

Specifying which plugins to build.

Using MariaDB with TCMalloc or jemalloc

TCMalloc is a malloc replacement library optimized for multi-threaded usage.

2.1.2.8.5.1 Using MariaDB with TCMalloc or jemalloc

Using tcmalloc

TCMalloc is a malloc replacement library optimized for multi-threaded usage. It also features a built-in heap debugger and profiler. You can build MariaDB with it or LD_PRELOAD it.

To build MariaDB 5.5 with `TCMalloc` , you need to use the following command

```
cmake -DCMAKE_EXE_LINKER_FLAGS='-ltcmalloc'  -DWITH_SAFEMALLOC=OFF
```

Many other malloc replacement libraries (as well as heap debuggers and profilers) can be used with MariaDB in a similar fashion.

You can also start a standard MariaDB server with `TCmalloc` with:

```
/usr/sbin/mysqld_safe --malloc-lib=tcmalloc
```

or add it to `my.cnf` . Alternatively just set LD_PRELOAD to point to the to be used malloc library:

```
export LD_PRELOAD=/path/to/library
```

Using jemalloc

The above procedure also works with jemalloc. Just replace tcmalloc with jemalloc in the above commands.

Finding memory leaks with jemalloc

jemalloc can provide a report of memory leaks at program exit:

```
MALLOC_CONF=prof_leak:true,lg_prof_sample:0,prof_final:true \
LD_PRELOAD=${JEMALLOC_PATH}/lib/libjemalloc.so.2  path-to-mariadbd
```

This will produce something like:

```
<jemalloc>: Leak summary: 267184 bytes, 473 objects, 20 contexts
<jemalloc>: Run jeprof on "jeprof.19678.0.f.heap" for leak detail
```

You can learn more about the memory leaks with jeprof, that is included with jemalloc:

```
jeprof --show_bytes path-to-mariadbd jeprof.19678.0.f.heap
```

You can also generate a PDF call graph of the leak:

```
jeprof --show_bytes --pdf path-to-mariadbd  jeprof.19678.0.f.heap > /tmp/mariadbd.pdf
```

2.1.2.8.5.2 Specifying Which Plugins to Build

By default all plugins are enabled and built as dynamic `.so` (or `.dll`) modules. If a plugin does not support dynamic builds, it is not built at all.

Use `PLUGIN_xxx` cmake variables. They can be set on the command line with `-DPLUGIN_xxx=value` or in the cmake gui. Supported values are

Value	Effect
NO	the plugin will be not compiled at all
STATIC	the plugin will be compiled statically, if supported. Otherwise it will be not compiled.
DYNAMIC	the plugin will be compiled dynamically, if supported. Otherwise it will be not compiled. This is the default behavior.
AUTO	the plugin will be compiled statically, if supported. Otherwise it will be compiled dynamically.
YES	same as **AUTO**, but if plugin prerequisites (for example, specific libraries) are missing, it will not be skipped, it will abort cmake with an error.

Note that unlike autotools, cmake tries to configure and build incrementally. You can modify one configuration option and cmake will only rebuild the part of the tree affected by it. For example, when you do `cmake -DWITH_EMBEDDED_SERVER=1` in the already-built tree, it will make libmysqld to be built, but no other configuration options will be changed or reset to their default values.

In particular this means that if you have run, for example `cmake -DPLUGIN_OQGRAPH=NO` and later you want to restore the default behavior (with OQGraph being built) in the same build tree, you would need to run `cmake -DPLUGIN_OQGRAPH=DYNAMIC`

Alternatively, you might simply delete the `CMakeCache.txt` file — this is the file where cmake stores current build configuration — and rebuild everything from scratch.

2.1.2.8.6 Creating the MariaDB Source Tarball

How to create a source tar.gz file.

First Setup your build environment.

Then use automake/configure/make to generate the tar file:

```
BUILD/autorun.sh
./configure --with-plugin-xtradb
make dist
```

This creates a source file with a name like `mysql-5.3.2-MariaDB-beta.tar.gz`

See also the generic build instructions.

2.1.2.8.7 Creating the MariaDB Binary Tarball

How to generate binary tar.gz files.

- Setup your build environment.
- Build binaries with your preferred options/plugins.

If the binaries are already built, you can generate a binary tarball with

```
make package
```

Prior to MariaDB 5.5, the following steps were required:

- Use `make_binary_distribution` to generate a binary tar file:

```
cd mariadb-source
./scripts/make_binary_distribution
```

This creates a source file with a name like `mariadb-5.3.2-MariaDB-beta-linux-x86_64.tar.gz` in your current directory.

The other option is to use the bakery scripts. In this case you don't have to compile MariaDB source first.

```
cd $PACKAGING_WORK
bakery/preheat.sh
cd bakery_{number}
bakery/tarbake51.sh last:1 $MARIA_WORK
bakery/autobake51-bintar.sh mariadb-{version_num}-maria-beta-ourdelta{number}.tar.gz
```

2.1.2.8.8 Build Environment Setup for Mac

XCode

- Install Xcode from Apple (free registration required): https://developer.apple.com/xcode/ or from your Mac OS X installation disk (macports needs XCode >= 3.1, so if you do not have that version or greater you will need to download the latest version, which is 900+ MB)

You can install the necessary dependencies using either MacPorts or Homebrew.

Using MacPorts

- Download and install the MacPorts dmg image from http://www.macports.org
- After installing, update it from the terminal: `sudo port -v selfupdate`

```
sudo port install cmake jemalloc judy openssl boost gnutls
```

Using Homebrew

- Download and install Homebrew from https:*brew.sh*

```
brew install cmake jemalloc traildb/judy/judy openssl boost gnutls
```

Your Mac should now have everything it needs to get, compile, and otherwise work with the MariaDB source code. The next step is to actually get a copy of the code. For help with this see the Getting the MariaDB Source Code page.

When building with Mac, you'll need `-DOPENSSL_ROOT_DIR=/usr/local/openssl` passed as a `cmake` argument to build against openssl correctly.

2.1.2.1.10 Building MariaDB From a Source RPM

2.1.2.8.10 Building MariaDB on CentOS

Contents

In the event that you are using the Linux-based operating system CentOS or any of its derivatives, you can optionally compile MariaDB from source code. This is useful in cases where you want use a more advanced release than the one that's available in the official repositories, or when you want to enable certain feature that are not otherwise accessible.

Installing Build Dependencies for MariaDB 5.5

Before you start building MariaDB, you first need to install the build dependencies required to run the compile. CentOS provides a tool for installing build dependencies. The `yum-builddep` utility reads a package and generates a list of the packages required to build from source, then calls YUM to install them for you. In the event that this utility is not available on your system, you can install it through the `yum-utils` package. Once you have it, install the MariaDB build dependencies.

```
yum install yum-utils
yum-builddep mariadb-server
```

Running the above command installs many of the build dependencies, but it **doesn't install all of them**. It will only install dependencies for MariaDB 5.5, which is not enough if you want to compile a newer MariaDB version!

Installing Build Dependencies for newer MariaDB versions

The following commands installs all packages needed to get and compile MariaDB 10.11:

```
yum install git
yum install gcc
yum install gcc-c++
yum install tar make cmake
yum install bison
yum install ncurses-devel
yum install openssl openssl-devel
yum install snappy snappy-devel
yum install valgrind
yum install libcurl-devel
yum install gzip
yum install zlib-devel
yum install lz4-devel
yum install lzo-devel
yum install bzip2-devel
yum install libxml2-devel
yum install libevent-devel
yum install libaio-devel
yum install boost
yum install pcre2-devel
yum install systemd-devel
yum install rpm-build
yum install libaio-devel
yum install zstd
yum install pam-devel
yum install checkpolicy
yum install policycoreutils-python
yum install galera.x86_64
```

You can replace `openssl` with `gnutls` above, depending on the TLS implementation you want to use.

If you plan to use the BUILD scripts to make it easier to build different configurations of MariaDB, then you should also install ccache to speed up your compilations:

```
yum install ccache
```

If you want to test the MariaDB installation, with the include mysql-test-run (mtr) system, you also need to install and configure cpan:

```
yum install cpan
# Complete Perl installing with the next command. Use the default answer to all questions
cpan App::cpanminus
```

For more information on dependencies, see Linux Build Environment.

Building MariaDB

Once you have the base dependencies installed, you can retrieve the source code and start building MariaDB. The source code is available on GitHub. Use the `--branch` option to specify the particular version of MariaDB you want to build.

```
$ git clone --branch 10.11 https://github.com/MariaDB/server.git
```

With the source repository cloned onto your system, you can start building MariaDB. Run CMake to ready MariaDB for the build,

```
$ cmake -DRPM=centos7 server/
```

Once CMake readies the relevant Makefile for your system, use Make to build MariaDB.

```
$ umask 0022
$ make package
```

This generates an RPM file, which you can then install on your system or copy over to install on other CentOS hosts. The umask is needed because of a bug in cmake / cmake scripts.

Alternative, use one of the build scripts in the `BUILD` directory that allows you to compile different versions of MariaDB (debug, optimized, profiling etc).

A good option for developers is:

```
./BUILD/compile-pentium64-debug
```

Creating MariaDB-compat package

MariaDB-compat package contains libraries from older MariaDB releases. They cannot be built from the current source tree, so cpack creates them by repackaging old MariaDB-shared packages. If you want to have -compat package created, you need to download MariaDB-shared-5.3 and MariaDB-shared-10.1 rpm packages for your architecture (any minor version will do) and put them *one level above* the source tree you're building. CMake will pick them up and create a MariaDB-compat package. CMake reports it as

```
$ ls ../*.rpm
../MariaDB-shared-10.1.17-centos7-x86_64.rpm
../MariaDB-shared-5.3.12-122.el5.x86_64.rpm
$ cmake -DRPM=centos7 .
...
Using ../MariaDB-shared-5.3.12-122.el5.x86_64.rpm to build MariaDB-compat
Using ../MariaDB-shared-10.1.17-centos7-x86_64.rpm to build MariaDB-compat
```

Additional Dependencies

In the event that you miss a package while installing build dependencies, CMake may continue to fail after you install the necessary packages. If this happens to you, delete the CMake cache then run the above the command again:

```
$ rm CMakeCache.txt
```

When CMake runs through the tests again, it should now find the packages it needs, instead of the cache telling it they're unavailable.

More about CMake and CPackRPM

See also building RPM packages from source

2.1.2.8.11 Building MariaDB on Fedora

In the event that you are using the Linux-based operating system Fedora or any of its derivatives and would like to compile MariaDB from source code, you can do so using the MariaDB build in the official repositories.

Installing Build Dependencies

MariaDB requires a number of packages to compile from source. Fortunately, you can use the package in the Fedora repository to retrieve most of the relevant build dependencies through DNF.

```
# dnf builddep mariadb-server
```

Running DNF in this way pulls the build dependencies for the release of MariaDB compiled by your version of Fedora. These may not be all the dependencies you need to build the particular version of MariaDB you want to use, but it will retrieve most of them.

You'll also need to install Git to retrieve the source repository:

```
# dnf install git
```

Building MariaDB

Once you have the base dependencies installed, you can retrieve the source code and start building MariaDB. The source code is available on GitHub. Use the `--branch` option to specify the particular version of MariaDB you want to build.

```
$ git clone --branch 10.3 https://github.com/MariaDB/server.git mariadb-server
```

With the source repository cloned onto your system, you can start building MariaDB. Change into the new `mariadb-server/` directory and run CMake to prepare the build.

```
$ mkdir mariadb-build
$ cd mariadb-build
$ cmake -DRPM=fedora ../mariadb-server
```

Once CMake readies the relevant Makefile for your system, use Make to build MariaDB.

```
$ make package
```

2.1.2.8.12 Building MariaDB on Debian

Contents

In the event that you are using the Linux-based operating system Debian or any of its direct derivatives and would like to compile MariaDB from source code, you can do so using the MariaDB source repository for the release that interests you. For Ubuntu and its derivatives, see Building on Ubuntu.

Before you begin, install the `software-properties-common` and `devscripts` packages:

```
$ sudo apt-get install -y software-properties-common \
      devscripts
```

Installing Build Dependencies

MariaDB requires a number of packages to compile from source. Fortunately, you can use the MariaDB repositories to retrieve the necessary code for the version you want. Use the Repository Configuration tool to determine how to set up the MariaDB repository for your release of Debian, the version of MariaDB that you want to install, and the mirror that you

want to use.

First add the authentication key for the repository, then add the repository.

```
$ sudo apt-key adv --recv-keys \
      --keyserver hkp://keyserver.ubuntu.com:80 \
      0xF1656F24C74CD1D8
$ sudo add-apt-repository 'deb [arch=amd64]
http://nyc2.mirrors.digitalocean.com/mariadb/repo/10.3/debian stretch main'
```

The second command added text to the `/etc/apt/sources.list` file. One of these lines is the repository containing binary packages for MariaDB, the other contains the source packages. The line for the source packages is commented out by default. This can be scripted:

```
sed -e '/^# deb-src.*mariadb/s/^# //' -i /etc/apt/sources.list
```

Alternately, open the file using your preferred text editor and uncomment the source repository.

```
$ sudo vim /etc/apt/sources.list

...
deb [arch=amd64] http://nyc2.mirrors.digitalocean.com/mariadb/repo/10.3/debian stretch main
deb-src [arch=amd64] http://nyc2.mirrors.digitalocean.com/mariadb/repo/10.3/debian stretch main
```

Once the repository is set up, you can use `apt-get` to retrieve the build dependencies. MariaDB packages supplied by Ubuntu and packages supplied by the MariaDB repository have the same base name of `mariadb-server`. You need to specify the specific version you want to retrieve.

```
$ sudo apt-get update
$ sudo apt-get build-dep -y mariadb-server-10.3
```

Building MariaDB

Once you have the base dependencies installed, you can retrieve the source code and start building MariaDB. The source code is available on GitHub. Use the `--branch` option to specify the particular version of MariaDB you want to build.

```
$ git clone --branch 10.3 https://github.com/MariaDB/server.git
```

The source code includes scripts to install the remaining build dependencies. For Ubuntu, they're located in the `debian/` directory. Navigate into the repository and run the `autobake-deb.sh` script. Then use

```
$ export DEB_BUILD_OPTIONS=parallel=$(nproc)
$ cd server/
$ ./debian/autobake-deb.sh
```

After Building

After building the packages, it is a good idea to put them in a repository. See the Creating a Debian Repository page for instructions.

2.1.2.8.13 Building MariaDB on FreeBSD

Contents

It is relatively straightforward to build MariaDB from source on FreeBSD. When working with an individual host, you can use Ports to compile particular or multiple versions of MariaDB. When working with multiple hosts, you can use Poudriere to build MariaDB once, then serve it as a package to multiple FreeBSD hosts.

Using Ports

The FreeBSD Ports Collection provides a series of Makefiles that you can use to retrieve source code, configure builds, install dependencies and compile software. This allows you to use more advanced releases than what is normally available through the package managers as well as enable any additional features that interest you.

In the event that you have not used Ports before on your system, you need to first fetch and extract the Ports tree. This downloads the Ports tree from FreeBSD and extracts it onto your system, placing the various Makefiles, patches and so on in the `/usr/ports/` directory.

```
# portsnap fetch extract
```

In the event that you have used Ports before on this system, run Portsnap again to download and install any updates to the Ports tree.

```
# portsnap fetch update
```

This ensures that you are using the most up to date release of the Ports tree that is available on your system.

Building MariaDB from Ports

Once Portsnap has installed or updated your Ports tree, you can change into the relevant directory and install MariaDB. Ports for MariaDB are located in the `/usr/ports/databases/` directory.

```
$ ls /usr/ports/databases | grep mariadb

mariadb-connector-c
mariadb-connector-odbc
mariadb100-client
mariadb100-server
mariadb101-client
mariadb101-server
mariadb102-client
mariadb102-server
mariadb103-client
mariadb103-server
mariadb55-client
mariadb55-server
```

Note that FreeBSD treats the Server and Client as separate packages. The Client is a dependency of the Server, so you only need to build the Server to get both. It also provides a number of different versions. You can search the available ports from Fresh Ports. Decide what version of MariaDB you want to install, the change into the relevant directory. Once in the directory, run Make to build MariaDB.

```
# cd /usr/ports/databases/mariadb103-server
# make
```

In addition to downloading and building MariaDB, Ports also downloads and build any libraries on which MariaDB depends. Each port it builds will take you to a GUI window where you can select various build options. In the case of MariaDB, this includes various storage engines and specific features you need in your build.

Once you finish building the ports, install MariaDB on your system and clean the directory to free up disk space.

```
# make install clean
```

This installs FreeBSD on your server. You can now enable, configure and start the service as you normally would after installing MariaDB from a package.

Using Poudriere

Poudriere is a utility for building FreeBSD packages. It allows you to build MariaDB from a FreeBSD Jail, then serve it as a binary package to other FreeBSD hosts. You may find this is particularly useful when building to deploy multiple MariaDB servers on FreeBSD, such as with Galera Cluster or similar deployments.

Building MariaDB

Once you've configured your host to use Jails and Poudriere, initialize a jail to use in building packages and a jail for managing ports.

```
# poudriere jail -c -j package-builder -v 11.2-RELEASE
# poudriere ports -c -p local-ports
```

This creates two jails, `package-builder` and `local-ports`, which you can then use to build MariaDB. Create a text file to define the packages you want to build. Poudriere will build these packages as well as their dependencies. MariaDB is located at `databases/mariadb103-server`. Adjust the path to match the version you want to install.

```
$ vi maraidb-package-builder.txt

databases/mariadb103-server
```

Use the `options` command to initialize the build options for the packages you want Poudriere to compile.

```
# poudriere options -j package-builder -p local-ports -z mariadb-builder -f mariadb-package-build
```

Lastly, use the `bulk` command to compile the packages.

```
# poudriere bulk -j package-builder -p local-ports -z mariadb-builder -f mariadb-package-builder.
```

Using Poudriere Repositories

In order to use Poudriere, you need to set up and configure a web server, such as Nginx or Apache to serve the directory that Poudriere built. For instance, in the case of the above example, you would map to the `package-builder` jail: `/usr/local/poudriere/data/packages/package-builder/`. You may find it useful to map this directory to a sub-domain, for instance `https`*`pkg.example.com`* or something similar.

Lastly, you need to configure the FreeBSD hosts to use the Poudriere repository you just created. On each host, disable the FreeBSD official repositories and enable your Poudriere repository as an alternative.

```
# vi /usr/local/etc/pkg/repos/FreeBSD.conf

FreeBSD: {
      enabled: no
}
```

Then add the URL for your Poudriere repository to configuration file:

```
# vi /usr/local/etc/pkg/repos/mariadb.conf

custom: {
      url: "https://pkg.example.com",
      enabled: yes
}
```

You can then install MariaDB from Poudriere using the package manager.

```
# pkg install mariadb103-server
```

2.1.2.8.14 Building MariaDB on Gentoo

MariaDB is in Gentoo, so the steps to build it are:

1. Synchronize your tree with
   ```
   emerge --sync
   ```
2. Build MariaDB using
   ```
   emerge mariadb
   ```

2.1.2.8.15 Building MariaDB on Solaris and OpenSolaris

The following two articles should help you get your Solaris machine prepared to build MariaDB (just ignore the parts about installing buildbot):

- Buildbot Setup for Solaris Sparc
- Buildbot Setup for Solaris x86

Notes

- The BUILD dir contains various scripts for compiling MariaDB on Solaris. The `BUILD/compile-solaris-amd64` and `BUILD/compile-solaris-amd64-debug` are probably the most useful.
- The scripts do not play nice with non-bash shells such as the Korn Shell (ksh). So if your /bin/sh is pointing at ksh or ksh93, you'll want to change it so that it points at bash.

2.1.2.8.16 Building MariaDB on Ubuntu

Contents

In the event that you are using the Linux-based operating system Ubuntu or any of its derivatives and would like to compile MariaDB from source code, you can do so using the MariaDB source repository for the release that interests you.

Before you begin, install the `software-properties-common`, `devscripts` and `equivs` packages.

```
$ sudo apt-get install software-properties-common \
      devscripts \
      equivs
```

Installing Build Dependencies

MariaDB requires a number of packages to compile from source. Fortunately, you can use the MariaDB repositories to retrieve the necessary code for the version you want. Use the Repository Configuration tool to determine how to set up the MariaDB repository for your release of Ubuntu, the version of MariaDB that you want to install, and the mirror that you want to use.

First add the authentication key for the repository, then add the repository.

```
$ sudo apt-key adv --recv-keys \
      --keyserver hkp://keyserver.ubuntu.com:80 \
      0xF1656F24C74CD1D8
$ sudo add-apt-repository --update --yes --enable-source \
       'deb [arch=amd64] http://nyc2.mirrors.digitalocean.com/mariadb/repo/10.3/ubuntu
'$(lsb_release -sc)' main'
```

Once the repository is set up, you can use `apt-get` to retrieve the build dependencies. MariaDB packages supplied by Ubuntu and packages supplied by the MariaDB repository have the same base name of `mariadb-server`. You need to specify the specific version you want to retrieve.

```
$ sudo apt-get build-dep mariadb-10.3
```

Building MariaDB

Once you have the base dependencies installed, you can retrieve the source code and start building MariaDB. The source code is available on GitHub. Use the `--branch` option to specify the particular version of MariaDB you want to build.

```
$ git clone --branch 10.3 https://github.com/MariaDB/server.git
```

The source code includes scripts to install the remaining build dependencies. For Ubuntu, they're located in the `debian/` directory. Navigate into the repository and run the `autobake-deb.sh` script. Then use

```
$ cd server/
$ ./debian/autobake-deb.sh
```

After Building

After building the packages, it is a good idea to put them in a repository. See the Creating a Debian Repository page for instructions.

2.1.2.8.17 Building MariaDB on Windows

Contents

Build Requirements

To build MariaDB you need the following:

- Visual C++: We currently support Visual Studio 2019 and 2022. Generally we try to support the two most recent VS versions, but build ourselves using the last one. Community editions will work fine; we only use them in our builds. While installing Visual Studio, make sure to add "Desktop Development with C++".
- CMake: We recommend the latest release. Older releases might not support your version of Visual Studio. Visual Studio 2019 requires cmake 3.14 at least.
- Git: Required to build newer versions from the source tree.
  - NOTE: run

```
git config --global core.autocrlf input
```

after the installation, otherwise some mtr tests will fail

In the "Adjusting your PATH" dialog, choose "Use Git from Windows command prompt", otherwise wrong (mingw64) git and perl will be in your PATH

- Bison from GnuWin32: Bison creates parts of the SQL parser. Choose "Complete package except sources" when downloading.
  - NOTE: **Do not** install this into your default path with spaces (e.g. under `C:\Program Files\GnuWin32`); the build will break due to this bison bug. Instead, install into `C:\GnuWin32`.
  - Add `C:\GnuWin32\bin` to your system `PATH` after installation.
- Strawberry perl: Used to run the test suite. ActiveState Perl is another Win32 Perl distribution and should work as well (but it is not as well tested). NOTE: Cygwin or mingw Perl versions **will not work** for testing. Use Windows native Perl, please.
- Optional: If you intend to build the MSI packages, install Windows Installer XML. If you build MSI with 10.4, also modify your Visual Studio installation, add "Redistributable MSMs" (see MDEV-22555)
- Gnu Diff, needed if you run mysql-test-run.pl tests.

Verify that bison.exe, or git.exe, cmake.exe and perl.exe can be found in the PATH environment variable with "`where bison`", "`where git`", "`where perl`" etc. from the command line prompt.

Building Windows Binaries

The above instructions assume MariaDB 10.2 or higher.

Branch the MariaDB repository, or unpack the source archive. On the command prompt, switch to your source directory, then execute:

```
mkdir bld
cd bld
cmake ..
cmake --build . --config RelWithDebInfo
```

The above example builds a release configured for 64 bit systems in a subdirectory named `bld`. "`cmake ...`" is the configuration step, "`cmake --build . --config Relwithdebinfo`" is the build step.

Build Variations

Debug Builds

Building Debug version is done with:

```
cmake --build . --config Debug
```

- 32bit and 64 bit Builds

Build 64 bit binary

Visual Studio 2019-2022 cmake generator will use host architecture by default, that is, with the steps above, cmake will build x64 binaries on x64 machine.

Build 32 bit binary

pass -A Win32 parameter for CMake, like this

```
cmake .. -A Win32
```

Historical note: With Visual Studio 2017 and earlier, one had to pass the name of 32bit generator ,e.g cmake .. -G "Visual Studio 15 2017"

For a complete list of available generators, call "cmake" without any parameters.

IDE Builds

Instead of calling "`cmake --build`" as above, open `MySQL.sln`. When Visual Studio starts, choose Build/Compile.

Building the ZIP Package

```
cmake --build . --config relwithdebinfo --target package
```

This is how it is "done by the book", standard cmake target.

MariaDB however uses non-standard target "win_package" for the packaging for its releases, it generates 2 ZIPs, a slim one with executables, and another one with debuginfo (.PDB files). The debuginfo is important to be able to debug released binaries, and to analyze crashes.

```
cmake --build . --config relwithdebinfo --target win_package
```

Building the MSI Package

```
cmake --build . --config relwithdebinfo
cmake --build . --config relwithdebinfo --target MSI
```

Including HeidiSQL in the MSI Installer

Starting with MariaDB 5.2.7, it is possible to build an installer which includes 3rd party products, as described in MWL#200. Currently only HeidiSQL support is implemented; it is also included in the official builds. Use the CMake parameter `-DWITH_THIRD_PARTY=HeidiSQL` to include it in the installer.

Code Signing

MariaDB builds optionally support authenticode code signing with an optional parameter `SIGNCODE`. Use `cmake -DSIGNCODE=1` during the configuration step to sign the binaries in the `ZIP` and `MSI` packages.

Important: for `SIGNCODE=1` to work, the user that runs the build needs to install a valid authenticode digital certificate into their certificate store, otherwise the packaging step will fail.

Building Packages for MariaDB Releases

The full script to create the release in an out-of-source build with Visual Studio with signed binaries might look like:

```
mkdir bld
cd bld
cmake .. -DSIGNCODE=1 -DWITH_THIRD_PARTY=HeidiSQL
cmake --build . --config relwithdebinfo --target win_package
cmake --build . --config relwithdebinfo  --target MSI
```

This command sequence will produce a ZIP package (e.g mariadb-5.2.6-win32.zip) and MSI package (e.g mariadb-5.2.6-win32.msi) in the `bld` directory.

Running Tests

- **Important: Do not use Cygwin** bash, MinGW bash, Git bash, WSL bash, or any other bash when running the test suite. You will then very likely use the wrong version of Perl too (a "Unix-flavoured" one on Windows), and spend a lot of time trying to figure out why this version of Perl does not work for the test suite. Use native perl, in cmd.exe , or powershell instead,
- Switch mysql-test subdirectory of the build directory

```
cd C:\server\bld\mysql-test
```

- Run the test suite

```
perl mysql-test-run.pl --suite=main --parallel=auto
```

Running a Test Under Debugger

Assuming VS is installed on the machine

```
perl mysql-test-run.pl  <test_name> --vsjitdebugger
```

If vsjitdebugger does not start, you can edit AeDebug registry key as mentioned in

https://docs.microsoft.com/en-us/visualstudio/debugger/debug-using-the-just-in-time-debugger?view=vs-2019#jit_errors

Alternatively:

```
perl mysql-test-run.pl  <test_name> --devenv
```

(devenv.exe needs to be in PATH)

or, if you prefer WinDBG

```
perl mysql-test-run.pl  <test_name> --windbg
```

2.1.2.8.18 Creating a Debian Repository

Below are instructions for creating your own Debian repository. The instructions are based on http://www.debian.org/doc/manuals/repository-howto/repository-howto.en.html

```
REPO_DIR={pick some location}
mkdir $REPO_DIR
mkdir $REPO_DIR/binary
mkdir $REPO_DIR/source
cp *.deb *.ddeb $REPO_DIR/binary
cd $REPO_DIR
dpkg-scanpackages binary  /dev/null | gzip -9c > binary/Packages.gz
dpkg-scansources  source  /dev/null | gzip -9c > source/Sources.gz
```

Using the Debian repository you just created

One needs to add a new file to the `/etc/apt/sources.list.d/` directory. For instance a new file called `mariadb.list`

```
# sergey's MariaDB repository
#
deb file:///home/psergey/testrepo binary/
deb-src file:///home/psergey/testrepo source/
```

after which one can run

```
apt-get update  # Let apt learn about the new repository
apt-get install mariadb-server
```

and collect bugs :-).

"apt-get install" will spray output of scripts and servers all over /var/log. It is also possible to set DEBIAN_SCRIPT_DEBUG=1 to get some (not all) of it to stdout.

Cleaning up after failed installation

Run

```
dpkg --get-selections | grep mariadb
dpkg --get-selections | grep mysql
```

to see what is installed, and then

```
 dpkg --purge <packages>
```

until the former produces empty output. Note: after some failures, /etc/mysql and /var/lib/mysql are not cleaned and still need to be removed manually.

2.1.2.8.19 Building MariaDB From Source Using musl-based GNU/Linux

Instructions on compiling MariaDB on musl-based operating systems (Alpine)

Contents

The instructions on this page will help you compile MariaDB from source. Links to more complete instructions for specific platforms can be found on the source page.

- First, get a copy of the MariaDB source.

- Next, prepare your system to be able to compile the source.

Using cmake

MariaDB 10.1 and above is compiled using *cmake*. You can configure your build simply by running *cmake* using special option, i.e.

```
cmake . -DWITHOUT_TOKUDB=1
```

To build and install MariaDB after running *cmake* use

```
make
sudo make install
```

Note that building with MariaDB this way will disable tokuDB, till tokuDB becomes fully supported on musl.

2.1.2.8.20 Compiling MariaDB for Debugging

Contents

Compiling MariaDB with full debug information includes all code symbols and also new code to do internal testing of structures and allow one to trace MariaDB execution. A full debug binary will be notably slower than a normal binary (30%).

Compiling MariaDB for Debugging Using the `CMAKE_BUILD_TYPE` Option

On Unix systems, you can build a debug build by executing `cmake` and by setting the `CMAKE_BUILD_TYPE` option to `Debug`. For example:

```
cmake -DCMAKE_BUILD_TYPE=Debug .
```

Compiling MariaDB for Debugging Using Build Scripts

The other option is to use the scripts in the BUILD directory that will compile MariaDB with most common debug options and plugins:

```
./BUILD/compile-pentium64-debug-max
```

or alternatively if you want to use the Valgrind memory checking tool with the MariaDB test system:

```
./BUILD/compile-pentium64-valgrind-max
```

There are separate build scripts for different configurations in the BUILD directory.

You can find a list of the needed packages/libraries for building on Linux here.

Example of Compiling MariaDB for Debugging Using Build Scripts

- Scripts containing "debug" in the name are for developers that want to build, develop and test MariaDB.
- Scripts containing "valgrind" in the name are for running mysqld under [[|http://valgrind.org|valgrind]]. Compiling for valgrind means that we are using another implementation of MEM_ROOT to allow valgrind to better detect memory overruns. In addition, some memory areas are marked as used/not used to remove some false positives.

- Scripts containing "max" in the name include all normal plugins.

Here is an example of how to compile MariaDB for debugging in your home directory with MariaDB 5.2.9 as an example:

```
cd ~
mkdir mariadb
cd mariadb
tar xvf mariadb-5.2.9.tar.gz
ln -s mariadb-5.2.9 current
cd current
./BUILD/compile-pentium64-debug-max
```

The last command will produce a debug version of `sql/mysqld`. If you have a system other than 64 bit Intel/AMD on Linux you can use a different `BUILD/...-debug-max` file. If this fails, you can try with:

```
cmake --build  .  --config Debug
make -j4
```

Building Optimized Build With Debug Symbols

To build MariaDB with symbols, to get better stack traces and to be able to debug the binary with `gdb`, you need to supply the `-g3` option to the `gcc` compiler.

Just compiling with `-g3` will make the binary much bigger but the slowdown of the server should be negligible.

One way to do this is to edit the script

```
BUILD/compile-pentium64-max
```

and add the -g3 last on the line with `extra_flags`, like this:

```
extra_flags="$pentium64_cflags $fast_cflags -g3"
```

After that you can compile MariaDB with debugging symbols by just execution the above script.

Doing a Debug Build on Debian/Ubuntu

To build a "mysqld" binary with debugging enabled that uses the same parameters as the ones used in Debian/Ubuntu binary packages, you must do as follows (you must have a deb-src line of one of the MariaDB repositories on your /etc/apt/sources.list in order to do that):

```
apt-get build-dep mariadb-10.2
apt-get install cmake libaio1 libaio-dev
apt-get source mariadb-10.2
cd mariadb-10.2*
./debian/rules configure
./BUILD/compile-pentuim64-debug-all
```

Then you will have your "debugging enabled" mysqld binary in the sql/ directory.

This binary can directly replace the one provided by the binary package that is placed on "/usr/bin/mysqld".

Temporarily Installing your Debug Build

The commands shown below replace the release `mysqld` binary with the debug `mysqld` binary that you compiled. Most importantly, they replace the binary in a way which makes it trivial to revert back to the original release `mysqld` binary.

First, stop MariaDB.

Then, use the `mv` utility to rename the release `mysqld` binary:

```
sudo mv /usr/sbin/mysqld /usr/sbin/mysqld-orig
```

Note: Do not use the `cp` utility because that will change the file modification timestamp.

Then, install the debug `mysqld` binary from your source tree:

```
sudo install ~/mariadb-10.3.14/sql/mysqld /usr/sbin/mysqld-debug
```

Then, link the `mysqld` path to the path of your debug `mysqld` binary:

```
sudo ln -s /usr/sbin/mysqld-debug /usr/sbin/mysqld
```

Then, start MariaDB.

Be sure to replace `/usr/sbin/mysqld` with the path to your `mysqld` binary and to also replace `~/mariadb-10.3.14/sql/mysqld` with the path to your debug `mysqld` binary.

Reinstalling your Release Build

If you want to restore your original `mysqld` binary, you can do it with the following process::

First, stop MariaDB.

Then, execute the following command to delete the symbolic link:

```
sudo rm /usr/sbin/mysqld
```

Then, execute the following command to move the original `mysqld` release binary back into place:

```
sudo mv /usr/sbin/mysqld-orig /usr/sbin/mysqld
```

Then, start MariaDB.

Be sure to replace `/usr/sbin/mysqld` with the path to your `mysqld` binary

Notice that the debug `mysqld` binary located at `/usr/sbin/mysqld-debug` was not deleted. Only the symbolic link to this file was deleted. The debug `mysqld` binary is still present if it is needed again in the future.

Different Compilation Options

Changing DBUG_ASSERT to Print to Error Log

A debug binary has lots of code checks and asserts, that are not checked in production. This is done to get more performance when running in production. In some cases, when one is trying to find a hard-to-repeat bug, it could be beneficial to have these checks in production builds too.

Compiling with `-DDBUG_ASSERT_AS_PRINTF` will change DBUG_ASSERT() to print any failed check to the error log.

```
cmake . -DDBUG_ASSERT_AS_PRINTF
```

Enabling the above option should not have any notable impact on performance (probably < 1% slowdown). This is achieved by grouping asserts in MariaDB server code into two groups:

- Fast checks, using `DBUG_ASSERT()` : These are converted to printing to error log.
- Slow checks, using `DBUG_SLOW_ASSERT()` . These will always be removed in production builds.

2.1.2.8.21 Cross-compiling MariaDB

Buildroot

Buildroot is a way to cross compile MariaDB and other packages into a root filesystem. In the menuconfig you need to enable "Enable C++ Support" first under "Toolchain". After C++ is enabled MariaDB is an option under "Target Packages" ->"Libraries" -> "Databases" -> "mysql support" -> "mysql variant" -> "mariadb". Also enable the "mariadb server" below the "mysql support" option.

Details

To cross-compile with cmake you will need a toolchain file. See, for example, here. Besides cmake specific variables it

should have, at least

```
SET(STACK_DIRECTION -1)
SET(HAVE_IB_GCC_ATOMIC_BUILTINS 1)
```

with appropriate values for your target architecture. Normally these MariaDB configuration settings are detected by running a small test program, and it cannot be done when cross-compiling.

Note that during the build few helper tools are compiled and then immediately used to generate more source files for this very build. When cross-compiling these tools naturally should be built for the host architecture, not for the target architecture. Do it like this (assuming you're in the mariadb source tree):

```
$ mkdir host
$ cd host
$ cmake ..
$ make import_executables
$ cd ..
```

Now the helpers are built and you can cross-compile:

```
$ mkdir target
$ cd target
$ cmake .. -DCMAKE_TOOLCHAIN_FILE=/path/to/toolchain/file.cmake -
DIMPORT_EXECUTABLES=../host/import_executables.cmake
$ make
```

Here you invoke cmake, specifying the path to your toolchain file and the path to the `import_executables.cmake` that you have just built on the previous step. Of course, you can also specify any other cmake parameters that could be necessary for this build, for example, enable or disable specific storage engines.

See also https://lists.launchpad.net/maria-discuss/msg02911.html

2.1.2.8.22 MariaDB Source Configuration Options

Contents

All CMake configuration options for MariaDB can be displayed with:

```
cmake . -LH
```

2.1.2.8.23 Building RPM Packages From Source

To generate RPM packages from the build, supply the `-DRPM=xxx` flag to CMake, where the value `xxx` is the name of the distribution you're building for. For example, centos7 or rocky8 or fedora39 or sles15.

What these do are controlled in the following CMake files:

- `cmake/cpack_rpm.cmake`
- `cmake/build_configurations/mysql_release.cmake`
- `cmake/mariadb_connector_c.cmake`

To build the packages you should execute:

```
$ umask 0022
$ cmake --build . --target package
```

2.1.2.8.24 Compile and Using MariaDB with Sanitizers (ASAN, UBSAN, TSAN, MSAN)

Contents

What are Sanitizers?

Sanitizers are open source runtime error detectors developed by Google that are enabled during the compile step. These sanitizers add extra code during compilation that will throw exceptions when certain errors are detected.

AddressSanitizer (aka ASAN) is a memory error detector for C/C++. It finds a lot of the same things as valgrind, but with a lot less overhead.

- Use after free (dangling pointer dereference)
- Heap buffer overflow
- Stack buffer overflow
- Global buffer overflow
- Use after return
- Use after scope
- Initialization order bugs
- Memory leaks

To use ASAN you need a gcc version that supports ASAN. gcc 4.8.5 and up are known to work.

In addition to ASAN there are sanitizers for Undefined Behaviour, Thread and Memory related errors.

UndefinedBehaviourSanitizer (aka UBSAN)

ThreadSanitizer (aka TSAN)

MemorySanitizer (aka MSAN)

How to Compile MariaDB with Sanitizers

Before using ASAN locally, please ensure that it is installed on the system:

```
yum install -y /usr/lib64/libasan.so.6.0.0
```

ASAN is supported in MariaDB 10.1 and up.

You can use one of the two following build commands:

```
cmake . -DWITH_ASAN=ON
```

or from MariaDB 10.2 and up:

```
./BUILD/compile-pentium64-asan-max
```

Additionally, UBSAN, TSAN, and MSAN can be enabled in a similar way:

UBSAN:

```
yum install -y /usr/lib64/libubsan.so.1.0.0
cmake . -DWITH_UBSAN=ON
```

TSAN:

```
yum install -y /usr/lib64/libtsan.so.0.0.0
cmake . -DWITH_TSAN=ON
```

MSAN:

Note: keep in mind that only clang supports MSAN, g++ or other compilers will not work.

```
cmake . -DWITH_MSAN=ON
```

Running an MSAN Build

The time consuming aspect of building with MSAN is having instrumented system libraries. As MariaDB Foundation have built the MSAN container already for buildbot, this is how you re-use this for building locally.

First, run the container where your current directory is the source directory:

```
podman run -v $PWD:/source:z -ti --user buildbot --entrypoint bash --shm-size 5G --env MSAN_SYMBO
```

Note: docker can be used instead of the lighter weight podman if you so desire.

The shm-size is for the MTR tests which exceed the 64k default shm-size.

All the following instructions are executed within the container. Now run the configure stage of cmake:

```
cmake /source -DCMAKE_C_COMPILER=clang-15 -DCMAKE_CXX_COMPILER=clang++-15 '-DCMAKE_C_FLAGS=-O2 -W
```

Run the build stage:

```
cmake --build . --parallel
...
[100%] Built target mariadbd
[100%] Linking CXX executable mariadb-backup
Creating mariabackup link
[100%] Built target mariadb-backup
```

As the important MTR step needs to use the instrumented libraries MTR is run using the LD_LIBRARY_PATH to use those.

```
LD_LIBRARY_PATH=/msan-libs mysql-test/mtr  --mem --big-test --force --retry=0 --skip-test=.*compr
```

As newer versions occur and improvements happen these instructions may change. Look at the execution on the buildbot builder to see if any changes have been made.

Running an ASAN Build

To run mysqld with instrumentation you have to set the `ASAN_OPTIONS` environment variable before starting `mysqld`. Either in your shell or in your mysqld_safe script.

```
export ASAN_OPTIONS=abort_on_error=1
```

The above command will abort any instrumented executable if any errors are found, which is good for debugging. If you set abort_on_error=0 all server errors are logged to your error log file (mysqld.err).

To catch errors for other processes than the server, you can set more options, like this:

```
export ASAN_OPTIONS=abort_on_error=1:log_path=/tmp/asan
```

If you are seeing an incomplete stack trace for a memory allocation, you may rerun the failing test with

```
export ASAN_OPTIONS=abort_on_error=1:log_path=/tmp/asan:fast_unwind_on_malloc=0
```

To get core dumps of failures:

```
export ASAN_OPTIONS=abort_on_error=1:disable_coredump=0
```

To see all the options (or to check if an executable is instrumented), you may try the following:

```
ASAN_OPTIONS=help=1 extra/perror 0
```

Using Valgrind

The MariaDB test system can use Valgrind for finding memory leaks and wrong memory accesses. Valgrind is an

instrumentation framework for building dynamic analysis tools. If Valgrind is installed on your system, you can simply use mysql-test-run --valgrind to run the test under Valgrind.

2.1.2.9 Distributions Which Include MariaDB

Contents

The following is a partial list of distributions which include MariaDB in their package repositories. For these you can use the distribution's management system to install MariaDB.

The term "default" in the list below refers to the distribution's default relational or MySQL-type database.

Linux Distributions

- AlmaLinux — MariaDB 10.5 was included since 8.8.
- Alpine Linux — Defaults to MariaDB. MariaDB 10.6 has been available 3.12.11 and MariaDB 10.11 since 3.18.2.
- 4mLinux — Defaults to MariaDB. MariaDB 10.6 has been available since 37.0
- ALT Linux — MariaDB 5.5 included in 7.0.0, MariaDB is default from 8.1, which includes MariaDB 10.1, 9.1 includes MariaDB 10.4
- Arch Linux — Features MariaDB 10.11, and replaced MySQL as a default
- Austrumi — Defaulted to MariaDB 5.3 in 2.4.8, 3.5.8 includes MariaDB 10.1
- BlackArch — Defaulted to MariaDB 5.5 in 2014.07.01, 2020.12.01 includes MariaDB 10.5
- BlueOnyx — 5209 defaults to MariaDB 5.5, 5210R to MariaDB 10.3
- BlueStar — 4.8.4 defaults to MariaDB 10.1, 5.4.2 to MariaDB 10.5
- CentOS — MariaDB 5.5 replaced MySQL in CentOS 7
- The Chakra Project — MariaDB replaced MySQL as default in 2013.05. 2016.02 includes MariaDB 10.1
- Debian — Debian 10 "Buster" includes MariaDB 10.3, Debian 11 "Bullseye" MariaDB 10.5, Debian 12 "Bookworm" MariaDB 10.11 as default.
- Elastix —Defaulted to MariaDB 5.5 in 4.0.76
- Exherbo —Includes MariaDB 10.4
- Fedora — MariaDB 5.5 became the default relational database in Fedora 19. Fedora 30 includes MariaDB 10.3, Fedora 34 includes MariaDB 10.5.
- Funtoo —Includes MariaDB 5.5
- Gentoo Linux
- Guix —11.2.0 includes MariaDB 10.1
- Hanthana — 19.1 defaulted to MariaDB 5.5, 21 includes MariaDB 10.0, 28.1.2 includes MariaDB 10.2, 30 includes MariaDB 10.3
- KaOS —Defaulted to MariaDB 5.5 in 2014.12, 2019.04 includes MariaDB 10.3
- Kali Linux —2017.3 Included MariaDB 10.1, 2023.1 includes MariaDB 10.11
- GNU/Linux KDu — MariaDB 5.5 replaced MySQL as a default in 2.0 Final.
- Korora —Defaulted to MariaDB in 19.1, 26 includes MariaDB 10.1
- Linux from Scratch —10.1-BLFS defaults to MariaDB 10.5
- Lunar —1.7.0 includes MariaDB 5.5, Moonbase includes MariaDB 10.5
- Mageia — MariaDB 5.5 replaced MySQL as default in version 3, MariaDB 10.3 from version 7.1, MariaDB 10.5 from 8, MariaDB 10.11 from 9.
- Manjaro Linux — Defaulted to MariaDB 5.5 in 0.8.11, 16.10.3 includes MariaDB 10.1.
- NixOS —14.0.4.630 included MariaDB 10.0, 18.09 includes MariaDB 10.2, Stable includes MariaDB 10.5
- Network Security Toolkit —20-5663 defaulted to MariaDB 5.5, 32-11992 includes MariaDB 10.4
- NuTyX —14.11 included MariaDB 10.0, defaulted to MariaDB 10.1 in 8.2.1, 20.12.1 includes MariaDB 10.5
- OpenELEC
- OpenEuler —21.9 includes 10.5, 22.03 LTS includes MariaDB 10.5
- Open Mandriva —Defaulted to MariaDB 10.0 in 2014.2, includes MariaDB 10.5 in 4.2
- openSUSE — MariaDB 5.5 became the default relational database in openSUSE 12.3, and MariaDB 10.6 the default since 15.5
- Oracle Linux — 7.3 includes MariaDB 5.5. 8.0 includes MariaDB 10.3
- Paldo —Defaults to MariaDB 10.5 in Stable
- Parabola GNU/Linux —Includes MariaDB 10.1 since 3.7
- Parrot Security —Based on Debian's testing branch (stretch), Parrot Security switched from MySQL to MariaDB 10.0 in 3.1, 4.7 includes MariaDB 10.3
- Parted Magic —Defaulted to MariaDB 5.5 in 2015_11_13
- PCLinuxOS —Replaced MySQL with MariaDB 10.1 in 2017.03
- Pisi Linux —Defaulted to MariaDB 10.0 in 1.1
- Plamo —Defaulted to MariaDB 5.5 in 5.3.1, 7.3 includes MariaDB 10.2
- PoliArch —Defaulted to MariaDB 5.5 in 13.1, 15.1 includes MariaDB 10.0
- Red Hat Enterprise Linux — MariaDB 5.5 was included as the default "MySQL" database since RHEL 7, RHEL 9 includes MariaDB 10.5
- Rocky Linux — MariaDB 10.5 was included since 8.7.
- ROSA —Defaulted to MariaDB 10.0 in R4 and MariaDB 10.1 in R9.
- Sabayon —Included MariaDB 10.0 in 14.12, includes MariaDB 10.3 since 19.03

- Scientific Linux —Defaulted to MariaDB 5.5 in 7.3
- Slackware — MariaDB 5.5 replaced MySQL as default in 14.1. 15.0 includes MariaDB 10.5, current includes MariaDB 10.11
- SliTaz GNU/Linux —Includes MariaDB 10.0 in 5.0-rolling
- SME Server— started to use MariaDB 5.5 from 10.0
- Springdale Linux —Defaulted to MariaDB 5.5 in 7.2, 8.1 includes MariaDB 10.3
- SuliX — Defaults to MariaDB 5.5 in 8.
- SUSE Linux Enterprise — MariaDB 10.6 is the default relational database option on 15-SP6
- Ubuntu —MariaDB 5.5 was included in Trusty Tahr 14.04. 20.04 includes MariaDB 10.3, and 22.04 includes 10.6.
- Void — Includes MariaDB 10.5 in current
- Wifislax — Defaulted to MariaDB 10.0 in 4.11.1

BSD Distributions

- Dragonfly BSD — 3.8 included MariaDB 5.5. 5.8.0 includes MariaDB 10.4.
- FreeBSD — MariaDB is available in the ports tree and the FreeBSD Manual has instructions on Installing Applications: Packages and Ports. MariaDB 10.5 is included in 12.2
  - MariaDB on FreshPorts
- NetBSD — 6.1 and 7.0 include MariaDB 5.5.
- OpenBSD — MariaDB 10.0 was included in 5.7, 6.8 includes MariaDB 10.5.

macOS

- Homebrew — If you have Homebrew installed, you can install MariaDB Server by executing `brew install mariadb`. Find out more at Installing MariaDB Server on macOS Using Homebrew.
- MacPorts —This provides mariadb and mariadb-server. A quick guide on how to install it.

2.1.2.10 Running Multiple MariaDB Server Processes

Contents

It is possible to run multiple MariaDB Server processes on the same server, but there are certain things that need to be kept in mind. This page will go over some of those things.

Configuring Multiple MariaDB Server Processes

If multiple MariaDB Server process are running on the same server, then at minimum, you will need to ensure that the different instances do not use the same `datadir`, `port`, and `socket`. The following example shows these options set in an option file:

```
[client]
# TCP port to use to connect to mysqld server
port=3306
# Socket to use to connect to mysqld server
socket=/tmp/mysql.sock
[mariadb]
# TCP port to make available for clients
port=3306
#  Socket to make available for clients
socket=/tmp/mysql.sock
# Where MariaDB should store all its data
datadir=/usr/local/mysql/data
```

The above values are the defaults. If you would like to run multiple MariaDB Server instances on the same server, then you

will need to set unique values for each instance.

There may be additional options that also need to be changed for each instance. Take a look at the full list of options for `mysqld`.

To see the current values set for an instance, see Checking Program Options for how to do so.

To list the default values, check the end of:

```
mysqld --help --verbose
```

Starting Multiple MariaDB Server Processes

There are several different methods to start or stop the MariaDB Server process. There are two primary categories that most of these methods fall into: starting the process with the help of a service manager, and starting the process manually. See Starting and Stopping MariaDB for more information.

Service Managers

sysVinit and systemd are the most common Linux service managers. launchd is used in MacOS X. Upstart is a less common service manager.

Systemd

RHEL/CentOS 7 and above, Debian 8 Jessie and above, and Ubuntu 15.04 and above use systemd by default.

For information on how to start and stop multiple MariaDB Server processes on the same server with this service manager, see systemd: Interacting with Multiple MariaDB Server Processes.

Starting the Server Process Manually

mysqld

`mysqld` is the actual MariaDB Server binary. It can be started manually on its own.

If you want to force each instance to read only a single option file, then you can use the `--defaults-file` option:

```
mysqld --defaults-file=/etc/my_instance1.cnf
```

mysqld_safe

`mysqld_safe` is a wrapper that can be used to start the `mysqld` server process. The script has some built-in safeguards, such as automatically restarting the server process if it dies. See mysqld_safe for more information.

If you want to force each instance to read only a single option file, then you can use the `--defaults-file` option:

```
mysqld_safe --defaults-file=/etc/my_instance1.cnf
```

mysqld_multi

`mysqld_multi` is a wrapper that can be used to start the `mysqld` server process if you plan to run multiple server processes on the same host. See mysqld_multi for more information.

Other Options

In some cases, there may be easier ways to run multiple MariaDB Server instances on the same server, such as:

- Using dbdeployer.
- Starting multiple Docker containers.

2.1.2.11 Installing MariaDB Alongside MySQL

MariaDB was originally designed as a drop-in replacement of MySQL, with more features, new storage engines, fewer bugs, and better performance, but you can also install it alongside MySQL. (This can be useful, for example, if you want to migrate databases/applications one by one.)

Here are the steps to install MariaDB near an existing MySQL installation.

- Download the compiled binary tar.gz that contains the latest version (mariadb-5.5.24-linux-x86_64.tar.gz - as of writing this article) and extract the files in a directory of your choice. I will assume for this article that the directory was **/opt**.

```
[root@mariadb-near-mysql ~]# cat /etc/issue
CentOS release 6.2 (Final)

[root@mariadb-near-mysql ~]# rpm -qa mysql*
mysql-5.1.61-1.el6_2.1.x86_64
mysql-libs-5.1.61-1.el6_2.1.x86_64
mysql-server-5.1.61-1.el6_2.1.x86_64

[root@mariadb-near-mysql ~]# ps axf | grep mysqld
 2072 pts/0    S+     0:00          \_ grep mysqld
 1867 ?        S      0:01 /bin/sh /usr/bin/mysqld_safe --datadir=/var/lib/mysql --
socket=/var/lib/mysql/mysql.sock ...
 1974 ?        Sl     0:06  \_ /usr/libexec/mysqld --basedir=/usr --datadir=/var/lib/mysql --
user=mysql ...
```

- Create data directory and symlinks as below:

```
[root@mariadb-near-mysql opt]# mkdir mariadb-data
[root@mariadb-near-mysql opt]# ln -s mariadb-5.5.24-linux-x86_64 mariadb
[root@mariadb-near-mysql opt]# ls -al
total 20
drwxr-xr-x.  5 root root 4096 2012-06-06 07:27 .
dr-xr-xr-x. 23 root root 4096 2012-06-06 06:38 ..
lrwxrwxrwx.  1 root root   27 2012-06-06 07:27 mariadb -> mariadb-5.5.24-linux-x86_64
drwxr-xr-x. 13 root root 4096 2012-06-06 07:07 mariadb-5.5.24-linux-x86_64
drwxr-xr-x.  2 root root 4096 2012-06-06 07:26 mariadb-data
```

- Create group **mariadb** and user **mariadb** and set correct ownerships:

```
[root@mariadb-near-mysql opt]# groupadd --system mariadb
[root@mariadb-near-mysql opt]# useradd -c "MariaDB Server" -d /opt/mariadb -g mariadb --system
mariadb
[root@mariadb-near-mysql opt]# chown -R mariadb:mariadb mariadb-5.5.24-linux-x86_64/
[root@mariadb-near-mysql opt]# chown -R mariadb:mariadb mariadb-data/
```

- Create a new **my.cnf** in **/opt/mariadb** from support files:

```
[root@mariadb-near-mysql opt]# cp mariadb/support-files/my-medium.cnf mariadb-data/my.cnf
[root@mariadb-near-mysql opt]# chown mariadb:mariadb mariadb-data/my.cnf
```

- Edit the file **/opt/mariadb-data/my.cnf** and add custom paths, socket, port, user and the most important of all: data directory and base directory. Finally the file should have at least the following:

```
[client]
port  = 3307
socket  = /opt/mariadb-data/mariadb.sock

[mysqld]
datadir         = /opt/mariadb-data
basedir         = /opt/mariadb
port  = 3307
socket  = /opt/mariadb-data/mariadb.sock
user            = mariadb
```

- Copy the init.d script from support files in the right location:

```
[root@mariadb-near-mysql opt]# cp mariadb/support-files/mysql.server /etc/init.d/mariadb
[root@mariadb-near-mysql opt]# chmod +x /etc/init.d/mariadb
```

- Edit **/etc/init.d/mariadb** replacing **mysql** with **mariadb** as below:

```
- # Provides: mysql
+ # Provides: mariadb
- basedir=
+ basedir=/opt/mariadb
- datadir=
+ datadir=/opt/mariadb-data
- lock_file_path="$lockdir/mysql"
+ lock_file_path="$lockdir/mariadb"
```

The trickiest part will be the last changes to this file. You need to tell mariadb to use only one cnf file. In the **start** section after **$bindir/mysqld_safe** add **--defaults-file=/opt/mariadb-data/my.cnf**. Finally the lines should look like:

```
# Give extra arguments to mysqld with the my.cnf file. This script
# may be overwritten at next upgrade.
$bindir/mysqld_safe --defaults-file=/opt/mariadb-data/my.cnf --datadir="$datadir" --pid-
file="$mysqld_pid_file_path" $other_args >/dev/null 2>&1 &
```

The same change needs to be made to the mariadb-admin command below in the wait_for_ready() function so that the mariadb start command can properly listen for the server start. In the **wait_for_ready()** function, after **$bindir/mariadb-admin** add **--defaults-file=/opt/mariadb-data/my.cnf**. The lines should look like:

```
wait_for_ready () {
[...]
    if $bindir/mariadb-admin --defaults-file=/opt/mariadb-data/my.cnf ping >/dev/null 2>&1;
then
```

- Run mariadb-install-db by explicitly giving it the my.cnf file as argument:

```
[root@mariadb-near-mysql opt]# cd mariadb
[root@mariadb-near-mysql mariadb]# scripts/mariadb-install-db --defaults-file=/opt/mariadb-
data/my.cnf
```

- Now you can start MariaDB by

```
[root@mariadb-near-mysql opt]# /etc/init.d/mariadb start
Starting MySQL...                                          [  OK  ]
```

- Make MariaDB start at system start:

```
[root@mariadb-near-mysql opt]# cd /etc/init.d
[root@mariadb-near-mysql init.d]# chkconfig --add mariadb
[root@mariadb-near-mysql init.d]# chkconfig --levels 3 mariadb on
```

- Finally test that you have both instances running:

```
[root@mariadb-near-mysql ~]# mysql -e "SELECT VERSION();"
+-----------+
| VERSION() |
+-----------+
| 5.1.61    |
+-----------+
[root@mariadb-near-mysql ~]# mysql -e "SELECT VERSION();" --socket=/opt/mariadb-
data/mariadb.sock
+----------------+
| VERSION()      |
+----------------+
| 5.5.24-MariaDB |
+----------------+
```

What about MariaDB Upgrades ?

By having the **mariadb.socket**, **my.cnf** file and **databases** in **/opt/mariadb-data** if you want to upgrade the MariaDB version you will will only need to:

- extract the new version from the archive in **/opt** near the current version
- stop MariaDB

- change the symlink **mariadb** to point to the new directory
- start MariaDB
- run upgrade script... but remember you will need to provide the socket option **--socket=/opt/mariadb-data/mariadb.sock**

2.1.2.12 GPG

Contents

The MariaDB project signs their MariaDB packages for Debian, Ubuntu, Fedora, CentOS, and Red Hat.

Debian / Ubuntu key

Our repositories for Debian "Sid" and the Ubuntu 16.04 and beyond "Xenial" use the following GPG signing key. As detailed in MDEV-9781, APT 1.2.7 (and later) prefers SHA2 GPG keys and now prints warnings when a repository is signed using a SHA1 key like our previous GPG key. We have created a SHA2 key for use with these.

Information about this key:

- The short Key ID is: `0xC74CD1D8`
- The long Key ID is: `0xF1656F24C74CD1D8`
- The full fingerprint of the key is: `177F 4010 FE56 CA33 3630 0305 F165 6F24 C74C D1D8`
- The key can be added on Debian-based systems using the following command:

```
sudo apt-key adv --recv-keys --keyserver hkp://keyserver.ubuntu.com:80 0xF1656F24C74CD1D8
```

- Usage of the `apt-key` command is deprecated in the latest versions of Debian and Ubuntu, and the replacement method is to download the keyring file to the `/etc/apt/trusted.gpg.d/` directory. This can be done with the following:

```
sudo curl -LsSo /etc/apt/trusted.gpg.d/mariadb-keyring-2019.gpg https://supplychain.mariadb.
```

RPM / Source Key 2023+

Beginning in 2023 we migrated the key used to sign our yum/dnf/zypper repositories and to sign our source code and binary tarballs to the same key we use for Debian and Ubuntu. This unifies our GPG signing and enables our repositories to be compatible with FIPS and other regulations that mandate a stronger signing key.

The key can be imported on RPM-based systems using the following command:

```
sudo rpm --import https://supplychain.mariadb.com/MariaDB-Server-GPG-KEY
```

or

```
sudo rpmkeys --import https://supplychain.mariadb.com/MariaDB-Server-GPG-KEY
```

RPM / Source key pre-2023

The GPG Key ID of the MariaDB signing key we used for yum/dnf/zypper repositories and to sign our source code tarballs until the end of 2022 was `0xCBCB082A1BB943DB`. The short form of the id is `0x1BB943DB` and the full key fingerprint is:

```
1993 69E5 404B D5FC 7D2F E43B CBCB 082A 1BB9 43DB
```

This key was used by the yum/dnf/zypper repositories for RedHat, CentOS, Fedora, openSUSE, and SLES.

If you configure the mariadb.org rpm repositories using the repository configuration tool (see below) then your package manager will prompt you to import the key the first time you install a package from the repository.

You can also import the key directly using the following command:

```
sudo rpmkeys --import https://supplychain.mariadb.com/MariaDB-Server-GPG-KEY
```

Configuring Repositories

See the this page for details on using the `mariadb_repo_setup` script to configure repositories that use these keys.

See the this page for details on configuring MariaDB Foundation repositories that use these keys.

2.1.2.13 MariaDB Platform Deprecation Policy

Contents

The MariaDB Foundation tries to support as many different Operating Systems, Linux Distributions, and processor architectures as possible. However, when a distribution or OS stops receiving security and other updates it becomes difficult for the MariaDB project to provide freely packages for that platform. In such cases, our policy is to deprecate the platform and stop providing binary packages for it.

This policy and related deprecated dates are from the MariaDB Foundation. For information on the MariaDB Corporation's policies related to supporting software, see the Engineering Policies page.

Current Package Platforms

The MariaDB project builds packages for the following:

Platform	Planned Deprecation Date
Windows Server 2019	Jan 2024
Ubuntu 23.04 "Lunar"	Jan 2024
Red Hat Enterprise Linux 7.x (x86_64 only)	Jun 2024
CentOS 7.x (x86_64 only)	Jun 2024
Debian 10 "Buster" (i386, amd64 and arm64)	Jun 2024
Ubuntu 23.10 "Mantic"	Jul 2024
SLES 12.x	Oct 2024
Ubuntu 20.04 "Focal"	Apr 2025
Windows 10	Oct 2025
Debian 11 "Bullseye"	Jun 2026
Windows Server 2022	Oct 2026
Ubuntu 22.04 "Jammy"	Apr 2027
SLES 15.x	Jul 2028
Red Hat Enterprise Linux 8.x	Jun 2029
Red Hat Enterprise Linux 9.x	Jun 2032
Debian 12 "Bookworm"	TBD
Fedora 37	approximately 1 month after release of Fedora 39
Fedora 38	approximately 1 month after release of Fedora 40
Fedora 39	approximately 1 month after release of Fedora 41
SLES 12.5	6 months after release of SLES 12.6
SLES 15.0	6 months after release of SLES 15.1
Windows 11	TBC

- Ubuntu Release Information (End of Standard Support)

- Debian LTS Information (i386, amd64 and arm64 only)
- General Debian Release Information
- Red Hat Enterprise Linux Release Information
- Fedora Release Information
- FreeBSD Security Information
- openSUSE Lifetime Information
- SLES Lifecycle Information
- Windows client Lifecycle Information
- Windows Server Lifecycle Information

Deprecated Package Platforms

The MariaDB project no longer builds packages for the following Operating Systems and Linux Distributions:

Platform	Deprecation Date	Final MariaDB Version(s)
Ubuntu 18.04 LTS "Bionic"	Jun 2023	MariaDB 10.4.31, MariaDB 10.5.22, MariaDB 10.6.15, MariaDB 10.7.8, MariaDB 10.8.8, MariaDB 10.9.8, MariaDB 10.10.6, MariaDB 10.11.5, MariaDB 11.0.3
Ubuntu 22.10 "Kinetic"	Jul 2023	MariaDB 10.6.15, MariaDB 10.7.8, MariaDB 10.8.8, MariaDB 10.9.8, MariaDB 10.10.6, MariaDB 10.11.5, MariaDB 11.0.3
Fedora 36	May 2023	MariaDB 10.6.13, MariaDB 10.8.8, MariaDB 10.9.6, MariaDB 10.10.4, MariaDB 10.11.3
Fedora 35	Jan 2023	MariaDB 10.5.19, MariaDB 10.6.12, MariaDB 10.7.8, MariaDB 10.9.5, MariaDB 10.10.3
Windows 8.1	Jan 2023	MariaDB 10.5.19, MariaDB 10.6.12, MariaDB 10.7.8, MariaDB 10.9.5, MariaDB 10.10.3
Debian 10 "Buster" (ppc64el)	Jul 2022	MariaDB 10.3.36, MariaDB 10.4.26, MariaDB 10.5.17, MariaDB 10.6.9, MariaDB 10.7.5, MariaDB 10.8.4
Ubuntu 21.10 "Impish"	Jul 2022	MariaDB 10.5.16, MariaDB 10.6.8, MariaDB 10.7.4, MariaDB 10.8.3, MariaDB 10.9.1
Debian 9 "Stretch"	Jun 2022	MariaDB 10.2.44, MariaDB 10.3.35, MariaDB 10.4.25, MariaDB 10.5.16, MariaDB 10.6.8, MariaDB 10.7.4, MariaDB 10.8.3, MariaDB 10.9.1
Red Hat Enterprise Linux 7.x (non-x86_64)	May 2022	MariaDB 10.2.44, MariaDB 10.3.35, MariaDB 10.4.25, MariaDB 10.5.16, MariaDB 10.6.8, MariaDB 10.7.4, MariaDB 10.8.3, MariaDB 10.9.1
CentOS 7.x (non-x86_64)	May 2022	MariaDB 10.2.44, MariaDB 10.3.35, MariaDB 10.4.25, MariaDB 10.5.16, MariaDB 10.6.8, MariaDB 10.7.4, MariaDB 10.8.3, MariaDB 10.9.1
Fedora 34	May 2022	MariaDB 10.5.16, MariaDB 10.6.8, MariaDB 10.7.4, MariaDB 10.8.3, MariaDB 10.9.1
Ubuntu 21.04 "Hirsute"	Feb 2022	MariaDB 10.7.2, MariaDB 10.6.6, MariaDB 10.5.14
Fedora 33	Feb 2022	MariaDB 10.7.2, MariaDB 10.6.6, MariaDB 10.5.14, MariaDB 10.4.23
CentOS 8.x	Feb 2022	MariaDB 10.7.2, MariaDB 10.6.6, MariaDB 10.5.14, MariaDB 10.4.23, MariaDB 10.3.33
Ubuntu 20.10 "Groovy"	Jul 2021	MariaDB 10.6.4, MariaDB 10.5.12, MariaDB 10.4.21, MariaDB 10.3.31
Fedora 32	Apr 2021	MariaDB 10.5.10, MariaDB 10.4.19, MariaDB 10.3.29
Ubuntu 16.04 LTS "Xenial"	Apr 2021	MariaDB 10.5.10, MariaDB 10.4.19, MariaDB 10.3.29, MariaDB 10.2.38
Mint 18 LTS "Serena"	Apr 2021	MariaDB 10.5.10, MariaDB 10.4.19, MariaDB 10.3.29, MariaDB 10.2.38
Fedora 31	Nov 2020	MariaDB 10.5.7, MariaDB 10.4.16, MariaDB 10.3.26
Red Hat Enterprise Linux 6.x	Nov 2020	MariaDB 10.4.16, MariaDB 10.3.26, MariaDB 10.2.35, MariaDB 10.1.48
CentOS 6.x	Nov 2020	MariaDB 10.4.16, MariaDB 10.3.26, MariaDB 10.2.35, MariaDB 10.1.48

Fedora 30	Aug 2020	MariaDB 10.5.5, MariaDB 10.4.14, MariaDB 10.3.24
Ubuntu 19.10 "Eoan"	Jul 2020	MariaDB 10.5.5, MariaDB 10.4.14, MariaDB 10.3.24
Debian 8 "Jessie"	Jun 2020	MariaDB 10.4.13, MariaDB 10.3.23, MariaDB 10.2.32, MariaDB 10.1.45
Ubuntu 19.04 "Disco"	Jan 2020	MariaDB 10.4.12, MariaDB 10.3.22
Windows Server 2008	Jan 2020	MariaDB 10.4.12, MariaDB 10.3.22
Windows Server 2008 R2	Jan 2020	MariaDB 10.4.12, MariaDB 10.3.22
Windows 7	Jan 2020	MariaDB 10.4.12, MariaDB 10.3.22
Fedora 29	Dec 2019	MariaDB 10.4.11, MariaDB 10.3.21
Ubuntu 18.10 "Cosmic"	Jul 2019	MariaDB 10.4.7, MariaDB 10.3.17, MariaDB 10.2.26, MariaDB 10.1.41
openSUSE 42.3	Jun 2019	MariaDB 10.4.7, MariaDB 10.3.16, MariaDB 10.2.25, MariaDB 10.1.41
Fedora 28	May 2019	MariaDB 10.4.5, MariaDB 10.3.15, MariaDB 10.2.24
Ubuntu 14.04 LTS "Trusty"	Apr 2019	MariaDB 10.4.4, MariaDB 10.3.14, MariaDB 10.2.23, MariaDB 10.1.40, MariaDB 5.5.64
Mint 17.1 LTS "Rebecca"	Apr 2019	MariaDB 10.4.4, MariaDB 10.3.14, MariaDB 10.2.23, MariaDB 10.1.40, MariaDB 5.5.64
Mint 17 LTS "Qiana"	Apr 2019	MariaDB 10.4.4, MariaDB 10.3.14, MariaDB 10.2.23, MariaDB 10.1.40, MariaDB 5.5.64
SLES 11.4	Mar 2019	MariaDB 10.1.40, MariaDB 5.5.64
Windows Server 2012 R2	Oct 2018	
Fedora 27	Nov 2018	MariaDB 10.3.11, MariaDB 10.2.19
Ubuntu 17.10 "Artful"	Jul 2018	MariaDB 10.3.8, MariaDB 10.2.16, MariaDB 10.1.34
Fedora 26	May 2018	MariaDB 10.3.7, MariaDB 10.2.15, MariaDB 10.1.33
Debian 7 "Wheezy"	May 2018	MariaDB 10.3.7, MariaDB 10.2.15, MariaDB 10.1.33
Fedora 25	Feb 2018	MariaDB 10.3.5, MariaDB 10.2.13, MariaDB 10.1.31
Ubuntu 17.04 "Zesty"	Jan 2018	MariaDB 10.3.4, MariaDB 10.2.12, MariaDB 10.1.30
openSUSE 42.2	Jan 2018	MariaDB 10.3.4, MariaDB 10.2.12, MariaDB 10.1.30
Red Hat Enterprise Linux 7.2	Nov 2017	MariaDB 10.3.3, MariaDB 10.2.12, MariaDB 10.1.30, MariaDB 10.0.33, MariaDB 5.5.58
CentOS 7.2	Nov 2017	MariaDB 10.3.3, MariaDB 10.2.12, MariaDB 10.1.30, MariaDB 10.0.33, MariaDB 5.5.58
Fedora 24	Aug 2017	MariaDB 10.2.8
Ubuntu 16.10 "Yakkety"	Jul 2017	MariaDB 10.2.7, MariaDB 10.1.26, MariaDB 10.0.32
Ubuntu 12.04 LTS "Precise"	Apr 2017	MariaDB 10.1.24, MariaDB 10.0.31, MariaDB 5.5.56
Mint 13 LTS "Maya"	Apr 2017	MariaDB 10.1.24, MariaDB 10.0.31, MariaDB 5.5.56
Red Hat Enterprise Linux 7.1	Mar 2017	MariaDB 10.1.24, MariaDB 10.0.31, MariaDB 5.5.56
CentOS 7.1	Mar 2017	MariaDB 10.1.24, MariaDB 10.0.31, MariaDB 5.5.56
Red Hat Enterprise Linux 5	Mar 2017	MariaDB 10.1.22, MariaDB 10.0.30, MariaDB 5.5.54
CentOS 5	Mar 2017	MariaDB 10.1.22, MariaDB 10.0.30, MariaDB 5.5.54
Fedora 23	Feb 2017	MariaDB 10.2.4, MariaDB 10.1.22, MariaDB 10.0.30
OpenSUSE 13	Jan 2017	MariaDB 10.2.4, MariaDB 10.1.22, MariaDB 10.0.30

Fedora 22	Aug 2016	MariaDB 10.1.17, MariaDB 10.0.27
Ubuntu 15.10 "Wily"	Jul 2016	MariaDB 10.1.16, MariaDB 10.0.26
Windows 2003 Server	Apr 2016	MariaDB 10.1.13, MariaDB 10.0.24, MariaDB 5.5.48
Windows XP	Apr 2016	MariaDB 10.1.13, MariaDB 10.0.24, MariaDB 5.5.48
Debian 6 "Squeeze"	Feb 2016	MariaDB 10.0.24, MariaDB 5.5.48
Ubuntu 15.04 "Vivid"	Jan 2016	MariaDB 10.1.11, MariaDB 10.0.24
Fedora 21	Dec 2015	MariaDB 10.1.10, MariaDB 10.0.23
Fedora 20	Oct 2015	MariaDB 10.0.22, MariaDB 5.5.46
Ubuntu 14.10 "Utopic"	Jul 2015	MariaDB 10.0.22, MariaDB 5.5.46
Ubuntu 10.04 LTS "Lucid"	Apr 2015	MariaDB 10.0.18, MariaDB 5.5.43
Mint 9 LTS "Isadora"	Apr 2015	MariaDB 10.0.18, MariaDB 5.5.43
Fedora 19	Apr 2015	MariaDB 10.0.18, MariaDB 5.5.43
FreeBSD 9.2	Sep 2014	
Ubuntu 13.10 "Saucy"	Jul 2014	MariaDB 10.0.14, MariaDB 5.5.40
Mint 16 "Petra"	Jul 2014	MariaDB 10.0.14, MariaDB 5.5.40
Ubuntu 12.10 "Quantal"	Apr 2014	MariaDB 10.0.11, MariaDB 5.5.37
Mint 14 "Nadia"	Apr 2014	MariaDB 10.0.11, MariaDB 5.5.37
Ubuntu 13.04 "Raring"	Jan 2014	MariaDB 10.0.8, MariaDB 5.5.35
Mint 15 "Olivia"	Jan 2014	MariaDB 10.0.8, MariaDB 5.5.35
Fedora 18	Dec 2013	MariaDB 10.0.8, MariaDB 5.5.35
Fedora 17	Aug 2013	MariaDB 10.0.5, MariaDB 5.5.34
Ubuntu 8.04 LTS "Hardy"	Apr 2013	MariaDB 10.0.2, MariaDB 5.5.31
Ubuntu 11.10 "Oneiric"	Apr 2013	MariaDB 10.0.2, MariaDB 5.5.31
Mint 12 "Lisa"	Apr 2013	MariaDB 10.0.2, MariaDB 5.5.31
Fedora 16	Feb 2013	MariaDB 10.0.1, MariaDB 5.5.29
Ubuntu 10.10 "Maverick"	Jan 2013	MariaDB 10.0.1, MariaDB 5.5.29
Ubuntu 11.04 "Natty"	Jan 2013	MariaDB 10.0.1, MariaDB 5.5.29
Debian 5 "Lenny"	Jan 2013	MariaDB 10.0.1, MariaDB 5.5.29
Debian 4 "Etch"		
Ubuntu 9.10 "Karmic"		
Ubuntu 9.04 "Jaunty"		
Ubuntu 8.10 "Intrepid"		

Support for Deprecated Platforms

If your chosen Linux Distribution or Operating System is deprecated, packages or support are not completely unavailable. The MariaDB Corporation provides support for all versions of MariaDB back to even very old MySQL versions. This includes packaged binaries. For specific dates related to each version and more details on the MariaDB Corporation's policies, see the Engineering Policies page.

2.1.2.14 Automated MariaDB Deployment and

Administration

It is possible to automate the deployment and administration of MariaDB servers and related technologies by using third-party software. This is especially useful when deploying and administering a large number of servers, but it also has benefits for small environments.

This section describes some automation technologies from MariaDB users perspective.

Why to Automate MariaDB Deployments and Management

The reasons to automate deployment and configuration of MariaDB.

A Comparison Between Automation Systems

A summary of the differences between automation systems, to help evaluating them.

Ansible and MariaDB

General information and hints on automating MariaDB deployments with Ansible.

Puppet and MariaDB

General information on how to automate MariaDB deployments and configuration with Puppet.

Vagrant and MariaDB

General information on how to setup development MariaDB servers with Vagrant.

MariaDB Containers

MariaDB containers and Docker Official Images.

Kubernetes and MariaDB

General information and tips on deploying MariaDB on Kubernetes.

Automating Upgrades with MariaDB.Org Downloads REST API

How to use MariaDB.Org Downloads APIs to automate upgrades.

HashiCorp Vault and MariaDB

An overview of secret management with Vault for MariaDB users.

Orchestrator Overview

Using Orchestrator to automate failover and replication operations.

Rotating Logs on Unix and Linux

Rotating logs on Unix and Linux with logrotate.

Automating MariaDB Tasks with Events

Using MariaDB events for automating tasks.

2.1.2.14.1 Why to Automate MariaDB Deployments and Management

MariaDB includes a powerful configuration system. This is enough when we need to deploy a single MariaDB instance, or a small number of instances. But many modern organisations have many database servers. Deploying and upgrading them manually could require too much time, and would be error-prone.

Contents

Infrastructure as Code

Several tools exist to deploy and manage several servers automatically. These tools operate at a higher level, and execute tasks like installing MariaDB, running queries, or generating new configuration files based on a template. Instead of upgrading servers manually, users can launch a command to upgrade a group of servers, and the automation software will run the necessary tasks.

Servers can be described in a code repository. This description can include MariaDB version, its configuration, users,

backup jobs, and so on. This code is human-readable, and can serve as a documentation of which servers exist and how they are configured. The code is typically versioned in a repository, to allow collaborative development and track the changes that occurred over time. This is a paradigm called **Infrastructure as Code**.

Automation code is high-level and one usually doesn't care how operations are implemented. Their implementation is delegated to modules that handle specific components of the infrastructure. For example a module could equally work with apt and yum package managers. Other modules can implement operations for a specific cloud vendor, so we declare we want a snapshot to be done, but we don't need to write the commands to make it happen. For special cases, it is of course possible to write Bash commands, or scripts in every language, and declare that they must be run.

Manual interventions on the servers will still be possible. This is useful, for example, to investigate performance problems. But it is important to leave the servers in the state that is described by the code.

This code is not something you write once and never touch again. It is periodically necessary to modify infrastructures to update some software, add new replicas, and so on. Once the base code is in place, making such changes is often trivial and potentially it can be done in minutes.

Automated Failover

Once replication is in place, two important aspects to automate are load balancing and failover.

Proxies can implement load balancing, redirecting the queries they receive to different server, trying to distribute the load equally. They can also monitor that MariaDB servers are running and in good health, thus avoiding sending queries to a server that is down or struggling.

However, this does not solve the problem with replication: if a primary server crashes, its replicas should point to another server. Usually this means that an existing replica is promoted to a master. This kind of changes are possible thanks to MariaDB GTID.

One can promote a replica to a primary by making change to existing automation code. This is typically simple and relatively quick to do for a human operator. But this operation takes time, and in the meanwhile the service could be down.

Automating failover will minimise the time to recover. A way to do it is to use Orchestrator, a tool that can automatically promote a replica to a primary. The choice of the replica to promote is done in a smart way, keeping into account things like the servers versions and the binary log format.

2.1.2.14.2 A Comparison Between Automation Systems

This page compares the automation systems that are covered by this section of the MariaDB Knowledge Base. More information about these systems are presented in the relevant pages, and more systems may be added in the future.

Contents

Code Structure Differences

Different automation systems provide different ways to describe our infrastructure. Understanding how they work is the first step to evaluate them and choose one for our organization.

Ansible Code Structure

Ansible code consists of the following components:

- An **inventory** determines which **hosts** Ansible should be able to deploy. Each host may belong to one or more **groups**. Groups may have **children**, forming a hierarchy. This is useful because it allows us to deploy on a group, or to assign variables to a group.
- A **role** describes the state that a host, or group of hosts, should reach after a deploy.
- A **play** associates hosts or groups to their roles. Each role/group can have more than one role.
- A role consists of a list of **tasks**. Despite its name a task is not necessarily something to do, but something that must exist in a certain state.
- Tasks can use **variables**. They can affect how a task is executed (for example a variable could be a file name), or even whether a task is executed or not. Variables exist at role, group or host level. Variables can also be passed by the user when a play is applied.
- **Playbooks** are the code that is used to define tasks and variables.
- **Facts** are data that Ansible retrieves from remote hosts before deploying. This is a very important step, because facts may determine which tasks are executed or how they are executed. Facts include, for example, the operating system family or its version. A playbook sees facts as pre-set variables.
- **Modules** implement **actions** that tasks can use. Action examples are **file** (to declare that files and directories must exist) or **mysql_variables** (to declare MySQL/MariaDB variables that need to be set).

See Ansible Overview - concepts for more details and an example.

Puppet Code Structure

Puppet code consists of the following components:

- An **inventory file** defines a set of **groups** and their **targets** (the members of a group). **plugins** can be used to retrieve groups and target dynamically, so they are equivalent to Ansible dynamic inventories.
- A **manifest** is a file that describes a configuration.
- A **resource** is a component that should run on a server. For example, "file" and "service" are existing support types.
- An **attribute** relates to a resource and affects the way it is applied. For example, a resource of type "file" can have attributes like "owner" and "mode".
- A **class** groups resources and variables, describing a logical part of server configuration. A class can be associated to several servers. A class is part of a manifest.
- A **module** is a set of manifests and describes an infrastructure or a part of it.
- Classes can have typed **parameters** that affect how they are applied.
- **Properties** are variables that are read from the remote server, and cannot be arbitrarily assigned.
- **Facts** are pre-set variables collected by Puppet before applying or compiling a manifest.

Architectural Differences

The architecture of the various systems is different. Their architectures determine how a deploy physically works, and what is needed to be able to deploy.

Ansible Architecture

Ansible architecture is simple. Ansible can run from any host, and can apply its playbooks on remote hosts. To do this, it runs commands via SSH. In practice, in most cases the commands will be run as superuser via `sudo`, though this is not always necessary.

Inventories can be dynamic. In this case, when we apply a playbook Ansible connects to remote services to discover hosts.

Ansible playbooks are applied via the `ansible-playbook` binary. Changes to playbooks are only applied when we perform this operation.

To recap, Ansible does not need to be installed on the server is administers. It needs an SSH access, and normally its user needs to be able to run `sudo`. It is also possible to configure a dynamic inventory, and a remote service to be used for this purpose.

Puppet Architecture

Puppet supports two types of architecture: agent-master or standalone. The agent-master architecture is recommended by Puppet Labs, and it is the most popular among Puppet users. For this reason, those who prefer a standalone architecture

tend to prefer Ansible.

Agent-Master Architecture

When this architecture is chosen, manifests are sent to the **Puppet master**. There can be more than one master, for high availability reasons. All target hosts run a **Puppet agent**. Normally this is a service that automatically starts at system boot. The agent contacts a master at a given interval. It sends facts, and uses them to compile a **catalog** from the manifests. A catalog is a description of what exactly an individual server should run. The agent receives the catalog and checks if there are differences between its current configuration and the catalog. If differences are found, the agent applies the relevant parts of the catalog.

An optional component is **PuppetDB**. This is a central place where some data are stored, including manifests, retrieved facts and logs. PuppetDB is based on PostgreSQL and there are no plans to support MariaDB or other DBMSs.

If a manual change is made to a remove server, it will likely be overwritten the next time Puppet agent runs. To avoid this, the Puppet agent service can be stopped.

Standalone Architecture

As mentioned, this architecture is not recommended by Puppet Labs nor popular amongst Puppet users. It is similar to Ansible architecture.

Users can apply manifests from any host with Puppet installed. This could be their laptop but, in order to emulate the behavior of an agent-master architecture, normally Puppet runs on a dedicated node as a cronjob. The **Puppet apply** application will require facts from remote hosts, it will compile a catalog for each host, will check which parts of it need to be applied, and will apply them remotely.

If a manual change is made to a remove server, it will be overwritten the next time Puppet apply runs. To avoid this, comment out any cron job running Puppet apply, or comment out the target server in the inventory.

Inventory

As mentioned, Puppet supports plugins to retrieve the inventory dynamically from remote services. In an agent-master architecture, one has to make sure that each target host has access to these services. In a standalone architecture, one has to make sure that the hosts running Puppet apply have access to these services.

Storing Secrets

Often our automation repositories need to contain secrets, like MariaDB user passwords or private keys for SSH authentication.

Both Ansible and Puppet support integration with secret stores, like Hashicorp Vault. For Puppet integration, see Integrations with secret stores.

In the simplest case, Ansible allows encrypting secrets in playbooks and decrypting them during execution using ansible-vault. This implies a minimal effort to handle secrets. However, it is not the most secure way to store secrets. The passwords to disclose certain secrets need to be shared with the users who have the right to use them. Also, brute force attacks are possible.

Ecosystems and Communities

Automation software communities are very important, because they make available a wide variety of modules to handle specific software.

Ansible Ecosystem

Ansible is open source, released under the terms of the GNU GPL. It is produced by RedHat. RedHat has a page about Red Hat Ansible Automation Platform Partners, who can provide support and consulting.

Ansible Galaxy is a big repository of Ansible roles produced by both the vendor and the community. Ansible comes with `ansible-galaxy`, a tool that can be used to create roles and upload them to Ansible Galaxy.

At the time of this writing, Ansible does not have specific MariaDB official modules. MySQL official modules can be used. However, be careful not try to use features that only apply to MySQL. There are several community-maintained MariaDB roles.

Puppet Ecosystem

Puppet is open source, released under the GNU GPL. It is produced by a homonym company. The page Puppet Partners

lists partners that can provide support and consulting about Puppet.

Puppet Forge is a big repository of modules produced by the vendor and by the community, as well as how-to guides.

Currently Puppet has many MariaDB modules.

2.1.2.14.3.1 Ansible Overview for MariaDB Users

Ansible is a tool to automate servers configuration management. It is produced by Red Hat and it is open source software released under the terms of the GNU GPL.

It is entirely possible to use Ansible to automate MariaDB deployments and configuration. This page contains generic information for MariaDB users who want to learn, or evaluate, Ansible.

For information about how to install Ansible, see Installing Ansible in Ansible documentation.

Contents

Automation Hubs

Normally, Ansible can run from any computer that has access to the target hosts to be automated. It is not uncommon that all members of a team has Ansible installed on their own laptop, and use it to deploy.

Red Hat offers a commercial version of Ansible called Ansible Tower. It consists of a REST API and a web-based interface that work as a hub that handles all normal Ansible operations.

An alternative is AWX. AWX is the open source upstream project from which many Ansible Tower features are originally developed. AWX is released under the terms of the Apache License 2.0. However, Red Hat does not recommend to run AWX in production.

AWX development is fast. It has several features that may or may not end up in Ansible Tower. Ansible Tower is more focused on making AWS features more robust, providing a stable tool to automate production environments.

Design Principles

Ansible allows us to write **playbooks** that describe how our servers should be configured. Playbooks are lists of **tasks**.

Tasks are usually **declarative**. You don't explain *how* to do something, you declare *what* should be done.

Playbooks are **idempotent**. When you apply a playbook, tasks are only run if necessary.

Here is a task example:

```
- name: Install Perl
  package:
    name: perl
    state: present
```

"Install Perl" is just a description that will appear on screen when the task is applied. Then we use the `package` module to declare that a package called "perl" should be installed. When we apply the playbook, if Perl is already installed nothing happens. Otherwise, Ansible installs it.

When we apply a playbook, the last information that appears on the screen is a recap like the following:

```
PLAY RECAP
*********************************************************************************************
****
mariadb-01        : ok=6    changed=2    unreachable=0    failed=0    skipped=0    rescued=0
ignored=0
```

This means that six tasks were already applied (so no action was taken), and two tasks were applied.

As the above example shows, Ansible playbooks are written in YAML.

Modules (like `package`) can be written in any language, as long as they are able to process a JSON input and produce a JSON output. However the Ansible community prefers to write them in Python, which is the language Ansible is written in.

Concepts

A piece of Ansible code that can be applied to a server is called a **playbook**.

A **task** is the smallest brick of code in a playbook. The name is a bit misleading, though, because an Ansible task should not be seen as "something to do". Instead, it is a minimal description of a component of a server. In the example above, we can see a task.

A task uses a single **module**, which is an interface that Ansible uses to interact with a specific system component. In the example, the module is "package".

A task also has attributes, that describe what should be done with that module, and how. In the example above, "name" and "state" are both attributes. The `state` attribute exists for every module, by convention (though there may be exceptions). Typically, it has at least the "present" and "absent" state, to indicate if an object should exist or not.

Other important code concepts are:

- An **inventory** determines which **hosts** Ansible should be able to deploy. Each host may belong to one or more **groups**. Groups may have **children**, forming a hierarchy. This is useful because it allows us to deploy on a group, or to assign variables to a group.
- A **role** describes the state that a host, or group of hosts, should reach after a deploy.
- A **play** associates hosts or groups to their roles. Each role/group can have more than one role.
- A role is a playbook that describes how certain servers should be configured, based on the logical role they have in the infrastructure. Servers can have multiple roles, for example the same server could have both the "mariadb" and the "mydumper" role, meaning that they run MariaDB and they have mydumper installed (as shown later).
- Tasks can use **variables**. They can affect how a task is executed (for example a variable could be a file name), or even whether a task is executed or not. Variables exist at role, group or host level. Variables can also be passed by the user when a play is applied.
- **Facts** are data that Ansible retrieves from remote hosts before deploying. This is a very important step, because facts may determine which tasks are executed or how they are executed. Facts include, for example, the operating system family or its version. A playbook sees facts as pre-set variables.
- **Modules** implement **actions** that tasks can use. Action examples are **file** (to declare that files and directories must exist) or **mysql_variables** (to declare MySQL/MariaDB variables that need to be set).

Example

Let's describe a hypothetical infrastructure to find out how these concepts can apply to MariaDB.

The **inventory** could define the following groups:

- "db-main" for the cluster used by our website. All nodes belong to this group.
- "db-analytics" for our replicas used by data analysts.
- "dump" for one or more servers that take dumps from the replicas.
- "proxysql" for one or more hosts that run ProxySQL.

Then we'll need the following nodes:

- "mariadb-node" for the nodes in "db-main". This role describes how to setup nodes of a cluster using Galera.
- "mariadb-replica" for the members of "db-analytics". It describes a running replica, and it includes the tasks that are necessary to provision the node if the data directory is empty when the playbook is applied. The hostname of the primary server is defined in a variable.
- "mariadb". The aforementioned "mariadb-node" and "mariadb-replica" can be children of this group. They have many things in common (filesystem for the data directory, some basic MariaDB configuration, some installed tools...), so it could make sense to avoid duplication and describe the common traits in a super-role.
- A "mariabackup" role to take backups with Mariabackup, running jobs during the night. We can associate this role to the "db-main" group, or we could create a child group for servers that will take the backups.
- "mariadb-dump" for the server that takes dumps with mariadb-dump. Note that we may decide to take dumps on a replica, so the same host may belong to "db-analytics" and "mariadb-dump".
- "proxysql" for the namesake group.

Architecture

Ansible architecture is extremely simple. Ansible can run on any host. To apply playbooks, it connects to the target hosts and runs system commands. By default the connection happens via ssh, though it is possible to develop connection plugins to use different methods. Applying playbooks locally without establishing a connection is also possible.

Modules can be written in any language, though Python is the most common choice in the Ansible community. Modules receive JSON "requests" and facts from Ansible core, they are supposed to run useful commands on a target host, and then they should return information in JSON. Their output informs Ansible whether something has changed on the remote server and if the operations succeeded.

Ansible is not centralized. It can run on any host, and it is common for a team to run it from several laptops. However, to simplify things and improve security, it may be desirable to run it from a dedicated host. Users will connect to that host, and apply Ansible playbooks.

2.1.2.14.3.2 Deploying to Remote Servers with Ansible

If we manage several remote servers, running commands on them manually can be frustrating and time consuming. Ansible allows one to run commands on a whole group of servers.

This page shows some examples of ansible-playbook invocations. We'll see how to deploy roles or parts of them to remote servers. Then we'll see how to run commands on remote hosts, and possibly to get information from them. Make sure to read Ansible Overview first, to understand Ansible general concepts.

Contents

Pinging Remote Servers

Let's start with the simplest example: we just want our local Ansible to ping remote servers to see if they are reachable. Here's how to do it:

```
ansible -i production-mariadb all -m ping
```

Before proceeding with more useful examples, let's discuss this syntax.

- **ansible** is the executable we can call to run a command from remote servers.
- **-i production-mariadb** means that the servers must be read from an inventory called production-mariadb.
- **all** means that the command must be executed against all servers from the above inventory.
- **-m ping** specifies that we want to run the ping module. This is not the ping Linux command. It tells us if Ansible is able to connect a remote server and run a simple commands on them.

To run ping on a specific group or host, we can just replace "all" with a group name or host name from the inventory:

```
ansible -i production-mariadb main_cluster -m ping
```

Running Commands on Remote Servers

The previous examples show how to run an Ansible module on remote servers. But it's also possible to run custom commands over SSH. Here's how:

```
ansible -i production-mariadb all -a 'echo $PATH'
```

This command shows the value of `$PATH` on all servers in the inventory "production-mariadb".

We can also run commands as root by adding the `-b` (or `--become`) option:

```
# print a MariaDB variable
ansible -i production-mariadb all -b -a 'mysql -e "SHOW GLOBAL VARIABLES LIKE
\'innodb_buffer_pool_size\';"'

# reboot servers
ansible -i production-mariadb all -b -a 'reboot'
```

Applying Roles to Remote Servers

We saw how to run commands on remote hosts. Applying roles to remote hosts is not much harder, we just need to add some information. An example:

```
ansible-playbook -i production-mariadb production-mariadb.yml
```

Let's see what changed:

- **ansible-playbook** is the executable file that we need to call to apply playbooks and roles.
- **production-mariadb.yml** is the play that associates the servers listed in the inventory to their roles.

If we call ansible-playbook with no additional arguments, we will apply all applicable roles to all the servers mentioned in the play.

To only apply roles to certain servers, we can use the `-l` parameter to specify a group, an individual host, or a pattern:

```
# Apply to the mariadb-main role role
ansible-playbook -i production-mariadb -l mariadb-main production-mariadb.yml

# Apply to the mariadb-main-01 host
ansible-playbook -i production-mariadb -l mariadb-main-01 production-mariadb.yml

# Apply to multiple hosts whose name starts with "mariadb-main-"
ansible-playbook -i production-mariadb -l mariadb-main-* production-mariadb.yml
```

We can also apply tasks from roles selectively. Tasks may optionally have tags, and each tag corresponds to an operation that we may want to run on our remote hosts. For example, a "mariadb" role could have the "timezone-update" tag, to update the contents of the timezone tables. To only apply the tasks with the "timezone-update" tag, we can use this command:

```
ansible-playbook -i production-mariadb --tag timezone-update production-mariadb.yml
```

Using tags is especially useful for database servers. While most of the technologies typically managed by Ansible are stateless (web servers, load balancers, etc.) database servers are not. We must pay special attention not to run tasks that could cause a database server outage, for example destroying its data directory or restarting the service when it is not necessary.

Check mode

We should always test our playbooks and roles on test servers before applying them to production. However, if test servers and production servers are not exactly in the same state (which means, some facts may differ) it is still possible that applying roles will fail. If it fails in the initial stage, Ansible will not touch the remote hosts at all. But there are cases where Ansible could successfully apply some tasks, and fail to apply another task. After the first failure, ansible-playbook will show errors and exit. But this could leave a host in an inconsistent state.

Ansible has a *check mode* that is meant to greatly reduce the chances of a failure. When run in check mode, ansible-playbook will read the inventory, the play and roles; it will figure out which tasks need to be applied; then it will connect to target hosts, read facts, and value all the relevant variables. If all these steps succeed, it is unlikely that running ansible-playbook without check mode will fail.

To run ansible-playbook in check mode, just add the `--check` (or `-C`) parameter.

References

Further documentation can be found in the Ansible website:

- ansible tool.
- ansible-playbook tool.
- Validating tasks: check mode and diff mode.

2.1.2.14.3.3 Deploying Docker Containers with Ansible

Ansible can be used to manage Docker container upgrades and configuration changes. Docker has native ways to do this, namely Dockerfiles and Docker Compose. But sometimes there are reasons to start basic containers from an image and then manage configuration with Ansible or similar software. See Benefits of Managing Docker Containers with Automation Software.

In this page we'll discuss how to use Ansible to manage Docker containers.

Contents

How to Deploy a Container with Ansible

Ansible has modules to manage the Docker server, Docker containers, and Docker Compose. These modules are maintained by the community.

A dynamic inventory plugin for Docker exists. It retrieves the list of existing containers from Docker.

Docker modules and the Docker inventory plugin communicate with Docker using its API. The connection to the API can use a TSL connection and supports key authenticity verification.

To communicate with Docker API, Ansible needs a proper Python module installed on the Ansible node (`docker` or `docker-py`).

Several roles exist to deploy Docker and configure it. They can be found in Ansible Galaxy.

References

Further information can be found in Ansible documentation.

- Docker Guide.
- docker_container module.

Content initially contributed by Vettabase Ltd.

2.1.2.14.3.4 Existing Ansible Modules and Roles for MariaDB

This page contains links to Ansible modules and roles that can be used to automate MariaDB deployment and configuration. The list is not meant to be exhaustive. Use it as a starting point, but then please do your own research.

Contents

Modules

At the time time of writing, there are no MariaDB-specific modules in Ansible Galaxy. MySQL modules can be used. Trying to use MySQL-specific features may result in errors or unexpected behavior. However, the same applies when trying to use a feature not supported by the MySQL version in use.

Currently, the MySQL collection in Ansible Galaxy contains at least the following modules:

- **mysql_db**: manages MySQL databases.
- **mysql_info**: gathers information about a MySQL server.
- **mysql_query**: runs SQL queries against MySQL.
- **mysql_replication**: configures and operates asynchronous replication.
- **mysql_user**: creates, modifies and deletes MySQL users.
- **mysql_variables**: manages MySQL configuration.

Note that some modules only exist as shortcuts, and it is possible to use mysql_query instead. However, it is important to notice that mysql_query is not idempotent. Ansible does not understand MySQL queries, therefore it cannot check whether a query needs to be run or not.

To install this collection locally:

```
ansible-galaxy collection install community.mysql
```

MariaDB Corporation maintains a ColumnStore playbook on GitHub.

Other Useful Modules

Let's see some other modules that are useful to manage MariaDB servers.

shell and command

Modules like shell and command allow one to run system commands.

To deploy on Windows, win_shell and win_command can be used.

Among other things, it is possible to use one of these modules to run MariaDB queries:

```
- name: Make the server read-only
  # become root to log into MariaDB with UNIX_SOCKET plugin
  become: yes
  shell: $( which mysql ) -e "SET GLOBAL read_only = 1;"
```

The main disadvantage with these modules is that they are not idempotent, because they're meant to run arbitrary system commands that Ansible can't understand. They are still useful in a variety of cases:

- To run queries, because mysql_query is also not idempotent.
- In cases when other modules do not allow us to use the exact arguments we need to use, we can achieve our goals by writing shell commands ourselves.
- To run custom scripts that implement non-trivial logic. Implementing complex logic in Ansible tasks is possible, but it can be tricky and inefficient.
- To call command-line tools. There may be specific roles for some of the most common tools, but most of the times using them is an unnecessary complication.

copy and template

An important part of configuration management is copying configuration files to remote servers.

The copy module allows us to copy files to target hosts. This is convenient for static files that we want to copy exactly as they are. An example task:

```
- name: Copy my.cnf
  copy:
    src: ./files/my.cnf.1
    dest: /etc/mysql/my.cnf
```

As you can see, the local name and the name on remote host don't need to match. This is convenient, because it makes it easy to use different configuration files with different servers. By default, files to copy are located in a `files` subdirectory in the role.

However, typically the content of a configuration file should vary based on the target host, the group and various variables. To do this, we can use the template module, which compiles and copies templates written in Jinja.

A simple template task:

```
- name: Compile and copy my.cnf
  copy:
    src: ./templates/my.cnf.j2
    dest: /etc/mysql/my.cnf
```

Again, the local and the remote names don't have to match. By default, Jinja templates are located in a `templates` subdirectory in the role, and by convention they have the `.j2` extension. This is because Ansible uses Jinja version 2 for templating, at the time writing.

A simple template example:

```
## WARNING: DO NOT EDIT THIS FILE MANUALLY !!
## IF YOU DO, THIS FILE WILL BE OVERWRITTEN BY ANSIBLE

[mysqld]
innodb_buffer_pool_size = {{ innodb_buffer_pool_size }}

{% if use_connect sameas true %}
connect_work_size = {{ connect_work_size }}
{% endif %}
```

Other Common Modules

The following modules are also often used for database servers:

- package, apt or yum. Package is package manager-agnostic. Use them to install, uninstall and upgrade packages.
- user, useful to create the system user and group that run MariaDB binary.
- file can be used to make sure that MariaDB directories (like the data directory) exist and have proper permissions. It can also be used to upload static files.

- template allows to create configuration files (like my.cnf) more dynamically, using the Jinja template language.
- service is useful after installing MariaDB as a service, to start it, restart it or stop it.

Roles

Specific roles exist for MariaDB in Ansible Galaxy. Using them for MariaDB is generally preferable, to be sure to avoid incompatibilities and to probably be able to use some MariaDB specific features. However, using MySQL or Percona Server roles is also possible. This probably makes sense for users who also administer MySQL and Percona Server instances.

To find roles that suits you, check Ansible Galaxy search page. Most roles are also available on GitHub.

You can also search roles using the ansible-galaxy tool:

```
ansible-galaxy search mariadb
```

2.1.2.14.3.5 Installing MariaDB .deb Files with Ansible

This page refers to the operations described in Installing MariaDB .deb Files. Refer to that page for a complete list and explanation of the tasks that should be performed.

Here we discuss how to automate such tasks using Ansible. For example, here we show how to install a package or how to import a GPG key; but for an updated list of the necessary packages and for the keyserver to use, you should refer to Installing MariaDB .deb Files.

Adding apt Repositories

To add a repository:

```
- name: Add specified repository into sources list
  ansible.builtin.apt_repository:
    repo: deb [arch=amd64,arm64,ppc64el]
http://sfo1.mirrors.digitalocean.com/mariadb/repo/10.3/ubuntu bionic main
    state: present
```

If you prefer to keep the repository information in a source list file in the Ansible repository, you can upload that file to the target hosts in this way:

```
- name: Create a symbolic link
  ansible.builtin.file:
    src: ./file/mariadb.list
    dest: /etc/apt/sources.list.d/
    owner: root
    group: root
    mod: 644
    state: file
```

Updating the Repository Cache

Both the Ansible modules ansible.builtin.apt and ansible.builtin.apt_repository have an `update_cache` attribute. In ansible.builtin.apt it is set to "no" by default. Whenever a task sets it to 'yes', `apt-get update` is run on the target system. You have three ways to make sure that repositories are updated.

The first is to use ansible.builtin.apt_repository to add the desired repository, as shown above. So you only need to worry about updating repositories if you use the file method.

The second is to make sure that `update_cache` is set to 'yes' when you install a repository:

```
- name: Install foo
  apt:
    name: foo
    update_cache: yes
```

But if you run certain tasks conditionally, this option may not be very convenient. So the third option is to update the

repository cache explicitly as a separate task:

```
- name: Update repositories
  apt:
    - update_cache: yes
```

Importing MariaDB GPG Key

To import the GPG key for MariaDB we can use the ansible.builtin.apt_key Ansible module. For example:

```
- name: Add an apt key by id from a keyserver
  ansible.builtin.apt_key:
    keyserver: hkp://keyserver.ubuntu.com:80
    id: 0xF1656F24C74CD1D8
```

Installing Packages

To install Deb packages into a system:

```
- name: Install software-properties-common
  apt:
    name: software-properties-common
    state: present
```

To make sure that a specific version is installed, performing an upgrade or a downgrade if necessary:

```
- name: Install foo 1.0
  apt:
    name: foo=1.0
```

To install a package or upgrade it to the latest version, use: `state: latest` .

To install multiple packages at once:

```
- name: Install the necessary packages
  apt:
    pkg:
    - pkg1
    - pkg2=1.0
```

If all your servers run on the same system, you will always use ansible.builtin.apt and the names and versions of the packages will be the same for all servers. But suppose you have some servers running systems from the Debian family, and others running systems from the Red Hat family. In this case, you may find convenient to use two different task files for two different types of systems. To include the proper file for the target host's system:

```
- include: mariadb-debian.yml
  when: "{{ ansible_facts['os_family'] }} == 'Debian'
```

The variables you can use to run the tasks related to the proper system are:

- ansible_fact['distribution']
- ansible_fact['distribution_major_version']
- ansible_fact['os_family']

There is also a system-independent package module, but if the package names depend on the target system using it may be of very little benefit.

2.1.2.14.3.6 Running mariadb-tzinfo-to-sql with Ansible

For documentation about the `mariadb-tzinfo-to-sql` utility, see mysql_tzinfo_to_sql. This page is about running it using Ansible.

Installing or Upgrading the Package

First, we should install `mariadb-tzinfo-to-sql` if it is available on our system. For example, to install it on Ubuntu, we can use this task. For other systems, use the proper module and package name.

```
- name: Update timezone info
  tags: [ timezone-update ]
  apt:
    name: tzdata
    state: latest
    install_recommends: no
  register: timezone_info
```

This task installs the latest version of the `tzdata`, unless it is already installed and up to date. We register the `timezone_info` variables, so we can only run the next task if the package was installed or updated.

We also specify a `timezone-update` tag, so we can apply the role to only update the timezone tables.

Running the Script

The next task runs `mariadb-tzinfo-to-sql`.

```
- name: Move system timezone info into MariaDB
  tags: [ timezone-update ]
  shell: >
    mysql_tzinfo_to_sql /usr/share/zoneinfo \
      | grep -v "^Warning" \
      | mysql --database=mysql
  when: timezone_info.changed
```

We use the `shell` module to run the command. Running a command in this way is not idempotent, so we specify `when: timezone_info.changed` to only run it when necessary. Some warnings may be generated, so we pipe the output of `mysql_tzinfo_to_sql` to `grep` to filter warnings out.

Using Galera

If we're using MariaDB Galera Cluster we'll want to only update the timezone tables in one node, because the other nodes will replicate the changes. For our convenience, we can run this operation on the first node. If the nodes hostnames are defined in a list called `cluster_hosts`, we can check if the current node is the first in this way:

```
  when: timezone_info.changed and inventory_hostname == cluster_hosts[0].hostname
```

Content initially contributed by Vettabase Ltd.

2.1.2.14.3.7 Managing Secrets in Ansible

An Ansible role often runs commands that require certain privileges, so it must perform some forms of login, using passwords or key pairs. In the context of database automation, we normally talk about: SSH access, sudo access, and access to MariaDB. If we write these secrets (passwords or private keys) in clear text in an Ansible repository, anyone who has access to the repository can access them, and this is not what we want.

Let's see how we can manage secrets.

Contents

The SSH Password or Keys

Most of the times, Ansible connects to the target hosts via SSH. It is common to use the system username and the SSH keys installed in `/.ssh`, which is the SSH clients default. In this case, nothing has to be done on the clients to be able to allow Ansible to use SSH, as long as they are already able to connect to the target hosts.

It is also possible to specify a different username as `ANSIBLE_REMOTE_USER` and an SSH configuration file as `ANSIBLE_NETCONF_SSH_CONFIG`. These settings can be specified in Ansible configuration file or as environment variables.

`ANSIBLE_ASK_PASS` can be specified. If this is the case, Ansible will prompt the user asking to type an SSH password.

Avoiding Sharing Secrets

As a general rule, any configuration that implies communicating sensible information to the persons who will connects to a system implies some degree of risk. Therefore, the most common choice is to allow users to login into remote systems with their local usernames, using SSH keys.

Once Ansible is able to connect remote hosts, it can also be used to install the public keys of some users to grant them access. Sharing these keys implies no risk. Sharing private keys is never necessary, and must be avoided.

MariaDB has a UNIX_SOCKET plugin that can be used to let some users avoid entering a password, as far as they're logged in the operating system. This authentication method is used by default for the root user. This is a good way to avoid having one more password and possibly writing to a `.my.cnf` file so that the user doesn't have to type it.

Even for users who connect remotely, it is normally not necessary to insert passwords in an Ansible file. When we create a user with a password, a hash of the original password is stored in MariaDB. That hash can be found in the mysql.user table. To know the hash of a password without even creating a user, we can use the PASSWORD() function:

```
SELECT PASSWORD('my_password12') AS hash;
```

When we create a user, we can actually specify a hash instead of the password the user will have to type:

```
CREATE USER user@host IDENTIFIED BY PASSWORD '*54958E764CE10E50764C2EECBB71D01F08549980';
```

ansible-vault

Even if you try to avoid sharing secrets, it's likely you'll have to keep some in Ansible. For example, MariaDB users that connect remotely have passwords, and if we want Ansible to create and manage those users, the hashes must be placed somewhere in our Ansible repository. While a hash cannot be converted back to a password, treating hashes as secrets is usually a good idea. Ansible provides a native way to handle secrets: ansible-vault.

In the simplest case, we can manage all our passwords with a single ansible-vault password. When we add or change a new password in some file (typically a file in `host_vars` or `group_vars`) we'll use ansible-vault to crypt this password. While doing so, we'll be asked to insert our ansible-vault password. When we apply a role and Ansible needs to decrypt this password, it will ask us to enter again our ansible-vault password.

ansible-vault can use more than one password. Each password can manage a different set of secrets. So, for example, some users may have the password to manage regular MariaDB users passwords, and only one may have the password that is needed to manage the root user.

2.1.2.14.4 Puppet and MariaDB

General information and hints on how to automate MariaDB deployments and configuration with Puppet.

Puppet is an open source tool deployment, configuration and operations.

Puppet Overview for MariaDB Users

Overview of Puppet and how it works with MariaDB.

Bolt Examples

How to invoke Bolt to run commands or apply roles on remote hosts.

Puppet hiera Configuration System

Using hiera to handle Puppet configuration files.

Deploying Docker Containers with Puppet

How to deploy and manage Docker containers with Puppet.

2.1.2.14.4.1 Puppet Overview for MariaDB Users

Puppet is a tool to automate servers configuration management. It is produced by Puppet Inc, and released under the terms of the Apache License, version 2.

It is entirely possible to use Ansible to automate MariaDB deployments and configuration. This page contains generic information for MariaDB users who want to learn, or evaluate, Puppet.

Puppet modules can be searched using Puppet Forge. Most of them are also published on GitHub with open source licenses. Puppet Forge allows filtering modules to only view the most reliable: supported by Puppet, supported by a Puppet partner, or approved.

For information about installing Puppet, see Installing and upgrading in Puppet documentation.

Contents

Design Principles

With Puppet, you write **manifests** that describe the resources you need to run on certain servers and their **attributes**.

Therefore manifests are **declarative**. You don't write the steps to achieve the desired result. Instead, you describe the desired result. When Puppet detects differences between your description and the current state of a server, it decides what to do to fix those differences.

Manifests are also **idempotent**. You don't need to worry about the effects of applying a manifest twice. This may happen (see Architecture below) but it won't have any side effects.

Defining Resources

Here's an example of how to describe a resource in a manifest:

```
file { '/etc/motd':
  content => '',
  ensure => present,
}
```

This block describes a resource. The resource type is `file`, while the resource itself is `/etc/motd`. The description consists of a set of attributes. The most important is `ensure`, which in this case states that the file must exist. It is also common to use this resource to indicate that a file (probably created by a previous version of the manifest) doesn't exist.

These classes of resource types exist:

- **Built-in resources**, or **Puppet core resources**: Resources that are part of Puppet, maintained by the Puppet team.
- **Defined resources**: Resources that are defined as a combination of other resources. They are written in the Puppet domain-specific language.
- **Custom resources**: Resources that are written by users, in the Ruby language.

To obtain information about resources:

```
# list existing resource types
puppet resource --types
# print information about the file resource type
puppet describe file
```

To group several resources in a reusable class:

```
class ssh_server {
  file { '/etc/motd':
    content => '',
    ensure => present,
  }
  file { '/etc/issue.net':
    content => '',
    ensure => present,
  }
}
```

There are several ways to include a class. For example:

```
include Class['ssh_server']
```

Defining Nodes

Puppet has a **main manifest** that could be a `site.pp` file or a directory containing `.pp` files. For simple infrastructures, we can define the nodes here. For more complex infrastructures, we may prefer to import other files that define the nodes.

Nodes are defined in this way:

```
node 'maria-1.example.com' {
  include common
  include mariadb
}
```

The resource type is `node`. Then we specify a hostname that is used to match this node to an existing host. This can also be a list of hostnames, a regular expression that matches multiple nodes, or the `default` keyword that matches all hosts. To use a regular expression:

```
node /^(maria|mysql)-[1-3]\.example\.com$/ {
  include common
}
```

Concepts

The most important Puppet concepts are the following:

- **Target**: A host whose configuration is managed via Puppet.
- **Group**: A logical group of targets. For example there may be a `mariadb` group, and several targets may be part of this group.
- **Facts**: Information collected from the targets, like the system name or system version. They're collected by a Ruby gem called Facter. They can be core facts (collected by default) or custom facts (defined by the user).
- **Manifest**: A description that can be applied to a target.
- **Catalog**: A compiled manifest.
- **Apply**: Modifying the state of a target so that it reflects its description in a manifest.
- **Module**: A set of manifests.
- **Resource**: A minimal piece of description. A manifest consists of a piece of resources, which describe components of a system, like a file or a service.
- **Resource type**: Determines the class of a resource. For example there is a `file` resource type, and a manifest can contain any number of resources of this type, which describe different files.
- **Attribute**: It's a characteristic of a resource, like a file owner, or its mode.
- **Class**: A group of resources that can be reused in several manifests.

Architecture

Depending on how the user decides to deploy changes, Puppet can use two different architectures:

- An **Agent-master** architecture. This is the preferred way to use Puppet.
- A **standalone architecture**, that is similar to Ansible architecture.

Agent-master Architecture

A **Puppet master** stores a catalog for each target. There may be more than one Puppet master, for redundancy.

Each target runs a **Puppet agent** in background. Each Puppet agent periodically connects to the Puppet master, sending its facts. The Puppet master compiles the relevant manifest using the facts it receives, and send back a catalog. Note that it is also possible to store the catalogs in PuppetDB instead.

Once the Puppet agent receives the up-to-date catalog, it checks all resources and compares them with its current state. It applies the necessary changes to make sure that its state reflects the resources present in the catalog.

Standalone Architecture

With this architecture, the targets run **Puppet apply**. This application usually runs as a Linux cron job or a Windows scheduled task, but it can also be manually invoked by the user.

When Puppet apply runs, it compiles the latest versions of manifests using the local facts. Then it checks every resource from the resulting catalogs and compares it to the state of the local system, applying changes where needed.

Newly created or modified manifests are normally deployed to the targets, so Puppet apply can read them from the local host. However it is possible to use PuppetDB instead.

PuppetDB

PuppetDB is a Puppet node that runs a PostgreSQL database to store information that can be used by other nodes. PuppetDB can be used with both the Agent-master and the standalone architectures, but it is always optional. However it is necessary to use some advanced Puppet features.

PuppetDB stored the following information:

- The latest facts from each target.
- The latest catalogs, compiled by Puppet apply or a Puppet master.
- Optionally, the recent history of each node activities.

External Node Classifiers

With both architectures, it is possible to have a component called an External Node Classifier (ENC). This is a script or an executable written in any language that Puppet can call to determine the list of classes that should be applied to a certain target.

An ENC received a node name in input, and should return a list of classes, parameters, etc, as a YAML hash.

Bolt

Bolt can be used in both architectures to run operations against a target or a set of targets. These operations can be commands passed manually to Bolt, scripts, Puppet tasks or plans. Bolt directly connects to targets via ssh and runs system commands.

See Bolt Examples to get an idea of what you can do with Bolt.

hiera

hiera is a hierarchical configuration system that allows us to:

- Store configuration in separate files;
- Include the relevant configuration files for every server we automate with Puppet.

See Puppet hiera Configuration System for more information.

2.1.2.14.4.2 Bolt Examples

Contents

This page shows some examples of what we can do with Bolt to administer a set of MariaDB servers. Bolt is a tool that is part of the Puppet ecosystem.

For information about installing Bolt, see Installing Bolt in Bolt documentation.

Inventory Files

The simplest way to call Bolt and instruct it to do something on some remote targets is the following:

```
bolt ... --nodes 100.100.100.100,200.200.200.200,300,300,300,300
```

However, for non-trivial setups it is usually better to use an inventory file. An example:

```
targets:
  - uri: maria-1.example.com
    name: maria_1
    alias: mariadb_main
  ...
```

In this way, it will be possible to refer the target by name or alias.

We can also define groups, followed by the group members. For example:

```
groups:
  - name: mariadb-staging
    targets:
        - uri: maria-1.example.com
        name: maria_1
        - uri: maria-2.example.com
        name: maria_2
  - name: mariadb-production
    targets:
      ...
...
```

With an inventory of this type, it will be possible to run Bolt actions against all the targets that are members of a group:

```
bolt ... --nodes mariadb-staging
```

In the examples in the rest of the page, the `--targets` parameter will be indicated in this way, for simplicity: `--targets`

<targets>.

Running Commands on Targets

The simplest way to run a command remotely is the following:

```
bolt command run 'mariadb-admin start-all-slaves' --targets <targets>
```

Copying Files

To copy a file or a whole directory to targets:

```
bolt file upload /path/to/source /path/to/destination --targets <targets>
```

To copy a file or a whole directory from the targets to the local host:

```
bolt file download /path/to/source /path/to/destination --targets <targets>
```

Running Scripts on Targets

We can use Bolt to run a local script on remote targets. Bolt will temporarily copy the script to the targets, run it, and delete it from the targets. This is convenient for scripts that are meant to only run once.

```
bolt script run rotate_logs.sh --targets <targets>
```

Running Tasks on Targets

Puppet tasks are not always as powerful as custom scripts, but they are simpler and many of them are idempotent. The following task stops MariaDB replication:

```
bolt task run mysql::sql --targets <targets> sql="STOP REPLICA"
```

Applying Puppet Code on Targets

It is also possible to apply whole manifests or portions of Puppet code (resources) on the targets.

To apply a manifest:

```
bolt apply manifests/server.pp  --targets <targets>
```

To apply a resource description:

```
bolt apply --execute "file { '/etc/mysql/my.cnf': ensure => present }" --targets <targets>
```

Bolt Resources and References

2.1.2.14.4.3 Puppet hiera Configuration System

hiera is part of Puppet. It is a hierarchical configuration system that allows us to:

- Store configuration in separate files;
- Include the relevant configuration files for every server we automate with Puppet.

Contents

hiera Configuration Files

Each hierarchy allows to one choose the proper configuration file for a resource, based on certain criteria. For example criteria may include node names, node groups, operating systems, or datacenters. Hierarchies are defined in a `hiera.yaml` file, which also defines a path for the files in each hierarchy.

Puppet facts are commonly used to select the proper files to use. For example, a path may be defined as `"os/%{facts.os.name}.yaml"`. In this case, each resource will use a file named after the operating system it uses, in the os directory. You may need to use custom facts, for example to check which microservices will use a MariaDB server, or in which datacenter it runs.

We do not have to create a file for each possible value of a certain fact. We can define a default configuration file with settings that are reasonable for most resources. Other files, when included, will override some of the default settings.

A hiera configuration file will look like this:

```
version: 5
defaults:
  datadir: global
  data_hash: yaml_data

hierarchy:
  - name: "Node data"
    path: "nodes/%{trusted.certname}.yaml"

  - name: "OS data"
    path: "os/%{facts.os.family}.yaml"

  - name: "Per-datacenter business group data" # Uses custom facts.
    path: "location/%{facts.whereami}/%{facts.group}.yaml"
```

This file would include the global files, the OS-specific files and the node-specific files. Each hierarchy will override settings from previous hierarchies.

We can actually have several hiera configuration files. `hiera.yaml` is the global file. But we will typically have additional hiera configuration files for each environment. So we can include the configuration files that apply to production, staging, etc, plus global configuration files that should be included for every environment.

Importantly, we can also have hiera configuration files for each module. So, for example, a separate `mariadb/hiera.yaml` file may defined the hierarchies for MariaDB servers. This allow us to define, for example, different configuration files for MariaDB and for MaxScale, as most of the needed settings are typically different.

Configuration files

You probably noticed that, in the previous example, we defined `data_hash: yaml_data`, which indicates that configuration files are written in YAML. Other allowed formats are JSON and HOCON. The `data_hash` setting is defined in `defaults`, but it can be overridden by hierarchies.

Content initially contributed by Vettabase Ltd.

2.1.2.14.4.4 Deploying Docker Containers with Puppet

Puppet can also be used to manage Docker container upgrades and configuration changes. Docker has more specific tools for this purpose, but sometimes there are reasons to choose alternatives. See Benefits of Managing Docker Containers with Automation Software.

In this page you will find out what managing Docker with Puppet looks like. All the snippets in this page use the `docker` resource type, supported by the Puppet company.

Contents

How to Install, Upgrade or Uninstall Docker with Puppet

Installing or upgrading Docker is simple:

```
class { 'docker':
  use_upstream_package_source => false,
  version => '17.09.0~ce-0~debian',
}
```

In this example we are using our system's repositories instead of Docker official repositories, and we are specifying the desired version. To upgrade Docker later, all we need to do is to modify the version number. While specifying a version is not mandatory, it is a good idea because it makes our manifest more reproducible.

To uninstall Docker:

```
class { 'docker':
  ensure => absent
}
```

Check the `docker` resource type documentation to find out how to use more features: for example you can use Docker Enterprise Edition, or bind the Docker daemon to a TCP port.

How to Build or Pull Docker Images with Puppet

To pull an image from Dockerhub:

```
docker::image { 'mariadb:10.0': }
```

We specified the `10.0` tag to get the desired MariaDB version. If we don't, the image with the `latest` tag will be used. Note that this is not desirable in production, because it can lead to unexpected upgrades.

You can also write a Dockerfile yourself, and then build it to create a Docker image. To do so, you need to instruct Puppet to copy the Dockerfile to the target and then build it::

```
file { '/path/to/remote/Dockerfile':
  ensure => file,
  source => 'puppet:///path/to/local/Dockerfile',
}

docker::image { 'image_name':
  docker_file => '/path/to/remote/Dockerfile'
}
```

It is also possible to subscribe to Dockerfile changes, and automatically rebuild the image whenever a new file is found:

```
docker::image { 'image_name':
  docker_file => '/path/to/remote/Dockerfile'
  subscribe => File['/path/to/remote/Dockerfile'],
}
```

To remove an image that was possibly built or pulled:

```
docker::image { 'mariadb':
  ensure => absent
}
```

How to Deploy Containers with Puppet

To run a container:

```
docker::run { 'mariadb-01':
    image   => 'mariadb:10.5',
    ports   => ['3306:6606']
}
```

`mariadb-01` is the contained name. We specified the optional `10.5` tag, and we mapped the guest port 3306 to the host port 6606. In production, you normally don't map ports because you don't need to connect MariaDB clients from the host system to MariaDB servers in the containers. Third-party tools can be installed as separate containers.

2.1.2.14.4.5 Existing Puppet Modules for MariaDB

This page contains links to Puppet modules that can be used to automate MariaDB deployment and configuration. The list is not meant to be exhaustive. Use it as a starting point, but then please do your own research.

Contents

Puppet Forge

Puppet Forge is the website to search for Puppet modules, maintained by the Puppet company. Modules are searched by the technology that needs to be automated, and the target operating system.

Search criteria include whether the modules are supported by Puppet or its partners, and whether a module is approved by Puppet. Approved modules are certified by Puppet based on their quality and maintenance standards.

Acceptance Tests

Some modules that support the Puppet Development Kit allow some types of acceptance tests.

We can run a static analysis on a module's source code to find certain bad practices that are likely to be a source of bugs:

```
pdk validate
```

If a module's authors wrote unit tests, we can run them in this way:

```
pdk test unit
```

Supported Modules for MariaDB

At the time of writing, there are no supported or approved modules for MariaDB.

However there is a mysql module supported by Puppet, that supports the Puppet Development Kit. Though it doesn't support MariaDB-specific features, it works with MariaDB. Its documentation shows how to use the module to install MariaDB on certain operating systems.

Several unsupported and not approved modules exist for MariaDB and MaxScale.

2.1.2.14.5.1 Vagrant Overview for MariaDB Users

Vagrant is a tool to create and manage development machines (Vagrant *boxes*). They are usually virtual machines on the localhost system, but they could also be Docker containers or remote machines. Vagrant is open source software maintained by HashiCorp and released under the MIT license.

Vagrant benefits include simplicity, and a system to create test boxes that is mostly independent from the technology used.

For information about installing Vagrant, see Installation in Vagrant documentation.

In this page we discuss basic Vagrant concepts.

Contents

Vagrant Concepts

A **Vagrant machine** is compiled from a box. It can be a virtual machine, a container or a remote server from a cloud service.

A **box** is a package that can be used to create Vagrant machines. We can download boxes from app.vagrantup.com, or we can build a new box from a Vagrantfile. A box can be used as a base for another box. The base boxes are usually operating system boxes downloaded from app.vagrantup.com.

A **provider** is responsible for providing the virtualization technology that will run our machine.

A **provisioner** is responsible for installing and configuring the necessary software on a newly created Vagrant machine.

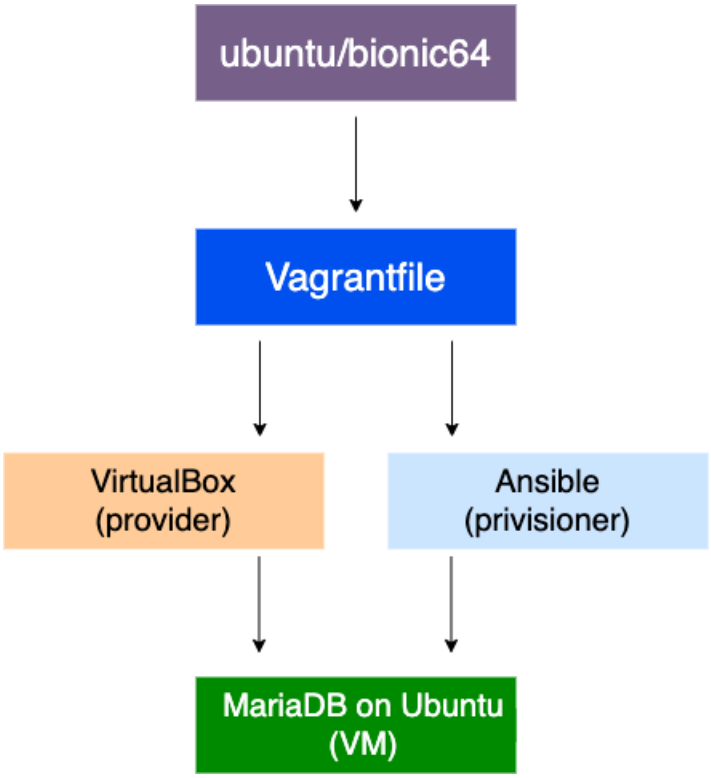
Example

The above concepts are probably easier to understand with an example.

We can use an Ubuntu box as a base to build a Vagrant machine with MariaDB. So we write a Vagrantfile for this purpose.

In the Vagrantfile we specify VirtualBox as a provider. And we use the Ansible provisioner to install and configure MariaDB. Once we finish this Vagrantfile, we can run a Vagrant command to start a Vagrant machine, which is actually a VirtualBox VM running MariaDB on Ubuntu.

The following diagram should make the example clear:



Vagrantfiles

A Vagrantfile is a file that describes how to create one or more Vagrant machines. Vagrantfiles use the Ruby language, as well as objects provided by Vagrant itself.

A Vagrantfile is often based on a box, which is usually an operating system in which we are going to install our software. For example, one can create a MariaDB Vagrantfile based on the `ubuntu/trusty64` box. A Vagrantfile can describe a box with a single server, like MariaDB, but it can also contain a whole environment, like LAMP. For most practical use cases, having the whole environment in a single box is more convenient.

Boxes can be searched in Vagrant Cloud. Most of their Vagrantfiles are available on GitHub. Searches can be made, among other things, by keyword to find a specific technology, and by provider.

Providers

A provider adds support for creating a specific type of machines. Vagrant comes with several providers, for example:

- `VirtualBox` allows one to create virtual machines with VirtualBox.
- `Microsoft-Hyper-V` allows one to create virtual machines with Microsoft Hyper-V.
- Docker allows one to create Docker containers. On non-Linux systems, Vagrant will create a VM to run Docker.

Alternative providers are maintained by third parties or sold by HashiCorp. They allow one to create different types of machines, for example using VMWare.

Some examples of useful providers, recognized by the community:

- Vagrant AWS Provider.
- Vagrant Google Compute Engine (GCE) Provider.
- Vagrant Azure Provider.
- OpenVZ.
- vagrant-lxc.

If you need to create machines with different technologies, or deploy them to unsupported cloud platforms, you can develop a custom provider in Ruby language. To find out how, see Plugin Development: Providers in Vagrant documentation. The Vagrant AWS Provider was initially written as an example provider.

Provisioners

A provisioner is a technology used to deploy software to the newly created machines.

The simplest provisioner is `shell`, which runs a shell file inside the Vagrant machine. `powershell` is also available.

Other providers use automation software to provision the machine. There are provisioners that allow one to use Ansible, Puppet, Chef or Salt. Where relevant, there are different provisioners allowing the use of these technologies in a distributed way (for example, using Puppet apply) or in a centralized way (for example, using a Puppet server).

It is interesting to note that there is both a Docker provider and a Docker provisioner. This means that a Vagrant machine can be a Docker container, thanks to the `docker` provisioner. Or it could be any virtualisation technology with Docker running in it, thanks to the `docker` provisioner. In this case, Docker pulls images and starts containers to run the software that should be running in the Vagrant machine.

If you need to use an unsupported provisioning method, you can develop a custom provisioner in Ruby language. See Plugin Development: Provisioners in Vagrant documentation.

Plugins

It is possible to install a plugin with this command:

```
vagrant plugin install <plugin_name>
```

A Vagrantfile can require that a plugin is installed in this way:

```
require 'plugin_name'
```

A plugin can be a Vagrant plugin or a Ruby gem installable from rubygems.org. It is possible to install a plugin that only exists locally by specifying its path.

Changes in Vagrant 3.0

HashiCorp published an article that describes its plans for Vagrant 3.0.

Vagrant will switch to a client-server architecture. Most of the logic will be stored in the server, while the development machines will run a thin client that communicates with the server. It will be possible to store the configuration in a central database.

Another notable change is that Vagrant is switching from Ruby to Go. For some time, it will still be possible to use Vagrantfiles and plugins written in Ruby. However, in the future Vagrantfiles and plugins should be written in one of the languages that support gRPC (not necessarily Go). Vagrantfiles can also be written in HCL, HashiCorp Configuration Language.

Vagrant Commands

This is a list of the most common Vagrant commands. For a complete list, see Command-Line Interface in Vagrant documentation.

To list the available machines:

```
vagrant box list
```

To start a machine from a box:

```
cd /box/directory
vagrant up
```

To connect to a machine:

```
vagrant ssh
```

To see all machines status and their id:

```
vagrant global-status
```

To destroy a machine:

```
vagrant destroy <id>
```

2.1.2.14.5.2 Creating a Vagrantfile

In this page we discuss how to create a Vagrantfile, which you can use to create new boxes or machines. This content is specifically written to address the needs of MariaDB users.

Contents

A Basic Vagrantfile

A Vagrantfile is a Ruby file that instructs Vagrant to create, depending on how it is executed, new Vagrant machines or boxes. You can see a box as a compiled Vagrantfile. It describes a type of Vagrant machines. From a box, we can create new Vagrant machines. However, while a box is easy to distribute to a team or to a wider public, a Vagrantfile can also directly create one or more Vagrant machines, without generating any box.

Here is a simple Vagrantfile example:

```
Vagrant.configure("2") do |config|
  config.vm.box = "hashicorp/bionic64"
  config.vm.provider "virtualbox"
  config.vm.provision :shell, path: "bootstrap.sh"
end
```

`Vagrant.configure("2")` returns the Vagrant configuration object for the new box. In the block, we'll use the `config` alias to refer this object. We are going to use version 2 of Vagrant API.

`vm.box` is the base box that we are going to use. It is Ubuntu BionicBeaver (18.04 LTS), 64-bit version, provided by HashiCorp. The schema for box names is simple: the maintainer account in Vagrant Cloud followed by the box name.

We use `vm.provision` to specify the name of the file that is going to be executed at the machine creation, to provision the machine. `bootstrap.sh` is the conventional name used in most cases.

To create new Vagrant machines from the Vagrantfile, move to the directory that contains the Vagrant project and run:

```
vagrant up
```

To compile the Vagrantfile into a box:

```
vagrant package
```

These operations can take time. To preventively check if the Vagrantfile contains syntax errors or certain types of bugs:

```
vagrant validate
```

Providers

A provider allows Vagrant to create a Vagrant machine using a certain technology. Different providers may enable a virtual machine manager (VirtualBox, VMWare, Hyper-V...), a container manager (Docker), or remote cloud hosts (AWS, Google Compute Engine...).

Some providers are developed by third parties. app.vagrant.com supports search for boxes that support the most important third parties providers. To find out how to develop a new provider, see Plugin Development: Providers.

Provider options can be specified. Options affect the type of Vagrant machine that is created, like the number of virtual CPUs. Different providers support different options.

It is possible to specify multiple providers. In this case, Vagrant will try to use them in the order they appear in the Vagrantfile. It will try the first provider; if it is not available it will try the second; and so on.

Here is an example of providers usage:

```
Vagrant.configure("2") do |config|
    config.vm.box = "hashicorp/bionic64"
    config.vm.provider "virtualbox" do |vb|
        vb.customize ["modifyvm", :id, "--memory", 1024 * 4]
    end
    config.vm.provider "vmware_fusion"
end
```

In this example, we try to use VirtualBox to create a virtual machine. We specify that this machine must have 4G of RAM (1024M * 4). If VirtualBox is not available, Vagrant will try to use VMWare.

This mechanism is useful for at least a couple of reasons:

- Different users may use different systems, and maybe they don't have the same virtualization technologies installed.
- We can gradually move from one provider to another. For a period of time, some users will have the new virtualization technology installed, and they will use it; other users will only have the old technology installed, but they will still be able to create machines with Vagrant.

Provisioners

We can use different methods for provisioning. The simplest provisioner is `shell`, that allows one to run a Bash file to provision a machine. Other provisioners allow setting up the machines using automation software, including Ansible, Puppet, Chef and Salt.

To find out how to develop a new provisioner, see Plugin Development: Provisioners.

The `shell` Provisioner

In the example above, the shell provisioner runs boostrap.sh inside the Vagrant machine to provision it. A simple bootstrap.sh may look like the following:

```
#!/bin/bash

apt-get update
apt-get install -y
```

To find out the steps to install MariaDB on your system of choice, see the Getting, Installing, and Upgrading MariaDB section.

You may also want to restore a database backup in the new Vagrant machine. In this way, you can have the database needed by the application you are developing. To find out how to do it, see Backup and Restore Overview. The most flexible type of backup (meaning that it works between different MariaDB versions, and in some cases even between MariaDB and different DBMSs) is a dump.

On Linux machines, the `shell` provisioner uses the default shell. On Windows machines, it uses PowerShell.

Uploading Files

If we use the `shell` provisioner, we need a way to upload files to the new machine when it is created. We could use the

`file` provisioner, but it works by connecting the machine via ssh, and the default user doesn't have permissions for any directory except for the synced folders. We could change the target directory owner, or we could add the default user to a group with the necessary privileges, but these are not considered good practices.

Instead, we can just put the file we need to upload somewhere in the synced folder, and then copy it with a shell command:

```
cp ./files/my.cnf /etc/mysql/conf.d/
```

Provisioning Vagrant with Ansible

Here is an example of how to provision a Vagrant machine or box by running Ansible:

```
Vagrant.configure("2") do |config|
  ...
  config.vm.provision "ansible" do |ansible|
    ansible.playbook = "vagrant.yml"
  end
end
```

With the Ansible provisioner, Ansible runs in the host system and applies a playbook in the guest system. In this example, it runs a playbook called `vagrant.yml`. The Ansible Local provisioner runs the playbook in the vagrant machine.

For more information, see Using Vagrant and Ansible in the Ansible documentation. For an introduction to Ansible for MariaDB users, see Ansible and MariaDB.

Provisioning Vagrant with Puppet

To provision a Vagrant machine or box by running Puppet:

```
Vagrant.configure("2") do |config|
  ...
  config.vm.provision "puppet" do |puppet|
    puppet.manifests_path = "manifests"
    puppet.manifest_file = "default.pp"
  end
end
```

In this example, Puppet Apply runs in the host system and no Puppet Server is needed. Puppet expects to find a `manifests` directory in the project directory. It expects it to contain `default.pp`, which will be used as an entry point. Note that `puppet.manifests_path` and `puppet.manifest_file` are set to their default values.

Puppet needs to be installed in the guest machine.

To use a Puppet server, the `puppet_server` provisioner can be used:

```
Vagrant.configure("2") do |config|
  ...
  config.vm.provision "puppet_server" do |puppet|
    puppet.puppet_server = "puppet.example.com"
  end
end
```

See the Puppet Apply provisioner and the Puppet Agent Provisioner.

For an introduction to Puppet for MariaDB users, see Puppet and MariaDB.

Sharing Files Between the Host and a Guest System

To restore a backup into MariaDB, in most cases we need to be able to copy it from the host system to the box. We may also want to occasionally copy MariaDB logs from the box to the host system, to be able to investigate problems.

The project directory (the one that contains the Vagrantfile) by default is shared with the virtual machine and mapped to the `/vagrant` directory (the synced folder). It is a good practice to put there all files that should be shared with the box when it is started. Those files should normally be versioned.

The synced folder can be changed. In the above example, we could simply add one line:

```
config.vm.synced_folder "/host/path", "/guest/path"
```

The synced folder can also be disabled:

```
config.vm.synced_folder '.', '/vagrant', disabled: true
```

Note that multiple Vagrant machines may have synced folders that point to the same directory on the host system. This can be useful in some cases, if you prefer to test some functionalities quickly, rather that replicating production environment as faithfully as possible. For example, to test if you're able to take a backup from one machine and restore it to another, you can store the backup in a common directory.

Network Communications

It is often desirable for a machine to be able to communicate with "the outside". This can be done in several ways:

- Private networks;
- Public networks;
- Exposing ports to the host.

Remembers that Vagrant doesn't create machines, but it asks a provisioner to create machines. Some provisioners support all of these communication methods, others may support some of them, or even none of them. When you create a Vagrantfile that starts machines using one of these features, it is implicit that this can only happen if the provisioner you are using supports the features you need. Check your provisioner documentation to find out which features it supports.

The default provisioner, VirtualBox, supports all these communication methods, including multiple networks.

Private Networks

A private network is a networks that can only be accesses by machines that run on the same host. Usually this also means that the machines must run on the same provisioner (for example, they all must be VirtualBox virtual machines).

Some provisioners support multiple private networks. This means that every network has a different name and can be accessed by different machines.

The following line shows how to create or join a private network called "example", where this machine's IP is assigned by the provisioner via DHCP:

```
config.vm.network 'private_network', name: 'example', type: 'dhcp'
```

While this is very convenient to avoid IP conflicts, sometimes you prefer to assign some IP's manually, in this way:

```
config.vm.network 'private_network', name: 'example', ip: '111.222.111.222'
```

Public Networks

As explained above, public networks are networks that can be accessed by machines that don't run on the same host with the same provider.

To let a machine join a public network:

```
# use provisioner DHCP:
config.vm.network "public_network", use_dhcp_assigned_default_route: true

# assign ip manually:
config.vm.network "public_network", ip: "111.222.111.222"
```

To improve security, you may want to configure a gateway:

```
config.vm.provision "shell", run: "always", inline: "route add default gw 111.222.111.222"
```

Exposing Ports

Vagrant allows us to map a TCP or UDP port in a guest system to a TCP or UDP port in the host system. For example, you can map a virtual machine port 3306 to the host port 12345. Then you can connect MariaDB in this way:

```
mariadb -hlocalhost -P12345 -u<user> -p<password>
```

You are not required to map a port to a port with a different number. In the above example, if the port 3306 in your host is

not in use, you are free to map the guest port 3306 to the host port 3306.

There are a couple of caveats:

- You can't map a single host port to multiple guest ports. If you want to expose the port 3306 from multiple Vagrant machines, you'll have to map them to different host ports. When running many machines this can be hard to maintain.
- Ports with numbers below 1024 are privileged ports. Mapping privileged ports requires root privileges.

To expose a port:

```
config.vm.network 'forwarded_port', guest: 3306, host: 3306
```

Use Cases

Suppose you run MariaDB and an application server in two separate Vagrant machines. It's usually best to let them communicate via a private network, because this greatly increases your security. The application server will still need to expose ports to the host, so the application can be tested with a web browser.

Suppose you have multiple environments of the same type, like the one described above. They run different applications that don't communicate with each other. In this case, if your provisioner supports this, you will run multiple private networks. You will need to expose the applications servers ports, mapping them to different host ports.

You may even want to implement different private networks to create an environment that reflects production complexity. Maybe in production you have a cluster of three MariaDB servers, and the application servers communicate with them via a proxy layer (ProxySQL, HAProxy, or MaxScale). So the applications can communicate with the proxies, but have no way to reach MariaDB directly. So there is a private network called "database" that can be accessed by the MariaDB servers and the proxy servers, and another private network called "application" that can be accessed by the proxy servers and the application servers. This requires that your provisioner supports multiple private networks.

Using public networks instead of private one will allow VMs that run on different hosts to be part of your topology. In general this is considered as an insecure practice, so you should probably ask yourself if you really need to do this.

2.1.2.14.5.3 Vagrant Security Concerns

Databases typically contain information to which access should be restricted. For this reason, it's worth discussing some security concerns that Vagrant users should be aware of.

Contents

Access to the Vagrant Machine

By default, Vagrant machines are only accessible from the localhost. SSH access uses randomly generated key pairs, and therefore it is secure.

The password for `root` and `vagrant` is "vagrant" by default. Consider changing it.

Synced Folders

By default, the project folder in the host system is shared with the machine, which sees it as `/vagrant`. This means that whoever has access to the project folder also has read and write access to the synced folder. If this is a problem, make sure to properly restrict the access to the synced folder.

If we need to exchange files between the host system and the Vagrant machine, it is not advisable to disable the synced folder. This is because the only alternative is to use the `file` provider, which works by copying files to the machine via ssh. The problem is that the default ssh user does not have permissions to write to any directory by default, and changing this would be less secure than using a synced folder.

When a machine is provisioned, it should read the needed files from the synced folder or copy them to other places. Files in the synced folder should not be accessed by the Vagrant machine during its normal activities. For example, it is fine to load a dump from the synced folder during provisioning; and it is fine to copy configuration files from the synced folder to directories in `/etc` during provisioning. But it is a bad practice to let MariaDB use table files located in the synced folder.

Reporting Security Bugs

Note that security bugs are not reported as normal bugs. Information about security bugs are not public. See Security at HashiCorp for details.

2.1.2.14.5.4 Running MariaDB ColumnStore containers on Linux, Windows and MacOS

Contents

Introduction

The ColumnStore container allows for a simple and lightweight setup of a MariaDB ColumnStore single server instance for evaluation purposes. The configuration is designed for simplified developer / evaluation setup rather than production use. It allows to evaluate ColumnStore on a Windows or MacOS system, setting up a Linux system in a container. The image uses a base OS of RockyLinux.

Windows Linux Subsystem

If you have Windows 10 Creators update installed, then you can install the Ubuntu installation into the Bash console. Please follow the Ubuntu instructions in getting started. If you have recently upgraded and had Bash installed previously, ensure you uninstall and reinstall Bash first to have a clean Ubuntu installation. Note that ColumnStore will be terminated should you terminate the Bash console.

MariaDB Containers

MariaDB Containers manages lightweight containers that allows for creation of lightweight and reproducible containers with a dedicated function. On Windows and MacOS systems, Docker Engine transparently runs on a Linux virtual machine.

Since MariaDB ColumnStore relies on a Syslog daemon, the container must start both ColumnStore and rsyslogd and the runit utility is used to achieve this.

A single node image can be found at MariaDB on Docker Hub.

```
docker run -d  --name mcs mariadb/columnstore
docker exec -it mcs bash
```

A ColumnStore cluster can be brought up using a compose file provided in the ColumnStore github repository:

```
git clone https://github.com/mariadb-corporation/mariadb-columnstore-docker.git
cd mariadb-columnstore-docker/columnstore
docker-compose up -d
```

For more information about how to manage containers, see Installing and Using MariaDB via Docker.

To test an application that uses ColumnStore, it is desirable to setup several containers that will communicate with each other. To do this, we can use Docker Compose. See Setting Up a LAMP Stack with Docker Compose for more information.

2.1.2.14.6 MariaDB Containers

Containers are an OCI standard format for software images and their specified time all bundled up into a single distributable time. They can be used for production, development or testing.

Docker Inc. run a Docker Official Images program to provide users with an essential base implementation of MariaDB in a container and to exemplify best practices of a container.

The containers are available on Docker Hub as **docker.io/library/mariadb** though many container runtime implementation will fill in the **docker.io/library** where the host/path isn't specified.

The containers are in a Open Container Initiative format that allows the containers to be interoperable with a number of container runtime implementations. Docker, or more fully Docker Engine, is just one of the many available runtimes.

Many people use MariaDB Docker Official Image containers in CI systems like GitHub Actions, though its possible to use these in production environments like kubernetes.

The MariaDB Server container images are available with a number of tags:

- A full version, like 10.11.5
- A major version like 10.11
- The most recent stable GA version - **latest**
- The most recent stable LTS version - **lts**

Versions that aren't stable will be suffixed with **-rc**, or **-alpha** to clearly show their release status, and enables Renovatebot and other that follow semantic versioning to follow updates.

For a consistent application between testing an production environment using the SHA hash of the image is recommended like **docker.io/library/mariadb@sha256:29fe5062baf36bae8ec68f21a3dce4f0372dadc185e687624f1252fc49d91c67**. There is a list of mapping and history of tags to SHA hash on the Docker Library repository.

2.1.2.14.6.1 Benefits of Managing MariaDB Containers with Orchestration Software

In this page we'll discuss why automating containers with software like Ansible or Puppet may be desirable in some cases. To talk about this, we'll first need to discuss why containers are defined *ephemeral*, and how this applies to containerized database servers (particularly MariaDB).

During the discussion, we should keep in mind that Docker Engine, CRI-I, containerd, Mirantis Container Runtime, Podman and other OCI container runtimes can be used to setup production and/or development environments. These use cases are very different from a database perspective: a production database may be big, and typically contains data that we don't want to lose. Development environments usually contain small sample data that can be rebuilt relatively quickly. This page focuses on the latter case.

Container Ephemeral Nature

Images are an OCI specified format that can be compiled from Dockerfiles as one of the ways. Containers are the OCI runtime specified way of creating a runtime version of an images. Normally, a container is not modified from the moment it is created. In other words, containers are usually designed to be **ephemeral**, meaning that they can be destroyed and replaced with new containers at any time. Provided that there is proper redundancy (for example, there are several web servers running the same services) destroying one container and starting a new one of the same type won't cause any damage.

We will discuss a bit later how this applies to MariaDB, and more generally to database servers.

When something should change, for example some software version or configuration, normally Dockerfiles are updated and containers are recreated from the latest image versions. For this reason, containers shouldn't contain anything that shouldn't be lost, and recreating them should be an extremely cheap operation. **Docker Compose** or the **Swarm mode** are used to declare which containers form a certain environment, and how they communicate with each other.

On the contrary, Ansible and Puppet are mainly built to manage the configuration of existing servers. It doesn't recreate servers, it changes their configuration. So Docker and Ansible have very different approaches. For this reason, Ansible and Puppet are not frequently used to deploy containers to production. However, using them together can bring some benefits, especially for development environments.

More on this later in the page. First, we need to understand how these concepts apply to database servers.

Stateful Technologies

Using ephemeral containers works very well for *stateless* technologies, like web servers and proxies. These technologies virtually only need binaries, configuration and small amounts of data (web pages). If some data need to be restored after a container creation, it will be a fast operation.

In the case of a database, the problem is that data can be large and need to be written somewhere. We don't want all databases to disappear when we destroy a container. Even if we had an up-to-date backup, restoring it would take time.

However, OCI Containers has features called **volumes**. A volume is a directory in the host system mapped to a directory in one or more containers. Volumes are not destroyed when containers are destroyed. They can be used to share data between any number of containers and the host system. Therefore, they are also a good way to persist data.

Suppose a MariaDB container called `mariadb-main-01` uses a volume that is mapped to `/var/docker/volumes/mariadb-main`. At some point we want to use a more recent MariaDB version. As explained earlier, the container way to do this is to destroy the container and create a new one that uses a more recent version of the MariaDB image.

So, we will destroy `mariadb-main-01`. The volume is still there. Then we create a new container with the same name, but based on a newer image. We make sure to link the volume to the new container too, so it will be able to use `/var/docker/volumes/mariadb-main` again. At this point we may want to run mariadb-upgrade, but apart from that, everything should *just work*.

The container runtime implementations also provide the opportunity to create a volume with an explicit name and this is also persistent. The actual location on the filesystem is managed by the runtime.

The above described steps are simple, but running them manually is time consuming and error-prone. Automating them with some automation software like Ansible or Puppet is often desirable.

Ways to Deploy Containers

Containers can be deployed in the following ways:

- Manually. See Installing and Using MariaDB via Docker. This is not recommended for production, or for complex environments. However, it can easily be done for the simplest cases. If we want to make changes to our custom images, we'll need to modify the Dockerfiles, destroy the containers and recreate them.
- With Docker Compose. See Setting Up a LAMP Stack with Docker Compose for a simple example. When we modify a Dockerfile, we'll need to destroy the containers and recreate them, which is usually as simple as running `docker-compose down` followed by `docker-compose-up`. After changing `docker-cmpose.yml` (maybe to add a container or a network) we'll simply need to run `docker-compose-up` again, because it is idempotent.
- Using Ansible, Puppet or other automation software, as mentioned before. We can use Ansible or Puppet to create the containers, and run them again every time we want to apply some change to the containers. This means that the containers are potentially created once and modified any number of times.

In all these cases, it is entirely possible to add Vagrant to the picture. Vagrant is a way to deploy or provision several hosts, including virtual machines (the most common case), and containers. It is agnostic in regarding the underlying technology, so it can deploy to a virtual machine, a container, or even a remote server in the same way. Containers can work with Vagrant in two ways:

- As a provisioner. In this case Vagrant will most commonly deploy a virtual machine, and will use Docker to setup the applications that need to run in it, as containers. This guarantees a higher level of isolation, compared to running the containers in the local host. Especially if you have different environments to deploy locally, because you can have them on different virtual machines.
- As a provider. Vagrant will deploy one or more containers locally. Once each container is up, Vagrant can optionally use a provisioner on it, to make sure that the container runs the proper software with proper configuration. In this case, Ansible, Puppet or other automation software can be used as a provisioner. But again, this is optional: it is possible to make changes to the Dockerfiles and recreate the containers every time.

Benefits of Managing Containers with Automation Software

Containers can be entirely managed with Docker Compose or the Swarm mode. This is often a good idea.

However, choosing to use automation software like Ansible or Puppet has some benefits too. Benefits include:

- Containers allow working without modifying the host system, and their creation is very fast. Much faster than virtual machines. This makes containers desirable for development environments.
- As explained, making all containers ephemeral and using volumes to store important data is possible. But this means adding some complexity to adapt an ephemeral philosophy to technologies that are not ephemeral by nature (databases). Also, many database professionals don't like this approach. Using automation software allows easily triggering upgrades and configuration changes in the containers, treating them as non-ephemeral systems.
- Sometimes containers are only used in development environments. If production databases are managed via Ansible, Puppet, or other automation software, this could lead to some code duplication. Dealing with configuration changes using the same procedures will reduce the cost of maintenance.
- While recreating containers is fast, being able to apply small changes with Ansible or Puppet can be more convenient in some cases: particularly if we write files into the container itself, or if recreating a container bootstrap involves some lengthy procedure.
- Trying to do something non-standard with Dockerfiles can be tricky. For example, running two processes in a

container is possible but can be problematic, as containers are designed to run single main process per container. However there are situations when this is desirable. For example PMM containers run several different processes. Launching additional processes with Ansible or Puppet may be easier than doing it with a Dockerfile.

With all this in mind, let's see some examples of cases when managing containers with Ansible, Puppet or other automation software is preferable, rather than destroying containers every time we want to make a change:

- We use Ansible or Puppet in production, and we try to keep development environments as similar as possible to production. By using Ansible/Puppet in development too, we can reuse part of the code.
- We make changes to the containers often, and recreating containers is not as fast as it should be (for example because a MariaDB dump needs to be restored).
- Creating a container implies some complex logic that does not easily fit a Dockerfile or Docker Compose (including, but not limited to, running multiple processes per container).

That said, every case is different. There are environments where these advantages do not apply, or bring a very small benefit. In those cases, the cost of adding some automation with Ansible, Puppet or similar software is probably not justified.

How to Deploy to Container from Orchestration Software

Suppose you want to manage containers configuration with Ansible.

At a first glance, the simplest way is to run Ansible in the host system. It will need to connect to the containers via SSH, so they need to expose the 22 port. But we have multiple containers, so we'll need to map the 22 port of each container to a different port in the host. This is hard to maintain and potentially insecure: in production you want to avoid exposing any container port to the host.

A better solution is to run Ansible itself in a container. The playbooks will be in a container volume, so we can access them from the host system to manage them more easily. The Ansible container will communicate with other containers using a container network, using the standard 22 port (or another port of your choice) for all containers.

2.1.2.14.6.2 Installing and Using MariaDB via Docker

Contents

Sometimes we want to install a specific version of MariaDB, MariaDB ColumnStore, or MaxScale on a certain system, but no packages are available. Or maybe, we simply want to isolate MariaDB from the rest of the system, to be sure that we won't cause any damage.

A virtual machine would certainly serve the scope. However, this means installing a system on the top of another system. It requires a lot of resources.

In many cases, the best solution is using containers. Docker is a framework that runs containers. A container is meant to run a specific daemon, and the software that is needed for that daemon to properly work. Docker does not virtualize a whole system; a container only includes the packages that are not included in the underlying system.

Docker requires a very small amount of resources. It can run on a virtualized system. It is used both in development and in production environments. Docker is an open source project, released under the Apache License, version 2.

Note that, while your package repositories could have a package called `docker`, it is probably not the Docker we are talking about. The Docker package could be called `docker.io` or `docker-engine`.

For information about installing Docker, see Get Docker in Docker documentation.

Installing Docker on Your System with the Universal Installation Script

The script below will install the Docker repositories, required kernel modules and packages on the most common Linux distributions:

```
curl -sSL https://get.docker.com/ | sh
```

Starting dockerd

On some systems you may have to start the `dockerd daemon` yourself:

```
sudo systemctl start docker
sudo gpasswd -a "${USER}" docker
```

If you don't have `dockerd` running, you will get the following error for most `docker` commands: installing-and-using-mariadb-via-docker Cannot connect to the Docker daemon at unix:*/var/run/docker.sock. Is the docker daemon running? <</code>>*

Using MariaDB Images

The easiest way to use MariaDB on Docker is choosing a MariaDB image and creating a container.

Downloading an Image

You can download a MariaDB image for Docker from the Offical Docker MariaDB, or choose another image that better suits your needs. You can search Docker Hub (the official set of repositories) for an image with this command:

```
 docker search mariadb
```

Once you have found an image that you want to use, you can download it via Docker. Some layers including necessary dependencies will be downloaded too. Note that, once a layer is downloaded for a certain image, Docker will not need to download it again for another image.

For example, if you want to install the default MariaDB image, you can type:

```
docker pull mariadb:10.4
```

This will install the 10.4 version. Versions 10.2, 10.3, 10.5 are also valid choices.

You will see a list of necessary layers. For each layer, Docker will say if it is already present, or its download progress.

To get a list of installed images:

```
docker images
```

Creating a Container

An image is not a running process; it is just the software needed to be launched. To run it, we must create a container first. The command needed to create a container can usually be found in the image documentation. For example, to create a container for the official MariaDB image:

```
docker run --name mariadbtest -e MYSQL_ROOT_PASSWORD=mypass -p 3306:3306 -d
docker.io/library/mariadb:10.3
```

`mariadbtest` is the name we want to assign the container. If we don't specify a name, an id will be automatically generated.

10.2 and 10.5 are also valid target versions:

```
docker run --name mariadbtest -e MYSQL_ROOT_PASSWORD=mypass -p 3306:3306 -d
docker.io/library/mariadb:10.2
```

```
docker run --name mariadbtest -e MYSQL_ROOT_PASSWORD=mypass -p 3306:3306  -d
docker.io/library/mariadb:10.5
```

Optionally, after the image name, we can specify some options for mysqld. For example:

```
docker run --name mariadbtest -e MYSQL_ROOT_PASSWORD=mypass -p 3306:3306 -d mariadb:10.3 --log-
bin --binlog-format=MIXED
```

Docker will respond with the container's id. But, just to be sure that the container has been created and is running, we can get a list of running containers in this way:

```
docker ps
```

We should get an output similar to this one:

```
CONTAINER ID        IMAGE                     COMMAND                CREATED
STATUS              PORTS               NAMES
819b786a8b48        mariadb                   "/docker-entrypoint.   4 minutes ago       Up 4
minutes        3306/tcp            mariadbtest
```

Running and Stopping the Container

Docker allows us to restart a container with a single command:

```
docker restart mariadbtest
```

The container can also be stopped like this:

```
docker stop mariadbtest
```

The container will not be destroyed by this command. The data will still live inside the container, even if MariaDB is not running. To restart the container and see our data, we can issue:

```
docker start mariadbtest
```

With `docker stop`, the container will be gracefully terminated: a `SIGTERM` signal will be sent to the `mysqld` process, and Docker will wait for the process to shutdown before returning the control to the shell. However, it is also possible to set a timeout, after which the process will be immediately killed with a `SIGKILL`. Or it is possible to immediately kill the process, with no timeout.

```
docker stop --time=30 mariadbtest
docker kill mariadbtest
```

In case we want to destroy a container, perhaps because the image does not suit our needs, we can stop it and then run:

```
docker rm mariadbtest
```

Note that the command above does not destroy the data volume that Docker has created for /var/lib/mysql. If you want to destroy the volume as well, use:

```
docker rm -v mariadbtest
```

Automatic Restart

When we start a container, we can use the `--restart` option to set an automatic restart policy. This is useful in production.

Allowed values are:

- `no` : No automatic restart.
- `on-failure` : The container restarts if it exits with a non-zero exit code.
- `unless-stopped` : Always restart the container, unless it was explicitly stopped as shown above.
- `always` : Similar to `unless-stopped`, but when Docker itself restarts, even containers that were explicitly stopped

will restart.

It is possible to change the restart policy of existing, possibly running containers:

```
docker update --restart always mariadb
# or, to change the restart policy of all containers:
docker update --restart always $(docker ps -q)
```

A use case for changing the restart policy of existing containers is performing maintenance in production. For example, before upgrading the Docker version, we may want to change all containers restart policy to `always`, so they will restart as soon as the new version is up and running. However, if some containers are stopped and not needed at the moment, we can change their restart policy to `unless-stopped`.

Pausing Containers

A container can also be frozen with the `pause` command. Docker will freeze the process using croups. MariaDB will not know that it is being frozen and, when we `unpause` it, MariaDB will resume its work as expected.

Both `pause` and `unpause` accept one or more container names. So, if we are running a cluster, we can freeze and resume all nodes simultaneously:

```
docker pause node1 node2 node3
docker unpause node1 node2 node3
```

Pausing a container is very useful when we need to temporarily free our system's resources. If the container is not crucial at this moment (for example, it is performing some batch work), we can free it to allow other programs to run faster.

Troubleshooting a Container

If the container doesn't start, or is not working properly, we can investigate with the following command:

```
docker logs mariadbtest
```

This command shows what the daemon sent to the stdout since the last attempt of starting - the text that we typically see when we invoke `mysqld` from the command line.

On some systems, commands such as `docker stop mariadbtest` and `docker restart mariadbtest` may fail with a permissions error. This can be caused by AppArmor, and even `sudo` won't allow you to execute the command. In this case, you will need to find out which profile is causing the problem and correct it, or disable it. **Disabling AppArmor altogether is not recommended, especially in production.**

To check which operations were prevented by AppArmor, see AppArmor Failures in AppArmor documentation.

To disable a profile, create a symlink with the profile name (in this example, `mysqld`) to `etc/apparmor.d/disable`, and then reload profiles:

```
ln -s /etc/apparmor.d/usr.sbin.mysqld /etc/apparmor.d/disable/
sudo apparmor_parser -R /etc/apparmor.d/usr.sbin.mysqld
```

For more information, see Policy Layout in AppArmor documentation.

After disabling the profile, you may need to run:

```
sudo service docker restart
docker system prune --all --volumes
```

Restarting the system will then allow Docker to operate normally.

Accessing the Container

To access the container via Bash, we can run this command:

```
docker exec -it mariadbtest bash
```

Now we can use normal Linux commands like *cd*, *ls*, etc. We will have root privileges. We can even install our favorite file editor, for example:

```
apt-get update
apt-get install vim
```

In some images, no repository is configured by default, so we may need to add them.

Note that if we run mariadb-admin shutdown or the SHUTDOWN command to stop the container, the container will be deactivated, and we will automatically exit to our system.

Connecting to MariaDB from Outside the Container

If we try to connect to the MariaDB server on `localhost`, the client will bypass networking and attempt to connect to the server using a socket file in the local filesystem. However, this doesn't work when MariaDB is running inside a container because the server's filesystem is isolated from the host. The client can't access the socket file which is inside the container, so it fails to connect.

Therefore connections to the MariaDB server must be made using TCP, even when the client is running on the same machine as the server container.

Find the IP address that has been assigned to the container:

```
docker inspect -f '{{range .NetworkSettings.Networks}}{{.IPAddress}}{{end}}' mariadbtest
```

You can now connect to the MariaDB server using a TCP connection to that IP address.

Forcing a TCP Connection

After enabling network connections in MariaDB as described above, we will be able to connect to the server from outside the container.

On the host, run the client and set the server address ("-h") to the container's IP address that you found in the previous step:

```
mysql -h 172.17.0.2 -u root -p
```

This simple form of the connection should work in most situations. Depending on your configuration, it may also be necessary to specify the port for the server or to force TCP mode:

```
mysql -h 172.17.0.2 -P 3306 --protocol=TCP -u root -p
```

Port Configuration for Clustered Containers and Replication

Multiple MariaDB servers running in separate Docker containers can connect to each other using TCP. This is useful for forming a Galera cluster or for replication.

When running a cluster or a replication setup via Docker, we will want the containers to use different ports. The fastest way to achieve this is mapping the containers ports to different port on our system. We can do this when creating the containers (`docker run` command), by using the `-p` option, several times if necessary. For example, for Galera nodes we will use a mapping similar to this one:

```
-p 4306:3306 -p 5567:5567 -p 5444:5444 -p 5568:5568
```

Installing MariaDB on Another Image

It is possible to download a Linux distribution image, and to install MariaDB on it. This is not much harder than installing MariaDB on a regular operating system (which is easy), but it is still the hardest option. Normally we will try existing images first. However, it is possible that no image is available for the exact version we want, or we want a custom installation, or perhaps we want to use a distribution for which no images are available. In these cases, we will install MariaDB in an operating system image.

Daemonizing the Operating System

First, we need the system image to run as a daemon. If we skip this step, MariaDB and all databases will be lost when the container stops.

To demonize an image, we need to give it a command that never ends. In the following example, we will create a Debian Jessie daemon that constantly pings the 8.8.8.8 special address:

```
docker run --name debian -p 3306:3306 -d debian /bin/sh -c "while true; do ping 8.8.8.8; done"
```

Installing MariaDB

At this point, we can enter the shell and issue commands. First we will need to update the repositories, or no packages will be available. We can also update the packages, in case some of them are newer than the image. Then, we will need to install a text editor; we will need it to edit configuration files. For example:

```
# start an interactive Bash session in the container
docker exec -ti debian bash
apt-get -y update
apt-get -y upgrade
apt-get -y install vim
```

Now we are ready to install MariaDB in the way we prefer.

2.1.2.14.6.3 Container Backup and Restoration

MariaDB databases in containers need backup and restore like their non-container equivalents.

Logicial Backups

Backup

mariadb-dump is in the Docker Official Image and can be used as follows:

```
$ docker exec some-%%REPO%% mariadb-dump --all-databases -uroot -p"$MARIADB_ROOT_PASSWORD"'
> /some/path/on/your/host/all-databases.sql
```

Restoring Data from Dump Files

For restoring data, you can use the `docker exec` command with the `-i` flag, similar to the following:

```
$ docker exec -i some-%%REPO%% sh -c 'exec mariadb -uroot -p"$MARIADB_ROOT_PASSWORD"'
< /some/path/on/your/host/all-databases.sql
```

Physical Backups

mariadb-backup is in the Docker Official Image.

Backup

MariaDB Backup can create a backup as follows:

To perform a backup using Mariabackup, a second container is started that shares the original container's data directory. An additional volume for the backup needs to be included in the second backup instance. Authentication against the MariaDB database instance is required to successfully complete the backup. In the example below, a `mysql@localhost` user is used with the MariaDB server's Unix socket shared with the backup container.

```
$ docker volume create some-%%REPO%%-socket
$ docker run --name some-%%REPO%% -v /my/own/datadir:/var/lib/mysql
-v some-%%REPO%%-socket:/var/run/mysqld -e MARIADB_MYSQL_LOCALHOST_USER=1
-e MARIADB_MYSQL_LOCALHOST_GRANTS="RELOAD, PROCESS, LOCK TABLES, BINLOG MONITOR"
-e MARIADB_ROOT_PASSWORD=my-secret-pw -d %%IMAGE%%:latest
```

Note: Privileges listed here are for 10.5+. For an exact list, see Mariabackup: Authentication and Privileges.

Mariabackup will run as the `mysql` user in the container, so the permissions on `/backup` will need to ensure that it can be written to by this user:

```
$ docker volume create some-%%REPO%%-backup
$ docker run --rm some-%%REPO%%-backup
-v some-%%REPO%%-backup:/backup %%IMAGE%%:latest chown mysql: /backup
```

Restore

These steps restore the backup made with Mariabackup.

At some point before doing the restore, the backup needs to be prepared. Perform the prepare like this:

```
$ docker run --user mysql --rm -v some-%%REPO%%-backup:/backup
%%IMAGE%%:latest mariabackup --prepare --target-dir=/backup
```

Now that the image is prepared, start the container with both the data and the backup volumes and restore the backup:

```
$ docker run --user mysql --rm -v /my/new/datadir:/var/lib/mysql
-v some-%%REPO%%-backup:/backup %%IMAGE%%:latest mariabackup --copy-back --target-dir=/backup
```

With `/my/new/datadir` containing the restored backup, start normally as this is an initialized data directory:

```
$ docker run --name some-%%REPO%% -v /my/new/datadir:/var/lib/mysql -d %%IMAGE%%:latest
```

For further information on Mariabackup, see Mariabackup Overview.

2.1.2.14.6.4 Container Security Concerns

When using containers in production, it is important to be aware of container security concerns.

Contents

Host System Security

Depending on the container runtime, containers may be running on the host system's kernel or a kernel shared with other containers. If this kernel has security bugs, those bugs are also present in the containers. Malicious containers may attempt to explain a kernel vulnerability to impact the confidentiality, integrity or availability of other containers.

In particular, Linux based containers have a container runtime that can use the following features:

- Namespaces, to isolate containers from each other and make sure that a container can't establish unauthorized connections to another container.
- Seccomp security profiles.
- Rootless operation in Docker, or Rootless Podman
- cgroups, to limit the resources (CPU, memory, IO) that each container can consume.

The administrators of a system should be particularly careful to upgrade the kernel whenever security bugs to these features are fixed.

It is important to note that when we upgrade the kernel, runC or Docker itself we cause downtime for all the containers running on the system.

Images Security

Containers are built from images. If security is a major concern, you should make sure that the images you use are secure.

If you want to be sure that you are pulling authentic images, you should only pull images signed with Docker Content Trust. Signing only ensure authenticity or origin, it doesn't dictate that entity is trustworthy.

Updated images should be used. An image usually downloads packages information at build time. If the image is not recently built, a newly created container will have old packages. Updating the packages on container creation and regularly re-updating them will ensure that the container uses packages with the most recent versions. Rebuilding an image often will reduce the time necessary to update the packages the first time.

Security bugs are usually important for a database server, so you don't want your version of MariaDB to contain known security bugs. But suppose you also have a bug in Docker, in runC, or in the kernel. A bug in a user-facing application may

allow an attacker to exploit a bug in those lower level technologies. So, after gaining access to the container, an attacker may gain access to the host system. This is why system administrators should keep both the host system and the software running in the containers updated.

2.1.2.14.6.5 Adding Plugins to the MariaDB Docker Official Image

MariaDB has many plugins. Most are not enabled by default, some are in the `mariadb` container, while others need to be installed from additional packages.

The following methods summarize Installing plugins in the MariaDB Docker Library Container (mariadb.org blog post) on this topic.

Which Plugins Does the Container Contain?

To see which plugins are available in the mariadb:

```
$ docker run --rm mariadb:latest ls -C /usr/lib/mysql/plugin
```

Enabling a Plugin Using Flags

Using the `--plugin-load-add` flag with the plugin name (can be repeated), the plugins will be loaded and ready when the container is started:

For example, to enable the `simple\_password\_check` plugin:

```
$ docker run --name some-%%REPO%% -e MARIADB_ROOT_PASSWORD=my-secret-pw --network=host -d mariadb
```

Enabling a Plugin in the Configuration Files

plugin-load-add` can be used as a configuration option to load plugins. The example below loads the FederatedX Storage Engine.

```
$ printf "[mariadb]\nplugin-load-add=ha_federatedx\n" > /my/custom/federatedx.conf
$ docker run --name some-mariadb -v /my/custom:/etc/mysql/conf.d -e MARIADB_ROOT_PASSWORD=my-secr
```

Install a Plugin Using SQL in /docker-entrypoint-initdb.d

INSTALL SONAME can be used to install a plugin as part of the database initialization.

Create the SQL file used in initialization:

```
$ echo 'INSTALL SONAME "disks";' > my_initdb/disks.sql
```

In this case, the `my\_initdb` is a `/docker-entrypoint-initdb.d` directory per "Initializing a fresh instance" section above.

Identifying Additional Plugins in Additional Packages

A number of plugins are in separate packages to reduce their installation size. The package names of MariaDB-created plugins can be determined using the following command:

```
$ docker run --rm mariadb:latest sh -c 'apt-get update -qq && apt-cache search mariadb-plugin'
```

Creating an Image With Plugins From Additional Packages

A new image needs to be created when using additional packages. The `mariadb` image can however be used as a base:

In the following, the CONNECT Storage Engine is installed:

```
FROM mariadb:latest
RUN apt-get update && \
    apt-get install mariadb-plugin-connect -y && \
    rm -rf /var/lib/apt/lists/*
```

Installing plugins from packages creates a configuration file in the directory `/etc/mysql/mariadb.conf.d/` that loads the plugin on startup.

2.1.2.14.6.6 Setting Up a LAMP Stack with Docker Compose

Docker Compose is a tool that allows one to declare which Docker containers should run, and which relationships should exist between them. It follows the **infrastructure as code** approach, just like most automation software and Docker itself.

For information about installing Docker Compose, see Install Docker Compose in Docker documentation.

Contents

The `docker-compose.yml` File

When using Docker Compose, the Docker infrastructure must be described in a YAML file called `docker-compose.yml`.

Let's see an example:

```
version: "3"

services:
  web:
    image: "apache:${PHP_VERSION}"
    restart: 'always'
    depends_on:
      - mariadb
    restart: 'always'
    ports:
      - '8080:80'
    links:
      - mariadb
  mariadb:
    image: "mariadb:${MARIADB_VERSION}"
    restart: 'always'
    volumes:
      - "/var/lib/mysql/data:${MARIADB_DATA_DIR}"
      - "/var/lib/mysql/logs:${MARIADB_LOG_DIR}"
      - /var/docker/mariadb/conf:/etc/mysql
    environment:
      MYSQL_ROOT_PASSWORD: "${MYSQL_ROOT_PASSWORD}"
      MYSQL_DATABASE: "${MYSQL_DATABASE}"
      MYSQL_USER: "${MYSQL_USER}"
      MYSQL_PASSWORD: "${MYSQL_PASSWORD}"
```

In the first line we declare that we are using version 3 of the Docker compose language.

Then we have the list of services, namely the `web` and the `mariadb` services.

Let's see the properties of the services:

- `port` maps the 8080 container port to the 80 host system port. This is very useful for a development environment, but not in production, because it allows us to connect our browser to the containerized web server. Normally there is no need to connect to MariaDB from the host system.
- `links` declares that this container must be able to connect `mariadb`. The hostname is the container name.
- `depends_on` declares that `mariadb` needs to start before `web`. This is because we cannot do anything with our application until MariaDB is ready to accept connections.
- `restart: always` declares that the containers must restart if they crash.
- `volumes` creates volumes for the container if it is set in a service definition, or a volume that can be used by any container if it is set globally, at the same level as `services`. Volumes are directories in the host system that can be accessed by any number of containers. This allows destroying a container without losing data.
- `environment` sets environment variables inside the container. This is important because in setting these variables we set the MariaDB root credentials for the container.

About Volumes

It is good practice to create volumes for:

- The data directory, so we don't lose data when a container is created or replaced, perhaps to upgrade MariaDB.
- The directory where we put all the logs, if it is not the datadir.
- The directory containing all configuration files (for development environments), so we can edit those files with the editor installed in the host system. Normally no editor is installed in containers. In production we don't need to do this, because we can copy files from a repository located in the host system to the containers.

Note that Docker Compose variables are just placeholders for values. Compose does not support assignment, conditionals or loops.

Using Variables

In the above example you can see several variables, like `${MARIADB_VERSION}`. Before executing the file, Docker Compose will replace this syntax with the `MARIADB_VERSION` variable.

Variables allow making Docker Compose files more re-usable: in this case, we can use any MariaDB image version without modifying the Docker Compose file.

The most common way to pass variables is to write them into a file. This has the benefit of allowing us to version the variable file along with the Docker Compose file. It uses the same syntax you would use in BASH:

```
PHP_VERSION=8.0
MARIADB_VERSION=10.5
...
```

For bigger setups, it could make sense to use different environment files for different services. To do so, we need to specify the file to use in the Compose file:

```
services:
  web:
    env_file:
      - web-variables.env
...
```

Docker Compose Commands

Docker Compose is operated using `docker-compose`. Here we'll see the most common commands. For more commands and for more information about the commands mentioned here, see the documentation.

Docker Compose assumes that the Composer file is located in the current directory and it's called `docker-compose.yml`. To use a different file, the `-f <filename>` parameter must be specified.

To pull the necessary images:

```
docker-compose pull
```

Containers described in the Compose file can be created in several ways.

To create them only if they do not exist:

```
docker-compose up --no-recreate
```

To create them if they do not exist and recreate them if their image or configuration have changed:

```
docker-compose up
```

To recreate containers in all cases:

```
docker-compose up --force-recreate
```

Normally `docker-compose up` starts the containers. To create them without starting them, add the `--no-start` option.

To restart containers without recreating them:

```
docker-compose restart
```

To kill a container by sending it a `SIGKILL`:

```
docker-compose kill <service>
```

To instantly remove a running container:

```
docker-compose rm -f <serice>
```

To tear down all containers created by the current Compose file:

```
docker-compose down
```

2.1.2.14.6.7 Creating a Custom Container Image

OCI containers, frequently and incorrectly called Docker containers, are created from OCI images. An image contains software that can be launched, including the underlying system. A container is an instance of that software.

When we want to automate MariaDB, creating an image with MariaDB and the desired configuration, we may want to create an image by ourselves, which fulfils our needs.

Contents

Images Architecture

One "source code" of an image is a Dockerfile. A Dockerfile is written in Docker specific language, and can be compiled into an image by the `docker` binary, using the `docker build` command. It can also be compiled by `buildah` using `buildah bud`.

Most images are based on another image. The base image is specified at the beginning of the Dockerfile, with the `FROM` directive. If the base image is not present in the local system, it is downloaded from the repository specified, or if not specified, from the default repository of the build program. This is often Docker Hub. For example, we can build a `mariadb-rocksdb:10.5` image starting from the `debian:13` image. In this way, we'll have all the software included in a standard Debian image, and we'll add MariaDB and its configuration upon that image.

All the following Dockerfile directives are compiled into a new Docker image, identified by an SHA256 string. Each of these images is based on the image compiled from the previous directive. A physical compiled image can serve as a base for any number of images. This mechanism saves a lot of disk space, download time and build time.

The following diagram shows the relationship between Dockerfiles, images and containers:

Dockerfile Syntax

Here's a simple Dockerfile example:

```
FROM ubuntu:20.04

RUN apt-get update
RUN apt-get install -y mariadb-server

EXPOSE 3306

LABEL version="1.0"
LABEL description="MariaDB Server"

HEALTHCHECK --start-period=5m \
  CMD mariadb -e 'SELECT @@datadir;' || exit 1

CMD ["mariadbd"]
```

This example is not very good for practical purposes, but it shows what a Dockerfile looks like.

First, we declare that the base image to use is `ubuntu:20.04`.

Then we run some commands to install MariaDB from the Ubuntu default repositories and stop the MariaDB service.

We define some metadata about the image with `LABEL`. Any label is valid.

We declare that the port 3306 (MariaDB default port) should be exposed. However, this has no effect if the port is not exposed at container creation.

We also define a healthcheck. This is a command that is run to check if the container is healthy. If the return code is 0 the healthcheck succeeds, if it's 1 it fails. In the MariaDB specific case, we want to check that it's running and able to answer a simple query. This is better than just checking that MariaDB process is running, because MariaDB could be running but unable to respond, for example because max_connections was reached or data si corrupted. We read a system variable, because we should not assume that any user-created table exists. We also specify `--start-period` to allow some time for MariaDB to start, keeping in mind that restarting it may take some time if some data is corrupted. Note that there can be only one healthcheck: if the command is specified multiple times, only the last occurrence will take effect.

Finally, we start the container command: mariadbd. This command is run when a container based on this image starts. When the process stops or crashes, the container will immediately stop.

Note that, in a container, we normally run mariadbd directly or in an entrypoint script `exec mariadbd`, rather than running mysqld_safe or running MariaDB as a service. Containers restart can be handled by the container service. See automatic restart.

See the documentation links below to learn the syntax allowed in a Dockerfile.

Using Variables

It is possible to use variables in a Dockerfile. This allows us, for example, to install different packages, install different versions of a package, or configure software differently depending on how variables are set, without modifying the Dockerfile itself.

To use a variable, we can do something like this:

```
FROM ubuntu:20.04

ARG MARIADB_CONFIG_FILE

...

ENTRYPOINT mariadbd --defaults-file=$MARIADB_CONFIG_FILE
```

Here `ARG` is used after the `FROM` directive, thus the variable cannot be used in `FROM`. It is also possible to declare a variable before `FROM`, so we can use a variable to select the base image to use or its tag, but in this case the variable cannot be used after the `FROM` directive, unless `ARG` is re-declared after the `FROM`. Here is an example:

```
ARG UBUNTU_VERSION
FROM ubuntu:$UBUNTU_VERSION

# Uncomment for the build error to be avoided
# ARG UBUNTU_VERSION

# But this will cause a build error:
RUN echo 'Ubuntu version: $UBUNTU_VERSION' > /var/build_log
```

We'll have to assign variables a value when we build the Dockerfile, in this way:

```
docker build --build-arg UBUNTU_VERSION=20.04 .
```

Note that Dockerfile variables are just placeholders for values. Dockerfiles do not support assignment, conditionals or loops.

Versioning and Deploying Images

Dockerfiles are normally versioned, as well as the files that are copied to the images.

Once an image is built, it can be pushed to a container registry. Whenever an image is needed on a host to start containers from it, it is pulled from the registry.

Container registries

A default container registry for OCI images is Docker Hub. It contains Docker Official Images maintained by the Docker Library team and the community. Any individual or organization can open an account and push images to Docker Hub. Most Docker images are open source: the Dockerfiles and the needed files to build the images are usually on GitHub.

It is also possible to setup a self-hosted registry. Images can be pushed to that registry and pulled from it, instead of using Docker Hub. If the registry is not publicly accessible, it can be used to store images used by the organization without making them publicly available.

But a self-hosted registry can also be useful for open source images: if an image is available on Docker Hub and also on a self-hosted registry, in case Docker Hub is down or not reachable, it will still be possible to pull images.

Choosing Image Names and Tags

The names of images developed by the community follow this schema:

```
repository/maintainer/technology
```

It doesn't matter if the maintainer is an individual or an organization. For images available on Docker Hub, the maintainer is the name of a Docker Hub account.

Official images maintained by the Docker Library maintainers have the implicit name of `library` filled in by the container fetching tool. For example, the official MariaDB image is called `mariadb` which is an alias for `docker.io/library/mariadb`.

All images have a tag, which identifies the version or the variant of an image. For example, all MariaDB versions available on Docker are used as image tags. MariaDB 10.11 is called `mariadb:10.11`.

By conversion, tags form a hierarchy. So for example, there is a `10.1.1` tag whose meaning will not change over time. `10.5` will always identify the latest stable version in the 10.5 branch. For some time it was `10.5.1`, then it became `10.5.2`, and so on.

When we pull an image without specifying a tag (ie, `docker pull mariadb`), we are implicitly requiring the image with the `latest` tag. This is even more mutable: at different periods of time, it pointed to the latest `10.0` version, to the latest `10.1` version, and so on.

In production, it is always better to know for sure which version we are installing. Therefore it is better to specify a tag whose meaning won't change over time, like `10.5.21`. To keep to a latest LTS version, the `lts` can be used.

Pushing and Pulling Images

To pull an image from Docker Hub or a self-hosted registry, we use the `docker pull` command. For example:

```
docker pull mariadb:10.5
```

This command downloads the specified image if it is not already present in the system, or if the local version is not up to date.

After modifying a Dockerfile, we can build an image in this way:

```
docker build .
```

This step can be automated by services like Docker Hub and GitHub. Check those service's documentation to find out how this feature works.

Once an image is created, it can be pushed to a registry. We can do it in this way:

```
docker push <image_name>:<tag>
```

Docker Content Trust

Docker has a feature called Docker Content Trust (DCT). It is a system used to digitally sign images, based on PEM keys. For environments where security is a major concern, it is important to sign images before pushing them. This can be done with both Docker Hub and self-hosted registries.

Good Practices and Caveats

As mentioned, a Dockerfile is built by creating a new image for each directive that follows `FROM`. This leads to some considerations.

- Sometimes it can be a good idea to run several shell commands in a single `RUN` directive to avoid creating images that are not useful.
- Modifying a directive means that all subsequent directives also need to be rebuilt. When possible, directives that are expected to change often should follow directives that will change seldom.
- Directives like `LABEL` or `EXPOSE` should be placed close to the end of Dockerfiles. In this way they will be rebuilt often, but this operation is cheap. On the other side, changing a label should not trigger a long rebuild process.
- Variables should be used to avoid Dockerfiles proliferation. But if a variable is used, changing its value should be tested. So, be sure not to use variables without a good reason.
- Writing logic into a Dockerfile is impossible or very hard. Call shell scripts instead, and write your logic into them. For example, in a shell script it is easy to perform a certain operation only if a variable is set to a certain value.
- If you need MariaDB containers with different configurations or different sets of plugins, use the method explained above. Do not create several Dockerfiles, with different tags, for each desired configuration or plugin set. This may lead to undesired code duplication and increased maintenance costs.

2.1.2.14.6.8 MariaDB Server Docker Official Image Environment Variables

Contents

When you start the image, you can adjust the initialization of the MariaDB Server instance by passing one or more environment variables on the docker run command line. Do note that all of the variables below, except `MARIADB_AUTO_UPGRADE`, will have now effect if you start the container with a data directory that already contains a database: any pre-existing database will always be left untouched on container startup.

From tag 10.2.38, 10.3.29, 10.4.19, 10.5.10 onwards, and all 10.6 and later tags, the MARIADB_* equivalent variables are provided. MARIADB_* variants will always be used in preference to MYSQL_* variants.

One of MARIADB_ROOT_PASSWORD_HASH, MARIADB_ROOT_PASSWORD, MARIADB_ALLOW_EMPTY_ROOT_PASSWORD, or MARIADB_RANDOM_ROOT_PASSWORD (or equivalents, including *_FILE), is required. The other environment variables are optional.

MARIADB_ROOT_PASSWORD_HASH / MARIADB_ROOT_PASSWORD / MYSQL_ROOT_PASSWORD

This specifies the password that will be set for the MariaDB root superuser account.

MARIADB_ALLOW_EMPTY_ROOT_PASSWORD / MYSQL_ALLOW_EMPTY_PASSWORD

Set to a non-empty value, like `1`, to allow the container to be started with a blank password for the root user. NOTE: Setting this variable to yes is not recommended unless you really know what you are doing, since this will leave your MariaDB instance completely unprotected, allowing anyone to gain complete superuser access.

MARIADB_RANDOM_ROOT_PASSWORD / MYSQL_RANDOM_ROOT_PASSWORD

Set to a non-empty value, like yes, to generate a random initial password for the root user. The generated root password will be printed to stdout (GENERATED ROOT PASSWORD: .....).

MARIADB_ROOT_HOST / MYSQL_ROOT_HOST

This is the hostname part of the root user created. By default this is %, however it can be set to any default MariaDB allowed hostname component. Setting this to localhost will prevent any root user being accessible except via the unix socket.

MARIADB_DATABASE / MYSQL_DATABASE

This variable allows you to specify the name of a database to be created on image startup.

MARIADB_USER / MYSQL_USER, MARIADB_PASSWORD_HASH / MARIADB_PASSWORD / MYSQL_PASSWORD

Both user and password variables, along with a database, are required for a user to be created. This user will be granted all access (corresponding to GRANT ALL) to the MARIADB_DATABASE database.

Do not use this mechanism to create the root superuser, that user gets created by default with the password specified by the MARIADB_ROOT_PASSWORD / MYSQL_ROOT_PASSWORD variable.

MARIADB_MYSQL_LOCALHOST_USER / MARIADB_MYSQL_LOCALHOST_GRANTS

Set MARIADB_MYSQL_LOCALHOST_USER to a non-empty value to create the mysql@locahost database user. This user is especially useful for a variety of health checks and backup scripts.

The mysql@localhost user gets `USAGE` privileges by default. If more access is required, additional global privileges in the form of a comma separated list can be provided. If you are sharing a volume containing MariaDB's unix socket (/var/run/mysqld by default), privileges beyond `USAGE` can result in confidentiality, integrity and availability risks, so use a minimal set. Its also possible to use for Mariadb-backup. The healthcheck.sh script also documents the required privileges for each health check test.

MARIADB_HEALTHCHECK_GRANTS

Set MARIADB_HEALTHCHECK_GRANTS to the grants required to be given to the `healtcheck@localhost`, `healtcheck@127.0.0.1`, `healtcheck@::1`, users. When not specified the default grant is `USAGE`.

The main value used here will be `REPLICA MONITOR for the healthcheck --replication test.`

MARIADB_INITDB_SKIP_TZINFO / MYSQL_INITDB_SKIP_TZINFO

By default, the entrypoint script automatically loads the timezone data needed for the CONVERT_TZ() function. If it is not needed, any non-empty value disables timezone loading.

MARIADB_AUTO_UPGRADE / MARIADB_DISABLE_UPGRADE_BACKUP

Set MARIADB_AUTO_UPGRADE to a non-empty value to have the entrypoint check whether mariadb-upgrade needs to run, and if so, run the upgrade before starting the MariaDB server.

Before the upgrade, a backup of the system database is created in the top of the datadir with the name system_mysql_backup_*.sql.zst. This backup process can be disabled with by setting MARIADB_DISABLE_UPGRADE_BACKUP to a non-empty value.

MARIADB_MASTER_HOST

When specified, the container will connect to this host and replicate from it.

MARIADB_REPLICATION_USER / MARIADB_REPLICATION_PASSWORD_HASH / MARIADB_REPLICATION_PASSWORD

When MARIADB_MASTER_HOST is specified, MARIADB_REPLICATION_USER and MARIADB_REPLICATION_PASSWORD will be used to connect to the master.

When not specified, the MARIADB_REPLICATION_USER will be created with the REPLICATION REPLICA grants required to a client to start replication.

2.1.2.14.5.4 Running MariaDB ColumnStore Docker containers on Linux, Windows and MacOS

2.1.2.14.6.10 Docker Official Image Frequently Asked Questions

Contents

Frequently asked questions about the Docker Official Image

How to Reset Passwords

If you have an existing data directory and wish to reset the root and user passwords, and to create a database which the user can fully modify, perform the following steps.

First create a `passwordreset.sql` file:

```
CREATE USER IF NOT EXISTS root@localhost IDENTIFIED BY 'thisismyrootpassword';
SET PASSWORD FOR root@localhost = PASSWORD('thisismyrootpassword');
GRANT ALL ON *.* TO root@localhost WITH GRANT OPTION;
GRANT PROXY ON ''@'%' ON root@localhost WITH GRANT OPTION;
CREATE USER IF NOT EXISTS root@'%' IDENTIFIED BY 'thisismyrootpassword';
SET PASSWORD FOR root@'%' = PASSWORD('thisismyrootpassword');
GRANT ALL ON *.* TO root@'%' WITH GRANT OPTION;
GRANT PROXY ON ''@'%' ON root@'%' WITH GRANT OPTION;
CREATE USER IF NOT EXISTS myuser@'%' IDENTIFIED BY 'thisismyuserpassword';
SET PASSWORD FOR myuser@'%' = PASSWORD('thisismyuserpassword');
CREATE DATABASE IF NOT EXISTS databasename;
GRANT ALL ON databasename.* TO myuser@'%';
```

Adjust `myuser`, `databasename` and passwords as needed.

Then:

```
$ docker run --rm -v /my/own/datadir:/var/lib/mysql -v /my/own/passwordreset.sql:/passwordreset.s
```

On restarting the MariaDB container in this `/my/own/datadir`, the `root` and `myuser` passwords will be reset.

Temp Server Start Timeout

Question, are you getting errors like the following where a temporary server start fails to succeed in 30 seconds?

Example of log:

```
2023-01-28 12:53:42+00:00 [Note] [Entrypoint]: Starting temporary server
2023-01-28 12:53:42+00:00 [Note] [Entrypoint]: Waiting for server startup
2023-01-28 12:53:42 0 [Note] mariadbd (server 10.10.2-MariaDB-1:10.10.2+maria~ubu2204) starting a
....
2023-01-28 12:53:42 0 [Note] InnoDB: Setting file './ibtmp1' size to 12.000MiB. Physically writin
2023-01-28 12:54:13 0 [Note] mariadbd: ready for connections.
Version: '10.10.2-MariaDB-1:10.10.2+maria~ubu2204'  socket: '/run/mysqld/mysqld.sock'  port: 0  m
2023-01-28 12:54:13+00:00 [ERROR] [Entrypoint]: Unable to start server.
```

The timeout on a temporary server start is a quite generous 30 seconds.

The lack of a message like the following indicates it failed to complete writing a temporary file of 12MiB in 30 seconds.

```
2023-01-28 12:53:46 0 [Note] InnoDB: File './ibtmp1' size is now 12.000MiB.
```

If the datadir where this is stored is remote storage maybe it's a bit slow. It's ideal to have an InnoDB temporary path local

so this can be configured using the command or configuration setting:

```
innodb_temp_data_file_path=/dev/shm/ibtmp1:12M:autoextend
```

Note: depending on container runtime this space may be limited.

Creating a replication pair

`MARIADB_REPLICATION_USER` / `MARIADB_REPLICATION_PASSWORD` specify the authentication for the connection. The `MARIADB_MASTER_HOST` is the indicator that it is a replica and specifies the container aka hostname, of the master.

A `docker-compose.yml` example:

```
version: "3"
services:
  master:
    image: mariadb:latest
    command: --log-bin --log-basename=mariadb
    environment:
      - MARIADB_ROOT_PASSWORD=password
      - MARIADB_USER=testuser
      - MARIADB_PASSWORD=password
      - MARIADB_DATABASE=testdb
      - MARIADB_REPLICATION_USER=repl
      - MARIADB_REPLICATION_PASSWORD=replicationpass
    healthcheck:
      test: ["CMD", "healthcheck.sh", "--connect", "--innodb_initialized"]
      interval: 10s
      timeout: 5s
      retries: 3
  replica:
    image: mariadb:latest
    command: --server-id=2 --log-basename=mariadb
    environment:
      - MARIADB_ROOT_PASSWORD=password
      - MARIADB_MASTER_HOST=master
      - MARIADB_REPLICATION_USER=repl
      - MARIADB_REPLICATION_PASSWORD=replicationpass
      - MARIADB_HEALTHCHECK_GRANTS=REPLICA MONITOR
    healthcheck:
      test: ["CMD", "healthcheck.sh", "--connect", "--replication_io", "--replication_sql", "--re
      interval: 10s
      timeout: 5s
      retries: 3
    depends_on:
      master:
        condition: service_healthy
```

InnoDB: Upgrade after a crash is not supported. The redo log was created with MariaDB X.Y.Z

This will show up in the error log as:

```
2022-05-23 12:29:20 0 [ERROR] InnoDB: Upgrade after a crash is not supported. The redo log was cr
2022-05-23 12:29:20 0 [ERROR] InnoDB: Plugin initialization aborted with error Generic error
```

This is attempting to start on a higher MariaDB version when the shutdown of the previous version crashed.

By crashed, it means the MariaDB was force killed or had a hard power failure. MariaDB, being a durable database, can recover from these, if started with the same version. The redo log however is a less stable format, so the recovery has to be on the same Major.Minor version, in this case 10.5. This error message is saying that you when from force killed MariaDB to a later version.

So whenever you encounter this message. Start with the again with the tag set to the version in the error message, like 10.5.4, or as the redo long format is consistent in the Major.Minor version 10.5 is sufficient. After this has been started correctly, cleanly shut the service down and it will be recovered.

The logs on shutdown should have a message like:

```
2023-11-06 10:49:23 0 [Note] InnoDB: Shutdown completed; log sequence number 84360; transaction i
2023-11-06 10:49:23 0 [Note] mariadbd: Shutdown complete
```

After you see this, you can update your MariaDB tag to a later version.

Every MariaDB start is a crash recovery

Do you get on every start:

```
db-1  | 2023-02-25 19:10:02 0 [Note] Starting MariaDB 10.11.2-MariaDB-1:10.11.2+maria~ubu2204-log
db-1  | 2023-02-25 19:10:02 0 [Note] mariadbd: Aria engine: starting recovery
db-1  | tables to flush: 3 2 1 0
db-1  |  (0.0 seconds);
db-1  | 2023-02-25 19:10:02 0 [Note] mariadbd: Aria engine: recovery done
...
db-1  | 2023-02-26 13:03:29 0 [Note] InnoDB: Initializing buffer pool, total size = 32.000GiB, ch
db-1  | 2023-02-26 13:03:29 0 [Note] InnoDB: Completed initialization of buffer pool
db-1  | 2023-02-26 13:03:29 0 [Note] InnoDB: File system buffers for log disabled (block size=512
db-1  | 2023-02-26 13:03:29 0 [Note] InnoDB: Starting crash recovery from checkpoint LSN=19379687
```

Container runtimes are assume to start and stop very quickly. Check the the shutdown logs. They may be a log like:

```
db-1  | 2023-02-26 13:03:17 0 [Note] InnoDB: Starting shutdown...
db-1  | 2023-02-26 13:03:17 0 [Note] InnoDB: Dumping buffer pool(s) to /var/lib/mysql/ib_buffer_p
db-1  | 2023-02-26 13:03:17 0 [Note] InnoDB: Restricted to 519200 pages due to innodb_buf_pool_du
db-1  | 2023-02-26 13:03:17 0 [Note] InnoDB: Buffer pool(s) dump completed at 230226 13:03:17
db-1 exited with code 0
```

Note that the logs didn't include the following messages:

```
db-1  | 2023-02-26 13:03:43 0 [Note] InnoDB: Shutdown completed; log sequence number 46590; trans
db-1  | 2023-02-26 13:03:43 0 [Note] mariadbd: Shutdown complete
```

As these messages aren't here, the container was killed off before it could just down cleanly. When this happens, the startup will be a crash recovery and you won't be able to upgrade your MariaDB instance (previous FAQ) to the next Major.Minor version.

Solution is to extend the timeout in the container runtime to allow MariaDB to complete its shutdown.

How do I create a MariaDB-backup of the data?

```
docker volume create backup
docker run --name mdb -v backup:/backup -v datavolume:/var/lib/mysql mariadb
docker exec mdb mariadb-backup --backup --target-dir=/backup/d --user root --password soverysecre
docker exec mdb mariadb-backup --prepare --target-dir=/backup/d
docker exec mdb sh -c '[ ! -f /backup/d/.my-healthcheck.cnf ] && cp /var/lib/mysql/.my-healthchec
docker exec --workdir /backup/d mdb tar -Jcf ../backup.tar.xz .
docker exec mdb  rm -rf /backup/d
```

How do I restore from a MariaDB-backup

With the backup prepared like previously:

```
docker run -v backup:/docker-entrypoint-initdb.d -v newdatavolume:/var/lib/mysql mariadb
```

2.1.2.14.6.11 MariaDB Container Cheat Sheet

Contents

Get the images

Images can be found on MariaDB Docker Hub.
To get the list of images run

```
$ docker images -a
```

Create the network

```
$ docker network create mynetwork
```

It is good practice to create the container network and attach the container to the network.

```
Start the container with server options
```

To start the container in the background with the MariaDB server image run:

```
$ docker run --rm --detach \
--env MARIADB_ROOT_PASSWORD=sosecret \
--network mynetwork \
--name mariadb-server \
mariadb:latest
```

Additionally |environment variables are also provided.

Get the list of running containers

```
$ docker ps
CONTAINER ID   IMAGE            COMMAND                  CREATED          STATUS
PORTS      NAMES
ad374ec8a272   mariadb:latest   "docker-entrypoint.s…"   3 seconds ago    Up 1 second
3306/tcp   mariadb-server
```

Note: specify the flag **-a** in case you want to see all containers

Start the client from the container

To start the *mariadb* client inside the created container and run specific commands, run the following:

```
$ docker exec -it mariadb-server mariadb -psosecret -e "SHOW PLUGINS"
```

Inspect logs of a container

```
$ docker logs mariadb-server
```

In the logs you can find status information about the server, plugins, generated passwords, errors and so on.

Restart the container

```
$ docker restart mariadb-server
```

Run commands within the container

```
$ docker exec -it mariadb-server bash
```

Use a volume to specify configuration options

```
$ docker run --detach --env MARIADB_USER=anel \
  --env MARIADB_PASSWORD=anel \
  --env MARIADB_DATABASE=my_db \
  --env MARIADB_RANDOM_ROOT_PASSWORD=1 \
  --volume $PWD/my_container_config:/etc/mysql/conf.d:z \
  --network mynetwork \
  --name mariadb-server1 \
   mariadb:latest
```

One can specify custom configuration files through the **/etc/mysql/conf.d** volume during container startup.

Use a volume to specify grants during container start

```
$ docker run --detach --env MARIADB_USER=anel\
  --env MARIADB_PASSWORD=anel \
  --env MARIADB_DATABASE=my_db \
  --env MARIADB_RANDOM_ROOT_PASSWORD=1 \
  --volume $PWD/my_init_db:/docker-entrypoint-initdb.d \
  --network mynetwork \
  --name mariadb-server1 \
   mariadb:latest
```

User created with the environment variables has full grants only to the *MARIADB_DATABASE*. In order to override those grants, one can specify grants to a user, or execute any SQL statements from host file to **docker-entrypoint-initdb.d**. In the *local_init_dir* directory we can find the file, created like this:

```
$ echo "GRANT ALL PRIVILEGES ON *.* TO anel;" > my_init_db/my_grants.sql
```

2.1.2.14.6.12 Using Healthcheck.sh

The healthcheck.sh script is part of the Docker Official Images of MariaDB Server. The script is part of the respository of the Docker Official Image of MariaDB Server.

The script processes a number of argument and tests, together, in strict order. Arguments pertaining to a test must occur before the test name. If a test fails, no further processing is performed. Both arguments and tests begin with a double-hyphen.

By default, (since 2023-06-27), official images will create healthcheck@localhost, healthcheck@127.0.0.1, healthcheck@::1 users with a random password and USAGE privileges. `MARIADB_HEALTHCHECK_GRANTS` can be used for `--replication` where additional grants are required. This is stored in .my-healthcheck.cnf in the datadir of the container and passed as the `--defaults-extra-file` to the healthcheck.sh script if it exists. The `.my-healthcheck.cnf` also sets `protocol=tcp` for the `mariadb` so `--connect` is effectively there on all tests.

The `MARIADB_MYSQL_LOCALHOST_USER=1, MARIADB_MYSQL_LOCALHOST_GRANTS` environment variables can also be used, but with the creation of the healthcheck user, these are backwards compatible.

Tests

--connect

This is active when a external user can connect to the TCP port of MariaDB Server. This strictly tests just the TCP connection and not if any authentication works.

--innodb_initialized

This test is true when InnoDB has completed initializing. This includes any rollback or crash recovery that may be occurring in the background as MariaDB is starting.

The connecting user must have USAGE privileges to perform this test.

--innodb_buffer_pool_loaded

This indicates that the buffer pool dump previously saved has been completed loaded into the InnoDB Buffer Pool and as such the server has a hot cache ready for use. This checks the innodb_buffer_pool_load_status for a "complete" indicator.

This test doesn't check if innodb-system-variables/#innodb_buffer_pool_load_at_startupinnodb_buffer_pool_load_at_startup is set at startup.

The connecting user must have USAGE privileges to perform this test.

--galera_online

This indicates that the galera node is online by the wsrep_local_state variable. This includes states like "joining" and "donor" where it cannot serve SQL queries.

The connecting user must have USAGE privileges to perform this test.

--replication

This tests a replica based on the `--replication_*` parameters. The replica test must pass all of the subtests to be true. The subtests are:

- io - the IO thread is running
- sql - the sql thread is running
- seconds_behind_master - the replica is less than X seconds behind the master.
- sql_remaining_delay - the delayed replica is less than X seconds behind the master's execution of the same SQL.

These are tested for all connections, if `--replication_all` is set (default), or `--replication_name`.

The connecting user must have REPLICATION_CLIENT if using a version less than MariaDB 10.5, or REPLICA MONITOR for MariaDB 10.5 or later.

--mariadbupgrade

This healthcheck indicates that the mariadb is upgrade to the current version.

Parameters

--replication_all

Checks all replication sources

--replication_name=n

Sets the multisource connection name tested. Unsets `--replication_all`.

--replication_io

IO thread is running

--replication_sql

SQL thread is running

--replication_seconds_behind_master=n

Less than or equal this seconds of delay

--replication_sql_remaining_delay=n

Less than or equal this seconds of remaining delay

--su=n

Change to this user. Can only be done once as the root user is default for healthchecks.

--su-mysql

Change to the `mysql` unix user. Like `--su` this respawns the script so will reset all parameters. Should be the first argument. The `MARIADB_MYSQL_LOCALHOST_USER=1` environment variable is designed around usage here.

--datadir=n

For the `--mariadbupgrade` test where the upgrade file is located.

--no-defaults --defaults-file --defaults-extra-file --defaults-group-suffix

These are passed to mariadb shell for all tests except `--mariadbupgrade`

Examples

```
healthcheck.sh --su-mysql --connect --innodb_initialized
```

Switch to `mysql` user, and check if can connect and the innodb is initialized.

```
healthcheck.sh --su-mysql --connect --replication_io --replication_sql --replication_seconds_behi
```

Switch to `mysql` user, check if connections can be made, for the replication channel "archive", ensure io and sql threads are running and the seconds behind master < 600 seconds and the sql remaining delay < 30 seconds. For the "channel1", the seconds behind master is limit to 10 seconds maximum.

2.1.2.14.6.13 Docker and AWS EC2

This process shows how to deploy MariaDB in a Docker container running on an EC2 instance. First we'll create the EC2 VM, then we'll deploy Docker to it. After that, we'll pull the MariaDB Docker image which we'll use to create a running container with a MariaDB instance. Finally, we'll load a sample database into the MariaDB instance.

Create a VM in AWS EC2

1. Install MariaDB client on your local machine, either bundled with Maria DB server or standalone.

2. Login to AWS, navigate to EC2 service home

3. Choose Region for EC2 in the upper right corner of the console

4. Launch (1) Instance, giving instance a name (e.g. mrdb-ubuntu-docker-use1) and create or re-use a key pair

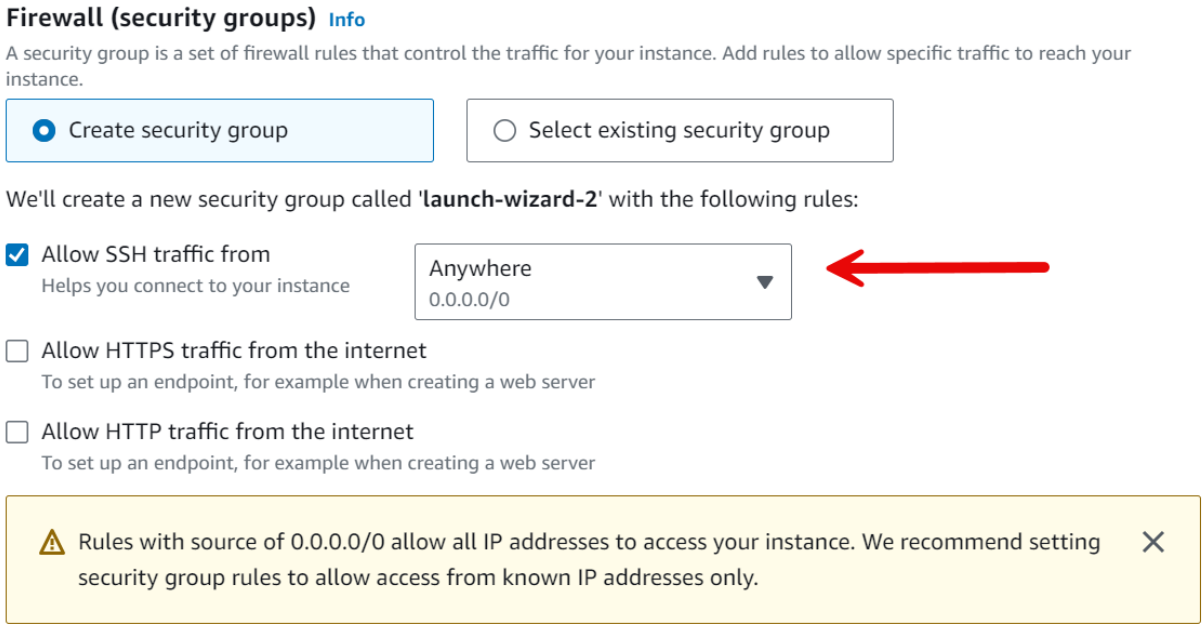
5. Choose Ubuntu 22.04 or similar free tier instance

6. Choose hardware, t2.micro or similar free tier instance

7. Create Key Pair with name (e.g. mrdb-docker-aws-pk.pem if using openSSH at the command line, or mrdb- docker-aws-pk..ppk for use with programs like PuTTY.)

9. Create or select a security group where SSH is allowed from anywhere 0.0.0.0/0. If you'd like to make this more secure, it

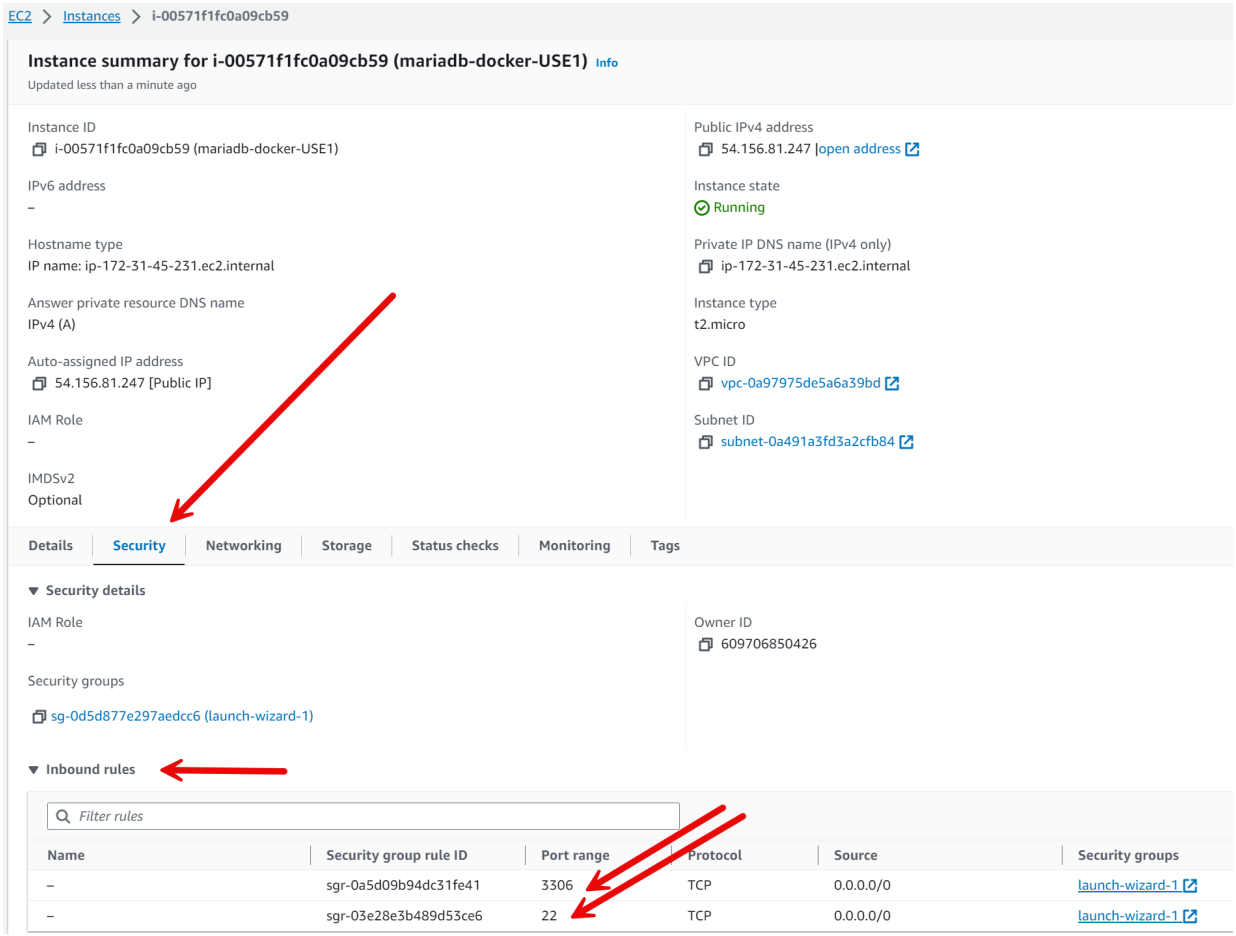
can be restricted to a specific IP address or CIDR block.



10. Accept remaining instance creation defaults and click “launch instance”.

11. Save the *.pem or *.ppk keyfile on your local hard drive when prompted. You will need it later. If you’re on Linux, don’t forget to change permissions on the downloaded *.pem / *.ppk key file: $ chmod 400 mrdb-docker-pk.pem

12. Click into the instance summary (EC2 > Instances > Instance ID) and click on the “security” tab towards the bottom.

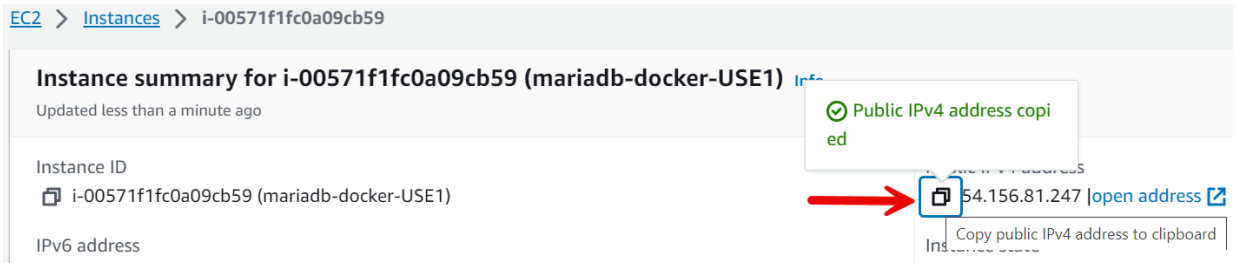


13. In the relevant security group for your instance, Create an inbound rule so that TCP port 3306 is open, allowing external connections to Maria DB (like your local command line client for MariaDB). Double check that port 22 is open while you're there for SSH.

Install Docker on the EC2 VM

For more detailed instructions, refer to Installing and Using MariaDB via Docker

14. Back in the instance summary (EC2 > Instances > Instance ID), copy the public IP (e.g. ww.xx.yyy.zzz)



15. Open terminal window, navigate to the directory with private key (*.pem or *.ppk) file and start a SSH remote shell session by typing:

$ ssh -i mrdb-docker-pk.pem ubuntu@ww.xx.yyy.zzz

(switch ww.xx.yyy.zzz for your IP address from step 14).

16. Are you sure you want to continue connecting (yes/no/[fingerprint])? Say yes

17. Escalate to root

$ sudo su

18. Install Docker

$ curl -fsSL https://get.docker.com | sudo sh

Pull the MariaDB Docker image and create the container

19. Pull MariaDB Docker image

$ docker pull mariadb:lts

20. Start MDRB docker process

at your terminal / command line, type:

$ docker run --detach --name mariadb-docker -v \Users\YouUID\Documents\YourDirName:/var/lib/mysql:Z -p 3306:3306 -e MARIADB_ROOT_PASSWORD=yoursecurepassword mariadb:lts

The -v flag mounts a directory that you choose as /var/lib/mysql will ensure that the volume is persistent. Windows file paths like C:\Users\YouUID\Documents\YourDirName should be represented as above. Linux file paths should also be absolute vs. relative. Obviously replace the root password with something that is a bit more secure than you see in this example for anything other than development purposes.

21. Shell into container

$ docker exec -it mariadb-docker bash

22. Login to MRDB inside container

Using the root password specified in step 20, type:

$ mariadb -pyoursecurepassword

23. Setup admin account with permission for remote connection, configure access control

MariaDB [(none)]> CREATE USER 'admin'@'%' IDENTIFIED BY 'admin';

MariaDB [(none)]> GRANT ALL ON *.* to 'admin'@'%' WITH GRANT OPTION;

MariaDB [(none)]> SHOW GRANTS FOR admin;

Obviously replace these passwords with something that is a bit more secure than you see in this example for anything other than development purposes.

24. Setup service account for your app with permission for remote connection, configure access control

MariaDB [(none)]> CREATE USER 'yourappname'@'%' IDENTIFIED BY 'yoursecurepassword';

MariaDB [(none)]> GRANT INSERT, UPDATE, DELETE ON *.* to 'yourappname'@'%';

MariaDB [(none)]> SHOW GRANTS FOR yourappname;

Obviously replace these passwords with something that is a bit more secure than you see in this example for anything other than development purposes.

25. Load up your database from your preexisting SQL script that contains CREATE DATABASE; USE DATABASE; and CREATE TABLE statements.

In a new local terminal window, not your SSH session, change directory to the directory containing your database creation script, say, init.sql in this example. Type:

$ mariadb --host=ww.xx.yyy.zzz --port=3306 --user=admin --password=admin -e “SOURCE init.sql”

(switch ww.xx.yyy.zzz for your IP address from step 14).

2.1.2.14.6.14 Docker and Google Cloud

This process shows how to deploy MariaDB in a Docker container running on an GCE instance. First we'll create the GCE VM, then we'll deploy Docker to it. After that, we'll pull the MariaDB Docker image which we'll use to create a running container with a MariaDB instance. Finally, we'll load a sample database into the MariaDB instance.

Create a VM in Google Cloud Compute Engine

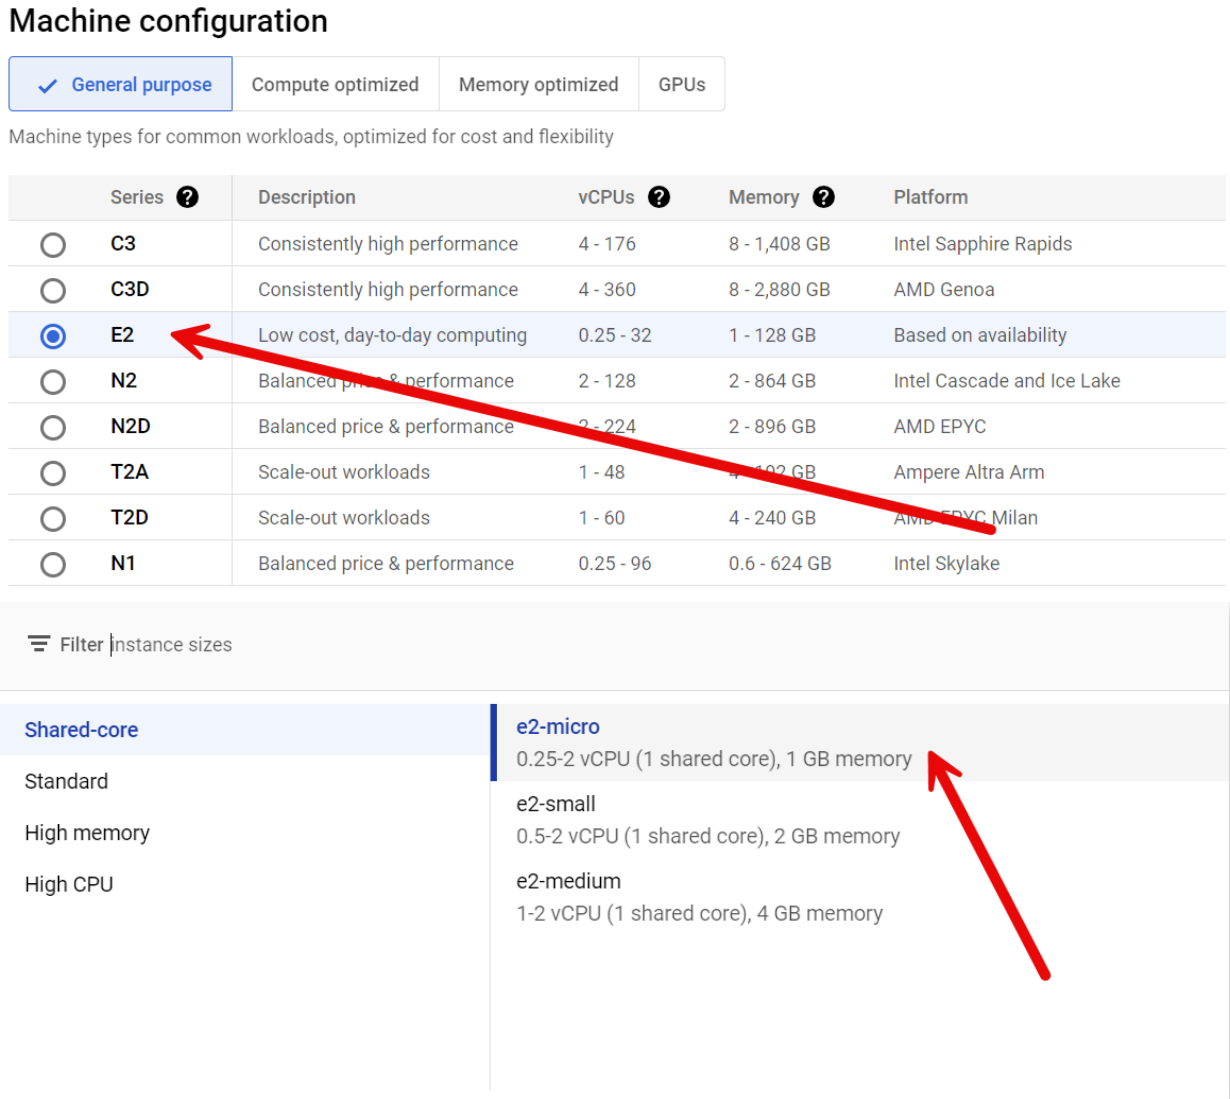
1. Install MariaDB client on your local machine, either bundled with Maria DB server or standalone.

2. Login to Google Cloud, navigate to VM instances

3. Enable Compute Engine API if you haven't already.

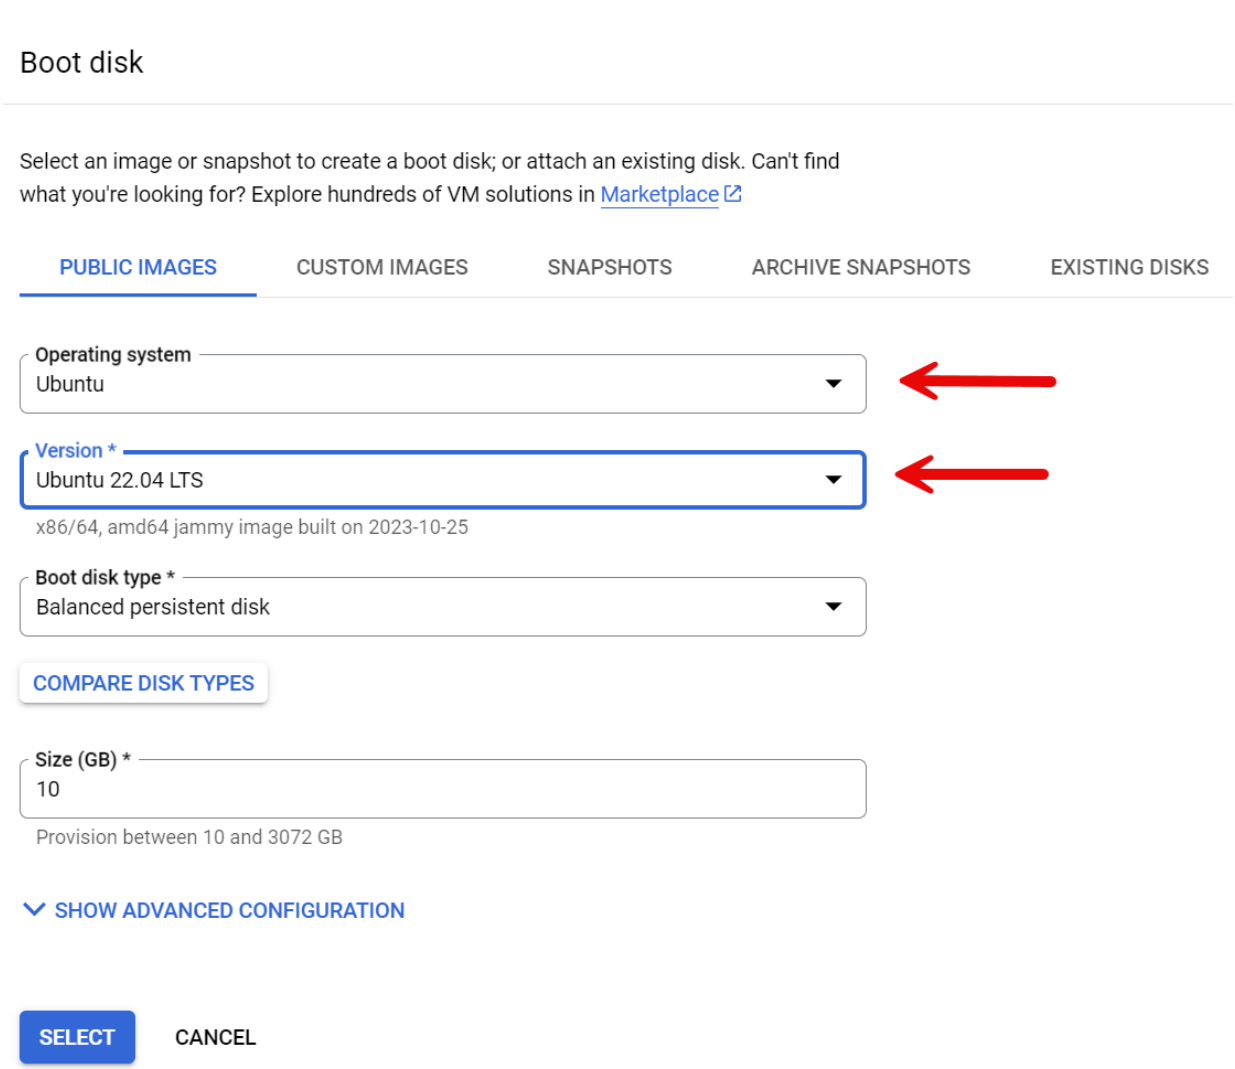
4. Click create instance, give instance a name (e.g. mrdb-ubuntu-docker-use1b), choose a region and zone.

5. Machine configuration: Choose general-purpose / E2 micro

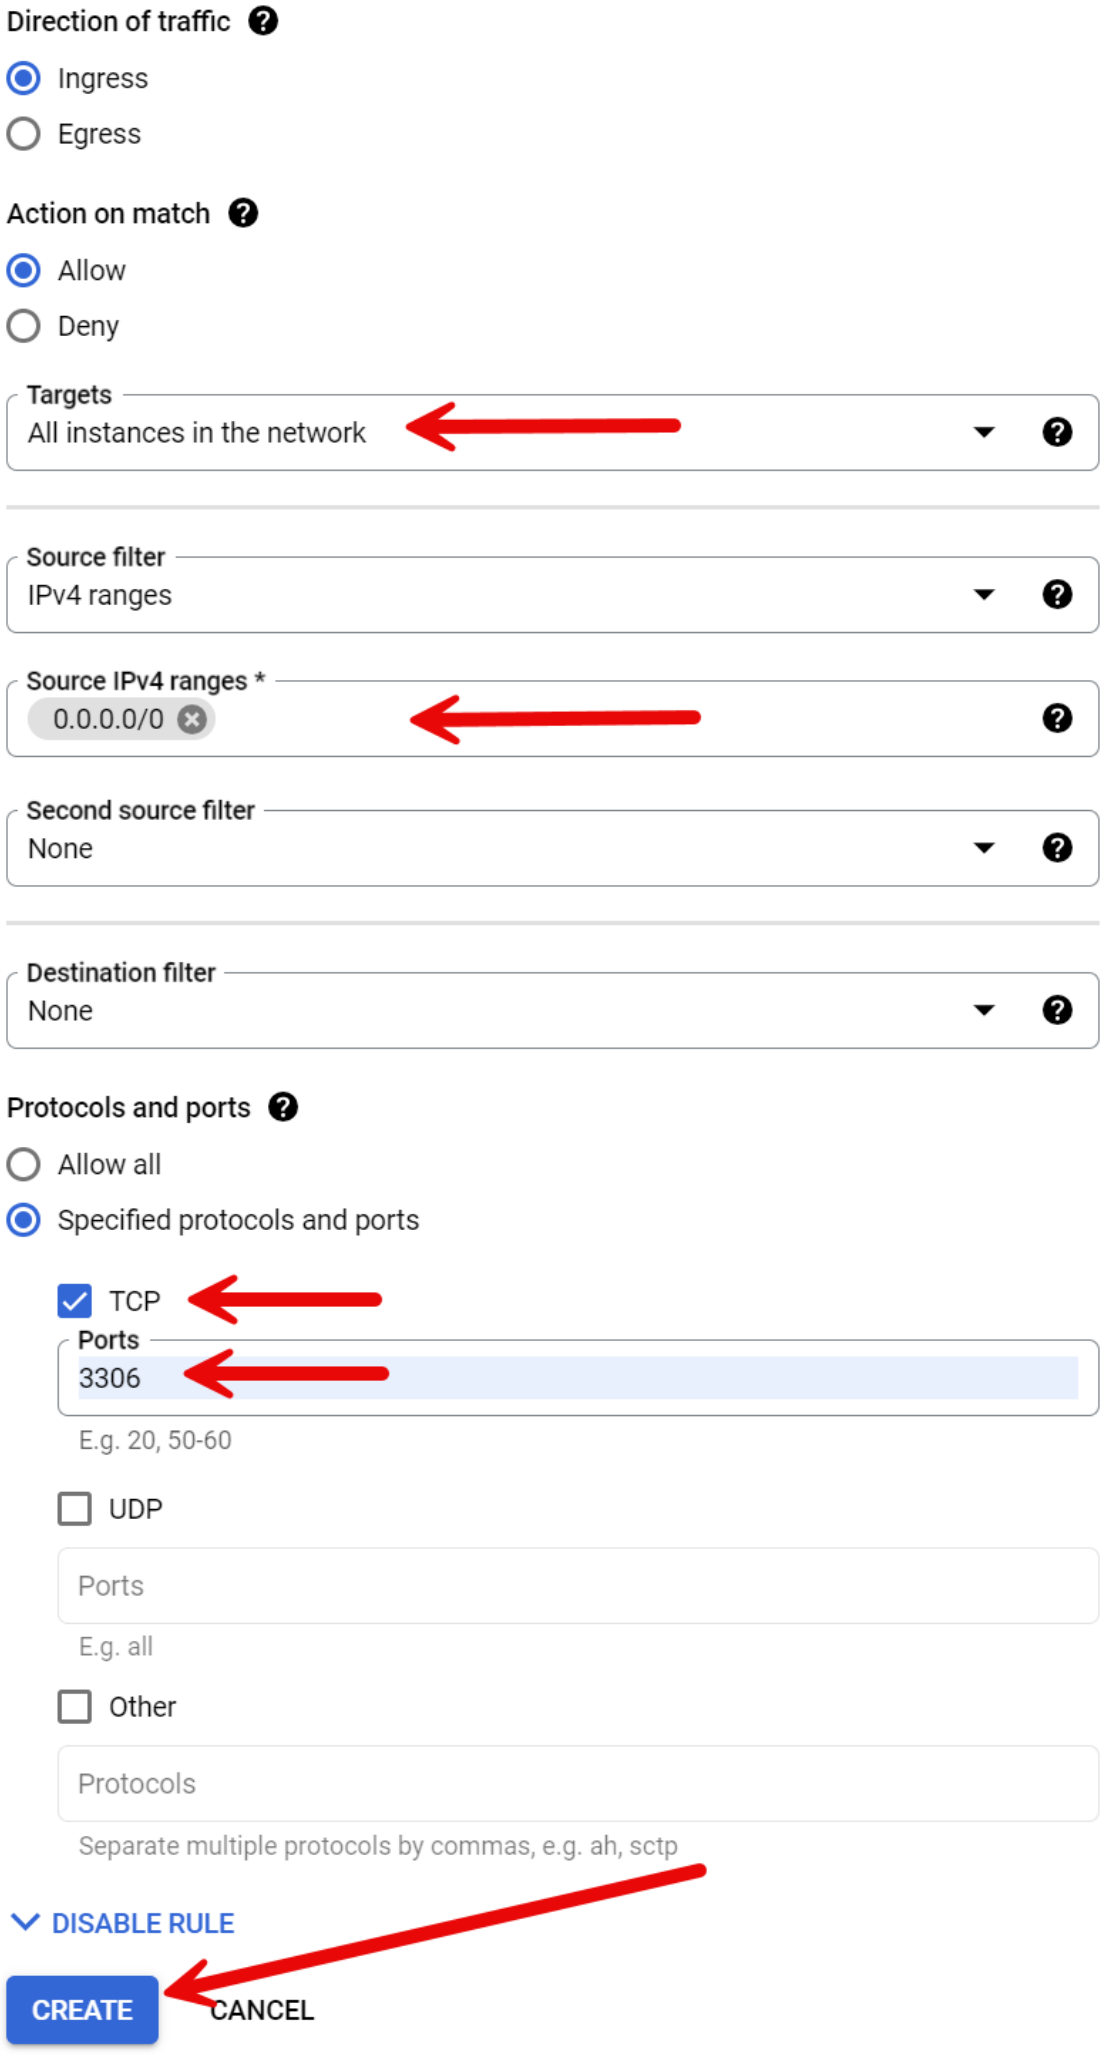


6. Boot Disk > Change

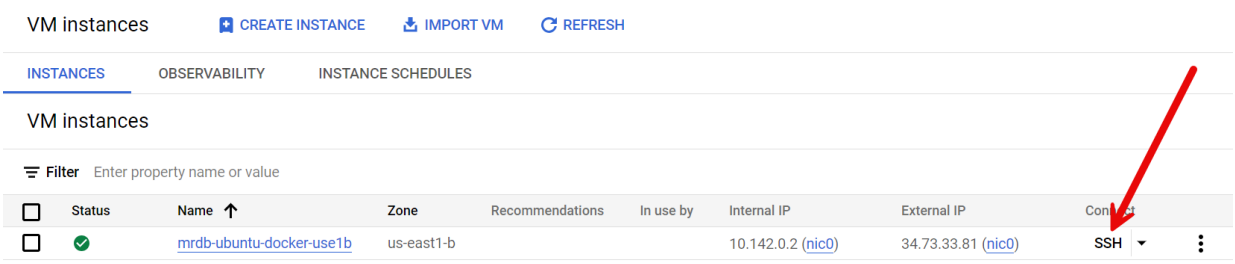
Switch the operating system to a modern Ubuntu release x86/64 CPU architecture, or similar free tier offering.



7. Create a firewall rule in the Firewall Policies section of the console. After naming it, change the targets, add 0.0.0.0/0 as a source IP range, and open TCP port 3306. Then Click create.



8. Connect using Google Cloud's built in browser SSH. Accept all prompts for authorization.



Install Docker on the GCE VM

For more detailed instructions, refer to Installing and Using MariaDB via Docker

9. Escalate to root Escalate to root

$ sudo su

10. Install Docker

$ curl -fsSL https://get.docker.com | sudo sh

11. Pull Docker image

$ docker pull mariadb:lts

12. Start MDRB docker process

at your terminal / command line, type:

$ docker run --detach --name mariadb-docker -v \Users\YouUID\Documents\YourDirName:/var/lib/mysql:Z -p 3306:3306 -e MARIADB_ROOT_PASSWORD=yoursecurepassword mariadb:lts

The -v flag mounts a directory that you choose as /var/lib/mysql will ensure that the volume is persistent. Windows file paths like C:\Users\YouUID\Documents\YourDirName should be represented as above. Linux file paths should also be absolute vs. relative. Obviously replace the root password with something that is a bit more secure than you see in this example for anything other than development purposes.

13. Shell into container $ docker exec -it mariadb-docker bash

14. Login to MRDB inside container

Using the root password specified in step 12, type:

$ mariadb -pyoursecurepassword

15. Setup admin account with permission for remote connection, configure access control Execute these SQL commands in sequence:

MariaDB [(none)]> CREATE USER 'admin'@'%' IDENTIFIED BY 'admin';

MariaDB [(none)]> GRANT ALL ON *.* to 'admin'@'%' WITH GRANT OPTION;

MariaDB [(none)]> SHOW GRANTS FOR admin;

Obviously replace these passwords with something that is a bit more secure than you see in this example for anything other than development purposes.

16. Setup service account for your app with permission for remote connection, configure access control Execute these SQL commands in sequence:

MariaDB [(none)]> CREATE USER 'yourappname'@'%' IDENTIFIED BY 'yoursecurepassword';

MariaDB [(none)]> GRANT INSERT, UPDATE, DELETE ON *.* to 'yourappname'@'%';

MariaDB [(none)]> SHOW GRANTS FOR yourappname;

Obviously replace these passwords with something that is a bit more secure than you see in this example for anything other than development purposes.

17. Load up your database from your preexisting SQL script that contains CREATE DATABASE; USE DATABASE; and CREATE TABLE statements.

Copy the external IP address of your VM instance from the Console in the VM instances list.

In a new local terminal window, not your SSH session, change directory to the directory containing your database creation script, say, init.sql in this example.

Type: $ mariadb --host=ww.xx.yyy.zzz --port=3306 --user=admin --password=admin -e “SOURCE init.sql” (switch ww.xx.yyy.zzz for your IP address from step 17.

2.1.2.14.6.15 Docker and Microsoft Azure

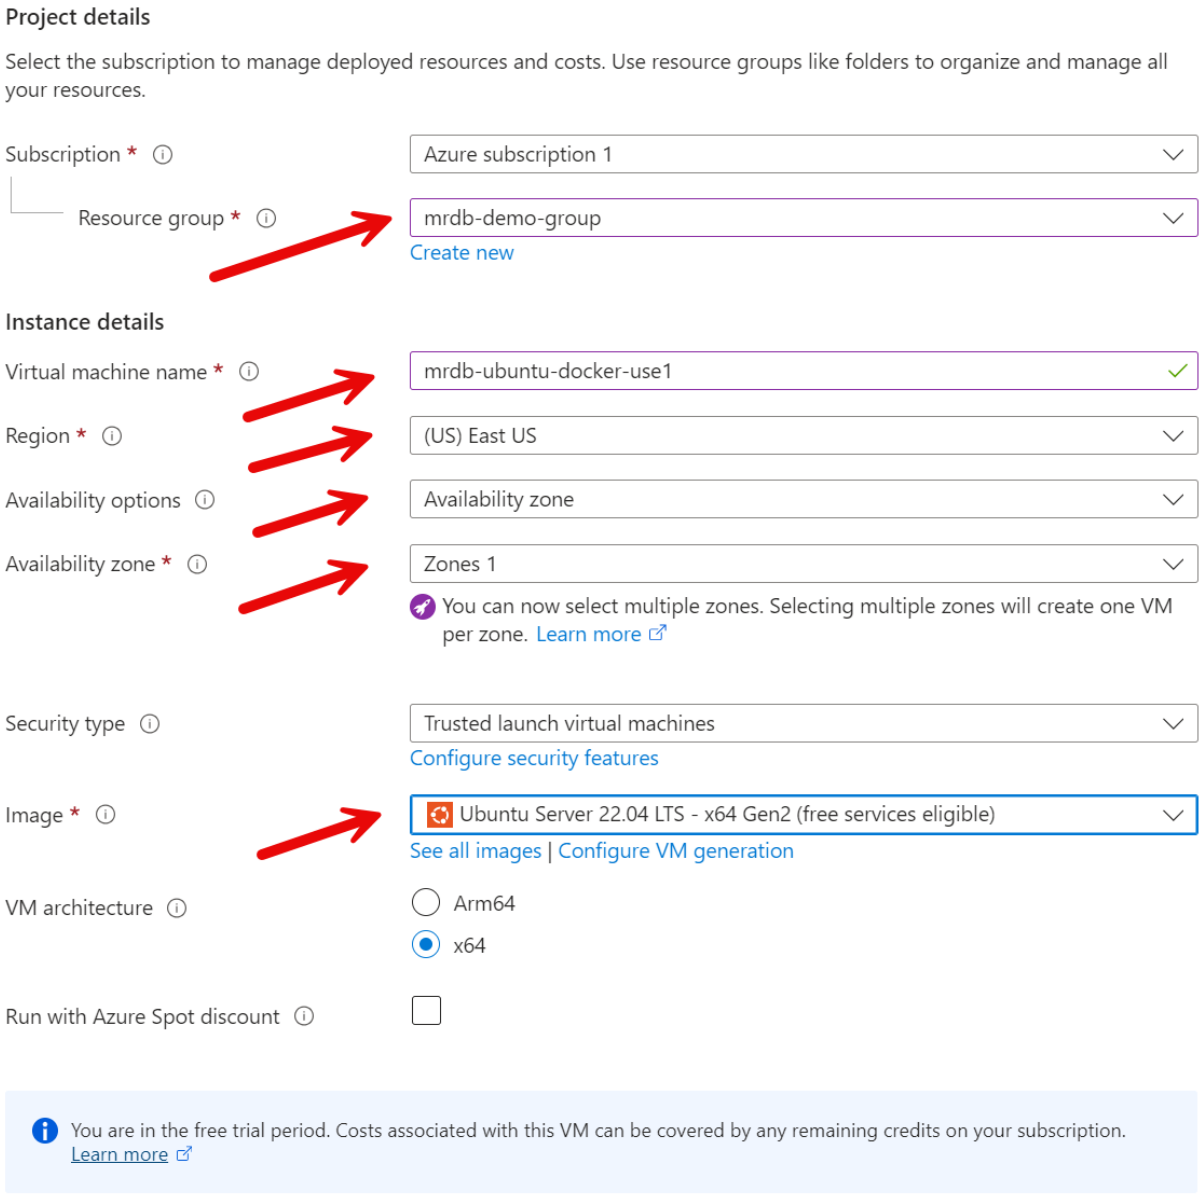
This process shows how to deploy MariaDB in a Docker container running on an Azure VM instance. First we'll create the Azure VM, then we'll deploy Docker to it. After that, we'll pull the MariaDB Docker image which we'll use to create a running container with a MariaDB instance. Finally, we'll load a sample database into the MariaDB instance.

Create a VM in Azure

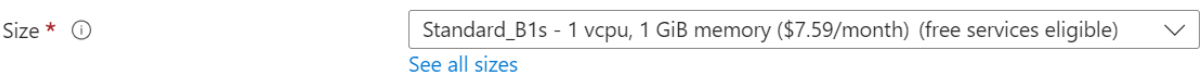
1. Install MariaDB client on your local machine, either bundled with Maria DB server or standalone.

2. Login to Azure, navigate to Azure Virtual Machine

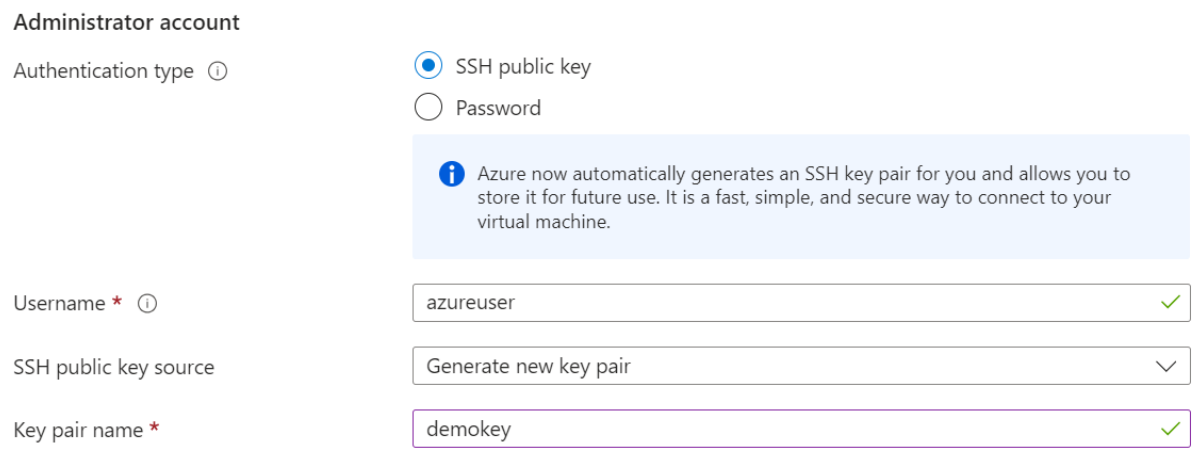
3. Create VM. Give the VM a name (e.g. mrdb-ubuntu-docker-use1), and create new or use an existing resource group. Selection region and availability zone, and choose Ubuntu 22.04 LTS x64 (free services eligible).



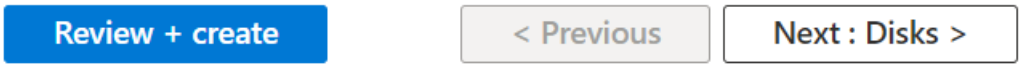
4. Choose the VM instance size, like a B1s or similar free tier. Note that Azure free works on a credit based system for new accounts



5. Configure an administrator account and generate a new key pair, and give the key pair a name.

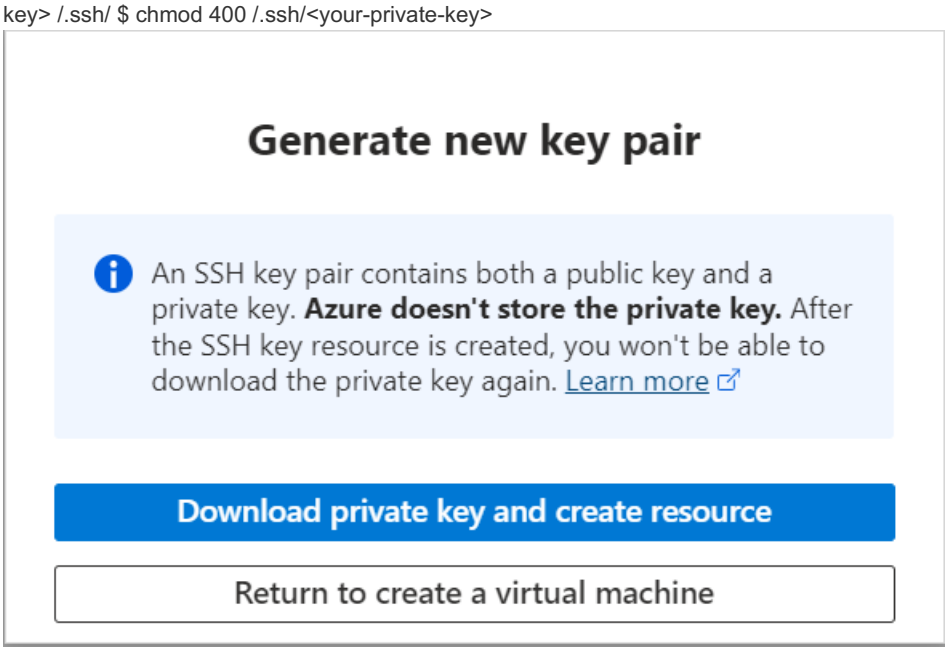


6. Click "Review + Create" at the very bottom of the "create virtual machine" page to create the VM.

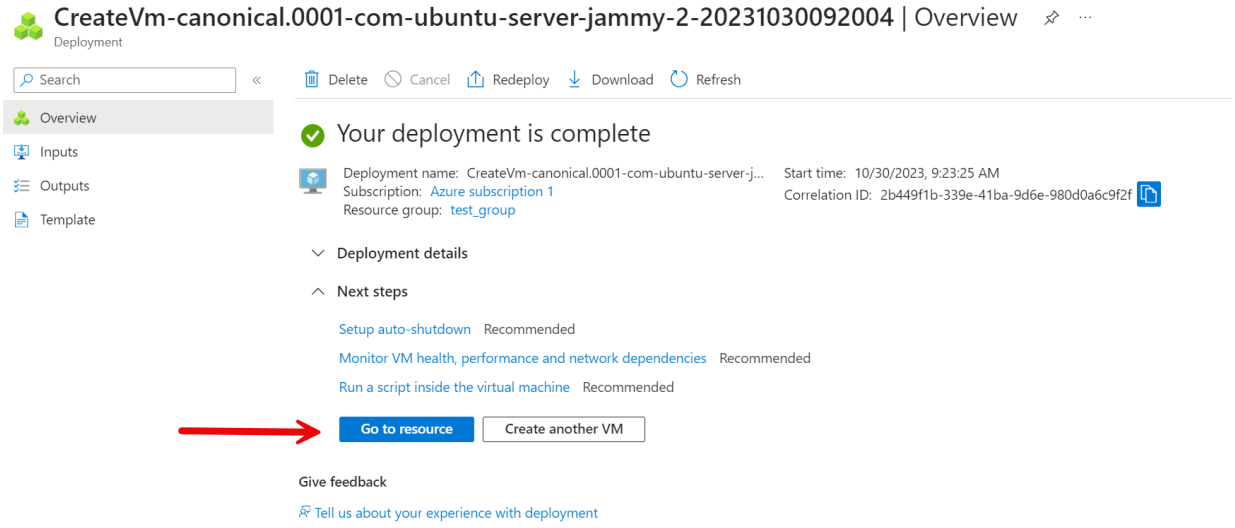


7. Download the SSH keys and them in a safe place, you will need them later. For this example, let's name the key file mrdb-docker-pk.pem.

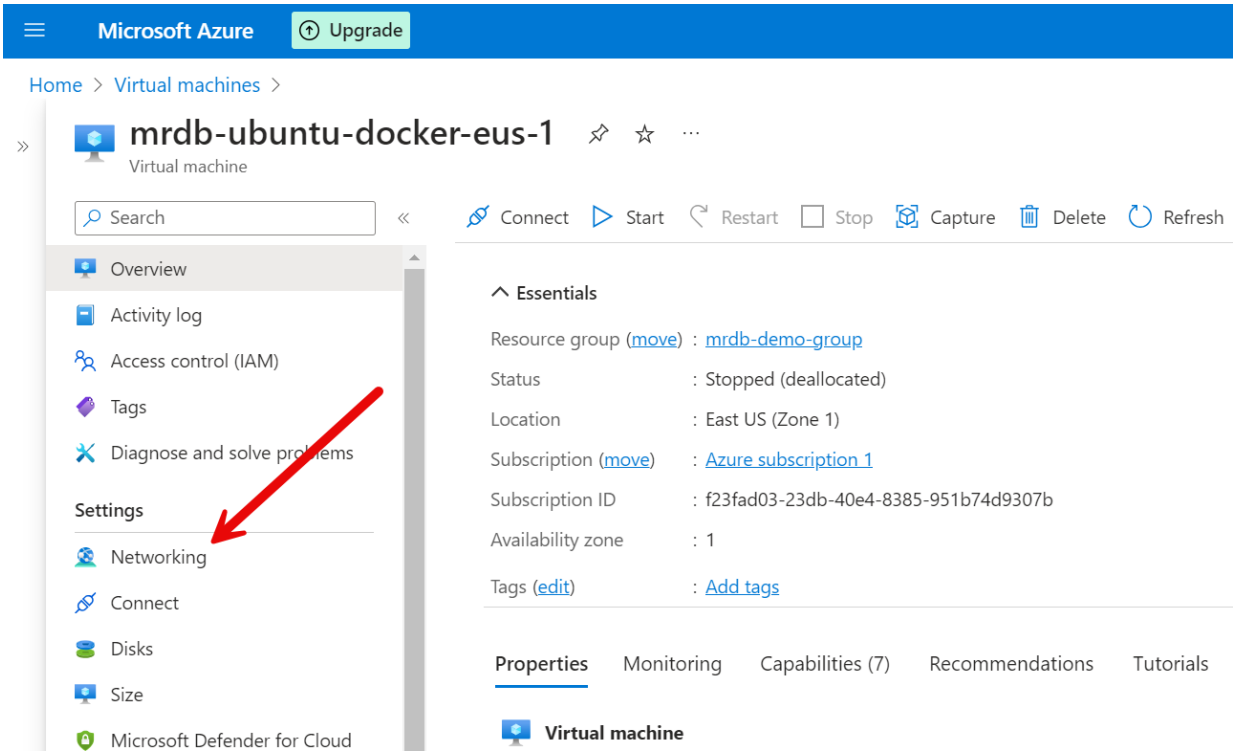
If your local machine is Linux or you are using WSL on Windows, open a terminal window and: $ mv /mnt/c/<your-private-key> /.ssh/ $ chmod 400 /.ssh/<your-private-key>



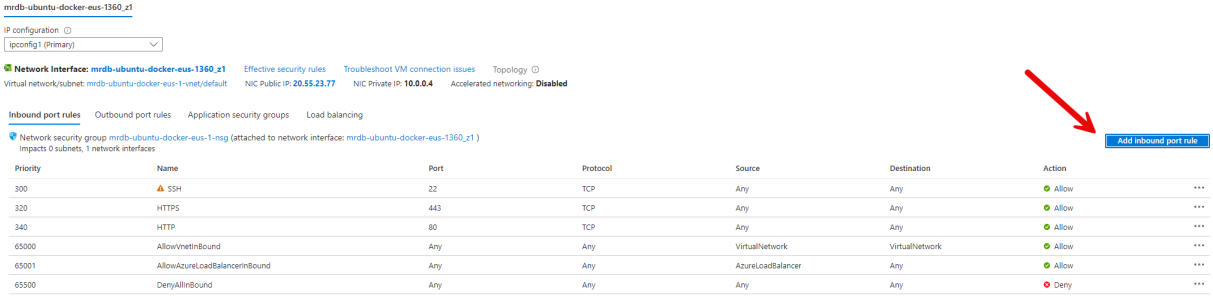
8. Once the VM is deployed, "click to resource" to get back to the virtual machine's overview page.



9. From the overview page, the left-hand navigation, choose settings > networking.



10. Click "add inbound port rule"



11. Configure the port rule to allow port TCP 3306 inbound (mySQL) so that you can make external connections from your local Maria DB command line client, to the dockerized Maria DB instance in your Azure Linux VM.

AllowCidrBlockCustom3306Inbound

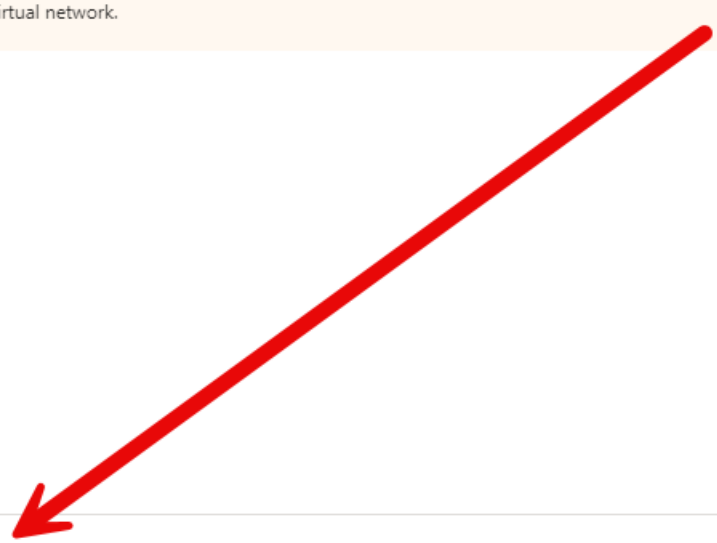
AllowCidrBlockCustom3306Inbound

Description

MariaDB

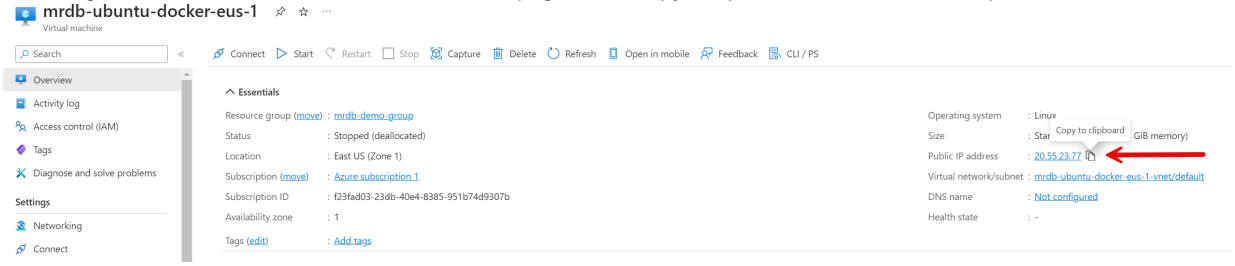
Mysql DB port 3306 is exposed to the Internet. We do not recommend exposing database ports to the Internet and suggest only exposing them to your front-end tier inside your virtual network.



Save | Cancel | Give feedback

Save

12. Navigate back to the virtual machine's overview page. Then copy the public IP address to the clipboard.



Install Docker on the Azure VM

For more detailed instructions, refer to Installing and Using MariaDB via Docker

16. Open terminal window, referencing the path to the private key (*.pem or *.ppk) file, and start a SSH remote shell session by typing:

$ ssh -i /.ssh/mrdb-docker-pk.pem azureuser@ww.xx.yyy.zzz

(switch ww.xx.yyy.zzz for your IP address from step 12, and replace "mrdb-docker-pk.pem" with your keyfile name if you chose something different).

If you forget your administrator account details, simply go to the left-hand navigation and choose settings > connect, and Azure will display the public IP address, admin username, and port for you.

17. Are you sure you want to continue connecting (yes/no/[fingerprint])? Say yes

18. Escalate to root

$ sudo su

19. Microsoft Azure on two machines come with docker preinstalled. For any reason you need to reinstall it , chose another machine type is not have docker preinstalled, you can install docker inside your SSH session with cURL by typing:

$ curl -fsSL https://get.docker.com | sudo sh

Pull the MariaDB Docker image and create the container

20. Pull MariaDB Docker image

$ docker pull mariadb:lts

21. Start MDRB docker process

at your terminal / command line, type:

$ docker run --detach --name mariadb-docker -v \Users\YouUID\Documents\YourDirName:/var/lib/mysql:Z -p 3306:3306 -e MARIADB_ROOT_PASSWORD=yoursecurepassword mariadb:lts

The -v flag mounts a directory that you choose as /var/lib/mysql will ensure that the volume is persistent. Windows file paths like C:\Users\YouUID\Documents\YourDirName should be represented as above. Linux file paths should also be absolute vs. relative. Obviously replace the root password with something that is a bit more secure than you see in this example for anything other than development purposes.

22. Shell into container

$ docker exec -it mariadb-docker bash

23. Login to MRDB inside container

Using the root password specified in step 20, type:

$ mariadb -pyoursecurepassword

24. Setup admin account with permission for remote connection, configure access control

MariaDB [(none)]> CREATE USER 'admin'@'%' IDENTIFIED BY 'admin';

MariaDB [(none)]> GRANT ALL ON *.* to 'admin'@'%' WITH GRANT OPTION;

MariaDB [(none)]> SHOW GRANTS FOR admin;

Obviously replace these passwords with something that is a bit more secure than you see in this example for anything other than development purposes.

25. Setup service account for your app with permission for remote connection, configure access control

MariaDB [(none)]> CREATE USER 'yourappname'@'%' IDENTIFIED BY 'yoursecurepassword';

MariaDB [(none)]> GRANT INSERT, UPDATE, DELETE ON *.* to 'yourappname'@'%';

MariaDB [(none)]> SHOW GRANTS FOR yourappname;

Obviously replace these passwords with something that is a bit more secure than you see in this example for anything other than development purposes.

26. Load up your database from your preexisting SQL script that contains CREATE DATABASE; USE DATABASE; and CREATE TABLE statements.

In a new local terminal window, not your SSH session, change directory to the directory containing your database creation script, say, init.sql in this example. Then type:

$ mariadb --host=ww.xx.yyy.zzz --port=3306 --user=admin --password=admin -e “SOURCE init.sql”

(switch ww.xx.yyy.zzz for your IP address from step 12).

2.1.2.14.7 Kubernetes and MariaDB

General information and hints on how to deploy MariaDB Kubernetes containers.

Kubernetes is an open source containers orchestration system. It automates deployments, horizontal scaling, configuration and operations. It is often referred to as K8s.

Kubernetes Overview for MariaDB Users

An overview of Kubernetes and how it works with MariaDB.

Kubernetes Operators for MariaDB

An overview of Kubernetes operators that can be used with MariaDB

2.1.2.14.8 Kubernetes Overview for MariaDB Users

Kubernetes, or K8s, is software to orchestrate containers. It is released under the terms of an open source license, Apache License 2.0.

Kubernetes was originally developed by Google. Currently it is maintained by the Cloud Native Computing Foundation (CNCF), with the status of Graduated Project.

For information about how to setup a learning environment or a production environment, see Getting started in Kubernetes documentation.

Contents

Architecture

Kubernetes runs in a **cluster**. A cluster runs a **workload**: a set of servers that are meant to work together (web servers, database servers, etc).

A Kubernetes cluster consists of the following components:

- **Nodes** run containers with the servers needed by our applications.
- **Controllers**constantly check the cluster nodes current state, and compare it with the desired state.
- A **Control Plane** is a set of different components that store the cluster desired state and take decisions about the nodes. The Control Plane provides an API that is used by the controllers.

For more information on Kubernetes architecture, see Concepts and Kubernetes Components in Kubernetes documentation.

Nodes

A node is a system that is responsible to run one or more pods. A pod is a set of containers that run a Kubernetes workload or part of it. All containers that run in the same pod are also located on the same node. Usually identical pods run on different nodes for fault tolerance.

For more details, see Nodes in the Kubernetes documentation.

Every node must necessarily have the following components:

- **kubelet**
- **kube-proxy**
- A **container runtime**

kubelet

kubelet has a set of **PodSpecs** which describe the desired state of pods. It checks that the current state of the pods matches the desired state. It especially takes care that containers don't crash.

kube-proxy

In a typical Kubernetes cluster, several containers located in different pods need to connect to other containers, located in the same pods (for performance and fault tolerance reasons). Therefore, when we develop and deploy an application, we can't know in advance the IPs of the containers to which it will have to connect. For example, an application server may need to connect to MariaDB, but the MariaDB IP will be different for every pod.

The main purpose of kube-proxy is to implement the concept of Kubernetes **services**. When an application needs to connect to MariaDB, it will connect to the MariaDB service. kube-proxy will receive the request and will redirect it to a running MariaDB container in the same pod.

Container Runtime

Kubernetes manages the containers in a pod via a container runtime, or container manager, that supports the Kubernetes Container Runtime Interface (CRI). Container runtimes that meet this requisite are listed in the Container runtimes page in the Kubernetes documentation. More information about the Container Runtime Interface can be found on GitHub.

Originally, Kubernetes used Docker as a container runtime. This was later deprecated, but Docker images can still be used using any container runtime.

Controllers

Controllers constantly check if there are differences between the pod's current state and their desired state. When differences are found, controllers try to fix them. Each node type controls one or more resource types. Several types of controllers are needed to run a cluster.

Most of the actions taken by the controllers user the API server in the Control Plane. However, this is not necessarily true for custom controllers. Also, some actions cannot be performed via the Control Plane. For example, if some nodes crashed, adding new nodes involves taking actions outside of the Kubernetes cluster, and controllers will have to do this themselves.

It is possible to write custom controllers to perform checks that require knowledge about a specific technology. For example, a MariaDB custom controller may want to check if replication is working by issuing SHOW REPLICA STATUS commands. This logic is specific to the way MariaDB works, and can only be implemented in a customer controller. Custom controllers are usually part of operators.

For more information, see Controllers in the Kubernetes documentation.

Control Plane

The control plane consists of the following components.

For more information about the control plane, see Control Plane Components in Kubernetes documentation.

API Server

An API Server exposes API functions both internally and externally. It is essential to coordinate Kubernetes components so that they react to node's change of state, and it allows the user to send commands.

The default implementation of the API Server is kube-apiserver. It is able to scale horizontally and to balance the load

between its instances.

kube-controller-manager

Most controllers run in this component.

etcd

etcd contains all data used by a Kubernetes cluster. It is a good idea to take regular backups of etcd data.

kube-scheduler

When a new pod is created, kube-scheduler decides which node should host it. The decision is made based on several criteria, like the resource requirements for the pod.

cloud-controller-manager

cloud-controller-manager implements the logic and API of a cloud provider. It receives requests from the API Server and performs specific actions, like creating an instance in AWS. It also runs controllers that are specific to a cloud vendor.

Clients and Tools

Kubernetes comes with a set of tools that allow us to communicate with the API server and test a cluster.

kubectl

kubectl allows communication with the API server and run commands on a Kubernetes cluster.

kubeadm

kubeadm allows creating a Kubernetes cluster that is ready to receive commands from kubectl.

kind and minikube

These tools are meant to create and manage test clusters on a personal machine. They work on Linux, MacOS and Windows. kind creates a cluster that consists of Docker containers, therefore it requires Docker to be installed. minikube runs a single-node cluster on the local machine.

2.1.2.14.9 Kubernetes Operators for MariaDB

Operators basically instruct Kubernetes about how to manage a certain technology. Kubernetes comes with some default operators, but it is possible to create custom operators. Operators created by the community can be found on OperatorHub.io.

Contents

Custom Operators

Kubernetes provides a declarative API. To support a specific (i.e. MariaDB) technology or implement a desired behavior (i.e. provisioning a replica), we extend Kubernetes API. This involves creating two main components:

- A custom resource.
- A custom controller.

A custom resource adds an API endpoint, so the resource can be managed via the API server. It includes functionality to get information about the resource, like a list of the existing servers.

A custom controller implements the checks that must be performed against the resource to check if its state should be corrected using the API. In the case of MariaDB, some reasonable checks would be verifying that it accepts connections, replication is running, and a server is (or is not) read only.

MariaDB Operator

mariadb-operator is a Kubernetes operator that allows you to run and operate MariaDB in a cloud native way. It aims for declaratively managing your MariaDB using Kubernetes CRDs rather than imperative commands.

It's available in both Artifact Hub and Operator Hub and supports the following features:

- Provisioning highly configurable MariaDB servers
- Multiple HA modes supported: SemiSync Replication and Galera. Automatic primary failover.
- Take and restore backups. Scheduled backups. Backup rotation
- PVCs and Kubernetes volumes (i.e. NFS) backup storage
- Bootstrap new instances from backups and volumes (i.e NFS)
- Manage users, grants and logical databases
- Configure connections for your applications
- Orchestrate and schedule sql scripts
- Prometheus metrics
- Validation webhooks to provide CRD inmutability
- Additional printer columns to report the current CRD status
- CRDs designed according to the Kubernetes API conventions
- GitOps friendly
- Multi-arch distroless based image
- Install it using kubectl, helm or OLM

This operator is open source and released under the terms of the MIT license. The source code is available on GitHub.

Other Operators

If you know about other MariaDB operators, feel free to add them to this page (see Writing and Editing Knowledge Base Articles).

MySQL and Percona Server operators should work as well, though some changes may be necessary to fix incompatibilities or take advantage of certain MariaDB features.

Content initially contributed by Vettabase Ltd.

2.1.2.14.10 Automating Upgrades with MariaDB.Org Downloads REST API

The MariaDB Foundation maintains a Downloads REST API. See the Downloads API documentation to find out all the tasks that you can accomplish with this API. Generally speaking, we can say that it provides information about MariaDB products and available versions. This allows to easily automate upgrades for MariaDB and related products.

The Downloads API exposes HTTPS endpoints that return information in JSON format. HTTP and JSON are extremely common standards that can be easily used with any programming language. All the information provided by the API is public, so no authentication is required.

How to Use the API with a Unix Shell

Linux shells are great for writing simple scripts. They are compatible to each other to some extent, so simple scripts can be run on almost any Unix/Linux system. In the following examples we'll use Bash.

On Linux, some programs you'll generally need to work with any REST API are:

- curl, to call HTTP URLs and get their output.
- js, to extract or transform information from a JSON document.

Example: Check When a New Version Becomes GA

A trivial use case is to write a script that checks the list of MariaDB GA major versions and, when something changes, send us an email. So we can test the newest GA version and eventually install it.

The script in this example will be extremely simple. We'll do it this way:

- Retrieve the JSON object describing all MariaDB versions.
- For each element of the array, only show the `release_id` and `release_status` properties, and concatenate them.
- Apply a filter, so we only select the rows containing 'stable' but not 'old' (so we exclude 'Old Stable').
- From the remaining rows, only show the first column (the version number).
- If the results we obtained are different from the previously written file (see last point) send an email.
- Save the results into a file.

This is something that we can easily do with a Unix shell:

```
#!/bin/bash

current_ga_versions=$(
    curl https://downloads.mariadb.org/rest-api/mariadb/ | \
    jq -r '.major_releases[] | .release_id + " " + .release_status' | \
    grep -i 'stable' | grep -vi 'old' | \
    cut -d ' ' -f 1
)

# create file if it doesn't exist, then compare version lists
touch ga_versions
previous_ga_versions=$( cat ga_versions )

echo "$current_ga_versions" > ga_versions

if [ "$current_ga_versions" != "$previous_ga_versions" ];
then
    mail -s 'NOTE: New MariaDB GA Versions' devops@example.com <<< 'There seems to be a new
MariaDB GA version! Yay!'
fi
```

The only non-standard command here is jq. It is a great way to manipulate JSON documents, so if you don't know it you may want to take a look at jq documentation.

How to Use the API with a Python Script

To use the API with Python, we need a module that is able to send HTTP requests and parse a JSON output. The `requests` module has both these features. It can be installed as follows:

```
pip install requests
```

The following script prints stable versions to the standard output:

```
#!/usr/bin/env python

import requests

response = requests.get('https://downloads.mariadb.org/rest-api/mariadb/').json()

for x in response['major_releases']:
    if x['release_status'] == 'Stable':
        print(x['release_id'])
```

`requests.get()` makes an HTTP call of type GET, and `requests.json()` returns a dictionary representing the previously obtained JSON document.

Content initially contributed by Vettabase Ltd.

2.1.2.14.11 HashiCorp Vault and MariaDB

Vault is open source software for secret management provided by HashiCorp. It is designed to avoid sharing secrets of various types, like passwords and private keys. When building automation, Vault is a good solution to avoid storing secrets in plain text in a repository.

MariaDB and Vault may relate to each other in several ways:

- MariaDB has a Hashicorp Key Management plugin, to manage and rotate SSH keys.
- Users passwords can be stored in Vault.
- MariaDB (and MySQL) can be used as a secret engine, a component which stores, generates, or encrypts data.
- MariaDB (and MySQL) can be used as a backend storage, providing durability for Vault data.

For information about how to install Vault, see Install Vault, as well as MySQL/MariaDB Database Secrets Engine.

Contents

Vault Features

Vault is used via an HTTP/HTTPS API.

Vault is identity-based. Users login and Vault sends them a token that is valid for a certain amount of time, or until certain conditions occur. Users with a valid token may request to obtain secrets for which they have proper permissions.

Vault encrypts the secrets it stores.

Vault can optionally audit changes to secrets and secrets requests by the users.

Vault Architecture

Vault is a server. This allows decoupling the secrets management logic from the clients, which only need to login and keep a token until it expires.

The sever can actually be a cluster of servers, to implement high availability.

The main Vault components are:

- **Storage Backed**: This is where the secrets are stored. Vault only send encrypted data to the backend storage.
- **HTTP API**: This API is used by the clients, and provides an access to Vault server.
- **Barrier**: Similarly to an actual barrier, it protects all inner Vault components. The HTTP API and the storage backend are outside of the barrier and could be accessed by anyone. All communications from and to these components have to pass through the barrier. The barrier verifies data and encrypts it. The barrier can have two states: *sealed* or *unsealed*. Data can only pass through when the barrier is unsealed. All the following components are located inside the barrier.
- **Auth Method**: Handles login attempts from clients. When a login succeeds, the auth method returns a list of security policies to Vault core.
- **Token Store**: Here the tokens generated as a result of a succeeded login are stored.
- **Secrets Engines**: These components manage secrets. They can have different levels of complexity. Some of them simply expect to receive a key, and return the corresponding secret. Others may generate secrets, including one-time-passwords.
- **Audit Devices**: These components log the requests received by Vault and the responses sent back to the clients.There may be multiple devices, in which case an **Audit Broker** sends the request or response to the proper device.

Dev Mode

It is possible to start Vault in dev mode:

```
vault server -dev
```

Dev mode is useful for learning Vault, or running experiments on some particular features. It is extremely insecure, because dev mode is equivalent to starting Vault with several insecure options. This means that Vault should never run in production in dev mode. However, this also means that all the regular Vault features are available in dev mode.

Dev mode simplifies all operations. Actually, no configuration is necessary to get Vault up and running in dev mode. It makes it possible to communicate with the Vault API from the shell without any authentication. Data is stored in memory by default. Vault is unsealed by default, and if explicitly sealed, it can be unsealed using only one key.

For more details, see "Dev" Server Mode in Vault documentation.

2.1.2.14.12 Orchestrator Overview

Orchestrator is a MySQL and MariaDB high availability and replication management tool. It is released by Shlomi Noach under the terms of the Apache License, version 2.0.

Orchestrator provides automation for MariaDB replication in the following ways:

- It can be used to perform certain operations, like repairing broken replication or moving a replica from one master to another. These operations can be requested using CLI commands, or via the GUI provided with Orchestrator. The actual commands sent to MariaDB are automated by Orchestrator, and the user doesn't have to worry about the details.
- Orchestrator can also automatically perform a failover in case a master crashes or is unreachable by its replicas. If that is the case, Orchestrator will promote one of the replicas to a master. The replica to promote is chosen based on several criteria, like the server versions, the binary log formats in use and the datacenters locations.

Note that, if we don't want to use Orchestrator to automate operations, we can still use it as a dynamic inventory. Other tools can use it to obtain a list of existing MariaDB servers via its REST API or CLI commands.

Orchestrator has several big users, listed in the documentation Users page. It is also included in the PMM monitoring solution.

To install Orchestrator, see:

- The install.md for a manual installation;
- The links in README.md, to install Orchestrator using automation tools.

Contents

Supported Topologies

Currently, Orchestrator fully supports MariaDB GTID, replication, and semi-synchronous replication. While Orchestrator does not support Galera specific logic, it works with Galera clusters. For details, see Supported Topologies and Versions in Orchestrator documentation.

Architecture

Orchestrator consists of a single executable called `orchestrator`. This is a process that periodically connects to the target servers. It will run SQL queries against target servers, so it needs a user with proper permissions. When the process is running, a GUI is available via a web browser, at the URL 'https://localhost:3000'. It also exposes a REST API (see Using the web API in the Orchestrator documentation).

Orchestrator expects to find a JSON configuration file called `orchestrator.conf.json`, in `/etc`.

A database is used to store the configuration and the state of the target servers. By default, this is done using built-in SQLite. However, it is possible to use an external MariaDB or MySQL server instance.

If a cluster of Orchestrator instances is running, only one central database is used. One Orchestrator node is active, while the others are passive and are only used for failover. If the active node crashes or becomes unreachable, one of the other nodes becomes the active instance. The `active_node` table shows which node is active. Nodes communicate between them using the Raft protocol.

CLI Examples

As mentioned, Orchestrator can be used from the command-line. Here you can find some examples.

List clusters:

```
orchestrator -c clusters
```

Discover a specified instance and add it to the known topology:

```
orchestrator -c discover -i <host>:<port>
```

Forget about an instance:

```
orchestrator -c topology -i <host>:<port>
```

Move a replica to a different master:

```
orchestrator -c move-up -i <replica-host>:<replica-port> -d <master-host>:<master-port>
```

Move a replica up, so that it becomes a "sibling" of its master:

```
orchestrator -c move-up -i <replica-host>:<replica-port>
```

Move a replica down, so that it becomes a replica of its"sibling":

```
orchestrator -c move-below -i <replica-host>:<replica-port> -d <master-host>:<master-port>
```

Make a node read-only:

```
orchestrator -c set-read-only -i <host>:<port>
```

Make a node writeable:

```
orchestrator -c set-writeable -i <host>:<port>
```

The `--debug` and `--stack` options can be added to the above commands to make them more verbose.

Orchestrator Resources and References

- Orchestrator on GitHub.
- Documentation.
- Raft consensus protocol website.

The README.md file lists some related community projects, including modules to automate Orchestrator with Puppet and other technologies.

On GitHub you can also find links to projects that allow the use of automation software to deploy and manage Orchestrator.

Content initially contributed by Vettabase Ltd.

2.4.6 Rotating Logs on Unix and Linux

2.1.2.14.14 Automating MariaDB Tasks with Events

MariaDB has an event scheduler that can be used to automate tasks, making them run at regular intervals of time. This page is about using events for automation. For more information about events themselves, and how to work with them, see event scheduler.

Pros and Cons of Using Events for Automation

Events can be compared to Unix cron jobs or Windows scheduled tasks. MariaDB events have at least the following benefits compared to those tools:

- Events are system-independent. The same code can run on any system.
- Events are written in procedural SQL. There is no need to install other languages or libraries.
- If you use user-defined functions, you can still take advantage of them in your events.
- Events run in MariaDB. An implication, for example, is that the results of queries remain in MariaDB itself and are not sent to a client. This means that network glitches don't affect events, there is no overhead due to data roundtrip, and therefore locks are held for a shorter time.

Some drawbacks of using events are the following:

- Events can only perform tasks that can be developed in SQL. So, for example, it is not possible to send alerts. Access to files or remote databases is limited.
- The event scheduler runs as a single thread. This means that events that are scheduled to run while another event is running will wait until the other event has stopped. This means that there is no guarantee that an event will run on exactly it's scheduled time. This should not be a problem as long as one ensures that events are short lived.
- For more events limitations, see Event Limitations.

In many cases you may prefer to develop scripts in an external programming language. However, you should know that simple tasks consisting of a few queries can easily be implemented as events.

Good Practices

When using events to automate tasks, there are good practices one may want to follow.

Move your SQL code in a stored procedure. All the event will do is to call a stored procedures. Several events may call the same stored procedure, maybe with different parameters. The procedure may also be called manually, if necessary. This will avoid code duplication. This will separate the logic from the schedule, making it possible to change an event without a risk of making changes to the logic, and the other way around.

Just like cron jobs, events should log whether if they succeed or not. Logging debug messages may also be useful for non-trivial events. This information can be logged into a dedicated table. The contents of the table can be monitored by a monitoring tool like Grafana. This allows to visualize in a dashboard the status of events, and send alerts in case of a failure.

Examples

Some examples of tasks that could easily be automated with events:

- Copying data from a remote table to a local table by night, using the CONNECT storage engine. This can be a good idea if many rows need be copied, because data won't be sent to an external client.
- Periodically delete historical data. For example, rows that are older than 5 years. Nothing prevents us from doing this with an external script, but probably this wouldn't add any value.
- Periodically delete invalid rows. In an e-commerce, they could be abandoned carts. In a messaging system, they could be messages to users that don't exist anymore.
- Add a new partition to a table and drop the oldest one (partition rotation).

2.1.2.15 MariaDB Package Repository Setup and Usage

If you are looking to set up MariaDB Server, it is often easiest to use a repository. The MariaDB Foundation has a repository configuration tool at https://mariadb.org/download/ and MariaDB Corporation provides a convenient shell script to configure access to their MariaDB Package Repositories. It is available at:

- https://r.mariadb.com/downloads/mariadb_repo_setup

The script by default sets up 3 different repositories in a single repository configuration file. The repositories are

- MariaDB Server Repository
- MariaDB MaxScale Repository
- MariaDB Tools Repository

The script can be executed in the following way:

```
curl -LsS https://r.mariadb.com/downloads/mariadb_repo_setup | sudo bash
```

For the script to work, the `curl` and `ca-certificates` packages need to be installed on your system. Additionally on Debian and Ubuntu the `apt-transport-https` package needs to be installed. The script will check if these are installed and let you know before it attempts to create the repository configuration on your system.

Contents

Repositories

The script will will set up 2 different repositories in a single repository configuration file.

MariaDB Repository

The **MariaDB Repository** contains software packages related to MariaDB Server, including the server itself, clients and utilities, client libraries, plugins, and Mariabackup.

The binaries in MariaDB Corporation's **MariaDB Repository** are currently identical to the binaries in MariaDB Foundation's MariaDB Repository that is configured with the MariaDB Repository Configuration Tool.

By default, the script will configure your system to install from the repository of the latest GA version of MariaDB. That is currently MariaDB 10.7. If a new major GA release occurs and you would like to upgrade to it, then you will need to either manually edit the repository configuration file to point to the new version, or run the MariaDB Package Repository setup script again.

The script can also configure your system to install from the repository of a different version of MariaDB if you use the `--mariadb-server-version` option.

If you would not like to configure the **MariaDB Repository** on your system, then you can use the `--skip-server` option to prevent the MariaDB Package Repository setup script from configuring it.

MariaDB MaxScale Repository

The **MariaDB MaxScale Repository** contains software packages related to MariaDB MaxScale.

By default, the script will configure your system to install from the repository of the *latest* GA version of MariaDB MaxScale. When a new major GA release occurs, the repository will automatically switch to the new version. If instead you would like to stay on a particular version you will need to manually edit the repository configuration file and change ' `latest` ' to the version you want (e.g. ' `6.1` ') or run the MariaDB Package Repository setup script again, specifying the particular version or series you want.

Older versions of the MariaDB Package Repository setup script would configure a specific MariaDB MaxScale series in the repository (i.e. '`2.4`'), so if you used the script in the past to set up your repository and want MariaDB MaxScale to automatically use the latest GA version then change '`2.4`' or '`2.3`' in the repository configuration to '`latest`'. Or download the current version of the script and re-run it to set up the repository again.

The script can configure your system to install from the repository of an older version of MariaDB MaxScale if you use the `--mariadb-maxscale-version` option. For example, `--mariadb-maxscale-version=2.4` if you want the latest release in the MariaDB MaxScale 2.4.x series.

If you do not want to configure the **MariaDB MaxScale Repository** on your system, then you can use the `--skip-maxscale` option to prevent the MariaDB Package Repository setup script from configuring it.

MariaDB MaxScale is licensed under the Business Source License 1.1, so it is not entirely free to use for organizations who do not have a subscription with MariaDB Corporation. If you would like more information, see the information at MariaDB Business Source License (BSL): Frequently Asked Questions. If you would like to know how much a subscription to use MariaDB MaxScale would cost, see MariaDB Corporation's subscription pricing.

Supported Distributions

The script supports Linux distributions that are officially supported by MariaDB Corporation's MariaDB TX subscription. However, a MariaDB TX subscription with MariaDB Corporation is not required to use the MariaDB Package Repository.

The distributions currently supported by the script include:

- Red Hat Enterprise Linux (RHEL) 7 and 8
- CentOS 7
- Debian 10 (Buster), 11 (Bullseye), 12 (Bookworm)
- Ubuntu 18.04 LTS (Bionic), and 20.04 LTS (Focal)
- SUSE Linux Enterprise Server (SLES) 12 and 15

To install MariaDB on distributions not supported by the MariaDB Package Repository setup script, please consider using MariaDB Foundation's MariaDB Repository Configuration Tool. Some Linux distributions also include MariaDB in their own repositories.

Using the MariaDB Package Repository Setup Script

The script can be executed in the following way:

```
curl -LsS https://r.mariadb.com/downloads/mariadb_repo_setup | sudo bash
```

The script will have to set up package repository configuration files, so it will need to be executed as root.

The script will also install the GPG public keys used to verify the signature of MariaDB software packages. If you want to avoid that, then you can use the `--skip-key-import` option.

If the script tries to create the repository configuration file and one with that name already exists, then the script will rename the existing file with an extension in the format ".old_[0-9]+", which would make the OS's package manager ignore the file. You can safely remove those files after you have confirmed that the updated repository configuration file works..

If you want to see the repository configuration file that would be created without actually doing so, then you can use the `--write-to-stdout` option. This also prevents the need to run the script as root,

If you want to download the script, rather than executing it, then you can do so in the following way:

```
curl -LO https://r.mariadb.com/downloads/mariadb_repo_setup
```

Options

To provide options to the script, you must tell bash to expect them by executing bash with the options `-s --`, for example:

```
curl -LsS https://r.mariadb.com/downloads/mariadb_repo_setup | sudo bash -s -- --help
```

Option	Description
`--help`	Display a usage message and exit.

`--mariadb-server-version=<version>`	Override the default MariaDB Server version.
`--mariadb-maxscale-version=<version>`	Override the default MariaDB MaxScale version. By default, the script will use 'latest'.
`--os-type=<type>`	Override detection of OS type. Acceptable values include `debian`, `ubuntu`, `rhel`, and `sles`.
`--os-version=<version>`	Override detection of OS version. Acceptable values depend on the OS type you specify.
`--skip-key-import`	Skip importing GPG signing keys.
`--skip-maxscale`	Skip the 'MaxScale' repository.
`--skip-server`	Skip the 'MariaDB Server' repository.
`--skip-tools`	Skip the 'Tools' repository.
`--skip-verify`	Skip verification of MariaDB Server versions. Use with caution as this can lead to an invalid repository configuration file being created.
`--skip-check-installed`	Skip tests for required prerequisites for this script.
`--skip-eol-check`	Skip tests for versions being past their EOL date
`--skip-os-eol-check`	Skip tests for operating system versions being past EOL date
`--write-to-stdout`	Write output to stdout instead of to the OS's repository configuration file. This will also skip importing GPG public keys and updating the package cache on platforms where that behavior exists.

`--mariadb-server-version`

By default, the script will configure your system to install from the repository of the latest GA version of MariaDB. If a new major GA release occurs and you would like to upgrade to it, then you will need to either manually edit the repository configuration file to point to the new version, or run the MariaDB Package Repository setup script again.

The script can also configure your system to install from the repository of a different version of MariaDB if you use the `--mariadb-server-version` option.

The string `mariadb-` has to be prepended to the version number. For example, to configure your system to install from the repository of MariaDB 10.6, that would be:

```
curl -LsS https://r.mariadb.com/downloads/mariadb_repo_setup | sudo bash -s -- --mariadb-server-version="mariadb-10.6"
```

The following MariaDB versions are currently supported:

- `mariadb-10.4`
- `mariadb-10.5`
- `mariadb-10.6`
- `mariadb-10.10`
- `mariadb-10.11`
- `mariadb-11.0`
- `mariadb-11.1`
- `mariadb-11.2`

If you want to pin the repository of a specific minor release, such as MariaDB 10.6.14, then you can also specify the minor release. For example, `mariadb-10.6.14`. This may be helpful if you want to avoid upgrades. However, avoiding upgrades is not recommended, since minor maintenance releases may contain important bug fixes and fixes for security vulnerabilities.

`--mariadb-maxscale-version`

By default, the script will configure your system to install from the repository of the latest GA version of MariaDB MaxScale.

If you would like to pin the repository to a specific version of MariaDB MaxScale then you will need to either manually edit the repository configuration file to point to the desired version, or use the `--mariadb-maxscale-version` option.

For example, to configure your system to install from the repository of MariaDB MaxScale 6.1, that would be:

```
curl -LsS https://r.mariadb.com/downloads/mariadb_repo_setup | sudo bash -s -- --mariadb-
maxscale-version="6.1"
```

The following MariaDB MaxScale versions are currently supported:

- MaxScale 1.4
- MaxScale 2.0
- MaxScale 2.1
- MaxScale 2.2
- MaxScale 2.3
- MaxScale 2.4
- MaxScale 2.5
- MaxScale 6.1
- MaxScale 6.2

The special identifiers `latest` (for the latest GA release) and `beta` (for the latest beta release) are also supported. By default the `mariadb_repo_setup` script uses `latest` as the version.

`--os-type` and `--os-version`

If you want to run this script on an unsupported OS that you believe to be package-compatible with an OS that is supported, then you can use the `--os-type` and `--os-version` options to override the script's OS detection. If you use either option, then you must use both options.

The supported values for `--os-type` are:

- `rhel`
- `debian`
- `ubuntu`
- `sles`

If you use a non-supported value, then the script will fail, just as it would fail if you ran the script on an unsupported OS.

The supported values for `--os-version` are entirely dependent on the OS type.

For Red Hat Enterprise Linux (RHEL) and CentOS, `7` and `8` are valid options.

For Debian and Ubuntu, the version must be specified as the codename of the specific release. For example, Debian 9 must be specified as `stretch`, and Ubuntu 18.04 must be specified as `bionic`.

These options can be useful if your distribution is a fork of another distribution. As an example, Linux Mint 8.1 is based on and is fully compatible with Ubuntu 16.04 LTS (Xenial). Therefore, If you are using Linux Mint 8.1, then you can configure your system to install from the repository of Ubuntu 16.04 LTS (Xenial). If you would like to do that, then you can do so by specifying `--os-type=ubuntu` and `--os-version=xenial` to the MariaDB Package Repository setup script.

For example, to manually set the `--os-type` and `--os-version` to RHEL 8 you could do:

```
curl -LsS https://r.mariadb.com/downloads/mariadb_repo_setup | sudo bash -s -- --os-type=rhel -
-os-version=8
```

`--write-to-stdout`

The `--write-to-stdout` option will prevent the script from modifying anything on the system. The repository configuration will not be written to the repository configuration file. Instead, it will be printed to standard output. That allows the configuration to be reviewed, redirected elsewhere, consumed by another script, or used in some other way.

The `--write-to-stdout` option automatically enables `--skip-key-import`.

For example:

```
curl -LsS https://r.mariadb.com/downloads/mariadb_repo_setup | sudo bash -s -- --write-to-
stdout
```

Platform-Specific Behavior

Platform-Specific Behavior on RHEL and CentOS

On Red Hat Enterprise Linux (RHEL) and CentOS, the MariaDB Package Repository setup script performs the following

tasks:

1. Creates a repository configuration file at `/etc/yum.repos.d/mariadb.repo`.
2. Imports the GPG public key used to verify the signature of MariaDB software packages with `rpm --import` from `downloads.mariadb.com`.

Platform-Specific Behavior on Debian and Ubuntu

On Debian and Ubuntu, the MariaDB Package Repository setup script performs the following tasks:

1. Creates a repository configuration file at `/etc/apt/sources.list.d/mariadb.list`.
2. Creates a package preferences file at `/etc/apt/preferences.d/mariadb-enterprise.pref`, which gives packages from MariaDB repositories a higher priority than packages from OS and other repositories, which can help avoid conflicts. It looks like the following:

   ```
   Package: *
   Pin: origin downloads.mariadb.com
   Pin-Priority: 1000
   ```

3. Imports the GPG public key used to verify the signature of MariaDB software package with `apt-key` from the `keyserver.ubuntu.com` key server.
4. Updates the package cache with package definitions from the MariaDB Package Repository with `apt-get update`.

Platform-Specific Behavior on SLES

On SUSE Linux Enterprise Server (SLES), the MariaDB Package Repository setup script performs the following tasks:

1. Creates a repository configuration file at `/etc/zypp/repos.d/mariadb.repo`.
2. Imports the GPG public key used to verify the signature of MariaDB software packages with `rpm --import` from `downloads.mariadb.com`.

Installing Packages with the MariaDB Package Repository

After setting up the MariaDB Package Repository, you can install the software packages in the supported repositories.

Installing Packages on RHEL and CentOS

To install MariaDB on Red Hat Enterprise Linux (RHEL) and CentOS, see the instructions at Installing MariaDB Packages with YUM. For example:

```
sudo yum install MariaDB-server MariaDB-client MariaDB-backup
```

To install MariaDB MaxScale on Red Hat Enterprise Linux (RHEL) and CentOS, see the instructions at MariaDB MaxScale Installation Guide. For example:

```
sudo yum install maxscale
```

Installing Packages on Debian and Ubuntu

To install MariaDB on Debian and Ubuntu, see the instructions at Installing MariaDB Packages with APT. For example:

```
sudo apt-get install mariadb-server mariadb-client mariadb-backup
```

To install MariaDB MaxScale on Debian and Ubuntu, see the instructions at MariaDB MaxScale Installation Guide. For example:

```
sudo apt-get install maxscale
```

Installing Packages on SLES

To install MariaDB on SUSE Linux Enterprise Server (SLES), see the instructions at Installing MariaDB Packages with

ZYpp. For example:

```
sudo zypper install MariaDB-server MariaDB-client MariaDB-backup
```

To install MariaDB MaxScale on SUSE Linux Enterprise Server (SLES), see the instructions at MariaDB MaxScale Installation Guide. For example:

```
sudo zypper install maxscale
```

2.1.3.1 Upgrading Between Major MariaDB Versions

Contents

MariaDB is designed to allow easy upgrades. You should be able to trivially upgrade from ANY earlier MariaDB version to the latest one (for example MariaDB 10.3.x to MariaDB 10.11.x), usually in a few seconds. This is also mainly true for any MySQL version < 8.0 to MariaDB 10.4 and up.

Upgrades are normally easy because:

- All MariaDB table data files are backward compatible
- The MariaDB connection protocol is backward compatible. You don't normally need to upgrade any of your old clients to be able to connect to a newer MariaDB version.
- The MariaDB replica can be of any newer version than the primary.

MariaDB Corporation regularly runs tests to check that one can upgrade from MariaDB 5.5 to the latest MariaDB version without any trouble. All older versions should work too (as long as the storage engines you were using are still around).

Note that if you are using MariaDB Galera Cluster, you have to follow the Galera upgrading instructions!

Requirements for Doing an Upgrade Between Major Versions

- Go through the individual version upgrade notes (listed below) to look for any major changes or configuration options that have changed.
- Ensure that the target MariaDB version supports the storage engines you are using. For example, in 10.5 TokuDB is not supported.
- Backup the database (just in case). At least, take a copy of the `mysql` data directory with mariadb-dump --add-drop-table mysql (called mysqldump in MariaDB 10.3 and earlier) as most of the upgrade changes are done there (adding new fields and new system tables etc).
- Cleanly shutdown the server. This is necessary because even if data files are compatible between versions, recovery logs may not be.
    - Ensure that the innodb_fast_shutdown variable is not 2 (fast crash shutdown) or 3. The default of this variable is 1. The safest and recommended option for upgrades is 0. The shutdown time may be notably larger with 0

than for 1 as there are a lot more cleanups done for 0, however when preparing for an upgrade this should not be an issue.
    - innodb_force_recovery must be less than `3`.

Note that rpms don't support upgrading between major versions, only minor like 10.4.1 to 10.4.2. If you are using rpms, you should de-install the old MariaDB rpms and install the new MariaDB rpms before running mariadb-upgrade. Note that when installing the new rpms, mariadb-upgrade may be run automatically. There is no problem with running mariadb-upgrade many times.

Recommended Steps

- If you have a primary-replica setup, first upgrade one replica and when you have verified that the replica works well, upgrade the rest of the replicas (if any). Then upgrade one replica to primary, upgrade the primary, and change the replica to a primary.
- If you don't have a primary-replica setup, then take a backup, shutdown MariaDB and do the upgrade.

Step by Step Instructions for Upgrades

- Upgrade MariaDB binaries and libraries, preferably without starting MariaDB.
- If the MariaDB server process, mysqld or mariadbd was not started as part of the upgrade, start it by executing `mysqld --skip-grant-tables`. This may produce some warnings about some system tables not being up to date, but you can ignore these for now as mariadb-upgrade will fix that.
- Run mariadb-upgrade
- Restart MariaDB server.

Work Done by mariadb-upgrade

The main work done when upgrading is done by running mariadb-upgrade. The main things it does are:

- Updating the system tables in the `mysql` database to the newest version. This is very quick.
- mariadb-upgrade also runs mariadb-check --check-upgrade to check if there have been any collation changes between the major versions. This recreates indexes in old tables that are using any of the changed collations. This can take a bit of time if there are a lot of tables or there are many tables which used the changed collation. The last time a collation changed was in MariaDB/MySQL 5.1.23.

Post Upgrade Work

Check the MariaDB error log for any problems during upgrade. If there are any warnings in the log files, do your best to get rid of them!

The common warnings/errors are:

- Using obsolete options. If this is the case, remove them from your my.cnf files.
- Check the manual for new features that have been added since your last MariaDB version.
- Test that your application works as before. The main difference from before is that because of optimizer improvements your application should work better than before, but in some rare cases the optimizer may get something wrong. In this case, you can try to use explain, optimizer trace or optimizer_switch to fix the queries.

If Something Goes Wrong

- First, check the MariaDB error log to see if you are using configure options that are not supported anymore.
- Check the upgrade notices for the MariaDB release that you are upgrading to.
- File an issue in the MariaDB bug tracker so that we know about the issue and can provide a fix to make upgrades even better.
- Add a comment to this manual entry for how we can improve it.

Disaster Recovery

In the unlikely event something goes wrong, you can try the following:

- Remove the InnoDB tables from the `mysql` data directory. They are:
    - gtid_slave_pos
    - innodb_table_stats
    - innodb_index_stats
    - transaction_registry

- Move the `mysql` data directory to `mysql-old` and run mariadb-install-db to generate a new one.
- After the above, you have to add back your old users.
- When done, delete the `mysql-old` data directory.

Downgrading

MariaDB server is not designed for downgrading. That said, in most cases, as long as you haven't run any ALTER TABLE or CREATE TABLE statements and you have a mariadb-dump of your old `mysql` database , you should be able to downgrade to your previous version by doing the following:

- Do a clean shutdown. For this special case you have to set innodb_fast_shutdown to 0,before taking down the new MariaDB server, to ensure there are no redo or undo logs that need to be applied on the downgraded server.
- Delete the tables in the `mysql` database (if you didn't use the option `--add-drop-table` to mariadb-dump)
- Delete the new MariaDB installation
- Install the old MariaDB version
- Start the server with mysqld --skip-grant-tables
- Install the old `mysql` database
- Execute in the mariadb client `FLUSH PRIVILEGES`

2.1.3.2 Upgrading Between Minor Versions on Linux

> For Windows, see Upgrading MariaDB on Windows instead.

> For MariaDB Galera Cluster, see Upgrading Between Minor Versions with Galera Cluster instead.

> Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend Mariabackup.

To upgrade between minor versions of MariaDB on Linux/Unix (for example from MariaDB 10.11.2 to MariaDB 10.11.3), the following procedure is suggested:

1. Stop MariaDB.
2. Uninstall the old version of MariaDB.
3. Install the new version of MariaDB.
    - On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
    - On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
    - On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.
4. Make any desired changes to configuration options in option files, such as `my.cnf` .
5. Start MariaDB.
6. Run mariadb-upgrade.
    - `mariadb-upgrade` does two things:
        1. Ensures that the system tables in the mysql database are fully compatible with the new version.
        2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .
    - In most cases this should be a fast operation (depending of course on the number of tables).

To upgrade between major versions, see the following:

- Upgrading Between Major MariaDB Versions
- Upgrading from MariaDB 10.6 to MariaDB 10.11
- Upgrading from MariaDB 10.5 to MariaDB 10.6
- Upgrading from MariaDB 10.4 to MariaDB 10.5
- Upgrading from MariaDB 10.3 to MariaDB 10.4
- Upgrading from MariaDB 10.2 to MariaDB 10.3

2.1.3.3 Upgrading from MariaDB 10.11 to

MariaDB 11.0

Contents

This page includes details for upgrading from MariaDB 10.11 to MariaDB 11.0. It is currently incomplete. Note that MariaDB 10.11 is maintained for five years, while MariaDB 11.0 is a short-term maintenance release, only maintained for one year.

How to Upgrade

For Windows, see Upgrading MariaDB on Windows.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend Mariabackup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 11.0. For example,
   - On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
   - On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
   - On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.
2. Stop MariaDB.
3. Uninstall the old version of MariaDB.
   - On Debian, Ubuntu, and other similar Linux distributions, execute the following:
     ```
     sudo apt-get remove mariadb-server
     ```
   - On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following:
     ```
     sudo yum remove MariaDB-server
     ```
   - On SLES, OpenSUSE, and other similar Linux distributions, execute the following:
     ```
     sudo zypper remove MariaDB-server
     ```
4. Install the new version of MariaDB.
   - On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
   - On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
   - On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.
5. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
6. Start MariaDB.
7. Run mariadb-upgrade.
   - `mariadb-upgrade` does two things:
     1. Ensures that the system tables in the mysql database are fully compatible with the new version.
     2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

Incompatible Changes Between 10.11 and 11.0

On most servers upgrading from 10.11 should be painless. However, there are some things that have changed which could affect an upgrade:

Options That Have Changed Default Values

Option	Old default	New default

innodb_undo_tablespaces	0	3
histogram_type	DOUBLE_PREC_HB	JSON_HB

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files:

Option	Reason
innodb_change_buffer_max_size	InnoDB Change Buffer removed
innodb_change_buffering	InnoDB Change Buffer removed

Deprecated Options

The following options have been deprecated. They have not yet been removed, but will be in a future version, and should ideally no longer be used.

Option	Reason
innodb_defragment	InnoDB Defragmentation is not particularly useful and causes a maintenance burden.
innodb_defragment_n_pages	
innodb_defragment_stats_accuracy	
innodb_defragment_fill_factor_n_recs	
innodb_defragment_fill_factor	
innodb_defragment_frequency	
innodb_file_per_table	
innodb_flush_method	
innodb_file_per_table	Has been set for many releases. Unsetting (the original InnoDB default) is no longer useful)
innodb_flush_method	Mapped it to 4 new boolean parameters that can be changed while the server is running

2.1.3.4 Upgrading from MariaDB 10.6 to MariaDB 10.11

Contents

This page includes details for upgrading from MariaDB 10.6 to the subsequent long-term maintenance version, MariaDB 10.11. It is currently incomplete.

How to Upgrade

For Windows, see Upgrading MariaDB on Windows.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend Mariabackup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 10.11. For example,
   - On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
   - On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
   - On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.
2. Stop MariaDB.
3. Uninstall the old version of MariaDB.
   - On Debian, Ubuntu, and other similar Linux distributions, execute the following:
     ```
     sudo apt-get remove mariadb-server
     ```
   - On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following:
     ```
     sudo yum remove MariaDB-server
     ```
   - On SLES, OpenSUSE, and other similar Linux distributions, execute the following:
     ```
     sudo zypper remove MariaDB-server
     ```
4. Install the new version of MariaDB.
   - On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
   - On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
   - On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.
5. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
6. Start MariaDB.
7. Run mariadb-upgrade.
   - `mariadb-upgrade` does two things:
     1. Ensures that the system tables in the mysql database are fully compatible with the new version.
     2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

Incompatible Changes Between 10.6 and 10.11

On most servers upgrading from 10.6 should be painless. However, there are some things that have changed which could affect an upgrade:

Compression

If a non-zlib compression algorithm was used in InnoDB or Mroonga before upgrading to 10.11, those tables will be unreadable until the appropriate compression library is installed. See Compression Plugins#Upgrading.

Options That Have Changed Default Values

Option	Old default	New default
innodb_buffer_pool_chunk_size	134217728	Autosized
spider_auto_increment_mode	-1	0
spider_bgs_first_read	-1	2
spider_bgs_mode	-1	0
spider_bgs_second_read	-1	100
spider_bka_mode	-1	1
spider_bka_table_name_type	-1	1
spider_buffer_size	-1	16000
spider_bulk_size	-1	16000
spider_bulk_update_mode	-1	0
spider_bulk_update_size	-1	16000
spider_casual_read	-1	0
spider_connect_timeout	-1	6

spider_crd_bg_mode	-1	2
spider_crd_interval	-1	51
spider_crd_mode	-1	1
spider_crd_sync	-1	0
spider_crd_type	-1	2
spider_crd_weight	-1	2
spider_delete_all_rows_type	-1	1
spider_direct_dup_insert	-1	0
spider_direct_order_limit	-1	9223372036854775807
spider_error_read_mode	-1	0
spider_error_write_mode	-1	0
spider_first_read	-1	0
spider_init_sql_alloc_size	-1	1024
spider_internal_limit	-1	9223372036854775807
spider_internal_offset	-1	0
spider_internal_optimize	-1	0
spider_internal_optimize_local	-1	0
spider_load_crd_at_startup	-1	1
spider_load_sts_at_startup	-1	1
spider_low_mem_read	-1	1
spider_max_order	-1	32767
spider_multi_split_read	-1	100
spider_net_read_timeout	-1	600
spider_net_write_timeout	-1	600
spider_quick_mode	-1	3
spider_quick_page_byte	-1	10485760
spider_quick_page_size	-1	1024
spider_read_only_mode	-1	0
spider_reset_sql_alloc	-1	1
spider_second_read	-1	0
spider_selupd_lock_mode	-1	1
spider_semi_split_read	-1	2
spider_semi_split_read_limit	-1	1
spider_semi_table_lock_connection	-1	1
spider_semi_table_lock	1	0

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files:

Option	Reason
innodb_log_write_ahead_size	On Linux and Windows, the physical block size of the underlying storage is instead detected and used.
innodb_version	Redundant
wsrep_replicate_myisam	Use wsrep_mode instead.

wsrep_strict_ddl	Use wsrep_mode instead.

Deprecated Options

The following options have been deprecated. They have not yet been removed, but will be in a future version, and should ideally no longer be used.

Option	Reason
keep_files_on_create	MariaDB now deletes orphan files, so this setting should never be necessary.

2.1.3.5 Upgrading from MariaDB 10.7 to MariaDB 10.8

Contents

Note that MariaDB 10.8 is only maintained for one year. MariaDB 10.6 is currently the latest long-term maintenance release.

How to Upgrade

For Windows, see Upgrading MariaDB on Windows.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend Mariabackup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 10.8. For example,
   - On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
   - On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
   - On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.
2. Stop MariaDB.
3. Uninstall the old version of MariaDB.
   - On Debian, Ubuntu, and other similar Linux distributions, execute the following:
     ```
     sudo apt-get remove mariadb-server
     ```
   - On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following:
     ```
     sudo yum remove MariaDB-server
     ```
   - On SLES, OpenSUSE, and other similar Linux distributions, execute the following:
     ```
     sudo zypper remove MariaDB-server
     ```
4. Install the new version of MariaDB.
   - On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
   - On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
   - On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.
5. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
6. Start MariaDB.
7. Run mariadb-upgrade.

- `mariadb-upgrade` does two things:
  1. Ensures that the system tables in the mysql database are fully compatible with the new version.
  2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

Incompatible Changes Between 10.7 and 10.8

On most servers upgrading from 10.7 should be painless. However, there are some things that have changed which could affect an upgrade:

Options That Have Changed Default Values

Option	Old default value	New default value
innodb_buffer_pool_chunk_size	134217728	Autosized
spider_semi_table_lock	1	0

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files:

Option	Reason
innodb_log_write_ahead_size	On Linux and Windows, the physical block size of the underlying storage is instead detected and used.

Deprecated Options

The following options have been deprecated. They have not yet been removed, but will be in a future version, and should ideally no longer be used.

Option	Reason
keep_files_on_create	MariaDB now deletes orphan files, so this setting should never be necessary.

Major New Features To Consider

You might consider using the following major new features in MariaDB 10.8:

- Stored procedures already have support for the IN, OUT and INOUT parameter qualifiers. Added as well for stored functions and (IN only) cursors (MDEV-10654).
- Individual columns in the index can now be explicitly sorted in the ascending or descending order. This can be useful for optimizing certain ORDER BY cases (MDEV-13756, MDEV-26938, MDEV-26939, MDEV-26996).
- See also System Variables Added in MariaDB 10.8.

2.1.3.6 Upgrading from MariaDB 10.6 to MariaDB 10.7

Contents

Note that MariaDB 10.7 is only maintained for one year. MariaDB 10.6 is currently the latest long-term maintenance release.

How to Upgrade

For Windows, see Upgrading MariaDB on Windows.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend Mariabackup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 10.7. For example,
   - On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
   - On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
   - On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.
2. Stop MariaDB.
3. Uninstall the old version of MariaDB.
   - On Debian, Ubuntu, and other similar Linux distributions, execute the following:
     ```
     sudo apt-get remove mariadb-server
     ```
   - On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following:
     ```
     sudo yum remove MariaDB-server
     ```
   - On SLES, OpenSUSE, and other similar Linux distributions, execute the following:
     ```
     sudo zypper remove MariaDB-server
     ```
4. Install the new version of MariaDB.
   - On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
   - On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
   - On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.
5. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
6. Start MariaDB.
7. Run mariadb-upgrade.
   - `mariadb-upgrade` does two things:
     1. Ensures that the system tables in the mysql database are fully compatible with the new version.
     2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

Incompatible Changes Between 10.6 and 10.7

On most servers upgrading from 10.6 should be painless. However, there are some things that have changed which could affect an upgrade:

Reserved Words

- ROW_NUMBER is now a reserved word.

Compression

If a non-zlib compression algorithm was used in InnoDB or Mroonga before upgrading to 10.7, those tables will be unreadable until the appropriate compression library is installed. See Compression Plugins#Upgrading.

Options That Have Changed Default Values

Option	Old default	New default
spider_auto_increment_mode	-1	0
spider_bgs_first_read	-1	2
spider_bgs_mode	-1	0
spider_bgs_second_read	-1	100
spider_bka_mode	-1	1
spider_bka_table_name_type	-1	1
spider_buffer_size	-1	16000

spider_bulk_size	-1	16000
spider_bulk_update_mode	-1	0
spider_bulk_update_size	-1	16000
spider_casual_read	-1	0
spider_connect_timeout	-1	6
spider_crd_bg_mode	-1	2
spider_crd_interval	-1	51
spider_crd_mode	-1	1
spider_crd_sync	-1	0
spider_crd_type	-1	2
spider_crd_weight	-1	2
spider_delete_all_rows_type	-1	1
spider_direct_dup_insert	-1	0
spider_direct_order_limit	-1	9223372036854775807
spider_error_read_mode	-1	0
spider_error_write_mode	-1	0
spider_first_read	-1	0
spider_init_sql_alloc_size	-1	1024
spider_internal_limit	-1	9223372036854775807
spider_internal_offset	-1	0
spider_internal_optimize	-1	0
spider_internal_optimize_local	-1	0
spider_load_crd_at_startup	-1	1
spider_load_sts_at_startup	-1	1
spider_low_mem_read	-1	1
spider_max_order	-1	32767
spider_multi_split_read	-1	100
spider_net_read_timeout	-1	600
spider_net_write_timeout	-1	600
spider_quick_mode	-1	3
spider_quick_page_byte	-1	10485760
spider_quick_page_size	-1	1024
spider_read_only_mode	-1	0
spider_reset_sql_alloc	-1	1
spider_second_read	-1	0
spider_selupd_lock_mode	-1	1
spider_semi_split_read	-1	2
spider_semi_split_read_limit	-1	1
spider_semi_table_lock_connection	-1	1
spider_reset_sql_alloc	-1	1

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files:

Option	Reason
wsrep_replicate_myisam	Use wsrep_mode instead.
wsrep_strict_ddl	Use wsrep_mode instead.

2.1.3.7 Upgrading from MariaDB 10.5 to MariaDB 10.6

Contents

How to Upgrade

For Windows, see Upgrading MariaDB on Windows.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend Mariabackup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 10.6. For example,
   - On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
   - On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
   - On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.
2. Stop MariaDB.
3. Uninstall the old version of MariaDB.
   - On Debian, Ubuntu, and other similar Linux distributions, execute the following:
     ```
     sudo apt-get remove mariadb-server
     ```
   - On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following:
     ```
     sudo yum remove MariaDB-server
     ```
   - On SLES, OpenSUSE, and other similar Linux distributions, execute the following:
     ```
     sudo zypper remove MariaDB-server
     ```
4. Install the new version of MariaDB.
   - On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
   - On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
   - On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.
5. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
6. Start MariaDB.
7. Run mariadb-upgrade.
   - `mariadb-upgrade` does two things:
     1. Ensures that the system tables in the mysql database are fully compatible with the new version.
     2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB.

Incompatible Changes Between 10.5 and 10.6

On most servers upgrading from 10.5 should be painless. However, there are some things that have changed which could

affect an upgrade:

The bahaviour of sorting non-deterministic variables in a Select query can be changed , see (MDEV-27745)

Reserved Word

- New reserved word: OFFSET. This can no longer be used as an identifier without being quoted.

InnoDB COMPRESSED Row Format

From MariaDB 10.6.0 until MariaDB 10.6.5, tables that are of the `COMPRESSED` row format are read-only by default. This was intended to be the first step towards removing write support and deprecating the feature.

This plan has been scrapped, and from MariaDB 10.6.6, `COMPRESSED` tables are no longer read-only by default.

From MariaDB 10.6.0 to MariaDB 10.6.5, set the innodb_read_only_compressed variable to `OFF` to make the tables writable.

Character Sets

From MariaDB 10.6, the `utf8` character set (and related collations) is by default an alias for `utf8mb3` rather than the other way around. It can be set to imply `utf8mb4` by changing the value of the old_mode system variable.

Options That Have Changed Default Values

Option	Old default value	New default value
character_set_client	utf8	utf8mb3
character_set_connection	utf8	utf8mb3
character_set_results	utf8	utf8mb3
character_set_system	utf8	utf8mb3
innodb_flush_method	fsync	O_DIRECT
old_mode	Empty	UTF8_IS_UTF8MB3

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files:

Option	Reason
innodb_adaptive_max_sleep_delay	
innodb_background_scrub_data_check_interval	
innodb_background_scrub_data_compressed	
innodb_background_scrub_data_interval	
innodb_background_scrub_data_uncompressed	
innodb_buffer_pool_instances	
innodb_checksum_algorithm	The variable is still present, but the `*innodb` and `*none` options have been removed as the `crc32` algorithm only is supported from MariaDB 10.6.
innodb_commit_concurrency	
innodb_concurrency_tickets	
innodb_file_format	
innodb_large_prefix	
innodb_lock_schedule_algorithm	
innodb_log_checksums	
innodb_log_compressed_pages	
innodb_log_files_in_group	

innodb_log_optimize_ddl	
innodb_page_cleaners	
innodb_replication_delay	
innodb_scrub_log	
innodb_scrub_log_speed	
innodb_sync_array_size	
innodb_thread_concurrency	
innodb_thread_sleep_delay	
innodb_undo_logs	

Deprecated Options

The following options have been deprecated. They have not yet been removed, but will be in a future version, and should ideally no longer be used.

Option	Reason
wsrep_replicate_myisam	Use wsrep_mode instead.
wsrep_strict_ddl	Use wsrep_mode instead.

Major New Features To Consider

- See also System Variables Added in MariaDB 10.6.

2.1.3.8 Upgrading from MariaDB 10.4 to MariaDB 10.5

Contents

How to Upgrade

For Windows, see Upgrading MariaDB on Windows instead.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend Mariabackup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 10.5. For example,
   - On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
   - On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
   - On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.
2. Stop MariaDB.
3. Uninstall the old version of MariaDB.
   - On Debian, Ubuntu, and other similar Linux distributions, execute the following:

```
sudo apt-get remove mariadb-server
```

- On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following:

```
sudo yum remove MariaDB-server
```

- On SLES, OpenSUSE, and other similar Linux distributions, execute the following:

```
sudo zypper remove MariaDB-server
```

4. Install the new version of MariaDB.
   - On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
   - On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
   - On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.
5. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
6. Start MariaDB.
7. Run mysql_upgrade.
   - `mysql_upgrade` does two things:
     1. Ensures that the system tables in the#mysql database are fully compatible with the new version.
     2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

Incompatible Changes Between 10.4 and 10.5

On most servers upgrading from 10.4 should be painless. However, there are some things that have changed which could affect an upgrade:

Binary name changes

All binaries previously beginning with mysql now begin with mariadb, with symlinks for the corresponding mysql command.

Usually that shouldn't cause any changed behavior, but when starting the MariaDB server via systemd, or via the mysqld_safe script symlink, the server process will now always be started as `mariadbd`, not `mysqld`.

So anything looking for the `mysqld` name in the system process list, like e.g. monitoring solutions, now needs for `mariadbd` instead when the server / service is not started directly, but via `mysqld_safe` or as a system service.

GRANT PRIVILEGE changes

A number of statements changed the privileges that they require. The old privileges were historically inappropriately chosen in the upstream. 10.5.2 fixes this problem. Note, these changes are incompatible to previous versions. A number of GRANT commands might be needed after upgrade.

- `SHOW BINLOG EVENTS` now requires the `BINLOG MONITOR` privilege (requred `REPLICATION SLAVE` prior to 10.5.2).
- `SHOW SLAVE HOSTS` now requires the `REPLICATION MASTER ADMIN` privilege (required `REPLICATION SLAVE` prior to 10.5.2).
- `SHOW SLAVE STATUS` now requires the `REPLICATION SLAVE ADMIN` or the `SUPER` privilege (required `REPLICATION CLIENT` or `SUPER` prior to 10.5.2).
- `SHOW RELAYLOG EVENTS` now requires the `REPLICATION SLAVE ADMIN` privilege (required `REPLICATION SLAVE` prior to 10.5.2).

Options That Have Changed Default Values

Option	Old default value	New default value
innodb_adaptive_hash_index	ON	OFF
innodb_checksum_algorithm	crc32	full_crc32
innodb_log_optimize_ddl	ON	OFF
slave_parallel_mode	conservative	optimistic
performance_schema_max_cond_classes	80	90
performance_schema_max_file_classes	50	80
performance_schema_max_mutex_classes	200	210
performance_schema_max_rwlock_classes	40	50
performance_schema_setup_actors_size	100	-1

performance_schema_setup_objects_size	100	-1

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files:

Option	Reason
innodb_checksums	Deprecated and functionality replaced by innodb_checksum_algorithms in MariaDB 10.0.
idle_flush_pct	Has had no effect since merging InnoDB 5.7 from mysql-5.7.9 (MariaDB 10.2.2).
innodb_locks_unsafe_for_binlog	Deprecated in MariaDB 10.0. Use READ COMMITTED transaction isolation level instead.
innodb_rollback_segments	Deprecated and replaced by innodb_undo_logs in MariaDB 10.0.
innodb_stats_sample_pages	Deprecated in MariaDB 10.0. Use innodb_stats_transient_sample_pages instead.
max_long_data_size	Deprecated and replaced by max_allowed_packet in MariaDB 5.5.
multi_range_count	Deprecated and has had no effect since MariaDB 5.3.
thread_concurrency	Deprecated and has had no effect since MariaDB 5.5.
timed_mutexes	Deprecated and has had no effect since MariaDB 5.5.

Deprecated Options

The following options have been deprecated. They have not yet been removed, but will be in a future version, and should ideally no longer be used.

Option	Reason
innodb_adaptive_max_sleep_delay	No need for thread throttling any more.
innodb_background_scrub_data_check_interval	Problematic 'background scrubbing' code removed.
innodb_background_scrub_data_interval	Problematic 'background scrubbing' code removed.
innodb_background_scrub_data_compressed	Problematic 'background scrubbing' code removed.
innodb_background_scrub_data_uncompressed	Problematic 'background scrubbing' code removed.
innodb_buffer_pool_instances	Having more than one buffer pool is no longer necessary.
innodb_commit_concurrency	No need for thread throttling any more.
innodb_concurrency_tickets	No need for thread throttling any more.
innodb_log_files_in_group	Redo log was unnecessarily split into multiple files. Limited to 1 from MariaDB 10.5.
innodb_log_optimize_ddl	Prohibited optimizations.
innodb_page_cleaners	Having more than one page cleaner task no longer necessary.
innodb_replication_delay	No need for thread throttling any more.
innodb_scrub_log	Never really worked as intended, redo log format is being redone.
innodb_scrub_log_speed	Never really worked as intended, redo log format is being redone.
innodb_thread_concurrency	No need for thread throttling any more.
innodb_thread_sleep_delay	No need for thread throttling any more.
innodb_undo_logs	It always makes sense to use the maximum number of rollback segments.
large_page_size	Unused since multiple page size support was added.

Major New Features To Consider

You might consider using the following major new features in MariaDB 10.5:

- The S3 storage engine allows one to archive MariaDB tables in Amazon S3, or any third-party public or private cloud

that implements S3 API.
- ColumnStore columnar storage engine.
- See also System Variables Added in MariaDB 10.5.

2.1.3.9 Upgrading from MariaDB 10.3 to MariaDB 10.4

Contents

How to Upgrade

For Windows, see Upgrading MariaDB on Windows instead.

For MariaDB Galera Cluster, see Upgrading from MariaDB 10.3 to MariaDB 10.4 with Galera Cluster instead.

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend Mariabackup.

The suggested upgrade procedure is:

1. Modify the repository configuration, so the system's package manager installs MariaDB 10.4. For example,
   - On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
   - On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to a New Major Release for more information.
   - On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.
2. Stop MariaDB.
3. Uninstall the old version of MariaDB.
   - On Debian, Ubuntu, and other similar Linux distributions, execute the following:
     ```
     sudo apt-get remove mariadb-server
     ```
   - On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following:
     ```
     sudo yum remove MariaDB-server
     ```
   - On SLES, OpenSUSE, and other similar Linux distributions, execute the following:
     ```
     sudo zypper remove MariaDB-server
     ```
4. Install the new version of MariaDB.
   - On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
   - On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
   - On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.
5. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any options that are no longer supported.
6. Start MariaDB.
7. Run `mysql_upgrade`.
   - `mysql_upgrade` does two things:
     1. Ensures that the system tables in the `mysql` database are fully compatible with the new version.
     2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB.

Incompatible Changes Between 10.3 and 10.4

On most servers upgrading from 10.3 should be painless. However, there are some things that have changed which could affect an upgrade:

Options That Have Changed Default Values

Option	Old default value	New default value
slave_transaction_retry_errors	1213,1205	1158,1159,1160,1161,1205,1213,1429,2013,12701
wsrep_debug	OFF	NONE
wsrep_load_data_splitting	ON	OFF

Options That Have Been Removed or Renamed

The following options should be removed or renamed if you use them in your option files:

Option	Reason

Authentication and TLS

- See Authentication from MariaDB 10.4 for an overview of the changes.
- The unix_socket authentication plugin is now default on Unix-like systems.
- TLSv1.0 is disabled by default in MariaDB 10.4. See tls_version and TLS Protocol Versions.

Major New Features To Consider

You might consider using the following major new features in MariaDB 10.4:

- Galera has been upgraded from Galera 3 to Galera 4.
- System-versioning extended with support for application-time periods.
- User password expiry
- Account Locking
- See also System Variables Added in MariaDB 10.4.

2.1.3.10 Upgrading MariaDB on Windows

Contents

For incompatibilities such as removed features, and changes to variables, see the pages describing changes by version on Upgrading MariaDB.

Minor Upgrades

To install a minor upgrade, e.g 10.1.27 on top of existing 10.1.26, with MSI, just download the 10.1.27 MSI and start it. It will do everything that needs to be done for minor upgrade automatically - shutdown MariaDB service(s), replace executables and DLLs, and start service(s) again.

The rest of the article is dedicated to *major* upgrades, e.g 10.1.x to 10.2.y.

General Information on Upgrade and Version Coexistence

This section assumes MSI installations.

First, check everything listed in the Incompatibilities section of the article relating to the version you are upgrading, for example, Upgrading from MariaDB 10.1 to MariaDB 10.2, to make sure you are prepared for the upgrade.

MariaDB (and also MySQL) allows different versions of the product to co-exist on the same machine, as long as these versions are different either in major or minor version numbers. For example, it is possible to have say MariaDB 5.1.51

and 5.2.6 to be installed on the same machine.

However only a single instance of 5.2 can exist. If for example 5.2.7 is installed on a machine where 5.2.6 is already installed, the installer will just replace 5.2.6 executables with 5.2.7 ones.

Now imagine, that both 5.1 and 5.2 are installed on the same machine and we want to upgrade the database instance running on 5.1 to the new version. In this case special tools are requied. Traditionally, `mysql_upgrade` is used to accomplish this. On Windows, the MySQL upgrade is a complicated multiple-step manual process.

Since MariaDB 5.2.6, the Windows distribution includes tools that simplify migration between different versions and also allow migration between MySQL and MariaDB.

Note. Automatic upgrades are only possible for DB instances that run as a Windows service.

General Recommendations

Important: Ignore any statement that tells you to *"just uninstall MySQL and install MariaDB"*. This does not work on Windows, never has, and never will. Keep your MySQL installed until after the database had been converted.

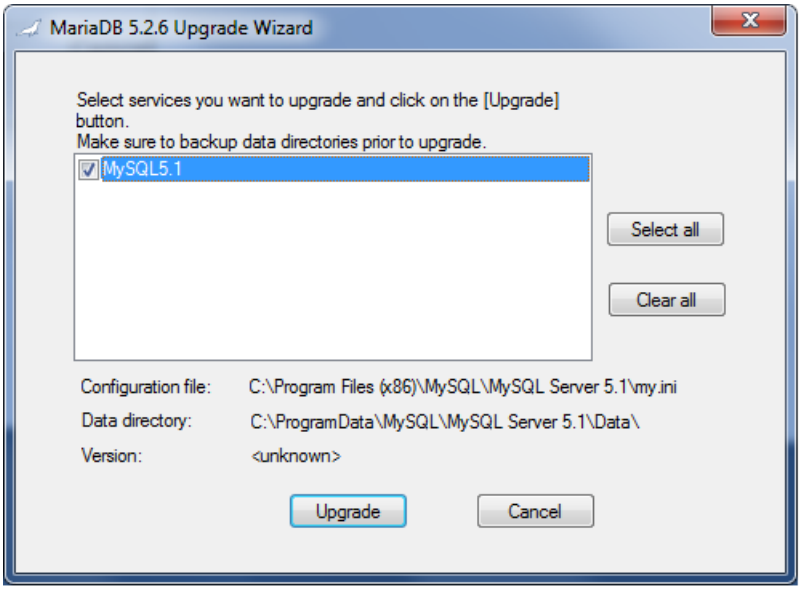
The following install/upgrade sequence is recommended in case of "major" upgrades, like going from 5.3 to 5.5

- Install new version, while still retaining the old one
- Upgrade services one by one, like described later in the document (e.g with mysql_upgrade_service). It is recommeded to have services cleanly shut down before the upgrade.
- Uninstall old version when previous step is done.

Note. This recommendation differs from the procedure on Unixes, where the upgrade sequence is "uninstall old version, install new version"

Upgrade Wizard

This is a GUI tool that is typically invoked at the end of a MariaDB installation if upgradable services are found. The UI allows you to select instances you want to upgrade.



mysql_upgrade_service

This is a command line tool that performs upgrades. The tool requires full administrative privileges (it has to start and stop services).

Example usage:

```
mysql_upgrade_service --service=MySQL
```

`mysql_upgrade_service` accepts a single parameter — the name of the MySQL or MariaDB service. It performs all the steps to convert a MariaDB/MySQL instance running as the service to the current version.

Migration to 64 bit MariaDB from 32 bit

Earlier we said that only single instance of "MariaDB <major>.<minor>" version can be installed on the same machine. This was almost correct, because MariaDB MSI installations allow 32 and 64-bit versions to be installed on the same machine, and in this case it is possible to have two instances of say 5.2 installed at the same time, an x86 one and an x64 one. One can use the x64 Upgrade wizard to upgrade an instance running as a 32-bit process to run as 64-bit.

Upgrading ZIP-based Installations.

Both UpgradeWizard and mysql_upgrade_service can also be used to upgrade database instances that were installed with the ZIP installation.

2.1.3.11.1 Upgrading Between Minor Versions with Galera Cluster

Performing a Rolling Upgrade

The following steps can be used to perform a rolling upgrade between minor versions of MariaDB (for example from MariaDB 10.3.12 to MariaDB 10.3.13) when Galera Cluster is being used. In a rolling upgrade, each node is upgraded individually, so the cluster is always operational. There is no downtime from the application's perspective.

> Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend Mariabackup.

For each node, perform the following steps:

1. Stop MariaDB.
2. Install the new version of MariaDB and the Galera wsrep provider.
   - On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
   - On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
   - On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.
3. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any system variables or options that are no longer supported.

4. Start MariaDB.
5. Run mariadb-upgrade with the `--skip-write-binlog` option.
    - `mariadb-upgrade` does two things:
        1. Ensures that the system tables in the `mysql` database are fully compatible with the new version.
        2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

When this process is done for one node, move onto the next node.

Note that when upgrading the Galera wsrep provider, sometimes the Galera protocol version can change. The Galera wsrep provider should not start using the new protocol version until all cluster nodes have been upgraded to the new version, so this is not generally an issue during a rolling upgrade. However, this can cause issues if you restart a non-upgraded node in a cluster where the rest of the nodes have been upgraded.

2.1.3.11.2 Upgrading from MariaDB 10.3 to MariaDB 10.4 with Galera Cluster

MariaDB starting with 10.1

Since MariaDB 10.1, the MySQL-wsrep patch has been merged into MariaDB Server. Therefore, in MariaDB 10.1 and above, the functionality of MariaDB Galera Cluster can be obtained by installing the standard MariaDB Server packages and the Galera wsrep provider library package.

Beginning in MariaDB 10.1, Galera Cluster ships with the MariaDB Server. Upgrading a Galera Cluster node is very similar to upgrading a server from MariaDB 10.3 to MariaDB 10.4. For more information on that process as well as incompatibilities between versions, see the Upgrade Guide.

Performing a Rolling Upgrade

The following steps can be used to perform a rolling upgrade from MariaDB 10.3 to MariaDB 10.4 when using Galera Cluster. In a rolling upgrade, each node is upgraded individually, so the cluster is always operational. There is no downtime from the application's perspective.

First, before you get started:

1. First, take a look at Upgrading from MariaDB 10.3 to MariaDB 10.4 to see what has changed between the major versions.
    1. Check whether any system variables or options have been changed or removed. Make sure that your server's configuration is compatible with the new MariaDB version before upgrading.
    2. Check whether replication has changed in the new MariaDB version in any way that could cause issues while the cluster contains upgraded and non-upgraded nodes.
    3. Check whether any new features have been added to the new MariaDB version. If a new feature in the new MariaDB version cannot be replicated to the old MariaDB version, then do not use that feature until all cluster nodes have been upgrades to the new MariaDB version.
2. Next, make sure that the Galera version numbers are compatible.
    1. If you are upgrading from the most recent MariaDB 10.3 release to MariaDB 10.4, then the versions will be compatible. MariaDB 10.3 uses Galera 3 (i.e. Galera wsrep provider versions 25.3.x), and MariaDB 10.4 uses Galera 4 (i.e. Galera wsrep provider versions 26.4.x). This means that upgrading to MariaDB 10.4 also upgrades the system to Galera 4. However, Galera 3 and Galera 4 should be compatible for the purposes of a rolling upgrade, as long as you are using Galera 26.4.2 or later.
    2. See What is MariaDB Galera Cluster?: Galera wsrep provider Versions for information on which MariaDB releases uses which Galera wsrep provider versions.
3. Ideally, you want to have a large enough gcache to avoid a State Snapshot Transfer (SST) during the rolling upgrade. The gcache size can be configured by setting `gcache.size` For example:
   ```
   wsrep_provider_options="gcache.size=2G"
   ```

Before you upgrade, it would be best to take a backup of your database. This is always a good idea to do before an upgrade. We would recommend Mariabackup.

Then, for each node, perform the following steps:

1. Modify the repository configuration, so the system's package manager installs MariaDB 10.4. For example,
    - On Debian, Ubuntu, and other similar Linux distributions, see Updating the MariaDB APT repository to a New Major Release for more information.
    - On RHEL, CentOS, Fedora, and other similar Linux distributions, see Updating the MariaDB YUM repository to

a New Major Release for more information.
    - On SLES, OpenSUSE, and other similar Linux distributions, see Updating the MariaDB ZYpp repository to a New Major Release for more information.
2. If you use a load balancing proxy such as MaxScale or HAProxy, make sure to drain the server from the pool so it does not receive any new connections.
3. Stop MariaDB.
4. Uninstall the old version of MariaDB and the Galera wsrep provider.
    - On Debian, Ubuntu, and other similar Linux distributions, execute the following:
      ```
      sudo apt-get remove mariadb-server galera
      ```
    - On RHEL, CentOS, Fedora, and other similar Linux distributions, execute the following:
      ```
      sudo yum remove MariaDB-server galera
      ```
    - On SLES, OpenSUSE, and other similar Linux distributions, execute the following:
      ```
      sudo zypper remove MariaDB-server galera
      ```
5. Install the new version of MariaDB and the Galera wsrep provider.
    - On Debian, Ubuntu, and other similar Linux distributions, see Installing MariaDB Packages with APT for more information.
    - On RHEL, CentOS, Fedora, and other similar Linux distributions, see Installing MariaDB Packages with YUM for more information.
    - On SLES, OpenSUSE, and other similar Linux distributions, see Installing MariaDB Packages with ZYpp for more information.
6. Make any desired changes to configuration options in option files, such as `my.cnf`. This includes removing any system variables or options that are no longer supported.
7. On Linux distributions that use `systemd` you may need to increase the service startup timeout as the default timeout of 90 seconds may not be sufficient. See Systemd: Configuring the Systemd Service Timeout for more information.
8. Start MariaDB.
9. Run `mysql_upgrade` with the `--skip-write-binlog` option.
    - `mysql_upgrade` does two things:
        1. Ensures that the system tables in the `mysql` database are fully compatible with the new version.
        2. Does a very quick check of all tables and marks them as compatible with the new version of MariaDB .

When this process is done for one node, move onto the next node.

> Note that when upgrading the Galera wsrep provider, sometimes the Galera protocol version can change. The Galera wsrep provider should not start using the new protocol version until all cluster nodes have been upgraded to the new version, so this is not generally an issue during a rolling upgrade. However, this can cause issues if you restart a non-upgraded node in a cluster where the rest of the nodes have been upgraded.

Upgrading to MariaDB From MySQL 5.0 or Older
Upgrading to MariaDB from MySQL 5.0 (or older version)

2.1.3.12.1 Upgrading from MySQL to MariaDB

Contents

For all practical purposes, you can view MariaDB as an upgrade of MySQL:

- Before upgrading, please check if there are any known incompatibilities between your MySQL release and the MariaDB release you want to move to.
- In particular, note that the JSON type in MariaDB is a LONGTEXT, while in MySQL it's a binary type. See Making MariaDB understand MySQL JSON.
- If you are using MySQL 8.0 or above, you have to use mysqldump to move your database to MariaDB.
- For upgrading from very old MySQL versions, see Upgrading to MariaDB from MySQL 5.0 (or older version).
- Within the same base version (for example MySQL 5.5 -> MariaDB 5.5, MySQL 5.6 -> MariaDB 10.0 and MySQL 5.7 -> MariaDB 10.2) you can in most cases just uninstall MySQL and install MariaDB and you are good to go. There is no need to dump and restore databases. As with any upgrade, we recommend making a backup of your data beforehand.
- You should run mariadb-upgrade (as you would with `mysql_upgrade` in MySQL) to finish the upgrade. This is needed to ensure that your mysql privilege and event tables are updated with the new fields MariaDB uses. Note that if you use a MariaDB package, `mariadb-upgrade` is usually run automatically.
- All your old clients and connectors (PHP, Perl, Python, Java, etc.) will work unchanged (no need to recompile). This works because MariaDB and MySQL use the same client protocol and the client libraries are binary compatible. You can also use your old MySQL connector packages with MariaDB if you want.

Upgrading on Windows

On Windows, you should not uninstall MySQL and install MariaDB, this would not work, the existing database will not be found.

Thus On Windows, just install MariaDB and use the upgrade wizard which is part of installer package and is launched by MSI installer. Or, in case you prefer command line, use `mysql_upgrade_service <service_name>` on the command line.

Upgrading my.cnf

All the options in your original MySQL `my.cnf` file should work fine for MariaDB.

However as MariaDB has more features than MySQL, there is a few things that you should consider changing in your `my.cnf` file.

- MariaDB uses by default the Aria storage engine for internal temporary files instead of MyISAM. If you have a lot of temporary files, you should add and set `aria-pagecache-buffer-size` to the same value as you have for `key-buffer-size`.
- If you don't use MyISAM tables, you can set `key-buffer-size` to a very low value, like 64K.
- If using MariaDB 10.1 or earlier, and your applications often connect and disconnect to MariaDB, you should set up `thread-cache-size` to the number of concurrent queries threads you are typically running. This is important in MariaDB as we are using the jemalloc memory allocator. jemalloc usually has better performance when running many threads compared to other memory allocators, except if you create and destroy a lot of threads, in which case it will spend a lot of resources trying to manage thread specific storage. Having a thread cache will fix this problem.
- If you have a LOT of connections (> 100) that mostly run short running queries, you should consider using the thread pool. For example using : `thread_handling=pool-of-threads` and `thread_pool_size=128` could give a notable performance boost in this case. Where the `thread_pool_size` should be about `2 * number of cores on your machine`.

Other Things to Think About

- Views with definition `ALGORITHM=MERGE` or `ALGORITHM=TEMPTABLE` got accidentally swapped between MariaDB and MySQL. You have to re-create views created with either of these definitions (see MDEV-6916).
- MariaDB has LGPL versions of the C connector and Java Client. If you are shipping an application that supports MariaDB or MySQL, you should consider using these!
- You should consider trying out the MyRocks storage engine or some of the other new storage engines that MariaDB provides.

2.1.3.12.2 Moving from MySQL to MariaDB in Debian 9

MariaDB 10.1 is now the default mysql server in Debian 9 "Stretch". This page provides information on this change and instructions to help with upgrading your Debian 8 "Jessie" version of MySQL or MariaDB to MariaDB 10.1 in Debian 9 "Stretch".

Contents

Background information

The version of MySQL in Debian 8 "Jessie" is 5.5. When installing, most users will install the `mysql-server` package, which depends on the `mysql-server-5.5 package` . In Debian 9 "Stretch" the `mysql-server` package depends on a new package called `default-mysql-server` . This package in turn depends on `mariadb-server-10.1` . There is no `default-mysql-server` package in Jessie.

In both Jessie and Stretch there is also a `mariadb-server` package which is a MariaDB-specific analog to the `mysql-server` package. In Jessie this package depends on `mariadb-server-10.0` and in Stretch this package depends on `mariadb-server-10.1` (the same as the `default-mysql-server` package).

So, the main repository difference in Debian 9 "Stretch" is that when you install the `mysql-server` package on Stretch you will get MariaDB 10.1 instead of MySQL, like you would with previous versions of Debian. Note that `mysql-server` is just an empty transitional meta-package and users are encouraged to install MariaDB using the actual package `mariadb-server` .

All apps and tools, such as the popular LAMP stack, in the repositories that depend on the `mysql-server` package will continue to work using MariaDB as the database. For new installs there is nothing different that needs to be done when installing the mysql-server or mariadb-server packages.

Before you upgrade

If you are currently running MySQL 5.5 on Debian 8 "Jessie" and are planning an upgrade to MariaDB 10.1 on Debian 9 "Stretch", there are some things to keep in mind:

Backup before you begin

This is a major upgrade, and so complete database backups are strongly suggested before you begin. MariaDB 10.1 is compatible on disk and wire with MySQL 5.5, and the MariaDB developer team has done extensive development and testing to make upgrades as painless and trouble-free as possible. Even so, it's always a good idea to do regular backups, especially before an upgrade. As the database has to shutdown anyway for the upgrade, this is a good opportunity to do a backup!

Changed, renamed, and removed options

Some default values have been changed, some have been renamed, and others have been removed between MySQL 5.5 and MariaDB 10.1. The following sections detail them.

Options with changed default values

Most of the following options have increased a bit in value to give better performance. They should not use much additional memory, but some of them do use a bit more disk space.

Option	Old default value	New default value
`aria-sort-buffer-size`	`128M`	`256M`
`back_log`	`50`	`150`

innodb-concurrency-tickets	500	5000
innodb-log-file-size	5M	48M
innodb_log_compressed_pages	ON	OFF
innodb-old-blocks-time	0	1000
innodb-open-files	300	400 [2]
innodb-purge-batch-size	20	300
innodb-undo-logs	ON	20
join_buffer_size	128K	256K
max_allowed_packet	1M	4M
max-connect-errors	10	100
max-relay-log-size	0	1024M
myisam-sort-buffer-size	8M	128M
optimizer-switch	...	Added extended_keys=on, exists_to_in=on
query_alloc_block_size	8192	16384
query_cache_size	0	1M
query_cache_type	ON	OFF
query_prealloc_size	8192	24576
secure_auth	OFF	ON
sql_log_bin		No longer affects replication of events in a Galera cluster.
sql_mode	empty	NO_AUTO_CREATE_USER, NO_ENGINE_SUBSTITUTION
sync_master_info	0	10000
sync_relay_log	0	10000
sync_relay_log_info	0	10000
table_open_cache	400	2000
thread_pool_max_threads	500	1000

Options that have been removed or renamed

The following options should be removed or renamed if you use them in your config files:

Option	Reason
engine-condition-pushdown	Replaced with set optimizer_switch='engine_condition_pushdown=on'
innodb-adaptive-flushing-method	Removed by XtraDB
innodb-autoextend-increment	Removed by XtraDB
innodb-blocking-buffer-pool-restore	Removed by XtraDB
innodb-buffer-pool-pages	Removed by XtraDB
innodb-buffer-pool-pages-blob	Removed by XtraDB
innodb-buffer-pool-pages-index	Removed by XtraDB
innodb-buffer-pool-restore-at-startup	Removed by XtraDB
innodb-buffer-pool-shm-checksum	Removed by XtraDB
innodb-buffer-pool-shm-key	Removed by XtraDB
innodb-checkpoint-age-target	Removed by XtraDB

innodb-dict-size-limit	Removed by XtraDB
innodb-doublewrite-file	Removed by XtraDB
innodb-fast-checksum	Renamed to innodb-checksum-algorithm
innodb-flush-neighbor-pages	Renamed to innodb-flush-neighbors
innodb-ibuf-accel-rate	Removed by XtraDB
innodb-ibuf-active-contract	Removed by XtraDB
innodb-ibuf-max-size	Removed by XtraDB
innodb-import-table-from-xtrabackup	Removed by XtraDB
innodb-index-stats	Removed by XtraDB
innodb-lazy-drop-table	Removed by XtraDB
innodb-merge-sort-block-size	Removed by XtraDB
innodb-persistent-stats-root-page	Removed by XtraDB
innodb-read-ahead	Removed by XtraDB
innodb-recovery-stats	Removed by XtraDB
innodb-recovery-update-relay-log	Removed by XtraDB
innodb-stats-auto-update	Renamed to innodb-stats-auto-recalc
innodb-stats-update-need-lock	Removed by XtraDB
innodb-sys-stats	Removed by XtraDB
innodb-table-stats	Removed by XtraDB
innodb-thread-concurrency-timer-based	Removed by XtraDB
innodb-use-sys-stats-table	Removed by XtraDB
rpl_recovery_rank	Unused in 10.0+
xtradb-admin-command	Removed by XtraDB

Suggested upgrade procedure for replication

If you have a master-slave setup, the normal procedure is to first upgrade your slaves to MariaDB, then move one of your slaves to be the master and then upgrade your original master. In this scenario you can upgrade from MySQL to MariaDB or upgrade later to a new version of MariaDB without any downtime.

Other resources to consult before beginning your upgrade

It may also be useful to check out the Upgrading MariaDB section. It contains several articles on upgrading from MySQL to MariaDB and from one version of MariaDB to another. For upgrade purposes, MySQL 5.5 and MariaDB 5.5 are very similar. In particular, see the Upgrading from MariaDB 5.5 to MariaDB 10.0 and Upgrading from MariaDB 10.0 to MariaDB 10.1 articles.

If you need help with upgrading or setting up replication, you can always contact the MariaDB corporation to find experts to help you with this.

Upgrading to MariaDB 10.1 from MySQL 5.5

The suggested upgrade procedure is:

1. Set innodb_fast_shutdown to `0`. This is to ensure that if you make a backup as part of the upgrade, all data is written to the InnoDB data files, which simplifies any restore in the future.
2. Shutdown MySQL 5.5
3. Take a backup
    - when the server is shut down is the perfect time to take a backup of your databases
    - store a copy of the backup on external media or a different machine for safety

4. Perform the upgrade from Debian 8 to Debian 9
5. During the upgrade, the mysql_upgrade script will be run automatically; this script does two things:
    1. Upgrades the permission tables in the `mysql` database with some new fields
    2. Does a very quick check of all tables and marks them as compatible with MariaDB 10.1
        - In most cases this should be a fast operation (depending of course on the number of tables)
6. Add new options to my.cnf to enable features
    - If you change `my.cnf` then you need to restart `mysqld` with e.g. `sudo service mysql restart` or `sudo service mariadb restart`.

Upgrading to MariaDB 10.1 from an older version of MariaDB

If you have installed MariaDB 5.5 or MariaDB 10.0 on your Debian 8 "Jessie" machine from the MariaDB repositories you will need to upgrade to MariaDB 10.1 when upgrading to Debian 9 "Stretch". You can choose to continue using the MariaDB repositories or move to using the Debian repositories.

If you want to continue using the MariaDB repositories edit the MariaDB entry in your sources.list and change every instance of 5.5 or 10.0 to 10.1. Then upgrade as suggested above.

If you want to move to using MariaDB 10.1 from the Debian repositories, delete or comment out the MariaDB entries in your sources.list file. Then upgrade as suggested above.

If you are already using MariaDB 10.1 on your Debian 8 "Jessie" machine, you can choose to continue to use the MariaDB repositories or move to using the Debian repositories as with MariaDB 5.5 and 10.0. In either case, the upgrade will at most be just a minor upgrade from one version of MariaDB 10.1 to a newer version. In the case that you are already on the current version of MariaDB that exists in the Debian repositories or a newer one) MariaDB will not be upgraded during the system upgrade but will be upgraded when future versions of MariaDB are released.

> You should always perform a compete backup of your data prior to performing any major system upgrade, even if MariaDB itself is not being upgraded!

MariaDB Galera Cluster

If you have been using MariaDB Galera Cluster 5.5 or 10.0 on Debian 8 "Jessie" it is worth mentioning that Galera Cluster is included by default in MariaDB 10.1, there is no longer a need to install a separate `mariadb-galera-server` package.

Configuration options for advanced database users

To get better performance from MariaDB used in production environments, here are some suggested additions to your configuration file which in Debian is at `/etc/mysql/mariadb.d/my.cnf`:

```
[[mysqld]]
# Cache for disk based temporary files
aria_pagecache_buffer_size=128M
# If you are not using MyISAM tables directly (most people are using InnoDB)
key_buffer_size=64K
```

The reason for the above change is that MariaDB is using the newer Aria storage engine for disk based temporary files instead of MyISAM. The main benefit of Aria is that it can cache both indexes and rows and thus gives better performance than MyISAM for large queries.

Secure passwordless root accounts only on new installs

Unlike the old MySQL packages in Debian, MariaDB 10.0 onwards in Debian uses unix socket authentication on new installs to avoid root password management issues and thus be more secure and easier to use with provision systems of the cloud age.

This only affects new installs. Upgrades from old versions will continue to use whatever authentication and user accounts already existed. This is however good to know, because it can affect upgrades of dependant systems, typically e.g. require users to rewrite their Ansible scripts and similar tasks. The new feature is much easier than the old, so adjusting for it requires little work.

2.1.3.12.3 Screencast for Upgrading MySQL to MariaDB

There is a screencast for upgrading from MySQL 5.1.55 to MariaDB. Watch this example to see how easy this process is. It really is just a "drop in replacement" to MySQL.

2.1.4 Downgrading between Major Versions of MariaDB

Downgrading MariaDB is not officially supported between major versions.

For minor versions, upgrade is supported to an earlier gamma/RC/GA version as we do not change the storage format after Alpha and very rarely during Beta (it has to be a very critical bug to require such a change). There are a few very rare cases when incompatible changes happen on a GA version, for example MariaDB 10.1.21 fixed a file format incompatibility bug that prevents a downgrade to earlier MariaDB 10.1 releases. After MariaDB 10.1.21 this has not happened in a GA release.

The main reason why downgrades between major versions do not work are:

- Changes in the privilege/status tables in the mysql schema. These changes happen between most major versions as we are continuously improving the privilege system.
- Changes that affect how data is stored on disk. This happens more rarely and is usually table specific. For example, if one has used Instant add column on a table in MariaDB 10.3, that table cannot be opened in MariaDB 10.2.
- Between major releases there are often substantial changes, even if none of the new features are used. For example, both MariaDB 10.2 and MariaDB 10.3 introduce new versions of the redo log.

The only reliable way to downgrade is to restore from a full backup made before upgrading, and start the old version of MariaDB. At least one should take a backup of the mysql schema as most upgrade changes happens in this directory. This may be of help if one needs to downgrade to an earlier MariaDB version. More about this later.

Some people have reported successfully downgrading, but there are many possible things that can go wrong, and downgrading between two major versions is not tested in any way by the MariaDB developers.

In general, one can downgrade a major version to an earlier version if one has not yet run mariadb-upgrade on the new version. Note however that it's recommended that one always uses mariadb-upgrade after upgrading to a new major version as otherwise some security features in the new server may not work and tables that have indexes using a character collation that has changed may not work properly.

Assuming one **must** downgrade to an earlier major version, here is a list of things one has to do:

- MariaDB **must** be shut down cleanly. This means that:
  - One should ensure that innodb_fast_shutdown≠2.
  - One uses the SHUTDOWN command, mariadb-admin shutdown or the operating system official commands, like systemctl stop mariadb.service.
- Start the old server with --skip-privilege-tables.
- Use ALTER TABLE to restore the mysql schema tables to their original definition or drop and recreate the mysql tables. One can find the old definition by using mariadb-install-db to create a separate temporary data directory. Starting the MariaDB server on the temporary directory will allow you to use SHOW CREATE TABLE to find the old definition.
- Execute FLUSH PRIVILEGES to reload the old tables.

The cases when the above will not work are when the table format has changed in an incompatible manner. In this case the affected tables may not be usable in the earlier version.

The following is an incomplete list of when one will not be able to use a table in an earlier major version:

- MariaDB 11.0 or later
  - A downgrade to MariaDB 10.4 or earlier is not possible, because MDEV-29694 removed the InnoDB change buffer.
  - A downgrade to MariaDB 10.5 or later is only possible if innodb_change_buffering=none (the default starting with MDEV-27734).
- MariaDB 10.8 or later
  - The InnoDB redo log file `ib_logfile0` would have to be replaced with a logically equivalent file, or the shutdown LSN has to be written to the `FIL_PAGE_FILE_FLUSH_LSN` field in the system tablespace (see MDEV-27199), or the data may be accessed read-only when using innodb_force_recovery=6.
- MariaDB 10.5 → MariaDB 10.4
  - The InnoDB redo log file `ib_logfile0` has to be deleted between a clean shutdown of the newer version and a startup of the older version. This is *not recommended*.
- MariaDB 10.4 → MariaDB 10.3

- Any InnoDB table where one has used `ALTER TABLE ALGORITHM=INSTANT DROP COLUMN` while innodb_instant_alter_column_allowed=add_drop_reorder
- Any InnoDB table that was created or rebuilt while innodb_checksum_algorithm=full_crc32
- In MariaDB 10.4, the MariaDB mysql.user table was replaced by mysql.global_priv table which may cause problems if ones wants to downgrade to 10.3.

- MariaDB 10.3 → MariaDB 10.2
  - Any InnoDB table where one has used `ALTER TABLE…ADD COLUMN` (unless innodb_instant_alter_column_allowed=never).
  - A prior shutdown with innodb_fast_shutdown=0 will be needed in order to empty the undo logs whose format changed in MDEV-12288, and even then, you might need to set innodb_force_recovery=3.

2.1.2.8 Compiling MariaDB From Source

2.1.6 Starting and Stopping MariaDB

Starting and Stopping MariaDB Server

Starting MariaDB, including details on service managers.

Configuring MariaDB with Option Files

Configuring MariaDB with my.cnf and other option files.

mysqld Configuration Files and Groups

Which configuration files and groups mysqld reads.

mariadbd Options

Lists of all the options for mariadbd (previously called mysqld).

What to Do if MariaDB Doesn't Start

Troubleshooting MariaDB when it fails to start.

Running MariaDB from the Build Directory

Running mariadbd (mysqld) directly from the source directory without make install.

mysql.server

Startup script included in MariaDB distributions on Unix

mysqld_safe

Recommended way to start a mysqld server on a non-systemd Unix.

mysqladmin

Old name or symlink for mariadb-admin.

Switching Between Different Installed MariaDB Versions

Managing different installed MariaDB versions and running them one at a time

Running Multiple MariaDB Server Processes

Running multiple MariaDB Server processes on the same server.

Specifying Permissions for Schema (Data) Directories and Tables

MariaDB uses the following modes for creating directories and files

mysqld_multi

Manage several mysqld processes.

launchd

launchd is the startup service used in MacOS X.

systemd

How systemd is configured on MariaDB packages and how to alter its configuration.

sysVinit

sysVinit is one of the most common service managers for Linux and Unix.

mariadb-admin

Admin tool for monitoring, creating/dropping databases, stopping MariaDB etc.

mariadbd

Symlink or new name for mysqld.

mariadbd-multi

Symlink or new name for mysqld_multi.

mariadbd-safe

Symlink or new name for mysqld_safe.

There are 21 related questions.

2.1.6.1 Starting and Stopping MariaDB Server

Contents

There are several different methods to start or stop the MariaDB Server process. There are two primary categories that most of these methods fall into: starting the process with the help of a service manager, and starting the process manually.

Service Managers

sysVinit and systemd are the most common Linux service managers. launchd is used in MacOS X. Upstart is a less common service manager.

Systemd

RHEL/CentOS 7 and above, Debian 8 Jessie and above, and Ubuntu 15.04 and above use systemd by default.

For information on how to start and stop MariaDB with this service manager, see systemd: Interacting with the MariaDB Server Process.

SysVinit

RHEL/CentOS 6 and below, and Debian 7 Wheezy and below use sysVinit by default.

For information on how to start and stop MariaDB with this service manager, see sysVinit: Interacting with the MariaDB Server Process.

launchd

launchd is used in MacOS X.

Upstart

Ubuntu 14.10 and below use Upstart by default.

Starting the Server Process Manually

mariadbd

mariadbd is the actual MariaDB Server binary. It can be started manually on its own.

mysqld_safe

mariadbd_safe is a wrapper that can be used to start the mariadbd server process. The script has some built-in safeguards, such as automatically restarting the server process if it dies. See mariadbd_safe for more information.

mysqld_multi

mariadbd_multi is a wrapper that can be used to start the mariadbd server process if you plan to run multiple server processes on the same host. See mariadbd_multi for more information.

mysql.server

mysql.server is a wrapper that works as a standard sysVinit script. However, it can be used independently of sysVinit as a regular `sh` script. The script starts the mariadbd server process by first changing its current working directory to the MariaDB install directory and then starting mysqld_safe. The script requires the standard sysVinit arguments, such as `start`, `stop`, and `status`. See mysql.server for more information.

2.1.6.2 Configuring MariaDB with Option Files

Contents

You can configure MariaDB to run the way you want by configuring the server with MariaDB's option files. The default MariaDB option file is called `my.cnf` (or `mariadb.cnf`) on Unix-like operating systems and `my.ini` on Windows. Depending on how you've installed MariaDB, the default option file may be in a number of places, or it may not exist at all.

Global Options Related to Option Files

The following options relate to how MariaDB handles option files. These options can be used with most of MariaDB's command-line tools, not just mariadbd. They must be given as the first argument on the command-line:

Option	Description
`--print-defaults`	Read options from option files, print all option values, and then exit the program.
`--no-defaults`	Don't read options from any option file.
`--defaults-file =path`	Only read options from the given option file.

`--defaults-extra-file =path`	Read this extra option file after all other option files are read.
`--defaults-group-suffix =suffix`	In addition to the default option groups, also read option groups with the given suffix.

Default Option File Locations

MariaDB reads option files from many different directories by default. See the sections below to find out which directories are checked for which system.

For an exact list of option files read on your system by a specific program, you can execute:

```
$program --help --verbose
```

For example:

```
$ mariadbd --help --verbose
mariadbd  Ver 10.11.2-MariaDB for linux-systemd on x86_64 (MariaDB Server)
Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Starts the MariaDB database server.

Usage: mariadbd [OPTIONS]

Default options are read from the following files in the given order:
/etc/my.cnf ~/.my.cnf
The following groups are read: mysqld server mysqld-10.11 mariadb mariadb-10.11 mariadbd mariadbd
....
```

The option files are each scanned once, in the order given by `--help --verbose`. The effect of the configuration options are as if they would have been given as command line options in the order they are found.

Default Option File Locations on Linux, Unix, Mac

On Linux, Unix, or Mac OS X, the default option file is called `my.cnf`. MariaDB looks for the MariaDB option file in the locations and orders listed below.

The locations are dependent on whether the `DEFAULT_SYSCONFDIR cmake` option was defined when MariaDB was built. This option is usually defined as `/etc` when building RPM packages, but it is usually not defined when building DEB packages or binary tarballs.

- When the `DEFAULT_SYSCONFDIR cmake` option was **not** defined, MariaDB looks for the MariaDB option file in the following locations in the following order:

Location	Scope
`/etc/my.cnf`	Global
`/etc/mysql/my.cnf`	Global
`$MARIADB_HOME/my.cnf`	Server
`$MYSQL_HOME/my.cnf`	Server
defaults-extra-file	File specified with `--defaults-extra-file`, if any
`~/.my.cnf`	User

- When the `DEFAULT_SYSCONFDIR cmake` option was defined, MariaDB looks for the MariaDB option file in the following locations in the following order:

Location	Scope
`DEFAULT_SYSCONFDIR/my.cnf`	Global
`$MARIADB_HOME/my.cnf`	Server (from MariaDB 10.6)
`$MYSQL_HOME/my.cnf`	Server
defaults-extra-file	File specified with `--defaults-extra-file`, if any

`~/.my.cnf`	User

- `MARIADB_HOME` (from MariaDB 10.6) or `MYSQL_HOME` is the environment variable containing the path to the directory holding the server-specific `my.cnf` file. If `MYSQL_HOME` is not set, and the server is started with mysqld_safe, `MYSQL_HOME` is set as follows:
  - If there is a `my.cnf` file in the MariaDB data directory, but not in the MariaDB base directory, `MYSQL_HOME` is set to the MariaDB data directory.
  - Else, `MYSQL_HOME` is set to the MariaDB base directory.
- Note that if `MARIADB_HOME` is set (from MariaDB 10.6), `MYSQL_HOME` will not be used, even if set.

Default Option File Locations on Windows

On Windows, the option file can be called either `my.ini` or `my.cnf`. MariaDB looks for the MariaDB option file in the following locations in the following order:

Location	Scope
`System Windows Directory\my.ini`	Global
`System Windows Directory\my.cnf`	Global
`Windows Directory\my.ini`	Global
`Windows Directory\my.cnf`	Global
`C:\my.ini`	Global
`C:\my.cnf`	Global
`INSTALLDIR\my.ini`	Server
`INSTALLDIR\my.cnf`	Server
`INSTALLDIR\data\my.ini`	Server
`INSTALLDIR\data\my.cnf`	Server
`%MARIADB_HOME%\my.ini`	Server (from MariaDB 10.6)
`%MARIADB_HOME%\my.cnf`	Server (from MariaDB 10.6)
`%MYSQL_HOME%\my.ini`	Server
`%MYSQL_HOME%\my.cnf`	Server
defaults-extra-file	File specified with `--defaults-extra-file`, if any

- The `System Windows Directory` is the directory returned by the `GetSystemWindowsDirectory` function. The value is usually `C:\Windows`. To find its specific value on your system, open `cmd.exe` and execute:

```
echo %WINDIR%
```

- The `Windows Directory` is the directory returned by the `GetWindowsDirectory` function. The value may be a private `Windows Directory` for the application, or it may be the same as the `System Windows Directory` returned by the `GetSystemWindowsDirectory` function.
- `INSTALLDIR` is the parent directory of the directory where `mysqld.exe` is located. For example, if `mysqld.exe` is in `C:\Program Files\MariaDB 10.3\bin`, then `INSTALLDIR` would be `C:\Program Files\MariaDB 10.3`.
- `MARIADB_HOME` (from MariaDB 10.6) or `MYSQL_HOME` is the environment variable containing the path to the directory holding the server-specific `my.cnf` file.
- Note that if `MARIADB_HOME` is set (from MariaDB 10.6), `MYSQL_HOME` will not be used, even if set.

Default Option File Hierarchy

MariaDB will look in all of the above locations, in order, even if has already found an option file, and it's possible for more than one option file to exist. For example, you could have an option file in `/etc/my.cnf` with global settings for all servers, and then you could another option file in `~/.my.cnf` (i.e.your user account's home directory) which will specify additional settings (or override previously specified setting) that are specific only to that user.

Option files are usually optional. However, if the `--defaults-file` option is set, and if the file does not exist, then MariaDB will raise an error. If the `--defaults-file` option is set, then MariaDB will *only* read the option file referred to by this option.

If an option or system variable is not explicitly set, then it will be set to its default value. See Server System Variables for a

full list of all server system variables and their default values.

Custom Option File Locations

MariaDB can be configured to read options from custom options files with the following command-line arguments. These command-line arguments can be used with most of MariaDB's command-line tools, not just `mariadbd`. They must be given as the first argument on the command-line:

Option	Description
`--defaults-file=path`	Only read options from the given option file.
`--defaults-extra-file=path`	Read this extra option file after all other option files are read.

Option File Syntax

The syntax of the MariaDB option files are:

- Lines starting with # are comments.
- Empty lines are ignored.
- Option groups use the syntax `[group-name]`. See the Option Groups section below for more information on available option groups.
- The same option group can appear multiple times.
- The `!include` directive can be used to include other option files. See the Including Option Files section below for more information on this syntax.
- The `!includedir` directive can be used to include all `.cnf` files (and potentially `.ini` files) in a given directory. The option files within the directory are read in alphabetical order. See the Including Option File Directories section below for more information on this syntax.
- Dashes (`-`) and underscores (`_`) in options are interchangeable.
- Double quotes can be used to quote values
- `\n`, `\r`, `\t`, `\b`, `\s`, `\"`, `\'`, and `\\` are recognized as character escapes for new line, carriage return, tab, backspace, space, double quote, single quote, and backslash respectively.
- Certain option prefixes are supported. See the Option Prefixes section below for information about available option prefixes.
- See the Options section below for information about available options.

Option Groups

A MariaDB program can read options from one or many option groups. For an exact list of option groups read on your system by a specific program, you can execute:

```
$program --help --verbose
```

For example:

```
$ mariadbd --help --verbose
mariadbd  Ver 10.11.2-MariaDB for linux-systemd on x86_64 (MariaDB Server)
Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Starts the MariaDB database server.

Usage: mariadbd [OPTIONS]

Default options are read from the following files in the given order:
/etc/my.cnf ~/.my.cnf
The following groups are read: mysqld server mysqld-10.11 mariadb mariadb-10.11 mariadbd mariadbd
....
```

Server Option Groups

MariaDB programs reads server options from the following server option groups:

Group	Description

`[client-server]`	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
`[server]`	Options read by MariaDB Server.
`[mysqld]`	Options read by `mysqld`, which includes both MariaDB Server and MySQL Server.
`[mysqld-X.Y]`	Options read by a specific version of `mysqld`, which includes both MariaDB Server and MySQL Server. For example, `[mysqld-10.4]`.
`[mariadb]`	Options read by MariaDB Server.
`[mariadb-X.Y]`	Options read by a specific version of MariaDB Server. For example, `[mariadb-10.4]`.
`[mariadbd]`	Options read by MariaDB Server. Available starting with MariaDB 10.4.6.
`[mariadbd-X.Y]`	Options read by a specific version of MariaDB Server. For example, `[mariadbd-10.4]`. Available starting with MariaDB 10.4.6.
`[galera]`	Options read by MariaDB Server, but only if it is compiled with Galera Cluster support. In MariaDB 10.1 and later, all builds on Linux are compiled with Galera Cluster support. When using one of these builds, options from this option group are read even if the Galera Cluster functionality is not enabled.

X.Y in the examples above refer to the base (major.minor) version of the server. For example, MariaDB 10.3.10 would read from `[mariadb-10.3]`. By using the `mariadb-X.Y` syntax, one can create option files that have MariaDB-only options in the MariaDB-specific option groups. That would allow the option file to work for both MariaDB and MySQL.

Client Option Groups

MariaDB programs reads client options from the following option groups:

Group	Description
`[client]`	Options read by all MariaDB and MySQL client programs, which includes both MariaDB and MySQL clients. For example, `mariadb-dump`.
`[client-server]`	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
`[client-mariadb]`	Options read by all MariaDB client programs.

Tool-Specific Option Groups

Many MariaDB tools reads options from their own option groups as well. Many of them are listed below:

Group	Description
`[mysqld_safe]`	Options read by mysqld_safe, which includes both MariaDB Server and MySQL Server.
`[safe_mysqld]`	Options read by mysqld_safe, which includes both MariaDB Server and MySQL Server.
`[mariadb_safe]`	Options read by mysqld_safe from MariaDB Server.
`[mariadb-safe]`	Options read by mysqld_safe from MariaDB Server. Available starting with MariaDB 10.4.6.
`[mariabackup]`	Options read by Mariabackup. Available starting with MariaDB 10.1.31 and MariaDB 10.2.13.
`[xtrabackup]`	Options read by Mariabackup and Percona XtraBackup.
`[mysql_upgrade]`	Options read by mysql_upgrade, which includes both MariaDB Server and MySQL Server.
`[mariadb-upgrade]`	Options read by mariadb-upgrade. Available starting with MariaDB 10.4.6.
`[sst]`	Specific options read by the mariabackup SST method and the xtrabackup-v2 SST method.
`[mysql]`	Options read by mysql, which includes both MariaDB Server and MySQL Server.
`[mariadb-client]`	Options read by mariadb. Available starting with MariaDB 10.4.6.
`[mysqldump]`	Options read by mysqldump, which includes both MariaDB Server and MySQL Server.

`[mariadb-dump]`	Options read by mariadb-dump. Available starting with MariaDB 10.4.6.
`[mysqlimport]`	Options read by mysqlimport, which includes both MariaDB Server and MySQL Server.
`[mariadb-import]`	Options read by mariadb-import. Available starting with MariaDB 10.4.6.
`[mysqlbinlog]`	Options read by mysqlbinlog, which includes both MariaDB Server and MySQL Server.
`[mariadb-binlog]`	Options read by mariadb-binlog. Available starting with MariaDB 10.4.6.
`[mysqladmin]`	Options read by mysqladmin, which includes both MariaDB Server and MySQL Server.
`[mariadb-admin]`	Options read by mariadb-admin. Available starting with MariaDB 10.4.6.
`[mysqlshow]`	Options read by mysqlshow, which includes both MariaDB Server and MySQL Server.
`[mariadb-show]`	Options read by mariadb-show. Available starting with MariaDB 10.4.6.
`[mysqlcheck]`	Options read by mariadb-check, which includes both MariaDB Server and MySQL Server.
`[mariadb-check]`	Options read by mariadb-check. Available starting with MariaDB 10.4.6.
`[mysqlslap]`	Options read by mysqlslap, which includes both MariaDB Server and MySQL Server.
`[mariadb-slap]`	Options read by `mariadb-slap`. Available starting with MariaDB 10.4.6.
`[odbc]`	Options read by MariaDB Connector/ODBC, but only if the `USE_MYCNF` parameter has been set.

Custom Option Group Suffixes

MariaDB can be configured to read options from option groups with a custom suffix by providing the following command-line argument. This command-line argument can be used with most of MariaDB's command-line tools, not just `mariadbd`. It must be given as the first argument on the command-line:

Option	Description
`--defaults-group-suffix=suffix`	In addition to the default option groups, also read option groups with the given suffix.

The default group suffix can also be specified via the `MYSQL_GROUP_SUFFIX` environment variable.

Including Option Files

It is possible to include additional option files from another option file. For example, to include `/etc/mysql/dbserver1.cnf`, an option file could contain:

```
[mariadb]
...
!include /etc/mysql/dbserver1.cnf
```

Including Option File Directories

It is also possible to include all option files in a directory from another option file. For example, to include all option files in `/etc/my.cnf.d/`, an option file could contain:

```
[mariadb]
...
!includedir /etc/my.cnf.d/
```

The option files within the directory are read in alphabetical order.

All option file names must end in `.cnf` on Unix-like operating systems. On Windows, all option file names must end in `.cnf` or `.ini`.

Checking Program Options

You can check which options a given program is going to use by using the `--print-defaults` command-line argument:

Option	Description
`--print-defaults`	Read options from option files, print all option values, and then exit the program.

This command-line argument can be used with most of MariaDB's command-line tools, not just `mariadbd`. It must be given as the first argument on the command-line. For example:

```
$ mariadb-dump --print-defaults
mariadb-dump would have been started with the following arguments:
--ssl_cert=/etc/my.cnf.d/certificates/client-cert.pem --
ssl_key=/etc/my.cnf.d/certificates/client-key.pem --ssl_ca=/etc/my.cnf.d/certificates/ca.pem --
ssl-verify-server-cert --max_allowed_packet=1GB
```

You can also check which options a given program is going to use by using the `my_print_defaults` utility and providing the names of the option groups that the program reads. For example:

```
$ my_print_defaults mariadb-dump client client-server client-mariadb
--ssl_cert=/etc/my.cnf.d/certificates/client-cert.pem
--ssl_key=/etc/my.cnf.d/certificates/client-key.pem
--ssl_ca=/etc/my.cnf.d/certificates/ca.pem
--ssl-verify-server-cert
--max_allowed_packet=1GB
```

The `my_print_defaults` utility's `--mariadbd` command-line option provides a shortcut to refer to all of the server option groups:

```
$ my_print_defaults --mysqld
--log_bin=mariadb-bin
--log_slave_updates=ON
--ssl_cert=/etc/my.cnf.d/certificates/server-cert.pem
--ssl_key=/etc/my.cnf.d/certificates/server-key.pem
--ssl_ca=/etc/my.cnf.d/certificates/ca.pem
```

MySQL 5.6 Obfuscated Authentication Credential Option File

MySQL 5.6 and above support an obfuscated authentication credential option file called `.mylogin.cnf` that is created with `mysql_config_editor`.

MariaDB does not support this. The passwords in MySQL's `.mylogin.cnf` are only obfuscated, rather than encrypted, so the feature does not really add much from a security perspective. It is more likely to give users a false sense of security, rather than to seriously protect them.

Option Prefixes

MariaDB supports certain prefixes that can be used with options. The supported option prefixes are:

Option Prefix	Description
`autoset`	Sets the option value automatically. Only supported for certain options.
`disable`	For all boolean options, disables the setting (equivalent to setting it to `0`). Same as `skip`.
`enable`	For all boolean options, enables the setting (equivalent to setting it to `1`).
`loose`	Don't produce an error if the option doesn't exist.
`maximum`	Sets the maximum value for the option.
`skip`	For all boolean options, disables the setting (equivalent to setting it to `0`). Same as `disable`.

For example:

```
[mariadb]
...
# determine a good value for open_files_limit automatically
autoset_open_files_limit

# disable the unix socket plugin
disable_unix_socket

# enable the slow query log
enable_slow_query_log

# don't produce an error if these options don't exist
loose_file_key_management_filename = /etc/mysql/encryption/keyfile.enc
loose_file_key_management_filekey = FILE:/etc/mysql/encryption/keyfile.key
loose_file_key_management_encryption_algorithm = AES_CTR

# set max_allowed_packet to maximum value
maximum_max_allowed_packet

# disable external locking for MyISAM
skip_external_locking
```

Options

Dashes (`-`) and underscores (`_`) in options are interchangeable.

If an option is not explicitly set, then the server or client will simply use the default value for that option.

MariaDB Server Options

MariaDB Server options can be set in server option groups.

For a list of options that can be set for MariaDB Server, see the list of options available for `mariadbd`.

Most of the server system variables can also be set in MariaDB's option file.

MariaDB Client Options

MariaDB client options can be set in client option groups.

See the specific page for each client program to determine what options are available for that program.

Example Option Files

Most MariaDB installations include a sample MariaDB option file called `my-default.cnf`. On older releases, you would have also found the following option files:

- `my-small.cnf`
- `my-medium.cnf`
- `my-large.cnf`
- `my-huge.cnf`

However, these option files are now very dated for modern servers, so they were removed in MariaDB 10.3.1.

In source distributions, the sample option files are usually found in the `support-files` directory, and in other distributions, the option files are usually found in the `share/mysql` directory that is relative to the MariaDB base installation directory.

You can copy one of these sample MariaDB option files and use it as the basis for building your server's primary MariaDB option file.

Example Minimal Option File

The following is a minimal my.cnf file that you can use to test MariaDB.

```
[client-server]
# Uncomment these if you want to use a nonstandard connection to MariaDB
#socket=/tmp/mysql.sock
#port=3306

# This will be passed to all MariaDB clients
[client]
#password=my_password

# The MariaDB server
[mysqld]
# Directory where you want to put your data
data=/usr/local/mysql/var
# Directory for the errmsg.sys file in the language you want to use
language=/usr/local/share/mysql/english

# This is the prefix name to be used for all log, error and replication files
log-basename=mysqld

# Enable logging by default to help find problems
general-log
log-slow-queries
```

Example Hybrid Option File

The following is an extract of an option file that one can use if one wants to work with both MySQL and MariaDB.

```
# Example mysql config file.

[client-server]
socket=/tmp/mysql-dbug.sock
port=3307

# This will be passed to all mariadb clients
[client]
password=my_password

# Here are entries for some specific programs
# The following values assume you have at least 32M ram

# The MariaDB server
[mysqld]
temp-pool
key_buffer_size=16M
datadir=/my/mysqldata
loose-innodb_file_per_table

[mariadb]
datadir=/my/data
default-storage-engine=aria
loose-mutex-deadlock-detector
max-connections=20

[mariadb-5.5]
language=/my/maria-5.5/sql/share/english/
socket=/tmp/mysql-dbug.sock
port=3307

[mariadb-10.1]
language=/my/maria-10.1/sql/share/english/
socket=/tmp/mysql2-dbug.sock

[mysqldump]
quick
max_allowed_packet=16M

[mysql]
no-auto-rehash
loose-abort-source-on-error
```

2.1.6.3 mysqld Configuration Files and Groups

For all about configuring mysqld, see Configuring MariaDB with Option Files.

2.1.6.4 mariadbd Options

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadbd` is a symlink to `mysqld`.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadbd` is the name of the binary, with `mysqld` a symlink.

This page lists all of the options for `mariadbd` (called mysqld before MariaDB 10.5), ordered by topic. For a full alphabetical list of all mariadbd options, as well as server and status variables, see Full list of MariaDB options, system and status variables.

In many cases, the entry here is a summary, and links to the full description.

By convention, server variables have usually been specified with an underscore in the configuration files, and a dash on the command line. You can however specify underscores as dashes - they are interchangeable.

See Configuring MariaDB with Option Files for which files and groups mariadbd reads for it's default options.

Option Prefixes

`--autoset-*`

- **Description:** Sets the option value automatically. Only supported for certain options.

`--disable-*`

- **Description:** For all boolean options, disables the setting (equivalent to setting it to `0`). Same as `--skip`.

`--enable-*`

- **Description:** For all boolean options, enables the setting (equivalent to setting it to `1`).

`--loose-*`

- **Description:** Don't produce an error if the option doesn't exist.

`--maximum-*`

- **Description:** Sets the maximum value for the option.

`--skip-*`

- **Description:** For all boolean options, disables the setting (equivalent to setting it to `0`). Same as `--disable`.

Option File Options

`--defaults-extra-file`

- **Commandline:** `--defaults-extra-file=name`
- **Description:** Read this extra option file after all other option files are read.
  - See Configuring MariaDB with Option Files.

`--defaults-file`

- **Commandline:** `--defaults-file=name`
- **Description:** Only read options from the given option file.
  - See Configuring MariaDB with Option Files.

`--defaults-group-suffix`

- **Commandline:** `--defaults-group-suffix=name`
- **Description:** In addition to the default option groups, also read option groups with the given suffix.
  - See Configuring MariaDB with Option Files.

`--no-defaults`

- **Commandline:** `--no-defaults`
- **Description:** Don't read options from any option file.
  - See Configuring MariaDB with Option Files.

`--print-defaults`

- **Commandline:** `--print-defaults`
- **Description:** Read options from option files, print all option values, and then exit the program.
  - See Configuring MariaDB with Option Files.

Compatibility Options

The following options have been added to MariaDB to make it more compliant with other MariaDB and MySQL versions.

Options that are also system variables are listed after:

`-a, --ansi`

- **Description:** Use ANSI SQL syntax instead of MariaDB syntax. This mode will also set transaction isolation level serializable.

`--new`

- **Description:** Use new functionality that will exist in next version of MariaDB. This function exists to make it easier to prepare for an upgrade. For version 5.1 this functions enables the LIST and RANGE partitions functions for ndbcluster.

`--old-style-user-limits`

- **Description:** Enable old-style user limits (before MySQL 5.0.3, user resources were counted per each user+host vs. per account).

`--safe-mode`

- **Description:** Disable some potential unsafe optimizations. For 5.2, INSERT DELAYED is disabled, myisam_recover_options is set to DEFAULT (automatically recover crashed MyISAM files) and the query cache is disabled. For Aria tables, disable bulk insert optimization to enable one to use aria_read_log to recover tables even if tables are deleted (good for testing recovery).

`--skip-new`

- **Description:** Disables --new in 5.2. In 5.1 used to disable some new potentially unsafe functions.

Compatibility Options and System Variables

- --old
- --old-alter-table
- --old-mode
- --old-passwords
- --show-old-temporals

Locale Options

Options that are also system variables are listed after:

`--character-set-client-handshake`

- **Commandline:** `--character-set-client-handshake`
- **Description:** Don't ignore client side character set value sent during handshake.

`--default-character-set`

- **Commandline:** `--default-character-set=name`
- **Description:** Still available as an option for setting the default character set for clients and their connections, it was deprecated and removed in MariaDB 10.2 as a server option. Use character-set-server instead.

`--language`

- **Description:** This option can be used to set the server's language for error messages. This option can be specified either as a language name or as the path to the directory storing the language's error message file. See Server Locales for a list of supported locales and their associated languages.

- This option is deprecated. Use the `lc_messages` and `lc_messages_dir` system variables instead.
- See Setting the Language for Error Messages for more information.

Locale Options and System Variables

- character-set-filesystem
- character-set-client
- character-set-connection
- character-set-database
- character-set-filesystem
- character-set-results
- character-set-server
- character-set-system
- character-sets-dir
- collation-connection
- collation-database
- collation-server
- default-week-format
- default-time-zone
- lc-messages
- lc-messages-dir
- lc-time-names

Windows Options

Options that are also system variables are listed after:

`--console`

- **Description:** Windows-only option that keeps the console window open and for writing log messages to stderr and stdout. If specified together with --log-error, the last option will take precedence.

`--install`

- **Description:** Windows-only option that installs the `mariadbd` process as a Windows service.
  - The Windows service created with this option auto-starts. If you want a service that is started on demand, then use the `--install-manual` option.
  - This option takes a service name as an argument. If this option is provided without a service name, then the service name defaults to "MARIADB".
  - This option is deprecated and may be removed in a future version. See MDEV-19358 for more information.

`--install-manual`

- **Description:** Windows-only option that installs the `mariadbd` process as a Windows service.
  - The Windows service created with this option is started on demand. If you want a service that auto-starts, use the `--install` option.
  - This option takes a service name as an argument. If this option is provided without a service name, then the service name defaults to "MARIADB".
  - This option is deprecated and may be removed in a future version. See MDEV-19358 for more information.

`--remove`

- **Description:** Windows-only option that removes the Windows service created by the `--install` or `--install-manual` options.
  - This option takes a service name as an argument. If this option is provided without a service name, then the service name defaults to "MARIADB".
  - This option is deprecated and may be removed in a future version. See MDEV-19358 for more information.

`--slow-start-timeout`

- **Description:** Windows-only option that defines the maximum number of milliseconds that the service control manager should wait before trying to kill the Windows service during startup. Defaults to `15000`.

`--standalone`

- **Description:** Windows-only option that has no effect. Kept for compatibility reasons.

Windows Options and System Variables

The following options and system variables are related to using MariaDB on Windows:

- `--named-pipe`

Replication and Binary Logging Options

The following options are related to replication and the binary log. Options that are also system variables are listed after:

`--abort-slave-event-count`

- **Commandline:** `--abort-slave-event-count=#`
- **Description:** Option used by mysql-test for debugging and testing of replication.

`--binlog-do-db`

- **Commandline:** `--binlog-do-db=name`
- **Description:** This option allows you to configure a replication master to write statements and transactions affecting databases that match a specified name into its binary log. Since the filtered statements or transactions will not be present in the binary log, its replicas will not be able to replicate them.
  - This option will **not** work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.
  - This option can **not** be set dynamically. Available as a system variable from MariaDB 11.2.0.
  - When setting it on the command-line or in a server option group in an option file, the option does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the option multiple times.
  - See Replication Filters for more information.

`--binlog-ignore-db`

- **Commandline:** `--binlog-ignore-db=name`
- **Description:** This option allows you to configure a replication master to **not** write statements and transactions affecting databases that match a specified name into its binary log. Since the filtered statements or transactions will not be present in the binary log, its replicas will not be able to replicate them.
  - This option will **not** work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.
  - This option can **not** be set dynamically. Available as a system variable from MariaDB 11.2.0.
  - When setting it on the command-line or in a server option group in an option file, the option does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the option multiple times.
  - See Replication Filters for more information.

`--binlog-row-event-max-size`

- **Commandline:** `--binlog-row-event-max-size=#`
- **Description:** The maximum size of a row-based binary log event in bytes. Rows will be grouped into events smaller than this size if possible. The value has to be a multiple of 256. Available as a system variable from MariaDB 11.2.0.
- **Default value** `8192`

`--disconnect-slave-event-count`

- **Commandline:** `--disconnect-slave-event-count=#`
- **Description:** Option used by mysql-test for debugging and testing of replication.

`--flashback`

- **Commandline:** `--flashback`
- **Description:** Setup the server to use flashback. This enables the binary log and sets `binlog_format=ROW`.
- **Introduced:** MariaDB 10.2.4

`--init-rpl-role`

- **Commandline:** `--init-rpl-role=name`
- **Description:** Set the replication role.

`--log-basename`

- **Commandline:** `--log-basename=name`
- **Description:** Basename for all log files and the .pid file. This sets all log file names at once (in 'datadir') and is normally the only option you need for specifying log files. This is especially recommended to be set if you are using replication as it ensures that your log file names are not dependent on your host name. Sets names for log-bin, log-bin-index, relay-log, relay-log-index, general-log-file, `--log-slow-query-log-file`, `--log-error-file`, and pid-file.
- **Introduced:** MariaDB 5.2

`--log-bin-trust-routine-creators`

- **Commandline:** `--log-bin-trust-routine-creators`
- **Description:** Deprecated, use log-bin-trust-function-creators.

`--master-host`

- **Commandline:** `--master-host=name`
- **Description:** Primary hostname or IP address for replication. If not set, the replica thread will not be started. Note that the setting of master-host will be ignored if there exists a valid master.info file.

`--master-info-file`

- **Commandline:** `--master-info-file=name`
- **Description:** Name and location of the file on the replica where the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options (i.e. the binary log position on the primary) and most other CHANGE MASTER options are written. The replica's I/O thread keeps this binary log position updated as it downloads events.
  - See CHANGE MASTER TO: Option Persistence for more information.

`--master-password`

- **Commandline:** `--master-password=name`
- **Description:** The password the replica thread will authenticate with when connecting to the primary. If not set, an empty password is assumed. The value in master.info will take precedence if it can be read.

`--master-port`

- **Commandline:** `--master-port=#`
- **Description:** The port the master is listening on. If not set, the compiled setting of MYSQL_PORT is assumed. If you have not tinkered with configure options, this should be 3306. The value in master.info will take precedence if it can be read.

--master-retry-count

- **Commandline:** `--master-retry-count=#`
- **Description:** Number of times a replica will attempt to connect to a primary before giving up. The retry interval is determined by the MASTER_CONNECT_RETRY option for the CHANGE MASTER statement. A value of 0 means the replica will not stop attempting to reconnect. Reconnects are triggered when a replica has timed out. See slave_net_timeout.
- **Default Value:** `86400`
- **Range - 32 bit:** `0 to 4294967295`
- **Range - 64 bit:** `0 to 18446744073709551615`

--master-ssl

- **Commandline:** `--master-ssl`
- **Description:** Enable the replica to connect to the master using TLS.

--master-ssl-ca

- **Commandline:** `--master-ssl-ca[=name]`
- **Description:** Master TLS CA file. Only applies if you have enabled master-ssl.

--master-ssl-capath

- **Commandline:** `--master-ssl-capath[=name]`
- **Description:** Master TLS CA path. Only applies if you have enabled master-ssl.

--master-ssl-cert

- **Commandline:** `--master-ssl-cert[=name]`
- **Description:** Master TLS certificate file name. Only applies if you have enabled master-ssl.

--master-ssl-cipher

- **Commandline:** `--master-ssl-cipher[=name]`
- **Description:** Master TLS cipher. Only applies if you have enabled master-ssl.

--master-ssl-key

- **Commandline:** `--master-ssl-key[=name]`
- **Description:** Master TLS keyfile name. Only applies if you have enabled master-ssl.

--master-user

- **Commandline:** `--master-user=name`
- **Description:** The username the replica thread will use for authentication when connecting to the primary. The user must have FILE privilege. If the primary user is not set, user test is assumed. The value in master.info will take precedence if it can be read.

--max-binlog-dump-events

- **Commandline:** `--max-binlog-dump-events=#`
- **Description:** Option used by mysql-test for debugging and testing of replication.

--replicate-same-server-id

- **Commandline:** `--replicate-same-server-id`

- **Description:** In replication, if set to 1, do not skip events having our server id. Default value is 0 (to break infinite loops in circular replication). Can't be set to 1 if log-slave-updates is used.

`--sporadic-binlog-dump-fail`

- **Commandline:** `--sporadic-binlog-dump-fail`
- **Description:** Option used by mysql-test for debugging and testing of replication.

`--sysdate-is-now`

- **Commandline:** `--sysdate-is-now`
- **Description:** Non-default option to alias SYSDATE() to NOW() to make it safe for replication. Since 5.0, SYSDATE() has returned a `dynamic' value different for different invocations, even within the same statement.

Replication and Binary Logging Options and System Variables

The following options and system variables are related to replication and the binary log:

- auto-increment-increment
- auto-increment-offset
- binlog-alter-two-phase
- binlog-annotate-row-events
- binlog-cache-size
- binlog-checksum
- binlog-commit-wait-count
- binlog-commit-wait-usec
- binlog-direct-non-transactional-updates|
- binlog-expire-logs-seconds
- binlog-file-cache-size
- binlog-format
- binlog-optimize-thread-scheduling
- binlog-row-image
- binlog-row-metadata
- binlog-stmt-cache-size
- default-master-connection
- gtid-cleanup-batch-size
- gtid-domain-id
- gtid-ignore-duplicates
- gtid-strict-mode
- init-slave
- log-bin
- log-bin-compress
- log-bin-compress-min-len
- log-bin-index
- log-bin-trust-function-creators
- log-slave-updates
- master-verify-checksum
- max-binlog-cache-size
- max-binlog-size
- max-binlog-stmt-cache-size
- max-relay-log-size
- read-binlog-speed-limit
- relay-log
- relay-log-index
- relay-log-info-file
- relay-log-purge
- relay-log-recovery
- relay-log-space-limit
- replicate-annotate-row-events
- replicate-do-db
- replicate-do-table
- replicate-events-marked-for-skip
- replicate-ignore-db
- replicate-ignore-table

- replicate-rewrite-db
- replicate-wild-do-table

- slave-parallel-threads
- slave-run-triggers-for-rbr
- slave-skip-errors
- slave-sql-verify-checksum
- slave-transaction-retries
- slave_transaction_retry_errors
- slave_transaction_retry_interval
- slave-type-conversions
- sync-binlog
- sync-master-info
- sync-relay-log
- sync-relay-log-info

Semisynchronous Replication Options and System Variables

The options and system variables related to Semisynchronous Replication are described here.

Optimizer Options

Options that are also system variables are listed after:

`--record-buffer`

- **Commandline:** `--record-buffer=#`
- **Description:** Old alias for read_buffer_size.
- **Removed:** MariaDB 5.5

`--table-cache`

- **Commandline:** `--table-open-cache=#`
- **Description:** Removed; use --table-open-cache instead.
- **Removed:** MariaDB 5.1.3

Optimizer Options and System Variables

- alter-algorithm
- analyze-sample-percentage
- big-tables
- bulk-insert-buffer-size
- expensive-subquery-limit
- join-buffer-size
- join-buffer-space-limit
- join-cache-level
- max-heap-table-size
- max-join-size

- max-seeks-for-key
- max-sort-length
- mrr-buffer-size
- optimizer-extra-pruning-depth
- optimizer-max-sel-arg-weight
- optimizer-prune-level
- optimizer-search-depth
- optimizer-selectivity-sampling-limit
- optimizer-switch
- optimizer-trace
- optimizer-trace-max-mem-size
- optimizer-use-condition-selectivity
- query-alloc-block-size
- query-prealloc-size
- range-alloc-block-size
- read-buffer-size
- rowid-merge-buff-size
- table-definition-cache
- table-open-cache
- table-open-cache-instances
- tmp-disk-table-size
- tmp-memory-table-size
- tmp-table-size
- use-stat-tables

Storage Engine Options

`--skip-bdb`

- **Commandline:** `----skip-bdb`
- **Description:** Deprecated option; Exists only for compatibility with very old my.cnf files.
- **Removed:** MariaDB 10.5.1

`--external-locking`

- **Commandline:** `--external-locking`
- **Description:** Use system (external) locking (disabled by default). With this option enabled you can run myisamchk to test (not repair) tables while the server is running. Disable with --skip-external-locking. From MariaDB 10.2.40, MariaDB 10.3.31, MariaDB 10.4.21, MariaDB 10.5.12, MariaDB 10.6.4 and all later version, this effects InnoDB and can be used to prevent multiple instances running on the same data.

MyISAM Storage Engine Options

The options related to the MyISAM storage engine are described below. Options that are also system variables are listed after:

`--log-isam`

- **Commandline:** `--log-isam[=file_name]`
- **Description:** Enable the MyISAM log, which logs all MyISAM changes to file. If no filename is provided, the default, *myisam.log* is used.

MyISAM Storage Engine Options and System Variables

Some options and system variables related to the MyISAM storage engine can be found here. Direct links to many of them can be found below.

- concurrent-insert
- delayed-insert-limit
- delayed-insert-timeout
- delayed-queue-size
- keep-files-on-create

- key-buffer-size
- key-cache-age-threshold
- key-cache-block-size
- key-cache-division-limit
- key-cache-file-hash-size
- key-cache-segments
- myisam-block-size
- myisam-data-pointer-size
- myisam-max-sort-file-size
- myisam-mmap-size
- myisam-recover-options
- myisam-repair-threads
- myisam-sort-buffer-size
- myisam-stats-method
- myisam-use-mmap

InnoDB Storage Engine Options

The options related to the InnoDB storage engine are described below. Options that are also system variables are listed after:

`--innodb`

- **Commandline:** `--innodb=value`, `--skip-innodb`
- **Description:** This variable controls whether or not to load the InnoDB storage engine. Possible values are `ON`, `OFF`, `FORCE` or `FORCE_PLUS_PERMANENT` (from MariaDB 5.5). If set to `OFF` (the same as --skip-innodb), since InnoDB is the default storage engine, the server will not start unless another storage engine has been chosen with --default-storage-engine. `FORCE` means that the storage engine must be successfully loaded, or else the server won't start. `FORCE_PLUS_PERMANENT` enables the plugin, but if plugin cannot initialize, the server will not start. In addition, the plugin cannot be uninstalled while the server is running.

`--innodb-cmp`

- **Commandline:** `--innodb-cmp`
- **Description:**
- **Default:** `ON`

`--innodb-cmp-reset`

- **Commandline:** `--innodb-cmp-reset`
- **Description:**
- **Default:** `ON`

`--innodb-cmpmem`

- **Commandline:** `--innodb-cmpmem`
- **Description:**
- **Default:** `ON`

`--innodb-cmpmem-reset`

- **Commandline:** `--innodb-cmpmem-reset`
- **Description:**
- **Default:** `ON`

`--innodb-file-io-threads`

- **Commandline:** `--innodb-file-io-threads`
- **Description:**
- **Default:** `4`

- **Removed:** MariaDB 10.3.0

`--innodb-index-stats`

- **Commandline:** `--innodb-index-stats`
- **Description:**
- **Default:** `ON`
- **Removed:** MariaDB 10.0.0

`--innodb-lock-waits`

- **Commandline:** `--innodb-lock-waits`
- **Description:**
- **Default:** `ON`

`--innodb-locks`

- **Commandline:** `--innodb-locks`
- **Description:**
- **Default:** `ON`

`--innodb-rseg`

- **Commandline:** `--innodb-rseg`
- **Description:**
- **Default:** `ON`
- **Removed:** MariaDB 10.0.0

`--innodb-status-file`

- **Commandline:** `--innodb-status-file`
- **Description:**
- **Default:** `FALSE`

`--innodb-sys-indexes`

- **Commandline:** `--innodb-sys-indexes`
- **Description:**
- **Default:** `ON`

`--innodb-sys-stats`

- **Commandline:** `--innodb-sys-stats`
- **Description:**
- **Default:** `ON`
- **Removed:** MariaDB 10.0.0

`--innodb-sys-tables`

- **Commandline:** `--innodb-sys-tables`
- **Description:**
- **Default:** `ON`

`--innodb-table-stats`

- **Commandline:** `--innodb-table-stats`
- **Description:**
- **Default:** `ON`
- **Removed:** MariaDB 10.0.0

`--innodb-trx`

- **Commandline:** `--innodb-trx`
- **Description:**
- **Default:** `ON`

Aria Storage Engine Options

The options related to the Aria storage engine are described below. Options that are also system variables are listed after:

`--aria-log-dir-path`

- **Commandline:** `--aria-log-dir-path=value`
- **Description:** Path to the directory where transactional log should be stored
- **Default:** `SAME AS DATADIR`

Aria Storage Engine Options and System Variables

Some options and system variables related to the Aria storage engine can be found here. Direct links to many of them can be found below.

MyRocks Storage Engine Options

The options and system variables related to the MyRocks storage engine can be found here.

S3 Storage Engine Options

The options and system variables related to the S3 storage engine can be found here.

CONNECT Storage Engine Options

The options related to the CONNECT storage engine are described below.

CONNECT Storage Engine Options and System Variables

Some options and system variables related to the CONNECT storage engine can be found here. Direct links to many of them can be found below.

- connect-class-path
- connect-cond-push
- connect-conv-size
- connect-default-depth
- connect-default-prec
- connect-enable-mongo
- connect-exact-info
- connect-force_bson
- connect-indx-map
- connect-java-wrapper
- connect-json-all-path
- connect-json-grp-size
- connect-json-null
- connect-jvm-path
- connect-type-conv
- connect-use-tempfile
- connect-work-size

- connect-xtrace

Spider Storage Engine Options

The options and system variables related to the Spider storage engine can be found here.

Mroonga Storage Engine Options

The options and system variables related to the Mroonga storage engine can be found here.

TokuDB Storage Engine Options

The options and system variables related to the TokuDB storage engine can be found here.

Performance Schema Options

The options related to the Performance Schema are described below. Options that are also system variables are listed after:

`--performance-schema-consumer-events-stages-current`

- **Commandline:** `--performance-schema-consumer-events-stages-current`
- **Description:** Enable the events-stages-current consumer.
- **Default:** `OFF`

`--performance-schema-consumer-events-stages-history`

- **Commandline:** `--performance-schema-consumer-events-stages-history`
- **Description:** Enable the events-stages-history consumer.
- **Default:** `OFF`

`--performance-schema-consumer-events-stages-history-long`

- **Commandline:** `--performance-schema-consumer-events-stages-history-long`
- **Description:** Enable the events-stages-history-long consumer.
- **Default:** `OFF`

`--performance-schema-consumer-events-statements-current`

- **Commandline:** `--performance-schema-consumer-events-statements-current`
- **Description:** Enable the events-statements-current consumer. Use `--skip-performance-schema-consumer-events-statements-current` to disable.
- **Default:** `ON`

`--performance-schema-consumer-events-statements-history`

- **Commandline:** `--performance-schema-consumer-events-statements-history`
- **Description:** Enable the events-statements-history consumer.
- **Default:** `OFF`

`--performance-schema-consumer-events-statements-history-long`

- **Commandline:** `--performance-schema-consumer-events-statements-history-long`
- **Description:** Enable the events-statements-history-long consumer.
- **Default:** `OFF`

`--performance-schema-consumer-events-waits-current`

- **Commandline:** `--performance-schema-consumer-events-waits-current`
- **Description:** Enable the events-waits-current consumer.
- **Default:** `OFF`

`--performance-schema-consumer-events-waits-history`

- **Commandline:** `--performance-schema-consumer-events-waits-history`
- **Description:** Enable the events-waits-history consumer.
- **Default:** `OFF`

`--performance-schema-consumer-events-waits-history-long`

- **Commandline:** `--performance-schema-consumer-events-waits-history-long`
- **Description:** Enable the events-waits-history-long consumer.
- **Default:** `OFF`

`--performance-schema-consumer-global-instrumentation`

- **Commandline:** `--performance-schema-consumer-global-instrumentation`
- **Description:** Enable the global-instrumentation consumer. Use `--skip-performance-schema-consumer-global-instrumentation` to disable.
- **Default:** `ON`

`--performance-schema-consumer-statements-digest`

- **Commandline:** `--performance-schema-consumer-statements-digest`
- **Description:** Enable the statements-digest consumer. Use `--skip-performance-schema-consumer-statements-digest` to disable.
- **Default:** `ON`

`--performance-schema-consumer-thread-instrumentation`

- **Commandline:** `--performance-schema-consumer-thread-instrumentation`
- **Description:** Enable the statements-thread-instrumentation. Use `--skip-performance-schema-thread-instrumentation` to disable.
- **Default:** `ON`

Performance Schema Options and System Variables

Galera Cluster Options

The options related to Galera Cluster are described below. Options that are also system variables are listed after:

`--wsrep-new-cluster`

- **Commandline:** `--wsrep-new-cluster`
- **Description:** Bootstrap a cluster. It works by overriding the current value of wsrep_cluster_address. It is recommended not to add this option to the config file as this will trigger bootstrap on every server start.

Galera Cluster Options and System Variables

Some options and system variables related to Galera Cluster can be found here. Direct links to many of them can be found below.

Options When Debugging mariadbd

`--debug-assert-if-crashed-table`

- **Description:** Do an assert in handler::print_error() if we get a crashed table.

`--debug-binlog-fsync-sleep`

- **Description:** `--debug-binlog-fsync-sleep=#` If not set to zero, sets the number of micro-seconds to sleep after running fsync() on the binary log to flush transactions to disk. This can thus be used to artificially increase the perceived cost of such an fsync().

`--debug-crc-break`

- **Description:** `--debug-crc-break=#` Call my_debug_put_break_here() if crc matches this number (for debug).

`--debug-flush`

- **Description:** Default debug log with flush after write.

`--debug-no-sync`

- **Description:** `debug-no-sync[=#]` Disables system sync calls. Only for running tests or debugging!

`--debug-sync-timeout`

- **Description:** `debug-sync-timeout[=#]` Enable the debug sync facility and optionally specify a default wait timeout in seconds. A zero value keeps the facility disabled.

`--gdb`

- **Description:** Set up signals usable for debugging.

`--silent-startup`

- **Description:** Don't print Notes to the error log during startup.

`--sync-sys`

- **Description:** Enable/disable system sync calls. Syncs should only be turned off (`--disable-sync-sys`) when

running tests or debugging! Replaced by debug-no-sync from MariaDB 5.5.
- **Removed:** MariaDB 5.5

`--thread-alarm`

- **Description:** Enable/disable system thread alarm calls. Should only be turned off (`--disable-thread-alarm`) when running tests or debugging!

Debugging Options and System Variables

- core-file
- debug
- debug-no-thread-alarm

Other Options

Options that are also system variables are listed after:

`--allow-suspicious-udfs`

- **Commandline:** `--allow-suspicious-udfs`
- **Description:** Allows use of user-defined functions consisting of only one symbol `x()` without corresponding `x_init()` or `x_deinit()` . That also means that one can load any function from any library, for example `exit()` from `libc.so` . Not recommended unless you require old UDFs with one symbol that cannot be recompiled. From MariaDB 10.10, available as a system variable as well.

`--bootstrap`

- **Commandline:** `--bootstrap`
- **Description:** Used by mariadb installation scripts, such as mariadb-install-db to execute SQL scripts before any privilege or system tables exist. Do no use while an existing MariaDB instance is running.

`--chroot`

- **Commandline:** `--chroot=name`
- **Description:** Chroot mariadbd daemon during startup.

`--des-key-file`

- **Commandline:** `--des-key-file=name`
- **Description:** Load keys for des_encrypt() and des_encrypt from given file.

`--exit-info`

- **Commandline:** `--exit-info[=#]`
- **Description:** Used for debugging. Use at your own risk.

`--getopt-prefix-matching`

- **Commandline:** `--getopt-prefix-matching={0|1}`
- **Description:** Makes it possible to disable historical "unambiguous prefix" matching in the command-line option parsing.
- **Default:** TRUE
- **Introduced:** MariaDB 10.1.3

--help

- **Commandline:** `--help`
- **Description:** Displays help with many commandline options described, and exits.

--log-ddl-recovery

- **Commandline:** `--log-ddl-recovery=name`
- **Description:** Path to file used for recovery of DDL statements after a crash.
- **Default Value:** `ddl-recover.log`
- **Introduced:** MariaDB 10.6.1

--log-short-format

- **Commandline:** `--log-short-format`
- **Description:** Don't log extra information to update and slow-query logs.

--log-slow-file

- **Commandline:** `--log-slow-file=name`
- **Description:** Log slow queries to given log file. Defaults logging to hostname-slow.log

---

--log-slow-time

- **Commandline:** `--log-slow-time=#`
- **Description:** Log all queries that have taken more than long-query-time seconds to execute to the slow query log, if active. The argument will be treated as a decimal value with microsecond precision.

--log-tc

- **Commandline:** `--log-tc=name`
- **Description:** Defines the path to the memory-mapped file-based transaction coordinator log, which is only used if the binary log is disabled. If you have two or more XA-capable storage engines enabled, then a transaction coordinator log must be available. See Transaction Coordinator Log for more information. Also see the the `log_tc_size` system variable and the `--tc-heuristic-recover` option.
- **Default Value:** `tc.log`

--master-connect-retry

- **Commandline:** `--master-connect-retry=#`
- **Description:** Deprecated in 5.1.17 and removed in 5.5. The number of seconds the replica thread will sleep before retrying to connect to the master, in case the master goes down or the connection is lost.

--memlock

- **Commandline:** `--memlock`
- **Description:** Lock mariadbd in memory.

--ndb-use-copying-alter-table

- **Commandline:** `--ndb-use-copying-alter-table`
- **Description:** Force ndbcluster to always copy tables at alter table (should only be used if on-line alter table fails).

--one-thread

- **Commandline:** `--one-thread`
- **Description:** (Deprecated): Only use one thread (for debugging under Linux). Use thread-handling=no-threads

instead.
- **Removed:** MariaDB 10.0.4

`--plugin-load`

- **Commandline:** `--plugin-load=name`
- **Description:** This option can be used to configure the server to load specific plugins. This option uses the following format:
  - Plugins can be specified in the format `name=library`, where `name` is the plugin name and `library` is the plugin library. This format installs a single plugin from the given plugin library.
  - Plugins can also be specified in the format `library`, where `library` is the plugin library. This format installs all plugins from the given plugin library.
  - Multiple plugins can be specified by separating them with semicolons.
- Special care must be taken when specifying the `--plugin-load` option multiple times, or when specifying both the `--plugin-load` option and the `--plugin-load-add` option together. The `--plugin-load` option resets the plugin load list, and this can cause unexpected problems if you are not aware. The `--plugin-load-add` option does **not** reset the plugin load list, so it is much safer to use. See Plugin Overview: Specifying Multiple Plugin Load Options for more information.
- See Plugin Overview: Installing a Plugin with Plugin Load Options for more information.

`--plugin-load-add`

- **Commandline:** `--plugin-load-add=name`
- **Description:** This option can be used to configure the server to load specific plugins. This option uses the following format:
  - Plugins can be specified in the format `name=library`, where `name` is the plugin name and `library` is the plugin library. This format installs a single plugin from the given plugin library.
  - Plugins can also be specified in the format `library`, where `library` is the plugin library. This format installs all plugins from the given plugin library.
  - Multiple plugins can be specified by separating them with semicolons.
- Special care must be taken when specifying both the `--plugin-load` option and the `--plugin-load-add` option together. The `--plugin-load` option resets the plugin load list, and this can cause unexpected problems if you are not aware. The `--plugin-load-add` option does **not** reset the plugin load list, so it is much safer to use. See Plugin Overview: Specifying Multiple Plugin Load Options for more information.
- See Plugin Overview: Installing a Plugin with Plugin Load Options for more information.

`--port-open-timeout`

- **Commandline:** `--port-open-timeout=#`
- **Description:** Maximum time in seconds to wait for the port to become free. (Default: No wait).

`--safe-user-create`

- **Commandline:** `--safe-user-create`
- **Description:** Don't allow new user creation by the user who has no write privileges to the mysql.user table.

`--safemalloc-mem-limit`

- **Commandline:** `--safemalloc-mem-limit=#`
- **Description:** Simulate memory shortage when compiled with the `--with-debug=full` option.

`--show-slave-auth-info`

- **Commandline:** `--show-slave-auth-info`
- **Description:** Show user and password in SHOW SLAVE HOSTS on this primary.

`--skip-grant-tables`

- **Commandline:** `--skip-grant-tables`
- **Description:** Start without grant tables. This gives all users FULL ACCESS to all tables, which is useful in case of a lost root password. Use mariadb-admin flush-privileges, mariadb-admin reload or FLUSH PRIVILEGES to resume using the grant tables. From MariaDB 10.10, available as a system variable as well.

Because the Event Scheduler also depends on the grant tables for its functionality, it is automatically disabled when running with `--skip-grant-tables`.

`--skip-host-cache`

- **Commandline:** `--skip-host-cache`
- **Description:** Don't cache host names.

`--skip-partition`

- **Commandline:** `--skip-partition`, `--disable-partition`
- **Description:** Disables user-defined partitioning. Previously partitioned tables cannot be accessed or modifed. Tables can still be seen with SHOW TABLES or by viewing the INFORMATION_SCHEMA.TABLES table. Tables can be dropped with DROP TABLE, but this only removes .frm files, not the associated .par files, which will need to be removed manually.

`--skip-slave-start`

- **Commandline:** `--skip-slave-start`
- **Description:** If set, replica is not autostarted.

`--skip-ssl`

- **Commandline:** `--skip-ssl`
- **Description:** Disable TLS connections.

`--skip-symlink`

- **Commandline:** `--skip-symlink`
- **Description:** Don't allow symlinking of tables. Deprecated and removed in MariaDB 5.5. Use symbolic-links with the `skip` option prefix instead.
- **Removed:** MariaDB 5.5

`--skip-thread-priority`

- **Commandline:** `--skip-thread-priority`
- **Description:** Don't give threads different priorities. Deprecated and removed in MariaDB 10.0.
- **Removed:** MariaDB 10.0

`--sql-bin-update-same`

- **Commandline:** `--sql-bin-update-same=#`
- **Description:** The update log was deprecated in version 5.0 and replaced by the binary log, so this option did nothing since then. Deprecated and removed in MariaDB 5.5.
- **Removed:** MariaDB 5.5

`--ssl`

- **Commandline:** `--ssl`
- **Description:** Enable TLS for connection (automatically enabled with other flags). Disable with '`--skip-ssl`'.

`--stack-trace`

- **Commandline:** `--stack-trace`, `--skip-stack-trace`
- **Description:** Print a stack trace on failure. Enabled by default, disable with `-skip-stack-trace`.

`--symbolic-links`

- **Commandline:** `--symbolic-links`
- **Description:** Enables symbolic link support. When set, the have_symlink system variable shows as `YES`. Silently ignored in Windows. Use `--skip-symbolic-links` to disable.

`--tc-heuristic-recover`

- **Commandline:** `--tc-heuristic-recover=name`
- **Description:** If manual heuristic recovery is needed, this option defines the decision to use in the heuristic recovery process. Manual heuristic recovery may be needed if the transaction coordination log is missing or if it doesn't contain all prepared transactions. This option can be set to `OFF`, `COMMIT`, or `ROLLBACK`. The default is `OFF`. See also the `--log-tc` server option and the `log_tc_size` system variable.

`--temp-pool`

- **Commandline:** `--temp-pool`
- **Description:** Using this option will cause most temporary files created to use a small set of names, rather than a unique name for each new file. Defaults to `1` until MariaDB 10.5.6, use `--skip-temp-pool` to disable. Deprecated and defaults to `0` from MariaDB 10.5.7, as benchmarking shows it causes a heavy mutex contention.

`--test-expect-abort`

- **Commandline:** `--test-expect-abort`
- **Description:** Expect that server aborts with 'abort'; Don't write out server variables on 'abort'. Useful only for test scripts.

`--test-ignore-wrong-options`

- **Commandline:** `--test-ignore-wrong-options`
- **Description:** Ignore wrong enums values in command line arguments. Useful only for test scripts.

`--user`

- **Commandline:** `--user=name`
- **Description:** Run mariadbd daemon as user.

`--verbose`

- **Commandline:** `-v`, `--verbose`
- **Description:** Used with help option for detailed help.

Replication Plugins - Options and System Variables

Replication Plugin - `rpl_semi_sync_master`

The system variables related to the `rpl_semi_sync_master` replication plugin can be found here.

The options related to the `rpl_semi_sync_master` replication plugin can be found here.

Replication Plugin - `rpl_semi_sync_slave`

The system variables related to the `rpl_semi_sync_slave` replication plugin can be found here.

The options related to the `rpl_semi_sync_slave` replication plugin can be found here.

Default Values

You can verify the default values for an option by doing:

```
mariadbd --no-defaults --help --verbose
```

2.1.6.5 What to Do if MariaDB Doesn't Start

Contents

There could be many reasons that MariaDB fails to start. This page will help troubleshoot some of the more common reasons and provide solutions.

If you have tried everything here, and still need help, you can ask for help on IRC or on the forums - see Where to find other MariaDB users and developers - or ask a question at the Starting and Stopping MariaDB page.

The Error Log and the Data Directory

The reason for the failure will almost certainly be written in the error log and, if you are starting MariaDB manually, to the console. By default, the error log is named *host-name*.err and is written to the data directory.

Common Locations:

- /var/log/
- /var/log/mysql
- C:\Program Files\MariaDB x.y\data (x.y refers to the version number)
- C:\Program Files (x86)\MariaDB x.y\data (32bit version on 64bit Windows)

It's also possible that the error log has been explicitly written to another location. This is often done by changing the `datadir` or `log_error` system variables in an option file. See Option Files below for more information about that.

A quick way to get the values of these system variables is to execute the following commands:

```
mysqld --help --verbose | grep 'log-error' | tail -1
mysqld --help --verbose | grep 'datadir' | tail -1
```

Option Files

Another kind of file to consider when troubleshooting is option files. The default option file is called `my.cnf`. Option files contain configuration options, such as the location of the data directory mentioned above. If you're unsure where the option file is located, see Configuring MariaDB with Option Files: Default Option File Locations for information on the default locations.

You can check which configuration options MariaDB server will use from its option files by executing the following command:

```
mysqld --print-defaults
```

You can also check by executing the following command:

```
my_print_defaults --mysqld
```

See Configuring MariaDB with Option Files: Checking Program Options for more information on checking configuration options.

Invalid Option or Option Value

Another potential reason for a startup failure is that an option file contains an invalid option or an invalid option value. In those cases, the error log should contain an error similar to this:

```
140514 12:19:37 [ERROR] /usr/local/mysql/bin/mysqld: unknown variable 'option=value'
```

This is more likely to happen when you upgrade to a new version of MariaDB. In most cases the option file from the old version of MariaDB will work just fine with the new version. However, occasionally, options are removed in new versions of MariaDB, or the valid values for options are changed in new versions of MariaDB. Therefore, it's possible for an option file to stop working after an upgrade.

Also remember that option names are case sensitive.

Examine the specifics of the error. Possible fixes are usually one of the following:

- If the option is completely invalid, then remove it from the option file.
- If the option's name has changed, then fix the name.
- If the option's valid values have changed, then change the option's value to a valid one.
- If the problem is caused by a simple typo, then fix the typo.

Can't Open Privilege Tables

It is possible to see errors similar to the following:

```
System error 1067 has occurred.
Fatal error: Can't open privilege tables: Table 'mysql.host' doesn't exist
```

If errors like this occur, then critical system tables are either missing or are in the wrong location. The above error is quite common after an upgrade if the option files set the `basedir` or `datadir` to a non-standard location, but the new server is using the default location. Therefore, make sure that the `basedir` and `datadir` variables are correctly set.

If you're unsure where the option file is located, see Configuring MariaDB with Option Files: Default Option File Locations for information on the default locations.

If the system tables really do not exist, then you may need to create them with mariadb-install-db. See Installing System Tables (mariadb-install-db) for more information.

Can't Create Test File

One of the first tests on startup is to check whether MariaDB can write to the data directory. When this fails, it will log an error like this:

```
May 13 10:24:28 mariadb3 mysqld[19221]: 2019-05-13 10:24:28 0 [Warning] Can't create test file
/usr/local/data/mariadb/mariadb3.lower-test
May 13 10:24:28 mariadb3 mysqld[19221]: 2019-05-13 10:24:28 0 [ERROR] Aborting
```

This is usually a permission error on the directory in which this file is being written. Ensure that the entire `datadir` is owned by the user running `mysqld`, usually `mysql`. Ensure that directories have the "x" (execute) directory permissions for the owner. Ensure that all the parent directories of the `datadir` upwards have "x" (execute) permissions for all (`user`, `group`, and `other`).

Once this is checked look at the systemd and selinux documentation below, or AppArmor.

Can't Lock Aria Control File

On starting MariaDB, the `aria_log_control` file is locked. If a lock cannot be obtained, it will log and error like this:

```
2023-05-01 16:27:03 0 [ERROR] mariadbd: Can't lock aria control file
'/var/lib/mysql/aria_log_control' for exclusive use, error: 11. Will retry for 30 seconds
```

This almost always cause for this is that there is already an existing MariaDB service running on this data directory. Recommend aborting this startup and looking closely for the other MariaDB instance.

The less likely case is there isn't locking available which might occur on a NFS data directory with explictly disable locking.

Unable to lock ./ibdata1 error 11

Like the above for the Aria Control File, this is a attempting to exclusively lock the `ibdata1` InnoDB system tablespace. Error 11 corresponds to the system error "OS error code 11: Resource temporarily unavailable" meaning the lock cannot be created.

```
2023-05-01 16:27:34 0 [ERROR] InnoDB: Unable to lock ./ibdata1 error: 11
2023-05-01 16:27:34 0 [Note] InnoDB: Check that you do not already have another mariadbd process
using the same InnoDB data or log files.
2023-05-01 16:27:34 0 [ERROR] InnoDB: Plugin initialization aborted with error Generic error
2023-05-01 16:27:35 0 [Note] InnoDB: Starting shutdown...
```

Like the above, this is an indication that a second MariaDB instance is already running on the data directory.

InnoDB

InnoDB is probably the MariaDB component that most frequently causes a crash. In the error log, lines containing InnoDB messages generally start with "InnoDB:".

Cannot Allocate Memory for the InnoDB Buffer Pool

In a typical installation on a dedicated server, at least 70% of your memory should be assigned to InnoDB buffer pool; sometimes it can even reach 85%. But be very careful: don't assign to the buffer pool more memory than it can allocate. If it cannot allocate memory, InnoDB will use the disk's swap area, which is very bad for performance. If swapping is disabled or the swap area is not big enough, InnoDB will crash. In this case, MariaDB will probably try to restart several times, and each time it will log a message like this:

```
140124 17:29:01 InnoDB: Fatal error: cannot allocate memory for the buffer pool
```

In that case, you will need to add more memory to your server/VM or decrease the value of the innodb_buffer_pool_size variables.

Remember that the buffer pool will slightly exceed that limit. Also, remember that MariaDB also needs allocate memory for other storage engines and several per-connection buffers. The operating system also needs memory.

InnoDB Table Corruption

By default, InnoDB deliberately crashes the server when it detects table corruption. The reason for this behavior is preventing corruption propagation. However, in some situations, server availability is more important than data integrity. For this reason, we can avoid these crashes by changing the value of innodb_corrupt_table_action to 'warn'.

If InnoDB crashes the server after detecting data corruption, it writes a detailed message in the error log. The first lines are similar to the following:

```
InnoDB: Database page corruption on disk or a failed
InnoDB: file read of page 7.
InnoDB: You may have to recover from a backup.
```

Generally, it is still possible to recover most of the corrupted data. To do so, restart the server in InnoDB recovery mode and try to extract the data that you want to backup. You can save them in a CSV file or in a non-InnoDB table. Then, restart the server in normal mode and restore the data.

MyISAM

Most tables in the mysql database are MyISAM tables. These tables are necessary for MariaDB to properly work, or even

start.

A MariaDB crash could cause system tables corruption. With the default settings, MariaDB will simply not start if the system tables are corrupted. With myisam_recover_options, we can force MyISAM to repair damaged tables.

systemd

If you are using `systemd`, then there are a few relevant notes about startup failures:

- If MariaDB is configured to access files under `/home`, `/root`, or `/run/user`, then the default systemd unit file will prevent access to these directories with a `Permission Denied` error. This happens because the unit file set `ProtectHome=true`. See Systemd: Configuring Access to Home Directories for information on how to work around this.
- The default systemd unit file also sets ProtectSystem=full, which places restrictions on writing to a few other directories. Overwriting this with `ProtectSystem=off` in the same way as above will restore access to these directories.
- If MariaDB takes longer than 90 seconds to start, then the default systemd unit file will cause it to fail with an error. This happens because the default value for the `TimeoutStartSec` option is 90 seconds. See Systemd: Configuring the Systemd Service Timeout for information on how to work around this.
- The systemd journal may also contain useful information about startup failures. See Systemd: Systemd Journal for more information.

See systemd documentation for further information on systemd configuration.

SELinux

Security-Enhanced Linux (SELinux) is a Linux kernel module that provides a framework for configuring mandatory access control (MAC) system for many resources on the system. It is enabled by default on some Linux distributions, including RHEL, CentOS, Fedora, and other similar Linux distribution. SELinux prevents programs from accessing files, directories or ports unless it is configured to access those resources.

You might need to troubleshoot SELinux-related issues in cases, such as:

- MariaDB is using a non-default port.
- MariaDB is reading from or writing to some files (datadir, log files, option files, etc.) located at non-default paths.
- MariaDB is using a plugin that requires access to resources that default installations do not use.

Setting SELinux state to `permissive` is a common way to investigate what is going wrong while allowing MariaDB to function normally. `permissive` is supposed to produce a log entry every time it should block a resource access, without actually blocking it. However, there are situations when SELinux blocks resource accesses even in `permissive` mode.

See SELinux for more information.

AppArmor

Add the following to `/etc/apparmor.d/tunables/alias` if you have moved the datadir:

```
alias /var/lib/mysql/ -> /data/mariadb/,
```

The restart AppArmor:

```
sudo systemctl restart apparmor
```

2.1.6.6 Running MariaDB from the Build Directory

You can run mariadbd directly from the build directory (without doing `make install`).

Starting mariadbd After Build on Windows

On Windows, the data directory is produced during the build.

The simplest way to start database from the command line is:

1. Go to the directory where mariadbd.exe is located (subdirectory sql\Debug or sql\Relwithdebinfo of the build directory)
2. From here, execute, if you are using MariaDB 10.5 or newer,

   ```
   mariadbd.exe --console
   ```

   else

   ```
   mariadbd.exe --console
   ```

As usual, you can pass other server parameters on the command line, or store them in a my.ini configuraton file and pass `--defaults-file=path\to\my.ini`

The default search path on Windows for the my.ini file is:

- GetSystemWindowsDirectory()
- GetWindowsDirectory()
- C:\
- Directory where the executable is located

Starting mariadbd After Build on Unix

Copy the following to your '`~/.my.cnf`' file.

There are two lines you have to edit: '`datadir=`' and '`language=`'. Be sure to change them to match your environment.

```
# Example MariadB config file.
# You can copy this to one of:
# /etc/my.cnf to set global options,
# /mysql-data-dir/my.cnf to get server specific options or
# ~/my.cnf for user specific options.
#
# One can use all long options that the program supports.
# Run the program with --help to get a list of available options

# This will be passed to all MariaDB clients
[client]
#password=my_password
#port=3306
#socket=/tmp/mysql.sock

# Here is entries for some specific programs
# The following values assume you have at least 32M ram

# The mariadb server  (both [mysqld] and [mariadb] works here)
[mariadb]
#port=3306
#socket=/tmp/mysql.sock

# The following three entries caused mysqld 10.0.1-MariaDB (and possibly other versions) to abort
# skip-locking
# set-variable  = key_buffer=16M

loose-innodb_data_file_path = ibdata1:1000M
loose-mutex-deadlock-detector
gdb

######### Fix the two following paths

# Where you want to have your database
datadir=/path/to/data/dir

# Where you have your mysql/MariaDB source + sql/share/english
language=/path/to/src/dir/sql/share/english

########## One can also have a different path for different versions, to simplify development.

[mariadb-10.1]
lc-messages-dir=/my/maria-10.1/sql/share

[mariadb-10.2]
lc-messages-dir=/my/maria-10.2/sql/share

[mysqldump]
quick
set-variable = max_allowed_packet=16M

[mysql]
no-auto-rehash

[myisamchk]
set-variable= key_buffer=128M
```

With the above file in place, go to your MariaDB source directory and execute:

```
./scripts/mariadb-install-db --srcdir=$PWD --datadir=/path/to/data/dir --user=$LOGNAME
```

Above '$PWD' is the environment variable that points to your current directory. If you added `datadir` to your `my.cnf`, you don't have to give this option above. Also above, --user=$LOGNAME is necessary when using msqyld 10.0.1-MariaDB (and possibly other versions)

Now you can start `mariadbd` (or `mysqld` if you are using a version older than MariaDB 10.5) in the debugger:

```
cd sql
ddd ./mariadbd &
```

Or start mariadbd on its own:

```
cd sql
./mariadbd &
```

After starting up `mariadbd` using one of the above methods (with the debugger or without), launch the client (as root if you don't have any users setup yet).

```
../client/mariadb
```

Using a Storage Engine Plugin

The simplest case is to compile the storage engine into MariaDB:

```
cmake -DWITH_PLUGIN_<plugin_name>=1` .
```

Another option is to point `mariadbd` to the storage engine directory:

```
./mariadbd --plugin-dir={build-dir-path}/storage/connect/.libs
```

2.1.6.7 mysql.server

Contents

The `mysql.server` startup script is in MariaDB distributions on Linux and Unix. It is a wrapper that works as a standard sysVinit script. However, it can be used independently of sysVinit as a regular `sh` script. The script starts the `mysqld` server process by first changing its current working directory to the MariaDB install directory and then starting `mysqld_safe`. The script requires the standard sysVinit arguments, such as `start`, `stop`, `restart`, and `status`. For example:

```
mysql.server start
mysql.server restart
mysql.server stop
mysql.server status
```

It can be used on systems such as Linux, Solaris, and Mac OS X.

The `mysql.server` script starts `mysqld` by first changing to the MariaDB install directory and then calling `mysqld_safe`.

Using mysql.server

The command to use `mysql.server` and the general syntax is:

```
mysql.server [ start | stop | restart | status ] <options> <mysqld_options>
```

Options

If an unknown option is provided to `mysqld_safe` on the command-line, then it is passed to `mysqld_safe`.

`mysql.server` supports the following options:

Option	Description

`--basedir=path`	The path to the MariaDB installation directory.
`--datadir=path`	The path to the MariaDB data directory.
`--pid-file=file_name`	The path name of the file in which the server should write its process ID. If not provided, the default, `host_name.pid` is used.
`--service-startup-timeout=file_name`	How long in seconds to wait for confirmation of server startup. If the server does not start within this time, *mysql.server* exits with an error. The default value is 900. A value of 0 means not to wait at all for startup. Negative values mean to wait forever (no timeout).
`--use-mysqld_safe`	Use mysqld_safe to start the server. This is the default.
`--use-manager`	Use Instance Manager to start the server.
`--user=user_name`	The login user name to use for running `mysqld`.

Option Files

In addition to reading options from the command-line, `mysql.server` can also read options from option files.

The following options relate to how MariaDB command-line tools handles option files. They must be given as the first argument on the command-line:

Option	Description
`--print-defaults`	Print the program argument list and exit.
`--no-defaults`	Don't read default options from any option file.
`--defaults-file=#`	Only read default options from the given file #.
`--defaults-extra-file=#`	Read this file after the global files are read.

Option Groups

`mysql.server` reads options from the following option groups from option files:

Group	Description
`[mysql.server]`	Options read by `mysql.server`, which includes both MariaDB Server and MySQL Server.

`mysql.server` also reads options from the following server option groups from option files:

Group	Description
`[mysqld]`	Options read by `mysqld`, which includes both MariaDB Server and MySQL Server.
`[server]`	Options read by MariaDB Server.
`[mysqld-X.Y]`	Options read by a specific version of `mysqld`, which includes both MariaDB Server and MySQL Server. For example, `[mysqld-5.5]`.
`[mariadb]`	Options read by MariaDB Server.
`[mariadb-X.Y]`	Options read by a specific version of MariaDB Server.
`[client-server]`	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
`[galera]`	Options read by a galera-capable MariaDB Server. Available on systems compiled with Galera support.

Customizing mysql.server

If you have installed MariaDB to a non-standard location, then you may need to edit the `mysql.server` script to get it to work right.

If you do not want to edit the `mysql.server` script itself, then `mysql.server` also sources a few other `sh` scripts. These files can be used to set any variables that might be needed to make the script work in your specific environment. The files are:

- /etc/default/mysql
- /etc/sysconfig/mysql
- /etc/conf.d/mysql

Installed Locations

`mysql.server` can be found in the `support-files` directory under your MariaDB installation directory or in a MariaDB source distribution.

Installed SysVinit Locations

On systems that use sysVinit, `mysql.server` may also be installed in other locations and with other names.

If you installed MariaDB on Linux using RPMs, then the `mysql.server` script will be installed into the `/etc/init.d` directory with the name `mysql`. You need not install it manually.

Manually Installing with SysVinit

If you install MariaDB from source or from a binary tarball that does not install `mysql.server` automatically, and if you are on a system that uses sysVinit, then you can manually install `mysql.server` with sysVinit. This is usually done by copying it to `/etc/init.d/` and then creating specially named symlinks in the appropriate `/etc/rcX.d/` directories (where 'X' is a number between 0 and 6).

> In the examples below we will follow the historical convention of renaming the `mysql.server` script to '`mysql`' when we copy it to `/etc/init.d/`.

The first step for most Linux distributions is to copy the `mysql.server` script to `/etc/init.d/` and make it executable:

```
cd /path/to/your/mariadb-version/support-files/
cp mysql.server /etc/init.d/mysql
chmod +x /etc/init.d/mysql
```

Now all that is needed is to create the specially-named symlinks. On both RPM and Debian-based Linux distributions there are tools which do this for you. Consult your distribution's documentation if neither of these work for you and follow their instructions for generating the symlinks or creating them manually.

On RPM-based distributions (like Fedora and CentOS), you use `chkconfig`:

```
chkconfig --add mysql
chkconfig --level 345 mysql on
```

On Debian-based distributions you use `update-rc.d`:

```
update-rc.d mysql defaults
```

On FreeBSD, the location for startup scripts is `/usr/local/etc/rc.d/` and when you copy the `mysql.server` script there you should rename it so that it matches the `*.sh` pattern, like so:

```
cd /path/to/your/mariadb/support-files/
cp mysql.server /usr/local/etc/rc.d/mysql.server.sh
```

As stated above, consult your distribution's documentation for more information on starting services like MariaDB at system startup.

See mysqld startup options for information on configuration options for `mysqld`.

2.1.6.8 mysqld_safe

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadbd-safe` is a symlink to `mysqld_safe`.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadbd-safe` is the name of the server, with `mysqld_safe` a symlink .

Contents

The `mysqld_safe` startup script is in MariaDB distributions on Linux and Unix. It is a wrapper that starts `mysqld` with some extra safety features. For example, if `mysqld_safe` notices that `mysqld` has crashed, then `mysqld_safe` will automatically restart `mysqld` .

`mysqld_safe` is the recommended way to start `mysqld` on Linux and Unix distributions that do not support `systemd` . Additionally, the `mysql.server` init script used by `sysVinit` starts `mysqld` with `mysqld_safe` by default.

Using mysqld_safe

The command to use `mysqld_safe` and the general syntax is:

```
mysqld_safe [ --no-defaults | --defaults-file | --defaults-extra-file | --defaults-group-suffix
| --print-defaults ] <options> <mysqld_options>
```

Options

Many of the options supported by `mysqld_safe` are identical to options supported by `mysqld` . If an unknown option is provided to `mysqld_safe` on the command-line, then it is passed to `mysqld` .

`mysqld_safe` supports the following options:

Option	Description
`--help`	Display a help message and exit.
`--autoclose`	(NetWare only) On NetWare, `mysqld_safe` provides a screen presence. When you unload (shut down) the `mysqld_safe` NLM, the screen does not by default go away. Instead, it prompts for user input: `NLM has terminated; Press any key to close the screen` . If you want NetWare to close the screen automatically instead, use the `--autoclose` option to mysqld_safe.
`--basedir=path`	The path to the MariaDB installation directory.
`--core-file-size=size`	The size of the core file that mysqld should be able to create. The option value is passed to ulimit -c.
`--crash-script=file`	Script to call in the event of mysqld crashing.
`--datadir=path`	The path to the data directory.
`--defaults-extra-file=path`	The name of an option file to be read in addition to the usual option files. This must be the first option on the command line if it is used. If the file does not exist or is otherwise inaccessible, the server will exit with an error.
`--defaults-file=file_name`	The name of an option file to be read instead of the usual option files. This must be the first option on the command line if it is used.
`--defaults-group-suffix=#`	In addition to the default option groups, also read option groups with this suffix.

`--flush-caches`	Flush and purge buffers/caches before starting the server.
`--ledir=path`	If mysqld_safe cannot find the server, use this option to indicate the path name to the directory where the server is located.
`--log-error=file_name`	Write the error log to the given file.
`--malloc-lib=lib`	Preload shared library *lib* if available. See debugging MariaDB for an example.
`--mysqld=prog_nam`	The name of the server program (in the ledir directory) that you want to start. This option is needed if you use the MariaDB binary distribution but have the data directory outside of the binary distribution. If mysqld_safe cannot find the server, use the `--ledir` option to indicate the path name to the directory where the server is located.
`--mysqld-version=suffix`	This option is similar to the `--mysqld` option, but you specify only the suffix for the server program name. The basename is assumed to be mysqld. For example, if you use `--mysqld-version=debug`, mysqld_safe starts the mysqld-debug program in the ledir directory. If the argument to `--mysqld-version` is empty, mysqld_safe uses mysqld in the ledir directory.
`--nice=priority`	Use the nice program to set the server´s scheduling priority to the given value.
`--no-defaults`	Do not read any option files. This must be the first option on the command line if it is used.
`--no-watch`, `--nowatch`, `--no-auto-restart`	Exit after starting mysqld.
`--numa-interleave`	Run mysqld with its memory interleaved on all NUMA nodes.
`--open-files-limit=count`	The number of files that mysqld should be able to open. The option value is passed to ulimit -n. Note that you need to start mysqld_safe as root for this to work properly.
`--pid-file=file_name`	The path name of the process ID file.
`--plugin-dir=dir_name`	Directory for client-side plugins.
`--port=port_num`	The port number that the server should use when listening for TCP/IP connections. The port number must be 1024 or higher unless the server is started by the root system user.
`--print-defaults`	Print the program argument list and exit.
`--skip-kill-mysqld`	Do not try to kill stray mysqld processes at startup. This option works only on Linux.
`--socket=path`	The Unix socket file that the server should use when listening for local connections.
`--syslog`, `--skip-syslog`	`--syslog` causes error messages to be sent to syslog on systems that support the logger program. `--skip-syslog` suppresses the use of syslog; messages are written to an error log file.
`--syslog-tag=tag`	For logging to syslog, messages from `mysqld_safe` and mysqld are written with a tag of mysqld_safe and mysqld, respectively. To specify a suffix for the tag, use `--syslog-tag=tag`, which modifies the tags to be `mysqld_safe-tag` and `mysqld-tag`.
`--timezone=timezone`	Set the TZ time zone environment variable to the given option value. Consult your operating system documentation for legal time zone specification formats. Also see Time Zones.
`--user={user_name or user_id}`	Run the mysqld server as the user having the name user_name or the numeric user ID user_id. (“User” in this context refers to a system login account, not a MariaDB user listed in the grant tables.)

Option Files

In addition to reading options from the command-line, `mysqld_safe` can also read options from option files. If an unknown option is provided to `mysqld_safe` in an option file, then it is ignored.

The following options relate to how MariaDB command-line tools handles option files. They must be given as the **first argument** on the command-line:

Option	Description
`--print-defaults`	Print the program argument list and exit.
`--no-defaults`	Don't read default options from any option file.
`--defaults-file=#`	Only read default options from the given file #.
`--defaults-extra-file=#`	Read this file after the global files are read.
`--defaults-group-suffix=#`	In addition to the default option groups, also read option groups with this suffix.

Option Groups

`mysqld_safe` reads options from the following option groups from option files:

Group	Description
`[mysqld_safe]`	Options read by `mysqld_safe`, which includes both MariaDB Server and MySQL Server.
`[safe_mysqld]`	Options read by `mysqld_safe`, which includes both MariaDB Server and MySQL Server.
`[mariadb_safe]`	Options read by `mysqld_safe` from MariaDB Server.
`[mariadb-safe]`	Options read by `mysqld_safe` from MariaDB Server. Available starting with MariaDB 10.4.6.

The `[safe_mysqld]` option group is primarily supported for backward compatibility. You should rename such option groups to `[mysqld_safe]` in MariaDB installations to prevent breakage in the future if this compatibility is removed.

`mysqld_safe` also reads options from the following server option groups from option files:

Group	Description
`[mysqld]`	Options read by `mysqld`, which includes both MariaDB Server and MySQL Server.
`[server]`	Options read by MariaDB Server.
`[mysqld-X.Y]`	Options read by a specific version of `mysqld`, which includes both MariaDB Server and MySQL Server. For example, `[mysqld-5.5]`.
`[mariadb]`	Options read by MariaDB Server.
`[mariadb-X.Y]`	Options read by a specific version of MariaDB Server.
`[client-server]`	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
`[galera]`	Options read by a galera-capable MariaDB Server. Available on systems compiled with Galera support.

For example, if you specify the `log_error` option in a server option group in an option file, like this:

```
[mariadb]
log_error=error.log
```

Then `mysqld_safe` will also use this value for its own `--log-error` option:

Configuring the Open Files Limit

When using `mysqld_safe`, the system's open files limit can be changed by providing the `--open-files-limit` option either on the command-line or in an option file. For example:

```
[mysqld_safe]
open_files_limit=4294967295
```

The option value is passed to `ulimit -n`. Note that you need to start `mysqld_safe` as root for this to work properly. However, you can't currently set this to `unlimited`. See MDEV-18410 about that.

When `mysqld_safe` starts `mysqld`, it also uses this option to set the value of the `open_files_limit` system variable for `mysqld`.

Configuring the Core File Size

When using `mysqld_safe`, if you would like to enable core dumps, the system's core file size limit can be changed by providing the `--core-file-size` option either on the command-line or in an option file. For example:

```
[mysqld_safe]
core_file_size=unlimited
```

The option value is passed to `ulimit -c`. Note that you need to start `mysqld_safe` as root for this to work properly.

Configuring MariaDB to Write the Error Log to Syslog

When using `mysqld_safe`, if you would like to redirect the error log to the syslog, then that can easily be done by using the `--syslog` option. `mysqld_safe` redirects two types of log messages to the syslog--its own log messages, and log messages for `mysqld`.

- `mysqld_safe` configures its own log messages to go to the `daemon` syslog facility. The log level for these messages is either `notice` or `error`, depending on the specific type of log message. The default tag is `mysqld_safe`.
- `mysqld_safe` also configures the log messages for `mysqld` to go to the `daemon` syslog facility. The log level for these messages is `error`. The default tag is `mysqld`.

Sometimes it can be helpful to add a suffix to the syslog tag, such as if you are running multiple instances of MariaDB on the same host. To add a suffix to each syslog tag, use the `--syslog-tag` option.

Specifying mysqld

By default, `mysqld_safe` tries to start an executable named `mysqld`.

You can also specify another executable for `mysqld_safe` to start instead of `mysqld` by providing the `--mysqld` or `--mysqld-version` options either on the command-line or in an option file.

By default, it will look for `mysqld` in the following locations in the following order:

- `$BASEDIR/libexec/mysqld`
- `$BASEDIR/sbin/mysqld`
- `$BASEDIR/bin/mysqld`
- `$PWD/bin/mysqld`
- `$PWD/libexec/mysqld`
- `$PWD/sbin/mysqld`
- `@libexecdir@/mysql`

Where `$BASEDIR` is set by the `--basedir` option, `$PWD` is the current working directory where `mysqld_safe` was invoked, and `@libexecdir@` is set at compile-time by the `INSTALL_BINDIR` option for `cmake`.

You can also specify where the executable is located by providing the `--ledir` option either on the command-line or in an option file.

Specifying datadir

By default, `mysqld_safe` will look for the `datadir` in the following locations in the following order:

- `$BASEDIR/data/mysql`
- `$BASEDIR/data`
- `$BASEDIR/var/mysql`
- `$BASEDIR/var`
- `@localstatedir@`

Where `$BASEDIR` is set by the `--basedir` option, and `@localstatedir@` is set at compile-time by the `INSTALL_MYSQLDATADIR` option for `cmake`.

You can also specify where the `datadir` is located by providing the `--datadir` option either on the command-line or in an option file.

Logging

When you use `mysqld_safe` to start `mysqld`, `mysqld_safe` logs to the same destination as `mysqld`.

`mysqld_safe` has several log-related options:

- `--syslog` : Write error messages to syslog on systems that support the logger program.
- `--skip-syslog` : Do not write error messages to syslog. Messages are written to the default error log file (host_name.err in the data directory), or to a named file if the `--log-error` option is given.
- `--log-error=file_name` : Write error messages to the named error file.

If none of these options is provided, then the default is `--skip-syslog` .

If `--syslog` and `--log-error` are both provided, then a warning is issued and `--log-error` takes precedence.

`mysqld_safe` also writes notices to `stdout` and errors to `stderr` .

Editing mysqld_safe

`mysqld_safe` is a `sh` script, so if you need to change its behavior, then it can easily be edited. However, you should not normally edit the script. A lot of behavior can be changed by providing options either on the command-line or in an option file.

If you do edit `mysqld_safe` , then you should be aware of the fact that a package upgrade can overwrite your changes. If you would like to preserve your changes, be sure to have a backup.

NetWare

On NetWare, mysqld_safe is a NetWare Loadable Module (NLM) that is ported from the original Unix shell script. It starts the server as follows:

1. Runs a number of system and option checks.
2. Runs a check on MyISAM tables.
3. Provides a screen presence for the MariaDB server.
4. Starts mysqld, monitors it, and restarts it if it terminates in error.
5. Sends error messages from mysqld to the host_name.err file in the data directory.
6. Sends mysqld_safe screen output to the host_name.safe file in the data directory.

1.3.15 mysqladmin

2.1.6.10 Switching Between Different Installed MariaDB Versions

Contents

This article is about managing many different installed MariaDB versions and running them one at a time. This is useful when doing benchmarking, testing, or for when developing different MariaDB versions.

This is most easily done using the tar files from mariadb.org/download/.

Stopping a pre-installed MySQL/MariaDB from interfering with your tests

If MySQL/MariaDB is already installed and running, you have two options:

1. Use test MariaDB servers with a different port & socket.
   - In this case you are probably best off creating a specific section for MariaDB in your `~/.my.cnf` file.
2. Stop mysqld with `/etc/rc.d/mysql stop` or `mariadb-admin shutdown` .

Note that you don't have to uninstall or otherwise remove MySQL!

How to create a binary distribution (tar file)

Here is a short description of how to generate a tar file from a source distribution. If you have downloaded a binary tar file, you can skip this section.

The steps to create a binary tar file are:

- Decide where to put the source. A good place is under `/usr/local/src/mariadb-5.#`.
- Get the source
- Compile the source
- Create the binary tar ball.

You will then be left with a tar file named something like: `mariadb-11.0.1-MariaDB-linux-x86_64.tar.gz`

Creating a directory structure for the different installations

Install the binary tar files under `/usr/local/` with the following directory names (one for each MariaDB version you want to use), for example:

- `mariadb-10.5`
- `mariadb-10.6`
- `mariadb-10.11`
- `mariadb-11.0`
- `mariadb-11.1`

The above assumes you are just testing major versions of MariaDB. If you are testing specific versions, use directory names like `mariadb-11.0.1`

With the directories in place, create a sym-link named `mariadb` which points at the `mariadb-XXX` directory you are currently testing. When you want to switch to testing a different version, just update the sym-link.

Example:

```
cd /usr/local
tar xfz /tmp/mariadb-11.0.1-linux-systemd-x86_64.tar.gz
mv -vi mariadb-11.0.1-MariaDB-systemd-linux-x86_64 mariadb-11.0
ln -vs mariadb-11.0 mariadb
```

Setting up the data directory

When setting up the data directory, you have the option of either using a shared database directory or creating a unique database directory for each server version. For testing, a common directory is probably easiest. Note that you can only have one `mysqld` server running against one data directory.

Setting up a common data directory

The steps are:

1. Create the `mysql` system user if you don't have it already! (On Linux you do it with the `useradd` command).
2. Create the directory (we call it `mariadb-data` in the example below) or add a symlink to a directory which is in some other place.
3. Create the `mysql` permission tables with mariadb-install-db

```
cd /usr/local/
mkdir mariadb-data
cd mariadb
./bin/mariadb-install-db --no-defaults --datadir=/usr/local/mariadb-data
chown -R mysql mariadb-data mariadb-data/*
```

The reason to use `--no-defaults` is to ensure that we don't inherit incorrect options from some old my.cnf.

Setting up different data directories

To create a different `data` directories for each installation:

```
cd mariadb
./scripts/mariadb-install-db --no-defaults
chown -R mysql mariadb-data mariadb-data/*
```

This will create a directory `data` inside the current directory.

If you want to use another disk you should do:

```
cd mariadb
ln -s path-to-empty-directory-for-data data
./scripts/mariadb-install-db --no-defaults --datadir=./data
chown -R mysql mariadb-data mariadb-data/*
```

Running a MariaDB server

The normal steps are:

```
rm mariadb
ln -s mariadb-# mariadb
cd mariadb
./bin/mysqld_safe --no-defaults --datadir=/usr/local/mariadb-data &
```

Setting up a .my.cnf file for running multiple MariaDB main versions

If you are going to start/stop MariaDB a lot of times, you should create a `~/.my.cnf` file for the common options you are using.

The following example shows how to use a non-standard TCP-port and socket (to not interfere with a main MySQL/MariaDB server) and how to setup different options for each main server:

```
[client-server]
socket=/tmp/mysql.sock
port=3306
[mysqld]
datadir=/usr/local/mariadb-data

[mariadb-11.0]
# Options for MariaDB 11.0
[mariadb-11.1]
# Options for MariaDB 11.1
```

If you create an `~/.my.cnf` file, you should start `mysqld` with `--defaults-file=~/.my.cnf` instead of `--no-defaults` in the examples above.

2.1.6.11 Specifying Permissions for Schema (Data) Directories and Tables

Default File Permissions

By default MariaDB uses the following permissions for files and directories:

Object Type	Default Mode	Default Permissions
Files	`0660`	`-rw-rw----`
Directories	`0700`	`drwx------`

Configuring File Permissions with Environment Variables

You can configure MariaDB to use different permissions for files and directories by setting the following environment variables before you start the server:

Object Type	Environment Variable
Files	`UMASK`
Directories	`UMASK_DIR`

In other words, if you would run the following in a shell:

```
export UMASK=0640
export UMASK_DIR=0750
```

These environment variables do not set the umask. They set the default file system permissions. See MDEV-23058 for more information.

Configuring File Permissions with systemd

If your server is started by `systemd`, then there is a specific way to configure the umask. See Systemd: Configuring the umask for more information.

2.1.6.12 mysqld_multi

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadbd-multi` is a symlink to `mysqld_multi`.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadbd-multi` is the name of the server, with `mysqld_multi` a symlink.

Before using mysqld_multi be sure that you understand the meanings of the options that are passed to the mysqld servers and why you would want to have separate mysqld processes. Beware of the dangers of using multiple mysqld servers with the same data directory. Use separate data directories, unless you know what you are doing. Starting multiple servers with the same data directory does not give you extra performance in a threaded system.

Contents

The `mysqld_multi` startup script is in MariaDB distributions on Linux and Unix. It is a wrapper that is designed to manage several `mysqld` processes running on the same host. In order for multiple `mysqld` processes to work on the same host, these processes must:

- Use different Unix socket files for local connections.
- Use different TCP/IP ports for network connections.
- Use different data directories.
- Use different process ID files (specified by the `--pid-file` option) if using `mysqld_safe` to start `mysqld`.

`mysqld_multi` can start or stop servers, or report their current status.

Using mysqld_multi

The command to use `mysqld_multi` and the general syntax is:

```
mysqld_multi [options] {start|stop|report} [GNR[,GNR] ...]
```

`start`, `stop`, and `report` indicate which operation to perform.

You can specify which servers to perform the operation on by providing one or more `GNR` values. `GNR` refers to an option

group number, and it is explained more in the option groups section below. If there is no `GNR` list, then `mysqld_multi` performs the operation for all `GNR` values found in its option files.

Multiple `GNR` values can be specified as a comma-separated list. `GNR` values can also be specified as a range by separating the numbers by a dash. There must not be any whitespace characters in the `GNR` list.

For example:

This command starts a single server using option group `[mysqld17]`:

```
mysqld_multi start 17
```

This command stops several servers, using option groups `[mysqld8]` and `[mysqld10]` through `[mysqld13]`:

```
mysqld_multi stop 8,10-13
```

Options

`mysqld_multi` supports the following options:

Option	Description
`--example`	Give an example of a config file with extra information.
`--help`	Display help and exit.
`--log=filename`	Specify the path and name of the log file. If the file exists, log output is appended to it.
`--mysqladmin=prog_name`	The mariadb-admin binary to be used to stop servers. Can be given within groups `[mysqld#]`.
`--mysqld=prog_name`	The mysqld binary to be used. Note that you can also specify mysqld_safe as the value for this option. If you use mysqld_safe to start the server, you can include the `mysqld` or `ledir` options in the corresponding `[mysqldN]` option group. These options indicate the name of the server that mysqld_safe should start and the path name of the directory where the server is located. Example: `[mysqld38]` `mysqld = mysqld-debug` `ledir = /opt/local/mysql/libexec`.
`--no-log`	Print to stdout instead of the log file. By default the log file is turned on.
`--password=password`	The password of the MariaDB account to use when invoking mariadb-admin. Note that the password value is not optional for this option, unlike for other MariaDB programs.
`--silent`	Silent mode; disable warnings.
`--tcp-ip`	Connect to the MariaDB server(s) via the TCP/IP port instead of the UNIX socket. This affects stopping and reporting. If a socket file is missing, the server may still be running, but can be accessed only via the TCP/IP port. By default connecting is done via the UNIX socket. This option affects stop and report operations.
`--user=username`	The user name of the MariaDB account to use when invoking mariadb-admin.
`--verbose`	Be more verbose.
`--version`	Display version information and exit.
`--wsrep-new-cluster`	Bootstrap a cluster. Added in MariaDB 10.1.15.

Option Files

In addition to reading options from the command-line, `mysqld_multi` can also read options from option files. If an unknown option is provided to `mysqld_multi` in an option file, then it is ignored.

The following options relate to how MariaDB command-line tools handles option files. They must be given as the first argument on the command-line:

Option	Description

`--print-defaults`	Print the program argument list and exit.
`--no-defaults`	Don't read default options from any option file.
`--defaults-file=#`	Only read default options from the given file #.
`--defaults-extra-file=#`	Read this file after the global files are read.
`--defaults-group-suffix=#`	In addition to the default option groups, also read option groups with this suffix.

Option Groups

`mysqld_safe` reads options from the following option groups from option files:

Group	Description
`[mysqld_multi]`	Options read by `mysqld_multi`, which includes both MariaDB Server and MySQL Server.

`mysqld_multi` also searches option files for option groups with names like `[mysqldN]`, where `N` can be any positive integer. This number is referred to in the following discussion as the option group number, or `GNR`:

Group	Description
`[mysqldN]`	Options read by a `mysqld` instance managed by `mysqld_multi`, which includes both MariaDB Server and MySQL Server. The `N` refers to the instance's `GNR`.

`GNR` values distinguish option groups from one another and are used as arguments to `mysqld_multi` to specify which servers you want to start, stop, or obtain a status report for. The `GNR` value should be the number at the end of the option group name in the option file. For example, the `GNR` for an option group named `[mysqld17]` is `17`.

Options listed in these option groups are the same that you would use in the regular server option groups used for configuring `mysqld`. However, when using multiple servers, it is necessary that each one use its own value for options such as the Unix socket file and TCP/IP port number.

The `[mysqld_multi]` option group can be used for options that are needed for `mysqld_multi` itself. `[mysqldN]` option groups can be used for options passed to specific `mysqld` instances.

The regular server option groups can also be used for common options that are read by all instances:

Group	Description
`[mysqld]`	Options read by `mysqld`, which includes both MariaDB Server and MySQL Server.
`[server]`	Options read by MariaDB Server.
`[mysqld-X.Y]`	Options read by a specific version of `mysqld`, which includes both MariaDB Server and MySQL Server. For example, `[mysqld-5.5]`.
`[mariadb]`	Options read by MariaDB Server.
`[mariadb-X.Y]`	Options read by a specific version of MariaDB Server.
`[client-server]`	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients.
`[galera]`	Options read by a galera-capable MariaDB Server. Available on systems compiled with Galera support.

For an example of how you might set up an option file, use this command:

```
mysqld_multi --example
```

Authentication and Privileges

Make sure that the MariaDB account used for stopping the `mysqld` processes (with the mariadb-admin utility) has the same user name and password for each server. Also, make sure that the account has the `SHUTDOWN` privilege. If the servers that you want to manage have different user names or passwords for the administrative accounts, you might want to create an account on each server that has the same user name and password. For example, you might set up a common `multi_admin` account by executing the following commands for each server:

```
shell> mysql -u root -S /tmp/mysql.sock -p
Enter password:
mysql> GRANT SHUTDOWN ON *.*
 -> TO ´multi_admin´@´localhost´ IDENTIFIED BY ´multipass´;
```

Change the connection parameters appropriately when connecting to each one. Note that the host name part of the account name must allow you to connect as `multi_admin` from the host where you want to run `mysqld_multi` .

User Account

Make sure that the data directory for each server is fully accessible to the Unix account that the specific `mysqld` process is started as. If you run the `mysqld_multi` script as the Unix `root` account, and if you want the `mysqld` process to be started with another Unix account, then you can use use the `--user` option with `mysqld` . If you specify the `--user` option in an option file, and if you did not run the `mysqld_multi` script as the Unix `root` account, then it will just log a warning and the `mysqld` processes are started under the original Unix account.

Do not run the `mysqld` process as the Unix `root` account, unless you know what you are doing.

Example

The following example shows how you might set up an option file for use with mysqld_multi. The order in which the mysqld programs are started or stopped depends on the order in which they appear in the option file. Group numbers need not form an unbroken sequence. The first and fifth [mysqldN] groups were intentionally omitted from the example to illustrate that you can have “gaps” in the option file. This gives you more flexibility.

```
# This file should probably be in your home dir (~/.my.cnf)
# or /etc/my.cnf
# Version 2.1 by Jani Tolonen
[mysqld_multi]
mysqld     = /usr/local/bin/mysqld_safe
mysqladmin = /usr/local/bin/mysqladmin
user       = multi_admin
password   = multipass
[mysqld2]
socket     = /tmp/mysql.sock2
port       = 3307
pid-file   = /usr/local/mysql/var2/hostname.pid2
datadir    = /usr/local/mysql/var2
language   = /usr/local/share/mysql/english
user       = john
[mysqld3]
socket     = /tmp/mysql.sock3
port       = 3308
pid-file   = /usr/local/mysql/var3/hostname.pid3
datadir    = /usr/local/mysql/var3
language   = /usr/local/share/mysql/swedish
user       = monty
[mysqld4]
socket     = /tmp/mysql.sock4
port       = 3309
pid-file   = /usr/local/mysql/var4/hostname.pid4
datadir    = /usr/local/mysql/var4
language   = /usr/local/share/mysql/estonia
user       = tonu
[mysqld6]
socket     = /tmp/mysql.sock6
port       = 3311
pid-file   = /usr/local/mysql/var6/hostname.pid6
datadir    = /usr/local/mysql/var6
language   = /usr/local/share/mysql/japanese
user       = jani
```

2.1.6.13 launchd

In MacOS, create a file called /Library/LaunchDaemons/com.mariadb.server.plist with the following contents (edit to suit):

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plist PUBLIC "-//Apple Computer//DTD PLIST 1.0//EN"
"http://www.apple.com/DTDs/PropertyList-1.0.dtd">
<plist version="1.0">
<dict>
  <key>Label</key> <string>com.mariadb.server</string>
  <key>KeepAlive</key><true/>
  <key>RunAtLoad</key><true/>
  <key>LaunchOnlyOnce</key><false/>
  <key>ExitTimeOut</key><integer>600</integer>
  <key>WorkingDirectory</key><string>/usr/local/var</string>
  <key>Program</key><string>/usr/local/bin/mysqld</string>
  <key>ProgramArguments</key>
  <array>
    <string>/usr/local/bin/mysqld</string>
    <string>--user=_mysql</string>
    <string>--basedir=/usr/local/opt/mariadb</string>
    <string>--plugin-dir=/usr/local/opt/mariadb/lib/plugin</string>
    <string>--datadir=/usr/local/var/mysql</string>
    <string>--log-error=/usr/local/var/mysql/Data-Server.local.err</string>
    <string>--pid-file=/usr/local/var/mysql/Data-Server.local.pid</string>
    <string>--sql-
mode=ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION</string>
  </array>
</dict>
</plist>
```

Then from a shell, run `launchctl load /Library/LaunchDaemons/com.mariadb.server.plist` and MariaDB will run immediately, and also upon reboot.

2.1.6.14 systemd

`systemd` is a `sysVinit` replacement that is the default service manager on the following Linux distributions:

- RHEL 7 and above
- CentOS 7 and above
- Fedora 15 and above
- Debian 8 and above
- Ubuntu 15.04 and above
- SLES 12 and above
- OpenSUSE 12.2 and above

MariaDB's `systemd` unit file is included in the server packages for RPMs and DEBs. It is also included in certain binary tarballs.

The service name is `mariadb.service` .

Installing & Starting MariaDB

When installing MariaDB server rpm / dep package, it will automatically run the mariadb-install-db script, that creates the initial databases and users.

When MariaDB is started with the `systemd` unit file, it directly starts the `mariadbd` process as the `mysql` user. Unlike with `sysVinit` , the `mariadbd` process is not started with `mysqld_safe` . As a consequence, options will not be read from the `[mysqld_safe]` option group from option files.

Contents

Contents of the MariaDB Service's Unit File

The contents of the `mariadb.service` file can be examined with `systemctl show mariadb.service`.

Interacting with the MariaDB Server Process

The service can be interacted with by using the `systemctl` command.

Starting the MariaDB Server Process on Boot

MariaDB's `systemd` service can be configured to start at boot by executing the following:

```
sudo systemctl enable mariadb.service
```

Starting the MariaDB Server Process

MariaDB's `systemd` service can be started by executing the following:

```
sudo systemctl start mariadb.service
```

MariaDB's `systemd` unit file has a default startup timeout of about 90 seconds on most systems. If certain startup tasks, such as crash recovery, take longer than this default startup timeout, then `systemd` will assume that `mariadbd` has failed to startup, which causes `systemd` to kill the `mariadbd` process. To work around this, you can reconfigure the MariaDB `systemd` unit to have an infinite timeout.

Note that systemd 236 added the `EXTEND_TIMEOUT_USEC` environment variable that allows services to extend the startup timeout during long-running processes. Starting with MariaDB 10.1.33, MariaDB 10.2.15, and MariaDB 10.3.6, on systems with systemd versions that support it, MariaDB uses this feature to extend the startup timeout during certain startup processes that can run long. Therefore, if you are using `systemd` 236 or later, then you should not need to manually override `TimeoutStartSec`, even if your startup tasks, such as crash recovery, run for longer than the configured value. See MDEV-14705 for more information.

Stopping the MariaDB Server Process

MariaDB's `systemd` service can be stopped by executing the following:

```
sudo systemctl stop mariadb.service
```

Restarting the MariaDB Server Process

MariaDB's `systemd` service can be restarted by executing the following:

```
sudo systemctl restart mariadb.service
```

Checking the Status of the MariaDB Server Process

The status of MariaDB's `systemd` service can be obtained by executing the following:

```
sudo systemctl status mariadb.service
```

Interacting with Multiple MariaDB Server Processes

A `systemd` template unit file with the name `mariadb@.service` is installed in `INSTALL_SYSTEMD_UNITDIR` on some systems. See Locating the MariaDB Service's Unit File to see what directory that refers to on each distribution.

This template unit file allows you to interact with multiple MariaDB instances on the same system using the same template unit file. When you interact with a MariaDB instance using this template unit file, you have to provide an instance name as a suffix. For example, the following command tries to start a MariaDB instance with the name `node1`:

```
sudo systemctl start mariadb@node1.service
```

MariaDB's build system cannot include the `mariadb@.service` template unit file in RPM packages on platforms that have `cmake` versions older than 3.3.0, because these `cmake` versions have a bug that causes it to encounter errors when packaging a file in RPMs if the file name contains the `@` character. MariaDB's RHEL 7 and CentOS 7 RPM build hosts only got a new enough `cmake` version starting with MariaDB 10.1.39, MariaDB 10.2.23, and MariaDB 10.3.14. To use this functionality on a MariaDB version that does not have the file, you can copy the file from a package that does have the file.

Default configuration of Multiple Instances in 10.4 and Later

`systemd` will also look for an option file for a specific MariaDB instance based on the instance name.

It will use the `.%I` as the custom option group suffix that is appended to any server option group, in any configuration file included by default.

In all distributions, the `%I` is the MariaDB instance name. In the above `node1` case, it would use the option file at the path `/etc/mynode1.cnf`.

When using multiple instances, each instance will of course also need their own `datadir`, `socket` and, `port` (unless `skip_networking` is specified). As `mariadb-install-db#option-groups` reads the same sections as the server, and ExecStartPre= `run mariadb-install-db` within the service, the instances are autocreated if there is sufficient priviledges.

To use a 10.3 configuration in 10.4 or later and the following customisation in the editor after running `sudo systemctl edit mariadb@.service`:

```
[Unit]
ConditionPathExists=

[Service]
Environment='MYSQLD_MULTI_INSTANCE=--defaults-file=/etc/my%I.cnf'
```

Custom configuration of Multiple Instances in 10.4 and Later

Because users may want to do many various things with their multiple instances, we've provided a way to let the user define how they wish their multiple instances to run. The systemd environment variable `MYSQLD_MULTI_INSTANCE` can be set to anything that mariadbd and mariadb-install-db will recognise.

A hosting environment where each user has their own instance may look like (with `sudo systemctl edit mariadb@.service`):

```
[Service]
ProtectHome=false
Environment='MYSQLD_MULTI_INSTANCE=--defaults-file=/home/%I/my.cnf \
                        --user=%I \
                        --socket=/home/%I.sock \
                        --datadir=/home/%I/mariadb_data \
                        --skip-networking'
```

Here the instance name is the unix user of the service.

Configuring Multiple Instances in 10.3 and Earlier

`systemd` will also look for an option file for a specific MariaDB instance based on the instance name. By default, it will look for the option file in a directory defined at build time by the `INSTALL_SYSCONF2DIR` option provided to `cmake`.

For example, on RHEL, CentOS, Fedora, and other similar Linux distributions, `INSTALL_SYSCONF2DIR` is defined as `/etc/my.cnf.d/`, so it will look for an option file that matches the format:

- `/etc/my.cnf.d/my%I.cnf`

And on Debian, Ubuntu, and other similar Linux distributions, `INSTALL_SYSCONF2DIR` is defined as `/etc/mysql/conf.d//`, so it will look for an option file that matches the format:

- `/etc/mysql/conf.d/my%I.cnf`

In all distributions, the `%I` is the MariaDB instance name. In the above `node1` case, it would use the option file at the path `/etc/my.cnf.d/mynode1.cnf` for RHEL-like distributions and `/etc/mysql/conf.d/mynode1.cnf` for Debian-like distributions.

When using multiple instances, each instance will of course also need their own `datadir`. See mariadb-install-db for information on how to initialize the `datadir` for additional MariaDB instances.

Systemd and Galera Cluster

Bootstrapping a New Cluster

When using Galera Cluster with systemd, the first node in a cluster has to be started with `galera_new_cluster`. See Getting Started with MariaDB Galera Cluster: Bootstrapping a New Cluster for more information.

Recovering a Node's Cluster Position

When using Galera Cluster with systemd, a node's position in the cluster can be recovered with `galera_recovery`. See Getting Started with MariaDB Galera Cluster: Determining the Most Advanced Node for more information.

SSTs and Systemd

MariaDB's `systemd` unit file has a default startup timeout of about 90 seconds on most systems. If an SST takes longer than this default startup timeout on a joiner node, then `systemd` will assume that `mariadbd` has failed to startup, which

causes `systemd` to kill the `mariadbd` process on the joiner node. To work around this, you can reconfigure the MariaDB `systemd` unit to have an infinite timeout. See Introduction to State Snapshot Transfers (SSTs): SSTs and Systemd for more information.

Note that systemd 236 added the `EXTEND_TIMEOUT_USEC` environment variable that allows services to extend the startup timeout during long-running processes. Starting with MariaDB 10.1.35, MariaDB 10.2.17, and MariaDB 10.3.8, on systems with systemd versions that support it, MariaDB uses this feature to extend the startup timeout during long SSTs. Therefore, if you are using `systemd` 236 or later, then you should not need to manually override `TimeoutStartSec`, even if your SSTs run for longer than the configured value. See MDEV-15607 for more information.

Configuring the Systemd Service

You can configure MariaDB's `systemd` service by creating a "drop-in" configuration file for the `systemd` service. On most systems, the `systemd` service's directory for "drop-in" configuration files is `/etc/systemd/system/mariadb.service.d/`. You can confirm the directory and see what "drop-in" configuration files are currently loaded by executing:

```
$ sudo systemctl status mariadb.service
● mariadb.service - MariaDB 10.1.37 database server
   Loaded: loaded (/usr/lib/systemd/system/mariadb.service; enabled; vendor preset: disabled)
  Drop-In: /etc/systemd/system/mariadb.service.d
           └─migrated-from-my.cnf-settings.conf, timeoutstartsec.conf
...
```

If you want to configure the `systemd` service, then you can create a file with the `.conf` extension in that directory. The configuration option(s) that you would like to change would need to be placed in an appropriate section within the file, usually `[Service]`. If a `systemd` option is a list, then you may need to set the option to empty before you set the replacement values. For example:

```
[Service]

ExecStart=
ExecStart=/usr/bin/numactl --interleave=all  /usr/sbin/mariadbd $MYSQLD_OPTS
$_WSREP_NEW_CLUSTER $_WSREP_START_POSITION
```

After any configuration change, you will need to execute the following for the change to go into effect:

```
sudo systemctl daemon-reload
```

Useful Systemd Options

Useful `systemd` options are listed below. If an option is equivalent to a common `mysqld_safe` option, then that is also listed. Use `systemctl edit mariadb.service` to create the systemd option under a `[Service]` section header.

mysqld_safe option	systemd option	Comments
no option	`ProtectHome=false`	If any MariaDB files are in /home/
no option	`PrivateDevices=false`	If any MariaDB storage references raw block devices
no option	`ProtectSystem=`	If any MariaDB write any files to anywhere under /boot, /usr or /etc
no option	`TimeoutStartSec={time}`	Service startup timeout. See Configuring the Systemd Service Timeout.
no option (see MDEV-9264)	`OOMScoreAdjust={priority}`	e.g. -600 to lower priority of OOM killer for mariadbd
`open-files-limit`	`LimitNOFILE={limit}`	Limit on number of open files. See Configuring the Open Files Limit.

core-file-size	LimitCORE={size}	Limit on core file size. Useful when enabling core dumps. See Configuring the Core File Size.
	LimitMEMLOCK={size} or infinity	Limit on how much can be locked in memory. Useful when large-pages or memlock is used
nice	Nice={nice value}	
syslog	StandardOutput=syslog	See Configuring MariaDB to Write the Error Log to Syslog.
	StandardError=syslog	
	SyslogFacility=daemon	
	SyslogLevel=err	
syslog-tag	SyslogIdentifier	
flush-caches	ExecStartPre=/usr/bin/sync	
	ExecStartPre=/usr/sbin/sysctl -q -w vm.drop_caches=3	
malloc-lib	Environment=LD_PRELOAD=/path/to/library	
numa-interleave	NUMAPolicy=interleave	from systemd v243 onwards
	or: ExecStart=/usr/bin/numactl --interleave=all /usr/sbin/mariadbd $MYSQLD_OPTS $_WSREP_NEW_CLUSTER $_WSREP_START_POSITION	prepending ExecStart=/usr/bin/numactl --interleave=all to existing ExecStart setting
no-auto-restart	Restart={exit-status}	

Note: the systemd manual contains the official meanings for these options. The manual also lists considerably more options than the ones listed above.

There are other options and the mariadb-service-convert script will attempt to convert these as accurately as possible.

Configuring the Systemd Service Timeout

MariaDB's systemd unit file has a default startup timeout of about 90 seconds on most systems. If a service startup takes longer than this default startup timeout, then systemd will assume that mariadbd has failed to startup, which causes systemd to kill the mariadbd process. To work around this, it can be changed by configuring the TimeoutStartSec option for the systemd service.

A similar problem can happen when stopping the MariaDB service. Therefore, it may also be a good idea to set TimeoutStopSec.

For example, you can reconfigure the MariaDB systemd service to have an infinite timeout by executing one of the following commands:

If you are using systemd 228 or older, then you can execute the following to set an infinite timeout:

```
sudo systemctl edit mariadb.service

[Service]

TimeoutStartSec=0
TimeoutStopSec=0
```

Systemd 229 added the infinity option, so if you are using systemd 229 or later, then you can execute the following to set an infinite timeout:

```
sudo systemctl edit mariadb.service

[Service]

TimeoutStartSec=infinity
TimeoutStopSec=infinity
```

Note that systemd 236 added the EXTEND_TIMEOUT_USEC environment variable that allows services to extend the startup timeout during long-running processes. On systems with systemd versions that support it, MariaDB uses this feature to extend the startup timeout during certain startup processes that can run long.

Configuring the Open Files Limit

When using `systemd`, rather than setting the open files limit by setting the `open-files-limit` option for `mysqld_safe` or the `open_files_limit` system variable, the limit can be changed by configuring the `LimitNOFILE` option for the MariaDB `systemd` service. The default is set to `LimitNOFILE=16364` in `mariadb.service`.

For example, you can reconfigure the MariaDB `systemd` service to have a larger limit for open files by executing the following commands:

```
sudo systemctl edit mariadb.service

[Service]

LimitNOFILE=infinity
```

An important note is that setting `LimitNOFILE=infinity` doesn't actually set the open file limit to *infinite*.

In `systemd` 234 and later, setting `LimitNOFILE=infinity` actually sets the open file limit to the value of the kernel's `fs.nr_open` parameter. Therefore, in these `systemd` versions, you may have to change this parameter's value.

The value of the `fs.nr_open` parameter can be changed permanently by setting the value in `/etc/sysctl.conf` and restarting the server.

The value of the `fs.nr_open` parameter can be changed temporarily by executing the `sysctl` utility. For example:

```
sudo sysctl -w fs.nr_open=1048576
```

In `systemd` 233 and before, setting `LimitNOFILE=infinity` actually sets the open file limit to `65536`. See systemd issue #6559 for more information. Therefore, in these `systemd` versions, it is not generally recommended to set `LimitNOFILE=infinity`. Instead, it is generally better to set `LimitNOFILE` to a very large integer. For example:

```
sudo systemctl edit mariadb.service

[Service]
LimitNOFILE=1048576
```

Configuring the Core File Size

When using `systemd`, if you would like to enable core dumps, rather than setting the core file size by setting the `core-file-size` option for `mysqld_safe`, the limit can be changed by configuring the `LimitCORE` option for the MariaDB `systemd` service. For example, you can reconfigure the MariaDB `systemd` service to have an infinite size for core files by executing the following commands:

```
sudo systemctl edit mariadb.service

[Service]
LimitCORE=infinity
```

Configuring MariaDB to Write the Error Log to Syslog

When using `systemd`, if you would like to redirect the error log to the syslog, then that can easily be done by doing the following:

- Ensure that `log_error` system variable is **not** set.

- Set `StandardOutput=syslog`.
- Set `StandardError=syslog`.
- Set `SyslogFacility=daemon`.
- Set `SysLogLevel=err`.

For example:

```
sudo systemctl edit mariadb.service

[Service]

StandardOutput=syslog
StandardError=syslog
SyslogFacility=daemon
SysLogLevel=err
```

If you have multiple instances of MariaDB, then you may also want to set `SyslogIdentifier` with a different tag for each instance.

Configuring LimitMEMLOCK

If using --memlock or the iouring in InnoDB in MariaDB 10.6 with a Linux Kernel version < 5.12, you will need to raise the LimitMEMLOCK limit.

```
sudo systemctl edit mariadb.service

[Service]

LimitMEMLOCK=2M
```

Note: Prior to MariaDB 10.1.10, the --memlock option could not be used with the MariaDB `systemd` service.

Configuring Access to Home Directories

MariaDB's systemd unit file restricts access to `/home`, `/root`, and `/run/user` by default. This restriction can be overridden by setting the ProtectHome option to `false` for the MariaDB `systemd` service. This is done by creating a "drop-in" directory `/etc/systemd/system/mariadb.service.d/` and in it a file with a `.conf` suffix that contains the `ProtectHome=false` directive.

You can reconfigure the MariaDB `systemd` service to allow access to `/home` by executing the following commands:

```
sudo systemctl edit mariadb.service

[Service]

ProtectHome=false
```

Configuring the umask

When using `systemd`, the default file permissions of `mariadbd` can be set by setting the `UMASK` and `UMASK_DIR` environment variables for the `systemd` service. For example, you can configure the MariaDB `systemd` service's umask by executing the following commands:

```
sudo systemctl edit mariadb.service

[Service]

Environment="UMASK=0750"
Environment="UMASK_DIR=0750"
```

These environment variables do not set the umask. They set the default file system permissions. See MDEV-23058 for more information.

Keep in mind that configuring the umask this way will only affect the permissions of files created by the `mariadbd`

process that is managed by `systemd`. The permissions of files created by components that are not managed by `systemd`, such as mariadb-install-db, will not be affected.

See Specifying Permissions for Schema (Data) Directories and Tables for more information.

Configuring the data directory

When doing a standard binary tarball install the datadir will be under /usr/local/data. The default systemd service file makes the whole /usr directory tree write protected however.

So when just copying the distributed service file a tarball install will not start up, complaining e.g. about

```
[Warning] Can't create test file /usr/local/.../data/ubuntu-focal.lower-test
[ERROR] mariadbd: File '/usr/local/.../data/aria_log_control' not found (Errcode: 30 "Read-only
file system")
[ERROR] mariadbd: Got error 'Can't open file' when trying to use aria control file
'/usr/local/.../data/aria_log_control'
```

So when using a data directory under /usr/local that specific directory needs to be made writable for the service using the ReadWritePaths setting:

```
sudo systemctl edit mariadb.service

[Service]
ReadWritePaths=/usr/local/mysql/data
```

Systemd Socket Activation

MariaDB starting with 10.6.0
MariaDB can use systemd's socket activation.

This is an on-demand service for MariaDB that will activate when required.

Systemd socket activation uses a `mariadb.socket` definition file to define a set of UNIX and TCP sockets. Systemd will listen on these sockets, and when they are connected to, systemd will start the `mariadb.service` and hand over the socket file descriptors for MariaDB to process the connection.

MariaDB remains running at this point and will have all sockets available and process connections exactly like it did before 10.6.

When MariaDB is shut down, the systemd `mariadb.socket` remains active, and a new connection will restart the `mariadb.service`.

Using Systemd Socket Activation

To use MariaDB systemd socket activation, instead of enabling/starting `mariadb.service`, `mariadb.socket` is used instead.

So the following commands work exactly like the `mariadb.service` equivalents.

```
systemctl start mariadb.socket
systemctl enable mariadb.socket
```

These files alone only contain the UNIX and TCP sockets and basic network connection information to which will be listening for connections. `@mariadb` is a UNIX abstract socket, which means it doesn't appear on the filesystem. Connectors based on MariaDB Connector/C will be able to connect with these by using the socket name directly, provided the higher level implementation doesn't try to test for the file's existence first. Some connectors like PHP use mysqlnd that is a pure PHP implementation and as such will only be able to connect to on filesystem UNIX sockets.

With systemd activated sockets there is only a file descriptor limit on the number of listening sockets that can be created.

When to Use Systemd Socket Activation

A common use case for systemd socket activated MariaDB is when there needs to be a quick boot up time. MariaDB needs to be ready to run, but it doesn't need to be running.

The ideal use case for systemd socket activation for MariaDB is for infrastructure providers running many multiple instances of MariaDB, where each instance is dedicated for a user.

Downsides to Using Systemd Socket Activiation

From the time the connection occurs, the client is going to be waiting until MariaDB has fully initialized before MariaDB can process the awaiting connection. If MariaDB was previously hard shutdown and needs to perform an extensive InnoDB rollback, then the activation time may be larger than the desired wait time of the client connection.

Configuring Systemd Socket Activation

When MariaDB is run under systemd socket activation, the usual socket , port, and backlog system variables are ignored, as these settings are contained within the systemd socket definition file.

There is no configuration required in MariaDB to use MariaDB under socket activation.

The systemd options available are from the `systemd documentation`, however `ListenStream` and `BackLog` would be the most common configuration options.

As MariaDB isn't creating these sockets, the sockets don't need to be created with a `mysql` user. The sockets MariaDB may end up listening to under systemd socket activation, it may have not had the privileges to create itself.

Changes to the default `mariadb.socket` can be made in the same way as services, `systemctl edit mariadb.socket` , or using `/etc/systemd/system/mariadb.socket.d/someconfig.conf` files.

Extra Port

A systemd socket can be configured as an `extra_port`, `by using the` FileDescriptorName=extra `in the` .socket `file`.

The `mariadb-extra.socket` is already packaged and ready for use.

Multi-instance socket activation

`mariadb@.socket` is MariaDB's packaged multi-instance defination. It creates multiple UNIX sockets based on the socket file started.

Starting `mariadb@bob.socket` will use the `mariadb@.socket` defination with `%I` within the defination replaced with "bob".

When something connects to a socket defined there, the `mariadb@bob.service` will be started.

Systemd Socket Activation for Hosting Service Providers

A systemd socket activation service with multi-instance can provide an on-demand per user access to a hosting service provider's dedicated database.

"User", in this case, refers to the customer of the hosting service provider.

End User Benefits

This provides the following benefits for the user:

- Each user has their own dedicated instance with the following benefits:
  - The instance is free from the database contention of neighbors on MariaDB shared resources (table cache, connections, etc)
  - The user is free to change their own configuration of MariaDB, within the limits and permissions of the service provider.
  - Database service level backups, like mariabackup, are now directly available.
  - A user can install their own plugins.
  - The user can run a different database version to their neighbors.
  - If a user's neighbor triggers a fault in the server, the uder's instance isn't affected.
- The database runs as their unix user in the server facilitating:
  - User can directly migrate their MariaDB data directory to a different provider.
  - The user's data is protected from other users on a kernel level.

Hosting Service Provider Benefits

In addition to providing user benefits as a sales item, the following are additional benefits for the hosting service provider compared to a monolith service:

- Without passwords for the database, while still having security, support may be easier.
- When a user's database isn't active, there is no resource usage, only listening file descriptors by systemd.
- The socket activation transparently, with a minor startup time, starts the service as required.
- When the user's database hasn't had any activity after a time, it will deactivate (MDEV-25282).
- Planned enhancements in InnoDB provide:
  - an on-demand consumption of memory (MDEV-25340 .
  - a proactive reduction in memory (MDEV-25341).
  - a memory resource pressure reduction in memory use (MDEV-24670).
- The service provider can still cap the user's database memory usage in a ulimit way that a user cannot override in settings.
- The service provider may choose a CPU/memory/IO based billing to the user on Linux cgroup accounting rather than the available comprared to the rather limited options in `CREATE USER` .
- Because a user's database will shutdown when inactive, a database upgrade on the server will not take effect for the user until it passively shuts down, restarts, and then gets reactivated hence reducing user downtime..

Downsides to the Hosting Service Provider

The extra memory used by more instances. This is mitigated by the on-demand activation. The deactivation when idle, and improved InnoDB memory management.

With plenty of medium size database servers running, the Linux OOM kill has the opportunity to kill off only a small number of database servers running rather than everyones.

Example on configuration Items for a per user, systemd socket activitated multi-instance service

From a server pespective the operation would be as follows;

To make the socket ready to connect and systemd will be listening to the socket:

```
# systemctl start mariadb@username.socket
# systemctl start mariadb-extra@username.socket
```

To enable this on reboot (the same way as a systemd service):

```
# systemctl enable mariadb@username.socket
# systemctl enable mariadb-extra@username.socket
```

A MariaDB Template File

A global template file. Once installed as a user's `$HOME/.my.cnf` file, it will becomes the default for many applications, and the MariaDB server itself.

```
# cat /etc/my.cnf.templ
[client]
socket=/home/USER/mariadb.sock

[client-server]
user=USER

[mariadbd]
datadir=/home/USER/mariadb-datadir
```

Custom Configuration for the Multi-instance Service

This extends/modifies the MariaDB multi-instance service.

The feature of this extension are:

- that it will autocreate configuration file for user applications
- It will install the database on first service start
- `auth-root-*` in mariadb-install-db means that the user is their own privileged user with unix socket authentication active. This means non-that user cannot access another users service, even with access to the unix socket(s). For more information see unix socket authentication security.
- If the MariaDB version was upgrade, the upgrade changes are made automatically

- `LimitData` places a hard upper limit so the user doesn't exceed a portion of the server resources

```
# cat /etc/systemd/system/mariadb@.service.d/user.conf
[Service]
User=%I
ProtectHome=false

Environment=MYSQLD_MULTI_INSTANCE="--defaults-file=/home/%I/.my.cnf"

ExecStartPre=
ExecStartPre=/bin/sh -c "[ -f /home/%I/.my.cnf ] || sed -e \"s/USER/%I/g\" /etc/my.cnf.templ >
/home/%I/.my.cnf"
ExecStartPre=mkdir -p /home/%I/mariadb-datadir
ExecStartPre=/usr/bin/mariadb-install-db $MYSQLD_MULTI_INSTANCE --rpm \
   --auth-root-authentication-method=socket --auth-root-socket-user=%I
ExecStartPost=/usr/bin/mariadb-upgrade $MYSQLD_MULTI_INSTANCE

# To limit user based tuning
LimitData=768M
# For io_uring use by innodb on < 5.12 kernels
LimitMEMLOCK=1M
```

Custom Configuration for the Multi-instance Socket

This extends/modifies the MariaDB socket defination to be per user.

Create sockets based on the user of the istance (`%I`). Permissions are only necessary in the sense that the user can connect to them. It won't matter to the server. Access control is enforced within the server, however if the user web services are run as the user, `Mode=777` can be reduced. `@mariadb-%I` is a abstract unix socket not on the filesystem. It may help if a user is in a chroot. Not all applications can connect to abstract sockets.

```
# cat /etc/systemd/system/mariadb@.socket.d/user.conf
[Socket]
SocketUser=%I
SocketMode=777
ListenSteam=
ListenStream=@mariadb-%I
ListenStream=/home/%I/mariadb.sock
```

The extra socket provides the user the ability to access the server when all max-connections are used:

```
# cat /etc/systemd/system/mariadb-extra@.socket.d/user.conf
[Socket]
SocketUser=%I
SocketMode=777
ListenSteam=
ListenStream=@mariadb-extra-%I
ListenStream=/home/%I/mariadb-extra.sock
```

Systemd Journal

`systemd` has its own logging system called the `systemd` journal. The `systemd` journal contains information about the service startup process. It is a good place to look when a failure has occurred.

The MariaDB `systemd` service's journal can be queried by using the `journalctl` command. For example:

```
$ sudo journalctl n 20 -u mariadb.service
-- Logs begin at Fri 2019-01-25 13:49:04 EST, end at Fri 2019-01-25 18:07:02 EST. --
Jan 25 13:49:15 ip-172-30-0-249.us-west-2.compute.internal systemd[1]: Starting MariaDB 10.1.37
database server...
Jan 25 13:49:16 ip-172-30-0-249.us-west-2.compute.internal mysqld[2364]: 2019-01-25 13:49:16
140547528317120 [Note] /usr/sbin/mysqld (mysqld 10.1.37-MariaDB) starting as process 2364 ...

10.1.37 database server.
Jan 25 18:08:32 ip-172-30-0-249.us-west-2.compute.internal systemd[1]: Unit mariadb.service
entered failed state.
Jan 25 18:08:32 ip-172-30-0-249.us-west-2.compute.internal systemd[1]: mariadb.service failed.
```

Converting mysqld_safe Options to Systemd Options

`mariadb-service-convert` is a script included in many MariaDB packages that is used by the package manager to convert `mysqld_safe` options to `systemd` options. It reads any explicit settings in the `[mysqld_safe]` option group from option files, and its output is directed to `/etc/systemd/system/mariadb.service.d/migrated-from-my.cnf-settings.conf`. This helps to keep the configuration the same when upgrading from a version of MariaDB that does not use `systemd` to one that does.

Implicitly high defaults of `open-files-limit` may be missed by the conversion script and require explicit configuration. See Configuring the Open Files Limit.

2.1.6.15 sysVinit

Contents

sysVinit is one of the most common service managers. On systems that use sysVinit, the `mysql.server` script is normally installed to `/etc/init.d/mysql`.

Interacting with the MariaDB Server Process

The service can be interacted with by using the `service` command.

Starting the MariaDB Server Process on Boot

On RHEL/CentOS and other similar distributions, the `chkconfig` command can be used to enable the MariaDB Server process at boot:

```
chkconfig --add mysql
chkconfig --level 345 mysql on
```

On Debian and Ubuntu and other similar distributions, the `update-rc.d` command can be used:

```
update-rc.d mysql defaults
```

Starting the MariaDB Server Process

```
service mysql start
```

Stopping the MariaDB Server Process

```
service mysql stop
```

Restarting the MariaDB Server Process

```
service mysql restart
```

Checking the Status of the MariaDB Server Process

```
service mysql status
```

Manually Installing mysql.server with SysVinit

If you install MariaDB from source or from a binary tarball that does not install `mysql.server` automatically, and if you are on a system that uses sysVinit, then you can manually install `mysql.server` with sysVinit. See mysql.server: Manually Installing with SysVinit for more information.

SysVinit and Galera Cluster

Bootstrapping a New Cluster

When using Galera Cluster with sysVinit, the first node in a cluster has to be started with `service mysql bootstrap`. See Getting Started with MariaDB Galera Cluster: Bootstrapping a New Cluster for more information.

1.3.25 Mariadb-admin

2.1.6.17 mariadbd

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadbd` is a symlink to mysqld, the MariaDB server.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadbd` is the name of the server, with `mysqld` a symlink .

See mysqld for details.

2.1.6.18 mariadbd-multi

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadbd-multi` is a symlink to `mysqld_multi`, the wrapper designed to manage several mysqld processes running on the same host.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadbd-multi` is the name of the server, with `mysqld_multi` a symlink .

See mysqld_multi for details.

2.1.6.19 mariadbd-safe

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadbd-safe` is a symlink to `mysqld_safe`, the tool for starting mysqld on Linux and Unix distributions that do not support systemd.

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadbd-safe` is the name of the binary, with `mysqld_safe` a symlink .

See mysqld_safe for details.

2.1.7.1.1 Fusion-io Introduction

Contents

Fusion-io develops PCIe based NAND flash memory cards and related software that can be used to speed up MariaDB databases.

The ioDrive branded products can be used as block devices (super-fast disks) or to extend basic DRAM memory. ioDrive is deployed by installing it on an x86 server and then installing the card driver under the operating system. All main line 64-bit operating systems and hypervisors are supported: RHEL, CentOS, SuSe, Debian, OEL etc. and VMware, Microsoft Windows/Server etc. Drivers and their features are constantly developed further.

ioDrive cards support software RAID and you can combine two or more physical cards into one logical drive. Through ioMemory SDK and its APIs, one can integrate and enable more thorough interworking between your own software and the cards - and cut latency.

The key differentiator between a Fusion-io and a legacy SSD/HDD is the following: **A Fusion-io card is connected directly on the system bus (PCIe)**, this enables high data transfer throughput (1.5 GB/s, 3.0 GB/s or 6GB/s) and the fast direct memory access (DMA) method can be used to transfer data. The ATA/SATA protocol stack is omitted and therefore latency is cut short. Fusion-io performance is dependent on server speed: the faster processors and the newer PCIe-bus version you have, the better is the ioDrive performance. Fusion-io memory is non-volatile, in other words, data remains on the card even when the server is powered off.

Use Cases

1. You can start by using ioDrive for database files that need heavy random access.
2. Whole database on ioDrive.
3. In some cases, Fusion-io devices allow for atomic writes, which allows the server to safely disable the doublewrite buffer.
4. Use ioDrive as a write-through read cache. This is possible on server level with Fusion-io directCache software or in VMware environments using ioTurbine software or the ioCache bundle product. Reads happen from ioDrive and all writes go directly to your SAN or disk.
5. Highly Available shared storage with ION. Have two different hosts, Fusion-io cards in them and share/replicate data with Fusion-io's ION software.
6. The luxurious Platinum setup: MariaDB Galera Cluster running on Fusion-io SLC cards on several hosts.

Atomic Writes

Starting with MariaDB 5.5.31, MariaDB Server supports atomic writes on Fusion-io devices that use the NVMFS (formerly called DirectFS) file system. Unfortunately, NVMFS was never offered under 'General Availability', and SanDisk declared that NVMFS would reach end-of-life in December 2015. Therefore, NVMFS support is no longer offered by SanDisk.

MariaDB Server does not currently support atomic writes on Fusion-io devices with any other file systems.

See atomic write support for more information about MariaDB Server's atomic write support.

Future Suggested Development

- Extend InnoDB disk cache to be stored on Fusion-io acting as extended memory.

Settings For Best Performance

Fusion-io memory can be formatted with different sector size of either 512 or 4096 bytes. Bigger sectors are expected to be faster, but only if I/O is done in blocks of 4KB or multiples of that. Speaking of MariaDB: if only InnoDB data files are stored in Fusion-io memory, all I/O is done in blocks of 16K and thus 4K sector size can be used. If the InnoDB redo log (I/O block size: 512 bytes) goes to the same Fusion-io memory, then short sectors should be used.

Note: XtraDB has the experimental feature of an increased InnoDB log block size of 4K. If this is enabled, then both redo log I/O and page I/O in InnoDB will match a sector size of 4K.

As of file systems: currently XFS is expected to yield the best performance with MariaDB. However depending on the exact kernel version and version of XFS code in use, one might be affected by a bug that severely limits XFS performance in

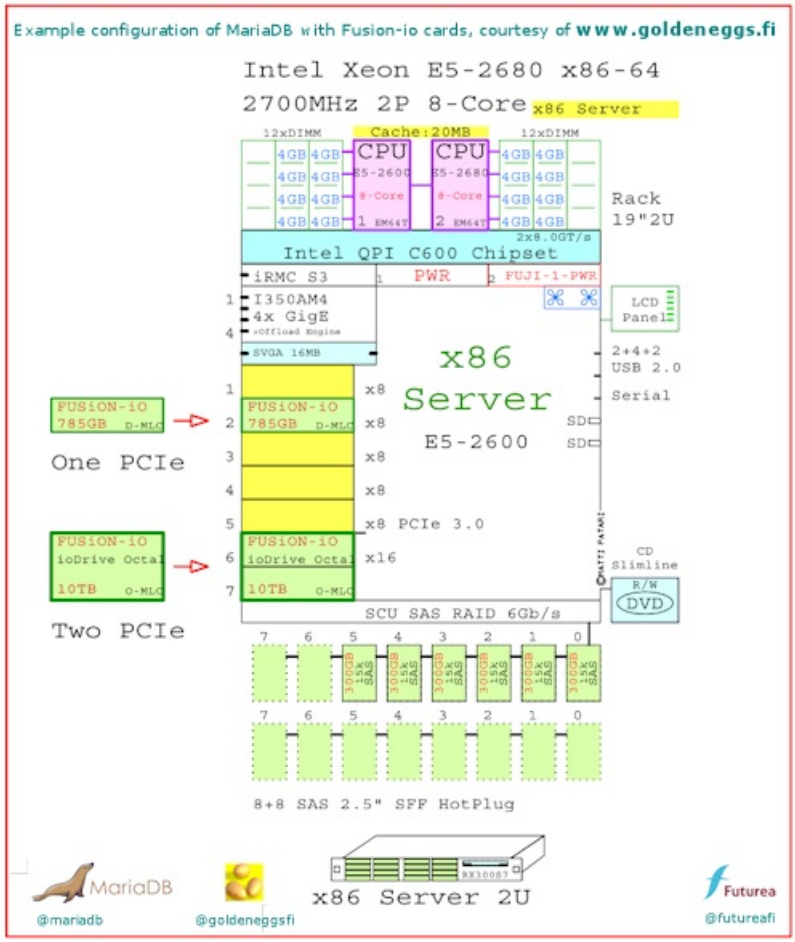
concurrent environments. This has been fixed in kernel versions above 3.5 or RHEL6 kernels kernel-2.6.32-358 or later (because of bug 807503 being fixed).

For the pitbull machine where I have run such tests, ext4 was faster than xfs for 32 or more threads:

- up to 8 threads xfs was few percent faster (10% on average).
- at 16 threads it was a draw (2036 tps vs. 2070 tps).
- at 32 threads ext4 was 28% faster (2345 tps vs. 1829 tps).
- at 64 threads ext4 was even 47% faster (2362 tps vs. 1601 tps).
- at higher concurrency ext4 lost it's bite, but was still constantly better than xfs.

Those numbers are for spinning disks. I guess for Fusion-io memory the XFS numbers will be even worse.

Example Configuration



Card Models

There are several card models. ioDrive is older generation, ioDrive2 is newer. SLC sustains more writes. MLC is good enough for normal use.

1. ioDrive2, capacities per card 365GB, 785GB, 1.2TB with MLC. 400GB and 600GB with SLC, performance up to 535000 IOPS & 1.5GB/s bandwidth
2. ioDrive2 Duo, capacities per card 2.4TB MLC and 1.2TB SLC, performance up to 935000 IOPS & 3.0GB/s bandwidth
3. ioDrive, capacities per card 320GB, 640GB MLC and 160GB, 320GB SLC, performance up to 145000 IOPS & 790MB/s bandwidth
4. ioDrive Duo, capacities per card 640GB, 1.28TB MLC and 320GB, 640GB SLC, performance up to 285000 IOPS & 1.5GB/s bandwidth
5. ioDrive Octal, capacities per card 5TB and 10TB MLC, performance up to 1350000 IOPS & 6.7GB/s bandwidth
6. ioFX, a 420GB QDP MLC workstation product, 1.4GB/s bandwidth
7. ioCache, a 600GB MLC card with ioTurbine software bundle that can be used to speed up VMware based virtual hosts.
8. ioScale, 3.2TB card, building block to enable all-flash data center build out in hyperscale web and cloud environments. Product has been developed in co-operation with Facebook.

Additional Software

- directCache - transforms ioDrive to work as a read cache in your server. Writes go directly to your SAN
- ioTurbine - read cache software for VMware
- ION - transforms ioDrive into a shareable storage
- ioSphere - software to manage and monitor several ioDrives

2.1.7.1.2 Atomic Write Support

Contents

Partial Write Operations

When Innodb writes to the filesystem, there is generally no guarantee that a given write operation will be complete (not partial) in cases of a poweroff event, or if the operating system crashes at the exact moment a write is being done.

Without detection or prevention of partial writes, the integrity of the database can be compromised after recovery.

innodb_doublewrite - an Imperfect Solution

Since its inception, Innodb has had a mechanism to detect and ignore partial writes via the InnoDB Doublewrite Buffer (also innodb_checksum can be used to detect a partial write).

Doublewrites, controlled by the innodb_doublewrite system variable, comes with its own set of problems. Especially on SSD, writing each page twice can have detrimental effects (write leveling).

Atomic Write - a Faster Alternative to innodb_doublewrite

A better solution is to directly ask the filesystem to provide an atomic (all or nothing) write guarantee. Currently this is only available on a few SSD cards.

Enabling Atomic Writes from MariaDB 10.2

When starting, MariaDB 10.2 and beyond automatically detects if any of the supported SSD cards are used.

When opening an InnoDB table, there is a check if the tablespace for the table is on a device that supports atomic writes and if yes, it will automatically enable atomic writes for the table. If atomic writes support is not detected, the doublewrite buffer will be used.

One can disable atomic write support for all cards by setting the variable innodb-use-atomic-writes to `OFF` in your my.cnf file. It's `ON` by default.

Enabling Atomic Writes in MariaDB 5.5 to MariaDB 10.1

To use atomic writes instead of the doublewrite buffer, add:

```
innodb_use_atomic_writes = 1
```

to the my.cnf config file.

Note that atomic writes are only supported on Fusion-io devices that use the NVMFS file system in these versions of MariaDB.

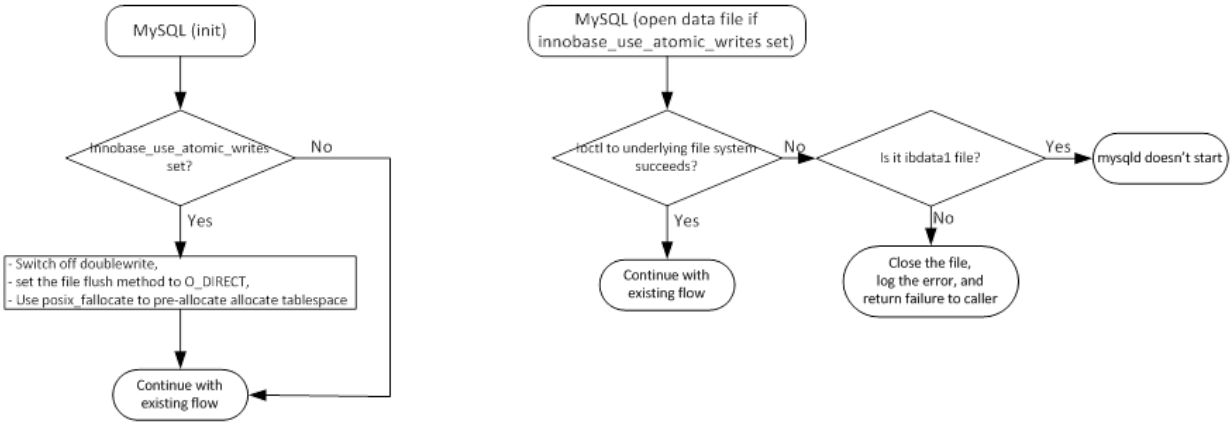
About innodb_use_atomic_writes (in MariaDB 5.5 to MariaDB 10.1)

The following happens when atomic writes are enabled

- if innodb_flush_method is neither `O_DIRECT`, `ALL_O_DIRECT`, or `O_DIRECT_NO_FSYNC`, it is switched to `O_DIRECT`

- innodb_use_fallocate is switched `ON` (files are extended using `posix_fallocate` rather than writing zeros behind the end of file)
- Whenever an Innodb datafile is opened, a special `ioctl()` is issued to switch on atomic writes. If the call fails, an error is logged and returned to the caller. This means that if the system tablespace is not located on an atomic write capable device or filesystem, InnoDB/XtraDB will refuse to start.
- if innodb_doublewrite is set to `ON`, `innodb_doublewrite` will be switched `OFF` and a message written to the error log.

Here is a flowchart showing how atomic writes work inside InnoDB:



Devices that Support Atomic Writes with MariaDB

MariaDB currently supports atomic writes on the following devices:

- Fusion-io devices with the NVMFS file system . MariaDB 5.5 and above.
- Shannon SSD . MariaDB 10.2 and above.

5.3.2.16 InnoDB Page Flushing

2.1.7.2 Configuring Linux for MariaDB

Contents

Linux kernel settings

IO scheduler

For optimal IO performance running a database we are using the *none* (previously called *noop*) scheduler. Recommended schedulers are *none* and *mq-deadline* (previously called *deadline*). You can check your scheduler setting with:

```
cat /sys/block/${DEVICE}/queue/scheduler
```

For instance, it should look like this output:

```
cat /sys/block/vdb/queue/scheduler
[none] mq-deadline kyber bfq
```

Older kernels may look like:

```
cat /sys/block/sda/queue/scheduler
[noop] deadline cfq
```

Writing the new scheduler name to the same /sys node will change the scheduler:

```
echo mq-deadline >  /sys/block/vdb/queue/scheduler
```

The impact of schedulers depend significantly on workload and hardware. You can measure the IO-latency using the biolatency bcc-tools script with an aim to keep the mean as low as possible.

Resource Limits

Configuring the Open Files Limit

By default, the system limits how many open file descriptors a process can have open at one time. It has both a soft and hard limit. On many systems, both the soft and hard limit default to 1024. On an active database server, it is very easy to exceed 1024 open file descriptors. Therefore, you may need to increase the soft and hard limits. There are a few ways to do so.

If you are using `mysqld_safe` to start `mysqld`, then see the instructions at mysqld_safe: Configuring the Open Files Limit.

If you are using `systemd` to start `mysqld`, then see the instructions at systemd: Configuring the Open Files Limit.

Otherwise, you can set the soft and hard limits for the `mysql` user account by adding the following lines to `/etc/security/limits.conf`:

```
mysql soft nofile 65535
mysql hard nofile 65535
```

After the system is rebooted, the `mysql` user should use the new limits, and the user's `ulimit` output should look like the following:

```
$ ulimit -Sn
65535
$ ulimit -Hn
65535
```

Configuring the Core File Size

By default, the system limits the size of core files that could be created. It has both a soft and hard limit. On many systems, the soft limit defaults to 0. If you want to enable core dumps, then you may need to increase this. Therefore, you may need to increase the soft and hard limits. There are a few ways to do so.

If you are using `mysqld_safe` to start `mysqld`, then see the instructions at mysqld_safe: Configuring the Core File Size.

If you are using `systemd` to start `mysqld`, then see the instructions at systemd: Configuring the Core File Size.

Otherwise, you can set the soft and hard limits for the `mysql` user account by adding the following lines to `/etc/security/limits.conf`:

```
mysql soft core unlimited
mysql hard core unlimited
```

After the system is rebooted, the `mysql` user should use the new limits, and the user's `ulimit` output should look like the following:

```
$ ulimit -Sc
unlimited
$ ulimit -Hc
unlimited
```

Swappiness

See configuring swappiness.

2.1.7.3 Configuring MariaDB for Optimal

Performance

Contents

This article is to help you configure MariaDB for optimal performance.

Note that by default MariaDB is configured to work on a desktop system and should because of this not take a lot of resources. To get things to work for a dedicated server, you have to do a few minutes of work.

For this article we assume that you are going to run MariaDB on a dedicated server.

Feel free to update this article if you have more ideas.

my.cnf Files

MariaDB is normally configured by editing the my.cnf file.

The following my.cnf example files were included with MariaDB until MariaDB 10.3.0. If present, you can examine them to see more complete examples of some of the many ways to configure MariaDB and use the one that fits you best as a base. Note that these files are now quite outdated, so what was huge a few years ago may no longer be seen as such.

- my-small.cnf
- my-medium.cnf
- my-large.cnf
- my-huge.cnf

InnoDB Storage Engine

InnoDB is normally the default storage engine with MariaDB.

- You should set innodb_buffer_pool_size to about 80% of your memory. The goal is to ensure that 80 % of your working set is in memory.

The other most important InnoDB variables are:

- innodb_log_file_size
- innodb_flush_method
- innodb_thread_sleep_delay

Some other important InnoDB variables:

- innodb_max_dirty_pages_pct_lwm
- innodb_read_ahead_threshold
- innodb_buffer_pool_instances. Deprecated and ignored from MariaDB 10.5.1.
- innodb_adaptive_max_sleep_delay. Deprecated and ignored from MariaDB 10.5.5.
- innodb_thread_concurrency. Deprecated and ignored from MariaDB 10.5.5.

Aria Storage Engine

- MariaDB uses by default the Aria storage engine for internal temporary files. If you have many temporary files, you should set aria_pagecache_buffer_size to a reasonably large value so that temporary overflow data is not flushed to disk. The default is 128M.

MyISAM

- If you don't use MyISAM tables explicitly (true for most MariaDB 10.4+ users), you can set key_buffer_size to a very low value, like 64K.

Lots of Connections

A Lot of Fast Connections + Small Set of Queries + Disconnects

- If you are doing a lot of fast connections / disconnects, you should increase back_log and if you are running MariaDB 10.1 or below thread_cache_size.
- If you have a lot (> 128) of simultaneous running fast queries, you should consider setting thread_handling to `pool_of_threads`.

Connecting From a Lot of Different Machines

- If you are connecting from a lot of different machines you should increase host_cache_size to the max number of machines (default 128) to cache the resolving of hostnames. If you don't connect from a lot of machines, you can set this to a very low value!

2.1.7.4 Configuring Swappiness

Contents

Why to Avoid Swapping

Obviously, accessing swap memory from disk is far slower than accessing RAM directly. This is particularly bad on a database server because:

- MariaDB's internal algorithms assume that memory is not swap, and are highly inefficient if it is. Some algorithms are intended to avoid or delay disk IO, and use memory where possible - performing this with swap can be worse than just doing it on disk in the first place.
- Swap increases IO over just using disk in the first place as pages are actively swapped in and out of swap. Even something like removing a dirty page that is no longer going to be stored in memory, while designed to improve efficiency, will under a swap situation cost more IO.
- Database locks are particularly inefficient in swap. They are designed to be obtained and released often and quickly, and pausing to perform disk IO will have a serious impact on their usability.

The main way to avoid swapping is to make sure you have enough RAM for all processes that need to run on the machine. Setting the system variables too high can mean that under load the server runs short of memory, and needs to use swap. So understanding what settings to use and how these impact your server's memory usage is critical.

Setting Swappiness on Linux

Linux has a swappiness setting which determines the balance between swapping out pages (chunks of memory) from RAM to a preconfigured swap space on the hard drive.

The setting is from 0 to 100, with lower values meaning a lower likelihood of swapping. The default is usually 60 - you can check this by running:

```
sysctl vm.swappiness
```

The default setting encourages the server to use swap. Since there probably won't be much else on the database server besides MariaDB processes to put into swap, you'll probably want to reduce this to zero to avoid swapping as much as possible. You can change the default by adding a line to the `sysctl.conf` file (usually found in `/etc/sysctl.conf`).

To set the swappiness to zero, add the line:

```
vm.swappiness = 0
```

This normally takes effect after a reboot, but you can change the value without rebooting as follows:

```
sysctl -w vm.swappiness=0
```

Since RHEL 6.4, setting swappiness=0 more aggressively avoids swapping out, which increases the risk of OOM killing under strong memory and I/O pressure.

A low swappiness setting is recommended for database workloads. For MariaDB databases, it is recommended to set swappiness to a value of 1.

```
vm.swappiness = 1
```

Disabling Swap Altogether

While some disable swap altogether, and you certainly want to avoid any database processes from using it, it can be prudent to leave some swap space to at least allow the kernel to fall over gracefully should a spike occur. Having emergency swap available at least allows you some scope to kill any runaway processes.

2.1.8 Troubleshooting Installation Issues

6.2.7 Troubleshooting Connection Issues

2.1.8.2 Installation issues on Windows

Contents

MariaDB 10.4.13

MariaDB 10.4.13 may not start on Windows. See MDEV-22555.

To resolve this, download, click and install https://aka.ms/vs/16/release/vc_redist.x64.exe and then install 10.4.13.

Unsupported Versions of Windows

Recent versions of MariaDB may not install on unsupported Windows versions. See Deprecated Package Platforms to find the final supported versions.

MariaDB 5.2.5 and earlier

On Windows Vista/7 , changes to database or my.ini are not persistent, when mysqld.exe is run from the command line.

The reason for this behavior is Vista/Win7 file system redirection. Writes to protected locations (in this case a subdirectory of Program Files) are redirected to the user's so-called "Virtual Store".

Workarounds:

- Run mysqld.exe as service. See answer here on how to create a MariaDB service.
- Run mysqld.exe from the elevated command prompt.
- Change the ACL of the data directory and add full control for the current user.

The Windows installer for MariaDB 5.2.6 and higher will set the data directory ACL to include full access rights for the user who runs the setup to prevent this issue from happening.

Systems with User Account Control

Running `mysql_install_db.exe` from a standard command prompt might cause the error:

```
FATAL ERROR: OpenSCManager failed
```

To get rid of it, use the elevated command prompt, for example on Windows 7 start it via 'Run as administrator' option.

There are 9 related questions.

2.1.8.4.1 Differences in MariaDB in Debian (and

Ubuntu)

Contents

The `.deb` packages provided by MariaDB Foundation's and MariaDB Corporation's repositories are not identical to the official `.deb` packages provided by Debian's and Ubuntu's default repositories.

The packages provided by MariaDB Foundation's and MariaDB Corporation's repositories are generated using the Debian packaging in MariaDB's official source code. The Debian packaging scripts are specifically in the `debian/` directory.

The packages provided by Debian's and Ubuntu's default repositories are generated using the Debian packaging in Debian's mirror of MariaDB's source code, which contains some custom changes. The source tree can be found here:

- https://salsa.debian.org/mariadb-team/mariadb-server

As a consequence, MariaDB behaves a bit differently if it is installed from Debian's and Ubuntu's default repositories.

Option File Locations

- The option file located at `/etc/mysql/my.cnf` is handled by the `update-alternatives` mechanism when the `mysql-common` package is installed. It is a symbolic link that references either `mysql.cnf` or `mariadb.cnf` depending on whether MySQL or MariaDB is installed. Most of the MariaDB option files are therefore actually located in `/etc/mysql/mariadb.d/`.

System Variables

Variable	MariaDB in Debian	Standard MariaDB	Notes
character_set_server	utf8mb4	latin1	Debian sets a default character set that can support emojis etc.
collation_server	utf8mb4_general_ci	latin1_swedish_ci	

Options

Option	MariaDB in Debian	Standard MariaDB	Notes
`plugin-load-add`	`auth_socket.so`	-	Before MariaDB 10.4.3, MariaDB did not enable the `unix_socket` authentication plugin by default.This is default in Debian, allowing passwordless login.

TLS

- MariaDB binaries from `.deb` packages provided by Debian's and Ubuntu's default repositories are linked with a different TLS library than MariaDB binaries from `.deb` packages provided by MariaDB Foundation's and MariaDB Corporation's repositories.
- MariaDB Server binaries:
  - In MariaDB 10.4.6 and later, MariaDB Server is statically linked with the bundled wolfSSL libraries in `.deb` packages provided by Debian's and Ubuntu's default repositories.
  - In MariaDB 10.4.5 and before, MariaDB Server is statically linked with the bundled yaSSL libraries in `.deb` packages provided by Debian's and Ubuntu's default repositories.
  - In contrast, MariaDB Server is dynamically linked with the system's OpenSSL libraries in `.deb` packages provided by MariaDB Foundation and MariaDB Corporation.
- MariaDB client and utility binaries:
  - In MariaDB 10.4.6 and later, MariaDB's clients and utilities and MariaDB Connector/C are dynamically linked with the system's GnuTLS libraries in `.deb` packages provided by Debian's and Ubuntu's default repositories. libmysqlclient is still statically linked with the bundled wolfSSL libraries.
  - In MariaDB 10.2 and later, MariaDB's clients and utilities and MariaDB Connector/C are dynamically linked with the system's GnuTLS libraries in `.deb` packages provided by Debian's and Ubuntu's default

repositories. libmysqlclient is still statically linked with the bundled yaSSL libraries.
    - In MariaDB 10.1 and earlier, MariaDB's clients and utilities and libmysqlclient are statically linked with the bundled yaSSL libraries in `.deb` packages provided by Debian's and Ubuntu's default repositories.
    - In contrast, MariaDB's clients and utilities, libmysqlclient, and MariaDB Connector/C are dynamically linked with the system's OpenSSL libraries in `.deb` packages provided by MariaDB Foundation's and MariaDB Corporation's repositories.
- See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

Authentication

- The `unix_socket` authentication plugin is installed by default in **new installations** that use the `.deb` packages provided by Debian's default repositories in Debian 9 and later and Ubuntu's default repositories in Ubuntu 15.10 and later.
- The `root@localhost` created by mariadb-install-db will also be created to authenticate via the unix_socket authentication plugin in these builds.

2.1.3.12.2 Upgrading from MySQL to MariaDB

2.1.2.8.18 Creating a Debian Repository

2.1.8.4.4 apt-upgrade Fails, But the Database is Running

After running `apt-upgrade mariadb`, it's possible that apt shows a fail in trying to start the server, but in fact the database is up and running, which then provokes apt to remain in a non finished state.

For example:

```
# apt-get upgrade
Reading package lists... Done
Building dependency tree
Reading state information... Done
Calculating upgrade... Done
0 upgraded, 0 newly installed, 0 to remove and 0 not upgraded.
2 not fully installed or removed.
After this operation, 0 B of additional disk space will be used.
Do you want to continue? [Y/n]
Setting up mariadb-server-10.1 (10.1.10+maria-1~trusty) ...
 * Stopping MariaDB database server mysqld
   ...done.
 * Starting MariaDB database server mysqld
   ...fail!
invoke-rc.d: initscript mysql, action "start" failed.
dpkg: error processing package mariadb-server-10.1 (--configure):
 subprocess installed post-installation script returned error exit status 1
dpkg: dependency problems prevent configuration of mariadb-server:
 mariadb-server depends on mariadb-server-10.1 (= 10.1.10+maria-1~trusty); however:
  Package mariadb-server-10.1 is not configured yet.

dpkg: error processing package mariadb-server (--configure):
 dependency problems - leaving unconfigured
No apport report written because the error message indicates its a followup error from a
previous failure.
Errors were encountered while processing:
 mariadb-server-10.1
 mariadb-server
E: Sub-process /usr/bin/dpkg returned an error code (1)
```

This situation could occur if the timeout for the init script was too short. For example, see MDEV-9382, a situation where the timeout was 30 seconds, but the server was taking 48 seconds to start.

To overcome this, the timeout needs to be increased. This can be achieved as follows:

- **On systems where systemd is not enabled/supported:** The timeout can be increased by setting

MYSQLD_STARTUP_TIMEOUT either directly in the script or via the command line. In MariaDB 10.1.13 and later versions, the init script also sources /etc/default/mariadb, so it can also be used to set MYSQLD_STARTUP_TIMEOUT to persistently change the startup timeout. The default timeout has been increased from 30s to 60s in MariaDB 10.1.13.

- **On systems that support systemd**: The startup timeout can be increased by setting TimeoutStartSec systemd option.

2.1.6.5 What to Do if MariaDB Doesn't Start

2.1.8.6 Installing on an Old Linux Version

This article lists some typical errors that may happen when you try to use an incompatible MariaDB binary on a linux system:

The following example errors are from trying to install MariaDB built for SuSE 11.x on a SuSE 9.0 server:

```
> scripts/mysql_install_db
./bin/my_print_defaults: /lib/i686/libc.so.6:
  version `GLIBC_2.4' not found (required by ./bin/my_print_defaults)
```

and

```
> ./bin/mysqld --skip-grant &
./bin/mysqld: error while loading shared libraries: libwrap.so.0:
cannot open shared object file: No such file or directory
```

If you see either of the above errors, the binary MariaDB package you installed is not compatible with your system.

The options you have are:

- Find another MariaDB package or tar from the download page that matches your system.

  or

- Download the source and build it.

2.1.8.7 Error: symbol mysql_get_server_name, version libmysqlclient_16 not defined

If you see the error message:

```
symbol mysql_get_server_name, version libmysqlclient_16 not defined in file libmysqlclient.so.16
with link time reference
```

...then you are probably trying to use the mysql command-line client from MariaDB with libmysqlclient.so from MySQL.

The symbol `mysql_get_server_name()` is something present in the MariaDB source tree and not in the MySQL tree.

If you have both the MariaDB client package and the MySQL client packages installed this error will happen if your system finds the MySQL version of `libmysqlclient.so` first.

To figure out which library is being linked in dynamically (ie, the wrong one) use the 'ldd' tool.

```
ldd $(which mysql) | grep mysql
```

or

```
ldd /path/to/the/binary | grep mysql
```

For example:

```
me@mybox:~$ ldd $(which mysql)|grep mysql
        libmysqlclient.so.16 => /usr/lib/libmysqlclient.so.16 (0xb74df000)
```

You can then use your package manager's tools to find out which package the library belongs to.

On CentOS the command to find out which package installed a specific file is:

```
rpm -qf /path/to/file
```

On Debian-based systems, the command is:

```
dpkg -S /path/to/file
```

Here's an example of locating the library and finding out which package it belongs to on an Ubuntu system:

```
me@mybox:~$ ldd $(which mysql)|grep mysql
 libmysqlclient.so.16 => /usr/lib/libmysqlclient.so.16 (0xb75f8000)
me@mybox:~$ dpkg -S /usr/lib/libmysqlclient.so.16
libmariadbclient16: /usr/lib/libmysqlclient.so.16
```

The above shows that the mysql command-line client is using the library `/usr/lib/libmysqlclient.so.16` and that that library is part of the `libmariadbclient16` Ubuntu package. Unsurprisingly, the mysql command-line client works perfectly on this system.

If the answer that came back had been something other than a MariaDB package, then it is likely there would have been issues with running the MariaDB mysql client application.

If the library that the system tries to use is not from a MariaDB package, the remedy is to remove the offending package (and possibly install or re-install the correct package) so that the correct library can be used.

2.1.9 Installing System Tables (mysql_install_db)

2.1.10 mysql_install_db.exe

Contents

The `mysql_install_db.exe` utility is the Windows equivalent of mysql_install_db.

Functionality

The functionality of `mysql_install_db.exe` is comparable with the shell script `mysql_install_db` used on Unix, however it has been extended with both Windows specific functionality (creating a Windows service) and to generally useful functionality. For example, it can set the 'root' user password during database creation. It also creates the `my.ini` configuration file in the data directory and adds most important parameters to it (e.g port).

`mysql_install_db.exe` is used by the MariaDB installer for Windows if the "Database instance" feature is selected. It obsoletes similar utilities and scripts that were used in the past such as `mysqld.exe --install`, `mysql_install_db.pl`, and `mysql_secure_installation.pl`.

Parameter	Description
`-?, --help`	Display help message and exit
`-d, --datadir=name`	Data directory of the new database
`-S, --service=name`	Name of the Windows service
`-p, --password=name`	Password of the root user
`-P, --port=#`	`mysqld` port
`-W, --socket=name`	named pipe name
`-D, --default-user`	Create default user
`-R, --allow-remote-root-access`	Allow remote access from network for user root
`-N, --skip-networking`	Do not use TCP connections, use pipe instead

`-i , --innodb-page-size`	Innodb page size, since MariaDB 10.2.5
`-s , --silent`	Print less information
`-o , --verbose-bootstrap`	Include mysqld bootstrap output
`-l , --large-pages`	Use large pages, since MariaDB 10.6.1
`-c , --config`	my.ini config template file, since MariaDB 10.6.1

Note : to create a Windows service, `mysql_install_db.exe` should be run by a user with full administrator privileges (which means elevated command prompt on systems with UAC). For example, if you are running it on Windows 7, make sure that your command prompt was launched via 'Run as Administrator' option.

Example

```
mysql_install_db.exe --datadir=C:\db --service=MyDB --password=secret
```

will create the database in the directory C:\db, register the auto-start Windows service "MyDB", and set the root password to 'secret'.

To start the service from the command line, execute

```
sc start MyDB
```

Removing Database Instances

If you run your database instance as service, to remove it completely from the command line, use

```
sc stop <servicename>
sc delete <servicename>
rmdir /s /q <path-to-datadir>
```

2.1.6.2 Configuring MariaDB with Option Files

2.1.12 MariaDB Environment Variables

MariaDB makes use of numerous environment variables that may be set on your system. Environment variables have the lowest precedence, so any options set on the command line or in an option file will take precedence.

It's usually better not to rely on environment variables, and to rather set the options you need directly, as this makes the system a little more robust and easy to administer.

Here is a list of environment variables used by MariaDB.

Environment Variable	Description
CXX	Name of the C++ compiler, used for running CMake.
CC	Name of the C compiler, used for running CMake.
DBI_USER	Perl DBI default username.
DBI_TRACE	Perl DBI trace options.
HOME	Default directory for the mysql_history file.
MYSQL_DEBUG	Debug trace options used when debugging.
MYSQL_GROUP_SUFFIX	In addition to the given option groups, also read groups with this suffix.
MYSQL_HISTFILE	Path to the mysql_history file, overriding the $HOME/.mysql_history setting.
MYSQL_HOME	Path to the directory containing the my.cnf file used by the server.
MYSQL_HOST	Default host name used by the mariadb command line client.
MYSQL_PS1	Command prompt for use by the mariadb command line client.

MYSQL_PWD	Default password when connecting to mysqld. It is strongly recommended to use a more secure method of sending the password to the server.
MYSQL_TCP_PORT	Default TCP/IP port number.
MYSQL_UNIX_PORT	On Unix, default socket file used for localhost connections.
PATH	Path to directories that hold executable programs (such as the mariadb client, mariadb-admin), so that these can be run from any location.
TMPDIR	Directory where temporary files are created.
TZ	Local time zone.
UMASK	Creation mode when creating files. See Specifying Permissions for Schema (Data) Directories and Tables.
UMASK_DIR	Creation mode when creating directories. See Specifying Permissions for Schema (Data) Directories and Tables.
USER	On Windows, up to MariaDB 5.5, the default user name when connecting to the mysqld server. API GetUserName() is used in later versions.

2.1.13 MariaDB on Amazon AWS

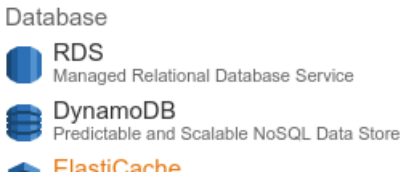
MariaDB is available on Amazon AWS through MariaDB SkySQL, as one of the database options when using Amazon's RDS service, or using a MariaDB AMI on Amazon EC2 from the AWS Marketplace.

MariaDB SkySQL

Cloud database service is available through MariaDB SkySQL on Amazon AWS. MariaDB SkySQL delivers MariaDB with enterprise features for mission-critical workloads. Support is provided directly by MariaDB. Refer to SkySQL Documentation for complete details. Get started to launch a MariaDB database on AWS in minutes.

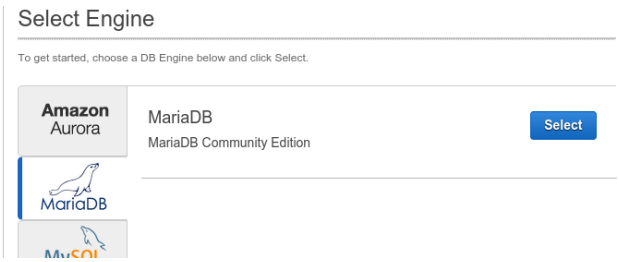
Amazon RDS

To get started with MariaDB on Amazon's RDS service, click on the RDS link in the Database section of the AWS console.



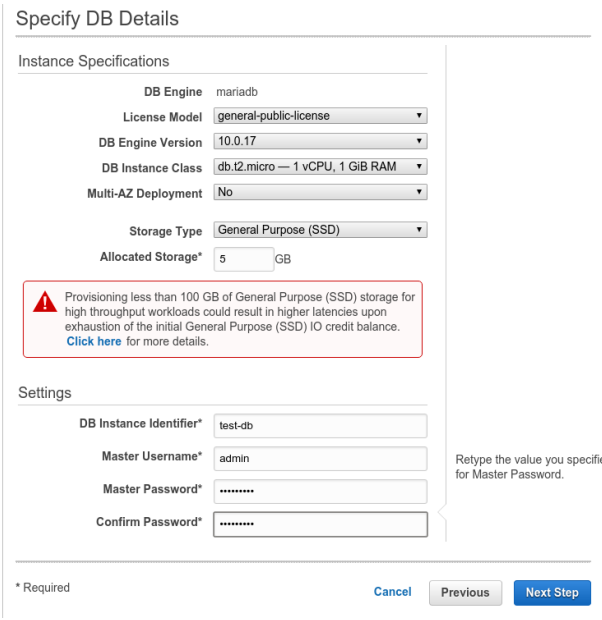
Next, click on the **Get Started Now** button. Alternatively, you can click on the **Launch DB Instance** button from the Instances section of the RDS Dashboard.

In either case, you will be brought to the page where you can select the database engine you want to use. Click on the **MariaDB** logo and then click on the **Select** button.



You will then move to step 2 where you choose whether or not you want to use your MariaDB instance for production or non-production usage. Amazon has links on this page to documentation on the various options.

After selecting the choice you want you will move to step 3 where you specify the details for your database, including setting up an admin user in the database.



You will then move to step 4 where you can configure advanced settings, including security settings, various options, backup settings, maintenance defaults, and so on.

Refer to Amazon's RDS documentation for complete documentation on all the various settings and for information on connecting to and using your RDS MariaDB instances.

AMI on EC2

MariaDB AMIs (Amazon Machine Images) are available in the AWS Marketplace. These AMIs, kept up-to-date with the most recently released versions of MariaDB, are a great way to try out the newest MariaDB versions before they make it to RDS and/or to use MariaDB in a more traditional server environment.

- Function Differences Between MariaDB 10.3 and MySQL 5.7
- Function Differences Between MariaDB 10.2 and MySQL 5.7

More Storage Engines

In addition to the standard MyISAM, BLACKHOLE, CSV, MEMORY, ARCHIVE, and MERGE storage engines, the following are also included with MariaDB Source and Binary packages:

- ColumnStore, a column oriented storage engine optimized for Data warehousing.
- MyRocks, a storage engine with great compression, in 10.2
- Aria, MyISAM replacement with better caching.
- FederatedX (drop-in replacement for Federated)
- OQGRAPH (In MariaDB 5.2 and later. Disabled in MariaDB 5.5 only.)
- SphinxSE (In MariaDB 5.2 and later)
- CONNECT in MariaDB 10.0 and later.
- SEQUENCE in MariaDB 10.0 and later.
- Spider in MariaDB 10.0 and later.
- TokuDB (In MariaDB 5.5 and later, removed in 10.6)
- Cassandra (In MariaDB 10.0, removed in 10.6)

Speed Improvements

- MariaDB now provides much faster privilege checks for setups with many user accounts or many database
- The new FLUSH SSL command allows SSL certificates to be reloaded without restarting the server
- Many optimizer enhancements in MariaDB 5.3. Subqueries are now finally usable. The complete list and a comparison with MySQL is here. A benchmark can be found here.
- Faster and safer replication: Group commit for the binary log. This makes many setups that use replication and lots of updates more than 2x times faster.
- Parallel replication *— new in 10.0*
- Improvements for InnoDB asynchronous IO subsystem on Windows.

- Indexes for the MEMORY(HEAP) engine are faster. According to a simple test, 24% faster on INSERT for integer index and 60% faster for index on a CHAR(20) column. Fixed in MariaDB 5.5 and MySQL 5.7.
- Segmented Key Cache for MyISAM. Can speed up MyISAM tables with up to 4x — *new in 5.2*
- Adjustable hash size for MyISAM and Aria. This can greatly improve shutdown time (from hours to minutes) if using a lot of MyISAM/Aria tables with delayed keys — *new in 10.0.13*
- CHECKSUM TABLE is faster.
- We improved the performance of character set conversions (and removed conversions when they were not really needed). Overall speed improvement is 1-5 % (according to sql-bench) but can be higher for big result sets with all characters between 0x00-0x7f.
- Pool of Threads in MariaDB 5.1 and even better in MariaDB 5.5. This allows MariaDB to run with 200,000+ connections and with a notable speed improvement when using many connections.
- Several speed improvements when a client connects to MariaDB. Many of the improvements were done in MariaDB 10.1 and MariaDB 10.2.
- There are some improvements to the DBUG code to make its execution faster when debug is compiled in but not used.
- Our use of the Aria storage engine enables faster complex queries (queries which normally use disk-based temporary tables). The Aria storage engine is used for internal temporary tables, which should give a speedup when doing complex selects. Aria is usually faster for temporary tables when compared to MyISAM because Aria caches row data in memory and normally doesn't have to write the temporary rows to disk.
- The test suite has been extended and now runs much faster than before, even though it tests more things.

Extensions & New Features

We've added a lot of new features to MariaDB. If a patch or feature is useful, safe, and stable — we make every effort to include it in MariaDB. The most notable features are:

- Support introduced for System-versioned tables. Allows queries to access both current and historic data, aiding in managing retention, analysis and point-in-time recovery. — *new in 10.3*
- ALTER TABLE... DROP COLUMN can now run as Instant operations. Can also now change the ordering of columns. — *new in 10.4*
- Support introduced for password expiration, using the user password expiry — *new in 10.4*
- In order to support the use of multiple authentication plugins for a single user, the `mysql.user` system table has been retired in favor of the `mysql.glob_priv` system table. — *new in 10.4*
- The unix_socket authentication plugin is now the default on Unix-like systems. This represents a major change to authentication in MariaDB — *new in 10.4*
- Support introduced for Optimizer Trace, which provides detailed information on how the Optimizer processes queries. To enable Optimizer Trace, set the `optimizer_trace` system variable — *new in 10.4*
- The MariaDB SQL/PL stored procedure dialect (enabled with sql_mode=ORACLE) now supports Oracle style packages. Support for the following statements are available: CREATE PACKAGE, CREATE PACKAGE BODY, DROP PACKAGE, DROP PACKAGE BODY, SHOW CREATE PACKAGE, SHOW CREATE PACKAGE BODY — *new in 10.3*
- Automatic collection of Engine Independent Table Statistics — *new in 10.4*
- Support for the use of parentheses (brackets) for specifying precedence in the ordering of execution for `SELECT` statements and Table Value Operations, (including the use of UNION, EXCEPT, INTERSECT operations) — *new in 10.4*
- Support for anchored data types added to local stored procedure variables. — *new in 10.3*
- Support added for Stored Aggregate functions — *new in 10.3*
- Oracle compatible SUBSTR() function is available — *new in 10.3*
- Oracle compatible SEQUENCE support is provided — *new in 10.3*
- Support for anchored data types added to stored routine variables — *new in 10.3*
- Support for anchored data types added to stored routine parameters — *new in 10.3*
- Cursors with parameters are now supported — *new in 10.3*
- INVISIBLE columns are now supported — *new in 10.3*
- Instant ADD COLUMN is now available for InnoDB — *new in 10.3*
- Window functions are supported — *new in 10.2*
- Number of supported decimals in DECIMAL has increased from `30` to `38` — *new in 10.2*
- Recursive Common Table Expressions — *new in 10.2*
- New WITH statement. `WITH` is a common table expression that allows one to refer to a subquery expression many times in a query — *new in 10.2*
- CHECK CONSTRAINT — *new in 10.2*
- DEFAULT expression, including `DEFAULT` for `BLOB` and `TEXT` — *new in 10.2*
- Added catchall for list partitions — *new in 10.2*
- Oracle-style EXECUTE IMMEDIATE statement — *new in 10.2*
- Several new JSON functions — *new in 10.2*
- Microsecond Precision in Processlist
- Table Elimination
- Virtual Columns — *new in 5.2*
- Microseconds in MariaDB — *new in 5.3*

- Extended User Statistics — *new in 5.2*
- KILL all queries for a user — *new in 5.3*,
- KILL QUERY ID - terminates the query by query_id, leaving the connection intact — *new in 10.0.5*,
- Pluggable Authentication — *new in 5.2*
- Storage-engine-specific CREATE TABLE — *new in 5.2*
- Enhancements to INFORMATION SCHEMA.PLUGINS table — *new in 5.2*
- Group commit for the binary log. This makes replication notably faster! — *new in 5.3*
- Added `--rewrite-db` mysqlbinlog option to change the used database — *new in 5.2*
- Progress reporting for `ALTER TABLE` and `LOAD DATA INFILE` — *new in 5.3*
- Faster joins and subqueries — *new in 5.3*
- HandlerSocket and faster HANDLER calls — *new in 5.3*
- Dynamic Columns support — *new in 5.3*
- GIS Functionality — *new in 5.3*
- Multi-source replication — *new in 10.0*
- Global Transaction ID — *new in 10.0*
- SHOW EXPLAIN gives the EXPLAIN plan for a query running in another thread. — *new in 10.0*
- Roles — *new in 10.0*
- PCRE Regular Expressions (including `REGEXP_REPLACE()`) — *new in 10.0*
- CREATE OR REPLACE
- DELETE ... RETURNING — *new in 10.0*
- MariaDB supports more collations than MySQL.

For a full list, please see features for each release

Better Testing

- More tests in the test suite.
- Bugs in tests fixed.
- Test builds with different configure options to get better feature testing.
- Remove invalid tests. (e.g. don't test feature "X" if that feature is not in the tested build)

Fewer Warnings and Fewer Bugs

- Bugs are bad. Fix as many bugs as possible and try to not introduce new ones.
- Compiler warnings are also bad. Eliminate as many compiler warnings as possible.

Truly Open Source

- All code in MariaDB is released under GPL, LGPL or BSD.
- MariaDB does not have closed source modules like the ones that can be found in MySQL Enterprise Edition. In fact, all the closed source features in MySQL 5.5 Enterprise Edition are found in the MariaDB open source version.
- MariaDB client libraries (for C, for Java (JDBC), for Windows (ODBC)) are released under LGPL to allow linking with closed source software. MySQL client libraries are released under GPL that does not allow linking with closed source software.
- MariaDB includes test cases for all fixed bugs. Oracle doesn't provide test cases for new bugs fixed in MySQL 5.5.
- All bugs and development plans are public.
- MariaDB is developed by the community in true open source spirit.

2.1.14.1.2 MariaDB versus MySQL: Compatibility

> See also **MariaDB vs MySQL - Features**

Contents

Replacement for MySQL

Until MariaDB 5.5, MariaDB versions functioned as a "drop-in replacement" for the equivalent MySQL version, with some limitations. From MariaDB 10.0, it is usually still very easy to upgrade from MySQL.

- MariaDB's data files are generally binary compatible with those from the equivalent MySQL version.
  - All filenames and paths are generally the same.
  - Data and table definition files (.frm) files are binary compatible.
  - See note below for an incompatibility with views!
- MariaDB's client protocol is binary compatible with MySQL's client protocol.
  - All client APIs and structs are identical.
  - All ports and sockets are generally the same.
  - All MySQL connectors (PHP, Perl, Python, Java, .NET, MyODBC, Ruby, MySQL C connector etc) work unchanged with MariaDB.
  - There are some installation issues with PHP5 that you should be aware of (a bug in how the old PHP5 client checks library compatibility).

This means that for many cases, you can just uninstall MySQL and install MariaDB and you are good to go. There is not generally any need to convert any data files.

However, you must still run mysql_upgrade to finish the upgrade. This is needed to ensure that your mysql privilege and event tables are updated with the new fields MariaDB uses.

That said, MariaDB has a lot of new options, extension, storage engines and bug fixes that are not in MySQL. You can find the feature set for the different MariaDB versions on the What is in the different MariaDB Releases page.

Drop-in Compatibility of Specific MariaDB Versions

MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4 function as limited drop-in replacements for MySQL 5.7, as far as InnoDB is concerned. However, the implementation differences continue to grow in each new MariaDB version.

MariaDB 10.0 and MariaDB 10.1 function as limited drop-in replacements for MySQL 5.6, as far as InnoDB is concerned. However, there are some implementation differences in some features.

MariaDB 5.5 functions as a drop-in replacement for MySQL 5.5.

MariaDB 5.1, MariaDB 5.2, and MariaDB 5.3 function as drop-in replacements for MySQL 5.1.

Replication Compatibility

Replication compatibility depends on:

- The MariaDB Server version
- The MySQL Server version
- The role of each server

Replication compatibility details are described below for each MySQL version that is still maintained.

For replication compatibility details between MariaDB versions, see Cross-Version Replication Compatibility.

MySQL 5.7

MariaDB Server 10.2 and later can replicate from a MySQL 5.7 primary server.

MariaDB Server does not support the MySQL implementation of Global Transaction IDs (GTIDs), so the MariaDB replica server must use the binary log file and position for replication. If GTID mode is enabled on the MySQL primary server, the MariaDB replica server will remove the MySQL GTID events and replace them with MariaDB GTID events.

Although MariaDB Server and MySQL 5.7 are compatible at the replication level, they may have some incompatibilities at the SQL (detailed below). Those differences can cause replication failures in some cases. To decrease the risk of compatibility issues, it is recommended to set binlog_format to `ROW`. When you want to replicate from MySQL 5.7 to MariaDB Server, it is recommended to test your application, so that any compatibility issues can be found and fixed.

MariaDB can't make any claims about whether a MySQL 5.7 replica server can replicate from a MariaDB primary server.

MySQL 8.0

MariaDB Server cannot replicate from a MySQL 8.0 primary server, because MySQL 8.0 has a binary log format that is incompatible.

Incompatibilities between Currently Maintained MariaDB Versions and MySQL

- System Variable Differences Between MariaDB 10.7 and MySQL 8.0

Incompatibilities between MariaDB 10.3 and MySQL 5.7

- See Incompatibilities and Feature Differences Between MariaDB 10.3 and MySQL 5.7 for details.
- Function Differences Between MariaDB 10.3 and MySQL 5.7
- System Variable Differences Between MariaDB 10.3 and MySQL 5.7

Incompatibilities between MariaDB 10.2 and MySQL 5.7

- See Incompatibilities and Feature Differences Between MariaDB 10.2 and MySQL 5.7 for details.
- System Variable Differences Between MariaDB 10.2 and MySQL 5.7

Incompatibilities between MariaDB 10.1 and MySQL 5.7

- MariaDB 10.1 and above does not support MySQL 5.7's packed JSON objects. MariaDB follows the SQL standard and stores the JSON as a normal TEXT/BLOB. If you want to replicate JSON columns from MySQL to MariaDB, you should store JSON objects in MySQL in a TEXT column or use statement based replication. If you are using JSON columns and want to upgrade to MariaDB, you can either convert the JSON columns to TEXT or use mysqldump to copy these tables to MariaDB. In MySQL, JSON is compared according to json values. In MariaDB JSON strings are normal strings and compared as strings.
- MariaDB 10.1's InnoDB encryption is implemented differently than MySQL 5.7's InnoDB encryption.
- MariaDB 10.1 does not support the ngram and MeCab full-text parser plugins - MDEV-10267, MDEV-10268.
- MariaDB 10.1 does not support multiple triggers for a table - MDEV-6112. This is fixed in MariaDB 10.2
- MariaDB 10.1 does not support CREATE TABLESPACE for InnoDB.
- MariaDB 10.1 does not support MySQL 5.7's “native” InnoDB partitioning handler. Fixed in MariaDB 10.6.15.
- MariaDB does not support MySQL 5.7's X protocol.
- MariaDB 10.1 does not support the use of multiple triggers of the same type for a table. This feature was introduced in MariaDB 10.2.2.
- MariaDB 10.1 does not support MySQL 5.7's transportable tablespaces for partitioned InnoDB tables. ALTER TABLE ... {DISCARD|IMPORT} PARTITION is not supported. For a workaround see the following blog post.
- MariaDB 10.1 does not support MySQL 5.7's online undo tablespace truncation. However, this feature was added to

MariaDB 10.2.

- MySQL 5.7 features a new implementation of the `performance_schema` and a `sys` schema wrapper. These are not yet supported in MariaDB.
- MySQL 5.7 adds multi-source replication and replication channels. Multi-source replication was added to MariaDB previously, in MariaDB 10.0, and uses a different syntax.
- MySQL 5.7 adds group replication. This feature is incompatible with MariaDB's galera-cluster replication.
- MariaDB 10.1 does not support MySQL 5.7's, `ACCOUNT LOCK/UNLOCK` synax for `CREATE USER` and `ALTER USER` statements.
- MariaDB 10.1 does not support MySQL 5.7's `ALTER TABLE...RENAME INDEX` statements.
- MariaDB 10.1 does not support MySQL 5.7's `STACKED` operation for `GET DIAGNOSTICS` statements.
- MariaDB 10.1 does not support MySQL 5.7's `{WITH|WITHOUT} VALIDATION` syntax for `ALTER TABLE.. EXCHANGE PARTITION` statements.
- MariaDB does not support the optional *init_vector* argument for AES_ENCRYPT and AES_DECRYPT or the block_encryption_mode variable - MDEV-9069
- MariaDB does not support the `--initialize` option. Use `mysql_install_db` instead. - MDEV-19010
- Also see Incompatibilities between MariaDB 10.0 and MySQL 5.6.
- Also see a detailed breakdown of System variable differences between MariaDB 10.1and MySQL 5.7.

Incompatibilities between MariaDB 10.0 and MySQL 5.6

- MySQL does not support MariaDB's Spider Storage Engine.
- All MySQL binaries (`mysqld` , myisamchk etc.) give a warning if one uses a prefix of an option (such as `--big-table` instead of `--big-tables`). MariaDB binaries work in the same way as most other Unix commands and don't give warnings when using unique prefixes.
- MariaDB GTID is not compatible with MySQL 5.6. This means that one can't have MySQL 5.6 as a slave for MariaDB 10.0. However MariaDB 10.0 can be a slave of MySQL 5.6 or any earlier MySQL/MariaDB version. Note that MariaDB and MySQL also have different GTID system variables, so these need to be adjusted when migrating.
- MariaDB 10.0 multi-source replication is not supported in MySQL 5.6.
- To make CREATE TABLE ... SELECT work the same way in statement based and row based replication it's by default executed as CREATE OR REPLACE TABLE on the slave. One benefit of this is that if the slave dies in the middle of CREATE ... SELECT it will be able to continue.
    - One can use the slave-ddl-exec-mode variable to specify how `CREATE TABLE` and `DROP TABLE` is replicated.
- See also a detailed breakdown of System variable differences between MariaDB 10.0 and MySQL 5.6.
- MySQL 5.6 has performance schema enabled by default. For performance reasons MariaDB 10.0 has it disabled by default. You can enable it by starting `mysqld` with the option `--performance-schema` .
- MariaDB 10.0 does not support the MySQL Memcached plugin. However, data stored using memcached can be retrieved because the data is stored as InnoDB tables. MariaDB is able to start successfully with an error message of not being able to find libmemcached.so library.
- Users created with MySQL's SHA256 password algorithm cannot be used in MariaDB 10.0 as MariaDB does not include MySQL's `sha256_password` plugin.
- MariaDB 10.0 does not support delayed replication - MDEV-7145.
- Also see a detailed breakdown of System variable differences between MariaDB 10.0 and MySQL 5.6.
- The low-level temporal format used by TIME, DATETIME and TIMESTAMP is different in MySQL 5.6 and MariaDB 10.0. (In MariaDB 10.1, the MySQL implementation is used by default - see mysql56_temporal_format.)
- MariaDB implements some changes in the SQL query optimizer over what's available in MySQL. This can result in `EXPLAIN` statements showing different plans.
- MySQL delayed replication, (through `MASTER_DELAY`), is not supported in MariaDB 10.0, it was implemented in MariaDB 10.2.5
- MariaDB does not support the optional *init_vector* argument for AES_ENCRYPT and AES_DECRYPT or the block_encryption_mode variable - MDEV-9069

Incompatibilities between MariaDB 5.5 and MySQL 5.5

- **Views with definition ALGORITHM=MERGE or ALGORITHM=TEMPTABLE got accidentally swapped between MariaDB and MySQL! You have to re-create views created with either of these definitions!**
- INSERT IGNORE also gives warnings for duplicate key errors. You can turn this off by setting `OLD_MODE=NO_DUP_KEY_WARNINGS_WITH_IGNORE` (see OLD_MODE).
- Before MariaDB 5.5.31, `X'HHHH'` , the standard SQL syntax for binary string literals, erroneously worked in the same way as `0xHHHH` , which could work as a number or string depending on the context. In 5.5.31 this was fixed to behave as a string in all contexts (and never as a number), introducing an incompatibility with previous versions of MariaDB, and all versions of MySQL. See CAST and Hexadecimal Literals for more details and examples.
- MariaDB dynamic columns are not supported by MySQL.
- MariaDB virtual columns are not supported by MySQL.
- MariaDB's HandlerSocket plugin is not supported by MySQL.
- MariaDB's Cassandra Storage Engine is not supported by MySQL.

- As of MariaDB 5.5.35, EXTRACT (HOUR FROM ...) adheres to the SQL standard and returns a result from 0 to 23. In MySQL, and earlier versions of MariaDB, the result can be greater than 23.
- See also a detailed breakdown of System variable differences between MariaDB 5.5 and MySQL 5.5.

Incompatibilities between MariaDB 5.3 and MySQL 5.1

- **Views with definition ALGORITHM=MERGE or ALGORITHM=TEMPTABLE got accidentally swapped between MariaDB 5.2 and MariaDB 5.3! You have to re-create views created with either of these definitions!**
- A few error messages related to wrong conversions are different as MariaDB provides more information in the message about what went wrong.
- Error numbers for MariaDB-specific errors have been moved to start from 1900 so as not to conflict with MySQL errors.
- Microseconds now work in all contexts; MySQL, in some contexts, lost the microsecond part from datetime and time.
- UNIX_TIMESTAMP(constant-date-string) returns a timestamp with 6 decimals in MariaDB while MySQL returns it without a decimal. This can cause a problem if you are using UNIX_TIMESTAMP() as a partitioning function. You can fix this by using FLOOR(UNIX_TIMESTAMP(..)) or changing the date string to a date number, like 20080101000000.
- MariaDB performs stricter checking of date, datetime and timestamp values. For example UNIX_TIMESTAMP('x') now returns NULL instead of 0.
- The old `--maria-` startup options are removed. You should use the `--aria-` prefix instead. (MariaDB 5.2 supports both `--maria-` and `--aria-`)
- `SHOW PROCESSLIST` has an extra `Progress` column which shows progress for some commands. You can disable it by starting `mysqld` with either `--old-mode=NO_PROGRESS_INFO` or with the `--old` flag (see OLD_MODE).
- `INFORMATION_SCHEMA.PROCESSLIST` has three new columns for progress reporting: `STAGE` , `MAX_STAGE` , and `PROGRESS` .
- Long comments which start with `/*M!` or `/*M!#####` are executed.
- If you use max_user_connections=0 (which means any number of connections) when starting mysqld, you can't change the global variable anymore while mysqld remains running. This is because when mysqld is started with `max_user_connections=0` it does not allocate counting structures (which also involve a mutex for each connection). This would lead to wrong counters if you later changed the variable. If you want to be able to change this variable at runtime, set it to a high value at startup.
- You can set `max_user_connections` (both the global variable and the `GRANT` option) to `-1` to stop users from connecting to the server. The global `max_user_connections` variable does not affect users with the `SUPER` privilege.
- The IGNORE directive does not ignore all errors (like fatal errors), only things that are safe to ignore.

Incompatibilities between MariaDB 5.2 and MySQL 5.1

The list is the same as between MariaDB 5.1 and MySQL 5.1, with one addition:

- A new SQL_MODE value was added: `IGNORE_BAD_TABLE_OPTIONS` . If it is not set, using a table, field, or index attribute (option) that is not supported by the chosen storage engine will cause an error. This change might cause warnings in the error log about incorrectly defined tables from the `mysql` database, fix that with mysql_upgrade.

For all practical purposes, MariaDB 5.2 is a drop in replacement for MariaDB 5.1 and MySQL 5.1.

Incompatibilities between MariaDB 5.1 and MySQL 5.1

In some few cases MariaDB has to be incompatible to allow MariaDB to provide more and better information than MySQL.

Here is the list of all known user level incompatibilities you may see when using MariaDB 5.1 instead of MySQL 5.1.

- The installation package names start with MariaDB instead of MySQL.
- Timings may be different as MariaDB is in many cases faster than MySQL.
- mysqld in MariaDB also reads the `[mariadb]` sections of your my.cnf files.
- You can't use a binary only storage engine library with MariaDB if it's not compiled for exactly the same MariaDB version. (This is because the server internal structure THD is different between MySQL and MariaDB. This is common also between different MySQL versions). This should not be a problem as most people don't load new storage engines and MariaDB comes with more storage engines than MySQL.
- `CHECKSUM TABLE` may give different result as MariaDB doesn't ignore NULL's in the columns as MySQL 5.1 does (Future MySQL versions should calculate checksums the same way as MariaDB). You can get the 'old style' checksum in MariaDB by starting mysqld with the `--old` option. Note however that that the MyISAM and Aria storage engines in MariaDB are using the new checksum internally, so if you are using `--old` , the `CHECKSUM` command will be slower as it needs to calculate the checksum row by row.
- The slow query log has more information about the query, which may be a problem if you have a script which parses the slow query log.
- MariaDB by default takes a bit more memory than MySQL because we have by default enabled the Aria storage engine for handling internal temporary tables. If you need MariaDB to take very little memory (at the expense of

performance), you can set the value of `aria_pagecache_buffer_size` to `1M` (the default is `128M`).
- If you are using new command options, new features of MariaDB or new storage engines, you can't move easily back and forth between MySQL and MariaDB anymore.

Old, Unsupported Configuration Options

If you are using any of the following options in your `/etc/my.cnf` or other `my.cnf` file you should remove them. This is also true for MySQL 5.1 or newer:

- `skip-bdb`

Replacing a MySQL RPM

If you uninstalled a MySQL RPM to install MariaDB, note that the MySQL RPM on uninstall renames `/etc/my.cnf` to `/etc/my.cnf.rpmsave`.

After installing MariaDB you should do the following to restore your old configuration options:

```
mv -vi /etc/my.cnf.rpmsave /etc/my.cnf
```

Incompatibilities between MariaDB and MySQL-Proxy

A MySQL client API is able to connect to MariaDB using MySQL-Proxy but a MariaDB client API will receive progress reporting informations that MySQL-Proxy does not implement, to get full compatibility in all case just disable progress reporting on the client or server side.

Another option is to use the MariaDB MaxScale proxy, that works with both MySQL and MariaDB.

2.1.3.12.1 Upgrading from MySQL to MariaDB

2.1.14.1.4 Incompatibilities and Feature Differences Between MariaDB 11.1 and MySQL 8.0

Contents

MariaDB maintains high levels of compatibility with MySQL, and most applications that use MySQL will work seamlessly with MariaDB. However, take note of the following incompatibilities and feature differences between MariaDB 11.1 and MySQL 8.0. It is based on the versions MySQL 8.0.34 and MariaDB 11.1.2. Note that MySQL 8 is an 'evergreen' release, so features may be added or removed in later releases.

Storage Engines

In addition to the standard InnoDB, MyISAM, BLACKHOLE, CSV, MEMORY, ARCHIVE, and MERGE storage engines, the following are also available with MariaDB 11.1:

- ColumnStore utilizes a massively parallel distributed data architecture and is designed for big data scaling to process petabytes of data.
- MyRocks, a storage engine with great compression
- S3 storage engine allows one to archive MariaDB tables in Amazon S3, or any third-party public or private cloud that

implements S3 API.
- Aria, MyISAM replacement with better caching.
- CONNECT
- SEQUENCE
- Spider
- SphinxSE
- FederatedX (drop-in replacement for Federated)
- OQGRAPH

Extensions and New Features

The most notable features available in MariaDB, but not in MySQL, are:

- Galera is a standard part of MariaDB Server.
- Temporal data tables in the form of:
  - System-versioned tables (allow you to query and operate on historic data).
  - Application-time periods (allow you to query and operate on a temporal range of data), including the WITHOUT OVERLAPS clause.
  - Bitemporal tables (which combine both system-versioning and application-time periods).
- DML-only flashback, allowing instances, databases or tables to be rolled back to an old snapshot.
- Oracle compatibility mode
- MariaDB supports localization in a number of additional languages: Bulgarian, Chinese, Georgian, Hindi, Serbian, and Ukrainian.
- MariaDB has made major improvements to the optimizer.
- Sequences
- Table Value Constructors
- Dynamic Columns support
- Semi-sync plugin merged into the server
- OR REPLACE syntax for CREATE statements, such as CREATE OR REPLACE TABLE, CREATE OR REPLACE DATABASE, etc
- DELETE ... RETURNING, INSERT ... RETURNING, REPLACE ... RETURNING
- GRANT to PUBLIC - MDEV-5215 (blog post)
- WAIT syntax for setting the lock wait timeout.
- UUID data type for storing UUIDs.
- INET6 and INET4 data types for storing IPv6 and IPv4 addresses.
- SUPER privileges made more granular.
- PROXY protocol support
- Multiple compression algorithms available as plugins
- Number of supported decimals in DECIMAL has increased from `30` to `38`
- Added catchall for list partitions
- Oracle-style EXECUTE IMMEDIATE statement
- Lots of new JSON functions
- Microsecond Precision in Processlist
- Table Elimination
- Virtual Columns
- Extended User Statistics
- KILL all queries for a user
- Storage-engine-specific CREATE TABLE
- MariaDB supports more collations (506) than MySQL (266).
- FLUSH SSL command to reload SSL certificates without server restart.
- `IF NOT EXISTS` clause added to INSTALL PLUGIN and `IF EXISTS` clause added to UNINSTALL PLUGIN and UNINSTALL SONAME
- Enhancements to INFORMATION SCHEMA.PLUGINS table
- Group commit for the binary log. This makes replication notably faster!
- The binary log in MariaDB can be compressed.
- BACKUP STAGE allows one to implement very efficient backups with minimal locking.
- Progress reporting for ALTER TABLE and LOAD DATA INFILE
- SHOW EXPLAIN gives the EXPLAIN plan for a query running in another thread. MySQL introduced the EXPLAIN FOR CONNECTION syntax to do the same thing.
- PCRE Regular Expressions (including REGEXP_REPLACE())
- HandlerSocket and faster HANDLER calls
- MySQL 8 does not support PROCEDURE ANALYSE
- MySQL 8 does not support the use of `\N` as an alias for NULL

Incompatibilities

When moving from MySQL 8.0 to MariaDB 11.1, please take note of the following incompatibilities:

- For a list of function differences, see Function Differences Between MariaDB 11.1 and MySQL 8.0
- For a list of system variable differences, see System Variable Differences Between MariaDB 11.1 and MySQL 8.0
- MariaDB does not support MySQL's SET PERSIST - MDEV-16228
- MariaDB's GTID is not compatible with MySQL's. Note that MariaDB and MySQL also have different GTID system variables, so these need to be adjusted when migrating.
- The unix_socket authentication plugin is now default on Unix-like systems, which is a major change to authentication in MariaDB. See Authentication from MariaDB 10.4 for an overview of the changes.
- All mysql* binaries are now named mariadb* (the previous mysql named is retained as a symlink for compatibility purposes)
- Not all character sets and collations are supported across both MySQL and MariaDB. As of 11.1, MariaDB supports 40 character sets and 506 collations . As of 8.0.34, MySQL supports 41 character sets (`gb18030` being the additional one - MDEV-7495) and 286 collations.
- MariaDB indicates collation pad status as part of the name (e.g. `utf8mb3_unicode_nopad_ci`), while MySQL indicates pad status by means of an extra column in SHOW COLLATION.
- To make CREATE TABLE ... SELECT work the same way in statement based and row based replication it's by default executed as CREATE OR REPLACE TABLE on the replica. One benefit of this is that if the replica dies in the middle of CREATE ... SELECT it will be able to continue.
  - One can use the slave-ddl-exec-mode variable to specify how `CREATE TABLE` and `DROP TABLE` is replicated.
- Users created with MySQL's SHA256 password algorithm cannot be used in MariaDB 11.1 - MDEV-9804.
- MariaDB 11.1 does not support Lateral Derived Tables - MDEV-19078.
- MariaDB 11.1 does not support CIDR notation for user accounts - MDEV-25515.
- MariaDB stores JSON as true text, not in binary format as MySQL. MariaDB's JSON functions are much faster than MySQL's so there is no need to store in binary format, which would add complexity when manipulating JSON objects.
- For the same reason, MariaDB's JSON data type is an alias for LONGTEXT. If you want to replicate JSON columns from MySQL to MariaDB, you should store JSON objects in MySQL in a TEXT or LONGTEXT column or use statement-based replication. If you are using JSON columns and want to upgrade to MariaDB, use the mysql_json plugin to automatically convert MySQL JSON to TEXT, or alternatively you need to either convert them to TEXT or use mysqldump to copy these tables to MariaDB.
- In MySQL, JSON is compared according to json values. In MariaDB JSON strings are normal strings and compared as strings.
- MariaDB 11.1 does not support MySQL's JSON operators (`->` and `->>`) - MDEV-13594
- MariaDB 11.1 supports the standard by producing null and a warning for JSON_SEARCH when given invalid data, while MySQL produces an error.
- Roles
  - MariaDB never allows authentication via roles, while MySQL permits this.
  - MySQL permits activating multiple roles at the same time. MariaDB can achieve the same result by creating an intermediate aggregate role.
  - In the INFORMATION_SCHEMA.ENABLED_ROLES table, MySQL reports just the direct list of enabled roles, while MariaDB reports the enabled role, plus the effective inherited roles.
  - MySQL extends the INFORMATION_SCHEMA.APPLICABLE_ROLES table .
  - MySQL includes the tables INFORMATION_SCHEMA.ROLE_TABLE_GRANTS, INFORMATION_SCHEMA.ROLE_ROUTINE_GRANTS, INFORMATION_SCHEMA.ROLE_COLUMN_GRANTS, and INFORMATION_SCHEMA ADMINISTRABLE_ROLE_AUTHORIZATIONS.
- MySQL has the performance schema enabled by default. For performance reasons MariaDB 11.1 has it disabled by default. You can enable it by starting `mariadbd` with the option `--performance-schema` .
- MariaDB has removed the InnoDB Change Buffer.
- In MariaDB 11.1, using FLUSH TABLES without any table list will only close tables not in use, and tables not locked by the FLUSH TABLES connection. If there are no locked tables, FLUSH TABLES will be instant and will not cause any waits, as it no longer waits for tables in use. When a table list is provided, the server will wait for the end of any transactions that are using the tables. In MySQL, FLUSH TABLES only waits for the statements to complete.
- MariaDB binaries (`mariadbd` , myisamchk etc.) give a warning if one uses a unique prefix of an option (such as `--big-table` instead of `--big-tables`). MySQL binaries require the full option name.
- MariaDB 11.1 implements InnoDB encryption in a different way to MySQL 8.0.
- MySQL's implementation of aborting statements that exceed a certain time to execute can only kill SELECTs, while MariaDB's can kill any queries (excluding stored procedures).
- MariaDB 11.1 does not support MySQL's `SELECT /*+ MAX_EXECUTION_TIME(n) */ ...` - see Aborting Statements that Exceed a Certain Time to Execute.
- MySQL 8.0 does not support the Query Cache.
- MariaDB 11.1 does not support the MySQL Memcached plugin (which has been deprecated in MySQL 8.0). However, data stored using memcached can be retrieved because the data is stored as InnoDB tables. MariaDB is able to start successfully with an error message of not being able to find libmemcached.so library.
- In MySQL, `X'HHHH'` , the standard SQL syntax for binary string literals, erroneously works in the same way as `0xHHHH` , which could work as a number or string depending on the context. In MariaDB, this has been fixed to behave as a string in all contexts (and never as a number). See CAST and Hexadecimal Literals for more details and

examples.
- In MariaDB 11.1, SHOW CREATE TABLE does not quote the DEFAULT value of an integer. MariaDB 10.2 and earlier, and MySQL, do. Since MariaDB can support defaults for BLOB and TEXT fields, while MySQL does not, SHOW CREATE TABLE will also append `DEFAULT NULL` where no default is explicitly provided to nullable BLOB or TEXT fields in MariaDB.
- As a result of implementing Table Value Constructors, the VALUES function has been renamed to VALUE().
- MariaDB's NOWAIT supports SELECT statements, LOCK TABLES and various DDL statements, while MySQL's NOWAIT only supports SELECT.
- MariaDB's NOWAIT cannot be added on views and stored procedures while MySQL's can - MDEV-25247
- MariaDB does not support RENAME table while it is write-locked - MDEV-30814
- MariaDB returns an `ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction` when unable to lock within the time, while MySQL returns `ERROR 3572 (HY000): Statement aborted because lock(s) could not be acquired immediately and NOWAIT is set`
- MariaDB does not support the optional *init_vector* argument for AES_ENCRYPT and AES_DECRYPT or the block_encryption_mode variable - MDEV-9069
- MariaDB does not support the `--initialize` option. Use mariadb-install-db instead. - MDEV-19010
- MariaDB 11.1 does not support the ngram and MeCab full-text parser plugins - MDEV-10267, MDEV-10268.
- MariaDB 11.1 does not support the MySQL X plugin.
- MariaDB 11.1 does not support CREATE TABLESPACE for InnoDB.
- The MySQL 8.0 and MariaDB 11.1 INFORMATION_SCHEMA.COLUMNS table contain slightly different fields.
- MariaDB 11.1 client executables allow the connection protocol to be forced by specifying only connection properties on the command-line. See mariadb Command-line client
- The MySQL binary log includes the thread_id, while MariaDB's binary log does not - MDEV-7850
- The MariaDB syntax supporting Spatial Reference System IDs for spatial data type columns with REF_SYSTEM_ID is not supported by MySQL. MySQL 8 introduced `CREATE SPATIAL REFERENCE SYSTEM`, which is not supported by MariaDB - MDEV-29953
- MariaDB 11.1 does not support the RESTART statement - MDEV-30813
- MariaDB 11.1 does not support the SELECT FOR UPDATE and FOR SHARE locks - MDEV-17514

2.1.14.1.5 Incompatibilities and Feature Differences Between MariaDB 11.0 and MySQL 8.0

Contents

MariaDB maintains high levels of compatibility with MySQL, and most applications that use MySQL will work seamlessly with MariaDB. However, take note of the following incompatibilities and feature differences between MariaDB 11.0 and MySQL 8.0. It is based on the versions MySQL 8.0.34 and MariaDB 11.0.2. Note that MySQL 8 is an 'evergreen' release, so features may be added or removed in later releases.

Storage Engines

In addition to the standard InnoDB, MyISAM, BLACKHOLE, CSV, MEMORY, ARCHIVE, and MERGE storage engines, the following are also available with MariaDB 11.0:

- ColumnStore utilizes a massively parallel distributed data architecture and is designed for big data scaling to process petabytes of data.
- MyRocks, a storage engine with great compression
- S3 storage engine allows one to archive MariaDB tables in Amazon S3, or any third-party public or private cloud that implements S3 API.
- Aria, MyISAM replacement with better caching.
- CONNECT
- SEQUENCE
- Spider
- SphinxSE
- FederatedX (drop-in replacement for Federated)
- OQGRAPH

Extensions and New Features

The most notable features available in MariaDB, but not in MySQL, are:

- Galera is a standard part of MariaDB Server.
- Temporal data tables in the form of:
  - System-versioned tables (allow you to query and operate on historic data).
  - Application-time periods (allow you to query and operate on a temporal range of data), including the WITHOUT OVERLAPS clause.
  - Bitemporal tables (which combine both system-versioning and application-time periods).
- DML-only flashback, allowing instances, databases or tables to be rolled back to an old snapshot.
- Oracle compatibility mode
- MariaDB supports localization in a number of additional languages: Bulgarian, Chinese, Georgian, Hindi, Serbian, and Ukrainian.
- MariaDB has made major improvements to the optimizer.
- Sequences
- Table Value Constructors
- Dynamic Columns support
- Semi-sync plugin merged into the server
- OR REPLACE syntax for CREATE statements, such as CREATE OR REPLACE TABLE, CREATE OR REPLACE DATABASE, etc
- DELETE ... RETURNING, INSERT ... RETURNING, REPLACE ... RETURNING
- GRANT to PUBLIC - MDEV-5215 (blog post)
- WAIT syntax for setting the lock wait timeout.
- UUID data type for storing UUIDs.
- INET6 and INET4 data types for storing IPv6 and IPv4 addresses.
- SUPER privileges made more granular.
- PROXY protocol support
- Multiple compression algorithms available as plugins
- Number of supported decimals in DECIMAL has increased from `30` to `38`
- Added catchall for list partitions
- Oracle-style EXECUTE IMMEDIATE statement
- Lots of new JSON functions
- Microsecond Precision in Processlist
- Table Elimination
- Virtual Columns
- Extended User Statistics
- KILL all queries for a user
- Storage-engine-specific CREATE TABLE
- MariaDB supports more collations (506) than MySQL (266).
- FLUSH SSL command to reload SSL certificates without server restart.
- `IF NOT EXISTS` clause added to INSTALL PLUGIN and `IF EXISTS` clause added to UNINSTALL PLUGIN and UNINSTALL SONAME
- Enhancements to INFORMATION SCHEMA.PLUGINS table
- Group commit for the binary log. This makes replication notably faster!
- The binary log in MariaDB can be compressed.
- BACKUP STAGE allows one to implement very efficient backups with minimal locking.
- Progress reporting for ALTER TABLE and LOAD DATA INFILE
- SHOW EXPLAIN gives the EXPLAIN plan for a query running in another thread. MySQL introduced the EXPLAIN FOR CONNECTION syntax to do the same thing.
- PCRE Regular Expressions (including REGEXP_REPLACE())
- HandlerSocket and faster HANDLER calls
- MySQL 8 does not support PROCEDURE ANALYSE
- MySQL 8 does not support the use of `\N` as an alias for NULL

Incompatibilities

When moving from MySQL 8.0 to MariaDB 11.0, please take note of the following incompatibilities:

- For a list of function differences, see Function Differences Between MariaDB 11.0 and MySQL 8.0
- For a list of system variable differences, see System Variable Differences Between MariaDB 11.0 and MySQL 8.0
- MariaDB does not support MySQL's SET PERSIST - MDEV-16228
- MariaDB's GTID is not compatible with MySQL's. Note that MariaDB and MySQL also have different GTID system variables, so these need to be adjusted when migrating.
- The unix_socket authentication plugin is now default on Unix-like systems, which is a major change to authentication in MariaDB. See Authentication from MariaDB 10.4 for an overview of the changes.
- All mysql* binaries are now named mariadb* (the previous mysql named is retained as a symlink for compatibility purposes)
- Not all character sets and collations are supported across both MySQL and MariaDB. As of 11.0, MariaDB supports

40 character sets and 506 collations . As of 8.0.34, MySQL supports 41 character sets (`gb18030` being the additional one - MDEV-7495) and 286 collations.

- MariaDB indicates collation pad status as part of the name (e.g. `utf8mb3_unicode_nopad_ci`), while MySQL indicates pad status by means of an extra column in SHOW COLLATION.
- To make CREATE TABLE ... SELECT work the same way in statement based and row based replication it's by default executed as CREATE OR REPLACE TABLE on the slave. One benefit of this is that if the slave dies in the middle of CREATE ... SELECT it will be able to continue.
  - One can use the slave-ddl-exec-mode variable to specify how `CREATE TABLE` and `DROP TABLE` is replicated.
- Users created with MySQL's SHA256 password algorithm cannot be used in MariaDB 11.0 - MDEV-9804.
- MariaDB 11.0 does not support Lateral Derived Tables - MDEV-19078.
- MariaDB 11.0 does not support CIDR notation for user accounts - MDEV-25515.
- MariaDB stores JSON as true text, not in binary format as MySQL. MariaDB's JSON functions are much faster than MySQL's so there is no need to store in binary format, which would add complexity when manipulating JSON objects.
- For the same reason, MariaDB's JSON data type is an alias for LONGTEXT. If you want to replicate JSON columns from MySQL to MariaDB, you should store JSON objects in MySQL in a TEXT or LONGTEXT column or use statement-based replication. If you are using JSON columns and want to upgrade to MariaDB, use the mysql_json plugin to automatically convert MySQL JSON to TEXT, or alternatively you need to either convert them to TEXT or use mysqldump to copy these tables to MariaDB.
- In MySQL, JSON is compared according to json values. In MariaDB JSON strings are normal strings and compared as strings.
- MariaDB 11.0 does not support MySQL's JSON operators (`->` and `->>`) - MDEV-13594
- MariaDB 11.0 supports the standard by producing null and a warning for JSON_SEARCH when given invalid data, while MySQL produces an error.
- Roles
  - MariaDB never allows authentication via roles, while MySQL permits this.
  - MySQL permits activating multiple roles at the same time. MariaDB can achieve the same result by creating an intermediate aggregate role.
  - In the INFORMATION_SCHEMA.ENABLED_ROLES table, MySQL reports just the direct list of enabled roles, while MariaDB reports the enabled role, plus the effective inherited roles.
  - MySQL extends the INFORMATION_SCHEMA.APPLICABLE_ROLES table .
  - MySQL includes the tables INFORMATION_SCHEMA.ROLE_TABLE_GRANTS, INFORMATION_SCHEMA.ROLE_ROUTINE_GRANTS, INFORMATION_SCHEMA.ROLE_COLUMN_GRANTS, and INFORMATION_SCHEMA ADMINISTRABLE_ROLE_AUTHORIZATIONS.
- MySQL has the performance schema enabled by default. For performance reasons MariaDB 11.0 has it disabled by default. You can enable it by starting `mariadbd` with the option `--performance-schema` .
- MariaDB has removed the InnoDB Change Buffer.
- In MariaDB 11.0, using FLUSH TABLES without any table list will only close tables not in use, and tables not locked by the FLUSH TABLES connection. If there are no locked tables, FLUSH TABLES will be instant and will not cause any waits, as it no longer waits for tables in use. When a table list is provided, the server will wait for the end of any transactions that are using the tables. In MySQL, FLUSH TABLES only waits for the statements to complete.
- MariaDB binaries (`mariadbd` , myisamchk etc.) give a warning if one uses a unique prefix of an option (such as `--big-table` instead of `--big-tables`). MySQL binaries require the full option name.
- MariaDB 11.0 implements InnoDB encryption in a different way to MySQL 8.0.
- MySQL's implementation of aborting statements that exceed a certain time to execute can only kill SELECTs, while MariaDB's can kill any queries (excluding stored procedures).
- MariaDB 11.0 does not support MySQL's `SELECT /*+ MAX_EXECUTION_TIME(n) */ ...` - see Aborting Statements that Exceed a Certain Time to Execute.
- MySQL 8.0 does not support the Query Cache.
- MariaDB 11.0 does not support the MySQL Memcached plugin (which has been deprecated in MySQL 8.0). However, data stored using memcached can be retrieved because the data is stored as InnoDB tables. MariaDB is able to start successfully with an error message of not being able to find libmemcached.so library.
- In MySQL, `X'HHHH'` , the standard SQL syntax for binary string literals, erroneously works in the same way as `0xHHHH` , which could work as a number or string depending on the context. In MariaDB, this has been fixed to behave as a string in all contexts (and never as a number). See CAST and Hexadecimal Literals for more details and examples.
- In MariaDB 11.0, SHOW CREATE TABLE does not quote the DEFAULT value of an integer. MariaDB 10.2 and earlier, and MySQL, do. Since MariaDB can support defaults for BLOB and TEXT fields, while MySQL does not, SHOW CREATE TABLE will also append `DEFAULT NULL` where no default is explicitly provided to nullable BLOB or TEXT fields in MariaDB.
- As a result of implementing Table Value Constructors, the VALUES function has been renamed to VALUE().
- MariaDB's NOWAIT supports SELECT statements, LOCK TABLES and various DDL statements, while MySQL's NOWAIT only supports SELECT.
- MariaDB's NOWAIT cannot be added on views and stored procedures while MySQL's can - MDEV-25247
- MariaDB does not support RENAME table while it is write-locked - MDEV-30814
- MariaDB returns an `ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction`

when unable to lock within the time, while MySQL returns `ERROR 3572 (HY000): Statement aborted because lock(s) could not be acquired immediately and NOWAIT is set`

- MariaDB does not support the optional *init_vector* argument for AES_ENCRYPT and AES_DECRYPT or the block_encryption_mode variable - MDEV-9069
- MariaDB does not support the `--initialize` option. Use mariadb-install-db instead. - MDEV-19010
- MariaDB 11.0 does not support the ngram and MeCab full-text parser plugins - MDEV-10267, MDEV-10268.
- MariaDB 11.0 does not support the MySQL X plugin.
- MariaDB 11.0 before MariaDB 11.0.3 does not support MySQL 8's "native" InnoDB partitioning handler - MDEV-29253
- MariaDB 11.0 does not support CREATE TABLESPACE for InnoDB.
- The MySQL 8.0 and MariaDB 11.0 INFORMATION_SCHEMA.COLUMNS table contain slightly different fields.
- MariaDB 11.0 client executables allow the connection protocol to be forced by specifying only connection properties on the command-line. See mariadb Command-line client
- The MySQL binary log includes the thread_id, while MariaDB's binary log does not - MDEV-7850
- The MariaDB syntax supporting Spatial Reference System IDs for spatial data type columns with REF_SYSTEM_ID is not supported by MySQL. MySQL 8 introduced `CREATE SPATIAL REFERENCE SYSTEM`, which is not supported by MariaDB - MDEV-29953
- MariaDB 11.0 does not support the RESTART statement - MDEV-30813
- MariaDB 11.0 does not support the SELECT FOR UPDATE and FOR SHARE locks - MDEV-17514

2.1.14.1.6 Incompatibilities and Feature Differences Between MariaDB 10.11 and MySQL 8.0

Contents

MariaDB maintains high levels of compatibility with MySQL, and most applications that use MySQL will work seamlessly with MariaDB. However, take note of the following incompatibilities and feature differences between MariaDB 10.11 and MySQL 8.0. It is based on the versions MySQL 8.0.32 and MariaDB 10.11.2. Note that MySQL 8 is an 'evergreen' release, so features may be added or removed in later releases.

Storage Engines

In addition to the standard InnoDB, MyISAM, BLACKHOLE, CSV, MEMORY, ARCHIVE, and MERGE storage engines, the following are also available with MariaDB 10.11:

- ColumnStore utilizes a massively parallel distributed data architecture and is designed for big data scaling to process petabytes of data.
- MyRocks, a storage engine with great compression
- S3 storage engine allows one to archive MariaDB tables in Amazon S3, or any third-party public or private cloud that implements S3 API.
- Aria, MyISAM replacement with better caching.
- CONNECT
- SEQUENCE
- Spider
- SphinxSE
- FederatedX (drop-in replacement for Federated)
- OQGRAPH

Extensions and New Features

The most notable features available in MariaDB, but not in MySQL, are:

- Galera is a standard part of MariaDB Server.
- Temporal data tables in the form of:
  - System-versioned tables (allow you to query and operate on historic data).
  - Application-time periods (allow you to query and operate on a temporal range of data), including the WITHOUT OVERLAPS clause.
  - Bitemporal tables (which combine both system-versioning and application-time periods).
- DML-only flashback, allowing instances, databases or tables to be rolled back to an old snapshot.

- Oracle compatibility mode
- MariaDB supports localization in a number of additional languages: Bulgarian, Chinese, Hindi, Serbian, and Ukrainian.
- Sequences
- Table Value Constructors
- Dynamic Columns support
- Semi-sync plugin merged into the server
- OR REPLACE syntax for CREATE statements, such as CREATE OR REPLACE TABLE, CREATE OR REPLACE DATABASE, etc
- DELETE ... RETURNING, INSERT ... RETURNING, REPLACE ... RETURNING
- GRANT to PUBLIC - MDEV-5215 (blog post)
- WAIT syntax for setting the lock wait timeout.
- UUID data type for storing UUIDs.
- INET6 and INET4 data types for storing IPv6 and IPv4 addresses.
- SUPER privileges made more granular.
- PROXY protocol support
- Multiple compression algorithms available as plugins
- Number of supported decimals in DECIMAL has increased from `30` to `38`
- Added catchall for list partitions
- Oracle-style EXECUTE IMMEDIATE statement
- Lots of new JSON functions
- Microsecond Precision in Processlist
- Table Elimination
- Virtual Columns
- Extended User Statistics
- KILL all queries for a user
- Storage-engine-specific CREATE TABLE
- MariaDB supports more collations (506) than MySQL (266).
- FLUSH SSL command to reload SSL certificates without server restart.
- `IF NOT EXISTS` clause added to INSTALL PLUGIN and `IF EXISTS` clause added to UNINSTALL PLUGIN and UNINSTALL SONAME
- Enhancements to INFORMATION SCHEMA.PLUGINS table
- Group commit for the binary log. This makes replication notably faster!
- The binary log in MariaDB can be compressed.
- BACKUP STAGE allows one to implement very efficient backups with minimal locking.
- Progress reporting for ALTER TABLE and LOAD DATA INFILE
- SHOW EXPLAIN gives the EXPLAIN plan for a query running in another thread. MySQL introduced the EXPLAIN FOR CONNECTION syntax to do the same thing.
- PCRE Regular Expressions (including REGEXP_REPLACE())
- HandlerSocket and faster HANDLER calls
- MySQL 8 does not support PROCEDURE ANALYSE
- MySQL 8 does not support the use of `\N` as an alias for NULL

Incompatibilities

When moving from MySQL 8.0 to MariaDB 10.11, please take note of the following incompatibilities:

- For a list of function differences, see Function Differences Between MariaDB 10.11 and MySQL 8.0
- For a list of system variable differences, see System Variable Differences Between MariaDB 10.11 and MySQL 8.0
- MariaDB does not support MySQL's SET PERSIST - MDEV-16228
- MariaDB's GTID is not compatible with MySQL's. Note that MariaDB and MySQL also have different GTID system variables, so these need to be adjusted when migrating.
- The unix_socket authentication plugin is now default on Unix-like systems, which is a major change to authentication in MariaDB. See Authentication from MariaDB 10.4 for an overview of the changes.
- All mysql* binaries are now named mariadb* (the previous mysql named is retained as a symlink for compatibility purposes)
- Not all character sets and collations are supported across both MySQL and MariaDB. As of 10.11, MariaDB supports 40 character sets and 506 collations . As of 8.0.32, MySQL supports 41 character sets (`gb18030` being the additional one - MDEV-7495) and 286 collations.
- MariaDB indicates collation pad status as part of the name (e.g. `utf8mb3_unicode_nopad_ci`), while MySQL indicates pad status by means of an extra column in SHOW COLLATION.
- To make CREATE TABLE ... SELECT work the same way in statement based and row based replication it's by default executed as CREATE OR REPLACE TABLE on the slave. One benefit of this is that if the slave dies in the middle of CREATE ... SELECT it will be able to continue.
  - One can use the slave-ddl-exec-mode variable to specify how `CREATE TABLE` and `DROP TABLE` is replicated.
- Users created with MySQL's SHA256 password algorithm cannot be used in MariaDB 10.11 - MDEV-9804.

- MariaDB 10.11 does not support Lateral Derived Tables - MDEV-19078.
- MariaDB 10.11 does not support CIDR notation for user accounts - MDEV-25515.
- MariaDB stores JSON as true text, not in binary format as MySQL. MariaDB's JSON functions are much faster than MySQL's so there is no need to store in binary format, which would add complexity when manipulating JSON objects.
- For the same reason, MariaDB's JSON data type is an alias for LONGTEXT. If you want to replicate JSON columns from MySQL to MariaDB, you should store JSON objects in MySQL in a TEXT or LONGTEXT column or use statement-based replication. If you are using JSON columns and want to upgrade to MariaDB, use the mysql_json plugin to automatically convert MySQL JSON to TEXT, or alternatively you need to either convert them to TEXT or use mysqldump to copy these tables to MariaDB.
- In MySQL, JSON is compared according to json values. In MariaDB JSON strings are normal strings and compared as strings.
- MariaDB 10.11 does not support MySQL's JSON operators (`->` and `->>`) - MDEV-13594
- MariaDB 10.11 supports the standard by producing null and a warning for JSON_SEARCH when given invalid data, while MySQL produces an error.
- Roles
  - MariaDB never allows authentication via roles, while MySQL permits this.
  - MySQL permits activating multiple roles at the same time. MariaDB can achieve the same result by creating an intermediate aggregate role.
  - In the INFORMATION_SCHEMA.ENABLED_ROLES table, MySQL reports just the direct list of enabled roles, while MariaDB reports the enabled role, plus the effective inherited roles.
  - MySQL extends the INFORMATION_SCHEMA.APPLICABLE_ROLES table .
  - MySQL includes the tables INFORMATION_SCHEMA.ROLE_TABLE_GRANTS, INFORMATION_SCHEMA.ROLE_ROUTINE_GRANTS, INFORMATION_SCHEMA.ROLE_COLUMN_GRANTS, and INFORMATION_SCHEMA ADMINISTRABLE_ROLE_AUTHORIZATIONS.
- MySQL has the performance schema enabled by default. For performance reasons MariaDB 10.11 has it disabled by default. You can enable it by starting `mysqld` with the option `--performance-schema` .
- In MariaDB 10.11, using FLUSH TABLES without any table list will only close tables not in use, and tables not locked by the FLUSH TABLES connection. If there are no locked tables, FLUSH TABLES will be instant and will not cause any waits, as it no longer waits for tables in use. When a table list is provided, the server will wait for the end of any transactions that are using the tables. In MySQL, FLUSH TABLES only waits for the statements to complete.
- MariaDB binaries (`mysqld` , myisamchk etc.) give a warning if one uses a unique prefix of an option (such as `--big-table` instead of `--big-tables`). MySQL binaries require the full option name.
- MariaDB 10.11 implements InnoDB encryption in a different way to MySQL 8.0.
- MySQL's implementation of aborting statements that exceed a certain time to execute can only kill SELECTs, while MariaDB's can kill any queries (excluding stored procedures).
- MariaDB 10.11 does not support MySQL's `SELECT /*+ MAX_EXECUTION_TIME(n) */ ...` - see Aborting Statements that Exceed a Certain Time to Execute.
- MySQL 8.0 does not support the Query Cache.
- MariaDB 10.11 does not support the MySQL Memcached plugin (which has been deprecated in MySQL 8.0). However, data stored using memcached can be retrieved because the data is stored as InnoDB tables. MariaDB is able to start successfully with an error message of not being able to find libmemcached.so library.
- In MySQL, `X'HHHH'` , the standard SQL syntax for binary string literals, erroneously works in the same way as `0xHHHH` , which could work as a number or string depending on the context. In MariaDB, this has been fixed to behave as a string in all contexts (and never as a number). See CAST and Hexadecimal Literals for more details and examples.
- In MariaDB 10.11, SHOW CREATE TABLE does not quote the DEFAULT value of an integer. MariaDB 10.2 and earlier, and MySQL, do. Since MariaDB can support defaults for BLOB and TEXT fields, while MySQL does not, SHOW CREATE TABLE will also append `DEFAULT NULL` where no default is explicitly provided to nullable BLOB or TEXT fields in MariaDB.
- As a result of implementing Table Value Constructors, the VALUES function has been renamed to VALUE().
- MariaDB's NOWAIT supports SELECT statements, LOCK TABLES and various DDL statements, while MySQL's NOWAIT only supports SELECT.
- MariaDB's NOWAIT cannot be added on views and stored procedures while MySQL's can - MDEV-25247
- MariaDB does not support RENAME table while it is write-locked - MDEV-30814
- MariaDB returns an `ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction` when unable to lock within the time, while MySQL returns `ERROR 3572 (HY000): Statement aborted because lock(s) could not be acquired immediately and NOWAIT is set`
- MariaDB does not support the optional *init_vector* argument for AES_ENCRYPT and AES_DECRYPT or the block_encryption_mode variable - MDEV-9069
- MariaDB does not support the `--initialize` option. Use mariadb-install-db instead. - MDEV-19010
- MariaDB 10.11 does not support the ngram and MeCab full-text parser plugins - MDEV-10267, MDEV-10268.
- MariaDB 10.11 does not support the MySQL X plugin.
- MariaDB 10.11 before MariaDB 10.11.5 does not support MySQL 8's “native” InnoDB partitioning handler - MDEV-29253
- MariaDB 10.11 does not support CREATE TABLESPACE for InnoDB.

- The MySQL 8.0 and MariaDB 10.11 INFORMATION_SCHEMA.COLUMNS table contain slightly different fields.
- MariaDB 10.11 client executables allow the connection protocol to be forced by specifying only connection properties on the command-line. See mariadb Command-line client
- The MySQL binary log includes the thread_id, while MariaDB's binary log does not - MDEV-7850
- The MariaDB syntax supporting Spatial Reference System IDs for spatial data type columns with REF_SYSTEM_ID is not supported by MySQL. MySQL 8 introduced `CREATE SPATIAL REFERENCE SYSTEM`, which is not supported by MariaDB - MDEV-29953
- MariaDB 10.11 does not support the RESTART statement - MDEV-30813
- MariaDB 10.11 does not support the SELECT FOR UPDATE and FOR SHARE locks - MDEV-17514

2.1.14.1.7 Incompatibilities and Feature Differences Between MariaDB 10.10 and MySQL 8.0

Contents

MariaDB maintains high levels of compatibility with MySQL, and most applications that use MySQL will work seamlessly with MariaDB. However, take note of the following incompatibilities and feature differences between MariaDB 10.10 and MySQL 8.0. It is based on the versions MySQL 8.0.32 and MariaDB 10.10.3. Note that MySQL 8 is an 'evergreen' release, so features may be added or removed in later releases.

Storage Engines

In addition to the standard InnoDB, MyISAM, BLACKHOLE, CSV, MEMORY, ARCHIVE, and MERGE storage engines, the following are also available with MariaDB 10.10:

- ColumnStore utilizes a massively parallel distributed data architecture and is designed for big data scaling to process petabytes of data.
- MyRocks, a storage engine with great compression
- S3 storage engine allows one to archive MariaDB tables in Amazon S3, or any third-party public or private cloud that implements S3 API.
- Aria, MyISAM replacement with better caching.
- CONNECT
- SEQUENCE
- Spider
- SphinxSE
- FederatedX (drop-in replacement for Federated)
- OQGRAPH

Extensions and New Features

The most notable features available in MariaDB, but not in MySQL, are:

- Galera is a standard part of MariaDB Server.
- Temporal data tables in the form of:
  - System-versioned tables (allow you to query and operate on historic data).
  - Application-time periods (allow you to query and operate on a temporal range of data), including the WITHOUT OVERLAPS clause.
  - Bitemporal tables (which combine both system-versioning and application-time periods).
- DML-only flashback, allowing instances, databases or tables to be rolled back to an old snapshot.
- Oracle compatibility mode
- Sequences
- Table Value Constructors
- Dynamic Columns support
- Semi-sync plugin merged into the server
- OR REPLACE syntax for CREATE statements, such as CREATE OR REPLACE TABLE, CREATE OR REPLACE DATABASE, etc
- DELETE ... RETURNING, INSERT ... RETURNING, REPLACE ... RETURNING
- WAIT syntax for setting the lock wait timeout.
- UUID data type for storing UUIDs.

- INET6 and INET4 data types for storing IPv6 and IPv4 addresses.
- SUPER privileges made more granular.
- PROXY protocol support
- Multiple compression algorithms available as plugins
- Number of supported decimals in DECIMAL has increased from `30` to `38`
- Added catchall for list partitions
- Oracle-style EXECUTE IMMEDIATE statement
- Lots of new JSON functions
- Microsecond Precision in Processlist
- Table Elimination
- Virtual Columns
- Extended User Statistics
- KILL all queries for a user
- Storage-engine-specific CREATE TABLE
- MariaDB supports more collations (506) than MySQL (266).
- FLUSH SSL command to reload SSL certificates without server restart.
- `IF NOT EXISTS` clause added to INSTALL PLUGIN and `IF EXISTS` clause added to UNINSTALL PLUGIN and UNINSTALL SONAME
- Enhancements to INFORMATION SCHEMA.PLUGINS table
- Group commit for the binary log. This makes replication notably faster!
- The binary log in MariaDB can be compressed.
- BACKUP STAGE allows one to implement very efficient backups with minimal locking.
- Progress reporting for ALTER TABLE and LOAD DATA INFILE
- SHOW EXPLAIN gives the EXPLAIN plan for a query running in another thread. MySQL introduced the EXPLAIN FOR CONNECTION syntax to do the same thing.
- PCRE Regular Expressions (including REGEXP_REPLACE())
- HandlerSocket and faster HANDLER calls
- MySQL 8 does not support PROCEDURE ANALYSE
- MySQL 8 does not support the use of `\N` as an alias for NULL

Incompatibilities

When moving from MySQL 8.0 to MariaDB 10.10, please take note of the following incompatibilities:

- For a list of function differences, see Function Differences Between MariaDB 10.10 and MySQL 8.0
- For a list of system variable differences, see System Variable Differences Between MariaDB 10.10 and MySQL 8.0
- MariaDB does not support MySQL's SET PERSIST - MDEV-16228
- MariaDB's GTID is not compatible with MySQL's. Note that MariaDB and MySQL also have different GTID system variables, so these need to be adjusted when migrating.
- The unix_socket authentication plugin is now default on Unix-like systems, which is a major change to authentication in MariaDB. See Authentication from MariaDB 10.4 for an overview of the changes.
- All mysql* binaries are now named mariadb* (the previous mysql named is retained as a symlink for compatibility purposes)
- Not all character sets and collations are supported across both MySQL and MariaDB. As of 10.10, MariaDB supports 40 character sets and 506 collations . As of 8.0.32, MySQL supports 41 character sets (`gb18030` being the additional one - MDEV-7495) and 286 collations.
- MariaDB indicates collation pad status as part of the name (e.g. `utf8mb3_unicode_nopad_ci`), while MySQL indicates pad status by means of an extra column in SHOW COLLATION.
- To make CREATE TABLE ... SELECT work the same way in statement based and row based replication it's by default executed as CREATE OR REPLACE TABLE on the slave. One benefit of this is that if the slave dies in the middle of CREATE ... SELECT it will be able to continue.
  - One can use the slave-ddl-exec-mode variable to specify how `CREATE TABLE` and `DROP TABLE` is replicated.
- Users created with MySQL's SHA256 password algorithm cannot be used in MariaDB 10.10 - MDEV-9804.
- MariaDB 10.10 does not support Lateral Derived Tables - MDEV-19078.
- MariaDB 10.10 does not support CIDR notation for user accounts - MDEV-25515.
- MariaDB stores JSON as true text, not in binary format as MySQL. MariaDB's JSON functions are much faster than MySQL's so there is no need to store in binary format, which would add complexity when manipulating JSON objects.
- For the same reason, MariaDB's JSON data type is an alias for LONGTEXT. If you want to replicate JSON columns from MySQL to MariaDB, you should store JSON objects in MySQL in a TEXT or LONGTEXT column or use statement-based replication. If you are using JSON columns and want to upgrade to MariaDB, use the mysql_json plugin to automatically convert MySQL JSON to TEXT, or alternatively you need to either convert them to TEXT or use mysqldump to copy these tables to MariaDB.
- In MySQL, JSON is compared according to json values. In MariaDB JSON strings are normal strings and compared as strings.
- MariaDB 10.10 does not support MySQL's JSON operators (`->` and `->>`) - MDEV-13594
- MariaDB 10.10 supports the standard by producing null and a warning for JSON_SEARCH when given invalid data,

while MySQL produces an error.

- Roles
  - MariaDB never allows authentication via roles, while MySQL permits this.
  - MySQL permits activating multiple roles at the same time. MariaDB can achieve the same result by creating an intermediate aggregate role.
  - In the INFORMATION_SCHEMA.ENABLED_ROLES table, MySQL reports just the direct list of enabled roles, while MariaDB reports the enabled role, plus the effective inherited roles.
  - MySQL extends the INFORMATION_SCHEMA.APPLICABLE_ROLES table .
  - MySQL includes the tables INFORMATION_SCHEMA.ROLE_TABLE_GRANTS, INFORMATION_SCHEMA.ROLE_ROUTINE_GRANTS, INFORMATION_SCHEMA.ROLE_COLUMN_GRANTS, and INFORMATION_SCHEMA ADMINISTRABLE_ROLE_AUTHORIZATIONS.
- MySQL has the performance schema enabled by default. For performance reasons MariaDB 10.10 has it disabled by default. You can enable it by starting `mariadbd` with the option `--performance-schema` .
- In MariaDB 10.10, using FLUSH TABLES without any table list will only close tables not in use, and tables not locked by the FLUSH TABLES connection. If there are no locked tables, FLUSH TABLES will be instant and will not cause any waits, as it no longer waits for tables in use. When a table list is provided, the server will wait for the end of any transactions that are using the tables. In MySQL, FLUSH TABLES only waits for the statements to complete.
- MariaDB binaries (`mariadbd` , myisamchk etc.) give a warning if one uses a unique prefix of an option (such as `--big-table` instead of `--big-tables`). MySQL binaries require the full option name.
- MariaDB 10.10 implements InnoDB encryption in a different way to MySQL 8.0.
- MySQL's implementation of aborting statements that exceed a certain time to execute can only kill SELECTs, while MariaDB's can kill any queries (excluding stored procedures).
- MariaDB 10.10 does not support MySQL's `SELECT /*+ MAX_EXECUTION_TIME(n) */ ...` - see Aborting Statements that Exceed a Certain Time to Execute.
- MySQL 8.0 does not support the Query Cache.
- MariaDB 10.10 does not support the MySQL Memcached plugin (which has been deprecated in MySQL 8.0). However, data stored using memcached can be retrieved because the data is stored as InnoDB tables. MariaDB is able to start successfully with an error message of not being able to find libmemcached.so library.
- In MySQL, `X'HHHH'` , the standard SQL syntax for binary string literals, erroneously works in the same way as `0xHHHH` , which could work as a number or string depending on the context. In MariaDB, this has been fixed to behave as a string in all contexts (and never as a number). See CAST and Hexadecimal Literals for more details and examples.
- In MariaDB 10.10, SHOW CREATE TABLE does not quote the DEFAULT value of an integer. MariaDB 10.2 and earlier, and MySQL, do. Since MariaDB can support defaults for BLOB and TEXT fields, while MySQL does not, SHOW CREATE TABLE will also append `DEFAULT NULL` where no default is explicitly provided to nullable BLOB or TEXT fields in MariaDB.
- As a result of implementing Table Value Constructors, the VALUES function has been renamed to VALUE().
- MariaDB's NOWAIT supports SELECT statements, LOCK TABLES and various DDL statements, while MySQL's NOWAIT only supports SELECT.
- MariaDB's NOWAIT cannot be added on views and stored procedures while MySQL's can - MDEV-25247
- MariaDB does not support RENAME table while it is write-locked - MDEV-30814
- MariaDB returns an `ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction` when unable to lock within the time, while MySQL returns `ERROR 3572 (HY000): Statement aborted because lock(s) could not be acquired immediately and NOWAIT is set`
- MariaDB does not support the optional *init_vector* argument for AES_ENCRYPT and AES_DECRYPT or the block_encryption_mode variable - MDEV-9069
- MariaDB does not support the `--initialize` option. Use mysql_install_db instead. - MDEV-19010
- MariaDB 10.10 does not support the ngram and MeCab full-text parser plugins - MDEV-10267, MDEV-10268.
- MariaDB 10.10 does not support the MySQL X plugin.
- MariaDB 10.10 before MariaDB 10.10.6 does not support MySQL 8's “native” InnoDB partitioning handler - MDEV-29253
- MariaDB 10.10 does not support CREATE TABLESPACE for InnoDB.
- The MySQL 8.0 and MariaDB 10.10 INFORMATION_SCHEMA.COLUMNS table contain slightly different fields.
- MariaDB 10.10 client executables allow the connection protocol to be forced by specifying only connection properties on the command-line. See mariadb Command-line client
- The MySQL binary log includes the thread_id, while MariaDB's binary log does not - MDEV-7850
- The MariaDB syntax supporting Spatial Reference System IDs for spatial data type columns with REF_SYSTEM_ID is not supported by MySQL. MySQL 8 introduced `CREATE SPATIAL REFERENCE SYSTEM` , which is not supported by MariaDB - MDEV-29953
- MariaDB 10.10 does not support the RESTART statement - MDEV-30813
- MariaDB 10.10 does not support the SELECT FOR UPDATE and FOR SHARE locks - MDEV-17514

2.1.14.1.8 Incompatibilities and Feature

Differences Between MariaDB 10.6 and MySQL 8.0

Contents

MariaDB maintains high levels of compatibility with MySQL, and most applications that use MySQL will work seamlessly with MariaDB. However, take note of the following incompatibilities and feature differences between MariaDB 10.6 and MySQL 8.0. It is based on the versions MySQL 8.0.25 and MariaDB 10.6.0. Note that MySQL 8 is an 'evergreen' release, so features may be added or removed in later releases.

Storage Engines

In addition to the standard InnoDB, MyISAM, BLACKHOLE, CSV, MEMORY, ARCHIVE, and MERGE storage engines, the following are also available with MariaDB 10.6:

- ColumnStore utilizes a massively parallel distributed data architecture and is designed for big data scaling to process petabytes of data.
- MyRocks, a storage engine with great compression
- S3 storage engine allows one to archive MariaDB tables in Amazon S3, or any third-party public or private cloud that implements S3 API.
- Aria, MyISAM replacement with better caching.
- CONNECT
- SEQUENCE
- Spider
- SphinxSE
- FederatedX (drop-in replacement for Federated)
- OQGRAPH

Extensions and New Features

The most notable features available in MariaDB, but not in MySQL, are:

- Galera is a standard part of MariaDB Server.
- Temporal data tables in the form of:
  - System-versioned tables (allow you to query and operate on historic data).
  - Application-time periods (allow you to query and operate on a temporal range of data), including the WITHOUT OVERLAPS clause.
  - Bitemporal tables (which combine both system-versioning and application-time periods).
- DML-only flashback, allowing instances, databases or tables to be rolled back to an old snapshot.
- Oracle compatibility mode
- Sequences
- Invisible Columns
- Table Value Constructors
- Dynamic Columns support
- Semi-sync plugin merged into the server
- INTERSECT/INTERSECT ALL and EXCEPT/EXCEPT ALL
- OR REPLACE syntax for CREATE statements, such as CREATE OR REPLACE TABLE, CREATE OR REPLACE DATABASE, etc
- DELETE ... RETURNING, INSERT ... RETURNING, REPLACE ... RETURNING
- WAIT syntax for setting the lock wait timeout.
- INET6 data type for storing IPv6 addresses.
- SUPER privileges made more granular.
- PROXY protocol support
- Number of supported decimals in DECIMAL has increased from `30` to `38`
- Added catchall for list partitions
- Oracle-style EXECUTE IMMEDIATE statement
- Lots of new JSON functions
- Microsecond Precision in Processlist
- Table Elimination
- Virtual Columns
- Extended User Statistics
- KILL all queries for a user

- Storage-engine-specific CREATE TABLE
- MariaDB supports more collations than MySQL, including `NO PAD` collations.
- FLUSH SSL command to reload SSL certificates without server restart.
- `IF NOT EXISTS` clause added to INSTALL PLUGIN and `IF EXISTS` clause added to UNINSTALL PLUGIN and UNINSTALL SONAME
- Enhancements to INFORMATION SCHEMA.PLUGINS table
- Group commit for the binary log. This makes replication notably faster!
- The binary log in MariaDB can be compressed.
- BACKUP STAGE allows one to implement very efficient backups with minimal locking.
- Progress reporting for ALTER TABLE and LOAD DATA INFILE
- SHOW EXPLAIN gives the EXPLAIN plan for a query running in another thread. MySQL introduced the EXPLAIN FOR CONNECTION syntax to do the same thing.
- PCRE Regular Expressions (including REGEXP_REPLACE())
- HandlerSocket and faster HANDLER calls
- MySQL 8 does not support PROCEDURE ANALYSE
- MySQL 8 does not support the use of `\N` as an alias for NULL

Incompatibilities

When moving from MySQL 8.0 to MariaDB 10.6, please take note of the following incompatibilities:

- For a list of function differences, see Function Differences Between MariaDB 10.6 and MySQL 8.0
- For a list of system variable differences, see System Variable Differences Between MariaDB 10.6 and MySQL 8.0
- MariaDB does not support MySQL's SET PERSIST - MDEV-16228
- MariaDB's GTID is not compatible with MySQL's. Note that MariaDB and MySQL also have different GTID system variables, so these need to be adjusted when migrating.
- The unix_socket authentication plugin is now default on Unix-like systems, which is a major change to authentication in MariaDB. See Authentication from MariaDB 10.4 for an overview of the changes.
- All mysql* binaries are now named mariadb* (the previous mysql named is retained as a symlink for compatibility purposes)
- Not all character sets and collations are supported across both MySQL and MariaDB. As of 10.6.0, MariaDB supports 40 character sets and 322 collations (armscii8_general_nopad_ci, armscii8_nopad_bin, ascbig5_chinese_nopad_ci, big5_nopad_bin, iicp1250_general_nopad_ci, cp1250_nopad_bin, cp1250_general_nopad_ci, cp1250_nopad_bin, cp1251_general_nopad_ci, cp1251_nopad_bin, cp1256_general_nopad_ci, cp1256_nopad_bin, cp1257_general_nopad_ci, cp1257_nopad_bin, cp850_general_nopad_ci, cp850_nopad_bin, cp852_general_nopad_ci, cp852_nopad_bin, cp866_general_nopad_ci, cp866_nopad_bin, cp932_japanese_nopad_ci, cp932_nopad_bin, dec8_nopad_bin, dec8_swedish_nopad_ci, eucjpms_japanese_nopad_ci, eucjpms_nopad_bin, eucjpms_japanese_nopad_ci, eucjpms_nopad_bin, euckr_korean_nopad_ci, euckr_nopad_bin, gb2312_chinese_nopad_ci, gb2312_nopad_bin, gbk_chinese_nopad_ci, gbk_nopad_bin, geostd8_general_nopad_ci, geostd8_nopad_bin, greek_general_nopad_ci, greek_nopad_bin, hebrew_general_nopad_ci, hebrew_nopad_bin, hp8_english_nopad_ci, hp8_nopad_bin, keybcs2_general_nopad_ci, keybcs2_nopad_bin, koi8r_general_nopad_ci, koi8r_nopad_bin, koi8u_general_nopad_ci, koi8u_nopad_bin, latin1_nopad_bin, latin1_swedish_nopad_ci, latin2_general_nopad_ci, latin2_nopad_bin, latin5_nopad_bin, latin5_turkish_ci, latin5_turkish_nopad_ci, latin7_general_nopad_ci, latin7_nopad_bin, macce_general_nopad_ci, macce_nopad_bin, macroman_general_nopad_ci, macroman_nopad_bin, sjis_japanese_nopad_ci, sjis_nopad_bin, swe7_nopad_bin, tis620_thai_nopad_ci, tis620_nopad_bin, ucs2_croatian_mysql561_ci, ucs2_general_mysql500_ci, ucs2_general_nopad_ci, ucs2_myanmar_ci, ucs2_nopad_bin, ucs2_swedish_ci, ucs2_thai_520_w2, ucs2_unicode_ci, ucs2_unicode_nopad_ci, ujis_japanese_nopad_ci, ujis_nopad_bin, utf16le_general_nopad_ci, utf16le_nopad_bin, utf16_croatian_mysql561_ci, utf16_general_nopad_ci, utf16_myanmar_ci, utf16_nopad_bin, utf16_thai_520_w2, utf16_unicode_520_nopad_ci, utf16_unicode_nopad_ci, utf32_croatian_mysql561_ci, utf32_general_nopad_ci, utf32_myanmar_ci, utf32_nopad_bin, utf32_thai_520_w2, utf32_unicode_520_nopad_ci, utf32_unicode_nopad_ci, utf8mb4_general_nopad_ci, utf8mb4_myanmar_ci, utf8mb4_nopad_bin, utf8mb4_thai_520_w2, utf8mb4_unicode_520_nopad_ci, utf8mb4_unicode_nopad_ci, utf8_croatian_mysql561_ci, utf8_general_nopad_ci, utf8_myanmar_ci, utf8_nopad_bin, utf8_thai_520_w2, utf8_unicode_520_nopad_ci, utf8_unicode_ci and utf8_unicode_nopad_ci being the additional ones).

  As of 8.0.25, MySQL supports 41 character sets (`gb18030` being the additional one - MDEV-7495) and 272 collations (gb18030_bin, gb18030_chinese_ci, gb18030_unicode_520_ci, utf8mb4_0900_ai_ci, utf8mb4_0900_as_ci, utf8mb4_0900_as_cs, utf8mb4_0900_bin, utf8mb4_cs_0900_ai_ci, utf8mb4_cs_0900_as_cs, utf8mb4_da_0900_ai_ci, utf8mb4_da_0900_as_cs, utf8mb4_de_pb_0900_ai_ci, utf8mb4_de_pb_0900_as_cs, utf8mb4_eo_0900_ai_ci, utf8mb4_eo_0900_as_cs, utf8mb4_es_0900_ai_ci, utf8mb4_es_0900_as_cs, utf8mb4_es_trad_0900_ai_ci, utf8mb4_es_trad_0900_as_cs, utf8mb4_et_0900_ai_ci, utf8mb4_et_0900_as_cs, utf8mb4_hr_0900_ai_ci, utf8mb4_hr_0900_as_cs, utf8mb4_hu_0900_ai_ci, utf8mb4_hu_0900_as_cs, utf8mb4_is_0900_ai_ci, utf8mb4_is_0900_as_cs, utf8mb4_ja_0900_as_cs, utf8mb4_ja_0900_as_cs_ks, utf8mb4_la_0900_ai_ci, utf8mb4_la_0900_as_cs, utf8mb4_lt_0900_ai_ci, utf8mb4_lt_0900_as_cs, utf8mb4_lv_0900_ai_ci, utf8mb4_lv_0900_as_cs, utf8mb4_pl_0900_ai_ci, utf8mb4_pl_0900_as_cs, utf8mb4_ro_0900_ai_ci, utf8mb4_ro_0900_as_cs, utf8mb4_ru_0900_ai_ci, utf8mb4_ru_0900_as_cs,

utf8mb4_sk_0900_ai_ci, utf8mb4_sk_0900_as_cs, utf8mb4_sl_0900_ai_ci, utf8mb4_sl_0900_as_cs, utf8mb4_sv_0900_ai_ci, utf8mb4_sv_0900_as_cs, utf8mb4_tr_0900_ai_ci, utf8mb4_vi_0900_ai_ci, utf8mb4_vi_0900_as_cs, utf8mb4_zh_0900_as_cs being the additional ones) - MDEV-20912.

- To make CREATE TABLE ... SELECT work the same way in statement based and row based replication it's by default executed as CREATE OR REPLACE TABLE on the slave. One benefit of this is that if the slave dies in the middle of CREATE ... SELECT it will be able to continue.
  - One can use the slave-ddl-exec-mode variable to specify how `CREATE TABLE` and `DROP TABLE` is replicated.
- Users created with MySQL's SHA256 password algorithm cannot be used in MariaDB 10.6 - MDEV-9804.
- MariaDB 10.6 does not support CIDR notation for user accounts - MDEV-25515.
- MariaDB stores JSON as true text, not in binary format as MySQL. MariaDB's JSON functions are much faster than MySQL's so there is no need to store in binary format, which would add complexity when manipulating JSON objects.
- For the same reason, MariaDB's JSON data type is an alias for LONGTEXT. If you want to replicate JSON columns from MySQL to MariaDB, you should store JSON objects in MySQL in a TEXT or LONGTEXT column or use statement-based replication. If you are using JSON columns and want to upgrade to MariaDB, use the mysql_json plugin to automatically convert MySQL JSON to TEXT, or alternatively you need to either convert them to TEXT or use mysqldump to copy these tables to MariaDB.
- In MySQL, JSON is compared according to json values. In MariaDB JSON strings are normal strings and compared as strings.
- MariaDB 10.6 does not support MySQL's JSON operators (`->` and `->>`) - MDEV-13594
- MariaDB 10.6 supports the standard by producing null and a warning for JSON_SEARCH when given invalid data, while MySQL produces an error.
- Roles
  - MariaDB never allows authentication via roles, while MySQL permits this.
  - MySQL permits activating multiple roles at the same time. MariaDB can achieve the same result by creating an intermediate aggregate role.
  - In the INFORMATION_SCHEMA.ENABLED_ROLES table, MySQL reports just the direct list of enabled roles, while MariaDB reports the enabled role, plus the effective inherited roles.
  - MySQL extends the INFORMATION_SCHEMA.APPLICABLE_ROLES table .
  - MySQL includes the tables INFORMATION_SCHEMA.ROLE_TABLE_GRANTS, INFORMATION_SCHEMA.ROLE_ROUTINE_GRANTS, INFORMATION_SCHEMA.ROLE_COLUMN_GRANTS, and INFORMATION_SCHEMA ADMINISTRABLE_ROLE_AUTHORIZATIONS.
- MySQL has the performance schema enabled by default. For performance reasons MariaDB 10.6 has it disabled by default. You can enable it by starting `mariadbd` with the option `--performance-schema` .
- In MariaDB 10.6, using FLUSH TABLES without any table list will only close tables not in use, and tables not locked by the FLUSH TABLES connection. If there are no locked tables, FLUSH TABLES will be instant and will not cause any waits, as it no longer waits for tables in use. When a table list is provided, the server will wait for the end of any transactions that are using the tables. In MySQL, FLUSH TABLES only waits for the statements to complete.
- MariaDB binaries (`mariadbd` , myisamchk etc.) give a warning if one uses a unique prefix of an option (such as `--big-table` instead of `--big-tables`). MySQL binaries require the full option name.
- MariaDB 10.6 implements InnoDB encryption in a different way to MySQL 8.0.
- MySQL's implementation of aborting statements that exceed a certain time to execute can only kill SELECTs, while MariaDB's can kill any queries (excluding stored procedures).
- MariaDB 10.6 does not support MySQL's `SELECT /*+ MAX_EXECUTION_TIME(n) */ ...` - see Aborting Statements that Exceed a Certain Time to Execute.
- MySQL 8.0 does not support the Query Cache.
- MariaDB 10.6 does not support the MySQL Memcached plugin (which has been deprecated in MySQL 8.0). However, data stored using memcached can be retrieved because the data is stored as InnoDB tables. MariaDB is able to start successfully with an error message of not being able to find libmemcached.so library.
- In MySQL, `X'HHHH'` , the standard SQL syntax for binary string literals, erroneously works in the same way as `0xHHHH` , which could work as a number or string depending on the context. In MariaDB, this has been fixed to behave as a string in all contexts (and never as a number). See CAST and Hexadecimal Literals for more details and examples.
- In MariaDB 10.6, SHOW CREATE TABLE does not quote the DEFAULT value of an integer. MariaDB 10.2 and earlier, and MySQL, do. Since MariaDB can support defaults for BLOB and TEXT fields, while MySQL does not, SHOW CREATE TABLE will also append `DEFAULT NULL` where no default is explicitly provided to nullable BLOB or TEXT fields in MariaDB.
- Since MariaDB supports INTERSECT and EXCEPT, these are both reserved words and can't be used as an identifier without being quoted.
- As a result of implementing Table Value Constructors, the VALUES function has been renamed to VALUE().
- MariaDB's NOWAIT supports SELECT statements, LOCK TABLES and various DDL statements, while MySQL's NOWAIT only supports SELECT.
- MariaDB's NOWAIT cannot be added on views and stored procedures while MySQL's can - MDEV-25247
- MariaDB returns an `ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction` when unable to lock within the time, while MySQL returns `ERROR 3572 (HY000): Statement aborted because lock(s) could not be acquired immediately and NOWAIT is set`

- MariaDB does not support RENAME table while it is write-locked - MDEV-30814
- MariaDB 10.6 does not support Lateral Derived Tables - MDEV-19078.
- MariaDB does not support the optional *init_vector* argument for AES_ENCRYPT and AES_DECRYPT or the block_encryption_mode variable - MDEV-9069
- MariaDB does not support the `--initialize` option. Use mysql_install_db instead. - MDEV-19010
- MariaDB 10.6 does not support the ngram and MeCab full-text parser plugins - MDEV-10267, MDEV-10268.
- MariaDB 10.6 does not support the MySQL X plugin.
- MariaDB 10.6 before MariaDB 10.6.15 does not support MySQL 8's “native” InnoDB partitioning handler - MDEV-29253
- MariaDB 10.6 does not support CREATE TABLESPACE for InnoDB.
- The MySQL 8.0 and MariaDB 10.6 INFORMATION_SCHEMA.COLUMNS table contain slightly different fields.
- MariaDB 10.6 client executables allow the connection protocol to be forced by specifying only connection properties on the command-line. See mariadb Command-line client
- The MySQL binary log includes the thread_id, while MariaDB's binary log does not - MDEV-7850
- The MariaDB syntax supporting Spatial Reference System IDs for spatial data type columns with REF_SYSTEM_ID is not supported by MySQL. MySQL 8 introduced `CREATE SPATIAL REFERENCE SYSTEM`, which is not supported by MariaDB - MDEV-29953
- MariaDB 10.6 does not support the RESTART statement - MDEV-30813
- MariaDB 10.6 does not support the SELECT FOR UPDATE and FOR SHARE locks - MDEV-17514

2.1.14.1.9 Incompatibilities and Feature Differences Between MariaDB 10.5 and MySQL 8.0

Contents

MariaDB maintains high levels of compatibility with MySQL, and most applications that use MySQL will work seamlessly with MariaDB. However, take note of the following incompatibilities and feature differences between MariaDB 10.5 and MySQL 8.0. It is based on the stable versions MySQL 8.0.22 and MariaDB 10.5.7. Note that MySQL 8 is an 'evergreen' release, so features may be added or removed in later releases.

Storage Engines

In addition to the standard InnoDB, MyISAM, BLACKHOLE, CSV, MEMORY, ARCHIVE, and MERGE storage engines, the following are also available with MariaDB 10.5:

- ColumnStore utilizes a massively parallel distributed data architecture and is designed for big data scaling to process petabytes of data.
- MyRocks, a storage engine with great compression
- S3 storage engine allows one to archive MariaDB tables in Amazon S3, or any third-party public or private cloud that implements S3 API.
- Aria, MyISAM replacement with better caching.
- CONNECT
- SEQUENCE
- Spider
- SphinxSE
- FederatedX (drop-in replacement for Federated)
- OQGRAPH

Extensions and New Features

The most notable features available in MariaDB, but not in MySQL, are:

- Galera is a standard part of MariaDB Server.
- Temporal data tables in the form of:
  - System-versioned tables (allow you to query and operate on historic data).
  - Application-time periods (allow you to query and operate on a temporal range of data), including the WITHOUT OVERLAPS clause added in 10.5.
  - Bitemporal tables (which combine both system-versioning and application-time periods).
- DML-only flashback, allowing instances, databases or tables to be rolled back to an old snapshot.

- Oracle compatibility mode
- Sequences
- Invisible Columns
- Table Value Constructors
- Dynamic Columns support
- Semi-sync plugin merged into the server
- INTERSECT/INTERSECT ALL and EXCEPT/EXCEPT ALL
- OR REPLACE syntax for CREATE statements, such as CREATE OR REPLACE TABLE, CREATE OR REPLACE DATABASE, etc
- DELETE ... RETURNING, INSERT ... RETURNING, REPLACE ... RETURNING
- WAIT syntax for setting the lock wait timeout.
- INET6 data type for storing IPv6 addresses.
- SUPER privileges made more granular.
- PROXY protocol support
- Number of supported decimals in DECIMAL has increased from `30` to `38`
- Added catchall for list partitions
- Oracle-style EXECUTE IMMEDIATE statement
- Lots of new JSON functions
- Microsecond Precision in Processlist
- Table Elimination
- Virtual Columns
- Extended User Statistics
- KILL all queries for a user
- Storage-engine-specific CREATE TABLE
- MariaDB supports more collations than MySQL, including `NO PAD` collations.
- FLUSH SSL command to reload SSL certificates without server restart.
- `IF NOT EXISTS` clause added to INSTALL PLUGIN and `IF EXISTS` clause added to UNINSTALL PLUGIN and UNINSTALL SONAME
- Enhancements to INFORMATION SCHEMA.PLUGINS table
- Group commit for the binary log. This makes replication notably faster!
- The binary log in MariaDB can be compressed.
- BACKUP STAGE allows one to implement very efficient backups with minimal locking.
- Progress reporting for ALTER TABLE and LOAD DATA INFILE
- SHOW EXPLAIN gives the EXPLAIN plan for a query running in another thread. MySQL introduced the EXPLAIN FOR CONNECTION syntax to do the same thing.
- PCRE Regular Expressions (including REGEXP_REPLACE())
- HandlerSocket and faster HANDLER calls
- MySQL 8 does not support PROCEDURE ANALYSE
- MySQL 8 does not support the use of `\N` as an alias for NULL

Incompatibilities

When moving from MySQL 8.0 to MariaDB 10.5, please take note of the following incompatibilities:

- For a list of function differences, see Function Differences Between MariaDB 10.5 and MySQL 8.0
- For a list of system variable differences, see System Variable Differences Between MariaDB 10.5 and MySQL 8.0
- MariaDB does not support MySQL's SET PERSIST - MDEV-16228
- MariaDB's GTID is not compatible with MySQL's. Note that MariaDB and MySQL also have different GTID system variables, so these need to be adjusted when migrating.
- The unix_socket authentication plugin is now default on Unix-like systems, which is a major change to authentication in MariaDB. See Authentication from MariaDB 10.4 for an overview of the changes.
- All mysql* binaries are now named mariadb* (the previous mysql named is retained as a symlink for compatibility purposes)
- Not all character sets and collations are supported across both MySQL and MariaDB. As of 10.5.4, MariaDB supports 40 character sets and 322 collations (armscii8_general_nopad_ci, armscii8_nopad_bin, ascbig5_chinese_nopad_ci, big5_nopad_bin, iicp1250_general_nopad_ci, cp1250_nopad_bin, cp1250_general_nopad_ci, cp1250_nopad_bin, cp1251_general_nopad_ci, cp1251_nopad_bin, cp1256_general_nopad_ci, cp1256_nopad_bin, cp1257_general_nopad_ci, cp1257_nopad_bin, cp850_general_nopad_ci, cp850_nopad_bin, cp852_general_nopad_ci, cp852_nopad_bin, cp866_general_nopad_ci, cp866_nopad_bin, cp932_japanese_nopad_ci, cp932_nopad_bin, dec8_nopad_bin, dec8_swedish_nopad_ci, eucjpms_japanese_nopad_ci, eucjpms_nopad_bin, eucjpms_japanese_nopad_ci, eucjpms_nopad_bin, euckr_korean_nopad_ci, euckr_nopad_bin, gb2312_chinese_nopad_ci, gb2312_nopad_bin, gbk_chinese_nopad_ci, gbk_nopad_bin, geostd8_general_nopad_ci, geostd8_nopad_bin, greek_general_nopad_ci, greek_nopad_bin, hebrew_general_nopad_ci, hebrew_nopad_bin, hp8_english_nopad_ci, hp8_nopad_bin, keybcs2_general_nopad_ci, keybcs2_nopad_bin, koi8r_general_nopad_ci, koi8r_nopad_bin, koi8u_general_nopad_ci, koi8u_nopad_bin, latin1_nopad_bin, latin1_swedish_nopad_ci, latin2_general_nopad_ci, latin2_nopad_bin, latin5_nopad_bin, latin5_turkish_ci, latin5_turkish_nopad_ci, latin7_general_nopad_ci, latin7_nopad_bin, macce_general_nopad_ci,

macce_nopad_bin, macroman_general_nopad_ci, macroman_nopad_bin, sjis_japanese_nopad_ci, sjis_nopad_bin, swe7_nopad_bin, tis620_thai_nopad_ci, tis620_nopad_bin, ucs2_croatian_mysql561_ci, ucs2_general_mysql500_ci, ucs2_general_nopad_ci, ucs2_myanmar_ci, ucs2_nopad_bin, ucs2_swedish_ci, ucs2_thai_520_w2, ucs2_unicode_ci, ucs2_unicode_nopad_ci, ujis_japanese_nopad_ci, ujis_nopad_bin, utf16le_general_nopad_ci, utf16le_nopad_bin, utf16_croatian_mysql561_ci, utf16_general_nopad_ci, utf16_myanmar_ci, utf16_nopad_bin, utf16_thai_520_w2, utf16_unicode_520_nopad_ci, utf16_unicode_nopad_ci, utf32_croatian_mysql561_ci, utf32_general_nopad_ci, utf32_myanmar_ci, utf32_nopad_bin, utf32_thai_520_w2, utf32_unicode_520_nopad_ci, utf32_unicode_nopad_ci, utf8mb4_general_nopad_ci, utf8mb4_myanmar_ci, utf8mb4_nopad_bin, utf8mb4_thai_520_w2, utf8mb4_unicode_520_nopad_ci, utf8mb4_unicode_nopad_ci, utf8_croatian_mysql561_ci, utf8_general_nopad_ci, utf8_myanmar_ci, utf8_nopad_bin, utf8_thai_520_w2, utf8_unicode_520_nopad_ci, utf8_unicode_ci and utf8_unicode_nopad_ci being the additional ones).

As of 8.0.21, MySQL supports 41 character sets (`gb18030` being the additional one) and 272 collations (gb18030_bin, gb18030_chinese_ci, gb18030_unicode_520_ci, utf8mb4_0900_ai_ci, utf8mb4_0900_as_ci, utf8mb4_0900_as_cs, utf8mb4_0900_bin, utf8mb4_cs_0900_ai_ci, utf8mb4_cs_0900_as_cs, utf8mb4_da_0900_ai_ci, utf8mb4_da_0900_as_cs, utf8mb4_de_pb_0900_ai_ci, utf8mb4_de_pb_0900_as_cs, utf8mb4_eo_0900_ai_ci, utf8mb4_eo_0900_as_cs, utf8mb4_es_0900_ai_ci, utf8mb4_es_0900_as_cs, utf8mb4_es_trad_0900_ai_ci, utf8mb4_es_trad_0900_as_cs, utf8mb4_et_0900_ai_ci, utf8mb4_et_0900_as_cs, utf8mb4_hr_0900_ai_ci, utf8mb4_hr_0900_as_cs, utf8mb4_hu_0900_ai_ci, utf8mb4_hu_0900_as_cs, utf8mb4_is_0900_ai_ci, utf8mb4_is_0900_as_cs, utf8mb4_ja_0900_as_cs, utf8mb4_ja_0900_as_cs_ks, utf8mb4_la_0900_ai_ci, utf8mb4_la_0900_as_cs, utf8mb4_lt_0900_ai_ci, utf8mb4_lt_0900_as_cs, utf8mb4_lv_0900_ai_ci, utf8mb4_lv_0900_as_cs, utf8mb4_pl_0900_ai_ci, utf8mb4_pl_0900_as_cs, utf8mb4_ro_0900_ai_ci, utf8mb4_ro_0900_as_cs, utf8mb4_ru_0900_ai_ci, utf8mb4_ru_0900_as_cs, utf8mb4_sk_0900_ai_ci, utf8mb4_sk_0900_as_cs, utf8mb4_sl_0900_ai_ci, utf8mb4_sl_0900_as_cs, utf8mb4_sv_0900_ai_ci, utf8mb4_sv_0900_as_cs, utf8mb4_tr_0900_ai_ci, utf8mb4_vi_0900_ai_ci, utf8mb4_vi_0900_as_cs, utf8mb4_zh_0900_as_cs being the additional ones).

- To make CREATE TABLE ... SELECT work the same way in statement based and row based replication it's by default executed as CREATE OR REPLACE TABLE on the slave. One benefit of this is that if the slave dies in the middle of CREATE ... SELECT it will be able to continue.
  - One can use the slave-ddl-exec-mode variable to specify how `CREATE TABLE` and `DROP TABLE` is replicated.
- Users created with MySQL's SHA256 password algorithm cannot be used in MariaDB 10.5 - MDEV-9804.
- MariaDB stores JSON as true text, not in binary format as MySQL. MariaDB's JSON functions are much faster than MySQL's so there is no need to store in binary format, which would add complexity when manipulating JSON objects.
- For the same reason, MariaDB's JSON data type is an alias for LONGTEXT. If you want to replicate JSON columns from MySQL to MariaDB, you should store JSON objects in MySQL in a TEXT or LONGTEXT column or use statement-based replication. If you are using JSON columns and want to upgrade to MariaDB, use the mysql_json plugin to automatically convert MySQL JSON to TEXT, or alternatively you need to either convert them to TEXT or use mysqldump to copy these tables to MariaDB.
- In MySQL, JSON is compared according to json values. In MariaDB JSON strings are normal strings and compared as strings.
- MariaDB 10.5 does not support MySQL's JSON operators (`->` and `->>`) - MDEV-13594
- MariaDB 10.5 supports the standard by producing null and a warning for JSON_SEARCH when given invalid data, while MySQL produces an error.
- Roles
  - MariaDB never allows authentication via roles, while MySQL permits this.
  - MySQL permits activating multiple roles at the same time. MariaDB can achieve the same result by creating an intermediate aggregate role.
  - In the INFORMATION_SCHEMA.ENABLED_ROLES table, MySQL reports just the direct list of enabled roles, while MariaDB reports the enabled role, plus the effective inherited roles.
  - MySQL extends the INFORMATION_SCHEMA.APPLICABLE_ROLES table .
  - MySQL includes the tables INFORMATION_SCHEMA.ROLE_TABLE_GRANTS, INFORMATION_SCHEMA.ROLE_ROUTINE_GRANTS, INFORMATION_SCHEMA.ROLE_COLUMN_GRANTS, and INFORMATION_SCHEMA ADMINISTRABLE_ROLE_AUTHORIZATIONS.
- MySQL has the performance schema enabled by default. For performance reasons MariaDB 10.5 has it disabled by default. You can enable it by starting `mariadbd` with the option `--performance-schema` .
- In MariaDB 10.5, using FLUSH TABLES without any table list will only close tables not in use, and tables not locked by the FLUSH TABLES connection. If there are no locked tables, FLUSH TABLES will be instant and will not cause any waits, as it no longer waits for tables in use. When a table list is provided, the server will wait for the end of any transactions that are using the tables. In MySQL, FLUSH TABLES only waits for the statements to complete.
- MariaDB binaries (`mariadbd` , myisamchk etc.) give a warning if one uses a unique prefix of an option (such as `--big-table` instead of `--big-tables`). MySQL binaries require the full option name.
- MariaDB 10.5 implements InnoDB encryption in a different way to MySQL 8.0.
- MySQL's implementation of aborting statements that exceed a certain time to execute can only kill SELECTs, while MariaDB's can kill any queries (excluding stored procedures).
- MariaDB 10.5 does not support MySQL's `SELECT /*+ MAX_EXECUTION_TIME(n) */ ...` - see Aborting Statements that Exceed a Certain Time to Execute.

- MySQL 8.0 does not support the Query Cache.
- MariaDB 10.5 does not support the MySQL Memcached plugin (which has been deprecated in MySQL 8.0). However, data stored using memcached can be retrieved because the data is stored as InnoDB tables. MariaDB is able to start successfully with an error message of not being able to find libmemcached.so library.
- In MySQL, `X'HHHH'`, the standard SQL syntax for binary string literals, erroneously works in the same way as `0xHHHH`, which could work as a number or string depending on the context. In MariaDB, this has been fixed to behave as a string in all contexts (and never as a number). See CAST and Hexadecimal Literals for more details and examples.
- In MariaDB 10.5, SHOW CREATE TABLE does not quote the DEFAULT value of an integer. MariaDB 10.2 and earlier, and MySQL, do. Since MariaDB can support defaults for BLOB and TEXT fields, while MySQL does not, SHOW CREATE TABLE will also append `DEFAULT NULL` where no default is explicitly provided to nullable BLOB or TEXT fields in MariaDB.
- Since MariaDB supports INTERSECT and EXCEPT, these are both reserved words and can't be used as an identifier without being quoted.
- As a result of implementing Table Value Constructors, the VALUES function has been renamed to VALUE().
- MariaDB's NOWAIT supports SELECT statements, LOCK TABLES and various DDL statements, while MySQL's NOWAIT only supports SELECT.
- MariaDB's NOWAIT cannot be added on views and stored procedures while MySQL's can - MDEV-25247
- MariaDB returns an `ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction` when unable to lock within the time, while MySQL returns `ERROR 3572 (HY000): Statement aborted because lock(s) could not be acquired immediately and NOWAIT is set`
- MariaDB does not support RENAME table while it is write-locked - MDEV-30814
- MariaDB 10.5 does not support Lateral Derived Tables - MDEV-19078.
- MariaDB does not support the optional *init_vector* argument for AES_ENCRYPT and AES_DECRYPT or the block_encryption_mode variable - MDEV-9069
- MariaDB does not support the `--initialize` option. Use mysql_install_db instead. - MDEV-19010
- MariaDB 10.5 does not support the ngram and MeCab full-text parser plugins - MDEV-10267, MDEV-10268.
- MariaDB 10.5 does not support the MySQL X plugin.
- MariaDB 10.5 does not support MySQL 8's “native” InnoDB partitioning handler - MDEV-29253
- MariaDB 10.5 does not support CREATE TABLESPACE for InnoDB.
- The MySQL 8.0 and MariaDB 10.5 INFORMATION_SCHEMA.COLUMNS table contain slightly different fields.
- The MySQL binary log includes the thread_id, while MariaDB's binary log does not - MDEV-7850
- The MariaDB 10.1 syntax supporting Spatial Reference System IDs for spatial data type columns with REF_SYSTEM_ID is not supported by MySQL. MySQL 8 introduced `CREATE SPATIAL REFERENCE SYSTEM`, which is not supported by MariaDB - MDEV-29953
- MariaDB 10.5 does not support the RESTART statement - MDEV-30813
- MariaDB 10.5 does not support the SELECT FOR UPDATE and FOR SHARE locks - MDEV-17514

2.1.14.1.10 Incompatibilities and Feature Differences Between MariaDB 10.4 and MySQL 8.0

Contents

MariaDB maintains high levels of compatibility with MySQL, and most applications that use MySQL will work seamlessly with MariaDB. However, take note of the following incompatibilities and feature differences between MariaDB 10.4 and MySQL 8.0. It is based on the stable versions MySQL 8.0.22 and MariaDB 10.4.15. Note that MySQL 8 is an 'evergreen' release, so features may be added or removed in later releases.

Storage Engines

In addition to the standard InnoDB, MyISAM, BLACKHOLE, CSV, MEMORY, ARCHIVE, and MERGE storage engines, the following are also available with MariaDB 10.4:

- MyRocks, a storage engine with great compression
- Aria, MyISAM replacement with better caching.
- CONNECT
- SEQUENCE

- Spider
- SphinxSE
- TokuDB
- FederatedX (drop-in replacement for Federated)
- OQGRAPH

Extensions and New Features

The most notable features available in MariaDB, but not in MySQL, are:

- Galera is a standard part of MariaDB Server.
- Temporal data tables in the form of:
  - System-versioned tables (allow you to query and operate on historic data).
  - Application-time periods (allow you to query and operate on a temporal range of data).
  - Bitemporal tables (which combine both system-versioning and application-time periods).
- DML-only flashback, allowing instances, databases or tables to be rolled back to an old snapshot.
- Oracle compatibility mode
- Sequences
- Invisible Columns
- Table Value Constructors
- Semi-sync plugin merged into the server
- INTERSECT and EXCEPT
- OR REPLACE syntax for CREATE statements, such as CREATE OR REPLACE TABLE, CREATE OR REPLACE DATABASE, etc
- DELETE ... RETURNING
- WAIT syntax for setting the lock wait timeout.
- PROXY protocol support
- Number of supported decimals in DECIMAL has increased from `30` to `38`
- Added catchall for list partitions
- Oracle-style EXECUTE IMMEDIATE statement
- Lots of new JSON functions
- Microsecond Precision in Processlist
- Table Elimination
- Virtual Columns
- Extended User Statistics
- KILL all queries for a user
- Storage-engine-specific CREATE TABLE
- MariaDB supports more collations than MySQL, including `NO PAD` collations.
- FLUSH SSL command to reload SSL certificates without server restart.
- `IF NOT EXISTS` clause added to INSTALL PLUGIN and `IF EXISTS` clause added to UNINSTALL PLUGIN and UNINSTALL SONAME
- Enhancements to INFORMATION SCHEMA.PLUGINS table
- Group commit for the binary log. This makes replication notably faster!
- The binary log in MariaDB can be compressed.
- New server command, SHUTDOWN WAIT FOR ALL SLAVES, and a new mysqladmin shutdown --wait-for-all-slaves option, are added to instruct the server to wait for the last binlog event to be sent to all connected slaves before shutting down.
- BACKUP STAGE allows one to implement very efficient backups with minimal locking.
- Progress reporting for ALTER TABLE and LOAD DATA INFILE
- SHOW EXPLAIN gives the EXPLAIN plan for a query running in another thread. MySQL introduced the EXPLAIN FOR CONNECTION syntax to do the same thing.
- PCRE Regular Expressions (including REGEXP_REPLACE())
- HandlerSocket and faster HANDLER calls
- MySQL 8 does not support PROCEDURE ANALYSE
- MySQL 8 does not support the use of `\N` as an alias for NULL

Incompatibilities

When moving from MySQL 8.0 to MariaDB 10.4, please take note of the following incompatibilities:

- For a list of function differences, see Function Differences Between MariaDB 10.4 and MySQL 8.0
- For a list of system variable differences, see System Variable Differences Between MariaDB 10.4 and MySQL 8.0
- MariaDB does not support MySQL's SET PERSIST - MDEV-16228
- MariaDB's GTID is not compatible with MySQL's. Note that MariaDB and MySQL also have different GTID system variables, so these need to be adjusted when migrating.
- The unix_socket authentication plugin is now default on Unix-like systems, which is a major change to authentication

in MariaDB. See Authentication from MariaDB 10.4 for an overview of the changes.

- Not all character sets and collations are supported across both MySQL and MariaDB. As of 10.4.14, MariaDB supports 40 character sets and 322 collations (armscii8_general_nopad_ci, armscii8_nopad_bin, ascbig5_chinese_nopad_ci, big5_nopad_bin, iicp1250_general_nopad_ci, cp1250_nopad_bin, cp1250_general_nopad_ci, cp1250_nopad_bin, cp1251_general_nopad_ci, cp1251_nopad_bin, cp1256_general_nopad_ci, cp1256_nopad_bin, cp1257_general_nopad_ci, cp1257_nopad_bin, cp850_general_nopad_ci, cp850_nopad_bin, cp852_general_nopad_ci, cp852_nopad_bin, cp866_general_nopad_ci, cp866_nopad_bin, cp932_japanese_nopad_ci, cp932_nopad_bin, dec8_nopad_bin, dec8_swedish_nopad_ci, eucjpms_japanese_nopad_ci, eucjpms_nopad_bin, eucjpms_japanese_nopad_ci, eucjpms_nopad_bin, euckr_korean_nopad_ci, euckr_nopad_bin, gb2312_chinese_nopad_ci, gb2312_nopad_bin, gbk_chinese_nopad_ci, gbk_nopad_bin, geostd8_general_nopad_ci, geostd8_nopad_bin, greek_general_nopad_ci, greek_nopad_bin, hebrew_general_nopad_ci, hebrew_nopad_bin, hp8_english_nopad_ci, hp8_nopad_bin, keybcs2_general_nopad_ci, keybcs2_nopad_bin, koi8r_general_nopad_ci, koi8r_nopad_bin, koi8u_general_nopad_ci, koi8u_nopad_bin, latin1_nopad_bin, latin1_swedish_nopad_ci, latin2_general_nopad_ci, latin2_nopad_bin, latin5_nopad_bin, latin5_turkish_ci, latin5_turkish_nopad_ci, latin7_general_nopad_ci, latin7_nopad_bin, macce_general_nopad_ci, macce_nopad_bin, macroman_general_nopad_ci, macroman_nopad_bin, sjis_japanese_nopad_ci, sjis_nopad_bin, swe7_nopad_bin, tis620_thai_nopad_ci, tis620_nopad_bin, ucs2_croatian_mysql561_ci, ucs2_general_mysql500_ci, ucs2_general_nopad_ci, ucs2_myanmar_ci, ucs2_nopad_bin, ucs2_swedish_ci, ucs2_thai_520_w2, ucs2_unicode_ci, ucs2_unicode_nopad_ci, ujis_japanese_nopad_ci, ujis_nopad_bin, utf16le_general_nopad_ci, utf16le_nopad_bin, utf16_croatian_mysql561_ci, utf16_general_nopad_ci, utf16_myanmar_ci, utf16_nopad_bin, utf16_thai_520_w2, utf16_unicode_520_nopad_ci, utf16_unicode_nopad_ci, utf32_croatian_mysql561_ci, utf32_general_nopad_ci, utf32_myanmar_ci, utf32_nopad_bin, utf32_thai_520_w2, utf32_unicode_520_nopad_ci, utf32_unicode_nopad_ci, utf8mb4_general_nopad_ci, utf8mb4_myanmar_ci, utf8mb4_nopad_bin, utf8mb4_thai_520_w2, utf8mb4_unicode_520_nopad_ci, utf8mb4_unicode_nopad_ci, utf8_croatian_mysql561_ci, utf8_general_nopad_ci, utf8_myanmar_ci, utf8_nopad_bin, utf8_thai_520_w2, utf8_unicode_520_nopad_ci, utf8_unicode_ci and utf8_unicode_nopad_ci being the additional ones).

  As of 8.0.21, MySQL supports 41 character sets (gb18030 being the additional one) and 272 collations (gb18030_bin, gb18030_chinese_ci, gb18030_unicode_520_ci, utf8mb4_0900_ai_ci, utf8mb4_0900_as_ci, utf8mb4_0900_as_cs, utf8mb4_0900_bin, utf8mb4_cs_0900_ai_ci, utf8mb4_cs_0900_as_cs, utf8mb4_da_0900_ai_ci, utf8mb4_da_0900_as_cs, utf8mb4_de_pb_0900_ai_ci, utf8mb4_de_pb_0900_as_cs, utf8mb4_eo_0900_ai_ci, utf8mb4_eo_0900_as_cs, utf8mb4_es_0900_ai_ci, utf8mb4_es_0900_as_cs, utf8mb4_es_trad_0900_ai_ci, utf8mb4_es_trad_0900_as_cs, utf8mb4_et_0900_ai_ci, utf8mb4_et_0900_as_cs, utf8mb4_hr_0900_ai_ci, utf8mb4_hr_0900_as_cs, utf8mb4_hu_0900_ai_ci, utf8mb4_hu_0900_as_cs, utf8mb4_is_0900_ai_ci, utf8mb4_is_0900_as_cs, utf8mb4_ja_0900_as_cs, utf8mb4_ja_0900_as_cs_ks, utf8mb4_la_0900_ai_ci, utf8mb4_la_0900_as_cs, utf8mb4_lt_0900_ai_ci, utf8mb4_lt_0900_as_cs, utf8mb4_lv_0900_ai_ci, utf8mb4_lv_0900_as_cs, utf8mb4_pl_0900_ai_ci, utf8mb4_pl_0900_as_cs, utf8mb4_ro_0900_ai_ci, utf8mb4_ro_0900_as_cs, utf8mb4_ru_0900_ai_ci, utf8mb4_ru_0900_as_cs, utf8mb4_sk_0900_ai_ci, utf8mb4_sk_0900_as_cs, utf8mb4_sl_0900_ai_ci, utf8mb4_sl_0900_as_cs, utf8mb4_sv_0900_ai_ci, utf8mb4_sv_0900_as_cs, utf8mb4_tr_0900_ai_ci, utf8mb4_vi_0900_ai_ci, utf8mb4_vi_0900_as_cs, utf8mb4_zh_0900_as_cs being the additional ones).
- To make CREATE TABLE ... SELECT work the same way in statement based and row based replication it's by default executed as CREATE OR REPLACE TABLE on the slave. One benefit of this is that if the slave dies in the middle of CREATE ... SELECT it will be able to continue.
  - One can use the slave-ddl-exec-mode variable to specify how `CREATE TABLE` and `DROP TABLE` is replicated.
- Users created with MySQL's SHA256 password algorithm cannot be used in MariaDB 10.4 - MDEV-9804.
- MariaDB stores JSON as true text, not in binary format as MySQL. MariaDB's JSON functions are much faster than MySQL's so there is no need to store in binary format, which would add complexity when manipulating JSON objects.
- For the same reason, MariaDB's JSON data type is an alias for LONGTEXT. If you want to replicate JSON columns from MySQL to MariaDB, you should store JSON objects in MySQL in a TEXT or LONGTEXT column or use statement based replication. If you are using JSON columns and want to upgrade to MariaDB, you need to either convert them to TEXT or use mysqldump to copy these tables to MariaDB.
- In MySQL, JSON is compared according to json values. In MariaDB JSON strings are normal strings and compared as strings.
- MariaDB 10.4 does not support MySQL's JSON operators (`->` and `->>`) - MDEV-13594
- MariaDB 10.4 supports the standard by producing null and a warning for JSON_SEARCH when given invalid data, while MySQL produces an error.
- Roles
  - MariaDB never allows authentication via roles, while MySQL permits this.
  - MySQL permits activating multiple roles at the same time. MariaDB can achieve the same result by creating an intermediate aggregate role.
  - In the INFORMATION_SCHEMA.ENABLED_ROLES table, MySQL reports just the direct list of enabled roles, while MariaDB reports the enabled role, plus the effective inherited roles.
  - MySQL extends the INFORMATION_SCHEMA.APPLICABLE_ROLES table .
  - MySQL includes the tables INFORMATION_SCHEMA.ROLE_TABLE_GRANTS, INFORMATION_SCHEMA.ROLE_ROUTINE_GRANTS,

INFORMATION_SCHEMA.ROLE_COLUMN_GRANTS, and INFORMATION_SCHEMA ADMINISTRABLE_ROLE_AUTHORIZATIONS.

- MySQL has the performance schema enabled by default. For performance reasons MariaDB 10.4 has it disabled by default. You can enable it by starting `mysqld` with the option `--performance-schema`.
- MySQL features a new implementation of the performance_schema and a sys schema wrapper. These are only supported in MariaDB 10.5.
- In MariaDB 10.4, using FLUSH TABLES without any table list will only close tables not in use, and tables not locked by the FLUSH TABLES connection. If there are no locked tables, FLUSH TABLES will be instant and will not cause any waits, as it no longer waits for tables in use. When a table list is provided, the server will wait for the end of any transactions that are using the tables. In MySQL, FLUSH TABLES only waits for the statements to complete.
- MariaDB binaries (`mysqld`, myisamchk etc.) give a warning if one uses a unique prefix of an option (such as `--big-table` instead of `--big-tables`). MySQL binaries require the full option name.
- MariaDB 10.4 implements InnoDB encryption in a different way to MySQL 8.0.
- MySQL's implementation of aborting statements that exceed a certain time to execute can only kill SELECTs, while MariaDB's can kill any queries (excluding stored procedures).
- MariaDB 10.4 does not support MySQL's `SELECT /*+ MAX_EXECUTION_TIME(n) */ ...` - see Aborting Statements that Exceed a Certain Time to Execute.
- MySQL 8.0 does not support the Query Cache.
- MariaDB 10.4 does not support the MySQL Memcached plugin (which has been deprecated in MySQL 8.0). However, data stored using memcached can be retrieved because the data is stored as InnoDB tables. MariaDB is able to start successfully with an error message of not being able to find libmemcached.so library.
- MariaDB 10.4 does not support MySQL 8.0's ALTER TABLE...RENAME INDEX statements (supported in MariaDB 10.5).
- In MySQL, `X'HHHH'`, the standard SQL syntax for binary string literals, erroneously works in the same way as `0xHHHH`, which could work as a number or string depending on the context. In MariaDB, this has been fixed to behave as a string in all contexts (and never as a number). See CAST and Hexadecimal Literals for more details and examples.
- In MariaDB 10.4, SHOW CREATE TABLE does not quote the DEFAULT value of an integer. MariaDB 10.2 and earlier, and MySQL, do. Since MariaDB can support defaults for BLOB and TEXT fields, while MySQL does not, SHOW CREATE TABLE will also append `DEFAULT NULL` where no default is explicitly provided to nullable BLOB or TEXT fields in MariaDB.
- Since MariaDB supports INTERSECT and EXCEPT, these are both reserved words and can't be used as an identifier without being quoted.
- As a result of implementing Table Value Constructors, the VALUES function has been renamed to VALUE().
- MariaDB's NOWAIT supports SELECT statements, LOCK TABLES and various DDL statements, while MySQL's NOWAIT only supports SELECT.
- MariaDB's NOWAIT cannot be added on views and stored procedures while MySQL's can - MDEV-25247
- MariaDB returns an `ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction` when unable to lock within the time, while MySQL returns `ERROR 3572 (HY000): Statement aborted because lock(s) could not be acquired immediately and NOWAIT is set`
- MariaDB does not support RENAME table while it is write-locked - MDEV-30814
- MariaDB 10.4 does not support Lateral Derived Tables - MDEV-19078.
- MariaDB does not support the optional *init_vector* argument for AES_ENCRYPT and AES_DECRYPT or the block_encryption_mode variable - MDEV-9069
- MySQL supports `SKIP LOCKED`, while MariaDB doesn't.
- MariaDB does not support the `--initialize` option. Use mysql_install_db instead. - MDEV-19010
- MariaDB 10.4 does not support the ngram and MeCab full-text parser plugins - MDEV-10267, MDEV-10268.
- MariaDB 10.4 does not support the MySQL X plugin.
- MariaDB 10.4 does not support MySQL 8's “native” InnoDB partitioning handler - MDEV-29253
- MariaDB 10.4 does not support CREATE TABLESPACE for InnoDB.
- The MySQL 8.0 and MariaDB 10.4 INFORMATION_SCHEMA.COLUMNS table contain slightly different fields.
- The MySQL binary log includes the thread_id, while MariaDB's binary log does not - MDEV-7850
- The MariaDB 10.1 syntax supporting Spatial Reference System IDs for spatial data type columns with REF_SYSTEM_ID is not supported by MySQL. MySQL 8 introduced `CREATE SPATIAL REFERENCE SYSTEM`, which is not supported by MariaDB - MDEV-29953
- MariaDB 10.4 does not support the RESTART statement - MDEV-30813
- MariaDB 10.4 does not support the SELECT FOR UPDATE and FOR SHARE locks - MDEV-17514

2.1.14.1.12 System Variable Differences between MariaDB and MySQL

The following articles list the differences between the system variables available in MariaDB and in MySQL for each of the major releases.

System Variable Differences Between MariaDB 11.1 and MySQL 8.0

Comparison of MariaDB 11.1 and MySQL 8.0 system variables.

System Variable Differences Between MariaDB 11.0 and MySQL 8.0
Comparison of MariaDB 11.0 and MySQL 8.0 system variables.

System Variable Differences Between MariaDB 10.11 and MySQL 8.0
Comparison of MariaDB 10.11 and MySQL 8.0 system variables.

System Variable Differences Between MariaDB 10.10 and MySQL 8.0
Comparison of MariaDB 10.10 and MySQL 8.0 system variables.

System Variable Differences Between MariaDB 10.6 and MySQL 8.0
Comparison of MariaDB 10.6 and MySQL 8.0 system variables.

System Variable Differences Between MariaDB 10.5 and MySQL 8.0
Comparison of MariaDB 10.5 and MySQL 8.0 system variables.

System Variable Differences Between MariaDB 10.4 and MySQL 8.0
Comparison of MariaDB 10.4 and MySQL 8.0 system variables.

System Variable Differences Between MariaDB and MySQL - Unmaintained Series
Comparison of variable differences between major series of MariaDB and MySQL.

2.1.14.1.12.1 System Variable Differences Between MariaDB 11.1 and MySQL 8.0

Contents

The following is a comparison of variables that either appear only in MariaDB 11.1 or MySQL 8.0, or have different default settings in MariaDB 11.1, and MySQL 8.0. The releases MariaDB 11.1.2 and MySQL 8.0.34, with only default plugins enabled, were used for the comparison. Note that MySQL 8 is an 'evergreen' release, so features may be added or removed in later releases.

For a more complete list of differences, see Incompatibilities and Feature Differences Between MariaDB 11.1 and MySQL 8.0 and Function Differences Between MariaDB 11.1 and MySQL 8.0

Comparison Table

Variable	MariaDB 11.1 Default	MySQL 8.0 Default	Notes
activate_all_roles_on_login	-	OFF	Determines whether to automatically activate roles on login.
admin*	-	*	MySQL admin connections.
allow_suspicious_udfs	0	-	Only available as an option in MySQL.
alter_algorithm	DEFAULT	-	MariaDB 10.3 introduced new ALTER TABLE ALGORITHM clauses to avoid slow copies in certain instances. This variable allows setting this if no `ALGORITHM` clause is specified.
analyze_sample_percentage	100.0000	-	Percentage of rows from the table ANALYZE TABLE will sample to collect table statistics.
aria_*	*	-	The Aria storage engine is only available in MariaDB.
authentication_policy	-	*,,	MySQL authentication policy.
auto_generate_certs	-	ON	Whether to automatically generate SSL key and certificate files.
avoid_temporal_upgrade	-	OFF	Determines whether ALTER TABLE implicitly upgrades temporal columns.
back_log	Autosized	Autosized	MariaDB and MySQL have different autosizing algorithms.
binlog_alter_two_phase	OFF	-	When set, split ALTER at binary logging into two statements: START ALTER and COMMIT/ROLLBACK ALTER.
binlog_annotate_row_events	ON	-	Introduced in MariaDB 5.3 for replicating between MariaDB 5.3 and MySQL/MariaDB 5.1.

binlog_commit_wait_count	0	-	For use in MariaDB's parallel replication.
binlog_commit_wait_usec	100000	-	For use in MariaDB's parallel replication.
binlog_encryption	-	OFF	MySQL name for encrypt_binlog.
binlog_error_action		ABORT_SERVER	MySQL-only variable for controlling what happens when the server cannot write to the binary log.
binlog_expire_logs_auto_purge	-	ON	Enables or disables automatic purging of binary log files.
binlog_expire_logs_seconds	0	2592000	Sets the binary log expiration period in seconds
binlog_file_cache_size	16184	-	For setting the size of the file cache for the binary log.
binlog_format	MIXED	ROW	MariaDB and MySQL have differing binary log formats.
binlog_group_commit_sync_delay		0	MySQL-only variable for controlling the wait time before synchronizing the binary log file to disk.
binlog_group_commit_sync_no_delay_count		0	MySQL-only variable for setting the maximum number of transactions to wait for before aborting the current `binlog_group_commit_sync_delay` delay.
binlog_gtid_simple_recovery	-	ON	MySQL-only GTID variable. MariaDB's GTID implementation is different.
binlog_max_flush_queue_time	-	0	Specifies a timeout for reading transactions from the flush queue before continuing with group commit and syncing log to disk.
binlog_optimize_thread_scheduling	ON	-	For optimized kernel thread scheduling.
binlog_order_commits	-	ON	Determines whether transactions may be committed in parallel.
binlog_rotate_encryption_master_key_at_startup	-	OFF	Specifically for use with MySQL binary key encryption.
binlog_row_event_max_size	-	8192	Only available as a system variable in MariaDB 11.2.
binlog_row_metadata	NO_LOG	MINIMAL	Determines the amount of table metadata added to the binary log with row-based logging.
binlog_row_value_options	-	(empty)	Permits an alternative binlog format for JSON document updates.
binlog_rows_query_log_events	-	OFF	MySQL-only variable for logging extra information in row-based logging.
binlog_transaction_compression*	-	*	MySQL variables relating to binary log compression.
binlog_transaction_dependency_history_size	-	25000	Maximum number of row hashes kept for looking up transactions that last modified a given row.
binlog_transaction_dependency_tracking	-	COMMIT_ORDER	For determining how to best use the slave's multithreaded applier.
block_encryption_mode	-	aes-128-ecb	MySQL-only variable for controlling the block encryption mode for block-based algorithms.
caching_sha2_password*	-	*	For use with MySQL's SHA-256 authentication with caching.
character_set_*	latin1 or utf8	utf8mb4	MySQL 8.0 defaults to the utf8mb4 character set.
check_constraint_checks	ON	-	Permits disabling constraint checks, for example when loading a table that violates some constraints that you plan to fix later.
check_proxy_users		OFF	MySQL-only variable for controlling whether the server performs proxy user mapping for authentication plugins.
collation_*	latin1_swedish_ci or utf8_general_ci	utf8mb4_0900_ai_ci	MySQL 8.0 defaults to the utf8mb4 character set.
column_compression_threshold	100	-	MariaDB supports Storage-engine Independent Column Compression.
column_compression_zlib_level	6	-	MariaDB supports Storage-engine Independent Column Compression.
column_compression_zlib_strategy	DEFAULT_STRATEGY	-	MariaDB supports Storage-engine Independent Column Compression.
column_compression_zlib_wrap	OFF	-	MariaDB supports Storage-engine Independent Column Compression.

connection_memory_chunk_size	-	8192	Chunk size for updates to the Global_connection_memory counter.
connection_memory_limit	-	18446744073709551615	Maximum memory for a single user connection.
create_admin_listener_thread	-	OFF	MySQL-only variable for whether to use a dedicated listening thread for admin network interface connections.
cte_max_recursion_depth	-	1000	When MySQL 8.0 introduced common table expressions they used a different name. MariaDB's variable is called max_recursive_iterations.
date_format	%Y-%m-%d	-	Unused variable removed in MySQL 8.0
datetime_format	%Y-%m-%d	-	Unused variable removed in MySQL 8.0
deadlock_search_depth_long	15	-	The Aria storage engine is only available in MariaDB.
deadlock_search_depth_short	4	-	The Aria storage engine is only available in MariaDB.
deadlock_timeout_long	50000000	-	The Aria storage engine is only available in MariaDB.
deadlock_timeout_short	10000	-	The Aria storage engine is only available in MariaDB.
debug_no_thread_alarm	OFF	-	Disable system thread alarm calls, for debugging or testing.
default_authentication_plugin	-	caching_sha2_password	MySQL 8 introduced a new authentication plugin.
default_collation_for_utf8mb4	-	utf8mb4_0900_ai_ci	For internal use in MySQL 8 replication.
default_master_connection	empty	-	For use with MariaDB's multi-source replication.
default_password_lifetime	0	360	MariaDB defaults to password expiration off.
default_regex_flags	empty	-	For handling incompatibilities between MariaDB's PCRE and the old regex library.
default_tmp_storage_engine	empty	InnoDB	Default storage engine used for tables created with CREATE TEMPORARY TABLE.
disabled_storage_engines		empty	MySQL-only variable for disabling specific storage engines.
disconnect_on_expired_password	OFF	ON	MariaDB password expiration is off by default, and by default does not disconnect a client when a password has expired.
encrypt_binlog	OFF	-	MariaDB enables table and tablespace encryption.
encrypt_tmp_files	OFF	-	MariaDB enables table and tablespace encryption.
encrypt_tmp_disk_tables	OFF	-	MariaDB enables table and tablespace encryption.
end_markers_in_json	-	OFF	MySQL-only variable for adding end markers to JSON output.
enforce_gtid_consistency	-	OFF	MariaDB and MySQL have different GTID implementations.
enforce_storage_engine	none		Forces the use of a particular storage engine for new tables.
eq_range_index_dive_limit	0	200	Variable for tuning when the optimizer should switch from using index dives to index statistics for qualifying rows estimation.
event_scheduler	OFF	ON	MySQL enables the event scheduler by default.
expensive_subquery_limit	100	-	Used for determining expensive queries for optimization.
extra_max_connections	1	-	Introduced in the MariaDB 5.1 threadpool.
extra_port	0	-	Introduced in the MariaDB 5.1 threadpool.
group_concat_max_len	1048576	1024	MariaDB increases the maximum length for a GROUP_CONCAT() result from 1K to 1M.
gtid_binlog_pos	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_binlog_state	empty	-	MariaDB and MySQL have different GTID implementations.

gtid_cleanup_batch_size	64	-	MariaDB and MySQL have different GTID implementations.
gtid_current_pos	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_domain_id	0	-	MariaDB and MySQL have different GTID implementations.
gtid_executed	-	empty	MariaDB and MySQL have different GTID implementations.
gtid_executed_compression_period	-	1000	MariaDB and MySQL have different GTID implementations.
gtid_ignore_duplicates	OFF	-	MariaDB and MySQL have different GTID implementations.
gtid_mode	-	OFF	MariaDB and MySQL have different GTID implementations.
gtid_next	-	AUTOMATIC	MariaDB and MySQL have different GTID implementations.
gtid_owned	-	empty	MariaDB and MySQL have different GTID implementations.
gtid_pos_auto_engines	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_purged	-	empty	MariaDB and MySQL have different GTID implementations.
gtid_seq_no	0	-	MariaDB and MySQL have different GTID implementations.
gtid_slave_pos	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_strict_mode	OFF	-	MariaDB and MySQL have different GTID implementations.
have_crypt	YES	-	MySQL has removed the ENCRYPT function.
have_openssl			MariaDB's version indicates whether YaSSL or openssl was used. MySQL's is a synonym for `have_ssl`.
have_query_cache	YES	-	MySQL has removed the query cache.
have_statement_timeout	-		Whether MySQL's statement execution timeout feature is available.
have_symlink	YES	DISABLED	MySQL has removed symlink support.
histogram_generation_max_mem_size	-	20000000	Added when MySQL 8 introduced Histogram-based Statistics. MariaDB uses histogram_size
histogram_size	0	-	MariaDB introduced Histogram-based Statistics.
histogram_type	JSON_HB	-	MariaDB introduced Histogram-based Statistics.
idle_readonly_transaction_timeout	0	-	Time in seconds that the server waits for idle read-only transactions.
idle_transaction_timeout	0	-	Time in seconds that the server waits for idle transactions.
idle_write_transaction_timeout	0	-	Time in seconds that the server waits for idle write transactions.
ignore_builtin_innodb	OFF	-	Ignored and removed in MySQL 8.
in_predicate_conversion_threshold	1000	-	Controls the Conversion of Big IN Predicates Into Subqueries optimization.
in_transaction	0	-	Set to `1` if you are in a transaction, and `0` if not.
information_schema_stats_expiry	-	86400	Time until MySQL Information Schema cached statistics expire.
innodb_adaptive_flushing_lwm	10.000000	10	Adaptive flushing is enabled when this this low water mark percentage of the redo log capacity is reached. MariaDB's variable is a double, MySQL's an integer.
innodb_adaptive_hash_index	OFF	ON	Defaulting to OFF is a performance improvement especially for DROP TABLE, TRUNCATE TABLE, ALTER TABLE, or DROP INDEX operations
innodb_adaptive_max_sleep_delay	-	150000	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_api_*	-	*	Specific to MySQL's memcached, removed in MariaDB 10.2.

innodb_autoinc_lock_mode	1	2	MariaDB has an extra mode, `3`, for skipping the rollback of connected transactions. MySQL defaults to row-based replication, so can safely use `2`.
innodb_buffer_pool_instances	-	1	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6 since the original reasons for introducing no longer apply.
innodb_change*		*	The InnoDB Change Buffer was removed in MariaDB 11.0.
innodb_checksum_algorithm	full_crc32	crc32	`fullcrc32` permits encryption to be supported over a SPATIAL INDEX, which crc32 does not support.
innodb_checksums	ON	-	Deprecated option removed in MySQL.
innodb_commit_concurrency	-	0	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_compression_*	*	-	Introduced with MariaDB's InnoDB compression.
innodb_concurrency_tickets	-	5000	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_deadlock_report	Full	-	How to report deadlocks.
innodb_dedicated_server	-	OFF	MySQL option that automatically configures various settings if the server is a dedicated InnoDB database server.
innodb_default_encryption_key_id	1	-	Default encryption key id used for table encryption. See Data at Rest Encryption.
innodb_directories	-	(empty)	Used to search for tablespace files when moving or restoring a new location.
innodb_disallow_writes	OFF	-	Tell InnoDB to stop any writes to disk.
innodb_encrypt_*	1	-	See MariaDB's Data at Rest Encryption.
innodb_fatal_semaphore_wait_threshold	600	-	MariaDB's fatal semaphore timeout is configurable.
innodb_flush_method	O_DIRECT	fsync	MariaDB InnoDB flushing method by default on Unix systems bypasses the file system cache for improved performance in most cases.
innodb_flush_neighbors	1	0	MySQL 8 by default now assumes the use of an SSD device.
innodb_force_primary_key	OFF	-	If set to 1 in MariaDB (0 is default) CREATE TABLEs without a primary or unique key where all keyparts are NOT NULL will not be accepted, and will return an error.
innodb_idle_flush_pct	100	-	Up to what percentage of dirty pages in MariaDB should be flushed when InnoDB finds it has spare resources to do so.
innodb_immediate_scrub_data_uncompressed	OFF	-	MariaDB has support for data scrubbing.
innodb_instant_alter_column_allowed	add_drop_reorder	-	See Instant ADD COLUMN for InnoDB.
innodb_locks_unsafe_for_binlog	OFF	-	Deprecated option in MariaDB for disabling gap locking for searches and index scans. Deprecated in MariaDB, use READ COMMITTED transaction isolation instead.
innodb_log_checksums	-	ON	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6, as there is no reason to allow checksums to be disabled on the redo log.
innodb_log_compressed_pages	-	ON	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6 as part of the InnoDB redo log performance improvements.
innodb_log_files_in_group	-	2	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6 as part of the InnoDB redo log performance improvements.
innodb_log_spin_*	-	*	MySQL variables for constraining CPU usage while waiting for flushed redo.
innodb_log_wait_for_flush_spin_hwm	-	*	MySQL variable for constraining CPU usage while waiting for flushed redo.
innodb_max_dirty_pages_pct	75	90	MySQL 8 increased the default to 90.
innodb_max_dirty_pages_pct_lwm	0	10	MySQL 8 increased the default to 10.
innodb_max_undo_log_size	10485760	1073741824	MariaDB 10.2 reduced the limit for when an undo tablespace is marked for truncation.

innodb_open_files	Autosized (2000)	Autosized (4000)	In most systems, autosized based on the table_open_cache setting, which differs between MariaDB and MySQL.
innodb_page_cleaners	-	1	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6 as the original reasons for for splitting the buffer pool have mostly gone away.
innodb_prefix_index_cluster_optimization	OFF	-	MariaDB includes the Facebook prefix index queries optimization.
innodb_print_ddl_logs	-	OFF	MySQL option for writing DDL logs to stderr.
innodb_read_only_compressed	ON	-	Whether to set ROW_FORMAT=COMPRESSED tables to read-only.
innodb_redo_log_encrypt	-	OFF	MySQL 8 has also now introduced redo log encryption, but used a different name. The equivalent option in MariaDB is innodb_encrypt_log.
innodb_replication_delay	-	0	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_spin_wait_delay	4	6	MariaDB changed the default from 6 to 4 based on extensive benchmarking.
innodb_stats_modified_counter	0	-	MariaDB option to control the calculation of new statistics.
innodb_stats_sample_pages	8	-	Deprecated MariaDB option for control over index distribution statistics.
innodb_stats_traditional	ON	-	Enabling gives a larger sample of pages for larger tables for the purposes of index statistics calculation.
innodb_sync_array_size	-	1	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_thread_concurrency	-	0	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_thread_sleep_delay	-	10000	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_undo_log_encrypt	-	OFF	MySQL option for encrypting undo logs residing in separate undo tablespaces.
innodb_undo_log_truncate	OFF	ON	MySQL 8 changes the default to ON, marking larger undo logs for truncation.
innodb_undo_tablespaces	3	2	Number of tablespace files used for dividing up the undo logs. MySQL 8 has deprecated this setting, and increased the default (and minimum) to 2.
innodb_use_atomic_writes	ON	-	Atomic writes are a faster alternative to innodb_doublewrite and MariaDB automatically detects when supporting SSD cards are used.
internal_tmp_disk_storage_engine	-	INNODB	MySQL uses this variable to set the storage engine for on-disk internal temporary tables.
internal_tmp_mem_storage_engine	-	TEMPTABLE	MySQL and MariaDB use different formats for temporary tables. In MariaDB, the aria_used_for_temp_tables performs a similar function.
join_buffer_space_limit	2097152	-	Maximum size in bytes of the query buffer. See block-based join algorithms.
join_cache_level	2	-	For determining the join algorithms. See block-based join algorithms
key_buffer_size	134217728	8388608	Size of the buffer for the index blocks used by MyISAM tables and shared for all threads.
key_cache_file_hash_size	512	-	Number of hash buckets for open and changed files.
key_cache_segments	0	-	The number of segments in a key cache. See Segmented Key Cache.
keyring_operations	-	ON	Whether MySQL 8's keyring operations are enabled.
last_gtid	-	empty	MariaDB and MySQL have different GTID implementations.
local_infile	ON	OFF	MySQL no longer supports LOAD DATA LOCAL by default.
lock_wait_timeout	86400	31536000	MariaDB has reduced the timeout for acquiring metadata locks.
log_bin	OFF	ON	MySQL 8 enables the binary log by default.

log_bin_compress	OFF	-	MariaDB setting for whether or not the binary log can be compressed.
log_bin_compress_min_len	256	-	Minimum length of sql statement (in statement mode) or record (in row mode) that can be compressed. See Compressing Events to Reduce Size of the Binary Log.
log_bin_use_v1_row_events	-	OFF	MySQL-only variable showing whether or not MySQL's version 2 binary logging format is being used.
log_disabled_statements	sp	-	Disable logging of certain statements to the general log.
log_error_services	-	log_filter_internal; log_sink_internal	Components to enable for MySQL error logging.
log_error_verbosity	-	3	MySQL variable for setting verbosity of error, warning, and note messages in the error log.
log_slave_updates	OFF	ON	MySQL 8 has by default enabled binary logging of updates a slave receives from a master.
log_slow_admin_statements	ON	OFF	MariaDB logs slow admin statements to the slow query log by default.
log_slow_disabled_statements	admin,call,slave,sp	-	Disable logging of certain statements to the slow query log.
log_slow_filter	admin, filesort, filesort_on_disk, full_join, full_scan, query_cache, query_cache_miss, tmp_table, tmp_table_on_disk	-	For slow query log filtering.
log_slow_rate_limit	1	-	Limits the number of queries logged to the slow query log.
log_slow_min_examined_row_limit	0	-	Previously named min_examined_row_limit (still an alias).
log_slow_query	0	-	Previously named log_slow_query (still an alias).
log_slow_query_file	host_name-slow.log	-	Previously named slow_query_log_file (still an alias).
log_slow_query_time	10.000000	-	Previously named long_query_time (still an alias).
log_slow_slave_statements	ON	OFF	MariaDB logs slow slave statements to the slow query log by default.
log_slow_verbosity	empty	-	Controls information to be added to the slow query log. See also Slow Query Log Extended Statistics.
log_statements_unsafe_for_binlog	-	ON	MySQL setting for controlling whether binlog warnings are written to the error log.
log_syslog*	platform-dependent	-	MySQL variables with settings for writing to syslog.
log_tc_size	24576	-	Size in bytes of the transaction coordinator log, defined in multiples of 4096.
log_throttle_queries_not_using_indexes	-	0	MySQL-only variable for limiting the number of statements without indexes written to the slow query log.
log_timestamps	-	UTC	MySQL-only variable controlling the timezone for certain logging conditions.
log_warnings	2	-	MySQL 8 has replaced with `log_error_verbosity`.
mandatory_roles	-	(empty)	MySQL variable for assigning roles to all users.
master_info_repository	-	TABLE	Whether slave logs master status and connection info to a table or a file.
max_allowed_packet	16M	64M	
max_error_count	64	1024	Specifies the maximum number of messages stored for display by SHOW ERRORS and SHOW WARNINGS statements.
max_execution_time	-	0	MySQL renamed the `max_statement_time` variable.

max_length_for_sort_data	64	1024	Used to decide which algorithm to choose when sorting rows. If the total size of the column data, not including columns that are part of the sort, is less than max_length_for_sort_data, then these are added to the sort key. This can speed up the sort as there's no need to re-read the same row again later. Setting the value too high can slow things down as there will be a higher disk activity for doing the sort.
max_long_data_size	16777216	-	Maximum size for parameter values sent with mysql_stmt_send_long_data(). Removed in MySQL 5.6.
max_password_errors	4294967295	-	Maximum number of failed connections attempts before no more are permitted.
max_points_in_geometry	-	65536	Maximum points_per_circle for MySQL's ST_Buffer_Strategy() function.
max_recursive_iterations	4294967295	-	Maximum number of iterations when executing recursive queries.
max_relay_log_size	1073741824	0	Can be set by session in MariaDB.
max_seeks_for_key	4294967295	4294967295 (32-bit) or 18446744073709547520 (64-bit)	The most key seeks required when searching with an index, regardless of the actual index cardinality. If this value is set lower than its default and maximum, indexes will tend to be preferred over table scans.
max_session_mem_used	9223372036854775807	-	Amount of memory a single user session is allowed to allocate.
max_statement_time	0	-	Maximum time in seconds that a query can execute before being aborted. MySQL used to have a variable of this name before renaming it `max_execution_time`.
max_tmp_tables	32	-	Unused variable removed in MySQL.
max_write_lock_count	4294967295	4294967295 (32-bit) or 18446744073709547520 (64-bit)	Read lock requests will be permitted for processing after this many write locks.
mrr_buffer_size	262144	-	Size of buffer to use when using multi-range read with range access. See Multi Range Read optimization.
myisam_block_size	1024	-	Block size used for MyISAM index pages.
myisam_recover_options	BACKUP,QUICK	OFF	MyISAM recovery mode.
myisam_sort_buffer_size	134216704	8388608	Size in bytes of the buffer allocated when creating or sorting indexes on a MyISAM table.
mysql_native_password_proxy_users	-	OFF	Whether MySQL's authentication plugin supports proxy users. I
mysql56_temporal_format	ON		Causes MariaDB to use the MySQL-5.6 low level formats for TIME, DATETIME and TIMESTAMP instead of the MariaDB 5.3+ version.
new	-	OFF	Used for backward-compatibility with MySQL 4.1, not present in MariaDB.
mysqlx+*	-	*	MySQL's X plugin related variables.
ngram_token_size	-	2	Sets the n-gram token size for MySQL's n-gram full-text parser.
offline_mode	-	OFF	MySQL settting for specifying whether the server should run in offline mode.
old_alter_table	DEFAULT	OFF	An alias for alter_algorithm.
old_mode	Empty string	-	Used for getting MariaDB to emulate behavior from an old version of MySQL or MariaDB. See OLD Mode.
old_passwords	OFF	-	MySQL 8 is no longer compatible with the old pre-MySQL 4.1 form of password hashing.
optimizer_extra_pruning_depth	8	-	If the optimizer needs to enumerate a join prefix of this size or larger, then it will try aggressively prune away the search space.
optimizer_selectivity_sampling_limit	100	-	Controls number of record samples to check condition selectivity.
optimizer_switch	See details		A series of flags for controlling the query optimizer. MariaDB has introduced a number of new settings.
optimizer_trace_*	-	*	MySQL has more settings for optimizer tracing.

optimizer_use_condition_selectivity	4	-	Controls which statistics can be used by the optimizer when looking for the best query execution plan.
original_commit_timestamp	-	*	Used by MySQL 8 for delaying replication.
parser_max_mem_size	-	4294967295 (32-bit) or 18446744073709547520 (64-bit)	MySQL variable for limiting memory available to the parser.
password_*	-	*	Controls reuse of previous passwords in MySQL.
performance_schema	OFF	ON	The Performance Schema is off by default in MariaDB.
performance_schema_*			Many performance schema variables are autoset in MySQL, and MySQL has a different version, with additional variables.
plugin_maturity	One less than the server maturity	-	Minimum acceptable plugin maturity.
progress_report_time	5	-	Time in seconds between sending progress reports to the client for time-consuming statements.
proxy_protocol_networks	(empty)	-	Enable proxy protocol for these source networks.
query_alloc_block_size	16384	8192	Size in bytes of the extra blocks allocated during query parsing and execution (after query_prealloc_size is used up).
query_cache_*	*	-	MySQL has removed the query cache.
query_prealloc_size	24576	8192	Size in bytes of the persistent buffer for query parsing and execution, allocated on connect and freed on disconnect.
range_optimizer_max_mem_size	-	8388608	MySQL-only variable setting a limit on the range optimizer's memory usage.
rbr_exec_mode	-	STRICT	MySQL-only variable for determining the handling of certain key errors.
read_binlog_speed_limit	0	-	Permits restricting the speed at which the slave reads the binlog from the master.
regexp_*	-	*	Memory and time limits for regular expression matching operations.
relay_log_info_repository	-	TABLE	MySQL-only variable determining whether the slave's position in the relay logs is written to a file or table.
replicate_annotate_row_events	ON	-	Tells the slave to reproduce annotate_rows_events received from the master in its own binary log.
replicate_do_db	empty string	-	See Dynamic Replication Variables.
replicate_do_table	empty string	-	See Dynamic Replication Variables.
replicate_events_marked_for_skip	replicate	-	See Selectively skipping replication of binlog events.
replicate_ignore_db	empty string	-	See Dynamic Replication Variables.
replicate_ignore_table	empty string	-	See Dynamic Replication Variables.
replicate_rewrite_db	empty string	-	Only available as an option in MySQL.
replicate_wild_do_table	empty string	-	See Dynamic Replication Variables.
replicate_wild_ignore_table	empty string	-	See Dynamic Replication Variables.
result_metadata	-	FULL	Determine whether the server returns result set metadata for connections where this is optional.
rowid_merge_buff_size	8388608	-	See Non-semi-join subquery optimizations.
rpl_read_size	-	8192	Minimum data in bytes read from the binary and relay log files.
rpl_semi_sync_*	-	-	MariaDB includes semisynchronous replication without the need to install a plugin.
rpl_stop_slave_timeout	-	31536000	Controls the time that STOP SLAVE waits before timing out.
s3_*	*	-	The S3 storage engine is only available in MariaDB.
schema_definition_cache	-	256	Limits the number of schema definition objects kept in the dictionary object cache.
secure_auth	ON	-	Removed in MySQL.

secure_timestamp	NO	-	MariaDB-only option permitting the restricting of direct setting of a session timestamp..
server_id_bits	-	server_id	MySQL-only variable for use in MySQL Cluster.
server_uuid	-	UUID	MySQL-only variable containing the UUID.
session_track_gtids	-	OFF	MySQL-only variables for tracking gtid changes. MariaDB and MySQL's gtid implementation is different.
sha256_password_proxy_users	-	OFF	MySQL-only variable determining whether the sha256_password plugin supports proxy users.
show_create_table_verbosity	-	OFF	Option to cause SHOW CREATE TABLE to display ROW_FORMAT in all cases.
show_old_temporals	-	OFF	MySQL-only variable for determining whether SHOW CREATE TABLE output should include comments for old format temporal columns.
skip_parallel_replication	OFF	-	See parallel replication.
skip_replication	OFF	-	See Selectively skipping replication of binlog events.
slave_allow_batching	-	OFF	MySQL-only replication variable.
slave_checkpoint_group	-	512	MySQL-only replication variable.
slave_checkpoint_period	-	300	MySQL-only replication variable.
slave_ddl_exec_mode	IDEMPOTENT	-	Modes for how replication of DDL events should be executed.
slave_domain_parallel_threads	0	-	For configuring parallel replication.
slave_net_timeout	3600	60	MySQL reduced the timeout to 60s.
slave_parallel_max_queued	131072	-	For configuring parallel replication.
skip_grant_tables	0	-	Only available as an option in MySQL.
slave_max_statement_time	0.000000	-	MariaDB setting to abort a query that has taken more than this in seconds to run on the replica.
slave_parallel_mode	optimistic	-	Controls what transactions are applied in parallel when using parallel_replication.
slave_parallel_threads	0	-	For configuring parallel replication.
slave_parallel_type	-	DATABASE	MySQL-only replication variable.
slave_pending_jobs_size_max	-	16777216	MySQL-only replication variable.
slave_preserve_commit_order	-	OFF	MySQL-only replication variable.
slave_rows_search_algorithms	-	INDEX_SCAN, HASH_SCAN	MySQL-only replication variable.
slave_run_triggers_for_rbr	NO		See Running triggers on the slave for Row-based events for a description and use-case for this setting.
slave_transaction_retry_errors	1213,1205	-	When an error occurs during a transaction on the slave, replication usually halts. By default, transactions that caused a deadlock or elapsed lock wait timeout will be retried. One can add other errors to the the list of errors that should be retried by adding a comma-separated list of error numbers to this variable.
slave_transaction_retry_interval	0	-	Interval in seconds for the slave SQL thread to retry a failed transaction due to a deadlock, elapsed lock wait timeout or an error listed in slave_transaction_retry_errors.
sort_buffer_size	2097152	262144	The default sort buffer allocated has been reduced in MySQL.
sql_if_exists	OFF	-	Adds an implicit IF EXISTS to ALTER, RENAME and DROP of TABLES, VIEWS, FUNCTIONS and PACKAGES
sql_mode	STRICT_TRANS_TABLES, ERROR_FOR_DIVISION_BY_ZERO, NO_AUTO_CREATE_USER, NO_ENGINE_SUBSTITUTION	ONLY_FULL_GROUP_BY, STRICT_TRANS_TABLES, NO_ZERO_IN_DATE, NO_ZERO_DATE, ERROR_FOR_DIVISION_BY_ZERO, NO_ENGINE_SUBSTITUTION	See SQL Mode.
ssl_fips_mode	-	OFF	Whether FIPS mode is enabled on the server side.
standard_compliant_cte	ON	-	See Common Table Expressions.
storage_engine	InnoDB	-	Alias for default_storage_engine, removed in MySQL.

strict_password_validation	ON	-	In MariaDB, when password validation plugins are enabled, reject passwords that cannot be validated (passwords specified as a hash).
stored_program_definition_cache	-	256	Limits the number of stored program definition objects kept in the dictionary object cache.
super_read_only	-	OFF	MySQL variable for prohibiting client updates from users with the SUPER privilege.
sync_binlog	0	1	MySQL synchronizes all actions to the binary log before they are committed.
sync_frm	1	-	.frm files have been removed in MySQL.
system_versioning_alter_history	ERROR	-	MariaDB has System-Versioned Tables
system_versioning_asof	DEFAULT	-	MariaDB has System-Versioned Tables
system_versioning_insert_history	OFF	-	MariaDB has System-Versioned Tables
table_definition_cache	400	-1 (autosized)	Number of table definitions that can be cached.
table_open_cache_instances	8	16	Maximum number of table cache instances.
tablespace_definition_cache	-	256	Limits the number of tablespace definition objects kept in the dictionary object cache.
tcp_keepalive_interval	0	-	Interval, in seconds, between when successive keep-alive packets are sent if no acknowledgement is received.
tcp_keepalive_probes	0	-	Number of unacknowledged probes to send before considering the connection dead and notifying the application layer.
tcp_keepalive_time	0	-	Set the TCP_NODELAY option (disable Nagle's algorithm) on socket.
tcp_nodelay	1	-	Timeout, in milliseconds, with no activity until the first TCP keep-alive packet is sent.
temptable_max_ram	-	1GB	Limits the RAM used by MySQL's TempTable storage engine.
thread_cache_size	Autosized	-1 (autosized)	MariaDB uses an improved thread pool.
thread_concurrency	10	-	Removed in MySQL 5.7.
thread_pool_dedicated_listener	0	-	Better precision for the data in the Information Schema THREADPOOL_QUEUES Table.
thread_pool_exact_stats	0	-	Better precision for the data in the Information Schema THREADPOOL_QUEUES Table.
thread_pool_idle_timeout	60	-	See Using the Thread Pool .
thread_pool_max_threads	65536	-	See Using the Thread Pool .
thread_pool_min_threads	1	-	Windows-only. See Using the Thread Pool.
thread_pool_oversubscribe	3	-	See Using the Thread Pool .
thread_pool_prio_kickup	auto	-	See Using the Thread Pool .
thread_pool_priority	auto	-	See Using the Thread Pool .
thread_pool_size	Number of processors	16*	See Using the Thread Pool . *Only available in MySQL with a commercial plugin.
thread_pool_stall_limit	500	6*	See Using the Thread Pool . *Only available in MySQL with a commercial plugin.
thread_stack	299008	Varies	See Using the Thread Pool .
time_format	%H:%i:%s	-	Removed in MySQL.
timed_mutexes	OFF	-	Removed in MySQL.
tmp_disk_table_size	18446744073709551615	-	Max size for data for an internal temporary on-disk MyISAM or Aria table.
tmp_memory_table_size	16777216	-	Alias for tmp_table_size.
transaction_allow_batching	-	OFF	Variable for enabling batching of statements within the same transaction in MySQL Cluster.
transaction_write_set_extraction	-	OFF	Unused MySQL-only variable.
tx_isolation	REPEATABLE-READ	-	A MariaDB-only variable, replaced with transaction_isolation.
tx_read_only	OFF	-	A MariaDB-only variable, replaced with transaction_read_only.

use_stat_tables	preferably_for_queries	-	Controls the use of engine-independent table statistics.
userstat	OFF	-	Whether to activate MariaDB's User Statistics implementation, not available in MySQL.
version_compile_zlib	-	*	Version of the zlib library compiled in.
version_malloc_library	*	-	Version of the used malloc library.
version_source_revision	Varies	-	Permits seeing exactly which version of the source was used for a build.
version_ssl_library	*	-	Version of the used TLS library.
windowing_high_use_precision	-	*	MySQL option allowing safety to be sacrificed for speed in window function calculations.
wsrep_*	*	-	Galera cluster is only available in MariaDB.
Variable	**MariaDB 11.1**	**MySQL 8.0**	**Notes**

2.1.14.1.12.2 System Variable Differences Between MariaDB 11.0 and MySQL 8.0

Contents

The following is a comparison of variables that either appear only in MariaDB 11.0 or MySQL 8.0, or have different default settings in MariaDB 11.0, and MySQL 8.0. The releases MariaDB 11.0.2 and MySQL 8.0.34, with only default plugins enabled, were used for the comparison. Note that MySQL 8 is an 'evergreen' release, so features may be added or removed in later releases.

For a more complete list of differences, see Incompatibilities and Feature Differences Between MariaDB 11.0 and MySQL 8.0 and Function Differences Between MariaDB 11.0 and MySQL 8.0

Comparison Table

Variable	MariaDB 11.0 Default	MySQL 8.0 Default	Notes
activate_all_roles_on_login	-	OFF	Determines whether to automatically activate roles on login.
admin*	-	*	MySQL admin connections.
allow_suspicious_udfs	0	-	Only available as an option in MySQL.
alter_algorithm	DEFAULT	-	MariaDB 10.3 introduced new ALTER TABLE ALGORITHM clauses to avoid slow copies in certain instances. This variable allows setting this if no `ALGORITHM` clause is specified.
analyze_sample_percentage	100.0000	-	Percentage of rows from the table ANALYZE TABLE will sample to collect table statistics.
aria_*	*	-	The Aria storage engine is only available in MariaDB.
authentication_policy	-	*,,	MySQL authentication policy.
auto_generate_certs	-	ON	Whether to automatically generate SSL key and certificate files.
avoid_temporal_upgrade	-	OFF	Determines whether ALTER TABLE implicitly upgrades temporal columns.
back_log	Autosized	Autosized	MariaDB and MySQL have different autosizing algorithms.
binlog_alter_two_phase	OFF	-	When set, split ALTER at binary logging into two statements: START ALTER and COMMIT/ROLLBACK ALTER.
binlog_annotate_row_events	ON	-	Introduced in MariaDB 5.3 for replicating between MariaDB 5.3 and MySQL/MariaDB 5.1.
binlog_commit_wait_count	0	-	For use in MariaDB's parallel replication.
binlog_commit_wait_usec	100000	-	For use in MariaDB's parallel replication.
binlog_encryption	-	OFF	MySQL name for encrypt_binlog.
binlog_error_action		ABORT_SERVER	MySQL-only variable for controlling what happens when the server cannot write to the binary log.

binlog_expire_logs_auto_purge	-	ON	Enables or disables automatic purging of binary log files.
binlog_expire_logs_seconds	0	2592000	Sets the binary log expiration period in seconds
binlog_file_cache_size	16184	-	For setting the size of the file cache for the binary log.
binlog_format	MIXED	ROW	MariaDB and MySQL have differing binary log formats.
binlog_group_commit_sync_delay		0	MySQL-only variable for controlling the wait time before synchronizing the binary log file to disk.
binlog_group_commit_sync_no_delay_count		0	MySQL-only variable for setting the maximum number of transactions to wait for before aborting the current `binlog_group_commit_sync_delay` delay.
binlog_gtid_simple_recovery	-	ON	MySQL-only GTID variable. MariaDB's GTID implementation is different.
binlog_max_flush_queue_time	-	0	Specifies a timeout for reading transactions from the flush queue before continuing with group commit and syncing log to disk.
binlog_optimize_thread_scheduling	ON	-	For optimized kernel thread scheduling.
binlog_order_commits	-	ON	Determines whether transactions may be committed in parallel.
binlog_rotate_encryption_master_key_at_startup	-	OFF	Specifically for use with MySQL binary key encryption.
binlog_row_event_max_size	-	8192	Only available as a system variable in MariaDB 11.2.
binlog_row_metadata	NO_LOG	MINIMAL	Determines the amount of table metadata added to the binary log with row-based logging.
binlog_row_value_options	-	(empty)	Permits an alternative binlog format for JSON document updates.
binlog_rows_query_log_events	-	OFF	MySQL-only variable for logging extra information in row-based logging.
binlog_transaction_compression*	-	*	MySQL variables relating to binary log compression.
binlog_transaction_dependency_history_size	-	25000	Maximum number of row hashes kept for looking up transactions that last modified a given row.
binlog_transaction_dependency_tracking	-	COMMIT_ORDER	For determining how to best use the slave's multithreaded applier.
block_encryption_mode	-	aes-128-ecb	MySQL-only variable for controlling the block encryption mode for block-based algorithms.
caching_sha2_password*	-	*	For use with MySQL's SHA-256 authentication with caching.
character_set_*	latin1 or utf8	utf8mb4	MySQL 8.0 defaults to the utf8mb4 character set.
check_constraint_checks	ON	-	Permits disabling constraint checks, for example when loading a table that violates some constraints that you plan to fix later.
check_proxy_users		OFF	MySQL-only variable for controlling whether the server performs proxy user mapping for authentication plugins.
collation_*	latin1_swedish_ci or utf8_general_ci	utf8mb4_0900_ai_ci	MySQL 8.0 defaults to the utf8mb4 character set.
column_compression_threshold	100	-	MariaDB supports Storage-engine Independent Column Compression.
column_compression_zlib_level	6	-	MariaDB supports Storage-engine Independent Column Compression.
column_compression_zlib_strategy	DEFAULT_STRATEGY	-	MariaDB supports Storage-engine Independent Column Compression.
column_compression_zlib_wrap	OFF	-	MariaDB supports Storage-engine Independent Column Compression.
connection_memory_chunk_size	-	8192	Chunk size for updates to the Global_connection_memory counter.
connection_memory_limit	-	18446744073709551615	Maximum memory for a single user connection.
create_admin_listener_thread	-	OFF	MySQL-only variable for whether to use a dedicated listening thread for admin network interface connections.

cte_max_recursion_depth	-	1000	When MySQL 8.0 introduced common table expressions they used a different name. MariaDB's variable is called max_recursive_iterations.
date_format	%Y-%m-%d	-	Unused variable removed in MySQL 8.0
datetime_format	%Y-%m-%d	-	Unused variable removed in MySQL 8.0
deadlock_search_depth_long	15	-	The Aria storage engine is only available in MariaDB.
deadlock_search_depth_short	4	-	The Aria storage engine is only available in MariaDB.
deadlock_timeout_long	50000000	-	The Aria storage engine is only available in MariaDB.
deadlock_timeout_short	10000	-	The Aria storage engine is only available in MariaDB.
debug_no_thread_alarm	OFF	-	Disable system thread alarm calls, for debugging or testing.
default_authentication_plugin	-	caching_sha2_password	MySQL 8 introduced a new authentication plugin.
default_collation_for_utf8mb4	-	utf8mb4_0900_ai_ci	For internal use in MySQL 8 replication.
default_master_connection	empty	-	For use with MariaDB's multi-source replication.
default_password_lifetime	0	360	MariaDB defaults to password expiration off.
default_regex_flags	empty	-	For handling incompatibilities between MariaDB's PCRE and the old regex library.
default_tmp_storage_engine	empty	InnoDB	Default storage engine used for tables created with CREATE TEMPORARY TABLE.
disabled_storage_engines		empty	MySQL-only variable for disabling specific storage engines.
disconnect_on_expired_password	OFF	ON	MariaDB password expiration is off by default, and by default does not disconnect a client when a password has expired.
encrypt_binlog	OFF	-	MariaDB enables table and tablespace encryption.
encrypt_tmp_files	OFF	-	MariaDB enables table and tablespace encryption.
encrypt_tmp_disk_tables	OFF	-	MariaDB enables table and tablespace encryption.
end_markers_in_json	-	OFF	MySQL-only variable for adding end markers to JSON output.
enforce_gtid_consistency	-	OFF	MariaDB and MySQL have different GTID implementations.
enforce_storage_engine	none		Forces the use of a particular storage engine for new tables.
eq_range_index_dive_limit	0	200	Variable for tuning when the optimizer should switch from using index dives to index statistics for qualifying rows estimation.
event_scheduler	OFF	ON	MySQL enables the event scheduler by default.
expensive_subquery_limit	100	-	Used for determining expensive queries for optimization.
extra_max_connections	1	-	Introduced in the MariaDB 5.1 threadpool.
extra_port	0	-	Introduced in the MariaDB 5.1 threadpool.
group_concat_max_len	1048576	1024	MariaDB increases the maximum length for a GROUP_CONCAT() result from 1K to 1M.
gtid_binlog_pos	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_binlog_state	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_cleanup_batch_size	64	-	MariaDB and MySQL have different GTID implementations.
gtid_current_pos	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_domain_id	0	-	MariaDB and MySQL have different GTID implementations.

gtid_executed	-	empty	MariaDB and MySQL have different GTID implementations.
gtid_executed_compression_period	-	1000	MariaDB and MySQL have different GTID implementations.
gtid_ignore_duplicates	OFF	-	MariaDB and MySQL have different GTID implementations.
gtid_mode	-	OFF	MariaDB and MySQL have different GTID implementations.
gtid_next	-	AUTOMATIC	MariaDB and MySQL have different GTID implementations.
gtid_owned	-	empty	MariaDB and MySQL have different GTID implementations.
gtid_pos_auto_engines	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_purged	-	empty	MariaDB and MySQL have different GTID implementations.
gtid_seq_no	0	-	MariaDB and MySQL have different GTID implementations.
gtid_slave_pos	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_strict_mode	OFF	-	MariaDB and MySQL have different GTID implementations.
have_crypt	YES	-	MySQL has removed the ENCRYPT function.
have_openssl			MariaDB's version indicates whether YaSSL or openssl was used. MySQL's is a synonym for `have_ssl`.
have_query_cache	YES	-	MySQL has removed the query cache.
have_statement_timeout	-		Whether MySQL's statement execution timeout feature is available.
have_symlink	YES	DISABLED	MySQL has removed symlink support.
histogram_generation_max_mem_size	-	20000000	Added when MySQL 8 introduced Histogram-based Statistics. MariaDB uses histogram_size
histogram_size	0	-	MariaDB introduced Histogram-based Statistics.
histogram_type	JSON_HB	-	MariaDB introduced Histogram-based Statistics.
idle_readonly_transaction_timeout	0	-	Time in seconds that the server waits for idle read-only transactions.
idle_transaction_timeout	0	-	Time in seconds that the server waits for idle transactions.
idle_write_transaction_timeout	0	-	Time in seconds that the server waits for idle write transactions.
ignore_builtin_innodb	OFF	-	Ignored and removed in MySQL 8.
in_predicate_conversion_threshold	1000	-	Controls the Conversion of Big IN Predicates Into Subqueries optimization.
in_transaction	0	-	Set to `1` if you are in a transaction, and `0` if not.
information_schema_stats_expiry	-	86400	Time until MySQL Information Schema cached statistics expire.
innodb_adaptive_flushing_lwm	10.000000	10	Adaptive flushing is enabled when this this low water mark percentage of the redo log capacity is reached. MariaDB's variable is a double, MySQL's an integer.
innodb_adaptive_hash_index	OFF	ON	Defaulting to OFF is a performance improvement especially for DROP TABLE, TRUNCATE TABLE, ALTER TABLE, or DROP INDEX operations
innodb_adaptive_max_sleep_delay	-	150000	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_api_*	-	*	Specific to MySQL's memcached, removed in MariaDB 10.2.
innodb_autoinc_lock_mode	1	2	MariaDB has an extra mode, `3`, for skipping the rollback of connected transactions. MySQL defaults to row-based replication, so can safely use `2`.
innodb_buffer_pool_instances	-	1	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6 since the original reasons for introducing no longer apply.
innodb_change*		*	The InnoDB Change Buffer was removed in MariaDB 11.0.

innodb_checksum_algorithm	full_crc32	crc32	`fullcrc32` permits encryption to be supported over a SPATIAL INDEX, which crc32 does not support.
innodb_checksums	ON	-	Deprecated option removed in MySQL.
innodb_commit_concurrency	-	0	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_compression_*	*	-	Introduced with MariaDB's InnoDB compression.
innodb_concurrency_tickets	-	5000	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_deadlock_report	Full	-	How to report deadlocks.
innodb_dedicated_server	-	OFF	MySQL option that automatically configures various settings if the server is a dedicated InnoDB database server.
innodb_default_encryption_key_id	1	-	Default encryption key id used for table encryption. See Data at Rest Encryption.
innodb_defragment	*	-	MariaDB can defragment InnoDB tablespaces.
innodb_directories	-	(empty)	Used to search for tablespace files when moving or restoring a new location.
innodb_disallow_writes	OFF	-	Tell InnoDB to stop any writes to disk.
innodb_encrypt_*	1	-	See MariaDB's Data at Rest Encryption.
innodb_fatal_semaphore_wait_threshold	600	-	MariaDB's fatal semaphore timeout is configurable.
innodb_flush_method	O_DIRECT	fsync	MariaDB InnoDB flushing method by default on Unix systems bypasses the file system cache for improved performance in most cases.
innodb_flush_neighbors	1	0	MySQL 8 by default now assumes the use of an SSD device.
innodb_force_primary_key	OFF	-	If set to 1 in MariaDB (0 is default) CREATE TABLEs without a primary or unique key where all keyparts are NOT NULL will not be accepted, and will return an error.
innodb_idle_flush_pct	100	-	Up to what percentage of dirty pages in MariaDB should be flushed when InnoDB finds it has spare resources to do so.
innodb_immediate_scrub_data_uncompressed	OFF	-	MariaDB has support for data scrubbing.
innodb_instant_alter_column_allowed	add_drop_reorder	-	See Instant ADD COLUMN for InnoDB.
innodb_locks_unsafe_for_binlog	OFF	-	Deprecated option in MariaDB for disabling gap locking for searches and index scans. Deprecated in MariaDB, use READ COMMITTED transaction isolation instead.
innodb_log_checksums	-	ON	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6, as there is no reason to allow checksums to be disabled on the redo log.
innodb_log_compressed_pages	-	ON	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6 as part of the InnoDB redo log performance improvements.
innodb_log_files_in_group	-	2	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6 as part of the InnoDB redo log performance improvements.
innodb_log_spin_*	-	*	MySQL variables for constraining CPU usage while waiting for flushed redo.
innodb_log_wait_for_flush_spin_hwm	-	*	MySQL variable for constraining CPU usage while waiting for flushed redo.
innodb_max_dirty_pages_pct	75	90	MySQL 8 increased the default to 90.
innodb_max_dirty_pages_pct_lwm	0	10	MySQL 8 increased the default to 10.
innodb_max_undo_log_size	10485760	1073741824	MariaDB 10.2 reduced the limit for when an undo tablespace is marked for truncation.
innodb_open_files	Autosized (2000)	Autosized (4000)	In most systems, autosized based on the table_open_cache setting, which differs between MariaDB and MySQL.
innodb_page_cleaners	-	1	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6 as the original reasons for for splitting the buffer pool have mostly gone away.

innodb_prefix_index_cluster_optimization	OFF	-	MariaDB includes the Facebook prefix index queries optimization.
innodb_print_ddl_logs	-	OFF	MySQL option for writing DDL logs to stderr.
innodb_read_only_compressed	ON	-	Whether to set ROW_FORMAT=COMPRESSED tables to read-only.
innodb_redo_log_encrypt	-	OFF	MySQL 8 has also now introduced redo log encryption, but used a different name. The equivalent option in MariaDB is innodb_encrypt_log.
innodb_replication_delay	-	0	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_spin_wait_delay	4	6	MariaDB changed the default from 6 to 4 based on extensive benchmarking.
innodb_stats_modified_counter	0	-	MariaDB option to control the calculation of new statistics.
innodb_stats_sample_pages	8	-	Deprecated MariaDB option for control over index distribution statistics.
innodb_stats_traditional	ON	-	Enabling gives a larger sample of pages for larger tables for the purposes of index statistics calculation.
innodb_sync_array_size	-	1	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_thread_concurrency	-	0	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_thread_sleep_delay	-	10000	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_undo_log_encrypt	-	OFF	MySQL option for encrypting undo logs residing in separate undo tablespaces.
innodb_undo_log_truncate	OFF	ON	MySQL 8 changes the default to ON, marking larger undo logs for truncation.
innodb_undo_tablespaces	3	2	Number of tablespace files used for dividing up the undo logs. MySQL 8 has deprecated this setting, and increased the default (and minimum) to 2.
innodb_use_atomic_writes	ON	-	Atomic writes are a faster alternative to innodb_doublewrite and MariaDB automatically detects when supporting SSD cards are used.
internal_tmp_disk_storage_engine	-	INNODB	MySQL uses this variable to set the storage engine for on-disk internal temporary tables.
internal_tmp_mem_storage_engine	-	TEMPTABLE	MySQL and MariaDB use different formats for temporary tables. In MariaDB, the aria_used_for_temp_tables performs a similar function.
join_buffer_space_limit	2097152	-	Maximum size in bytes of the query buffer. See block-based join algorithms.
join_cache_level	2	-	For determining the join algorithms. See block-based join algorithms
key_buffer_size	134217728	8388608	Size of the buffer for the index blocks used by MyISAM tables and shared for all threads.
key_cache_file_hash_size	512	-	Number of hash buckets for open and changed files.
key_cache_segments	0	-	The number of segments in a key cache. See Segmented Key Cache.
keyring_operations	-	ON	Whether MySQL 8's keyring operations are enabled.
last_gtid	-	empty	MariaDB and MySQL have different GTID implementations.
local_infile	ON	OFF	MySQL no longer supports LOAD DATA LOCAL by default.
lock_wait_timeout	86400	31536000	MariaDB has reduced the timeout for acquiring metadata locks.
log_bin	OFF	ON	MySQL 8 enables the binary log by default.
log_bin_compress	OFF	-	MariaDB setting for whether or not the binary log can be compressed.
log_bin_compress_min_len	256	-	Minimum length of sql statement (in statement mode) or record (in row mode) that can be compressed. See Compressing Events to Reduce Size of the Binary Log.

log_bin_use_v1_row_events	-	OFF	MySQL-only variable showing whether or not MySQL's version 2 binary logging format is being used.
log_disabled_statements	sp	-	Disable logging of certain statements to the general log.
log_error_services	-	log_filter_internal; log_sink_internal	Components to enable for MySQL error logging.
log_error_verbosity	-	3	MySQL variable for setting verbosity of error, warning, and note messages in the error log.
log_slave_updates	OFF	ON	MySQL 8 has by default enabled binary logging of updates a slave receives from a master.
log_slow_admin_statements	ON	OFF	MariaDB logs slow admin statements to the slow query log by default.
log_slow_disabled_statements	admin,call,slave,sp	-	Disable logging of certain statements to the slow query log.
log_slow_filter	admin, filesort, filesort_on_disk, full_join, full_scan, query_cache, query_cache_miss, tmp_table, tmp_table_on_disk	-	For slow query log filtering.
log_slow_rate_limit	1	-	Limits the number of queries logged to the slow query log.
log_slow_min_examined_row_limit	0	-	Previously named min_examined_row_limit (still an alias).
log_slow_query	0	-	Previously named log_slow_query (still an alias).
log_slow_query_file	host_name-slow.log	-	Previously named slow_query_log_file (still an alias).
log_slow_query_time	10.000000	-	Previously named long_query_time (still an alias).
log_slow_slave_statements	ON	OFF	MariaDB logs slow slave statements to the slow query log by default.
log_slow_verbosity	empty	-	Controls information to be added to the slow query log. See also Slow Query Log Extended Statistics.
log_statements_unsafe_for_binlog	-	ON	MySQL setting for controlling whether binlog warnings are written to the error log.
log_syslog*	platform-dependent	-	MySQL variables with settings for writing to syslog.
log_tc_size	24576	-	Size in bytes of the transaction coordinator log, defined in multiples of 4096.
log_throttle_queries_not_using_indexes	-	0	MySQL-only variable for limiting the number of statements without indexes written to the slow query log.
log_timestamps	-	UTC	MySQL-only variable controlling the timezone for certain logging conditions.
log_warnings	2	-	MySQL 8 has replaced with `log_error_verbosity`.
mandatory_roles	-	(empty)	MySQL variable for assigning roles to all users.
master_info_repository	-	TABLE	Whether slave logs master status and connection info to a table or a file.
max_allowed_packet	16M	64M	
max_error_count	64	1024	Specifies the maximum number of messages stored for display by SHOW ERRORS and SHOW WARNINGS statements.
max_execution_time	-	0	MySQL renamed the `max_statement_time` variable.
max_length_for_sort_data	64	1024	Used to decide which algorithm to choose when sorting rows. If the total size of the column data, not including columns that are part of the sort, is less than max_length_for_sort_data, then these are added to the sort key. This can speed up the sort as there's no need to re-read the same row again later. Setting the value too high can slow things down as there will be a higher disk activity for doing the sort.
max_long_data_size	16777216	-	Maximum size for parameter values sent with mysql_stmt_send_long_data(). Removed in MySQL 5.6.

max_password_errors	4294967295	-	Maximum number of failed connections attempts before no more are permitted.
max_points_in_geometry	-	65536	Maximum points_per_circle for MySQL's ST_Buffer_Strategy() function.
max_recursive_iterations	4294967295	-	Maximum number of iterations when executing recursive queries.
max_relay_log_size	1073741824	0	Can be set by session in MariaDB.
max_seeks_for_key	4294967295	4294967295 (32-bit) or 18446744073709547520 (64-bit)	The most key seeks required when searching with an index, regardless of the actual index cardinality. If this value is set lower than its default and maximum, indexes will tend to be preferred over table scans.
max_session_mem_used	9223372036854775807	-	Amount of memory a single user session is allowed to allocate.
max_statement_time	0	-	Maximum time in seconds that a query can execute before being aborted. MySQL used to have a variable of this name before renaming it `max_execution_time`.
max_tmp_tables	32	-	Unused variable removed in MySQL.
max_write_lock_count	4294967295	4294967295 (32-bit) or 18446744073709547520 (64-bit)	Read lock requests will be permitted for processing after this many write locks.
mrr_buffer_size	262144	-	Size of buffer to use when using multi-range read with range access. See Multi Range Read optimization.
myisam_block_size	1024	-	Block size used for MyISAM index pages.
myisam_recover_options	BACKUP,QUICK	OFF	MyISAM recovery mode.
myisam_sort_buffer_size	134216704	8388608	Size in bytes of the buffer allocated when creating or sorting indexes on a MyISAM table.
mysql_native_password_proxy_users	-	OFF	Whether MySQL's authentication plugin supports proxy users. I
mysql56_temporal_format	ON		Causes MariaDB to use the MySQL-5.6 low level formats for TIME, DATETIME and TIMESTAMP instead of the MariaDB 5.3+ version.
new	-	OFF	Used for backward-compatibility with MySQL 4.1, not present in MariaDB.
mysqlx+*	-	*	MySQL's X plugin related variables.
ngram_token_size	-	2	Sets the n-gram token size for MySQL's n-gram full-text parser.
offline_mode	-	OFF	MySQL settting for specifying whether the server should run in offline mode.
old_alter_table	DEFAULT	OFF	An alias for alter_algorithm.
old_mode	Empty string	-	Used for getting MariaDB to emulate behavior from an old version of MySQL or MariaDB. See OLD Mode.
old_passwords	OFF	-	MySQL 8 is no longer compatible with the old pre-MySQL 4.1 form of password hashing.
optimizer_extra_pruning_depth	8	-	If the optimizer needs to enumerate a join prefix of this size or larger, then it will try aggressively prune away the search space.
optimizer_selectivity_sampling_limit	100	-	Controls number of record samples to check condition selectivity.
optimizer_switch	See details		A series of flags for controlling the query optimizer. MariaDB has introduced a number of new settings.
optimizer_trace_*	-	*	MySQL has more settings for optimizer tracing.
optimizer_use_condition_selectivity	4	-	Controls which statistics can be used by the optimizer when looking for the best query execution plan.
original_commit_timestamp	-	*	Used by MySQL 8 for delaying replication.
parser_max_mem_size	-	4294967295 (32-bit) or 18446744073709547520 (64-bit)	MySQL variable for limiting memory available to the parser.
password_*	-	*	Controls reuse of previous passwords in MySQL.
performance_schema	OFF	ON	The Performance Schema is off by default in MariaDB.

performance_schema_*			Many performance schema variables are autoset in MySQL, and MySQL has a different version, with additional variables.
plugin_maturity	One less than the server maturity	-	Minimum acceptable plugin maturity.
progress_report_time	5	-	Time in seconds between sending progress reports to the client for time-consuming statements.
proxy_protocol_networks	(empty)	-	Enable proxy protocol for these source networks.
query_alloc_block_size	16384	8192	Size in bytes of the extra blocks allocated during query parsing and execution (after query_prealloc_size is used up).
query_cache_*	*	-	MySQL has removed the query cache.
query_prealloc_size	24576	8192	Size in bytes of the persistent buffer for query parsing and execution, allocated on connect and freed on disconnect.
range_optimizer_max_mem_size	-	8388608	MySQL-only variable setting a limit on the range optimizer's memory usage.
rbr_exec_mode	-	STRICT	MySQL-only variable for determining the handling of certain key errors.
read_binlog_speed_limit	0	-	Permits restricting the speed at which the slave reads the binlog from the master.
regexp_*	-	*	Memory and time limits for regular expression matching operations.
relay_log_info_repository	-	TABLE	MySQL-only variable determining whether the slave's position in the relay logs is written to a file or table.
replicate_annotate_row_events	ON	-	Tells the slave to reproduce annotate_rows_events received from the master in its own binary log.
replicate_do_db	empty string	-	See Dynamic Replication Variables.
replicate_do_table	empty string	-	See Dynamic Replication Variables.
replicate_events_marked_for_skip	replicate	-	See Selectively skipping replication of binlog events.
replicate_ignore_db	empty string	-	See Dynamic Replication Variables.
replicate_ignore_table	empty string	-	See Dynamic Replication Variables.
replicate_rewrite_db	empty string	-	Only available as an option in MySQL.
replicate_wild_do_table	empty string	-	See Dynamic Replication Variables.
replicate_wild_ignore_table	empty string	-	See Dynamic Replication Variables.
result_metadata	-	FULL	Determine whether the server returns result set metadata for connections where this is optional.
rowid_merge_buff_size	8388608	-	See Non-semi-join subquery optimizations.
rpl_read_size	-	8192	Minimum data in bytes read from the binary and relay log files.
rpl_semi_sync_*	-	-	MariaDB includes semisynchronous replication without the need to install a plugin.
rpl_stop_slave_timeout	-	31536000	Controls the time that STOP SLAVE waits before timing out.
s3_*	*	-	The S3 storage engine is only available in MariaDB.
schema_definition_cache	-	256	Limits the number of schema definition objects kept in the dictionary object cache.
secure_auth	ON	-	Removed in MySQL.
secure_timestamp	NO	-	MariaDB-only option permitting the restricting of direct setting of a session timestamp..
server_id_bits	-	server_id	MySQL-only variable for use in MySQL Cluster.
server_uuid	-	UUID	MySQL-only variable containing the UUID.
session_track_gtids	-	OFF	MySQL-only variables for tracking gtid changes. MariaDB and MySQL's gtid implementation is different.
sha256_password_proxy_users	-	OFF	MySQL-only variable determining whether the sha256_password plugin supports proxy users.

show_create_table_verbosity	-	OFF	Option to cause SHOW CREATE TABLE to display ROW_FORMAT in all cases.
show_old_temporals	-	OFF	MySQL-only variable for determining whether SHOW CREATE TABLE output should include comments for old format temporal columns.
skip_parallel_replication	OFF	-	See parallel replication.
skip_replication	OFF	-	See Selectively skipping replication of binlog events.
slave_allow_batching	-	OFF	MySQL-only replication variable.
slave_checkpoint_group	-	512	MySQL-only replication variable.
slave_checkpoint_period	-	300	MySQL-only replication variable.
slave_ddl_exec_mode	IDEMPOTENT	-	Modes for how replication of DDL events should be executed.
slave_domain_parallel_threads	0	-	For configuring parallel replication.
slave_net_timeout	3600	60	MySQL reduced the timeout to 60s.
slave_parallel_max_queued	131072	-	For configuring parallel replication.
skip_grant_tables	0	-	Only available as an option in MySQL.
slave_max_statement_time	0.000000	-	MariaDB setting to abort a query that has taken more than this in seconds to run on the replica.
slave_parallel_mode	optimistic	-	Controls what transactions are applied in parallel when using parallel_replication.
slave_parallel_threads	0	-	For configuring parallel replication.
slave_parallel_type	-	DATABASE	MySQL-only replication variable.
slave_pending_jobs_size_max	-	16777216	MySQL-only replication variable.
slave_preserve_commit_order	-	OFF	MySQL-only replication variable.
slave_rows_search_algorithms	-	INDEX_SCAN, HASH_SCAN	MySQL-only replication variable.
slave_run_triggers_for_rbr	NO		See Running triggers on the slave for Row-based events for a description and use-case for this setting.
slave_transaction_retry_errors	1213,1205	-	When an error occurs during a transaction on the slave, replication usually halts. By default, transactions that caused a deadlock or elapsed lock wait timeout will be retried. One can add other errors to the the list of errors that should be retried by adding a comma-separated list of error numbers to this variable.
slave_transaction_retry_interval	0	-	Interval in seconds for the slave SQL thread to retry a failed transaction due to a deadlock, elapsed lock wait timeout or an error listed in slave_transaction_retry_errors.
sort_buffer_size	2097152	262144	The default sort buffer allocated has been reduced in MySQL.
sql_if_exists	OFF	-	Adds an implicit IF EXISTS to ALTER, RENAME and DROP of TABLES, VIEWS, FUNCTIONS and PACKAGES
sql_mode	STRICT_TRANS_TABLES, ERROR_FOR_DIVISION_BY_ZERO, NO_AUTO_CREATE_USER, NO_ENGINE_SUBSTITUTION	ONLY_FULL_GROUP_BY, STRICT_TRANS_TABLES, NO_ZERO_IN_DATE, NO_ZERO_DATE, ERROR_FOR_DIVISION_BY_ZERO, NO_ENGINE_SUBSTITUTION	See SQL Mode.
ssl_fips_mode	-	OFF	Whether FIPS mode is enabled on the server side.
standard_compliant_cte	ON	-	See Common Table Expressions.
storage_engine	InnoDB	-	Alias for default_storage_engine, removed in MySQL.
strict_password_validation	ON	-	In MariaDB, when password validation plugins are enabled, reject passwords that cannot be validated (passwords specified as a hash).
stored_program_definition_cache	-	256	Limits the number of stored program definition objects kept in the dictionary object cache.
super_read_only	-	OFF	MySQL variable for prohibiting client updates from users with the SUPER privilege.
sync_binlog	0	1	MySQL synchronizes all actions to the binary log before they are committed.
sync_frm	1	-	.frm files have been removed in MySQL.

system_versioning_alter_history	ERROR	-	MariaDB has System-Versioned Tables
system_versioning_asof	DEFAULT	-	MariaDB has System-Versioned Tables
system_versioning_insert_history	OFF	-	MariaDB has System-Versioned Tables
table_definition_cache	400	-1 (autosized)	Number of table definitions that can be cached.
table_open_cache_instances	8	16	Maximum number of table cache instances.
tablespace_definition_cache	-	256	Limits the number of tablespace definition objects kept in the dictionary object cache.
tcp_keepalive_interval	0	-	Interval, in seconds, between when successive keep-alive packets are sent if no acknowledgement is received.
tcp_keepalive_probes	0	-	Number of unacknowledged probes to send before considering the connection dead and notifying the application layer.
tcp_keepalive_time	0	-	Set the TCP_NODELAY option (disable Nagle's algorithm) on socket.
tcp_nodelay	1	-	Timeout, in milliseconds, with no activity until the first TCP keep-alive packet is sent.
temptable_max_ram	-	1GB	Limits the RAM used by MySQL's TempTable storage engine.
thread_cache_size	Autosized	-1 (autosized)	MariaDB uses an improved thread pool.
thread_concurrency	10	-	Removed in MySQL 5.7.
thread_pool_dedicated_listener	0	-	Better precision for the data in the Information Schema THREADPOOL_QUEUES Table.
thread_pool_exact_stats	0	-	Better precision for the data in the Information Schema THREADPOOL_QUEUES Table.
thread_pool_idle_timeout	60	-	See Using the Thread Pool.
thread_pool_max_threads	65536	-	See Using the Thread Pool.
thread_pool_min_threads	1	-	Windows-only. See Using the Thread Pool.
thread_pool_oversubscribe	3	-	See Using the Thread Pool.
thread_pool_prio_kickup	auto	-	See Using the Thread Pool.
thread_pool_priority	auto	-	See Using the Thread Pool.
thread_pool_size	Number of processors	16*	See Using the Thread Pool. *Only available in MySQL with a commercial plugin.
thread_pool_stall_limit	500	6*	See Using the Thread Pool. *Only available in MySQL with a commercial plugin.
thread_stack	299008	Varies	See Using the Thread Pool.
time_format	%H:%i:%s	-	Removed in MySQL.
timed_mutexes	OFF	-	Removed in MySQL.
tmp_disk_table_size	18446744073709551615	-	Max size for data for an internal temporary on-disk MyISAM or Aria table.
tmp_memory_table_size	16777216	-	Alias for tmp_table_size.
transaction_allow_batching	-	OFF	Variable for enabling batching of statements within the same transaction in MySQL Cluster.
transaction_isolation	-	REPEATABLE-READ	The MariaDB equivalent is tx_isolation.
transaction_read_only	-	OFF	The MariaDB equivalent is tx_read_only.
transaction_write_set_extraction	-	OFF	Unused MySQL-only variable.
tx_isolation	REPEATABLE-READ	-	The MySQL equivalent is transaction_isolation.
tx_read_only	OFF	-	The MySQL equivalent is transaction_read_only.
use_stat_tables	preferably_for_queries	-	Controls the use of engine-independent table statistics.
userstat	OFF	-	Whether to activate MariaDB's User Statistics implementation, not available in MySQL.
version_compile_zlib	-	*	Version of the zlib library compiled in.
version_malloc_library	*	-	Version of the used malloc library.
version_source_revision	Varies	-	Permits seeing exactly which version of the source was used for a build.
version_ssl_library	*	-	Version of the used TLS library.

windowing_high_use_precision	-	*	MySQL option allowing safety to be sacrificed for speed in window function calculations.
wsrep_*	*	-	Galera cluster is only available in MariaDB.
Variable	**MariaDB 11.01**	**MySQL 8.0**	**Notes**

2.1.14.1.12.3 System Variable Differences Between MariaDB 10.11 and MySQL 8.0

Contents

The following is a comparison of variables that either appear only in MariaDB 10.11 or MySQL 8.0, or have different default settings in MariaDB 10.11, and MySQL 8.0. The releases MariaDB 10.11.2 and MySQL 8.0.34, with only default plugins enabled, were used for the comparison. Note that MySQL 8 is an 'evergreen' release, so features may be added or removed in later releases.

For a more complete list of differences, see Incompatibilities and Feature Differences Between MariaDB 10.11 and MySQL 8.0 and Function Differences Between MariaDB 10.11 and MySQL 8.0

Comparison Table

Variable	MariaDB 10.11 Default	MySQL 8.0 Default	Notes
activate_all_roles_on_login	-	OFF	Determines whether to automatically activate roles on login.
admin*	-	*	MySQL admin connections.
allow_suspicious_udfs	0	-	Only available as an option in MySQL.
alter_algorithm	DEFAULT	-	MariaDB 10.3 introduced new ALTER TABLE ALGORITHM clauses to avoid slow copies in certain instances. This variable allows setting this if no `ALGORITHM` clause is specified.
analyze_sample_percentage	100.0000	-	Percentage of rows from the table ANALYZE TABLE will sample to collect table statistics.
aria_*	*	-	The Aria storage engine is only available in MariaDB.
authentication_policy	-	*,,	MySQL authentication policy.
auto_generate_certs	-	ON	Whether to automatically generate SSL key and certificate files.
avoid_temporal_upgrade	-	OFF	Determines whether ALTER TABLE implicitly upgrades temporal columns.
back_log	Autosized	Autosized	MariaDB and MySQL have different autosizing algorithms.
binlog_alter_two_phase	OFF	-	When set, split ALTER at binary logging into two statements: START ALTER and COMMIT/ROLLBACK ALTER.
binlog_annotate_row_events	ON	-	Introduced in MariaDB 5.3 for replicating between MariaDB 5.3 and MySQL/MariaDB 5.1.
binlog_commit_wait_count	0	-	For use in MariaDB's parallel replication.
binlog_commit_wait_usec	100000	-	For use in MariaDB's parallel replication.
binlog_encryption	-	OFF	MySQL name for encrypt_binlog.
binlog_error_action		ABORT_SERVER	MySQL-only variable for controlling what happens when the server cannot write to the binary log.
binlog_expire_logs_auto_purge	-	ON	Enables or disables automatic purging of binary log files.
binlog_expire_logs_seconds	0	2592000	Sets the binary log expiration period in seconds
binlog_file_cache_size	16184	-	For setting the size of the file cache for the binary log.
binlog_format	MIXED	ROW	MariaDB and MySQL have differing binary log formats.
binlog_group_commit_sync_delay		0	MySQL-only variable for controlling the wait time before synchronizing the binary log file to disk.

binlog_group_commit_sync_no_delay_count		0	MySQL-only variable for setting the maximum number of transactions to wait for before aborting the current `binlog_group_commit_sync_delay` delay.
binlog_gtid_simple_recovery	-	ON	MySQL-only GTID variable. MariaDB's GTID implementation is different.
binlog_max_flush_queue_time	-	0	Specifies a timeout for reading transactions from the flush queue before continuing with group commit and syncing log to disk.
binlog_optimize_thread_scheduling	ON	-	For optimized kernel thread scheduling.
binlog_order_commits	-	ON	Determines whether transactions may be committed in parallel.
binlog_rotate_encryption_master_key_at_startup	-	OFF	Specifically for use with MySQL binary key encryption.
binlog_row_event_max_size	-	8192	Only available as a system variable in MariaDB 11.2.
binlog_row_metadata	NO_LOG	MINIMAL	Determines the amount of table metadata added to the binary log with row-based logging.
binlog_row_value_options	-	(empty)	Permits an alternative binlog format for JSON document updates.
binlog_rows_query_log_events	-	OFF	MySQL-only variable for logging extra information in row-based logging.
binlog_transaction_compression*	-	*	MySQL variables relating to binary log compression.
binlog_transaction_dependency_history_size	-	25000	Maximum number of row hashes kept for looking up transactions that last modified a given row.
binlog_transaction_dependency_tracking	-	COMMIT_ORDER	For determining how to best use the slave's multithreaded applier.
block_encryption_mode	-	aes-128-ecb	MySQL-only variable for controlling the block encryption mode for block-based algorithms.
caching_sha2_password*	-	*	For use with MySQL's SHA-256 authentication with caching.
character_set_*	latin1 or utf8	utf8mb4	MySQL 8.0 defaults to the utf8mb4 character set.
check_constraint_checks	ON	-	Permits disabling constraint checks, for example when loading a table that violates some constraints that you plan to fix later.
check_proxy_users		OFF	MySQL-only variable for controlling whether the server performs proxy user mapping for authentication plugins.
collation_*	latin1_swedish_ci or utf8_general_ci	utf8mb4_0900_ai_ci	MySQL 8.0 defaults to the utf8mb4 character set.
column_compression_threshold	100	-	MariaDB supports Storage-engine Independent Column Compression.
column_compression_zlib_level	6	-	MariaDB supports Storage-engine Independent Column Compression.
column_compression_zlib_strategy	DEFAULT_STRATEGY	-	MariaDB supports Storage-engine Independent Column Compression.
column_compression_zlib_wrap	OFF	-	MariaDB supports Storage-engine Independent Column Compression.
connection_memory_chunk_size	-	8192	Chunk size for updates to the Global_connection_memory counter.
connection_memory_limit	-	18446744073709551615	Maximum memory for a single user connection.
create_admin_listener_thread	-	OFF	MySQL-only variable for whether to use a dedicated listening thread for admin network interface connections.
cte_max_recursion_depth	-	1000	When MySQL 8.0 introduced common table expressions they used a different name. MariaDB's variable is called max_recursive_iterations.
date_format	%Y-%m-%d	-	Unused variable removed in MySQL 8.0
datetime_format	%Y-%m-%d	-	Unused variable removed in MySQL 8.0
deadlock_search_depth_long	15	-	The Aria storage engine is only available in MariaDB.
deadlock_search_depth_short	4	-	The Aria storage engine is only available in MariaDB.

deadlock_timeout_long	50000000	-	The Aria storage engine is only available in MariaDB.
deadlock_timeout_short	10000	-	The Aria storage engine is only available in MariaDB.
debug_no_thread_alarm	OFF	-	Disable system thread alarm calls, for debugging or testing.
default_authentication_plugin	-	caching_sha2_password	MySQL 8 introduced a new authentication plugin.
default_collation_for_utf8mb4	-	utf8mb4_0900_ai_ci	For internal use in MySQL 8 replication.
default_master_connection	empty	-	For use with MariaDB's multi-source replication.
default_password_lifetime	0	360	MariaDB defaults to password expiration off.
default_regex_flags	empty	-	For handling incompatibilities between MariaDB's PCRE and the old regex library.
default_tmp_storage_engine	empty	InnoDB	Default storage engine used for tables created with CREATE TEMPORARY TABLE.
disabled_storage_engines		empty	MySQL-only variable for disabling specific storage engines.
disconnect_on_expired_password	OFF	ON	MariaDB password expiration is off by default, and by default does not disconnect a client when a password has expired.
encrypt_binlog	OFF	-	MariaDB enables table and tablespace encryption.
encrypt_tmp_files	OFF	-	MariaDB enables table and tablespace encryption.
encrypt_tmp_disk_tables	OFF	-	MariaDB enables table and tablespace encryption.
end_markers_in_json	-	OFF	MySQL-only variable for adding end markers to JSON output.
enforce_gtid_consistency	-	OFF	MariaDB and MySQL have different GTID implementations.
enforce_storage_engine	none		Forces the use of a particular storage engine for new tables.
eq_range_index_dive_limit	0	200	Variable for tuning when the optimizer should switch from using index dives to index statistics for qualifying rows estimation.
event_scheduler	OFF	ON	MySQL enables the event scheduler by default.
expensive_subquery_limit	100	-	Used for determining expensive queries for optimization.
extra_max_connections	1	-	Introduced in the MariaDB 5.1 threadpool.
extra_port	0	-	Introduced in the MariaDB 5.1 threadpool.
group_concat_max_len	1048576	1024	MariaDB increases the maximum length for a GROUP_CONCAT() result from 1K to 1M.
gtid_binlog_pos	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_binlog_state	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_cleanup_batch_size	64	-	MariaDB and MySQL have different GTID implementations.
gtid_current_pos	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_domain_id	0	-	MariaDB and MySQL have different GTID implementations.
gtid_executed	-	empty	MariaDB and MySQL have different GTID implementations.
gtid_executed_compression_period	-	1000	MariaDB and MySQL have different GTID implementations.
gtid_ignore_duplicates	OFF	-	MariaDB and MySQL have different GTID implementations.
gtid_mode	-	OFF	MariaDB and MySQL have different GTID implementations.
gtid_next	-	AUTOMATIC	MariaDB and MySQL have different GTID implementations.
gtid_owned	-	empty	MariaDB and MySQL have different GTID implementations.

gtid_pos_auto_engines	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_purged	-	empty	MariaDB and MySQL have different GTID implementations.
gtid_seq_no	0	-	MariaDB and MySQL have different GTID implementations.
gtid_slave_pos	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_strict_mode	OFF	-	MariaDB and MySQL have different GTID implementations.
have_crypt	YES	-	MySQL has removed the ENCRYPT function.
have_openssl			MariaDB's version indicates whether YaSSL or openssl was used. MySQL's is a synonym for `have_ssl`.
have_query_cache	YES	-	MySQL has removed the query cache.
have_statement_timeout	-		Whether MySQL's statement execution timeout feature is available.
have_symlink	YES	DISABLED	MySQL has removed symlink support.
histogram_generation_max_mem_size	-	20000000	Added when MySQL 8 introduced Histogram-based Statistics. MariaDB uses histogram_size
histogram_size	0	-	MariaDB introduced Histogram-based Statistics.
histogram_type	DOUBLE_PREC_HB	-	MariaDB introduced Histogram-based Statistics.
idle_readonly_transaction_timeout	0	-	Time in seconds that the server waits for idle read-only transactions.
idle_transaction_timeout	0	-	Time in seconds that the server waits for idle transactions.
idle_write_transaction_timeout	0	-	Time in seconds that the server waits for idle write transactions.
ignore_builtin_innodb	OFF	-	Ignored and removed in MySQL 8.
in_predicate_conversion_threshold	1000	-	Controls the Conversion of Big IN Predicates Into Subqueries optimization.
in_transaction	0	-	Set to `1` if you are in a transaction, and `0` if not.
information_schema_stats_expiry	-	86400	Time until MySQL Information Schema cached statistics expire.
innodb_adaptive_flushing_lwm	10.000000	10	Adaptive flushing is enabled when this this low water mark percentage of the redo log capacity is reached. MariaDB's variable is a double, MySQL's an integer.
innodb_adaptive_hash_index	OFF	ON	Defaulting to OFF is a performance improvement especially for DROP TABLE, TRUNCATE TABLE, ALTER TABLE, or DROP INDEX operations
innodb_adaptive_max_sleep_delay	-	150000	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_api_*	-	*	Specific to MySQL's memcached, removed in MariaDB 10.2.
innodb_autoinc_lock_mode	1	2	MariaDB has an extra mode, `3`, for skipping the rollback of connected transactions. MySQL defaults to row-based replication, so can safely use `2`.
innodb_buffer_pool_instances	-	1	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6 since the original reasons for introducing no longer apply.
innodb_checksum_algorithm	full_crc32	crc32	`fullcrc32` permits encryption to be supported over a SPATIAL INDEX, which crc32 does not support.
innodb_checksums	ON	-	Deprecated option removed in MySQL.
innodb_commit_concurrency	-	0	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_compression_*	*	-	Introduced with MariaDB's InnoDB compression.
innodb_concurrency_tickets	-	5000	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_deadlock_report	Full	-	How to report deadlocks.
innodb_dedicated_server	-	OFF	MySQL option that automatically configures various settings if the server is a dedicated InnoDB database server.

innodb_default_encryption_key_id	1	-	Default encryption key id used for table encryption. See Data at Rest Encryption.
innodb_defragment	*	-	MariaDB can defragment InnoDB tablespaces.
innodb_directories	-	(empty)	Used to search for tablespace files when moving or restoring a new location.
innodb_disallow_writes	OFF	-	Tell InnoDB to stop any writes to disk.
innodb_encrypt_*	1	-	See MariaDB's Data at Rest Encryption.
innodb_fatal_semaphore_wait_threshold	600	-	MariaDB's fatal semaphore timeout is configurable.
innodb_flush_method	O_DIRECT	fsync	MariaDB InnoDB flushing method by default on Unix systems bypasses the file system cache for improved performance in most cases.
innodb_flush_neighbors	1	0	MySQL 8 by default now assumes the use of an SSD device.
innodb_force_primary_key	OFF	-	If set to 1 in MariaDB (0 is default) CREATE TABLEs without a primary or unique key where all keyparts are NOT NULL will not be accepted, and will return an error.
innodb_idle_flush_pct	100	-	Up to what percentage of dirty pages in MariaDB should be flushed when InnoDB finds it has spare resources to do so.
innodb_immediate_scrub_data_uncompressed	OFF	-	MariaDB has support for data scrubbing.
innodb_instant_alter_column_allowed	add_drop_reorder	-	See Instant ADD COLUMN for InnoDB.
innodb_locks_unsafe_for_binlog	OFF	-	Deprecated option in MariaDB for disabling gap locking for searches and index scans. Deprecated in MariaDB, use READ COMMITTED transaction isolation instead.
innodb_log_checksums	-	ON	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6, as there is no reason to allow checksums to be disabled on the redo log.
innodb_log_compressed_pages	-	ON	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6 as part of the InnoDB redo log performance improvements.
innodb_log_files_in_group	-	2	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6 as part of the InnoDB redo log performance improvements.
innodb_log_spin_*	-	*	MySQL variables for constraining CPU usage while waiting for flushed redo.
innodb_log_wait_for_flush_spin_hwm	-	*	MySQL variable for constraining CPU usage while waiting for flushed redo.
innodb_max_dirty_pages_pct	75	90	MySQL 8 increased the default to 90.
innodb_max_dirty_pages_pct_lwm	0	10	MySQL 8 increased the default to 10.
innodb_max_undo_log_size	10485760	1073741824	MariaDB 10.2 reduced the limit for when an undo tablespace is marked for truncation.
innodb_open_files	Autosized (2000)	Autosized (4000)	In most systems, autosized based on the table_open_cache setting, which differs between MariaDB and MySQL.
innodb_page_cleaners	-	1	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6 as the original reasons for for splitting the buffer pool have mostly gone away.
innodb_prefix_index_cluster_optimization	OFF	-	MariaDB includes the Facebook prefix index queries optimization.
innodb_print_ddl_logs	-	OFF	MySQL option for writing DDL logs to stderr.
innodb_read_only_compressed	ON	-	Whether to set ROW_FORMAT=COMPRESSED tables to read-only.
innodb_redo_log_encrypt	-	OFF	MySQL 8 has also now introduced redo log encryption, but used a different name. The equivalent option in MariaDB is innodb_encrypt_log.
innodb_replication_delay	-	0	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_spin_wait_delay	4	6	MariaDB changed the default from 6 to 4 based on extensive benchmarking.

innodb_stats_modified_counter	0	-	MariaDB option to control the calculation of new statistics.
innodb_stats_sample_pages	8	-	Deprecated MariaDB option for control over index distribution statistics.
innodb_stats_traditional	ON	-	Enabling gives a larger sample of pages for larger tables for the purposes of index statistics calculation.
innodb_sync_array_size	-	1	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_thread_concurrency	-	0	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_thread_sleep_delay	-	10000	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_undo_log_encrypt	-	OFF	MySQL option for encrypting undo logs residing in separate undo tablespaces.
innodb_undo_log_truncate	OFF	ON	MySQL 8 changes the default to ON, marking larger undo logs for truncation.
innodb_undo_tablespaces	0	2	Number of tablespace files used for dividing up the undo logs. MySQL 8 has deprecated this setting, and increased the default (and minimum) to 2.
innodb_use_atomic_writes	ON	-	Atomic writes are a faster alternative to innodb_doublewrite and MariaDB automatically detects when supporting SSD cards are used.
internal_tmp_disk_storage_engine	-	INNODB	MySQL uses this variable to set the storage engine for on-disk internal temporary tables.
internal_tmp_mem_storage_engine	-	TEMPTABLE	MySQL and MariaDB use different formats for temporary tables. In MariaDB, the aria_used_for_temp_tables performs a similar function.
join_buffer_space_limit	2097152	-	Maximum size in bytes of the query buffer. See block-based join algorithms.
join_cache_level	2	-	For determining the join algorithms. See block-based join algorithms
key_buffer_size	134217728	8388608	Size of the buffer for the index blocks used by MyISAM tables and shared for all threads.
key_cache_file_hash_size	512	-	Number of hash buckets for open and changed files.
key_cache_segments	0	-	The number of segments in a key cache. See Segmented Key Cache.
keyring_operations	-	ON	Whether MySQL 8's keyring operations are enabled.
last_gtid	-	empty	MariaDB and MySQL have different GTID implementations.
local_infile	ON	OFF	MySQL no longer supports LOAD DATA LOCAL by default.
lock_wait_timeout	86400	31536000	MariaDB has reduced the timeout for acquiring metadata locks.
log_bin	OFF	ON	MySQL 8 enables the binary log by default.
log_bin_compress	OFF	-	MariaDB setting for whether or not the binary log can be compressed.
log_bin_compress_min_len	256	-	Minimum length of sql statement (in statement mode) or record (in row mode) that can be compressed. See Compressing Events to Reduce Size of the Binary Log.
log_bin_use_v1_row_events	-	OFF	MySQL-only variable showing whether or not MySQL's version 2 binary logging format is being used.
log_disabled_statements	sp	-	Disable logging of certain statements to the general log.
log_error_services	-	log_filter_internal; log_sink_internal	Components to enable for MySQL error logging.
log_error_verbosity	-	3	MySQL variable for setting verbosity of error, warning, and note messages in the error log.
log_slave_updates	OFF	ON	MySQL 8 has by default enabled binary logging of updates a slave receives from a master.
log_slow_admin_statements	ON	OFF	MariaDB logs slow admin statements to the slow query log by default.

log_slow_disabled_statements	admin,call,slave,sp	-	Disable logging of certain statements to the slow query log.
log_slow_filter	admin, filesort, filesort_on_disk, full_join, full_scan, query_cache, query_cache_miss, tmp_table, tmp_table_on_disk	-	For slow query log filtering.
log_slow_rate_limit	1	-	Limits the number of queries logged to the slow query log.
log_slow_min_examined_row_limit	0	-	Previously named min_examined_row_limit (still an alias).
log_slow_query	0	-	Previously named log_slow_query (still an alias).
log_slow_query_file	host_name-slow.log	-	Previously named slow_query_log_file (still an alias).
log_slow_query_time	10.000000	-	Previously named long_query_time (still an alias).
log_slow_slave_statements	ON	OFF	MariaDB logs slow slave statements to the slow query log by default.
log_slow_verbosity	empty	-	Controls information to be added to the slow query log. See also Slow Query Log Extended Statistics.
log_statements_unsafe_for_binlog	-	ON	MySQL setting for controlling whether binlog warnings are written to the error log.
log_syslog*	platform-dependent	-	MySQL variables with settings for writing to syslog.
log_tc_size	24576	-	Size in bytes of the transaction coordinator log, defined in multiples of 4096.
log_throttle_queries_not_using_indexes	-	0	MySQL-only variable for limiting the number of statements without indexes written to the slow query log.
log_timestamps	-	UTC	MySQL-only variable controlling the timezone for certain logging conditions.
log_warnings	2	-	MySQL 8 has replaced with `log_error_verbosity`.
mandatory_roles	-	(empty)	MySQL variable for assigning roles to all users.
master_info_repository	-	TABLE	Whether slave logs master status and connection info to a table or a file.
max_allowed_packet	16M	64M	
max_error_count	64	1024	Specifies the maximum number of messages stored for display by SHOW ERRORS and SHOW WARNINGS statements.
max_execution_time	-	0	MySQL renamed the `max_statement_time` variable.
max_length_for_sort_data	64	1024	Used to decide which algorithm to choose when sorting rows. If the total size of the column data, not including columns that are part of the sort, is less than max_length_for_sort_data, then these are added to the sort key. This can speed up the sort as there's no need to re-read the same row again later. Setting the value too high can slow things down as there will be a higher disk activity for doing the sort.
max_long_data_size	16777216	-	Maximum size for parameter values sent with mysql_stmt_send_long_data(). Removed in MySQL 5.6.
max_password_errors	4294967295	-	Maximum number of failed connections attempts before no more are permitted.
max_points_in_geometry	-	65536	Maximum points_per_circle for MySQL's ST_Buffer_Strategy() function.
max_recursive_iterations	4294967295	-	Maximum number of iterations when executing recursive queries.
max_relay_log_size	1073741824	0	Can be set by session in MariaDB.
max_seeks_for_key	4294967295	4294967295 (32-bit) or 18446744073709547520 (64-bit)	The most key seeks required when searching with an index, regardless of the actual index cardinality. If this value is set lower than its default and maximum, indexes will tend to be preferred over table scans.
max_session_mem_used	9223372036854775807	-	Amount of memory a single user session is allowed to allocate.

max_statement_time	0	-	Maximum time in seconds that a query can execute before being aborted. MySQL used to have a variable of this name before renaming it `max_execution_time`.
max_tmp_tables	32	-	Unused variable removed in MySQL.
max_write_lock_count	4294967295	4294967295 (32-bit) or 18446744073709547520 (64-bit)	Read lock requests will be permitted for processing after this many write locks.
mrr_buffer_size	262144	-	Size of buffer to use when using multi-range read with range access. See Multi Range Read optimization.
myisam_block_size	1024	-	Block size used for MyISAM index pages.
myisam_recover_options	BACKUP,QUICK	OFF	MyISAM recovery mode.
myisam_sort_buffer_size	134216704	8388608	Size in bytes of the buffer allocated when creating or sorting indexes on a MyISAM table.
mysql_native_password_proxy_users	-	OFF	Whether MySQL's authentication plugin supports proxy users. I
mysql56_temporal_format	ON		Causes MariaDB to use the MySQL-5.6 low level formats for TIME, DATETIME and TIMESTAMP instead of the MariaDB 5.3+ version.
new	-	OFF	Used for backward-compatibility with MySQL 4.1, not present in MariaDB.
mysqlx+*	-	*	MySQL's X plugin related variables.
ngram_token_size	-	2	Sets the n-gram token size for MySQL's n-gram full-text parser.
offline_mode	-	OFF	MySQL setttting for specifying whether the server should run in offline mode.
old_alter_table	DEFAULT	OFF	An alias for alter_algorithm.
old_mode	Empty string	-	Used for getting MariaDB to emulate behavior from an old version of MySQL or MariaDB. See OLD Mode.
old_passwords	OFF	-	MySQL 8 is no longer compatible with the old pre-MySQL 4.1 form of password hashing.
optimizer_extra_pruning_depth	8	-	If the optimizer needs to enumerate a join prefix of this size or larger, then it will try aggressively prune away the search space.
optimizer_selectivity_sampling_limit	100	-	Controls number of record samples to check condition selectivity.
optimizer_switch	See details		A series of flags for controlling the query optimizer. MariaDB has introduced a number of new settings.
optimizer_trace_*	-	*	MySQL has more settings for optimizer tracing.
optimizer_use_condition_selectivity	4	-	Controls which statistics can be used by the optimizer when looking for the best query execution plan.
original_commit_timestamp	-	*	Used by MySQL 8 for delaying replication.
parser_max_mem_size	-	4294967295 (32-bit) or 18446744073709547520 (64-bit)	MySQL variable for limiting memory available to the parser.
password_*	-	*	Controls reuse of previous passwords in MySQL.
performance_schema	OFF	ON	The Performance Schema is off by default in MariaDB.
performance_schema_*			Many performance schema variables are autoset in MySQL, and MySQL has a different version, with additional variables.
plugin_maturity	One less than the server maturity	-	Minimum acceptable plugin maturity.
progress_report_time	5	-	Time in seconds between sending progress reports to the client for time-consuming statements.
proxy_protocol_networks	(empty)	-	Enable proxy protocol for these source networks.
query_alloc_block_size	16384	8192	Size in bytes of the extra blocks allocated during query parsing and execution (after query_prealloc_size is used up).
query_cache_*	*	-	MySQL has removed the query cache.

query_prealloc_size	24576	8192	Size in bytes of the persistent buffer for query parsing and execution, allocated on connect and freed on disconnect.
range_optimizer_max_mem_size	-	8388608	MySQL-only variable setting a limit on the range optimizer's memory usage.
rbr_exec_mode	-	STRICT	MySQL-only variable for determining the handling of certain key errors.
read_binlog_speed_limit	0	-	Permits restricting the speed at which the slave reads the binlog from the master.
regexp_*	-	*	Memory and time limits for regular expression matching operations.
relay_log_info_repository	-	TABLE	MySQL-only variable determining whether the slave's position in the relay logs is written to a file or table.
replicate_annotate_row_events	ON	-	Tells the slave to reproduce annotate_rows_events received from the master in its own binary log.
replicate_do_db	empty string	-	See Dynamic Replication Variables.
replicate_do_table	empty string	-	See Dynamic Replication Variables.
replicate_events_marked_for_skip	replicate	-	See Selectively skipping replication of binlog events.
replicate_ignore_db	empty string	-	See Dynamic Replication Variables.
replicate_ignore_table	empty string	-	See Dynamic Replication Variables.
replicate_rewrite_db	empty string	-	Only available as an option in MySQL.
replicate_wild_do_table	empty string	-	See Dynamic Replication Variables.
replicate_wild_ignore_table	empty string	-	See Dynamic Replication Variables.
result_metadata	-	FULL	Determine whether the server returns result set metadata for connections where this is optional.
rowid_merge_buff_size	8388608	-	See Non-semi-join subquery optimizations.
rpl_read_size	-	8192	Minimum data in bytes read from the binary and relay log files.
rpl_semi_sync_*	-	-	MariaDB includes semisynchronous replication without the need to install a plugin.
rpl_stop_slave_timeout	-	31536000	Controls the time that STOP SLAVE waits before timing out.
s3_*	*	-	The S3 storage engine is only available in MariaDB.
schema_definition_cache	-	256	Limits the number of schema definition objects kept in the dictionary object cache.
secure_auth	ON	-	Removed in MySQL.
secure_timestamp	NO	-	MariaDB-only option permitting the restricting of direct setting of a session timestamp..
server_id_bits	-	server_id	MySQL-only variable for use in MySQL Cluster.
server_uuid	-	UUID	MySQL-only variable containing the UUID.
session_track_gtids	-	OFF	MySQL-only variables for tracking gtid changes. MariaDB and MySQL's gtid implementation is different.
sha256_password_proxy_users	-	OFF	MySQL-only variable determining whether the sha256_password plugin supports proxy users.
show_create_table_verbosity	-	OFF	Option to cause SHOW CREATE TABLE to display ROW_FORMAT in all cases.
show_old_temporals	-	OFF	MySQL-only variable for determining whether SHOW CREATE TABLE output should include comments for old format temporal columns.
skip_parallel_replication	OFF	-	See parallel replication.
skip_replication	OFF	-	See Selectively skipping replication of binlog events.
slave_allow_batching	-	OFF	MySQL-only replication variable.
slave_checkpoint_group	-	512	MySQL-only replication variable.
slave_checkpoint_period	-	300	MySQL-only replication variable.
slave_ddl_exec_mode	IDEMPOTENT	-	Modes for how replication of DDL events should be executed.

slave_domain_parallel_threads	0	-	For configuring parallel replication.
slave_max_statement_time	0.000000	-	MariaDB setting to abort a query that has taken more than this in seconds to run on the replica.
slave_net_timeout	3600	60	MySQL reduced the timeout to 60s.
slave_parallel_max_queued	131072	-	For configuring parallel replication.
skip_grant_tables	0	-	Only available as an option in MySQL.
slave_parallel_mode	optimistic	-	Controls what transactions are applied in parallel when using parallel_replication.
slave_parallel_threads	0	-	For configuring parallel replication.
slave_parallel_type	-	DATABASE	MySQL-only replication variable.
slave_pending_jobs_size_max	-	16777216	MySQL-only replication variable.
slave_preserve_commit_order	-	OFF	MySQL-only replication variable.
slave_rows_search_algorithms	-	INDEX_SCAN, HASH_SCAN	MySQL-only replication variable.
slave_run_triggers_for_rbr	NO		See Running triggers on the slave for Row-based events for a description and use-case for this setting.
slave_transaction_retry_errors	1213,1205	-	When an error occurs during a transaction on the slave, replication usually halts. By default, transactions that caused a deadlock or elapsed lock wait timeout will be retried. One can add other errors to the the list of errors that should be retried by adding a comma-separated list of error numbers to this variable.
slave_transaction_retry_interval	0	-	Interval in seconds for the slave SQL thread to retry a failed transaction due to a deadlock, elapsed lock wait timeout or an error listed in slave_transaction_retry_errors.
sort_buffer_size	2097152	262144	The default sort buffer allocated has been reduced in MySQL.
sql_if_exists	OFF	-	Adds an implicit IF EXISTS to ALTER, RENAME and DROP of TABLES, VIEWS, FUNCTIONS and PACKAGES
sql_mode	STRICT_TRANS_TABLES, ERROR_FOR_DIVISION_BY_ZERO, NO_AUTO_CREATE_USER, NO_ENGINE_SUBSTITUTION	ONLY_FULL_GROUP_BY, STRICT_TRANS_TABLES, NO_ZERO_IN_DATE, NO_ZERO_DATE, ERROR_FOR_DIVISION_BY_ZERO, NO_ENGINE_SUBSTITUTION	See SQL Mode.
ssl_fips_mode	-	OFF	Whether FIPS mode is enabled on the server side.
standard_compliant_cte	ON	-	See Common Table Expressions.
storage_engine	InnoDB	-	Alias for default_storage_engine, removed in MySQL.
strict_password_validation	ON	-	In MariaDB, when password validation plugins are enabled, reject passwords that cannot be validated (passwords specified as a hash).
stored_program_definition_cache	-	256	Limits the number of stored program definition objects kept in the dictionary object cache.
super_read_only	-	OFF	MySQL variable for prohibiting client updates from users with the SUPER privilege.
sync_binlog	0	1	MySQL synchronizes all actions to the binary log before they are committed.
sync_frm	1	-	.frm files have been removed in MySQL.
system_versioning_alter_history	ERROR	-	MariaDB has System-Versioned Tables
system_versioning_asof	DEFAULT	-	MariaDB has System-Versioned Tables
system_versioning_insert_history	OFF	-	MariaDB has System-Versioned Tables
table_definition_cache	400	-1 (autosized)	Number of table definitions that can be cached.
table_open_cache_instances	8	16	Maximum number of table cache instances.
tablespace_definition_cache	-	256	Limits the number of tablespace definition objects kept in the dictionary object cache.
tcp_keepalive_interval	0	-	Interval, in seconds, between when successive keep-alive packets are sent if no acknowledgement is received.

tcp_keepalive_probes	0	-	Number of unacknowledged probes to send before considering the connection dead and notifying the application layer.
tcp_keepalive_time	0	-	Set the TCP_NODELAY option (disable Nagle's algorithm) on socket.
tcp_nodelay	1	-	Timeout, in milliseconds, with no activity until the first TCP keep-alive packet is sent.
temptable_max_ram	-	1GB	Limits the RAM used by MySQL's TempTable storage engine.
thread_cache_size	Autosized	-1 (autosized)	MariaDB uses an improved thread pool.
thread_concurrency	10	-	Removed in MySQL 5.7.
thread_pool_dedicated_listener	0	-	Better precision for the data in the Information Schema THREADPOOL_QUEUES Table.
thread_pool_exact_stats	0	-	Better precision for the data in the Information Schema THREADPOOL_QUEUES Table.
thread_pool_idle_timeout	60	-	See Using the Thread Pool.
thread_pool_max_threads	65536	-	See Using the Thread Pool.
thread_pool_min_threads	1	-	Windows-only. See Using the Thread Pool.
thread_pool_oversubscribe	3	-	See Using the Thread Pool.
thread_pool_prio_kickup	auto	-	See Using the Thread Pool.
thread_pool_priority	auto	-	See Using the Thread Pool.
thread_pool_size	Number of processors	16*	See Using the Thread Pool. *Only available in MySQL with a commercial plugin.
thread_pool_stall_limit	500	6*	See Using the Thread Pool. *Only available in MySQL with a commercial plugin.
thread_stack	299008	Varies	See Using the Thread Pool.
time_format	%H:%i:%s	-	Removed in MySQL.
timed_mutexes	OFF	-	Removed in MySQL.
tmp_disk_table_size	18446744073709551615	-	Max size for data for an internal temporary on-disk MyISAM or Aria table.
tmp_memory_table_size	16777216	-	Alias for tmp_table_size.
transaction_allow_batching	-	OFF	Variable for enabling batching of statements within the same transaction in MySQL Cluster.
transaction_isolation	-	REPEATABLE-READ	The MariaDB equivalent is tx_isolation.
transaction_read_only	-	OFF	The MariaDB equivalent is tx_read_only.
transaction_write_set_extraction	-	OFF	Unused MySQL-only variable.
tx_isolation	REPEATABLE-READ	-	The MySQL equivalent is transaction_isolation.
tx_read_only	OFF	-	The MySQL equivalent is transaction_read_only.
use_stat_tables	preferably_for_queries	-	Controls the use of engine-independent table statistics.
userstat	OFF	-	Whether to activate MariaDB's User Statistics implementation, not available in MySQL.
version_compile_zlib	-	*	Version of the zlib library compiled in.
version_malloc_library	*	-	Version of the used malloc library.
version_source_revision	Varies	-	Permits seeing exactly which version of the source was used for a build.
version_ssl_library	*	-	Version of the used TLS library.
windowing_high_use_precision	-	*	MySQL option allowing safety to be sacrificed for speed in window function calculations.
wsrep_*	*	-	Galera cluster is only available in MariaDB.
Variable	**MariaDB 10.11**	**MySQL 8.0**	**Notes**

2.1.14.1.12.4 System Variable Differences Between MariaDB 10.10 and MySQL 8.0

Contents

The following is a comparison of variables that either appear only in MariaDB 10.10 or MySQL 8.0, or have different default settings in MariaDB 10.10, and MySQL 8.0. The releases MariaDB 10.10.3 and MySQL 8.0.11, with only default plugins enabled, were used for the comparison. Note that MySQL 8 is an 'evergreen' release, so features may be added or removed in later releases.

For a more complete list of differences, see Incompatibilities and Feature Differences Between MariaDB 10.10 and MySQL 8.0 and Function Differences Between MariaDB 10.10 and MySQL 8.0

Comparison Table

Variable	MariaDB 10.10 Default	MySQL 8.0 Default	Notes
activate_all_roles_on_login	-	OFF	Determines whether to automatically activate roles on login.
allow_suspicious_udfs	0	-	Only available as an option in MySQL.
alter_algorithm	DEFAULT	-	MariaDB 10.3 introduced new ALTER TABLE ALGORITHM clauses to avoid slow copies in certain instances. This variable allows setting this if no `ALGORITHM` clause is specified.
analyze_sample_percentage	100.0000	-	Percentage of rows from the table ANALYZE TABLE will sample to collect table statistics.
aria_*	*	-	The Aria storage engine is only available in MariaDB.
auto_generate_certs	-	ON	Whether to automatically generate SSL key and certificate files.
avoid_temporal_upgrade	-	OFF	Determines whether ALTER TABLE implicitly upgrades temporal columns.
back_log	Autosized	Autosized	MariaDB and MySQL have different autosizing algorithms.
binlog_alter_two_phase	OFF	-	When set, split ALTER at binary logging into two statements: START ALTER and COMMIT/ROLLBACK ALTER.
binlog_annotate_row_events	ON	-	Introduced in MariaDB 5.3 for replicating between MariaDB 5.3 and MySQL/MariaDB 5.1.
binlog_commit_wait_count	0	-	For use in MariaDB's parallel replication.
binlog_commit_wait_usec	100000	-	For use in MariaDB's parallel replication.
binlog_error_action		ABORT_SERVER	MySQL-only variable for controlling what happens when the server cannot write to the binary log.
binlog_expire_logs_seconds	0	2592000	Sets the binary log expiration period in seconds
binlog_file_cache_size	16184	-	For setting the size of the file cache for the binary log.
binlog_format	MIXED	ROW	MariaDB and MySQL have differing binary log formats.
binlog_group_commit_sync_delay		0	MySQL-only variable for controlling the wait time before synchronizing the binary log file to disk.
binlog_group_commit_sync_no_delay_count		0	MySQL-only variable for setting the maximum number of transactions to wait for before aborting the current `binlog_group_commit_sync_delay` delay.
binlog_gtid_simple_recovery	-	ON	MySQL-only GTID variable. MariaDB's GTID implementation is different.
binlog_max_flush_queue_time	-	0	Specifies a timeout for reading transactions from the flush queue before continuing with group commit and syncing log to disk.
binlog_optimize_thread_scheduling	ON	-	For optimized kernel thread scheduling.
binlog_order_commits	-	ON	Determines whether transactions may be committed in parallel.
binlog_row_metadata	NO_LOG	MINIMAL	Determines the amount of table metadata added to the binary log with row-based logging.
binlog_row_value_options	-	(empty)	Permits an alternative binlog format for JSON document updates.

binlog_rows_query_log_events	-	OFF	MySQL-only variable for logging extra information in row-based logging.
binlog_transaction_dependency_history_size	-	25000	Maximum number of row hashes kept for looking up transactions that last modified a given row.
binlog_transaction_dependency_tracking	-	COMMIT_ORDER	For determining how to best use the slave's multithreaded applier.
block_encryption_mode	-	aes-128-ecb	MySQL-only variable for controlling the block encryption mode for block-based algorithms.
caching_sha2_password*	-	*	For use with MySQL's SHA-256 authentication with caching.
character_set_*	latin1 or utf8	utf8mb4	MySQL 8.0 defaults to the utf8mb4 character set.
check_constraint_checks	ON	-	Permits disabling constraint checks, for example when loading a table that violates some constraints that you plan to fix later.
check_proxy_users		OFF	MySQL-only variable for controlling whether the server performs proxy user mapping for authentication plugins.
collation_*	latin1_swedish_ci or utf8_general_ci	utf8mb4_0900_ai_ci	MySQL 8.0 defaults to the utf8mb4 character set.
column_compression_threshold	100	-	MariaDB supports Storage-engine Independent Column Compression.
column_compression_zlib_level	6	-	MariaDB supports Storage-engine Independent Column Compression.
column_compression_zlib_strategy	DEFAULT_STRATEGY	-	MariaDB supports Storage-engine Independent Column Compression.
column_compression_zlib_wrap	OFF	-	MariaDB supports Storage-engine Independent Column Compression.
cte_max_recursion_depth	-	1000	When MySQL 8.0 introduced common table expressions they used a different name. MariaDB's variable is called max_recursive_iterations.
date_format	%Y-%m-%d	-	Unused variable removed in MySQL 8.0
datetime_format	%Y-%m-%d	-	Unused variable removed in MySQL 8.0
deadlock_search_depth_long	15	-	The Aria storage engine is only available in MariaDB.
deadlock_search_depth_short	4	-	The Aria storage engine is only available in MariaDB.
deadlock_timeout_long	50000000	-	The Aria storage engine is only available in MariaDB.
deadlock_timeout_short	10000	-	The Aria storage engine is only available in MariaDB.
debug_no_thread_alarm	OFF	-	Disable system thread alarm calls, for debugging or testing.
default_authentication_plugin	-	caching_sha2_password	MySQL 8 introduced a new authentication plugin.
default_collation_for_utf8mb4	-	utf8mb4_0900_ai_ci	For internal use in MySQL 8 replication.
default_master_connection	empty	-	For use with MariaDB's multi-source replication.
default_password_lifetime	0	360	MariaDB defaults to password expiration off.
default_regex_flags	empty	-	For handling incompatibilities between MariaDB's PCRE and the old regex library.
default_tmp_storage_engine	empty	InnoDB	Default storage engine used for tables created with CREATE TEMPORARY TABLE.
disabled_storage_engines		empty	MySQL-only variable for disabling specific storage engines.
disconnect_on_expired_password	OFF	ON	MariaDB password expiration is off by default, and by default does not disconnect a client when a password has expired.
encrypt_binlog	OFF	-	MariaDB enables table and tablespace encryption.
encrypt_tmp_files	OFF	-	MariaDB enables table and tablespace encryption.
encrypt_tmp_disk_tables	OFF	-	MariaDB enables table and tablespace encryption.
end_markers_in_json	-	OFF	MySQL-only variable for adding end markers to JSON output.

enforce_gtid_consistency	-	OFF	MariaDB and MySQL have different GTID implementations.
enforce_storage_engine	none		Forces the use of a particular storage engine for new tables.
eq_range_index_dive_limit	0	200	Variable for tuning when the optimizer should switch from using index dives to index statistics for qualifying rows estimation.
event_scheduler	OFF	ON	MySQL enables the event scheduler by default.
expensive_subquery_limit	100	-	Used for determining expensive queries for optimization.
extra_max_connections	1	-	Introduced in the MariaDB 5.1 threadpool.
extra_port	0	-	Introduced in the MariaDB 5.1 threadpool.
group_concat_max_len	1048576	1024	MariaDB increases the maximum length for a GROUP_CONCAT() result from 1K to 1M.
gtid_binlog_pos	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_binlog_state	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_cleanup_batch_size	64	-	MariaDB and MySQL have different GTID implementations.
gtid_current_pos	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_domain_id	0	-	MariaDB and MySQL have different GTID implementations.
gtid_executed	-	empty	MariaDB and MySQL have different GTID implementations.
gtid_executed_compression_period	-	1000	MariaDB and MySQL have different GTID implementations.
gtid_ignore_duplicates	OFF	-	MariaDB and MySQL have different GTID implementations.
gtid_mode	-	OFF	MariaDB and MySQL have different GTID implementations.
gtid_next	-	AUTOMATIC	MariaDB and MySQL have different GTID implementations.
gtid_owned	-	empty	MariaDB and MySQL have different GTID implementations.
gtid_pos_auto_engines	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_purged	-	empty	MariaDB and MySQL have different GTID implementations.
gtid_seq_no	0	-	MariaDB and MySQL have different GTID implementations.
gtid_slave_pos	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_strict_mode	OFF	-	MariaDB and MySQL have different GTID implementations.
have_crypt	YES	-	MySQL has removed the ENCRYPT function.
have_openssl			MariaDB's version indicates whether YaSSL or openssl was used. MySQL's is a synonym for `have_ssl`.
have_query_cache	YES	-	MySQL has removed the query cache.
have_statement_timeout	-		Whether MySQL's statement execution timeout feature is available.
have_symlink	YES	DISABLED	MySQL has removed symlink support.
histogram_generation_max_mem_size	-	20000000	Added when MySQL 8 introduced Histogram-based Statistics. MariaDB uses histogram_size
histogram_size	0	-	MariaDB introduced Histogram-based Statistics.
histogram_type	SINGLE_PREC_HB	-	MariaDB introduced Histogram-based Statistics.
idle_readonly_transaction_timeout	0	-	Time in seconds that the server waits for idle read-only transactions.
idle_transaction_timeout	0	-	Time in seconds that the server waits for idle transactions.
idle_write_transaction_timeout	0	-	Time in seconds that the server waits for idle write transactions.
ignore_builtin_innodb	OFF	-	Ignored and removed in MySQL 8.

in_predicate_conversion_threshold	1000	-	Controls the Conversion of Big IN Predicates Into Subqueries optimization.
in_transaction	0	-	Set to `1` if you are in a transaction, and `0` if not.
information_schema_stats_expiry	-	86400	Time until MySQL Information Schema cached statistics expire.
innodb_adaptive_flushing_lwm	10.000000	10	Adaptive flushing is enabled when this this low water mark percentage of the redo log capacity is reached. MariaDB's variable is a double, MySQL's an integer.
innodb_adaptive_hash_index	OFF	ON	Defaulting to OFF is a performance improvement especially for DROP TABLE, TRUNCATE TABLE, ALTER TABLE, or DROP INDEX operations
innodb_adaptive_max_sleep_delay	-	150000	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_api_*	-	*	Specific to MySQL's memcached, removed in MariaDB 10.2.
innodb_autoinc_lock_mode	1	2	MariaDB has an extra mode, `3`, for skipping the rollback of connected transactions. MySQL defaults to row-based replication, so can safely use `2`.
innodb_buffer_pool_instances	-	1	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6 since the original reasons for introducing no longer apply.
innodb_checksum_algorithm	full_crc32	crc32	`fullcrc32` permits encryption to be supported over a SPATIAL INDEX, which crc32 does not support.
innodb_checksums	ON	-	Deprecated option removed in MySQL.
innodb_commit_concurrency	-	0	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_compression_*	*	-	Introduced with MariaDB's InnoDB compression.
innodb_concurrency_tickets	-	5000	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_deadlock_report	Full	-	How to report deadlocks.
innodb_dedicated_server	-	OFF	MySQL option that automatically configures various settings if the server is a dedicated InnoDB database server.
innodb_default_encryption_key_id	1	-	Default encryption key id used for table encryption. See Data at Rest Encryption.
innodb_defragment	*	-	MariaDB can defragment InnoDB tablespaces.
innodb_directories	-	(empty)	Used to search for tablespace files when moving or restoring a new location.
innodb_disallow_writes	OFF	-	Tell InnoDB to stop any writes to disk.
innodb_encrypt_*	1	-	See MariaDB's Data at Rest Encryption.
innodb_fatal_semaphore_wait_threshold	600	-	MariaDB's fatal semaphore timeout is configurable.
innodb_flush_method	O_DIRECT	fsync	MariaDB InnoDB flushing method by default on Unix systems bypasses the file system cache for improved performance in most cases.
innodb_flush_neighbors	1	0	MySQL 8 by default now assumes the use of an SSD device.
innodb_force_primary_key	OFF	-	If set to 1 in MariaDB (0 is default) CREATE TABLEs without a primary or unique key where all keyparts are NOT NULL will not be accepted, and will return an error.
innodb_idle_flush_pct	100	-	Up to what percentage of dirty pages in MariaDB should be flushed when InnoDB finds it has spare resources to do so.
innodb_immediate_scrub_data_uncompressed	OFF	-	MariaDB has support for data scrubbing.
innodb_instant_alter_column_allowed	add_drop_reorder	-	See Instant ADD COLUMN for InnoDB.
innodb_locks_unsafe_for_binlog	OFF	-	Deprecated option in MariaDB for disabling gap locking for searches and index scans. Deprecated in MariaDB, use READ COMMITTED transaction isolation instead.
innodb_log_checksums	-	ON	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6, as there is no reason to allow checksums to be disabled on the redo log.

innodb_log_compressed_pages	-	ON	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6 as part of the InnoDB redo log performance improvements.
innodb_log_files_in_group	-	2	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6 as part of the InnoDB redo log performance improvements.
innodb_log_spin_*	-	*	MySQL variables for constraining CPU usage while waiting for flushed redo.
innodb_log_wait_for_flush_spin_hwm	-	*	MySQL variable for constraining CPU usage while waiting for flushed redo.
innodb_max_dirty_pages_pct	75	90	MySQL 8 increased the default to 90.
innodb_max_dirty_pages_pct_lwm	0	10	MySQL 8 increased the default to 10.
innodb_max_undo_log_size	10485760	1073741824	MariaDB 10.2 reduced the limit for when an undo tablespace is marked for truncation.
innodb_open_files	Autosized (2000)	Autosized (4000)	In most systems, autosized based on the table_open_cache setting, which differs between MariaDB and MySQL.
innodb_page_cleaners	-	1	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6 as the original reasons for for splitting the buffer pool have mostly gone away.
innodb_prefix_index_cluster_optimization	OFF	-	MariaDB includes the Facebook prefix index queries optimization.
innodb_print_ddl_logs	-	OFF	MySQL option for writing DDL logs to stderr.
innodb_read_only_compressed	ON	-	Whether to set ROW_FORMAT=COMPRESSED tables to read-only.
innodb_redo_log_encrypt	-	OFF	MySQL 8 has also now introduced redo log encryption, but used a different name. The equivalent option in MariaDB is innodb_encrypt_log.
innodb_replication_delay	-	0	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_spin_wait_delay	4	6	MariaDB changed the default from 6 to 4 based on extensive benchmarking.
innodb_stats_modified_counter	0	-	MariaDB option to control the calculation of new statistics.
innodb_stats_sample_pages	8	-	Deprecated MariaDB option for control over index distribution statistics.
innodb_stats_traditional	ON	-	Enabling gives a larger sample of pages for larger tables for the purposes of index statistics calculation.
innodb_sync_array_size	-	1	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_thread_concurrency	-	0	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_thread_sleep_delay	-	10000	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_undo_log_encrypt	-	OFF	MySQL option for encrypting undo logs residing in separate undo tablespaces.
innodb_undo_log_truncate	OFF	ON	MySQL 8 changes the default to ON, marking larger undo logs for truncation.
innodb_undo_tablespaces	0	2	Number of tablespace files used for dividing up the undo logs. MySQL 8 has deprecated this setting, and increased the default (and minimum) to 2.
innodb_use_atomic_writes	ON	-	Atomic writes are a faster alternative to innodb_doublewrite and MariaDB automatically detects when supporting SSD cards are used.
internal_tmp_disk_storage_engine	-	INNODB	MySQL uses this variable to set the storage engine for on-disk internal temporary tables.
internal_tmp_mem_storage_engine	-	TEMPTABLE	MySQL and MariaDB use different formats for temporary tables. In MariaDB, the aria_used_for_temp_tables performs a similar function.
join_buffer_space_limit	2097152	-	Maximum size in bytes of the query buffer. See block-based join algorithms.
join_cache_level	2	-	For determining the join algorithms. See block-based join algorithms

key_buffer_size	134217728	8388608	Size of the buffer for the index blocks used by MyISAM tables and shared for all threads.
key_cache_file_hash_size	512	-	Number of hash buckets for open and changed files.
key_cache_segments	0	-	The number of segments in a key cache. See Segmented Key Cache.
keyring_operations	-	ON	Whether MySQL 8's keyring operations are enabled.
last_gtid	-	empty	MariaDB and MySQL have different GTID implementations.
local_infile	ON	OFF	MySQL no longer supports LOAD DATA LOCAL by default.
lock_wait_timeout	86400	31536000	MariaDB has reduced the timeout for acquiring metadata locks.
log_bin	OFF	ON	MySQL 8 enables the binary log by default.
log_bin_compress	OFF	-	MariaDB setting for whether or not the binary log can be compressed.
log_bin_compress_min_len	256	-	Minimum length of sql statement (in statement mode) or record (in row mode) that can be compressed. See Compressing Events to Reduce Size of the Binary Log.
log_bin_use_v1_row_events	-	OFF	MySQL-only variable showing whether or not MySQL's version 2 binary logging format is being used.
log_disabled_statements	sp	-	Disable logging of certain statements to the general log.
log_error_services	-	log_filter_internal; log_sink_internal	Components to enable for MySQL error logging.
log_error_verbosity	-	3	MySQL variable for setting verbosity of error, warning, and note messages in the error log.
log_slave_updates	OFF	ON	MySQL 8 has by default enabled binary logging of updates a slave receives from a master.
log_slow_admin_statements	ON	OFF	MariaDB logs slow admin statements to the slow query log by default.
log_slow_disabled_statements	admin,call,slave,sp	-	Disable logging of certain statements to the slow query log.
log_slow_filter	admin, filesort, filesort_on_disk, full_join, full_scan, query_cache, query_cache_miss, tmp_table, tmp_table_on_disk	-	For slow query log filtering.
log_slow_rate_limit	1	-	Limits the number of queries logged to the slow query log.
log_slow_slave_statements	ON	OFF	MariaDB logs slow slave statements to the slow query log by default.
log_slow_verbosity	empty	-	Controls information to be added to the slow query log. See also Slow Query Log Extended Statistics.
log_statements_unsafe_for_binlog	-	ON	MySQL setting for controlling whether binlog warnings are written to the error log.
log_syslog*	platform-dependent	-	MySQL variables with settings for writing to syslog.
log_tc_size	24576	-	Size in bytes of the transaction coordinator log, defined in multiples of 4096.
log_throttle_queries_not_using_indexes	-	0	MySQL-only variable for limiting the number of statements without indexes written to the slow query log.
log_timestamps	-	UTC	MySQL-only variable controlling the timezone for certain logging conditions.
log_warnings	2	-	MySQL 8 has replaced with `log_error_verbosity`.
mandatory_roles	-	(empty)	MySQL variable for assigning roles to all users.
master_info_repository	-	TABLE	Whether slave logs master status and connection info to a table or a file.
max_allowed_packet	16M	64M	
max_error_count	64	1024	Specifies the maximum number of messages stored for display by SHOW ERRORS and SHOW WARNINGS statements.

max_execution_time	-	0	MySQL renamed the `max_statement_time` variable.
max_length_for_sort_data	64	1024	Used to decide which algorithm to choose when sorting rows. If the total size of the column data, not including columns that are part of the sort, is less than max_length_for_sort_data, then these are added to the sort key. This can speed up the sort as there's no need to re-read the same row again later. Setting the value too high can slow things down as there will be a higher disk activity for doing the sort.
max_long_data_size	16777216	-	Maximum size for parameter values sent with mysql_stmt_send_long_data(). Removed in MySQL 5.6.
max_password_errors	4294967295	-	Maximum number of failed connections attempts before no more are permitted.
max_points_in_geometry	-	65536	Maximum points_per_circle for MySQL's ST_Buffer_Strategy() function.
max_recursive_iterations	4294967295	-	Maximum number of iterations when executing recursive queries.
max_relay_log_size	1073741824	0	Can be set by session in MariaDB.
max_seeks_for_key	4294967295	4294967295 (32-bit) or 18446744073709547520 (64-bit)	The most key seeks required when searching with an index, regardless of the actual index cardinality. If this value is set lower than its default and maximum, indexes will tend to be preferred over table scans.
max_session_mem_used	9223372036854775807	-	Amount of memory a single user session is allowed to allocate.
max_statement_time	0	-	Maximum time in seconds that a query can execute before being aborted. MySQL used to have a variable of this name before renaming it `max_execution_time`.
max_tmp_tables	32	-	Unused variable removed in MySQL.
max_write_lock_count	4294967295	4294967295 (32-bit) or 18446744073709547520 (64-bit)	Read lock requests will be permitted for processing after this many write locks.
mrr_buffer_size	262144	-	Size of buffer to use when using multi-range read with range access. See Multi Range Read optimization.
myisam_block_size	1024	-	Block size used for MyISAM index pages.
myisam_recover_options	BACKUP,QUICK	OFF	MyISAM recovery mode.
myisam_sort_buffer_size	134216704	8388608	Size in bytes of the buffer allocated when creating or sorting indexes on a MyISAM table.
mysql_native_password_proxy_users	-	OFF	Whether MySQL's authentication plugin supports proxy users. I
mysql56_temporal_format	ON		Causes MariaDB to use the MySQL-5.6 low level formats for TIME, DATETIME and TIMESTAMP instead of the MariaDB 5.3+ version.
new	-	OFF	Used for backward-compatibility with MySQL 4.1, not present in MariaDB.
mysqlx+*	-	*	MySQL's X plugin related variables.
ngram_token_size	-	2	Sets the n-gram token size for MySQL's n-gram full-text parser.
offline_mode	-	OFF	MySQL settting for specifying whether the server should run in offline mode.
old_alter_table	DEFAULT	OFF	An alias for alter_algorithm.
old_mode	Empty string	-	Used for getting MariaDB to emulate behavior from an old version of MySQL or MariaDB. See OLD Mode.
old_passwords	OFF	-	MySQL 8 is no longer compatible with the old pre-MySQL 4.1 form of password hashing.
optimizer_extra_pruning_depth	8	-	If the optimizer needs to enumerate a join prefix of this size or larger, then it will try aggressively prune away the search space.
optimizer_selectivity_sampling_limit	100	-	Controls number of record samples to check condition selectivity.
optimizer_switch	See details		A series of flags for controlling the query optimizer. MariaDB has introduced a number of new settings.

optimizer_trace_*	-	*	MySQL has more settings for optimizer tracing.
optimizer_use_condition_selectivity	4	-	Controls which statistics can be used by the optimizer when looking for the best query execution plan.
original_commit_timestamp	-	*	Used by MySQL 8 for delaying replication.
parser_max_mem_size	-	4294967295 (32-bit) or 18446744073709547520 (64-bit)	MySQL variable for limiting memory available to the parser.
password_*	-	*	Controls reuse of previous passwords in MySQL.
performance_schema	OFF	ON	The Performance Schema is off by default in MariaDB.
performance_schema_*			Many performance schema variables are autoset in MySQL, and MySQL has a different version, with additional variables.
plugin_maturity	One less than the server maturity	-	Minimum acceptable plugin maturity.
progress_report_time	5	-	Time in seconds between sending progress reports to the client for time-consuming statements.
proxy_protocol_networks	(empty)	-	Enable proxy protocol for these source networks.
query_alloc_block_size	16384	8192	Size in bytes of the extra blocks allocated during query parsing and execution (after query_prealloc_size is used up).
query_cache_*	*	-	MySQL has removed the query cache.
query_prealloc_size	24576	8192	Size in bytes of the persistent buffer for query parsing and execution, allocated on connect and freed on disconnect.
range_optimizer_max_mem_size	-	8388608	MySQL-only variable setting a limit on the range optimizer's memory usage.
rbr_exec_mode	-	STRICT	MySQL-only variable for determining the handling of certain key errors.
read_binlog_speed_limit	0	-	Permits restricting the speed at which the slave reads the binlog from the master.
regexp_*	-	*	Memory and time limits for regular expression matching operations.
relay_log_info_repository	-	TABLE	MySQL-only variable determining whether the slave's position in the relay logs is written to a file or table.
replicate_annotate_row_events	ON	-	Tells the slave to reproduce annotate_rows_events received from the master in its own binary log.
replicate_do_db	empty string	-	See Dynamic Replication Variables.
replicate_do_table	empty string	-	See Dynamic Replication Variables.
replicate_events_marked_for_skip	replicate	-	See Selectively skipping replication of binlog events.
replicate_ignore_db	empty string	-	See Dynamic Replication Variables.
replicate_ignore_table	empty string	-	See Dynamic Replication Variables.
replicate_wild_do_table	empty string	-	See Dynamic Replication Variables.
replicate_wild_ignore_table	empty string	-	See Dynamic Replication Variables.
result_metadata	-	FULL	Determine whether the server returns result set metadata for connections where this is optional.
rowid_merge_buff_size	8388608	-	See Non-semi-join subquery optimizations.
rpl_read_size	-	8192	Minimum data in bytes read from the binary and relay log files.
rpl_semi_sync_*	-	-	MariaDB includes semisynchronous replication without the need to install a plugin.
rpl_stop_slave_timeout	-	31536000	Controls the time that STOP SLAVE waits before timing out.
s3_*	*	-	The S3 storage engine is only available in MariaDB.
schema_definition_cache	-	256	Limits the number of schema definition objects kept in the dictionary object cache.
secure_auth	ON	-	Removed in MySQL.
secure_timestamp	NO	-	MariaDB-only option permitting the restricting of direct setting of a session timestamp..
server_id_bits	-	server_id	MySQL-only variable for use in MySQL Cluster.

server_uuid	-	UUID	MySQL-only variable containing the UUID.
session_track_gtids	-	OFF	MySQL-only variables for tracking gtid changes. MariaDB and MySQL's gtid implementation is different.
sha256_password_proxy_users	-	OFF	MySQL-only variable determining whether the sha256_password plugin supports proxy users.
show_create_table_verbosity	-	OFF	Option to cause SHOW CREATE TABLE to display ROW_FORMAT in all cases.
show_old_temporals	-	OFF	MySQL-only variable for determining whether SHOW CREATE TABLE output should include comments for old format temporal columns.
skip_parallel_replication	OFF	-	See parallel replication.
skip_replication	OFF	-	See Selectively skipping replication of binlog events.
slave_allow_batching	-	OFF	MySQL-only replication variable.
slave_checkpoint_group	-	512	MySQL-only replication variable.
slave_checkpoint_period	-	300	MySQL-only replication variable.
slave_ddl_exec_mode	IDEMPOTENT	-	Modes for how replication of DDL events should be executed.
slave_domain_parallel_threads	0	-	For configuring parallel replication.
slave_net_timeout	3600	60	MySQL reduced the timeout to 60s.
slave_parallel_max_queued	131072	-	For configuring parallel replication.
skip_grant_tables	0	-	Only available as an option in MySQL.
slave_max_statement_time	0.000000	-	MariaDB setting to abort a query that has taken more than this in seconds to run on the replica.
slave_parallel_mode	optimistic	-	Controls what transactions are applied in parallel when using parallel_replication.
slave_parallel_threads	0	-	For configuring parallel replication.
slave_parallel_type	-	DATABASE	MySQL-only replication variable.
slave_pending_jobs_size_max	-	16777216	MySQL-only replication variable.
slave_preserve_commit_order	-	OFF	MySQL-only replication variable.
slave_rows_search_algorithms	-	INDEX_SCAN, HASH_SCAN	MySQL-only replication variable.
slave_run_triggers_for_rbr	NO		See Running triggers on the slave for Row-based events for a description and use-case for this setting.
slave_transaction_retry_errors	1213,1205	-	When an error occurs during a transaction on the slave, replication usually halts. By default, transactions that caused a deadlock or elapsed lock wait timeout will be retried. One can add other errors to the the list of errors that should be retried by adding a comma-separated list of error numbers to this variable.
slave_transaction_retry_interval	0	-	Interval in seconds for the slave SQL thread to retry a failed transaction due to a deadlock, elapsed lock wait timeout or an error listed in slave_transaction_retry_errors.
sort_buffer_size	2097152	262144	The default sort buffer allocated has been reduced in MySQL.
sql_if_exists	OFF	-	Adds an implicit IF EXISTS to ALTER, RENAME and DROP of TABLES, VIEWS, FUNCTIONS and PACKAGES
sql_mode	STRICT_TRANS_TABLES, ERROR_FOR_DIVISION_BY_ZERO, NO_AUTO_CREATE_USER, NO_ENGINE_SUBSTITUTION	ONLY_FULL_GROUP_BY, STRICT_TRANS_TABLES, NO_ZERO_IN_DATE, NO_ZERO_DATE, ERROR_FOR_DIVISION_BY_ZERO, NO_ENGINE_SUBSTITUTION	See SQL Mode.
ssl_fips_mode	-	OFF	Whether FIPS mode is enabled on the server side.
standard_compliant_cte	ON	-	See Common Table Expressions.
storage_engine	InnoDB	-	Alias for default_storage_engine, removed in MySQL.
strict_password_validation	ON	-	In MariaDB, when password validation plugins are enabled, reject passwords that cannot be validated (passwords specified as a hash).
stored_program_definition_cache	-	256	Limits the number of stored program definition objects kept in the dictionary object cache.

super_read_only	-	OFF	MySQL variable for prohibiting client updates from users with the SUPER privilege.
sync_binlog	0	1	MySQL synchronizes all actions to the binary log before they are committed.
sync_frm	1	-	.frm files have been removed in MySQL.
system_versioning_alter_history	ERROR	-	MariaDB has System-Versioned Tables
system_versioning_asof	DEFAULT	-	MariaDB has System-Versioned Tables
table_definition_cache	400	-1 (autosized)	Number of table definitions that can be cached.
table_open_cache_instances	8	16	Maximum number of table cache instances.
tablespace_definition_cache	-	256	Limits the number of tablespace definition objects kept in the dictionary object cache.
tcp_keepalive_interval	0	-	Interval, in seconds, between when successive keep-alive packets are sent if no acknowledgement is received.
tcp_keepalive_probes	0	-	Number of unacknowledged probes to send before considering the connection dead and notifying the application layer.
tcp_keepalive_time	0	-	Set the TCP_NODELAY option (disable Nagle's algorithm) on socket.
tcp_nodelay	1	-	Timeout, in milliseconds, with no activity until the first TCP keep-alive packet is sent.
temptable_max_ram	-	1GB	Limits the RAM used by MySQL's TempTable storage engine.
thread_cache_size	Autosized	-1 (autosized)	MariaDB uses an improved thread pool.
thread_concurrency	10	-	Removed in MySQL 5.7.
thread_pool_dedicated_listener	0	-	Better precision for the data in the Information Schema THREADPOOL_QUEUES Table.
thread_pool_exact_stats	0	-	Better precision for the data in the Information Schema THREADPOOL_QUEUES Table.
thread_pool_idle_timeout	60	-	See Using the Thread Pool.
thread_pool_max_threads	65536	-	See Using the Thread Pool.
thread_pool_min_threads	1	-	Windows-only. See Using the Thread Pool.
thread_pool_oversubscribe	3	-	See Using the Thread Pool.
thread_pool_prio_kickup	auto	-	See Using the Thread Pool.
thread_pool_priority	auto	-	See Using the Thread Pool.
thread_pool_size	Number of processors	16*	See Using the Thread Pool. *Only available in MySQL with a commercial plugin.
thread_pool_stall_limit	500	6*	See Using the Thread Pool. *Only available in MySQL with a commercial plugin.
thread_stack	299008	Varies	See Using the Thread Pool.
time_format	%H:%i:%s	-	Removed in MySQL.
timed_mutexes	OFF	-	Removed in MySQL.
tmp_disk_table_size	18446744073709551615	-	Max size for data for an internal temporary on-disk MyISAM or Aria table.
tmp_memory_table_size	16777216	-	Alias for tmp_table_size.
transaction_allow_batching	-	OFF	Variable for enabling batching of statements within the same transaction in MySQL Cluster.
transaction_isolation	-	REPEATABLE-READ	The MariaDB equivalent is tx_isolation.
transaction_read_only	-	OFF	The MariaDB equivalent is tx_read_only.
transaction_write_set_extraction	-	OFF	Unused MySQL-only variable.
tx_isolation	REPEATABLE-READ	-	The MySQL equivalent is transaction_isolation.
tx_read_only	OFF	-	The MySQL equivalent is transaction_read_only.
use_stat_tables	preferably_for_queries	-	Controls the use of engine-independent table statistics.
userstat	OFF	-	Whether to activate MariaDB's User Statistics implementation, not available in MySQL.
version_compile_zlib	-	*	Version of the zlib library compiled in.

version_malloc_library	*	-	Version of the used malloc library.
version_source_revision	Varies	-	Permits seeing exactly which version of the source was used for a build.
version_ssl_library	*	-	Version of the used TLS library.
windowing_high_use_precision	-	*	MySQL option allowing safety to be sacrificed for speed in window function calculations.
wsrep_*	*	-	Galera cluster is only available in MariaDB.
Variable	**MariaDB 10.10**	**MySQL 8.0**	**Notes**

2.1.14.1.12.5 System Variable Differences Between MariaDB 10.6 and MySQL 8.0

Contents

The following is a comparison of variables that either appear only in MariaDB 10.6 or MySQL 8.0, or have different default settings in MariaDB 10.6, and MySQL 8.0. The stable releases MariaDB 10.6.4 and MySQL 8.0.11, with only default plugins enabled, were used for the comparison. Note that MySQL 8 is an 'evergreen' release, so features may be added or removed in later releases.

For a more complete list of differences, see Incompatibilities and Feature Differences Between MariaDB 10.6 and MySQL 8.0 and Function Differences Between MariaDB 10.6 and MySQL 8.0

The most notable differences are that MariaDB includes, by default, the Aria storage engine (resulting in extra memory allocation), Galera Cluster, and has a different thread pool implementation. For this reason, a default implementation of MariaDB 10.6 will use more memory than MySQL 8.0. MariaDB 10.6 and MySQL 8.0 also have different GTID implementations.

MariaDB's extra memory usage can be handled with the following rules of thumb:

- If you are not using MyISAM and don't plan to use Aria:
  - Set key_buffer_size to something very low (16K) as it's not used.
  - Set aria_pagecache_buffer_size to what you think you need for handling internal tmp tables that didn't fit in memory.
  - Normally this is what before you had set for key_buffer_size (at least 1M).
- If you are using MyISAM and not planning to use Aria:
  - Set aria_pagecache_buffer_size to what you think you need for handling internal tmp tables that didn't fit in memory.
- If you are planning to use Aria, you should set aria_pagecache_buffer_size to something that fits a big part of your normal data + overflow temporary tables.

Comparison Table

Variable	MariaDB 10.6 Default	MySQL 8.0 Default	Notes
activate_all_roles_on_login	-	OFF	Determines whether to automatically activate roles on login.
alter_algorithm	DEFAULT	-	MariaDB 10.3 introduced new ALTER TABLE ALGORITHM clauses to avoid slow copies in certain instances. This variable allows setting this if no `ALGORITHM` clause is specified.
analyze_sample_percentage	100.0000	-	Percentage of rows from the table ANALYZE TABLE will sample to collect table statistics.
aria_*	*	-	The Aria storage engine is only available in MariaDB.
auto_generate_certs	-	ON	Whether to automatically generate SSL key and certificate files.
avoid_temporal_upgrade	-	OFF	Determines whether ALTER TABLE implicitly upgrades temporal columns.
back_log	Autosized	Autosized	MariaDB and MySQL have different autosizing algorithms.
binlog-annotate-row-events	ON	-	Introduced in MariaDB 5.3 for replicating between MariaDB 5.3 and MySQL/MariaDB 5.1.
binlog_commit_wait_count	0	-	For use in MariaDB's parallel replication.

binlog_commit_wait_usec	100000	-	For use in MariaDB's parallel replication.
binlog_error_action		ABORT_SERVER	MySQL-only variable for controlling what happens when the server cannot write to the binary log.
binlog_expire_logs_seconds	0	2592000	Sets the binary log expiration period in seconds
binlog_file_cache_size	16184	-	For setting the size of the file cache for the binary log.
binlog_format	MIXED	ROW	MariaDB and MySQL have differing binary log formats.
binlog_group_commit_sync_delay		0	MySQL-only variable for controlling the wait time before synchronizing the binary log file to disk.
binlog_group_commit_sync_no_delay_count		0	MySQL-only variable for setting the maximum number of transactions to wait for before aborting the current `binlog_group_commit_sync_delay` delay.
binlog_gtid_simple_recovery	-	ON	MySQL-only GTID variable. MariaDB's GTID implementation is different.
binlog_max_flush_queue_time	-	0	Specifies a timeout for reading transactions from the flush queue before continuing with group commit and syncing log to disk.
binlog_optimize_thread_scheduling	ON	-	For optimized kernel thread scheduling.
binlog_order_commits	-	ON	Determines whether transactions may be committed in parallel.
binlog_row_metadata	NO_LOG	MINIMAL	Determines the amount of table metadata added to the binary log with row-based logging.
binlog_row_value_options	-	(empty)	Permits an alternative binlog format for JSON document updates.
binlog_rows_query_log_events	-	OFF	MySQL-only variable for logging extra information in row-based logging.
binlog_transaction_dependency_history_size	-	25000	Maximum number of row hashes kept for looking up transactions that last modified a given row.
binlog_transaction_dependency_tracking	-	COMMIT_ORDER	For determining how to best use the slave's multithreaded applier.
block_encryption_mode	-	aes-128-ecb	MySQL-only variable for controlling the block encryption mode for block-based algorithms.
caching_sha2_password*	-	*	For use with MySQL's SHA-256 authentication with caching.
character_set_*	latin1 or utf8	utf8mb4	MySQL 8.0 defaults to the utf8mb4 character set.
check_constraint_checks	ON	-	Permits disabling constraint checks, for example when loading a table that violates some constraints that you plan to fix later.
check_proxy_users		OFF	MySQL-only variable for controlling whether the server performs proxy user mapping for authentication plugins.
collation_*	latin1_swedish_ci or utf8_general_ci	utf8mb4_0900_ai_ci	MySQL 8.0 defaults to the utf8mb4 character set.
column_compression_threshold	100	-	MariaDB supports Storage-engine Independent Column Compression.
column_compression_zlib_level	6	-	MariaDB supports Storage-engine Independent Column Compression.
column_compression_zlib_strategy	DEFAULT_STRATEGY	-	MariaDB supports Storage-engine Independent Column Compression.
column_compression_zlib_wrap	OFF	-	MariaDB supports Storage-engine Independent Column Compression.
cte_max_recursion_depth	-	1000	When MySQL 8.0 introduced common table expressions they used a different name. MariaDB's variable is called max_recursive_iterations.
date_format	%Y-%m-%d	-	Unused variable removed in MySQL 8.0
datetime_format	%Y-%m-%d	-	Unused variable removed in MySQL 8.0
deadlock_search_depth_long	15	-	The Aria storage engine is only available in MariaDB.
deadlock_search_depth_short	4	-	The Aria storage engine is only available in MariaDB.
deadlock_timeout_long	50000000	-	The Aria storage engine is only available in MariaDB.

deadlock_timeout_short	10000	-	The Aria storage engine is only available in MariaDB.
debug_no_thread_alarm	OFF	-	Disable system thread alarm calls, for debugging or testing.
default_authentication_plugin	-	caching_sha2_password	MySQL 8 introduced a new authentication plugin.
default_collation_for_utf8mb4	-	utf8mb4_0900_ai_ci	For internal use in MySQL 8 replication.
default_master_connection	empty	-	For use with MariaDB's multi-source replication.
default_password_lifetime	0	360	MariaDB defaults to password expiration off.
default_regex_flags	empty	-	For handling incompatibilities between MariaDB's PCRE and the old regex library.
default_tmp_storage_engine	empty	InnoDB	Default storage engine used for tables created with CREATE TEMPORARY TABLE.
disabled_storage_engines		empty	MySQL-only variable for disabling specific storage engines.
disconnect_on_expired_password	OFF	ON	MariaDB password expiration is off by default, and by default does not disconnect a client when a password has expired.
encrypt_binlog	OFF	-	MariaDB enables table and tablespace encryption.
encrypt_tmp_files	OFF	-	MariaDB enables table and tablespace encryption.
encrypt_tmp_disk_tables	OFF	-	MariaDB enables table and tablespace encryption.
end_markers_in_json	-	OFF	MySQL-only variable for adding end markers to JSON output.
enforce_gtid_consistency	-	OFF	MariaDB and MySQL have different GTID implementations.
enforce_storage_engine	none		Forces the use of a particular storage engine for new tables.
eq_range_index_dive_limit	0	200	Variable for tuning when the optimizer should switch from using index dives to index statistics for qualifying rows estimation.
event_scheduler	OFF	ON	MySQL enables the event scheduler by default.
expensive_subquery_limit	100	-	Used for determining expensive queries for optimization.
explicit_defaults_for_timestamp	OFF	ON	MySQL 8 disables the old timestamp behavior.
extra_max_connections	1	-	Introduced in the MariaDB 5.1 threadpool.
extra_port	0	-	Introduced in the MariaDB 5.1 threadpool.
group_concat_max_len	1048576	1024	MariaDB increases the maximum length for a GROUP_CONCAT() result from 1K to 1M.
gtid_binlog_pos	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_binlog_state	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_cleanup_batch_size	64	-	MariaDB and MySQL have different GTID implementations.
gtid_current_pos	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_domain_id	0	-	MariaDB and MySQL have different GTID implementations.
gtid_executed	-	empty	MariaDB and MySQL have different GTID implementations.
gtid_executed_compression_period	-	1000	MariaDB and MySQL have different GTID implementations.
gtid_ignore_duplicates	OFF	-	MariaDB and MySQL have different GTID implementations.
gtid_mode	-	OFF	MariaDB and MySQL have different GTID implementations.
gtid_next	-	AUTOMATIC	MariaDB and MySQL have different GTID implementations.
gtid_owned	-	empty	MariaDB and MySQL have different GTID implementations.
gtid_pos_auto_engines	empty	-	MariaDB and MySQL have different GTID implementations.

gtid_purged	-	empty	MariaDB and MySQL have different GTID implementations.
gtid_seq_no	0	-	MariaDB and MySQL have different GTID implementations.
gtid_slave_pos	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_strict_mode	OFF	-	MariaDB and MySQL have different GTID implementations.
have_crypt	YES	-	MySQL has removed the ENCRYPT function.
have_openssl			MariaDB's version indicates whether YaSSL or openssl was used. MySQL's is a synonym for `have_ssl`.
have_query_cache	YES	-	MySQL has removed the query cache.
have_statement_timeout	-		Whether MySQL's statement execution timeout feature is available.
have_symlink	YES	DISABLED	MySQL has removed symlink support.
histogram_generation_max_mem_size	-	20000000	Added when MySQL 8 introduced Histogram-based Statistics. MariaDB uses histogram_size
histogram_size	0	-	MariaDB introduced Histogram-based Statistics.
histogram_type	DOUBLE_PREC_HB	-	MariaDB introduced Histogram-based Statistics.
idle_readonly_transaction_timeout	0	-	Time in seconds that the server waits for idle read-only transactions.
idle_transaction_timeout	0	-	Time in seconds that the server waits for idle transactions.
idle_write_transaction_timeout	0	-	Time in seconds that the server waits for idle write transactions.
ignore_builtin_innodb	OFF	-	Ignored and removed in MySQL 8.
in_predicate_conversion_threshold	1000	-	Controls the Conversion of Big IN Predicates Into Subqueries optimization.
in_transaction	0	-	Set to `1` if you are in a transaction, and `0` if not.
information_schema_stats_expiry	-	86400	Time until MySQL Information Schema cached statistics expire.
innodb_adaptive_flushing_lwm	10.000000	10	Adaptive flushing is enabled when this this low water mark percentage of the redo log capacity is reached. MariaDB's variable is a double, MySQL's an integer.
innodb_adaptive_hash_index	OFF	ON	Defaulting to OFF is a performance improvement especially for DROP TABLE, TRUNCATE TABLE, ALTER TABLE, or DROP INDEX operations
innodb_adaptive_max_sleep_delay	-	150000	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_api_*	-	*	Specific to MySQL's memcached, removed in MariaDB 10.2.
innodb_autoinc_lock_mode	1	2	MariaDB has an extra mode, `3`, for skipping the rollback of connected transactions. MySQL defaults to row-based replication, so can safely use `2`.
innodb_buffer_pool_instances	-	1	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6 since the original reasons for introducing no longer apply.
innodb_checksum_algorithm	full_crc32	crc32	`fullcrc32` permits encryption to be supported over a SPATIAL INDEX, which crc32 does not support.
innodb_checksums	ON	-	Deprecated option removed in MySQL.
innodb_commit_concurrency	-	0	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_compression_*	*	-	Introduced with MariaDB's InnoDB compression.
innodb_concurrency_tickets	-	5000	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_deadlock_report	Full	-	How to report deadlocks.
innodb_dedicated_server	-	OFF	MySQL option that automatically configures various settings if the server is a dedicated InnoDB database server.
innodb_default_encryption_key_id	1	-	Default encryption key id used for table encryption. See Data at Rest Encryption.

innodb_defragment	*	-	MariaDB can defragment InnoDB tablespaces.
innodb_directories	-	(empty)	Used to search for tablespace files when moving or restoring a new location.
innodb_disallow_writes	OFF	-	Tell InnoDB to stop any writes to disk.
innodb_encrypt_*	1	-	See MariaDB's Data at Rest Encryption.
innodb_fatal_semaphore_wait_threshold	600	-	MariaDB's fatal semaphore timeout is configurable.
innodb_flush_method	O_DIRECT	fsync	MariaDB 10.6 InnoDB flushing method by default on Unix systems bypasses the file system cache for improved performance in most cases.
innodb_flush_neighbors	1	0	MySQL 8 by default now assumes the use of an SSD device.
innodb_force_primary_key	OFF	-	If set to 1 in MariaDB (0 is default) CREATE TABLEs without a primary or unique key where all keyparts are NOT NULL will not be accepted, and will return an error.
innodb_idle_flush_pct	100	-	Up to what percentage of dirty pages in MariaDB should be flushed when InnoDB finds it has spare resources to do so.
innodb_immediate_scrub_data_uncompressed	OFF	-	MariaDB has support for data scrubbing.
innodb_instant_alter_column_allowed	add_drop_reorder	-	See Instant ADD COLUMN for InnoDB.
innodb_locks_unsafe_for_binlog	OFF	-	Deprecated option in MariaDB for disabling gap locking for searches and index scans. Deprecated in MariaDB, use READ COMMITTED transaction isolation instead.
innodb_log_checksums	-	ON	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6, as there is no reason to allow checksums to be disabled on the redo log.
innodb_log_compressed_pages	-	ON	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6 as part of the InnoDB redo log performance improvements.
innodb_log_files_in_group	-	2	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6 as part of the InnoDB redo log performance improvements.
innodb_log_spin_*	-	*	MySQL variables for constraining CPU usage while waiting for flushed redo.
innodb_log_wait_for_flush_spin_hwm	-	*	MySQL variable for constraining CPU usage while waiting for flushed redo.
innodb_max_dirty_pages_pct	75	90	MySQL 8 increased the default to 90.
innodb_max_dirty_pages_pct_lwm	0	10	MySQL 8 increased the default to 10.
innodb_max_undo_log_size	10485760	1073741824	MariaDB 10.2 reduced the limit for when an undo tablespace is marked for truncation.
innodb_open_files	Autosized (2000)	Autosized (4000)	In most systems, autosized based on the table_open_cache setting, which differs between MariaDB and MySQL.
innodb_page_cleaners	-	1	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6 as the original reasons for for splitting the buffer pool have mostly gone away.
innodb_prefix_index_cluster_optimization	OFF	-	MariaDB includes the Facebook prefix index queries optimization.
innodb_print_ddl_logs	-	OFF	MySQL option for writing DDL logs to stderr.
innodb_read_only_compressed	ON	-	Whether to set ROW_FORMAT=COMPRESSED tables to read-only.
innodb_redo_log_encrypt	-	OFF	MySQL 8 has also now introduced redo log encryption, but used a different name. The equivalent option in MariaDB is innodb_encrypt_log.
innodb_replication_delay	-	0	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_spin_wait_delay	4	6	MariaDB changed the default from 6 to 4 based on extensive benchmarking.
innodb_stats_modified_counter	0	-	MariaDB option to control the calculation of new statistics.
innodb_stats_sample_pages	8	-	Deprecated MariaDB option for control over index distribution statistics.

innodb_stats_traditional	ON	-	Enabling gives a larger sample of pages for larger tables for the purposes of index statistics calculation.
innodb_sync_array_size	-	1	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_thread_concurrency	-	0	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_thread_sleep_delay	-	10000	Deprecated and ignored in MariaDB 10.5 and removed in MariaDB 10.6.
innodb_undo_log_encrypt	-	OFF	MySQL option for encrypting undo logs residing in separate undo tablespaces.
innodb_undo_log_truncate	OFF	ON	MySQL 8 changes the default to ON, marking larger undo logs for truncation.
innodb_undo_tablespaces	0	2	Number of tablespace files used for dividing up the undo logs. MySQL 8 has deprecated this setting, and increased the default (and minimum) to 2.
innodb_use_atomic_writes	ON	-	Atomic writes are a faster alternative to innodb_doublewrite and MariaDB automatically detects when supporting SSD cards are used.
internal_tmp_disk_storage_engine	-	INNODB	MySQL uses this variable to set the storage engine for on-disk internal temporary tables.
internal_tmp_mem_storage_engine	-	TEMPTABLE	MySQL and MariaDB use different formats for temporary tables. In MariaDB, the aria_used_for_temp_tables performs a similar function.
join_buffer_space_limit	2097152	-	Maximum size in bytes of the query buffer. See block-based join algorithms.
join_cache_level	2	-	For determining the join algorithms. See block-based join algorithms
key_buffer_size	134217728	8388608	Size of the buffer for the index blocks used by MyISAM tables and shared for all threads.
key_cache_file_hash_size	512	-	Number of hash buckets for open and changed files.
key_cache_segments	0	-	The number of segments in a key cache. See Segmented Key Cache.
keyring_operations	-	ON	Whether MySQL 8's keyring operations are enabled.
last_gtid	-	empty	MariaDB and MySQL have different GTID implementations.
local_infile	ON	OFF	MySQL no longer supports LOAD DATA LOCAL by default.
lock_wait_timeout	86400	31536000	MariaDB has reduced the timeout for acquiring metadata locks.
log_bin	OFF	ON	MySQL 8 enables the binary log by default.
log_bin_compress	OFF	-	MariaDB setting for whether or not the binary log can be compressed.
log_bin_compress_min_len	256	-	Minimum length of sql statement (in statement mode) or record (in row mode) that can be compressed. See Compressing Events to Reduce Size of the Binary Log.
log_bin_use_v1_row_events	-	OFF	MySQL-only variable showing whether or not MySQL's version 2 binary logging format is being used.
log_disabled_statements	sp	-	Disable logging of certain statements to the general log.
log_error_services	-	log_filter_internal; log_sink_internal	Components to enable for MySQL error logging.
log_error_verbosity	-	3	MySQL variable for setting verbosity of error, warning, and note messages in the error log.
log_slave_updates	OFF	ON	MySQL 8 has by default enabled binary logging of updates a slave receives from a master.
log_slow_admin_statements	ON	OFF	MariaDB logs slow admin statements to the slow query log by default.
log_slow_disabled_statements	admin,call,slave,sp	-	Disable logging of certain statements to the slow query log.

log_slow_filter	admin, filesort, filesort_on_disk, full_join, full_scan, query_cache, query_cache_miss, tmp_table, tmp_table_on_disk	-	For slow query log filtering.
log_slow_rate_limit	1	-	Limits the number of queries logged to the slow query log.
log_slow_slave_statements	ON	OFF	MariaDB logs slow slave statements to the slow query log by default.
log_slow_verbosity	empty	-	Controls information to be added to the slow query log. See also Slow Query Log Extended Statistics.
log_statements_unsafe_for_binlog	-	ON	MySQL setting for controlling whether binlog warnings are written to the error log.
log_syslog*	platform-dependent	-	MySQL variables with settings for writing to syslog.
log_tc_size	24576	-	Size in bytes of the transaction coordinator log, defined in multiples of 4096.
log_throttle_queries_not_using_indexes	-	0	MySQL-only variable for limiting the number of statements without indexes written to the slow query log.
log_timestamps	-	UTC	MySQL-only variable controlling the timezone for certain logging conditions.
log_warnings	2	-	MySQL 8 has replaced with `log_error_verbosity`.
mandatory_roles	-	(empty)	MySQL variable for assigning roles to all users.
master_info_repository	-	TABLE	Whether slave logs master status and connection info to a table or a file.
max_allowed_packet	16M	64M	
max_error_count	64	1024	Specifies the maximum number of messages stored for display by SHOW ERRORS and SHOW WARNINGS statements.
max_execution_time	-	0	MySQL renamed the `max_statement_time` variable.
max_length_for_sort_data	64	1024	Used to decide which algorithm to choose when sorting rows. If the total size of the column data, not including columns that are part of the sort, is less than max_length_for_sort_data, then these are added to the sort key. This can speed up the sort as there's no need to re-read the same row again later. Setting the value too high can slow things down as there will be a higher disk activity for doing the sort.
max_long_data_size	16777216	-	Maximum size for parameter values sent with mysql_stmt_send_long_data(). Removed in MySQL 5.6.
max_password_errors	4294967295	-	Maximum number of failed connections attempts before no more are permitted.
max_points_in_geometry	-	65536	Maximum points_per_circle for MySQL's ST_Buffer_Strategy() function.
max_recursive_iterations	4294967295	-	Maximum number of iterations when executing recursive queries.
max_relay_log_size	1073741824	0	Can be set by session in MariaDB.
max_seeks_for_key	4294967295	4294967295 (32-bit) or 18446744073709547520 (64-bit)	The most key seeks required when searching with an index, regardless of the actual index cardinality. If this value is set lower than its default and maximum, indexes will tend to be preferred over table scans.
max_session_mem_used	9223372036854775807	-	Amount of memory a single user session is allowed to allocate.
max_statement_time	0	-	Maximum time in seconds that a query can execute before being aborted. MySQL used to have a variable of this name before renaming it `max_execution_time`.
max_tmp_tables	32	-	Unused variable removed in MySQL.
max_write_lock_count	4294967295	4294967295 (32-bit) or 18446744073709547520 (64-bit)	Read lock requests will be permitted for processing after this many write locks.
mrr_buffer_size	262144	-	Size of buffer to use when using multi-range read with range access. See Multi Range Read optimization.
myisam_block_size	1024	-	Block size used for MyISAM index pages.

myisam_recover_options	BACKUP,QUICK	OFF	MyISAM recovery mode.
myisam_sort_buffer_size	134216704	8388608	Size in bytes of the buffer allocated when creating or sorting indexes on a MyISAM table.
mysql_native_password_proxy_users	-	OFF	Whether MySQL's authentication plugin supports proxy users. I
mysql56_temporal_format	ON		Causes MariaDB to use the MySQL-5.6 low level formats for TIME, DATETIME and TIMESTAMP instead of the MariaDB 5.3+ version.
new	-	OFF	Used for backward-compatibility with MySQL 4.1, not present in MariaDB.
mysqlx+*	-	*	MySQL's X plugin related variables.
ngram_token_size	-	2	Sets the n-gram token size for MySQL's n-gram full-text parser.
offline_mode	-	OFF	MySQL settting for specifying whether the server should run in offline mode.
old_alter_table	DEFAULT	OFF	An alias for alter_algorithm.
old_mode	Empty string	-	Used for getting MariaDB to emulate behavior from an old version of MySQL or MariaDB. See OLD Mode.
old_passwords	OFF	-	MySQL 8 is no longer compatible with the old pre-MySQL 4.1 form of password hashing.
optimizer_selectivity_sampling_limit	100	-	Controls number of record samples to check condition selectivity.
optimizer_switch	See details		A series of flags for controlling the query optimizer. MariaDB has introduced a number of new settings.
optimizer_trace_*	-	*	MySQL has more settings for optimizer tracing.
optimizer_use_condition_selectivity	4	-	Controls which statistics can be used by the optimizer when looking for the best query execution plan.
original_commit_timestamp	-	*	Used by MySQL 8 for delaying replication.
parser_max_mem_size	-	4294967295 (32-bit) or 18446744073709547520 (64-bit)	MySQL variable for limiting memory available to the parser.
password_*	-	*	Controls reuse of previous passwords in MySQL.
performance_schema	OFF	ON	The Performance Schema is off by default in MariaDB.
performance_schema_*			Many performance schema variables are autoset in MySQL, and MySQL has a different version, with additional variables.
plugin_maturity	One less than the server maturity	-	Minimum acceptable plugin maturity.
progress_report_time	5	-	Time in seconds between sending progress reports to the client for time-consuming statements.
proxy_protocol_networks	(empty)	-	Enable proxy protocol for these source networks.
query_alloc_block_size	16384	8192	Size in bytes of the extra blocks allocated during query parsing and execution (after query_prealloc_size is used up).
query_cache_*	*	-	MySQL has removed the query cache.
query_prealloc_size	24576	8192	Size in bytes of the persistent buffer for query parsing and execution, allocated on connect and freed on disconnect.
range_optimizer_max_mem_size	-	8388608	MySQL-only variable setting a limit on the range optimizer's memory usage.
rbr_exec_mode	-	STRICT	MySQL-only variable for determining the handling of certain key errors.
read_binlog_speed_limit	0	-	Permits restricting the speed at which the slave reads the binlog from the master.
regexp_*	-	*	Memory and time limits for regular expression matching operations.
relay_log_info_repository	-	TABLE	MySQL-only variable determining whether the slave's position in the relay logs is written to a file or table.
replicate_annotate_row_events	ON	-	Tells the slave to reproduce annotate_rows_events received from the master in its own binary log.
replicate_do_db	empty string	-	See Dynamic Replication Variables.

replicate_do_table	empty string	-	See Dynamic Replication Variables.
replicate_events_marked_for_skip	replicate	-	See Selectively skipping replication of binlog events.
replicate_ignore_db	empty string	-	See Dynamic Replication Variables.
replicate_ignore_table	empty string	-	See Dynamic Replication Variables.
replicate_wild_do_table	empty string	-	See Dynamic Replication Variables.
replicate_wild_ignore_table	empty string	-	See Dynamic Replication Variables.
result_metadata	-	FULL	Determine whether the server returns result set metadata for connections where this is optional.
rowid_merge_buff_size	8388608	-	See Non-semi-join subquery optimizations.
rpl_read_size	-	8192	Minimum data in bytes read from the binary and relay log files.
rpl_semi_sync_*	-	-	MariaDB includes semisynchronous replication without the need to install a plugin.
rpl_stop_slave_timeout	-	31536000	Controls the time that STOP SLAVE waits before timing out.
s3_*	*	-	The S3 storage engine is only available in MariaDB.
schema_definition_cache	-	256	Limits the number of schema definition objects kept in the dictionary object cache.
secure_auth	ON	-	Removed in MySQL.
secure_timestamp	NO	-	MariaDB-only option permitting the restricting of direct setting of a session timestamp..
server_id_bits	-	server_id	MySQL-only variable for use in MySQL Cluster.
server_uuid	-	UUID	MySQL-only variable containing the UUID.
session_track_gtids	-	OFF	MySQL-only variables for tracking gtid changes. MariaDB and MySQL's gtid implementation is different.
sha256_password_proxy_users	-	OFF	MySQL-only variable determining whether the sha256_password plugin supports proxy users.
show_create_table_verbosity	-	OFF	Option to cause SHOW CREATE TABLE to display ROW_FORMAT in all cases.
show_old_temporals	-	OFF	MySQL-only variable for determining whether SHOW CREATE TABLE output should include comments for old format temporal columns.
skip_parallel_replication	OFF	-	See parallel replication.
skip_replication	OFF	-	See Selectively skipping replication of binlog events.
slave_allow_batching	-	OFF	MySQL-only replication variable.
slave_checkpoint_group	-	512	MySQL-only replication variable.
slave_checkpoint_period	-	300	MySQL-only replication variable.
slave_ddl_exec_mode	IDEMPOTENT	-	Modes for how replication of DDL events should be executed.
slave_domain_parallel_threads	0	-	For configuring parallel replication.
slave_net_timeout	3600	60	MySQL reduced the timeout to 60s.
slave_parallel_max_queued	131072	-	For configuring parallel replication.
slave_parallel_mode	optimistic	-	Controls what transactions are applied in parallel when using parallel_replication.
slave_parallel_threads	0	-	For configuring parallel replication.
slave_parallel_type	-	DATABASE	MySQL-only replication variable.
slave_pending_jobs_size_max	-	16777216	MySQL-only replication variable.
slave_preserve_commit_order	-	OFF	MySQL-only replication variable.
slave_rows_search_algorithms	-	INDEX_SCAN, HASH_SCAN	MySQL-only replication variable.
slave_run_triggers_for_rbr	NO		See Running triggers on the slave for Row-based events for a description and use-case for this setting.
slave_transaction_retry_errors	1213,1205	-	When an error occurs during a transaction on the slave, replication usually halts. By default, transactions that caused a deadlock or elapsed lock wait timeout will be retried. One can add other errors to the the list of errors that should be retried by adding a comma-separated list of error numbers to this variable.

slave_transaction_retry_interval	0	-	Interval in seconds for the slave SQL thread to retry a failed transaction due to a deadlock, elapsed lock wait timeout or an error listed in slave_transaction_retry_errors.
sort_buffer_size	2097152	262144	The default sort buffer allocated has been reduced in MySQL.
sql_if_exists	OFF	-	Adds an implicit IF EXISTS to ALTER, RENAME and DROP of TABLES, VIEWS, FUNCTIONS and PACKAGES
sql_mode	STRICT_TRANS_TABLES, ERROR_FOR_DIVISION_BY_ZERO, NO_AUTO_CREATE_USER, NO_ENGINE_SUBSTITUTION	ONLY_FULL_GROUP_BY, STRICT_TRANS_TABLES, NO_ZERO_IN_DATE, NO_ZERO_DATE, ERROR_FOR_DIVISION_BY_ZERO, NO_ENGINE_SUBSTITUTION	See SQL Mode.
ssl_fips_mode	-	OFF	Whether FIPS mode is enabled on the server side.
standard_compliant_cte	ON	-	See Common Table Expressions.
storage_engine	InnoDB	-	Alias for default_storage_engine, removed in MySQL.
strict_password_validation	ON	-	In MariaDB, when password validation plugins are enabled, reject passwords that cannot be validated (passwords specified as a hash).
stored_program_definition_cache	-	256	Limits the number of stored program definition objects kept in the dictionary object cache.
super_read_only	-	OFF	MySQL variable for prohibiting client updates from users with the SUPER privilege.
sync_binlog	0	1	MySQL synchronizes all actions to the binary log before they are committed.
sync_frm	1	-	.frm files have been removed in MySQL.
system_versioning_alter_history	ERROR	-	MariaDB has System-Versioned Tables
system_versioning_asof	DEFAULT	-	MariaDB has System-Versioned Tables
table_definition_cache	400	-1 (autosized)	Number of table definitions that can be cached.
table_open_cache_instances	8	16	Maximum number of table cache instances.
tablespace_definition_cache	-	256	Limits the number of tablespace definition objects kept in the dictionary object cache.
tcp_keepalive_interval	0	-	Interval, in seconds, between when successive keep-alive packets are sent if no acknowledgement is received.
tcp_keepalive_probes	0	-	Number of unacknowledged probes to send before considering the connection dead and notifying the application layer.
tcp_keepalive_time	0	-	Set the TCP_NODELAY option (disable Nagle's algorithm) on socket.
tcp_nodelay	1	-	Timeout, in milliseconds, with no activity until the first TCP keep-alive packet is sent.
temptable_max_ram	-	1GB	Limits the RAM used by MySQL's TempTable storage engine.
thread_cache_size	Autosized	-1 (autosized)	MariaDB uses an improved thread pool.
thread_concurrency	10	-	Removed in MySQL 5.7.
thread_pool_dedicated_listener	0	-	Better precision for the data in the Information Schema THREADPOOL_QUEUES Table.
thread_pool_exact_stats	0	-	Better precision for the data in the Information Schema THREADPOOL_QUEUES Table.
thread_pool_idle_timeout	60	-	See Using the Thread Pool.
thread_pool_max_threads	65536	-	See Using the Thread Pool.
thread_pool_min_threads	1	-	Windows-only. See Using the Thread Pool.
thread_pool_oversubscribe	3	-	See Using the Thread Pool.
thread_pool_prio_kickup	auto	-	See Using the Thread Pool.
thread_pool_priority	auto	-	See Using the Thread Pool.
thread_pool_size	Number of processors	16*	See Using the Thread Pool. *Only available in MySQL with a commercial plugin.

thread_pool_stall_limit	500	6*	See Using the Thread Pool. *Only available in MySQL with a commercial plugin.
thread_stack	299008	Varies	See Using the Thread Pool.
time_format	%H:%i:%s	-	Removed in MySQL.
timed_mutexes	OFF	-	Removed in MySQL.
tmp_disk_table_size	18446744073709551615	-	Max size for data for an internal temporary on-disk MyISAM or Aria table.
tmp_memory_table_size	16777216	-	Alias for tmp_table_size.
transaction_allow_batching	-	OFF	Variable for enabling batching of statements within the same transaction in MySQL Cluster.
transaction_isolation	-	REPEATABLE-READ	The MariaDB equivalent is tx_isolation.
transaction_read_only	-	OFF	The MariaDB equivalent is tx_read_only.
transaction_write_set_extraction	-	OFF	Unused MySQL-only variable.
tx_isolation	REPEATABLE-READ	-	The MySQL equivalent is transaction_isolation.
tx_read_only	OFF	-	The MySQL equivalent is transaction_read_only.
use_stat_tables	preferably_for_queries	-	Controls the use of engine-independent table statistics.
userstat	OFF	-	Whether to activate MariaDB's User Statistics implementation, not available in MySQL.
version_compile_zlib	-	*	Version of the zlib library compiled in.
version_malloc_library	*	-	Version of the used malloc library.
version_source_revision	Varies	-	Permits seeing exactly which version of the source was used for a build.
version_ssl_library	*	-	Version of the used TLS library.
windowing_high_use_precision	-	*	MySQL option allowing safety to be sacrificed for speed in window function calculations.
wsrep_*	*	-	Galera cluster is only available in MariaDB.
Variable	**MariaDB 10.6**	**MySQL 8.0**	**Notes**

2.1.14.1.12.6 System Variable Differences Between MariaDB 10.5 and MySQL 8.0

Contents

The following is a comparison of variables that either appear only in MariaDB 10.5 or MySQL 8.0, or have different default settings in MariaDB 10.5, and MySQL 8.0. The RC release MariaDB 10.5.3 and the stable MySQL 8.0.11, with only default plugins enabled, were used for the comparison. Note that MySQL 8 is an 'evergreen' release, so features may be added or removed in later releases.

For a more complete list of differences, see Incompatibilities and Feature Differences Between MariaDB 10.5 and MySQL 8.0 and Function Differences Between MariaDB 10.5 and MySQL 8.0

The most notable differences are that MariaDB includes, by default, the Aria storage engine (resulting in extra memory allocation), Galera Cluster, and has a different thread pool implementation. For this reason, a default implementation of MariaDB 10.5 will use more memory than MySQL 8.0. MariaDB 10.5 and MySQL 8.0 also have different GTID implementations.

MariaDB's extra memory usage can be handled with the following rules of thumb:

- If you are not using MyISAM and don't plan to use Aria:
  - Set key_buffer_size to something very low (16K) as it's not used.
  - Set aria_pagecache_buffer_size to what you think you need for handling internal tmp tables that didn't fit in memory.
  - Normally this is what before you had set for key_buffer_size (at least 1M).
- If you are using MyISAM and not planning to use Aria:
  - Set aria_pagecache_buffer_size to what you think you need for handling internal tmp tables that didn't fit in memory.
- If you are planning to use Aria, you should set aria_pagecache_buffer_size to something that fits a big part of your normal data + overflow temporary tables.

Comparison Table

Variable	MariaDB 10.5 Default	MySQL 8.0 Default	Notes
activate_all_roles_on_login	-	OFF	Determines whether to automatically activate roles on login.
alter_algorithm	DEFAULT	-	MariaDB 10.3 introduced new ALTER TABLE ALGORITHM clauses to avoid slow copies in certain instances. This variable allows setting this if no `ALGORITHM` clause is specified.
analyze_sample_percentage	100.0000	-	Percentage of rows from the table ANALYZE TABLE will sample to collect table statistics.
aria_*	*	-	The Aria storage engine is only available in MariaDB.
auto_generate_certs	-	ON	Whether to automatically generate SSL key and certificate files.
avoid_temporal_upgrade	-	OFF	Determines whether ALTER TABLE implicitly upgrades temporal columns.
back_log	Autosized	Autosized	MariaDB and MySQL have different autosizing algorithms.
binlog-annotate-row-events	ON	-	Introduced in MariaDB 5.3 for replicating between MariaDB 5.3 and MySQL/MariaDB 5.1.
binlog_commit_wait_count	0	-	For use in MariaDB's parallel replication.
binlog_commit_wait_usec	100000	-	For use in MariaDB's parallel replication.
binlog_error_action		ABORT_SERVER	MySQL-only variable for controlling what happens when the server cannot write to the binary log.
binlog_expire_logs_seconds	-	2592000	Sets the binary log expiration period in seconds
binlog_file_cache_size	16184	-	For setting the size of the file cache for the binary log.
binlog_format	MIXED	ROW	MariaDB and MySQL have differing binary log formats.
binlog_group_commit_sync_delay		0	MySQL-only variable for controlling the wait time before synchronizing the binary log file to disk.
binlog_group_commit_sync_no_delay_count		0	MySQL-only variable for setting the maximum number of transactions to wait for before aborting the current `binlog_group_commit_sync_delay` delay.
binlog_gtid_simple_recovery	-	ON	MySQL-only GTID variable. MariaDB's GTID implementation is different.
binlog_max_flush_queue_time	-	0	Specifies a timeout for reading transactions from the flush queue before continuing with group commit and syncing log to disk.
binlog_optimize_thread_scheduling	ON	-	For optimized kernel thread scheduling.
binlog_order_commits	-	ON	Determines whether transactions may be committed in parallel.
binlog_row_metadata	NO_LOG	MINIMAL	Determines the amount of table metadata added to the binary log with row-based logging.
binlog_row_value_options	-	(empty)	Permits an alternative binlog format for JSON document updates.
binlog_rows_query_log_events	-	OFF	MySQL-only variable for logging extra information in row-based logging.
binlog_transaction_dependency_history_size	-	25000	Maximum number of row hashes kept for looking up transactions that last modified a given row.
binlog_transaction_dependency_tracking	-	COMMIT_ORDER	For determining how to best use the slave's multithreaded applier.
block_encryption_mode	-	aes-128-ecb	MySQL-only variable for controlling the block encryption mode for block-based algorithms.
caching_sha2_password*	-	*	For use with MySQL's SHA-256 authentication with caching.
character_set_*	latin1 or utf8	utf8mb4	MySQL 8.0 defaults to the utf8mb4 character set.
check_constraint_checks	ON	-	Permits disabling constraint checks, for example when loading a table that violates some constraints that you plan to fix later.

check_proxy_users		OFF	MySQL-only variable for controlling whether the server performs proxy user mapping for authentication plugins.
collation_*	latin1_swedish_ci or utf8_general_ci	utf8mb4_0900_ai_ci	MySQL 8.0 defaults to the utf8mb4 character set.
column_compression_threshold	100	-	MariaDB supports Storage-engine Independent Column Compression.
column_compression_zlib_level	6	-	MariaDB supports Storage-engine Independent Column Compression.
column_compression_zlib_strategy	DEFAULT_STRATEGY	-	MariaDB supports Storage-engine Independent Column Compression.
column_compression_zlib_wrap	OFF	-	MariaDB supports Storage-engine Independent Column Compression.
cte_max_recursion_depth	-	1000	When MySQL 8.0 introduced common table expressions they used a different name. MariaDB's variable is called max_recursive_iterations.
date_format	%Y-%m-%d	-	Unused variable removed in MySQL 8.0
datetime_format	%Y-%m-%d	-	Unused variable removed in MySQL 8.0
deadlock_search_depth_long	15	-	The Aria storage engine is only available in MariaDB.
deadlock_search_depth_short	4	-	The Aria storage engine is only available in MariaDB.
deadlock_timeout_long	50000000	-	The Aria storage engine is only available in MariaDB.
deadlock_timeout_short	10000	-	The Aria storage engine is only available in MariaDB.
debug_no_thread_alarm	OFF	-	Disable system thread alarm calls, for debugging or testing.
default_authentication_plugin	-	caching_sha2_password	MySQL 8 introduced a new authentication plugin.
default_collation_for_utf8mb4	-	utf8mb4_0900_ai_ci	For internal use in MySQL 8 replication.
default_master_connection	empty	-	For use with MariaDB's multi-source replication.
default_password_lifetime	0	360	MariaDB defaults to password expiration off.
default_regex_flags	empty	-	For handling incompatibilities between MariaDB's PCRE and the old regex library.
default_tmp_storage_engine	empty	InnoDB	Default storage engine used for tables created with CREATE TEMPORARY TABLE.
disabled_storage_engines		empty	MySQL-only variable for disabling specific storage engines.
disconnect_on_expired_password	OFF	ON	MariaDB password expiration is off by default, and by default does not disconnect a client when a password has expired.
encrypt_binlog	OFF	-	MariaDB enables table and tablespace encryption.
encrypt_tmp_files	OFF	-	MariaDB enables table and tablespace encryption.
encrypt_tmp_disk_tables	OFF	-	MariaDB enables table and tablespace encryption.
end_markers_in_json	-	OFF	MySQL-only variable for adding end markers to JSON output.
enforce_gtid_consistency	-	OFF	MariaDB and MySQL have different GTID implementations.
enforce_storage_engine	none		Forces the use of a particular storage engine for new tables.
eq_range_index_dive_limit	0	200	Variable for tuning when the optimizer should switch from using index dives to index statistics for qualifying rows estimation.
event_scheduler	OFF	ON	MySQL enables the event scheduler by default.
expensive_subquery_limit	100	-	Used for determining expensive queries for optimization.
explicit_defaults_for_timestamp	OFF	ON	MySQL 8 disables the old timestamp behavior.
extra_max_connections	1	-	Introduced in the MariaDB 5.1 threadpool.
extra_port	0	-	Introduced in the MariaDB 5.1 threadpool.

group_concat_max_len	1048576	1024	MariaDB increases the maximum length for a GROUP_CONCAT() result from 1K to 1M.
gtid_binlog_pos	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_binlog_state	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_cleanup_batch_size	64	-	MariaDB and MySQL have different GTID implementations.
gtid_current_pos	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_domain_id	0	-	MariaDB and MySQL have different GTID implementations.
gtid_executed	-	empty	MariaDB and MySQL have different GTID implementations.
gtid_executed_compression_period	-	1000	MariaDB and MySQL have different GTID implementations.
gtid_ignore_duplicates	OFF	-	MariaDB and MySQL have different GTID implementations.
gtid_mode	-	OFF	MariaDB and MySQL have different GTID implementations.
gtid_next	-	AUTOMATIC	MariaDB and MySQL have different GTID implementations.
gtid_owned	-	empty	MariaDB and MySQL have different GTID implementations.
gtid_pos_auto_engines	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_purged	-	empty	MariaDB and MySQL have different GTID implementations.
gtid_seq_no	0	-	MariaDB and MySQL have different GTID implementations.
gtid_slave_pos	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_strict_mode	OFF	-	MariaDB and MySQL have different GTID implementations.
have_crypt	YES	-	MySQL has removed the ENCRYPT function.
have_openssl			MariaDB's version indicates whether YaSSL or openssl was used. MySQL's is a synonym for `have_ssl`.
have_query_cache	YES	-	MySQL has removed the query cache.
have_statement_timeout	-		Whether MySQL's statement execution timeout feature is available.
have_symlink	YES	DISABLED	MySQL has removed symlink support.
histogram_generation_max_mem_size	-	20000000	Added when MySQL 8 introduced Histogram-based Statistics. MariaDB uses histogram_size
histogram_size	0	-	MariaDB introduced Histogram-based Statistics.
histogram_type	DOUBLE_PREC_HB	-	MariaDB introduced Histogram-based Statistics.
idle_readonly_transaction_timeout	0	-	Time in seconds that the server waits for idle read-only transactions.
idle_transaction_timeout	0	-	Time in seconds that the server waits for idle transactions.
idle_write_transaction_timeout	0	-	Time in seconds that the server waits for idle write transactions.
ignore_builtin_innodb	OFF	-	Ignored and removed in MySQL 8.
in_predicate_conversion_threshold	1000	-	Controls the Conversion of Big IN Predicates Into Subqueries optimization.
in_transaction	0	-	Set to `1` if you are in a transaction, and `0` if not.
information_schema_stats_expiry	-	86400	Time until MySQL Information Schema cached statistics expire.
innodb_adaptive_flushing_lwm	10.000000	10	Adaptive flushing is enabled when this this low water mark percentage of the redo log capacity is reached. MariaDB's variable is a double, MySQL's an integer.
innodb_adaptive_hash_index	OFF	ON	Defaulting to OFF is a performance improvement especially for DROP TABLE, TRUNCATE TABLE, ALTER TABLE, or DROP INDEX operations

innodb_api_*	-	*	Specific to MySQL's memcached, removed in MariaDB 10.2.
innodb_autoinc_lock_mode	1	2	MariaDB has an extra mode, `3`, for skipping the rollback of connected transactions. MySQL defaults to row-based replication, so can safely use `2`.
innodb_background_*	*	-	Earlier versions of MariaDB had support for background data scrubbing.
innodb_checksum_algorithm	full_crc32	crc32	`fullcrc32` permits encryption to be supported over a SPATIAL INDEX, which crc32 does not support.
innodb_checksums	ON	-	Deprecated option removed in MySQL.
innodb_compression_*	*	-	Introduced with MariaDB's InnoDB compression.
innodb_dedicated_server	-	OFF	MySQL option that automatically configures various settings if the server is a dedicated InnoDB database server.
innodb_default_encryption_key_id	1	-	Default encryption key id used for table encryption. See Data at Rest Encryption.
innodb_defragment	*	-	MariaDB can defragment InnoDB tablespaces.
innodb_directories	-	(empty)	Used to search for tablespace files when moving or restoring a new location.
innodb_disallow_writes	OFF	-	Tell InnoDB to stop any writes to disk.
innodb_encrypt_*	1	-	See MariaDB's Data at Rest Encryption.
innodb_fatal_semaphore_wait_threshold	600	-	MariaDB's fatal semaphore timeout is configurable.
innodb_file_format	(empty)	-	MariaDB 10.4 has restored this unused, deprecated variable for compatibility reasons.
innodb_flush_neighbors	1	0	MySQL 8 by default now assumes the use of an SSD device.
innodb_force_primary_key	OFF	-	If set to 1 in MariaDB (0 is default) CREATE TABLEs without a primary or unique key where all keyparts are NOT NULL will not be accepted, and will return an error.
innodb_idle_flush_pct	100	-	Up to what percentage of dirty pages in MariaDB should be flushed when InnoDB finds it has spare resources to do so.
innodb_immediate_scrub_data_uncompressed	OFF	-	MariaDB has support for data scrubbing.
innodb_instant_alter_column_allowed	add_drop_reorder	-	See Instant ADD COLUMN for InnoDB.
innodb_large_prefix	(empty)	-	MariaDB 10.4 has restored this unused, deprecated variable for compatibility reasons.
innodb_lock_schedule_algorithm	VATS	-	MariaDB has an improved algorithm for deciding which of the waiting transactions should be granted a lock once it has been released.
innodb_locks_unsafe_for_binlog	OFF	-	Deprecated option in MariaDB for disabling gap locking for searches and index scans. Deprecated in MariaDB, use READ COMMITTED transaction isolation instead.
innodb_log_optimize_ddl	OFF	-	Deprecated and ignored in MariaDB. Previously determined whether redo logging should be reduced when natively creating indexes or rebuilding tables.
innodb_log_spin_*	-	*	MySQL variables for constraining CPU usage while waiting for flushed redo.
innodb_log_wait_for_flush_spin_hwm	-	*	MySQL variable for constraining CPU usage while waiting for flushed redo.
innodb_max_dirty_pages_pct	75	90	MySQL 8 increased the default to 90.
innodb_max_dirty_pages_pct_lwm	0	10	MySQL 8 increased the default to 10.
innodb_max_undo_log_size	10485760	1073741824	MariaDB 10.2 reduced the limit for when an undo tablespace is marked for truncation.
innodb_open_files	Autosized (2000)	Autosized (4000)	In most systems, autosized based on the table_open_cache setting, which differs between MariaDB and MySQL.
innodb_prefix_index_cluster_optimization	OFF	-	MariaDB includes the Facebook prefix index queries optimization.
innodb_print_ddl_logs	-	OFF	MySQL option for writing DDL logs to stderr.

innodb_redo_log_encrypt	-	OFF	MySQL 8 has also now introduced redo log encryption, but used a different name. The equivalent option in MariaDB is innodb_encrypt_log.
innodb_scrub_*	*	-	Earlier version of MariaDB included options to scrub the redo log.
innodb_spin_wait_delay	4	6	MariaDB changed the default from 6 to 4 based on extensive benchmarking.
innodb_stats_modified_counter	0	-	MariaDB option to control the calculation of new statistics.
innodb_stats_sample_pages	8	-	Deprecated MariaDB option for control over index distribution statistics.
innodb_stats_traditional	ON	-	Enabling gives a larger sample of pages for larger tables for the purposes of index statistics calculation.
innodb_undo_log_encrypt	-	OFF	MySQL option for encrypting undo logs residing in separate undo tablespaces.
innodb_undo_log_truncate	OFF	ON	MySQL 8 changes the default to ON, marking larger undo logs for truncation.
innodb_undo_logs	128	-	Removed in MySQL 8.
innodb_undo_tablespaces	0	2	Number of tablespace files used for dividing up the undo logs. MySQL 8 has deprecated this setting, and increased the default (and minimum) to 2.
innodb_use_atomic_writes	ON	-	Atomic writes are a faster alternative to innodb_doublewrite and MariaDB automatically detects when supporting SSD cards are used.
internal_tmp_disk_storage_engine	-	INNODB	MySQL uses this variable to set the storage engine for on-disk internal temporary tables.
internal_tmp_mem_storage_engine	-	TEMPTABLE	MySQL and MariaDB use different formats for temporary tables. In MariaDB, the aria_used_for_temp_tables performs a similar function.
join_buffer_space_limit	2097152	-	Maximum size in bytes of the query buffer. See block-based join algorithms.
join_cache_level	2	-	For determining the join algorithms. See block-based join algorithms
key_buffer_size	134217728	8388608	Size of the buffer for the index blocks used by MyISAM tables and shared for all threads.
key_cache_file_hash_size	512	-	Number of hash buckets for open and changed files.
key_cache_segments	0	-	The number of segments in a key cache. See Segmented Key Cache.
keyring_operations	-	ON	Whether MySQL 8's keyring operations are enabled.
last_gtid	-	empty	MariaDB and MySQL have different GTID implementations.
local_infile	ON	OFF	MySQL no longer supports LOAD DATA LOCAL by default.
lock_wait_timeout	86400	31536000	MariaDB has reduced the timeout for acquiring metadata locks.
log_bin	OFF	ON	MySQL 8 enables the binary log by default.
log_bin_compress	OFF	-	MariaDB setting for whether or not the binary log can be compressed.
log_bin_compress_min_len	256	-	Minimum length of sql statement (in statement mode) or record (in row mode) that can be compressed. See Compressing Events to Reduce Size of the Binary Log.
log_bin_use_v1_row_events	-	OFF	MySQL-only variable showing whether or not MySQL's version 2 binary logging format is being used.
log_disabled_statements	sp	-	Disable logging of certain statements to the general log.
log_error_services	-	log_filter_internal; log_sink_internal	Components to enable for MySQL error logging.
log_error_verbosity	-	3	MySQL variable for setting verbosity of error, warning, and note messages in the error log.
log_slave_updates	OFF	ON	MySQL 8 has by default enabled binary logging of updates a slave receives from a master.

log_slow_admin_statements	ON	OFF	MariaDB logs slow admin statements to the slow query log by default.
log_slow_disabled_statements	admin,call,slave,sp	-	Disable logging of certain statements to the slow query log.
log_slow_filter	admin, filesort, filesort_on_disk, full_join, full_scan, query_cache, query_cache_miss, tmp_table, tmp_table_on_disk	-	For slow query log filtering.
log_slow_rate_limit	1	-	Limits the number of queries logged to the slow query log.
log_slow_slave_statements	ON	OFF	MariaDB logs slow slave statements to the slow query log by default.
log_slow_verbosity	empty	-	Controls information to be added to the slow query log. See also Slow Query Log Extended Statistics.
log_statements_unsafe_for_binlog	-	ON	MySQL setting for controlling whether binlog warnings are written to the error log.
log_syslog*	platform-dependent	-	MySQL variables with settings for writing to syslog.
log_tc_size	24576	-	Size in bytes of the transaction coordinator log, defined in multiples of 4096.
log_throttle_queries_not_using_indexes	-	0	MySQL-only variable for limiting the number of statements without indexes written to the slow query log.
log_timestamps	-	UTC	MySQL-only variable controlling the timezone for certain logging conditions.
log_warnings	2	-	MySQL 8 has replaced with `log_error_verbosity`.
mandatory_roles	-	(empty)	MySQL variable for assigning roles to all users.
master_info_repository	-	TABLE	Whether slave logs master status and connection info to a table or a file.
max_allowed_packet	16M	64M	
max_error_count	64	1024	Specifies the maximum number of messages stored for display by SHOW ERRORS and SHOW WARNINGS statements.
max_execution_time	-	0	MySQL renamed the `max_statement_time` variable.
max_length_for_sort_data	64	1024	Used to decide which algorithm to choose when sorting rows. If the total size of the column data, not including columns that are part of the sort, is less than max_length_for_sort_data, then these are added to the sort key. This can speed up the sort as there's no need to re-read the same row again later. Setting the value too high can slow things down as there will be a higher disk activity for doing the sort.
max_long_data_size	16777216	-	Maximum size for parameter values sent with mysql_stmt_send_long_data(). Removed in MySQL 5.6.
max_password_errors	4294967295	-	Maximum number of failed connections attempts before no more are permitted.
max_points_in_geometry	-	65536	Maximum points_per_circle for MySQL's ST_Buffer_Strategy() function.
max_recursive_iterations	4294967295	-	Maximum number of iterations when executing recursive queries.
max_relay_log_size	1073741824	0	Can be set by session in MariaDB.
max_seeks_for_key	4294967295	4294967295 (32-bit) or 18446744073709547520 (64-bit)	The most key seeks required when searching with an index, regardless of the actual index cardinality. If this value is set lower than its default and maximum, indexes will tend to be preferred over table scans.
max_session_mem_used	9223372036854775807	-	Amount of memory a single user session is allowed to allocate.
max_statement_time	0	-	Maximum time in seconds that a query can execute before being aborted. MySQL used to have a variable of this name before renaming it `max_execution_time`.
max_tmp_tables	32	-	Unused variable removed in MySQL.
max_write_lock_count	4294967295	4294967295 (32-bit) or 18446744073709547520 (64-bit)	Read lock requests will be permitted for processing after this many write locks.

mrr_buffer_size	262144	-	Size of buffer to use when using multi-range read with range access. See Multi Range Read optimization.
myisam_block_size	1024	-	Block size used for MyISAM index pages.
myisam_recover_options	BACKUP,QUICK	OFF	MyISAM recovery mode.
myisam_sort_buffer_size	134216704	8388608	Size in bytes of the buffer allocated when creating or sorting indexes on a MyISAM table.
mysql_native_password_proxy_users	-	OFF	Whether MySQL's authentication plugin supports proxy users. I
mysql56_temporal_format	ON		Causes MariaDB to use the MySQL-5.6 low level formats for TIME, DATETIME and TIMESTAMP instead of the MariaDB 5.3+ version.
new	-	OFF	Used for backward-compatibility with MySQL 4.1, not present in MariaDB.
mysqlx+*	-	*	MySQL's X plugin related variables.
ngram_token_size	-	2	Sets the n-gram token size for MySQL's n-gram full-text parser.
offline_mode	-	OFF	MySQL settting for specifying whether the server should run in offline mode.
old_alter_table	DEFAULT	OFF	An alias for alter_algorithm.
old_mode	Empty string	-	Used for getting MariaDB to emulate behavior from an old version of MySQL or MariaDB. See OLD Mode.
old_passwords	OFF	-	MySQL 8 is no longer compatible with the old pre-MySQL 4.1 form of password hashing.
optimizer_selectivity_sampling_limit	100	-	Controls number of record samples to check condition selectivity.
optimizer_switch	See details		A series of flags for controlling the query optimizer. MariaDB has introduced a number of new settings.
optimizer_trace_*	-	*	MySQL has more settings for optimizer tracing.
optimizer_use_condition_selectivity	4	-	Controls which statistics can be used by the optimizer when looking for the best query execution plan.
original_commit_timestamp	-	*	Used by MySQL 8 for delaying replication.
