Preface

If you're contemplating whether to devote some time to this book, read this:

- MariaDB Server is a general-purpose, open source, relational database management system, optimised for performance and easy usabiility; it has its roots in MySQL Server, and is an alternative to Postgres, Oracle Database and other relational and NoSQL databases
- This book is the full documentation on MariaDB Server, a "Reference Manual Plus" which includes aspects of a User's Guide; it is based on the contents of the MariaDB Knowledge base (https://mariadb.com/kb/), an open, community-edited site contributed to since the inception of MariaDB in 2009
- This edition is not specific to any version of MariaDB Server, but includes functionality up to the latest version of MariaDB at the time of generation

This preface describes the goals, structure and contents of the documentation. Reading it is intended as a helpful step in understanding how to best use the manual to improve productivity in using MariaDB Server.

This Book's "Prehistory"

As noted, MariaDB Server has its roots in MySQL Server. It started as a fork of MySQL Server, using the same GPLv2 license. However, although the MySQL Server documentation was always publicly available, it was never released using a free documentation license. This means that the documentation of MariaDB Server was created from scratch. Or rather, from the online help texts, which had a compatible open licence that made them usable as a starting point.

The place to which documentation was written was labelled the "Knowledge Base", by MySQL and MariaDB creator Michael "Monty" Widenius. The Knowledge Base was – and remains – a community effort. As with many community efforts, there are core contributors around whom the work is centered. This is where Daniel Bartholomew loaded the online help text, as a first seed. For roughly the last ten years, the core editor of the MariaDB Knowledge Base has been Ian Gilfillan, working for MariaDB Foundation and based in South Africa. Hence, his name is on the cover of the book. However, there are a large number of other contributors, many of whom come from MariaDB Corporation – both as developers of code and as documentation writers. They are listed on https://mariadb.com/kb/stats/users/.

With now some 3000 pages in this book, most of the initial holes in the documentation have been filled. There should now be no reason to do as in the very early days of MariaDB Server – namely look up MariaDB features in the MySQL documentation. On the contrary, the functionality of the two databases have diverged considerably, so you would be ill advised not to use this MariaDB Server specific documentation.

The First Edition

The first edition of the MariaDB Server Documentation as a PDF file was released in April 2022. Prior to this, the contents were accessible as individual Knowledge Base (KB) articles. But already in 2014 – over seven years before – the user base requested a PDF version, as seen by MariaDB's Jira entry https://jira.mariadb.org/browse/MDEV-6881 MariaDB Documentation improvements. There, user Stoykov pointed out that MariaDB documentation already had search capabilities and a way to mirror the KB in an offline version – but lacked downloadable PDF and EPUB versions,

Fast forward some seven years and a number of upvotes and watchers, we decided to devote resources to it. Creating a PDF from an HTML file is something Python is good at, and Dorje Gilfillan did all the tweaking necessary to merge the individual KB pages into one huge HTML file for PDF conversion.

This Book's Structure

We had to impose a chapter structure on the book which is only indirectly visible from a collection of KB articles on the web. This means that the work in compiling the PDF isn't just about merging many KB pages in an order that could be derived from the hierarchical pointers between the articles. It also involves cleaning up that structure.

As a result, you will see two tables of contents. One is a one-pager overview with just the two top levels of hierarchy. The other is over 30 pages long. True to the Open Source mantra of "release early, release often", we believe that the structure can still be improved upon – but it is a good starting point. We have seven overall chapters, and the structures below them all make sense at some level.

To get the most out of the book, we recommend you to spend time making yourself familiar with the table of contents. It will give you an idea of existing functionality. Just browsing it through may give you ideas of commands you didn't know existed.

This Book's Format

There is currently just one version of the book. It's delivered in the PDF format, and in the Golden Ratio aspect ratio – meaning, A4. As we envision it to be read mostly on-screen anyway, we wanted to avoid the additional complexity of also providing a US Letter format. If we meet demand for further versions, doing US Letter is of course an option; however, given there are many ways to improve the documentation, we would also like to understand how adding another aspect ratio of the PDF would benefit the users in practice.

We don't yet provide the ePub format. Again, if you desire ePub, please educate us as to what added benefits you expect of ePub on top of PDF.

Use Cases For This Book

We expect the main use case for the PDF version of the book to be offline access. Offline may be imposed by a flaky or non-existent internet, but also by self-imposed abstinence from the many distractions of being online.

We expect that browsing the PDF will enable concentrated time to be spent on learning about MariaDB Server. The search functionality of PDF browsers helps in finding out about commands and syntax you already know of; browsing through a PDF – in particular the clickable Table of Contents – will hopefully provide you with an educational overview better than the online KB does.

We expect downloading the manual into laptops, tablets and phones will make sense. If you have the MariaDB Server Documentation on your phone, you can turn waiting time into something productive, perhaps even fun.

What we should work on

We have lots of room for improvement. That said, our foremost goal now is to get the book out, to get it used. User feedback will help us determine the right priority for our already existing ideas for improvements. We will likely get other requests beyond what we currently have in mind.

In the area of basic usability, an index has been spoken about. Looking up commands through searches or through browsing the table of contents is ok, but an index also has use cases. Our plan here starts from automatic indexing based on keywords of the headers of individual articles.

In the area of layout, we are looking at finding icons that make the PDF look more like a book, and less like a web page. We already solved the first issue, which was to find a clearer visual distinction between links within the PDF and links to the web.

In the area of structure, the length of individual chapters varies a lot. It may make sense to move around chapters in the TOC tree, to be more balanced. It may be that the reader expects another ordering based on experiences from other databases. It may even be that we lack entire topics. For instance, we eliminated the Release Notes for unsupported versions of MariaDB, even though these are still accessible on the KB.

In the area of accessibility, there may be places we should publish the PDF to make it easier to find, download, and use.

The common denominator for all of the above is that we need your feedback on what makes sense for you as a user of MariaDB Server.

Give Us Feedback

We would like to pick the brains of individual users. At conferences, asking open-ended questions is easy and feels productive for both parties, when meeting in the corridors between talks. Replicating the same productive discussion on-line is much harder. It takes effort from both parties. It feels like work.

We are still looking for the best way for you to give us meaningful feedback. Feel free to approach us over Zulip (https://mariadb.zulipchat.com/ – the Documentation topic). Also email to foundation@mariadb.org will find its way to us.

When you find individual bugs, please enter them into Jira using the guidelines mentioned in the KB article https://mariadb.com/kb/en/reporting-documentation-bugs/.

Acknowledgements

Compiling any book requires more effort than expected by the authors, and more than visible to the readers. This book is no exception. It has been over ten years in the making.

The primary thanks go to Ian Gilfillan, as the overall editor of the book and as the individually most productive author.

Close to Ian, we have Daniel Bartholomew. Daniel even beats Ian when it comes to articles created, and comes second on articles edited.

Among the community contributors, we want to highlight Federico Razzoli. He has two accounts, totalling 4488, at the time of writing – making him rank third amongst personal contributors.

When it comes to organisational contributors, the largest one is MariaDB Corporation. With them coding most of the features, they also stand for the lion's share of their documentation. As writers, besides Daniel Bartholomew whom we already mentioned several times, we want to highlight Russell Dyer, Kenneth Dyer, Geoff Montee, and Jacob Moorman.

As the developer of the KB software itself, Bryan Alsdorf deserves special acknowledgement.

A special thanks goes to Michael "Monty" Widenius, the creator of MariaDB. Monty has always understood the importance of documentation. He is leading by example, with a large number of personal edits. In fact, Monty has the second highest number of edits amongst developers, after Sergei Golubchik and followed by Sergey Petrunia – all of which have over a thousand edits.

Amongst the prolific contributors within the MariaDB Corporation Engineering team, the Connectors team stands out, with Diego Dupin, Georg Richter, and Lawrin Novitzky ranking near the top. However, we have decided not to include Connectors documentation in this first edition; we are contemplating whether it should be a separate PDF manual.

Other past and present Engineering team members, in decreasing order of number of edits, are David Hill, Dipti Joshi, David

Thompson, Massimiliano Pinto, Kolbe Kegel, Vladislav Vaintroub, Ralf Gebhardt, Markus Mäkelä, Sunanda Menon, the late Rasmus Johansson, Todd Stoffel, Elena Stepanova, Julien Fritsch, and Alexander Barkov. They all have more than one hundred edits, which is a lot.

As a true Open Source project, MariaDB Server documentation attracts attention and plentiful contributions also from outside the MariaDB Corporation Documentation and Engineering teams. We want to highlight those with over a hundred edits: Colin Charles and Stephane Varoqui, both of MariaDB Corporation, and Daniel Black, of MariaDB Foundation.

Amongst community contributors in the over-a-hundred-edits category, we want to mention especially Alena Subotina, with edits related to the dbforge documentation tool, and Juan Telleria, with edits often related to R Statistical Programming. Prolific contributors whose contributions are not visible in this English manual are Esper Ecyan (Japanese) and Hector Stredel (French); Federico Razzoli (Italian) has many edits also in English.

We also want to extend a thank you to the code developers who make work easy for the documentation team through thoroughly prepared, reusable texts in Jira; in this category, Marko Mäkelä and Oleksandr Byelkin come to mind.

As for the PDF manual, it has been teamwork between Ian and his son Dorje Gilfillan. Ian has done what editors do, Dorje has coded the Python code that compiles the KB pages into one.

All in all, thank you to everyone who has contributed to this book! We hope compiling it into one volume is of use for you, and we would love to hear what you think about the end result.

Munich, Germany, October 2022

Kaj Arnö, CEO, MariaDB Foundation

Chapter Contents

Table of Contents

1 Using MariaDB Server

Documentation on using MariaDB Server.

SQL Statements & Structure

SQL statements, structure, and rules.

Built-in Functions

Functions and procedures in MariaDB.

Clients & Utilities

Client and utility programs for MariaDB.

1.1 SQL Statements & Structure

The letters *SQL* stand for Structured Query Language. As with all languages—even computer languages—there are grammar rules. This includes a certain structure to statements, acceptable punctuation (i.e., operators and delimiters), and a vocabulary (i.e., reserve words).

SQL Statements

Explanations of all of the MariaDB SQL statements.

SQL Language Structure

Explanation of SQL grammar rules, including reserved words and literals.

Geographic & Geometric Features

Spatial extensions for geographic and geometric features.

NoSQL

NoSQL-related commands and interfaces

Operators

Operators for comparing and assigning values.

Sequences

Sequence objects, an alternative to AUTO_INCREMENT.

Temporal Tables

MariaDB supports system-versioning, application-time periods and bitemporal tables.

Unleashing the Power of Advanced SQL: Joins, Subqueries, and Set Operations

SQL (Structured Query Language) is a highly potent language used in the rea...

There are 19 related questions.

1.1.1 SQL Statements

Complete list of SQL statements for data definition, data manipulation, etc.

Account Management SQL Commands

CREATE/DROP USER, GRANT, REVOKE, SET PASSWORD etc.

Administrative SQL Statements

SQL statements for setting, flushing and displaying server variables and resources.

Data Definition

SQL commands for defining data, such as ALTER, CREATE, DROP, RENAME etc.

Data Manipulation

SQL commands for querying and manipulating data, such as SELECT, UPDATE, DELETE etc.

Prepared Statements

Prepared statements from any client using the text based prepared statement interface.

Programmatic & Compound Statements

Compound SQL statements for stored routines and in general.

Stored Routine Statements

SQL statements related to creating and using stored routines.

Table Statements

Documentation on creating, altering, analyzing and maintaining tables.

Transactions

Sequence of statements that are either completely successful, or have no effect on any schemas

HELP Command

The HELP command will retrieve syntax and help within the mariadb client.

Comment Syntax

Comment syntax and style.

Built-in Functions

Functions and procedures in MariaDB.

There are 24 related questions.

1.1.1.1 Account Management SQL Commands

CREATE/DROP USER, GRANT, REVOKE, SET PASSWORD etc.

CREATE USER

Create new MariaDB accounts.

ALTER USER

Modify an existing MariaDB account.

DROP USER

Remove one or more MariaDB accounts.

GRANT

Create accounts and set privileges or roles.

RENAME USER

Rename user account.

REVOKE

Remove privileges or roles.

SET PASSWORD

Assign password to an existing MariaDB user.

CREATE ROLE

Add new roles.

DROP ROLE

Drop a role.

SET ROLE

Enable a role.

SET DEFAULT ROLE
Sets a default role for a specified (or current) user.

SHOW GRANTS
View GRANT statements.

SHOW CREATE USER
Show the CREATE USER statement for a specified user.

There are 3 related questions.

1.1.1.1.1 CREATE USER

Syntax

```
CREATE [OR REPLACE] USER [IF NOT EXISTS]
 user_specification [,user_specification ...]
  [REQUIRE {NONE | tls_option [[AND] tls_option ...] }]
  [WITH resource_option [resource_option ...] ]
  [lock_option] [password_option]

user_specification:
  username [authentication_option]

authentication_option:
  IDENTIFIED BY 'password'
  | IDENTIFIED BY PASSWORD 'password_hash'
  | IDENTIFIED {VIA|WITH} authentication_rule [OR authentication_rule  ...]

authentication_rule:
    authentication_plugin
  | authentication_plugin {USING|AS} 'authentication_string'
  | authentication_plugin {USING|AS} PASSWORD('password')

tls_option:
  SSL
  | X509
  | CIPHER 'cipher'
  | ISSUER 'issuer'
  | SUBJECT 'subject'

resource_option:
  MAX_QUERIES_PER_HOUR count
  | MAX_UPDATES_PER_HOUR count
  | MAX_CONNECTIONS_PER_HOUR count
  | MAX_USER_CONNECTIONS count
  | MAX_STATEMENT_TIME time

password_option:
  PASSWORD EXPIRE
  | PASSWORD EXPIRE DEFAULT
  | PASSWORD EXPIRE NEVER
  | PASSWORD EXPIRE INTERVAL N DAY

lock_option:
    ACCOUNT LOCK
  | ACCOUNT UNLOCK
}
```

Contents

Description

The `CREATE USER` statement creates new MariaDB accounts. To use it, you must have the global CREATE USER privilege or the INSERT privilege for the mysql database. For each account, `CREATE USER` creates a new row in mysql.user (until MariaDB 10.3 this is a table, from MariaDB 10.4 it's a view) or mysql.global_priv_table (from MariaDB 10.4) that has no privileges.

If any of the specified accounts, or any permissions for the specified accounts, already exist, then the server returns `ERROR 1396 (HY000)`. If an error occurs, `CREATE USER` will still create the accounts that do not result in an error. Only one error is produced for all users which have not been created:

```
ERROR 1396 (HY000):
  Operation CREATE USER failed for 'u1'@'%','u2'@'%'
```

`CREATE USER`, DROP USER, CREATE ROLE, and DROP ROLE all produce the same error code when they fail.

See Account Names below for details on how account names are specified.

OR REPLACE

If the optional `OR REPLACE` clause is used, it is basically a shortcut for:

```
DROP USER IF EXISTS name;
CREATE USER name ...;
```

For example:

```
CREATE USER foo2@test IDENTIFIED BY 'password';
ERROR 1396 (HY000): Operation CREATE USER failed for 'foo2'@'test'

CREATE OR REPLACE USER foo2@test IDENTIFIED BY 'password';
Query OK, 0 rows affected (0.00 sec)
```

IF NOT EXISTS

When the `IF NOT EXISTS` clause is used, MariaDB will return a warning instead of an error if the specified user already exists.

For example:

```
CREATE USER foo2@test IDENTIFIED BY 'password';
ERROR 1396 (HY000): Operation CREATE USER failed for 'foo2'@'test'

CREATE USER IF NOT EXISTS foo2@test IDENTIFIED BY 'password';
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-------+------+-----------------------------------------------------+
| Level | Code | Message                                             |
+-------+------+-----------------------------------------------------+
| Note  | 1973 | Can't create user 'foo2'@'test'; it already exists |
+-------+------+-----------------------------------------------------+
```

Authentication Options

IDENTIFIED BY 'password'

The optional `IDENTIFIED BY` clause can be used to provide an account with a password. The password should be specified in plain text. It will be hashed by the PASSWORD function prior to being stored in the mysql.user/mysql.global_priv_table table.

For example, if our password is `mariadb`, then we can create the user with:

```
CREATE USER foo2@test IDENTIFIED BY 'mariadb';
```

If you do not specify a password with the `IDENTIFIED BY` clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

The only authentication plugins that this clause supports are mysql_native_password and mysql_old_password.

IDENTIFIED BY PASSWORD 'password_hash'

The optional `IDENTIFIED BY PASSWORD` clause can be used to provide an account with a password that has already been hashed. The password should be specified as a hash that was provided by the PASSWORD function. It will be stored in the mysql.user/mysql.global_priv_table table as-is.

For example, if our password is `mariadb`, then we can find the hash with:

```
SELECT PASSWORD('mariadb');
+-------------------------------------------+
| PASSWORD('mariadb')                       |
+-------------------------------------------+
| *54958E764CE10E50764C2EECBB71D01F08549980 |
+-------------------------------------------+
1 row in set (0.00 sec)
```

And then we can create a user with the hash:

```
CREATE USER foo2@test IDENTIFIED BY PASSWORD '*54958E764CE10E50764C2EECBB71D01F08549980';
```

If you do not specify a password with the `IDENTIFIED BY` clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

The only authentication plugins that this clause supports are mysql_native_password and mysql_old_password.

IDENTIFIED {VIA|WITH} authentication_plugin

The optional `IDENTIFIED VIA authentication_plugin` allows you to specify that the account should be authenticated by a specific authentication plugin. The plugin name must be an active authentication plugin as per SHOW PLUGINS. If it doesn't show up in that output, then you will need to install it with INSTALL PLUGIN or INSTALL SONAME.

`VIA` and `WITH` are synonyms.

For example, this could be used with the PAM authentication plugin:

```
CREATE USER foo2@test IDENTIFIED VIA pam;
```

Some authentication plugins allow additional arguments to be specified after a `USING` or `AS` keyword. For example, the PAM authentication plugin accepts a service name:

```
CREATE USER foo2@test IDENTIFIED VIA pam USING 'mariadb';
```

The exact meaning of the additional argument would depend on the specific authentication plugin.

MariaDB starting with 10.4.0

The `USING` or `AS` keyword can also be used to provide a plain-text password to a plugin if it's provided as an argument to the PASSWORD() function. This is only valid for authentication plugins that have implemented a hook for the PASSWORD() function. For example, the ed25519 authentication plugin supports this:

```
CREATE USER safe@'%' IDENTIFIED VIA ed25519 USING PASSWORD('secret');
```

MariaDB starting with 10.4.3

One can specify many authentication plugins, they all work as alternatives ways of authenticating a user:

```
CREATE USER safe@'%' IDENTIFIED VIA ed25519 USING PASSWORD('secret') OR unix_socket;
```

By default, when you create a user without specifying an authentication plugin, MariaDB uses the mysql_native_password plugin.

TLS Options

By default, MariaDB transmits data between the server and clients without encrypting it. This is generally acceptable when the server and client run on the same host or in networks where security is guaranteed through other means. However, in cases where the server and client exist on separate networks or they are in a high-risk network, the lack of encryption does introduce security concerns as a malicious actor could potentially eavesdrop on the traffic as it is sent over the network between them.

To mitigate this concern, MariaDB allows you to encrypt data in transit between the server and clients using the Transport Layer Security (TLS) protocol. TLS was formerly known as Secure Socket Layer (SSL), but strictly speaking the SSL protocol is a predecessor to TLS and, that version of the protocol is now considered insecure. The documentation still uses the term SSL often and for compatibility reasons TLS-related server system and status variables still use the prefix ssl_, but internally, MariaDB only supports its secure successors.

See Secure Connections Overview for more information about how to determine whether your MariaDB server has TLS support.

You can set certain TLS-related restrictions for specific user accounts. For instance, you might use this with user accounts that require access to sensitive data while sending it across networks that you do not control. These restrictions can be enabled for a user account with the CREATE USER, ALTER USER, or GRANT statements. The following options are available:

Option	Description
`REQUIRE NONE`	TLS is not required for this account, but can still be used.
`REQUIRE SSL`	The account must use TLS, but no valid X509 certificate is required. This option cannot be combined with other TLS options.
`REQUIRE X509`	The account must use TLS and must have a valid X509 certificate. This option implies `REQUIRE SSL`. This option cannot be combined with other TLS options.
`REQUIRE ISSUER 'issuer'`	The account must use TLS and must have a valid X509 certificate. Also, the Certificate Authority must be the one specified via the string `issuer`. This option implies `REQUIRE X509`. This option can be combined with the `SUBJECT`, and `CIPHER` options in any order.
`REQUIRE SUBJECT 'subject'`	The account must use TLS and must have a valid X509 certificate. Also, the certificate's Subject must be the one specified via the string `subject`. This option implies `REQUIRE X509`. This option can be combined with the `ISSUER`, and `CIPHER` options in any order.

`REQUIRE CIPHER 'cipher'`	The account must use TLS, but no valid X509 certificate is required. Also, the encryption used for the connection must use a specific cipher method specified in the string `cipher`. This option implies `REQUIRE SSL`. This option can be combined with the `ISSUER`, and `SUBJECT` options in any order.

The `REQUIRE` keyword must be used only once for all specified options, and the `AND` keyword can be used to separate individual options, but it is not required.

For example, you can create a user account that requires these TLS options with the following:

```
CREATE USER 'alice'@'%'
 REQUIRE SUBJECT '/CN=alice/O=My Dom, Inc./C=US/ST=Oregon/L=Portland'
 AND ISSUER '/C=FI/ST=Somewhere/L=City/ O=Some Company/CN=Peter
Parker/emailAddress=p.parker@marvel.com'
 AND CIPHER 'SHA-DES-CBC3-EDH-RSA';
```

If any of these options are set for a specific user account, then any client who tries to connect with that user account will have to be configured to connect with TLS.

See Securing Connections for Client and Server for information on how to enable TLS on the client and server.

Resource Limit Options

It is possible to set per-account limits for certain server resources. The following table shows the values that can be set per account:

Limit Type	Decription
`MAX_QUERIES_PER_HOUR`	Number of statements that the account can issue per hour (including updates)
`MAX_UPDATES_PER_HOUR`	Number of updates (not queries) that the account can issue per hour
`MAX_CONNECTIONS_PER_HOUR`	Number of connections that the account can start per hour
`MAX_USER_CONNECTIONS`	Number of simultaneous connections that can be accepted from the same account; if it is 0, `max_connections` will be used instead; if `max_connections` is 0, there is no limit for this account's simultaneous connections.
`MAX_STATEMENT_TIME`	Timeout, in seconds, for statements executed by the user. See also Aborting Statements that Exceed a Certain Time to Execute.

If any of these limits are set to `0`, then there is no limit for that resource for that user.

Here is an example showing how to create a user with resource limits:

```
CREATE USER 'someone'@'localhost' WITH
    MAX_USER_CONNECTIONS 10
    MAX_QUERIES_PER_HOUR 200;
```

The resources are tracked per account, which means `'user'@'server'`; not per user name or per connection.

The count can be reset for all users using FLUSH USER_RESOURCES, FLUSH PRIVILEGES or mariadb-admin reload.

Per account resource limits are stored in the user table, in the mysql database. Columns used for resources limits are named `max_questions`, `max_updates`, `max_connections` (for `MAX_CONNECTIONS_PER_HOUR`), and `max_user_connections` (for `MAX_USER_CONNECTIONS`).

Account Names

Account names have both a user name component and a host name component, and are specified as `'user_name'@'host_name'`.

The user name and host name may be unquoted, quoted as strings using double quotes (`"`) or single quotes (`'`), or quoted as identifiers using backticks (`` ` ``). You must use quotes when using special characters (such as a hyphen) or wildcard characters. If you quote, you must quote the user name and host name separately (for example `'user_name'@'host_name'`).

Host Name Component

If the host name is not provided, it is assumed to be `'%'`.

Host names may contain the wildcard characters `%` and `_`. They are matched as if by the LIKE clause. If you need to use a wildcard character literally (for example, to match a domain name with an underscore), prefix the character with a backslash. See `LIKE` for more information on escaping wildcard characters.

Host name matches are case-insensitive. Host names can match either domain names or IP addresses. Use `'localhost'` as the host name to allow only local client connections. On Linux, the loopback interface (127.0.0.1) will not match 'localhost' as it is not considered a local connection: this means that only connections via UNIX-domain sockets will match 'localhost'.

You can use a netmask to match a range of IP addresses using `'base_ip/netmask'` as the host name. A user with an IP address *ip_addr* will be allowed to connect if the following condition is true:

```
ip_addr & netmask = base_ip
```

For example, given a user:

```
CREATE USER 'maria'@'247.150.130.0/255.255.255.0';
```

the IP addresses satisfying this condition range from 247.150.130.0 to 247.150.130.255.

Using `255.255.255.255` is equivalent to not using a netmask at all. Netmasks cannot be used for IPv6 addresses.

Note that the credentials added when creating a user with the `'%'` wildcard host will not grant access in all cases. For example, some systems come with an anonymous localhost user, and when connecting from localhost this will take precedence.

Before MariaDB 10.6, the host name component could be up to 60 characters in length. Starting from MariaDB 10.6, it can be up to 255 characters.

User Name Component

User names must match exactly, including case. A user name that is empty is known as an anonymous account and is allowed to match a login attempt with any user name component. These are described more in the next section.

For valid identifiers to use as user names, see Identifier Names.

It is possible for more than one account to match when a user connects. MariaDB selects the first matching account after sorting according to the following criteria:

- Accounts with an exact host name are sorted before accounts using a wildcard in the host name. Host names using a netmask are considered to be exact for sorting.
- Accounts with a wildcard in the host name are sorted according to the position of the first wildcard character. Those with a wildcard character later in the host name sort before those with a wildcard character earlier in the host name.
- Accounts with a non-empty user name sort before accounts with an empty user name.
- Accounts with an empty user name are sorted last. As mentioned previously, these are known as anonymous accounts. These are described more in the next section.

The following table shows a list of example account as sorted by these criteria:

```
+---------+-------------+
| User    | Host        |
+---------+-------------+
| joffrey | 192.168.0.3 |
|         | 192.168.0.% |
| joffrey | 192.168.%   |
|         | 192.168.%   |
+---------+-------------+
```

Once connected, you only have the privileges granted to the account that matched, not all accounts that could have matched. For example, consider the following commands:

```
CREATE USER 'joffrey'@'192.168.0.3';
CREATE USER 'joffrey'@'%';
GRANT SELECT ON test.t1 to 'joffrey'@'192.168.0.3';
GRANT SELECT ON test.t2 to 'joffrey'@'%';
```

If you connect as joffrey from `192.168.0.3`, you will have the `SELECT` privilege on the table `test.t1`, but not on the table `test.t2`. If you connect as joffrey from any other IP address, you will have the `SELECT` privilege on the table `test.t2`, but not on the table `test.t1`.

Usernames can be up to 80 characters long before 10.6 and starting from 10.6 it can be 128 characters long.

Anonymous Accounts

Anonymous accounts are accounts where the user name portion of the account name is empty. These accounts act as special catch-all accounts. If a user attempts to log into the system from a host, and an anonymous account exists with a host name portion that matches the user's host, then the user will log in as the anonymous account if there is no more specific account match for the user name that the user entered.

For example, here are some anonymous accounts:

```
CREATE USER ''@'localhost';
CREATE USER ''@'192.168.0.3';
```

Fixing a Legacy Default Anonymous Account

On some systems, the mysql.db table has some entries for the `''@'%'` anonymous account by default. Unfortunately, there is no matching entry in the mysql.user/mysql.global_priv_table table, which means that this anonymous account doesn't exactly exist, but it does have privileges--usually on the default `test` database created by mariadb-install-db. These account-less privileges are a legacy that is leftover from a time when MySQL's privilege system was less advanced.

This situation means that you will run into errors if you try to create a `''@'%'` account. For example:

```
CREATE USER ''@'%';
ERROR 1396 (HY000): Operation CREATE USER failed for ''@'%'
```

The fix is to DELETE the row in the mysql.db table and then execute FLUSH PRIVILEGES:

```
DELETE FROM mysql.db WHERE User='' AND Host='%';
FLUSH PRIVILEGES;
```

Note that `FLUSH PRIVILEGES` is only needed if one modifies the `mysql` tables directly. It is not needed when using `CREATE USER`, `DROP USER`, `GRANT` etc.

And then the account can be created:

```
CREATE USER ''@'%';
Query OK, 0 rows affected (0.01 sec)
```

See MDEV-13486 for more information.

Password Expiry

MariaDB starting with 10.4.3

Besides automatic password expiry, as determined by default_password_lifetime, password expiry times can be set on an individual user basis, overriding the global setting, for example:

```
CREATE USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY;
```

See User Password Expiry for more details.

Account Locking

MariaDB starting with 10.4.2

Account locking permits privileged administrators to lock/unlock user accounts. No new client connections will be permitted if an account is locked (existing connections are not affected). For example:

```
CREATE USER 'marijn'@'localhost' ACCOUNT LOCK;
```

See Account Locking for more details.

From MariaDB 10.4.7 and MariaDB 10.5.8, the *lock_option* and *password_option* clauses can occur in either order.

1.1.1.1.2 ALTER USER

Syntax

```
ALTER USER [IF EXISTS]
 user_specification [,user_specification] ...
  [REQUIRE {NONE | tls_option [[AND] tls_option] ...}]
  [WITH resource_option [resource_option] ...]
  [lock_option] [password_option]

user_specification:
  username [authentication_option]

authentication_option:
  IDENTIFIED BY 'password'
  | IDENTIFIED BY PASSWORD 'password_hash'
  | IDENTIFIED {VIA|WITH} authentication_rule [OR authentication_rule] ...

authentication_rule:
  authentication_plugin
  | authentication_plugin {USING|AS} 'authentication_string'
  | authentication_plugin {USING|AS} PASSWORD('password')

tls_option
  SSL
  | X509
  | CIPHER 'cipher'
  | ISSUER 'issuer'
  | SUBJECT 'subject'

resource_option
  MAX_QUERIES_PER_HOUR count
  | MAX_UPDATES_PER_HOUR count
  | MAX_CONNECTIONS_PER_HOUR count
  | MAX_USER_CONNECTIONS count
  | MAX_STATEMENT_TIME time

password_option:
  PASSWORD EXPIRE
  | PASSWORD EXPIRE DEFAULT
  | PASSWORD EXPIRE NEVER
  | PASSWORD EXPIRE INTERVAL N DAY

lock_option:
    ACCOUNT LOCK
  | ACCOUNT UNLOCK
}
```

Contents

Description

The `ALTER USER` statement modifies existing MariaDB accounts. To use it, you must have the global CREATE USER privilege or the UPDATE privilege for the mysql database. The global SUPER privilege is also required if the read_only system variable is enabled.

If any of the specified user accounts do not yet exist, an error results. If an error occurs, `ALTER USER` will still modify the accounts that do not result in an error. Only one error is produced for all users which have not been modified.

For renaming an existing account (user name and/or host), see RENAME USER.

IF EXISTS

When the `IF EXISTS` clause is used, MariaDB will return a warning instead of an error for each specified user that does not exist.

Account Names

For `ALTER USER` statements, account names are specified as the `username` argument in the same way as they are for CREATE USER statements. See account names from the `CREATE USER` page for details on how account names are specified.

CURRENT_USER or `CURRENT_USER()` can also be used to alter the account logged into the current session. For example, to change the current user's password to `mariadb`:

```
ALTER USER CURRENT_USER() IDENTIFIED BY 'mariadb';
```

Authentication Options

MariaDB starting with 10.4

From MariaDB 10.4, it is possible to use more than one authentication plugin for each user account. For example, this can be useful to slowly migrate users to the more secure ed25519 authentication plugin over time, while allowing the old mysql_native_password authentication plugin as an alternative for the transitional period. See Authentication from MariaDB 10.4 for more.

When running `ALTER USER`, not specifying an authentication option in the IDENTIFIED VIA clause will remove that authentication method. (However this was not the case before MariaDB 10.4.13, see MDEV-21928)

For example, a user is created with the ability to authenticate via both a password and unix_socket:

```
CREATE USER 'bob'@'localhost'
  IDENTIFIED VIA mysql_native_password USING PASSWORD('pwd')
  OR unix_socket;

SHOW CREATE USER 'bob'@'localhost'\G
*************************** 1. row ***************************
CREATE USER for bob@localhost: CREATE USER `bob`@`localhost`
  IDENTIFIED VIA mysql_native_password
  USING '*975B2CD4FF9AE554FE8AD33168FBFC326D2021DD'
  OR unix_socket
```

If the user's password is updated, but unix_socket authentication is not specified in the `IDENTIFIED VIA` clause, unix_socket authentication will no longer be permitted.

```
ALTER USER 'bob'@'localhost' IDENTIFIED VIA mysql_native_password
  USING PASSWORD('pwd2');

SHOW CREATE USER 'bob'@'localhost'\G
*************************** 1. row ***************************
CREATE USER for bob@localhost: CREATE USER `bob`@`localhost`
  IDENTIFIED BY PASSWORD '*38366FDA01695B6A5A9DD4E428D9FB8F7EB75512'
```

IDENTIFIED BY 'password'

The optional `IDENTIFIED BY` clause can be used to provide an account with a password. The password should be specified in plain text. It will be hashed by the PASSWORD function prior to being stored to the mysql.user table.

For example, if our password is `mariadb`, then we can set the account's password with:

```
ALTER USER foo2@test IDENTIFIED BY 'mariadb';
```

If you do not specify a password with the `IDENTIFIED BY` clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

The only authentication plugins that this clause supports are mysql_native_password and mysql_old_password.

IDENTIFIED BY PASSWORD 'password_hash'

The optional `IDENTIFIED BY PASSWORD` clause can be used to provide an account with a password that has already been hashed. The password should be specified as a hash that was provided by the PASSWORD#function. It will be stored to the mysql.user table as-is.

For example, if our password is `mariadb`, then we can find the hash with:

```
SELECT PASSWORD('mariadb');
+-------------------------------------------+
| PASSWORD('mariadb')                       |
+-------------------------------------------+
| *54958E764CE10E50764C2EECBB71D01F08549980 |
+-------------------------------------------+
```

And then we can set an account's password with the hash:

```
ALTER USER foo2@test
  IDENTIFIED BY PASSWORD '*54958E764CE10E50764C2EECBB71D01F08549980';
```

If you do not specify a password with the `IDENTIFIED BY` clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

The only authentication plugins that this clause supports are mysql_native_password and mysql_old_password.

IDENTIFIED {VIA|WITH} authentication_plugin

The optional `IDENTIFIED VIA authentication_plugin` allows you to specify that the account should be authenticated by a specific authentication plugin. The plugin name must be an active authentication plugin as per SHOW PLUGINS. If it doesn't show up in that output, then you will need to install it with INSTALL PLUGIN or INSTALL SONAME.

For example, this could be used with the PAM authentication plugin:

```
ALTER USER foo2@test IDENTIFIED VIA pam;
```

Some authentication plugins allow additional arguments to be specified after a `USING` or `AS` keyword. For example, the PAM authentication plugin accepts a service name:

```
ALTER USER foo2@test IDENTIFIED VIA pam USING 'mariadb';
```

The exact meaning of the additional argument would depend on the specific authentication plugin.

In MariaDB 10.4 and later, the `USING` or `AS` keyword can also be used to provide a plain-text password to a plugin if it's provided as an argument to the PASSWORD() function. This is only valid for authentication plugins that have implemented a hook for the PASSWORD() function. For example, the ed25519 authentication plugin supports this:

```
ALTER USER safe@'%' IDENTIFIED VIA ed25519 USING PASSWORD('secret');
```

TLS Options

By default, MariaDB transmits data between the server and clients without encrypting it. This is generally acceptable when the server and client run on the same host or in networks where security is guaranteed through other means. However, in cases where the server and client exist on separate networks or they are in a high-risk network, the lack of encryption does introduce security concerns as a malicious actor could potentially eavesdrop on the traffic as it is sent over the network between them.

To mitigate this concern, MariaDB allows you to encrypt data in transit between the server and clients using the Transport Layer Security (TLS) protocol. TLS was formerly known as Secure Socket Layer (SSL), but strictly speaking the SSL protocol is a predecessor to TLS and, that version of the protocol is now considered insecure. The documentation still uses

the term SSL often and for compatibility reasons TLS-related server system and status variables still use the prefix ssl_, but internally, MariaDB only supports its secure successors.

See Secure Connections Overview for more information about how to determine whether your MariaDB server has TLS support.

You can set certain TLS-related restrictions for specific user accounts. For instance, you might use this with user accounts that require access to sensitive data while sending it across networks that you do not control. These restrictions can be enabled for a user account with the CREATE USER, ALTER USER, or GRANT statements. The following options are available:

Option	Description
`REQUIRE NONE`	TLS is not required for this account, but can still be used.
`REQUIRE SSL`	The account must use TLS, but no valid X509 certificate is required. This option cannot be combined with other TLS options.
`REQUIRE X509`	The account must use TLS and must have a valid X509 certificate. This option implies `REQUIRE SSL`. This option cannot be combined with other TLS options.
`REQUIRE ISSUER 'issuer'`	The account must use TLS and must have a valid X509 certificate. Also, the Certificate Authority must be the one specified via the string `issuer`. This option implies `REQUIRE X509`. This option can be combined with the `SUBJECT`, and `CIPHER` options in any order.
`REQUIRE SUBJECT 'subject'`	The account must use TLS and must have a valid X509 certificate. Also, the certificate's Subject must be the one specified via the string `subject`. This option implies `REQUIRE X509`. This option can be combined with the `ISSUER`, and `CIPHER` options in any order.
`REQUIRE CIPHER 'cipher'`	The account must use TLS, but no valid X509 certificate is required. Also, the encryption used for the connection must use a specific cipher method specified in the string `cipher`. This option implies `REQUIRE SSL`. This option can be combined with the `ISSUER`, and `SUBJECT` options in any order.

The `REQUIRE` keyword must be used only once for all specified options, and the `AND` keyword can be used to separate individual options, but it is not required.

For example, you can alter a user account to require these TLS options with the following:

```
ALTER USER 'alice'@'%'
 REQUIRE SUBJECT '/CN=alice/O=My Dom, Inc./C=US/ST=Oregon/L=Portland' AND
 ISSUER '/C=FI/ST=Somewhere/L=City/ O=Some Company/CN=Peter Parker/emailAddress=p.parker@marvel.c
 AND CIPHER 'SHA-DES-CBC3-EDH-RSA';
```

If any of these options are set for a specific user account, then any client who tries to connect with that user account will have to be configured to connect with TLS.

See Securing Connections for Client and Server for information on how to enable TLS on the client and server.

Resource Limit Options

It is possible to set per-account limits for certain server resources. The following table shows the values that can be set per account:

Limit Type	Description
`MAX_QUERIES_PER_HOUR`	Number of statements that the account can issue per hour (including updates)
`MAX_UPDATES_PER_HOUR`	Number of updates (not queries) that the account can issue per hour
`MAX_CONNECTIONS_PER_HOUR`	Number of connections that the account can start per hour
`MAX_USER_CONNECTIONS`	Number of simultaneous connections that can be accepted from the same account; if it is 0, `max_connections` will be used instead; if `max_connections` is 0, there is no limit for this account's simultaneous connections.
`MAX_STATEMENT_TIME`	Timeout, in seconds, for statements executed by the user. See also Aborting Statements that Exceed a Certain Time to Execute.

If any of these limits are set to `0`, then there is no limit for that resource for that user.

Here is an example showing how to set an account's resource limits:

```
ALTER USER 'someone'@'localhost' WITH
    MAX_USER_CONNECTIONS 10
    MAX_QUERIES_PER_HOUR 200;
```

The resources are tracked per account, which means `'user'@'server'`; not per user name or per connection.

The count can be reset for all users using FLUSH USER_RESOURCES, FLUSH PRIVILEGES or mysqladmin reload.

Per account resource limits are stored in the user table, in the mysql database. Columns used for resources limits are named `max_questions`, `max_updates`, `max_connections` (for `MAX_CONNECTIONS_PER_HOUR`), and `max_user_connections` (for `MAX_USER_CONNECTIONS`).

Password Expiry

MariaDB starting with 10.4.3

Besides automatic password expiry, as determined by default_password_lifetime, password expiry times can be set on an individual user basis, overriding the global setting, for example:

```
ALTER USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY;
ALTER USER 'monty'@'localhost' PASSWORD EXPIRE NEVER;
ALTER USER 'monty'@'localhost' PASSWORD EXPIRE DEFAULT;
```

See User Password Expiry for more details.

Account Locking

MariaDB starting with 10.4.2

Account locking permits privileged administrators to lock/unlock user accounts. No new client connections will be permitted if an account is locked (existing connections are not affected). For example:

```
ALTER USER 'marijn'@'localhost' ACCOUNT LOCK;
```

See Account Locking for more details.

From MariaDB 10.4.7 and MariaDB 10.5.8, the *lock_option* and *password_option* clauses can occur in either order.

1.1.1.1.3 DROP USER

Syntax

```
DROP USER [IF EXISTS] user_name [, user_name] ...
```

Contents

Description

The `DROP USER` statement removes one or more MariaDB accounts. It removes privilege rows for the account from all grant tables. To use this statement, you must have the global CREATE USER privilege or the DELETE privilege for the mysql database. Each account is named using the same format as for the `CREATE USER` statement; for example, `'jeffrey'@'localhost'`. If you specify only the user name part of the account name, a host name part of `'%'` is used. For additional information about specifying account names, see CREATE USER.

Note that, if you specify an account that is currently connected, it will not be deleted until the connection is closed. The connection will not be automatically closed.

If any of the specified user accounts do not exist, `ERROR 1396 (HY000)` results. If an error occurs, `DROP USER` will still drop the accounts that do not result in an error. Only one error is produced for all users which have not been dropped:

```
ERROR 1396 (HY000): Operation DROP USER failed for 'u1'@'%','u2'@'%'
```

Failed `CREATE` or `DROP` operations, for both users and roles, produce the same error code.

IF EXISTS

If the `IF EXISTS` clause is used, MariaDB will return a note instead of an error if the user does not exist.

Examples

```
DROP USER bob;

DROP USER foo2@localhost,foo2@'127.%';
```

`IF EXISTS`:

```
DROP USER bob;
ERROR 1396 (HY000): Operation DROP USER failed for 'bob'@'%'

DROP USER IF EXISTS bob;
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-------+------+-----------------------------------------+
| Level | Code | Message                                 |
+-------+------+-----------------------------------------+
| Note  | 1974 | Can't drop user 'bob'@'%'; it doesn't exist |
+-------+------+-----------------------------------------+
```

1.1.1.1.4 GRANT

Contents

Syntax

```
GRANT
    priv_type [(column_list)]
      [, priv_type [(column_list)]] ...
    ON [object_type] priv_level
    TO user_specification [ user_options ...]

user_specification:
  username [authentication_option]
  | PUBLIC
authentication_option:
  IDENTIFIED BY 'password'
  | IDENTIFIED BY PASSWORD 'password_hash'
  | IDENTIFIED {VIA|WITH} authentication_rule [OR authentication_rule  ...]

authentication_rule:
    authentication_plugin
  | authentication_plugin {USING|AS} 'authentication_string'
  | authentication_plugin {USING|AS} PASSWORD('password')

GRANT PROXY ON username
    TO user_specification [, user_specification ...]
    [WITH GRANT OPTION]

GRANT rolename TO grantee [, grantee ...]
    [WITH ADMIN OPTION]

grantee:
    rolename
    username [authentication_option]

user_options:
    [REQUIRE {NONE | tls_option [[AND] tls_option] ...}]
    [WITH with_option [with_option] ...]

object_type:
    TABLE
  | FUNCTION
  | PROCEDURE
  | PACKAGE
  | PACKAGE BODY

priv_level:
    *
  | *.*
  | db_name.*
  | db_name.tbl_name
  | tbl_name
  | db_name.routine_name

with_option:
    GRANT OPTION
  | resource_option

resource_option:
  MAX_QUERIES_PER_HOUR count
  | MAX_UPDATES_PER_HOUR count
  | MAX_CONNECTIONS_PER_HOUR count
  | MAX_USER_CONNECTIONS count
  | MAX_STATEMENT_TIME time

tls_option:
  SSL
  | X509
  | CIPHER 'cipher'
  | ISSUER 'issuer'
  | SUBJECT 'subject'
```

Description

The `GRANT` statement allows you to grant privileges or roles to accounts. To use `GRANT`, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are granting.

Use the REVOKE statement to revoke privileges granted with the `GRANT` statement.

Use the SHOW GRANTS statement to determine what privileges an account has.

Account Names

For `GRANT` statements, account names are specified as the `username` argument in the same way as they are for CREATE USER statements. See account names from the `CREATE USER` page for details on how account names are specified.

Implicit Account Creation

The `GRANT` statement also allows you to implicitly create accounts in some cases.

If the account does not yet exist, then `GRANT` can implicitly create it. To implicitly create an account with `GRANT`, a user is required to have the same privileges that would be required to explicitly create the account with the `CREATE USER` statement.

If the `NO_AUTO_CREATE_USER` SQL_MODE is set, then accounts can only be created if authentication information is specified, or with a CREATE USER statement. If no authentication information is provided, `GRANT` will produce an error when the specified account does not exist, for example:

```
show variables like '%sql_mode%' ;
+---------------+---------------------------------------------+
| Variable_name | Value                                       |
+---------------+---------------------------------------------+
| sql_mode      | NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION |
+---------------+---------------------------------------------+

GRANT USAGE ON *.* TO 'user123'@'%' IDENTIFIED BY '';
ERROR 1133 (28000): Can't find any matching row in the user table

GRANT USAGE ON *.* TO 'user123'@'%'
  IDENTIFIED VIA PAM using 'mariadb' require ssl ;
Query OK, 0 rows affected (0.00 sec)

select host, user from mysql.user where user='user123' ;

+------+----------+
| host | user     |
+------+----------+
| %    | user123 |
+------+----------+
```

Privilege Levels

Privileges can be set globally, for an entire database, for a table or routine, or for individual columns in a table. Certain privileges can only be set at certain levels.

Global privileges do not take effect immediately and are only applied to connections created after the `GRANT` statement was executed.

- Global privileges *priv_type* are granted using `*.*` for *priv_level*. Global privileges include privileges to administer the database and manage user accounts, as well as privileges for all tables, functions, and procedures. Global privileges are stored in the mysql.user table prior to MariaDB 10.4, and in mysql.global_priv table afterwards.
- Database privileges *priv_type* are granted using `db_name.*` for *priv_level*, or using just `*` to use default database. Database privileges include privileges to create tables and functions, as well as privileges for all tables, functions, and procedures in the database. Database privileges are stored in the mysql.db table.
- Table privileges *priv_type* are granted using `db_name.tbl_name` for *priv_level*, or using just `tbl_name` to specify a table in the default database. The `TABLE` keyword is optional. Table privileges include the ability to select and change data in the table. Certain table privileges can be granted for individual columns.
- Column privileges *priv_type* are granted by specifying a table for *priv_level* and providing a column list after the privilege type. They allow you to control exactly which columns in a table users can select and change.
- Function privileges *priv_type* are granted using `FUNCTION db_name.routine_name` for *priv_level*, or using just `FUNCTION routine_name` to specify a function in the default database.
- Procedure privileges *priv_type* are granted using `PROCEDURE db_name.routine_name` for *priv_level*, or using just `PROCEDURE routine_name` to specify a procedure in the default database.

The `USAGE` Privilege

The `USAGE` privilege grants no real privileges. The SHOW GRANTS statement will show a global `USAGE` privilege for a newly-created user. You can use `USAGE` with the `GRANT` statement to change options like `GRANT OPTION` and `MAX_USER_CONNECTIONS` without changing any account privileges.

The `ALL PRIVILEGES` Privilege

The `ALL PRIVILEGES` privilege grants all available privileges. Granting all privileges only affects the given privilege level. For example, granting all privileges on a table does not grant any privileges on the database or globally.

Using `ALL PRIVILEGES` does not grant the special `GRANT OPTION` privilege.

You can use `ALL` instead of `ALL PRIVILEGES`.

The `GRANT OPTION` Privilege

Use the `WITH GRANT OPTION` clause to give users the ability to grant privileges to other users at the given privilege level. Users with the `GRANT OPTION` privilege can only grant privileges they have. They cannot grant privileges at a higher privilege level than they have the `GRANT OPTION` privilege.

The `GRANT OPTION` privilege cannot be set for individual columns. If you use `WITH GRANT OPTION` when specifying column privileges, the `GRANT OPTION` privilege will be granted for the entire table.

Using the `WITH GRANT OPTION` clause is equivalent to listing `GRANT OPTION` as a privilege.

Global Privileges

The following table lists the privileges that can be granted globally. You can also grant all database, table, and function privileges globally. When granted globally, these privileges apply to all databases, tables, or functions, including those created later.

To set a global privilege, use `*.*` for *priv_level*.

BINLOG ADMIN

Enables administration of the binary log, including the PURGE BINARY LOGS statement and setting the system variables:

- binlog_annotate_row_events
- binlog_cache_size
- binlog_commit_wait_count
- binlog_commit_wait_usec
- binlog_direct_non_transactional_updates
- binlog_expire_logs_seconds
- binlog_file_cache_size
- binlog_format
- binlog_row_image
- binlog_row_metadata
- binlog_stmt_cache_size
- expire_logs_days
- log_bin_compress
- log_bin_compress_min_len
- log_bin_trust_function_creators
- max_binlog_cache_size
- max_binlog_size
- max_binlog_stmt_cache_size
- sql_log_bin and
- sync_binlog.

Added in MariaDB 10.5.2.

BINLOG MONITOR

New name for REPLICATION CLIENT from MariaDB 10.5.2, (`REPLICATION CLIENT` still supported as an alias for compatibility purposes). Permits running SHOW commands related to the binary log, in particular the SHOW BINLOG STATUS and SHOW BINARY LOGS statements. Unlike REPLICATION CLIENT prior to MariaDB 10.5, SHOW REPLICA STATUS isn't included in this privilege, and REPLICA MONITOR is required.

BINLOG REPLAY

Enables replaying the binary log with the BINLOG statement (generated by mariadb-binlog), executing SET timestamp

when secure_timestamp is set to `replication`, and setting the session values of system variables usually included in BINLOG output, in particular:

- gtid_domain_id
- gtid_seq_no
- pseudo_thread_id
- server_id.

Added in MariaDB 10.5.2

CONNECTION ADMIN

Enables administering connection resource limit options. This includes ignoring the limits specified by:

- max_connections
- max_user_connections and
- max_password_errors.

The statements specified in init_connect are not executed, killing connections and queries owned by other users is permitted. The following connection-related system variables can be changed:

- connect_timeout
- disconnect_on_expired_password
- extra_max_connections
- init_connect
- max_connections
- max_connect_errors
- max_password_errors
- proxy_protocol_networks
- secure_auth
- slow_launch_time
- thread_pool_exact_stats
- thread_pool_dedicated_listener
- thread_pool_idle_timeout
- thread_pool_max_threads
- thread_pool_min_threads
- thread_pool_oversubscribe
- thread_pool_prio_kickup_timer
- thread_pool_priority
- thread_pool_size, and
- thread_pool_stall_limit.

Added in MariaDB 10.5.2.

CREATE USER

Create a user using the CREATE USER statement, or implicitly create a user with the `GRANT` statement.

FEDERATED ADMIN

Execute CREATE SERVER, ALTER SERVER, and DROP SERVER statements. Added in MariaDB 10.5.2.

FILE

Read and write files on the server, using statements like LOAD DATA INFILE or functions like LOAD_FILE(). Also needed to create CONNECT outward tables. MariaDB server must have the permissions to access those files.

GRANT OPTION

Grant global privileges. You can only grant privileges that you have.

PROCESS

Show information about the active processes, for example via SHOW PROCESSLIST or mariadb-admin processlist. If you have the PROCESS privilege, you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MariaDB account that you are using).

READ_ONLY ADMIN

User can set the read_only system variable and allows the user to perform write operations, even when the `read_only` option is active. Added in MariaDB 10.5.2.

From MariaDB 10.11.0, the `READ_ONLY ADMIN` privilege has been removed from SUPER. The benefit of this is that one can remove the READ_ONLY ADMIN privilege from all users and ensure that no one can make any changes on any non-temporary tables. This is useful on replicas when one wants to ensure that the replica is kept identical to the primary.

RELOAD

Execute FLUSH statements or equivalent mariadb-admin commands.

REPLICATION CLIENT

Execute SHOW MASTER STATUS and SHOW BINARY LOGS informative statements. Renamed to BINLOG MONITOR in MariaDB 10.5.2 (but still supported as an alias for compatibility reasons). SHOW SLAVE STATUS was part of REPLICATION CLIENT prior to MariaDB 10.5.

REPLICATION MASTER ADMIN

Permits administration of primary servers, including the SHOW REPLICA HOSTS statement, and setting the gtid_binlog_state, gtid_domain_id, master_verify_checksum and server_id system variables. Added in MariaDB 10.5.2.

REPLICA MONITOR

Permit SHOW REPLICA STATUS and SHOW RELAYLOG EVENTS. From MariaDB 10.5.9.

When a user would upgrade from an older major release to a MariaDB 10.5 minor release prior to MariaDB 10.5.9, certain user accounts would lose capabilities. For example, a user account that had the REPLICATION CLIENT privilege in older major releases could run SHOW REPLICA STATUS, but after upgrading to a MariaDB 10.5 minor release prior to MariaDB 10.5.9, they could no longer run SHOW REPLICA STATUS, because that statement was changed to require the REPLICATION REPLICA ADMIN privilege.

This issue is fixed in MariaDB 10.5.9 with this new privilege, which now grants the user the ability to execute SHOW [ALL] (SLAVE | REPLICA) STATUS.

When a database is upgraded from an older major release to MariaDB Server 10.5.9 or later, any user accounts with the REPLICATION CLIENT or REPLICATION SLAVE privileges will automatically be granted the new REPLICA MONITOR privilege. The privilege fix occurs when the server is started up, not when mariadb-upgrade is performed.

However, when a database is upgraded from an early 10.5 minor release to 10.5.9 and later, the user will have to fix any user account privileges manually.

REPLICATION REPLICA

Synonym for REPLICATION SLAVE. From MariaDB 10.5.1.

REPLICATION SLAVE

Accounts used by replica servers on the primary need this privilege. This is needed to get the updates made on the master. From MariaDB 10.5.1, REPLICATION REPLICA is an alias for `REPLICATION SLAVE`.

REPLICATION SLAVE ADMIN

Permits administering replica servers, including START REPLICA/SLAVE, STOP REPLICA/SLAVE, CHANGE MASTER, SHOW REPLICA/SLAVE STATUS, SHOW RELAYLOG EVENTS statements, replaying the binary log with the BINLOG statement (generated by mariadb-binlog), and setting the system variables:

- gtid_cleanup_batch_size
- gtid_ignore_duplicates
- gtid_pos_auto_engines
- gtid_slave_pos
- gtid_strict_mode
- init_slave
- read_binlog_speed_limit
- relay_log_purge
- relay_log_recovery
- replicate_do_db
- replicate_do_table
- replicate_events_marked_for_skip
- replicate_ignore_db
- replicate_ignore_table
- replicate_wild_do_table
- replicate_wild_ignore_table

- slave_compressed_protocol
- slave_ddl_exec_mode
- slave_domain_parallel_threads
- slave_exec_mode
- slave_max_allowed_packet
- slave_net_timeout
- slave_parallel_max_queued
- slave_parallel_mode
- slave_parallel_threads
- slave_parallel_workers
- slave_run_triggers_for_rbr
- slave_sql_verify_checksum
- slave_transaction_retry_interval
- slave_type_conversions
- sync_master_info
- sync_relay_log, and
- sync_relay_log_info.

Added in MariaDB 10.5.2.

SET USER

Enables setting the `DEFINER` when creating triggers, views, stored functions and stored procedures. Added in MariaDB 10.5.2.

SHOW DATABASES

List all databases using the SHOW DATABASES statement. Without the `SHOW DATABASES` privilege, you can still issue the `SHOW DATABASES` statement, but it will only list databases containing tables on which you have privileges.

SHUTDOWN

Shut down the server using SHUTDOWN or the mariadb-admin shutdown command.

SUPER

Execute superuser statements: CHANGE MASTER TO, KILL (users who do not have this privilege can only `KILL` their own threads), PURGE LOGS, SET global system variables, or the mariadb-admin debug command. Also, this permission allows the user to write data even if the read_only startup option is set, enable or disable logging, enable or disable replication on replica, specify a `DEFINER` for statements that support that clause, connect once reaching the `MAX_CONNECTIONS`. If a statement has been specified for the init-connect `mysqld` option, that command will not be executed when a user with `SUPER` privileges connects to the server.

The SUPER privilege has been split into multiple smaller privileges from MariaDB 10.5.2 to allow for more fine-grained privileges (MDEV-21743). The privileges are:

- SET USER
- FEDERATED ADMIN
- CONNECTION ADMIN
- REPLICATION SLAVE ADMIN
- BINLOG ADMIN
- BINLOG REPLAY
- REPLICA MONITOR
- BINLOG MONITOR
- REPLICATION MASTER ADMIN
- READ_ONLY ADMIN

However, the smaller privileges are still a part of the SUPER grant in MariaDB 10.5.2. From MariaDB 11.0.1 onwards, these grants are no longer a part of SUPER and need to be granted separately (MDEV-29668).

From MariaDB 10.11.0, the READ_ONLY ADMIN privilege has been removed from `SUPER`. The benefit of this is that one can remove the READ_ONLY ADMIN privilege from all users and ensure that no one can make any changes on any non-temporary tables. This is useful on replicas when one wants to ensure that the replica is kept identical to the primary (MDEV-29596).

Database Privileges

The following table lists the privileges that can be granted at the database level. You can also grant all table and function privileges at the database level. Table and function privileges on a database apply to all tables or functions in that database,

including those created later.

To set a privilege for a database, specify the database using `db_name.*` for *priv_level*, or just use `*` to specify the default database.

Privilege	Description
`CREATE`	Create a database using the CREATE DATABASE statement, when the privilege is granted for a database. You can grant the `CREATE` privilege on databases that do not yet exist. This also grants the `CREATE` privilege on all tables in the database.
`CREATE ROUTINE`	Create Stored Programs using the CREATE PROCEDURE and CREATE FUNCTION statements.
`CREATE TEMPORARY TABLES`	Create temporary tables with the CREATE TEMPORARY TABLE statement. This privilege enable writing and dropping those temporary tables
`DROP`	Drop a database using the DROP DATABASE statement, when the privilege is granted for a database. This also grants the `DROP` privilege on all tables in the database.
`EVENT`	Create, drop and alter `EVENT` s.
`GRANT OPTION`	Grant database privileges. You can only grant privileges that you have.
`LOCK TABLES`	Acquire explicit locks using the LOCK TABLES statement; you also need to have the `SELECT` privilege on a table, in order to lock it.
`SHOW CREATE ROUTINE`	Permit viewing the `SHOW CREATE` definition statement of a routine, for example SHOW CREATE FUNCTION, even if not the routine owner. From MariaDB 11.3.0.

Table Privileges

Privilege	Description
`ALTER`	Change the structure of an existing table using the ALTER TABLE statement.
`CREATE`	Create a table using the CREATE TABLE statement. You can grant the `CREATE` privilege on tables that do not yet exist.
`CREATE VIEW`	Create a view using the CREATE_VIEW statement.
`DELETE`	Remove rows from a table using the DELETE statement.
`DELETE HISTORY`	Remove historical rows from a table using the DELETE HISTORY statement. Displays as `DELETE VERSIONING ROWS` when running SHOW GRANTS until MariaDB 10.3.15 and until MariaDB 10.4.5 (MDEV-17655), or when running SHOW PRIVILEGES until MariaDB 10.5.2, MariaDB 10.4.13 and MariaDB 10.3.23 (MDEV-20382). From MariaDB 10.3.4. From MariaDB 10.3.5, if a user has the `SUPER` privilege but not this privilege, running mariadb-upgrade will grant this privilege as well.
`DROP`	Drop a table using the DROP TABLE statement or a view using the DROP VIEW statement. Also required to execute the TRUNCATE TABLE statement.
`GRANT OPTION`	Grant table privileges. You can only grant privileges that you have.
`INDEX`	Create an index on a table using the CREATE INDEX statement. Without the `INDEX` privilege, you can still create indexes when creating a table using the CREATE TABLE statement if the you have the `CREATE` privilege, and you can create indexes using the ALTER TABLE statement if you have the `ALTER` privilege.
`INSERT`	Add rows to a table using the INSERT statement. The `INSERT` privilege can also be set on individual columns; see Column Privileges below for details.
`REFERENCES`	Unused.
`SELECT`	Read data from a table using the SELECT statement. The `SELECT` privilege can also be set on individual columns; see Column Privileges below for details.
`SHOW VIEW`	Show the CREATE VIEW statement to create a view using the SHOW CREATE VIEW statement.

`TRIGGER`	Required to run the CREATE TRIGGER, DROP TRIGGER, and SHOW CREATE TRIGGER statements. When another user activates a trigger (running INSERT, UPDATE, or DELETE statements on the associated table), for the trigger to execute, the user that defined the trigger should have the TRIGGER privilege for the table. The user running the INSERT, UPDATE, or DELETE statements on the table is not required to have the TRIGGER privilege.
`UPDATE`	Update existing rows in a table using the UPDATE statement. `UPDATE` statements usually include a `WHERE` clause to update only certain rows. You must have `SELECT` privileges on the table or the appropriate columns for the `WHERE` clause. The `UPDATE` privilege can also be set on individual columns; see Column Privileges below for details.

Column Privileges

Some table privileges can be set for individual columns of a table. To use column privileges, specify the table explicitly and provide a list of column names after the privilege type. For example, the following statement would allow the user to read the names and positions of employees, but not other information from the same table, such as salaries.

```
GRANT SELECT (name, position) on Employee to 'jeffrey'@'localhost';
```

Privilege	Description
`INSERT (column_list)`	Add rows specifying values in columns using the INSERT statement. If you only have column-level `INSERT` privileges, you must specify the columns you are setting in the `INSERT` statement. All other columns will be set to their default values, or `NULL`.
`REFERENCES (column_list)`	Unused.
`SELECT (column_list)`	Read values in columns using the SELECT statement. You cannot access or query any columns for which you do not have `SELECT` privileges, including in `WHERE`, `ON`, `GROUP BY`, and `ORDER BY` clauses.
`UPDATE (column_list)`	Update values in columns of existing rows using the UPDATE statement. `UPDATE` statements usually include a `WHERE` clause to update only certain rows. You must have `SELECT` privileges on the table or the appropriate columns for the `WHERE` clause.

Function Privileges

Privilege	Description
`ALTER ROUTINE`	Change the characteristics of a stored function using the ALTER FUNCTION statement.
`EXECUTE`	Use a stored function. You need `SELECT` privileges for any tables or columns accessed by the function.
`GRANT OPTION`	Grant function privileges. You can only grant privileges that you have.

Procedure Privileges

Privilege	Description
`ALTER ROUTINE`	Change the characteristics of a stored procedure using the ALTER PROCEDURE statement.
`EXECUTE`	Execute a stored procedure using the CALL statement. The privilege to call a procedure may allow you to perform actions you wouldn't otherwise be able to do, such as insert rows into a table.
`GRANT OPTION`	Grant procedure privileges. You can only grant privileges that you have.

```
GRANT EXECUTE ON PROCEDURE mysql.create_db TO maintainer;
```

Proxy Privileges

Privilege	Description

PROXY	Permits one user to be a proxy for another.

The PROXY privilege allows one user to proxy as another user, which means their privileges change to that of the proxy user, and the CURRENT_USER() function returns the user name of the proxy user.

The PROXY privilege only works with authentication plugins that support it. The default mysql_native_password authentication plugin does not support proxy users.

The pam authentication plugin is the only plugin included with MariaDB that currently supports proxy users. The PROXY privilege is commonly used with the pam authentication plugin to enable user and group mapping with PAM.

For example, to grant the PROXY privilege to an anonymous account that authenticates with the pam authentication plugin, you could execute the following:

```
CREATE USER 'dba'@'%' IDENTIFIED BY 'strongpassword';
GRANT ALL PRIVILEGES ON *.* TO 'dba'@'%' ;

CREATE USER ''@'%' IDENTIFIED VIA pam USING 'mariadb';
GRANT PROXY ON 'dba'@'%' TO ''@'%';
```

A user account can only grant the PROXY privilege for a specific user account if the granter also has the PROXY privilege for that specific user account, and if that privilege is defined WITH GRANT OPTION. For example, the following example fails because the granter does not have the PROXY privilege for that specific user account at all:

```
SELECT USER(), CURRENT_USER();
+-----------------+-----------------+
| USER()          | CURRENT_USER()  |
+-----------------+-----------------+
| alice@localhost | alice@localhost |
+-----------------+-----------------+

SHOW GRANTS;
+-------------------------------------------------------------------------------------------------
--------------------------+
| Grants for alice@localhost
|
+-------------------------------------------------------------------------------------------------
--------------------------+
| GRANT ALL PRIVILEGES ON *.* TO 'alice'@'localhost' IDENTIFIED BY PASSWORD
'*2470C0C06DEE42FD1618BB99005ADCA2EC9D1E19' |
+-------------------------------------------------------------------------------------------------
--------------------------+

GRANT PROXY ON 'dba'@'localhost' TO 'bob'@'localhost';
ERROR 1698 (28000): Access denied for user 'alice'@'localhost'
```

And the following example fails because the granter does have the PROXY privilege for that specific user account, but it is not defined WITH GRANT OPTION:

```
SELECT USER(), CURRENT_USER();
+----------------+----------------+
| USER()         | CURRENT_USER() |
+----------------+----------------+
| alice@localhost | alice@localhost |
+----------------+----------------+

SHOW GRANTS;
+-----------------------------------------------------------------------------------------------
--------------------------+
| Grants for alice@localhost
|
+-----------------------------------------------------------------------------------------------
--------------------------+
| GRANT ALL PRIVILEGES ON *.* TO 'alice'@'localhost' IDENTIFIED BY PASSWORD
'*2470C0C06DEE42FD1618BB99005ADCA2EC9D1E19' |
| GRANT PROXY ON 'dba'@'localhost' TO 'alice'@'localhost'
|
+-----------------------------------------------------------------------------------------------
--------------------------+

GRANT PROXY ON 'dba'@'localhost' TO 'bob'@'localhost';
ERROR 1698 (28000): Access denied for user 'alice'@'localhost'
```

But the following example succeeds because the granter does have the `PROXY` privilege for that specific user account, and it is defined `WITH GRANT OPTION`:

```
SELECT USER(), CURRENT_USER();
+----------------+----------------+
| USER()         | CURRENT_USER() |
+----------------+----------------+
| alice@localhost | alice@localhost |
+----------------+----------------+

SHOW GRANTS;
+-----------------------------------------------------------------------------------------------
-------------------------------------------+
| Grants for alice@localhost
|
+-----------------------------------------------------------------------------------------------
-------------------------------------------+
| GRANT ALL PRIVILEGES ON *.* TO 'alice'@'localhost' IDENTIFIED BY PASSWORD
'*2470C0C06DEE42FD1618BB99005ADCA2EC9D1E19' WITH GRANT OPTION |
| GRANT PROXY ON 'dba'@'localhost' TO 'alice'@'localhost' WITH GRANT OPTION
|
+-----------------------------------------------------------------------------------------------
-------------------------------------------+

GRANT PROXY ON 'dba'@'localhost' TO 'bob'@'localhost';
```

A user account can grant the `PROXY` privilege for any other user account if the granter has the `PROXY` privilege for the `''@'%'` anonymous user account, like this:

```
GRANT PROXY ON ''@'%' TO 'dba'@'localhost' WITH GRANT OPTION;
```

For example, the following example succeeds because the user can grant the `PROXY` privilege for any other user account:

```
SELECT USER(), CURRENT_USER();
+----------------+----------------+
| USER()         | CURRENT_USER() |
+----------------+----------------+
| alice@localhost | alice@localhost |
+----------------+----------------+

SHOW GRANTS;
+-------------------------------------------------------------------------------------------------
-----------------------------------------+
| Grants for alice@localhost
|
+-------------------------------------------------------------------------------------------------
-----------------------------------------+
| GRANT ALL PRIVILEGES ON *.* TO 'alice'@'localhost' IDENTIFIED BY PASSWORD
'*2470C0C06DEE42FD1618BB99005ADCA2EC9D1E19' WITH GRANT OPTION |
| GRANT PROXY ON ''@'%' TO 'alice'@'localhost' WITH GRANT OPTION
|
+-------------------------------------------------------------------------------------------------
-----------------------------------------+

GRANT PROXY ON 'app1_dba'@'localhost' TO 'bob'@'localhost';
Query OK, 0 rows affected (0.004 sec)

GRANT PROXY ON 'app2_dba'@'localhost' TO 'carol'@'localhost';
Query OK, 0 rows affected (0.004 sec)
```

The default `root` user accounts created by mariadb-install-db have this privilege. For example:

```
GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' WITH GRANT OPTION;
GRANT PROXY ON ''@'%' TO 'root'@'localhost' WITH GRANT OPTION;
```

This allows the default `root` user accounts to grant the `PROXY` privilege for any other user account, and it also allows the default `root` user accounts to grant others the privilege to do the same.

Authentication Options

The authentication options for the `GRANT` statement are the same as those for the CREATE USER statement.

IDENTIFIED BY 'password'

The optional `IDENTIFIED BY` clause can be used to provide an account with a password. The password should be specified in plain text. It will be hashed by the PASSWORD function prior to being stored.

For example, if our password is `mariadb` , then we can create the user with:

```
GRANT USAGE ON *.* TO foo2@test IDENTIFIED BY 'mariadb';
```

If you do not specify a password with the `IDENTIFIED BY` clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

If the user account already exists and if you provide the `IDENTIFIED BY` clause, then the user's password will be changed. You must have the privileges needed for the SET PASSWORD statement to change a user's password with `GRANT` .

The only authentication plugins that this clause supports are mysql_native_password and mysql_old_password.

IDENTIFIED BY PASSWORD 'password_hash'

The optional `IDENTIFIED BY PASSWORD` clause can be used to provide an account with a password that has already been hashed. The password should be specified as a hash that was provided by the PASSWORD function. It will be stored as-is.

For example, if our password is `mariadb` , then we can find the hash with:

```
SELECT PASSWORD('mariadb');
+-------------------------------------------+
| PASSWORD('mariadb')                       |
+-------------------------------------------+
| *54958E764CE10E50764C2EECBB71D01F08549980 |
+-------------------------------------------+
1 row in set (0.00 sec)
```

And then we can create a user with the hash:

```
GRANT USAGE ON *.* TO foo2@test IDENTIFIED BY
  PASSWORD '*54958E764CE10E50764C2EECBB71D01F08549980';
```

If you do not specify a password with the `IDENTIFIED BY` clause, the user will be able to connect without a password. A blank password is not a wildcard to match any password. The user must connect without providing a password if no password is set.

If the user account already exists and if you provide the `IDENTIFIED BY` clause, then the user's password will be changed. You must have the privileges needed for the SET PASSWORD statement to change a user's password with `GRANT`.

The only authentication plugins that this clause supports are mysql_native_password and mysql_old_password.

IDENTIFIED {VIA|WITH} authentication_plugin

The optional `IDENTIFIED VIA authentication_plugin` allows you to specify that the account should be authenticated by a specific authentication plugin. The plugin name must be an active authentication plugin as per SHOW PLUGINS. If it doesn't show up in that output, then you will need to install it with INSTALL PLUGIN or INSTALL SONAME.

For example, this could be used with the PAM authentication plugin:

```
GRANT USAGE ON *.* TO foo2@test IDENTIFIED VIA pam;
```

Some authentication plugins allow additional arguments to be specified after a `USING` or `AS` keyword. For example, the PAM authentication plugin accepts a service name:

```
GRANT USAGE ON *.* TO foo2@test IDENTIFIED VIA pam USING 'mariadb';
```

The exact meaning of the additional argument would depend on the specific authentication plugin.

MariaDB starting with 10.4.0

The `USING` or `AS` keyword can also be used to provide a plain-text password to a plugin if it's provided as an argument to the PASSWORD() function. This is only valid for authentication plugins that have implemented a hook for the PASSWORD() function. For example, the ed25519 authentication plugin supports this:

```
CREATE USER safe@'%' IDENTIFIED VIA ed25519
  USING PASSWORD('secret');
```

MariaDB starting with 10.4.3

One can specify many authentication plugins, they all work as alternatives ways of authenticating a user:

```
CREATE USER safe@'%' IDENTIFIED VIA ed25519
  USING PASSWORD('secret') OR unix_socket;
```

By default, when you create a user without specifying an authentication plugin, MariaDB uses the mysql_native_password plugin.

Resource Limit Options

It is possible to set per-account limits for certain server resources. The following table shows the values that can be set per account:

Limit Type	Decription
`MAX_QUERIES_PER_HOUR`	Number of statements that the account can issue per hour (including updates)

MAX_UPDATES_PER_HOUR	Number of updates (not queries) that the account can issue per hour
MAX_CONNECTIONS_PER_HOUR	Number of connections that the account can start per hour
MAX_USER_CONNECTIONS	Number of simultaneous connections that can be accepted from the same account; if it is 0, max_connections will be used instead; if max_connections is 0, there is no limit for this account's simultaneous connections.
MAX_STATEMENT_TIME	Timeout, in seconds, for statements executed by the user. See also Aborting Statements that Exceed a Certain Time to Execute.

If any of these limits are set to 0, then there is no limit for that resource for that user.

To set resource limits for an account, if you do not want to change that account's privileges, you can issue a GRANT statement with the USAGE privilege, which has no meaning. The statement can name some or all limit types, in any order.

Here is an example showing how to set resource limits:

```
GRANT USAGE ON *.* TO 'someone'@'localhost' WITH
    MAX_USER_CONNECTIONS 0
    MAX_QUERIES_PER_HOUR 200;
```

The resources are tracked per account, which means 'user'@'server'; not per user name or per connection.

The count can be reset for all users using FLUSH USER_RESOURCES, FLUSH PRIVILEGES or mariadb-admin reload.

Users with the CONNECTION ADMIN privilege (in MariaDB 10.5.2 and later) or the SUPER privilege are not restricted by max_user_connections, max_connections, or max_password_errors.

Per account resource limits are stored in the user table, in the mysql database. Columns used for resources limits are named max_questions, max_updates, max_connections (for MAX_CONNECTIONS_PER_HOUR), and max_user_connections (for MAX_USER_CONNECTIONS).

TLS Options

By default, MariaDB transmits data between the server and clients without encrypting it. This is generally acceptable when the server and client run on the same host or in networks where security is guaranteed through other means. However, in cases where the server and client exist on separate networks or they are in a high-risk network, the lack of encryption does introduce security concerns as a malicious actor could potentially eavesdrop on the traffic as it is sent over the network between them.

To mitigate this concern, MariaDB allows you to encrypt data in transit between the server and clients using the Transport Layer Security (TLS) protocol. TLS was formerly known as Secure Socket Layer (SSL), but strictly speaking the SSL protocol is a predecessor to TLS and, that version of the protocol is now considered insecure. The documentation still uses the term SSL often and for compatibility reasons TLS-related server system and status variables still use the prefix ssl_, but internally, MariaDB only supports its secure successors.

See Secure Connections Overview for more information about how to determine whether your MariaDB server has TLS support.

You can set certain TLS-related restrictions for specific user accounts. For instance, you might use this with user accounts that require access to sensitive data while sending it across networks that you do not control. These restrictions can be enabled for a user account with the CREATE USER, ALTER USER, or GRANT statements. The following options are available:

Option	Description
REQUIRE NONE	TLS is not required for this account, but can still be used.
REQUIRE SSL	The account must use TLS, but no valid X509 certificate is required. This option cannot be combined with other TLS options.
REQUIRE X509	The account must use TLS and must have a valid X509 certificate. This option implies REQUIRE SSL. This option cannot be combined with other TLS options.
REQUIRE ISSUER 'issuer'	The account must use TLS and must have a valid X509 certificate. Also, the Certificate Authority must be the one specified via the string issuer. This option implies REQUIRE X509. This option can be combined with the SUBJECT, and CIPHER options in any order.

`REQUIRE SUBJECT 'subject'`	The account must use TLS and must have a valid X509 certificate. Also, the certificate's Subject must be the one specified via the string `subject`. This option implies `REQUIRE X509`. This option can be combined with the `ISSUER`, and `CIPHER` options in any order.
`REQUIRE CIPHER 'cipher'`	The account must use TLS, but no valid X509 certificate is required. Also, the encryption used for the connection must use a specific cipher method specified in the string `cipher`. This option implies `REQUIRE SSL`. This option can be combined with the `ISSUER`, and `SUBJECT` options in any order.

The `REQUIRE` keyword must be used only once for all specified options, and the `AND` keyword can be used to separate individual options, but it is not required.

For example, you can create a user account that requires these TLS options with the following:

```
GRANT USAGE ON *.* TO 'alice'@'%'
  REQUIRE SUBJECT '/CN=alice/O=My Dom, Inc./C=US/ST=Oregon/L=Portland'
  AND ISSUER '/C=FI/ST=Somewhere/L=City/ O=Some Company/CN=Peter
Parker/emailAddress=p.parker@marvel.com'
  AND CIPHER 'SHA-DES-CBC3-EDH-RSA';
```

If any of these options are set for a specific user account, then any client who tries to connect with that user account will have to be configured to connect with TLS.

See Securing Connections for Client and Server for information on how to enable TLS on the client and server.

Roles

Syntax

```
GRANT role TO grantee [, grantee ... ]
[ WITH ADMIN OPTION ]

grantee:
    rolename
    username [authentication_option]
```

The GRANT statement is also used to grant the use of a role to one or more users or other roles. In order to be able to grant a role, the grantor doing so must have permission to do so (see WITH ADMIN in the CREATE ROLE article).

Specifying the `WITH ADMIN OPTION` permits the grantee to in turn grant the role to another.

For example, the following commands show how to grant the same role to a couple different users.

```
GRANT journalist TO hulda;

GRANT journalist TO berengar WITH ADMIN OPTION;
```

If a user has been granted a role, they do not automatically obtain all permissions associated with that role. These permissions are only in use when the user activates the role with the SET ROLE statement.

TO PUBLIC

MariaDB starting with 10.11

Syntax

```
GRANT <privilege> ON <database>.<object> TO PUBLIC;
REVOKE <privilege> ON <database>.<object> FROM PUBLIC;
```

GRANT ... TO PUBLIC grants privileges to all users with access to the server. The privileges also apply to users created after the privileges are granted. This can be useful when one only wants to state once that all users need to have a certain set of privileges.

When running SHOW GRANTS, a user will also see all privileges inherited from PUBLIC. SHOW GRANTS FOR PUBLIC will only show TO PUBLIC grants.

Grant Examples

Granting Root-like Privileges

You can create a user that has privileges similar to the default `root` accounts by executing the following:

```
CREATE USER 'alexander'@'localhost';
GRANT ALL PRIVILEGES ON  *.* to 'alexander'@'localhost' WITH GRANT OPTION;
```

1.1.1.1.5 RENAME USER

Syntax

```
RENAME USER old_user TO new_user
    [, old_user TO new_user] ...
```

Description

The RENAME USER statement renames existing MariaDB accounts. To use it, you must have the global CREATE USER privilege or the `UPDATE` privilege for the `mysql` database. Each account is named using the same format as for the CREATE USER statement; for example, `'jeffrey'@'localhost'` . If you specify only the user name part of the account name, a host name part of `'%'` is used.

If any of the old user accounts do not exist or any of the new user accounts already exist, `ERROR 1396 (HY000)` results. If an error occurs, `RENAME USER` will still rename the accounts that do not result in an error.

For modifying an existing account, see ALTER USER.

Examples

```
CREATE USER 'donald', 'mickey';
RENAME USER 'donald' TO 'duck'@'localhost', 'mickey' TO 'mouse'@'localhost';
```

Renaming the host component of a user

```
RENAME USER 'foo'@'1.2.3.4' TO 'foo'@'10.20.30.40';
```

1.1.1.1.6 REVOKE

Contents

Privileges

Syntax

```
REVOKE
    priv_type [(column_list)]
      [, priv_type [(column_list)]] ...
    ON [object_type] priv_level
    FROM user [, user] ...

REVOKE ALL PRIVILEGES, GRANT OPTION
    FROM user [, user] ...
```

Description

The `REVOKE` statement enables system administrators to revoke privileges (or roles - see section below) from MariaDB accounts. Each account is named using the same format as for the `GRANT` statement; for example, '`jeffrey'@'localhost`'. If you specify only the user name part of the account name, a host name part of '`%`' is used. For details on the levels at which privileges exist, the allowable `priv_type` and `priv_level` values, and the syntax for specifying users and passwords, see GRANT.

To use the first `REVOKE` syntax, you must have the `GRANT OPTION` privilege, and you must have the privileges that you are revoking.

To revoke all privileges, use the second syntax, which drops all global, database, table, column, and routine privileges for the named user or users:

```
REVOKE ALL PRIVILEGES, GRANT OPTION FROM user [, user] ...
```

To use this `REVOKE` syntax, you must have the global CREATE USER privilege or the UPDATE privilege for the mysql database. See GRANT.

Examples

```
REVOKE SUPER ON *.* FROM 'alexander'@'localhost';
```

Roles

Syntax

```
REVOKE role  [, role ...]
    FROM grantee [, grantee2 ... ]

REVOKE ADMIN OPTION FOR role FROM grantee [, grantee2]
```

Description

`REVOKE` is also used to remove a role from a user or another role that it's previously been assigned to. If a role has previously been set as a default role, `REVOKE` does not remove the record of the default role from the mysql.user table. If the role is subsequently granted again, it will again be the user's default. Use SET DEFAULT ROLE NONE to explicitly remove this.

Before MariaDB 10.1.13, the `REVOKE role` statement was not permitted in prepared statements.

Example

```
REVOKE journalist FROM hulda
```

1.1.1.1.7 SET PASSWORD

Syntax

```
SET PASSWORD [FOR user] =
    {
        PASSWORD('some password')
      | OLD_PASSWORD('some password')
      | 'encrypted password'
    }
```

Contents

Description

The `SET PASSWORD` statement assigns a password to an existing MariaDB user account.

If the password is specified using the `PASSWORD()` or `OLD_PASSWORD()` function, the literal text of the password should be given. If the password is specified without using either function, the password should be the already-encrypted password value as returned by `PASSWORD()`.

`OLD_PASSWORD()` should only be used if your MariaDB/MySQL clients are very old (< 4.0.0).

With no `FOR` clause, this statement sets the password for the current user. Any client that has connected to the server using a non-anonymous account can change the password for that account.

With a `FOR` clause, this statement sets the password for a specific account on the current server host. Only clients that have the `UPDATE` privilege for the `mysql` database can do this. The user value should be given in `user_name@host_name` format, where `user_name` and `host_name` are exactly as they are listed in the User and Host columns of the `mysql.user` table (or view in MariaDB-10.4 onwards) entry.

The argument to `PASSWORD()` and the password given to MariaDB clients can be of arbitrary length.

Authentication Plugin Support

MariaDB starting with 10.4

In MariaDB 10.4 and later, `SET PASSWORD` (with or without `PASSWORD()`) works for accounts authenticated via any authentication plugin that supports passwords stored in the `mysql.global_priv` table.

The `ed25519`, `mysql_native_password`, and `mysql_old_password` authentication plugins store passwords in the `mysql.global_priv` table.

If you run `SET PASSWORD` on an account that authenticates with one of these authentication plugins that stores passwords in the `mysql.global_priv` table, then the `PASSWORD()` function is evaluated by the specific authentication plugin used by the account. The authentication plugin hashes the password with a method that is compatible with that specific authentication plugin.

The `unix_socket`, `named_pipe`, `gssapi`, and `pam` authentication plugins do **not** store passwords in the `mysql.global_priv` table. These authentication plugins rely on other methods to authenticate the user.

If you attempt to run `SET PASSWORD` on an account that authenticates with one of these authentication plugins that doesn't store a password in the `mysql.global_priv` table, then MariaDB Server will raise a warning like the following:

```
SET PASSWORD is ignored for users authenticating via unix_socket plugin
```

See Authentication from MariaDB 10.4 for an overview of authentication changes in MariaDB 10.4.

MariaDB until 10.3

In MariaDB 10.3 and before, `SET PASSWORD` (with or without `PASSWORD()`) only works for accounts authenticated via `mysql_native_password` or `mysql_old_password` authentication plugins

Passwordless User Accounts

User accounts do not always require passwords to login.

The `unix_socket` , `named_pipe` and `gssapi` authentication plugins do not require a password to authenticate the user.

The `pam` authentication plugin may or may not require a password to authenticate the user, depending on the specific configuration.

The `mysql_native_password` and `mysql_old_password` authentication plugins require passwords for authentication, but the password can be blank. In that case, no password is required.

If you provide a password while attempting to log into the server as an account that doesn't require a password, then MariaDB server will simply ignore the password.

MariaDB starting with 10.4

In MariaDB 10.4 and later, a user account can be defined to use multiple authentication plugins in a specific order of preference. This specific scenario may be more noticeable in these versions, since an account could be associated with some authentication plugins that require a password, and some that do not.

Example

For example, if you had an entry with User and Host column values of ' `bob` ' and ' `%.loc.gov` ', you would write the statement like this:

```
SET PASSWORD FOR 'bob'@'%.loc.gov' = PASSWORD('newpass');
```

If you want to delete a password for a user, you would do:

```
SET PASSWORD FOR 'bob'@localhost = PASSWORD("");
```

1.1.1.1.8 CREATE ROLE

Syntax

```
CREATE [OR REPLACE] ROLE [IF NOT EXISTS] role
  [WITH ADMIN
    {CURRENT_USER | CURRENT_ROLE | user | role}]
```

Contents

Description

The `CREATE ROLE` statement creates one or more MariaDB roles. To use it, you must have the global CREATE USER privilege or the INSERT privilege for the mysql database. For each account, `CREATE ROLE` creates a new row in the mysql.user table that has no privileges, and with the corresponding `is_role` field set to `Y` . It also creates a record in the mysql.roles_mapping table.

If any of the specified roles already exist, `ERROR 1396 (HY000)` results. If an error occurs, `CREATE ROLE` will still create the roles that do not result in an error. The maximum length for a role is 128 characters. Role names can be quoted, as explained in the Identifier names page. Only one error is produced for all roles which have not been created:

```
ERROR 1396 (HY000): Operation CREATE ROLE failed for 'a','b','c'
```

Failed `CREATE` or `DROP` operations, for both users and roles, produce the same error code.

`PUBLIC` and `NONE` are reserved, and cannot be used as role names. `NONE` is used to unset a role and `PUBLIC` has a special use in other systems, such as Oracle, so is reserved for compatibility purposes.

For valid identifiers to use as role names, see Identifier Names.

WITH ADMIN

The optional `WITH ADMIN` clause determines whether the current user, the current role or another user or role has use of the newly created role. If the clause is omitted, `WITH ADMIN CURRENT_USER` is treated as the default, which means that the current user will be able to GRANT this role to users.

OR REPLACE

If the optional `OR REPLACE` clause is used, it acts as a shortcut for:

```
DROP ROLE IF EXISTS name;
CREATE ROLE name ...;
```

IF NOT EXISTS

When the `IF NOT EXISTS` clause is used, MariaDB will return a warning instead of an error if the specified role already exists. Cannot be used together with the `OR REPLACE` clause.

Examples

```
CREATE ROLE journalist;

CREATE ROLE developer WITH ADMIN lorinda@localhost;
```

Granting the role to another user. Only user `lorinda@localhost` has permission to grant the `developer` role:

```
 SELECT USER();
+-------------------+
| USER()            |
+-------------------+
| henning@localhost |
+-------------------+
...
GRANT developer TO ian@localhost;
Access denied for user 'henning'@'localhost'

 SELECT USER();
+-------------------+
| USER()            |
+-------------------+
| lorinda@localhost |
+-------------------+

GRANT m_role TO ian@localhost;
```

The `OR REPLACE` and `IF NOT EXISTS` clauses. The `journalist` role already exists:

```
CREATE ROLE journalist;
ERROR 1396 (HY000): Operation CREATE ROLE failed for 'journalist'

CREATE OR REPLACE ROLE journalist;
Query OK, 0 rows affected (0.00 sec)

CREATE ROLE IF NOT EXISTS journalist;
Query OK, 0 rows affected, 1 warning (0.00 sec)
```

```
SHOW WARNINGS;
+-------+------+-----------------------------------------------------+
| Level | Code | Message                                             |
+-------+------+-----------------------------------------------------+
| Note  | 1975 | Can't create role 'journalist'; it already exists |
+-------+------+-----------------------------------------------------+
```

1.1.1.1.9 DROP ROLE

Syntax

```
DROP ROLE [IF EXISTS] role_name [,role_name ...]
```

Contents

Description

The `DROP ROLE` statement removes one or more MariaDB roles. To use this statement, you must have the global CREATE USER privilege or the DELETE privilege for the mysql database.

`DROP ROLE` does not disable roles for connections which selected them with SET ROLE. If a role has previously been set as a default role, `DROP ROLE` does not remove the record of the default role from the mysql.user table. If the role is subsequently recreated and granted, it will again be the user's default. Use SET DEFAULT ROLE NONE to explicitly remove this.

If any of the specified user accounts do not exist, `ERROR 1396 (HY000)` results. If an error occurs, `DROP ROLE` will still drop the roles that do not result in an error. Only one error is produced for all roles which have not been dropped:

```
ERROR 1396 (HY000): Operation DROP ROLE failed for 'a','b','c'
```

Failed `CREATE` or `DROP` operations, for both users and roles, produce the same error code.

IF EXISTS

If the `IF EXISTS` clause is used, MariaDB will return a warning instead of an error if the role does not exist.

Examples

```
DROP ROLE journalist;
```

The same thing using the optional `IF EXISTS` clause:

```
DROP ROLE journalist;
ERROR 1396 (HY000): Operation DROP ROLE failed for 'journalist'

DROP ROLE IF EXISTS journalist;
Query OK, 0 rows affected, 1 warning (0.00 sec)

Note (Code 1975): Can't drop role 'journalist'; it doesn't exist
```

1.1.1.1.10 SET ROLE

Syntax

```
SET ROLE { role | NONE }
```

Contents

Description

The `SET ROLE` statement enables a role, along with all of its associated permissions, for the current session. To unset a role, use `NONE` .

If a role that doesn't exist, or to which the user has not been assigned, is specified, an `ERROR 1959 (OP000): Invalid role specification` error occurs.

An automatic SET ROLE is implicitly performed when a user connects if that user has been assigned a default role. See SET DEFAULT ROLE.

Example

```
SELECT CURRENT_ROLE;
+--------------+
| CURRENT_ROLE |
+--------------+
| NULL         |
+--------------+

SET ROLE staff;

SELECT CURRENT_ROLE;
+--------------+
| CURRENT_ROLE |
+--------------+
| staff        |
+--------------+

SET ROLE NONE;

SELECT CURRENT_ROLE();
+----------------+
| CURRENT_ROLE() |
+----------------+
| NULL           |
+----------------+
```

1.1.1.1.11 SET DEFAULT ROLE

Contents

Syntax

```
SET DEFAULT ROLE { role | NONE } [ FOR user@host ]
```

Description

The `SET DEFAULT ROLE` statement sets a **default role** for a specified (or current) user. A default role is automatically enabled when a user connects (an implicit SET ROLE statement is executed immediately after a connection is established).

To be able to set a role as a default, the role must already have been granted to that user, and one needs the privileges to enable this role (if you cannot do `SET ROLE X` , you won't be able to do `SET DEFAULT ROLE X`). To set a default role for another user one needs to have write access to the `mysql` database.

To remove a user's default role, use `SET DEFAULT ROLE NONE [ FOR user@host ]` . The record of the default role is not removed if the role is dropped or revoked, so if the role is subsequently re-created or granted, it will again be the user's default role.

The default role is stored in the `default_role` column in the mysql.user table/view, as well as in the Information Schema APPLICABLE_ROLES table, so these can be viewed to see which role has been assigned to a user as the default.

Examples

Setting a default role for the current user:

```
SET DEFAULT ROLE journalist;
```

Removing a default role from the current user:

```
SET DEFAULT ROLE NONE;
```

Setting a default role for another user. The role has to have been granted to the user before it can be set as default:

```
CREATE ROLE journalist;
CREATE USER taniel;

SET DEFAULT ROLE journalist FOR taniel;
ERROR 1959 (OP000): Invalid role specification `journalist`

GRANT journalist TO taniel;
SET DEFAULT ROLE journalist FOR taniel;
```

Viewing mysql.user:

```
select * from mysql.user where user='taniel'\G
*************************** 1. row ***************************
                  Host: %
                  User: taniel
...
               is_role: N
          default_role: journalist
...
```

Removing a default role for another user

```
SET DEFAULT ROLE NONE FOR taniel;
```

1.1.1.1.12 SHOW GRANTS

Contents

Syntax

```
SHOW GRANTS [FOR user|role]
```

Description

The `SHOW GRANTS` statement lists privileges granted to a particular user or role.

Users

The statement lists the GRANT statement or statements that must be issued to duplicate the privileges that are granted to a MariaDB user account. The account is named using the same format as for the `GRANT` statement; for example, '`jeffrey'@'localhost`'. If you specify only the user name part of the account name, a host name part of '`%`' is used. For additional information about specifying account names, see GRANT.

```
SHOW GRANTS FOR 'root'@'localhost';
+---------------------------------------------------------------------+
| Grants for root@localhost                                           |
+---------------------------------------------------------------------+
| GRANT ALL PRIVILEGES ON *.* TO 'root'@'localhost' WITH GRANT OPTION |
+---------------------------------------------------------------------+
```

To list the privileges granted to the account that you are using to connect to the server, you can use any of the following statements:

```
SHOW GRANTS;
SHOW GRANTS FOR CURRENT_USER;
SHOW GRANTS FOR CURRENT_USER();
```

If `SHOW GRANTS FOR CURRENT_USER` (or any of the equivalent syntaxes) is used in `DEFINER` context (such as within a stored procedure that is defined with `SQL SECURITY DEFINER`), the grants displayed are those of the definer and not the invoker.

Note that the `DELETE HISTORY` privilege, introduced in MariaDB 10.3.4, was displayed as `DELETE VERSIONING ROWS` when running `SHOW GRANTS` until MariaDB 10.3.15 (MDEV-17655).

Roles

`SHOW GRANTS` can also be used to view the privileges granted to a role.

Example

```
SHOW GRANTS FOR journalist;
+-----------------------------------------+
| Grants for journalist                   |
+-----------------------------------------+
| GRANT USAGE ON *.* TO 'journalist'      |
| GRANT DELETE ON `test`.* TO 'journalist' |
+-----------------------------------------+
```

FOR PUBLIC

MariaDB starting with 10.11

GRANT ... TO PUBLIC was introduced in MariaDB 10.11 to grant privileges to all users. `SHOW GRANTS FOR PUBLIC` shows all these grants.

```
SHOW GRANTS FOR public;
+-------------------------------------------------+
| Grants for PUBLIC                               |
+-------------------------------------------------+
| GRANT ALL PRIVILEGES ON `dev_db`.* TO `PUBLIC` |
+-------------------------------------------------+
```

1.1.1.1.13 SHOW CREATE USER

Syntax

```
SHOW CREATE USER [user]
```

Description

Shows the CREATE USER statement that created the given user. The statement requires the SELECT privilege for the mysql database, except for the current user. The CREATE USER statement for the current user is shown where no user is specified.

Examples

```
CREATE USER foo4@test require cipher 'text'
  issuer 'foo_issuer' subject 'foo_subject';

SHOW CREATE USER foo4@test\G
*************************** 1. row ***************************
CREATE USER 'foo4'@'test'
  REQUIRE ISSUER 'foo_issuer'
  SUBJECT 'foo_subject'
  CIPHER 'text'
```

User Password Expiry:

```
CREATE USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY;

SHOW CREATE USER 'monty'@'localhost';
+-----------------------------------------------------------------------+
| CREATE USER for monty@localhost                                       |
+-----------------------------------------------------------------------+
| CREATE USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY |
+-----------------------------------------------------------------------+
```

1.1.1.2 Administrative SQL Statements

SQL statements for administering MariaDB.

Table Statements

Documentation on creating, altering, analyzing and maintaining tables.

ANALYZE and EXPLAIN Statements

Articles on the ANALYZE and EXPLAIN statements

BACKUP Commands

Commands used by backup tools.

FLUSH Commands

Commands to flush or reset various caches in MariaDB.

Replication Commands

List of replication-related commands.

Plugin SQL Statements

List of SQL statements related to plugins.

SET Commands

The SET commands

SHOW

Articles on the various SHOW commands.

System Tables

BINLOG

Internal statement generated by mariadb-binlog.

PURGE BINARY LOGS

PURGE BINARY LOGS removes all binary logs from the server, prior to the provided date or log file.

CACHE INDEX

Caches MyISAM or Aria indexes

DESCRIBE

Information about columns in a table.

EXECUTE Statement

Executes a previously PREPAREd statement

HELP Command

The HELP command will retrieve syntax and help within the mariadb client.

KILL [CONNECTION | QUERY]

Kill connection by query or thread id.

LOAD INDEX

Loads one or more indexes from one or more MyISAM/Aria tables into a key buffer.

RESET

Overall description of the different RESET commands

SHUTDOWN

Shuts down the server.

USE [DATABASE]

Set the current default database.

There are 2 related questions.

1.1.1.2.1 Table Statements

Articles about creating, modifying, and maintaining tables in MariaDB.

ALTER

The various ALTER statements in MariaDB.

ANALYZE TABLE

Store key distributions for a table.

CHECK TABLE

Check table for errors.

CHECK VIEW

Check whether the view algorithm is correct.

CHECKSUM TABLE

Report a table checksum.

CREATE TABLE

Creates a new table.

DELETE

Delete rows from one or more tables.

DROP TABLE

Removes definition and data from one or more tables.

Installing System Tables (mariadb-install-db)

Using mariadb-install-db to create the system tables in the 'mysql' database directory.

mysqlcheck

Symlink or old name for mariadb-check.

mysql_upgrade

Symlink or old name for mariadb-upgrade.

OPTIMIZE TABLE

Reclaim unused space and defragment data.

RENAME TABLE

Change a table's name.

REPAIR TABLE

Repairs a table, if the storage engine supports this statement.

REPAIR VIEW

Fix view if the algorithms are swapped.

REPLACE

Equivalent to DELETE + INSERT, or just an INSERT if no rows are returned.

SHOW COLUMNS

Column information.

SHOW CREATE TABLE

Shows the CREATE TABLE statement that created the table.

SHOW INDEX

Information about table indexes.

TRUNCATE TABLE

DROP and re-CREATE a table.

UPDATE

Modify rows in one or more tables.

Obsolete Table Commands

Table commands that have been removed from MariaDB

IGNORE

Suppress errors while trying to violate a UNIQUE constraint.

System-Versioned Tables

System-versioned tables record the history of all changes to table data.

There are 2 related questions.

1.1.1.2.1.1 ALTER

This category is for documentation on the various ALTER statements.

ALTER TABLE

Modify a table's definition.

ALTER DATABASE

Change the overall characteristics of a database.

ALTER EVENT

Change an existing event.

ALTER FUNCTION

Change the characteristics of a stored function.

ALTER LOGFILE GROUP

Only useful with MySQL Cluster, and has no effect in MariaDB.

ALTER PROCEDURE

Change stored procedure characteristics.

ALTER SEQUENCE

Change options for a SEQUENCE.

ALTER SERVER

Updates mysql.servers table.

ALTER TABLESPACE

ALTER TABLESPACE is not available in MariaDB.

ALTER USER

Modify an existing MariaDB account.

ALTER VIEW

Change a view definition.

There are 1 related questions.

1.1.1.2.1.1.1 ALTER TABLE

Syntax

```
ALTER [ONLINE] [IGNORE] TABLE [IF EXISTS] tbl_name
    [WAIT n | NOWAIT]
    alter_specification [, alter_specification] ...

alter_specification:
    table_option ...
  | ADD [COLUMN] [IF NOT EXISTS] col_name column_definition
        [FIRST | AFTER col_name ]
  | ADD [COLUMN] [IF NOT EXISTS] (col_name column_definition,...)
  | ADD {INDEX|KEY} [IF NOT EXISTS] [index_name]
        [index_type] (index_col_name,...) [index_option] ...
  | ADD [CONSTRAINT [symbol]] PRIMARY KEY
        [index_type] (index_col_name,...) [index_option] ...
  | ADD [CONSTRAINT [symbol]]
        UNIQUE [INDEX|KEY] [index_name]
        [index_type] (index_col_name,...) [index_option] ...
  | ADD FULLTEXT [INDEX|KEY] [index_name]
        (index_col_name,...) [index_option] ...
  | ADD SPATIAL [INDEX|KEY] [index_name]
        (index_col_name,...) [index_option] ...
  | ADD [CONSTRAINT [symbol]]
        FOREIGN KEY [IF NOT EXISTS] [index_name] (index_col_name,...)
        reference_definition
  | ADD PERIOD FOR SYSTEM_TIME (start_column_name, end_column_name)
  | ALTER [COLUMN] col_name SET DEFAULT literal | (expression)
  | ALTER [COLUMN] col_name DROP DEFAULT
  | ALTER {INDEX|KEY} index_name [NOT] INVISIBLE
  | CHANGE [COLUMN] [IF EXISTS] old_col_name new_col_name column_definition
        [FIRST|AFTER col_name]
  | MODIFY [COLUMN] [IF EXISTS] col_name column_definition
        [FIRST | AFTER col_name]
  | DROP [COLUMN] [IF EXISTS] col_name [RESTRICT|CASCADE]
  | DROP PRIMARY KEY
  | DROP {INDEX|KEY} [IF EXISTS] index_name
  | DROP FOREIGN KEY [IF EXISTS] fk_symbol
```

```
  | DROP CONSTRAINT [IF EXISTS] constraint_name
  | DISABLE KEYS
  | ENABLE KEYS
  | RENAME [TO] new_tbl_name
  | ORDER BY col_name [, col_name] ...
  | RENAME COLUMN old_col_name TO new_col_name
  | RENAME {INDEX|KEY} old_index_name TO new_index_name
  | CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
  | [DEFAULT] CHARACTER SET [=] charset_name
  | [DEFAULT] COLLATE [=] collation_name
  | DISCARD TABLESPACE
  | IMPORT TABLESPACE
  | ALGORITHM [=] {DEFAULT|INPLACE|COPY|NOCOPY|INSTANT}
  | LOCK [=] {DEFAULT|NONE|SHARED|EXCLUSIVE}
  | FORCE
  | partition_options
  | CONVERT TABLE normal_table TO partition_definition
  | CONVERT PARTITION partition_name TO TABLE tbl_name
  | ADD PARTITION [IF NOT EXISTS] (partition_definition)
  | DROP PARTITION [IF EXISTS] partition_names
  | TRUNCATE PARTITION partition_names
  | COALESCE PARTITION number
  | REORGANIZE PARTITION [partition_names INTO (partition_definitions)]
  | ANALYZE PARTITION partition_names
  | CHECK PARTITION partition_names
  | OPTIMIZE PARTITION partition_names
  | REBUILD PARTITION partition_names
  | REPAIR PARTITION partition_names
  | EXCHANGE PARTITION partition_name WITH TABLE tbl_name
  | REMOVE PARTITIONING
  | ADD SYSTEM VERSIONING
  | DROP SYSTEM VERSIONING

index_col_name:
    col_name [(length)] [ASC | DESC]

    USING {BTREE | HASH | RTREE}

index_option:
    [ KEY_BLOCK_SIZE [=] value
  | index_type
  | WITH PARSER parser_name
  | COMMENT 'string'
  | CLUSTERING={YES| NO} ]
  [ IGNORED | NOT IGNORED ]

table_options:
    table_option [[,] table_option] ...
```

Contents

Description

`ALTER TABLE` enables you to change the structure of an existing table. For example, you can add or delete columns, create or destroy indexes, change the type of existing columns, or rename columns or the table itself. You can also change the comment for the table and the storage engine of the table.

If another connection is using the table, a metadata lock is active, and this statement will wait until the lock is released. This is also true for non-transactional tables.

When adding a `UNIQUE` index on a column (or a set of columns) which have duplicated values, an error will be produced and the statement will be stopped. To suppress the error and force the creation of `UNIQUE` indexes, discarding duplicates, the IGNORE option can be specified. This can be useful if a column (or a set of columns) should be UNIQUE but it contains duplicate values; however, this technique provides no control on which rows are preserved and which are deleted. Also, note that `IGNORE` is accepted but ignored in `ALTER TABLE ... EXCHANGE PARTITION` statements.

This statement can also be used to rename a table. For details see RENAME TABLE.

When an index is created, the storage engine may use a configurable buffer in the process. Incrementing the buffer speeds up the index creation. Aria and MyISAM allocate a buffer whose size is defined by aria_sort_buffer_size or myisam_sort_buffer_size, also used for REPAIR TABLE. InnoDB allocates three buffers whose size is defined by innodb_sort_buffer_size.

Privileges

Executing the `ALTER TABLE` statement generally requires at least the ALTER privilege for the table or the database..

If you are renaming a table, then it also requires the DROP, CREATE and INSERT privileges for the table or the database as well.

Online DDL

Online DDL is supported with the ALGORITHM and LOCK clauses.

See InnoDB Online DDL Overview for more information on online DDL with InnoDB.

ALTER ONLINE TABLE

ALTER ONLINE TABLE also works for partitioned tables.

Online `ALTER TABLE` is available by executing the following:

```
ALTER ONLINE TABLE ...;
```

This statement has the following semantics:

This statement is equivalent to the following:

```
ALTER TABLE ... LOCK=NONE;
```

See the LOCK alter specification for more information.

WAIT/NOWAIT

Set the lock wait timeout. See WAIT and NOWAIT.

IF EXISTS

The `IF EXISTS` and `IF NOT EXISTS` clauses are available for the following:

```
ADD COLUMN       [IF NOT EXISTS]
ADD INDEX        [IF NOT EXISTS]
ADD FOREIGN KEY  [IF NOT EXISTS]
ADD PARTITION    [IF NOT EXISTS]
CREATE INDEX     [IF NOT EXISTS]

DROP COLUMN      [IF EXISTS]
DROP INDEX       [IF EXISTS]
DROP FOREIGN KEY [IF EXISTS]
DROP PARTITION   [IF EXISTS]
CHANGE COLUMN    [IF EXISTS]
MODIFY COLUMN    [IF EXISTS]
DROP INDEX       [IF EXISTS]
```

When `IF EXISTS` and `IF NOT EXISTS` are used in clauses, queries will not report errors when the condition is triggered for that clause. A warning with the same message text will be issued and the ALTER will move on to the next clause in the statement (or end if finished).

MariaDB starting with 10.5.2

If this is directive is used after `ALTER ... TABLE`, one will not get an error if the table doesn't exist.

Column Definitions

See CREATE TABLE: Column Definitions for information about column definitions.

Index Definitions

See CREATE TABLE: Index Definitions for information about index definitions.

The CREATE INDEX and DROP INDEX statements can also be used to add or remove an index.

Character Sets and Collations

```
CONVERT TO CHARACTER SET charset_name [COLLATE collation_name]
[DEFAULT] CHARACTER SET [=] charset_name
[DEFAULT] COLLATE [=] collation_name
```

See Setting Character Sets and Collations for details on setting the character sets and collations.

Alter Specifications

Table Options

See CREATE TABLE: Table Options for information about table options.

ADD COLUMN

```
... ADD COLUMN [IF NOT EXISTS]  (col_name column_definition,...)
```

Adds a column to the table. The syntax is the same as in CREATE TABLE. If you are using `IF NOT_EXISTS` the column will not be added if it was not there already. This is very useful when doing scripts to modify tables.

The `FIRST` and `AFTER` clauses affect the physical order of columns in the datafile. Use `FIRST` to add a column in the first (leftmost) position, or `AFTER` followed by a column name to add the new column in any other position. Note that, nowadays, the physical position of a column is usually irrelevant.

See also Instant ADD COLUMN for InnoDB.

DROP COLUMN

```
... DROP COLUMN [IF EXISTS] col_name [CASCADE|RESTRICT]
```

Drops the column from the table. If you are using `IF EXISTS` you will not get an error if the column didn't exist. If the column is part of any index, the column will be dropped from them, except if you add a new column with identical name at the same time. The index will be dropped if all columns from the index were dropped. If the column was used in a view or trigger, you will get an error next time the view or trigger is accessed. Dropping a column that is part of a multi-column `UNIQUE` constraint is not permitted. For example:

```
CREATE TABLE a (
  a int,
  b int,
  primary key (a,b)
);

ALTER TABLE x DROP COLUMN a;
[42000][1072] Key column 'A' doesn't exist in table
```

The reason is that dropping column `a` would result in the new constraint that all values in column `b` be unique. In order to drop the column, an explicit `DROP PRIMARY KEY` and `ADD PRIMARY KEY` would be required. Up until MariaDB 10.2.7, the column was dropped and the additional constraint applied, resulting in the following structure:

```
ALTER TABLE x DROP COLUMN a;
Query OK, 0 rows affected (0.46 sec)

DESC x;
+-------+---------+------+-----+---------+-------+
| Field | Type    | Null | Key | Default | Extra |
+-------+---------+------+-----+---------+-------+
| b     | int(11) | NO   | PRI | NULL    |       |
+-------+---------+------+-----+---------+-------+
```

MariaDB starting with 10.4.0

MariaDB 10.4.0 supports instant DROP COLUMN. DROP COLUMN of an indexed column would imply DROP INDEX (and in the case of a non-UNIQUE multi-column index, possibly ADD INDEX). These will not be allowed with ALGORITHM=INSTANT, but unlike before, they can be allowed with ALGORITHM=NOCOPY

`RESTRICT` and `CASCADE` are allowed to make porting from other database systems easier. In MariaDB, they do nothing.

MODIFY COLUMN

Allows you to modify the type of a column. The column will be at the same place as the original column and all indexes on the column will be kept. Note that when modifying column, you should specify all attributes for the new column.

```
CREATE TABLE t1 (a INT UNSIGNED AUTO_INCREMENT, PRIMARY KEY((a));
ALTER TABLE t1 MODIFY a BIGINT UNSIGNED AUTO_INCREMENT;
```

CHANGE COLUMN

Works like `MODIFY COLUMN` except that you can also change the name of the column. The column will be at the same place as the original column and all index on the column will be kept.

```
CREATE TABLE t1 (a INT UNSIGNED AUTO_INCREMENT, PRIMARY KEY(a));
ALTER TABLE t1 CHANGE a b BIGINT UNSIGNED AUTO_INCREMENT;
```

ALTER COLUMN

This lets you change column options.

```
CREATE TABLE t1 (a INT UNSIGNED AUTO_INCREMENT, b varchar(50), PRIMARY KEY(a));
ALTER TABLE t1 ALTER b SET DEFAULT 'hello';
```

RENAME INDEX/KEY

MariaDB starting with 10.5.2

MariaDB starting with 10.5.2

From MariaDB 10.5.2, it is possible to rename an index using the `RENAME INDEX` (or `RENAME KEY`) syntax, for example:

```
ALTER TABLE t1 RENAME INDEX i_old TO i_new;
```

RENAME COLUMN

MariaDB starting with 10.5.2

From MariaDB 10.5.2, it is possible to rename a column using the `RENAME COLUMN` syntax, for example:

```
ALTER TABLE t1 RENAME COLUMN c_old TO c_new;
```

ADD PRIMARY KEY

Add a primary key.

For `PRIMARY KEY` indexes, you can specify a name for the index, but it is silently ignored, and the name of the index is always `PRIMARY`.

See Getting Started with Indexes: Primary Key for more information.

DROP PRIMARY KEY

Drop a primary key.

For `PRIMARY KEY` indexes, you can specify a name for the index, but it is silently ignored, and the name of the index is always `PRIMARY`.

See Getting Started with Indexes: Primary Key for more information.

ADD FOREIGN KEY

Add a foreign key.

For `FOREIGN KEY` indexes, a reference definition must be provided.

For `FOREIGN KEY` indexes, you can specify a name for the constraint, using the `CONSTRAINT` keyword. That name will be used in error messages.

First, you have to specify the name of the target (parent) table and a column or a column list which must be indexed and whose values must match to the foreign key's values. The `MATCH` clause is accepted to improve the compatibility with other DBMS's, but has no meaning in MariaDB. The `ON DELETE` and `ON UPDATE` clauses specify what must be done when a `DELETE` (or a `REPLACE`) statements attempts to delete a referenced row from the parent table, and when an `UPDATE` statement attempts to modify the referenced foreign key columns in a parent table row, respectively. The following options are allowed:

- `RESTRICT`: The delete/update operation is not performed. The statement terminates with a 1451 error (SQLSTATE '2300').
- `NO ACTION`: Synonym for `RESTRICT`.
- `CASCADE`: The delete/update operation is performed in both tables.
- `SET NULL`: The update or delete goes ahead in the parent table, and the corresponding foreign key fields in the child table are set to `NULL`. (They must not be defined as `NOT NULL` for this to succeed).
- `SET DEFAULT`: This option is implemented only for the legacy PBXT storage engine, which is disabled by default and no longer maintained. It sets the child table's foreign key fields to their `DEFAULT` values when the referenced parent table key entries are updated or deleted.

If either clause is omitted, the default behavior for the omitted clause is `RESTRICT`.

See Foreign Keys for more information.

DROP FOREIGN KEY

Drop a foreign key.

See Foreign Keys for more information.

ADD INDEX

Add a plain index.

Plain indexes are regular indexes that are not unique, and are not acting as a primary key or a foreign key. They are also not the "specialized" `FULLTEXT` or `SPATIAL` indexes.

See Getting Started with Indexes: Plain Indexes for more information.

DROP INDEX

Drop a plain index.

Plain indexes are regular indexes that are not unique, and are not acting as a primary key or a foreign key. They are also not the "specialized" `FULLTEXT` or `SPATIAL` indexes.

See Getting Started with Indexes: Plain Indexes for more information.

ADD UNIQUE INDEX

Add a unique index.

The `UNIQUE` keyword means that the index will not accept duplicated values, except for NULLs. An error will raise if you try to insert duplicate values in a UNIQUE index.

For `UNIQUE` indexes, you can specify a name for the constraint, using the `CONSTRAINT` keyword. That name will be used in error messages.

See Getting Started with Indexes: Unique Index for more information.

DROP UNIQUE INDEX

Drop a unique index.

The `UNIQUE` keyword means that the index will not accept duplicated values, except for NULLs. An error will raise if you try to insert duplicate values in a UNIQUE index.

For `UNIQUE` indexes, you can specify a name for the constraint, using the `CONSTRAINT` keyword. That name will be used in error messages.

See Getting Started with Indexes: Unique Index for more information.

ADD FULLTEXT INDEX

Add a `FULLTEXT` index.

See Full-Text Indexes for more information.

DROP FULLTEXT INDEX

Drop a `FULLTEXT` index.

See Full-Text Indexes for more information.

ADD SPATIAL INDEX

Add a SPATIAL index.

See SPATIAL INDEX for more information.

DROP SPATIAL INDEX

Drop a SPATIAL index.

See SPATIAL INDEX for more information.

ENABLE/ DISABLE KEYS

`DISABLE KEYS` will disable all non unique keys for the table for storage engines that support this (at least MyISAM and Aria). This can be used to speed up inserts into empty tables.

`ENABLE KEYS` will enable all disabled keys.

RENAME TO

Renames the table. See also RENAME TABLE.

ADD CONSTRAINT

Modifies the table adding a constraint on a particular column or columns.

```
ALTER TABLE table_name
ADD CONSTRAINT [constraint_name] CHECK(expression);
```

Before a row is inserted or updated, all constraints are evaluated in the order they are defined. If any constraint fails, then the row will not be updated. One can use most deterministic functions in a constraint, including UDF's.

```
CREATE TABLE account_ledger (
 id INT PRIMARY KEY AUTO_INCREMENT,
 transaction_name VARCHAR(100),
 credit_account VARCHAR(100),
 credit_amount INT,
 debit_account VARCHAR(100),
 debit_amount INT);

ALTER TABLE account_ledger
ADD CONSTRAINT is_balanced
    CHECK((debit_amount + credit_amount) = 0);
```

The `constraint_name` is optional. If you don't provide one in the `ALTER TABLE` statement, MariaDB auto-generates a name for you. This is done so that you can remove it later using DROP CONSTRAINT clause.

You can disable all constraint expression checks by setting the variable check_constraint_checks to `OFF`. You may find this useful when loading a table that violates some constraints that you want to later find and fix in SQL.

To view constraints on a table, query information_schema.TABLE_CONSTRAINTS:

```
SELECT CONSTRAINT_NAME, TABLE_NAME, CONSTRAINT_TYPE
FROM information_schema.TABLE_CONSTRAINTS
WHERE TABLE_NAME = 'account_ledger';

+-----------------+----------------+-----------------+
| CONSTRAINT_NAME | TABLE_NAME     | CONSTRAINT_TYPE |
+-----------------+----------------+-----------------+
| is_balanced     | account_ledger | CHECK           |
+-----------------+----------------+-----------------+
```

DROP CONSTRAINT

`DROP CONSTRAINT` for `UNIQUE` and `FOREIGN KEY` constraints was introduced in MariaDB 10.2.22 and MariaDB 10.3.13.

`DROP CONSTRAINT` for `CHECK` constraints was introduced in MariaDB 10.2.1

Modifies the table, removing the given constraint.

```
ALTER TABLE table_name
DROP CONSTRAINT constraint_name;
```

When you add a constraint to a table, whether through a CREATE TABLE or ALTER TABLE...ADD CONSTRAINT statement, you can either set a `constraint_name` yourself, or allow MariaDB to auto-generate one for you. To view constraints on a table, query information_schema.TABLE_CONSTRAINTS. For instance,

```
CREATE TABLE t (
   a INT,
   b INT,
   c INT,
   CONSTRAINT CHECK(a > b),
   CONSTRAINT check_equals CHECK(a = c));

SELECT CONSTRAINT_NAME, TABLE_NAME, CONSTRAINT_TYPE
FROM information_schema.TABLE_CONSTRAINTS
WHERE TABLE_NAME = 't';

+-----------------+---------------+-----------------+
| CONSTRAINT_NAME | TABLE_NAME    | CONSTRAINT_TYPE |
+-----------------+---------------+-----------------+
| check_equals    | t             | CHECK           |
| CONSTRAINT_1    | t             | CHECK           |
+-----------------+---------------+-----------------+
```

To remove a constraint from the table, issue an `ALTER TABLE...DROP CONSTRAINT` statement. For example,

```
ALTER TABLE t DROP CONSTRAINT is_unique;
```

ADD SYSTEM VERSIONING

Add system versioning. See System-versioned tables.

DROP SYSTEM VERSIONING

Drop system versioning. See System-versioned tables.

ADD PERIOD FOR SYSTEM_TIME

See System-versioned tables.

FORCE

`ALTER TABLE ... FORCE` can force MariaDB to re-build the table.

In MariaDB 5.5 and before, this could only be done by setting the ENGINE table option to its old value. For example, for an InnoDB table, one could execute the following:

```
ALTER TABLE tab_name ENGINE = InnoDB;
```

The `FORCE` option can be used instead. For example, :

```
ALTER TABLE tab_name FORCE;
```

With InnoDB, the table rebuild will only reclaim unused space (i.e. the space previously used for deleted rows) if the innodb_file_per_table system variable is set to `ON` (the default). If the system variable is `OFF`, then the space will not be reclaimed, but it will be-re-used for new data that's later added.

ADD PARTITION

See Partitioning Overview: Adding Partitions.

CONVERT PARTITION

`CONVERT PARTITION` was introduced in MariaDB 10.7.1.

`CONVERT PARTITION` can be used to remove a partition from a table and make this an ordinary table. For example:

```
ALTER TABLE partitioned_table CONVERT PARTITION part1 TO TABLE normal_table;
```

See Partitioning Overview: Converting Partitions to Tables for more details.

CONVERT TABLE /

`CONVERT TABLE` was introduced in MariaDB 10.7.1.

`CONVERT PARTITION` will take an existing table and move this to another table as its own partition with a specified partition definition. For example the following moves `normal_table` to a partition of `partitioned_table` with a definition that its values, based on the `PARTITION BY` of the `partitioned_table`, are less than 12345.

```
ALTER TABLE partitioned_table CONVERT TABLE normal_table
  TO PARTITION part1 VALUES LESS THAN (12345);
```

See also 10.7 preview feature: CONVERT PARTITION (mariadb.org blog post)

DROP PARTITION

See Partitioning Overview: Dropping Partitions.

EXCHANGE PARTITION

This is used to exchange the contents of a partition with another table.

This is performed by swapping the tablespaces of the partition with the other table.

See copying InnoDB's transportable tablespaces for more information.

REMOVE PARTITIONING

See Partitioning Overview: Removing Partitioning.

TRUNCATE PARTITION

See Partitioning Overview: Truncating Partitions.

DISCARD TABLESPACE

This is used to discard an InnoDB table's tablespace.

See copying InnoDB's transportable tablespaces for more information.

IMPORT TABLESPACE

This is used to import an InnoDB table's tablespace. The tablespace should have been copied from its original server after executing FLUSH TABLES FOR EXPORT.

See copying InnoDB's transportable tablespaces for more information.

`ALTER TABLE ... IMPORT` only applies to InnoDB tables. Most other popular storage engines, such as Aria and MyISAM, will recognize their data files as soon as they've been placed in the proper directory under the datadir, and no special DDL is required to import them.

ALGORITHM

The `ALTER TABLE` statement supports the `ALGORITHM` clause. This clause is one of the clauses that is used to implement online DDL. `ALTER TABLE` supports several different algorithms. An algorithm can be explicitly chosen for an `ALTER TABLE` operation by setting the `ALGORITHM` clause. The supported values are:

- `ALGORITHM=DEFAULT` - This implies the default behavior for the specific statement, such as if no `ALGORITHM` clause is specified.
- `ALGORITHM=COPY`
- `ALGORITHM=INPLACE`
- `ALGORITHM=NOCOPY` - This was added in MariaDB 10.3.7.
- `ALGORITHM=INSTANT` - This was added in MariaDB 10.3.7.

See InnoDB Online DDL Overview: ALGORITHM for information on how the `ALGORITHM` clause affects InnoDB.

ALGORITHM=DEFAULT

The default behavior, which occurs if `ALGORITHM=DEFAULT` is specified, or if `ALGORITHM` is not specified at all, usually only makes a copy if the operation doesn't support being done in-place at all. In this case, the most efficient available algorithm will usually be used.

However, in MariaDB 10.3.6 and before, if the value of the old_alter_table system variable is set to `ON`, then the default behavior is to perform `ALTER TABLE` operations by making a copy of the table using the old algorithm.

In MariaDB 10.3.7 and later, the old_alter_table system variable is deprecated. Instead, the alter_algorithm system variable defines the default algorithm for `ALTER TABLE` operations.

ALGORITHM=COPY

`ALGORITHM=COPY` is the name for the original ALTER TABLE algorithm from early MariaDB versions.

When `ALGORITHM=COPY` is set, MariaDB essentially does the following operations:

```
-- Create a temporary table with the new definition
CREATE TEMPORARY TABLE tmp_tab (
...
);

-- Copy the data from the original table
INSERT INTO tmp_tab
   SELECT * FROM original_tab;

-- Drop the original table
DROP TABLE original_tab;

-- Rename the temporary table, so that it replaces the original one
RENAME TABLE tmp_tab TO original_tab;
```

This algorithm is very inefficient, but it is generic, so it works for all storage engines.

If `ALGORITHM=COPY` is specified, then the copy algorithm will be used even if it is not necessary. This can result in a lengthy table copy. If multiple ALTER TABLE operations are required that each require the table to be rebuilt, then it is best to specify all operations in a single ALTER TABLE statement, so that the table is only rebuilt once.

From MariaDB 11.2, ALTER TABLE can now do most operations with ALGORITHM=COPY, LOCK=NONE. See LOCK=NONE.

ALGORITHM=INPLACE

`ALGORITHM=COPY` can be incredibly slow, because the whole table has to be copied and rebuilt. `ALGORITHM=INPLACE` was introduced as a way to avoid this by performing operations in-place and avoiding the table copy and rebuild, when possible.

When `ALGORITHM=INPLACE` is set, the underlying storage engine uses optimizations to perform the operation while avoiding the table copy and rebuild. However, `INPLACE` is a bit of a misnomer, since some operations may still require the table to be rebuilt for some storage engines. Regardless, several operations can be performed without a full copy of the table for some storage engines.

A more accurate name would have been `ALGORITHM=ENGINE`, where `ENGINE` refers to an "engine-specific" algorithm.

If an ALTER TABLE operation supports `ALGORITHM=INPLACE`, then it can be performed using optimizations by the underlying storage engine, but it may rebuilt.

See InnoDB Online DDL Operations with ALGORITHM=INPLACE for more.

ALGORITHM=NOCOPY

`ALGORITHM=NOCOPY` was introduced in MariaDB 10.3.7.

`ALGORITHM=INPLACE` can sometimes be surprisingly slow in instances where it has to rebuild the clustered index, because when the clustered index has to be rebuilt, the whole table has to be rebuilt. `ALGORITHM=NOCOPY` was introduced as a way to avoid this.

If an `ALTER TABLE` operation supports `ALGORITHM=NOCOPY`, then it can be performed without rebuilding the clustered index.

If `ALGORITHM=NOCOPY` is specified for an `ALTER TABLE` operation that does not support `ALGORITHM=NOCOPY`, then an error will be raised. In this case, raising an error is preferable, if the alternative is for the operation to rebuild the clustered index, and perform unexpectedly slowly.

See InnoDB Online DDL Operations with ALGORITHM=NOCOPY for more.

ALGORITHM=INSTANT

`ALGORITHM=INSTANT` was introduced in MariaDB 10.3.7.

`ALGORITHM=INPLACE` can sometimes be surprisingly slow in instances where it has to modify data files. `ALGORITHM=INSTANT` was introduced as a way to avoid this.

If an `ALTER TABLE` operation supports `ALGORITHM=INSTANT`, then it can be performed without modifying any data files.

If `ALGORITHM=INSTANT` is specified for an `ALTER TABLE` operation that does not support `ALGORITHM=INSTANT`, then an error will be raised. In this case, raising an error is preferable, if the alternative is for the operation to modify data files, and perform unexpectedly slowly.

See InnoDB Online DDL Operations with ALGORITHM=INSTANT for more.

LOCK

The `ALTER TABLE` statement supports the `LOCK` clause. This clause is one of the clauses that is used to implement online DDL. `ALTER TABLE` supports several different locking strategies. A locking strategy can be explicitly chosen for an `ALTER TABLE` operation by setting the `LOCK` clause. The supported values are:

DEFAULT

Acquire the least restrictive lock on the table that is supported for the specific operation. Permit the maximum amount of concurrency that is supported for the specific operation.

NONE

Acquire no lock on the table. Permit **all** concurrent DML. If this locking strategy is not permitted for an operation, then an error is raised. From MariaDB 11.2, `ALTER TABLE` can do most operations with `ALGORITHM=COPY, LOCK=NONE`, that is, in most cases, unless the algorithm and lock level are explicitly specified, `ALTER TABLE` will be performed using the `COPY` algorithm while simultaneously allowing concurrent DML statements on the altered table. If this is not desired, one can explicitly specify a different lock level or set old_mode to LOCK_ALTER_TABLE_COPY that will make `ALGORITHM=COPY` use `LOCK=SHARED` by default (but still allowing `LOCK=NONE` to be specified explicitly).

SHARED

Acquire a read lock on the table. Permit **read-only** concurrent DML. If this locking strategy is not permitted for an operation, then an error is raised.

EXCLUSIVE

Acquire a write lock on the table. Do **not** permit concurrent DML.

Different storage engines support different locking strategies for different operations. If a specific locking strategy is chosen for an `ALTER TABLE` operation, and that table's storage engine does not support that locking strategy for that specific operation, then an error will be raised.

If the `LOCK` clause is not explicitly set, then the operation uses `LOCK=DEFAULT`.

ALTER ONLINE TABLE is equivalent to `LOCK=NONE`. Therefore, the ALTER ONLINE TABLE statement can be used to ensure that your `ALTER TABLE` operation allows all concurrent DML.

See InnoDB Online DDL Overview: LOCK for information on how the `LOCK` clause affects InnoDB.

Progress Reporting

MariaDB provides progress reporting for `ALTER TABLE` statement for clients that support the new progress reporting protocol. For example, if you were using the mariadb client, then the progress report might look like this::

```
ALTER TABLE test ENGINE=Aria;
Stage: 1 of 2 'copy to tmp table'    46% of stage
```

The progress report is also shown in the output of the SHOW PROCESSLIST statement and in the contents of the information_schema.PROCESSLIST table.

See Progress Reporting for more information.

Aborting ALTER TABLE Operations

If an `ALTER TABLE` operation is being performed and the connection is killed, the changes will be rolled back in a controlled manner. The rollback can be a slow operation as the time it takes is relative to how far the operation has progressed.

Aborting `ALTER TABLE ... ALGORITHM=COPY` was made faster in MariaDB 10.2.13 by removing excessive undo logging (MDEV-11415). This significantly shortened the time it takes to abort a running ALTER TABLE operation, compared with earlier releases.

Atomic ALTER TABLE

MariaDB starting with 10.6.1

From MariaDB 10.6, `ALTER TABLE` is atomic for most engines, including InnoDB, MyRocks, MyISAM and Aria (MDEV-25180). This means that if there is a crash (server down or power outage) during an `ALTER TABLE` operation, after recovery, either the old table and associated triggers and status will be intact, or the new table will be active.

In older MariaDB versions one could get leftover #sql-alter..', '#sql-backup..' or 'table_name.frm~' files if the system crashed during the `ALTER TABLE` operation.

See Atomic DDL for more information.

Replication

MariaDB starting with 10.8.1

Before MariaDB 10.8.1, ALTER TABLE got fully executed on the primary first, and only then was it replicated and started executing on replicas. From MariaDB 10.8.1, ALTER TABLE gains an option to replicate sooner and begin executing on replicas when it merely *starts* executing on the primary, not when it *finishes*. This way the replication lag caused by a heavy ALTER TABLE can be completely eliminated (MDEV-11675).

Examples

Adding a new column:

```
ALTER TABLE t1 ADD x INT;
```

Dropping a column:

```
ALTER TABLE t1 DROP x;
```

Modifying the type of a column:

```
ALTER TABLE t1 MODIFY x bigint unsigned;
```

Changing the name and type of a column:

```
ALTER TABLE t1 CHANGE a b bigint unsigned auto_increment;
```

Combining multiple clauses in a single ALTER TABLE statement, separated by commas:

```
ALTER TABLE t1 DROP x, ADD x2 INT,  CHANGE y y2 INT;
```

Changing the storage engine and adding a comment:

```
ALTER TABLE t1
  ENGINE = InnoDB
  COMMENT = 'First of three tables containing usage info';
```

Rebuilding the table (the previous example will also rebuild the table if it was already InnoDB):

```
ALTER TABLE t1 FORCE;
```

Dropping an index:

```
ALTER TABLE rooms DROP INDEX u;
```

Adding a unique index:

```
ALTER TABLE rooms ADD UNIQUE INDEX u(room_number);
```

From MariaDB 10.5.3, adding a primary key for an application-time period table with a WITHOUT OVERLAPS constraint:

```
ALTER TABLE rooms ADD PRIMARY KEY(room_number, p WITHOUT OVERLAPS);
```

From MariaDB 10.8.1, ALTER query can be replicated faster with the setting of

```
SET @@SESSION.binlog_alter_two_phase = true;
```

prior the ALTER query. Binlog would contain two event groups

```
| master-bin.000001 | 495 | Gtid              |         1 |         537 | GTID 0-1-2 START ALTER
| master-bin.000001 | 537 | Query             |         1 |         655 | use `test`; alter table
| master-bin.000001 | 655 | Gtid              |         1 |         700 | GTID 0-1-3 COMMIT ALTER
| master-bin.000001 | 700 | Query             |         1 |         835 | use `test`; alter table
```

of which the first one gets delivered to replicas before ALTER is taken to actual execution on the primary.

1.1.1.2.1.1.2 ALTER DATABASE

Modifies a database, changing its overall characteristics.

Syntax

```
ALTER {DATABASE | SCHEMA} [db_name]
    alter_specification ...
ALTER {DATABASE | SCHEMA} db_name
    UPGRADE DATA DIRECTORY NAME

alter_specification:
    [DEFAULT] CHARACTER SET [=] charset_name
  | [DEFAULT] COLLATE [=] collation_name
  | COMMENT [=] 'comment'
```

Contents

Description

`ALTER DATABASE` enables you to change the overall characteristics of a database. These characteristics are stored in the `db.opt` file in the database directory. To use `ALTER DATABASE`, you need the `ALTER` privilege on the database. `ALTER SCHEMA` is a synonym for ALTER DATABASE.

The `CHARACTER SET` clause changes the default database character set. The `COLLATE` clause changes the default database collation. See Character Sets and Collations for more.

You can see what character sets and collations are available using, respectively, the SHOW CHARACTER SET and SHOW COLLATION statements.

Changing the default character set/collation of a database does not change the character set/collation of any stored procedures or stored functions that were previously created, and relied on the defaults. These need to be dropped and recreated in order to apply the character set/collation changes.

The database name can be omitted from the first syntax, in which case the statement applies to the default database.

The syntax that includes the `UPGRADE DATA DIRECTORY NAME` clause was added in MySQL 5.1.23. It updates the name of the directory associated with the database to use the encoding implemented in MySQL 5.1 for mapping database names to database directory names (see Identifier to File Name Mapping). This clause is for use under these conditions:

- It is intended when upgrading MySQL to 5.1 or later from older versions.
- It is intended to update a database directory name to the current encoding format if the name contains special characters that need encoding.
- The statement is used by mariadb-check (as invoked by mariadb-upgrade).

For example,if a database in MySQL 5.0 has a name of a-b-c, the name contains instance of the `-' character. In 5.0, the database directory is also named a-b-c, which is not necessarily safe for all file systems. In MySQL 5.1 and up, the same database name is encoded as a@002db@002dc to produce a file system-neutral directory name.

When a MySQL installation is upgraded to MySQL 5.1 or later from an older version,the server displays a name such as a-b-c (which is in the old format) as #mysql50#a-b-c, and you must refer to the name using the #mysql50# prefix. Use `UPGRADE DATA DIRECTORY NAME` in this case to explicitly tell the server to re-encode the database directory name to the current encoding format:

```
ALTER DATABASE `#mysql50#a-b-c` UPGRADE DATA DIRECTORY NAME;
```

After executing this statement, you can refer to the database as a-b-c without the special #mysql50# prefix.

COMMENT

MariaDB starting with 10.5.0

From MariaDB 10.5.0, it is possible to add a comment of a maximum of 1024 bytes. If the comment length exceeds this length, a error/warning code 4144 is thrown. The database comment is also added to the db.opt file, as well as to the information_schema.schemata table.

Examples

```
ALTER DATABASE test CHARACTER SET='utf8'  COLLATE='utf8_bin';
```

From MariaDB 10.5.0:

```
ALTER DATABASE p COMMENT='Presentations';
```

1.1.1.2.1.1.3 ALTER EVENT

Modifies one or more characteristics of an existing event.

Syntax

```
ALTER
    [DEFINER = { user | CURRENT_USER }]
    EVENT event_name
    [ON SCHEDULE schedule]
    [ON COMPLETION [NOT] PRESERVE]
    [RENAME TO new_event_name]
    [ENABLE | DISABLE | DISABLE ON SLAVE]
    [COMMENT 'comment']
    [DO sql_statement]
```

Contents

Description

The `ALTER EVENT` statement is used to change one or more of the characteristics of an existing event without the need to drop and recreate it. The syntax for each of the `DEFINER`, `ON SCHEDULE`, `ON COMPLETION`, `COMMENT`, `ENABLE` /

`DISABLE` , and `DO` clauses is exactly the same as when used with CREATE EVENT.

This statement requires the EVENT privilege. When a user executes a successful `ALTER EVENT` statement, that user becomes the definer for the affected event.

(In MySQL 5.1.11 and earlier, an event could be altered only by its definer, or by a user having the SUPER privilege.)

`ALTER EVENT` works only with an existing event:

```
ALTER EVENT no_such_event ON SCHEDULE EVERY '2:3' DAY_HOUR;
ERROR 1539 (HY000): Unknown event 'no_such_event'
```

Examples

```
ALTER EVENT myevent
  ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 2 HOUR
  DO
    UPDATE myschema.mytable SET mycol = mycol + 1;
```

1.1.1.2.1.1.4 ALTER FUNCTION

Syntax

```
ALTER FUNCTION func_name [characteristic ...]

characteristic:
    { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
  | COMMENT 'string'
```

Contents

Description

This statement can be used to change the characteristics of a stored function. More than one change may be specified in an `ALTER FUNCTION` statement. However, you cannot change the parameters or body of a stored function using this statement; to make such changes, you must drop and re-create the function using DROP FUNCTION and CREATE FUNCTION.

You must have the `ALTER ROUTINE` privilege for the function. (That privilege is granted automatically to the function creator.) If binary logging is enabled, the `ALTER FUNCTION` statement might also require the `SUPER` privilege, as described in Binary Logging of Stored Routines.

Example

```
ALTER FUNCTION hello SQL SECURITY INVOKER;
```

1.1.1.2.1.1.5 ALTER LOGFILE GROUP

Syntax

```
ALTER LOGFILE GROUP logfile_group
    ADD UNDOFILE 'file_name'
    [INITIAL_SIZE [=] size]
    [WAIT]
    ENGINE [=] engine_name
```

The `ALTER LOGFILE GROUP` statement is not supported by MariaDB. It was originally inherited from MySQL NDB Cluster. See MDEV-19295 for more information.

1.1.1.2.1.1.6 ALTER PROCEDURE

Syntax

```
ALTER PROCEDURE proc_name [characteristic ...]

characteristic:
    { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
  | COMMENT 'string'
```

Description

This statement can be used to change the characteristics of a stored procedure. More than one change may be specified in an `ALTER PROCEDURE` statement. However, you cannot change the parameters or body of a stored procedure using this statement. To make such changes, you must drop and re-create the procedure using either CREATE OR REPLACE PROCEDURE (since MariaDB 10.1.3) or DROP PROCEDURE and CREATE PROCEDURE (MariaDB 10.1.2 and before).

You must have the `ALTER ROUTINE` privilege for the procedure. By default, that privilege is granted automatically to the procedure creator. See Stored Routine Privileges.

Example

```
ALTER PROCEDURE simpleproc SQL SECURITY INVOKER;
```

1.1.6.4 ALTER SEQUENCE

1.1.1.2.1.1.8 ALTER SERVER

Syntax

```
ALTER SERVER server_name
    OPTIONS (option [, option] ...)
```

Contents

Description

Alters the server information for *server_name*, adjusting the specified options as per the CREATE SERVER command. The corresponding fields in the mysql.servers table are updated accordingly. This statement requires the SUPER privilege or, from MariaDB 10.5.2, the FEDERATED ADMIN privilege.

ALTER SERVER is not written to the binary log, irrespective of the binary log format being used. From MariaDB 10.1.13, Galera replicates the CREATE SERVER, ALTER SERVER and DROP SERVER statements.

Examples

```
ALTER SERVER s OPTIONS (USER 'sally');
```

1.1.1.2.1.1.9 ALTER TABLESPACE

The `ALTER TABLESPACE` statement is not supported by MariaDB. It was originally inherited from MySQL NDB Cluster. In MySQL 5.7 and later, the statement is also supported for InnoDB. However, MariaDB has chosen not to include that specific feature. See MDEV-19294 for more information.

1.1.1.1.2 ALTER USER

1.1.1.2.1.1.11 ALTER VIEW

Syntax

```
ALTER
    [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
    [DEFINER = { user | CURRENT_USER }]
    [SQL SECURITY { DEFINER | INVOKER }]
    VIEW view_name [(column_list)]
    AS select_statement
    [WITH [CASCADED | LOCAL] CHECK OPTION]
```

Contents

Description

This statement changes the definition of a view, which must exist. The syntax is similar to that for CREATE VIEW and the effect is the same as for `CREATE OR REPLACE VIEW` if the view exists. This statement requires the `CREATE VIEW` and `DROP` privileges for the view, and some privilege for each column referred to in the `SELECT` statement. `ALTER VIEW` is allowed only to the definer or users with the SUPER privilege.

Example

```
ALTER VIEW v AS SELECT a, a*3 AS a2 FROM t;
```

1.1.1.2.1.2 ANALYZE TABLE

Syntax

```
ANALYZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE tbl_name [,tbl_name ...]
  [PERSISTENT FOR
    { ALL
      | COLUMNS ([col_name [,col_name ...]]) INDEXES ([index_name [,index_name ...]])
    }
  ]
```

Contents

Description

`ANALYZE TABLE` analyzes and stores the key distribution for a table (index statistics). This statement works with MyISAM, Aria and InnoDB tables. During the analysis, InnoDB will allow reads/writes, and MyISAM/Aria reads/inserts. For MyISAM tables, this statement is equivalent to using myisamchk --analyze.

For more information on how the analysis works within InnoDB, see InnoDB Limitations.

MariaDB uses the stored key distribution to decide the order in which tables should be joined when you perform a join on something other than a constant. In addition, key distributions can be used when deciding which indexes to use for a specific table within a query.

This statement requires SELECT and INSERT privileges for the table.

By default, ANALYZE TABLE statements are written to the binary log and will be replicated. The `NO_WRITE_TO_BINLOG` keyword (`LOCAL` is an alias) will ensure the statement is not written to the binary log.

From MariaDB 10.3.19, `ANALYZE TABLE` statements are not logged to the binary log if read_only is set. See also Read-Only Replicas.

`ANALYZE TABLE` is also supported for partitioned tables. You can use `ALTER TABLE ... ANALYZE PARTITION` to analyze one or more partitions.

The Aria storage engine supports progress reporting for the `ANALYZE TABLE` statement.

Engine-Independent Statistics / PERSISTENT FOR

`ANALYZE TABLE` supports engine-independent statistics. See Engine-Independent Table Statistics: Collecting Statistics with the ANALYZE TABLE Statement for more information.

Useful Variables

For calculating the number of duplicates, `ANALYZE TABLE` uses a buffer of sort_buffer_size bytes per column. You can slightly increase the speed of `ANALYZE TABLE` by increasing this variable.

Examples

```
-- update all engine-independent statistics for all columns and indexes
ANALYZE TABLE tbl PERSISTENT FOR ALL;

-- update specific columns and indexes:
ANALYZE TABLE tbl PERSISTENT FOR COLUMNS (col1,col2,...) INDEXES (idx1,idx2,...);

-- empty lists are allowed:
ANALYZE TABLE tbl PERSISTENT FOR COLUMNS (col1,col2,...) INDEXES ();
ANALYZE TABLE tbl PERSISTENT FOR COLUMNS () INDEXES (idx1,idx2,...);

-- the following will only update mysql.table_stats fields:
ANALYZE TABLE tbl PERSISTENT FOR COLUMNS () INDEXES ();

-- when use_stat_tables is set to 'COMPLEMENTARY' or 'PREFERABLY',
-- a simple ANALYZE TABLE  collects engine-independent statistics for all columns and indexes.
SET SESSION use_stat_tables='COMPLEMENTARY';
ANALYZE TABLE tbl;
```

1.1.1.2.1.3 CHECK TABLE

Syntax

```
CHECK TABLE tbl_name [, tbl_name] ... [option] ...

option = {FOR UPGRADE | QUICK | FAST | MEDIUM | EXTENDED | CHANGED}
```

Description

`CHECK TABLE` checks a table or tables for errors. `CHECK TABLE` works for Archive, Aria, CSV, InnoDB and MyISAM tables. For Aria and MyISAM tables, the key statistics are updated as well. For CSV, see also Checking and Repairing CSV Tables.

As an alternative, myisamchk is a commandline tool for checking MyISAM tables when the tables are not being accessed. For Aria tables, there is a similar tool: aria_chk.

For checking dynamic columns integrity, COLUMN_CHECK() can be used.

`CHECK TABLE` can also check views for problems, such as tables that are referenced in the view definition that no longer exist.

`CHECK TABLE` is also supported for partitioned tables. You can use `ALTER TABLE ... CHECK PARTITION` to check one or more partitions.

The meaning of the different options are as follows - note that this can vary a bit between storage engines:

FOR UPGRADE	Do a very quick check if the storage format for the table has changed so that one needs to do a REPAIR. This is only needed when one upgrades between major versions of MariaDB or MySQL. This is usually done by running mariadb-upgrade.
FAST	Only check tables that has not been closed properly or are marked as corrupt. Only supported by the MyISAM and Aria engines. For other engines the table is checked normally
CHANGED	Check only tables that has changed since last REPAIR / CHECK. Only supported by the MyISAM and Aria engines. For other engines the table is checked normally.
QUICK	Do a fast check. For MyISAM and Aria, this means skipping the check of the delete link chain, which may take some time.
MEDIUM	Scan also the data files. Checks integrity between data and index files with checksums. In most cases this should find all possible errors.
EXTENDED	Does a full check to verify every possible error. For InnoDB, Aria, and MyISAM, verify for each row that all its keys exists, and for those index keys, they point back to the primary clustered key. This may take a long time on large tables. This option was previously ignored by InnoDB before MariaDB 10.6.11, MariaDB 10.7.7, MariaDB 10.8.6 and MariaDB 10.9.4.

For most cases running `CHECK TABLE` without options or `MEDIUM` should be good enough.

The Aria storage engine supports progress reporting for this statement.

If you want to know if two tables are identical, take a look at CHECKSUM TABLE.

InnoDB

If `CHECK TABLE` finds an error in an InnoDB table, MariaDB might shutdown to prevent the error propagation. In this case, the problem will be reported in the error log. Otherwise the table or an index might be marked as corrupted, to prevent use. This does not happen with some minor problems, like a wrong number of entries in a secondary index. Those problems are reported in the output of `CHECK TABLE` .

Each tablespace contains a header with metadata. This header is not checked by this statement.

During the execution of `CHECK TABLE` , other threads may be blocked.

Examples

```
check table y extended;
+--------+-------+----------+----------+
| Table  | Op    | Msg_type | Msg_text |
+--------+-------+----------+----------+
| test.y | check | status   | OK       |
+--------+-------+----------+----------+
```

1.1.1.2.1.4 CHECK VIEW

Syntax

```
CHECK VIEW view_name
```

Description

The `CHECK VIEW` statement was introduced in MariaDB 10.0.18 to assist with fixing MDEV-6916, an issue introduced in MariaDB 5.2 where the view algorithms were swapped. It checks whether the view algorithm is correct. It is run as part of mariadb-upgrade, and should not normally be required in regular use.

1.1.1.2.1.5 CHECKSUM TABLE

Syntax

```
CHECKSUM TABLE tbl_name [, tbl_name] ... [ QUICK | EXTENDED ]
```

Contents

Description

`CHECKSUM TABLE` reports a table checksum. This is very useful if you want to know if two tables are the same (for example on a master and slave).

With `QUICK` , the live table checksum is reported if it is available, or `NULL` otherwise. This is very fast. A live checksum is enabled by specifying the `CHECKSUM=1` table option when you create the table; currently, this is supported only for Aria and MyISAM tables.

With `EXTENDED` , the entire table is read row by row and the checksum is calculated. This can be very slow for large tables.

If neither `QUICK` nor `EXTENDED` is specified, MariaDB returns a live checksum if the table storage engine supports it and scans the table otherwise.

`CHECKSUM TABLE` requires the SELECT privilege for the table.

For a nonexistent table, `CHECKSUM TABLE` returns `NULL` and generates a warning.

The table row format affects the checksum value. If the row format changes, the checksum will change. This means that when a table created with a MariaDB/MySQL version is upgraded to another version, the checksum value will probably change.

Two identical tables should always match to the same checksum value; however, also for non-identical tables there is a very slight chance that they will return the same value as the hashing algorithm is not completely collision-free.

Identical Tables

Identical tables mean that the CREATE statement is identical and that the following variable, which affects the storage formats, was the same when the tables were created:

- mysql56-temporal-format

Differences Between MariaDB and MySQL

`CHECKSUM TABLE` may give a different result as MariaDB doesn't ignore `NULL` s in the columns as MySQL 5.1 does (Later MySQL versions should calculate checksums the same way as MariaDB). You can get the 'old style' checksum in MariaDB by starting mysqld with the `--old` option. Note however that that the MyISAM and Aria storage engines in MariaDB are using the new checksum internally, so if you are using `--old` , the `CHECKSUM` command will be slower as it needs to calculate the checksum row by row. Starting from MariaDB Server 10.9, `--old` is deprecated and will be removed in a future release. Set `--old-mode` or `OLD_MODE` to `COMPAT_5_1_CHECKSUM` to get 'old style' checksum.

1.1.1.2.1.6 CREATE TABLE

Syntax

```
CREATE [OR REPLACE] [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
    (create_definition,...) [table_options    ]... [partition_options]
CREATE [OR REPLACE] [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
    [(create_definition,...)] [table_options   ]... [partition_options]
    select_statement
CREATE [OR REPLACE] [TEMPORARY] TABLE [IF NOT EXISTS] tbl_name
   { LIKE old_table_name | (LIKE old_table_name) }

select_statement:
    [IGNORE | REPLACE] [AS] SELECT ...   (Some legal select statement)
```

Contents

Description

Use the `CREATE TABLE` statement to create a table with the given name.

In its most basic form, the `CREATE TABLE` statement provides a table name followed by a list of columns, indexes, and constraints. By default, the table is created in the default database. Specify a database with *`db_name.tbl_name`*. If you quote the table name, you must quote the database name and table name separately as *`` `db_name`.`tbl_name` ``*. This is particularly useful for CREATE TABLE ... SELECT, because it allows to create a table into a database, which contains data

from other databases. See Identifier Qualifiers.

If a table with the same name exists, error 1050 results. Use IF NOT EXISTS to suppress this error and issue a note instead. Use SHOW WARNINGS to see notes.

The `CREATE TABLE` statement automatically commits the current transaction, except when using the TEMPORARY keyword.

For valid identifiers to use as table names, see Identifier Names.

> **Note:** if the default_storage_engine is set to ColumnStore then it needs setting on all UMs. Otherwise when the tables using the default engine are replicated across UMs they will use the wrong engine. You should therefore not use this option as a session variable with ColumnStore.

Microsecond precision can be between 0-6. If no precision is specified it is assumed to be 0, for backward compatibility reasons.

Privileges

Executing the `CREATE TABLE` statement requires the CREATE privilege for the table or the database.

CREATE OR REPLACE

If the `OR REPLACE` clause is used and the table already exists, then instead of returning an error, the server will drop the existing table and replace it with the newly defined table.

This syntax was originally added to make replication more robust if it has to rollback and repeat statements such as `CREATE ... SELECT` on replicas.

```
CREATE OR REPLACE TABLE table_name (a int);
```

is basically the same as:

```
DROP TABLE IF EXISTS table_name;
CREATE TABLE table_name (a int);
```

with the following exceptions:

- If `table_name` was locked with LOCK TABLES it will continue to be locked after the statement.
- Temporary tables are only dropped if the `TEMPORARY` keyword was used. (With DROP TABLE, temporary tables are preferred to be dropped before normal tables).

Things to be Aware of With CREATE OR REPLACE

- The table is dropped first (if it existed), after that the `CREATE` is done. Because of this, if the `CREATE` fails, then the table will not exist anymore after the statement. If the table was used with `LOCK TABLES` it will be unlocked.
- One can't use `OR REPLACE` together with `IF EXISTS`.
- Slaves in replication will by default use `CREATE OR REPLACE` when replicating `CREATE` statements that don"t use `IF EXISTS`. This can be changed by setting the variable slave-ddl-exec-mode to `STRICT`.

CREATE TABLE IF NOT EXISTS

If the `IF NOT EXISTS` clause is used, then the table will only be created if a table with the same name does not already exist. If the table already exists, then a warning will be triggered by default.

CREATE TEMPORARY TABLE

Use the `TEMPORARY` keyword to create a temporary table that is only available to the current session. Temporary tables are dropped when the session ends. Temporary table names are specific to the session. They will not conflict with other temporary tables from other sessions even if they share the same name. They will shadow names of non-temporary tables or views, if they are identical. A temporary table can have the same name as a non-temporary table which is located in the same database. In that case, their name will reference the temporary table when used in SQL statements. You must have the CREATE TEMPORARY TABLES privilege on the database to create temporary tables. If no storage engine is specified,

the default_tmp_storage_engine setting will determine the engine.

ROCKSDB temporary tables cannot be created by setting the default_tmp_storage_engine system variable, or using `CREATE TEMPORARY TABLE LIKE`. Before MariaDB 10.7, they could be specified, but would silently fail, and a MyISAM table would be created instead. From MariaDB 10.7 an error is returned. Explicitly creating a temporary table with `ENGINE=ROCKSDB` has never been permitted.

CREATE TABLE ... LIKE

Use the `LIKE` clause instead of a full table definition to create a table with the same definition as another table, including columns, indexes, and table options. Foreign key definitions, as well as any DATA DIRECTORY or INDEX DIRECTORY table options specified on the original table, will not be created.

CREATE TABLE ... SELECT

You can create a table containing data from other tables using the `CREATE ... SELECT` statement. Columns will be created in the table for each field returned by the `SELECT` query.

You can also define some columns normally and add other columns from a `SELECT`. You can also create columns in the normal way and assign them some values using the query, this is done to force a certain type or other field characteristics. The columns that are not named in the query will be placed before the others. For example:

```
CREATE TABLE test (a INT NOT NULL, b CHAR(10)) ENGINE=MyISAM
    SELECT 5 AS b, c, d FROM another_table;
```

Remember that the query just returns data. If you want to use the same indexes, or the same columns attributes (`[NOT] NULL`, `DEFAULT`, `AUTO_INCREMENT`) in the new table, you need to specify them manually. Types and sizes are not automatically preserved if no data returned by the `SELECT` requires the full size, and `VARCHAR` could be converted into `CHAR`. The CAST() function can be used to forcee the new table to use certain types.

Aliases (`AS`) are taken into account, and they should always be used when you `SELECT` an expression (function, arithmetical operation, etc).

If an error occurs during the query, the table will not be created at all.

If the new table has a primary key or `UNIQUE` indexes, you can use the IGNORE or `REPLACE` keywords to handle duplicate key errors during the query. `IGNORE` means that the newer values must not be inserted an identical value exists in the index. `REPLACE` means that older values must be overwritten.

If the columns in the new table are more than the rows returned by the query, the columns populated by the query will be placed after other columns. Note that if the strict `SQL_MODE` is on, and the columns that are not names in the query do not have a `DEFAULT` value, an error will raise and no rows will be copied.

Concurrent inserts are not used during the execution of a `CREATE ... SELECT`.

If the table already exists, an error similar to the following will be returned:

```
ERROR 1050 (42S01): Table 't' already exists
```

If the `IF NOT EXISTS` clause is used and the table exists, a note will be produced instead of an error.

To insert rows from a query into an existing table, INSERT ... SELECT can be used.

Column Definitions

```
create_definition:
  { col_name column_definition | index_definition | period_definition | CHECK (expr) }

column_definition:
  data_type
    [NOT NULL | NULL] [DEFAULT default_value | (expression)]
    [ON UPDATE [NOW | CURRENT_TIMESTAMP] [(precision)]]
    [AUTO_INCREMENT] [ZEROFILL] [UNIQUE [KEY] | [PRIMARY] KEY]
    [INVISIBLE] [{WITH|WITHOUT} SYSTEM VERSIONING]
    [COMMENT 'string'] [REF_SYSTEM_ID = value]
    [reference_definition]
  | data_type [GENERATED ALWAYS]
  AS { { ROW {START|END} } | { (expression) [VIRTUAL | PERSISTENT | STORED] } }
      [UNIQUE [KEY]] [COMMENT 'string']

constraint_definition:
   CONSTRAINT [constraint_name] CHECK (expression)
```

Note: Until MariaDB 10.4, MariaDB accepts the shortcut format with a REFERENCES clause only in ALTER TABLE and CREATE TABLE statements, but that syntax does nothing. For example:

```
CREATE TABLE b(for_key INT REFERENCES a(not_key));
```

MariaDB simply parses it without returning any error or warning, for compatibility with other DBMS's. Before MariaDB 10.2.1 this was also true for `CHECK` constraints. However, only the syntax described below creates foreign keys.

From MariaDB 10.5, MariaDB will attempt to apply the constraint. See Foreign Keys examples.

Each definition either creates a column in the table or specifies and index or constraint on one or more columns. See Indexes below for details on creating indexes.

Create a column by specifying a column name and a data type, optionally followed by column options. See Data Types for a full list of data types allowed in MariaDB.

NULL and NOT NULL

Use the `NULL` or `NOT NULL` options to specify that values in the column may or may not be `NULL`, respectively. By default, values may be `NULL`. See also NULL Values in MariaDB.

DEFAULT Column Option

Specify a default value using the `DEFAULT` clause. If you don't specify `DEFAULT` then the following rules apply:

- If the column is not defined with `NOT NULL`, `AUTO_INCREMENT` or `TIMESTAMP`, an explicit `DEFAULT NULL` will be added. Note that in MySQL and in MariaDB before 10.1.6, you may get an explicit `DEFAULT` for primary key parts, if not specified with NOT NULL.

The default value will be used if you INSERT a row without specifying a value for that column, or if you specify DEFAULT for that column. Before MariaDB 10.2.1 you couldn't usually provide an expression or function to evaluate at insertion time. You had to provide a constant default value instead. The one exception is that you may use CURRENT_TIMESTAMP as the default value for a TIMESTAMP column to use the current timestamp at insertion time.

CURRENT_TIMESTAMP may also be used as the default value for a DATETIME

You can use most functions in `DEFAULT`. Expressions should have parentheses around them. If you use a non deterministic function in `DEFAULT` then all inserts to the table will be replicated in row mode. You can even refer to earlier columns in the `DEFAULT` expression (excluding `AUTO_INCREMENT` columns):

```
CREATE TABLE t1 (a int DEFAULT (1+1), b int DEFAULT (a+1));
CREATE TABLE t2 (a bigint primary key DEFAULT UUID_SHORT());
```

The `DEFAULT` clause cannot contain any stored functions or subqueries, and a column used in the clause must already have been defined earlier in the statement.

It is possible to assign BLOB or TEXT columns a `DEFAULT` value. In versions prior to MariaDB 10.2.1, assigning a default to these columns was not possible.

You can also use DEFAULT (NEXT VALUE FOR sequence)

AUTO_INCREMENT Column Option

Use AUTO_INCREMENT to create a column whose value can can be set automatically from a simple counter. You can only use `AUTO_INCREMENT` on a column with an integer type. The column must be a key, and there can only be one `AUTO_INCREMENT` column in a table. If you insert a row without specifying a value for that column (or if you specify `0` , `NULL` , or DEFAULT as the value), the actual value will be taken from the counter, with each insertion incrementing the counter by one. You can still insert a value explicitly. If you insert a value that is greater than the current counter value, the counter is set based on the new value. An `AUTO_INCREMENT` column is implicitly `NOT NULL` . Use LAST_INSERT_ID to get the AUTO_INCREMENT value most recently used by an INSERT statement.

ZEROFILL Column Option

If the `ZEROFILL` column option is specified for a column using a numeric data type, then the column will be set to `UNSIGNED` and the spaces used by default to pad the field are replaced with zeros. `ZEROFILL` is ignored in expressions or as part of a UNION. `ZEROFILL` is a non-standard MySQL and MariaDB enhancement.

PRIMARY KEY Column Option

Use `PRIMARY KEY` to make a column a primary key. A primary key is a special type of a unique key. There can be at most one primary key per table, and it is implicitly `NOT NULL` .

Specifying a column as a unique key creates a unique index on that column. See the Index Definitions section below for more information.

UNIQUE KEY Column Option

Use `UNIQUE KEY` (or just `UNIQUE`) to specify that all values in the column must be distinct from each other. Unless the column is `NOT NULL` , there may be multiple rows with `NULL` in the column.

Specifying a column as a unique key creates a unique index on that column.

See the Index Definitions section below for more information.

COMMENT Column Option

You can provide a comment for each column using the `COMMENT` clause. The maximum length is 1024 characters. Use the SHOW FULL COLUMNS statement to see column comments.

REF_SYSTEM_ID

`REF_SYSTEM_ID` can be used to specify Spatial Reference System IDs for spatial data type columns. For example:

```
CREATE TABLE t1(g GEOMETRY(9,4) REF_SYSTEM_ID=101);
```

Generated Columns

A generated column is a column in a table that cannot explicitly be set to a specific value in a DML query. Instead, its value is automatically generated based on an expression. This expression might generate the value based on the values of other columns in the table, or it might generate the value by calling built-in functions or user-defined functions (UDFs).

There are two types of generated columns:

- `PERSISTENT` or `STORED` : This type's value is actually stored in the table.
- `VIRTUAL` : This type's value is not stored at all. Instead, the value is generated dynamically when the table is queried. This type is the default.

Generated columns are also sometimes called computed columns or virtual columns.

For a complete description about generated columns and their limitations, see Generated (Virtual and Persistent/Stored) Columns.

COMPRESSED

Certain columns may be compressed. See Storage-Engine Independent Column Compression.

INVISIBLE

Columns may be made invisible, and hidden in certain contexts. See Invisible Columns.

WITH SYSTEM VERSIONING Column Option

Columns may be explicitly marked as included from system versioning. See System-versioned tables for details.

WITHOUT SYSTEM VERSIONING Column Option

Columns may be explicitly marked as excluded from system versioning. See System-versioned tables for details.

Index Definitions

```
index_definition:
    {INDEX|KEY} [index_name] [index_type] (index_col_name,...) [index_option] ...
  {{{|}}} {FULLTEXT|SPATIAL} [INDEX|KEY] [index_name] (index_col_name,...) [index_option] ...
  {{{|}}} [CONSTRAINT [symbol]] PRIMARY KEY [index_type] (index_col_name,...) [index_option] ...
  {{{|}}} [CONSTRAINT [symbol]] UNIQUE [INDEX|KEY] [index_name] [index_type]
(index_col_name,...) [index_option] ...
  {{{|}}} [CONSTRAINT [symbol]] FOREIGN KEY [index_name] (index_col_name,...)
reference_definition

index_col_name:
    col_name [(length)] [ASC | DESC]

index_type:
    USING {BTREE | HASH | RTREE}

index_option:
    [ KEY_BLOCK_SIZE [=] value
  {{{|}}} index_type
  {{{|}}} WITH PARSER parser_name
  {{{|}}} COMMENT 'string'
  {{{|}}} CLUSTERING={YES| NO} ]
  [ IGNORED | NOT IGNORED ]

reference_definition:
    REFERENCES tbl_name (index_col_name,...)
      [MATCH FULL | MATCH PARTIAL | MATCH SIMPLE]
      [ON DELETE reference_option]
      [ON UPDATE reference_option]

reference_option:
    RESTRICT | CASCADE | SET NULL | NO ACTION
```

`INDEX` and `KEY` are synonyms.

Index names are optional, if not specified an automatic name will be assigned. Index name are needed to drop indexes and appear in error messages when a constraint is violated.

Index Categories

Plain Indexes

Plain indexes are regular indexes that are not unique, and are not acting as a primary key or a foreign key. They are also not the "specialized" `FULLTEXT` or `SPATIAL` indexes.

See Getting Started with Indexes: Plain Indexes for more information.

PRIMARY KEY

For `PRIMARY KEY` indexes, you can specify a name for the index, but it is ignored, and the name of the index is always `PRIMARY`. From MariaDB 10.3.18 and MariaDB 10.4.8, a warning is explicitly issued if a name is specified. Before then,

the name was silently ignored.

See Getting Started with Indexes: Primary Key for more information.

UNIQUE

The `UNIQUE` keyword means that the index will not accept duplicated values, except for NULLs. An error will raise if you try to insert duplicate values in a UNIQUE index.

For `UNIQUE` indexes, you can specify a name for the constraint, using the `CONSTRAINT` keyword. That name will be used in error messages.

> **MariaDB starting with 10.5**
> Unique, if index type is not specified, is normally a BTREE index that can also be used by the optimizer to find rows. If the key is longer than the max key length for the used storage engine, a HASH key will be created. This enables MariaDB to enforce uniqueness for any type or number of columns.

See Getting Started with Indexes: Unique Index for more information.

FOREIGN KEY

For `FOREIGN KEY` indexes, a reference definition must be provided.

For `FOREIGN KEY` indexes, you can specify a name for the constraint, using the `CONSTRAINT` keyword. That name will be used in error messages.

First, you have to specify the name of the target (parent) table and a column or a column list which must be indexed and whose values must match to the foreign key's values. The `MATCH` clause is accepted to improve the compatibility with other DBMS's, but has no meaning in MariaDB. The `ON DELETE` and `ON UPDATE` clauses specify what must be done when a `DELETE` (or a `REPLACE`) statements attempts to delete a referenced row from the parent table, and when an `UPDATE` statement attempts to modify the referenced foreign key columns in a parent table row, respectively. The following options are allowed:

- `RESTRICT`: The delete/update operation is not performed. The statement terminates with a 1451 error (SQLSTATE '2300').
- `NO ACTION`: Synonym for `RESTRICT`.
- `CASCADE`: The delete/update operation is performed in both tables.
- `SET NULL`: The update or delete goes ahead in the parent table, and the corresponding foreign key fields in the child table are set to `NULL`. (They must not be defined as `NOT NULL` for this to succeed).
- `SET DEFAULT`: This option is currently implemented only for the PBXT storage engine, which is disabled by default and no longer maintained. It sets the child table's foreign key fields to their `DEFAULT` values when the referenced parent table key entries are updated or deleted.

If either clause is omitted, the default behavior for the omitted clause is `RESTRICT`.

See Foreign Keys for more information.

FULLTEXT

Use the `FULLTEXT` keyword to create full-text indexes.

See Full-Text Indexes for more information.

SPATIAL

Use the `SPATIAL` keyword to create geometric indexes.

See SPATIAL INDEX for more information.

Index Options

KEY_BLOCK_SIZE Index Option

The `KEY_BLOCK_SIZE` index option is similar to the KEY_BLOCK_SIZE table option.

With the InnoDB storage engine, if you specify a non-zero value for the `KEY_BLOCK_SIZE` table option for the whole table, then the table will implicitly be created with the ROW_FORMAT table option set to `COMPRESSED`. However, this does not happen if you just set the `KEY_BLOCK_SIZE` index option for one or more indexes in the table. The InnoDB storage engine ignores the `KEY_BLOCK_SIZE` index option. However, the SHOW CREATE TABLE statement may still report it for the

index.

For information about the `KEY_BLOCK_SIZE` index option, see the KEY_BLOCK_SIZE table option below.

Index Types

Each storage engine supports some or all index types. See Storage Engine Index Types for details on permitted index types for each storage engine.

Different index types are optimized for different kind of operations:

- `BTREE` is the default type, and normally is the best choice. It is supported by all storage engines. It can be used to compare a column's value with a value using the =, >, >=, <, <=, `BETWEEN` , and `LIKE` operators. `BTREE` can also be used to find `NULL` values. Searches against an index prefix are possible.
- `HASH` is only supported by the MEMORY storage engine. `HASH` indexes can only be used for =, <=, and >= comparisons. It can not be used for the `ORDER BY` clause. Searches against an index prefix are not possible.
- `RTREE` is the default for SPATIAL indexes, but if the storage engine does not support it `BTREE` can be used.

Index columns names are listed between parenthesis. After each column, a prefix length can be specified. If no length is specified, the whole column will be indexed. `ASC` and `DESC` can be specified for compatibility with are DBMS's, but have no meaning in MariaDB.

WITH PARSER Index Option

The `WITH PARSER` index option only applies to FULLTEXT indexes and contains the fulltext parser name. The fulltext parser must be an installed plugin.

COMMENT Index Option

A comment of up to 1024 characters is permitted with the `COMMENT` index option.

The `COMMENT` index option allows you to specify a comment with user-readable text describing what the index is for. This information is not used by the server itself.

CLUSTERING Index Option

The `CLUSTERING` index option is only valid for tables using the TokuDB storage engine.

IGNORED / NOT IGNORED

MariaDB starting with 10.6.0

From MariaDB 10.6.0, indexes can be specified to be ignored by the optimizer. See Ignored Indexes.

Periods

```
period_definition:
    PERIOD FOR SYSTEM_TIME (start_column_name, end_column_name)
```

MariaDB supports a subset of the standard syntax for periods. At the moment it's only used for creating System-versioned tables. Both columns must be created, must be either of a `TIMESTAMP(6)` or `BIGINT UNSIGNED` type, and be generated as `ROW START` and `ROW END` accordingly. See System-versioned tables for details.

The table must also have the `WITH SYSTEM VERSIONING` clause.

Constraint Expressions

Note: Before MariaDB 10.2.1, constraint expressions were accepted in the syntax but ignored.

MariaDB 10.2.1 introduced two ways to define a constraint:

- `CHECK(expression)` given as part of a column definition.
- `CONSTRAINT [constraint_name] CHECK (expression)`

Before a row is inserted or updated, all constraints are evaluated in the order they are defined. If any constraints fails, then the row will not be updated. One can use most deterministic functions in a constraint, including UDFs.

```
create table t1 (a int check(a>0) ,b int check (b> 0), constraint abc check (a>b));
```

If you use the second format and you don't give a name to the constraint, then the constraint will get a auto generated name. This is done so that you can later delete the constraint with ALTER TABLE DROP constraint_name.

One can disable all constraint expression checks by setting the variable `check_constraint_checks` to `OFF`. This is useful for example when loading a table that violates some constraints that you want to later find and fix in SQL.

See CONSTRAINT for more information.

Table Options

For each individual table you create (or alter), you can set some table options. The general syntax for setting options is:

<OPTION_NAME> = <option_value>, [<OPTION_NAME> = <option_value> ...]

The equal sign is optional.

Some options are supported by the server and can be used for all tables, no matter what storage engine they use; other options can be specified for all storage engines, but have a meaning only for some engines. Also, engines can extend `CREATE TABLE` with new options.

If the `IGNORE_BAD_TABLE_OPTIONS` SQL_MODE is enabled, wrong table options generate a warning; otherwise, they generate an error.

```
table_option:
    [STORAGE] ENGINE [=] engine_name
  | AUTO_INCREMENT [=] value
  | AVG_ROW_LENGTH [=] value
  | [DEFAULT] CHARACTER SET [=] charset_name
  | CHECKSUM [=] {0 | 1}
  | [DEFAULT] COLLATE [=] collation_name
  | COMMENT [=] 'string'
  | CONNECTION [=] 'connect_string'
  | DATA DIRECTORY [=] 'absolute path to directory'
  | DELAY_KEY_WRITE [=] {0 | 1}
  | ENCRYPTED [=] {YES | NO}
  | ENCRYPTION_KEY_ID [=] value
  | IETF_QUOTES [=] {YES | NO}
  | INDEX DIRECTORY [=] 'absolute path to directory'
  | INSERT_METHOD [=] { NO | FIRST | LAST }
  | KEY_BLOCK_SIZE [=] value
  | MAX_ROWS [=] value
  | MIN_ROWS [=] value
  | PACK_KEYS [=] {0 | 1 | DEFAULT}
  | PAGE_CHECKSUM [=] {0 | 1}
  | PAGE_COMPRESSED [=] {0 | 1}
  | PAGE_COMPRESSION_LEVEL [=] {0 .. 9}
  | PASSWORD [=] 'string'
  | ROW_FORMAT [=] {DEFAULT|DYNAMIC|FIXED|COMPRESSED|REDUNDANT|COMPACT|PAGE}
  | SEQUENCE [=] {0|1}
  | STATS_AUTO_RECALC [=] {DEFAULT|0|1}
  | STATS_PERSISTENT [=] {DEFAULT|0|1}
  | STATS_SAMPLE_PAGES [=] {DEFAULT|value}
  | TABLESPACE tablespace_name
  | TRANSACTIONAL [=]  {0 | 1}
  | UNION [=] (tbl_name[,tbl_name]...)
  | WITH SYSTEM VERSIONING
```

[STORAGE] ENGINE

`[STORAGE] ENGINE` specifies a storage engine for the table. If this option is not used, the default storage engine is used instead. That is, the default_storage_engine session option value if it is set, or the value specified for the `--default-storage-engine` mariadbd startup option, or the default storage engine, InnoDB. If the specified storage engine is not installed and active, the default value will be used, unless the `NO_ENGINE_SUBSTITUTION` SQL MODE is set (default). This is only true for `CREATE TABLE`, not for `ALTER TABLE`. For a list of storage engines that are present in your server, issue a SHOW ENGINES.

AUTO_INCREMENT

`AUTO_INCREMENT` specifies the initial value for the AUTO_INCREMENT primary key. This works for MyISAM, Aria, InnoDB, MEMORY, and ARCHIVE tables. You can change this option with `ALTER TABLE`, but in that case the new value must be higher than the highest value which is present in the `AUTO_INCREMENT` column. If the storage engine does not support this option, you can insert (and then delete) a row having the wanted value - 1 in the `AUTO_INCREMENT` column.

AVG_ROW_LENGTH

`AVG_ROW_LENGTH` is the average rows size. It only applies to tables using MyISAM and Aria storage engines that have the ROW_FORMAT table option set to `FIXED` format.

MyISAM uses `MAX_ROWS` and `AVG_ROW_LENGTH` to decide the maximum size of a table (default: 256TB, or the maximum file size allowed by the system).

[DEFAULT] CHARACTER SET/CHARSET

`[DEFAULT] CHARACTER SET` (or `[DEFAULT] CHARSET`) is used to set a default character set for the table. This is the character set used for all columns where an explicit character set is not specified. If this option is omitted or `DEFAULT` is specified, database's default character set will be used. See Setting Character Sets and Collations for details on setting the character sets.

CHECKSUM/TABLE_CHECKSUM

`CHECKSUM` (or `TABLE_CHECKSUM`) can be set to 1 to maintain a live checksum for all table's rows. This makes write operations slower, but CHECKSUM TABLE will be very fast. This option is only supported for MyISAM and Aria tables.

[DEFAULT] COLLATE

`[DEFAULT] COLLATE` is used to set a default collation for the table. This is the collation used for all columns where an explicit character set is not specified. If this option is omitted or `DEFAULT` is specified, database's default option will be used. See Setting Character Sets and Collations for details on setting the collations

COMMENT

`COMMENT` is a comment for the table. The maximum length is 2048 characters. Also used to define table parameters when creating a Spider table.

CONNECTION

`CONNECTION` is used to specify a server name or a connection string for a Spider, CONNECT, Federated or FederatedX table.

DATA DIRECTORY/INDEX DIRECTORY

`DATA DIRECTORY` and `INDEX DIRECTORY` are supported for MyISAM and Aria, and DATA DIRECTORY is also supported by InnoDB if the innodb_file_per_table server system variable is enabled, but only in CREATE TABLE, not in ALTER TABLE. So, carefully choose a path for InnoDB tables at creation time, because it cannot be changed without dropping and re-creating the table. These options specify the paths for data files and index files, respectively. If these options are omitted, the database's directory will be used to store data files and index files. Note that these table options do not work for partitioned tables (use the partition options instead), or if the server has been invoked with the --skip-symbolic-links startup option. To avoid the overwriting of old files with the same name that could be present in the directories, you can use the `--keep_files_on_create` option (an error will be issued if files already exist). These options are ignored if the `NO_DIR_IN_CREATE` SQL_MODE is enabled (useful for replication slaves). Also note that symbolic links cannot be used for InnoDB tables.

`DATA DIRECTORY` works by creating symlinks from where the table would normally have been (inside the datadir) to where the option specifies. For security reasons, to avoid bypassing the privilege system, the server does not permit symlinks inside the datadir. Therefore, `DATA DIRECTORY` cannot be used to specify a location inside the datadir. An attempt to do so will result in an error `1210 (HY000) Incorrect arguments to DATA DIRECTORY`.

DELAY_KEY_WRITE

DELAY_KEY_WRITE is supported by MyISAM and Aria, and can be set to 1 to speed up write operations. In that case, when data are modified, the indexes are not updated until the table is closed. Writing the changes to the index file altogether can be much faster. However, note that this option is applied only if the delay_key_write server variable is set to 'ON'. If it is 'OFF' the delayed index writes are always disabled, and if it is 'ALL' the delayed index writes are always used, disregarding the value of DELAY_KEY_WRITE .

ENCRYPTED

The ENCRYPTED table option can be used to manually set the encryption status of an InnoDB table. See InnoDB Encryption for more information.

Aria does not support the ENCRYPTED table option. See MDEV-18049.

See Data-at-Rest Encryption for more information.

ENCRYPTION_KEY_ID

The ENCRYPTION_KEY_ID table option can be used to manually set the encryption key of an InnoDB table. See InnoDB Encryption for more information.

Aria does not support the ENCRYPTION_KEY_ID table option. See MDEV-18049.

See Data-at-Rest Encryption for more information.

IETF_QUOTES

For the CSV storage engine, the IETF_QUOTES option, when set to YES , enables IETF-compatible parsing of embedded quote and comma characters. Enabling this option for a table improves compatibility with other tools that use CSV, but is not compatible with MySQL CSV tables, or MariaDB CSV tables created without this option. Disabled by default.

INSERT_METHOD

INSERT_METHOD is only used with MERGE tables. This option determines in which underlying table the new rows should be inserted. If you set it to 'NO' (which is the default) no new rows can be added to the table (but you will still be able to perform INSERT s directly against the underlying tables). FIRST means that the rows are inserted into the first table, and LAST means that thet are inserted into the last table.

KEY_BLOCK_SIZE

KEY_BLOCK_SIZE is used to determine the size of key blocks, in bytes or kilobytes. However, this value is just a hint, and the storage engine could modify or ignore it. If KEY_BLOCK_SIZE is set to 0, the storage engine's default value will be used.

With the InnoDB storage engine, if you specify a non-zero value for the KEY_BLOCK_SIZE table option for the whole table, then the table will implicitly be created with the ROW_FORMAT table option set to COMPRESSED .

MIN_ROWS/MAX_ROWS

MIN_ROWS and MAX_ROWS let the storage engine know how many rows you are planning to store as a minimum and as a maximum. These values will not be used as real limits, but they help the storage engine to optimize the table. MIN_ROWS is only used by MEMORY storage engine to decide the minimum memory that is always allocated. MAX_ROWS is used to decide the minimum size for indexes.

PACK_KEYS

PACK_KEYS can be used to determine whether the indexes will be compressed. Set it to 1 to compress all keys. With a value of 0, compression will not be used. With the DEFAULT value, only long strings will be compressed. Uncompressed keys are faster.

PAGE_CHECKSUM

PAGE_CHECKSUM is only applicable to Aria tables, and determines whether indexes and data should use page checksums for extra safety.

PAGE_COMPRESSED

`PAGE_COMPRESSED` is used to enable InnoDB page compression for InnoDB tables.

PAGE_COMPRESSION_LEVEL

`PAGE_COMPRESSION_LEVEL` is used to set the compression level for InnoDB page compression for InnoDB tables. The table must also have the PAGE_COMPRESSED table option set to `1`.

Valid values for `PAGE_COMPRESSION_LEVEL` are 1 (the best speed) through 9 (the best compression), .

PASSWORD

`PASSWORD` is unused.

RAID_TYPE

`RAID_TYPE` is an obsolete option, as the raid support has been disabled since MySQL 5.0.

ROW_FORMAT

The `ROW_FORMAT` table option specifies the row format for the data file. Possible values are engine-dependent.

Supported MyISAM Row Formats

For MyISAM, the supported row formats are:

- `FIXED`
- `DYNAMIC`
- `COMPRESSED`

The `COMPRESSED` row format can only be set by the `myisampack` command line tool.

See MyISAM Storage Formats for more information.

Supported Aria Row Formats

For Aria, the supported row formats are:

- `PAGE`
- `FIXED`
- `DYNAMIC`.

See Aria Storage Formats for more information.

Supported InnoDB Row Formats

For InnoDB, the supported row formats are:

- `COMPACT`
- `REDUNDANT`
- `COMPRESSED`
- `DYNAMIC`.

If the `ROW_FORMAT` table option is set to `FIXED` for an InnoDB table, then the server will either return an error or a warning depending on the value of the innodb_strict_mode system variable. If the innodb_strict_mode system variable is set to `OFF`, then a warning is issued, and MariaDB will create the table using the default row format for the specific MariaDB server version. If the innodb_strict_mode system variable is set to `ON`, then an error will be raised.

See InnoDB Storage Formats for more information.

Other Storage Engines and ROW_FORMAT

Other storage engines do not support the `ROW_FORMAT` table option.

SEQUENCE

If the table is a sequence, then it will have the `SEQUENCE` set to `1`.

STATS_AUTO_RECALC

`STATS_AUTO_RECALC` indicates whether to automatically recalculate persistent statistics (see `STATS_PERSISTENT`, below) for an InnoDB table. If set to `1`, statistics will be recalculated when more than 10% of the data has changed. When set to `0`, stats will be recalculated only when an ANALYZE TABLE is run. If set to `DEFAULT`, or left out, the value set by the innodb_stats_auto_recalc system variable applies. See InnoDB Persistent Statistics.

STATS_PERSISTENT

`STATS_PERSISTENT` indicates whether the InnoDB statistics created by ANALYZE TABLE will remain on disk or not. It can be set to `1` (on disk), `0` (not on disk, the pre-MariaDB 10 behavior), or `DEFAULT` (the same as leaving out the option), in which case the value set by the innodb_stats_persistent system variable will apply. Persistent statistics stored on disk allow the statistics to survive server restarts, and provide better query plan stability. See InnoDB Persistent Statistics.

STATS_SAMPLE_PAGES

`STATS_SAMPLE_PAGES` indicates how many pages are used to sample index statistics. If 0 or DEFAULT, the default value, the innodb_stats_sample_pages value is used. See InnoDB Persistent Statistics.

TRANSACTIONAL

`TRANSACTIONAL` is only applicable for Aria tables. In future Aria tables created with this option will be fully transactional, but currently this provides a form of crash protection. See Aria Storage Engine for more details.

UNION

`UNION` must be specified when you create a MERGE table. This option contains a comma-separated list of MyISAM tables which are accessed by the new table. The list is enclosed between parenthesis. Example: `UNION = (t1,t2)`

WITH SYSTEM VERSIONING

`WITH SYSTEM VERSIONING` is used for creating System-versioned tables.

Partitions

```
partition_options:
    PARTITION BY
        { [LINEAR] HASH(expr)
        | [LINEAR] KEY(column_list)
        | RANGE(expr)
        | LIST(expr)
        | SYSTEM_TIME [INTERVAL time_quantity time_unit] [LIMIT num] }
    [PARTITIONS num]
    [SUBPARTITION BY
        { [LINEAR] HASH(expr)
        | [LINEAR] KEY(column_list) }
      [SUBPARTITIONS num]
    ]
    [(partition_definition [, partition_definition] ...)]

partition_definition:
    [PARTITION] partition_name
        [VALUES {LESS THAN {(expr) | MAXVALUE} | IN (value_list)}]
        [[STORAGE] ENGINE [=] engine_name]
        [COMMENT [=] 'comment_text' ]
        [DATA DIRECTORY [=] 'data_dir']
        [INDEX DIRECTORY [=] 'index_dir']
        [MAX_ROWS [=] max_number_of_rows]
        [MIN_ROWS [=] min_number_of_rows]
        [TABLESPACE [=] tablespace_name]
        [NODEGROUP [=] node_group_id]
        [(subpartition_definition [, subpartition_definition] ...)]

subpartition_definition:
    SUBPARTITION logical_name
        [[STORAGE] ENGINE [=] engine_name]
        [COMMENT [=] 'comment_text' ]
        [DATA DIRECTORY [=] 'data_dir']
        [INDEX DIRECTORY [=] 'index_dir']
        [MAX_ROWS [=] max_number_of_rows]
        [MIN_ROWS [=] min_number_of_rows]
        [TABLESPACE [=] tablespace_name]
        [NODEGROUP [=] node_group_id]
```

If the `PARTITION BY` clause is used, the table will be partitioned. A partition method must be explicitly indicated for partitions and subpartitions. Partition methods are:

- `[LINEAR] HASH` creates a hash key which will be used to read and write rows. The partition function can be any valid SQL expression which returns an `INTEGER` number. Thus, it is possible to use the HASH method on an integer column, or on functions which accept integer columns as an argument. However, `VALUES LESS THAN` and `VALUES IN` clauses can not be used with HASH. An example:

```
CREATE TABLE t1 (a INT, b CHAR(5), c DATETIME)
    PARTITION BY HASH ( YEAR(c) );
```

`[LINEAR] HASH` can be used for subpartitions, too.

- `[LINEAR] KEY` is similar to HASH, but the index has an even distribution of data. Also, the expression can only be a column or a list of columns. `VALUES LESS THAN` and `VALUES IN` clauses can not be used with KEY.
- RANGE partitions the rows using on a range of values, using the `VALUES LESS THAN` operator. `VALUES IN` is not allowed with `RANGE`. The partition function can be any valid SQL expression which returns a single value.
- LIST assigns partitions based on a table's column with a restricted set of possible values. It is similar to `RANGE`, but `VALUES IN` must be used for at least 1 columns, and `VALUES LESS THAN` is disallowed.
- `SYSTEM_TIME` partitioning is used for System-versioned tables to store historical data separately from current data.

Only HASH and KEY can be used for subpartitions, and they can be `[LINEAR]`.

It is possible to define up to 8092 partitions and subpartitions.

The number of defined partitions can be optionally specified as `PARTITION count`. This can be done to avoid specifying all partitions individually. But you can also declare each individual partition and, additionally, specify a `PARTITIONS count` clause; in the case, the number of `PARTITION`s must equal count.

Also see Partitioning Types Overview.

MariaDB starting with 10.7.1

From MariaDB 10.7, the PARTITION keyword is now optional as part of the partition definition, for example, instead of:

```
create or replace table t1 (x int)
  partition by range(x) (
    partition p1 values less than (10),
    partition p2 values less than (20),
    partition p3 values less than (30),
    partition p4 values less than (40),
    partition p5 values less than (50),
    partition pn values less than maxvalue);
```

the following can also be used:

```
create or replace table t1 (x int)
  partition by range(x) (
    p1 values less than (10),
    p2 values less than (20),
    p3 values less than (30),
    p4 values less than (40),
    p5 values less than (50),
    pn values less than maxvalue);
```

Sequences

`CREATE TABLE` can also be used to create a SEQUENCE. See CREATE SEQUENCE and Sequence Overview.

Atomic DDL

MariaDB starting with 10.6.1

MariaDB 10.6.1 supports Atomic DDL. `CREATE TABLE` is atomic, except for `CREATE OR REPLACE`, which is only crash safe.

Examples

```
create table if not exists test (
a bigint auto_increment primary key,
name varchar(128) charset utf8,
key name (name(32))
) engine=InnoDB default charset latin1;
```

This example shows a couple of things:

- Usage of `IF NOT EXISTS`; If the table already existed, it will not be created. There will not be any error for the client, just a warning.
- How to create a `PRIMARY KEY` that is automatically generated.
- How to specify a table-specific character set and another for a column.
- How to create an index (`name`) that is only partly indexed (to save space).

The following clauses will work from MariaDB 10.2.1 only.

```
CREATE TABLE t1(
  a int DEFAULT (1+1),
  b int DEFAULT (a+1),
  expires DATETIME DEFAULT(NOW() + INTERVAL 1 YEAR),
  x BLOB DEFAULT USER()
);
```

1.1.1.2.1.7 DELETE

Contents

Syntax

Single-table syntax:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
  FROM tbl_name [PARTITION (partition_list)]
  [FOR PORTION OF period FROM expr1 TO expr2]
  [WHERE where_condition]
  [ORDER BY ...]
  [LIMIT row_count]
  [RETURNING select_expr
    [, select_expr ...]]
```

Multiple-table syntax:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
    tbl_name[.*] [, tbl_name[.*]] ...
    FROM table_references
    [WHERE where_condition]
```

Or:

```
DELETE [LOW_PRIORITY] [QUICK] [IGNORE]
    FROM tbl_name[.*] [, tbl_name[.*]] ...
    USING table_references
    [WHERE where_condition]
```

Trimming history:

```
DELETE HISTORY
  FROM tbl_name [PARTITION (partition_list)]
  [BEFORE SYSTEM_TIME [TIMESTAMP|TRANSACTION] expression]
```

Description

Option	Description
LOW_PRIORITY	Wait until all SELECT's are done before starting the statement. Used with storage engines that uses table locking (MyISAM, Aria etc). See HIGH_PRIORITY and LOW_PRIORITY clauses for details.
QUICK	Signal the storage engine that it should expect that a lot of rows are deleted. The storage engine engine can do things to speed up the DELETE like ignoring merging of data blocks until all rows are deleted from the block (instead of when a block is half full). This speeds up things at the expanse of lost space in data blocks. At least MyISAM and Aria support this feature.
IGNORE	Don't stop the query even if a not-critical error occurs (like data overflow). See How IGNORE works for a full description.

For the single-table syntax, the `DELETE` statement deletes rows from tbl_name and returns a count of the number of deleted rows. This count can be obtained by calling the ROW_COUNT() function. The `WHERE` clause, if given, specifies the conditions that identify which rows to delete. With no `WHERE` clause, all rows are deleted. If the ORDER BY clause is specified, the rows are deleted in the order that is specified. The LIMIT clause places a limit on the number of rows that can be deleted.

For the multiple-table syntax, `DELETE` deletes from each `tbl_name` the rows that satisfy the conditions. In this case,

ORDER BY and LIMIT> cannot be used. A `DELETE` can also reference tables which are located in different databases; see Identifier Qualifiers for the syntax.

`where_condition` is an expression that evaluates to true for each row to be deleted. It is specified as described in SELECT.

Currently, you cannot delete from a table and select from the same table in a subquery.

You need the `DELETE` privilege on a table to delete rows from it. You need only the `SELECT` privilege for any columns that are only read, such as those named in the `WHERE` clause. See GRANT.

As stated, a `DELETE` statement with no `WHERE` clause deletes all rows. A faster way to do this, when you do not need to know the number of deleted rows, is to use `TRUNCATE TABLE` . However, within a transaction or if you have a lock on the table, `TRUNCATE TABLE` cannot be used whereas `DELETE` can. See TRUNCATE TABLE, and LOCK.

PARTITION

See Partition Pruning and Selection for details.

FOR PORTION OF

MariaDB starting with 10.4.3

See Application Time Periods - Deletion by Portion.

RETURNING

It is possible to return a resultset of the deleted rows for a single table to the client by using the syntax `DELETE ... RETURNING select_expr [, select_expr2 ...]]`

Any of SQL expression that can be calculated from a single row fields is allowed. Subqueries are allowed. The AS keyword is allowed, so it is possible to use aliases.

The use of aggregate functions is not allowed. RETURNING cannot be used in multi-table DELETEs.

MariaDB starting with 10.3.1

Same Source and Target Table

Until MariaDB 10.3.1, deleting from a table with the same source and target was not possible. From MariaDB 10.3.1, this is now possible. For example:

```
DELETE FROM t1 WHERE c1 IN (SELECT b.c1 FROM t1 b WHERE b.c2=0);
```

MariaDB starting with 10.3.4

DELETE HISTORY

One can use `DELETE HISTORY` to delete historical information from System-versioned tables.

Examples

How to use the ORDER BY and LIMIT clauses:

```
DELETE FROM page_hit ORDER BY timestamp LIMIT 1000000;
```

How to use the RETURNING clause:

```
DELETE FROM t RETURNING f1;
+------+
| f1   |
+------+
|    5 |
|   50 |
|  500 |
+------+
```

The following statement joins two tables: one is only used to satisfy a WHERE condition, but no row is deleted from it; rows from the other table are deleted, instead.

```
DELETE post FROM blog INNER JOIN post WHERE blog.id = post.blog_id;
```

Deleting from the Same Source and Target

```
CREATE TABLE t1 (c1 INT, c2 INT);
DELETE FROM t1 WHERE c1 IN (SELECT b.c1 FROM t1 b WHERE b.c2=0);
```

Until MariaDB 10.3.1, this returned:

```
ERROR 1093 (HY000): Table 't1' is specified twice, both as a target for 'DELETE'
  and as a separate source for
```

From MariaDB 10.3.1:

```
Query OK, 0 rows affected (0.00 sec)
```

1.1.1.2.1.8 DROP TABLE

Syntax

```
DROP [TEMPORARY] TABLE [IF EXISTS] [/*COMMENT TO SAVE*/]
    tbl_name [, tbl_name] ...
    [WAIT n|NOWAIT]
    [RESTRICT | CASCADE]
```

Contents

Description

`DROP TABLE` removes one or more tables. You must have the `DROP` privilege for each table. All table data and the table definition are removed, as well as triggers associated to the table, so be careful with this statement! If any of the tables named in the argument list do not exist, MariaDB returns an error indicating by name which non-existing tables it was unable to drop, but it also drops all of the tables in the list that do exist.

Important: When a table is dropped, user privileges on the table are not automatically dropped. See GRANT.

If another thread is using the table in an explicit transaction or an autocommit transaction, then the thread acquires a metadata lock (MDL) on the table. The `DROP TABLE` statement will wait in the "Waiting for table metadata lock" thread state until the MDL is released. MDLs are released in the following cases:

- If an MDL is acquired in an explicit transaction, then the MDL will be released when the transaction ends.
- If an MDL is acquired in an autocommit transaction, then the MDL will be released when the statement ends.
- Transactional and non-transactional tables are handled the same.

Note that for a partitioned table, `DROP TABLE` permanently removes the table definition, all of its partitions, and all of the data which was stored in those partitions. It also removes the partitioning definition (.par) file associated with the dropped table.

For each referenced table, `DROP TABLE` drops a temporary table with that name, if it exists. If it does not exist, and the `TEMPORARY` keyword is not used, it drops a non-temporary table with the same name, if it exists. The `TEMPORARY` keyword ensures that a non-temporary table will not accidentally be dropped.

Use `IF EXISTS` to prevent an error from occurring for tables that do not exist. A `NOTE` is generated for each non-existent table when using `IF EXISTS`. See SHOW WARNINGS.

If a foreign key references this table, the table cannot be dropped. In this case, it is necessary to drop the foreign key first.

`RESTRICT` and `CASCADE` are allowed to make porting from other database systems easier. In MariaDB, they do nothing.

The comment before the table names (`/*COMMENT TO SAVE*/`) is stored in the binary log. That feature can be used by replication tools to send their internal messages.

It is possible to specify table names as `db_name.tab_name`. This is useful to delete tables from multiple databases with one statement. See Identifier Qualifiers for details.

The DROP privilege is required to use `DROP TABLE` on non-temporary tables. For temporary tables, no privilege is required, because such tables are only visible for the current session.

Note: `DROP TABLE` automatically commits the current active transaction, unless you use the `TEMPORARY` keyword.

MariaDB starting with 10.5.4

From MariaDB 10.5.4, `DROP TABLE` reliably deletes table remnants inside a storage engine even if the `.frm` file is missing. Before then, a missing `.frm` file would result in the statement failing.

MariaDB starting with 10.3.1

WAIT/NOWAIT

Set the lock wait timeout. See WAIT and NOWAIT.

DROP TABLE in replication

`DROP TABLE` has the following characteristics in replication:

- `DROP TABLE IF EXISTS` are always logged.
- `DROP TABLE` without `IF EXISTS` for tables that don't exist are not written to the binary log.
- Dropping of `TEMPORARY` tables are prefixed in the log with `TEMPORARY`. These drops are only logged when running statement or mixed mode replication.
- One `DROP TABLE` statement can be logged with up to 3 different `DROP` statements:
  - `DROP TEMPORARY TABLE list_of_non_transactional_temporary_tables`
  - `DROP TEMPORARY TABLE list_of_transactional_temporary_tables`
  - `DROP TABLE list_of_normal_tables`

`DROP TABLE` on the primary is treated on the replica as `DROP TABLE IF EXISTS`. You can change that by setting slave-ddl-exec-mode to `STRICT`.

Dropping an Internal #sql-... Table

From MariaDB 10.6, DROP TABLE is atomic and the following does not apply. Until MariaDB 10.5, if the mariadbd/mysqld process is killed during an ALTER TABLE you may find a table named #sql-... in your data directory. In MariaDB 10.3, InnoDB tables with this prefix will be deleted automatically during startup. From MariaDB 10.4, these temporary tables will always be deleted automatically.

If you want to delete one of these tables explicitly you can do so by using the following syntax:

```
DROP TABLE `#mysql50##sql-...`;
```

When running an `ALTER TABLE…ALGORITHM=INPLACE` that rebuilds the table, InnoDB will create an internal `#sql-ib` table. Until MariaDB 10.3.2, for these tables, the `.frm` file will be called something else. In order to drop such a table after a server crash, you must rename the `#sql*.frm` file to match the `#sql-ib*.ibd` file.

From MariaDB 10.3.3, the same name as the .frm file is used for the intermediate copy of the table. The #sql-ib names are used by TRUNCATE and delayed DROP.

From MariaDB 10.2.19 and MariaDB 10.3.10, the #sql-ib tables will be deleted automatically.

Dropping All Tables in a Database

The best way to drop all tables in a database is by executing DROP DATABASE, which will drop the database itself, and all

tables in it.

However, if you want to drop all tables in the database, but you also want to keep the database itself and any other non-table objects in it, then you would need to execute `DROP TABLE` to drop each individual table. You can construct these `DROP TABLE` commands by querying the TABLES table in the information_schema database. For example:

```
SELECT CONCAT('DROP TABLE IF EXISTS `', TABLE_SCHEMA, '`.`', TABLE_NAME, '`;')
FROM information_schema.TABLES
WHERE TABLE_SCHEMA = 'mydb';
```

Atomic DROP TABLE

MariaDB starting with 10.6.1

From MariaDB 10.6, `DROP TABLE` for a single table is atomic (MDEV-25180) for most engines, including InnoDB, MyRocks, MyISAM and Aria.

This means that if there is a crash (server down or power outage) during `DROP TABLE`, all tables that have been processed so far will be completely dropped, including related trigger files and status entries, and the binary log will include a `DROP TABLE` statement for the dropped tables. Tables for which the drop had not started will be left intact.

In older MariaDB versions, there was a small chance that, during a server crash happening in the middle of `DROP TABLE`, some storage engines that were using multiple storage files, like MyISAM, could have only a part of its internal files dropped.

In MariaDB 10.5, `DROP TABLE` was extended to be able to delete a table that was only partly dropped (MDEV-11412) as explained above. Atomic `DROP TABLE` is the final piece to make `DROP TABLE` fully reliable.

Dropping multiple tables is crash-safe.

See Atomic DDL for more information.

Examples

```
DROP TABLE Employees, Customers;
```

Notes

Beware that `DROP TABLE` can drop both tables and sequences. This is mainly done to allow old tools like mariadb-dump (previously mysqldump) to work with sequences.

1.1.1.2.1.9 Installing System Tables (mariadb-install-db)

`mariadb-install-db` initializes the MariaDB data directory and creates the system tables in the mysql database, if they do not exist. MariaDB uses these tables to manage privileges, roles, and plugins. It also uses them to provide the data for the help command in the mariadb client.

mariadb-install-db works by starting MariaDB Server's `mysqld` process in --bootstrap mode and sending commands to create the system tables and their content.

There is a version specifically for Windows, mysql_install_db.exe.

To invoke `mariadb-install-db`, use the following syntax:

```
mariadb-install-db --user=mysql
```

For the options supported by mariadb-install-db, see mariadb-install-db: Options.

For the option groups read by mariadb-install-db, see mariadb-install-db: Option Groups.

See mariadb-install-db: Installing System Tables for information on the installation process.

See mariadb-install-db: Troubleshooting Issues for information on how to troubleshoot the installation process.

1.1.1.2.1.10 mysqlcheck

`mariadb-check` is a tool for checking, repairing, analyzing and optimizing tables.

MariaDB starting with 10.4.6

From MariaDB 10.4.6, `mariadb-check` is a symlink to `mysqlcheck, the old name for the tool.`

MariaDB starting with 10.5.2

From MariaDB 10.5.2, `mariadb-check` is the name of the tool, with `mysqlcheck` a symlink .

See mariadb-check for details.

1.1.1.2.1.11 OPTIMIZE TABLE

Syntax

```
OPTIMIZE [NO_WRITE_TO_BINLOG | LOCAL] TABLE
    tbl_name [, tbl_name] ...
    [WAIT n | NOWAIT]
```

Contents

Description

`OPTIMIZE TABLE` has two main functions. It can either be used to defragment tables, or to update the InnoDB fulltext index.

WAIT/NOWAIT

Set the lock wait timeout. See WAIT and NOWAIT.

Defragmenting

`OPTIMIZE TABLE` works for InnoDB (before MariaDB 10.1.1, only if the innodb_file_per_table server system variable is set), Aria, MyISAM and ARCHIVE tables, and should be used if you have deleted a large part of a table or if you have made many changes to a table with variable-length rows (tables that have VARCHAR, VARBINARY, BLOB, or TEXT columns). Deleted rows are maintained in a linked list and subsequent `INSERT` operations reuse old row positions.

This statement requires SELECT and INSERT privileges for the table.

By default, `OPTIMIZE TABLE` statements are written to the binary log and will be replicated. The `NO_WRITE_TO_BINLOG` keyword (`LOCAL` is an alias) will ensure the statement is not written to the binary log.

`OPTIMIZE TABLE` statements are not logged to the binary log if read_only is set. See also Read-Only Replicas.

`OPTIMIZE TABLE` is also supported for partitioned tables. You can use `ALTER TABLE ... OPTIMIZE PARTITION` to optimize one or more partitions.

You can use `OPTIMIZE TABLE` to reclaim the unused space and to defragment the data file. With other storage engines, `OPTIMIZE TABLE` does nothing by default, and returns this message: " The storage engine for the table doesn't support optimize". However, if the server has been started with the `--skip-new` option, `OPTIMIZE TABLE` is linked to ALTER TABLE, and recreates the table. This operation frees the unused space and updates index statistics.

The Aria storage engine supports progress reporting for this statement.

If a MyISAM table is fragmented, concurrent inserts will not be performed until an `OPTIMIZE TABLE` statement is executed on that table, unless the concurrent_insert server system variable is set to `ALWAYS` .

Updating an InnoDB fulltext index

When rows are added or deleted to an InnoDB fulltext index, the index is not immediately re-organized, as this can be an expensive operation. Change statistics are stored in a separate location . The fulltext index is only fully re-organized when an `OPTIMIZE TABLE` statement is run.

By default, an OPTIMIZE TABLE will defragment a table. In order to use it to update fulltext index statistics, the innodb_optimize_fulltext_only system variable must be set to `1` . This is intended to be a temporary setting, and should be reset to `0` once the fulltext index has been re-organized.

Since fulltext re-organization can take a long time, the innodb_ft_num_word_optimize variable limits the re-organization to a number of words (2000 by default). You can run multiple OPTIMIZE statements to fully re-organize the index.

Defragmenting InnoDB tablespaces

MariaDB 10.1.1 merged the Facebook/Kakao defragmentation patch, allowing one to use `OPTIMIZE TABLE` to defragment InnoDB tablespaces. For this functionality to be enabled, the innodb_defragment system variable must be enabled. No new tables are created and there is no need to copy data from old tables to new tables. Instead, this feature loads `n` pages (determined by innodb-defragment-n-pages) and tries to move records so that pages would be full of records and then frees pages that are fully empty after the operation. Note that tablespace files (including ibdata1) will not shrink as the result of defragmentation, but one will get better memory utilization in the InnoDB buffer pool as there are fewer data pages in use.

See Defragmenting InnoDB Tablespaces for more details.

1.1.1.2.1.12 RENAME TABLE

Syntax

```
RENAME TABLE[S] [IF EXISTS] tbl_name
  [WAIT n | NOWAIT]
  TO new_tbl_name
    [, tbl_name2 TO new_tbl_name2] ...
```

Contents

Description

This statement renames one or more tables or views, but not the privileges associated with them.

IF EXISTS

MariaDB starting with 10.5.2

If this directive is used, one will not get an error if the table to be renamed doesn't exist.

The rename operation is done atomically, which means that no other session can access any of the tables while the rename is running. For example, if you have an existing table `old_table` , you can create another table `new_table` that has the same structure but is empty, and then replace the existing table with the empty one as follows (assuming that `backup_table` does not already exist):

```
CREATE TABLE new_table (...);
RENAME TABLE old_table TO backup_table, new_table TO old_table;
```

`tbl_name` can optionally be specified as `db_name . tbl_name` . See Identifier Qualifiers. This allows to use `RENAME` to move a table from a database to another (as long as they are on the same filesystem):

```
RENAME TABLE db1.t TO db2.t;
```

Note that moving a table to another database is not possible if it has some triggers. Trying to do so produces the following error:

```
ERROR 1435 (HY000): Trigger in wrong schema
```

Also, views cannot be moved to another database:

```
ERROR 1450 (HY000): Changing schema from 'old_db' to 'new_db' is not allowed.
```

Multiple tables can be renamed in a single statement. The presence or absence of the optional `S` (`RENAME TABLE` or `RENAME TABLES`) has no impact, whether a single or multiple tables are being renamed.

If a `RENAME TABLE` renames more than one table and one renaming fails, all renames executed by the same statement are rolled back.

Renames are always executed in the specified order. Knowing this, it is also possible to swap two tables' names:

```
RENAME TABLE t1 TO tmp_table,
    t2 TO t1,
    tmp_table TO t2;
```

WAIT/NOWAIT

Set the lock wait timeout. See WAIT and NOWAIT.

Privileges

Executing the `RENAME TABLE` statement requires the DROP, CREATE and INSERT privileges for the table or the database.

Atomic RENAME TABLE

MariaDB starting with 10.6.1

From MariaDB 10.6, `RENAME TABLE` is atomic for most engines, including InnoDB, MyRocks, MyISAM and Aria (MDEV-23842). This means that if there is a crash (server down or power outage) during `RENAME TABLE`, all tables will revert to their original names and any changes to trigger files will be reverted.

In older MariaDB version there was a small chance that, during a server crash happening in the middle of `RENAME TABLE`, some tables could have been renamed (in the worst case partly) while others would not be renamed.

See Atomic DDL for more information.

1.1.1.2.1.13 REPAIR TABLE

Syntax

```
REPAIR [NO_WRITE_TO_BINLOG | LOCAL] TABLE
    tbl_name [, tbl_name] ...
    [QUICK] [EXTENDED] [USE_FRM]
```

Description

`REPAIR TABLE` repairs a possibly corrupted table. By default, it has the same effect as

```
myisamchk --recover tbl_name
```

or

```
aria_chk --recover tbl_name
```

See aria_chk and myisamchk for more.

`REPAIR TABLE` works for Archive, Aria, CSV and MyISAM tables. For InnoDB, see recovery modes. For CSV, see also Checking and Repairing CSV Tables. For Archive, this statement also improves compression. If the storage engine does not support this statement, a warning is issued.

This statement requires SELECT and INSERT privileges for the table.

By default, `REPAIR TABLE` statements are written to the binary log and will be replicated. The `NO_WRITE_TO_BINLOG` keyword (`LOCAL` is an alias) will ensure the statement is not written to the binary log.

From MariaDB 10.3.19, `REPAIR TABLE` statements are not logged to the binary log if read_only is set. See also Read-Only Replicas.

When an index is recreated, the storage engine may use a configurable buffer in the process. Incrementing the buffer speeds up the index creation. Aria and MyISAM allocate a buffer whose size is defined by `aria_sort_buffer_size` or `myisam_sort_buffer_size` , also used for `ALTER TABLE` .

`REPAIR TABLE` is also supported for partitioned tables. However, the `USE_FRM` option cannot be used with this statement on a partitioned table.

`ALTER TABLE ... REPAIR PARTITION` can be used to repair one or more partitions.

The Aria storage engine supports progress reporting for this statement.

1.1.1.2.1.14 REPAIR VIEW

Syntax

```
REPAIR [NO_WRITE_TO_BINLOG | LOCAL] VIEW  view_name[, view_name] ... [FROM MYSQL]
```

Contents

Description

The `REPAIR VIEW` statement was introduced to assist with fixing MDEV-6916, an issue introduced in MariaDB 5.2 where the view algorithms were swapped compared to their MySQL on disk representation. It checks whether the view algorithm is correct. It is run as part of mariadb-upgrade, and should not normally be required in regular use.

By default it corrects the checksum and if necessary adds the mariadb-version field. If the optional `FROM MYSQL` clause is used, and no mariadb-version field is present, the MERGE and TEMPTABLE algorithms are toggled.

By default, `REPAIR VIEW` statements are written to the binary log and will be replicated. The `NO_WRITE_TO_BINLOG` keyword (`LOCAL` is an alias) will ensure the statement is not written to the binary log.

1.1.1.2.1.15 REPLACE

Syntax

```
REPLACE [LOW_PRIORITY | DELAYED]
 [INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
 {VALUES | VALUE} ({expr | DEFAULT},...),(...),...
[RETURNING select_expr
      [, select_expr ...]]
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
    [INTO] tbl_name [PARTITION (partition_list)]
    SET col={expr | DEFAULT}, ...
[RETURNING select_expr
      [, select_expr ...]]
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
    [INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
    SELECT ...
[RETURNING select_expr
      [, select_expr ...]]
```

Contents

Description

`REPLACE` works exactly like `INSERT`, except that if an old row in the table has the same value as a new row for a `PRIMARY KEY` or a `UNIQUE` index, the old row is deleted before the new row is inserted. If the table has more than one `UNIQUE` keys, it is possible that the new row conflicts with more than one row. In this case, all conflicting rows will be deleted.

The table name can be specified in the form `db_name.tbl_name` or, if a default database is selected, in the form `tbl_name` (see Identifier Qualifiers). This allows to use `REPLACE ... SELECT` to copy rows between different databases.

MariaDB starting with 10.5.0

The RETURNING clause was introduced in MariaDB 10.5.0

Basically it works like this:

```
BEGIN;
SELECT 1 FROM t1 WHERE key=# FOR UPDATE;
IF found-row
  DELETE FROM t1 WHERE key=# ;
ENDIF
INSERT INTO t1 VALUES (...);
END;
```

The above can be replaced with:

```
REPLACE INTO t1 VALUES (...)
```

`REPLACE` is a MariaDB/MySQL extension to the SQL standard. It either inserts, or deletes and inserts. For other MariaDB/MySQL extensions to standard SQL --- that also handle duplicate values --- see IGNORE and INSERT ON DUPLICATE KEY UPDATE.

Note that unless the table has a `PRIMARY KEY` or `UNIQUE` index, using a `REPLACE` statement makes no sense. It becomes equivalent to `INSERT`, because there is no index to be used to determine whether a new row duplicates another.

Values for all columns are taken from the values sSee Partition Pruning and Selection for details.pecified in the `REPLACE` statement. Any missing columns are set to their default values, just as happens for `INSERT`. You cannot refer to values from the current row and use them in the new row. If you use an assignment such as `'SET col = col + 1'`, the reference to the column name on the right hand side is treated as `DEFAULT(col)`, so the assignment is equivalent to `'SET col = DEFAULT(col) + 1'`.

To use `REPLACE`, you must have both the `INSERT` and `DELETE` privileges for the table.

There are some gotchas you should be aware of, before using `REPLACE`:

- If there is an `AUTO_INCREMENT` field, a new value will be generated.
- If there are foreign keys, `ON DELETE` action will be activated by `REPLACE`.
- Triggers on `DELETE` and `INSERT` will be activated by `REPLACE`.

To avoid some of these behaviors, you can use `INSERT ... ON DUPLICATE KEY UPDATE`.

This statement activates INSERT and DELETE triggers. See Trigger Overview for details.

PARTITION

See Partition Pruning and Selection for details.

REPLACE RETURNING

`REPLACE ... RETURNING` returns a resultset of the replaced rows.

This returns the listed columns for all the rows that are replaced, or alternatively, the specified SELECT expression. Any SQL expressions which can be calculated can be used in the select expression for the RETURNING clause, including virtual columns and aliases, expressions which use various operators such as bitwise, logical and arithmetic operators, string functions, date-time functions, numeric functions, control flow functions, secondary functions and stored functions. Along with this, statements which have subqueries and prepared statements can also be used.

Examples

Simple REPLACE statement

```
REPLACE INTO t2 VALUES (1,'Leopard'),(2,'Dog') RETURNING id2, id2+id2
as Total ,id2|id2, id2&&id2;
+-----+-------+---------+----------+
| id2 | Total | id2|id2 | id2&&id2 |
+-----+-------+---------+----------+
|   1 |     2 |       1 |        1 |
|   2 |     4 |       2 |        1 |
+-----+-------+---------+----------+
```

Using stored functions in RETURNING

```
DELIMITER |
CREATE FUNCTION f(arg INT) RETURNS INT
    BEGIN
      RETURN (SELECT arg+arg);
    END|

DELIMITER ;
PREPARE stmt FROM "REPLACE INTO t2 SET id2=3, animal2='Fox' RETURNING f2(id2),
UPPER(animal2)";

EXECUTE stmt;
+---------+-----------------+
| f2(id2) | UPPER(animal2) |
+---------+-----------------+
|       6 | FOX             |
+---------+-----------------+
```

Subqueries in the statement

```
REPLACE INTO t1 SELECT * FROM t2 RETURNING (SELECT id2 FROM t2 WHERE
id2 IN (SELECT id2 FROM t2 WHERE id2=1)) AS new_id;
+--------+
| new_id |
+--------+
|      1 |
|      1 |
|      1 |
|      1 |
+--------+
```

Subqueries in the RETURNING clause that return more than one row or column cannot be used..

Aggregate functions cannot be used in the RETURNING clause. Since aggregate functions work on a set of values and if the purpose is to get the row count, ROW_COUNT() with SELECT can be used, or it can be used in REPLACE...SEL== Description

`REPLACE ... RETURNING` returns a resultset of the replaced rows.

This returns the listed columns for all the rows that are replaced, or alternatively, the specified SELECT expression. Any SQL expressions which can be calculated can be used in the select expression for the RETURNING clause, including virtual columns and aliases, expressions which use various operators such as bitwise, logical and arithmetic operators, string functions, date-time functions, numeric functions, control flow functions, secondary functions and stored functions. Along with this, statements which have subqueries and prepared statements can also be used.

Examples

Simple REPLACE statement

```
REPLACE INTO t2 VALUES (1,'Leopard'),(2,'Dog') RETURNING id2, id2+id2
as Total ,id2|id2, id2&&id2;
+-----+-------+---------+----------+
| id2 | Total | id2|id2 | id2&&id2 |
+-----+-------+---------+----------+
|   1 |     2 |       1 |        1 |
|   2 |     4 |       2 |        1 |
+-----+-------+---------+----------+
```

Using stored functions in RETURNING

```
DELIMITER |
CREATE FUNCTION f(arg INT) RETURNS INT
    BEGIN
      RETURN (SELECT arg+arg);
    END|

DELIMITER ;
PREPARE stmt FROM "REPLACE INTO t2 SET id2=3, animal2='Fox' RETURNING f2(id2),
UPPER(animal2)";

EXECUTE stmt;
+---------+----------------+
| f2(id2) | UPPER(animal2) |
+---------+----------------+
|       6 | FOX            |
+---------+----------------+
```

Subqueries in the statement

```
REPLACE INTO t1 SELECT * FROM t2 RETURNING (SELECT id2 FROM t2 WHERE
id2 IN (SELECT id2 FROM t2 WHERE id2=1)) AS new_id;
+--------+
| new_id |
+--------+
|      1 |
|      1 |
|      1 |
|      1 |
+--------+
```

Subqueries in the RETURNING clause that return more than one row or column cannot be used..

Aggregate functions cannot be used in the RETURNING clause. Since aggregate functions work on a set of values and if the purpose is to get the row count, ROW_COUNT() with SELECT can be used, or it can be used in REPLACE...SELECT...RETURNING if the table in the RETURNING clause is not the same as the REPLACE table. ECT...RETURNING if the table in the RETURNING clause is not the same as the REPLACE table.

1.1.1.2.1.16 SHOW COLUMNS

Syntax

```
SHOW [FULL] {COLUMNS | FIELDS} FROM tbl_name [FROM db_name]
    [LIKE 'pattern' | WHERE expr]
```

Contents

Description

`SHOW COLUMNS` displays information about the columns in a given table. It also works for views. The `LIKE` clause, if present on its own, indicates which column names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

If the data types differ from what you expect them to be based on a `CREATE TABLE` statement, note that MariaDB sometimes changes data types when you create or alter a table. The conditions under which this occurs are described in the Silent Column Changes article.

The `FULL` keyword causes the output to include the column collation and comments, as well as the privileges you have for each column.

You can use `db_name.tbl_name` as an alternative to the `tbl_name FROM db_name` syntax. In other words, these two statements are equivalent:

```
SHOW COLUMNS FROM mytable FROM mydb;
SHOW COLUMNS FROM mydb.mytable;
```

`SHOW COLUMNS` displays the following values for each table column:

Field indicates the column name.

Type indicates the column data type.

Collation indicates the collation for non-binary string columns, or NULL for other columns. This value is displayed only if you use the FULL keyword.

The **Null** field contains YES if NULL values can be stored in the column, NO if not.

The **Key** field indicates whether the column is indexed:

- If **Key** is empty, the column either is not indexed or is indexed only as a secondary column in a multiple-column, non-unique index.
- If **Key** is ***PRI***, the column is a `PRIMARY KEY` or is one of the columns in a multiple-column `PRIMARY KEY`.
- If **Key** is ***UNI***, the column is the first column of a unique-valued index that cannot contain `NULL` values.
- If **Key** is ***MUL***, multiple occurrences of a given value are allowed within the column. The column is the first column of a non-unique index or a unique-valued index that can contain `NULL` values.

If more than one of the **Key** values applies to a given column of a table, **Key** displays the one with the highest priority, in the order PRI, UNI, MUL.

A `UNIQUE` index may be displayed as `PRI` if it cannot contain `NULL` values and there is no `PRIMARY KEY` in the table. A `UNIQUE` index may display as `MUL` if several columns form a composite `UNIQUE` index; although the combination of the columns is unique, each column can still hold multiple occurrences of a given value.

The **Default** field indicates the default value that is assigned to the column.

The **Extra** field contains any additional information that is available about a given column.

Value	Description
`AUTO_INCREMENT`	The column was created with the `AUTO_INCREMENT` keyword.
`PERSISTENT`	The column was created with the `PERSISTENT` keyword. (New in 5.3)
`VIRTUAL`	The column was created with the `VIRTUAL` keyword. (New in 5.3)
on update `CURRENT_TIMESTAMP`	The column is a `TIMESTAMP` column that is automatically updated on `INSERT` and `UPDATE`.

Privileges indicates the privileges you have for the column. This value is displayed only if you use the `FULL` keyword.

Comment indicates any comment the column has. This value is displayed only if you use the `FULL` keyword.

`SHOW FIELDS` is a synonym for `SHOW COLUMNS`. Also DESCRIBE and EXPLAIN can be used as shortcuts.

You can also list a table's columns with:

```
mariadb-show db_name tbl_name
```

See the mariadb-show command for more details.

The DESCRIBE statement provides information similar to `SHOW COLUMNS`. The information_schema.COLUMNS table provides similar, but more complete, information.

The SHOW CREATE TABLE, SHOW TABLE STATUS, and SHOW INDEX statements also provide information about tables.

Examples

```
SHOW COLUMNS FROM city;
+------------+----------+------+-----+---------+----------------+
| Field      | Type     | Null | Key | Default | Extra          |
+------------+----------+------+-----+---------+----------------+
| Id         | int(11)  | NO   | PRI | NULL    | auto_increment |
| Name       | char(35) | NO   |     |         |                |
| Country    | char(3)  | NO   | UNI |         |                |
| District   | char(20) | YES  | MUL |         |                |
| Population | int(11)  | NO   |     | 0       |                |
+------------+----------+------+-----+---------+----------------+
```

```
SHOW COLUMNS FROM employees WHERE Type LIKE 'Varchar%';
+---------------+-------------+------+-----+---------+-------+
| Field         | Type        | Null | Key | Default | Extra |
+---------------+-------------+------+-----+---------+-------+
| first_name    | varchar(30) | NO   | MUL | NULL    |       |
| last_name     | varchar(40) | NO   |     | NULL    |       |
| position      | varchar(25) | NO   |     | NULL    |       |
| home_address  | varchar(50) | NO   |     | NULL    |       |
| home_phone    | varchar(12) | NO   |     | NULL    |       |
| employee_code | varchar(25) | NO   | UNI | NULL    |       |
+---------------+-------------+------+-----+---------+-------+
```

1.1.1.2.1.17 SHOW CREATE TABLE

Syntax

```
SHOW CREATE TABLE tbl_name
```

Contents

Description

Shows the CREATE TABLE statement that created the given table. The statement requires the SELECT privilege for the table. This statement also works with views and SEQUENCE.

`SHOW CREATE TABLE` quotes table and column names according to the value of the sql_quote_show_create server system variable.

Certain SQL_MODE values can result in parts of the original CREATE statement not being included in the output. MariaDB-specific table options, column options, and index options are not included in the output of this statement if the NO_TABLE_OPTIONS, NO_FIELD_OPTIONS and NO_KEY_OPTIONS SQL_MODE flags are used. All MariaDB-specific table attributes are also not shown when a non-MariaDB/MySQL emulation mode is used, which includes ANSI, DB2, POSTGRESQL, MSSQL, MAXDB or ORACLE.

Invalid table options, column options and index options are normally commented out (note, that it is possible to create a table with invalid options, by altering a table of a different engine, where these options were valid). To have them uncommented, enable the IGNORE_BAD_TABLE_OPTIONS SQL_MODE. Remember that replaying a CREATE TABLE statement with uncommented invalid options will fail with an error, unless the IGNORE_BAD_TABLE_OPTIONS SQL_MODE is in effect.

Note that `SHOW CREATE TABLE` is not meant to provide metadata about a table. It provides information about how the table was declared, but the real table structure could differ a bit. For example, if an index has been declared as `HASH`, the `CREATE TABLE` statement returned by `SHOW CREATE TABLE` will declare that index as `HASH`; however, it is possible that the index is in fact a `BTREE`, because the storage engine does not support `HASH`.

MariaDB permits TEXT and BLOB data types to be assigned a DEFAULT value. As a result, `SHOW CREATE TABLE` will append a `DEFAULT NULL` to nullable TEXT or BLOB fields if no specific default is provided.

Numbers are no longer quoted in the `DEFAULT` clause in `SHOW CREATE` statement. Prior to MariaDB 10.2.2, MariaDB quoted numbers.

Index Order

Indexes are sorted and displayed in the following order, which may differ from the order of the CREATE TABLE statement.

- PRIMARY KEY
- UNIQUE keys where all column are NOT NULL
- UNIQUE keys that don't contain partial segments
- Other UNIQUE keys
- LONG UNIQUE keys
- Normal keys
- Fulltext keys

See sql/sql_table.cc for details.

Examples

```
SHOW CREATE TABLE t\G
*************************** 1. row ***************************
       Table: t
Create Table: CREATE TABLE `t` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `s` char(60) DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

With sql_quote_show_create off:

```
SHOW CREATE TABLE t\G
*************************** 1. row ***************************
       Table: t
Create Table: CREATE TABLE t (
  id int(11) NOT NULL AUTO_INCREMENT,
  s char(60) DEFAULT NULL,
  PRIMARY KEY (id)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

Unquoted numeric DEFAULTs, from MariaDB 10.2.2:

```
CREATE TABLE td (link TINYINT DEFAULT 1);

SHOW CREATE TABLE td\G
*************************** 1. row ***************************
       Table: td
Create Table: CREATE TABLE `td` (
  `link` tinyint(4) DEFAULT 1
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

Quoted numeric DEFAULTs, until MariaDB 10.2.1:

```
CREATE TABLE td (link TINYINT DEFAULT 1);

SHOW CREATE TABLE td\G
*************************** 1. row ***************************
       Table: td
Create Table: CREATE TABLE `td` (
  `link` tinyint(4) DEFAULT '1'
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

SQL_MODE impacting the output:

```
SELECT @@sql_mode;
+--------------------------------------------------------------------------------------------+
| @@sql_mode                                                                                 |
+--------------------------------------------------------------------------------------------+
| STRICT_TRANS_TABLES,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION |
+--------------------------------------------------------------------------------------------+

CREATE TABLE `t1` (
       `id` int(11) NOT NULL AUTO_INCREMENT,
       `msg` varchar(100) DEFAULT NULL,
       PRIMARY KEY (`id`)
     ) ENGINE=InnoDB DEFAULT CHARSET=latin1
;

SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
       Table: t1
Create Table: CREATE TABLE `t1` (
  `id` int(11) NOT NULL AUTO_INCREMENT,

  PRIMARY KEY ("id")
```

1.1.1.2.1.18 SHOW INDEX

Syntax

```
SHOW {INDEX | INDEXES | KEYS}
 FROM tbl_name [FROM db_name]
 [WHERE expr]
```

Contents

Description

`SHOW INDEX` returns table index information. The format resembles that of the SQLStatistics call in ODBC.

You can use `db_name.tbl_name` as an alternative to the `tbl_name FROM db_name` syntax. These two statements are equivalent:

```
SHOW INDEX FROM mytable FROM mydb;
SHOW INDEX FROM mydb.mytable;
```

`SHOW KEYS` and `SHOW INDEXES` are synonyms for `SHOW INDEX`.

You can also list a table's indexes with the mariadb-show command:

```
mariadb-show -k db_name tbl_name
```

The information_schema.STATISTICS table stores similar information.

The following fields are returned by `SHOW INDEX`.

Field	Description
`Table`	Table name
`Non_unique`	`1` if the index permits duplicate values, `0` if values must be unique.
`Key_name`	Index name. The primary key is always named `PRIMARY`.
`Seq_in_index`	The column's sequence in the index, beginning with `1`.
`Column_name`	Column name.
`Collation`	Either `A`, if the column is sorted in ascending order in the index, or `NULL` if it's not sorted.
`Cardinality`	Estimated number of unique values in the index. The cardinality statistics are calculated at various times, and can help the optimizer make improved decisions.
`Sub_part`	`NULL` if the entire column is included in the index, or the number of included characters if not.
`Packed`	`NULL` if the index is not packed, otherwise how the index is packed.
`Null`	`NULL` if `NULL` values are permitted in the column, an empty string if `NULL`s are not permitted.
`Index_type`	The index type, which can be `BTREE`, `FULLTEXT`, `HASH` or `RTREE`. See Storage Engine Index Types.
`Comment`	Other information, such as whether the index is disabled.
`Index_comment`	Contents of the `COMMENT` attribute when the index was created.
`Ignored`	Whether or not an index will be ignored by the optimizer. See Ignored Indexes. From MariaDB 10.6.0.

The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

Examples

```
CREATE TABLE IF NOT EXISTS `employees_example` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `first_name` varchar(30) NOT NULL,
  `last_name` varchar(40) NOT NULL,
  `position` varchar(25) NOT NULL,
  `home_address` varchar(50) NOT NULL,
  `home_phone` varchar(12) NOT NULL,
  `employee_code` varchar(25) NOT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `employee_code` (`employee_code`),
  KEY `first_name` (`first_name`,`last_name`)
) ENGINE=Aria;

INSERT INTO `employees_example` (`first_name`, `last_name`, `position`, `home_address`,
`home_phone`, `employee_code`)
  VALUES
  ('Mustapha', 'Mond', 'Chief Executive Officer', '692 Promiscuous Plaza', '326-555-3492',
'MM1'),
  ('Henry', 'Foster', 'Store Manager', '314 Savage Circle', '326-555-3847', 'HF1'),
  ('Bernard', 'Marx', 'Cashier', '1240 Ambient Avenue', '326-555-8456', 'BM1'),

```

1.1.1.2.1.19 TRUNCATE TABLE

Syntax

```
TRUNCATE [TABLE] tbl_name
  [WAIT n | NOWAIT]
```

Contents

Description

`TRUNCATE TABLE` empties a table completely. It requires the `DROP` privilege. See GRANT.

`tbl_name` can also be specified in the form `db_name . tbl_name` (see Identifier Qualifiers).

Logically, `TRUNCATE TABLE` is equivalent to a DELETE statement that deletes all rows, but there are practical differences under some circumstances.

`TRUNCATE TABLE` will fail for an InnoDB table if any FOREIGN KEY constraints from other tables reference the table, returning the error:

```
ERROR 1701 (42000): Cannot truncate a table referenced in a foreign key constraint
```

Foreign Key constraints between columns in the same table are permitted.

For an InnoDB table, if there are no `FOREIGN KEY` constraints, InnoDB performs fast truncation by dropping the original table and creating an empty one with the same definition, which is much faster than deleting rows one by one. The AUTO_INCREMENT counter is reset by `TRUNCATE TABLE`, regardless of whether there is a `FOREIGN KEY` constraint.

The count of rows affected by `TRUNCATE TABLE` is accurate only when it is mapped to a `DELETE` statement.

For other storage engines, `TRUNCATE TABLE` differs from `DELETE` in the following ways:

- Truncate operations drop and re-create the table, which is much faster than deleting rows one by one, particularly for large tables.
- Truncate operations cause an implicit commit.
- Truncation operations cannot be performed if the session holds an active table lock.
- Truncation operations do not return a meaningful value for the number of deleted rows. The usual result is "0 rows affected," which should be interpreted as "no information."
- As long as the table format file `tbl_name.frm` is valid, the table can be re-created as an empty table with `TRUNCATE TABLE`, even if the data or index files have become corrupted.
- The table handler does not remember the last used AUTO_INCREMENT value, but starts counting from the beginning. This is true even for MyISAM and InnoDB, which normally do not reuse sequence values.
- When used with partitioned tables, `TRUNCATE TABLE` preserves the partitioning; that is, the data and index files are dropped and re-created, while the partition definitions (.par) file is unaffected.
- Since truncation of a table does not make any use of `DELETE`, the `TRUNCATE` statement does not invoke `ON DELETE` triggers.
- `TRUNCATE TABLE` will only reset the values in the Performance Schema summary tables to zero or null, and will not remove the rows.

For the purposes of binary logging and replication, `TRUNCATE TABLE` is treated as DROP TABLE followed by CREATE TABLE (DDL rather than DML).

`TRUNCATE TABLE` does not work on views. Currently, `TRUNCATE TABLE` drops all historical records from a system-versioned table.

WAIT/NOWAIT

Set the lock wait timeout. See WAIT and NOWAIT.

Oracle-mode

Oracle-mode from MariaDB 10.3 permits the optional keywords REUSE STORAGE or DROP STORAGE to be used.

```
TRUNCATE [TABLE] tbl_name [{DROP | REUSE} STORAGE] [WAIT n | NOWAIT]
```

These have no effect on the operation.

Performance

`TRUNCATE TABLE` is faster than DELETE, because it drops and re-creates a table.

With InnoDB, `TRUNCATE TABLE` is slower if innodb_file_per_table=ON is set (the default). This is because `TRUNCATE TABLE` unlinks the underlying tablespace file, which can be an expensive operation. See MDEV-8069 for more details.

The performance issues with innodb_file_per_table=ON can be exacerbated in cases where the InnoDB buffer pool is very large and innodb_adaptive_hash_index=ON is set. In that case, using DROP TABLE followed by CREATE TABLE instead of `TRUNCATE TABLE` may perform better. Setting innodb_adaptive_hash_index=OFF (it defaults to ON before MariaDB 10.5) can also help. In MariaDB 10.2 only, from MariaDB 10.2.19, this performance can also be improved by setting innodb_safe_truncate=OFF. See MDEV-9459 for more details.

Setting innodb_adaptive_hash_index=OFF can also improve `TRUNCATE TABLE` performance in general. See MDEV-16796 for more details.

1.1.1.2.1.20 UPDATE

Syntax

Single-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_reference
  [PARTITION (partition_list)]
  [FOR PORTION OF period FROM expr1 TO expr2]
  SET col1={expr1|DEFAULT} [,col2={expr2|DEFAULT}] ...
  [WHERE where_condition]
  [ORDER BY ...]
  [LIMIT row_count]
```

Multiple-table syntax:

```
UPDATE [LOW_PRIORITY] [IGNORE] table_references
    SET col1={expr1|DEFAULT} [, col2={expr2|DEFAULT}] ...
    [WHERE where_condition]
```

Contents

Description

For the single-table syntax, the `UPDATE` statement updates columns of existing rows in the named table with new values. The `SET` clause indicates which columns to modify and the values they should be given. Each value can be given as an expression, or the keyword `DEFAULT` to set a column explicitly to its default value. The `WHERE` clause, if given, specifies the conditions that identify which rows to update. With no `WHERE` clause, all rows are updated. If the ORDER BY clause is specified, the rows are updated in the order that is specified. The LIMIT clause places a limit on the number of rows that can be updated.

Until MariaDB 10.3.2, for the multiple-table syntax, `UPDATE` updates rows in each table named in table_references that satisfy the conditions. In this case, ORDER BY and LIMIT cannot be used. This restriction was lifted in MariaDB 10.3.2 and both clauses can be used with multiple-table updates. An `UPDATE` can also reference tables which are located in different databases; see Identifier Qualifiers for the syntax.

`where_condition` is an expression that evaluates to true for each row to be updated.

`table_references` and `where_condition` are as specified as described in SELECT.

For single-table updates, assignments are evaluated in left-to-right order, while for multi-table updates, there is no guarantee of a particular order. If the `SIMULTANEOUS_ASSIGNMENT` sql_mode (available from MariaDB 10.3.5) is set, UPDATE statements evaluate all assignments simultaneously.

You need the `UPDATE` privilege only for columns referenced in an `UPDATE` that are actually updated. You need only the SELECT privilege for any columns that are read but not modified. See GRANT.

The `UPDATE` statement supports the following modifiers:

- If you use the `LOW_PRIORITY` keyword, execution of the `UPDATE` is delayed until no other clients are reading from the table. This affects only storage engines that use only table-level locking (MyISAM, MEMORY, MERGE). See HIGH_PRIORITY and LOW_PRIORITY clauses for details.
- If you use the `IGNORE` keyword, the update statement does not abort even if errors occur during the update. Rows for which duplicate-key conflicts occur are not updated. Rows for which columns are updated to values that would cause data conversion errors are updated to the closest valid values instead.

PARTITION

See Partition Pruning and Selection for details.

FOR PORTION OF

MariaDB starting with 10.4.3

See Application Time Periods - Updating by Portion.

UPDATE Statements With the Same Source and Target

MariaDB starting with 10.3.2

From MariaDB 10.3.2, UPDATE statements may have the same source and target.

For example, given the following table:

```
DROP TABLE t1;
CREATE TABLE t1 (c1 INT, c2 INT);
INSERT INTO t1 VALUES (10,10), (20,20);
```

Until MariaDB 10.3.1, the following UPDATE statement would not work:

```
UPDATE t1 SET c1=c1+1 WHERE c2=(SELECT MAX(c2) FROM t1);
ERROR 1093 (HY000): Table 't1' is specified twice,
  both as a target for 'UPDATE' and as a separate source for data
```

From MariaDB 10.3.2, the statement executes successfully:

```
UPDATE t1 SET c1=c1+1 WHERE c2=(SELECT MAX(c2) FROM t1);

SELECT * FROM t1;
+------+------+
| c1   | c2   |
+------+------+
|   10 |   10 |
|   21 |   20 |
+------+------+
```

Example

Single-table syntax:

```
UPDATE table_name SET column1 = value1, column2 = value2 WHERE id=100;
```

Multiple-table syntax:

```
UPDATE tab1, tab2 SET tab1.column1 = value1, tab1.column2 = value2 WHERE tab1.id = tab2.id;
```

1.1.1.2.1.21 IGNORE

The `IGNORE` option tells the server to ignore some common errors.

`IGNORE` can be used with the following statements:

- DELETE
- INSERT (see also INSERT IGNORE)
- LOAD DATA INFILE
- UPDATE
- ALTER TABLE
- CREATE TABLE ... SELECT
- INSERT ... SELECT

The logic used:

- Variables out of ranges are replaced with the maximum/minimum value.
- SQL_MODEs `STRICT_TRANS_TABLES`, `STRICT_ALL_TABLES`, `NO_ZERO_IN_DATE`, `NO_ZERO_DATE` are ignored.
- Inserting `NULL` in a `NOT NULL` field will insert 0 (in a numerical field), 0000-00-00 (in a date field) or an empty string (in a character field).
- Rows that cause a duplicate key error or break a foreign key constraint are not inserted, updated, or deleted.

The following errors are ignored:

Error number	Symbolic error name	Description
1022	ER_DUP_KEY	Can't write; duplicate key in table '%s'
1048	ER_BAD_NULL_ERROR	Column '%s' cannot be null
1062	ER_DUP_ENTRY	Duplicate entry '%s' for key %d
1242	ER_SUBQUERY_NO_1_ROW	Subquery returns more than 1 row
1264	ER_WARN_DATA_OUT_OF_RANGE	Out of range value for column '%s' at row %ld
1265	WARN_DATA_TRUNCATED	Data truncated for column '%s' at row %ld
1292	ER_TRUNCATED_WRONG_VALUE	Truncated incorrect %s value: '%s'
1366	ER_TRUNCATED_WRONG_VALUE_FOR_FIELD	Incorrect integer value
1369	ER_VIEW_CHECK_FAILED	CHECK OPTION failed '%s.%s'
1451	ER_ROW_IS_REFERENCED_2	Cannot delete or update a parent row
1452	ER_NO_REFERENCED_ROW_2	Cannot add or update a child row: a foreign key constraint fails (%s)
1526	ER_NO_PARTITION_FOR_GIVEN_VALUE	Table has no partition for value %s
1586	ER_DUP_ENTRY_WITH_KEY_NAME	Duplicate entry '%s' for key '%s'
1591	ER_NO_PARTITION_FOR_GIVEN_VALUE_SILENT	Table has no partition for some existing values
1748	ER_ROW_DOES_NOT_MATCH_GIVEN_PARTITION_SET	Found a row not matching the given partition set

Ignored errors normally generate a warning.

A property of the `IGNORE` clause consists in causing transactional engines and non-transactional engines (like InnoDB and Aria) to behave the same way. For example, normally a multi-row insert which tries to violate a `UNIQUE` contraint is completely rolled back on InnoDB, but might be partially executed on Aria. With the `IGNORE` clause, the statement will be partially executed in both engines.

Duplicate key errors also generate warnings. The OLD_MODE server variable can be used to prevent this.

1.1.7.1 System-Versioned Tables

1.1.1.2.2 ANALYZE and EXPLAIN Statements

ANALYZE FORMAT=JSON

Mix of the EXPLAIN FORMAT=JSON and ANALYZE statement features.

ANALYZE FORMAT=JSON Examples

Examples with ANALYZE FORMAT=JSON.

ANALYZE Statement

Invokes the optimizer, executes the statement, and then produces EXPLAIN output.

EXPLAIN

EXPLAIN returns information about index usage, as well as being a synonym for DESCRIBE.

EXPLAIN ANALYZE

Old implementation, now ANALYZE statement

EXPLAIN FORMAT=JSON

Variant of EXPLAIN that produces output in JSON form

SHOW EXPLAIN

Shows an execution plan for a running query.

Using Buffer UPDATE Algorithm

Explanation of UPDATE's "Using Buffer" algorithm.

1.1.1.2.2.1 ANALYZE FORMAT=JSON

Contents

`ANALYZE FORMAT=JSON` is a mix of the EXPLAIN FORMAT=JSON and ANALYZE statement features. The `ANALYZE FORMAT=JSON $statement` will execute `$statement`, and then print the output of `EXPLAIN FORMAT=JSON`, amended with data from the query execution.

Basic Execution Data

You can get the following also from tabular `ANALYZE` statement form:

- **`r_rows`** is provided for any node that reads rows. It shows how many rows were read, on average
- **`r_filtered`** is provided whenever there is a condition that is checked. It shows the percentage of rows left after checking the condition.

Advanced Execution Data

The most important data not available in the regular tabular `ANALYZE` statement are:

- **`r_loops`** field. This shows how many times the node was executed. Most query plan elements have this field.
- **`r_total_time_ms`** field. It shows how much time in total, in milliseconds, was spent executing this node. If the node has subnodes, their execution time is included.
- **`r_buffer_size`** field. Query plan nodes that make use of buffers report the size of buffer that was was used.

InnoDB engine statistics

Starting from MariaDB 10.6.15, MariaDB 10.8.8, MariaDB 10.9.8, MariaDB 10.10.6, MariaDB 10.11.5, MariaDB 11.0.3, MariaDB 11.1.2 and MariaDB 11.2.1 (MDEV-31577), the following statistics are reported for InnoDB tables:

```
      "r_engine_stats": {
        "pages_accessed":  integer,
        "pages_read_count": integer,
        "pages_read_time_ms": double,
        "old_rows_read": integer
      }
```

Only non-zero members are printed.

- `pages_accessed` is the total number of buffer pool pages accessed when reading this table

- `pages_read_count` is the number of pages that InnoDB had to read from disk for this table. (If the query touches "hot" data in the InnoDB buffer pool, this value will be 0 and not present)
- `pages_read_time_ms` is the total time spent reading the table.
- `old_rows_read` is the number of old row versions that InnoDB had to read. Old row version is the version of the row that is not visible to this transaction.

SHOW ANALYZE FORMAT=JSON

MariaDB starting with 10.9

`SHOW ANALYZE FORMAT=JSON for <connection_id>` extends `ANALYZE [FORMAT=JSON] <select>` to allow one to analyze a query currently running in another connection.

Data About Individual Query Plan Nodes

- **`filesort`** node reports whether sorting was done with `LIMIT n` parameter, and how many rows were in the sort result.
- **`block-nl-join`** node has `r_loops` field, which allows to tell whether `Using join buffer` was efficient
- **`range-checked-for-each-record`** reports counters that show the result of the check.
- **`expression-cache`** is used for subqueries, and it reports how many times the cache was used, and what cache hit ratio was.
- **`union_result`** node has `r_rows` so one can see how many rows were produced after UNION operation
- and so forth

Use Cases

See Examples of ANALYZE FORMAT=JSON.

1.1.1.2.2.2 ANALYZE FORMAT=JSON Examples

Example #1

Customers who have ordered more than 1M goods.

```
ANALYZE FORMAT=JSON
SELECT COUNT(*)
FROM customer
WHERE
  (SELECT SUM(o_totalprice) FROM orders WHERE o_custkey=c_custkey) > 1000*1000;
```

The query takes 40 seconds over cold cache

```
EXPLAIN: {
  "query_block": {
    "select_id": 1,
    "r_loops": 1,
    "r_total_time_ms": 39872,
    "table": {
      "table_name": "customer",
      "access_type": "index",
      "key": "i_c_nationkey",
      "key_length": "5",
      "used_key_parts": ["c_nationkey"],
      "r_loops": 1,
      "rows": 150303,
      "r_rows": 150000,
      "r_total_time_ms": 270.3,
      "filtered": 100,
      "r_filtered": 60.691,
      "attached_condition": "((subquery#2) > <cache>((1000 * 1000)))",
      "using_index": true
    },
    "subqueries": [
      {
        "query_block": {
          "select_id": 2,
          "r_loops": 150000,
          "r_total_time_ms": 39531,
          "table": {
            "table_name": "orders",
            "access_type": "ref",
            "possible_keys": ["i_o_custkey"],
            "key": "i_o_custkey",
            "key_length": "5",
            "used_key_parts": ["o_custkey"],
            "ref": ["dbt3sf1.customer.c_custkey"],
            "r_loops": 150000,
            "rows": 7,
            "r_rows": 10,
            "r_total_time_ms": 39208,
            "filtered": 100,
            "r_filtered": 100
          }
        }
      }
    ]
  }
}
```

`ANALYZE` shows that 39.2 seconds were spent in the subquery, which was executed 150K times (for every row of outer table).

1.1.1.2.2.3 ANALYZE Statement

Contents

Description

The `ANALYZE statement` is similar to the `EXPLAIN statement`. `ANALYZE statement` will invoke the optimizer, execute

the statement, and then produce `EXPLAIN` output instead of the result set. The `EXPLAIN` output will be annotated with statistics from statement execution.

This lets one check how close the optimizer's estimates about the query plan are to the reality. `ANALYZE` produces an overview, while the ANALYZE FORMAT=JSON command provides a more detailed view of the query plan and the query execution.

The syntax is

```
ANALYZE explainable_statement;
```

where the statement is any statement for which one can run EXPLAIN.

Command Output

Consider an example:

```
ANALYZE SELECT * FROM tbl1
WHERE key1
  BETWEEN 10 AND 200 AND
  col1 LIKE 'foo%'\G
```

```
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: tbl1
         type: range
possible_keys: key1
          key: key1
      key_len: 5
          ref: NULL
         rows: 181
       r_rows: 181
     filtered: 100.00
   r_filtered: 10.50
        Extra: Using index condition; Using where
```

Compared to `EXPLAIN`, `ANALYZE` produces two extra columns:

- **`r_rows`** is an observation-based counterpart of the **rows** column. It shows how many rows were actually read from the table.
- **`r_filtered`** is an observation-based counterpart of the **filtered** column. It shows which fraction of rows was left after applying the WHERE condition.

Interpreting the Output

Joins

Let's consider a more complicated example.

```
ANALYZE SELECT *
FROM orders, customer
WHERE
  customer.c_custkey=orders.o_custkey AND
  customer.c_acctbal < 0 AND
  orders.o_totalprice > 200*1000
```

```
+----+-------------+----------+------+---------------+-------------+---------+---------------
-----+--------+--------+----------+------------+-------------+
| id | select_type | table    | type | possible_keys | key         | key_len | ref
| rows   | r_rows | filtered | r_filtered | Extra       |
+----+-------------+----------+------+---------------+-------------+---------+---------------
-----+--------+--------+----------+------------+-------------+
|  1 | SIMPLE      | customer | ALL  | PRIMARY,...   | NULL        | NULL    | NULL
| 149095 | 150000 |    18.08 |       9.13 | Using where |
|  1 | SIMPLE      | orders   | ref  | i_o_custkey   | i_o_custkey | 5       |
customer.c_custkey |      7 |     10 |   100.00 |      30.03 | Using where |
+----+-------------+----------+------+---------------+-------------+---------+---------------
-----+--------+--------+----------+------------+-------------+
```

Here, one can see that

- For table customer, **customer.rows=149095, customer.r_rows=150000**. The estimate for number of rows we will read was fairly precise
- **customer.filtered=18.08, customer.r_filtered=9.13**. The optimizer somewhat overestimated the number of records that will match selectivity of condition attached to `customer` table (in general, when you have a full scan and r_filtered is less than 15%, it's time to consider adding an appropriate index).
- For table orders, **orders.rows=7, orders.r_rows=10**. This means that on average, there are 7 orders for a given c_custkey, but in our case there were 10, which is close to the expectation (when this number is consistently far from the expectation, it may be time to run ANALYZE TABLE, or even edit the table statistics manually to get better query plans).
- **orders.filtered=100, orders.r_filtered=30.03**. The optimizer didn't have any way to estimate which fraction of records will be left after it checks the condition that is attached to table orders (it's orders.o_totalprice > 200*1000). So, it used 100%. In reality, it is 30%. 30% is typically not selective enough to warrant adding new indexes. For joins with many tables, it might be worth to collect and use column statistics for columns in question, this may help the optimizer to pick a better query plan.

Meaning of NULL in r_rows and r_filtered

Let's modify the previous example slightly

```
ANALYZE SELECT *
FROM orders, customer
WHERE
  customer.c_custkey=orders.o_custkey AND
  customer.c_acctbal < -0 AND
  customer.c_comment LIKE '%foo%' AND
  orders.o_totalprice > 200*1000;
```

```
+----+-------------+----------+------+---------------+-------------+---------+---------------
-----+--------+--------+----------+------------+-------------+
| id | select_type | table    | type | possible_keys | key         | key_len | ref
| rows   | r_rows | filtered | r_filtered | Extra       |
+----+-------------+----------+------+---------------+-------------+---------+---------------
-----+--------+--------+----------+------------+-------------+
|  1 | SIMPLE      | customer | ALL  | PRIMARY,...   | NULL        | NULL    | NULL
| 149095 | 150000 |    18.08 |       0.00 | Using where |
|  1 | SIMPLE      | orders   | ref  | i_o_custkey   | i_o_custkey | 5       |
customer.c_custkey |      7 |   NULL |   100.00 |       NULL | Using where |
+----+-------------+----------+------+---------------+-------------+---------+---------------
-----+--------+--------+----------+------------+-------------+
```

Here, one can see that **orders.r_rows=NULL** and **orders.r_filtered=NULL**. This means that table orders was not scanned even once. Indeed, we can also see customer.r_filtered=0.00. This shows that a part of WHERE attached to table `customer` was never satisfied (or, satisfied in less than 0.01% of cases).

ANALYZE FORMAT=JSON

ANALYZE FORMAT=JSON produces JSON output. It produces much more information than tabular `ANALYZE`.

Notes

- `ANALYZE UPDATE` or `ANALYZE DELETE` will actually make updates/deletes (`ANALYZE SELECT` will perform the

select operation and then discard the resultset).
- PostgreSQL has a similar command, `EXPLAIN ANALYZE`.
- The EXPLAIN in the slow query log feature allows MariaDB to have `ANALYZE` output of slow queries printed into the slow query log (see MDEV-6388).

1.1.1.2.2.4 EXPLAIN

Syntax

```
EXPLAIN tbl_name [col_name | wild]
```

Or

```
EXPLAIN [EXTENDED | PARTITIONS | FORMAT=JSON]
  {SELECT select_options | UPDATE update_options | DELETE delete_options}
```

Contents

Description

The `EXPLAIN` statement can be used either as a synonym for DESCRIBE or as a way to obtain information about how MariaDB executes a `SELECT`, `UPDATE` or `DELETE` statement:

- `'EXPLAIN tbl_name'` is synonymous with `'DESCRIBE tbl_name'` or `'SHOW COLUMNS FROM tbl_name'`.
- When you precede a `SELECT`, `UPDATE` or a `DELETE` statement with the keyword `EXPLAIN`, MariaDB displays information from the optimizer about the query execution plan. That is, MariaDB explains how it would process the `SELECT`, `UPDATE` or `DELETE`, including information about how tables are joined and in which order. `EXPLAIN EXTENDED` can be used to provide additional information.
- `EXPLAIN PARTITIONS` is useful only when examining queries involving partitioned tables. For details, see Partition pruning and selection.
- ANALYZE statement performs the query as well as producing EXPLAIN output, and provides actual as well as estimated statistics.
- `EXPLAIN` output can be printed in the slow query log. See EXPLAIN in the Slow Query Log for details.

SHOW EXPLAIN shows the output of a running statement. In some cases, its output can be closer to reality than `EXPLAIN`.

The ANALYZE statement runs a statement and returns information about its execution plan. It also shows additional columns, to check how much the optimizer's estimation about filtering and found rows are close to reality.

There is an online EXPLAIN Analyzer that you can use to share `EXPLAIN` and `EXPLAIN EXTENDED` output with others.

> `EXPLAIN` can acquire metadata locks in the same way that `SELECT` does, as it needs to know table metadata and, sometimes, data as well.

Columns in EXPLAIN ... SELECT

Column name	Description
`id`	Sequence number that shows in which order tables are joined.
`select_type`	What kind of `SELECT` the table comes from.
`table`	Alias name of table. Materialized temporary tables for sub queries are named <subquery#>

type	How rows are found from the table (join type).
possible_keys	keys in table that could be used to find rows in the table
key	The name of the key that is used to retrieve rows. NULL is no key was used.
key_len	How many bytes of the key that was used (shows if we are using only parts of the multi-column key).
ref	The reference that is used as the key value.
rows	An estimate of how many rows we will find in the table for each key lookup.
Extra	Extra information about this join.

Here are descriptions of the values for some of the more complex columns in EXPLAIN ... SELECT:

"Select_type" Column

The select_type column can have the following values:

Value	Description	Comment
DEPENDENT SUBQUERY	The SUBQUERY is DEPENDENT.	
DEPENDENT UNION	The UNION is DEPENDENT.	
DERIVED	The SELECT is DERIVED from the PRIMARY.	
MATERIALIZED	The SUBQUERY is MATERIALIZED.	Materialized tables will be populated at first access and will be accessed by the primary key (= one key lookup). Number of rows in EXPLAIN shows the cost of populating the table
PRIMARY	The SELECT is in the outermost query, but there is also a SUBQUERY within it.	
SIMPLE	It is a simple SELECT query without any SUBQUERY or UNION.	
SUBQUERY	The SELECT is a SUBQUERY of the PRIMARY.	
UNCACHEABLE SUBQUERY	The SUBQUERY is UNCACHEABLE.	
UNCACHEABLE UNION	The UNION is UNCACHEABLE.	
UNION	The SELECT is a UNION of the PRIMARY.	
UNION RESULT	The result of the UNION.	
LATERAL DERIVED	The SELECT uses a Lateral Derived optimization	

"Type" Column

This column contains information on how the table is accessed.

Value	Description
ALL	A full table scan is done for the table (all rows are read). This is bad if the table is large and the table is joined against a previous table! This happens when the optimizer could not find any usable index to access rows.
const	There is only one possibly matching row in the table. The row is read before the optimization phase and all columns in the table are treated as constants.
eq_ref	A unique index is used to find the rows. This is the best possible plan to find the row.

`fulltext`	A fulltext index is used to access the rows.
`index_merge`	A 'range' access is done for for several index and the found rows are merged. The key column shows which keys are used.
`index_subquery`	This is similar as ref, but used for sub queries that are transformed to key lookups.
`index`	A full scan over the used index. Better than ALL but still bad if index is large and the table is joined against a previous table.
`range`	The table will be accessed with a key over one or more value ranges.
`ref_or_null`	Like 'ref' but in addition another search for the 'null' value is done if the first value was not found. This happens usually with sub queries.
`ref`	A non unique index or prefix of an unique index is used to find the rows. Good if the prefix doesn't match many rows.
`system`	The table has 0 or 1 rows.
`unique_subquery`	This is similar as eq_ref, but used for sub queries that are transformed to key lookups

"Extra" Column

This column consists of one or more of the following values, separated by ';'

Note that some of these values are detected after the optimization phase.

The optimization phase can do the following changes to the `WHERE` clause:

- Add the expressions from the `ON` and `USING` clauses to the `WHERE` clause.
- Constant propagation: If there is `column=constant` , replace all column instances with this constant.
- Replace all columns from ' `const` ' tables with their values.
- Remove the used key columns from the `WHERE` (as this will be tested as part of the key lookup).
- Remove impossible constant sub expressions. For example `WHERE '(a=1 and a=2) OR b=1'` becomes `'b=1'` .
- Replace columns with other columns that has identical values: Example: `WHERE a=b` and `a=c` may be treated as `'WHERE a=b and a=c and b=c'` .
- Add extra conditions to detect impossible row conditions earlier. This happens mainly with `OUTER JOIN` where we in some cases add detection of `NULL` values in the `WHERE` (Part of ' `Not exists` ' optimization). This can cause an unexpected ' `Using where` ' in the Extra column.
- For each table level we remove expressions that have already been tested when we read the previous row. Example: When joining tables `t1` with `t2` using the following `WHERE 't1.a=1 and t1.a=t2.b'` , we don't have to test `'t1.a=1'` when checking rows in `t2` as we already know that this expression is true.

Value	Description
`const row not found`	The table was a system table (a table with should exactly one row), but no row was found.
`Distinct`	If distinct optimization (remove duplicates) was used. This is marked only for the last table in the `SELECT` .
`Full scan on NULL key`	The table is a part of the sub query and if the value that is used to match the sub query will be `NULL` , we will do a full table scan.
`Impossible HAVING`	The used `HAVING` clause is always false so the `SELECT` will return no rows.
`Impossible WHERE noticed after reading const tables.`	The used `WHERE` clause is always false so the `SELECT` will return no rows. This case was detected after we had read all 'const' tables and used the column values as constant in the `WHERE` clause. For example: `WHERE const_column=5` and `const_column` had a value of 4.
`Impossible WHERE`	The used `WHERE` clause is always false so the `SELECT` will return no rows. For example: `WHERE 1=2`
`No matching min/max row`	During early optimization of `MIN()` / `MAX()` values it was detected that no row could match the `WHERE` clause. The `MIN()` / `MAX()` function will return `NULL` .
`no matching row in const table`	The table was a const table (a table with only one possible matching row), but no row was found.
`No tables used`	The `SELECT` was a sub query that did not use any tables. For example a there was no `FROM` clause or a `FROM DUAL` clause.

`Not exists`	Stop searching after more row if we find one single matching row. This optimization is used with `LEFT JOIN` where one is explicitly searching for rows that doesn't exists in the `LEFT JOIN TABLE`. Example: `SELECT * FROM t1 LEFT JOIN t2 on (...) WHERE t2.not_null_column IS NULL`. As `t2.not_null_column` can only be `NULL` if there was no matching row for on condition, we can stop searching if we find a single matching row.
`Open_frm_only`	For `information_schema` tables. Only the `frm` (table definition file was opened) was opened for each matching row.
`Open_full_table`	For `information_schema` tables. A full table open for each matching row is done to retrieve the requested information. (Slow)
`Open_trigger_only`	For `information_schema` tables. Only the trigger file definition was opened for each matching row.
`Range checked for each record (index map: ...)`	This only happens when there was no good default index to use but there may some index that could be used when we can treat all columns from previous table as constants. For each row combination the optimizer will decide which index to use (if any) to fetch a row from this table. This is not fast, but faster than a full table scan that is the only other choice. The index map is a bitmask that shows which index are considered for each row condition.
`Scanned 0/1/all databases`	For `information_schema` tables. Shows how many times we had to do a directory scan.
`Select tables optimized away`	All tables in the join was optimized away. This happens when we are only using `COUNT(*)`, `MIN()` and `MAX()` functions in the `SELECT` and we where able to replace all of these with constants.
`Skip_open_table`	For `information_schema` tables. The queried table didn't need to be opened.
`unique row not found`	The table was detected to be a const table (a table with only one possible matching row) during the early optimization phase, but no row was found.
`Using filesort`	Filesort is needed to resolve the query. This means an extra phase where we first collect all columns to sort, sort them with a disk based merge sort and then use the sorted set to retrieve the rows in sorted order. If the column set is small, we store all the columns in the sort file to not have to go to the database to retrieve them again.
`Using index`	Only the index is used to retrieve the needed information from the table. There is no need to perform an extra seek to retrieve the actual record.
`Using index condition`	Like '`Using where`' but the where condition is pushed down to the table engine for internal optimization at the index level.
`Using index condition(BKA)`	Like '`Using index condition`' but in addition we use batch key access to retrieve rows.
`Using index for group-by`	The index is being used to resolve a `GROUP BY` or `DISTINCT` query. The rows are not read. This is very efficient if the table has a lot of identical index entries as duplicates are quickly jumped over.
`Using intersect(...)`	For `index_merge` joins. Shows which index are part of the intersect.
`Using join buffer`	We store previous row combinations in a row buffer to be able to match each row against all of the rows combinations in the join buffer at one go.
`Using sort_union(...)`	For `index_merge` joins. Shows which index are part of the union.
`Using temporary`	A temporary table is created to hold the result. This typically happens if you are using `GROUP BY`, `DISTINCT` or `ORDER BY`.
`Using where`	A `WHERE` expression (in additional to the possible key lookup) is used to check if the row should be accepted. If you don't have 'Using where' together with a join type of `ALL`, you are probably doing something wrong!
`Using where with pushed condition`	Like '`Using where`' but the where condition is pushed down to the table engine for internal optimization at the row level.
`Using buffer`	The `UPDATE` statement will first buffer the rows, and then run the updates, rather than do updates on the fly. See Using Buffer UPDATE Algorithm for a detailed explanation.

EXPLAIN EXTENDED

The `EXTENDED` keyword adds another column, *filtered*, to the output. This is a percentage estimate of the table rows that will be filtered by the condition.

An `EXPLAIN EXTENDED` will always throw a warning, as it adds extra *Message* information to a subsequent `SHOW WARNINGS` statement. This includes what the `SELECT` query would look like after optimizing and rewriting rules are applied and how the optimizer qualifies columns and tables.

Examples

As synonym for `DESCRIBE` or `SHOW COLUMNS FROM`:

```
DESCRIBE city;
+------------+----------+------+-----+---------+----------------+
| Field      | Type     | Null | Key | Default | Extra          |
+------------+----------+------+-----+---------+----------------+
| Id         | int(11)  | NO   | PRI | NULL    | auto_increment |
| Name       | char(35) | YES  |     | NULL    |                |
| Country    | char(3)  | NO   | UNI |         |                |
| District   | char(20) | YES  | MUL |         |                |
| Population | int(11)  | YES  |     | NULL    |                |
+------------+----------+------+-----+---------+----------------+
```

A simple set of examples to see how `EXPLAIN` can identify poor index usage:

```
CREATE TABLE IF NOT EXISTS `employees_example` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `first_name` varchar(30) NOT NULL,
  `last_name` varchar(40) NOT NULL,
  `position` varchar(25) NOT NULL,
  `home_address` varchar(50) NOT NULL,
  `home_phone` varchar(12) NOT NULL,
  `employee_code` varchar(25) NOT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `employee_code` (`employee_code`),
  KEY `first_name` (`first_name`,`last_name`)
) ENGINE=Aria;

INSERT INTO `employees_example` (`first_name`, `last_name`, `position`, `home_address`,
`home_phone`, `employee_code`)
  VALUES
  ('Mustapha', 'Mond', 'Chief Executive Officer', '692 Promiscuous Plaza', '326-555-3492',
'MM1'),
  ('Henry', 'Foster', 'Store Manager', '314 Savage Circle', '326-555-3847', 'HF1'),
  ('Bernard', 'Marx', 'Cashier', '1240 Ambient Avenue', '326-555-8456', 'BM1'),
  ('Lenina', 'Crowne', 'Cashier', '281 Bumblepuppy Boulevard', '328-555-2349', 'LC1'),
  ('Fanny', 'Crowne', 'Restocker', '1023 Bokanovsky Lane', '326-555-6329', 'FC1'),
  ('Helmholtz', 'Watson', 'Janitor', '944 Soma Court', '329-555-2478', 'HW1');

SHOW INDEXES FROM employees_example;
+------------------+------------+---------------+--------------+---------------+-----------
+-------------+----------+--------+------+------------+---------+---------------+
| Table            | Non_unique | Key_name      | Seq_in_index | Column_name   | Collation |
Cardinality | Sub_part | Packed | Null | Index_type | Comment | Index_comment |
+------------------+------------+---------------+--------------+---------------+-----------
+-------------+----------+--------+------+------------+---------+---------------+
| employees_example |          0 | PRIMARY       |            1 | id            | A         |
7 |     NULL | NULL   |      | BTREE      |         |               |
| employees_example |          0 | employee_code |            1 | employee_code | A         |
7 |     NULL | NULL   |      | BTREE      |         |               |
| employees_example |          1 | first_name    |            1 | first_name    | A         |
NULL |     NULL | NULL   |      | BTREE      |         |               |
| employees_example |          1 | first_name    |            2 | last_name     | A         |
NULL |     NULL | NULL   |      | BTREE      |         |               |
+------------------+------------+---------------+--------------+---------------+-----------
+-------------+----------+--------+------+------------+---------+---------------+
```

`SELECT` on a primary key:

```
EXPLAIN SELECT * FROM employees_example WHERE id=1;
+------+-------------+------------------+-------+---------------+---------+---------+-------
+------+-------+
| id   | select_type | table            | type  | possible_keys | key     | key_len | ref   |
rows | Extra |
+------+-------------+------------------+-------+---------------+---------+---------+-------
+------+-------+
|    1 | SIMPLE      | employees_example | const | PRIMARY       | PRIMARY | 4       | const |
1 |       |
+------+-------------+------------------+-------+---------------+---------+---------+-------
+------+-------+
```

The type is *const*, which means that only one possible result could be returned. Now, returning the same record but searching by their phone number:

```
EXPLAIN SELECT * FROM employees_example WHERE home_phone='326-555-3492';
+------+-------------+------------------+------+---------------+------+---------+------+----
--+-------------+
| id   | select_type | table            | type | possible_keys | key  | key_len | ref  | rows
| Extra       |
+------+-------------+------------------+------+---------------+------+---------+------+----
--+-------------+
|    1 | SIMPLE      | employees_example | ALL  | NULL          | NULL | NULL    | NULL |    6
| Using where |
+------+-------------+------------------+------+---------------+------+---------+------+----
--+-------------+
```

Here, the type is *All*, which means no index could be used. Looking at the rows count, a full table scan (all six rows) had to be performed in order to retrieve the record. If it's a requirement to search by phone number, an index will have to be created.

SHOW EXPLAIN example:

```
SHOW EXPLAIN FOR 1;
+------+-------------+-------+-------+---------------+------+---------+------+---------+---------
| id   | select_type | table | type  | possible_keys | key  | key_len | ref  | rows    | Extra
+------+-------------+-------+-------+---------------+------+---------+------+---------+---------
|    1 | SIMPLE      | tbl   | index | NULL          | a    | 5       | NULL | 1000107 | Using in
+------+-------------+-------+-------+---------------+------+---------+------+---------+---------
1 row in set, 1 warning (0.00 sec)
```

Example of `ref_or_null` Optimization

```
SELECT * FROM table_name
  WHERE key_column=expr OR key_column IS NULL;
```

`ref_or_null` is something that often happens when you use subqueries with `NOT IN` as then one has to do an extra check for `NULL` values if the first value didn't have a matching row.

1.1.1.2.2.5 EXPLAIN ANALYZE

The syntax for the `EXPLAIN ANALYZE` feature was changed to `ANALYZE statement` , available since MariaDB 10.1.0. See ANALYZE statement.

1.1.1.2.2.6 EXPLAIN FORMAT=JSON

Contents

Synopsis

`EXPLAIN FORMAT=JSON` is a variant of EXPLAIN command that produces output in JSON form. The output always has one row which has only one column titled " `JSON` ". The contents are a JSON representation of the query plan, formatted for readability:

```
EXPLAIN FORMAT=JSON SELECT * FROM t1 WHERE col1=1\G
```

```
*************************** 1. row ***************************
EXPLAIN: {
  "query_block": {
    "select_id": 1,
    "table": {
      "table_name": "t1",
      "access_type": "ALL",
      "rows": 1000,
      "filtered": 100,
      "attached_condition": "(t1.col1 = 1)"
    }
  }
}
```

Output is different from MySQL

The output of MariaDB's `EXPLAIN FORMAT=JSON` is different from `EXPLAIN FORMAT=JSON` in MySQL.The reasons for that are:

- MySQL's output has deficiencies. Some are listed here: EXPLAIN FORMAT=JSON in MySQL
- The output of MySQL's `EXPLAIN FORMAT=JSON` is not defined. Even MySQL Workbench has trouble parsing it (see this blog post).
- MariaDB has query optimizations that MySQL does not have. Ergo, MariaDB generates query plans that MySQL does not generate.

A (as yet incomplete) list of how MariaDB's output is different from MySQL can be found here: EXPLAIN FORMAT=JSON differences from MySQL.

Output Format

TODO: MariaDB's output format description.

1.1.1.2.2.7 SHOW EXPLAIN

Contents

Syntax

```
SHOW EXPLAIN [FORMAT=JSON] FOR <connection_id>;
EXPLAIN [FORMAT=JSON] FOR CONNECTION <connection_id>;
```

Description

The `SHOW EXPLAIN` command allows one to get an EXPLAIN (that is, a description of a query plan) of a query running in a certain connection.

```
SHOW EXPLAIN FOR <connection_id>;
```

will produce an `EXPLAIN` output for the query that connection number `connection_id` is running. The connection id can be obtained with SHOW PROCESSLIST.

```
SHOW EXPLAIN FOR 1;
+------+-------------+-------+-------+---------------+------+---------+------+---------+---------
| id   | select_type | table | type  | possible_keys | key  | key_len | ref  | rows    | Extra
+------+-------------+-------+-------+---------------+------+---------+------+---------+---------
|    1 | SIMPLE      | tbl   | index | NULL          | a    | 5       | NULL | 1000107 | Using in
+------+-------------+-------+-------+---------------+------+---------+------+---------+---------
1 row in set, 1 warning (0.00 sec)
```

The output is always accompanied with a warning which shows the query the target connection is running (this shows what the `EXPLAIN` is for):

```
SHOW WARNINGS;
+-------+------+-----------------------+
| Level | Code | Message               |
+-------+------+-----------------------+
| Note  | 1003 | select sum(a) from tbl |
+-------+------+-----------------------+
1 row in set (0.00 sec)
```

EXPLAIN FOR CONNECTION

MariaDB starting with 10.9

The `EXPLAIN FOR CONNECTION` syntax was added for MySQL compatibility.

FORMAT=JSON

MariaDB starting with 10.9

`SHOW EXPLAIN [FORMAT=JSON] FOR <connection_id>` extends `SHOW EXPLAIN` to return more detailed JSON output.

Possible Errors

The output can be only produced if the target connection is *currently* running a query, which has a ready query plan. If this is not the case, the output will be:

```
SHOW EXPLAIN FOR 2;
ERROR 1932 (HY000): Target is not running an EXPLAINable command
```

You will get this error when:

- the target connection is not running a command for which one can run `EXPLAIN`
- the target connection is running a command for which one can run `EXPLAIN` , but
  - there is no query plan yet (for example, tables are open and locks are acquired before the query plan is produced)

Differences Between SHOW EXPLAIN and EXPLAIN Outputs

Background

In MySQL, `EXPLAIN` execution takes a slightly different route from the way the real query (typically the `SELECT`) is optimized. This is unfortunate, and has caused a number of bugs in `EXPLAIN` . (For example, see MDEV-326, MDEV-410, and lp:1013343. lp:992942 is not directly about `EXPLAIN` , but it also would not have existed if MySQL didn't try to delete parts of a query plan in the middle of the query)

`SHOW EXPLAIN` examines a running `SELECT` , and hence its output may be slightly different from what `EXPLAIN SELECT` would produce. We did our best to make sure that either the difference is negligible, or `SHOW EXPLAIN` 's output is closer to reality than `EXPLAIN` 's output.

List of Recorded Differences

- `SHOW EXPLAIN` may have Extra='`no matching row in const table`', where `EXPLAIN` would produce Extra='`Impossible WHERE ...`'
- For queries with subqueries, `SHOW EXPLAIN` may print `select_type==PRIMARY` where regular `EXPLAIN` used to print `select_type==SIMPLE`, or vice versa.

Required Permissions

Running `SHOW EXPLAIN` requires the same permissions as running `SHOW PROCESSLIST` would.

1.1.1.2.2.8 Using Buffer UPDATE Algorithm

This article explains the UPDATE statement's *Using Buffer* algorithm.

Take the following table and query:

Name	Salary
Babatunde	1000
Jolana	1050
Pankaja	1300

```
UPDATE employees SET salary = salary+100 WHERE salary < 2000;
```

Suppose the *employees* table has an index on the *salary* column, and the optimizer decides to use a range scan on that index.

The optimizer starts a range scan on the *salary* index. We find the first record *Babatunde, 1000*. If we do an on-the-fly update, we immediately instruct the storage engine to change this record to be *Babatunde, 1000+100=1100*.

Then we proceed to search for the next record, and find *Jolana, 1050*. We instruct the storage engine to update it to be *Jolana, 1050+100=1150*.

Then we proceed to search for the next record ... and what happens next depends on the storage engine. In some storage engines, data changes are visible immediately, so we will find find the *Babatunde, 1100* record that we wrote at the first step, modifying it again, giving Babatunde an undeserved raise. Then we will see Babatunde again and again, looping continually.

In order to prevent such situations, the optimizer checks whether the UPDATE statement is going to change key values for the keys it is using. In that case, it will use a different algorithm:

1. Scan everyone with "salary<2000", remembering the rowids of the rows in a buffer.
2. Read the buffer and apply the updates.

This way, each row will be updated only once.

The `Using buffer` EXPLAIN output indicates that the buffer as described above will be used.

1.1.1.2.3 BACKUP Commands

Commands used by backup tools

BACKUP STAGE

Commands to be used by a MariaDB backup tool.

BACKUP LOCK

Blocks a table from DDL statements.

Mariabackup and BACKUP STAGE Commands

How Mariabackup could use BACKUP STAGE commands.

Storage Snapshots and BACKUP STAGE Commands

How storage snapshots could use BACKUP STAGE commands.

1.1.1.2.3.1 BACKUP STAGE

MariaDB starting with 10.4.1

The `BACKUP STAGE` commands were introduced in MariaDB 10.4.1.

Contents

The `BACKUP STAGE` commands are a set of commands to make it possible to make an efficient external backup tool.

Syntax

```
BACKUP STAGE [START | FLUSH | BLOCK_DDL | BLOCK_COMMIT | END ]
```

In the following text, a transactional table means InnoDB or "InnoDB-like engine with redo log that can lock redo purges and can be copied without locks by an outside process".

Goals with BACKUP STAGE Commands

- To be able to do a majority of the backup with the minimum possible server locks. Especially for transactional tables (InnoDB, MyRocks etc) there is only need for a very short block of new commits while copying statistics and log tables.
- DDL are only needed to be blocked for a very short duration of the backup while mariabackup is copying the tables affected by DDL during the initial part of the backup.
- Most non transactional tables (those that are not in use) will be copied during `BACKUP STAGE START`. The exceptions are system statistic and log tables that are not blocked during the backup until `BLOCK_COMMIT`.
- Should work efficiently with backup tools that use disk snapshots.
- Should work as efficiently as possible for all table types that store data on the local disks.
- As little copying as possible under higher level stages/locks. For example, .frm (dictionary) and .trn (trigger) files should be copying while copying the table data.

`BACKUP STAGE` Commands

`BACKUP STAGE START`

The `START` stage is designed for the following tasks:

- Blocks purge of redo files for storage engines that needs this (Aria)
- Start logging of DDL commands into 'datadir'/ddl.log. This may take a short time as the command has to wait until there are no active DDL commands.

`BACKUP STAGE FLUSH`

The `FLUSH` stage is designed for the following tasks:

- FLUSH all changes for inactive non-transactional tables, except for statistics and log tables.
- Close all tables that are not in use, to ensure they are marked as closed for the backup.
- BLOCK all new write locks for all non transactional tables (except statistics and log tables). The command will not wait for tables that are in use by read-only transactions.

DDLs don't have to be blocked at this stage as they can't cause the table to be in an inconsistent state. This is true also for non-transactional tables.

BACKUP STAGE BLOCK_DDL

The BLOCK_DDL stage is designed for the following tasks:

- Wait for all statements using write locked non-transactional tables to end.
- Blocks CREATE TABLE, DROP TABLE, TRUNCATE TABLE, and RENAME TABLE.
- Blocks also start off a **new** ALTER TABLE and the **final rename phase** of ALTER TABLE. Running ALTER TABLES are not blocked.

BACKUP STAGE BLOCK_COMMIT

The BLOCK_COMMIT stage is designed for the following tasks:

- Lock the binary log and commit/rollback to ensure that no changes are committed to any tables. If there are active commits or data to be copied to the binary log this will be allowed to finish. Active transactions will not affect BLOCK_COMMIT .
- This doesn't lock temporary tables that are not used by replication. However these will be blocked when it's time to write to the binary log.
- Lock system log tables and statistics tables, flush them and mark them closed.

When the BLOCK_COMMIT 's stages return, this is the 'backup time'. Everything committed will be in the backup and everything not committed will roll back.

Transactional engines will continue to do changes to the redo log during the BLOCK COMMIT stage, but this is not important as all of these will roll back later as the changes will not be committed.

BACKUP STAGE END

The END stage is designed for the following tasks:

- End DDL logging
- Free resources

Using BACKUP STAGE Commands with Backup Tools

Using BACKUP STAGE Commands with Mariabackup

The BACKUP STAGE commands are a set of commands to make it possible to make an efficient external backup tool. How Mariabackup uses these commands depends on whether you are using the version that is bundled with MariaDB Community Server or the version that is bundled with MariaDB Enterprise Server. See Mariabackup and BACKUP STAGE Commands for some examples on how Mariabackup uses these commands.

> If you would like to use a version of Mariabackup that uses the BACKUP STAGE commands in an efficient way, then one option is to use MariaDB Enterprise Backup that is bundled with MariaDB Enterprise Server.

Using BACKUP STAGE Commands with Storage Snapshots

The BACKUP STAGE commands are a set of commands to make it possible to make an efficient external backup tool. These commands could even be used by tools that perform backups by taking a snapshot of a file system, SAN, or some other kind of storage device. See Storage Snapshots and BACKUP STAGE Commands for some examples on how to use each BACKUP STAGE command in an efficient way.

Privileges

BACKUP STAGE requires the RELOAD privilege.

Notes

- Only one connection can run BACKUP STAGE START . If a second connection tries, it will wait until the first one has executed BACKUP STAGE END .
- If the user skips a BACKUP STAGE , then all intermediate backup stages will automatically be run. This will allow us to add new stages within the BACKUP STAGE hierarchy in the future with even more precise locks without causing

problems for tools using an earlier version of the `BACKUP STAGE` implementation.
- One can use the max_statement_time or lock_wait_timeout system variables to ensure that a `BACKUP STAGE` command doesn't block the server too long.
- DDL logging will only be available in MariaDB Enterprise Server 10.2 and later.
- A disconnect will automatically release backup stages.
- There is no easy way to see which is the current stage.

1.1.1.2.3.2 BACKUP LOCK

MariaDB starting with 10.4.2
The BACKUP LOCK command was introduced in MariaDB 10.4.2.

Contents

BACKUP LOCK blocks a table from DDL statements. This is mainly intended to be used by tools like mariabackup that need to ensure there are no DDLs on a table while the table files are opened. For example, for an Aria table that stores data in 3 files with extensions .frm, .MAI and .MAD. Normal read/write operations can continue as normal.

Syntax

To lock a table:

```
BACKUP LOCK table_name
```

To unlock a table:

```
BACKUP UNLOCK
```

Usage in a Backup Tool

```
BACKUP LOCK [database.]table_name;
 - Open all files related to a table (for example, t.frm, t.MAI and t.MYD)
BACKUP UNLOCK;
- Copy data
- Close files
```

This ensures that all files are from the same generation, that is created at the same time by the MariaDB server. This works, because the open files will point to the original table files which will not be affected if there is any ALTER TABLE while copying the files.

Privileges

BACKUP LOCK requires the RELOAD privilege.

Notes

- The idea is that the `BACKUP LOCK` should be held for as short a time as possible by the backup tool. The time to take an uncontested lock is very short! One can easily do 50,000 locks/unlocks per second on low end hardware.
- One should use different connections for BACKUP STAGE commands and `BACKUP LOCK` .

Implementation

- Internally, BACKUP LOCK is implemented by taking an `MDLSHARED_HIGH_PRIO` MDL lock on the table object, which protects the table from any DDL operations.

2.3.4.12 Mariabackup and BACKUP STAGE Commands

1.1.1.2.3.4 Storage Snapshots and BACKUP STAGE Commands

MariaDB starting with 10.4.1

The `BACKUP STAGE` commands were introduced in MariaDB 10.4.1.

Contents

The BACKUP STAGE commands are a set of commands to make it possible to make an efficient external backup tool. These commands could even be used by tools that perform backups by taking a snapshot of a file system, SAN, or some other kind of storage device.

Generic Backup Process with Storage Snapshots

A tool that backs up MariaDB by taking a snapshot of a file system, SAN, or some other kind of storage device could use each `BACKUP STAGE` command in the following way:

- First, execute the following:

```
BACKUP STAGE START
BACKUP STAGE BLOCK_COMMIT
```

- Then, take the snapshot.
- Then, execute the following:

```
BACKUP STAGE END
```

The above ensures that all non-transactional tables are properly flushed to disk before the snapshot is done. Using `BACKUP STAGE` commands is also more efficient than using the FLUSH TABLES WITH READ LOCK command as the above set of commands will not block or be blocked by write operations to transactional tables.

Note that when the backup is completed, one should delete all files with the "#sql" prefix, as these are files used by concurrent running `ALTER TABLE` . Note that InnoDB will on server restart automatically delete any tables with the "#sql" prefix.

1.1.1.2.4 FLUSH Commands

Commands to reset (flush) various caches in MariaDB.

FLUSH

Clear or reload various internal caches.

FLUSH QUERY CACHE

Defragmenting the query cache

FLUSH TABLES FOR EXPORT

Flushes changes to disk for specific tables.

There are 2 related questions.

1.1.1.2.4.1 FLUSH

Syntax

```
FLUSH [NO_WRITE_TO_BINLOG | LOCAL]
    flush_option [, flush_option] ...
```

or when flushing tables:

```
FLUSH [NO_WRITE_TO_BINLOG | LOCAL] TABLES [table_list]  [table_flush_option]
```

Contents

where `table_list` is a list of tables separated by `,` (comma).

Description

The `FLUSH` statement clears or reloads various internal caches used by MariaDB. To execute `FLUSH`, you must have the `RELOAD` privilege. See GRANT.

The `RESET` statement is similar to `FLUSH`. See RESET.

You cannot issue a FLUSH statement from within a stored function or a trigger. Doing so within a stored procedure is permitted, as long as it is not called by a stored function or trigger. See Stored Routine Limitations, Stored Function Limitations and Trigger Limitations.

If a listed table is a view, an error like the following will be produced:

```
ERROR 1347 (HY000): 'test.v' is not BASE TABLE
```

By default, `FLUSH` statements are written to the binary log and will be replicated. The `NO_WRITE_TO_BINLOG` keyword (`LOCAL` is an alias) will ensure the statement is not written to the binary log.

The different flush options are:

Option	Description
`CHANGED_PAGE_BITMAPS`	XtraDB only. Internal command used for backup purposes. See the Information Schema CHANGED_PAGE_BITMAPS Table.
`CLIENT_STATISTICS`	Reset client statistics (see SHOW CLIENT_STATISTICS).
`DES_KEY_FILE`	Reloads the DES key file (Specified with the --des-key-file startup option).
`HOSTS`	Flush the hostname cache (used for converting ip to host names and for unblocking blocked hosts. See max_connect_errors and performance_schema.host_cache

INDEX_STATISTICS	Reset index statistics (see SHOW INDEX_STATISTICS).
[ERROR | ENGINE | GENERAL | SLOW | BINARY | RELAY] LOGS	Close and reopen the specified log type, or all log types if none are specified. FLUSH RELAY LOGS [connection-name] can be used to flush the relay logs for a specific connection. Only one connection can be specified per FLUSH command. See Multi-source replication. FLUSH ENGINE LOGS will delete all unneeded Aria redo logs. FLUSH BINARY LOGS DELETE_DOMAIN_ID=(list-of-domains) can be used to discard obsolete GTID domains from the server's binary log state. In order for this to be successful, no event group from the listed GTID domains can be present in existing binary log files. If some still exist, then they must be purged prior to executing this command. If the command completes successfully, then it also rotates the binary log.
MASTER	Deprecated option, use RESET MASTER instead.
PRIVILEGES	Reload all privileges from the privilege tables in the mysql database. If the server is started with --skip-grant-table option, this will activate the privilege tables again.
QUERY CACHE	Defragment the query cache to better utilize its memory. If you want to reset the query cache, you can do it with RESET QUERY CACHE.
QUERY_RESPONSE_TIME	See the QUERY_RESPONSE_TIME plugin.
SLAVE	Deprecated option, use RESET REPLICA or RESET SLAVE instead.
SSL	Used to dynamically reinitialize the server's TLS context by reloading the files defined by several TLS system variables. See FLUSH SSL for more information.
STATUS	Resets all server status variables that can be reset to 0. Not all global status variables support this, so not all global values are reset. See FLUSH STATUS for more information.
TABLE	Close tables given as options or all open tables if no table list was used. From MariaDB 10.4.1, using without any table list will only close tables not in use, and tables not locked by the FLUSH TABLES connection. If there are no locked tables, FLUSH TABLES will be instant and will not cause any waits, as it no longer waits for tables in use. When a table list is provided, from MariaDB 10.4.1, the server will wait for the end of any transactions that are using the tables. Previously, FLUSH TABLES only waited for the statements to complete.
TABLES	Same as FLUSH TABLE .
TABLES ... FOR EXPORT	For InnoDB tables, flushes table changes to disk to permit binary table copies while the server is running. See FLUSH TABLES ... FOR EXPORT for more.
TABLES WITH READ LOCK	Closes all open tables. New tables are only allowed to be opened with read locks until an UNLOCK TABLES is given.
TABLES WITH READ LOCK AND DISABLE CHECKPOINT	As TABLES WITH READ LOCK but also disable all checkpoint writes by transactional table engines. This is useful when doing a disk snapshot of all tables.
TABLE_STATISTICS	Reset table statistics (see SHOW TABLE_STATISTICS).
USER_RESOURCES	Resets all per hour user resources. This enables clients that have exhausted their resources to connect again.
USER_STATISTICS	Reset user statistics (see SHOW USER_STATISTICS).
USER_VARIABLES	Reset user variables (see User-defined variables).

You can also use the mariadb-admin client to flush things. Use mariadb-admin --help to examine what flush commands it supports.

FLUSH RELAY LOGS

```
FLUSH RELAY LOGS 'connection_name';
```

Compatibility with MySQL

MariaDB starting with 10.7.0

The FOR CHANNEL keyword was added for MySQL compatibility. This is identical to using the channel_name directly after the FLUSH command .

For example, one can now use:

```
FLUSH RELAY LOGS FOR CHANNEL 'connection_name';
```

FLUSH STATUS

Server status variables can be reset by executing the following:

```
FLUSH STATUS;
```

Global Status Variables that Support `FLUSH STATUS`

Not all global status variables support being reset by `FLUSH STATUS`. Currently, the following status variables are reset by `FLUSH STATUS`:

- Aborted_clients
- Aborted_connects
- Binlog_cache_disk_use
- Binlog_cache_use
- Binlog_stmt_cache_disk_use
- Binlog_stmt_cache_use
- Connection_errors_accept
- Connection_errors_internal
- Connection_errors_max_connections
- Connection_errors_peer_address
- Connection_errors_select

The different usage of FLUSH TABLES

Purpose of FLUSH TABLES

The purpose of `FLUSH TABLES` is to clean up the open table cache and table definition cache from not in use tables. This frees up memory and file descriptors. Normally this is not needed as the caches works on a FIFO bases, but can be useful if the server seams to use up to much memory for some reason.

Purpose of FLUSH TABLES WITH READ LOCK

`FLUSH TABLES WITH READ LOCK` is useful if you want to take a backup of some tables. When `FLUSH TABLES WITH READ LOCK` returns, all write access to tables are blocked and all tables are marked as 'properly closed' on disk. The tables can still be used for read operations.

Purpose of FLUSH TABLES table_list

`FLUSH TABLES` table_list is useful if you want to copy a table object/files to or from the server. This command puts a lock that stops new users of the table and will wait until everyone has stopped using the table. The table is then removed from the table definition and table cache.

Note that it's up to the user to ensure that no one is accessing the table between `FLUSH TABLES` and the table is copied to or from the server. This can be secured by using LOCK TABLES.

If there are any tables locked by the connection that is using `FLUSH TABLES` all the locked tables will be closed as part of the flush and reopened and relocked before `FLUSH TABLES` returns. This allows one to copy the table after `FLUSH TABLES` returns without having any writes on the table. For now this works works with most tables, except InnoDB as InnoDB may do background purges on the table even while it's write locked.

Purpose of FLUSH TABLES table_list WITH READ LOCK

`FLUSH TABLES table_list WITH READ LOCK` should work as `FLUSH TABLES WITH READ LOCK`, but only those tables that are listed will be properly closed. However in practice this works exactly like `FLUSH TABLES WITH READ LOCK` as the `FLUSH` command has anyway to wait for all WRITE operations to end because we are depending on a global read lock for this code. In the future we should consider fixing this to instead use meta data locks.

Implementation of FLUSH TABLES commands from MariaDB 10.4.8

Implementation of FLUSH TABLES

- Free memory and file descriptors not in use

Implementation of FLUSH TABLES WITH READ LOCK

- Lock all tables read only for simple old style backup.
- All background writes are suspended and tables are marked as closed.
- No statement requiring table changes are allowed for any user until `UNLOCK TABLES`.

Instead of using `FLUSH TABLE WITH READ LOCK` one should in most cases instead use BACKUP STAGE BLOCK_COMMIT.

Implementation of FLUSH TABLES table_list

- Free memory and file descriptors for tables not in use from table list.
- Lock given tables as read only.
- Wait until all translations has ended that uses any of the given tables.
- Wait until all background writes are suspended and tables are marked as closed.

Implementation of FLUSH TABLES table_list FOR EXPORT

- Free memory and file descriptors for tables not in use from table list
- Lock given tables as read.
- Wait until all background writes are suspended and tables are marked as closed.
- Check that all tables supports `FOR EXPORT`
- No changes to these tables allowed until `UNLOCK TABLES`

This is basically the same behavior as in old MariaDB version if one first lock the tables, then do `FLUSH TABLES`. The tables will be copyable until `UNLOCK TABLES`.

FLUSH SSL

In MariaDB 10.4 and later, the `FLUSH SSL` command can be used to dynamically reinitialize the server's TLS context. This is most useful if you need to replace a certificate that is about to expire without restarting the server.

This operation is performed by reloading the files defined by the following TLS system variables:

- ssl_cert
- ssl_key
- ssl_ca
- ssl_capath
- ssl_crl
- ssl_crlpath

These TLS system variables are not dynamic, so their values can **not** be changed without restarting the server.

If you want to dynamically reinitialize the server's TLS context, then you need to change the certificate and key files at the relevant paths defined by these TLS system variables, without actually changing the values of the variables. See MDEV-19341 for more information.

Reducing Memory Usage

To flush some of the global caches that take up memory, you could execute the following command:

```
FLUSH LOCAL HOSTS,
   QUERY CACHE,
   TABLE_STATISTICS,
   INDEX_STATISTICS,
   USER_STATISTICS;
```

1.1.1.2.4.2 FLUSH QUERY CACHE

Description

You can defragment the query cache to better utilize its memory with the `FLUSH QUERY CACHE` statement. The statement does not remove any queries from the cache.

The RESET QUERY CACHE statement removes all query results from the query cache. The FLUSH TABLES statement also does this.

1.1.1.2.4.3 FLUSH TABLES FOR EXPORT

Syntax

```
FLUSH TABLES table_name [, table_name] FOR EXPORT
```

Contents

Description

`FLUSH TABLES ... FOR EXPORT` flushes changes to the specified tables to disk so that binary copies can be made while the server is still running. This works for Archive, Aria, CSV, InnoDB, MyISAM, MERGE, and XtraDB tables.

The table is read locked until one has issued UNLOCK TABLES.

If a storage engine does not support `FLUSH TABLES FOR EXPORT`, a 1031 error (SQLSTATE 'HY000') is produced.

If `FLUSH TABLES ... FOR EXPORT` is in effect in the session, the following statements will produce an error if attempted:

- `FLUSH TABLES WITH READ LOCK`
- `FLUSH TABLES ... WITH READ LOCK`
- `FLUSH TABLES ... FOR EXPORT`
- Any statement trying to update any table

If any of the following statements is in effect in the session, attempting `FLUSH TABLES ... FOR EXPORT` will produce an error.

- `FLUSH TABLES ... WITH READ LOCK`
- `FLUSH TABLES ... FOR EXPORT`
- `LOCK TABLES ... READ`
- `LOCK TABLES ... WRITE`

`FLUSH FOR EXPORT` is not written to the binary log.

This statement requires the RELOAD and the LOCK TABLES privileges.

If one of the specified tables cannot be locked, none of the tables will be locked.

If a table does not exist, an error like the following will be produced:

```
ERROR 1146 (42S02): Table 'test.xxx' doesn't exist
```

If a table is a view, an error like the following will be produced:

```
ERROR 1347 (HY000): 'test.v' is not BASE TABLE
```

Example

```
FLUSH TABLES test.t1 FOR EXPORT;
#  Copy files related to the table (see below)
UNLOCK TABLES;
```

For a full description, please see copying MariaDB tables.

1.1.1.2.5 Replication Commands

The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

A list of replication-related commands. See replication for more replication-related information.

CHANGE MASTER TO
Set or change replica parameters for connecting to the primary.

START SLAVE
Start replica threads.

STOP SLAVE
Stop replica threads.

RESET REPLICA/SLAVE
Forget replica connection information and start a new relay log file.

SET GLOBAL SQL_SLAVE_SKIP_COUNTER
Skips a number of events from the primary.

SHOW RELAYLOG EVENTS
Show events in the relay log.

SHOW SLAVE STATUS
Show status for one or all primaries.

SHOW MASTER STATUS
Status information about the binary log.

SHOW SLAVE HOSTS
Display replicas currently registered with the primary.

RESET MASTER
Delete binary log files.

1.1.1.2.5.1 CHANGE MASTER TO

The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Syntax

```
CHANGE MASTER ['connection_name'] TO master_def  [, master_def] ...
  [FOR CHANNEL 'channel_name']

master_def:
    MASTER_BIND = 'interface_name'
  | MASTER_HOST = 'host_name'
  | MASTER_USER = 'user_name'
  | MASTER_PASSWORD = 'password'
  | MASTER_PORT = port_num
  | MASTER_CONNECT_RETRY = interval
  | MASTER_HEARTBEAT_PERIOD = interval
  | MASTER_LOG_FILE = 'master_log_name'
  | MASTER_LOG_POS = master_log_pos
  | RELAY_LOG_FILE = 'relay_log_name'
  | RELAY_LOG_POS = relay_log_pos
  | MASTER_DELAY = interval
  | MASTER_SSL = {0|1}
  | MASTER_SSL_CA = 'ca_file_name'
  | MASTER_SSL_CAPATH = 'ca_directory_name'
  | MASTER_SSL_CERT = 'cert_file_name'
  | MASTER_SSL_CRL = 'crl_file_name'
  | MASTER_SSL_CRLPATH = 'crl_directory_name'
  | MASTER_SSL_KEY = 'key_file_name'
  | MASTER_SSL_CIPHER = 'cipher_list'
  | MASTER_SSL_VERIFY_SERVER_CERT = {0|1}
  | MASTER_USE_GTID = {current_pos|slave_pos|no}
  | MASTER_DEMOTE_TO_SLAVE = bool
  | IGNORE_SERVER_IDS = (server_id_list)
  | DO_DOMAIN_IDS = ([N,..])
  | IGNORE_DOMAIN_IDS = ([N,..])
```

Contents

Description

The `CHANGE MASTER` statement sets the options that a replica uses to connect to and replicate from a primary.

MariaDB starting with 10.7.0

The `FOR CHANNEL` keyword was added for MySQL compatibility. This is identical to using the channel_name directly after `CHANGE MASTER`.

Multi-Source Replication

If you are using multi-source replication, then you need to specify a connection name when you execute `CHANGE MASTER`. There are two ways to do this:

- Setting the default_master_connection system variable prior to executing `CHANGE MASTER`.
- Setting the `connection_name` parameter when executing `CHANGE MASTER`.

default_master_connection

```
SET default_master_connection = 'gandalf';
STOP SLAVE;
CHANGE MASTER TO
   MASTER_PASSWORD='new3cret';
START SLAVE;
```

connection_name

```
STOP SLAVE 'gandalf';
CHANGE MASTER 'gandalf' TO
   MASTER_PASSWORD='new3cret';
START SLAVE 'gandalf';
```

Options

Connection Options

MASTER_USER

The `MASTER_USER` option for `CHANGE MASTER` defines the user account that the replica will use to connect to the primary.

This user account will need the REPLICATION SLAVE privilege (or, from MariaDB 10.5.1, the REPLICATION REPLICA on the primary.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_USER='repl',
   MASTER_PASSWORD='new3cret';
START SLAVE;
```

The maximum length of the `MASTER_USER` string is 96 characters until MariaDB 10.5, and 128 characters from MariaDB 10.6.

MASTER_PASSWORD

The `MASTER_PASSWORD` option for `CHANGE MASTER` defines the password that the replica will use to connect to the primary as the user account defined by the MASTER_USER option.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_PASSWORD='new3cret';
START SLAVE;
```

The maximum length of the `MASTER_PASSWORD` string is 32 characters. The effective maximum length of the string depends on how many bytes are used per character and can be up to 96 characters.

Due to MDEV-29994, the password can be silently truncated to 41 characters when MariaDB is restarted. For this reason it is recommended to use a password that is shorter than this.

MASTER_HOST

The `MASTER_HOST` option for `CHANGE MASTER` defines the hostname or IP address of the primary.

If you set the value of the `MASTER_HOST` option to the empty string, then that is not the same as not setting the option's value at all. If you set the value of the `MASTER_HOST` option to the empty string, then the `CHANGE MASTER` command will fail with an error. In MariaDB 5.3 and before, if you set the value of the `MASTER_HOST` option to the empty string, then the `CHANGE MASTER` command would succeed, but the subsequent START SLAVE command would fail.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_HOST='dbserver1.example.com',
   MASTER_USER='repl',
   MASTER_PASSWORD='new3cret',
   MASTER_USE_GTID=slave_pos;
START SLAVE;
```

If you set the value of the `MASTER_HOST` option in a `CHANGE MASTER` command, then the replica assumes that the primary is different from before, even if you set the value of this option to the same value it had previously. In this scenario, the replica will consider the old values for the primary's binary log file name and position to be invalid for the new primary. As a side effect, if you do not explicitly set the values of the MASTER_LOG_FILE and MASTER_LOG_POS options in the statement, then the statement will be implicitly appended with `MASTER_LOG_FILE=''` and `MASTER_LOG_POS=4`. However, if you enable GTID mode for replication by setting the MASTER_USE_GTID option to some value other than `no` in the statement, then these values will effectively be ignored anyway.

Replicas cannot connect to primaries using Unix socket files or Windows named pipes. The replica must connect to the primary using TCP/IP.

The maximum length of the `MASTER_HOST` string is 60 characters until MariaDB 10.5, and 255 characters from MariaDB 10.6.

MASTER_PORT

The `MASTER_PORT` option for `CHANGE MASTER` defines the TCP/IP port of the primary.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_HOST='dbserver1.example.com',
   MASTER_PORT=3307,
   MASTER_USER='repl',
   MASTER_PASSWORD='new3cret',
   MASTER_USE_GTID=slave_pos;
START SLAVE;
```

If you set the value of the `MASTER_PORT` option in a `CHANGE MASTER` command, then the replica assumes that the primary is different from before, even if you set the value of this option to the same value it had previously. In this scenario, the replica will consider the old values for the primary's binary log file name and position to be invalid for the new primary. As a side effect, if you do not explicitly set the values of the MASTER_LOG_FILE and MASTER_LOG_POS options in the statement, then the statement will be implicitly appended with `MASTER_LOG_FILE=''` and `MASTER_LOG_POS=4`. However, if you enable GTID mode for replication by setting the MASTER_USE_GTID option to some value other than `no` in the statement, then these values will effectively be ignored anyway.

Replicas cannot connect to primaries using Unix socket files or Windows named pipes. The replica must connect to the primary using TCP/IP.

MASTER_CONNECT_RETRY

The `MASTER_CONNECT_RETRY` option for `CHANGE MASTER` defines how many seconds that the replica will wait between connection retries. The default is `60`.

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_CONNECT_RETRY=20;
START SLAVE;
```

The number of connection attempts is limited by the master_retry_count option. It can be set either on the command-line or in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
master_retry_count=4294967295
```

MASTER_BIND

The `MASTER_BIND` option for `CHANGE MASTER` is only supported by MySQL 5.6.2 and later and by MySQL NDB Cluster 7.3.1 and later. This option is not supported by MariaDB. See MDEV-19248 for more information.

MASTER_HEARTBEAT_PERIOD

The `MASTER_HEARTBEAT_PERIOD` option for `CHANGE MASTER` can be used to set the interval in seconds between replication heartbeats. Whenever the primary's binary log is updated with an event, the waiting period for the next heartbeat is reset.

This option's *interval* argument has the following characteristics:

- It is a decimal value with a range of `0` to `4294967` seconds.
- It has a resolution of hundredths of a second.
- Its smallest valid non-zero value is `0.001`.
- Its default value is the value of the slave_net_timeout system variable divided by 2.
- If it's set to `0`, then heartbeats are disabled.

Heartbeats are sent by the primary only if there are no unsent events in the binary log file for a period longer than the interval.

If the RESET SLAVE statement is executed, then the heartbeat interval is reset to the default.

If the slave_net_timeout system variable is set to a value that is lower than the current heartbeat interval, then a warning will be issued.

TLS Options

The TLS options are used for providing information about TLS. The options can be set even on replicas that are compiled without TLS support. The TLS options are saved to either the default `master.info` file or the file that is configured by the master_info_file option, but these TLS options are ignored unless the replica supports TLS.

See Replication with Secure Connections for more information.

MASTER_SSL

The `MASTER_SSL` option for `CHANGE MASTER` tells the replica whether to force TLS for the connection. The valid values are `0` or `1`. Required to be set to `1` for the other `MASTER_SSL*` options to have any effect.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_SSL=1;
START SLAVE;
```

MASTER_SSL_CA

The `MASTER_SSL_CA` option for `CHANGE MASTER` defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This option requires that you use the absolute path, not a relative path.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
   MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
   MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
   MASTER_SSL_VERIFY_SERVER_CERT=1;
START SLAVE;
```

See Secure Connections Overview: Certificate Authorities (CAs) for more information.

The maximum length of `MASTER_SSL_CA` string is 511 characters.

MASTER_SSL_CAPATH

The `MASTER_SSL_CAPATH` option for `CHANGE MASTER` defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this option needs to be run through the openssl rehash command.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
   MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
   MASTER_SSL_CAPATH='/etc/my.cnf.d/certificates/ca/',
   MASTER_SSL_VERIFY_SERVER_CERT=1;
START SLAVE;
```

See Secure Connections Overview: Certificate Authorities (CAs) for more information.

The maximum length of `MASTER_SSL_CA_PATH` string is 511 characters.

MASTER_SSL_CERT

The `MASTER_SSL_CERT` option for `CHANGE MASTER` defines a path to the X509 certificate file to use for TLS. This option requires that you use the absolute path, not a relative path.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
   MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
   MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
   MASTER_SSL_VERIFY_SERVER_CERT=1;
START SLAVE;
```

The maximum length of `MASTER_SSL_CERT` string is 511 characters.

MASTER_SSL_CRL

The `MASTER_SSL_CRL` option for `CHANGE MASTER` defines a path to a PEM file that should contain one or more revoked X509 certificates to use for TLS. This option requires that you use the absolute path, not a relative path.

This option is only supported if the server was built with OpenSSL. If the server was built with yaSSL, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
   MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
   MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
   MASTER_SSL_VERIFY_SERVER_CERT=1,
   MASTER_SSL_CRL='/etc/my.cnf.d/certificates/crl.pem';
START SLAVE;
```

See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information.

The maximum length of `MASTER_SSL_CRL` string is 511 characters.

MASTER_SSL_CRLPATH

The `MASTER_SSL_CRLPATH` option for `CHANGE MASTER` defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for TLS. This option requires that you use the absolute path, not a relative path. The directory specified by this variable needs to be run through the openssl rehash command.

This option is only supported if the server was built with OpenSSL. If the server was built with yaSSL, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
   MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
   MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
   MASTER_SSL_VERIFY_SERVER_CERT=1,
   MASTER_SSL_CRLPATH='/etc/my.cnf.d/certificates/crl/';
START SLAVE;
```

See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information.

The maximum length of `MASTER_SSL_CRL_PATH` string is 511 characters.

MASTER_SSL_KEY

The `MASTER_SSL_KEY` option for `CHANGE MASTER` defines a path to a private key file to use for TLS. This option requires that you use the absolute path, not a relative path.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
   MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
   MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
   MASTER_SSL_VERIFY_SERVER_CERT=1;
START SLAVE;
```

The maximum length of `MASTER_SSL_KEY` string is 511 characters.

MASTER_SSL_CIPHER

The `MASTER_SSL_CIPHER` option for `CHANGE MASTER` defines the list of permitted ciphers or cipher suites to use for TLS. Besides cipher names, if MariaDB was compiled with OpenSSL, this option could be set to "SSLv3" or "TLSv1.2" to allow all SSLv3 or all TLSv1.2 ciphers. Note that the TLSv1.3 ciphers cannot be excluded when using OpenSSL, even by using this option. See Using TLSv1.3 for details.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
   MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
   MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
   MASTER_SSL_VERIFY_SERVER_CERT=1,
   MASTER_SSL_CIPHER='TLSv1.2';
START SLAVE;
```

The maximum length of `MASTER_SSL_CIPHER` string is 511 characters.

MASTER_SSL_VERIFY_SERVER_CERT

The `MASTER_SSL_VERIFY_SERVER_CERT` option for `CHANGE MASTER` enables server certificate verification. This option is disabled by default prior to MariaDB 11.3.0, and enabled by default from MariaDB 11.3.0.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_SSL_CERT='/etc/my.cnf.d/certificates/server-cert.pem',
   MASTER_SSL_KEY='/etc/my.cnf.d/certificates/server-key.pem',
   MASTER_SSL_CA='/etc/my.cnf.d/certificates/ca.pem',
   MASTER_SSL_VERIFY_SERVER_CERT=1;
START SLAVE;
```

See Secure Connections Overview: Server Certificate Verification for more information.

Binary Log Options

These options are related to the binary log position on the primary.

MASTER_LOG_FILE

The `MASTER_LOG_FILE` option for `CHANGE MASTER` can be used along with `MASTER_LOG_POS` to specify the coordinates at which the replica's I/O thread should begin reading from the primary's binary logs the next time the thread starts.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_LOG_FILE='master2-bin.001',
   MASTER_LOG_POS=4;
START SLAVE;
```

The MASTER_LOG_FILE and MASTER_LOG_POS options cannot be specified if the RELAY_LOG_FILE and RELAY_LOG_POS options were also specified.

The MASTER_LOG_FILE and MASTER_LOG_POS options are effectively ignored if you enable GTID mode for replication by setting the MASTER_USE_GTID option to some value other than `no` in the statement.

MASTER_LOG_POS

The `MASTER_LOG_POS` option for `CHANGE MASTER` can be used along with `MASTER_LOG_FILE` to specify the coordinates at which the replica's I/O thread should begin reading from the primary's binary logs the next time the thread starts.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_LOG_FILE='master2-bin.001',
   MASTER_LOG_POS=4;
START SLAVE;
```

The MASTER_LOG_FILE and MASTER_LOG_POS options cannot be specified if the RELAY_LOG_FILE and RELAY_LOG_POS options were also specified.

The MASTER_LOG_FILE and MASTER_LOG_POS options are effectively ignored if you enable GTID mode for replication by setting the MASTER_USE_GTID option to some value other than `no` in the statement.

Relay Log Options

These options are related to the relay log position on the replica.

RELAY_LOG_FILE

The `RELAY_LOG_FILE` option for `CHANGE MASTER` can be used along with the RELAY_LOG_POS option to specify the coordinates at which the replica's SQL thread should begin reading from the relay log the next time the thread starts.

The `CHANGE MASTER` statement usually deletes all relay log files. However, if the `RELAY_LOG_FILE` and/or `RELAY_LOG_POS` options are specified, then existing relay log files are kept.

When you want to change the relay log position, you only need to stop the replica's SQL thread. The replica's I/O thread can continue running. The STOP SLAVE and START SLAVE statements support the `SQL_THREAD` option for this scenario. For example:

```
STOP SLAVE SQL_THREAD;
CHANGE MASTER TO
   RELAY_LOG_FILE='slave-relay-bin.006',
   RELAY_LOG_POS=4025;
START SLAVE SQL_THREAD;
```

When the value of this option is changed, the metadata about the replica's SQL thread's position in the relay logs will also be changed in the `relay-log.info` file or the file that is configured by the relay_log_info_file system variable.

> The RELAY_LOG_FILE and RELAY_LOG_POS options cannot be specified if the MASTER_LOG_FILE and MASTER_LOG_POS options were also specified.

RELAY_LOG_POS

The `RELAY_LOG_POS` option for `CHANGE MASTER` can be used along with the RELAY_LOG_FILE option to specify the coordinates at which the replica's SQL thread should begin reading from the relay log the next time the thread starts.

The `CHANGE MASTER` statement usually deletes all relay log files. However, if the `RELAY_LOG_FILE` and/or `RELAY_LOG_POS` options are specified, then existing relay log files are kept.

When you want to change the relay log position, you only need to stop the replica's SQL thread. The replica's I/O thread can continue running. The STOP SLAVE and START SLAVE statements support the `SQL_THREAD` option for this scenario. For example:

```
STOP SLAVE SQL_THREAD;
CHANGE MASTER TO
   RELAY_LOG_FILE='slave-relay-bin.006',
   RELAY_LOG_POS=4025;
START SLAVE SQL_THREAD;
```

When the value of this option is changed, the metadata about the replica's SQL thread's position in the relay logs will also be changed in the `relay-log.info` file or the file that is configured by the relay_log_info_file system variable.

> The RELAY_LOG_FILE and RELAY_LOG_POS options cannot be specified if the MASTER_LOG_FILE and MASTER_LOG_POS options were also specified.

GTID Options

MASTER_USE_GTID

The `MASTER_USE_GTID` option for `CHANGE MASTER` can be used to configure the replica to use the global transaction ID (GTID) when connecting to a primary. The possible values are:

- `current_pos` - Replicate in GTID mode and use gtid_current_pos as the position to start downloading transactions from the primary. Deprecated from MariaDB 10.10. Using to transition to primary can break the replication state if the replica executes local transactions due to actively updating gtid_current_pos with gtid_binlog_pos and gtid_slave_pos. Use the new, safe, MASTER_DEMOTE_TO_SLAVE=<bool> option instead.
- `slave_pos` - Replicate in GTID mode and use gtid_slave_pos as the position to start downloading transactions from the primary. From MariaDB 10.5.1, `replica_pos` is an alias for `slave_pos`.
- `no` - Don't replicate in GTID mode.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_USE_GTID = current_pos;
START SLAVE;
```

Or:

```
STOP SLAVE;
SET GLOBAL gtid_slave_pos='0-1-153';
CHANGE MASTER TO
   MASTER_USE_GTID = slave_pos;
START SLAVE;
```

MASTER_DEMOTE_TO_SLAVE

MariaDB starting with 10.10

Used to transition a primary to become a replica. Replaces the old MASTER_USE_GTID=current_pos with a safe alternative by forcing users to set `Using_Gtid=Slave_Pos` and merging `gtid_binlog_pos` into `gtid_slave_pos` once at `CHANGE MASTER TO` time. If `gtid_slave_pos` is more recent than `gtid_binlog_pos` (as in the case of chain replication), the replication state should be preserved.

For example:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_DEMOTE_TO_SLAVE = 1;
START SLAVE;
```

Replication Filter Options

Also see Replication filters.

IGNORE_SERVER_IDS

The `IGNORE_SERVER_IDS` option for `CHANGE MASTER` can be used to configure a replica to ignore binary log events that originated from certain servers. Filtered binary log events will not get logged to the replica's relay log, and they will not be applied by the replica.

The option's value can be specified by providing a comma-separated list of server_id values. For example:

```
STOP SLAVE;
CHANGE MASTER TO
   IGNORE_SERVER_IDS = (3,5);
START SLAVE;
```

If you would like to clear a previously set list, then you can set the value to an empty list. For example:

```
STOP SLAVE;
CHANGE MASTER TO
   IGNORE_SERVER_IDS = ();
START SLAVE;
```

DO_DOMAIN_IDS

The `DO_DOMAIN_IDS` option for `CHANGE MASTER` can be used to configure a replica to only apply binary log events if the transaction's GTID is in a specific gtid_domain_id value. Filtered binary log events will not get logged to the replica's relay log, and they will not be applied by the replica.

The option's value can be specified by providing a comma-separated list of gtid_domain_id values. Duplicate values are automatically ignored. For example:

```
STOP SLAVE;
CHANGE MASTER TO
   DO_DOMAIN_IDS = (1,2);
START SLAVE;
```

If you would like to clear a previously set list, then you can set the value to an empty list. For example:

```
STOP SLAVE;
CHANGE MASTER TO
   DO_DOMAIN_IDS = ();
START SLAVE;
```

The DO_DOMAIN_IDS option and the IGNORE_DOMAIN_IDS option cannot both be set to non-empty values at the same time. If you want to set the DO_DOMAIN_IDS option, and the IGNORE_DOMAIN_IDS option was previously set, then you need to clear the value of the IGNORE_DOMAIN_IDS option. For example:

```
STOP SLAVE;
CHANGE MASTER TO
   IGNORE_DOMAIN_IDS = (),
   DO_DOMAIN_IDS = (1,2);
START SLAVE;
```

The `DO_DOMAIN_IDS` option can only be specified if the replica is replicating in GTID mode. Therefore, the MASTER_USE_GTID option must also be set to some value other than `no` in order to use this option.

IGNORE_DOMAIN_IDS

The `IGNORE_DOMAIN_IDS` option for `CHANGE MASTER` can be used to configure a replica to ignore binary log events if the transaction's GTID is in a specific gtid_domain_id value. Filtered binary log events will not get logged to the replica's relay log, and they will not be applied by the replica.

The option's value can be specified by providing a comma-separated list of gtid_domain_id values. Duplicate values are automatically ignored. For example:

```
STOP SLAVE;
CHANGE MASTER TO
   IGNORE_DOMAIN_IDS = (1,2);
START SLAVE;
```

If you would like to clear a previously set list, then you can set the value to an empty list. For example:

```
STOP SLAVE;
CHANGE MASTER TO
   IGNORE_DOMAIN_IDS = ();
START SLAVE;
```

The DO_DOMAIN_IDS option and the IGNORE_DOMAIN_IDS option cannot both be set to non-empty values at the same time. If you want to set the IGNORE_DOMAIN_IDS option, and the DO_DOMAIN_IDS option was previously set, then you need to clear the value of the DO_DOMAIN_IDS option. For example:

```
STOP SLAVE;
CHANGE MASTER TO
   DO_DOMAIN_IDS = (),
   IGNORE_DOMAIN_IDS = (1,2);
START SLAVE;
```

The `IGNORE_DOMAIN_IDS` option can only be specified if the replica is replicating in GTID mode. Therefore, the MASTER_USE_GTID option must also be set to some value other than `no` in order to use this option.

Delayed Replication Options

MASTER_DELAY

The `MASTER_DELAY` option for `CHANGE MASTER` can be used to enable delayed replication. This option specifies the time in seconds (at least) that a replica should lag behind the primary up to a maximum value of 2147483647, or about 68 years. Before executing an event, the replica will first wait, if necessary, until the given time has passed since the event was created on the primary. The result is that the replica will reflect the state of the primary some time back in the past. The default is zero, no delay.

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_DELAY=3600;
START SLAVE;
```

Changing Option Values

If you don't specify a given option when executing the `CHANGE MASTER` statement, then the option keeps its old value in most cases. Most of the time, there is no need to specify the options that do not need to change. For example, if the password for the user account that the replica uses to connect to its primary has changed, but no other options need to change, then you can just change the MASTER_PASSWORD option by executing the following commands:

```
STOP SLAVE;
CHANGE MASTER TO
   MASTER_PASSWORD='new3cret';
START SLAVE;
```

There are some cases where options are implicitly reset, such as when the MASTER_HOST and MASTER_PORT options are changed.

Option Persistence

The values of the MASTER_LOG_FILE and MASTER_LOG_POS options (i.e. the binary log position on the primary) and most other options are written to either the default `master.info` file or the file that is configured by the master_info_file option. The replica's I/O thread keeps this binary log position updated as it downloads events only when MASTER_USE_GTID option is set to `NO`. Otherwise the file is not updated on a per event basis.

The master_info_file option can be set either on the command-line or in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
master_info_file=/mariadb/myserver1-master.info
```

The values of the RELAY_LOG_FILE and RELAY_LOG_POS options (i.e. the relay log position) are written to either the default `relay-log.info` file or the file that is configured by the relay_log_info_file system variable. The replica's SQL thread keeps this relay log position updated as it applies events.

The relay_log_info_file system variable can be set either on the command-line or in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
relay_log_info_file=/mariadb/myserver1-relay-log.info
```

GTID Persistence

If the replica is replicating binary log events that contain GTIDs, then the replica's SQL thread will write every GTID that it applies to the mysql.gtid_slave_pos table. This GTID can be inspected and modified through the gtid_slave_pos system variable.

If the replica has the log_slave_updates system variable enabled and if the replica has the binary log enabled, then every write by the replica's SQL thread will also go into the replica's binary log. This means that GTIDs of replicated transactions would be reflected in the value of the gtid_binlog_pos system variable.

Creating a Replica from a Backup

The `CHANGE MASTER` statement is useful for setting up a replica when you have a backup of the primary and you also have

the binary log position or GTID position corresponding to the backup.

After restoring the backup on the replica, you could execute something like this to use the binary log position:

```
CHANGE MASTER TO
   MASTER_LOG_FILE='master2-bin.001',
   MASTER_LOG_POS=4;
START SLAVE;
```

Or you could execute something like this to use the GTID position:

```
SET GLOBAL gtid_slave_pos='0-1-153';
CHANGE MASTER TO
   MASTER_USE_GTID=slave_pos;
START SLAVE;
```

See Setting up a Replication Slave with Mariabackup for more information on how to do this with Mariabackup.

Example

The following example changes the primary and primary's binary log coordinates. This is used when you want to set up the replica to replicate the primary:

```
CHANGE MASTER TO
   MASTER_HOST='master2.mycompany.com',
   MASTER_USER='replication',
   MASTER_PASSWORD='bigs3cret',
   MASTER_PORT=3306,
   MASTER_LOG_FILE='master2-bin.001',
   MASTER_LOG_POS=4,
   MASTER_CONNECT_RETRY=10;
START SLAVE;
```

1.1.1.2.5.2 START SLAVE

The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Syntax

```
START SLAVE ["connection_name"] [thread_type [, thread_type] ... ] [FOR CHANNEL
"connection_name"]
START SLAVE ["connection_name"] [SQL_THREAD] UNTIL
    MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos [FOR CHANNEL "connection_name"]
START SLAVE ["connection_name"] [SQL_THREAD] UNTIL
    RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos [FOR CHANNEL "connection_name"]
START SLAVE ["connection_name"] [SQL_THREAD] UNTIL
    MASTER_GTID_POS = <GTID position> [FOR CHANNEL "connection_name"]
START ALL SLAVES [thread_type [, thread_type]]

START REPLICA ["connection_name"] [thread_type [, thread_type] ... ] -- from 10.5.1
START REPLICA ["connection_name"] [SQL_THREAD] UNTIL
    MASTER_LOG_FILE = 'log_name', MASTER_LOG_POS = log_pos -- from 10.5.1
START REPLICA ["connection_name"] [SQL_THREAD] UNTIL
    RELAY_LOG_FILE = 'log_name', RELAY_LOG_POS = log_pos -- from 10.5.1
START REPLICA ["connection_name"] [SQL_THREAD] UNTIL
    MASTER_GTID_POS = <GTID position> -- from 10.5.1
START ALL REPLICAS [thread_type [, thread_type]] -- from 10.5.1

thread_type: IO_THREAD | SQL_THREAD
```

Contents

Description

`START SLAVE` (`START REPLICA` from MariaDB 10.5.1) with no thread_type options starts both of the replica threads (see replication). The I/O thread reads events from the primary server and stores them in the relay log. The SQL thread reads events from the relay log and executes them. `START SLAVE` requires the SUPER privilege, or, from MariaDB 10.5.2, the REPLICATION SLAVE ADMIN privilege.

If `START SLAVE` succeeds in starting the replica threads, it returns without any error. However, even in that case, it might be that the replica threads start and then later stop (for example, because they do not manage to connect to the primary or read its binary log, or some other problem). `START SLAVE` does not warn you about this. You must check the replica's error log for error messages generated by the replica threads, or check that they are running satisfactorily with SHOW SLAVE STATUS (SHOW REPLICA STATUS from MariaDB 10.5.1).

START SLAVE UNTIL

`START SLAVE UNTIL` refers to the `SQL_THREAD` replica position at which the `SQL_THREAD` replication will halt. If `SQL_THREAD` isn't specified both threads are started.

`START SLAVE UNTIL master_gtid_pos=xxx` is also supported. See Global Transaction ID/START SLAVE UNTIL master_gtid_pos=xxx for more details.

MariaDB starting with 11.3.0

SQL_BEFORE_GTIDS|SQL_AFTER_GTIDS

MariaDB 11.3 extended the START SLAVE UNTIL command with the options `SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS` to allow control of whether the replica stops before or after a provided GTID state. Its syntax is:

```
START SLAVE UNTIL (SQL_BEFORE_GTIDS|SQL_AFTER_GTIDS)="<gtid_list>"
```

See Global Transaction ID#SQL_BEFORE_GTIDS/SQL_AFTER_GTIDS for details.

connection_name

If there is only one nameless primary, or the default primary (as specified by the default_master_connection system variable) is intended, `connection_name` can be omitted. If provided, the `START SLAVE` statement will apply to the specified primary. `connection_name` is case-insensitive.

MariaDB starting with 10.7.0

The `FOR CHANNEL` keyword was added for MySQL compatibility. This is identical as using the channel_name directly after `START SLAVE`.

START ALL SLAVES

`START ALL SLAVES` starts all configured replicas (replicas with master_host not empty) that were not started before. It will give a `note` for all started connections. You can check the notes with SHOW WARNINGS.

START REPLICA

MariaDB starting with 10.5.1

`START REPLICA` is an alias for `START SLAVE` from MariaDB 10.5.1.

1.1.1.2.5.3 STOP SLAVE

The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Syntax

```
STOP SLAVE ["connection_name"] [thread_type [, thread_type] ... ] [FOR CHANNEL "connection_name"]

STOP ALL SLAVES [thread_type [, thread_type]]

STOP REPLICA ["connection_name"] [thread_type [, thread_type] ... ] -- from 10.5.1

STOP ALL REPLICAS [thread_type [, thread_type]] -- from 10.5.1

thread_type: IO_THREAD | SQL_THREAD
```

Contents

Description

Stops the replica threads. `STOP SLAVE` requires the SUPER privilege, or, from MariaDB 10.5.2, the REPLICATION SLAVE ADMIN privilege.

Like START SLAVE, this statement may be used with the `IO_THREAD` and `SQL_THREAD` options to name the thread or threads to be stopped. In almost all cases, one never need to use the `thread_type` options.

`STOP SLAVE` waits until any current replication event group affecting one or more non-transactional tables has finished executing (if there is any such replication group), or until the user issues a KILL QUERY or KILL CONNECTION statement.

Note that `STOP SLAVE` doesn't delete the connection permanently. Next time you execute START SLAVE or the MariaDB server restarts, the replica connection is restored with it's original arguments. If you want to delete a connection, you should execute RESET SLAVE.

STOP ALL SLAVES

`STOP ALL SLAVES` stops all your running replicas. It will give you a `note` for every stopped connection. You can check the notes with SHOW WARNINGS.

connection_name

The `connection_name` option is used for multi-source replication.

If there is only one nameless master, or the default master (as specified by the default_master_connection system variable) is intended, `connection_name` can be omitted. If provided, the `STOP SLAVE` statement will apply to the specified master. `connection_name` is case-insensitive.

MariaDB starting with 10.7.0

The `FOR CHANNEL` keyword was added for MySQL compatibility. This is identical as using the channel_name directly after `STOP SLAVE`.

STOP REPLICA

MariaDB starting with 10.5.1

`STOP REPLICA` is an alias for `STOP SLAVE` from MariaDB 10.5.1.

1.1.1.2.5.4 RESET REPLICA/SLAVE

The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Syntax

```
RESET REPLICA ["connection_name"] [ALL]  [FOR CHANNEL "connection_name"] -- from MariaDB 10.5.1
RESET SLAVE ["connection_name"] [ALL]  [FOR CHANNEL "connection_name"]
```

Contents

Description

RESET REPLICA/SLAVE makes the replica forget its replication position in the master's binary log. This statement is meant to be used for a clean start. It deletes the master.info and relay-log.info files, all the relay log files, and starts a new relay log file. To use RESET REPLICA/SLAVE, the replica threads must be stopped (use STOP REPLICA/SLAVE if necessary).

> Note: All relay log files are deleted, even if they have not been completely executed by the slave SQL thread. (This is a condition likely to exist on a replication slave if you have issued a STOP REPLICA/SLAVE statement or if the slave is highly loaded.)

> Note: `RESET REPLICA` does not reset the global `gtid_slave_pos` variable. This means that a replica server configured with `CHANGE MASTER TO MASTER_USE_GTID=slave_pos` will not receive events with GTIDs occurring before the state saved in `gtid_slave_pos`. If the intent is to reprocess these events, `gtid_slave_pos` must be manually reset, e.g. by executing `set global gtid_slave_pos=""`.

Connection information stored in the master.info file is immediately reset using any values specified in the corresponding startup options. This information includes values such as master host, master port, master user, and master password. If the replica SQL thread was in the middle of replicating temporary tables when it was stopped, and RESET REPLICA/SLAVE is issued, these replicated temporary tables are deleted on the slave.

The `ALL` also resets the `PORT`, `HOST`, `USER` and `PASSWORD` parameters for the slave. If you are using a connection name, it will permanently delete it and it will not show up anymore in SHOW ALL REPLICAS/SLAVE STATUS.

connection_name

The `connection_name` option is used for multi-source replication.

If there is only one nameless primary, or the default primary (as specified by the default_master_connection system variable) is intended, `connection_name` can be omitted. If provided, the `RESET REPLICA/SLAVE` statement will apply to the specified primary. `connection_name` is case-insensitive.

MariaDB starting with 10.7.0

The `FOR CHANNEL` keyword was added for MySQL compatibility. This is identical as using the channel_name directly after `RESET REPLICA`.

RESET REPLICA

MariaDB starting with 10.5.1

`RESET REPLICA` is an alias for `RESET SLAVE` from MariaDB 10.5.1.

1.1.1.2.5.5 SET GLOBAL SQL_SLAVE_SKIP_COUNTER

Syntax

```
SET GLOBAL sql_slave_skip_counter = N
```

Contents

Description

This statement skips the next `N` events from the primary. This is useful for recovering from replication stops caused by a statement.

If multi-source replication is used, this statement applies to the default connection. It could be necessary to change the value of the default_master_connection system variable.

Note that, if the event is a transaction, the whole transaction will be skipped. With non-transactional engines, an event is always a single statement.

This statement is valid only when the replica threads are not running. Otherwise, it produces an error.

The statement does not automatically restart the replica threads.

Example

```
SHOW SLAVE STATUS \G
...
SET GLOBAL sql_slave_skip_counter = 1;
START SLAVE;
```

Multi-source replication:

```
SET @@default_master_connection = 'master_01';
SET GLOBAL SQL_SLAVE_SKIP_COUNTER = 1;
START SLAVE;
```

Multiple Replication Domains

`sql_slave_skip_counter` can't be used to skip transactions on a replica if GTID replication is in use and if gtid_slave_pos contains multiple gtid_domain_id values. In that case, you'll get an error like the following:

```
ERROR 1966 (HY000): When using parallel replication and GTID with multiple
 replication domains, @@sql_slave_skip_counter can not be used. Instead,
 setting @@gtid_slave_pos explicitly can be  used to skip to after a given GTID
 position.
```

In order to skip transactions in cases like this, you will have to manually change gtid_slave_pos.

1.1.1.2.5.6 SHOW RELAYLOG EVENTS

> The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Syntax

```
SHOW RELAYLOG ['connection_name'] EVENTS
    [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
    [ FOR CHANNEL 'channel_name']
```

Description

On replicas, this command shows the events in the relay log. If `'log_name'` is not specified, the first relay log is shown.

Syntax for the `LIMIT` clause is the same as for SELECT ... LIMIT.

> Using the `LIMIT` clause is highly recommended because the `SHOW RELAYLOG EVENTS` command returns the complete contents of the relay log, which can be quite large.

This command does not return events related to setting user and system variables. If you need those, use mariadb-binlog.

On the primary, this command does nothing.

Requires the REPLICA MONITOR privilege (>= MariaDB 10.5.9), the REPLICATION SLAVE ADMIN privilege (>= MariaDB 10.5.2) or the REPLICATION SLAVE privilege (<= MariaDB 10.5.1).

connection_name

If there is only one nameless primary, or the default primary (as specified by the default_master_connection system variable) is intended, `connection_name` can be omitted. If provided, the `SHOW RELAYLOG` statement will apply to the specified primary. `connection_name` is case-insensitive.

MariaDB starting with 10.7.0

The `FOR CHANNEL` keyword was added for MySQL compatibility. This is identical as using the channel_name directly after `SHOW RELAYLOG`.

1.1.1.2.5.7 SHOW SLAVE STATUS

Syntax

```
SHOW SLAVE ["connection_name"] STATUS [FOR CHANNEL "connection_name"]
SHOW REPLICA ["connection_name"] STATUS -- From MariaDB 10.5.1
```

or

```
SHOW ALL SLAVES STATUS
SHOW ALL REPLICAS STATUS -- From MariaDB 10.5.1
```

Contents

Description

This statement is to be run on a replica and provides status information on essential parameters of the replica threads.

This statement requires the SUPER privilege, the REPLICATION_CLIENT privilege, or, from MariaDB 10.5.2, the REPLICATION SLAVE ADMIN privilege, or, from MariaDB 10.5.9, the REPLICA MONITOR privilege.

Multi-Source

The `ALL` and `"connection_name"` options allow you to connect to many primaries at the same time.

`ALL SLAVES` (or `ALL REPLICAS` from MariaDB 10.5.1) gives you a list of all connections to the primary nodes.

The rows will be sorted according to `Connection_name`.

If you specify a `connection_name`, you only get the information about that connection. If `connection_name` is not used, then the name set by `default_master_connection` is used. If the connection name doesn't exist you will get an error: `There is no master connection for 'xxx'`.

MariaDB starting with 10.7.0

The `FOR CHANNEL` keyword was added for MySQL compatibility. This is identical to using the channel_name directly after `SHOW SLAVE`.

Column Descriptions

The order in which the columns appear depends on the MariaDB version. This means that extracting a column value is best done by comparing the field name instead of using a fixed offset into the row.

Name	Description
Connection_name	Name of the primary connection. Returned with `SHOW ALL SLAVES STATUS` (or `SHOW ALL REPLICAS STATUS` from MariaDB 10.5.1) only.
Slave_SQL_State	State of SQL thread. Returned with `SHOW ALL SLAVES STATUS` (or `SHOW ALL REPLICAS STATUS` from MariaDB 10.5.1) only. See Slave SQL Thread States.
Slave_IO_State	State of I/O thread. See Slave I/O Thread States.
Master_host	Master host that the replica is connected to.
Master_user	Account user name being used to connect to the primary.
Master_port	The port being used to connect to the primary.
Connect_Retry	Time in seconds between retries to connect. The default is 60. The CHANGE MASTER TO statement can set this. The master-retry-count option determines the maximum number of reconnection attempts.
Master_Log_File	Name of the primary binary log file that the I/O thread is currently reading from.
Read_Master_Log_Pos	Position up to which the I/O thread has read in the current primary binary log file.
Relay_Log_File	Name of the relay log file that the SQL thread is currently processing.
Relay_Log_Pos	Position up to which the SQL thread has finished processing in the current relay log file.
Relay_Master_Log_File	Name of the primary binary log file that contains the most recent event executed by the SQL thread.
Slave_IO_Running	Whether the replica I/O thread is running and connected (`Yes`), running but not connected to a primary (`Connecting`) or not running (`No`).
Slave_SQL_Running	Whether or not the SQL thread is running.
Replicate_Rewrite_DB	Databases specified for replicating and rewriting with the `replicate_rewrite_db` option. Added in MariaDB 10.11
Replicate_Do_DB	Databases specified for replicating with the `replicate_do_db` option.
Replicate_Ignore_DB	Databases specified for ignoring with the `replicate_ignore_db` option.
Replicate_Do_Table	Tables specified for replicating with the `replicate_do_table` option.
Replicate_Ignore_Table	Tables specified for ignoring with the `replicate_ignore_table` option.
Replicate_Wild_Do_Table	Tables specified for replicating with the `replicate_wild_do_table` option.
Replicate_Wild_Ignore_Table	Tables specified for ignoring with the `replicate_wild_ignore_table` option.
Last_Errno	Alias for `Last_SQL_Errno` (see below)
Last Error	Alias for `Last_SQL_Error` (see below)
Skip_Counter	Number of events that a replica skips from the master, as recorded in the sql_slave_skip_counter system variable.

Exec_Master_Log_Pos	Position up to which the SQL thread has processed in the current master binary log file. Can be used to start a new replica from a current replica with the CHANGE MASTER TO ... MASTER_LOG_POS option.
Relay_Log_Space	Total size of all relay log files combined.
Until_Condition	
Until_Log_File	The `MASTER_LOG_FILE` value of the START SLAVE UNTIL condition.
Until_Log_Pos	The `MASTER_LOG_POS` value of the START SLAVE UNTIL condition.
Master_SSL_Allowed	Whether an SSL connection is permitted (`Yes`), not permitted (`No`) or permitted but without the replica having SSL support enabled (`Ignored`)
Master_SSL_CA_File	The `MASTER_SSL_CA` option of the `CHANGE MASTER TO` statement.
Master_SSL_CA_Path	The `MASTER_SSL_CAPATH` option of the `CHANGE MASTER TO` statement.
Master_SSL_Cert	The `MASTER_SSL_CERT` option of the `CHANGE MASTER TO` statement.
Master_SSL_Cipher	The `MASTER_SSL_CIPHER` option of the `CHANGE MASTER TO` statement.
Master_SSL_Key	The `MASTER_SSL_KEY` option of the `CHANGE MASTER TO` statement.
Seconds_Behind_Master	Difference between the timestamp logged on the master for the event that the replica is currently processing, and the current timestamp on the replica. Zero if the replica is not currently processing an event. With serial replication, `seconds_behind_master` is updated when the SQL thread begins executing a transaction. With parallel replication, `seconds_behind_master` is updated only after transactions commit. Starting in MariaDB 10.3.38, 10.4.28, 10.5.19, 10.6.12, 10.8.7, 10.9.5, 10.10.3, and 10.11.2, an exception is drawn on the parallel replica to additionally update `seconds_behind_master` when the first transaction received after idling is queued to a worker for execution, to provide a reliable initial value for the duration until a transaction commits. Additional behaviors to be aware of are as follows: 1) `Seconds_Behind_Master` will update for ignored events, e.g. those skipped due to sql_slave_skip_counter. 2) On the serial replica, transactions with prior timestamps can update `Seconds_Behind_Master` such that it can go backwards, though this is not true for the parallel replica. 3) When configured with MASTER_DELAY, as a replicated transaction begins executing (i.e. on a serial or post-idle parallel replica), `Seconds_Behind_Master` will update before delaying, and while delaying occurs will grow to encompass the configured value. 4) There is a known issue, tracked by MDEV-17516, such that `Seconds_Behind_Master` will initially present as `0` on replica restart until a replicated transaction begins executing, even if the last replica session was lagging behind when stopped.
Master_SSL_Verify_Server_Cert	The `MASTER_SSL_VERIFY_SERVER_CERT` option of the `CHANGE MASTER TO` statement.
Last_IO_Errno	Error code of the most recent error that caused the I/O thread to stop (also recorded in the replica's error log). `0` means no error. RESET SLAVE or RESET MASTER will reset this value.
Last_IO_Error	Error message of the most recent error that caused the I/O thread to stop (also recorded in the replica's error log). An empty string means no error. RESET SLAVE or RESET MASTER will reset this value.
Last_SQL_Errno	Error code of the most recent error that caused the SQL thread to stop (also recorded in the replica's error log). `0` means no error. RESET SLAVE or RESET MASTER will reset this value.
Last_SQL_Error	Error message of the most recent error that caused the SQL thread to stop (also recorded in the replica's error log). An empty string means no error. RESET SLAVE or RESET MASTER will reset this value.
Replicate_Ignore_Server_Ids	List of server_ids that are currently being ignored for replication purposes, or an empty string for none, as specified in the `IGNORE_SERVER_IDS` option of the `CHANGE MASTER TO` statement.
Master_Server_Id	The master's server_id value.
Master_SSL_Crl	The `MASTER_SSL_CRL` option of the `CHANGE MASTER TO` statement.

Master_SSL_Crlpath	The `MASTER_SSL_CRLPATH` option of the `CHANGE MASTER TO` statement.
Using_Gtid	Whether or not global transaction ID's are being used for replication (can be `No`, `Slave_Pos`, or `Current_Pos`).
Gtid_IO_Pos	Current global transaction ID value.
Retried_transactions	Number of retried transactions for this connection. Returned with `SHOW ALL SLAVES STATUS` only.
Max_relay_log_size	Max relay log size for this connection. Returned with `SHOW ALL SLAVES STATUS` only.
Executed_log_entries	How many log entries the replica has executed. Returned with `SHOW ALL SLAVES STATUS` only.
Slave_received_heartbeats	How many heartbeats we have got from the master. Returned with `SHOW ALL SLAVES STATUS` only.
Slave_heartbeat_period	How often to request a heartbeat packet from the master (in seconds). Returned with `SHOW ALL SLAVES STATUS` only.
Gtid_Slave_Pos	GTID of the last event group replicated on a replica server, for each replication domain, as stored in the gtid_slave_pos system variable. Returned with `SHOW ALL SLAVES STATUS` only.
SQL_Delay	Value specified by `MASTER_DELAY` in `CHANGE MASTER` (or 0 if none).
SQL_Remaining_Delay	When the replica is delaying the execution of an event due to `MASTER_DELAY`, this is the number of seconds of delay remaining before the event will be applied. Otherwise, the value is `NULL`.
Slave_SQL_Running_State	The state of the SQL driver threads, same as in SHOW PROCESSLIST. When the replica is delaying the execution of an event due to `MASTER_DELAY`, this field displays: "`Waiting until MASTER_DELAY seconds after master executed event`".
Slave_DDL_Groups	This status variable counts the occurrence of DDL statements. This is a replica-side counter for optimistic parallel replication.
Slave_Non_Transactional_Groups	This status variable counts the occurrence of non-transactional event groups. This is a replica-side counter for optimistic parallel replication.
Slave_Transactional_Groups	This status variable counts the occurrence of transactional event groups. This is a replica-side counter for optimistic parallel replication.

SHOW REPLICA STATUS

MariaDB starting with 10.5.1

`SHOW REPLICA STATUS` is an alias for `SHOW SLAVE STATUS` from MariaDB 10.5.1.

Examples

If you issue this statement using the mariadb client, you can use a `\G` statement terminator rather than a semicolon to obtain a more readable vertical layout.

```
SHOW SLAVE STATUS\G
*************************** 1. row ***************************
               Slave_IO_State: Waiting for master to send event
                  Master_Host: db01.example.com
                  Master_User: replicant
                  Master_Port: 3306
                Connect_Retry: 60
              Master_Log_File: mariadb-bin.000010

1.1.1.2.5.8 SHOW MASTER STATUS

Syntax

```
SHOW MASTER STATUS
SHOW BINLOG STATUS -- From MariaDB 10.5.2
```

Description

Provides status information about the binary log files of the primary.

This statement requires the SUPER privilege, the REPLICATION_CLIENT privilege, or, from MariaDB 10.5.2, the BINLOG MONITOR privilege.

To see information about the current GTIDs in the binary log, use the gtid_binlog_pos variable.

`SHOW MASTER STATUS` was renamed to `SHOW BINLOG STATUS` in MariaDB 10.5.2, but the old name remains an alias for compatibility purposes.

Example

```
SHOW MASTER STATUS;
+--------------------+----------+--------------+------------------+
| File               | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+--------------------+----------+--------------+------------------+
| mariadb-bin.000016 |      475 |              |                  |
+--------------------+----------+--------------+------------------+
SELECT @@global.gtid_binlog_pos;
+---------------------------+
| @@global.gtid_binlog_pos |
+---------------------------+
| 0-1-2                     |
+---------------------------+
```

1.1.1.2.5.9 SHOW SLAVE HOSTS

Contents

Syntax

```
SHOW SLAVE HOSTS
SHOW REPLICA HOSTS -- from MariaDB 10.5.1
```

Description

This command is run on the primary and displays a list of replicas that are currently registered with it. Only replicas started with the `--report-host=host_name` option are visible in this list.

The output looks like this:

```
SHOW SLAVE HOSTS;
+------------+-----------+------+-----------+
| Server_id  | Host      | Port | Master_id |
+------------+-----------+------+-----------+
|  192168010 | iconnect2 | 3306 | 192168011 |
| 1921680101 | athena    | 3306 | 192168011 |
+------------+-----------+------+-----------+
```

- **`Server_id`**: The unique server ID of the replica server, as configured in the server's option file, or on the command line with --server-id=value.
- **`Host`**: The host name of the replica server, as configured in the server's option file, or on the command line with `--report-host=host_name`. Note that this can differ from the machine name as configured in the operating system.
- **`Port`**: The port the replica server is listening on.
- **`Master_id`**: The unique server ID of the primary server that the replica server is replicating from.

Some MariaDB and MySQL versions report another variable, rpl_recovery_rank. This variable was never used, and was eventually removed in MariaDB 10.1.2.

Requires the REPLICATION MASTER ADMIN privilege (>= MariaDB 10.5.2) or the REPLICATION SLAVE privilege (<= MariaDB 10.5.1).

SHOW REPLICA HOSTS

MariaDB starting with 10.5.1

`SHOW REPLICA HOSTS` is an alias for `SHOW SLAVE HOSTS` from MariaDB 10.5.1.

1.1.1.2.5.10 RESET MASTER

```
RESET MASTER [TO #]
```

Deletes all binary log files listed in the index file, resets the binary log index file to be empty, and creates a new binary log file with a suffix of .000001.

If `TO #` is given, then the first new binary log file will start from number #.

> This statement is for use only when the master is started for the first time, and should never be used if any slaves are actively replicating from the binary log.

1.1.1.2.6 Plugin SQL Statements

Plugin commands.

SHOW PLUGINS

Display information about installed plugins.

SHOW PLUGINS SONAME

Information about all available plugins, installed or not.

INSTALL PLUGIN

Install a plugin.

UNINSTALL PLUGIN

Remove a single installed plugin.

INSTALL SONAME

Installs all plugins from a given library.

UNINSTALL SONAME

Remove all plugins belonging to a specified library.

mysql_plugin

Symlink or old name for mariadb-plugin.

1.1.1.2.6.1 SHOW PLUGINS

Syntax

```
SHOW PLUGINS;
```

Contents

Description

`SHOW PLUGINS` displays information about installed plugins. The `Library` column indicates the plugin library - if it is `NULL`, the plugin is built-in and cannot be uninstalled.

The `PLUGINS` table in the `information_schema` database contains more detailed information.

For specific information about storage engines (a particular type of plugin), see the `information_schema.ENGINES` table and the `SHOW ENGINES` statement.

Examples

```
SHOW PLUGINS;
+----------------------------+----------+--------------------+-------------+---------+
| Name                       | Status   | Type               | Library     | License |
+----------------------------+----------+--------------------+-------------+---------+
| binlog                     | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| mysql_native_password      | ACTIVE   | AUTHENTICATION     | NULL        | GPL     |
| mysql_old_password         | ACTIVE   | AUTHENTICATION     | NULL        | GPL     |
| MRG_MyISAM                 | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| MyISAM                     | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| CSV                        | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| MEMORY                     | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| FEDERATED                  | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| PERFORMANCE_SCHEMA         | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| Aria                       | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| InnoDB                     | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| INNODB_TRX                 | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
...
| INNODB_SYS_FOREIGN         | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_SYS_FOREIGN_COLS    | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| SPHINX                     | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| ARCHIVE                    | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| BLACKHOLE                  | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| FEEDBACK                   | DISABLED | INFORMATION SCHEMA | NULL        | GPL     |
| partition                  | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| pam                        | ACTIVE   | AUTHENTICATION     | auth_pam.so | GPL     |
+----------------------------+----------+--------------------+-------------+---------+
```

1.1.1.2.6.2 SHOW PLUGINS SONAME

Syntax

```
SHOW PLUGINS SONAME { library | LIKE 'pattern' | WHERE expr };
```

Description

`SHOW PLUGINS SONAME` displays information about compiled-in and all server plugins in the `plugin_dir` directory, including plugins that haven't been installed.

Examples

```
SHOW PLUGINS SONAME 'ha_example.so';
+----------+---------------+----------------+---------------+---------+
| Name     | Status        | Type           | Library       | License |
+----------+---------------+----------------+---------------+---------+
| EXAMPLE  | NOT INSTALLED | STORAGE ENGINE | ha_example.so | GPL     |
| UNUSABLE | NOT INSTALLED | DAEMON         | ha_example.so | GPL     |
+----------+---------------+----------------+---------------+---------+
```

There is also a corresponding `information_schema` table, called `ALL_PLUGINS`, which contains more complete information.

1.1.1.2.6.3 INSTALL PLUGIN

Syntax

```
INSTALL PLUGIN [IF NOT EXISTS] plugin_name SONAME 'plugin_library'
```

Contents

Description

This statement installs an individual plugin from the specified library. To install the whole library (which could be required), use INSTALL SONAME. See also Installing a Plugin.

`plugin_name` is the name of the plugin as defined in the plugin declaration structure contained in the library file. Plugin names are not case sensitive. For maximal compatibility, plugin names should be limited to ASCII letters, digits, and underscore, because they are used in C source files, shell command lines, M4 and Bourne shell scripts, and SQL environments.

`plugin_library` is the name of the shared library that contains the plugin code. The file name extension can be omitted (which makes the statement look the same on all architectures).

The shared library must be located in the plugin directory (that is, the directory named by the plugin_dir system variable). The library must be in the plugin directory itself, not in a subdirectory. By default, `plugin_dir` is plugin directory under the directory named by the `pkglibdir` configuration variable, but it can be changed by setting the value of `plugin_dir` at server startup. For example, set its value in a `my.cnf` file:

```
[mysqld]
plugin_dir=/path/to/plugin/directory
```

If the value of plugin_dir is a relative path name, it is taken to be relative to the MySQL base directory (the value of the basedir system variable).

`INSTALL PLUGIN` adds a line to the `mysql.plugin` table that describes the plugin. This table contains the plugin name and library file name.

`INSTALL PLUGIN` causes the server to read option (`my.cnf`) files just as during server startup. This enables the plugin to pick up any relevant options from those files. It is possible to add plugin options to an option file even before loading a plugin (if the loose prefix is used). It is also possible to uninstall a plugin, edit `my.cnf` , and install the plugin again. Restarting the plugin this way enables it to the new option values without a server restart.

`INSTALL PLUGIN` also loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which handles any setup that the plugin must perform before it can be used.

To use `INSTALL PLUGIN` , you must have the INSERT privilege for the `mysql.plugin` table.

At server startup, the server loads and initializes any plugin that is listed in the `mysql.plugin` table. This means that a plugin is installed with `INSTALL PLUGIN` only once, not every time the server starts. Plugin loading at startup does not occur if the server is started with the `--skip-grant-tables` option.

When the server shuts down, it executes the de-initialization function for each plugin that is loaded so that the plugin has a chance to perform any final cleanup.

If you need to load plugins for a single server startup when the `--skip-grant-tables` option is given (which tells the server not to read system tables), use the `--plugin-load` mysqld option.

MariaDB starting with 10.4.0

IF NOT EXISTS

When the `IF NOT EXISTS` clause is used, MariaDB will return a note instead of an error if the specified plugin already exists. See SHOW WARNINGS.

Examples

```
INSTALL PLUGIN sphinx SONAME 'ha_sphinx.so';
```

The extension can also be omitted:

```
INSTALL PLUGIN innodb SONAME 'ha_xtradb';
```

From MariaDB 10.4.0:

```
INSTALL PLUGIN IF NOT EXISTS example SONAME 'ha_example';
Query OK, 0 rows affected (0.104 sec)

INSTALL PLUGIN IF NOT EXISTS example SONAME 'ha_example';
Query OK, 0 rows affected, 1 warning (0.000 sec)

SHOW WARNINGS;
+-------+------+--------------------------------------+
| Level | Code | Message                              |
+-------+------+--------------------------------------+
| Note  | 1968 | Plugin 'example' already installed |
+-------+------+--------------------------------------+
```

1.1.1.2.6.4 UNINSTALL PLUGIN

Syntax

```
UNINSTALL PLUGIN [IF EXISTS] plugin_name
```

Contents
1. Syntax
2. Description
   1. IF EXISTS
3. Examples

Description

This statement removes a single installed plugin. To uninstall the whole library which contains the plugin, use UNINSTALL SONAME. You cannot uninstall a plugin if any table that uses it is open.

`plugin_name` must be the name of some plugin that is listed in the mysql.plugin table. The server executes the plugin's deinitialization function and removes the row for the plugin from the `mysql.plugin` table, so that subsequent server restarts will not load and initialize the plugin. `UNINSTALL PLUGIN` does not remove the plugin's shared library file.

To use `UNINSTALL PLUGIN`, you must have the DELETE privilege for the mysql.plugin table.

MariaDB starting with 10.4.0

IF EXISTS

If the `IF EXISTS` clause is used, MariaDB will return a note instead of an error if the plugin does not exist. See SHOW WARNINGS.

Examples

```
UNINSTALL PLUGIN example;
```

From MariaDB 10.4.0:

```
UNINSTALL PLUGIN IF EXISTS example;
Query OK, 0 rows affected (0.099 sec)

UNINSTALL PLUGIN IF EXISTS example;
Query OK, 0 rows affected, 1 warning (0.000 sec)

SHOW WARNINGS;
+-------+------+--------------------------------+
| Level | Code | Message                        |
+-------+------+--------------------------------+
| Note  | 1305 | PLUGIN example does not exist |
+-------+------+--------------------------------+
```

1.1.1.2.6.5 INSTALL SONAME

Syntax

```
INSTALL SONAME 'plugin_library'
```

Contents
1. Syntax
2. Description
3. Examples

Description

This statement is a variant of INSTALL PLUGIN. It installs **all** plugins from a given `plugin_library`. See INSTALL PLUGIN for details.

`plugin_library` is the name of the shared library that contains the plugin code. The file name extension (for example, `libmyplugin.so` or `libmyplugin.dll`) can be omitted (which makes the statement look the same on all architectures).

The shared library must be located in the plugin directory (that is, the directory named by the `plugin_dir` system

variable). The library must be in the plugin directory itself, not in a subdirectory. By default, `plugin_dir` is plugin directory under the directory named by the `pkglibdir` configuration variable, but it can be changed by setting the value of `plugin_dir` at server startup. For example, set its value in a `my.cnf` file:

```
[mysqld]
plugin_dir=/path/to/plugin/directory
```

If the value of plugin_dir is a relative path name, it is taken to be relative to the MySQL base directory (the value of the `basedir` system variable).

`INSTALL SONAME` adds one or more lines to the `mysql.plugin` table that describes the plugin. This table contains the plugin name and library file name.

`INSTALL SONAME` causes the server to read option (`my.cnf`) files just as during server startup. This enables the plugin to pick up any relevant options from those files. It is possible to add plugin options to an option file even before loading a plugin (if the loose prefix is used). It is also possible to uninstall a plugin, edit `my.cnf` , and install the plugin again. Restarting the plugin this way enables it to the new option values without a server restart.

`INSTALL SONAME` also loads and initializes the plugin code to make the plugin available for use. A plugin is initialized by executing its initialization function, which handles any setup that the plugin must perform before it can be used.

To use `INSTALL SONAME` , you must have the INSERT privilege for the `mysql.plugin` table.

At server startup, the server loads and initializes any plugin that is listed in the `mysql.plugin` table. This means that a plugin is installed with `INSTALL SONAME` only once, not every time the server starts. Plugin loading at startup does not occur if the server is started with the `--skip-grant-tables` option.

When the server shuts down, it executes the de-initialization function for each plugin that is loaded so that the plugin has a chance to perform any final cleanup.

If you need to load plugins for a single server startup when the `--skip-grant-tables` option is given (which tells the server not to read system tables), use the `--plugin-load` mysqld option.

If you need to install only one plugin from a library, use the INSTALL PLUGIN statement.

Examples

To load the XtraDB storage engine and all of its `information_schema` tables with one statement, use

```
INSTALL SONAME 'ha_xtradb';
```

This statement can be used instead of `INSTALL PLUGIN` even when the library contains only one plugin:

```
INSTALL SONAME 'ha_sequence';
```

1.1.1.2.6.6 UNINSTALL SONAME

Syntax

```
UNINSTALL SONAME  [IF EXISTS] 'plugin_library'
```

Contents

Description

This statement is a variant of UNINSTALL PLUGIN statement, that removes all plugins belonging to a specified `plugin_library` . See UNINSTALL PLUGIN for details.

`plugin_library` is the name of the shared library that contains the plugin code. The file name extension (for example,

`libmyplugin.so` or `libmyplugin.dll`) can be omitted (which makes the statement look the same on all architectures).

To use `UNINSTALL SONAME` , you must have the DELETE privilege for the `mysql.plugin` table.

MariaDB starting with 10.4.0

IF EXISTS

If the `IF EXISTS` clause is used, MariaDB will return a note instead of an error if the plugin library does not exist. See SHOW WARNINGS.

Examples

To uninstall the XtraDB plugin and all of its `information_schema` tables with one statement, use

```
UNINSTALL SONAME 'ha_xtradb';
```

From MariaDB 10.4.0:

```
UNINSTALL SONAME IF EXISTS 'ha_example';
Query OK, 0 rows affected (0.099 sec)

UNINSTALL SONAME IF EXISTS 'ha_example';
Query OK, 0 rows affected, 1 warning (0.000 sec)

SHOW WARNINGS;
+-------+------+--------------------------------------+
| Level | Code | Message                              |
+-------+------+--------------------------------------+
| Note  | 1305 | SONAME ha_example.so does not exist |
+-------+------+--------------------------------------+
```

1.3.43.12 mysql_plugin

1.1.1.2.7 SET Commands

SET

Set a variable value.

SET CHARACTER SET

Maps all strings sent between the current client and the server with the given mapping.

SET GLOBAL SQL_SLAVE_SKIP_COUNTER

Skips a number of events from the primary.

SET NAMES

The character set used to send statements to the server, and results back to the client.

SET PASSWORD

Assign password to an existing MariaDB user.

SET ROLE

Enable a role.

SET SQL_LOG_BIN

Set binary logging for the current connection.

SET STATEMENT

Set variable values on a per-query basis.

SET TRANSACTION

Sets the transaction isolation level.

SET Variable

Used to insert a value into a variable with a code block.

There are 1 related questions.

1.1.1.2.7.1 SET

Syntax

```
SET variable_assignment [, variable_assignment] ...

variable_assignment:
      user_var_name = expr
    | [GLOBAL | SESSION] system_var_name = expr
    | [@@global. | @@session. | @@]system_var_name = expr
```

Contents

One can also set a user variable in any expression with this syntax:

```
user_var_name:= expr
```

Description

The `SET` statement assigns values to different types of variables that affect the operation of the server or your client. Older versions of MySQL employed `SET OPTION`, but this syntax was deprecated in favor of `SET` without `OPTION`, and was removed in MariaDB 10.0.

Changing a system variable by using the SET statement does not make the change permanently. To do so, the change must be made in a configuration file.

For setting variables on a per-query basis, see SET STATEMENT.

See SHOW VARIABLES for documentation on viewing server system variables.

See Server System Variables for a list of all the system variables.

GLOBAL / SESSION

When setting a system variable, the scope can be specified as either GLOBAL or SESSION.

A global variable change affects all new sessions. It does not affect any currently open sessions, including the one that made the change.

A session variable change affects the current session only.

If the variable has a session value, not specifying either GLOBAL or SESSION will be the same as specifying SESSION. If the variable only has a global value, not specifying GLOBAL or SESSION will apply to the change to the global value.

DEFAULT

Setting a global variable to DEFAULT will restore it to the server default, and setting a session variable to DEFAULT will restore it to the current global value.

Examples

- innodb_sync_spin_loops is a global variable.

- skip_parallel_replication is a session variable.
- max_error_count is both global and session.

```
SELECT VARIABLE_NAME, SESSION_VALUE, GLOBAL_VALUE FROM
 INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
  VARIABLE_NAME IN ('max_error_count', 'skip_parallel_replication', 'innodb_sync_spin_loops');
+---------------------------+---------------+--------------+
| VARIABLE_NAME             | SESSION_VALUE | GLOBAL_VALUE |
+---------------------------+---------------+--------------+
| MAX_ERROR_COUNT           | 64            | 64           |
| SKIP_PARALLEL_REPLICATION | OFF           | NULL         |
| INNODB_SYNC_SPIN_LOOPS    | NULL          | 30           |
+---------------------------+---------------+--------------+
```

Setting the session values:

```
SET max_error_count=128;Query OK, 0 rows affected (0.000 sec)

SET skip_parallel_replication=ON;Query OK, 0 rows affected (0.000 sec)

SET innodb_sync_spin_loops=60;
ERROR 1229 (HY000): Variable 'innodb_sync_spin_loops' is a GLOBAL variable
  and should be set with SET GLOBAL

SELECT VARIABLE_NAME, SESSION_VALUE, GLOBAL_VALUE FROM
 INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
  VARIABLE_NAME IN ('max_error_count', 'skip_parallel_replication', 'innodb_sync_spin_loops');
+---------------------------+---------------+--------------+
| VARIABLE_NAME             | SESSION_VALUE | GLOBAL_VALUE |
+---------------------------+---------------+--------------+
| MAX_ERROR_COUNT           | 128           | 64           |
| SKIP_PARALLEL_REPLICATION | ON            | NULL         |
| INNODB_SYNC_SPIN_LOOPS    | NULL          | 30           |
+---------------------------+---------------+--------------+
```

Setting the global values:

```
SET GLOBAL max_error_count=256;

SET GLOBAL skip_parallel_replication=ON;
ERROR 1228 (HY000): Variable 'skip_parallel_replication' is a SESSION variable
  and can't be used with SET GLOBAL

SET GLOBAL innodb_sync_spin_loops=120;

SELECT VARIABLE_NAME, SESSION_VALUE, GLOBAL_VALUE FROM
 INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
  VARIABLE_NAME IN ('max_error_count', 'skip_parallel_replication', 'innodb_sync_spin_loops');
+---------------------------+---------------+--------------+
| VARIABLE_NAME             | SESSION_VALUE | GLOBAL_VALUE |
+---------------------------+---------------+--------------+
| MAX_ERROR_COUNT           | 128           | 256          |
| SKIP_PARALLEL_REPLICATION | ON            | NULL         |
| INNODB_SYNC_SPIN_LOOPS    | NULL          | 120          |
+---------------------------+---------------+--------------+
```

SHOW VARIABLES will by default return the session value unless the variable is global only.

```
SHOW VARIABLES LIKE 'max_error_count';
+-----------------+-------+
| Variable_name   | Value |
+-----------------+-------+
| max_error_count | 128   |
+-----------------+-------+

SHOW VARIABLES LIKE 'skip_parallel_replication';
+---------------------------+-------+
| Variable_name             | Value |
+---------------------------+-------+
| skip_parallel_replication | ON    |
+---------------------------+-------+

SHOW VARIABLES LIKE 'innodb_sync_spin_loops';
+------------------------+-------+
| Variable_name          | Value |
+------------------------+-------+
| innodb_sync_spin_loops | 120   |
+------------------------+-------+
```

Using the inplace syntax:

```
SELECT (@a:=1);
+---------+
| (@a:=1) |
+---------+
|       1 |
+---------+

SELECT @a;
+------+
| @a   |
+------+
|    1 |
+------+
```

1.1.1.2.7.2 SET CHARACTER SET

Syntax

```
SET {CHARACTER SET | CHARSET}
    {charset_name | DEFAULT}
```

Description

Sets the character_set_client and character_set_results session system variables to the specified character set and collation_connection to the value of collation_database, which implicitly sets character_set_connection to the value of character_set_database.

This maps all strings sent between the current client and the server with the given mapping.

Example

```
SHOW VARIABLES LIKE 'character_set\_%';
+--------------------------+--------+
| Variable_name            | Value  |
+--------------------------+--------+
| character_set_client     | utf8   |
| character_set_connection | utf8   |
| character_set_database   | latin1 |
| character_set_filesystem | binary |
| character_set_results    | utf8   |
| character_set_server     | latin1 |
| character_set_system     | utf8   |
+--------------------------+--------+

SHOW VARIABLES LIKE 'collation%';
+----------------------+-------------------+
| Variable_name        | Value             |
+----------------------+-------------------+
| collation_connection | utf8_general_ci   |
| collation_database   | latin1_swedish_ci |
| collation_server     | latin1_swedish_ci |
+----------------------+-------------------+

SET CHARACTER SET utf8mb4;

SHOW VARIABLES LIKE 'character_set\_%';
+--------------------------+---------+
| Variable_name            | Value   |
+--------------------------+---------+
| character_set_client     | utf8mb4 |
| character_set_connection | latin1  |
| character_set_database   | latin1  |
| character_set_filesystem | binary  |
| character_set_results    | utf8mb4 |
| character_set_server     | latin1  |
| character_set_system     | utf8    |
+--------------------------+---------+

SHOW VARIABLES LIKE 'collation%';
+----------------------+-------------------+
| Variable_name        | Value             |
+----------------------+-------------------+
| collation_connection | latin1_swedish_ci |
| collation_database   | latin1_swedish_ci |
| collation_server     | latin1_swedish_ci |
+----------------------+-------------------+
```

1.1.1.2.5.5 SET GLOBAL SQL_SLAVE_SKIP_COUNTER

1.1.1.2.7.4 SET NAMES

Syntax

```
SET NAMES {'charset_name'
    [COLLATE 'collation_name'] | DEFAULT}
```

Contents

Description

Sets the character_set_client, character_set_connection, character_set_results and, implicitly, the collation_connection session system variables to the specified character set and collation.

This determines which character set the client will use to send statements to the server, and the server will use for sending

results back to the client.

`ucs2`, `utf16`, `utf16le` and `utf32` are not valid character sets for `SET NAMES`, as they cannot be used as client character sets.

The collation clause is optional. If not defined (or if `DEFAULT` is specified), the default collation for the character set will be used.

Quotes are optional for the character set or collation clauses.

Examples

```
SELECT VARIABLE_NAME, SESSION_VALUE
  FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
  VARIABLE_NAME LIKE 'character_set_c%' OR
  VARIABLE_NAME LIKE 'character_set_re%' OR
  VARIABLE_NAME LIKE 'collation_c%';
+--------------------------+-----------------+
| VARIABLE_NAME            | SESSION_VALUE   |
+--------------------------+-----------------+
| CHARACTER_SET_RESULTS    | utf8            |
| CHARACTER_SET_CONNECTION | utf8            |
| CHARACTER_SET_CLIENT     | utf8            |
| COLLATION_CONNECTION     | utf8_general_ci |
+--------------------------+-----------------+

SET NAMES big5;

SELECT VARIABLE_NAME, SESSION_VALUE
  FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
  VARIABLE_NAME LIKE 'character_set_c%' OR
  VARIABLE_NAME LIKE 'character_set_re%' OR
  VARIABLE_NAME LIKE 'collation_c%';
+--------------------------+-----------------+
| VARIABLE_NAME            | SESSION_VALUE   |
+--------------------------+-----------------+
| CHARACTER_SET_RESULTS    | big5            |
| CHARACTER_SET_CONNECTION | big5            |
| CHARACTER_SET_CLIENT     | big5            |
| COLLATION_CONNECTION     | big5_chinese_ci |
+--------------------------+-----------------+

SET NAMES 'latin1' COLLATE 'latin1_bin';

SELECT VARIABLE_NAME, SESSION_VALUE
  FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
  VARIABLE_NAME LIKE 'character_set_c%' OR
  VARIABLE_NAME LIKE 'character_set_re%' OR
  VARIABLE_NAME LIKE 'collation_c%';
+--------------------------+---------------+
| VARIABLE_NAME            | SESSION_VALUE |
+--------------------------+---------------+
| CHARACTER_SET_RESULTS    | latin1        |
| CHARACTER_SET_CONNECTION | latin1        |
| CHARACTER_SET_CLIENT     | latin1        |
| COLLATION_CONNECTION     | latin1_bin    |
+--------------------------+---------------+

SET NAMES DEFAULT;

SELECT VARIABLE_NAME, SESSION_VALUE
  FROM INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
  VARIABLE_NAME LIKE 'character_set_c%' OR
  VARIABLE_NAME LIKE 'character_set_re%' OR
  VARIABLE_NAME LIKE 'collation_c%';
+--------------------------+-------------------+
| VARIABLE_NAME            | SESSION_VALUE     |
+--------------------------+-------------------+
| CHARACTER_SET_RESULTS    | latin1            |
| CHARACTER_SET_CONNECTION | latin1            |
| CHARACTER_SET_CLIENT     | latin1            |
| COLLATION_CONNECTION     | latin1_swedish_ci |
+--------------------------+-------------------+
```

1.1.1.1.7 SET PASSWORD

1.1.1.1.10 SET ROLE

1.1.1.2.7.7 SET SQL_LOG_BIN

Syntax

```
SET [SESSION] sql_log_bin = {0|1}
```

Description

Sets the sql_log_bin system variable, which disables or enables binary logging for the current connection, if the client has the `SUPER` privilege. The statement is refused with an error if the client does not have that privilege.

Before MariaDB 5.5 and before MySQL 5.6 one could also set `sql_log_bin` as a global variable. This was disabled as this was too dangerous as it could damage replication.

1.1.1.2.7.8 SET STATEMENT

Contents

`SET STATEMENT` can be used to set the value of a system variable for the duration of the statement. It is also possible to set multiple variables.

Syntax

```
SET STATEMENT var1=value1 [, var2=value2, ...]
  FOR <statement>
```

where `varN` is a system variable (list of allowed variables is provided below), and `valueN` is a constant literal.

Description

`SET STATEMENT var1=value1 FOR stmt`

is roughly equivalent to

```
SET @save_value=@@var1;
SET SESSION var1=value1;
stmt;
SET SESSION var1=@save_value;
```

The server parses the whole statement before executing it, so any variables set in this fashion that affect the parser may not have the expected effect. Examples include the charset variables, sql_mode=ansi_quotes, etc.

Examples

One can limit statement execution time `max_statement_time`:

```
SET STATEMENT max_statement_time=1000 FOR SELECT ... ;
```

One can switch on/off individual optimizations:

```
SET STATEMENT optimizer_switch='materialization=off' FOR SELECT ....;
```

It is possible to enable MRR/BKA for a query:

```
SET STATEMENT  join_cache_level=6, optimizer_switch='mrr=on'  FOR SELECT ...
```

Note that it makes no sense to try to set a session variable inside a `SET STATEMENT`:

```
#USELESS STATEMENT
SET STATEMENT sort_buffer_size = 100000 for SET SESSION sort_buffer_size = 200000;
```

For the above, after setting sort_buffer_size to 200000 it will be reset to its original state (the state before the `SET STATEMENT` started) after the statement execution.

Limitations

There are a number of variables that cannot be set on per-query basis. These include:

- `autocommit`
- `character_set_client`
- `character_set_connection`
- `character_set_filesystem`
- `collation_connection`
- `default_master_connection`
- `debug_sync`
- `interactive_timeout`
- `gtid_domain_id`
- `last_insert_id`
- `log_slow_filter`
- `log_slow_rate_limit`
- `log_slow_verbosity`
- `long_query_time`
- `min_examined_row_limit`
- `profiling`
- `profiling_history_size`
- `query_cache_type`
- `rand_seed1`
- `rand_seed2`
- `skip_replication`
- `slow_query_log`
- `sql_log_off`
- `tx_isolation`
- `wait_timeout`

Source

- The feature was originally implemented as a Google Summer of Code 2009 project by Joseph Lukas.
- Percona Server 5.6 included it as Per-query variable statement
- MariaDB ported the patch and fixed *many* bugs. The task in MariaDB Jira is MDEV-5231.

1.1.1.9.4 SET TRANSACTION

1.1.1.2.7.10 SET Variable

Syntax

```
SET var_name = expr [, var_name = expr] ...
```

Contents

Description

The `SET` statement in stored programs is an extended version of the general `SET` statement. Referenced variables may be ones declared inside a stored program, global system variables, or user-defined variables.

The `SET` statement in stored programs is implemented as part of the pre-existing SET syntax. This allows an extended syntax of `SET a=x, b=y, ...` where different variable types (locally declared variables, global and session server variables, user-defined variables) can be mixed. This also allows combinations of local variables and some options that make sense only for system variables; in that case, the options are recognized but ignored.

`SET` can be used with both local variables and user-defined variables.

When setting several variables using the columns returned by a query, `SELECT INTO` should be preferred.

To set many variables to the same value, the `LAST_VALUE( )` function can be used.

Below is an example of how a user-defined variable may be set:

```
SET @x = 1;
```

1.1.1.2.8 SHOW

Articles on the various SHOW commands.

About SHOW

General information about the SHOW statement.

Extended Show

Extended SHOW with WHERE and LIKE.

SHOW AUTHORS

Information about the people who work on MariaDB.

SHOW BINARY LOGS

SHOW BINARY LOGS lists all binary logs on the server.

SHOW BINLOG EVENTS

Show events in the binary log.

SHOW CHARACTER SET

Available character sets.

SHOW CLIENT_STATISTICS

Statistics about client connections.

SHOW COLLATION

Supported collations.

SHOW COLUMNS

Column information.

SHOW CONTRIBUTORS

Companies and people who financially contribute to MariaDB.

SHOW CREATE DATABASE

Shows the CREATE DATABASE statement that created the database.

SHOW CREATE EVENT

Displays the CREATE EVENT statement needed to re-create a given event

SHOW CREATE FUNCTION

Statement that created the function.

SHOW CREATE PACKAGE

Show the CREATE statement that creates the given package specification.

SHOW CREATE PACKAGE BODY

Show the CREATE statement that creates the given package body (i.e. implementation).

SHOW CREATE PROCEDURE

Returns the string used for creating a stored procedure.

SHOW CREATE SEQUENCE

Shows the CREATE SEQUENCE statement that created the sequence.

SHOW CREATE TABLE

Shows the CREATE TABLE statement that created the table.

SHOW CREATE TRIGGER

Shows the CREATE TRIGGER statement used to create the trigger

SHOW CREATE USER

Show the CREATE USER statement for a specified user.

SHOW CREATE VIEW

Show the CREATE VIEW statement that created a view.

SHOW DATABASES

Lists the databases on the server.

SHOW ENGINE

Show storage engine information.

SHOW ENGINE INNODB STATUS

Display extensive InnoDB information.

SHOW ENGINES

Server storage engine info

SHOW ERRORS

Displays errors.

SHOW EVENTS

Shows information about events

SHOW EXPLAIN

Shows an execution plan for a running query.

SHOW FUNCTION CODE

Representation of the internal implementation of the stored function

SHOW FUNCTION STATUS

Stored function characteristics

SHOW GRANTS

View GRANT statements.

SHOW INDEX

Information about table indexes.

SHOW INDEX_STATISTICS

Index usage statistics.

SHOW INNODB STATUS (removed)

Removed synonym for SHOW ENGINE INNODB STATUS

SHOW LOCALES

View locales information.

SHOW MASTER STATUS

Status information about the binary log.

SHOW OPEN TABLES

List non-temporary open tables.

SHOW PACKAGE BODY STATUS

Returns characteristics of stored package bodies (implementations).

SHOW PACKAGE STATUS

Returns characteristics of stored package specifications.

SHOW PLUGINS

Display information about installed plugins.

SHOW PLUGINS SONAME

Information about all available plugins, installed or not.

SHOW PRIVILEGES

Shows the list of supported system privileges.

SHOW PROCEDURE CODE

Display internal implementation of a stored procedure.

SHOW PROCEDURE STATUS

Stored procedure characteristics.

SHOW PROCESSLIST

Running threads and information about them.

SHOW PROFILE

Display statement resource usage

SHOW PROFILES

Show statement resource usage

SHOW QUERY_RESPONSE_TIME

Retrieving information from the QUERY_RESPONSE_TIME plugin.

SHOW RELAYLOG EVENTS

Show events in the relay log.

SHOW SLAVE HOSTS

Display replicas currently registered with the primary.

SHOW SLAVE STATUS

Show status for one or all primaries.

SHOW STATUS

Server status information.

SHOW TABLE STATUS

SHOW TABLES with information about non-temporary tables.

SHOW TABLES

List of non-temporary tables, views or sequences.

SHOW TABLE_STATISTICS

Table usage statistics.

SHOW TRIGGERS

Shows currently-defined triggers

SHOW USER_STATISTICS

User activity statistics.

SHOW VARIABLES

Displays the values of system variables.

SHOW WARNINGS

Displays errors, warnings and notes.

SHOW WSREP_MEMBERSHIP

Galera node cluster membership information.

SHOW WSREP_STATUS

Galera node cluster status information.

There are 1 related questions.

1.1.1.2.8.1 About SHOW

`SHOW` has many forms that provide information about databases, tables, columns, or status information about the server. These include:

- SHOW AUTHORS
- SHOW CHARACTER SET [like_or_where]
- SHOW COLLATION [like_or_where]
- SHOW [FULL] COLUMNS FROM tbl_name [FROM db_name] [like_or_where]
- SHOW CONTRIBUTORS
- SHOW CREATE DATABASE db_name
- SHOW CREATE EVENT event_name
- SHOW CREATE PACKAGE package_name
- SHOW CREATE PACKAGE BODY package_name
- SHOW CREATE PROCEDURE proc_name
- SHOW CREATE TABLE tbl_name
- SHOW CREATE TRIGGER trigger_name
- SHOW CREATE VIEW view_name
- SHOW DATABASES [like_or_where]
- SHOW ENGINE engine_name {STATUS | MUTEX}
- SHOW [STORAGE] ENGINES
- SHOW ERRORS [LIMIT [offset,] row_count]
- SHOW [FULL] EVENTS
- SHOW FUNCTION CODE func_name
- SHOW FUNCTION STATUS [like_or_where]
- SHOW GRANTS FOR user
- SHOW INDEX FROM tbl_name [FROM db_name]
- SHOW INNODB STATUS
- SHOW OPEN TABLES [FROM db_name] [like_or_where]
- SHOW PLUGINS
- SHOW PROCEDURE CODE proc_name
- SHOW PROCEDURE STATUS [like_or_where]
- SHOW PRIVILEGES
- SHOW [FULL] PROCESSLIST
- SHOW PROFILE [types] [FOR QUERY n] [OFFSET n] [LIMIT n]
- SHOW PROFILES
- SHOW [GLOBAL | SESSION] STATUS [like_or_where]
- SHOW TABLE STATUS [FROM db_name] [like_or_where]
- SHOW TABLES [FROM db_name] [like_or_where]
- SHOW TRIGGERS [FROM db_name] [like_or_where]

- SHOW [GLOBAL | SESSION] VARIABLES [like_or_where]
- SHOW WARNINGS [LIMIT [offset,] row_count]

```
like_or_where:
    LIKE 'pattern'
  | WHERE expr
```

If the syntax for a given `SHOW` statement includes a `LIKE 'pattern'` part, `'pattern'` is a string that can contain the SQL " `%` " and " _ " wildcard characters. The pattern is useful for restricting statement output to matching values.

Several `SHOW` statements also accept a `WHERE` clause that provides more flexibility in specifying which rows to display. See Extended Show.

1.1.1.2.8.2 Extended Show

Contents

The following `SHOW` statements can be extended by using a `WHERE` clause and a `LIKE` clause to refine the results:

- SHOW CHARACTER SET
- SHOW COLLATION
- SHOW COLUMNS
- SHOW DATABASES
- SHOW FUNCTION STATUS
- SHOW INDEX
- SHOW OPEN TABLES
- SHOW PACKAGE STATUS
- SHOW PACKAGE BODY STATUS
- SHOW INDEX
- SHOW PROCEDURE STATUS
- SHOW STATUS
- SHOW TABLE STATUS
- SHOW TABLES
- SHOW TRIGGERS
- SHOW VARIABLES

As with a regular `SELECT`, the `WHERE` clause can be used for the specific columns returned, and the `LIKE` clause with the regular wildcards.

Examples

```
SHOW TABLES;
+----------------------+
| Tables_in_test       |
+----------------------+
| animal_count         |
| animals              |
| are_the_mooses_loose |
| aria_test2           |
| t1                   |
| view1                |
+----------------------+
```

Showing the tables beginning with *a* only.

```
SHOW TABLES WHERE Tables_in_test LIKE 'a%';
+----------------------+
| Tables_in_test       |
+----------------------+
| animal_count         |
| animals              |
| are_the_mooses_loose |
| aria_test2           |
+----------------------+
```

Variables whose name starts with *aria* and with a valued of greater than 8192:

```
SHOW VARIABLES WHERE Variable_name LIKE 'aria%' AND Value >8192;
+-----------------------------+---------------------+
| Variable_name               | Value               |
+-----------------------------+---------------------+
| aria_checkpoint_log_activity | 1048576             |
| aria_log_file_size          | 1073741824          |
| aria_max_sort_file_size     | 9223372036853727232 |
| aria_pagecache_buffer_size  | 134217728           |
| aria_sort_buffer_size       | 134217728           |
+-----------------------------+---------------------+
```

Shortcut, just returning variables whose name begins with *aria*.

```
SHOW VARIABLES LIKE 'aria%';
+-----------------------------------------+---------------------+
| Variable_name                           | Value               |
+-----------------------------------------+---------------------+
| aria_block_size                         | 8192                |
| aria_checkpoint_interval                | 30                  |
| aria_checkpoint_log_activity            | 1048576             |
| aria_force_start_after_recovery_failures | 0                   |
| aria_group_commit                       | none                |
| aria_group_commit_interval              | 0                   |
| aria_log_file_size                      | 1073741824          |
| aria_log_purge_type                     | immediate           |
| aria_max_sort_file_size                 | 9223372036853727232 |
| aria_page_checksum                      | ON                  |
| aria_pagecache_age_threshold            | 300                 |
| aria_pagecache_buffer_size              | 134217728           |
| aria_pagecache_division_limit           | 100                 |
| aria_recover                            | NORMAL              |
| aria_repair_threads                     | 1                   |
| aria_sort_buffer_size                   | 134217728           |
| aria_stats_method                       | nulls_unequal       |
| aria_sync_log_dir                       | NEWFILE             |
| aria_used_for_temp_tables               | ON                  |
+-----------------------------------------+---------------------+
```

1.1.1.2.8.3 SHOW AUTHORS

Syntax

```
SHOW AUTHORS
```

Description

The `SHOW AUTHORS` statement displays information about the people who work on MariaDB. For each author, it displays Name, Location, and Comment values. All columns are encoded as latin1.

These include:

- First the active people in MariaDB are listed.
- Then the active people in MySQL.
- Last the people that have contributed to MariaDB/MySQL in the past.

The order is somewhat related to importance of the contribution given to the MariaDB project, but this is not 100% accurate. There is still room for improvement and debate...

Example

```
SHOW AUTHORS\G
*************************** 1. row ***************************
    Name: Michael (Monty) Widenius
Location: Tusby, Finland
```

```
 Comment: Lead developer and main author
*************************** 2. row ***************************
    Name: Sergei Golubchik
Location: Kerpen, Germany
 Comment: Architect, Full-text search, precision math, plugin framework, merges etc
*************************** 3. row ***************************
    Name: Igor Babaev
Location: Bellevue, USA
 Comment: Optimizer, keycache, core work
*************************** 4. row ***************************
    Name: Sergey Petrunia
Location: St. Petersburg, Russia
 Comment: Optimizer
*************************** 5. row ***************************
    Name: Oleksandr Byelkin
Location: Lugansk, Ukraine
 Comment: Query Cache (4.0), Subqueries (4.1), Views (5.0)
*************************** 6. row ***************************
    Name: Timour Katchaounov
Location: Sofia , Bulgaria
 Comment: Optimizer
*************************** 7. row ***************************
    Name: Kristian Nielsen
Location: Copenhagen, Denmark
 Comment: Replication, Async client prototocol, General buildbot stuff
*************************** 8. row ***************************
    Name: Alexander (Bar) Barkov

```

1.1.1.2.8.4 SHOW BINARY LOGS

Syntax

```
SHOW BINARY LOGS
SHOW MASTER LOGS
```

Description

Lists the binary log files on the server. This statement is used as part of the procedure described in `PURGE BINARY LOGS`

, that shows how to determine which logs can be purged.

This statement requires the SUPER privilege, the REPLICATION_CLIENT privilege, or, from MariaDB 10.5.2, the BINLOG MONITOR privilege.

Examples

```
SHOW BINARY LOGS;
+--------------------+-----------+
| Log_name           | File_size |
+--------------------+-----------+
| mariadb-bin.000001 |     19039 |
| mariadb-bin.000002 |    717389 |
| mariadb-bin.000003 |       300 |
| mariadb-bin.000004 |       333 |
| mariadb-bin.000005 |       899 |
| mariadb-bin.000006 |       125 |
| mariadb-bin.000007 |     18907 |
| mariadb-bin.000008 |     19530 |
| mariadb-bin.000009 |       151 |
| mariadb-bin.000010 |       151 |
| mariadb-bin.000011 |       125 |
| mariadb-bin.000012 |       151 |
| mariadb-bin.000013 |       151 |
| mariadb-bin.000014 |       125 |
| mariadb-bin.000015 |       151 |
| mariadb-bin.000016 |       314 |
+--------------------+-----------+
```

1.1.1.2.8.5 SHOW BINLOG EVENTS

Syntax

```
SHOW BINLOG EVENTS
   [IN 'log_name'] [FROM pos] [LIMIT [offset,] row_count]
```

Description

Shows the events in the binary log. If you do not specify ' `log_name` ', the first binary log is displayed.

Requires the BINLOG MONITOR privilege (>= MariaDB 10.5.2) or the REPLICATION SLAVE privilege (<= MariaDB 10.5.1).

Example

```
SHOW BINLOG EVENTS IN 'mysql_sandbox10019-bin.000002';
+------------------------------+-----+------------------+-----------+-------------+--------
---------------------------------------+
| Log_name                     | Pos | Event_type       | Server_id | End_log_pos | Info
|
+------------------------------+-----+------------------+-----------+-------------+--------

---------------------------------------+
```

1.1.1.2.8.6 SHOW CHARACTER SET

Syntax

```
SHOW CHARACTER SET
    [LIKE 'pattern' | WHERE expr]
```

Contents

Description

The `SHOW CHARACTER SET` statement shows all available character sets. The `LIKE` clause, if present on its own, indicates which character set names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

The same information can be queried from the Information Schema CHARACTER_SETS table.

See Setting Character Sets and Collations for details on specifying the character set at the server, database, table and column levels.

Examples

```
SHOW CHARACTER SET LIKE 'latin%';
+---------+-----------------------------+-------------------+--------+
| Charset | Description                 | Default collation | Maxlen |
+---------+-----------------------------+-------------------+--------+
| latin1  | cp1252 West European        | latin1_swedish_ci |      1 |
| latin2  | ISO 8859-2 Central European | latin2_general_ci |      1 |
| latin5  | ISO 8859-9 Turkish          | latin5_turkish_ci |      1 |
| latin7  | ISO 8859-13 Baltic          | latin7_general_ci |      1 |
+---------+-----------------------------+-------------------+--------+
```

```
SHOW CHARACTER SET WHERE Maxlen LIKE '2';
+---------+----------------------------+-------------------+--------+
| Charset | Description                | Default collation | Maxlen |
+---------+----------------------------+-------------------+--------+
| big5    | Big5 Traditional Chinese   | big5_chinese_ci   |      2 |
| sjis    | Shift-JIS Japanese         | sjis_japanese_ci  |      2 |
| euckr   | EUC-KR Korean              | euckr_korean_ci   |      2 |
| gb2312  | GB2312 Simplified Chinese  | gb2312_chinese_ci |      2 |
| gbk     | GBK Simplified Chinese     | gbk_chinese_ci    |      2 |
| ucs2    | UCS-2 Unicode              | ucs2_general_ci   |      2 |
| cp932   | SJIS for Windows Japanese  | cp932_japanese_ci |      2 |
+---------+----------------------------+-------------------+--------+
```

1.1.1.2.8.7 SHOW CLIENT_STATISTICS

Syntax

```
SHOW CLIENT_STATISTICS
```

Description

The `SHOW CLIENT_STATISTICS` statement is part of the User Statistics feature. It was removed as a separate statement in MariaDB 10.1.1, but effectively replaced by the generic SHOW information_schema_table statement. The information_schema.CLIENT_STATISTICS table holds statistics about client connections.

The userstat system variable must be set to 1 to activate this feature. See the User Statistics and information_schema.CLIENT_STATISTICS articles for more information.

Example

```
SHOW CLIENT_STATISTICS\G
*************************** 1. row ***************************
               Client: localhost
     Total_connections: 35
Concurrent_connections: 0
        Connected_time: 708
             Busy_time: 2.5557979999999985
              Cpu_time: 0.04123740000000002
        Bytes_received: 3883
            Bytes_sent: 21595
  Binlog_bytes_written: 0
             Rows_read: 18
             Rows_sent: 115
          Rows_deleted: 0
         Rows_inserted: 0
          Rows_updated: 0
       Select_commands: 70
       Update_commands: 0
        Other_commands: 0
   Commit_transactions: 1
 Rollback_transactions: 0
    Denied_connections: 0
      Lost_connections: 0
         Access_denied: 0
         Empty_queries: 35
```

5.2.6 SHOW COLLATION

1.1.1.2.1.16 SHOW COLUMNS

1.1.1.2.8.10 SHOW CONTRIBUTORS

Syntax

```
SHOW CONTRIBUTORS
```

Description

The `SHOW CONTRIBUTORS` statement displays information about the companies and people who financially contribute to MariaDB. For each contributor, it displays `Name`, `Location`, and `Comment` values. All columns are encoded as `latin1`.

It displays all members and sponsors of the MariaDB Foundation as well as other financial contributors.

Example

```
SHOW CONTRIBUTORS;
+---------------------+------------------------------+--------------------------------------
-----------------------+
| Name                | Location                     | Comment
|
+---------------------+------------------------------+--------------------------------------
-----------------------+
| Alibaba Cloud       | https://www.alibabacloud.com/ | Platinum Sponsor of the MariaDB
Foundation                  |
| Tencent Cloud       | https://cloud.tencent.com     | Platinum Sponsor of the MariaDB
Foundation                  |
| Microsoft           | https://microsoft.com/        | Platinum Sponsor of the MariaDB
Foundation                  |
| MariaDB Corporation | https://mariadb.com           | Founding member, Platinum Sponsor of
the MariaDB Foundation |
| ServiceNow          | https://servicenow.com        | Platinum Sponsor of the MariaDB
Foundation                  |
| Intel               | https://www.intel.com         | Platinum Sponsor of the MariaDB
Foundation                  |
| SIT                 | https://sit.org               | Platinum Sponsor of the MariaDB
Foundation                  |
| Visma               | https://visma.com             | Gold Sponsor of the MariaDB Foundation

|
| IBM                 | https://www.ibm.com           | Gold Sponsor of the MariaDB Foundation
|
| Automattic          | https://automattic.com        | Silver Sponsor of the MariaDB
Foundation                   |
| Percona             | https://www.percona.com/      | Sponsor of the MariaDB Foundation
|
| Galera Cluster      | https://galeracluster.com     | Sponsor of the MariaDB Foundation
|
| Google              | USA                           | Sponsoring encryption, parallel
replication and GTID        |
| Facebook            | USA                           | Sponsoring non-blocking API, LIMIT
ROWS EXAMINED etc         |
| Ronald Bradford     | Brisbane, Australia           | EFF contribution for UC2006 Auction
|
| Sheeri Kritzer      | Boston, Mass. USA             | EFF contribution for UC2006 Auction
|
| Mark Shuttleworth   | London, UK.                   | EFF contribution for UC2006 Auction
|
+---------------------+------------------------------+--------------------------------------
-----------------------+
```

1.1.1.2.8.11 SHOW CREATE DATABASE

Syntax

```
SHOW CREATE {DATABASE | SCHEMA} db_name
```

Contents

Description

Shows the CREATE DATABASE statement that creates the given database. `SHOW CREATE SCHEMA` is a synonym for `SHOW CREATE DATABASE`. `SHOW CREATE DATABASE` quotes database names according to the value of the sql_quote_show_create server system variable.

Examples

```
SHOW CREATE DATABASE test;
+----------+-----------------------------------------------------------------+
| Database | Create Database                                                 |
+----------+-----------------------------------------------------------------+
| test     | CREATE DATABASE `test` /*!40100 DEFAULT CHARACTER SET latin1 */ |
+----------+-----------------------------------------------------------------+

SHOW CREATE SCHEMA test;
+----------+-----------------------------------------------------------------+
| Database | Create Database                                                 |
+----------+-----------------------------------------------------------------+
| test     | CREATE DATABASE `test` /*!40100 DEFAULT CHARACTER SET latin1 */ |
+----------+-----------------------------------------------------------------+
```

With `sql_quote_show_create` off:

```
SHOW CREATE DATABASE test;
+----------+-----------------------------------------------------------------+
| Database | Create Database                                                 |
+----------+-----------------------------------------------------------------+
| test     | CREATE DATABASE test /*!40100 DEFAULT CHARACTER SET latin1 */ |
+----------+-----------------------------------------------------------------+
```

With a comment, from MariaDB 10.5:

```
SHOW CREATE DATABASE p;
+----------+-----------------------------------------------------------------------------------------------
| Database | Create Database
+----------+-----------------------------------------------------------------------------------------------
| p        | CREATE DATABASE `p` /*!40100 DEFAULT CHARACTER SET latin1 */ COMMENT 'presentations'
+----------+-----------------------------------------------------------------------------------------------
```

1.1.1.2.8.12 SHOW CREATE EVENT

Syntax

```
SHOW CREATE EVENT event_name
```

Description

This statement displays the `CREATE EVENT` statement needed to re-create a given event, as well as the `SQL_MODE` that was used when the trigger has been created and the character set used by the connection. To find out which events are present, use `SHOW EVENTS`.

The output of this statement is unreliably affected by the `sql_quote_show_create` server system variable - see

http://bugs.mysql.com/bug.php?id=12719

The `information_schema.EVENTS` table provides similar, but more complete, information.

Examples

```
SHOW CREATE EVENT test.e_daily\G
*************************** 1. row ***************************
               Event: e_daily
            sql_mode:
           time_zone: SYSTEM
       Create Event: CREATE EVENT `e_daily`
                       ON SCHEDULE EVERY 1 DAY
                       STARTS CURRENT_TIMESTAMP + INTERVAL 6 HOUR
                       ON COMPLETION NOT PRESERVE
                       ENABLE
                       COMMENT 'Saves total number of sessions then
                               clears the table each day'
                       DO BEGIN
                         INSERT INTO site_activity.totals (time, total)
                           SELECT CURRENT_TIMESTAMP, COUNT(*)
                           FROM site_activity.sessions;
                         DELETE FROM site_activity.sessions;
                       END
character_set_client: latin1
collation_connection: latin1_swedish_ci
  Database Collation: latin1_swedish_ci
```

1.1.1.2.8.13 SHOW CREATE FUNCTION

Syntax

```
SHOW CREATE FUNCTION func_name
```

Description

This statement is similar to SHOW CREATE PROCEDURE but for stored functions.

The output of this statement is unreliably affected by the sql_quote_show_create server system variable - see http://bugs.mysql.com/bug.php?id=12719

Example

```
SHOW CREATE FUNCTION VatCents\G
*************************** 1. row ***************************
            Function: VatCents
            sql_mode:
     Create Function: CREATE DEFINER=`root`@`localhost` FUNCTION `VatCents`(price
DECIMAL(10,2)) RETURNS int(11)
    DETERMINISTIC
BEGIN
 DECLARE x INT;
 SET x = price * 114;
 RETURN x;
END
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

1.1.1.2.8.14 SHOW CREATE PACKAGE

MariaDB starting with 10.3.5
Oracle-style packages were introduced in MariaDB 10.3.5.

Syntax

```
SHOW CREATE PACKAGE  [ db_name . ] package_name
```

Contents

Description

The `SHOW CREATE PACKAGE` statement can be used when Oracle SQL_MODE is set.

Shows the `CREATE` statement that creates the given package specification.

Examples

```
SHOW CREATE PACKAGE employee_tools\G
*************************** 1. row ***************************
             Package: employee_tools
            sql_mode:
PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,ORACLE,NO_KEY_OPTIONS,NO_TABLE_OPTIONS,NO_FIELD_OPTION
S,NO_AUTO_CREATE_USER
      Create Package: CREATE DEFINER="root"@"localhost" PACKAGE "employee_tools" AS
  FUNCTION getSalary(eid INT) RETURN DECIMAL(10,2);
  PROCEDURE raiseSalary(eid INT, amount DECIMAL(10,2));
  PROCEDURE raiseSalaryStd(eid INT);
  PROCEDURE hire(ename TEXT, esalary DECIMAL(10,2));
END
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

1.1.1.2.8.15 SHOW CREATE PACKAGE BODY

MariaDB starting with 10.3.5
Oracle-style packages were introduced in MariaDB 10.3.5.

Syntax

```
SHOW CREATE PACKAGE BODY  [ db_name . ] package_name
```

Contents

Description

The `SHOW CREATE PACKAGE BODY` statement can be used when Oracle SQL_MODE is set.

Shows the `CREATE` statement that creates the given package body (i.e. the implementation).

Examples

```
SHOW CREATE PACKAGE BODY employee_tools\G
*************************** 1. row ***************************
        Package body: employee_tools
            sql_mode:
PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,ORACLE,NO_KEY_OPTIONS,NO_TABLE_OPTIONS,NO_FIELD_OPTION
S,NO_AUTO_CREATE_USER
 Create Package Body: CREATE DEFINER="root"@"localhost" PACKAGE BODY "employee_tools" AS

  stdRaiseAmount DECIMAL(10,2):=500;

  PROCEDURE log (eid INT, ecmnt TEXT) AS
  BEGIN
    INSERT INTO employee_log (id, cmnt) VALUES (eid, ecmnt);
  END;

  PROCEDURE hire(ename TEXT, esalary DECIMAL(10,2)) AS
    eid INT;
  BEGIN
    INSERT INTO employee (name, salary) VALUES (ename, esalary);
    eid:= last_insert_id();
    log(eid, 'hire ' || ename);
  END;

  FUNCTION getSalary(eid INT) RETURN DECIMAL(10,2) AS
    nSalary DECIMAL(10,2);
  BEGIN
    SELECT salary INTO nSalary FROM employee WHERE id=eid;
    log(eid, 'getSalary id=' || eid || ' salary=' || nSalary);
    RETURN nSalary;
  END;

  PROCEDURE raiseSalary(eid INT, amount DECIMAL(10,2)) AS
  BEGIN
    UPDATE employee SET salary=salary+amount WHERE id=eid;
    log(eid, 'raiseSalary id=' || eid || ' amount=' || amount);
  END;

  PROCEDURE raiseSalaryStd(eid INT) AS
  BEGIN
    raiseSalary(eid, stdRaiseAmount);
    log(eid, 'raiseSalaryStd id=' || eid);
  END;

BEGIN
  log(0, 'Session ' || connection_id() || ' ' || current_user || ' started');
END
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

1.1.1.2.8.16 SHOW CREATE PROCEDURE

Syntax

```
SHOW CREATE PROCEDURE proc_name
```

Contents

Description

This statement is a MariaDB extension. It returns the exact string that can be used to re-create the named stored procedure, as well as the `SQL_MODE` that was used when the trigger has been created and the character set used by the connection.. A similar statement, `SHOW CREATE FUNCTION`, displays information about stored functions.

Both statements require that you are the owner of the routine or have the `SELECT` privilege on the `mysql.proc` table. When neither is true, the statements display `NULL` for the `Create Procedure` or `Create Function` field.

Warning Users with `SELECT` privileges on `mysql.proc` or `USAGE` privileges on `*.*` can view the text of routines, even when they do not have privileges for the function or procedure itself.

The output of these statements is unreliably affected by the `sql_quote_show_create` server system variable - see http://bugs.mysql.com/bug.php?id=12719

Examples

Here's a comparison of the `SHOW CREATE PROCEDURE` and `SHOW CREATE FUNCTION` statements.

```
SHOW CREATE PROCEDURE test.simpleproc\G
*************************** 1. row ***************************
           Procedure: simpleproc
            sql_mode:
    Create Procedure: CREATE PROCEDURE `simpleproc`(OUT param1 INT)
                      BEGIN
                      SELECT COUNT(*) INTO param1 FROM t;
                      END
character_set_client: latin1
collation_connection: latin1_swedish_ci
  Database Collation: latin1_swedish_ci

SHOW CREATE FUNCTION test.hello\G
*************************** 1. row ***************************
            Function: hello
            sql_mode:
     Create Function: CREATE FUNCTION `hello`(s CHAR(20))
                      RETURNS CHAR(50)
                      RETURN CONCAT('Hello, ',s,'!')
character_set_client: latin1
collation_connection: latin1_swedish_ci
  Database Collation: latin1_swedish_ci
```

When the user issuing the statement does not have privileges on the routine, attempting to `CALL` the procedure raises Error 1370.

```
CALL test.prc1();
Error 1370 (42000): execute command denied to
  user 'test_user'@'localhost' for routine 'test'.'prc1'
```

If the user neither has privilege to the routine nor the SELECT privilege on mysql.proc table, it raises Error 1305, informing them that the procedure does not exist.

```
SHOW CREATE TABLES test.prc1\G
Error 1305 (42000): PROCEDURE prc1 does not exist
```

1.1.1.2.8.17 SHOW CREATE SEQUENCE

Syntax

```
SHOW CREATE SEQUENCE sequence_name;
```

Contents

Description

Shows the CREATE SEQUENCE statement that created the given sequence. The statement requires the `SELECT` privilege for the table.

Example

```
CREATE SEQUENCE s1 START WITH 50;
SHOW CREATE SEQUENCE s1\G;
*************************** 1. row ***************************
       Table: s1
Create Table: CREATE SEQUENCE `s1` start with 50 minvalue 1 maxvalue 9223372036854775806
  increment by 1 cache 1000 nocycle ENGINE=InnoDB
```

Notes

If you want to see the underlying table structure used for the `SEQUENCE` you can use SHOW CREATE TABLE on the `SEQUENCE`. You can also use `SELECT` to read the current recorded state of the `SEQUENCE`:

```
SHOW CREATE TABLE s1\G
*************************** 1. row ***************************
       Table: s1
Create Table: CREATE TABLE `s1` (
  `next_not_cached_value` bigint(21) NOT NULL,
  `minimum_value` bigint(21) NOT NULL,
  `maximum_value` bigint(21) NOT NULL,
  `start_value` bigint(21) NOT NULL COMMENT 'start value when sequences is created
     or value if RESTART is used',
  `increment` bigint(21) NOT NULL COMMENT 'increment value',
  `cache_size` bigint(21) unsigned NOT NULL,
  `cycle_option` tinyint(1) unsigned NOT NULL COMMENT '0 if no cycles are allowed,
     1 if the sequence should begin a new cycle when maximum_value is passed',
  `cycle_count` bigint(21) NOT NULL COMMENT 'How many cycles have been done'
) ENGINE=InnoDB SEQUENCE=1

SELECT * FROM s1\G
*************************** 1. row ***************************
next_not_cached_value: 50
        minimum_value: 1
        maximum_value: 9223372036854775806
          start_value: 50
            increment: 1
           cache_size: 1000
         cycle_option: 0
          cycle_count: 0
```

1.1.1.2.1.17 SHOW CREATE TABLE

1.1.1.2.8.19 SHOW CREATE TRIGGER

Syntax

```
SHOW CREATE TRIGGER trigger_name
```

Contents

Description

This statement shows a `CREATE TRIGGER` statement that creates the given trigger, as well as the `SQL_MODE` that was used when the trigger has been created and the character set used by the connection.

The `TRIGGER` privilege is required on the table the trigger is defined for to execute this statement.

The output of this statement is unreliably affected by the `sql_quote_show_create` server system variable - see http://bugs.mysql.com/bug.php?id=12719

Examples

```
SHOW CREATE TRIGGER example\G
*************************** 1. row ***************************
               Trigger: example
              sql_mode: ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,STRICT_ALL_TABLES
,NO_ZERO_IN_DATE,NO_ZERO_DATE,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_
ENGINE_SUBSTITUTION
SQL Original Statement: CREATE DEFINER=`root`@`localhost` TRIGGER example BEFORE
 INSERT ON t FOR EACH ROW
BEGIN
        SET NEW.c = NEW.c * 2;
END
  character_set_client: cp850
  collation_connection: cp850_general_ci
  Database Collation: utf8_general_ci
  Created: 2016-09-29 13:53:34.35
```

MariaDB starting with 10.2.3

The `Created` column was added in MySQL 5.7 and MariaDB 10.2.3 as part of introducing multiple trigger events per action.

1.1.1.1.13 SHOW CREATE USER

1.1.1.2.8.21 SHOW CREATE VIEW

Syntax

```
SHOW CREATE VIEW view_name
```

Description

This statement shows a CREATE VIEW statement that creates the given view, as well as the character set used by the connection when the view was created. This statement also works with views.

`SHOW CREATE VIEW` quotes table, column and stored function names according to the value of the sql_quote_show_create server system variable.

Examples

```
SHOW CREATE VIEW example\G
*************************** 1. row ***************************
                View: example
         Create View: CREATE ALGORITHM=UNDEFINED DEFINER=`root`@`localhost` SQL
SECURITY DEFINER VIEW `example` AS (select `t`.`id` AS `id`,`t`.`s` AS `s` from
`t`)
character_set_client: cp850
collation_connection: cp850_general_ci
```

With `sql_quote_show_create` off:

```
SHOW CREATE VIEW example\G
*************************** 1. row ***************************
                View: example
         Create View: CREATE ALGORITHM=UNDEFINED DEFINER=root@localhost SQL SECU
RITY DEFINER VIEW example AS (select t.id AS id,t.s AS s from t)
character_set_client: cp850
collation_connection: cp850_general_ci
```

Grants

To be able to see a view, you need to have the SHOW VIEW and the SELECT privilege on the view:

```
GRANT SHOW VIEW,SELECT ON test_database.test_view TO 'test'@'localhost';
```

1.1.1.2.8.22 SHOW DATABASES

Syntax

```
SHOW {DATABASES | SCHEMAS}
    [LIKE 'pattern' | WHERE expr]
```

Contents

Description

`SHOW DATABASES` lists the databases on the MariaDB server host. `SHOW SCHEMAS` is a synonym for `SHOW DATABASES`. The `LIKE` clause, if present on its own, indicates which database names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

You see only those databases for which you have some kind of privilege, unless you have the global SHOW DATABASES privilege. You can also get this list using the mariadb-show command.

If the server was started with the `--skip-show-database` option, you cannot use this statement at all unless you have the SHOW DATABASES privilege.

The list of results returned by `SHOW DATABASES` is based on directories in the data directory, which is how MariaDB implements databases. It's possible that output includes directories that do not correspond to actual databases.

The Information Schema SCHEMATA table also contains database information.

Examples

```
SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| mysql              |
| performance_schema |
| test               |
+--------------------+
```

```
SHOW DATABASES LIKE 'm%';
+---------------+
| Database (m%) |
+---------------+
| mysql         |
+---------------+
```

1.1.1.2.8.23 SHOW ENGINE

Contents

Syntax

```
SHOW ENGINE engine_name {STATUS | MUTEX}
```

Description

`SHOW ENGINE` displays operational information about a storage engine. The following statements currently are supported:

```
SHOW ENGINE INNODB STATUS
SHOW ENGINE INNODB MUTEX
SHOW ENGINE PERFORMANCE_SCHEMA STATUS
SHOW ENGINE ROCKSDB STATUS
```

If the Sphinx Storage Engine is installed, the following is also supported:

```
SHOW ENGINE SPHINX STATUS
```

See `SHOW ENGINE SPHINX STATUS`.

Older (and now removed) synonyms were `SHOW INNODB STATUS` for `SHOW ENGINE INNODB STATUS` and `SHOW MUTEX STATUS` for `SHOW ENGINE INNODB MUTEX`.

SHOW ENGINE INNODB STATUS

`SHOW ENGINE INNODB STATUS` displays extensive information from the standard InnoDB Monitor about the state of the InnoDB storage engine. See `SHOW ENGINE INNODB STATUS` for more.

SHOW ENGINE INNODB MUTEX

`SHOW ENGINE INNODB MUTEX` displays InnoDB mutex statistics.

The statement displays the following output fields:

- **Type:** Always InnoDB.
- **Name:** The source file where the mutex is implemented, and the line number in the file where the mutex is created. The line number is dependent on the MariaDB version.
- **Status:** This field displays the following values if `UNIV_DEBUG` was defined at compilation time (for example, in include/univ.h in the InnoDB part of the source tree). Only the `os_waits` value is displayed if `UNIV_DEBUG` was not defined. Without `UNIV_DEBUG`, the information on which the output is based is insufficient to distinguish regular mutexes and mutexes that protect rw-locks (which allow multiple readers or a single writer). Consequently, the output may appear to contain multiple rows for the same mutex.
  - **count** indicates how many times the mutex was requested.
  - **spin_waits** indicates how many times the spinlock had to run.
  - **spin_rounds** indicates the number of spinlock rounds. (spin_rounds divided by spin_waits provides the average round count.)
  - **os_waits** indicates the number of operating system waits. This occurs when the spinlock did not work (the mutex was not locked during the spinlock and it was necessary to yield to the operating system and wait).
  - **os_yields** indicates the number of times a the thread trying to lock a mutex gave up its timeslice and yielded to the operating system (on the presumption that allowing other threads to run will free the mutex so that it can be locked).
  - **os_wait_times** indicates the amount of time (in ms) spent in operating system waits, if the timed_mutexes system variable is 1 (ON). If timed_mutexes is 0 (OFF), timing is disabled, so os_wait_times is 0. timed_mutexes is off by default.

Information from this statement can be used to diagnose system problems. For example, large values of spin_waits and spin_rounds may indicate scalability problems.

The `information_schema.INNODB_MUTEXES` table provides similar information.

SHOW ENGINE PERFORMANCE_SCHEMA STATUS

This statement shows how much memory is used for `performance_schema` tables and internal buffers.

The output contains the following fields:

- **Type:** Always `performance_schema` .
- **Name:** The name of a table, the name of an internal buffer, or the `performance_schema` word, followed by a dot and an attribute. Internal buffers names are enclosed by parenthesis. `performance_schema` means that the attribute refers to the whole database (it is a total).
- **Status:** The value for the attribute.

The following attributes are shown, in this order, for all tables:

- **row_size:** The memory used for an individual record. This value will never change.
- **row_count:** The number of rows in the table or buffer. For some tables, this value depends on a server system variable.
- **memory:** For tables and `performance_schema` , this is the result of `row_size` * `row_count` .

For internal buffers, the attributes are:

- **count**
- **size**

SHOW ENGINE ROCKSDB STATUS

See also MyRocks Performance Troubleshooting

1.1.1.2.8.24 SHOW ENGINE INNODB STATUS

`SHOW ENGINE INNODB STATUS` is a specific form of the SHOW ENGINE statement that displays the InnoDB Monitor output, which is extensive InnoDB information which can be useful in diagnosing problems.

The following sections are displayed

- **Status:** Shows the timestamp, monitor name and the number of seconds, or the elapsed time between the current time and the time the InnoDB Monitor output was last displayed. The per-second averages are based upon this time.
- **BACKGROUND THREAD:** srv_master_thread lines show work performed by the main background thread.
- **SEMAPHORES:** Threads waiting for a semaphore and stats on how the number of times threads have needed a spin or a wait on a mutex or rw-lock semaphore. If this number of threads is large, there may be I/O or contention issues. Reducing the size of the innodb_thread_concurrency system variable may help if contention is related to thread scheduling. `Spin rounds per wait` shows the number of spinlock rounds per OS wait for a mutex.
- **LATEST FOREIGN KEY ERROR:** Only shown if there has been a foreign key constraint error, it displays the failed statement and information about the constraint and the related tables.
- **LATEST DETECTED DEADLOCK:** Only shown if there has been a deadlock, it displays the transactions involved in the deadlock and the statements being executed, held and required locked and the transaction rolled back to.
- **TRANSACTIONS:** The output of this section can help identify lock contention, as well as reasons for the deadlocks.
- **FILE I/O:** InnoDB thread information as well as pending I/O operations and I/O performance statistics.
- **INSERT BUFFER AND ADAPTIVE HASH INDEX:** InnoDB insert buffer (old name for the change buffer) and adaptive hash index status information, including the number of each type of operation performed, and adaptive hash index performance.
- **LOG:** InnoDB log information, including current log sequence number, how far the log has been flushed to disk, the position at which InnoDB last took a checkpoint, pending writes and write performance statistics.
- **BUFFER POOL AND MEMORY:** Information on buffer pool pages read and written, which allows you to see the number of data file I/O operations performed by your queries. See InnoDB Buffer Pool for more. Similar information is also available from the INFORMATION_SCHEMA.INNODB_BUFFER_POOL_STATS table.
- **ROW OPERATIONS:**Information about the main thread, including the number and performance rate for each type of row operation.

If the innodb_status_output_locks system variable is set to `1` , extended lock information will be displayed.

Example output:

```
=====================================
2019-09-06 12:44:13 0x7f93cc236700 INNODB MONITOR OUTPUT
=====================================
```

```

END OF INNODB MONITOR OUTPUT
============================
```

1.1.1.2.8.25 SHOW ENGINES

Syntax

```
SHOW [STORAGE] ENGINES
```

Description

`SHOW ENGINES` displays status information about the server's storage engines. This is particularly useful for checking whether a storage engine is supported, or to see what the default engine is. `SHOW TABLE TYPES` is a deprecated synonym.

The `information_schema.ENGINES` table provides the same information.

Since storage engines are plugins, different information about them is also shown in the `information_schema.PLUGINS` table and by the `SHOW PLUGINS` statement.

Note that both MySQL's InnoDB and Percona's XtraDB replacement are labeled as `InnoDB`. However, if XtraDB is in use, it will be specified in the `COMMENT` field. See XtraDB and InnoDB. The same applies to FederatedX.

The output consists of the following columns:

- `Engine` indicates the engine's name.
- `Support` indicates whether the engine is installed, and whether it is the default engine for the current session.
- `Comment` is a brief description.
- `Transactions`, `XA` and `Savepoints` indicate whether transactions, XA transactions and transaction savepoints are supported by the engine.

Examples

```
SHOW ENGINES\G
*************************** 1. row ***************************
      Engine: InnoDB
     Support: DEFAULT
     Comment: Supports transactions, row-level locking, and foreign keys
Transactions: YES
          XA: YES
  Savepoints: YES
*************************** 2. row ***************************
      Engine: CSV
     Support: YES
     Comment: CSV storage engine
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 3. row ***************************
      Engine: MyISAM
     Support: YES
     Comment: MyISAM storage engine
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 4. row ***************************
      Engine: BLACKHOLE
     Support: YES
     Comment: /dev/null storage engine (anything you write to it disappears)
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 5. row ***************************
      Engine: FEDERATED
     Support: YES
     Comment: FederatedX pluggable storage engine
Transactions: YES
          XA: NO
  Savepoints: YES
*************************** 6. row ***************************
      Engine: MRG_MyISAM
     Support: YES
     Comment: Collection of identical MyISAM tables
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 7. row ***************************
      Engine: ARCHIVE
     Support: YES
     Comment: Archive storage engine
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 8. row ***************************
      Engine: MEMORY
     Support: YES
     Comment: Hash based, stored in memory, useful for temporary tables
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 9. row ***************************
      Engine: PERFORMANCE_SCHEMA
     Support: YES
     Comment: Performance Schema
Transactions: NO
          XA: NO
  Savepoints: NO
*************************** 10. row ***************************
      Engine: Aria
     Support: YES
     Comment: Crash-safe tables with MyISAM heritage
Transactions: NO
          XA: NO
  Savepoints: NO
10 rows in set (0.00 sec)
```

1.1.1.2.8.26 SHOW ERRORS

Syntax

```
SHOW ERRORS [LIMIT [offset,] row_count]
SHOW ERRORS [LIMIT row_count OFFSET offset]
SHOW COUNT(*) ERRORS
```

Contents

Description

This statement is similar to SHOW WARNINGS, except that instead of displaying errors, warnings, and notes, it displays only errors.

The `LIMIT` clause has the same syntax as for the SELECT statement.

The `SHOW COUNT(*) ERRORS` statement displays the number of errors. You can also retrieve this number from the error_count variable.

```
SHOW COUNT(*) ERRORS;
SELECT @@error_count;
```

The value of error_count might be greater than the number of messages displayed by SHOW WARNINGS if the max_error_count system variable is set so low that not all messages are stored.

For a list of MariaDB error codes, see MariaDB Error Codes.

Examples

```
SELECT f();
ERROR 1305 (42000): FUNCTION f does not exist

SHOW COUNT(*) ERRORS;
+-----------------------+
| @@session.error_count |
+-----------------------+
|                     1 |
+-----------------------+

SHOW ERRORS;
+-------+------+---------------------------+
| Level | Code | Message                   |
+-------+------+---------------------------+
| Error | 1305 | FUNCTION f does not exist |
+-------+------+---------------------------+
```

1.1.1.2.8.27 SHOW EVENTS

Syntax

```
SHOW EVENTS [{FROM | IN} schema_name]
    [LIKE 'pattern' | WHERE expr]
```

Description

Shows information about Event Manager events (created with `CREATE EVENT`). Requires the `EVENT` privilege. Without any

arguments, `SHOW EVENTS` lists all of the events in the current schema:

```
SELECT CURRENT_USER(), SCHEMA();
+----------------+----------+
| CURRENT_USER() | SCHEMA() |
+----------------+----------+
| jon@ghidora    | myschema |
+----------------+----------+

SHOW EVENTS\G
*************************** 1. row ***************************
                  Db: myschema
                Name: e_daily
             Definer: jon@ghidora
           Time zone: SYSTEM
                Type: RECURRING
          Execute at: NULL
      Interval value: 10
      Interval field: SECOND
             Starts: 2006-02-09 10:41:23
               Ends: NULL
              Status: ENABLED
          Originator: 0
character_set_client: latin1
collation_connection: latin1_swedish_ci
  Database Collation: latin1_swedish_ci
```

To see the event action, use `SHOW CREATE EVENT` instead, or look at the `information_schema.EVENTS` table.

To see events for a specific schema, use the `FROM` clause. For example, to see events for the test schema, use the following statement:

```
SHOW EVENTS FROM test;
```

The `LIKE` clause, if present, indicates which event names to match. The `WHERE` clause can be given to select rows using more general conditions, as discussed in Extended Show.

4.2.2.8 SHOW FUNCTION CODE

1.1.1.2.8.29 SHOW FUNCTION STATUS

Syntax

```
SHOW FUNCTION STATUS
    [LIKE 'pattern' | WHERE expr]
```

Description

This statement is similar to `SHOW PROCEDURE STATUS` but for stored functions.

The LIKE clause, if present on its own, indicates which function names to match.

The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

The `information_schema.ROUTINES` table contains more detailed information.

Examples

Showing all stored functions:

```
SHOW FUNCTION STATUS\G
*************************** 1. row ***************************
                  Db: test
                Name: VatCents
                Type: FUNCTION
             Definer: root@localhost
            Modified: 2013-06-01 12:40:31
             Created: 2013-06-01 12:40:31
       Security_type: DEFINER
             Comment:
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

Stored functions whose name starts with 'V':

```
SHOW FUNCTION STATUS LIKE 'V%' \G
*************************** 1. row ***************************
                  Db: test
                Name: VatCents
                Type: FUNCTION
             Definer: root@localhost
            Modified: 2013-06-01 12:40:31
             Created: 2013-06-01 12:40:31
       Security_type: DEFINER
             Comment:
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

Stored functions with a security type of 'DEFINER':

```
SHOW FUNCTION STATUS WHERE Security_type LIKE 'DEFINER' \G
*************************** 1. row ***************************
                  Db: test
                Name: VatCents
                Type: FUNCTION
             Definer: root@localhost
            Modified: 2013-06-01 12:40:31
             Created: 2013-06-01 12:40:31
       Security_type: DEFINER
             Comment:
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

1.1.1.1.12 SHOW GRANTS

1.1.1.2.1.18 SHOW INDEX

1.1.1.2.8.32 SHOW INDEX_STATISTICS

Syntax

```
SHOW INDEX_STATISTICS
```

Description

The `SHOW INDEX_STATISTICS` statement was introduced in MariaDB 5.2 as part of the User Statistics feature. It was removed as a separate statement in MariaDB 10.1.1, but effectively replaced by the generic SHOW information_schema_table statement. The information_schmea.INDEX_STATISTICS table shows statistics on index usage and makes it possible to do such things as locating unused indexes and generating the commands to remove them.

The userstat system variable must be set to 1 to activate this feature. See the User Statistics and information_schema.INDEX_STATISTICS table for more information.

Example

```
SHOW INDEX_STATISTICS;
+--------------+------------------+------------+-----------+
| Table_schema | Table_name       | Index_name | Rows_read |
+--------------+------------------+------------+-----------+
| test         | employees_example | PRIMARY    |         1 |
+--------------+------------------+------------+-----------+
```

1.1.1.2.8.33 SHOW LOCALES

`SHOW LOCALES` was introduced as part of the Information Schema plugin extension.

`SHOW LOCALES` is used to return `locales` information as part of the Locales plugin. While the `information_schema.LOCALES` table has 8 columns, the `SHOW LOCALES` statement will only display 4 of them:

Example

```
SHOW LOCALES;
+-----+-------+-----------------------------------+-------------------------+
| Id  | Name  | Description                       | Error_Message_Language |
+-----+-------+-----------------------------------+-------------------------+
|   0 | en_US | English - United States           | english                 |
|   1 | en_GB | English - United Kingdom          | english                 |
|   2 | ja_JP | Japanese - Japan                  | japanese                |
|   3 | sv_SE | Swedish - Sweden                  | swedish                 |
...
```

1.1.1.2.5.8 SHOW BINLOG STATUS

1.1.1.2.8.35 SHOW OPEN TABLES

Syntax

```
SHOW OPEN TABLES [FROM db_name]
    [LIKE 'pattern' | WHERE expr]
```

Description

`SHOW OPEN TABLES` lists the non- `TEMPORARY` tables that are currently open in the table cache. See http://dev.mysql.com/doc/refman/5.1/en/table-cache.html.

The `FROM` and `LIKE` clauses may be used.

The `FROM` clause, if present, restricts the tables shown to those present in the `db_name` database.

The `LIKE` clause, if present on its own, indicates which table names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

The following information is returned:

Column	Description
Database	Database name.
Name	Table name.
In_use	Number of table instances being used.

Name_locked	`1` if the table is name-locked, e.g. if it is being dropped or renamed, otherwise `0`.

Before MariaDB 5.5, each use of, for example, LOCK TABLE ... WRITE would increment `In_use` for that table. With the implementation of the metadata locking improvements in MariaDB 5.5, `LOCK TABLE... WRITE` acquires a strong MDL lock, and concurrent connections will wait on this MDL lock, so any subsequent `LOCK TABLE... WRITE` will not increment `In_use`.

Example

```
SHOW OPEN TABLES;
+----------+----------------------------+--------+-------------+
| Database | Table                      | In_use | Name_locked |
+----------+----------------------------+--------+-------------+
...
| test     | xjson                      |      0 |           0 |
| test     | jauthor                    |      0 |           0 |
| test     | locks                      |      1 |           0 |
...
+----------+----------------------------+--------+-------------+
```

1.1.1.2.8.36 SHOW PACKAGE BODY STATUS

MariaDB starting with 10.3.5
Oracle-style packages were introduced in MariaDB 10.3.5.

Syntax

```
SHOW PACKAGE BODY STATUS
    [LIKE 'pattern' | WHERE expr]
```

Contents

Description

The `SHOW PACKAGE BODY STATUS` statement returns characteristics of stored package bodies (implementations), such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement, `SHOW PACKAGE STATUS`, displays information about stored package specifications.

The `LIKE` clause, if present, indicates which package names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

The ROUTINES table in the INFORMATION_SCHEMA database contains more detailed information.

Examples

```
SHOW PACKAGE BODY STATUS LIKE 'pkg1'\G
*************************** 1. row ***************************
                  Db: test
                Name: pkg1
                Type: PACKAGE BODY
             Definer: root@localhost
            Modified: 2018-02-27 14:44:14
             Created: 2018-02-27 14:44:14
       Security_type: DEFINER
             Comment: This is my first package body
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

1.1.1.2.8.37 SHOW PACKAGE STATUS

MariaDB starting with 10.3.5
Oracle-style packages were introduced in MariaDB 10.3.5.

Syntax

```
SHOW PACKAGE STATUS
    [LIKE 'pattern' | WHERE expr]
```

Contents

Description

The `SHOW PACKAGE STATUS` statement returns characteristics of stored package specifications, such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement, `SHOW PACKAGE BODY STATUS`, displays information about stored package bodies (i.e. implementations).

The `LIKE` clause, if present, indicates which package names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

The ROUTINES table in the INFORMATION_SCHEMA database contains more detailed information.

Examples

```
SHOW PACKAGE STATUS LIKE 'pkg1'\G
*************************** 1. row ***************************
                  Db: test
                Name: pkg1
                Type: PACKAGE
             Definer: root@localhost
            Modified: 2018-02-27 14:38:15
             Created: 2018-02-27 14:38:15
       Security_type: DEFINER
             Comment: This is my first package
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

1.1.1.2.6.1 SHOW PLUGINS

1.1.1.2.6.2 SHOW PLUGINS SONAME

1.1.1.2.8.40 SHOW PRIVILEGES

Syntax

```
SHOW PRIVILEGES
```

Description

`SHOW PRIVILEGES` shows the list of system privileges that the MariaDB server supports. The exact list of privileges depends on the version of your server.

Note that before MariaDB 10.3.23, MariaDB 10.4.13 and MariaDB 10.5.2, the Delete history privilege displays as

`Delete versioning rows` (MDEV-20382).

Example

From MariaDB 10.5.9

```
SHOW PRIVILEGES;
+--------------------------+---------------------------------------+-------------------------
-----------------------------------------+
| Privilege                | Context                               | Comment
|
+--------------------------+---------------------------------------+-------------------------
-----------------------------------------+
| Alter                    | Tables                                | To alter the table
|
| Alter routine            | Functions,Procedures                  | To alter or drop stored
functions/procedures                      |
| Create                   | Databases,Tables,Indexes              | To create new databases
and tables                                |
| Create routine           | Databases                             | To use CREATE
FUNCTION/PROCEDURE                                 |
| Create temporary tables  | Databases                             | To use CREATE TEMPORARY
TABLE                                     |
| Create view              | Tables                                | To create new views
|
| Create user              | Server Admin                          | To create new users
|
| Delete                   | Tables                                | To delete existing rows
|
| Delete history           | Tables                                | To delete versioning
table historical rows                          |
| Drop                     | Databases,Tables                      | To drop databases,
tables, and views                               |
| Event                    | Server Admin                          | To create, alter, drop
and execute events                             |
| Execute                  | Functions,Procedures                  | To execute stored routines
|
| File                     | File access on server                 | To read and write files
on the server                             |
| Grant option             | Databases,Tables,Functions,Procedures | To give to other users
those privileges you possess                   |
| Index                    | Tables                                | To create or drop indexes
|
| Insert                   | Tables                                | To insert data into
tables                                      |
| Lock tables              | Databases                             | To use LOCK TABLES
(together with SELECT privilege)                |
| Process                  | Server Admin                          | To view the plain text of
currently executing queries                |
| Proxy                    | Server Admin                          | To make proxy user
possible                                        |
| References               | Databases,Tables                      | To have references on
tables                                        |
| Reload                   | Server Admin                          | To reload or refresh
tables, logs and privileges                     |
| Binlog admin             | Server                                | To purge binary logs
|
| Binlog monitor           | Server                                | To use SHOW BINLOG STATUS
and SHOW BINARY LOG                           |
| Binlog replay            | Server                                | To use BINLOG (generated
by mariadb-binlog)                             |
| Replication master admin | Server                                | To monitor connected
slaves                                          |
| Replication slave admin  | Server                                | To start/stop slave and
apply binlog events                            |
| Slave monitor            | Server                                | To use SHOW SLAVE STATUS
and SHOW RELAYLOG EVENTS                       |
| Replication slave        | Server Admin                          | To read binary log events
from the master                               |
| Select                   | Tables                                | To retrieve rows from
table                                         |
| Show databases           | Server Admin                          | To see all databases with
SHOW DATABASES                                |
```

```
| Show view                | Tables                                  | To see views with SHOW
CREATE VIEW                                 |
| Shutdown                 | Server Admin                            | To shut down the server
|
| Super                    | Server Admin                            | To use KILL thread, SET
GLOBAL, CHANGE MASTER, etc.                 |
| Trigger                  | Tables                                  | To use triggers
|
| Create tablespace        | Server Admin                            | To create/alter/drop
tablespaces                                   |
| Update                   | Tables                                  | To update existing rows
|
| Set user                 | Server                                  | To create views and
stored routines with a different definer       |
| Federated admin          | Server                                  | To execute the CREATE
SERVER, ALTER SERVER, DROP SERVER statements |
| Connection admin         | Server                                  | To bypass connection
limits and kill other users' connections      |
| Read_only admin          | Server                                  | To perform write
operations even if @@read_only=ON                |
| Usage                    | Server Admin                            | No privileges - allow
connect only                                 |

```

1.1.1.2.8.41 SHOW PROCEDURE CODE

Syntax

```
SHOW PROCEDURE CODE proc_name
```

Contents

Description

This statement is a MariaDB extension that is available only for servers that have been built with debugging support. It displays a representation of the internal implementation of the named stored procedure. A similar statement, `SHOW FUNCTION CODE`, displays information about stored functions.

Both statements require that you be the owner of the routine or have `SELECT` access to the `mysql.proc` table.

If the named routine is available, each statement produces a result set. Each row in the result set corresponds to one "instruction" in the routine. The first column is Pos, which is an ordinal number beginning with 0. The second column is Instruction, which contains an SQL statement (usually changed from the original source), or a directive which has meaning only to the stored-routine handler.

Examples

```
DELIMITER //

CREATE PROCEDURE p1 ()
  BEGIN
    DECLARE fanta INT DEFAULT 55;
    DROP TABLE t2;
    LOOP
      INSERT INTO t3 VALUES (fanta);
      END LOOP;
  END//
Query OK, 0 rows affected (0.00 sec)

SHOW PROCEDURE CODE p1//
+-----+----------------------------------------+
| Pos | Instruction                            |
+-----+----------------------------------------+
|   0 | set fanta@0 55                         |
|   1 | stmt 9 "DROP TABLE t2"                 |
|   2 | stmt 5 "INSERT INTO t3 VALUES (fanta)" |
|   3 | jump 2                                 |
+-----+----------------------------------------+
```

1.1.1.2.8.42 SHOW PROCEDURE STATUS

Syntax

```
SHOW PROCEDURE STATUS
    [LIKE 'pattern' | WHERE expr]
```

Description

This statement is a MariaDB extension. It returns characteristics of a stored procedure, such as the database, name, type, creator, creation and modification dates, and character set information. A similar statement, `SHOW FUNCTION STATUS`, displays information about stored functions.

The `LIKE` clause, if present, indicates which procedure or function names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

The ROUTINES table in the INFORMATION_SCHEMA database contains more detailed information.

Examples

```
SHOW PROCEDURE STATUS LIKE 'p1'\G
*************************** 1. row ***************************
                  Db: test
                Name: p1
                Type: PROCEDURE
             Definer: root@localhost
            Modified: 2010-08-23 13:23:03
             Created: 2010-08-23 13:23:03
       Security_type: DEFINER
             Comment:
character_set_client: latin1
collation_connection: latin1_swedish_ci
  Database Collation: latin1_swedish_ci
```

1.1.1.2.8.43 SHOW PROCESSLIST

Syntax

```
SHOW [FULL] PROCESSLIST
```

Description

`SHOW PROCESSLIST` shows you which threads are running. You can also get this information from the information_schema.PROCESSLIST table or the mariadb-admin processlist command. If you have the `PROCESS` privilege, you can see all threads. Otherwise, you can see only your own threads (that is, threads associated with the MariaDB account that you are using). If you do not use the `FULL` keyword, only the first 100 characters of each statement are shown in the Info field.

The columns shown in `SHOW PROCESSLIST` are:

Name	Description
`ID`	The client's process ID.
`USER`	The username associated with the process.
`HOST`	The host the client is connected to.
`DB`	The default database of the process (NULL if no default).
`COMMAND`	The command type. See Thread Command Values.
`TIME`	The amount of time, in seconds, the process has been in its current state. For a replica SQL thread before MariaDB 10.1, this is the time in seconds between the last replicated event's timestamp and the replica machine's real time.
`STATE`	See Thread States.
`INFO`	The statement being executed.
`PROGRESS`	The total progress of the process (0-100%) (see Progress Reporting).

See `TIME_MS` column in information_schema.PROCESSLIST for differences in the `TIME` column between MariaDB and MySQL.

The information_schema.PROCESSLIST table contains the following additional columns:

Name	Description
`TIME_MS`	The amount of time, in milliseconds, the process has been in its current state.
`STAGE`	The stage the process is currently in.
`MAX_STAGE`	The maximum number of stages.
`PROGRESS`	The progress of the process within the current stage (0-100%).
`MEMORY_USED`	The amount of memory used by the process.
`EXAMINED_ROWS`	The number of rows the process has examined.
`QUERY_ID`	Query ID.

Note that the `PROGRESS` field from the information schema, and the `PROGRESS` field from `SHOW PROCESSLIST` display different results. `SHOW PROCESSLIST` shows the total progress, while the information schema shows the progress for the current stage only.

Threads can be killed using their thread_id or their query_id, with the KILL statement.

Since queries on this table are locking, if the performance_schema is enabled, you may want to query the `THREADS` table instead.

Examples

```
SHOW PROCESSLIST;
+----+-----------------+-----------+------+---------+------+-------------------------+--------
----------+----------+
| Id | User            | Host      | db   | Command | Time | State                   | Info
| Progress |
+----+-----------------+-----------+------+---------+------+-------------------------+--------
----------+----------+
|  2 | event_scheduler | localhost | NULL | Daemon  | 2693 | Waiting on empty queue | NULL
|    0.000 |
|  4 | root            | localhost | NULL | Query   |    0 | Table lock             | SHOW
PROCESSLIST |    0.000 |
+----+-----------------+-----------+------+---------+------+-------------------------+--------
----------+----------+
```

1.1.1.2.8.44 SHOW PROFILE

Syntax

```
SHOW PROFILE [type [, type] ... ]
    [FOR QUERY n]
    [LIMIT row_count [OFFSET offset]]

type:
    ALL
  | BLOCK IO
  | CONTEXT SWITCHES
  | CPU
  | IPC
  | MEMORY
  | PAGE FAULTS
  | SOURCE
  | SWAPS
```

Description

The `SHOW PROFILE` and `SHOW PROFILES` statements display profiling information that indicates resource usage for statements executed during the course of the current session.

Profiling is controlled by the profiling session variable, which has a default value of `0` (`OFF`). Profiling is enabled by setting profiling to `1` or `ON` :

```
SET profiling = 1;
```

`SHOW PROFILES` displays a list of the most recent statements sent to the master. The size of the list is controlled by the `profiling_history_size` session variable, which has a default value of `15` . The maximum value is `100` . Setting the value to `0` has the practical effect of disabling profiling.

All statements are profiled except `SHOW PROFILES` and `SHOW PROFILE` , so you will find neither of those statements in the profile list. Malformed statements are profiled. For example, `SHOW PROFILING` is an illegal statement, and a syntax error occurs if you try to execute it, but it will show up in the profiling list.

`SHOW PROFILE` displays detailed information about a single statement. Without the `FOR QUERY n` clause, the output pertains to the most recently executed statement. If `FOR QUERY n` is included, `SHOW PROFILE` displays information for statement *n*. The values of *n* correspond to the `Query_ID` values displayed by `SHOW PROFILES` .

The `LIMIT row_count` clause may be given to limit the output to *row_count* rows. If `LIMIT` is given, `OFFSET offset` may be added to begin the output offset rows into the full set of rows.

By default, `SHOW PROFILE` displays Status and Duration columns. The Status values are like the State values displayed by `SHOW PROCESSLIST` , although there might be some minor differences in interpretation for the two statements for some status values (see http://dev.mysql.com/doc/refman/5.6/en/thread-information.html).

Optional type values may be specified to display specific additional types of information:

- **`ALL`** displays all information
- **`BLOCK IO`** displays counts for block input and output operations

- `CONTEXT SWITCHES` displays counts for voluntary and involuntary context switches
- `CPU` displays user and system CPU usage times
- `IPC` displays counts for messages sent and received
- `MEMORY` is not currently implemented
- `PAGE FAULTS` displays counts for major and minor page faults
- `SOURCE` displays the names of functions from the source code, together with the name and line number of the file in which the function occurs
- `SWAPS` displays swap counts

Profiling is enabled per session. When a session ends, its profiling information is lost.

The `information_schema.PROFILING` table contains similar information.

Examples

```
SELECT @@profiling;
+-------------+
| @@profiling |
+-------------+
|           0 |
+-------------+

SET profiling = 1;

USE test;

DROP TABLE IF EXISTS t1;

CREATE TABLE T1 (id INT);

SHOW PROFILES;
+----------+------------+--------------------------+
| Query_ID | Duration   | Query                    |
+----------+------------+--------------------------+
|        1 | 0.00009200 | SELECT DATABASE()        |
|        2 | 0.00023800 | show databases           |
|        3 | 0.00018900 | show tables              |
|        4 | 0.00014700 | DROP TABLE IF EXISTS t1  |
|        5 | 0.24476900 | CREATE TABLE T1 (id INT) |
+----------+------------+--------------------------+

| query end            | 0.000003 | 0.000000 |   0.000000 |
| freeing items        | 0.000016 | 0.000000 |   0.000000 |
| logging slow query   | 0.000003 | 0.000000 |   0.000000 |
| cleaning up          | 0.000003 | 0.000000 |   0.000000 |
+----------------------+----------+----------+------------+
```

1.1.1.2.8.45 SHOW PROFILES

Syntax

```
SHOW PROFILES
```

Description

The `SHOW PROFILES` statement displays profiling information that indicates resource usage for statements executed during the course of the current session. It is used together with `SHOW PROFILE`.

1.1.1.2.8.46 SHOW QUERY_RESPONSE_TIME

It is possible to use `SHOW QUERY_RESPONSE_TIME` as an alternative for retrieving information from the QUERY_RESPONSE_TIME plugin.

This was introduced as part of the Information Schema plugin extension.

1.1.1.2.5.6 SHOW RELAYLOG EVENTS

1.1.1.2.5.9 SHOW REPLICA HOSTS

1.1.1.2.5.7 SHOW REPLICA STATUS

1.1.1.2.8.50 SHOW STATUS

Syntax

```
SHOW [GLOBAL | SESSION] STATUS
    [LIKE 'pattern' | WHERE expr]
```

Description

`SHOW STATUS` provides server status information. This information also can be obtained using the mariadb-admin extended-status command, or by querying the Information Schema GLOBAL_STATUS and SESSION_STATUS tables. The `LIKE` clause, if present, indicates which variable names to match. The `WHERE` clause can be given to select rows using more general conditions.

With the `GLOBAL` modifier, `SHOW STATUS` displays the status values for all connections to MariaDB. With `SESSION`, it displays the status values for the current connection. If no modifier is present, the default is `SESSION`. `LOCAL` is a synonym for `SESSION`. If you see a lot of 0 values, the reason is probably that you have used `SHOW STATUS` with a new connection instead of `SHOW GLOBAL STATUS`.

Some status variables have only a global value. For these, you get the same value for both `GLOBAL` and `SESSION`.

See Server Status Variables for a full list, scope and description of the variables that can be viewed with `SHOW STATUS`.

The `LIKE` clause, if present on its own, indicates which variable name to match.

The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

Examples

```
SHOW GLOBAL STATUS;
+-----------------------------------------------------------------+----------------------------
----------+
| Variable_name                                                   | Value
|
+-----------------------------------------------------------------+----------------------------
----------+
| Aborted_clients                                                 | 0
|
| Aborted_connects                                                | 0
|
| Access_denied_errors                                            | 0
|
| Acl_column_grants                                               | 0

+------------------------+--------+
8 rows in set (0.00 sec)
```

1.1.1.2.8.51 SHOW TABLE STATUS

Syntax

```
SHOW TABLE STATUS [{FROM | IN} db_name]
    [LIKE 'pattern' | WHERE expr]
```

Contents

Description

`SHOW TABLE STATUS` works like SHOW TABLES, but provides more extensive information about each table (until MariaDB 11.2.0, only non-TEMPORARY tables are shown).

The `LIKE` clause, if present on its own, indicates which table names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

The following information is returned:

Column	Description
Name	Table name.
Engine	Table storage engine.
Version	Version number from the table's .frm file.
Row_format	Row format (see InnoDB, Aria and MyISAM row formats).
Rows	Number of rows in the table. Some engines, such as InnoDB may store an estimate.
Avg_row_length	Average row length in the table.
Data_length	For InnoDB, the index size, in pages, multiplied by the page size. For Aria and MyISAM, length of the data file, in bytes. For MEMORY, the approximate allocated memory.
Max_data_length	Maximum length of the data file, ie the total number of bytes that could be stored in the table. Not used in InnoDB.
Index_length	Length of the index file.
Data_free	Bytes allocated but unused. For InnoDB tables in a shared tablespace, the free space of the shared tablespace with small safety margin. An estimate in the case of partitioned tables - see the PARTITIONS table.
Auto_increment	Next AUTO_INCREMENT value.
Create_time	Time the table was created. Some engines just return the ctime information from the file system layer here, in that case the value is not necessarily the table creation time but rather the time the file system metadata for it had last changed.
Update_time	Time the table was last updated. On Windows, the timestamp is not updated on update, so MyISAM values will be inaccurate. In InnoDB, if shared tablespaces are used, will be `NULL`, while buffering can also delay the update, so the value will differ from the actual time of the last `UPDATE`, `INSERT` or `DELETE`.
Check_time	Time the table was last checked. Not kept by all storage engines, in which case will be `NULL`.
Collation	Character set and collation.
Checksum	Live checksum value, if any.
Create_options	Extra CREATE TABLE options.
Comment	Table comment provided when MariaDB created the table.
Max_index_length	Maximum index length (supported by MyISAM and Aria tables).
Temporary	Until MariaDB 11.2.0, placeholder to signal that a table is a temporary table and always "N", except "Y" for generated information_schema tables and NULL for views. From MariaDB 11.2.0, will also be set to "Y" for local temporary tables.

Similar information can be found in the information_schema.TABLES table as well as by using mariadb-show:

```
mariadb-show --status db_name
```

Views

For views, all columns in `SHOW TABLE STATUS` are `NULL` except 'Name' and 'Comment'

Example

```
show table status\G
*************************** 1. row ***************************
           Name: bus_routes
         Engine: InnoDB
        Version: 10
     Row_format: Dynamic
           Rows: 5
 Avg_row_length: 3276
    Data_length: 16384
Max_data_length: 0
   Index_length: 0
      Data_free: 0
 Auto_increment: NULL
    Create_time: 2017-05-24 11:17:46
    Update_time: NULL
     Check_time: NULL
      Collation: latin1_swedish_ci
       Checksum: NULL
 Create_options:
        Comment:
```

1.1.1.2.8.52 SHOW TABLES

Syntax

```
SHOW [FULL] TABLES [FROM db_name]
    [LIKE 'pattern' | WHERE expr]
```

Contents

Description

`SHOW TABLES` lists the tables (until MariaDB 11.2.0, only non- `TEMPORARY` tables are shown), sequences and views in a given database.

The `LIKE` clause, if present on its own, indicates which table names to match. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW. For example, when searching for tables in the `test` database, the column name for use in the `WHERE` and `LIKE` clauses will be `Tables_in_test`

The `FULL` modifier is supported such that `SHOW FULL TABLES` displays a second output column. Values for the second column, `Table_type`, are `BASE TABLE` for a table, `VIEW` for a view and `SEQUENCE` for a sequence.

You can also get this information using:

```
mariadb-show db_name
```

See mariadb-show for more details.

If you have no privileges for a base table or view, it does not show up in the output from `SHOW TABLES` or `mariadb-show db_name`.

The information_schema.TABLES table, as well as the SHOW TABLE STATUS statement, provide extended information about tables.

Examples

```
SHOW TABLES;
+----------------------+
| Tables_in_test       |
+----------------------+
| animal_count         |
| animals              |
| are_the_mooses_loose |
| aria_test2           |
| t1                   |
| view1                |
+----------------------+
```

Showing the tables beginning with *a* only.

```
SHOW TABLES WHERE Tables_in_test LIKE 'a%';
+----------------------+
| Tables_in_test       |
+----------------------+
| animal_count         |
| animals              |
| are_the_mooses_loose |
| aria_test2           |
+----------------------+
```

Showing tables and table types:

```
SHOW FULL TABLES;
+----------------+------------+
| Tables_in_test | Table_type |
+----------------+------------+
| s1             | SEQUENCE   |
| student        | BASE TABLE |
| v1             | VIEW       |
+----------------+------------+
```

Showing temporary tables: <= MariaDB 11.1

```
CREATE TABLE t (t int(11));
CREATE TEMPORARY TABLE t (t int(11));
CREATE TEMPORARY TABLE te (t int(11));

SHOW TABLES;
+----------------+
| Tables_in_test |
+----------------+
| t              |
+----------------+
```

From MariaDB 11.2.0:

```
CREATE TABLE t (t int(11));
CREATE TEMPORARY TABLE t (t int(11));
CREATE TEMPORARY TABLE te (t int(11));

SHOW TABLES;
+----------------+
| Tables_in_test |
+----------------+
| te             |
| t              |
| t              |
+----------------+
```

1.1.1.2.8.53 SHOW TABLE_STATISTICS

Syntax

```
SHOW TABLE_STATISTICS
```

Description

The `SHOW TABLE_STATISTICS` statementis part of the User Statistics feature. It was removed as a separate statement in MariaDB 10.1.1, but effectively replaced by the generic SHOW information_schema_table statement. The information_schema.TABLE_STATISTICS table shows statistics on table usage

The userstat system variable must be set to 1 to activate this feature. See the User Statistics and information_schema.TABLE_STATISTICS articles for more information.

Example

```
SHOW TABLE_STATISTICS\G
*************************** 1. row ***************************
           Table_schema: mysql
             Table_name: proxies_priv
              Rows_read: 2
           Rows_changed: 0
Rows_changed_x_#indexes: 0
*************************** 2. row ***************************
           Table_schema: test
             Table_name: employees_example
              Rows_read: 7
           Rows_changed: 0
Rows_changed_x_#indexes: 0
*************************** 3. row ***************************
           Table_schema: mysql
             Table_name: user
              Rows_read: 16
           Rows_changed: 0
Rows_changed_x_#indexes: 0
*************************** 4. row ***************************
           Table_schema: mysql
             Table_name: db
              Rows_read: 2
           Rows_changed: 0
Rows_changed_x_#indexes: 0
```

1.1.1.2.8.54 SHOW TRIGGERS

Syntax

```
SHOW TRIGGERS [FROM db_name]
    [LIKE 'pattern' | WHERE expr]
```

Contents

Description

`SHOW TRIGGERS` lists the triggers currently defined for tables in a database (the default database unless a `FROM` clause is given). This statement requires the `TRIGGER` privilege (prior to MySQL 5.1.22, it required the `SUPER` privilege).

The `LIKE` clause, if present on its own, indicates which table names to match and causes the statement to display triggers for those tables. The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

Similar information is stored in the `information_schema.TRIGGERS` table.

MariaDB starting with 10.2.3

If there are multiple triggers for the same action, then the triggers are shown in action order.

Examples

For the trigger defined at Trigger Overview:

```
SHOW triggers Like 'animals' \G
*************************** 1. row ***************************
             Trigger: the_mooses_are_loose
               Event: INSERT
               Table: animals
           Statement: BEGIN
 IF NEW.name = 'Moose' THEN
  UPDATE animal_count SET animal_count.animals = animal_count.animals+100;
 ELSE
  UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
 END IF;
END
              Timing: AFTER
             Created: 2016-09-29 13:53:34.35
            sql_mode:
             Definer: root@localhost
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

Listing all triggers associated with a certain table:

```
SHOW TRIGGERS FROM test WHERE `Table` = 'user' \G
*************************** 1. row ***************************
             Trigger: user_ai
               Event: INSERT
               Table: user
           Statement: BEGIN END
              Timing: AFTER
             Created:  2016-09-29 13:53:34.35
            sql_mode:
             Definer: root@%
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

```
SHOW triggers WHERE Event Like 'Insert' \G
*************************** 1. row ***************************
             Trigger: the_mooses_are_loose
               Event: INSERT
               Table: animals
           Statement: BEGIN
 IF NEW.name = 'Moose' THEN
  UPDATE animal_count SET animal_count.animals = animal_count.animals+100;
 ELSE
  UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
 END IF;
END
              Timing: AFTER
             Created: 2016-09-29 13:53:34.35
            sql_mode:
             Definer: root@localhost
character_set_client: utf8
collation_connection: utf8_general_ci
  Database Collation: latin1_swedish_ci
```

- `character_set_client` is the session value of the `character_set_client` system variable when the trigger was created.
- `collation_connection` is the session value of the `collation_connection` system variable when the trigger was created.
- `Database Collation` is the collation of the database with which the trigger is associated.

These columns were added in MariaDB/MySQL 5.1.21.

Old triggers created before MySQL 5.7 and MariaDB 10.2.3 has NULL in the `Created` column.

1.1.1.2.8.55 SHOW USER_STATISTICS

Syntax

```
SHOW USER_STATISTICS
```

Description

The `SHOW USER_STATISTICS` statement is part of the User Statistics feature. It was removed as a separate statement in MariaDB 10.1.1, but effectively replaced by the generic SHOW information_schema_table statement. The information_schema.USER_STATISTICS table holds statistics about user activity. You can use this table to find out such things as which user is causing the most load and which users are being abusive. You can also use this table to measure how close to capacity the server may be.

The userstat system variable must be set to 1 to activate this feature. See the User Statistics and information_schema.USER_STATISTICS table for more information.

Example

```
SHOW USER_STATISTICS\G
*************************** 1. row ***************************
                  User: root
     Total_connections: 1
Concurrent_connections: 0
        Connected_time: 3297
             Busy_time: 0.14113400000000006
              Cpu_time: 0.017637000000000003
        Bytes_received: 969
            Bytes_sent: 22355
  Binlog_bytes_written: 0
             Rows_read: 10
             Rows_sent: 67
          Rows_deleted: 0
         Rows_inserted: 0
          Rows_updated: 0
       Select_commands: 7
       Update_commands: 0
        Other_commands: 0
   Commit_transactions: 1
 Rollback_transactions: 0
    Denied_connections: 0
      Lost_connections: 0
         Access_denied: 0
         Empty_queries: 7
```

1.1.1.2.8.56 SHOW VARIABLES

Syntax

```
SHOW [GLOBAL | SESSION] VARIABLES
    [LIKE 'pattern' | WHERE expr]
```

Contents

Description

`SHOW VARIABLES` shows the values of MariaDB system variables. This information also can be obtained using the mariadb-admin variables command. The `LIKE` clause, if present, indicates which variable names to match. The `WHERE` clause can be given to select rows using more general conditions.

With the `GLOBAL` modifier, `SHOW VARIABLES` displays the values that are used for new connections to MariaDB. With `SESSION`, it displays the values that are in effect for the current connection. If no modifier is present, the default is `SESSION`. `LOCAL` is a synonym for `SESSION`. With a `LIKE` clause, the statement displays only rows for those variables with names that match the pattern. To obtain the row for a specific variable, use a `LIKE` clause as shown:

```
SHOW VARIABLES LIKE 'maria_group_commit';
SHOW SESSION VARIABLES LIKE 'maria_group_commit';
```

To get a list of variables whose name match a pattern, use the " `%` " wildcard character in a `LIKE` clause:

```
SHOW VARIABLES LIKE '%maria%';
SHOW GLOBAL VARIABLES LIKE '%maria%';
```

Wildcard characters can be used in any position within the pattern to be matched. Strictly speaking, because " `_` " is a wildcard that matches any single character, you should escape it as " `\_` " to match it literally. In practice, this is rarely necessary.

The `WHERE` and `LIKE` clauses can be given to select rows using more general conditions, as discussed in Extended SHOW.

See `SET` for information on setting server system variables.

See Server System Variables for a list of all the variables that can be set.

You can also see the server variables by querying the Information Schema GLOBAL_VARIABLES and SESSION_VARIABLES tables.

Examples

```
SHOW VARIABLES LIKE 'aria%';
+-----------------------------------------+---------------------+
| Variable_name                           | Value               |
+-----------------------------------------+---------------------+
| aria_block_size                         | 8192                |
| aria_checkpoint_interval                | 30                  |
| aria_checkpoint_log_activity            | 1048576             |
| aria_force_start_after_recovery_failures | 0                   |
| aria_group_commit                       | none                |
| aria_group_commit_interval              | 0                   |
| aria_log_file_size                      | 1073741824          |
| aria_log_purge_type                     | immediate           |
| aria_max_sort_file_size                 | 9223372036853727232 |
| aria_page_checksum                      | ON                  |
| aria_pagecache_age_threshold            | 300                 |
| aria_pagecache_buffer_size              | 134217728           |
| aria_pagecache_division_limit           | 100                 |
| aria_recover                            | NORMAL              |

| aria_sort_buffer_size                   | 134217728           |
| aria_stats_method                       | nulls_unequal       |
| aria_sync_log_dir                       | NEWFILE             |
| aria_used_for_temp_tables               | ON                  |
+-----------------------------------------+---------------------+
```

```
SELECT VARIABLE_NAME, SESSION_VALUE, GLOBAL_VALUE FROM
  INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
  VARIABLE_NAME LIKE 'max_error_count' OR
  VARIABLE_NAME LIKE 'innodb_sync_spin_loops';
+--------------------------+---------------+--------------+
| VARIABLE_NAME            | SESSION_VALUE | GLOBAL_VALUE |
+--------------------------+---------------+--------------+
| MAX_ERROR_COUNT          | 64            | 64           |
| INNODB_SYNC_SPIN_LOOPS   | NULL          | 30           |
+--------------------------+---------------+--------------+

SET GLOBAL max_error_count=128;

SELECT VARIABLE_NAME, SESSION_VALUE, GLOBAL_VALUE FROM
  INFORMATION_SCHEMA.SYSTEM_VARIABLES WHERE
  VARIABLE_NAME LIKE 'max_error_count' OR
  VARIABLE_NAME LIKE 'innodb_sync_spin_loops';
+--------------------------+---------------+--------------+
| VARIABLE_NAME            | SESSION_VALUE | GLOBAL_VALUE |
+--------------------------+---------------+--------------+
| MAX_ERROR_COUNT          | 64            | 128          |
| INNODB_SYNC_SPIN_LOOPS   | NULL          | 30           |
+--------------------------+---------------+--------------+

SET GLOBAL max_error_count=128;

SHOW VARIABLES LIKE 'max_error_count';
+-----------------+-------+
| Variable_name   | Value |
+-----------------+-------+
| max_error_count | 64    |
+-----------------+-------+

SHOW GLOBAL VARIABLES LIKE 'max_error_count';
+-----------------+-------+
| Variable_name   | Value |
+-----------------+-------+
| max_error_count | 128   |
+-----------------+-------+
```

Because the following variable only has a global scope, the global value is returned even when specifying SESSION (in this case by default):

```
SHOW VARIABLES LIKE 'innodb_sync_spin_loops';
+------------------------+-------+
| Variable_name          | Value |
+------------------------+-------+
| innodb_sync_spin_loops | 30    |
+------------------------+-------+
```

1.1.1.2.8.57 SHOW WARNINGS

Syntax

```
SHOW WARNINGS [LIMIT [offset,] row_count]
SHOW ERRORS [LIMIT row_count OFFSET offset]
SHOW COUNT(*) WARNINGS
```

Contents

Description

`SHOW WARNINGS` shows the error, warning, and note messages that resulted from the last statement that generated messages in the current session. It shows nothing if the last statement used a table and generated no messages. (That is, a statement that uses a table but generates no messages clears the message list.) Statements that do not use tables and do not generate messages have no effect on the message list.

A note is different to a warning in that it only appears if the sql_notes variable is set to 1 (the default), and is not converted to an error if strict mode is enabled.

A related statement, `SHOW ERRORS`, shows only the errors.

The `SHOW COUNT(*) WARNINGS` statement displays the total number of errors, warnings, and notes. You can also retrieve this number from the warning_count variable:

```
SHOW COUNT(*) WARNINGS;
SELECT @@warning_count;
```

The value of warning_count might be greater than the number of messages displayed by `SHOW WARNINGS` if the max_error_count system variable is set so low that not all messages are stored.

The `LIMIT` clause has the same syntax as for the `SELECT statement`.

`SHOW WARNINGS` can be used after EXPLAIN EXTENDED to see how a query is internally rewritten by MariaDB.

If the sql_notes server variable is set to 1, Notes are included in the output of `SHOW WARNINGS`; if it is set to 0, this statement will not show (or count) Notes.

The results of `SHOW WARNINGS` and `SHOW COUNT(*) WARNINGS` are directly sent to the client. If you need to access those information in a stored program, you can use the GET DIAGNOSTICS statement instead.

For a list of MariaDB error codes, see MariaDB Error Codes.

The mariadb client also has a number of options related to warnings. The `\W` command will show warnings after every statement, while `\w` will disable this. Starting the client with the `--show-warnings` option will show warnings after every statement.

MariaDB implements a stored routine error stack trace. `SHOW WARNINGS` can also be used to show more information. See the example below.

Examples

```
SELECT 1/0;
+------+
| 1/0  |
+------+
| NULL |
+------+

SHOW COUNT(*) WARNINGS;
+--------------------------+
| @@session.warning_count |
+--------------------------+
|                        1 |
+--------------------------+

SHOW WARNINGS;
+---------+------+---------------+
| Level   | Code | Message       |
+---------+------+---------------+
| Warning | 1365 | Division by 0 |
+---------+------+---------------+
```

Stack Trace

Displaying a stack trace:

```
DELIMITER $$
CREATE OR REPLACE PROCEDURE p1()
  BEGIN
    DECLARE c CURSOR FOR SELECT * FROM not_existing;
    OPEN c;
    CLOSE c;
  END;
$$
CREATE OR REPLACE PROCEDURE p2()
  BEGIN
    CALL p1;
  END;
$$
DELIMITER ;
CALL p2;
ERROR 1146 (42S02): Table 'test.not_existing' doesn't exist

SHOW WARNINGS;
+-------+------+----------------------------------------+
| Level | Code | Message                                |
+-------+------+----------------------------------------+
| Error | 1146 | Table 'test.not_existing' doesn't exist |
| Note  | 4091 | At line 6 in test.p1                   |
| Note  | 4091 | At line 4 in test.p2                   |
+-------+------+----------------------------------------+
```

`SHOW WARNINGS` displays a stack trace, showing where the error actually happened:

- Line 4 in test.p1 is the OPEN command which actually raised the error
- Line 3 in test.p2 is the CALL statement, calling p1 from p2.

1.1.1.2.8.58 SHOW WSREP_MEMBERSHIP

`SHOW WSREP_MEMBERSHIP` is part of the `WSREP_INFO` plugin.

Syntax

```
SHOW WSREP_MEMBERSHIP
```

Description

The `SHOW WSREP_MEMBERSHIP` statement returns Galera node cluster membership information. It returns the same information as found in the `information_schema.WSREP_MEMBERSHIP` table. Only users with the `SUPER` privilege can access this information.

Examples

```
SHOW WSREP_MEMBERSHIP;
+-------+--------------------------------------+----------+-----------------+
| Index | Uuid                                 | Name     | Address         |
+-------+--------------------------------------+----------+-----------------+
|     0 | 19058073-8940-11e4-8570-16af7bf8fced | my_node1 | 10.0.2.15:16001 |
|     1 | 19f2b0e0-8942-11e4-9cb8-b39e8ee0b5dd | my_node3 | 10.0.2.15:16003 |
|     2 | d85e62db-8941-11e4-b1ef-4bc9980e476d | my_node2 | 10.0.2.15:16002 |
+-------+--------------------------------------+----------+-----------------+
```

1.1.1.2.8.59 SHOW WSREP_STATUS

`SHOW WSREP_STATUS` is part of the `WSREP_INFO` plugin.

Syntax

```
SHOW WSREP_STATUS
```

Description

The `SHOW WSREP_STATUS` statement returns Galera node and cluster status information. It returns the same information as found in the `information_schema.WSREP_STATUS` table. Only users with the `SUPER` privilege can access this information.

Examples

```
SHOW WSREP_STATUS;
+------------+-------------+----------------+--------------+
| Node_Index | Node_Status | Cluster_Status | Cluster_Size |
+------------+-------------+----------------+--------------+
|          0 | Synced      | Primary        |            3 |
+------------+-------------+----------------+--------------+
```

1.1.1.2.9.1.1.1.1 Information Schema INNODB_BUFFER_PAGE Table

The Information Schema `INNODB_BUFFER_PAGE` table contains information about pages in the buffer pool.

The `PROCESS` privilege is required to view the table.

It has the following columns:

Column	Description
`POOL_ID`	Buffer Pool identifier. From MariaDB 10.5.1 returns a value of 0, since multiple InnoDB buffer pool instances has been removed.
`BLOCK_ID`	Buffer Pool Block identifier.
`SPACE`	Tablespace identifier. Matches the `SPACE` value in the `INNODB_SYS_TABLES` table.
`PAGE_NUMBER`	Buffer pool page number.
`PAGE_TYPE`	Page type; one of `allocated` (newly-allocated page), `index` (B-tree node), `undo_log` (undo log page), `inode` (index node), `ibuf_free_list` (insert buffer free list), `ibuf_bitmap` (insert buffer bitmap), `system` (system page), `trx_system` (transaction system data), `file_space_header` (file space header), `extent_descriptor` (extent descriptor page), `blob` (uncompressed blob page), `compressed_blob` (first compressed blob page), `compressed_blob2` (subsequent compressed blob page) or `unknown`.
`FLUSH_TYPE`	Flush type.
`FIX_COUNT`	Count of the threads using this block in the buffer pool. When it is zero, the block can be evicted from the buffer pool.
`IS_HASHED`	Whether or not a hash index has been built on this page.
`NEWEST_MODIFICATION`	Most recent modification's Log Sequence Number.
`OLDEST_MODIFICATION`	Oldest modification's Log Sequence Number.
`ACCESS_TIME`	Abstract number representing the time the page was first accessed.
`TABLE_NAME`	Table that the page belongs to.
`INDEX_NAME`	Index that the page belongs to, either a clustered index or a secondary index.
`NUMBER_RECORDS`	Number of records the page contains.
`DATA_SIZE`	Size in bytes of all the records contained in the page.
`COMPRESSED_SIZE`	Compressed size in bytes of the page, or `NULL` for pages that aren't compressed.
`PAGE_STATE`	Page state; one of `FILE_PAGE` (page from a file) or `MEMORY` (page from an in-memory object) for valid data, or one of `NULL`, `READY_FOR_USE`, `NOT_USED`, `REMOVE_HASH`.
`IO_FIX`	Whether there is I/O pending for the page; one of `IO_NONE` (no pending I/O), `IO_READ` (read pending), `IO_WRITE` (write pending).
`IS_OLD`	Whether the page is old or not.
`FREE_PAGE_CLOCK`	Freed_page_clock counter, which tracks the number of blocks removed from the end of the least recently used (LRU) list, at the time the block was last placed at the head of the list.

The related INFORMATION_SCHEMA.INNODB_BUFFER_PAGE_LRU table contains the same information, but with an LRU (least recently used) position rather than block id.

Examples

```
DESC information_schema.innodb_buffer_page;
+--------------------+---------------------+------+-----+---------+-------+
| Field              | Type                | Null | Key | Default | Extra |
+--------------------+---------------------+------+-----+---------+-------+
| POOL_ID            | bigint(21) unsigned | NO   |     | 0       |       |
| BLOCK_ID           | bigint(21) unsigned | NO   |     | 0       |       |
| SPACE              | bigint(21) unsigned | NO   |     | 0       |       |
| PAGE_NUMBER        | bigint(21) unsigned | NO   |     | 0       |       |
| PAGE_TYPE          | varchar(64)         | YES  |     | NULL    |       |
| FLUSH_TYPE         | bigint(21) unsigned | NO   |     | 0       |       |
| FIX_COUNT          | bigint(21) unsigned | NO   |     | 0       |       |
| IS_HASHED          | varchar(3)          | YES  |     | NULL    |       |
| NEWEST_MODIFICATION | bigint(21) unsigned | NO   |     | 0       |       |
| OLDEST_MODIFICATION | bigint(21) unsigned | NO   |     | 0       |       |
| ACCESS_TIME        | bigint(21) unsigned | NO   |     | 0       |       |
| TABLE_NAME         | varchar(1024)       | YES  |     | NULL    |       |
| INDEX_NAME         | varchar(1024)       | YES  |     | NULL    |       |
| NUMBER_RECORDS     | bigint(21) unsigned | NO   |     | 0       |       |
| DATA_SIZE          | bigint(21) unsigned | NO   |     | 0       |       |
| COMPRESSED_SIZE    | bigint(21) unsigned | NO   |     | 0       |       |
| PAGE_STATE         | varchar(64)         | YES  |     | NULL    |       |
| IO_FIX             | varchar(64)         | YES  |     | NULL    |       |
| IS_OLD             | varchar(3)          | YES  |     | NULL    |       |
| FREE_PAGE_CLOCK    | bigint(21) unsigned | NO   |     | 0       |       |
+--------------------+---------------------+------+-----+---------+-------+
```

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_BUFFER_PAGE\G
...
*************************** 6. row ***************************
            POOL_ID: 0
          BLOCK_ID: 5
             SPACE: 0
       PAGE_NUMBER: 11
         PAGE_TYPE: INDEX
        FLUSH_TYPE: 1
         FIX_COUNT: 0
         IS_HASHED: NO
NEWEST_MODIFICATION: 2046835

...
```

1.1.1.2.9.1.1.1.2 Information Schema INNODB_BUFFER_PAGE_LRU Table

The Information Schema `INNODB_BUFFER_PAGE_LRU` table contains information about pages in the buffer pool and how they are ordered for eviction purposes.

The `PROCESS` privilege is required to view the table.

It has the following columns:

Column	Description
`POOL_ID`	Buffer Pool identifier. From MariaDB 10.5.1 returns a value of 0, since multiple InnoDB buffer pool instances has been removed.
`LRU_POSITION`	LRU (Least recently-used), for determining eviction order from the buffer pool.
`SPACE`	Tablespace identifier. Matches the `SPACE` value on the `INNODB_SYS_TABLES` table.

PAGE_NUMBER	Buffer pool page number.
PAGE_TYPE	Page type; one of `allocated` (newly-allocated page), `index` (B-tree node), `undo_log` (undo log page), `inode` (index node), `ibuf_free_list` (insert buffer free list), `ibuf_bitmap` (insert buffer bitmap), `system` (system page), `trx_system` (transaction system data), `file_space_header` (file space header), `extent_descriptor` (extent descriptor page), `blob` (uncompressed blob page), `compressed_blob` (first compressed blob page), `compressed_blob2` (subsequent compressed blob page) or `unknown` .
FLUSH_TYPE	Flush type.
FIX_COUNT	Count of the threads using this block in the buffer pool. When it is zero, the block can be evicted from the buffer pool.
IS_HASHED	Whether or not a hash index has been built on this page.
NEWEST_MODIFICATION	Most recent modification's Log Sequence Number.
OLDEST_MODIFICATION	Oldest modification's Log Sequence Number.
ACCESS_TIME	Abstract number representing the time the page was first accessed.
TABLE_NAME	Table that the page belongs to.
INDEX_NAME	Index that the page belongs to, either a clustered index or a secondary index.
NUMBER_RECORDS	Number of records the page contains.
DATA_SIZE	Size in bytes of all the records contained in the page.
COMPRESSED_SIZE	Compressed size in bytes of the page, or `NULL` for pages that aren't compressed.
PAGE_STATE	Page state; one of `FILE_PAGE` (page from a file) or `MEMORY` (page from an in-memory object) for valid data, or one of `NULL` , `READY_FOR_USE` , `NOT_USED` , `REMOVE_HASH` .
IO_FIX	Whether there is I/O pending for the page; one of `IO_NONE` (no pending I/O), `IO_READ` (read pending), `IO_WRITE` (write pending).
IS_OLD	Whether the page is old or not.
FREE_PAGE_CLOCK	Freed_page_clock counter, which tracks the number of blocks removed from the end of the LRU list, at the time the block was last placed at the head of the list.

The related INFORMATION_SCHEMA.INNODB_BUFFER_PAGE table contains the same information, but with a block id rather than LRU position.

Example

```
DESC information_schema.innodb_buffer_page_lru;
+---------------------+---------------------+------+-----+---------+-------+
| Field               | Type                | Null | Key | Default | Extra |
+---------------------+---------------------+------+-----+---------+-------+
| POOL_ID             | bigint(21) unsigned | NO   |     | 0       |       |
| LRU_POSITION        | bigint(21) unsigned | NO   |     | 0       |       |
| SPACE               | bigint(21) unsigned | NO   |     | 0       |       |
| PAGE_NUMBER         | bigint(21) unsigned | NO   |     | 0       |       |
| PAGE_TYPE           | varchar(64)         | YES  |     | NULL    |       |
| FLUSH_TYPE          | bigint(21) unsigned | NO   |     | 0       |       |
| FIX_COUNT           | bigint(21) unsigned | NO   |     | 0       |       |
| IS_HASHED           | varchar(3)          | YES  |     | NULL    |       |
| NEWEST_MODIFICATION | bigint(21) unsigned | NO   |     | 0       |       |
| OLDEST_MODIFICATION | bigint(21) unsigned | NO   |     | 0       |       |
| ACCESS_TIME         | bigint(21) unsigned | NO   |     | 0       |       |
| TABLE_NAME          | varchar(1024)       | YES  |     | NULL    |       |

1.1.1.2.9.1.1.1.3 Information Schema INNODB_BUFFER_POOL_PAGES Table

The Information Schema `INNODB_BUFFER_POOL_PAGES` table is a Percona enhancement, and is only available for XtraDB, not InnoDB (see XtraDB and InnoDB). It contains a record for each page in the buffer pool.

It has the following columns:

Column	Description
`PAGE_TYPE`	Type of page; one of `index`, `undo_log`, `inode`, `ibuf_free_list`, `allocated`, `bitmap`, `sys`, `trx_sys`, `fsp_hdr`, `xdes`, `blob`, `zblob`, `zblob2` and `unknown`.
`SPACE_ID`	Tablespace ID.
`PAGE_NO`	Page offset within tablespace.
`LRU_POSITION`	Page position in the LRU (least-recently-used) list.
`FIX_COUNT`	Page reference count, incremented each time the page is accessed. `0` if the page is not currently being accessed.
`FLUSH_TYPE`	Flush type of the most recent flush. `0` (LRU), `2` (flush_list)

1.1.1.2.9.1.1.1.4 Information Schema INNODB_BUFFER_POOL_PAGES_BLOB Table

The Information Schema `INNODB_BUFFER_POOL_PAGES_BLOB` table is a Percona enchancement, and is only available for XtraDB, not InnoDB (see XtraDB and InnoDB). It contains information about buffer pool blob pages.

It has the following columns:

Column	Description
`SPACE_ID`	Tablespace ID.
`PAGE_NO`	Page offset within tablespace.
`COMPRESSED`	`1` if the blob contains compressed data, `0` if not.
`PART_LEN`	Page data length.

NEXT_PAGE_NO	Next page number.
LRU_POSITION	Page position in the LRU (least-recently-used) list.
FIX_COUNT	Page reference count, incremented each time the page is accessed. 0 if the page is not currently being accessed.
FLUSH_TYPE	Flush type of the most recent flush. 0 (LRU), 2 (flush_list)

1.1.1.2.9.1.1.1.5 Information Schema INNODB_BUFFER_POOL_PAGES_INDEX Table

The Information Schema INNODB_BUFFER_POOL_PAGES table is a Percona enhancement, and is only available for XtraDB, not InnoDB (see XtraDB and InnoDB). It contains information about buffer pool index pages.

It has the following columns:

Column	Description
INDEX_ID	Index name
SPACE_ID	Tablespace ID
PAGE_NO	Page offset within tablespace.
N_RECS	Number of user records on the page.
DATA_SIZE	Total data size in bytes of records in the page.
HASHED	1 if the block is in the adaptive hash index, 0 if not.
ACCESS_TIME	Page's last access time.
MODIFIED	1 if the page has been modified since being loaded, 0 if not.
DIRTY	1 if the page has been modified since it was last flushed, 0 if not
OLD	1 if the page in the in the *old* blocks of the LRU (least-recently-used) list, 0 if not.
LRU_POSITION	Position in the LRU (least-recently-used) list.
FIX_COUNT	Page reference count, incremented each time the page is accessed. 0 if the page is not currently being accessed.
FLUSH_TYPE	Flush type of the most recent flush. 0 (LRU), 2 (flush_list)

1.1.1.2.9.1.1.1.6 Information Schema INNODB_BUFFER_POOL_STATS Table

The Information Schema INNODB_BUFFER_POOL_STATS table contains information about pages in the buffer pool, similar to what is returned with the SHOW ENGINE INNODB STATUS statement.

The PROCESS privilege is required to view the table.

It has the following columns:

Column	Description
POOL_ID	Buffer Pool identifier. From MariaDB 10.5.1 returns a value of 0, since multiple InnoDB buffer pool instances has been removed.
POOL_SIZE	Size in pages of the buffer pool.
FREE_BUFFERS	Number of free pages in the buffer pool.
DATABASE_PAGES	Total number of pages in the buffer pool.
OLD_DATABASE_PAGES	Number of pages in the *old* sublist.

MODIFIED_DATABASE_PAGES	Number of dirty pages.
PENDING_DECOMPRESS	Number of pages pending decompression.
PENDING_READS	Pending buffer pool level reads.
PENDING_FLUSH_LRU	Number of pages in the LRU pending flush.
PENDING_FLUSH_LIST	Number of pages in the flush list pending flush.
PAGES_MADE_YOUNG	Pages moved from the *old* sublist to the *new* sublist.
PAGES_NOT_MADE_YOUNG	Pages that have remained in the *old* sublist without moving to the *new* sublist.
PAGES_MADE_YOUNG_RATE	Hits that cause blocks to move to the top of the *new* sublist.
PAGES_MADE_NOT_YOUNG_RATE	Hits that do not cause blocks to move to the top of the *new* sublist due to the `innodb_old_blocks` delay not being met.
NUMBER_PAGES_READ	Number of pages read.
NUMBER_PAGES_CREATED	Number of pages created.
NUMBER_PAGES_WRITTEN	Number of pages written.
PAGES_READ_RATE	Number of pages read since the last printout divided by the time elapsed, giving pages read per second.
PAGES_CREATE_RATE	Number of pages created since the last printout divided by the time elapsed, giving pages created per second.
PAGES_WRITTEN_RATE	Number of pages written since the last printout divided by the time elapsed, giving pages written per second.
NUMBER_PAGES_GET	Number of logical read requests.
HIT_RATE	Buffer pool hit rate.
YOUNG_MAKE_PER_THOUSAND_GETS	For every 1000 gets, the number of pages made young.
NOT_YOUNG_MAKE_PER_THOUSAND_GETS	For every 1000 gets, the number of pages not made young.
NUMBER_PAGES_READ_AHEAD	Number of pages read ahead.
NUMBER_READ_AHEAD_EVICTED	Number of pages read ahead by the read-ahead thread that were later evicted without being accessed by any queries.
READ_AHEAD_RATE	Pages read ahead since the last printout divided by the time elapsed, giving read-ahead rate per second.
READ_AHEAD_EVICTED_RATE	Read-ahead pages not accessed since the last printout divided by time elapsed, giving the number of read-ahead pages evicted without access per second.
LRU_IO_TOTAL	Total least-recently used I/O.
LRU_IO_CURRENT	Least-recently used I/O for the current interval.
UNCOMPRESS_TOTAL	Total number of pages decompressed.
UNCOMPRESS_CURRENT	Number of pages decompressed in the current interval

Examples

```
DESC information_schema.innodb_buffer_pool_stats;

+---------------------------------+---------------------+------+-----+---------+-------+
```

1.1.1.2.9.1.1.1.7 Information Schema INNODB_CHANGED_PAGES Table

The Information Schema `INNODB_CHANGED_PAGES` Table contains data about modified pages from the bitmap file. It is updated at checkpoints by the log tracking thread parsing the log, so does not contain real-time data.

The number of records is limited by the value of the innodb_max_changed_pages system variable.

The `PROCESS` privilege is required to view the table.

It has the following columns:

Column	Description
`SPACE_ID`	Modified page space id
`PAGE_ID`	Modified page id
`START_LSN`	Interval start after which page was changed (equal to checkpoint LSN)
`END_LSN`	Interval end before which page was changed (equal to checkpoint LSN)

1.1.1.2.9.1.1.1.8 Information Schema INNODB_CMP and INNODB_CMP_RESET Tables

The `INNODB_CMP` and `INNODB_CMP_RESET` tables contain status information on compression operations related to compressed XtraDB/InnoDB tables.

The `PROCESS` privilege is required to query this table.

These tables contain the following columns:

Column Name	Description
`PAGE_SIZE`	Compressed page size, in bytes. This value is unique in the table; other values are totals which refer to pages of this size.
`COMPRESS_OPS`	How many times a page of the size `PAGE_SIZE` has been compressed. This happens when a new page is created because the compression log runs out of space. This value includes both successful operations and *compression failures*.
`COMPRESS_OPS_OK`	How many times a page of the size `PAGE_SIZE` has been successfully compressed. This value should be as close as possible to `COMPRESS_OPS`. If it is notably lower, either avoid compressing some tables, or increase the `KEY_BLOCK_SIZE` for some compressed tables.
`COMPRESS_TIME`	Time (in seconds) spent to compress pages of the size `PAGE_SIZE`. This value includes time spent in *compression failures*.
`UNCOMPRESS_OPS`	How many times a page of the size `PAGE_SIZE` has been uncompressed. This happens when an uncompressed version of a page is created in the buffer pool, or when a *compression failure* occurs.
`UNCOMPRESS_TIME`	Time (in seconds) spent to uncompress pages of the size `PAGE_SIZE`.

These tables can be used to measure the effectiveness of XtraDB/InnoDB table compression. When you have to decide a value for `KEY_BLOCK_SIZE`, you can create more than one version of the table (one for each candidate value) and run a realistic workload on them. Then, these tables can be used to see how the operations performed with different page sizes.

`INNODB_CMP` and `INNODB_CMP_RESET` have the same columns and always contain the same values, but when `INNODB_CMP_RESET` is queried, both the tables are cleared. `INNODB_CMP_RESET` can be used, for example, if a script periodically logs the performances of compression in the last period of time. `INNODB_CMP` can be used to see the cumulated statistics.

Examples

```
SELECT * FROM information_schema.INNODB_CMP\G
*************************** 1. row ***************************
      page_size: 1024
   compress_ops: 0
compress_ops_ok: 0
  compress_time: 0
 uncompress_ops: 0
uncompress_time: 0
...
```

1.1.1.2.9.1.1.1.9 Information Schema INNODB_CMPMEM and INNODB_CMPMEM_RESET Tables

The `INNODB_CMPMEM` and `INNODB_CMPMEM_RESET` tables contain status information on compressed pages in the buffer pool (see InnoDB COMPRESSED format).

The PROCESS privilege is required to query this table.

These tables contain the following columns:

Column Name	Description
`PAGE_SIZE`	Compressed page size, in bytes. This value is unique in the table; other values are totals which refer to pages of this size.
`BUFFER_POOL_INSTANCE`	Buffer Pool identifier. From MariaDB 10.5.1 returns a value of 0, since multiple InnoDB buffer pool instances has been removed.
`PAGES_USED`	Number of pages of the size `PAGE_SIZE` which are currently in the buffer pool.

PAGES_FREE	Number of pages of the size PAGE_SIZE which are currently free, and thus are available for allocation. This value represents the buffer pool's fragmentation. A totally unfragmented buffer pool has at most 1 free page.
RELOCATION_OPS	How many times a page of the size PAGE_SIZE has been relocated. This happens when data exceeds a page (because a row must be copied into a new page) and when two pages are merged (because their data shrunk and can now be contained in one page).
RELOCATION_TIME	Time (in seconds) spent in relocation operations for pages of the size PAGE_SIZE . This column is reset when the INNODB_CMPMEM_RESET table is queried.

These tables can be used to measure the effectiveness of InnoDB table compression. When you have to decide a value for KEY_BLOCK_SIZE , you can create more than one version of the table (one for each candidate value) and run a realistic workload on them. Then, these tables can be used to see how the operations performed with different page sizes.

INNODB_CMPMEM and INNODB_CMPMEM_RESET have the same columns and always contain the same values, but when INNODB_CMPMEM_RESET is queried, the RELOCATION_TIME column from both the tables are cleared. INNODB_CMPMEM_RESET can be used, for example, if a script periodically logs the performances of compression in the last period of time. INNODB_CMPMEM can be used to see the cumulated statistics.

Example

```
SELECT * FROM information_schema.INNODB_CMPMEM\G
********************* 1. row *********************
            page_size: 1024
 buffer_pool_instance: 0
           pages_used: 0
           pages_free: 0
      reloacation_ops: 0
      relocation_time: 0
```

1.1.1.2.9.1.1.1.10 Information Schema INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET Tables

The INNODB_CMP_PER_INDEX and INNODB_CMP_PER_INDEX_RESET tables contain status information on compression operations related to compressed XtraDB/InnoDB tables, grouped by individual indexes. These tables are only populated if the innodb_cmp_per_index_enabled system variable is set to ON .

The PROCESS privilege is required to query this table.

These tables contains the following columns:

Column Name	Description
DATABASE_NAME	Database containing the index.
TABLE_NAME	Table containing the index.
INDEX_NAME	Other values are totals which refer to this index's compression.
COMPRESS_OPS	How many times a page of INDEX_NAME has been compressed. This happens when a new page is created because the compression log runs out of space. This value includes both successful operations and *compression failures*.
COMPRESS_OPS_OK	How many times a page of INDEX_NAME has been successfully compressed. This value should be as close as possible to COMPRESS_OPS . If it is notably lower, either avoid compressing some tables, or increase the KEY_BLOCK_SIZE for some compressed tables.
COMPRESS_TIME	Time (in seconds) spent to compress pages of the size PAGE_SIZE . This value includes time spent in *compression failures*.
UNCOMPRESS_OPS	How many times a page of INDEX_NAME has been uncompressed. This happens when an uncompressed version of a page is created in the buffer pool, or when a *compression failure* occurs.
UNCOMPRESS_TIME	Time (in seconds) spent to uncompress pages of INDEX_NAME .

These tables can be used to measure the effectiveness of XtraDB/InnoDB compression, per table or per index. The values

in these tables show which tables perform better with index compression, and which tables cause too many *compression failures* or perform too many compression/uncompression operations. When compression performs badly for a table, this might mean that you should change its `KEY_BLOCK_SIZE`, or that the table should not be compressed.

`INNODB_CMP_PER_INDEX` and `INNODB_CMP_PER_INDEX_RESET` have the same columns and always contain the same values, but when `INNODB_CMP_PER_INDEX_RESET` is queried, both the tables are cleared. `INNODB_CMP_PER_INDEX_RESET` can be used, for example, if a script periodically logs the performances of compression in the last period of time. `INNODB_CMP_PER_INDEX` can be used to see the cumulated statistics.

1.1.1.2.9.1.1.1.11 Information Schema INNODB_FT_BEING_DELETED Table

The Information Schema `INNODB_FT_BEING_DELETED` table is only used while document ID's in the related INNODB_FT_DELETED are being removed from an InnoDB fulltext index while an OPTIMIZE TABLE is underway. At all other times the table will be empty.

The `SUPER` privilege is required to view the table, and it also requires the innodb_ft_aux_table system variable to be set.

It has the following column:

Column	Description
`DOC_ID`	Document ID of the row being deleted. Either an underlying ID value, or a sequence value generated by InnoDB if no usable option exists.

1.1.1.2.9.1.1.1.12 Information Schema INNODB_FT_CONFIG Table

The Information Schema `INNODB_FT_CONFIG` table contains InnoDB fulltext index metadata.

The `SUPER` privilege is required to view the table, and it also requires the innodb_ft_aux_table system variable to be set.

It has the following columns:

Column	Description
`KEY`	Metadata item name.
`VALUE`	Associated value.

Example

```
SELECT * FROM INNODB_FT_CONFIG;
+---------------------------+-------+
| KEY                       | VALUE |
+---------------------------+-------+
| optimize_checkpoint_limit | 180   |
| synced_doc_id             | 6     |
| last_optimized_word       |       |
| deleted_doc_count         | 0     |
| total_word_count          |       |
| optimize_start_time       |       |
| optimize_end_time         |       |
| stopword_table_name       |       |
| use_stopword              | 1     |
| table_state               | 0     |
+---------------------------+-------+
```

1.1.1.2.9.1.1.1.13 Information Schema INNODB_FT_DEFAULT_STOPWORD Table

The Information Schema `INNODB_FT_DEFAULT_STOPWORD` table contains a list of default stopwords used when creating an InnoDB fulltext index.

The `PROCESS` privilege is required to view the table.

It has the following column:

Column	Description
`VALUE`	Default `stopword` for an InnoDB fulltext index. Setting either the innodb_ft_server_stopword_table or the innodb_ft_user_stopword_table system variable will override this.

Example

```
SELECT * FROM information_schema.INNODB_FT_DEFAULT_STOPWORD\G
*************************** 1. row ***************************
value: a
*************************** 2. row ***************************
value: about
*************************** 3. row ***************************
value: an
*************************** 4. row ***************************
value: are
...
*************************** 36. row ***************************
value: www
```

1.1.1.2.9.1.1.1.14 Information Schema INNODB_FT_DELETED Table

The Information Schema `INNODB_FT_DELETED` table contains rows that have been deleted from an InnoDB fulltext index. This information is then used to filter results on subsequent searches, removing the need to expensively reorganise the index each time a row is deleted.

The fulltext index is then only reorganized when an OPTIMIZE TABLE statement is underway. The related INNODB_FT_BEING_DELETED table contains rows being deleted while an `OPTIMIZE TABLE` is in the process of running.

The `SUPER` privilege is required to view the table, and it also requires the innodb_ft_aux_table system variable to be set.

It has the following column:

Column	Description
`DOC_ID`	Document ID of the deleted row deleted. Either an underlying ID value, or a sequence value generated by InnoDB if no usable option exists.

Example

```
SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
+--------+
| DOC_ID |
+--------+
|      2 |
+--------+

DELETE FROM test.ft_innodb LIMIT 1;

SELECT * FROM INFORMATION_SCHEMA.INNODB_FT_DELETED;
+--------+
| DOC_ID |
+--------+
|      2 |
|      3 |
+--------+
```

1.1.1.2.9.1.1.1.15 Information Schema

INNODB_FT_INDEX_CACHE Table

The Information Schema `INNODB_FT_INDEX_CACHE` table contains information about rows that have recently been inserted into an InnoDB fulltext index. To avoid re-organizing the fulltext index each time a change is made, which would be very expensive, new changes are stored separately and only integrated when an OPTIMIZE TABLE is run.

The `SUPER` privilege is required to view the table, and it also requires the innodb_ft_aux_table system variable to be set.

It has the following columns:

Column	Description
`WORD`	Word from the text of a newly added row. Words can appear multiple times in the table, once per `DOC_ID` and `POSITION` combination.
`FIRST_DOC_ID`	First document ID where this word appears in the index.
`LAST_DOC_ID`	Last document ID where this word appears in the index.
`DOC_COUNT`	Number of rows containing this word in the index.
`DOC_ID`	Document ID of the newly added row, either an appropriate ID column or an internal InnoDB value.
`POSITION`	Position of this word instance within the `DOC_ID`, as an offset added to the previous `POSITION` instance.

Note that for `OPTIMIZE TABLE` to process InnoDB fulltext index data, the innodb_optimize_fulltext_only system variable needs to be set to `1`. When this is done, and an `OPTIMIZE TABLE` statement run, the `INNODB_FT_INDEX_CACHE` table will be emptied, and the INNODB_FT_INDEX_TABLE table will be updated.

Examples

```
SELECT * FROM INNODB_FT_INDEX_CACHE;
+------------+--------------+-------------+-----------+--------+----------+
| WORD       | FIRST_DOC_ID | LAST_DOC_ID | DOC_COUNT | DOC_ID | POSITION |
+------------+--------------+-------------+-----------+--------+----------+

+--------------------------------+-------+
| innodb_optimize_fulltext_only | OFF   |
+--------------------------------+-------+

SET GLOBAL innodb_optimize_fulltext_only =1;

OPTIMIZE TABLE test.ft_innodb;
+----------------+----------+----------+----------+
| Table          | Op       | Msg_type | Msg_text |
+----------------+----------+----------+----------+
| test.ft_innodb | optimize | status   | OK       |
+----------------+----------+----------+----------+

SELECT * FROM INNODB_FT_INDEX_CACHE;
Empty set (0.00 sec)
```

1.1.1.2.9.1.1.1.16 Information Schema INNODB_FT_INDEX_TABLE Table

The Information Schema `INNODB_FT_INDEX_TABLE` table contains information about InnoDB fulltext indexes. To avoid re-organizing the fulltext index each time a change is made, which would be very expensive, new changes are stored separately and only integrated when an OPTIMIZE TABLE is run. See the INNODB_FT_INDEX_CACHE table.

The `SUPER` privilege is required to view the table, and it also requires the innodb_ft_aux_table system variable to be set.

It has the following columns:

Column	Description
`WORD`	Word from the text of a column with a fulltext index. Words can appear multiple times in the table, once per `DOC_ID` and `POSITION` combination.

FIRST_DOC_ID	First document ID where this word appears in the index.
LAST_DOC_ID	Last document ID where this word appears in the index.
DOC_COUNT	Number of rows containing this word in the index.
DOC_ID	Document ID of the newly added row, either an appropriate ID column or an internal InnoDB value.
POSITION	Position of this word instance within the DOC_ID , as an offset added to the previous POSITION instance.

Note that for OPTIMIZE TABLE to process InnoDB fulltext index data, the innodb_optimize_fulltext_only system variable needs to be set to 1 . When this is done, and an OPTIMIZE TABLE statement run, the INNODB_FT_INDEX_CACHE table will be emptied, and the INNODB_FT_INDEX_TABLE table will be updated.

Examples

```
SELECT * FROM INNODB_FT_INDEX_TABLE;
Empty set (0.00 sec)

SET GLOBAL innodb_optimize_fulltext_only =1;

OPTIMIZE TABLE test.ft_innodb;
+----------------+----------+----------+----------+
| Table          | Op       | Msg_type | Msg_text |
+----------------+----------+----------+----------+
| test.ft_innodb | optimize | status   | OK       |
+----------------+----------+----------+----------+

SELECT * FROM INNODB_FT_INDEX_TABLE;
+------------+--------------+-------------+-----------+--------+----------+
| WORD       | FIRST_DOC_ID | LAST_DOC_ID | DOC_COUNT | DOC_ID | POSITION |
+------------+--------------+-------------+-----------+--------+----------+
| and        |            4 |           5 |         2 |      4 |        0 |
| and        |            4 |           5 |         2 |      5 |        0 |
| arrived    |            4 |           4 |         1 |      4 |       20 |
| ate        |            1 |           5 |         2 |      1 |        4 |
| ate        |            1 |           5 |         2 |      5 |        8 |
| everybody  |            1 |           1 |         1 |      1 |        8 |
| goldilocks |            4 |           4 |         1 |      4 |        9 |
| hungry     |            3 |           3 |         1 |      3 |        8 |
| pear       |            5 |           5 |         1 |      5 |       14 |
| she        |            5 |           5 |         1 |      5 |        4 |
| then       |            4 |           4 |         1 |      4 |        4 |
| wicked     |            2 |           2 |         1 |      2 |        4 |
| witch      |            2 |           2 |         1 |      2 |       11 |
+------------+--------------+-------------+-----------+--------+----------+
```

1.1.1.2.9.1.1.1.17 Information Schema INNODB_LOCK_WAITS Table

The Information Schema INNODB_LOCK_WAITS table contains information about blocked InnoDB transactions. The PROCESS privilege is required to view the table.

It contains the following columns:

Column	Description
REQUESTING_TRX_ID	Requesting transaction ID from the INNODB_TRX table.
REQUESTED_LOCK_ID	Lock ID from the INNODB.LOCKS table for the waiting transaction.
BLOCKING_TRX_ID	Blocking transaction ID from the INNODB_TRX table.
BLOCKING_LOCK_ID	Lock ID from the INNODB.LOCKS table of a lock held by a transaction that is blocking another transaction.

The table is often used in conjunction with the INNODB_LOCKS and INNODB_TRX tables to diagnose problematic locks and transactions.

1.1.1.2.9.1.1.1.18 Information Schema INNODB_LOCKS Table

The Information Schema `INNODB_LOCKS` table stores information about locks that InnoDB transactions have requested but not yet acquired, or that are blocking another transaction.

It has the following columns:

Column	Description
`LOCK_ID`	Lock ID number - the format is not fixed, so do not rely upon the number for information.
`LOCK_TRX_ID`	Lock's transaction ID. Matches the INNODB_TRX.TRX_ID column.
`LOCK_MODE`	Lock mode. One of `S` (shared), `X` (exclusive), `IS` (intention shared), `IX` (intention exclusive row lock), `S_GAP` (shared gap lock), `X_GAP` (exclusive gap lock), `IS_GAP` (intention shared gap lock), `IX_GAP` (intention exclusive gap lock) or `AUTO_INC` (auto-increment table level lock).
`LOCK_TYPE`	Whether the lock is `RECORD` (row level) or `TABLE` level.
`LOCK_TABLE`	Name of the locked table,or table containing locked rows.
`LOCK_INDEX`	Index name if a `RECORD LOCK_TYPE`, or `NULL` if not.
`LOCK_SPACE`	Tablespace ID if a `RECORD LOCK_TYPE`, or `NULL` if not.
`LOCK_PAGE`	Locked record page number if a `RECORD LOCK_TYPE`, or `NULL` if not.
`LOCK_REC`	Locked record heap number if a `RECORD LOCK_TYPE`, or `NULL` if not.
`LOCK_DATA`	Locked record primary key as an SQL string if a `RECORD LOCK_TYPE`, or `NULL` if not. If no primary key exists, the internal InnoDB row_id number is instead used. To avoid unnecessary IO, also `NULL` if the locked record page is not in the buffer pool

The table is often used in conjunction with the INNODB_LOCK_WAITS and INNODB_TRX tables to diagnose problematic locks and transactions

Example

```
-- session 1
START TRANSACTION;
UPDATE t SET id = 15 WHERE id = 10;

-- session 2
DELETE FROM t WHERE id = 10;

-- session 1
USE information_schema;
SELECT l.*, t.*
    FROM information_schema.INNODB_LOCKS l
    JOIN information_schema.INNODB_TRX t
        ON l.lock_trx_id = t.trx_id
    WHERE trx_state = 'LOCK WAIT' \G
*************************** 1. row ***************************
                    lock_id: 840:40:3:2
                lock_trx_id: 840
                  lock_mode: X
                  lock_type: RECORD
                 lock_table: `test`.`t`
                 lock_index: PRIMARY
                 lock_space: 40
                  lock_page: 3
                   lock_rec: 2
                  lock_data: 10
                     trx_id: 840
                  trx_state: LOCK WAIT
              trx_started: 2019-12-23 18:43:46
     trx_requested_lock_id: 840:40:3:2
          trx_wait_started: 2019-12-23 18:43:46
                trx_weight: 2
       trx_mysql_thread_id: 46
                 trx_query: DELETE FROM t WHERE id = 10
       trx_operation_state: starting index read
         trx_tables_in_use: 1
         trx_tables_locked: 1
          trx_lock_structs: 2
     trx_lock_memory_bytes: 1136
           trx_rows_locked: 1
         trx_rows_modified: 0
   trx_concurrency_tickets: 0
       trx_isolation_level: REPEATABLE READ
         trx_unique_checks: 1
    trx_foreign_key_checks: 1
trx_last_foreign_key_error: NULL
          trx_is_read_only: 0
trx_autocommit_non_locking: 0
```

.

1.1.1.2.9.1.1.1.19 Information Schema INNODB_METRICS Table

Contents

The Information Schema `INNODB_METRICS` table contains a list of useful InnoDB performance metrics. Each row in the table represents an instrumented counter that can be stopped, started and reset, and which can be grouped together by module.

The `PROCESS` privilege is required to view the table.

It has the following columns:

Column	Description
`NAME`	Unique counter name.

SUBSYSTEM	InnoDB subsystem. See below for the matching module to use to enable/disable monitoring this subsytem with the innodb_monitor_enable and innodb_monitor_disable system variables.
COUNT	Count since being enabled.
MAX_COUNT	Maximum value since being enabled.
MIN_COUNT	Minimum value since being enabled.
AVG_COUNT	Average value since being enabled.
COUNT_RESET	Count since last being reset.
MAX_COUNT_RESET	Maximum value since last being reset.
MIN_COUNT_RESET	Minimum value since last being reset.
AVG_COUNT_RESET	Average value since last being reset.
TIME_ENABLED	Time last enabled.
TIME_DISABLED	Time last disabled
TIME_ELAPSED	Time since enabled
TIME_RESET	Time last reset.
STATUS	Whether the counter is currently enabled to disabled.
TYPE	Item type; one of `counter`, `value`, `status_counter`, `set_owner`, `set_member`.
COMMENT	Counter description.

Enabling and Disabling Counters

Most of the counters are disabled by default. To enable them, use the innodb_monitor_enable system variable. You can either enable a variable by its name, for example:

```
SET GLOBAL innodb_monitor_enable = icp_match;
```

or enable a number of counters grouped by module. The `SUBSYSTEM` field indicates which counters are grouped together, but the following module names need to be used:

Module Name	Subsytem Field
module_metadata	metadata
module_lock	lock
module_buffer	buffer
module_buf_page	buffer_page_io
module_os	os
module_trx	transaction
module_purge	purge
module_compress	compression
module_file	file_system
module_index	index
module_adaptive_hash	adaptive_hash_index From MariaDB 10.6.2, if innodb_adaptive_hash_index is disabled (the default), adaptive_hash_index will not be updated.
module_ibuf_system	change_buffer
module_srv	server
module_ddl	ddl
module_dml	dml
module_log	recovery

module_icp	icp

There are four counters in the `icp` subsystem:

```
SELECT NAME, SUBSYSTEM FROM INNODB_METRICS WHERE SUBSYSTEM='icp';
+------------------+-----------+
| NAME             | SUBSYSTEM |
+------------------+-----------+
| icp_attempts     | icp       |
| icp_no_match     | icp       |
| icp_out_of_range | icp       |
| icp_match        | icp       |
+------------------+-----------+
```

To enable them all, use the associated module name from the table above, `module_icp`.

```
SET GLOBAL innodb_monitor_enable = module_icp;
```

The `%` wildcard, used to represent any number of characters, can also be used when naming counters, for example:

```
SET GLOBAL innodb_monitor_enable = 'buffer%'
```

To disable counters, use the innodb_monitor_disable system variable, using the same naming rules as described above for enabling.

Counter status is not persistent, and will be reset when the server restarts. It is possible to use the options on the command line, or the `innodb_monitor_enable` option only in a configuration file.

Resetting Counters

Counters can also be reset. Resetting sets all the `*_COUNT_RESET` values to zero, while leaving the `*_COUNT` values, which perform counts since the counter was enabled, untouched. Resetting is performed with the innodb_monitor_reset (for individual counters) and innodb_monitor_reset_all (for all counters) system variables.

Simplifying from MariaDB 10.6

MariaDB starting with 10.6

From MariaDB 10.6, the interface was simplified by removing the following:

- buffer_LRU_batches_flush
- buffer_LRU_batch_flush_pages
- buffer_LRU_batches_evict
- buffer_LRU_batch_evict_pages

and by making the following reflect the status variables:

- buffer_LRU_batch_flush_total_pages: innodb_buffer_pool_pages_LRU_flushed
- buffer_LRU_batch_evict_total_pages: innodb_buffer_pool_pages_LRU_freed

The intention is to eventually remove the interface entirely (see MDEV-15706).

Examples

MariaDB 10.8:

```
SELECT name,subsystem,type,comment FROM INFORMATION_SCHEMA.INNODB_METRICS\G
*************************** 1. row ***************************
     name: metadata_table_handles_opened
subsystem: metadata
     type: counter
  comment: Number of table handles opened
*************************** 2. row ***************************
     name: lock_deadlocks
subsystem: lock
     type: value
  comment: Number of deadlocks
*************************** 3. row ***************************
     name: lock_timeouts
```

```
     name: lock_timeouts
subsystem: lock
     type: value
  comment: Number of lock timeouts
*************************** 4. row ***************************
     name: lock_rec_lock_waits
subsystem: lock
     type: counter
  comment: Number of times enqueued into record lock wait queue
*************************** 5. row ***************************
     name: lock_table_lock_waits
subsystem: lock
     type: counter
  comment: Number of times enqueued into table lock wait queue
*************************** 6. row ***************************
     name: lock_rec_lock_requests
subsystem: lock
     type: counter
  comment: Number of record locks requested
*************************** 7. row ***************************
     name: lock_rec_lock_created
subsystem: lock
     type: counter
  comment: Number of record locks created
*************************** 8. row ***************************
     name: lock_rec_lock_removed
subsystem: lock
     type: counter
  comment: Number of record locks removed from the lock queue
*************************** 9. row ***************************
     name: lock_rec_locks
subsystem: lock
     type: counter
  comment: Current number of record locks on tables
*************************** 10. row ***************************
     name: lock_table_lock_created
subsystem: lock
     type: counter
  comment: Number of table locks created

...

*************************** 207. row ***************************
     name: icp_attempts
subsystem: icp
     type: counter
  comment: Number of attempts for index push-down condition checks

```

1.1.1.2.9.1.1.1.20 Information Schema INNODB_MUTEXES Table

The `INNODB_MUTEXES` table monitors mutex and rw locks waits. It has the following columns:

Column	Description
`NAME`	Name of the lock, as it appears in the source code.

CREATE_FILE	File name of the mutex implementation.
CREATE_LINE	Line number of the mutex implementation.
OS_WAITS	How many times the mutex occurred.

The CREATE_FILE and CREATE_LINE columns depend on the InnoDB/XtraDB version.

Note that since MariaDB 10.2.2, the table has only been providing information about rw_lock_t, not any mutexes. From MariaDB 10.2.2 until MariaDB 10.2.32, MariaDB 10.3.23, MariaDB 10.4.13 and MariaDB 10.5.1, the NAME column was not populated (MDEV-21636).

The SHOW ENGINE INNODB STATUS statement provides similar information.

Examples

```
SELECT * FROM INNODB_MUTEXES;
+-------------------------------+---------------------+-------------+----------+
| NAME                          | CREATE_FILE         | CREATE_LINE | OS_WAITS |
+-------------------------------+---------------------+-------------+----------+
| &dict_sys->mutex              | dict0dict.cc        |         989 |        2 |
| &buf_pool->flush_state_mutex | buf0buf.cc          |        1388 |        1 |
| &log_sys->checkpoint_lock     | log0log.cc          |        1014 |        2 |
| &block->lock                  | combined buf0buf.cc |        1120 |        1 |
+-------------------------------+---------------------+-------------+----------+
```

1.1.1.2.9.1.1.1.21 Information Schema INNODB_SYS_COLUMNS Table

The Information Schema INNODB_SYS_COLUMNS table contains information about InnoDB fields.

The PROCESS privilege is required to view the table.

It has the following columns:

Column	Description
TABLE_ID	Table identifier, matching the value from INNODB_SYS_TABLES.TABLE_ID.
NAME	Column name.
POS	Ordinal position of the column in the table, starting from 0. This value is adjusted when columns are added or removed.
MTYPE	Numeric column type identifier, (see the table below for an explanation of its values).
PRTYPE	Binary value of the InnoDB precise type, representing the data type, character set code and nullability.
LEN	Column length. For multi-byte character sets, represents the length in bytes.

The column MTYPE uses a numeric column type identifier, which has the following values:

Column Type Identifier	Description
1	VARCHAR
2	CHAR
3	FIXBINARY
4	BINARY
5	BLOB
6	INT
7	SYS_CHILD
8	SYS
9	FLOAT

10	DOUBLE
11	DECIMAL
12	VARMYSQL
13	MYSQL

Example

```
SELECT * FROM information_schema.INNODB_SYS_COLUMNS LIMIT 3\G
*************************** 1. row ***************************
TABLE_ID: 11
    NAME: ID
     POS: 0
   MTYPE: 1
  PRTYPE: 524292
     LEN: 0
*************************** 2. row ***************************
TABLE_ID: 11
    NAME: FOR_NAME
     POS: 0
   MTYPE: 1
  PRTYPE: 524292
    LEN: 0
*************************** 3. row ***************************
TABLE_ID: 11
    NAME: REF_NAME
     POS: 0
   MTYPE: 1
  PRTYPE: 524292
     LEN: 0
3 rows in set (0.00 sec)
```

1.1.1.2.9.1.1.1.22 Information Schema INNODB_SYS_DATAFILES Table

MariaDB until 10.5

The `INNODB_SYS_DATAFILES` table was added in MariaDB 10.0.4, and removed in MariaDB 10.6.0.

The Information Schema `INNODB_SYS_DATAFILES` table contains information about InnoDB datafile paths. It was intended to provide metadata for tablespaces inside InnoDB tables, which was never implemented in MariaDB and was removed in MariaDB 10.6. The `PROCESS` privilege is required to view the table.

It contains the following columns:

Column	Description
`SPACE`	Numeric tablespace. Matches the INNODB_SYS_TABLES.SPACE value.
`PATH`	Tablespace datafile path.

Example

```
SELECT * FROM INNODB_SYS_DATAFILES;
+-------+---------------------------------+
| SPACE | PATH                            |
+-------+---------------------------------+
|    19 | ./test/t2.ibd                   |
|    20 | ./test/t3.ibd                   |
...
|    68 | ./test/animals.ibd              |
|    69 | ./test/animal_count.ibd         |
|    70 | ./test/t.ibd                    |
+-------+---------------------------------+
```

1.1.1.2.9.1.1.1.23 Information Schema INNODB_SYS_FIELDS Table

The Information Schema `INNODB_SYS_FIELDS` table contains information about fields that are part of an InnoDB index.

The `PROCESS` privilege is required to view the table.

It has the following columns:

Column	Description
`INDEX_ID`	Index identifier, matching the value from INNODB_SYS_INDEXES.INDEX_ID.
`NAME`	Field name, matching the value from INNODB_SYS_COLUMNS.NAME.
`POS`	Ordinal position of the field within the index, starting from `0` . This is adjusted as columns are removed.

Example

```
SELECT * FROM information_schema.INNODB_SYS_FIELDS LIMIT 3\G
*************************** 1. row ***************************
INDEX_ID: 11
    NAME: ID
     POS: 0
*************************** 2. row ***************************
INDEX_ID: 12
    NAME: FOR_NAME
     POS: 0
*************************** 3. row ***************************
INDEX_ID: 13
    NAME: REF_NAME
     POS: 0
3 rows in set (0.00 sec)
```

1.1.1.2.9.1.1.1.24 Information Schema INNODB_SYS_FOREIGN Table

The Information Schema `INNODB_SYS_FOREIGN` table contains information about InnoDB foreign keys.

The `PROCESS` privilege is required to view the table.

It has the following columns:

Column	Description
`ID`	Database name and foreign key name.
`FOR_NAME`	Database and table name of the foreign key child.
`REF_NAME`	Database and table name of the foreign key parent.
`N_COLS`	Number of foreign key index columns.
`TYPE`	Bit flag providing information about the foreign key.

The `TYPE` column provides a bit flag with information about the foreign key. This information is `OR` 'ed together to read:

Bit Flag	Description
1	ON DELETE CASCADE
2	ON UPDATE SET NULL
4	ON UPDATE CASCADE
8	ON UPDATE SET NULL
16	ON DELETE NO ACTION

32	ON UPDATE NO ACTION

Example

```
SELECT * FROM INNODB_SYS_FOREIGN\G
*************************** 1. row ***************************
      ID: mysql/innodb_index_stats_ibfk_1
FOR_NAME: mysql/innodb_index_stats
REF_NAME: mysql/innodb_table_stats
  N_COLS: 2
    TYPE: 0
...
```

1.1.1.2.9.1.1.1.25 Information Schema INNODB_SYS_FOREIGN_COLS Table

The Information Schema `INNODB_SYS_FOREIGN_COLS` table contains information about InnoDB foreign key columns.

The `PROCESS` privilege is required to view the table.

It has the following columns:

Column	Description
`ID`	Foreign key index associated with this column, matching the INNODB_SYS_FOREIGN.ID field.
`FOR_COL_NAME`	Child column name.
`REF_COL_NAME`	Parent column name.
`POS`	Ordinal position of the column in the table, starting from 0.

1.1.1.2.9.1.1.1.26 Information Schema INNODB_SYS_INDEXES Table

The Information Schema `INNODB_SYS_INDEXES` table contains information about InnoDB indexes.

The `PROCESS` privilege is required to view the table.

It has the following columns:

Field	Type	Null	Key	Default	Description
INDEX_ID	bigint(21) unsigned	NO		0	A unique index identifier.
NAME	varchar(64)	NO			Index name, lowercase for all user-created indexes, or uppercase for implicitly-created indexes; `PRIMARY` (primary key), `GEN_CLUST_INDEX` (index representing primary key where there isn't one), `ID_IND` , `FOR_IND` (validating foreign key constraint) , `REF_IND` .
TABLE_ID	bigint(21) unsigned	NO		0	Table identifier, matching the value from INNODB_SYS_TABLES.TABLE_ID.
TYPE	int(11)	NO		0	Numeric type identifier; one of `0` (secondary index), `1` (clustered index), `2` (unique index), `3` (primary index), `32` (full-text index).
N_FIELDS	int(11)	NO		0	Number of columns in the index. GEN_CLUST_INDEX's have a value of 0 as the index is not based on an actual column in the table.
PAGE_NO	int(11)	NO		0	Index B-tree's root page number. `-1` (unused) for full-text indexes, as they are laid out over several auxiliary tables.

SPACE	int(11)	NO		0	Tablespace identifier where the index resides. `0` represents the InnoDB system tablespace, while any other value represents a table created in file-per-table mode (see the innodb_file_per_table system variable). Remains unchanged after a TRUNCATE TABLE statement, and not necessarily unique.
MERGE_THRESHOLD	int(11)	NO		0	

Example

```
SELECT * FROM information_schema.INNODB_SYS_INDEXES LIMIT 3\G
*************************** 1. row ***************************
       INDEX_ID: 11
           NAME: ID_IND
       TABLE_ID: 11
           TYPE: 3
       N_FIELDS: 1
        PAGE_NO: 302
          SPACE: 0
MERGE_THRESHOLD: 50
*************************** 2. row ***************************
       INDEX_ID: 12
           NAME: FOR_IND
       TABLE_ID: 11
           TYPE: 0
       N_FIELDS: 1
        PAGE_NO: 303
          SPACE: 0
MERGE_THRESHOLD: 50
*************************** 3. row ***************************
       INDEX_ID: 13
           NAME: REF_IND
       TABLE_ID: 11
           TYPE: 3
       N_FIELDS: 1
        PAGE_NO: 304
          SPACE: 0
MERGE_THRESHOLD: 50
3 rows in set (0.00 sec)
```

1.1.1.2.9.1.1.1.27 Information Schema INNODB_SYS_SEMAPHORE_WAITS Table

The Information Schema INNODB_SYS_SEMAPHORE_WAITS table is meant to contain information about current semaphore waits. At present it is not correctly populated. See MDEV-21330.

The PROCESS privilege is required to view the table.

It contains the following columns:

Column	Description
THREAD_ID	Thread id waiting for semaphore
OBJECT_NAME	Semaphore name
FILE	File name where semaphore was requested
LINE	Line number on above file
WAIT_TIME	Wait time
WAIT_OBJECT	
WAIT_TYPE	Object type (mutex, rw-lock)
HOLDER_THREAD_ID	Holder thread id
HOLDER_FILE	File name where semaphore was acquired

HOLDER_LINE	Line number for above
CREATED_FILE	Creation file name
CREATED_LINE	Line number for above
WRITER_THREAD	Last write request thread id
RESERVATION_MODE	Reservation mode (shared, exclusive)
READERS	Number of readers if only shared mode
WAITERS_FLAG	Flags
LOCK_WORD	Lock word (for developers)
LAST_READER_FILE	Removed
LAST_READER_LINE	Removed
LAST_WRITER_FILE	Last writer file name
LAST_WRITER_LINE	Above line number
OS_WAIT_COUNT	Wait count

1.1.1.2.9.1.1.1.28 Information Schema INNODB_SYS_TABLES Table

The Information Schema `INNODB_SYS_TABLES` table contains information about InnoDB tables.

The `PROCESS` privilege is required to view the table.

It has the following columns:

Field	Type	Null	Key	Default	Description
TABLE_ID	bigint(21) unsigned	NO		0	Unique InnoDB table identifier.
NAME	varchar(655)	NO			Database and table name, or the uppercase InnoDB system table name.
FLAG	int(11)	NO		0	See Flag below
N_COLS	int(11) unsigned (>= MariaDB 10.5) int(11) (<= MariaDB 10.4)	NO		0	Number of columns in the table. The count includes two or three hidden InnoDB system columns, appended to the end of the column list: DB_ROW_ID (if there is no primary key or unique index on NOT NULL columns), DB_TRX_ID, DB_ROLL_PTR.
SPACE	int(11) unsigned (>= MariaDB 10.5) int(11) (<= MariaDB 10.4)	NO		0	Tablespace identifier where the index resides. `0` represents the InnoDB system tablespace, while any other value represents a table created in file-per-table mode (see the innodb_file_per_table system variable). Remains unchanged after a TRUNCATE TABLE statement.
FILE_FORMAT	varchar(10)	YES		NULL	InnoDB file format (Antelope or Barracuda). Removed in MariaDB 10.3.
ROW_FORMAT	enum('Redundant', 'Compact', 'Compressed', 'Dynamic') (>= MariaDB 10.5) varchar(12) (<= MariaDB 10.4)	YES		NULL	InnoDB storage format (Compact, Redundant, Dynamic, or Compressed).
ZIP_PAGE_SIZE	int(11) unsigned	NO		0	For Compressed tables, the zipped page size.
SPACE_TYPE	enum('Single','System') (>= MariaDB 10.5) varchar(10) (<= MariaDB 10.4)	YES		NULL	

Flag

The flag field returns the dict_table_t::flags that correspond to the data dictionary record.

Bit	Description
0	Set if ROW_FORMAT is not REDUNDANT.
1 to 4	0, except for ROW_FORMAT=COMPRESSED, where they will determine the KEY_BLOCK_SIZE (the compressed page size).
5	Set for ROW_FORMAT=DYNAMIC or ROW_FORMAT=COMPRESSED.
6	Set if the DATA DIRECTORY attribute was present when the table was originally created.
7	Set if the page_compressed attribute is present.
8 to 11	Determine the page_compression_level.
12 13	Normally 00, but 11 for "no-rollback tables" (MariaDB 10.3 CREATE SEQUENCE). In MariaDB 10.1, these bits could be 01 or 10 for ATOMIC_WRITES=ON or ATOMIC_WRITES=OFF.

Note that the table flags returned here are not the same as tablespace flags (FSP_SPACE_FLAGS).

Example

```
SELECT * FROM information_schema.INNODB_SYS_TABLES LIMIT 2\G
*************************** 1. row ***************************
     TABLE_ID: 14
         NAME: SYS_DATAFILES
         FLAG: 0
       N_COLS: 5
        SPACE: 0
   ROW_FORMAT: Redundant
ZIP_PAGE_SIZE: 0
   SPACE_TYPE: System
*************************** 2. row ***************************
     TABLE_ID: 11
         NAME: SYS_FOREIGN
         FLAG: 0
       N_COLS: 7
        SPACE: 0
   ROW_FORMAT: Redundant
ZIP_PAGE_SIZE: 0
   SPACE_TYPE: System
2 rows in set (0.00 sec)
```

1.1.1.2.9.1.1.1.29 Information Schema INNODB_SYS_TABLESPACES Table

The Information Schema INNODB_SYS_TABLESPACES table contains information about InnoDB tablespaces. Until MariaDB 10.5 it was based on the internal SYS_TABLESPACES table. This internal table was removed in MariaDB 10.6.0, so this Information Schema table has been repurposed to directly reflect the filesystem (fil_system.space_list).

The PROCESS privilege is required to view the table.

It has the following columns:

Column	Description
SPACE	Unique InnoDB tablespace identifier.
NAME	Database and table name separated by a backslash, or the uppercase InnoDB system table name.
FLAG	1 if a DATA DIRECTORY option has been specified in CREATE TABLE, otherwise 0.
FILE_FORMAT	InnoDB file format. Removed in MariaDB 10.3.1

ROW_FORMAT	InnoDB storage format used for this tablespace. If the Antelope file format is used, this value is always `Compact or Redundant`. When a table's checksum algorithm is `full_crc32` (the default from MariaDB 10.5), the value can only be `Compressed` or `NULL`.
PAGE_SIZE	Page size in bytes for this tablespace. Until MariaDB 10.5.0, this was the value of the innodb_page_size variable. From MariaDB 10.6.0, contains the physical page size of a page (previously `ZIP_PAGE_SIZE`).
ZIP_PAGE_SIZE	Zip page size for this tablespace. Removed in MariaDB 10.6.0.
SPACE_TYPE	Tablespace type. Can be `General` for general tablespaces or `Single` for file-per-table tablespaces. Introduced MariaDB 10.2.1. Removed MariaDB 10.5.0.
FS_BLOCK_SIZE	File system block size. Introduced MariaDB 10.2.1.
FILE_SIZE	Maximum size of the file, uncompressed. Introduced MariaDB 10.2.1.
ALLOCATED_SIZE	Actual size of the file as per space allocated on disk. Introduced MariaDB 10.2.1.
FILENAME	Tablespace datafile path, previously part of the INNODB_SYS_DATAFILES table. Added in MariaDB 10.6.0.

Examples

MariaDB 10.4:

```
DESC information_schema.innodb_sys_tablespaces;
+---------------+---------------------+------+-----+---------+-------+
| Field         | Type                | Null | Key | Default | Extra |
+---------------+---------------------+------+-----+---------+-------+
| SPACE         | int(11) unsigned    | NO   |     | 0       |       |
| NAME          | varchar(655)        | NO   |     |         |       |
| FLAG          | int(11) unsigned    | NO   |     | 0       |       |
| ROW_FORMAT    | varchar(22)         | YES  |     | NULL    |       |
| PAGE_SIZE     | int(11) unsigned    | NO   |     | 0       |       |
| ZIP_PAGE_SIZE | int(11) unsigned    | NO   |     | 0       |       |
| SPACE_TYPE    | varchar(10)         | YES  |     | NULL    |       |
| FS_BLOCK_SIZE | int(11) unsigned    | NO   |     | 0       |       |
| FILE_SIZE     | bigint(21) unsigned | NO   |     | 0       |       |
| ALLOCATED_SIZE | bigint(21) unsigned | NO   |     | 0       |       |
+---------------+---------------------+------+-----+---------+-------+
```

From MariaDB 10.4:

```
SELECT * FROM information_schema.INNODB_SYS_TABLESPACES LIMIT 2\G
*************************** 1. row ***************************
         SPACE: 2
          NAME: mysql/innodb_table_stats
          FLAG: 33
    ROW_FORMAT: Dynamic
     PAGE_SIZE: 16384
 ZIP_PAGE_SIZE: 0
    SPACE_TYPE: Single
 FS_BLOCK_SIZE: 4096
     FILE_SIZE: 98304
ALLOCATED_SIZE: 98304
*************************** 2. row ***************************
         SPACE: 3
          NAME: mysql/innodb_index_stats
          FLAG: 33
    ROW_FORMAT: Dynamic
     PAGE_SIZE: 16384
 ZIP_PAGE_SIZE: 0
    SPACE_TYPE: Single
 FS_BLOCK_SIZE: 4096
     FILE_SIZE: 98304
ALLOCATED_SIZE: 98304
```

1.1.1.2.9.1.1.1.30 Information Schema

INNODB_SYS_TABLESTATS Table

The Information Schema `INNODB_SYS_TABLESTATS` table contains InnoDB status information. It can be used for developing new performance-related extensions, or high-level performance monitoring.

The `PROCESS` privilege is required to view the table.

Note that the MySQL InnoDB and Percona XtraDB versions of the tables differ (see XtraDB and InnoDB).

It contains the following columns:

Column	Description
`TABLE_ID`	Table ID, matching the INNODB_SYS_TABLES.TABLE_ID value.
`SCHEMA`	Database name (XtraDB only).
`NAME`	Table name, matching the INNODB_SYS_TABLES.NAME value.
`STATS_INITIALIZED`	`Initialized` if statistics have already been collected, otherwise `Uninitialized`.
`NUM_ROWS`	Estimated number of rows currently in the table. Updated after each statement modifying the data, but uncommited transactions mean it may not be accurate.
`CLUST_INDEX_SIZE`	Number of pages on disk storing the clustered index, holding InnoDB table data in primary key order, or `NULL` if not statistics yet collected.
`OTHER_INDEX_SIZE`	Number of pages on disk storing secondary indexes for the table, or `NULL` if not statistics yet collected.
`MODIFIED_COUNTER`	Number of rows modified by statements modifying data.
`AUTOINC`	Auto_increment value.
`REF_COUNT`	Countdown to zero, when table metadata can be removed from the table cache. (InnoDB only)
`MYSQL_HANDLES_OPENED`	(XtraDB only).

1.1.1.2.9.1.1.1.31 Information Schema INNODB_SYS_VIRTUAL Table

MariaDB starting with 10.2

The `INNODB_SYS_VIRTUAL` table was added in MariaDB 10.2.

The Information Schema `INNODB_SYS_VIRTUAL` table contains information about base columns of virtual columns. The `PROCESS` privilege is required to view the table.

It contains the following columns:

Field	Type	Null	Key	Default	Description
TABLE_ID	bigint(21) unsigned	NO		0	
POS	int(11) unsigned	NO		0	
BASE_POS	int(11) unsigned	NO		0	

1.1.1.2.9.1.1.1.32 Information Schema INNODB_TABLESPACES_ENCRYPTION Table

The Information Schema `INNODB_TABLESPACES_ENCRYPTION` table contains metadata about encrypted InnoDB tablespaces. When you enable encryption for an InnoDB tablespace, an entry for the tablespace is added to this table. If you later disable encryption for the InnoDB tablespace, then the row still remains in this table, but the `ENCRYPTION_SCHEME` and `CURRENT_KEY_VERSION` columns will be set to `0`.

Viewing this table requires the PROCESS privilege, although a bug in versions before MariaDB 10.1.46, 10.2.33, 10.3.24, 10.4.14 and 10.5.5 mean the SUPER privilege was required (MDEV-23003).

It has the following columns:

Column	Description	Added
`SPACE`	InnoDB tablespace ID.	
`NAME`	Path to the InnoDB tablespace file, without the extension.	
`ENCRYPTION_SCHEME`	Key derivation algorithm. Only `1` is currently used to represent an algorithm. If this value is `0`, then the tablespace is unencrypted.	
`KEYSERVER_REQUESTS`	Number of times InnoDB has had to request a key from the encryption key management plugin. The three most recent keys are cached internally.	
`MIN_KEY_VERSION`	Minimum key version used to encrypt a page in the tablespace. Different pages may be encrypted with different key versions.	
`CURRENT_KEY_VERSION`	Key version that will be used to encrypt pages. If this value is `0`, then the tablespace is unencrypted.	
`KEY_ROTATION_PAGE_NUMBER`	Page that a background encryption thread is currently rotating. If key rotation is not enabled, then the value will be `NULL`.	
`KEY_ROTATION_MAX_PAGE_NUMBER`	When a background encryption thread starts rotating a tablespace, the field contains its current size. If key rotation is not enabled, then the value will be `NULL`.	
`CURRENT_KEY_ID`	Key ID for the encryption key currently in use.	MariaDB 10.1.13
`ROTATING_OR_FLUSHING`	Current key rotation status. If this value is `1`, then the background encryption threads are working on the tablespace. See MDEV-11738.	MariaDB 10.2.5, MariaDB 10.1.23

When the InnoDB system tablespace is encrypted, it is represented in this table with the special name: `innodb_system`.

Example

```
SELECT * FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME LIKE 'db_encrypt%';
+-------+-----------------------------------------------+------------------+-----------------
---+-----------------+--------------------+--------------------------+----------------------
--------+
| SPACE | NAME                                          | ENCRYPTION_SCHEME |
KEYSERVER_REQUESTS | MIN_KEY_VERSION | CURRENT_KEY_VERSION | KEY_ROTATION_PAGE_NUMBER |
KEY_ROTATION_MAX_PAGE_NUMBER |
+-------+-----------------------------------------------+------------------+-----------------
---+-----------------+--------------------+--------------------------+----------------------
--------+
|    18 | db_encrypt/t_encrypted_existing_key           |                1 |
1 |               1 |                  1 |                     NULL |
NULL |
|    19 | db_encrypt/t_not_encrypted_existing_key       |                1 |
0 |               1 |                  1 |                     NULL |
NULL |
|    20 | db_encrypt/t_not_encrypted_non_existing_key   |                1 |
0 |      4294967295 |          4294967295 |                     NULL |

1.1.1.2.9.1.1.1.33 Information Schema INNODB_TABLESPACES_SCRUBBING Table

MariaDB 10.1.3 - 10.5.1

InnoDB and XtraDB data scrubbing was introduced in MariaDB 10.1.3. The table was removed in MariaDB 10.5.2 - see MDEV-15528.

The Information Schema `INNODB_TABLESPACES_SCRUBBING` table contains data scrubbing information.

The `PROCESS` privilege is required to view the table.

It has the following columns:

Column	Description
`SPACE`	InnoDB table space id number.
`NAME`	Path to the table space file, without the extension.
`COMPRESSED`	The compressed page size, or zero if uncompressed.
`LAST_SCRUB_COMPLETED`	Date and time when the last scrub was completed, or `NULL` if never been performed.
`CURRENT_SCRUB_STARTED`	Date and time when the current scrub started, or `NULL` if never been performed.
`CURRENT_SCRUB_ACTIVE_THREADS`	Number of threads currently scrubbing the tablespace.
`CURRENT_SCRUB_PAGE_NUMBER`	Page that the scrubbing thread is currently scrubbing, or `NULL` if not enabled.
`CURRENT_SCRUB_MAX_PAGE_NUMBER`	When a scrubbing starts rotating a table space, the field contains its current size. `NULL` if not enabled.

ON_SSD	The field contains 1 when MariaDB detects that the table space is on a SSD based storage. 0 if not SSD or it could not be determined (since MariaDB 10.4.4)

Example

```
SELECT * FROM information_schema.INNODB_TABLESPACES_SCRUBBING LIMIT 1\G
*************************** 1. row ***************************
                       SPACE: 1
                        NAME: mysql/innodb_table_stats
                  COMPRESSED: 0
         LAST_SCRUB_COMPLETED: NULL
        CURRENT_SCRUB_STARTED: NULL
    CURRENT_SCRUB_PAGE_NUMBER: NULL
CURRENT_SCRUB_MAX_PAGE_NUMBER: 0
         ROTATING_OR_FLUSHING: 0
1 rows in set (0.00 sec)
```

1.1.1.2.9.1.1.1.34 Information Schema INNODB_TRX Table

The Information Schema INNODB_TRX table stores information about all currently executing InnoDB transactions.

It has the following columns:

Column	Description
TRX_ID	Unique transaction ID number.
TRX_STATE	Transaction execution state; one of RUNNING, LOCK WAIT, ROLLING BACK or COMMITTING.
TRX_STARTED	Time that the transaction started.
TRX_REQUESTED_LOCK_ID	If TRX_STATE is LOCK_WAIT, the INNODB_LOCKS.LOCK_ID value of the lock being waited on. NULL if any other state.
TRX_WAIT_STARTED	If TRX_STATE is LOCK_WAIT, the time the transaction started waiting for the lock, otherwise NULL.
TRX_WEIGHT	Transaction weight, based on the number of locked rows and the number of altered rows. To resolve deadlocks, lower weighted transactions are rolled back first. Transactions that have affected non-transactional tables are always treated as having a heavier weight.
TRX_MYSQL_THREAD_ID	Thread ID from the PROCESSLIST table (note that the locking and transaction information schema tables use a different snapshot from the processlist, so records may appear in one but not the other).
TRX_QUERY	SQL that the transaction is currently running.
TRX_OPERATION_STATE	Transaction's current state, or NULL.
TRX_TABLES_IN_USE	Number of InnoDB tables currently being used for processing the current SQL statement.
TRX_TABLES_LOCKED	Number of InnoDB tables that that have row locks held by the current SQL statement.
TRX_LOCK_STRUCTS	Number of locks reserved by the transaction.
TRX_LOCK_MEMORY_BYTES	Total size in bytes of the memory used to hold the lock structures for the current transaction in memory.
TRX_ROWS_LOCKED	Number of rows the current transaction has locked. locked by this transaction. An approximation, and may include rows not visible to the current transaction that are delete-marked but physically present.
TRX_ROWS_MODIFIED	Number of rows added or changed in the current transaction.
TRX_CONCURRENCY_TICKETS	Indicates how much work the current transaction can do before being swapped out, see the innodb_concurrency_tickets system variable.

TRX_ISOLATION_LEVEL	Isolation level of the current transaction.
TRX_UNIQUE_CHECKS	Whether unique checks are `on` or `off` for the current transaction. Bulk data are a case where unique checks would be off.
TRX_FOREIGN_KEY_CHECKS	Whether foreign key checks are `on` or `off` for the current transaction. Bulk data are a case where foreign keys checks would be off.
TRX_LAST_FOREIGN_KEY_ERROR	Error message for the most recent foreign key error, or `NULL` if none.
TRX_ADAPTIVE_HASH_LATCHED	Whether the adaptive hash index is locked by the current transaction or not. One transaction at a time can change the adaptive hash index.
TRX_ADAPTIVE_HASH_TIMEOUT	Whether the adaptive hash index search latch shoild be relinquished immediately or reserved across all MariaDB calls. `0` if there is no contention on the adaptive hash index, in which case the latch is reserved until completion, otherwise counts down to zero and the latch is released after each row lookup.
TRX_IS_READ_ONLY	`1` if a read-only transaction, otherwise `0`.
TRX_AUTOCOMMIT_NON_LOCKING	`1` if the transaction only contains this one statement, that is, a `SELECT` statement not using `FOR UPDATE` or `LOCK IN SHARED MODE`, and with autocommit on. If this and `TRX_IS_READ_ONLY` are both 1, the transaction can be optimized by the storrage engine to reduce some overheads

The table is often used in conjunction with the INNODB_LOCKS and INNODB_LOCK_WAITS tables to diagnose problematic locks and transactions.

XA transactions are not stored in this table. To see them, `XA RECOVER` can be used.

Example

```
-- session 1
START TRANSACTION;
UPDATE t SET id = 15 WHERE id = 10;

-- session 2
DELETE FROM t WHERE id = 10;

-- session 1
USE information_schema;
SELECT l.*, t.*
    FROM information_schema.INNODB_LOCKS l
    JOIN information_schema.INNODB_TRX t
        ON l.lock_trx_id = t.trx_id
    WHERE trx_state = 'LOCK WAIT' \G
*************************** 1. row ***************************
                    lock_id: 840:40:3:2
                lock_trx_id: 840
                  lock_mode: X
                  lock_type: RECORD
                 lock_table: `test`.`t`
                 lock_index: PRIMARY
                 lock_space: 40
                  lock_page: 3
                   lock_rec: 2
                  lock_data: 10
                     trx_id: 840
                  trx_state: LOCK WAIT
                trx_started: 2019-12-23 18:43:46
     trx_requested_lock_id: 840:40:3:2
          trx_wait_started: 2019-12-23 18:43:46
                trx_weight: 2
       trx_mysql_thread_id: 46
                 trx_query: DELETE FROM t WHERE id = 10
       trx_operation_state: starting index read
         trx_tables_in_use: 1
         trx_tables_locked: 1
          trx_lock_structs: 2
     trx_lock_memory_bytes: 1136
           trx_rows_locked: 1
         trx_rows_modified: 0
   trx_concurrency_tickets: 0
       trx_isolation_level: REPEATABLE READ
         trx_unique_checks: 1
    trx_foreign_key_checks: 1
trx_last_foreign_key_error: NULL
          trx_is_read_only: 0
trx_autocommit_non_locking: 0
```

1.1.1.2.9.1.1.1.35 Information Schema TEMP_TABLES_INFO Table

MariaDB 10.2.2 - 10.2.3

The `TEMP_TABLES_INFO` table was introduced in MariaDB 10.2.2 and was removed in MariaDB 10.2.4. See MDEV-12459 progress on an alternative.

The Information Schema `TEMP_TABLES_INFO` table contains information about active InnoDB temporary tables. All user and system-created temporary tables are reported when querying this table, with the exception of optimized internal temporary tables. The data is stored in memory.

Previously, InnoDB temp table metadata was rather stored in InnoDB system tables.

It has the following columns:

Column	Description
`TABLE_ID`	Table ID.
`NAME`	Table name.

N_COLS	Number of columns in the temporary table, including three hidden columns that InnoDB creates (DB_ROW_ID , DB_TRX_ID , and DB_ROLL_PTR).
SPACE	Numerical identifier for the tablespace identifier holding the temporary table. Compressed temporary tables are stored by default in separate per-table tablespaces in the temporary file directory. For non-compressed tables, the shared temporary table is named ibtmp1 , found in the data directory. Always a non-zero value, and regenerated on server restart.
PER_TABLE_TABLESPACE	If TRUE , the temporary table resides in a separate per-table tablespace. If FALSE , it resides in the shared temporary tablespace.
IS_COMPRESSED	TRUE if the table is compressed.

The PROCESS privilege is required to view the table.

Examples

```
CREATE TEMPORARY TABLE t (i INT) ENGINE=INNODB;

SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO;
+----------+--------------+--------+-------+----------------------+----------------+
| TABLE_ID | NAME         | N_COLS | SPACE | PER_TABLE_TABLESPACE | IS_COMPRESSED |
+----------+--------------+--------+-------+----------------------+----------------+
|       39 | #sql1c93_3_1 |      4 |    64 | FALSE                | FALSE          |
+----------+--------------+--------+-------+----------------------+----------------+
```

Adding a compressed table:

```
SET GLOBAL innodb_file_format="Barracuda";

CREATE TEMPORARY TABLE t2 (i INT) ROW_FORMAT=COMPRESSED ENGINE=INNODB;

SELECT * FROM INFORMATION_SCHEMA.INNODB_TEMP_TABLE_INFO;
+----------+--------------+--------+-------+----------------------+----------------+
| TABLE_ID | NAME         | N_COLS | SPACE | PER_TABLE_TABLESPACE | IS_COMPRESSED |
+----------+--------------+--------+-------+----------------------+----------------+
|       40 | #sql1c93_3_3 |      4 |    65 | TRUE                 | TRUE           |
|       39 | #sql1c93_3_1 |      4 |    64 | FALSE                | FALSE          |
+----------+--------------+--------+-------+----------------------+----------------+
```

1.1.1.2.9.1.1.2.1 Information Schema ROCKSDB_CFSTATS Table

The Information Schema `ROCKSDB_CFSTATS` table is included as part of the MyRocks storage engine.

The `PROCESS` privilege is required to view the table.

It contains the following columns:

Column	Description
`CF_NAME`	
`STAT_TYPE`	
`VALUE`	

1.1.1.2.9.1.1.2.2 Information Schema ROCKSDB_CF_OPTIONS Table

The Information Schema `ROCKSDB_CF_OPTIONS` table is included as part of the MyRocks storage engine, and contains infomation about MyRocks column families.

The `PROCESS` privilege is required to view the table.

It contains the following columns:

Column	Description
`CF_NAME`	Column family name.
`OPTION_TYPE`	
`VALUE`	

1.1.1.2.9.1.1.2.3 Information Schema ROCKSDB_COMPACTION_STATS Table

The Information Schema `ROCKSDB_COMPACTION_STATS` table is included as part of the MyRocks storage engine.

The `PROCESS` privilege is required to view the table.

It contains the following columns:

Column	Description
CF_NAME	
LEVEL	
TYPE	
VALUE	

1.1.1.2.9.1.1.2.4 Information Schema ROCKSDB_DBSTATS Table

The Information Schema `ROCKSDB_DBSTATS` table is included as part of the MyRocks storage engine.

The `PROCESS` privilege is required to view the table.

It contains the following columns:

Column	Description
STAT_TYPE	
VALUE	

1.1.1.2.9.1.1.2.5 Information Schema ROCKSDB_DDL Table

The Information Schema `ROCKSDB_DDL` table is included as part of the MyRocks storage engine.

The `PROCESS` privilege is required to view the table.

It contains the following columns:

Column	Description
TABLE_SCHEMA	
TABLE_NAME	
PARTITION_NAME	
INDEX_NAME	
COLUMN_FAMILY	
INDEX_NUMBER	
INDEX_TYPE	
KV_FORMAT_VERSION	
TTL_DURATION	
INDEX_FLAGS	
CF	
AUTO_INCREMENT	

1.1.1.2.9.1.1.2.6 Information Schema ROCKSDB_DEADLOCK Table

The Information Schema `ROCKSDB_DEADLOCK` table is included as part of the MyRocks storage engine.

The `PROCESS` privilege is required to view the table.

It contains the following columns:

Column	Description

DEADLOCK_ID	
TIMESTAMP	
TRANSACTION_ID	
CF_NAME	
WAITING_KEY	
LOCK_TYPE	
INDEX_NAME	
TABLE_NAME	
ROLLED_BACK	

1.1.1.2.9.1.1.2.7 Information Schema ROCKSDB_GLOBAL_INFO Table

The Information Schema `ROCKSDB_GLOBAL_INFO` table is included as part of the MyRocks storage engine.

The `PROCESS` privilege is required to view the table.

It contains the following columns:

Column	Description
TYPE	
NAME	
VALUE	

1.1.1.2.9.1.1.2.8 Information Schema ROCKSDB_INDEX_FILE_MAP Table

The Information Schema `ROCKSDB_INDEX_FILE_MAP` table is included as part of the MyRocks storage engine.

The `PROCESS` privilege is required to view the table.

It contains the following columns:

Column	Description
COLUMN_FAMILY	
INDEX_NUMBER	
SST_NAME	
NUM_ROWS	
DATA_SIZE	
ENTRY_DELETES	
ENTRY_SINGLEDELETES	
ENTRY_MERGES	
ENTRY_OTHERS	
DISTINCT_KEYS_PREFIX	

1.1.1.2.9.1.1.2.9 Information Schema ROCKSDB_LOCKS Table

The Information Schema `ROCKSDB_LOCKS` table is included as part of the MyRocks storage engine.

The PROCESS privilege is required to view the table.

It contains the following columns:

Column	Description
COLUMN_FAMILY_ID	
TRANSACTION_ID	
KEY	
MODE	

1.1.1.2.9.1.1.2.10 Information Schema ROCKSDB_PERF_CONTEXT Table

The Information Schema ROCKSDB_PERF_CONTEXT table is included as part of the MyRocks storage engine and includes per-table/partition counters .

The PROCESS privilege is required to view the table.

It contains the following columns:

Column	Description
TABLE_SCHEMA	
TABLE_NAME	
PARTITION_NAME	
STAT_TYPE	
VALUE	

Note: for multi-table queries, all counter increments are "billed" to the first table in the query:
https://github.com/facebook/mysql-5.6/issues/1018

1.1.1.2.9.1.1.2.11 Information Schema ROCKSDB_PERF_CONTEXT_GLOBAL Table

The Information Schema ROCKSDB_PERF_CONTEXT_GLOBAL table is included as part of the MyRocks storage engine and includes global counter information.

The PROCESS privilege is required to view the table.

It contains the following columns:

Column	Description
STAT_TYPE	
VALUE	

1.1.1.2.9.1.1.2.12 Information Schema ROCKSDB_SST_PROPS Table

The Information Schema ROCKSDB_SST_PROPS table is included as part of the MyRocks storage engine.

The PROCESS privilege is required to view the table.

It contains the following columns:

Column	Description
SST_NAME	
COLUMN_FAMILY	

DATA_BLOCKS	
ENTRIES	
RAW_KEY_SIZE	
RAW_VALUE_SIZE	
DATA_BLOCK_SIZE	
INDEX_BLOCK_SIZE	
INDEX_PARTITIONS	
TOP_LEVEL_INDEX_SIZE	
FILTER_BLOCK_SIZE	
COMPRESSION_ALGO	
CREATION_TIME	

1.1.1.2.9.1.1.2.13 Information Schema ROCKSDB_TRX Table

The Information Schema `ROCKSDB_TRX` table is included as part of the MyRocks storage engine.

The `PROCESS` privilege is required to view the table.

It contains the following columns:

Column	Description
TRANSACTION_ID	
STATE	
NAME	
WRITE_COUNT	
LOCK_COUNT	
TIMEOUT_SEC	
WAITING_KEY	
WAITING_COLUMN_FAMILY_ID	
IS_REPLICATION	
SKIP_TRX_API	
READ_ONLY	
HAS_DEADLOCK_DETECTION	
NUM_ONGOING_BULKLOAD	
THREAD_ID	
QUERY	

1.1.1.2.9.1.1.3 ColumnStore Information Schema Tables

MariaDB ColumnStore has four Information Schema tables that expose information about the table and column storage. These tables were added in version 1.0.5 of ColumnStore and were heavily modified for 1.0.6.

COLUMNSTORE_TABLES

The first table is the INFORMATION_SCHEMA.COLUMNSTORE_TABLES. This contains information about the tables inside ColumnStore. The table layout is as follows:

Column	Description
TABLE_SCHEMA	The database schema for the table
TABLE_NAME	The table name
OBJECT_ID	The ColumnStore object ID for the table
CREATION_DATE	The date the table was created
COLUMN_COUNT	The number of columns in the table
AUTOINCREMENT	The start autoincrement value for the table set during CREATE TABLE

Note: Tables created with ColumnStore 1.0.4 or lower will have the year field of the creation data set incorrectly by 1900 years.

COLUMNSTORE_COLUMNS

The INFORMATION_SCHEMA.COLUMNSTORE_COLUMNS table contains information about every single column inside ColumnStore. The table layout is as follows:

Column	Description
TABLE_SCHEMA	The database schema for the table
TABLE_NAME	The table name for the column
COLUMN_NAME	The column name
OBJECT_ID	The object ID for the column
DICTIONARY_OBJECT_ID	The dictionary object ID for the column (NULL if there is no dictionary object
LIST_OBJECT_ID	Placeholder for future information
TREE_OBJECT_ID	Placeholder for future information
DATA_TYPE	The data type for the column
COLUMN_LENGTH	The data length for the column
COLUMN_POSITION	The position of the column in the table, starting at 0
COLUMN_DEFAULT	The default value for the column
IS_NULLABLE	Whether or not the column can be set to NULL
NUMERIC_PRECISION	The numeric precision for the column
NUMERIC_SCALE	The numeric scale for the column
IS_AUTOINCREMENT	Set to 1 if the column is an autoincrement column
COMPRESSION_TYPE	The type of compression (either "None" or "Snappy")

COLUMNSTORE_EXTENTS

This table displays the extent map in a user consumable form. An extent is a collection of details about a section of data related to a columnstore column. A majority of columns in ColumnStore will have multiple extents and the columns table above can be joined to this one to filter results by table or column. The table layout is as follows:

Column	Description
OBJECT_ID	The object ID for the extent
OBJECT_TYPE	Whether this is a "Column" or "Dictionary" extent
LOGICAL_BLOCK_START	ColumnStore's internal start LBID for this extent
LOGICAL_BLOCK_END	ColumnStore's internal end LBID for this extent
MIN_VALUE	This minimum value stored in this extent
MAX_VALUE	The maximum value stored in this extent
WIDTH	The data width for the extent
DBROOT	The DBRoot number for the extent
PARTITION_ID	The parition ID for the extent
SEGMENT_ID	The segment ID for the extent
BLOCK_OFFSET	The block offset for the data file, each data file can contain multiple extents for a column
MAX_BLOCKS	The maximum number of blocks for the extent
HIGH_WATER_MARK	The last block committed to the extent (starting at 0)
STATE	The state of the extent (see below)
STATUS	The availability status for the column which is either "Available", "Unavailable" or "Out of service"
DATA_SIZE	The uncompressed data size for the extent calculated as (HWM + 1) * BLOCK_SIZE

Notes:

1. The state is "Valid" for a normal state, "Invalid" if a cpimport has completed but the table has not yet been accessed (min/max values will be invalid) or "Updating" if there is a DML statement writing to the column
2. In ColumnStore the block size is 8192 bytes
3. By default ColumnStore will write create an extent file of 256*1024*WIDTH bytes for the first partition, if this is too small then for uncompressed data it will create a file of the maximum size for the extent (MAX_BLOCKS * BLOCK_SIZE). Snappy always compression adds a header block.
4. Object IDs of less than 3000 are for internal tables and will not appear in any of the information schema tables
5. Prior to 1.0.12 / 1.1.2 DATA_SIZE was incorrectly calculated
6. HWM is set to zero for the lower segments when there are multiple segments in an extent file, these can be observed when BLOCK_OFFSET > 0
7. When HWM is 0 the DATA_SIZE will show 0 instead of 8192 to avoid confusion when there is multiple segments in an extent file

COLUMNSTORE_FILES

The columnstore_files table provides information about each file associated with extensions. Each extension can reuse a file at different block offsets so this is not a 1:1 relationship to the columnstore_extents table.

Column	Description
OBJECT_ID	The object ID for the extent
SEGMENT_ID	The segment ID for the extent
PARTITION_ID	The partition ID for the extent
FILENAME	The full path and filename for the extent file, multiple extents for the same column can point to this file with different BLOCK_OFFSETs
FILE_SIZE	The disk file size for the extent

COMPRESSED_DATA_SIZE	The amount of the compressed file used, NULL if this is an uncompressed file

Stored Procedures

A few stored procedures were added in 1.0.6 to provide summaries based on the information schema tables. These can be accessed from the COLUMNSTORE_INFO schema.

total_usage()

The total_usage() procedure gives a total disk usage summary for all the columns in ColumnStore with the exception of the columns used for internal maintenance. It is executed using the following query:

```
> call columnstore_info.total_usage();
```

table_usage()

The table_usage() procedure gives a the total data disk usage, dictionary disk usage and grand total disk usage per-table. It can be called in several ways, the first gives a total for each table:

```
> call columnstore_info.table_usage(NULL, NULL);
```

Or for a specific table, my_table in my_schema in this example:

```
> call columnstore_info.table_usage('my_schema', 'my_table');
```

You can also request all tables for a specified schema:

```
> call columnstore_info.table_usage('my_schema', NULL);
```

Note: The quotes around the table name are required, an error will occur without them.

compression_ratio()

The compression_ratio() procedure calculates the average compression ratio across all the compressed extents in ColumnStore. It is called using:

```
> call columnstore_info.compression_ratio();
```

Note: The compression ratio is incorrectly calculated before versions 1.0.12 / 1.1.2

1.1.1.2.9.1.1.4 Information Schema ALL_PLUGINS Table

Description

The Information Schema `ALL_PLUGINS` table contains information about server plugins, whether installed or not.

It contains the following columns:

Column	Description
`PLUGIN_NAME`	Name of the plugin.
`PLUGIN_VERSION`	Version from the plugin's general type descriptor.
`PLUGIN_STATUS`	Plugin status, one of `ACTIVE`, `INACTIVE`, `DISABLED`, `DELETED` or `NOT INSTALLED`.

PLUGIN_TYPE	Plugin type; STORAGE ENGINE, INFORMATION_SCHEMA, AUTHENTICATION, REPLICATION, DAEMON or AUDIT.
PLUGIN_TYPE_VERSION	Version from the plugin's type-specific descriptor.
PLUGIN_LIBRARY	Plugin's shared object file name, located in the directory specified by the plugin_dir system variable, and used by the INSTALL PLUGIN and UNINSTALL PLUGIN statements. NULL if the plugin is complied in and cannot be uninstalled.
PLUGIN_LIBRARY_VERSION	Version from the plugin's API interface.
PLUGIN_AUTHOR	Author of the plugin.
PLUGIN_DESCRIPTION	Description.
PLUGIN_LICENSE	Plugin's licence.
LOAD_OPTION	How the plugin was loaded; one of OFF, ON, FORCE or FORCE_PLUS_PERMANENT. See Installing Plugins.
PLUGIN_MATURITY	Plugin's maturity level; one of Unknown, Experimental, Alpha, Beta, 'Gamma, and Stable.
PLUGIN_AUTH_VERSION	Plugin's version as determined by the plugin author. An example would be '0.99 beta 1'.

It provides a superset of the information shown by the SHOW PLUGINS SONAME statement, as well as the information_schema.PLUGINS table. For specific information about storage engines (a particular type of plugin), see the Information Schema ENGINES table and the SHOW ENGINES statement.

The table is not a standard Information Schema table, and is a MariaDB extension.

Example

```
SELECT * FROM information_schema.all_plugins\G
*************************** 1. row ***************************
           PLUGIN_NAME: binlog
        PLUGIN_VERSION: 1.0
         PLUGIN_STATUS: ACTIVE
           PLUGIN_TYPE: STORAGE ENGINE

1.1.1.2.9.1.1.5 Information Schema APPLICABLE_ROLES Table

The Information Schema `APPLICABLE_ROLES` table shows the role authorizations that the current user may use.

It contains the following columns:

Column	Description	Added
`GRANTEE`	Account that the role was granted to.	
`ROLE_NAME`	Name of the role.	
`IS_GRANTABLE`	Whether the role can be granted or not.	
`IS_DEFAULT`	Whether the role is the user's default role or not	MariaDB 10.1.3

The current role is in the ENABLED_ROLES Information Schema table.

Example

```
SELECT * FROM information_schema.APPLICABLE_ROLES;
+----------------+-------------+--------------+------------+
| GRANTEE        | ROLE_NAME   | IS_GRANTABLE | IS_DEFAULT |
+----------------+-------------+--------------+------------+
| root@localhost | journalist  | YES          | NO         |
| root@localhost | staff       | YES          | NO         |
| root@localhost | dd          | YES          | NO         |
| root@localhost | dog         | YES          | NO         |
+----------------+-------------+--------------+------------+
```

1.1.1.2.9.1.1.6 Information Schema CHARACTER_SETS Table

The Information Schema `CHARACTER_SETS` table contains a list of supported character sets, their default collations and maximum lengths.

It contains the following columns:

Column	Description
`CHARACTER_SET_NAME`	Name of the character set.
`DEFAULT_COLLATE_NAME`	Default collation used.
`DESCRIPTION`	Character set description.
`MAXLEN`	Maximum length.

The SHOW CHARACTER SET statement returns the same results (although in a different order), and both can be refined in the same way. For example, the following two statements return the same results:

```
SHOW CHARACTER SET WHERE Maxlen LIKE '2';
```

and

```
SELECT * FROM information_schema.CHARACTER_SETS
WHERE MAXLEN LIKE '2';
```

See Setting Character Sets and Collations for details on specifying the character set at the server, database, table and column levels, and Supported Character Sets and Collations for a full list of supported characters sets and collations.

Example

```
SELECT CHARACTER_SET_NAME FROM information_schema.CHARACTER_SETS
WHERE DEFAULT_COLLATE_NAME LIKE '%chinese%';
+--------------------+
| CHARACTER_SET_NAME |
+--------------------+
| big5               |
| gb2312             |
| gbk                |
+--------------------+
```

1.1.1.2.9.1.1.7 Information Schema CHECK_CONSTRAINTS Table

The Information Schema `CHECK_CONSTRAINTS` table stores metadata about the constraints defined for tables in all databases.

It contains the following columns:

Column	Description
`CONSTRAINT_CATALOG`	Always contains the string 'def'.
`CONSTRAINT_SCHEMA`	Database name.
`CONSTRAINT_NAME`	Constraint name.
`TABLE_NAME`	Table name.
`LEVEL`	Type of the constraint ('Column' or 'Table'). From MariaDB 10.5.10
`CHECK_CLAUSE`	Constraint clause.

Example

A table with a numeric table check constraint and with a default check constraint name:

```
CREATE TABLE t ( a int, CHECK (a>10));
```

To see check constraint call `check_constraints` table from information schema.

```
SELECT * from INFORMATION_SCHEMA.CHECK_CONSTRAINTS\G
```

```
*************************** 1. row ***************************
CONSTRAINT_CATALOG: def
 CONSTRAINT_SCHEMA: test
   CONSTRAINT_NAME: CONSTRAINT_1
        TABLE_NAME: t
      CHECK_CLAUSE: `a` > 10
```

A new table check constraint called `a_upper` :

```
ALTER TABLE t ADD CONSTRAINT a_upper CHECK (a<100);
```

```
SELECT * from INFORMATION_SCHEMA.CHECK_CONSTRAINTS\G
```

```
*************************** 1. row ***************************
CONSTRAINT_CATALOG: def
 CONSTRAINT_SCHEMA: test
   CONSTRAINT_NAME: CONSTRAINT_1
        TABLE_NAME: t
      CHECK_CLAUSE: `a` > 10
*************************** 2. row ***************************
CONSTRAINT_CATALOG: def
 CONSTRAINT_SCHEMA: test
   CONSTRAINT_NAME: a_upper
        TABLE_NAME: t
      CHECK_CLAUSE: `a` < 100
```

A new table `tt` with a field check constraint called `b`, as well as a table check constraint called `b_upper`:

```
CREATE TABLE tt(b int CHECK(b>0),CONSTRAINT b_upper CHECK(b<50));

SELECT * from INFORMATION_SCHEMA.CHECK_CONSTRAINTS;
+--------------------+-------------------+-----------------+------------+--------------+
| CONSTRAINT_CATALOG | CONSTRAINT_SCHEMA | CONSTRAINT_NAME | TABLE_NAME | CHECK_CLAUSE |
+--------------------+-------------------+-----------------+------------+--------------+
| def                | test              | b               | tt         | `b` > 0      |
| def                | test              | b_upper         | tt         | `b` < 50     |
| def                | test              | CONSTRAINT_1    | t          | `a` > 10     |
| def                | test              | a_upper         | t          | `a` < 100    |
+--------------------+-------------------+-----------------+------------+--------------+
```

Note: The name of the field constraint is the same as the field name.

After dropping the default table constraint called `CONSTRAINT_1`:

```
ALTER TABLE t DROP CONSTRAINT CONSTRAINT_1;

SELECT * from INFORMATION_SCHEMA.CHECK_CONSTRAINTS;
+--------------------+-------------------+-----------------+------------+--------------+
| CONSTRAINT_CATALOG | CONSTRAINT_SCHEMA | CONSTRAINT_NAME | TABLE_NAME | CHECK_CLAUSE |
+--------------------+-------------------+-----------------+------------+--------------+
| def                | test              | b               | tt         | `b` > 0      |
| def                | test              | b_upper         | tt         | `b` < 50     |
| def                | test              | a_upper         | t          | `a` < 100    |
+--------------------+-------------------+-----------------+------------+--------------+
```

Trying to insert invalid arguments into table `t` and `tt` generates an error.

```
INSERT INTO t VALUES (10),(20),(100);
ERROR 4025 (23000): CONSTRAINT `a_upper` failed for `test`.`t`

INSERT INTO tt VALUES (10),(-10),(100);
ERROR 4025 (23000): CONSTRAINT `b` failed for `test`.`tt`

INSERT INTO tt VALUES (10),(20),(100);
ERROR 4025 (23000): CONSTRAINT `b_upper` failed for `test`.`tt`
```

From MariaDB 10.5.10:

```
create table majra(check(x>0), x int, y int check(y < 0), z int,
                           constraint z check(z>0), constraint xyz check(x<10 and y<10 and
z<10));
Query OK, 0 rows affected (0.036 sec)

show create table majra;

1.1.1.2.9.1.1.8 Information Schema CLIENT_STATISTICS Table

The Information Schema `CLIENT_STATISTICS` table holds statistics about client connections. This is part of the User Statistics feature, which is not enabled by default.

It contains the following columns:

Field	Type	Notes
`CLIENT`	`VARCHAR(64)`	The IP address or hostname the connection originated from.
`TOTAL_CONNECTIONS`	`INT(21)`	The number of connections created for this client.
`CONCURRENT_CONNECTIONS`	`INT(21)`	The number of concurrent connections for this client.
`CONNECTED_TIME`	`INT(21)`	The cumulative number of seconds elapsed while there were connections from this client.

BUSY_TIME	DOUBLE	The cumulative number of seconds there was activity on connections from this client.
CPU_TIME	DOUBLE	The cumulative CPU time elapsed while servicing this client's connections. Note that this number may be wrong on SMP system if there was a CPU migration for the thread during the execution of the query.
BYTES_RECEIVED	INT(21)	The number of bytes received from this client's connections.
BYTES_SENT	INT(21)	The number of bytes sent to this client's connections.
BINLOG_BYTES_WRITTEN	INT(21)	The number of bytes written to the binary log from this client's connections.
ROWS_READ	INT(21)	The number of rows read by this client's connections.
ROWS_SENT	INT(21)	The number of rows sent by this client's connections.
ROWS_DELETED	INT(21)	The number of rows deleted by this client's connections.
ROWS_INSERTED	INT(21)	The number of rows inserted by this client's connections.
ROWS_UPDATED	INT(21)	The number of rows updated by this client's connections.
SELECT_COMMANDS	INT(21)	The number of `SELECT` commands executed from this client's connections.
UPDATE_COMMANDS	INT(21)	The number of `UPDATE` commands executed from this client's connections.
OTHER_COMMANDS	INT(21)	The number of other commands executed from this client's connections.
COMMIT_TRANSACTIONS	INT(21)	The number of `COMMIT` commands issued by this client's connections.
ROLLBACK_TRANSACTIONS	INT(21)	The number of `ROLLBACK` commands issued by this client's connections.
DENIED_CONNECTIONS	INT(21)	The number of connections denied to this client.
LOST_CONNECTIONS	INT(21)	The number of this client's connections that were terminated uncleanly.
ACCESS_DENIED	INT(21)	The number of times this client's connections issued commands that were denied.
EMPTY_QUERIES	INT(21)	The number of times this client's connections sent queries that returned no results to the server.
TOTAL_SSL_CONNECTIONS	INT(21)	The number of TLS connections created for this client. (>= MariaDB 10.1.1)
MAX_STATEMENT_TIME_EXCEEDED	INT(21)	The number of times a statement was aborted, because it was executed longer than its `MAX_STATEMENT_TIME` threshold. (>= MariaDB 10.1.1)

Example

```
SELECT * FROM information_schema.CLIENT_STATISTICS\G
*************************** 1. row ***************************
                CLIENT: localhost
     TOTAL_CONNECTIONS: 3
CONCURRENT_CONNECTIONS: 0
        CONNECTED_TIME: 4883
             BUSY_TIME: 0.009722
              CPU_TIME: 0.0102131
        BYTES_RECEIVED: 841
            BYTES_SENT: 13897
  BINLOG_BYTES_WRITTEN: 0
             ROWS_READ: 0
             ROWS_SENT: 214
          ROWS_DELETED: 0
         ROWS_INSERTED: 207
          ROWS_UPDATED: 0
       SELECT_COMMANDS: 10
       UPDATE_COMMANDS: 0
        OTHER_COMMANDS: 13
   COMMIT_TRANSACTIONS: 0
 ROLLBACK_TRANSACTIONS: 0
    DENIED_CONNECTIONS: 0
      LOST_CONNECTIONS: 0
         ACCESS_DENIED: 0
         EMPTY_QUERIES: 1
```

1.1.1.2.9.1.1.9 Information Schema COLLATION_CHARACTER_SET_APPLICABILIT Table

The Information Schema `COLLATION_CHARACTER_SET_APPLICABILITY` table shows which character sets are associated with which collations.

It contains the following columns:

Column	Description
`COLLATION_NAME`	Collation name.
`CHARACTER_SET_NAME`	Name of the associated character set.

`COLLATION_CHARACTER_SET_APPLICABILITY` is essentially a subset of the `COLLATIONS` table.

```
SELECT COLLATION_NAME,CHARACTER_SET_NAME FROM information_schema.COLLATIONS;
```

and

```
SELECT * FROM information_schema.COLLATION_CHARACTER_SET_APPLICABILITY;
```

will return identical results.

See Setting Character Sets and Collations for details on specifying the character set at the server, database, table and column levels.

Example

```
SELECT * FROM information_schema.COLLATION_CHARACTER_SET_APPLICABILITY
WHERE CHARACTER_SET_NAME='utf32';
+---------------------+--------------------+
| COLLATION_NAME      | CHARACTER_SET_NAME |
+---------------------+--------------------+
| utf32_general_ci    | utf32              |
| utf32_bin           | utf32              |
| utf32_unicode_ci    | utf32              |
| utf32_icelandic_ci  | utf32              |
| utf32_latvian_ci    | utf32              |
| utf32_romanian_ci   | utf32              |
| utf32_slovenian_ci  | utf32              |
| utf32_polish_ci     | utf32              |
| utf32_estonian_ci   | utf32              |
| utf32_spanish_ci    | utf32              |
| utf32_swedish_ci    | utf32              |
| utf32_turkish_ci    | utf32              |
| utf32_czech_ci      | utf32              |
| utf32_danish_ci     | utf32              |
| utf32_lithuanian_ci | utf32              |
| utf32_slovak_ci     | utf32              |
| utf32_spanish2_ci   | utf32              |
| utf32_roman_ci      | utf32              |
| utf32_persian_ci    | utf32              |
| utf32_esperanto_ci  | utf32              |
| utf32_hungarian_ci  | utf32              |
| utf32_sinhala_ci    | utf32              |
| utf32_german2_ci    | utf32              |
| utf32_croatian_ci   | utf32              |
+---------------------+--------------------+
```

1.1.1.2.9.1.1.10 Information Schema COLLATIONS Table

Contents

The Information Schema `COLLATIONS` table contains a list of supported collations.

It contains the following columns:

Column	Description
`COLLATION_NAME`	Name of the collation.
`CHARACTER_SET_NAME`	Associated character set.
`ID`	Collation id.
`IS_DEFAULT`	Whether the collation is the character set's default.
`IS_COMPILED`	Whether the collation is compiled into the server.
`SORTLEN`	Sort length, used for determining the memory used to sort strings in this collation.

The SHOW COLLATION statement returns the same results and both can be reduced in a similar way.

For example, in MariaDB 10.6, the following two statements return the same results:

```
SHOW COLLATION WHERE Charset LIKE 'utf8mb3';
```

and

```
SELECT * FROM information_schema.COLLATIONS
WHERE CHARACTER_SET_NAME LIKE 'utf8mb3';
```

In MariaDB 10.5 and before, `utf8` should be specified instead of `utf8mb3`.

NO PAD collations

`NO PAD` collations regard trailing spaces as normal characters. You can get a list of all `NO PAD` collations as follows:

```
SELECT collation_name FROM information_schema.COLLATIONS
WHERE collation_name LIKE "%nopad%";
+----------------------------+
| collation_name             |
+----------------------------+
| big5_chinese_nopad_ci      |
| big5_nopad_bin             |
...
```

Example

```
SELECT * FROM information_schema.COLLATIONS;
+----------------------------+--------------------+------+------------+-------------+---------+
| COLLATION_NAME             | CHARACTER_SET_NAME | ID   | IS_DEFAULT | IS_COMPILED | SORTLEN |
+----------------------------+--------------------+------+------------+-------------+---------+
| big5_chinese_ci            | big5               |    1 | Yes        | Yes         |       1 |
| big5_bin                   | big5               |   84 |            | Yes         |       1 |
| big5_chinese_nopad_ci      | big5               | 1025 |            | Yes         |       1 |
| big5_nopad_bin             | big5               | 1108 |            | Yes         |       1 |
| dec8_swedish_ci            | dec8               |    3 | Yes        | Yes         |       1 |
| dec8_bin                   | dec8               |   69 |            | Yes         |       1 |
| dec8_swedish_nopad_ci      | dec8               | 1027 |            | Yes         |       1 |
| dec8_nopad_bin             | dec8               | 1093 |            | Yes         |       1 |
| cp850_general_ci           | cp850              |    4 | Yes        | Yes         |       1 |
| cp850_bin                  | cp850              |   80 |            | Yes         |       1 |
...
```

1.1.1.2.9.1.1.11 Information Schema COLUMN_PRIVILEGES Table

The Information Schema `COLUMN_PRIVILEGES` table contains column privilege information derived from the `mysql.columns_priv` grant table.

It has the following columns:

Column	Description
`GRANTEE`	In the format `user_name@host_name`.
`TABLE_CATALOG`	Always `def`.
`TABLE_SCHEMA`	Database name.
`TABLE_NAME`	Table name.
`COLUMN_NAME`	Column name.
`PRIVILEGE_TYPE`	One of `SELECT`, `INSERT`, `UPDATE` or `REFERENCES`.
`IS_GRANTABLE`	Whether the user has the `GRANT OPTION` for this privilege.

Similar information can be accessed with the `SHOW FULL COLUMNS` and `SHOW GRANTS` statements. See the `GRANT` article for more about privileges.

This information is also stored in the `columns_priv` table, in the `mysql` system database.

For a description of the privileges that are shown in this table, see column privileges.

Example

In the following example, no column-level privilege has been explicitly assigned:

```
SELECT * FROM information_schema.COLUMN_PRIVILEGES;
Empty set
```

1.1.1.2.9.1.1.12 Information Schema COLUMNS Table

The Information Schema `COLUMNS` table provides information about columns in each table on the server.

It contains the following columns:

Column	Description
`TABLE_CATALOG`	Always contains the string 'def'.
`TABLE_SCHEMA`	Database name.
`TABLE_NAME`	Table name.
`COLUMN_NAME`	Column name.
`ORDINAL_POSITION`	Column position in the table. Can be used for ordering.
`COLUMN_DEFAULT`	Default value for the column. Literals are quoted to distinguish them from expressions. `NULL` means that the column has no default. In MariaDB 10.2.6 and earlier, no quotes were used for any type of default and `NULL` can either mean that there is no default, or that the default column value is `NULL`.
`IS_NULLABLE`	Whether the column can contain `NULL`s.
`DATA_TYPE`	The column's data type.
`CHARACTER_MAXIMUM_LENGTH`	Maximum length.
`CHARACTER_OCTET_LENGTH`	Same as the `CHARACTER_MAXIMUM_LENGTH` except for multi-byte character sets.
`NUMERIC_PRECISION`	For numeric types, the precision (number of significant digits) for the column. `NULL` if not a numeric field.
`NUMERIC_SCALE`	For numeric types, the scale (significant digits to the right of the decimal point). NULL if not a numeric field.
`DATETIME_PRECISION`	Fractional-seconds precision, or `NULL` if not a time data type.
`CHARACTER_SET_NAME`	Character set if a non-binary string data type, otherwise NULL.
`COLLATION_NAME`	Collation if a non-binary string data type, otherwise NULL.
`COLUMN_TYPE`	Column definition, a MySQL and MariaDB extension.
`COLUMN_KEY`	Index type. `PRI` for primary key, `UNI` for unique index, `MUL` for multiple index. A MySQL and MariaDB extension.
`EXTRA`	Additional information about a column, for example whether the column is an invisible column, or `WITHOUT SYSTEM VERSIONING` if the table is not a system-versioned table. A MySQL and MariaDB extension.
`PRIVILEGES`	Which privileges you have for the column. A MySQL and MariaDB extension.
`COLUMN_COMMENT`	Column comments.
`IS_GENERATED`	Indicates whether the column value is generated (virtual, or computed). Can be `ALWAYS` or `NEVER`.
`GENERATION_EXPRESSION`	The expression used for computing the column value in a generated (virtual, or computed) column.
`IS_SYSTEM_TIME_PERIOD_START`	From MariaDB 11.3.0.
`IS_SYSTEM_TIME_PERIOD_END`	From MariaDB 11.3.0.

It provides information similar to, but more complete, than SHOW COLUMNS and mariadb-show.

Examples

```
SELECT * FROM information_schema.COLUMNS\G
...
*************************** 9. row ***************************
           TABLE_CATALOG: def
            TABLE_SCHEMA: test
              TABLE_NAME: t2
             COLUMN_NAME: j
        ORDINAL_POSITION: 1
          COLUMN_DEFAULT: NULL
             IS_NULLABLE: YES
               DATA_TYPE: longtext
CHARACTER_MAXIMUM_LENGTH: 4294967295
  CHARACTER_OCTET_LENGTH: 4294967295
       NUMERIC_PRECISION: NULL
           NUMERIC_SCALE: NULL
      DATETIME_PRECISION: NULL
      CHARACTER_SET_NAME: utf8mb4
          COLLATION_NAME: utf8mb4_bin
             COLUMN_TYPE: longtext
              COLUMN_KEY:
                   EXTRA:
              PRIVILEGES: select,insert,update,references
          COLUMN_COMMENT:
            IS_GENERATED: NEVER
   GENERATION_EXPRESSION: NULL
...
```

```
CREATE TABLE t (
  s1 VARCHAR(20) DEFAULT 'ABC',
  s2 VARCHAR(20) DEFAULT (concat('A','B')),
  s3 VARCHAR(20) DEFAULT ("concat('A','B')"),
  s4 VARCHAR(20),
  s5 VARCHAR(20) DEFAULT NULL,
  s6 VARCHAR(20) NOT NULL,
  s7 VARCHAR(20) DEFAULT 'NULL' NULL,
  s8 VARCHAR(20) DEFAULT 'NULL' NOT NULL
);

SELECT
  table_name,
  column_name,
  ordinal_position,
  column_default,
  column_default IS NULL
FROM information_schema.COLUMNS
WHERE table_schema=DATABASE()
AND TABLE_NAME='t';
+------------+-------------+------------------+----------------------+------------------------+
| table_name | column_name | ordinal_position | column_default       | column_default IS NULL |
+------------+-------------+------------------+----------------------+------------------------+
| t          | s1          |                1 | 'ABC'                |                      0 |
| t          | s2          |                2 | concat('A','B')      |                      0 |
| t          | s3          |                3 | 'concat(''A'',''B'')' |                      0 |
| t          | s4          |                4 | NULL                 |                      0 |
| t          | s5          |                5 | NULL                 |                      0 |
| t          | s6          |                6 | NULL                 |                      1 |
| t          | s7          |                7 | 'NULL'               |                      0 |
| t          | s8          |                8 | 'NULL'               |                      0 |
+------------+-------------+------------------+----------------------+------------------------+
```

In the results above, the two single quotes in `concat(''A'',''B'')` indicate an escaped single quote - see string-literals. Note that while mariadb client appears to show the same default value for columns `s5` and `s6`, the first is a 4-character string "NULL", while the second is the SQL NULL value.

From MariaDB 11.3:

```
CREATE TABLE t(
     x INT,
     start_timestamp TIMESTAMP(6) GENERATED ALWAYS AS ROW START,
     end_timestamp TIMESTAMP(6) GENERATED ALWAYS AS ROW END,
     PERIOD FOR SYSTEM_TIME(start_timestamp, end_timestamp)
) WITH SYSTEM VERSIONING;

SELECT TABLE_NAME, COLUMN_NAME, ORDINAL_POSITION,
  IS_SYSTEM_TIME_PERIOD_START, IS_SYSTEM_TIME_PERIOD_END
  FROM INFORMATION_SCHEMA.COLUMNS WHERE TABLE_NAME='t'\G
*************************** 1. row ***************************
                TABLE_NAME: t
               COLUMN_NAME: x
          ORDINAL_POSITION: 1
IS_SYSTEM_TIME_PERIOD_START: NO
  IS_SYSTEM_TIME_PERIOD_END: NO
*************************** 2. row ***************************
                TABLE_NAME: t
               COLUMN_NAME: start_timestamp
          ORDINAL_POSITION: 2
IS_SYSTEM_TIME_PERIOD_START: YES
  IS_SYSTEM_TIME_PERIOD_END: NO
*************************** 3. row ***************************
                TABLE_NAME: t
               COLUMN_NAME: end_timestamp
          ORDINAL_POSITION: 3
IS_SYSTEM_TIME_PERIOD_START: NO
  IS_SYSTEM_TIME_PERIOD_END: YES
```

1.1.1.2.9.1.1.13 Information Schema DISKS Table

Contents

Description

The `DISKS` table is created when the DISKS plugin is enabled, and shows metadata about disks on the system.

Before MariaDB 10.4.7, MariaDB 10.3.17, MariaDB 10.2.26 and MariaDB 10.1.41, this plugin did **not** check user privileges. When it is enabled, **any** user can query the `INFORMATION_SCHEMA.DISKS` table and see all the information it provides.

Since MariaDB 10.4.7, MariaDB 10.3.17, MariaDB 10.2.26 and MariaDB 10.1.41, it requires the FILE privilege.

The plugin only works on Linux.

The table contains the following columns:

Column	Description
`DISK`	Name of the disk itself.
`PATH`	Mount point of the disk.
`TOTAL`	Total space in KiB.
`USED`	Used amount of space in KiB.
`AVAILABLE`	Amount of space in KiB available to non-root users.

Note that as the amount of space available to root (OS user) may be more that what is available to non-root users, 'available' + 'used' may be less than 'total'.

All paths to which a particular disk has been mounted are reported. The rationale is that someone might want to take different action e.g. depending on which disk is relevant for a particular path. This leads to the same disk being reported multiple times.

Example

```
SELECT * FROM information_schema.DISKS;

+-----------+-------+----------+---------+-----------+
| Disk      | Path  | Total    | Used    | Available |
+-----------+-------+----------+---------+-----------+
| /dev/vda1 | /     | 26203116 | 2178424 |  24024692 |
| /dev/vda1 | /boot | 26203116 | 2178424 |  24024692 |
| /dev/vda1 | /etc  | 26203116 | 2178424 |  24024692 |
+-----------+-------+----------+---------+-----------+
```

1.1.1.2.9.1.1.14 Information Schema ENABLED_ROLES Table

The Information Schema `ENABLED_ROLES` table shows the enabled roles for the current session.

It contains the following column:

Column	Description
`ROLE_NAME`	The enabled role name, or `NULL`.

This table lists all roles that are currently enabled, one role per row — the current role, roles granted to the current role, roles granted to these roles and so on. If no role is set, the row contains a `NULL` value.

The roles that the current user can enable are listed in the APPLICABLE_ROLES Information Schema table.

See also CURRENT_ROLE().

Examples

```
SELECT * FROM information_schema.ENABLED_ROLES;
+-----------+
| ROLE_NAME |
+-----------+
| NULL      |
+-----------+

SET ROLE staff;

SELECT * FROM information_schema.ENABLED_ROLES;
+-----------+
| ROLE_NAME |
+-----------+
| staff     |
+-----------+
```

1.1.1.2.9.1.1.15 Information Schema ENGINES Table

The Information Schema `ENGINES` table displays status information about the server's storage engines.

It contains the following columns:

Column	Description
`ENGINE`	Name of the storage engine.
`SUPPORT`	Whether the engine is the default, or is supported or not.
`COMMENT`	Storage engine comments.
`TRANSACTIONS`	Whether or not the engine supports transactions.
`XA`	Whether or not the engine supports XA transactions.

SAVEPOINTS	Whether or not savepoints are supported.

It provides identical information to the `SHOW ENGINES` statement. Since storage engines are plugins, different information about them is also shown in the `information_schema.PLUGINS` table and by the `SHOW PLUGINS` statement.

The table is not a standard Information Schema table, and is a MySQL and MariaDB extension.

Note that both MySQL's InnoDB and Percona's XtraDB replacement are labeled as `InnoDB`. However, if XtraDB is in use, it will be specified in the `COMMENT` field. See XtraDB and InnoDB. The same applies to FederatedX.

Example

```
SELECT * FROM information_schema.ENGINES\G;
*************************** 1. row ***************************
      ENGINE: InnoDB
     SUPPORT: DEFAULT
     COMMENT: Supports transactions, row-level locking, and foreign keys
TRANSACTIONS: YES
          XA: YES
  SAVEPOINTS: YES
*************************** 2. row ***************************
      ENGINE: CSV
     SUPPORT: YES
     COMMENT: CSV storage engine
TRANSACTIONS: NO
          XA: NO
  SAVEPOINTS: NO
*************************** 3. row ***************************
      ENGINE: MyISAM
     SUPPORT: YES
     COMMENT: MyISAM storage engine
TRANSACTIONS: NO
          XA: NO
  SAVEPOINTS: NO
*************************** 4. row ***************************
      ENGINE: BLACKHOLE
     SUPPORT: YES
     COMMENT: /dev/null storage engine (anything you write to it disappears)
TRANSACTIONS: NO
          XA: NO
  SAVEPOINTS: NO
*************************** 5. row ***************************
      ENGINE: FEDERATED
     SUPPORT: YES
     COMMENT: FederatedX pluggable storage engine
TRANSACTIONS: YES
          XA: NO
  SAVEPOINTS: YES
*************************** 6. row ***************************
      ENGINE: MRG_MyISAM
     SUPPORT: YES
     COMMENT: Collection of identical MyISAM tables
TRANSACTIONS: NO
          XA: NO
  SAVEPOINTS: NO
*************************** 7. row ***************************
      ENGINE: ARCHIVE
     SUPPORT: YES
     COMMENT: Archive storage engine
TRANSACTIONS: NO
          XA: NO
  SAVEPOINTS: NO
*************************** 8. row ***************************
      ENGINE: MEMORY
     SUPPORT: YES
     COMMENT: Hash based, stored in memory, useful for temporary tables
TRANSACTIONS: NO
          XA: NO
  SAVEPOINTS: NO
*************************** 9. row ***************************
      ENGINE: PERFORMANCE_SCHEMA
     SUPPORT: YES
     COMMENT: Performance Schema
TRANSACTIONS: NO
          XA: NO
  SAVEPOINTS: NO
*************************** 10. row ***************************
      ENGINE: Aria
     SUPPORT: YES
     COMMENT: Crash-safe tables with MyISAM heritage
TRANSACTIONS: NO
          XA: NO
  SAVEPOINTS: NO
10 rows in set (0.00 sec)
```

Check if a given storage engine is available:

```
SELECT SUPPORT FROM information_schema.ENGINES WHERE ENGINE LIKE 'tokudb';
Empty set
```

Check which storage engine supports XA transactions:

```
SELECT ENGINE FROM information_schema.ENGINES WHERE XA = 'YES';
+--------+
| ENGINE |
+--------+
| InnoDB |
+--------+
```

1.1.1.2.9.1.1.16 Information Schema EVENTS Table

The Information Schema `EVENTS` table stores information about Events on the server.

It contains the following columns:

Column	Description
`EVENT_CATALOG`	Always `def`.
`EVENT_SCHEMA`	Database where the event was defined.
`EVENT_NAME`	Event name.
`DEFINER`	Event definer.
`TIME_ZONE`	Time zone used for the event's scheduling and execution, by default `SYSTEM`.
`EVENT_BODY`	`SQL`.
`EVENT_DEFINITION`	The SQL defining the event.
`EVENT_TYPE`	Either `ONE TIME` or `RECURRING`.
`EXECUTE_AT`	`DATETIME` when the event is set to execute, or `NULL` if recurring.
`INTERVAL_VALUE`	Numeric interval between event executions for a recurring event, or `NULL` if not recurring.
`INTERVAL_FIELD`	Interval unit (e.g., `HOUR`)
`SQL_MODE`	The `SQL_MODE` at the time the event was created.
`STARTS`	Start `DATETIME` for a recurring event, `NULL` if not defined or not recurring.
`ENDS`	End `DATETIME` for a recurring event, `NULL` if not defined or not recurring.
`STATUS`	One of `ENABLED`, `DISABLED` or / `SLAVESIDE_DISABLED`.
`ON_COMPLETION`	The `ON COMPLETION` clause, either `PRESERVE` or `NOT PRESERVE`.
`CREATED`	When the event was created.
`LAST_ALTERED`	When the event was last changed.
`LAST_EXECUTED`	When the event was last run.
`EVENT_COMMENT`	The comment provided in the `CREATE EVENT` statement, or an empty string if none.
`ORIGINATOR`	MariaDB server ID on which the event was created.
`CHARACTER_SET_CLIENT`	`character_set_client` system variable session value at the time the event was created.
`COLLATION_CONNECTION`	collation_connection system variable session value at the time the event was created.
`DATABASE_COLLATION`	Database collation with which the event is linked.

The `SHOW EVENTS` and `SHOW CREATE EVENT` statements provide similar information.

1.1.1.2.9.1.1.17 Information Schema FEEDBACK Table

The Information Schema `FEEDBACK` table is created when the Feedback Plugin is enabled, and contains the complete contents submitted by the plugin.

It contains two columns:

Column	Description
`VARIABLE_NAME`	Name of the item of information being collected.
`VARIABLE_VALUE`	Contents of the item of information being collected.

It is possible to disable automatic collection, by setting the `feedback_url` variable to an empty string, and to submit the contents manually, as follows:

```
$ mysql -e 'SELECT * FROM information_schema.FEEDBACK' > report.txt
```

Then you can send it by opening `https://mariadb.org/feedback_plugin/post` in your browser, and uploading your generated `report.txt`. Or you can do it from the command line with (for example):

```
$ curl -F data=@report.txt https://mariadb.org/feedback_plugin/post
```

Manual uploading allows you to be absolutely sure that we receive only the data shown in the `information_schema.FEEDBACK` table and that no private or sensitive information is being sent.

Example

```
SELECT * FROM information_schema.FEEDBACK\G
...
*************************** 906. row ***************************
 VARIABLE_NAME: Uname_sysname
VARIABLE_VALUE: Linux
*************************** 907. row ***************************
 VARIABLE_NAME: Uname_release
VARIABLE_VALUE: 3.13.0-53-generic
*************************** 908. row ***************************
 VARIABLE_NAME: Uname_version
VARIABLE_VALUE: #89-Ubuntu SMP Wed May 20 10:34:39 UTC 2015
*************************** 909. row ***************************
 VARIABLE_NAME: Uname_machine
VARIABLE_VALUE: x86_64
*************************** 910. row ***************************
 VARIABLE_NAME: Uname_distribution
VARIABLE_VALUE: lsb: Ubuntu 14.04.2 LTS
*************************** 911. row ***************************
 VARIABLE_NAME: Collation used latin1_german1_ci
VARIABLE_VALUE: 1
*************************** 912. row ***************************
 VARIABLE_NAME: Collation used latin1_swedish_ci
VARIABLE_VALUE: 18
*************************** 913. row ***************************
 VARIABLE_NAME: Collation used utf8_general_ci
VARIABLE_VALUE: 567
*************************** 914. row ***************************
 VARIABLE_NAME: Collation used latin1_bin
VARIABLE_VALUE: 1
*************************** 915. row ***************************
 VARIABLE_NAME: Collation used binary
VARIABLE_VALUE: 16
*************************** 916. row ***************************
 VARIABLE_NAME: Collation used utf8_bin
VARIABLE_VALUE: 4044
```

1.1.1.2.9.1.1.18 Information Schema FILES

Table

The `FILES` tables is unused in MariaDB. See MDEV-11426.

1.1.1.2.9.1.1.19 Information Schema GEOMETRY_COLUMNS Table

Description

The Information Schema `GEOMETRY_COLUMNS` table provides support for Spatial Reference systems for GIS data.

It contains the following columns:

Column	Type	Null	Description
`F_TABLE_CATALOG`	`VARCHAR(512)`	NO	Together with `F_TABLE_SCHEMA` and `F_TABLE_NAME`, the fully qualified name of the featured table containing the geometry column.
`F_TABLE_SCHEMA`	`VARCHAR(64)`	NO	Together with `F_TABLE_CATALOG` and `F_TABLE_NAME`, the fully qualified name of the featured table containing the geometry column.
`F_TABLE_NAME`	`VARCHAR(64)`	NO	Together with `F_TABLE_CATALOG` and `F_TABLE_SCHEMA`, the fully qualified name of the featured table containing the geometry column.
`F_GEOMETRY_COLUMN`	`VARCHAR(64)`	NO	Name of the column in the featured table that is the geometry golumn.
`G_TABLE_CATALOG`	`VARCHAR(512)`	NO	
`G_TABLE_SCHEMA`	`VARCHAR(64)`	NO	Database name of the table implementing the geometry column.
`G_TABLE_NAME`	`VARCHAR(64)`	NO	Table name that is implementing the geometry column.
`G_GEOMETRY_COLUMN`	`VARCHAR(64)`	NO	
`STORAGE_TYPE`	`TINYINT(2)`	NO	Binary geometry implementation. Always 1 in MariaDB.
`GEOMETRY_TYPE`	`INT(7)`	NO	Integer reflecting the type of geometry stored in this column (see table below).
`COORD_DIMENSION`	`TINYINT(2)`	NO	Number of dimensions in the spatial reference system. Always 2 in MariaDB.
`MAX_PPR`	`TINYINT(2)`	NO	Always 0 in MariaDB.
`SRID`	`SMALLINT(5)`	NO	ID of the Spatial Reference System used for the coordinate geometry in this table. It is a foreign key reference to the `SPATIAL_REF_SYS table`.

Storage_type

The integers in the `storage_type` field match the geometry types as follows:

Integer	Type
0	`GEOMETRY`
1	`POINT`
3	`LINESTRING`
5	`POLYGON`
7	`MULTIPOINT`
9	`MULTILINESTRING`
11	`MULTIPOLYGON`

Example

```
CREATE TABLE g1(g GEOMETRY(9,4) REF_SYSTEM_ID=101);

SELECT * FROM information_schema.GEOMETRY_COLUMNS\G
*************************** 1. row ***************************
  F_TABLE_CATALOG: def
   F_TABLE_SCHEMA: test
     F_TABLE_NAME: g1
F_GEOMETRY_COLUMN:
  G_TABLE_CATALOG: def
   G_TABLE_SCHEMA: test
     G_TABLE_NAME: g1
G_GEOMETRY_COLUMN: g
     STORAGE_TYPE: 1
    GEOMETRY_TYPE: 0
  COORD_DIMENSION: 2
          MAX_PPR: 0
             SRID: 101
```

1.1.1.2.9.1.1.20 Information Schema GLOBAL_STATUS and SESSION_STATUS Tables

The Information Schema `GLOBAL_STATUS` and `SESSION_STATUS` tables store a record of all status variables and their global and session values respectively. This is the same information as displayed by the `SHOW STATUS` commands `SHOW GLOBAL STATUS` and `SHOW SESSION STATUS`.

They contain the following columns:

Column	Description
`VARIABLE_NAME`	Status variable name.
`VARIABLE_VALUE`	Global or session value.

Example

```
SELECT * FROM information_schema.GLOBAL_STATUS;
+-----------------------------------------------+--------------------+
| VARIABLE_NAME                                 | VARIABLE_VALUE     |
+-----------------------------------------------+--------------------+
...
| BINLOG_SNAPSHOT_FILE                          | mariadb-bin.000208 |
| BINLOG_SNAPSHOT_POSITION                      | 369                |
...
| THREADS_CONNECTED                             | 1                  |
| THREADS_CREATED                               | 1                  |
| THREADS_RUNNING                               | 1                  |
| UPTIME                                        | 57358              |
| UPTIME_SINCE_FLUSH_STATUS                     | 57358              |
+-----------------------------------------------+--------------------+
```

1.1.1.2.9.1.1.21 Information Schema GLOBAL_VARIABLES and SESSION_VARIABLES Tables

The Information Schema `GLOBAL_VARIABLES` and `SESSION_VARIABLES` tables stores a record of all system variables and their global and session values respectively. This is the same information as displayed by the `SHOW VARIABLES` commands `SHOW GLOBAL VARIABLES` and `SHOW SESSION VARIABLES`.

It contains the following columns:

Column	Description

VARIABLE_NAME	System variable name.
VARIABLE_VALUE	Global or session value.

Example

```
SELECT * FROM information_schema.GLOBAL_VARIABLES ORDER BY VARIABLE_NAME\G
*************************** 1. row ***************************
 VARIABLE_NAME: ARIA_BLOCK_SIZE
VARIABLE_VALUE: 8192
*************************** 2. row ***************************
 VARIABLE_NAME: ARIA_CHECKPOINT_LOG_ACTIVITY
VARIABLE_VALUE: 1048576
*************************** 3. row ***************************
 VARIABLE_NAME: ARIA_CHECKPOINT_INTERVAL
VARIABLE_VALUE: 30
...
*************************** 455. row ***************************
 VARIABLE_NAME: VERSION_COMPILE_MACHINE
VARIABLE_VALUE: x86_64
*************************** 456. row ***************************
 VARIABLE_NAME: VERSION_COMPILE_OS
VARIABLE_VALUE: debian-linux-gnu
*************************** 457. row ***************************
 VARIABLE_NAME: WAIT_TIMEOUT
VARIABLE_VALUE: 600
```

1.1.1.2.9.1.1.22 Information Schema INDEX_STATISTICS Table

The Information Schema `INDEX_STATISTICS` table shows statistics on index usage and makes it possible to do such things as locating unused indexes and generating the commands to remove them.

This is part of the User Statistics feature, which is not enabled by default.

It contains the following columns:

Field	Type	Notes
TABLE_SCHEMA	VARCHAR(192)	The schema (database) name.
TABLE_NAME	VARCHAR(192)	The table name.
INDEX_NAME	VARCHAR(192)	The index name (as visible in `SHOW CREATE TABLE`).
ROWS_READ	INT(21)	The number of rows read from this index.

Example

```
SELECT * FROM information_schema.INDEX_STATISTICS
WHERE TABLE_NAME = "author";
+--------------+------------+------------+-----------+
| TABLE_SCHEMA | TABLE_NAME | INDEX_NAME | ROWS_READ |
+--------------+------------+------------+-----------+
| books        | author     | by_name    |        15 |
+--------------+------------+------------+-----------+
```

1.1.1.2.9.1.1.23 Information Schema KEY_CACHES Table

The Information Schema `KEY_CACHES` table shows statistics about the segmented key cache,.

It contains the following columns:

Column Name	Description
KEY_CACHE_NAME	The name of the key cache
SEGMENTS	total number of segments (set to NULL for regular key caches)
SEGMENT_NUMBER	segment number (set to NULL for any regular key caches and for rows containing aggregation statistics for segmented key caches)
FULL_SIZE	memory for cache buffers/auxiliary structures
BLOCK_SIZE	size of the blocks
USED_BLOCKS	number of currently used blocks
UNUSED_BLOCKS	number of currently unused blocks
DIRTY_BLOCKS	number of currently dirty blocks
READ_REQUESTS	number of read requests
READS	number of actual reads from files into buffers
WRITE_REQUESTS	number of write requests
WRITES	number of actual writes from buffers into files

Example

```
SELECT * FROM information_schema.KEY_CACHES \G
*********************** 1. row ***********************
KEY_CACHE_NAME: default
SEGMENTS: NULL
SEGMENT_NUMBER: NULL
     FULL_SIZE: 134217728
    BLOCK_SIZE: 1024
   USED_BLOCKS: 36
 UNUSED_BLOCKS: 107146
  DIRTY_BLOCKS: 0
 READ_REQUESTS: 40305
         READS: 21
WRITE_REQUESTS: 19239
        WRITES: 358
```

1.1.1.2.9.1.1.24 Information Schema KEY_COLUMN_USAGE Table

The Information Schema KEY_COLUMN_USAGE table shows which key columns have constraints.

It contains the following columns:

Column	Description
CONSTRAINT_CATALOG	Always def .
CONSTRAINT_SCHEMA	Database name of the constraint.
CONSTRAINT_NAME	Name of the constraint (PRIMARY for the primary key).
TABLE_CATALOG	Always #def .
TABLE_SCHEMA	Database name of the column constraint.
TABLE_NAME	Table name of the column constraint.
COLUMN_NAME	Column name of the constraint.
ORDINAL_POSITION	Position of the column within the constraint.
POSITION_IN_UNIQUE_CONSTRAINT	For foreign keys, the position in the unique constraint.
REFERENCED_TABLE_SCHEMA	For foreign keys, the referenced database name.

REFERENCED_TABLE_NAME	For foreign keys, the referenced table name.
REFERENCED_COLUMN_NAME	For foreign keys, the referenced column name.

Example

```
SELECT * FROM information_schema.KEY_COLUMN_USAGE LIMIT 1 \G
*********************** 1. row ***********************
           CONSTRAINT_CATALOG: def
            CONSTRAINT_SCHEMA: my_website
              CONSTRAINT_NAME: PRIMARY
                TABLE_CATALOG: def
                 TABLE_SCHEMA: users
                  COLUMN_NAME: user_id
             ORDINAL_POSITION: 1
POSITION_IN_UNIQUE_CONSTRAINT: NULL
      REFERENCED_TABLE_SCHEMA: NULL
        REFERENCED_TABLE_NAME: NULL
       REFERENCED_COLUMN_NAME: NULL
```

1.1.1.2.9.1.1.25 Information Schema KEY_PERIOD_USAGE Table

MariaDB starting with 11.3.0

The Information Schema `KEY_PERIOD_USAGE` table shows information about Application-Time Periods.

It contains the following columns:

Column	Description
CONSTRAINT_CATALOG	
CONSTRAINT_SCHEMA	
CONSTRAINT_NAME	
TABLE_CATALOG	
TABLE_SCHEMA	
TABLE_NAME	
PERIOD_NAME	

Example

1.1.1.2.9.1.1.26 Information Schema KEYWORDS Table

MariaDB starting with 10.6.3

The `KEYWORDS` table was added in MariaDB 10.6.3.

Description

The Information Schema `KEYWORDS` table contains the list of MariaDB keywords.

It contains a single column:

Column	Description
WORD	Keyword

The table is not a standard Information Schema table, and is a MariaDB extension.

Example

```
SELECT * FROM INFORMATION_SCHEMA.KEYWORDS;
+-------------------------------+
| WORD                          |
+-------------------------------+
| &&                            |
| <=                            |
| <>                            |
| !=                            |
| >=                            |
| <<                            |
| >>                            |
| <=>                           |
| ACCESSIBLE                    |
| ACCOUNT                       |
| ACTION                        |

1.1.1.2.9.1.1.27 Information Schema LOCALES Table

Description

The Information Schema `LOCALES` table contains a list of all compiled-in locales. It is only available if the LOCALES plugin has been installed.

It contains the following columns:

Column	Description
`ID`	Row ID.
`NAME`	Locale name, for example `en_GB`.
`DESCRIPTION`	Locale description, for example `English - United Kingdom`.
`MAX_MONTH_NAME_LENGTH`	Numeric length of the longest month in the locale
`MAX_DAY_NAME_LENGTH`	Numeric length of the longest day name in the locale.
`DECIMAL_POINT`	Decimal point character (some locales use a comma).
`THOUSAND_SEP`	Thousand's character separator,
`ERROR_MESSAGE_LANGUAGE`	Error message language.

The table is not a standard Information Schema table, and is a MariaDB extension.

The SHOW LOCALES statement returns a subset of the information.

Example

```
SELECT * FROM information_schema.LOCALES;
+-----+-------+--------------------------------------+----------------------+----------------
-----+---------------+-------------+------------------------+
| ID  | NAME  | DESCRIPTION                          | MAX_MONTH_NAME_LENGTH |
MAX_DAY_NAME_LENGTH | DECIMAL_POINT | THOUSAND_SEP | ERROR_MESSAGE_LANGUAGE |
+-----+-------+--------------------------------------+----------------------+----------------
-----+---------------+-------------+------------------------+
|   0 | en_US | English - United States              |                    9 |
9 | .             | ,           | english                |
|   1 | en_GB | English - United Kingdom             |                    9 |
9 | .             | ,           | english                |
|   2 | ja_JP | Japanese - Japan                     |                    3 |

```

1.1.1.2.9.1.1.28 Information Schema METADATA_LOCK_INFO Table

The Information Schema `METADATA_LOCK_INFO` table is created by the metadata_lock_info plugin. It shows active metadata locks and user locks (the locks acquired with GET_LOCK).

It has the following columns:

Column	Description
`THREAD_ID`	
`LOCK_MODE`	One of `MDL_INTENTION_EXCLUSIVE`, `MDL_SHARED`, `MDL_SHARED_HIGH_PRIO`, `MDL_SHARED_READ`, `MDL_SHARED_READ_ONLY`, `MDL_SHARED_WRITE`, `MDL_SHARED_NO_WRITE`, `MDL_SHARED_NO_READ_WRITE`, `MDL_SHARED_UPGRADABLE` or `MDL_EXCLUSIVE`.
`LOCK_DURATION`	One of `MDL_STATEMENT`, `MDL_TRANSACTION` or `MDL_EXPLICIT`
`LOCK_TYPE`	One of `Global read lock`, `Schema metadata lock`, `Table metadata lock`, `Stored function metadata lock`, `Stored procedure metadata lock`, `Trigger metadata lock`, `Event metadata lock`, `Commit lock` or `User lock`.
`TABLE_SCHEMA`	
`TABLE_NAME`	

"LOCK_MODE" Descriptions

The `LOCK_MODE` column can have the following values:

Value	Description

MDL_INTENTION_EXCLUSIVE	An intention exclusive metadata lock (IX). Used only for scoped locks. Owner of this type of lock can acquire upgradable exclusive locks on individual objects. Compatible with other IX locks, but is incompatible with scoped S and X locks. IX lock is taken in SCHEMA namespace when we intend to modify object metadata. Object may refer table, stored procedure, trigger, view/etc.
MDL_SHARED	A shared metadata lock (S). To be used in cases when we are interested in object metadata only and there is no intention to access object data (e.g. for stored routines or during preparing prepared statements). We also mis-use this type of lock for open HANDLERs, since lock acquired by this statement has to be compatible with lock acquired by LOCK TABLES ... WRITE statement, i.e. SNRW (We can't get by by acquiring S lock at HANDLER ... OPEN time and upgrading it to SR lock for HANDLER ... READ as it doesn't solve problem with need to abort DML statements which wait on table level lock while having open HANDLER in the same connection). To avoid deadlock which may occur when SNRW lock is being upgraded to X lock for table on which there is an active S lock which is owned by thread which waits in its turn for table-level lock owned by thread performing upgrade we have to use thr_abort_locks_for_thread() facility in such situation. This problem does not arise for locks on stored routines as we don't use SNRW locks for them. It also does not arise when S locks are used during PREPARE calls as table-level locks are not acquired in this case. This lock is taken for global read lock, when caching a stored procedure in memory for the duration of the transaction and for tables used by prepared statements.
MDL_SHARED_HIGH_PRIO	A high priority shared metadata lock. Used for cases when there is no intention to access object data (i.e. data in the table). "High priority" means that, unlike other shared locks, it is granted ignoring pending requests for exclusive locks. Intended for use in cases when we only need to access metadata and not data, e.g. when filling an INFORMATION_SCHEMA table. Since SH lock is compatible with SNRW lock, the connection that holds SH lock lock should not try to acquire any kind of table-level or row-level lock, as this can lead to a deadlock. Moreover, after acquiring SH lock, the connection should not wait for any other resource, as it might cause starvation for X locks and a potential deadlock during upgrade of SNW or SNRW to X lock (e.g. if the upgrading connection holds the resource that is being waited for).
MDL_SHARED_READ	A shared metadata lock (SR) for cases when there is an intention to read data from table. A connection holding this kind of lock can read table metadata and read table data (after acquiring appropriate table and row-level locks). This means that one can only acquire TL_READ, TL_READ_NO_INSERT, and similar table-level locks on table if one holds SR MDL lock on it. To be used for tables in SELECTs, subqueries, and LOCK TABLE ... READ statements.
MDL_SHARED_WRITE	A shared metadata lock (SW) for cases when there is an intention to modify (and not just read) data in the table. A connection holding SW lock can read table metadata and modify or read table data (after acquiring appropriate table and row-level locks). To be used for tables to be modified by INSERT, UPDATE, DELETE statements, but not LOCK TABLE ... WRITE or DDL). Also taken by SELECT ... FOR UPDATE.
MDL_SHARED_UPGRADABLE	An upgradable shared metadata lock for cases when there is an intention to modify (and not just read) data in the table. Can be upgraded to MDL_SHARED_NO_WRITE and MDL_EXCLUSIVE. A connection holding SU lock can read table metadata and modify or read table data (after acquiring appropriate table and row-level locks). To be used for the first phase of ALTER TABLE.
MDL_SHARED_READ_ONLY	A shared metadata lock for cases when we need to read data from table and block all concurrent modifications to it (for both data and metadata). Used by LOCK TABLES READ statement.
MDL_SHARED_NO_WRITE	An upgradable shared metadata lock which blocks all attempts to update table data, allowing reads. A connection holding this kind of lock can read table metadata and read table data. Can be upgraded to X metadata lock. Note, that since this type of lock is not compatible with SNRW or SW lock types, acquiring appropriate engine-level locks for reading (TL_READ* for MyISAM, shared row locks in InnoDB) should be contention-free. To be used for the first phase of ALTER TABLE, when copying data between tables, to allow concurrent SELECTs from the table, but not UPDATEs.

MDL_SHARED_NO_READ_WRITE	An upgradable shared metadata lock which allows other connections to access table metadata, but not data. It blocks all attempts to read or update table data, while allowing INFORMATION_SCHEMA and SHOW queries. A connection holding this kind of lock can read table metadata modify and read table data. Can be upgraded to X metadata lock. To be used for LOCK TABLES WRITE statement. Not compatible with any other lock type except S and SH.
MDL_EXCLUSIVE	An exclusive metadata lock (X). A connection holding this lock can modify both table's metadata and data. No other type of metadata lock can be granted while this lock is held. To be used for CREATE/DROP/RENAME TABLE statements and for execution of certain phases of other DDL statements.

Examples

User lock:

```
SELECT GET_LOCK('abc',1000);
+----------------------+
| GET_LOCK('abc',1000) |
+----------------------+
|                    1 |
+----------------------+

SELECT * FROM information_schema.METADATA_LOCK_INFO;
+-----------+---------------------------+---------------+-----------+--------------+------------+
| THREAD_ID | LOCK_MODE                 | LOCK_DURATION | LOCK_TYPE | TABLE_SCHEMA | TABLE_NAME |
+-----------+---------------------------+---------------+-----------+--------------+------------+
|        61 | MDL_SHARED_NO_READ_WRITE | MDL_EXPLICIT  | User lock | abc          |            |
+-----------+---------------------------+---------------+-----------+--------------+------------+
```

Table metadata lock:

```
START TRANSACTION;

INSERT INTO t VALUES (1,2);

SELECT * FROM information_schema.METADATA_LOCK_INFO \G
*************************** 1. row ***************************
    THREAD_ID: 4
    LOCK_MODE: MDL_SHARED_WRITE
LOCK_DURATION: MDL_TRANSACTION
    LOCK_TYPE: Table metadata lock
 TABLE_SCHEMA: test
   TABLE_NAME: t
```

```
SELECT * FROM information_schema.METADATA_LOCK_INFO;
+-----------+---------------------------+---------------+---------------------+--------------
---+-------------+
| THREAD_ID | LOCK_MODE | LOCK_DURATION | LOCK_TYPE | TABLE_SCHEMA | TABLE_NAME |
+-----------+---------------------------+---------------+---------------------+--------------
---+-------------+
| 31 | MDL_INTENTION_EXCLUSIVE | MDL_EXPLICIT | Global read lock | | |
| 31 | MDL_INTENTION_EXCLUSIVE | MDL_EXPLICIT | Commit lock | | |
| 31 | MDL_INTENTION_EXCLUSIVE | MDL_EXPLICIT | Schema metadata lock | dbname | |
| 31 | MDL_SHARED_NO_READ_WRITE | MDL_EXPLICIT | Table metadata lock | dbname | exotics |
+-----------+---------------------------+---------------+---------------------+--------------
---+-------------+
```

1.1.1.2.9.1.1.29 Information Schema MROONGA_STATS Table

The Information Schema `MROONGA_STATS` table only exists if the Mroonga storage engine is installed, and contains information about its activities.

Column	Description
VERSION	Mroonga version.
rows_written	Number of rows written into Mroonga tables.
rows_read	Number of rows read from all Mroonga tables.

This table always contains 1 row.

1.1.1.2.9.1.1.30 Information Schema OPTIMIZER_TRACE Table

MariaDB starting with 10.4.3

Optimizer Trace was introduced in MariaDB 10.4.3.

Description

The Information Schema OPTIMIZER_TRACE table contains Optimizer Trace information.

It contains the following columns:

Column	Description
QUERY	Displays the query that was asked to be traced.
TRACE	A JSON document displaying the stats we collected when the query was run.
MISSING_BYTES_BEYOND_MAX_MEM_SIZE	For huge trace, where the trace is truncated due to the optimizer_trace_max_mem_size limit being reached, displays the bytes that are missing in the trace
INSUFFICENT_PRIVILEGES	Set to 1 if the user running the trace does not have the privileges to see the trace.

Structure:

```
SHOW CREATE TABLE INFORMATION_SCHEMA.OPTIMIZER_TRACE \G
*************************** 1. row ***************************
       Table: OPTIMIZER_TRACE
Create Table: CREATE TEMPORARY TABLE `OPTIMIZER_TRACE` (
  `QUERY` longtext NOT NULL DEFAULT '',
  `TRACE` longtext NOT NULL DEFAULT '',
  `MISSING_BYTES_BEYOND_MAX_MEM_SIZE` int(20) NOT NULL DEFAULT 0,
  `INSUFFICIENT_PRIVILEGES` tinyint(1) NOT NULL DEFAULT 0
) ENGINE=Aria DEFAULT CHARSET=utf8 PAGE_CHECKSUM=0
```

1.1.1.2.9.1.1.31 Information Schema PARAMETERS Table

The Information Schema PARAMETERS table stores information about stored procedures and stored functions parameters.

It contains the following columns:

Column	Description
SPECIFIC_CATALOG	Always def.
SPECIFIC_SCHEMA	Database name containing the stored routine parameter.
SPECIFIC_NAME	Stored routine name.
ORDINAL_POSITION	Ordinal position of the parameter, starting at 1. 0 for a function RETURNS clause.
PARAMETER_MODE	One of IN, OUT, INOUT or NULL for RETURNS.
PARAMETER_NAME	Name of the parameter, or NULL for RETURNS.

DATA_TYPE	The column's data type.
CHARACTER_MAXIMUM_LENGTH	Maximum length.
CHARACTER_OCTET_LENGTH	Same as the CHARACTER_MAXIMUM_LENGTH except for multi-byte character sets.
NUMERIC_PRECISION	For numeric types, the precision (number of significant digits) for the column. NULL if not a numeric field.
NUMERIC_SCALE	For numeric types, the scale (significant digits to the right of the decimal point). NULL if not a numeric field.
DATETIME_PRECISION	Fractional-seconds precision, or NULL if not a time data type.
CHARACTER_SET_NAME	Character set if a non-binary string data type, otherwise NULL.
COLLATION_NAME	Collation if a non-binary string data type, otherwise NULL.
DTD_IDENTIFIER	Description of the data type.
ROUTINE_TYPE	PROCEDURE or FUNCTION.

Information from this table is similar to that found in the param_list column in the mysql.proc table, and the output of the SHOW CREATE PROCEDURE and SHOW CREATE FUNCTION statements.

To obtain information about the routine itself, you can query the Information Schema ROUTINES table.

Example

```
SELECT * FROM information_schema.PARAMETERS
LIMIT 1 \G
********************* 1. row *********************
        SPECIFIC_CATALOG: def
         SPECIFIC_SCHEMA: accounts
           SPECIFIC_NAME: user_counts
        ORDINAL_POSITION: 1
          PARAMETER_MODE: IN
          PARAMETER_NAME: user_order
               DATA_TYPE: varchar
CHARACTER_MAXIMUM_LENGTH: 255
  CHARACTER_OCTET_LENGTH: 765
       NUMERIC_PRECISION: NULL
           NUMERIC_SCALE: NULL
      DATETIME_PRECISION: NULL
      CHARACTER_SET_NAME: utf8
          COLLATION_NAME: utf8_general_ci
          DTD_IDENTIFIER: varchar(255)
            ROUTINE_TYPE: PROCEDURE
```

1.1.1.2.9.1.1.32 Information Schema PARTITIONS Table

The Information Schema PARTITIONS contains information about table partitions, with each record corresponding to a single partition or subpartition of a partitioned table. Each non-partitioned table also has a record in the PARTITIONS table, but most of the values are NULL.

It contains the following columns:

Column	Description
TABLE_CATALOG	Always def.
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name containing the partition.
PARTITION_NAME	Partition name.
SUBPARTITION_NAME	Subpartition name, or NULL if not a subpartition.
PARTITION_ORDINAL_POSITION	Order of the partition starting from 1.

SUBPARTITION_ORDINAL_POSITION	Order of the subpartition starting from 1.
PARTITION_METHOD	The partitioning type; one of RANGE, LIST, HASH, LINEAR HASH, KEY or LINEAR KEY.
SUBPARTITION_METHOD	Subpartition type; one of HASH, LINEAR HASH, KEY or LINEAR KEY, or NULL if not a subpartition.
PARTITION_EXPRESSION	Expression used to create the partition by the CREATE TABLE or ALTER TABLE statement.
SUBPARTITION_EXPRESSION	Expression used to create the subpartition by the CREATE TABLE or ALTER TABLE statement, or NULL if not a subpartition.
PARTITION_DESCRIPTION	For a RANGE partition, contains either MAXINTEGER or an integer, as set in the VALUES LESS THAN clause. For a LIST partition, contains a comma-separated list of integers, as set in the VALUES IN. For a SYSTEM_TIME INTERVAL partition, shows a defined upper boundary timestamp for historical values (the last history partition can contain values above the upper boundary). NULL if another type of partition.
TABLE_ROWS	Number of rows in the table (may be an estimate for some storage engines).
AVG_ROW_LENGTH	Average row length, that is DATA_LENGTH divided by TABLE_ROWS
DATA_LENGTH	Total number of bytes stored in all rows of the partition.
MAX_DATA_LENGTH	Maximum bytes that could be stored in the partition.
INDEX_LENGTH	Size in bytes of the partition index file.
DATA_FREE	Unused bytes allocated to the partition.
CREATE_TIME	Time the partition was created
UPDATE_TIME	Time the partition was last modified.
CHECK_TIME	Time the partition was last checked, or NULL for storage engines that don't record this information.
CHECKSUM	Checksum value, or NULL if none.
PARTITION_COMMENT	Partition comment, truncated to 80 characters, or an empty string if no comment.
NODEGROUP	Node group, only used for MySQL Cluster, defaults to 0.
TABLESPACE_NAME	Always default.

1.1.1.2.9.1.1.33 Information Schema PERIODS Table

MariaDB starting with 11.3.0

The Information Schema PERIODS table provides information about Application-Time Periods.

It contains the following columns:

Column	Description
TABLE_CATALOG	
TABLE_SCHEMA	
TABLE_NAME	
PERIOD	
START_COLUMN_NAME	
END_COLUMN_NAME	

Example

```
CREATE OR REPLACE TABLE t1(
 name VARCHAR(50),
 date_1 DATE,
 date_2 DATE,
 PERIOD FOR date_period(date_1, date_2)
);

SELECT * FROM INFORMATION_SCHEMA.PERIODS;
+---------------+--------------+------------+-------------+-------------------+-----------------+
| TABLE_CATALOG | TABLE_SCHEMA | TABLE_NAME | PERIOD      | START_COLUMN_NAME | END_COLUMN_NAME |
+---------------+--------------+------------+-------------+-------------------+-----------------+
| def           | test         | t1         | date_period | date_1            | date_2          |
+---------------+--------------+------------+-------------+-------------------+-----------------+
```

1.1.1.2.9.1.1.34 Information Schema PLUGINS Table

The Information Schema `PLUGINS` table contains information about server plugins.

It contains the following columns:

Column	Description
`PLUGIN_NAME`	Name of the plugin.
`PLUGIN_VERSION`	Version from the plugin's general type descriptor.
`PLUGIN_STATUS`	Plugin status, one of `ACTIVE`, `INACTIVE`, `DISABLED` or `DELETED`.
`PLUGIN_TYPE`	Plugin type; `STORAGE ENGINE`, `INFORMATION_SCHEMA`, `AUTHENTICATION`, `REPLICATION`, `DAEMON` or `AUDIT`.
`PLUGIN_TYPE_VERSION`	Version from the plugin's type-specific descriptor.
`PLUGIN_LIBRARY`	Plugin's shared object file name, located in the directory specified by the plugin_dir system variable, and used by the INSTALL PLUGIN and UNINSTALL PLUGIN statements. `NULL` if the plugin is complied in and cannot be uninstalled.
`PLUGIN_LIBRARY_VERSION`	Version from the plugin's API interface.
`PLUGIN_AUTHOR`	Author of the plugin.
`PLUGIN_DESCRIPTION`	Description.
`PLUGIN_LICENSE`	Plugin's licence.
`LOAD_OPTION`	How the plugin was loaded; one of `OFF`, `ON`, `FORCE` or `FORCE_PLUS_PERMANENT`. See Installing Plugins.
`PLUGIN_MATURITY`	Plugin's maturity level; one of `Unknown`, `Experimental`, `Alpha`, `Beta`, `'Gamma`, and `Stable`.
`PLUGIN_AUTH_VERSION`	Plugin's version as determined by the plugin author. An example would be '0.99 beta 1'.

It provides a superset of the information shown by the SHOW PLUGINS statement. For specific information about storage engines (a particular type of plugins), see the information_schema.ENGINES table and the SHOW ENGINES statement.

This table provides a subset of the Information Schema information_schema.ALL_PLUGINS table, which contains all available plugins, installed or not.

The table is not a standard Information Schema table, and is a MariaDB extension.

Examples

The easiest way to get basic information on plugins is with SHOW PLUGINS:

```
SHOW PLUGINS;

+----------------------------+----------+--------------------+-------------+---------+
| Name                       | Status   | Type               | Library     | License |
+----------------------------+----------+--------------------+-------------+---------+
| binlog                     | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| mysql_native_password      | ACTIVE   | AUTHENTICATION     | NULL        | GPL     |
| mysql_old_password         | ACTIVE   | AUTHENTICATION     | NULL        | GPL     |
| MRG_MyISAM                 | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| MyISAM                     | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| CSV                        | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| MEMORY                     | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| FEDERATED                  | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| PERFORMANCE_SCHEMA         | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| Aria                       | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| InnoDB                     | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| INNODB_TRX                 | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_LOCKS               | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_LOCK_WAITS          | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_CMP                 | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_CMP_RESET           | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_CMPMEM              | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_CMPMEM_RESET        | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_BUFFER_PAGE         | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_BUFFER_PAGE_LRU     | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_BUFFER_POOL_STATS   | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_METRICS             | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_FT_DEFAULT_STOPWORD | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_FT_INSERTED         | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_FT_DELETED          | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_FT_BEING_DELETED    | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_FT_CONFIG           | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_FT_INDEX_CACHE      | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_FT_INDEX_TABLE      | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_SYS_TABLES          | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_SYS_TABLESTATS      | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_SYS_INDEXES         | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_SYS_COLUMNS         | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_SYS_FIELDS          | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_SYS_FOREIGN         | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| INNODB_SYS_FOREIGN_COLS    | ACTIVE   | INFORMATION SCHEMA | NULL        | GPL     |
| SPHINX                     | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| ARCHIVE                    | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| BLACKHOLE                  | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| FEEDBACK                   | DISABLED | INFORMATION SCHEMA | NULL        | GPL     |
| partition                  | ACTIVE   | STORAGE ENGINE     | NULL        | GPL     |
| pam                        | ACTIVE   | AUTHENTICATION     | auth_pam.so | GPL     |
+----------------------------+----------+--------------------+-------------+---------+
```

```
SELECT LOAD_OPTION
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'tokudb';
Empty set
```

The equivalent SELECT query would be:

```
SELECT PLUGIN_NAME, PLUGIN_STATUS,
PLUGIN_TYPE, PLUGIN_LIBRARY, PLUGIN_LICENSE
FROM INFORMATION_SCHEMA.PLUGINS;
```

Other SELECT queries can be used to see additional information. For example:

```
SELECT PLUGIN_NAME, PLUGIN_DESCRIPTION,
PLUGIN_MATURITY, PLUGIN_AUTH_VERSION
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_TYPE='STORAGE ENGINE'
ORDER BY PLUGIN_MATURITY \G

*************************** 1. row ***************************
        PLUGIN_NAME: FEDERATED
 PLUGIN_DESCRIPTION: FederatedX pluggable storage engine
    PLUGIN_MATURITY: Beta
PLUGIN_AUTH_VERSION: 2.1
*************************** 2. row ***************************
        PLUGIN_NAME: Aria
 PLUGIN_DESCRIPTION: Crash-safe tables with MyISAM heritage
    PLUGIN_MATURITY: Gamma
PLUGIN_AUTH_VERSION: 1.5
*************************** 3. row ***************************
        PLUGIN_NAME: PERFORMANCE_SCHEMA
 PLUGIN_DESCRIPTION: Performance Schema
    PLUGIN_MATURITY: Gamma
PLUGIN_AUTH_VERSION: 0.1
*************************** 4. row ***************************
        PLUGIN_NAME: binlog
 PLUGIN_DESCRIPTION: This is a pseudo storage engine to represent the binlog in a transaction
    PLUGIN_MATURITY: Stable
PLUGIN_AUTH_VERSION: 1.0
*************************** 5. row ***************************
        PLUGIN_NAME: MEMORY
 PLUGIN_DESCRIPTION: Hash based, stored in memory, useful for temporary tables
    PLUGIN_MATURITY: Stable
PLUGIN_AUTH_VERSION: 1.0
*************************** 6. row ***************************
        PLUGIN_NAME: MyISAM
 PLUGIN_DESCRIPTION: MyISAM storage engine

```

Check if a given plugin is available:

```
SELECT LOAD_OPTION
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_NAME LIKE 'tokudb';
Empty set
```

Show authentication plugins:

```
SELECT PLUGIN_NAME, LOAD_OPTION
FROM INFORMATION_SCHEMA.PLUGINS
WHERE PLUGIN_TYPE LIKE 'authentication' \G

*************************** 1. row ***************************
PLUGIN_NAME: mysql_native_password
LOAD_OPTION: FORCE
*************************** 2. row ***************************
PLUGIN_NAME: mysql_old_password
LOAD_OPTION: FORCE
```

1.1.1.2.9.1.1.35 Information Schema PROCESSLIST Table

Contents

The Information Schema `PROCESSLIST` table contains information about running threads.

Similar information can also be returned with the `SHOW [FULL] PROCESSLIST` statement, or the mariadb-admin processlist command.

It contains the following columns:

Column	Description
`ID`	Connection identifier.
`USER`	MariaDB User.
`HOST`	The hostname from which this thread is connected. For Unix socket connections, `localhost`. For TCP/IP connections, the TCP port is appended (e.g. `192.168.1.17:58061` or `other-host.company.com:58061`). For `system user`, this column is blank (`''`).
`DB`	Default database, or `NULL` if none.
`COMMAND`	Type of command running, corresponding to the `Com_` status variables. See Thread Command Values.
`TIME`	Seconds that the thread has spent on the current `COMMAND` so far.
`STATE`	Current state of the thread. See Thread States.
`INFO`	Statement the thread is executing, or `NULL` if none.
`TIME_MS`	Time in milliseconds with microsecond precision that the thread has spent on the current `COMMAND` so far (see more).
`STAGE`	The stage the process is currently in.
`MAX_STAGE`	The maximum number of stages.
`PROGRESS`	The progress of the process within the current stage (0-100%).
`MEMORY_USED`	Memory in bytes used by the thread.
`MAX_MEMORY_USED`	Maximum memory in bytes used by the thread.
`EXAMINED_ROWS`	Rows examined by the thread. Only updated by UPDATE, DELETE, and similar statements. For SELECT and other statements, the value remains zero.
`SENT_ROWS`	Number of rows sent by the statement being executed. From MariaDB 11.3.0.

QUERY_ID	Query ID.
INFO_BINARY	Binary data information
TID	Thread ID (MDEV-6756)

Note that as a difference to MySQL, in MariaDB the TIME column (and also the TIME_MS column) are not affected by any setting of @TIMESTAMP. This means that it can be reliably used also for threads that change @TIMESTAMP (such as the replication SQL thread). See also MySQL Bug #22047.

As a consequence of this, the TIME column of SHOW FULL PROCESSLIST and INFORMATION_SCHEMA.PROCESSLIST can not be used to determine if a slave is lagging behind. For this, use instead the Seconds_Behind_Master column in the output of SHOW SLAVE STATUS.

Note that the PROGRESS field from the information schema, and the PROGRESS field from SHOW PROCESSLIST display different results. SHOW PROCESSLIST shows the total progress, while the information schema shows the progress for the current stage only.. To retrieve a similar "total" Progress value from information_schema.PROCESSLIST as the one from SHOW PROCESSLIST, use

```
SELECT CASE WHEN Max_Stage < 2 THEN Progress ELSE (Stage-1)/Max_Stage*100+Progress/Max_Stage END
  AS Progress FROM INFORMATION_SCHEMA.PROCESSLIST;
```

Example

```
SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST\G
*************************** 1. row ***************************
           ID: 9
         USER: msandbox
         HOST: localhost
           DB: NULL
      COMMAND: Query
         TIME: 0
        STATE: Filling schema table
         INFO: SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST
      TIME_MS: 0.351
        STAGE: 0
    MAX_STAGE: 0
     PROGRESS: 0.000
  MEMORY_USED: 85392
EXAMINED_ROWS: 0
     QUERY_ID: 15
  INFO_BINARY: SELECT * FROM INFORMATION_SCHEMA.PROCESSLIST
          TID: 11838
*************************** 2. row ***************************
           ID: 5
         USER: system user
         HOST:
           DB: NULL
      COMMAND: Daemon
         TIME: 0
        STATE: InnoDB shutdown handler
         INFO: NULL
      TIME_MS: 0.000
        STAGE: 0
    MAX_STAGE: 0
     PROGRESS: 0.000
  MEMORY_USED: 24160
EXAMINED_ROWS: 0
     QUERY_ID: 0
  INFO_BINARY: NULL
          TID: 3856
...
```

1.1.1.2.9.1.1.36 Information Schema PROFILING Table

The Information Schema `PROFILING` table contains information about statement resource usage. Profiling information is only recorded if the `profiling` session variable is set to 1.

It contains the following columns:

Column Name	Description
`QUERY_ID`	Query_ID.
`SEQ`	Sequence number showing the display order for rows with the same `QUERY_ID`.
`STATE`	Profiling state.
`DURATION`	Time in seconds that the statement has been in the current state.
`CPU_USER`	User CPU usage in seconds.
`CPU_SYSTEM`	System CPU usage in seconds.
`CONTEXT_VOLUNTARY`	Number of voluntary context switches.
`CONTEXT_INVOLUNTARY`	Number of involuntary context switches.
`BLOCK_OPS_IN`	Number of block input operations.
`BLOCK_OPS_OUT`	Number of block output operations.
`MESSAGES_SENT`	Number of communications sent.
`MESSAGES_RECEIVED`	Number of communications received.
`PAGE_FAULTS_MAJOR`	Number of major page faults.
`PAGE_FAULTS_MINOR`	Number of minor page faults.
`SWAPS`	Number of swaps.
`SOURCE_FUNCTION`	Function in the source code executed by the profiled state.
`SOURCE_FILE`	File in the source code executed by the profiled state.
`SOURCE_LINE`	Line in the source code executed by the profiled state.

It contains similar information to the `SHOW PROFILE and SHOW PROFILES` statements.

Profiling is enabled per session. When a session ends, its profiling information is lost.

1.1.1.2.9.1.1.37 Information Schema QUERY_CACHE_INFO Table

Description

The table is not a standard Information Schema table, and is a MariaDB extension.

The `QUERY_CACHE_INFO` table is created by the QUERY_CACHE_INFO plugin, and allows you to see the contents of the query cache. It creates a table in the information_schema database that shows all queries that are in the cache. You must have the `PROCESS` privilege (see GRANT) to use this table.

It contains the following columns:

Column	Description
`STATEMENT_SCHEMA`	Database used when query was included
`STATEMENT_TEXT`	Query text
`RESULT_BLOCKS_COUNT`	Number of result blocks
`RESULT_BLOCKS_SIZE`	Size in bytes of result blocks
`RESULT_BLOCKS_SIZE_USED`	Size in bytes of used blocks
`LIMIT`	Added MariaDB 10.1.8.
`MAX_SORT_LENGTH`	Added MariaDB 10.1.8.

GROUP_CONCAT_MAX_LENGTH	Added MariaDB 10.1.8.
CHARACTER_SET_CLIENT	Added MariaDB 10.1.8.
CHARACTER_SET_RESULT	Added MariaDB 10.1.8.
COLLATION	Added MariaDB 10.1.8.
TIMEZONE	Added MariaDB 10.1.8.
DEFAULT_WEEK_FORMAT	Added MariaDB 10.1.8.
DIV_PRECISION_INCREMENT	Added MariaDB 10.1.8.
SQL_MODE	Added MariaDB 10.1.8.
LC_TIME_NAMES	Added MariaDB 10.1.8.
CLIENT_LONG_FLAG	Added MariaDB 10.1.8.
CLIENT_PROTOCOL_41	Added MariaDB 10.1.8.
PROTOCOL_TYPE	Added MariaDB 10.1.8.
MORE_RESULTS_EXISTS	Added MariaDB 10.1.8.
IN_TRANS	Added MariaDB 10.1.8.
AUTOCOMMIT	Added MariaDB 10.1.8.
PACKET_NUMBER	Added MariaDB 10.1.8.
HITS	Incremented each time the query cache is hit. Added MariaDB 10.3.2.

For example:

```
SELECT * FROM information_schema.QUERY_CACHE_INFO;
+------------------+-----------------+---------------------+--------------------+------------
-------------+
| STATEMENT_SCHEMA | STATEMENT_TEXT  | RESULT_BLOCKS_COUNT | RESULT_BLOCKS_SIZE |
RESULT_BLOCKS_SIZE_USED |
+------------------+-----------------+---------------------+--------------------+------------
-------------+
...
| test             | SELECT * FROM a |                   1 |                512 |
143 |
| test             | select * FROM a |                   1 |                512 |
143 |
...
+------------------+-----------------+---------------------+--------------------+------------
-------------
```

1.1.1.2.9.1.1.38 Information Schema QUERY_RESPONSE_TIME Table

Description

The Information Schema `QUERY_RESPONSE_TIME` table contains information about queries that take a long time to execute. It is only available if the QUERY_RESPONSE_TIME plugin has been installed.

It contains the following columns:

Column	Description
TIME	Time interval
COUNT	Count of queries falling into the time interval
TOTAL	Total execution time of all queries for this interval

See QUERY_RESPONSE_TIME plugin for a full description.

The table is not a standard Information Schema table, and is a MariaDB extension.

`SHOW QUERY_RESPONSE_TIME` is available from MariaDB 10.1.1 as an alternative for retrieving the data.

Example

```
SELECT * FROM information_schema.QUERY_RESPONSE_TIME;
+----------------+-------+----------------+
| TIME           | COUNT | TOTAL          |
+----------------+-------+----------------+
|       0.000001 |     0 |       0.000000 |
|       0.000010 |    17 |       0.000094 |
|       0.000100 |  4301 |       0.236555 |
|       0.001000 |  1499 |       0.824450 |
|       0.010000 | 14851 |      81.680502 |
|       0.100000 |  8066 |     443.635693 |
|       1.000000 |     0 |       0.000000 |
|      10.000000 |     0 |       0.000000 |
|     100.000000 |     1 |      55.937094 |
|    1000.000000 |     0 |       0.000000 |
|   10000.000000 |     0 |       0.000000 |
|  100000.000000 |     0 |       0.000000 |
| 1000000.000000 |     0 |       0.000000 |
| TOO LONG       |     0 | TOO LONG       |
+----------------+-------+----------------+
```

1.1.1.2.9.1.1.39 Information Schema REFERENTIAL_CONSTRAINTS Table

The Information Schema `REFERENTIAL_CONSTRAINTS` table contains information about foreign keys. The single columns are listed in the `KEY_COLUMN_USAGE` table.

It has the following columns:

Column	Description
`CONSTRAINT_CATALOG`	Always `def`.
`CONSTRAINT_SCHEMA`	Database name, together with `CONSTRAINT_NAME` identifies the foreign key.
`CONSTRAINT_NAME`	Foreign key name, together with `CONSTRAINT_SCHEMA` identifies the foreign key.
`UNIQUE_CONSTRAINT_CATALOG`	Always `def`.
`UNIQUE_CONSTRAINT_SCHEMA`	Database name, together with `UNIQUE_CONSTRAINT_NAME` and `REFERENCED_TABLE_NAME` identifies the referenced key.
`UNIQUE_CONSTRAINT_NAME`	Referenced key name, together with `UNIQUE_CONSTRAINT_SCHEMA` and `REFERENCED_TABLE_NAME` identifies the referenced key.
`MATCH_OPTION`	Always `NONE`.
`UPDATE_RULE`	The Update Rule; one of `CASCADE`, `SET NULL`, `SET DEFAULT`, `RESTRICT`, `NO ACTION`.
`DELETE_RULE`	The Delete Rule; one of `CASCADE`, `SET NULL`, `SET DEFAULT`, `RESTRICT`, `NO ACTION`.
`TABLE_NAME`	Table name from the `TABLE_CONSTRAINTS` table.
`REFERENCED_TABLE_NAME`	Referenced key table name, together with `UNIQUE_CONSTRAINT_SCHEMA` and `UNIQUE_CONSTRAINT_NAME` identifies the referenced key.

1.1.1.2.9.1.1.40 Information Schema ROUTINES Table

The Information Schema `ROUTINES` table stores information about stored procedures and stored functions.

It contains the following columns:

Column	Description
SPECIFIC_NAME	
ROUTINE_CATALOG	Always def.
ROUTINE_SCHEMA	Database name associated with the routine.
ROUTINE_NAME	Name of the routine.
ROUTINE_TYPE	Whether the routine is a PROCEDURE or a FUNCTION.
DATA_TYPE	The return value's data type (for stored functions).
CHARACTER_MAXIMUM_LENGTH	Maximum length.
CHARACTER_OCTET_LENGTH	Same as the CHARACTER_MAXIMUM_LENGTH except for multi-byte character sets.
NUMERIC_PRECISION	For numeric types, the precision (number of significant digits) for the column. NULL if not a numeric field.
NUMERIC_SCALE	For numeric types, the scale (significant digits to the right of the decimal point). NULL if not a numeric field.
DATETIME_PRECISION	Fractional-seconds precision, or NULL if not a time data type.
CHARACTER_SET_NAME	Character set if a non-binary string data type, otherwise NULL.
COLLATION_NAME	Collation if a non-binary string data type, otherwise NULL.
DATA_TYPE	The column's data type.
ROUTINE_BODY	Always SQL.
ROUTINE_DEFINITION	Definition of the routine.
EXTERNAL_NAME	Always NULL.
EXTERNAL_LANGUAGE	Always SQL.
PARAMETER_STYLE	Always SQL.
IS_DETERMINISTIC	Whether the routine is deterministic (can produce only one result for a given list of parameters) or not.
SQL_DATA_ACCESS	One of READS SQL DATA, MODIFIES SQL DATA, CONTAINS SQL, or NO SQL.
SQL_PATH	Always NULL.
SECURITY_TYPE	INVOKER or DEFINER. Indicates which user's privileges apply to this routine.
CREATED	Date and time the routine was created.
LAST_ALTERED	Date and time the routine was last changed.
SQL_MODE	The SQL_MODE at the time the routine was created.
ROUTINE_COMMENT	Comment associated with the routine.
DEFINER	If the SECURITY_TYPE is DEFINER, this value indicates which user defined this routine.
CHARACTER_SET_CLIENT	The character set used by the client that created the routine.
COLLATION_CONNECTION	The collation (and character set) used by the connection that created the routine.
DATABASE_COLLATION	The default collation (and character set) for the database, at the time the routine was created.

It provides information similar to, but more complete, than the SHOW PROCEDURE STATUS and SHOW FUNCTION STATUS statements.

For information about the parameters accepted by the routine, you can query the information_schema.PARAMETERS table.

1.1.1.2.9.1.1.41 Information Schema SCHEMA_PRIVILEGES Table

The Information Schema `SCHEMA_PRIVILEGES` table contains information about database privileges.

It contains the following columns:

Column	Description
`GRANTEE`	Account granted the privilege in the format `user_name@host_name`.
`TABLE_CATALOG`	Always `def`
`TABLE_SCHEMA`	Database name.
`PRIVILEGE_TYPE`	The granted privilege.
`IS_GRANTABLE`	Whether the privilege can be granted.

The same information in a different format can be found in the `mysql.db` table.

1.1.1.2.9.1.1.42 Information Schema SCHEMATA Table

The Information Schema `SCHEMATA` table stores information about databases on the server.

It contains the following columns:

Column	Description
`CATALOG_NAME`	Always `def`.
`SCHEMA_NAME`	Database name.
`DEFAULT_CHARACTER_SET_NAME`	Default character set for the database.
`DEFAULT_COLLATION_NAME`	Default collation.
`SQL_PATH`	Always `NULL`.
`SCHEMA_COMMENT`	Database comment. From MariaDB 10.5.0.

Example

```
SELECT * FROM INFORMATION_SCHEMA.SCHEMATA\G
*************************** 1. row ***************************
              CATALOG_NAME: def
               SCHEMA_NAME: information_schema
DEFAULT_CHARACTER_SET_NAME: utf8
    DEFAULT_COLLATION_NAME: utf8_general_ci
                  SQL_PATH: NULL
*************************** 2. row ***************************
              CATALOG_NAME: def
               SCHEMA_NAME: mysql
DEFAULT_CHARACTER_SET_NAME: latin1
    DEFAULT_COLLATION_NAME: latin1_swedish_ci
                  SQL_PATH: NULL
*************************** 3. row ***************************
              CATALOG_NAME: def
               SCHEMA_NAME: performance_schema
DEFAULT_CHARACTER_SET_NAME: utf8
    DEFAULT_COLLATION_NAME: utf8_general_ci
                  SQL_PATH: NULL
*************************** 4. row ***************************
              CATALOG_NAME: def
               SCHEMA_NAME: test
DEFAULT_CHARACTER_SET_NAME: latin1
    DEFAULT_COLLATION_NAME: latin1_swedish_ci
                  SQL_PATH: NULL
...
```

From MariaDB 10.5.0:

```
SELECT * FROM INFORMATION_SCHEMA.SCHEMATA\G
...
*************************** 2. row ***************************
              CATALOG_NAME: def
               SCHEMA_NAME: presentations
DEFAULT_CHARACTER_SET_NAME: latin1
    DEFAULT_COLLATION_NAME: latin1_swedish_ci
                  SQL_PATH: NULL
            SCHEMA_COMMENT: Presentations for conferences
...
```

1.1.1.2.9.1.1.43 Information Schema SPATIAL_REF_SYS Table

Description

The Information Schema `SPATIAL_REF_SYS` table stores information on each spatial reference system used in the database.

It contains the following columns:

Column	Type	Null	Description
`SRID`	`smallint(5)`	`NO`	An integer value that uniquely identifies each Spatial Reference System within a database.
`AUTH_NAME`	`varchar(512)`	`NO`	The name of the standard or standards body that is being cited for this reference system.
`AUTH_SRID`	`smallint(5)`	`NO`	The numeric ID of the coordinate system in the above authority's catalog.
`SRTEXT`	`varchar(2048)`	`NO`	The Well-known Text Representation of the Spatial Reference System.

Note: See MDEV-7540.

See Aso

- information_schema.GEOMETRY_COLUMNS table.

1.1.1.2.9.1.1.44 Information Schema SPIDER_ALLOC_MEM Table

The Information Schema `SPIDER_ALLOC_MEM` table is installed along with the Spider storage engine. It shows information about Spider's memory usage.

It contains the following columns:

Column	Description
`ID`	
`FUNC_NAME`	
`FILE_NAME`	
`LINE_NO`	
`TOTAL_ALLOC_MEM`	
`CURRENT_ALLOC_MEM`	
`ALLOC_MEM_COUNT`	
`FREE_MEM_COUNT`	

1.1.1.2.9.1.1.45 Information Schema SPIDER_WRAPPER_PROTOCOLS Table

MariaDB starting with 10.5.4

The Information Schema `SPIDER_WRAPPER_PROTOCOLS` table is installed along with the Spider storage engine from MariaDB 10.5.4.

It contains the following columns:

Column	Type	Description
`WRAPPER_NAME`	varchar(64)	
`WRAPPER_VERSION`	varchar(20)	
`WRAPPER_DESCRIPTION`	longtext	
`WRAPPER_MATURITY`	varchar(12)	

1.1.1.2.9.1.1.46 Information Schema SQL_FUNCTIONS Table

MariaDB starting with 10.6.3

The `SQL_FUNCTIONS` table was added in MariaDB 10.6.3.

Description

The Information Schema `SQL_FUNCTIONS` table contains the list of MariaDB functions.

It contains a single column:

Column	Description
`FUNCTION`	Function name

The table is not a standard Information Schema table, and is a MariaDB extension.

Example

```
SELECT * FROM INFORMATION_SCHEMA.SQL_FUNCTIONS;
+---------------------------+
| FUNCTION                  |
+---------------------------+
| ADDDATE                   |
| ADD_MONTHS                |
| BIT_AND                   |
| BIT_OR                    |
| BIT_XOR                   |
| CAST                      |
| COUNT                     |
| CUME_DIST                 |
| CURDATE                   |
| CURTIME                   |
| DATE_ADD                  |
| DATE_SUB                  |
| DATE_FORMAT               |
| DECODE                    |
| DENSE_RANK                |
| EXTRACT                   |
| FIRST_VALUE               |
| GROUP_CONCAT              |
| JSON_ARRAYAGG             |
| JSON_OBJECTAGG            |

1.1.1.2.9.1.1.47 Information Schema STATISTICS Table

The Information Schema `STATISTICS` table provides information about table indexes.

It contains the following columns:

Column	Description
TABLE_CATALOG	Always def.
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name.
NON_UNIQUE	1 if the index can have duplicates, 0 if not.
INDEX_SCHEMA	Database name.
INDEX_NAME	Index name. The primary key is always named PRIMARY.
SEQ_IN_INDEX	The column sequence number, starting at 1.
COLUMN_NAME	Column name.
COLLATION	A for sorted in ascending order, or NULL for unsorted.
CARDINALITY	Estimate of the number of unique values stored in the index based on statistics stored as integers. Higher cardinalities usually mean a greater chance of the index being used in a join. Updated by the ANALYZE TABLE statement or myisamchk -a.
SUB_PART	NULL if the whole column is indexed, or the number of indexed characters if partly indexed.
PACKED	NULL if not packed, otherwise how the index is packed.
NULLABLE	YES if the column may contain NULLs, empty string if not.
INDEX_TYPE	Index type, one of BTREE, RTREE, HASH or FULLTEXT. See Storage Engine Index Types.
COMMENT	Index comments from the CREATE INDEX statement.
IGNORED	Whether or not an index will be ignored by the optimizer. See Ignored Indexes. From MariaDB 10.6.0.

The SHOW INDEX statement produces similar output.

Example

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS\G
...
*************************** 85. row ***************************
TABLE_CATALOG: def
 TABLE_SCHEMA: test
   TABLE_NAME: table1
   NON_UNIQUE: 1
 INDEX_SCHEMA: test
   INDEX_NAME: col2
 SEQ_IN_INDEX: 1
  COLUMN_NAME: col2
    COLLATION: A
  CARDINALITY: 6
     SUB_PART: NULL
       PACKED: NULL
     NULLABLE:
   INDEX_TYPE: BTREE
      COMMENT:
INDEX_COMMENT:
...
```

1.1.1.2.9.1.1.48 Information Schema SYSTEM_VARIABLES Table

The Information Schema SYSTEM_VARIABLES table shows current values and various metadata of all system variables.

It contains the following columns:

Column	Description

VARIABLE_NAME	System variable name.
SESSION_VALUE	Session value of the variable or NULL if the variable only has a global scope.
GLOBAL_VALUE	Global value of the variable or NULL if the variable only has a session scope.
GLOBAL_VALUE_ORIGIN	How the global value was set — a compile-time default, auto-configured by the server, configuration file (or a command line), with the SQL statement.
DEFAULT_VALUE	Compile-time default value of the variable.
VARIABLE_SCOPE	Global, session, or session-only.
VARIABLE_TYPE	Data type of the variable value.
VARIABLE_COMMENT	Help text, usually shown in `mysqld --help --verbose`.
NUMERIC_MIN_VALUE	For numeric variables — minimal allowed value.
NUMERIC_MAX_VALUE	For numeric variables — maximal allowed value.
NUMERIC_BLOCK_SIZE	For numeric variables — a valid value must be a multiple of the "block size".
ENUM_VALUE_LIST	For `ENUM`, `SET`, and `FLAGSET` variables — the list of recognized values.
READ_ONLY	Whether a variable can be set with the SQL statement. Note that many "read only" variables can still be set on the command line.
COMMAND_LINE_ARGUMENT	Whether an argument is required when setting the variable on the command line. `NULL` when a variable can not be set on the command line.
GLOBAL_VALUE_PATH	Which config file the variable got its value from. `NULL` if not set in any config file. Added in MariaDB 10.5.0.

Example

```
SELECT * FROM information_schema.SYSTEM_VARIABLES
  WHERE VARIABLE_NAME='JOIN_BUFFER_SIZE'\G
*************************** 1. row ***************************
        VARIABLE_NAME: JOIN_BUFFER_SIZE
        SESSION_VALUE: 131072
         GLOBAL_VALUE: 131072
  GLOBAL_VALUE_ORIGIN: COMPILE-TIME
        DEFAULT_VALUE: 131072
       VARIABLE_SCOPE: SESSION
        VARIABLE_TYPE: BIGINT UNSIGNED
     VARIABLE_COMMENT: The size of the buffer that is used for joins
    NUMERIC_MIN_VALUE: 128
    NUMERIC_MAX_VALUE: 18446744073709551615
   NUMERIC_BLOCK_SIZE: 128
      ENUM_VALUE_LIST: NULL
            READ_ONLY: NO
COMMAND_LINE_ARGUMENT: REQUIRED
```

1.1.1.2.9.1.1.49 Information Schema TABLE_CONSTRAINTS Table

The Information Schema `TABLE_CONSTRAINTS` table contains information about tables that have constraints.

It has the following columns:

Column	Description
CONSTRAINT_CATALOG	Always `def`.
CONSTRAINT_SCHEMA	Database name containing the constraint.
CONSTRAINT_NAME	Constraint name.
TABLE_SCHEMA	Database name.

TABLE_NAME	Table name.
CONSTRAINT_TYPE	Type of constraint; one of UNIQUE, PRIMARY KEY, FOREIGN KEY or CHECK.

The REFERENTIAL_CONSTRAINTS table has more information about foreign keys.

1.1.1.2.9.1.1.50 Information Schema TABLE_PRIVILEGES Table

The Information Schema TABLE_PRIVILEGES table contains table privilege information derived from the mysql.tables_priv grant table.

It has the following columns:

Column	Description
GRANTEE	In the format user_name@host_name.
TABLE_CATALOG	Always def.
TABLE_SCHEMA	Database name.
TABLE_NAME	Table name.
PRIVILEGE_TYPE	One of SELECT, INSERT, UPDATE, REFERENCES, ALTER, INDEX, DROP or CREATE VIEW.
IS_GRANTABLE	Whether the user has the GRANT OPTION for this privilege.

Similar information can be accessed with the SHOW GRANTS statement. See the GRANT article for more about privileges.

For a description of the privileges that are shown in this table, see table privileges.

1.1.1.2.9.1.1.51 Information Schema TABLE_STATISTICS Table

The Information Schema TABLE_STATISTICS table shows statistics on table usage.

This is part of the User Statistics feature, which is not enabled by default.

It contains the following columns:

Field	Type	Notes
TABLE_SCHEMA	varchar(192)	The schema (database) name.
TABLE_NAME	varchar(192)	The table name.
ROWS_READ	int(21)	The number of rows read from the table.
ROWS_CHANGED	int(21)	The number of rows changed in the table.
ROWS_CHANGED_X_INDEXES	int(21)	The number of rows changed in the table, multiplied by the number of indexes changed.

Example

```
SELECT * FROM INFORMATION_SCHEMA.TABLE_STATISTICS WHERE TABLE_NAME='user';
+--------------+------------+-----------+--------------+------------------------+
| TABLE_SCHEMA | TABLE_NAME | ROWS_READ | ROWS_CHANGED | ROWS_CHANGED_X_INDEXES |
+--------------+------------+-----------+--------------+------------------------+
| mysql        | user       |         5 |            2 |                      2 |
+--------------+------------+-----------+--------------+------------------------+
```

1.1.1.2.9.1.1.52 Information Schema TABLES Table

Contents

The Information Schema table shows information about the various tables (until MariaDB 11.2.0, only non- `TEMPORARY` tables, except for tables from the `Information Schema` database) and views on the server.

It contains the following columns:

Column	Description
`TABLE_CATALOG`	Always `def`.
`TABLE_SCHEMA`	Database name.
`TABLE_NAME`	Table name.
`TABLE_TYPE`	One of `BASE TABLE` for a regular table, `VIEW` for a view, `SYSTEM VIEW` for Information Schema tables, `SYSTEM VERSIONED` for system-versioned tables, `SEQUENCE` for sequences or, from MariaDB 11.2.0, `TEMPORARY` for local temporary tables.
`ENGINE`	Storage Engine.
`VERSION`	Version number from the table's .frm file
`ROW_FORMAT`	Row format (see InnoDB, Aria and MyISAM row formats).
`TABLE_ROWS`	Number of rows in the table. Some engines, such as XtraDB and InnoDB may store an estimate.
`AVG_ROW_LENGTH`	Average row length in the table.
`DATA_LENGTH`	For InnoDB/XtraDB, the index size, in pages, multiplied by the page size. For Aria and MyISAM, length of the data file, in bytes. For MEMORY, the approximate allocated memory.
`MAX_DATA_LENGTH`	Maximum length of the data file, ie the total number of bytes that could be stored in the table. Not used in XtraDB and InnoDB.
`INDEX_LENGTH`	Length of the index file.
`DATA_FREE`	Bytes allocated but unused. For InnoDB tables in a shared tablespace, the free space of the shared tablespace with small safety margin. An estimate in the case of partitioned tables - see the `PARTITIONS` table.
`AUTO_INCREMENT`	Next AUTO_INCREMENT value.
`CREATE_TIME`	Time the table was created. Some engines just return the `ctime` information from the file system layer here, in that case the value is not necessarily the table creation time but rather the time the file system metadata for it had last changed.
`UPDATE_TIME`	Time the table was last updated. On Windows, the timestamp is not updated on update, so MyISAM values will be inaccurate. In InnoDB, if shared tablespaces are used, will be NULL, while buffering can also delay the update, so the value will differ from the actual time of the last `UPDATE`, `INSERT` or `DELETE`.
`CHECK_TIME`	Time the table was last checked. Not kept by all storage engines, in which case will be `NULL`.
`TABLE_COLLATION`	Character set and collation.
`CHECKSUM`	Live checksum value, if any.
`CREATE_OPTIONS`	Extra `CREATE TABLE` options.
`TABLE_COMMENT`	Table comment provided when MariaDB created the table.
`MAX_INDEX_LENGTH`	Maximum index length (supported by MyISAM and Aria tables). Added in MariaDB 10.3.5.
`TEMPORARY`	Until MariaDB 11.2.0, placeholder to signal that a table is a temporary table and always "N", except "Y" for generated information_schema tables and NULL for views. From MariaDB 11.2.0, will also be set to "Y" for local temporary tables. Added in MariaDB 10.3.5.

Although the table is standard in the Information Schema, all but `TABLE_CATALOG`, `TABLE_SCHEMA`, `TABLE_NAME`, `TABLE_TYPE`, `ENGINE` and `VERSION` are MySQL and MariaDB extensions.

SHOW TABLES lists all tables in a database.

Examples

From MariaDB 10.3.5:

```
SELECT * FROM information_schema.tables WHERE table_schema='test'\G
*************************** 1. row ***************************
   TABLE_CATALOG: def
    TABLE_SCHEMA: test
      TABLE_NAME: xx5

View Tables in Order of Size

Returns a list of all tables in the database, ordered by size:

```
SELECT table_schema as `DB`, table_name AS `Table`,
  ROUND(((data_length + index_length) / 1024 / 1024), 2) `Size (MB)`
  FROM information_schema.TABLES
  ORDER BY (data_length + index_length) DESC;

+--------------------+---------------------------------------+-----------+
| DB                 | Table                                 | Size (MB) |
+--------------------+---------------------------------------+-----------+
| wordpress          | wp_simple_history_contexts            |      7.05 |
| wordpress          | wp_posts                              |      6.59 |
| wordpress          | wp_simple_history                     |      3.05 |
| wordpress          | wp_comments                           |      2.73 |
| wordpress          | wp_commentmeta                        |      2.47 |
| wordpress          | wp_simple_login_log                   |      2.03 |
...
```

From MariaDB 11.2.0

```
CREATE TEMPORARY TABLE foo.t1 (a int);

SELECT * FROM INFORMATION_SCHEMA.TABLES WHERE TABLE_SCHEMA='foo' AND TEMPORARY='y'\G
*************************** 1. row ***************************
   TABLE_CATALOG: def
    TABLE_SCHEMA: foo
      TABLE_NAME: t1
      TABLE_TYPE: TEMPORARY
...
       TEMPORARY: Y
```

1.1.1.2.9.1.1.53 Information Schema TABLESPACES Table

The Information Schema `TABLESPACES` table contains information about active tablespaces..

The table is a MariaDB and MySQL extension, and does not include information about InnoDB tablespaces.

Column	Description

TABLESPACE_NAME	
ENGINE	
TABLESPACE_TYPE	
LOGFILE_GROUP_NAME	
EXTENT_SIZE	
AUTOEXTEND_SIZE	
MAXIMUM_SIZE	
NODEGROUP_ID	
TABLESPACE_COMMENT	

1.1.1.2.9.1.1.54 Information Schema THREAD_POOL_GROUPS Table

MariaDB starting with 10.5

The Information Schema `THREAD_POOL_GROUPS` table was introduced in MariaDB 10.5.0.

The table provides information about thread pool groups, and contains the following columns:

Column	Description
GROUP_ID	the thread group this row is showing data for
CONNECTIONS	the number of clients currently connected to this thread group
THREADS	total number of threads in this group (ACTIVE+STANDBY+LISTENER)
ACTIVE_THREADS	number of threads currently executing a query
STANDBY_THREADS	number of threads in reserve that do not currently execute anything
QUEUE_LENGTH	number of client requests waiting for execution
HAS_LISTENER	whether there is an active listener thread right now, always 1 if thread_pool_dedicated_listener is ON
IS_STALLED	whether there's currently an active worker thread in this group that has exceeded thread_pool_stall_limit time

Setting thread_pool_dedicated_listener will give each group its own dedicated listener, and the listener thread will not pick up work items. As a result, the actual queue size in the table will be more exact, since IO requests are immediately dequeued from poll, without delay.

1.1.1.2.9.1.1.55 Information Schema THREAD_POOL_QUEUES Table

MariaDB starting with 10.5

The Information Schema `THREAD_POOL_QUEUES` table was introduced in MariaDB 10.5.0.

The table provides information about thread pool queues, and contains the following columns:

Column	Description
GROUP_ID	the thread group this row is showing data for
POSITION	position in the groups queue
PRIORITY	request priority, see priority scheduling
CONNECTION_ID	ID of the client connection that submitted the queued request

QUEUEING_TIME_MICROSECONDS	how long the request has already been waiting in the queue in microseconds

Setting thread_poll_exact_stats will provides better queueing time statistics by using a high precision timestamp, at a small performance cost, for the time when the connection was added to the queue. This timestamp helps calculate the queuing time shown in the table.

Setting thread_pool_dedicated_listener will give each group its own dedicated listener, and the listener thread will not pick up work items. As a result, the queueing time in the table will be more exact, since IO requests are immediately dequeued from poll, without delay.

1.1.1.2.9.1.1.56 Information Schema THREAD_POOL_STATS Table

MariaDB starting with 10.5

The Information Schema THREAD_POOL_STATS table was introduced in MariaDB 10.5.0.

The table provides performance counter information for the thread pool, and contains the following columns:

Column	Description
GROUP_ID	the thread group this row is showing data for
THREAD_CREATIONS	number of threads created for this group so far
THREAD_CREATIONS_DUE_TO_STALL	number of threads created due to detected stalls
WAKES	
WAKES_DUE_TO_STALL	
THROTTLES	how often thread creation was throttled, see also: thread-creation-throttling
STALLS	number of detected stalls
POLLS_BY_LISTENER	
POLLS_BY_WORKER	
DEQUEUES_BY_LISTENER	
DEQUEUES_BY_WORKER	

1.1.1.2.9.1.1.57 Information Schema THREAD_POOL_WAITS Table

MariaDB starting with 10.5

The Information Schema THREAD_POOL_WAITS table was introduced in MariaDB 10.5.0.

The table provides wait counters for the thread pool, and contains the following columns:

Column	Description
REASON	name of the reason for waiting, e.g. ROW_LOCK, DISKIO, NET ...
COUNT	how often a wait for this specific reason has happened so far

1.1.1.2.9.1.1.58 Information Schema TRIGGERS Table

Contents

The Information Schema TRIGGERS table contains information about triggers.

It has the following columns:

Column	Description
TRIGGER_CATALOG	Always def.
TRIGGER_SCHEMA	Database name in which the trigger occurs.
TRIGGER_NAME	Name of the trigger.
EVENT_MANIPULATION	The event that activates the trigger. One of INSERT, UPDATE or 'DELETE.
EVENT_OBJECT_CATALOG	Always def.
EVENT_OBJECT_SCHEMA	Database name on which the trigger acts.
EVENT_OBJECT_TABLE	Table name on which the trigger acts.
ACTION_ORDER	Indicates the order that the action will be performed in (of the list of a table's triggers with identical EVENT_MANIPULATION and ACTION_TIMING values). Before MariaDB 10.2.3 introduced the FOLLOWS and PRECEDES clauses, always 0
ACTION_CONDITION	NULL
ACTION_STATEMENT	Trigger body, UTF-8 encoded.
ACTION_ORIENTATION	Always ROW.
ACTION_TIMING	Whether the trigger acts BEFORE or AFTER the event that triggers it.
ACTION_REFERENCE_OLD_TABLE	Always NULL.
ACTION_REFERENCE_NEW_TABLE	Always NULL.
ACTION_REFERENCE_OLD_ROW	Always OLD.
ACTION_REFERENCE_NEW_ROW	Always NEW.
CREATED	Always NULL.
SQL_MODE	The SQL_MODE when the trigger was created, and which it uses for execution.
DEFINER	The account that created the trigger, in the form user_name@host_name
CHARACTER_SET_CLIENT	The client character set when the trigger was created, from the session value of the character_set_client system variable.
COLLATION_CONNECTION	The client collation when the trigger was created, from the session value of the collation_connection system variable.
DATABASE_COLLATION	Collation of the associated database.

Queries to the TRIGGERS table will return information only for databases and tables for which you have the TRIGGER privilege. Similar information is returned by the SHOW TRIGGERS statement.

1.1.1.2.9.1.1.59 Information Schema USER_PRIVILEGES Table

The Information Schema USER_PRIVILEGES table contains global user privilege information derived from the mysql.global_priv grant table.

It contains the following columns:

Column	Description
GRANTEE	In the format user_name@host_name.
TABLE_CATALOG	Always def.
PRIVILEGE_TYPE	The specific privilege, for example CREATE USER, RELOAD, SHUTDOWN, SELECT, INSERT, UPDATE or REFERENCES.
IS_GRANTABLE	Whether the user has the GRANT OPTION for this privilege.

The database, table and column privileges returned here are the ones granted on all databases and tables, and by implication all columns.

Similar information can be accessed with the SHOW GRANTS statement. See the GRANT article for more about privileges.

This information is also stored in the mysql.global_priv table, in the `mysql` system database.

1.1.1.2.9.1.1.60 Information Schema USER_STATISTICS Table

The Information Schema `USER_STATISTICS` table holds statistics about user activity. This is part of the User Statistics feature, which is not enabled by default.

You can use this table to find out such things as which user is causing the most load and which users are being abusive. You can also use this table to measure how close to capacity the server may be.

It contains the following columns:

Field	Type	Notes
USER	varchar(48)	The username. The value `'#mysql_system_user#'` appears when there is no username (such as for the slave SQL thread).
TOTAL_CONNECTIONS	int(21)	The number of connections created for this user.
CONCURRENT_CONNECTIONS	int(21)	The number of concurrent connections for this user.
CONNECTED_TIME	int(21)	The cumulative number of seconds elapsed while there were connections from this user.
BUSY_TIME	double	The cumulative number of seconds there was activity on connections from this user.
CPU_TIME	double	The cumulative CPU time elapsed while servicing this user's connections.
BYTES_RECEIVED	int(21)	The number of bytes received from this user's connections.
BYTES_SENT	int(21)	The number of bytes sent to this user's connections.
BINLOG_BYTES_WRITTEN	int(21)	The number of bytes written to the binary log from this user's connections.
ROWS_READ	int(21)	The number of rows read by this user's connections.
ROWS_SENT	int(21)	The number of rows sent by this user's connections.
ROWS_DELETED	int(21)	The number of rows deleted by this user's connections.
ROWS_INSERTED	int(21)	The number of rows inserted by this user's connections.
ROWS_UPDATED	int(21)	The number of rows updated by this user's connections.
SELECT_COMMANDS	int(21)	The number of `SELECT` commands executed from this user's connections.
UPDATE_COMMANDS	int(21)	The number of `UPDATE` commands executed from this user's connections.
OTHER_COMMANDS	int(21)	The number of other commands executed from this user's connections.
COMMIT_TRANSACTIONS	int(21)	The number of `COMMIT` commands issued by this user's connections.
ROLLBACK_TRANSACTIONS	int(21)	The number of `ROLLBACK` commands issued by this user's connections.
DENIED_CONNECTIONS	int(21)	The number of connections denied to this user.
LOST_CONNECTIONS	int(21)	The number of this user's connections that were terminated uncleanly.
ACCESS_DENIED	int(21)	The number of times this user's connections issued commands that were denied.
EMPTY_QUERIES	int(21)	The number of times this user's connections sent queries to the server that did not return data to the client (a per-user aggregate of the empty_queries status variable).

TOTAL_SSL_CONNECTIONS	int(21)	The number of TLS connections created for this user.
MAX_STATEMENT_TIME_EXCEEDED	int(21)	The number of times a statement was aborted, because it was executed longer than its MAX_STATEMENT_TIME threshold.

Example

```
SELECT * FROM information_schema.USER_STATISTICS\G
*************************** 1. row ***************************
                  USER: root
     TOTAL_CONNECTIONS: 1
CONCURRENT_CONNECTIONS: 0
        CONNECTED_TIME: 297
             BUSY_TIME: 0.001725
              CPU_TIME: 0.001982
        BYTES_RECEIVED: 388
            BYTES_SENT: 2327
  BINLOG_BYTES_WRITTEN: 0
             ROWS_READ: 0
             ROWS_SENT: 12
          ROWS_DELETED: 0
         ROWS_INSERTED: 13
          ROWS_UPDATED: 0
       SELECT_COMMANDS: 4
       UPDATE_COMMANDS: 0
        OTHER_COMMANDS: 3
   COMMIT_TRANSACTIONS: 0
 ROLLBACK_TRANSACTIONS: 0
    DENIED_CONNECTIONS: 0
      LOST_CONNECTIONS: 0
         ACCESS_DENIED: 0
         EMPTY_QUERIES: 1
```

1.1.1.2.9.1.1.61 Information Schema USER_VARIABLES Table

Contents

Description

The USER_VARIABLES table is created when the user_variables plugin is enabled, and contains information about user-defined variables.

The table contains the following columns:

Column	Description
VARIABLE_NAME	Variable name.
VARIABLE_VALUE	Variable value.
VARIABLE_TYPE	Variable type.
CHARACTER_SET_NAME	Character set.

User variables are reset and the table emptied with the FLUSH USER_VARIABLES statement.

Example

```
SELECT * FROM information_schema.USER_VARIABLES ORDER BY VARIABLE_NAME;
+---------------+----------------+---------------+--------------------+
| VARIABLE_NAME | VARIABLE_VALUE | VARIABLE_TYPE | CHARACTER_SET_NAME |
+---------------+----------------+---------------+--------------------+
| var           | 0              | INT           | utf8               |
| var2          | abc            | VARCHAR       | utf8               |
+---------------+----------------+---------------+--------------------+
```

1.1.1.2.9.1.1.62 Information Schema VIEWS Table

The Information Schema `VIEWS` table contains information about views. The `SHOW VIEW` privilege is required to view the table.

It has the following columns:

Column	Description
`TABLE_CATALOG`	Aways `def`.
`TABLE_SCHEMA`	Database name containing the view.
`TABLE_NAME`	View table name.
`VIEW_DEFINITION`	Definition of the view.
`CHECK_OPTION`	`YES` if the `WITH CHECK_OPTION` clause has been specified, `NO` otherwise.
`IS_UPDATABLE`	Whether the view is updatable or not.
`DEFINER`	Account specified in the DEFINER clause (or the default when created).
`SECURITY_TYPE`	`SQL SECURITY` characteristic, either `DEFINER` or `INVOKER`.
`CHARACTER_SET_CLIENT`	The client character set when the view was created, from the session value of the character_set_client system variable.
`COLLATION_CONNECTION`	The client collation when the view was created, from the session value of the collation_connection system variable.
`ALGORITHM`	The algorithm used in the view. See View Algorithms.

Example

```
SELECT * FROM information_schema.VIEWS\G
*************************** 1. row ***************************
       TABLE_CATALOG: def
        TABLE_SCHEMA: test
          TABLE_NAME: v
     VIEW_DEFINITION: select `test`.`t`.`qty` AS `qty`,`test`.`t`.`price` AS `price`,
(`test`.`t`.`qty` * `test`.`t`.`price`) AS `value` from `test`.`t`
        CHECK_OPTION: NONE
        IS_UPDATABLE: YES
             DEFINER: root@localhost
       SECURITY_TYPE: DEFINER
CHARACTER_SET_CLIENT: utf8
COLLATION_CONNECTION: utf8_general_ci
           ALGORITHM: UNDEFINED
```

1.1.1.2.9.1.1.63 Information Schema WSREP_MEMBERSHIP Table

The `WSREP_STATUS` table makes Galera node cluster membership information available through the Information Schema. The same information can be returned using the SHOW WSREP_MEMBERSHIP statement. Only users with the SUPER can access information from this table.

The `WSREP_MEMBERSHIP` table is part of the WSREP_INFO plugin.

Example

```
SELECT * FROM information_schema.WSREP_MEMBERSHIP;
+-------+--------------------------------------+-------+-----------------+
| INDEX | UUID                                 | NAME  | ADDRESS         |
+-------+--------------------------------------+-------+-----------------+
|     0 | 46da96e3-6e9e-11e4-95a2-f609aa5444b3 | node1 | 10.0.2.15:16000 |
|     1 | 5f6bc72a-6e9e-11e4-84ed-57ec6780a3d3 | node2 | 10.0.2.15:16001 |
|     2 | 7473fd75-6e9e-11e4-91de-0b541ad91bd0 | node3 | 10.0.2.15:16002 |
+-------+--------------------------------------+-------+-----------------+
```

1.1.1.2.9.1.1.64 Information Schema WSREP_STATUS Table

The WSREP_STATUS table makes Galera node cluster status information available through the Information Schema. The same information can be returned using the SHOW WSREP_STATUS statement. Only users with the SUPER privilege can access information from this table.

The `WSREP_STATUS` table is part of the WSREP_INFO plugin.

Example

```
SELECT * FROM information_schema.WSREP_STATUS\G
*************************** 1. row ***************************
         NODE_INDEX: 0
        NODE_STATUS: Synced
     CLUSTER_STATUS: Primary
       CLUSTER_SIZE: 3
 CLUSTER_STATE_UUID: 00b0fbad-6e84-11e4-8a8b-376f19ce8ee7
CLUSTER_STATE_SEQNO: 2
    CLUSTER_CONF_ID: 3
                GAP: NO
   PROTOCOL_VERSION: 3
```

1.1.1.2.8.2 Extended SHOW

1.1.1.2.9.1.3 TIME_MS column in INFORMATION_SCHEMA.PROCESSLIST

In MariaDB, an extra column `TIME_MS` has been added to the INFORMATION_SCHEMA.PROCESSLIST table. This column shows the same information as the column ' `TIME` ', but in units of milliseconds with microsecond precision (the unit and precision of the `TIME` column is one second).

For details about microseconds support in MariaDB, see microseconds in MariaDB.

The value displayed in the `TIME` and `TIME_MS` columns is the period of time that the given thread has been in its current state. Thus it can be used to check for example how long a thread has been executing the current query, or for how long it has been idle.

```
select id, time, time_ms, command, state from
   information_schema.processlist, (select sleep(2)) t;
+----+------+----------+---------+-----------+
| id | time | time_ms  | command | state     |
+----+------+----------+---------+-----------+
| 37 |    2 | 2000.493 | Query   | executing |
+----+------+----------+---------+-----------+
```

Note that as a difference to MySQL, in MariaDB the `TIME` column (and also the `TIME_MS` column) are not affected by any setting of @TIMESTAMP. This means that it can be reliably used also for threads that change `@TIMESTAMP` (such as the replication SQL thread). See also MySQL Bug #22047.

As a consequence of this, the `TIME` column of `SHOW FULL PROCESSLIST` and `INFORMATION_SCHEMA.PROCESSLIST` can not be used to determine if a slave is lagging behind. For this, use instead the `Seconds_Behind_Master` column in the output of SHOW SLAVE STATUS.

The addition of the TIME_MS column is based on the microsec_process patch, developed by Percona.

1.1.1.2.9.2 Performance Schema

The MariaDB Performance Schema is a feature for monitoring the performance of your MariaDB server. It is not enabled by default - see the overview for details on activating.

Performance Schema Tables

Tables making up the MariaDB Performance Schema.

Performance Schema Overview

Quick overview of the Performance Schema.

Performance Schema Status Variables

Performance Schema status variables.

Performance Schema System Variables

Performance Schema system variables.

Performance Schema Digests

Normalized statements with data values removed

PERFORMANCE_SCHEMA Storage Engine

PERFORMANCE_SCHEMA storage engine, a mechanism for implementing the feature.

There are 4 related questions.

1.1.1.2.9.2.1 Performance Schema Tables

Tables that are part of the MariaDB Performance Schema, a feature for monitoring the performance of MariaDB server.

List of Performance Schema Tables

List and short description of all performance_schema tables.

Performance Schema accounts Table

Account connection information.

Performance Schema cond_instances Table

List of instrumented condition objects.

Performance Schema events_stages_current Table

Current stage events.

Performance Schema events_stages_history Table

Most recent stage events per thread.

Performance Schema events_stages_history_long Table

Most recent completed stage events.

Performance Schema events_stages_summary_by_account_by_event_name Table

Stage events, summarized by account and event name.

Performance Schema events_stages_summary_by_host_by_event_name Table

Stage events summarized by host and event name.

Performance Schema events_stages_summary_by_thread_by_event_name Table

Stage events summarized by thread and event name.

Performance Schema events_stages_summary_by_user_by_event_name Table

Stage events summarized by user and event name.

Performance Schema events_stages_summary_global_by_event_name Table

Event summaries.

Performance Schema events_statements_current Table

Current statement events.

Performance Schema events_statements_history Table

Most recent statement events per thread

Performance Schema events_statements_history_long Table

Most recent statement events.

Performance Schema events_statements_summary_by_account_by_event_name Table

Statement events summarized by account and event name.

Performance Schema events_statements_summary_by_digest Table

Statement events summarized by schema and digest.

Performance Schema events_statements_summary_by_host_by_event_name Table

Statement events summarized by host and event name.

Performance Schema events_statements_summary_by_program Table

Summarizes events for a particular stored program.

Performance Schema events_statements_summary_by_thread_by_event_name Table

Statement events summarized by thread and event name.

Performance Schema events_statements_summary_by_user_by_event_name Table

Statement events summarized by user and event name.

Performance Schema events_statements_summary_global_by_event_name Table

Statement events summarized by event name.

Performance Schema events_transactions_current Table

Current transaction events for each thread.

Performance Schema events_transactions_history Table

Most recent completed transaction events for each thread.

Performance Schema events_transactions_history_long Table

Most recent completed transaction events that have ended globally.

Performance Schema events_transactions_summary_by_account_by_event_name Table

Transaction events aggregated by account and event name.

Performance Schema events_transactions_summary_by_host_by_event_name Table

Transaction events aggregated by host and event name.

Performance Schema events_transactions_summary_by_thread_by_event_name Table

Transaction events aggregated by thread and event name.

Performance Schema events_transactions_summary_by_user_by_event_name Table

Transaction events aggregated by user and event name.

Performance Schema events_transactions_summary_global_by_event_name Table

Transaction events aggregated by event name.

Performance Schema events_waits_current Table

Current wait events

Performance Schema events_waits_history Table

Most recent wait events per thread

Performance Schema events_waits_history_long Table

Most recent completed wait events

Performance Schema events_waits_summary_by_account_by_event_name Table

Wait events summarized by account and event name.

Performance Schema events_waits_summary_by_host_by_event_name Table

Wait events summarized by host and event name.

Performance Schema events_waits_summary_by_instance Table

Wait events summarized by instance

Performance Schema events_waits_summary_by_thread_by_event_name Table

Wait events summarized by thread and event name.

Performance Schema events_waits_summary_by_user_by_event_name Table

Wait events summarized by user and event name.

Performance Schema events_waits_summary_global_by_event_name Table

Wait events summarized by event name.

Performance Schema file_instances Table

List of file instruments.

Performance Schema file_summary_by_event_name Table

File events summarized by event name.

Performance Schema file_summary_by_instance Table

File events summarized by instance.

Performance Schema global_status Table

Status variables and their global values.

Performance Schema hosts Table

Hosts used to connect to the server.

Performance Schema host_cache Table

Host_cache information.

Performance Schema memory_summary_by_account_by_event_name Table

Memory usage statistics aggregated by account and event.

Performance Schema memory_summary_by_host_by_event_name Table

Memory usage statistics aggregated by host and event.

Performance Schema memory_summary_by_thread_by_event_name Table

Memory usage statistics aggregated by thread and event.

Performance Schema memory_summary_by_user_by_event_name Table

Memory usage statistics aggregated by user and event.

Performance Schema memory_summary_global_by_event_name Table

Memory usage statistics aggregated by event and event.

Performance Schema metadata_locks Table

Metadata lock information.

Performance Schema mutex_instances Table

Seen mutexes

Performance Schema objects_summary_global_by_type Table

Aggregates object wait events.

Performance Schema performance_timers Table

Available event timers

Performance Schema prepared_statements_instances Table

Aggregated statistics of prepared statements.

Performance Schema replication_applier_configuration Table

Configuration settings affecting replica transactions.

Performance Schema replication_applier_status Table

Information about the general transaction execution status on the slave.

Performance Schema replication_applier_status_by_coordinator Table

Coordinator thread status used in multi-threaded replicas to manage multiple workers.

Performance Schema replication_applier_status_by_worker Table

Slave worker thread specific information.

Performance Schema replication_connection_configuration Table

Replica configuration settings used for connecting to the primary.

Performance Schema rwlock_instances Table

Seen read-write locks

Performance Schema session_account_connect_attrs Table

Connection attributes for the current session.

Performance Schema session_connect_attrs Table

Connection attributes for all sessions.

Performance Schema session_status Table

Status variables and their session values.

Performance Schema setup_actors Table

Determines whether monitoring is enabled for host/user combinations.

Performance Schema setup_consumers Table

Lists the types of consumers for which event information is available.

Performance Schema setup_instruments Table

List of instrumented object classes

Performance Schema setup_objects Table

Which objects are monitored.

Performance Schema setup_timers Table

Currently selected event timers

Performance Schema socket_instances Table

Active server connections.

Performance Schema socket_summary_by_event_name Table

Aggregates timer and byte count statistics for all socket I/O operations by socket instrument.

Performance Schema socket_summary_by_instance Table

Aggregates timer and byte count statistics for all socket I/O operations by socket instance.

Performance Schema status_by_account Table

Status variable information by user/host account.

Performance Schema status_by_host Table

Status variable information by host.

Performance Schema status_by_thread Table

Status variable information about active foreground threads.

Performance Schema status_by_user Table

Status variable information by user.

Performance Schema table_handles Table

Table lock information.

Performance Schema table_io_waits_summary_by_index_usage Table

Table I/O waits by index.

Performance Schema table_io_waits_summary_by_table Table

Table I/O waits by table.

Performance Schema table_lock_waits_summary_by_table Table

Table lock waits by table.

Performance Schema threads Table

Each server thread is represented as a row in the threads table.

Performance Schema users Table

User connection information.

Performance Schema user_variables_by_thread Table

User-defined variables and the threads that defined them.

1.1.1.2.9.2.1.1 List of Performance Schema Tables

Below is a list of all Performance Schema tables as well as a brief description of each of them.

Table	Description
accounts	Client account connection statistics.
cond_instances	Synchronization object instances.
events_stages_current	Current stage events.
events_stages_history	Ten most recent stage events per thread.
events_stages_history_long	Ten thousand most recent stage events.
events_stages_summary_by_account_by_event_name	Summarized stage events per account and event name.
events_stages_summary_by_host_by_event_name	Summarized stage events per host and event name.
events_stages_summary_by_thread_by_event_name	Summarized stage events per thread and event name.
events_stages_summary_by_user_by_event_name	Summarized stage events per user name and event name.
events_stages_summary_global_by_event_name	Summarized stage events per event name.
events_statements_current	Current statement events.

events_statements_history	Ten most recent events per thread.
events_statements_history_long	Ten thousand most recent stage events.
events_statements_summary_by_account_by_event_name	Summarized statement events per account and event name.
events_statements_summary_by_digest	Summarized statement events by scheme and digest.
events_statements_summary_by_host_by_event_name	Summarized statement events by host and event name.
events_statements_summary_by_program	Events for a particular stored program.
events_statements_summary_by_thread_by_event_name	Summarized statement events by thread and event name.
events_statements_summary_by_user_by_event_name	Summarized statement events by user and event name.
events_statements_summary_global_by_event_name	Summarized statement events by event name.
events_transactions_current	Current transaction events for each thread.
events_transactions_history	Most recent completed transaction events for each thread.
events_transactions_history_long	Most recent completed transaction events that have ended globally.
events_transactions_summary_by_account_by_event_name	Transaction events aggregated by account and event.
events_transactions_summary_by_host_by_event_name	Transaction events aggregated by host and event..
events_transactions_summary_by_thread_by_event_name	Transaction events aggregated by thread and event..
events_transactions_summary_by_user_by_event_name	Transaction events aggregated by user and event..
events_transactions_summary_global_by_event_name	Transaction events aggregated by event name.
events_waits_current	Current wait events.
events_waits_history	Ten most recent wait events per thread.
events_waits_history_long	Ten thousand most recent wait events per thread.
events_waits_summary_by_account_by_event_name	Summarized wait events by account and event name.
events_waits_summary_by_host_by_event_name	Summarized wait events by host and event name.
events_waits_summary_by_instance	Summarized wait events by instance.
events_waits_summary_by_thread_by_event_name	Summarized wait events by thread and event name.
events_waits_summary_by_user_by_event_name	Summarized wait events by user and event name.
events_waits_summary_global_by_event_name	Summarized wait events by event name.
file_instances	Seen files.
file_summary_by_event_name	File events summarized by event name.
file_summary_by_instance	File events summarized by instance.
global_status	Global status variables and values.
host_cache	Host and IP information.
hosts	Connections by host.
memory_summary_by_account_by_event_name	Memory usage statistics aggregated by account and event.
memory_summary_by_host_by_event_name	Memory usage statistics aggregated by host. and event.

memory_summary_by_thread_by_event_name	Memory usage statistics aggregated by thread and event..
memory_summary_by_user_by_event_name	Memory usage statistics aggregated by user and event..
memory_summary_global_by_event_name	Memory usage statistics aggregated by event.
metadata_locks	Metadata locks.
mutex_instances	Seen mutexes.
objects_summary_global_by_type	Object wait events.
performance_timers	Available event timers.
prepared_statements_instances	Aggregate statistics of prepared statements.
replication_applier_configuration	Configuration settings affecting replica transactions.
replication_applier_status	General transaction execution status on the replica.
replication_applier_status_by_coordinator	Coordinator thread specific information.
replication_applier_status_by_worker	Replica worker thread specific information.
replication_connection_configuration	Rreplica's configuration settings used for connecting to the primary.
rwlock_instances	Seen read-write locks.
session_account_connect_attrs	Current session connection attributes.
session_connect_attrs	All session connection attributes.
session_status	Session status variables and values.
setup_actors	Details on foreground thread monitoring.
setup_consumers	Consumers for which event information is stored.
setup_instruments	Instrumented objects for which events are collected.
setup_objects	Objects to be monitored.
setup_timers	Currently selected event timers.
socket_instances	Active connections.
socket_summary_by_event_name	Timer and byte count statistics by socket instrument.
socket_summary_by_instance	Timer and byte count statistics by socket instance.
status_by_account	Status variable info by host/user account.
status_by_host	Status variable info by host.
status_by_thread	Status variable info about active foreground threads.
status_by_user	Status variable info by user.
table_handles	Table lock information.
table_io_waits_summary_by_index_usage	Aggregate table I/O wait events by index.
table_io_waits_summary_by_table	Aggregate table I/O wait events by table.
table_lock_waits_summary_by_table	Aggregate table lock wait events by table.
threads	Server thread information.
user_variables_by_thread	User-defined variables by thread.
users	Connection statistics by user.

1.1.1.2.9.2.1.2 Performance Schema accounts Table

Description

Each account that connects to the server is stored as a row in the accounts table, along with current and total connections.

The table size is determined at startup by the value of the performance_schema_accounts_size system variable. If this is set to 0, account statistics will be disabled.

Column	Description
USER	The connection's client user name for the connection, or NULL if an internal thread.
HOST	The connection client's host name, or NULL if an internal thread.
CURRENT_CONNECTIONS	Current connections for the account.
TOTAL_CONNECTIONS	Total connections for the account.

The USER and HOST values shown here are the username and host used for user connections, not the patterns used to check permissions.

Example

```
SELECT * FROM performance_schema.accounts;
+------------------+-----------+---------------------+-------------------+
| USER             | HOST      | CURRENT_CONNECTIONS | TOTAL_CONNECTIONS |
+------------------+-----------+---------------------+-------------------+
| root             | localhost |                   1 |                 2 |
| NULL             | NULL      |                  20 |                23 |
| debian-sys-maint | localhost |                   0 |                35 |
+------------------+-----------+---------------------+-------------------+
```

1.1.1.2.9.2.1.3 Performance Schema cond_instances Table

Description

The cond_instances table lists all conditions while the server is executing. A condition, or instrumented condition object, is an internal code mechanism used for signalling that a specific event has occurred so that any threads waiting for this condition can continue.

The maximum number of conditions stored in the performance schema is determined by the performance_schema_max_cond_instances system variable.

Column	Description
NAME	Client user name for the connection, or NULL if an internal thread.
OBJECT_INSTANCE_BEGIN	Address in memory of the instrumented condition.

1.1.1.2.9.2.1.4 Performance Schema events_stages_current Table

The events_stages_current table contains current stage events, with each row being a record of a thread and its most recent stage event.

The table contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with EVENT_ID uniquely identifies the row.
EVENT_ID	Thread's current event number at the start of the event. Together with THREAD_ID uniquely identifies the row.

END_EVENT_ID	NULL when the event starts, set to the thread's current event number at the end of the event.
EVENT_NAME	Event instrument name and a NAME from the setup_instruments table
SOURCE	Name and line number of the source file containing the instrumented code that produced the event.
TIMER_START	Value in picoseconds when the event timing started or NULL if timing is not collected.
TIMER_END	Value in picoseconds when the event timing ended, or NULL if the event has not ended or timing is not collected.
TIMER_WAIT	Value in picoseconds of the event's duration or NULL if the event has not ended or timing is not collected.
NESTING_EVENT_ID	EVENT_ID of event within which this event nests.
NESTING_EVENT_TYPE	Nesting event type. One of transaction, statement, stage or wait.

It is possible to empty this table with a TRUNCATE TABLE statement.

The related tables, events_stages_history and events_stages_history_long derive their values from the current events.

1.1.1.2.9.2.1.5 Performance Schema events_stages_history Table

The events_stages_history table by default contains the ten most recent completed stage events per thread. This number can be adjusted by setting the performance_schema_events_stages_history_size system variable when the server starts up.

The table structure is identical to the events_stage_current table structure, and contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with EVENT_ID uniquely identifies the row.
EVENT_ID	Thread's current event number at the start of the event. Together with THREAD_ID uniquely identifies the row.
END_EVENT_ID	NULL when the event starts, set to the thread's current event number at the end of the event.
EVENT_NAME	Event instrument name and a NAME from the setup_instruments table
SOURCE	Name and line number of the source file containing the instrumented code that produced the event.
TIMER_START	Value in picoseconds when the event timing started or NULL if timing is not collected.
TIMER_END	Value in picoseconds when the event timing ended, or NULL if timing is not collected.
TIMER_WAIT	Value in picoseconds of the event's duration or NULL if timing is not collected.
NESTING_EVENT_ID	EVENT_ID of event within which this event nests.
NESTING_EVENT_TYPE	Nesting event type. One of transaction, statement, stage or wait.

It is possible to empty this table with a TRUNCATE TABLE statement.

events_stages_current and events_stages_history_long are related tables.

1.1.1.2.9.2.1.6 Performance Schema events_stages_history_long Table

The events_stages_history_long table by default contains the ten thousand most recent completed stage events. This number can be adjusted by setting the performance_schema_events_stages_history_long_size system variable when the server starts up.

The table structure is identical to the events_stage_current table structure, and contains the following columns:

Column	Description

THREAD_ID	Thread associated with the event. Together with EVENT_ID uniquely identifies the row.
EVENT_ID	Thread's current event number at the start of the event. Together with THREAD_ID uniquely identifies the row.
END_EVENT_ID	NULL when the event starts, set to the thread's current event number at the end of the event.
EVENT_NAME	Event instrument name and a NAME from the setup_instruments table
SOURCE	Name and line number of the source file containing the instrumented code that produced the event.
TIMER_START	Value in picoseconds when the event timing started or NULL if timing is not collected.
TIMER_END	Value in picoseconds when the event timing ended, or NULL if timing is not collected.
TIMER_WAIT	Value in picoseconds of the event's duration or NULL if timing is not collected.
NESTING_EVENT_ID	EVENT_ID of event within which this event nests.
NESTING_EVENT_TYPE	Nesting event type. One of transaction , statement , stage or wait .

It is possible to empty this table with a TRUNCATE TABLE statement.

events_stages_current and events_stages_history are related tables.

1.1.1.2.9.2.1.7 Performance Schema events_stages_summary_by_account_by_event_ Table

The table lists stage events, summarized by account and event name.

It contains the following columns:

Column	Description
USER	User. Used together with HOST and EVENT_NAME for grouping events.
HOST	Host. Used together with USER and EVENT_NAME for grouping events.
EVENT_NAME	Event name. Used together with USER and HOST for grouping events.
COUNT_STAR	Number of summarized events, which includes all timed and untimed events.
SUM_TIMER_WAIT	Total wait time of the timed summarized events.
MIN_TIMER_WAIT	Minimum wait time of the timed summarized events.
AVG_TIMER_WAIT	Average wait time of the timed summarized events.
MAX_TIMER_WAIT	Maximum wait time of the timed summarized events.

Example

```
SELECT * FROM events_stages_summary_by_account_by_event_name\G
...
*************************** 325. row ***************************
          USER: NULL
          HOST: NULL
    EVENT_NAME: stage/sql/Waiting for event metadata lock
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 326. row ***************************
          USER: NULL
          HOST: NULL
    EVENT_NAME: stage/sql/Waiting for commit lock
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 327. row ***************************
          USER: NULL
          HOST: NULL
    EVENT_NAME: stage/aria/Waiting for a resource
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
```

1.1.1.2.9.2.1.8 Performance Schema events_stages_summary_by_host_by_event_nan Table

The table lists stage events, summarized by host and event name.

It contains the following columns:

Column	Description
`HOST`	Host. Used together with `EVENT_NAME` for grouping events.
`EVENT_NAME`	Event name. Used together with `HOST` for grouping events.
`COUNT_STAR`	Number of summarized events, which includes all timed and untimed events.
`SUM_TIMER_WAIT`	Total wait time of the timed summarized events.
`MIN_TIMER_WAIT`	Minimum wait time of the timed summarized events.
`AVG_TIMER_WAIT`	Average wait time of the timed summarized events.
`MAX_TIMER_WAIT`	Maximum wait time of the timed summarized events.

Example

```
SELECT * FROM events_stages_summary_by_host_by_event_name\G
...
*************************** 216. row ***************************
          HOST: NULL
    EVENT_NAME: stage/sql/Waiting for event metadata lock
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 217. row ***************************
          HOST: NULL
    EVENT_NAME: stage/sql/Waiting for commit lock
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 218. row ***************************
          HOST: NULL
    EVENT_NAME: stage/aria/Waiting for a resource
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
```

1.1.1.2.9.2.1.9 Performance Schema events_stages_summary_by_thread_by_event_n Table

The table lists stage events, summarized by thread and event name.

It contains the following columns:

Column	Description
`THREAD_ID`	Thread associated with the event. Together with `EVENT_NAME` uniquely identifies the row.
`EVENT_NAME`	Event name. Used together with `THREAD_ID` for grouping events.
`COUNT_STAR`	Number of summarized events, which includes all timed and untimed events.
`SUM_TIMER_WAIT`	Total wait time of the timed summarized events.
`MIN_TIMER_WAIT`	Minimum wait time of the timed summarized events.
`AVG_TIMER_WAIT`	Average wait time of the timed summarized events.
`MAX_TIMER_WAIT`	Maximum wait time of the timed summarized events.

Example

```
SELECT * FROM events_stages_summary_by_thread_by_event_name\G
...
*************************** 2287. row ***************************
     THREAD_ID: 64
    EVENT_NAME: stage/sql/Waiting for event metadata lock
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 2288. row ***************************
     THREAD_ID: 64
    EVENT_NAME: stage/sql/Waiting for commit lock
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 2289. row ***************************
     THREAD_ID: 64
    EVENT_NAME: stage/aria/Waiting for a resource
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
```

1.1.1.2.9.2.1.10 Performance Schema events_stages_summary_by_user_by_event_nan Table

The table lists stage events, summarized by user and event name.

It contains the following columns:

Column	Description
`USER`	User. Used together with `EVENT_NAME` for grouping events.
`EVENT_NAME`	Event name. Used together with `USER` for grouping events.
`COUNT_STAR`	Number of summarized events, which includes all timed and untimed events.
`SUM_TIMER_WAIT`	Total wait time of the timed summarized events.
`MIN_TIMER_WAIT`	Minimum wait time of the timed summarized events.
`AVG_TIMER_WAIT`	Average wait time of the timed summarized events.
`MAX_TIMER_WAIT`	Maximum wait time of the timed summarized events.

Example

```
SELECT * FROM events_stages_summary_by_user_by_event_name\G
...
*************************** 325. row ***************************
          USER: NULL
    EVENT_NAME: stage/sql/Waiting for event metadata lock
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 326. row ***************************
          USER: NULL
    EVENT_NAME: stage/sql/Waiting for commit lock
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 327. row ***************************
          USER: NULL
    EVENT_NAME: stage/aria/Waiting for a resource
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
```

1.1.1.2.9.2.1.11 Performance Schema events_stages_summary_global_by_event_name Table

The table lists stage events, summarized by thread and event name.

It contains the following columns:

Column	Description
EVENT_NAME	Event name.
COUNT_STAR	Number of summarized events, which includes all timed and untimed events.
SUM_TIMER_WAIT	Total wait time of the timed summarized events.
MIN_TIMER_WAIT	Minimum wait time of the timed summarized events.
AVG_TIMER_WAIT	Average wait time of the timed summarized events.
MAX_TIMER_WAIT	Maximum wait time of the timed summarized events.

Example

```
SELECT * FROM events_stages_summary_global_by_event_name\G
...
*************************** 106. row ***************************
    EVENT_NAME: stage/sql/Waiting for trigger metadata lock
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 107. row ***************************
    EVENT_NAME: stage/sql/Waiting for event metadata lock
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 108. row ***************************
    EVENT_NAME: stage/sql/Waiting for commit lock
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 109. row ***************************
    EVENT_NAME: stage/aria/Waiting for a resource
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
```

1.1.1.2.9.2.1.12 Performance Schema events_statements_current Table

The `events_statements_current` table contains current statement events, with each row being a record of a thread and its most recent statement event.

The table contains the following columns:

Column	Description
`THREAD_ID`	Thread associated with the event. Together with `EVENT_ID` uniquely identifies the row.
`EVENT_ID`	Thread's current event number at the start of the event. Together with `THREAD_ID` uniquely identifies the row.
`END_EVENT_ID`	`NULL` when the event starts, set to the thread's current event number at the end of the event.
`EVENT_NAME`	Event instrument name and a `NAME` from the `setup_instruments` table
`SOURCE`	Name and line number of the source file containing the instrumented code that produced the event.
`TIMER_START`	Value in picoseconds when the event timing started or `NULL` if timing is not collected.
`TIMER_END`	Value in picoseconds when the event timing ended, or `NULL` if the event has not ended or timing is not collected.
`TIMER_WAIT`	Value in picoseconds of the event's duration or `NULL` if the event has not ended or timing is not collected.
`LOCK_TIME`	Time in picoseconds spent waiting for locks. The time is calculated in microseconds but stored in picoseconds for compatibility with other timings.
`SQL_TEXT`	The SQL statement, or `NULL` if the command is not associated with an SQL statement.
`DIGEST`	Statement digest.
`DIGEST_TEXT`	Statement digest text.
`CURRENT_SCHEMA`	Statement's default database for the statement, or `NULL` if there was none.

OBJECT_SCHEMA	Reserved, currently NULL
OBJECT_NAME	Reserved, currently NULL
OBJECT_TYPE	Reserved, currently NULL
OBJECT_INSTANCE_BEGIN	Address in memory of the statement object.
MYSQL_ERRNO	Error code. See MariaDB Error Codes for a full list.
RETURNED_SQLSTATE	The SQLSTATE value.
MESSAGE_TEXT	Statement error message. See MariaDB Error Codes.
ERRORS	0 if SQLSTATE signifies completion (starting with 00) or warning (01), otherwise 1.
WARNINGS	Number of warnings from the diagnostics area.
ROWS_AFFECTED	Number of rows affected the statement affected.
ROWS_SENT	Number of rows returned.
ROWS_EXAMINED	Number of rows read during the statement's execution.
CREATED_TMP_DISK_TABLES	Number of on-disk temp tables created by the statement.
CREATED_TMP_TABLES	Number of temp tables created by the statement.
SELECT_FULL_JOIN	Number of joins performed by the statement which did not use an index.
SELECT_FULL_RANGE_JOIN	Number of joins performed by the statement which used a range search of the first table.
SELECT_RANGE	Number of joins performed by the statement which used a range of the first table.
SELECT_RANGE_CHECK	Number of joins without keys performed by the statement that check for key usage after each row.
SELECT_SCAN	Number of joins performed by the statement which used a full scan of the first table.
SORT_MERGE_PASSES	Number of merge passes by the sort algorithm performed by the statement. If too high, you may need to increase the sort_buffer_size.
SORT_RANGE	Number of sorts performed by the statement which used a range.
SORT_ROWS	Number of rows sorted by the statement.
SORT_SCAN	Number of sorts performed by the statement which used a full table scan.
NO_INDEX_USED	0 if the statement performed a table scan with an index, 1 if without an index.
NO_GOOD_INDEX_USED	0 if a good index was found for the statement, 1 if no good index was found. See the Range checked for each record description in the EXPLAIN article.
NESTING_EVENT_ID	Reserved, currently NULL.
NESTING_EVENT_TYPE	Reserved, currently NULL.

It is possible to empty this table with a TRUNCATE TABLE statement.

The related tables, events_statements_history and events_statements_history_long derive their values from the current events table.

1.1.1.2.9.2.1.13 Performance Schema events_statements_history Table

The events_statements_history table by default contains the ten most recent completed statement events per thread. This number can be adjusted by setting the performance_schema_events_statements_history_size system variable when the server starts up.

The table structure is identical to the events_statements_current table structure, and contains the following columns:

The table contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with EVENT_ID uniquely identifies the row.

EVENT_ID	Thread's current event number at the start of the event. Together with THREAD_ID uniquely identifies the row.
END_EVENT_ID	NULL when the event starts, set to the thread's current event number at the end of the event.
EVENT_NAME	Event instrument name and a NAME from the setup_instruments table
SOURCE	Name and line number of the source file containing the instrumented code that produced the event.
TIMER_START	Value in picoseconds when the event timing started or NULL if timing is not collected.
TIMER_END	Value in picoseconds when the event timing ended, or NULL if timing is not collected.
TIMER_WAIT	Value in picoseconds of the event's duration or NULL if timing is not collected.
LOCK_TIME	Time in picoseconds spent waiting for locks. The time is calculated in microseconds but stored in picoseconds for compatibility with other timings.
SQL_TEXT	The SQL statement, or NULL if the command is not associated with an SQL statement.
DIGEST	Statement digest.
DIGEST_TEXT	Statement digest text.
CURRENT_SCHEMA	Statement's default database for the statement, or NULL if there was none.
OBJECT_SCHEMA	Reserved, currently NULL
OBJECT_NAME	Reserved, currently NULL
OBJECT_TYPE	Reserved, currently NULL
OBJECT_INSTANCE_BEGIN	Address in memory of the statement object.
MYSQL_ERRNO	Error code. See MariaDB Error Codes for a full list.
RETURNED_SQLSTATE	The SQLSTATE value.
MESSAGE_TEXT	Statement error message. See MariaDB Error Codes.
ERRORS	0 if SQLSTATE signifies completion (starting with 00) or warning (01), otherwise 1 .
WARNINGS	Number of warnings from the diagnostics area.
ROWS_AFFECTED	Number of rows affected the statement affected.
ROWS_SENT	Number of rows returned.
ROWS_EXAMINED	Number of rows read during the statement's execution.
CREATED_TMP_DISK_TABLES	Number of on-disk temp tables created by the statement.
CREATED_TMP_TABLES	Number of temp tables created by the statement.
SELECT_FULL_JOIN	Number of joins performed by the statement which did not use an index.
SELECT_FULL_RANGE_JOIN	Number of joins performed by the statement which used a range search of the first table.
SELECT_RANGE	Number of joins performed by the statement which used a range of the first table.
SELECT_RANGE_CHECK	Number of joins without keys performed by the statement that check for key usage after each row.
SELECT_SCAN	Number of joins performed by the statement which used a full scan of the first table.
SORT_MERGE_PASSES	Number of merge passes by the sort algorithm performed by the statement. If too high, you may need to increase the sort_buffer_size.
SORT_RANGE	Number of sorts performed by the statement which used a range.
SORT_ROWS	Number of rows sorted by the statement.
SORT_SCAN	Number of sorts performed by the statement which used a full table scan.
NO_INDEX_USED	0 if the statement performed a table scan with an index, 1 if without an index.
NO_GOOD_INDEX_USED	0 if a good index was found for the statement, 1 if no good index was found. See the Range checked for each record description in the EXPLAIN article.

NESTING_EVENT_ID	Reserved, currently NULL.
NESTING_EVENT_TYPE	Reserved, currently NULL.

It is possible to empty this table with a TRUNCATE TABLE statement.

events_statements_current and events_statements_history_long are related tables.

1.1.1.2.9.2.1.14 Performance Schema events_statements_history_long Table

The events_statements_history_long table by default contains the ten thousand most recent completed statement events. This number can be adjusted by setting the performance_schema_events_statements_history_long_size system variable when the server starts up.

The table structure is identical to the events_statements_current table structure, and contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with EVENT_ID uniquely identifies the row.
EVENT_ID	Thread's current event number at the start of the event. Together with THREAD_ID uniquely identifies the row.
END_EVENT_ID	NULL when the event starts, set to the thread's current event number at the end of the event.
EVENT_NAME	Event instrument name and a NAME from the setup_instruments table
SOURCE	Name and line number of the source file containing the instrumented code that produced the event.
TIMER_START	Value in picoseconds when the event timing started or NULL if timing is not collected.
TIMER_END	Value in picoseconds when the event timing ended, or NULL if timing is not collected.
TIMER_WAIT	Value in picoseconds of the event's duration or NULL if timing is not collected.
LOCK_TIME	Time in picoseconds spent waiting for locks. The time is calculated in microseconds but stored in picoseconds for compatibility with other timings.
SQL_TEXT	The SQL statement, or NULL if the command is not associated with an SQL statement.
DIGEST	Statement digest.
DIGEST_TEXT	Statement digest text.
CURRENT_SCHEMA	Statement's default database for the statement, or NULL if there was none.
OBJECT_SCHEMA	Reserved, currently NULL
OBJECT_NAME	Reserved, currently NULL
OBJECT_TYPE	Reserved, currently NULL
OBJECT_INSTANCE_BEGIN	Address in memory of the statement object.
MYSQL_ERRNO	Error code. See MariaDB Error Codes for a full list.
RETURNED_SQLSTATE	The SQLSTATE value.
MESSAGE_TEXT	Statement error message. See MariaDB Error Codes.
ERRORS	0 if SQLSTATE signifies completion (starting with 00) or warning (01), otherwise 1.
WARNINGS	Number of warnings from the diagnostics area.
ROWS_AFFECTED	Number of rows affected the statement affected.
ROWS_SENT	Number of rows returned.
ROWS_EXAMINED	Number of rows read during the statement's execution.
CREATED_TMP_DISK_TABLES	Number of on-disk temp tables created by the statement.
CREATED_TMP_TABLES	Number of temp tables created by the statement.

SELECT_FULL_JOIN	Number of joins performed by the statement which did not use an index.
SELECT_FULL_RANGE_JOIN	Number of joins performed by the statement which used a range search of the first table.
SELECT_RANGE	Number of joins performed by the statement which used a range of the first table.
SELECT_RANGE_CHECK	Number of joins without keys performed by the statement that check for key usage after each row.
SELECT_SCAN	Number of joins performed by the statement which used a full scan of the first table.
SORT_MERGE_PASSES	Number of merge passes by the sort algorithm performed by the statement. If too high, you may need to increase the sort_buffer_size.
SORT_RANGE	Number of sorts performed by the statement which used a range.
SORT_ROWS	Number of rows sorted by the statement.
SORT_SCAN	Number of sorts performed by the statement which used a full table scan.
NO_INDEX_USED	0 if the statement performed a table scan with an index, 1 if without an index.
NO_GOOD_INDEX_USED	0 if a good index was found for the statement, 1 if no good index was found. See the Range checked for each record description in the EXPLAIN article.
NESTING_EVENT_ID	Reserved, currently NULL.
NESTING_EVENT_TYPE	Reserved, currently NULL.

It is possible to empty this table with a TRUNCATE TABLE statement.

events_statements_current and events_statements_history are related tables.

1.1.1.2.9.2.1.15 Performance Schema events_statements_summary_by_account_by_ev Table

The Performance Schema events_statements_summary_by_account_by_event_name table contains statement events summarized by account and event name. It contains the following columns:

Column	Description
USER	User. Used together with HOST and EVENT_NAME for grouping events.
HOST	Host. Used together with USER and EVENT_NAME for grouping events.
EVENT_NAME	Event name. Used together with USER and HOST for grouping events.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
SUM_LOCK_TIME	Sum of the LOCK_TIME column in the events_statements_current table.
SUM_ERRORS	Sum of the ERRORS column in the events_statements_current table.
SUM_WARNINGS	Sum of the WARNINGS column in the events_statements_current table.
SUM_ROWS_AFFECTED	Sum of the ROWS_AFFECTED column in the events_statements_current table.
SUM_ROWS_SENT	Sum of the ROWS_SENT column in the events_statements_current table.
SUM_ROWS_EXAMINED	Sum of the ROWS_EXAMINED column in the events_statements_current table.
SUM_CREATED_TMP_DISK_TABLES	Sum of the CREATED_TMP_DISK_TABLES column in the events_statements_current table.
SUM_CREATED_TMP_TABLES	Sum of the CREATED_TMP_TABLES column in the events_statements_current table.

SUM_SELECT_FULL_JOIN	Sum of the SELECT_FULL_JOIN column in the events_statements_current table.
SUM_SELECT_FULL_RANGE_JOIN	Sum of the SELECT_FULL_RANGE_JOIN column in the events_statements_current table.
SUM_SELECT_RANGE	Sum of the SELECT_RANGE column in the events_statements_current table.
SUM_SELECT_RANGE_CHECK	Sum of the SELECT_RANGE_CHECK column in the events_statements_current table.
SUM_SELECT_SCAN	Sum of the SELECT_SCAN column in the events_statements_current table.
SUM_SORT_MERGE_PASSES	Sum of the SORT_MERGE_PASSES column in the events_statements_current table.
SUM_SORT_RANGE	Sum of the SORT_RANGE column in the events_statements_current table.
SUM_SORT_ROWS	Sum of the SORT_ROWS column in the events_statements_current table.
SUM_SORT_SCAN	Sum of the SORT_SCAN column in the events_statements_current table.
SUM_NO_INDEX_USED	Sum of the NO_INDEX_USED column in the events_statements_current table.
SUM_NO_GOOD_INDEX_USED	Sum of the NO_GOOD_INDEX_USED column in the events_statements_current table.

The *_TIMER_WAIT columns only calculate results for timed events, as non-timed events have a NULL wait time.

Example

```
SELECT * FROM events_statements_summary_by_account_by_event_name\G
...
*************************** 521. row ***************************
                    USER: NULL
                    HOST: NULL
              EVENT_NAME: statement/com/Error
              COUNT_STAR: 0
          SUM_TIMER_WAIT: 0
          MIN_TIMER_WAIT: 0
          AVG_TIMER_WAIT: 0
          MAX_TIMER_WAIT: 0
           SUM_LOCK_TIME: 0
              SUM_ERRORS: 0
            SUM_WARNINGS: 0
       SUM_ROWS_AFFECTED: 0
           SUM_ROWS_SENT: 0
       SUM_ROWS_EXAMINED: 0
SUM_CREATED_TMP_DISK_TABLES: 0
     SUM_CREATED_TMP_TABLES: 0
       SUM_SELECT_FULL_JOIN: 0
 SUM_SELECT_FULL_RANGE_JOIN: 0
           SUM_SELECT_RANGE: 0
     SUM_SELECT_RANGE_CHECK: 0
            SUM_SELECT_SCAN: 0
      SUM_SORT_MERGE_PASSES: 0
             SUM_SORT_RANGE: 0
              SUM_SORT_ROWS: 0
              SUM_SORT_SCAN: 0
          SUM_NO_INDEX_USED: 0
     SUM_NO_GOOD_INDEX_USED: 0
*************************** 522. row ***************************
                    USER: NULL
                    HOST: NULL
              EVENT_NAME: statement/com/
              COUNT_STAR: 0
          SUM_TIMER_WAIT: 0
          MIN_TIMER_WAIT: 0
          AVG_TIMER_WAIT: 0
          MAX_TIMER_WAIT: 0
           SUM_LOCK_TIME: 0
              SUM_ERRORS: 0
            SUM_WARNINGS: 0
       SUM_ROWS_AFFECTED: 0
           SUM_ROWS_SENT: 0
       SUM_ROWS_EXAMINED: 0
SUM_CREATED_TMP_DISK_TABLES: 0
     SUM_CREATED_TMP_TABLES: 0
       SUM_SELECT_FULL_JOIN: 0
 SUM_SELECT_FULL_RANGE_JOIN: 0
           SUM_SELECT_RANGE: 0
     SUM_SELECT_RANGE_CHECK: 0
            SUM_SELECT_SCAN: 0
      SUM_SORT_MERGE_PASSES: 0
             SUM_SORT_RANGE: 0
              SUM_SORT_ROWS: 0
              SUM_SORT_SCAN: 0
          SUM_NO_INDEX_USED: 0
     SUM_NO_GOOD_INDEX_USED: 0
```

1.1.1.2.9.2.1.16 Performance Schema events_statements_summary_by_digest Table

The Performance Schema digest is a hashed, normalized form of a statement with the specific data values removed. It allows statistics to be gathered for similar kinds of statements.

The Performance Schema `events_statements_summary_by_digest` table records statement events summarized by schema and digest. It contains the following columns:

Column	Description

SCHEMA_NAME	Database name. Records are summarised together with DIGEST.
DIGEST	Performance Schema digest. Records are summarised together with SCHEMA_NAME.
DIGEST_TEXT	The unhashed form of the digest.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
SUM_LOCK_TIME	Sum of the LOCK_TIME column in the events_statements_current table.
SUM_ERRORS	Sum of the ERRORS column in the events_statements_current table.
SUM_WARNINGS	Sum of the WARNINGS column in the events_statements_current table.
SUM_ROWS_AFFECTED	Sum of the ROWS_AFFECTED column in the events_statements_current table.
SUM_ROWS_SENT	Sum of the ROWS_SENT column in the events_statements_current table.
SUM_ROWS_EXAMINED	Sum of the ROWS_EXAMINED column in the events_statements_current table.
SUM_CREATED_TMP_DISK_TABLES	Sum of the CREATED_TMP_DISK_TABLES column in the events_statements_current table.
SUM_CREATED_TMP_TABLES	Sum of the CREATED_TMP_TABLES column in the events_statements_current table.
SUM_SELECT_FULL_JOIN	Sum of the SELECT_FULL_JOIN column in the events_statements_current table.
SUM_SELECT_FULL_RANGE_JOIN	Sum of the SELECT_FULL_RANGE_JOIN column in the events_statements_current table.
SUM_SELECT_RANGE	Sum of the SELECT_RANGE column in the events_statements_current table.
SUM_SELECT_RANGE_CHECK	Sum of the SELECT_RANGE_CHECK column in the events_statements_current table.
SUM_SELECT_SCAN	Sum of the SELECT_SCAN column in the events_statements_current table.
SUM_SORT_MERGE_PASSES	Sum of the SORT_MERGE_PASSES column in the events_statements_current table.
SUM_SORT_RANGE	Sum of the SORT_RANGE column in the events_statements_current table.
SUM_SORT_ROWS	Sum of the SORT_ROWS column in the events_statements_current table.
SUM_SORT_SCAN	Sum of the SORT_SCAN column in the events_statements_current table.
SUM_NO_INDEX_USED	Sum of the NO_INDEX_USED column in the events_statements_current table.
SUM_NO_GOOD_INDEX_USED	Sum of the NO_GOOD_INDEX_USED column in the events_statements_current table.
FIRST_SEEN	Time at which the digest was first seen.
LAST_SEEN	Time at which the digest was most recently seen.

The *_TIMER_WAIT columns only calculate results for timed events, as non-timed events have a NULL wait time.

The events_statements_summary_by_digest table is limited in size by the performance_schema_digests_size system variable. Once the limit has been reached and the table is full, all entries are aggregated in a row with a NULL digest. The COUNT_STAR value of this NULL row indicates how many digests are recorded in the row and therefore gives an indication of whether performance_schema_digests_size should be increased to provide more accurate statistics.

1.1.1.2.9.2.1.17 Performance Schema events_statements_summary_by_host_by_event_

Table

The Performance Schema events_statements_summary_by_host_by_event_name table contains statement events summarized by host and event name. It contains the following columns:

Column	Description
HOST	Host. Used together with EVENT_NAME for grouping events.
EVENT_NAME	Event name. Used together with HOST for grouping events.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
SUM_LOCK_TIME	Sum of the LOCK_TIME column in the events_statements_currentd table.
SUM_ERRORS	Sum of the ERRORS column in the events_statements_current table.
SUM_WARNINGS	Sum of the WARNINGS column in the events_statements_current table.
SUM_ROWS_AFFECTED	Sum of the ROWS_AFFECTED column in the events_statements_current table.
SUM_ROWS_SENT	Sum of the ROWS_SENT column in the events_statements_current table.
SUM_ROWS_EXAMINED	Sum of the ROWS_EXAMINED column in the events_statements_current table.
SUM_CREATED_TMP_DISK_TABLES	Sum of the CREATED_TMP_DISK_TABLES column in the events_statements_current table.
SUM_CREATED_TMP_TABLES	Sum of the CREATED_TMP_TABLES column in the events_statements_current table.
SUM_SELECT_FULL_JOIN	Sum of the SELECT_FULL_JOIN column in the events_statements_current table.
SUM_SELECT_FULL_RANGE_JOIN	Sum of the SELECT_FULL_RANGE_JOINW column in the events_statements_current table.
SUM_SELECT_RANGE	Sum of the SELECT_RANGE column in the events_statements_current table.
SUM_SELECT_RANGE_CHECK	Sum of the SELECT_RANGE_CHECK column in the events_statements_current table.
SUM_SELECT_SCAN	Sum of the SELECT_SCAN column in the events_statements_current table.
SUM_SORT_MERGE_PASSES	Sum of the SORT_MERGE_PASSES column in the events_statements_current table.
SUM_SORT_RANGE	Sum of the SORT_RANGE column in the events_statements_current table.
SUM_SORT_ROWS	Sum of the SORT_ROWS column in the events_statements_current table.
SUM_SORT_SCAN	Sum of the SORT_SCAN column in the events_statements_current table.
SUM_NO_INDEX_USED	Sum of the NO_INDEX_USED column in the events_statements_current table.
SUM_NO_GOOD_INDEX_USED	Sum of the NO_GOOD_INDEX_USED column in the events_statements_current table.

The *_TIMER_WAIT columns only calculate results for timed events, as non-timed events have a NULL wait time.

Example

```
SELECT * FROM events_statements_summary_by_host_by_event_name\G
...
*************************** 347. row ***************************
                    HOST: NULL
              EVENT_NAME: statement/com/Error
              COUNT_STAR: 0
          SUM_TIMER_WAIT: 0
          MIN_TIMER_WAIT: 0
          AVG_TIMER_WAIT: 0
          MAX_TIMER_WAIT: 0
           SUM_LOCK_TIME: 0
              SUM_ERRORS: 0
            SUM_WARNINGS: 0
       SUM_ROWS_AFFECTED: 0
           SUM_ROWS_SENT: 0
       SUM_ROWS_EXAMINED: 0
SUM_CREATED_TMP_DISK_TABLES: 0
     SUM_CREATED_TMP_TABLES: 0
       SUM_SELECT_FULL_JOIN: 0
 SUM_SELECT_FULL_RANGE_JOIN: 0
           SUM_SELECT_RANGE: 0
     SUM_SELECT_RANGE_CHECK: 0
            SUM_SELECT_SCAN: 0
      SUM_SORT_MERGE_PASSES: 0
             SUM_SORT_RANGE: 0
              SUM_SORT_ROWS: 0
              SUM_SORT_SCAN: 0
          SUM_NO_INDEX_USED: 0
     SUM_NO_GOOD_INDEX_USED: 0
*************************** 348. row ***************************
                    HOST: NULL
              EVENT_NAME: statement/com/
              COUNT_STAR: 0
          SUM_TIMER_WAIT: 0
          MIN_TIMER_WAIT: 0
          AVG_TIMER_WAIT: 0
          MAX_TIMER_WAIT: 0
           SUM_LOCK_TIME: 0
              SUM_ERRORS: 0
            SUM_WARNINGS: 0
       SUM_ROWS_AFFECTED: 0
           SUM_ROWS_SENT: 0
       SUM_ROWS_EXAMINED: 0
SUM_CREATED_TMP_DISK_TABLES: 0
     SUM_CREATED_TMP_TABLES: 0
       SUM_SELECT_FULL_JOIN: 0
 SUM_SELECT_FULL_RANGE_JOIN: 0
           SUM_SELECT_RANGE: 0
     SUM_SELECT_RANGE_CHECK: 0
            SUM_SELECT_SCAN: 0
      SUM_SORT_MERGE_PASSES: 0
             SUM_SORT_RANGE: 0
              SUM_SORT_ROWS: 0
              SUM_SORT_SCAN: 0
          SUM_NO_INDEX_USED: 0
     SUM_NO_GOOD_INDEX_USED: 0
```

1.1.1.2.9.2.1.18 Performance Schema events_statements_summary_by_program Table

MariaDB starting with 10.5.2

The `events_statements_summary_by_program` table, along with many other new Performance Schema tables, was added in MariaDB 10.5.2.

Each row in the the Performance Schema events_statements_summary_by_program table summarizes events for a particular stored program (stored procedure, stored function, trigger or event).

It contains the following fields.

Column	Type	Null	Description
OBJECT_TYPE	enum('EVENT', 'FUNCTION', 'PROCEDURE', 'TABLE', 'TRIGGER')	YES	Object type for which the summary is generated.
OBJECT_SCHEMA	varchar(64)	NO	The schema of the object for which the summary is generated.
OBJECT_NAME	varchar(64)	NO	The name of the object for which the summary is generated.
COUNT_STAR	bigint(20) unsigned	NO	The number of summarized events (from events_statements_current). This value includes all events, whether timed or nontimed.
SUM_TIMER_WAIT	bigint(20) unsigned	NO	The number of summarized events (from events_statements_current). This value includes all events, whether timed or nontimed.
MIN_TIMER_WAIT	bigint(20) unsigned	NO	The minimum wait time of the summarized timed events.
AVG_TIMER_WAIT	bigint(20) unsigned	NO	The average wait time of the summarized timed events.
MAX_TIMER_WAIT	bigint(20) unsigned	NO	The maximum wait time of the summarized timed events.
COUNT_STATEMENTS	bigint(20) unsigned	NO	Total number of nested statements invoked during stored program execution.
SUM_STATEMENTS_WAIT	bigint(20) unsigned	NO	The total wait time of the summarized timed statements. This value is calculated only for timed statements because nontimed statements have a wait time of NULL. The same is true for the other xxx_STATEMENT_WAIT values.
MIN_STATEMENTS_WAIT	bigint(20) unsigned	NO	The minimum wait time of the summarized timed statements.
AVG_STATEMENTS_WAIT	bigint(20) unsigned	NO	The average wait time of the summarized timed statements.
MAX_STATEMENTS_WAIT	bigint(20) unsigned	NO	The maximum wait time of the summarized timed statements.
SUM_LOCK_TIME	bigint(20) unsigned	NO	The total time spent (in picoseconds) waiting for table locks for the summarized statements.
SUM_ERRORS	bigint(20) unsigned	NO	The total number of errors that occurend for the summarized statements.
SUM_WARNINGS	bigint(20) unsigned	NO	The total number of warnings that occurend for the summarized statements.
SUM_ROWS_AFFECTED	bigint(20) unsigned	NO	The total number of affected rows by the summarized statements.
SUM_ROWS_SENT	bigint(20) unsigned	NO	The total number of rows returned by the summarized statements.
SUM_ROWS_EXAMINED	bigint(20) unsigned	NO	The total number of rows examined by the summarized statements.The total number of affected rows by the summarized statements.
SUM_CREATED_TMP_DISK_TABLES	bigint(20) unsigned	NO	The total number of on-disk temporary tables created by the summarized statements.
SUM_CREATED_TMP_TABLES	bigint(20) unsigned	NO	The total number of in-memory temporary tables created by the summarized statements.

SUM_SELECT_FULL_JOIN	bigint(20) unsigned	NO	The total number of full joins executed by the summarized statements.
SUM_SELECT_FULL_RANGE_JOIN	bigint(20) unsigned	NO	The total number of range search joins executed by the summarized statements.
SUM_SELECT_RANGE	bigint(20) unsigned	NO	The total number of joins that used ranges on the first table executed by the summarized statements.
SUM_SELECT_RANGE_CHECK	bigint(20) unsigned	NO	The total number of joins that check for key usage after each row executed by the summarized statements.
SUM_SELECT_SCAN	bigint(20) unsigned	NO	The total number of joins that did a full scan of the first table executed by the summarized statements.
SUM_SORT_MERGE_PASSES	bigint(20) unsigned	NO	The total number of merge passes that the sort algorithm has had to do for the summarized statements.
SUM_SORT_RANGE	bigint(20) unsigned	NO	The total number of sorts that were done using ranges for the summarized statements.
SUM_SORT_ROWS	bigint(20) unsigned	NO	The total number of sorted rows that were sorted by the summarized statements.
SUM_SORT_SCAN	bigint(20) unsigned	NO	The total number of sorts that were done by scanning the table by the summarized statements.
SUM_NO_INDEX_USED	bigint(20) unsigned	NO	The total number of statements that performed a table scan without using an index.
SUM_NO_GOOD_INDEX_USED	bigint(20) unsigned	NO	The total number of statements where no good index was found.

1.1.1.2.9.2.1.19 Performance Schema events_statements_summary_by_thread_by_eve Table

The Performance Schema `events_statements_summary_by_thread_by_event_name` table contains statement events summarized by thread and event name. It contains the following columns:

Column	Description
`THREAD_ID`	Thread associated with the event. Together with `EVENT_NAME` uniquely identifies the row.
`EVENT_NAME`	Event name. Used together with `THREAD_ID` for grouping events.
`COUNT_STAR`	Number of summarized events
`SUM_TIMER_WAIT`	Total wait time of the summarized events that are timed.
`MIN_TIMER_WAIT`	Minimum wait time of the summarized events that are timed.
`AVG_TIMER_WAIT`	Average wait time of the summarized events that are timed.
`MAX_TIMER_WAIT`	Maximum wait time of the summarized events that are timed.
`SUM_LOCK_TIME`	Sum of the `LOCK_TIME` column in the `events_statements_current` table.
`SUM_ERRORS`	Sum of the `ERRORS` column in the `events_statements_current` table.
`SUM_WARNINGS`	Sum of the `WARNINGS` column in the `events_statements_current` table.
`SUM_ROWS_AFFECTED`	Sum of the `ROWS_AFFECTED` column in the `events_statements_current` table.
`SUM_ROWS_SENT`	Sum of the `ROWS_SENT` column in the `events_statements_current` table.
`SUM_ROWS_EXAMINED`	Sum of the `ROWS_EXAMINED` column in the `events_statements_current` table.
`SUM_CREATED_TMP_DISK_TABLES`	Sum of the `CREATED_TMP_DISK_TABLES` column in the `events_statements_current` table.
`SUM_CREATED_TMP_TABLES`	Sum of the `CREATED_TMP_TABLES` column in the `events_statements_current` table.

SUM_SELECT_FULL_JOIN	Sum of the SELECT_FULL_JOIN column in the events_statements_current table.
SUM_SELECT_FULL_RANGE_JOIN	Sum of the SELECT_FULL_RANGE_JOIN column in the events_statements_current table.
SUM_SELECT_RANGE	Sum of the SELECT_RANGE column in the events_statements_current table.
SUM_SELECT_RANGE_CHECK	Sum of the SELECT_RANGE_CHECK column in the events_statements_current table.
SUM_SELECT_SCAN	Sum of the SELECT_SCAN column in the events_statements_current table.
SUM_SORT_MERGE_PASSES	Sum of the SORT_MERGE_PASSES column in the events_statements_current table.
SUM_SORT_RANGE	Sum of the SORT_RANGE column in the events_statements_current table.
SUM_SORT_ROWS	Sum of the SORT_ROWS column in the events_statements_current table.
SUM_SORT_SCAN	Sum of the SORT_SCAN column in the events_statements_current table.
SUM_NO_INDEX_USED	Sum of the NO_INDEX_USED column in the events_statements_current table.
SUM_NO_GOOD_INDEX_USED	Sum of the NO_GOOD_INDEX_USED column in the events_statements_current table.

The *_TIMER_WAIT columns only calculate results for timed events, as non-timed events have a NULL wait time.

Example

```
SELECT * FROM events_statements_summary_by_thread_by_event_name\G
...
*************************** 3653. row ***************************
                  THREAD_ID: 64
                 EVENT_NAME: statement/com/Error
                 COUNT_STAR: 0
             SUM_TIMER_WAIT: 0
             MIN_TIMER_WAIT: 0
             AVG_TIMER_WAIT: 0
             MAX_TIMER_WAIT: 0
              SUM_LOCK_TIME: 0
                 SUM_ERRORS: 0
               SUM_WARNINGS: 0
          SUM_ROWS_AFFECTED: 0

1.1.1.2.9.2.1.20 Performance Schema events_statements_summary_by_user_by_event_ Table

The Performance Schema `events_statements_summary_by_user_by_event_name` table contains statement events summarized by user and event name. It contains the following columns:

Column	Description
`USER`	User. Used together with `EVENT_NAME` for grouping events.
`EVENT_NAME`	Event name. Used together with `USER` for grouping events.

COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
SUM_LOCK_TIME	Sum of the LOCK_TIME column in the events_statements_current table.
SUM_ERRORS	Sum of the ERRORS column in the events_statements_current table.
SUM_WARNINGS	Sum of the WARNINGS column in the events_statements_current table.
SUM_ROWS_AFFECTED	Sum of the ROWS_AFFECTED column in the events_statements_current table.
SUM_ROWS_SENT	Sum of the ROWS_SENT column in the events_statements_current table.
SUM_ROWS_EXAMINED	Sum of the ROWS_EXAMINED column in the events_statements_current table.
SUM_CREATED_TMP_DISK_TABLES	Sum of the CREATED_TMP_DISK_TABLES column in the events_statements_current table.
SUM_CREATED_TMP_TABLES	Sum of the CREATED_TMP_TABLES column in the events_statements_current table.
SUM_SELECT_FULL_JOIN	Sum of the SELECT_FULL_JOIN column in the events_statements_current table.
SUM_SELECT_FULL_RANGE_JOIN	Sum of the SELECT_FULL_RANGE_JOIN column in the events_statements_current table.
SUM_SELECT_RANGE	Sum of the SELECT_RANGE column in the events_statements_current table.
SUM_SELECT_RANGE_CHECK	Sum of the SELECT_RANGE_CHECK column in the events_statements_current table.
SUM_SELECT_SCAN	Sum of the SELECT_SCAN column in the events_statements_current table.
SUM_SORT_MERGE_PASSES	Sum of the SORT_MERGE_PASSES column in the events_statements_current table.
SUM_SORT_RANGE	Sum of the SORT_RANGE column in the events_statements_current table.
SUM_SORT_ROWS	Sum of the SORT_ROWS column in the events_statements_current table.
SUM_SORT_SCAN	Sum of the SORT_SCAN column in the events_statements_current table.
SUM_NO_INDEX_USED	Sum of the NO_INDEX_USED column in the events_statements_current table.
SUM_NO_GOOD_INDEX_USED	Sum of the NO_GOOD_INDEX_USED column in the events_statements_current table.

The *_TIMER_WAIT columns only calculate results for timed events, as non-timed events have a NULL wait time.

Example

```
SELECT * FROM events_statements_summary_by_user_by_event_name\G
...
*************************** 521. row ***************************
                    USER: NULL

              SUM_SORT_SCAN: 0
          SUM_NO_INDEX_USED: 0
     SUM_NO_GOOD_INDEX_USED: 0
```

1.1.1.2.9.2.1.21 Performance Schema events_statements_summary_global_by_event_n Table

The Performance Schema `events_statements_summary_global_by_event_name` table contains statement events summarized by event name. It contains the following columns:

Column	Description
`EVENT_NAME`	Event name.
`COUNT_STAR`	Number of summarized events

SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
SUM_LOCK_TIME	Sum of the LOCK_TIME column in the events_statements_current table.
SUM_ERRORS	Sum of the ERRORS column in the events_statements_current table.
SUM_WARNINGS	Sum of the WARNINGS column in the events_statements_current table.
SUM_ROWS_AFFECTED	Sum of the ROWS_AFFECTED column in the events_statements_current table.
SUM_ROWS_SENT	Sum of the ROWS_SENT column in the events_statements_current table.
SUM_ROWS_EXAMINED	Sum of the ROWS_EXAMINED column in the events_statements_current table.
SUM_CREATED_TMP_DISK_TABLES	Sum of the CREATED_TMP_DISK_TABLES column in the events_statements_current table.
SUM_CREATED_TMP_TABLES	Sum of the CREATED_TMP_TABLES column in the events_statements_current table.
SUM_SELECT_FULL_JOIN	Sum of the SELECT_FULL_JOIN column in the events_statements_current table.
SUM_SELECT_FULL_RANGE_JOIN	Sum of the SELECT_FULL_RANGE_JOIN column in the events_statements_current table.
SUM_SELECT_RANGE	Sum of the SELECT_RANGE column in the events_statements_current table.
SUM_SELECT_RANGE_CHECK	Sum of the SELECT_RANGE_CHECK column in the events_statements_current table.
SUM_SELECT_SCAN	Sum of the SELECT_SCAN column in the events_statements_current table.
SUM_SORT_MERGE_PASSES	Sum of the SORT_MERGE_PASSES column in the events_statements_current table.
SUM_SORT_RANGE	Sum of the SORT_RANGE column in the events_statements_current table.
SUM_SORT_ROWS	Sum of the SORT_ROWS column in the events_statements_current table.
SUM_SORT_SCAN	Sum of the SORT_SCAN column in the events_statements_current table.
SUM_NO_INDEX_USED	Sum of the NO_INDEX_USED column in the events_statements_current table.
SUM_NO_GOOD_INDEX_USED	Sum of the NO_GOOD_INDEX_USED column in the events_statements_current table.

The *_TIMER_WAIT columns only calculate results for timed events, as non-timed events have a NULL wait time.

Example

```
SELECT * FROM events_statements_summary_global_by_event_name\G
...
*************************** 173. row ***************************
                 EVENT_NAME: statement/com/Error

     SUM_NO_GOOD_INDEX_USED: 0
```

1.1.1.2.9.2.1.22 Performance Schema events_transactions_current Table

MariaDB starting with 10.5.2

The events_transactions_current table was introduced in MariaDB 10.5.2.

The `events_transactions_current` table contains current transaction events for each thread.

The table size cannot be figured, and always stores one row for each thread, showing the current status of the thread's most recent monitored transaction event.

The table contains the following columns:

Column	Type	Description

THREAD_ID	bigint(20) unsigned	The thread associated with the event.
EVENT_ID	bigint(20) unsigned	The event id associated with the event.
END_EVENT_ID	bigint(20) unsigned	This column is set to NULL when the event starts and updated to the thread current event number when the event ends.
EVENT_NAME	varchar(128)	The name of the instrument from which the event was collected. This is a NAME value from the setup_instruments table.
STATE	enum('ACTIVE', 'COMMITTED', 'ROLLED BACK')	The current transaction state. The value is ACTIVE (after START TRANSACTION or BEGIN), COMMITTED (after COMMIT), or ROLLED BACK (after ROLLBACK).
TRX_ID	bigint(20) unsigned	Unused.
GTID	varchar(64)	Transaction GTID, using the format DOMAIN-SERVER_ID-SEQUENCE_NO.
XID_FORMAT_ID	int(11)	XA transaction format ID for GTRID and BQUAL values.
XID_GTRID	varchar(130)	XA global transaction ID.
XID_BQUAL	varchar(130)	XA transaction branch qualifier.
XA_STATE	varchar(64)	The state of the XA transaction. The value is ACTIVE (after XA START), IDLE (after XA END), PREPARED (after XA PREPARE), ROLLED BACK (after XA ROLLBACK), or COMMITTED (after XA COMMIT).
SOURCE	varchar(64)	The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs.
TIMER_START	bigint(20) unsigned	The unit is picoseconds. When event timing started. NULL if event has no timing information.
TIMER_END	bigint(20) unsigned	The unit is picoseconds. When event timing ended. NULL if event has no timing information.
TIMER_WAIT	bigint(20) unsigned	The unit is picoseconds. Event duration. NULL if event has not timing information.
ACCESS_MODE	enum('READ ONLY', 'READ WRITE')	Transaction access mode.
ISOLATION_LEVEL	varchar(64)	Transaction isolation level. One of: REPEATABLE READ, READ COMMITTED, READ UNCOMMITTED, or SERIALIZABLE.
AUTOCOMMIT	enum('YES','NO')	Whether autcommit mode was enabled when the transaction started.
NUMBER_OF_SAVEPOINTS	bigint(20) unsigned	The number of SAVEPOINT statements issued during the transaction.
NUMBER_OF_ROLLBACK_TO_SAVEPOINT	bigint(20) unsigned	The number of ROLLBACK_TO_SAVEPOINT statements issued during the transaction.
NUMBER_OF_RELEASE_SAVEPOINT	bigint(20) unsigned	The number of RELEASE_SAVEPOINT statements issued during the transaction.
OBJECT_INSTANCE_BEGIN	bigint(20) unsigned	Unused.
NESTING_EVENT_ID	bigint(20) unsigned	The EVENT_ID value of the event within which this event is nested.
NESTING_EVENT_TYPE	enum('TRANSACTION', 'STATEMENT', 'STAGE', 'WAIT')	The nesting event type.

1.1.1.2.9.2.1.23 Performance Schema events_transactions_history Table

MariaDB starting with 10.5.2

The events_transactions_history table was introduced in MariaDB 10.5.2.

The `events_transactions_history` table contains the most recent completed transaction events for each thread.

The number of records stored per thread in the table is determined by the performance_schema_events_transactions_history_size system variable, which is autosized on startup.

If adding a completed transaction event would cause the table to exceed this limit, the oldest thread row is discarded.

All of a thread's rows are discarded when the thread ends.

The table contains the following columns:

Column	Type	Description
THREAD_ID	bigint(20) unsigned	The thread associated with the event.
EVENT_ID	bigint(20) unsigned	The event id associated with the event.
END_EVENT_ID	bigint(20) unsigned	This column is set to NULL when the event starts and updated to the thread current event number when the event ends.
EVENT_NAME	varchar(128)	The name of the instrument from which the event was collected. This is a NAME value from the setup_instruments table.
STATE	enum('ACTIVE', 'COMMITTED',' ROLLED BACK')	The current transaction state. The value is ACTIVE (after START TRANSACTION or BEGIN), COMMITTED (after COMMIT), or ROLLED BACK (after ROLLBACK).
TRX_ID	bigint(20) unsigned	Unused.
GTID	varchar(64)	Transaction GTID, using the format DOMAIN-SERVER_ID-SEQUENCE_NO.
XID_FORMAT_ID	int(11)	XA transaction format ID for GTRID and BQUAL values.
XID_GTRID	varchar(130)	XA global transaction ID.
XID_BQUAL	varchar(130)	XA transaction branch qualifier.
XA_STATE	varchar(64)	The state of the XA transaction. The value is ACTIVE (after XA START), IDLE (after XA END), PREPARED (after XA PREPARE), ROLLED BACK (after XA ROLLBACK), or COMMITTED (after XA COMMIT).
SOURCE	varchar(64)	The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs.
TIMER_START	bigint(20) unsigned	The unit is picoseconds. When event timing started. NULL if event has no timing information.
TIMER_END	bigint(20) unsigned	The unit is picoseconds. When event timing ended. NULL if event has no timing information.
TIMER_WAIT	bigint(20) unsigned	The unit is picoseconds. Event duration. NULL if event has not timing information.
ACCESS_MODE	enum('READ ONLY', 'READ WRITE')	Transaction access mode.

ISOLATION_LEVEL	varchar(64)	Transaction isolation level. One of: REPEATABLE READ, READ COMMITTED, READ UNCOMMITTED, or SERIALIZABLE.
AUTOCOMMIT	enum('YES', 'NO')	NO
NUMBER_OF_SAVEPOINTS	bigint(20) unsigned	The number of SAVEPOINT statements issued during the transaction.
NUMBER_OF_ROLLBACK_TO_SAVEPOINT	bigint(20) unsigned	The number of ROLLBACK_TO_SAVEPOINT statements issued during the transaction.
NUMBER_OF_RELEASE_SAVEPOINT	bigint(20) unsigned	The number of RELEASE_SAVEPOINT statements issued during the transaction.
OBJECT_INSTANCE_BEGIN	bigint(20) unsigned	Unused.
NESTING_EVENT_ID	bigint(20) unsigned	The EVENT_ID value of the event within which this event is nested.
NESTING_EVENT_TYPE	enum('TRANSACTION','STATEMENT', 'STAGE', 'WAIT')	The nesting event type.

1.1.1.2.9.2.1.24 Performance Schema events_transactions_history_long Table

MariaDB starting with 10.5.2

The events_transactions_history_long table was introduced in MariaDB 10.5.2.

The `events_transactions_history_long` table contains the most recent completed transaction events that have ended globally, across all threads.

The number of records stored in the table is determined by the performance_schema_events_transactions_history_long_size system variable, which is autosized on startup.

If adding a completed transaction would cause the table to exceed this limit, the oldest row, regardless of thread, is discarded.

The table contains the following columns:

Column	Type	Description
THREAD_ID	bigint(20) unsigned	The thread associated with the event.
EVENT_ID	bigint(20) unsigned	The event id associated with the event.
END_EVENT_ID	bigint(20) unsigned	This column is set to NULL when the event starts and updated to the thread current event number when the event ends.
EVENT_NAME	varchar(128)	The name of the instrument from which the event was collected. This is a NAME value from the setup_instruments table.
STATE	enum('ACTIVE', 'COMMITTED','ROLLED BACK')	The current transaction state. The value is ACTIVE (after START TRANSACTION or BEGIN), COMMITTED (after COMMIT), or ROLLED BACK (after ROLLBACK).
TRX_ID	bigint(20) unsigned	Unused.
GTID	varchar(64)	Transaction GTID, using the format DOMAIN-SERVER_ID-SEQUENCE_NO.
XID_FORMAT_ID	int(11)	XA transaction format ID for GTRID and BQUAL values.
XID_GTRID	varchar(130)	XA global transaction ID.
XID_BQUAL	varchar(130)	XA transaction branch qualifier.

XA_STATE	varchar(64)	The state of the XA transaction. The value is ACTIVE (after XA START), IDLE (after XA END), PREPARED (after XA PREPARE), ROLLED BACK (after XA ROLLBACK), or COMMITTED (after XA COMMIT).
SOURCE	varchar(64)	The name of the source file containing the instrumented code that produced the event and the line number in the file at which the instrumentation occurs.
TIMER_START	bigint(20) unsigned	The unit is picoseconds. When event timing started. NULL if event has no timing information.
TIMER_END	bigint(20) unsigned	The unit is picoseconds. When event timing ended. NULL if event has no timing information.
TIMER_WAIT	bigint(20) unsigned	The unit is picoseconds. Event duration. NULL if event has not timing information.
ACCESS_MODE	enum('READ ONLY', 'READ WRITE')	Transaction access mode.
ISOLATION_LEVEL	varchar(64)	Transaction isolation level. One of: REPEATABLE READ, READ COMMITTED, READ UNCOMMITTED, or SERIALIZABLE.
AUTOCOMMIT	enum('YES', 'NO')	NO
NUMBER_OF_SAVEPOINTS	bigint(20) unsigned	The number of SAVEPOINT statements issued during the transaction.
NUMBER_OF_ROLLBACK_TO_SAVEPOINT	bigint(20) unsigned	The number of ROLLBACK_TO_SAVEPOINT statements issued during the transaction.
NUMBER_OF_RELEASE_SAVEPOINT	bigint(20) unsigned	The number of RELEASE_SAVEPOINT statements issued during the transaction.
OBJECT_INSTANCE_BEGIN	bigint(20) unsigned	Unused.
NESTING_EVENT_ID	bigint(20) unsigned	The EVENT_ID value of the event within which this event is nested.
NESTING_EVENT_TYPE	enum('TRANSACTION','STATEMENT', 'STAGE', 'WAIT')	The nesting event type.

1.1.1.2.9.2.1.25 Performance Schema events_transactions_summary_by_account_by_e Table

MariaDB starting with 10.5.2

The events_transactions_summary_by_account_by_event_name table was introduced in MariaDB 10.5.2.

The `events_transactions_summary_by_account_by_event_name` table contains information on transaction events aggregated by account and event name.

The table contains the following columns:

Column	Type	Description
USER	char(32)	User for which summary is generated.
HOST	char(60)	Host for which summary is generated.
EVENT_NAME	varchar(128)	Event name for which summary is generated.
COUNT_STAR	bigint(20) unsigned	The number of summarized events. This value includes all events, whether timed or nontimed.

SUM_TIMER_WAIT	bigint(20) unsigned	The total wait time of the summarized timed events. This value is calculated only for timed events because nontimed events have a wait time of NULL. The same is true for the other xxx_TIMER_WAIT values.
MIN_TIMER_WAIT	bigint(20) unsigned	The minimum wait time of the summarized timed events.
AVG_TIMER_WAIT	bigint(20) unsigned	The average wait time of the summarized timed events.
MAX_TIMER_WAIT	bigint(20) unsigned	The maximum wait time of the summarized timed events.
COUNT_READ_WRITE	bigint(20) unsigned	The total number of only READ/WRITE transaction events.
SUM_TIMER_READ_WRITE	bigint(20) unsigned	The total wait time of only READ/WRITE transaction events.
MIN_TIMER_READ_WRITE	bigint(20) unsigned	The minimum wait time of only READ/WRITE transaction events.
AVG_TIMER_READ_WRITE	bigint(20) unsigned	The average wait time of only READ/WRITE transaction events.
MAX_TIMER_READ_WRITE	bigint(20) unsigned	The maximum wait time of only READ/WRITE transaction events.
COUNT_READ_ONLY	bigint(20) unsigned	The total number of only READ ONLY transaction events.
SUM_TIMER_READ_ONLY	bigint(20) unsigned	The total wait time of only READ ONLY transaction events.
MIN_TIMER_READ_ONLY	bigint(20) unsigned	The minimum wait time of only READ ONLY transaction events.
AVG_TIMER_READ_ONLY	bigint(20) unsigned	The average wait time of only READ ONLY transaction events.
MAX_TIMER_READ_ONLY	bigint(20) unsigned	The maximum wait time of only READ ONLY transaction events.

1.1.1.2.9.2.1.26 Performance Schema events_transactions_summary_by_host_by_even Table

MariaDB starting with 10.5.2

The events_transactions_summary_by_host_by_event_name table was introduced in MariaDB 10.5.2.

The `events_transactions_summary_by_host_by_event_name` table contains information on transaction events aggregated by host and event name.

The table contains the following columns:

Column	Type	Description
HOST	char(60)	Host for which summary is generated.
EVENT_NAME	varchar(128)	Event name for which summary is generated.
COUNT_STAR	bigint(20) unsigned	The number of summarized events. This value includes all events, whether timed or nontimed.
SUM_TIMER_WAIT	bigint(20) unsigned	The total wait time of the summarized timed events. This value is calculated only for timed events because nontimed events have a wait time of NULL. The same is true for the other xxx_TIMER_WAIT values.
MIN_TIMER_WAIT	bigint(20) unsigned	The minimum wait time of the summarized timed events.

AVG_TIMER_WAIT	bigint(20) unsigned	The average wait time of the summarized timed events.
MAX_TIMER_WAIT	bigint(20) unsigned	The maximum wait time of the summarized timed events.
COUNT_READ_WRITE	bigint(20) unsigned	The total number of only READ/WRITE transaction events.
SUM_TIMER_READ_WRITE	bigint(20) unsigned	The total wait time of only READ/WRITE transaction events.
MIN_TIMER_READ_WRITE	bigint(20) unsigned	The minimum wait time of only READ/WRITE transaction events.
AVG_TIMER_READ_WRITE	bigint(20) unsigned	The average wait time of only READ/WRITE transaction events.
MAX_TIMER_READ_WRITE	bigint(20) unsigned	The maximum wait time of only READ/WRITE transaction events.
COUNT_READ_ONLY	bigint(20) unsigned	The total number of only READ ONLY transaction events.
SUM_TIMER_READ_ONLY	bigint(20) unsigned	The total wait time of only READ ONLY transaction events.
MIN_TIMER_READ_ONLY	bigint(20) unsigned	The minimum wait time of only READ ONLY transaction events.
AVG_TIMER_READ_ONLY	bigint(20) unsigned	The average wait time of only READ ONLY transaction events.
MAX_TIMER_READ_ONLY	bigint(20) unsigned	The maximum wait time of only READ ONLY transaction events.

1.1.1.2.9.2.1.27 Performance Schema events_transactions_summary_by_thread_by_ev Table

MariaDB starting with 10.5.2

The events_transactions_summary_by_thread_by_event_name table was introduced in MariaDB 10.5.2.

The `events_transactions_summary_by_thread_by_event_name` table contains information on transaction events aggregated by thread and event name.

The table contains the following columns:

```
+----------------------+---------------------+------+-----+---------+-------+
| Field                | Type                | Null | Key | Default | Extra |
+----------------------+---------------------+------+-----+---------+-------+
| THREAD_ID            | bigint(20) unsigned | NO   |     | NULL    |       |
| EVENT_NAME           | varchar(128)        | NO   |     | NULL    |       |
| COUNT_STAR           | bigint(20) unsigned | NO   |     | NULL    |       |
| SUM_TIMER_WAIT       | bigint(20) unsigned | NO   |     | NULL    |       |
| MIN_TIMER_WAIT       | bigint(20) unsigned | NO   |     | NULL    |       |
| AVG_TIMER_WAIT       | bigint(20) unsigned | NO   |     | NULL    |       |
| MAX_TIMER_WAIT       | bigint(20) unsigned | NO   |     | NULL    |       |
| COUNT_READ_WRITE     | bigint(20) unsigned | NO   |     | NULL    |       |
| SUM_TIMER_READ_WRITE | bigint(20) unsigned | NO   |     | NULL    |       |
| MIN_TIMER_READ_WRITE | bigint(20) unsigned | NO   |     | NULL    |       |
| AVG_TIMER_READ_WRITE | bigint(20) unsigned | NO   |     | NULL    |       |
| MAX_TIMER_READ_WRITE | bigint(20) unsigned | NO   |     | NULL    |       |
| COUNT_READ_ONLY      | bigint(20) unsigned | NO   |     | NULL    |       |
| SUM_TIMER_READ_ONLY  | bigint(20) unsigned | NO   |     | NULL    |       |
| MIN_TIMER_READ_ONLY  | bigint(20) unsigned | NO   |     | NULL    |       |
| AVG_TIMER_READ_ONLY  | bigint(20) unsigned | NO   |     | NULL    |       |
| MAX_TIMER_READ_ONLY  | bigint(20) unsigned | NO   |     | NULL    |       |
+----------------------+---------------------+------+-----+---------+-------+
```

1.1.1.2.9.2.1.28 Performance Schema events_transactions_summary_by_user_by_even Table

MariaDB starting with 10.5.2

The events_transactions_summary_by_user_by_event_name table was introduced in MariaDB 10.5.2.

The `events_transactions_summary_by_user_by_event_name` table contains information on transaction events aggregated by user and event name.

The table contains the following columns:

```
+----------------------+---------------------+------+-----+---------+-------+
| Field                | Type                | Null | Key | Default | Extra |
+----------------------+---------------------+------+-----+---------+-------+
| USER                 | char(32)            | YES  |     | NULL    |       |
| EVENT_NAME           | varchar(128)        | NO   |     | NULL    |       |
| COUNT_STAR           | bigint(20) unsigned | NO   |     | NULL    |       |
| SUM_TIMER_WAIT       | bigint(20) unsigned | NO   |     | NULL    |       |
| MIN_TIMER_WAIT       | bigint(20) unsigned | NO   |     | NULL    |       |
| AVG_TIMER_WAIT       | bigint(20) unsigned | NO   |     | NULL    |       |
| MAX_TIMER_WAIT       | bigint(20) unsigned | NO   |     | NULL    |       |
| COUNT_READ_WRITE     | bigint(20) unsigned | NO   |     | NULL    |       |
| SUM_TIMER_READ_WRITE | bigint(20) unsigned | NO   |     | NULL    |       |
| MIN_TIMER_READ_WRITE | bigint(20) unsigned | NO   |     | NULL    |       |
| AVG_TIMER_READ_WRITE | bigint(20) unsigned | NO   |     | NULL    |       |
| MAX_TIMER_READ_WRITE | bigint(20) unsigned | NO   |     | NULL    |       |
| COUNT_READ_ONLY      | bigint(20) unsigned | NO   |     | NULL    |       |
| SUM_TIMER_READ_ONLY  | bigint(20) unsigned | NO   |     | NULL    |       |
| MIN_TIMER_READ_ONLY  | bigint(20) unsigned | NO   |     | NULL    |       |
| AVG_TIMER_READ_ONLY  | bigint(20) unsigned | NO   |     | NULL    |       |
| MAX_TIMER_READ_ONLY  | bigint(20) unsigned | NO   |     | NULL    |       |
+----------------------+---------------------+------+-----+---------+-------+
```

1.1.1.2.9.2.1.29 Performance Schema events_transactions_summary_global_by_event_ Table

MariaDB starting with 10.5.2

The events_transactions_summary_global_by_event_name table was introduced in MariaDB 10.5.2.

The `events_transactions_summary_global_by_event_name` table contains information on transaction events aggregated by event name.

The table contains the following columns:

```
+----------------------+---------------------+------+-----+---------+-------+
| Field                | Type                | Null | Key | Default | Extra |
+----------------------+---------------------+------+-----+---------+-------+
| EVENT_NAME           | varchar(128)        | NO   |     | NULL    |       |
| COUNT_STAR           | bigint(20) unsigned | NO   |     | NULL    |       |
| SUM_TIMER_WAIT       | bigint(20) unsigned | NO   |     | NULL    |       |
| MIN_TIMER_WAIT       | bigint(20) unsigned | NO   |     | NULL    |       |
| AVG_TIMER_WAIT       | bigint(20) unsigned | NO   |     | NULL    |       |
| MAX_TIMER_WAIT       | bigint(20) unsigned | NO   |     | NULL    |       |
| COUNT_READ_WRITE     | bigint(20) unsigned | NO   |     | NULL    |       |
| SUM_TIMER_READ_WRITE | bigint(20) unsigned | NO   |     | NULL    |       |
| MIN_TIMER_READ_WRITE | bigint(20) unsigned | NO   |     | NULL    |       |
| AVG_TIMER_READ_WRITE | bigint(20) unsigned | NO   |     | NULL    |       |
| MAX_TIMER_READ_WRITE | bigint(20) unsigned | NO   |     | NULL    |       |
| COUNT_READ_ONLY      | bigint(20) unsigned | NO   |     | NULL    |       |
| SUM_TIMER_READ_ONLY  | bigint(20) unsigned | NO   |     | NULL    |       |
| MIN_TIMER_READ_ONLY  | bigint(20) unsigned | NO   |     | NULL    |       |
| AVG_TIMER_READ_ONLY  | bigint(20) unsigned | NO   |     | NULL    |       |
| MAX_TIMER_READ_ONLY  | bigint(20) unsigned | NO   |     | NULL    |       |
+----------------------+---------------------+------+-----+---------+-------+
```

1.1.1.2.9.2.1.30 Performance Schema events_waits_current Table

The `events_waits_current` table contains the status of a thread's most recently monitored wait event, listing one event per thread.

The table contains the following columns:

Column	Description
`THREAD_ID`	Thread associated with the event. Together with `EVENT_ID` uniquely identifies the row.
`EVENT_ID`	Thread's current event number at the start of the event. Together with `THREAD_ID` uniquely identifies the row.
`END_EVENT_ID`	`NULL` when the event starts, set to the thread's current event number at the end of the event.
`EVENT_NAME`	Event instrument name and a `NAME` from the `setup_instruments` table
`SOURCE`	Name and line number of the source file containing the instrumented code that produced the event.
`TIMER_START`	Value in picoseconds when the event timing started or `NULL` if timing is not collected.
`TIMER_END`	Value in picoseconds when the event timing ended, or `NULL` if the event has not ended or timing is not collected.
`TIMER_WAIT`	Value in picoseconds of the event's duration or `NULL` if the event has not ended or timing is not collected.
`SPINS`	Number of spin rounds for a mutex, or `NULL` if spin rounds are not used, or spinning is not instrumented.
`OBJECT_SCHEMA`	Name of the schema that contains the table for table I/O objects, otherwise `NULL` for file I/O and synchronization objects.
`OBJECT_NAME`	File name for file I/O objects, table name for table I/O objects, the socket's `IP:PORT` value for a socket object or `NULL` for a synchronization object.
`INDEX NAME`	Name of the index, `PRIMARY` for the primary key, or `NULL` for no index used.
`OBJECT_TYPE`	FILE for a file object, `TABLE` or `TEMPORARY TABLE` for a table object, or `NULL` for a synchronization object.
`OBJECT_INSTANCE_BEGIN`	Address in memory of the object.
`NESTING_EVENT_ID`	`EVENT_ID` of event within which this event nests.
`NESTING_EVENT_TYPE`	Nesting event type. Either `statement`, `stage` or `wait`.

OPERATION	Operation type, for example read, write or lock
NUMBER_OF_BYTES	Number of bytes that the operation read or wrote, or NULL for table I/O waits.
FLAGS	Reserved for use in the future.

It is possible to empty this table with a TRUNCATE TABLE statement.

The related tables, events_waits_history and events_waits_history_long derive their values from the current events.

1.1.1.2.9.2.1.31 Performance Schema events_waits_history Table

The events_waits_history table by default contains the ten most recent completed wait events per thread. This number can be adjusted by setting the performance_schema_events_waits_history_size system variable when the server starts up.

The table structure is identical to the events_waits_current table structure, and contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with EVENT_ID uniquely identifies the row.
EVENT_ID	Thread's current event number at the start of the event. Together with THREAD_ID uniquely identifies the row.
END_EVENT_ID	NULL when the event starts, set to the thread's current event number at the end of the event.
EVENT_NAME	Event instrument name and a NAME from the setup_instruments table
SOURCE	Name and line number of the source file containing the instrumented code that produced the event.
TIMER_START	Value in picoseconds when the event timing started or NULL if timing is not collected.
TIMER_END	Value in picoseconds when the event timing ended, or NULL if timing is not collected.
TIMER_WAIT	Value in picoseconds of the event's duration or NULL if timing is not collected.
SPINS	Number of spin rounds for a mutex, or NULL if spin rounds are not used, or spinning is not instrumented.
OBJECT_SCHEMA	Name of the schema that contains the table for table I/O objects, otherwise NULL for file I/O and synchronization objects.
OBJECT_NAME	File name for file I/O objects, table name for table I/O objects, the socket's IP:PORT value for a socket object or NULL for a synchronization object.
INDEX NAME	Name of the index, PRIMARY for the primary key, or NULL for no index used.
OBJECT_TYPE	FILE for a file object, TABLE or TEMPORARY TABLE for a table object, or NULL for a synchronization object.
OBJECT_INSTANCE_BEGIN	Address in memory of the object.
NESTING_EVENT_ID	EVENT_ID of event within which this event nests.
NESTING_EVENT_TYPE	Nesting event type. Either statement, stage or wait.
OPERATION	Operation type, for example read, write or lock
NUMBER_OF_BYTES	Number of bytes that the operation read or wrote, or NULL for table I/O waits.
FLAGS	Reserved for use in the future.

It is possible to empty this table with a TRUNCATE TABLE statement.

events_waits_current and events_waits_history_long are related tables.

1.1.1.2.9.2.1.32 Performance Schema events_waits_history_long Table

The events_waits_history_long table by default contains the ten thousand most recent completed wait events. This

number can be adjusted by setting the performance_schema_events_waits_history_long_size system variable when the server starts up.

The table structure is identical to the events_waits_current table structure, and contains the following columns:

Column	Description
THREAD_ID	Thread associated with the event. Together with EVENT_ID uniquely identifies the row.
EVENT_ID	Thread's current event number at the start of the event. Together with THREAD_ID uniquely identifies the row.
END_EVENT_ID	NULL when the event starts, set to the thread's current event number at the end of the event.
EVENT_NAME	Event instrument name and a NAME from the setup_instruments table
SOURCE	Name and line number of the source file containing the instrumented code that produced the event.
TIMER_START	Value in picoseconds when the event timing started or NULL if timing is not collected.
TIMER_END	Value in picoseconds when the event timing ended, or NULL if timing is not collected.
TIMER_WAIT	Value in picoseconds of the event's duration or NULL if timing is not collected.
SPINS	Number of spin rounds for a mutex, or NULL if spin rounds are not used, or spinning is not instrumented.
OBJECT_SCHEMA	Name of the schema that contains the table for table I/O objects, otherwise NULL for file I/O and synchronization objects.
OBJECT_NAME	File name for file I/O objects, table name for table I/O objects, the socket's IP:PORT value for a socket object or NULL for a synchronization object.
INDEX_NAME	Name of the index, PRIMARY for the primary key, or NULL for no index used.
OBJECT_TYPE	FILE for a file object, TABLE or TEMPORARY TABLE for a table object, or NULL for a synchronization object.
OBJECT_INSTANCE_BEGIN	Address in memory of the object.
NESTING_EVENT_ID	EVENT_ID of event within which this event nests.
NESTING_EVENT_TYPE	Nesting event type. Either statement, stage or wait.
OPERATION	Operation type, for example read, write or lock
NUMBER_OF_BYTES	Number of bytes that the operation read or wrote, or NULL for table I/O waits.
FLAGS	Reserved for use in the future.

It is possible to empty this table with a TRUNCATE TABLE statement.

events_waits_current and events_waits_history are related tables.

1.1.1.2.9.2.1.33 Performance Schema events_waits_summary_by_account_by_event_n Table

The Performance Schema events_waits_summary_by_account_by_event_name table contains wait events summarized by account and event name. It contains the following columns:

Column	Description
USER	User. Used together with HOST and EVENT_NAME for grouping events.
HOST	Host. Used together with USER and EVENT_NAME for grouping events.
EVENT_NAME	Event name. Used together with USER and HOST for grouping events.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.

MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.

The *_TIMER_WAIT columns only calculate results for timed events, as non-timed events have a NULL wait time.

Example

```
SELECT * FROM events_waits_summary_by_account_by_event_name\G
...
*************************** 915. row ***************************
          USER: NULL
          HOST: NULL
    EVENT_NAME: wait/io/socket/sql/server_tcpip_socket
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 916. row ***************************
          USER: NULL
          HOST: NULL
    EVENT_NAME: wait/io/socket/sql/server_unix_socket
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 917. row ***************************
          USER: NULL
          HOST: NULL
    EVENT_NAME: wait/io/socket/sql/client_connection
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 918. row ***************************
          USER: NULL
          HOST: NULL
    EVENT_NAME: idle
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
```

1.1.1.2.9.2.1.34 Performance Schema events_waits_summary_by_host_by_event_name Table

The Performance Schema events_waits_summary_by_host_by_event_name table contains wait events summarized by host and event name. It contains the following columns:

Column	Description
HOST	Host. Used together with EVENT_NAME for grouping events.
EVENT_NAME	Event name. Used together with USER and HOST for grouping events.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.

AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.

The *_TIMER_WAIT columns only calculate results for timed events, as non-timed events have a NULL wait time.

Example

```
SELECT * FROM events_waits_summary_by_host_by_event_name\G
...
*************************** 610. row ***************************
          HOST: NULL
    EVENT_NAME: wait/io/socket/sql/server_unix_socket
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 611. row ***************************
          HOST: NULL
    EVENT_NAME: wait/io/socket/sql/client_connection
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 612. row ***************************
          HOST: NULL
    EVENT_NAME: idle
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
```

1.1.1.2.9.2.1.35 Performance Schema events_waits_summary_by_instance Table

The Performance Schema events_waits_summary_by_instance table contains wait events summarized by instance. It contains the following columns:

Column	Description
EVENT_NAME	Event name. Used together with OBJECT_INSTANCE_BEGIN for grouping events.
OBJECT_INSTANCE_BEGIN	If an instrument creates multiple instances, each instance has a unique OBJECT_INSTANCE_BEGIN value to allow for grouping by instance.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.

The *_TIMER_WAIT columns only calculate results for timed events, as non-timed events have a NULL wait time.

Example

```
SELECT * FROM events_waits_summary_by_instance\G
...
*************************** 202. row ***************************
           EVENT_NAME: wait/io/file/sql/binlog
OBJECT_INSTANCE_BEGIN: 140578961969856
           COUNT_STAR: 6
       SUM_TIMER_WAIT: 90478331960
       MIN_TIMER_WAIT: 263344
       AVG_TIMER_WAIT: 15079721848
       MAX_TIMER_WAIT: 67760576376
*************************** 203. row ***************************
           EVENT_NAME: wait/io/file/sql/dbopt
OBJECT_INSTANCE_BEGIN: 140578961970560
           COUNT_STAR: 6
       SUM_TIMER_WAIT: 39891428472
       MIN_TIMER_WAIT: 387168
       AVG_TIMER_WAIT: 6648571412
       MAX_TIMER_WAIT: 24503293304
*************************** 204. row ***************************
           EVENT_NAME: wait/io/file/sql/dbopt
OBJECT_INSTANCE_BEGIN: 140578961971264
           COUNT_STAR: 6
       SUM_TIMER_WAIT: 39902495024
       MIN_TIMER_WAIT: 177888
       AVG_TIMER_WAIT: 6650415692
       MAX_TIMER_WAIT: 21026400404
```

1.1.1.2.9.2.1.36 Performance Schema events_waits_summary_by_thread_by_event_nar Table

The Performance Schema `events_waits_summary_by_thread_by_event_name` table contains wait events summarized by thread and event name. It contains the following columns:

Column	Description
`THREAD_ID`	Thread associated with the event. Together with `EVENT_NAME` uniquely identifies the row.
`EVENT_NAME`	Event name. Used together with `THREAD_ID` for grouping events.
`COUNT_STAR`	Number of summarized events
`SUM_TIMER_WAIT`	Total wait time of the summarized events that are timed.
`MIN_TIMER_WAIT`	Minimum wait time of the summarized events that are timed.
`AVG_TIMER_WAIT`	Average wait time of the summarized events that are timed.
`MAX_TIMER_WAIT`	Maximum wait time of the summarized events that are timed.

The `*_TIMER_WAIT` columns only calculate results for timed events, as non-timed events have a `NULL` wait time.

Example

```
SELECT * FROM events_waits_summary_by_thread_by_event_name\G
...
*************************** 6424. row ***************************
     THREAD_ID: 64
    EVENT_NAME: wait/io/socket/sql/server_unix_socket
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 6425. row ***************************
     THREAD_ID: 64
    EVENT_NAME: wait/io/socket/sql/client_connection
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 6426. row ***************************
     THREAD_ID: 64
    EVENT_NAME: idle
    COUNT_STAR: 73
SUM_TIMER_WAIT: 22005252162000000
MIN_TIMER_WAIT: 3000000
AVG_TIMER_WAIT: 301441810000000
MAX_TIMER_WAIT: 4912417573000000
```

1.1.1.2.9.2.1.37 Performance Schema events_waits_summary_by_user_by_event_name Table

The Performance Schema `events_waits_summary_by_user_by_event_name` table contains wait events summarized by user and event name. It contains the following columns:

Column	Description
`USER`	User. Used together with `EVENT_NAME` for grouping events.
`EVENT_NAME`	Event name. Used together with `USER` for grouping events.
`COUNT_STAR`	Number of summarized events
`SUM_TIMER_WAIT`	Total wait time of the summarized events that are timed.
`MIN_TIMER_WAIT`	Minimum wait time of the summarized events that are timed.
`AVG_TIMER_WAIT`	Average wait time of the summarized events that are timed.
`MAX_TIMER_WAIT`	Maximum wait time of the summarized events that are timed.

The `*_TIMER_WAIT` columns only calculate results for timed events, as non-timed events have a `NULL` wait time.

Example

```
SELECT * FROM events_waits_summary_by_user_by_event_name\G
...
*************************** 916. row ***************************
          USER: NULL
    EVENT_NAME: wait/io/socket/sql/server_unix_socket
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 917. row ***************************
          USER: NULL
    EVENT_NAME: wait/io/socket/sql/client_connection
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 918. row ***************************
          USER: NULL
    EVENT_NAME: idle
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
```

1.1.1.2.9.2.1.38 Performance Schema events_waits_summary_global_by_event_name Table

The Performance Schema `events_waits_summary_global_by_event_name` table contains wait events summarized by event name. It contains the following columns:

Column	Description
`EVENT_NAME`	Event name.
`COUNT_STAR`	Number of summarized events
`SUM_TIMER_WAIT`	Total wait time of the summarized events that are timed.
`MIN_TIMER_WAIT`	Minimum wait time of the summarized events that are timed.
`AVG_TIMER_WAIT`	Average wait time of the summarized events that are timed.
`MAX_TIMER_WAIT`	Maximum wait time of the summarized events that are timed.

The `*_TIMER_WAIT` columns only calculate results for timed events, as non-timed events have a `NULL` wait time.

Example

```
SELECT * FROM events_waits_summary_global_by_event_name\G
...
*************************** 303. row ***************************
    EVENT_NAME: wait/io/socket/sql/server_tcpip_socket
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 304. row ***************************
    EVENT_NAME: wait/io/socket/sql/server_unix_socket
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 305. row ***************************
    EVENT_NAME: wait/io/socket/sql/client_connection
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 306. row ***************************
    EVENT_NAME: idle
    COUNT_STAR: 265
SUM_TIMER_WAIT: 46861125181000000
MIN_TIMER_WAIT: 1000000
AVG_TIMER_WAIT: 176834434000000
MAX_TIMER_WAIT: 4912417573000000
```

1.1.1.2.9.2.1.39 Performance Schema file_instances Table

Description

The `file_instances` table lists instances of instruments seen by the Performance Schema when executing file I/O instrumentation, and the associated files. Only files that have been opened, and that have not been deleted, will be listed in the table.

The performance_schema_max_file_instances system variable specifies the maximum number of instrumented file objects.

Column	Description
`FILE_NAME`	File name.
`EVENT_NAME`	Instrument name associated with the file.
`OPEN_COUNT`	Open handles on the file. A value of greater than zero means that the file is currently open.

Example

```
SELECT * FROM performance_schema.file_instances WHERE OPEN_COUNT>0;
+----------------------------------------------------+-------------------------------------
+------------+
| FILE_NAME                                          | EVENT_NAME                          |
OPEN_COUNT |
+----------------------------------------------------+-------------------------------------
+------------+
| /var/log/mysql/mariadb-bin.index                   | wait/io/file/sql/binlog_index       |
1 |
| /var/lib/mysql/ibdata1                             | wait/io/file/innodb/innodb_data_file |
2 |
| /var/lib/mysql/ib_logfile0                         | wait/io/file/innodb/innodb_log_file  |
2 |
| /var/lib/mysql/ib_logfile1                         | wait/io/file/innodb/innodb_log_file  |
2 |
| /var/lib/mysql/mysql/gtid_slave_pos.ibd            | wait/io/file/innodb/innodb_data_file |
3 |
| /var/lib/mysql/mysql/innodb_index_stats.ibd        | wait/io/file/innodb/innodb_data_file |
3 |
| /var/lib/mysql/mysql/innodb_table_stats.ibd        | wait/io/file/innodb/innodb_data_file |
3 |
...
```

1.1.1.2.9.2.1.40 Performance Schema file_summary_by_event_name Table

The Performance Schema `file_summary_by_event_name` table contains file events summarized by event name. It contains the following columns:

Column	Description
`EVENT_NAME`	Event name.
`COUNT_STAR`	Number of summarized events
`SUM_TIMER_WAIT`	Total wait time of the summarized events that are timed.
`MIN_TIMER_WAIT`	Minimum wait time of the summarized events that are timed.
`AVG_TIMER_WAIT`	Average wait time of the summarized events that are timed.
`MAX_TIMER_WAIT`	Maximum wait time of the summarized events that are timed.
`COUNT_READ`	Number of all read operations, including `FGETS`, `FGETC`, `FREAD`, and `READ`.
`SUM_TIMER_READ`	Total wait time of all read operations that are timed.
`MIN_TIMER_READ`	Minimum wait time of all read operations that are timed.
`AVG_TIMER_READ`	Average wait time of all read operations that are timed.
`MAX_TIMER_READ`	Maximum wait time of all read operations that are timed.
`SUM_NUMBER_OF_BYTES_READ`	Bytes read by read operations.
`COUNT_WRITE`	Number of all write operations, including `FPUTS`, `FPUTC`, `FPRINTF`, `VFPRINTF`, `FWRITE`, and `PWRITE`.
`SUM_TIMER_WRITE`	Total wait time of all write operations that are timed.
`MIN_TIMER_WRITE`	Minimum wait time of all write operations that are timed.
`AVG_TIMER_WRITE`	Average wait time of all write operations that are timed.
`MAX_TIMER_WRITE`	Maximum wait time of all write operations that are timed.
`SUM_NUMBER_OF_BYTES_WRITE`	Bytes written by write operations.
`COUNT_MISC`	Number of all miscellaneous operations not counted above, including `CREATE`, `DELETE`, `OPEN`, `CLOSE`, `STREAM_OPEN`, `STREAM_CLOSE`, `SEEK`, `TELL`, `FLUSH`, `STAT`, `FSTAT`, `CHSIZE`, `RENAME`, and `SYNC`.
`SUM_TIMER_MISC`	Total wait time of all miscellaneous operations that are timed.

MIN_TIMER_MISC	Minimum wait time of all miscellaneous operations that are timed.
AVG_TIMER_MISC	Average wait time of all miscellaneous operations that are timed.
MAX_TIMER_MISC	Maximum wait time of all miscellaneous operations that are timed.

I/O operations can be avoided by caching, in which case they will not be recorded in this table.

You can TRUNCATE the table, which will reset all counters to zero.

Example

```
SELECT * FROM file_summary_by_event_name\G
...
*************************** 49. row ***************************
               EVENT_NAME: wait/io/file/aria/MAD
               COUNT_STAR: 60
           SUM_TIMER_WAIT: 397234368
           MIN_TIMER_WAIT: 0
           AVG_TIMER_WAIT: 6620224
           MAX_TIMER_WAIT: 16808672
               COUNT_READ: 0
           SUM_TIMER_READ: 0
           MIN_TIMER_READ: 0
           AVG_TIMER_READ: 0
           MAX_TIMER_READ: 0
 SUM_NUMBER_OF_BYTES_READ: 0
              COUNT_WRITE: 0
          SUM_TIMER_WRITE: 0
          MIN_TIMER_WRITE: 0
          AVG_TIMER_WRITE: 0
          MAX_TIMER_WRITE: 0
SUM_NUMBER_OF_BYTES_WRITE: 0
               COUNT_MISC: 60
           SUM_TIMER_MISC: 397234368
           MIN_TIMER_MISC: 0
           AVG_TIMER_MISC: 6620224
           MAX_TIMER_MISC: 16808672
*************************** 50. row ***************************
               EVENT_NAME: wait/io/file/aria/control
               COUNT_STAR: 3
           SUM_TIMER_WAIT: 24055778544
           MIN_TIMER_WAIT: 0
           AVG_TIMER_WAIT: 8018592848
           MAX_TIMER_WAIT: 24027262400
               COUNT_READ: 1
           SUM_TIMER_READ: 24027262400
           MIN_TIMER_READ: 0
           AVG_TIMER_READ: 24027262400
           MAX_TIMER_READ: 24027262400
 SUM_NUMBER_OF_BYTES_READ: 52
              COUNT_WRITE: 0
          SUM_TIMER_WRITE: 0
          MIN_TIMER_WRITE: 0
          AVG_TIMER_WRITE: 0
          MAX_TIMER_WRITE: 0
SUM_NUMBER_OF_BYTES_WRITE: 0
               COUNT_MISC: 2
           SUM_TIMER_MISC: 28516144
           MIN_TIMER_MISC: 0
           AVG_TIMER_MISC: 14258072
           MAX_TIMER_MISC: 27262208
```

1.1.1.2.9.2.1.41 Performance Schema file_summary_by_instance Table

The Performance Schema `file_summary_by_instance` table contains file events summarized by instance. It contains the following columns:

Column	Description
FILE_NAME	File name.
EVENT_NAME	Event name.
OBJECT_INSTANCE_BEGIN	Address in memory. Together with FILE_NAME and EVENT_NAME uniquely identifies a row.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
COUNT_READ	Number of all read operations, including FGETS , FGETC , FREAD , and READ .
SUM_TIMER_READ	Total wait time of all read operations that are timed.
MIN_TIMER_READ	Minimum wait time of all read operations that are timed.
AVG_TIMER_READ	Average wait time of all read operations that are timed.
MAX_TIMER_READ	Maximum wait time of all read operations that are timed.
SUM_NUMBER_OF_BYTES_READ	Bytes read by read operations.
COUNT_WRITE	Number of all write operations, including FPUTS , FPUTC , FPRINTF , VFPRINTF , FWRITE , and PWRITE .
SUM_TIMER_WRITE	Total wait time of all write operations that are timed.
MIN_TIMER_WRITE	Minimum wait time of all write operations that are timed.
AVG_TIMER_WRITE	Average wait time of all write operations that are timed.
MAX_TIMER_WRITE	Maximum wait time of all write operations that are timed.
SUM_NUMBER_OF_BYTES_WRITE	Bytes written by write operations.
COUNT_MISC	Number of all miscellaneous operations not counted above, including CREATE , DELETE , OPEN , CLOSE , STREAM_OPEN , STREAM_CLOSE , SEEK , TELL , FLUSH , STAT , FSTAT , CHSIZE , RENAME , and SYNC .
SUM_TIMER_MISC	Total wait time of all miscellaneous operations that are timed.
MIN_TIMER_MISC	Minimum wait time of all miscellaneous operations that are timed.
AVG_TIMER_MISC	Average wait time of all miscellaneous operations that are timed.
MAX_TIMER_MISC	Maximum wait time of all miscellaneous operations that are timed.

I/O operations can be avoided by caching, in which case they will not be recorded in this table.

You can TRUNCATE the table, which will reset all counters to zero.

Example

```
SELECT * FROM file_summary_by_instance\G
...
*************************** 204. row ***************************
                FILE_NAME: /var/lib/mysql/test/db.opt
               EVENT_NAME: wait/io/file/sql/dbopt
    OBJECT_INSTANCE_BEGIN: 140578961971264
               COUNT_STAR: 6
           SUM_TIMER_WAIT: 39902495024
           MIN_TIMER_WAIT: 177888
           AVG_TIMER_WAIT: 6650415692
           MAX_TIMER_WAIT: 21026400404
               COUNT_READ: 1
           SUM_TIMER_READ: 21026400404
           MIN_TIMER_READ: 21026400404
           AVG_TIMER_READ: 21026400404
           MAX_TIMER_READ: 21026400404
 SUM_NUMBER_OF_BYTES_READ: 65
              COUNT_WRITE: 0
          SUM_TIMER_WRITE: 0
          MIN_TIMER_WRITE: 0
          AVG_TIMER_WRITE: 0
          MAX_TIMER_WRITE: 0
SUM_NUMBER_OF_BYTES_WRITE: 0
               COUNT_MISC: 5
           SUM_TIMER_MISC: 18876094620
           MIN_TIMER_MISC: 177888
           AVG_TIMER_MISC: 3775218924
           MAX_TIMER_MISC: 18864558060
*************************** 205. row ***************************
                FILE_NAME: /var/log/mysql/mariadb-bin.000157
               EVENT_NAME: wait/io/file/sql/binlog
    OBJECT_INSTANCE_BEGIN: 140578961971968
               COUNT_STAR: 6

           MIN_TIMER_WAIT: 251136
           AVG_TIMER_WAIT: 12330979468
           MAX_TIMER_WAIT: 73846656340
               COUNT_READ: 0
           SUM_TIMER_READ: 0
           MIN_TIMER_READ: 0
           AVG_TIMER_READ: 0
           MAX_TIMER_READ: 0
 SUM_NUMBER_OF_BYTES_READ: 0
              COUNT_WRITE: 2
          SUM_TIMER_WRITE: 62583004
          MIN_TIMER_WRITE: 27630192
          AVG_TIMER_WRITE: 31291284
          MAX_TIMER_WRITE: 34952812
SUM_NUMBER_OF_BYTES_WRITE: 369
               COUNT_MISC: 4
           SUM_TIMER_MISC: 73923294676
           MIN_TIMER_MISC: 251136
           AVG_TIMER_MISC: 18480823560
           MAX_TIMER_MISC: 73846656340
```

1.1.1.2.9.2.1.42 Performance Schema global_status Table

MariaDB starting with 10.5.2

The `global_status` table was added in MariaDB 10.5.2.

The `global_status` table contains a list of status variables and their global values. The table only stores status variable statistics for threads which are instrumented, and does not collect statistics for `Com_xxx` variables.

The table contains the following columns:

Column	Description
`VARIABLE_NAME`	The global status variable name.

VARIABLE_VALUE	The global status variable value.

TRUNCATE TABLE resets global status variables, including thread, account, host, and user status, but not those that are never reset by the server.

1.1.1.2.9.2.1.43 Performance Schema hosts Table

Description

The `hosts` table contains a row for each host used by clients to connect to the server, containing current and total connections.

The size is determined by the performance_schema_hosts_size system variable, which, if set to zero, will disable connection statistics in the hosts table.

It contains the following columns:

Column	Description
HOST	Host name used by the client to connect, `NULL` for internal threads or user sessions that failed to authenticate.
CURRENT_CONNECTIONS	Current number of the host's connections.
TOTAL_CONNECTIONS	Total number of the host's connections

Example

```
SELECT * FROM hosts;
+-----------+---------------------+-------------------+
| HOST      | CURRENT_CONNECTIONS | TOTAL_CONNECTIONS |
+-----------+---------------------+-------------------+
| localhost |                   1 |                45 |
| NULL      |                  20 |                23 |
+-----------+---------------------+-------------------+
```

1.1.1.2.9.2.1.44 Performance Schema host_cache Table

The `host_cache` table contains host and IP information from the host_cache, used for avoiding DNS lookups for new client connections.

The host_cache table contains the following columns:

Column	Description
IP	Client IP address.
HOST	IP's resolved DNS host name, or `NULL` if unknown.
HOST_VALIDATED	YES if the IP-to-host DNS lookup was successful, and the `HOST` column can be used to avoid DNS calls, or NO if unsuccessful, in which case DNS lookup is performed for each connect until either successful or a permanent error.
SUM_CONNECT_ERRORS	Number of connection errors. Counts only protocol handshake errors for hosts that passed validation. These errors count towards max_connect_errors.
COUNT_HOST_BLOCKED_ERRORS	Number of blocked connections because `SUM_CONNECT_ERRORS` exceeded the max_connect_errors system variable.
COUNT_NAMEINFO_TRANSIENT_ERRORS	Number of transient errors during IP-to-host DNS lookups.

COUNT_NAMEINFO_PERMANENT_ERRORS	Number of permanent errors during IP-to-host DNS lookups.
COUNT_FORMAT_ERRORS	Number of host name format errors, for example a numeric host column.
COUNT_ADDRINFO_TRANSIENT_ERRORS	Number of transient errors during host-to-IP reverse DNS lookups.
COUNT_ADDRINFO_PERMANENT_ERRORS	Number of permanent errors during host-to-IP reverse DNS lookups.
COUNT_FCRDNS_ERRORS	Number of forward-confirmed reverse DNS errors, which occur when IP-to-host DNS lookup does not match the originating IP address.
COUNT_HOST_ACL_ERRORS	Number of errors occurring because no user from the host is permitted to log in. These attempts return error code 1130 ER_HOST_NOT_PRIVILEGED and do not proceed to username and password authentication.
COUNT_NO_AUTH_PLUGIN_ERRORS	Number of errors due to requesting an authentication plugin that was not available. This can be due to the plugin never having been loaded, or the load attempt failing.
COUNT_AUTH_PLUGIN_ERRORS	Number of errors reported by an authentication plugin. Plugins can increment COUNT_AUTHENTICATION_ERRORS or COUNT_HANDSHAKE_ERRORS instead, but, if specified or the error is unknown, this column is incremented.
COUNT_HANDSHAKE_ERRORS	Number of errors detected at the wire protocol level.
COUNT_PROXY_USER_ERRORS	Number of errors detected when a proxy user is proxied to a user that does not exist.
COUNT_PROXY_USER_ACL_ERRORS	Number of errors detected when a proxy user is proxied to a user that exists, but the proxy user doesn't have the PROXY privilege.
COUNT_AUTHENTICATION_ERRORS	Number of errors where authentication failed.
COUNT_SSL_ERRORS	Number of errors due to TLS problems.
COUNT_MAX_USER_CONNECTIONS_ERRORS	Number of errors due to the per-user quota being exceeded.
COUNT_MAX_USER_CONNECTIONS_PER_HOUR_ERRORS	Number of errors due to the per-hour quota being exceeded.
COUNT_DEFAULT_DATABASE_ERRORS	Number of errors due to the user not having permission to access the specified default database, or it not existing.
COUNT_INIT_CONNECT_ERRORS	Number of errors due to statements in the init_connect system variable.
COUNT_LOCAL_ERRORS	Number of local server errors, such as out-of-memory errors, unrelated to network, authentication, or authorization.
COUNT_UNKNOWN_ERRORS	Number of unknown errors that cannot be allocated to another column.
FIRST_SEEN	Timestamp of the first connection attempt by the IP.
LAST_SEEN	Timestamp of the most recent connection attempt by the IP.
FIRST_ERROR_SEEN	Timestamp of the first error seen from the IP.
LAST_ERROR_SEEN	Timestamp of the most recent error seen from the IP.

The host_cache table, along with the host_cache , is cleared with FLUSH HOSTS, TRUNCATE TABLE host_cache or by setting the host_cache_size system variable at runtime.

1.1.1.2.9.2.1.45 Performance Schema memory_summary_by_account_by_event_name Table

MariaDB starting with 10.5.2

The memory_summary_by_account_by_event_name table was introduced in MariaDB 10.5.2.

There are five memory summary tables in the Performance Schema that share a number of fields in common. These include:

- memory_summary_by_account_by_event_name
- memory_summary_by_host_by_event_name
- memory_summary_by_thread_by_event_name
- memory_summary_by_user_by_event_name
- memory_global_by_event_name

The `memory_summary_by_account_by_event_name` table contains memory usage statistics aggregated by account and event.

The table contains the following columns:

Field	Type	Null	Default	Description
USER	char(32)	YES	NULL	User portion of the account.
HOST	char(60)	YES	NULL	Host portion of the account.
EVENT_NAME	varchar(128)	NO	NULL	Event name.
COUNT_ALLOC	bigint(20) unsigned	NO	NULL	Total number of allocations to memory.
COUNT_FREE	bigint(20) unsigned	NO	NULL	Total number of attempts to free the allocated memory.
SUM_NUMBER_OF_BYTES_ALLOC	bigint(20) unsigned	NO	NULL	Total number of bytes allocated.
SUM_NUMBER_OF_BYTES_FREE	bigint(20) unsigned	NO	NULL	Total number of bytes freed
LOW_COUNT_USED	bigint(20)	NO	NULL	Lowest number of allocated blocks (lowest value of CURRENT_COUNT_USED).
CURRENT_COUNT_USED	bigint(20)	NO	NULL	Currently allocated blocks that have not been freed (COUNT_ALLOC minus COUNT_FREE).
HIGH_COUNT_USED	bigint(20)	NO	NULL	Highest number of allocated blocks (highest value of CURRENT_COUNT_USED).
LOW_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Lowest number of bytes used.
CURRENT_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Current number of bytes used (total allocated minus total freed).
HIGH_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Highest number of bytes used.

1.1.1.2.9.2.1.46 Performance Schema memory_summary_by_host_by_event_name Table

MariaDB starting with 10.5.2

The memory_summary_by_host_by_event_name table was introduced in MariaDB 10.5.2.

There are five memory summary tables in the Performance Schema that share a number of fields in common. These include:

- memory_summary_by_account_by_event_name
- memory_summary_by_host_by_event_name
- memory_summary_by_thread_by_event_name
- memory_summary_by_user_by_event_name
- memory_global_by_event_name

The `memory_summary_by_host_by_event_name` table contains memory usage statistics aggregated by host and event.

The table contains the following columns:

Field	Type	Null	Default	Description
HOST	char(60)	YES	NULL	Host portion of the account.
EVENT_NAME	varchar(128)	NO	NULL	Event name.
COUNT_ALLOC	bigint(20) unsigned	NO	NULL	Total number of allocations to memory.
COUNT_FREE	bigint(20) unsigned	NO	NULL	Total number of attempts to free the allocated memory.
SUM_NUMBER_OF_BYTES_ALLOC	bigint(20) unsigned	NO	NULL	Total number of bytes allocated.
SUM_NUMBER_OF_BYTES_FREE	bigint(20) unsigned	NO	NULL	Total number of bytes freed
LOW_COUNT_USED	bigint(20)	NO	NULL	Lowest number of allocated blocks (lowest value of CURRENT_COUNT_USED).
CURRENT_COUNT_USED	bigint(20)	NO	NULL	Currently allocated blocks that have not been freed (COUNT_ALLOC minus COUNT_FREE).
HIGH_COUNT_USED	bigint(20)	NO	NULL	Highest number of allocated blocks (highest value of CURRENT_COUNT_USED).
LOW_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Lowest number of bytes used.
CURRENT_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Current number of bytes used (total allocated minus total freed).
HIGH_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Highest number of bytes used.

1.1.1.2.9.2.1.47 Performance Schema memory_summary_by_thread_by_event_name Table

MariaDB starting with 10.5.2

The memory_summary_by_thread_by_event_name table was introduced in MariaDB 10.5.2.

There are five memory summary tables in the Performance Schema that share a number of fields in common. These include:

- memory_summary_by_account_by_event_name
- memory_summary_by_host_by_event_name
- memory_summary_by_thread_by_event_name
- memory_summary_by_user_by_event_name
- memory_global_by_event_name

The `memory_summary_by_thread_by_event_name` table contains memory usage statistics aggregated by thread and event.

The table contains the following columns:

Field	Type	Null	Default	Description
THREAD_ID	bigint(20) unsigned	NO	NULL	Thread id.
EVENT_NAME	varchar(128)	NO	NULL	Event name.
COUNT_ALLOC	bigint(20) unsigned	NO	NULL	Total number of allocations to memory.
COUNT_FREE	bigint(20) unsigned	NO	NULL	Total number of attempts to free the allocated memory.
SUM_NUMBER_OF_BYTES_ALLOC	bigint(20) unsigned	NO	NULL	Total number of bytes allocated.

SUM_NUMBER_OF_BYTES_FREE	bigint(20) unsigned	NO	NULL	Total number of bytes freed
LOW_COUNT_USED	bigint(20)	NO	NULL	Lowest number of allocated blocks (lowest value of CURRENT_COUNT_USED).
CURRENT_COUNT_USED	bigint(20)	NO	NULL	Currently allocated blocks that have not been freed (COUNT_ALLOC minus COUNT_FREE).
HIGH_COUNT_USED	bigint(20)	NO	NULL	Highest number of allocated blocks (highest value of CURRENT_COUNT_USED).
LOW_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Lowest number of bytes used.
CURRENT_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Current number of bytes used (total allocated minus total freed).
HIGH_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Highest number of bytes used.

1.1.1.2.9.2.1.48 Performance Schema memory_summary_by_user_by_event_name Table

MariaDB starting with 10.5.2

The memory_summary_by_user_by_event_name table was introduced in MariaDB 10.5.2.

There are five memory summary tables in the Performance Schema that share a number of fields in common. These include:

- memory_summary_by_account_by_event_name
- memory_summary_by_host_by_event_name
- memory_summary_by_thread_by_event_name
- memory_summary_by_user_by_event_name
- memory_global_by_event_name

The `memory_summary_by_user_by_event_name` table contains memory usage statistics aggregated by user and event.

The table contains the following columns:

Field	Type	Null	Default	Description
USER	char(32)	YES	NULL	User portion of the account.
EVENT_NAME	varchar(128)	NO	NULL	Event name.
COUNT_ALLOC	bigint(20) unsigned	NO	NULL	Total number of allocations to memory.
COUNT_FREE	bigint(20) unsigned	NO	NULL	Total number of attempts to free the allocated memory.
SUM_NUMBER_OF_BYTES_ALLOC	bigint(20) unsigned	NO	NULL	Total number of bytes allocated.
SUM_NUMBER_OF_BYTES_FREE	bigint(20) unsigned	NO	NULL	Total number of bytes freed
LOW_COUNT_USED	bigint(20)	NO	NULL	Lowest number of allocated blocks (lowest value of CURRENT_COUNT_USED).
CURRENT_COUNT_USED	bigint(20)	NO	NULL	Currently allocated blocks that have not been freed (COUNT_ALLOC minus COUNT_FREE).
HIGH_COUNT_USED	bigint(20)	NO	NULL	Highest number of allocated blocks (highest value of CURRENT_COUNT_USED).
LOW_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Lowest number of bytes used.
CURRENT_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Current number of bytes used (total allocated minus total freed).
HIGH_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Highest number of bytes used.

1.1.1.2.9.2.1.49 Performance Schema memory_summary_global_by_event_name Table

MariaDB starting with 10.5.2

The memory_summary_global_by_event_name table was introduced in MariaDB 10.5.2.

There are five memory summary tables in the Performance Schema that share a number of fields in common. These include:

- memory_summary_by_account_by_event_name
- memory_summary_by_host_by_event_name
- memory_summary_by_thread_by_event_name
- memory_summary_by_user_by_event_name
- memory_global_by_event_name

The `memory_summary_global_by_event_name` table contains memory usage statistics aggregated by event and event.

The table contains the following columns:

Field	Type	Null	Default	Description
EVENT_NAME	varchar(128)	NO	NULL	Event name.
COUNT_ALLOC	bigint(20) unsigned	NO	NULL	Total number of allocations to memory.
COUNT_FREE	bigint(20) unsigned	NO	NULL	Total number of attempts to free the allocated memory.
SUM_NUMBER_OF_BYTES_ALLOC	bigint(20) unsigned	NO	NULL	Total number of bytes allocated.
SUM_NUMBER_OF_BYTES_FREE	bigint(20) unsigned	NO	NULL	Total number of bytes freed
LOW_COUNT_USED	bigint(20)	NO	NULL	Lowest number of allocated blocks (lowest value of CURRENT_COUNT_USED).
CURRENT_COUNT_USED	bigint(20)	NO	NULL	Currently allocated blocks that have not been freed (COUNT_ALLOC minus COUNT_FREE).
HIGH_COUNT_USED	bigint(20)	NO	NULL	Highest number of allocated blocks (highest value of CURRENT_COUNT_USED).
LOW_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Lowest number of bytes used.
CURRENT_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Current number of bytes used (total allocated minus total freed).
HIGH_NUMBER_OF_BYTES_USED	bigint(20)	NO	NULL	Highest number of bytes used.

Example

Seeing what memory was most often allocated for:

```
SELECT * FROM memory_summary_global_by_event_name
  ORDER BY count_alloc DESC LIMIT 1\G
*************************** 1. row ***************************
                  EVENT_NAME: memory/sql/QUICK_RANGE_SELECT::alloc
                 COUNT_ALLOC: 147976
                  COUNT_FREE: 147976
   SUM_NUMBER_OF_BYTES_ALLOC: 600190656
    SUM_NUMBER_OF_BYTES_FREE: 600190656
              LOW_COUNT_USED: 0
          CURRENT_COUNT_USED: 0
             HIGH_COUNT_USED: 68
    LOW_NUMBER_OF_BYTES_USED: 0
CURRENT_NUMBER_OF_BYTES_USED: 0
   HIGH_NUMBER_OF_BYTES_USED: 275808
```

1.1.1.2.9.2.1.50 Performance Schema metadata_locks Table

MariaDB starting with 10.5.2

The metadata_locks table was introduced in MariaDB 10.5.2.

The `metadata_locks` table contains metadata lock information.

To enable metadata lock instrumention, at runtime:

```
UPDATE performance_schema.setup_instruments SET enabled='YES', timed='YES'
  WHERE name LIKE 'wait/lock/metadata%';
```

or in the configuration file:

```
performance-schema-instrument='wait/lock/metadata/sql/mdl=ON'
```

The table is by default autosized, but the size can be configured with the performance_schema_max_metadata_locks system variabe.

The table is read-only, and TRUNCATE TABLE cannot be used to empty the table.

The table contains the following columns:

Field	Type	Null	Default	Description
OBJECT_TYPE	varchar(64)	NO	NULL	Object type. One of `BACKUP`, `COMMIT`, `EVENT`, `FUNCTION`, `GLOBAL`, `LOCKING SERVICE`, `PROCEDURE`, `SCHEMA`, `TABLE`, `TABLESPACE`, `TRIGGER` (unused) or `USER LEVEL LOCK`.
OBJECT_SCHEMA	varchar(64)	YES	NULL	Object schema.
OBJECT_NAME	varchar(64)	YES	NULL	Object name.
OBJECT_INSTANCE_BEGIN	bigint(20) unsigned	NO	NULL	Address in memory of the instrumented object.
LOCK_TYPE	varchar(32)	NO	NULL	Lock type. One of `BACKUP_FTWRL1`, `BACKUP_START`, `BACKUP_TRANS_DML`, `EXCLUSIVE`, `INTENTION_EXCLUSIVE`, `SHARED`, `SHARED_HIGH_PRIO`, `SHARED_NO_READ_WRITE`, `SHARED_NO_WRITE`, `SHARED_READ`, `SHARED_UPGRADABLE` or `SHARED_WRITE`.
LOCK_DURATION	varchar(32)	NO	NULL	Lock duration. One of `EXPLICIT` (locks released by explicit action, for example a global lock acquired with FLUSH TABLES WITH READ LOCK), `STATEMENT` (locks implicitly released at statement end) or `TRANSACTION` (locks implicitly released at transaction end).
LOCK_STATUS	varchar(32)	NO	NULL	Lock status. One of `GRANTED`, `KILLED`, `PENDING`, `POST_RELEASE_NOTIFY`, `PRE_ACQUIRE_NOTIFY`, `TIMEOUT` or `VICTIM`.
SOURCE	varchar(64)	YES	NULL	Source file containing the instrumented code that produced the event, as well as the line number where the instrumentation occurred. This allows one to examine the source code involved.
OWNER_THREAD_ID	bigint(20) unsigned	YES	NULL	Thread that requested the lock.
OWNER_EVENT_ID	bigint(20) unsigned	YES	NULL	Event that requested the lock.

1.1.1.2.9.2.1.51 Performance Schema mutex_instances Table

Description

The `mutex_instances` table lists all mutexes that the Performance Schema seeing while the server is executing.

A mutex is a code mechanism for ensuring that threads can only access resources one at a time. A second thread attempting to access a resource will find it protected by a mutex, and will wait for it to be unlocked.

The performance_schema_max_mutex_instances system variable specifies the maximum number of instrumented mutex instances.

Column	Description
`NAME`	Instrument name associated with the mutex.
`OBJECT_INSTANCE_BEGIN`	Memory address of the instrumented mutex.
`LOCKED_BY_THREAD_ID`	The `THREAD_ID` of the locking thread if a thread has a mutex locked, otherwise `NULL`.

1.1.1.2.9.2.1.52 Performance Schema objects_summary_global_by_type Table

It aggregates object wait events, and contains the following columns:

Column	Description
`OBJECT_TYPE`	Groups records together with `OBJECT_SCHEMA` and `OBJECT_NAME`.
`OBJECT_SCHEMA`	Groups records together with `OBJECT_TYPE` and `OBJECT_NAME`.
`OBJECT_NAME`	Groups records together with `OBJECT_SCHEMA` and `OBJECT_TYPE`.
`COUNT_STAR`	Number of summarized events
`SUM_TIMER_WAIT`	Total wait time of the summarized events that are timed.
`MIN_TIMER_WAIT`	Minimum wait time of the summarized events that are timed.
`AVG_TIMER_WAIT`	Average wait time of the summarized events that are timed.
`MAX_TIMER_WAIT`	Maximum wait time of the summarized events that are timed.

You can TRUNCATE the table, which will reset all counters to zero.

Example

```
SELECT * FROM objects_summary_global_by_type\G
...
*************************** 101. row ***************************
   OBJECT_TYPE: TABLE
 OBJECT_SCHEMA: test
   OBJECT_NAME: v
    COUNT_STAR: 0
SUM_TIMER_WAIT: 0
MIN_TIMER_WAIT: 0
AVG_TIMER_WAIT: 0
MAX_TIMER_WAIT: 0
*************************** 102. row ***************************
   OBJECT_TYPE: TABLE
 OBJECT_SCHEMA: test
   OBJECT_NAME: xx2
    COUNT_STAR: 2
SUM_TIMER_WAIT: 1621920
MIN_TIMER_WAIT: 481344
AVG_TIMER_WAIT: 810960
MAX_TIMER_WAIT: 1140576
```

1.1.1.2.9.2.1.53 Performance Schema

performance_timers Table

Description

The `performance_timers` table lists available event timers.

It contains the following columns:

Column	Description
`TIMER_NAME`	Time name, used in the setup_timers table.
`TIMER_FREQUENCY`	Number of timer units per second. Dependent on the processor speed.
`TIMER_RESOLUTION`	Number of timer units by which timed values increase each time.
`TIMER_OVERHEAD`	Minimum timer overhead, determined during initialization by calling the timer 20 times and selecting the smallest value. Total overhead will be at least double this, as the timer is called at the beginning and end of each timed event.

Any `NULL` values indicate that that particular timer is not available on your platform, Any timer names with a non-NULL value can be used in the setup_timers table.

Example

```
SELECT * FROM performance_timers;
+-------------+-----------------+------------------+----------------------+
| TIMER_NAME  | TIMER_FREQUENCY | TIMER_RESOLUTION | TIMER_OVERHEAD       |
+-------------+-----------------+------------------+----------------------+
| CYCLE       |      2293651741 |                1 |                   28 |
| NANOSECOND  |      1000000000 |                1 |                   48 |
| MICROSECOND |         1000000 |                1 |                   52 |
| MILLISECOND |            1000 |             1000 | 9223372036854775807 |
| TICK        |             106 |                1 |                  496 |
+-------------+-----------------+------------------+----------------------+
```

1.1.1.2.9.2.1.54 Performance Schema prepared_statements_instances Table

MariaDB starting with 10.5.2

The prepared_statements_instances table was introduced in MariaDB 10.5.2.

The `prepared_statements_instances` table contains aggregated statistics of prepared statements.

The maximum number of rows in the table is determined by the performance_schema_max_prepared_statement_instances system variable, which is by default autosized on startup.

The table contains the following columns:

```
+----------------------------+-------------------------------------------------------------+-----
-+-----+---------+-------+
| Field                      | Type                                                        | Null
| Key | Default | Extra |
+----------------------------+-------------------------------------------------------------+-----
-+-----+---------+-------+
| OBJECT_INSTANCE_BEGIN      | bigint(20) unsigned                                         | NO
|     | NULL    |       |
| STATEMENT_ID               | bigint(20) unsigned                                         | NO
|     | NULL    |       |
| STATEMENT_NAME             | varchar(64)                                                 | YES
|     | NULL    |       |
| SQL_TEXT                   | longtext                                                    | NO
|     | NULL    |       |
| OWNER_THREAD_ID            | bigint(20) unsigned                                         | NO
|     | NULL    |       |
| OWNER_EVENT_ID             | bigint(20) unsigned                                         | NO
|     | NULL    |       |
```

```
| OWNER_OBJECT_TYPE           | enum('EVENT','FUNCTION','PROCEDURE','TABLE','TRIGGER') | YES  |
| NULL    |       |
| OWNER_OBJECT_SCHEMA         | varchar(64)                                            | YES
|     | NULL    |       |
| OWNER_OBJECT_NAME           | varchar(64)                                            | YES
|     | NULL    |       |
| TIMER_PREPARE               | bigint(20) unsigned                                    | NO
|     | NULL    |       |
| COUNT_REPREPARE             | bigint(20) unsigned                                    | NO
|     | NULL    |       |
| COUNT_EXECUTE               | bigint(20) unsigned                                    | NO
|     | NULL    |       |
| SUM_TIMER_EXECUTE           | bigint(20) unsigned                                    | NO
|     | NULL    |       |
| MIN_TIMER_EXECUTE           | bigint(20) unsigned                                    | NO
|     | NULL    |       |
| AVG_TIMER_EXECUTE           | bigint(20) unsigned                                    | NO
|     | NULL    |       |
| MAX_TIMER_EXECUTE           | bigint(20) unsigned                                    | NO
|     | NULL    |       |
| SUM_LOCK_TIME               | bigint(20) unsigned                                    | NO
|     | NULL    |       |
| SUM_ERRORS                  | bigint(20) unsigned                                    | NO
|     | NULL    |       |
| SUM_WARNINGS                | bigint(20) unsigned                                    | NO
|     | NULL    |       |
| SUM_ROWS_AFFECTED           | bigint(20) unsigned                                    | NO
|     | NULL    |       |
| SUM_ROWS_SENT               | bigint(20) unsigned                                    | NO
|     | NULL    |       |
| SUM_ROWS_EXAMINED           | bigint(20) unsigned                                    | NO
|     | NULL    |       |
| SUM_CREATED_TMP_DISK_TABLES | bigint(20) unsigned                                    | NO
|     | NULL    |       |
| SUM_CREATED_TMP_TABLES      | bigint(20) unsigned                                    | NO
|     | NULL    |       |
| SUM_SELECT_FULL_JOIN        | bigint(20) unsigned                                    | NO

+-----------------------------+--------------------------------------------------------+-----
-+-----+---------+-------+
```

1.1.1.2.9.2.1.55 Performance Schema replication_applier_configuration Table

MariaDB starting with 10.5.2

The `replication_applier_configuration` table, along with many other new Performance Schema tables, was added in MariaDB 10.5.2.

The Performance Schema replication_applier_configuration table contains configuration settings affecting replica

transactions.

It contains the following fields.

Field	Type	Null	Description
CHANNEL_NAME	char(64)	NO	Replication channel name.
DESIRED_DELAY	int(11)	NO	Target number of seconds the replica should be delayed to the master.

1.1.1.2.9.2.1.56 Performance Schema replication_applier_status Table

MariaDB starting with 10.5.2

The `replication_applier_status` table, along with many other new Performance Schema tables, was added in MariaDB 10.5.2.

The Performance Schema replication_applier_status table contains information about the general transaction execution status on the replica.

It contains the following fields.

Field	Type	Null	Description
CHANNEL_NAME	char(64)	NO	The replication channel name.
SERVICE_STATE	enum('ON','OFF')	NO	Shows ON when the replication channel's applier threads are active or idle, OFF means that the applier threads are not active.
REMAINING_DELAY	int(10) unsigned	YES	Seconds the replica needs to wait to reach the desired delay from master.
COUNT_TRANSACTIONS_RETRIES	bigint(20) unsigned	NO	The number of retries that were made because the replication SQL thread failed to apply a transaction.

1.1.1.2.9.2.1.57 Performance Schema replication_applier_status_by_coordinator Table

MariaDB starting with 10.5.2

The `replication_applier_status_by_coordinator` table was added in MariaDB 10.5.2.

The Performance Schema replication_applier_status_by_coordinator table displays the status of the coordinator thread used in multi-threaded replicas to manage multiple worker threads.

It contains the following fields.

Column	Type	Null	Description
CHANNEL_NAME	varchar(256)	NO	Replication channel name.
THREAD_ID	bigint(20) unsigned	YES	The SQL/coordinator thread ID.
SERVICE_STATE	enum('ON','OFF')	NO	ON (thread exists and is active or idle) or OFF (thread no longer exists).
LAST_ERROR_NUMBER	int(11)	NO	Last error number that caused the SQL/coordinator thread to stop.
LAST_ERROR_MESSAGE	varchar(1024)	NO	Last error message that caused the SQL/coordinator thread to stop.
LAST_ERROR_TIMESTAMP	timestamp	NO	Timestamp that shows when the most recent SQL/coordinator error occured.
LAST_SEEN_TRANSACTION	char(57)	NO	The transaction the worker has last seen.
LAST_TRANS_RETRY_COUNT	int(11)	NO	Total number of retries attempted by last transaction.

1.1.1.2.9.2.1.58 Performance Schema replication_applier_status_by_worker Table

MariaDB starting with 10.6.0

The `replication_applier_status_by_worker` table was added in MariaDB 10.6.0.

The Performance Schema replication_applier_status_by_worker table displays replica worker thread specific information.

It contains the following fields.

Column	Description
CHANNEL_NAME	Name of replication channel through which the transaction is received.
THREAD_ID	Thread_Id as displayed in the performance_schema.threads table for thread with name 'thread/sql/rpl_parallel_thread'. THREAD_ID will be NULL when worker threads are stopped due to error/force stop.
SERVICE_STATE	Whether or not the thread is running.
LAST_SEEN_TRANSACTION	Last GTID executed by worker
LAST_ERROR_NUMBER	Last Error that occurred on a particular worker.
LAST_ERROR_MESSAGE	Last error specific message.
LAST_ERROR_TIMESTAMP	Time stamp of last error.
WORKER_IDLE_TIME	Total idle time in seconds that the worker thread has spent waiting for work from SQL thread.
LAST_TRANS_RETRY_COUNT	Total number of retries attempted by last transaction.

1.1.1.2.9.2.1.59 Performance Schema replication_connection_configuration Table

MariaDB starting with 10.5.2

The `replication_connection_configuration` table was added in MariaDB 10.6.0.

The Performance Schema replication_connection_configuration table displays replica's configuration settings used for connecting to the primary.

It contains the following fields.

Column	Type	Null	Description
CHANNEL_NAME	varchar(256)	NO	The replication channel used.
HOST	char(60)	NO	The host name of the source that the replica is connected to.
PORT	int(11)	NO	The port used to connect to the source.
USER	char(32)	NO	The user name of the replication user account used to connect to the source.
USING_GTID	enum('NO', 'CURRENT_POS', 'SLAVE_POS')	NO	Whether replication is using GTIDs or not.
SSL_ALLOWED	enum('YES', 'NO', 'IGNORED')	NO	Whether SSL is allowed for the replica connection.
SSL_CA_FILE	varchar(512)	NO	Path to the file that contains one or more certificates for trusted Certificate Authorities (CA) to use for TLS.

SSL_CA_PATH	varchar(512)	NO	Path to a directory that contains one or more PEM files that contain X509 certificates for a trusted Certificate Authority (CA) to use for TLS.
SSL_CERTIFICATE	varchar(512)	NO	Path to the certificate used to authenticate the master.
SSL_CIPHER	varchar(512)	NO	Which cipher is used for encription.
SSL_KEY	varchar(512)	NO	Path to the private key used for TLS.
SSL_VERIFY_SERVER_CERTIFICATE	enum('YES','NO')	NO	Whether the server certificate is verified as part of the SSL connection.
SSL_CRL_FILE	varchar(255)	NO	Path to the PEM file containing one or more revoked X.509 certificates.
SSL_CRL_PATH	varchar(255)	NO	PATH to a folder containing PEM files containing one or more revoked X.509 certificates.
CONNECTION_RETRY_INTERVAL	int(11)	NO	The number of seconds between connect retries.
CONNECTION_RETRY_COUNT	bigint(20) unsigned	NO	The number of times the replica can attempt to reconnect to the source in the event of a lost connection.
HEARTBEAT_INTERVAL	double(10,3) unsigned	NO	Number of seconds after which a heartbeat will be sent.
IGNORE_SERVER_IDS	longtext	NO	Binary log events from servers (ids) to ignore.
REPL_DO_DOMAIN_IDS	longtext	NO	Only apply binary logs from these domain ids.
REPL_IGNORE_DOMAIN_IDS	longtext	NO	Binary log events from domains to ignore.

1.1.1.2.9.2.1.60 Performance Schema rwlock_instances Table

The `rwlock_instances` table lists all read write lock (rwlock) instances that the Performance Schema sees while the server is executing. A read write is a mechanism for ensuring threads can either share access to common resources, or have exclusive access.

The performance_schema_max_rwlock_instances system variable specifies the maximum number of instrumented rwlock objects.

The `rwlock_instances` table contains the following columns:

Column	Description
`NAME`	Instrument name associated with the read write lock
`OBJECT_INSTANCE_BEGIN`	Address in memory of the instrumented lock
`WRITE_LOCKED_BY_THREAD_ID`	`THREAD_ID` of the locking thread if locked in write (exclusive) mode, otherwise `NULL` .
`READ_LOCKED_BY_COUNT`	Count of current read locks held

1.1.1.2.9.2.1.61 Performance Schema session_account_connect_attrs Table

Description

The `session_account_connect_attrs` table shows connection attributes for the current session.

Applications can pass key/value connection attributes to the server when a connection is made. The session_connect_attrs and `session_account_connect_attrs` tables provide access to this information, for all sessions and the current session respectively.

The C API functions mysql_options() and mysql_optionsv() are used for passing connection attributes to the server.

`session_account_connect_attrs` contains the following columns:

Column	Description
`PROCESSLIST_ID`	Session connection identifier.
`ATTR_NAME`	Attribute name.
`ATTR_VALUE`	Attribute value.
`ORDINAL_POSITION`	Order in which attribute was added to the connection attributes.

Example

```
SELECT * FROM performance_schema.session_account_connect_attrs;
+----------------+-----------------+------------------+------------------+
| PROCESSLIST_ID | ATTR_NAME       | ATTR_VALUE       | ORDINAL_POSITION |
+----------------+-----------------+------------------+------------------+
|             45 | _os             | debian-linux-gnu |                0 |
|             45 | _client_name    | libmysql         |                1 |
|             45 | _pid            | 7711             |                2 |
|             45 | _client_version | 10.0.5           |                3 |
|             45 | _platform       | x86_64           |                4 |
|             45 | program_name    | mysql            |                5 |
+----------------+-----------------+------------------+------------------+
```

1.1.1.2.9.2.1.62 Performance Schema session_connect_attrs Table

Contents

Description

`session_connect_attrs` is a Performance Schema table that shows connection attributes for all sessions. The Performance Schema needs to be enabled for the table to be populated.

Applications can pass key/value connection attributes to the server when a connection is made. The `session_connect_attrs` and session_account_connect_attrs tables provide access to this information, for all sessions and the current session respectively.

The C API functions mysql_options() and mysql_optionsv() are used for passing connection attributes to the server.

`session_connect_attrs` contains the following columns:

Column	Description
`PROCESSLIST_ID`	Session connection identifier.
`ATTR_NAME`	Attribute name.
`ATTR_VALUE`	Attribute value.
`ORDINAL_POSITION`	Order in which attribute was added to the connection attributes.

Example

Returning the current connection's attributes:

```
SELECT * FROM performance_schema.session_connect_attrs WHERE processlist_id=CONNECTION_ID();
+---------------+----------------+-----------------+------------------+
| PROCESSLIST_ID | ATTR_NAME      | ATTR_VALUE      | ORDINAL_POSITION |
+---------------+----------------+-----------------+------------------+
|             45 | _os            | debian-linux-gnu |                0 |
|             45 | _client_name   | libmysql        |                1 |
|             45 | _pid           | 7711            |                2 |
|             45 | _client_version | 10.0.5          |                3 |
|             45 | _platform      | x86_64          |                4 |
|             45 | program_name   | mysql           |                5 |
+---------------+----------------+-----------------+------------------+
```

Using Other Connectors

JDBC

Connection attributes values are set using the option connectionAttributes.

Example using connection string `jdbc:mariadb://localhost/?connectionAttributes=test:test1,test2:test2Val,test3`

```
SELECT * FROM performance_schema.session_connect_attrs WHERE processlist_id=17;
+---------------+----------------+--------------------+------------------+
| PROCESSLIST_ID | ATTR_NAME      | ATTR_VALUE         | ORDINAL_POSITION |
+---------------+----------------+--------------------+------------------+
|             17 | _client_name   | MariaDB Connector/J |                0 |
|             17 | _client_version | 3.1.3              |                1 |
|             17 | _server_host   | localhost          |                2 |
|             17 | _os            | Windows 11         |                3 |
|             17 | _thread        | 1                  |                4 |
|             17 | _java_vendor   | Oracle Corporation |                5 |
|             17 | _java_version  | 19.0.2             |                6 |
|             17 | test           | test1              |                7 |
|             17 | test2          | test2Val           |                8 |
|             17 | test3          | NULL               |                9 |
+---------------+----------------+--------------------+------------------+
```

Node.js

Connection attributes values are set using the option connectAttributes

Example using connection

```
const conn = await mariadb.createConnection({
 host: 'localhost',
 user: 'root',
 connectAttributes: { test: 'test1', test2: 'test2Val', test3: 'f' }
});
```

```
SELECT * FROM performance_schema.session_connect_attrs WHERE processlist_id=30;
+---------------+----------------+-----------------------+------------------+
| PROCESSLIST_ID | ATTR_NAME      | ATTR_VALUE            | ORDINAL_POSITION |
+---------------+----------------+-----------------------+------------------+
|             30 | _client_name   | MariaDB connector/Node |                0 |
|             30 | _client_version | 3.1.1                 |                1 |
|             30 | _server_host   | ::1                   |                2 |
|             30 | _os            | win32                 |                3 |
|             30 | _client_host   | NOSTROMO              |                4 |
|             30 | _node_version  | 18.15.0               |                5 |
|             30 | test           | test1                 |                6 |
|             30 | test2          | test2Val              |                7 |
|             30 | test3          | f                     |                8 |
+---------------+----------------+-----------------------+------------------+
```

R2DBC

Connection attributes values are set using the option connectionAttributes.

Example using connection string `jdbc:mariadb://localhost/?connectionAttributes=test:test1,test2:test2Val,test3`

```
    TreeMap<String, String> connectionAttributes = new TreeMap<>();
    connectionAttributes.put("entry1", "val1");
    connectionAttributes.put("entry2", "val2");

     MariadbConnectionConfiguration conf = MariadbConnectionConfiguration.builder()
            .host("localhost")
            .port(3306)
            .username("root")
            .connectionAttributes(connectionAttributes)
            .database("test")
            .build();
     MariadbConnectionFactory connFactory = new MariadbConnectionFactory(conf);
     MariadbConnection connection = connFactory.create().block();
```

```
SELECT * FROM performance_schema.session_connect_attrs WHERE processlist_id=34;
+----------------+-----------------+--------------------+------------------+
| PROCESSLIST_ID | ATTR_NAME       | ATTR_VALUE         | ORDINAL_POSITION |
+----------------+-----------------+--------------------+------------------+
|             34 | _client_name    | mariadb            |                0 |
|             34 | _client_version | 1.1.4              |                1 |
|             34 | _server_host    | localhost          |                2 |
|             34 | _os             | Windows 11         |                3 |
|             34 | _thread         | 49                 |                4 |
|             34 | _java_vendor    | Oracle Corporation |                5 |
|             34 | _java_version   | 19.0.2             |                6 |
|             34 | entry1          | val1               |                7 |
|             34 | entry2          | val2               |                8 |
+----------------+-----------------+--------------------+------------------+
```

1.1.1.2.9.2.1.63 Performance Schema session_status Table

MariaDB starting with 10.5.2

The `session_status` table was added in MariaDB 10.5.2.

The `session_status` table contains a list of status variables for the current session. The table only stores status variable statistics for threads which are instrumented, and does not collect statistics for `Com_xxx` variables.

The table contains the following columns:

Column	Description
`VARIABLE_NAME`	The session status variable name.
`VARIABLE_VALUE`	The session status variable value.

It is not possible to empty this table with a `TRUNCATE TABLE` statement.

1.1.1.2.9.2.1.64 Performance Schema setup_actors Table

The `setup_actors` table contains information for determining whether monitoring should be enabled for new client connection threads.

The default size is 100 rows, which can be changed by modifying the `performance_schema_setup_actors_size` system variable at server startup.

If a row in the table matches a new foreground thread's client and host, the matching `INSTRUMENTED` column in the threads table is set to either `YES` or `NO`, which allows selective application of instrumenting by host, by user, or combination thereof.

Column	Description

HOST	Host name, either a literal, or the % wildcard representing any host.
USER	User name, either a literal or the % wildcard representing any name.
ROLE	Unused

Initially, any user and host is matched:

```
SELECT * FROM performance_schema.setup_actors;
+------+------+------+
| HOST | USER | ROLE |
+------+------+------+
| %    | %    | %    |
+------+------+------+
```

1.1.1.2.9.2.1.65 Performance Schema setup_consumers Table

Lists the types of consumers for which event information is available.

The setup_consumers table contains the following columns:

Column	Description
NAME	Consumer name
ENABLED	YES or NO for whether or not the consumer is enabled. You can modify this column to ensure that event information is added, or is not added.

The table can be modified directly, or the server started with the option enabled, for example:

```
performance-schema-consumer-events-waits-history=ON
```

Example

```
SELECT * FROM performance_schema.setup_consumers;

+--------------------------------+---------+
| NAME                           | ENABLED |
+--------------------------------+---------+
| events_stages_current          | NO      |
| events_stages_history          | NO      |
| events_stages_history_long     | NO      |
| events_statements_current      | YES     |
| events_statements_history      | NO      |
| events_statements_history_long | NO      |
| events_waits_current           | NO      |
| events_waits_history           | NO      |
| events_waits_history_long      | NO      |
| global_instrumentation         | YES     |
| thread_instrumentation         | YES     |
| statements_digest              | YES     |
+--------------------------------+---------+
```

1.1.1.2.9.2.1.66 Performance Schema setup_instruments Table

The setup_instruments table contains a list of instrumented object classes for which it is possible to collect events. There is one row for each instrument in the source code. When an instrument is enabled and executed, instances are created which are then stored in the cond_instances, file_instances, mutex_instances, rwlock_instances or socket_instance tables.

It contains the following columns:

Column	Description
NAME	Instrument name
ENABLED	Whether or not the instrument is enabled. It can be disabled, and the instrument will produce no events.
TIMED	Whether or not the instrument is timed. It can be set, but if disabled, events produced by the instrument will have NULL values for the corresponding TIMER_START, TIMER_END, and TIMER_WAIT values.

Example

From MariaDB 10.5.7, default settings with the Performance Schema enabled:

```
SELECT * FROM setup_instruments ORDER BY name;
+--------------------------------------------------------------------------------+---------+-----
| NAME                                                                           | ENABLED | TIME
+--------------------------------------------------------------------------------+---------+-----
| idle                                                                           | YES     | YES
| memory/csv/blobroot                                                            | NO      | NO
| memory/csv/row                                                                 | NO      | NO
| memory/csv/tina_set                                                            | NO      | NO
| memory/csv/TINA_SHARE                                                          | NO      | NO
| memory/csv/Transparent_file                                                    | NO      | NO
| memory/innodb/adaptive hash index                                              | NO      | NO
| memory/innodb/btr0btr                                                          | NO      | NO
| memory/innodb/btr0buf                                                          | NO      | NO
| memory/innodb/btr0bulk                                                         | NO      | NO
| memory/innodb/btr0cur                                                          | NO      | NO
| memory/innodb/btr0pcur                                                         | NO      | NO
| memory/innodb/btr0sea                                                          | NO      | NO
| memory/innodb/buf0buf                                                          | NO      | NO
| memory/innodb/buf0dblwr                                                        | NO      | NO
| memory/innodb/buf0dump                                                         | NO      | NO
| memory/innodb/buf_buf_pool                                                     | NO      | NO
| memory/innodb/dict0dict                                                        | NO      | NO
| memory/innodb/dict0mem                                                         | NO      | NO
| memory/innodb/dict0stats                                                       | NO      | NO
| memory/innodb/dict_stats_bg_recalc_pool_t                                      | NO      | NO
| memory/innodb/dict_stats_index_map_t                                           | NO      | NO
| memory/innodb/dict_stats_n_diff_on_level                                       | NO      | NO
| memory/innodb/eval0eval                                                        | NO      | NO
| memory/innodb/fil0crypt                                                        | NO      | NO
| memory/innodb/fil0fil                                                          | NO      | NO
| memory/innodb/fsp0file                                                         | NO      | NO
| memory/innodb/fts0ast                                                          | NO      | NO
| memory/innodb/fts0blex                                                         | NO      | NO
| memory/innodb/fts0config                                                       | NO      | NO
| memory/innodb/fts0file                                                         | NO      | NO
| memory/innodb/fts0fts                                                          | NO      | NO

1.1.1.2.9.2.1.67 Performance Schema setup_objects Table

Description

The `setup_objects` table determines whether objects are monitored by the performance schema or not. By default limited to 100 rows, this can be changed by setting the performance_schema_setup_objects_size system variable when the server starts.

It contains the following columns:

Column	Description
`OBJECT_TYPE`	Type of object to instrument, currently only . Currently, only `TABLE'` , for base table.
`OBJECT_SCHEMA`	Schema containing the object, either the literal or `%` for any schema.
`OBJECT_NAME`	Name of the instrumented object, either the literal or `%` for any object.
`ENABLED`	Whether the object's events are instrumented or not. Can be disabled, in which case monitoring is not enabled for those objects.
`TIMED`	Whether the object's events are timed or not. Can be modified.

When the Performance Schema looks for matches in the `setup_objects`, there may be more than one row matching, with different `ENABLED` and `TIMED` values. It looks for the most specific matches first, that is, it will first look for the specific database and table name combination, then the specific database, only then falling back to a wildcard for both.

Rows can be added or removed from the table, while for existing rows, only the `TIMED` and `ENABLED` columns can be updated. By default, all tables except those in the `performance_schema`, `information_schema` and `mysql` databases are instrumented.

1.1.1.2.9.2.1.68 Performance Schema setup_timers Table

Description

The `setup_timers` table shows the currently selected event timers.

It contains the following columns:

Column	Description
`NAME`	Type of instrument the timer is used for.
`TIMER_NAME`	Timer applying to the instrument type. Can be modified.

The `TIMER_NAME` value can be changed to choose a different timer, and can be any non-NULL value in the performance_timers.TIMER_NAME column.

If you modify the table, monitoring is immediately affected, and currently monitored events would use a combination of old and new timers, which is probably undesirable. It is best to reset the Performance Schema statistics if you make changes to this table.

Example

```
SELECT * FROM setup_timers;
+-----------+-------------+
| NAME      | TIMER_NAME  |
+-----------+-------------+
| idle      | MICROSECOND |
| wait      | CYCLE       |
| stage     | NANOSECOND  |
| statement | NANOSECOND  |
+-----------+-------------+
```

1.1.1.2.9.2.1.69 Performance Schema socket_instances Table

The `socket_instances` table lists active server connections, with each record being a Unix socket file or TCP/IP connection.

The `socket_instances` table contains the following columns:

Column	Description
`EVENT_NAME`	`NAME` from the `setup_instruments` table, and the name of the `wait/io/socket/*` instrument that produced the event.
`OBJECT_INSTANCE_BEGIN`	Memory address of the object.
`THREAD_ID`	Thread identifier that the server assigns to each socket.
`SOCKET_ID`	The socket's internal file handle.
`IP`	Client IP address. Blank for Unix socket file, otherwise an IPv4 or IPv6 address. Together with the PORT identifies the connection.
`PORT`	TCP/IP port number, from 0 to 65535. Together with the IP identifies the connection.

STATE	Socket status, either IDLE if waiting to receive a request from a client, or ACTIVE

1.1.1.2.9.2.1.70 Performance Schema socket_summary_by_event_name Table

It aggregates timer and byte count statistics for all socket I/O operations by socket instrument.

Column	Description
EVENT_NAME	Socket instrument.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
COUNT_READ	Number of all read operations, including RECV , RECVFROM , and RECVMSG .
SUM_TIMER_READ	Total wait time of all read operations that are timed.
MIN_TIMER_READ	Minimum wait time of all read operations that are timed.
AVG_TIMER_READ	Average wait time of all read operations that are timed.
MAX_TIMER_READ	Maximum wait time of all read operations that are timed.
SUM_NUMBER_OF_BYTES_READ	Bytes read by read operations.
COUNT_WRITE	Number of all write operations, including SEND , SENDTO , and SENDMSG .
SUM_TIMER_WRITE	Total wait time of all write operations that are timed.
MIN_TIMER_WRITE	Minimum wait time of all write operations that are timed.
AVG_TIMER_WRITE	Average wait time of all write operations that are timed.
MAX_TIMER_WRITE	Maximum wait time of all write operations that are timed.
SUM_NUMBER_OF_BYTES_WRITE	Bytes written by write operations.
COUNT_MISC	Number of all miscellaneous operations not counted above, including CONNECT , LISTEN , ACCEPT , CLOSE , and SHUTDOWN .
SUM_TIMER_MISC	Total wait time of all miscellaneous operations that are timed.
MIN_TIMER_MISC	Minimum wait time of all miscellaneous operations that are timed.
AVG_TIMER_MISC	Average wait time of all miscellaneous operations that are timed.
MAX_TIMER_MISC	Maximum wait time of all miscellaneous operations that are timed.

You can TRUNCATE the table, which will reset all counters to zero.

Example

```
SELECT * FROM socket_summary_by_event_name\G
*************************** 1. row ***************************
               EVENT_NAME: wait/io/socket/sql/server_tcpip_socket
               COUNT_STAR: 0
           SUM_TIMER_WAIT: 0
           MIN_TIMER_WAIT: 0
           AVG_TIMER_WAIT: 0
           MAX_TIMER_WAIT: 0
               COUNT_READ: 0
           SUM_TIMER_READ: 0
           MIN_TIMER_READ: 0
           AVG_TIMER_READ: 0
           MAX_TIMER_READ: 0

           AVG_TIMER_MISC: 0
           MAX_TIMER_MISC: 0
...
```

1.1.1.2.9.2.1.71 Performance Schema socket_summary_by_instance Table

It aggregates timer and byte count statistics for all socket I/O operations by socket instance.

Column	Description
EVENT_NAME	Socket instrument.
OBJECT_INSTANCE_BEGIN	Address in memory.
COUNT_STAR	Number of summarized events
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.

MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
COUNT_READ	Number of all read operations, including RECV, RECVFROM, and RECVMSG.
SUM_TIMER_READ	Total wait time of all read operations that are timed.
MIN_TIMER_READ	Minimum wait time of all read operations that are timed.
AVG_TIMER_READ	Average wait time of all read operations that are timed.
MAX_TIMER_READ	Maximum wait time of all read operations that are timed.
SUM_NUMBER_OF_BYTES_READ	Bytes read by read operations.
COUNT_WRITE	Number of all write operations, including SEND, SENDTO, and SENDMSG.
SUM_TIMER_WRITE	Total wait time of all write operations that are timed.
MIN_TIMER_WRITE	Minimum wait time of all write operations that are timed.
AVG_TIMER_WRITE	Average wait time of all write operations that are timed.
MAX_TIMER_WRITE	Maximum wait time of all write operations that are timed.
SUM_NUMBER_OF_BYTES_WRITE	Bytes written by write operations.
COUNT_MISC	Number of all miscellaneous operations not counted above, including CONNECT, LISTEN, ACCEPT, CLOSE, and SHUTDOWN.
SUM_TIMER_MISC	Total wait time of all miscellaneous operations that are timed.
MIN_TIMER_MISC	Minimum wait time of all miscellaneous operations that are timed.
AVG_TIMER_MISC	Average wait time of all miscellaneous operations that are timed.
MAX_TIMER_MISC	Maximum wait time of all miscellaneous operations that are timed.

The corresponding row in the table is deleted when a connection terminates.

You can TRUNCATE the table, which will reset all counters to zero.

1.1.1.2.9.2.1.72 Performance Schema status_by_account Table

MariaDB starting with 10.5.2

The status_by_account table was added in MariaDB 10.5.2.

The status_by_account table contains status variable information by user/host account. The table does not collect statistics for Com_xxx variables.

The table contains the following columns:

Column	Description
USER	User for which the status variable is reported.
HOST	Host for which the status variable is reported.
VARIABLE_NAME	Status variable name.
VARIABLE_VALUE	Aggregated status variable value

If TRUNCATE TABLE is run, will aggregate the status from terminated sessions to user and host status, then reset the account status.

If FLUSH STATUS is run, session status from all active sessions are added to the global status variables, the status of all active sessions are reset, and values aggregated from disconnected sessions are reset.

1.1.1.2.9.2.1.73 Performance Schema status_by_host Table

MariaDB starting with 10.5.2

The `status_by_host` table was added in MariaDB 10.5.2.

The `status_by_host` table contains status variable information by host. The table does not collect statistics for `Com_xxx` variables.

The table contains the following columns:

Column	Description
HOST	Host for which the status variable is reported.
VARIABLE_NAME	Status variable name.
VARIABLE_VALUE	Aggregated status variable value

If TRUNCATE TABLE is run, will reset the aggregated host status from terminated sessions.

If FLUSH STATUS is run, session status from all active sessions are added to the global status variables, the status of all active sessions are reset, and values aggregated from disconnected sessions are reset.

1.1.1.2.9.2.1.74 Performance Schema status_by_thread Table

MariaDB starting with 10.5.2

The `session_status` table was added in MariaDB 10.5.2.

The `status_by_thread` table contains status variable information about active foreground threads. The table does not collect statistics for `Com_xxx` variables.

The table contains the following columns:

Column	Description
`THREAD_ID`	The thread identifier of the session in which the status variable is defined.
`VARIABLE_NAME`	Status variable name.
`VARIABLE_VALUE`	Aggregated status variable value.

If TRUNCATE TABLE is run, will aggregate the status for all threads to the global status and account status, then reset the thread status. If account statistics are not collected but host and user status are, the session status is added to host and user status.

1.1.1.2.9.2.1.75 Performance Schema status_by_user Table

MariaDB starting with 10.5.2

The `status_by_account` table was added in MariaDB 10.5.2.

The `status_by_account` table contains status variable information by user. The table does not collect statistics for `Com_xxx` variables.

The table contains the following columns:

Column	Description
USER	User for which the status variable is reported.
VARIABLE_NAME	Status variable name.
VARIABLE_VALUE	Aggregated status variable value

If TRUNCATE TABLE is run, will reset the aggregated user status from terminated sessions.

If FLUSH STATUS is run, session status from all active sessions are added to the global status variables, the status of all active sessions are reset, and values aggregated from disconnected sessions are reset.

1.1.1.2.9.2.1.76 Performance Schema table_handles Table

MariaDB starting with 10.5.2

The `table_handles` table was added in MariaDB 10.5.2.

The `table_handles` table contains table lock information. It uses the `wait/lock/table/sql/handler` instrument, which is enabled by default.

Information includes which table handles are open, which sessions are holding the locks, and how they are locked.

The table is read-only, and TRUNCATE TABLE cannot be performed on the table.

The maximum number of opened table objects is determined by the performance_schema_max_table_handles system variable.

The table contains the following columns:

Column	Description
OBJECT_TYPE	The table opened by a table handle.
OBJECT_SCHEMA	The schema that contains the object.
OBJECT_NAME	The name of the instrumented object.
OBJECT_INSTANCE_BEGIN	The table handle address in memory.
OWNER_THREAD_ID	The thread owning the table handle.
OWNER_EVENT_ID	The event which caused the table handle to be opened.
INTERNAL_LOCK	The table lock used at the SQL level.
EXTERNAL_LOCK	The table lock used at the storage engine level.

1.1.1.2.9.2.1.77 Performance Schema table_io_waits_summary_by_index_usage Table

The `table_io_waits_summary_by_index_usage` table records table I/O waits by index.

Column	Description
`OBJECT_TYPE`	`TABLE` in the case of all indexes.
`OBJECT_SCHEMA`	Schema name.
`OBJECT_NAME`	Table name.
`INDEX_NAME`	Index name, or `PRIMARY` for the primary index, `NULL` for no index (inserts are counted in this case).
`COUNT_STAR`	Number of summarized events and the sum of the `x_READ` and `x_WRITE` columns.
`SUM_TIMER_WAIT`	Total wait time of the summarized events that are timed.
`MIN_TIMER_WAIT`	Minimum wait time of the summarized events that are timed.
`AVG_TIMER_WAIT`	Average wait time of the summarized events that are timed.
`MAX_TIMER_WAIT`	Maximum wait time of the summarized events that are timed.
`COUNT_READ`	Number of all read operations, and the sum of the equivalent `x_FETCH` columns.
`SUM_TIMER_READ`	Total wait time of all read operations that are timed.
`MIN_TIMER_READ`	Minimum wait time of all read operations that are timed.
`AVG_TIMER_READ`	Average wait time of all read operations that are timed.
`MAX_TIMER_READ`	Maximum wait time of all read operations that are timed.

COUNT_WRITE	Number of all write operations, and the sum of the equivalent x_INSERT, x_UPDATE and x_DELETE columns.
SUM_TIMER_WRITE	Total wait time of all write operations that are timed.
MIN_TIMER_WRITE	Minimum wait time of all write operations that are timed.
AVG_TIMER_WRITE	Average wait time of all write operations that are timed.
MAX_TIMER_WRITE	Maximum wait time of all write operations that are timed.
COUNT_FETCH	Number of all fetch operations.
SUM_TIMER_FETCH	Total wait time of all fetch operations that are timed.
MIN_TIMER_FETCH	Minimum wait time of all fetch operations that are timed.
AVG_TIMER_FETCH	Average wait time of all fetch operations that are timed.
MAX_TIMER_FETCH	Maximum wait time of all fetch operations that are timed.
COUNT_INSERT	Number of all insert operations.
SUM_TIMER_INSERT	Total wait time of all insert operations that are timed.
MIN_TIMER_INSERT	Minimum wait time of all insert operations that are timed.
AVG_TIMER_INSERT	Average wait time of all insert operations that are timed.
MAX_TIMER_INSERT	Maximum wait time of all insert operations that are timed.
COUNT_UPDATE	Number of all update operations.
SUM_TIMER_UPDATE	Total wait time of all update operations that are timed.
MIN_TIMER_UPDATE	Minimum wait time of all update operations that are timed.
AVG_TIMER_UPDATE	Average wait time of all update operations that are timed.
MAX_TIMER_UPDATE	Maximum wait time of all update operations that are timed.
COUNT_DELETE	Number of all delete operations.
SUM_TIMER_DELETE	Total wait time of all delete operations that are timed.
MIN_TIMER_DELETE	Minimum wait time of all delete operations that are timed.
AVG_TIMER_DELETE	Average wait time of all delete operations that are timed.
MAX_TIMER_DELETE	Maximum wait time of all delete operations that are timed.

You can TRUNCATE the table, which will reset all counters to zero. The table is also truncated if the table_io_waits_summary_by_table table is truncated.

If a table's index structure is changed, index statistics recorded in this table may also be reset.

1.1.1.2.9.2.1.78 Performance Schema table_io_waits_summary_by_table Table

The table_io_waits_summary_by_table table records table I/O waits by table.

Column	Description
OBJECT_TYPE	Since this table records waits by table, always set to TABLE.
OBJECT_SCHEMA	Schema name.
OBJECT_NAME	Table name.
COUNT_STAR	Number of summarized events and the sum of the x_READ and x_WRITE columns.
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.

COUNT_READ	Number of all read operations, and the sum of the equivalent x_FETCH columns.
SUM_TIMER_READ	Total wait time of all read operations that are timed.
MIN_TIMER_READ	Minimum wait time of all read operations that are timed.
AVG_TIMER_READ	Average wait time of all read operations that are timed.
MAX_TIMER_READ	Maximum wait time of all read operations that are timed.
COUNT_WRITE	Number of all write operations, and the sum of the equivalent x_INSERT, x_UPDATE and x_DELETE columns.
SUM_TIMER_WRITE	Total wait time of all write operations that are timed.
MIN_TIMER_WRITE	Minimum wait time of all write operations that are timed.
AVG_TIMER_WRITE	Average wait time of all write operations that are timed.
MAX_TIMER_WRITE	Maximum wait time of all write operations that are timed.
COUNT_FETCH	Number of all fetch operations.
SUM_TIMER_FETCH	Total wait time of all fetch operations that are timed.
MIN_TIMER_FETCH	Minimum wait time of all fetch operations that are timed.
AVG_TIMER_FETCH	Average wait time of all fetch operations that are timed.
MAX_TIMER_FETCH	Maximum wait time of all fetch operations that are timed.
COUNT_INSERT	Number of all insert operations.
SUM_TIMER_INSERT	Total wait time of all insert operations that are timed.
MIN_TIMER_INSERT	Minimum wait time of all insert operations that are timed.
AVG_TIMER_INSERT	Average wait time of all insert operations that are timed.
MAX_TIMER_INSERT	Maximum wait time of all insert operations that are timed.
COUNT_UPDATE	Number of all update operations.
SUM_TIMER_UPDATE	Total wait time of all update operations that are timed.
MIN_TIMER_UPDATE	Minimum wait time of all update operations that are timed.
AVG_TIMER_UPDATE	Average wait time of all update operations that are timed.
MAX_TIMER_UPDATE	Maximum wait time of all update operations that are timed.
COUNT_DELETE	Number of all delete operations.
SUM_TIMER_DELETE	Total wait time of all delete operations that are timed.
MIN_TIMER_DELETE	Minimum wait time of all delete operations that are timed.
AVG_TIMER_DELETE	Average wait time of all delete operations that are timed.
MAX_TIMER_DELETE	Maximum wait time of all delete operations that are timed.

You can TRUNCATE the table, which will reset all counters to zero. Truncating this table will also truncate the table_io_waits_summary_by_index_usage table.

1.1.1.2.9.2.1.79 Performance Schema table_lock_waits_summary_by_table Table

The table_lock_waits_summary_by_table table records table lock waits by table.

Column	Description
OBJECT_TYPE	Since this table records waits by table, always set to TABLE.
OBJECT_SCHEMA	Schema name.

OBJECT_NAME	Table name.
COUNT_STAR	Number of summarized events and the sum of the x_READ and x_WRITE columns.
SUM_TIMER_WAIT	Total wait time of the summarized events that are timed.
MIN_TIMER_WAIT	Minimum wait time of the summarized events that are timed.
AVG_TIMER_WAIT	Average wait time of the summarized events that are timed.
MAX_TIMER_WAIT	Maximum wait time of the summarized events that are timed.
COUNT_READ	Number of all read operations, and the sum of the equivalent x_READ_NORMAL, x_READ_WITH_SHARED_LOCKS, x_READ_HIGH_PRIORITY and x_READ_NO_INSERT columns.
SUM_TIMER_READ	Total wait time of all read operations that are timed.
MIN_TIMER_READ	Minimum wait time of all read operations that are timed.
AVG_TIMER_READ	Average wait time of all read operations that are timed.
MAX_TIMER_READ	Maximum wait time of all read operations that are timed.
COUNT_WRITE	Number of all write operations, and the sum of the equivalent x_WRITE_ALLOW_WRITE, x_WRITE_CONCURRENT_INSERT, x_WRITE_DELAYED, x_WRITE_LOW_PRIORITY and x_WRITE_NORMAL columns.
SUM_TIMER_WRITE	Total wait time of all write operations that are timed.
MIN_TIMER_WRITE	Minimum wait time of all write operations that are timed.
AVG_TIMER_WRITE	Average wait time of all write operations that are timed.
MAX_TIMER_WRITE	Maximum wait time of all write operations that are timed.
COUNT_READ_NORMAL	Number of all internal read normal locks.
SUM_TIMER_READ_NORMAL	Total wait time of all internal read normal locks that are timed.
MIN_TIMER_READ_NORMAL	Minimum wait time of all internal read normal locks that are timed.
AVG_TIMER_READ_NORMAL	Average wait time of all internal read normal locks that are timed.
MAX_TIMER_READ_NORMAL	Maximum wait time of all internal read normal locks that are timed.
COUNT_READ_WITH_SHARED_LOCKS	Number of all internal read with shared locks.
SUM_TIMER_READ_WITH_SHARED_LOCKS	Total wait time of all internal read with shared locks that are timed.
MIN_TIMER_READ_WITH_SHARED_LOCKS	Minimum wait time of all internal read with shared locks that are timed.
AVG_TIMER_READ_WITH_SHARED_LOCKS	Average wait time of all internal read with shared locks that are timed.
MAX_TIMER_READ_WITH_SHARED_LOCKS	Maximum wait time of all internal read with shared locks that are timed.
COUNT_READ_HIGH_PRIORITY	Number of all internal read high priority locks.
SUM_TIMER_READ_HIGH_PRIORITY	Total wait time of all internal read high priority locks that are timed.
MIN_TIMER_READ_HIGH_PRIORITY	Minimum wait time of all internal read high priority locks that are timed.
AVG_TIMER_READ_HIGH_PRIORITY	Average wait time of all internal read high priority locks that are timed.
MAX_TIMER_READ_HIGH_PRIORITY	Maximum wait time of all internal read high priority locks that are timed.
COUNT_READ_NO_INSERT	Number of all internal read no insert locks.
SUM_TIMER_READ_NO_INSERT	Total wait time of all internal read no insert locks that are timed.
MIN_TIMER_READ_NO_INSERT	Minimum wait time of all internal read no insert locks that are timed.
AVG_TIMER_READ_NO_INSERT	Average wait time of all internal read no insert locks that are timed.
MAX_TIMER_READ_NO_INSERT	Maximum wait time of all internal read no insert locks that are timed.
COUNT_READ_EXTERNAL	Number of all external read locks.

SUM_TIMER_READ_EXTERNAL	Total wait time of all external read locks that are timed.
MIN_TIMER_READ_EXTERNAL	Minimum wait time of all external read locks that are timed.
AVG_TIMER_READ_EXTERNAL	Average wait time of all external read locks that are timed.
MAX_TIMER_READ_EXTERNAL	Maximum wait time of all external read locks that are timed.
COUNT_WRITE_ALLOW_WRITE	Number of all internal read normal locks.
SUM_TIMER_WRITE_ALLOW_WRITE	Total wait time of all internal write allow write locks that are timed.
MIN_TIMER_WRITE_ALLOW_WRITE	Minimum wait time of all internal write allow write locks that are timed.
AVG_TIMER_WRITE_ALLOW_WRITE	Average wait time of all internal write allow write locks that are timed.
MAX_TIMER_WRITE_ALLOW_WRITE	Maximum wait time of all internal write allow write locks that are timed.
COUNT_WRITE_CONCURRENT_INSERT	Number of all internal concurrent insert write locks.
SUM_TIMER_WRITE_CONCURRENT_INSERT	Total wait time of all internal concurrent insert write locks that are timed.
MIN_TIMER_WRITE_CONCURRENT_INSERT	Minimum wait time of all internal concurrent insert write locks that are timed.
AVG_TIMER_WRITE_CONCURRENT_INSERT	Average wait time of all internal concurrent insert write locks that are timed.
MAX_TIMER_WRITE_CONCURRENT_INSERT	Maximum wait time of all internal concurrent insert write locks that are timed.
COUNT_WRITE_DELAYED	Number of all internal write delayed locks.
SUM_TIMER_WRITE_DELAYED	Total wait time of all internal write delayed locks that are timed.
MIN_TIMER_WRITE_DELAYED	Minimum wait time of all internal write delayed locks that are timed.
AVG_TIMER_WRITE_DELAYED	Average wait time of all internal write delayed locks that are timed.
MAX_TIMER_WRITE_DELAYED	Maximum wait time of all internal write delayed locks that are timed.
COUNT_WRITE_LOW_PRIORITY	Number of all internal write low priority locks.
SUM_TIMER_WRITE_LOW_PRIORITY	Total wait time of all internal write low priority locks that are timed.
MIN_TIMER_WRITE_LOW_PRIORITY	Minimum wait time of all internal write low priority locks that are timed.
AVG_TIMER_WRITE_LOW_PRIORITY	Average wait time of all internal write low priority locks that are timed.
MAX_TIMER_WRITE_LOW_PRIORITY	Maximum wait time of all internal write low priority locks that are timed.
COUNT_WRITE_NORMAL	Number of all internal write normal locks.
SUM_TIMER_WRITE_NORMAL	Total wait time of all internal write normal locks that are timed.
MIN_TIMER_WRITE_NORMAL	Minimum wait time of all internal write normal locks that are timed.
AVG_TIMER_WRITE_NORMAL	Average wait time of all internal write normal locks that are timed.
MAX_TIMER_WRITE_NORMAL	Maximum wait time of all internal write normal locks that are timed.
COUNT_WRITE_EXTERNAL	Number of all external write locks.
SUM_TIMER_WRITE_EXTERNAL	Total wait time of all external write locks that are timed.
MIN_TIMER_WRITE_EXTERNAL	Minimum wait time of all external write locks that are timed.
AVG_TIMER_WRITE_EXTERNAL	Average wait time of all external write locks that are timed.
MAX_TIMER_WRITE_EXTERNAL	Maximum wait time of all external write locks that are timed.

You can TRUNCATE the table, which will reset all counters to zero.

1.1.1.2.9.2.1.80 Performance Schema threads Table

Each server thread is represented as a row in the `threads` table.

The `threads` table contains the following columns:

Column	Description

THREAD_ID	A unique thread identifier.
NAME	Name associated with the server's thread instrumentation code, for example thread/sql/main for the server's main() function, and thread/sql/one_connection for a user connection.
TYPE	FOREGROUND or BACKGROUND, depending on the thread type. User connection threads are FOREGROUND, internal server threads are BACKGROUND.
PROCESSLIST_ID	The PROCESSLIST.ID value for threads displayed in the INFORMATION_SCHEMA.PROCESSLIST table, or 0 for background threads. Also corresponds with the CONNECTION_ID() return value for the thread.
PROCESSLIST_USER	Foreground thread user, or NULL for a background thread.
PROCESSLIST_HOST	Foreground thread host, or NULL for a background thread.
PROCESSLIST_DB	Thread's default database, or NULL if none exists.
PROCESSLIST_COMMAND	Type of command executed by the thread. These correspond to the the COM_xxx client/server protocol commands, and the Com_xxx status variables. See Thread Command Values.
PROCESSLIST_TIME	Time in seconds the thread has been in its current state.
PROCESSLIST_STATE	Action, event or state indicating what the thread is doing.
PROCESSLIST_INFO	Statement being executed by the thread, or NULL if a statement is not being executed. If a statement results in calling other statements, such as for a stored procedure, the innermost statement from the stored procedure is shown here.
PARENT_THREAD_ID	THREAD_ID of the parent thread, if any. Subthreads can for example be spawned as a result of INSERT DELAYED statements.
ROLE	Unused.
INSTRUMENTED	YES or NO for Whether the thread is instrumented or not. For foreground threads, the initial value is determined by whether there's a user/host match in the setup_actors table. Subthreads are again matched, while for background threads, this will be set to YES by default. To monitor events that the thread executes, INSTRUMENTED must be YES and the thread_instrumentation consumer in the setup_consumers table must also be YES.
HISTORY	YES or NO for Whether to log historical events for the thread. For foreground threads, the initial value is determined by whether there's a user/host match in the setup_actors table. Subthreads are again matched, while for background threads, this will be set to YES by default. To monitor events that the thread executes, INSTRUMENTED must be YES and the thread_instrumentation consumer in the setup_consumers table must also be YES. Added in MariaDB 10.5.
CONNECTION_TYPE	The protocol used to establish the connection. One of TCP/IP, SSL/TLS, Socket, Named Pipe, Shared Memory, or NULL for background threads. Added in MariaDB 10.5.
THREAD_OS_ID	The thread or task identifier as defined by the underlying operating system, if there is one. Added in MariaDB 10.5

Example

```
SELECT * FROM performance_schema.threads\G;
*************************** 1. row ***************************
          THREAD_ID: 1
               NAME: thread/sql/main
               TYPE: BACKGROUND
     PROCESSLIST_ID: NULL
   PROCESSLIST_USER: NULL
   PROCESSLIST_HOST: NULL
     PROCESSLIST_DB: NULL
PROCESSLIST_COMMAND: NULL
   PROCESSLIST_TIME: 215859
  PROCESSLIST_STATE: Table lock
   PROCESSLIST_INFO: INTERNAL DDL LOG RECOVER IN PROGRESS
   PARENT_THREAD_ID: NULL
               ROLE: NULL
       INSTRUMENTED: YES
...
*************************** 21. row ***************************
          THREAD_ID: 64
               NAME: thread/sql/one_connection
               TYPE: FOREGROUND
     PROCESSLIST_ID: 44
   PROCESSLIST_USER: root
   PROCESSLIST_HOST: localhost
     PROCESSLIST_DB: NULL
PROCESSLIST_COMMAND: Query
   PROCESSLIST_TIME: 0
  PROCESSLIST_STATE: Sending data
   PROCESSLIST_INFO: SELECT * FROM performance_schema.threads
   PARENT_THREAD_ID: NULL
               ROLE: NULL
       INSTRUMENTED: YES
```

1.1.1.2.9.2.1.81 Performance Schema user_variables_by_thread Table

MariaDB starting with 10.5.2

The `user_variables_by_thread` table was added in MariaDB 10.5.2.

The `user_variables_by_thread` table contains information about user-defined variables and the threads that defined them.

TRUNCATE TABLE cannot be performed on the table.

The table contains the following columns:

Column	Description
THREAD_ID	The thread identifier of the session in which the variable is defined.
VARIABLE_NAME	The variable name, without the leading @ character.
VARIABLE_VALUE	The variable value

Example

```
SET @var = 0;

SELECT * FROM user_variables_by_thread;
+-----------+---------------+----------------+
| THREAD_ID | VARIABLE_NAME | VARIABLE_VALUE |
+-----------+---------------+----------------+
|        11 | var           | 0              |
+-----------+---------------+----------------+
```

1.1.1.2.9.2.1.82 Performance Schema users Table

Description

Each user that connects to the server is stored as a row in the `users` table, along with current and total connections.

The table size is determined at startup by the value of the performance_schema_users_size system variable. If this is set to `0`, user statistics will be disabled.

Column	Description
`USER`	The connection's client user name for the connection, or `NULL` if an internal thread.
`CURRENT_CONNECTIONS`	Current connections for the user.
`TOTAL_CONNECTIONS`	Total connections for the user.

Example

```
SELECT * FROM performance_schema.users;
+------------------+---------------------+-------------------+
| USER             | CURRENT_CONNECTIONS | TOTAL_CONNECTIONS |
+------------------+---------------------+-------------------+
| debian-sys-maint |                   0 |                35 |
| NULL             |                  20 |                23 |
| root             |                   1 |                 2 |
+------------------+---------------------+-------------------+
```

1.1.1.2.9.2.2 Performance Schema Overview

Contents

The Performance Schema is a feature for monitoring server performance.

Introduction

It is implemented as a storage engine, and so will appear in the list of storage engines available.

```
SHOW ENGINES;
+--------------------+---------+----------------------------------+--------------+------+--------
| Engine             | Support | Comment                          | Transactions | XA   | Savepoi
+--------------------+---------+----------------------------------+--------------+------+--------
| ...                |         |                                  |              |      |
| PERFORMANCE_SCHEMA | YES     | Performance Schema               | NO           | NO   | NO
| ...                |         |                                  |              |      |
+--------------------+---------+----------------------------------+--------------+------+--------
```

However, `performance_schema` is not a regular storage engine for storing data, it's a mechanism for implementing the Performance Schema feature.

The storage engine contains a database called `performance_schema`, which in turn consists of a number of tables that can be queried with regular SQL statements, returning specific performance information.

```
USE performance_schema
```

```
SHOW TABLES;
+-----------------------------------------------+
| Tables_in_performance_schema                  |
+-----------------------------------------------+
| accounts                                      |
...
| users                                         |
+-----------------------------------------------+
80 rows in set (0.00 sec)
```

See List of Performance Schema Tables for a full list and links to detailed descriptions of each table. From MariaDB 10.5, there are 80 Performance Schema tables, while until MariaDB 10.4, there are 52.

Activating the Performance Schema

The performance schema is disabled by default for performance reasons. You can check its current status by looking at the value of the performance_schema system variable.

```
SHOW VARIABLES LIKE 'performance_schema';
+--------------------+-------+
| Variable_name      | Value |
+--------------------+-------+
| performance_schema | ON    |
+--------------------+-------+
```

The performance schema cannot be activated at runtime - it must be set when the server starts by adding the following line in your `my.cnf` configuration file.

```
performance_schema=ON
```

Until MariaDB 10.4, all memory used by the Performance Schema is allocated at startup. From MariaDB 10.5, some memory is allocated dynamically, depending on load, number of connections, number of tables open etc.

Enabling the Performance Schema

You need to set up all consumers (starting collection of data) and instrumentations (what to collect):

```
UPDATE performance_schema.setup_consumers SET ENABLED = 'YES';
UPDATE performance_schema.setup_instruments SET ENABLED = 'YES', TIMED = 'YES';
```

You can decide what to enable/disable with `WHERE NAME like "%what_to_enable"` ; You can disable instrumentations by setting `ENABLED` to `"NO"` .

You can also do this in your my.cnf file. The following enables all instrumentation of all stages (computation units) in MariaDB:

```
[mysqld]
performance_schema=ON
performance-schema-instrument='stage/%=ON'
performance-schema-consumer-events-stages-current=ON
performance-schema-consumer-events-stages-history=ON
performance-schema-consumer-events-stages-history-long=ON
```

Listing Performance Schema Variables

```
SHOW VARIABLES LIKE "perf%";
+----------------------------------------------------+-------+
| Variable_name                                      | Value |
+----------------------------------------------------+-------+
| performance_schema                                 | ON    |
...
| performance_schema_users_size                      | 100   |
+----------------------------------------------------+-------+
```

See Performance Schema System Variables for a full list of available system variables.

Note that the "consumer" events are not shown on this list, as they are only available as options, not as system variables, and they can only be enabled at startup.

Column Comments

MariaDB starting with 10.7.1

From MariaDB 10.7.1, comments have been added to table columns in the Performance Schema. These can be viewed with, for example:

```
SELECT column_name, column_comment FROM information_schema.columns
  WHERE table_schema='performance_schema' AND table_name='file_instances';
...
*************************** 2. row ***************************
   column_name: EVENT_NAME
column_comment: Instrument name associated with the file.
*************************** 3. row ***************************
   column_name: OPEN_COUNT
column_comment: Open handles on the file. A value of greater than zero means
                that the file is currently open.
...
```

1.1.1.2.9.2.3 Performance Schema Status Variables

Contents

This page documents status variables related to the Performance Schema. See Server Status Variables for a complete list of status variables that can be viewed with SHOW STATUS.

See also the Full list of MariaDB options, system and status variables.

`Performance_schema_accounts_lost`

- **Description:** Number of times a row could not be added to the performance schema accounts table due to it being full. The global value can be flushed by FLUSH STATUS.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Performance_schema_cond_classes_lost

- **Description:** Number of condition instruments that could not be loaded.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Performance_schema_cond_instances_lost

- **Description:** Number of instances a condition object could not be created. The global value can be flushed by FLUSH STATUS.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Performance_schema_digest_lost

- **Description:** The global value can be flushed by FLUSH STATUS.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Performance_schema_file_classes_lost

- **Description:** Number of file instruments that could not be loaded.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Performance_schema_file_handles_lost

- **Description:** Number of instances a file object could not be opened. The global value can be flushed by FLUSH STATUS.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Performance_schema_file_instances_lost

- **Description:** Number of instances a file object could not be created. The global value can be flushed by FLUSH STATUS.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Performance_schema_hosts_lost

- **Description:** Number of times a row could not be added to the performance schema hosts table due to it being full. The global value can be flushed by FLUSH STATUS.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Performance_schema_index_stat_lost

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.5.2

Performance_schema_locker_lost

- **Description:** Number of events not recorded, due to either being recursive, or having a deeper nested events stack than the implementation limit. The global value can be flushed by FLUSH STATUS.

- **Scope:** Global, Session
- **Data Type:** `numeric`

`Performance_schema_memory_classes_lost`

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.5.2

`Performance_schema_metadata_lock_lost`

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.5.2

`Performance_schema_mutex_classes_lost`

- **Description:** Number of mutual exclusion instruments that could not be loaded.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Performance_schema_mutex_instances_lost`

- **Description:** Number of instances a mutual exclusion object could not be created. The global value can be flushed by FLUSH STATUS.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Performance_schema_nested_statement_lost`

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.5.2

`Performance_schema_prepared_statements_lost`

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.5.2

`Performance_schema_program_lost`

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.5.2

`Performance_schema_rwlock_classes_lost`

- **Description:** Number of read/write lock instruments that could not be loaded.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Performance_schema_rwlock_instances_lost

- **Description:** Number of instances a read/write lock object could not be created. The global value can be flushed by FLUSH STATUS.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Performance_schema_session_connect_attrs_lost

- **Description:** Number of connections for which connection attribute truncation has occurred. The global value can be flushed by FLUSH STATUS.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Performance_schema_socket_classes_lost

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`

Performance_schema_socket_instances_lost

- **Description:** Number of instances a socket object could not be created. The global value can be flushed by FLUSH STATUS.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Performance_schema_stage_classes_lost

- **Description:** Number of stage event instruments that could not be loaded. The global value can be flushed by FLUSH STATUS.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Performance_schema_statement_classes_lost

- **Description:** Number of statement instruments that could not be loaded. The global value can be flushed by FLUSH STATUS.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Performance_schema_table_handles_lost

- **Description:** Number of instances a table object could not be opened. The global value can be flushed by FLUSH STATUS.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Performance_schema_table_instances_lost

- **Description:** Number of instances a table object could not be created. The global value can be flushed by FLUSH STATUS.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Performance_schema_table_lock_stat_lost

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.5.2

`Performance_schema_thread_classes_lost`

- **Description:** Number of thread instruments that could not be loaded.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Performance_schema_thread_instances_lost`

- **Description:** Number of instances thread object could not be created. The global value can be flushed by FLUSH STATUS.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Performance_schema_users_lost`

- **Description:** Number of times a row could not be added to the performance schema users table due to it being full. The global value can be flushed by FLUSH STATUS.
- **Scope:** Global, Session
- **Data Type:** `numeric`

1.1.1.2.9.2.4 Performance Schema System Variables

Contents

The following variables are used with MariaDB's Performance Schema. See Performance Schema Options for Performance Schema options that are not system variables. See Server System Variables for a complete list of system variables and instructions on setting them.

See also the Full list of MariaDB options, system and status variables.

performance_schema

- **Description:** If set to `1` (`0` is default), enables the Performance Schema
- **Commandline:** `--performance-schema=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

performance_schema_accounts_size

- **Description:** Maximum number of rows in the performance_schema.accounts table. If set to 0, the Performance Schema will not store statistics in the accounts table. Use `-1` (the default) for automated sizing.
- **Commandline:** `--performance-schema-accounts-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1048576`

---

performance_schema_digests_size

- **Description:** Maximum number of rows that can be stored in the events_statements_summary_by_digest table. `0` for disabling, `-1` (the default) for automated sizing.
- **Commandline:** `--performance-schema-digests-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1048576`

---

performance_schema_events_stages_history_long_size

- **Description:** Number of rows in the events_stages_history_long table. `0` for disabling, `-1` (the default) for automated sizing.
- **Commandline:** `--performance-schema-events-stages-history-long-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1048576`

---

performance_schema_events_stages_history_size

- **Description:** Number of rows per thread in the events_stages_history table. `0` for disabling, `-1` (the default) for automated sizing.
- **Commandline:** `--performance-schema-events-stages-history-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1024`

---

performance_schema_events_statements_history_long_size

- **Description:** Number of rows in the events_statements_history_long table. `0` for disabling, `-1` (the default) for automated sizing.
- **Commandline:** `--performance-schema-events-statements-history-long-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1048576`

---

performance_schema_events_statements_history_size

- **Description:** Number of rows per thread in the events_statements_history table. `0` for disabling, `-1` (the default) for automated sizing.
- **Commandline:** `--performance-schema-events-statements-history-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1024`

---

performance_schema_events_transactions_history_long_size

- **Description:** Number of rows in events_transactions_history_long table. Use `0` to disable, `-1` for automated sizing.
- **Commandline:** `--performance-schema-events-transactions-history-long-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1048576`
- **Introduced:** MariaDB 10.5.2

---

performance_schema_events_transactions_history_size

- **Description:**Number of rows per thread in events_transactions_history. Use 0 to disable, -1 for automated sizing.
- **Commandline:** `--performance-schema-events-transactions-history-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1024`
- **Introduced:** MariaDB 10.5.2

---

performance_schema_events_waits_history_long_size

- **Description:** Number of rows contained in the events_waits_history_long table. `0` for disabling, `-1` (the default) for automated sizing.
- **Commandline:** `--performance-schema-events-waits-history-long-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1048576`

---

performance_schema_events_waits_history_size

- **Description:** Number of rows per thread contained in the events_waits_history table. `0` for disabling, `-1` (the default) for automated sizing.
- **Commandline:** `--performance-schema-events-waits-history-size=#`
- **Scope:** Global

- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1024`

---

performance_schema_hosts_size

- **Description:** Number of rows stored in the hosts table. If set to zero, no connection statistics are kept for the hosts table. `-1` (the default) for automated sizing.
- **Commandline:** `--performance-schema-hosts-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1048576`

---

performance_schema_max_cond_classes

- **Description:** Specifies the maximum number of condition instruments.
- **Commandline:** `--performance-schema-max-cond-classes=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `90` (>= MariaDB 10.5.1), `80` (<= MariaDB 10.5.0)
- **Range:** `0` to `256`

---

performance_schema_max_cond_instances

- **Description:** Specifies the maximum number of instrumented condition objects. `0` for disabling, `-1` (the default) for automated sizing.
- **Commandline:** `--performance-schema-max-cond-instances=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1048576`

---

performance_schema_max_digest_length

- **Description:** Maximum length considered for digest text, when stored in performance_schema tables.
- **Commandline:** `--performance-schema-max-digest-length=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `1024`
- **Range:** `0` to `1048576`

---

performance_schema_max_file_classes

- **Description:** Specifies the maximum number of file instruments.
- **Commandline:** `--performance-schema-max-file-classes=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `80` (>= MariaDB 10.5.2), `50` (<= MariaDB 10.5.1)
- **Range:** `0` to `256`

---

performance_schema_max_file_handles

- **Description:** Specifies the maximum number of opened file objects. Should always be higher than open_files_limit.
- **Commandline:** `--performance-schema-max-file-handles=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `32768`
- **Range:** `-1` to `32768`

---

performance_schema_max_file_instances

- **Description:** Specifies the maximum number of instrumented file objects. `0` for disabling, `-1` (the default) for automated sizing.
- **Commandline:** `--performance-schema-max-file-instances=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1048576`

---

performance_schema_max_index_stat

- **Description:** Maximum number of index statistics for instrumented tables. Use 0 to disable, -1 for automated scaling.
- **Commandline:** `--performance-schema-max-index-stat=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1048576`
- **Introduced:** MariaDB 10.5.2

---

performance_schema_max_memory_classes

- **Description:** Maximum number of memory pool instruments.
- **Commandline:** `--performance-schema-max-memory-classes=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `320`
- **Range:** `0` to `1024`
- **Introduced:** MariaDB 10.5.2

---

performance_schema_max_metadata_locks

- **Description:** Maximum number of Performance Schema metadata locks. Use 0 to disable, -1 for automated scaling.
- **Commandline:** `--performance-schema-max-metadata-locks=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `104857600`
- **Introduced:** MariaDB 10.5.2

---

performance_schema_max_mutex_classes

- **Description:** Specifies the maximum number of mutex instruments.
- **Commandline:** `--performance-schema-max-mutex-classes=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `210` (>= MariaDB 10.5.2), `200` (<= MariaDB 10.5.1)

- **Range:** `0` to `256`

---

performance_schema_max_mutex_instances

- **Description:** Specifies the maximum number of instrumented mutex instances. `0` for disabling, `-1` (the default) for automated sizing.
- **Commandline:** `--performance-schema-max-mutex-instances=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `104857600`

---

performance_schema_max_prepared_statement_instances

- **Description:** Maximum number of instrumented prepared statements. Use 0 to disable, -1 for automated scaling.
- **Commandline:** `--performance-schema-max-prepared-statement-instances=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1048576`
- **Introduced:** MariaDB 10.5.2

---

performance_schema_max_program_instances

- **Description:** Maximum number of instrumented programs. Use 0 to disable, -1 for automated scaling.
- **Commandline:** `--performance-schema-max-program-instances=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1048576`
- **Introduced:** MariaDB 10.5.2

---

performance_schema_max_rwlock_classes

- **Description:** Specifies the maximum number of rwlock instruments.
- **Commandline:** `--performance-schema-max-rwlock-classes=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `50` (>= MariaDB 10.5.2), `40` (<= MariaDB 10.5.1)
- **Range:** `0` to `256`

---

performance_schema_max_rwlock_instances

- **Description:** Specifies the maximum number of instrumented rwlock objects. `0` for disabling, `-1` (the default) for automated sizing.
- **Commandline:** `--performance-schema-max-rwlock-instances=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `104857600`

---

performance_schema_max_socket_classes

- **Description:** Specifies the maximum number of socket instruments.

- **Commandline:** `--performance-schema-max-socket-classes=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `10`
- **Range:** `0` to `256`

---

performance_schema_max_socket_instances

- **Description:** Specifies the maximum number of instrumented socket objects. `0` for disabling, `-1` (the default) for automated sizing.
- **Commandline:** `--performance-schema-max-socket-instances=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1048576`

---

performance_schema_max_sql_text_length

- **Description:** Maximum length of displayed sql text.
- **Commandline:** `--performance-schema-max-sql-text-length=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `1024`
- **Range:** `0` to `1048576`
- **Introduced:** MariaDB 10.5.2

---

performance_schema_max_stage_classes

- **Description:** Specifies the maximum number of stage instruments.
- **Commandline:** `--performance-schema-max-stage-classes=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `160`
- **Range:** `0` to `256`

---

performance_schema_max_statement_classes

- **Description:** Specifies the maximum number of statement instruments. Automatically calculated at server build based on the number of available statements. Should be left as either autosized or disabled, as changing to any positive value has no benefit and will most likely allocate unnecessary memory. Setting to zero disables all statement instrumentation, and no memory will be allocated for this purpose.
- **Commandline:** `--performance-schema-max-statement-classes=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** Autosized (see description)
- **Range:** `0` to `256`

---

performance_schema_max_statement_stack

- **Description:** Number of rows per thread in EVENTS_STATEMENTS_CURRENT.
- **Commandline:** `--performance-schema-max-statement-stack=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `10`

- **Range:** `1` to `256`
- **Introduced:** MariaDB 10.5.2

---

performance_schema_max_table_handles

- **Description:** Specifies the maximum number of opened table objects. `0` for disabling, `-1` (the default) for automated sizing. See also the Performance Schema table_handles table.
- **Commandline:** `--performance-schema-max-table-handles=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1048576`

---

performance_schema_max_table_instances

- **Description:** Specifies the maximum number of instrumented table objects. `0` for disabling, `-1` (the default) for automated sizing.
- **Commandline:** `--performance-schema-max-table-instances=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1048576`

---

performance_schema_max_table_lock_stat

- **Description:** Maximum number of lock statistics for instrumented tables. Use 0 to disable, -1 for automated scaling.
- **Commandline:** `--performance-schema-max-table-lock-stat=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1048576`
- **Introduced:** MariaDB 10.5.2

---

performance_schema_max_thread_classes

- **Description:** Specifies the maximum number of thread instruments.
- **Commandline:** `--performance-schema-max-thread-classes=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `50`
- **Range:** `0` to `256`

---

performance_schema_max_thread_instances

- **Description:** Specifies how many of the running server threads (see max_connections and max_delayed_threads) can be instrumented. Should be greater than the sum of max_connections and max_delayed_threads. `0` for disabling, `-1` (the default) for automated sizing.
- **Commandline:** `--performance-schema-max-thread-instances=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1048576`

---

performance_schema_session_connect_attrs_size

- **Description:** Per thread preallocated memory for holding connection attribute strings. Incremented if the strings are larger than the reserved space. `0` for disabling, `-1` (the default) for automated sizing.
- **Commandline:** `--performance-schema-session-connect-attrs-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1048576`

---

performance_schema_setup_actors_size

- **Description:** The maximum number of rows to store in the performance schema setup_actors table. `-1` (from MariaDB 10.5.2) denotes automated sizing.
- **Commandline:** `--performance-schema-setup-actors-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1` (>= MariaDB 10.5.2), `100` (<= MariaDB 10.5.1)
- **Range:** `-1` to `1024` (>= MariaDB 10.5.2), `0` to `1024` (<= MariaDB 10.5.1)

---

performance_schema_setup_objects_size

- **Description:** The maximum number of rows that can be stored in the performance schema setup_objects table. `-1` (from MariaDB 10.5.2) denotes automated sizing.
- **Commandline:** `--performance-schema-setup-objects-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1` (>= MariaDB 10.5.2), `100` (<= MariaDB 10.5.1)
- **Range:** `-1` to `1048576` (>= MariaDB 10.5.2), `0` to `1048576` (<= MariaDB 10.5.1)

---

performance_schema_users_size

- **Description:** Number of rows in the performance_schema.users table. If set to 0, the Performance Schema will not store connection statistics in the users table. `-1` (the default) for automated sizing.
- **Commandline:** `--performance-schema-users-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `-1`
- **Range:** `-1` to `1048576`

1.1.1.2.9.2.5 Performance Schema Digests

The Performance Schema digest is a normalized form of a statement, with the specific data values removed. It allows statistics to be gathered for similar kinds of statements.

For example:

```
SELECT * FROM customer WHERE age < 20
SELECT * FROM customer WHERE age < 30
```

With the data values removed, both of these statements normalize to:

```
SELECT * FROM customer WHERE age < ?
```

which is the digest text. The digest text is then MD5 hashed, resulting in a digest. For example:

```
DIGEST_TEXT: SELECT * FROM `performance_schema` . `users`
DIGEST: 0f70cec4015f2a346df4ac0e9475d9f1
```

By contrast, the following two statements would not have the same digest as, while the data values are the same, they call upon different tables.

```
SELECT * FROM customer1 WHERE age < 20
SELECT * FROM customer2 WHERE age < 20
```

The digest text is limited to 1024 bytes. Queries exceeding this limit are truncated with '...', meaning that long queries that would otherwise have different digests may share the same digest.

Digest information is used in a number of performance scheme tables. These include

- events_statements_current
- events_statements_history
- events_statements_history_long
- events_statements_summary_by_digest (a summary table by schema and digest)

1.1.1.2.9.2.6 PERFORMANCE_SCHEMA Storage Engine

If you run SHOW ENGINES, you'll see the following storage engine listed.

```
SHOW ENGINES\G
...
      Engine: PERFORMANCE_SCHEMA
     Support: YES
     Comment: Performance Schema
Transactions: NO
          XA: NO
  Savepoints: NO
...
```

The PERFORMANCE_SCHEMA is not a regular storage engine for storing data, it's a mechanism for implementing the Performance Schema feature.

The SHOW ENGINE PERFORMANCE_SCHEMA STATUS statement is also available, which shows how much memory is used by the tables and internal buffers.

See Performance Schema for more details.

1.1.1.2.9.3 The mysql Database Tables

MariaDB comes pre-installed with a system database called `mysql` containing many important tables storing, in particular, grant and privilege information. Before MariaDB 10.4, system tables used the MyISAM storage engine. From MariaDB 10.4, they use Aria.

mysql.column_stats Table

Column stats for engine-independent statistics.

mysql.columns_priv Table

Column-level privileges

mysql.db Table

Database-level access and privileges.

mysql.event Table

Information about MariaDB events.

mysql.func Table

User-defined function information

mysql.general_log Table

Contents of the general query log if written to table

mysql.global_priv Table

Global privileges.

mysql.gtid_slave_pos Table

For replicas to keep track of the GTID.

mysql.help_category Table

Help categories.

mysql.help_keyword Table

Help keywords.

mysql.help_relation Table

HELP command relations

mysql.help_topic Table

Help topics.

mysql.index_stats Table

Index stats for engine-independent statistics.

mysql.innodb_index_stats

Data related to particular persistent index statistics, multiple rows for each index.

mysql.innodb_table_stats

Data related to persistent indexes, one row per table.

mysql.password_reuse_check_history Table

Contains old passwords for purposes of preventing password reuse.

mysql.plugin Table

Plugins loaded with INSTALL SONAME, INSTALL PLUGIN or the mariadb-plugin utility.

mysql.proc Table

Information about stored routines.

mysql.procs_priv Table

Stored procedure and stored function privileges

mysql.proxies_priv Table

Proxy privileges.

mysql.roles_mapping Table

MariaDB roles information.

mysql.servers Table

MariaDB servers.

mysql.slow_log Table

Contents of the slow query log if written to table.

mysql.tables_priv Table

Table-level privileges

mysql.table_stats Table

Table stats for engine-independent statistics.

mysql.time_zone Table

Time zone table in the mysql database.

mysql.time_zone_leap_second Table

Time zone leap second.

mysql.time_zone_name Table

Time zone name.

mysql.time_zone_transition Table

Time zone transition table.

mysql.time_zone_transition_type Table

Time zone transition type table.

mysql.transaction_registry Table

Used for transaction-precise versioning.

mysql.user Table

User access and global privileges.

Obsolete mysql Database Tables

Tables no longer present in the mysql system database.

Spider mysql Database Tables

System tables related to the Spider storage engine.

There are 2 related questions.

1.1.1.2.9.3.1 mysql.column_stats Table

The `mysql.column_stats` table is one of three tables storing data used for Engine-independent table statistics. The others are mysql.table_stats and mysql.index_stats.

Note that statistics for blob and text columns are not collected. If explicitly specified, a warning is returned.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

The `mysql.column_stats` table contains the following fields:

Field	Type	Null	Key	Default	Description
`db_name`	`varchar(64)`	NO	PRI	`NULL`	Database the table is in.
`table_name`	`varchar(64)`	NO	PRI	`NULL`	Table name.
`column_name`	`varchar(64)`	NO	PRI	`NULL`	Name of the column.
`min_value`	`varchar(255)`	YES		`NULL`	Minimum value in the table (in text form).
`max_value`	`varchar(255)`	YES		`NULL`	Maximum value in the table (in text form).
`nulls_ratio`	`decimal(12,4)`	YES		`NULL`	Fraction of `NULL` values (0- no `NULL`s, 0.5 - half values are `NULL`s, 1 - all values are `NULL`s).
`avg_length`	`decimal(12,4)`	YES		`NULL`	Average length of column value, in bytes. Counted as if one ran `SELECT AVG(LENGTH(col))`. This doesn't count `NULL` bytes, assumes endspace removal for `CHAR(n)`, etc.
`avg_frequency`	`decimal(12,4)`	YES		`NULL`	Average number of records with the same value

hist_size	tinyint(3) unsigned	YES		NULL	Histogram size in bytes, from 0-255, or, from MariaDB 10.7, number of buckets if the histogram type is JSON_HB.
hist_type	enum('SINGLE_PREC_HB', 'DOUBLE_PREC_HB') (>= MariaDB 10.7) enum('SINGLE_PREC_HB', 'DOUBLE_PREC_HB','JSON_HB') (<= MariaDB 10.6)	YES		NULL	Histogram type. See the histogram_type system variable.
histogram	blob (>= MariaDB 10.7) varbinary(255) (<=MariaDB 10.6)	YES		NULL	

It is possible to manually update the table. See Manual updates to statistics tables for details.

1.1.1.2.9.3.2 mysql.columns_priv Table

The mysql.columns_priv table contains information about column-level privileges. The table can be queried and although it is possible to directly update it, it is best to use GRANT for setting privileges.

Note that the MariaDB privileges occur at many levels. A user may be granted a privilege at the column level, but may still not have permission on a table level, for example. See privileges for a more complete view of the MariaDB privilege system.

The INFORMATION_SCHEMA.COLUMN_PRIVILEGES table derives its contents from mysql.columns_priv.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

The mysql.columns_priv table contains the following fields:

Field	Type	Null	Key	Default	Description
Host	char(60)	NO	PRI		Host (together with User, Db, Table_name and Column_name makes up the unique identifier for this record.
Db	char(64)	NO	PRI		Database name (together with User, Host, Table_name and Column_name makes up the unique identifier for this record.
User	char(80)	NO	PRI		User (together with Host, Db, Table_name and Column_name makes up the unique identifier for this record.
Table_name	char(64)	NO	PRI		Table name (together with User, Db, Host and Column_name makes up the unique identifier for this record.
Column_name	char(64)	NO	PRI		Column name (together with User, Db, Table_name and Host makes up the unique identifier for this record.
Timestamp	timestamp	NO		CURRENT_TIMESTAMP	
Column_priv	set('Select', 'Insert', 'Update', 'References')	NO			The privilege type. See Column Privileges for details.

The Acl_column_grants status variable, added in MariaDB 10.1.4, indicates how many rows the mysql.columns_priv table contains.

1.1.1.2.9.3.3 mysql.db Table

The `mysql.db` table contains information about database-level privileges. The table can be queried and although it is possible to directly update it, it is best to use GRANT for setting privileges.

Note that the MariaDB privileges occur at many levels. A user may not be granted a privilege at the database level, but may still have permission on a table level, for example. See privileges for a more complete view of the MariaDB privilege system.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

The `mysql.db` table contains the following fields:

Field	Type	Null	Key	Default	Description	Introduced
`Host`	`char(60)`	NO	PRI		Host (together with `User` and `Db` makes up the unique identifier for this record. Until MariaDB 5.5, if the host field was blank, the corresponding record in the mysql.host table would be examined. From MariaDB 10.0, a blank host field is the same as the `%` wildcard.	
`Db`	`char(64)`	NO	PRI		Database (together with `User` and `Host` makes up the unique identifier for this record.	
`User`	`char(80)`	NO	PRI		User (together with `Host` and `Db` makes up the unique identifier for this record.	
`Select_priv`	`enum('N','Y')`	NO		N	Can perform SELECT statements.	
`Insert_priv`	`enum('N','Y')`	NO		N	Can perform INSERT statements.	
`Update_priv`	`enum('N','Y')`	NO		N	Can perform UPDATE statements.	
`Delete_priv`	`enum('N','Y')`	NO		N	Can perform DELETE statements.	
`Create_priv`	`enum('N','Y')`	NO		N	Can CREATE TABLE's.	
`Drop_priv`	`enum('N','Y')`	NO		N	Can DROP DATABASE's or DROP TABLE's.	
`Grant_priv`	`enum('N','Y')`	NO		N	User can grant privileges they possess.	
`References_priv`	`enum('N','Y')`	NO		N	Unused	
`Index_priv`	`enum('N','Y')`	NO		N	Can create an index on a table using the CREATE INDEX statement. Without the `INDEX` privilege, user can still create indexes when creating a table using the CREATE TABLE statement if the user has have the `CREATE` privilege, and user can create indexes using the ALTER TABLE statement if they have the `ALTER` privilege.	
`Alter_priv`	`enum('N','Y')`	NO		N	Can perform ALTER TABLE statements.	
`Create_tmp_table_priv`	`enum('N','Y')`	NO		N	Can create temporary tables with the CREATE TEMPORARY TABLE statement.	

Lock_tables_priv	enum('N','Y')	NO		N	Acquire explicit locks using the LOCK TABLES statement; user also needs to have the SELECT privilege on a table in order to lock it.	
Create_view_priv	enum('N','Y')	NO		N	Can create a view using the CREATE_VIEW statement.	
Show_view_priv	enum('N','Y')	NO		N	Can show the CREATE VIEW statement to create a view using the SHOW CREATE VIEW statement.	
Create_routine_priv	enum('N','Y')	NO		N	Can create stored programs using the CREATE PROCEDURE and CREATE FUNCTION statements.	
Alter_routine_priv	enum('N','Y')	NO		N	Can change the characteristics of a stored function using the ALTER FUNCTION statement.	
Execute_priv	enum('N','Y')	NO		N	Can execute stored procedure or functions.	
Event_priv	enum('N','Y')	NO		N	Create, drop and alter events.	
Trigger_priv	enum('N','Y')	NO		N	Can execute triggers associated with tables the user updates, execute the CREATE TRIGGER and DROP TRIGGER statements.	
Delete_history_priv	enum('N','Y')	NO		N	Can delete rows created through system versioning.	MariaDB 10.3.5

The Acl_database_grants status variable, added in MariaDB 10.1.4, indicates how many rows the mysql.db table contains.

1.1.1.2.9.3.4 mysql.event Table

The mysql.event table contains information about MariaDB events. Similar information can be obtained by viewing the INFORMATION_SCHEMA.EVENTS table, or with the SHOW EVENTS and SHOW CREATE EVENT statements.

The table is upgraded live, and there is no need to restart the server if the table has changed.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

The mysql.event table contains the following fields:

Field	Type	Null	Key	Default	Description
db	char(64)	NO	PRI		
name	char(64)	NO	PRI		
body	longblob	NO		NULL	
definer	char(141)	NO			
execute_at	datetime	YES		NULL	
interval_value	int(11)	YES		NULL	

interval_field	enum('YEAR', 'QUARTER', 'MONTH', 'DAY', 'HOUR', 'MINUTE', 'WEEK', 'SECOND', 'MICROSECOND', 'YEAR_MONTH', 'DAY_HOUR', 'DAY_MINUTE', 'DAY_SECOND', 'HOUR_MINUTE', 'HOUR_SECOND', 'MINUTE_SECOND', 'DAY_MICROSECOND', 'HOUR_MICROSECOND', 'MINUTE_MICROSECOND', 'SECOND_MICROSECOND')	YES		NULL	
created	timestamp	NO		CURRENT_TIMESTAMP	
modified	timestamp	NO		0000-00-00 00:00:00	
last_executed	datetime	YES		NULL	
starts	datetime	YES		NULL	
ends	datetime	YES		NULL	
status	enum('ENABLED', 'DISABLED', 'SLAVESIDE_DISABLED')	NO		ENABLED	Current status of the event, one of enabled, disabled, or disabled on the slaveside.
on_completion	enum('DROP','PRESERVE')	NO		DROP	
sql_mode	set('REAL_AS_FLOAT', 'PIPES_AS_CONCAT', 'ANSI_QUOTES', 'IGNORE_SPACE', 'IGNORE_BAD_TABLE_OPTIONS', 'ONLY_FULL_GROUP_BY', 'NO_UNSIGNED_SUBTRACTION', 'NO_DIR_IN_CREATE', 'POSTGRESQL', 'ORACLE', 'MSSQL', 'DB2', 'MAXDB', 'NO_KEY_OPTIONS', 'NO_TABLE_OPTIONS', 'NO_FIELD_OPTIONS', 'MYSQL323', 'MYSQL40', 'ANSI', 'NO_AUTO_VALUE_ON_ZERO', 'NO_BACKSLASH_ESCAPES', 'STRICT_TRANS_TABLES', 'STRICT_ALL_TABLES', 'NO_ZERO_IN_DATE', 'NO_ZERO_DATE', 'INVALID_DATES', 'ERROR_FOR_DIVISION_BY_ZERO', 'TRADITIONAL', 'NO_AUTO_CREATE_USER', 'HIGH_NOT_PRECEDENCE', 'NO_ENGINE_SUBSTITUTION', 'PAD_CHAR_TO_FULL_LENGTH')	NO			The SQL_MODE at the time the event was created.
comment	char(64)	NO			
originator	int(10) unsigned	NO		NULL	
time_zone	char(64)	NO		SYSTEM	
character_set_client	char(32)	YES		NULL	
collation_connection	char(32)	YES		NULL	
db_collation	char(32)	YES		NULL	
body_utf8	longblob	YES		NULL	

1.1.1.2.9.3.5 mysql.func Table

The `mysql.func` table stores information about user-defined functions (UDFs) created with the CREATE FUNCTION UDF statement.

MariaDB starting with 10.4
In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3
In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

The `mysql.func` table contains the following fields:

Field	Type	Null	Key	Default	Description
`name`	`char(64)`	NO	PRI		UDF name
`ret`	`tinyint(1)`	NO		0	
`dl`	`char(128)`	NO			Shared library name
`type`	`enum('function','aggregate')`	NO		`NULL`	Type, either `function` or `aggregate`. Aggregate functions are summary functions such as SUM() and AVG().

Example

```
SELECT * FROM mysql.func;
+------------------------------+-----+--------------+-----------+
| name                         | ret | dl           | type      |
+------------------------------+-----+--------------+-----------+
| spider_direct_sql            |   2 | ha_spider.so | function  |
| spider_bg_direct_sql         |   2 | ha_spider.so | aggregate |
| spider_ping_table            |   2 | ha_spider.so | function  |
| spider_copy_tables           |   2 | ha_spider.so | function  |
| spider_flush_table_mon_cache |   2 | ha_spider.so | function  |
+------------------------------+-----+--------------+-----------+
```

1.1.1.2.9.3.6 mysql.general_log Table

The `mysql.general_log` table stores the contents of the General Query Log if general logging is active and the output is being written to table (see Writing logs into tables).

It contains the following fields:

Field	Type	Null	Key	Default	Description
`event_time`	`timestamp(6)`	NO		`CURRENT_TIMESTAMP(6)`	Time the query was executed.
`user_host`	`mediumtext`	NO		`NULL`	User and host combination.
`thread_id`	`int(11)`	NO		`NULL`	Thread id.
`server_id`	`int(10) unsigned`	NO		`NULL`	Server id.
`command_type`	`varchar(64)`	NO		`NULL`	Type of command.
`argument`	`mediumtext`	NO		`NULL`	Full query.

Example

```
SELECT * FROM mysql.general_log\G
*************************** 1. row ***************************
  event_time: 2014-11-11 08:40:04.117177
   user_host: root[root] @ localhost []
   thread_id: 74
   server_id: 1
command_type: Query
    argument: SELECT * FROM test.s
*************************** 2. row ***************************
  event_time: 2014-11-11 08:40:10.501131
   user_host: root[root] @ localhost []
   thread_id: 74
   server_id: 1
command_type: Query
    argument: SELECT * FROM mysql.general_log
...
```

1.1.1.2.9.3.7 mysql.global_priv Table

MariaDB starting with 10.4.1

The `mysql.global_priv` table was introduced in MariaDB 10.4.1 to replace the mysql.user table.

The `mysql.global_priv` table contains information about users that have permission to access the MariaDB server, and their global privileges.

Note that the MariaDB privileges occur at many levels. A user may not be granted `create` privilege at the user level, but may still have `create` permission on certain tables or databases, for example. See privileges for a more complete view of the MariaDB privilege system.

The `mysql.global_priv` table contains the following fields:

Field	Type	Null	Key	Default	Description
`Host`	`char(60)`	NO	PRI		Host (together with `User` makes up the unique identifier for this account).
`User`	`char(80)`	NO	PRI		User (together with `Host` makes up the unique identifier for this account).
`Priv`	`longtext`	NO			Global privileges, granted to the account and other account properties

From MariaDB 10.5.2, in order to help the server understand which version a privilege record was written by, the `priv` field contains a new JSON field, `version_id` (MDEV-21704).

Examples

```
select * from mysql.global_priv;
+-----------+-------------+-------------------------------------------------------------------------
-------------------------------------------------------------------+
| Host      | User        | Priv
|
+-----------+-------------+-------------------------------------------------------------------------
-------------------------------------------------------------------+
| localhost | root        | {"access":
18446744073709551615,"plugin":"mysql_native_password","authentication_string":"*6C387FC3893DBA1
E3BA155E74754DA6682D04747"} |
| 127.%     | msandbox    |
{"access":1073740799,"plugin":"mysql_native_password","authentication_string":"*6C387FC3893DBA1
E3BA155E74754DA6682D04747"}            |
| localhost | msandbox    |
{"access":1073740799,"plugin":"mysql_native_password","authentication_string":"*6C387FC3893DBA1
E3BA155E74754DA6682D04747"}            |
| localhost | msandbox_rw |
{"access":487487,"plugin":"mysql_native_password","authentication_string":"*6C387FC3893DBA1E3BA
155E74754DA6682D04747"}                |
| 127.%     | msandbox_rw |
{"access":487487,"plugin":"mysql_native_password","authentication_string":"*6C387FC3893DBA1E3BA
155E74754DA6682D04747"}                |
| 127.%     | msandbox_ro |
{"access":262145,"plugin":"mysql_native_password","authentication_string":"*6C387FC3893DBA1E3BA
155E74754DA6682D04747"}                |
| localhost | msandbox_ro |
{"access":262145,"plugin":"mysql_native_password","authentication_string":"*6C387FC3893DBA1E3BA
155E74754DA6682D04747"}                |
| 127.%     | rsandbox    |
{"access":524288,"plugin":"mysql_native_password","authentication_string":"*B07EB15A2E7BD9620DA
E47B194D5B9DBA14377AD"}                |
+-----------+-------------+-------------------------------------------------------------------------
-------------------------------------------------------------------+
```

Readable format:

```
SELECT CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv)) FROM mysql.global_priv;

+-----------------------------------------------------------------------------------------------+
| CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv))                                          |
+-----------------------------------------------------------------------------------------------+
| root@localhost => {
    "access": 18446744073709551615,
    "plugin": "mysql_native_password",
    "authentication_string": "*6C387FC3893DBA1E3BA155E74754DA6682D04747"
} |
| msandbox@127.% => {
    "access": 1073740799,
    "plugin": "mysql_native_password",
    "authentication_string": "*6C387FC3893DBA1E3BA155E74754DA6682D04747"
}           |
+-----------------------------------------------------------------------------------------------+
```

A particular user:

```
SELECT CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv)) FROM mysql.global_priv
  WHERE user='marijn';
+-----------------------------------------------------------------------------------------------+
| CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv))                                          |
+-----------------------------------------------------------------------------------------------+
| marijn@localhost => {
    "access": 0,
    "plugin": "mysql_native_password",
    "authentication_string": "",
    "account_locked": true,
    "password_last_changed": 1558017158
} |
+-----------------------------------------------------------------------------------------------+
```

From MariaDB 10.5.2:

```
GRANT FILE ON *.* TO user1@localhost;
SELECT Host, User, JSON_DETAILED(Priv) FROM mysql.global_priv WHERE user='user1'\G

*************************** 1. row ***************************
               Host: localhost
               User: user1
JSON_DETAILED(Priv): {
    "access": 512,
    "plugin": "mysql_native_password",
    "authentication_string": "",
    "password_last_changed": 1581070979,
    "version_id": 100502
}
```

1.1.1.2.9.3.8 mysql.gtid_slave_pos Table

The `mysql.gtid_slave_pos` table is used in replication by replica servers to keep track of their current position (the global transaction ID of the last transaction applied). Using the table allows the replica to maintain a consistent value for the gtid_slave_pos system variable across server restarts. See Global Transaction ID.

You should never attempt to modify the table directly. If you do need to change the global gtid_slave_pos value, use `SET GLOBAL gtid_slave_pos = ...` instead.

The table is updated with the new position as part of each transaction committed during replication. This makes it preferable that the table is using the same storage engine as the tables otherwise being modified in the transaction, since otherwise a multi-engine transaction is needed that can reduce performance.

Starting from MariaDB 10.3.1, multiple versions of this table are supported, each using a different storage engine. This is selected with the gtid_pos_auto_engines option, by giving a comma-separated list of engine names. The server will then on-demand create an extra version of the table using the appropriate storage engine, and select the table version using the same engine as the rest of the transaction, avoiding multi-engine transactions.

For example, when `gtid_pos_auto_engines=innodb,rocksdb` , tables `mysql.gtid_slave_pos_InnoDB` and `mysql.gtid_slave_pos_RocksDB` will be created and used, if needed. If there is no match to the storage engine, the default `mysql.gtid_slave_pos` table will be used; this also happens if non-transactional updates (like MyISAM) are replicated, since there is then no active transaction at the time of the `mysql.gtid_slave_pos` table update.

Prior to MariaDB 10.3.1, only the default `mysql.gtid_slave_pos` table is available. In these versions, the table should preferably be using the storage engine that is used for most replicated transactions.

The default `mysql.gtid_slave_pos` table will be initially created using the default storage engine set for the server (which itself defaults to InnoDB). If the application load is primarily non-transactional MyISAM or Aria tables, it can be beneficial to change the storage engine to avoid including an InnoDB update with every operation:

```
ALTER TABLE mysql.gtid_slave_pos ENGINE=MyISAM;
```

The `mysql.gtid_slave_pos` table should not be changed manually in any other way. From MariaDB 10.3.1, it is preferable to use the `gtid_pos_auto_engines` server variable to get the GTID position updates to use the TokuDB or RocksDB storage engine.

Note that for scalability reasons, the automatic creation of a new `mysql.gtid_slave_posXXX` table happens asynchronously when the first transaction with the new storage engine is committed. So the very first few transactions will update the old version of the table, until the new version is created and available.

The table `mysql.gtid_slave_pos` contains the following fields

Field	Type	Null	Key	Default	Description
`domain_id`	`int(10) unsigned`	NO	PRI	`NULL`	Domain id (see Global Transaction ID domain ID.
`sub_id`	`bigint(20) unsigned`	NO	PRI	`NULL`	This field enables multiple parallel transactions within same `domain_id` to update this table without contention. At any instant, the replication state corresponds to records with largest `sub_id` for each `domain_id` .
`server_id`	`int(10) unsigned`	NO		`NULL`	Server id.

seq_no	bigint(20) unsigned	NO		NULL	Sequence number, an integer that is monotonically increasing for each new event group logged into the binlog.

From MariaDB 10.3.1, some status variables are available to monitor the use of the different gtid_slave_pos table versions:

Transactions_gtid_foreign_engine

Number of replicated transactions where the update of the gtid_slave_pos table had to choose a storage engine that did not otherwise participate in the transaction. This can indicate that setting gtid_pos_auto_engines might be useful.

Rpl_transactions_multi_engine

Number of replicated transactions that involved changes in multiple (transactional) storage engines, before considering the update of gtid_slave_pos . These are transactions that were already cross-engine, independent of the GTID position update introduced by replication

Transactions_multi_engine

Number of transactions that changed data in multiple (transactional) storage engines. If this is significantly larger than Rpl_transactions_multi_engine, it indicates that setting gtid_pos_auto_engines could reduce the need for cross-engine transactions.

1.1.1.2.9.3.9 mysql.help_category Table

mysql.help_category is one of the four tables used by the HELP command. It is populated when the server is installed by the fill_help_tables.sql script. The other help tables are help_relation, help_topic and help_keyword.

This table uses the Aria storage engine. Prior to MariaDB 10.4 it used the MyISAM engine.

The mysql.help_category table contains the following fields:

Field	Type	Null	Key	Default	Description
help_category_id	smallint(5) unsigned	NO	PRI	NULL	
name	char(64)	NO	UNI	NULL	
parent_category_id	smallint(5) unsigned	YES		NULL	
url	char(128)	NO		NULL	

Example

```
SELECT * FROM help_category;
+------------------+----------------------------------------------+--------------------+-----+
| help_category_id | name                                         | parent_category_id | url |
+------------------+----------------------------------------------+--------------------+-----+
|                1 | Geographic                                   |                  0 |     |
|                2 | Polygon properties                           |                 34 |     |
|                3 | WKT                                          |                 34 |     |
|                4 | Numeric Functions                            |                 38 |     |
|                5 | Plugins                                      |                 35 |     |
|                6 | MBR                                          |                 34 |     |
|                7 | Control flow functions                       |                 38 |     |
|                8 | Transactions                                 |                 35 |     |
|                9 | Help Metadata                                |                 35 |     |
|               10 | Account Management                           |                 35 |     |
|               11 | Point properties                             |                 34 |     |
|               12 | Encryption Functions                         |                 38 |     |
|               13 | LineString properties                        |                 34 |     |
|               14 | Miscellaneous Functions                      |                 38 |     |
|               15 | Logical operators                            |                 38 |     |
|               16 | Functions and Modifiers for Use with GROUP BY |                 35 |     |
|               17 | Information Functions                        |                 38 |     |
|               18 | Comparison operators                         |                 38 |     |
|               19 | Bit Functions                                |                 38 |     |
|               20 | Table Maintenance                            |                 35 |     |
|               21 | User-Defined Functions                       |                 35 |     |
|               22 | Data Types                                   |                 35 |     |
|               23 | Compound Statements                          |                 35 |     |
|               24 | Geometry constructors                        |                 34 |     |
|               25 | GeometryCollection properties                |                  1 |     |
|               26 | Administration                               |                 35 |     |

+------------------+----------------------------------------------+--------------------+-----+
```

1.1.1.2.9.3.10 mysql.help_keyword Table

`mysql.help_keyword` is one of the four tables used by the HELP command. It is populated when the server is installed by the `fill_help_tables.sql` script. The other help tables are help_relation, help_category and help_topic.

This table uses the Aria storage engine. Prior to MariaDB 10.4 it used the MyISAM engine.

The `mysql.help_keyword` table contains the following fields:

Field	Type	Null	Key	Default	Description
`help_keyword_id`	`int(10) unsigned`	NO	PRI	`NULL`	
`name`	`char(64)`	NO	UNI	`NULL`	

Example

```
SELECT * FROM help_keyword;
+-----------------+---------------------------------+
| help_keyword_id | name                            |
+-----------------+---------------------------------+
|               0 | JOIN                            |
|               1 | HOST                            |
|               2 | REPEAT                          |
|               3 | SERIALIZABLE                    |
|               4 | REPLACE                         |
|               5 | AT                              |
|               6 | SCHEDULE                        |
|               7 | RETURNS                         |
|               8 | STARTS                          |
|               9 | MASTER_SSL_CA                   |
|              10 | NCHAR                           |
|              11 | COLUMNS                         |
|              12 | COMPLETION                      |
...
```

1.1.1.2.9.3.11 mysql.help_relation Table

`mysql.help_relation` is one of the four tables used by the HELP command. It is populated when the server is installed by the `fill_help_tables.sql` script. The other help tables are help_topic, help_category and help_keyword.

This table uses the Aria storage engine. Prior to MariaDB 10.4 it used the MyISAM engine.

The `mysql.help_relation` table contains the following fields:

Field	Type	Null	Key	Default	Description
help_topic_id	int(10) unsigned	NO	PRI	NULL	
help_keyword_id	int(10) unsigned	NO	PRI	NULL	

Example

```
...
|           106 |             456 |
|           463 |             456 |
|           468 |             456 |
|           463 |             457 |
|           194 |             458 |
|           478 |             458 |
|           374 |             459 |
|           459 |             459 |
|            39 |             460 |
|            58 |             460 |
|           185 |             460 |
|           264 |             460 |
|           269 |             460 |
|           209 |             461 |
|           468 |             461 |
|           201 |             462 |
|           468 |             463 |
+---------------+-----------------+
```

1.1.1.2.9.3.12 mysql.help_topic Table

`mysql.help_topic` is one of the four tables used by the HELP command. It is populated when the server is installed by the `fill_help_tables.sql` script. The other help tables are help_relation, help_category and help_keyword.

This table uses the Aria storage engine. Prior to MariaDB 10.4 it used the MyISAM engine.

The `mysql.help_topic` table contains the following fields:

Field	Type	Null	Key	Default	Description

help_topic_id	int(10) unsigned	NO	PRI	NULL	
name	char(64)	NO	UNI	NULL	
help_category_id	smallint(5) unsigned	NO		NULL	
description	text	NO		NULL	
example	text	NO		NULL	
url	char(128)	NO		NULL	

Example

```
SELECT * FROM help_topic\G;
...
*************************** 704. row ***************************
   help_topic_id: 692
           name: JSON_DEPTH
help_category_id: 41
     description: JSON functions were added in MariaDB 10.2.3.

Syntax
------
JSON_DEPTH(json_doc)

Description
-----------
Returns the maximum depth of the given JSON document, or
NULL if the argument is null. An error will occur if the
argument is an invalid JSON document.
Scalar values or empty arrays or objects have a depth of 1.
Arrays or objects that are not empty but contain only
elements or member values of depth 1 will have a depth of 2.
In other cases, the depth will be greater than 2.

Examples
--------
SELECT JSON_DEPTH('[]'), JSON_DEPTH('true'),
JSON_DEPTH('{}');
+------------------+--------------------+------------------+
| JSON_DEPTH('[]') | JSON_DEPTH('true') |
JSON_DEPTH('{}') |
+------------------+--------------------+------------------+
| 1 | 1 | 1 |
+------------------+--------------------+------------------+

SELECT JSON_DEPTH('[1, 2, 3]'), JSON_DEPTH('[[], {},
[]]');
+-------------------------+-----------------------------+
| JSON_DEPTH('[1, 2, 3]') | JSON_DEPTH('[[], {}, []]') |
+-------------------------+-----------------------------+
| 2 | 2 |
+-------------------------+-----------------------------+

SELECT JSON_DEPTH('[1, 2, [3, 4, 5, 6], 7]');
+---------------------------------------+
| JSON_DEPTH('[1, 2, [3, 4, 5, 6], 7]') |
+---------------------------------------+
| 3 |
+---------------------------------------+

URL: https://mariadb.com/kb/en/json_depth/
         example:
             url: https://mariadb.com/kb/en/json_depth/
```

1.1.1.2.9.3.13 mysql.index_stats Table

The `mysql.index_stats` table is one of three tables storing data used for Engine-independent table statistics. The others are mysql.column_stats and mysql.table_stats.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

The `mysql.index_stats` table contains the following fields:

Field	Type	Null	Key	Default	Description
`db_name`	`varchar(64)`	NO	PRI	`NULL`	Database the table is in.
`table_name`	`varchar(64)`	NO	PRI	`NULL`	Table name
`index_name`	`varchar(64)`	NO	PRI	`NULL`	Name of the index
`prefix_arity`	`int(11) unsigned`	NO	PRI	`NULL`	Index prefix length. 1 for the first keypart, 2 for the first two, and so on. InnoDB's extended keys are supported.
`avg_frequency`	`decimal(12,4)`	YES		`NULL`	Average number of records one will find for given values of (keypart1, keypart2, ..), provided the values will be found in the table.

It is possible to manually update the table. See Manual updates to statistics tables for details.

1.1.1.2.9.3.14 mysql.innodb_index_stats

Contents

1. Example

The `mysql.innodb_index_stats` table stores data related to particular InnoDB Persistent Statistics, and contains multiple rows for each index.

This table, along with the related mysql.innodb_table_stats table, can be manually updated in order to force or test differing query optimization plans. After updating, `FLUSH TABLE innodb_index_stats` is required to load the changes.

`mysql.innodb_index_stats` is not replicated, although any ANALYZE TABLE statements on the table will be by default..

It contains the following fields:

Field	Type	Null	Key	Default	Description
`database_name`	`varchar(64)`	NO	PRI	`NULL`	Database name.
`table_name`	`varchar(64)`	NO	PRI	`NULL`	Table, partition or subpartition name.
`index_name`	`varchar(64)`	NO	PRI	`NULL`	Index name.
`last_update`	`timestamp`	NO		`current_timestamp()`	Time that this row was last updated.
`stat_name`	`varchar(64)`	NO	PRI	`NULL`	Statistic name.
`stat_value`	`bigint(20) unsigned`	NO		`NULL`	Estimated statistic value.
`sample_size`	`bigint(20) unsigned`	YES		`NULL`	Number of pages sampled for the estimated statistic value.
`stat_description`	`varchar(1024)`	NO		`NULL`	Statistic description.

Example

```
SELECT * FROM mysql.innodb_index_stats\G
*************************** 1. row ***************************
   database_name: mysql
      table_name: gtid_slave_pos
      index_name: PRIMARY
     last_update: 2017-08-19 20:38:34
       stat_name: n_diff_pfx01
      stat_value: 0
     sample_size: 1
stat_description: domain_id
*************************** 2. row ***************************
   database_name: mysql
      table_name: gtid_slave_pos
      index_name: PRIMARY
     last_update: 2017-08-19 20:38:34
       stat_name: n_diff_pfx02
      stat_value: 0
     sample_size: 1
stat_description: domain_id,sub_id
*************************** 3. row ***************************
   database_name: mysql
      table_name: gtid_slave_pos
      index_name: PRIMARY
     last_update: 2017-08-19 20:38:34
       stat_name: n_leaf_pages
      stat_value: 1
     sample_size: NULL
stat_description: Number of leaf pages in the index
*************************** 4. row ***************************
   database_name: mysql
      table_name: gtid_slave_pos
      index_name: PRIMARY
     last_update: 2017-08-19 20:38:34
       stat_name: size
      stat_value: 1
     sample_size: NULL
stat_description: Number of pages in the index
*************************** 5. row ***************************
   database_name: test
      table_name: ft
      index_name: FTS_DOC_ID_INDEX
     last_update: 2017-09-15 12:58:39
       stat_name: n_diff_pfx01
      stat_value: 0
     sample_size: 1
stat_description: FTS_DOC_ID
*************************** 6. row ***************************
   database_name: test
      table_name: ft
      index_name: FTS_DOC_ID_INDEX
     last_update: 2017-09-15 12:58:39
       stat_name: n_leaf_pages
      stat_value: 1
     sample_size: NULL
stat_description: Number of leaf pages in the index
...
```

1.1.1.2.9.3.15 mysql.innodb_table_stats

Contents

The `mysql.innodb_table_stats` table stores data related to InnoDB Persistent Statistics, and contains one row per table.

This table, along with the related mysql.innodb_index_stats table, can be manually updated in order to force or test differing query optimization plans. After updating, `FLUSH TABLE innodb_table_stats` is required to load the changes.

`mysql.innodb_table_stats` is not replicated, although any ANALYZE TABLE statements on the table will be by default..

It contains the following fields:

Field	Type	Null	Key	Default	Description
database_name	varchar(64)	NO	PRI	NULL	Database name.
table_name	varchar(64)	NO	PRI	NULL	Table, partition or subpartition name.
last_update	timestamp	NO		current_timestamp()	Time that this row was last updated.
n_rows	bigint(20) unsigned	NO		NULL	Number of rows in the table.
clustered_index_size	bigint(20) unsigned	NO		NULL	Size, in pages, of the primary index.
sum_of_other_index_sizes	bigint(20) unsigned	NO		NULL	Size, in pages, of non-primary indexes.

Example

```
SELECT * FROM mysql.innodb_table_stats\G
*************************** 1. row ***************************
           database_name: mysql
              table_name: gtid_slave_pos
             last_update: 2017-08-19 20:38:34
                 n_rows: 0
    clustered_index_size: 1
sum_of_other_index_sizes: 0
*************************** 2. row ***************************
           database_name: test
              table_name: ft
             last_update: 2017-09-15 12:58:39
                 n_rows: 0
    clustered_index_size: 1
sum_of_other_index_sizes: 2
...
```

1.1.1.2.9.3.16 mysql.password_reuse_check_history Table

MariaDB starting with 10.7.0

The mysql.password_reuse_check_history Table is installed as part of the password_reuse_check plugin, available from MariaDB 10.7.0.

The `mysql.password_reuse_check_history` table stores old passwords, so that when a user sets a new password, it can be checked for purposes of preventing password reuse.

It contains the following fields:

Field	Type	Null	Key	Default	Description
hash	binary(64)	NO	PRI	NULL	
time	timestamp	NO	MUL	current_timestamp()	

1.1.1.2.9.3.17 mysql.plugin Table

The `mysql.plugin` table can be queried to get information about installed plugins.

This table only contains information about plugins that have been installed via the following methods:

- The INSTALL SONAME statement.
- The INSTALL PLUGIN statement.
- The mariadb-plugin utility.

This table does not contain information about:

- Built-in plugins.
- Plugins loaded with the --plugin-load-add option.
- Plugins loaded with the --plugin-load option.

This table only contains enough information to reload the plugin when the server is restarted, which means it only contains the plugin name and the plugin library.

This table uses the Aria storage engine.

The `mysql.plugin` table contains the following fields:

Field	Type	Null	Key	Default	Description
`name`	`varchar(64)`	NO	PRI		Plugin name.
`dl`	`varchar(128)`	NO			Name of the plugin library.

Example

```
SELECT * FROM mysql.plugin;
+---------------------------+------------------------+
| name                      | dl                     |
+---------------------------+------------------------+
| spider                    | ha_spider.so           |
| spider_alloc_mem          | ha_spider.so           |
| METADATA_LOCK_INFO        | metadata_lock_info.so  |
| OQGRAPH                   | ha_oqgraph.so          |
| cassandra                 | ha_cassandra.so        |
| QUERY_RESPONSE_TIME       | query_response_time.so |
| QUERY_RESPONSE_TIME_AUDIT | query_response_time.so |
| LOCALES                   | locales.so             |
| sequence                  | ha_sequence.so         |
+---------------------------+------------------------+
```

1.1.1.2.9.3.18 mysql.proc Table

The `mysql.proc` table contains information about stored procedures and stored functions. It contains similar information to that stored in the INFORMATION SCHEMA.ROUTINES table.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

The `mysql.proc` table contains the following fields:

Field	Type	Null	Key	Default	Description
`db`	`char(64)`	NO	PRI		Database name.
`name`	`char(64)`	NO	PRI		Routine name.
`type`	`enum('FUNCTION','PROCEDURE','PACKAGE', 'PACKAGE BODY')`	NO	PRI	`NULL`	Whether stored procedure, stored function or, from MariaDB 10.3.5, a package or package body.
`specific_name`	`char(64)`	NO			
`language`	`enum('SQL')`	NO		SQL	Always `SQL`.
`sql_data_access`	`enum('CONTAINS_SQL', 'NO_SQL', 'READS_SQL_DATA', 'MODIFIES_SQL_DATA')`	NO		`CONTAINS_SQL`	
`is_deterministic`	`enum('YES','NO')`	NO		NO	Whether the routine is deterministic (can produce only one result for a given list of parameters) or not.

security_type	enum('INVOKER','DEFINER')	NO		DEFINER	INVOKER or DEFINER. Indicates which user's privileges apply to this routine.
param_list	blob	NO		NULL	List of parameters.
returns	longblob	NO		NULL	What the routine returns.
body	longblob	NO		NULL	Definition of the routine.
definer	char(141)	NO			If the security_type is DEFINER, this value indicates which user defined this routine.
created	timestamp	NO		CURRENT_TIMESTAMP	Date and time the routine was created.
modified	timestamp	NO		0000-00-00 00:00:00	Date and time the routine was modified.
sql_mode	set('REAL_AS_FLOAT', 'PIPES_AS_CONCAT', 'ANSI_QUOTES', 'IGNORE_SPACE', 'IGNORE_BAD_TABLE_OPTIONS', 'ONLY_FULL_GROUP_BY', 'NO_UNSIGNED_SUBTRACTION', 'NO_DIR_IN_CREATE', 'POSTGRESQL', 'ORACLE', 'MSSQL', 'DB2', 'MAXDB', 'NO_KEY_OPTIONS', 'NO_TABLE_OPTIONS', 'NO_FIELD_OPTIONS', 'MYSQL323', 'MYSQL40', 'ANSI', 'NO_AUTO_VALUE_ON_ZERO', 'NO_BACKSLASH_ESCAPES', 'STRICT_TRANS_TABLES', 'STRICT_ALL_TABLES', 'NO_ZERO_IN_DATE', 'NO_ZERO_DATE', 'INVALID_DATES', 'ERROR_FOR_DIVISION_BY_ZERO', 'TRADITIONAL', 'NO_AUTO_CREATE_USER', 'HIGH_NOT_PRECEDENCE', 'NO_ENGINE_SUBSTITUTION', 'PAD_CHAR_TO_FULL_LENGTH', 'EMPTY_STRING_IS_NULL', 'SIMULTANEOUS_ASSIGNMENT')	NO			The SQL_MODE at the time the routine was created.
comment	text	NO		NULL	Comment associated with the routine.
character_set_client	char(32)	YES		NULL	The character set used by the client that created the routine.
collation_connection	char(32)	YES		NULL	The collation (and character set) used by the connection that created the routine.
db_collation	char(32)	YES		NULL	The default collation (and character set) for the database, at the time the routine was created.
body_utf8	longblob	YES		NULL	Definition of the routine in utf8.
aggregate	enum('NONE', 'GROUP')	NO		NONE	From MariaDB 10.3.3
Field	**Type**	**Null**	**Key**	**Default**	**Description**

1.1.1.2.9.3.19 mysql.procs_priv Table

The `mysql.procs_priv` table contains information about stored procedure and stored function privileges. See CREATE PROCEDURE and CREATE FUNCTION on creating these.

The INFORMATION_SCHEMA.ROUTINES table derives its contents from `mysql.procs_priv`.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

The `mysql.procs_priv` table contains the following fields:

Field	Type	Null	Key	Default	Description
`Host`	`char(60)`	NO	PRI		Host (together with `Db`, `User`, `Routine_name` and `Routine_type` makes up the unique identifier for this record).
`Db`	`char(64)`	NO	PRI		Database (together with `Host`, `User`, `Routine_name` and `Routine_type` makes up the unique identifier for this record).
`User`	`char(80)`	NO	PRI		User (together with `Host`, `Db`, `Routine_name` and `Routine_type` makes up the unique identifier for this record).
`Routine_name`	`char(64)`	NO	PRI		Routine_name (together with `Host`, `Db` `User` and `Routine_type` makes up the unique identifier for this record).
`Routine_type`	`enum('FUNCTION','PROCEDURE', 'PACKAGE', 'PACKAGE BODY')`	NO	PRI	`NULL`	Whether the routine is a stored procedure, stored function, or, from MariaDB 10.3.5, a package or package body.
`Grantor`	`char(141)`	NO	MUL		
`Proc_priv`	`set('Execute','Alter Routine','Grant')`	NO			The routine privilege. See Function Privileges and Procedure Privileges for details.
`Timestamp`	`timestamp`	NO		`CURRENT_TIMESTAMP`	

The Acl_function_grants status variable, added in MariaDB 10.1.4, indicates how many rows the `mysql.columns_priv` table contains with the `FUNCTION` routine type.

The Acl_procedure_grants status variable, added in MariaDB 10.1.4, indicates how many rows the `mysql.columns_priv` table contains with the `PROCEDURE` routine type.

1.1.1.2.9.3.20 mysql.roles_mapping Table

The `mysql.roles_mapping` table contains information about mariaDB roles.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

The `mysql.roles_mapping` table contains the following fields:

Field	Type	Null	Key	Default	Description
`Host`	`char(60)`	NO	PRI		Host (together with `User` and `Role` makes up the unique identifier for this record.

`User`	`char(80)`	NO	PRI		User (together with `Host` and `Role` makes up the unique identifier for this record.
`Role`	`char(80)`	NO	PRI		Role (together with `Host` and `User` makes up the unique identifier for this record.
`Admin_option`	`enum('N','Y')`	NO		N	Whether the role can be granted (see the CREATE ROLE `WITH ADMIN` clause).

The Acl_role_grants status variable, added in MariaDB 10.1.4, indicates how many rows the `mysql.roles_mapping` table contains.

1.1.1.2.9.3.21 mysql.servers Table

The `mysql.servers` table contains information about servers as used by the Spider, FEDERATED or FederatedX, Connect storage engines (see CREATE SERVER).

This table uses the Aria storage engine (until MariaDB 10.3, it used the MyISAM storage engine).

The `mysql.servers` table contains the following fields:

Field	Type	Null	Key	Default	Description
`Server_name`	`char(64)`	NO	PRI		
`Host`	`char(64)`	NO			
`Db`	`char(64)`	NO			
`Username`	`char(80)`	NO			
`Password`	`char(64)`	NO			
`Port`	`int(4)`	NO		0	
`Socket`	`char(64)`	NO			
`Wrapper`	`char(64)`	NO			`mysql` or `mariadb`
`Owner`	`char(64)`	NO			

Example

```
SELECT * FROM mysql.servers\G
*************************** 1. row ***************************
Server_name: s
       Host: 192.168.1.106
         Db: test
   Username: Remote
   Password:
       Port: 0
     Socket:
    Wrapper: mariadb
      Owner:
```

1.1.1.2.9.3.22 mysql.slow_log Table

The `mysql.slow_log` table stores the contents of the Slow Query Log if slow logging is active and the output is being written to table (see Writing logs into tables).

It contains the following fields:

Field	Type	Null	Key	Default	Description
`start_time`	`timestamp(6)`	NO		`CURRENT_TIMESTAMP(6)`	Time the query began.
`user_host`	`mediumtext`	NO		`NULL`	User and host combination.
`query_time`	`time(6)`	NO		`NULL`	Total time the query took to execute.
`lock_time`	`time(6)`	NO		`NULL`	Total time the query was locked.

rows_sent	int(11)	NO		NULL	Number of rows sent.
rows_examined	int(11)	NO		NULL	Number of rows examined.
db	varchar(512)	NO		NULL	Default database.
last_insert_id	int(11)	NO		NULL	last_insert_id.
insert_id	int(11)	NO		NULL	Insert id.
server_id	int(10) unsigned	NO		NULL	The server's id.
sql_text	mediumtext	NO		NULL	Full query.
thread_id	bigint(21) unsigned	NO		NULL	Thread id.
rows_affected	int(11)	NO		NULL	Number of rows affected by an UPDATE or DELETE (from MariaDB 10.1.2)

Example

```
SELECT * FROM mysql.slow_log\G
...
*************************** 2. row ***************************
    start_time: 2014-11-11 07:56:28.721519
     user_host: root[root] @ localhost []
    query_time: 00:00:12.000215
     lock_time: 00:00:00.000000
     rows_sent: 1
 rows_examined: 0
            db: test
last_insert_id: 0
     insert_id: 0
     server_id: 1
      sql_text: SELECT SLEEP(12)
     thread_id: 74
...
```

1.1.1.2.9.3.23 mysql.tables_priv Table

The `mysql.tables_priv` table contains information about table-level privileges. The table can be queried and although it is possible to directly update it, it is best to use GRANT for setting privileges.

Note that the MariaDB privileges occur at many levels. A user may be granted a privilege at the table level, but may still not have permission on a database level, for example. See privileges for a more complete view of the MariaDB privilege system.

The INFORMATION_SCHEMA.TABLE_PRIVILEGES table derives its contents from `mysql.tables_priv`.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

The `mysql.tables_priv` table contains the following fields:

Field	Type	Null	Key	Default	Description
Host	char(60)	NO	PRI		Host (together with `User`, `Db` and `Table_name` makes up the unique identifier for this record.

`Db`	`char(64)`	NO	PRI		Database (together with `User`, `Host` and `Table_name` makes up the unique identifier for this record.
`User`	`char(80)`	NO	PRI		User (together with `Host`, `Db` and `Table_name` makes up the unique identifier for this record.
`Table_name`	`char(64)`	NO	PRI		Table name (together with `User`, `Db` and `Table` makes up the unique identifier for this record.
`Grantor`	`char(141)`	NO	MUL		
`Timestamp`	`timestamp`	NO		`CURRENT_TIMESTAMP`	
`Table_priv`	`set('Select', 'Insert', 'Update', 'Delete', 'Create', 'Drop', 'Grant', 'References', 'Index', 'Alter', 'Create View', 'Show view', 'Trigger', 'Delete versioning rows')`	NO			The table privilege type. See Table Privileges for details.
`Column_priv`	`set('Select', 'Insert', 'Update', 'References')`	NO			The column privilege type. See Column Privileges for details.

The Acl_table_grants status variable, added in MariaDB 10.1.4, indicates how many rows the `mysql.tables_priv` table contains.

1.1.1.2.9.3.24 mysql.table_stats Table

The `mysql.table_stats` table is one of three tables storing data used for Engine-independent table statistics. The others are mysql.column_stats and mysql.index_stats.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

The `mysql.table_stats` table contains the following fields:

Field	Type	Null	Key	Default	Description
`db_name`	`varchar(64)`	NO	PRI	`NULL`	Database the table is in .
`table_name`	`varchar(64)`	NO	PRI	`NULL`	Table name.
`cardinality`	`bigint(21) unsigned`	YES		`NULL`	Number of records in the table.

It is possible to manually update the table. See Manual updates to statistics tables for details.

1.1.1.2.9.3.25 mysql.time_zone Table

The `mysql.time_zone` table is one of the mysql system tables that can contain time zone information. It is usually

preferable for the system to handle the time zone, in which case the table will be empty (the default), but you can populate the mysql time zone tables using the mariadb-tzinfo-to-sql utility. See Time Zones for details.

This table uses the Aria storage engine.

The `mysql.time_zone` table contains the following fields:

Field	Type	Null	Key	Default	Description
`Time_zone_id`	`int(10) unsigned`	NO	PRI	`NULL`	ID field, auto_increments.
`Use_leap_seconds`	`enum('Y','N')`	NO		N	Whether or not leap seconds are used.

Example

```
SELECT * FROM mysql.time_zone;
+--------------+------------------+
| Time_zone_id | Use_leap_seconds |
+--------------+------------------+
|            1 | N                |
|            2 | N                |
|            3 | N                |
|            4 | N                |
|            5 | N                |
|            6 | N                |
|            7 | N                |
|            8 | N                |
|            9 | N                |
|           10 | N                |
...
+--------------+------------------+
```

1.1.1.2.9.3.26 mysql.time_zone_leap_second Table

The `mysql.time_zone_leap_second` table is one of the mysql system tables that can contain time zone information. It is usually preferable for the system to handle the time zone, in which case the table will be empty (the default), but you can populate the mysql time zone tables using the mariadb-tzinfo-to-sql utility. See Time Zones for details.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

The `mysql.time_zone_leap_second` table contains the following fields:

Field	Type	Null	Key	Default	Description
`Transition_time`	`bigint(20)`	NO	PRI	`NULL`	
`Correction`	`int(11)`	NO		`NULL`	

1.1.1.2.9.3.27 mysql.time_zone_name Table

The `mysql.time_zone_name` table is one of the mysql system tables that can contain time zone information. It is usually preferable for the system to handle the time zone, in which case the table will be empty (the default), but you can populate the mysql time zone tables using the mariadb-tzinfo-to-sql utility. See Time Zones for details.

This table uses the Aria storage engine.

The `mysql.time_zone_name` table contains the following fields:

Field	Type	Null	Key	Default	Description
`Name`	`char(64)`	NO	PRI	`NULL`	Name of the time zone.

Time_zone_id	int(10) unsigned	NO	PRI	NULL	ID field, auto_increments.

Example

```
SELECT * FROM mysql.time_zone_name;
+--------------------+--------------+
| Name               | Time_zone_id |
+--------------------+--------------+
| Africa/Abidjan     |            1 |
| Africa/Accra       |            2 |
| Africa/Addis_Ababa |            3 |
| Africa/Algiers     |            4 |
| Africa/Asmara      |            5 |
| Africa/Asmera      |            6 |
| Africa/Bamako      |            7 |
| Africa/Bangui      |            8 |
| Africa/Banjul      |            9 |
| Africa/Bissau      |           10 |
...
+--------------------+--------------+
```

1.1.1.2.9.3.28 mysql.time_zone_transition Table

The `mysql.time_zone_transition` table is one of the `mysql` system tables that can contain time zone information. It is usually preferable for the system to handle the time zone, in which case the table will be empty (the default), but you can populate the `mysql` time zone tables using the mariadb-tzinfo-to-sql utility. See Time Zones for details.

This table uses the Aria storage engine.

The `mysql.time_zone_transition` table contains the following fields:

Field	Type	Null	Key	Default	Description
Time_zone_id	int(10) unsigned	NO	PRI	NULL	
Transition_time	bigint(20)	NO	PRI	NULL	
Transition_type_id	int(10) unsigned	NO		NULL	

Example

```
SELECT * FROM mysql.time_zone_transition;
+--------------+-----------------+--------------------+
| Time_zone_id | Transition_time | Transition_type_id |
+--------------+-----------------+--------------------+
|            1 |     -1830383032 |                  1 |
|            2 |     -1640995148 |                  2 |
|            2 |     -1556841600 |                  1 |
|            2 |     -1546388400 |                  2 |
|            2 |     -1525305600 |                  1 |
|            2 |     -1514852400 |                  2 |
|            2 |     -1493769600 |                  1 |
|            2 |     -1483316400 |                  2 |
|            2 |     -1462233600 |                  1 |
|            2 |     -1451780400 |                  2 |
...
+--------------+-----------------+--------------------+
```

1.1.1.2.9.3.29 mysql.time_zone_transition_type Table

The `mysql.time_zone_transition_type` table is one of the `mysql` system tables that can contain time zone information. It is usually preferable for the system to handle the time zone, in which case the table will be empty (the default), but you can populate the `mysql` time zone tables using the mariadb-tzinfo-to-sql utility. See Time Zones for details.

This table uses the Aria storage engine.

The `mysql.time_zone_transition_type` table contains the following fields:

Field	Type	Null	Key	Default	Description
`Time_zone_id`	`int(10) unsigned`	NO	PRI	`NULL`	
`Transition_type_id`	`int(10) unsigned`	NO	PRI	`NULL`	
`Offset`	`int(11)`	NO		0	
`Is_DST`	`tinyint(3) unsigned`	NO		0	
`Abbreviation`	`char(8)`	NO			

Example

```
SELECT * FROM mysql.time_zone_transition_type;
+--------------+--------------------+--------+--------+--------------+
| Time_zone_id | Transition_type_id | Offset | Is_DST | Abbreviation |
+--------------+--------------------+--------+--------+--------------+
|            1 |                  0 |   -968 |      0 | LMT          |
|            1 |                  1 |      0 |      0 | GMT          |
|            2 |                  0 |    -52 |      0 | LMT          |
|            2 |                  1 |   1200 |      1 | GHST         |
|            2 |                  2 |      0 |      0 | GMT          |
|            3 |                  0 |   8836 |      0 | LMT          |
|            3 |                  1 |  10800 |      0 | EAT          |
|            3 |                  2 |   9000 |      0 | BEAT         |
|            3 |                  3 |   9900 |      0 | BEAUT        |
|            3 |                  4 |  10800 |      0 | EAT          |
...
+--------------+--------------------+--------+--------+--------------+
```

1.1.1.2.9.3.30 mysql.transaction_registry Table

The `mysql.transaction_registry` table was introduced in MariaDB 10.3.4 as part of system-versioned tables. It is used for transaction-precise versioning, and contains the following fields:

Field	Type	Null	Key	Default	Description
transaction_id	bigint(20) unsigned	NO	Primary	NULL	
commit_id	bigint(20) unsigned	NO	Unique	NULL	
begin_timestamp	timestamp(6)	NO	Multiple	0000-00-00 00:00:00.000000	Timestamp when the transaction began (BEGIN statement), however see MDEV-16024.
commit	timestamp(6)	NO	Multiple	0000-00-00 00:00:00.000000	Timestamp when the transaction was committed.
isolation_level	enum('READ-UNCOMMITTED','READ-COMMITTED','REPEATABLE-READ','SERIALIZABLE')	NO		NULL	Transaction isolation level.

1.1.1.2.9.3.31 mysql.user Table

MariaDB starting with 10.4

In MariaDB 10.4 and later, the mysql.global_priv table has replaced the `mysql.user` table, and `mysql.user` should be considered obsolete. It is now a view into `mysql.global_priv` created for compatibility with older applications and monitoring scripts. New tools are supposed to use `INFORMATION_SCHEMA` tables. From MariaDB 10.4.13, the dedicated `mariadb.sys` user is created as the definer of the view. Previously, `root` was the definer, which resulted in privilege problems when this username was changed (MDEV-19650).

The `mysql.user` table contains information about users that have permission to access the MariaDB server, and their global privileges. The table can be queried and although it is possible to directly update it, it is best to use GRANT and CREATE USER for adding users and privileges.

Note that the MariaDB privileges occur at many levels. A user may not be granted `create` privilege at the user level, but may still have `create` permission on certain tables or databases, for example. See privileges for a more complete view of the MariaDB privilege system.

The `mysql.user` table contains the following fields:

Field	Type	Null	Key	Default	Description
`Host`	`char(60)`	NO	PRI		Host (together with `User` makes up the unique identifier for this account.
`User`	`char(80)`	NO	PRI		User (together with `Host` makes up the unique identifier for this account.
`Password`	`longtext` (>= MariaDB 10.4.1), `char(41)` (<= MariaDB 10.4.0)	NO			Hashed password, generated by the PASSWORD() function.
`Select_priv`	`enum('N','Y')`	NO		N	Can perform SELECT statements.
`Insert_priv`	`enum('N','Y')`	NO		N	Can perform INSERT statements.
`Update_priv`	`enum('N','Y')`	NO		N	Can perform UPDATE statements.
`Delete_priv`	`enum('N','Y')`	NO		N	Can perform DELETE statements.
`Create_priv`	`enum('N','Y')`	NO		N	Can CREATE DATABASE's or CREATE TABLE's.
`Drop_priv`	`enum('N','Y')`	NO		N	Can DROP DATABASE's or DROP TABLE's.
`Reload_priv`	`enum('N','Y')`	NO		N	Can execute FLUSH statements or equivalent mariadb-admin commands.
`Shutdown_priv`	`enum('N','Y')`	NO		N	Can shut down the server with SHUTDOWN or mariadb-admin shutdown.
`Process_priv`	`enum('N','Y')`	NO		N	Can show information about active processes, via SHOW PROCESSLIST or mariadb-admin processlist.
`File_priv`	`enum('N','Y')`	NO		N	Read and write files on the server, using statements like LOAD DATA INFILE or functions like LOAD_FILE(). Also needed to create CONNECT outward tables. MariaDB server must have permission to access those files.
`Grant_priv`	`enum('N','Y')`	NO		N	User can grant privileges they possess.
`References_priv`	`enum('N','Y')`	NO		N	Unused
`Index_priv`	`enum('N','Y')`	NO		N	Can create an index on a table using the CREATE INDEX statement. Without the `INDEX` privilege, user can still create indexes when creating a table using the CREATE TABLE statement if the user has have the `CREATE` privilege, and user can create indexes using the ALTER TABLE statement if they have the `ALTER` privilege.
`Alter_priv`	`enum('N','Y')`	NO		N	Can perform ALTER TABLE statements.
`Show_db_priv`	`enum('N','Y')`	NO		N	Can list all databases using the SHOW DATABASES statement. Without the `SHOW DATABASES` privilege, user can still issue the `SHOW DATABASES` statement, but it will only list databases containing tables on which they have privileges.

Super_priv	enum('N','Y')	NO		N	Can execute superuser statements: CHANGE MASTER TO, KILL (users who do not have this privilege can only KILL their own threads), PURGE LOGS, SET global system variables, or the mariadb-admin debug command. Also, this permission allows the user to write data even if the read_only startup option is set, enable or disable logging, enable or disable replication on slaves, specify a DEFINER for statements that support that clause, connect once after reaching the MAX_CONNECTIONS. If a statement has been specified for the init-connect mysqld option, that command will not be executed when a user with SUPER privileges connects to the server.
Create_tmp_table_priv	enum('N','Y')	NO		N	Can create temporary tables with the CREATE TEMPORARY TABLE statement.
Lock_tables_priv	enum('N','Y')	NO		N	Acquire explicit locks using the LOCK TABLES statement; user also needs to have the SELECT privilege on a table in order to lock it.
Execute_priv	enum('N','Y')	NO		N	Can execute stored procedure or functions.
Repl_slave_priv	enum('N','Y')	NO		N	Accounts used by slave servers on the master need this privilege. This is needed to get the updates made on the master.
Repl_client_priv	enum('N','Y')	NO		N	Can execute SHOW MASTER STATUS and SHOW SLAVE STATUS statements.
Create_view_priv	enum('N','Y')	NO		N	Can create a view using the CREATE_VIEW statement.
Show_view_priv	enum('N','Y')	NO		N	Can show the CREATE VIEW statement to create a view using the SHOW CREATE VIEW statement.
Create_routine_priv	enum('N','Y')	NO		N	Can create stored programs using the CREATE PROCEDURE and CREATE FUNCTION statements.
Alter_routine_priv	enum('N','Y')	NO		N	Can change the characteristics of a stored function using the ALTER FUNCTION statement.
Create_user_priv	enum('N','Y')	NO		N	Can create a user using the CREATE USER statement, or implicitly create a user with the GRANT statement.
Event_priv	enum('N','Y')	NO		N	Create, drop and alter events.
Trigger_priv	enum('N','Y')	NO		N	Can execute triggers associated with tables the user updates, execute the CREATE TRIGGER and DROP TRIGGER statements.
Create_tablespace_priv	enum('N','Y')	NO		N	
Delete_history_priv	enum('N','Y')	NO		N	Can delete rows created through system versioning.
ssl_type	enum('', 'ANY', 'X509', 'SPECIFIED')	NO			TLS type - see TLS options.
ssl_cipher	blob	NO		NULL	TLS cipher - see TLS options.
x509_issuer	blob	NO		NULL	X509 cipher - see TLS options.
x509_subject	blob	NO		NULL	SSL subject - see TLS options.
max_questions	int(11) unsigned	NO		0	Number of queries the user can perform per hour. Zero is unlimited. See per-account resource limits.

max_updates	int(11) unsigned	NO		0	Number of updates the user can perform per hour. Zero is unlimited. See per-account resource limits.
max_connections	int(11) unsigned	NO		0	Number of connections the account can start per hour. Zero is unlimited. See per-account resource limits.
max_user_connections	int(11)	NO		0	Number of simultaneous connections the account can have. Zero is unlimited. See per-account resource limits.
plugin	char(64)	NO			Authentication plugin used on connection. If empty, uses the default.
authentication_string	text	NO		NULL	Authentication string for the authentication plugin.
password_expired	enum('N','Y')	NO		N	MySQL-compatibility option, not implemented in MariaDB.
is_role	enum('N','Y')	NO		N	Whether the user is a role.
default_role	char(80)	NO		N	Role which will be enabled on user login automatically.
max_statement_time	decimal(12,6)	NO		0.000000	If non-zero, how long queries can run before being killed automatically.
Field	**Type**	**Null**	**Key**	**Default**	**Description**

The Acl_roles status variable indicates how many rows the `mysql.user` table contains where `is_role='Y'`.

The Acl_users status variable, indicates how many rows the `mysql.user` table contains where `is_role='N'`.

Authentication Plugin

When the `plugin` column is empty, MariaDB defaults to authenticating accounts with either the `mysql_native_password` or the `mysql_old_password` plugins. It decides which based on the hash used in the value for the `Password` column. When there's no password set or when the 4.1 password hash is used, (which is 41 characters long), MariaDB uses the `mysql_native_password` plugin. The `mysql_old_password` plugin is used with pre-4.1 password hashes, (which are 16 characters long).

MariaDB also supports the use of alternative authentication plugins. When the `plugin` column is not empty for the given account, MariaDB uses it to authenticate connection attempts. The specific plugin then uses the value of either the `Password` column or the `authentication_string` column to authenticate the user.

A specific authentication plugin can be used for an account by providing the `IDENTIFIED VIA authentication_plugin` clause with the CREATE USER, ALTER USER, or GRANT statements.

For example, the following statement would create an account that authenticates with the PAM authentication plugin:

```
CREATE USER foo2@test IDENTIFIED VIA pam;
```

If the specific authentication plugin uses the `authentication_string` column, then this value for the account can be specified after a `USING` or `AS` keyword. For example, the PAM authentication plugin accepts a service name that would go into the `authentication_string` column for the account:

```
CREATE USER foo2@test IDENTIFIED VIA pam USING 'mariadb';
```

1.1.1.2.9.3.32 Spider mysql Database Tables

The Spider storage engine installs the following system tables in the `mysql` database.

mysql.spider_link_failed_log Table

The mysql.spider_link_failed_log table.

mysql.spider_link_mon_servers Table

The mysql.spider_link_mon_servers table.

mysql.spider_tables Table

The mysql.spider_tables table.

mysql.spider_table_crd Table

The mysql.spider_table_crd table.

mysql.spider_table_position_for_recovery Table

The mysql.spider_table_position_for_recovery table.

mysql.spider_table_sts Table

The mysql.spider_table_sts table.

mysql.spider_xa Table

The mysql.spider_xa table.

mysql.spider_xa_failed_log Table

The mysql.spider_xa_failed_log table.

mysql.spider_xa_member Table

The mysql.spider_xa_member table.

1.1.1.2.9.3.32.1 mysql.spider_link_failed_log Table

The `mysql.spider_link_failed_log` table is installed by the Spider storage engine.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
db_name	char(64)	NO			
table_name	char(199)	NO			
link_id	char(64)	NO			
failed_time	timestamp	NO		current_timestamp()	

1.1.1.2.9.3.32.2 mysql.spider_link_mon_servers Table

The `mysql.spider_link_mon_servers` table is installed by the Spider storage engine.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description

db_name	char(64)	NO	PRI		
table_name	char(199)	NO	PRI		
link_id	char(64)	NO	PRI		
sid	int(10) unsigned	NO	PRI	0	
server	char(64)	YES		NULL	
scheme	char(64)	YES		NULL	
host	char(64)	YES		NULL	
port	char(5)	YES		NULL	
socket	text	YES		NULL	
username	char(64)	YES		NULL	
password	char(64)	YES		NULL	
ssl_ca	text	YES		NULL	
ssl_capath	text	YES		NULL	
ssl_cert	text	YES		NULL	
ssl_cipher	char(64)	YES		NULL	
ssl_key	text	YES		NULL	
ssl_verify_server_cert	tinyint(4)	NO		0	
default_file	text	YES		NULL	
default_group	char(64)	YES		NULL	
dsn	char(64)	YES		NULL	
filedsn	text	YES		NULL	
driver	char(64)	YES		NULL	

1.1.1.2.9.3.32.3 mysql.spider_tables Table

The `mysql.spider_tables` table is installed by the Spider storage engine.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
db_name	char(64)	NO	PRI		
table_name	char(199)	NO	PRI		
link_id	int(11)	NO	PRI	0	
priority	bigint(20)	NO	MUL	0	
server	char(64)	YES		NULL	
scheme	char(64)	YES		NULL	
host	char(64)	YES		NULL	
port	char(5)	YES		NULL	
socket	text	YES		NULL	
username	char(64)	YES		NULL	
password	char(64)	YES		NULL	

ssl_ca	text	YES		NULL	
ssl_capath	text	YES		NULL	
ssl_cert	text	YES		NULL	
ssl_cipher	char(64)	YES		NULL	
ssl_key	text	YES		NULL	
ssl_verify_server_cert	tinyint(4)	NO		0	
monitoring_binlog_pos_at_failing	tinyint(4)	NO		0	
default_file	text	YES		NULL	
default_group	char(64)	YES		NULL	
dsn	char(64)	YES		NULL	
filedsn	text	YES		NULL	
driver	char(64)	YES		NULL	
tgt_db_name	char(64)	YES		NULL	
tgt_table_name	char(64)	YES		NULL	
link_status	tinyint(4)	NO		1	
block_status	tinyint(4)	NO		0	
static_link_id	char(64)	YES		NULL	

1.1.1.2.9.3.32.4 mysql.spider_table_crd Table

The `mysql.spider_table_crd` table is installed by the Spider storage engine.

MariaDB starting with 10.4
In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3
In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
db_name	char(64)	NO	PRI		
table_name	char(199)	NO	PRI		
key_seq	int(10) unsigned	NO	PRI	0	
cardinality	bigint(20)	NO		0	

1.1.1.2.9.3.32.5 mysql.spider_table_position_for_recovery Table

The `mysql.spider_table_position_for_recovery` table is installed by the Spider storage engine.

MariaDB starting with 10.4
In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3
In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description

db_name	char(64)	NO	PRI		
table_name	char(199)	NO	PRI		
failed_link_id	int(11)	NO	PRI	0	
source_link_id	int(11)	NO	PRI	0	
file	text	YES		NULL	
position	text	YES		NULL	
gtid	text	YES		NULL	

1.1.1.2.9.3.32.6 mysql.spider_table_sts Table

The `mysql.spider_table_sts` table is installed by the Spider storage engine.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
db_name	char(64)	NO	PRI		
table_name	char(199)	NO	PRI		
data_file_length	bigint(20) unsigned	NO		0	
max_data_file_length	bigint(20) unsigned	NO		0	
index_file_length	bigint(20) unsigned	NO		0	
records	bigint(20) unsigned	NO		0	
mean_rec_length	bigint(20) unsigned	NO		0	
check_time	datetime	NO		0000-00-00 00:00:00	
create_time	datetime	NO		0000-00-00 00:00:00	
update_time	datetime	NO		0000-00-00 00:00:00	
checksum	bigint(20) unsigned	YES		NULL	

1.1.1.2.9.3.32.7 mysql.spider_xa Table

The `mysql.spider_xa` table is installed by the Spider storage engine.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
format_id	int(11)	NO	PRI	0	
gtrid_length	int(11)	NO	PRI	0	
bqual_length	int(11)	NO		0	
data	binary(128)	NO	PRI		

status	char(8)	NO	MUL		

1.1.1.2.9.3.32.8 mysql.spider_xa_failed_log Table

The `mysql.spider_xa_failed_log` table is installed by the Spider storage engine.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
format_id	int(11)	NO		0	
gtrid_length	int(11)	NO		0	
bqual_length	int(11)	NO		0	
data	binary(128)	NO	MUL		
scheme	char(64)	NO			
host	char(64)	NO			
port	char(5)	NO			
socket	text	NO		NULL	
username	char(64)	NO			
password	char(64)	NO			
ssl_ca	text	YES		NULL	
ssl_capath	text	YES		NULL	
ssl_cert	text	YES		NULL	
ssl_cipher	char(64)	YES		NULL	
ssl_key	text	YES		NULL	
ssl_verify_server_cert	tinyint(4)	NO		0	
default_file	text	YES		NULL	
default_group	char(64)	YES		NULL	
dsn	char(64)	YES		NULL	
filedsn	text	YES		NULL	
driver	char(64)	YES		NULL	
thread_id	int(11)	YES		NULL	
status	char(8)	NO			
failed_time	timestamp	NO		current_timestamp()	

1.1.1.2.9.3.32.9 mysql.spider_xa_member Table

The `mysql.spider_xa_member` table is installed by the Spider storage engine.

MariaDB starting with 10.4

In MariaDB 10.4 and later, this table uses the Aria storage engine.

MariaDB until 10.3

In MariaDB 10.3 and before, this table uses the MyISAM storage engine.

It contains the following fields:

Field	Type	Null	Key	Default	Description
format_id	int(11)	NO		0	
gtrid_length	int(11)	NO		0	
bqual_length	int(11)	NO		0	
data	binary(128)	NO	MUL		
scheme	char(64)	NO			
host	char(64)	NO			
port	char(5)	NO			
socket	text	NO		NULL	
username	char(64)	NO			
password	char(64)	NO			
ssl_ca	text	YES		NULL	
ssl_capath	text	YES		NULL	
ssl_cert	text	YES		NULL	
ssl_cipher	char(64)	YES		NULL	
ssl_key	text	YES		NULL	
ssl_verify_server_cert	tinyint(4)	NO		0	
default_file	text	YES		NULL	
default_group	char(64)	YES		NULL	
dsn	char(64)	YES		NULL	
filedsn	text	YES		NULL	
driver	char(64)	YES		NULL	

1.1.1.2.9.4 Sys Schema

MariaDB starting with 10.6.0

The sys_schema is a collection of views, functions and procedures to help administrators get insight into database usage.

This article is currently incomplete.

Sys Schema sys_config Table
Configuration options for the Sys Schema.

Sys Schema Stored Functions
Stored functions available in the Sys Schema.

Sys Schema Stored Procedures
Stored procedures available in the Sys Schema.

1.1.1.2.9.4.1 Sys Schema sys_config Table

MariaDB starting with 10.6.0

The Sys Schema *sys_config* table was added in MariaDB 10.6.0. The *sys_config* table is also backported to MariaDB-10.5-enterprise.

The *sys.sys_config* table holds configuration options for the Sys Schema.

This is a persistent table (using the Aria storage engine), with the configuration persisting across upgrades (new options are added with INSERT IGNORE.

The table also has two related triggers, which maintain the user that INSERTs or UPDATEs the configuration - sys_config_insert_set_user and sys_config_update_set_user respectively.

Its structure is as follows:

```
+----------+--------------+------+-----+-------------------+-----------------------------+
| Field    | Type         | Null | Key | Default           | Extra                       |
+----------+--------------+------+-----+-------------------+-----------------------------+
| variable | varchar(128) | NO   | PRI | NULL              |                             |
| value    | varchar(128) | YES  |     | NULL              |                             |
| set_time | timestamp    | NO   |     | CURRENT_TIMESTAMP | on update CURRENT_TIMESTAMP |
| set_by   | varchar(128) | YES  |     | NULL              |                             |
+----------+--------------+------+-----+-------------------+-----------------------------+
```

Note, when functions check for configuration options, they first check whether a similar named user variable exists with a value, and if this is not set then pull the configuration option from this table in to that named user variable. This is done for performance reasons (to not continually SELECT from the table), however this comes with the side effect that once inited, the values last with the session, somewhat like how session variables are inited from global variables. If the values within this table are changed, they will not take effect until the user logs in again.

Options Included

Variable	Default Value	Description
statement_truncate_len	64	Sets the size to truncate statements to, for the format_statement function.
statement_performance_analyzer.limit	100	The maximum number of rows to include for the views that does not have a built-in limit (e.g. the 95th percentile view). If not set the limit is 100.
statement_performance_analyzer.view	NULL	Used together with the 'custom' view. If the value contains a space, it is considered a query, otherwise it must be an existing view querying the performance_schema.events_statements_summary_by_digest table.
diagnostics.allow_i_s_tables	OFF	Specifies whether it is allowed to do table scan queries on information_schema.TABLES for the diagnostics procedure.
diagnostics.include_raw	OFF	Set to 'ON' to include the raw data (e.g. the original output of "SELECT * FROM sys.metrics") for the diagnostics procedure.
ps_thread_trx_info.max_length	65535	Sets the maximum output length for JSON object output by the ps_thread_trx_info() function.

Notes

Some early versions of *sys_config* were stored in InnoDB format.

1.1.1.2.9.4.2 Sys Schema Stored Functions

The following stored functions are available in the Sys Schema.

extract_schema_from_file_name

Returns the schema (database) name.

extract_table_from_file_name

Returns the table name from the provided path.

format_bytes

Returns a string consisting of a value and the units in a human-readable format.

format_path

Returns a modified path, replacing subpaths matching the values of various system variables.

format_statement

Returns a reduced length string.

format_time

Given a time in picoseconds, returns a human-readable time and unit.

list_add

Takes a list to be be modified and a value to be added to the list, returning the resulting value.

list_drop

Takes a list to be be modified and a value to be dropped, returning the resulting value.

ps_is_account_enabled

Whether or not Performance Schema instrumentation for a given account is enabled.

ps_is_consumer_enabled

Whether or not Performance Schema instrumentation for a given consumer is enabled.

ps_is_instrument_default_enabled

Whether or not a Performance Schema instrument is enabled by default.

ps_is_instrument_default_timed

Whether or not a Performance Schema instrument is timed by default.

ps_is_thread_instrumented

Whether or not instrumentation for a given connection_id is enabled.

ps_thread_account

Returns the account associated with the given thread_id.

ps_thread_id

Returns the thread_id associated with the given connection_id.

ps_thread_stack

Returns statements, stages, events within the Performance Schema for a given thread_id.

ps_thread_trx_info

Returns a JSON object with information about the thread specified by the given thread_id.

quote_identifier

Returns quoted, properly escaped identifier.

sys_get_config

Returns a configuration option value from the sys_config table.

version_major

Returns the MariaDB Server major release version.

version_minor

Returns the MariaDB Server minor release version.

version_patch

MariaDB Server patch release version.

1.1.1.2.9.4.2.1 extract_schema_from_file_name

Syntax

```
sys.extract_schema_from_file_name(path)
```

Description

`extract_schema_from_file_name` is a stored function available with the Sys Schema.

Given a file path, it returns the schema (database) name. The file name is assumed to be within the schema directory, and therefore the function will not return the expected result with partitions, or when tables are defined using the DATA_DIRECTORY table option.

The function does not examine anything on disk. The return value, a VARCHAR(64), is determined solely from the provided path.

Examples

```
SELECT sys.extract_schema_from_file_name('/usr/local/mysql/data/db/t1.ibd');
+-----------------------------------------------------------------------+
| sys.extract_schema_from_file_name('/usr/local/mysql/data/db/t1.ibd') |
+-----------------------------------------------------------------------+
| db                                                                    |
+-----------------------------------------------------------------------+
```

1.1.1.2.9.4.2.2 extract_table_from_file_name

Syntax

```
sys.extract_table_from_file_name(path)
```

Description

`extract_table_from_file_name` is a stored function available with the Sys Schema.

Given a file path, it returns the table name.

The function does not examine anything on disk. The return value, a VARCHAR(64), is determined solely from the provided path.

Examples

```
SELECT sys.extract_table_from_file_name('/usr/local/mysql/data/db/t1.ibd');
+-----------------------------------------------------------------------+
| sys.extract_table_from_file_name('/usr/local/mysql/data/db/t1.ibd') |
+-----------------------------------------------------------------------+
| t1                                                                    |
+-----------------------------------------------------------------------+
```

1.1.1.2.9.4.2.3 format_bytes

Syntax

```
sys.format_bytes(double)
```

Description

`format_bytes` is a stored function available with the Sys Schema.

Given a byte count, returns a string consisting of a value and the units in a human-readable format. The units will be in

bytes, KiB (kibibytes), MiB (mebibytes), GiB (gibibytes), TiB (tebibytes), or PiB (pebibytes).

The binary prefixes (kibi, mebi, gibi, tebi and pebi) were created in December 1998 by the International Electrotechnical Commission to avoid possible ambiguity, as the widely-used prefixes kilo, mega, giga, tera and peta can be used to refer to both the power-of-10 decimal system multipliers and the power-of-two binary system multipliers.

Examples

```
SELECT sys.format_bytes(1000),sys.format_bytes(1024);
+-----------------------+-----------------------+
| sys.format_bytes(1000) | sys.format_bytes(1024) |
+-----------------------+-----------------------+
| 1000 bytes             | 1.00 KiB              |
+-----------------------+-----------------------+

SELECT sys.format_bytes(1000000),sys.format_bytes(1048576);
+--------------------------+--------------------------+
| sys.format_bytes(1000000) | sys.format_bytes(1048576) |
+--------------------------+--------------------------+
| 976.56 KiB                | 1.00 MiB                 |
+--------------------------+--------------------------+

SELECT sys.format_bytes(1000000000),sys.format_bytes(1073741874);
+-----------------------------+-----------------------------+
| sys.format_bytes(1000000000) | sys.format_bytes(1073741874) |
+-----------------------------+-----------------------------+
| 953.67 MiB                  | 1.00 GiB                    |
+-----------------------------+-----------------------------+

SELECT sys.format_bytes(1000000000000),sys.format_bytes(1099511627776);
+--------------------------------+--------------------------------+
| sys.format_bytes(1000000000000) | sys.format_bytes(1099511627776) |
+--------------------------------+--------------------------------+
| 931.32 GiB                     | 1.00 TiB                       |
+--------------------------------+--------------------------------+

SELECT sys.format_bytes(1000000000000000),sys.format_bytes(1125899906842624);
+-----------------------------------+-----------------------------------+
| sys.format_bytes(1000000000000000) | sys.format_bytes(1125899906842624) |
+-----------------------------------+-----------------------------------+
| 909.49 TiB                        | 1.00 PiB                          |
+-----------------------------------+-----------------------------------+
```

1.1.1.2.9.4.2.4 format_path

Syntax

```
sys.format_path(path)
```

Description

`format_path` is a stored function available with the Sys Schema that, given a path, returns a modified path after replacing subpaths matching the values of various system variables with the variable name.

The system variables that are matched are, in order:

- datadir
- tmpdir
- slave_load_tmpdir
- innodb_data_home_dir
- innodb_log_group_home_dir
- innodb_undo_directory
- basedir

Examples

```
SELECT @@tmpdir;
+-----------------------------------+
| @@tmpdir                          |
+-----------------------------------+
| /home/ian/sandboxes/msb_10_8_2/tmp |
+-----------------------------------+

SELECT sys.format_path('/home/ian/sandboxes/msb_10_8_2/tmp/testdb.ibd');
+-----------------------------------------------------------------+
| sys.format_path('/home/ian/sandboxes/msb_10_8_2/tmp/testdb.ibd') |
+-----------------------------------------------------------------+
| @@tmpdir/testdb.ibd                                             |
+-----------------------------------------------------------------+
```

1.1.1.2.9.4.2.5 format_statement

Syntax

```
sys.format_statement(statement)
```

Description

Returns a reduced length string. The length is specified by the statement_truncate_len configuration option (default 64), and the removed part of the string (if any) is replaced with an ellipsis (three dots).

The function is intended for use in formatting lengthy SQL statements to a fixed length.

Examples

Default truncation length 64:

```
SELECT sys.format_statement(
  'SELECT field1, field2, field3, field4, field5, field6 FROM table1'
  ) AS formatted_statement;
+-----------------------------------------------------------------+
| formatted_statement                                             |
+-----------------------------------------------------------------+
| SELECT field1, field2, field3, ... d4, field5, field6 FROM table1 |
+-----------------------------------------------------------------+
```

Reducing the truncation length to 48:

```
SET @sys.statement_truncate_len = 48;

SELECT sys.format_statement(
  'SELECT field1, field2, field3, field4, field5, field6 FROM table1'
  ) AS formatted_statement;
+-------------------------------------------------+
| formatted_statement                             |
+-------------------------------------------------+
| SELECT field1, field2, ... d5, field6 FROM table1 |
+-------------------------------------------------+
```

1.1.1.2.9.4.2.6 format_time

Syntax

```
sys.format_time(picoseconds)
```

Description

`format_time` is a stored function available with the Sys Schema. Given a time in picoseconds, returns a human-readable time value and unit indicator. Unit can be:

- ps - picoseconds
- ns - nanoseconds
- us - microseconds
- ms - milliseconds
- s - seconds
- m - minutes
- h - hours
- d - days
- w - weeks

This function is very similar to the FORMAT_PICO_TIME function introduced in MariaDB 11.0.2, but with the following differences:

- Represents minutes as `m` rather than `min`.
- Represent weeks.

Examples

```
SELECT
    sys.format_time(43) AS ps,
    sys.format_time(4321) AS ns,
    sys.format_time(43211234) AS us,
    sys.format_time(432112344321) AS ms,
    sys.format_time(43211234432123) AS s,
    sys.format_time(432112344321234) AS m,
    sys.format_time(4321123443212345) AS h,
    sys.format_time(43211234432123545) AS d,
    sys.format_time(432112344321234543) AS w;
+-------+---------+----------+-----------+---------+--------+--------+--------+---------+
| ps    | ns      | us       | ms        | s       | m      | h      | d      | w       |
+-------+---------+----------+-----------+---------+--------+--------+--------+---------+
| 43 ps | 4.32 ns | 43.21 us | 432.11 ms | 43.21 s | 7.20 m | 1.20 h | 5.00 d | 71.45 w |

```

1.1.1.2.9.4.2.7 list_add

Syntax

```
sys.list_add(list,value)
```

Description

`list_add` is a stored function available with the Sys Schema.

It takes a *list* to be be modified and a *value* to be added to the list, returning the resulting value. This can be used, for example, to add a value to a system variable taking a comma-delimited list of options, such as sql_mode.

The related function list_drop can be used to drop a value from a list.

Examples

```
SELECT @@sql_mode;
+--------------------------------------------------------------------+
| @@sql_mode                                                         |
+--------------------------------------------------------------------+
| STRICT_TRANS_TABLES,ERROR_FOR_DIVISION_BY_ZERO,
NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION |
+--------------------------------------------------------------------+

SET @@sql_mode = sys.list_add(@@sql_mode, 'NO_ZERO_DATE');

SELECT @@sql_mode;
+--------------------------------------------------------------------+
| @@sql_mode                                                         |
+--------------------------------------------------------------------+
| STRICT_TRANS_TABLES,NO_ZERO_DATE,ERROR_FOR_DIVISION_BY_ZERO,
NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION |
+--------------------------------------------------------------------+
```

1.1.1.2.9.4.2.8 list_drop

Syntax

```
sys.list_drop(list,value)
```

Description

`list_drop` is a stored function available with the Sys Schema.

It takes a *list* to be be modified and a *value* to be dropped from the list, returning the resulting value. This can be used, for example, to remove a value from a system variable taking a comma-delimited list of options, such as sql_mode.

The related function list_add can be used to add a value to a list.

Examples

```
SELECT @@sql_mode;
+--------------------------------------------------------------------+
| @@sql_mode                                                         |
+--------------------------------------------------------------------+
| STRICT_TRANS_TABLES,ERROR_FOR_DIVISION_BY_ZERO,
NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION |
+--------------------------------------------------------------------+

SET @@sql_mode = sys.list_drop(@@sql_mode, 'NO_ENGINE_SUBSTITUTION');

SELECT @@sql_mode;
+--------------------------------------------------------------------+
| @@sql_mode                                                         |
+--------------------------------------------------------------------+
| STRICT_TRANS_TABLES,ERROR_FOR_DIVISION_BY_ZERO,
NO_AUTO_CREATE_USER |
+--------------------------------------------------------------------+
```

1.1.1.2.9.4.2.9 ps_is_account_enabled

Syntax

```
sys.ps_is_account_enabled(host,user)
```

Description

`ps_is_account_enabled` is a stored function available with the Sys Schema.

It takes *host* and *user* arguments, and returns an ENUM('YES','NO') depending on whether Performance Schema instrumentation for the given account is enabled.

Examples

```
SELECT sys.ps_is_account_enabled('localhost', 'root');
+-----------------------------------------------+
| sys.ps_is_account_enabled('localhost', 'root') |
+-----------------------------------------------+
| YES                                           |
+-----------------------------------------------+
```

1.1.1.2.9.4.2.10 ps_is_consumer_enabled

Syntax

```
sys.ps_is_consumer_enabled(consumer)
```

Description

`ps_is_consumer_enabled` is a stored function available with the Sys Schema.

It returns an ENUM('YES','NO') depending on whether Performance Schema instrumentation for the given consumer is enabled, and NULL if not given a valid consumer name.

Examples

```
SELECT sys.ps_is_consumer_enabled('global_instrumentation');
+-------------------------------------------------------+
| sys.ps_is_consumer_enabled('global_instrumentation') |
+-------------------------------------------------------+
| YES                                                   |
+-------------------------------------------------------+

SELECT sys.ps_is_consumer_enabled('events_stages_current');
+-----------------------------------------------------+
| sys.ps_is_consumer_enabled('events_stages_current') |
+-----------------------------------------------------+
| NO                                                  |
+-----------------------------------------------------+

SELECT sys.ps_is_consumer_enabled('nonexistent_consumer');
+-------------------------------------------------------+
| sys.ps_is_consumer_enabled('nonexistent_consumer') |
+-------------------------------------------------------+
| NULL                                                  |
+-------------------------------------------------------+
```

1.1.1.2.9.4.2.11 ps_is_instrument_default_enabled

Syntax

```
sys.ps_is_instrument_default_enabled(instrument)
```

Description

`ps_is_instrument_default_enabled` is a stored function available with the Sys Schema.

It returns `YES` if the given Performance Schema *instrument* is enabled by default, and `NO` if it is not, does not exist, or is a NULL value.

Examples

```
SELECT sys.ps_is_instrument_default_enabled('statement/sql/select');
+-----------------------------------------------------------+
| sys.ps_is_instrument_default_enabled('statement/sql/select') |
+-----------------------------------------------------------+
| YES                                                       |
+-----------------------------------------------------------+

SELECT sys.ps_is_instrument_default_enabled('memory/sql/udf_mem');
+-----------------------------------------------------------+
| sys.ps_is_instrument_default_enabled('memory/sql/udf_mem') |
+-----------------------------------------------------------+
| NO                                                        |
+-----------------------------------------------------------+

SELECT sys.ps_is_instrument_default_enabled('memory/sql/nonexistent');
+-----------------------------------------------------------------+
| sys.ps_is_instrument_default_enabled('memory/sql/nonexistent') |
+-----------------------------------------------------------------+
| NO                                                              |
+-----------------------------------------------------------------+

SELECT sys.ps_is_instrument_default_enabled(NULL);
+-------------------------------------------+
| sys.ps_is_instrument_default_enabled(NULL) |
+-------------------------------------------+
| NO                                        |
+-------------------------------------------+
```

1.1.1.2.9.4.2.12 ps_is_instrument_default_timed

Syntax

```
sys.ps_is_instrument_default_timed(instrument)
```

Description

`ps_is_instrument_default_timed` is a stored function available with the Sys Schema.

It returns `YES` if the given Performance Schema *instrument* is timed by default, and `NO` if it is not, does not exist, or is a NULL value.

Examples

```
SELECT sys.ps_is_instrument_default_timed('statement/sql/select');
+-----------------------------------------------------------+
| sys.ps_is_instrument_default_timed('statement/sql/select') |
+-----------------------------------------------------------+
| YES                                                       |
+-----------------------------------------------------------+

SELECT sys.ps_is_instrument_default_timed('memory/sql/udf_mem');
+---------------------------------------------------------+
| sys.ps_is_instrument_default_timed('memory/sql/udf_mem') |
+---------------------------------------------------------+
| NO                                                      |
+---------------------------------------------------------+

SELECT sys.ps_is_instrument_default_timed('memory/sql/nonexistent');
+-------------------------------------------------------------+
| sys.ps_is_instrument_default_timed('memory/sql/udf_memsds') |
+-------------------------------------------------------------+
| NO                                                          |
+-------------------------------------------------------------+

SELECT sys.ps_is_instrument_default_timed(NULL);
+-----------------------------------------+
| sys.ps_is_instrument_default_timed(NULL) |
+-----------------------------------------+
| NO                                      |
+-----------------------------------------+
```

1.1.1.2.9.4.2.13 ps_is_thread_instrumented

Syntax

```
sys.ps_is_thread_instrumented(connection_id)
```

Description

`ps_is_thread_instrumented` is a stored function available with the Sys Schema that returns whether or not Performance Schema instrumentation for the given *connection_id* is enabled.

- `YES` - instrumentation is enabled
- `NO` - instrumentation is not enabled
- `UNKNOWN` - the connection ID is unknown
- `NULL` - NULL value

Examples

```
SELECT sys.ps_is_thread_instrumented(CONNECTION_ID());
+-----------------------------------------------+
| sys.ps_is_thread_instrumented(CONNECTION_ID()) |
+-----------------------------------------------+
| YES                                           |
+-----------------------------------------------+

SELECT sys.ps_is_thread_instrumented(2042);
+-----------------------------------+
| sys.ps_is_thread_instrumented(2042) |
+-----------------------------------+
| UNKNOWN                           |
+-----------------------------------+

SELECT sys.ps_is_thread_instrumented(NULL);
+-----------------------------------+
| sys.ps_is_thread_instrumented(NULL) |
+-----------------------------------+
| NULL                              |
+-----------------------------------+
```

1.1.1.2.9.4.2.14 ps_thread_account

Syntax

```
sys.ps_thread_account(thread_id)
```

Description

`ps_thread_account` is a stored function available with the Sys Schema that returns the account (username@hostname) associated with the given *thread_id*.

Returns `NULL` if the thread_id is not found.

Examples

```
SELECT sys.ps_thread_account(sys.ps_thread_id(CONNECTION_ID()));
+-----------------------------------------------------------+
| sys.ps_thread_account(sys.ps_thread_id(CONNECTION_ID())) |
+-----------------------------------------------------------+
| msandbox@localhost                                        |
+-----------------------------------------------------------+

SELECT sys.ps_thread_account(sys.ps_thread_id(2042));
+-----------------------------------------------+
| sys.ps_thread_account(sys.ps_thread_id(2042)) |
+-----------------------------------------------+
| NULL                                          |
+-----------------------------------------------+

SELECT sys.ps_thread_account(sys.ps_thread_id(NULL));
+-----------------------------------------------+
| sys.ps_thread_account(sys.ps_thread_id(NULL)) |
+-----------------------------------------------+
| msandbox@localhost                            |
+-----------------------------------------------+
```

1.1.1.2.9.4.2.15 ps_thread_id

Syntax

```
sys.ps_thread_id(connection_id)
```

Description

`ps_thread_id` is a stored function available with the Sys Schema that returns the thread_id associated with the given *connection_id*. If the *connection_id* is NULL, returns the thread_id for the current connection.

Examples

```
SELECT * FROM performance_schema.threads\G
*************************** 13. row ***************************
          THREAD_ID: 13
               NAME: thread/sql/one_connection
               TYPE: FOREGROUND
     PROCESSLIST_ID: 3
   PROCESSLIST_USER: msandbox
   PROCESSLIST_HOST: localhost
     PROCESSLIST_DB: test
PROCESSLIST_COMMAND: Query
   PROCESSLIST_TIME: 0
  PROCESSLIST_STATE: Sending data
   PROCESSLIST_INFO: SELECT * FROM performance_schema.threads
   PARENT_THREAD_ID: 1
               ROLE: NULL
       INSTRUMENTED: YES
            HISTORY: YES
    CONNECTION_TYPE: Socket
       THREAD_OS_ID: 24379

SELECT sys.ps_thread_id(3);
+----------------------+
| sys.ps_thread_id(3) |
+----------------------+
|                   13 |
+----------------------+

SELECT sys.ps_thread_id(NULL);
+------------------------+
| sys.ps_thread_id(NULL) |
+------------------------+
|                     13 |
+------------------------+
```

1.1.1.2.9.4.2.16 ps_thread_stack

Syntax

```
sys.ps_thread_stack(thread_id, verbose)
```

Description

`ps_thread_stack` is a stored function available with the Sys Schema that, for a given *thread_id*, returns all statements, stages, and events within the Performance Schema, as a JSON formatted stack.

The boolean *verbose* argument specifies whether or not to include `file:lineno` information in the events.

Examples

```
SELECT sys.ps_thread_stack(13, FALSE) AS thread_stack\G
*************************** 1. row ***************************
thread_stack: {"rankdir": "LR","nodesep": "0.10",
  "stack_created": "2022-03-28 16:01:06",
  "mysql_version": "10.8.2-MariaDB",
  "mysql_user": "msandbox@localhost",
  "events": []}
```

1.1.1.2.9.4.2.17 ps_thread_trx_info

Syntax

```
sys.ps_thread_trx_info(thread_id)
```

Contents

Description

`ps_thread_trx_info` is a stored function available with the Sys Schema.

It returns a JSON object with information about the thread specified by the given *thread_id*. This information includes:

- the current transaction
- executed statements (derived from the Performance Schema events_transactions_current Table and the Performance Schema events_statements_history Table (full data will only returned if the consumers for those tables are enabled).

The maximum length of the returned JSON object is determined by the value of the ps_thread_trx_info.max_length sys_config option (by default 65535). If the returned value exceeds this length, a JSON object error is returned.

Examples

```
```

1.1.1.2.9.4.2.18 quote_identifier

Syntax

```
sys.quote_identifier(str)
```

Description

`quote_identifier` is a stored function available with the Sys Schema.

It quotes a string to produce a result that can be used as an identifier in an SQL statement. The string is returned enclosed by backticks (" ` ") and with each instance of backtick (" ` ") doubled. If the argument is `NULL`, the return value is the word "`NULL`" without enclosing backticks.

Examples

```
SELECT sys.quote_identifier("Identifier with spaces");
+-----------------------------------------------+
| sys.quote_identifier("Identifier with spaces") |
+-----------------------------------------------+
| `Identifier with spaces`                      |
+-----------------------------------------------+

SELECT sys.quote_identifier("Identifier` containing `backticks");
+-------------------------------------------------------------+
| sys.quote_identifier("Identifier` containing `backticks") |
+-------------------------------------------------------------+
| `Identifier`` containing ``backticks`                      |
+-------------------------------------------------------------+
```

1.1.1.2.9.4.2.19 sys_get_config

Syntax

```
sys.sys_get_config(name,default)
```

Contents

Description

`sys_get_config` is a stored function available with the Sys Schema.

The function returns a configuration option value from the sys_config table. It takes two arguments; *name*, a configuration option name, and *default*, which is returned if the given option does not exist in the table.

Both arguments are VARCHAR(128) and can be NULL. Returns NULL if *name* is NULL, or if the given option is not found and *default* is NULL.

Examples

```
SELECT sys.sys_get_config('ps_thread_trx_info.max_length',NULL);
+-----------------------------------------------------------+
| sys.sys_get_config('ps_thread_trx_info.max_length',NULL) |
+-----------------------------------------------------------+
| 65535                                                     |
+-----------------------------------------------------------+
```

1.1.1.2.9.4.2.20 version_major

Syntax

```
sys.version_major()
```

Description

`version_major` is a stored function available with the Sys Schema.

It returns the MariaDB Server major release version.

Examples

```
SELECT VERSION(),
 sys.version_major() AS major,
 sys.version_minor() AS minor,
 sys.version_patch() AS patch;
+----------------+-------+-------+-------+
| VERSION()      | major | minor | patch |
+----------------+-------+-------+-------+
| 10.8.2-MariaDB |    10 |     8 |     2 |
+----------------+-------+-------+-------+
```

1.1.1.2.9.4.2.21 version_minor

Syntax

```
sys.version_minor()
```

Description

`version_minor` is a stored function available with the Sys Schema.

It returns the MariaDB Server minor release version.

Examples

```
SELECT VERSION(),
 sys.version_major() AS major,
 sys.version_minor() AS minor,
 sys.version_patch() AS patch;
+----------------+-------+-------+-------+
| VERSION()      | major | minor | patch |
+----------------+-------+-------+-------+
| 10.8.2-MariaDB |    10 |     8 |     2 |
+----------------+-------+-------+-------+
```

1.1.1.2.9.4.2.22 version_patch

Syntax

```
sys.version_patch()
```

Description

`version_patch` is a stored function available with the Sys Schema.

It returns the MariaDB Server patch release version.

Examples

```
SELECT VERSION(),
 sys.version_major() AS major,
 sys.version_minor() AS minor,
 sys.version_patch() AS patch;
+----------------+-------+-------+-------+
| VERSION()      | major | minor | patch |
+----------------+-------+-------+-------+
| 10.8.2-MariaDB |    10 |     8 |     2 |
+----------------+-------+-------+-------+
```

1.1.1.2.9.4.3 Sys Schema Stored Procedures

This article is currently incomplete.

The following stored procedures are available in the Sys Schema.

create_synonym_db

Takes a source db and create a synonym db with views that point to all of t...

optimizer_switch Helper Functions

Syntax optimizer_switch_on() optimizer_switch_off() optimizer_switch_choice...

ps_trace_thread

Dumps all Performance Schema data for an instrumented thread to a .dot formatted graph file.

ps_truncate_all_tables

Resets all aggregated instrumentation.

statement_performance_analyzer

Returns a report on running statements.

table_exists

Given a database and table name, returns the table type.

1.1.1.2.9.4.3.1 create_synonym_db

Syntax

```
create_synonym_db(db_name,synonym)

# db_name (VARCHAR(64))
# synonym (VARCHAR(64))
```

Description

`create_synonym_db` is a stored procedure available with the Sys Schema.

Takes a source database name *db_name* and *synonym* name and creates a synonym database with views that point to all of the tables within the source database. Useful for example for creating a synonym for the performance_schema or information_schema databases.

Returns an error if the source database doesn't exist, or the synonym already exists.

Example

```
SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| mysql              |
| performance_schema |
| sys                |
| test               |
+--------------------+

CALL sys.create_synonym_db('performance_schema', 'perf');
+----------------------------------------+
| summary                                |
+----------------------------------------+
| Created 81 views in the `perf` database |
+----------------------------------------+

SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| mysql              |
| perf               |
| performance_schema |
| sys                |
| test               |
+--------------------+

SHOW FULL TABLES FROM perf;
+-----------------------------------------------------+------------+
| Tables_in_perf                                      | Table_type |
+-----------------------------------------------------+------------+
| accounts                                            | VIEW       |
| cond_instances                                      | VIEW       |
| events_stages_current                               | VIEW       |
| events_stages_history                               | VIEW       |
| events_stages_history_long                          | VIEW       |
...
```

1.1.1.2.9.4.3.2 optimizer_switch Helper Functions

Syntax

```
optimizer_switch_on()
optimizer_switch_off()
optimizer_switch_choice("on" | "off")
```

Contents

Description

The above procedures can be used to check which optimizer_switch options are `on` or `off`. The result set is sorted according to optimizer_switch option name.

Example

```
select @@optimizer_switch\G
*************************** 1. row ***************************
index_merge=on,index_merge_union=on,index_merge_sort_union=on,index_merge_intersection=on,
index_merge_sort_intersection=off,engine_condition_pushdown=off,index_condition_pushdown=on,
derived_merge=on,derived_with_keys=on,firstmatch=on,loosescan=on,materialization=on,

+-------------------------------+------+
```

Notes

`sys.optimizer_switch_on()` is a shortcut for `sys.optimizer_switch_choice("on");`
`sys.optimizer_switch_off()` is a shortcut for `sys.optimizer_switch_choice("off");`

1.1.1.2.9.4.3.3 ps_trace_thread

Syntax

```
ps_trace_thread(thread_id, outfile, max_runtime, interval, start_fresh, auto_setup, debug)
```

Description

`ps_trace_thread` is a stored procedure available with the Sys Schema.

Parameters:

- thread_id INT: The thread to trace.
- outfile VARCHAR(255): Name of the .dot file to be create.
- max_runtime DECIMAL(20,2): Maximum time in seconds to collect data. Fractional seconds can be used, and NULL results in data being collected for the default sixty seconds.
- interval DECIMAL(20,2): Time in seconds to sleep between data collection. Fractional seconds can be used, and NULL results in the sleep being the default one second.
- start_fresh BOOLEAN: Whether to reset all Performance Schema data before tracing.
- auto_setup BOOLEAN: Whether to disable all other threads, enable all instruments and consumers, and reset the settings at the end of the run.
- debug BOOLEAN: Whether to include file:lineno information in the graph.

Dumps all Performance Schema data for an instrumented thread to a .dot formatted graph file (for use with the DOT graph description language). All returned result sets should be used for a complete graph.

Session binary logging is disabled during execution, by adjusting the sql_log_bin session value (note the permissions required).

Examples

```
CALL sys.ps_trace_thread(25, CONCAT('/tmp/stack-', REPLACE(NOW(), ' ', '-'), '.dot'),
  NULL, NULL, TRUE, TRUE, TRUE);

--------------------+
| summary            |

| dot -Tpng -o /tmp/stack_25.png /tmp/stack-2023-04-05-19:06:29.dot |
+-------------------------------------------------------------------------+
```

1.1.1.2.9.4.3.4 ps_truncate_all_tables

Syntax

```
ps_truncate_all_tables(bool display)
```

Description

`ps_truncate_all_tables` is a stored procedure available with the Sys Schema.

The procedure resets all aggregated instrumentation as a snapshot, producing a result set indicating the number of truncated tables. The boolean parameter *display* specifies whether to display each TRUNCATE TABLE statement before execution.

Examples

```
CALL sys.ps_truncate_all_tables(false);
+---------------------+
| summary             |
+---------------------+
| Truncated 44 tables |
+---------------------+
```

```
CALL sys.ps_truncate_all_tables(true);
+-----------------------------------------------------------------+
| status                                                          |
+-----------------------------------------------------------------+
| Running: TRUNCATE TABLE performance_schema.events_stages_history |
+-----------------------------------------------------------------+

...

+-------------------------------------------------------------------------------+
| status                                                                        |
+-------------------------------------------------------------------------------+
| Running: TRUNCATE TABLE performance_schema.table_lock_waits_summary_by_table |
+-------------------------------------------------------------------------------+

+---------------------+
| summary             |
+---------------------+
| Truncated 44 tables |
+---------------------+
```

1.1.1.2.9.4.3.5 statement_performance_analyzer

Syntax

```
statement_performance_analyzer(in_action,in_table, in_views)

# in_action ENUM('snapshot', 'overall', 'delta', 'create_tmp',
                 'create_table', 'save', 'cleanup')
# in_table VARCHAR(129)
# in_views SET ('with_runtimes_in_95th_percentile', 'analysis',
                'with_errors_or_warnings', 'with_full_table_scans',
                'with_sorting', 'with_temp_tables', 'custom')
```

Description

`statement_performance_analyzer` is a stored procedure available with the Sys Schema which returns a report on running statements.

The following options from the sys_config table impact the output:

- statement_performance_analyzer.limit - maximum number of rows (default 100) returned for views that have no built-in limit.
- statement_performance_analyzer.view - custom query/view to be used (default NULL). If the statement_performance_analyzer.limit configuration option is greater than 0, there can't be a LIMIT clause in the query/view definition

If the debug option is set (default OFF), the procedure will also produce debugging output.

1.1.1.2.9.4.3.6 table_exists

Syntax

```
table_exists(in_db_name,in_table_name, out_table_type)

# in_db_name VARCHAR(64)
# in_table_name VARCHAR(64)
# out_table_type ENUM('', 'BASE TABLE', 'VIEW', 'TEMPORARY')
```

Description

`table_exists` is a stored procedure available with the Sys Schema.

Given a database *in_db_name* and table name *in_table_name*, returns the table type in the OUT parameter *out_table_type*. The return value is an ENUM field containing one of:

- '' - the table does not exist
- 'BASE TABLE' - a regular table
- 'VIEW' - a view
- 'TEMPORARY' - a temporary table

Examples

```
CALL sys.table_exists('mysql', 'time_zone', @table_type); SELECT @table_type;
+-------------+
| @table_type |
+-------------+
| BASE TABLE  |
+-------------+

CALL sys.table_exists('mysql', 'user', @table_type); SELECT @table_type;
+-------------+
| @table_type |
+-------------+
| VIEW        |
+-------------+
```

1.1.1.2.9.5 mariadb_schema

Contents

1. History

`mariadb_schema` is a data type qualifier that allows one to create MariaDB native date types in an SQL_MODE that has conflicting data type translations.

`mariadb_schema` was introduced in MariaDB 10.3.24, MariaDB 10.4.14 and MariaDB 10.5.5.

For example, in SQL_MODE=ORACLE, if one creates a table with the DATE type, it will actually create a DATETIME column to match what an Oracle user is expecting. To be able to create a MariaDB DATE in Oracle mode one would have to use `mariadb_schema`:

```
CREATE TABLE t1 (d mariadb_schema.DATE);
```

`mariadb_schema` is also shown if one creates a table with `DATE` in MariaDB native mode and then does a SHOW CREATE TABLE in `ORACLE` mode:

```
SET sql_mode=DEFAULT;
CREATE OR REPLACE TABLE t1 (
  d DATE
);
SET SQL_mode=ORACLE;
SHOW CREATE TABLE t1;
+-------+-----------------------------------------------------------------+
| Table | Create Table                                                    |
+-------+-----------------------------------------------------------------+
| t1    | CREATE TABLE "t1" (
  "d" mariadb_schema.date DEFAULT NULL
) |
+-------+-----------------------------------------------------------------+
```

When the server sees the `mariadb_schema` qualifier, it disables sql_mode-specific data type translation and interprets the data type literally, so for example `mariadb_schema.DATE` is interpreted as the traditional MariaDB `DATE` data type, no matter what the current sql_mode is.

The `mariadb_schema` prefix is displayed only when the data type name would be ambiguous otherwise. The prefix is displayed together with MariaDB `DATE` when SHOW CREATE TABLE is executed in SQL_MODE=ORACLE. The prefix is not displayed when SHOW CREATE TABLE is executed in SQL_MODE=DEFAULT, or when a non-ambiguous data type is displayed.

Note, the `mariadb_schema` prefix can be used with any data type, including non-ambiguous ones:

```
CREATE OR REPLACE TABLE t1 (a mariadb_schema.INT);
SHOW CREATE TABLE t1;
+-------+-----------------------------------------------------+
| Table | Create Table                                        |
+-------+-----------------------------------------------------+
| t1    | CREATE TABLE "t1" (
  "a" int(11) DEFAULT NULL
) |
+-------+-----------------------------------------------------+
```

Currently the `mariadb_schema` prefix is only used in the following case:

- For a MariaDB native DATE type when running SHOW CREATE TABLE in Oracle mode.

History

When running with SQL_MODE=ORACLE, MariaDB server translates the data type `DATE` to `DATETIME`, for better Oracle compatibility:

```
SET SQL_mode=ORACLE;
CREATE OR REPLACE TABLE t1 (
  d DATE
);
SHOW CREATE TABLE t1;
+-------+-----------------------------------------------------+
| Table | Create Table                                        |
+-------+-----------------------------------------------------+
| t1    | CREATE TABLE "t1" (
  "d" datetime DEFAULT NULL
) |
+-------+-----------------------------------------------------+
```

Notice, `DATE` was translated to `DATETIME`.

This translation may cause some ambiguity. Suppose a user creates a table with a column of the traditional MariaDB `DATE` data type using the default sql_mode, but then switches to SQL_MODE=ORACLE and runs a SHOW CREATE TABLE statement:

```
SET sql_mode=DEFAULT;
CREATE OR REPLACE TABLE t1 (
  d DATE
);
SET SQL_mode=ORACLE;
SHOW CREATE TABLE t1;
```

Before `mariadb_schema` was introduced, the above script displayed:

```
CREATE TABLE "t1" (
  "d" date DEFAULT NULL
);
```

which had two problems:

- It was confusing for the reader: its not clear if it is the traditional MariaDB `DATE`, or is it Oracle-alike date (which is actually `DATETIME`);
- It broke replication and caused data type mismatch on the master and on the slave (see MDEV-19632).

To address this problem, starting from the mentioned versions, MariaDB uses the idea of qualified data types:

```
SET sql_mode=DEFAULT;
CREATE OR REPLACE TABLE t1 (
  d DATE
);
SET SQL_mode=ORACLE;
SHOW CREATE TABLE t1;
+-------+-----------------------------------------------------------------+
| Table | Create Table                                                    |
+-------+-----------------------------------------------------------------+
| t1    | CREATE TABLE "t1" (
  "d" mariadb_schema.date DEFAULT NULL
) |
+-------+-----------------------------------------------------------------+
```

1.1.1.2.9.6 Writing Logs Into Tables

By default, all logs are disabled or written into files. The general query log and the slow query log can also be written to special tables in the `mysql` database. During the startup, entries will always be written into files.

Note that EXPLAIN output will only be recorded if the slow query log is written to a file and not to a table.

To write logs into tables, the log_output server system variable is used. Allowed values are `FILE`, `TABLE` and `NONE`. It is possible to specify multiple values, separated with commas, to write the logs into both tables and files. `NONE` disables logging and has precedence over the other values.

So, to write logs into tables, one of the following settings can be used:

```
SET GLOBAL log_output = 'TABLE';
SET GLOBAL log_output = 'FILE,TABLE';
```

The general log will be written into the general_log table, and the slow query log will be written into the slow_log table. Only a limited set of operations are supported for those special tables. For example, direct DML statements (like `INSERT`) on those tables will fail with an error similar to the following:

```
ERROR 1556 (HY000): You can't use locks with log tables.
```

To flush data to the tables, use FLUSH TABLES instead of FLUSH LOGS.

To empty the contents of the log tables, TRUNCATE TABLE can be used.

The log tables use the CSV storage engine by default. This allows an external program to read the files if needed: normal CSV files are stored in the `mysql` subdirectory, in the data dir. However that engine is slow because it does not support indexes, so you can convert the tables to MyISAM (but not other storage engines). To do so, first temporarily disable logging:

```
SET GLOBAL general_log = 'OFF';
ALTER TABLE mysql.general_log ENGINE = MyISAM;
ALTER TABLE mysql.slow_log ENGINE = MyISAM;
SET GLOBAL general_log = @old_log_state;
```

CHECK TABLE and CHECKSUM TABLE are supported.

CREATE TABLE is supported. ALTER TABLE, RENAME TABLE and DROP TABLE are supported when logging is disabled, but log tables cannot be partitioned.

The contents of the log tables is not logged in the binary log thus cannot be replicated.

1.1.1.2.10 BINLOG

Syntax

```
BINLOG 'str'
```

Description

`BINLOG` is an internal-use statement. It is generated by the mariadb-binlog program as the printable representation of certain events in binary log files. The `'str'` value is a base 64-encoded string that the server decodes to determine the data change indicated by the corresponding event. This statement requires the SUPER privilege (<= MariaDB 10.5.1) or the BINLOG REPLAY privilege (>= MariaDB 10.5.2).

1.1.1.2.11 PURGE BINARY LOGS

Syntax

```
PURGE { BINARY | MASTER } LOGS
    { TO 'log_name' | BEFORE datetime_expr }
```

Description

The `PURGE BINARY LOGS` statement deletes all the binary log files listed in the log index file prior to the specified log file name or date. `BINARY` and `MASTER` are synonyms. Deleted log files also are removed from the list recorded in the index file, so that the given log file becomes the first in the list.

The datetime expression is in the format 'YYYY-MM-DD hh:mm:ss'.

> If a replica is active but has yet to read from a binary log file you attempt to delete, the statement will fail with an error. However, if the replica is not connected and has yet to read from a log file you delete, the file will be deleted, but the replica will be unable to continue replicating once it connects again.

This statement has no effect if the server was not started with the --log-bin option to enable binary logging.

To list the binary log files on the server, use SHOW BINARY LOGS. To see which files they are reading, use SHOW SLAVE STATUS (or SHOW REPLICA STATUS from MariaDB 10.5.1). You can only delete the files that are older than the oldest file that is used by the slaves.

To delete all binary log files, use RESET MASTER. To move to a new log file (for example if you want to remove the current log file), use FLUSH LOGS before you execute `PURGE LOGS`.

If the expire_logs_days server system variable is not set to 0, the server automatically deletes binary log files after the given number of days. From MariaDB 10.6, the binlog_expire_logs_seconds variable allows more precise control over binlog deletion, and takes precedence if both are non-zero.

Requires the SUPER privilege or, from MariaDB 10.5.2, the BINLOG ADMIN privilege, to run.

Examples

```
PURGE BINARY LOGS TO 'mariadb-bin.000063';
```

```
PURGE BINARY LOGS BEFORE '2013-04-21';
```

```
PURGE BINARY LOGS BEFORE '2013-04-22 09:55:22';
```

1.1.1.2.12 CACHE INDEX

Syntax

```
CACHE INDEX
  tbl_index_list [, tbl_index_list] ...
  IN key_cache_name

tbl_index_list:
  tbl_name [[INDEX|KEY] (index_name[, index_name] ...)]
```

Description

The `CACHE INDEX` statement assigns table indexes to a specific key cache. It is used only for MyISAM tables.

A default key cache exists and cannot be destroyed. To create more key caches, the key_buffer_size server system variable.

The associations between tables indexes and key caches are lost on server restart. To recreate them automatically, it is necessary to configure caches in a configuration file and include some `CACHE INDEX` (and optionally `LOAD INDEX`) statements in the init file.

Examples

The following statement assigns indexes from the tables t1, t2, and t3 to the key cache named hot_cache:

```
CACHE INDEX t1, t2, t3 IN hot_cache;
+---------+--------------------+----------+----------+
| Table   | Op                 | Msg_type | Msg_text |
+---------+--------------------+----------+----------+
| test.t1 | assign_to_keycache | status   | OK       |
| test.t2 | assign_to_keycache | status   | OK       |
| test.t3 | assign_to_keycache | status   | OK       |
+---------+--------------------+----------+----------+
```

Implementation (for MyISAM)

Normally CACHE INDEX should not take a long time to execute. Internally it's implemented the following way:

- Find the right key cache (under LOCK_global_system_variables)
- Open the table with a TL_READ_NO_INSERT lock.
- Flush the original key cache for the given file (under key cache lock)
- Flush the new key cache for the given file (safety)
- Move the file to the new key cache (under file share lock)

The only possible long operations are getting the locks for the table and flushing the original key cache, if there were many key blocks for the file in it.

We plan to also add CACHE INDEX for Aria tables if there is a need for this.

1.1.1.2.13 DESCRIBE

Syntax

```
{DESCRIBE | DESC} tbl_name [col_name | wild]
```

Contents

Description

`DESCRIBE` provides information about the columns in a table. It is a shortcut for `SHOW COLUMNS FROM`. These statements also display information for views.

`col_name` can be a column name, or a string containing the SQL " `%` " and " `_` " wildcard characters to obtain output only for the columns with names matching the string. There is no need to enclose the string within quotes unless it contains spaces or other special characters.

```
DESCRIBE city;
+------------+----------+------+-----+---------+----------------+
| Field      | Type     | Null | Key | Default | Extra          |
+------------+----------+------+-----+---------+----------------+
| Id         | int(11)  | NO   | PRI | NULL    | auto_increment |
| Name       | char(35) | YES  |     | NULL    |                |
| Country    | char(3)  | NO   | UNI |         |                |
| District   | char(20) | YES  | MUL |         |                |
| Population | int(11)  | YES  |     | NULL    |                |
+------------+----------+------+-----+---------+----------------+
```

The description for `SHOW COLUMNS` provides more information about the output columns.

1.1.1.2.14 EXECUTE Statement

Syntax

```
EXECUTE stmt_name
    [USING expression[, expression] ...]
```

Contents

MariaDB starting with 10.2.3

`EXECUTE` with expression as parameters was introduced in MariaDB 10.2.3. Before that one could only use variables (@var_name) as parameters.

Description

After preparing a statement with `PREPARE`, you execute it with an `EXECUTE` statement that refers to the prepared statement name. If the prepared statement contains any parameter markers, you must supply a `USING` clause that lists user variables containing the values to be bound to the parameters. Parameter values can be supplied only by user variables, and the `USING` clause must name exactly as many variables as the number of parameter markers in the statement.

You can execute a given prepared statement multiple times, passing different variables to it or setting the variables to different values before each execution.

If the specified statement has not been PREPAREd, an error similar to the following is produced:

```
ERROR 1243 (HY000): Unknown prepared statement handler (stmt_name) given to EXECUTE
```

Example

See example in PREPARE.

1.1.1.2.15 HELP Command

Syntax

```
HELP search_string
```

Description

The `HELP` command can be used in any MariaDB client, such as the mariadb command-line client, to get basic syntax help and a short description for most commands and functions.

If you provide an argument to the `HELP` command, the mariadb client uses it as a search string to access server-side help. The proper operation of this command requires that the help tables in the `mysql` database be initialized with help topic information.

If there is no match for the search string, the search fails. Use `HELP contents` to see a list of the help categories:

```
HELP contents
You asked for help about help category: "Contents"
For more information, type 'help <item>', where <item> is one of the following
categories:
   Account Management
   Administration
   Compound Statements
   Data Definition
   Data Manipulation
   Data Types
   Functions
   Functions and Modifiers for Use with GROUP BY
   Geographic Features
   Help Metadata
   Language Structure
   Plugins
   Procedures
   Sequences
   Table Maintenance
   Transactions
   User-Defined Functions
   Utility
```

If a search string matches multiple items, MariaDB shows a list of matching topics:

```
HELP drop
Many help items for your request exist.
To make a more specific request, please type 'help <item>',
where <item> is one of the following
topics:
   ALTER TABLE
   DROP DATABASE
   DROP EVENT
   DROP FUNCTION
   DROP FUNCTION UDF
   DROP INDEX
   DROP PACKAGE
   DROP PACKAGE BODY
   DROP PROCEDURE
   DROP ROLE
   DROP SEQUENCE
   DROP SERVER
   DROP TABLE
   DROP TRIGGER
   DROP USER
   DROP VIEW
```

Then you can enter a topic as the search string to see the help entry for that topic.

The help is provided with the MariaDB server and makes use of four help tables found in the `mysql` database: help_relation, help_topic, help_category and help_keyword. These tables are populated by the mariadb-install-db or `fill_help_table.sql` scripts.

1.1.1.2.16 KILL [CONNECTION | QUERY]

Syntax

```
KILL [HARD | SOFT] { {CONNECTION|QUERY} thread_id | QUERY ID query_id | USER user_name }
```

Contents

Description

Each connection to mysqld runs in a separate thread. You can see which threads are running with the `SHOW PROCESSLIST` statement and kill a thread with the `KILL thread_id` statement. `KILL` allows the optional `CONNECTION` or `QUERY` modifier:

- `KILL CONNECTION` is the same as `KILL` with no modifier: It terminates the connection associated with the given thread or query id.
- `KILL QUERY` terminates the statement that the connection thread_id is currently executing, but leaves the connection itself intact.
- `KILL QUERY ID` terminates the query by query_id, leaving the connection intact.

If a connection is terminated that has an active transaction, the transaction will be rolled back. If only a query is killed, the current transaction will stay active. See also idle_transaction_timeout.

If you have the PROCESS privilege, you can see all threads. If you have the SUPER privilege, or, from MariaDB 10.5.2, the CONNECTION ADMIN privilege, you can kill all threads and statements. Otherwise, you can see and kill only your own threads and statements.

> Killing queries that repair or create indexes on MyISAM and Aria tables may result in corrupted tables. Use the `SOFT` option to avoid this!

The `HARD` option (default) kills a command as soon as possible. If you use `SOFT`, then critical operations that may leave a table in an inconsistent state will not be interrupted. Such operations include `REPAIR` and `INDEX` creation for MyISAM and Aria tables (REPAIR TABLE, OPTIMIZE TABLE).

`KILL ... USER username` will kill all connections/queries for a given user. `USER` can be specified one of the following ways:

- username (Kill without regard to hostname)
- username@hostname
- CURRENT_USER or CURRENT_USER()

If you specify a thread id and that thread does not exist, you get the following error:

```
ERROR 1094 (HY000): Unknown thread id: <thread_id>
```

If you specify a query id that doesn't exist, you get the following error:

```
ERROR 1957 (HY000): Unknown query id: <query_id>
```

However, if you specify a user name, no error is issued for non-connected (or even non-existing) users. To check if the connection/query has been killed, you can use the ROW_COUNT() function.

A client whose connection is killed receives the following error:

```
ERROR 1317 (70100): Query execution was interrupted
```

To obtain a list of existing sessions, use the SHOW PROCESSLIST statement or query the Information Schema

PROCESSLIST table.

Note: You cannot use `KILL` with the Embedded MariaDB Server library because the embedded server merely runs inside the threads of the host application. It does not create any connection threads of its own.

Note: You can also use `mariadb-admin kill thread_id [,thread_id...]` to kill connections. To get a list of running queries, use `mariadb-admin processlist`. See mariadb-admin.

Percona Toolkit contains a program, pt-kill that can be used to automatically kill connections that match certain criteria. For example, it can be used to terminate idle connections, or connections that have been busy for more than 60 seconds.

1.1.1.2.17 LOAD INDEX

Syntax

```
LOAD INDEX INTO CACHE
  tbl_index_list [, tbl_index_list] ...

tbl_index_list:
  tbl_name
    [[INDEX|KEY] (index_name[, index_name] ...)]
    [IGNORE LEAVES]
```

Description

The `LOAD INDEX INTO CACHE` statement preloads a table index into the key cache to which it has been assigned by an explicit `CACHE INDEX` statement, or into the default key cache otherwise. `LOAD INDEX INTO CACHE` is used only for MyISAM or Aria tables.

The `IGNORE LEAVES` modifier causes only blocks for the nonleaf nodes of the index to be preloaded.

1.1.1.2.18 RESET

Syntax

```
RESET reset_option [, reset_option] ...
```

Description

The `RESET` statement is used to clear the state of various server operations. You must have the `RELOAD privilege` to execute `RESET`.

`RESET` acts as a stronger version of the FLUSH statement.

The different `RESET` options are:

Option	Description
SLAVE ["connection_name"] [ALL]	Deletes all relay logs from the slave and reset the replication position in the master binary log.
MASTER	Deletes all old binary logs, makes the binary index file (--log-bin-index) empty and creates a new binary log file. This is useful when you want to reset the master to an initial state. If you want to just delete old, not used binary logs, you should use the PURGE BINARY LOGS command.
QUERY CACHE	Removes all queries from the query cache. See also FLUSH QUERY CACHE.

1.1.1.2.19 SHUTDOWN

Contents

Syntax

```
SHUTDOWN [WAIT FOR ALL { SLAVES | REPLICAS } ]
```

Description

The `SHUTDOWN` command shuts the server down.

WAIT FOR ALL REPLICAS / SLAVES

MariaDB starting with 10.4.4

The `WAIT FOR ALL SLAVES` option was first added in MariaDB 10.4.4. `WAIT FOR ALL REPLICAS` has been a synonym since MariaDB 10.5.1.

When a primary server is shutdown and it goes through the normal shutdown process, the primary kills client threads in random order. By default, the primary also considers its binary log dump threads to be regular client threads. As a consequence, the binary log dump threads can be killed while client threads still exist, and this means that data can be written on the primary during a normal shutdown that won't be replicated. This is true even if semi-synchronous replication is being used.

In MariaDB 10.4 and later, this problem can be solved by shutting down the server with the SHUTDOWN command and by providing the `WAIT FOR ALL REPLICAS` / `WAIT FOR ALL SLAVES` option to the command. For example:

```
SHUTDOWN WAIT FOR ALL REPLICAS;
```

When the `WAIT FOR ALL REPLICAS` option is provided, the server only kills its binary log dump threads after all client threads have been killed, and it only completes the shutdown after the last binary log has been sent to all connected replicas.

See Replication Threads: Binary Log Dump Threads and the Shutdown Process for more information.

Required Permissions

One must have a `SHUTDOWN` privilege (see GRANT) to use this command. It is the same privilege one needs to use the mariadb-admin shutdown command.

Shutdown for Upgrades

If you are doing a shutdown to migrate to another major version of MariaDB, please ensure that the innodb_fast_shutdown variable is not 2 (fast crash shutdown). The default of this variable is 1.

Example

The following example shows how to create an event which turns off the server at a certain time:

```
CREATE EVENT `test`.`shutd`
    ON SCHEDULE
        EVERY 1 DAY
        STARTS '2014-01-01 20:00:00'
    COMMENT 'Shutdown Maria when the office is closed'
DO BEGIN
    SHUTDOWN;
END;
```

Other Ways to Stop mariadbd

You can use the mariadb-admin shutdown command to take down mariadbd cleanly.

You can also use the system kill command on Unix with signal SIGTERM (15)

```
kill -SIGTERM pid-of-mariadbd-process
```

You can find the process number of the server process in the file that ends with `.pid` in your data directory.

The above is identical to `mariadb-admin shutdown` .

On windows you should use:

```
NET STOP MariaDB
```

1.1.1.2.20 USE [DATABASE]

Syntax

```
USE db_name
```

In MariaDB 11.3 one can also use

```
USE DATABASE db_name;
```

Description

The `'USE db_name'` statement tells MariaDB to use the `db_name` database as the default (current) database for subsequent statements. The database remains the default until the end of the session or another `USE` statement is issued:

```
USE db1;
SELECT COUNT(*) FROM mytable;   # selects from db1.mytable
USE db2;
SELECT COUNT(*) FROM mytable;   # selects from db2.mytable
```

The DATABASE() function (SCHEMA() is a synonym) returns the default database.

Another way to set the default database is specifying its name at mariadb command line client startup.

One cannot use `USE DATABASE` to a database one has no privileges to. The reason is that a user with no privileges to a database should not be able to know if a database exists or not.

1.1.1.3 Data Definition

SQL Commands for defining data, such as ALTER, CREATE, DROP, RENAME etc.

CREATE

Articles on the various CREATE statements.

ALTER

The various ALTER statements in MariaDB.

DROP
Articles on various DROP commands.

Atomic DDL
Making DDL Atomic/Crash-safe.

CONSTRAINT
Define a CHECK or FOREIGN KEY constraint.

MERGE
Allows you to access a collection of identical MyISAM tables as one.

RENAME TABLE
Change a table's name.

TRUNCATE TABLE
DROP and re-CREATE a table.

There are 3 related questions.

1.1.1.3.1 CREATE

Articles on the various CREATE statements.

CREATE DATABASE
Create a database.

CREATE EVENT
Create and schedule a new event.

CREATE FUNCTION
Creates a stored function.

CREATE FUNCTION UDF
Create a user-defined function.

CREATE INDEX
Create an index on one or more columns.

CREATE LOGFILE GROUP
The CREATE LOGFILE GROUP statement is not supported by MariaDB. It was orig...

CREATE PACKAGE
Create a stored package, in Oracle-mode.

CREATE PACKAGE BODY
Creates the package body for a stored package.

CREATE PROCEDURE
Creates a stored procedure.

CREATE ROLE
Add new roles.

CREATE SEQUENCE
Creates a sequence that generates new values when called with NEXT VALUE FOR.

CREATE SERVER
Define a server.

CREATE TABLE
Creates a new table.

CREATE TABLESPACE
CREATE TABLESPACE is not available in MariaDB.

CREATE TRIGGER
Create a new trigger.

CREATE USER
Create new MariaDB accounts.

CREATE VIEW
Create or replace a view.

Silent Column Changes
MariaDB silently changes column specifications in certain situations.

Generated (Virtual and Persistent/Stored) Columns
Generated (virtual and persistent/stored) columns.

Invisible Columns
Invisible columns are hidden in certain contexts.

There are 1 related questions.

1.1.1.3.1.1 CREATE DATABASE

Syntax

```
CREATE [OR REPLACE] {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
    [create_specification] ...

create_specification:
    [DEFAULT] CHARACTER SET [=] charset_name
  | [DEFAULT] COLLATE [=] collation_name
  | COMMENT [=] 'comment'
```

Contents

Description

`CREATE DATABASE` creates a database with the given name. To use this statement, you need the CREATE privilege for the database. `CREATE SCHEMA` is a synonym for `CREATE DATABASE`.

For valid identifiers to use as database names, see Identifier Names.

OR REPLACE

If the optional `OR REPLACE` clause is used, it acts as a shortcut for:

```
DROP DATABASE IF EXISTS db_name;
CREATE DATABASE db_name ...;
```

IF NOT EXISTS

When the `IF NOT EXISTS` clause is used, MariaDB will return a warning instead of an error if the specified database already exists.

COMMENT

MariaDB starting with 10.5.0

From MariaDB 10.5.0, it is possible to add a comment of a maximum of 1024 bytes. If the comment length exceeds this length, a error/warning code 4144 is thrown. The database comment is also added to the db.opt file, as well as to the information_schema.schemata table.

Examples

```
CREATE DATABASE db1;
Query OK, 1 row affected (0.18 sec)

CREATE DATABASE db1;
ERROR 1007 (HY000): Can't create database 'db1'; database exists

CREATE OR REPLACE DATABASE db1;
Query OK, 2 rows affected (0.00 sec)

CREATE DATABASE IF NOT EXISTS db1;
Query OK, 1 row affected, 1 warning (0.01 sec)

SHOW WARNINGS;
+-------+------+----------------------------------------------+
| Level | Code | Message                                      |
+-------+------+----------------------------------------------+
| Note  | 1007 | Can't create database 'db1'; database exists |
+-------+------+----------------------------------------------+
```

Setting the character sets and collation. See Setting Character Sets and Collations for more details.

```
CREATE DATABASE czech_slovak_names
  CHARACTER SET = 'keybcs2'
  COLLATE = 'keybcs2_bin';
```

Comments, from MariaDB 10.5.0:

```
CREATE DATABASE presentations COMMENT 'Presentations for conferences';
```

1.1.1.3.1.2 CREATE EVENT

Syntax

```
CREATE [OR REPLACE]
    [DEFINER = { user | CURRENT_USER | role | CURRENT_ROLE }]
    EVENT
    [IF NOT EXISTS]
    event_name
    ON SCHEDULE schedule
    [ON COMPLETION [NOT] PRESERVE]
    [ENABLE | DISABLE | DISABLE ON SLAVE]
    [COMMENT 'comment']
    DO sql_statement;

schedule:
    AT timestamp [+ INTERVAL interval] ...
  | EVERY interval
    [STARTS timestamp [+ INTERVAL interval] ...]
    [ENDS timestamp [+ INTERVAL interval] ...]

interval:
    quantity {YEAR | QUARTER | MONTH | DAY | HOUR | MINUTE |
              WEEK | SECOND | YEAR_MONTH | DAY_HOUR | DAY_MINUTE |
              DAY_SECOND | HOUR_MINUTE | HOUR_SECOND | MINUTE_SECOND}
```

Contents

Description

This statement creates and schedules a new event. It requires the `EVENT` privilege for the schema in which the event is to be created.

The minimum requirements for a valid CREATE EVENT statement are as follows:

- The keywords `CREATE EVENT` plus an event name, which uniquely identifies the event in the current schema. (Prior to MySQL 5.1.12, the event name needed to be unique only among events created by the same user on a given database.)
- An `ON SCHEDULE` clause, which determines when and how often the event executes.
- A `DO` clause, which contains the SQL statement to be executed by an event.

Here is an example of a minimal `CREATE EVENT` statement:

```
CREATE EVENT myevent
    ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
    DO
      UPDATE myschema.mytable SET mycol = mycol + 1;
```

The previous statement creates an event named myevent. This event executes once — one hour following its creation — by running an SQL statement that increments the value of the myschema.mytable table's mycol column by 1.

The event_name must be a valid MariaDB identifier with a maximum length of 64 characters. It may be delimited using back ticks, and may be qualified with the name of a database schema. An event is associated with both a MariaDB user (the definer) and a schema, and its name must be unique among names of events within that schema. In general, the rules governing event names are the same as those for names of stored routines. See Identifier Names.

If no schema is indicated as part of event_name, the default (current) schema is assumed.

For valid identifiers to use as event names, see Identifier Names.

OR REPLACE

The `OR REPLACE` clause was included in MariaDB 10.1.4. If used and the event already exists, instead of an error being returned, the existing event will be dropped and replaced by the newly defined event.

IF NOT EXISTS

If the `IF NOT EXISTS` clause is used, MariaDB will return a warning instead of an error if the event already exists. Cannot be used together with OR REPLACE.

ON SCHEDULE

The `ON SCHEDULE` clause can be used to specify when the event must be triggered.

AT

If you want to execute the event only once (one time event), you can use the `AT` keyword, followed by a timestamp. If you use `CURRENT_TIMESTAMP`, the event acts as soon as it is created. As a convenience, you can add one or more intervals to that timestamp. You can also specify a timestamp in the past, so that the event is stored but not triggered, until you modify it via ALTER EVENT.

The following example shows how to create an event that will be triggered tomorrow at a certain time:

```
CREATE EVENT example
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 DAY + INTERVAL 3 HOUR
DO something;
```

You can also specify that an event must be triggered at a regular interval (recurring event). In such cases, use the `EVERY` clause followed by the interval.

If an event is recurring, you can specify when the first execution must happen via the `STARTS` clause and a maximum time for the last execution via the `ENDS` clause. `STARTS` and `ENDS` clauses are followed by a timestamp and, optionally, one or more intervals. The `ENDS` clause can specify a timestamp in the past, so that the event is stored but not executed until you modify it via ALTER EVENT.

In the following example, next month a recurring event will be triggered hourly for a week:

```
CREATE EVENT example
ON SCHEDULE EVERY 1 HOUR
STARTS CURRENT_TIMESTAMP + INTERVAL 1 MONTH
ENDS CURRENT_TIMESTAMP + INTERVAL 1 MONTH + INTERVAL 1 WEEK
DO some_task;
```

Intervals consist of a quantity and a time unit. The time units are the same used for other staments and time functions, except that you can't use microseconds for events. For simple time units, like `HOUR` or `MINUTE`, the quantity is an integer number, for example '10 MINUTE'. For composite time units, like `HOUR_MINUTE` or `HOUR_SECOND`, the quantity must be a string with all involved simple values and their separators, for example '2:30' or '2:30:30'.

ON COMPLETION [NOT] PRESERVE

The `ON COMPLETION` clause can be used to specify if the event must be deleted after its last execution (that is, after its `AT` or `ENDS` timestamp is past). By default, events are dropped when they are expired. To explicitly state that this is the desired behaviour, you can use `ON COMPLETION NOT PRESERVE`. Instead, if you want the event to be preserved, you can use `ON COMPLETION PRESERVE`.

In you specify `ON COMPLETION NOT PRESERVE`, and you specify a timestamp in the past for `AT` or `ENDS` clause, the event will be immediatly dropped. In such cases, you will get a Note 1558: "Event execution time is in the past and ON COMPLETION NOT PRESERVE is set. The event was dropped immediately after creation".

ENABLE/DISABLE/DISABLE ON SLAVE

Events are `ENABLE`d by default. If you want to stop MariaDB from executing an event, you may specify `DISABLE`. When it is ready to be activated, you may enable it using `ALTER EVENT`. Another option is `DISABLE ON SLAVE`, which indicates that an event was created on a master and has been replicated to the slave, which is prevented from executing the event. If `DISABLE ON SLAVE` is specifically set, the event will be disabled everywhere. It will not be executed on the mater or the slaves.

COMMENT

The `COMMENT` clause may be used to set a comment for the event. Maximum length for comments is 64 characters. The comment is a string, so it must be quoted. To see events comments, you can query the INFORMATION_SCHEMA.EVENTS table (the column is named `EVENT_COMMENT`).

Examples

Minimal `CREATE EVENT` statement:

```
CREATE EVENT myevent
    ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
    DO
      UPDATE myschema.mytable SET mycol = mycol + 1;
```

An event that will be triggered tomorrow at a certain time:

```
CREATE EVENT example
ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 DAY + INTERVAL 3 HOUR
DO something;
```

Next month a recurring event will be triggered hourly for a week:

```
CREATE EVENT example
ON SCHEDULE EVERY 1 HOUR
STARTS CURRENT_TIMESTAMP + INTERVAL 1 MONTH
ENDS CURRENT_TIMESTAMP + INTERVAL 1 MONTH + INTERVAL 1 WEEK
DO some_task;
```

OR REPLACE and IF NOT EXISTS:

```
CREATE EVENT myevent
    ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
    DO
      UPDATE myschema.mytable SET mycol = mycol + 1;
ERROR 1537 (HY000): Event 'myevent' already exists

CREATE OR REPLACE EVENT myevent
    ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
    DO
      UPDATE myschema.mytable SET mycol = mycol + 1;;
Query OK, 0 rows affected (0.00 sec)

CREATE EVENT IF NOT EXISTS myevent
    ON SCHEDULE AT CURRENT_TIMESTAMP + INTERVAL 1 HOUR
    DO
      UPDATE myschema.mytable SET mycol = mycol + 1;
Query OK, 0 rows affected, 1 warning (0.00 sec)

 SHOW WARNINGS;
+-------+------+---------------------------------+
| Level | Code | Message                         |
+-------+------+---------------------------------+
| Note  | 1537 | Event 'myevent' already exists |
+-------+------+---------------------------------+
```

1.1.1.3.1.3 CREATE FUNCTION

Syntax

```
CREATE [OR REPLACE]
    [DEFINER = {user | CURRENT_USER | role | CURRENT_ROLE }]
    [AGGREGATE] FUNCTION [IF NOT EXISTS] func_name ([func_parameter[,...]])
    RETURNS type
    [characteristic ...]
    RETURN func_body

func_parameter:
    [ IN | OUT | INOUT | IN OUT ]  param_name type

type:
    Any valid MariaDB data type

characteristic:
    LANGUAGE SQL
  | [NOT] DETERMINISTIC
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
  | COMMENT 'string'

func_body:
    Valid SQL procedure statement
```

Contents

Description

Use the `CREATE FUNCTION` statement to create a new stored function. You must have the CREATE ROUTINE database privilege to use `CREATE FUNCTION`. A function takes any number of arguments and returns a value from the function body. The function body can be any valid SQL expression as you would use, for example, in any select expression. If you have the appropriate privileges, you can call the function exactly as you would any built-in function. See Security below for details on privileges.

You can also use a variant of the `CREATE FUNCTION` statement to install a user-defined function (UDF) defined by a plugin. See CREATE FUNCTION (UDF) for details.

You can use a SELECT statement for the function body by enclosing it in parentheses, exactly as you would to use a subselect for any other expression. The `SELECT` statement must return a single value. If more than one column is returned when the function is called, error 1241 results. If more than one row is returned when the function is called, error 1242 results. Use a `LIMIT` clause to ensure only one row is returned.

You can also replace the `RETURN` clause with a BEGIN...END compound statement. The compound statement must contain a `RETURN` statement. When the function is called, the `RETURN` statement immediately returns its result, and any statements after `RETURN` are effectively ignored.

By default, a function is associated with the current database. To associate the function explicitly with a given database, specify the fully-qualified name as *`db_name.func_name`* when you create it. If the function name is the same as the name of a built-in function, you must use the fully qualified name when you call it.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list

of () should be used. Parameter names are not case sensitive.

Each parameter can be declared to use any valid data type, except that the COLLATE attribute cannot be used.

For valid identifiers to use as function names, see Identifier Names.

IN | OUT | INOUT | IN OUT

MariaDB starting with 10.8.0

The function parameter qualifiers for `IN`, `OUT`, `INOUT`, and `IN OUT` were added in a 10.8.0 preview release. Prior to 10.8.0 quantifiers were supported only in procedures.

`OUT`, `INOUT` and its equivalent `IN OUT`, are only valid if called from `SET` and not `SELECT`. These quantifiers are especially useful for creating functions with more than one return value. This allows functions to be more complex and nested.

```
DELIMITER $$
CREATE FUNCTION add_func3(IN a INT, IN b INT, OUT c INT) RETURNS INT
BEGIN
  SET c = 100;
  RETURN a + b;
END;
$$
DELIMITER ;

SET @a = 2;
SET @b = 3;
SET @c = 0;
SET @res= add_func3(@a, @b, @c);

SELECT add_func3(@a, @b, @c);
ERROR 4186 (HY000): OUT or INOUT argument 3 for function add_func3 is not allowed here

DELIMITER $$
CREATE FUNCTION add_func4(IN a INT, IN b INT, d INT) RETURNS INT
BEGIN
  DECLARE c, res INT;
  SET res = add_func3(a, b, c) + d;
  if (c > 99) then
    return  3;
  else
    return res;
  end if;
END;
$$

DELIMITER ;

SELECT add_func4(1,2,3);
+------------------+
| add_func4(1,2,3) |
+------------------+
|                3 |
+------------------+
```

AGGREGATE

It is possible to create stored aggregate functions as well. See Stored Aggregate Functions for details.

RETURNS

The `RETURNS` clause specifies the return type of the function. `NULL` values are permitted with all return types.

What happens if the `RETURN` clause returns a value of a different type? It depends on the SQL_MODE in effect at the moment of the function creation.

If the SQL_MODE is strict (STRICT_ALL_TABLES or STRICT_TRANS_TABLES flags are specified), a 1366 error will be produced.

Otherwise, the value is coerced to the proper type. For example, if a function specifies an `ENUM` or `SET` value in the `RETURNS` clause, but the `RETURN` clause returns an integer, the value returned from the function is the string for the

corresponding `ENUM` member of set of `SET` members.

MariaDB stores the SQL_MODE system variable setting that is in effect at the time a routine is created, and always executes the routine with this setting in force, regardless of the server SQL mode in effect when the routine is invoked.

LANGUAGE SQL

`LANGUAGE SQL` is a standard SQL clause, and it can be used in MariaDB for portability. However that clause has no meaning, because SQL is the only supported language for stored functions.

A function is deterministic if it can produce only one result for a given list of parameters. If the result may be affected by stored data, server variables, random numbers or any value that is not explicitly passed, then the function is not deterministic. Also, a function is non-deterministic if it uses non-deterministic functions like NOW() or CURRENT_TIMESTAMP(). The optimizer may choose a faster execution plan if it known that the function is deterministic. In such cases, you should declare the routine using the `DETERMINISTIC` keyword. If you want to explicitly state that the function is not deterministic (which is the default) you can use the `NOT DETERMINISTIC` keywords.

If you declare a non-deterministic function as `DETERMINISTIC`, you may get incorrect results. If you declare a deterministic function as `NOT DETERMINISTIC`, in some cases the queries will be slower.

OR REPLACE

If the optional `OR REPLACE` clause is used, it acts as a shortcut for:

```
DROP FUNCTION IF EXISTS function_name;
CREATE FUNCTION function_name ...;
```

with the exception that any existing privileges for the function are not dropped.

IF NOT EXISTS

If the IF NOT EXISTS clause is used, MariaDB will return a warning instead of an error if the function already exists. Cannot be used together with OR REPLACE.

[NOT] DETERMINISTIC

The `[NOT] DETERMINISTIC` clause also affects binary logging, because the `STATEMENT` format can not be used to store or replicate non-deterministic statements.

`CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` are informative clauses that tell the server what the function does. MariaDB does not check in any way whether the specified clause is correct. If none of these clauses are specified, `CONTAINS SQL` is used by default.

MODIFIES SQL DATA

`MODIFIES SQL DATA` means that the function contains statements that may modify data stored in databases. This happens if the function contains statements like DELETE, UPDATE, INSERT, REPLACE or DDL.

READS SQL DATA

`READS SQL DATA` means that the function reads data stored in databases, but does not modify any data. This happens if SELECT statements are used, but there no write operations are executed.

CONTAINS SQL

`CONTAINS SQL` means that the function contains at least one SQL statement, but it does not read or write any data stored in a database. Examples include SET or DO.

NO SQL

`NO SQL` means nothing, because MariaDB does not currently support any language other than SQL.

Oracle Mode

A subset of Oracle's PL/SQL language is supported in addition to the traditional SQL/PSM-based MariaDB syntax. See Oracle mode for details on changes when running Oracle mode.

Security

You must have the EXECUTE privilege on a function to call it. MariaDB automatically grants the `EXECUTE` and `ALTER ROUTINE` privileges to the account that called `CREATE FUNCTION`, even if the `DEFINER` clause was used.

Each function has an account associated as the definer. By default, the definer is the account that created the function. Use the `DEFINER` clause to specify a different account as the definer. You must have the SUPER privilege, or, from MariaDB 10.5.2, the SET USER privilege, to use the `DEFINER` clause. See Account Names for details on specifying accounts.

The `SQL SECURITY` clause specifies what privileges are used when a function is called. If `SQL SECURITY` is `INVOKER`, the function body will be evaluated using the privileges of the user calling the function. If `SQL SECURITY` is `DEFINER`, the function body is always evaluated using the privileges of the definer account. `DEFINER` is the default.

This allows you to create functions that grant limited access to certain data. For example, say you have a table that stores some employee information, and that you've granted `SELECT` privileges only on certain columns to the user account `roger`.

```
CREATE TABLE employees (name TINYTEXT, dept TINYTEXT, salary INT);
GRANT SELECT (name, dept) ON employees TO roger;
```

To allow the user the get the maximum salary for a department, define a function and grant the `EXECUTE` privilege:

```
CREATE FUNCTION max_salary (dept TINYTEXT) RETURNS INT RETURN
  (SELECT MAX(salary) FROM employees WHERE employees.dept = dept);
GRANT EXECUTE ON FUNCTION max_salary TO roger;
```

Since `SQL SECURITY` defaults to `DEFINER`, whenever the user `roger` calls this function, the subselect will execute with your privileges. As long as you have privileges to select the salary of each employee, the caller of the function will be able to get the maximum salary for each department without being able to see individual salaries.

Character sets and collations

Function return types can be declared to use any valid character set and collation. If used, the COLLATE attribute needs to be preceded by a CHARACTER SET attribute.

If the character set and collation are not specifically set in the statement, the database defaults at the time of creation will be used. If the database defaults change at a later stage, the stored function character set/collation will not be changed at the same time; the stored function needs to be dropped and recreated to ensure the same character set/collation as the database is used.

Examples

The following example function takes a parameter, performs an operation using an SQL function, and returns the result.

```
CREATE FUNCTION hello (s CHAR(20))
    RETURNS CHAR(50) DETERMINISTIC
    RETURN CONCAT('Hello, ',s,'!');

SELECT hello('world');
+----------------+
| hello('world') |
+----------------+
| Hello, world!  |
+----------------+
```

You can use a compound statement in a function to manipulate data with statements like `INSERT` and `UPDATE`. The following example creates a counter function that uses a temporary table to store the current value. Because the compound statement contains statements terminated with semicolons, you have to first change the statement delimiter with the `DELIMITER` statement to allow the semicolon to be used in the function body. See Delimiters in the mariadb client for more.

```
CREATE TEMPORARY TABLE counter (c INT);
INSERT INTO counter VALUES (0);
DELIMITER //
CREATE FUNCTION counter () RETURNS INT
  BEGIN
    UPDATE counter SET c = c + 1;
    RETURN (SELECT c FROM counter LIMIT 1);
  END //
DELIMITER ;
```

Character set and collation:

```
CREATE FUNCTION hello2 (s CHAR(20))
  RETURNS CHAR(50) CHARACTER SET 'utf8' COLLATE 'utf8_bin' DETERMINISTIC
  RETURN CONCAT('Hello, ',s,'!');
```

1.1.1.3.1.4 CREATE FUNCTION UDF

Syntax

```
CREATE [OR REPLACE] [AGGREGATE] FUNCTION [IF NOT EXISTS] function_name
    RETURNS {STRING|INTEGER|REAL|DECIMAL}
    SONAME shared_library_name
```

Contents

Description

A user-defined function (UDF) is a way to extend MariaDB with a new function that works like a native (built-in) MariaDB function such as ABS() or CONCAT().

`function_name` is the name that should be used in SQL statements to invoke the function.

To create a function, you must have the INSERT privilege for the mysql database. This is necessary because `CREATE FUNCTION` adds a row to the mysql.func system table that records the function's name, type, and shared library name. If you do not have this table, you should run the mariadb-upgrade command to create it.

UDFs need to be written in C, C++ or another language that uses C calling conventions, MariaDB needs to have been dynamically compiled, and your operating system must support dynamic loading.

For an example, see `sql/udf_example.cc` in the source tree. For a collection of existing UDFs see http://www.mysqludf.org/.

Statements making use of user-defined functions are not safe for replication.

For creating a stored function as opposed to a user-defined function, see CREATE FUNCTION.

For valid identifiers to use as function names, see Identifier Names.

RETURNS

The `RETURNS` clause indicates the type of the function's return value, and can be one of STRING, INTEGER, REAL or DECIMAL. `DECIMAL` functions currently return string values and should be written like STRING functions.

shared_library_name

`shared_library_name` is the basename of the shared object file that contains the code that implements the function. The file must be located in the plugin directory. This directory is given by the value of the plugin_dir system variable. Note that before MariaDB/MySQL 5.1, the shared object could be located in any directory that was searched by your system's dynamic linker.

AGGREGATE

Aggregate functions are summary functions such as SUM() and AVG().

> **MariaDB starting with 10.4**
> Aggregate UDF functions can be used as window functions.

OR REPLACE

> **MariaDB starting with 10.1.3**
> The `OR REPLACE` clause was added in MariaDB 10.1.3

If the optional `OR REPLACE` clause is used, it acts as a shortcut for:

```
DROP FUNCTION IF EXISTS function_name;
CREATE FUNCTION name ...;
```

IF NOT EXISTS

> **MariaDB starting with 10.1.3**
> The `IF NOT EXISTS` clause was added in MariaDB 10.1.3

When the IF NOT EXISTS clause is used, MariaDB will return a warning instead of an error if the specified function already exists. Cannot be used together with OR REPLACE.

Upgrading a UDF

To upgrade the UDF's shared library, first run a DROP FUNCTION statement, then upgrade the shared library and finally run the CREATE FUNCTION statement. If you upgrade without following this process, you may crash the server.

Examples

```
CREATE FUNCTION jsoncontains_path RETURNS integer SONAME 'ha_connect.so';
Query OK, 0 rows affected (0.00 sec)
```

OR REPLACE and IF NOT EXISTS:

```
CREATE FUNCTION jsoncontains_path RETURNS integer SONAME 'ha_connect.so';
ERROR 1125 (HY000): Function 'jsoncontains_path' already exists

CREATE OR REPLACE FUNCTION jsoncontains_path RETURNS integer SONAME 'ha_connect.so';
Query OK, 0 rows affected (0.00 sec)

CREATE FUNCTION IF NOT EXISTS jsoncontains_path RETURNS integer SONAME 'ha_connect.so';
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-------+------+----------------------------------------------+
| Level | Code | Message                                      |
+-------+------+----------------------------------------------+
| Note  | 1125 | Function 'jsoncontains_path' already exists |
+-------+------+----------------------------------------------+
```

1.1.1.3.1.5 CREATE INDEX

Syntax

```
CREATE [OR REPLACE] [UNIQUE|FULLTEXT|SPATIAL] INDEX
  [IF NOT EXISTS] index_name
    [index_type]
    ON tbl_name (index_col_name,...)
    [WAIT n | NOWAIT]
    [index_option]
    [algorithm_option | lock_option] ...

index_col_name:
    col_name [(length)] [ASC | DESC]

index_type:
    USING {BTREE | HASH | RTREE}

index_option:
    [ KEY_BLOCK_SIZE [=] value
  | index_type
  | WITH PARSER parser_name
  | COMMENT 'string'
  | CLUSTERING={YES| NO} ]
  [ IGNORED | NOT IGNORED ]

algorithm_option:
    ALGORITHM [=] {DEFAULT|INPLACE|COPY|NOCOPY|INSTANT}

lock_option:
    LOCK [=] {DEFAULT|NONE|SHARED|EXCLUSIVE}
```

Contents

Description

The *CREATE INDEX* statement is used to add indexes to a table. Indexes can be created at the same as the table, with the [[|create-table|CREATE TABLE]] statement. In some cases, such as for InnoDB primary keys, doing so during creation is preferable, as adding a primary key will involve rebuilding the table.

The statement is mapped to an ALTER TABLE statement to create indexes. See ALTER TABLE. CREATE INDEX cannot be used to create a PRIMARY KEY; use ALTER TABLE instead.

If another connection is using the table, a metadata lock is active, and this statement will wait until the lock is released. This is also true for non-transactional tables.

Another shortcut, DROP INDEX, allows the removal of an index.

For valid identifiers to use as index names, see Identifier Names.

Note that KEY_BLOCK_SIZE is currently ignored in CREATE INDEX, although it is included in the output of SHOW CREATE TABLE.

Privileges

Executing the `CREATE INDEX` statement requires the `INDEX` privilege for the table or the database.

Online DDL

Online DDL is supported with the ALGORITHM and LOCK clauses.

See InnoDB Online DDL Overview for more information on online DDL with InnoDB.

CREATE OR REPLACE INDEX

If the `OR REPLACE` clause is used and if the index already exists, then instead of returning an error, the server will drop the existing index and replace it with the newly defined index.

CREATE INDEX IF NOT EXISTS

If the `IF NOT EXISTS` clause is used, then the index will only be created if an index with the same name does not already exist. If the index already exists, then a warning will be triggered by default.

Index Definitions

See CREATE TABLE: Index Definitions for information about index definitions.

WAIT/NOWAIT

Set the lock wait timeout. See WAIT and NOWAIT.

ALGORITHM

See ALTER TABLE: ALGORITHM for more information.

LOCK

See ALTER TABLE: LOCK for more information.

Progress Reporting

MariaDB provides progress reporting for `CREATE INDEX` statement for clients that support the new progress reporting protocol. For example, if you were using the mariadb client, then the progress report might look like this::

```
CREATE INDEX i ON tab (num);
Stage: 1 of 2 'copy to tmp table'    46% of stage
```

The progress report is also shown in the output of the SHOW PROCESSLIST statement and in the contents of the information_schema.PROCESSLIST table.

See Progress Reporting for more information.

WITHOUT OVERLAPS

MariaDB starting with 10.5.3

The WITHOUT OVERLAPS clause allows one to constrain a primary or unique index such that application-time periods cannot overlap.

Examples

Creating a unique index:

```
CREATE UNIQUE INDEX HomePhone ON Employees(Home_Phone);
```

OR REPLACE and IF NOT EXISTS:

```
CREATE INDEX xi ON xx5 (x);
Query OK, 0 rows affected (0.03 sec)

CREATE INDEX xi ON xx5 (x);
ERROR 1061 (42000): Duplicate key name 'xi'

CREATE OR REPLACE INDEX xi ON xx5 (x);
Query OK, 0 rows affected (0.03 sec)

CREATE INDEX IF NOT EXISTS xi ON xx5 (x);
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-------+------+-------------------------+
| Level | Code | Message                 |
+-------+------+-------------------------+
| Note  | 1061 | Duplicate key name 'xi' |
+-------+------+-------------------------+
```

From MariaDB 10.5.3, creating a unique index for an application-time period table with a WITHOUT OVERLAPS constraint:

```
CREATE UNIQUE INDEX u ON rooms (room_number, p WITHOUT OVERLAPS);
```

1.1.1.3.1.6 CREATE LOGFILE GROUP

The `CREATE LOGFILE GROUP` statement is not supported by MariaDB. It was originally inherited from MySQL NDB Cluster. See MDEV-19295 for more information.

1.1.1.3.1.7 CREATE PACKAGE

MariaDB starting with 10.3.5

Oracle-style packages were introduced in MariaDB 10.3.5.

Syntax

```
CREATE
    [ OR REPLACE]
    [DEFINER = { user | CURRENT_USER | role | CURRENT_ROLE }]
    PACKAGE [ IF NOT EXISTS ]
    [ db_name . ] package_name
    [ package_characteristic ... ]
{ AS | IS }
    [ package_specification_element ... ]
END [ package_name ]

package_characteristic:
    COMMENT 'string'
  | SQL SECURITY { DEFINER | INVOKER }

package_specification_element:
    FUNCTION_SYM package_specification_function ;
  | PROCEDURE_SYM package_specification_procedure ;

package_specification_function:
    func_name [ ( func_param [, func_param]... ) ]
    RETURNS func_return_type
    [ package_routine_characteristic... ]

package_specification_procedure:
    proc_name [ ( proc_param [, proc_param]... ) ]
    [ package_routine_characteristic... ]

func_return_type:
    type

func_param:
    param_name [ IN | OUT | INOUT | IN OUT ] type

proc_param:
    param_name [ IN | OUT | INOUT | IN OUT ] type

type:
    Any valid MariaDB explicit or anchored data type

package_routine_characteristic:
      COMMENT  'string'
    | LANGUAGE SQL
    | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
    | SQL SECURITY { DEFINER | INVOKER }
```

Contents

Description

The `CREATE PACKAGE` statement can be used when Oracle SQL_MODE is set.

The `CREATE PACKAGE` creates the specification for a stored package (a collection of logically related stored objects). A stored package specification declares public routines (procedures and functions) of the package, but does not implement these routines.

A package whose specification was created by the `CREATE PACKAGE` statement, should later be implemented using the CREATE PACKAGE BODY statement.

Function parameter quantifiers IN | OUT | INOUT | IN OUT

MariaDB starting with 10.8.0

The function parameter quantifiers for `IN`, `OUT`, `INOUT`, and `IN OUT` where added in a 10.8.0 preview release. Prior to 10.8.0 quantifiers were supported only in procedures.

`OUT`, `INOUT` and its equivalent `IN OUT`, are only valid if called from `SET` and not `SELECT`. These quantifiers are especially useful for creating functions and procedures with more than one return value. This allows functions and procedures to be more complex and nested.

Examples

```
SET sql_mode=ORACLE;
DELIMITER $$
CREATE OR REPLACE PACKAGE employee_tools AS
  FUNCTION getSalary(eid INT) RETURN DECIMAL(10,2);
  PROCEDURE raiseSalary(eid INT, amount DECIMAL(10,2));
  PROCEDURE raiseSalaryStd(eid INT);
  PROCEDURE hire(ename TEXT, esalary DECIMAL(10,2));
END;
$$
DELIMITER ;
```

1.1.1.3.1.8 CREATE PACKAGE BODY

MariaDB starting with 10.3.5

Oracle-style packages were introduced in MariaDB 10.3.5.

Syntax

```
CREATE [ OR REPLACE ]
    [DEFINER = { user | CURRENT_USER | role | CURRENT_ROLE }]
    PACKAGE BODY
    [ IF NOT EXISTS ]
    [ db_name . ] package_name
    [ package_characteristic... ]
{ AS | IS }
    package_implementation_declare_section
    package_implementation_executable_section
END [ package_name]

package_implementation_declare_section:
    package_implementation_item_declaration
      [ package_implementation_item_declaration... ]
      [ package_implementation_routine_definition... ]
  | package_implementation_routine_definition
      [ package_implementation_routine_definition...]

package_implementation_item_declaration:
    variable_declaration ;

variable_declaration:
    variable_name[,...] type [:= expr ]

package_implementation_routine_definition:
    FUNCTION package_specification_function
       [ package_implementation_function_body ] ;
  | PROCEDURE package_specification_procedure
       [ package_implementation_procedure_body ] ;

package_implementation_function_body:
    { AS | IS } package_routine_body [func_name]

package_implementation_procedure_body:
    { AS | IS } package_routine_body [proc_name]

package_routine_body:
```

```
    [ package_routine_declarations ]
    BEGIN
      statements [ EXCEPTION exception_handlers ]
    END

package_routine_declarations:
    package_routine_declaration ';' [package_routine_declaration ';']...

package_routine_declaration:
          variable_declaration
        | condition_name CONDITION FOR condition_value
        | user_exception_name EXCEPTION
        | CURSOR_SYM cursor_name
          [ ( cursor_formal_parameters ) ]
          IS select_statement
        ;

package_implementation_executable_section:
          END
        | BEGIN
            statement ; [statement ; ]...
          [EXCEPTION exception_handlers]
          END

exception_handlers:
           exception_handler [exception_handler...]

exception_handler:
          WHEN_SYM condition_value [, condition_value]...
            THEN_SYM statement ; [statement ;]...

condition_value:
          condition_name
        | user_exception_name
        | SQLWARNING
        | SQLEXCEPTION
        | NOT FOUND
        | OTHERS_SYM
        | SQLSTATE [VALUE] sqlstate_value
        | mariadb_error_code
```

Contents

Description

The `CREATE PACKAGE BODY` statement can be used when Oracle SQL_MODE is set.

The `CREATE PACKAGE BODY` statement creates the package body for a stored package. The package specification must be previously created using the CREATE PACKAGE statement.

A package body provides implementations of the package public routines and can optionally have:

- package-wide private variables
- package private routines
- forward declarations for private routines
- an executable initialization section

Examples

```
SET sql_mode=ORACLE;
DELIMITER $$
CREATE OR REPLACE PACKAGE employee_tools AS
  FUNCTION getSalary(eid INT) RETURN DECIMAL(10,2);
  PROCEDURE raiseSalary(eid INT, amount DECIMAL(10,2));
  PROCEDURE raiseSalaryStd(eid INT);
  PROCEDURE hire(ename TEXT, esalary DECIMAL(10,2));
END;
$$
CREATE PACKAGE BODY employee_tools AS
  -- package body variables
  stdRaiseAmount DECIMAL(10,2):=500;

  -- private routines
  PROCEDURE log (eid INT, ecmnt TEXT) AS
  BEGIN
    INSERT INTO employee_log (id, cmnt) VALUES (eid, ecmnt);
  END;

  -- public routines
  PROCEDURE hire(ename TEXT, esalary DECIMAL(10,2)) AS
    eid INT;
  BEGIN
    INSERT INTO employee (name, salary) VALUES (ename, esalary);
    eid:= last_insert_id();
    log(eid, 'hire ' || ename);
  END;

  FUNCTION getSalary(eid INT) RETURN DECIMAL(10,2) AS
    nSalary DECIMAL(10,2);
  BEGIN
    SELECT salary INTO nSalary FROM employee WHERE id=eid;
    log(eid, 'getSalary id=' || eid || ' salary=' || nSalary);
    RETURN nSalary;
  END;

  PROCEDURE raiseSalary(eid INT, amount DECIMAL(10,2)) AS
  BEGIN
    UPDATE employee SET salary=salary+amount WHERE id=eid;
    log(eid, 'raiseSalary id=' || eid || ' amount=' || amount);
  END;

  PROCEDURE raiseSalaryStd(eid INT) AS
  BEGIN
    raiseSalary(eid, stdRaiseAmount);
    log(eid, 'raiseSalaryStd id=' || eid);
  END;

BEGIN
  -- This code is executed when the current session
  -- accesses any of the package routines for the first time
  log(0, 'Session ' || connection_id() || ' ' || current_user || ' started');
END;
$$

DELIMITER ;
```

1.1.1.3.1.9 CREATE PROCEDURE

Syntax

```
CREATE
    [OR REPLACE]
    [DEFINER = { user | CURRENT_USER | role | CURRENT_ROLE }]
    PROCEDURE [IF NOT EXISTS] sp_name ([proc_parameter[,...]])
    [characteristic ...] routine_body

proc_parameter:
    [ IN | OUT | INOUT ] param_name type

type:
    Any valid MariaDB data type

characteristic:
    LANGUAGE SQL
  | [NOT] DETERMINISTIC
  | { CONTAINS SQL | NO SQL | READS SQL DATA | MODIFIES SQL DATA }
  | SQL SECURITY { DEFINER | INVOKER }
  | COMMENT 'string'

routine_body:
    Valid SQL procedure statement
```

Contents

Description

Creates a stored procedure. By default, a routine is associated with the default database. To associate the routine explicitly with a given database, specify the name as db_name.sp_name when you create it.

When the routine is invoked, an implicit USE db_name is performed (and undone when the routine terminates). The causes the routine to have the given default database while it executes. USE statements within stored routines are disallowed.

When a stored procedure has been created, you invoke it by using the `CALL` statement (see CALL).

To execute the `CREATE PROCEDURE` statement, it is necessary to have the `CREATE ROUTINE` privilege. By default, MariaDB automatically grants the `ALTER ROUTINE` and `EXECUTE` privileges to the routine creator. See also Stored Routine Privileges.

The `DEFINER` and SQL SECURITY clauses specify the security context to be used when checking access privileges at routine execution time, as described here. Requires the SUPER privilege, or, from MariaDB 10.5.2, the SET USER privilege.

If the routine name is the same as the name of a built-in SQL function, you must use a space between the name and the following parenthesis when defining the routine, or a syntax error occurs. This is also true when you invoke the routine later. For this reason, we suggest that it is better to avoid re-using the names of existing SQL functions for your own stored routines.

The IGNORE_SPACE SQL mode applies to built-in functions, not to stored routines. It is always allowable to have spaces after a routine name, regardless of whether IGNORE_SPACE is enabled.

The parameter list enclosed within parentheses must always be present. If there are no parameters, an empty parameter list of () should be used. Parameter names are not case sensitive.

Each parameter can be declared to use any valid data type, except that the COLLATE attribute cannot be used.

For valid identifiers to use as procedure names, see Identifier Names.

Things to be Aware of With CREATE OR REPLACE

- One can't use `OR REPLACE` together with `IF EXISTS`.

CREATE PROCEDURE IF NOT EXISTS

If the `IF NOT EXISTS` clause is used, then the procedure will only be created if a procedure with the same name does not already exist. If the procedure already exists, then a warning will be triggered by default.

IN/OUT/INOUT

Each parameter is an `IN` parameter by default. To specify otherwise for a parameter, use the keyword `OUT` or `INOUT` before the parameter name.

An `IN` parameter passes a value into a procedure. The procedure might modify the value, but the modification is not visible to the caller when the procedure returns. An `OUT` parameter passes a value from the procedure back to the caller. Its initial value is NULL within the procedure, and its value is visible to the caller when the procedure returns. An `INOUT` parameter is initialized by the caller, can be modified by the procedure, and any change made by the procedure is visible to the caller when the procedure returns.

For each `OUT` or `INOUT` parameter, pass a user-defined variable in the `CALL` statement that invokes the procedure so that you can obtain its value when the procedure returns. If you are calling the procedure from within another stored procedure or function, you can also pass a routine parameter or local routine variable as an `IN` or `INOUT` parameter.

DETERMINISTIC/NOT DETERMINISTIC

`DETERMINISTIC` and `NOT DETERMINISTIC` apply only to functions. Specifying `DETERMINISTC` or `NON-DETERMINISTIC` in procedures has no effect. The default value is `NOT DETERMINISTIC`. Functions are `DETERMINISTIC` when they always return the same value for the same input. For example, a truncate or substring function. Any function involving data, therefore, is always `NOT DETERMINISTIC`.

CONTAINS SQL/NO SQL/READS SQL DATA/MODIFIES SQL DATA

`CONTAINS SQL`, `NO SQL`, `READS SQL DATA`, and `MODIFIES SQL DATA` are informative clauses that tell the server what the function does. MariaDB does not check in any way whether the specified clause is correct. If none of these clauses are specified, `CONTAINS SQL` is used by default.

`MODIFIES SQL DATA` means that the function contains statements that may modify data stored in databases. This happens if the function contains statements like DELETE, UPDATE, INSERT, REPLACE or DDL.

`READS SQL DATA` means that the function reads data stored in databases, but does not modify any data. This happens if SELECT statements are used, but there no write operations are executed.

`CONTAINS SQL` means that the function contains at least one SQL statement, but it does not read or write any data stored in a database. Examples include SET or DO.

`NO SQL` means nothing, because MariaDB does not currently support any language other than SQL.

The routine_body consists of a valid SQL procedure statement. This can be a simple statement such as SELECT or INSERT, or it can be a compound statement written using BEGIN and END. Compound statements can contain declarations, loops, and other control structure statements. See Programmatic and Compound Statements for syntax details.

MariaDB allows routines to contain DDL statements, such as `CREATE` and DROP. MariaDB also allows stored procedures (but not stored functions) to contain SQL transaction statements such as `COMMIT`.

For additional information about statements that are not allowed in stored routines, see Stored Routine Limitations.

Invoking stored procedure from within programs

For information about invoking stored procedures from within programs written in a language that has a MariaDB/MySQL interface, see CALL.

OR REPLACE

If the optional `OR REPLACE` clause is used, it acts as a shortcut for:

```
DROP PROCEDURE IF EXISTS name;
CREATE PROCEDURE name ...;
```

with the exception that any existing privileges for the procedure are not dropped.

sql_mode

MariaDB stores the sql_mode system variable setting that is in effect at the time a routine is created, and always executes the routine with this setting in force, regardless of the server SQL mode in effect when the routine is invoked.

Character Sets and Collations

Procedure parameters can be declared with any character set/collation. If the character set and collation are not specifically set, the database defaults at the time of creation will be used. If the database defaults change at a later stage, the stored procedure character set/collation will not be changed at the same time; the stored procedure needs to be dropped and recreated to ensure the same character set/collation as the database is used.

Oracle Mode

A subset of Oracle's PL/SQL language is supported in addition to the traditional SQL/PSM-based MariaDB syntax. See Oracle mode for details on changes when running Oracle mode.

Examples

The following example shows a simple stored procedure that uses an `OUT` parameter. It uses the DELIMITER command to set a new delimiter for the duration of the process — see Delimiters in the mariadb client.

```
DELIMITER //

CREATE PROCEDURE simpleproc (OUT param1 INT)
 BEGIN
  SELECT COUNT(*) INTO param1 FROM t;
 END;
//

DELIMITER ;

CALL simpleproc(@a);

SELECT @a;
+------+
| @a   |
+------+
|    1 |
+------+
```

Character set and collation:

```
DELIMITER //

CREATE PROCEDURE simpleproc2 (
  OUT param1 CHAR(10) CHARACTER SET 'utf8' COLLATE 'utf8_bin'
)
 BEGIN
  SELECT CONCAT('a'),f1 INTO param1 FROM t;
 END;
//

DELIMITER ;
```

CREATE OR REPLACE:

```
DELIMITER //

CREATE PROCEDURE simpleproc2 (
  OUT param1 CHAR(10) CHARACTER SET 'utf8' COLLATE 'utf8_bin'
)
 BEGIN
  SELECT CONCAT('a'),f1 INTO param1 FROM t;
 END;
//
ERROR 1304 (42000): PROCEDURE simpleproc2 already exists

DELIMITER ;

DELIMITER //

CREATE OR REPLACE PROCEDURE simpleproc2 (
  OUT param1 CHAR(10) CHARACTER SET 'utf8' COLLATE 'utf8_bin'
)
 BEGIN
  SELECT CONCAT('a'),f1 INTO param1 FROM t;
 END;
//
ERROR 1304 (42000): PROCEDURE simpleproc2 already exists

DELIMITER ;
Query OK, 0 rows affected (0.03 sec)
```

1.1.1.1.8 CREATE ROLE

1.1.6.2 CREATE SEQUENCE

1.1.1.3.1.12 CREATE SERVER

Syntax

```
CREATE [OR REPLACE] SERVER [IF NOT EXISTS] server_name
    FOREIGN DATA WRAPPER wrapper_name
    OPTIONS (option [, option] ...)

option:
  { HOST character-literal
  | DATABASE character-literal
  | USER character-literal
  | PASSWORD character-literal
  | SOCKET character-literal
  | OWNER character-literal
  | PORT numeric-literal }
```

Contents

Description

This statement creates the definition of a server for use with the Spider, Connect, FEDERATED or FederatedX storage engine. The CREATE SERVER statement creates a new row within the servers table within the mysql database. This statement requires the SUPER privilege or, from MariaDB 10.5.2, the FEDERATED ADMIN privilege.

The server_name should be a unique reference to the server. Server definitions are global within the scope of the server, it is not possible to qualify the server definition to a specific database. server_name has a maximum length of 64 characters (names longer than 64 characters are silently truncated), and is case insensitive. You may specify the name as a quoted

string.

The wrapper_name may be quoted with single quotes. Supported values are:

- `mysql`
- `mariadb` (in MariaDB 10.3 and later)

For each option you must specify either a character literal or numeric literal. Character literals are UTF-8, support a maximum length of 64 characters and default to a blank (empty) string. String literals are silently truncated to 64 characters. Numeric literals must be a number between 0 and 9999, default value is 0.

Note: The `OWNER` option is currently not applied, and has no effect on the ownership or operation of the server connection that is created.

The CREATE SERVER statement creates an entry in the mysql.servers table that can later be used with the CREATE TABLE statement when creating a Spider, Connect, FederatedX or FEDERATED table. The options that you specify will be used to populate the columns in the mysql.servers table. The table columns are Server_name, Host, Db, Username, Password, Port and Socket.

DROP SERVER removes a previously created server definition.

CREATE SERVER is not written to the binary log, irrespective of the binary log format being used and therefore will not replicate. From MariaDB 10.1.13, Galera replicates the CREATE SERVER, ALTER SERVER and DROP SERVER statements.

For valid identifiers to use as server names, see Identifier Names.

OR REPLACE

If the optional `OR REPLACE` clause is used, it acts as a shortcut for:

```
DROP SERVER IF EXISTS name;
CREATE SERVER server_name ...;
```

IF NOT EXISTS

If the IF NOT EXISTS clause is used, MariaDB will return a warning instead of an error if the server already exists. Cannot be used together with OR REPLACE.

Examples

```
CREATE SERVER s
FOREIGN DATA WRAPPER mariadb
OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');
```

OR REPLACE and IF NOT EXISTS:

```
CREATE SERVER s
FOREIGN DATA WRAPPER mariadb
OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');
ERROR 1476 (HY000): The foreign server, s, you are trying to create already exists

CREATE OR REPLACE SERVER s
FOREIGN DATA WRAPPER mariadb
OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');
Query OK, 0 rows affected (0.00 sec)

CREATE SERVER IF NOT EXISTS s
FOREIGN DATA WRAPPER mariadb
OPTIONS (USER 'Remote', HOST '192.168.1.106', DATABASE 'test');
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-------+------+-----------------------------------------------------------------+
| Level | Code | Message                                                         |
+-------+------+-----------------------------------------------------------------+
| Note  | 1476 | The foreign server, s, you are trying to create already exists  |
+-------+------+-----------------------------------------------------------------+
```

1.1.1.2.1.6 CREATE TABLE

1.1.1.3.1.14 CREATE TABLESPACE

The `CREATE TABLESPACE` statement is not supported by MariaDB. It was originally inherited from MySQL NDB Cluster. In MySQL 5.7 and later, the statement is also supported for InnoDB. However, MariaDB has chosen not to include that specific feature. See MDEV-19294 for more information.

1.1.1.3.1.15 CREATE TRIGGER

Syntax

```
CREATE [OR REPLACE]
    [DEFINER = { user | CURRENT_USER | role | CURRENT_ROLE }]
    TRIGGER [IF NOT EXISTS] trigger_name trigger_time trigger_event
    ON tbl_name FOR EACH ROW
   [{ FOLLOWS | PRECEDES } other_trigger_name ]
   trigger_stmt;
```

Contents

Description

This statement creates a new trigger. A trigger is a named database object that is associated with a table, and that activates when a particular event occurs for the table. The trigger becomes associated with the table named `tbl_name`, which must refer to a permanent table. You cannot associate a trigger with a `TEMPORARY` table or a view.

`CREATE TRIGGER` requires the TRIGGER privilege for the table associated with the trigger.

You can have multiple triggers for the same `trigger_time` and `trigger_event`.

For valid identifiers to use as trigger names, see Identifier Names.

OR REPLACE

If used and the trigger already exists, instead of an error being returned, the existing trigger will be dropped and replaced by the newly defined trigger.

DEFINER

The `DEFINER` clause determines the security context to be used when checking access privileges at trigger activation time. Usage requires the SUPER privilege, or, from MariaDB 10.5.2, the SET USER privilege.

IF NOT EXISTS

If the `IF NOT EXISTS` clause is used, the trigger will only be created if a trigger of the same name does not exist. If the trigger already exists, by default a warning will be returned.

trigger_time

`trigger_time` is the trigger action time. It can be `BEFORE` or `AFTER` to indicate that the trigger activates before or after each row to be modified.

trigger_event

`trigger_event` indicates the kind of statement that activates the trigger. The `trigger_event` can be one of the following:

- `INSERT` : The trigger is activated whenever a new row is inserted into the table; for example, through INSERT, LOAD DATA, and REPLACE statements.
- `UPDATE` : The trigger is activated whenever a row is modified; for example, through UPDATE statements.
- `DELETE` : The trigger is activated whenever a row is deleted from the table; for example, through DELETE and REPLACE statements. However, `DROP TABLE` and `TRUNCATE` statements on the table do not activate this trigger, because they do not use `DELETE` . Dropping a partition does not activate `DELETE` triggers, either.

FOLLOWS/PRECEDES other_trigger_name

The `FOLLOWS other_trigger_name` and `PRECEDES other_trigger_name` options were added in MariaDB 10.2.3 as part of supporting multiple triggers per action time. This is the same syntax used by MySQL 5.7, although MySQL 5.7 does not have multi-trigger support.

`FOLLOWS` adds the new trigger after another trigger while `PRECEDES` adds the new trigger before another trigger. If neither option is used, the new trigger is added last for the given action and time.

`FOLLOWS` and `PRECEDES` are not stored in the trigger definition. However the trigger order is guaranteed to not change over time. mariadb-dump and other backup methods will not change trigger order. You can verify the trigger order from the `ACTION_ORDER` column in INFORMATION_SCHEMA.TRIGGERS table.

```
SELECT trigger_name, action_order FROM information_schema.triggers
  WHERE event_object_table='t1';
```

Atomic DDL

MariaDB starting with 10.6.1

MariaDB 10.6.1 supports Atomic DDL and `CREATE TRIGGER` is atomic.

Examples

```
CREATE DEFINER=`root`@`localhost` TRIGGER increment_animal
  AFTER INSERT ON animals FOR EACH ROW
   UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
```

OR REPLACE and IF NOT EXISTS

```
CREATE DEFINER=`root`@`localhost` TRIGGER increment_animal
  AFTER INSERT ON animals FOR EACH ROW
    UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
ERROR 1359 (HY000): Trigger already exists

CREATE OR REPLACE DEFINER=`root`@`localhost` TRIGGER increment_animal
  AFTER INSERT ON animals  FOR EACH ROW
    UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
Query OK, 0 rows affected (0.12 sec)

CREATE DEFINER=`root`@`localhost` TRIGGER IF NOT EXISTS increment_animal
  AFTER INSERT ON animals FOR EACH ROW
    UPDATE animal_count SET animal_count.animals = animal_count.animals+1;
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-------+------+-----------------------+
| Level | Code | Message               |
+-------+------+-----------------------+
| Note  | 1359 | Trigger already exists |
+-------+------+-----------------------+
1 row in set (0.00 sec)
```

1.1.1.1.1 CREATE USER

1.1.1.3.1.17 CREATE VIEW

Syntax

```
CREATE
    [OR REPLACE]
    [ALGORITHM = {UNDEFINED | MERGE | TEMPTABLE}]
    [DEFINER = { user | CURRENT_USER | role | CURRENT_ROLE }]
    [SQL SECURITY { DEFINER | INVOKER }]
    VIEW [IF NOT EXISTS] view_name [(column_list)]
    AS select_statement
    [WITH [CASCADED | LOCAL] CHECK OPTION]
```

Contents

Description

The CREATE VIEW statement creates a new view, or replaces an existing one if the OR REPLACE clause is given. If the view does not exist, CREATE OR REPLACE VIEW is the same as CREATE VIEW. If the view does exist, CREATE OR REPLACE VIEW is the same as ALTER VIEW.

The select_statement is a SELECT statement that provides the definition of the view. (When you select from the view, you select in effect using the SELECT statement.) select_statement can select from base tables or other views.

The view definition is "frozen" at creation time, so changes to the underlying tables afterwards do not affect the view definition. For example, if a view is defined as SELECT * on a table, new columns added to the table later do not become part of the view. A SHOW CREATE VIEW shows that such queries are rewritten and column names are included in the view definition.

The view definition must be a query that does not return errors at view creation times. However, the base tables used by the views might be altered later and the query may not be valid anymore. In this case, querying the view will result in an error. CHECK TABLE helps in finding this kind of problems.

The ALGORITHM clause affects how MariaDB processes the view. The DEFINER and SQL SECURITY clauses specify the security context to be used when checking access privileges at view invocation time. The WITH CHECK OPTION clause can be given to constrain inserts or updates to rows in tables referenced by the view. These clauses are described later in this section.

The CREATE VIEW statement requires the CREATE VIEW privilege for the view, and some privilege for each column selected by the SELECT statement. For columns used elsewhere in the SELECT statement you must have the SELECT privilege. If the OR REPLACE clause is present, you must also have the DROP privilege for the view.

A view belongs to a database. By default, a new view is created in the default database. To create the view explicitly in a given database, specify the name as db_name.view_name when you create it.

```
CREATE VIEW test.v AS SELECT * FROM t;
```

Base tables and views share the same namespace within a database, so a database cannot contain a base table and a view that have the same name.

Views must have unique column names with no duplicates, just like base tables. By default, the names of the columns retrieved by the SELECT statement are used for the view column names. To define explicit names for the view columns, the optional column_list clause can be given as a list of comma-separated identifiers. The number of names in column_list must be the same as the number of columns retrieved by the SELECT statement.

MySQL until 5.1.28

Prior to MySQL 5.1.29, When you modify an existing view, the current view definition is backed up and saved. It is stored in that table's database directory, in a subdirectory named arc. The backup file for a view v is named v.frm-00001. If you alter the view again, the next backup is named v.frm-00002. The three latest view backup definitions are stored. Backed

up view definitions are not preserved by mysqldump, or any other such programs, but you can retain them using a file copy operation. However, they are not needed for anything but to provide you with a backup of your previous view definition. It is safe to remove these backup definitions, but only while mysqld is not running. If you delete the arc subdirectory or its files while mysqld is running, you will receive an error the next time you try to alter the view:

```
MariaDB [test]> ALTER VIEW v AS SELECT * FROM t;
ERROR 6 (HY000): Error on delete of '.\test\arc/v.frm-0004' (Errcode: 2)
```

Columns retrieved by the SELECT statement can be simple references to table columns. They can also be expressions that use functions, constant values, operators, and so forth.

Unqualified table or view names in the SELECT statement are interpreted with respect to the default database. A view can refer to tables or views in other databases by qualifying the table or view name with the proper database name.

A view can be created from many kinds of SELECT statements. It can refer to base tables or other views. It can use joins, UNION, and subqueries. The SELECT need not even refer to any tables. The following example defines a view that selects two columns from another table, as well as an expression calculated from those columns:

```
CREATE TABLE t (qty INT, price INT);

INSERT INTO t VALUES(3, 50);

CREATE VIEW v AS SELECT qty, price, qty*price AS value FROM t;

SELECT * FROM v;
+------+-------+-------+
| qty  | price | value |
+------+-------+-------+
|    3 |    50 |   150 |
+------+-------+-------+
```

A view definition is subject to the following restrictions:

- The SELECT statement cannot contain a subquery in the FROM clause.
- The SELECT statement cannot refer to system or user variables.
- Within a stored program, the definition cannot refer to program parameters or local variables.
- The SELECT statement cannot refer to prepared statement parameters.
- Any table or view referred to in the definition must exist. However, after a view has been created, it is possible to drop a table or view that the definition refers to. In this case, use of the view results in an error. To check a view definition for problems of this kind, use the CHECK TABLE statement.
- The definition cannot refer to a TEMPORARY table, and you cannot create a TEMPORARY view.
- Any tables named in the view definition must exist at definition time.
- You cannot associate a trigger with a view.
- For valid identifiers to use as view names, see Identifier Names.

ORDER BY is allowed in a view definition, but it is ignored if you select from a view using a statement that has its own ORDER BY.

For other options or clauses in the definition, they are added to the options or clauses of the statement that references the view, but the effect is undefined. For example, if a view definition includes a LIMIT clause, and you select from the view using a statement that has its own LIMIT clause, it is undefined which limit applies. This same principle applies to options such as ALL, DISTINCT, or SQL_SMALL_RESULT that follow the SELECT keyword, and to clauses such as INTO, FOR UPDATE, and LOCK IN SHARE MODE.

The PROCEDURE clause cannot be used in a view definition, and it cannot be used if a view is referenced in the FROM clause.

If you create a view and then change the query processing environment by changing system variables, that may affect the results that you get from the view:

```
CREATE VIEW v (mycol) AS SELECT 'abc';

SET sql_mode = '';

SELECT "mycol" FROM v;
+-------+
| mycol |
+-------+
| mycol |
+-------+

SET sql_mode = 'ANSI_QUOTES';

SELECT "mycol" FROM v;
+-------+
| mycol |
+-------+
| abc   |
+-------+
```

The DEFINER and SQL SECURITY clauses determine which MariaDB account to use when checking access privileges for the view when a statement is executed that references the view. They were added in MySQL 5.1.2. The legal SQL SECURITY characteristic values are DEFINER and INVOKER. These indicate that the required privileges must be held by the user who defined or invoked the view, respectively. The default SQL SECURITY value is DEFINER.

If a user value is given for the DEFINER clause, it should be a MariaDB account in 'user_name'@'host_name' format (the same format used in the GRANT statement). The user_name and host_name values both are required. The definer can also be given as CURRENT_USER or CURRENT_USER(). The default DEFINER value is the user who executes the CREATE VIEW statement. This is the same as specifying DEFINER = CURRENT_USER explicitly.

If you specify the DEFINER clause, these rules determine the legal DEFINER user values:

- If you do not have the SUPER privilege, or, from MariaDB 10.5.2, the SET USER privilege, the only legal user value is your own account, either specified literally or by using CURRENT_USER. You cannot set the definer to some other account.
- If you have the SUPER privilege, or, from MariaDB 10.5.2, the SET USER privilege, you can specify any syntactically legal account name. If the account does not actually exist, a warning is generated.
- If the SQL SECURITY value is DEFINER but the definer account does not exist when the view is referenced, an error occurs.

Within a view definition, CURRENT_USER returns the view's DEFINER value by default. For views defined with the SQL SECURITY INVOKER characteristic, CURRENT_USER returns the account for the view's invoker. For information about user auditing within views, see http://dev.mysql.com/doc/refman/5.1/en/account-activity-auditing.html.

Within a stored routine that is defined with the SQL SECURITY DEFINER characteristic, CURRENT_USER returns the routine's DEFINER value. This also affects a view defined within such a program, if the view definition contains a DEFINER value of CURRENT_USER.

View privileges are checked like this:

- At view definition time, the view creator must have the privileges needed to use the top-level objects accessed by the view. For example, if the view definition refers to table columns, the creator must have privileges for the columns, as described previously. If the definition refers to a stored function, only the privileges needed to invoke the function can be checked. The privileges required when the function runs can be checked only as it executes: For different invocations of the function, different execution paths within the function might be taken.
- When a view is referenced, privileges for objects accessed by the view are checked against the privileges held by the view creator or invoker, depending on whether the SQL SECURITY characteristic is DEFINER or INVOKER, respectively.
- If reference to a view causes execution of a stored function, privilege checking for statements executed within the function depend on whether the function is defined with a SQL SECURITY characteristic of DEFINER or INVOKER. If the security characteristic is DEFINER, the function runs with the privileges of its creator. If the characteristic is INVOKER, the function runs with the privileges determined by the view's SQL SECURITY characteristic.

Example: A view might depend on a stored function, and that function might invoke other stored routines. For example, the following view invokes a stored function f():

```
CREATE VIEW v AS SELECT * FROM t WHERE t.id = f(t.name);

Suppose that f() contains a statement such as this:

IF name IS NULL then
  CALL p1();
ELSE
  CALL p2();
END IF;
```

The privileges required for executing statements within f() need to be checked when f() executes. This might mean that privileges are needed for p1() or p2(), depending on the execution path within f(). Those privileges must be checked at runtime, and the user who must possess the privileges is determined by the SQL SECURITY values of the view v and the function f().

The DEFINER and SQL SECURITY clauses for views are extensions to standard SQL. In standard SQL, views are handled using the rules for SQL SECURITY INVOKER.

If you invoke a view that was created before MySQL 5.1.2, it is treated as though it was created with a SQL SECURITY DEFINER clause and with a DEFINER value that is the same as your account. However, because the actual definer is unknown, MySQL issues a warning. To make the warning go away, it is sufficient to re-create the view so that the view definition includes a DEFINER clause.

The optional ALGORITHM clause is an extension to standard SQL. It affects how MariaDB processes the view. ALGORITHM takes three values: MERGE, TEMPTABLE, or UNDEFINED. The default algorithm is UNDEFINED if no ALGORITHM clause is present. See View Algorithms for more information.

Some views are updatable. That is, you can use them in statements such as UPDATE, DELETE, or INSERT to update the contents of the underlying table. For a view to be updatable, there must be a one-to-one relationship between the rows in the view and the rows in the underlying table. There are also certain other constructs that make a view non-updatable. See Inserting and Updating with Views.

WITH CHECK OPTION

The WITH CHECK OPTION clause can be given for an updatable view to prevent inserts or updates to rows except those for which the WHERE clause in the select_statement is true.

In a WITH CHECK OPTION clause for an updatable view, the LOCAL and CASCADED keywords determine the scope of check testing when the view is defined in terms of another view. The LOCAL keyword restricts the CHECK OPTION only to the view being defined. CASCADED causes the checks for underlying views to be evaluated as well. When neither keyword is given, the default is CASCADED.

For more information about updatable views and the WITH CHECK OPTION clause, see Inserting and Updating with Views.

IF NOT EXISTS

MariaDB starting with 10.1.3

The `IF NOT EXISTS` clause was added in MariaDB 10.1.3

When the IF NOT EXISTS clause is used, MariaDB will return a warning instead of an error if the specified view already exists. Cannot be used together with the `OR REPLACE` clause.

Atomic DDL

MariaDB starting with 10.6.1

MariaDB 10.6.1 supports Atomic DDL and `CREATE VIEW` is atomic.

Examples

```
CREATE TABLE t (a INT, b INT) ENGINE = InnoDB;

INSERT INTO t VALUES (1,1), (2,2), (3,3);

CREATE VIEW v AS SELECT a, a*2 AS a2 FROM t;

SELECT * FROM v;
+------+------+
| a    | a2   |
+------+------+
|    1 |    2 |
|    2 |    4 |
|    3 |    6 |
+------+------+
```

OR REPLACE and IF NOT EXISTS:

```
CREATE VIEW v AS SELECT a, a*2 AS a2 FROM t;
ERROR 1050 (42S01): Table 'v' already exists

CREATE OR REPLACE VIEW v AS SELECT a, a*2 AS a2 FROM t;
Query OK, 0 rows affected (0.04 sec)

CREATE VIEW IF NOT EXISTS v AS SELECT a, a*2 AS a2 FROM t;
Query OK, 0 rows affected, 1 warning (0.01 sec)

SHOW WARNINGS;
+-------+------+--------------------------+
| Level | Code | Message                  |
+-------+------+--------------------------+
| Note  | 1050 | Table 'v' already exists |
+-------+------+--------------------------+
```

1.1.1.3.1.18 Silent Column Changes

When a CREATE TABLE or ALTER TABLE command is issued, MariaDB will silently change a column specification in the following cases:

- PRIMARY KEY columns are always NOT NULL.
- Any trailing spaces from SET and ENUM values are discarded.
- TIMESTAMP columns are always NOT NULL, and display sizes are discarded
- A row-size limit of 65535 bytes applies
- If strict SQL mode is not enabled (it is enabled by default from MariaDB 10.2), a VARCHAR column longer than 65535 become TEXT, and a VARBINARY columns longer than 65535 becomes a BLOB. If strict mode is enabled the silent changes will not be made, and an error will occur.
- If a USING clause specifies an index that's not permitted by the storage engine, the engine will instead use another available index type that can be applied without affecting results.
- If the CHARACTER SET binary attribute is specified, the column is created as the matching binary data type. A TEXT becomes a BLOB, CHAR a BINARY and VARCHAR a VARBINARY. ENUMs and SETs are created as defined.

To ease imports from other RDBMSs, MariaDB will also silently map the following data types:

Other Vendor Type	MariaDB Type
BOOL	TINYINT
BOOLEAN	TINYINT
CHARACTER VARYING(M)	VARCHAR(M)
FIXED	DECIMAL
FLOAT4	FLOAT
FLOAT8	DOUBLE
INT1	TINYINT
INT2	SMALLINT
INT3	MEDIUMINT

INT4	INT
INT8	BIGINT
LONG VARBINARY	MEDIUMBLOB
LONG VARCHAR	MEDIUMTEXT
LONG	MEDIUMTEXT
MIDDLEINT	MEDIUMINT
NUMERIC	DECIMAL

Currently, all MySQL types are supported in MariaDB.

For type mapping between Cassandra and MariaDB, see Cassandra storage engine.

Example

Silent changes in action:

```
CREATE TABLE SilenceIsGolden
   (
    f1 TEXT CHARACTER SET binary,
    f2 VARCHAR(15) CHARACTER SET binary,
    f3 CHAR CHARACTER SET binary,
    f4 ENUM('x','y','z') CHARACTER SET binary,
    f5 VARCHAR (65536),
    f6 VARBINARY (65536),
    f7 INT1
   );
Query OK, 0 rows affected, 2 warnings (0.31 sec)

SHOW WARNINGS;
+-------+------+-----------------------------------------------+
| Level | Code | Message                                       |
+-------+------+-----------------------------------------------+
| Note  | 1246 | Converting column 'f5' from VARCHAR to TEXT   |
| Note  | 1246 | Converting column 'f6' from VARBINARY to BLOB |
+-------+------+-----------------------------------------------+

DESCRIBE SilenceIsGolden;
+-------+-------------------+------+-----+---------+-------+
| Field | Type              | Null | Key | Default | Extra |
+-------+-------------------+------+-----+---------+-------+
| f1    | blob              | YES  |     | NULL    |       |
| f2    | varbinary(15)     | YES  |     | NULL    |       |
| f3    | binary(1)         | YES  |     | NULL    |       |
| f4    | enum('x','y','z') | YES  |     | NULL    |       |
| f5    | mediumtext        | YES  |     | NULL    |       |
| f6    | mediumblob        | YES  |     | NULL    |       |
| f7    | tinyint(4)        | YES  |     | NULL    |       |
+-------+-------------------+------+-----+---------+-------+
```

1.1.1.3.1.19 Generated (Virtual and Persistent/Stored) Columns

Syntax

```
<type>  [GENERATED ALWAYS]  AS   ( <expression> )
[VIRTUAL | PERSISTENT | STORED]  [UNIQUE] [UNIQUE KEY] [COMMENT <text>]
```

Contents

MariaDB's generated columns syntax is designed to be similar to the syntax for Microsoft SQL Server's computed columns and Oracle Database's virtual columns. In MariaDB 10.2 and later, the syntax is also compatible with the syntax for MySQL's generated columns.

Description

A generated column is a column in a table that cannot explicitly be set to a specific value in a DML query. Instead, its value is automatically generated based on an expression. This expression might generate the value based on the values of other columns in the table, or it might generate the value by calling built-in functions or user-defined functions (UDFs).

There are two types of generated columns:

- `PERSISTENT` (a.k.a. `STORED`): This type's value is actually stored in the table.
- `VIRTUAL`: This type's value is not stored at all. Instead, the value is generated dynamically when the table is queried. This type is the default.

Generated columns are also sometimes called computed columns or virtual columns.

Supported Features

Storage Engine Support

- Generated columns can only be used with storage engines which support them. If you try to use a storage engine that does not support them, then you will see an error similar to the following:

```
ERROR 1910 (HY000): TokuDB storage engine does not support computed columns
```

- InnoDB, Aria, MyISAM and CONNECT support generated columns.
- A column in a MERGE table can be built on a `PERSISTENT` generated column.
  - However, a column in a MERGE table can **not** be defined as a `VIRTUAL` and `PERSISTENT` generated column.

Data Type Support

- All data types are supported when defining generated columns.
- Using the ZEROFILL column option is supported when defining generated columns.
- Using the AUTO_INCREMENT column option is **not** supported when defining generated columns. Until MariaDB 10.2.25, it was supported, but this support was removed, because it would not work correctly. See MDEV-11117.

Index Support

- Using a generated column as a table's primary key is **not** supported. See MDEV-5590 for more information. If you try to use one as a primary key, then you will see an error similar to the following:

```
ERROR 1903 (HY000): Primary key cannot be defined upon a computed column
```

- Using `PERSISTENT` generated columns as part of a foreign key is supported.

- Referencing `PERSISTENT` generated columns as part of a foreign key is also supported.
  - However, using the `ON UPDATE CASCADE`, `ON UPDATE SET NULL`, or `ON DELETE SET NULL` clauses is **not** supported. If you try to use an unsupported clause, then you will see an error similar to the following:

```
ERROR 1905 (HY000): Cannot define foreign key with ON UPDATE SET NULL clause on a computed
column
```

- Defining indexes on both `VIRTUAL` and `PERSISTENT` generated columns is supported.
  - If an index is defined on a generated column, then the optimizer considers using it in the same way as indexes based on "real" columns.

Statement Support

- Generated columns are used in DML queries just as if they were "real" columns.
  - However, `VIRTUAL` and `PERSISTENT` generated columns differ in how their data is stored.
    - Values for `PERSISTENT` generated columns are generated whenever a DML queries inserts or updates the row with the special `DEFAULT` value. This generates the columns value, and it is stored in the table like the other "real" columns. This value can be read by other DML queries just like the other "real" columns.
    - Values for `VIRTUAL` generated columns are not stored in the table. Instead, the value is generated dynamically whenever the column is queried. If other columns in a row are queried, but the `VIRTUAL` generated column is not one of the queried columns, then the column's value is not generated.
- The SELECT statement supports generated columns.
- Generated columns can be referenced in the INSERT, UPDATE, and DELETE statements.
  - However, `VIRTUAL` or `PERSISTENT` generated columns cannot be explicitly set to any other values than `NULL` or DEFAULT. If a generated column is explicitly set to any other value, then the outcome depends on whether strict mode is enabled in sql_mode. If it is not enabled, then a warning will be raised and the default generated value will be used instead. If it is enabled, then an error will be raised instead.
- The CREATE TABLE statement has limited support for generated columns.
  - It supports defining generated columns in a new table.
  - It supports using generated columns to partition tables.
  - It does **not** support using the versioning clauses with generated columns.
- The ALTER TABLE statement has limited support for generated columns.
  - It supports the `MODIFY` and `CHANGE` clauses for `PERSISTENT` generated columns.
  - It does **not** support the `MODIFY` clause for `VIRTUAL` generated columns if ALGORITHM is not set to `COPY`. See MDEV-15476 for more information.
  - It does **not** support the `CHANGE` clause for `VIRTUAL` generated columns if ALGORITHM is not set to `COPY`. See MDEV-17035 for more information.
  - It does **not** support altering a table if ALGORITHM is not set to `COPY` if the table has a `VIRTUAL` generated column that is indexed. See MDEV-14046 for more information.
  - It does **not** support adding a `VIRTUAL` generated column with the `ADD` clause if the same statement is also adding other columns if ALGORITHM is not set to `COPY`. See MDEV-17468 for more information.
  - It also does **not** support altering an existing column into a `VIRTUAL` generated column.
  - It supports using generated columns to partition tables.
  - It does **not** support using the versioning clauses with generated columns.
- The SHOW CREATE TABLE statement supports generated columns.
- The DESCRIBE statement can be used to check whether a table has generated columns.
  - You can tell which columns are generated by looking for the ones where the `Extra` column is set to either `VIRTUAL` or `PERSISTENT`. For example:

```
DESCRIBE table1;
+-------+-------------+------+-----+---------+------------+
| Field | Type        | Null | Key | Default | Extra      |
+-------+-------------+------+-----+---------+------------+
| a     | int(11)     | NO   |     | NULL    |            |
| b     | varchar(32) | YES  |     | NULL    |            |
| c     | int(11)     | YES  |     | NULL    | VIRTUAL    |
| d     | varchar(5)  | YES  |     | NULL    | PERSISTENT |
+-------+-------------+------+-----+---------+------------+
```

- Generated columns can be properly referenced in the `NEW` and `OLD` rows in triggers.
- Stored procedures support generated columns.

- The HANDLER statement supports generated columns.

Expression Support

- Most legal, deterministic expressions which can be calculated are supported in expressions for generated columns.
- Most built-in functions are supported in expressions for generated columns.
  - However, some built-in functions can't be supported for technical reasons. For example, If you try to use an unsupported function in an expression, an error is generated similar to the following:

```
ERROR 1901 (HY000): Function or expression 'dayname()' cannot be used in the GENERATED ALWAYS AS clause of `v`
```

- Subqueries are **not** supported in expressions for generated columns because the underlying data can change.
- Using anything that depends on data outside the row is **not** supported in expressions for generated columns.
- Stored functions are **not** supported in expressions for generated columns. See MDEV-17587 for more information.
- Non-deterministic built-in functions are supported in expressions for not indexed `VIRTUAL` generated columns.
- Non-deterministic built-in functions are **not** supported in expressions for `PERSISTENT` or indexed `VIRTUAL` generated columns.
- User-defined functions (UDFs) are supported in expressions for generated columns.
  - However, MariaDB can't check whether a UDF is deterministic, so it is up to the user to be sure that they do not use non-deterministic UDFs with `VIRTUAL` generated columns.
- Defining a generated column based on other generated columns defined before it in the table definition is supported. For example:

```
CREATE TABLE t1 (a int as (1), b int as (a));
```

- However, defining a generated column based on other generated columns defined after in the table definition is **not** supported in expressions for generation columns because generated columns are calculated in the order they are defined.
- Using an expression that exceeds 255 characters in length is supported in expressions for generated columns. The new limit for the entire table definition, including all expressions for generated columns, is 65,535 bytes.
- Using constant expressions is supported in expressions for generated columns. For example:

```
CREATE TABLE t1 (a int as (1));
```

Making Stored Values Consistent

When a generated column is `PERSISTENT` or indexed, the value of the expression needs to be consistent regardless of the SQL Mode flags in the current session. If it is not, then the table will be seen as corrupted when the value that should actually be returned by the computed expression and the value that was previously stored and/or indexed using a different sql_mode setting disagree.

There are currently two affected classes of inconsistencies: character padding and unsigned subtraction:

- For a `VARCHAR` or `TEXT` generated column the length of the value returned can vary depending on the PAD_CHAR_TO_FULL_LENGTH sql_mode flag. To make the value consistent, create the generated column using an RTRIM() or RPAD() function. Alternately, create the generated column as a `CHAR` column so that its data is always fully padded.
- If a `SIGNED` generated column is based on the subtraction of an `UNSIGNED` value, the resulting value can vary depending on how large the value is and the NO_UNSIGNED_SUBTRACTION sql_mode flag. To make the value consistent, use CAST() to ensure that each `UNSIGNED` operand is `SIGNED` before the subtraction.

MariaDB starting with 10.5

Beginning in MariaDB 10.5, there is a fatal error generated when trying to create a generated column whose value can change depending on the SQL Mode when its data is `PERSISTENT` or indexed.

For an existing generated column that has a potentially inconsistent value, a warning about a bad expression is generated the first time it is used (if warnings are enabled).

Beginning in MariaDB 10.4.8, MariaDB 10.3.18, and MariaDB 10.2.27 a potentially inconsistent generated column outputs a warning when created or first used (without restricting their creation).

Here is an example of two tables that would be rejected in MariaDB 10.5 and warned about in the other listed versions:

```
CREATE TABLE bad_pad (
  txt CHAR(5),
  -- CHAR -> VARCHAR or CHAR -> TEXT can't be persistent or indexed:
  vtxt VARCHAR(5) AS (txt) PERSISTENT
);

CREATE TABLE bad_sub (
  num1 BIGINT UNSIGNED,
  num2 BIGINT UNSIGNED,
  -- The resulting value can vary for some large values
  vnum BIGINT AS (num1 - num2) VIRTUAL,
  KEY(vnum)
);
```

The warnings for the above tables look like this:

```
Warning (Code 1901): Function or expression '`txt`' cannot be used in the GENERATED ALWAYS AS
clause of `vtxt`
Warning (Code 1105): Expression depends on the @@sql_mode value PAD_CHAR_TO_FULL_LENGTH

Warning (Code 1901): Function or expression '`num1` - `num2`' cannot be used in the GENERATED
ALWAYS AS clause of `vnum`
Warning (Code 1105): Expression depends on the @@sql_mode value NO_UNSIGNED_SUBTRACTION
```

To work around the issue, force the padding or type to make the generated column's expression return a consistent value. For example:

```
CREATE TABLE good_pad (
  txt CHAR(5),
  -- Using RTRIM() or RPAD() makes the value consistent:
  vtxt VARCHAR(5) AS (RTRIM(txt)) PERSISTENT,
  -- When not persistent or indexed, it is OK for the value to vary by mode:
  vtxt2 VARCHAR(5) AS (txt) VIRTUAL,
  -- CHAR -> CHAR is always OK:
  txt2 CHAR(5) AS (txt) PERSISTENT
);

CREATE TABLE good_sub (
  num1 BIGINT UNSIGNED,
  num2 BIGINT UNSIGNED,
  -- The indexed value will always be consistent in this expression:
  vnum BIGINT AS (CAST(num1 AS SIGNED) - CAST(num2 AS SIGNED)) VIRTUAL,
  KEY(vnum)
);
```

MySQL Compatibility Support

- The `STORED` keyword is supported as an alias for the `PERSISTENT` keyword.
- Tables created with MySQL 5.7 or later that contain MySQL's generated columns can be imported into MariaDB without a dump and restore.

Implementation Differences

Generated columns are subject to various constraints in other DBMSs that are not present in MariaDB's implementation. Generated columns may also be called computed columns or virtual columns in different implementations. The various details for a specific implementation can be found in the documentation for each specific DBMS.

Implementation Differences Compared to Microsoft SQL Server

MariaDB's generated columns implementation does not enforce the following restrictions that are present in Microsoft SQL Server's computed columns implementation:

- MariaDB allows server variables in generated column expressions, including those that change dynamically, such as warning_count.
- MariaDB allows the CONVERT_TZ() function to be called with a named time zone as an argument, even though time zone names and time offsets are configurable.

- MariaDB allows the CAST() function to be used with non-unicode character sets, even though character sets are configurable and differ between binaries/versions.
- MariaDB allows FLOAT expressions to be used in generated columns. Microsoft SQL Server considers these expressions to be "imprecise" due to potential cross-platform differences in floating-point implementations and precision.
- Microsoft SQL Server requires the ARITHABORT mode to be set, so that division by zero returns an error, and not a NULL.
- Microsoft SQL Server requires `QUOTED_IDENTIFIER` to be set in sql_mode. In MariaDB, if data is inserted without `ANSI_QUOTES` set in sql_mode, then it will be processed and stored differently in a generated column that contains quoted identifiers.

Microsoft SQL Server enforces the above restrictions by doing one of the following things:

- Refusing to create computed columns.
- Refusing to allow updates to a table containing them.
- Refusing to use an index over such a column if it can not be guaranteed that the expression is fully deterministic.

In MariaDB, as long as the sql_mode, language, and other settings that were in effect during the CREATE TABLE remain unchanged, the generated column expression will always be evaluated the same. If any of these things change, then please be aware that the generated column expression might not be evaluated the same way as it previously was.

If you try to update a virtual column, you will get an error if the default strict mode is enabled in sql_mode, or a warning otherwise.

Development History

Generated columns was originally developed by Andrey Zhakov. It was then modified by Sanja Byelkin and Igor Babaev at Monty Program for inclusion in MariaDB. Monty did the work on MariaDB 10.2 to lift a some of the old limitations.

Examples

Here is an example table that uses both `VIRTUAL` and `PERSISTENT` virtual columns:

```
USE TEST;

CREATE TABLE table1 (
     a INT NOT NULL,
     b VARCHAR(32),
     c INT AS (a mod 10) VIRTUAL,
     d VARCHAR(5) AS (left(b,5)) PERSISTENT);
```

If you describe the table, you can easily see which columns are virtual by looking in the "Extra" column:

```
DESCRIBE table1;
+-------+-------------+------+-----+---------+------------+
| Field | Type        | Null | Key | Default | Extra      |
+-------+-------------+------+-----+---------+------------+
| a     | int(11)     | NO   |     | NULL    |            |
| b     | varchar(32) | YES  |     | NULL    |            |
| c     | int(11)     | YES  |     | NULL    | VIRTUAL    |
| d     | varchar(5)  | YES  |     | NULL    | PERSISTENT |
+-------+-------------+------+-----+---------+------------+
```

To find out what function(s) generate the value of the virtual column you can use `SHOW CREATE TABLE`:

```
SHOW CREATE TABLE table1;

| table1 | CREATE TABLE `table1` (
  `a` int(11) NOT NULL,
  `b` varchar(32) DEFAULT NULL,
  `c` int(11) AS (a mod 10) VIRTUAL,
  `d` varchar(5) AS (left(b,5)) PERSISTENT
) ENGINE=MyISAM DEFAULT CHARSET=latin1 |
```

If you try to insert non-default values into a virtual column, you will receive a warning and what you tried to insert will be ignored and the derived value inserted instead:

```
WARNINGS;
Show warnings enabled.

INSERT INTO table1 VALUES (1, 'some text',default,default);
Query OK, 1 row affected (0.00 sec)

INSERT INTO table1 VALUES (2, 'more text',5,default);
Query OK, 1 row affected, 1 warning (0.00 sec)

Warning (Code 1645): The value specified for computed column 'c' in table 'table1' has been ignor

INSERT INTO table1 VALUES (123, 'even more text',default,'something');
Query OK, 1 row affected, 2 warnings (0.00 sec)

Warning (Code 1645): The value specified for computed column 'd' in table 'table1' has been ignor
Warning (Code 1265): Data truncated for column 'd' at row 1

SELECT * FROM table1;
+-----+----------------+------+-------+
| a   | b              | c    | d     |
+-----+----------------+------+-------+
|   1 | some text      |    1 | some  |
|   2 | more text      |    2 | more  |
| 123 | even more text |    3 | even  |
+-----+----------------+------+-------+
3 rows in set (0.00 sec)
```

If the `ZEROFILL` clause is specified, it should be placed directly after the type definition, before the `AS (<expression>)`:

```
CREATE TABLE table2 (a INT, b INT ZEROFILL AS (a*2) VIRTUAL);
INSERT INTO table2 (a) VALUES (1);

SELECT * FROM table2;
+------+------------+
| a    | b          |
+------+------------+
|    1 | 0000000002 |
+------+------------+
1 row in set (0.00 sec)
```

You can also use virtual columns to implement a "poor man's partial index". See example at the end of Unique Index.

1.1.1.3.1.20 Invisible Columns

MariaDB starting with 10.3.3

Invisible columns (sometimes also called hidden columns) first appeared in MariaDB 10.3.3.

Columns can be given an `INVISIBLE` attribute in a CREATE TABLE or ALTER TABLE statement. These columns will then not be listed in the results of a SELECT * statement, nor do they need to be assigned a value in an INSERT statement, unless INSERT explicitly mentions them by name.

Since `SELECT *` does not return the invisible columns, new tables or views created in this manner will have no trace of the invisible columns. If specifically referenced in the SELECT statement, the columns will be brought into the view/new table, but the INVISIBLE attribute will not.

Invisible columns can be declared as `NOT NULL`, but then require a `DEFAULT` value.

It is not possible for all columns in a table to be invisible.

Examples

```
CREATE TABLE t (x INT INVISIBLE);
ERROR 1113 (42000): A table must have at least 1 column

CREATE TABLE t (x INT, y INT INVISIBLE, z INT INVISIBLE NOT NULL);
ERROR 4106 (HY000): Invisible column `z` must have a default value

CREATE TABLE t (x INT, y INT INVISIBLE, z INT INVISIBLE NOT NULL DEFAULT 4);

INSERT INTO t VALUES (1),(2);

INSERT INTO t (x,y) VALUES (3,33);

SELECT * FROM t;
+------+
| x    |
+------+
|    1 |
|    2 |
|    3 |
+------+

SELECT x,y,z FROM t;
+------+------+---+
| x    | y    | z |
+------+------+---+
|    1 | NULL | 4 |
|    2 | NULL | 4 |
|    3 |   33 | 4 |
+------+------+---+

DESC t;
+-------+---------+------+-----+---------+-----------+
| Field | Type    | Null | Key | Default | Extra     |
+-------+---------+------+-----+---------+-----------+
| x     | int(11) | YES  |     | NULL    |           |
| y     | int(11) | YES  |     | NULL    | INVISIBLE |
| z     | int(11) | NO   |     | 4       | INVISIBLE |
+-------+---------+------+-----+---------+-----------+

ALTER TABLE t MODIFY x INT INVISIBLE, MODIFY y INT, MODIFY z INT NOT NULL DEFAULT 4;

DESC t;
+-------+---------+------+-----+---------+-----------+
| Field | Type    | Null | Key | Default | Extra     |
+-------+---------+------+-----+---------+-----------+
| x     | int(11) | YES  |     | NULL    | INVISIBLE |
| y     | int(11) | YES  |     | NULL    |           |
| z     | int(11) | NO   |     | 4       |           |
+-------+---------+------+-----+---------+-----------+
```

Creating a view from a table with hidden columns:

```
CREATE VIEW v1 AS SELECT * FROM t;

DESC v1;
+-------+---------+------+-----+---------+-------+
| Field | Type    | Null | Key | Default | Extra |
+-------+---------+------+-----+---------+-------+
| y     | int(11) | YES  |     | NULL    |       |
| z     | int(11) | NO   |     | 4       |       |
+-------+---------+------+-----+---------+-------+

CREATE VIEW v2 AS SELECT x,y,z FROM t;

DESC v2;
+-------+---------+------+-----+---------+-------+
| Field | Type    | Null | Key | Default | Extra |
+-------+---------+------+-----+---------+-------+
| x     | int(11) | YES  |     | NULL    |       |
| y     | int(11) | YES  |     | NULL    |       |
| z     | int(11) | NO   |     | 4       |       |
+-------+---------+------+-----+---------+-------+
```

Adding a Surrogate Primary Key:

```
create table t1 (x bigint unsigned not null, y varchar(16), z text);

insert into t1 values (123, 'qq11', 'ipsum');

insert into t1 values (123, 'qq22', 'lorem');

alter table t1 add pkid serial primary key invisible first;

insert into t1 values (123, 'qq33', 'amet');

select * from t1;
+-----+------+-------+
| x   | y    | z     |
+-----+------+-------+
| 123 | qq11 | ipsum |
| 123 | qq22 | lorem |
| 123 | qq33 | amet  |
+-----+------+-------+

select pkid, z from t1;
+------+-------+
| pkid | z     |
+------+-------+
|    1 | ipsum |
|    2 | lorem |
|    3 | amet  |
+------+-------+
```

1.1.1.2.1.1 ALTER

1.1.1.2.1.1.1 ALTER TABLE

1.1.1.2.1.1.2 ALTER DATABASE

1.1.1.2.1.1.3 ALTER EVENT

1.1.1.2.1.1.4 ALTER FUNCTION

1.1.1.2.1.1.5 ALTER LOGFILE GROUP

1.1.1.1.2 ALTER USER

1.1.1.2.1.1.11 ALTER VIEW

1.1.1.3.3 DROP

Articles on various DROP commands.

DROP DATABASE
Drop all tables and delete database.

DROP EVENT
Removes an existing event.

DROP FUNCTION
Drop a stored function.

DROP FUNCTION UDF
Drop a user-defined function.

DROP INDEX
Drops an index from a table.

DROP LOGFILE GROUP
The DROP LOGFILE GROUP statement is not supported by MariaDB. It was origin...

DROP PACKAGE
Drops a stored package entirely.

DROP PACKAGE BODY
Drops a package body (i.e the implementation) previously created using the CREATE PACKAGE BODY.

DROP PROCEDURE
Drop stored procedure.

DROP ROLE
Drop a role.

DROP SEQUENCE
Deleting a SEQUENCE.

DROP SERVER
Dropping a server definition.

DROP TABLE
Removes definition and data from one or more tables.

DROP TABLESPACE
DROP TABLESPACE is not available in MariaDB.

DROP TRIGGER
Drops a trigger.

DROP USER
Remove one or more MariaDB accounts.

DROP VIEW
Removes one or more views.

There are 1 related questions.

1.1.1.3.3.1 DROP DATABASE

Syntax

```
DROP {DATABASE | SCHEMA} [IF EXISTS] db_name
```

Contents

Description

`DROP DATABASE` drops all tables in the database and deletes the database. Be very careful with this statement! To use DROP DATABASE, you need the DROP privilege on the database. `DROP SCHEMA` is a synonym for `DROP DATABASE`.

Important: When a database is dropped, user privileges on the database are not automatically dropped. See GRANT.

IF EXISTS

Use `IF EXISTS` to prevent an error from occurring for databases that do not exist. A `NOTE` is generated for each non-existent database when using `IF EXISTS`. See SHOW WARNINGS.

Atomic DDL

MariaDB starting with 10.6.1

MariaDB 10.6.1 supports Atomic DDL.

`DROP DATABASE` is implemented as

```
loop over all tables
  DROP TABLE table
```

Each individual DROP TABLE is atomic while `DROP DATABASE` as a whole is crash-safe.

Examples

```
DROP DATABASE bufg;
Query OK, 0 rows affected (0.39 sec)

DROP DATABASE bufg;
ERROR 1008 (HY000): Can't drop database 'bufg'; database doesn't exist

 \W
Show warnings enabled.

DROP DATABASE IF EXISTS bufg;
Query OK, 0 rows affected, 1 warning (0.00 sec)
Note (Code 1008): Can't drop database 'bufg'; database doesn't exist
```

1.1.1.3.3.2 DROP EVENT

Syntax

```
DROP EVENT [IF EXISTS] event_name
```

Description

This statement drops the event named `event_name`. The event immediately ceases being active, and is deleted completely from the server.

If the event does not exist, the error `ERROR 1517 (HY000): Unknown event 'event_name'` results. You can override this and cause the statement to generate a `NOTE` for non-existent events instead by using `IF EXISTS`. See `SHOW WARNINGS`.

This statement requires the `EVENT` privilege. In MySQL 5.1.11 and earlier, an event could be dropped only by its definer, or by a user having the `SUPER` privilege.

Examples

```
DROP EVENT myevent3;
```

Using the IF EXISTS clause:

```
DROP EVENT IF EXISTS myevent3;
Query OK, 0 rows affected, 1 warning (0.01 sec)

SHOW WARNINGS;
+-------+------+-------------------------------+
| Level | Code | Message                       |
+-------+------+-------------------------------+
| Note  | 1305 | Event myevent3 does not exist |
+-------+------+-------------------------------+
```

1.1.1.3.3.3 DROP FUNCTION

Syntax

```
DROP FUNCTION [IF EXISTS] f_name
```

Contents

Description

The DROP FUNCTION statement is used to drop a stored function or a user-defined function (UDF). That is, the specified routine is removed from the server, along with all privileges specific to the function. You must have the `ALTER ROUTINE` privilege for the routine in order to drop it. If the automatic_sp_privileges server system variable is set, both the `ALTER ROUTINE` and `EXECUTE` privileges are granted automatically to the routine creator - see Stored Routine Privileges.

IF EXISTS

The `IF EXISTS` clause is a MySQL/MariaDB extension. It prevents an error from occurring if the function does not exist. A `NOTE` is produced that can be viewed with SHOW WARNINGS.

For dropping a user-defined functions (UDF), see DROP FUNCTION UDF.

Examples

```
DROP FUNCTION hello;
Query OK, 0 rows affected (0.042 sec)

DROP FUNCTION hello;
ERROR 1305 (42000): FUNCTION test.hello does not exist

DROP FUNCTION IF EXISTS hello;
Query OK, 0 rows affected, 1 warning (0.000 sec)

SHOW WARNINGS;
+-------+------+-----------------------------------+
| Level | Code | Message                           |
+-------+------+-----------------------------------+
| Note  | 1305 | FUNCTION test.hello does not exist |
+-------+------+-----------------------------------+
```

1.1.1.3.3.4 DROP FUNCTION UDF

Syntax

```
DROP FUNCTION [IF EXISTS] function_name
```

Contents

Description

This statement drops the user-defined function (UDF) named `function_name`.

To drop a function, you must have the `DELETE privilege` for the mysql database. This is because `DROP FUNCTION` removes the row from the mysql.func system table that records the function's name, type and shared library name.

For dropping a stored function, see DROP FUNCTION.

Upgrading a UDF

To upgrade the UDF's shared library, first run a DROP FUNCTION statement, then upgrade the shared library and finally run the CREATE FUNCTION statement. If you upgrade without following this process, you may crash the server.

Examples

```
DROP FUNCTION jsoncontains_path;
```

IF EXISTS:

```
DROP FUNCTION jsoncontains_path;
ERROR 1305 (42000): FUNCTION test.jsoncontains_path does not exist

DROP FUNCTION IF EXISTS jsoncontains_path;
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-------+------+-------------------------------------------------+
| Level | Code | Message                                         |
+-------+------+-------------------------------------------------+
| Note  | 1305 | FUNCTION test.jsoncontains_path does not exist |
+-------+------+-------------------------------------------------+
```

1.1.1.3.3.5 DROP INDEX

Syntax

```
DROP INDEX [IF EXISTS] index_name ON tbl_name
    [WAIT n |NOWAIT]
```

Contents

Description

`DROP INDEX` drops the index named `index_name` from the table `tbl_name`. This statement is mapped to an `ALTER TABLE` statement to drop the index.

If another connection is using the table, a metadata lock is active, and this statement will wait until the lock is released. This is also true for non-transactional tables.

See ALTER TABLE.

Another shortcut, CREATE INDEX, allows the creation of an index.

To remove the primary key, `` `PRIMARY` `` must be specified as index_name. Note that the quotes are necessary, because `PRIMARY` is a keyword.

Privileges

Executing the `DROP INDEX` statement requires the `INDEX` privilege for the table or the database.

Online DDL

Online DDL is used by default with InnoDB, when the drop index operation supports it.

See InnoDB Online DDL Overview for more information on online DDL with InnoDB.

DROP INDEX IF EXISTS ...

If the `IF EXISTS` clause is used, then MariaDB will return a warning instead of an error if the index does not exist.

WAIT/NOWAIT

Sets the lock wait timeout. See WAIT and NOWAIT.

Progress Reporting

MariaDB provides progress reporting for `DROP INDEX` statement for clients that support the new progress reporting protocol. For example, if you were using the mariadb client, then the progress report might look like this::

1.1.1.3.3.6 DROP LOGFILE GROUP

The `DROP LOGFILE GROUP` statement is not supported by MariaDB. It was originally inherited from MySQL NDB Cluster. See MDEV-19295 for more information.

1.1.1.3.3.7 DROP PACKAGE

MariaDB starting with 10.3.5
Oracle-style packages were introduced in MariaDB 10.3.5.

Syntax

```
DROP PACKAGE [IF EXISTS]  [ db_name . ] package_name
```

Contents
1. Syntax
2. Description

Description

The `DROP PACKAGE` statement can be used when Oracle SQL_MODE is set.

The `DROP PACKAGE` statement drops a stored package entirely:

- Drops the package specification (earlier created using the CREATE PACKAGE statement).
- Drops the package implementation, if the implementation was already created using the CREATE PACKAGE BODY statement.

1.1.1.3.3.8 DROP PACKAGE BODY

MariaDB starting with 10.3.5
Oracle-style packages were introduced in MariaDB 10.3.5.

Syntax

```
DROP PACKAGE BODY [IF EXISTS]  [ db_name . ] package_name
```

Contents
1. Syntax
2. Description

Description

The `DROP PACKAGE BODY` statement can be used when Oracle SQL_MODE is set.

The `DROP PACKAGE BODY` statement drops the package body (i.e the implementation), previously created using the CREATE PACKAGE BODY statement.

Note, `DROP PACKAGE BODY` drops only the package implementation, but does not drop the package specification. Use DROP PACKAGE to drop the package entirely (i.e. both implementation and specification).

1.1.1.3.3.9 DROP PROCEDURE

Syntax

```
DROP PROCEDURE [IF EXISTS] sp_name
```

Contents
1. Syntax
2. Description
3. Examples

Description

This statement is used to drop a stored procedure. That is, the specified routine is removed from the server along with all privileges specific to the procedure. You must have the `ALTER ROUTINE` privilege for the routine. If the `automatic_sp_privileges` server system variable is set, that privilege and `EXECUTE` are granted automatically to the routine creator - see Stored Routine Privileges.

The `IF EXISTS` clause is a MySQL/MariaDB extension. It prevents an error from occurring if the procedure or function does not exist. A `NOTE` is produced that can be viewed with `SHOW WARNINGS`.

While this statement takes effect immediately, threads which are executing a procedure can continue execution.

Examples

```
DROP PROCEDURE simpleproc;
```

IF EXISTS:

```
DROP PROCEDURE simpleproc;
ERROR 1305 (42000): PROCEDURE test.simpleproc does not exist

DROP PROCEDURE IF EXISTS simpleproc;
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;
+-------+------+-----------------------------------------+
| Level | Code | Message                                 |
+-------+------+-----------------------------------------+
| Note  | 1305 | PROCEDURE test.simpleproc does not exist |
+-------+------+-----------------------------------------+
```

1.1.1.1.9 DROP ROLE

1.1.6.5 DROP SEQUENCE

1.1.1.3.3.12 DROP SERVER

Syntax

```
DROP SERVER [ IF EXISTS ] server_name
```

Contents

Description

Drops the server definition for the server named *server_name*. The corresponding row within the mysql.servers table will be deleted. This statement requires the SUPER privilege or, from MariaDB 10.5.2, the FEDERATED ADMIN privilege.

Dropping a server for a table does not affect any FederatedX, FEDERATED, Connect or Spider tables that used this connection information when they were created.

DROP SERVER is not written to the binary log, irrespective of the binary log format being used. From MariaDB 10.1.13, Galera replicates the CREATE SERVER, ALTER SERVER and DROP SERVER statements.

IF EXISTS

If the IF EXISTS clause is used, MariaDB will not return an error if the server does not exist. Unlike all other statements,

DROP SERVER IF EXISTS does not issue a note if the server does not exist. See MDEV-9400.

Examples

```
DROP SERVER s;
```

IF EXISTS:

```
DROP SERVER s;
ERROR 1477 (HY000): The foreign server name you are trying to reference
  does not exist. Data source error:  s

DROP SERVER IF EXISTS s;
Query OK, 0 rows affected (0.00 sec)
```

1.1.1.2.1.8 DROP TABLE

1.1.1.3.3.14 DROP TABLESPACE

The `DROP TABLESPACE` statement is not supported by MariaDB. It was originally inherited from MySQL NDB Cluster. In MySQL 5.7 and later, the statement is also supported for InnoDB. However, MariaDB has chosen not to include that specific feature. See MDEV-19294 for more information.

1.1.1.3.3.15 DROP TRIGGER

Syntax

```
DROP TRIGGER [IF EXISTS] [schema_name.]trigger_name
```

Contents

Description

This statement drops a trigger. The schema (database) name is optional. If the schema is omitted, the trigger is dropped from the default schema. Its use requires the `TRIGGER` privilege for the table associated with the trigger.

Use `IF EXISTS` to prevent an error from occurring for a trigger that does not exist. A `NOTE` is generated for a non-existent trigger when using `IF EXISTS`. See SHOW WARNINGS.

Note: Triggers for a table are also dropped if you drop the table.

Atomic DDL

MariaDB starting with 10.6.1

MariaDB 10.6.1 supports Atomic DDL and `DROP TRIGGER` is atomic.

Examples

```
DROP TRIGGER test.example_trigger;
```

Using the IF EXISTS clause:

```
DROP TRIGGER IF EXISTS test.example_trigger;
Query OK, 0 rows affected, 1 warning (0.01 sec)

SHOW WARNINGS;
+-------+------+-----------------------+
| Level | Code | Message               |
+-------+------+-----------------------+
| Note  | 1360 | Trigger does not exist |
+-------+------+-----------------------+
```

1.1.1.1.3 DROP USER

1.1.1.3.3.17 DROP VIEW

Syntax

```
DROP VIEW [IF EXISTS]
    view_name [, view_name] ...
    [RESTRICT | CASCADE]
```

Contents

Description

`DROP VIEW` removes one or more views. You must have the DROP privilege for each view. If any of the views named in the argument list do not exist, MariaDB returns an error indicating by name which non-existing views it was unable to drop, but it also drops all of the views in the list that do exist.

The `IF EXISTS` clause prevents an error from occurring for views that don't exist. When this clause is given, a `NOTE` is generated for each non-existent view. See SHOW WARNINGS.

`RESTRICT` and `CASCADE`, if given, are parsed and ignored.

It is possible to specify view names as `db_name.view_name`. This is useful to delete views from multiple databases with one statement. See Identifier Qualifiers for details.

The DROP privilege is required to use `DROP TABLE` on non-temporary tables. For temporary tables, no privilege is required, because such tables are only visible for the current session.

If a view references another view, it will be possible to drop the referenced view. However, the other view will reference a view which does not exist any more. Thus, querying it will produce an error similar to the following:

```
ERROR 1356 (HY000): View 'db_name.view_name' references invalid table(s) or
column(s) or function(s) or definer/invoker of view lack rights to use them
```

This problem is reported in the output of CHECK TABLE.

Note that it is not necessary to use `DROP VIEW` to replace an existing view, because `CREATE VIEW` has an `OR REPLACE` clause.

Atomic DDL

MariaDB starting with 10.6.1

MariaDB 10.6.1 supports Atomic DDL and `DROP VIEW` for a singular view is atomic. Dropping multiple views is crash-safe.

Examples

```
DROP VIEW v,v2;
```

Given views `v` and `v2`, but no view `v3`

```
DROP VIEW v,v2,v3;
ERROR 1051 (42S02): Unknown table 'v3'
```

```
DROP VIEW IF EXISTS v,v2,v3;
Query OK, 0 rows affected, 1 warning (0.01 sec)

SHOW WARNINGS;
+-------+------+-------------------------+
| Level | Code | Message                 |
+-------+------+-------------------------+
| Note  | 1051 | Unknown table 'test.v3' |
+-------+------+-------------------------+
```

1.1.1.3.4 Atomic DDL

From MariaDB 10.6.1, we have improved readability for DDL (Data Definition Language) operations to make most of them atomic, and the rest crash-safe, even if the server crashes in the middle of an operation.

The design of Atomic/Crash-safe DDL (MDEV-17567) allows it to work with all storage engines.

Definitions

- Atomic means that either the operation succeeds (and is logged to the binary log or is completely reversed.
- Crash-safe means that in case of a crash, after the server has restarted, all tables are consistent, there are no temporary files or tables on disk and the binary log matches the status of the server.
- DDL Data definition language.
- DML Data manipulation language.
- 'DDL recovery log' or 'DDL log' for short, is the new log file, `ddl_recovery.log` by default, that stores all DDL operations in progress. This is used to recover the state of the server in case of sudden crash.

Background

Before 10.6, in case of a crash, there was a small possibility that one of the following things could happen:

- There could be temporary tables starting with `#sql-alter` or `#sql-shadow` or temporary files ending with '' left.
- The table in the storage engine and the table's .frm file could be out of sync.
- During a multi-table rename, only some of the tables were renamed.

Which DDL Operations are Now Atomic

- CREATE TABLE, except when used with CREATE OR REPLACE, which is only crash safe.
- RENAME TABLE and RENAME TABLES.
- CREATE VIEW
- CREATE SEQUENCE
- CREATE TRIGGER
- DROP TRIGGER
- DROP TABLE and DROP VIEW. Dropping multiple tables is only crash safe.
- ALTER TABLE
- ALTER SEQUENCE is not listed above as it is internally implemented as a DML.

Which DDL Operations are Now Crash Safe

DROP TABLE of Multiple Tables.

DROP TABLE over multiple tables is treated as if every DROP is a separate, atomic operation. This means that after a crash, all fully, or partly, dropped tables will be dropped and logged to the binary log. The undropped tables will be left untouched.

CREATE OR REPLACE TABLE

CREATE OR REPLACE TABLE foo is implemented as:

```
DROP TABLE IF EXISTS foo;
CREATE TABLE foo ...
```

This means that if there is a crash during `CREATE TABLE` then the original table 'foo' will be dropped even if the new table was not created. If the table was not re-created, the binary log will contain the `DROP TABLE` .

DROP DATABASE

DROP DATABASE is implemented as:

```
loop over all tables
  DROP TABLE table
```

Each DROP TABLE is atomic, but in case of a crash, things will work the same way as DROP TABLE with multiple tables.

Atomic with Different Storage Engines

Atomic/Crash-safe DDL works with all storage engines that either have atomic DDLs internally or are able to re-execute `DROP` or `RENAME` in case of failure.

This should be true for most storage engines. The ones that still need some work are:

- The S3 storage engine.
- The partitioning engine. Partitioning should be atomic for most cases, but there are still some known issues that need to be tested and fixed.

The DDL Log Recovery File

The new startup option --log-ddl-recovery=path (`ddl_recovery.log` by default) can be used to specify the place for the DDL log file. This is mainly useful in the case when one has a filesystem on persistent memory, as there is a lot of sync on this file during DDL operations.

This file contains all DDL operations that are in progress.

At MariaDB server startup, the DDL log file is copied to a file with the same base name but with a `-backup.log` suffix. This is mainly done to be able to find out what went wrong if recovery fails.

If the server crashes during recovery (unlikely but possible), the recovery will continue where it was before. The recovery will retry each entry up to 3 times before giving up and proceeding with the next entry.

Conclusions

- We believe that a clean separation of layers leads to an easier-to-maintain solution. The Atomic DDL implementation in MariaDB 10.6 introduced minimal changes to the storage engine API, mainly for native ALTER TABLE.
- In our InnoDB implementation, no file format changes were needed on top of the RENAME undo log that was introduced in MariaDB 10.2.19 for a backup-safe TRUNCATE re-implementation. Correct use of sound design principles (write-ahead logging and transactions; also file creation now follows the ARIES protocol) is sufficient. We removed the hacks (at most one CREATE or DROP per transaction) and correctly implemented `rollback` and `purge` triggers for the InnoDB SYS_INDEXES table.
- Numerous DDL recovery bugs in InnoDB were found and fixed quickly thanks to https://rr-project.org. We are still working on one: data files must not be deleted before the DDL transaction is committed.

Thanks to Atomic/Crash-safe DDL, the MariaDB server is now much more stable and reliable in unstable environments. There is still ongoing work to fix the few remaining issues mentioned above to make all DDL operations Atomic. The target for these is MariaDB 10.7.

1.1.1.3.5 CONSTRAINT

MariaDB supports the implementation of constraints at the table-level using either CREATE TABLE or ALTER TABLE statements. A table constraint restricts the data you can add to the table. If you attempt to insert invalid data on a column, MariaDB throws an error.

Syntax

```
[CONSTRAINT [symbol]] constraint_expression

constraint_expression:
  | PRIMARY KEY [index_type] (index_col_name, ...) [index_option] ...
  | FOREIGN KEY [index_name] (index_col_name, ...)
       REFERENCES tbl_name (index_col_name, ...)
       [ON DELETE reference_option]
       [ON UPDATE reference_option]
  | UNIQUE [INDEX|KEY] [index_name]
       [index_type] (index_col_name, ...) [index_option] ...
  | CHECK (check_constraints)

index_type:
  USING {BTREE | HASH | RTREE}

index_col_name:
  col_name [(length)] [ASC | DESC]

index_option:
  | KEY_BLOCK_SIZE [=] value
  | index_type
  | WITH PARSER parser_name
  | COMMENT 'string'
  | CLUSTERING={YES|NO}

reference_option:
  RESTRICT | CASCADE | SET NULL | NO ACTION | SET DEFAULT
```

Contents

Description

Constraints provide restrictions on the data you can add to a table. This allows you to enforce data integrity from MariaDB, rather than through application logic. When a statement violates a constraint, MariaDB throws an error.

There are four types of table constraints:

Constraint	Description
`PRIMARY KEY`	Sets the column for referencing rows. Values must be unique and not null.
`FOREIGN KEY`	Sets the column to reference the primary key on another table.
`UNIQUE`	Requires values in column or columns only occur once in the table.
`CHECK`	Checks whether the data meets the given condition.

The Information Schema TABLE_CONSTRAINTS Table contains information about tables that have constraints.

FOREIGN KEY Constraints

InnoDB supports foreign key constraints. The syntax for a foreign key constraint definition in InnoDB looks like this:

```
[CONSTRAINT [symbol]] FOREIGN KEY
    [index_name] (index_col_name, ...)
    REFERENCES tbl_name (index_col_name,...)
    [ON DELETE reference_option]
    [ON UPDATE reference_option]

reference_option:
    RESTRICT | CASCADE | SET NULL | NO ACTION
```

The Information Schema REFERENTIAL_CONSTRAINTS table has more information about foreign keys.

CHECK Constraints

Constraints are enforced. Before MariaDB 10.2.1 constraint expressions were accepted in the syntax but ignored.

You can define constraints in 2 different ways:

- `CHECK(expression)` given as part of a column definition.
- `CONSTRAINT [constraint_name] CHECK (expression)`

Before a row is inserted or updated, all constraints are evaluated in the order they are defined. If any constraint expression returns false, then the row will not be inserted or updated. One can use most deterministic functions in a constraint, including UDFs.

```
CREATE TABLE t1 (a INT CHECK (a>2), b INT CHECK (b>2), CONSTRAINT a_greater CHECK (a>b));
```

If you use the second format and you don't give a name to the constraint, then the constraint will get an automatically generated name. This is done so that you can later delete the constraint with ALTER TABLE DROP constraint_name.

One can disable all constraint expression checks by setting the check_constraint_checks variable to `OFF`. This is useful for example when loading a table that violates some constraints that you want to later find and fix in SQL.

Replication

In row-based replication, only the master checks constraints, and failed statements will not be replicated. In statement-based replication, the slaves will also check constraints. Constraints should therefore be identical, as well as deterministic, in a replication environment.

Auto_increment

auto_increment columns are not permitted in check constraints. Before MariaDB 10.2.6, they were permitted, but would not work correctly. See MDEV-11117.

Examples

```
CREATE TABLE product (category INT NOT NULL, id INT NOT NULL,
                      price DECIMAL,
                      PRIMARY KEY(category, id)) ENGINE=INNODB;
CREATE TABLE customer (id INT NOT NULL,
                       PRIMARY KEY (id)) ENGINE=INNODB;
CREATE TABLE product_order (no INT NOT NULL AUTO_INCREMENT,
                            product_category INT NOT NULL,
                            product_id INT NOT NULL,
                            customer_id INT NOT NULL,
                            PRIMARY KEY(no),
                            INDEX (product_category, product_id),
                            FOREIGN KEY (product_category, product_id)
                              REFERENCES product(category, id)
                              ON UPDATE CASCADE ON DELETE RESTRICT,
                            INDEX (customer_id),
                            FOREIGN KEY (customer_id)
                              REFERENCES customer(id)) ENGINE=INNODB;
```

The following examples will work from MariaDB 10.2.1 onwards.

Numeric constraints and comparisons:

```
CREATE TABLE t1 (a INT CHECK (a>2), b INT CHECK (b>2), CONSTRAINT a_greater CHECK (a>b));

INSERT INTO t1(a) VALUES (1);
ERROR 4022 (23000): CONSTRAINT `a` failed for `test`.`t1`

INSERT INTO t1(a,b) VALUES (3,4);
ERROR 4022 (23000): CONSTRAINT `a_greater` failed for `test`.`t1`

INSERT INTO t1(a,b) VALUES (4,3);
Query OK, 1 row affected (0.04 sec)
```

Dropping a constraint:

```
ALTER TABLE t1 DROP CONSTRAINT a_greater;
```

Adding a constraint:

```
ALTER TABLE t1 ADD CONSTRAINT a_greater CHECK (a>b);
```

Date comparisons and character length:

```
CREATE TABLE t2 (name VARCHAR(30) CHECK (CHAR_LENGTH(name)>2), start_date DATE,
  end_date DATE CHECK (start_date IS NULL OR end_date IS NULL OR start_date<end_date));

INSERT INTO t2(name, start_date, end_date) VALUES('Ione', '2003-12-15', '2014-11-09');
Query OK, 1 row affected (0.04 sec)

INSERT INTO t2(name, start_date, end_date) VALUES('Io', '2003-12-15', '2014-11-09');
ERROR 4022 (23000): CONSTRAINT `name` failed for `test`.`t2`

INSERT INTO t2(name, start_date, end_date) VALUES('Ione', NULL, '2014-11-09');
Query OK, 1 row affected (0.04 sec)

INSERT INTO t2(name, start_date, end_date) VALUES('Ione', '2015-12-15', '2014-11-09');
ERROR 4022 (23000): CONSTRAINT `end_date` failed for `test`.`t2`
```

A misplaced parenthesis:

```
CREATE TABLE t3 (name VARCHAR(30) CHECK (CHAR_LENGTH(name>2)), start_date DATE,
  end_date DATE CHECK (start_date IS NULL OR end_date IS NULL OR start_date<end_date));
Query OK, 0 rows affected (0.32 sec)

INSERT INTO t3(name, start_date, end_date) VALUES('Io', '2003-12-15', '2014-11-09');
Query OK, 1 row affected, 1 warning (0.04 sec)

SHOW WARNINGS;
+---------+------+-----------------------------------------+
| Level   | Code | Message                                 |
+---------+------+-----------------------------------------+
| Warning | 1292 | Truncated incorrect DOUBLE value: 'Io' |
+---------+------+-----------------------------------------+
```

Compare the definition of table *t2* to table *t3*. `CHAR_LENGTH(name)>2` is very different to `CHAR_LENGTH(name>2)` as the latter mistakenly performs a numeric comparison on the *name* field, leading to unexpected results.

Contents

Description

`SELECT` is used to retrieve rows selected from one or more tables, and can include UNION statements and subqueries.

- Each *select_expr* expression indicates a column or data that you want to retrieve. You must have at least one select expression. See Select Expressions below.
- The `FROM` clause indicates the table or tables from which to retrieve rows. Use either a single table name or a `JOIN` expression. See JOIN for details. If no table is involved, FROM DUAL can be specified.
- Each table can also be specified as `db_name.tabl_name`. Each column can also be specified as `tbl_name.col_name` or even `db_name.tbl_name.col_name`. This allows one to write queries which involve multiple databases. See Identifier Qualifiers for syntax details.
- The `WHERE` clause, if given, indicates the condition or conditions that rows must satisfy to be selected.

`where_condition` is an expression that evaluates to true for each row to be selected. The statement selects all rows if there is no WHERE clause.
    - In the `WHERE` clause, you can use any of the functions and operators that MariaDB supports, except for aggregate (summary) functions. See Functions and Operators and Functions and Modifiers for use with GROUP BY (aggregate).
- Use the ORDER BY clause to order the results.
- Use the LIMIT clause allows you to restrict the results to only a certain number of rows, optionally with an offset.
- Use the GROUP BY and `HAVING` clauses to group rows together when they have columns or computed values in common.

SELECT can also be used to retrieve rows computed without reference to any table.

Select Expressions

A `SELECT` statement must contain one or more select expressions, separated by commas. Each select expression can be one of the following:

- The name of a column.
- Any expression using functions and operators.
- `*` to select all columns from all tables in the `FROM` clause.
- `tbl_name.*` to select all columns from just the table *tbl_name*.

When specifying a column, you can either use just the column name or qualify the column name with the name of the table using `tbl_name.col_name`. The qualified form is useful if you are joining multiple tables in the `FROM` clause. If you do not qualify the column names when selecting from multiple tables, MariaDB will try to find the column in each table. It is an error if that column name exists in multiple tables.

You can quote column names using backticks. If you are qualifying column names with table names, quote each part separately as `` `tbl_name`.`col_name` ``.

If you use any grouping functions in any of the select expressions, all rows in your results will be implicitly grouped, as if you had used `GROUP BY NULL`.

DISTINCT

A query may produce some identical rows. By default, all rows are retrieved, even when their values are the same. To explicitly specify that you want to retrieve identical rows, use the `ALL` option. If you want duplicates to be removed from the resultset, use the `DISTINCT` option. `DISTINCTROW` is a synonym for `DISTINCT`. See also COUNT DISTINCT and SELECT UNIQUE in Oracle mode.

INTO

The `INTO` clause is used to specify that the query results should be written to a file or variable.

- SELECT INTO OUTFILE - formatting and writing the result to an external file.
- SELECT INTO DUMPFILE - binary-safe writing of the unformatted results to an external file.
- SELECT INTO Variable - selecting and setting variables.

The reverse of `SELECT INTO OUTFILE` is LOAD DATA.

LIMIT

Restricts the number of returned rows. See LIMIT and LIMIT ROWS EXAMINED for details.

LOCK IN SHARE MODE/FOR UPDATE

See LOCK IN SHARE MODE and FOR UPDATE for details on the respective locking clauses.

OFFSET ... FETCH

MariaDB starting with 10.6

See SELECT ... OFFSET ... FETCH.

ORDER BY

Order a resultset. See ORDER BY for details.

PARTITION

Specifies to the optimizer which partitions are relevant for the query. Other partitions will not be read. See Partition Pruning and Selection for details.

PROCEDURE

Passes the whole result set to a C Procedure. See PROCEDURE and PROCEDURE ANALYSE (the only built-in procedure not requiring the server to be recompiled).

SKIP LOCKED

MariaDB starting with 10.6

The SKIP LOCKED clause was introduced in MariaDB 10.6.0.

This causes those rows that couldn't be locked (LOCK IN SHARE MODE or FOR UPDATE) to be excluded from the result set. An explicit `NOWAIT` is implied here. This is only implemented on InnoDB tables and ignored otherwise.

SQL_CALC_FOUND_ROWS

When `SQL_CALC_FOUND_ROWS` is used, then MariaDB will calculate how many rows would have been in the result, if there would be no LIMIT clause. The result can be found by calling the function FOUND_ROWS() in your next sql statement.

max_statement_time clause

By using max_statement_time in conjunction with SET STATEMENT, it is possible to limit the execution time of individual queries. For example:

```
SET STATEMENT max_statement_time=100 FOR
  SELECT field1 FROM table_name ORDER BY field1;
```

WAIT/NOWAIT

Set the lock wait timeout. See WAIT and NOWAIT.

Examples

```
SELECT f1,f2 FROM t1 WHERE (f3<=10) AND (f4='y');
```

See Getting Data from MariaDB (Beginner tutorial), or the various sub-articles, for more examples.

1.1.1.4.1.2 Joins & Subqueries

Documentation on the JOIN, UNION, EXCEPT and INTERSECT clauses, and on subqueries.

Joins
Querying from multiple tables.

Subqueries
Queries within queries.

UNION
Combine the results from multiple SELECT statements into a single result set.

EXCEPT
Subtraction of two result sets.

INTERSECT

Records that are present in both result sets will be included in the result of the operation.

Precedence Control in Table Operations

Controlling order of execution in SELECT, UNION, EXCEPT, and INTERSECT.

MINUS

Synonym for EXCEPT.

Contents

This article is a follow up to the Introduction to JOINs page. If you're just getting started with JOINs, go through that page first and then come back here.

The Employee Database

Let us begin by using an example employee database of a fairly small family business, which does not anticipate expanding in the future.

First, we create the table that will hold all of the employees and their contact information:

```
CREATE TABLE `Employees` (
  `ID` TINYINT(3) UNSIGNED NOT NULL AUTO_INCREMENT,
  `First_Name` VARCHAR(25) NOT NULL,
  `Last_Name` VARCHAR(25) NOT NULL,
  `Position` VARCHAR(25) NOT NULL,
  `Home_Address` VARCHAR(50) NOT NULL,
  `Home_Phone` VARCHAR(12) NOT NULL,
  PRIMARY KEY (`ID`)
) ENGINE=MyISAM;
```

Next, we add a few employees to the table:

```
INSERT INTO `Employees` (`First_Name`, `Last_Name`, `Position`, `Home_Address`, `Home_Phone`)
  VALUES
  ('Mustapha', 'Mond', 'Chief Executive Officer', '692 Promiscuous Plaza', '326-555-3492'),
  ('Henry', 'Foster', 'Store Manager', '314 Savage Circle', '326-555-3847'),
  ('Bernard', 'Marx', 'Cashier', '1240 Ambient Avenue', '326-555-8456'),
  ('Lenina', 'Crowne', 'Cashier', '281 Bumblepuppy Boulevard', '328-555-2349'),
  ('Fanny', 'Crowne', 'Restocker', '1023 Bokanovsky Lane', '326-555-6329'),
  ('Helmholtz', 'Watson', 'Janitor', '944 Soma Court', '329-555-2478');
```

Now, we create a second table, containing the hours which each employee clocked in and out during the week:

```
CREATE TABLE `Hours` (
  `ID` TINYINT(3) UNSIGNED NOT NULL,
  `Clock_In` DATETIME NOT NULL,
  `Clock_Out` DATETIME NOT NULL
) ENGINE=MyISAM;
```

Finally, although it is a lot of information, we add a full week of hours for each of the employees into the second table that we created:

```
INSERT INTO `Hours`
  VALUES
  ('1', '2005-08-08 07:00:42', '2005-08-08 17:01:36'),
  ('1', '2005-08-09 07:01:34', '2005-08-09 17:10:11'),
  ('1', '2005-08-10 06:59:56', '2005-08-10 17:09:29'),
  ('1', '2005-08-11 07:00:17', '2005-08-11 17:00:47'),
  ('1', '2005-08-12 07:02:29', '2005-08-12 16:59:12'),
  ('2', '2005-08-08 07:00:25', '2005-08-08 17:03:13'),
  ('2', '2005-08-09 07:00:57', '2005-08-09 17:05:09'),
  ('2', '2005-08-10 06:58:43', '2005-08-10 16:58:24'),
  ('2', '2005-08-11 07:01:58', '2005-08-11 17:00:45'),
  ('2', '2005-08-12 07:02:12', '2005-08-12 16:58:57'),
  ('3', '2005-08-08 07:00:12', '2005-08-08 17:01:32'),
  ('3', '2005-08-09 07:01:10', '2005-08-09 17:00:26'),
  ('3', '2005-08-10 06:59:53', '2005-08-10 17:02:53'),
  ('3', '2005-08-11 07:01:15', '2005-08-11 17:04:23'),
  ('3', '2005-08-12 07:00:51', '2005-08-12 16:57:52'),
  ('4', '2005-08-08 06:54:37', '2005-08-08 17:01:23'),
  ('4', '2005-08-09 06:58:23', '2005-08-09 17:00:54'),
  ('4', '2005-08-10 06:59:14', '2005-08-10 17:00:12'),
  ('4', '2005-08-11 07:00:49', '2005-08-11 17:00:34'),

```

Working with the Employee Database

Now that we have a cleanly structured database to work with, let us begin this tutorial by stepping up one notch from the last tutorial and filtering our information a little.

Filtering by Name

Earlier in the week, an anonymous employee reported that Helmholtz came into work almost four minutes late; to verify this, we will begin our investigation by filtering out employees whose first names are "Helmholtz":

```
SELECT
  `Employees`.`First_Name`,
  `Employees`.`Last_Name`,
  `Hours`.`Clock_In`,
  `Hours`.`Clock_Out`
FROM `Employees`
INNER JOIN `Hours` ON `Employees`.`ID` = `Hours`.`ID`
WHERE `Employees`.`First_Name` = 'Helmholtz';
```

The result:

```
+------------+-----------+---------------------+---------------------+
| First_Name | Last_Name | Clock_In            | Clock_Out           |
+------------+-----------+---------------------+---------------------+
| Helmholtz  | Watson    | 2005-08-08 07:00:12 | 2005-08-08 17:01:02 |
| Helmholtz  | Watson    | 2005-08-09 07:03:44 | 2005-08-09 17:00:00 |
| Helmholtz  | Watson    | 2005-08-10 06:54:19 | 2005-08-10 17:03:31 |
| Helmholtz  | Watson    | 2005-08-11 07:00:05 | 2005-08-11 17:02:57 |
| Helmholtz  | Watson    | 2005-08-12 07:02:07 | 2005-08-12 16:58:23 |
+------------+-----------+---------------------+---------------------+
5 rows in set (0.00 sec)
```

This is obviously more information than we care to trudge through, considering we only care about when he arrived past 7:00:59 on any given day within this week; thus, we need to add a couple more conditions to our WHERE clause.

Filtering by Name, Date and Time

In the following example, we will filter out all of the times which Helmholtz clocked in that were before 7:01:00 and during the work week that lasted from the 8th to the 12th of August:

```
SELECT
  `Employees`.`First_Name`,
  `Employees`.`Last_Name`,
  `Hours`.`Clock_In`,
  `Hours`.`Clock_Out`
FROM `Employees`
INNER JOIN `Hours` ON `Employees`.`ID` = `Hours`.`ID`
WHERE `Employees`.`First_Name` = 'Helmholtz'
AND DATE_FORMAT(`Hours`.`Clock_In`, '%Y-%m-%d') >= '2005-08-08'
AND DATE_FORMAT(`Hours`.`Clock_In`, '%Y-%m-%d') <= '2005-08-12'
AND DATE_FORMAT(`Hours`.`Clock_In`, '%H:%i:%S') > '07:00:59';
```

The result:

```
+------------+-----------+---------------------+---------------------+
| First_Name | Last_Name | Clock_In            | Clock_Out           |
+------------+-----------+---------------------+---------------------+
| Helmholtz  | Watson    | 2005-08-09 07:03:44 | 2005-08-09 17:00:00 |
| Helmholtz  | Watson    | 2005-08-12 07:02:07 | 2005-08-12 16:58:23 |
+------------+-----------+---------------------+---------------------+
2 rows in set (0.00 sec)
```

We have now, by merely adding a few more conditions, eliminated all of the irrelevant information; Helmholtz was late to work on the 9th and the 12th of August.

Displaying Total Work Hours per Day

Suppose you would like toâ€”based on the information stored in both of our tables in the employee databaseâ€”develop a quick list of the total hours each employee has worked for each day recorded; a simple way to estimate the time each employee worked per day is exemplified below:

```
SELECT
  `Employees`.`ID`,
  `Employees`.`First_Name`,
  `Employees`.`Last_Name`,
  `Hours`.`Clock_In`,
  `Hours`.`Clock_Out`,
DATE_FORMAT(`Hours`.`Clock_Out`, '%T')-DATE_FORMAT(`Hours`.`Clock_In`, '%T') AS 'Total_Hours'
FROM `Employees` INNER JOIN `Hours` ON `Employees`.`ID` = `Hours`.`ID`;
```

The result (limited by 10):

```
+----+------------+-----------+---------------------+---------------------+-------------+
| ID | First_Name | Last_Name | Clock_In            | Clock_Out           | Total_Hours |
+----+------------+-----------+---------------------+---------------------+-------------+
|  1 | Mustapha   | Mond      | 2005-08-08 07:00:42 | 2005-08-08 17:01:36 |          10 |
|  1 | Mustapha   | Mond      | 2005-08-09 07:01:34 | 2005-08-09 17:10:11 |          10 |
|  1 | Mustapha   | Mond      | 2005-08-10 06:59:56 | 2005-08-10 17:09:29 |          11 |
|  1 | Mustapha   | Mond      | 2005-08-11 07:00:17 | 2005-08-11 17:00:47 |          10 |
|  1 | Mustapha   | Mond      | 2005-08-12 07:02:29 | 2005-08-12 16:59:12 |           9 |
|  2 | Henry      | Foster    | 2005-08-08 07:00:25 | 2005-08-08 17:03:13 |          10 |
|  2 | Henry      | Foster    | 2005-08-09 07:00:57 | 2005-08-09 17:05:09 |          10 |
|  2 | Henry      | Foster    | 2005-08-10 06:58:43 | 2005-08-10 16:58:24 |          10 |

|  2 | Henry      | Foster    | 2005-08-12 07:02:12 | 2005-08-12 16:58:57 |           9 |
+----+------------+-----------+---------------------+---------------------+-------------+
10 rows in set (0.00 sec)
```

1.1.1.4.1.2.1.3 JOIN Syntax

Description

MariaDB supports the following `JOIN` syntaxes for the `table_references` part of `SELECT` statements and multiple-table `DELETE` and `UPDATE` statements:

```
table_references:
    table_reference [, table_reference] ...

table_reference:
    table_factor
  | join_table

table_factor:
    tbl_name [PARTITION (partition_list)]
        [query_system_time_period_specification] [[AS] alias] [index_hint_list]
  | table_subquery [query_system_time_period_specification] [AS] alias
  | ( table_references )
  | { ON table_reference LEFT OUTER JOIN table_reference
        ON conditional_expr }

join_table:
    table_reference [INNER | CROSS] JOIN table_factor [join_condition]
  | table_reference STRAIGHT_JOIN table_factor
  | table_reference STRAIGHT_JOIN table_factor ON conditional_expr
  | table_reference {LEFT|RIGHT} [OUTER] JOIN table_reference join_condition
  | table_reference NATURAL [{LEFT|RIGHT} [OUTER]] JOIN table_factor

join_condition:
    ON conditional_expr
  | USING (column_list)

query_system_time_period_specification:
    FOR SYSTEM_TIME AS OF point_in_time
  | FOR SYSTEM_TIME BETWEEN point_in_time AND point_in_time
  | FOR SYSTEM_TIME FROM point_in_time TO point_in_time
  | FOR SYSTEM_TIME ALL

point_in_time:
    [TIMESTAMP] expression
  | TRANSACTION expression

index_hint_list:
    index_hint [, index_hint] ...

index_hint:
    USE {INDEX|KEY}
      [{FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
  | IGNORE {INDEX|KEY}
      [{FOR {JOIN|ORDER BY|GROUP BY}] (index_list)
  | FORCE {INDEX|KEY}
      [{FOR {JOIN|ORDER BY|GROUP BY}] (index_list)

index_list:
    index_name [, index_name] ...
```

A table reference is also known as a join expression.

Each table can also be specified as `db_name.tabl_name`. This allows to write queries which involve multiple databases. See Identifier Qualifiers for syntax details.

The syntax of `table_factor` is extended in comparison with the SQL Standard. The latter accepts only `table_reference`, not a list of them inside a pair of parentheses.

This is a conservative extension if we consider each comma in a list of table_reference items as equivalent to an inner join. For example:

```
SELECT * FROM t1 LEFT JOIN (t2, t3, t4)
                 ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

is equivalent to:

```
SELECT * FROM t1 LEFT JOIN (t2 CROSS JOIN t3 CROSS JOIN t4)
                 ON (t2.a=t1.a AND t3.b=t1.b AND t4.c=t1.c)
```

In MariaDB, `CROSS JOIN` is a syntactic equivalent to `INNER JOIN` (they can replace each other). In standard SQL, they are not equivalent. `INNER JOIN` is used with an `ON` clause, `CROSS JOIN` is used otherwise.

In general, parentheses can be ignored in join expressions containing only inner join operations. MariaDB also supports nested joins (see http://dev.mysql.com/doc/refman/5.1/en/nested-join-optimization.html).

See System-versioned tables for more information about `FOR SYSTEM_TIME` syntax.

Index hints can be specified to affect how the MariaDB optimizer makes use of indexes. For more information, see How to force query plans.

Examples

```
SELECT left_tbl.*
  FROM left_tbl LEFT JOIN right_tbl ON left_tbl.id = right_tbl.id
  WHERE right_tbl.id IS NULL;
```

1.1.1.4.1.2.1.4 Comma vs JOIN

A query to grab the list of phone numbers for clients who ordered in the last two weeks might be written in a couple of ways. Here are two:

```
SELECT *
FROM
  clients,
  orders,
  phoneNumbers
WHERE
  clients.id = orders.clientId
  AND clients.id = phoneNumbers.clientId
  AND orderPlaced >= NOW() - INTERVAL 2 WEEK;
```

```
SELECT *
FROM
  clients
  INNER JOIN orders ON clients.id = orders.clientId
  INNER JOIN phoneNumbers ON clients.id = phoneNumbers.clientId
WHERE
  orderPlaced >= NOW() - INTERVAL 2 WEEK;
```

Does it make a difference? Not much as written. But you should use the second form. Why?

- **Readability.** Once the WHERE clause contains more than two conditions, it becomes tedious to pick out the difference between business logic (only dates in the last two weeks) and relational logic (which fields relate clients to orders). Using the JOIN syntax with an ON clause makes the WHERE list shorter, and makes it very easy to see how tables relate to each other.
- **Flexibility.** Let's say we need to see all clients even if they don't have a phone number in the system. With the second version, it's easy; just change `INNER JOIN phoneNumbers` to `LEFT JOIN phoneNumbers`. Try that with the first version, and MySQL version 5.0.12+ will issue a syntax error because of the change in precedence between the comma operator and the JOIN keyword. The solution is to rearrange the FROM clause or add parentheses to override the precedence, and that quickly becomes frustrating.
- **Portability.** The changes in 5.0.12 were made to align with SQL:2003. If your queries use standard syntax, you will have an easier time switching to a different database should the need ever arise.

1.1.1.4.1.2.2 Subqueries

A subquery is a query nested in another query.

Scalar Subqueries

Subquery returning a single value.

Row Subqueries

Subquery returning a row.

Subqueries and ALL

Return true if the comparison returns true for each row, or the subquery returns no rows.

Subqueries and ANY

Return true if the comparison returns true for at least one row returned by the subquery.

Subqueries and EXISTS

Returns true if the subquery returns any rows.

Subqueries in a FROM Clause

Subqueries are more commonly placed in a WHERE clause, but can also form part of the FROM clause.

Subquery Optimizations

Articles about subquery optimizations in MariaDB.

Subqueries and JOINs

Rewriting subqueries as JOINs, and using subqueries instead of JOINs.

Subquery Limitations

There are a number of limitations regarding subqueries.

There are 1 related questions.

1.1.1.4.1.2.2.1 Scalar Subqueries

A scalar subquery is a subquery that returns a single value. This is the simplest form of a subquery, and can be used in most places a literal or single column value is valid.

The data type, length and character set and collation are all taken from the result returned by the subquery. The result of a subquery can always be NULL, that is, no result returned. Even if the original value is defined as NOT NULL, this is disregarded.

A subquery cannot be used where only a literal is expected, for example LOAD DATA INFILE expects a literal string containing the file name, and LIMIT requires a literal integer.

Examples

```
CREATE TABLE sq1 (num TINYINT);

CREATE TABLE sq2 (num TINYINT);

INSERT INTO sq1 VALUES (1);

INSERT INTO sq2 VALUES (10* (SELECT num FROM sq1));

SELECT * FROM sq2;
+------+
| num  |
+------+
|   10 |
+------+
```

Inserting a second row means the subquery is no longer a scalar, and this particular query is not valid:

```
INSERT INTO sq1 VALUES (2);

INSERT INTO sq2 VALUES (10* (SELECT num FROM sq1));
ERROR 1242 (21000): Subquery returns more than 1 row
```

No rows in the subquery, so the scalar is NULL:

```
INSERT INTO sq2 VALUES (10* (SELECT num FROM sq3 WHERE num='3'));

SELECT * FROM sq2;
+------+
| num  |
+------+
|   10 |
| NULL |
+------+
```

A more traditional scalar subquery, as part of a WHERE clause:

```
SELECT * FROM sq1 WHERE num = (SELECT MAX(num)/10 FROM sq2);
+------+
| num  |
+------+
|    1 |
+------+
```

1.1.1.4.1.2.2.2 Row Subqueries

A row subquery is a subquery returning a single row, as opposed to a scalar subquery, which returns a single column from a row, or a literal.

Examples

```
CREATE TABLE staff (name VARCHAR(10), age TINYINT);

CREATE TABLE customer (name VARCHAR(10), age TINYINT);

INSERT INTO staff VALUES ('Bilhah',37), ('Valerius',61), ('Maia',25);

INSERT INTO customer VALUES ('Thanasis',48), ('Valerius',61), ('Brion',51);

SELECT * FROM staff WHERE (name,age) = (SELECT name,age FROM customer WHERE name='Valerius');
+----------+------+
| name     | age  |
+----------+------+
| Valerius |   61 |
+----------+------+
```

Finding all rows in one table also in another:

```
SELECT name,age FROM staff WHERE (name,age) IN (SELECT name,age FROM customer);
+----------+------+
| name     | age  |
+----------+------+
| Valerius |   61 |
+----------+------+
```

1.1.1.4.1.2.2.3 Subqueries and ALL

Contents

Subqueries using the ALL keyword will return `true` if the comparison returns `true` for each row returned by the subquery, or the subquery returns no rows.

Syntax

```
scalar_expression comparison_operator ALL <Table subquery>
```

- `scalar_expression` may be any expression that evaluates to a single value
- `comparison_operator` may be any one of: `=`, `>`, `<`, `>=`, `<=`, `<>` or `!=`

`ALL` returns:

- `NULL` if the comparison operator returns `NULL` for at least one row returned by the Table subquery or scalar_expression returns `NULL`.
- `FALSE` if the comparison operator returns `FALSE` for at least one row returned by the Table subquery.
- `TRUE` if the comparison operator returns `TRUE` for all rows returned by the Table subquery, or if Table subquery returns no rows.

`NOT IN` is an alias for `<> ALL`.

Examples

```
CREATE TABLE sq1 (num TINYINT);

CREATE TABLE sq2 (num2 TINYINT);

INSERT INTO sq1 VALUES(100);

INSERT INTO sq2 VALUES(40),(50),(60);

SELECT * FROM sq1 WHERE num > ALL (SELECT * FROM sq2);
+------+
| num  |
+------+
|  100 |
+------+
```

Since `100` > all of `40`, `50` and `60`, the evaluation is true and the row is returned

Adding a second row to sq1, where the evaluation for that record is false:

```
INSERT INTO sq1 VALUES(30);

SELECT * FROM sq1 WHERE num > ALL (SELECT * FROM sq2);
+------+
| num  |
+------+
|  100 |
+------+
```

Adding a new row to sq2, causing all evaluations to be false:

```
INSERT INTO sq2 VALUES(120);

SELECT * FROM sq1 WHERE num > ALL (SELECT * FROM sq2);
Empty set (0.00 sec)
```

When the subquery returns no results, the evaluation is still true:

```
SELECT * FROM sq1 WHERE num > ALL (SELECT * FROM sq2 WHERE num2 > 300);
+------+
| num  |
+------+
|  100 |
|   30 |
+------+
```

Evaluating against a NULL will cause the result to be unknown, or not true, and therefore return no rows:

```
INSERT INTO sq2 VALUES (NULL);

SELECT * FROM sq1 WHERE num > ALL (SELECT * FROM sq2);
```

1.1.1.4.1.2.2.4 Subqueries and ANY

Contents

Subqueries using the ANY keyword will return `true` if the comparison returns `true` for at least one row returned by the subquery.

Syntax

The required syntax for an `ANY` or `SOME` quantified comparison is:

```
scalar_expression comparison_operator ANY <Table subquery>
```

Or:

```
scalar_expression comparison_operator SOME <Table subquery>
```

- `scalar_expression` may be any expression that evaluates to a single value.
- `comparison_operator` may be any one of `=`, `>`, `<`, `>=`, `<=`, `<>` or `!=`.

`ANY` returns:

- `TRUE` if the comparison operator returns `TRUE` for at least one row returned by the Table subquery.
- `FALSE` if the comparison operator returns `FALSE` for all rows returned by the Table subquery, or Table subquery has zero rows.
- `NULL` if the comparison operator returns `NULL` for at least one row returned by the Table subquery and doesn't returns `TRUE` for any of them, or if scalar_expression returns `NULL`.

`SOME` is a synmonym for `ANY`, and `IN` is a synonym for `= ANY`

Examples

```
CREATE TABLE sq1 (num TINYINT);

CREATE TABLE sq2 (num2 TINYINT);

INSERT INTO sq1 VALUES(100);

INSERT INTO sq2 VALUES(40),(50),(120);

SELECT * FROM sq1 WHERE num > ANY (SELECT * FROM sq2);
+------+
| num  |
+------+
|  100 |
+------+
```

`100` is greater than two of the three values, and so the expression evaluates as true.

SOME is a synonym for ANY:

```
SELECT * FROM sq1 WHERE num < SOME (SELECT * FROM sq2);
+------+
| num  |
+------+
|  100 |
+------+
```

`IN` is a synonym for `= ANY`, and here there are no matches, so no results are returned:

```
SELECT * FROM sq1 WHERE num IN (SELECT * FROM sq2);
Empty set (0.00 sec)
```

```
INSERT INTO sq2 VALUES(100);
Query OK, 1 row affected (0.05 sec)

SELECT * FROM sq1 WHERE num <> ANY (SELECT * FROM sq2);
+------+
| num  |
+------+
|  100 |
+------+
```

Reading this query, the results may be counter-intuitive. It may seem to read as "SELECT * FROM sq1 WHERE num does not match any results in sq2. Since it does match 100, it could seem that the results are incorrect. However, the query returns a result if the match does not match any *of* sq2. Since `100` already does not match `40`, the expression evaluates to true immediately, regardless of the 100's matching. It may be more easily readable to use SOME in a case such as this:

```
SELECT * FROM sq1 WHERE num <> SOME (SELECT * FROM sq2);
+------+
| num  |
+------+
|  100 |
+------+
```

1.1.1.4.1.2.2.5 Subqueries and EXISTS

Syntax

```
SELECT ... WHERE EXISTS <Table subquery>
```

Description

Subqueries using the `EXISTS` keyword will return `true` if the subquery returns any rows. Conversely, subqueries using `NOT EXISTS` will return `true` only if the subquery returns no rows from the table.

EXISTS subqueries ignore the columns specified by the SELECT of the subquery, since they're not relevant. For example,

```
SELECT col1 FROM t1 WHERE EXISTS (SELECT * FROM t2);
```

and

```
SELECT col1 FROM t1 WHERE EXISTS (SELECT col2 FROM t2);
```

produce identical results.

Examples

```
CREATE TABLE sq1 (num TINYINT);

CREATE TABLE sq2 (num2 TINYINT);

INSERT INTO sq1 VALUES(100);

INSERT INTO sq2 VALUES(40),(50),(60);

SELECT * FROM sq1 WHERE EXISTS (SELECT * FROM sq2 WHERE num2>50);
+------+
| num  |
+------+
|  100 |
+------+

SELECT * FROM sq1 WHERE NOT EXISTS (SELECT * FROM sq2 GROUP BY num2 HAVING MIN(num2)=40);
Empty set (0.00 sec)
```

1.1.1.4.1.2.2.6 Subqueries in a FROM Clause

Although subqueries are more commonly placed in a WHERE clause, they can also form part of the FROM clause. Such subqueries are commonly called derived tables.

If a subquery is used in this way, you must also use an AS clause to name the result of the subquery.

ORACLE mode

MariaDB starting with 10.6.0
From MariaDB 10.6.0, anonymous subqueries in a FROM clause (no AS clause) are permitted in ORACLE mode.

Examples

```
CREATE TABLE student (name CHAR(10), test CHAR(10), score TINYINT);

INSERT INTO student VALUES
  ('Chun', 'SQL', 75), ('Chun', 'Tuning', 73),
  ('Esben', 'SQL', 43), ('Esben', 'Tuning', 31),
  ('Kaolin', 'SQL', 56), ('Kaolin', 'Tuning', 88),
  ('Tatiana', 'SQL', 87), ('Tatiana', 'Tuning', 83);
```

Assume that, given the data above, you want to return the average total for all students. In other words, the average of Chun's 148 (75+73), Esben's 74 (43+31), etc.

You cannot do the following:

```
SELECT AVG(SUM(score)) FROM student GROUP BY name;
ERROR 1111 (HY000): Invalid use of group function
```

A subquery in the FROM clause is however permitted:

```
SELECT AVG(sq_sum) FROM (SELECT SUM(score) AS sq_sum FROM student GROUP BY name) AS t;
+-------------+
| AVG(sq_sum) |
+-------------+
|    134.0000 |
+-------------+
```

From MariaDB 10.6 in ORACLE mode, the following is permitted:

```
SELECT * FROM (SELECT 1 FROM DUAL), (SELECT 2 FROM DUAL);
```

3.3.4.2.9 Optimizing GROUP BY and DISTINCE Clauses in Subqueries

1.1.1.4.1.2.2.8 Subqueries and JOINs

A subquery can quite often, but not in all cases, be rewritten as a JOIN.

Contents

Rewriting Subqueries as JOINS

A subquery using `IN` can be rewritten with the `DISTINCT` keyword, for example:

```
SELECT * FROM table1 WHERE col1 IN (SELECT col1 FROM table2);
```

can be rewritten as:

```
SELECT DISTINCT table1.* FROM table1, table2 WHERE table1.col1=table2.col1;
```

`NOT IN` or `NOT EXISTS` queries can also be rewritten. For example, these two queries returns the same result:

```
SELECT * FROM table1 WHERE col1 NOT IN (SELECT col1 FROM table2);
SELECT * FROM table1 WHERE NOT EXISTS (SELECT col1 FROM table2 WHERE table1.col1=table2.col1);
```

and both can be rewritten as:

```
SELECT table1.* FROM table1 LEFT JOIN table2 ON table1.id=table2.id WHERE table2.id IS NULL;
```

Subqueries that can be rewritten as a LEFT JOIN are sometimes more efficient.

Using Subqueries instead of JOINS

There are some scenarios, though, which call for subqueries rather than joins:

- When you want duplicates, but not false duplicates. Suppose `Table_1` has three rows — { `1` , `1` , `2` } — and `Table_2` has two rows — { `1` , `2` , `2` }. If you need to list the rows in `Table_1` which are also in `Table_2` , only this subquery-based `SELECT` statement will give the right answer (`1` , `1` , `2`):

```
SELECT Table_1.column_1
FROM   Table_1
WHERE  Table_1.column_1 IN
  (SELECT Table_2.column_1
    FROM   Table_2);
```

  This SQL statement won't work:

```
SELECT Table_1.column_1
FROM   Table_1,Table_2
WHERE  Table_1.column_1 = Table_2.column_1;
```

  because the result will be { `1` , `1` , `2` , `2` } — and the duplication of 2 is an error. This SQL statement won't work either:

```
SELECT DISTINCT Table_1.column_1
FROM   Table_1,Table_2
WHERE  Table_1.column_1 = Table_2.column_1;
```

  because the result will be { `1` , `2` } — and the removal of the duplicated 1 is an error too.

- When the outermost statement is not a query. The SQL statement:

```
UPDATE Table_1 SET column_1 = (SELECT column_1 FROM Table_2);
```

  can't be expressed using a join unless some rare SQL3 features are used.

- When the join is over an expression. The SQL statement:

```
SELECT * FROM Table_1
WHERE column_1 + 5 =
  (SELECT MAX(column_1) FROM Table_2);
```

  is hard to express with a join. In fact, the only way we can think of is this SQL statement:

```
SELECT Table_1.*
FROM   Table_1,
      (SELECT MAX(column_1) AS max_column_1 FROM Table_2) AS Table_2
WHERE  Table_1.column_1 + 5 = Table_2.max_column_1;
```

  which still involves a parenthesized query, so nothing is gained from the transformation.

- When you want to see the exception. For example, suppose the question is: what books are longer than Das Kapital? These two queries are effectively almost the same:

```
SELECT DISTINCT Bookcolumn_1.*
FROM   Books AS Bookcolumn_1 JOIN Books AS Bookcolumn_2 USING(page_count)
WHERE  title = 'Das Kapital';

SELECT DISTINCT Bookcolumn_1.*
FROM   Books AS Bookcolumn_1
WHERE  Bookcolumn_1.page_count >
  (SELECT DISTINCT page_count
  FROM   Books AS Bookcolumn_2
  WHERE  title = 'Das Kapital');
```

  The difference is between these two SQL statements is, if there are two editions of *Das Kapital* (with different page counts), then the self-join example will return the books which are longer than the shortest edition of *Das Kapital*. That might be the wrong answer, since the original question didn't ask for "... longer than `ANY` book named *Das Kapital*" (it seems to contain a false assumption that there's only one edition).

1.1.1.4.1.2.2.9 Subquery Limitations

Contents

There are a number of limitations regarding subqueries, which are discussed below.

The following tables and data will be used in the examples that follow:

```
CREATE TABLE staff(name VARCHAR(10),age TINYINT);

CREATE TABLE customer(name VARCHAR(10),age TINYINT);
```

```
INSERT INTO staff VALUES
('Bilhah',37), ('Valerius',61), ('Maia',25);

INSERT INTO customer VALUES
('Thanasis',48), ('Valerius',61), ('Brion',51);
```

ORDER BY and LIMIT

To use ORDER BY or limit LIMIT in subqueries both must be used.. For example:

```
SELECT * FROM staff WHERE name IN (SELECT name FROM customer ORDER BY name);
+----------+------+
| name     | age  |
+----------+------+
| Valerius |   61 |
+----------+------+
```

is valid, but

```
SELECT * FROM staff WHERE name IN (SELECT NAME FROM customer ORDER BY name LIMIT 1);
ERROR 1235 (42000): This version of MariaDB doesn't
  yet support 'LIMIT & IN/ALL/ANY/SOME subquery'
```

is not.

Modifying and Selecting from the Same Table

It's not possible to both modify and select from the same table in a subquery. For example:

```
DELETE FROM staff WHERE name = (SELECT name FROM staff WHERE age=61);
ERROR 1093 (HY000): Table 'staff' is specified twice, both
  as a target for 'DELETE' and as a separate source for data
```

Row Comparison Operations

There is only partial support for row comparison operations. The expression in

```
expr op {ALL|ANY|SOME} subquery,
```

must be scalar and the subquery can only return a single column.

However, because of the way `IN` is implemented (it is rewritten as a sequence of `=` comparisons and `AND`), the expression in

```
expression [NOT] IN subquery
```

is permitted to be an n-tuple and the subquery can return rows of n-tuples.

For example:

```
SELECT * FROM staff WHERE (name,age) NOT IN (
  SELECT name,age FROM customer WHERE age >=51]
);
+--------+------+
| name   | age  |
+--------+------+
| Bilhah |   37 |
| Maia   |   25 |
+--------+------+
```

is permitted, but

```
SELECT * FROM staff WHERE (name,age) = ALL (
  SELECT name,age FROM customer WHERE age >=51
);
ERROR 1241 (21000): Operand should contain 1 column(s)
```

is not.

Correlated Subqueries

Subqueries in the FROM clause cannot be correlated subqueries. They cannot be evaluated for each row of the outer query

since they are evaluated to produce a result set during when the query is executed.

Stored Functions

A subquery can refer to a stored function which modifies data. This is an extension to the SQL standard, but can result in indeterminate outcomes. For example, take:

```
SELECT ... WHERE x IN (SELECT f() ...);
```

where *f()* inserts rows. The function *f()* could be executed a different number of times depending on how the optimizer chooses to handle the query.

This sort of construct is therefore not safe to use in replication that is not row-based, as there could be different results on the master and the slave.

1.1.1.4.1.2.3 UNION

`UNION` is used to combine the results from multiple SELECT statements into a single result set.

Syntax

```
SELECT ...
UNION [ALL | DISTINCT] SELECT ...
[UNION [ALL | DISTINCT] SELECT ...]
[ORDER BY [column [, column ...]]]
[LIMIT {[offset,] row_count | row_count OFFSET offset}]
```

Contents

Description

`UNION` is used to combine the results from multiple SELECT statements into a single result set.

The column names from the first `SELECT` statement are used as the column names for the results returned. Selected columns listed in corresponding positions of each SELECT statement should have the same data type. (For example, the first column selected by the first statement should have the same type as the first column selected by the other statements.)

If they don't, the type and length of the columns in the result take into account the values returned by all of the SELECTs, so there is no need for explicit casting. Note that currently this is not the case for recursive CTEs - see MDEV-12325.

Table names can be specified as `db_name.tbl_name`. This permits writing `UNION`s which involve multiple databases. See Identifier Qualifiers for syntax details.

UNION queries cannot be used with aggregate functions.

`EXCEPT` and `UNION` have the same operation precedence and `INTERSECT` has a higher precedence, unless running in Oracle mode, in which case all three have the same precedence.

ALL/DISTINCT

The `ALL` keyword causes duplicate rows to be preserved. The `DISTINCT` keyword (the default if the keyword is omitted) causes duplicate rows to be removed by the results.

UNION ALL and UNION DISTINCT can both be present in a query. In this case, UNION DISTINCT will override any UNION ALLs to its left.

MariaDB starting with 10.1.1

Until MariaDB 10.1.1, all `UNION ALL` statements required the server to create a temporary table. Since MariaDB

10.1.1, the server can in most cases execute `UNION ALL` without creating a temporary table, improving performance (see MDEV-334).

ORDER BY and LIMIT

Individual SELECTs can contain their own ORDER BY and LIMIT clauses. In this case, the individual queries need to be wrapped between parentheses. However, this does not affect the order of the UNION, so they only are useful to limit the record read by one SELECT.

The UNION can have global ORDER BY and LIMIT clauses, which affect the whole resultset. If the columns retrieved by individual SELECT statements have an alias (AS), the ORDER BY must use that alias, not the real column names.

HIGH_PRIORITY

Specifying a query as HIGH_PRIORITY will not work inside a UNION. If applied to the first SELECT, it will be ignored. Applying to a later SELECT results in a syntax error:

```
ERROR 1234 (42000): Incorrect usage/placement of 'HIGH_PRIORITY'
```

SELECT ... INTO ...

Individual SELECTs cannot be written INTO DUMPFILE or INTO OUTFILE. If the last SELECT statement specifies INTO DUMPFILE or INTO OUTFILE, the entire result of the UNION will be written. Placing the clause after any other SELECT will result in a syntax error.

If the result is a single row, SELECT ... INTO @var_name can also be used.

MariaDB starting with 10.4.0

Parentheses

From MariaDB 10.4.0, parentheses can be used to specify precedence. Before this, a syntax error would be returned.

Examples

`UNION` between tables having different column names:

```
(SELECT e_name AS name, email FROM employees)
UNION
(SELECT c_name AS name, email FROM customers);
```

Specifying the `UNION` 's global order and limiting total rows:

```
(SELECT name, email FROM employees)
UNION
(SELECT name, email FROM customers)
ORDER BY name LIMIT 10;
```

Adding a constant row:

```
(SELECT 'John Doe' AS name, 'john.doe@example.net' AS email)
UNION
(SELECT name, email FROM customers);
```

Differing types:

```
SELECT CAST('x' AS CHAR(1)) UNION SELECT REPEAT('y',4);
+----------------------+
| CAST('x' AS CHAR(1)) |
+----------------------+
| x                    |
| yyyy                 |
+----------------------+
```

Returning the results in order of each individual SELECT by use of a sort column:

```
(SELECT 1 AS sort_column, e_name AS name, email FROM employees)
UNION
(SELECT 2, c_name AS name, email FROM customers) ORDER BY sort_column;
```

Difference between UNION, EXCEPT and INTERSECT. `INTERSECT ALL` and `EXCEPT ALL` are available from MariaDB 10.5.0.

```
CREATE TABLE seqs (i INT);
INSERT INTO seqs VALUES (1),(2),(2),(3),(3),(4),(5),(6);

SELECT i FROM seqs WHERE i <= 3 UNION SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
|    3 |
|    4 |
|    5 |
|    6 |
+------+

SELECT i FROM seqs WHERE i <= 3 UNION ALL SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
|    2 |
|    3 |
|    3 |
|    3 |
|    3 |
|    4 |
|    5 |
|    6 |
+------+

SELECT i FROM seqs WHERE i <= 3 EXCEPT SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
+------+

SELECT i FROM seqs WHERE i <= 3 EXCEPT ALL SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
|    2 |
+------+

SELECT i FROM seqs WHERE i <= 3 INTERSECT SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    3 |
+------+

SELECT i FROM seqs WHERE i <= 3 INTERSECT ALL SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    3 |
|    3 |
+------+
```

Parentheses for specifying precedence, from MariaDB 10.4.0

```
CREATE OR REPLACE TABLE t1 (a INT);
CREATE OR REPLACE TABLE t2 (b INT);
CREATE OR REPLACE TABLE t3 (c INT);

INSERT INTO t1 VALUES (1),(2),(3),(4);
INSERT INTO t2 VALUES (5),(6);
INSERT INTO t3 VALUES (1),(6);

((SELECT a FROM t1) UNION (SELECT b FROM t2)) INTERSECT (SELECT c FROM t3);
+------+
| a    |
+------+
|    1 |
|    6 |
+------+

(SELECT a FROM t1) UNION ((SELECT b FROM t2) INTERSECT (SELECT c FROM t3));
+------+
| a    |
+------+
|    1 |
|    2 |
|    3 |
|    4 |
|    6 |
+------+
```

1.1.1.4.1.2.4 EXCEPT

The result of `EXCEPT` is all records of the left `SELECT` result set except records which are in right `SELECT` result set, i.e. it is subtraction of two result sets. From MariaDB 10.6.1, `MINUS` is a synonym when SQL_MODE=ORACLE is set.

Syntax

```
SELECT ...
(INTERSECT [ALL | DISTINCT] | EXCEPT [ALL | DISTINCT] | UNION [ALL | DISTINCT])
  SELECT ...
[(INTERSECT [ALL | DISTINCT] | EXCEPT [ALL | DISTINCT] | UNION [ALL | DISTINCT])
  SELECT ...]
[ORDER BY [{col_name | expr | position} [ASC | DESC]
  [, {col_name | expr | position} [ASC | DESC] ...]]]
[LIMIT {[offset,] row_count | row_count OFFSET offset}
| OFFSET start { ROW | ROWS }
| FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } { ONLY | WITH TIES } ]
```

Contents

Please note:

- Brackets for explicit operation precedence are not supported; use a subquery in the `FROM` clause as a workaround).

Description

MariaDB has supported `EXCEPT` and INTERSECT in addition to UNION since MariaDB 10.3.

The queries before and after `EXCEPT` must be SELECT or VALUES statements.

All behavior for naming columns, `ORDER BY` and `LIMIT` is the same as for `UNION`. Note that the alternative SELECT ... OFFSET ... FETCH syntax is only supported. This allows us to use the `WITH TIES` clause.

`EXCEPT` implicitly supposes a `DISTINCT` operation.

The result of `EXCEPT` is all records of the left `SELECT` result except records which are in right `SELECT` result set, i.e. it is subtraction of two result sets.

`EXCEPT` and `UNION` have the same operation precedence and `INTERSECT` has a higher precedence, unless running in Oracle mode, in which case all three have the same precedence.

MariaDB starting with 10.4.0

Parentheses

From MariaDB 10.4.0, parentheses can be used to specify precedence. Before this, a syntax error would be returned.

MariaDB starting with 10.5.0

ALL/DISTINCT

`EXCEPT ALL` and `EXCEPT DISTINCT` were introduced in MariaDB 10.5.0. The `ALL` operator leaves duplicates intact, while the `DISTINCT` operator removes duplicates. `DISTINCT` is the default behavior if neither operator is supplied, and the only behavior prior to MariaDB 10.5.

Examples

Show customers which are not employees:

```
(SELECT e_name AS name, email FROM customers)
EXCEPT
(SELECT c_name AS name, email FROM employees);
```

Difference between UNION, EXCEPT and INTERSECT. `INTERSECT ALL` and `EXCEPT ALL` are available from MariaDB 10.5.0.

```
CREATE TABLE seqs (i INT);
INSERT INTO seqs VALUES (1),(2),(2),(3),(3),(4),(5),(6);

SELECT i FROM seqs WHERE i <= 3 UNION SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
|    3 |
|    4 |
|    5 |
|    6 |
+------+

SELECT i FROM seqs WHERE i <= 3 UNION ALL SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
|    2 |
|    3 |
|    3 |
|    3 |
|    3 |
|    4 |
|    5 |
|    6 |
+------+

SELECT i FROM seqs WHERE i <= 3 EXCEPT SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
+------+

SELECT i FROM seqs WHERE i <= 3 EXCEPT ALL SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
|    2 |
+------+

SELECT i FROM seqs WHERE i <= 3 INTERSECT SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    3 |
+------+

SELECT i FROM seqs WHERE i <= 3 INTERSECT ALL SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    3 |
|    3 |
+------+
```

Parentheses for specifying precedence, from MariaDB 10.4.0

```
CREATE OR REPLACE TABLE t1 (a INT);
CREATE OR REPLACE TABLE t2 (b INT);
CREATE OR REPLACE TABLE t3 (c INT);

INSERT INTO t1 VALUES (1),(2),(3),(4);
INSERT INTO t2 VALUES (5),(6);
INSERT INTO t3 VALUES (1),(6);

((SELECT a FROM t1) UNION (SELECT b FROM t2)) EXCEPT (SELECT c FROM t3);
+------+
| a    |
+------+
|    2 |
|    3 |
|    4 |
|    5 |
+------+

(SELECT a FROM t1) UNION ((SELECT b FROM t2) EXCEPT (SELECT c FROM t3));
+------+
| a    |
+------+
|    1 |
|    2 |
|    3 |
|    4 |
|    5 |
+------+
```

Here is an example that makes use of the SEQUENCE storage engine and the VALUES statement, to generate a numeric sequence and remove some arbitrary numbers from it:

```
(SELECT seq FROM seq_1_to_10) EXCEPT VALUES (2), (3), (4);
+-----+
| seq |
+-----+
|   1 |
|   5 |
|   6 |
|   7 |
|   8 |
|   9 |
|  10 |
+-----+
```

1.1.1.4.1.2.5 INTERSECT

MariaDB starting with 10.3.0

INTERSECT was introduced in MariaDB 10.3.0.

The result of an intersect is the intersection of right and left `SELECT` results, i.e. only records that are present in both result sets will be included in the result of the operation.

Syntax

```
SELECT ...
(INTERSECT [ALL | DISTINCT] | EXCEPT [ALL | DISTINCT] | UNION [ALL | DISTINCT]) SELECT ...
[(INTERSECT [ALL | DISTINCT] | EXCEPT [ALL | DISTINCT] | UNION [ALL | DISTINCT]) SELECT ...]
[ORDER BY [column [, column ...]]]
[LIMIT {[offset,] row_count | row_count OFFSET offset}]
```

Contents

Description

MariaDB has supported `INTERSECT` (as well as EXCEPT) in addition to UNION since MariaDB 10.3.

All behavior for naming columns, `ORDER BY` and `LIMIT` is the same as for UNION.

`INTERSECT` implicitly supposes a `DISTINCT` operation.

The result of an intersect is the intersection of right and left `SELECT` results, i.e. only records that are present in both result sets will be included in the result of the operation.

`INTERSECT` has higher precedence than `UNION` and `EXCEPT` (unless running running in Oracle mode, in which case all three have the same precedence). If possible it will be executed linearly but if not it will be translated to a subquery in the `FROM` clause:

```
(select a,b from t1)
union
(select c,d from t2)
intersect
(select e,f from t3)
union
(select 4,4);
```

will be translated to:

```
(select a,b from t1)
union
select c,d from
  ((select c,d from t2)
   intersect
   (select e,f from t3)) dummy_subselect
union
(select 4,4)
```

MariaDB starting with 10.4.0

Parentheses

From MariaDB 10.4.0, parentheses can be used to specify precedence. Before this, a syntax error would be returned.

MariaDB starting with 10.5.0

ALL/DISTINCT

`INTERSECT ALL` and `INTERSECT DISTINCT` were introduced in MariaDB 10.5.0. The `ALL` operator leaves duplicates intact, while the `DISTINCT` operator removes duplicates. `DISTINCT` is the default behavior if neither operator is supplied, and the only behavior prior to MariaDB 10.5.

Examples

Show customers which are employees:

```
(SELECT e_name AS name, email FROM employees)
INTERSECT
(SELECT c_name AS name, email FROM customers);
```

Difference between UNION, EXCEPT and INTERSECT. `INTERSECT ALL` and `EXCEPT ALL` are available from MariaDB

10.5.0.

```
CREATE TABLE seqs (i INT);
INSERT INTO seqs VALUES (1),(2),(2),(3),(3),(4),(5),(6);

SELECT i FROM seqs WHERE i <= 3 UNION SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
|    3 |
|    4 |
|    5 |
|    6 |
+------+

SELECT i FROM seqs WHERE i <= 3 UNION ALL SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
|    2 |
|    3 |
|    3 |
|    3 |
|    3 |
|    4 |
|    5 |
|    6 |
+------+

SELECT i FROM seqs WHERE i <= 3 EXCEPT SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
+------+

SELECT i FROM seqs WHERE i <= 3 EXCEPT ALL SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
|    2 |
+------+

SELECT i FROM seqs WHERE i <= 3 INTERSECT SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    3 |
+------+

SELECT i FROM seqs WHERE i <= 3 INTERSECT ALL SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    3 |
|    3 |
+------+
```

Parentheses for specifying precedence, from MariaDB 10.4.0

```
CREATE OR REPLACE TABLE t1 (a INT);
CREATE OR REPLACE TABLE t2 (b INT);
CREATE OR REPLACE TABLE t3 (c INT);

INSERT INTO t1 VALUES (1),(2),(3),(4);
INSERT INTO t2 VALUES (5),(6);
INSERT INTO t3 VALUES (1),(6);

((SELECT a FROM t1) UNION (SELECT b FROM t2)) INTERSECT (SELECT c FROM t3);
+------+
| a    |
+------+
|    1 |
|    6 |
+------+

(SELECT a FROM t1) UNION ((SELECT b FROM t2) INTERSECT (SELECT c FROM t3));
+------+
| a    |
+------+
|    1 |
|    2 |
|    3 |
|    4 |
|    6 |
+------+
```

1.1.1.4.1.2.6 Precedence Control in Table Operations

MariaDB starting with 10.4.0

Beginning in MariaDB 10.4, you can control the ordering of execution on table operations using parentheses.

Syntax

```
(  expression )
[ORDER BY [column[, column...]]]
[LIMIT {[offset,] row_count | row_count OFFSET offset}]
```

Contents

Description

Using parentheses in your SQL allows you to control the order of execution for `SELECT` statements and Table Value Constructor, including `UNION`, `EXCEPT`, and `INTERSECT` operations. MariaDB executes the parenthetical expression before the rest of the statement. You can then use `ORDER BY` and `LIMIT` clauses the further organize the result-set.

Note: In practice, the Optimizer may rearrange the exact order in which MariaDB executes different parts of the statement. When it calculates the result-set, however, it returns values as though the parenthetical expression were executed first.

Example

```
CREATE TABLE test.t1 (num INT);

INSERT INTO test.t1 VALUES (1),(2),(3);

(SELECT * FROM test.t1
 UNION
 VALUES (10))
INTERSECT
VALUES (1),(3),(10),(11);
+------+
| num  |
+------+
|    1 |
|    3 |
|   10 |
+------+

((SELECT * FROM test.t1
  UNION
  VALUES (10))
 INTERSECT
 VALUES (1),(3),(10),(11))
ORDER BY 1 DESC;
+------+
| num  |
+------+
|   10 |
|    3 |
|    1 |
+------+
```

1.1.1.4.1.2.7 MINUS

MariaDB starting with 10.6.1

`MINUS` was introduced as a synonym for EXCEPT from MariaDB 10.6.1 when SQL_MODE=ORACLE is set.

```
CREATE TABLE seqs (i INT);
INSERT INTO seqs VALUES (1),(2),(2),(3),(3),(4),(5),(6);

SET SQL_MODE='ORACLE';

SELECT i FROM seqs WHERE i <= 3 MINUS SELECT i FROM seqs WHERE i>=3;
+------+
| i    |
+------+
|    1 |
|    2 |
+------+
```

1.1.1.4.1.3 LIMIT

Contents

Description

Use the `LIMIT` clause to restrict the number of returned rows. When you use a single integer *n* with `LIMIT`, the first *n* rows will be returned. Use the ORDER BY clause to control which rows come first. You can also select a number of rows after an offset using either of the following:

```
LIMIT offset, row_count
LIMIT row_count OFFSET offset
```

When you provide an offset *m* with a limit *n*, the first *m* rows will be ignored, and the following *n* rows will be returned.

Executing an UPDATE with the `LIMIT` clause is not safe for replication. `LIMIT 0` is an exception to this rule (see MDEV-6170).

There is a LIMIT ROWS EXAMINED optimization which provides the means to terminate the execution of SELECT statements which examine too many rows, and thus use too many resources. See LIMIT ROWS EXAMINED.

Multi-Table Updates

Until MariaDB 10.3.1, it was not possible to use `LIMIT` (or ORDER BY) in a multi-table UPDATE statement. This restriction was lifted in MariaDB 10.3.2.

GROUP_CONCAT

Starting from MariaDB 10.3.3, it is possible to use `LIMIT` with GROUP_CONCAT().

Examples

```
CREATE TABLE members (name VARCHAR(20));
INSERT INTO members VALUES('Jagdish'),('Kenny'),('Rokurou'),('Immaculada');

SELECT * FROM members;
+------------+
| name       |
+------------+
| Jagdish    |
| Kenny      |
| Rokurou    |
| Immaculada |
+------------+
```

Select the first two names (no ordering specified):

```
SELECT * FROM members LIMIT 2;
+---------+
| name    |
+---------+
| Jagdish |
| Kenny   |
+---------+
```

All the names in alphabetical order:

```
SELECT * FROM members ORDER BY name;
+------------+
| name       |
+------------+
| Immaculada |
| Jagdish    |
| Kenny      |
| Rokurou    |
+------------+
```

The first two names, ordered alphabetically:

```
SELECT * FROM members ORDER BY name LIMIT 2;
+------------+
| name       |
+------------+
| Immaculada |
| Jagdish    |
+------------+
```

The third name, ordered alphabetically (the first name would be offset zero, so the third is offset two):

```
SELECT * FROM members ORDER BY name LIMIT 2,1;
+-------+
| name  |
+-------+
| Kenny |
+-------+
```

From MariaDB 10.3.2, `LIMIT` can be used in a multi-table update:

```
CREATE TABLE warehouse (product_id INT, qty INT);
INSERT INTO warehouse VALUES (1,100),(2,100),(3,100),(4,100);

CREATE TABLE store (product_id INT, qty INT);
INSERT INTO store VALUES (1,5),(2,5),(3,5),(4,5);

UPDATE warehouse,store SET warehouse.qty = warehouse.qty-2, store.qty = store.qty+2
  WHERE (warehouse.product_id = store.product_id AND store.product_id  >= 1)
    ORDER BY store.product_id DESC LIMIT 2;

SELECT * FROM warehouse;
+------------+------+
| product_id | qty  |
+------------+------+
|          1 |  100 |
|          2 |  100 |
|          3 |   98 |
|          4 |   98 |
+------------+------+

SELECT * FROM store;
+------------+------+
| product_id | qty  |
+------------+------+
|          1 |    5 |
|          2 |    5 |
|          3 |    7 |
|          4 |    7 |
+------------+------+
```

From MariaDB 10.3.3, `LIMIT` can be used with GROUP_CONCAT, so, for example, given the following table:

```
CREATE TABLE d (dd DATE, cc INT);

INSERT INTO d VALUES ('2017-01-01',1);
INSERT INTO d VALUES ('2017-01-02',2);
INSERT INTO d VALUES ('2017-01-04',3);
```

the following query:

```
SELECT SUBSTRING_INDEX(GROUP_CONCAT(CONCAT_WS(":",dd,cc) ORDER BY cc DESC),",",1) FROM d;
+-----------------------------------------------------------------------------+
| SUBSTRING_INDEX(GROUP_CONCAT(CONCAT_WS(":",dd,cc) ORDER BY cc DESC),",",1) |
+-----------------------------------------------------------------------------+
| 2017-01-04:3                                                                |
+-----------------------------------------------------------------------------+
```

can be more simply rewritten as:

```
SELECT GROUP_CONCAT(CONCAT_WS(":",dd,cc) ORDER BY cc DESC LIMIT 1) FROM d;
+-----------------------------------------------------------+
| GROUP_CONCAT(CONCAT_WS(":",dd,cc) ORDER BY cc DESC LIMIT 1) |
+-----------------------------------------------------------+
| 2017-01-04:3                                              |
+-----------------------------------------------------------+
```

1.1.1.4.1.4 ORDER BY

Contents

Description

Use the `ORDER BY` clause to order a resultset, such as that are returned from a SELECT statement. You can specify just a column or use any expression with functions. If you are using the `GROUP BY` clause, you can use grouping functions in `ORDER BY`. Ordering is done after grouping.

You can use multiple ordering expressions, separated by commas. Rows will be sorted by the first expression, then by the second expression if they have the same value for the first, and so on.

You can use the keywords `ASC` and `DESC` after each ordering expression to force that ordering to be ascending or descending, respectively. Ordering is ascending by default.

You can also use a single integer as the ordering expression. If you use an integer *n*, the results will be ordered by the *n*th column in the select expression.

When string values are compared, they are compared as if by the STRCMP function. `STRCMP` ignores trailing whitespace and may normalize characters and ignore case, depending on the collation in use.

Duplicated entries in the `ORDER BY` clause are removed.

`ORDER BY` can also be used to order the activities of a DELETE or UPDATE statement (usually with the LIMIT clause).

MariaDB starting with 10.3.2

Until MariaDB 10.3.1, it was not possible to use `ORDER BY` (or LIMIT) in a multi-table UPDATE statement. This restriction was lifted in MariaDB 10.3.2.

MariaDB starting with 10.5

From MariaDB 10.5, MariaDB allows packed sort keys and values of non-sorted fields in the sort buffer. This can make filesort temporary files much smaller when VARCHAR, CHAR or BLOBs are used, notably speeding up some ORDER BY sorts.

Examples

```
CREATE TABLE seq (i INT, x VARCHAR(1));
INSERT INTO seq VALUES (1,'a'), (2,'b'), (3,'b'), (4,'f'), (5,'e');

SELECT * FROM seq ORDER BY i;
+------+------+
| i    | x    |
+------+------+
|    1 | a    |
|    2 | b    |
|    3 | b    |
|    4 | f    |
|    5 | e    |
+------+------+

SELECT * FROM seq ORDER BY i DESC;
+------+------+
| i    | x    |
+------+------+
|    5 | e    |
|    4 | f    |
|    3 | b    |
|    2 | b    |
|    1 | a    |
+------+------+

SELECT * FROM seq ORDER BY x,i;
+------+------+
| i    | x    |
+------+------+
|    1 | a    |
|    2 | b    |
|    3 | b    |
|    5 | e    |
|    4 | f    |
+------+------+
```

ORDER BY in an UPDATE statement, in conjunction with LIMIT:

```
UPDATE seq SET x='z' WHERE x='b' ORDER BY i DESC LIMIT 1;

SELECT * FROM seq;
+------+------+
| i    | x    |
+------+------+
|    1 | a    |
|    2 | b    |
|    3 | z    |
|    4 | f    |
|    5 | e    |
+------+------+
```

From MariaDB 10.3.2, `ORDER BY` can be used in a multi-table update:

```
CREATE TABLE warehouse (product_id INT, qty INT);
INSERT INTO warehouse VALUES (1,100),(2,100),(3,100),(4,100);

CREATE TABLE store (product_id INT, qty INT);
INSERT INTO store VALUES (1,5),(2,5),(3,5),(4,5);

UPDATE warehouse,store SET warehouse.qty = warehouse.qty-2, store.qty = store.qty+2
  WHERE (warehouse.product_id = store.product_id AND store.product_id  >= 1)
    ORDER BY store.product_id DESC LIMIT 2;

SELECT * FROM warehouse;
+------------+------+
| product_id | qty  |
+------------+------+
|          1 |  100 |
|          2 |  100 |
|          3 |   98 |
|          4 |   98 |
+------------+------+

SELECT * FROM store;
+------------+------+
| product_id | qty  |
+------------+------+
|          1 |    5 |
|          2 |    5 |
|          3 |    7 |
|          4 |    7 |
+------------+------+
```

1.1.1.4.1.5 GROUP BY

Contents

Use the `GROUP BY` clause in a SELECT statement to group rows together that have the same value in one or more column, or the same computed value using expressions with any functions and operators except grouping functions. When you use a `GROUP BY` clause, you will get a single result row for each group of rows that have the same value for the expression given in `GROUP BY`.

When grouping rows, grouping values are compared as if by the `=` operator. For string values, the `=` operator ignores trailing whitespace and may normalize characters and ignore case, depending on the collation in use.

You can use any of the grouping functions in your select expression. Their values will be calculated based on all the rows that have been grouped together for each result row. If you select a non-grouped column or a value computed from a non-grouped column, it is undefined which row the returned value is taken from. This is not permitted if the `ONLY_FULL_GROUP_BY` SQL_MODE is used.

You can use multiple expressions in the `GROUP BY` clause, separated by commas. Rows are grouped together if they match on each of the expressions.

You can also use a single integer as the grouping expression. If you use an integer *n*, the results will be grouped by the *n*th column in the select expression.

The `WHERE` clause is applied before the `GROUP BY` clause. It filters non-aggregated rows before the rows are grouped together. To filter grouped rows based on aggregate values, use the `HAVING` clause. The `HAVING` clause takes any expression and evaluates it as a boolean, just like the `WHERE` clause. You can use grouping functions in the `HAVING` clause. As with the select expression, if you reference non-grouped columns in the `HAVING` clause, the behavior is undefined.

By default, if a `GROUP BY` clause is present, the rows in the output will be sorted by the expressions used in the `GROUP BY`. You can also specify `ASC` or `DESC` (ascending, descending) after those expressions, like in ORDER BY. The default is `ASC`.

If you want the rows to be sorted by another field, you can add an explicit ORDER BY. If you don't want the result to be ordered, you can add ORDER BY NULL.

WITH ROLLUP

The `WITH ROLLUP` modifer adds extra rows to the resultset that represent super-aggregate summaries. For a full description with examples, see SELECT WITH ROLLUP.

GROUP BY Examples

Consider the following table that records how many times each user has played and won a game:

```
CREATE TABLE plays (name VARCHAR(16), plays INT, wins INT);
INSERT INTO plays VALUES
  ("John", 20, 5),
  ("Robert", 22, 8),
  ("Wanda", 32, 8),
  ("Susan", 17, 3);
```

Get a list of win counts along with a count:

```
SELECT wins, COUNT(*) FROM plays GROUP BY wins;
+------+----------+
| wins | COUNT(*) |
+------+----------+
|    3 |        1 |
|    5 |        1 |
|    8 |        2 |
+------+----------+
3 rows in set (0.00 sec)
```

The `GROUP BY` expression can be a computed value, and can refer back to an identifer specified with `AS`. Get a list of win averages along with a count:

```
SELECT (wins / plays) AS winavg, COUNT(*) FROM plays GROUP BY winavg;
+--------+----------+
| winavg | COUNT(*) |
+--------+----------+
| 0.1765 |        1 |
| 0.2500 |        2 |
| 0.3636 |        1 |
+--------+----------+
3 rows in set (0.00 sec)
```

You can use any grouping function in the select expression. For each win average as above, get a list of the average play count taken to get that average:

```
SELECT (wins / plays) AS winavg, AVG(plays) FROM plays
  GROUP BY winavg;
+--------+------------+
| winavg | AVG(plays) |
+--------+------------+
| 0.1765 |    17.0000 |
| 0.2500 |    26.0000 |
| 0.3636 |    22.0000 |
+--------+------------+
3 rows in set (0.00 sec)
```

You can filter on aggregate information using the `HAVING` clause. The `HAVING` clause is applied after `GROUP BY` and allows you to filter on aggregate data that is not available to the `WHERE` clause. Restrict the above example to results that involve an average number of plays over 20:

```
SELECT (wins / plays) AS winavg, AVG(plays) FROM plays
  GROUP BY winavg HAVING AVG(plays) > 20;
+--------+------------+
| winavg | AVG(plays) |
+--------+------------+
| 0.2500 |    26.0000 |
| 0.3636 |    22.0000 |
+--------+------------+
2 rows in set (0.00 sec)
```

1.1.1.4.1.6 Common Table Expressions

WITH

Allows reference to subqueries as temporary tables within queries.

Non-Recursive Common Table Expressions Overview

Common Table Expressions (CTEs) are essentially Temporary Named Result Sets.

Recursive Common Table Expressions Overview

A recursive CTE will repeatedly execute subsets of the data until obtaining the complete results.

There are 1 related questions.

1.1.1.4.1.6.1 WITH

MariaDB starting with 10.2.1

Common Table Expressions were introduced in MariaDB 10.2.1.

Syntax

```
WITH [RECURSIVE] table_reference [(columns_list)] AS  (
  SELECT ...
)
[CYCLE cycle_column_list RESTRICT]
SELECT ...
```

Contents

Description

The `WITH` keyword signifies a Common Table Expression (CTE). It allows you to refer to a subquery expression many times in a query, as if having a temporary table that only exists for the duration of a query.

There are two kinds of CTEs:

- Non-Recursive
- Recursive (signified by the `RECURSIVE` keyword, supported since MariaDB 10.2.2)

You can use `table_reference` as any normal table in the external `SELECT` part. You can also use `WITH` in subqueries, as well as with EXPLAIN and SELECT.

Poorly-formed recursive CTEs can in theory cause infinite loops. The max_recursive_iterations system variable limits the number of recursions.

CYCLE ... RESTRICT

MariaDB starting with 10.5.2

The CYCLE clause enables CTE cycle detection, avoiding excessive or infinite loops, MariaDB supports a relaxed, non-standard grammar.

The SQL Standard permits a CYCLE clause, as follows:

```
WITH RECURSIVE ... (
   ...
)
CYCLE <cycle column list>
SET <cycle mark column> TO <cycle mark value> DEFAULT <non-cycle mark value>
USING <path column>
```

where all clauses are mandatory.

MariaDB does not support this, but from 10.5.2 permits a non-standard relaxed grammar, as follows:

```
WITH RECURSIVE ... (
  ...
)
CYCLE <cycle column list> RESTRICT
```

With the use of `CYCLE ... RESTRICT` it makes no difference whether the CTE uses `UNION ALL` or `UNION DISTINCT` anymore. `UNION ALL` means "all rows, but without cycles", which is exactly what the `CYCLE` clause enables. And `UNION DISTINCT` means all rows should be different, which, again, is what will happen — as uniqueness is enforced over a subset of columns, complete rows will automatically all be different.

Examples

Below is an example with the `WITH` at the top level:

```
WITH t AS (SELECT a FROM t1 WHERE b >= 'c')
  SELECT * FROM t2, t WHERE t2.c = t.a;
```

The example below uses `WITH` in a subquery:

```
SELECT t1.a, t1.b FROM t1, t2
  WHERE t1.a > t2.c
     AND t2.c IN(WITH t AS (SELECT * FROM t1 WHERE t1.a < 5)
                 SELECT t2.c FROM t2, t WHERE t2.c = t.a);
```

Below is an example of a Recursive CTE:

```
WITH RECURSIVE ancestors AS
 ( SELECT * FROM folks
   WHERE name="Alex"
   UNION
   SELECT f.*
   FROM folks AS f, ancestors AS a
   WHERE f.id = a.father OR f.id = a.mother )
SELECT * FROM ancestors;
```

Take the following structure, and data,

```
CREATE TABLE t1 (from_ int, to_ int);
INSERT INTO t1 VALUES (1,2), (1,100), (2,3), (3,4), (4,1);
SELECT * FROM t1;
+-------+------+
| from_ | to_  |
+-------+------+
|     1 |    2 |
|     1 |  100 |
|     2 |    3 |
|     3 |    4 |
|     4 |    1 |
+-------+------+
```

Given the above, the following query would theoretically result in an infinite loop due to the last record in t1 (note that max_recursive_iterations is set to 10 for the purposes of this example, to avoid the excessive number of cycles):

```
SET max_recursive_iterations=10;

WITH RECURSIVE cte (depth, from_, to_) AS (
  SELECT 0,1,1 UNION DISTINCT SELECT depth+1, t1.from_, t1.to_
    FROM t1, cte  WHERE t1.from_ = cte.to_
)
SELECT * FROM cte;
+-------+-------+------+
| depth | from_ | to_  |
+-------+-------+------+
|     0 |     1 |    1 |
|     1 |     1 |    2 |
|     1 |     1 |  100 |
|     2 |     2 |    3 |
|     3 |     3 |    4 |
|     4 |     4 |    1 |
|     5 |     1 |    2 |
|     5 |     1 |  100 |
|     6 |     2 |    3 |
|     7 |     3 |    4 |
|     8 |     4 |    1 |
|     9 |     1 |    2 |
|     9 |     1 |  100 |
|    10 |     2 |    3 |
+-------+-------+------+
```

However, the CYCLE ... RESTRICT clause (from MariaDB 10.5.2) can overcome this:

```
WITH RECURSIVE cte (depth, from_, to_) AS (
  SELECT 0,1,1 UNION SELECT depth+1, t1.from_, t1.to_
    FROM t1, cte WHERE t1.from_ = cte.to_
)
CYCLE from_, to_ RESTRICT
SELECT * FROM cte;
+-------+-------+------+
| depth | from_ | to_  |
+-------+-------+------+
|     0 |     1 |    1 |
|     1 |     1 |    2 |
|     1 |     1 |  100 |
|     2 |     2 |    3 |
|     3 |     3 |    4 |
|     4 |     4 |    1 |
+-------+-------+------+
```

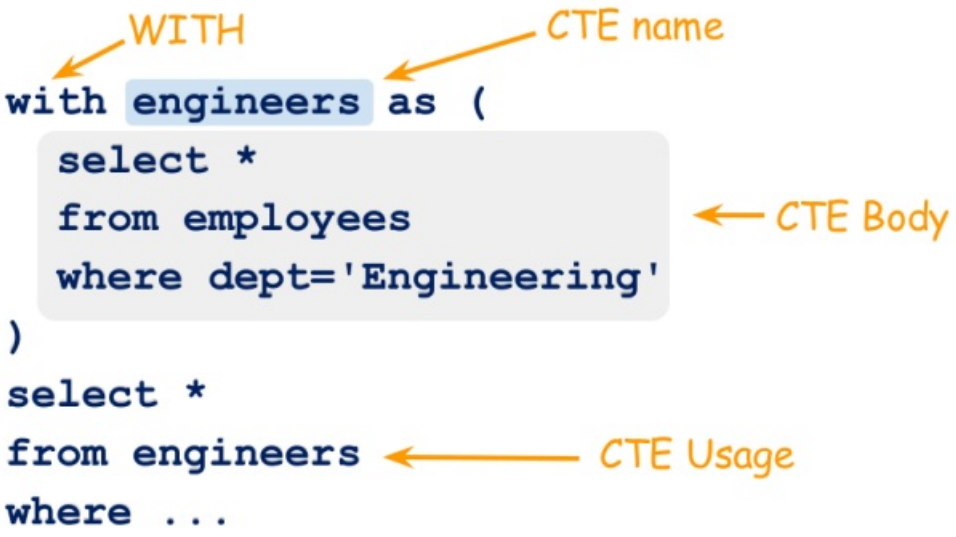
1.1.1.4.1.6.2 Non-Recursive Common Table Expressions Overview

Contents

Common Table Expressions (CTEs) are a standard SQL feature, and are essentially temporary named result sets. There are two kinds of CTEs: Non-Recursive, which this article covers; and Recursive.

Non-Recursive CTEs

The WITH keyword signifies a CTE. It is given a name, followed by a body (the main query) as follows:



CTEs are similar to derived tables. For example

```
WITH engineers AS
   ( SELECT * FROM employees
     WHERE dept = 'Engineering' )

SELECT * FROM engineers
WHERE ...
```

```
SELECT * FROM
   ( SELECT * FROM employees
     WHERE dept = 'Engineering' ) AS engineers
WHERE
...
```

A non-recursive CTE is basically a query-local VIEW. There are several advantages and caveats to them. The syntax is more readable than nested `FROM (SELECT ...)` . A CTE can refer to another and it can be referenced from multiple places.

A CTE referencing Another CTE

Using this format makes for a more readable SQL than a nested `FROM(SELECT ...)` clause. Below is an example of this:

```
WITH engineers AS (
SELECT * FROM employees
WHERE dept IN('Development','Support') ),
eu_engineers AS ( SELECT * FROM engineers WHERE country IN('NL',...) )
SELECT
...
FROM eu_engineers;
```

Multiple Uses of a CTE

This can be an 'anti-self join', for example:

```
WITH engineers AS (
SELECT * FROM employees
WHERE dept IN('Development','Support') )

SELECT * FROM engineers E1
WHERE NOT EXISTS
   (SELECT 1 FROM engineers E2
    WHERE E2.country=E1.country
    AND E2.name <> E1.name );
```

Or, for year-over-year comparisons, for example:

```
WITH sales_product_year AS (
SELECT product, YEAR(ship_date) AS year,
SUM(price) AS total_amt
FROM item_sales
GROUP BY product, year )

SELECT *
FROM sales_product_year CUR,
sales_product_year PREV,
WHERE CUR.product=PREV.product
AND  CUR.year=PREV.year + 1
AND CUR.total_amt > PREV.total_amt
```

Another use is to compare individuals against their group. Below is an example of how this might be executed:

```
WITH sales_product_year AS (
SELECT product,
YEAR(ship_date) AS year,
SUM(price) AS total_amt
FROM item_sales
GROUP BY product, year
)

SELECT *
FROM sales_product_year S1
WHERE
total_amt >
    (SELECT 0.1 * SUM(total_amt)
     FROM sales_product_year S2
     WHERE S2.year = S1.year)
```

1.1.1.4.1.6.3 Recursive Common Table Expressions Overview

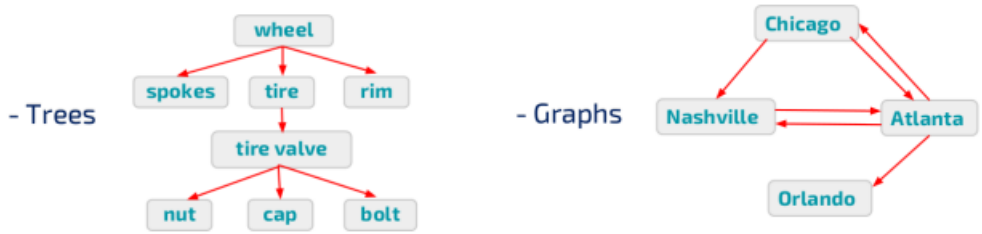
Contents

Common Table Expressions (CTEs) are a standard SQL feature, and are essentially temporary named result sets. CTEs first appeared in the SQL standard in 1999, and the first implementations began appearing in 2007.

There are two kinds of CTEs:

- Non-recursive
- Recursive, which this article covers.

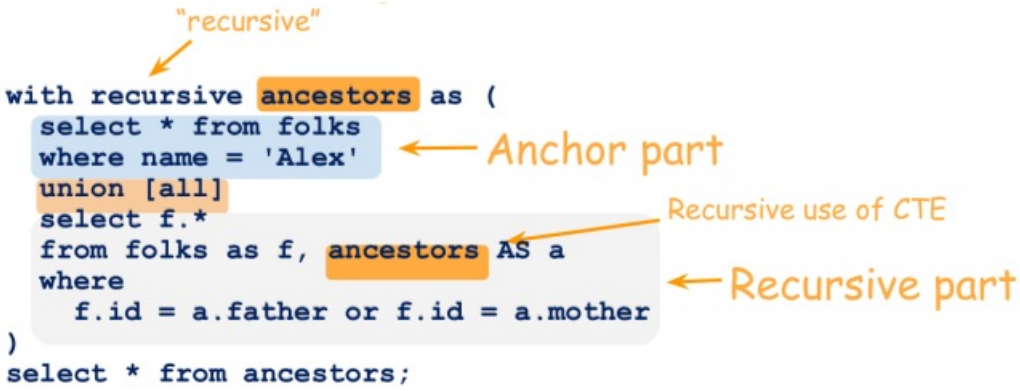
SQL is generally poor at recursive structures.

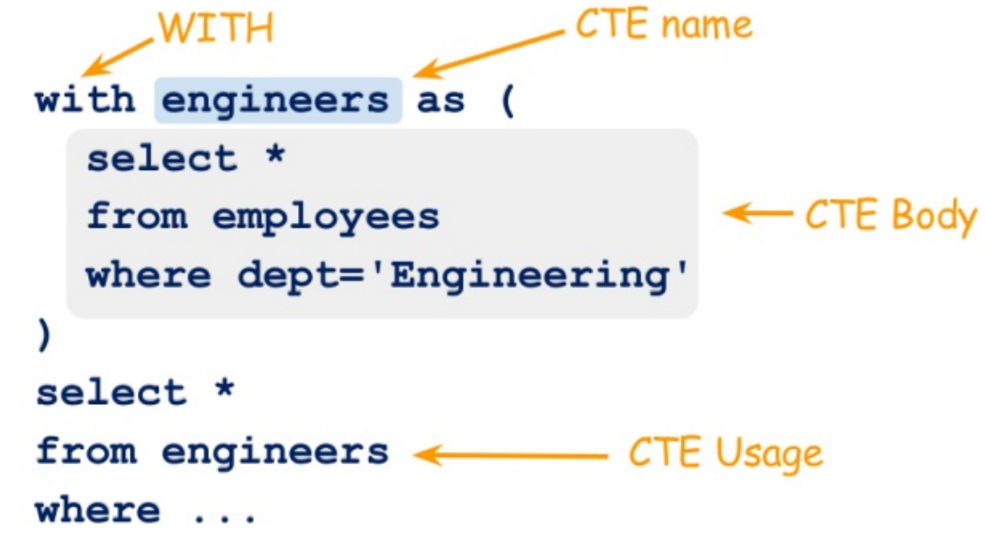


CTEs permit a query to reference itself. A recursive CTE will repeatedly execute subsets of the data until it obtains the complete result set. This makes it particularly useful for handing hierarchical or tree-structured data. max_recursive_iterations avoids infinite loops.

Syntax example

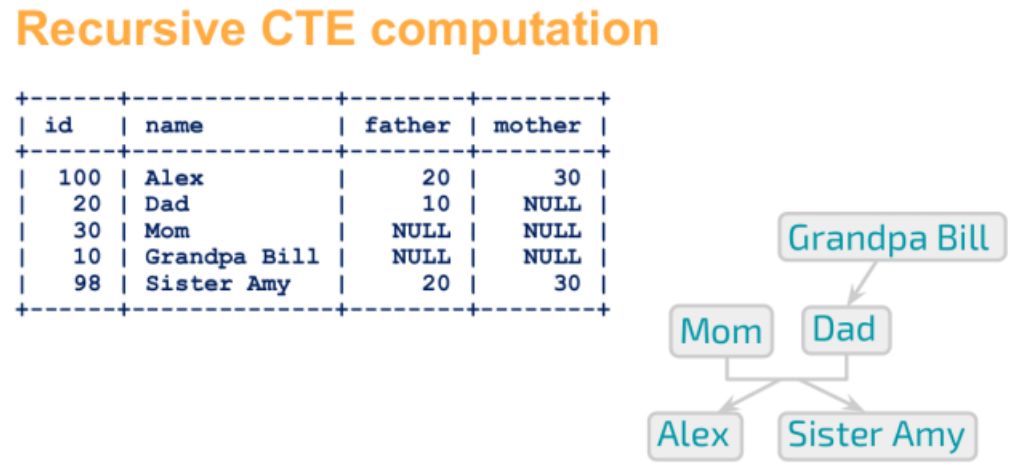
WITH RECURSIVE signifies a recursive CTE. It is given a name, followed by a body (the main query) as follows:





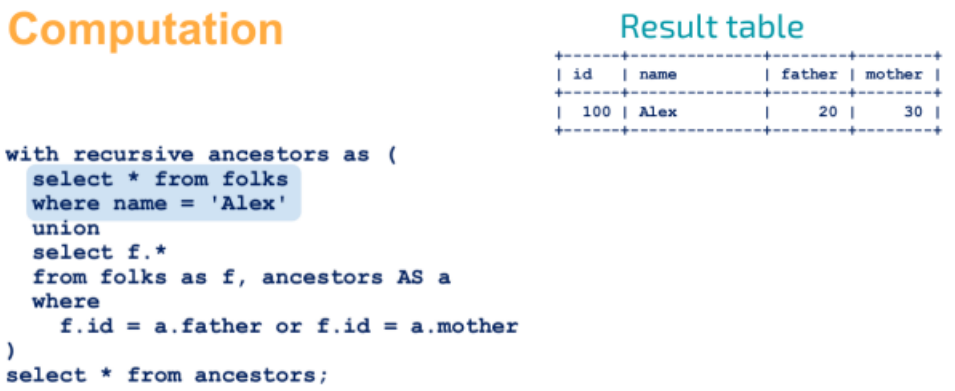
Computation

Given the following structure:



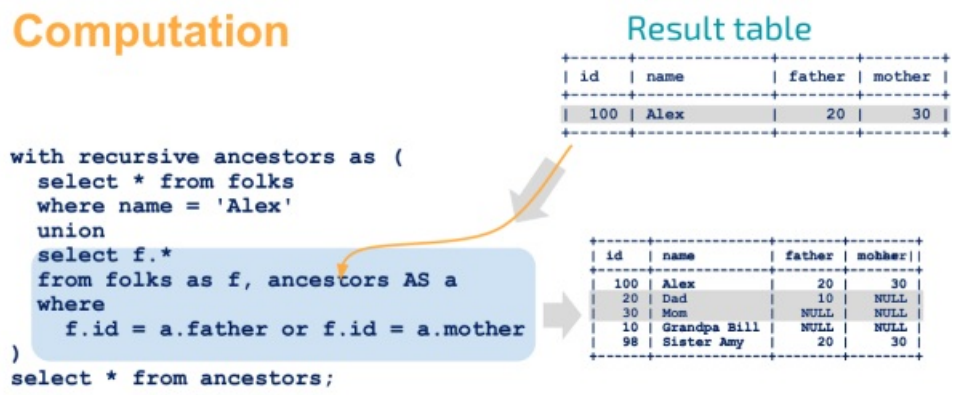
id	name	father	mother
100	Alex	20	30
20	Dad	10	NULL
30	Mom	NULL	NULL
10	Grandpa Bill	NULL	NULL
98	Sister Amy	20	30

First execute the anchor part of the query:

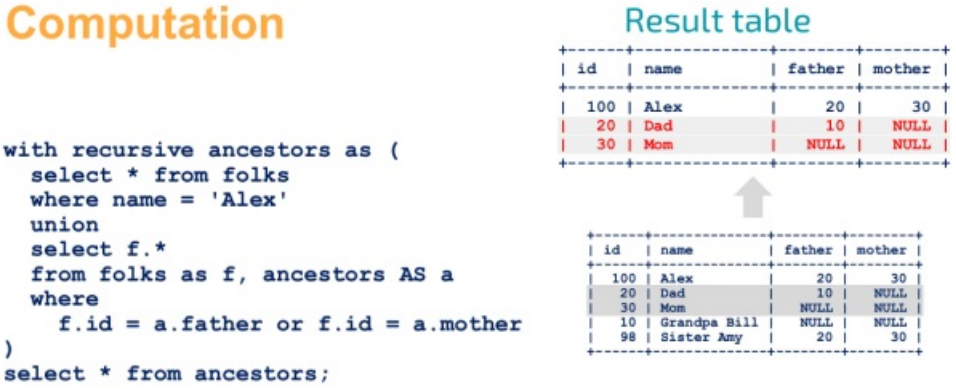


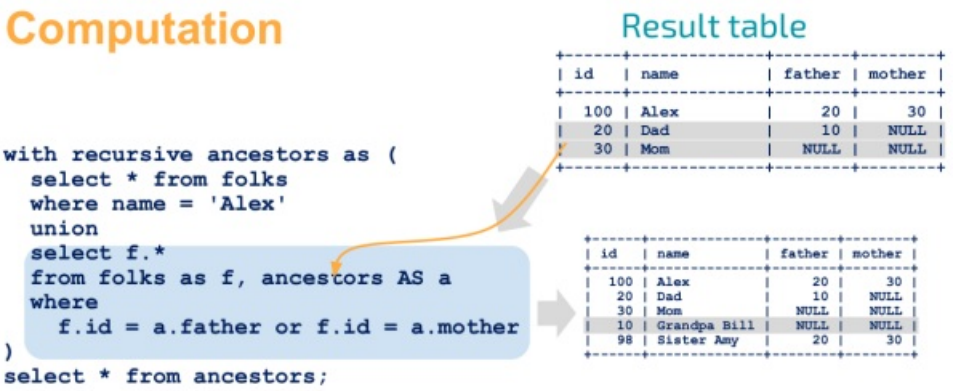
Step #1:
execution of the anchor part

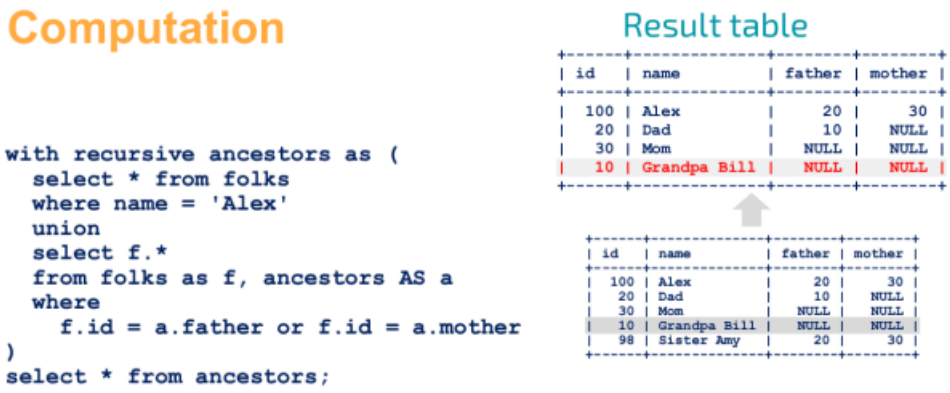
Next, execute the recursive part of the query:

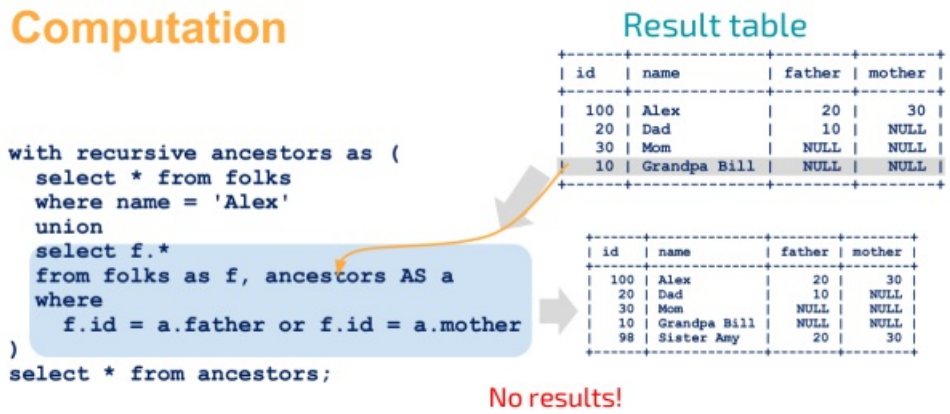


Step #2:
execution of the recursive part









Summary so far

```
with recursive R as (
  select anchor_data
  union [all]
  select recursive_part
  from R, ...
)
select ...
```

1. Compute anchor_data
2. Compute recursive_part to get the new data
3. if (new data is non-empty) goto 2;

CAST to avoid truncating data

As currently implemented by MariaDB and by the SQL Standard, data may be truncated if not correctly cast. It is necessary to CAST the column to the correct width if the CTE's recursive part produces wider values for a column than the CTE's nonrecursive part. Some other DBMS give an error in this situation, and MariaDB's behavior may change in future - see MDEV-12325. See the examples below.

Examples

Transitive closure - determining bus destinations

Sample data:

```
CREATE TABLE bus_routes (origin varchar(50), dst varchar(50));
INSERT INTO bus_routes VALUES
  ('New York', 'Boston'),
  ('Boston', 'New York'),
  ('New York', 'Washington'),
  ('Washington', 'Boston'),
  ('Washington', 'Raleigh');
```

Now, we want to return the bus destinations with New York as the origin:

```
WITH RECURSIVE bus_dst as (
    SELECT origin as dst FROM bus_routes WHERE origin='New York'
  UNION
    SELECT bus_routes.dst FROM bus_routes JOIN bus_dst ON bus_dst.dst= bus_routes.origin
)
SELECT * FROM bus_dst;
+------------+
| dst        |
+------------+
| New York   |
| Boston     |
| Washington |
| Raleigh    |
+------------+
```

The above example is computed as follows:

First, the anchor data is calculated:

- Starting from New York
- Boston and Washington are added

Next, the recursive part:

- Starting from Boston and then Washington
- Raleigh is added
- UNION excludes nodes that are already present.

Computing paths - determining bus routes

This time, we are trying to get bus routes such as “New York -> Washington -> Raleigh”.

Using the same sample data as the previous example:

```
WITH RECURSIVE paths (cur_path, cur_dest) AS (
    SELECT origin, origin FROM bus_routes WHERE origin='New York'
  UNION
    SELECT CONCAT(paths.cur_path, ',', bus_routes.dst), bus_routes.dst
     FROM paths
     JOIN bus_routes
       ON paths.cur_dest = bus_routes.origin AND
         NOT FIND_IN_SET(bus_routes.dst, paths.cur_path)
)
SELECT * FROM paths;
+---------------------------+------------+
| cur_path                  | cur_dest   |
+---------------------------+------------+
| New York                  | New York   |
| New York,Boston           | Boston     |
| New York,Washington       | Washington |
| New York,Washington,Boston | Boston     |
| New York,Washington,Raleigh | Raleigh    |
+---------------------------+------------+
```

CAST to avoid data truncation

In the following example, data is truncated because the results are not specifically cast to a wide enough type:

```
WITH RECURSIVE tbl AS (
  SELECT NULL AS col
  UNION
  SELECT "THIS NEVER SHOWS UP" AS col FROM tbl
)
SELECT col FROM tbl
+------+
| col  |
+------+
| NULL |
|      |
+------+
```

Explicitly use CAST to overcome this:

```
WITH RECURSIVE tbl AS (
  SELECT CAST(NULL AS CHAR(50)) AS col
  UNION SELECT "THIS NEVER SHOWS UP" AS col FROM tbl
)
SELECT * FROM tbl;
+---------------------+
| col                 |
+---------------------+
| NULL                |
| THIS NEVER SHOWS UP |
+---------------------+
```

1.1.1.4.1.7 SELECT WITH ROLLUP

Contents

Syntax

See SELECT for the full syntax.

Description

The `WITH ROLLUP` modifier adds extra rows to the resultset that represent super-aggregate summaries. The super-aggregated column is represented by a `NULL` value. Multiple aggregates over different columns will be added if there are multiple `GROUP BY` columns.

The LIMIT clause can be used at the same time, and is applied after the `WITH ROLLUP` rows have been added.

`WITH ROLLUP` cannot be used with ORDER BY. Some sorting is still possible by using `ASC` or `DESC` clauses with the `GROUP BY` column, although the super-aggregate rows will always be added last.

Examples

These examples use the following sample table

```
CREATE TABLE booksales (
  country VARCHAR(35), genre ENUM('fiction','non-fiction'), year YEAR, sales INT);

INSERT INTO booksales VALUES
  ('Senegal','fiction',2014,12234), ('Senegal','fiction',2015,15647),
  ('Senegal','non-fiction',2014,64980), ('Senegal','non-fiction',2015,78901),
  ('Paraguay','fiction',2014,87970), ('Paraguay','fiction',2015,76940),
  ('Paraguay','non-fiction',2014,8760), ('Paraguay','non-fiction',2015,9030);
```

The addition of the `WITH ROLLUP` modifier in this example adds an extra row that aggregates both years:

```
SELECT year, SUM(sales) FROM booksales GROUP BY year;
+------+------------+
| year | SUM(sales) |
+------+------------+
| 2014 |     173944 |
| 2015 |     180518 |
+------+------------+
2 rows in set (0.08 sec)

SELECT year, SUM(sales) FROM booksales GROUP BY year WITH ROLLUP;
+------+------------+
| year | SUM(sales) |
+------+------------+
| 2014 |     173944 |
| 2015 |     180518 |
| NULL |     354462 |
+------+------------+
```

In the following example, each time the genre, the year or the country change, another super-aggregate row is added:

```
SELECT country, year, genre, SUM(sales)
  FROM booksales GROUP BY country, year, genre;
+----------+------+-------------+------------+
| country  | year | genre       | SUM(sales) |
+----------+------+-------------+------------+
| Paraguay | 2014 | fiction     |      87970 |
| Paraguay | 2014 | non-fiction |       8760 |
| Paraguay | 2015 | fiction     |      76940 |
| Paraguay | 2015 | non-fiction |       9030 |
| Senegal  | 2014 | fiction     |      12234 |
| Senegal  | 2014 | non-fiction |      64980 |
| Senegal  | 2015 | fiction     |      15647 |
| Senegal  | 2015 | non-fiction |      78901 |
+----------+------+-------------+------------+

SELECT country, year, genre, SUM(sales)
  FROM booksales GROUP BY country, year, genre WITH ROLLUP;
+----------+------+-------------+------------+
| country  | year | genre       | SUM(sales) |
+----------+------+-------------+------------+
| Paraguay | 2014 | fiction     |      87970 |
| Paraguay | 2014 | non-fiction |       8760 |
| Paraguay | 2014 | NULL        |      96730 |
| Paraguay | 2015 | fiction     |      76940 |
| Paraguay | 2015 | non-fiction |       9030 |
| Paraguay | 2015 | NULL        |      85970 |
| Paraguay | NULL | NULL        |     182700 |
| Senegal  | 2014 | fiction     |      12234 |
| Senegal  | 2014 | non-fiction |      64980 |
| Senegal  | 2014 | NULL        |      77214 |
| Senegal  | 2015 | fiction     |      15647 |
| Senegal  | 2015 | non-fiction |      78901 |
| Senegal  | 2015 | NULL        |      94548 |
| Senegal  | NULL | NULL        |     171762 |
| NULL     | NULL | NULL        |     354462 |
+----------+------+-------------+------------+
```

The LIMIT clause, applied after WITH ROLLUP:

```
SELECT country, year, genre, SUM(sales)
  FROM booksales GROUP BY country, year, genre WITH ROLLUP LIMIT 4;
+----------+------+-------------+------------+
| country  | year | genre       | SUM(sales) |
+----------+------+-------------+------------+
| Paraguay | 2014 | fiction     |      87970 |
| Paraguay | 2014 | non-fiction |       8760 |
| Paraguay | 2014 | NULL        |      96730 |
| Paraguay | 2015 | fiction     |      76940 |
+----------+------+-------------+------------+
```

Sorting by year descending:

```
SELECT country, year, genre, SUM(sales)
  FROM booksales GROUP BY country, year DESC, genre WITH ROLLUP;
+----------+------+-------------+------------+
| country  | year | genre       | SUM(sales) |
+----------+------+-------------+------------+
| Paraguay | 2015 | fiction     |      76940 |
| Paraguay | 2015 | non-fiction |       9030 |
| Paraguay | 2015 | NULL        |      85970 |
| Paraguay | 2014 | fiction     |      87970 |
| Paraguay | 2014 | non-fiction |       8760 |
| Paraguay | 2014 | NULL        |      96730 |
| Paraguay | NULL | NULL        |     182700 |
| Senegal  | 2015 | fiction     |      15647 |
| Senegal  | 2015 | non-fiction |      78901 |
| Senegal  | 2015 | NULL        |      94548 |
| Senegal  | 2014 | fiction     |      12234 |
| Senegal  | 2014 | non-fiction |      64980 |
| Senegal  | 2014 | NULL        |      77214 |
| Senegal  | NULL | NULL        |     171762 |
| NULL     | NULL | NULL        |     354462 |
+----------+------+-------------+------------+
```

1.1.1.4.1.8 SELECT INTO OUTFILE

Syntax

```
SELECT ... INTO OUTFILE 'file_name'
        [CHARACTER SET charset_name]
        [export_options]

export_options:
    [{FIELDS | COLUMNS}
        [TERMINATED BY 'string']
        [[OPTIONALLY] ENCLOSED BY 'char']
        [ESCAPED BY 'char']
    ]
    [LINES
        [STARTING BY 'string']
        [TERMINATED BY 'string']
    ]
```

Contents

Description

`SELECT INTO OUTFILE` writes the resulting rows to a file, and allows the use of column and row terminators to specify a particular output format. The default is to terminate fields with tabs (`\t`) and lines with newlines (`\n`).

The file must not exist. It cannot be overwritten. A user needs the FILE privilege to run this statement. Also, MariaDB needs permission to write files in the specified location. If the secure_file_priv system variable is set to a non-empty directory name, the file can only be written to that directory.

The `LOAD DATA INFILE` statement complements `SELECT INTO OUTFILE` .

Character-sets

The `CHARACTER SET` clause specifies the character set in which the results are to be written. Without the clause, no conversion takes place (the binary character set). In this case, if there are multiple character sets, the output will contain these too, and may not easily be able to be reloaded.

In cases where you have two servers using different character-sets, using `SELECT INTO OUTFILE` to transfer data from one to the other can have unexpected results. To ensure that MariaDB correctly interprets the escape sequences, use the

`CHARACTER SET` clause on both the `SELECT INTO OUTFILE` statement and the subsequent `LOAD DATA INFILE` statement.

Example

The following example produces a file in the CSV format:

```
SELECT customer_id, firstname, surname from customer
  INTO OUTFILE '/exportdata/customers.txt'
  FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
  LINES TERMINATED BY '\n';
```

The following ANSI syntax is also supported for simple `SELECT` without `UNION`

```
SELECT customer_id, firstname, surname INTO OUTFILE '/exportdata/customers.txt'
  FIELDS TERMINATED BY ',' OPTIONALLY ENCLOSED BY '"'
  LINES TERMINATED BY '\n'
  FROM customers;
```

If you want to use the ANSI syntax with `UNION` or similar construct you have to use the syntax:

```
SELECT  * INTO OUTFILE "/tmp/skr3" FROM (SELECT * FROM t1 UNION SELECT * FROM t1);
```

1.1.1.4.1.9 SELECT INTO DUMPFILE

Contents

Syntax

```
SELECT ... INTO DUMPFILE 'file_path'
```

Description

`SELECT ... INTO DUMPFILE` is a SELECT clause which writes the resultset into a single unformatted row, without any separators, in a file. The results will not be returned to the client.

file_path can be an absolute path, or a relative path starting from the data directory. It can only be specified as a string literal, not as a variable. However, the statement can be dynamically composed and executed as a prepared statement to work around this limitation.

This statement is binary-safe and so is particularly useful for writing BLOB values to file. It can be used, for example, to copy an image or an audio document from the database to a file. SELECT ... INTO FILE can be used to save a text file.

The file must not exist. It cannot be overwritten. A user needs the FILE privilege to run this statement. Also, MariaDB needs permission to write files in the specified location. If the secure_file_priv system variable is set to a non-empty directory name, the file can only be written to that directory.

Since MariaDB 5.1, the character_set_filesystem system variable has controlled interpretation of file names that are given as literal strings.

Example

```
SELECT _utf8'Hello world!' INTO DUMPFILE '/tmp/world';

SELECT LOAD_FILE('/tmp/world') AS world;
+--------------+
| world        |
+--------------+
| Hello world! |
+--------------+
```

1.1.1.4.1.10 FOR UPDATE

InnoDB supports row-level locking. Selected rows can be locked using LOCK IN SHARE MODE or FOR UPDATE. In both cases, a lock is acquired on the rows read by the query, and it will be released when the current transaction is committed.

The `FOR UPDATE` clause of SELECT applies only when autocommit is set to 0 or the `SELECT` is enclosed in a transaction. A lock is acquired on the rows, and other transactions are prevented from writing the rows, acquire locks, and from reading them (unless their isolation level is `READ UNCOMMITTED`).

If `autocommit` is set to 1, the LOCK IN SHARE MODE and `FOR UPDATE` clauses have no effect in InnoDB. For non-transactional storage engines like MyISAM and ARIA, a table level lock will be taken even if autocommit is set to 1.

If the isolation level is set to SERIALIZABLE, all plain `SELECT` statements are converted to `SELECT ... LOCK IN SHARE MODE`.

Example

```
SELECT * FROM trans WHERE period=2001 FOR UPDATE;
```

1.1.1.4.1.11 LOCK IN SHARE MODE

InnoDB supports row-level locking. Selected rows can be locked using `LOCK IN SHARE MODE` or FOR UPDATE. In both cases, a lock is acquired on the rows read by the query, and it will be released when the current transaction is committed.

When `LOCK IN SHARE MODE` is specified in a SELECT statement, MariaDB will wait until all transactions that have modified the rows are committed. Then, a write lock is acquired. All transactions can read the rows, but if they want to modify them, they have to wait until your transaction is committed.

If autocommit is set to 1 (the default), the LOCK IN SHARE MODE and FOR UPDATE clauses have no effect in InnoDB. For non-transactional storage engines like MyISAM and ARIA, a table level lock will be taken even if autocommit is set to 1.

1.1.1.4.1.12 Optimizer Hints

Optimizer hints

There are some options available in SELECT to affect the execution plan. These are known as optimizer hints.

HIGH PRIORITY

`HIGH_PRIORITY` gives the statement a higher priority. If the table is locked, high priority `SELECT`s will be executed as soon as the lock is released, even if other statements are queued. `HIGH_PRIORITY` applies only if the storage engine only supports table-level locking (`MyISAM`, `MEMORY`, `MERGE`). See HIGH_PRIORITY and LOW_PRIORITY clauses for details.

SQL_CACHE / SQL_NO_CACHE

If the query_cache_type system variable is set to 2 or `DEMAND`, and the current statement is cacheable, `SQL_CACHE` causes the query to be cached and `SQL_NO_CACHE` causes the query not to be cached. For `UNION`s, `SQL_CACHE` or `SQL_NO_CACHE` should be specified for the first query. See also The Query Cache for more detail and a list of the types of statements that aren't cacheable.

SQL_BUFFER_RESULT

`SQL_BUFFER_RESULT` forces the optimizer to use a temporary table to process the result. This is useful to free locks as soon as possible.

SQL_SMALL_RESULT / SQL_BIG_RESULT

`SQL_SMALL_RESULT` and `SQL_BIG_RESULT` tell the optimizer whether the result is very big or not. Usually, `GROUP BY` and `DISTINCT` operations are performed using a temporary table. Only if the result is very big, using a temporary table is not convenient. The optimizer automatically knows if the result is too big, but you can force the optimizer to use a temporary table with `SQL_SMALL_RESULT`, or avoid the temporary table using `SQL_BIG_RESULT`.

STRAIGHT_JOIN

`STRAIGHT_JOIN` applies to the JOIN queries, and tells the optimizer that the tables must be read in the order they appear in the `SELECT`. For `const` and `system` table this options is sometimes ignored.

SQL_CALC_FOUND_ROWS

`SQL_CALC_FOUND_ROWS` is only applied when using the `LIMIT` clause. If this option is used, MariaDB will count how many rows would match the query, without the `LIMIT` clause. That number can be retrieved in the next query, using FOUND_ROWS().

USE/FORCE/IGNORE INDEX

`USE INDEX`, `FORCE INDEX` and `IGNORE INDEX` constrain the query planning to a specific index.

For further information about some of these options, see How to force query plans.

1.1.1.4.1.13 PROCEDURE

The `PROCEDURE` clause of SELECT passes the whole result set to a Procedure which will process it. These Procedures are not Stored Procedures, and can only be written in the C language, so it is necessary to recompile the server.

Currently, the only available procedure is ANALYSE, which examines the resultset and suggests the optimal datatypes for each column. It is defined in the `sql/sql_analyse.cc` file, and can be used as an example to create more Procedures.

This clause cannot be used in a view's definition.

1.1.4.2 HANDLER

1.1.1.4.1.15 DUAL

Description

You are allowed to specify `DUAL` as a dummy table name in situations where no tables are referenced, such as the following SELECT statement:

```
SELECT 1 + 1 FROM DUAL;
+-------+
| 1 + 1 |
+-------+
|     2 |
+-------+
```

`DUAL` is purely for the convenience of people who require that all `SELECT` statements should have `FROM` and possibly other clauses. MariaDB ignores the clauses. MariaDB does not require `FROM DUAL` if no tables are referenced.

FROM DUAL could be used when you only SELECT computed values, but require a WHERE clause, perhaps to test that a script correctly handles empty resultsets:

```
SELECT 1 FROM DUAL WHERE FALSE;
Empty set (0.00 sec)
```

1.1.1.4.1.16 SELECT ... OFFSET ... FETCH

MariaDB starting with 10.6.0

`SELECT ... OFFSET ... FETCH` was introduced in MariaDB 10.6.

Syntax

```
OFFSET start { ROW | ROWS }
FETCH { FIRST | NEXT } [ count ] { ROW | ROWS } { ONLY | WITH TIES }
```

Description

The `OFFSET` clause allows one to return only those elements of a resultset that come after a specified offset. The `FETCH` clause specifies the number of rows to return, while `ONLY` or `WITH TIES` specifies whether or not to also return any further results that tie for last place according to the ordered resultset.

Either the singular `ROW` or the plural `ROWS` can be used after the `OFFSET` and `FETCH` clauses; the choice has no impact on the results.

In the case of `WITH TIES`, an ORDER BY clause is required, otherwise an ERROR will be returned.

```
SELECT i FROM t1 FETCH FIRST 2 ROWS WITH TIES;
ERROR 4180 (HY000): FETCH ... WITH TIES requires ORDER BY clause to be present
```

Examples

Given a table with 6 rows:

```
CREATE OR REPLACE TABLE t1 (i INT);
INSERT INTO t1 VALUES (1),(2),(3),(4), (4), (5);
SELECT i FROM t1 ORDER BY i ASC;
+------+
| i    |
+------+
|    1 |
|    2 |
|    3 |
|    4 |
|    4 |
|    5 |
+------+
```

`OFFSET 2` allows one to skip the first two results.

```
SELECT i FROM t1 ORDER BY i ASC OFFSET 2 ROWS;
+------+
| i    |
+------+
|    3 |
|    4 |
|    4 |
|    5 |
+------+
```

`FETCH FIRST 3 ROWS ONLY` limits the results to three rows only

```
SELECT i FROM t1 ORDER BY i ASC OFFSET 1 ROWS FETCH FIRST 3 ROWS ONLY;
+------+
| i    |
+------+
|    2 |
|    3 |
|    4 |
+------+
```

The same outcome can also be achieved with the LIMIT clause:

```
SELECT i FROM t1 ORDER BY i ASC LIMIT 3 OFFSET 1;
+------+
| i    |
+------+
|    2 |
|    3 |
|    4 |
+------+
```

`WITH TIES` ensures the tied result `4` is also returned.

```
SELECT i FROM t1 ORDER BY i ASC OFFSET 1 ROWS FETCH FIRST 3 ROWS WITH TIES;
+------+
| i    |
+------+
|    2 |
|    3 |
|    4 |
|    4 |
+------+
```

1.1.1.4.2 Inserting & Loading Data

The `INSERT` statement is the primary SQL statement for adding data into a table in MariaDB.

INSERT

Insert rows into a table.

INSERT DELAYED

Queue row to be inserted when thread is free.

INSERT SELECT

Insert the rows returned by a SELECT into a table

LOAD Data into Tables or Index

Loading data quickly into MariaDB

Concurrent Inserts

Under some circumstances, MyISAM allows INSERTs and SELECTs to be executed concurrently.

HIGH_PRIORITY and LOW_PRIORITY

Modifying statement priority in storage engines supporting table-level locks.

IGNORE

Suppress errors while trying to violate a UNIQUE constraint.

INSERT - Default & Duplicate Values

Default and duplicate values when inserting.

INSERT IGNORE

Convert errors to warnings, permitting inserts of additional rows to continue.

INSERT ON DUPLICATE KEY UPDATE

INSERT if no duplicate key is found, otherwise UPDATE.

INSERT...RETURNING

Returns a resultset of the inserted rows.

There are 3 related questions.

1.1.1.4.2.1 INSERT

Syntax

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
 [INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
 {VALUES | VALUE} ({expr | DEFAULT},...),(...),...
 [ ON DUPLICATE KEY UPDATE
   col=expr
     [, col=expr] ... ] [RETURNING select_expr
      [, select_expr ...]]
```

Or:

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name [PARTITION (partition_list)]
    SET col={expr | DEFAULT}, ...
    [ ON DUPLICATE KEY UPDATE
      col=expr
        [, col=expr] ... ] [RETURNING select_expr
      [, select_expr ...]]
```

Or:

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
    SELECT ...
    [ ON DUPLICATE KEY UPDATE
      col=expr
        [, col=expr] ... ] [RETURNING select_expr
      [, select_expr ...]]
```

Contents

The `INSERT` statement is used to insert new rows into an existing table. The `INSERT ... VALUES` and `INSERT ... SET` forms of the statement insert rows based on explicitly specified values. The `INSERT ... SELECT` form inserts rows selected from another table or tables. `INSERT ... SELECT` is discussed further in the `INSERT ... SELECT` article.

The table name can be specified in the form `db_name . tbl_name` or, if a default database is selected, in the form `tbl_name` (see Identifier Qualifiers). This allows to use INSERT ... SELECT to copy rows between different databases.

The PARTITION clause can be used in both the INSERT and the SELECT part. See Partition Pruning and Selection for details.

MariaDB starting with 10.5

The RETURNING clause was introduced in MariaDB 10.5.

The columns list is optional. It specifies which values are explicitly inserted, and in which order. If this clause is not specified, all values must be explicitly specified, in the same order they are listed in the table definition.

The list of value follow the `VALUES` or `VALUE` keyword (which are interchangeable, regardless how much values you want to insert), and is wrapped by parenthesis. The values must be listed in the same order as the columns list. It is possible to specify more than one list to insert more than one rows with a single statement. If many rows are inserted, this is a speed optimization.

For one-row statements, the `SET` clause may be more simple, because you don't need to remember the columns order. All values are specified in the form `col = expr .`

Values can also be specified in the form of a SQL expression or subquery. However, the subquery cannot access the same table that is named in the `INTO` clause.

If you use the `LOW_PRIORITY` keyword, execution of the `INSERT` is delayed until no other clients are reading from the table. If you use the `HIGH_PRIORITY` keyword, the statement has the same priority as `SELECT` s. This affects only storage engines that use only table-level locking (MyISAM, MEMORY, MERGE). However, if one of these keywords is specified, concurrent inserts cannot be used. See HIGH_PRIORITY and LOW_PRIORITY clauses for details.

INSERT DELAYED

For more details on the `DELAYED` option, see INSERT DELAYED.

HIGH PRIORITY and LOW PRIORITY

See HIGH_PRIORITY and LOW_PRIORITY.

Defaults and Duplicate Values

See INSERT - Default & Duplicate Values for details..

INSERT IGNORE

See INSERT IGNORE.

INSERT ON DUPLICATE KEY UPDATE

See INSERT ON DUPLICATE KEY UPDATE.

Examples

Specifying the column names:

```
INSERT INTO person (first_name, last_name) VALUES ('John', 'Doe');
```

Inserting more than 1 row at a time:

```
INSERT INTO tbl_name VALUES (1, "row 1"), (2, "row 2");
```

Using the `SET` clause:

```
INSERT INTO person SET first_name = 'John', last_name = 'Doe';
```

SELECTing from another table:

```
INSERT INTO contractor SELECT * FROM person WHERE status = 'c';
```

See INSERT ON DUPLICATE KEY UPDATE and INSERT IGNORE for further examples.

INSERT ... RETURNING

`INSERT ... RETURNING` returns a resultset of the inserted rows.

This returns the listed columns for all the rows that are inserted, or alternatively, the specified SELECT expression. Any SQL expressions which can be calculated can be used in the select expression for the RETURNING clause, including virtual columns and aliases, expressions which use various operators such as bitwise, logical and arithmetic operators, string functions, date-time functions, numeric functions, control flow functions, secondary functions and stored functions. Along with this, statements which have subqueries and prepared statements can also be used.

Examples

Simple INSERT statement

```
INSERT INTO t2 VALUES (1,'Dog'),(2,'Lion'),(3,'Tiger'),(4,'Leopard')
RETURNING id2,id2+id2,id2&id2,id2||id2;
+-----+---------+---------+----------+
| id2 | id2+id2 | id2&id2 | id2||id2 |
+-----+---------+---------+----------+
|   1 |       2 |       1 |        1 |
|   2 |       4 |       2 |        1 |
|   3 |       6 |       3 |        1 |
|   4 |       8 |       4 |        1 |
+-----+---------+---------+----------+
```

Using stored functions in RETURNING

```
DELIMITER |
CREATE FUNCTION f(arg INT) RETURNS INT
    BEGIN
       RETURN (SELECT arg+arg);
    END|

DELIMITER ;

PREPARE stmt FROM "INSERT INTO t1 SET id1=1, animal1='Bear' RETURNING f(id1), UPPER(animal1)";

EXECUTE stmt;
+---------+----------------+
| f(id1)  | UPPER(animal1) |
+---------+----------------+
|       2 | BEAR           |
+---------+----------------+
```

Subqueries in the RETURNING clause that return more than one row or column cannot be used.

Aggregate functions cannot be used in the RETURNING clause. Since aggregate functions work on a set of values, and if the purpose is to get the row count, ROW_COUNT() with SELECT can be used or it can be used in INSERT...SELECT...RETURNING if the table in the RETURNING clause is not the same as the INSERT table.

1.1.1.4.2.2 INSERT DELAYED

Syntax

```
INSERT DELAYED ...
```

Contents

Description

The `DELAYED` option for the `INSERT` statement is a MariaDB/MySQL extension to standard SQL that is very useful if you have clients that cannot or need not wait for the `INSERT` to complete. This is a common situation when you use MariaDB for logging and you also periodically run `SELECT` and `UPDATE` statements that take a long time to complete.

When a client uses `INSERT DELAYED`, it gets an okay from the server at once, and the row is queued to be inserted when the table is not in use by any other thread.

Another major benefit of using `INSERT DELAYED` is that inserts from many clients are bundled together and written in one block. This is much faster than performing many separate inserts.

Note that `INSERT DELAYED` is slower than a normal `INSERT` if the table is not otherwise in use. There is also the additional overhead for the server to handle a separate thread for each table for which there are delayed rows. This means that you should use `INSERT DELAYED` only when you are really sure that you need it.

The queued rows are held only in memory until they are inserted into the table. This means that if you terminate mysqld forcibly (for example, with kill -9) or if mysqld dies unexpectedly, any queued rows that have not been written to disk are lost.

The number of concurrent `INSERT DELAYED` threads is limited by the `max_delayed_threads` server system variables. If

it is set to 0, `INSERT DELAYED` is disabled. The session value can be equal to the global value, or 0 to disable this statement for the current session. If this limit has been reached, the `DELAYED` clause will be silently ignore for subsequent statements (no error will be produced).

Limitations

There are some limitations on the use of `DELAYED`:

- `INSERT DELAYED` works only with MyISAM, MEMORY, ARCHIVE, and BLACKHOLE tables. If you execute INSERT DELAYED with another storage engine, you will get an error like this: `ERROR 1616 (HY000): DELAYED option not supported for table 'tab_name'`
- For MyISAM tables, if there are no free blocks in the middle of the data file, concurrent SELECT and INSERT statements are supported. Under these circumstances, you very seldom need to use `INSERT DELAYED` with MyISAM.
- `INSERT DELAYED` should be used only for `INSERT` statements that specify value lists. The server ignores `DELAYED` for `INSERT ... SELECT` or `INSERT ... ON DUPLICATE KEY UPDATE` statements.
- Because the `INSERT DELAYED` statement returns immediately, before the rows are inserted, you cannot use `LAST_INSERT_ID()` to get the `AUTO_INCREMENT` value that the statement might generate.
- `DELAYED` rows are not visible to `SELECT` statements until they actually have been inserted.
- After `INSERT DELAYED`, ROW_COUNT() returns the number of the rows you tried to insert, not the number of the successful writes.
- `DELAYED` is ignored on slave replication servers, so that `INSERT DELAYED` is treated as a normal `INSERT` on slaves. This is because `DELAYED` could cause the slave to have different data than the master. `INSERT DELAYED` statements are not safe for replication.
- Pending `INSERT DELAYED` statements are lost if a table is write locked and ALTER TABLE is used to modify the table structure.
- `INSERT DELAYED` is not supported for views. If you try, you will get an error like this: `ERROR 1347 (HY000): 'view_name' is not BASE TABLE`
- `INSERT DELAYED` is not supported for partitioned tables.
- `INSERT DELAYED` is not supported within stored programs.
- `INSERT DELAYED` does not work with triggers.
- `INSERT DELAYED` does not work if there is a check constraint in place.
- `INSERT DELAYED` does not work if skip-new mode is active.

1.1.1.4.2.3 INSERT SELECT

Syntax

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name [(col_name,...)]
    SELECT ...
    [ ON DUPLICATE KEY UPDATE col_name=expr, ... ]
```

Contents

Description

With `INSERT ... SELECT`, you can quickly insert many rows into a table from one or more other tables. For example:

```
INSERT INTO tbl_temp2 (fld_id)
  SELECT tbl_temp1.fld_order_id
  FROM tbl_temp1 WHERE tbl_temp1.fld_order_id > 100;
```

`tbl_name` can also be specified in the form `db_name.tbl_name` (see Identifier Qualifiers). This allows to copy rows between different databases.

If the new table has a primary key or UNIQUE indexes, you can use IGNORE to handle duplicate key errors during the query. The newer values will not be inserted if an identical value already exists.

`REPLACE` can be used instead of `INSERT` to prevent duplicates on `UNIQUE` indexes by deleting old values. In that case, `ON DUPLICATE KEY UPDATE` cannot be used.

`INSERT ... SELECT` works for tables which already exist. To create a table for a given resultset, you can use CREATE TABLE ... SELECT.

1.1.1.4.2.4 LOAD Data into Tables or Index

Loading data quickly into MariaDB

LOAD DATA INFILE

Read rows from a text file into a table.

LOAD INDEX

Loads one or more indexes from one or more MyISAM/Aria tables into a key buffer.

LOAD XML

Load XML data into a table.

LOAD_FILE

Returns file contents as a string.

There are 4 related questions.

1.1.1.4.2.4.1 LOAD DATA INFILE

Syntax

```
LOAD DATA [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
    [REPLACE | IGNORE]
    INTO TABLE tbl_name
    [CHARACTER SET charset_name]
    [{FIELDS | COLUMNS}
        [TERMINATED BY 'string']
        [[OPTIONALLY] ENCLOSED BY 'char']
        [ESCAPED BY 'char']
    ]
    [LINES
        [STARTING BY 'string']
        [TERMINATED BY 'string']
    ]
    [IGNORE number {LINES|ROWS}]
    [(col_name_or_user_var,...)]
    [SET col_name = expr,...]
```

Contents

Description

`LOAD DATA INFILE` is unsafe for statement-based replication.

Reads rows from a text file into the designated table on the database at a very high speed. The file name must be given as a

literal string.

Files are written to disk using the SELECT INTO OUTFILE statement. You can then read the files back into a table using the `LOAD DATA INFILE` statement. The `FIELDS` and `LINES` clauses are the same in both statements. These clauses are optional, but if both are specified then the `FIELDS` clause must precede `LINES`.

Executing this statement activates `INSERT` triggers.

One must have the FILE privilege to be able to execute LOAD DATA INFILE. This is to ensure normal users cannot read system files. LOAD DATA LOCAL INFILE does not have this requirement.

If the secure_file_priv system variable is set (by default it is not), the loaded file must be present in the specified directory.

Note that MariaDB's systemd unit file restricts access to `/home`, `/root`, and `/run/user` by default. See Configuring access to home directories.

`LOAD DATA LOCAL INFILE`

When you execute the `LOAD DATA INFILE` statement, MariaDB Server attempts to read the input file from its own file system. By contrast, when you execute the `LOAD DATA LOCAL INFILE` statement, the client attempts to read the input file from its file system, and it sends the contents of the input file to the MariaDB Server. This allows you to load files from the client's local file system into the database.

If you don't want to permit this operation (perhaps for security reasons), you can disable the `LOAD DATA LOCAL INFILE` statement on either the server or the client.

- The `LOAD DATA LOCAL INFILE` statement can be disabled on the server by setting the local_infile system variable to `0`.
- The `LOAD DATA LOCAL INFILE` statement can be disabled on the client. If you are using MariaDB Connector/C, this can be done by unsetting the `CLIENT_LOCAL_FILES` capability flag with the mysql_real_connect function or by unsetting the `MYSQL_OPT_LOCAL_INFILE` option with mysql_optionsv function. If you are using a different client or client library, then see the documentation for your specific client or client library to determine how it handles the `LOAD DATA LOCAL INFILE` statement.

If the `LOAD DATA LOCAL INFILE` statement is disabled by either the server or the client and if the user attempts to execute it, then the server will cause the statement to fail with the following error message:

```
The used command is not allowed with this MariaDB version
```

Note that it is not entirely accurate to say that the MariaDB version does not support the command. It would be more accurate to say that the MariaDB configuration does not support the command. See MDEV-20500 for more information.

From MariaDB 10.5.2, the error message is more accurate:

```
The used command is not allowed because the MariaDB server or client
  has disabled the local infile capability
```

`REPLACE` and `IGNORE`

If you load data from a file into a table that already contains data and has a primary key, you may encounter issues where the statement attempts to insert a row with a primary key that already exists. When this happens, the statement fails with Error 1064, protecting the data already on the table. If you want MariaDB to overwrite duplicates, use the `REPLACE` keyword.

The `REPLACE` keyword works like the REPLACE statement. Here, the statement attempts to load the data from the file. If the row does not exist, it adds it to the table. If the row contains an existing primary key, it replaces the table data. That is, in the event of a conflict, it assumes the file contains the desired row.

This operation can cause a degradation in load speed by a factor of 20 or more if the part that has already been loaded is larger than the capacity of the InnoDB Buffer Pool. This happens because it causes a lot of turnaround in the buffer pool.

Use the `IGNORE` keyword when you want to skip any rows that contain a conflicting primary key. Here, the statement attempts to load the data from the file. If the row does not exist, it adds it to the table. If the row contains an existing primary key, it ignores the addition request and moves on to the next. That is, in the event of a conflict, it assumes the table contains the desired row.

Character-sets

When the statement opens the file, it attempts to read the contents using the default character-set, as defined by the character_set_database system variable.

In the cases where the file was written using a character-set other than the default, you can specify the character-set to use with the `CHARACTER SET` clause in the statement. It ignores character-sets specified by the SET NAMES statement and by the character_set_client system variable. Setting the `CHARACTER SET` clause to a value of `binary` indicates "no conversion."

The statement interprets all fields in the file as having the same character-set, regardless of the column data type. To properly interpret file contents, you must ensure that it was written with the correct character-set. If you write a data file with mariadb-dump -T or with the SELECT INTO OUTFILE statement with the mariadb client, be sure to use the `--default-character-set` option, so that the output is written with the desired character-set.

When using mixed character sets, use the `CHARACTER SET` clause in both SELECT INTO OUTFILE and `LOAD DATA INFILE` to ensure that MariaDB correctly interprets the escape sequences.

The character_set_filesystem system variable controls the interpretation of the filename.

It is currently not possible to load data files that use the `ucs2` character set.

Preprocessing Inputs

col_name_or_user_var can be a column name, or a user variable. In the case of a variable, the SET statement can be used to preprocess the value before loading into the table.

Priority and Concurrency

In storage engines that perform table-level locking (MyISAM, MEMORY and MERGE), using the LOW_PRIORITY keyword, MariaDB delays insertions until no other clients are reading from the table. Alternatively, when using the MyISAM storage engine, you can use the CONCURRENT keyword to perform concurrent insertion.

The `LOW_PRIORITY` and `CONCURRENT` keywords are mutually exclusive. They cannot be used in the same statement.

Progress Reporting

The `LOAD DATA INFILE` statement supports progress reporting. You may find this useful when dealing with long-running operations. Using another client you can issue a SHOW PROCESSLIST query to check the progress of the data load.

Using mariadb-import

MariaDB ships with a separate utility for loading data from files: mariadb-import (or `mysqlimport` before MariaDB 10.5). It operates by sending `LOAD DATA INFILE` statements to the server.

Using mariadb-import you can compress the file using the `--compress` option, to get better performance over slow networks, providing both the client and server support the compressed protocol. Use the `--local` option to load from the local file system.

Indexing

In cases where the storage engine supports ALTER TABLE... DISABLE KEYS statements (MyISAM and Aria), the `LOAD DATA INFILE` statement automatically disables indexes during the execution.

Examples

You have a file with this content (note the the separator is ',', not tab, which is the default):

```
2,2
3,3
4,4
5,5
6,8
```

```
CREATE TABLE t1 (a int, b int, c int, d int, PRIMARY KEY (a));
LOAD DATA LOCAL INFILE
 '/tmp/loaddata7.dat' INTO TABLE t1 FIELDS TERMINATED BY ',' (a,b) SET c=a+b;
SELECT * FROM t1;
+------+------+------+
| a    | b    | c    |
+------+------+------+
|    2 |    2 |    4 |
|    3 |    3 |    6 |
|    4 |    4 |    8 |
|    5 |    5 |   10 |
|    6 |    8 |   14 |
+------+------+------+
```

Another example, given the following data (the separator is a tab):

```
1       a
2       b
```

The value of the first column is doubled before loading:

```
LOAD DATA INFILE 'ld.txt' INTO TABLE ld (@i,v) SET i=@i*2;

SELECT * FROM ld;
+------+------+
| i    | v    |
+------+------+
|    2 | a    |
|    4 | b    |
+------+------+
```

1.1.1.2.17 LOAD INDEX

1.1.1.4.2.4.3 LOAD XML

Syntax

```
LOAD XML [LOW_PRIORITY | CONCURRENT] [LOCAL] INFILE 'file_name'
    [REPLACE | IGNORE]
    INTO TABLE [db_name.]tbl_name
    [CHARACTER SET charset_name]
    [ROWS IDENTIFIED BY '<tagname>']
    [IGNORE number {LINES | ROWS}]
    [(column_or_user_var,...)]
    [SET col_name = expr,...]
```

Description

The LOAD XML statement reads data from an XML file into a table. The `file_name` must be given as a literal string. The `tagname` in the optional ROWS IDENTIFIED BY clause must also be given as a literal string, and must be surrounded by angle brackets (< and >).

LOAD XML acts as the complement of running the mariadb client in XML output mode (that is, starting the client with the --xml option). To write data from a table to an XML file, use a command such as the following one from the system shell:

```
shell> mariadb --xml -e 'SELECT * FROM mytable' > file.xml
```

To read the file back into a table, use LOAD XML INFILE. By default, the <row> element is considered to be the equivalent of a database table row; this can be changed using the ROWS IDENTIFIED BY clause.

This statement supports three different XML formats:

- Column names as attributes and column values as attribute values:

```
<row column1="value1" column2="value2" .../>
```

- Column names as tags and column values as the content of these tags:

```
<row>
  <column1>value1</column1>
  <column2>value2</column2>
</row>
```

- Column names are the name attributes of <field> tags, and values are the contents of these tags:

```
<row>
  <field name='column1'>value1</field>
  <field name='column2'>value2</field>
</row>
```

This is the format used by other tools, such as mariadb-dump.

All 3 formats can be used in the same XML file; the import routine automatically detects the format for each row and interprets it correctly. Tags are matched based on the tag or attribute name and the column name.

The following clauses work essentially the same way for LOAD XML as they do for LOAD DATA:

- LOW_PRIORITY or CONCURRENT
- LOCAL
- REPLACE or IGNORE
- CHARACTER SET
- (column_or_user_var,...)
- SET

See LOAD DATA for more information about these clauses.

The IGNORE number LINES or IGNORE number ROWS clause causes the first number rows in the XML file to be skipped. It is analogous to the LOAD DATA statement's IGNORE ... LINES clause.

If the `LOW_PRIORITY` keyword is used, insertions are delayed until no other clients are reading from the table. The `CONCURRENT` keyword allows the use of concurrent inserts. These clauses cannot be specified together.

This statement activates INSERT triggers.

1.1.1.4.2.4.4 LOAD_FILE

Syntax

```
LOAD_FILE(file_name)
```

Contents

Description

Reads the file and returns the file contents as a string. To use this function, the file must be located on the server host, you must specify the full path name to the file, and you must have the FILE privilege. The file must be readable by all and it must be less than the size, in bytes, of the max_allowed_packet system variable. If the secure_file_priv system variable is set to a non-empty directory name, the file to be loaded must be located in that directory.

If the file does not exist or cannot be read because one of the preceding conditions is not satisfied, the function returns NULL.

Since MariaDB 5.1, the character_set_filesystem system variable has controlled interpretation of file names that are given as literal strings.

Statements using the LOAD_FILE() function are not safe for statement based replication. This is because the slave will execute the LOAD_FILE() command itself. If the file doesn't exist on the slave, the function will return NULL.

Examples

```
UPDATE t SET blob_col=LOAD_FILE('/tmp/picture') WHERE id=1;
```

1.1.1.4.2.5 Concurrent Inserts

Contents

The MyISAM storage engine supports concurrent inserts. This feature allows SELECT statements to be executed during INSERT operations, reducing contention.

Whether concurrent inserts can be used or not depends on the value of the concurrent_insert server system variable:

- `NEVER` (0) disables concurrent inserts.
- `AUTO` (1) allows concurrent inserts only when the target table has no free blocks (no data in the middle of the table has been deleted after the last OPTIMIZE TABLE). This is the default.
- `ALWAYS` (2) always enables concurrent inserts, in which case new rows are added at the end of a table if the table is being used by another thread.

If the binary log is used, CREATE TABLE ... SELECT and INSERT ... SELECT statements cannot use concurrent inserts. These statements acquire a read lock on the table, so concurrent inserts will need to wait. This way the log can be safely used to restore data.

Concurrent inserts are not used by replicas with the row based replication (see binary log formats).

If an INSERT statement contain the HIGH_PRIORITY clause, concurrent inserts cannot be used. INSERT ... DELAYED is usually unneeded if concurrent inserts are enabled.

LOAD DATA INFILE uses concurrent inserts if the `CONCURRENT` keyword is specified and concurrent_insert is not `NEVER`. This makes the statement slower (even if no other sessions access the table) but reduces contention.

LOCK TABLES allows non-conflicting concurrent inserts if a `READ LOCAL` lock is used. Concurrent inserts are not allowed if the `LOCAL` keyword is omitted.

Notes

The decision to enable concurrent insert for a table is done when the table is opened. If you change the value of concurrent_insert it will only affect new opened tables. If you want it to work for also for tables in use or cached, you should do FLUSH TABLES after setting the variable.

1.1.1.4.2.6 HIGH_PRIORITY and LOW_PRIORITY

Contents

The InnoDB storage engine uses row-level locking to ensure data integrity. However some storage engines (such as MEMORY, MyISAM, Aria and MERGE) lock the whole table to prevent conflicts. These storage engines use two separate queues to remember pending statements; one is for SELECTs and the other one is for write statements (INSERT, DELETE, UPDATE). By default, the latter has a higher priority.

To give write operations a lower priority, the low_priority_updates server system variable can be set to `ON`. The option is available on both the global and session levels, and it can be set at startup or via the SET statement.

When too many table locks have been set by write statements, some pending SELECTs are executed. The maximum number of write locks that can be acquired before this happens is determined by the max_write_lock_count server system variable, which is dynamic.

If write statements have a higher priority (default), the priority of individual write statements (INSERT, REPLACE, UPDATE, DELETE) can be changed via the `LOW_PRIORITY` attribute, and the priority of a `SELECT` statement can be raised via the `HIGH_PRIORITY` attribute. Also, LOCK TABLES supports a `LOW_PRIORITY` attribute for `WRITE` locks.

If read statements have a higher priority, the priority of an `INSERT` can be changed via the `HIGH_PRIORITY` attribute. However, the priority of other write statements cannot be raised individually.

The use of `LOW_PRIORITY` or `HIGH_PRIORITY` for an `INSERT` prevents Concurrent Inserts from being used.

1.1.1.2.1.21 IGNORE

1.1.1.4.2.8 INSERT - Default & Duplicate Values

Contents

Default Values

If the `SQL_MODE` contains `STRICT_TRANS_TABLES` and you are inserting into a transactional table (like InnoDB), or if the SQL_MODE contains `STRICT_ALL_TABLES`, all `NOT NULL` columns which do not have a `DEFAULT` value (and are not AUTO_INCREMENT) must be explicitly referenced in `INSERT` statements. If not, an error like this is produced:

```
ERROR 1364 (HY000): Field 'col' doesn't have a default value
```

In all other cases, if a `NOT NULL` column without a `DEFAULT` value is not referenced, an empty value will be inserted (for example, 0 for `INTEGER` columns and '' for `CHAR` columns). See NULL Values in MariaDB:Inserting for examples.

If a `NOT NULL` column having a `DEFAULT` value is not referenced, `NULL` will be inserted.

If a `NULL` column having a `DEFAULT` value is not referenced, its default value will be inserted. It is also possible to explicitly assign the default value using the `DEFAULT` keyword or the `DEFAULT()` function.

If the `DEFAULT` keyword is used but the column does not have a `DEFAULT` value, an error like this is produced:

```
ERROR 1364 (HY000): Field 'col' doesn't have a default value
```

Duplicate Values

By default, if you try to insert a duplicate row and there is a `UNIQUE` index, `INSERT` stops and an error like this is produced:

```
ERROR 1062 (23000): Duplicate entry 'dup_value' for key 'col'
```

To handle duplicates you can use the IGNORE clause, INSERT ON DUPLICATE KEY UPDATE or the REPLACE statement. Note that the IGNORE and DELAYED options are ignored when you use ON DUPLICATE KEY UPDATE.

1.1.1.4.2.9 INSERT IGNORE

Contents

Ignoring Errors

Normally INSERT stops and rolls back when it encounters an error.

By using the IGNORE keyword all errors are converted to warnings, which will not stop inserts of additional rows.

Invalid values are changed to the closest valid value and inserted, with a warning produced.

The IGNORE and DELAYED options are ignored when you use ON DUPLICATE KEY UPDATE.

Prior to MySQL and MariaDB 5.5.28, no warnings were issued for duplicate key errors when using `IGNORE`. You can get the old behavior if you set OLD_MODE to `NO_DUP_KEY_WARNINGS_WITH_IGNORE`.

See IGNORE for a full description of effects.

Examples

```
CREATE TABLE t1 (x INT UNIQUE);

INSERT INTO t1 VALUES(1),(2);

INSERT INTO t1 VALUES(2),(3);
ERROR 1062 (23000): Duplicate entry '2' for key 'x'
SELECT * FROM t1;
+------+
| x    |
+------+
|    1 |
|    2 |
+------+

INSERT IGNORE INTO t1 VALUES(2),(3);
Query OK, 1 row affected, 1 warning (0.04 sec)

SHOW WARNINGS;
+---------+------+----------------------------------+
| Level   | Code | Message                          |
+---------+------+----------------------------------+
| Warning | 1062 | Duplicate entry '2' for key 'x' |
+---------+------+----------------------------------+

SELECT * FROM t1;
+------+
| x    |
+------+
|    1 |
|    2 |
|    3 |
+------+
```

Converting values:

```
CREATE OR REPLACE TABLE t2(id INT, t VARCHAR(2) NOT NULL, n INT NOT NULL);

INSERT INTO t2(id) VALUES (1),(2);
ERROR 1364 (HY000): Field 't' doesn't have a default value

INSERT IGNORE INTO t2(id) VALUES (1),(2);
Query OK, 2 rows affected, 2 warnings (0.026 sec)
Records: 2  Duplicates: 0  Warnings: 2

SHOW WARNINGS;
+---------+------+---------------------------------------+
| Level   | Code | Message                               |
+---------+------+---------------------------------------+
| Warning | 1364 | Field 't' doesn't have a default value |
| Warning | 1364 | Field 'n' doesn't have a default value |
+---------+------+---------------------------------------+

SELECT * FROM t2;
+------+---+---+
| id   | t | n |
+------+---+---+
|    1 |   | 0 |
|    2 |   | 0 |
+------+---+---+
```

See INSERT ON DUPLICATE KEY UPDATE for further examples using that syntax.

1.1.1.4.2.10 INSERT ON DUPLICATE KEY UPDATE

Syntax

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
  [INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
  {VALUES | VALUE} ({expr | DEFAULT},...),(...),...
  [ ON DUPLICATE KEY UPDATE
    col=expr
      [, col=expr] ... ]
```

Or:

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name [PARTITION (partition_list)]
    SET col={expr | DEFAULT}, ...
    [ ON DUPLICATE KEY UPDATE
      col=expr
        [, col=expr] ... ]
```

Or:

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
    SELECT ...
    [ ON DUPLICATE KEY UPDATE
      col=expr
        [, col=expr] ... ]
```

Contents

Description

INSERT ... ON DUPLICATE KEY UPDATE is a MariaDB/MySQL extension to the INSERT statement that, if it finds a duplicate unique or primary key, will instead perform an UPDATE.

The row/s affected value is reported as 1 if a row is inserted, and 2 if a row is updated, unless the API's `CLIENT_FOUND_ROWS` flag is set.

If more than one unique index is matched, only the first is updated. It is not recommended to use this statement on tables with more than one unique index.

If the table has an AUTO_INCREMENT primary key and the statement inserts or updates a row, the LAST_INSERT_ID() function returns its AUTO_INCREMENT value.

The VALUES() function can only be used in a `ON DUPLICATE KEY UPDATE` clause and has no meaning in any other context. It returns the column values from the `INSERT` portion of the statement. This function is particularly useful for multi-rows inserts.

The IGNORE and DELAYED options are ignored when you use `ON DUPLICATE KEY UPDATE`.

See Partition Pruning and Selection for details on the PARTITION clause.

This statement activates INSERT and UPDATE triggers. See Trigger Overview for details.

See also a similar statement, REPLACE.

Examples

```
CREATE TABLE ins_duplicate (id INT PRIMARY KEY, animal VARCHAR(30));
INSERT INTO ins_duplicate VALUES (1,'Aardvark'), (2,'Cheetah'), (3,'Zebra');
```

If there is no existing key, the statement runs as a regular INSERT:

```
INSERT INTO ins_duplicate VALUES (4,'Gorilla')
  ON DUPLICATE KEY UPDATE animal='Gorilla';
Query OK, 1 row affected (0.07 sec)
```

```
SELECT * FROM ins_duplicate;
+----+----------+
| id | animal   |
+----+----------+
|  1 | Aardvark |
|  2 | Cheetah  |
|  3 | Zebra    |
|  4 | Gorilla  |
+----+----------+
```

A regular INSERT with a primary key value of 1 will fail, due to the existing key:

```
INSERT INTO ins_duplicate VALUES (1,'Antelope');
ERROR 1062 (23000): Duplicate entry '1' for key 'PRIMARY'
```

However, we can use an INSERT ON DUPLICATE KEY UPDATE instead:

```
INSERT INTO ins_duplicate VALUES (1,'Antelope')
  ON DUPLICATE KEY UPDATE animal='Antelope';
Query OK, 2 rows affected (0.09 sec)
```

Note that there are two rows reported as affected, but this refers only to the UPDATE.

```
SELECT * FROM ins_duplicate;
+----+----------+
| id | animal   |
+----+----------+
|  1 | Antelope |
|  2 | Cheetah  |
|  3 | Zebra    |
|  4 | Gorilla  |
+----+----------+
```

Adding a second unique column:

```
ALTER TABLE ins_duplicate ADD id2 INT;
UPDATE ins_duplicate SET id2=id+10;
ALTER TABLE ins_duplicate ADD UNIQUE KEY(id2);
```

Where two rows match the unique keys match, only the first is updated. This can be unsafe and is not recommended unless you are certain what you are doing.

```
INSERT INTO ins_duplicate VALUES (2,'Lion',13)
  ON DUPLICATE KEY UPDATE animal='Lion';
Query OK, 2 rows affected (0.004 sec)

SELECT * FROM ins_duplicate;
+----+----------+------+
| id | animal   | id2  |
+----+----------+------+
|  1 | Antelope |   11 |
|  2 | Lion     |   12 |
|  3 | Zebra    |   13 |
|  4 | Gorilla  |   14 |
+----+----------+------+
```

Although the third row with an id of 3 has an id2 of 13, which also matched, it was not updated.

Changing id to an auto_increment field. If a new row is added, the auto_increment is moved forward. If the row is updated, it remains the same.

```
ALTER TABLE `ins_duplicate` CHANGE `id` `id` INT( 11 ) NOT NULL AUTO_INCREMENT;
ALTER TABLE ins_duplicate DROP id2;
SELECT Auto_increment FROM INFORMATION_SCHEMA.TABLES
  WHERE TABLE_NAME='ins_duplicate';
+----------------+
| Auto_increment |
+----------------+
|              5 |
+----------------+

INSERT INTO ins_duplicate VALUES (2,'Leopard')
  ON DUPLICATE KEY UPDATE animal='Leopard';
Query OK, 2 rows affected (0.00 sec)

SELECT Auto_increment FROM INFORMATION_SCHEMA.TABLES
  WHERE TABLE_NAME='ins_duplicate';
+----------------+
| Auto_increment |
+----------------+
|              5 |
+----------------+

INSERT INTO ins_duplicate VALUES (5,'Wild Dog')
  ON DUPLICATE KEY UPDATE animal='Wild Dog';
Query OK, 1 row affected (0.09 sec)

SELECT * FROM ins_duplicate;
+----+----------+
| id | animal   |
+----+----------+
|  1 | Antelope |
|  2 | Leopard  |
|  3 | Zebra    |
|  4 | Gorilla  |
|  5 | Wild Dog |
+----+----------+

SELECT Auto_increment FROM INFORMATION_SCHEMA.TABLES
  WHERE TABLE_NAME='ins_duplicate';
+----------------+
| Auto_increment |
+----------------+
|              6 |
+----------------+
```

Refering to column values from the INSERT portion of the statement:

```
INSERT INTO table (a,b,c) VALUES (1,2,3),(4,5,6)
    ON DUPLICATE KEY UPDATE c=VALUES(a)+VALUES(b);
```

See the VALUES() function for more.

1.1.1.4.2.11 INSERT...RETURNING

MariaDB starting with 10.5.0

INSERT ... RETURNING was added in MariaDB 10.5.0, and returns a resultset of the inserted rows.

Syntax

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
 [INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
 {VALUES | VALUE} ({expr | DEFAULT},...),(...),...
 [ ON DUPLICATE KEY UPDATE
   col=expr
     [, col=expr] ... ] [RETURNING select_expr
      [, select_expr ...]]
```

Or:

```
INSERT [LOW_PRIORITY | DELAYED | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name [PARTITION (partition_list)]
    SET col={expr | DEFAULT}, ...
    [ ON DUPLICATE KEY UPDATE
      col=expr
        [, col=expr] ... ] [RETURNING select_expr
      [, select_expr ...]]
```

Or:

```
INSERT [LOW_PRIORITY | HIGH_PRIORITY] [IGNORE]
    [INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
    SELECT ...
    [ ON DUPLICATE KEY UPDATE
      col=expr
        [, col=expr] ... ] [RETURNING select_expr
      [, select_expr ...]]
```

Contents

Description

`INSERT ... RETURNING` returns a resultset of the inserted rows.

This returns the listed columns for all the rows that are inserted, or alternatively, the specified SELECT expression. Any SQL expressions which can be calculated can be used in the select expression for the RETURNING clause, including virtual columns and aliases, expressions which use various operators such as bitwise, logical and arithmetic operators, string functions, date-time functions, numeric functions, control flow functions, secondary functions and stored functions. Along with this, statements which have subqueries and prepared statements can also be used.

Examples

Simple INSERT statements:

```
CREATE OR REPLACE TABLE t2 (id INT, animal VARCHAR(20), t TIMESTAMP);

INSERT INTO t2 (id) VALUES (2),(3) RETURNING id,t;
+------+---------------------+
| id   | t                   |
+------+---------------------+
|    2 | 2021-04-28 00:59:32 |
|    3 | 2021-04-28 00:59:32 |
+------+---------------------+
```

```
INSERT INTO t2(id,animal) VALUES (1,'Dog'),(2,'Lion'),(3,'Tiger'),(4,'Leopard')
  RETURNING id,id+id,id&id,id||id;
+------+-------+-------+--------+
| id   | id+id | id&id | id||id |
+------+-------+-------+--------+
|    1 |     2 |     1 |      1 |
|    2 |     4 |     2 |      1 |
|    3 |     6 |     3 |      1 |
|    4 |     8 |     4 |      1 |
+------+-------+-------+--------+
```

Using stored functions in RETURNING

```
DELIMITER |
CREATE FUNCTION f(arg INT) RETURNS INT
    BEGIN
       RETURN (SELECT arg+arg);
    END|

DELIMITER ;

PREPARE stmt FROM "INSERT INTO t1 SET id1=1, animal1='Bear' RETURNING f(id1), UPPER(animal1)";

EXECUTE stmt;
+---------+----------------+
| f(id1)  | UPPER(animal1) |
+---------+----------------+
|       2 | BEAR           |
+---------+----------------+
```

Subqueries in the RETURNING clause that return more than one row or column cannot be used.

Aggregate functions cannot be used in the RETURNING clause. Since aggregate functions work on a set of values, and if the purpose is to get the row count, ROW_COUNT() with SELECT can be used or it can be used in INSERT...SELECT...RETURNING if the table in the RETURNING clause is not the same as the INSERT table.

1.1.1.4.3 Changing & Deleting Data

DELETE
Delete rows from one or more tables.

HIGH_PRIORITY and LOW_PRIORITY
Modifying statement priority in storage engines supporting table-level locks.

IGNORE
Suppress errors while trying to violate a UNIQUE constraint.

REPLACE
Equivalent to DELETE + INSERT, or just an INSERT if no rows are returned.

REPLACE...RETURNING
Returns a resultset of the replaced rows.

TRUNCATE TABLE
DROP and re-CREATE a table.

UPDATE
Modify rows in one or more tables.

1.1.1.2.1.7 DELETE

1.1.1.4.2.6 HIGH_PRIORITY and LOW_PRIORITY

1.1.1.2.1.21 IGNORE

1.1.1.2.1.15 REPLACE

1.1.1.4.3.5 REPLACE...RETURNING

MariaDB starting with 10.5.0
REPLACE ... RETURNING was added in MariaDB 10.5.0, and returns a resultset of the replaced rows.

Syntax

```
REPLACE [LOW_PRIORITY | DELAYED]
 [INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
 {VALUES | VALUE} ({expr | DEFAULT},...),(...),...
[RETURNING select_expr
      [, select_expr ...]]
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
    [INTO] tbl_name [PARTITION (partition_list)]
    SET col={expr | DEFAULT}, ...
[RETURNING select_expr
      [, select_expr ...]]
```

Or:

```
REPLACE [LOW_PRIORITY | DELAYED]
    [INTO] tbl_name [PARTITION (partition_list)] [(col,...)]
    SELECT ...
[RETURNING select_expr
      [, select_expr ...]]
```

Contents

Description

`REPLACE ... RETURNING` returns a resultset of the replaced rows.

This returns the listed columns for all the rows that are replaced, or alternatively, the specified SELECT expression. Any SQL expressions which can be calculated can be used in the select expression for the RETURNING clause, including virtual columns and aliases, expressions which use various operators such as bitwise, logical and arithmetic operators, string functions, date-time functions, numeric functions, control flow functions, secondary functions and stored functions. Along with this, statements which have subqueries and prepared statements can also be used.

Examples

Simple REPLACE statement

```
REPLACE INTO t2 VALUES (1,'Leopard'),(2,'Dog') RETURNING id2, id2+id2
as Total ,id2|id2, id2&&id2;
+-----+-------+---------+----------+
| id2 | Total | id2|id2 | id2&&id2 |
+-----+-------+---------+----------+
|   1 |     2 |       1 |        1 |
|   2 |     4 |       2 |        1 |
+-----+-------+---------+----------+
```

Using stored functions in RETURNING

```
DELIMITER |
CREATE FUNCTION f(arg INT) RETURNS INT
    BEGIN
      RETURN (SELECT arg+arg);
    END|

DELIMITER ;
PREPARE stmt FROM "REPLACE INTO t2 SET id2=3, animal2='Fox' RETURNING f2(id2),
UPPER(animal2)";

EXECUTE stmt;
+---------+----------------+
| f2(id2) | UPPER(animal2) |
+---------+----------------+
|       6 | FOX            |
+---------+----------------+
```

Subqueries in the statement

```
REPLACE INTO t1 SELECT * FROM t2 RETURNING (SELECT id2 FROM t2 WHERE
id2 IN (SELECT id2 FROM t2 WHERE id2=1)) AS new_id;
+--------+
| new_id |
+--------+
|      1 |
|      1 |
|      1 |
|      1 |
+--------+
```

Subqueries in the RETURNING clause that return more than one row or column cannot be used..

Aggregate functions cannot be used in the RETURNING clause. Since aggregate functions work on a set of values and if the purpose is to get the row count, ROW_COUNT() with SELECT can be used, or it can be used in REPLACE...SELECT...RETURNING if the table in the RETURNING clause is not the same as the REPLACE table.

1.1.1.2.1.19 TRUNCATE TABLE

1.1.1.2.1.20 UPDATE

1.1.1.5 Prepared Statements

In addition to using prepared statements from the libmysqld, you can also do prepared statements from any client by using the text based prepared statement interface.

You first prepare the statement with PREPARE, execute with EXECUTE, and release it with DEALLOCATE.

PREPARE Statement

Define a prepare statement.

EXECUTE Statement

Executes a previously PREPAREd statement

DEALLOCATE / DROP PREPARE

Deallocates a prepared statement.

EXECUTE IMMEDIATE

Immediately execute a dynamic SQL statement

Out Parameters in PREPARE

Using question mark placeholders for out-parameters in the PREPARE statement

There are 1 related questions.

1.1.1.5.1 PREPARE Statement

Syntax

```
PREPARE stmt_name FROM preparable_stmt
```

Contents

Description

The `PREPARE` statement prepares a statement and assigns it a name, `stmt_name`, by which to refer to the statement later. Statement names are not case sensitive. `preparable_stmt` is either a string literal or a user variable (not a local variable, an SQL expression or a subquery) that contains the text of the statement. The text must represent a single SQL statement, not multiple statements. Within the statement, "?" characters can be used as parameter markers to indicate where data values are to be bound to the query later when you execute it. The "?" characters should not be enclosed within quotes, even if you intend to bind them to string values. Parameter markers can be used only where expressions should appear, not for SQL keywords, identifiers, and so forth.

The scope of a prepared statement is the session within which it is created. Other sessions cannot see it.

If a prepared statement with the given name already exists, it is deallocated implicitly before the new statement is prepared. This means that if the new statement contains an error and cannot be prepared, an error is returned and no statement with the given name exists.

Prepared statements can be PREPAREd and EXECUTEd in a stored procedure, but not in a stored function or trigger. Also, even if the statement is PREPAREd in a procedure, it will not be deallocated when the procedure execution ends.

A prepared statement can access user-defined variables, but not local variables or procedure's parameters.

If the prepared statement contains a syntax error, PREPARE will fail. As a side effect, stored procedures can use it to check if a statement is valid. For example:

```
CREATE PROCEDURE `test_stmt`(IN sql_text TEXT)
BEGIN
        DECLARE EXIT HANDLER FOR SQLEXCEPTION
        BEGIN
                SELECT CONCAT(sql_text, ' is not valid');
        END;
        SET @SQL := sql_text;
        PREPARE stmt FROM @SQL;
        DEALLOCATE PREPARE stmt;
END;
```

The FOUND_ROWS() and ROW_COUNT() functions, if called immediatly after EXECUTE, return the number of rows read or affected by the prepared statements; however, if they are called after DEALLOCATE PREPARE, they provide information about this statement. If the prepared statement produces errors or warnings, GET DIAGNOSTICS return information about them. DEALLOCATE PREPARE shouldn't clear the diagnostics area, unless it produces an error.

A prepared statement is executed with `EXECUTE` and released with `DEALLOCATE PREPARE`.

The max_prepared_stmt_count server system variable determines the number of allowed prepared statements that can be prepared on the server. If it is set to 0, prepared statements are not allowed. If the limit is reached, an error similar to the following will be produced:

```
ERROR 1461 (42000): Can't create more than max_prepared_stmt_count statements
  (current value: 0)
```

Oracle Mode

MariaDB starting with 10.3

In Oracle mode from MariaDB 10.3, `PREPARE stmt FROM 'SELECT :1, :2'` is used, instead of `?`.

Permitted Statements

MariaDB starting with 10.6.2
All statements can be prepared, except PREPARE, EXECUTE, and DEALLOCATE / DROP PREPARE.

Prior to this, not all statements can be prepared. Only the following SQL commands are permitted:

- ALTER TABLE
- ANALYZE TABLE
- BINLOG
- CACHE INDEX
- CALL
- CHANGE MASTER
- CHECKSUM {TABLE | TABLES}
- COMMIT
- {CREATE | DROP} DATABASE
- {CREATE | DROP} INDEX
- {CREATE | RENAME | DROP} TABLE
- {CREATE | RENAME | DROP} USER
- {CREATE | DROP} VIEW
- DELETE
- DESCRIBE
- DO
- EXPLAIN
- FLUSH {TABLE | TABLES | TABLES WITH READ LOCK | HOSTS | PRIVILEGES | LOGS | STATUS | MASTER | SLAVE | DES_KEY_FILE | USER_RESOURCES | QUERY CACHE | TABLE_STATISTICS | INDEX_STATISTICS | USER_STATISTICS | CLIENT_STATISTICS}
- GRANT
- INSERT
- INSTALL {PLUGIN | SONAME}
- HANDLER READ
- KILL
- LOAD INDEX INTO CACHE
- OPTIMIZE TABLE
- REPAIR TABLE
- REPLACE
- RESET {MASTER | SLAVE | QUERY CACHE}
- REVOKE
- ROLLBACK
- SELECT
- SET
- SET GLOBAL SQL_SLAVE_SKIP_COUNTER
- SET ROLE
- SET SQL_LOG_BIN
- SET TRANSACTION ISOLATION LEVEL
- SHOW EXPLAIN
- SHOW {DATABASES | TABLES | OPEN TABLES | TABLE STATUS | COLUMNS | INDEX | TRIGGERS | EVENTS | GRANTS | CHARACTER SET | COLLATION | ENGINES | PLUGINS [SONAME] | PRIVILEGES | PROCESSLIST | PROFILE | PROFILES | VARIABLES | STATUS | WARNINGS | ERRORS | TABLE_STATISTICS | INDEX_STATISTICS | USER_STATISTICS | CLIENT_STATISTICS | AUTHORS | CONTRIBUTORS}
- SHOW CREATE {DATABASE | TABLE | VIEW | PROCEDURE | FUNCTION | TRIGGER | EVENT}
- SHOW {FUNCTION | PROCEDURE} CODE
- SHOW BINLOG EVENTS
- SHOW SLAVE HOSTS
- SHOW {MASTER | BINARY} LOGS
- SHOW {MASTER | SLAVE | TABLES | INNODB | FUNCTION | PROCEDURE} STATUS
- SLAVE {START | STOP}
- TRUNCATE TABLE
- SHUTDOWN
- UNINSTALL {PLUGIN | SONAME}
- UPDATE

Synonyms are not listed here, but can be used. For example, DESC can be used instead of DESCRIBE.

Compound statements can be prepared too.

Note that if a statement can be run in a stored routine, it will work even if it is called by a prepared statement. For example, SIGNAL can't be directly prepared. However, it is allowed in stored routines. If the x() procedure contains SIGNAL, you can

still prepare and execute the 'CALL x();' prepared statement.

PREPARE supports most kinds of expressions as well, for example:

```
PREPARE stmt FROM CONCAT('SELECT * FROM ', table_name);
```

When PREPARE is used with a statement which is not supported, the following error is produced:

```
ERROR 1295 (HY000): This command is not supported in the prepared statement protocol yet
```

Example

```
create table t1 (a int,b char(10));
insert into t1 values (1,"one"),(2, "two"),(3,"three");
prepare test from "select * from t1 where a=?";
set @param=2;
execute test using @param;
+------+------+
| a    | b    |
+------+------+
|    2 | two  |
+------+------+
set @param=3;
execute test using @param;
+------+-------+
| a    | b     |
+------+-------+
|    3 | three |
+------+-------+
deallocate prepare test;
```

Since identifiers are not permitted as prepared statements parameters, sometimes it is necessary to dynamically compose an SQL statement. This technique is called *dynamic SQL*). The following example shows how to use dynamic SQL:

```
CREATE PROCEDURE test.stmt_test(IN tab_name VARCHAR(64))
BEGIN
 SET @sql = CONCAT('SELECT COUNT(*) FROM ', tab_name);
 PREPARE stmt FROM @sql;
 EXECUTE stmt;
 DEALLOCATE PREPARE stmt;
END;

CALL test.stmt_test('mysql.user');
+----------+
| COUNT(*) |
+----------+
|        4 |
+----------+
```

Use of variables in prepared statements:

```
PREPARE stmt FROM 'SELECT @x;';

SET @x = 1;

EXECUTE stmt;
+------+
| @x   |
+------+
|    1 |
+------+

SET @x = 0;

EXECUTE stmt;
+------+
| @x   |
+------+
|    0 |
+------+

DEALLOCATE PREPARE stmt;
```

1.1.1.5.2 Out Parameters in PREPARE

MariaDB 10.1.1

Out parameters in PREPARE were only available in MariaDB 10.1.1

One can use question mark placeholders for out-parameters in the PREPARE statement. Only SELECT ... INTO can be used this way:

```
prepare test from "select id into ? from t1 where val=?";
execute test using @out, @in;
```

This is particularly convenient when used with compound statements:

```
PREPARE stmt FROM "BEGIN NOT ATOMIC
  DECLARE v_res INT;
  SELECT COUNT(*) INTO v_res FROM t1;
  SELECT 'Hello World', v_res INTO ?,?;
END"|
```

1.1.1.2.14 EXECUTE STATEMENT

1.1.1.5.4 DEALLOCATE / DROP PREPARE

Syntax

```
{DEALLOCATE | DROP} PREPARE stmt_name
```

Description

To deallocate a prepared statement produced with `PREPARE`, use a `DEALLOCATE PREPARE` statement that refers to the prepared statement name.

A prepared statement is implicitly deallocated when a new `PREPARE` command is issued. In that case, there is no need to use `DEALLOCATE`.

Attempting to execute a prepared statement after deallocating it results in an error, as if it was not prepared at all:

```
ERROR 1243 (HY000): Unknown prepared statement handler (stmt_name) given to EXECUTE
```

If the specified statement has not been PREPAREd, an error similar to the following will be produced:

```
ERROR 1243 (HY000): Unknown prepared statement handler (stmt_name) given to DEALLOCATE PREPARE
```

Example

See example in PREPARE.

1.1.1.5.5 EXECUTE IMMEDIATE

MariaDB starting with 10.2.3
EXECUTE IMMEDIATE was introduced in MariaDB 10.2.3.

Syntax

```
EXECUTE IMMEDIATE statement
    [USING param[, param] ...]

param:
    expression | IGNORE | DEFAULT
```

Description

`EXECUTE IMMEDIATE` executes a dynamic SQL statement created on the fly, which can reduce performance overhead.

For example:

```
EXECUTE IMMEDIATE 'SELECT 1'
```

which is shorthand for:

```
prepare stmt from "select 1";
execute stmt;
deallocate prepare stmt;
```

EXECUTE IMMEDIATE supports complex expressions as prepare source and parameters:

```
EXECUTE IMMEDIATE CONCAT('SELECT COUNT(*) FROM ', 't1', ' WHERE a=?') USING 5+5;
```

Limitations: subselects and stored function calls are not supported as a prepare source.

The following examples return an error:

```
CREATE OR REPLACE FUNCTION f1() RETURNS VARCHAR(64) RETURN 'SELECT * FROM t1';
EXECUTE IMMEDIATE f1();
ERROR 1970 (42000): EXECUTE IMMEDIATE does not support subqueries or stored functions

EXECUTE IMMEDIATE (SELECT 'SELECT * FROM t1');
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
  corresponds to your MariaDB server version for the right syntax to use near
  'SELECT 'SELECT * FROM t1')' at line 1

CREATE OR REPLACE FUNCTION f1() RETURNS INT RETURN 10;
EXECUTE IMMEDIATE 'SELECT * FROM t1 WHERE a=?' USING f1();
ERROR 1970 (42000): EXECUTE..USING does not support subqueries or stored functions

EXECUTE IMMEDIATE 'SELECT * FROM t1 WHERE a=?' USING (SELECT 10);
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that
  corresponds to your MariaDB server version for the right syntax to use near
  'SELECT 10)' at line 1
```

One can use a user or an SP variable as a workaround:

```
CREATE OR REPLACE FUNCTION f1() RETURNS VARCHAR(64) RETURN 'SELECT * FROM t1';
SET @stmt=f1();
EXECUTE IMMEDIATE @stmt;

SET @stmt=(SELECT 'SELECT 1');
EXECUTE IMMEDIATE @stmt;

CREATE OR REPLACE FUNCTION f1() RETURNS INT RETURN 10;
SET @param=f1();
EXECUTE IMMEDIATE 'SELECT * FROM t1 WHERE a=?' USING @param;

SET @param=(SELECT 10);
EXECUTE IMMEDIATE 'SELECT * FROM t1 WHERE a=?' USING @param;
```

EXECUTE IMMEDIATE supports user variables and SP variables as OUT parameters

```
DELIMITER $$
CREATE OR REPLACE PROCEDURE p1(OUT a INT)
BEGIN
  SET a:= 10;
END;
$$
DELIMITER ;
SET @a=2;
EXECUTE IMMEDIATE 'CALL p1(?)' USING @a;
SELECT @a;
+------+
| @a   |
+------+
|   10 |
+------+
```

Similar to PREPARE, EXECUTE IMMEDIATE is allowed in stored procedures but is not allowed in stored functions.

This example uses EXECUTE IMMEDIATE inside a stored procedure:

```
DELIMITER $$
CREATE OR REPLACE PROCEDURE p1()
BEGIN
  EXECUTE IMMEDIATE 'SELECT 1';
END;
$$
DELIMITER ;
CALL p1;
+---+
| 1 |
+---+
| 1 |
+---+
```

This script returns an error:

```
DELIMITER $$
CREATE FUNCTION f1() RETURNS INT
BEGIN
  EXECUTE IMMEDIATE 'DO 1';
  RETURN 1;
END;
$$
ERROR 1336 (0A000): Dynamic SQL is not allowed in stored function or trigger
```

EXECUTE IMMEDIATE can use DEFAULT and IGNORE indicators as bind parameters:

```
CREATE OR REPLACE TABLE t1 (a INT DEFAULT 10);
EXECUTE IMMEDIATE 'INSERT INTO t1 VALUES (?)' USING DEFAULT;
SELECT * FROM t1;
+------+
| a    |
+------+
|   10 |
+------+
```

EXECUTE IMMEDIATE increments the Com_execute_immediate status variable, as well as the Com_stmt_prepare, Com_stmt_execute and Com_stmt_close status variables.

Note, EXECUTE IMMEDIATE does not increment the Com_execute_sql status variable. *Com_execute_sql* is used only for PREPARE..EXECUTE.

This session screenshot demonstrates how EXECUTE IMMEDIATE affects status variables:

```
SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS WHERE VARIABLE_NAME RLIKE
  ('COM_(EXECUTE|STMT_PREPARE|STMT_EXECUTE|STMT_CLOSE)');

+-----------------------+----------------+
| VARIABLE_NAME         | VARIABLE_VALUE |
+-----------------------+----------------+
| COM_EXECUTE_IMMEDIATE | 0              |
| COM_EXECUTE_SQL       | 0              |
| COM_STMT_CLOSE        | 0              |
| COM_STMT_EXECUTE      | 0              |
| COM_STMT_PREPARE      | 0              |
+-----------------------+----------------+

EXECUTE IMMEDIATE 'SELECT 1';
+---+
| 1 |
+---+
| 1 |
+---+

SELECT * FROM INFORMATION_SCHEMA.SESSION_STATUS WHERE VARIABLE_NAME RLIKE
  ('COM_(EXECUTE|STMT_PREPARE|STMT_EXECUTE|STMT_CLOSE)');
+-----------------------+----------------+
| VARIABLE_NAME         | VARIABLE_VALUE |
+-----------------------+----------------+
| COM_EXECUTE_IMMEDIATE | 1              |
| COM_EXECUTE_SQL       | 0              |
| COM_STMT_CLOSE        | 1              |
| COM_STMT_EXECUTE      | 1              |
| COM_STMT_PREPARE      | 1              |
+-----------------------+----------------+
```

1.1.1.6 Programmatic & Compound Statements

Compound statements in MariaDB can be used both inside and outside of stored programs.

Using Compound Statements Outside of Stored Programs

Compound statements are not just for stored programs.

BEGIN END

How to write compound statements.

CASE Statement

Conditional construct with multiple choices.

DECLARE CONDITION

For declaring a named error condition (SQLSTATE or error code).

DECLARE HANDLER

Construct to declare how errors are handled.

DECLARE Variable

Declare local variables within stored programs.

FOR

FOR loops allow code to be executed a fixed number of times.

GOTO

Jump to the given label.

IF

A basic conditional construct statement.

ITERATE

Used to repeat the execution of the current loop.

Labels

Identifiers used to identify a BEGIN ... END construct.

LEAVE

Used to exit a code block.

LOOP

Used to loop within a code block without a condition.

REPEAT LOOP

Used to repeat statements until a search condition is true.

RESIGNAL

Used to send a SIGNAL again for the previous error.

RETURN

Statement to terminate execution of a stored function and return a value.

SELECT INTO

SQL statement for inserting values into variables.

SET Variable

Used to insert a value into a variable with a code block.

SIGNAL

May be used to produce a custom error message.

WHILE

Used to repeat a block of SQL statements while a search condition is true.

Cursors

Structure for traversing and processing results, sequentially.

Diagnostics

Error conditions and statement information.

1.1.1.6.1 Using Compound Statements Outside of Stored Programs

Compound statements can also be used outside of stored programs.

```
delimiter |
IF @have_innodb THEN
  CREATE TABLE IF NOT EXISTS innodb_index_stats (
    database_name    VARCHAR(64) NOT NULL,
    table_name       VARCHAR(64) NOT NULL,
    index_name       VARCHAR(64) NOT NULL,
    last_update      TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    stat_name        VARCHAR(64) NOT NULL,
    stat_value       BIGINT UNSIGNED NOT NULL,
    sample_size      BIGINT UNSIGNED,
    stat_description VARCHAR(1024) NOT NULL,
    PRIMARY KEY (database_name, table_name, index_name, stat_name)
  ) ENGINE=INNODB DEFAULT CHARSET=utf8 COLLATE=utf8_bin STATS_PERSISTENT=0;
END IF|
Query OK, 0 rows affected, 2 warnings (0.00 sec)
```

Note, that using compound statements this way is subject to following limitations:

- Only BEGIN, IF, CASE, LOOP, WHILE, REPEAT statements may start a compound statement outside of stored programs.
- BEGIN must use the `BEGIN NOT ATOMIC` syntax (otherwise it'll be confused with BEGIN that starts a transaction).
- A compound statement might not start with a label.
- A compound statement is parsed completely—note "2 warnings" in the above example, even if the condition was false (InnoDB was, indeed, disabled), and the CREATE TABLE statement was not executed, it was still parsed and the parser produced "Unknown storage engine" warning.

Inside a compound block first three limitations do not apply, one can use anything that can be used inside a stored program — including labels, condition handlers, variables, and so on:

```
BEGIN NOT ATOMIC
    DECLARE foo CONDITION FOR 1146;
    DECLARE x INT DEFAULT 0;
    DECLARE CONTINUE HANDLER FOR SET x=1;
    INSERT INTO test.t1 VALUES ("hndlr1", val, 2);
    END|
```

Example how to use `IF` :

```
IF (1>0) THEN BEGIN NOT ATOMIC SELECT 1; END ; END IF;;
```

Example of how to use `WHILE` loop:

```
DELIMITER |
BEGIN NOT ATOMIC
    DECLARE x INT DEFAULT 0;
    WHILE x <= 10 DO
        SET x = x + 1;
        SELECT x;
    END WHILE;
END|
DELIMITER ;
```

1.1.1.6.2 BEGIN END

Syntax

```
[begin_label:] BEGIN [NOT ATOMIC]
    [statement_list]
END [end_label]
```

Contents

`NOT ATOMIC` is required when used outside of a stored procedure. Inside stored procedures or within an anonymous block, `BEGIN` alone starts a new anonymous block.

Description

`BEGIN ... END` syntax is used for writing compound statements. A compound statement can contain multiple statements, enclosed by the `BEGIN` and `END` keywords. statement_list represents a list of one or more statements, each terminated by a semicolon (i.e., `;`) statement delimiter. statement_list is optional, which means that the empty compound statement (`BEGIN END`) is legal.

Note that `END` will perform a commit. If you are running in autocommit mode, every statement will be committed separately. If you are not running in `autocommit` mode, you must execute a COMMIT or ROLLBACK after `END` to get the database up to date.

Use of multiple statements requires that a client is able to send statement strings containing the ; statement delimiter. This is handled in the mysql command-line client with the DELIMITER command. Changing the `;` end-of-statement delimiter (for example, to `//`) allows `;` to be used in a program body.

A compound statement within a stored program can be labeled. `end_label` cannot be given unless `begin_label` also is present. If both are present, they must be the same.

`BEGIN ... END` constructs can be nested. Each block can define its own variables, a `CONDITION` , a `HANDLER` and a CURSOR, which don't exist in the outer blocks. The most local declarations override the outer objects which use the same name (see example below).

The declarations order is the following:

- `DECLARE` local variables;
- `DECLARE CONDITION` s;
- `DECLARE CURSOR` s;
- `DECLARE HANDLER` s;

Note that `DECLARE HANDLER` contains another `BEGIN ... END` construct.

Here is an example of a very simple, anonymous block:

```
BEGIN NOT ATOMIC
SET @a=1;
CREATE TABLE test.t1(a INT);
END|
```

Below is an example of nested blocks in a stored procedure:

```
CREATE PROCEDURE t( )
BEGIN
   DECLARE x TINYINT UNSIGNED DEFAULT 1;
   BEGIN
      DECLARE x CHAR(2) DEFAULT '02';
       DECLARE y TINYINT UNSIGNED DEFAULT 10;
       SELECT x, y;
   END;
   SELECT x;
END;
```

In this example, a TINYINT variable, `x` is declared in the outter block. But in the inner block `x` is re-declared as a CHAR and an `y` variable is declared. The inner SELECT shows the "new" value of `x` , and the value of `y` . But when x is selected in the outer block, the "old" value is returned. The final SELECT doesn't try to read `y` , because it doesn't exist in that context.

1.1.1.6.3 CASE Statement

Syntax

```
CASE case_value
    WHEN when_value THEN statement_list
    [WHEN when_value THEN statement_list] ...
    [ELSE statement_list]
END CASE
```

Or:

```
CASE
    WHEN search_condition THEN statement_list
    [WHEN search_condition THEN statement_list] ...
    [ELSE statement_list]
END CASE
```

Description

The text on this page describes the `CASE` statement for stored programs. See the CASE OPERATOR for details on the CASE operator outside of stored programs.

The `CASE` statement for stored programs implements a complex conditional construct. If a `search_condition` evaluates to true, the corresponding SQL statement list is executed. If no search condition matches, the statement list in the `ELSE` clause is executed. Each `statement_list` consists of one or more statements.

The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`. implements a complex conditional construct. If a `search_condition` evaluates to true, the corresponding SQL statement list is executed. If no search condition matches, the statement list in the `ELSE` clause is executed. Each `statement_list` consists of one or more statements.

If no when_value or search_condition matches the value tested and the `CASE` statement contains no `ELSE` clause, a Case not found for `CASE` statement error results.

Each statement_list consists of one or more statements; an empty `statement_list` is not allowed. To handle situations where no value is matched by any `WHEN` clause, use an `ELSE` containing an empty BEGIN ... END block, as shown in this example:

```
DELIMITER |
CREATE PROCEDURE p()
BEGIN
  DECLARE v INT DEFAULT 1;
  CASE v
    WHEN 2 THEN SELECT v;
    WHEN 3 THEN SELECT 0;
    ELSE BEGIN END;
  END CASE;
END;
|
```

The indentation used here in the `ELSE` clause is for purposes of clarity only, and is not otherwise significant. See Delimiters in the mariadb client for more on the use of the delimiter command.

Note: The syntax of the `CASE` statement used inside stored programs differs slightly from that of the SQL CASE expression described in CASE OPERATOR. The `CASE` statement cannot have an `ELSE NULL` clause, and it is terminated with `END CASE` instead of `END`.

1.1.1.6.4 DECLARE CONDITION

Syntax

```
DECLARE condition_name CONDITION FOR condition_value

condition_value:
    SQLSTATE [VALUE] sqlstate_value
  | mysql_error_code
```

Description

The `DECLARE ... CONDITION` statement defines a named error condition. It specifies a condition that needs specific handling and associates a name with that condition. Later, the name can be used in a DECLARE ... HANDLER, SIGNAL or RESIGNAL statement (as long as the statement is located in the same BEGIN ... END block).

Conditions must be declared after local variables, but before CURSORs and HANDLERs.

A condition_value for `DECLARE ... CONDITION` can be an SQLSTATE value (a 5-character string literal) or a MySQL error code (a number). You should not use SQLSTATE value '00000' or MySQL error code 0, because those indicate sucess rather than an error condition. If you try, or if you specify an invalid SQLSTATE value, an error like this is produced:

```
ERROR 1407 (42000): Bad SQLSTATE: '00000'
```

For a list of SQLSTATE values and MariaDB error codes, see MariaDB Error Codes.

1.1.1.6.5 DECLARE HANDLER

Syntax

```
DECLARE handler_type HANDLER
    FOR condition_value [, condition_value] ...
    statement

handler_type:
    CONTINUE
  | EXIT
  | UNDO

condition_value:
    SQLSTATE [VALUE] sqlstate_value
  | condition_name
  | SQLWARNING
  | NOT FOUND
  | SQLEXCEPTION
  | mariadb_error_code
```

Description

The `DECLARE ... HANDLER` statement specifies handlers that each may deal with one or more conditions. If one of these conditions occurs, the specified statement is executed. statement can be a simple statement (for example, `SET var_name = value`), or it can be a compound statement written using BEGIN and END.

Handlers must be declared after local variables, a `CONDITION` and a CURSOR.

For a `CONTINUE` handler, execution of the current program continues after execution of the handler statement. For an EXIT handler, execution terminates for the BEGIN ... END compound statement in which the handler is declared. (This is true even if the condition occurs in an inner block.) The `UNDO` handler type statement is not supported.

If a condition occurs for which no handler has been declared, the default action is `EXIT` .

A condition_value for `DECLARE ... HANDLER` can be any of the following values:

- An SQLSTATE value (a 5-character string literal) or a MariaDB error code (a number). You should not use `SQLSTATE` value '00000' or MariaDB error code 0, because those indicate sucess rather than an error condition. For a list of `SQLSTATE` values and MariaDB error codes, see MariaDB Error Codes.
- A condition name previously specified with `DECLARE ... CONDITION` . It must be in the same stored program. See DECLARE CONDITION.
- `SQLWARNING` is shorthand for the class of SQLSTATE values that begin with '01'.
- `NOT FOUND` is shorthand for the class of `SQLSTATE` values that begin with '02'. This is relevant only the context of cursors and is used to control what happens when a cursor reaches the end of a data set. If no more rows are available, a No Data condition occurs with `SQLSTATE` value 02000. To detect this condition, you can set up a handler for it (or for a `NOT FOUND` condition). An example is shown in Cursor Overview. This condition also occurs for SELECT ... INTO var_list statements that retrieve no rows.
- SQLEXCEPTION is shorthand for the class of SQLSTATE values that do not begin with '00', '01', or '02'.

When an error raises, in some cases it could be handled by multiple `HANDLER`s. For example, there may be an handler for 1050 error, a separate handler for the 42S01 SQLSTATE, and another separate handler for the `SQLEXCEPTION` class: in theory all occurrences of `HANDLER` may catch the 1050 error, but MariaDB chooses the `HANDLER` with the highest precedence. Here are the precedence rules:

- Handlers which refer to an error code have the highest precedence.
- Handlers which refer to a SQLSTATE come next.
- Handlers which refer to an error class have the lowest precedence.

In some cases, a statement could produce multiple errors. If this happens, in some cases multiple handlers could have the highest precedence. In such cases, the choice of the handler is indeterminate.

Note that if an error occurs within a `CONTINUE HANDLER` block, it can be handled by another `HANDLER`. However, a `HANDLER` which is already in the stack (that is, it has been called to handle an error and its execution didn't finish yet) cannot handle new errors—this prevents endless loops. For example, suppose that a stored procedure contains a `CONTINUE HANDLER` for `SQLWARNING` and another `CONTINUE HANDLER` for `NOT FOUND`. At some point, a NOT FOUND error occurs, and the execution enters the `NOT FOUND HANDLER`. But within that handler, a warning occurs, and the execution enters the `SQLWARNING HANDLER`. If another `NOT FOUND` error occurs, it cannot be handled again by the `NOT FOUND HANDLER`, because its execution is not finished.

When a `DECLARE HANDLER` block can handle more than one error condition, it may be useful to know which errors occurred. To do so, you can use the GET DIAGNOSTICS statement.

An error that is handled by a `DECLARE HANDLER` construct can be issued again using the RESIGNAL statement.

Below is an example using `DECLARE HANDLER`:

```
CREATE TABLE test.t (s1 INT, PRIMARY KEY (s1));

DELIMITER //

CREATE PROCEDURE handlerdemo ( )
     BEGIN
       DECLARE CONTINUE HANDLER FOR SQLSTATE '23000' SET @x2 = 1;
       SET @x = 1;
       INSERT INTO test.t VALUES (1);
       SET @x = 2;
       INSERT INTO test.t VALUES (1);
       SET @x = 3;
     END;
     //

DELIMITER ;

CALL handlerdemo( );

SELECT @x;
+------+
| @x   |
+------+
|    3 |
+------+
```

1.1.1.6.6 DECLARE Variable

Syntax

```
DECLARE var_name [, var_name] ... [[ROW] TYPE OF]] type [DEFAULT value]
```

Contents

Description

This statement is used to declare local variables within stored programs. To provide a default value for the variable, include a `DEFAULT` clause. The value can be specified as an expression (even subqueries are permitted); it need not be a constant. If the `DEFAULT` clause is missing, the initial value is `NULL`.

Local variables are treated like stored routine parameters with respect to data type and overflow checking. See CREATE PROCEDURE.

Local variables must be declared before `CONDITION`s, CURSORs and `HANDLER`s.

Local variable names are not case sensitive.

The scope of a local variable is within the `BEGIN ... END` block where it is declared. The variable can be referred to in blocks nested within the declaring block, except those blocks that declare a variable with the same name.

TYPE OF / ROW TYPE OF

MariaDB starting with 10.3

`TYPE OF` and `ROW TYPE OF` anchored data types for stored routines were introduced in MariaDB 10.3.

Anchored data types allow a data type to be defined based on another object, such as a table row, rather than specifically set in the declaration. If the anchor object changes, so will the anchored data type. This can lead to routines being easier to maintain, so that if the data type in the table is changed, it will automatically be changed in the routine as well.

Variables declared with `ROW TYPE OF` will have the same features as implicit ROW variables. It is not possible to use `ROW TYPE OF` variables in a LIMIT clause.

The real data type of `TYPE OF` and `ROW TYPE OF table_name` will become known at the very beginning of the stored routine call. ALTER TABLE or DROP TABLE statements performed inside the current routine on the tables that appear in anchors won't affect the data type of the anchored variables, even if the variable is declared after an ALTER TABLE or DROP TABLE statement.

The real data type of a `ROW TYPE OF cursor_name` variable will become known when execution enters into the block where the variable is declared. Data type instantiation will happen only once. In a cursor `ROW TYPE OF` variable that is declared inside a loop, its data type will become known on the very first iteration and won't change on further loop iterations.

The tables referenced in `TYPE OF` and `ROW TYPE OF` declarations will be checked for existence at the beginning of the stored routine call. CREATE PROCEDURE or CREATE FUNCTION will not check the referenced tables for existence.

Examples

`TYPE OF` and `ROW TYPE OF` from MariaDB 10.3:

```
DECLARE tmp TYPE OF t1.a; -- Get the data type from the column {{a}} in the table {{t1}}

DECLARE rec1 ROW TYPE OF t1; -- Get the row data type from the table {{t1}}

DECLARE rec2 ROW TYPE OF cur1; -- Get the row data type from the cursor {{cur1}}
```

1.1.1.6.7 FOR

MariaDB starting with 10.3

FOR loops were introduced in MariaDB 10.3.

Syntax

Integer range FOR loop:

```
[begin_label:]
FOR var_name IN [ REVERSE ] lower_bound .. upper_bound
DO statement_list
END FOR [ end_label ]
```

Explicit cursor FOR loop

```
[begin_label:]
FOR record_name IN cursor_name [ ( cursor_actual_parameter_list)]
DO statement_list
END FOR [ end_label ]
```

Explicit cursor FOR loop (Oracle mode)

```
[begin_label:]
FOR record_name IN cursor_name [ ( cursor_actual_parameter_list)]
LOOP
  statement_list
END LOOP [ end_label ]
```

Implicit cursor FOR loop

```
[begin_label:]
FOR record_name IN ( select_statement )
DO statement_list
END FOR [ end_label ]
```

Contents

Description

FOR loops allow code to be executed a fixed number of times.

In an integer range FOR loop, MariaDB will compare the lower bound and upper bound values, and assign the lower bound value to a counter. If REVERSE is not specified, and the upper bound value is greater than or equal to the counter, the counter will be incremented and the statement will continue, after which the loop is entered again. If the upper bound value is greater than the counter, the loop will be exited.

If REVERSE is specified, the counter is decremented, and the upper bound value needs to be less than or equal for the loop to continue.

Examples

Intger range FOR loop:

```
CREATE TABLE t1 (a INT);

DELIMITER //

FOR i IN 1..3
DO
  INSERT INTO t1 VALUES (i);
END FOR;
//

DELIMITER ;

SELECT * FROM t1;
+------+
| a    |
+------+
|    1 |
|    2 |
|    3 |
+------+
```

REVERSE integer range FOR loop:

```
CREATE OR REPLACE TABLE t1 (a INT);

DELIMITER //
FOR i IN REVERSE 4..12
    DO
    INSERT INTO t1 VALUES (i);
END FOR;
//
Query OK, 9 rows affected (0.422 sec)

DELIMITER ;

SELECT * FROM t1;
+------+
| a    |
+------+
|   12 |
|   11 |
|   10 |
|    9 |
|    8 |
|    7 |
|    6 |
|    5 |
|    4 |
+------+
```

Explicit cursor in Oracle mode:

```
SET sql_mode=ORACLE;

CREATE OR REPLACE TABLE t1 (a INT, b VARCHAR(32));

INSERT INTO t1 VALUES (10,'b0');
INSERT INTO t1 VALUES (11,'b1');
INSERT INTO t1 VALUES (12,'b2');

DELIMITER //

CREATE OR REPLACE PROCEDURE p1(pa INT) AS
  CURSOR cur(va INT) IS
    SELECT a, b FROM t1 WHERE a=va;
BEGIN
  FOR rec IN cur(pa)
  LOOP
    SELECT rec.a, rec.b;
  END LOOP;
END;
//

DELIMITER ;

CALL p1(10);
+-------+-------+
| rec.a | rec.b |
+-------+-------+
|    10 | b0    |
+-------+-------+

CALL p1(11);
+-------+-------+
| rec.a | rec.b |
+-------+-------+
|    11 | b1    |
+-------+-------+

CALL p1(12);
+-------+-------+
| rec.a | rec.b |
+-------+-------+
|    12 | b2    |
+-------+-------+

CALL p1(13);
Query OK, 0 rows affected (0.000 sec)
```

1.1.1.6.8 GOTO

MariaDB starting with 10.3

The GOTO statement was introduced in MariaDB 10.3 for Oracle compatibility.

Syntax

```
GOTO label
```

Contents

Description

The `GOTO` statement causes the code to jump to the specified label, and continue operating from there. It is only accepted when in Oracle mode.

Example

```
SET sql_mode=ORACLE;

DELIMITER //

CREATE OR REPLACE PROCEDURE p1 AS

BEGIN

  SELECT 1;
  GOTO label;
  SELECT 2;
  <<label>>
  SELECT 3;

END;

//

DELIMITER

call p1();
+---+
| 1 |
+---+
| 1 |
+---+
1 row in set (0.000 sec)

+---+
| 3 |
+---+
| 3 |
+---+
1 row in set (0.000 sec)
```

1.1.1.6.9 IF

Syntax

```
IF search_condition THEN statement_list
    [ELSEIF search_condition THEN statement_list] ...
    [ELSE statement_list]
END IF;
```

Description

`IF` implements a basic conditional construct. If the `search_condition` evaluates to true, the corresponding SQL statement list is executed. If no `search_condition` matches, the statement list in the `ELSE` clause is executed. Each statement_list consists of one or more statements.

1.1.1.6.10 ITERATE

Syntax

```
ITERATE label
```

`ITERATE` can appear only within LOOP, REPEAT, and WHILE statements. `ITERATE` means "do the loop again", and uses the statement's label to determine which statements to repeat. The label must be in the same stored program, not in a caller procedure.

If you try to use `ITERATE` with a non-existing label, or if the label is associated to a construct which is not a loop, the following error will be produced:

```
ERROR 1308 (42000): ITERATE with no matching label: <label_name>
```

Below is an example of how `ITERATE` might be used:

```
CREATE PROCEDURE doiterate(p1 INT)
BEGIN
  label1: LOOP
    SET p1 = p1 + 1;
    IF p1 < 10 THEN ITERATE label1; END IF;
    LEAVE label1;
  END LOOP label1;
  SET @x = p1;
END
```

1.1.1.6.11 Labels

Syntax

```
label: <construct>
[label]
```

Labels are MariaDB identifiers which can be used to identify a `BEGIN ... END` construct or a loop. They have a maximum length of 16 characters and can be quoted with backticks (i.e.., `` ` ``).

Labels have a start part and an end part. The start part must precede the portion of code it refers to, must be followed by a colon (`:`) and can be on the same or different line. The end part is optional and adds nothing, but can make the code more readable. If used, the end part must precede the construct's delimiter (`;`). Constructs identified by a label can be nested. Each construct can be identified by only one label.

Labels need not be unique in the stored program they belong to. However, a label for an inner loop cannot be identical to a label for an outer loop. In this case, the following error would be produced:

```
ERROR 1309 (42000): Redefining label <label_name>
```

LEAVE and ITERATE statements can be used to exit or repeat a portion of code identified by a label. They must be in the same Stored Routine, Trigger or Event which contains the target label.

Below is an example using a simple label that is used to exit a LOOP:

```
CREATE PROCEDURE `test_sp`()
BEGIN
   `my_label`:
   LOOP
      SELECT 'looping';
      LEAVE `my_label`;
   END LOOP;
   SELECT 'out of loop';
END;
```

The following label is used to exit a procedure, and has an end part:

```
CREATE PROCEDURE `test_sp`()
`my_label`:
BEGIN
   IF @var = 1 THEN
      LEAVE `my_label`;
   END IF;
   DO something();
END `my_label`;
```

1.1.1.6.12 LEAVE

Syntax

```
LEAVE label
```

This statement is used to exit the flow control construct that has the given label. The label must be in the same stored program, not in a caller procedure. `LEAVE` can be used within BEGIN ... END or loop constructs (LOOP, REPEAT, WHILE). In Stored Procedures, Triggers and Events, LEAVE can refer to the outmost BEGIN ... END construct; in that case, the program exits the procedure. In Stored Functions, RETURN can be used instead.

Note that LEAVE cannot be used to exit a DECLARE HANDLER block.

If you try to LEAVE a non-existing label, or if you try to LEAVE a HANDLER block, the following error will be produced:

```
ERROR 1308 (42000): LEAVE with no matching label: <label_name>
```

The following example uses `LEAVE` to exit the procedure if a condition is true:

```
CREATE PROCEDURE proc(IN p TINYINT)
CONTAINS SQL
`whole_proc`:
BEGIN
   SELECT 1;
   IF p < 1 THEN
      LEAVE `whole_proc`;
   END IF;
   SELECT 2;
END;

CALL proc(0);
+---+
| 1 |
+---+
| 1 |
+---+
```

1.1.1.6.13 LOOP

Syntax

```
[begin_label:] LOOP
    statement_list
END LOOP [end_label]
```

Contents

Description

`LOOP` implements a simple loop construct, enabling repeated execution of the statement list, which consists of one or more statements, each terminated by a semicolon (i.e., `;`) statement delimiter. The statements within the loop are repeated until the loop is exited; usually this is accomplished with a LEAVE statement.

A `LOOP` statement can be labeled. `end_label` cannot be given unless `begin_label` also is present. If both are present, they must be the same.

See Delimiters in the mariadb client for more on delimiter usage in the client.

1.1.1.6.14 REPEAT LOOP

Syntax

```
[begin_label:] REPEAT
    statement_list
UNTIL search_condition
END REPEAT [end_label]
```

The statement list within a `REPEAT` statement is repeated until the search_condition is true. Thus, a `REPEAT` always enters the loop at least once. statement_list consists of one or more statements, each terminated by a semicolon (i.e., `;`) statement delimiter.

A `REPEAT` statement can be labeled. end_label cannot be given unless begin_label also is present. If both are present, they must be the same.

See Delimiters in the mariadb client for more on client delimiter usage.

```
DELIMITER //

CREATE PROCEDURE dorepeat(p1 INT)
  BEGIN
    SET @x = 0;
    REPEAT SET @x = @x + 1; UNTIL @x > p1 END REPEAT;
  END
//

CALL dorepeat(1000)//

SELECT @x//
+------+
| @x   |
+------+
| 1001 |
+------+
```

1.1.1.6.15 RESIGNAL

Syntax

```
RESIGNAL [error_condition]
    [SET error_property
    [, error_property] ...]

error_condition:
    SQLSTATE [VALUE] 'sqlstate_value'
  | condition_name

error_property:
    error_property_name = <error_property_value>

error_property_name:
    CLASS_ORIGIN
  | SUBCLASS_ORIGIN
  | MESSAGE_TEXT
  | MYSQL_ERRNO
  | CONSTRAINT_CATALOG
  | CONSTRAINT_SCHEMA
  | CONSTRAINT_NAME
  | CATALOG_NAME
  | SCHEMA_NAME
  | TABLE_NAME
  | COLUMN_NAME
  | CURSOR_NAME
```

Contents

Description

The syntax of `RESIGNAL` and its semantics are very similar to SIGNAL. This statement can only be used within an error HANDLER. It produces an error, like SIGNAL. `RESIGNAL` clauses are the same as SIGNAL, except that they all are optional, even SQLSTATE. All the properties which are not specified in `RESIGNAL`, will be identical to the properties of the error that was received by the error HANDLER. For a description of the clauses, see diagnostics area.

Note that `RESIGNAL` does not empty the diagnostics area: it just appends another error condition.

`RESIGNAL`, without any clauses, produces an error which is identical to the error that was received by HANDLER.

If used out of a HANDLER construct, RESIGNAL produces the following error:

```
ERROR 1645 (0K000): RESIGNAL when handler not active
```

In MariaDB 5.5, if a HANDLER contained a CALL to another procedure, that procedure could use `RESIGNAL`. Since MariaDB 10.0, trying to do this raises the above error.

For a list of `SQLSTATE` values and MariaDB error codes, see MariaDB Error Codes.

The following procedure tries to query two tables which don't exist, producing a 1146 error in both cases. Those errors will trigger the HANDLER. The first time the error will be ignored and the client will not receive it, but the second time, the error is re-signaled, so the client will receive it.

```
CREATE PROCEDURE test_error( )
BEGIN
   DECLARE CONTINUE HANDLER
      FOR 1146
   BEGIN
   IF @hide_errors IS FALSE THEN
      RESIGNAL;
   END IF;
   END;
   SET @hide_errors = TRUE;
   SELECT 'Next error will be ignored' AS msg;
   SELECT `c` FROM `temptab_one`;
   SELECT 'Next error won''t be ignored' AS msg;
   SET @hide_errors = FALSE;
   SELECT `c` FROM `temptab_two`;
END;

CALL test_error( );

+----------------------------+
| msg                        |
+----------------------------+
| Next error will be ignored |
+----------------------------+

+-----------------------------+
| msg                         |
+-----------------------------+
| Next error won't be ignored |
+-----------------------------+

ERROR 1146 (42S02): Table 'test.temptab_two' doesn't exist
```

The following procedure re-signals an error, modifying only the error message to clarify the cause of the problem.

```
CREATE PROCEDURE test_error()
BEGIN
   DECLARE CONTINUE HANDLER
   FOR 1146
   BEGIN
      RESIGNAL SET
      MESSAGE_TEXT = '`temptab` does not exist';
   END;
   SELECT `c` FROM `temptab`;
END;

CALL test_error( );
ERROR 1146 (42S02): `temptab` does not exist
```

As explained above, this works on MariaDB 5.5, but produces a 1645 error since 10.0.

```
CREATE PROCEDURE handle_error()
BEGIN
  RESIGNAL;
END;
CREATE PROCEDURE p()
BEGIN
  DECLARE EXIT HANDLER FOR SQLEXCEPTION CALL p();
  SIGNAL SQLSTATE '45000';
END;
```

1.1.1.6.16 RETURN

Syntax

```
RETURN expr
```

The `RETURN` statement terminates execution of a stored function and returns the value *`expr`* to the function caller. There must be at least one `RETURN` statement in a stored function. If the function has multiple exit points, all exit points must have a `RETURN`.

This statement is not used in stored procedures, triggers, or events. LEAVE can be used instead.

The following example shows that `RETURN` can return the result of a scalar subquery:

```
CREATE FUNCTION users_count() RETURNS BOOL
   READS SQL DATA
BEGIN
   RETURN (SELECT COUNT(DISTINCT User) FROM mysql.user);
END;
```

1.1.1.6.17 SELECT INTO

Syntax

```
SELECT col_name [, col_name] ...
    INTO var_name [, var_name] ...
    table_expr
```

Contents

Description

SELECT ... INTO enables selected columns to be stored directly into variables. No resultset is produced. The query should return a single row. If the query returns no rows, a warning with error code 1329 occurs (No data), and the variable values remain unchanged. If the query returns multiple rows, error 1172 occurs (Result consisted of more than one row). If it is possible that the statement may retrieve multiple rows, you can use `LIMIT 1` to limit the result set to a single row.

The INTO clause can also be specified at the end of the statement.

In the context of such statements that occur as part of events executed by the Event Scheduler, diagnostics messages (not only errors, but also warnings) are written to the error log, and, on Windows, to the application event log.

This statement can be used with both local variables and user-defined variables.

For the complete syntax, see SELECT.

Another way to set a variable's value is the SET statement.

`SELECT ... INTO` results are not stored in the query cache even if `SQL_CACHE` is specified.

Examples

```
SELECT id, data INTO @x,@y
FROM test.t1 LIMIT 1;
SELECT * from t1 where t1.a=@x and t1.b=@y
```

If you want to use this construct with `UNION` you have to use the syntax:

```
SELECT  * INTO @x FROM (SELECT t1.a FROM t1 UNION SELECT t2.a FROM t2) dt;
```

1.1.1.2.7.10 SET Variable

1.1.1.6.19 SIGNAL

Syntax

```
SIGNAL error_condition
    [SET error_property
    [, error_property] ...]

error_condition:
    SQLSTATE [VALUE] 'sqlstate_value'
  | condition_name

error_property:
    error_property_name = <error_property_value>

error_property_name:

`SIGNAL` empties the diagnostics area and produces a custom error. This statement can be used anywhere, but is

generally useful when used inside a stored program. When the error is produced, it can be caught by a HANDLER. If not, the current stored program, or the current statement, will terminate with the specified error.

Sometimes an error HANDLER just needs to SIGNAL the same error it received, optionally with some changes. Usually the RESIGNAL statement is the most convenient way to do this.

`error_condition` can be an SQLSTATE value or a named error condition defined via DECLARE CONDITION. SQLSTATE must be a constant string consisting of five characters. These codes are standard to ODBC and ANSI SQL. For customized errors, the recommended SQLSTATE is '45000'. For a list of SQLSTATE values used by MariaDB, see the MariaDB Error Codes page. The SQLSTATE can be read via the API method `mysql_sqlstate( )`.

To specify error properties user-defined variables and local variables can be used, as well as character set conversions (but you can't set a collation).

The error properties, their type and their default values are explained in the diagnostics area page.

Errors

If the SQLSTATE is not valid, the following error like this will be produced:

```
ERROR 1407 (42000): Bad SQLSTATE: '123456'
```

If a property is specified more than once, an error like this will be produced:

```
ERROR 1641 (42000): Duplicate condition information item 'MESSAGE_TEXT'
```

If you specify a condition name which is not declared, an error like this will be produced:

```
ERROR 1319 (42000): Undefined CONDITION: cond_name
```

If MYSQL_ERRNO is out of range, you will get an error like this:

```
ERROR 1231 (42000): Variable 'MYSQL_ERRNO' can't be set to the value of '0'
```

Examples

Here's what happens if SIGNAL is used in the client to generate errors:

```
SIGNAL SQLSTATE '01000';
Query OK, 0 rows affected, 1 warning (0.00 sec)

SHOW WARNINGS;

+---------+------+----------------------------------------+
| Level   | Code | Message                                |
+---------+------+----------------------------------------+
| Warning | 1642 | Unhandled user-defined warning condition |
+---------+------+----------------------------------------+
1 row in set (0.06 sec)

SIGNAL SQLSTATE '02000';
ERROR 1643 (02000): Unhandled user-defined not found condition
```

How to specify MYSQL_ERRNO and MESSAGE_TEXT properties:

```
SIGNAL SQLSTATE '45000' SET MYSQL_ERRNO=30001, MESSAGE_TEXT='H
ello, world!';

ERROR 30001 (45000): Hello, world!
```

The following code shows how to use user variables, local variables and character set conversion with SIGNAL:

```
CREATE PROCEDURE test_error(x INT)
BEGIN
   DECLARE errno SMALLINT UNSIGNED DEFAULT 31001;
   SET @errmsg = 'Hello, world!';
   IF x = 1 THEN
      SIGNAL SQLSTATE '45000' SET
      MYSQL_ERRNO = errno,
      MESSAGE_TEXT = @errmsg;
   ELSE
      SIGNAL SQLSTATE '45000' SET
      MYSQL_ERRNO = errno,
      MESSAGE_TEXT = _utf8'Hello, world!';
   END IF;
END;
```

How to use named error conditions:

```
CREATE PROCEDURE test_error(n INT)
BEGIN
   DECLARE `too_big` CONDITION FOR SQLSTATE '45000';
   IF n > 10 THEN
      SIGNAL `too_big`;
   END IF;
END;
```

In this example, we'll define a HANDLER for an error code. When the error occurs, we SIGNAL a more informative error which makes sense for our procedure:

```
CREATE PROCEDURE test_error()
BEGIN
   DECLARE EXIT HANDLER
   FOR 1146
   BEGIN
      SIGNAL SQLSTATE '45000' SET
      MESSAGE_TEXT = 'Temporary tables not found; did you call init() procedure?';
   END;
   -- this will produce a 1146 error
   SELECT `c` FROM `temptab`;
END;
```

1.1.1.6.20 WHILE

Syntax

```
[begin_label:] WHILE search_condition DO
    statement_list
END WHILE [end_label]
```

Description

The statement list within a `WHILE` statement is repeated as long as the `search_condition` is true. statement_list consists of one or more statements. If the loop must be executed at least once, `REPEAT ... LOOP` can be used instead.

A `WHILE` statement can be labeled. end_label cannot be given unless begin_label also is present. If both are present, they must be the same.

Examples

```
CREATE PROCEDURE dowhile()
BEGIN
  DECLARE v1 INT DEFAULT 5;

  WHILE v1 > 0 DO
    ...
    SET v1 = v1 - 1;
  END WHILE;
END
```

1.1.1.6.21 Cursors

A cursor is a structure that allows you to go over records sequentially, and perform processing based on the result.

Cursor Overview

Structure for traversing and processing results sequentially.

DECLARE CURSOR

Declares a cursor which can be used inside stored programs.

OPEN

Open a previously declared cursor.

FETCH

Fetch a row from a cursor.

CLOSE

Close a previously opened cursor.

There are 1 related questions.

1.1.1.6.21.1 Cursor Overview

Contents

Description

A cursor is a structure that allows you to go over records sequentially, and perform processing based on the result.

MariaDB permits cursors inside stored programs, and MariaDB cursors are non-scrollable, read-only and asensitive.

- Non-scrollable means that the rows can only be fetched in the order specified by the SELECT statement. Rows cannot be skipped, you cannot jump to a specific row, and you cannot fetch rows in reverse order.
- Read-only means that data cannot be updated through the cursor.
- Asensitive means that the cursor points to the actual underlying data. This kind of cursor is quicker than the alternative, an insensitive cursor, as no data is copied to a temporary table. However, changes to the data being used by the cursor will affect the cursor data.

Cursors are created with a DECLARE CURSOR statement and opened with an OPEN statement. Rows are read with a FETCH statement before the cursor is finally closed with a CLOSE statement.

When FETCH is issued and there are no more rows to extract, the following error is produced:

```
ERROR 1329 (02000): No data - zero rows fetched, selected, or processed
```

To avoid problems, a DECLARE HANDLER statement is generally used. The HANDLER should handler the 1329 error, or the '02000' SQLSTATE, or the NOT FOUND error class.

Only SELECT statements are allowed for cursors, and they cannot be contained in a variable - so, they cannot be composed dynamically. However, it is possible to SELECT from a view. Since the CREATE VIEW statement can be executed as a prepared statement, it is possible to dynamically create the view that is queried by the cursor.

From MariaDB 10.3.0, cursors can have parameters. Cursor parameters can appear in any part of the DECLARE CURSOR select_statement where a stored procedure variable is allowed (select list, WHERE, HAVING, LIMIT etc). See DECLARE CURSOR and OPEN for syntax, and below for an example:

Examples

```
CREATE TABLE c1(i INT);

CREATE TABLE c2(i INT);

CREATE TABLE c3(i INT);

DELIMITER //

CREATE PROCEDURE p1()
BEGIN
  DECLARE done INT DEFAULT FALSE;
  DECLARE x, y INT;
  DECLARE cur1 CURSOR FOR SELECT i FROM test.c1;
  DECLARE cur2 CURSOR FOR SELECT i FROM test.c2;
  DECLARE CONTINUE HANDLER FOR NOT FOUND SET done = TRUE;

  OPEN cur1;
  OPEN cur2;

  read_loop: LOOP
    FETCH cur1 INTO x;
    FETCH cur2 INTO y;
    IF done THEN
      LEAVE read_loop;
    END IF;
    IF x < y THEN
      INSERT INTO test.c3 VALUES (x);
    ELSE
      INSERT INTO test.c3 VALUES (y);
    END IF;
  END LOOP;

  CLOSE cur1;
  CLOSE cur2;
END; //

DELIMITER ;

INSERT INTO c1 VALUES(5),(50),(500);

INSERT INTO c2 VALUES(10),(20),(30);

CALL p1;

SELECT * FROM c3;
+------+
| i    |
+------+
|    5 |
|   20 |
|   30 |
+------+
```

From MariaDB 10.3.0

```
DROP PROCEDURE IF EXISTS p1;
DROP TABLE IF EXISTS t1;
CREATE TABLE t1 (a INT, b VARCHAR(10));

INSERT INTO t1 VALUES (1,'old'),(2,'old'),(3,'old'),(4,'old'),(5,'old');

DELIMITER //

CREATE PROCEDURE p1(min INT,max INT)
BEGIN
  DECLARE done INT DEFAULT FALSE;
  DECLARE va INT;
  DECLARE cur CURSOR(pmin INT, pmax INT) FOR SELECT a FROM t1 WHERE a BETWEEN pmin AND pmax;
  DECLARE CONTINUE HANDLER FOR NOT FOUND SET done=TRUE;
  OPEN cur(min,max);
  read_loop: LOOP
    FETCH cur INTO va;
    IF done THEN
      LEAVE read_loop;
    END IF;
    INSERT INTO t1 VALUES (va,'new');
  END LOOP;
  CLOSE cur;
END;
//

DELIMITER ;

CALL p1(2,4);

SELECT * FROM t1;
+------+------+
| a    | b    |
+------+------+
|    1 | old  |
|    2 | old  |
|    3 | old  |
|    4 | old  |
|    5 | old  |
|    2 | new  |
|    3 | new  |
|    4 | new  |
+------+------+
```

1.1.1.6.21.2 DECLARE CURSOR

Syntax

<= MariaDB 10.2

```
DECLARE cursor_name CURSOR FOR select_statement
```

From MariaDB 10.3

```
DECLARE cursor_name CURSOR [(cursor_formal_parameter[,...])] FOR select_statement

cursor_formal_parameter:
    name type [collate clause]
```

From MariaDB 10.8

```
DECLARE cursor_name CURSOR [(cursor_formal_parameter[,...])] FOR select_statement

cursor_formal_parameter:
    [IN] name type [collate clause]
```

Contents
1. Syntax
2. Description
   1. Parameters
   2. IN

Description

This statement declares a cursor. Multiple cursors may be declared in a stored program, but each cursor in a given block must have a unique name.

`select_statement` is not executed until the OPEN statement is executed. It is important to remember this if the query produces an error, or calls functions which have side effects.

A `SELECT` associated to a cursor can use variables, but the query itself cannot be a variable, and cannot be dynamically composed. The `SELECT` statement cannot have an `INTO` clause.

Cursors must be declared before HANDLERs, but after local variables and CONDITIONs.

Parameters

MariaDB starting with 10.3.0

From MariaDB 10.3.0, cursors can have parameters. This is a non-standard SQL extension. Cursor parameters can appear in any part of the DECLARE CURSOR select_statement where a stored procedure variable is allowed (select list, WHERE, HAVING, LIMIT etc).

IN

MariaDB starting with 10.8.0

From MariaDB 10.8.0 preview release, the `IN` qualifier is supported in the `cursor_format_parameter` part of the syntax.

See Cursor Overview for an example.

1.1.1.6.21.3 OPEN

Syntax

<= MariaDB 10.2

```
OPEN cursor_name
```

From MariaDB 10.3

```
OPEN cursor_name [expression[,...]];
```

Contents
1. Syntax
2. Description

Description

This statement opens a cursor which was previously declared with DECLARE CURSOR.

The query associated to the DECLARE CURSOR is executed when OPEN is executed. It is important to remember this if the query produces an error, or calls functions which have side effects.

This is necessary in order to FETCH rows from a cursor.

See Cursor Overview for an example.

1.1.1.6.21.4 FETCH

Syntax

```
FETCH cursor_name INTO var_name [, var_name] ...
```

Contents

Description

This statement fetches the next row (if a row exists) using the specified open cursor, and advances the cursor pointer.

`var_name` can be a local variable, but *not* a user-defined variable.

If no more rows are available, a No Data condition occurs with `SQLSTATE` value `02000`. To detect this condition, you can set up a handler for it (or for a `NOT FOUND` condition).

See Cursor Overview for an example.

1.1.1.6.21.5 CLOSE

Syntax

```
CLOSE cursor_name
```

Contents

Description

This statement closes a previously opened cursor. The cursor must have been previously opened or else an error occurs.

If not closed explicitly, a cursor is closed at the end of the compound statement in which it was declared.

See Cursor Overview for an example.

1.1.1.7 Stored Routine Statements

CALL

Invokes a stored procedure.

DO

Executes expressions without returning results.

There are 1 related questions.

1.1.1.7.1 CALL

Syntax

```
CALL sp_name([parameter[,...]])
CALL sp_name[()]
```

Description

The `CALL` statement invokes a stored procedure that was defined previously with CREATE PROCEDURE.

Stored procedure names can be specified as `database_name.procedure_name`. Procedure names and database names can be quoted with backticks (). This is necessary if they are reserved words, or contain special characters. See identifier qualifiers for details.

`CALL p()` and `CALL p` are equivalent.

If parentheses are used, any number of spaces, tab characters and newline characters are allowed between the procedure's name and the open parenthesis.

`CALL` can pass back values to its caller using parameters that are declared as `OUT` or `INOUT` parameters. If no value is assigned to an `OUT` parameter, `NULL` is assigned (and its former value is lost). To pass such values from another stored program you can use user-defined variables, local variables or routine's parameters; in other contexts, you can only use user-defined variables.

`CALL` can also be executed as a prepared statement. Placeholders can be used for `IN` parameters in all versions of MariaDB; for `OUT` and `INOUT` parameters, placeholders can be used since MariaDB 5.5.

When the procedure returns, a client program can also obtain the number of rows affected for the final statement executed within the routine: At the SQL level, call the `ROW_COUNT()` function; from the C API, call the `mysql_affected_rows()` function.

If the `CLIENT_MULTI_RESULTS` API flag is set, `CALL` can return any number of resultsets and the called stored procedure can execute prepared statements. If it is not set, at most one resultset can be returned and prepared statements cannot be used within procedures.

1.1.1.7.2 DO

Syntax

```
DO expr [, expr] ...
```

Description

`DO` executes the expressions but does not return any results. In most respects, `DO` is shorthand for `SELECT expr, ...,` but has the advantage that it is slightly faster when you do not care about the result.

`DO` is useful primarily with functions that have side effects, such as `RELEASE_LOCK()`.

1.1.1.2.1 Table Statements

1.1.1.9 Transactions

"An SQL-transaction (transaction) is a sequence of executions of SQL-statements that is atomic with respect to recovery. That is to say: either the execution result is completely successful, or it has no effect on any SQL-schemas or SQL-data."

— The SQL Standard

The InnoDB storage engine supports ACID-compliant transactions.

Transaction Articles

START TRANSACTION

Basic transaction control statements.

COMMIT

Ends a transaction, making changes visible to subsequent transactions

ROLLBACK

Cancel current transaction and the changes to data

SET TRANSACTION
Sets the transaction isolation level.

LOCK TABLES
Explicitly lock tables.

SAVEPOINT
SAVEPOINT for a ROLLBACK.

Metadata Locking
A lock which protects each transaction from external DDL statements.

SQL statements That Cause an Implicit Commit
List of statements which implicitly commit the current transaction

Transaction Timeouts
Timing out idle transactions

UNLOCK TABLES
Explicitly releases any table locks held by the current session.

WAIT and NOWAIT
Extended syntax so that it is possible to set lock wait timeout for certain statements.

XA Transactions
Transactions designed to allow distributed transactions.

READ COMMITTED
Each consistent read, even within the same transaction, sets and reads its own fresh snapshot.

READ UNCOMMITTED
SELECT statements are performed in a non-locking fashion, but a possible ea...

REPEATABLE READ
All consistent reads within the same transaction read the snapshot established by the first read.

SERIALIZABLE
Similar to REPEATABLE READ, with SELECT ... LOCK IN SHARE MODE if autocommit is disabled.

1.1.1.9.1 START TRANSACTION

Syntax

```
START TRANSACTION [transaction_property [, transaction_property] ...] | BEGIN [WORK]
COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
ROLLBACK [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
SET autocommit = {0 | 1}

transaction_property:
    WITH CONSISTENT SNAPSHOT
  | READ WRITE
  | READ ONLY
```

Contents

Description

The `START TRANSACTION` or `BEGIN` statement begins a new transaction. COMMIT commits the current transaction, making its changes permanent. ROLLBACK rolls back the current transaction, canceling its changes. The SET autocommit statement disables or enables the default autocommit mode for the current session.

START TRANSACTION and SET autocommit = 1 implicitly commit the current transaction, if any.

The optional `WORK` keyword is supported for `COMMIT` and `ROLLBACK`, as are the `CHAIN` and `RELEASE` clauses. `CHAIN` and `RELEASE` can be used for additional control over transaction completion. The value of the completion_type system variable determines the default completion behavior.

The `AND CHAIN` clause causes a new transaction to begin as soon as the current one ends, and the new transaction has the same isolation level as the just-terminated transaction. The `RELEASE` clause causes the server to disconnect the current client session after terminating the current transaction. Including the `NO` keyword suppresses `CHAIN` or `RELEASE` completion, which can be useful if the completion_type system variable is set to cause chaining or release completion by default.

Access Mode

The access mode specifies whether the transaction is allowed to write data or not. By default, transactions are in `READ WRITE` mode (see the tx_read_only system variable). `READ ONLY` mode allows the storage engine to apply optimizations that cannot be used for transactions which write data. Note that unlike the global `read_only` mode, `READ_ONLY ADMIN` (and `SUPER` before MariaDB 10.11.0) privilege doesn't allow writes and DDL statements on temporary tables are not allowed either.

It is not permitted to specify both `READ WRITE` and `READ ONLY` in the same statement.

`READ WRITE` and `READ ONLY` can also be specified in the `SET TRANSACTION` statement, in which case the specified mode is valid for all sessions, or for all subsequent transaction used by the current session.

autocommit

By default, MariaDB runs with autocommit mode enabled. This means that as soon as you execute a statement that updates (modifies) a table, MariaDB stores the update on disk to make it permanent. To disable autocommit mode, use the following statement:

```
SET autocommit=0;
```

After disabling autocommit mode by setting the autocommit variable to zero, changes to transaction-safe tables (such as those for InnoDB or `NDBCLUSTER`) are not made permanent immediately. You must use `COMMIT` to store your changes to disk or ROLLBACK to ignore the changes.

To disable autocommit mode for a single series of statements, use the `START TRANSACTION` statement.

DDL Statements

DDL statements (`CREATE`, `ALTER`, `DROP`) and administrative statements (`FLUSH`, `RESET`, `OPTIMIZE`, `ANALYZE`, `CHECK`, `REPAIR`, `CACHE INDEX`), transaction management statements (`BEGIN`, `START TRANSACTION`) and `LOAD DATA INFILE`, cause an implicit `COMMIT` and start a new transaction. An exception to this rule are the DDL that operate on temporary tables: you can `CREATE`, `ALTER` and `DROP` them without causing any `COMMIT`, but those actions cannot be rolled back. This means that if you call `ROLLBACK`, the temporary tables you created in the transaction will remain, while the rest of the transaction will be rolled back.

Transactions cannot be used in Stored Functions or Triggers. In Stored Procedures and Events BEGIN is not allowed, so you should use START TRANSACTION instead.

A transaction acquires a metadata lock on every table it accesses to prevent other connections from altering their structure. The lock is released at the end of the transaction. This happens even with non-transactional storage engines (like MEMORY or CONNECT), so it makes sense to use transactions with non-transactional tables.

in_transaction

The in_transaction system variable is a session-only, read-only variable that returns `1` inside a transaction, and `0` if not in a transaction.

WITH CONSISTENT SNAPSHOT

The `WITH CONSISTENT SNAPSHOT` option starts a consistent read for storage engines such as InnoDB that can do so, the same as if a START TRANSACTION followed by a SELECT from any InnoDB table was issued.

See Enhancements for START TRANSACTION WITH CONSISTENT SNAPSHOT.

Examples

```
START TRANSACTION;
SELECT @A:=SUM(salary) FROM table1 WHERE type=1;
UPDATE table2 SET summary=@A WHERE type=1;
COMMIT;
```

1.1.1.9.2 COMMIT

The `COMMIT` statement ends a transaction, saving any changes to the data so that they become visible to subsequent transactions. Also, unlocks metadata changed by current transaction. If autocommit is set to 1, an implicit commit is performed after each statement. Otherwise, all transactions which don't end with an explicit `COMMIT` are implicitly rollbacked and the changes are lost. The `ROLLBACK` statement can be used to do this explicitly.

The required syntax for the `COMMIT` statement is as follows:

```
COMMIT [WORK] [AND [NO] CHAIN] [[NO] RELEASE]
```

`COMMIT` is the more important transaction terminator, as well as the more interesting one. The basic form of the `COMMIT` statement is simply the keyword `COMMIT` (the keyword `WORK` is simply noise and can be omitted without changing the effect).

The optional `AND CHAIN` clause is a convenience for initiating a new transaction as soon as the old transaction terminates. If `AND CHAIN` is specified, then there is effectively nothing between the old and new transactions, although they remain separate. The characteristics of the new transaction will be the same as the characteristics of the old one — that is, the new transaction will have the same access mode, isolation level and diagnostics area size (we'll discuss all of these shortly) as the transaction just terminated.

`RELEASE` tells the server to disconnect the client immediately after the current transaction.

There are `NO RELEASE` and `AND NO CHAIN` options. By default, commits do not `RELEASE` or `CHAIN`, but it's possible to change this default behavior with the completion_type server system variable. In this case, the `AND NO CHAIN` and `NO RELEASE` options override the server default.

1.1.1.9.3 ROLLBACK

The `ROLLBACK` statement rolls back (ends) a transaction, destroying any changes to SQL-data so that they never become visible to subsequent transactions. The required syntax for the `ROLLBACK` statement is as follows.

```
ROLLBACK [ WORK ] [ AND [ NO ] CHAIN ]
[ TO [ SAVEPOINT ] {<savepoint name> | <simple target specification>} ]
```

The `ROLLBACK` statement will either end a transaction, destroying all data changes that happened during any of the transaction, or it will just destroy any data changes that happened since you established a savepoint. The basic form of the `ROLLBACK` statement is just the keyword `ROLLBACK` (the keyword `WORK` is simply noise and can be omitted without changing the effect).

The optional `AND CHAIN` clause is a convenience for initiating a new transaction as soon as the old transaction terminates. If `AND CHAIN` is specified, then there is effectively nothing between the old and new transactions, although they remain separate. The characteristics of the new transaction will be the same as the characteristics of the old one — that is, the new transaction will have the same access mode, isolation level and diagnostics area size (we'll discuss all of these shortly) as the transaction just terminated. The `AND NO CHAIN` option just tells your DBMS to end the transaction — that is, these four SQL statements are equivalent:

```
ROLLBACK;
ROLLBACK WORK;
ROLLBACK AND NO CHAIN;
ROLLBACK WORK AND NO CHAIN;
```

All of them end a transaction without saving any transaction characteristics. The only other options, the equivalent statements:

```
ROLLBACK AND CHAIN;
ROLLBACK WORK AND CHAIN;
```

both tell your DBMS to end a transaction, but to save that transaction's characteristics for the next transaction.

`ROLLBACK` is much simpler than `COMMIT` : it may involve no more than a few deletions (of Cursors, locks, prepared SQL statements and log-file entries). It's usually assumed that `ROLLBACK` can't fail, although such a thing is conceivable (for example, an encompassing transaction might reject an attempt to `ROLLBACK` because it's lining up for a `COMMIT`).

`ROLLBACK` cancels all effects of a transaction. It does not cancel effects on objects outside the DBMS's control (for example the values in host program variables or the settings made by some SQL/CLI function calls). But in general, it is a convenient statement for those situations when you say "oops, this isn't working" or when you simply don't care whether your temporary work becomes permanent or not.

Here is a moot question. If all you've been doing is `SELECT` s, so that there have been no data changes, should you end the transaction with `ROLLBACK` or `COMMIT` ? It shouldn't really matter because both `ROLLBACK` and `COMMIT` do the same transaction-terminating job. However, the popular conception is that `ROLLBACK` implies failure, so after a successful series of `SELECT` statements the convention is to end the transaction with `COMMIT` rather than `ROLLBACK` .

MariaDB (and most other DBMSs) supports rollback of SQL-data change statements, but not of SQL-Schema statements. This means that if you use any of `CREATE` , `ALTER` , `DROP` , `GRANT` , `REVOKE` , you are implicitly committing at execution time.

```
INSERT INTO Table_2 VALUES(5);
DROP TABLE Table_3 CASCADE;
ROLLBACK;
```

The result will be that both the `INSERT` and the `DROP` will go through as separate transactions so the `ROLLBACK` will have no effect.

1.1.1.9.4 SET TRANSACTION

Syntax

```
SET [GLOBAL | SESSION] TRANSACTION
    transaction_property [, transaction_property] ...

transaction_property:
    ISOLATION LEVEL level
  | READ WRITE
  | READ ONLY

level:
     REPEATABLE READ
   | READ COMMITTED
   | READ UNCOMMITTED
   | SERIALIZABLE
```

Contents

Description

This statement sets the transaction isolation level or the transaction access mode globally, for the current session, or for the next transaction:

- With the `GLOBAL` keyword, the statement sets the default transaction level globally for all subsequent sessions. Existing sessions are unaffected.
- With the `SESSION` keyword, the statement sets the default transaction level for all subsequent transactions performed within the current session.
- Without any `SESSION` or `GLOBAL` keyword, the statement sets the isolation level for only the next (not started) transaction performed within the current session. After that it reverts to using the session value.

A change to the global default isolation level requires the `SUPER` privilege. Any session is free to change its session isolation level (even in the middle of a transaction), or the isolation level for its next transaction.

Isolation Level

To set the global default isolation level at server startup, use the --transaction-isolation=level option on the command line or in an option file. Values of level for this option use dashes rather than spaces, so the allowable values are READ_UNCOMMITTED, READ-COMMITTED, REPEATABLE-READ, or SERIALIZABLE. For example, to set the default isolation level to `REPEATABLE READ`, use these lines in the [mariadb] section of an option file:

```
[mariadb]
transaction-isolation = REPEATABLE-READ
```

To determine the global and session transaction isolation levels at runtime, check the value of the tx_isolation system variable (note that the variable has been renamed transaction_isolation from MariaDB 11.1.1, to match the option, and the old name deprecated).

```
SELECT @@GLOBAL.tx_isolation, @@tx_isolation;
```

From MariaDB 11.1.1:

```
SELECT @@GLOBAL.transaction_isolation, @@transaction_isolation;
```

InnoDB supports each of the translation isolation levels described here using different locking strategies. The default level is `REPEATABLE READ`. For additional information about InnoDB record-level locks and how it uses them to execute various types of statements, see InnoDB Lock Modes, and http://dev.mysql.com/doc/refman/en/innodb-locks-set.html.

Isolation Levels

The following sections describe how MariaDB supports the different transaction levels.

READ UNCOMMITTED

`SELECT` statements are performed in a non-locking fashion, but a possible earlier version of a row might be used. Thus, using this isolation level, such reads are not consistent. This is also called a "dirty read." Otherwise, this isolation level works like `READ COMMITTED`.

READ COMMITTED

A somewhat Oracle-like isolation level with respect to consistent (non-locking) reads: Each consistent read, even within the same transaction, sets and reads its own fresh snapshot. See http://dev.mysql.com/doc/refman/en/innodb-consistent-

read.html.

For locking reads (`SELECT` with `FOR UPDATE` or `LOCK IN SHARE MODE`), InnoDB locks only index records, not the gaps before them, and thus allows the free insertion of new records next to locked records. For `UPDATE` and `DELETE` statements, locking depends on whether the statement uses a unique index with a unique search condition (such as `WHERE id = 100`), or a range-type search condition (such as `WHERE id > 100`). For a unique index with a unique search condition, InnoDB locks only the index record found, not the gap before it. For range-type searches, InnoDB locks the index range scanned, using gap locks or next-key (gap plus index-record) locks to block insertions by other sessions into the gaps covered by the range. This is necessary because "phantom rows" must be blocked for MariaDB replication and recovery to work.

Note: If the `READ COMMITTED` isolation level is used or the innodb_locks_unsafe_for_binlog system variable is enabled, there is no InnoDB gap locking except for foreign-key constraint checking and duplicate-key checking. Also, record locks for non-matching rows are released after MariaDB has evaluated the `WHERE` condition.If you use `READ COMMITTED` or enable innodb_locks_unsafe_for_binlog, you must use row-based binary logging.

REPEATABLE READ

This is the default isolation level for InnoDB. For consistent reads, there is an important difference from the `READ COMMITTED` isolation level: All consistent reads within the same transaction read the snapshot established by the first read. This convention means that if you issue several plain (non-locking) `SELECT` statements within the same transaction, these `SELECT` statements are consistent also with respect to each other. See http://dev.mysql.com/doc/refman/en/innodb-consistent-read.html.

For locking reads (SELECT with FOR UPDATE or LOCK IN SHARE MODE), UPDATE, and DELETE statements, locking depends on whether the statement uses a unique index with a unique search condition, or a range-type search condition. For a unique index with a unique search condition, InnoDB locks only the index record found, not the gap before it. For other search conditions, InnoDB locks the index range scanned, using gap locks or next-key (gap plus index-record) locks to block insertions by other sessions into the gaps covered by the range.

This is the minimum isolation level for non-distributed XA transactions.

SERIALIZABLE

This level is like REPEATABLE READ, but InnoDB implicitly converts all plain SELECT statements to SELECT ... LOCK IN SHARE MODE if autocommit is disabled. If autocommit is enabled, the SELECT is its own transaction. It therefore is known to be read only and can be serialized if performed as a consistent (non-locking) read and need not block for other transactions. (This means that to force a plain SELECT to block if other transactions have modified the selected rows, you should disable autocommit.)

Distributed XA transactions should always use this isolation level.

Access Mode

The access mode specifies whether the transaction is allowed to write data or not. By default, transactions are in `READ WRITE` mode (see the tx_read_only system variable). `READ ONLY` mode allows the storage engine to apply optimizations that cannot be used for transactions which write data. Note that unlike the global read_only mode, READ_ONLY ADMIN (and SUPER before MariaDB 10.11.0) privilege doesn't allow writes and DDL statements on temporary tables are not allowed either.

It is not permitted to specify both `READ WRITE` and `READ ONLY` in the same statement.

`READ WRITE` and `READ ONLY` can also be specified in the START TRANSACTION statement, in which case the specified mode is only valid for one transaction.

Examples

```
SET GLOBAL TRANSACTION ISOLATION LEVEL SERIALIZABLE;
```

Attempting to set the isolation level within an existing transaction without specifying `GLOBAL` or `SESSION` .

```
START TRANSACTION;

SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
ERROR 1568 (25001): Transaction characteristics can't be changed while a transaction is in progre
```

1.1.1.9.5 LOCK TABLES

Syntax

```
LOCK TABLE[S]
    tbl_name [[AS] alias] lock_type
    [, tbl_name [[AS] alias] lock_type] ...
    [WAIT n|NOWAIT]

lock_type:
    READ [LOCAL]
  | [LOW_PRIORITY] WRITE
  | WRITE CONCURRENT

UNLOCK TABLES
```

Contents

Description

The *lock_type* can be one of:

Option	Description
READ	Read lock, no writes allowed
READ LOCAL	Read lock, but allow concurrent inserts
WRITE	Exclusive write lock. No other connections can read or write to this table
LOW_PRIORITY WRITE	Exclusive write lock, but allow new read locks on the table until we get the write lock.
WRITE CONCURRENT	Exclusive write lock, but allow READ LOCAL locks to the table.

MariaDB enables client sessions to acquire table locks explicitly for the purpose of cooperating with other sessions for access to tables, or to prevent other sessions from modifying tables during periods when a session requires exclusive access to them. A session can acquire or release locks only for itself. One session cannot acquire locks for another session or release locks held by another session.

Locks may be used to emulate transactions or to get more speed when updating tables.

`LOCK TABLES` explicitly acquires table locks for the current client session. Table locks can be acquired for base tables or views. To use `LOCK TABLES`, you must have the `LOCK TABLES` privilege, and the `SELECT` privilege for each object to be locked. See `GRANT`

For view locking, `LOCK TABLES` adds all base tables used in the view to the set of tables to be locked and locks them automatically. If you lock a table explicitly with `LOCK TABLES`, any tables used in triggers are also locked implicitly, as described in Triggers and Implicit Locks.

UNLOCK TABLES explicitly releases any table locks held by the current session.

MariaDB starting with 10.3.0

WAIT/NOWAIT

Set the lock wait timeout. See WAIT and NOWAIT.

Limitations

- `LOCK TABLES` doesn't work when using Galera cluster. You may experience crashes or locks when used with Galera.
- `LOCK TABLES` works on XtraDB/InnoDB tables only if the innodb_table_locks system variable is set to 1 (the default) and autocommit is set to 0 (1 is default). Please note that no error message will be returned on LOCK TABLES with

innodb_table_locks = 0.

- `LOCK TABLES` implicitly commits the active transaction, if any. Also, starting a transaction always releases all table locks acquired with LOCK TABLES. This means that there is no way to have table locks and an active transaction at the same time. The only exceptions are the transactions in autocommit mode. To preserve the data integrity between transactional and non-transactional tables, the GET_LOCK() function can be used.
- When using `LOCK TABLES` on a `TEMPORARY` table, it will always be locked with a `WRITE` lock.
- While a connection holds an explicit read lock on a table, it cannot modify it. If you try, the following error will be produced:

```
ERROR 1099 (HY000): Table 'tab_name' was locked with a READ lock and can't be updated
```

- While a connection holds an explicit lock on a table, it cannot access a non-locked table. If you try, the following error will be produced:

```
ERROR 1100 (HY000): Table 'tab_name' was not locked with LOCK TABLES
```

- While a connection holds an explicit lock on a table, it cannot issue the following: INSERT DELAYED, CREATE TABLE, CREATE TABLE ... LIKE, and DDL statements involving stored programs and views (except for triggers). If you try, the following error will be produced:

```
ERROR 1192 (HY000): Can't execute the given command because you have active locked tables or an
active transaction
```

- `LOCK TABLES` can not be used in stored routines - if you try, the following error will be produced on creation:

```
ERROR 1314 (0A000): LOCK is not allowed in stored procedures
```

1.1.1.9.6 SAVEPOINT

Syntax

```
SAVEPOINT identifier
ROLLBACK [WORK] TO [SAVEPOINT] identifier
RELEASE SAVEPOINT identifier
```

Contents

Description

InnoDB supports the SQL statements `SAVEPOINT`, `ROLLBACK TO SAVEPOINT`, `RELEASE SAVEPOINT` and the optional `WORK` keyword for `ROLLBACK`.

Each savepoint must have a legal MariaDB identifier. A savepoint is a named sub-transaction.

Normally ROLLBACK undoes the changes performed by the whole transaction. When used with the TO clause, it undoes the changes performed after the specified savepoint, and erases all subsequent savepoints. However, all locks that have been acquired after the save point will survive. RELEASE SAVEPOINT does not rollback or commit any changes, but removes the specified savepoint.

When the execution of a trigger or a stored function begins, it is not possible to use statements which reference a savepoint which was defined from out of that stored program.

When a COMMIT (including implicit commits) or a ROLLBACK statement (with no TO clause) is performed, they act on the whole transaction, and all savepoints are removed.

Errors

If COMMIT or ROLLBACK is issued and no transaction was started, no error is reported.

If SAVEPOINT is issued and no transaction was started, no error is reported but no savepoint is created. When ROLLBACK

TO SAVEPOINT or RELEASE SAVEPOINT is called for a savepoint that does not exist, an error like this is issued:

```
ERROR 1305 (42000): SAVEPOINT svp_name does not exist
```

1.1.1.9.7 Metadata Locking

MariaDB supports metadata locking. This means that when a transaction (including XA transactions) uses a table, it locks its metadata until the end of transaction. Non-transactional tables are also locked, as well as views and objects which are related to locked tables/views (stored functions, triggers, etc). When a connection tries to use a DDL statement (like an ALTER TABLE) which modifies a table that is locked, that connection is queued, and has to wait until it's unlocked. Using savepoints and performing a partial rollback does not release metadata locks.

LOCK TABLES ... WRITE are also queued. Some wrong statements which produce an error may not need to wait for the lock to be freed.

The metadata lock's timeout is determined by the value of the lock_wait_timeout server system variable (in seconds). However, note that its default value is 31536000 (1 year, MariaDB <= 10.2.3), or 86400 (1 day, MariaDB >= 10.2.4). If this timeout is exceeded, the following error is returned:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

If the metadata_lock_info plugin is installed, the Information Schema metadata_lock_info table stores information about existing metadata locks.

MariaDB starting with 10.5.2

From MariaDB 10.5, the Performance Schema metadata_locks table contains metadata lock information.

Example

Let's use the following MEMORY (non-transactional) table:

```
CREATE TABLE t (a INT) ENGINE = MEMORY;
```

Connection 1 starts a transaction, and INSERTs a row into t:

```
START TRANSACTION;

INSERT INTO t SET a=1;
```

`t` 's metadata is now locked by connection 1. Connection 2 tries to alter `t` , but has to wait:

```
ALTER TABLE t ADD COLUMN b INT;
```

Connection 2's prompt is blocked now.

Now connection 1 ends the transaction:

```
COMMIT;
```

...and connection 2 finally gets the output of its command:

```
Query OK, 1 row affected (35.23 sec)
Records: 1  Duplicates: 0  Warnings: 0
```

1.1.1.9.8 SQL statements That Cause an Implicit Commit

Some SQL statements cause an implicit commit. As a rule of thumb, such statements are DDL statements. The same statements (except for SHUTDOWN) produce a 1400 error (SQLSTATE 'XAE09') if a XA transaction is in effect.

Here is the list:

```
ALTER DATABASE ... UPGRADE DATA DIRECTORY NAME
ALTER EVENT
ALTER FUNCTION
ALTER PROCEDURE
ALTER SEQUENCE
ALTER SERVER
ALTER TABLE
ALTER VIEW
ANALYZE TABLE
BEGIN
CACHE INDEX
CHANGE MASTER TO
CHECK TABLE
CREATE DATABASE
CREATE EVENT
CREATE FUNCTION
CREATE INDEX
CREATE PROCEDURE
CREATE ROLE
CREATE SEQUENCE
CREATE SERVER
CREATE TABLE
CREATE TRIGGER
CREATE USER
CREATE VIEW
DROP DATABASE
DROP EVENT
DROP FUNCTION
DROP INDEX
DROP PROCEDURE
DROP ROLE
DROP SEQUENCE
DROP SERVER
DROP TABLE
DROP TRIGGER
DROP USER
DROP VIEW
FLUSH
GRANT
LOAD INDEX INTO CACHE
LOCK TABLES
OPTIMIZE TABLE
RENAME TABLE
RENAME USER
REPAIR TABLE
RESET
REVOKE
SET PASSWORD
SHUTDOWN
START SLAVE
START TRANSACTION
STOP SLAVE
TRUNCATE TABLE
```

`SET autocommit = 1` causes an implicit commit if the value was 0.

All these statements cause an implicit commit before execution. This means that, even if the statement fails with an error, the transaction is committed. Some of them, like `CREATE TABLE ... SELECT`, also cause a commit immediatly after execution. Such statements couldn't be rollbacked in any case.

If you are not sure whether a statement has implicitly committed the current transaction, you can query the in_transaction server system variable.

Note that when a transaction starts (not in autocommit mode), all locks acquired with LOCK TABLES are released. And acquiring such locks always commits the current transaction. To preserve the data integrity between transactional and non-transactional tables, the GET_LOCK() function can be used.

Exceptions

These statements do not cause an implicit commit in the following cases:

- CREATE TABLE and DROP TABLE, when the `TEMPORARY` keyword is used.

    - However, TRUNCATE TABLE causes an implicit commit even when used on a temporary table.
- CREATE FUNCTION and DROP FUNCTION, when used to create a UDF (instead of a stored function). However, CREATE INDEX and DROP INDEX cause commits even when used with temporary tables.
- UNLOCK TABLES causes a commit only if a LOCK TABLES was used on non-transactional tables.
- START SLAVE, STOP SLAVE, RESET SLAVE and CHANGE MASTER TO did not cause implicit commits prior to MariaDB 10.0.

1.1.1.9.9 Transaction Timeouts

MariaDB has always had the wait_timeout and interactive_timeout settings, which close connections after a certain period of inactivity.

However, these are by default set to a long wait period. In situations where transactions may be started, but not committed or rolled back, more granular control and a shorter timeout may be desirable so as to avoid locks being held for too long.

MariaDB 10.3 introduced three new variables to handle this situation.

- idle_transaction_timeout (all transactions)
- idle_write_transaction_timeout (write transactions - called `idle_readwrite_transaction_timeout` until MariaDB 10.3.2)
- idle_readonly_transaction_timeout (read transactions)

These accept a time in seconds to time out, by closing the connection, transactions that are idle for longer than this period. By default all are set to zero, or no timeout.

idle_transaction_timeout affects all transactions, idle_write_transaction_timeout affects write transactions only and idle_readonly_transaction_timeout affects read transactions only. The latter two variables work independently. However, if either is set along with idle_transaction_timeout, the settings for idle_write_transaction_timeout or idle_readonly_transaction_timeout will take precedence.

Examples

```
SET SESSION idle_transaction_timeout=2;
BEGIN;
SELECT * FROM t;
Empty set (0.000 sec)
## wait 3 seconds
SELECT * FROM t;
ERROR 2006 (HY000): MySQL server has gone away
```

```
SET SESSION idle_write_transaction_timeout=2;
BEGIN;
SELECT * FROM t;
Empty set (0.000 sec)
## wait 3 seconds
SELECT * FROM t;
Empty set (0.000 sec)
INSERT INTO t VALUES(1);
## wait 3 seconds
SELECT * FROM t;
ERROR 2006 (HY000): MySQL server has gone away
```

```
SET SESSION idle_transaction_timeout=2, SESSION idle_readonly_transaction_timeout=10;
BEGIN;
SELECT * FROM t;
Empty set (0.000 sec)
 ## wait 3 seconds
SELECT * FROM t;
Empty set (0.000 sec)
## wait 11 seconds
SELECT * FROM t;
ERROR 2006 (HY000): MySQL server has gone away
```

1.1.1.9.10 UNLOCK TABLES

Syntax

```
UNLOCK TABLES
```

Contents

Description

`UNLOCK TABLES` explicitly releases any table locks held by the current session. See `LOCK TABLES` for more information.

In addition to releasing table locks acquired by the `LOCK TABLES` statement, the `UNLOCK TABLES` statement also releases the global read lock acquired by the `FLUSH TABLES WITH READ LOCK` statement. The `FLUSH TABLES WITH READ LOCK` statement is very useful for performing backups. See `FLUSH` for more information about `FLUSH TABLES WITH READ LOCK`.

1.1.1.9.11 WAIT and NOWAIT

Extended syntax so that it is possible to set innodb_lock_wait_timeout and lock_wait_timeout for the following statements:

Syntax

```
ALTER TABLE tbl_name [WAIT n|NOWAIT] ...
CREATE ... INDEX ON tbl_name (index_col_name, ...) [WAIT n|NOWAIT] ...
DROP INDEX ... [WAIT n|NOWAIT]
DROP TABLE tbl_name [WAIT n|NOWAIT] ...
LOCK TABLE ... [WAIT n|NOWAIT]
OPTIMIZE TABLE tbl_name [WAIT n|NOWAIT]
RENAME TABLE tbl_name [WAIT n|NOWAIT] ...
SELECT ... FOR UPDATE [WAIT n|NOWAIT]
SELECT ... LOCK IN SHARE MODE [WAIT n|NOWAIT]
TRUNCATE TABLE tbl_name [WAIT n|NOWAIT]
```

Description

The lock wait timeout can be explicitly set in the statement by using either `WAIT n` (to set the wait in seconds) or `NOWAIT`, in which case the statement will immediately fail if the lock cannot be obtained. `WAIT 0` is equivalent to `NOWAIT`.

1.1.1.9.12 XA Transactions

Contents

Overview

The MariaDB XA implementation is based on the X/Open CAE document Distributed Transaction Processing: The XA Specification. This document is published by The Open Group and available at http://www.opengroup.org/public/pubs/catalog/c193.htm.

XA transactions are designed to allow distributed transactions, where a transaction manager (the application) controls a transaction which involves multiple resources. Such resources are usually DBMSs, but could be resources of any type. The whole set of required transactional operations is called a global transaction. Each subset of operations which involve a

single resource is called a local transaction. XA used a 2-phases commit (2PC). With the first commit, the transaction manager tells each resource to prepare an effective commit, and waits for a confirm message. The changes are not still made effective at this point. If any of the resources encountered an error, the transaction manager will rollback the global transaction. If all resources communicate that the first commit is successful, the transaction manager can require a second commit, which makes the changes effective.

In MariaDB, XA transactions can only be used with storage engines that support them. At least InnoDB, TokuDB, SPIDER and MyRocks support them. For InnoDB, until MariaDB 10.2, XA transactions can be disabled by setting the innodb_support_xa server system variable to 0. From MariaDB 10.3, XA transactions are always supported.

Like regular transactions, XA transactions create metadata locks on accessed tables.

XA transactions require REPEATABLE READ as a minimum isolation level. However, distributed transactions should always use SERIALIZABLE.

Trying to start more than one XA transaction at the same time produces a 1400 error (SQLSTATE 'XAE09'). The same error is produced when attempting to start an XA transaction while a regular transaction is in effect. Trying to start a regular transaction while an XA transaction is in effect produces a 1399 error (SQLSTATE 'XAE07').

The statements that cause an implicit COMMIT for regular transactions produce a 1400 error (SQLSTATE 'XAE09') if a XA transaction is in effect.

Internal XA vs External XA

XA transactions are an overloaded term in MariaDB. If a storage engine is XA-capable, it can mean one or both of these:

- It supports MariaDB's internal two-phase commit API. This is transparent to the user. Sometimes this is called "internal XA", since MariaDB's internal transaction coordinator log can handle coordinating these transactions.
- It supports XA transactions, with the `XA START`, `XA PREPARE`, `XA COMMIT`, etc. statements. Sometimes this is called "external XA", since it requires the use of an external transaction coordinator to use this feature properly.

Transaction Coordinator Log

If you have two or more XA-capable storage engines enabled, then a transaction coordinator log must be available.

There are currently two implementations of the transaction coordinator log:

- Binary log-based transaction coordinator log
- Memory-mapped file-based transaction coordinator log

If the binary log is enabled on a server, then the server will use the binary log-based transaction coordinator log. Otherwise, it will use the memory-mapped file-based transaction coordinator log.

See Transaction Coordinator Log for more information.

Syntax

```
XA {START|BEGIN} xid [JOIN|RESUME]

XA END xid [SUSPEND [FOR MIGRATE]]

XA PREPARE xid

XA COMMIT xid [ONE PHASE]

XA ROLLBACK xid

XA RECOVER [FORMAT=['RAW'|'SQL']]

xid: gtrid [, bqual [, formatID ]]
```

The interface to XA transactions is a set of SQL statements starting with `XA`. Each statement changes a transaction's state, determining which actions it can perform. A transaction which does not exist is in the `NON-EXISTING` state.

`XA START` (or `BEGIN`) starts a transaction and defines its `xid` (a transaction identifier). The `JOIN` or `RESUME` keywords have no effect. The new transaction will be in `ACTIVE` state.

The `xid` can have 3 components, though only the first one is mandatory. `gtrid` is a quoted string representing a global transaction identifier. `bqual` is a quoted string representing a local transaction identifier. `formatID` is an unsigned integer indicating the format used for the first two components; if not specified, defaults to 1. MariaDB does not interpret in any way

these components, and only uses them to identify a transaction. `xid`s of transactions in effect must be unique.

`XA END` declares that the specified `ACTIVE` transaction is finished and it changes its state to `IDLE`. `SUSPEND [FOR MIGRATE]` has no effect.

`XA PREPARE` prepares an `IDLE` transaction for commit, changing its state to `PREPARED`. This is the first commit.

`XA COMMIT` definitely commits and terminates a transaction which has already been `PREPARED`. If the `ONE PHASE` clause is specified, this statements performs a 1-phase commit on an `IDLE` transaction.

`XA ROLLBACK` rolls back and terminates an `IDLE` or `PREPARED` transaction.

`XA RECOVER` shows information about all `PREPARED` transactions.

When trying to execute an operation which is not allowed for the transaction's current state, an error is produced:

```
XA COMMIT 'test' ONE PHASE;
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed when global transaction is in
the  ACTIVE state

XA COMMIT 'test2';
ERROR 1399 (XAE07): XAER_RMFAIL: The command cannot be executed when global transaction is in
the  NON-EXISTING state
```

XA RECOVER

The `XA RECOVER` statement shows information about all transactions which are in the `PREPARED` state. It does not matter which connection created the transaction: if it has been `PREPARED`, it appears. But this does not mean that a connection can commit or rollback a transaction which was started by another connection. Note that transactions using a 1-phase commit are never in the `PREPARED` state, so they cannot be shown by `XA RECOVER`.

`XA RECOVER` produces four columns:

```
XA RECOVER;
+----------+--------------+--------------+------+
| formatID | gtrid_length | bqual_length | data |
+----------+--------------+--------------+------+
|        1 |            4 |            0 | test |
+----------+--------------+--------------+------+
```

MariaDB starting with 10.3.3

You can use `XA RECOVER FORMAT='SQL'` to get the data in a human readable form that can be directly copy-pasted into `XA COMMIT` or `XA ROLLBACK`. This is particularly useful for binary `xid` generated by some transaction coordinators.

`formatID` is the `formatID` part of `xid`.

`data` are the `gtrid` and `bqual` parts of `xid`, concatenated.

`gtrid_length` and `bqual_length` are the lengths of `gtrid` and `bqual`, respectevely.

Examples

2-phases commit:

```
XA START 'test';

INSERT INTO t VALUES (1,2);

XA END 'test';

XA PREPARE 'test';

XA COMMIT 'test';
```

1-phase commit:

```
XA START 'test';

INSERT INTO t VALUES (1,2);

XA END 'test';

XA COMMIT 'test' ONE PHASE;
```

Human-readable:

```
xa start '12\r34\t67\v78', 'abc\ndef', 3;

insert t1 values (40);

xa end '12\r34\t67\v78', 'abc\ndef', 3;

xa prepare '12\r34\t67\v78', 'abc\ndef', 3;

xa recover format='RAW';
+----------+--------------+--------------+--------------------+
| formatID | gtrid_length | bqual_length | data               |
+----------+--------------+--------------+--------------------+
34      67v78abc       11 |            7 | 12
def |
+----------+--------------+--------------+--------------------+

xa recover format='SQL';
+----------+--------------+--------------+-----------------------------------------------------+
| formatID | gtrid_length | bqual_length | data                                                |
+----------+--------------+--------------+-----------------------------------------------------+
|        3 |           11 |            7 | X'31320d3334093637763738',X'6162630a646566',3 |
+----------+--------------+--------------+-----------------------------------------------------+

xa rollback X'31320d3334093637763738',X'6162630a646566',3;
```

Known Issues

MariaDB Galera Cluster

MariaDB Galera Cluster does not support XA transactions.

However, MariaDB Galera Cluster builds include a built-in plugin called `wsrep`. Prior to MariaDB 10.4.3, this plugin was internally considered an XA-capable storage engine. Consequently, these MariaDB Galera Cluster builds have multiple XA-capable storage engines by default, even if the only "real" storage engine that supports external XA transactions enabled on these builds by default is InnoDB. Therefore, when using one these builds MariaDB would be forced to use a transaction coordinator log by default, which could have performance implications.

See Transaction Coordinator Log Overview: MariaDB Galera Cluster for more information.

1.1.1.9.13 READ COMMITTED

`READ COMMITTED` is one of the transaction isolation levels. Each consistent read, even within the same transaction, sets and reads its own fresh snapshot.

See SET TRANSACTION#Isolation Levels for details.

1.1.1.9.14 READ UNCOMMITTED

`READ UNCOMMITTED` is one of the transaction isolation levels. SELECT statements are performed in a non-locking fashion, but a possible earlier version of a row might be used

See SET TRANSACTION#Isolation Levels for details.

1.1.1.9.15 REPEATABLE READ

`REPEATABLE READ` is one of the transaction isolation levels. All consistent reads within the same transaction read the

snapshot established by the first read.

See SET TRANSACTION#Isolation Levels for details.

1.1.1.9.16 SERIALIZABLE

`SERIALIZABLE` is one of the transaction isolation levels. Similar to REPEATABLE READ, but InnoDB implicitly converts all plain SELECT statements to SELECT ... LOCK IN SHARE MODE if autocommit is disabled.

See SET TRANSACTION#Isolation Levels for details.

1.1.1.2.15 HELP Command

1.1.1.11 Comment Syntax

There are three supported comment styles in MariaDB:

1. From a ' `#` ' to the end of a line:
   ```
   SELECT * FROM users; # This is a comment
   ```
2. From a ' `--` ' to the end of a line. The space after the two dashes is required (as in MySQL).
   ```
   SELECT * FROM users; -- This is a comment
   ```
3. C style comments from an opening ' `/*` ' to a closing ' `*/` '. Comments of this form can span multiple lines:
   ```
   SELECT * FROM users; /* This is a
   multi-line
   comment */
   ```

Nested comments are possible in some situations, but they are not supported or recommended.

Executable Comments

As an aid to portability between different databases, MariaDB supports executable comments. These special comments allow you to embed SQL code which will not execute when run on other databases, but will execute when run on MariaDB.

MariaDB supports both MySQL's executable comment format, and a slightly modified version specific to MariaDB. This way, if you have SQL code that works on MySQL and MariaDB, but not other databases, you can wrap it in a MySQL executable comment, and if you have code that specifically takes advantage of features only available in MariaDB you can use the MariaDB specific format to hide the code from MySQL.

Executable Comment Syntax

MySQL and MariaDB executable comment syntax:

```
/*! MySQL or MariaDB-specific code */
```

Code that should be executed only starting from a specific MySQL or MariaDB version:

```
/*!##### MySQL or MariaDB-specific code */
```

The numbers, represented by ' `######` ' in the syntax examples above specify the specific the minimum versions of MySQL and MariaDB that should execute the comment. The first number is the major version, the second 2 numbers are the minor version and the last 2 is the patch level.

For example, if you want to embed some code that should only execute on MySQL or MariaDB starting from 5.1.0, you would do the following:

```
/*!50100 MySQL and MariaDB 5.1.0 (and above) code goes here. */
```

MariaDB-only executable comment syntax (starting from MariaDB 5.3.1):

```
/*M! MariaDB-specific code */
/*M!###### MariaDB-specific code */
```

MariaDB ignores MySQL-style executable comments that have a version number in the range `50700..99999`. This is needed to skip features introduced in MySQL-5.7 that are not ported to MariaDB 10.x yet.

```
/*!50701 MariaDB-10.x ignores MySQL-5.7 specific code */
```

Note: comments which have a version number in the range `50700..99999` that use MariaDB-style executable comment syntax are still executed.

```
/*M!50701 MariaDB-10.x does not ignore this */
```

Statement delimiters cannot be used within executable comments.

Examples

In MySQL all the following will return 2: In MariaDB, the last 2 queries would return 3.

```
SELECT 2 /* +1 */;
SELECT 1 /*! +1 */;
SELECT 1 /*!50101 +1 */;
SELECT 2 /*M! +1 */;
SELECT 2 /*M!50301 +1 */;
```

The following executable statement will not work due to the delimiter inside the executable portion:

```
/*M!100100 select 1 ; */
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual that corresponds to
your MariaDB server version for the right syntax to use near '' at line 1
```

Instead, the delimiter should be placed outside the executable portion:

```
/*M!100100 select 1 */;
+---+
| 1 |
+---+
| 1 |
+---+
```

1.2 Built-in Functions

1.1.2 SQL Language Structure

SQL language structure rules.

Identifier Names

Naming rules for identifiers.

Identifier Case-sensitivity

Whether objects are case-sensitive or not is partly determined by the under...

Binary Literals

Binary literals can be written in one of the following formats.

Boolean Literals

True and false.

Date and Time Literals

Literals regarding date and time.

Hexadecimal Literals
Hexadecimal literals can be written using any of the following syntaxes

Identifier Qualifiers
How to reference an object and its context in an SQL statement.

Identifier to File Name Mapping
Some identifiers map to a file name on the filesystem. Databases each have ...

MariaDB Error Codes
MariaDB error codes reference list.

Numeric Literals
Numeric literals are written as a sequence of digits from 0 to 9

Reserved Words
List of reserved words in MariaDB.

SQLSTATE
A string which identifies a condition's class and subclass

String Literals
Strings are sequences of characters and are enclosed with quotes.

Table Value Constructors
Documents adding arbitrary values to the result-set.

User-Defined Variables
Variables which exist within a session.

1.1.2.1 Identifier Names

Contents

Databases, tables, indexes, columns, aliases, views, stored routines, triggers, events, variables, partitions, tablespaces, savepoints, labels, users, roles, are collectively known as identifiers, and have certain rules for naming.

Identifiers may be quoted using the backtick character - `` ` ``. Quoting is optional for identifiers that don't contain special characters, or for identifiers that are not reserved words. If the `ANSI_QUOTES` SQL_MODE flag is set, double quotes (`"`) can also be used to quote identifiers. If the `MSSQL` flag is set, square brackets (`[` and `]`) can be used for quoting.

Even when using reserved words as names, fully qualified names do not need to be quoted. For example, `test.select` has only one possible meaning, so it is correctly parsed even without quotes.

Unquoted

The following characters are valid, and allow identifiers to be unquoted:

- ASCII: [0-9,a-z,A-Z$_] (numerals 0-9, basic Latin letters, both lowercase and uppercase, dollar sign, underscore)
- Extended: U+0080 .. U+FFFF

Quoted

The following characters are valid, but identifiers using them must be quoted:

- ASCII: U+0001 .. U+007F (full Unicode Basic Multilingual Plane (BMP) except for U+0000)
- Extended: U+0080 .. U+FFFF
- Identifier quotes can themselves be used as part of an identifier, as long as they are quoted.

Further Rules

There are a number of other rules for identifiers:

- Identifiers are stored as Unicode (UTF-8)
- Identifiers may or may not be case-sensitive. See Indentifier Case-sensitivity.
- Database, table and column names can't end with space characters
- Identifier names may begin with a numeral, but can't only contain numerals unless quoted.
- An identifier starting with a numeral, followed by an 'e', may be parsed as a floating point number, and needs to be quoted.
- Identifiers are not permitted to contain the ASCII NUL character (U+0000) and supplementary characters (U+10000 and higher).
- Names such as 5e6, 9e are not prohibited, but it's strongly recommended not to use them, as they could lead to ambiguity in certain contexts, being treated as a number or expression.
- User variables cannot be used as part of an identifier, or as an identifier in an SQL statement.

Quote Character

The regular quote character is the backtick character - `` ` ``, but if the `ANSI_QUOTES` SQL_MODE option is specified, a regular double quote - `"` may be used as well.

The backtick character can be used as part of an identifier. In that case the identifier needs to be quoted. The quote character can be the backtick, but in that case, the backtick in the name must be escaped with another backtick.

Maximum Length

- Databases, tables, columns, indexes, constraints, stored routines, triggers, events, views, tablespaces, servers and log file groups have a maximum length of 64 characters.
- Compound statement labels have a maximum length of 16 characters
- Aliases have a maximum length of 256 characters, except for column aliases in CREATE VIEW statements, which are checked against the maximum column length of 64 characters (not the maximum alias length of 256 characters).
- Users have a maximum length of 80 characters.
- Roles have a maximum length of 128 characters.
- Multi-byte characters do not count extra towards towards the character limit.

Multiple Identifiers

MariaDB allows the column name to be used on its own if the reference will be unambiguous, or the table name to be used with the column name, or all three of the database, table and column names. A period is used to separate the identifiers, and the period can be surrounded by spaces.

Examples

Using the period to separate identifiers:

```
CREATE TABLE t1 (i int);

INSERT INTO t1(i) VALUES (10);

SELECT i FROM t1;
+------+
| i    |
+------+
|   10 |
+------+

SELECT t1.i FROM t1;
+------+
| i    |
+------+
|   10 |
+------+

SELECT test.t1.i FROM t1;
+------+
| i    |
+------+
|   10 |
+------+
```

The period can be separated by spaces:

```
SELECT test . t1 . i FROM t1;
+------+
| i    |
+------+
|   10 |
+------+
```

Resolving ambiguity:

```
CREATE TABLE t2 (i int);

SELECT i FROM t1 LEFT JOIN t2 ON t1.i=t2.i;
ERROR 1052 (23000): Column 'i' in field list is ambiguous

SELECT t1.i FROM t1 LEFT JOIN t2 ON t1.i=t2.i;
+------+
| i    |
+------+
|   10 |
+------+
```

Creating a table with characters that require quoting:

```
CREATE TABLE 123% (i int);
ERROR 1064 (42000): You have an error in your SQL syntax;
  check the manual that corresponds to your MariaDB server version for the right syntax
  to use near '123% (i int)' at line 1

CREATE TABLE `123%` (i int);
Query OK, 0 rows affected (0.85 sec)

CREATE TABLE `TABLE` (i int);
Query OK, 0 rows affected (0.36 sec)
```

Using double quotes as a quoting character:

```
CREATE TABLE "SELECT" (i int);
ERROR 1064 (42000): You have an error in your SQL syntax;
  check the manual that corresponds to your MariaDB server version for the right syntax
  to use near '"SELECT" (i int)' at line 1

SET sql_mode='ANSI_QUOTES';
Query OK, 0 rows affected (0.03 sec)

CREATE TABLE "SELECT" (i int);
Query OK, 0 rows affected (0.46 sec)
```

Using an identifier quote as part of an identifier name:

```
SHOW VARIABLES LIKE 'sql_mode';
+---------------+-------------+
| Variable_name | Value       |
+---------------+-------------+
| sql_mode      | ANSI_QUOTES |
+---------------+-------------+

CREATE TABLE "fg`d" (i int);
Query OK, 0 rows affected (0.34 sec)
```

Creating the table named `*` (Unicode number: U+002A) requires quoting.

```
CREATE TABLE `*` (a INT);
```

Floating point ambiguity:

```
CREATE TABLE 8984444cce5d (x INT);
Query OK, 0 rows affected (0.38 sec)

CREATE TABLE 8981e56cce5d (x INT);
ERROR 1064 (42000): You have an error in your SQL syntax;
  check the manual that corresponds to your MariaDB server version for the right syntax
  to use near '8981e56cce5d (x INT)' at line 1

CREATE TABLE `8981e56cce5d` (x INT);
Query OK, 0 rows affected (0.39 sec)
```

1.1.2.2 Identifier Case-sensitivity

Whether objects are case-sensitive or not is partly determined by the underlying operating system. Unix-based systems are case-sensitive, Windows is not, while Mac OS X is usually case-insensitive by default, but devices can be configured as case-sensitive using Disk Utility.

Database, table, table aliases and trigger names are affected by the systems case-sensitivity, while index, column, column aliases, stored routine and event names are never case sensitive.

Log file group name are case sensitive.

The lower_case_table_names server system variable plays a key role. It determines whether table names, aliases and database names are compared in a case-sensitive manner. If set to 0 (the default on Unix-based systems), table names and aliases and database names are compared in a case-sensitive manner. If set to 1 (the default on Windows), names are stored in lowercase and not compared in a case-sensitive manner. If set to 2 (the default on Mac OS X), names are stored as declared, but compared in lowercase.

It is thus possible to make Unix-based systems behave like Windows and ignore case-sensitivity, but the reverse is not true, as the underlying Windows filesystem can not support this.

Even on case-insensitive systems, you are required to use the same case consistently within the same statement. The following statement fails, as it refers to the table name in a different case.

```
SELECT * FROM a_table WHERE A_table.id>10;
```

For a full list of identifier naming rules, see Identifier Names.

Please note that lower_case_table_names is a database initialization parameter. This means that, along with innodb_page_size, this variable must be set before running mariadb-install-db, and will not change the behavior of servers

unless applied before the creation of core system databases.

1.1.2.3 Binary Literals

Binary literals can be written in one of the following formats: `b'value'`, `B'value'` or `0bvalue`, where `value` is a string composed by `0` and `1` digits.

Binary literals are interpreted as binary strings, and are convenient to represent VARBINARY, BINARY or BIT values.

To convert a binary literal into an integer, just add 0.

Examples

Printing the value as a binary string:

```
SELECT 0b1000001;
+-----------+
| 0b1000001 |
+-----------+
| A         |
+-----------+
```

Converting the same value into a number:

```
SELECT 0b1000001+0;
+-------------+
| 0b1000001+0 |
+-------------+
|          65 |
+-------------+
```

1.1.2.4 Boolean Literals

In MariaDB, `FALSE` is a synonym of 0 and `TRUE` is a synonym of 1. These constants are case insensitive, so `TRUE`, `True`, and `true` are equivalent.

These terms are not synonyms of 0 and 1 when used with the `IS` operator. So, for example, `10 IS TRUE` returns 1, while `10 = TRUE` returns 0 (because 1 != 10).

The `IS` operator accepts a third constant exists: `UNKNOWN`. It is always a synonym of NULL.

`TRUE` and `FALSE` are reserved words, while `UNKNOWN` is not.

1.1.2.5 Date and Time Literals

Contents

Standard syntaxes

MariaDB supports the SQL standard and ODBC syntaxes for DATE, TIME and TIMESTAMP literals.

SQL standard syntax:

- DATE 'string'
- TIME 'string'
- TIMESTAMP 'string'

ODBC syntax:

- {d 'string'}
- {t 'string'}
- {ts 'string'}

The timestamp literals are treated as DATETIME literals, because in MariaDB the range of `DATETIME` is closer to the `TIMESTAMP` range in the SQL standard.

`string` is a string in a proper format, as explained below.

`DATE` literals

A `DATE` string is a string in one of the following formats: `'YYYY-MM-DD'` or `'YY-MM-DD'`. Note that any punctuation character can be used as delimiter. All delimiters must consist of 1 character. Different delimiters can be used in the same string. Delimiters are optional (but if one delimiter is used, all delimiters must be used).

A `DATE` literal can also be an integer, in one of the following formats: `YYYYMMDD` or `YYMMDD`.

All the following `DATE` literals are valid, and they all represent the same value:

```
'19940101'
'940101'
'1994-01-01'
'94/01/01'
'1994-01/01'
'94:01!01'
19940101
940101
```

`DATETIME` literals

A `DATETIME` string is a string in one of the following formats: `'YYYY-MM-DD HH:MM:SS'` or `'YY-MM-DD HH:MM:SS'`. Note that any punctuation character can be used as delimiter for the date part and for the time part. All delimiters must consist of 1 character. Different delimiters can be used in the same string. The hours, minutes and seconds parts can consist of one character. For this reason, delimiters are mandatory for `DATETIME` literals.

The delimiter between the date part and the time part can be a `T` or any sequence of space characters (including tabs, new lines and carriage returns).

A `DATETIME` literal can also be a number, in one of the following formats: `YYYYMMDDHHMMSS`, `YYMMDDHHMMSS`, `YYYYMMDD` or `YYMMDD`. In this case, all the time subparts must consist of 2 digits.

All the following `DATE` literals are valid, and they all represent the same value:

```
'1994-01-01T12:30:03'
'1994/01/01\n\t 12+30+03'
'1994/01\\01\n\t 12+30-03'
'1994-01-01 12:30:3'
```

`TIME` literals

A `TIME` string is a string in one of the following formats: `'D HH:MM:SS'`, `'HH:MM:SS`, `'D HH:MM'`, `'HH:MM'`, `'D HH'`, or `'SS'`. `D` is a value from 0 to 34 which represents days. `:` is the only allowed delimiter for `TIME` literals. Delimiters are mandatory, with an exception: the `'HHMMSS'` format is allowed. When delimiters are used, each part of the literal can consist of one character.

A `TIME` literal can also be a number in one of the following formats: `HHMMSS`, `MMSS`, or `SS`.

The following literals are equivalent:

```
'09:05:00'
'9:05:0'
'9:5:0'
'090500'
```

- 2-digit years

The year part in `DATE` and `DATETIME` literals is determined as follows:

- `70 - 99 = 1970 - 1999`
- `00 - 69 = 2000 - 2069`

Microseconds

`DATETIME` and `TIME` literals can have an optional microseconds part. For both string and numeric forms, it is expressed as a decimal part. Up to 6 decimal digits are allowed. Examples:

```
'12:30:00.123456'
123000.123456
```

See Microseconds in MariaDB for details.

Date and time literals and the `SQL_MODE`

Unless the SQL_MODE `NO_ZERO_DATE` flag is set, some special values are allowed: the `'0000-00-00'` `DATE`, the `'00:00:00'` `TIME`, and the `0000-00-00 00:00:00` `DATETIME`.

If the `ALLOW_INVALID_DATES` flag is set, the invalid dates (for example, 30th February) are allowed. If not, if the `NO_ZERO_DATE` is set, an error is produced; otherwise, a zero-date is returned.

Unless the `NO_ZERO_IN_DATE` flag is set, each subpart of a date or time value (years, hours...) can be set to 0.

1.1.2.6 Hexadecimal Literals

Contents

Hexadecimal literals can be written using any of the following syntaxes:

- x'`value`'
- X'`value`' (SQL standard)
- 0x`value` (ODBC)

`value` is a sequence of hexadecimal digits (from `0` to `9` and from `A` to `F`). The case of the digits does not matter. With the first two syntaxes, `value` must consist of an even number of digits. With the last syntax, digits can be even, and they are treated as if they had an extra 0 at the beginning.

Normally, hexadecimal literals are interpreted as binary string, where each pair of digits represents a character. When used in a numeric context, they are interpreted as integers. (See the example below). In no case can a hexadecimal literal be a decimal number.

The first two syntaxes; `X'value'` and x'`value`', follow the SQL standard, and behave as a string in all contexts in MariaDB since MariaDB 10.0.3 and MariaDB 5.5.31 (fixing MDEV-4489). The latter syntax, 0x`value`, is a MySQL/MariaDB extension for hex hybrids and behaves as a string or as a number depending on context. MySQL treats all syntaxes the same, so there may be different results in MariaDB and MySQL (see below).

Examples

Representing the `a` character with the three syntaxes explained above:

```
SELECT x'61', X'61', 0x61;
+-------+-------+------+
| x'61' | X'61' | 0x61 |
+-------+-------+------+
| a     | a     | a    |
+-------+-------+------+
```

Hexadecimal literals in a numeric context:

```
SELECT 0 + 0xF, -0xF;
+---------+------+
| 0 + 0xF | -0xF |
+---------+------+
|      15 |  -15 |
+---------+------+
```

Fun with Types

```
CREATE TABLE t1 (a INT, b VARCHAR(10));
INSERT INTO t1 VALUES (0x31, 0x61),(COALESCE(0x31), COALESCE(0x61));

SELECT * FROM t1;
+------+------+
| a    | b    |
+------+------+
|   49 | a    |
|    1 | a    |
+------+------+
```

The reason for the differing results above is that when 0x31 is inserted directly to the column, it's treated as a number, while when 0x31 is passed to COALESCE(), it's treated as a string, because:

- HEX values have a string data type by default.
- COALESCE() has the same data type as the argument.

Differences Between MariaDB and MySQL

```
SELECT x'0a'+0;
+---------+
| x'0a'+0 |
+---------+
|       0 |
+---------+
1 row in set, 1 warning (0.00 sec)

Warning (Code 1292): Truncated incorrect DOUBLE value: '\x0A'

SELECT X'0a'+0;
+---------+
| X'0a'+0 |
+---------+
|       0 |
+---------+
1 row in set, 1 warning (0.00 sec)

Warning (Code 1292): Truncated incorrect DOUBLE value: '\x0A'

SELECT 0x0a+0;
+--------+
| 0x0a+0 |
+--------+
|     10 |
+--------+
```

In MySQL (up until at least MySQL 8.0.26):

```
SELECT x'0a'+0;
+---------+
| x'0a'+0 |
+---------+
|      10 |
+---------+

SELECT X'0a'+0;
+---------+
| X'0a'+0 |
+---------+
|      10 |
+---------+

SELECT 0x0a+0;
+--------+
| 0x0a+0 |
+--------+
|     10 |
+--------+
```

1.1.2.7 Identifier Qualifiers

Contents

Qualifiers are used within SQL statements to reference data structures, such as databases, tables, or columns. For example, typically a SELECT query contains references to some columns and at least one table.

Qualifiers can be composed by one or more identifiers, where the initial parts affect the context within which the final identifier is interpreted:

- For a database, only the database identifier needs to be specified.
- For objects which are contained in a database (like tables, views, functions, etc) the database identifier can be specified. If no database is specified, the current database is assumed (see USE and DATABASE() for more details). If there is no default database and no database is specified, an error is issued.
- For column names, the table and the database are generally obvious from the context of the statement. It is however possible to specify the table identifier, or the database identifier plus the table identifier.
- An identifier is fully-qualified if it contains all possible qualifiers, for example, the following column is fully qualified: `db_name.tbl_name.col_name`.

If a qualifier is composed by more than one identifier, a dot (.) must be used as a separator. All identifiers can be quoted individually. Extra spacing (including new lines and tabs) is allowed.

All the following examples are valid:

- db_name.tbl_name.col_name
- tbl_name
- `db_name`.`tbl_name`.`col_name`
- `db_name` . `tbl_name`
- db_name. tbl_name

If a table identifier is prefixed with a dot (.), the default database is assumed. This syntax is supported for ODBC compliance, but has no practical effect on MariaDB. These qualifiers are equivalent:

- tbl_name
- . tbl_name
- .`tbl_name`
- . `tbl_name`

For DML statements, it is possible to specify a list of the partitions using the PARTITION clause. See Partition Pruning and Selection for details.

1.1.2.8 Identifier to File Name Mapping

Some identifiers map to a file name on the filesystem. Databases each have their own directory, while, depending on the storage engine, table names and index names may map to a file name.

Not all characters that are allowed in table names can be used in file names. Every filesystem has its own rules of what characters can be used in file names. To let the user create tables using all characters allowed in the SQL Standard and to not depend on whatever particular filesystem a particular database resides, MariaDB encodes "potentially unsafe"

characters in the table name to derive the corresponding file name.

This is implemented using a special character set. MariaDB converts a table name to the "filename" character set to get the file name for this table. And it converts the file name from the "filename" character set to, for example, utf8 to get the table name for this file name.

The conversion rules are as follows: if the identifier is made up only of basic Latin numbers, letters and/or the underscore character, the encoding matches the name (see however Identifier Case Sensitivity). Otherwise they are encoded according to the following table:

Code Range	Pattern	Number	Used	Unused	Blocks
00C0..017F	[@][0..4][g..z]	5*20= 100	97	3	Latin-1 Supplement + Latin Extended-A
0370..03FF	[@][5..9][g..z]	5*20= 100	88	12	Greek and Coptic
0400..052F	[@][g..z][0..6]	20*7= 140	137	3	Cyrillic + Cyrillic Supplement
0530..058F	[@][g..z][7..8]	20*2= 40	38	2	Armenian
2160..217F	[@][g..z][9]	20*1= 20	16	4	Number Forms
0180..02AF	[@][g..z][a..k]	20*11=220	203	17	Latin Extended-B + IPA Extensions
1E00..1EFF	[@][g..z][l..r]	20*7= 140	136	4	Latin Extended Additional
1F00..1FFF	[@][g..z][s..z]	20*8= 160	144	16	Greek Extended
....	[@][a..f][g..z]	6*20= 120	0	120	RESERVED
24B6..24E9	[@][@][a..z]	26	26	0	Enclosed Alphanumerics
FF21..FF5A	[@][a..z][@]	26	26	0	Halfwidth and Fullwidth forms

Code Range values are UCS-2.

All of this encoding happens transparently at the filesystem level with one exception. Until MySQL 5.1.6, an old encoding was used. Identifiers created in a version before MySQL 5.1.6, and which haven't been updated to the new encoding, the server prefixes `mysql50` to their name.

Examples

Find the file name for a table with a non-Latin1 name:

```
select cast(convert("this_is_таблица" USING filename) as binary);
+-----------------------------------------------------------------+
| cast(convert("this_is_таблица" USING filename) as binary)       |
+-----------------------------------------------------------------+
| this_is_@y0@g0@h0@r0@o0@i1@g0                                   |
+-----------------------------------------------------------------+
```

Find the table name for a file name:

```
select convert(_filename "this_is_@y0@g0@h0@r0@o0@i1@g0" USING utf8);
+-------------------------------------------------------------------+
| convert(_filename "this_is_@y0@g0@h0@r0@o0@i1@g0" USING utf8) |
+-------------------------------------------------------------------+
| this_is_таблица                                                   |
+-------------------------------------------------------------------+
```

An old table created before MySQL 5.1.6, with the old encoding:

```
SHOW TABLES;
+--------------------+
| Tables_in_test     |
+--------------------+
| #mysql50#table@1   |
+--------------------+
```

The prefix needs to be supplied to reference this table:

```
SHOW COLUMNS FROM `table@1`;
ERROR 1146 (42S02): Table 'test.table@1' doesn't exist

SHOW COLUMNS FROM `#mysql50#table@1`;
+-------+---------+------+-----+---------+-------+
| Field | Type    | Null | Key | Default | Extra |
+-------+---------+------+-----+---------+-------+
| i     | int(11) | YES  |     | NULL    |       |
+-------+---------+------+-----+---------+-------+
```

1.1.2.9 MariaDB Error Codes

MariaDB shares error codes with MySQL, as well as adding a number of new error codes specific to MariaDB.

An example of an error code is as follows:

```
SELECT * FROM x;
ERROR 1046 (3D000): No database selected
```

Contents

There are three pieces of information returned in an error:

- A numeric error code, in this case `1046`. Error codes from 1900 and up are specific to MariaDB, while error codes from 1000 to 1800 are shared by MySQL and MariaDB.
- An SQLSTATE value, consisting of five characters, in this case `3D000`. These codes are standard to ODBC and ANSI SQL. When MariaDB cannot allocate a standard SQLSTATE code, a generic `HY000`, or general error, is used.
- A string describing the error, in this case `No database selected`.

New error codes are being continually being added as new features are added. For a definitive list, see the file `sql/share/errmsg-utf8.txt`, as well as `include/mysqld_error.h` in the build directory, generated by the `comp_err` tool. Also, the perror tool can be used to get the error message which is associated with a given error code.

Shared MariaDB/MySQL error codes

Error Code	SQLSTATE	Error	Description
1000	HY000	ER_HASHCHK	hashchk
1001	HY000	ER_NISAMCHK	isamchk
1002	HY000	ER_NO	NO
1003	HY000	ER_YES	YES
1004	HY000	ER_CANT_CREATE_FILE	Can't create file '%s' (errno: %d)
1005	HY000	ER_CANT_CREATE_TABLE	Can't create table '%s' (errno: %d)
1006	HY000	ER_CANT_CREATE_DB	Can't create database '%s' (errno: %d
1007	HY000	ER_DB_CREATE_EXISTS	Can't create database '%s'; database exists
1008	HY000	ER_DB_DROP_EXISTS	Can't drop database '%s'; database doesn't exist
1009	HY000	ER_DB_DROP_DELETE	Error dropping database (can't delete '%s', errno: %d)
1010	HY000	ER_DB_DROP_RMDIR	Error dropping database (can't rmdir '%s', errno: %d)
1011	HY000	ER_CANT_DELETE_FILE	Error on delete of '%s' (errno: %d)
1012	HY000	ER_CANT_FIND_SYSTEM_REC	Can't read record in system table
1013	HY000	ER_CANT_GET_STAT	Can't get status of '%s' (errno: %d)
1014	HY000	ER_CANT_GET_WD	Can't get working directory (errno: %d)
1015	HY000	ER_CANT_LOCK	Can't lock file (errno: %d)

1016	HY000	ER_CANT_OPEN_FILE	Can't open file: '%s' (errno: %d)
1017	HY000	ER_FILE_NOT_FOUND	Can't find file: '%s' (errno: %d)
1018	HY000	ER_CANT_READ_DIR	Can't read dir of '%s' (errno: %d)
1019	HY000	ER_CANT_SET_WD	Can't change dir to '%s' (errno: %d)
1020	HY000	ER_CHECKREAD	Record has changed since last read in table '%s'
1021	HY000	ER_DISK_FULL	Disk full (%s); waiting for someone to free some space...
1022	23000	ER_DUP_KEY	Can't write; duplicate key in table '%s'
1023	HY000	ER_ERROR_ON_CLOSE	Error on close of '%s' (errno: %d)
1024	HY000	ER_ERROR_ON_READ	Error reading file '%s' (errno: %d)
1025	HY000	ER_ERROR_ON_RENAME	Error on rename of '%s' to '%s' (errno: %d)
1026	HY000	ER_ERROR_ON_WRITE	Error writing file '%s' (errno: %d)
1027	HY000	ER_FILE_USED	'%s' is locked against change
1028	HY000	ER_FILSORT_ABORT	Sort aborted
1029	HY000	ER_FORM_NOT_FOUND	View '%s' doesn't exist for '%s'
1030	HY000	ER_GET_ERRN	Got error %d from storage engine
1031	HY000	ER_ILLEGAL_HA	Table storage engine for '%s' doesn't have this option
1032	HY000	ER_KEY_NOT_FOUND	Can't find record in '%s'
1033	HY000	ER_NOT_FORM_FILE	Incorrect information in file: '%s'
1034	HY000	ER_NOT_KEYFILE	Incorrect key file for table '%s'; try to repair it
1035	HY000	ER_OLD_KEYFILE	Old key file for table '%s'; repair it!
1036	HY000	ER_OPEN_AS_READONLY	Table '%s' is read only
1037	HY001	ER_OUTOFMEMORY	Out of memory; restart server and try again (needed %d bytes)
1038	HY001	ER_OUT_OF_SORTMEMORY	Out of sort memory, consider increasing server sort buffer size
1039	HY000	ER_UNEXPECTED_EOF	Unexpected EOF found when reading file '%s' (Errno: %d)
1040	08004	ER_CON_COUNT_ERROR	Too many connections
1041	HY000	ER_OUT_OF_RESOURCES	Out of memory; check if mysqld or some other process uses all available memory; if not, you may have to use 'ulimit' to allow mysqld to use more memory or you can add more swap space
1042	08S01	ER_BAD_HOST_ERROR	Can't get hostname for your address
1043	08S01	ER_HANDSHAKE_ERROR	Bad handshake
1044	42000	ER_DBACCESS_DENIED_ERROR	Access denied for user '%s'@'%s' to database '%s'
1045	28000	ER_ACCESS_DENIED_ERROR	Access denied for user '%s'@'%s' (using password: %s)
1046	3D000	ER_NO_DB_ERROR	No database selected
1047	08S01	ER_UNKNOWN_COM_ERROR	Unknown command
1048	23000	ER_BAD_NULL_ERROR	Column '%s' cannot be null
1049	42000	ER_BAD_DB_ERROR	Unknown database '%s'
1050	42S01	ER_TABLE_EXISTS_ERROR	Table '%s' already exists
1051	42S02	ER_BAD_TABLE_ERROR	Unknown table '%s'
1052	23000	ER_NON_UNIQ_ERROR	Column '%s' in %s is ambiguous
1053	08S01	ER_SERVER_SHUTDOWN	Server shutdown in progress
1054	42S22	ER_BAD_FIELD_ERROR	Unknown column '%s' in '%s'

1055	42000	ER_WRONG_FIELD_WITH_GROUP	'%s' isn't in GROUP BY
1056	42000	ER_WRONG_GROUP_FIELD	Can't group on '%s'
1057	42000	ER_WRONG_SUM_SELECT	Statement has sum functions and columns in same statement
1058	21S01	ER_WRONG_VALUE_COUNT	Column count doesn't match value count
1059	42000	ER_TOO_LONG_IDENT	Identifier name '%s' is too long
1060	42S21	ER_DUP_FIELDNAME	Duplicate column name '%s'
1061	42000	ER_DUP_KEYNAME	Duplicate key name '%s'
1062	23000	ER_DUP_ENTRY	Duplicate entry '%s' for key %d
1063	42000	ER_WRONG_FIELD_SPEC	Incorrect column specifier for column '%s'
1064	42000	ER_PARSE_ERROR	%s near '%s' at line %d
1065	42000	ER_EMPTY_QUERY	Query was empty
1066	42000	ER_NONUNIQ_TABLE	Not unique table/alias: '%s'
1067	42000	ER_INVALID_DEFAULT	Invalid default value for '%s'
1068	42000	ER_MULTIPLE_PRI_KEY	Multiple primary key defined
1069	42000	ER_TOO_MANY_KEYS	Too many keys specified; max %d keys allowed
1070	42000	ER_TOO_MANY_KEY_PARTS	Too many key parts specified; max %d parts allowed
1071	42000	ER_TOO_LONG_KEY	Specified key was too long; max key length is %d bytes
1072	42000	ER_KEY_COLUMN_DOES_NOT_EXITS	Key column '%s' doesn't exist in table
1073	42000	ER_BLOB_USED_AS_KEY	BLOB column '%s' can't be used in key specification with the used table type
1074	42000	ER_TOO_BIG_FIELDLENGTH	Column length too big for column '%s' (max = %lu); use BLOB or TEXT instead
1075	42000	ER_WRONG_AUTO_KEY	Incorrect table definition; there can be only one auto column and it must be defined as a key
1076	HY000	ER_READY	%s: ready for connections. Version: '%s' socket: '%s' port: %d
1077	HY000	ER_NORMAL_SHUTDOWN	%s: Normal shutdown
1078	HY000	ER_GOT_SIGNAL	%s: Got signal %d. Aborting!
1079	HY000	ER_SHUTDOWN_COMPLETE	%s: Shutdown complete
1080	08S01	ER_FORCING_CLOSE	%s: Forcing close of thread %ld user: '%s'
1081	08S01	ER_IPSOCK_ERROR	Can't create IP socket
1082	42S12	ER_NO_SUCH_INDEX	Table '%s' has no index like the one used in CREATE INDEX; recreate the table
1083	42000	ER_WRONG_FIELD_TERMINATORS	Field separator argument is not what is expected; check the manual
1084	42000	ER_BLOBS_AND_NO_TERMINATED	You can't use fixed rowlength with BLOBs; please use 'fields terminated by'
1085	HY000	ER_TEXTFILE_NOT_READABLE	The file '%s' must be in the database directory or be readable by all
1086	HY000	ER_FILE_EXISTS_ERROR	File '%s' already exists
1087	HY000	ER_LOAD_INF	Records: %ld Deleted: %ld Skipped: %ld Warnings: %ld
1088	HY000	ER_ALTER_INF	Records: %ld Duplicates: %ld
1089	HY000	ER_WRONG_SUB_KEY	Incorrect prefix key; the used key part isn't a string, the used length is longer than the key part, or the storage engine doesn't support unique prefix keys

1090	42000	ER_CANT_REMOVE_ALL_FIELDS	You can't delete all columns with ALTER TABLE; use DROP TABLE instead
1091	42000	ER_CANT_DROP_FIELD_OR_KEY	Can't DROP '%s'; check that column/key exists
1092	HY000	ER_INSERT_INF	Records: %ld Duplicates: %ld Warnings: %ld
1093	HY000	ER_UPDATE_TABLE_USED	You can't specify target table '%s' for update in FROM clause
1094	HY000	ER_NO_SUCH_THREAD	Unknown thread id: %lu
1095	HY000	ER_KILL_DENIED_ERROR	You are not owner of thread %lu
1096	HY000	ER_NO_TABLES_USED	No tables used
1097	HY000	ER_TOO_BIG_SET	Too many strings for column %s and SET
1098	HY000	ER_NO_UNIQUE_LOGFILE	Can't generate a unique log-filename %s.(1-999)
1099	HY000	ER_TABLE_NOT_LOCKED_FOR_WRITE	Table '%s' was locked with a READ lock and can't be updated

Error Code	SQLSTATE	Error	Description
1100	HY000	ER_TABLE_NOT_LOCKED	Table '%s' was not locked with LOCK TABLES
1101		ER_UNUSED_17	You should never see it
1102	42000	ER_WRONG_DB_NAME	Incorrect database name '%s'
1103	42000	ER_WRONG_TABLE_NAME	Incorrect table name '%s'
1104	42000	ER_TOO_BIG_SELECT	The SELECT would examine more than MAX_JOIN_SIZE rows; check your WHERE and use SET SQL_BIG_SELECTS=1 or SET MAX_JOIN_SIZE=# if the SELECT is okay
1105	HY000	ER_UNKNOWN_ERROR	Unknown error
1106	42000	ER_UNKNOWN_PROCEDURE	Unknown procedure '%s'
1107	42000	ER_WRONG_PARAMCOUNT_TO_PROCEDURE	Incorrect parameter count to procedure '%s'
1108	HY000	ER_WRONG_PARAMETERS_TO_PROCEDURE	Incorrect parameters to procedure '%s'
1109	42S02	ER_UNKNOWN_TABLE	Unknown table '%s' in %s
1110	42000	ER_FIELD_SPECIFIED_TWICE	Column '%s' specified twice
1111	HY000	ER_INVALID_GROUP_FUNC_USE	Invalid use of group function
1112	42000	ER_UNSUPPORTED_EXTENSION	Table '%s' uses an extension that doesn't exist in this MariaDB version
1113	42000	ER_TABLE_MUST_HAVE_COLUMNS	A table must have at least 1 column
1114	HY000	ER_RECORD_FILE_FULL	The table '%s' is full
1115	42000	ER_UNKNOWN_CHARACTER_SET	Unknown character set: '%s'
1116	HY000	ER_TOO_MANY_TABLES	Too many tables; MariaDB can only use %d tables in a join
1117	HY000	ER_TOO_MANY_FIELDS	Too many columns
1118	42000	ER_TOO_BIG_ROWSIZE	Row size too large. The maximum row size for the used table type, not counting BLOBs, is %ld. You have to change some columns to TEXT or BLOBs
1119	HY000	ER_STACK_OVERRUN	Thread stack overrun: Used: %ld of a %ld stack. Use 'mysqld --thread_stack=#' to specify a bigger stack if needed
1120	42000	ER_WRONG_OUTER_JOIN	Cross dependency found in OUTER JOIN; examine your ON conditions

1121	42000	ER_NULL_COLUMN_IN_INDEX	Table handler doesn't support NULL in given index. Please change column '%s' to be NOT NULL or use another handler
1122	HY000	ER_CANT_FIND_UDF	Can't load function '%s'
1123	HY000	ER_CANT_INITIALIZE_UDF	Can't initialize function '%s'; %s
1124	HY000	ER_UDF_NO_PATHS	No paths allowed for shared library
1125	HY000	ER_UDF_EXISTS	Function '%s' already exists
1126	HY000	ER_CANT_OPEN_LIBRARY	Can't open shared library '%s' (Errno: %d %s)
1127	HY000	ER_CANT_FIND_DL_ENTRY	Can't find symbol '%s' in library
1128	HY000	ER_FUNCTION_NOT_DEFINED	Function '%s' is not defined
1129	HY000	ER_HOST_IS_BLOCKED	Host '%s' is blocked because of many connection errors; unblock with 'mysqladmin flush-hosts'
1130	HY000	ER_HOST_NOT_PRIVILEGED	Host '%s' is not allowed to connect to this MariaDB server
1131	42000	ER_PASSWORD_ANONYMOUS_USER	You are using MariaDB as an anonymous user and anonymous users are not allowed to change passwords
1132	42000	ER_PASSWORD_NOT_ALLOWED	You must have privileges to update tables in the mysql database to be able to change passwords for others
1133	42000	ER_PASSWORD_NO_MATCH	Can't find any matching row in the user table
1134	HY000	ER_UPDATE_INF	Rows matched: %ld Changed: %ld Warnings: %ld
1135	HY000	ER_CANT_CREATE_THREAD	Can't create a new thread (Errno %d); if you are not out of available memory, you can consult the manual for a possible OS-dependent bug
1136	21S01	ER_WRONG_VALUE_COUNT_ON_ROW	Column count doesn't match value count at row %ld
1137	HY000	ER_CANT_REOPEN_TABLE	Can't reopen table: '%s'
1138	22004	ER_INVALID_USE_OF_NULL	Invalid use of NULL value
1139	42000	ER_REGEXP_ERROR	Got error '%s' from regexp
1140	42000	ER_MIX_OF_GROUP_FUNC_AND_FIELDS	Mixing of GROUP columns (MIN(),MAX(),COUNT(),...) with no GROUP columns is illegal if there is no GROUP BY clause
1141	42000	ER_NONEXISTING_GRANT	There is no such grant defined for user '%s' on host '%s'
1142	42000	ER_TABLEACCESS_DENIED_ERROR	%s command denied to user '%s'@'%s' for table '%s'
1143	42000	ER_COLUMNACCESS_DENIED_ERROR	%s command denied to user '%s'@'%s' for column '%s' in table '%s'
1144	42000	ER_ILLEGAL_GRANT_FOR_TABLE	Illegal GRANT/REVOKE command; please consult the manual to see which privileges can be used
1145	42000	ER_GRANT_WRONG_HOST_OR_USER	The host or user argument to GRANT is too long
1146	42S02	ER_NO_SUCH_TABLE	Table '%s.%s' doesn't exist
1147	42000	ER_NONEXISTING_TABLE_GRANT	There is no such grant defined for user '%s' on host '%s' on table '%s'

1148	42000	ER_NOT_ALLOWED_COMMAND	The used command is not allowed with this MariaDB version
1149	42000	ER_SYNTAX_ERROR	You have an error in your SQL syntax; check the manual that corresponds to your MariaDB server version for the right syntax to use
1150	HY000	ER_DELAYED_CANT_CHANGE_LOCK	Delayed insert thread couldn't get requested lock for table %s
1151	HY000	ER_TOO_MANY_DELAYED_THREADS	Too many delayed threads in use
1152	08S01	ER_ABORTING_CONNECTION	Aborted connection %ld to db: '%s' user: '%s' (%s)
1153	08S01	ER_NET_PACKET_TOO_LARGE	Got a packet bigger than 'max_allowed_packet' bytes
1154	08S01	ER_NET_READ_ERROR_FROM_PIPE	Got a read error from the connection pipe
1155	08S01	ER_NET_FCNTL_ERROR	Got an error from fcntl()
1156	08S01	ER_NET_PACKETS_OUT_OF_ORDER	Got packets out of order
1157	08S01	ER_NET_UNCOMPRESS_ERROR	Couldn't uncompress communication packet
1158	08S01	ER_NET_READ_ERROR	Got an error reading communication packets
1159	08S01	ER_NET_READ_INTERRUPTED	Got timeout reading communication packets
1160	08S01	ER_NET_ERROR_ON_WRITE	Got an error writing communication packets
1161	08S01	ER_NET_WRITE_INTERRUPTED	Got timeout writing communication packets
1162	42000	ER_TOO_LONG_STRING	Result string is longer than 'max_allowed_packet' bytes
1163	42000	ER_TABLE_CANT_HANDLE_BLOB	The used table type doesn't support BLOB/TEXT columns
1164	42000	ER_TABLE_CANT_HANDLE_AUTO_INCREMENT	The used table type doesn't support AUTO_INCREMENT columns
1165	HY000	ER_DELAYED_INSERT_TABLE_LOCKED	INSERT DELAYED can't be used with table '%s' because it is locked with LOCK TABLES
1166	42000	ER_WRONG_COLUMN_NAME	Incorrect column name '%s'
1167	42000	ER_WRONG_KEY_COLUMN	The used storage engine can't index column '%s'
1168	HY000	ER_WRONG_MRG_TABLE	Unable to open underlying table which is differently defined or of non-MyISAM type or doesn't exist
1169	23000	ER_DUP_UNIQUE	Can't write, because of unique constraint, to table '%s'
1170	42000	ER_BLOB_KEY_WITHOUT_LENGTH	BLOB/TEXT column '%s' used in key specification without a key length
1171	42000	ER_PRIMARY_CANT_HAVE_NULL	All parts of a PRIMARY KEY must be NOT NULL; if you need NULL in a key, use UNIQUE instead
1172	42000	ER_TOO_MANY_ROWS	Result consisted of more than one row
1173	42000	ER_REQUIRES_PRIMARY_KEY	This table type requires a primary key
1174	HY000	ER_NO_RAID_COMPILED	This version of MariaDB is not compiled with RAID support
1175	HY000	ER_UPDATE_WITHOUT_KEY_IN_SAFE_MODE	You are using safe update mode and you tried to update a table without a WHERE that uses a KEY column
1176	42000	ER_KEY_DOES_NOT_EXITS	Key '%s' doesn't exist in table '%s'
1177	42000	ER_CHECK_NO_SUCH_TABLE	Can't open table

1178	42000	ER_CHECK_NOT_IMPLEMENTED	The storage engine for the table doesn't support %s
1179	25000	ER_CANT_DO_THIS_DURING_AN_TRANSACTION	You are not allowed to execute this command in a transaction
1180	HY000	ER_ERROR_DURING_COMMIT	Got error %d during COMMIT
1181	HY000	ER_ERROR_DURING_ROLLBACK	Got error %d during ROLLBACK
1182	HY000	ER_ERROR_DURING_FLUSH_LOGS	Got error %d during FLUSH_LOGS
1183	HY000	ER_ERROR_DURING_CHECKPOINT	Got error %d during CHECKPOINT
1184	08S01	ER_NEW_ABORTING_CONNECTION	Aborted connection %ld to db: '%s' user: '%s' host: '%s' (%s)
1185		ER_UNUSED_10	You should never see it
1186	HY000	ER_FLUSH_MASTER_BINLOG_CLOSED	Binlog closed, cannot RESET MASTER
1187	HY000	ER_INDEX_REBUILD	Failed rebuilding the index of dumped table '%s'
1188	HY000	ER_MASTER	Error from master: '%s'
1189	08S01	ER_MASTER_NET_READ	Net error reading from master
1190	08S01	ER_MASTER_NET_WRITE	Net error writing to master
1191	HY000	ER_FT_MATCHING_KEY_NOT_FOUND	Can't find FULLTEXT index matching the column list
1192	HY000	ER_LOCK_OR_ACTIVE_TRANSACTION	Can't execute the given command because you have active locked tables or an active transaction
1193	HY000	ER_UNKNOWN_SYSTEM_VARIABLE	Unknown system variable '%s'
1194	HY000	ER_CRASHED_ON_USAGE	Table '%s' is marked as crashed and should be repaired
1195	HY000	ER_CRASHED_ON_REPAIR	Table '%s' is marked as crashed and last (automatic?) repair failed
1196	HY000	ER_WARNING_NOT_COMPLETE_ROLLBACK	Some non-transactional changed tables couldn't be rolled back
1197	HY000	ER_TRANS_CACHE_FULL	Multi-statement transaction required more than 'max_binlog_cache_size' bytes of storage; increase this mysqld variable and try again
1198	HY000	ER_SLAVE_MUST_STOP	This operation cannot be performed with a running slave; run STOP SLAVE first
1199	HY000	ER_SLAVE_NOT_RUNNING	This operation requires a running slave; configure slave and do START SLAVE

Error Code	SQLSTATE	Error	Description
1200	HY000	ER_BAD_SLAVE	The server is not configured as slave; fix in config file or with CHANGE MASTER TO
1201	HY000	ER_MASTER_INFO	Could not initialize master info structure; more error messages can be found in the MariaDB error log
1202	HY000	ER_SLAVE_THREAD	Could not create slave thread; check system resources
1203	42000	ER_TOO_MANY_USER_CONNECTIONS	User %s already has more than 'max_user_connections' active connections
1204	HY000	ER_SET_CONSTANTS_ONLY	You may only use constant expressions with SET

1205	HY000	ER_LOCK_WAIT_TIMEOUT	Lock wait timeout exceeded; try restarting transaction
1206	HY000	ER_LOCK_TABLE_FULL	The total number of locks exceeds the lock table size
1207	25000	ER_READ_ONLY_TRANSACTION	Update locks cannot be acquired during a READ UNCOMMITTED transaction
1208	HY000	ER_DROP_DB_WITH_READ_LOCK	DROP DATABASE not allowed while thread is holding global read lock
1209	HY000	ER_CREATE_DB_WITH_READ_LOCK	CREATE DATABASE not allowed while thread is holding global read lock
1210	HY000	ER_WRONG_ARGUMENTS	Incorrect arguments to %s
1211	42000	ER_NO_PERMISSION_TO_CREATE_USER	'%s'@'%s' is not allowed to create new users
1212	HY000	ER_UNION_TABLES_IN_DIFFERENT_DIR	Incorrect table definition; all MERGE tables must be in the same database
1213	40001	ER_LOCK_DEADLOCK	Deadlock found when trying to get lock; try restarting transaction
1214	HY000	ER_TABLE_CANT_HANDLE_FT	The used table type doesn't support FULLTEXT indexes
1215	HY000	ER_CANNOT_ADD_FOREIGN	Cannot add foreign key constraint
1216	23000	ER_NO_REFERENCED_ROW	Cannot add or update a child row: a foreign key constraint fails
1217	23000	ER_ROW_IS_REFERENCED	Cannot delete or update a parent row: a foreign key constraint fails
1218	08S01	ER_CONNECT_TO_MASTER	Error connecting to master: %s
1219	HY000	ER_QUERY_ON_MASTER	Error running query on master: %s
1220	HY000	ER_ERROR_WHEN_EXECUTING_COMMAND	Error when executing command %s: %s
1221	HY000	ER_WRONG_USAGE	Incorrect usage of %s and %s
1222	21000	ER_WRONG_NUMBER_OF_COLUMNS_IN_SELECT	The used SELECT statements have a different number of columns
1223	HY000	ER_CANT_UPDATE_WITH_READLOCK	Can't execute the query because you have a conflicting read lock
1224	HY000	ER_MIXING_NOT_ALLOWED	Mixing of transactional and non-transactional tables is disabled
1225	HY000	ER_DUP_ARGUMENT	Option '%s' used twice in statement
1226	42000	ER_USER_LIMIT_REACHED	User '%s' has exceeded the '%s' resource (current value: %ld)
1227	42000	ER_SPECIFIC_ACCESS_DENIED_ERROR	Access denied; you need (at least one of) the %s privilege(s) for this operation
1228	HY000	ER_LOCAL_VARIABLE	Variable '%s' is a SESSION variable and can't be used with SET GLOBAL
1229	HY000	ER_GLOBAL_VARIABLE	Variable '%s' is a GLOBAL variable and should be set with SET GLOBAL
1230	42000	ER_NO_DEFAULT	Variable '%s' doesn't have a default value
1231	42000	ER_WRONG_VALUE_FOR_VAR	Variable '%s' can't be set to the value of '%s'
1232	42000	ER_WRONG_TYPE_FOR_VAR	Incorrect argument type to variable '%s'
1233	HY000	ER_VAR_CANT_BE_READ	Variable '%s' can only be set, not read
1234	42000	ER_CANT_USE_OPTION_HERE	Incorrect usage/placement of '%s'

1235	42000	ER_NOT_SUPPORTED_YET	This version of MariaDB doesn't yet support '%s'
1236	HY000	ER_MASTER_FATAL_ERROR_READING_BINLOG	Got fatal error %d from master when reading data from binary log: '%s'
1237	HY000	ER_SLAVE_IGNORED_TABLE	Slave SQL thread ignored the query because of replicate-*-table rules
1238	HY000	ER_INCORRECT_GLOBAL_LOCAL_VAR	Variable '%s' is a %s variable
1239	42000	ER_WRONG_FK_DEF	Incorrect foreign key definition for '%s': %s
1240	HY000	ER_KEY_REF_DO_NOT_MATCH_TABLE_REF	Key reference and table reference don't match
1241	21000	ER_OPERAND_COLUMNS	Operand should contain %d column(s)
1242	21000	ER_SUBQUERY_NO_1_ROW	Subquery returns more than 1 row
1243	HY000	ER_UNKNOWN_STMT_HANDLER	Unknown prepared statement handler (%.*s) given to %s
1244	HY000	ER_CORRUPT_HELP_DB	Help database is corrupt or does not exist
1245	HY000	ER_CYCLIC_REFERENCE	Cyclic reference on subqueries
1246	HY000	ER_AUTO_CONVERT	Converting column '%s' from %s to %s
1247	42S22	ER_ILLEGAL_REFERENCE	Reference '%s' not supported (%s)
1248	42000	ER_DERIVED_MUST_HAVE_ALIAS	Every derived table must have its own alias
1249	01000	ER_SELECT_REDUCED	Select %u was reduced during optimization
1250	42000	ER_TABLENAME_NOT_ALLOWED_HERE	Table '%s' from one of the SELECTs cannot be used in %s
1251	08004	ER_NOT_SUPPORTED_AUTH_MODE	Client does not support authentication protocol requested by server; consider upgrading MariaDB client
1252	42000	ER_SPATIAL_CANT_HAVE_NULL	All parts of a SPATIAL index must be NOT NULL
1253	42000	ER_COLLATION_CHARSET_MISMATCH	COLLATION '%s' is not valid for CHARACTER SET '%s'
1254	HY000	ER_SLAVE_WAS_RUNNING	Slave is already running
1255	HY000	ER_SLAVE_WAS_NOT_RUNNING	Slave already has been stopped
1256	HY000	ER_TOO_BIG_FOR_UNCOMPRESS	Uncompressed data size too large; the maximum size is %d (probably, length of uncompressed data was corrupted)
1257	HY000	ER_ZLIB_Z_MEM_ERROR	ZLIB: Not enough memory
1258	HY000	ER_ZLIB_Z_BUF_ERROR	ZLIB: Not enough room in the output buffer (probably, length of uncompressed data was corrupted)
1259	HY000	ER_ZLIB_Z_DATA_ERROR	ZLIB: Input data corrupted
1260	HY000	ER_CUT_VALUE_GROUP_CONCAT	Row %u was cut by GROUP_CONCAT()
1261	01000	ER_WARN_TOO_FEW_RECORDS	Row %ld doesn't contain data for all columns
1262	01000	ER_WARN_TOO_MANY_RECORDS	Row %ld was truncated; it contained more data than there were input columns
1263	22004	ER_WARN_NULL_TO_NOTNULL	Column set to default value; NULL supplied to NOT NULL column '%s' at row %ld
1264	22003	ER_WARN_DATA_OUT_OF_RANGE	Out of range value for column '%s' at row %ld
1265	01000	WARN_DATA_TRUNCATED	Data truncated for column '%s' at row %ld

1266	HY000	ER_WARN_USING_OTHER_HANDLER	Using storage engine %s for table '%s'
1267	HY000	ER_CANT_AGGREGATE_2COLLATIONS	Illegal mix of collations (%s,%s) and (%s,%s) for operation '%s'
1268	HY000	ER_DROP_USER	Cannot drop one or more of the requested users
1269	HY000	ER_REVOKE_GRANTS	Can't revoke all privileges for one or more of the requested users
1270	HY000	ER_CANT_AGGREGATE_3COLLATIONS	Illegal mix of collations (%s,%s), (%s,%s), (%s,%s) for operation '%s'
1271	HY000	ER_CANT_AGGREGATE_NCOLLATIONS	Illegal mix of collations for operation '%s'
1272	HY000	ER_VARIABLE_IS_NOT_STRUCT	Variable '%s' is not a variable component (can't be used as XXXX.variable_name)
1273	HY000	ER_UNKNOWN_COLLATION	Unknown collation: '%s'
1274	HY000	ER_SLAVE_IGNORED_SSL_PARAMS	SSL parameters in CHANGE MASTER are ignored because this MariaDB slave was compiled without SSL support; they can be used later if MariaDB slave with SSL is started
1275	HY000	ER_SERVER_IS_IN_SECURE_AUTH_MODE	Server is running in --secure-auth mode, but '%s'@'%s' has a password in the old format; please change the password to the new format
1276	HY000	ER_WARN_FIELD_RESOLVED	Field or reference '%s%s%s%s%s' of SELECT #%d was resolved in SELECT #%d
1277	HY000	ER_BAD_SLAVE_UNTIL_COND	Incorrect parameter or combination of parameters for START SLAVE UNTIL
1278	HY000	ER_MISSING_SKIP_SLAVE	It is recommended to use --skip-slave-start when doing step-by-step replication with START SLAVE UNTIL; otherwise, you will get problems if you get an unexpected slave's mysqld restart
1279	HY000	ER_UNTIL_COND_IGNORED	SQL thread is not to be started so UNTIL options are ignored
1280	42000	ER_WRONG_NAME_FOR_INDEX	Incorrect index name '%s'

1344	HY000	ER_FPARSER_EOF_IN_UNKNOWN_PARAMETER	Unexpected end of file while skipping unknown parameter '%s'
1345	HY000	ER_VIEW_NO_EXPLAIN	EXPLAIN/SHOW can not be issued; lacking privileges for underlying table
1346	HY000	ER_FRM_UNKNOWN_TYPE	File '%s' has unknown type '%s' in its header
1347	HY000	ER_WRONG_OBJECT	'%s.%s' is not %s
1348	HY000	ER_NONUPDATEABLE_COLUMN	Column '%s' is not updatable
1349	HY000	ER_VIEW_SELECT_DERIVED	View's SELECT contains a subquery in the FROM clause
1350	HY000	ER_VIEW_SELECT_CLAUSE	View's SELECT contains a '%s' clause
1351	HY000	ER_VIEW_SELECT_VARIABLE	View's SELECT contains a variable or parameter
1352	HY000	ER_VIEW_SELECT_TMPTABLE	View's SELECT refers to a temporary table '%s'
1353	HY000	ER_VIEW_WRONG_LIST	View's SELECT and view's field list have different column counts
1354	HY000	ER_WARN_VIEW_MERGE	View merge algorithm can't be used here for now (assumed undefined algorithm)

1355	HY000	ER_WARN_VIEW_WITHOUT_KEY	View being updated does not have complete key of underlying table in it
1356	HY000	ER_VIEW_INVALID	View '%s.%s' references invalid table(s) or column(s) or function(s) or definer/invoker of view lack rights to use them
1357	HY000	ER_SP_NO_DROP_SP	Can't drop or alter a %s from within another stored routine
1358	HY000	ER_SP_GOTO_IN_HNDLR	GOTO is not allowed in a stored procedure handler
1359	HY000	ER_TRG_ALREADY_EXISTS	Trigger already exists
1360	HY000	ER_TRG_DOES_NOT_EXIST	Trigger does not exist
1361	HY000	ER_TRG_ON_VIEW_OR_TEMP_TABLE	Trigger's '%s' is view or temporary table
1362	HY000	ER_TRG_CANT_CHANGE_ROW	Updating of %s row is not allowed in %strigger
1363	HY000	ER_TRG_NO_SUCH_ROW_IN_TRG	There is no %s row in %s trigger
1364	HY000	ER_NO_DEFAULT_FOR_FIELD	Field '%s' doesn't have a default value
1365	22012	ER_DIVISION_BY_ZER	Division by 0
1366	HY000	ER_TRUNCATED_WRONG_VALUE_FOR_FIELD	Incorrect %s value: '%s' for column '%s' at row %ld
1367	22007	ER_ILLEGAL_VALUE_FOR_TYPE	Illegal %s '%s' value found during parsing
1368	HY000	ER_VIEW_NONUPD_CHECK	CHECK OPTION on non-updatable view '%s.%s'
1369	HY000	ER_VIEW_CHECK_FAILED	CHECK OPTION failed '%s.%s'
1370	42000	ER_PROCACCESS_DENIED_ERROR	%s command denied to user '%s'@'%s' for routine '%s'
1371	HY000	ER_RELAY_LOG_FAIL	Failed purging old relay logs: %s
1372	HY000	ER_PASSWD_LENGTH	Password hash should be a %d-digit hexadecimal number
1373	HY000	ER_UNKNOWN_TARGET_BINLOG	Target log not found in binlog index
1374	HY000	ER_IO_ERR_LOG_INDEX_READ	I/O error reading log index file
1375	HY000	ER_BINLOG_PURGE_PROHIBITED	Server configuration does not permit binlog purge
1376	HY000	ER_FSEEK_FAIL	Failed on fseek()
1377	HY000	ER_BINLOG_PURGE_FATAL_ERR	Fatal error during log purge
1378	HY000	ER_LOG_IN_USE	A purgeable log is in use, will not purge
1379	HY000	ER_LOG_PURGE_UNKNOWN_ERR	Unknown error during log purge
1380	HY000	ER_RELAY_LOG_INIT	Failed initializing relay log position: %s
1381	HY000	ER_NO_BINARY_LOGGING	You are not using binary logging
1382	HY000	ER_RESERVED_SYNTAX	The '%s' syntax is reserved for purposes internal to the MariaDB server
1383	HY000	ER_WSAS_FAILED	WSAStartup Failed
1384	HY000	ER_DIFF_GROUPS_PROC	Can't handle procedures with different groups yet
1385	HY000	ER_NO_GROUP_FOR_PROC	Select must have a group with this procedure
1386	HY000	ER_ORDER_WITH_PROC	Can't use ORDER clause with this procedure
1387	HY000	ER_LOGGING_PROHIBIT_CHANGING_OF	Binary logging and replication forbid changing the global server %s
1388	HY000	ER_NO_FILE_MAPPING	Can't map file: %s, errno: %d

1389	HY000	ER_WRONG_MAGIC	Wrong magic in %s
1390	HY000	ER_PS_MANY_PARAM	Prepared statement contains too many placeholders
1391	HY000	ER_KEY_PART_0	Key part '%s' length cannot be 0
1392	HY000	ER_VIEW_CHECKSUM	View text checksum failed
1393	HY000	ER_VIEW_MULTIUPDATE	Can not modify more than one base table through a join view '%s.%s'
1394	HY000	ER_VIEW_NO_INSERT_FIELD_LIST	Can not insert into join view '%s.%s' without fields list
1395	HY000	ER_VIEW_DELETE_MERGE_VIEW	Can not delete from join view '%s.%s'
1396	HY000	ER_CANNOT_USER	Operation %s failed for %s
1397	XAE04	ER_XAER_NOTA	XAER_NOTA: Unknown XID
1398	XAE05	ER_XAER_INVAL	XAER_INVAL: Invalid arguments (or unsupported command)
1399	XAE07	ER_XAER_RMFAIL	XAER_RMFAIL: The command cannot be executed when global transaction is in the %s state

Error Code	SQLSTATE	Error	Description
1400	XAE09	ER_XAER_OUTSIDE	XAER_OUTSIDE: Some work is done outside global transaction
1401	XAE03	ER_XAER_RMERR	XAER_RMERR: Fatal error occurred in the transaction branch - check your data for consistency
1402	XA100	ER_XA_RBROLLBACK	XA_RBROLLBACK: Transaction branch was rolled back
1403	42000	ER_NONEXISTING_PROC_GRANT	There is no such grant defined for user '%s' on host '%s' on routine '%s'
1404	HY000	ER_PROC_AUTO_GRANT_FAIL	Failed to grant EXECUTE and ALTER ROUTINE privileges
1405	HY000	ER_PROC_AUTO_REVOKE_FAIL	Failed to revoke all privileges to dropped routine
1406	22001	ER_DATA_TOO_LONG	Data too long for column '%s' at row %ld
1407	42000	ER_SP_BAD_SQLSTATE	Bad SQLSTATE: '%s'
1408	HY000	ER_STARTUP	%s: ready for connections. Version: '%s' socket: '%s' port: %d %s
1409	HY000	ER_LOAD_FROM_FIXED_SIZE_ROWS_TO_VAR	Can't load value from file with fixed size rows to variable
1410	42000	ER_CANT_CREATE_USER_WITH_GRANT	You are not allowed to create a user with GRANT
1411	HY000	ER_WRONG_VALUE_FOR_TYPE	Incorrect %s value: '%s' for function %s
1412	HY000	ER_TABLE_DEF_CHANGED	Table definition has changed, please retry transaction
1413	42000	ER_SP_DUP_HANDLER	Duplicate handler declared in the same block
1414	42000	ER_SP_NOT_VAR_ARG	OUT or INOUT argument %d for routine %s is not a variable or NEW pseudo-variable in BEFORE trigger

1415	0A000	ER_SP_NO_RETSET	Not allowed to return a result set from a %s
1416	22003	ER_CANT_CREATE_GEOMETRY_OBJECT	Cannot get geometry object from data you send to the GEOMETRY field
1417	HY000	ER_FAILED_ROUTINE_BREAK_BINLOG	A routine failed and has neither NO SQL nor READS SQL DATA in its declaration and binary logging is enabled; if non-transactional tables were updated, the binary log will miss their changes
1418	HY000	ER_BINLOG_UNSAFE_ROUTINE	This function has none of DETERMINISTIC, NO SQL, or READS SQL DATA in its declaration and binary logging is enabled (you *might* want to use the less safe log_bin_trust_function_creators variable)
1419	HY000	ER_BINLOG_CREATE_ROUTINE_NEED_SUPER	You do not have the SUPER privilege and binary logging is enabled (you *might* want to use the less safe log_bin_trust_function_creators variable)
1420	HY000	ER_EXEC_STMT_WITH_OPEN_CURSOR	You can't execute a prepared statement which has an open cursor associated with it. Reset the statement to re-execute it.
1421	HY000	ER_STMT_HAS_NO_OPEN_CURSOR	The statement (%lu) has no open cursor.
1422	HY000	ER_COMMIT_NOT_ALLOWED_IN_SF_OR_TRG	Explicit or implicit commit is not allowed in stored function or trigger.
1423	HY000	ER_NO_DEFAULT_FOR_VIEW_FIELD	Field of view '%s.%s' underlying table doesn't have a default value
1424	HY000	ER_SP_NO_RECURSION	Recursive stored functions and triggers are not allowed.
1425	42000	ER_TOO_BIG_SCALE	Too big scale %d specified for column '%s'. Maximum is %lu.
1426	42000	ER_TOO_BIG_PRECISION	Too big precision %d specified for column '%s'. Maximum is %lu.
1427	42000	ER_M_BIGGER_THAN_D	For float(M,D, double(M,D or decimal(M,D, M must be >= D (column '%s').
1428	HY000	ER_WRONG_LOCK_OF_SYSTEM_TABLE	You can't combine write-locking of system tables with other tables or lock types
1429	HY000	ER_CONNECT_TO_FOREIGN_DATA_SOURCE	Unable to connect to foreign data source: %s
1430	HY000	ER_QUERY_ON_FOREIGN_DATA_SOURCE	There was a problem processing the query on the foreign data source. Data source error: %s
1431	HY000	ER_FOREIGN_DATA_SOURCE_DOESNT_EXIST	The foreign data source you are trying to reference does not exist. Data source error: %s
1432	HY000	ER_FOREIGN_DATA_STRING_INVALID_CANT_CREATE	Can't create federated table. The data source connection string '%s' is not in the correct format

1433	HY000	ER_FOREIGN_DATA_STRING_INVALID	The data source connection string '%s' is not in the correct format
1434	HY000	ER_CANT_CREATE_FEDERATED_TABLE	Can't create federated table. Foreign data src error: %s
1435	HY000	ER_TRG_IN_WRONG_SCHEMA	Trigger in wrong schema
1436	HY000	ER_STACK_OVERRUN_NEED_MORE	Thread stack overrun: %ld bytes used of a %ld byte stack, and %ld bytes needed. Use 'mysqld --thread_stack=#' to specify a bigger stack.
1437	42000	ER_TOO_LONG_BODY	Routine body for '%s' is too long
1438	HY000	ER_WARN_CANT_DROP_DEFAULT_KEYCACHE	Cannot drop default keycache
1439	42000	ER_TOO_BIG_DISPLAYWIDTH	Display width out of range for column '%s' (max = %lu)
1440	XAE08	ER_XAER_DUPID	XAER_DUPID: The XID already exists
1441	22008	ER_DATETIME_FUNCTION_OVERFLOW	Datetime function: %s field overflow
1442	HY000	ER_CANT_UPDATE_USED_TABLE_IN_SF_OR_TRG	Can't update table '%s' in stored function/trigger because it is already used by statement which invoked this stored function/trigger.
1443	HY000	ER_VIEW_PREVENT_UPDATE	The definition of table '%s' prevents operation %s on table '%s'.
1444	HY000	ER_PS_NO_RECURSION	The prepared statement contains a stored routine call that refers to that same statement. It's not allowed to execute a prepared statement in such a recursive manner
1445	HY000	ER_SP_CANT_SET_AUTOCOMMIT	Not allowed to set autocommit from a stored function or trigger
1446	HY000	ER_MALFORMED_DEFINER	Definer is not fully qualified
1447	HY000	ER_VIEW_FRM_NO_USER	View '%s'.'%s' has no definer information (old table format). Current user is used as definer. Please recreate the view!
1448	HY000	ER_VIEW_OTHER_USER	You need the SUPER privilege for creation view with '%s'@'%s' definer
1449	HY000	ER_NO_SUCH_USER	The user specified as a definer ('%s'@'%s') does not exist
1450	HY000	ER_FORBID_SCHEMA_CHANGE	Changing schema from '%s' to '%s' is not allowed.
1451	23000	ER_ROW_IS_REFERENCED_2	Cannot delete or update a parent row: a foreign key constraint fails (%s)
1452	23000	ER_NO_REFERENCED_ROW_2	Cannot add or update a child row: a foreign key constraint fails (%s)
1453	42000	ER_SP_BAD_VAR_SHADOW	Variable '%s' must be quoted with `...`, or renamed
1454	HY000	ER_TRG_NO_DEFINER	No definer attribute for trigger '%s'.'%s'. The trigger will be activated under the authorization of the invoker, which may have insufficient privileges. Please recreate the trigger.
1455	HY000	ER_OLD_FILE_FORMAT	'%s' has an old format, you should re-create the '%s' object(s)

1456	HY000	ER_SP_RECURSION_LIMIT	Recursive limit %d (as set by the max_sp_recursion_depth variable) was exceeded for routine %s
1457	HY000	ER_SP_PROC_TABLE_CORRUPT	Failed to load routine %s. The table mysql.proc is missing, corrupt, or contains bad data (internal code %d)
1458	42000	ER_SP_WRONG_NAME	Incorrect routine name '%s'
1459	HY000	ER_TABLE_NEEDS_UPGRADE	Table upgrade required. Please do "REPAIR TABLE `%s`" or dump/reload to fix it!
1460	42000	ER_SP_NO_AGGREGATE	AGGREGATE is not supported for stored functions
1461	42000	ER_MAX_PREPARED_STMT_COUNT_REACHED	Can't create more than max_prepared_stmt_count statements (current value: %lu)
1462	HY000	ER_VIEW_RECURSIVE	`%s`.`%s` contains view recursion
1463	42000	ER_NON_GROUPING_FIELD_USED	Non-grouping field '%s' is used in %s clause
1464	HY000	ER_TABLE_CANT_HANDLE_SPKEYS	The used table type doesn't support SPATIAL indexes
1465	HY000	ER_NO_TRIGGERS_ON_SYSTEM_SCHEMA	Triggers can not be created on system tables
1466	HY000	ER_REMOVED_SPACES	Leading spaces are removed from name '%s'
1467	HY000	ER_AUTOINC_READ_FAILED	Failed to read auto-increment value from storage engine
1468	HY000	ER_USERNAME	user name
1469	HY000	ER_HOSTNAME	host name
1470	HY000	ER_WRONG_STRING_LENGTH	String '%s' is too long for %s (should be no longer than %d)
1471	HY000	ER_NON_INSERTABLE_TABLE	The target table %s of the %s is not insertable-into
1472	HY000	ER_ADMIN_WRONG_MRG_TABLE	Table '%s' is differently defined or of non-MyISAM type or doesn't exist
1473	HY000	ER_TOO_HIGH_LEVEL_OF_NESTING_FOR_SELECT	Too high level of nesting for select
1474	HY000	ER_NAME_BECOMES_EMPTY	Name '%s' has become ''
1475	HY000	ER_AMBIGUOUS_FIELD_TERM	First character of the FIELDS TERMINATED string is ambiguous; please use non-optional and non-empty FIELDS ENCLOSED BY
1476	HY000	ER_FOREIGN_SERVER_EXISTS	The foreign server, %s, you are trying to create already exists.
1477	HY000	ER_FOREIGN_SERVER_DOESNT_EXIST	The foreign server name you are trying to reference does not exist. Data source error: %s
1478	HY000	ER_ILLEGAL_HA_CREATE_OPTION	Table storage engine '%s' does not support the create option '%s'

1917		ER_DATA_TRUNCATED 22003	Truncated value '%-.128s' when converting to %-.32s
1918		ER_BAD_DATA 22007	Encountered illegal value '%-.128s' when converting to %-.32s
1919		ER_DYN_COL_WRONG_FORMAT	Encountered illegal format of dynamic column string
1920		ER_DYN_COL_IMPLEMENTATION_LIMIT	Dynamic column implementation limit reached
1921		ER_DYN_COL_DATA 22007	Illegal value used as argument of dynamic column function
1922		ER_DYN_COL_WRONG_CHARSET	Dynamic column contains unknown character set
1923		ER_ILLEGAL_SUBQUERY_OPTIMIZER_SWITCHES	At least one of the 'in_to_exists' or 'materialization' optimizer_switch flags must be 'on'.
1924		ER_QUERY_CACHE_IS_DISABLED	Query cache is disabled (resize or similar command in progress); repeat this command later
1925		ER_QUERY_CACHE_IS_GLOBALY_DISABLED	Query cache is globally disabled and you can't enable it only for this session
1926		ER_VIEW_ORDERBY_IGNORED	View '%-.192s'.'%-.192s' ORDER BY clause ignored because there is other ORDER BY clause already.
1927		ER_CONNECTION_KILLED 70100	Connection was killed
1928	ER_UNUSED_11	You should never see it	
1929		ER_INSIDE_TRANSACTION_PREVENTS_SWITCH_SKIP_REPLICATION	Cannot modify @@session.skip_replication inside a transaction
1930		ER_STORED_FUNCTION_PREVENTS_SWITCH_SKIP_REPLICATION	Cannot modify @@session.skip_replication inside a stored function or trigger
1931		ER_QUERY_EXCEEDED_ROWS_EXAMINED_LIMIT	Query execution was interrupted. The query examined at least %llu rows, which exceeds LIMIT ROWS EXAMINED (%llu). The query result may be incomplete.
1932		ER_NO_SUCH_TABLE_IN_ENGINE 42S02	Table '%-.192s.%-.192s' doesn't exist in engine
1933		ER_TARGET_NOT_EXPLAINABLE	Target is not running an EXPLAINable command
1934		ER_CONNECTION_ALREADY_EXISTS	Connection '%.*s' conflicts with existing connection '%.*s'
1935		ER_MASTER_LOG_PREFIX	Master '%.*s':

1936		ER_CANT_START_STOP_SLAVE	Can't %s SLAVE '%.*s'
1937		ER_SLAVE_STARTED	SLAVE '%.*s' started
1938		ER_SLAVE_STOPPED	SLAVE '%.*s' stopped
1939		ER_SQL_DISCOVER_ERROR	Engine %s failed to discover table %`-.192s.%`-.192s with '%s'
1940		ER_FAILED_GTID_STATE_INIT	Failed initializing replication GTID state
1941		ER_INCORRECT_GTID_STATE	Could not parse GTID list
1942		ER_CANNOT_UPDATE_GTID_STATE	Could not update replication slave gtid state
1943		ER_DUPLICATE_GTID_DOMAIN	GTID %u-%u-%llu and %u-%u-%llu conflict (duplicate domain id %u)
1944		ER_GTID_OPEN_TABLE_FAILED	Failed to open %s.%s
1945		ER_GTID_POSITION_NOT_FOUND_IN_BINLOG	Connecting slave requested to start from GTID %u-%u-%llu, which is not in the master's binlog
1946		ER_CANNOT_LOAD_SLAVE_GTID_STATE	Failed to load replication slave GTID position from table %s.%s
1947		ER_MASTER_GTID_POS_CONFLICTS_WITH_BINLOG	Specified GTID %u-%u-%llu conflicts with the binary log which contains a more recent GTID %u-%u-%llu. If MASTER_GTID_POS=CURRENT_POS is used, the binlog position will override the new value of @@gtid_slave_pos.
1948		ER_MASTER_GTID_POS_MISSING_DOMAIN	Specified value for @@gtid_slave_pos contains no value for replication domain %u. This conflicts with the binary log which contains GTID %u-%u-%llu. If MASTER_GTID_POS=CURRENT_POS is used, the binlog position will override the new value of @@gtid_slave_pos.
1949		ER_UNTIL_REQUIRES_USING_GTID	START SLAVE UNTIL master_gtid_pos requires that slave is using GTID
1950		ER_GTID_STRICT_OUT_OF_ORDER	An attempt was made to binlog GTID %u-%u-%llu which would create an out-of-order sequence number with existing GTID %u-%u-%llu, and gtid strict mode is enabled.
1951		ER_GTID_START_FROM_BINLOG_HOLE	The binlog on the master is missing the GTID %u-%u-%llu requested by the slave (even though a subsequent sequence number does exist), and GTID strict mode is enabled
1952		ER_SLAVE_UNEXPECTED_MASTER_SWITCH	Unexpected GTID received from master after reconnect. This normally indicates that the master server was replaced without restarting the slave threads. %s
1953		ER_INSIDE_TRANSACTION_PREVENTS_SWITCH_GTID_DOMAIN_ID_SEQ_NO	Cannot modify @@session.gtid_domain_id or @@session.gtid_seq_no inside a transaction
1954		ER_STORED_FUNCTION_PREVENTS_SWITCH_GTID_DOMAIN_ID_SEQ_NO	Cannot modify @@session.gtid_domain_id or @@session.gtid_seq_no inside a stored function or trigger
1955		ER_GTID_POSITION_NOT_FOUND_IN_BINLOG2	Connecting slave requested to start from GTID %u-%u-%llu, which is not in the master's binlog. Since the master's binlog contains GTIDs with higher sequence numbers, it probably means that the slave has diverged due to executing extra errorneous transactions
1956		ER_BINLOG_MUST_BE_EMPTY	This operation is not allowed if any GTID has been logged to the binary log. Run RESET MASTER first to erase the log
1957		ER_NO_SUCH_QUERY	Unknown query id: %lld
1958		ER_BAD_BASE64_DATA	Bad base64 data as position %u
1959		ER_INVALID_ROLE	Invalid role specification %`s.
1960		ER_INVALID_CURRENT_USER	The current user is invalid.

4082		ER_ROW_VARIABLE_DOES_NOT_HAVE_FIELD	Row variable '%-.192s' does not have a field '%-.192s'
4083		ER_END_IDENTIFIER_DOES_NOT_MATCH	END identifier '%-.192s' does not match '%-.192s'
4084		ER_SEQUENCE_RUN_OUT	Sequence '%-.64s.%-.64s' has run out
4085		ER_SEQUENCE_INVALID_DATA	Sequence '%-.64s.%-.64s' values are conflicting
4086		ER_SEQUENCE_INVALID_TABLE_STRUCTURE	Sequence '%-.64s.%-.64s' table structure is invalid (%s)
4087		ER_SEQUENCE_ACCESS_ERROR	Sequence '%-.64s.%-.64s' access error
4088		ER_SEQUENCE_BINLOG_FORMAT	Sequences requires binlog_format mixed or row
4089		ER_NOT_SEQUENCE	'%-.64s.%-.64s' is not a SEQUENCE
4090		ER_NOT_SEQUENCE2	'%-.192s' is not a SEQUENCE
4091		ER_UNKNOWN_SEQUENCES	Unknown SEQUENCE: '%-.300s'
4092		ER_UNKNOWN_VIEW	Unknown VIEW: '%-.300s'
4093		ER_WRONG_INSERT_INTO_SEQUENCE	Wrong INSERT into a SEQUENCE. One can only do single table INSERT into a sequence object (like with mysqldump) If you want to change the SEQUENCE, use ALTER SEQUENCE instead.
4094		ER_SP_STACK_TRACE	At line %u in %s
4095		ER_PACKAGE_ROUTINE_IN_SPEC_NOT_DEFINED_IN_BODY	Subroutine '%-.192s' is declared in the package specification but is not defined in the package body
4096		ER_PACKAGE_ROUTINE_FORWARD_DECLARATION_NOT_DEFINED	Subroutine '%-.192s' has a forward declaration but is not defined
4097		ER_COMPRESSED_COLUMN_USED_AS_KEY	Compressed column '%-.192s' can't be used in key specification
4098		ER_UNKNOWN_COMPRESSION_METHOD	Unknown compression method: %s
4099		ER_WRONG_NUMBER_OF_VALUES_IN_TVC	The used table value constructor has a different number of values
4100		ER_FIELD_REFERENCE_IN_TVC	Field reference '%-.192s' can't be used in table value constructor
4101		ER_WRONG_TYPE_FOR_PERCENTILE_FUNC	Numeric datatype is required for %s function
4102		ER_ARGUMENT_NOT_CONSTANT	Argument to the %s function is not a constant for a partition
4103		ER_ARGUMENT_OUT_OF_RANGE	Argument to the %s function does not belong to the range [0,1]
4104		ER_WRONG_TYPE_OF_ARGUMENT	%s function only accepts arguments that can be converted to numerical types
4105		ER_NOT_AGGREGATE_FUNCTION	Aggregate specific instruction (FETCH GROUP NEXT ROW) used in a wrong context
4106		ER_INVALID_AGGREGATE_FUNCTION	Aggregate specific instruction(FETCH GROUP NEXT ROW) missing from the aggregate function
4107		ER_INVALID_VALUE_TO_LIMIT	Limit only accepts integer values

4108		ER_INVISIBLE_NOT_NULL_WITHOUT_DEFAULT	Invisible column %`s must have a defa value
4109		ER_UPDATE_INFO_WITH_SYSTEM_VERSIONING	Rows matched: %ld Changed: %ld Inserted: %ld Warnings: %ld
4110		ER_VERS_FIELD_WRONG_TYPE	%`s must be of type %s for system-versioned table %`s
4111		ER_VERS_ENGINE_UNSUPPORTED	Transaction-precise system versioning %`s is not supported
4112		ER_UNUSED_23	You should never see it
4113		ER_PARTITION_WRONG_TYPE	Wrong partitioning type, expected type %`s
4114		WARN_VERS_PART_FULL	Versioned table %`s.%`s: last HISTOR partition (%`s) is out of %s, need more HISTORY partitions
4115		WARN_VERS_PARAMETERS	Maybe missing parameters: %s
4116		ER_VERS_DROP_PARTITION_INTERVAL	Can only drop oldest partitions when rotating by INTERVAL
4117		ER_UNUSED_25	You should never see it
4118		WARN_VERS_PART_NON_HISTORICAL	Partition %`s contains non-historical da
4119		ER_VERS_ALTER_NOT_ALLOWED	Not allowed for system-versioned %`s.%`s. Change @@system_versioning_alter_history t proceed with ALTER.
4120		ER_VERS_ALTER_ENGINE_PROHIBITED	Not allowed for system-versioned %`s.%`s. Change to/from native syster versioning engine is not supported.
4121		ER_VERS_RANGE_PROHIBITED	SYSTEM_TIME range selector is not allowed
4122		ER_CONFLICTING_FOR_SYSTEM_TIME	Conflicting FOR SYSTEM_TIME claus in WITH RECURSIVE
4123		ER_VERS_TABLE_MUST_HAVE_COLUMNS	Table %`s must have at least one versioned column
4124		ER_VERS_NOT_VERSIONED	Table %`s is not system-versioned
4125		ER_MISSING	Wrong parameters for %`s: missing '%
4126		ER_VERS_PERIOD_COLUMNS	PERIOD FOR SYSTEM_TIME must us columns %`s and %`s
4127		ER_PART_WRONG_VALUE	Wrong parameters for partitioned %`s: wrong value for '%s'
4128		ER_VERS_WRONG_PARTS	Wrong partitions for %`s: must have at least one HISTORY and exactly one la CURRENT
4129		ER_VERS_NO_TRX_ID	TRX_ID %llu not found in `mysql.transaction_registry`
4130		ER_VERS_ALTER_SYSTEM_FIELD	Can not change system versioning fiel %`s
4131		ER_DROP_VERSIONING_SYSTEM_TIME_PARTITION	Can not DROP SYSTEM VERSIONIN for table %`s partitioned BY SYSTEM_TIME
4132		ER_VERS_DB_NOT_SUPPORTED	System-versioned tables in the %`s database are not supported
4133		ER_VERS_TRT_IS_DISABLED	Transaction registry is disabled
4134		ER_VERS_DUPLICATE_ROW_START_END	Duplicate ROW %s column %`s
4135		ER_VERS_ALREADY_VERSIONED	Table %`s is already system-versioned
4136		ER_UNUSED_24	You should never see it
4137		ER_VERS_NOT_SUPPORTED	System-versioned tables do not suppo %s

4138		ER_VERS_TRX_PART_HISTORIC_ROW_NOT_SUPPORTED	Transaction-precise system-versioned tables do not support partitioning by R(START or ROW END
4139		ER_INDEX_FILE_FULL	The index file for table '%-.192s' is full
4140		ER_UPDATED_COLUMN_ONLY_ONCE	The column %`s.%`s cannot be change more than once in a single UPDATE statement
4141		ER_EMPTY_ROW_IN_TVC	Row with no elements is not allowed in table value constructor in this context
4142		ER_VERS_QUERY_IN_PARTITION	SYSTEM_TIME partitions in table %`s does not support historical query
4143		ER_KEY_DOESNT_SUPPORT	%s index %`s does not support this operation
4144		ER_ALTER_OPERATION_TABLE_OPTIONS_NEED_REBUILD	Changing table options requires the tal to be rebuilt
4145		ER_BACKUP_LOCK_IS_ACTIVE	Can't execute the command as you ha BACKUP STAGE active
4146		ER_BACKUP_NOT_RUNNING	You must start backup with \"BACKUP STAGE START\"
4147		ER_BACKUP_WRONG_STAGE	Backup stage '%s' is same or before current backup stage '%s'
4148		ER_BACKUP_STAGE_FAILED	Backup stage '%s' failed
4149		ER_BACKUP_UNKNOWN_STAGE	Unknown backup stage: '%s'. Stage should be one of START, FLUSH, BLOCK_DDL, BLOCK_COMMIT or EN
4150		ER_USER_IS_BLOCKED	User is blocked because of too many credential errors; unblock with 'FLUSH PRIVILEGES'
4151		ER_ACCOUNT_HAS_BEEN_LOCKED	Access denied, this account is locked
4152		ER_PERIOD_TEMPORARY_NOT_ALLOWED	Application-time period table cannot be temporary
4153		ER_PERIOD_TYPES_MISMATCH	Fields of PERIOD FOR %`s have differ types
4154		ER_MORE_THAN_ONE_PERIOD	Cannot specify more than one applicat time period
4155		ER_PERIOD_FIELD_WRONG_ATTRIBUTES	Period field %`s cannot be %s
4156		ER_PERIOD_NOT_FOUND	Period %`s is not found in table
4157		ER_PERIOD_COLUMNS_UPDATED	Column %`s used in period %`s specifi in update SET list
4158		ER_PERIOD_CONSTRAINT_DROP	Can't DROP CONSTRAINT `%s`. Use DROP PERIOD `%s` for this
4159	42000 S1009	ER_TOO_LONG_KEYPART	Specified key part was too long; max k part length is %u bytes
4160		ER_TOO_LONG_DATABASE_COMMENT	Comment for database '%-.64s' is too l (max = %u)
4161		ER_UNKNOWN_DATA_TYPE	Unknown data type: '%-.64s'
4162		ER_UNKNOWN_OPERATOR	Operator does not exists: '%-.128s'
4163		ER_WARN_HISTORY_ROW_START_TIME	Table `%s.%s` history row start '%s' is later than row end '%s'
4164		ER_PART_STARTS_BEYOND_INTERVAL	%`s: STARTS is later than query time, history partition may exceed INTERVA value
4165		ER_GALERA_REPLICATION_NOT_SUPPORTED	DDL-statement is forbidden as table storage engine does not support Galer replication

4166	HY000	ER_LOAD_INFILE_CAPABILITY_DISABLED	The used command is not allowed because the MariaDB server or client h disabled the local infile capability
4167		ER_NO_SECURE_TRANSPORTS_CONFIGURED	No secure transports are configured, unable to set --require_secure_transport=ON
4168		ER_SLAVE_IGNORED_SHARED_TABLE	Slave SQL thread ignored the '%s' because table is shared
4169		ER_NO_AUTOINCREMENT_WITH_UNIQUE	AUTO_INCREMENT column %`s cann be used in the UNIQUE index %`s
4170		ER_KEY_CONTAINS_PERIOD_FIELDS	Key %`s cannot explicitly include colun %`s
4171		ER_KEY_CANT_HAVE_WITHOUT_OVERLAPS	Key %`s cannot have WITHOUT OVERLAPS
4172		ER_NOT_ALLOWED_IN_THIS_CONTEXT	'%-.128s' is not allowed in this context
4173		ER_DATA_WAS_COMMITED_UNDER_ROLLBACK	Engine %s does not support rollback. Changes where commited during rollba call
4174		ER_PK_INDEX_CANT_BE_IGNORED	A primary key cannot be marked as IGNORE
4175		ER_BINLOG_UNSAFE_SKIP_LOCKED	SKIP LOCKED makes this statement unsafe
4176		ER_JSON_TABLE_ERROR_ON_FIELD	Field '%s' can't be set for JSON_TABL '%s'.
4177		ER_JSON_TABLE_ALIAS_REQUIRED	Every table function must have an alias
4178		ER_JSON_TABLE_SCALAR_EXPECTED	Can't store an array or an object in the scalar column '%s' of JSON_TABLE '%
4179		ER_JSON_TABLE_MULTIPLE_MATCHES	Can't store multiple matches of the pat the column '%s' of JSON_TABLE '%s'.
4180		ER_WITH_TIES_NEEDS_ORDER	FETCH ... WITH TIES requires ORDEF BY clause to be present
4181		ER_REMOVED_ORPHAN_TRIGGER	Dropped orphan trigger '%-.64s', origin created for table: '%-.192s'
4182		ER_STORAGE_ENGINE_DISABLED	Storage engine %s is disabled

1.1.2.10 Numeric Literals

Numeric literals are written as a sequence of digits from `0` to `9`. Initial zeros are ignored. A sign can always precede the digits, but it is optional for positive numbers. In decimal numbers, the integer part and the decimal part are divided with a dot (`.`).

If the integer part is zero, it can be omitted, but the literal must begin with a dot.

The notation with exponent can be used. The exponent is preceded by an `E` or `e` character. The exponent can be preceded by a sign and must be an integer. A number `N` with an exponent part `X`, is calculated as `N * POW(10, X)`.

In some cases, adding zeroes at the end of a decimal number can increment the precision of the expression where the number is used. For example, `PI()` by default returns a number with 6 decimal digits. But the `PI()+0.0000000000` expression (with 10 zeroes) returns a number with 10 decimal digits.

Hexadecimal literals are interpreted as numbers when used in numeric contexts.

Examples

```
10
+10
-10
```

All these literals are equivalent:

```
0.1
.1
+0.1
+.1
```

With exponents:

```
0.2E3 -- 0.2 * POW(10, 3) = 200
.2e3
.2e+2
1.1e-10 -- 0.00000000011
-1.1e10 -- -11000000000
```

1.1.2.11 Reserved Words

Contents

The following is a list of all reserved words in MariaDB.

Reserved words cannot be used as Identifiers, unless they are quoted.

The definitive list of reserved words for each version can be found by examining the `sql/lex.h` and `sql/sql_yacc.yy` files.

Reserved Words

Keyword	Notes

Exceptions

Some keywords are exceptions for historical reasons, and are permitted as unquoted identifiers. These include:

Keyword
ACTION
BIT
DATE
ENUM
NO
TEXT
TIME
TIMESTAMP

Oracle Mode

In Oracle mode, from MariaDB 10.3, there are a number of extra reserved words:

Keyword	Notes
BODY	
ELSIF	
GOTO	
HISTORY	<= MariaDB 10.3.6 only
MINUS	From MariaDB 10.6.1
OTHERS	
PACKAGE	
PERIOD	<= MariaDB 10.3.6 only
RAISE	
ROWNUM	From MariaDB 10.6.1
ROWTYPE	

SYSDATE	From MariaDB 10.6.1
SYSTEM	<= MariaDB 10.3.6 only. Note however that SYSTEM sometimes needs to be quoted to avoid confusion with System-versioned tables.
SYSTEM_TIME	<= MariaDB 10.3.6 only
VERSIONING	<= MariaDB 10.3.6 only
WITHOUT	<= MariaDB 10.3.6 only

Function Names

If the `IGNORE_SPACE` SQL_MODE flag is set, function names become reserved words.

6.4.1.1.2.1.3 SQLSTATE

1.1.2.13 String Literals

Strings are sequences of characters and are enclosed with quotes.

The syntax is:

```
[_charset_name]'string' [COLLATE collation_name]
```

For example:

```
'The MariaDB Foundation'
_utf8 'Foundation' COLLATE utf8_unicode_ci;
```

Strings can either be enclosed in single quotes or in double quotes (the same character must be used to both open and close the string).

The ANSI SQL-standard does not permit double quotes for enclosing strings, and although MariaDB does by default, if the MariaDB server has enabled the ANSI_QUOTES_SQL SQL_MODE, double quotes will be treated as being used for identifiers instead of strings.

Strings that are next to each other are automatically concatenated. For example:

```
'The ' 'MariaDB ' 'Foundation'
```

and

```
'The MariaDB Foundation'
```

are equivalent.

The `\` (backslash character) is used to escape characters (unless the SQL_MODE hasn't been set to NO_BACKSLASH_ESCAPES). For example:

```
'MariaDB's new features'
```

is not a valid string because of the single quote in the middle of the string, which is treated as if it closes the string, but is actually meant as part of the string, an apostrophe. The backslash character helps in situations like this:

```
'MariaDB\'s new features'
```

is now a valid string, and if displayed, will appear without the backslash.

```
SELECT 'MariaDB\'s new features';
+------------------------+
| MariaDB's new features |
+------------------------+
| MariaDB's new features |
+------------------------+
```

Another way to escape the quoting character is repeating it twice:

```
SELECT 'I''m here', """Double""";
+----------+----------+
| I'm here | "Double" |
+----------+----------+
| I'm here | "Double" |
+----------+----------+
```

Escape Sequences

There are other escape sequences also. Here is a full list:

Escape sequence	Character
`\0`	ASCII NUL (0x00).
`\'`	Single quote (“'”).
`\"`	Double quote (“"”).
`\b`	Backspace.
`\n`	Newline, or linefeed,.
`\r`	Carriage return.
`\t`	Tab.
`\Z`	ASCII 26 (Control+Z). See note following the table.
`\\`	Backslash (“\”).
`\%`	“%” character. See note following the table.
`\_`	A “_” character. See note following the table.

Escaping the `%` and `_` characters can be necessary when using the LIKE operator, which treats them as special characters.

The ASCII 26 character (`\Z`) needs to be escaped when included in a batch file which needs to be executed in Windows. The reason is that ASCII 26, in Windows, is the end of file (EOF).

Backslash (`\`), if not used as an escape character, must always be escaped. When followed by a character that is not in the above table, backslashes will simply be ignored.

1.1.2.14 Table Value Constructors

MariaDB starting with 10.3.3
Table Value Constructors were introduced in MariaDB 10.3.3

Syntax

```
VALUES ( row_value[, row_value...]), (...)...
```

Description

Contents

In Unions, Views, and sub-queries, a Table Value Constructor (TVC) allows you to inject arbitrary values into the result-set. The given values must have the same number of columns as the result-set, otherwise it returns Error 1222.

Examples

Using TVC's with `UNION` operations:

```
CREATE TABLE test.t1 (val1 INT, val2 INT);
INSERT INTO test.t1 VALUES(5, 8), (3, 4), (1, 2);

SELECT * FROM test.t1
UNION
VALUES (70, 90), (100, 110);

+------+------+
| val1 | val2 |
+------+------+
|    5 |    8 |
|    3 |    4 |
|    1 |    2 |
|   70 |   90 |
|  100 |  110 |
+------+------+
```

Using TVC's with a `CREATE VIEW` statement:

```
CREATE VIEW v1 AS VALUES (7, 9), (9, 10);

SELECT * FROM v1;
+---+----+
| 7 |  9 |
+---+----+
| 7 |  9 |
| 9 | 10 |
+---+----+
```

Using TVC with an `ORDER BY` clause:

```
SELECT * FROM test.t1
UNION
VALUES (10, 20), (30, 40), (50, 60), (70, 80)
ORDER BY val1 DESC;
```

Using TVC with `LIMIT` clause:

```
SELECT * FROM test.t1
UNION
VALUES (10, 20), (30, 40), (50, 60), (70, 80)
LIMIT 2 OFFSET 4;

+------+------+
| val1 | val2 |
+------+------+
|   30 |   40 |
|   50 |   60 |
+------+------+
```

1.1.2.15 User-Defined Variables

Contents

User-defined variables are variables which can be created by the user and exist in the session. This means that no one can access user-defined variables that have been set by another user, and when the session is closed these variables expire. However, these variables can be shared between several queries and stored programs.

User-defined variables names must be preceded by a single *at* character (`@`). While it is safe to use a reserved word as a user-variable name, the only allowed characters are ASCII letters, digits, dollar sign (`$`), underscore (`_`) and dot (`.`). If other characters are used, the name can be quoted in one of the following ways:

- @`var_name`
- @'var_name'

- @"var_name"

These characters can be escaped as usual.

User-variables names are case insensitive, though they were case sensitive in MySQL 4.1 and older versions.

User-defined variables cannot be declared. They can be read even if no value has been set yet; in that case, they are NULL. To set a value for a user-defined variable you can use:

- SET statement;
- := operator within a SQL statement;
- SELECT ... INTO.

Since user-defined variables type cannot be declared, the only way to force their type is using CAST() or CONVERT():

```
SET @str = CAST(123 AS CHAR(5));
```

If a variable has not been used yet, its value is NULL:

```
SELECT @x IS NULL;
+------------+
| @x IS NULL |
+------------+
|          1 |
+------------+
```

It is unsafe to read a user-defined variable and set its value in the same statement (unless the command is SET), because the order of these actions is undefined.

User-defined variables can be used in most MariaDB's statements and clauses which accept an SQL expression. However there are some exceptions, like the LIMIT clause.

They must be used to PREPARE a prepared statement:

```
@sql = 'DELETE FROM my_table WHERE c>1;';
PREPARE stmt FROM @sql;
EXECUTE stmt;
DEALLOCATE PREPARE stmt;
```

Another common use is to include a counter in a query:

```
SET @var = 0;
SELECT a, b, c, (@var:=@var+1) AS counter FROM my_table;
```

Information Schema

User-defined variables can be viewed in the Information Schema USER_VARIABLES Table (as part of the User Variables plugin) from MariaDB 10.2.

Flushing User-Defined Variables

User-defined variables are reset and the Information Schema table emptied with the FLUSH USER_VARIABLES statement.

```
SET @str = CAST(123 AS CHAR(5));

SELECT * FROM information_schema.USER_VARIABLES ORDER BY VARIABLE_NAME;
+---------------+----------------+---------------+--------------------+
| VARIABLE_NAME | VARIABLE_VALUE | VARIABLE_TYPE | CHARACTER_SET_NAME |
+---------------+----------------+---------------+--------------------+
| str           | 123            | VARCHAR       | utf8mb3            |
+---------------+----------------+---------------+--------------------+

FLUSH USER_VARIABLES;

SELECT * FROM information_schema.USER_VARIABLES ORDER BY VARIABLE_NAME;
Empty set (0.000 sec)
```

1.1.3 Geographic & Geometric Features

MariaDB supports spatial extensions that enable the creation, storage and analysis of geographic features. These can be used in the Aria, MyISAM, InnoDB/XtraDB and ARCHIVE engines in MariaDB.

Partitioned tables do not support geometric types.

Note: This page is obsolete. The information is old, outdated, or otherwise...

GeoJSON

GeoJSON functions

There are 5 related questions.

1.1.3.1 GIS Resources

Here are a few resources for those interested in GIS in MariaDB.

- OGC Simple Feature Access - the Open Geospatial Consortium's OpenGIS Simple Features Specifications For SQL.
- Geo/Spatial Search with MySQL - a presentation by Alexander Rubin, from the MySQL Conference in 2006.

There are currently no differences between GIS in stable versions of MariaDB and GIS in MySQL. There are, however, some extensions and enhancements being worked on. See "MariaDB Plans - GIS" for more information.

1.1.3.2 GIS features in 5.3.3

Basic information about the existing spatial features can be found in the Geographic Features section of the Knowlegebase. The Spatial Extensions page of the MySQL manual also applies to MariaDB.

The MariaDB 5.3.3 release , contains code improving the spatial functionality in MariaDB.

MySQL operates on spatial data based on the OpenGIS standards, particularly the OpenGIS SFS (Simple feature access, SQL option).

Initial support was based on version 05-134 of the standard. MariaDB implements a subset of the 'SQL with Geometry Types' environment proposed by the OGC. And the SQL environment was extended with a set of geometry types.

MariaDB supports spatial extensions to operate on spatial features. These features are available for Aria, MyISAM, InnoDB, NDB, and ARCHIVE tables.

For spatial columns, Aria and MyISAM supports both SPATIAL and non-SPATIAL indexes. Other storage engines support non-SPATIAL indexes.

The most recent changes in the code are aimed at meeting the OpenGIS requirements. One thing missed in previous versions is that the functions which check spatial relations didn't consider the actual shape of an object, instead they operate only on their bounding rectangles. These legacy functions have been left as they are and new, properly-working functions are named with an ' `ST_` ' prefix, in accordance with the latest OpenGIS requirements. Also, operations over geometry features were added.

The list of new functions:

Spatial operators. They produce new geometries.

Name	Description
ST_UNION(A, B)	union of A and B
ST_INTERSECTION(A, B)	intersection of A and B
ST_SYMDIFFERENCE(A, B)	symdifference, notintersecting parts of A and B
ST_BUFFER(A, radius)	returns the shape of the area that lies in 'radius' distance from the shape A.

Predicates, return boolean result of the relationship

Name	Description
ST_INTERSECTS(A, B)	if A and B have an intersection
ST_CROSSES(A, B)	if A and B cross
ST_EQUALS(A, B)	if A and B are equal
ST_WITHIN(A, B)	if A lies within B
ST_CONTAINS(A,B)	if B lies within A
ST_DISJOINT(A,B)	if A and B have no intersection
ST_TOUCHES(A,B)	if A touches B

1.1.3.3 Geometry Types

Contents

Description

MariaDB provides a standard way of creating spatial columns for geometry types, for example, with CREATE TABLE or ALTER TABLE. Currently, spatial columns are supported for MyISAM, InnoDB and ARCHIVE tables. See also SPATIAL INDEX.

The basic geometry type is `GEOMETRY`. But the type can be more specific. The following types are supported:

Geometry Types
POINT
LINESTRING
POLYGON
MULTIPOINT
MULTILINESTRING
MULTIPOLYGON
GEOMETRYCOLLECTION
GEOMETRY

Examples

Note: For clarity, only one type is listed per table in the examples below, but a table row can contain multiple types. For example:

```
CREATE TABLE object (shapeA POLYGON, shapeB LINESTRING);
```

POINT

```
CREATE TABLE gis_point  (g POINT);
SHOW FIELDS FROM gis_point;
INSERT INTO gis_point VALUES
    (PointFromText('POINT(10 10)')),
    (PointFromText('POINT(20 10)')),
    (PointFromText('POINT(20 20)')),
    (PointFromWKB(AsWKB(PointFromText('POINT(10 20)'))));
```

LINESTRING

```
CREATE TABLE gis_line  (g LINESTRING);
SHOW FIELDS FROM gis_line;
INSERT INTO gis_line VALUES
    (LineFromText('LINESTRING(0 0,0 10,10 0)')),
    (LineStringFromText('LINESTRING(10 10,20 10,20 20,10 20,10 10)')),
    (LineStringFromWKB(AsWKB(LineString(Point(10, 10), Point(40, 10)))));
```

POLYGON

```
CREATE TABLE gis_polygon    (g POLYGON);
SHOW FIELDS FROM gis_polygon;
INSERT INTO gis_polygon VALUES
    (PolygonFromText('POLYGON((10 10,20 10,20 20,10 20,10 10))')),
    (PolyFromText('POLYGON((0 0,50 0,50 50,0 50,0 0), (10 10,20 10,20 20,10 20,10 10))')),
    (PolyFromWKB(AsWKB(Polygon(LineString(Point(0, 0), Point(30, 0), Point(30, 30), Point(0,
0))))));
```

MULTIPOINT

```
CREATE TABLE gis_multi_point (g MULTIPOINT);
SHOW FIELDS FROM gis_multi_point;
INSERT INTO gis_multi_point VALUES
    (MultiPointFromText('MULTIPOINT(0 0,10 10,10 20,20 20)')),
    (MPointFromText('MULTIPOINT(1 1,11 11,11 21,21 21)')),
    (MPointFromWKB(AsWKB(MultiPoint(Point(3, 6), Point(4, 10)))));
```

MULTILINESTRING

```
CREATE TABLE gis_multi_line (g MULTILINESTRING);
SHOW FIELDS FROM gis_multi_line;
INSERT INTO gis_multi_line VALUES
    (MultiLineStringFromText('MULTILINESTRING((10 48,10 21,10 0),(16 0,16 23,16 48))')),
    (MLineFromText('MULTILINESTRING((10 48,10 21,10 0))')),
    (MLineFromWKB(AsWKB(MultiLineString(LineString(Point(1, 2), Point(3, 5)),
LineString(Point(2, 5), Point(5, 8), Point(21, 7))))));
```

MULTIPOLYGON

```
CREATE TABLE gis_multi_polygon  (g MULTIPOLYGON);
SHOW FIELDS FROM gis_multi_polygon;
INSERT INTO gis_multi_polygon VALUES
    (MultiPolygonFromText('MULTIPOLYGON(((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48
6,52 18)),((59 18,67 18,67 13,59 13,59 18)))')),
    (MPolyFromText('MULTIPOLYGON(((28 26,28 0,84 0,84 42,28 26),(52 18,66 23,73 9,48 6,52 18)),
((59 18,67 18,67 13,59 13,59 18)))')),
    (MPolyFromWKB(AsWKB(MultiPolygon(Polygon(LineString(Point(0, 3), Point(3, 3), Point(3, 0),
Point(0, 3)))))));
```

GEOMETRYCOLLECTION

```
CREATE TABLE gis_geometrycollection  (g GEOMETRYCOLLECTION);
SHOW FIELDS FROM gis_geometrycollection;
INSERT INTO gis_geometrycollection VALUES
    (GeomCollFromText('GEOMETRYCOLLECTION(POINT(0 0), LINESTRING(0 0,10 10))')),
    (GeometryFromWKB(AsWKB(GeometryCollection(Point(44, 6), LineString(Point(3, 6), Point(7,
9))))),
    (GeomFromText('GeometryCollection()')),
    (GeomFromText('GeometryCollection EMPTY'));
```

GEOMETRY

```
CREATE TABLE gis_geometry (g GEOMETRY);
SHOW FIELDS FROM gis_geometry;
INSERT into gis_geometry SELECT * FROM gis_point;
INSERT into gis_geometry SELECT * FROM gis_line;
INSERT into gis_geometry SELECT * FROM gis_polygon;
INSERT into gis_geometry SELECT * FROM gis_multi_point;
INSERT into gis_geometry SELECT * FROM gis_multi_line;
INSERT into gis_geometry SELECT * FROM gis_multi_polygon;
INSERT into gis_geometry SELECT * FROM gis_geometrycollection;
```

1.1.3.4 Geometry Hierarchy

Description

Geometry is the base class. It is an abstract class. The instantiable subclasses of Geometry are restricted to zero-, one-, and two-dimensional geometric objects that exist in two-dimensional coordinate space. All instantiable geometry classes are defined so that valid instances of a geometry class are topologically closed (that is, all defined geometries include their boundary).

The base Geometry class has subclasses for Point, Curve, Surface, and GeometryCollection:

- Point represents zero-dimensional objects.
- Curve represents one-dimensional objects, and has subclass LineString, with sub-subclasses Line and LinearRing.
- Surface is designed for two-dimensional objects and has subclass Polygon.
- GeometryCollection has specialized zero-, one-, and two-dimensional collection classes named MultiPoint, MultiLineString, and MultiPolygon for modeling geometries corresponding to collections of Points, LineStrings, and Polygons, respectively. MultiCurve and MultiSurface are introduced as abstract superclasses that generalize the collection interfaces to handle Curves and Surfaces.

Geometry, Curve, Surface, MultiCurve, and MultiSurface are defined as non-instantiable classes. They define a common set of methods for their subclasses and are included for extensibility.

Point, LineString, Polygon, GeometryCollection, MultiPoint, MultiLineString, and MultiPolygon are instantiable classes.

1.2.9.3.1 Geometry Constructors

1.2.9.3.2 Geometry Properties

1.2.9.3.3 Geometry Relations

1.2.9.3.4 LineString Properties

1.2.9.3.5 MBR (Minimum Bounding Rectangle)

1.2.9.3.6 Point Properties

1.2.9.3.7 Polygon Properties

1.2.9.3.8 WKB

1.2.9.3.9 WKT

1.1.3.14 MySQL/MariaDB Spatial Support Matrix

This table shows when different spatial features were introduced into MySQL and MariaDB.

My	MySQL
MDB	MariaDB
x	This feature is supported.
MBR	This feature is present, but operates on the Minimum Bounding Rectangle instead of the actual shape.
d	This feature is present, but has been deprecated and will be removed in a future version.
*****	This feature is present, but may not work the way you expect.
-	This feature is not supported.

1.1.3.15 SPATIAL INDEX

Contents

Description

On MyISAM, Aria and InnoDB tables, MariaDB can create spatial indexes (an R-tree index) using syntax similar to that for creating regular indexes, but extended with the `SPATIAL` keyword. Currently, columns in spatial indexes must be declared `NOT NULL`.

Spatial indexes can be created when the table is created, or added after the fact like so:

- with CREATE TABLE:

```
CREATE TABLE geom (g GEOMETRY NOT NULL, SPATIAL INDEX(g));
```

- with ALTER TABLE:

```
ALTER TABLE geom ADD SPATIAL INDEX(g);
```

- with CREATE INDEX:

```
CREATE SPATIAL INDEX sp_index ON geom (g);
```

`SPATIAL INDEX` creates an `R-tree` index. For storage engines that support non-spatial indexing of spatial columns, the engine creates a `B-tree` index. A `B-tree` index on spatial values is useful for exact-value lookups, but not for range scans.

For more information on indexing spatial columns, see CREATE INDEX.

To drop spatial indexes, use ALTER TABLE or DROP INDEX:

- with ALTER TABLE:

```
ALTER TABLE geom DROP INDEX g;
```

- with DROP INDEX:

```
DROP INDEX sp_index ON geom;
```

Data-at-Rest Encyption

Before MariaDB 10.4.3, InnoDB's spatial indexes could not be encrypted. If an InnoDB table was encrypted and if it contained spatial indexes, then those indexes would be unencrypted.

In MariaDB 10.4.3 and later, if `innodb_checksum_algorithm` is set to `full_crc32` or `strict_full_crc32`, and if the table does not use `ROW_FORMAT=COMPRESSED`, then InnoDB spatial indexes will be encrypted if the table is encrypted.

See MDEV-12026 for more information.

1.1.3.16 GeoJSON

GeoJSON is a format for encoding various geographic data structures.

ST_AsGeoJSON

Returns the given geometry as a GeoJSON element.

ST_GeomFromGeoJSON

Given a GeoJSON input, returns a geometry object

1.1.3.16.1 ST_AsGeoJSON

Syntax

```
ST_AsGeoJSON(g[, max_decimals[, options]])
```

Description

Returns the given geometry *g* as a GeoJSON element. The optional *max_decimals* limits the maximum number of decimals displayed.

The optional *options* flag can be set to `1` to add a bounding box to the output.

Examples

```
SELECT ST_AsGeoJSON(ST_GeomFromText('POINT(5.3 7.2)'));
+-------------------------------------------------+
| ST_AsGeoJSON(ST_GeomFromText('POINT(5.3 7.2)')) |
+-------------------------------------------------+
| {"type": "Point", "coordinates": [5.3, 7.2]}    |
+-------------------------------------------------+
```

1.1.3.16.2 ST_GeomFromGeoJSON

MariaDB starting with 10.2.4
ST_GeomFromGeoJSON was added in MariaDB 10.2.4

Syntax

```
ST_GeomFromGeoJSON(g[, option])
```

Description

Given a GeoJSON input *g*, returns a geometry object. The *option* specifies what to do if *g* contains geometries with coordinate dimensions higher than 2.

Option	Description
1	Return an error (the default)
2 - 4	The document is accepted, but the coordinates for higher coordinate dimensions are stripped off.

Note that this function did not work correctly before MariaDB 10.2.8 - see MDEV-12180.

Examples

```
SET @j = '{ "type": "Point", "coordinates": [5.3, 15.0]}';

SELECT ST_AsText(ST_GeomFromGeoJSON(@j));
+-----------------------------------+
| ST_AsText(ST_GeomFromGeoJSON(@j)) |
+-----------------------------------+
| POINT(5.3 15)                     |
+-----------------------------------+
```

1.1.4 NoSQL

MariaDB supports a lot of commands and interfaces that are closer to NoSQL than to SQL.

CONNECT

The CONNECT storage engine enables MariaDB to access external local or remote data.

HANDLER

Direct access to reading rows from the storage engine.

HandlerSocket

A NoSQL plugin giving you direct access to InnoDB and SPIDER.

Dynamic Columns

Dynamic columns allow one to store different sets of columns for each row in a table

Dynamic Columns from MariaDB 10

Improvements to Dynamic Columns from MariaDB 10.

Dynamic Column API

Client-side API for reading and writing Dynamic Columns blobs

Dynamic Columns API

MariaDB 10.0 API for reading and writing dynamic-columns blobs

JSON Functions

Built-in functions related to JSON.

LOAD_FILE

Returns file contents as a string.

Cassandra Storage Engine

A storage engine interface to Cassandra.

There are 1 related questions.

5.3.7 CONNECT

1.1.4.2 HANDLER

The `HANDLER` statements give you direct access to reading rows from the storage engine. This is much faster than normal access through SELECT as there is less parsing involved and no optimizer involved.

You can use prepared statements for `HANDLER READ`, which should give you a speed comparable to HandlerSocket. Also see Yoshinori Matsunobu's blog post Using MySQL as a NoSQL - A story for exceeding 750,000 qps on a commodity server.

HANDLER Commands

Direct access to table storage engine interfaces for key lookups and key or table scans.

HANDLER for MEMORY Tables

Using HANDLER commands efficiently with MEMORY/HEAP tables

1.1.4.2.1 HANDLER Commands

Syntax

```
HANDLER tbl_name OPEN [ [AS] alias]
HANDLER tbl_name READ index_name { = | >= | <= | < } (value1,value2,...)
    [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ index_name { FIRST | NEXT | PREV | LAST }
    [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name READ { FIRST | NEXT }
    [ WHERE where_condition ] [LIMIT ... ]
HANDLER tbl_name CLOSE
```

Contents

Description

The `HANDLER` statement provides direct access to table storage engine interfaces for key lookups and key or table scans. It is available for at least Aria, Memory, MyISAM and InnoDB tables (and should work with most 'normal' storage engines, but not with system tables, MERGE or views).

`HANDLER ... OPEN` opens a table, allowing it to be accessible to subsequent `HANDLER ... READ` statements. The table can either be opened using an alias (which must then be used by `HANDLER ... READ`, or a table name.

The table object is only closed when `HANDLER ... CLOSE` is called by the session, and is not shared by other sessions.

Prepared statements work with `HANDLER READ`, which gives a much higher performance (50% speedup) as there is no parsing and all data is transformed in binary (without conversions to text, as with the normal protocol).

The HANDLER command does not work with partitioned tables.

Key Lookup

A key lookup is started with:

```
HANDLER tbl_name READ index_name { = | >= | <= | < }  (value,value) [LIMIT...]
```

The values stands for the value of each of the key columns. For most key types (except for HASH keys in MEMORY storage engine) you can use a prefix subset of it's columns.

If you are using LIMIT, then in case of >= or > then there is an implicit NEXT implied, while if you are using <= or < then there is an implicit PREV implied.

After the initial read, you can use

```
HANDLER tbl_name READ index_name NEXT [ LIMIT ... ]
or
HANDLER tbl_name READ index_name PREV [ LIMIT ... ]
```

to scan the rows in key order.

Note that the row order is not defined for keys with duplicated values and will vary from engine to engine.

Key Scans

You can scan a table in key order by doing:

```
HANDLER tbl_name READ index_name FIRST [ LIMIT ... ]
HANDLER tbl_name READ index_name NEXT  [ LIMIT ... ]
```

or, if the handler supports backwards key scans (most do):

```
HANDLER tbl_name READ index_name LAST [ LIMIT ... ]
HANDLER tbl_name READ index_name PREV [ LIMIT ... ]
```

Table Scans

You can scan a table in row order by doing:

```
HANDLER tbl_name READ FIRST [ LIMIT ... ]
HANDLER tbl_name READ NEXT  [ LIMIT ... ]
```

Limitations

As this is a direct interface to the storage engine, some limitations may apply for what you can do and what happens if the table changes. Here follows some of the common limitations:

Finding 'Old Rows'

HANDLER READ is not transaction safe, consistent or atomic. It's ok for the storage engine to returns rows that existed when you started the scan but that were later deleted. This can happen as the storage engine may cache rows as part of the scan from a previous read.

You may also find rows committed since the scan originally started.

Invisible Columns

`HANDLER ... READ` also reads the data of invisible-columns.

System-Versioned Tables

`HANDLER ... READ` reads everything from system-versioned tables, and so includes `row_start` and `row_end` fields, as well as all rows that have since been deleted or changed, including when history partitions are used.

Other Limitations

- If you do an ALTER TABLE, all your HANDLERs for that table are automatically closed.
- If you do an ALTER TABLE for a table that is used by some other connection with HANDLER, the ALTER TABLE will wait for the HANDLER to be closed.
- For HASH keys, you must use all key parts when searching for a row.
- For HASH keys, you can't do a key scan of all values. You can only find all rows with the same key value.
- While each HANDLER READ command is atomic, if you do a scan in many steps, then some engines may give you error 1020 if the table changed between the commands. Please refer to the specific engine handler page if this happens.

Error Codes

- Error 1031 (ER_ILLEGAL_HA) Table storage engine for 't1' doesn't have this option
  - If you get this for HANDLER OPEN it means the storage engine doesn't support HANDLER calls.
  - If you get this for HANDLER READ it means you are trying to use an incomplete HASH key.
- Error 1020 (ER_CHECKREAD) Record has changed since last read in table '...'
  - This means that the table changed between two reads and the handler can't handle this case for the given scan.

1.1.4.2.2 HANDLER for MEMORY Tables

This article explains how to use HANDLER commands efficiently with MEMORY/HEAP tables.

If you want to scan a table for over different key values, not just search for exact key values, you should create your keys with 'USING BTREE':

```
CREATE TABLE t1 (a INT, b INT, KEY(a), KEY b USING BTREE (b)) engine=memory;
```

In the above table, `a` is a HASH key that only supports exact matches (=) while `b` is a BTREE key that you can use to scan the table in key order, starting from start or from a given key value.

The limitations for HANDLER READ with Memory|HEAP tables are:

Limitations for HASH keys

- You must use all key parts when searching for a row.
- You can't do a key scan of all values. You can only find all rows with the same key value.
- READ NEXT gives error 1031 if the tables changed since last read.

Limitations for BTREE keys

- READ NEXT gives error 1031 if the tables changed since last read. This limitation can be lifted in the future.

Limitations for table scans

- READ NEXT gives error 1031 if the table was truncated since last READ call.

1.1.4.3 HandlerSocket

HandlerSocket gives you direct access to InnoDB and SPIDER. It is included in MariaDB as a ready-to use plugin.

HandlerSocket is a NoSQL plugin for MariaDB. It works as a daemon inside the mysqld process, accepting TCP connections, and executing requests from clients. HandlerSocket does not support SQL queries. Instead, it supports simple CRUD operations on tables.

HandlerSocket can be much faster than mysqld/libmysql in some cases because it has lower CPU, disk, and network overhead:

1. To lower CPU usage it does not parse SQL.
2. Next, it batch-processes requests where possible, which further reduces CPU usage and lowers disk usage.
3. Lastly, the client/server protocol is very compact compared to mysql/libmysql, which reduces network usage.

HandlerSocket Installation

Installing the HandlerSocket plugin.

HandlerSocket Configuration Options

HandlerSocket configuration options.

HandlerSocket Client Libraries

Available HandlerSocket Client Libraries

Testing HandlerSocket in a Source Distribution

Testing HandlerSocket in a source distribution.

HandlerSocket External Resources

HandlerSocket external resources and documentation

1.1.4.3.1 HandlerSocket Installation

After MariaDB is installed, use the INSTALL PLUGIN command (as the root user) to install the HandlerSocket plugin. This command only needs to be run once, like so:

```
INSTALL PLUGIN handlersocket SONAME 'handlersocket.so';
```

After installing the plugin, SHOW PROCESSLIST you first need to configure some settings. All HandlerSocket configuration options are placed in the [mysqld] section of your my.cnf file.

At least the handlersocket_address, handlersocket_port and handlersocket_port_wr options need to be set. For example:

```
handlersocket_address="127.0.0.1"
handlersocket_port="9998"
handlersocket_port_wr="9999"
```

After updating the configuration options, restart MariaDB.

On the client side, to make use of the plugin you will need to install the appropriate client library (i.e. libhsclient for C++ applications and perl-Net-HandlerSocket for perl applications).

1.1.4.3.2 HandlerSocket Configuration Options

Contents

The HandlerSocket plugin has the following options.

See also the Full list of MariaDB options, system and status variables.

Add the options to the [mysqld] section of your my.cnf file.

---

handlersocket_accept_balance

- **Description:** When set to a value other than zero (' `0` '), handlersocket will try to balance accepted connections among threads. Default is `0` but if you use persistent connections (for example if you use client-side connection pooling) then a non-zero value is recommended.
- **Commandline:** `--handlersocket-accept-balance="value"`
- **Scope:** Global
- **Dynamic:** No
- **Type:** number
- **Range:** `0` to `10000`
- **Default Value:** `0`

---

handlersocket_address

- **Description:** Specify the IP address to bind to.
- **Commandline:** `--handlersocket-address="value"`
- **Scope:** Global
- **Dynamic:** No
- **Type:** IP Address
- **Default Value:** Empty, previously `0.0.0.0`

---

handlersocket_backlog

- **Description:** Specify the listen backlog length.
- **Commandline:** `--handlersocket-backlog="value"`
- **Scope:** Global
- **Dynamic:** No
- **Type:** number
- **Range:** `5` to `1000000`
- **Default Value:** `32768`

---

handlersocket_epoll

- **Description:** Specify whether to use epoll for I/O multiplexing.
- **Commandline:** `--handlersocket-epoll="value"`
- **Scope:** Global
- **Dynamic:** No
- **Type:** number
- **Valid values:**
  - **Min:** `0`
  - **Max:** `1`
- **Default Value:** `1`

---

handlersocket_plain_secret

- **Description:** When set, enables plain-text authentication for the listener for read requests, with the value of the option specifying the secret authentication key.
- **Commandline:** `--handlersocket-plain-secret="value"`
- **Dynamic:** No
- **Type:** string
- **Default Value:** Empty

---

handlersocket_plain_secret_wr

- **Description:** When set, enables plain-text authentication for the listener for write requests, with the value of the option specifying the secret authentication key.
- **Commandline:** `--handlersocket-plain-secret-wr="value"`
- **Dynamic:** No
- **Type:** string
- **Default Value:** Empty

---

handlersocket_port

- **Description:** Specify the port to bind to for reads. An empty value disables the listener.
- **Commandline:** `--handlersocket-port="value"`
- **Scope:** Global
- **Dynamic:** No
- **Type:** number
- **Default Value:** Empty, previously `9998`

---

handlersocket_port_wr

- **Description:** Specify the port to bind to for writes. An empty value disables the listener.
- **Commandline:** `--handlersocket-port-wr="value"`
- **Scope:** Global
- **Dynamic:** No
- **Type:** number
- **Default Value:** Empty, previously `9999`

---

handlersocket_rcvbuf

- **Description:** Specify the maximum socket receive buffer (in bytes). If '0' then the system default is used.
- **Commandline:** `--handlersocket-rcvbuf="value"`
- **Scope:** Global
- **Dynamic:** No
- **Type:** number
- **Range:** `0` to `1677216`
- **Default Value:** `0`

---

handlersocket_readsize

- **Description:** Specify the minimum length of the request buffer. Larger values consume available memory but can make handlersocket faster for large requests.
- **Commandline:** `--handlersocket-readsize="value"`
- **Scope:** Global
- **Dynamic:** No
- **Type:** number
- **Range:** `0` to `1677216`
- **Default Value:** `0` (possibly `4096`)

---

handlersocket_sndbuf

- **Description:** Specify the maximum socket send buffer (in bytes). If '0' then the system default is used.
- **Commandline:** `--handlersocket-sndbuf="value"`
- **Scope:** Global
- **Dynamic:** No
- **Type:** number
- **Range:** `0` to `1677216`
- **Default Value:** `0`

---

handlersocket_threads

- **Description:** Specify the number of worker threads for reads. Recommended value = ((# CPU cores) * 2).
- **Commandline:** `--handlersocket-threads="value"`
- **Scope:** Global
- **Dynamic:** No
- **Type:** number
- **Range:** `1` to `3000`
- **Default Value:** `16`

---

handlersocket_threads_wr

- **Description:** Specify the number of worker threads for writes. Recommended value = 1.
- **Commandline:** `--handlersocket-threads-wr="value"`
- **Scope:** Global
- **Dynamic:** No
- **Type:** number
- **Range:** `1` to `3000`
- **Default Value:** `1`

---

handlersocket_timeout

- **Description:** Specify the socket timeout in seconds.
- **Commandline:** `--handlersocket-timeout="value"`
- **Scope:** Global
- **Dynamic:** No
- **Type:** number
- **Range:** `30` to `3600`
- **Default Value:** `300`

---

handlersocket_verbose

- **Description:** Specify the logging verbosity.
- **Commandline:** `--handlersocket-verbose="value"`
- **Scope:** Global
- **Dynamic:** No
- **Type:** number

- **Valid values:**
  - **Min:** `0`
  - **Max:** `10000`
- **Default Value:** `10`

`handlersocket_wrlock_timeout`

- **Description:** The write lock timeout in seconds. When acting on write requests, handlersocket locks an advisory lock named 'handlersocket_wr' and this option sets the timeout for it.
- **Commandline:** `--handlersocket-wrlock-timeout="value"`
- **Scope:** Global
- **Dynamic:** No
- **Type:** number
- **Range:** `0` to `3600`

1.1.4.3.3 HandlerSocket Client Libraries

In order to make use of the HandlerSocket plugin in your applications, you will need to use the appropriate client library. The following client libraries are available:

- C++
  - libhsclient *(included with the HandlerSocket plugin source)*
- Perl
  - perl-Net-HandlerSocket *(included with the HandlerSocket plugin source)*
- PHP
  - Net_HandlerSocket
  - HSPHP
  - php-ext-handlersocketi
- Java
  - hs4j
  - handlersocketforjava
- Python
  - python-handler-socket
  - pyhandlersocket
- Ruby
  - ruby-handlersocket
  - handlersocket
- JavaScript
  - node-handlersocket
- Scala
  - hs2client
- Haskell
  - HandlerSocket-Haskell-Client

1.1.4.3.4 Testing HandlerSocket in a Source Distribution

Contents

MariaDB 5.5

In MariaDB 5.5, which is built using `cmake`, `Makefile.PL` is not generated automatically. If you want to run the perl tests, you will need to create it manually from `Makefile.PL.in`. It is fairly easy to do by replacing `LIB` and `INC` values with the correct ones. Also, `libhsclient.so` is not built by default; `libhsclient.a` can be found in `plugin/handler_socket` folder.

MariaDB 5.3

If you want to test or use handlersocket with a source installation of MariaDB 5.3, here is one way to do this:

1. Compile with one of the build scripts that has the `-max` option, like `BUILD/compile-pentium64-max` or `BUILD/compile-pentium64-debug-max`
2. Start mysqld with the test framework

```
cd mysql-test
LD_LIBRARY_PATH=../plugin/handler_socket/libhsclient/.libs \
MTR_VERSION=1 perl mysql-test-run.pl --start-and-exit 1st \
--mysqld=--plugin-dir=../plugin/handler_socket/handlersocket/.libs \
--mysqld=--loose-handlersocket_port=9998 \
--mysqld=--loose-handlersocket_port_wr=9999 \
--master_port=9306 --mysqld=--innodb
```

3. This will end with:

```
Servers started, exiting
```

4. Load handlersocket

```
client/mysql -uroot --protocol=tcp --port=9306 \
-e 'INSTALL PLUGIN handlersocket soname "handlersocket.so"'
```

5. Configure and compile the handlersocket perl module

```
cd plugin/handler_socket/perl-Net-HandlerSocket
perl Makefile.PL
make
```

6. If you would like to install the handlersocket perl module permanently, you should do:

```
make install
```

   If you do this, you don't have to set `PERL5LIB` below.
7. Run the handlersocket test suite

```
cd plugin/handler_socket/regtest/test_01_lib
MYHOST=127.0.0.1 MYPORT=9306 LD_LIBRARY_PATH=../../libhsclient/.libs/ \
PERL5LIB=../common:../../perl-Net-HandlerSocket/lib:../../perl-Net-
HandlerSocket/blib/arch/auto/Net/HandlerSocket/ ./run.sh
```

1.1.4.3.5 HandlerSocket External Resources

Some resources and documentation about HandlerSocket.

- The home of HandlerSocket is here.
- The story of handlersocket can be found here.
- Comparison of HANDLER and HandlerSocket can be found here.

1.1.4.4 Dynamic Columns

Contents

Dynamic columns allow one to store different sets of columns for each row in a table. It works by storing a set of columns in a blob and having a small set of functions to manipulate it.

Dynamic columns should be used when it is not possible to use regular columns.

A typical use case is when one needs to store items that may have many different attributes (like size, color, weight, etc), and the set of possible attributes is very large and/or unknown in advance. In that case, attributes can be put into dynamic columns.

Dynamic Columns Basics

The table should have a blob column which will be used as storage for dynamic columns:

```
create table assets (
  item_name varchar(32) primary key, -- A common attribute for all items
  dynamic_cols  blob  -- Dynamic columns will be stored here
);
```

Once created, one can access dynamic columns via dynamic column functions:

Insert a row with two dynamic columns: color=blue, size=XL

```
INSERT INTO assets VALUES
  ('MariaDB T-shirt', COLUMN_CREATE('color', 'blue', 'size', 'XL'));
```

Insert another row with dynamic columns: color=black, price=500

```
INSERT INTO assets VALUES
  ('Thinkpad Laptop', COLUMN_CREATE('color', 'black', 'price', 500));
```

Select dynamic column 'color' for all items:

```
SELECT item_name, COLUMN_GET(dynamic_cols, 'color' as char)
  AS color FROM assets;
+-----------------+-------+
| item_name       | color |
+-----------------+-------+
| MariaDB T-shirt | blue  |
| Thinkpad Laptop | black |
+-----------------+-------+
```

It is possible to add and remove dynamic columns from a row:

```
-- Remove a column:
UPDATE assets SET dynamic_cols=COLUMN_DELETE(dynamic_cols, "price")
WHERE COLUMN_GET(dynamic_cols, 'color' as char)='black';

-- Add a column:
UPDATE assets SET dynamic_cols=COLUMN_ADD(dynamic_cols, 'warranty', '3 years')
WHERE item_name='Thinkpad Laptop';
```

You can also list all columns, or get them together with their values in JSON format:

```
SELECT item_name, column_list(dynamic_cols) FROM assets;
+-----------------+---------------------------+
| item_name       | column_list(dynamic_cols) |
+-----------------+---------------------------+
| MariaDB T-shirt | `size`,`color`            |
| Thinkpad Laptop | `color`,`warranty`        |
+-----------------+---------------------------+

SELECT item_name, COLUMN_JSON(dynamic_cols) FROM assets;
+-----------------+-----------------------------------------+
| item_name       | COLUMN_JSON(dynamic_cols)               |
+-----------------+-----------------------------------------+
| MariaDB T-shirt | {"size":"XL","color":"blue"}            |
| Thinkpad Laptop | {"color":"black","warranty":"3 years"} |
+-----------------+-----------------------------------------+
```

Dynamic Columns Reference

The rest of this page is a complete reference of dynamic columns in MariaDB

Dynamic Columns Functions

COLUMN_CREATE

```
COLUMN_CREATE(column_nr, value [as type], [column_nr, value
  [as type]]...);
COLUMN_CREATE(column_name, value [as type], [column_name, value
  [as type]]...);
```

Return a dynamic columns blob that stores the specified columns with values.

The return value is suitable for

- storing in a table
- further modification with other dynamic columns functions

The `as type` part allows one to specify the value type. In most cases, this is redundant because MariaDB will be able to deduce the type of the value. Explicit type specification may be needed when the type of the value is not apparent. For example, a literal `'2012-12-01'` has a CHAR type by default, one will need to specify `'2012-12-01' AS DATE` to have it stored as a date. See the Datatypes section for further details. Note also MDEV-597.

Typical usage:

```
-- MariaDB 5.3+:
INSERT INTO tbl SET dyncol_blob=COLUMN_CREATE(1 /*column id*/, "value");
-- MariaDB 10.0.1+:
INSERT INTO tbl SET dyncol_blob=COLUMN_CREATE("column_name", "value");
```

COLUMN_ADD

```
COLUMN_ADD(dyncol_blob, column_nr, value [as type],
  [column_nr, value [as type]]...);
COLUMN_ADD(dyncol_blob, column_name, value [as type],
  [column_name, value [as type]]...);
```

Adds or updates dynamic columns.

- `dyncol_blob` must be either a valid dynamic columns blob (for example, `COLUMN_CREATE` returns such blob), or an empty string.
- `column_name` specifies the name of the column to be added. If `dyncol_blob` already has a column with this name, it will be overwritten.
- `value` specifies the new value for the column. Passing a NULL value will cause the column to be deleted.
- `as type` is optional. See #datatypes section for a discussion about types.

The return value is a dynamic column blob after the modifications.

Typical usage:

```
-- MariaDB 5.3+:
UPDATE tbl SET dyncol_blob=COLUMN_ADD(dyncol_blob, 1 /*column id*/, "value")
  WHERE id=1;
-- MariaDB 10.0.1+:
UPDATE t1 SET dyncol_blob=COLUMN_ADD(dyncol_blob, "column_name", "value")
  WHERE id=1;
```

Note: `COLUMN_ADD()` is a regular function (just like `CONCAT()`), hence, in order to update the value in the table you have to use the `UPDATE ... SET dynamic_col=COLUMN_ADD(dynamic_col, ....)` pattern.

COLUMN_GET

```
COLUMN_GET(dyncol_blob, column_nr as type);
COLUMN_GET(dyncol_blob, column_name as type);
```

Get the value of a dynamic column by its name. If no column with the given name exists, `NULL` will be returned.

`column_name as type` requires that one specify the datatype of the dynamic column they are reading.

This may seem counter-intuitive: why would one need to specify which datatype they're retrieving? Can't the dynamic columns system figure the datatype from the data being stored?

The answer is: SQL is a statically-typed language. The SQL interpreter needs to know the datatypes of all expressions before the query is run (for example, when one is using prepared statements and runs `"select COLUMN_GET(...)"`, the prepared statement API requires the server to inform the client about the datatype of the column being read before the query is executed and the server can see what datatype the column actually has).

See the Datatypes section for more information about datatypes.

COLUMN_DELETE

```
COLUMN_DELETE(dyncol_blob, column_nr, column_nr...);
COLUMN_DELETE(dyncol_blob, column_name, column_name...);
```

Delete a dynamic column with the specified name. Multiple names can be given.

The return value is a dynamic column blob after the modification.

COLUMN_EXISTS

```
COLUMN_EXISTS(dyncol_blob, column_nr);
COLUMN_EXISTS(dyncol_blob, column_name);
```

Check if a column with name `column_name` exists in `dyncol_blob`. If yes, return `1`, otherwise return `0`.

COLUMN_LIST

```
COLUMN_LIST(dyncol_blob);
```

Return a comma-separated list of column names. The names are quoted with backticks.

```
SELECT column_list(column_create('col1','val1','col2','val2'));
+-----------------------------------------------------+
| column_list(column_create('col1','val1','col2','val2')) |
+-----------------------------------------------------+
| `col1`,`col2`                                       |
+-----------------------------------------------------+
```

COLUMN_CHECK

```
COLUMN_CHECK(dyncol_blob);
```

Check if `dyncol_blob` is a valid packed dynamic columns blob. Return value of 1 means the blob is valid, return value of 0 means it is not.

Rationale: Normally, one works with valid dynamic column blobs. Functions like `COLUMN_CREATE`, `COLUMN_ADD`, `COLUMN_DELETE` always return valid dynamic column blobs. However, if a dynamic column blob is accidentally truncated, or transcoded from one character set to another, it will be corrupted. This function can be used to check if a value in a blob field is a valid dynamic column blob.

Note: It is possible that a truncation cut a Dynamic Column "clearly" so that COLUMN_CHECK will not notice the corruption, but in any case of truncation a warning is issued during value storing.

COLUMN_JSON

```
COLUMN_JSON(dyncol_blob);
```

Return a JSON representation of data in `dyncol_blob`.

Example:

```
SELECT item_name, COLUMN_JSON(dynamic_cols) FROM assets;
+-----------------+-----------------------------------------+
| item_name       | COLUMN_JSON(dynamic_cols)               |
+-----------------+-----------------------------------------+
| MariaDB T-shirt | {"size":"XL","color":"blue"}            |
| Thinkpad Laptop | {"color":"black","warranty":"3 years"} |
+-----------------+-----------------------------------------+
```

Limitation: `COLUMN_JSON` will decode nested dynamic columns at a nesting level of not more than 10 levels deep. Dynamic columns that are nested deeper than 10 levels will be shown as BINARY string, without encoding.

Nesting Dynamic Columns

It is possible to use nested dynamic columns by putting one dynamic column blob inside another. The `COLUMN_JSON` function will display nested columns.

```
SET @tmp= column_create('parent_column',
  column_create('child_column', 12345));
Query OK, 0 rows affected (0.00 sec)

SELECT column_json(@tmp);
+-----------------------------------------+
| column_json(@tmp)                       |
+-----------------------------------------+
| {"parent_column":{"child_column":12345}} |
+-----------------------------------------+

SELECT column_get(column_get(@tmp, 'parent_column' AS char),
  'child_column' AS int);
+-------------------------------------------------------------------------------+
| column_get(column_get(@tmp, 'parent_column' as char), 'child_column' as int) |
+-------------------------------------------------------------------------------+
|                                                                         12345 |
+-------------------------------------------------------------------------------+
```

If you are trying to get a nested dynamic column as a string use 'as BINARY' as the last argument of COLUMN_GET (otherwise problems with character set conversion and illegal symbols are possible):

```
select column_json( column_get(
  column_create('test1',
    column_create('key1','value1','key2','value2','key3','value3')),
  'test1' as BINARY));
```

Datatypes

In SQL, one needs to define the type of each column in a table. Dynamic columns do not provide any way to declare a type in advance ("whenever there is a column 'weight', it should be integer" is not possible). However, each particular dynamic column value is stored together with its datatype.

The set of possible datatypes is mostly the same as that used by the SQL `CAST` and `CONVERT` functions. However, note that there are currently some differences - see MDEV-597.

type	dynamic column internal type	description
`BINARY[(N)]`	`DYN_COL_STRING`	(variable length string with binary charset)
`CHAR[(N)]`	`DYN_COL_STRING`	(variable length string with charset)
`DATE`	`DYN_COL_DATE`	(date - 3 bytes)
`DATETIME[(D)]`	`DYN_COL_DATETIME`	(date and time (with microseconds) - 9 bytes)
`DECIMAL[(M[,D])]`	`DYN_COL_DECIMAL`	(variable length binary decimal representation with MariaDB limitation)
`DOUBLE[(M,D)]`	`DYN_COL_DOUBLE`	(64 bit double-precision floating point)
`INTEGER`	`DYN_COL_INT`	(variable length, up to 64 bit signed integer)
`SIGNED [INTEGER]`	`DYN_COL_INT`	(variable length, up to 64 bit signed integer)
`TIME[(D)]`	`DYN_COL_TIME`	(time (with microseconds, may be negative) - 6 bytes)
`UNSIGNED [INTEGER]`	`DYN_COL_UINT`	(variable length, up to 64bit unsigned integer)

A Note About Lengths

If you're running queries like

```
SELECT COLUMN_GET(blob, 'colname' as CHAR) ...
```

without specifying a maximum length (i.e. using #as CHAR#, not `as CHAR(n)`), MariaDB will report the maximum length of the resultset column to be `53,6870,911` (bytes or characters?) for MariaDB 5.3-10.0.0 and `16,777,216` for MariaDB 10.0.1+. This may cause excessive memory usage in some client libraries, because they try to pre-allocate a buffer of maximum resultset width. If you suspect you're hitting this problem, use `CHAR(n)` whenever you're using `COLUMN_GET` in the select list.

MariaDB 5.3 vs MariaDB 10.0

The dynamic columns feature was introduced into MariaDB in two steps:

1. MariaDB 5.3 was the first version to support dynamic columns. Only numbers could be used as column names in this version.
2. In MariaDB 10.0.1, column names can be either numbers or strings. Also, the `COLUMN_JSON` and `COLUMN_CHECK` functions were added.

See also Dynamic Columns in MariaDB 10.

Client-side API

It is also possible to create or parse dynamic columns blobs on the client side. `libmysql` client library now includes an API for writing/reading dynamic column blobs. See dynamic-columns-api for details.

Limitations

Description	Limit
Max number of columns	65535
Max total length of packed dynamic column	max_allowed_packet (1G)

1.1.4.5 Dynamic Columns from MariaDB 10

Contents

MariaDB starting with 10.0.1

MariaDB 10.0.1 introduced the following improvements to the dynamic columns feature.

Column Name Support

It is possible to refer to column by names. Names can be used everywhere where in MariaDB 5.3 one could use only strings:

- Create a dynamic column blob:

```
COLUMN_CREATE('int_col', 123 as int, 'double_col', 3.14 as double, 'string_col', 'text-
data' as char);
```

- Set a column value:

```
COLUMN_ADD(dyncol_blob, 'intcol', 1234);
```

- Get a column value:

```
COLUMN_GET(dynstr, 'column1' as char(10));
```

- Check whether a column exists

```
COLUMN_EXISTS(dyncol_blob, 'column_name');
```

Changes in Behavior

- Column list output now includes quoting:

```
select column_list(column_create(1, 22, 2, 23));
+----------------------------------------+
| column_list(column_create(1, 22, 2, 23)) |
+----------------------------------------+
| `1`,`2`                                |
+----------------------------------------+
select column_list(column_create('column1', 22, 'column2', 23));
+-------------------------------------------------------+
| column_list(column_create('column1', 22, 'column2', 23)) |
+-------------------------------------------------------+
| `column1`,`column2`                                   |
+-------------------------------------------------------+
```

- Column name interpretation has been changed so that the string now is not converted to a number. So some "magic" tricks will not work any more, for example, "1test" and "1" now become different column names:

```
select column_list(column_add(column_create('1a', 22), '1b', 23));
+-----------------------------------------------------------+
| column_list(column_add(column_create('1a', 22), '1b', 23)) |
+-----------------------------------------------------------+
| `1a`,`1b`                                                 |
+-----------------------------------------------------------+
```

Old behavior:

```
select column_list(column_add(column_create('1a', 22), '1b', 23));
+-----------------------------------------------------------+
| column_list(column_add(column_create('1a', 22), '1b', 23)) |
+-----------------------------------------------------------+
| 1                                                         |
+-----------------------------------------------------------+
```

New Functions

The following new functions have been added to dynamic columns in MariaDB 10

COLUMN_CHECK

COLUMN_CHECK is used to check a column's integrity. When it encounters an error it does not return illegal format errors but returns false instead. It also checks integrity more thoroughly and finds errors in the dynamic column internal structures which might not be found by other functions.

```
select column_check(column_create('column1', 22));
+-----------------------------------------+
| column_check(column_create('column1', 22)) |
+-----------------------------------------+
|                                       1 |
+-----------------------------------------+
select column_check('abracadabra');
+----------------------------+
| column_check('abracadabra') |
+----------------------------+
|                          0 |
+----------------------------+
```

COLUMN_JSON

COLUMN_JSON converts all dynamic column record content to a JSON object.

```
select column_json(column_create('column1', 1, 'column2', "two"));
+-----------------------------------------------------------+
| column_json(column_create('column1', 1, 'column2', "two")) |
+-----------------------------------------------------------+
| {"column1":1,"column2":"two"}                             |
+-----------------------------------------------------------+
```

Other Changes

- All API functions has prefix mariadb_dyncol_ (old prefix dynamic_column_ is depricated
- API changed to be able to work with the new format (*_named functions).
- Removed 'delete' function because deleting could be done by adding NULL value.
- 'Time' and 'datetime' in the new format are stored without microseconds if they are 0.
- New function added to API (except that two which are representing SQL level functions):
  - 'Unpack' the dynamic columns content to an arrays of values and names.
  - 3 functions to get any column value as string, integer (long long) or floating point (double).
- New type of "dynamic column" row added on the API level (in SQL level output it is a string but if you use dynamic column functions to construct object it will be added as dynamic column value) which allow to add dynamic columns inside dynamic columns. JSON function represent such recursive constructions correctly but limit depth of representation as current implementation limit (internally depth of dynamic columns embedding is not limited).

Interface with Cassandra

> CassandraSE is no longer actively being developed and has been removed in MariaDB 10.6. See MDEV-23024.

Some internal changes were added to dynamic columns to allow them to serve as an interface to Apache Cassandra dynamic columns. The Cassandra engine may pack all columns which were not mentioned in the MariaDB interface table definition and even bring changes in the dynamic column contents back to the cassandra columns family (the table analog in cassandra).

1.1.4.6 Dynamic Column API

This page describes the client-side API for reading and writing Dynamic Columns blobs.

Normally, you should use Dynamic column functions which are run inside the MariaDB server and allow one to access Dynamic Columns content without any client-side libraries.

If you need to read/write dynamic column blobs **on the client** for some reason, this API enables that.

Contents

Where to get it

The API is a part of `libmysql` C client library. In order to use it, you need to include this header file

```
#include <mysql/ma_dyncol.h>
```

and link against `libmysql` .

Data structures

DYNAMIC_COLUMN

`DYNAMIC_COLUMN` represents a packed dynamic column blob. It is essentially a string-with-length and is defined as follows:

```
/* A generic-purpose arbitrary-length string defined in MySQL Client API */
typedef struct st_dynamic_string
{
  char *str;
  size_t length,max_length,alloc_increment;
} DYNAMIC_STRING;

...

typedef DYNAMIC_STRING DYNAMIC_COLUMN;
```

DYNAMIC_COLUMN_VALUE

Dynamic columns blob stores {name, value} pairs. `DYNAMIC_COLUMN_VALUE` structure is used to represent the value in accessible form.

```
struct st_dynamic_column_value
{
  DYNAMIC_COLUMN_TYPE type;
  union
  {
    long long long_value;
    unsigned long long ulong_value;
    double double_value;
    struct {
      MYSQL_LEX_STRING value;
      CHARSET_INFO *charset;
    } string;
    struct {
      decimal_digit_t buffer[DECIMAL_BUFF_LENGTH];
      decimal_t value;
    } decimal;
    MYSQL_TIME time_value;
  } x;
};
typedef struct st_dynamic_column_value DYNAMIC_COLUMN_VALUE;
```

Every value has a type, which is determined by the `type` member.

type	structure field
DYN_COL_NULL	-
DYN_COL_INT	value.x.long_value
DYN_COL_UINT	value.x.ulong_value
DYN_COL_DOUBLE	value.x.double_value
DYN_COL_STRING	value.x.string.value , value.x.string.charset
DYN_COL_DECIMAL	value.x.decimal.value
DYN_COL_DATETIME	value.x.time_value
DYN_COL_DATE	value.x.time_value
DYN_COL_TIME	value.x.time_value
DYN_COL_DYNCOL	value.x.string.value

Notes

- Values with type `DYN_COL_NULL` do not ever occur in dynamic columns blobs.
- Type `DYN_COL_DYNCOL` means that the value is a packed dynamic blob. This is how nested dynamic columns are done.
- Before storing a value to `value.x.decimal.value` , one must call `mariadb_dyncol_prepare_decimal()` to initialize the space for storage.

enum_dyncol_func_result

`enum enum_dyncol_func_result` is used as return value.

value	name	meaning
0	ER_DYNCOL_OK	OK
0	ER_DYNCOL_NO	(the same as ER_DYNCOL_OK but for functions which return a YES/NO)
1	ER_DYNCOL_YES	YES response or success
2	ER_DYNCOL_TRUNCATED	Operation succeeded but the data was truncated
-1	ER_DYNCOL_FORMAT	Wrong format of the encoded string
-2	ER_DYNCOL_LIMIT	A limit of implementation reached
-3	ER_DYNCOL_RESOURCE	Out of resources
-4	ER_DYNCOL_DATA	Incorrect input data
-5	ER_DYNCOL_UNKNOWN_CHARSET	Unknown character set

Result codes that are less than zero represent error conditions.

Function reference

Functions come in pairs:

- `xxx()` operates on the old (pre-MariaDB-10.0.1) dynamic column blob format where columns were identified by numbers.
- `xxx_named()` can operate on both old or new data format. If it modifies the blob, it will convert it to the new data format.

You should use `xxx_named()` functions, unless you need to keep the data compatible with MariaDB versions before 10.0.1.

mariadb_dyncol_create_many

Create a packed dynamic blob from arrays of values and names.

```
enum enum_dyncol_func_result
mariadb_dyncol_create_many(DYNAMIC_COLUMN *str,
                           uint column_count,
                           uint *column_numbers,
                           DYNAMIC_COLUMN_VALUE *values,
                           my_bool new_string);
enum enum_dyncol_func_result
mariadb_dyncol_create_many_named(DYNAMIC_COLUMN *str,
                                 uint column_count,
                                 MYSQL_LEX_STRING *column_keys,
                                 DYNAMIC_COLUMN_VALUE *values,
                                 my_bool new_string);
```

where

`str`	`OUT`	Packed dynamic blob will be put here
`column_count`	`IN`	Number of columns
`column_numbers`	`IN`	Column numbers array (old format)
`column_keys`	`IN`	Column names array (new format)
`values`	`IN`	Column values array
`new_string`	`IN`	If TRUE then the `str` will be reinitialized (not freed) before usage

mariadb_dyncol_update_many

Add or update columns in a dynamic columns blob. To delete a column, update its value to a "non-value" of type `DYN_COL_NULL`

```
enum enum_dyncol_func_result
mariadb_dyncol_update_many(DYNAMIC_COLUMN *str,
                           uint column_count,
                           uint *column_numbers,
                           DYNAMIC_COLUMN_VALUE *values);
enum enum_dyncol_func_result
mariadb_dyncol_update_many_named(DYNAMIC_COLUMN *str,
                                 uint column_count,
                                 MYSQL_LEX_STRING *column_keys,
                                 DYNAMIC_COLUMN_VALUE *values);
```

str	IN/OUT	Dynamic columns blob to be modified.
column_count	IN	Number of columns in following arrays
column_numbers	IN	Column numbers array (old format)
column_keys	IN	Column names array (new format)
values	IN	Column values array

mariadb_dyncol_exists

Check if column with given name exists in the blob

```
enum enum_dyncol_func_result
mariadb_dyncol_exists(DYNAMIC_COLUMN *str, uint column_number);
enum enum_dyncol_func_result
mariadb_dyncol_exists_named(DYNAMIC_COLUMN *str, MYSQL_LEX_STRING *column_key);
```

str	IN	Packed dynamic columns string.
column_number	IN	Column number (old format)
column_key	IN	Column name (new format)

The function returns YES/NO or Error code

mariadb_dyncol_column_count

Get number of columns in a dynamic column blob

```
enum enum_dyncol_func_result
mariadb_dyncol_column_count(DYNAMIC_COLUMN *str, uint *column_count);
```

str	IN	Packed dynamic columns string.
column_count	OUT	Number of not NULL columns in the dynamic columns string

mariadb_dyncol_list

List columns in a dynamic column blob.

```
enum enum_dyncol_func_result
mariadb_dyncol_list(DYNAMIC_COLUMN *str, uint *column_count, uint **column_numbers);
enum enum_dyncol_func_result
mariadb_dyncol_list_named(DYNAMIC_COLUMN *str, uint *column_count,
                          MYSQL_LEX_STRING **column_keys);
```

str	IN	Packed dynamic columns string.
column_count	OUT	Number of columns in following arrays
column_numbers	OUT	Column numbers array (old format). Caller should free this array.
column_keys	OUT	Column names array (new format). Caller should free this array.

mariadb_dyncol_get

Get a value of one column

```
enum enum_dyncol_func_result
mariadb_dyncol_get(DYNAMIC_COLUMN *org, uint column_number,
                   DYNAMIC_COLUMN_VALUE *value);
enum enum_dyncol_func_result
mariadb_dyncol_get_named(DYNAMIC_COLUMN *str, MYSQL_LEX_STRING *column_key,
                         DYNAMIC_COLUMN_VALUE *value);
```

str	IN	Packed dynamic columns string.
column_number	IN	Column numbers array (old format)
column_key	IN	Column names array (new format)
value	OUT	Value of the column

If the column is not found NULL returned as a value of the column.

mariadb_dyncol_unpack

Get value of all columns

```
enum enum_dyncol_func_result
mariadb_dyncol_unpack(DYNAMIC_COLUMN *str,
                      uint *column_count,
                      MYSQL_LEX_STRING **column_keys,
                      DYNAMIC_COLUMN_VALUE **values);
```

str	IN	Packed dynamic columns string to unpack.
column_count	OUT	Number of columns in following arrays
column_keys	OUT	Column names array (should be free by caller)
values	OUT	Values of the columns array (should be free by caller)

mariadb_dyncol_has_names

Check whether the dynamic columns blob uses new data format (the one where columns are identified by names)

```
my_bool mariadb_dyncol_has_names(DYNAMIC_COLUMN *str);
```

str	IN	Packed dynamic columns string.

mariadb_dyncol_check

Check whether dynamic column blob has correct data format.

```
enum enum_dyncol_func_result
mariadb_dyncol_check(DYNAMIC_COLUMN *str);
```

str	IN	Packed dynamic columns string.

mariadb_dyncol_json

Get contents od a dynamic columns blob in a JSON form

```
enum enum_dyncol_func_result
mariadb_dyncol_json(DYNAMIC_COLUMN *str, DYNAMIC_STRING *json);
```

str	IN	Packed dynamic columns string.

`json` `OUT` JSON representation

mariadb_dyncol_val_TYPE

Get dynamic column value as one of the base types

```
enum enum_dyncol_func_result
mariadb_dyncol_val_str(DYNAMIC_STRING *str, DYNAMIC_COLUMN_VALUE *val,
                       CHARSET_INFO *cs, my_bool quote);
enum enum_dyncol_func_result
mariadb_dyncol_val_long(longlong *ll, DYNAMIC_COLUMN_VALUE *val);
enum enum_dyncol_func_result
mariadb_dyncol_val_double(double *dbl, DYNAMIC_COLUMN_VALUE *val);
```

`str` or `ll` or `dbl` `OUT` value of the column

`val` `IN` Value

mariadb_dyncol_prepare_decimal

Initialize `DYNAMIC_COLUMN_VALUE` before value of `value.x.decimal.value` can be set

```
void mariadb_dyncol_prepare_decimal(DYNAMIC_COLUMN_VALUE *value);
```

`value` `OUT` Value of the column

This function links `value.x.decimal.value` to `value.x.decimal.buffer` .

mariadb_dyncol_value_init

Initialize a `DYNAMIC_COLUMN_VALUE` structure to a safe default.

```
#define mariadb_dyncol_value_init(V) (V)->type= DYN_COL_NULL
```

mariadb_dyncol_column_cmp_named

Compare two column names (currently, column names are compared with memcmp())

```
int mariadb_dyncol_column_cmp_named(const MYSQL_LEX_STRING *s1,
                                    const MYSQL_LEX_STRING *s2);
```

1.1.4.7 Dynamic Columns from MariaDB 10

Contents

MariaDB starting with 10.0.1

MariaDB 10.0.1 introduced the following improvements to the dynamic columns feature.

Column Name Support

It is possible to refer to column by names. Names can be used everywhere where in MariaDB 5.3 one could use only strings:

- Create a dynamic column blob:

```
COLUMN_CREATE('int_col', 123 as int, 'double_col', 3.14 as double, 'string_col', 'text-
data' as char);
```

- Set a column value:

```
COLUMN_ADD(dyncol_blob, 'intcol', 1234);
```

- Get a column value:

```
COLUMN_GET(dynstr, 'column1' as char(10));
```

- Check whether a column exists

```
COLUMN_EXISTS(dyncol_blob, 'column_name');
```

Changes in Behavior

- Column list output now includes quoting:

```
select column_list(column_create(1, 22, 2, 23));
+----------------------------------------+
| column_list(column_create(1, 22, 2, 23)) |
+----------------------------------------+
| `1`,`2`                                |
+----------------------------------------+
select column_list(column_create('column1', 22, 'column2', 23));
+-------------------------------------------------------+
| column_list(column_create('column1', 22, 'column2', 23)) |
+-------------------------------------------------------+
| `column1`,`column2`                                   |
+-------------------------------------------------------+
```

- Column name interpretation has been changed so that the string now is not converted to a number. So some "magic" tricks will not work any more, for example, "1test" and "1" now become different column names:

```
select column_list(column_add(column_create('1a', 22), '1b', 23));
+-----------------------------------------------------------+
| column_list(column_add(column_create('1a', 22), '1b', 23)) |
+-----------------------------------------------------------+
| `1a`,`1b`                                                 |
+-----------------------------------------------------------+
```

  Old behavior:

```
select column_list(column_add(column_create('1a', 22), '1b', 23));
+-----------------------------------------------------------+
| column_list(column_add(column_create('1a', 22), '1b', 23)) |
+-----------------------------------------------------------+
| 1                                                         |
+-----------------------------------------------------------+
```

New Functions

The following new functions have been added to dynamic columns in MariaDB 10

COLUMN_CHECK

COLUMN_CHECK is used to check a column's integrity. When it encounters an error it does not return illegal format errors but returns false instead. It also checks integrity more thoroughly and finds errors in the dynamic column internal structures which might not be found by other functions.

```
select column_check(column_create('column1', 22));
+-----------------------------------------+
| column_check(column_create('column1', 22)) |
+-----------------------------------------+
|                                       1 |
+-----------------------------------------+
select column_check('abracadabra');
+----------------------------+
| column_check('abracadabra') |
+----------------------------+
|                          0 |
+----------------------------+
```

COLUMN_JSON

COLUMN_JSON converts all dynamic column record content to a JSON object.

```
select column_json(column_create('column1', 1, 'column2', "two"));
+-------------------------------------------------------------+
| column_json(column_create('column1', 1, 'column2', "two")) |
+-------------------------------------------------------------+
| {"column1":1,"column2":"two"}                               |
+-------------------------------------------------------------+
```

Other Changes

- All API functions has prefix mariadb_dyncol_ (old prefix dynamic_column_ is depricated
- API changed to be able to work with the new format (*_named functions).
- Removed 'delete' function because deleting could be done by adding NULL value.
- 'Time' and 'datetime' in the new format are stored without microseconds if they are 0.
- New function added to API (except that two which are representing SQL level functions):
  - 'Unpack' the dynamic columns content to an arrays of values and names.
  - 3 functions to get any column value as string, integer (long long) or floating point (double).
- New type of "dynamic column" row added on the API level (in SQL level output it is a string but if you use dynamic column functions to construct object it will be added as dynamic column value) which allow to add dynamic columns inside dynamic columns. JSON function represent such recursive constructions correctly but limit depth of representation as current implementation limit (internally depth of dynamic columns embedding is not limited).

Interface with Cassandra

> CassandraSE is no longer actively being developed and has been removed in MariaDB 10.6. See MDEV-23024.

Some internal changes were added to dynamic columns to allow them to serve as an interface to Apache Cassandra dynamic columns. The Cassandra engine may pack all columns which were not mentioned in the MariaDB interface table definition and even bring changes in the dynamic column contents back to the cassandra columns family (the table analog in cassandra).

1.2.9.4 JSON Functions

1.1.1.4.2.4.4 LOAD_FILE

1.1.5 Operators

Operators can be used for comparing values or for assigning values. There are several operators and they may be used in different SQL statements and clauses. Some can be used somewhat on their own, not within an SQL statement clause.

For comparing values—string or numeric—you can use symbols such as the equal-sign (i.e., `=`) or the exclamation point and the equal-sign together (i.e., `!=`). You might use these in `WHERE` clauses or within a flow-control statement or function (e.g., IF( )). You can also use basic regular expressions with the `LIKE` operator.

For assigning values, you can also use the equal-sign or other arithmetic symbols (e.g. plus-sign). You might do this with the SET statement or in a `SET` clause in an UPDATE statement.

Arithmetic Operators

Addition Operator (+)

Addition.

DIV

Integer division.

Division Operator (/)

Division.

MOD

Modulo operation. Remainder of N divided by M.

Modulo Operator (%)

Modulo operator. Returns the remainder of N divided by M.

Multiplication Operator (*)

Multiplication.

Subtraction Operator (-)

Subtraction and unary minus.

Assignment Operators

Assignment Operator (:=)

Assignment operator for assigning a value.

Assignment Operator (=)

The equal sign as an assignment operator.

Bit Functions and Operators

Operator Precedence

Precedence of SQL operators

&

Bitwise AND

<<

Left shift

>>

Shift right

BIT_COUNT

Returns the number of set bits

^

Bitwise XOR

|

Bitwise OR

~

Bitwise NOT

Parentheses

Parentheses modify the precedence of other operators in an expression

TRUE FALSE

TRUE and FALSE evaluate to 1 and 0

Comparison Operators

!=

Not equal operator.

<

Less than operator.

<=

Less than or equal operator.

<=>

NULL-safe equal operator.

=

Equal operator.

>

Greater than operator.

>=

Greater than or equal operator.

BETWEEN AND

True if expression between two values.

COALESCE

Returns the first non-NULL parameter

GREATEST

Returns the largest argument.

IN

True if expression equals any of the values in the list.

INTERVAL

Index of the argument that is less than the first argument

IS

Tests whether a boolean is TRUE, FALSE, or UNKNOWN.

IS NOT

Tests whether a boolean value is not TRUE, FALSE, or UNKNOWN

IS NOT NULL

Tests whether a value is not NULL

IS NULL

Tests whether a value is NULL

ISNULL

Checks if an expression is NULL

LEAST

Returns the smallest argument.

NOT BETWEEN

Same as NOT (expr BETWEEN min AND max)

NOT IN

Same as NOT (expr IN (value,...))

Logical Operators

!

Logical NOT.

&&

Logical AND.

XOR

Logical XOR.

||

Logical OR.

1.1.5.1 Arithmetic Operators

Arithmetic operators for addition, subtraction, multiplication, division and the modulo operator

Addition Operator (+)

Addition.

DIV

Integer division.

Division Operator (/)

Division.

MOD

Modulo operation. Remainder of N divided by M.

Modulo Operator (%)

Modulo operator. Returns the remainder of N divided by M.

Multiplication Operator (*)

Multiplication.

Subtraction Operator (-)

Subtraction and unary minus.

1.1.5.1.1 Addition Operator (+)

Syntax

```
+
```

Contents

Description

Addition.

If both operands are integers, the result is calculated with BIGINT precision. If either integer is unsigned, the result is also an unsigned integer.

For real or string operands, the operand with the highest precision determines the result precision.

Examples

```
SELECT 3+5;
+-----+
| 3+5 |
+-----+
|   8 |
+-----+
```

1.2.5.6 DIV

1.1.5.1.3 Division Operator (/)

Syntax

```
/
```

Contents

Description

Division operator. Dividing by zero will return NULL. By default, returns four digits after the decimal. This is determined by the server system variable div_precision_increment which by default is four. It can be set from 0 to 30.

Dividing by zero returns `NULL`. If the `ERROR_ON_DIVISION_BY_ZERO` SQL_MODE is used (the default since MariaDB 10.2.4), a division by zero also produces a warning.

Examples

```
SELECT 4/5;
+--------+
| 4/5    |
+--------+
| 0.8000 |
+--------+

SELECT 300/(2-2);
+-----------+
| 300/(2-2) |
+-----------+
|      NULL |
+-----------+

SELECT 300/7;
+---------+
| 300/7   |
+---------+
| 42.8571 |
+---------+
```

Changing div_precision_increment for the session from the default of four to six:

```
SET div_precision_increment = 6;

SELECT 300/7;
+-----------+
| 300/7     |
+-----------+
| 42.857143 |
+-----------+

SELECT 300/7;
+-----------+
| 300/7     |
+-----------+
| 42.857143 |
+-----------+
```

1.2.5.28 MOD

1.1.5.1.5 Modulo Operator (%)

Syntax

```
N % M
```

Description

Modulo operator. Returns the remainder of `N` divided by `M`. See also MOD.

Examples

```
SELECT 1042 % 50;
+-----------+
| 1042 % 50 |
+-----------+
|        42 |
+-----------+
```

1.1.5.1.6 Multiplication Operator (*)

Syntax

```
*
```

Contents

Description

Multiplication operator.

Examples

```
SELECT 7*6;
+-----+
| 7*6 |
+-----+
|  42 |
+-----+

SELECT 1234567890*9876543210;
+----------------------+
| 1234567890*9876543210 |
+----------------------+
|  -6253480962446024716 |
+----------------------+

SELECT 18014398509481984*18014398509481984.0;
+---------------------------------------+
| 18014398509481984*18014398509481984.0 |
+---------------------------------------+
|   324518553658426726783156020576256.0 |
+---------------------------------------+

SELECT 18014398509481984*18014398509481984;
+-------------------------------------+
| 18014398509481984*18014398509481984 |
+-------------------------------------+
|                                   0 |
+-------------------------------------+
```

1.1.5.1.7 Subtraction Operator (-)

Syntax

```
-
```

Description

Subtraction. The operator is also used as the unary minus for changing sign.

If both operands are integers, the result is calculated with BIGINT precision. If either integer is unsigned, the result is also an unsigned integer, unless the NO_UNSIGNED_SUBTRACTION SQL_MODE is enabled, in which case the result is always signed.

For real or string operands, the operand with the highest precision determines the result precision.

Examples

```
SELECT 96-9;
+------+
| 96-9 |
+------+
|   87 |
+------+

SELECT 15-17;
+-------+
| 15-17 |
+-------+
|    -2 |
+-------+

SELECT 3.66 + 1.333;
+--------------+
| 3.66 + 1.333 |
+--------------+
|        4.993 |
+--------------+
```

Unary minus:

```
 SELECT - (3+5);
+---------+
| - (3+5) |
+---------+
|      -8 |
+---------+
```

1.1.5.2 Assignment Operators

Operators for assigning a value

Assignment Operator (:=)

Assignment operator for assigning a value.

Assignment Operator (=)

The equal sign as an assignment operator.

1.1.5.2.1 Assignment Operator (:=)

Syntax

```
var_name := expr
```

Description

Assignment operator for assigning a value. The value on the right is assigned to the variable on left.

Unlike the = operator, `:=` can always be used to assign a value to a variable.

This operator works with both user-defined variables and local variables.

When assigning the same value to several variables, LAST_VALUE() can be useful.

Examples

```
 SELECT @x := 10;
+----------+
| @x := 10 |
+----------+
|       10 |
+----------+

SELECT @x, @y := @x;
+------+----------+
| @x   | @y := @x |
+------+----------+
|   10 |       10 |
+------+----------+
```

1.1.5.2.2 Assignment Operator (=)

Syntax

```
identifier = expr
```

Contents

Description

The equal sign is used as both an assignment operator in certain contexts, and as a comparison operator. When used as assignment operator, the value on the right is assigned to the variable (or column, in some contexts) on the left.

Since its use can be ambiguous, unlike the := assignment operator, the = assignment operator cannot be used in all contexts, and is only valid as part of a SET statement, or the SET clause of an UPDATE statement

This operator works with both user-defined variables and local variables.

Examples

```
UPDATE table_name SET x = 2 WHERE x > 100;
```

```
SET @x = 1, @y := 2;
```

1.2.8.1 Bit Functions and Operators

1.1.5.4 Comparison Operators

The comparison operators include: !=, <, <=, <=>, >=, >, etc...

!=

Not equal operator.

<

Less than operator.

<=

Less than or equal operator.

<=>

NULL-safe equal operator.

=

Equal operator.

>

Greater than operator.

>=

Greater than or equal operator.

BETWEEN AND

True if expression between two values.

COALESCE

Returns the first non-NULL parameter

GREATEST

Returns the largest argument.

IN

True if expression equals any of the values in the list.

INTERVAL

Index of the argument that is less than the first argument

IS

Tests whether a boolean is TRUE, FALSE, or UNKNOWN.

IS NOT

Tests whether a boolean value is not TRUE, FALSE, or UNKNOWN

IS NOT NULL

Tests whether a value is not NULL

IS NULL

Tests whether a value is NULL

ISNULL

Checks if an expression is NULL

LEAST

Returns the smallest argument.

NOT BETWEEN

Same as NOT (expr BETWEEN min AND max)

NOT IN

Same as NOT (expr IN (value,...))

1.1.5.4.1 Not Equal Operator: !=

Syntax

```
<>, !=
```

Contents

Description

Not equal operator. Evaluates both SQL expressions and returns 1 if they are not equal and 0 if they are equal, or `NULL` if either expression is NULL. If the expressions return different data types, (for instance, a number and a string), performs type conversion.

When used in row comparisons these two queries return the same results:

```
SELECT (t1.a, t1.b) != (t2.x, t2.y)
FROM t1 INNER JOIN t2;

SELECT (t1.a != t2.x) OR (t1.b != t2.y)
FROM t1 INNER JOIN t2;
```

Examples

```
SELECT '.01' <> '0.01';
+-----------------+
| '.01' <> '0.01' |
+-----------------+
|               1 |
+-----------------+

SELECT .01 <> '0.01';
+---------------+
| .01 <> '0.01' |
+---------------+
|             0 |
+---------------+

SELECT 'zapp' <> 'zappp';
+-------------------+
| 'zapp' <> 'zappp' |
+-------------------+
|                 1 |
+-------------------+
```

1.1.5.4.2 <

Syntax

```
<
```

Contents

Description

Less than operator. Evaluates both SQL expressions and returns 1 if the left value is less than the right value and 0 if it is not, or `NULL` if either expression is NULL. If the expressions return different data types, (for instance, a number and a string), performs type conversion.

When used in row comparisons these two queries return the same results:

```
SELECT (t1.a, t1.b) < (t2.x, t2.y)
FROM t1 INNER JOIN t2;

SELECT (t1.a < t2.x) OR ((t1.a = t2.x) AND (t1.b < t2.y))
FROM t1 INNER JOIN t2;
```

Examples

```
SELECT 2 < 2;
+-------+
| 2 < 2 |
+-------+
|     0 |
+-------+
```

Type conversion:

```
SELECT 3<'4';
+-------+
| 3<'4' |
+-------+
|     1 |
+-------+
```

Case insensitivity - see Character Sets and Collations:

```
SELECT 'a'<'A';
+---------+
| 'a'<'A' |
+---------+
|       0 |
+---------+
```

1.1.5.4.3 <=

Syntax

```
<=
```

Contents

Description

Less than or equal operator. Evaluates both SQL expressions and returns 1 if the left value is less than or equal to the right value and 0 if it is not, or `NULL` if either expression is NULL. If the expressions return different data types, (for instance, a number and a string), performs type conversion.

When used in row comparisons these two queries return the same results:

```
SELECT (t1.a, t1.b) <= (t2.x, t2.y)
FROM t1 INNER JOIN t2;

SELECT (t1.a < t2.x) OR ((t1.a = t2.x) AND (t1.b <= t2.y))
FROM t1 INNER JOIN t2;
```

Examples

```
SELECT 0.1 <= 2;
+----------+
| 0.1 <= 2 |
+----------+
|        1 |
+----------+
```

```
SELECT 'a'<='A';
+----------+
| 'a'<='A' |
+----------+
|        1 |
+----------+
```

1.1.5.4.4 <=>

Syntax

```
<=>
```

Description

NULL-safe equal operator. It performs an equality comparison like the = operator, but returns 1 rather than NULL if both operands are NULL, and 0 rather than NULL if one operand is NULL.

`a <=> b` is equivalent to `a = b OR (a IS NULL AND b IS NULL)`.

When used in row comparisons these two queries return the same results:

```
SELECT (t1.a, t1.b) <=> (t2.x, t2.y)
FROM t1 INNER JOIN t2;

SELECT (t1.a <=> t2.x) AND (t1.b <=> t2.y)
FROM t1 INNER JOIN t2;
```

See also NULL Values in MariaDB.

Examples

```
SELECT 1 <=> 1, NULL <=> NULL, 1 <=> NULL;
+---------+---------------+-------------+
| 1 <=> 1 | NULL <=> NULL | 1 <=> NULL |
+---------+---------------+-------------+
|       1 |             1 |           0 |
+---------+---------------+-------------+

SELECT 1 = 1, NULL = NULL, 1 = NULL;
+-------+-------------+----------+
| 1 = 1 | NULL = NULL | 1 = NULL |
+-------+-------------+----------+
|     1 |        NULL |     NULL |
+-------+-------------+----------+
```

1.1.5.4.5 =

Syntax

```
left_expr = right_expr
```

Contents

Description

Equal operator. Evaluates both SQL expressions and returns 1 if they are equal, 0 if they are not equal, or `NULL` if either expression is NULL. If the expressions return different data types (for example, a number and a string), a type conversion is performed.

When used in row comparisons these two queries are synonymous and return the same results:

```
SELECT (t1.a, t1.b) = (t2.x, t2.y) FROM t1 INNER JOIN t2;

SELECT (t1.a = t2.x) AND (t1.b = t2.y) FROM t1 INNER JOIN t2;
```

To perform a NULL-safe comparison, use the `<=>` operator.

`=` can also be used as an assignment operator.

Examples

```
SELECT 1 = 0;
+-------+
| 1 = 0 |
+-------+
|     0 |
+-------+

SELECT '0' = 0;
+---------+
| '0' = 0 |
+---------+
|       1 |
+---------+

SELECT '0.0' = 0;
+-----------+
| '0.0' = 0 |
+-----------+
|         1 |
+-----------+

SELECT '0.01' = 0;
+------------+
| '0.01' = 0 |
+------------+
|          0 |
+------------+

SELECT '.01' = 0.01;
+--------------+
| '.01' = 0.01 |
+--------------+
|            1 |
+--------------+

SELECT (5 * 2) = CONCAT('1', '0');
+----------------------------+
| (5 * 2) = CONCAT('1', '0') |
+----------------------------+
|                          1 |
+----------------------------+

SELECT 1 = NULL;
+----------+
| 1 = NULL |
+----------+
|     NULL |
+----------+

SELECT NULL = NULL;
+-------------+
| NULL = NULL |
+-------------+
|        NULL |
+-------------+
```

1.1.5.4.6 >

Syntax

```
>
```

Contents

Description

Greater than operator. Evaluates both SQL expressions and returns 1 if the left value is greater than the right value and 0 if it is not, or `NULL` if either expression is NULL. If the expressions return different data types, (for instance, a number and a string), performs type conversion.

When used in row comparisons these two queries return the same results:

```
SELECT (t1.a, t1.b) > (t2.x, t2.y)
FROM t1 INNER JOIN t2;

SELECT (t1.a > t2.x) OR ((t1.a = t2.x) AND (t1.b > t2.y))
FROM t1 INNER JOIN t2;
```

Examples

```
SELECT 2 > 2;
+-------+
| 2 > 2 |
+-------+
|     0 |
+-------+

SELECT 'b' > 'a';
+-----------+
| 'b' > 'a' |
+-----------+
|         1 |
+-----------+
```

1.1.5.4.7 >=

Syntax

```
>=
```

Contents

Description

Greater than or equal operator. Evaluates both SQL expressions and returns 1 if the left value is greater than or equal to the right value and 0 if it is not, or `NULL` if either expression is NULL. If the expressions return different data types, (for instance, a number and a string), performs type conversion.

When used in row comparisons these two queries return the same results:

```
SELECT (t1.a, t1.b) >= (t2.x, t2.y)
FROM t1 INNER JOIN t2;

SELECT (t1.a > t2.x) OR ((t1.a = t2.x) AND (t1.b >= t2.y))
FROM t1 INNER JOIN t2;
```

Examples

```
SELECT 2 >= 2;
+--------+
| 2 >= 2 |
+--------+
|      1 |
+--------+

SELECT 'A' >= 'a';
+------------+
| 'A' >= 'a' |
+------------+
|          1 |
+------------+
```

1.1.5.4.8 BETWEEN AND

Syntax

```
expr BETWEEN min AND max
```

Contents

Description

If expr is greater than or equal to min and expr is less than or equal to max, BETWEEN returns 1, otherwise it returns 0. This is equivalent to the expression (min <= expr AND expr <= max) if all the arguments are of the same type. Otherwise type conversion takes place according to the rules described at Type Conversion, but applied to all the three arguments.

Examples

```
SELECT 1 BETWEEN 2 AND 3;
+-------------------+
| 1 BETWEEN 2 AND 3 |
+-------------------+
|                 0 |
+-------------------+
```

```
SELECT 'b' BETWEEN 'a' AND 'c';
+-------------------------+
| 'b' BETWEEN 'a' AND 'c' |
+-------------------------+
|                       1 |
+-------------------------+
```

```
SELECT 2 BETWEEN 2 AND '3';
+--------------------+
| 2 BETWEEN 2 AND '3' |
+--------------------+
|                  1 |
+--------------------+
```

```
SELECT 2 BETWEEN 2 AND 'x-3';
+----------------------+
| 2 BETWEEN 2 AND 'x-3' |
+----------------------+
|                    0 |
+----------------------+
1 row in set, 1 warning (0.00 sec)

Warning (Code 1292): Truncated incorrect DOUBLE value: 'x-3'
```

NULL:

```
SELECT 1 BETWEEN 1 AND NULL;
+----------------------+
| 1 BETWEEN 1 AND NULL |
+----------------------+
|                 NULL |
+----------------------+
```

DATE, DATETIME and TIMESTAMP examples. Omitting the time component compares against `00:00`, so later times on the same date are not returned:

```
CREATE TABLE `x` (
  a date ,
  b datetime,
  c timestamp
)

INSERT INTO x VALUES
 ('2018-11-11', '2018-11-11 05:15', '2018-11-11 05:15'),
 ('2018-11-12', '2018-11-12 05:15', '2018-11-12 05:15');

SELECT * FROM x WHERE a BETWEEN '2018-11-11' AND '2018-11-12';
+------------+---------------------+---------------------+
| a          | b                   | c                   |
+------------+---------------------+---------------------+
| 2018-11-11 | 2018-11-11 05:15:00 | 2018-11-11 05:15:00 |
| 2018-11-12 | 2018-11-12 05:15:00 | 2018-11-12 05:15:00 |
+------------+---------------------+---------------------+

SELECT * FROM x WHERE b BETWEEN '2018-11-11' AND '2018-11-12';
+------------+---------------------+---------------------+
| a          | b                   | c                   |
+------------+---------------------+---------------------+
| 2018-11-11 | 2018-11-11 05:15:00 | 2018-11-11 05:15:00 |
+------------+---------------------+---------------------+

SELECT * FROM x WHERE c BETWEEN '2018-11-11' AND '2018-11-12';
+------------+---------------------+---------------------+
| a          | b                   | c                   |
+------------+---------------------+---------------------+
| 2018-11-11 | 2018-11-11 05:15:00 | 2018-11-11 05:15:00 |
+------------+---------------------+---------------------+
```

1.1.5.4.9 COALESCE

Syntax

```
COALESCE(value,...)
```

Description

Returns the first non-NULL value in the list, or NULL if there are no non-NULL values. At least one parameter must be passed.

The function is useful when substituting a default value for null values when displaying data.

See also NULL Values in MariaDB.

Examples

```
SELECT COALESCE(NULL,1);
+------------------+
| COALESCE(NULL,1) |
+------------------+
|                1 |
+------------------+
```

```
SELECT COALESCE(NULL,NULL,NULL);
+--------------------------+
| COALESCE(NULL,NULL,NULL) |
+--------------------------+
|                     NULL |
+--------------------------+
```

When two arguments are given, COALESCE() is the same as IFNULL():

```
SET @a=NULL, @b=1;

SELECT COALESCE(@a, @b), IFNULL(@a, @b);
+-------------------+----------------+
| COALESCE(@a, @b) | IFNULL(@a, @b) |
+-------------------+----------------+
|                1 |              1 |
+-------------------+----------------+
```

Hex type confusion:

```
CREATE TABLE t1 (a INT, b VARCHAR(10));
INSERT INTO t1 VALUES (0x31, 0x61),(COALESCE(0x31), COALESCE(0x61));

SELECT * FROM t1;
+------+------+
| a    | b    |
+------+------+
|   49 | a    |
|    1 | a    |
+------+------+
```

The reason for the differing results above is that when 0x31 is inserted directly to the column, it's treated as a number (see Hexadecimal Literals), while when 0x31 is passed to COALESCE(), it's treated as a string, because:

- HEX values have a string data type by default.
- COALESCE() has the same data type as the argument.

Substituting zero for NULL (in this case when the aggregate function returns NULL after finding no rows):

```
SELECT SUM(score) FROM student;
+------------+
| SUM(score) |
+------------+
|       NULL |
+------------+

SELECT COALESCE(SUM(score),0) FROM student;
+-------------------------+
| COALESCE(SUM(score),0) |
+-------------------------+
|                       0 |
+-------------------------+
```

1.1.5.4.10 GREATEST

Syntax

```
GREATEST(value1,value2,...)
```

Description

With two or more arguments, returns the largest (maximum-valued) argument. The arguments are compared using the same rules as for LEAST().

Examples

```
SELECT GREATEST(2,0);
+---------------+
| GREATEST(2,0) |
+---------------+
|             2 |
+---------------+
```

```
SELECT GREATEST(34.0,3.0,5.0,767.0);
+-----------------------------+
| GREATEST(34.0,3.0,5.0,767.0) |
+-----------------------------+
|                       767.0 |
+-----------------------------+
```

```
SELECT GREATEST('B','A','C');
+-----------------------+
| GREATEST('B','A','C') |
+-----------------------+
| C                     |
+-----------------------+
```

1.1.5.4.11 IN

Syntax

```
expr IN (value,...)
```

Description

Returns 1 if *expr* is equal to any of the values in the IN list, else returns 0. If all values are constants, they are evaluated according to the type of *expr* and sorted. The search for the item then is done using a binary search. This means IN is very quick if the IN value list consists entirely of constants. Otherwise, type conversion takes place according to the rules described at Type Conversion, but applied to all the arguments.

If *expr* is NULL, IN always returns NULL. If at least one of the values in the list is NULL, and one of the comparisons is true, the result is 1. If at least one of the values in the list is NULL and none of the comparisons is true, the result is NULL.

Examples

```
SELECT 2 IN (0,3,5,7);
+---------------+
| 2 IN (0,3,5,7) |
+---------------+
|              0 |
+---------------+
```

```
SELECT 'wefwf' IN ('wee','wefwf','weg');
+---------------------------------+
| 'wefwf' IN ('wee','wefwf','weg') |
+---------------------------------+
|                                1 |
+---------------------------------+
```

Type conversion:

```
SELECT 1 IN ('1', '2', '3');
+----------------------+
| 1 IN ('1', '2', '3') |
+----------------------+
|                    1 |
+----------------------+
```

```
SELECT NULL IN (1, 2, 3);
+------------------+
| NULL IN (1, 2, 3) |
+------------------+
|             NULL |
+------------------+

SELECT 1 IN (1, 2, NULL);
+------------------+
| 1 IN (1, 2, NULL) |
+------------------+
|                1 |
+------------------+

SELECT 5 IN (1, 2, NULL);
+------------------+
| 5 IN (1, 2, NULL) |
+------------------+
|             NULL |
+------------------+
```

1.1.5.4.12 INTERVAL

Syntax

```
INTERVAL(N,N1,N2,N3,...)
```

Description

Returns the index of the last argument that is less than the first argument or is NULL.

Returns 0 if N < N1, 1 if N < N2, 2 if N < N3 and so on or -1 if N is NULL. All arguments are treated as integers. It is required that N1 < N2 < N3 < ... < Nn for this function to work correctly. This is because a fast binary search is used.

Examples

```
SELECT INTERVAL(23, 1, 15, 17, 30, 44, 200);
+-------------------------------------+
| INTERVAL(23, 1, 15, 17, 30, 44, 200) |
+-------------------------------------+
|                                   3 |
+-------------------------------------+

SELECT INTERVAL(10, 1, 10, 100, 1000);
+---------------------------------+
| INTERVAL(10, 1, 10, 100, 1000) |
+---------------------------------+
|                               2 |
+---------------------------------+

SELECT INTERVAL(22, 23, 30, 44, 200);
+--------------------------------+
| INTERVAL(22, 23, 30, 44, 200) |
+--------------------------------+
|                              0 |
+--------------------------------+

SELECT INTERVAL(10, 2, NULL);
+-----------------------+
| INTERVAL(10, 2, NULL) |
+-----------------------+
|                     2 |
+-----------------------+
```

1.1.5.4.13 IS

Syntax

```
IS boolean_value
```

Description

Tests a value against a boolean value, where `boolean_value` can be TRUE, FALSE, or UNKNOWN.

There is an important difference between using IS TRUE or comparing a value with TRUE using `=`. When using `=`, only `1` equals to TRUE. But when using IS TRUE, all values which are logically true (like a number > 1) return TRUE.

Examples

```
SELECT 1 IS TRUE, 0 IS FALSE, NULL IS UNKNOWN;
+-----------+------------+----------------+
| 1 IS TRUE | 0 IS FALSE | NULL IS UNKNOWN |
+-----------+------------+----------------+
|         1 |          1 |               1 |
+-----------+------------+----------------+
```

Difference between `=` and `IS TRUE`:

```
SELECT 2 = TRUE, 2 IS TRUE;
+----------+-----------+
| 2 = TRUE | 2 IS TRUE |
+----------+-----------+
|        0 |         1 |
+----------+-----------+
```

1.1.5.4.14 IS NOT

Syntax

```
IS NOT boolean_value
```

Description

Tests a value against a boolean value, where boolean_value can be TRUE, FALSE, or UNKNOWN.

Examples

```
SELECT 1 IS NOT UNKNOWN, 0 IS NOT UNKNOWN, NULL IS NOT UNKNOWN;
+------------------+------------------+----------------------+
| 1 IS NOT UNKNOWN | 0 IS NOT UNKNOWN | NULL IS NOT UNKNOWN |
+------------------+------------------+----------------------+
|                1 |                1 |                    0 |
+------------------+------------------+----------------------+
```

```
SELECT NULL IS NOT TRUE, NULL IS NOT FALSE;
+------------------+-------------------+
| NULL IS NOT TRUE | NULL IS NOT FALSE |
+------------------+-------------------+
|                1 |                 1 |
+------------------+-------------------+
```

1.1.5.4.15 IS NOT NULL

Syntax

```
IS NOT NULL
```

Description

Tests whether a value is not NULL. See also NULL Values in MariaDB.

Examples

```
SELECT 1 IS NOT NULL, 0 IS NOT NULL, NULL IS NOT NULL;
+--------------+--------------+------------------+
| 1 IS NOT NULL | 0 IS NOT NULL | NULL IS NOT NULL |
+--------------+--------------+------------------+
|             1 |             1 |                0 |
+--------------+--------------+------------------+
```

1.1.5.4.16 IS NULL

Syntax

```
IS NULL
```

Description

Tests whether a value is NULL. See also NULL Values in MariaDB.

Examples

```
SELECT 1 IS NULL, 0 IS NULL, NULL IS NULL;
+-----------+-----------+--------------+
| 1 IS NULL | 0 IS NULL | NULL IS NULL |
+-----------+-----------+--------------+
|         0 |         0 |            1 |
+-----------+-----------+--------------+
```

Compatibility

Some `ODBC` applications use the syntax `auto_increment_field IS NOT NULL` to find the latest row that was inserted with an autogenerated key value. If your applications need this, you can set the sql_auto_is_null variable to 1.

```
SET @@sql_auto_is_null=1;
CREATE TABLE t1 (auto_increment_column INT NOT NULL AUTO_INCREMENT PRIMARY KEY);
INSERT INTO t1 VALUES (NULL);
SELECT * FROM t1 WHERE auto_increment_column IS NULL;

+-----------------------+
| auto_increment_column |
+-----------------------+
|                     1 |
+-----------------------+
```

1.1.5.4.17 ISNULL

Syntax

```
ISNULL(expr)
```

Description

If *`expr`* is NULL, ISNULL() returns 1, otherwise it returns 0.

See also NULL Values in MariaDB.

Examples

```
SELECT ISNULL(1+1);
+-------------+
| ISNULL(1+1) |
+-------------+
|           0 |
+-------------+

SELECT ISNULL(1/0);
+-------------+
| ISNULL(1/0) |
+-------------+
|           1 |
+-------------+
```

1.1.5.4.18 LEAST

Syntax

```
LEAST(value1,value2,...)
```

Description

With two or more arguments, returns the smallest (minimum-valued) argument. The arguments are compared using the following rules:

- If the return value is used in an INTEGER context or all arguments are integer-valued, they are compared as integers.
- If the return value is used in a REAL context or all arguments are real-valued, they are compared as reals.
- If any argument is a case-sensitive string, the arguments are compared as case-sensitive strings.
- In all other cases, the arguments are compared as case-insensitive strings.

LEAST() returns NULL if any argument is NULL.

Examples

```
SELECT LEAST(2,0);
+------------+
| LEAST(2,0) |
+------------+
|          0 |
+------------+
```

```
SELECT LEAST(34.0,3.0,5.0,767.0);
+--------------------------+
| LEAST(34.0,3.0,5.0,767.0) |
+--------------------------+
|                      3.0 |
+--------------------------+
```

```
SELECT LEAST('B','A','C');
+--------------------+
| LEAST('B','A','C') |
+--------------------+
| A                  |
+--------------------+
```

1.1.5.4.19 NOT BETWEEN

Syntax

```
expr NOT BETWEEN min AND max
```

Description

This is the same as NOT (expr BETWEEN min AND max).

Note that the meaning of the alternative form `NOT expr BETWEEN min AND max` is affected by the `HIGH_NOT_PRECEDENCE` SQL_MODE flag.

Examples

```
SELECT 1 NOT BETWEEN 2 AND 3;
+----------------------+
| 1 NOT BETWEEN 2 AND 3 |
+----------------------+
|                    1 |
+----------------------+
```

```
SELECT 'b' NOT BETWEEN 'a' AND 'c';
+-----------------------------+
| 'b' NOT BETWEEN 'a' AND 'c' |
+-----------------------------+
|                           0 |
+-----------------------------+
```

NULL:

```
SELECT 1 NOT BETWEEN 1 AND NULL;
+--------------------------+
| 1 NOT BETWEEN 1 AND NULL |
+--------------------------+
|                     NULL |
+--------------------------+
```

1.1.5.4.20 NOT IN

Syntax

```
expr NOT IN (value,...)
```

Description

This is the same as NOT (expr IN (value,...)).

Examples

```
SELECT 2 NOT IN (0,3,5,7);
+--------------------+
| 2 NOT IN (0,3,5,7) |
+--------------------+
|                  1 |
+--------------------+
```

```
SELECT 'wefwf' NOT IN ('wee','wefwf','weg');
+-------------------------------------+
| 'wefwf' NOT IN ('wee','wefwf','weg') |
+-------------------------------------+
|                                   0 |
+-------------------------------------+
```

```
SELECT 1 NOT IN ('1', '2', '3');
+--------------------------+
| 1 NOT IN ('1', '2', '3') |
+--------------------------+
|                        0 |
+--------------------------+
```

NULL:

```
SELECT NULL NOT IN (1, 2, 3);
+-----------------------+
| NULL NOT IN (1, 2, 3) |
+-----------------------+
|                  NULL |
+-----------------------+

SELECT 1 NOT IN (1, 2, NULL);
+-----------------------+
| 1 NOT IN (1, 2, NULL) |
+-----------------------+
|                     0 |
+-----------------------+

SELECT 5 NOT IN (1, 2, NULL);
+-----------------------+
| 5 NOT IN (1, 2, NULL) |
+-----------------------+
|                  NULL |
+-----------------------+
```

1.1.5.5 Logical Operators

NOT, AND, Exclusive OR and OR

!

Logical NOT.

&&

Logical AND.

XOR

Logical XOR.

||

Logical OR.

1.1.5.5.1 !

Syntax

```
NOT, !
```

Contents

Description

Logical NOT. Evaluates to 1 if the operand is 0, to 0 if the operand is non-zero, and NOT NULL returns NULL.

By default, the `!` operator has a higher precedence. If the `HIGH_NOT_PRECEDENCE` SQL_MODE flag is set, `NOT` and `!` have the same precedence.

Examples

```
SELECT NOT 10;
+--------+
| NOT 10 |
+--------+
|      0 |
+--------+

SELECT NOT 0;
+-------+
| NOT 0 |
+-------+
|     1 |
+-------+

SELECT NOT NULL;
+----------+
| NOT NULL |
+----------+
|     NULL |
+----------+

SELECT ! (1+1);
+---------+
| ! (1+1) |
+---------+
|       0 |
+---------+

SELECT ! 1+1;
+-------+
| ! 1+1 |
+-------+
|     1 |
+-------+
```

1.1.5.5.2 &&

Syntax

```
AND, &&
```

Contents

Description

Logical AND. Evaluates to 1 if all operands are non-zero and not NULL, to 0 if one or more operands are 0, otherwise NULL is returned.

For this operator, short-circuit evaluation can be used.

Examples

```
SELECT 1 && 1;
+--------+
| 1 && 1 |
+--------+
|      1 |
+--------+

SELECT 1 && 0;
+--------+
| 1 && 0 |
+--------+
|      0 |
+--------+

SELECT 1 && NULL;
+-----------+
| 1 && NULL |
+-----------+
|      NULL |
+-----------+

SELECT 0 && NULL;
+-----------+
| 0 && NULL |
+-----------+
|         0 |
+-----------+

SELECT NULL && 0;
+-----------+
| NULL && 0 |
+-----------+
|         0 |
+-----------+
```

1.1.5.5.3 XOR

Syntax

```
XOR
```

Contents

Description

XOR stands for eXclusive OR. Returns NULL if either operand is NULL. For non-NULL operands, evaluates to 1 if an odd number of operands is non-zero, otherwise 0 is returned.

Examples

```
SELECT 1 XOR 1;
+---------+
| 1 XOR 1 |
+---------+
|       0 |
+---------+

SELECT 1 XOR 0;
+---------+
| 1 XOR 0 |
+---------+
|       1 |
+---------+

SELECT 1 XOR NULL;
+------------+
| 1 XOR NULL |
+------------+
|       NULL |
+------------+
```

In the following example, the right `1 XOR 1` is evaluated first, and returns `0`. Then, `1 XOR 0` is evaluated, and `1` is returned.

```
SELECT 1 XOR 1 XOR 1;
+---------------+
| 1 XOR 1 XOR 1 |
+---------------+
|             1 |
+---------------+
```

1.1.5.5.4 ||

Syntax

```
OR, ||
```

Contents

Description

Logical OR. When both operands are non-NULL, the result is 1 if any operand is non-zero, and 0 otherwise. With a NULL operand, the result is 1 if the other operand is non-zero, and NULL otherwise. If both operands are NULL, the result is NULL.

For this operator, short-circuit evaluation can be used.

Note that, if the `PIPES_AS_CONCAT` SQL_MODE is set, `||` is used as a string concatenation operator. This means that `a || b` is the same as `CONCAT(a,b)`. See `CONCAT()` for details.

Oracle Mode

MariaDB starting with 10.3

In Oracle mode from MariaDB 10.3, `||` ignores NULL.

Examples

```
SELECT 1 || 1;
+--------+
| 1 || 1 |
+--------+
|      1 |
+--------+

SELECT 1 || 0;
+--------+
| 1 || 0 |
+--------+
|      1 |
+--------+

SELECT 0 || 0;
+--------+
| 0 || 0 |
+--------+
|      0 |
+--------+

SELECT 0 || NULL;
+-----------+
| 0 || NULL |
+-----------+
|      NULL |
+-----------+

SELECT 1 || NULL;
+-----------+
| 1 || NULL |
+-----------+
|         1 |
+-----------+
```

In Oracle mode, from MariaDB 10.3:

```
SELECT 0 || NULL;
+-----------+
| 0 || NULL |
+-----------+
| 0         |
+-----------+
```

1.1.5.6 Operator Precedence

The precedence is the order in which the SQL operators are evaluated.

The following list shows the SQL operator precedence. Operators that appear first in the list have a higher precedence. Operators which are listed together have the same precedence.

- `INTERVAL`
- `BINARY`, `COLLATE`
- `!`
- `-` (unary minus), [[bitwise-not|]] (unary bit inversion)
- `||` (string concatenation)
- `^`
- `*`, `/`, `DIV`, `%`, `MOD`
- `-`, `+`
- `<<`, `>>`
- `&`
- `|`
- `=` (comparison), `<=>`, `>=`, `>`, `<=`, `<`, `<>`, `!=`, `IS`, `LIKE`, `REGEXP`, `IN`
- `BETWEEN`, `CASE`, `WHEN`, `THEN`, `ELSE`, `END`
- `NOT`
- `&&`, `AND`
- `XOR`
- `||` (logical or), `OR`

- `=` (assignment), `:=`

Functions precedence is always higher than operators precedence.

In this page `CASE` refers to the CASE operator, not to the CASE statement .

If the `HIGH_NOT_PRECEDENCE` SQL_MODE is set, `NOT` has the same precedence as `!` .

The `||` operator's precedence, as well as its meaning, depends on the `PIPES_AS_CONCAT` SQL_MODE flag: if it is on, `||` can be used to concatenate strings (like the CONCAT() function) and has a higher precedence.

The `=` operator's precedence depends on the context - it is higher when `=` is used as a comparison operator.

Parenthesis can be used to modify the operators precedence in an expression.

Short-circuit evaluation

The `AND` , `OR` , `&&` and `||` operators support short-circuit evaluation. This means that, in some cases, the expression on the right of those operators is not evaluated, because its result cannot affect the result. In the following cases, short-circuit evaluation is used and `x()` is not evaluated:

- `FALSE AND x()`
- `FALSE && x()`
- `TRUE OR x()`
- `TRUE || x()`
- `NULL BETWEEN x() AND x()`

Note however that the short-circuit evaluation does *not* apply to `NULL AND x()` . Also, `BETWEEN` 's right operands are not evaluated if the left operand is `NULL` , but in all other cases all the operands are evaluated.

This is a speed optimization. Also, since functions can have side-effects, this behavior can be used to choose whether execute them or not using a concise syntax:

```
SELECT some_function() OR log_error();
```

1.1.6 Sequences

This section is about sequence objects. For details about the storage engine, see Sequence Storage Engine.

A sequence is an object that generates a sequence of numeric values, as specified by the CREATE SEQUENCE statement. Sequences are an alternative to AUTO_INCREMENT when you want more control over how sequence numbers are generated.

Since a `SEQUENCE` caches values, it can sometimes be faster. Also, you can access the last value generated by all used sequences; it's not subjected to limitations of LAST_INSERT_ID( ).

See also Sequence Storage Engine.

Sequence Overview

Object that generates a sequence of numeric values.

CREATE SEQUENCE

Creates a sequence that generates new values when called with NEXT VALUE FOR.

SHOW CREATE SEQUENCE

Shows the CREATE SEQUENCE statement that created the sequence.

ALTER SEQUENCE

Change options for a SEQUENCE.

DROP SEQUENCE

Deleting a SEQUENCE.

SEQUENCE Functions

Functions that can be used on SEQUENCEs.

SHOW TABLES

List of non-temporary tables, views or sequences.

1.1.6.1 Sequence Overview

This page is about sequence objects. For details about the storage engine, see Sequence Storage Engine.

Introduction

A sequence is an object that generates a sequence of numeric values, as specified by the CREATE SEQUENCE statement.

CREATE SEQUENCE will create a sequence that generates new values when called with NEXT VALUE FOR sequence_name. It's an alternative to AUTO INCREMENT when one wants to have more control of how the numbers are generated. As the SEQUENCE caches values (up to the CACHE value in the CREATE SEQUENCE statement, by default 1000) it can in some cases be much faster than AUTO INCREMENT. Another benefit is that one can access the last value generated by all used sequences, which solves one of the limitations with LAST_INSERT_ID().

Creating a Sequence

The CREATE SEQUENCE statement is used to create a sequence. Here is an example of a sequence starting at 100, incrementing by 10 each time:

```
CREATE SEQUENCE s START WITH 100 INCREMENT BY 10;
```

The CREATE SEQUENCE statement, along with defaults, can be viewd with the SHOW CREATE SEQUENCE STATEMENT, for example:

```
SHOW CREATE SEQUENCE s\G
*************************** 1. row ***************************
       Table: s
Create Table: CREATE SEQUENCE `s` start with 100 minvalue 1 maxvalue 9223372036854775806
  increment by 10 cache 1000 nocycle ENGINE=InnoDB
```

Using Sequence Objects

To get the next value from a sequence, use

```
NEXT VALUE FOR sequence_name
```

or

```
NEXTVAL(sequence_name)
```

or in Oracle mode (SQL_MODE=ORACLE)

```
sequence_name.nextval
```

For retrieving the last value used by the current connection from a sequence use:

```
PREVIOUS VALUE FOR sequence_name
```

or

```
LASTVAL(sequence_name)
```

or in Oracle mode (SQL_MODE=ORACLE)

```
sequence_name.currval
```

For example:

```
SELECT NEXTVAL(s);
+------------+
| NEXTVAL(s) |
+------------+
|        100 |
+------------+

SELECT NEXTVAL(s);
+------------+
| NEXTVAL(s) |
+------------+
|        110 |
+------------+

SELECT LASTVAL(s);
+------------+
| LASTVAL(s) |
+------------+
|        110 |
+------------+
```

Using Sequences in DEFAULT

Sequences can be used in DEFAULT:

```
create sequence s1;
create table t1 (a int primary key default (next value for s1), b int);
insert into t1 (b) values (1),(2);
select * from t1;
+---+------+
| a | b    |
+---+------+
| 1 |    1 |
| 2 |    2 |
+---+------+
```

Changing a Sequence

The ALTER SEQUENCE statement is used for changing sequences. For example, to restart the sequence at another value:

```
ALTER SEQUENCE s RESTART 50;

SELECT NEXTVAL(s);
+------------+
| NEXTVAL(s) |
+------------+
|         50 |
+------------+
```

The SETVAL function can also be used to set the next value to be returned for a SEQUENCE, for example:

```
SELECT SETVAL(s, 100);
+----------------+
| SETVAL(s, 100) |
+----------------+
|            100 |
+----------------+
```

`SETVAL` can only be used to increase the sequence value. Attempting to set a lower value will fail, returning NULL:

```
SELECT SETVAL(s, 50);
+---------------+
| SETVAL(s, 50) |
+---------------+
|          NULL |
+---------------+
```

Dropping a Sequence

The DROP SEQUENCE statement is used to drop a sequence, for example:

```
DROP SEQUENCE s;
```

Replication

If one wants to use Sequences in a master-master setup or with Galera one should use `INCREMENT=0`. This will tell the Sequence to use auto_increment_increment and auto_increment_offset to generate unique values for each server.

Standards Compliance

MariaDB supports both ANSI SQL and Oracle syntax for sequences.

However as `SEQUENCE` is implemented as a special kind of table, it uses the same namespace as tables. The benefits are that sequences show up in SHOW TABLES, and one can also create a sequence with CREATE TABLE and drop it with DROP TABLE. One can SELECT from it as from any other table. This ensures that all old tools that work with tables should work with sequences.

Since sequence objects act as regular tables in many contexts, they will be affected by LOCK TABLES. This is not the case in other DBMS, such as Oracle, where LOCK TABLE does not affect sequences.

Notes

One of the goals with the Sequence implementation is that all old tools, such as mariadb-dump (previously mysqldump), should work unchanged, while still keeping the normal usage of sequence standard compatibly.

To make this possible, `sequence` is currently implemented as a table with a few exclusive properties.

The special properties for sequence tables are:

- A sequence table has always one row.
- When one creates a sequence, either with CREATE TABLE or CREATE SEQUENCE, one row will be inserted.
- If one tries to insert into a sequence table, the single row will be updated. This allows mariadb-dump to work but also gives the additional benefit that one can change all properties of a sequence with a single insert. New applications should of course also use `ALTER SEQUENCE`.
- UPDATE or DELETE can't be performed on Sequence objects.
- Doing a select on the sequence shows the current state of the sequence, except the values that are reserved in the cache. The `next_value` column shows the next value not reserved by the cache.
- FLUSH TABLES will close the sequence and the next sequence number generated will be according to what's stored in the Sequence object. In effect, this will discard the cached values.
- A number of normal table operations work on Sequence tables. See next section.

Table Operations that Work with Sequences

- SHOW CREATE TABLE sequence_name. This shows the table structure that is behind the `SEQUENCE` including the field names that can be used with SELECT or even CREATE TABLE.
- CREATE TABLE sequence-structure ... SEQUENCE=1
- ALTER TABLE sequence RENAME TO sequence2
- RENAME TABLE sequence_name TO new_sequence_name
- DROP TABLE sequence_name. This is allowed mainly to get old tools like mariadb-dump to work with sequence tables.
- SHOW TABLES

Implementation

Internally, sequence tables are created as a normal table without rollback (the InnoDB, Aria and MySAM engines support this), wrapped by a sequence engine object. This allowed us to create sequences with almost no performance impact for normal tables. (The cost is one 'if' per insert if the binary log is enabled).

Underlying Table Structure

The following example shows the table structure of sequences and how it can be used as a table. (Output of results are

slightly edited to make them easier to read)

```
create sequence t1;
show create sequence t1\G
*************************** 1. row ***************************
  CREATE SEQUENCE `t1` start with 1 minvalue 1 maxvalue 9223372036854775806
  increment by 1 cache 1000 nocycle ENGINE=InnoDB

show create table t1\G
*************************** 1. row ***************************
Create Table: CREATE TABLE `t1` (
  `next_not_cached_value` bigint(21) NOT NULL,
  `minimum_value` bigint(21) NOT NULL,
  `maximum_value` bigint(21) NOT NULL,
  `start_value` bigint(21) NOT NULL COMMENT 'start value when sequences is created or value if
RESTART is used',
  `increment` bigint(21) NOT NULL COMMENT 'increment value',
  `cache_size` bigint(21) unsigned NOT NULL,
  `cycle_option` tinyint(1) unsigned NOT NULL COMMENT '0 if no cycles are allowed, 1 if the
sequence should begin a new cycle when maximum_value is passed',
  `cycle_count` bigint(21) NOT NULL COMMENT 'How many cycles have been done'
) ENGINE=InnoDB SEQUENCE=1

select * from t1\G
next_not_cached_value: 1
 minimum_value: 1
 maximum_value: 9223372036854775806
  start_value: 1
  increment: 1
  cache_size: 1000
  cycle_option: 0
  cycle_count: 0
```

The `cycle_count` column is incremented every time the sequence wraps around.

Credits

- Thanks to Jianwe Zhao from Aliyun for his work on SEQUENCE in AliSQL, which gave ideas and inspiration for this work.
- Thanks to Peter Gulutzan,who helped test and gave useful comments about the implementation.

1.1.6.2 CREATE SEQUENCE

Syntax

```
CREATE [OR REPLACE] [TEMPORARY] SEQUENCE [IF NOT EXISTS] sequence_name
[ INCREMENT [ BY | = ] increment ]
[ MINVALUE [=] minvalue | NO MINVALUE | NOMINVALUE ]
[ MAXVALUE [=] maxvalue | NO MAXVALUE | NOMAXVALUE ]
[ START [ WITH | = ] start ]
[ CACHE [=] cache | NOCACHE ] [ CYCLE | NOCYCLE]
[table_options]
```

Contents

The options for `CREATE SEQUENCE` can be given in any order, optionally followed by `table_options`.

table_options can be any of the normal table options in CREATE TABLE but the most usable ones are `ENGINE=...` and `COMMENT=`.

`NOMAXVALUE` and `NOMINVALUE` are there to allow one to create SEQUENCEs using the Oracle syntax.

Description

CREATE SEQUENCE will create a sequence that generates new values when called with `NEXT VALUE FOR sequence_name`. It's an alternative to AUTO INCREMENT when one wants to have more control of how the numbers are generated. As the SEQUENCE caches values (up to `CACHE`) it can in some cases be much faster than AUTO INCREMENT. Another benefit is that one can access the last value generated by all used sequences, which solves one of the limitations with LAST_INSERT_ID().

CREATE SEQUENCE requires the CREATE privilege.

DROP SEQUENCE can be used to drop a sequence, and ALTER SEQUENCE to change it.

Arguments to Create

The following options may be used:

Option	Default value	Description
INCREMENT	1	Increment to use for values. May be negative. Setting an increment of 0 causes the sequence to use the value of the auto_increment_increment system variable at the time of creation, which is always a positive number. (see MDEV-16035).
MINVALUE	1 if INCREMENT > 0 and -9223372036854775807 if INCREMENT < 0	Minimum value for the sequence
MAXVALUE	9223372036854775806 if INCREMENT > 0 and -1 if INCREMENT < 0	Max value for sequence
START	MINVALUE if INCREMENT > 0 and MAX_VALUE if INCREMENT< 0	First value that the sequence will generate
CACHE	1000	Number of values that should be cached. 0 if no CACHE. The underlying table will be updated first time a new sequence number is generated and each time the cache runs out.

If `CYCLE` is used then the sequence should start again from `MINVALUE` after it has run out of values. Default value is `NOCYCLE`.

Constraints on Create Arguments

To be able to create a legal sequence, the following must hold:

- MAXVALUE >= start
- MAXVALUE > MINVALUE
- START >= MINVALUE
- MAXVALUE <= 9223372036854775806 (LONGLONG_MAX-1)
- MINVALUE >= -9223372036854775807 (LONGLONG_MIN+1)

Note that sequences can't generate the maximum/minimum 64 bit number because of the constraint of `MINVALUE` and `MAXVALUE`.

Atomic DDL

MariaDB starting with 10.6.1

MariaDB 10.6.1 supports Atomic DDL and `CREATE SEQUENCE` is atomic.

Examples

```
CREATE SEQUENCE s START WITH 100 INCREMENT BY 10;

CREATE SEQUENCE s2 START WITH -100 INCREMENT BY -10;
```

The following statement fails, as the increment conflicts with the defaults

```
CREATE SEQUENCE s3 START WITH -100 INCREMENT BY 10;
ERROR 4082 (HY000): Sequence 'test.s3' values are conflicting
```

The sequence can be created by specifying workable minimum and maximum values:

```
CREATE SEQUENCE s3 START WITH -100 INCREMENT BY 10 MINVALUE=-100 MAXVALUE=1000;
```

1.1.1.2.8.17 SHOW CREATE SEQUENCE

1.1.6.4 ALTER SEQUENCE

Syntax

```
ALTER SEQUENCE [IF EXISTS] sequence_name
[ INCREMENT [ BY | = ] increment ]
[ MINVALUE [=] minvalue | NO MINVALUE | NOMINVALUE ]
[ MAXVALUE [=] maxvalue | NO MAXVALUE | NOMAXVALUE ]
[ START [ WITH | = ] start ] [ CACHE [=] cache ] [ [ NO ] CYCLE ]
[ RESTART [[WITH | =] restart]
```

Contents

`ALTER SEQUENCE` allows one to change any values for a `SEQUENCE` created with CREATE SEQUENCE.

The options for `ALTER SEQUENCE` can be given in any order.

Description

`ALTER SEQUENCE` changes the parameters of an existing sequence generator. Any parameters not specifically set in the `ALTER SEQUENCE` command retain their prior settings.

`ALTER SEQUENCE` requires the ALTER privilege.

Arguments to `ALTER SEQUENCE`

The following options may be used:

Option	Default value	Description
`INCREMENT`	1	Increment to use for values. May be negative.
`MINVALUE`	1 if `INCREMENT` > 0 and -9223372036854775807 if `INCREMENT` < 0	Minimum value for the sequence.
`MAXVALUE`	9223372036854775806 if `INCREMENT` > 0 and -1 if `INCREMENT` < 0	Max value for sequence.

START	MINVALUE if INCREMENT > 0 and MAX_VALUE if INCREMENT < 0	First value that the sequence will generate.
CACHE	1000	Number of values that should be cached. 0 if no CACHE . The underlying table will be updated first time a new sequence number is generated and each time the cache runs out.
CYCLE	0 (= NO CYCLE)	1 if the sequence should start again from MINVALUE # after it has run out of values.
RESTART	START if restart value not is given	If RESTART option is used, NEXT VALUE will return the restart value.

The optional clause RESTART [WITH restart] sets the next value for the sequence. This is equivalent to calling the SETVAL() function with the is_used argument as 0. The specified value will be returned by the next call of nextval. Using RESTART with no restart value is equivalent to supplying the start value that was recorded by CREATE SEQUENCE or last set by ALTER SEQUENCE START WITH .

ALTER SEQUENCE will not allow you to change the sequence so that it's inconsistent. For example:

```
CREATE SEQUENCE s1;
ALTER SEQUENCE s1 MINVALUE 10;
ERROR 4061 (HY000): Sequence 'test.t1' values are conflicting

ALTER SEQUENCE s1 MINVALUE 10 RESTART 10;
ERROR 4061 (HY000): Sequence 'test.t1' values are conflicting

ALTER SEQUENCE s1 MINVALUE 10 START 10 RESTART 10;
```

INSERT

To allow SEQUENCE objects to be backed up by old tools, like mariadb-dump, one can use SELECT to read the current state of a SEQUENCE object and use an INSERT to update the SEQUENCE object. INSERT is only allowed if all fields are specified:

```
CREATE SEQUENCE s1;
INSERT INTO s1 VALUES(1000,10,2000,1005,1,1000,0,0);
SELECT * FROM s1;

+------------+-----------+-----------+-------+-----------+-------+-------+-------+
| next_value | min_value | max_value | start | increment | cache | cycle | round |
+------------+-----------+-----------+-------+-----------+-------+-------+-------+
|       1000 |        10 |      2000 |  1005 |         1 |  1000 |     0 |     0 |
+------------+-----------+-----------+-------+-----------+-------+-------+-------+

SHOW CREATE SEQUENCE s1;
+-------+-----------------------------------------------------------------------------------------
--------------------------+
| Table | Create Table
|
+-------+-----------------------------------------------------------------------------------------
--------------------------+
| s1    | CREATE SEQUENCE `s1` start with 1005 minvalue 10 maxvalue 2000 increment by 1 cache
1000 nocycle ENGINE=Aria |
+-------+-----------------------------------------------------------------------------------------
--------------------------+
```

Notes

ALTER SEQUENCE will instantly affect all future SEQUENCE operations. This is in contrast to some other databases where the changes requested by ALTER SEQUENCE will not be seen until the sequence cache has run out.

ALTER SEQUENCE will take a full table lock of the sequence object during its (brief) operation. This ensures that ALTER SEQUENCE is replicated correctly. If you only want to set the next sequence value to a higher value than current, then you should use SETVAL() instead, as this is not blocking.

If you want to change storage engine, sequence comment or rename the sequence, you can use ALTER TABLE for this.

1.1.6.5 DROP SEQUENCE

Syntax

```
DROP [TEMPORARY] SEQUENCE [IF EXISTS] [/*COMMENT TO SAVE*/]
    sequence_name [, sequence_name] ...
```

Contents

Description

`DROP SEQUENCE` removes one or more sequences created with CREATE SEQUENCE. You must have the `DROP` privilege for each sequence. MariaDB returns an error indicating by name which non-existing tables it was unable to drop, but it also drops all of the tables in the list that do exist.

Important: When a table is dropped, user privileges on the table are not automatically dropped. See GRANT.

If another connection is using the sequence, a metadata lock is active, and this statement will wait until the lock is released. This is also true for non-transactional tables.

For each referenced sequence, DROP SEQUENCE drops a temporary sequence with that name, if it exists. If it does not exist, and the `TEMPORARY` keyword is not used, it drops a non-temporary sequence with the same name, if it exists. The `TEMPORARY` keyword ensures that a non-temporary sequence will not accidentally be dropped.

Use `IF EXISTS` to prevent an error from occurring for sequences that do not exist. A NOTE is generated for each non-existent sequence when using `IF EXISTS`. See SHOW WARNINGS.

DROP SEQUENCE requires the DROP privilege.

Notes

DROP SEQUENCE only removes sequences, not tables. However, DROP TABLE can remove both sequences and tables.

1.1.6.6 SEQUENCE Functions

Functions that can be used on SEQUENCEs

LASTVAL

Synonym for PREVIOUS VALUE for sequence_name.

NEXT VALUE for sequence_name

Generate next value for a SEQUENCE. Same as NEXTVAL().

NEXTVAL

Synonym for NEXT VALUE for sequence_name.

PREVIOUS VALUE FOR sequence_name

Get last value generated from a SEQUENCE. Same as LASTVAL().

SETVAL

Set the next value to be returned from a SEQUENCE.

1.1.6.6.1 LASTVAL

`LASTVAL` is a synonym for PREVIOUS VALUE for sequence_name.

1.1.6.6.2 NEXT VALUE for sequence_name

Syntax

```
NEXT VALUE FOR sequence
```

or

```
NEXTVAL(sequence_name)
```

or in Oracle mode (SQL_MODE=ORACLE)

```
sequence_name.nextval
```

Contents

`NEXT VALUE FOR` is ANSI SQL syntax while `NEXTVAL()` is PostgreSQL syntax.

Description

Generate next value for a `SEQUENCE`.

- You can greatly speed up `NEXT VALUE` by creating the sequence with the `CACHE` option. If not, every `NEXT VALUE` usage will cause changes in the stored `SEQUENCE` table.
- When using `NEXT VALUE` the value will be reserved at once and will not be reused, except if the `SEQUENCE` was created with `CYCLE`. This means that when you are using `SEQUENCE`s you have to expect gaps in the generated sequence numbers.
- If one updates the `SEQUENCE` with SETVAL() or ALTER SEQUENCE ... RESTART, `NEXT VALUE FOR` will notice this and start from the next requested value.
- FLUSH TABLES will close the sequence and the next sequence number generated will be according to what's stored in the `SEQUENCE` object. In effect, this will discard the cached values.
- A server restart (or closing the current connection) also causes a drop of all cached values. The cached sequence numbers are reserved only for the current connection.
- `NEXT VALUE` requires the `INSERT` privilege.
- You can also use `NEXT VALUE FOR sequence` for column `DEFAULT`.

1.1.6.6.3 NEXTVAL

`NEXTVAL` is a synonym for NEXT VALUE for sequence_name.

1.1.6.6.4 PREVIOUS VALUE FOR sequence_name

Syntax

```
PREVIOUS VALUE FOR sequence_name
```

or

```
LASTVAL(sequence_name)
```

or in Oracle mode (SQL_MODE=ORACLE)

```
sequence_name.currval
```

Contents

`PREVIOUS VALUE FOR` is IBM DB2 syntax while `LASTVAL()` is PostgreSQL syntax.

Description

Get last value in the current connection generated from a sequence.

- If the sequence has not yet been used by the connection, `PREVIOUS VALUE FOR` returns `NULL` (the same thing applies with a new connection which doesn't see a last value for an existing sequence).
- If a `SEQUENCE` has been dropped and re-created then it's treated as a new `SEQUENCE` and `PREVIOUS VALUE FOR` will return `NULL`.
- `FLUSH TABLES` has no effect on `PREVIOUS VALUE FOR`.
- Previous values for all used sequences are stored per connection until connection ends.
- `PREVIOUS VALUE FOR` requires the SELECT privilege.

Example

```
CREATE SEQUENCE s START WITH 100 INCREMENT BY 10;

SELECT PREVIOUS VALUE FOR s;
+----------------------+
| PREVIOUS VALUE FOR s |
+----------------------+
|                 NULL |
+----------------------+

# The function works for sequences only, if the table is used an error is generated
SELECT PREVIOUS VALUE FOR t;
ERROR 4089 (42S02): 'test.t' is not a SEQUENCE

# Call the NEXT VALUE FOR s:
SELECT NEXT VALUE FOR s;
+------------------+
| NEXT VALUE FOR s |
+------------------+
|              100 |
+------------------+

SELECT PREVIOUS VALUE FOR s;
+----------------------+
| PREVIOUS VALUE FOR s |
+----------------------+
|                  100 |
+----------------------+
```

Now try to start the new connection and check that the last value is still NULL, before updating the value in the new connection after the output of the new connection gets current value (110 in the example below). Note that first connection cannot see this change and the result of last value still remains the same (100 in the example above).

```
$ .mysql -uroot test -e"SELECT PREVIOUS VALUE FOR s; SELECT NEXT VALUE FOR s; SELECT PREVIOUS
VALUE FOR s;"
+----------------------+
| PREVIOUS VALUE FOR s |
+----------------------+
|                 NULL |
+----------------------+
+------------------+
| NEXT VALUE FOR s |
+------------------+
|              110 |
+------------------+
+----------------------+
| PREVIOUS VALUE FOR s |
+----------------------+
|                  110 |
+----------------------+
```

1.1.6.6.5 SETVAL

Syntax

```
SETVAL(sequence_name, next_value, [is_used, [round]])
```

Contents

Description

Set the next value to be returned for a `SEQUENCE`.

This function is compatible with PostgreSQL syntax, extended with the `round` argument.

If the `is_used` argument is not given or is `1` or `true`, then the next used value will one after the given value. If `is_used` is `0` or `false` then the next generated value will be the given value.

If `round` is used then it will set the `round` value (or the internal cycle count, starting at zero) for the sequence. If `round` is not used, it's assumed to be 0.

`next_value` must be an integer literal.

For `SEQUENCE` tables defined with `CYCLE` (see CREATE SEQUENCE) one should use both `next_value` and `round` to define the next value. In this case the current sequence value is defined to be `round`, `next_value`.

The result returned by `SETVAL()` is `next_value` or NULL if the given `next_value` and `round` is smaller than the current value.

`SETVAL()` will not set the `SEQUENCE` value to a something that is less than its current value. This is needed to ensure that `SETVAL()` is replication safe. If you want to set the SEQUENCE to a smaller number use ALTER SEQUENCE.

If `CYCLE` is used, first `round` and then `next_value` are compared to see if the value is bigger than the current value.

Internally, in the MariaDB server, `SETVAL()` is used to inform slaves that a `SEQUENCE` has changed value. The slave may get `SETVAL()` statements out of order, but this is ok as only the biggest one will have an effect.

`SETVAL` requires the INSERT privilege.

Examples

```
SELECT setval(foo, 42);           -- Next nextval will return 43
SELECT setval(foo, 42, true);     -- Same as above
SELECT setval(foo, 42, false);    -- Next nextval will return 42
```

SETVAL setting higher and lower values on a sequence with an increment of 10:

```
SELECT NEXTVAL(s);
+------------+
| NEXTVAL(s) |
+------------+
|         50 |
+------------+

SELECT SETVAL(s, 100);
+----------------+
| SETVAL(s, 100) |
+----------------+
|            100 |
+----------------+

SELECT NEXTVAL(s);
+------------+
| NEXTVAL(s) |
+------------+
|        110 |
+------------+

SELECT SETVAL(s, 50);
+---------------+
| SETVAL(s, 50) |
+---------------+
|          NULL |
+---------------+

SELECT NEXTVAL(s);
+------------+
| NEXTVAL(s) |
+------------+
|        120 |
+------------+
```

Example demonstrating `round`:

```
CREATE OR REPLACE SEQUENCE s1
  START WITH 1
  MINVALUE 1
  MAXVALUE 99
  INCREMENT BY 1
  CACHE 20
  CYCLE;

SELECT SETVAL(s1, 99, 1, 0);
+----------------------+
| SETVAL(s1, 99, 1, 0) |
+----------------------+
|                   99 |
+----------------------+

SELECT NEXTVAL(s1);
+-------------+
| NEXTVAL(s1) |
+-------------+
|           1 |
+-------------+
```

The following statement returns NULL, as the given `next_value` and `round` is smaller than the current value.

```
SELECT SETVAL(s1, 99, 1, 0);
+----------------------+
| SETVAL(s1, 99, 1, 0) |
+----------------------+
|                 NULL |
+----------------------+

SELECT NEXTVAL(s1);
+-------------+
| NEXTVAL(s1) |
+-------------+
|           2 |
+-------------+
```

Increasing the round from zero to 1 will allow `next_value` to be returned.

```
SELECT SETVAL(s1, 99, 1, 1);
+----------------------+
| SETVAL(s1, 99, 1, 1) |
+----------------------+
|                   99 |
+----------------------+

SELECT NEXTVAL(s1);
+-------------+
| NEXTVAL(s1) |
+-------------+
|           1 |
+-------------+
```

1.1.1.2.8.52 SHOW TABLES

1.1.7 Temporal Tables

MariaDB supports temporal data tables in the form of system-versioning tables (allowing you to query and operate on historic data), application-time periods (allow you to query and operate on a temporal range of data), and bitemporal tables (which combine both system-versioning and application-time periods).

System-Versioned Tables

System-versioned tables record the history of all changes to table data.

Application-Time Periods

Application-time period tables, defined by a range between two temporal columns.

Bitemporal Tables

Bitemporal tables use versioning both at the system and application-time period levels.

1.1.7.1 System-Versioned Tables

Contents

MariaDB supports temporal data tables in the form of system-versioning tables (allowing you to query and operate on historic data, discussed below), application-time periods (allow you to query and operate on a temporal range of data), and bitemporal tables (which combine both system-versioning and application-time periods).

System-Versioned Tables

System-versioned tables store the history of all changes, not only data which is currently valid. This allows data analysis for any point in time, auditing of changes and comparison of data from different points in time. Typical uses cases are:

- Forensic analysis & legal requirements to store data for N years.
- Data analytics (retrospective, trends etc.), e.g. to get your staff information as of one year ago.
- Point-in-time recovery - recover a table state as of particular point in time.

System-versioned tables were first introduced in the SQL:2011 standard.

Creating a System-Versioned Table

The CREATE TABLE syntax has been extended to permit creating a system-versioned table. To be system-versioned, according to SQL:2011, a table must have two generated columns, a period, and a special table option clause:

```
CREATE TABLE t(
   x INT,
   start_timestamp TIMESTAMP(6) GENERATED ALWAYS AS ROW START,
   end_timestamp TIMESTAMP(6) GENERATED ALWAYS AS ROW END,
   PERIOD FOR SYSTEM_TIME(start_timestamp, end_timestamp)
) WITH SYSTEM VERSIONING;
```

In MariaDB one can also use a simplified syntax:

```
CREATE TABLE t (
   x INT
) WITH SYSTEM VERSIONING;
```

In the latter case no extra columns will be created and they won't clutter the output of, say, `SELECT * FROM t`. The versioning information will still be stored, and it can be accessed via the pseudo-columns `ROW_START` and `ROW_END`:

```
SELECT x, ROW_START, ROW_END FROM t;
```

Adding or Removing System Versioning To/From a Table

An existing table can be altered to enable system versioning for it.

```
CREATE TABLE t(
  x INT
);
```

```
ALTER TABLE t ADD SYSTEM VERSIONING;
```

```
SHOW CREATE TABLE t\G
*************************** 1. row ***************************
       Table: t
Create Table: CREATE TABLE `t` (
  `x` int(11) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1 WITH SYSTEM VERSIONING
```

Similarly, system versioning can be removed from a table:

```
ALTER TABLE t DROP SYSTEM VERSIONING;
```

```
SHOW CREATE TABLE t\G
*************************** 1. row ***************************
       Table: t
Create Table: CREATE TABLE `t` (
  `x` int(11) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

One can also add system versioning with all columns created explicitly:

```
ALTER TABLE t ADD COLUMN ts TIMESTAMP(6) GENERATED ALWAYS AS ROW START,
              ADD COLUMN te TIMESTAMP(6) GENERATED ALWAYS AS ROW END,
              ADD PERIOD FOR SYSTEM_TIME(ts, te),
              ADD SYSTEM VERSIONING;
```

```
SHOW CREATE TABLE t\G
*************************** 1. row ***************************
       Table: t
Create Table: CREATE TABLE `t` (
  `x` int(11) DEFAULT NULL,
  `ts` timestamp(6) GENERATED ALWAYS AS ROW START,
  `te` timestamp(6) GENERATED ALWAYS AS ROW END,
  PERIOD FOR SYSTEM_TIME (`ts`, `te`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 WITH SYSTEM VERSIONING
```

Inserting Data

When data is inserted into a system-versioned table, it is given a *row_start* value of the current timestamp, and a *row_end* value of FROM_UNIXTIME(2147483647.999999). The current timestamp can be adjusted by setting the timestamp system variable, for example:

```
SELECT NOW();
+---------------------+
| NOW()               |
+---------------------+
| 2022-10-24 23:09:38 |
+---------------------+

INSERT INTO t VALUES(1);

SET @@timestamp = UNIX_TIMESTAMP('2033-10-24');

INSERT INTO t VALUES(2);

SET @@timestamp = default;

INSERT INTO t VALUES(3);

SELECT a,row_start,row_end FROM t;
+------+----------------------------+----------------------------+
| a    | row_start                  | row_end                    |
+------+----------------------------+----------------------------+
|    1 | 2022-10-24 23:09:38.951347 | 2038-01-19 05:14:07.999999 |
|    2 | 2033-10-24 00:00:00.000000 | 2038-01-19 05:14:07.999999 |
|    3 | 2022-10-24 23:09:38.961857 | 2038-01-19 05:14:07.999999 |
+------+----------------------------+----------------------------+
```

Querying Historical Data

`SELECT`

To query the historical data one uses the clause `FOR SYSTEM_TIME` directly after the table name (before the table alias, if any). SQL:2011 provides three syntactic extensions:

- `AS OF` is used to see the table as it was at a specific point in time in the past:

```
SELECT * FROM t FOR SYSTEM_TIME AS OF TIMESTAMP'2016-10-09 08:07:06';
```

- `BETWEEN start AND end` will show all rows that were visible at any point between two specified points in time. It works inclusively, a row visible exactly at *start* or exactly at *end* will be shown too.

```
SELECT * FROM t FOR SYSTEM_TIME BETWEEN (NOW() - INTERVAL 1 YEAR) AND NOW();
```

- `FROM start TO end` will also show all rows that were visible at any point between two specified points in time, including *start*, but **excluding** *end*.

```
SELECT * FROM t FOR SYSTEM_TIME FROM '2016-01-01 00:00:00' TO '2017-01-01 00:00:00';
```

Additionally MariaDB implements a non-standard extension:

- `ALL` will show all rows, historical and current.

```
SELECT * FROM t FOR SYSTEM_TIME ALL;
```

If the `FOR SYSTEM_TIME` clause is not used, the table will show the *current* data. This is usually the same as if one had specified `FOR SYSTEM_TIME AS OF CURRENT_TIMESTAMP`, unless one has adjusted the *row_start* value (until MariaDB 10.11, only possible by setting the secure_timestamp variable). For example:

```
CREATE OR REPLACE TABLE t (a int) WITH SYSTEM VERSIONING;

SELECT NOW();
+---------------------+
| NOW()               |
+---------------------+
| 2022-10-24 23:43:37 |
+---------------------+

INSERT INTO t VALUES (1);

SET @@timestamp = UNIX_TIMESTAMP('2033-03-03');

INSERT INTO t VALUES (2);

DELETE FROM t;

SET @@timestamp = default;

SELECT a, row_start, row_end FROM t FOR SYSTEM_TIME ALL;
+------+----------------------------+----------------------------+
| a    | row_start                  | row_end                    |
+------+----------------------------+----------------------------+
|    1 | 2022-10-24 23:43:37.192725 | 2033-03-03 00:00:00.000000 |
|    2 | 2033-03-03 00:00:00.000000 | 2033-03-03 00:00:00.000000 |
+------+----------------------------+----------------------------+
2 rows in set (0.000 sec)

SELECT a, row_start, row_end FROM t FOR SYSTEM_TIME AS OF CURRENT_TIMESTAMP;
+------+----------------------------+----------------------------+
| a    | row_start                  | row_end                    |
+------+----------------------------+----------------------------+
|    1 | 2022-10-24 23:43:37.192725 | 2033-03-03 00:00:00.000000 |
+------+----------------------------+----------------------------+
1 row in set (0.000 sec)

SELECT a, row_start, row_end FROM t;
Empty set (0.001 sec)
```

Views and Subqueries

When a system-versioned tables is used in a view or in a subquery in the from clause, `FOR SYSTEM_TIME` can be used directly in the view or subquery body, or (non-standard) applied to the whole view when it's being used in a `SELECT`:

```
CREATE VIEW v1 AS SELECT * FROM t FOR SYSTEM_TIME AS OF TIMESTAMP'2016-10-09 08:07:06';
```

Or

```
CREATE VIEW v1 AS SELECT * FROM t;
SELECT * FROM v1 FOR SYSTEM_TIME AS OF TIMESTAMP'2016-10-09 08:07:06';
```

Use in Replication and Binary Logs

Tables that use system-versioning implicitly add the `row_end` column to the Primary Key. While this is generally not an issue for most use cases, it can lead to problems when re-applying write statements from the binary log or in replication environments, where a primary retries an SQL statement on the replica.

Specifically, these writes include a value on the `row_end` column containing the timestamp from when the write was initially made. The re-occurrence of the Primary Key with the old system-versioning columns raises an error due to the duplication.

To mitigate this with MariaDB Replication, set the secure_timestamp system variable to `YES` on the replica. When set, the replica uses its own system clock when applying to the row log, meaning that the primary can retry as many times as needed without causing a conflict. The retries generate new historical rows with new values for the `row_start` and `row_end` columns.

Transaction-Precise History in InnoDB

A point in time when a row was inserted or deleted does not necessarily mean that a change became visible at the same moment. With transactional tables, a row might have been inserted in a long transaction, and became visible hours after it was inserted.

For some applications — for example, when doing data analytics on one-year-old data — this distinction does not matter much. For others — forensic analysis — it might be crucial.

MariaDB supports transaction-precise history (only for the InnoDB storage engine) that allows seeing the data exactly as it would've been seen by a new connection doing a `SELECT` at the specified point in time — rows inserted *before* that point, but committed *after* will not be shown.

To use transaction-precise history, InnoDB needs to remember not timestamps, but transaction identifier per row. This is done by creating generated columns as `BIGINT UNSIGNED`, not `TIMESTAMP(6)`:

```
CREATE TABLE t(
   x INT,
   start_trxid BIGINT UNSIGNED GENERATED ALWAYS AS ROW START,
   end_trxid BIGINT UNSIGNED GENERATED ALWAYS AS ROW END,
   PERIOD FOR SYSTEM_TIME(start_trxid, end_trxid)
) WITH SYSTEM VERSIONING;
```

These columns must be specified explicitly, but they can be made INVISIBLE to avoid cluttering `SELECT *` output.

When one uses transaction-precise history, one can optionally use transaction identifiers in the `FOR SYSTEM_TIME` clause:

```
SELECT * FROM t FOR SYSTEM_TIME AS OF TRANSACTION 12345;
```

This will show the data, exactly as it was seen by the transaction with the identifier 12345.

Storing the History Separately

When the history is stored together with the current data, it increases the size of the table, so current data queries — table scans and index searches — will take more time, because they will need to skip over historical data. If most queries on that table use only current data, it might make sense to store the history separately, to reduce the overhead from versioning.

This is done by partitioning the table by `SYSTEM_TIME`. Because of the partition pruning optimization, all current data queries will only access one partition, the one that stores current data.

This example shows how to create such a partitioned table:

```
CREATE TABLE t (x INT) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME (
    PARTITION p_hist HISTORY,
    PARTITION p_cur CURRENT
  );
```

In this example all history will be stored in the partition `p_hist` while all current data will be in the partition `p_cur`. The table must have exactly one current partition and at least one historical partition.

Partitioning by `SYSTEM_TIME` also supports automatic partition rotation. One can rotate historical partitions by time or by size. This example shows how to rotate partitions by size:

```
CREATE TABLE t (x INT) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME LIMIT 100000 (
    PARTITION p0 HISTORY,
    PARTITION p1 HISTORY,
    PARTITION pcur CURRENT
  );
```

MariaDB will start writing history rows into partition `p0`, and when it reaches a size of 100000 rows, MariaDB will switch to partition `p1`. There are only two historical partitions, so when `p1` overflows, MariaDB will issue a warning, but will continue writing into it.

Similarly, one can rotate partitions by time:

```
CREATE TABLE t (x INT) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME INTERVAL 1 WEEK (
    PARTITION p0 HISTORY,
    PARTITION p1 HISTORY,
    PARTITION p2 HISTORY,
    PARTITION pcur CURRENT
  );
```

This means that the history for the first week after the table was created will be stored in `p0`. The history for the second week — in `p1`, and all later history will go into `p2`. One can see the exact rotation time for each partition in the INFORMATION_SCHEMA.PARTITIONS table.

It is possible to combine partitioning by `SYSTEM_TIME` and subpartitions:

```
CREATE TABLE t (x INT) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME
    SUBPARTITION BY KEY (x)
    SUBPARTITIONS 4 (
    PARTITION ph HISTORY,
    PARTITION pc CURRENT
  );
```

Default Partitions

MariaDB starting with 10.5.0

Since partitioning by current and historical data is such a typical usecase, from MariaDB 10.5, it is possible to use a simplified statement to do so. For example, instead of

```
CREATE TABLE t (x INT) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME (
    PARTITION p0 HISTORY,
    PARTITION pn CURRENT
);
```

you can use

```
CREATE TABLE t (x INT) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME;
```

You can also specify the number of partitions, which is useful if you want to rotate history by time, for example:

```
CREATE TABLE t (x INT) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME
    INTERVAL 1 MONTH
    PARTITIONS 12;
```

Specifying the number of partitions without specifying a rotation condition will result in a warning:

```
CREATE OR REPLACE TABLE t (x INT) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME PARTITIONS 12;
Query OK, 0 rows affected, 1 warning (0.518 sec)

Warning (Code 4115): Maybe missing parameters: no rotation condition for multiple HISTORY
partitions.
```

while specifying only 1 partition will result in an error:

```
CREATE OR REPLACE TABLE t (x INT) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME PARTITIONS 1;
ERROR 4128 (HY000): Wrong partitions for `t`: must have at least one HISTORY and exactly
one last CURRENT
```

Automatically Creating Partitions

MariaDB starting with 10.9.1

From MariaDB 10.9.1, the `AUTO` keyword can be used to automatically create history partitions.

For example

```
CREATE TABLE t1 (x int) WITH SYSTEM VERSIONING
    PARTITION BY SYSTEM_TIME INTERVAL 1 HOUR AUTO;

CREATE TABLE t1 (x int) WITH SYSTEM VERSIONING
   PARTITION BY SYSTEM_TIME INTERVAL 1 MONTH
   STARTS '2021-01-01 00:00:00' AUTO PARTITIONS 12;

CREATE TABLE t1 (x int) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME LIMIT 1000 AUTO;
```

Or with explicit partitions:

```
CREATE TABLE t1 (x int) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME INTERVAL 1 HOUR AUTO
  (PARTITION p0 HISTORY, PARTITION pn CURRENT);
```

To disable or enable auto-creation one can use ALTER TABLE by adding or removing AUTO from the partitioning specification:

```
CREATE TABLE t1 (x int) WITH SYSTEM VERSIONING
  PARTITION BY SYSTEM_TIME INTERVAL 1 HOUR AUTO;

# Disables auto-creation:
ALTER TABLE t1 PARTITION BY SYSTEM_TIME INTERVAL 1 HOUR;

# Enables auto-creation:
ALTER TABLE t1 PARTITION BY SYSTEM_TIME INTERVAL 1 HOUR AUTO;
```

If the rest of the partitioning specification is identical to CREATE TABLE, no repartitioning will be done (for details see MDEV-27328).

Removing Old History

Because it stores all the history, a system-versioned table might grow very large over time. There are many options to trim down the space and remove the old history.

One can completely drop the versioning from the table and add it back again, this will delete all the history:

```
ALTER TABLE t DROP SYSTEM VERSIONING;
ALTER TABLE t ADD SYSTEM VERSIONING;
```

It might be a rather time-consuming operation, though, as the table will need to be rebuilt, possibly twice (depending on the storage engine).

Another option would be to use partitioning and drop some of historical partitions:

```
ALTER TABLE t DROP PARTITION p0;
```

Note, that one cannot drop a current partition or the only historical partition.

And the third option; one can use a variant of the DELETE statement to prune the history:

```
DELETE HISTORY FROM t;
```

or only old history up to a specific point in time:

```
DELETE HISTORY FROM t BEFORE SYSTEM_TIME '2016-10-09 08:07:06';
```

or to a specific transaction (with `BEFORE SYSTEM_TIME TRANSACTION xxx`).

To protect the integrity of the history, this statement requires a special DELETE HISTORY privilege.

Currently, using the DELETE HISTORY statement with a BEFORE SYSTEM_TIME greater than the ROW_END of the active records (as a TIMESTAMP, this has a maximum value of '2038-01-19 03:14:07' UTC) will result in the historical records being dropped, and the active records being deleted and moved to history. See MDEV-25468.

Prior to MariaDB 10.4.5, the TRUNCATE TABLE statement drops all historical records from a system-versioned-table.

From MariaDB 10.4.5, historic data is protected from TRUNCATE statements, as per the SQL standard, and an Error 4137 is instead raised:

```
TRUNCATE t;
ERROR 4137 (HY000): System-versioned tables do not support TRUNCATE TABLE
```

Excluding Columns From Versioning

Another MariaDB extension allows one to version only a subset of columns in a table. This is useful, for example, if you have a table with user information that should be versioned, but one column is, let's say, a login counter that is incremented often and is not interesting to version. Such a column can be excluded from versioning by declaring it `WITHOUT VERSIONING`

```
CREATE TABLE t (
   x INT,
   y INT WITHOUT SYSTEM VERSIONING
) WITH SYSTEM VERSIONING;
```

A column can also be declared `WITH VERSIONING`, that will automatically make the table versioned. The statement below is equivalent to the one above:

```
CREATE TABLE t (
   x INT WITH SYSTEM VERSIONING,
   y INT
);
```

System Variables

There are a number of system variables related to system-versioned tables:

system_versioning_alter_history

- **Description:** SQL:2011 does not allow ALTER TABLE on system-versioned tables. When this variable is set to `ERROR`, an attempt to alter a system-versioned table will result in an error. When this variable is set to `KEEP`, ALTER TABLE will be allowed, but the history will become incorrect — querying historical data will show the new table structure. This mode is still useful, for example, when adding new columns to a table. Note that if historical data contains or would contain nulls, attempting to ALTER these columns to be `NOT NULL` will return an error (or warning if strict_mode is not set).
- **Commandline:** `--system-versioning-alter-history=value`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Type:** Enum
- **Default Value:** `ERROR`
- **Valid Values:** `ERROR`, `KEEP`

---

system_versioning_asof

- **Description:** If set to a specific timestamp value, an implicit `FOR SYSTEM_TIME AS OF` clause will be applied to all queries. This is useful if one wants to do many queries for history at the specific point in time. Set it to `DEFAULT` to restore the default behavior. Has no effect on DML, so queries such as INSERT .. SELECT and REPLACE .. SELECT need to state AS OF explicitly.
- **Commandline:** None
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Type:** Varchar
- **Default Value:** `DEFAULT`

---

system_versioning_innodb_algorithm_simple

- **Description:** Never fully implemented and removed in the following release.
- **Commandline:** `--system-versioning-innodb-algorithm-simple[={0|1}]`

- **Scope:** Global, Session
- **Dynamic:** Yes
- **Type:** Boolean
- **Default Value:** `ON`
- **Introduced:** MariaDB 10.3.4
- **Removed:** MariaDB 10.3.5

---

system_versioning_insert_history

- **Description:** Allows direct inserts into ROW_START and ROW_END columns if secure_timestamp allows changing timestamp.
- **Commandline:** `--system-versioning-insert-history[={0|1}]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Type:** Boolean
- **Default Value:** `OFF`
- **Introduced:** MariaDB 10.11.0

Limitations

- Versioning clauses can not be applied to generated (virtual and persistent) columns.
- Before MariaDB 10.11, mariadb-dump did not read historical rows from versioned tables, and so historical data would not be backed up. Also, a restore of the timestamps would not be possible as they cannot be defined by an insert/a user. From MariaDB 10.11, use the `-H` or `--dump-history` options to include the history.

1.1.7.2 Application-Time Periods

Contents

MariaDB starting with 10.4.3

Support for application-time period-versioning was added in MariaDB 10.4.3.

Extending system-versioned tables, MariaDB 10.4 supports application-time period tables. Time periods are defined by a range between two temporal columns. The columns must be of the same temporal data type, i.e. DATE, TIMESTAMP or DATETIME (TIME and YEAR are not supported), and of the same width.

Using time periods implicitly defines the two columns as `NOT NULL`. It also adds a constraint to check whether the first value is less than the second value. The constraint is invisible to SHOW CREATE TABLE statements. The name of this constraint is prefixed by the time period name, to avoid conflict with other constraints.

Creating Tables with Time Periods

To create a table with a time period, use a CREATE TABLE statement with the `PERIOD` table option.

```
CREATE TABLE t1(
   name VARCHAR(50),
   date_1 DATE,
   date_2 DATE,
   PERIOD FOR date_period(date_1, date_2));
```

This creates a table with a `time_period` period and populates the table with some basic temporal values.

Examples are available in the MariaDB Server source code, at `mysql-test/suite/period/r/create.result`.

Adding and Removing Time Periods

The ALTER TABLE statement now supports syntax for adding and removing time periods from a table. To add a period, use the `ADD PERIOD` clause.

For example:

```
CREATE OR REPLACE TABLE rooms (
 room_number INT,
 guest_name VARCHAR(255),
 checkin DATE,
 checkout DATE
 );

ALTER TABLE rooms ADD PERIOD FOR p(checkin,checkout);
```

To remove a period, use the `DROP PERIOD` clause:

```
ALTER TABLE rooms DROP PERIOD FOR p;
```

Both `ADD PERIOD` and `DROP PERIOD` clauses include an option to handle whether the period already exists:

```
ALTER TABLE rooms ADD PERIOD IF NOT EXISTS FOR p(checkin,checkout);

ALTER TABLE rooms DROP PERIOD IF EXISTS FOR p;
```

Deletion by Portion

You can also remove rows that fall within certain time periods.

When MariaDB executes a `DELETE FOR PORTION` statement, it removes the row:

- When the row period falls completely within the delete period, it removes the row.
- When the row period overlaps the delete period, it shrinks the row, removing the overlap from the first or second row period value.
- When the delete period falls completely within the row period, it splits the row into two rows. The first row runs from the starting row period to the starting delete period. The second runs from the ending delete period to the ending row period.

To test this, first populate the table with some data to operate on:

```
CREATE TABLE t1(
   name VARCHAR(50),
   date_1 DATE,
   date_2 DATE,
   PERIOD FOR date_period(date_1, date_2));

INSERT INTO t1 (name, date_1, date_2) VALUES
    ('a', '1999-01-01', '2000-01-01'),
    ('b', '1999-01-01', '2018-12-12'),
    ('c', '1999-01-01', '2017-01-01'),
    ('d', '2017-01-01', '2019-01-01');

SELECT * FROM t1;
+------+------------+------------+
| name | date_1     | date_2     |
+------+------------+------------+
| a    | 1999-01-01 | 2000-01-01 |
| b    | 1999-01-01 | 2018-12-12 |
| c    | 1999-01-01 | 2017-01-01 |
| d    | 2017-01-01 | 2019-01-01 |
+------+------------+------------+
```

Then, run the `DELETE FOR PORTION` statement:

```
DELETE FROM t1
FOR PORTION OF date_period
    FROM '2001-01-01' TO '2018-01-01';
Query OK, 3 rows affected (0.028 sec)

SELECT * FROM t1 ORDER BY name;
+------+------------+------------+
| name | date_1     | date_2     |
+------+------------+------------+
| a    | 1999-01-01 | 2000-01-01 |
| b    | 1999-01-01 | 2001-01-01 |
| b    | 2018-01-01 | 2018-12-12 |
| c    | 1999-01-01 | 2001-01-01 |
| d    | 2018-01-01 | 2019-01-01 |
+------+------------+------------+
```

Here:

- *a* is unchanged, as the range falls entirely out of the specified portion to be deleted.
- *b*, with values ranging from 1999 to 2018, is split into two rows, 1999 to 2000 and 2018-01 to 2018-12.
- *c*, with values ranging from 1999 to 2017, where only the upper value falls within the portion to be deleted, has been shrunk to 1999 to 2001.
- *d*, with values ranging from 2017 to 2019, where only the lower value falls within the portion to be deleted, has been shrunk to 2018 to 2019.

The `DELETE FOR PORTION` statement has the following restrictions

- The `FROM...TO` clause must be constant
- Multi-delete is not supported

If there are `DELETE` or `INSERT` triggers, it works as follows: any matched row is deleted, and then one or two rows are inserted. If the record is deleted completely, nothing is inserted.

Updating by Portion

The UPDATE syntax now supports `UPDATE FOR PORTION`, which modifies rows based on their occurrence in a range:

To test it, first populate the table with some data:

```
TRUNCATE t1;

INSERT INTO t1 (name, date_1, date_2) VALUES
    ('a', '1999-01-01', '2000-01-01'),
    ('b', '1999-01-01', '2018-12-12'),
    ('c', '1999-01-01', '2017-01-01'),
    ('d', '2017-01-01', '2019-01-01');

SELECT * FROM t1;
+------+------------+------------+
| name | date_1     | date_2     |
+------+------------+------------+
| a    | 1999-01-01 | 2000-01-01 |
| b    | 1999-01-01 | 2018-12-12 |
| c    | 1999-01-01 | 2017-01-01 |
| d    | 2017-01-01 | 2019-01-01 |
+------+------------+------------+
```

Then run the update:

```
UPDATE t1 FOR PORTION OF date_period
  FROM '2000-01-01' TO '2018-01-01'
SET name = CONCAT(name,'_original');

SELECT * FROM t1 ORDER BY name;
+------------+------------+------------+
| name       | date_1     | date_2     |
+------------+------------+------------+
| a          | 1999-01-01 | 2000-01-01 |
| b          | 1999-01-01 | 2000-01-01 |
| b          | 2018-01-01 | 2018-12-12 |
| b_original | 2000-01-01 | 2018-01-01 |
| c          | 1999-01-01 | 2000-01-01 |
| c_original | 2000-01-01 | 2017-01-01 |
| d          | 2018-01-01 | 2019-01-01 |
| d_original | 2017-01-01 | 2018-01-01 |
+------------+------------+------------+
```

- *a* is unchanged, as the range falls entirely out of the specified portion to be deleted.
- *b*, with values ranging from 1999 to 2018, is split into two rows, 1999 to 2000 and 2018-01 to 2018-12.
- *c*, with values ranging from 1999 to 2017, where only the upper value falls within the portion to be deleted, has been shrunk to 1999 to 2001.
- *d*, with values ranging from 2017 to 2019, where only the lower value falls within the portion to be deleted, has been shrunk to 2018 to 2019.
- Original rows affected by the update have "_original" appended to the name.

The `UPDATE FOR PORTION` statement has the following limitations:

- The operation cannot modify the two temporal columns used by the time period
- The operation cannot reference period values in the `SET` expression
- `FROM...TO` expressions must be constant

WITHOUT OVERLAPS

MariaDB starting with 10.5.3

MariaDB 10.5 introduced a new clause, `WITHOUT OVERLAPS`, which allows one to create an index specifying that application time periods should not overlap.

An index constrained by `WITHOUT OVERLAPS` is required to be either a primary key or a unique index.

Take the following example, an application time period table for a booking system:

```
CREATE OR REPLACE TABLE rooms (
 room_number INT,
 guest_name VARCHAR(255),
 checkin DATE,
 checkout DATE,
 PERIOD FOR p(checkin,checkout)
 );

INSERT INTO rooms VALUES
 (1, 'Regina', '2020-10-01', '2020-10-03'),
 (2, 'Cochise', '2020-10-02', '2020-10-05'),
 (1, 'Nowell', '2020-10-03', '2020-10-07'),
 (2, 'Eusebius', '2020-10-04', '2020-10-06');
```

Our system is not intended to permit overlapping bookings, so the fourth record above should not have been inserted. Using `WITHOUT OVERLAPS` in a unique index (in this case based on a combination of room number and the application time period) allows us to specify this constraint in the table definition.

```
CREATE OR REPLACE TABLE rooms (
 room_number INT,
 guest_name VARCHAR(255),
 checkin DATE,
 checkout DATE,
 PERIOD FOR p(checkin,checkout),
 UNIQUE (room_number, p WITHOUT OVERLAPS)
 );

INSERT INTO rooms VALUES
 (1, 'Regina', '2020-10-01', '2020-10-03'),
 (2, 'Cochise', '2020-10-02', '2020-10-05'),
 (1, 'Nowell', '2020-10-03', '2020-10-07'),
 (2, 'Eusebius', '2020-10-04', '2020-10-06');
ERROR 1062 (23000): Duplicate entry '2-2020-10-06-2020-10-04' for key 'room_number'
```

Further Examples

The implicit change from NULL to NOT NULL:

```
CREATE TABLE `t2` (
  `id` int(11) DEFAULT NULL,
  `d1` datetime DEFAULT NULL,
  `d2` datetime DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1;

ALTER TABLE t2 ADD PERIOD FOR p(d1,d2);

SHOW CREATE TABLE t2\G
*************************** 1. row ***************************
       Table: t2
Create Table: CREATE TABLE `t2` (
  `id` int(11) DEFAULT NULL,
  `d1` datetime NOT NULL,
  `d2` datetime NOT NULL,
  PERIOD FOR `p` (`d1`, `d2`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

Due to this constraint, trying to add a time period where null data already exists will fail.

```
CREATE OR REPLACE TABLE `t2` (
  `id` int(11) DEFAULT NULL,
  `d1` datetime DEFAULT NULL,
  `d2` datetime DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1;

INSERT INTO t2(id) VALUES(1);

ALTER TABLE t2 ADD PERIOD FOR p(d1,d2);
ERROR 1265 (01000): Data truncated for column 'd1' at row 1
```

1.1.7.3 Bitemporal Tables

MariaDB starting with 10.4.3

Bitemporal tables are tables that use versioning both at the system and application-time period levels.

Contents

Using Bitemporal Tables

To create a bitemporal table, use:

```
CREATE TABLE test.t3 (
   date_1 DATE,
   date_2 DATE,
   row_start TIMESTAMP(6) AS ROW START INVISIBLE,
   row_end TIMESTAMP(6) AS ROW END INVISIBLE,
   PERIOD FOR application_time(date_1, date_2),
   PERIOD FOR system_time(row_start, row_end))
WITH SYSTEM VERSIONING;
```

Note that, while `system_time` here is also a time period, it cannot be used in `DELETE FOR PORTION` or `UPDATE FOR PORTION` statements.

```
DELETE FROM test.t3
FOR PORTION OF system_time
    FROM '2000-01-01' TO '2018-01-01';
ERROR 42000: You have an error in your SQL syntax; check the manual that corresponds
  to your MariaDB server version for the right syntax to use near
  'of system_time from '2000-01-01' to '2018-01-01'' at line 1
```

1.2 Built-in Functions

Functions and procedures in MariaDB

Function and Operator Reference

A complete list of MariaDB functions and operators in alphabetical order.

String Functions

Built-In functions for the handling of strings and columns containing string values.

Date & Time Functions

Built-In functions for the handling of dates and times.

Aggregate Functions

Aggregate functions used with GROUP BY clauses.

Numeric Functions

Numeric and arithmetic related functions in MariaDB.

Control Flow Functions

Built-In functions for assessing data to determine what results to return.

Pseudo Columns

MariaDB has pseudo columns that can be used for different purposes.

Secondary Functions

Bit Functions and Operators

Operators for comparison and setting of values, and related functions.

Encryption, Hashing and Compression Functions

Functions used for encryption, hashing and compression.

Information Functions

Functions which return information on the server, the user, or a given query.

Miscellaneous Functions

Functions for very singular and specific needs.

Special Functions

Dynamic Columns Functions

Functions for storing key/value pairs of data within a column.

Galera Functions

Built-in functions related to Galera.

Geographic Functions

Geographic, as well as geometric functions.

JSON Functions

Built-in functions related to JSON.

SEQUENCE Functions

Functions that can be used on SEQUENCEs.

Spider Functions

User-defined functions available with the Spider storage engine.

Window Functions

Window functions for performing calculations on a set of rows related to the current row.

There are 11 related questions.

1.2.1 Function and Operator Reference

Name	Description	Added
+	Addition operator	
/	Division operator	
*	Multiplication operator	
%	Modulo operator. Returns the remainder of N divided by M	
-	Subtraction operator	
!=	Not equals	
<	Less than	
<=	Less than or equal	
<=>	NULL-safe equal	
=	Equal	
>	Greater than	
>=	Greater than or equal	
&	Bitwise AND	
<<	Shift left	
>>	Shift right	
^	Bitwise XOR	
!	Logical NOT	
&&	Logical AND	
XOR	Logical XOR	
||	Logical OR	
|	Bitwise OR	
:=	Assignment operator	
=	Assignment and comparison operator	
~	Bitwise NOT	
ABS	Returns an absolute value	
ACOS	Returns an arc cosine	

ADD_MONTHS	Add months to a date	
ADDDATE	Add days or another interval to a date	
ADDTIME	Adds a time to a time or datetime	
AES_DECRYPT	Decryption data encrypted with AES_ENCRYPT	
AES_ENCRYPT	Encrypts a string with the AES algorithm	
AREA	Synonym for ST_AREA	
AsBinary	Synonym for ST_AsBinary	
ASCII	Numeric ASCII value of leftmost character	
ASIN	Returns the arc sine	
AsText	Synonym for ST_AsText	
AsWKB	Synonym for ST_AsBinary	
AsWKT	Synonym for ST_AsText	
ATAN	Returns the arc tangent	
ATAN2	Returns the arc tangent of two variables	
AVG	Returns the average value	
BENCHMARK	Executes an expression repeatedly	
BETWEEN AND	True if expression between two values	
BIN	Returns binary value	
BINARY OPERATOR	Casts to a binary string	
BINLOG_GTID_POS	Returns a string representation of the corresponding GTID position	
BIT_AND	Bitwise AND	
BIT_COUNT	Returns the number of set bits	
BIT_LENGTH	Returns the length of a string in bits	
BIT_OR	Bitwise OR	
BIT_XOR	Bitwise XOR	
BOUNDARY	Synonym for ST_BOUNDARY	
BUFFER	Synonym for ST_BUFFER	
CASE	Returns the result where value=compare_value or for the first condition that is true	
CAST	Casts a value of one type to another type	
CEIL	Synonym for CEILING()	
CEILING	Returns the smallest integer not less than X	
CENTROID	Synonym for ST_CENTROID	
CHAR Function	Returns string based on the integer values for the individual characters	
CHARACTER_LENGTH	Synonym for CHAR_LENGTH()	
CHAR_LENGTH	Length of the string in characters	
CHARSET	Returns the character set	
CHR	Returns a string consisting of the character given by the code values of the integer	

COALESCE	Returns the first non-NULL parameter	
COERCIBILITY	Returns the collation coercibility value	
COLLATION	Collation of the string argument	
COLUMN_ADD	Adds or updates dynamic columns	
COLUMN_CHECK	Checks if a dynamic column blob is valid	
COLUMN_CREATE	Returns a dynamic columns blob	
COLUMN_DELETE	Deletes a dynamic column	
COLUMN_EXISTS	Checks is a column exists	
COLUMN_GET	Gets a dynamic column value by name	
COLUMN_JSON	Returns a JSON representation of dynamic column blob data	
COLUMN_LIST	Returns comma-separated list	
COMPRESS	Returns a binary, compressed string	
CONCAT	Returns concatenated string	
CONCAT_WS	Concatenate with separator	
CONNECTION_ID	Connection thread ID	
CONTAINS	Whether one geometry contains another	
CONVERT	Convert a value from one type to another type	
CONV	Converts numbers between different number bases	
CONVERT_TZ	Converts a datetime from on time zone to another	
CONVEXHULL	Synonym for ST_CONVEXHULL	
COS	Returns the cosine	
COT	Returns the cotangent	
COUNT	Returns count of non-null values	
COUNT DISTINCT	Returns count of number of different non-NULL values	
CRC32	Computes a cyclic redundancy check value	
CRC32C	Computes a cyclic redundancy check value	MariaDB 10.8
CROSSES	Whether two geometries spatially cross	
CUME_DIST	Window function that returns the cumulative distribution of a given row	
CURDATE	Returns the current date	
CURRENT_DATE	Synonym for CURDATE()	
CURRENT_ROLE	Current role name	
CURRENT_TIME	Synonym for CURTIME()	
CURRENT_TIMESTAMP	Synonym for NOW()	
CURRENT_USER	Username/host that authenicated the current client	
CURTIME	Returns the current time	
DATABASE	Current default database	

DATE FUNCTION	Extracts the date portion of a datetime	
DATEDIFF	Difference in days between two date/time values	
DATE_ADD	Date arithmetic - addition	
DATE_FORMAT	Formats the date value according to the format string	
DATE_SUB	Date arithmetic - subtraction	
DAY	Synonym for DAYOFMONTH()	
DAYNAME	Return the name of the weekday	
DAYOFMONTH	Returns the day of the month	
DAYOFWEEK	Returns the day of the week index	
DAYOFYEAR	Returns the day of the year	
DECODE	Decrypts a string encoded with ENCODE()	
DECODE_HISTOGRAM	Returns comma separated numerics corresponding to a probability distribution represented by a histogram	
DEFAULT	Returns column default	
DEGREES	Converts from radians to degrees	
DENSE_RANK	Rank of a given row with identical values receiving the same result, no skipping	
DES_DECRYPT	Decrypts a string encrypted with DES_ENCRYPT()	
DES_ENCRYPT	Encrypts a string using the Triple-DES algorithm	
DIMENSION	Synonym for ST_DIMENSION	
DISJOINT	Whether the two elements do not intersect	
DIV	Integer division	
ELT	Returns the N'th element from a set of strings	
ENCODE	Encrypts a string	
ENCRYPT	Encrypts a string with Unix crypt()	
ENDPOINT	Synonym for ST_ENDPOINT	
ENVELOPE	Synonym for ST_ENVELOPE	
EQUALS	Indicates whether two geometries are spatially equal	
EXP	e raised to the power of the argument	
EXPORT_SET	Returns an on string for every bit set, an off string for every bit not set	
ExteriorRing	Synonym for ST_ExteriorRing	
EXTRACT	Extracts a portion of the date	
EXTRACTVALUE	Returns the text of the first text node matched by the XPath expression	
FIELD	Returns the index position of a string in a list	
FIND_IN_SET	Returns the position of a string in a set of strings	

FLOOR	Largest integer value not greater than the argument	
FORMAT	Formats a number	
FORMAT_PICO_TIME	Given a time in picoseconds, returns a human-readable time value and unit indicator	MariaDB 11.0.2
FOUND_ROWS	Number of (potentially) returned rows	
FROM_BASE64	Given a base-64 encoded string, returns the decoded result as a binary string	
FROM_DAYS	Returns a date given a day	
FROM_UNIXTIME	Returns a datetime from a Unix timestamp	
GeomCollFromText	Synonym for ST_GeomCollFromText	
GeomCollFromWKB	Synonym for ST_GeomCollFromWKB	
GeometryCollectionFromText	Synonym for ST_GeomCollFromText	
GeometryCollectionFromWKB	Synonym for ST_GeomCollFromWKB	
GeometryFromText	Synonym for ST_GeomFromText	
GeometryFromWKB	Synonym for ST_GeomFromWKB	
GeomFromText	Synonym for ST_GeomFromText	
GeomFromWKB	Synonym for ST_GeomFromWKB	
GeometryN	Synonym for ST_GeometryN	
GEOMETRYCOLLECTION	Constructs a WKB GeometryCollection	
GeometryType	Synonym for ST_GeometryType	
GET_FORMAT	Returns a format string	
GET_LOCK	Obtain LOCK	
GLENGTH	Length of a LineString value	
GREATEST	Returns the largest argument	
GROUP_CONCAT	Returns string with concatenated values from a group	
HEX	Returns hexadecimal value	
HOUR	Returns the hour	
IF	If expr1 is TRUE, returns expr2; otherwise returns expr3	
IFNULL	Check whether an expression is NULL	
IN	True if expression equals any of the values in the list	
INTERVAL	Index of the argument that is less than the first argument	
INET6_ATON	Given an IPv6 or IPv4 network address, returns a VARBINARY numeric value	
INET6_NTOA	Given an IPv6 or IPv4 network address, returns the address as a nonbinary string	
INET_ATON	Returns numeric value of IPv4 address	

INET_NTOA	Returns dotted-quad representation of IPv4 address	
INSERT Function	Replaces a part of a string with another string	
INSTR	Returns the position of a string withing a string	
InteriorRingN	Synonym for ST_InteriorRingN	
INTERSECTS	Indicates whether two geometries spatially intersect	
IS	Tests whether a boolean is TRUE, FALSE, or UNKNOWN	
IsClosed	Synonym for ST_IsClosed	
IsEmpty	Synonym for ST_IsEmpty	
IS_FREE_LOCK	Checks whether lock is free to use	
IS_IPV4	Whether or not an expression is a valid IPv4 address	
IS_IPV4_COMPAT	Whether or not an IPv6 address is IPv4-compatible	
IS_IPV4_MAPPED	Whether an IPv6 address is a valid IPv4-mapped address	
IS_IPV6	Whether or not an expression is a valid IPv6 address	
IS NOT	Tests whether a boolean value is not TRUE, FALSE, or UNKNOWN	
IS NOT NULL	Tests whether a value is not NULL	
IS NULL	Tests whether a value is NULL	
ISNULL	Checks if an expression is NULL	
IsRing	Synonym for ST_IsRing	
IsSimple	Synonym for ST_IsSimple	
IS_USED_LOCK	Check if lock is in use	
JSON_ARRAY	Returns a JSON array containing the listed values	
JSON_ARRAY_INTERSECT		MariaDB 11.2.0
JSON_ARRAY_APPEND	Appends values to the end of the given arrays within a JSON document	
JSON_ARRAY_INSERT	Inserts a value into a JSON document	
JSON_COMPACT	Removes all unnecessary spaces so the json document is as short as possible	
JSON_CONTAINS	Whether a value is found in a given JSON document or at a specified path within the document	
JSON_CONTAINS_PATH	Indicates whether the given JSON document contains data at the specified path or paths	
JSON_DEPTH	Maximum depth of a JSON document	
JSON_DETAILED	Represents JSON in the most understandable way emphasizing nested structures	
JSON_EQUALS	Check for equality between JSON objects.	

JSON_EXISTS	Determines whether a specified JSON value exists in the given data	
JSON_EXTRACT	Extracts data from a JSON document.	
JSON_INSERT	Inserts data into a JSON document	
JSON_KEYS	Returns keys from top-level value of a JSON object or top-level keys from the path	
JSON_LENGTH	Returns the length of a JSON document, or the length of a value within the document	
JSON_LOOSE	Adds spaces to a JSON document to make it look more readable	
JSON_MERGE	Merges the given JSON documents	
JSON_MERGE_PATCH	RFC 7396-compliant merge of the given JSON documents	
JSON_MERGE_PRESERVE	Synonym for JSON_MERGE_PATCH.	
JSON_NORMALIZE	Recursively sorts keys and removes spaces, allowing comparison of json documents for equality	
JSON_OBJECT	Returns a JSON object containing the given key/value pairs	
JSON_OBJECT_FILTER_KEYS		MariaDB 11.2.0
JSON_OBJECT_TO_ARRAY		MariaDB 11.2.0
JSON_OBJECTAGG	Returns a JSON object containing key-value pairs	
JSON_OVERLAPS	Compares two json documents for overlaps	
JSON_PRETTY	Alias for json_detailed	MariaDB 10.10.3, MariaDB 10.9.5, MariaDB 10.8.7, MariaDB 10.7.8, MariaDB 10.6.12, MariaDB 10.5.19 and MariaDB 10.4.28
JSON_QUERY	Given a JSON document, returns an object or array specified by the path	
JSON_QUOTE	Quotes a string as a JSON value	
JSON_REMOVE	Removes data from a JSON document	
JSON_REPLACE	Replaces existing values in a JSON document	
JSON_SCHEMA_VALID	Validates a JSON schema	MariaDB 11.1.0
JSON_SEARCH	Returns the path to the given string within a JSON document	
JSON_SET	Updates or inserts data into a JSON document	
JSON_TABLE	Returns a representation of a JSON document as a relational table	
JSON_TYPE	Returns the type of a JSON value	
JSON_UNQUOTE	Unquotes a JSON value, returning a string	
JSON_VALID	Whether a value is a valid JSON document or not	
JSON_VALUE	Given a JSON document, returns the specified scalar	
KDF	Key derivation function	MariaDB 11.3.0

LAST_DAY	Returns the last day of the month	
LAST_INSERT_ID	Last inserted autoinc value	
LAST_VALUE	Returns the last value in a list	
LASTVAL	Get last value generated from a sequence	
LCASE	Synonym for [LOWER()	
LEAST	Returns the smallest argument	
LEFT	Returns the leftmost characters from a string	
LENGTH	Length of the string in bytes	
LIKE	Whether expression matches a pattern	
LineFromText	Synonym for ST_LineFromText	
LineFromWKB	Synonym for ST_LineFromWKB	
LINESTRING	Constructs a WKB LineString value from a number of WKB Point arguments	
LineStringFromText	Synonym for ST_LineFromText	
LineStringFromWKB	Synonym for ST_LineFromWKB	
LN	Returns natural logarithm	
LOAD_FILE	Returns file contents as a string	
LOCALTIME	Synonym for NOW()	
LOCALTIMESTAMP	Synonym for NOW()	
LOCATE	Returns the position of a substring in a string	
LOG	Returns the natural logarithm	
LOG10	Returns the base-10 logarithm	
LOG2	Returns the base-2 logarithm	
LOWER	Returns a string with all characters changed to lowercase	
LPAD	Returns the string left-padded with another string to a given length	
LTRIM	Returns the string with leading space characters removed	
MAKE_SET	Make a set of strings that matches a bitmask	
MAKEDATE	Returns a date given a year and day	
MAKETIME	Returns a time	
MASTER_GTID_WAIT	Wait until slave reaches the GTID position	
MASTER_POS_WAIT	Blocks until the slave has applied all specified updates	
MATCH AGAINST	Perform a fulltext search on a fulltext index	
MAX	Returns the maximum value	
MBRContains	Indicates one Minimum Bounding Rectangle contains another	
MBRDisjoint	Indicates whether the Minimum Bounding Rectangles of two geometries are disjoint	
MBREqual	Whether the Minimum Bounding Rectangles of two geometries are the same.	

MBRIntersects	Indicates whether the Minimum Bounding Rectangles of the two geometries intersect	
MBROverlaps	Whether the Minimum Bounding Rectangles of two geometries overlap	
MBRTouches	Whether the Minimum Bounding Rectangles of two geometries touch.	
MBRWithin	Indicates whether one Minimum Bounding Rectangle is within another	
MD5	MD5 checksum	
MEDIAN	Window function that returns the median value of a range of values	
MICROSECOND	Returns microseconds from a date or datetime	
MID	Synonym for SUBSTRING(str,pos,len)	
MIN	Returns the minimum value	
MINUTE	Returns a minute from 0 to 59	
MLineFromText	Constructs MULTILINESTRING using its WKT representation and SRID	
MLineFromWKB	Constructs a MULTILINESTRING	
MOD	Modulo operation. Remainder of N divided by M	
MONTH	Returns a month from 1 to 12	
MONTHNAME	Returns the full name of the month	
MPointFromText	Constructs a MULTIPOINT value using its WKT and SRID	
MPointFromWKB	Constructs a MULTIPOINT value using its WKB representation and SRID	
MPolyFromText	Constructs a MULTIPOLYGON value	
MPolyFromWKB	Constructs a MULTIPOLYGON value using its WKB representation and SRID	
MultiLineStringFromText	Synonym for MLineFromText	
MultiLineStringFromWKB	A synonym for MLineFromWKB	
MULTIPOINT	Constructs a WKB MultiPoint value	
MultiPointFromText	Synonym for MPointFromText	
MultiPointFromWKB	Synonym for MPointFromWKB	
MULTIPOLYGON	Constructs a WKB MultiPolygon	
MultiPolygonFromText	Synonym for MPolyFromText	
MultiPolygonFromWKB	Synonym for MPolyFromWKB	
MULTILINESTRING	Constructs a MultiLineString value	
NAME_CONST	Returns the given value	
NATURAL_SORT_KEY	Sorting that is more more similar to natural human sorting	
NOT LIKE	Same as NOT(expr LIKE pat [ESCAPE 'escape_char'])	
NOT REGEXP	Same as NOT (expr REGEXP pat)	
NULLIF	Returns NULL if expr1 = expr2	

NEXTVAL	Generate next value for sequence	
NOT BETWEEN	Same as NOT (expr BETWEEN min AND max)	
NOT IN	Same as NOT (expr IN (value,...))	
NOW	Returns the current date and time	
NTILE	Returns an integer indicating which group a given row falls into	
NumGeometries	Synonym for ST_NumGeometries	
NumInteriorRings	Synonym for NumInteriorRings	
NumPoints	Synonym for ST_NumPoints	
OCT	Returns octal value	
OCTET_LENGTH	Synonym for LENGTH()	
OLD_PASSWORD	Pre MySQL 4.1 password implementation	
ORD	Return ASCII or character code	
OVERLAPS	Indicates whether two elements spatially overlap	
PASSWORD	Calculates a password string	
PERCENT_RANK	Window function that returns the relative percent rank of a given row	
PERCENTILE_CONT	Returns a value which corresponds to the given fraction in the sort order.	
PERCENTILE_DISC	Returns the first value in the set whose ordered position is the same or more than the specified fraction.	
PERIOD_ADD	Add months to a period	
PERIOD_DIFF	Number of months between two periods	
PI	Returns the value of π (pi)	
POINT	Constructs a WKB Point	
PointFromText	Synonym for ST_PointFromText	
PointFromWKB	Synonym for PointFromWKB	
PointN	Synonym for PointN	
PointOnSurface	Synonym for ST_PointOnSurface	
POLYGON	Constructs a WKB Polygon value from a number of WKB LineString arguments	
PolyFromText	Synonym for ST_PolyFromText	
PolyFromWKB	Synonym for ST_PolyFromWKB	
PolygonFromText	Synonym for ST_PolyFromText	
PolygonFromWKB	Synonym for ST_PolyFromWKB	
POSITION	Returns the position of a substring in a string	
POW	Returns X raised to the power of Y	
POWER	Synonym for POW()	
QUARTER	Returns year quarter from 1 to 4	
QUOTE	Returns quoted, properly escaped string	
RADIANS	Converts from degrees to radians	
RAND	Random floating-point value	

RANK	Rank of a given row with identical values receiving the same result	
REGEXP	Performs pattern matching	
REGEXP_INSTR	Position of the first appearance of a regex	
REGEXP_REPLACE	Replaces all occurrences of a pattern	
REGEXP_SUBSTR	Returns the matching part of a string	
RELEASE_LOCK	Releases lock obtained with GET_LOCK()	
REPEAT Function	Returns a string repeated a number of times	
REPLACE Function	Replace occurrences of a string	
REVERSE	Reverses the order of a string	
RIGHT	Returns the rightmost N characters from a string	
RLIKE	Synonym for REGEXP()	
RPAD	Returns the string right-padded with another string to a given length	
ROUND	Rounds a number	
ROW_COUNT	Number of rows affected by previous statement	
ROW_NUMBER	Row number of a given row with identical values receiving a different result	
RTRIM	Returns the string with trailing space characters removed	
SCHEMA	Synonym for DATABASE()	
SECOND	Returns the second of a time	
SEC_TO_TIME	Converts a second to a time	
SETVAL	Set the next value to be returned by a sequence	
SESSION_USER	Synonym for USER()	
SHA	Synonym for SHA1()	
SHA1	Calculates an SHA-1 checksum	
SHA2	Calculates an SHA-2 checksum	
SIGN	Returns 1, 0 or -1	
SIN	Returns the sine	
SLEEP	Pauses for the given number of seconds	
SOUNDEX	Returns a string based on how the string sounds	
SOUNDS LIKE	SOUNDEX(expr1) = SOUNDEX(expr2)	
SPACE	Returns a string of space characters	
SPIDER_BG_DIRECT_SQL	Background SQL execution	
SPIDER_COPY_TABLES	Copy table data	
SPIDER_DIRECT_SQL	Execute SQL on the remote server	
SPIDER_FLUSH_TABLE_MON_CACHE	Refreshing Spider monitoring server information	
SQRT	Square root	
SRID	Synonym for ST_SRID	

ST_AREA	Area of a Polygon	
ST_AsBinary	Converts a value to its WKB representation	
ST_AsText	Converts a value to its WKT-Definition	
ST_AsWKB	Synonym for ST_AsBinary	
ST_ASWKT	Synonym for ST_ASTEXT()	
ST_BOUNDARY	Returns a geometry that is the closure of a combinatorial boundary	
ST_BUFFER	A new geometry with a buffer added to the original geometry	
ST_CENTROID	The mathematical centroid (geometric center) for a MultiPolygon	
ST_CONTAINS	Whether one geometry is contained by another	
ST_CONVEXHULL	The minimum convex geometry enclosing all geometries within the set	
ST_CROSSES	Whether two geometries spatially cross	
ST_DIFFERENCE	Point set difference	
ST_DIMENSION	Inherent dimension of a geometry value	
ST_DISJOINT	Whether one geometry is spatially disjoint from another	
ST_DISTANCE	The distance between two geometries	
ST_DISTANCE_SPHERE	The spherical distance between two geometries	
ST_ENDPOINT	Returns the endpoint of a LineString	
ST_ENVELOPE	Returns the Minimum Bounding Rectangle for a geometry value	
ST_EQUALS	Whether two geometries are spatoially equal	
ST_ExteriorRing	Returns the exterior ring of a Polygon as a LineString	
ST_GeomCollFromText	Constructs a GEOMETRYCOLLECTION value	
ST_GeomCollFromWKB	Constructs a GEOMETRYCOLLECTION value from a WKB	
ST_GeometryCollectionFromText	Synonym for ST_GeomCollFromText	
ST_GeometryCollectionFromWKB	Synonym for ST_GeomCollFromWKB	
ST_GeometryFromText	Synonym for ST_GeomFromText	
ST_GeometryFromWKB	Synonym for ST_GeomFromWKB	
ST_GEOMETRYN	Returns the N-th geometry in a GeometryCollection	
ST_GEOMETRYTYPE	Returns name of the geometry type of which a given geometry instance is a member	
ST_GeomFromText	Constructs a geometry value using its WKT and SRID	

ST_GeomFromWKB	Constructs a geometry value using its WKB representation and SRID	
ST_InteriorRingN	Returns the N-th interior ring for a Polygon	
ST_INTERSECTION	The intersection, or shared portion, of two geometries	
ST_INTERSECTS	Whether two geometries spatially intersect	
ST_ISCLOSED	Returns true if a given LINESTRING's start and end points are the same	
ST_ISEMPTY	Indicated validity of geometry value	
ST_IsRing	Returns true if a given LINESTRING is both ST_IsClosed and ST_IsSimple	
ST_IsSimple	Returns true if the given Geometry has no anomalous geometric points	
ST_LENGTH	Length of a LineString value	
ST_LineFromText	Creates a linestring value	
ST_LineFromWKB	Constructs a LINESTRING using its WKB and SRID	
ST_LineStringFromText	Synonym for ST_LineFromText	
ST_LineStringFromWKB	Synonym for ST_LineFromWKB	
ST_NUMGEOMETRIES	Number of geometries in a GeometryCollection	
ST_NumInteriorRings	Number of interior rings in a Polygon	
ST_NUMPOINTS	Returns the number of Point objects in a LineString	
ST_OVERLAPS	Whether two geometries overlap	
ST_PointFromText	Constructs a POINT value	
ST_PointFromWKB	Constructs POINT using its WKB and SRID	
ST_POINTN	Returns the N-th Point in the LineString	
ST_POINTONSURFACE	Returns a POINT guaranteed to intersect a surface	
ST_PolyFromText	Constructs a POLYGON value	
ST_PolyFromWKB	Constructs POLYGON value using its WKB representation and SRID	
ST_PolygonFromText	Synonym for ST_PolyFromText	
ST_PolygonFromWKB	Synonym for ST_PolyFromWKB	
ST_RELATE	Returns true if two geometries are related	
ST_SRID	Returns a Spatial Reference System ID	
ST_STARTPOINT	Returns the start point of a LineString	
ST_SYMDIFFERENCE	Portions of two geometries that don't intersect	
ST_TOUCHES	Whether one geometry g1 spatially touches another	
ST_UNION	Union of two geometries	
ST_WITHIN	Whether one geometry is within another	

ST_X	X-coordinate value for a point	
ST_Y	Y-coordinate for a point	
STARTPOINT	Synonym for ST_StartPoint	
STD	Population standard deviation	
STDDEV	Population standard deviation	
STDDEV_POP	Returns the population standard deviation	
STDDEV_SAMP	Standard deviation	
STR_TO_DATE	Converts a string to date	
STRCMP	Compares two strings in sort order	
SUBDATE	Subtract a date unit or number of days	
SUBSTR	Returns a substring from string starting at a given position	
SUBSTRING	Returns a substring from string starting at a given position	
SUBSTRING_INDEX	Returns the substring from string before count occurrences of a delimiter	
SUBTIME	Subtracts a time from a date/time	
SUM	Sum total	
SYS.EXTRACT_SCHEMA_FROM_FILE_NAME	Given a file path, returns the schema (database) name	MariaDB 10.6
SYS.EXTRACT_TABLE_FROM_FILE_NAME	Given a file path, returns the table name	MariaDB 10.6
SYS.FORMAT_BYTES	Returns a string consisting of a value and the units in a human-readable format	MariaDB 10.6
SYS.FORMAT_PATH	Returns a modified path after replacing subpaths matching the values of various system variables with the variable name	MariaDB 10.6
SYS.FORMAT_STATEMENT	Returns a reduced length string	MariaDB 10.6
SYS.FORMAT_TIME	Returns a human-readable time value and unit indicator	MariaDB 10.6
SYS.LIST_ADD	Adds a value to a given list	MariaDB 10.6
SYS.LIST_DROP	Drops a value from a given list	MariaDB 10.6
SYS.PS_IS_ACCOUNT_ENABLED	Whether Performance Schema instrumentation for the given account is enabled	MariaDB 10.6
SYS.PS_IS_CONSUMER_ENABLED	Whether Performance Schema instrumentation for the given consumer is enabled	MariaDB 10.6
SYS.PS_IS_INSTRUMENT_DEFAULT_ENABLED	Whether a given Performance Schema instrument is enabled by default	MariaDB 10.6
SYS.PS_IS_INSTRUMENT_DEFAULT_TIMED	Returns whether a given Performance Schema instrument is timed by default	MariaDB 10.6
SYS.PS_IS_THREAD_INSTRUMENTED	Returns whether or not Performance Schema instrumentation for the given connection_id is enabled	MariaDB 10.6
SYS.PS_THREAD_ACCOUNT	Returns the account (username@hostname) associated with the given thread_id	MariaDB 10.6

SYS.PS_THREAD_ID	Returns the thread_id associated with the given connection_id	MariaDB 10.6
SYS.PS_THREAD_STACK	Returns all statements, stages, and events within the Performance Schema for a given thread_id	MariaDB 10.6
SYS.PS_THREAD_TRX_INFO	Returns a JSON object with information about the thread specified by the given thread_id	MariaDB 10.6
SYS.QUOTE_IDENTIFIER	Quotes a string to produce a result that can be used as an identifier in an SQL statement	MariaDB 10.6
SYS.SYS_GET_CONFIG	Returns a configuration option value from the sys_config table	MariaDB 10.6
SYS.VERSION_MAJOR	Returns the MariaDB Server major release version	MariaDB 10.6
SYS.VERSION_MINOR	Returns the MariaDB Server minor release version	MariaDB 10.6
SYS.VERSION_PATCH	Returns the MariaDB Server patch release version	MariaDB 10.6
SYS_GUID	Generates a globally unique identifier	
SYSDATE	Returns the current date and time	
SYSTEM_USER	Synonym for USER()	
TAN	Returns the tangent	
TIME function	Extracts the time	
TIMEDIFF	Returns the difference between two date/times	
TIMESTAMP FUNCTION	Return the datetime, or add a time to a date/time	
TIMESTAMPADD	Add interval to a date or datetime	
TIMESTAMPDIFF	Difference between two datetimes	
TIME_FORMAT	Formats the time value according to the format string	
TIME_TO_SEC	Returns the time argument, converted to seconds	
TO_BASE64	Converts a string to its base-64 encoded form	
TO_CHAR	Converts a date/time type to a char	
TO_DAYS	Number of days since year 0	
TO_SECONDS	Number of seconds since year 0	
TOUCHES	Whether two geometries spatially touch	
TRIM	Returns a string with all given prefixes or suffixes removed	
TRUNCATE	Truncates X to D decimal places	
UCASE	Synonym for UPPER]]()	
UNHEX	Interprets pairs of hex digits as a number and converts to the character represented by the number	
UNCOMPRESS	Uncompresses string compressed with COMPRESS()	
UNCOMPRESSED_LENGTH	Returns length of a string before being compressed with COMPRESS()	

UNIX_TIMESTAMP	Returns a Unix timestamp	
UPDATEXML	Replace XML	
UPPER	Changes string to uppercase	
USER	Current user/host	
UTC_DATE	Returns the current UTC date	
UTC_TIME	Returns the current UTC time	
UTC_TIMESTAMP	Returns the current UTC date and time	
UUID	Returns a Universal Unique Identifier	
UUID_SHORT	Return short universal identifier	
VALUES or VALUE	Refer to columns in INSERT ... ON DUPLICATE KEY UPDATE	
VAR_POP	Population standard variance	
VAR_SAMP	Returns the sample variance	
VARIANCE	Population standard variance	
VERSION	MariaDB server version	
WEEK	Returns the week number	
WEEKDAY	Returns the weekday index	
WEEKOFYEAR	Returns the calendar week of the date as a number in the range from 1 to 53	
WEIGHT_STRING	Weight of the input string	
WITHIN	Indicate whether a geographic element is spacially within another	
WSREP_LAST_SEEN_GTID	Returns the Global Transaction ID of the most recent write transaction observed by the client.	
WSREP_LAST_WRITTEN_GTID	Returns the Global Transaction ID of the most recent write transaction performed by the client.	
WSREP_SYNC_WAIT_UPTO_GTID	Blocks the client until the transaction specified by the given Global Transaction ID is applied and committed by the node	
X	Synonym for ST_X	
Y	Synonym for ST_Y	
YEAR	Returns the year for the given date	
YEARWEEK	Returns year and week for a date	

1.2.2 String Functions

Functions dealing with strings, such as CHAR, CONVERT, CONCAT, PAD, REGEXP, TRIM, etc.

Regular Expressions Functions

Functions for dealing with regular expressions

Dynamic Columns Functions

Functions for storing key/value pairs of data within a column.

ASCII

Numeric ASCII value of leftmost character.

BIN

Returns binary value.

BINARY Operator

Casts to a binary string.

BIT_LENGTH

Returns the length of a string in bits.

CAST

Casts a value of one type to another type.

CHAR Function

Returns string based on the integer values for the individual characters.

CHARACTER_LENGTH

Synonym for CHAR_LENGTH().

CHAR_LENGTH

Length of the string in characters.

CHR

Returns string based on integer values of the individual characters.

CONCAT

Returns concatenated string.

CONCAT_WS

Concatenate with separator.

CONVERT

Convert a value from one type to another type.

ELT

Returns the N'th element from a set of strings.

EXPORT_SET

Returns an on string for every bit set, an off string for every bit not set.

EXTRACTVALUE

Returns the text of the first text node matched by the XPath expression.

FIELD

Returns the index position of a string in a list.

FIND_IN_SET

Returns the position of a string in a set of strings.

FORMAT

Formats a number.

FROM_BASE64

Given a base-64 encoded string, returns the decoded result as a binary string.

HEX

Returns hexadecimal value.

INSERT Function

Replaces a part of a string with another string.

INSTR

Returns the position of a string within a string.

LCASE

Synonym for LOWER().

LEFT

Returns the leftmost characters from a string.

LENGTH

Length of the string in bytes.

LENGTHB

Length of the given string, in bytes.

LIKE

Whether expression matches a pattern.

LOAD_FILE

Returns file contents as a string.

LOCATE

Returns the position of a substring in a string.

LOWER

Returns a string with all characters changed to lowercase.

LPAD

Returns the string left-padded with another string to a given length.

LTRIM

Returns the string with leading space characters removed.

MAKE_SET

Make a set of strings that matches a bitmask.

MATCH AGAINST

Perform a fulltext search on a fulltext index.

Full-Text Index Stopwords

Default list of full-text stopwords used by MATCH...AGAINST.

MID

Synonym for SUBSTRING(str,pos,len).

NATURAL_SORT_KEY

Sorting that is closer to natural human sorting.

NOT LIKE

Same as NOT(expr LIKE pat [ESCAPE 'escape_char']).

NOT REGEXP

Same as NOT (expr REGEXP pat).

OCTET_LENGTH

Returns the length of the given string, in bytes.

ORD

Return ASCII or character code.

POSITION

Returns the position of a substring in a string.

QUOTE

Returns quoted, properly escaped string.

REPEAT Function

Returns a string repeated a number of times.

REPLACE Function

Replace occurrences of a string.

REVERSE

Reverses the order of a string.

RIGHT

Returns the rightmost N characters from a string.

RPAD

Returns the string right-padded with another string to a given length.

RTRIM

Returns the string with trailing space characters removed.

SFORMAT

Given a string and a formatting specification, returns a formatted string.

SOUNDEX

Returns a string based on how the string sounds.

SOUNDS LIKE

SOUNDEX(expr1) = SOUNDEX(expr2).

SPACE

Returns a string of space characters.

STRCMP

Compares two strings in sort order.

SUBSTR

Returns a substring from string starting at a given position.

SUBSTRING

Returns a substring from string starting at a given position.

SUBSTRING_INDEX

Returns the substring from string before count occurrences of a delimiter.

TO_BASE64

Converts a string to its base-64 encoded form.

TO_CHAR

Converts a date/time/timestamp type expression to a string.

TRIM

Returns a string with all given prefixes or suffixes removed.

TRIM_ORACLE

Synonym for the Oracle mode version of TRIM().

UCASE

Synonym for UPPER().

UNCOMPRESS

Uncompresses string compressed with COMPRESS().

UNCOMPRESSED_LENGTH

Returns length of a string before being compressed with COMPRESS().

UNHEX

Interprets pairs of hex digits as numbers and converts to the character represented by the number.

UPDATEXML
Replace XML.

UPPER
Changes string to uppercase.

WEIGHT_STRING
Weight of the input string.

Type Conversion
When implicit type conversion takes place.

There are 3 related questions.

1.2.2.1 Regular Expressions Functions

MariaDB includes a number of functions for dealing with regular expressions.

Regular Expressions Overview
Regular Expressions allow MariaDB to perform complex pattern matching on a string.

PCRE - Perl Compatible Regular Expressions
PCRE (Perl Compatible Regular Expressions) for enhanced regular expressions.

NOT REGEXP
Same as NOT (expr REGEXP pat).

REGEXP
Performs pattern matching

REGEXP_INSTR
Position of the first appearance of a regex.

REGEXP_REPLACE
Replaces all occurrences of a pattern.

REGEXP_SUBSTR
Returns the matching part of a string.

RLIKE
Synonym for REGEXP

There are 1 related questions.

1.2.2.1.1 Regular Expressions Overview

Contents

Regular Expressions allow MariaDB to perform complex pattern matching on a string. In many cases, the simple pattern matching provided by LIKE is sufficient. `LIKE` performs two kinds of matches:

- `_` - the underscore, matching a single character
- `%` - the percentage sign, matching any number of characters.

In other cases you may need more control over the returned matches, and will need to use regular expressions.

Until MariaDB 10.0.5, MariaDB used the POSIX 1003.2 compliant regular expression library. The current PCRE library is mostly backwards compatible with what is described below - see the PCRE Regular Expressions article for the enhancements made in 10.0.5.

Regular expression matches are performed with the REGEXP function. `RLIKE` is a synonym for `REGEXP`.

> Comparisons are performed on the byte value, so characters that are treated as equivalent by a collation, but do not have the same byte-value, such as accented characters, could evaluate as unequal.

Without any special characters, a regular expression match is true if the characters match. The match is case-insensitive, except in the case of BINARY strings.

```
SELECT 'Maria' REGEXP 'Maria';
+------------------------+
| 'Maria' REGEXP 'Maria' |
+------------------------+
|                      1 |
+------------------------+

SELECT 'Maria' REGEXP 'maria';
+------------------------+
| 'Maria' REGEXP 'maria' |
+------------------------+
|                      1 |
+------------------------+

SELECT BINARY 'Maria' REGEXP 'maria';
+-------------------------------+
| BINARY 'Maria' REGEXP 'maria' |
+-------------------------------+
|                             0 |
+-------------------------------+
```

Note that the word being matched must match the whole pattern:

```
SELECT 'Maria' REGEXP 'Mari';
+-----------------------+
| 'Maria' REGEXP 'Mari' |
+-----------------------+
|                     1 |
+-----------------------+

SELECT 'Mari' REGEXP 'Maria';
+-----------------------+
| 'Mari' REGEXP 'Maria' |
+-----------------------+
|                     0 |
+-----------------------+
```

The first returns true because the pattern "Mari" exists in the expression "Maria". When the order is reversed, the result is false, as the pattern "Maria" does not exist in the expression "Mari"

A match can be performed against more than one word with the `|` character. For example:

```
SELECT 'Maria' REGEXP 'Monty|Maria';
+------------------------------+
| 'Maria' REGEXP 'Monty|Maria' |
+------------------------------+
|                            1 |
+------------------------------+
```

Special Characters

The above examples introduce the syntax, but are not very useful on their own. It's the special characters that give regular expressions their power.

^

`^` matches the beginning of a string (inside square brackets it can also mean NOT - see below):

```
SELECT 'Maria' REGEXP '^Ma';
+----------------------+
| 'Maria' REGEXP '^Ma' |
+----------------------+
|                    1 |
+----------------------+
```

$

`$` matches the end of a string:

```
SELECT 'Maria' REGEXP 'ia$';
+----------------------+
| 'Maria' REGEXP 'ia$' |
+----------------------+
|                    1 |
+----------------------+
```

.

`.` matches any single character:

```
SELECT 'Maria' REGEXP 'Ma.ia';
+------------------------+
| 'Maria' REGEXP 'Ma.ia' |
+------------------------+
|                      1 |
+------------------------+

SELECT 'Maria' REGEXP 'Ma..ia';
+-------------------------+
| 'Maria' REGEXP 'Ma..ia' |
+-------------------------+
|                       0 |
+-------------------------+
```

*

`x*` matches zero or more of a character `x`. In the examples below, it's the `r` character.

```
SELECT 'Maria' REGEXP 'Mar*ia';
+-------------------------+
| 'Maria' REGEXP 'Mar*ia' |
+-------------------------+
|                       1 |
+-------------------------+

SELECT 'Maia' REGEXP 'Mar*ia';
+------------------------+
| 'Maia' REGEXP 'Mar*ia' |
+------------------------+
|                      1 |
+------------------------+

SELECT 'Marrria' REGEXP 'Mar*ia';
+---------------------------+
| 'Marrria' REGEXP 'Mar*ia' |
+---------------------------+
|                         1 |
+---------------------------+
```

+

`x+` matches one or more of a character `x`. In the examples below, it's the `r` character.

```
SELECT 'Maria' REGEXP 'Mar+ia';
+-------------------------+
| 'Maria' REGEXP 'Mar+ia' |
+-------------------------+
|                       1 |
+-------------------------+

SELECT 'Maia' REGEXP 'Mar+ia';
+------------------------+
| 'Maia' REGEXP 'Mar+ia' |
+------------------------+
|                      0 |
+------------------------+

SELECT 'Marrria' REGEXP 'Mar+ia';
+---------------------------+
| 'Marrria' REGEXP 'Mar+ia' |
+---------------------------+
|                         1 |
+---------------------------+
```

?

`x?` matches zero or one of a character `x`. In the examples below, it's the `r` character.

```
SELECT 'Maria' REGEXP 'Mar?ia';
+-------------------------+
| 'Maria' REGEXP 'Mar?ia' |
+-------------------------+
|                       1 |
+-------------------------+

SELECT 'Maia' REGEXP 'Mar?ia';
+------------------------+
| 'Maia' REGEXP 'Mar?ia' |
+------------------------+
|                      1 |
+------------------------+

SELECT 'Marrria' REGEXP 'Mar?ia';
+---------------------------+
| 'Marrria' REGEXP 'Mar?ia' |
+---------------------------+
|                         0 |
+---------------------------+
```

()

`(xyz)` - combine a sequence, for example `(xyz)+` or `(xyz)*`

```
SELECT 'Maria' REGEXP '(ari)+';
+-------------------------+
| 'Maria' REGEXP '(ari)+' |
+-------------------------+
|                       1 |
+-------------------------+
```

{}

`x{n}` and `x{m,n}` This notation is used to match many instances of the `x` . In the case of `x{n}` the match must be exactly that many times. In the case of `x{m,n}` , the match can occur from `m` to `n` times. For example, to match zero or one instance of the string `ari` (which is identical to `(ari)?`), the following can be used:

```
SELECT 'Maria' REGEXP '(ari){0,1}';
+-----------------------------+
| 'Maria' REGEXP '(ari){0,1}' |
+-----------------------------+
|                           1 |
+-----------------------------+
```

[]

`[xy]` groups characters for matching purposes. For example, to match either the `p` or the `r` character:

```
SELECT 'Maria' REGEXP 'Ma[pr]ia';
+---------------------------+
| 'Maria' REGEXP 'Ma[pr]ia' |
+---------------------------+
|                         1 |
+---------------------------+
```

The square brackets also permit a range match, for example, to match any character from a-z, `[a-z]` is used. Numeric ranges are also permitted.

```
SELECT 'Maria' REGEXP 'Ma[a-z]ia';
+---------------------------+
| 'Maria' REGEXP 'Ma[a-z]ia' |
+---------------------------+
|                          1 |
+---------------------------+
```

The following does not match, as `r` falls outside of the range `a-p` .

```
SELECT 'Maria' REGEXP 'Ma[a-p]ia';
+----------------------------+
| 'Maria' REGEXP 'Ma[a-p]ia' |
+----------------------------+
|                          0 |
+----------------------------+
```

^

The `^` character means does `NOT` match, for example:

```
SELECT 'Maria' REGEXP 'Ma[^p]ia';
+----------------------------+
| 'Maria' REGEXP 'Ma[^p]ia' |
+----------------------------+
|                          1 |
+----------------------------+

SELECT 'Maria' REGEXP 'Ma[^r]ia';
+----------------------------+
| 'Maria' REGEXP 'Ma[^r]ia' |
+----------------------------+
|                          0 |
+----------------------------+
```

The `[` and `]` characters on their own can be literally matched inside a `[]` block, without escaping, as long as they immediately match the opening bracket:

```
SELECT '[Maria' REGEXP '[[]';
+-----------------------+
| '[Maria' REGEXP '[[]' |
+-----------------------+
|                     1 |
+-----------------------+

SELECT '[Maria' REGEXP '[]]';
+-----------------------+
| '[Maria' REGEXP '[]]' |
+-----------------------+
|                     0 |
+-----------------------+

SELECT ']Maria' REGEXP '[]]';
+-----------------------+
| ']Maria' REGEXP '[]]' |
+-----------------------+
|                     1 |
+-----------------------+

SELECT ']Maria' REGEXP '[]a]';
+------------------------+
| ']Maria' REGEXP '[]a]' |
+------------------------+
|                      1 |
+------------------------+
```

Incorrect order, so no match:

```
SELECT ']Maria' REGEXP '[a]]';
+------------------------+
| ']Maria' REGEXP '[a]]' |
+------------------------+
|                      0 |
+------------------------+
```

The `-` character can also be matched in the same way:

```
SELECT '-Maria' REGEXP '[1-10]';
+--------------------------+
| '-Maria' REGEXP '[1-10]' |
+--------------------------+
|                        0 |
+--------------------------+

SELECT '-Maria' REGEXP '[-1-10]';
+---------------------------+
| '-Maria' REGEXP '[-1-10]' |
+---------------------------+
|                         1 |
+---------------------------+
```

Word boundaries

The `:<:` and `:>:` patterns match the beginning and the end of a word respectively. For example:

```
SELECT 'How do I upgrade MariaDB?' REGEXP '[[:<:]]MariaDB[[:>:]]';
+-----------------------------------------------------------+
| 'How do I upgrade MariaDB?' REGEXP '[[:<:]]MariaDB[[:>:]]' |
+-----------------------------------------------------------+
|                                                         1 |
+-----------------------------------------------------------+

SELECT 'How do I upgrade MariaDB?' REGEXP '[[:<:]]Maria[[:>:]]';
+-----------------------------------------------------------+
| 'How do I upgrade MariaDB?' REGEXP '[[:<:]]Maria[[:>:]]' |
+-----------------------------------------------------------+
|                                                         0 |
+-----------------------------------------------------------+
```

Character Classes

There are a number of shortcuts to match particular preset character classes. These are matched with the `[:character_class:]` pattern (inside a `[]` set). The following character classes exist:

Character Class	Description
alnum	Alphanumeric
alpha	Alphabetic
blank	Whitespace
cntrl	Control characters
digit	Digits
graph	Graphic characters
lower	Lowercase alphabetic
print	Graphic or space characters
punct	Punctuation
space	Space, tab, newline, and carriage return
upper	Uppercase alphabetic
xdigit	Hexadecimal digit

For example:

```
SELECT 'Maria' REGEXP 'Mar[[:alnum:]]*';
+---------------------------------+
| 'Maria' REGEXP 'Mar[:alnum:]*' |
+---------------------------------+
|                               1 |
+---------------------------------+
```

Remember that matches are by default case-insensitive, unless a binary string is used, so the following example, specifically looking for an uppercase, counter-intuitively matches a lowercase character:

```
SELECT 'Mari' REGEXP 'Mar[[:upper:]]+';
+---------------------------------+
| 'Mari' REGEXP 'Mar[[:upper:]]+' |
+---------------------------------+
|                               1 |
+---------------------------------+

SELECT BINARY 'Mari' REGEXP 'Mar[[:upper:]]+';
+----------------------------------------+
| BINARY 'Mari' REGEXP 'Mar[[:upper:]]+' |
+----------------------------------------+
|                                      0 |
+----------------------------------------+
```

Character Names

There are also number of shortcuts to match particular preset character names. These are matched with the `[.character.]` pattern (inside a `[]` set). The following character classes exist:

Name	Character
NUL	0
SOH	001
STX	002
ETX	003
EOT	004
ENQ	005
ACK	006
BEL	007
alert	007
BS	010
backspace	'\b'
HT	011
tab	'\t'
LF	012
newline	'\n'
VT	013
vertical-tab	'\v'
FF	014
form-feed	'\f'
CR	015
carriage-return	'\r'
SO	016
SI	017
DLE	020
DC1	021
DC2	022
DC3	023
DC4	024
NAK	025
SYN	026

ETB	027
CAN	030
EM	031
SUB	032
ESC	033
IS4	034
FS	034
IS3	035
GS	035
IS2	036
RS	036
IS1	037
US	037
space	' '
exclamation-mark	'!'
quotation-mark	'"'
number-sign	'#'
dollar-sign	'$'
percent-sign	'%'
ampersand	'&'
apostrophe	'\''
left-parenthesis	'('
right-parenthesis	')'
asterisk	'*'
plus-sign	'+'
comma	','
hyphen	'-'
hyphen-minus	'-'
period	'.'
full-stop	'.'
slash	'/'
solidus	'/'
zero	'0'
one	'1'
two	'2'
three	'3'
four	'4'
five	'5'
six	'6'
seven	'7'
eight	'8'
nine	'9'
colon	':'

semicolon	';'
less-than-sign	'<'
equals-sign	'='
greater-than-sign	'>'
question-mark	'?'
commercial-at	'@'
left-square-bracket	'['
backslash	' '
reverse-solidus	' '
right-square-bracket	']'
circumflex	'^'
circumflex-accent	'^'
underscore	'_'
low-line	'_'
grave-accent	'`'
left-brace	'{'
left-curly-bracket	'{'
vertical-line	'|'
right-brace	'}'
right-curly-bracket	'}'
tilde	''
DEL	177

For example:

```
SELECT '|' REGEXP '[[.vertical-line.]]';
+----------------------------------+
| '|' REGEXP '[[.vertical-line.]]' |
+----------------------------------+
|                                1 |
+----------------------------------+
```

Combining

The true power of regular expressions is unleashed when the above is combined, to form more complex examples. Regular expression's reputation for complexity stems from the seeming complexity of multiple combined regular expressions, when in reality, it's simply a matter of understanding the characters and how they apply:

The first example fails to match, as while the `Ma` matches, either `i` or `r` only matches once before the `ia` characters at the end.

```
SELECT 'Maria' REGEXP 'Ma[ir]{2}ia';
+------------------------------+
| 'Maria' REGEXP 'Ma[ir]{2}ia' |
+------------------------------+
|                            0 |
+------------------------------+
```

This example matches, as either `i` or `r` match exactly twice after the `Ma`, in this case one `r` and one `i`.

```
SELECT 'Maria' REGEXP 'Ma[ir]{2}';
+----------------------------+
| 'Maria' REGEXP 'Ma[ir]{2}' |
+----------------------------+
|                          1 |
+----------------------------+
```

Escaping

With the large number of special characters, care needs to be taken to properly escape characters. Two backslash characters,
(one for the MariaDB parser, one for the regex library), are required to properly escape a character. For example:

To match the literal `(Ma` :

```
SELECT '(Maria)' REGEXP '(Ma';
ERROR 1139 (42000): Got error 'parentheses not balanced' from regexp

SELECT '(Maria)' REGEXP '\(Ma';
ERROR 1139 (42000): Got error 'parentheses not balanced' from regexp

SELECT '(Maria)' REGEXP '\\(Ma';
+--------------------------+
| '(Maria)' REGEXP '\\(Ma' |
+--------------------------+
|                        1 |
+--------------------------+
```

To match `r+` : The first two examples are incorrect, as they match `r` one or more times, not `r+` :

```
SELECT 'Mar+ia' REGEXP 'r+';
+----------------------+
| 'Mar+ia' REGEXP 'r+' |
+----------------------+
|                    1 |
+----------------------+

SELECT 'Maria' REGEXP 'r+';
+--------------------+
| 'Maria' REGEXP 'r+' |
+--------------------+
|                  1 |
+--------------------+

SELECT 'Maria' REGEXP 'r\\+';
+----------------------+
| 'Maria' REGEXP 'r\\+' |
+----------------------+
|                    0 |
+----------------------+

SELECT 'Maria' REGEXP 'r+';
+--------------------+
| 'Maria' REGEXP 'r+' |
+--------------------+
|                  1 |
+--------------------+
```

1.2.2.1.2 Perl Compatible Regular Expressions (PCRE) Documentation

Contents

PCRE Versions

PCRE Version	Introduced	Maturity
PCRE2 10.34	MariaDB 10.5.1	Stable
PCRE 8.43	MariaDB 10.1.39	Stable
PCRE 8.42	MariaDB 10.2.15, MariaDB 10.1.33, MariaDB 10.0.35	Stable
PCRE 8.41	MariaDB 10.2.8, MariaDB 10.1.26, MariaDB 10.0.32	Stable
PCRE 8.40	MariaDB 10.2.5, MariaDB 10.1.22, MariaDB 10.0.30	Stable
PCRE 8.39	MariaDB 10.1.15, MariaDB 10.0.26	Stable
PCRE 8.38	MariaDB 10.1.10, MariaDB 10.0.23	Stable
PCRE 8.37	MariaDB 10.1.5, MariaDB 10.0.18	Stable
PCRE 8.36	MariaDB 10.1.2, MariaDB 10.0.15	Stable
PCRE 8.35	MariaDB 10.1.0, MariaDB 10.0.12	Stable
PCRE 8.34	MariaDB 10.0.8	Stable

PCRE Enhancements

MariaDB 10.0.5 switched to the PCRE library, which significantly improved the power of the REGEXP/RLIKE operator.

The switch to PCRE added a number of features, including recursive patterns, named capture, look-ahead and look-behind assertions, non-capturing groups, non-greedy quantifiers, Unicode character properties, extended syntax for characters and character classes, multi-line matching, and many other.

Additionally, MariaDB 10.0.5 introduced three new functions that work with regular expressions: REGEXP_REPLACE(), REGEXP_INSTR() and REGEXP_SUBSTR().

Also, REGEXP/RLIKE, and the new functions, now work correctly with all multi-byte character sets supported by MariaDB, including East-Asian character sets (big5, gb2313, gbk, eucjp, eucjpms, cp932, ujis, euckr), and Unicode character sets (utf8, utf8mb4, ucs2, utf16, utf16le, utf32). In earlier versions of MariaDB (and all MySQL versions) REGEXP/RLIKE works correctly only with 8-bit character sets.

New Regular Expression Functions

- REGEXP_REPLACE(subject, pattern, replace) - Replaces all occurrences of a pattern.
- REGEXP_INSTR(subject, pattern) - Position of the first appearance of a regex .
- REGEXP_SUBSTR(subject,pattern) - Returns the matching part of a string.

See the individual articles for more details and examples.

PCRE Syntax

In most cases PCRE is backward compatible with the old POSIX 1003.2 compliant regexp library (see Regular Expressions Overview), so you won't need to change your applications that use SQL queries with the REGEXP/RLIKE predicate.

MariaDB 10.0.11 introduced the default_regex_flags variable to address the remaining compatibilities between PCRE and the old regex library.

This section briefly describes the most important extended PCRE features. For more details please refer to the documentation on the PCRE site, or to the documentation which is bundled in the /pcre/doc/html/ directory of a MariaDB sources distribution. The pages pcresyntax.html and pcrepattern.html should be a good start. Regular-Expressions.Info is another good resource to learn about PCRE and regular expressions generally.

Special Characters

PCRE supports the following escape sequences to match special characters:

Sequence	Description
\a	0x07 (BEL)
\cx	"control-x", where x is any ASCII character
\e	0x1B (escape)
\f	0x0C (form feed)
\n	0x0A (newline)
\r	0x0D (carriage return)
\t	0x09 (TAB)
\ddd	character with octal code ddd
\xhh	character with hex code hh
\x{hhh..}	character with hex code hhh..

Note, the backslash characters (here, and in all examples in the sections below) must be escaped with another backslash, unless you're using the SQL_MODE `NO_BACKSLASH_ESCAPES` .

This example tests if a character has hex code 0x61:

```
SELECT 'a' RLIKE '\\x{61}';
-> 1
```

Character Classes

PCRE supports the standard POSIX character classes such as `alnum` , `alpha` , `blank` , `cntrl` , `digit` , `graph` , `lower` , `print` , `punct` , `space` , `upper` , `xdigit` , with the following additional classes:

Class	Description
ascii	any ASCII character (0x00..0x7F)

word	any "word" character (a letter, a digit, or an underscore)

This example checks if the string consists of ASCII characters only:

```
SELECT 'abc' RLIKE '^[[:ascii:]]+$';
-> 1
```

Generic Character Types

Generic character types complement the POSIX character classes and serve to simplify writing patterns:

Class	Description
\d	a decimal digit (same as [:digit:])
\D	a character that is not a decimal digit
\h	a horizontal white space character
\H	a character that is not a horizontal white space character
\N	a character that is not a new line
\R	a newline sequence
\s	a white space character
\S	a character that is not a white space character
\v	a vertical white space character
\V	a character that is not a vertical white space character
\w	a "word" character (same as [:word:])
\W	a "non-word" character

This example checks if the string consists of "word" characters only:

```
SELECT 'abc' RLIKE '^\\w+$';
-> 1
```

Unicode Character Properties

`\p{xx}` is a character with the `xx` property, and `\P{xx}` is a character without the `xx` property.

The property names represented by `xx` above are limited to the Unicode script names, the general category properties, and "Any", which matches any character (including newline). Those that are not part of an identified script are lumped together as "Common".

General Category Properties For \p and \P

Property	Description
C	Other
Cc	Control
Cf	Format
Cn	Unassigned
Co	Private use
Cs	Surrogate
L	Letter
Ll	Lower case letter
Lm	Modifier letter
Lo	Other letter
Lt	Title case letter

Lu	Upper case letter
L&	Ll, Lu, or Lt
M	Mark
Mc	Spacing mark
Me	Enclosing mark
Mn	Non-spacing mark
N	Number
Nd	Decimal number
Nl	Letter number
No	Other number
P	Punctuation
Pc	Connector punctuation
Pd	Dash punctuation
Pe	Close punctuation
Pf	Final punctuation
Pi	Initial punctuation
Po	Other punctuation
Ps	Open punctuation
S	Symbol
Sc	Currency symbol
Sk	Modifier symbol
Sm	Mathematical symbol
So	Other symbol
Z	Separator
Zl	Line separator
Zp	Paragraph separator
Zs	Space separator

This example checks if the string consists only of characters with property N (number):

```
SELECT '1¼①' RLIKE '^\\p{N}+$';
-> 1
```

Special Category Properties For \p and \P

Property	Description
Xan	Alphanumeric: union of properties L and N
Xps	POSIX space: property Z or tab, NL, VT, FF, CR
Xsp	Perl space: property Z or tab, NL, FF, CR
Xuc	A character than can be represented by a Universal Character Name
Xwd	Perl word: property Xan or underscore

The property `Xuc` matches any character that can be represented by a Universal Character Name (in C++ and other programming languages). These include `$`, `@`, `` ` ``, and all characters with Unicode code points greater than `U+00A0`, excluding the surrogates `U+D800` .. `U+DFFF`.

Script Names For \p and \P

Arabic, Armenian, Avestan, Balinese, Bamum, Batak, Bengali, Bopomofo, Brahmi, Braille, Buginese, Buhid,

Canadian_Aboriginal, Carian, Chakma, Cham, Cherokee, Common, Coptic, Cuneiform, Cypriot, Cyrillic, Deseret, Devanagari, Egyptian_Hieroglyphs, Ethiopic, Georgian, Glagolitic, Gothic, Greek, Gujarati, Gurmukhi, Han, Hangul, Hanunoo, Hebrew, Hiragana, Imperial_Aramaic, Inherited, Inscriptional_Pahlavi, Inscriptional_Parthian, Javanese, Kaithi, Kannada, Katakana, Kayah_Li, Kharoshthi, Khmer, Lao, Latin, Lepcha, Limbu, Linear_B, Lisu, Lycian, Lydian, Malayalam, Mandaic, Meetei_Mayek, Meroitic_Cursive, Meroitic_Hieroglyphs, Miao, Mongolian, Myanmar, New_Tai_Lue, Nko, Ogham, Old_Italic, Old_Persian, Old_South_Arabian, Old_Turkic, Ol_Chiki, Oriya, Osmanya, Phags_Pa, Phoenician, Rejang, Runic, Samaritan, Saurashtra, Sharada, Shavian, Sinhala, Sora_Sompeng, Sundanese, Syloti_Nagri, Syriac, Tagalog, Tagbanwa, Tai_Le, Tai_Tham, Tai_Viet, Takri, Tamil, Telugu, Thaana, Thai, Tibetan, Tifinagh, Ugaritic, Vai, Yi.

This example checks if the string consists only of Greek characters:

```
SELECT 'ΣΦΩ' RLIKE '^\\p{Greek}+$';
-> 1
```

Extended Unicode Grapheme Sequence

The `\X` escape sequence matches a character sequence that makes an "extended grapheme cluster", i.e. a composite character that consists of multiple Unicode code points.

One of the examples of a composite character can be a letter followed by non-spacing accent marks. This example demonstrates that `U+0045 LATIN CAPITAL LETTER E` followed by `U+0302 COMBINING CIRCUMFLEX ACCENT` followed by `U+0323 COMBINING DOT BELOW` together form an extended grapheme cluster:

```
SELECT _ucs2 0x004503020323 RLIKE '^\\X$';
-> 1
```

See the PCRE documentation for the other types of extended grapheme clusters.

Simple Assertions

An assertion specifies a certain condition that must match at a particular point, but without consuming characters from the subject string. In addition to the standard POSIX simple assertions `^` (that matches at the beginning of a line) and `$` (that matches at the end of a line), PCRE supports a number of other assertions:

Assertion	Description
\b	matches at a word boundary
\B	matches when not at a word boundary
\A	matches at the start of the subject
\Z	matches at the end of the subject, also matches before a newline at the end of the subject
\z	matches only at the end of the subject
\G	matches at the first matching position in the subject

This example cuts a word that consists only of 3 characters from a string:

```
SELECT REGEXP_SUBSTR('---abcd---xyz---', '\\b\\w{3}\\b');
-> xyz
```

Notice that the two `\b` assertions checked the word boundaries but did not get into the matching pattern.

The `\b` assertions work well in the beginning and the end of the subject string:

```
SELECT REGEXP_SUBSTR('xyz', '\\b\\w{3}\\b');
-> xyz
```

By default, the `^` and `$` assertions have the same meaning with `\A`, `\Z`, and `\z`. However, the meanings of `^` and `$` can change in multiline mode (see below). By contrast, the meanings of `\A`, `\Z`, and `\z` are always the same; they are independent of the multiline mode.

Option Setting

A number of options that control the default match behavior can be changed within the pattern by a sequence of option letters enclosed between `(?` and `)`.

Option	Description
(?i)	case insensitive match
(?m)	multiline mode
(?s)	dotall mode (dot matches newline characters)
(?x)	extended (ignore white space)
(?U)	ungreedy (lazy) match
(?J)	allow named subpatterns with duplicate names
(?X)	extra PCRE functionality (e.g. force error on unknown escaped character)
(?-...)	unset option(s)

For example, `(?im)` sets case insensitive multiline matching.

A hyphen followed by the option letters unset the options. For example, `(?-im)` means case sensitive single line match.

A combined setting and unsetting is also possible, e.g. `(?im-sx)`.

If an option is set outside of subpattern parentheses, the option applies to the remainder of the pattern that follows the option. If an option is set inside a subpattern, it applies to the part of this subpattern that follows the option.

In this example the pattern `(?i)m((?-i)aria)db` matches the words `MariaDB`, `Mariadb`, `mariadb`, but not `MARIADB`:

```
SELECT 'MariaDB' RLIKE '(?i)m((?-i)aria)db';
-> 1

SELECT 'mariaDB' RLIKE '(?i)m((?-i)aria)db';
-> 1

SELECT 'Mariadb' RLIKE '(?i)m((?-i)aria)db';
-> 1

SELECT 'MARIADB' RLIKE '(?i)m((?-i)aria)db';
-> 0
```

This example demonstrates that the `(?x)` option makes the regexp engine ignore all white spaces in the pattern (other than in a class).

```
SELECT 'ab' RLIKE '(?x)a b';
-> 1
```

Note, putting spaces into a pattern in combination with the (?x) option can be useful to split different logical parts of a complex pattern, to make it more readable.

Multiline Matching

Multiline matching changes the meaning of `^` and `$` from "the beginning of the subject string" and "the end of the subject string" to "the beginning of any line in the subject string" and "the end of any line in the subject string" respectively.

This example checks if the subject string contains two consequent lines that fully consist of digits:

```
SELECT 'abc\n123\n456\nxyz\n' RLIKE '(?m)^\\d+\\R\\d+$';
-> 1
```

Notice the `(?m)` option in the beginning of the pattern, which switches to the multiline matching mode.

Newline Conventions

PCRE supports five line break conventions:

- `CR (\r)` - a single carriage return character
- `LF (\n)` - a single linefeed character
- `CRLF (\r\n)` - a carriage return followed by a linefeed
- any of the previous three

- any Unicode newline sequence

By default, the newline convention is set to any Unicode newline sequence, which includes:

Sequence	Description
LF	(U+000A, carriage return)
CR	(U+000D, carriage return)
CRLF	(a carriage return followed by a linefeed)
VT	(U+000B, vertical tab)
FF	(U+000C, form feed)
NEL	(U+0085, next line)
LS	(U+2028, line separator)
PS	(U+2029, paragraph separator)

The newline convention can be set by starting a pattern with one of the following sequences:

Sequence	Description
(*CR)	carriage return
(*LF)	linefeed
(*CRLF)	carriage return followed by linefeed
(*ANYCRLF)	any of the previous three
(*ANY)	all Unicode newline sequences

The newline conversion affects the `^` and `$` assertions, the interpretation of the dot metacharacter, and the behavior of `\N`.

Note, the new line convention does not affect the meaning of `\R`.

This example demonstrates that the dot metacharacter matches `\n`, because it is not a newline sequence anymore:

```
SELECT 'a\nb' RLIKE '(*CR)a.b';
-> 1
```

Newline Sequences

By default, the escape sequence `\R` matches any Unicode newline sequences.

The meaning of `\R` can be set by starting a pattern with one of the following sequences:

Sequence	Description
(*BSR_ANYCRLF)	any of CR, LF or CRLF
(*BSR_UNICODE)	any Unicode newline sequence

Comments

It's possible to include comments inside a pattern. Comments do not participate in the pattern matching. Comments start at the `(?#` sequence and continue up to the next closing parenthesis:

```
SELECT 'ab12' RLIKE 'ab(?#expect digits)12';
-> 1
```

Quoting

POSIX uses the backslash to remove a special meaning from a character. PCRE introduces a syntax to remove special meaning from a sequence of characters. The characters inside `\Q` ... `\E` are treated literally, without their special meaning.

This example checks if the string matches a dollar sign followed by a parenthesized name (a variable reference in some languages):

```
SELECT '$(abc)' RLIKE '^\\Q$(\\E\\w+\\Q)\\E$';
-> 1
```

Note that the leftmost dollar sign and the parentheses are used literally, while the rightmost dollar sign is still used to match the end of the string.

Resetting the Match Start

The escape sequence `\K` causes any previously matched characters to be excluded from the final matched sequence. For example, the pattern: `(foo)\Kbar` matches `foobar`, but reports that it has matched `bar`. This feature is similar to a look-behind assertion. However, in this case, the part of the subject before the real match does not have to be of fixed length:

```
SELECT REGEXP_SUBSTR('aaa123', '[a-z]*\\K[0-9]*');
-> 123
```

Non-Capturing Groups

The question mark and the colon after the opening parenthesis create a non-capturing group: `(?:...)`.

This example removes an optional article from a word, for example for better sorting of the results.

```
SELECT REGEXP_REPLACE('The King','(?:the|an|a)[^a-z]([a-z]+)','\\1');
-> King
```

Note that the articles are listed inside the left parentheses using the alternation operator `|` but they do not produce a captured subpattern, so the word followed by the article is referenced by `'\1'` in the third argument to the function. Using non-capturing groups can be useful to save numbers on the sup-patterns that won't be used in the third argument of REGEXP_REPLACE(), as well as for performance purposes.

Non-Greedy Quantifiers

By default, the repetition quantifiers `?`, `*`, `+` and `{n,m}` are "greedy", that is, they try to match as much as possible. Adding a question mark after a repetition quantifier makes it "non-greedy", so the pattern matches the minimum number of times possible.

This example cuts C comments from a line:

```
SELECT REGEXP_REPLACE('/* Comment1 */ i+= 1; /* Comment2 */', '/[*].*?[*]/','');
->  i+= 1;
```

The pattern without the non-greedy flag to the quantifier `/[*].*[*]/` would match the entire string between the leftmost `/*` and the rightmost `*/`.

Atomic Groups

A sequence inside `(?>...)` makes an atomic group. Backtracking inside an atomic group is prevented once it has matched; however, backtracking past to the previous items works normally.

Consider the pattern `\d+foo` applied to the subject string `123bar`. Once the engine scans `123` and fails on the letter `b`, it would normally backtrack to `2` and try to match again, then fail and backtrack to `1` and try to match and fail again, and finally fail the entire pattern. In case of an atomic group `(?>\d+)foo` with the same subject string `123bar`, the engine gives up immediately after the first failure to match `foo`. An atomic group with a quantifier can match all or nothing.

Atomic groups produce faster false results (i.e. in case when a long subject string does not match the pattern), because the regexp engine saves performance on backtracking. However, don't hurry to put everything into atomic groups. This example demonstrates the difference between atomic and non-atomic match:

```
SELECT 'abcc' RLIKE 'a(?>bc|b)c' AS atomic1;
-> 1

SELECT 'abc' RLIKE 'a(?>bc|b)c' AS atomic2;
-> 0

SELECT 'abcc' RLIKE 'a(bc|b)c' AS non_atomic1;
-> 1

SELECT 'abc' RLIKE 'a(bc|b)c' AS non_atomic2;
-> 1
```

The non-atomic pattern matches both `abbc` and `abc`, while the atomic pattern matches `abbc` only.

The atomic group `(?>bc|b)` in the above example can be "translated" as "if there is `bc`, then don't try to match as `b`". So `b` can match only if `bc` is not found.

Atomic groups are not capturing. To make an atomic group capturing, put it into parentheses:

```
SELECT REGEXP_REPLACE('abcc','a((?>bc|b))c','\\1');
-> bc
```

Possessive quantifiers

An atomic group which ends with a quantifier can be rewritten using a so called "possessive quantifier" syntax by putting an additional `+` sign following the quantifier.

The pattern `(?>\d+)foo` from the previous section's example can be rewritten as `\d++foo`.

Absolute and Relative Numeric Backreferences

Backreferences match the same text as previously matched by a capturing group. Backreferences can be written using:

- a backslash followed by a digit
- the `\g` escape sequence followed by a positive or negative number
- the `\g` escape sequence followed by a positive or negative number enclosed in braces

The following backreferences are identical and refer to the first capturing group:

- `\1`
- `\g1`
- `\g{1}`

This example demonstrates a pattern that matches "sense and sensibility" and "response and responsibility", but not "sense and responsibility":

```
SELECT 'sense and sensibility' RLIKE '(sens|respons)e and \\1ibility';
-> 1
```

This example removes doubled words that can unintentionally creep in when you edit a text in a text editor:

```
SELECT REGEXP_REPLACE('using using the the regexp regexp',
 '\\b(\\w+)\\s+\\1\\b','\\1');
-> using the regexp
```

Note that all double words were removed, in the beginning, in the middle and in the end of the subject string.

A negative number in a `\g` sequence means a relative reference. Relative references can be helpful in long patterns, and also in patterns that are created by joining fragments together that contain references within themselves. The sequence `\g{-1}` is a reference to the most recently started capturing subpattern before `\g`.

In this example `\g{-1}` is equivalent to `\2`:

```
SELECT 'abc123def123' RLIKE '(abc(123)def)\\g{-1}';
-> 1

SELECT 'abc123def123' RLIKE '(abc(123)def)\\2';
-> 1
```

Named Subpatterns and Backreferences

Using numeric backreferences for capturing groups can be hard to track in a complicated regular expression. Also, the numbers can change if an expression is modified. To overcome these difficulties, PCRE supports named subpatterns.

A subpattern can be named in one of three ways: `(?<name> ... )` or `(?'name' ... )` as in Perl, or `(?P<name> ... )` as in Python. References to capturing subpatterns from other parts of the pattern, can be made by name as well as by number.

Backreferences to a named subpattern can be written using the .NET syntax `\k{name}`, the Perl syntax `\k<name>` or `\k'name'` or `\g{name}`, or the Python syntax `(?P=name)`.

This example tests if the string is a correct HTML tag:

```
SELECT '<a href="../">Up</a>' RLIKE '<(?<tag>[a-z][a-z0-9]*)[^>]*>[^<]*</(?P=tag)>';
-> 1
```

Positive and Negative Look-Ahead and Look-Behind Assertions

Look-ahead and look-behind assertions serve to specify the context for the searched regular expression pattern. Note that the assertions only check the context, they do not capture anything themselves!

This example finds the letter which is not followed by another letter (negative look-ahead):

```
SELECT REGEXP_SUBSTR('ab1','[a-z](?![a-z])');
-> b
```

This example finds the letter which is followed by a digit (positive look-ahead):

```
SELECT REGEXP_SUBSTR('ab1','[a-z](?=[0-9])');
-> b
```

This example finds the letter which does not follow a digit character (negative look-behind):

```
SELECT REGEXP_SUBSTR('1ab','(?<![0-9])[a-z]');
-> b
```

This example finds the letter which follows another letter character (positive look-behind):

```
SELECT REGEXP_SUBSTR('1ab','(?<=[a-z])[a-z]');
-> b
```

Note that look-behind assertions can only be of fixed length; you cannot have repetition operators or alternations with different lengths:

```
SELECT 'aaa' RLIKE '(?<=(a|bc))a';
ERROR 1139 (42000): Got error 'lookbehind assertion is not fixed length at offset 10' from regexp
```

Subroutine Reference and Recursive Patterns

PCRE supports a special syntax to recourse the entire pattern or its individual subpatterns:

Syntax	Description
(?R)	Recourse the entire pattern
(?n)	call subpattern by absolute number
(?+n)	call subpattern by relative number
(?-n)	call subpattern by relative number
(?&name)	call subpattern by name (Perl)
(?P>name)	call subpattern by name (Python)
\g<name>	call subpattern by name (Oniguruma)
\g'name'	call subpattern by name (Oniguruma)

\g<n>	call subpattern by absolute number (Oniguruma)
\g'n'	call subpattern by absolute number (Oniguruma)
\g<+n>	call subpattern by relative number
\g<-n>	call subpattern by relative number
\g'+n'	call subpattern by relative number
\g'-n'	call subpattern by relative number

This example checks for a correct additive arithmetic expression consisting of numbers, unary plus and minus, binary plus and minus, and parentheses:

```
SELECT '1+2-3+(+(4-1)+(-2)+(+1))' RLIKE  '^(([+-]?(\\d+|[(](?1)[)]))(([+-](?1))*))$';
-> 1
```

The recursion is done using `(?1)` to call for the first parenthesized subpattern, which includes everything except the leading `^` and the trailing `$`.

The regular expression in the above example implements the following BNF grammar:

1. `<expression> ::= <term> [(<sign> <term>)...]`
2. `<term> ::= [ <sign> ] <primary>`
3. `<primary> ::= <number> | <left paren> <expression> <right paren>`
4. `<sign> ::= <plus sign> | <minus sign>`

Defining Subpatterns For Use By Reference

Use the `(?(DEFINE) ... )` syntax to define subpatterns that can be referenced from elsewhere.

This example defines a subpattern with the name `letters` that matches one or more letters, which is further reused two times:

```
SELECT 'abc123xyz' RLIKE '^(?(DEFINE)(?<letters>[a-z]+))(?&letters)[0-9]+(?&letters)$';
-> 1
```

The above example can also be rewritten to define the digit part as a subpattern as well:

```
SELECT 'abc123xyz' RLIKE
 '^(?(DEFINE)(?<letters>[a-z]+)(?<digits>[0-9]+))(?&letters)(?&digits)(?&letters)$';
-> 1
```

Conditional Subpatterns

There are two forms of conditional subpatterns:

```
(?(condition)yes-pattern)
(?(condition)yes-pattern|no-pattern)
```

The `yes-pattern` is used if the condition is satisfied, otherwise the `no-pattern` (if any) is used.

Conditions With Subpattern References

If a condition consists of a number, it makes a condition with a subpattern reference. Such a condition is true if a capturing subpattern corresponding to the number has previously matched.

This example finds an optionally parenthesized number in a string:

```
SELECT REGEXP_SUBSTR('a(123)b', '([(])?[0-9]+(?(1)[)])');
-> (123)
```

The `([(])?` part makes a capturing subpattern that matches an optional opening parenthesis; the `[0-9]+` part matches a number, and the `(?(1)[)])` part matches a closing parenthesis, but only if the opening parenthesis has been previously found.

Other Kinds of Conditions

The other possible condition kinds are: recursion references and assertions. See the PCRE documentation for details.

Matching Zero Bytes (0x00)

PCRE correctly works with zero bytes in the subject strings:

```
SELECT 'a\0b' RLIKE '^a.b$';
-> 1
```

Zero bytes, however, are not supported literally in the pattern strings and should be escaped using the `\xhh` or `\x{hh}` syntax:

```
SELECT 'a\0b' RLIKE '^a\\x{00}b$';
-> 1
```

Other PCRE Features

PCRE provides other extended features that were not covered in this document, such as duplicate subpattern numbers, backtracking control, breaking utf-8 sequences into individual bytes, setting the match limit, setting the recursion limit, optimization control, recursion conditions, assertion conditions and more types of extended grapheme clusters. Please refer to the PCRE documentation for details.

Enhanced regex was implemented as a GSoC 2013 project by Sudheera Palihakkara.

default_regex_flags Examples

The default_regex_flags variable was introduced to address the remaining incompatibilities between PCRE and the old regex library. Here are some examples of its usage:

The default behaviour (multiline match is off)

```
SELECT 'a\nb\nc' RLIKE '^b$';
+----------------------------+
| '(?m)a\nb\nc' RLIKE '^b$' |
+----------------------------+
|                          0 |
+----------------------------+
```

Enabling the multiline option using the PCRE option syntax:

```
SELECT 'a\nb\nc' RLIKE '(?m)^b$';
+----------------------------+
| 'a\nb\nc' RLIKE '(?m)^b$' |
+----------------------------+
|                          1 |
+----------------------------+
```

Enabling the miltiline option using default_regex_flags

```
SET default_regex_flags='MULTILINE';
SELECT 'a\nb\nc' RLIKE '^b$';
+-----------------------+
| 'a\nb\nc' RLIKE '^b$' |
+-----------------------+
|                     1 |
+-----------------------+
```

1.2.2.1.3 NOT REGEXP

Syntax

```
expr NOT REGEXP pat, expr NOT RLIKE pat
```

Description

This is the same as NOT (expr REGEXP pat).

1.2.2.1.4 REGEXP

Syntax

```
expr REGEXP pat, expr RLIKE pat
```

Description

Performs a pattern match of a string expression `expr` against a pattern `pat`. The pattern can be an extended regular expression. See Regular Expressions Overview for details on the syntax for regular expressions (see also PCRE Regular Expressions).

Returns `1` if `expr` matches `pat` or `0` if it doesn't match. If either `expr` or `pat` are NULL, the result is NULL.

The negative form NOT REGEXP also exists, as an alias for `NOT (string REGEXP pattern)`. RLIKE and NOT RLIKE are synonyms for REGEXP and NOT REGEXP, originally provided for mSQL compatibility.

The pattern need not be a literal string. For example, it can be specified as a string expression or table column.

Note: Because MariaDB uses the C escape syntax in strings (for example, "\n" to represent the newline character), you must double any "\" that you use in your REGEXP strings.

REGEXP is not case sensitive, except when used with binary strings.

MariaDB 10.0.5 moved to the PCRE regex library - see PCRE Regular Expressions for enhancements to REGEXP introduced in MariaDB 10.0.5.

The default_regex_flags variable addresses the remaining compatibilities between PCRE and the old regex library.

Examples

```
SELECT 'Monty!' REGEXP 'm%y%%';
+-------------------------+
| 'Monty!' REGEXP 'm%y%%' |
+-------------------------+
|                       0 |
+-------------------------+

SELECT 'Monty!' REGEXP '.*';
+----------------------+
| 'Monty!' REGEXP '.*' |
+----------------------+
|                    1 |
+----------------------+

SELECT 'new*\n*line' REGEXP 'new\\*.\\*line';
+---------------------------------------+
| 'new*\n*line' REGEXP 'new\\*.\\*line' |
+---------------------------------------+
|                                     1 |
+---------------------------------------+

SELECT 'a' REGEXP 'A', 'a' REGEXP BINARY 'A';
+----------------+-----------------------+
| 'a' REGEXP 'A' | 'a' REGEXP BINARY 'A' |
+----------------+-----------------------+
|              1 |                     0 |
+----------------+-----------------------+

SELECT 'a' REGEXP '^[a-d]';
+---------------------+
| 'a' REGEXP '^[a-d]' |
+---------------------+
|                   1 |
+---------------------+
```

default_regex_flags examples

MariaDB 10.0.11 introduced the default_regex_flags variable to address the remaining compatibilities between PCRE and the old regex library.

The default behaviour (multiline match is off)

```
SELECT 'a\nb\nc' RLIKE '^b$';
+---------------------------+
| '(?m)a\nb\nc' RLIKE '^b$' |
+---------------------------+
|                         0 |
+---------------------------+
```

Enabling the multiline option using the PCRE option syntax:

```
SELECT 'a\nb\nc' RLIKE '(?m)^b$';
+---------------------------+
| 'a\nb\nc' RLIKE '(?m)^b$' |
+---------------------------+
|                         1 |
+---------------------------+
```

Enabling the multiline option using default_regex_flags

```
SET default_regex_flags='MULTILINE';
SELECT 'a\nb\nc' RLIKE '^b$';
+-----------------------+
| 'a\nb\nc' RLIKE '^b$' |
+-----------------------+
|                     1 |
+-----------------------+
```

1.2.2.1.5 REGEXP_INSTR

Syntax

```
REGEXP_INSTR(subject, pattern)
```

Returns the position of the first occurrence of the regular expression `pattern` in the string `subject`, or 0 if pattern was not found.

The positions start with 1 and are measured in characters (i.e. not in bytes), which is important for multi-byte character sets. You can cast a multi-byte character set to BINARY to get offsets in bytes.

The function follows the case sensitivity rules of the effective collation. Matching is performed case insensitively for case insensitive collations, and case sensitively for case sensitive collations and for binary data.

The collation case sensitivity can be overwritten using the (?i) and (?-i) PCRE flags.

MariaDB uses the PCRE regular expression library for enhanced regular expression performance, and REGEXP_INSTR was introduced as part of this enhancement.

Examples

```
SELECT REGEXP_INSTR('abc','b');
-> 2

SELECT REGEXP_INSTR('abc','x');
-> 0

SELECT REGEXP_INSTR('BJÖRN','N');
-> 5
```

Casting a multi-byte character set as BINARY to get offsets in bytes:

```
SELECT REGEXP_INSTR(BINARY 'BJÖRN','N') AS cast_utf8_to_binary;
-> 6
```

Case sensitivity:

```
SELECT REGEXP_INSTR('ABC','b');
-> 2

SELECT REGEXP_INSTR('ABC' COLLATE utf8_bin,'b');
-> 0

SELECT REGEXP_INSTR(BINARY'ABC','b');
-> 0

SELECT REGEXP_INSTR('ABC','(?-i)b');
-> 0

SELECT REGEXP_INSTR('ABC' COLLATE utf8_bin,'(?i)b');
-> 2
```

1.2.2.1.6 REGEXP_REPLACE

Syntax

```
REGEXP_REPLACE(subject, pattern, replace)
```

Description

`REGEXP_REPLACE` returns the string `subject` with all occurrences of the regular expression `pattern` replaced by the string `replace`. If no occurrences are found, then `subject` is returned as is.

The replace string can have backreferences to the subexpressions in the form \N, where N is a number from 1 to 9.

The function follows the case sensitivity rules of the effective collation. Matching is performed case insensitively for case insensitive collations, and case sensitively for case sensitive collations and for binary data.

The collation case sensitivity can be overwritten using the (?i) and (?-i) PCRE flags.

MariaDB uses the PCRE regular expression library for enhanced regular expression performance, and `REGEXP_REPLACE` was introduced as part of this enhancement.

The default_regex_flags variable addresses the remaining compatibilities between PCRE and the old regex library.

Examples

```
SELECT REGEXP_REPLACE('ab12cd','[0-9]','') AS remove_digits;
-> abcd

SELECT REGEXP_REPLACE('<html><head><title>title</title><body>body</body></htm>', '<.+?>',' ')
AS strip_html;
-> title  body
```

Backreferences to the subexpressions in the form `\N`, where N is a number from 1 to 9:

```
SELECT REGEXP_REPLACE('James Bond','^(.*) (.*)$','\\2, \\1') AS reorder_name;
-> Bond, James
```

Case insensitive and case sensitive matches:

```
SELECT REGEXP_REPLACE('ABC','b','-') AS case_insensitive;
-> A-C

SELECT REGEXP_REPLACE('ABC' COLLATE utf8_bin,'b','-') AS case_sensitive;
-> ABC

SELECT REGEXP_REPLACE(BINARY 'ABC','b','-') AS binary_data;
-> ABC
```

Overwriting the collation case sensitivity using the (?i) and (?-i) PCRE flags.

```
SELECT REGEXP_REPLACE('ABC','(?-i)b','-') AS force_case_sensitive;
-> ABC

SELECT REGEXP_REPLACE(BINARY 'ABC','(?i)b','-') AS force_case_insensitive;
-> A-C
```

1.2.2.1.7 REGEXP_SUBSTR

Syntax

```
REGEXP_SUBSTR(subject,pattern)
```

Description

Returns the part of the string `subject` that matches the regular expression `pattern`, or an empty string if `pattern` was not found.

The function follows the case sensitivity rules of the effective collation. Matching is performed case insensitively for case insensitive collations, and case sensitively for case sensitive collations and for binary data.

The collation case sensitivity can be overwritten using the (?i) and (?-i) PCRE flags.

MariaDB uses the PCRE regular expression library for enhanced regular expression performance, and `REGEXP_SUBSTR`

was introduced as part of this enhancement.

The default_regex_flags variable addresses the remaining compatibilities between PCRE and the old regex library.

Examples

```
SELECT REGEXP_SUBSTR('ab12cd','[0-9]+');
-> 12

SELECT REGEXP_SUBSTR(
  'See https://mariadb.org/en/foundation/ for details',
  'https?://[^/]*');
-> https://mariadb.org
```

```
SELECT REGEXP_SUBSTR('ABC','b');
-> B

SELECT REGEXP_SUBSTR('ABC' COLLATE utf8_bin,'b');
->

SELECT REGEXP_SUBSTR(BINARY'ABC','b');
->

SELECT REGEXP_SUBSTR('ABC','(?i)b');
-> B

SELECT REGEXP_SUBSTR('ABC' COLLATE utf8_bin,'(?+i)b');
-> B
```

1.2.2.1.8 RLIKE

Syntax

```
expr REGEXP pat, expr RLIKE pat
```

Description

`RLIKE` is a synonym for REGEXP.

1.2.2.2 Dynamic Columns Functions

Dynamic columns is a feature that allows one to store different sets of columns for each row in a table. It works by storing a set of columns in a blob and having a small set of functions to manipulate it.

COLUMN_ADD

Adds or updates dynamic columns.

COLUMN_CHECK

Checks if a dynamic column blob is valid

COLUMN_CREATE

Returns a dynamic columns blob.

COLUMN_DELETE

Deletes a dynamic column.

COLUMN_EXISTS

Checks is a column exists.

COLUMN_GET

Gets a dynamic column value by name.

COLUMN_JSON

Returns a JSON representation of dynamic column blob data

COLUMN_LIST

Returns comma-separated list of columns names.

1.2.2.2.1 COLUMN_ADD

Syntax

```
COLUMN_ADD(dyncol_blob, column_nr, value [as type], [column_nr, value [as type]]...);
COLUMN_ADD(dyncol_blob, column_name, value [as type], [column_name, value [as type]]...);
```

Description

Adds or updates dynamic columns.

- **`dyncol_blob`** must be either a valid dynamic columns blob (for example, `COLUMN_CREATE` returns such blob), or an empty string.
- **`column_name`** specifies the name of the column to be added. If `dyncol_blob` already has a column with this name, it will be overwritten.
- **`value`** specifies the new value for the column. Passing a NULL value will cause the column to be deleted.
- **`as type`** is optional. See #datatypes section for a discussion about types.

The return value is a dynamic column blob after the modifications.

Examples

```
UPDATE t1 SET dyncol_blob=COLUMN_ADD(dyncol_blob, "column_name", "value") WHERE id=1;
```

Note: `COLUMN_ADD()` is a regular function (just like `CONCAT()`), hence, in order to update the value in the table you have to use the `UPDATE ... SET dynamic_col=COLUMN_ADD(dynamic_col, ....)` pattern.

1.2.2.2.2 COLUMN_CHECK

Syntax

```
COLUMN_CHECK(dyncol_blob);
```

Description

Check if `dyncol_blob` is a valid packed dynamic columns blob. Return value of 1 means the blob is valid, return value of 0 means it is not.

Rationale: Normally, one works with valid dynamic column blobs. Functions like COLUMN_CREATE, COLUMN_ADD, COLUMN_DELETE always return valid dynamic column blobs. However, if a dynamic column blob is accidentally truncated, or transcoded from one character set to another, it will be corrupted. This function can be used to check if a value in a blob field is a valid dynamic column blob.

1.2.2.2.3 COLUMN_CREATE

Syntax

```
COLUMN_CREATE(column_nr, value [as type], [column_nr, value [as type]]...);
COLUMN_CREATE(column_name, value [as type], [column_name, value [as type]]...);
```

Description

Returns a dynamic columns blob that stores the specified columns with values.

The return value is suitable for

- storing in a table
- further modification with other dynamic columns functions

The `as type` part allows one to specify the value type. In most cases, this is redundant because MariaDB will be able to deduce the type of the value. Explicit type specification may be needed when the type of the value is not apparent. For example, a literal `'2012-12-01'` has a CHAR type by default, one will need to specify `'2012-12-01' AS DATE` to have it stored as a date. See Dynamic Columns:Datatypes for further details.

Examples

```
INSERT INTO tbl SET dyncol_blob=COLUMN_CREATE("column_name", "value");
```

1.2.2.2.4 COLUMN_DELETE

Syntax

```
COLUMN_DELETE(dyncol_blob, column_nr, column_nr...);
COLUMN_DELETE(dyncol_blob, column_name, column_name...);
```

Description

Deletes a dynamic column with the specified name. Multiple names can be given. The return value is a dynamic column blob after the modification.

1.2.2.2.5 COLUMN_EXISTS

Syntax

```
COLUMN_EXISTS(dyncol_blob, column_nr);
COLUMN_EXISTS(dyncol_blob, column_name);
```

Description

Checks if a column with name `column_name` exists in `dyncol_blob`. If yes, return `1`, otherwise return `0`. See dynamic columns for more information.

1.2.2.2.6 COLUMN_GET

Syntax

```
COLUMN_GET(dyncol_blob, column_nr as type);
COLUMN_GET(dyncol_blob, column_name as type);
```

Description

Gets the value of a dynamic column by its name. If no column with the given name exists, `NULL` will be returned.

`column_name as type` requires that one specify the datatype of the dynamic column they are reading.

This may seem counter-intuitive: why would one need to specify which datatype they're retrieving? Can't the dynamic columns system figure the datatype from the data being stored?

The answer is: SQL is a statically-typed language. The SQL interpreter needs to know the datatypes of all expressions before the query is run (for example, when one is using prepared statements and runs `"select COLUMN_GET(...)"`, the prepared statement API requires the server to inform the client about the datatype of the column being read before the query is executed and the server can see what datatype the column actually has).

Lengths

If you're running queries like:

```
SELECT COLUMN_GET(blob, 'colname' as CHAR) ...
```

without specifying a maximum length (i.e. using `as CHAR`, not `as CHAR(n)`), MariaDB will report the maximum length of the resultset column to be 16,777,216. This may cause excessive memory usage in some client libraries, because they try to pre-allocate a buffer of maximum resultset width. To avoid this problem, use CHAR(n) whenever you're using COLUMN_GET in the select list.

See Dynamic Columns:Datatypes for more information about datatypes.

1.2.2.2.7 COLUMN_JSON

Syntax

```
COLUMN_JSON(dyncol_blob)
```

Description

Returns a JSON representation of data in `dyncol_blob`. Can also be used to display nested columns. See dynamic columns for more information.

Example

```
select item_name, COLUMN_JSON(dynamic_cols) from assets;
+-----------------+-----------------------------------------+
| item_name       | COLUMN_JSON(dynamic_cols)               |
+-----------------+-----------------------------------------+
| MariaDB T-shirt | {"size":"XL","color":"blue"}            |
| Thinkpad Laptop | {"color":"black","warranty":"3 years"} |
+-----------------+-----------------------------------------+
```

Limitation: `COLUMN_JSON` will decode nested dynamic columns at a nesting level of not more than 10 levels deep. Dynamic columns that are nested deeper than 10 levels will be shown as BINARY string, without encoding.

1.2.2.2.8 COLUMN_LIST

Syntax

```
COLUMN_LIST(dyncol_blob);
```

Description

Returns a comma-separated list of column names. The names are quoted with backticks.

See dynamic columns for more information.

1.2.2.3 ASCII

Syntax

```
ASCII(str)
```

Description

Returns the numeric ASCII value of the leftmost character of the string argument. Returns `0` if the given string is empty and `NULL` if it is `NULL`.

`ASCII()` works for 8-bit characters.

Examples

```
SELECT ASCII(9);
+----------+
| ASCII(9) |
+----------+
|       57 |
+----------+

SELECT ASCII('9');
+------------+
| ASCII('9') |
+------------+
|         57 |
+------------+

SELECT ASCII('abc');
+--------------+
| ASCII('abc') |
+--------------+
|           97 |
+--------------+
```

1.2.2.4 BIN

Syntax

```
BIN(N)
```

Description

Returns a string representation of the binary value of the given longlong (that is, `BIGINT`) number. This is equivalent to `CONV(N,10,2)`. The argument should be positive. If it is a `FLOAT`, it will be truncated. Returns `NULL` if the argument is `NULL`.

Examples

```
SELECT BIN(12);
+---------+
| BIN(12) |
+---------+
| 1100    |
+---------+
```

1.2.2.5 BINARY Operator

This page describes the BINARY operator. For details about the data type, see Binary Data Type.

Syntax

```
BINARY
```

Description

The `BINARY` operator casts the string following it to a binary string. This is an easy way to force a column comparison to be done byte by byte rather than character by character. This causes the comparison to be case sensitive even if the column isn't defined as `BINARY` or `BLOB`.

`BINARY` also causes trailing spaces to be significant.

Examples

```
SELECT 'a' = 'A';
+-----------+
| 'a' = 'A' |
+-----------+
|         1 |
+-----------+

SELECT BINARY 'a' = 'A';
+------------------+
| BINARY 'a' = 'A' |
+------------------+
|                0 |
+------------------+

SELECT 'a' = 'a ';
+------------+
| 'a' = 'a ' |
+------------+
|          1 |
+------------+

SELECT BINARY 'a' = 'a ';
+-------------------+
| BINARY 'a' = 'a ' |
+-------------------+
|                 0 |
+-------------------+
```

1.2.2.6 BIT_LENGTH

Syntax

```
BIT_LENGTH(str)
```

Contents

Description

Returns the length of the given string argument in bits. If the argument is not a string, it will be converted to string. If the argument is `NULL`, it returns `NULL`.

Examples

```
SELECT BIT_LENGTH('text');
+--------------------+
| BIT_LENGTH('text') |
+--------------------+
|                 32 |
+--------------------+
```

```
SELECT BIT_LENGTH('');
+----------------+
| BIT_LENGTH('') |
+----------------+
|              0 |
+----------------+
```

Compatibility

PostgreSQL and Sybase support BIT_LENGTH().

1.2.2.7 CAST

Syntax

```
CAST(expr AS type)
```

Contents

Description

The `CAST()` function takes a value of one type and produces a value of another type, similar to the CONVERT() function.

The type can be one of the following values:

- BINARY
- CHAR
- DATE
- DATETIME
- DECIMAL[(M[,D])]
- DOUBLE
- FLOAT (from MariaDB 10.4.5)
- INTEGER
  - Short for `SIGNED INTEGER`
- SIGNED [INTEGER]
- UNSIGNED [INTEGER]
- TIME
- VARCHAR (in Oracle mode, from MariaDB 10.3)

The main difference between `CAST` and CONVERT() is that `CONVERT(expr,type)` is ODBC syntax while `CAST(expr as type)` and `CONVERT(... USING ...)` are SQL92 syntax.

In MariaDB 10.4 and later, you can use the `CAST()` function with the `INTERVAL` keyword.

Until MariaDB 5.5.31, `X'HHHH'`, the standard SQL syntax for binary string literals, erroneously worked in the same way as `0xHHHH`. In 5.5.31 it was intentionally changed to behave as a string in all contexts (and never as a number).

This introduced an incompatibility with previous versions of MariaDB, and all versions of MySQL (see the example below).

Examples

Simple casts:

```
SELECT CAST("abc" AS BINARY);
SELECT CAST("1" AS UNSIGNED INTEGER);
SELECT CAST(123 AS CHAR CHARACTER SET utf8)
```

Note that when one casts to CHAR without specifying the character set, the collation_connection character set collation will be used. When used with `CHAR CHARACTER SET`, the default collation for that character set will be used.

```
SELECT COLLATION(CAST(123 AS CHAR));
+-----------------------------+
| COLLATION(CAST(123 AS CHAR)) |
+-----------------------------+
| latin1_swedish_ci           |
+-----------------------------+

SELECT COLLATION(CAST(123 AS CHAR CHARACTER SET utf8));
+-----------------------------------------------+
| COLLATION(CAST(123 AS CHAR CHARACTER SET utf8)) |
+-----------------------------------------------+
| utf8_general_ci                               |
+-----------------------------------------------+
```

If you also want to change the collation, you have to use the `COLLATE` operator:

```
SELECT COLLATION(CAST(123 AS CHAR CHARACTER SET utf8)
  COLLATE utf8_unicode_ci);
+-----------------------------------------------------------------------------+
| COLLATION(CAST(123 AS CHAR CHARACTER SET utf8) COLLATE utf8_unicode_ci) |
+-----------------------------------------------------------------------------+
| utf8_unicode_ci                                                             |
+-----------------------------------------------------------------------------+
```

Using `CAST()` to order an `ENUM` field as a `CHAR` rather than the internal numerical value:

```
CREATE TABLE enum_list (enum_field enum('c','a','b'));

INSERT INTO enum_list (enum_field)
VALUES('c'),('a'),('c'),('b');

SELECT * FROM enum_list
ORDER BY enum_field;
+------------+
| enum_field |
+------------+
| c          |
| c          |
| a          |
| b          |
+------------+

SELECT * FROM enum_list
ORDER BY CAST(enum_field AS CHAR);
+------------+
| enum_field |
+------------+
| a          |
| b          |
| c          |
| c          |
+------------+
```

From MariaDB 5.5.31, the following will trigger warnings, since `x'aa'` and `'X'aa'` no longer behave as a number. Previously, and in all versions of MySQL, no warnings are triggered since they did erroneously behave as a number:

```
SELECT CAST(0xAA AS UNSIGNED), CAST(x'aa' AS UNSIGNED), CAST(X'aa' AS UNSIGNED);
+------------------------+-------------------------+-------------------------+
| CAST(0xAA AS UNSIGNED) | CAST(x'aa' AS UNSIGNED) | CAST(X'aa' AS UNSIGNED) |
+------------------------+-------------------------+-------------------------+
|                    170 |                       0 |                       0 |
+------------------------+-------------------------+-------------------------+
1 row in set, 2 warnings (0.00 sec)

Warning (Code 1292): Truncated incorrect INTEGER value: '\xAA'
Warning (Code 1292): Truncated incorrect INTEGER value: '\xAA'
```

Casting to intervals:

```
SELECT CAST(2019-01-04 INTERVAL AS DAY_SECOND(2)) AS "Cast";

+-------------+
| Cast        |
+-------------+
| 00:20:17.00 |
+-------------+
```

1.2.2.8 CHAR Function

Syntax

```
CHAR(N,... [USING charset_name])
```

Description

`CHAR()` interprets each argument as an `INT` and returns a string consisting of the characters given by the code values of those integers. `NULL` values are skipped. By default, `CHAR()` returns a binary string. To produce a string in a given character set, use the optional `USING` clause:

```
SELECT CHARSET(CHAR(0x65)), CHARSET(CHAR(0x65 USING utf8));
+---------------------+-------------------------------+
| CHARSET(CHAR(0x65)) | CHARSET(CHAR(0x65 USING utf8)) |
+---------------------+-------------------------------+
| binary              | utf8                          |
+---------------------+-------------------------------+
```

If `USING` is given and the result string is illegal for the given character set, a warning is issued. Also, if strict SQL mode is enabled, the result from `CHAR()` becomes `NULL`.

Examples

```
SELECT CHAR(77,97,114,'105',97,'68',66);
+----------------------------------+
| CHAR(77,97,114,'105',97,'68',66) |
+----------------------------------+
| MariaDB                          |
+----------------------------------+

SELECT CHAR(77,77.3,'77.3');
+----------------------+
| CHAR(77,77.3,'77.3') |
+----------------------+
| MMM                  |
+----------------------+
1 row in set, 1 warning (0.00 sec)

Warning (Code 1292): Truncated incorrect INTEGER value: '77.3'
```

1.2.2.9 CHAR_LENGTH

Syntax

```
CHAR_LENGTH(str)
CHARACTER_LENGTH(str)
```

Contents

Description

Returns the length of the given string argument, measured in characters. A multi-byte character counts as a single character. This means that for a string containing five two-byte characters, LENGTH() (or OCTET_LENGTH() in Oracle mode) returns 10, whereas `CHAR_LENGTH()` returns 5. If the argument is `NULL`, it returns `NULL`.

If the argument is not a string value, it is converted into a string.

It is synonymous with the `CHARACTER_LENGTH()` function.

Examples

```
SELECT CHAR_LENGTH('MariaDB');
+------------------------+
| CHAR_LENGTH('MariaDB') |
+------------------------+
|                      7 |
+------------------------+
```

When Oracle mode from MariaDB 10.3 is not set:

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');
+--------------------+--------------+---------------+--------------------+
| CHAR_LENGTH('π')   | LENGTH('π')  | LENGTHB('π')  | OCTET_LENGTH('π')  |
+--------------------+--------------+---------------+--------------------+
|                  1 |            2 |             2 |                  2 |
+--------------------+--------------+---------------+--------------------+
```

In Oracle mode from MariaDB 10.3:

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');
+--------------------+--------------+---------------+--------------------+
| CHAR_LENGTH('π')   | LENGTH('π')  | LENGTHB('π')  | OCTET_LENGTH('π')  |
+--------------------+--------------+---------------+--------------------+
|                  1 |            1 |             2 |                  2 |
+--------------------+--------------+---------------+--------------------+
```

1.2.2.10 CHARACTER_LENGTH

Syntax

```
CHARACTER_LENGTH(str)
```

Description

`CHARACTER_LENGTH()` is a synonym for `CHAR_LENGTH()`.

1.2.2.11 CHR

Syntax

```
CHR(N)
```

Description

`CHR()` interprets each argument N as an integer and returns a `VARCHAR(1)` string consisting of the character given by the code values of the integer. The character set and collation of the string are set according to the values of the `character_set_database` and `collation_database` system variables.

`CHR()` is similar to the `CHAR()` function, but only accepts a single argument.

`CHR()` is available in all sql_modes.

Examples

```
SELECT CHR(67);
+---------+
| CHR(67) |
+---------+
| C       |
+---------+

SELECT CHR('67');
+-----------+
| CHR('67') |
+-----------+
| C         |
+-----------+

SELECT CHR('C');
+----------+
| CHR('C') |
+----------+
|          |
+----------+
1 row in set, 1 warning (0.000 sec)

SHOW WARNINGS;
+---------+------+----------------------------------------+
| Level   | Code | Message                                |
+---------+------+----------------------------------------+
| Warning | 1292 | Truncated incorrect INTEGER value: 'C' |
+---------+------+----------------------------------------+
```

1.2.2.12 CONCAT

Syntax

```
CONCAT(str1,str2,...)
```

Contents

Description

Returns the string that results from concatenating the arguments. May have one or more arguments. If all arguments are non-binary strings, the result is a non-binary string. If the arguments include any binary strings, the result is a binary string. A numeric argument is converted to its equivalent binary string form; if you want to avoid that, you can use an explicit type cast, as in this example:

```
SELECT CONCAT(CAST(int_col AS CHAR), char_col);
```

`CONCAT()` returns `NULL` if any argument is `NULL`.

A `NULL` parameter hides all information contained in other parameters from the result. Sometimes this is not desirable; to avoid this, you can:

- Use the `CONCAT_WS()` function with an empty separator, because that function is `NULL`-safe.
- Use `IFNULL()` to turn NULLs into empty strings.

Oracle Mode

In Oracle mode, `CONCAT` ignores NULL.

Examples

```
SELECT CONCAT('Ma', 'ria', 'DB');
+--------------------------+
| CONCAT('Ma', 'ria', 'DB') |
+--------------------------+
| MariaDB                  |
+--------------------------+

SELECT CONCAT('Ma', 'ria', NULL, 'DB');
+---------------------------------+
| CONCAT('Ma', 'ria', NULL, 'DB') |
+---------------------------------+
| NULL                            |
+---------------------------------+

SELECT CONCAT(42.0);
+-------------+
| CONCAT(42.0) |
+-------------+
| 42.0         |
+-------------+
```

Using `IFNULL()` to handle NULLs:

```
SELECT CONCAT('The value of @v is: ', IFNULL(@v, ''));
+-----------------------------------------------+
| CONCAT('The value of @v is: ', IFNULL(@v, '')) |
+-----------------------------------------------+
| The value of @v is:                           |
+-----------------------------------------------+
```

In Oracle mode, from MariaDB 10.3:

```
SELECT CONCAT('Ma', 'ria', NULL, 'DB');
+---------------------------------+
| CONCAT('Ma', 'ria', NULL, 'DB') |
+---------------------------------+
| MariaDB                         |
+---------------------------------+
```

1.2.2.13 CONCAT_WS

Syntax

```
CONCAT_WS(separator,str1,str2,...)
```

Description

`CONCAT_WS()` stands for Concatenate With Separator and is a special form of `CONCAT()`. The first argument is the separator for the rest of the arguments. The separator is added between the strings to be concatenated. The separator can be a string, as can the rest of the arguments.

If the separator is `NULL`, the result is `NULL`; all other `NULL` values are skipped. This makes `CONCAT_WS()` suitable when you want to concatenate some values and avoid losing all information if one of them is `NULL`.

Examples

```
SELECT CONCAT_WS(',','First name','Second name','Last Name');
+----------------------------------------------------+
| CONCAT_WS(',','First name','Second name','Last Name') |
+----------------------------------------------------+
| First name,Second name,Last Name                   |
+----------------------------------------------------+

SELECT CONCAT_WS('-','Floor',NULL,'Room');
+-----------------------------------+
| CONCAT_WS('-','Floor',NULL,'Room') |
+-----------------------------------+
| Floor-Room                        |
+-----------------------------------+
```

In some cases, remember to include a space in the separator string:

```
SET @a = 'gnu', @b = 'penguin', @c = 'sea lion';
Query OK, 0 rows affected (0.00 sec)

SELECT CONCAT_WS(', ', @a, @b, @c);
+-----------------------------+
| CONCAT_WS(', ', @a, @b, @c) |
+-----------------------------+
| gnu, penguin, sea lion      |
+-----------------------------+
```

Using `CONCAT_WS()` to handle `NULL`s:

```
SET @a = 'a', @b = NULL, @c = 'c';

SELECT CONCAT_WS('', @a, @b, @c);
+--------------------------+
| CONCAT_WS('', @a, @b, @c) |
+--------------------------+
| ac                       |
+--------------------------+
```

1.2.2.14 CONVERT

Syntax

```
CONVERT(expr,type), CONVERT(expr USING transcoding_name)
```

Contents

Description

The `CONVERT()` and CAST() functions take a value of one type and produce a value of another type.

The type can be one of the following values:

- BINARY
- CHAR
- DATE
- DATETIME
- DECIMAL[(M[,D])]
- DOUBLE
- FLOAT (from MariaDB 10.4.5)
- INTEGER
  - Short for `SIGNED INTEGER`
- SIGNED [INTEGER]
- UNSIGNED [INTEGER]
- TIME
- VARCHAR (in Oracle mode, from MariaDB 10.3)

Note that in MariaDB, `INT` and `INTEGER` are the same thing.

`BINARY` produces a string with the BINARY data type. If the optional length is given, `BINARY(N)` causes the cast to use no more than `N` bytes of the argument. Values shorter than the given number in bytes are padded with 0x00 bytes to make them equal the length value.

`CHAR(N)` causes the cast to use no more than the number of characters given in the argument.

The main difference between the CAST() and `CONVERT()` is that `CONVERT(expr,type)` is ODBC syntax while CAST(expr as type) and `CONVERT(... USING ...)` are SQL92 syntax.

`CONVERT()` with `USING` is used to convert data between different character sets. In MariaDB, transcoding names are the same as the corresponding character set names. For example, this statement converts the string 'abc' in the default character set to the corresponding string in the utf8 character set:

```
SELECT CONVERT('abc' USING utf8);
```

Examples

```
SELECT enum_col FROM tbl_name
ORDER BY CAST(enum_col AS CHAR);
```

Converting a BINARY to string to permit the LOWER function to work:

```
SET @x = 'AardVark';

SET @x = BINARY 'AardVark';

SELECT LOWER(@x), LOWER(CONVERT (@x USING latin1));
+-----------+-----------------------------------+
| LOWER(@x) | LOWER(CONVERT (@x USING latin1)) |
+-----------+-----------------------------------+
| AardVark  | aardvark                          |
+-----------+-----------------------------------+
```

1.2.2.15 ELT

Syntax

```
ELT(N, str1[, str2, str3,...])
```

Description

Takes a numeric argument and a series of string arguments. Returns the string that corresponds to the given numeric position. For instance, it returns `str1` if `N` is 1, `str2` if `N` is 2, and so on. If the numeric argument is a `FLOAT`, MariaDB rounds it to the nearest `INTEGER`. If the numeric argument is less than 1, greater than the total number of arguments, or not a number, `ELT()` returns `NULL`. It must have at least two arguments.

It is complementary to the `FIELD()` function.

Examples

```
SELECT ELT(1, 'ej', 'Heja', 'hej', 'foo');
+----------------------------------+
| ELT(1, 'ej', 'Heja', 'hej', 'foo') |
+----------------------------------+
| ej                               |
+----------------------------------+

SELECT ELT(4, 'ej', 'Heja', 'hej', 'foo');
+----------------------------------+
| ELT(4, 'ej', 'Heja', 'hej', 'foo') |
+----------------------------------+
| foo                              |
+----------------------------------+
```

1.2.2.16 EXPORT_SET

Syntax

```
EXPORT_SET(bits, on, off[, separator[, number_of_bits]])
```

Description

Takes a minimum of three arguments. Returns a string where each bit in the given `bits` argument is returned, with the string values given for `on` and `off`.

Bits are examined from right to left, (from low-order to high-order bits). Strings are added to the result from left to right, separated by a separator string (defaults as ' , '). You can optionally limit the number of bits the `EXPORT_SET()` function examines using the `number_of_bits` option.

If any of the arguments are set as `NULL`, the function returns `NULL`.

Examples

```
SELECT EXPORT_SET(5,'Y','N',',',4);
+-----------------------------+
| EXPORT_SET(5,'Y','N',',',4) |
+-----------------------------+
| Y,N,Y,N                     |
+-----------------------------+

SELECT EXPORT_SET(6,'1','0',',',10);
+------------------------------+
| EXPORT_SET(6,'1','0',',',10) |
+------------------------------+
| 0,1,1,0,0,0,0,0,0,0          |
+------------------------------+
```

1.2.2.17 EXTRACTVALUE

Syntax

```
EXTRACTVALUE(xml_frag, xpath_expr)
```

Contents

Description

The `EXTRACTVALUE()` function takes two string arguments: a fragment of XML markup and an XPath expression, (also known as a locator). It returns the text (That is, CDDATA), of the first text node which is a child of the element or elements matching the XPath expression.

In cases where a valid XPath expression does not match any text nodes in a valid XML fragment, (including the implicit `/text()` expression), the `EXTRACTVALUE()` function returns an empty string.

Invalid Arguments

When either the XML fragment or the XPath expression is `NULL`, the `EXTRACTVALUE()` function returns `NULL`. When the XML fragment is invalid, it raises a warning Code 1525:

```
Warning (Code 1525): Incorrect XML value: 'parse error at line 1 pos 11: unexpected END-OF-
INPUT'
```

When the XPath value is invalid, it generates an Error 1105:

```
ERROR 1105 (HY000): XPATH syntax error: ')'
```

Explicit text() Expressions

This function is the equivalent of performing a match using the XPath expression after appending `/text()`. In other words:

```
SELECT
   EXTRACTVALUE('<cases><case>example</case></cases>', '/cases/case')
    AS 'Base Example',
   EXTRACTVALUE('<cases><case>example</case></cases>', '/cases/case/text()')
    AS 'text() Example';
+--------------+----------------+
| Base Example | text() Example |
+--------------+----------------+
| example      | example        |
+--------------+----------------+
```

Count Matches

When `EXTRACTVALUE()` returns multiple matches, it returns the content of the first child text node of each matching element, in the matched order, as a single, space-delimited string.

By design, the `EXTRACTVALUE()` function makes no distinction between a match on an empty element and no match at all. If you need to determine whether no matching element was found in the XML fragment or if an element was found that contained no child text nodes, use the XPath `count()` function.

For instance, when looking for a value that exists, but contains no child text nodes, you would get a count of the number of matching instances:

```
SELECT
   EXTRACTVALUE('<cases><case/></cases>', '/cases/case')
    AS 'Empty Example',
   EXTRACTVALUE('<cases><case/></cases>', 'count(/cases/case)')
    AS 'count() Example';
+---------------+-----------------+
| Empty Example | count() Example |
+---------------+-----------------+
|               |               1 |
+---------------+-----------------+
```

Alternatively, when looking for a value that doesn't exist, `count()` returns 0.

```
SELECT
   EXTRACTVALUE('<cases><case/></cases>', '/cases/person')
    AS 'No Match Example',
   EXTRACTVALUE('<cases><case/></cases>', 'count(/cases/person)')
    AS 'count() Example';
+------------------+-----------------+
| No Match Example | count() Example |
+------------------+-----------------+
|                  |               0|
+------------------+-----------------+
```

Matches

Important: The `EXTRACTVALUE()` function only returns CDDATA. It does not return tags that the element might contain or the text that these child elements contain.

```
SELECT
  EXTRACTVALUE('<cases><case>Person<email>x@example.com</email></case></cases>', '/cases')
   AS Case;
+--------+
| Case   |
+--------+
| Person |
+--------+
```

Note, in the above example, while the XPath expression matches to the parent `<case>` instance, it does not return the contained `<email>` tag or its content.

Examples

```
SELECT
    ExtractValue('<a>ccc<b>ddd</b></a>', '/a')            AS val1,
    ExtractValue('<a>ccc<b>ddd</b></a>', '/a/b')          AS val2,
    ExtractValue('<a>ccc<b>ddd</b></a>', '//b')           AS val3,
    ExtractValue('<a>ccc<b>ddd</b></a>', '/b')            AS val4,
    ExtractValue('<a>ccc<b>ddd</b><b>eee</b></a>', '//b') AS val5;
+------+------+------+------+---------+
| val1 | val2 | val3 | val4 | val5    |
+------+------+------+------+---------+
| ccc  | ddd  | ddd  |      | ddd eee |
+------+------+------+------+---------+
```

1.2.2.18 FIELD

Syntax

```
FIELD(pattern, str1[,str2,...])
```

Description

Returns the index position of the string or number matching the given pattern. Returns `0` in the event that none of the arguments match the pattern. Raises an Error 1582 if not given at least two arguments.

When all arguments given to the `FIELD()` function are strings, they are treated as case-insensitive. When all the arguments are numbers, they are treated as numbers. Otherwise, they are treated as doubles.

If the given pattern occurs more than once, the `FIELD()` function only returns the index of the first instance. If the given pattern is `NULL`, the function returns `0`, as a `NULL` pattern always fails to match.

This function is complementary to the `ELT()` function.

Examples

```
SELECT FIELD('ej', 'Hej', 'ej', 'Heja', 'hej', 'foo')
   AS 'Field Results';
+---------------+
| Field Results |
+---------------+
|             2 |
+---------------+

SELECT FIELD('fo', 'Hej', 'ej', 'Heja', 'hej', 'foo')
   AS 'Field Results';
+---------------+
| Field Results |
+---------------+
|             0 |
+---------------+

SELECT FIELD(1, 2, 3, 4, 5, 1) AS 'Field Results';
+---------------+
| Field Results |
+---------------+
|             5 |
+---------------+

SELECT FIELD(NULL, 2, 3) AS 'Field Results';
+---------------+
| Field Results |
+---------------+
|             0 |
+---------------+

SELECT FIELD('fail') AS 'Field Results';
Error 1582 (42000): Incorrect parameter count in call
to native function 'field'
```

1.2.2.19 FIND_IN_SET

Syntax

```
FIND_IN_SET(pattern, strlist)
```

Description

Returns the index position where the given pattern occurs in a string list. The first argument is the pattern you want to search for. The second argument is a string containing comma-separated variables. If the second argument is of the `SET` data-type, the function is optimized to use bit arithmetic.

If the pattern does not occur in the string list or if the string list is an empty string, the function returns `0`. If either argument is `NULL`, the function returns `NULL`. The function does not return the correct result if the pattern contains a comma (" , ") character.

Examples

```
SELECT FIND_IN_SET('b','a,b,c,d') AS "Found Results";
+---------------+
| Found Results |
+---------------+
|             2 |
+---------------+
```

1.2.2.20 FORMAT

Syntax

```
FORMAT(num, decimal_position[, locale])
```

Description

Formats the given number for display as a string, adding separators to appropriate position and rounding the results to the given decimal position. For instance, it would format `15233.345` to `15,233.35`.

If the given decimal position is `0`, it rounds to return no decimal point or fractional part. You can optionally specify a locale value to format numbers to the pattern appropriate for the given region.

Examples

```
SELECT FORMAT(1234567890.09876543210, 4) AS 'Format';
+--------------------+
| Format             |
+--------------------+
| 1,234,567,890.0988 |
+--------------------+

SELECT FORMAT(1234567.89, 4) AS 'Format';
+----------------+
| Format         |
+----------------+
| 1,234,567.8900 |
+----------------+

SELECT FORMAT(1234567.89, 0) AS 'Format';
+-----------+
| Format    |
+-----------+
| 1,234,568 |
+-----------+

SELECT FORMAT(123456789,2,'rm_CH') AS 'Format';
+----------------+
| Format         |
+----------------+
| 123'456'789,00 |
+----------------+
```

1.2.2.21 FROM_BASE64

Syntax

```
FROM_BASE64(str)
```

Description

Decodes the given base-64 encode string, returning the result as a binary string. Returns `NULL` if the given string is `NULL` or if it's invalid.

It is the reverse of the `TO_BASE64` function.

There are numerous methods to base-64 encode a string. MariaDB uses the following:

- It encodes alphabet value 64 as '`+`'.
- It encodes alphabet value 63 as '`/`'.
- It codes output in groups of four printable characters. Each three byte of data encoded uses four characters. If the final group is incomplete, it pads the difference with the '`=`' character.
- It divides long output, adding a new line very 76 characters.
- In decoding, it recognizes and ignores newlines, carriage returns, tabs and space whitespace characters.

```
SELECT TO_BASE64('Maria') AS 'Input';
+-----------+
| Input     |
+-----------+
| TWFyaWE=  |
+-----------+

SELECT FROM_BASE64('TWFyaWE=') AS 'Output';
+--------+
| Output |
+--------+
| Maria  |
+--------+
```

1.2.2.22 HEX

Syntax

```
HEX(N_or_S)
```

Description

If `N_or_S` is a number, returns a string representation of the hexadecimal value of `N`, where `N` is a `longlong` (`BIGINT`) number. This is equivalent to `CONV(N,10,16)`.

If `N_or_S` is a string, returns a hexadecimal string representation of `N_or_S` where each byte of each character in `N_or_S` is converted to two hexadecimal digits. If `N_or_S` is NULL, returns NULL. The inverse of this operation is performed by the UNHEX() function.

MariaDB starting with 10.5.0

HEX() with an INET6 argument returns a hexadecimal representation of the underlying 16-byte binary string.

Examples

```
SELECT HEX(255);
+----------+
| HEX(255) |
+----------+
| FF       |
+----------+

SELECT 0x4D617269614442;
+------------------+
| 0x4D617269614442 |
+------------------+
| MariaDB          |
+------------------+

SELECT HEX('MariaDB');
+----------------+
| HEX('MariaDB') |
+----------------+
| 4D617269614442 |
+----------------+
```

From MariaDB 10.5.0:

```
SELECT HEX(CAST('2001:db8::ff00:42:8329' AS INET6));
+---------------------------------------------+
| HEX(CAST('2001:db8::ff00:42:8329' AS INET6)) |
+---------------------------------------------+
| 20010DB8000000000000FF0000428329             |
+---------------------------------------------+
```

1.2.2.23 INSTR

Syntax

```
INSTR(str,substr)
```

Contents

Description

Returns the position of the first occurrence of substring *substr* in string *str*. This is the same as the two-argument form of LOCATE(), except that the order of the arguments is reversed.

`INSTR()` performs a case-insensitive search.

If any argument is `NULL`, returns `NULL`.

Examples

```
SELECT INSTR('foobarbar', 'bar');
+--------------------------+
| INSTR('foobarbar', 'bar') |
+--------------------------+
|                        4 |
+--------------------------+

SELECT INSTR('My', 'Maria');
+----------------------+
| INSTR('My', 'Maria') |
+----------------------+
|                    0 |
+----------------------+
```

1.2.2.24 LCASE

Syntax

```
LCASE(str)
```

Description

LCASE() is a synonym for LOWER().

1.2.2.25 LEFT

Syntax

```
LEFT(str,len)
```

Description

Returns the leftmost `len` characters from the string `str`, or NULL if any argument is NULL.

Examples

```
SELECT LEFT('MariaDB', 5);
+--------------------+
| LEFT('MariaDB', 5) |
+--------------------+
| Maria              |
+--------------------+
```

1.2.2.26 INSERT Function

Syntax

```
INSERT(str,pos,len,newstr)
```

Description

Returns the string `str`, with the substring beginning at position `pos` and `len` characters long replaced by the string `newstr`. Returns the original string if `pos` is not within the length of the string. Replaces the rest of the string from position

`pos` if `len` is not within the length of the rest of the string. Returns NULL if any argument is NULL.

Examples

```
SELECT INSERT('Quadratic', 3, 4, 'What');
+--------------------------------+
| INSERT('Quadratic', 3, 4, 'What') |
+--------------------------------+
| QuWhattic                      |
+--------------------------------+

SELECT INSERT('Quadratic', -1, 4, 'What');
+---------------------------------+
| INSERT('Quadratic', -1, 4, 'What') |
+---------------------------------+
| Quadratic                       |
+---------------------------------+

SELECT INSERT('Quadratic', 3, 100, 'What');
+-----------------------------------+
| INSERT('Quadratic', 3, 100, 'What') |
+-----------------------------------+
| QuWhat                            |
+-----------------------------------+
```

1.2.2.27 LENGTH

Syntax

```
LENGTH(str)
```

Contents

Description

Returns the length of the string `str`.

In the default mode, when Oracle mode from MariaDB 10.3 is not set, the length is measured in bytes. In this case, a multi-byte character counts as multiple bytes. This means that for a string containing five two-byte characters, `LENGTH()` returns 10, whereas CHAR_LENGTH() returns 5.

When running Oracle mode from MariaDB 10.3, the length is measured in characters, and `LENGTH` is a synonym for CHAR_LENGTH().

If `str` is not a string value, it is converted into a string. If `str` is `NULL`, the function returns `NULL`.

Examples

```
SELECT LENGTH('MariaDB');
+-------------------+
| LENGTH('MariaDB') |
+-------------------+
|                 7 |
+-------------------+
```

When Oracle mode from MariaDB 10.3 is not set:

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');
+------------------+-------------+--------------+--------------------+
| CHAR_LENGTH('π') | LENGTH('π') | LENGTHB('π') | OCTET_LENGTH('π') |
+------------------+-------------+--------------+--------------------+
|                1 |           2 |            2 |                  2 |
+------------------+-------------+--------------+--------------------+
```

In Oracle mode from MariaDB 10.3:

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');
+------------------+-------------+--------------+--------------------+
| CHAR_LENGTH('π') | LENGTH('π') | LENGTHB('π') | OCTET_LENGTH('π') |
+------------------+-------------+--------------+--------------------+
|                1 |           1 |            2 |                  2 |
+------------------+-------------+--------------+--------------------+
```

1.2.2.28 LENGTHB

MariaDB starting with 10.3.1

Introduced in MariaDB 10.3.1 as part of the Oracle compatibility enhancements.

Syntax

```
LENGTHB(str)
```

Description

`LENGTHB()` returns the length of the given string, in bytes. When Oracle mode is not set, this is a synonym for LENGTH.

A multi-byte character counts as multiple bytes. This means that for a string containing five two-byte characters, `LENGTHB()` returns 10, whereas CHAR_LENGTH() returns 5.

If `str` is not a string value, it is converted into a string. If `str` is `NULL`, the function returns `NULL`.

Examples

When Oracle mode from MariaDB 10.3 is not set:

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');
+------------------+-------------+--------------+--------------------+
| CHAR_LENGTH('π') | LENGTH('π') | LENGTHB('π') | OCTET_LENGTH('π') |
+------------------+-------------+--------------+--------------------+
|                1 |           2 |            2 |                  2 |
+------------------+-------------+--------------+--------------------+
```

In Oracle mode from MariaDB 10.3:

```
SELECT CHAR_LENGTH('π'), LENGTH('π'), LENGTHB('π'), OCTET_LENGTH('π');
+------------------+-------------+--------------+--------------------+
| CHAR_LENGTH('π') | LENGTH('π') | LENGTHB('π') | OCTET_LENGTH('π') |
+------------------+-------------+--------------+--------------------+
|                1 |           1 |            2 |                  2 |
+------------------+-------------+--------------+--------------------+
```

1.2.2.29 LIKE

Syntax

```
expr LIKE pat [ESCAPE 'escape_char']
expr NOT LIKE pat [ESCAPE 'escape_char']
```

Contents

Description

Tests whether *expr* matches the pattern *pat*. Returns either 1 (`TRUE`) or 0 (`FALSE`). Both *expr* and *pat* may be any valid expression and are evaluated to strings. Patterns may use the following wildcard characters:

- `%` matches any number of characters, including zero.
- `_` matches any single character.

Use `NOT LIKE` to test if a string does not match a pattern. This is equivalent to using the `NOT` operator on the entire `LIKE` expression.

If either the expression or the pattern is `NULL` , the result is `NULL` .
