parser_max_mem_size	-	4294967295 (32-bit) or 18446744073709547520 (64-bit)	MySQL variable for limiting memory available to the parser.
password_*	-	*	Controls reuse of previous passwords in MySQL.
performance_schema	OFF	ON	The Performance Schema is off by default in MariaDB.
performance_schema_*			Many performance schema variables are autoset in MySQL, and MySQL has a different version, with additional variables.
plugin_maturity	One less than the server maturity	-	Minimum acceptable plugin maturity.
progress_report_time	5	-	Time in seconds between sending progress reports to the client for time-consuming statements.
proxy_protocol_networks	(empty)	-	Enable proxy protocol for these source networks.
query_alloc_block_size	16384	8192	Size in bytes of the extra blocks allocated during query parsing and execution (after query_prealloc_size is used up).
query_cache_*	*	-	MySQL has removed the query cache.
query_prealloc_size	24576	8192	Size in bytes of the persistent buffer for query parsing and execution, allocated on connect and freed on disconnect.
range_optimizer_max_mem_size	-	8388608	MySQL-only variable setting a limit on the range optimizer's memory usage.
rbr_exec_mode	-	STRICT	MySQL-only variable for determining the handling of certain key errors.
read_binlog_speed_limit	0	-	Permits restricting the speed at which the slave reads the binlog from the master.
regexp_*	-	*	Memory and time limits for regular expression matching operations.
relay_log_info_repository	-	TABLE	MySQL-only variable determining whether the slave's position in the relay logs is written to a file or table.

replicate_annotate_row_events	ON	-	Tells the slave to reproduce annotate_rows_events received from the master in its own binary log.
replicate_do_db	empty string	-	See Dynamic Replication Variables.
replicate_do_table	empty string	-	See Dynamic Replication Variables.
replicate_events_marked_for_skip	replicate	-	See Selectively skipping replication of binlog events.
replicate_ignore_db	empty string	-	See Dynamic Replication Variables.
replicate_ignore_table	empty string	-	See Dynamic Replication Variables.
replicate_wild_do_table	empty string	-	See Dynamic Replication Variables.
replicate_wild_ignore_table	empty string	-	See Dynamic Replication Variables.
result_metadata	-	FULL	Determine whether the server returns result set metadata for connections where this is optional.
rowid_merge_buff_size	8388608	-	See Non-semi-join subquery optimizations.
rpl_read_size	-	8192	Minimum data in bytes read from the binary and relay log files.
rpl_semi_sync_*	-	-	MariaDB includes semisynchronous replication without the need to install a plugin.
rpl_stop_slave_timeout	-	31536000	Controls the time that STOP SLAVE waits before timing out.
s3_*	*	-	The S3 storage engine is only available in MariaDB.
schema_definition_cache	-	256	Limits the number of schema definition objects kept in the dictionary object cache.
secure_auth	ON	-	Removed in MySQL.
secure_timestamp	NO	-	MariaDB-only option permitting the restricting of direct setting of a session timestamp..
server_id_bits	-	server_id	MySQL-only variable for use in MySQL Cluster.
server_uuid	-	UUID	MySQL-only variable containing the UUID.
session_track_gtids	-	OFF	MySQL-only variables for tracking gtid changes. MariaDB and MySQL's gtid implementation is different.
sha256_password_proxy_users	-	OFF	MySQL-only variable determining whether the sha256_password plugin supports proxy users.
show_create_table_verbosity	-	OFF	Option to cause SHOW CREATE TABLE to display ROW_FORMAT in all cases.
show_old_temporals	-	OFF	MySQL-only variable for determining whether SHOW CREATE TABLE output should include comments for old format temporal columns.
skip_parallel_replication	OFF	-	See parallel replication.
skip_replication	OFF	-	See Selectively skipping replication of binlog events.
slave_allow_batching	-	OFF	MySQL-only replication variable.
slave_checkpoint_group	-	512	MySQL-only replication variable.
slave_checkpoint_period	-	300	MySQL-only replication variable.
slave_ddl_exec_mode	IDEMPOTENT	-	Modes for how replication of DDL events should be executed.
slave_domain_parallel_threads	0	-	For configuring parallel replication.
slave_net_timeout	3600	60	MySQL reduced the timeout to 60s.
slave_parallel_max_queued	131072	-	For configuring parallel replication.
slave_parallel_mode	optimistic	-	Controls what transactions are applied in parallel when using parallel_replication.
slave_parallel_threads	0	-	For configuring parallel replication.
slave_parallel_type	-	DATABASE	MySQL-only replication variable.
slave_pending_jobs_size_max	-	16777216	MySQL-only replication variable.
slave_preserve_commit_order	-	OFF	MySQL-only replication variable.
slave_rows_search_algorithms	-	INDEX_SCAN, HASH_SCAN	MySQL-only replication variable.
slave_run_triggers_for_rbr	NO		See Running triggers on the slave for Row-based events for a description and use-case for this setting.

slave_transaction_retry_errors	1213,1205	-	When an error occurs during a transaction on the slave, replication usually halts. By default, transactions that caused a deadlock or elapsed lock wait timeout will be retried. One can add other errors to the the list of errors that should be retried by adding a comma-separated list of error numbers to this variable.
slave_transaction_retry_interval	0	-	Interval in seconds for the slave SQL thread to retry a failed transaction due to a deadlock, elapsed lock wait timeout or an error listed in slave_transaction_retry_errors.
sort_buffer_size	2097152	262144	The default sort buffer allocated has been reduced in MySQL.
sql_if_exists	OFF	-	Adds an implicit IF EXISTS to ALTER, RENAME and DROP of TABLES, VIEWS, FUNCTIONS and PACKAGES
sql_mode	STRICT_TRANS_TABLES, ERROR_FOR_DIVISION_BY_ZERO, NO_AUTO_CREATE_USER, NO_ENGINE_SUBSTITUTION	ONLY_FULL_GROUP_BY, STRICT_TRANS_TABLES, NO_ZERO_IN_DATE, NO_ZERO_DATE, ERROR_FOR_DIVISION_BY_ZERO, NO_ENGINE_SUBSTITUTION	See SQL Mode.
ssl_fips_mode	-	OFF	Whether FIPS mode is enabled on the server side.
standard_compliant_cte	ON	-	See Common Table Expressions.
storage_engine	InnoDB	-	Alias for default_storage_engine, removed in MySQL.
strict_password_validation	ON	-	In MariaDB, when password validation plugins are enabled, reject passwords that cannot be validated (passwords specified as a hash).
stored_program_definition_cache	-	256	Limits the number of stored program definition objects kept in the dictionary object cache.
super_read_only	-	OFF	MySQL variable for prohibiting client updates from users with the SUPER privilege.
sync_binlog	0	1	MySQL synchronizes all actions to the binary log before they are committed.
sync_frm	1	-	.frm files have been removed in MySQL.
system_versioning_alter_history	ERROR	-	MariaDB has System-Versioned Tables
system_versioning_asof	DEFAULT	-	MariaDB has System-Versioned Tables
table_definition_cache	400	-1 (autosized)	Number of table definitions that can be cached.
table_open_cache_instances	8	16	Maximum number of table cache instances.
tablespace_definition_cache	-	256	Limits the number of tablespace definition objects kept in the dictionary object cache.
tcp_keepalive_interval	0	-	Interval, in seconds, between when successive keep-alive packets are sent if no acknowledgement is received.
tcp_keepalive_probes	0	-	Number of unacknowledged probes to send before considering the connection dead and notifying the application layer.
tcp_keepalive_time	0	-	Set the TCP_NODELAY option (disable Nagle's algorithm) on socket.
tcp_nodelay	1	-	Timeout, in milliseconds, with no activity until the first TCP keep-alive packet is sent.
temptable_max_ram	-	1GB	Limits the RAM used by MySQL's TempTable storage engine.
thread_cache_size	Autosized	-1 (autosized)	MariaDB uses an improved thread pool.
thread_concurrency	10	-	Removed in MySQL 5.7.
thread_pool_dedicated_listener	0	-	Better precision for the data in the Information Schema THREADPOOL_QUEUES Table.
thread_pool_exact_stats	0	-	Better precision for the data in the Information Schema THREADPOOL_QUEUES Table.
thread_pool_idle_timeout	60	-	See Using the Thread Pool.
thread_pool_max_threads	65536	-	See Using the Thread Pool.
thread_pool_min_threads	1	-	Windows-only. See Using the Thread Pool.

thread_pool_oversubscribe	3	-	See Using the Thread Pool.
thread_pool_prio_kickup	auto	-	See Using the Thread Pool.
thread_pool_priority	auto	-	See Using the Thread Pool.
thread_pool_size	Number of processors	16*	See Using the Thread Pool. *Only available in MySQL with a commercial plugin.
thread_pool_stall_limit	500	6*	See Using the Thread Pool. *Only available in MySQL with a commercial plugin.
thread_stack	299008	Varies	See Using the Thread Pool.
time_format	%H:%i:%s	-	Removed in MySQL.
timed_mutexes	OFF	-	Removed in MySQL.
tmp_disk_table_size	18446744073709551615	-	Max size for data for an internal temporary on-disk MyISAM or Aria table.
tmp_memory_table_size	16777216	-	Alias for tmp_table_size.
transaction_allow_batching	-	OFF	Variable for enabling batching of statements within the same transaction in MySQL Cluster.
transaction_isolation	-	REPEATABLE-READ	The MariaDB equivalent is tx_isolation.
transaction_read_only	-	OFF	The MariaDB equivalent is tx_read_only.
transaction_write_set_extraction	-	OFF	Unused MySQL-only variable.
tx_isolation	REPEATABLE-READ	-	The MySQL equivalent is transaction_isolation.
tx_read_only	OFF	-	The MySQL equivalent is transaction_read_only.
use_stat_tables	preferably_for_queries	-	Controls the use of engine-independent table statistics.
userstat	OFF	-	Whether to activate MariaDB's User Statistics implementation, not available in MySQL.
version_compile_zlib	-	*	Version of the zlib library compiled in.
version_malloc_library	*	-	Version of the used malloc library.
version_source_revision	Varies	-	Permits seeing exactly which version of the source was used for a build.
version_ssl_library	*	-	Version of the used TLS library.
windowing_high_use_precision	-	*	MySQL option allowing safety to be sacrificed for speed in window function calculations.
wsrep_*	*	-	Galera cluster is only available in MariaDB.
Variable	**MariaDB 10.5**	**MySQL 8.0**	**Notes**

2.1.14.1.12.7 System Variable Differences Between MariaDB 10.4 and MySQL 8.0

Contents

The following is a comparison of variables that either appear only in MariaDB 10.4 or MySQL 8.0, or have different default settings in MariaDB 10.4, and MySQL 8.0. The stable releases MariaDB 10.4.6 and MySQL 8.0.11, with only default plugins enabled, were used for the comparison. Note that MySQL 8 is an 'evergreen' release, so features may be added or removed in later releases.

For a more complete list of differences, see Incompatibilities and Feature Differences Between MariaDB 10.4 and MySQL 8.0 and Function Differences Between MariaDB 10.4 and MySQL 8.0

The most notable differences are that MariaDB includes, by default, the Aria storage engine (resulting in extra memory allocation), Galera Cluster, and has a different thread pool implementation. For this reason, a default implementation of MariaDB 10.4 will use more memory than MySQL 8.0. MariaDB 10.4 and MySQL 8.0 also have different GTID implementations.

MariaDB's extra memory usage can be handled with the following rules of thumb:

- If you are not using MyISAM and don't plan to use Aria:
  - Set key_buffer_size to something very low (16K) as it's not used.
  - Set aria_pagecache_buffer_size to what you think you need for handling internal tmp tables that didn't fit in memory.
  - Normally this is what before you had set for key_buffer_size (at least 1M).

- If you are using MyISAM and not planning to use Aria:
  - Set aria_pagecache_buffer_size to what you think you need for handling internal tmp tables that didn't fit in memory.
- If you are planning to use Aria, you should set aria_pagecache_buffer_size to something that fits a big part of your normal data + overflow temporary tables.

Comparison Table

Variable	MariaDB 10.4 Default	MySQL 8.0 Default	Notes
activate_all_roles_on_login	-	OFF	Determines whether to automatically activate roles on login.
alter_algorithm	DEFAULT	-	MariaDB 10.3 introduced new ALTER TABLE ALGORITHM clauses to avoid slow copies in certain instances. This variable allows setting this if no `ALGORITHM` clause is specified.
analyze_sample_percentage	100.0000	-	Percentage of rows from the table ANALYZE TABLE will sample to collect table statistics.
aria_*	*	-	The Aria storage engine is only available in MariaDB.
auto_generate_certs	-	ON	Whether to automatically generate SSL key and certificate files.
avoid_temporal_upgrade	-	OFF	Determines whether ALTER TABLE implicitly upgrades temporal columns.
back_log	Autosized	Autosized	MariaDB and MySQL have different autosizing algorithms.
binlog-annotate-row-events	ON	-	Introduced in MariaDB 5.3 for replicating between MariaDB 5.3 and MySQL/MariaDB 5.1.
binlog_commit_wait_count	0	-	For use in MariaDB's parallel replication.
binlog_commit_wait_usec	100000	-	For use in MariaDB's parallel replication.
binlog_error_action		ABORT_SERVER	MySQL-only variable for controlling what happens when the server cannot write to the binary log.
binlog_expire_logs_seconds	-	2592000	Sets the binary log expiration period in seconds
binlog_file_cache_size	16184	-	For setting the size of the file cache for the binary log.
binlog_format	MIXED	ROW	MariaDB and MySQL have differing binary log formats.
binlog_group_commit_sync_delay		0	MySQL-only variable for controlling the wait time before synchronizing the binary log file to disk.
binlog_group_commit_sync_no_delay_count		0	MySQL-only variable for setting the maximum number of transactions to wait for before aborting the current `binlog_group_commit_sync_delay` delay.
binlog_gtid_simple_recovery	-	ON	MySQL-only GTID variable. MariaDB's GTID implementation is different.
binlog_max_flush_queue_time	-	0	Specifies a timeout for reading transactions from the flush queue before continuing with group commit and syncing log to disk.
binlog_optimize_thread_scheduling	ON	-	For optimized kernel thread scheduling.
binlog_order_commits	-	ON	Determines whether transactions may be committed in parallel.
binlog_row_metadata	-	MINIMAL	Determines the amount of table metadata added to the binary log with row-based logging.
binlog_row_value_options	-	(empty)	Permits an alternative binlog format for JSON document updates.
binlog_rows_query_log_events	-	OFF	MySQL-only variable for logging extra information in row-based logging.
binlog_transaction_dependency_history_size	-	25000	Maximum number of row hashes kept for looking up transactions that last modified a given row.
binlog_transaction_dependency_tracking	-	COMMIT_ORDER	For determining how to best use the slave's multithreaded applier.
block_encryption_mode	-	aes-128-ecb	MySQL-only variable for controlling the block encryption mode for block-based algorithms.

caching_sha2_password*	-	*	For use with MySQL's SHA-256 authentication with caching.
character_set_*	latin1 or utf8	utf8mb4	MySQL 8.0 defaults to the utf8mb4 character set.
check_constraint_checks	ON	-	Permits disabling constraint checks, for example when loading a table that violates some constraints that you plan to fix later.
check_proxy_users		OFF	MySQL-only variable for controlling whether the server performs proxy user mapping for authentication plugins.
collation_*	latin1_swedish_ci or utf8_general_ci	utf8mb4_0900_ai_ci	MySQL 8.0 defaults to the utf8mb4 character set.
column_compression_threshold	100	-	MariaDB supports Storage-engine Independent Column Compression.
column_compression_zlib_level	6	-	MariaDB supports Storage-engine Independent Column Compression.
column_compression_zlib_strategy	DEFAULT_STRATEGY	-	MariaDB supports Storage-engine Independent Column Compression.
column_compression_zlib_wrap	OFF	-	MariaDB supports Storage-engine Independent Column Compression.
cte_max_recursion_depth	-	1000	When MySQL 8.0 introduced common table expressions they used a different name. MariaDB's variable is called max_recursive_iterations.
date_format	%Y-%m-%d	-	Unused variable removed in MySQL 8.0
datetime_format	%Y-%m-%d	-	Unused variable removed in MySQL 8.0
deadlock_search_depth_long	15	-	The Aria storage engine is only available in MariaDB.
deadlock_search_depth_short	4	-	The Aria storage engine is only available in MariaDB.
deadlock_timeout_long	50000000	-	The Aria storage engine is only available in MariaDB.
deadlock_timeout_short	10000	-	The Aria storage engine is only available in MariaDB.
debug_no_thread_alarm	OFF	-	Disable system thread alarm calls, for debugging or testing.
default_authentication_plugin	-	caching_sha2_password	MySQL 8 introduced a new authentication plugin.
default_collation_for_utf8mb4	-	utf8mb4_0900_ai_ci	For internal use in MySQL 8 replication.
default_master_connection	empty	-	For use with MariaDB's multi-source replication.
default_password_lifetime	0	360	MariaDB defaults to password expiration off.
default_regex_flags	empty	-	For handling incompatibilities between MariaDB's PCRE and the old regex library.
default_tmp_storage_engine	empty	InnoDB	Default storage engine used for tables created with CREATE TEMPORARY TABLE.
disabled_storage_engines		empty	MySQL-only variable for disabling specific storage engines.
disconnect_on_expired_password	OFF	ON	MariaDB password expiration is off by default, and by default does not disconnect a client when a password has expired.
encrypt_binlog	OFF	-	MariaDB enables table and tablespace encryption.
encrypt_tmp_files	OFF	-	MariaDB enables table and tablespace encryption.
encrypt_tmp_disk_tables	OFF	-	MariaDB enables table and tablespace encryption.
end_markers_in_json	-	OFF	MySQL-only variable for adding end markers to JSON output.
enforce_gtid_consistency	-	OFF	MariaDB and MySQL have different GTID implementations.
enforce_storage_engine	none		Forces the use of a particular storage engine for new tables.
eq_range_index_dive_limit	0	200	Variable for tuning when the optimizer should switch from using index dives to index statistics for qualifying rows estimation.
event_scheduler	OFF	ON	MySQL enables the event scheduler by default.

expensive_subquery_limit	100	-	Used for determining expensive queries for optimization.
explicit_defaults_for_timestamp	OFF	ON	MySQL 8 disables the old timestamp behavior.
extra_max_connections	1	-	Introduced in the MariaDB 5.1 threadpool.
extra_port	0	-	Introduced in the MariaDB 5.1 threadpool.
group_concat_max_len	1048576	1024	MariaDB increases the maximum length for a GROUP_CONCAT() result from 1K to 1M.
gtid_binlog_pos	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_binlog_state	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_cleanup_batch_size	64	-	MariaDB and MySQL have different GTID implementations.
gtid_current_pos	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_domain_id	0	-	MariaDB and MySQL have different GTID implementations.
gtid_executed	-	empty	MariaDB and MySQL have different GTID implementations.
gtid_executed_compression_period	-	1000	MariaDB and MySQL have different GTID implementations.
gtid_ignore_duplicates	OFF	-	MariaDB and MySQL have different GTID implementations.
gtid_mode	-	OFF	MariaDB and MySQL have different GTID implementations.
gtid_next	-	AUTOMATIC	MariaDB and MySQL have different GTID implementations.
gtid_owned	-	empty	MariaDB and MySQL have different GTID implementations.
gtid_pos_auto_engines	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_purged	-	empty	MariaDB and MySQL have different GTID implementations.
gtid_seq_no	0	-	MariaDB and MySQL have different GTID implementations.
gtid_slave_pos	empty	-	MariaDB and MySQL have different GTID implementations.
gtid_strict_mode	OFF	-	MariaDB and MySQL have different GTID implementations.
have_crypt	YES	-	MySQL has removed the ENCRYPT function.
have_openssl			MariaDB's version indicates whether YaSSL or openssl was used. MySQL's is a synonym for `have_ssl`.
have_query_cache	YES	-	MySQL has removed the query cache.
have_statement_timeout	-		Whether MySQL's statement execution timeout feature is available.
have_symlink	YES	DISABLED	MySQL has removed symlink support.
histogram_generation_max_mem_size	-	20000000	Added when MySQL 8 introduced Histogram-based Statistics. MariaDB uses histogram_size
histogram_size	0	-	MariaDB introduced Histogram-based Statistics.
histogram_type	SINGLE_PREC_HB	-	MariaDB introduced Histogram-based Statistics.
idle_readonly_transaction_timeout	0	-	Time in seconds that the server waits for idle read-only transactions.
idle_transaction_timeout	0	-	Time in seconds that the server waits for idle transactions.
idle_write_transaction_timeout	0	-	Time in seconds that the server waits for idle write transactions.
ignore_builtin_innodb	OFF	-	Ignored and removed in MySQL 8.
in_predicate_conversion_threshold	1000	-	Controls the Conversion of Big IN Predicates Into Subqueries optimization.
in_transaction	0	-	Set to `1` if you are in a transaction, and `0` if not.
information_schema_stats_expiry	-	86400	Time until MySQL Information Schema cached statistics expire.

innodb_adaptive_flushing_lwm	10.000000	10	Adaptive flushing is enabled when this this low water mark percentage of the redo log capacity is reached. MariaDB's variable is a double, MySQL's an integer.
innodb_api_*	-	*	Specific to MySQL's memcached, removed in MariaDB 10.2.
innodb_autoinc_lock_mode	1	2	MariaDB has an extra mode, `3`, for skipping the rollback of connected transactions. MySQL defaults to row-based replication, so can safely use `2`.
innodb_background_*	*	-	MariaDB has support for data scrubbing.
innodb_checksums	ON	-	Deprecated option removed in MySQL.
innodb_compression_*	*	-	Introduced with MariaDB's InnoDB compression.
innodb_dedicated_server	-	OFF	MySQL option that automatically configures various settings if the server is a dedicated InnoDB database server.
innodb_default_encryption_key_id	1	-	Default encryption key id used for table encryption. See Data at Rest Encryption.
innodb_defragment	*	-	MariaDB can defragment InnoDB tablespaces.
innodb_directories	-	(empty)	Used to search for tablespace files when moving or restoring a new location.
innodb_disallow_writes	OFF	-	Tell InnoDB to stop any writes to disk.
innodb_encrypt_*	1	-	See MariaDB's Data at Rest Encryption.
innodb_fatal_semaphore_wait_threshold	600	-	MariaDB's fatal semaphore timeout is configurable.
innodb_file_format	(empty)	-	MariaDB 10.4 has restored this unused, deprecated variable for compatibility reasons.
innodb_flush_neighbors	1	0	MySQL 8 by default now assumes the use of an SSD device.
innodb_force_primary_key	OFF	-	If set to 1 in MariaDB (0 is default) CREATE TABLEs without a primary or unique key where all keyparts are NOT NULL will not be accepted, and will return an error.
innodb_idle_flush_pct	100	-	Up to what percentage of dirty pages in MariaDB should be flushed when InnoDB finds it has spare resources to do so.
innodb_immediate_scrub_data_uncompressed	OFF	-	MariaDB has support for data scrubbing.
innodb_large_prefix	(empty)	-	MariaDB 10.4 has restored this unused, deprecated variable for compatibility reasons.
innodb_lock_schedule_algorithm	VATS	-	MariaDB has an improved algorithm for deciding which of the waiting transactions should be granted a lock once it has been released.
innodb_locks_unsafe_for_binlog	OFF	-	Deprecated option in MariaDB for disabling gap locking for searches and index scans. Deprecated in MariaDB, use READ COMMITTED transaction isolation instead.
innodb_log_optimize_ddl	ON	-	Whether redo logging should be reduced when natively creating indexes or rebuilding tables
innodb_log_spin_*	-	*	MySQL variables for constraining CPU usage while waiting for flushed redo.
innodb_log_wait_for_flush_spin_hwm	-	*	MySQL variable for constraining CPU usage while waiting for flushed redo.
innodb_max_dirty_pages_pct	75	90	MySQL 8 increased the default to 90.
innodb_max_dirty_pages_pct_lwm	0	10	MySQL 8 increased the default to 10.
innodb_max_undo_log_size	10485760	1073741824	MariaDB 10.2 reduced the limit for when an undo tablespace is marked for truncation.
innodb_open_files	Autosized (2000)	Autosized (4000)	In most systems, autosized based on the table_open_cache setting, which differs between MariaDB and MySQL.
innodb_prefix_index_cluster_optimization	OFF	-	MariaDB includes the Facebook prefix index queries optimization.
innodb_print_ddl_logs	-	OFF	MySQL option for writing DDL logs to stderr.

innodb_redo_log_encrypt	-	OFF	MySQL 8 has also now introduced redo log encryption, but used a different name. The equivalent option in MariaDB is innodb_encrypt_log.
innodb_scrub_*	*	-	MariaDB includes options to scrub the redo log.
innodb_spin_wait_delay	4	6	MariaDB changed the default from 6 to 4 based on extensive benchmarking.
innodb_stats_modified_counter	0	-	MariaDB option to control the calculation of new statistics.
innodb_stats_sample_pages	8	-	Deprecated MariaDB option for control over index distribution statistics.
innodb_stats_traditional	ON	-	Enabling gives a larger sample of pages for larger tables for the purposes of index statistics calculation.
innodb_undo_log_encrypt	-	OFF	MySQL option for encrypting undo logs residing in separate undo tablespaces.
innodb_undo_log_truncate	OFF	ON	MySQL 8 changes the default to ON, marking larger undo logs for truncation.
innodb_undo_logs	128	-	Removed in MySQL 8.
innodb_undo_tablespaces	0	2	Number of tablespace files used for dividing up the undo logs. MySQL 8 has deprecated this setting, and increased the default (and minimum) to 2.
innodb_use_atomic_writes	ON	-	Atomic writes are a faster alternative to innodb_doublewrite and MariaDB automatically detects when supporting SSD cards are used.
internal_tmp_disk_storage_engine	-	INNODB	MySQL uses this variable to set the storage engine for on-disk internal temporary tables.
internal_tmp_mem_storage_engine	-	TEMPTABLE	MySQL and MariaDB use different formats for temporary tables. In MariaDB, the aria_used_for_temp_tables performs a similar function.
join_buffer_space_limit	2097152	-	Maximum size in bytes of the query buffer. See block-based join algorithms.
join_cache_level	2	-	For determining the join algorithms. See block-based join algorithms
key_buffer_size	134217728	8388608	Size of the buffer for the index blocks used by MyISAM tables and shared for all threads.
key_cache_file_hash_size	512	-	Number of hash buckets for open and changed files.
key_cache_segments	0	-	The number of segments in a key cache. See Segmented Key Cache.
keyring_operations	-	ON	Whether MySQL 8's keyring operations are enabled.
last_gtid	-	empty	MariaDB and MySQL have different GTID implementations.
local_infile	ON	OFF	MySQL no longer supports LOAD DATA LOCAL by default.
lock_wait_timeout	86400	31536000	MariaDB has reduced the timeout for acquiring metadata locks.
log_bin	OFF	ON	MySQL 8 enables the binary log by default.
log_bin_compress	OFF	-	MariaDB setting for whether or not the binary log can be compressed.
log_bin_compress_min_len	256	-	Minimum length of sql statement (in statement mode) or record (in row mode) that can be compressed. See Compressing Events to Reduce Size of the Binary Log.
log_bin_use_v1_row_events	-	OFF	MySQL-only variable showing whether or not MySQL's version 2 binary logging format is being used.
log_disabled_statements	sp	-	Disable logging of certain statements to the general log.
log_error_services	-	log_filter_internal; log_sink_internal	Components to enable for MySQL error logging.
log_error_verbosity	-	3	MySQL variable for setting verbosity of error, warning, and note messages in the error log.
log_slave_updates	OFF	ON	MySQL 8 has by default enabled binary logging of updates a slave receives from a master.

log_slow_admin_statements	ON	OFF	MariaDB logs slow admin statements to the slow query log by default.
log_slow_disabled_statements	admin,call,slave,sp	-	Disable logging of certain statements to the slow query log.
log_slow_filter	admin, filesort, filesort_on_disk, full_join, full_scan, query_cache, query_cache_miss, tmp_table, tmp_table_on_disk	-	For slow query log filtering.
log_slow_rate_limit	1	-	Limits the number of queries logged to the slow query log.
log_slow_slave_statements	ON	OFF	MariaDB logs slow slave statements to the slow query log by default.
log_slow_verbosity	empty	-	Controls information to be added to the slow query log. See also Slow Query Log Extended Statistics.
log_statements_unsafe_for_binlog	-	ON	MySQL setting for controlling whether binlog warnings are written to the error log.
log_syslog*	platform-dependent	-	MySQL variables with settings for writing to syslog.
log_tc_size	24576	-	Size in bytes of the transaction coordinator log, defined in multiples of 4096.
log_throttle_queries_not_using_indexes	-	0	MySQL-only variable for limiting the number of statements without indexes written to the slow query log.
log_timestamps	-	UTC	MySQL-only variable controlling the timezone for certain logging conditions.
log_warnings	2	-	MySQL 8 has replaced with `log_error_verbosity`.
mandatory_roles	-	(empty)	MySQL variable for assigning roles to all users.
master_info_repository	-	TABLE	Whether slave logs master status and connection info to a table or a file.
max_allowed_packet	16M	64M	
max_error_count	64	1024	Specifies the maximum number of messages stored for display by SHOW ERRORS and SHOW WARNINGS statements.
max_execution_time	-	0	MySQL renamed the `max_statement_time` variable.
max_length_for_sort_data	64	1024	Used to decide which algorithm to choose when sorting rows. If the total size of the column data, not including columns that are part of the sort, is less than max_length_for_sort_data, then these are added to the sort key. This can speed up the sort as there's no need to re-read the same row again later. Setting the value too high can slow things down as there will be a higher disk activity for doing the sort.
max_long_data_size	16777216	-	Maximum size for parameter values sent with mysql_stmt_send_long_data(). Removed in MySQL 5.6.
max_password_errors	4294967295	-	Maximum number of failed connections attempts before no more are permitted.
max_points_in_geometry	-	65536	Maximum points_per_circle for MySQL's ST_Buffer_Strategy() function.
max_recursive_iterations	4294967295	-	Maximum number of iterations when executing recursive queries.
max_relay_log_size	1073741824	0	Can be set by session in MariaDB.
max_seeks_for_key	4294967295	4294967295 (32-bit) or 18446744073709547520 (64-bit)	The most key seeks required when searching with an index, regardless of the actual index cardinality. If this value is set lower than its default and maximum, indexes will tend to be preferred over table scans.
max_session_mem_used	9223372036854775807	-	Amount of memory a single user session is allowed to allocate.
max_statement_time	0	-	Maximum time in seconds that a query can execute before being aborted. MySQL used to have a variable of this name before renaming it `max_execution_time`.
max_tmp_tables	32	-	Unused variable removed in MySQL.

max_write_lock_count	4294967295	4294967295 (32-bit) or 18446744073709547520 (64-bit)	Read lock requests will be permitted for processing after this many write locks.
mrr_buffer_size	262144	-	Size of buffer to use when using multi-range read with range access. See Multi Range Read optimization.
multi_range_count	1024	-	Unused variable removed in MySQL.
myisam_block_size	1024	-	Block size used for MyISAM index pages.
myisam_recover_options	BACKUP,QUICK	OFF	MyISAM recovery mode.
myisam_sort_buffer_size	134216704	8388608	Size in bytes of the buffer allocated when creating or sorting indexes on a MyISAM table.
mysql_native_password_proxy_users	-	OFF	Whether MySQL's authentication plugin supports proxy users. I
mysql56_temporal_format	ON		Causes MariaDB to use the MySQL-5.6 low level formats for TIME, DATETIME and TIMESTAMP instead of the MariaDB 5.3+ version.
new	-	OFF	Used for backward-compatibility with MySQL 4.1, not present in MariaDB.
mysqlx+*	-	*	MySQL's X plugin related variables.
ngram_token_size	-	2	Sets the n-gram token size for MySQL's n-gram full-text parser.
offline_mode	-	OFF	MySQL settting for specifying whether the server should run in offline mode.
old_alter_table	DEFAULT	OFF	An alias for alter_algorithm.
old_mode	Empty string	-	Used for getting MariaDB to emulate behavior from an old version of MySQL or MariaDB. See OLD Mode.
old_passwords	OFF	-	MySQL 8 is no longer compatible with the old pre-MySQL 4.1 form of password hashing.
optimizer_selectivity_sampling_limit	100	-	Controls number of record samples to check condition selectivity.
optimizer_switch	See details		A series of flags for controlling the query optimizer. MariaDB has introduced a number of new settings.
optimizer_trace_*	-	*	MySQL has more settings for optimizer tracing.
optimizer_use_condition_selectivity	4	-	Controls which statistics can be used by the optimizer when looking for the best query execution plan.
original_commit_timestamp	-	*	Used by MySQL 8 for delaying replication.
parser_max_mem_size	-	4294967295 (32-bit) or 18446744073709547520 (64-bit)	MySQL variable for limiting memory available to the parser.
password_*	-	*	Controls reuse of previous passwords in MySQL.
performance_schema	OFF	ON	The Performance Schema is off by default in MariaDB.
performance_schema_*			Many performance schema variables are autoset in MySQL, and MySQL has a different version, with additional variables.
plugin_maturity	One less than the server maturity	-	Minimum acceptable plugin maturity.
progress_report_time	5	-	Time in seconds between sending progress reports to the client for time-consuming statements.
proxy_protocol_networks	(empty)	-	Enable proxy protocol for these source networks.
query_alloc_block_size	16384	8192	Size in bytes of the extra blocks allocated during query parsing and execution (after query_prealloc_size is used up).
query_cache_*	*	-	MySQL has removed the query cache.
query_prealloc_size	24576	8192	Size in bytes of the persistent buffer for query parsing and execution, allocated on connect and freed on disconnect.
range_optimizer_max_mem_size	-	8388608	MySQL-only variable setting a limit on the range optimizer's memory usage.
rbr_exec_mode	-	STRICT	MySQL-only variable for determining the handling of certain key errors.
read_binlog_speed_limit	0	-	Permits restricting the speed at which the slave reads the binlog from the master.
regexp_*	-	*	Memory and time limits for regular expression matching operations.

relay_log_info_repository	-	TABLE	MySQL-only variable determining whether the slave's position in the relay logs is written to a file or table.
replicate_annotate_row_events	ON	-	Tells the slave to reproduce annotate_rows_events received from the master in its own binary log.
replicate_do_db	empty string	-	See Dynamic Replication Variables.
replicate_do_table	empty string	-	See Dynamic Replication Variables.
replicate_events_marked_for_skip	replicate	-	See Selectively skipping replication of binlog events.
replicate_ignore_db	empty string	-	See Dynamic Replication Variables.
replicate_ignore_table	empty string	-	See Dynamic Replication Variables.
replicate_wild_do_table	empty string	-	See Dynamic Replication Variables.
replicate_wild_ignore_table	empty string	-	See Dynamic Replication Variables.
require_secure_transport	-	OFF	MySQL-only variable determining whether client to server connections need to be secure.
result_metadata	-	FULL	Determine whether the server returns result set metadata for connections where this is optional.
rowid_merge_buff_size	8388608	-	See Non-semi-join subquery optimizations.
rpl_read_size	-	8192	Minimum data in bytes read from the binary and relay log files.
rpl_semi_sync_*	-	-	MariaDB includes semisynchronous replication without the need to install a plugin.
rpl_stop_slave_timeout	-	31536000	Controls the time that STOP SLAVE waits before timing out.
schema_definition_cache	-	256	Limits the number of schema definition objects kept in the dictionary object cache.
secure_auth	ON	-	Removed in MySQL.
secure_timestamp	NO	-	MariaDB-only option permitting the restricting of direct setting of a session timestamp..
server_id_bits	-	server_id	MySQL-only variable for use in MySQL Cluster.
server_uuid	-	UUID	MySQL-only variable containing the UUID.
session_track_gtids	-	OFF	MySQL-only variables for tracking gtid changes. MariaDB and MySQL's gtid implementation is different.
sha256_password_proxy_users	-	OFF	MySQL-only variable determining whether the sha256_password plugin supports proxy users.
show_create_table_verbosity	-	OFF	Option to cause SHOW CREATE TABLE to display ROW_FORMAT in all cases.
show_old_temporals	-	OFF	MySQL-only variable for determining whether SHOW CREATE TABLE output should include comments for old format temporal columns.
skip_parallel_replication	OFF	-	See parallel replication.
skip_replication	OFF	-	See Selectively skipping replication of binlog events.
slave_allow_batching	-	OFF	MySQL-only replication variable.
slave_checkpoint_group	-	512	MySQL-only replication variable.
slave_checkpoint_period	-	300	MySQL-only replication variable.
slave_ddl_exec_mode	IDEMPOTENT	-	Modes for how replication of DDL events should be executed.
slave_domain_parallel_threads	0	-	For configuring parallel replication.
slave_net_timeout	3600	60	MySQL reduced the timeout to 60s.
slave_parallel_max_queued	131072	-	For configuring parallel replication.
slave_parallel_mode	conservative	-	Controls what transactions are applied in parallel when using parallel_replication.
slave_parallel_threads	0	-	For configuring parallel replication.
slave_parallel_type	-	DATABASE	MySQL-only replication variable.
slave_pending_jobs_size_max	-	16777216	MySQL-only replication variable.
slave_preserve_commit_order	-	OFF	MySQL-only replication variable.
slave_rows_search_algorithms	-	INDEX_SCAN, HASH_SCAN	MySQL-only replication variable.

slave_run_triggers_for_rbr	NO		See Running triggers on the slave for Row-based events for a description and use-case for this setting.
slave_transaction_retry_errors	1213,1205	-	When an error occurs during a transaction on the slave, replication usually halts. By default, transactions that caused a deadlock or elapsed lock wait timeout will be retried. One can add other errors to the the list of errors that should be retried by adding a comma-separated list of error numbers to this variable.
slave_transaction_retry_interval	0	-	Interval in seconds for the slave SQL thread to retry a failed transaction due to a deadlock, elapsed lock wait timeout or an error listed in slave_transaction_retry_errors.
sort_buffer_size	2097152	262144	The default sort buffer allocated has been reduced in MySQL.
sql_mode	STRICT_TRANS_TABLES, ERROR_FOR_DIVISION_BY_ZERO, NO_AUTO_CREATE_USER, NO_ENGINE_SUBSTITUTION	ONLY_FULL_GROUP_BY, STRICT_TRANS_TABLES, NO_ZERO_IN_DATE, NO_ZERO_DATE, ERROR_FOR_DIVISION_BY_ZERO, NO_ENGINE_SUBSTITUTION	See SQL Mode.
ssl_fips_mode	-	OFF	Whether FIPS mode is enabled on the server side.
standard_compliant_cte	ON	-	See Common Table Expressions.
storage_engine	InnoDB	-	Alias for default_storage_engine, removed in MySQL.
strict_password_validation	ON	-	In MariaDB, when password validation plugins are enabled, reject passwords that cannot be validated (passwords specified as a hash).
stored_program_definition_cache	-	256	Limits the number of stored program definition objects kept in the dictionary object cache.
super_read_only	-	OFF	MySQL variable for prohibiting client updates from users with the SUPER privilege.
sync_binlog	0	1	MySQL synchronizes all actions to the binary log before they are committed.
sync_frm	1	-	.frm files have been removed in MySQL.
system_versioning_alter_history	ERROR	-	MariaDB has System-Versioned Tables
system_versioning_asof	DEFAULT	-	MariaDB has System-Versioned Tables
table_definition_cache	400	-1 (autosized)	Number of table definitions that can be cached.
table_open_cache_instances	8	16	Maximum number of table cache instances.
tablespace_definition_cache	-	256	Limits the number of tablespace definition objects kept in the dictionary object cache.
tcp_keepalive_interval	0	-	Interval, in seconds, between when successive keep-alive packets are sent if no acknowledgement is received.
tcp_keepalive_probes	0	-	Number of unacknowledged probes to send before considering the connection dead and notifying the application layer.
tcp_keepalive_time	0	-	Set the TCP_NODELAY option (disable Nagle's algorithm) on socket.
tcp_nodelay	1	-	Timeout, in milliseconds, with no activity until the first TCP keep-alive packet is sent.
temptable_max_ram	-	1GB	Limits the RAM used by MySQL's TempTable storage engine.
thread_cache_size	Autosized	-1 (autosized)	MariaDB uses an improved thread pool.
thread_concurrency	10	-	Removed in MySQL 5.7.
thread_pool_idle_timeout	60	-	See Using the Thread Pool.
thread_pool_max_threads	65536	-	See Using the Thread Pool.
thread_pool_min_threads	1	-	Windows-only. See Using the Thread Pool.
thread_pool_oversubscribe	3	-	See Using the Thread Pool.
thread_pool_prio_kickup	auto	-	See Using the Thread Pool.
thread_pool_priority	auto	-	See Using the Thread Pool.
thread_pool_size	Number of processors	16*	See Using the Thread Pool. *Only available in MySQL with a commercial plugin.

thread_pool_stall_limit	500	6*	See Using the Thread Pool. *Only available in MySQL with a commercial plugin.
thread_stack	299008	Varies	See Using the Thread Pool.
time_format	%H:%i:%s	-	Removed in MySQL.
timed_mutexes	OFF	-	Removed in MySQL.
tmp_disk_table_size	18446744073709551615	-	Max size for data for an internal temporary on-disk MyISAM or Aria table.
tmp_memory_table_size	16777216	-	Alias for tmp_table_size.
transaction_allow_batching	-	OFF	Variable for enabling batching of statements within the same transaction in MySQL Cluster.
transaction_isolation	-	REPEATABLE-READ	The MariaDB equivalent is tx_isolation.
transaction_read_only	-	OFF	The MariaDB equivalent is tx_read_only.
transaction_write_set_extraction	-	OFF	Unused MySQL-only variable.
tx_isolation	REPEATABLE-READ	-	The MySQL equivalent is transaction_isolation.
tx_read_only	OFF	-	The MySQL equivalent is transaction_read_only.
use_stat_tables	preferably_for_queries	-	Controls the use of engine-independent table statistics.
userstat	OFF	-	Whether to activate MariaDB's User Statistics implementation, not available in MySQL.
version_compile_zlib	-	*	Version of the zlib library compiled in.
version_malloc_library	*	-	Version of the used malloc library.
version_source_revision	Varies	-	Permits seeing exactly which version of the source was used for a build.
version_ssl_library	*	-	Version of the used TLS library.
windowing_high_use_precision	-	*	MySQL option allowing safety to be sacrificed for speed in window function calculations.
wsrep_*	*	-	Galera cluster is only available in MariaDB.
Variable	**MariaDB 10.4**	**MySQL 8.0**	**Notes**

2.1.14.1.13 Upgrading from MySQL 5.7 to MariaDB 10.2

Following compatibility report was done on 10.2.4 and may get some fixing in next minor releases

- MySQL unix socket plugin can be different. MariaDB can get similar usage via INSTALL PLUGIN unix_socket SONAME 'auth_socket.so'; you may have to enable this plugin in config files via load plugin.
- When using data type JSON , one should convert type to TEXT, virtual generated column works the same after.
- When using InnoDB FULLTEXT index one should not use innodb_defragment
- MySQL re-implemented partitioning in 5.7, thus you cannot perform in-place upgrades for partitioned tables. They will require mysqldump/import to work correctly in MariaDB.

2.1.2.11 Installing MariaDB Alongside MySQL

2.1.3.12.2 Moving from MySQL to MariaDB in Debian 9

2.1.14.2 Migrating to MariaDB from SQL Server

This section is a guide to help you migrate from SQL Server to MariaDB. This includes a general understanding of MariaDB, information to help plan the migration, and differences in the configuration and syntax.

Understanding MariaDB Architecture

An overview of MariaDB server architecture, especially where it differs from SQL Server.

2.1.14.2.1 Understanding MariaDB Architecture

Contents

MariaDB architecture is partly different from the architecture of traditional DBMSs, like SQL Server. Here we will examine the main components that a new MariaDB DBA needs to know. We will also discuss a bit of history, because this may help understand MariaDB philosophy and certain design choices.

This section is an overview of the most important components. More information is included in specific sections of this migration guide, or in other pages of the MariaDB Knowledge Base (see the links scattered over the text).

Storage Engines

MariaDB was born from the source code of MySQL, in 2008. Therefore, its history begins with MySQL.

MySQL was born at the beginning of the 90s. Back in the days, if compared to its existing competitors, MySQL was lightweight, simple to install, easy to learn. While it had a very limited set of features, it was also fast in certain common operations. And it was open source. These characteristics made it suitable to back the simple websites that existed at that time.

The web evolved rapidly, and the same happened to MySQL. Being open source helped a lot in this respect, because the community needed functionalities that weren't supported at that time.

MySQL was probably the first database system to support a pluggable storage engine architecture. Basically, this means that MySQL knows very little about creating or populating a table, reading from it, building proper indexes and caches. It just delegated all these operations to a special plugin type called a storage engine.

One of the first plugins developed by third parties was InnoDB. It is very fast, and it adds two important features that are not otherwise supported: transactions and foreign keys.

Note that when MariaDB asks a storage engine to write or read a row, the storage engine could theoretically do anything. This led to the creation of very interesting alternative engines, like BLACKHOLE (which doesn't write or read any data, acting like the /dev/null file in Linux), or CONNECT (which can read and write to files written in many different formats, or remote DBMSs, or some other special data sources).

Nowadays InnoDB is the default MariaDB storage engine, and it is the best choice for most use cases. But for particular needs, sometimes using a different storage engine is desirable. In case of doubts about the best storage engine to use for a specific case, check the Choosing the Right Storage Engine page.

When we create a table, we specify its storage engine or use the default one. It is possible to convert an existing table to another storage engine, though this is a blocking operation which requires a complete table copy. Third-party storage engines can also be installed while MariaDB is running.

Note that it is perfectly possible to use tables with different storage engines in the same transaction (even if some engines are not transactional). It is even possible to use different engines in the same query, for example with JOINs and subqueries.

The default storage engine can be changed by changing the default_storage_engine variable. A different default can be specified for temporary tables by setting default_tmp_storage_engine. MariaDB uses Aria for system tables and temporary tables created internally to store the intermediate results of a query.

InnoDB

It is worth spending some more words here about InnoDB, the default storage engine.

Primary Key and Indexes

InnoDB primary keys are always the equivalent of SQL Server clustered indexes. In other words, an InnoDB table is always ordered by the primary key.

If an InnoDB table doesn't have a user-defined primary key, the first `UNIQUE` index whose columns are all `NOT NULL` is used as a primary key. If there is no such index, the table will have a *clustered index*. The terminology here can be a bit confusing for SQL Server and other DBMS users. A clustered index in InnoDB is a 6 bytes value that is added to the table. This index and its values are completely invisible to the users. It's important to note that clustered indexes are governed by a global mutex that greatly reduces their scalability.

Secondary indexes are ordered by the columns that are part of the index, and contain a reference to each entry's corresponding primary key value.

Some consequences of these design choices are the following:

- For performance reasons, a primary key value should be inserted in order. In other words, the last inserted value should be the highest. This order is normally followed when inserting values into an `AUTO_INCREMENT` primary key. The reason is that inserting values in the middle of an ordered data structure is slower, unless they fit into existing holes. If we insert primary key values randomly, InnoDB often has to rearrange pages to make some room for the new data.
- A big primary keys means that all secondary indexes are also big.
- A query by primary key will require a single search. A query on a secondary index that also reads columns not contained in the index will require one search on the index, plus one more search for each row that satisfies the index condition.
- We shouldn't explicitly include the primary key in a secondary index. If we do so, the primary key column will be duplicated in the index.

Tablespaces

For InnoDB, a *tablespace* is a file containing data (not a file group as in SQL Server). The types of tablespaces are:

- System tablespace.
- File-per-table tablespaces.
- Temporary tablespaces.

The system tablespace is stored in the file `ibdata`. It contains information used by InnoDB internally, like rollback segments, as well as some system tables. Historically, the system tablespace also contained all tables created by the user. In modern MariaDB versions, a table is created in the system tablespace only if the innodb_file_per_table system variable is set to 0 at the moment of the table creation. By default, innodb_file_per_table is 1.

Tables created while `innodb_file_per_table=1` are written into their own tablespace. These are `.ibd` files.

Starting from MariaDB 10.2, temporary tables are written into temporary tablespaces, which means `ibtmp*` files. Previously, they were created in the system tablespace or in file-per-table tablespaces according to the value of `innodb_file_per_table`, just like regular tables. Temporary tablespaces, if present, are deleted when MariaDB starts.

It is important to remember that tablespaces can never shrink. If a file-per-table tablespace grows too much, deleting data won't recover space. Instead, a new table must be created and data needs to be copied. Finally, the old table will be deleted. If the system tablespace grows too much, the only solution is to move data into a new MariaDB installation.

Transaction Logs

In SQL Server, the transaction log contains both the undo log and the redo log. Usually we have only one transaction log.

In MariaDB the undo log and the redo log are stored separately. By default, the redo log is written to two files, called `ib_logfile0` and `ib_logfile1`. The undo log by default is written to the *system tablespace*, which is in the `ibdata1` file. However, it is possible to write it in separate files in a specified directory.

MariaDB provides no way to inspect the contents of the transaction logs. However, it is possible to inspect the binary log.

InnoDB transaction logs are written in a circular fashion: their size is normally fixed, and when the end is reached, InnoDB continues to write from the beginning. However, if very long transactions are running, InnoDB cannot overwrite the oldest data, so it has to expand the log size instead.

InnoDB Buffer Pool

MariaDB doesn't have a central buffer pool. Each storage engine may or may not have a buffer pool. The InnoDB buffer

pool is typically assigned a big amount of memory. See MariaDB Memory Allocation.

MariaDB has no extension like the SQL Server buffer pool extension.

A part of the buffer pool is called the change buffer. It contains dirty pages that have been modified in memory and not yet flushed.

InnoDB Background Threads

InnoDB has background threads that take care of flushing dirty pages from the change buffer to the tablespaces. They don't directly affect the latency of queries, but they are very important for performance.

SHOW ENGINE InnoDB STATUS shows information about them in the `BACKGROUND THREAD` section. They can also be seen using the threads table, in the performance_schema.

InnoDB flushing is similar to *lazy writes* and *checkpoints* in SQL Server. It has no equivalent for *eager writing*.

For more information, see InnoDB Page Flushing and InnoDB Purge.

Checksums and Doublewrite Buffer

InnoDB pages have checksums. After writing pages to disk, InnoDB verifies that the checksums match. The checksum algorithm is determined by innodb_checksum_algorithm. Check the variable documentation for its consequences on performance, backward compatibility and encryption.

In case of a system crash, hardware failure or power outage, a page could be half-written on disk. For some pages, this causes a disaster. Therefore, InnoDB writes essential pages to disk twice. A backup copy of the new page version is written first. Then, the old page is overwritten. The backup copies are written into a file called the *doublewrite buffer*.

- If an event prevents the first page from being written, the old version of the page will still be available.
- If an event prevents the old page from being completely overwritten by its new version, the page can still be recovered using the doublewrite buffer.

The doublewrite buffer can disabled using the innodb_doublewrite variable, but this usually doesn't bring big performance benefits. The doublewrite buffer location can be changed with innodb_doublewrite_file.

Aria

Even if we only create InnoDB tables, we use Aria indirectly, in two ways:

- For system tables.
- For internal temporary tables.

Aria is a non-transactional storage engine. By default it is crash-safe, meaning that all changes to data are written and fsynced to a write-ahead log and can always be recovered in case of a crash.

Aria caches indexes into the pagecache. Data are not directly cached by Aria, so it's important that the underlying filesystem caches reads and writes.

The pagecache size is determined by the aria_pagecache_buffer_size system variable. To know if it is big enough we can check the proportion of free pages (the ratio between Aria_pagecache_blocks_used and Aria_pagecache_blocks_unused) and the proportion of cache misses (the ratio between Aria_pagecache_read_requests and Aria_pagecache_reads.

The proportion of dirty pages is the ratio between Aria_pagecache_blocks_used and Aria_pagecache_blocks_not_flushed tells us if the log file is big enough.

The size of Aria log is determined by aria_log_file_size.

Databases

MariaDB does not support the concept of schema. In MariaDB SQL, *schema* and *schemas* are synonyms for *database* and *databases*.

When a user connects to MariaDB, they don't connect to a specific database. Instead, they can access any table they have permissions for. There is however a concept of *default database*, see below.

A database is a container for database objects like tables and views. A database serves the following purposes:

- A database is a namespace.
- A database is a logical container to separate objects.
- A database has a default character set and collation, which are inherited by their tables.
- Permissions can be assigned on a whole database, to make permission maintenance simpler.
- Physical data files are stored in a directory which has the same name as the database to which they belong.

System Databases

MariaDB has the following system databases:

- mysql is for internal use only, and should not be read or written directly.
- information_schema contains all information that can be found in SQL Server's information_schema and more. However, while SQL Server's `information_schema` is a schema containing information about the local database, MariaDB's `information_schema` is a database that contains information about all databases.
- performance_schema contains information about MariaDB runtime. It is disabled by default. Enabling it requires setting the performance_schema system variable to 1 and restarting MariaDB.

Default Database

When a user connects to MariaDB, they can optionally specify a default database. A default database can also be specified or changed later, with the USE command.

Having a default database specified allows one to specify tables without specifying the name of the database where they are located. If no default database is specified, all table names must be fully qualified.

For example, the two following snippets are equivalent:

```
SELECT * FROM my_database.my_table;

-- is equivalent to:
USE my_database;
SELECT * FROM my_table;
```

Even if a default database is specified, tables from other databases can be accessed by specifying their fully qualified names:

```
-- this query joins my_database.my_table to your_database.your_table
USE my_database;
SELECT m.*
    FROM my_table m
    JOIN your_database.your_table y
        ON m.xyz = y.xyz;
```

MariaDB has the DATABASE() function to determine the current database:

```
SELECT DATABASE();
```

Stored procedures and triggers don't inherit a default database from the session, nor by a caller procedure. In that context, the default database is the database which contains the procedure. `USE` can be used to change it. The default database will only be valid for the rest of the procedure.

The Binary Log

Different tables can be built using different storage engines. It is important to note that not all engines are transactional, and that different engines implement the transaction logs in different ways. For this reason, MariaDB cannot replicate data from a primary to a replica using an equivalent of SQL Server transactional replication.

Instead, it needs a global mechanism to log the changes that are applied to data. This mechanism is the binary log, often abbreviated to binlog.

The binary log can be written in the following formats:

- STATEMENT logs SQL statements that modify data;
- ROW logs a reference to the rows that have been modified, if any (usually it's the primary key), and the new values that have been added or modified, in a binary format.
- MIXED is a combination of the above formats. It means that ROW is used for statements that can safely be logged in this way (see below), and STATEMENT is used in other cases. This is the default format from MariaDB 10.2.

In most cases, STATEMENT is slower because the SQL statement needs to be re-executed by the replica, and because certain statements may produce a different result in the replica (think about queries that use LIMIT without ORDER BY, or the CURRENT_TIMESTAMP() function). But there are exceptions, and besides, DDL statements are always logged as STATEMENT to avoid flooding the binary log. Therefore, the binary log may well contain both ROW and STATEMENT entries.

See Binary Log Formats.

The binary log allows:

- replication, if enabled on the primary;
- promoting a replica to a primary, if enabled on that replica;
- incremental backups;
- seeing data as they were in a point of time in the past (flashback);
- restoring a backup and re-appling the binary log, with the exception of a data change which caused problems (human mistake, application bug, SQL injection);
- Capture Data Changes (CDC), by streaming the binary log to technologies like Apache Kafka.

If you don't plan to use any of these features on a server, it is possible to disable the binary log to slightly improve the performance.

The binary log can be inspected using the mariadb-binlog utility, which comes with MariaDB. Enabling or disabling the binary log requires restarting MariaDB.

See also MariaDB Replication Overview for SQL Server Users and MariaDB Backups Overview for SQL Server Users for a better understanding of how the binary log is used.

Plugins

Storage engines are a special type of plugin. But others exist. For example, plugins can add authentication methods, new features, SQL syntax, functions, informative tables, and more.

A plugin may add some server variables and some status variables. Server variables can be used to configure the plugin, and status variables can be used to monitor its activities and status. These variables generally use the plugin's name as a prefix. For example InnoDB has a server variable called innodb_buffer_pool_size to configure the size of its buffer pool, and a status variable called Innodb_pages_read which indicates the number of memory pages read from the buffer pool. The category system variables of the MariaDB Knowledge Base has specific pages for system and status variables associated with various plugins.

Many plugins are installed by default, or available but not installed by default. They can be installed or uninstalled at runtime with SQL statements, like `INSTALL PLUGIN`, `UNINSTALL PLUGIN` and others; see Plugin SQL Statements. 3rd party plugins can be made available for installation by simply copying them to the plugin_dir.

It is important to note that different plugins may have different maturity levels. It is possible to prevent the installation of plugins we don’t consider production-ready by setting the plugin_maturity system variable. For plugins that are distributed with MariaDB, the maturity level is determined by the MariaDB team based on the bugs reported and fixed.

Some plugins are developed by 3rd parties. Even some 3rd party plugins are included in MariaDB official distributions - the ones available on mariadb.org.

In MariaDB every authorization method (including the default one) is provided by an authentication plugin. A user can be required to use a certain authentication plugin. This gives us much flexibility and control. Windows users may be interested in gsapi (which supports Windows authentication, Kerberos and NTLM) and named_pipe (which uses named pipe impersonation).

Other plugins that can be very useful include userstat, which includes statistics about resources and table usage, and METADATA_LOCK_INFO, which provides information about metadata locks.

Thread Pool

MariaDB supports thread pool. It works differently on UNIX and on Windows. On Windows, it is enabled by default and its implementation is quite similar to SQL Server. It uses the Windows native CreateThreadpool API.

If we don't use the thread pool, MariaDB will use its traditional method to handle connections. It consists of using a dedicated thread for each client connection. Creating a new thread has a cost in terms of CPU time. To mitigate this cost, after a client disconnects, the thread may be preserved for a certain time in the thread cache.

Whichever connection method we use, MariaDB has a maximum number of simultaneous connections, which can be changed at runtime. When the limit is reached, if more clients try to connect they will receive an error. This prevents MariaDB from consuming all the server resources and freezing or crashing. See Handling Too Many Connections.

Configuration

MariaDB has many settings that control the server behavior. These can be set up when starting mysqld (mysqld options), and the vast majority are also accessible as server system variables. These can be classified in these ways:

- **Dynamic** or **static**;
- **Global**, **session**, or both.

Note that server system variables are not to be confused with user-defined variables. The latter are not used for MariaDB

configuration.

Configuration Files

MariaDB can use several configuration files. Configuration files are searched in several locations, including in the user directory, and if present they all are read and used. They are read in a consistent order. These locations depend on the operating system; see Default Option File Locations. It is possible to tell MariaDB which files it should read; see Global Options Related to Option Files.

On Linux, by default the configuration files are called `my.cnf`. On Windows, by default the configuration files can be called `my.ini` or `my.cnf`. The former is more common.

If a variable is mentioned multiple times in different files, the occurrence that is read last will overwrite the others. Similarly, if a variable is mentioned several times in a single file, the occurrence that is read last overwrites the others.

The contents of each configuration file are organized by *option groups*. MariaDB Server and client programs read different groups. The read groups also depend on the MariaDB version. See Option Groups for the details. Most commonly, the `[server]` or `[mysqld]` groups are used to contain all server configuration. The `[client-server]` group can be used for options that are shared by the server and the clients (like the port to use), to avoid repeating those variables multiple times.

Dynamic and Static Variables

Dynamic variables have a value that can be changed at runtime, using the SET SQL statement. Static variables have a value that is decided at startup (see below) and cannot be changed without a restart.

The Server System Variables page states if variables are dynamic or static.

Scope

A global system variable is one that affects the general behavior of MariaDB. For example innodb_buffer_pool_size determines the size of the InnoDB buffer pool, which is used by read and write operations, no matter which user issued them. A session system variable is one that affects MariaDB behavior for the current connection; changing it will not affect other connected users, or future connections from the current user.

A variable could exist in both the global and session scopes. In this case, the session value is what affects the current connection. When a user connects, the current global value is copied to the session scope. Changing the global value afterward will not change existing connections.

The Server System Variables page states the scope of each variable.

Global variables and some session variables can only be modified by a user with the SUPER privilege (typically root).

Syntax

To see the value of a system variable:

```
-- global variables:
SELECT @@global.variable_name;
-- session variables:
SELECT @@session.variable_name;
-- or just use the shortcut:
SELECT @@variable_name;
```

A longer syntax, which is mostly useful to get multiple variables, makes use of the same pattern syntax that is used by the LIKE operator:

```
-- global variables whose name starts with 'innodb':
SHOW GLOBAL VARIABLES LIKE 'innodb%';
-- session variables whose name starts with 'innodb':
SHOW SESSION VARIABLES LIKE 'innodb%';
SHOW VARIABLES LIKE 'innodb%';
```

To modify the global or session value of a dynamic variable:

```
SET @@global.variable_name = 'new 'value';
SET @@session.variable_name = 'new 'value';
```

Notice that if we modify a global variable in this way, the new value will be lost at server restart. For this reason we probably want to change the value in the configuration file too.

For further information see:

- The SET statement.
- The SHOW VARIABLES statement.

Setting System Variables with Startup Parameters

System variables can be set at server startup without writing their values into a configuration file. This is useful if we want a value to be set once, until we change it or restart MariaDB. Values passed in this way override values written in the configuration files.

The general rule is that every global variable can be passed as an argument of `mysqld` by prefixing its name with `--` and by replacing every occurrence of `_` with `-` in its name.

For example, to pass `bind_address` as a startup argument:

```
mysqld --bind-address=127.0.0.1
```

Debugging Configuration

Mistyping a variable can prevent MariaDB from starting. We cannot set a variable that doesn't exist in the MariaDB version in use. In these cases, an error is written in the error log.

Having several configuration files and configuration groups, as well as being able to pass variables as command-line arguments, brings a lot of flexibility but can sometimes be confusing. When we are unsure about which values will be used, we can run:

```
mysqld --print-defaults
```

Status Variables

MariaDB status variables and some system tables allow external tools to monitor a server, building graphs on how they change over time, and allow the user to inspect what is happening inside the server.

Status variables cannot be directly modified by the user. Their values indicate how MariaDB is operating. Their scope can be:

- **Global**, meaning that the value is about some MariaDB activity.
- **Session**, meaning that the value measures activities taking place in the current session.

Many status variables exist in both scopes. For example,Cpu_time at global level indicates how much time the CPU was used by the MariaDB process (including all user sessions and all the background threads). At session level, it indicates how much time the CPU was used by the current session.

The status variables created by a plugin, usually, use the plugin name as a prefix.

The SHOW STATUS statement prints the values of the status variables that match a certain pattern.

```
-- Show all InnoDB global status variables
SHOW GLOBAL STATUS LIKE 'innodb%';
-- Show all InnoDB session status variables
SHOW SESSION STATUS LIKE 'innodb%';
SHOW STATUS LIKE 'innodb%';
-- Show global variables that contain the "size" substring:
SHOW GLOBAL STATUS LIKE '%size%';
```

Some status variables values are reset when FLUSH STATUS is executed. A possible use:

```
DELIMITER ||
BEGIN NOT ATOMIC
SET @i = 0;
WHILE @i < 60 DO
    SHOW GLOBAL STATUS LIKE 'Com_select';
    FLUSH STATUS;
    DO SLEEP(1);
    SET @i = @i + 1;
END WHILE;
END ||
```

2.1.14.2.2 SQL Server Features Not Available in MariaDB

Contents

When planning a migration between different DBMSs, one of the most important aspects to consider is that the new database system will probably miss some features supported by the old one. This is not relevant for all users. The most widely used features are supported by most DBMSs. However, it is important to make a list of unsupported features and check which of them are currently used by applications. In most cases it is possible to implement such features on the application side, or simply stop using them.

This page has a list of SQL Server features that are not supported in MariaDB. The list is not exhaustive.

Introduced in SQL Server versions older than 2016

- Full outer joins.
- `GROUP BY CUBE` syntax.
- `MERGE` statement.
- In MariaDB, indexes are always ascending. Defining them as `ASC` or `DESC` has no effect.
  - For single-column indexes, the performance difference between an `ORDER BY ... ASC` and `DESC` is negligible.
  - For multiple-column indexes, an index may be unusable for certain queries because `DESC` is not supported. In some cases, a generated column can be used to invert the order of an index (for example, the expression `0 - price` can be indexed to index the prices in a descending order).
- The WITH syntax is currently only supported for the `SELECT` statement.
- Filtered indexes (`CREATE INDEX ... WHERE`).
- Autonomous transactions.
- User-defined types.
- Rules.
- Triggers don't support the following features:
  - Triggers on DDL and login.
  - `INSTEAD OF` triggers.
  - The `DISABLE TRIGGER` syntax.
- Cursors advanced features.
  - Global cursors.
  - `DELETE ... CURRENT OF` , `UPDATE ... CURRENT OF` statements: MariaDB cursors are read-only.
  - Specifying a direction (MariaDB cursors can only advance by one row).
- Synonyms.
- Table variables.
- Queues.
- XML indexes, XML schema collection, XQuery.
- User access to system functionalities, for example:
  - Running system commands (`xp_cmdshell()`).
  - Sending emails (`sp_send_dbmail()`).
  - Sending HTTP requests.
- External languages, external libraries (MariaDB only supports procedural SQL and PL/SQL).
- Negative permissions (the `DENY` command).
- Snapshot replication. See Provisioning a Slave.

Introduced in SQL Server 2016

- Native data masking
- PolyBase (however, MariaDB 10.5 supports accessing Amazon S3 via the S3 storage engine and several DBMSs via CONNECT)
- R and Python services
- ColumnStore indexes. MariaDB has a storage engine called ColumnStore, but this is a completely different feature.

Introduced in SQL Server 2017

- Adaptive joins
- Graph SQL

2.1.14.2.3 SQL Server Features Implemented Differently in MariaDB

Contents

Modern DBMSs implement several advanced features. While an SQL standard exists, the complete feature list is different for every database system. Sometimes different features allow achieving the same purpose, but with a different logic and different limitations. This is something to take into account when planning a migration.

Some features are implemented by different DBMSs, with a similar logic and similar syntax. But there could be important differences that users should be aware of.

This page has a list of SQL Server features that MariaDB implements in a different way, and SQL Server features for which MariaDB has an alternative feature. Minor differences are not taken into account here. The list is not exhaustive.

SQL

- The list of supported data types is different.
- There are relevant differences in transaction isolation levels.
- `SNAPSHOT` isolation level is not supported. Instead, you can use `START TRANSACTION WITH CONSISTENT SNAPSHOT` to acquire a snapshot at the beginning of the transaction. This is compatible with all isolation levels. See How Isolation Levels are Implemented in MariaDB.
- JSON support is different.

Indexes and Performance

- Clustered indexes. In MariaDB, the physical order of rows is delegated to the storage engine. InnoDB uses the primary key as a clustered index.
- Hash indexes. Only some storage engines support `HASH` indexes.
  - The InnoDB storage engine has a feature called adaptive hash index, enabled by default. It means that in InnoDB all indexes are created as `BTREE`, and depending on how they are used, InnoDB could convert them from BTree to hash indexes, or the other way around. This happens in the background.
  - The MEMORY storage engine uses hash indexes by default, if we don't specify the `BTREE` keyword.
  - See Storage Engine Index Types for more information.
- Query store. MariaDB allows query performance analysis using the slow log and performance_schema. Some open source or commercial 3rd party tools read that information to produce statistics and make it easy to identify slow queries.

Tables

- Computed columns are called generated columns in MariaDB and are created with a different syntax. See also Implementation Differences Compared to Microsoft SQL Server.
- Temporal tables use a different (more standard) syntax on MariaDB. In MariaDB, the history is stored in the same

table as current data (but optionally in different partitions). MariaDB supports both SYSTEM_TIME and APPLICATION_TIME.
- Hidden columns are Invisible columns in MariaDB.
- Temporary tables are implemented and used differently.

High Availability

- `NOT FOR REPLICATION`
  - MariaDB supports replication filters to exclude some tables or databases from replication
  - It is possible to keep a table empty in a slave (or in the master) by using the BLACKHOLE storage engine.
  - The master can have columns that are not present in a slave (the other way around is also supported). Before using this feature, carefully read the Replication When the Master and Slave Have Different Table Definitions page.
  - With MariaDB it's possible to prevent a trigger from running on slaves .
  - It's possible to run events without replicating them. The same applies to some administrative statements.
  - MariaDB superusers can run statements without replicating them, by using the sql_log_bin system variable.
  - Constraints and triggers cannot be disabled for replication, but it is possible to drop them on the slaves.
  - The `IF EXISTS` syntax allows one to easily create a table on the master that already exists (possibly in a different version) on a slave.
- pollinginterval option. See Delayed Replication.

Security

- The list of permissions is different.
- Security policies. MariaDB allows one to achieve the same results by assigning permissions on views and stored procedures. However, this is not a common practice and it's more complicated than defining security policies. See Other Uses of Views.
- MariaDB does not support an `OUTPUT` clause. Instead, we can use DELETE RETURNING and, since MariaDB 10.5, INSERT RETURNING and REPLACE RETURNING.

Other Features

- Linked servers. MariaDB supports storage engines to read from, and write to, remote tables. When using the CONNECT engine, those tables could be in different DBMSs, including SQL Server.
- Job scheduler: MariaDB uses an event scheduler to schedule events instead.

2.1.14.2.4 MariaDB Features Not Available in SQL Server

Contents

Some MariaDB features are not available in SQL Server.

At first glance, it is not important to know about those features to migrate from SQL Server to MariaDB. However, this is not the case. Using MariaDB features that are not in SQL Server allows one to obtain more advantages from the migration, getting the most from MariaDB.

This page has a list of MariaDB features that are not supported in SQL Server. The list is not exhaustive.

Plugin Architecture

- Storage engines.
- Authentication plugins.
- Encryption plugins.
- ColumnStore is a columnar storage engine designed to scale horizontally. It runs on a specific edition of MariaDB, so currently it cannot be used in combination with other engines.

SQL

- The sql_mode variable determines in which cases an SQL statement should fail with an error, and in which cases it should succeed with a warning even if it is not entirely correct. For example, when a statement tries to insert a string in a column which is not big enough to contain it, it could fail, or it could insert a truncated string and emit a warning. It is a tradeoff between reliability and flexibility.
  - SQL_MODE=MSSQL allows one to use a small subset of SQL Server proprietary syntax.
- The `CREATE ... IF EXISTS`, `CREATE OR REPLACE`, `DROP ... IF NOT EXISTS` options are supported for most DDL statements.
- SHOW statements.
- SHOW CREATE statements.
- SHOW PROCESSLIST and PERFORMANCE_SCHEMA THREAD table provide much richer information, compared to SQL Server `sp_who()` and `sp_who2()` procedures.
- CHECKSUM TABLE statement.
- PL/SQL support (only for stored procedures and stored functions).
- Row constructors.
- `BEFORE` triggers.
- HANDLER statements, to scroll table rows ordered by an index or in their physical order.
- DO statement, to call functions without returning a result set.
- BENCHMARK() function, to measure the speed of an SQL expression.

See also Syntax Differences between MariaDB and SQL Server.

Types

- Character sets and collations don't depend on column type. They can be set globally, or at database, table or column level.
- Columns may use non-constant expressions as the DEFAULT value. TIMESTAMP columns may have a `DEFAULT` value.
- UNSIGNED numeric types.
- Dynamic columns (note that JSON is usually preferred to this feature).

See also SQL Server and MariaDB Types Comparison.

JSON

For compatibility with some other database systems, MariaDB supports the JSON pseudo-type. However, it is just an alias for:

```
LONGTEXT CHECK (JSON_VALID(column_name))
```

JSON_VALID() is the MariaDB equivalent of SQL Server's `ISJSON()`.

Features

- Flashback functionality allows one to "undo" the changes that happened after a certain point in time.
- Partitioned tables support the following features:
  - Tables can be partitioned based on multiple columns.
  - Several partitioning types are available.
  - Subpartitions.
- Progress reporting for some typically expensive statements.

2.1.14.2.5 Setting Up MariaDB for Testing for SQL Server Users

Contents

This page contains links and hints to setup MariaDB for testing. The page is designed for SQL Server users, assuming that

they are mostly familiar with Windows and they are not familiar with MariaDB.

Choosing a MariaDB Version

As a general rule, for new installations it's better to choose the latest Generally Available (GA) version.

If you need a feature that is only present in a version that is not yet production-ready, and the project will surely not go to production before that version is GA, it could make sense to use a non-GA version. In this case however, keep in mind that you are using a version that is only suitable for testing.

If you need to work with an existing production instance, you should of course use the same version in testing. However, deprecated versions should not be used in production, because they could be exposed to vulnerabilities that will never be fixed. See deprecation policies if you are not sure about the version you are using.

Setting up MariaDB on Windows

There are two different ways to use MariaDB on Windows natively: using Zip packages or MSI packages.

In both cases, 32-bit platforms are still supported.

Check the page Installation issues on Windows to verify if current versions of MariaDB have troubles on Windows. More generally, it is a good idea to check the Troubleshooting Installation Issues category.

ZIP Packages

Windows users don't necessarily need to install MariaDB to use it. They can download ready-to-use ZIP packages to avoid any change in the system (except for downloading MariaDB and writing databases on the disk). This is very useful for testing without risking some undesired side effect on the machine in use. And it avoids the hassle of installing Docker or virtual machines.

> **MariaDB starting with 10.4.3**
> Starting with MariaDB 10.4.3, it is necessary to run mysql_install_db.exe to install the data directory.

The drawback is that MariaDB will need to be started and stopped from the command line.

See Installing MariaDB Windows ZIP Packages.

MSI Packages

MSI packages provide a friendly graphical interface to install MariaDB. The installation process is easy but flexible. For example, the user can decide which components to install, whether to install it as a service or not, and if networking should be enabled. An interface to uninstall MariaDB is also provided.

See Installing MariaDB MSI Packages on Windows.

Installing MariaDB on Docker

Docker is a container platform that runs natively on Linux. A Docker image is a representation of a basic Linux system, which usually runs a single process - in our case, that process is MariaDB. A container is an instance of an image, which can be created or destroyed instantaneously. Once a container is started, it can be used just like a normal system.

Docker runs on all major operating systems. On Windows and MacOS it runs on a Linux virtual machine, but this additional complexity is transparent for the end user.

Docker's characteristics makes it optimal to test MariaDB functionalities without wasting time on installation and without making changes to the host system. However, it is not ideal to test MariaDB performance.

See Installing and Using MariaDB via Docker.

Reinitializing MariaDB Data Directory

While experimenting with MariaDB, you could end up with an unusable installation. This occurs for example if you deliberately delete files that you shouldn't delete. If it happens, there is no need to uninstall and reinstall MariaDB. Instead, you can simply delete the contents of the data directory and run mariadb-install-db. The program will recreate your system tables and the essential files.

To know where your data directory is, check the datadir system variable.

2.1.14.2.6 Syntax Differences between MariaDB and SQL Server

Contents

This article contains a non-exhaustive list of syntax differences between MariaDB and SQL Server, and is written for SQL Server users that are unfamiliar with MariaDB.

Compatibility Features

Some features are meant to improve syntax and semantics compatibility between MariaDB versions, between MariaDB and MySQL, and between MariaDB and other DBMSs. This section focuses on compatibility between MariaDB and SQL Server.

sql_mode and old_mode

SQL semantics and syntax, in MariaDB, are affected by the sql_mode variable. Its value is a comma-separated list of flags, and each of them, if specified, affects a different aspect of SQL syntax and semantics.

A particularly important flag for users familiar with SQL Server is MSSQL.

sql_mode can be changed locally, in which case it only affects the current session; or globally, in which case it will affect all new connections (but not the connections already established). sql_mode must be assigned a comma-separated list of flags.

A usage example:

```
# check the current global and local sql_mode values
SELECT @@global.sql_mode;
SELECT @@session.sql_mode;
# empty sql_mode for all usaers
SET GLOBAL sql_mode = '';
# add MSSQL flag to the sql_mode for the current session
SET SESSION sql_mode = CONCAT(sql_mode, ',MSSQL');
```

old_mode is very similar to sql_mode, but its purpose is to provide compatibility with older MariaDB versions. Its flags shouldn't affect compatibility with SQL Server (though it is theoretically possible that some of them do, as a side effect).

Executable Comments

MariaDB supports executable comments. These are designed to write generic queries that are only executed by MariaDB, and optionally only certain versions.

The following examples show how to insert SQL code that will be ignored by SQL Server but executed by MariaDB, or some of its versions.

- Executed by MariaDB and MySQL (see below):

```
SELECT * FROM tab /*! FORCE INDEX (idx_a) */ WHERE a = 1 OR b = 2;
```

- Executed by MariaDB only:

```
SELECT * /*M! , @in_transaction */ FROM tab;
```

- Executed by MariaDB starting from version 10.0.5:

```
DELETE FROM user WHERE id = 100 /*!M100005 RETURNING email */;
```

As explained in the Understanding MariaDB Architecture page, MariaDB was initially forked from MySQL. At that time, executable comments were already supported by MySQL. This is why the `/*! ... */` syntax is supported by both MariaDB and MySQL. But because MariaDB also supports specific syntax not supported by MySQL, it added the `/*M! ... */` syntax.

Generic Syntax

Here we discuss some differences between MariaDB and SQL Server syntax that may affect any user, as well as some hints to make queries compatible with a reasonable amount of work.

Delimiters

SQL Server uses two different terminators:

- The *batch terminator* is the `go` command. It tells Microsoft clients to send the text we typed to SQL Server.
- The *query terminator* is a semicolon (`;`) and it tells SQL Server where a query ends.

It is rarely necessary to use `;` in SQL Server. It is required for certain common table expressions, for example.

But the same doesn't apply to MariaDB. **Normally, with MariaDB you only use `;`.**

However, MariaDB also has some situations where you want to use a `;` but you don't want the mariadb command-line client to send the query yet. This can be done in any situation, but it is particularly useful when creating stored routines or using BEGIN NOT ATOMIC.

The reason is better explained with an example:

```
CREATE PROCEDURE p()
BEGIN
    SELECT * FROM t1;
    SELECT * FROM t2;
END;
```

If we enter this procedure in this way in the `mariadb` client, as soon as we type the first `;` (after the first `SELECT`) and press enter, the statement will be sent. MariaDB will try to parse it, and will return an error.

To avoid this, `mariadb` implements the DELIMITER statement. This client statement is never sent to MariaDB. Instead, the client uses it to find out when the typed query should be sent. Let's correct the above example:

```
DELIMITER ||

CREATE PROCEDURE p()
BEGIN
    SELECT * FROM t1;
    SELECT * FROM t2;
END;

DELIMITER ;
```

Names

In MariaDB, most names have a maximum length of 64 characters. When migrating an SQL Server database to MariaDB, check if some names exceed this limit (SQL Server maximum length is 128).

By default, MariaDB names are case-sensitive if the operating system has case-sensitive file names (Linux), and case-insensitive if the operating system is case-insensitive (Windows). SQL Server is case-insensitive by default on all operating systems.

When migrating a SQL Server database to MariaDB on Linux, to avoid problems you may want to set the lower_case_table_names system variable to 1, making table names, database names and aliases case-insensitive.

Names can be quoted inside backtick characters (`` ` ``). This character can be used in names, in which case it should be doubled. By default this is the only way to quote names.

To also enable the use of double quotes (`"`), modify sql_mode adding the `ANSI_QUOTES` flag. This is the equivalent of setting QUOTED_IDENTIFIER ON in SQL Server.

To also enable the use of SQL Server style quotes (`[` and `]`), modify sql_mode adding the `MSSQL` flag.

The case-sensitivity of stored procedures and functions is never a problem, as they are case-insensitive in SQL Server.

Quoting Strings

In SQL Server, by default strings can only be quoted with single-quotes (`'`), and to use a double quote in a string it should be doubled (`''`). This also works by default in MariaDB.

SQL Server also allows to use double quotes (`"`) to quote strings. This works by default in MariaDB, but as mentioned before it won't work if sql_mode contains the `ANSI_QUOTES` flag.

NULL

The default semantics of NULL in SQL Server and MariaDB is the same, by default.

However, SQL Server allows one to change it globally with SET ANSI_NULLS OFF, or at database level with ALTER DATABASE.

There is no way to achieve exactly the same result in MariaDB. To perform NULL-safe comparisons in MariaDB, one should replace the = operator with the <=> operator.

Also, note that MariaDB doesn't support the `UNKNOWN` pseudo-value. An expression like `NULL OR 0` returns `NULL` in MariaDB.

LIKE

In MariaDB, LIKE expressions only have two characters with special meanings: `%` and `_` . These two characters have the same meanings they have in SQL Server.

The additional characters recognized by SQL Server (`[` , `]` and `^`) are part of regular expressions. MariaDB supports the REGEXP operator, that supports the full regular expressions syntax.

Data Definition Language

Here we discuss some DDL differences that database administrators will want to be aware of.

While this section is meant to highlight the most noticeable DDL differences between MariaDB and SQL Server, there are many others, both in the syntax and in the semantics. See the ALTER statement documentation.

Altering Tables Online

Altering tables online can be a problem, especially when the tables are big and we don't want to cause a disruption.

MariaDB offers the following solutions to help:

- The ALTER TABLE ... ALGORITHM clause allows one to specify which algorithm should be used to run a certain operation. For example `INPLACE` tells MariaDB not to create a table copy (perhaps because we don't have enough disk space), and `INSTANT` tells MariaDB to execute the operation instantaneously. Not all algorithms are supported for certain operations. If the algorithm we've chosen cannot be used, the ALTER TABLE statement will fail with an error.
- The ALTER TABLE ... LOCK clause allows one to specify which lock type should be used. For example `NONE` tells MariaDB to avoid any lock on the table, and `SHARED` only allows one to acquire a share lock. If the operation requires a lock that is more strict than the one we are requesting, the ALTER TABLE statement will fail with an error. Sometimes this happens because the `LOCK` level we want is not available for the specified `ALGORITHM` .

To find out which operations require a table copy and which lock levels are necessary, see InnoDB Online DDL Overview.

An `ALTER TABLE` can be queued because a long-running statement (even a `SELECT`) required a metadata lock. Since this may cause troubles, sometimes we want the operation to simply fail if the wait is too long. This can be achieved with the WAIT and NOWAIT clauses, whose syntax is a bit different from SQL Server.

SQL Server `WITH ONLINE = ON` is equivalent to MariaDB `LOCK = NONE`. However, note that most ALTER TABLE statements support `ALGORITHM = INSTANT`, which is non-blocking and much faster (almost instantaneous, as the syntax suggests).

IF EXISTS, IF NOT EXISTS, OR REPLACE

Most DDL statements, including ALTER TABLE, support the following syntax:

- `DROP IF EXISTS`: A warning (not an error) is produced if the object does not exist.
- `OR REPLACE`: If the object exists, it is dropped and recreated; otherwise it is created. This operation is atomic, so at no point in time does the object not exist.
- `CREATE IF NOT EXISTS`: If the object already exists, a warning (not an error) is produced. The object will not be replaced.

These statements are functionally similar (but less verbose) than SQL Server snippets similar to the following:

```
IF NOT EXISTS (
        SELECT name
            FROM sysobjects
            WHERE name = 'my_table' AND xtype = 'U'
    )
    CREATE TABLE my_table (
        ...
    )
go
```

Altering Columns

With SQL Server, the only syntax to alter a table column is `ALTER TABLE ... ALTER COLUMN`. MariaDB provides more ALTER TABLE commands to obtain the same result:

- CHANGE COLUMN allows one to perform any change by specifying a new column definition, including the name.
- MODIFY COLUMN allows any change, except renaming the column. This is a slightly simpler syntax that we can use when we don't want to change a column name.
- ALTER COLUMN allows one to change or drop the `DEFAULT` value.
- RENAME COLUMN allows one to only change the column name.

Using a more specific syntax is less error-prone. For example, by using `ALTER TABLE ... ALTER COLUMN` we will not accidentally change the data type.

The word `COLUMN` is usually optional, except in the case of `RENAME COLUMN`.

SHOW Statements

MariaDB supports SHOW statements to quickly list all objects of a certain type (tables, views, triggers...). Most `SHOW` statements support a `LIKE` clause to filter data. For example, to list the tables in the current database whose name begins with 'wp_':

```
SHOW TABLES LIKE 'wp\_%';
```

This is the equivalent of this query, which would work on both MariaDB and SQL Server:

```
SELECT TABLE_SCHEMA, TABLE_NAME
    FROM INFORMATION_SCHEMA.TABLES
    WHERE TABLE_NAME LIKE 'wp\_';
```

SHOW CREATE Statements

In general, for each `CREATE` statement MariaDB also supports a `SHOW CREATE` statement. For example there is a SHOW CREATE TABLE that returns the CREATE TABLE statement that can be used to recreate a table.

Though SQL Server has no way to show the DDL statement to recreate an object, `SHOW CREATE` statements are functionally similar to `sp_helptext()`.

Database Comments

MariaDB does not support extended properties. Instead, it supports a `COMMENT` clause for most CREATE and ALTER statements.

For example, to create and then change a table comment:

```
CREATE TABLE counter (
    c INT UNSIGNED AUTO_INCREMENT PRIMARY KEY
)
    COMMENT 'Monotonic counter'
;
ALTER TABLE counter COMMENT
    'Counter. It can contain many values, we only care about the max';
```

Comments can be seen with `SHOW CREATE` statements, or by querying `information_schema` tables. For example:

```
SELECT TABLE_COMMENT
    FROM information_schema.TABLES
    WHERE TABLE_SCHEMA = 'test' AND TABLE_NAME = 'counter';
+-------------------------------------------------------------------+
| TABLE_COMMENT                                                     |
+-------------------------------------------------------------------+
| Counter. It can contain many values, we only care about the max |
+-------------------------------------------------------------------+
```

Error Handling

MariaDB SHOW ERRORS and SHOW WARNINGS statements can be used to show errors, or warning and errors. This is convenient for clients, but stored procedures cannot work with the output of these commands.

Instead, inside stored procedures you can:

- Use the GET DIAGNOSTICS command to assign error properties to variables. This is the equivalent of using SQL Server functions like `ERROR_NUMBER()` or `ERROR_STATE()`.
- Add a DECLARE HANDLER block to handle all errors, a class of errors, or a specific error. This is the equivalent of SQL Server `TRY ... CATCH`.
- An error or warning can be generated on purpose using SIGNAL. Inside a `DECLARE HANDLER` block, RESIGNAL can be used to issue the error again, and interrupt the execution of the block. These are the equivalents of SQL Server `RAISERROR()`.

Administration

Administration and maintenance commands in MariaDB use different syntax to SQL Server.

- OPTIMIZE TABLE rebuilds table data and indexes. It can be considered as the MariaDB equivalent of SQL Server's `ALTER INDEX REBUILD`. See Defragmenting InnoDB Tablespaces for more information. This statement is always locking. It supports WAIT and NOWAIT syntax,
- MariaDB has an ANALYZE TABLE command, which is an equivalent of `UPDATE STATISTICS`.

BULK INSERT

MariaDB has no `BULK INSERT` statement. Instead, it supports:

- LOAD DATA INFILE to load data from files in CSV or similar formats;
- LOAD XML INFILE to load data from XML files.

See also How to Quickly Insert Data Into MariaDB.

2.1.14.2.7 SQL Server and MariaDB Types Comparison

Contents

This page helps to map each SQL Server type to the matching MariaDB type.

Numbers

In MariaDB, numeric types can be declared as `SIGNED` or `UNSIGNED`. By default, numeric columns are `SIGNED`, so not specifying either will not break compatibility with SQL Server.

When using `UNSIGNED` values, there is a potential problem with subtractions. When subtracting an `UNSIGNED` valued from another, the result is usually of an `UNSIGNED` type. But if the result is negative, this will cause an error. To solve this problem, we can enable the NO_UNSIGNED_SUBTRACTION flag in sql_mode.

For more information see Numeric Data Type Overview.

Integer Numbers

SQL Server Types	Size (bytes)	MariaDB Types	Size (bytes)	Notes
`tinyint`	1	TINYINT	1	
`smallint`	2	SMALLINT	2	
		MEDIUMINT	3	Takes 3 bytes on disk, but 4 bytes in memory
`int`	1	INT / INTEGER	4	
`bigint`	8	BIGINT	8	

Real Numbers (approximated)

SQL Server Types	Precision	Size	MariaDB Types	Size
`float(1-24)`	7 digits	4	FLOAT(0-23)	4
`float(25-53)`	15 digist	8	FLOAT(24-53)	8

MariaDB supports an alternative syntax: `FLOAT(M, D)`. M is the total number of digits, and D is the number of digits after the decimal point.

See also: Floating-point Accuracy.

Aliases

In SQL Server `real` is an alias for `float(24)`.

In MariaDB DOUBLE, and DOUBLE PRECISION are aliases for `FLOAT(24-53)`.

Normally, `REAL` is also a synonym for `FLOAT(24-53)`. However, the sql_mode variable can be set with the `REAL_AS_FLOAT` flag to make `REAL` a synonym for `FLOAT(0-23)`.

Real Numbers (Exact)

SQL Server Types	Precision	Size (bytes)	MariaDB Types	Precision	Size (bytes)
`decimal`	0 - 38	Up to 17	DECIMAL	0 - 38	See table

MariaDB supports this syntax: `DECIMAL(M, D)`. M and D are both optional. M is the total number of digits (10 by default), and D is the number of digits after the decimal point (0 by default). In SQL Server, defaults are 18 and 0, respectively. The reason for this difference is that SQL standard imposes a default of 0 for D, but it leaves the implementation free to choose any default for M.

SQL Server `DECIMAL` is equivalent to MariaDB `DECIMAL(18)`.

Aliases

The following aliases for `DECIMAL` are recognized in both SQL Server and MariaDB: `DEC`, `NUMERIC`. MariaDB also allows one to use `FIXED`.

Money

SQL Server `money` and `smallmoney` types represent real numbers guaranteeing a very low level of approximation (five decimal digits are accurate), optionally associated with one of the supported currencies.

MariaDB doesn't have monetary types. To represent amounts of money:

- Store the currency in a separate column, if necessary. It's possible to use a foreign key to a currencies table, or the ENUM type.
- Use a non-approximated type:
  - DECIMAL is very convenient, as it allows one to store the number as-is. But calculations are potentially slower.
  - An integer type is faster for calculations. It is possible to store, for example, the amount of money multiplied by 100.

There is a small incompatibility that users should be aware about. `money` and `smallmoney` are accurate to about 4 decimal digits. This means that, if you use enough decimal digits, operations on these types may produce different results than the results they would produce on MariaDB types.

Bits

The BIT type is supported in MariaDB. Its maximum size is `BIT(64)`. The `BIT` type has a fixed length. If we insert a value which requires less bits than the ones that are allocated, zero-bits are padded on the left.

In MariaDB, binary values can be written in one of the following ways:

- `b'value'`
- `0value` where `value` is a sequence of 0 and 1 digits. Hexadecimal syntax can also be used. For more details, see Binary Literals and Hexadecimal Literals.

MariaDB and SQL Server have different sets of bitwise operators. See Bit Functions and Operators.

BOOLEAN Pseudo-Type

In SQL Server, it is common to use `bit` to represent boolean values. In MariaDB it is possible to do the same, but this is not a common practice.

A column can also be defined as BOOLEAN or `BOOL`, which is just a synonym for TINYINT. `TRUE` and `FALSE` keywords also exist, but they are synonyms for 1 and 0. To understand what this implies, see Boolean Literals.

In MariaDB `'True'` and `'False'` are always strings.

Date and Time

SQL Server Types	Range	Precision	Size (bytes)	MariaDB Types	Range	Size (bytes)	Precision	Notes
`date`	0001-01-01 - 9999-12-31	3	/	DATE	0001-01-01 - 9999-12-31	3	/	They cover the same range
`datetime`	1753-01-01 - 9999-12-31	8	0 to 3, rounded	DATETIME	001-01-01 - 9999-12-31	8	0 to 6	MariaDB values are not approximated, see below.
`datetime2`	001-01-01 - 9999-12-31	8	6 to 8	DATETIME	001-01-01 - 9999-12-31	8	0 to 6	MariaDB values are not approximated, see below.
`smalldatetime`				DATETIME				
`datetimeoffset`				DATETIME				
`time`				TIME				

You may also consider the following MariaDB types:

- TIMESTAMP has little to do with SQL Server's `timestamp`. In MariaDB it is the number of seconds elapsed since the beginning of 1970-01-01, with a decimal precision up to 6 digits (0 by default). The maximum allowed value is '2038-01-19 03:14:07'. Values are always stored in UTC. A TIMESTAMP column can optionally be automatically set to the current timestamp on insert, on update, or both. It is not meant to be a unique row identifier. Also, in MariaDB the range of TIMESTAMP values is
- YEAR is a 1-byte type representing years between 1901 and 2155, as well as 0000.

Zero Values

MariaDB allows a special value where all the parts of a date are zeroes: `'0000-00-00'`. This can be disallowed by setting sql_mode=NO_ZERO_DATE.

It is also possible to use values where only some date parts are zeroes, for example `'1994-01-00'` or `'1994-00-00'`. These values can be disallowed by setting sql_mode=NO_ZERO_IN_DATE. They are not affected by `NO_ZERO_DATE`.

Syntax

Several different date formats are understood. Typically used formats are `'YYYY-MM-DD'` and `YYYYMMDD`. Several separators are accepted.

The syntax defined in standard SQL and ODBC are understood - for example, `DATE '1994-01-01'` and `{d '1994-01-01'}`. Using these eliminates possible ambiguities in contexts where a temporal value could be interpreted as a string or as an integer.

See Date and Time Literals for the details.

Precision

For temporal types that include a day time, MariaDB allows a precision from 0 to 6 (microseconds), 0 being the default. The subsecond part is never approximated. It adds up to 3 bytes. See Data Type Storage Requirements for the details.

String and Binary

Binary Strings

SQL Server Types	Size (bytes)	MariaDB Types	Notes
`binary`	1 to 8000	VARBINARY or BLOB	See below for `BLOB` types
`varbinary`	1 to 8000	VARBINARY or BLOB	See below for `BLOB` types
`image`	2^31-1	VARBINARY or BLOB	See below for `BLOB` types

The `VARBINARY` type is similar to `VARCHAR`, but stores binary byte strings, just like SQL Server `binary` does.

For large binary strings, MariaDB has four `BLOB` types, with different sizes. See BLOB and TEXT Data Types for more information.

Character Strings

One important difference between SQL Server and MariaDB is that **in MariaDB character sets do not depend on types and collations**. Character sets can be set at database, table or column level. If this is not done, the default character sets applies, which is specified by the character_set_server system variable.

To create a MariaDB table that is identical to a SQL Server table, **it may be necessary to specify a character set for each string column**. However, in many cases using UTF-8 will work.

SQL Server Types	Size (bytes)	MariaDB Types	Size (bytes)	Character set
`char`	1 to 8000	CHAR	0 to 255	`utf8mb4` (1, 4)
`varchar`	1 to 8000	VARCHAR	0 to 65,532 (2)	`utf8mb4` (1)
`text`	2^31-1	TEXT	2^31-1	`ucs2`
`nchar`	2 to 8000	CHAR	0 to 255	`utf16` or `ucs2` (3, 4)
`nvarchar`	2 to 8000	VARCHAR	0 to 65,532 (2) (5)	`utf16` or `ucs2` (1) (3)
`ntext`	2^30 - 1	TEXT	2^31-1	`ucs2`

Notes:

1) If SQL Server uses a non-unicode collation, a subset of UTF-8 is used. So it is possible to use a smaller character set on MariaDB too.

2) InnoDB has a maximum row length of 65,535 bytes. TEXT columns do not contribute to the row size, because they are stored separately (except for the first 12 bytes).

3) In SQL Server, UTF-16 is used if data contains Supplementary Characters, otherwise UCS-2 is used. If not sure, use `utf16` in MariaDB.

4) In SQL Server, the value of `ANSI_PADDING` determines if `char` values should be padded with spaces to their maximum length. In MariaDB, this depends on the PAD_CHAR_TO_FULL_LENGTH sql_mode flag.

5) See JSON, below.

SQL Server Special Types

rowversion

MariaDB does not have the `rowversion` type.

If the only purpose is to check if a row has been modified since its last read, a TIMESTAMP column can be used instead. Its default value should be `ON UPDATE CURRENT_TIMESTAMP`. In this way, the timestamp will be updated whenever the column is modified.

A way to preserve much more information is to use a temporal table. Past versions of the row will be preserved.

sql_variant

MariaDB does not support the `sql_variant` type.

MariaDB is quite flexible about implicit and explicit type conversions. Therefore, for most cases storing the values as a string should be equivalent to using `sql_variant`.

Be aware that the maximum length of an `sql_variant` value is 8,000 bytes. In MariaDB, you may need to use `TINYBLOB`.

uniqueidentifier

While MariaDB does not support the `uniqueidentifier` type, the UUID type can typically be used for the same purpose.

`uniqueidentifier` columns contain 16-bit GUIDs. MariaDB UUID columns store UUIDv1 values (128 bits).

The UUID type was implemented in MariaDB 10.7. On older versions, you can generate unique values with the UUID() or UUID_SHORT() functions, and store them in `BIT(128)` or `BIT(64)` columns, respectively.

xml

MariaDB does not support the `xml` type.

XML data can be stored in string columns. MariaDB supports several XML functions.

JSON

With SQL Server, typically JSON documents are stored in `nvarchar` columns in a text form.

MariaDB has a JSON pseudo-type that maps to LONGTEXT. However, from MariaDB 10.5 the `JSON` pseudo-type also checks that the value is valid a JSON document.

MariaDB supports different JSON functions than SQL Server. MariaDB currently has more functions, and SQL Server syntax will not work. See JSON functions for more information.

MariaDB Specific Types

The following types are supported by MariaDB and don't have a direct equivalent in SQL Server. If you are migrating your database to MariaDB, you can consider using these types.

- INET6 - IPv6 addresses.
- INET4 - IPv4 addresses.

2.1.14.2.8 MariaDB Transactions and Isolation Levels for SQL Server Users

Contents

This page explains how transactions work in MariaDB, and highlights the main differences between MariaDB and SQL Server transactions.

Note that XA transactions are handled in a completely different way and are not covered in this page. See XA Transactions.

Missing Features

These SQL Server features are not available in MariaDB:

- Autonomous transactions;
- Distributed transactions.

Transactions, Storage Engines and the Binary Log

In MariaDB, transactions are optionally implemented by storage engines. The default storage engine, InnoDB, fully supports transactions. Other transactional storage engines include MyRocks and TokuDB. Most storage engines are not transactional, therefore they should not considered general purpose engines.

Most of the information in this page refers to generic MariaDB server behaviors or InnoDB. For MyRocks and TokuDB please check the proper KnowledgeBase sections.

Writing into a non-transactional table in a transaction can still be useful. The reason is that a metadata lock is acquired on the table for the duration of the transaction, so that ALTER TABLEs are queued.

It is possible to write into transactional and non-transactional tables within a single transaction. It is important to remember that non-transactional engines will have the following limitations:

- In case of rollback, changes to non-transactional engines won't be undone. We will receive a warning `1196` which reminds us of this.
- Data in transactional tables cannot be changed by other connections in the middle of a transaction, but data in non-transactional tables can.
- In case of a crash, committed data written into a transactional table can always be recovered, but this is not necessarily true for non-transactional tables.

If the binary log is enabled, writing into different transactional storage engines in a single transaction, or writing into transactional and non-transactional engines inside the same transaction, implies some extra work for MariaDB. It needs to perform a two-phase commit to be sure that changes to different tables are logged in the correct order. This affects the performance.

Transaction Syntax

The first read or write to an InnoDB table starts a transaction. No data access is possible outside a transaction.

By default autocommit is on, which means that the transaction is committed automatically after each SQL statement. We can disable it, and manually commit transactions:

```
SET SESSION autocommit = 0;
SELECT ... ;
DELETE ... ;
COMMIT;
```

Whether autocommit is enabled or not, we can start transactions explicitly, and they will not be automatically committed:

```
START TRANSACTION;
SELECT ... ;
DELETE ... ;
COMMIT;
```

`BEGIN` can also be used to start a transaction, but does not work in stored procedures.

Read-only transactions are also available using `START TRANSACTION READ ONLY`. This is a small performance optimization. MariaDB will issue an error when trying to write data in the middle of a read-only transaction.

Only DML statements are transactional and can be rolled back. This may change in a future version, see MDEV-17567 - Atomic DDL and MDEV-4259 - transactional DDL.

Changing autocommit and explicitly starting a transaction will implicitly commit the active transaction, if any. DDL statements, and several other statements, implicitly commit the active transaction. See SQL statements That Cause an Implicit Commit for the complete list of these statements.

A rollback can also be triggered implicitly, when certain errors occur.

You can experiment with transactions to check in which cases they implicitly commit or rollback. The in_transaction system variable can help: it is set to 1 when a transaction is in progress, or 0 when no transaction is in progress.

This section only covers the basic syntax for transactions. Much more options are available. For more information, see Transactions.

Constraint Checking

MariaDB supports the following constraints:

- Primary keys
- UNIQUE
- CHECK
- Foreign keys

In some databases, constraints can temporarily be violated during a transaction, and their enforcement can be deferred to the commit time. SQL Server does not support this, and always validates data against constraints at the end of each statement.

MariaDB does something different: it always checks constraints after each row change. There are cases this policy makes some statements fail with an error, even if those statements would work on SQL Server.

For example, suppose you have an `id` column that is the primary key, and you need to increase its value for some reason:

```
SELECT id FROM customer;
+----+
| id |
+----+
|  1 |
|  2 |
|  3 |
|  4 |
|  5 |
+----+

UPDATE customer SET id = id + 1;
ERROR 1062 (23000): Duplicate entry '2' for key 'PRIMARY'
```

The reason why this happens is that, as the first thing, MariaDB tries to change 1 to 2, but a value of 2 is already present in the primary key.

A solution is to use this non-standard syntax:

```
UPDATE customer SET id = id + 1 ORDER BY id DESC;
Query OK, 5 rows affected (0.00 sec)
Rows matched: 5  Changed: 5  Warnings: 0
```

Changing the ids in reversed order won't duplicate any value.

Similar problems can happen with `CHECK` constraints and foreign keys. To solve them, we can use a different approach:

```
SET SESSION check_constraint_checks = 0;
-- run some queries
-- that temporarily violate a CHECK clause
SET SESSION check_constraint_checks = 1;

SET SESSION foreign_key_checks = 0;
-- run some queries
-- that temporarily violate a foreign key
SET SESSION foreign_key_checks = 1;
```

The last solutions temporarily disable `CHECK` constraints and foreign keys. Note that, while this may solve practical problems, it is dangerous because:

- This doesn't disable a single `CHECK` or foreign key, but also others, that you don't expect to violate.
- This doesn't defer the constraint checks, but it simply disables them for a while. This means that, if you insert some invalid values, they will not be detected.

See check_constraint_checks and foreign_key_checks system variables.

Isolation Levels and Locks

For more information about MariaDB isolation levels see SET TRANSACTION.

Locking Reads

In MariaDB, the locks acquired by a read do not depend on the isolation level (with one exception noted below).

As a general rule:

- Plain SELECTs are not locking, they acquire snapshots instead.
- To force a read to acquire a shared lock, use SELECT ... LOCK IN SHARED MODE.
- To force a read to acquire an exclusive lock, use SELECT ... FOR UPDATE.

Changing the Isolation Level

The default, the isolation level in MariaDB is `REPEATABLE READ`. This can be changed with the tx_isolation system variable.

Applications developed for SQL Server and later ported to MariaDB may run with `READ COMMITTED` without problems. Using a stricter level would reduce scalability. To use `READ COMMITTED` by default, add the following line to the MariaDB configuration file:

```
tx_isolation = 'READ COMMITTED'
```

It is also possible to change the default isolation level for the current session:

```
SET SESSION tx_isolation = 'read-committed';
```

Or just for one transaction, by issuing the following statement before starting a transaction:

```
SET TRANSACTION ISOLATION LEVEL READ COMMITTED;
```

How Isolation Levels are Implemented in MariaDB

MariaDB supports the following isolation levels:

- `READ UNCOMMITTED`
- `READ COMMITTED`
- `REPEATABLE READ`
- `SERIALIZABLE`

MariaDB isolation levels differ from SQL Server in the following ways:

- `REPEATABLE READ` does not acquire share locks on all read rows, nor a range lock on the missing values that match a `WHERE` clause.
- It is not possible to change the isolation level in the middle of a transaction.
- `SNAPSHOT` isolation level is not supported. Instead, you can use `START TRANSACTION WITH CONSISTENT SNAPSHOT` to acquire a snapshot at the beginning of the transaction. This is compatible with all isolation levels.

Here is an example of `WITH CONSISTENT SNAPSHOT` usage:

```
-- session 1
SELECT * FROM t1;
+----+
| id |
+----+
|  1 |
+----+

SELECT * FROM t2;
+----+
| id |
+----+
|  1 |
+----+

START TRANSACTION WITH CONSISTENT SNAPSHOT;

-- session 2
INSERT INTO t1 VALUES (2);

-- session 1
SELECT * FROM t1;
+----+
| id |
+----+
|  1 |
+----+

-- session 2
INSERT INTO t2 VALUES (2);

-- session 1
SELECT * FROM t2;
+----+
| id |
+----+
|  1 |
+----+
```

As you can see, session 1 uses `WITH CONSISTENT SNAPSHOT`, thus it sees all tables as they were when the transaction begun.

Avoiding Lock Waits

When we try to read or modify a row that is exclusive-locked by another transaction, our transaction is queued until that lock is released. There could be more queued transactions waiting to acquire the same lock, in which case we will wait even more.

There is a timeout for such waits, defined by the innodb_lock_wait_timeout variable. If it is set to 0, statements that encounter a row lock will fail immediately. When the timeout is exceeded, MariaDB produces the following error:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

It is important to note that this variable has two limitations (by design):

- It only affects transactional statements, not statements like `ALTER TABLE` or `TRUNCATE TABLE`.
- It only concerns row locks. It does not put a timeout on metadata locks, or table locks acquired - for example - with the LOCK TABLES statement.

Note however that lock_wait_timeout can be used for metadata locks.

There is a special syntax that can be used with `SELECT` and some non-transactional statements including `ALTER TABLE`: the WAIT and NOWAIT clauses. This syntax puts a timeout in seconds for all lock types, including row locks, table locks, and metadata locks. For example:

```
Session 1:
START TRANSACTION;
-- let's acquire a metadata lock
SELECT id FROM t WHERE 0;

Session 2:
DROP TABLE t WAIT 0;
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

InnoDB Transactions

InnoDB Lock Types

InnoDB locks are classified based on what exactly they lock, and which operations they lock.

The first classification is the following:

- Record Locks lock a row or, more precisely, an index entry.
- Gap Locks lock an interval between two index entries. Note that indexes have virtual values of -Infinum and Infinum, so a gap lock can cover the gap before the first or after the last index entry.
- Next-Key Locks lock an index entry and the gap between it and the next entry. They're a combination of record locks and gap locks.
- Insert Intention Locks are gap locks acquired before inserting a new row.

Lock modes are the following:

- Exclusive Locks (X) are generally acquired on writes, e.g. immediately before deleting a row. Only one exclusive lock can be acquired on a resource simultaneously.
- Shared Locks (S) can be acquired acquired on reads. Multiple shared locks can be acquired at the same time (because the rows are not supposed to change when shared-locked) but are incompatible with exclusive locks.
- Intention locks (IS, XS) are acquired when it is not possible to acquire an exclusive lock or a shared lock. When a lock on a row or gap is released, the oldest intention lock on that resource (if any) is converted to an X or S lock.

For more information see InnoDB Lock Modes.

Information Schema

Querying the information_schema is the best way to see which transactions have acquired some locks and which transactions are waiting for some locks to be released.

In particular, check the following tables:

- INNODB_LOCKS: requests for locks not yet fulfilled, or that are blocking another transaction.
- INNODB_LOCK_WAITS: queued requests to acquire a lock.
- INNODB_TRX: information about all currently executing InnoDB transactions, including SQL queries that are running.

Here is an example of their usage.

```
-- session 1
START TRANSACTION;
UPDATE t SET id = 15 WHERE id = 10;

-- session 2
DELETE FROM t WHERE id = 10;

-- session 1
USE information_schema;
SELECT l.*, t.*
    FROM information_schema.INNODB_LOCKS l
    JOIN information_schema.INNODB_TRX t
        ON l.lock_trx_id = t.trx_id
    WHERE trx_state = 'LOCK WAIT' \G
*************************** 1. row ***************************
                    lock_id: 840:40:3:2
                lock_trx_id: 840
                  lock_mode: X
                  lock_type: RECORD
                 lock_table: `test`.`t`
                 lock_index: PRIMARY
                 lock_space: 40
                  lock_page: 3
                   lock_rec: 2
                  lock_data: 10
                     trx_id: 840
                  trx_state: LOCK WAIT
                trx_started: 2019-12-23 18:43:46
     trx_requested_lock_id: 840:40:3:2
          trx_wait_started: 2019-12-23 18:43:46

```

Deadlocks

InnoDB detects deadlocks automatically. Since this consumes CPU time, some users prefer to disable this feature by setting the innodb_deadlock_detect variable to 0. If this is done, locked transactions will wait until the they exceed the innodb_lock_wait_timeout. Therefore it is important to set innodb_lock_wait_timeout to a very low value, like 1.

When InnoDB detects a deadlock, it kills the transaction that modified the least amount of data. The client will receive the following error:

```
ERROR 1213 (40001): Deadlock found when trying to get lock; try restarting transaction
```

The latest detected deadlock, and the killed transaction, can be viewed in the output of SHOW ENGINE InnoDB STATUS. Here's an example:

```
------------------------
LATEST DETECTED DEADLOCK

 0: len 4; hex 8000000b; asc     ;;
 1: len 6; hex 00000000034f; asc      O;;
 2: len 7; hex 770000019d031d; asc w      ;;

*** WE ROLL BACK TRANSACTION (2)
```

The latest detected deadlock never disappears from the output of `SHOW ENGINE InnoDB STATUS`. If you cannot see any, MariaDB hasn't detected any InnoDB deadlocks since the last restart.

Another way to monitor deadlocks is to set innodb_print_all_deadlocks to 1 (0 is the default). InnoDB will log all detected deadlocks into the error log.

2.1.14.2.9 MariaDB Authorization and Permissions for SQL Server Users

Contents

Understanding Accounts and Users

MariaDB authorizes access and check permissions on accounts, rather than users. Even if MariaDB supports standard SQL commands like CREATE USER and DROP USER, it is important to remember that it actually works with accounts.

An account is specified in the format `'user'@'host'`. The quotes are optional and allow one to include special characters, like dots. The host part can actually be a pattern, which follows the same syntax used in `LIKE` comparisons. Patterns are often convenient because they can match several hostnames.

Here are some examples.

Omitting the host part indicates an account that can access from any host. So the following statements are equivalent:

```
CREATE USER viviana;
CREATE USER viviana@'%';
```

However, such accounts may be unable to connect from localhost if an anonymous user `''@'%'` is present. See localhost and % for the details.

Accounts are not bound to a specific database. They are global. Once an account is created, it is possible to assign it permissions on any existing or non existing database.

The sql_mode system variable has a NO_AUTO_CREATE_USER flag. In recent MariaDB versions it is enabled by default. If it is not enabled, a GRANT statement specifying privileges for a non-existent account will automatically create that account.

For more information: Account Management SQL Commands.

Setting or Changing Passwords

Accounts with the same username can have different passwords.

By default, an account has no password. A password can be set, or changed, in the following way:

- By specifying it in CREATE USER.
- By the user, with SET PASSWORD.
- By root, with `SET PASSWORD` or ALTER USER.

With all these statements (`CREATE USER` , `ALTER USER` , `SET PASSWORD`) it is possible to specify the password in plain or as a hash:

```
-- specifying plain passwords:
CREATE USER tom@'%.example.com' IDENTIFIED BY 'plain secret';
ALTER USER tom@'%.example.com' IDENTIFIED BY 'plain secret';
SET PASSWORD = 'plain secret';
-- specifying hashes:
CREATE USER tom@'%.example.com' IDENTIFIED BY PASSWORD 'secret hash';
ALTER USER tom@'%.example.com' IDENTIFIED BY PASSWORD 'secret hash';
SET PASSWORD = PASSWORD('secret hash');
```

The PASSWORD() function uses the same algorithm used internally by MariaDB to generate hashes. Therefore it can be used to get a hash from a plain password. Note that this function should not be used by applications, as its output may depend on MariaDB version and configuration.

`SET PASSWORD` applies to the current account, by default. Superusers can change other accounts passwords in this way:

```
SET PASSWORD FOR tom@'%.example.com' = PASSWORD 'secret hash';
```

MariaDB starting with 10.4.3

Passwords can have an expiry date, set by default_password_lifetime. To set a different date for a particular user:

```
CREATE USER 'tom'@'%.example.com' PASSWORD EXPIRE INTERVAL 365 DAY;
```

To set no expiry date for a particular user:

```
CREATE USER 'tom'@'%.example.com' PASSWORD EXPIRE NEVER;
```

For more details, see User Password Expiry.

MariaDB starting with 10.4.2

It is also possible to lock an account with immediate effect:

```
CREATE USER 'tom'@'%.example.com' ACCOUNT LOCK;
```

See Account Locking for more details.

Authentication Plugins

MariaDB supports authentication plugins. These plugins implement user's login and authorization before they can use MariaDB.

Each user has one or more authentication plugins assigned. The default one is mysql_native_password. It is the traditional login using the username and password set in MariaDB, as described above.

MariaDB starting with 10.4

On UNIX systems, root is also assigned the unix_socket plugin, which allows a user logged in the operating system to be recognized by MariaDB.

Windows users may be interested in the named pipe and GSSAPI plugins. GSSAPI also requires the use of a plugin on the client side.

A plugin can be assigned to a user with `CREATE USER`, `ALTER USER` or `GRANT`, using the `IDENTIFIED VIA` syntax. For example:

```
CREATE USER username@hostname IDENTIFIED VIA gssapi;
GRANT SELECT ON db.* TO username@hostname IDENTIFIED VIA named_pipe;
```

TLS connections

A particular user can be required to use TLS connections. Additional requirements can be set:

- Having a valid X509 certificate.
- The certificate may be required to be issued by a particular authority.
- A particular certificate subject can be required.
- A particular certificate cipher suite can be required.

These requirements can be set with `CREATE USER`, `ALTER USER` or `GRANT`. For the syntax, see CREATE USER.

MariaDB can be bundled with several cryptography libraries, depending on its version. For more information about the libraries, see TLS and Cryptography Libraries Used by MariaDB.

For more information about secure connections, see Secure Connections Overview.

Permissions

Permissions can be granted to accounts. As mentioned before, the specified accounts can actually be patterns, and multiple accounts may match a pattern. For example, in this example we are creating three accounts, and we are assigning permissions to all of them:

```
CREATE USER 'tom'@'example.com';
CREATE USER 'tom'@'123.123.123.123;
CREATE USER 'tom'@'tomlaptop';
GRANT USAGE ON *.* TO tom@'%';
```

The following permission levels exist in MariaDB:

- Global privileges;
- Database privileges;
- Table privileges;
- Column privileges;
- Function and procedure privileges.

Note that database and schema are synonymous in MariaDB.

Permissions can be granted for non-existent objects that could exist in the future.

The list of supported privileges can be found in the GRANT page. Some highlights can be useful for SQL Server users:

- `USAGE` privilege has no effect. The `GRANT` command fails if we don't grant at least one privilege; but sometimes we want to run it for other purposes, for example to require a user to use TLS connections. In such cases, it is useful to grant `USAGE`.
- Normally we can obtain a list of all databases for which we have at least one permission. The `SHOW DATABASES` permission allows getting a list of all databases.
- There is no `SHOWPLAN` privilege in MariaDB. Instead, EXPLAIN requires the `SELECT` privilege for each accessed table and the `SHOW VIEW` privilege for each accessed view.
- The same permissions are needed to see a table structure (`SELECT`) or a view definition (`SHOW VIEW`).
- `REFERENCES` has no effect.

MariaDB does not support negative permissions (the `DENY` command).

Some differences concerning the SQL commands:

- In MariaDB `GRANT` and `REVOKE` statements can only assign/revoke permissions to one user at a time.
- While we can assign/revoke privileges at column level, we have to run a `GRANT` or `REVOKE` statement for each column. The `table (column_list)` syntax is not recognized by MariaDB.
- In MariaDB it is not needed (or possible) to specify a class type.

Roles

MariaDB supports roles. Permissions can be assigned to roles, and roles can be assigned to accounts.

An account may have zero or one default roles. A default role is a role that is automatically active for a user when they connect. To assign an account or remove a default role, these SQL statements can be used:

```
SET DEFAULT ROLE some_role FOR username@hostname;
SET DEFAULT ROLE NONE FOR username@hostname;
```

Normally a role is not a default role. If we assign a role in this way:

```
GRANT some_role TO username@hostname;
```

...the user will not have that role automatically enabled. They will have to enable it explicitly:

```
SET ROLE some_role;
```

MariaDB does not have predefined roles, like public.

For an introduction to roles, see Roles Overview.

2.1.14.2.10 Repairing MariaDB Tables for SQL Server Users

Contents

Repairing tables in MariaDB is not similar to repairing tables in SQL Server.

The first thing to understand is that every MariaDB table is handled by a storage engine. Storage engines are plugins that know how to physically read and write a table, so each storage engine allows one to repair tables in different ways. The default storage engine is InnoDB.

MariaDB provides specific SQL statements to deal with corrupted tables:

- CHECK TABLE checks if a table is corrupted;
- REPAIR TABLE repairs a table if it is corrupted.

As a general rule, there is no reason why a table that is corrupted on a master should also be corrupted on the slaves. Therefore, `REPAIR` is generally used with the `NO_WRITE_TO_BINLOG` option, to avoid replicating it to the slaves.

Partitioned Tables

Partitioned tables are normally split into multiple physical files (one per partition). Even if one of the partitions is corrupted, in most cases other partitions are healthy.

For this reason, `CHECK TABLE` and `REPAIR TABLE` don't work on partitioned tables. Instead, use ALTER TABLE to check or repair a single partition.

For example:

```
ALTER TABLE orders CHECK PARTITION p_2019, p_2020;
ALTER TABLE orders REPAIR PARTITION p_2019, p_2020;
```

Indexes

Indexes can get corrupted. However, as long as data is not corrupted, indexes can always be dropped and rebuilt with ALTER TABLE:

```
ALTER TABLE customer DROP INDEX idx_email;
ALTER TABLE customer ADD INDEX idx_email (email);
```

Checking and Repairing Tables

Here we discuss how to repair tables, depending on the storage engine.

InnoDB

InnoDB follows the "fail fast" philosophy. If table corruption is detected, by default InnoDB deliberately causes MariaDB to crash to avoid corruption propagation, logging an error into the error log. This happens even if the corruption is found with a `CHECK TABLE` statement. This behavior can be changed with the innodb_corrupt_table_action server variable.

To repair an InnoDB table after a crash:

1. Restart MariaDB with the `--innodb-force-recovery` option set to a low but non-zero value.
2. If MariaDB fails to start, retry with a higher value. Repeat until you succeed.

At this point, you can follow two different procedures, depending if you can use a backup or not. Provided that you have a usable backup, it is often the best option to bring the database up quickly. But if you want to reduce the data loss as much as possible, you prefer to follow the second method.

Restoring a backup:

1. Drop the whole database with DROP DATABASE.
2. Restore a backup of the database. The exact procedure depends on the type of backup.

Recovering existing data:

1. Dump data from the corrupter table, ordered by primary key. MariaDB could crash when it finds damaged data. Repeat the process skipping damaged data.
2. Save somewhere the table structure with SHOW CREATE TABLE.
3. Restart MariaDB.
4. Drop the table with DROP TABLE.
5. Recreate the table and restore the dump.

For more details, see InnoDB Recovery Modes.

Aria and MyISAM

MyISAM is not crash-safe. In case of a MariaDB crash, the changes applied to MyISAM tables but not yet flushed to the disk are lost.

Aria is crash-safe by default, which means that in case of a crash, after repairing any table that is damaged, no changes are lost. However, Aria tables are not crash-safe if created with `TRANSACTIONAL=0` or `ROW_FORMAT` set to `FIXED` or `DYNAMIC`.

System tables use the Aria storage engine and they are crash-safe.

To check if a MyISAM/Aria table is corrupted, we can use CHECK TABLE. To repair a MyISAM/Aria table, one can use REPAIR TABLE. Before running `REPAIR TABLE` against big tables, consider increasing myisam_repair_threads or aria_repair_threads.

MyISAM and Aria tables can also be automatically repaired when corruption is detected. This is particularly useful for Aria, in case corrupted system tables prevent MariaDB from starting. See myisam_recover_options and aria_recover_options. By default Aria runs the quickest repair type. Occasionally, to repair a system table, we may have to start MariaDB in this way:

```
mysqld --aria-recover-options=BACKUP,FORCE
```

It is also possible to stop MariaDB and repair MyISAM tables with myisamchk, and Aria tables with aria_chk. With default values, a repair can be unnecessarily very slow. Before running these tools, be sure to check the Memory and Disk Use

With myisamchk page.

Other Storage Engines

Notes on the different storage engines:

- For MyRocks, see MyRocks and CHECK TABLE.
- With ARCHIVE, `REPAIR TABLE` also improves the compression rate.
- For CSV, see Checking and Rpairing CSV Tables.
- Some special storage engines, like MEMORY or BLACKHOLE, do not support any form of check and repair.

2.1.14.2.11 MariaDB Backups Overview for SQL Server Users

Contents

MariaDB has the following types of backups:

- Logical backups (dumps).
- Hot backups with Mariabackup.
- Snapshots.
- Incremental backups.

Logical Backups (Dumps)

A *dump*, also called a *logical backup*, consists of the SQL statements needed to recreate MariaDB databases and their data into another server. A dump is the slowest form of backup to restore, because it implies executing all the SQL statements needed to recreate data. However it is also the most flexible, because restoring will work on any MariaDB version, because the SQL syntax is usually compatible. It is even possible to restore a dump into an older version, though the incompatible syntax (new features) will be ignored. Under certain conditions, MariaDB dumps may also be restored on other DBMSs, including SQL Server.

The compatibility between different versions and technologies is achieved by using executable comments, but we should be aware of how they work. If we use a feature introduced in version 11.1, for example, it will be included in the dump inside an executable comment. If we restore that backup on a server with MariaDB 10.11, the 11.1 feature will be ignored. This is the only way to restore backups in older MariaDB versions.

mariadb-dump

Logical backups are usually taken with mariadb-dump (previously called mysqldump).

mariadb-dump allows one to dump all databases, a single database, or a set of tables from a database. It is even possible to specify a `WHERE` clause, which under certain circumstances allows to obtain incremental dumps.

For consistency reasons, when using the default storage engine InnoDB, it is important to use the `--single-transaction` option. This will read all data in a single transaction. It's important however to understand that long transactions may have a big impact on performance.

The `--master-data` option adds the statements to setup a slave to the dump.

MariaDB also supports statements which make easy to write applications to obtain custom types of dumps. For most `CREATE <object_type>` statement, a corresponding `SHOW CREATE <object_type>` exists. For example, SHOW CREATE TABLE returns the `CREATE TABLE` statement that can be used to recreate a certain table, without data.

mydumper

mydumper is a 3rd party tools to take dumps from MariaDB and MySQL databases. It is much faster than mariadb-dump because it takes backups with several parallel threads, usually one thread for each available CPU core. It produces several files, that can be used to restore a database using the related tool myloader.

Since is it a 3rd party tool, it could be incompatible with some present or future MariaDB features.

Hot Backups (mariabackup)

Mariabackup is a tool for taking a backup of MariaDB files while MariaDB is working. A lock is only held for a small amount of time, so it is suitable to backup a server without causing disruptions. It works by taking corrupted backups and then bringing them to a consistent state by using the InnoDB undo log. Mariabackup also properly backups MyRocks tables and non-transactional storage engines.

Cold Backups and Snapshots

A copy of all MariaDB files is a working backup. Therefore, the easiest way to backup a dataset is to shutdown the server and copy all its files. It will be entirely possible to start another server with a copy of those files. This is often referred to as a *cold backup*. However, in most cases we don't want to do this, because it implies downtime for the server: it will not be working at least for the time necessary to copy the files.

Snapshots are usually a better idea, as they are a consistent copy of the files at a given moment in time, taken without stopping the normal operations.

A snapshot of the files can be taken at several levels: filesystem level, if the filesystem supports snapshots, for example zfs; Linux Logical Volume Manager (LVM) also supports snapshots; and virtual machines also allow one to take snapshots. Windows shadow copies are also snapshots, with a benefit: it is possible to restore a single file from a shadow copy. A snapshot is not an expensive operation, because it does not imply a copy of the files. The current files will not be modified anymore, and changes to them will be written in separate places.

The problem with snapshots is that they behave like a logical copy of the files as they are in a given point in time. But database files are not guaranteed to be consistent in every moment, because contents can be buffered before being flushed to the disk. You can think a database snapshot like a database after an operating system crash.

With non-transactional tables, some data is typically lost. Data changes that are present in a buffer before the snapshot, but not written on a disk, cannot be recovered in any way. Data changes in transactional tables, like InnoDB tables, can always be recovered after restoring a snapshot (or after a crash), as long as a commit was done. Tables will still need to be repaired, just like it happens after an SQL Server crash.

Snapshots can be taken while MariaDB is running. To restore them, stop MariaDB first - or kill the process, because you don't really care of the consequences in this case. Then restore a snapshot and start MariaDB again.

For more information about snapshots, check your filesystem, LVM or virtual machine documentation.

Incremental Backups

The term incremental backup in MariaDB indicates what SQL Server calls a *differential backup*. An important difference is that in SQL Server such backups are based on the transaction log, which wouldn't be possible in MariaDB because transaction logs are handled at storage engine level.

As mentioned here, MariaDB can use the binary log instead for backup purposes. Such incremental backups can be done manually. This means that:

- The binary log files are copied just like any other regular file.
- To copy those files it is necessary to have the proper permissions at filesystem level, not in MariaDB.
- Backups do not expire until we delete the last needed complete backup.

Replaying the Binary Log

The page Using mariadb-binlog shows how to use the mariadb-binlog utility to replay a binary log file.

The page also shows how to edit the binary log before replaying it. This allows one to undo an SQL statement that was executed by mistake, for example a `DROP TABLE` against a wrong table. The high level procedure is the following:

- Restore a backup that is older than the SQL statement to undo.
- Use `mariadb-binlog` to generate a file with the SQL statements that were executed after the backup.
- Edit the SQL file, erasing the unwanted statement.
- Run the SQL file.

Incremental Backups with mariabackup

The simplest way to take an incremental backup is to use Mariabackup. This tool is able to take and restore incremental backups. For the complete procedure to use, see Incremental Backup and Restore with Mariabackup.

Mariabackup can run on both Linux and Windows systems.

Flashback

Flashback is a feature that allows one to bring all databases, some databases or some tables back to a certain point in time. This can only be done if the binary log is enabled. Flashback is not a proper backup, but it can be used to restore a certain set of data.

Copying Individual Tables

It is entirely possible to restore a single table from a physical backup, or to copy the table to another server.

With the MyISAM storage engine it was very easy to move tables between different servers, as long as the MySQL or MariaDB version was the same.

InnoDB is nowadays the default storage engine, and it is more complex, as it supports transactions for example. It still supports restoring a table from a physical file, this feature is called *transportable tablespaces*. There is a particular procedure to follow, and some limitations. This is basically the MariaDB equivalent of detaching and re-attaching tables in SQL Server.

For more information, see InnoDB File-Per-Table Tablespaces.

By default. all table files are located in the *data directory*, which is defined by the system variable datadir. There may be exceptions, because a table's files can be located elsewhere using the `DATA DIRECTORY` and `INDEX DIRECTORY` options in `CREATE TABLE`.

Regardless of the storage engine used, each table's structure is generally stored in a file with the `.frm` extension.

The files used for partitioned tables are different from the files used for non-partitioned tables. See Partitions Files for details.

2.1.14.2.12 MariaDB Replication Overview for SQL Server Users

Contents

MariaDB supports the following types of replication:

- Asynchronous replication.
- Semi-synchronous replication.
- Galera Cluster.

MariaDB starting with 10.5.1

Note: in the snippets in this page, several SQL statements use the keyword `SLAVE`. This word is considered inappropriate by some persons or cultures, so from MariaDB 10.5 it is possible to use the `REPLICA` keyword, as a synonym.

Similar synonyms will be created in the future for status variables and system variables. See MDEV-18777 to track

the status of these changes.

Asynchronous Replication

The original MariaDB replication system is asynchronous primary-replica replication.

A primary needs to have the binary log enabled. The primary logs all data changes in the binary log. Every *event* (a binary log entry) is sent to all the replicas.

For a high-level description of the binary log for SQL Server users, see Understanding MariaDB Architecture.

The events can be written in two formats: as an SQL statement (*statement-based replication*, or SBR), or as a binary representation of the change (*row-based replication*, or RBR). The former is generally slower, because the statement needs to be re-executed by the replicas. It is also less reliable, because some SQL statements are not deterministic, so they could produce different results on the replicas. On the other hand row-based replication could make the binary log much bigger, and require more network traffic. For this reason, DML statements are always logged in statement format.

For more details on replication formats, see binary log formats.

The replicas have an I/O thread that receives the binary log events and writes them to the relay log. These events are then read by the SQL thread. This thread could directly apply the changes to the local databases, and this was the only option before MariaDB 10.0.5. If parallel replication is enabled, the SQL thread hands the events to the worker thread, that apply them to the databases. The latter method is recommended for performance reasons.

When a replica cannot apply an event to the local data, the SQL thread stops. This happens, for example, if the event is a row deletion but that row doesn't exist on the replica. There can be several reasons for this, for example non-deterministic statements, or a user deleted the row in the replica. To reduce the risk, it is recommended to set read_only to 1 in the replicas.

SHOW SLAVE STATUS has columns named `Slave_SQL_State` and `Slave_IO_State` that show, respectively, if the SQL thread and the IO thread are running. If they are not, the column `Last_IO_Errno` and `Last_IO_Error` (for the IO thread) or `Last_SQL_Errno` and `Last_SQL_Error` (for the SQL thread) show what the problem is.

In a replication chain, every server must have a unique server_id.

For more information on replication, see standard replication.

Binary Log Coordinates, Relay Log Coordinates and GTID

The binary log coordinates provide a way to identify a certain data change made by a server. Coordinates consist of a file name and the position of the latest event, expressed as an integer. The last event coordinates can be seen with the SHOW MASTER STATUS columns `File` and `Position`. mariadb-dump includes them in a dump if the `--master-data` option is used.

A replica uses primary binary log coordinates to identify the last event it read. This can be seen with the SHOW SLAVE STATUS columns `Master_Log_File` and `Read_Master_Log_Pos`.

The columns `Relay_Master_Log_File` and `Exec_Master_Log_Pos` identify the primary event that corresponds to the last event applied by the SQL thread.

The replica relay log also has coordinates. The coordinates of the last applied event can be seen with the `SHOW SLAVE STATUS` columns `Relay_Log_File` and `Relay_Log_Pos`.

To easily find out how far the replica is lagging behind the primary, we can look at `Seconds_Behind_Master`.

Coordinates represented in this way have a problem: they are different on each server. Each server can use files with different (or the same) names, depending on its configuration. And files can be rotated at different times, including when a user runs FLUSH LOGS. By enabling the GTID (global transaction id) an event will have the same id on the primary and on all the replicas.

When GTID is enabled, `SHOW SLAVE STATUS` shows two GTIDs: `Gtid_IO_Pos` is the last event written into the relay log, and `Gtid_Slave_Pos` is the last event applied by the SQL thread. There is no need for a column identifying the same event in the primary, because the id is the same.

Provisioning a Replica

MariaDB does not have an equivalent to SQL Server's snapshot replication.

To setup a replica, it is necessary to manually provision it. It can be provisioned from the primary in this way:

- A backup from the primary must be restored on the new replica;
- The binary log coordinates at the moment of the backup should be set as replication coordinates in the replica, via

CHANGE MASTER TO.

However, if there is at least one existing replica, it is better to use it to provision the new replica:

- A backup from the existing replica must be restored in the new replica;
- The backup should include the system tables. In this way it will not be necessary to set the correct coordinates manually.

For more information see Setting Up Replication and Setting up a Replica with Mariabackup.

Replication and Permissions

A replica connects to a primary using its credentials. See CHANGE MASTER TO.

The appropriate account must be created in the primary, and it needs to have the `REPLICATION SLAVE` permission.

See Setting Up Replication for more information.

Parallel Replication and Group Commit

MariaDB uses group commit, which means that a group of events are physically written in the binary log altogether. This reduces the number of IOPS (input/output operations per second). Group commit cannot be disabled, but it can be tuned with variables like binlog_commit_wait_count and binlog_commit_wait_usec.

Replicas can apply the changes using multiple threads. This is known as parallel replication. Before MariaDB 10.0.5 only one thread was used to apply changes. Since a primary can use many threads to write data, mono-thread replication is a well-known bottleneck. Parallel replication is not enabled by default. To use it, set the slave_parallel_threads variable to a number greater than 1. If replication is running, the replica threads must be stopped in order to change this value:

```
STOP SLAVE SQL_THREAD;
SET GLOBAL slave_parallel_threads = 4;
START SLAVE SQL_THREAD;
```

There are different parallel replication styles available: in-order and out-of-order. The exact mode in use is determined by the slave_parallel_mode system variable. In parallel replication, the events are not replicated exactly in the same order as they occurred in the primary. But with an in-order replication mode the commit phase is always applied simultaneously. In this way data in the replica always reflect data as they have been in the primary at a certain point in time. Out-of-order replication is faster because there is less queuing, but it's not completely consistent with the primary. If two transactions modified different sets of rows in the primary, they could become visible in the replica in a different order.

`conservative` relies on primary group commit: events in different groups are executed in a parallel way.

`optimistic` does not try to find out which transaction can be executed in a parallel way - except for transactions that conflicted on the primary. Instead, it always tries to apply many events together, and rolls transactions back when there is a conflict.

`aggressive` is similar to optimistic, but it does not take into account which transactions conflicted in the primary.

`minimal` applies commits together, but all other events are applied in order.

Out-of-order replication cannot be enabled automatically by changing a variable in the replica. Instead, it must be enabled by the applications that run transactions in the primary. They can do this if the GTID is enabled. They can set different values for the gtid_domain_id variable in different transactions. This shifts a lot of responsibility to the application layer; however, if the application is aware of which transactions are not going to conflict and this information allows one to sensibly increase the parallelism, and using out-of-order replication can be a good idea.

Even if out-of-order replication is not normally used, it can be a good idea to use it for long running transactions or ALTER TABLEs, so they can be applied at the same time as normal operations that are not conflicting.

The impact of the number of threads and mode on performance can be partly seen with SHOW PROCESSLIST, which shows the state of all threads. This includes the replication worker threads, and shows if they are blocking each other.

Differences Between the Primary and the Replicas

As a general rule, we want the primary and the replicas to contain exactly the same data. In this way, no conflicts are possible. Conflicts are the most likely cause of replication outages.

To reduce the possible causes of conflicts, the following best practices are recommended:

- Users must not change data in the replica directly. Set read_only to 1. Note that this won't prevent root from making changes.
- Use the same table definitions in the primary and in the replica.
- Use `ROW` binary log format on the primary.

Another cause of inconsistencies include MariaDB bugs and failover in case the primary crashes.

An open source third party tool is available to check if the primary and a replica are consistent. It is called pt-table-checksum. Another tool, pt-table-sync, can be used to eliminate the differences. Both are part of Percona Toolkit. The advice is to run pt-table-checksum periodically, and use pt-table-sync if inconsistencies are found.

If a replication outage occurs because an inconsistency is found, sometimes we want to quickly bring the replica up again as quickly as possible, and solve the core problem later. If GTID is not used, a way to do this is to run SET GLOBAL SQL_SLAVE_SKIP_COUNTER = 1, which skips the problematic replication event.

If GTID is used, the gtid_slave_pos variable can be used instead. See the link for an explanation of how it works.

There are ways to have different data on the replicas. For example:

- Multi-source replication is possible. In this way, a replica will replicate data from multiple primaries. This feature is described below.
- Replication filters are supported. This allows one to exclude or include in replication specific tables, entire databases, or tables whose name matches a certain pattern. This allows one to avoid replicating data that is present in the primary but can always be rebuilt.
- Differences in table definitions are also possible. For example, a replica could have more columns or less columns compared to the primary. In this way we can avoid replicating columns whose values can be rebuilt. Or we can add columns for analytics purposes, without having them in the primary. Be sure to understand the limitations and risks of this technique.

Delayed Replication

MariaDB supports delayed replication. This is the equivalent of setting a `pollinginterval` in SQL Server.

To delay replication in a MariaDB replica, use CHANGE MASTER TO to specify a delay in seconds.

For more information, see Delayed Replication.

Multi-Source Replication

Multi-source replication is an equivalent to peer-to-peer replication, available in SQL Server Enterprise Edition.

A MariaDB replica can replicate from any number of primaries. It is very important that different primaries don't have the same tables. Otherwise there could be conflicts between data changes made on different primaries, and this will result in a replication outage.

In multi-source replication different channels exist, one for each primary.

This changed the way SQL replication statements work. SHOW PROCESSLIST returns a different row for each channel. Several statements, like CHANGE MASTER TO, START SLAVE or STOP SLAVE. accept a parameter which specifies which replication channel they should affect. For example, to stop a channel called `wp1`:

```
STOP SLAVE "wp1";
```

Furthermore, variables that affect parallel replication can be prefixed with a channel name. This allow one to only use parallel replication for certain channels, or to tune it differently for each channel. For example, to enable parallel replication on a channel called `wp1`:

```
SET GLOBAL wp1.slave_parallel_threads = 4;
```

Dual Primary

It is possible to configure two servers in a way that each of them acts as a primary for the other server.

In this way, data could theoretically be inserted into any of these servers, and will then be replicated to the other server. However, in such a configuration conflicts are very likely. So it is impractical to use this technique to scale writes.

A dual primary (or primary-primary) configuration however can be useful for failover. In this case we talk about an *active primary* that receives reads and writes from the clients, and a *passive primary* that is not used until the active primary crashes.

Several problems should be considered in this scenario:

- If the active primary crashes, it is very possible that the passive primary did not receive all events yet, because replication is asynchronous. If the primary data are lost (for example because the disk is damaged), some data are also lost.
- If data is not lost, when we bring the primary up again, the latest events will be replicated by the other server. There could be conflicts that will break replication.

- When is the active primary considered down? Even if a server cannot reach it, the active primary could be running and it could be able to communicate with the passive primary. Switching the clients to the passive primary could lead to unnecessary problems. It is a good idea to always check `SHOW SLAVE STATUS` to be sure that the two primary are not communicating.
- If we want to have more replicas, we should attach some of them to the active primary, and some of them to the passive primary. The reason is that when a server crashes, its replicas stop receiving any data. Failover is still possible, but it's better to have some servers that will not need any failover.

A safe primary-primary configuration where both servers accept writes, however, is possible. This is the case is data never conflicts. For example, the two servers could accept writes on different databases. We will have to decide what should happens in case of a server crash:

- Writes can be stopped until the server is up again. Reads can be sent to the other server, but keep in mind that the most recently written data could be missing.
- Both writes and reads can failover to the other server. All the problems mentioned above may apply to this situation.

See Sveta Smirnova's slides at MariaDB Day 2020: "How Safe is Asynchronous Master-Master Setup?".

Semi-Synchronous Replication

Semi-synchronous replication was initially implemented as a plugin, in MySQL. Two different plugins needed to be used, one on the primary and the other on the replicas. Starting from MariaDB 10.3.3 it is built-in, which improved its performance.

The problem with standard replication is that there is no guarantee that it will not lag, even by long amounts of time. Semi-synchronous replication reduces this problem, at the cost of reducing the speed of the primary.

In semi-synchronous replication, when a transaction is committed on the primary, the primary does not immediately return control to the client. Instead, it sends the event to the replicas. After one replica reported that the commit was executed with success, the primary reports success to the client.

Semi-synchronous replication is useful for failover, therefore a dual primary setup is not needed in this case. If the primary crashes, the most up-to-date replica can be promoted to primary without losing any data.

Enabling Semi-Synchronous Replication

Semi-synchronous replication can be enabled at runtime in this way on the primary:

```
SET GLOBAL rpl_semi_sync_master_enabled = ON;
```

Semi-synchronous replication is not used until it has been enabled on the replicas also. If the replicas are already replicating, the io_thread needs to be stopped and restarted. This can be done as follows:

```
SET GLOBAL rpl_semi_sync_slave_enabled = ON;
STOP SLAVE IO_THREAD;
START SLAVE IO_THREAD;
```

Tuning the Wait Point and the Primary Timeout

The most important aspects to tune are the wait point and the primary timeout.

When the binary log is enabled, transactions must be committed both in the storage engine (usually InnoDB) and in the binary log. Semi-synchronous replication requires that the transaction is also acknowledged by at least one replica before the primary can report success to the client.

The wait point determines at which point the primary must stop and wait for a confirmation from a replica. This is an important decision from disaster recovery standpoint, in case the primary crashes when a transaction is not fully committed. The rpl_semi_sync_master_wait_point is used to set the wait point, Its allowed values are:

- `AFTER_SYNC` : After committing the transaction in the binary log, but before committing it to the storage engine. After a crash, a transaction may be present in the binary log even if it was not committed.
- `AFTER_COMMIT` . After committing a transaction both in the binary log and in the storage engine. In case of a crash, a transaction could possibly be committed in the primary but not replicated in the slaves. This is the default.

Primary timeout is meant to avoid that a primary remains stuck for a long time, or virtually forever, because no replica acknowledges a transaction. If primary timeout is reached, the primary switches to asynchronous replication. Before doing that, the primary writes an error in the error log and increments the Rpl_semi_sync_master_no_times status variable.

The timeout is set via the rpl_semi_sync_master_timeout variable.

Galera Cluster

Galera is a technology that implements virtually synchronous, primary-primary replication for a cluster of MariaDB servers.

Raft and the Primary Cluster

Nodes of the cluster communicate using the Raft protocol. In case the cluster is partitioned or some nodes crash, a cluster knows that it's still the *primary cluster* if it has the *quorum*: half of the nodes + 1. Only the primary cluster accepts reads and writes.

For this reason a cluster should consist of an odd number of nodes. Imagine for example that a cluster consists of two nodes: if one of them crashes of the connection between them is interrupted, there will be no primary cluster.

Transaction Certification

A transaction can be executed against any node. The node will use a 2-phase commit. After running the transaction locally, the node will ask other nodes to *certify* it. This means that other nodes will receive it, and will try to apply it, and will report success or a failure. The node that received the transaction will not wait for an answer from all the nodes. Once it succeeded on more than half of the nodes (the quorum) the node will run the final commit and data becomes visible.

It is desirable to write data on only one node (unless it fails), or write different databases on different nodes. This will minimize the risk of conflicts.

Galera Cache and SST

Data changes applied are recorded for some time in the *Galera cache*. This is an on-disk cache, written in a circularly written file.

The size of Galera cache can be tuned using the wsrep_provider_options system variable, which contains many flags. We need to tune gcache.size. To tune it, add a line similar to the following to a configuration file:

```
wsrep_provider_options = 'gcache.size=2G';
```

If a single transaction is bigger than half of the Galera cache, it needs to be written in a separate file, as *on-demand pages*. On-demand pages are regularly replaced. Whether a new page replaces an old one depends on another wsrep_provider_options flag: `wsrep_provider_options#gcachekeep_pages_size|gcache.keep_pages_size`, which limits the total size of on-demand pages.

When a node is restarted (after a crash or for maintenance reasons), it will need to receive all the changes that were written by other nodes since the moment it was unreachable. A node is therefore chosen as a donor, possibly using the gcssync_donor wsrep_provider_options flag.

If possible, the donor will send all the recent changes, reading them from the Galera cache and on-demand pages. However, sometimes the Galera cache is not big enough to contain all the needed changes, or the on-demand pages have been overwritten because `gcache.keep_pages_size` is not big enough. In these cases, a State Snapshot Transfer (SST) needs to be sent. This means that the donor will send the whole dataset to the restarted node. Most commonly, this happens using the mariabackup method.

Flow Control

While transaction certification is synchronous, certified transactions are applied locally in asynchronous fashion. However, a node should never lag too much behind others. To avoid that, a node may occasionally trigger a mechanism called *flow control* to ask other nodes to stop replication until its situation improves. Several wsrep_provider_options flags affect flow control.

gcs.fc_master_slave should normally be set to 1 if all writes are sent to a single node.

gcs.fc_limit is tuned automatically, unless gcs.fc_master_slave is set to 0. The *receive queue* (the transactions received and not yet applied) should not exceed this limit. When this happens, flow control is triggered by the node to pause other node's replication.

Once flow control is activated, gcs.fc_factor determines when it is released. It is a number from 0 to 1, and it represents a fraction. When the receive queue is below this fraction, the flow control is released.

Flow control and the receive queue can and should be monitored. The most useful metrics are:

- wsrep_flow_control_paused indicates how many times the replication has been paused as requested by other nodes, since the last `FLUSH STATUS`.
- wsrep_flow_control_sent indicates how many times this node requested other nodes to pause replication.

- wsrep_local_recv_queue is the size of the receive queue.

Configuration

Galera is implemented as a plugin. Starting from version 10.1, MariaDB comes with Galera pre-installed, but not in use by default. To enable it one has to set the wsrep_on system variable.

Like asynchronous replication, Galera uses the binary log. It also requires that data changes are logged in the `ROW` format.

For other required settings, see Mandatory Options.

Galera Limitations

Galera is not suitable for all databases and workloads.

- Galera only replicates InnoDB tables. Other storage engines should not be used.
- For performance reasons, it is highly desirable that all tables have a primary key.
- Long transactions will damage performance.
- Some applications use an integer AUTO_INCREMENT primary key. In case of failover from a crashed node to another, Galera does not guarantee that `AUTO_INCREMENT` follows a chronological order. Therere, applications should use TIMESTAMP columns for chronological order instead.

2.1.14.2.13 Moving Data Between SQL Server and MariaDB

Contents

There are several ways to move data between SQL Server and MariaDB. Here we will discuss them and we will highlight some caveats.

Moving Data Definition from SQL Server to MariaDB

To copy SQL Server data structures to MariaDB, one has to:

1. Generate a CSV file from SQL Server data.
2. Modify the syntax so that it works in MariaDB.
3. Run the file in MariaDB.

Variables That Affect DDL Statements

DDL statements are affected by some server system variables.

sql_mode determines the behavior of some SQL statements and expressions, including how strict error checking is, and some details regarding the syntax. Objects like stored procedures, stored functions triggers and views, are always executed with the sql_mode that was in effect during their creation. sql_mode='MSSQL' can be used to have MariaDB behaving as close to SQL Server as possible.

innodb_strict_mode enables the so-called InnoDB strict mode. Normally some errors in the CREATE TABLE options are ignored. When InnoDB strict mode is enabled, the creation of InnoDB tables will fail with an error when certain mistakes are made.

updatable_views_with_limit determines whether view updates can be made with an UPDATE or DELETE statement with a `LIMIT` clause if the view does not contain all primary or not null unique key columns from the underlying table.

Dumps and sys.sql_modules

SQL Server Management Studio allows one to create a working SQL script to recreate a database - something that MariaDB users refer to as a *dump*. Several options allow fine-tuning the generated syntax. It could be necessary to adjust some of these options to make the output compatible with MariaDB. It is possible to export schemas, data or both. One can create a single global file, or one file for each exported object. Normally, producing a single file is more practical.

Alternatively, the sp_helptext() procedure returns information about how to recreate a certain object. Similar information is also present in the sql_modules table (`definition` column), in the `sys` schema. Such information, however, is not a ready-to-use set of SQL statements.

Remember however that MariaDB does not support schemas. An SQL Server schema is approximately a MariaDB database.

To execute a dump, we can pass the file to `mariadb`, the MariaDB command-line client.

Provided that a dump file contains syntax that is valid in MariaDB, it can be executed in this way:

```
mariadb --show-warnings < dump.sql
```

`--show-warnings` tells MariaDB to output any warnings produced by the statements contained in the dump. Without this option, warnings will not appear on screen. Warnings don't stop the dump execution.

Errors will appear on screen. Errors will stop the dump execution, unless the `--force` option (or just `-f`) is specified.

For other `mariadb` options, see mariadb Command-line Client Options.

Another way to achieve the same purpose is to start the `mariadb` client in interactive mode first, and then run the `source` command. For example:

```
root@d5a54a082d1b:/# mariadb -uroot -psecret
Welcome to the MariaDB monitor.  Commands end with ; or \g.
Your MariaDB connection id is 22
Server version: 10.4.7-MariaDB-1:10.4.7+maria~bionic mariadb.org binary distribution

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

MariaDB [(none)]> \W
Show warnings enabled.
MariaDB [(none)]> source dump.sql
```

In this case, to show warnings we used the `\W` command, where "w" is uppercase. To hide warnings (which is the default), we can use `\w` (lowercase).

For other `mariadb` commands, see mariadb Commands.

CSV Data

If the table structures are already in MariaDB, we need only to import table data. While this can still be done as explained above, it may be more practical to export CSV files from SQL Server and import them into MariaDB.

SQL Server Management Studio and several other Microsoft tools allow one to export CSV files.

MariaDB allows importing CSV files with the LOAD DATA INFILE statement, which is essentially the MariaDB equivalent of `BULK INSERT`.

It can happen that we don't want to import the whole data, but some filtered or transformed version of it. In that case, we may prefer to use the CONNECT storage engine to access CSV files and query them. The results of a query can be inserted into a table using INSERT SELECT.

Moving Data from MariaDB to SQL Server

There are several ways to move data from MariaDB to SQL Server:

- If the tables don't exist at all in SQL Server, we need to generate a dump first. The dump can include data or not.
- If the tables are already in SQL Server, we can use CSV files instead of dumps to move the rows. CSV files are the most concise format to move data between different technologies.
- With the tables already in SQL Server, another way to move data is to insert the rows into CONNECT tables that "point" to remote SQL Server tables.

Using a Dump (Structure)

mariadb-dump can be used to generate dumps of all databases, a specified database, or a set of tables. It is even possible to only dump a set of rows by specifying the `WHERE` clause.

By specifying the `--no-data` option we can dump the table structures without data.

`--compatible=mssql` will produce an output that should be usable in SQL Server.

Using a Dump (Data)

mariadb-dump by default produces an output with both data and structure.

`--no-create-info` can be used to skip the CREATE TABLE statements.

`--compatible=mssql` will produce an output that should be usable in SQL Server.

`--single-transaction` should be specified to select the source data in a single transaction, so that a consistent dump is produced.

`--quick` speeds up the dump process when dumping big tables.

Using a CSV File

CSV files can also be used to export data to SQL Server. There are several ways to produce CSV files from MariaDB:

- The SELECT INTO OUTFILE statement.
- The CONNECT storage engine, with the CSV table type.
- The CSV storage engine (note that it doesn't support `NULL` and indexes).

Using CONNECT Tables

The CONNECT storage engine allows one to access external data, in many forms:

- Data files (CSV, JSON, XML, HTML and more).
- Remote databases, using the ODBC or JDBC standards, or MariaDB/MySQL native protocol.
- Some special data sources.

`CONNECT` was mentioned previously because it could allow one to read a CSV file and query it in SQL, filtering and transforming the data that we want to move into regular MariaDB tables.

However, `CONNECT` can also access remote SQL Server tables. We can read data from it, or even write data.

To enable `CONNECT` to work with SQL Server, we need to fulfill these requirements:

- Install the ODBC driver, downloadable form Microsoft website. The driver is also available for Linux and MacOS.
- Install unixODBC.
- Install `CONNECT` (unless it is already installed).

Here is an example of a `CONNECT` table that points to a SQL Server table:

```
CREATE TABLE city (
    id INT PRIMARY KEY,
    city_name VARCHAR(100),
    province_id INT NOT NULL
)
    ENGINE=CONNECT,
    TABLE_TYPE=ODBC,
    TABNAME='city'
    CONNECTION='Driver=SQL Server Native Client 13.0;Server=sql-server-
hostname;Database=world;UID=mariadb_connect;PWD=secret';
```

The key points here are:

- `ENGINE=CONNECT` tells MariaDB that we want to create a `CONNECT` table.
- `TABLE_TYPE` must be 'ODBC', so `CONNECT` knows what type of data source it has to use.
- `CONNECTION` is the connection string to use, including server address, username and password.
- `TABNAME` tells `CONNECT` what the remote table is called. The local name could be different.

`CONNECT` is able to query SQL Server to find out the remote table structure. We can use this feature to avoid specifying the column names and types:

```
CREATE TABLE city
    ENGINE=CONNECT,
    TABLE_TYPE=ODBC,
    TABNAME='city'
    CONNECTION='Driver=SQL Server Native Client 13.0;Server=sql-server-
hostname;Database=world;UID=mariadb_connect;PWD=secret';
```

However, we may prefer to manually specify the MariaDB types, sizes and character sets to use.

Linked Server

Instead of using MariaDB `CONNECT`, it is possible to use SQL Server Linked Server functionality. This will allow one to read data from a remote MariaDB database and copy it into local SQL Server tables. However, note that `CONNECT` allows more control on types and character sets mapping.

Refer to Linked Servers section in Microsoft documentation.

2.1.14.2.14 SQL_MODE=MSSQL

Contents

`SET SQL_MODE=MSSQL` implies all the following sql_mode flags:

- PIPES_AS_CONCAT
- ANSI_QUOTES
- IGNORE_SPACE
- NO_KEY_OPTIONS
- NO_TABLE_OPTIONS
- NO_FIELD_OPTIONS

Setting the sql_mode system variable to `MSSQL` allows the server to understand a small subset of Microsoft SQL Server's language. For the moment `MSSQL` mode only has limited functionality, but we plan to add more later according to demand.

Supported Syntax in MSSQL Mode

Using [] for Quoting

One can use [] instead of "" or `` for quoting identifiers:

```
SET SQL_MODE="MSSQL";
CREATE TABLE [t 1] ([a b] INT);
SHOW CREATE TABLE [t 1];
Table  Create Table
t 1    CREATE TABLE "t 1" (
  "a b" int(11) DEFAULT NULL
)
```

You can use '[' in identifiers. If you want to use ']' in identifiers you have to specify it twice.

2.1.14.3 Migrating to MariaDB from PostgreSQL

There are many different ways to migrate from PostgreSQL to MariaDB. This article will discuss some of those options.

Contents

MariaDB's CONNECT Storage Engine

MariaDB's CONNECT storage engine can be used to migrate from PostgreSQL to MariaDB. There are two primary ways that this can be done.

See Loading the CONNECT Storage Engine for information on how to install the CONNECT storage engine.

Tables with ODBC table_type

The CONNECT storage engine allows you to create tables that refer to tables on an external server, and it can fetch the data using a compatible ODBC driver. PostgreSQL does have a freely available ODBC driver called `psqlODBC`. Therefore, if you install `psqlODBC` on the MariaDB Server, and then configure the system's ODBC framework (such as unixODBC), then the MariaDB server will be able to connect to the remote PostgreSQL server. At that point, you can create tables with the `ENGINE=CONNECT` and `table_type=ODBC` table options set, so that you can access the PostgreSQL tables from MariaDB.

See CONNECT ODBC Table Type: Accessing Tables From Another DBMS for more information on how to do that.

Once the remote table is setup, you can migrate the data to local tables very simply. For example:

```
CREATE TABLE psql_tab (
   id int,
   str varchar(50)
) ENGINE = CONNECT
table_type=ODBC
tabname='tab'
connection='DSN=psql_server';

CREATE TABLE tab (
   id int,
   str varchar(50)
) ENGINE = InnoDB;

INSERT INTO tab SELECT * FROM psql_tab;
```

Tables with JDBC table_type

The CONNECT storage engine allows you to create tables that refer to tables on an external server, and it can fetch the data using a compatible JDBC driver. PostgreSQL does have a freely available JDBC driver. If you install this JDBC driver on the MariaDB server, then the MariaDB server will be able to connect to the remote PostgreSQL server via JDBC. At that point, you can create tables with the `ENGINE=CONNECT` and `table_type=JDBC` table options set, so that you can access the PostgreSQL tables from MariaDB.

See CONNECT JDBC Table Type: Accessing Tables from Another DBMS for more information on how to do that.

Once the remote table is setup, you can migrate the data to local tables very simply. For example:

```
CREATE TABLE psql_tab (
   id int,
   str varchar(50)
) ENGINE = CONNECT
table_type=JDBC
tabname='tab'
connection='jdbc:postgresql://psql_server/db1';

CREATE TABLE tab (
   id int,
   str varchar(50)
) ENGINE = InnoDB;

INSERT INTO tab SELECT * FROM psql_tab;
```

PostgreSQL's Foreign Data Wrappers

PostgreSQL's foreign data wrappers can also be used to migrate from PostgreSQL to MariaDB.

mysql_fdw

mysql_fdw allows you to create a table in PostgreSQL that actual refers to a remote MySQL or MariaDB server. Since MySQL and MariaDB are compatible at the protocol level, this should also support MariaDB.

The foreign data wrapper also supports writes, so you should be able to write to the remote MariaDB table to migrate your PostgreSQL data. For example:

```
CREATE TABLE tab (
   id int,
   str text
);

INSERT INTO tab VALUES (1, 'str1');

CREATE SERVER mariadb_server
   FOREIGN DATA WRAPPER mysql_fdw
   OPTIONS (host '10.1.1.101', port '3306');

CREATE USER MAPPING FOR postgres
   SERVER mariadb_server
   OPTIONS (username 'foo', password 'bar');

CREATE FOREIGN TABLE mariadb_tab (
   id int,
   str text
)
SERVER mariadb_server
OPTIONS (dbname 'db1', table_name 'tab');

INSERT INTO mariadb_tab SELECT * FROM tab;
```

PostgreSQL's COPY TO

PostgreSQL's `COPY TO` allows you to copy the data from a PostgreSQL table to a text file. This data can then be loaded into MariaDB with `LOAD DATA INFILE`.

MySQL Workbench

MySQL Workbench has a migration feature that requires an ODBC driver. PostgreSQL does have a freely available ODBC driver called `psqlODBC`.

See Set up and configure PostgreSQL ODBC drivers for the MySQL Workbench Migration Wizard for more information.

Known Issues

Migrating Functions and Procedures

PostgreSQL's functions and procedures use a language called `PL/pgSQL`. This language is quite different than the default `SQL/PSM` language used for MariaDB's stored procedures. `PL/pgSQL` is more similar to `PL/PSQL` from Oracle, so you may find it beneficial to try migrate with `SQL_MODE=ORACLE` set.

2.1.14.3.1 SQL_MODE=ORACLE

From MariaDB 10.3, setting the sql_mode system variable to `Oracle` allows the server to understand a subset of Oracle's PL/SQL language. For example:

```
SET SQL_MODE='ORACLE';
```

All traditional MariaDB SQL/PSM syntax should work as before, as long as it does not conflict with Oracle's PL/SQL syntax. All MariaDB functions should be supported in both normal and Oracle modes.

Prior to MariaDB 10.3, MariaDB does not support Oracle's PL/SQL language, and `SET SQL_MODE=ORACLE` is only an alias for the following sql_mode in those versions:

```
SET SQL_MODE='PIPES_AS_CONCAT, ANSI_QUOTES, IGNORE_SPACE, NO_KEY_OPTIONS,
NO_TABLE_OPTIONS, NO_FIELD_OPTIONS, NO_AUTO_CREATE_USER';
```

From MariaDB 10.3, `SET SQL_MODE=ORACLE` is same as:

```
SET SQL_MODE='PIPES_AS_CONCAT,ANSI_QUOTES,IGNORE_SPACE,ORACLE,NO_KEY_OPTIONS,
NO_TABLE_OPTIONS,NO_FIELD_OPTIONS,NO_AUTO_CREATE_USER,SIMULTANEOUS_ASSIGNMENT';
```

Contents

Supported Syntax in Oracle Mode

Stored Procedures and Stored Functions

Oracle mode makes the following changes to Stored Procedures and Stored Functions:

Oracle syntax	Description
CREATE PROCEDURE p1 `(param OUT INT)`	ANSI uses `(OUT param INT)`
CREATE PROCEDURE p1 `(a IN OUT INT)`	ANSI uses `(INOUT param INT)`
`AS` before function body	CREATE FUNCTION f1 RETURN NUMBER `AS` BEGIN...
`IS` before function body	CREATE FUNCTION f1 RETURN NUMBER `IS` BEGIN...
If function has no parameters then parentheses must be omitted	Example: CREATE PROCEDURE p1 AS BEGIN NULL; END;

CREATE PROCEDURE p1 AS BEGIN END `p1` ;	Optional routine name after END keyword. MDEV-12089
CREATE FUNCTION f1(a `VARCHAR`)	VARCHAR can be used without length for routine parameters and RETURN clause. The length is inherited from the argument at call time. MDEV-10596
CREATE AGGREGATE FUNCTION f1( )	Creates an aggregate function, which performs the function against a set of rows and returns one aggregate result.
No `CALL` needed in Stored Procedures	In Oracle mode one can call other stored procedures with name only. MDEV-12107
`RETURN` . Can also be used in stored procedures	ANSI uses `RETURNS` . MariaDB mode only supports RETURNS in stored functions

Cursors

Oracle mode makes the following changes to Cursors:

Oracle syntax	Description
CREATE PROCEDURE p1 AS CURSOR cur IS (SELECT a, b FROM t1); BEGIN FOR rec IN cur ...	Explicit cursor with FOR loop. MDEV-10581
CREATE PROCEDURE p1 AS `rec IN (SELECT a, b FROM t1)`	Implicit cursor with FOR loop. MDEV-12098
`CURSOR` c(prm_a VARCHAR2, prm_b VARCHAR2) ... `OPEN c(1,2)`	Cursor with parameters. MDEV-10597
`CURSOR` c(prm_a VARCHAR2, prm_b VARCHAR2) ... FOR `rec in c(1,2)`	Cursor with parameters and FOR loop. MDEV-12314
s %ISOPEN, %ROWCOUNT, %FOUND, %NOTFOUND	Explicit cursor attributes. MDEV-10582

LOOP

Oracle mode makes the following changes to LOOP:

Oracle syntax	Description
`FOR i IN 1..10 LOOP ... END LOOP`	Numeric FOR loop. MDEV-10580
`GOTO`	GOTO statement. MDEV-10697
`<<label>>` used with GOTO	ANSI uses `label:` . MDEV-10697
To leave loop block: `EXIT [ label ] [ WHEN bool_expr ]`	ANSI syntax is `IF bool_expr THEN LEAVE label`
[`<<label>>`] WHILE boolean_expression LOOP statement... END LOOP [label] ;	Oracle style `WHILE` loop
`CONTINUE` [label] [WHEN boolean_expression]	`CONTINUE` is only valid inside a loop

Variables

Oracle syntax	Version	Description
`var:= 10` ; Can also be used with MariaDB systemvariables	10.3	MariaDB uses `SET var= 10` ;
`var INT := 10`	10.3	Default variable value
`var1 table_name.column_name%TYPE`	10.3	Take data type from a table column. MDEV-10577
`var2 var1%TYPE`	10.3	Take data type from another variable
`rec1 table_name%ROWTYPE`	10.3	Take ROW structure from a table. MDEV-12133
`rec2 rec1%ROWTYPE`	10.3	Take ROW structure from ROW variable
CURSOR c1 IS SELECT a,b FROM t1; rec1 c1%ROWTYPE;	10.3	Take ROW structure from a cursor. MDEV-12011
Variables can be declared after cursor declarations	10.3	In MariaDB mode, variables must be declared before cursors. MDEV-10598
Triggers uses `:NEW` and `:OLD`	10.3	ANSI uses `NEW` and `OLD` . MDEV-10579

`SQLCODE`	10.3	Returns the number code of the most recent exception. Can only be used in Stored Procedures. MDEV-10578
`SQLERRM`	10.3	Returns the error message associdated to it's error number argument or `SQLCODE` if no argument is given. Can only be used in Stored Procedures. MDEV-10578
`SQL%ROWCOUNT`	10.3	Almost same as ROW_COUNT(). MDEV-10583
`ROWNUM`	10.6.1	Returns number of accepted rows

Exceptions

Oracle syntax	Description
BEGIN ... EXCEPTION WHEN OTHERS THEN BEGIN .. END; END;	Exception handlers are declared at the end of a block
TOO_MANY_ROWS, NO_DATA_FOUND, DUP_VAL_ON_INDEX	Predefined exceptions. MDEV-10839
RAISE TOO_MANY_ROWS ; .... EXCEPTION WHEN TOO_MANY_ROWS THEN ...	Exception can be used with RAISE and EXCEPTION...WHEN. MDEV-10840
CREATE OR REPLACE FUNCTION f1 (a INT) RETURN INT AS `e1 EXCEPTION` ...	User defined exceptions. MDEV-10587

BEGIN Blocks

Oracle syntax	Description
`BEGIN` to start a block	MariaDB uses `BEGIN NOT ATOMIC` for anyonymous blocks. MDEV-10655
`DECLARE` is used before `BEGIN`	DECLARE a INT; b VARCHAR(10); BEGIN v:= 10; END;
WHEN DUP_VAL_ON_INDEX THEN NULL ; NULL; WHEN OTHERS THEN NULL	Do not require BEGIN..END in multi-statement exception handlers in THEN clause. MDEV-12088

Simple Syntax Compatibility

Oracle syntax	Version	Description
`ELSIF`	10.3	ANSI uses `ELSEIF`
SELECT `UNIQUE`	10.3	Same as `SELECT DISTINCT` . MDEV-12086
TRUNCATE TABLE t1 [`DROP STORAGE`] or [`REUSE STORAGE`]	10.3	DROP STORAGE and REUSE STORAGE are allowed as optional keywords for TRUNCATE TABLE. MDEV-10588
Subqueries in a FROM clause without an alias	10.6	`SELECT * FROM (SELECT 1 FROM DUAL), (SELECT 2 FROM DUAL)`
UNION, EXCEPT and INTERSECT all have the same precedence.	10.3	INTERSECT has higher precedence than UNION and EXCEPT in non-Oracle modes.
`MINUS`	10.6	`MINUS` is a synonym for EXCEPT.

Functions

Oracle syntax	Version	Description
ADD_MONTHS()	10.6.1	Added as a wrapper for DATE_ADD() to enhance Oracle compatibility. All modes.
CAST(expr `as VARCHAR(N)`)	10.3	Cast expression to a `VARCHAR(N)` . MDEV-11275
DECODE	10.3	In Oracle mode, compares and matches search expressions
`LENGTH()` is same as CHAR_LENGTH()	10.3	MariaDB translates LENGTH() to OCTET_LENGTH(). In all modes one can use `LENGTHB()` as a synonym to `OCTET_LENGTH()`
CHR(num)	10.3	Returns a VARCHAR(1) with character set and collation according to @@character_set_database and @@collation_database
`substr('abc',0 ,3)` same as `substr('abc', 1 ,3)`	10.3	Position 0 for substr() is same as position 1

SYS_GUID	10.6.1	Generates a globally unique identifier. Similar to UUID but without the - . All modes.
TO_CHAR	10.6.1	Added to enhance Oracle compatibility. All modes.
TRIM, LTRIM, RTRIM, LPAD and RPAD	10.3	Returns NULL instead of an empty string if returning an empty result. These functions can also be accessed outside of ORACLE mode by suffixing _ORACLE onto the end of the function name, such as TRIM_ORACLE.

Prepared Statements

Oracle mode makes the following changes to Prepared Statements:

Oracle syntax	Description
PREPARE stmt FROM 'SELECT :1 , :2 '	ANSI uses ? . MDEV-10801
EXECUTE IMMEDIATE 'INSERT INTO t1 SELECT (:x,:y) FROM DUAL' USING 10,20	Dynamic placeholders. MDEV-10801

Synonyms for Basic SQL Types

Oracle type	MariaDB synonym
VARCHAR2	VARCHAR
NUMBER	DECIMAL
DATE (with time portion)	MariaDB DATETIME
RAW	VARBINARY
CLOB	LONGTEXT
BLOB	LONGBLOB

This was implemented as part of MDEV-10343.

If one does a SHOW CREATE TABLE in `ORACLE` mode on a table that has a native MariaDB `DATE` column, it will be displayed as mariadb_schema.date to not conflict with the Oracle `DATE` type.

Packages

The following syntax has been supported since MariaDB 10.3.5:

- CREATE PACKAGE
- CREATE PACKAGE BODY
- DROP PACKAGE
- DROP PACKAGE BODY
- SHOW CREATE PACKAGE
- SHOW CREATE PACKAGE BODY

NULL Handling

Oracle mode makes the following changes to NULL handling:

NULL As a Statement

`NULL` can be used as a statement:

```
IF a=10 THEN NULL; ELSE NULL; END IF
```

Translating Empty String Literals to NULL

In Oracle, empty string ('') and NULL are the same thing,

By using `sql_mode=EMPTY_STRING_IS_NULL` you can get a similar experience in MariaDB:

```
SET sql_mode=EMPTY_STRING_IS_NULL;
SELECT '' IS NULL; -- returns TRUE
INSERT INTO t1 VALUES (''); -- inserts NULL
```

Concat Operator Ignores NULL

CONCAT() and || ignore NULL in Oracle mode. Can also be accessed outside of ORACLE mode by using CONCAT_OPERATOR_ORACLE. MDEV-11880 and MDEV-12143.

Reserved Words

There are a number of extra reserved words in Oracle mode.

SHOW CREATE TABLE

The SHOW CREATE TABLE statement will not display MariaDB-specific table options, such as AUTO_INCREMENT or CHARSET, when Oracle mode is set.

2.1.14.4 Installing MariaDB on IBM Cloud

Contents

Get MariaDB on IBM Cloud

You should have an IBM Cloud account, otherwise you can register here. At the end of the tutorial you will have a cluster with MariaDB up and running. IBM Cloud uses Bitnami charts to deploy MariaDB on with helm

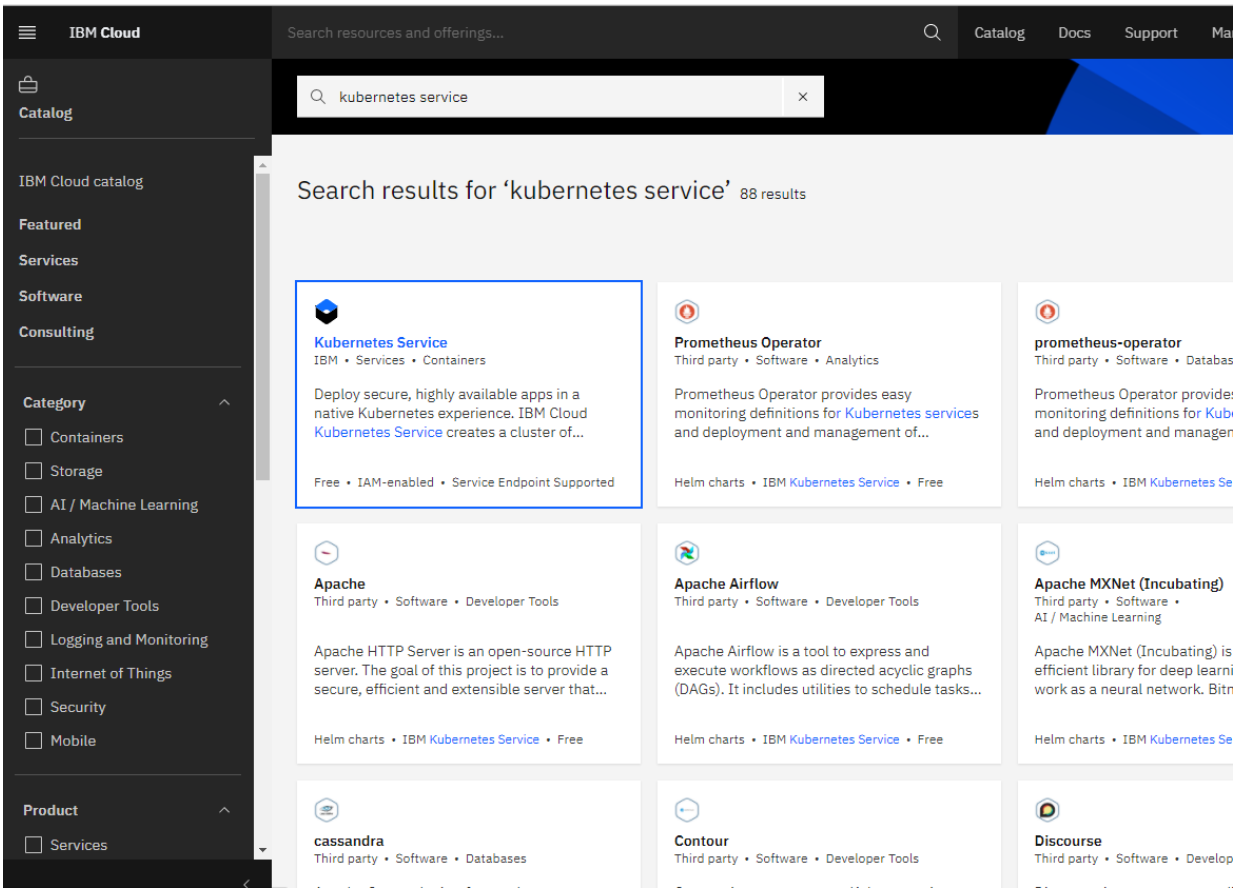
1. We will provision a new Kubernetes Cluster for you if, you already have one skip to step **2**

2. We will deploy the IBM Cloud Block Storage plug-in, if already have it skip to step **3**

3. MariaDB deployment

Step 1 provision Kubernetes Cluster

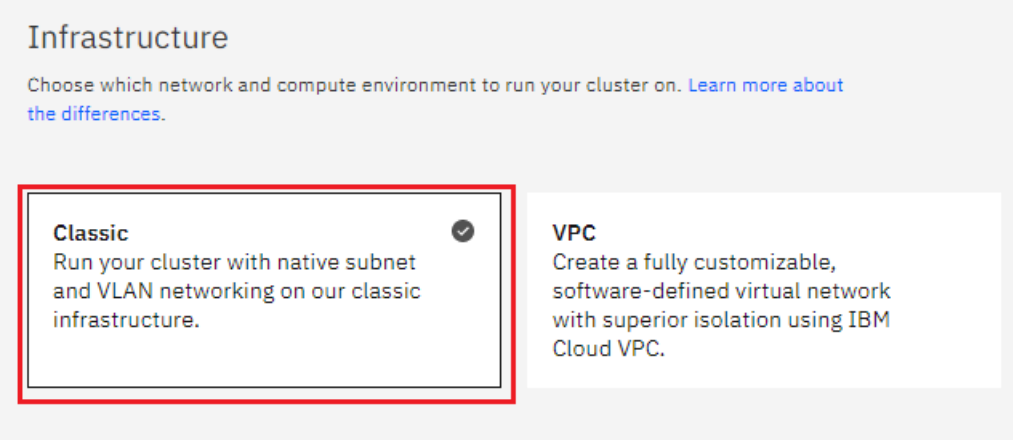
- Click the **Catalog** button on the top
- Select **Service** from the catalog
- Search for **Kubernetes Service** and click on it



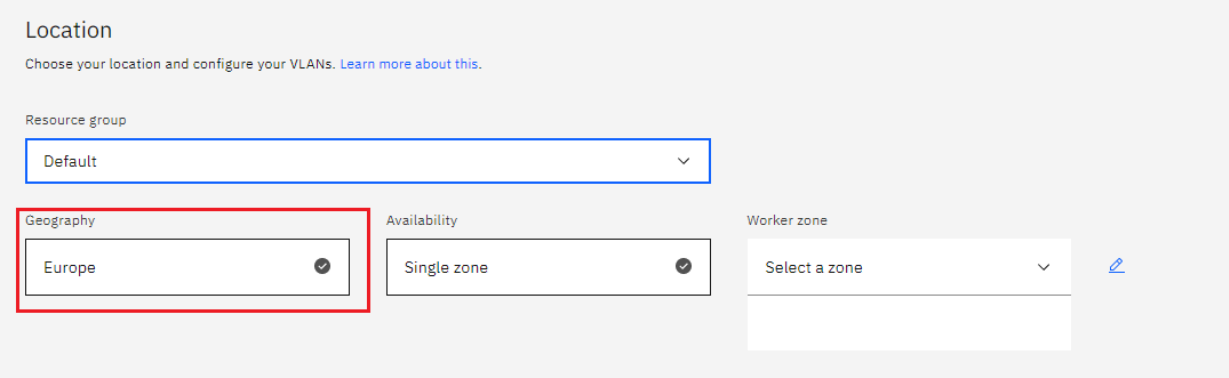
- You are now at the Kubernetes deployment page, you need to specify some details about the cluster
- Choose a plan **standard** or **free**, the free plan only has one worker node and no subnet, to provision a standard

cluster, you will need to upgrade you account to Pay-As-You-Go
- To upgrade to a Pay-As-You-Go account, complete the following steps:

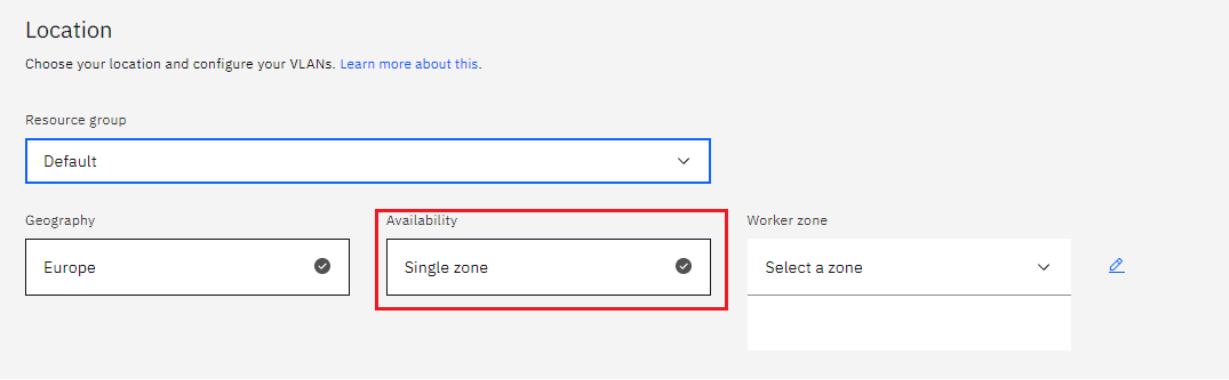
- In the console, go to Manage > Account.
- Select Account settings, and click Add credit card.
- Enter your payment information, click Next, and submit your information
- Choose **classic** or **VPC**, read the docs and choose the most suitable type for yourself



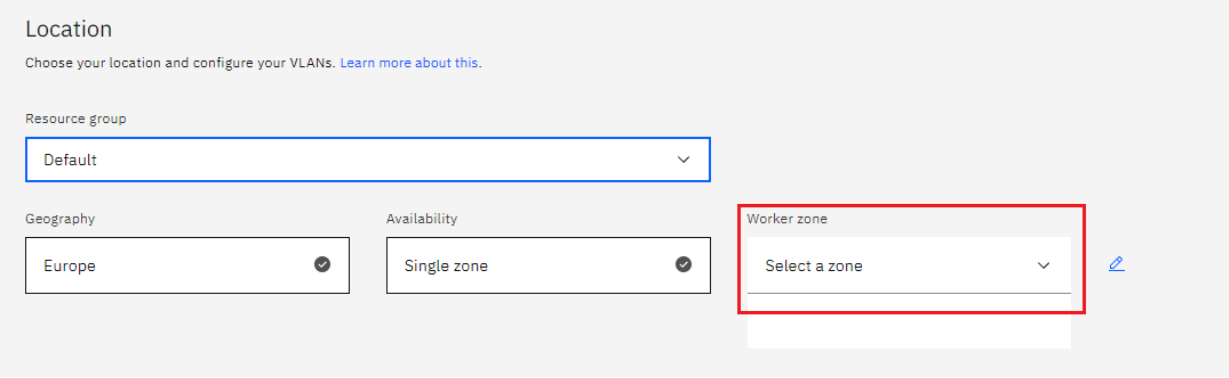
- Now choose your location settings, for more information please visit Locations
- Choose **Geography** (continent)



- Choose **Single** or **Multizone**, in single zone your data is only kept in on datacenter, on the other hand with Multizone it is distributed to multiple zones, thus safer in an unforseen zone failure

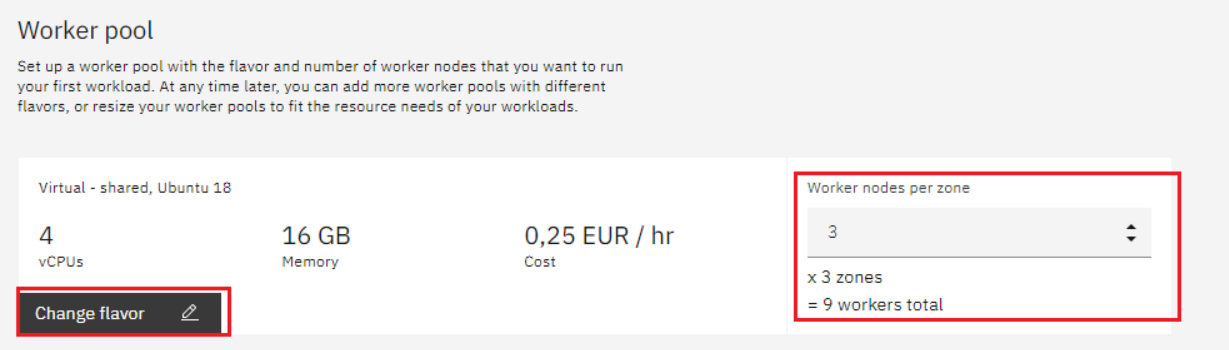


- Choose a **Worker Zone** if using Single zones or **Metro** if Multizone

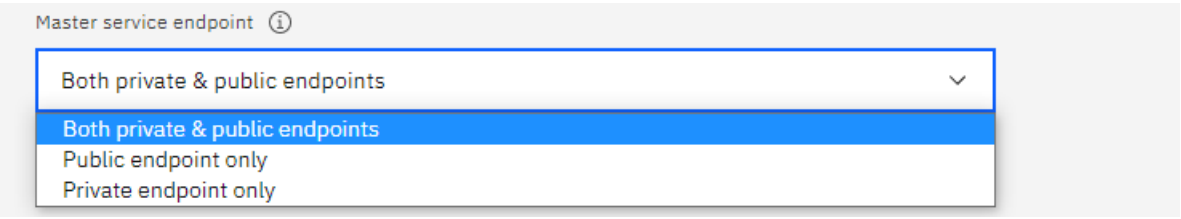


- If you wish to use Multizone please set up your account with VRF or enable Vlan spanning
- If at your current location selection, there is no available Virtual LAN, a new Vlan will be created for you

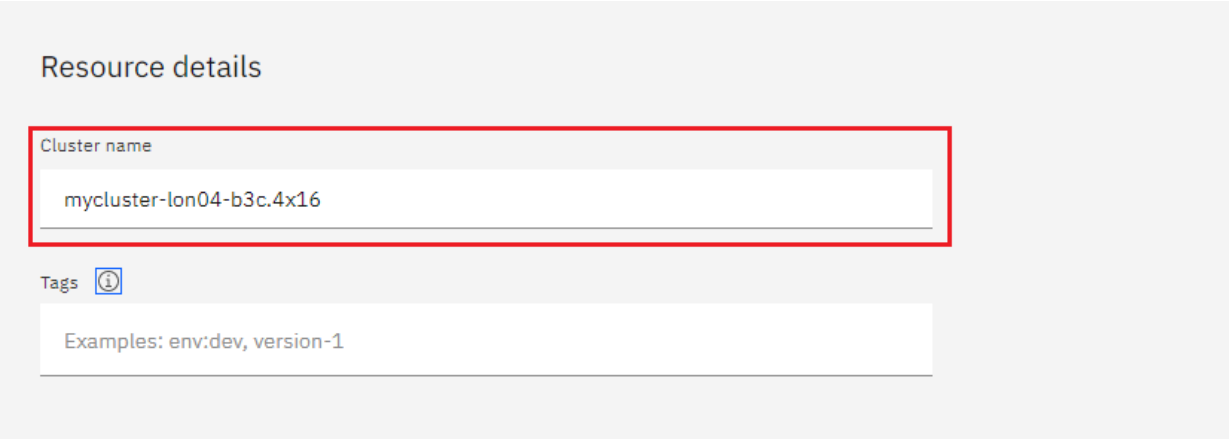
- Choose a **Worker node setup** or use the preselected one, set **Worker node amount per zone**



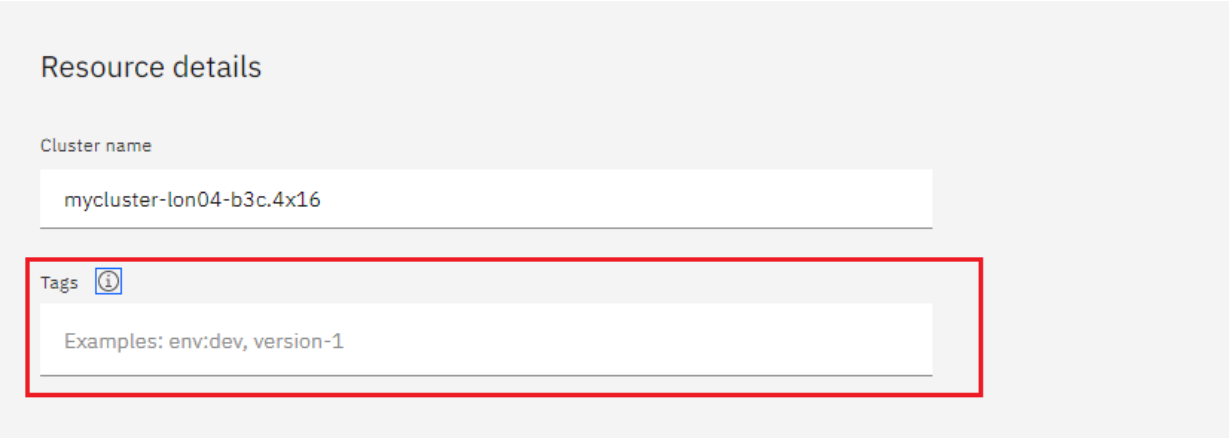
- Choose **Master Service Endpoint**, In VRF-enabled accounts, you can choose private-only to make your master accessible on the private network or via VPN tunnel. Choose public-only to make your master publicly accessible. When you have a VRF-enabled account, your cluster is set up by default to use both private and public endpoints. For more information visit endpoints.



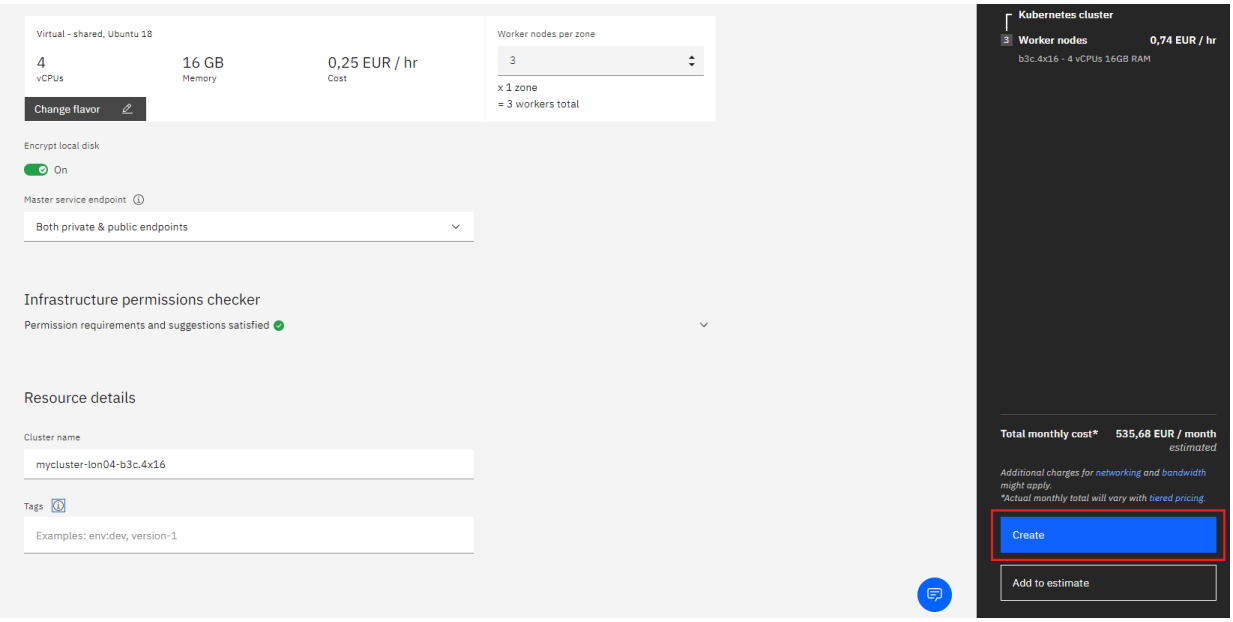
- Give cluster a **name**



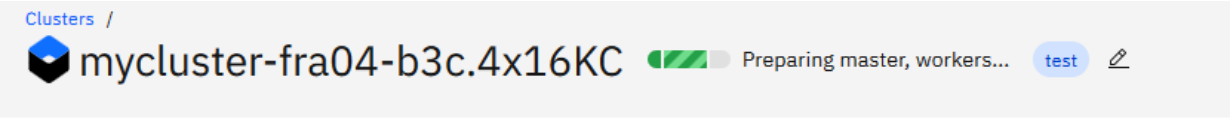
- Give desired **tags** to your cluster, for more information visit tags



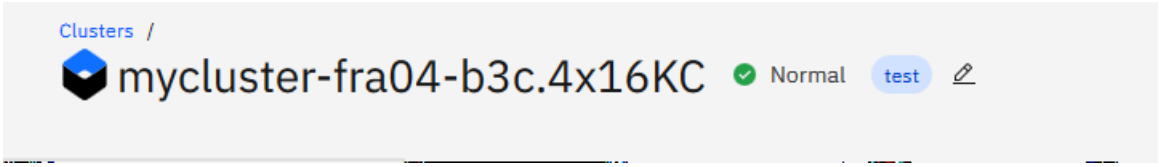
- Click **create**



- Wait for you cluster to be provisioned



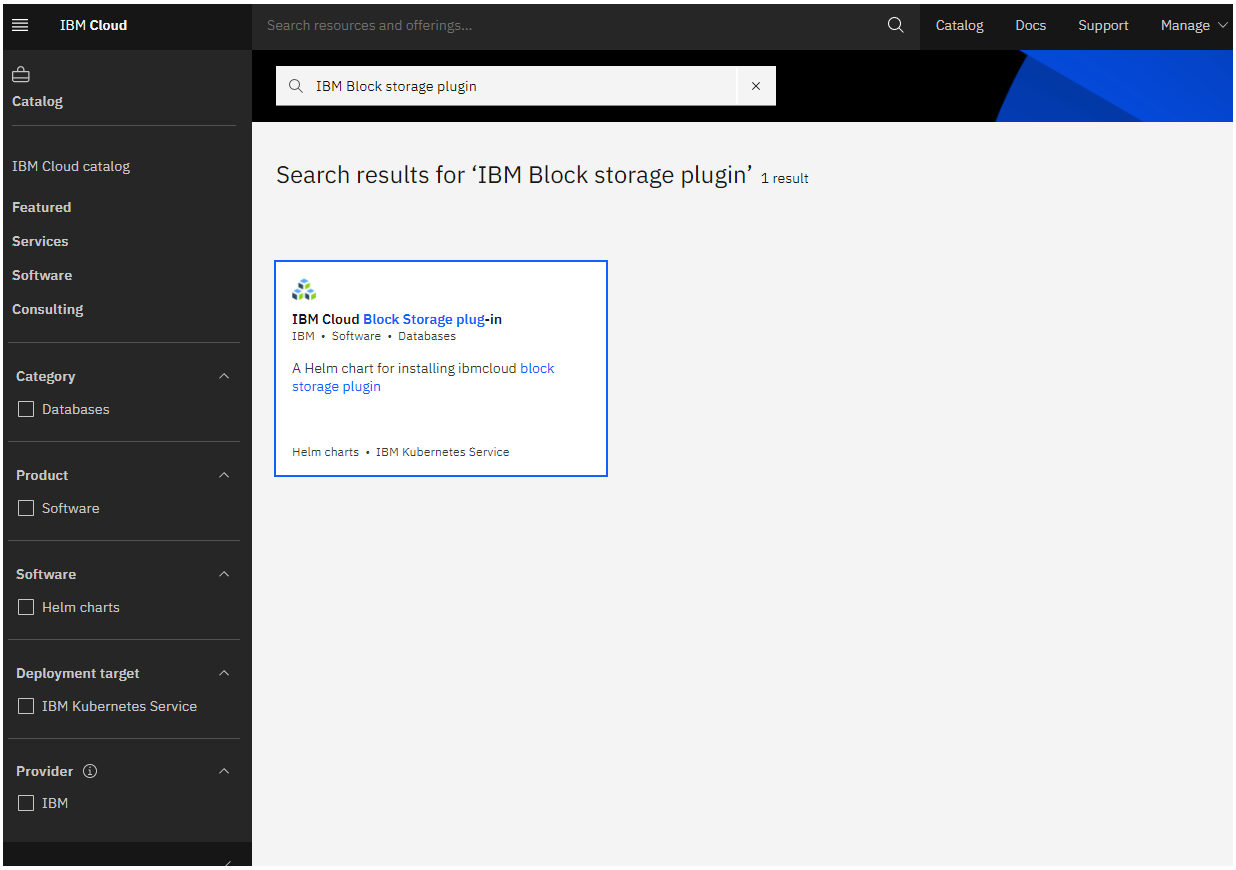
- Your cluster is ready for usage



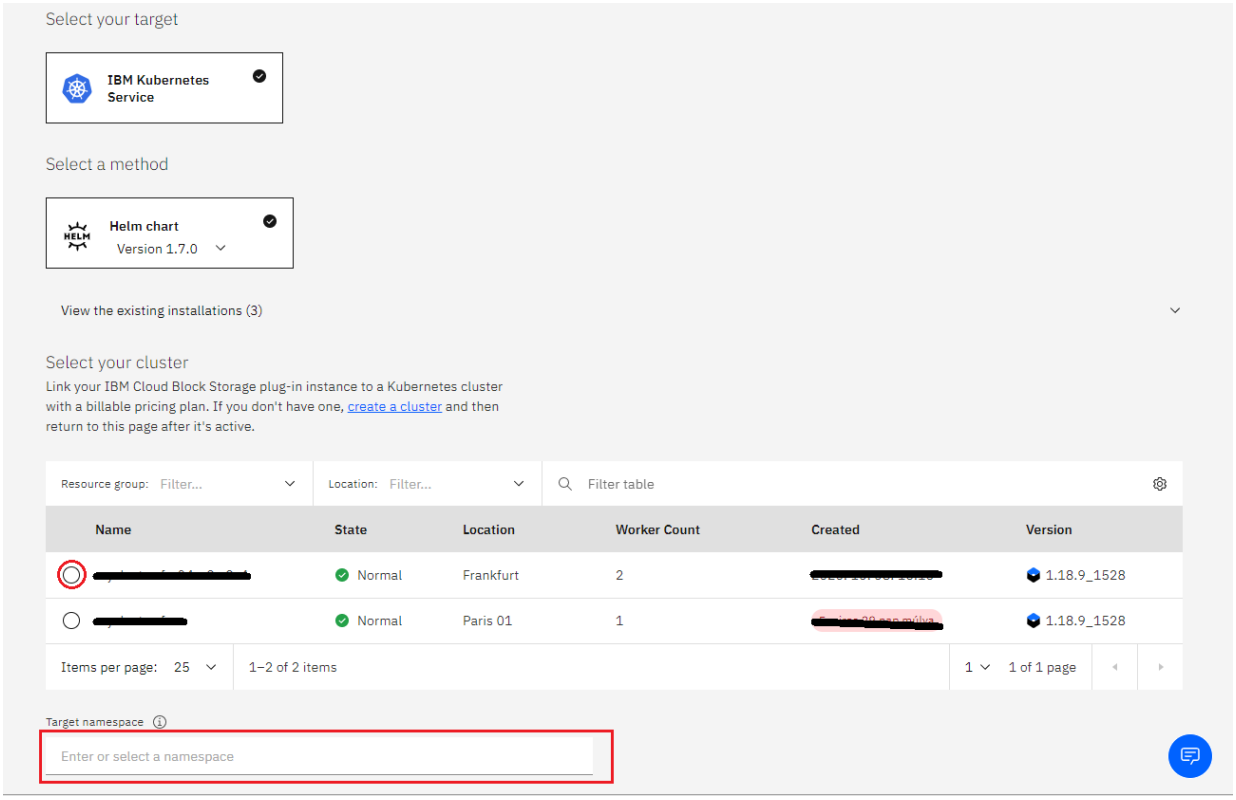
Step 2 deploy IBM Cloud Block Storage plug-in

The Block Storage plug-in is a persistent, high-performance iSCSI storage that you can add to your apps by using Kubernetes Persistent Volumes (PVs).

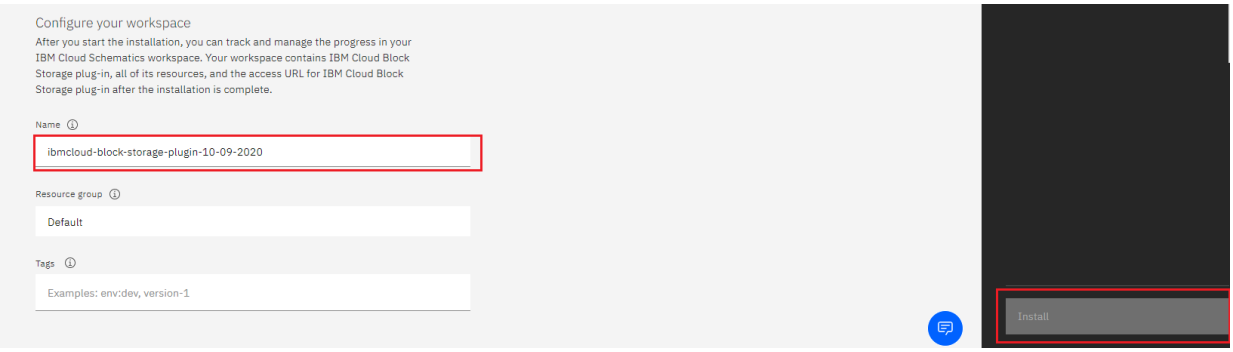
- Click the **Catalog** button on the top
- Select **Software** from the catalog
- Search for **IBM Cloud Block Storage plug-in** and click on it



- On the application page Click in the dot next to the cluster, you wish to use
- Click on **Enter or Select Namespace** and choose the default Namespace or use a custom one (if you get error please wait 30 minutes for the cluster to finalize)



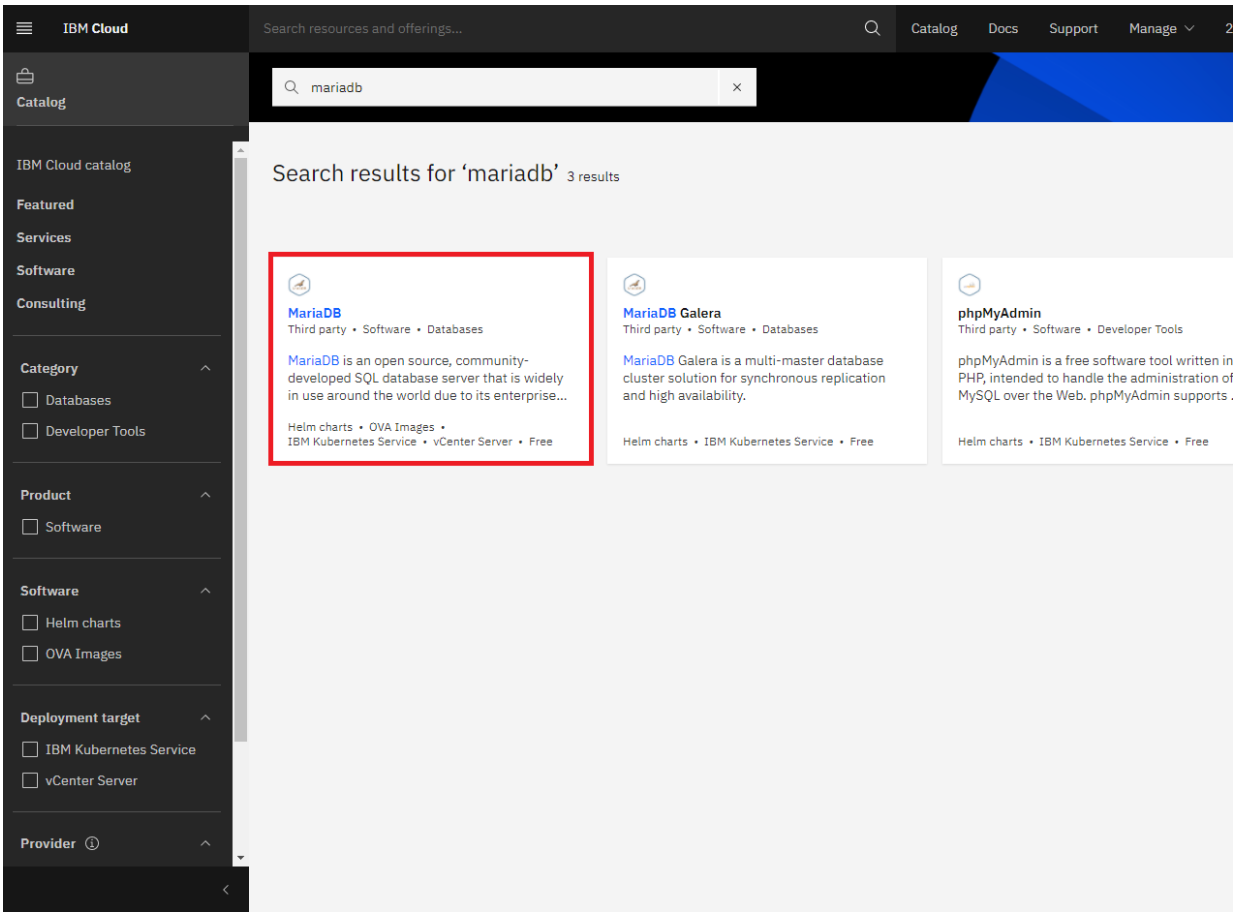
- Give a **name** to this workspace
- Click **install** and wait for the deployment



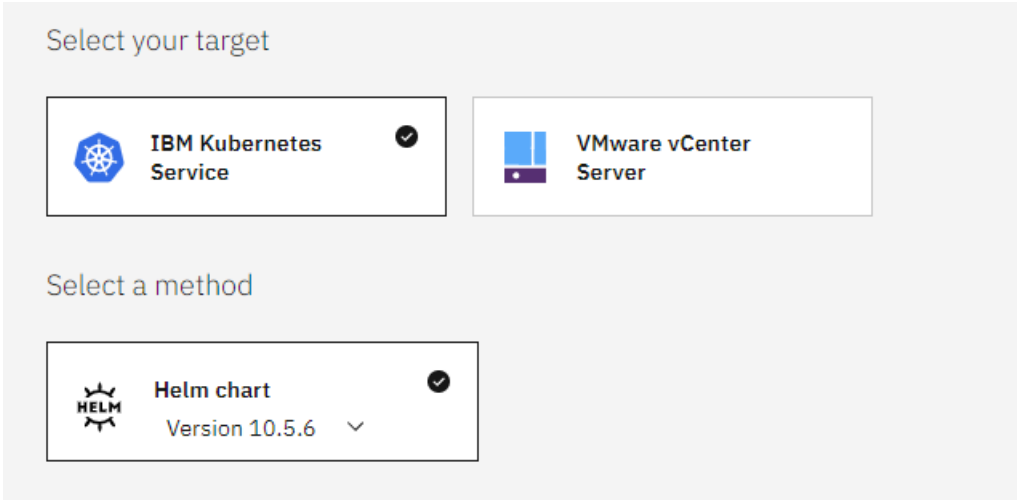
Step 3 deploy MariaDB

We will deploy MariaDB on our cluster

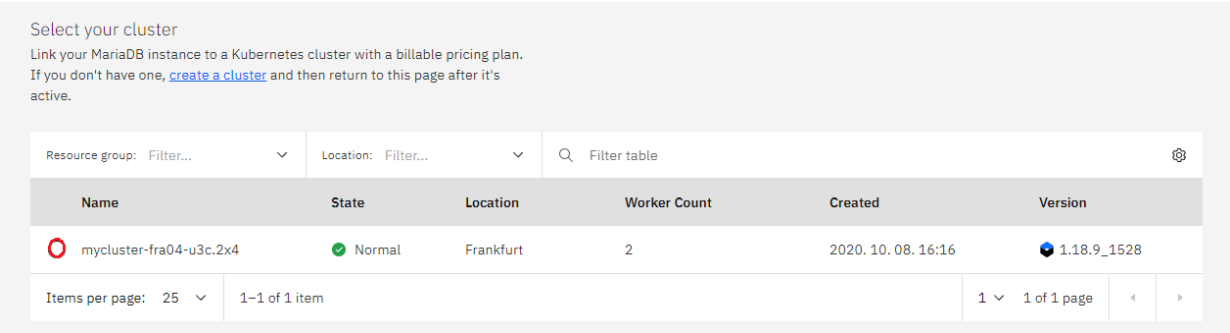
- Click the **Catalog** button on the top
- Select **Software** from the catalog
- Search for **MariaDB** and click on it



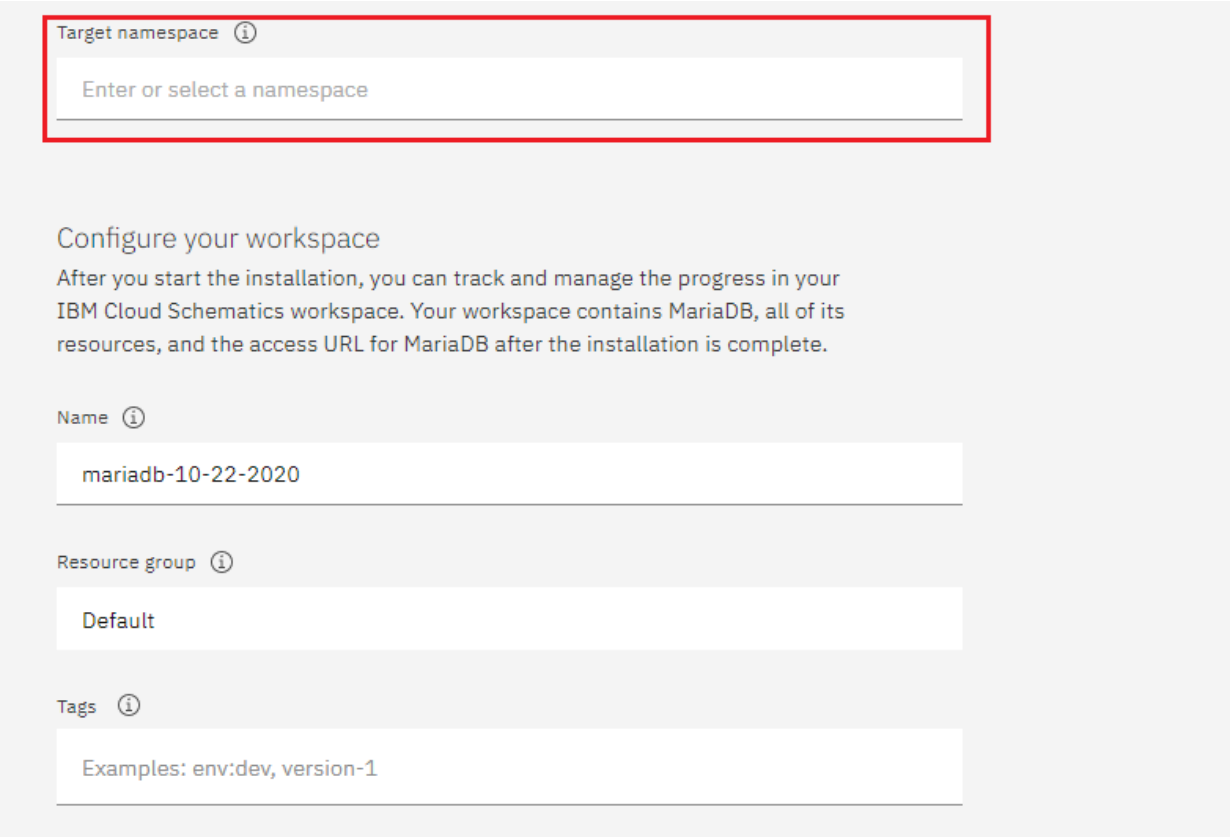
- Please select IBM Kubernetes Service



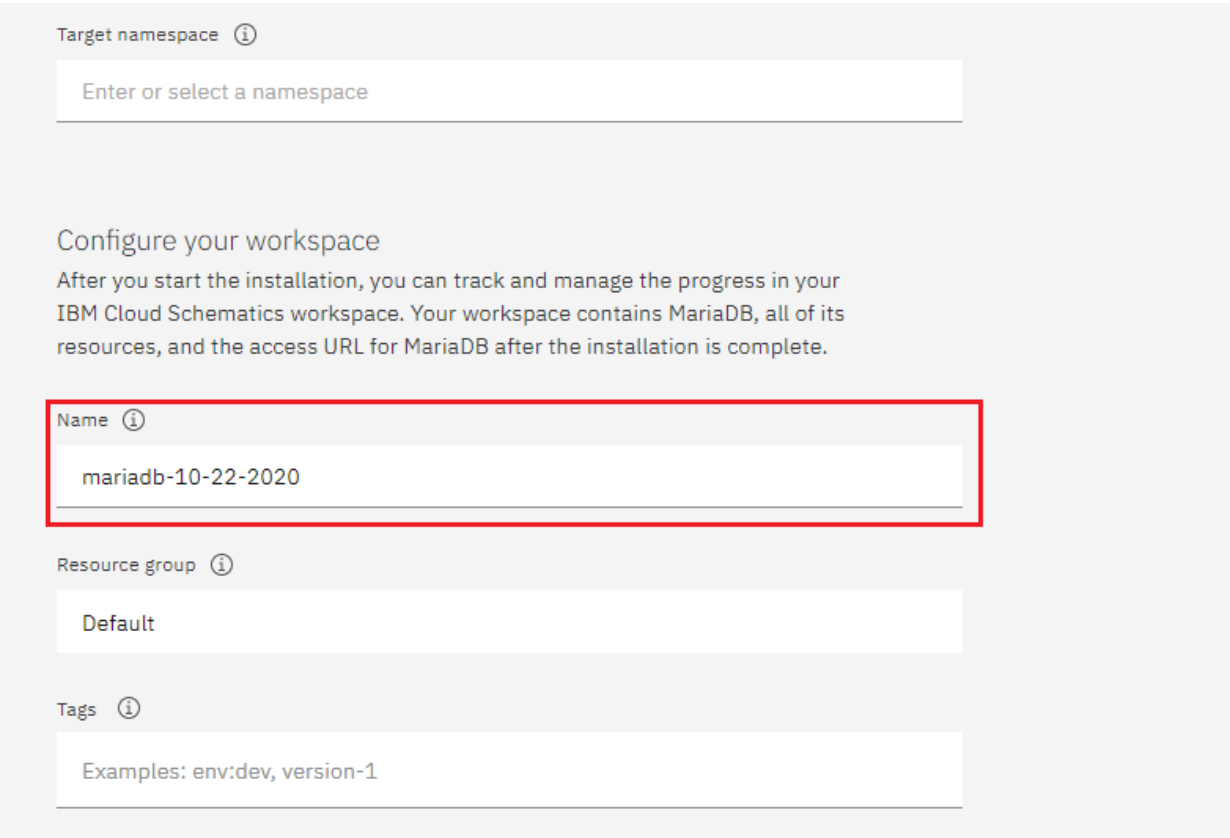
- On the application page Click in the dot next to the cluster, you wish to use



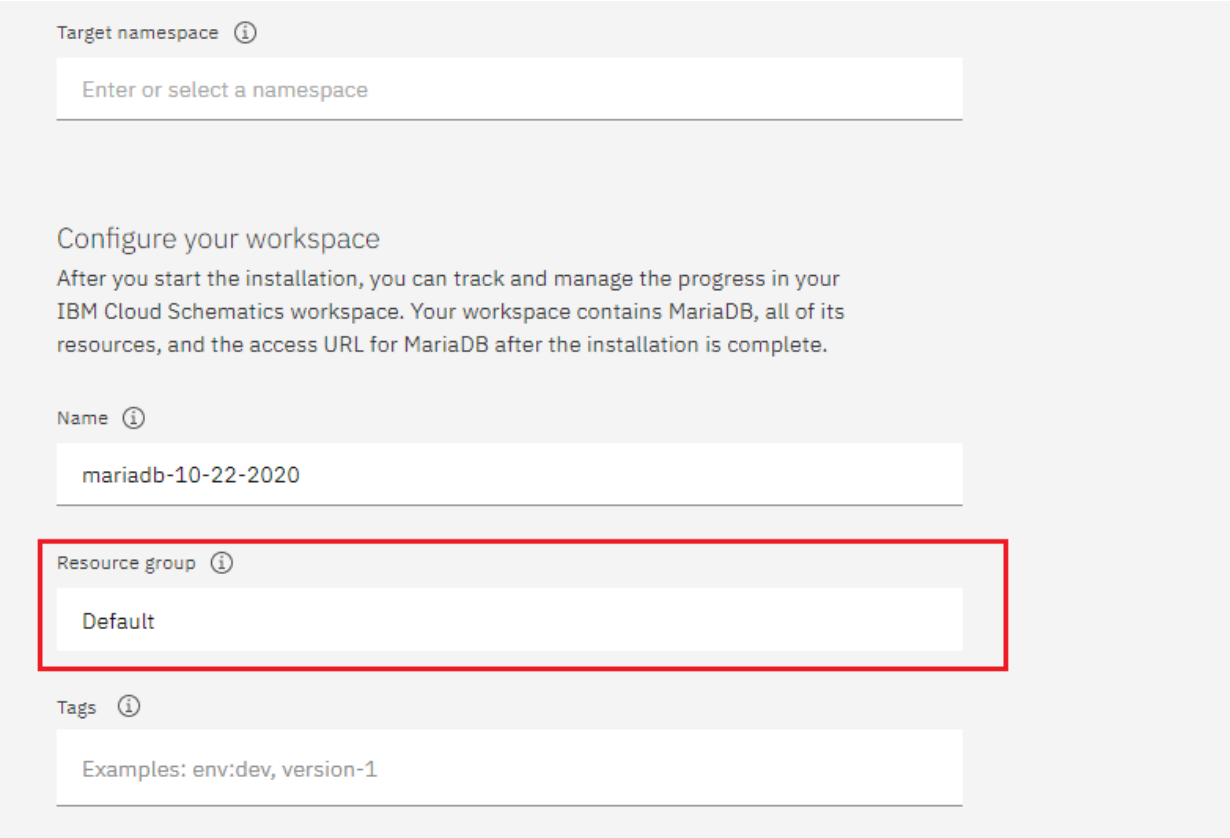
- Click on **Enter or Select Namespace** and choose the default Namespace or use a custom one



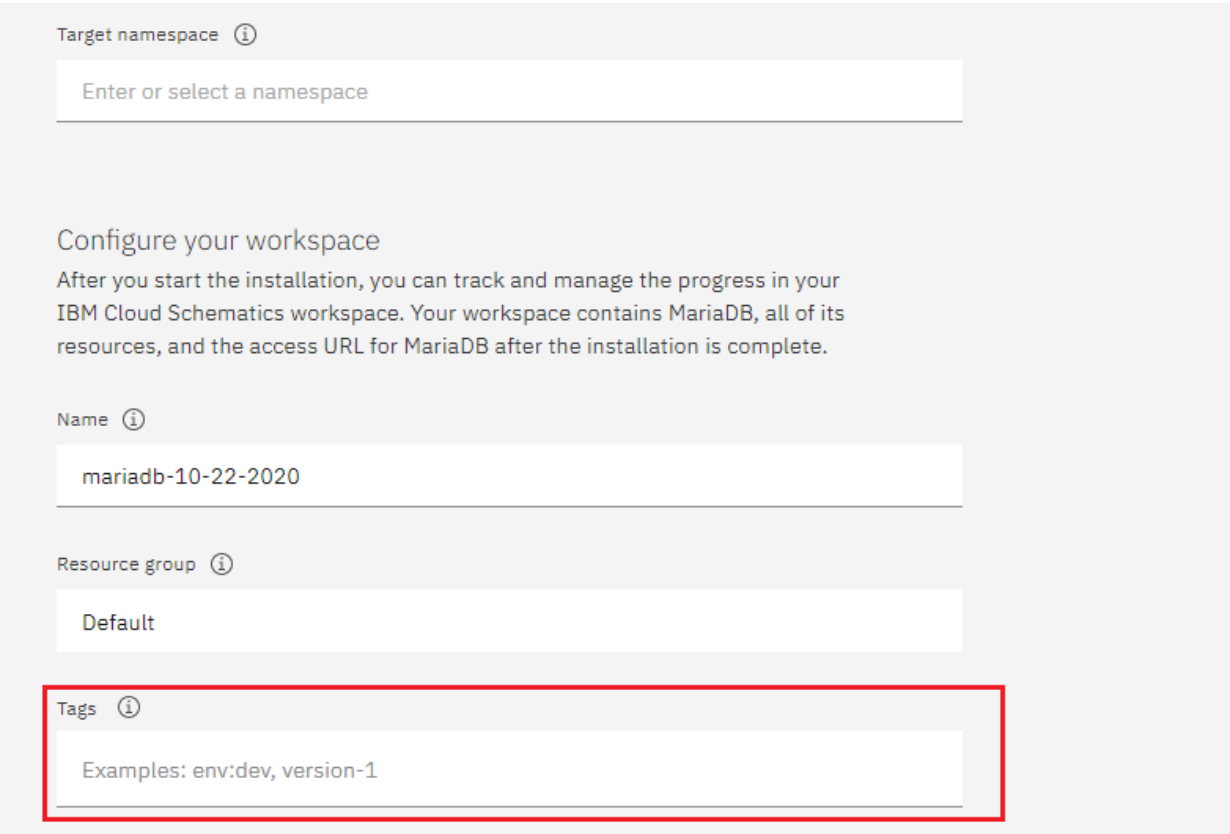
- Give a unique **name** to workspace, which you can easily recognize



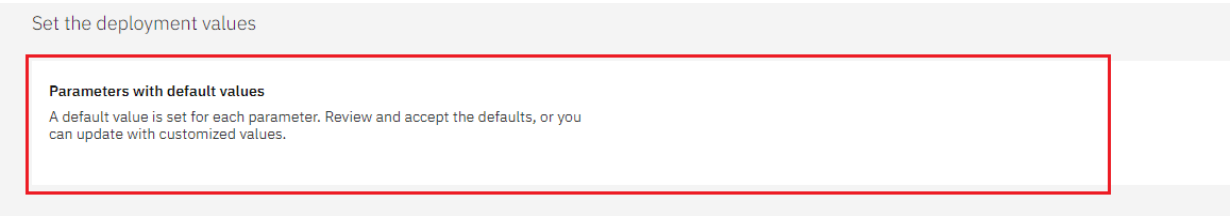
- Select which resource group you want to use, it's for access controll and billing purposes. For more information please visit resource groups



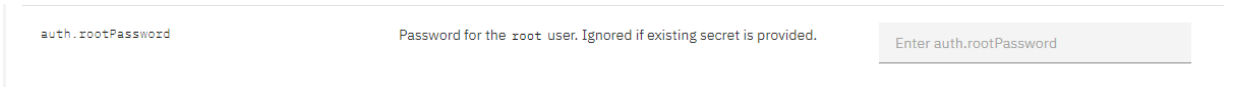
- Give **tags** to your MariaDB, for more information visit tags



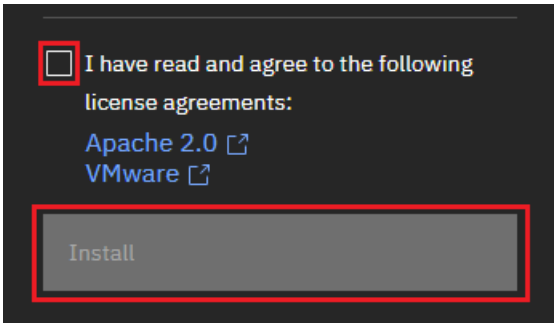
- Click on **Parameters with default values**, You can set deployment values or use the default ones



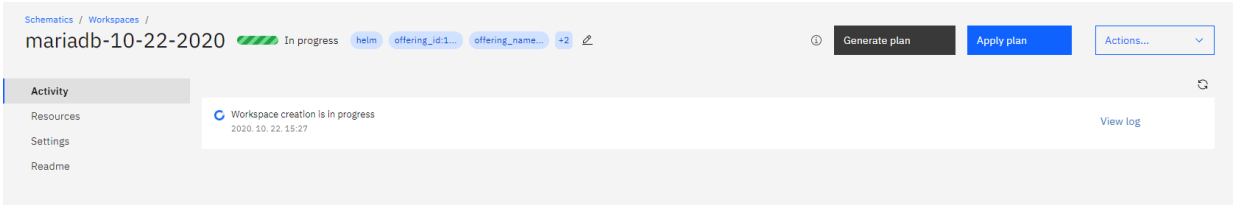
- Please set the MariaDB root password in the parameters



- After finishing everything, **tick** the box next to the agreements and click **install**



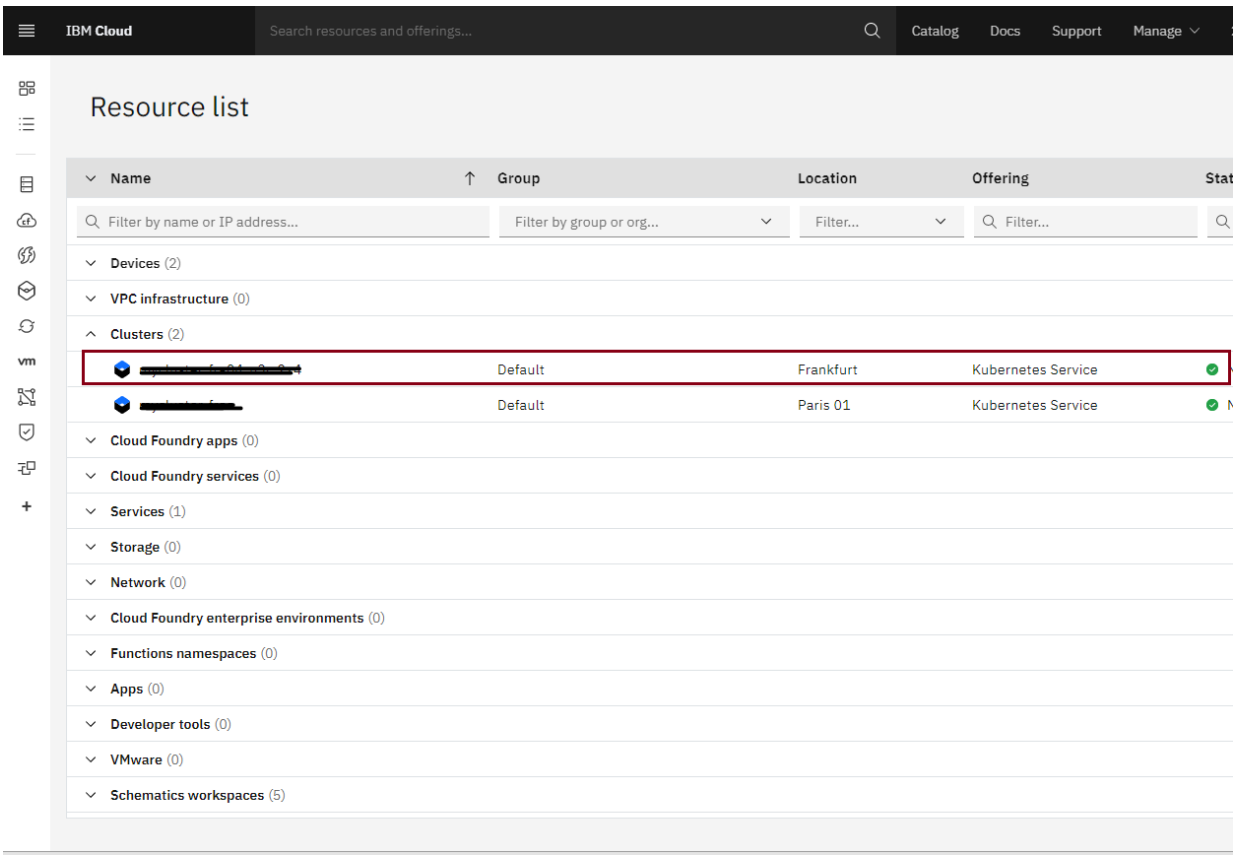
- The MariaDB workspace will start installing, wait a couple of minutes



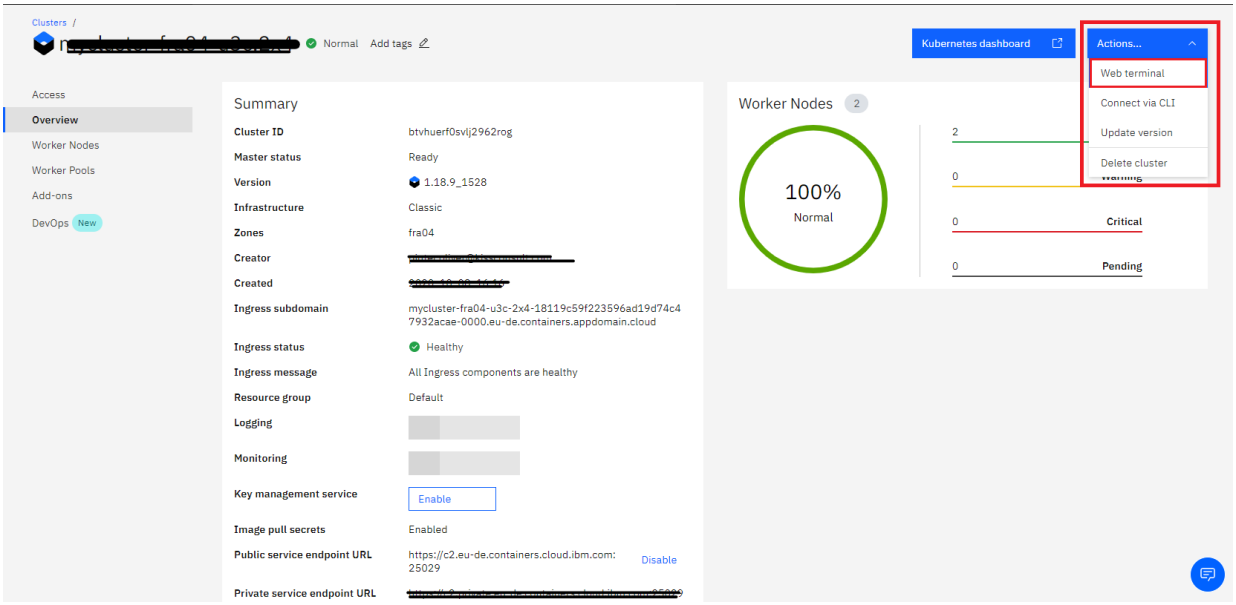
- Your MariaDB workspace has been successfully deployed

Verify MariaDB installation

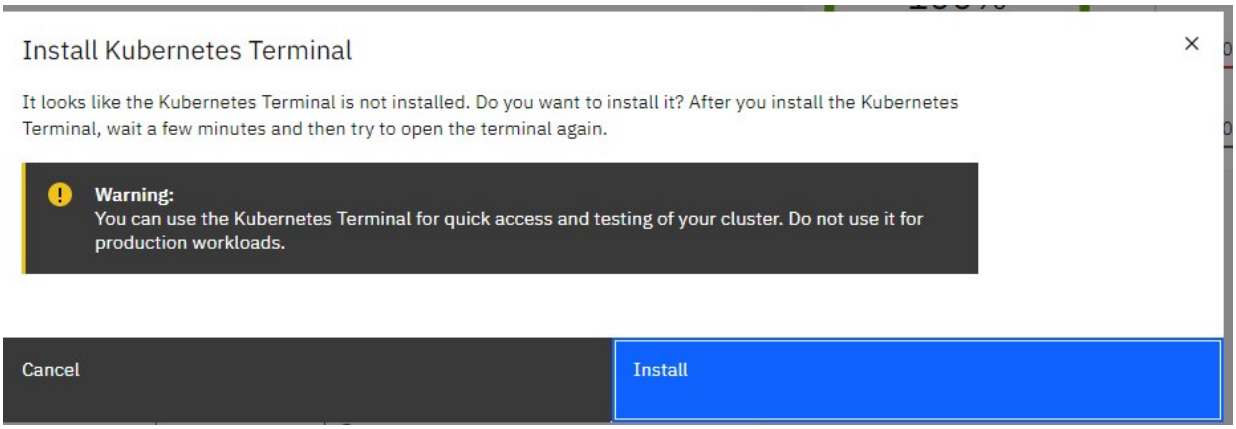
- Go to Resources in your browser
- Click on **Clusters**
- Click on your Cluster



- Now you are at you clusters overview, here Click on **Actions** and **Web terminal** from the dropdown menu



- Click **install** - wait couple of minutes



- Click on **Actions**
- Click **Web terminal** --> a terminal will open up

- **Type** in the terminal, please change NAMESPACE to the namespace you choose at the deployment setup:

```
$ kubectl get ns
```

```
pinter.oliver@k8s-terminal ~ (⎈ mycluster-fra04-u3c.2x4/btvhuerf0svlj2962rog:default)$ kubectl get ns
NAME                STATUS   AGE
default             Active   13d
discourse           Active   3d
grafana             Active   24m
ibm-cert-store      Active   13d
ibm-operators       Active   13d
ibm-system          Active   13d
kube-node-lease     Active   13d
kube-public         Active   13d
kube-system         Active   13d
mariadb             Active   20m
opencart            Active   3d3h
pinter.oliver@k8s-terminal ~ (⎈ mycluster-fra04-u3c.2x4/btvhuerf0svlj2962rog:default)$
```

```
$ kubectl get pod -n NAMESPACE -o wide
```

```
pinter.oliver@k8s-terminal ~ (⎈ mycluster-fra04-u3c.2x4/btvhuerf0svlj2962rog:default)$ kubectl get pods -n mariadb -o wide
NAME                READY   STATUS    RESTARTS   AGE   IP              NODE            NOMINATED NODE   READINESS GATES
mariadb2f-c27f-41-0   1/1     Running   0          21m   172.30.40.152   10.240.129.19   <none>           <none>
pinter.oliver@k8s-terminal ~ (⎈ mycluster-fra04-u3c.2x4/btvhuerf0svlj2962rog:default)$
```

```
$ kubectl get service -n NAMESPACE
```

```
pinter.oliver@k8s-terminal ~ (⎈ mycluster-fra04-u3c.2x4/btvhuerf0svlj2962rog:default)$ kubectl get service -n mariadb
NAME                TYPE        CLUSTER-IP       EXTERNAL-IP   PORT(S)    AGE
mariadb2f-c27f-41   ClusterIP   172.21.247.125   <none>        3306/TCP   22m
pinter.oliver@k8s-terminal ~ (⎈ mycluster-fra04-u3c.2x4/btvhuerf0svlj2962rog:default)$
```

- Enter your pod with bash , please replace PODNAME with your mariadb pod's name

```
$ kubectl exec --stdin --tty PODNAME -n NAMESPACE -- /bin/bash
```

```
pinter.oliver@k8s-terminal ~ (⎈ mycluster-fra04-u3c.2x4/btvhuerf0svlj2962rog:default)$ kubectl exec --stdin --tty mariadb2f-c27f-41-0 -n mariadb -- /bin/bash
```

- After you are in your pod please enter enter Mariadb and enter your root password after the prompt

```
$ mysql -u root -p
```

```
I have no name!@mariadb2f-c27f-41-0:/$ mysql -u root -p
Enter password:
Welcome to the MariaDB monitor.  Commands end with ; or \g.

MariaDB [(none)]>
```

You have succesfully deployed MariaDB IBM Cloud!

2.1.6.3 mysqld Configuration Files and Groups

2.2 User & Server Security

Securing MariaDB
Securing your MariaDB installation

User Account Management
Administering user accounts in MariaDB

There are 4 related questions.

2.2.1 Securing MariaDB

> This section is about securing your MariaDB installation. If you are looking for the list of security vulnerabilities fixed in MariaDB, see Security Vulnerabilities Fixed in MariaDB.

There are a number of issues to consider when looking at improving the security of your MariaDB installation. These include:

Encryption
MariaDB supports encryption for data while at rest and while in transit.

Running mysqld as root
MariaDB should never normally be run as root

mysql_secure_installation
Symlink or old name for mariadb-secure-installation.

SecuRich
Library of security-related stored procedures.

SELinux
Security-Enhanced Linux (SELinux) is a Linux kernel module that provides a ...

SSL/TLS System Variables

List and description of Transport Layer Security (TLS)-related system variables.

SSL/TLS Status Variables

List and description of Transport Layer Security (TLS)-related status variables.

Using TLSv1.3

TLSv1.3 is a major rewrite of the protocol.

There are 6 related questions.

2.2.1.1.1.1 Secure Connections Overview

Contents

By default, MariaDB transmits data between the server and clients without encrypting it. This is generally acceptable when the server and client run on the same host or in networks where security is guaranteed through other means. However, in cases where the server and client exist on separate networks or they are in a high-risk network, the lack of encryption does introduce security concerns as a malicious actor could potentially eavesdrop on the traffic as it is sent over the network between them.

To mitigate this concern, MariaDB allows you to encrypt data in transit between the server and clients using the Transport Layer Security (TLS) protocol. TLS was formerly known as Secure Socket Layer (SSL), but strictly speaking the SSL protocol is a predecessor to TLS and, that version of the protocol is now considered insecure. The documentation still uses the term SSL often and for compatibility reasons TLS-related server system and status variables still use the prefix `ssl_`, but internally, MariaDB only supports its secure successors.

Checking MariaDB Server for TLS Support

In order for MariaDB Server to use TLS, it needs to be compiled with TLS support. All MariaDB packages distributed by MariaDB Foundation and MariaDB Corporation are compiled with TLS support.

If you aren't sure whether your MariaDB Server binary was compiled with TLS support, then you can check the value of the `have_ssl` system variable. For example:

```
SHOW GLOBAL VARIABLES LIKE 'have_ssl';
+---------------+----------+
| Variable_name | Value    |
+---------------+----------+
| have_ssl      | DISABLED |
+---------------+----------+
```

The possible values are:

- If it is `DISABLED`, then the server was compiled with TLS support, but TLS is not enabled.
- If it is `YES`, then the server was compiled with TLS support, and TLS is enabled.
- If it is `NO`, then the server was not compiled with TLS support.

TLS Libraries

When MariaDB is compiled with TLS and cryptography support, it is usually either statically linked with MariaDB's bundled TLS and cryptography library, which might be wolfSSL or yaSSL, or dynamically linked with the system's TLS and cryptography library, which might be OpenSSL, GnuTLS, or Schannel.

See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

TLS Protocol Versions

There are 4 versions of the TLS protocol:

- `TLSv1.0`
- `TLSv1.1`
- `TLSv1.2`
- `TLSv1.3`

Enabling Specific TLS Protocol Versions

MariaDB starting with 10.4

The `tls_version` system variable was first introduced in MariaDB 10.4.6.

In some cases, it might make sense to only enable specific TLS protocol versions. For example, it would make sense if your organization has to comply with a specific security standard. It would also make sense if a vulnerability is found in a specific TLS protocol version, and you would like to ensure that your server does not use the vulnerable protocol version.

The PCI DSS v3.2 recommends using a minimum protocol version of TLSv1.2.

On the **server** side, users can enable specific TLS protocol versions by setting the `tls_version` system variable. This system variable accepts a comma-separated list of TLS protocol versions. A TLS protocol version will only be enabled if it is present in this list. All other TLS protocol versions will not be permitted. This system variable can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
tls_version = TLSv1.2,TLSv1.3
```

You can check which TLS protocol versions are enabled on a server by executing `SHOW GLOBAL VARIABLES`. For example:

```
SHOW GLOBAL VARIABLES LIKE 'tls_version';
```

On the **client** side, users can enable specific TLS protocol versions by setting the `--tls-version` option. This option accepts a comma-separated list of TLS protocol versions. A TLS protocol version will only be enabled if it is present in this list. All other TLS protocol versions will not be permitted. For example, to specify this option in a relevant client option group in an option file, you could set the following:

```
[client-mariadb]
...
tls_version = TLSv1.2,TLSv1.3
```

Or if you wanted to specify it on the command-line with the mariadb client, then you could execute something like this:

```
$ mariadb -u myuser -p -h myserver.mydomain.com \
   --ssl \
   --tls-version="TLSv1.2,TLSv1.3"
```

TLS Protocol Version Support

The TLS protocol versions that are supported depend on the underlying TLS library used by the specific MariaDB binary.

TLS Library	Supported TLS Protocol Versions
openSSL	TLSv1, TLSv1.1, TLSv1.2, TLSv1.3
wolfSSL	TLSv1, TLSv1.1, TLSv1.2, TLSv1.3
yaSSL	TLSv1, TLSv1.1
Schannel	TLSv1, TLSv1.1, TLSv1.2
GnuTLS	TLSv1, TLSv1.1, TLSv1.2, TLSv1.3

See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used by the server and by clients on each platform.

TLS Protocol Version Support in OpenSSL

MariaDB binaries built with the OpenSSL library (OpenSSL 1.0.1 or later) support TLSv1.1 and TLSv1.2 since MariaDB 5.5.41, MariaDB 10.0.15, and MariaDB 10.1.4.

MariaDB binaries built with the OpenSSL library (OpenSSL 1.1.1 or later) support TLSv1.3 since MariaDB 10.2.16 and MariaDB 10.3.8.

If your MariaDB Server binary is built with OpenSSL, then you can set the `ssl_cipher` system variable to values like `SSLv3` or `TLSv1.2` to allow all SSLv3.0 or all TLSv1.2 ciphers. However, this does not necessarily limit the protocol version to TLSv1.2. See MDEV-14101 for more information about that.

Note that the `TLSv1.3` ciphers cannot be excluded when using OpenSSL, even by using the `ssl_cipher` system variable. See Using TLSv1.3 for details.

SSLv3.0 is known to be vulnerable to the POODLE attack, so it should not be used. SSLv2.0 and SSLv3.0 are disabled for MariaDB Server binaries linked with OpenSSL since MariaDB 5.5.41, MariaDB 10.0.15, and MariaDB 10.1.4. If you are using a MariaDB version older than that and you cannot upgrade, then please see the section titled "SSL 3.0 Fallback protection" in OpenSSL Security Advisory - 15 Oct 2014.

TLS Protocol Version Support in wolfSSL

MariaDB binaries built with the bundled wolfSSL library support TLSv1.0, TLSv1.1, TLSv1.2, and TLSv1.3.

TLS Protocol Version Support in yaSSL

MariaDB binaries built with the bundled yaSSL library support SSLv3.0, TLSv1.0, and TLSv1.1.

SSLv3.0 is known to be vulnerable to the POODLE attack, so it should not be used. SSLv2.0 and SSLv3.0 are disabled for MariaDB Server binaries linked with yaSSL since MariaDB 5.5.41, MariaDB 10.0.15, and MariaDB 10.1.4.

TLS Protocol Version Support in Schannel

MariaDB binaries built with the Schannel library support different versions of TLS on different versions of Windows. See the Protocols in TLS/SSL (Schannel SSP) documentation from Microsoft to determine which versions of TLS are supported on each version of Windows.

TLS Protocol Version Support in GnuTLS

MariaDB binaries built with the GnuTLS library support TLSv1.0, TLSv1.1, TLSv1.2, and TLSv1.3.

Enabling TLS

See Securing Connections for Client and Server for information on how to enable TLS on the client and server.

Certificate Verification

Certificate verification is how TLS authenticates its connections by verifying that it is talking to who it says it is. There are multiple components to this verification process:

- Was the certificate signed by a trusted Certificate Authority (CA)?
- Is the certificate expired?
- Is the certificate on my Certificate Revocation List (CRL)?
- Does the certificate belong to who I believe that I'm communicating with?

Certificate Authorities (CAs)

Certificate Authorities (CAs) are entities that you trust to sign TLS certificates. Your organization might have its own internal CA, or it might use trusted third-party CAs.

CAs are specified on the server and client by using the `ssl_ca` and `ssl_capath` options.

The `ssl_ca` option defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs). This option requires that you use the absolute path, not a relative path.

The `ssl_capath` option defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA). This option requires that you use the absolute path, not a relative path. The `ssl_capath` option is only supported if the server or client was built with OpenSSL, wolfSSL, or yaSSL. If the client was built with GnuTLS or Schannel, then the `ssl_capath` option is not supported.

See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

The directory specified by `ssl_capath` needs to be run through the `openssl rehash` command. For example, if the following is configured:

```
ssl_capath=/etc/my.cnf.d/certificates/ca/
```

Then you would have to execute the following:

```
openssl rehash /etc/my.cnf.d/certificates/ca/
```

Requiring a Specific Certificate Authority (CA)

The server can require a specific Certificate Authority (CA) for a client if the client's user account has been defined with `REQUIRE ISSUER`. See Securing Connections for Client and Server: Requiring TLS for more information.

Certificate Revocation Lists (CRLs)

Certificate Revocation Lists (CRLs) are lists of certificates that have been revoked by the Certificate Authority (CA) before they were due to expire.

CRLs are specified on the server and client by using the `ssl_crl` and `ssl_crlpath` options.

The `ssl_crl` option defines a path to a PEM file that should contain one or more X509 revoked certificates. This option requires that you use the absolute path, not a relative path. For servers, the `ssl_crl` option is only valid if the server was built with OpenSSL. If the server was built with wolfSSL or yaSSL, then the `ssl_crl` option is not supported. For clients, the `ssl_crl` option is only valid if the client was built with OpenSSL or Schannel. Likewise, if the client was built with GnuTLS, wolfSSL or yaSSL, then the `ssl_crl` option is not supported.

The `ssl_crlpath` option defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate. This option requires that you use the absolute path, not a relative path. The `ssl_crlpath` option is only supported if the server or client was built with OpenSSL. If the server was built with wolfSSL or yaSSL, then the `ssl_crlpath` option is not supported. Likewise, if the client was built with GnuTLS, Schannel, wolfSSL, or yaSSL, then the `ssl_crlpath` option is not supported.

See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

The directory specified by `ssl_crlpath` needs to be run through the `openssl rehash` command. For example, if the following is configured:

```
ssl_crlpath=/etc/my.cnf.d/certificates/crl/
```

Then you would have to execute the following:

```
openssl rehash /etc/my.cnf.d/certificates/crl/
```

Server Certificate Verification

Clients and utilities verify a server certificate by checking the server's host name and IP address against certain attributes in the certificate. For most clients and utilities, server certificate verification is disabled by default, and it is only enabled if an option, such as `ssl-verify-server-cert` is specified.

To verify the server's certificate, clients and utilities will check the **Common Name (CN)** attribute located in the **Subject** field of the certificate against the server's host name and IP address. If the **Common Name (CN)** matches either of those, then the certificate is verified.

Server Certificate Verification with Subject Alternative Names (SANs)

The **Subject Alternative Name (SAN)** field, which is an X.509v3 extension, can also be used for server certificate verification, if it is present in the server certificate. This field is also sometimes called **subjectAltName**. When using a client

or utility that supports server certificate verification with **subjectAltName** fields, if the server certificate contains any **subjectAltName** fields, then those fields will also be checked against the server's host name and IP address.

Whether server certificate verification with **subjectAltName** fields is supported depends on the underlying TLS library used by the client or utility.

See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

SAN Support with OpenSSL, wolfSSL, and yaSSL

For clients and utilities built with OpenSSL (OpenSSL 1.0.2 or later), support for server certificate verification with **subjectAltName** fields that contain the server's **host name** was added in MariaDB 10.1.23 and MariaDB 10.2.6. See MDEV-10594 for more information.

For clients and utilities built with OpenSSL (OpenSSL 1.0.2 or later), support for server certificate verification with **subjectAltName** fields that contain the server's **IP address** was added in MariaDB 10.1.39, MariaDB 10.2.24, MariaDB 10.3.15, and MariaDB 10.4.5. See MDEV-18131 for more information.

This support also applies to other TLS libraries that use OpenSSL's API. In OpenSSL's API, server certificate verification with **subjectAltName** fields depends on the `X509_check_host` and `X509_check_ip` functions. These functions are supported in the following TLS libraries:

- OpenSSL 1.0.2 or later
- wolfSSL

And they are **not** supported in the following TLS libraries:

- yaSSL

MariaDB's RPM packages were built with OpenSSL 1.0.1 on RHEL 7 and CentOS 7, even after OpenSSL 1.0.2 became available on those distributions. As a side effect, the clients and utilities bundled in these packages did not support server certificate verification with the **subjectAltName** field, even if the packages were installed on a system that had OpenSSL 1.0.2 installed. Starting with MariaDB MariaDB 10.1.39, MariaDB 10.2.23, MariaDB 10.3.14, and MariaDB 10.4.4, MariaDB's RPM packages on RHEL 7 and CentOS 7 are built with OpenSSL 1.0.2. See MDEV-18277 for more information.

SAN Support with Schannel

For clients and utilities linked with Schannel, support for server certificate verification with **subjectAltName** fields was added in MariaDB Connector/C 3.0.2. See CONC-250 for more information.

SAN Support with GnuTLS

For clients and utilities linked with GnuTLS, support for server certificate verification with **subjectAltName** fields was added in MariaDB Connector/C 3.0.0. See CONC-250 for more information.

Client Certificate Verification

The server verifies a client certificate by checking the client's known `SUBJECT` against the **Subject** attribute in the client's certificate. This is only done for user accounts that have been defined with `REQUIRE SUBJECT`. See Securing Connections for Client and Server: Requiring TLS for more information.

2.2.1.1.1.2 Certificate Creation with OpenSSL

Contents

Warning: the instructions below generate version 1 certificates only. These work fine with servers and clients using OpenSSL, but fail if WolfSSL is used instead, as is the case for our Windows MSI packages and our binary tarballs for Linux.

WolfSSL requires version 3 certificates instead when using TLS v1.2 or higher, and so won't work with certificates generated as shown here when using two-way TLS with explicit client certificates.

Generating version 3 certificates requires a few more minor steps, we will upgrade the instructions below soon to

include these.

See also: MDEV-25701

In order to secure communications with the MariaDB Server using TLS, you need to create a private key and an X509 certificate for the server. You may also want to create additional private keys and X509 certificates for any clients that need to connect to the server with TLS. This guide covers how to create a private key and a self-signed X509 certificate with OpenSSL.

Certificate Creation

The OpenSSL library provides a command-line tool called `openssl`, which can be used for performing various tasks with the library, such as generating private keys, creating X509 certificate requests, signing X509 certificates as a Certificate Authority (CA), and verifying X509 certificates.

Creating a Certificate Authority Private Key and Certificate

The Certificate Authority (CA) is typically an organization (such as Let's Encrypt) that signs the X509 certificate and validates ownership of the domain. However, when you would like to use self-signed certificates, you need to create the private key and certificate for the CA yourself, and then you can use them to sign your own X509 certificates.

To start, generate a private key for the CA using the `openssl genrsa` command. For example:

```
# openssl genrsa 2048 > ca-key.pem
```

After that, you can use the private key to generate the X509 certificate for the CA using the `openssl req` command. For example:

```
# openssl req -new -x509 -nodes -days 365000 \
      -key ca-key.pem -out ca.pem
```

The above commands create two files in the working directory: The `ca-key.pem` private key and the `ca.pem` X509 certificate are both are used by the CA to create self-signed X509 certificates below.

Creating a Private Key and a Self-signed Certificate

Once you have the CA's private key and X509 certificate, you can create the self-signed X509 certificates to use for the MariaDB Server, client, replication and other purposes.

To start, generate a private key and create a certificate request using the `openssl req` command. For example:

```
# openssl req -newkey rsa:2048 -days 365000 \
      -nodes -keyout server-key.pem -out server-req.pem
```

After that, process the key to remove the passphrase using the `openssl rsa` command. For example:

```
# openssl rsa -in server-key.pem -out server-key.pem
```

Lastly, using the certificate request and the CA's private key and X509 certificate, you can generate a self-signed X509 certificate from the certificate request using the `openssl x509` command. For example:

```
# openssl x509 -req -in server-req.pem -days 365000 \
      -CA ca.pem -CAkey ca-key.pem -set_serial 01 \
      -out server-cert.pem
```

This creates a `server-cert.pem` file, which is the self-signed X509 certificate.

Certificate Verification

Once you have created the CA's X509 certificate and a self-signed X509 certificate, you can verify that the X509 certificate was correctly generated using the `openssl verify` command. For example:

```
# openssl verify -CAfile ca.pem server-cert.pem
server-cert.pem: OK
```

You can add as many X509 certificates to check against the CA's X509 certificate as you want to verify. A value of `OK` indicates that you can use it was correctly generated and is ready for use with MariaDB.

2.2.1.1.1.3 Securing Connections for Client and Server

Contents

By default, MariaDB transmits data between the server and clients without encrypting it. This is generally acceptable when the server and client run on the same host or in networks where security is guaranteed through other means. However, in cases where the server and client exist on separate networks or they are in a high-risk network, the lack of encryption does introduce security concerns as a malicious actor could potentially eavesdrop on the traffic as it is sent over the network between them.

To mitigate this concern, MariaDB allows you to encrypt data in transit between the server and clients using the Transport Layer Security (TLS) protocol. TLS was formerly known as Secure Socket Layer (SSL), but strictly speaking the SSL protocol is a predecessor to TLS and, that version of the protocol is now considered insecure. The documentation still uses the term SSL often and for compatibility reasons TLS-related server system and status variables still use the prefix `ssl_`, but internally, MariaDB only supports its secure successors.

In order to secure connections between the server and client, you need to ensure that your server was compiled with TLS support. See Secure Connections Overview to determine how to check whether a server was compiled with TLS support.

You also need an X509 certificate, a private key, and the Certificate Authority (CA) chain to verify the X509 certificate for the server. If you want to use two-way TLS, then you will also need an X509 certificate, a private key, and the Certificate Authority (CA) chain to verify the X509 certificate for the client. If you want to use self-signed certificates that are created with OpenSSL, then see Certificate Creation with OpenSSL for information on how to create those.

Enabling TLS

Enabling TLS for MariaDB Server

In order to enable TLS on a MariaDB server that was compiled with TLS support, there are a number of system variables that you need to set, such as:

- You need to set the path to the server's X509 certificate by setting the ssl_cert system variable.
- You need to set the path to the server's private key by setting the ssl_key system variable.
- You need to set the path to the certificate authority (CA) chain that can verify the server's certificate by setting either the ssl_ca or the ssl_capath system variables.
- If you want to restrict the server to certain ciphers, then you also need to set the ssl_cipher system variable.

For example, to set these variables for the server, add the system variables to a relevant server option group in an option file:

```
[mariadb]
...
ssl_cert = /etc/my.cnf.d/certificates/server-cert.pem
ssl_key = /etc/my.cnf.d/certificates/server-key.pem
ssl_ca = /etc/my.cnf.d/certificates/ca.pem
```

And then restart the server to make the changes persistent.

Once the server is back up, you can check that TLS is enabled by checking the value of the have_ssl system variable. For example:

```
SHOW VARIABLES LIKE 'have_ssl';

+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| have_ssl      | YES   |
+---------------+-------+
```

Reloading the Server's Certificates and Keys Dynamically

MariaDB starting with 10.4

The `FLUSH SSL` command was first added in MariaDB 10.4.

In MariaDB 10.4 and later, the `FLUSH SSL` command can be used to dynamically reinitialize the server's TLS context.

See FLUSH SSL for more information.

Enabling TLS for MariaDB Clients

Different clients and utilities may use different methods to enable TLS.

For many of the standard clients and utilities that come bundled with MariaDB, you can enable two-way TLS by adding the same options that were set for the server to a relevant client option group in an option file. For example:

```
[client-mariadb]
...
ssl_cert = /etc/my.cnf.d/certificates/client-cert.pem
ssl_key = /etc/my.cnf.d/certificates/client-key.pem
ssl_ca = /etc/my.cnf.d/certificates/ca.pem
```

The specific options that you would need to set would depend on whether you want one-way TLS or two-way TLS, and whether you want to verify the server certificate.

The same options may also enable TLS on non-standard clients and utilities that are linked with either libmysqlclient or MariaDB Connector/C.

Enabling Two-Way TLS for MariaDB Clients

Two-way TLS means that both the client and server provide a private key and an X509 certificate. It is called "two-way" TLS because both the client and server can be authenticated. For example, to specify these options in a relevant client option group in an option file, you could set the following:

```
[client-mariadb]
...
ssl_cert = /etc/my.cnf.d/certificates/client-cert.pem
ssl_key = /etc/my.cnf.d/certificates/client-key.pem
ssl_ca = /etc/my.cnf.d/certificates/ca.pem
ssl-verify-server-cert
```

Or if you wanted to specify them on the command-line with the mariadb client, then you could execute something like this:

```
$ mariadb -u myuser -p -h myserver.mydomain.com \
   --ssl-cert=/etc/my.cnf.d/certificates/client-cert.pem \
   --ssl-key=/etc/my.cnf.d/certificates/client-key.pem \
   --ssl-ca=/etc/my.cnf.d/certificates/ca.pem \
   --ssl-verify-server-cert
```

Two-way SSL is required for an account if the `REQUIRE X509`, `REQUIRE SUBJECT`, and/or `REQUIRE ISSUER` clauses are specified for the account.

Enabling One-Way TLS for MariaDB Clients

Enabling One-Way TLS for MariaDB Clients with Server Certificate Verification

One-way TLS means that only the server provides a private key and an X509 certificate. When TLS is used without a client certificate, it is called "one-way" TLS, because only the server can be authenticated, so authentication is only possible in one direction. However, encryption is still possible in both directions. Server certificate verification means that the client verifies that the certificate belongs to the server. For example, to specify these options in a a relevant client option group in an option file, you could set the following:

```
[client-mariadb]
...
ssl_ca = /etc/my.cnf.d/certificates/ca.pem
ssl-verify-server-cert
```

Or if you wanted to specify them on the command-line with the mariadb client, then you could execute something like this:

```
$ mariadb -u myuser -p -h myserver.mydomain.com \
   --ssl-ca=/etc/my.cnf.d/certificates/ca.pem \
   --ssl-verify-server-cert
```

Enabling One-Way TLS for MariaDB Clients without Server Certificate Verification

One-way TLS means that only the server provides a private key and an X509 certificate. When TLS is used without a client certificate, it is called "one-way" TLS, because only the server can be authenticated, so authentication is only possible in one direction. However, encryption is still possible in both directions. For example, to specify these options in a a relevant client option group in an option file, you could set the following:

```
[client-mariadb]
...
ssl
```

Or if you wanted to specify them on the command-line with the mariadb client, then you could execute something like this:

```
$ mariadb -u myuser -p -h myserver.mydomain.com \
   --ssl
```

Enabling TLS for MariaDB Connector/C Clients

See the documentation on MariaDB Connector/C's TLS Options for information on how to enable TLS for clients that use MariaDB Connector/C.

Enabling TLS for MariaDB Connector/ODBC Clients

See the documentation on MariaDB Connector/ODBC's TLS-Related Connection Parameters for information on how to enable TLS for clients that use MariaDB Connector/ODBC.

Enabling TLS for MariaDB Connector/J Clients

See the documentation on Using TLS/SSL with MariaDB Connector/J for information on how to enable TLS for clients that use MariaDB Connector/J.

Verifying that a Connection is Using TLS

You can verify that a connection is using TLS by checking the connection's Ssl_cipher status variable. If it is non-empty, then the connection is using TLS. For example:

```
SHOW SESSION STATUS LIKE 'Ssl_cipher';
+---------------+--------------------------+
| Variable_name | Value                    |
+---------------+--------------------------+
| Ssl_cipher    | DHE-RSA-AES256-GCM-SHA384 |
+---------------+--------------------------+
1 row in set (0.00 sec)
```

Requiring TLS

From MariaDB 10.5.2, the require_secure_transport system variable is available. When set (by default it is off), connections attempted using insecure transport will be rejected. Secure transports are SSL/TLS, Unix sockets or named pipes. Note that requirements set for specific user accounts will take precedence over this setting.

Requiring TLS for Specific User Accounts

You can set certain TLS-related restrictions for specific user accounts. For instance, you might use this with user accounts that require access to sensitive data while sending it across networks that you do not control. These restrictions can be enabled for a user account with the CREATE USER, ALTER USER, or GRANT statements. For example:

- A user account must connect via TLS if the user account is defined with the `REQUIRE SSL` clause.

```
ALTER USER 'alice'@'%'
   REQUIRE SSL;
```

- A user account must connect via TLS with a specific cipher if the user account is defined with the `REQUIRE CIPHER` clause.

```
ALTER USER 'alice'@'%'
   REQUIRE CIPHER 'ECDH-RSA-AES256-SHA384';
```

- A user account must connect via TLS with a valid client certificate if the user account is defined with the `REQUIRE X509` clause.

```
ALTER USER 'alice'@'%'
   REQUIRE X509;
```

- A user account must connect via TLS with a specific client certificate if the user account is defined with the `REQUIRE SUBJECT` clause.

```
ALTER USER 'alice'@'%'
   REQUIRE SUBJECT '/CN=alice/O=My Dom, Inc./C=US/ST=Oregon/L=Portland';
```

- A user account must connect via TLS with a client certificate that must be signed by a specific certificate authority if the user account is defined with the `REQUIRE ISSUER` clause.

```
ALTER USER 'alice'@'%'
   REQUIRE SUBJECT '/CN=alice/O=My Dom, Inc./C=US/ST=Oregon/L=Portland'
   AND ISSUER '/C=FI/ST=Somewhere/L=City/ O=Some Company/CN=Peter
Parker/emailAddress=p.parker@marvel.com';
```

Requiring TLS for Specific User Accounts from Specific Hosts

A user account can have different definitions depending on what host the user account is logging in from. Therefore, it is possible to have different TLS requirements for the same username for different hosts. For example:

```
CREATE USER 'alice'@'localhost'
   REQUIRE NONE;

CREATE USER 'alice'@'%'
   REQUIRE SUBJECT '/CN=alice/O=My Dom, Inc./C=US/ST=Oregon/L=Portland'
   AND ISSUER '/C=FI/ST=Somewhere/L=City/ O=Some Company/CN=Peter
Parker/emailAddress=p.parker@marvel.com'
   AND CIPHER 'ECDHE-ECDSA-AES256-SHA384';
```

In the above example, the `alice` user account does not require TLS when logging in from localhost. However, when the `alice` user account logs in from any other host, they must use TLS with the given cipher, and they must provide a valid client certificate with the given subject that must have been signed by the given issuer.

2.2.1.1.1.4 Replication with Secure Connections

The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Contents

By default, MariaDB replicates data between primaries and replicas without encrypting it. This is generally acceptable when the primary and replica run are in networks where security is guaranteed through other means. However, in cases where the primary and replica exist on separate networks or they are in a high-risk network, the lack of encryption does introduce security concerns as a malicious actor could potentially eavesdrop on the traffic as it is sent over the network between them.

To mitigate this concern, MariaDB allows you to encrypt replicated data in transit between primaries and replicas using the Transport Layer Security (TLS) protocol. TLS was formerly known as Secure Socket Layer (SSL), but strictly speaking the SSL protocol is a predecessor to TLS and, that version of the protocol is now considered insecure. The documentation still uses the term SSL often and for compatibility reasons TLS-related server system and status variables still use the prefix `ssl_`, but internally, MariaDB only supports its secure successors.

In order to secure connections between the primary and replica, you need to ensure that both servers were compiled with TLS support. See Secure Connections Overview to determine how to check whether a server was compiled with TLS support.

You also need an X509 certificate, a private key, and the Certificate Authority (CA) chain to verify the X509 certificate for the primary. If you want to use two-way TLS, then you will also an X509 certificate, a private key, and the Certificate Authority (CA) chain to verify the X509 certificate for the replica. If you want to use self-signed certificates that are created with OpenSSL, then see Certificate Creation with OpenSSL for information on how to create those.

Securing Replication Traffic

In order to secure replication traffic, you will need to ensure that TLS is enabled on the primary. If you want to use two-way TLS, then you will also need to ensure that TLS is enabled on the replica. See Securing Connections for Client and Server for information on how to do that.

For example, to set the TLS system variables for each server, add them to a relevant server option group in an option file on each server:

```
[mariadb]
...
ssl_cert = /etc/my.cnf.d/certificates/server-cert.pem
ssl_key = /etc/my.cnf.d/certificates/server-key.pem
ssl_ca = /etc/my.cnf.d/certificates/ca.pem
```

And then restart the server to make the changes persistent.

At this point, you can reconfigure the replicas to use TLS to encrypt replicated data in transit. There are two methods available to do this:

- Executing the CHANGE MASTER statement to set the relevant TLS options.
- Setting TLS client options in an option file.

Executing CHANGE MASTER

TLS can be enabled on a replication replica by executing the CHANGE MASTER statement. In order to do so, there are a

number of options that you would need to set. The specific options that you would need to set would depend on whether you want one-way TLS or two-way TLS, and whether you want to verify the server certificate.

Enabling Two-Way TLS with CHANGE MASTER

Two-way TLS means that both the client and server provide a private key and an X509 certificate. It is called "two-way" TLS because both the client and server can be authenticated. In this case, the "client" is the replica. To configure two-way TLS, you would need to set the following options:

- You need to set the path to the server's certificate by setting the MASTER_SSL_CERT option.
- You need to set the path to the server's private key by setting the MASTER_SSL_KEY option.
- You need to set the path to the certificate authority (CA) chain that can verify the server's certificate by setting either the MASTER_SSL_CA or the MASTER_SSL_CAPATH options.
- If you want server certificate verification, then you also need to set the MASTER_SSL_VERIFY_SERVER_CERT option (enabled by default from MariaDB 11.3).
- If you want to restrict the server to certain ciphers, then you also need to set the MASTER_SSL_CIPHER option.

If the replica threads are currently running, you first need to stop them by executing the STOP SLAVE statement. For example:

```
STOP SLAVE;
```

Then, execute the CHANGE MASTER statement to configure the replica to use TLS. For example:

```
CHANGE MASTER TO
   MASTER_SSL_CERT = '/path/to/client-cert.pem',
   MASTER_SSL_KEY = '/path/to/client-key.pem',
   MASTER_SSL_CA = '/path/to/ca/ca.pem',
   MASTER_SSL_VERIFY_SERVER_CERT=1;
```

At this point, you can start replication by executing the START SLAVE statement. For example:

```
START SLAVE;
```

The replica now uses TLS to encrypt data in transit as it replicates it from the primary.

Enabling One-Way TLS with CHANGE MASTER

Enabling One-Way TLS with CHANGE MASTER with Server Certificate Verification

One-way TLS means that only the server provides a private key and an X509 certificate. When TLS is used without a client certificate, it is called "one-way" TLS, because only the server can be authenticated, so authentication is only possible in one direction. However, encryption is still possible in both directions. Server certificate verification means that the client verifies that the certificate belongs to the server. In this case, the "client" is the replica. This mode is enabled by default starting from MariaDB 11.3. To configure one-way TLS in earlier versions, you would need to set the following options:

- You need to set the path to the certificate authority (CA) chain that can verify the server's certificate by setting either the MASTER_SSL_CA or the MASTER_SSL_CAPATH options.
- You need to set the MASTER_SSL_VERIFY_SERVER_CERT option.
- If you want to restrict the server to certain ciphers, then you also need to set the MASTER_SSL_CIPHER option.

If the replica threads are currently running, you first need to stop them by executing the STOP SLAVE statement. For example:

```
STOP SLAVE;
```

Then, execute the CHANGE MASTER statement to configure the replica to use TLS. For example:

```
CHANGE MASTER TO
   MASTER_SSL_CA = '/path/to/ca/ca.pem',
   MASTER_SSL_VERIFY_SERVER_CERT=1;
```

At this point, you can start replication by executing the START SLAVE statement. For example:

```
START SLAVE;
```

The replica now uses TLS to encrypt data in transit as it replicates it from the primary.

Enabling One-Way TLS with CHANGE MASTER without Server Certificate Verification

One-way TLS means that only the server provides a private key and an X509 certificate. When TLS is used without a client certificate, it is called "one-way" TLS, because only the server can be authenticated, so authentication is only possible in one direction. However, encryption is still possible in both directions. In this case, the "client" is the replica. To configure two-way TLS without server certificate verification, you would need to set the following options:

- You need to configure the replica to use TLS by setting the MASTER_SSL option.
- If you want to restrict the server to certain ciphers, then you also need to set the MASTER_SSL_CIPHER option.
- Starting from MariaDB 11.3 you need to disable the MASTER_SSL_VERIFY_SERVER_CERT option.

If the replica threads are currently running, you first need to stop them by executing the STOP SLAVE statement. For example:

```
STOP SLAVE;
```

Then, execute the CHANGE MASTER statement to configure the replica to use TLS. For example:

```
CHANGE MASTER TO
   MASTER_SSL=1, MASTER_SSL_VERIFY_SERVER_CERT=0;
```

At this point, you can start replication by executing the START SLAVE statement. For example:

```
START SLAVE;
```

The replica now uses TLS to encrypt data in transit as it replicates it from the primary.

2.2.1.1.1.5 Securing Communications in Galera Cluster

Contents

By default, Galera Cluster replicates data between each node without encrypting it. This is generally acceptable when the cluster nodes runs on the same host or in networks where security is guaranteed through other means. However, in cases where the cluster nodes exist on separate networks or they are in a high-risk network, the lack of encryption does introduce security concerns as a malicious actor could potentially eavesdrop on the traffic or get a complete copy of the data by triggering an SST.

To mitigate this concern, Galera Cluster allows you to encrypt data in transit as it is replicated between each cluster node using the Transport Layer Security (TLS) protocol. TLS was formerly known as Secure Socket Layer (SSL), but strictly speaking the SSL protocol is a predecessor to TLS and, that version of the protocol is now considered insecure. The documentation still uses the term SSL often and for compatibility reasons TLS-related server system and status variables still use the prefix `ssl_`, but internally, MariaDB only supports its secure successors.

In order to secure connections between the cluster nodes, you need to ensure that all servers were compiled with TLS support. See Secure Connections Overview to determine how to check whether a server was compiled with TLS support.

For each cluster node, you also need a certificate, private key, and the Certificate Authority (CA) chain to verify the certificate. If you want to use self-signed certificates that are created with OpenSSL, then see Certificate Creation with OpenSSL for information on how to create those.

Securing Galera Cluster Replication Traffic

In order to enable TLS for Galera Cluster's replication traffic, there are a number of wsrep_provider_options that you need to set, such as:

- You need to set the path to the server's certificate by setting the `socket.ssl_cert` wsrep_provider_option.
- You need to set the path to the server's private key by setting the `socket.ssl_key` wsrep_provider_option.
- You need to set the path to the certificate authority (CA) chain that can verify the server's certificate by setting the `socket.ssl_ca` wsrep_provider_option.

- If you want to restrict the server to certain ciphers, then you also need to set the `socket.ssl_cipher` wsrep_provider_option.

It is also a good idea to set MariaDB Server's regular TLS-related system variables, so that TLS will be enabled for regular client connections as well. See Securing Connections for Client and Server for information on how to do that.

For example, to set these variables for the server, add the system variables to a relevant server option group in an option file:

```
[mariadb]
...
ssl_cert = /etc/my.cnf.d/certificates/server-cert.pem
ssl_key = /etc/my.cnf.d/certificates/server-key.pem
ssl_ca = /etc/my.cnf.d/certificates/ca.pem
wsrep_provider_options="socket.ssl_cert=/etc/my.cnf.d/certificates/server-
cert.pem;socket.ssl_key=/etc/my.cnf.d/certificates/server-
key.pem;socket.ssl_ca=/etc/my.cnf.d/certificates/ca.pem"
```

And then restart the server to make the changes persistent.

By setting both MariaDB Server's TLS-related system variables and Galera Cluster's TLS-related wsrep_provider_options, the server can secure both external client connections and Galera Cluster's replication traffic.

Securing State Snapshot Transfers

The method that you would use to enable TLS for State Snapshot Transfers (SSTs) would depend on the value of `wsrep_sst_method`.

mariabackup

See mariabackup SST Method: TLS for more information.

xtrabackup-v2

See xtrabackup-v2 SST Method: TLS for more information.

mysqldump

This SST method simply uses the mariadb-dump (previously mysqldump) utility, so TLS would be enabled by following the guide at Securing Connections for Client and Server: Enabling TLS for MariaDB Clients

rsync

This SST method supports encryption in transit via `stunnel`. See Introduction to State Snapshot Transfers (SSTs): rsync for more information.

2.2.1.1.1.6 SSL/TLS System Variables

Contents

The system variables listed on this page relate to encrypting data during transfer between servers and clients using the Transport Layer Security (TLS) protocol. Often, the term Secure Sockets Layer (SSL) is used interchangeably with TLS, although strictly speaking the SSL protocol is the predecessor of TLS and is no longer considered secure.

For compatibility reasons, the TLS system variables in MariaDB still use the `ssl_` prefix, but MariaDB only supports its more secure successors. For more information on SSL/TLS in MariaDB, see Secure Connections Overview.

Variables

have_openssl

- **Description:** This variable shows whether the server is linked with OpenSSL rather than MariaDB's bundled TLS library, which might be wolfSSL or yaSSL.
  - In MariaDB 10.0.1 and later, if this system variable shows `YES`, then the server is linked with OpenSSL.
  - In MariaDB 10.0.0 and before, this system variable was an alias for the `have_ssl` system variable.
  - See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
- **Scope:** Global
- **Dynamic:** No

---

have_ssl

- **Description:** This variable shows whether the server supports using TLS to secure connections.
  - If the value is `YES`, then the server supports TLS, and TLS is enabled.
  - If the value is `DISABLED`, then the server supports TLS, but TLS is **not** enabled.
  - If the value is `NO`, then the server was not compiled with TLS support, so TLS cannot be enabled.
  - When TLS is supported, check the `have_openssl` system variable to determine whether the server is using OpenSSL or MariaDB's bundled TLS library. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
- **Scope:** Global
- **Dynamic:** No

---

ssl_ca

- **Description:** Defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This system variable requires that you use the absolute path, not a relative path. This system variable implies the `ssl` option.
  - See Secure Connections Overview: Certificate Authorities (CAs) for more information.
- **Commandline:** `--ssl-ca=file_name`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `file name`

---

ssl_capath

- **Description:** Defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This system variable requires that you use the absolute path, not a relative path. The directory specified by this variable needs to be run through the `openssl rehash` command. This system variable implies the `ssl` option.
  - See Secure Connections Overview: Certificate Authorities (CAs) for more information.
- **Commandline:** `--ssl-capath=directory_name`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `directory name`

---

ssl_cert

- **Description:** Defines a path to the X509 certificate file to use for TLS. This system variable requires that you use the absolute path, not a relative path. This system variable implies the `ssl` option.
- **Commandline:** `--ssl-cert=name`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `file name`
- **Default Value:** None

ssl_cipher

- **Description:** List of permitted ciphers or cipher suites to use for TLS. Besides cipher names, if MariaDB was compiled with OpenSSL, this variable could be set to "SSLv3" or "TLSv1.2" to allow all SSLv3 or all TLSv1.2 ciphers. Note that the TLSv1.3 ciphers cannot be excluded when using OpenSSL, even by using this system variable. See Using TLSv1.3 for details. This system variable implies the `ssl` option.
- **Commandline:** `--ssl-cipher=name`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** None

ssl_crl

- **Description:** Defines a path to a PEM file that should contain one or more revoked X509 certificates to use for TLS. This system variable requires that you use the absolute path, not a relative path.
  - See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information.
  - This variable is only valid if the server was built with OpenSSL. If the server was built with wolfSSL or yaSSL, then this variable is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
- **Commandline:** `--ssl-crl=name`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `file name`
- **Default Value:** None

ssl_crlpath

- **Description:** Defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for TLS. This system variable requires that you use the absolute path, not a relative path. The directory specified by this variable needs to be run through the `openssl rehash` command.
  - See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information.
  - This variable is only supported if the server was built with OpenSSL. If the server was built with wolfSSL or yaSSL, then this variable is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.
- **Commandline:** `--ssl-crlpath=name`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `directory name`
- **Default Value:** None

ssl_key

- **Description:** Defines a path to a private key file to use for TLS. This system variable requires that you use the absolute path, not a relative path. This system variable implies the ssl option.
- **Commandline:** `--ssl-key=name`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** None

tls_version

- **Description:** This system variable accepts a comma-separated list (with no whitespaces) of TLS protocol versions. A TLS protocol version will only be enabled if it is present in this list. All other TLS protocol versions will not be permitted.
  - See Secure Connections Overview: TLS Protocol Versions for more information.
- **Commandline:** `--tls-version=value`
- **Scope:** Global
- **Dynamic:** No

- **Data Type:** `enumerated`
- **Default Value:** TLSv1.1,TLSv1.2,TLSv1.3
- **Valid Values:** TLSv1.0,TLSv1.1,TLSv1.2,TLSv1.3
- **Introduced:** MariaDB 10.4.6

`version_ssl_library`

- **Description:** The version of the TLS library that is being used. Note that the version returned by this system variable does not always necessarily correspond to the exact version of the OpenSSL package installed on the system. OpenSSL shared libraries tend to contain interfaces for multiple versions at once to allow for backward compatibility. Therefore, if the OpenSSL package installed on the system is newer than the OpenSSL version that the MariaDB server binary was built with, then the MariaDB server binary might use one of the interfaces for an older version.
  - See TLS and Cryptography Libraries Used by MariaDB: Checking the Server's OpenSSL Version for more information.
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** None

2.2.1.1.1.7 SSL/TLS Status Variables

Contents

The status variables listed on this page relate to encrypting data during transfer with the Transport Layer Security (TLS) protocol. Often, the term Secure Socket Layer (SSL) is used interchangeably with TLS, although strictly speaking, the SSL protocol is a predecessor to TLS and is no longer considered secure.

For compatibility reasons, the TLS status variables in MariaDB still use the `Ssl_` prefix, but MariaDB only supports its more secure successors. For more information on SSL/TLS in MariaDB, see Secure Connections Overview.

Variables

`Ssl_accept_renegotiates`

- **Description:** Number of negotiations needed to establish the TLS connection. The global value can be flushed by `FLUSH STATUS`.

- **Scope:** Global
- **Data Type:** `numeric`

`Ssl_accepts`

- **Description:** Number of accepted TLS handshakes. The global value can be flushed by `FLUSH STATUS`.
- **Scope:** Global
- **Data Type:** `numeric`

`Ssl_callback_cache_hits`

- **Description:** Number of sessions retrieved from the session cache. The global value can be flushed by `FLUSH STATUS`.
- **Scope:** Global
- **Data Type:** `numeric`

`Ssl_cipher`

- **Description:** The TLS cipher currently in use.
- **Scope:** Global, Session
- **Data Type:** `string`

`Ssl_cipher_list`

- **Description:** List of the available TLS ciphers.
- **Scope:** Global, Session
- **Data Type:** `string`

`Ssl_client_connects`

- **Description:** Number of TLS handshakes started in client mode. The global value can be flushed by `FLUSH STATUS`.
- **Scope:** Global
- **Data Type:** `numeric`

`Ssl_connect_renegotiates`

- **Description:** Number of negotiations needed to establish the connection to a TLS-enabled master. The global value can be flushed by `FLUSH STATUS`.
- **Scope:** Global
- **Data Type:** `numeric`

`Ssl_ctx_verify_depth`

- **Description:** Number of tested TLS certificates in the chain. The global value can be flushed by `FLUSH STATUS`.
- **Scope:** Global
- **Data Type:** `numeric`

`Ssl_ctx_verify_mode`

- **Description:** Mode used for TLS context verification.The global value can be flushed by `FLUSH STATUS`.
- **Scope:** Global
- **Data Type:** `numeric`

`Ssl_default_timeout`

- **Description:** Default timeout for TLS, in seconds.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Ssl_finished_accepts

- **Description:** Number of successful TLS sessions in server mode. The global value can be flushed by `FLUSH STATUS`.
- **Scope:** Global
- **Data Type:** `numeric`

Ssl_finished_connects

- **Description:** Number of successful TLS sessions in client mode. The global value can be flushed by `FLUSH STATUS`.
- **Scope:** Global
- **Data Type:** `numeric`

Ssl_server_not_after

- **Description:** Last valid date for the TLS certificate.
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** `MariaDB 10.0`

Ssl_server_not_before

- **Description:** First valid date for the TLS certificate.
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** `MariaDB 10.0`

Ssl_session_cache_hits

- **Description:** Number of TLS sessions found in the session cache. The global value can be flushed by `FLUSH STATUS`.
- **Scope:** Global
- **Data Type:** `numeric`

Ssl_session_cache_misses

- **Description:** Number of TLS sessions not found in the session cache. The global value can be flushed by `FLUSH STATUS`.
- **Scope:** Global
- **Data Type:** `numeric`

Ssl_session_cache_mode

- **Description:** Mode used for TLS caching by the server.
- **Scope:** Global
- **Data Type:** `string`

Ssl_session_cache_overflows

- **Description:** Number of sessions removed from the session cache because it was full. The global value can be flushed by `FLUSH STATUS`.

- **Scope:** Global
- **Data Type:** `numeric`

`Ssl_session_cache_size`

- **Description:** Size of the session cache. The global value can be flushed by `FLUSH STATUS`.
- **Scope:** Global
- **Data Type:** `numeric`

`Ssl_session_cache_timeouts`

- **Description:** Number of sessions which have timed out. The global value can be flushed by `FLUSH STATUS`.
- **Scope:** Global
- **Data Type:** `numeric`

`Ssl_sessions_reused`

- **Description:** Number of sessions reused. The global value can be flushed by `FLUSH STATUS`.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Ssl_used_session_cache_entries`

- **Description:** Current number of sessions in the session cache. The global value can be flushed by `FLUSH STATUS`.
- **Scope:** Global
- **Data Type:** `numeric`

`Ssl_verify_depth`

- **Description:** TLS verification depth.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Ssl_verify_mode`

- **Description:** TLS verification mode.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Ssl_version`

- **Description:** TLS version in use.
- **Scope:** Global, Session
- **Data Type:** `string`

2.2.1.1.1.8 Using TLSv1.3

Contents

OpenSSL 1.1.1 introduced support for TLSv1.3. TLSv1.3 is a major rewrite of the TLS protocol. Some even argued it should've been called TLSv2.0. One of the changes is that it introduces a new set of cipher suites that only work with TLSv1.3. Additionally, TLSv1.3 does not support cipher suites from previous TLS protocol versions.

This incompatible change had a non-obvious consequence. If a user had been explicitly specifying cipher suites to disable old and obsolete TLS protocol version, then that user may have also inadvertently prevented TLSv1.3 from working, unless the user remembered to add the TLSv1.3 cipher suites to their cipher list. After upgrading to OpenSSL 1.1.1, this user might

believe they are using TLSv1.3, when their existing cipher suite configuration might be preventing it.

To avoid this problem, OpenSSL developers decided that TLSv1.3 cipher suites should not be affected by the normal cipher-selecting API. This means that `ssl_cipher` system variable has no effect on the TLSv1.3 cipher suites.

See this OpenSSL blog post and GitHub issue for more information.

2.2.1.1.2 Data-at-Rest Encryption

MariaDB supports the use of data-at-rest encryption for tables and tablespaces. For a minor performance overhead of 3-5%, this makes it almost impossible for someone with access to the host system or who steals a hard drive to read the original data.

Data-at-Rest Encryption Overview

Having data encrypted will make it hard for someone to steal your data.

Why Encrypt MariaDB Data?

When to use encryption for MariaDB data.

Key Management and Encryption Plugins

MariaDB uses plugins to handle key management and encryption of data.

Encrypting Binary Logs

Data-at-rest encryption for binary logs and relay logs.

Aria Encryption

Configuration and use of data-at-rest encryption with the Aria storage engine.

InnoDB Encryption

Articles on using data-at-rest encryption with the InnoDB storage engine.

There are 4 related questions.

2.2.1.1.2.1 Data-at-Rest Encryption Overview

Contents

Overview

Having tables encrypted makes it almost impossible for someone to access or steal a hard disk and get access to the original data. MariaDB got Data-at-Rest Encryption with MariaDB 10.1. This functionality is also known as "Transparent Data Encryption (TDE)".

This assumes that encryption keys are stored on another system.

Using encryption has an overhead of roughly *3-5%*.

Which Storage Engines Does MariaDB Encryption Support?

MariaDB encryption is fully supported for the InnoDB storage engines. Encryption is also supported for the Aria storage engine, but only for tables created with `ROW_FORMAT=PAGE` (the default), and for the binary log (replication log).

MariaDB allows the user to configure flexibly what to encrypt. In or InnoDB, one can choose to encrypt:

- everything — all tablespaces (with all tables)
- individual tables
- everything, excluding individual tables

Additionally, one can choose to encrypt InnoDB log files (recommended).

Limitations

These limitations exist in the data-at-rest encryption implementation:

- Only **data** and only **at rest** is encrypted. Metadata (for example `.frm` files) and data sent to the client are not encrypted (but see Secure Connections).
- Only the MariaDB server knows how to decrypt the data, in particular
  - mariadb-binlog can read encrypted binary logs only when --read-from-remote-server is used (MDEV-8813).
  - Percona XtraBackup cannot back up instances that use encrypted InnoDB. However, MariaDB's fork, MariaDB Backup, can back up encrypted instances.
- The disk-based Galera gcache is not encrypted in the community version of MariaDB Server (MDEV-9639). However, this file is encrypted in MariaDB Enterprise Server 10.4.
- The Audit plugin cannot create encrypted output. Send it to syslog and configure the protection there instead.
- File-based general query log and slow query log cannot be encrypted (MDEV-9639).
- The Aria log is not encrypted (MDEV-8587). This affects only non-temporary Aria tables though.
- The MariaDB error log is not encrypted. The error log can contain query text and data in some cases, including crashes, assertion failures, and cases where InnoDB write monitor output to the log to aid in debugging. It can be sent to syslog too, if needed.

Encryption Key Management

MariaDB's data-at-rest encryption requires the use of a key management and encryption plugin. These plugins are responsible both for the management of encryption keys and for the actual encryption and decryption of data.

MariaDB supports the use of multiple encryption keys. Each encryption key uses a 32-bit integer as a key identifier. If the specific plugin supports key rotation, then encryption keys can also be rotated, which creates a new version of the encryption key.

How MariaDB manages encryption keys depends on which encryption key management solution you choose. Currently, MariaDB has four options:

- File Key Management Plugin
- AWS Key Management Plugin
- Eperi Key Management Plugin
- Hashicorp Key Management Plugin

Once you have an key management and encryption plugin set up and configured for your server, you can begin using encryption options to better secure your data.

Encrypting Data

Encryption occurs whenever MariaDB writes pages to disk. Encrypting table data requires that you install a key management and encryption plugin, such as the File Key Management plugin. Once you have a plugin set up and configured, you can enable encryption for your InnoDB and Aria tables.

Encrypting Table Data

MariaDB supports data-at-rest encryption for InnoDB and Aria storage engines. Additionally, it supports encrypting the InnoDB redo log and internal on-disk temporary tables that use the Aria storage engine..

- Encrypting Data for InnoDB
- Encrypting Data for Aria

Encrypting Temporary Files

MariaDB also creates temporary files on disk. For example, a binary log cache will be written to a temporary file if the binary log cache exceeds `binlog_cache_size` or `binlog_stmt_cache_size`, and temporary files are also often used for filesorts during query execution. Since MariaDB 10.1.5, these temporary files can also be encrypted if encrypt_tmp_files=ON is set.

Since MariaDB 10.1.27, MariaDB 10.2.9 and MariaDB 10.3.2, temporary files created internally by InnoDB, such as those used for merge sorts and row logs can also be encrypted if innodb_encrypt_log=ON is set. These files are encrypted regardless of whether the tables involved are encrypted or not, and regardless of whether encrypt_tmp_files is set or not.

Encrypting Binary Logs

MariaDB can also encrypt binary logs (including relay logs).

- Encrypting Binary Logs

Encryption and Page Compression

Data-at-rest encryption and InnoDB page compression can be used together. When they are used together, data is first compressed, and then it is encrypted. In this case you save space and still have your data protected.

Thanks

- Tablespace encryption was donated to the MariaDB project by Google.
- Per-table encryption and key identifier support was donated to the MariaDB project by eperi.

We are grateful to these companies for their support of MariaDB!

2.2.1.1.2.2 Why Encrypt MariaDB Data?

Nearly everyone owns data of immense value: customer data, construction plans, recipes, product designs and other information. These data are stored in clear text on your storage media. Everyone with file system access is able to read and modify the data. If this data falls into the wrong hands (criminals or competitors) this may result in serious consequences.

With encryption you protect Data At Rest (see the Wikipedia article). That way, the database files are protected against unauthorized access.

When Does Encryption Help to Protect Your Data?

Encryption helps in case of threats against the database files:

- An attacker gains access to the system and copies the database files to avoid the MariaDB authorization check.
- MariaDB is operated by a service provider who should not gain access to the sensitive data.

When is Encryption No Help?

Encryption provides no additional protection against threats caused by authorized database users. Specifically, SQL injections aren't prevented.

What to Encrypt?

All data that is not supposed to fall into possible attackers hands should be encrypted. Especially information, subject to strict data protection regulations, is to be protected by encryption (e.g. in the healthcare sector: patient records). Additionally data being of interest for criminals should be protected. Data which should be encrypted are:

- Personal related information
- Customer details
- Financial and credit card data
- Public authorities data
- Construction plans and research and development results

How to Handle Key Management?

There are currently three options for key management:

- File Key Management Plugin
- AWS Key Management Plugin
- eperi Gateway for Databases

See Encryption Key Management for details.

5.4.8 Key Management and Encryption Plugins

2.2.1.1.2.4 Encrypting Binary Logs

Contents

MariaDB Server can encrypt the server's binary logs and relay logs. This ensures that your binary logs are only accessible through MariaDB.

Basic Configuration

Since MariaDB 10.1.7, MariaDB can also encrypt binary logs (including relay logs). Encryption of binary logs is configured by the encrypt_binlog system variable.

Users of data-at-rest encryption will also need to have a key management and encryption plugin configured. Some examples are File Key Management Plugin and AWS Key Management Plugin.

```
[mariadb]
...

# File Key Management
plugin_load_add = file_key_management
file_key_management_filename = /etc/mysql/encryption/keyfile.enc
file_key_management_filekey = FILE:/etc/mysql/encryption/keyfile.key
file_key_management_encryption_algorithm = AES_CTR

# Binary Log Encryption
encrypt_binlog=ON
```

Encryption Keys

Key management and encryption plugins support using multiple encryption keys. Each encryption key can be defined with a different 32-bit integer as a key identifier.

MariaDB uses the encryption key with ID 1 to encrypt binary logs.

Key Rotation

Some key management and encryption plugins allow you to automatically rotate and version your encryption keys. If a plugin support key rotation, and if it rotates the encryption keys, then InnoDB's background encryption threads can re-encrypt InnoDB pages that use the old key version with the new key version. However, the binary log does **not** have a similar mechanism, which means that existing binary logs remain encrypted with the older key version, but new binary logs will be encrypted with the new key version. For more information, see MDEV-20098.

In order for key rotation to work, both the backend key management service (KMS) and the corresponding key management and encryption plugin have to support key rotation. See Encryption Key Management: Support for Key Rotation in Encryption Plugins to determine which plugins currently support key rotation.

Enabling Encryption

Encryption of binary logs can be enabled by doing the following process.

- First, stop the server.
- Then, set `encrypt_binlog=ON` in the MariaDB configuration file.

- Then, start the server.

From that point forward, any new binary logs will be encrypted. To delete old unencrypted binary logs, you can use RESET MASTER or PURGE BINARY LOGS.

Disabling Encryption

Encryption of binary logs can be disabled by doing the following process.

- First, stop the server.
- Then, set `encrypt_binlog=OFF` in the MariaDB configuration file.
- Then, start the server.

From that point forward, any new binary logs will be unencrypted. If you would like the server to continue to have access to old encrypted binary logs, then make sure to keep your key management and encryption plugin loaded.

Understanding Binlog Encryption

When starting with binary log encryption, MariaDB Server logs a `Format_descriptor_log_event` and a `START_ENCRYPTION_EVENT`, then encrypts all subsequent events for the binary log.

Each event's header and footer are created and processed to produce encrypted blocks. These encrypted blocks are produced before transactions are committed and before the events are flushed to the binary log. As such, they exist in an encrypted state in memory buffers and in the `IO_CACHE` files for user connections.

Effects of Data-at-Rest Encryption on Replication

When using encrypted binary logs with replication, it is completely supported to have different encryption keys on the master and slave. The master decrypts encrypted binary log events as it reads them from disk, and before its binary log dump thread sends them to the slave, so the slave actually receives the unencrypted binary log events.

If you want to ensure that binary log events are encrypted as they are transmitted between the master and slave, then you will have to use TLS with the replication connection.

Effects of Data-at-Rest Encryption on mariadb-binlog

mariadb-binlog does not currently have the ability to decrypt encrypted binary logs on its own (see MDEV-8813 about that). In order to use mariadb-binlog with encrypted binary logs, you have to use the --read-from-remote-server command-line option, so that the server can decrypt the binary logs for mariadb-binlog.

Note, using the `--read-from-remote-server` option on versions of the `mariadb-binlog` utility that do not have the MDEV-20574 fix (<=MariaDB 10.4.9, MariaDB 10.3.19, MariaDB 10.2.28) can corrupt binlog positions when the binary log is encrypted.

2.2.1.1.2.5.2 Aria Enabling Encryption

Contents

In order to enable data-at-rest encryption for tables using the Aria storage engine, you first need to configure the server to use an Encryption Key Management plugin. Once this is done, you can enable encryption by setting the relevant system variables.

Encrypting User-created Tables

With tables that the user creates, you can enable encryption by setting the `aria_encrypt_tables` system variable to `ON`, then restart the Server. Once this is set, Aria automatically enables encryption on all tables you create after with the `ROW_FORMAT` table option set to `PAGE`.

Currently, Aria does not support encryption on tables where the `ROW_FORMAT` table option is set to the `FIXED` or `DYNAMIC` values.

Unlike InnoDB, Aria does not support the `ENCRYPTED` table option (see MDEV-18049 about that). Encryption for Aria can only be enabled globally using the `aria_encrypt_tables` system variable.

Encrypting Existing Tables

In cases where you have existing Aria tables that you would like to encrypt, the process is a little more complicated. Unlike InnoDB, Aria does not utilize background encryption threads to automatically perform encryption changes (see MDEV-18971 about that). Therefore, to encrypt existing tables, you need to identify each table that needs to be encrypted, and then you need to manually rebuild each table.

First, set the `aria_encrypt_tables` system variable to encrypt new tables.

```
SET GLOBAL aria_encrypt_tables=ON;
```

Identify Aria tables that have the `ROW_FORMAT` table option set to `PAGE`.

```
SELECT TABLE_SCHEMA, TABLE_NAME
FROM information_schema.TABLES
WHERE ENGINE='Aria'
  AND ROW_FORMAT='PAGE'
  AND TABLE_SCHEMA != 'information_schema';
```

For each table in the result-set, issue an `ALTER TABLE` statement to rebuild the table.

```
ALTER TABLE test.aria_table ENGINE=Aria ROW_FORMAT=PAGE;
```

This statement causes Aria to rebuild the table using the `ROW_FORMAT` table option. In the process, with the new default setting, it encrypts the table when it writes to disk.

Encrypting Internal On-disk Temporary Tables

During the execution of queries, MariaDB routinely creates internal temporary tables. These internal temporary tables initially use the MEMORY storage engine, which is entirely stored in memory. When the table size exceeds the allocation defined by the `max_heap_table_size` system variable, MariaDB writes the data to disk using another storage engine. If you have the `aria_used_for_temp_tables` set to `ON`, MariaDB uses Aria in writing the internal temporary tables to disk.

Encryption for internal temporary tables is handled separately from encryption for user-created tables. To enable encryption for these tables, set the `encrypt_tmp_disk_tables` system variable to `ON`. Once set, all internal temporary tables that are written to disk using Aria are automatically encrypted.

Manually Encrypting Tables

Currently, Aria does not support manually encrypting tables through the `ENCRYPTED` and `ENCRYPTION_KEY_ID` table

options. For more information, see MDEV-18049.

In cases where you want to encrypt tables manually or set the specific encryption key, use InnoDB.

2.2.1.1.2.5.3 Aria Disabling Encryption

Contents

The process involved in safely disabling data-at-rest encryption for your Aria tables is very similar to that of enabling encryption. To disable, you need to set the relevant system variables and then rebuild each table into an unencrypted state.

Don't remove the Encryption Key Management plugin from your configuration file until you have unencrypted all tables in your database. MariaDB cannot read encrypted tables without the relevant encryption key.

Disabling Encryption on User-created Tables

With tables that the user creates, you can disable encryption by setting the `aria_encrypt_tables` system variable to `OFF`. Once this is set, MariaDB no longer encrypts new tables created with the Aria storage engine.

```
SET GLOBAL aria_encrypt_tables = OFF;
```

Unlike InnoDB, Aria does not currently use background encryption threads. Before removing the Encryption Key Management plugin from the configuration file, you first need to manually rebuild each table to an unencrypted state.

To find the encrypted tables, query the Information Schema, filtering the `TABLES` table for those that use the Aria storage engine and the `PAGE ROW_FORMAT`.

```
SELECT TABLE_SCHEMA, TABLE_NAME
FROM information_schema.TABLES
WHERE ENGINE = 'Aria'
  AND ROW_FORMAT = 'PAGE'
  AND TABLE_SCHEMA != 'information_schema';
```

Each table in the result-set was potentially written to disk in an encrypted state. Before removing the configuration for the encryption keys, you need to rebuild each of these to an unencrypted state. This can be done with an `ALTER TABLE` statement.

```
ALTER TABLE test.aria_table ENGINE = Aria ROW_FORMAT = PAGE;
```

Once all of the Aria tables are rebuilt, they're safely unencrypted.

Disabling Encryption for Internal On-disk Temporary Tables

MariaDB routinely creates internal temporary tables. When these temporary tables are written to disk and the `aria_used_for_temp_tables` system variable is set to `ON`, MariaDB uses the Aria storage engine.

To decrypt these tables, set the `encrypt_tmp_disk_tables` to `OFF`. Once set, all internal temporary tables that are created from that point on are written unencrypted to disk.

2.2.1.1.2.5.4 Aria Encryption Keys

Contents

As with other storage engines that support data-at-rest encryption, Aria relies on an Encryption Key Management plugin to handle its encryption keys. Where the support is available, Aria can use multiple keys.

Encryption Keys

MariaDB keeps track of each encryption key internally using a 32-bit integer, which serves as the key identifier. Unlike InnoDB, Aria does not support the `ENCRYPTION_KEY_ID` table option (for more information, see MDEV-18049), which allows the user to specify the encryption key to use. Instead, Aria defaults to specific encryption keys provided by the Encryption Key Management plugin.

- When working with user-created tables, Aria encrypts them to disk using the ID 1 key.
- When working with internal temporary tables written to disk, Aria encrypts them to disk using the ID 2 key, unless there is no ID 2 key, then it falls back on the ID 1 key.

Key Rotation

Some key management and encryption plugins allow you to automatically rotate and version your encryption keys. If a plugin support key rotation, and if it rotates the encryption keys, then InnoDB's background encryption threads can re-encrypt InnoDB pages that use the old key version with the new key version. However, Aria does **not** have a similar mechanism, which means that the tables remain encrypted with the older key version. For more information, see MDEV-18971.

> In order for key rotation to work, both the backend key management service (KMS) and the corresponding key management and encryption plugin have to support key rotation. See Encryption Key Management: Support for Key Rotation in Encryption Plugins to determine which plugins currently support key rotation.

2.2.1.1.2.6 InnoDB Encryption

Data-at-rest encryption configuration and use with the InnoDB storage engine.

InnoDB Encryption Overview

Data-at-rest encryption for tables that use the InnoDB storage engine.

Enabling InnoDB Encryption

Configuration and procedure for enabling data-at-rest encryption for InnoDB tables.

Disabling InnoDB Encryption

Configuration and procedure to disable data-at-rest encryption for InnoDB tables.

InnoDB Background Encryption Threads

InnoDB performs some encryption and decryption operations with background encryption threads.

InnoDB Encryption Keys

InnoDB uses encryption key management plugins to support the use of multiple encryption keys.

InnoDB Encryption Troubleshooting

Troubleshooting InnoDB encryption

5.3.2.25 InnoDB Encryption Overview

2.2.1.1.2.6.2 Enabling InnoDB Encryption

Contents

In order to enable data-at-rest encryption for tables using the InnoDB storage engines, you first need to configure the Server to use an Encryption Key Management plugin. Once this is done, you can enable encryption by setting the innodb_encrypt_tables system variable to encrypt the InnoDB system and file tablespaces and setting the innodb_encrypt_log system variable to encrypt the InnoDB Redo Log.

Setting these system variables enables the encryption feature for InnoDB tables on your server. To use the feature, you

need to use the ENCRYPTION_KEY_ID table option to set what encryption key you want to use and set the ENCRYPTED table option to enable encryption.

> When encrypting any InnoDB tables, the best practice is also enable encryption for the Redo Log. If you have encrypted InnoDB tables and have not encrypted the Redo Log, data written to an encrypted table may be found unencrypted in the Redo Log.

Enabling Encryption for Automatically Encrypted Tablespaces

The innodb_encrypt_tables system variable controls the configuration of automatic encryption of InnoDB tables. It has the following possible values:

Option	Description
OFF	Disables table encryption.
ON	Enables table encryption, but allows unencrypted tables to be created.
FORCE	Enables table encryption, and doesn't allow unencrypted tables to be created. Added in MariaDB 10.1.4.

When innodb_encrypt_tables is set to ON, InnoDB tables are automatically encrypted by default. For example, the following statements create an encrypted table and confirm that it is encrypted:

```
SET GLOBAL innodb_encryption_threads=4;

SET GLOBAL innodb_encrypt_tables=ON;

SET SESSION innodb_default_encryption_key_id=100;

CREATE TABLE tab1 (
   id int PRIMARY KEY,
   str varchar(50)
);

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME='db1/tab1';
+----------+-------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+-------------------+----------------+
| db1/tab1 |                 1 |            100 |
+----------+-------------------+----------------+
```

When innodb_encrypt_tables is set to ON, an unencrypted InnoDB table can be created by setting the ENCRYPTED table option to NO for the table. For example, the following statements create an unencrypted table and confirm that it is not encrypted:

```
SET GLOBAL innodb_encryption_threads=4;

SET GLOBAL innodb_encrypt_tables=ON;

SET SESSION innodb_default_encryption_key_id=100;

CREATE TABLE tab1 (
   id int PRIMARY KEY,
   str varchar(50)
) ENCRYPTED=NO;

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME='db1/tab1';
+----------+-------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+-------------------+----------------+
| db1/tab1 |                 0 |            100 |
+----------+-------------------+----------------+
```

When innodb_encrypt_tables is set to FORCE, InnoDB tables are automatically encrypted by default, and unencrypted InnoDB tables can **not** be created. In this scenario, if you set the ENCRYPTED table option to NO for a table, then you will

encounter an error. For example:

```
SET GLOBAL innodb_encryption_threads=4;

SET GLOBAL innodb_encrypt_tables='FORCE';

SET SESSION innodb_default_encryption_key_id=100;

CREATE TABLE tab1 (
   id int PRIMARY KEY,
   str varchar(50)
) ENCRYPTED=NO;
ERROR 1005 (HY000): Can't create table `db1`.`tab1` (errno: 140 "Wrong create options")

SHOW WARNINGS;
+---------+------+-----------------------------------------------------------------------+
| Level   | Code | Message                                                               |
+---------+------+-----------------------------------------------------------------------+
| Warning |  140 | InnoDB: ENCRYPTED=NO implies ENCRYPTION_KEY_ID=1                      |
| Warning |  140 | InnoDB: ENCRYPTED=NO cannot be used with innodb_encrypt_tables=FORCE |
| Error   | 1005 | Can't create table `db1`.`tab1` (errno: 140 "Wrong create options")   |
| Warning | 1030 | Got error 140 "Wrong create options" from storage engine InnoDB       |
+---------+------+-----------------------------------------------------------------------+
4 rows in set (0.00 sec)
```

When innodb_encrypt_tables is set to `ON` or `FORCE`, then you must ensure that innodb_encryption_threads is set to a non-zero value, so that InnoDB can perform any necessary encryption operations in the background. See background operations for more information about that. innodb_encryption_rotate_key_age must also be set to a non-zero value for the initial encryption operations to happen in the background. See disabling key rotations for more information about that.

Enabling Encryption for Manually Encrypted Tablespaces

If you do not want to automatically encrypt every InnoDB table, then it is possible to manually enable encryption for just the subset of InnoDB tables that you would like to encrypt. MariaDB provides the ENCRYPTED and ENCRYPTION_KEY_ID table options that can be used to manually enable encryption for specific InnoDB tables. These table options can be used with CREATE TABLE and ALTER TABLE statements. These table options can only be used with InnoDB tables that have their own InnoDB's file-per-table tablespaces, meaning that tables that were created with innodb_file_per_table=ON set.

Table Option	Value	Description
`ENCRYPTED`	Boolean	Defines whether to encrypt the table
`ENCRYPTION_KEY_ID`	32-bit integer	Defines the identifier for the encryption key to use

You can manually enable or disable encryption for a table by using the ENCRYPTED table option. If you only need to protect a subset of InnoDB tables with encryption, then it can be a good idea to manually encrypt each table that needs the extra protection, rather than encrypting all InnoDB tables globally with innodb_encrypt_tables. This allows you to balance security with speed, as it means the encryption and decryption performance overhead only applies to those tables that require the additional security.

If a manually encrypted InnoDB table contains a FULLTEXT INDEX, then the internal table for the full-text index will not also be manually encrypted. To encrypt internal tables for InnoDB full-text indexes, you must enable automatic InnoDB encryption by setting innodb_encrypt_tables to `ON` or `FORCE`.

You can also manually specify a encryption key for a table by using the ENCRYPTION_KEY_ID table option. This allows you to use different encryption keys for different tables. For example, you might create a table using a statement like this:

```
CREATE TABLE tab1 (
   id int PRIMARY KEY,
   str varchar(50)
) ENCRYPTED=YES ENCRYPTION_KEY_ID=100;

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME='db1/tab1';
+----------+-------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+-------------------+----------------+
| db1/tab1 |                 1 |            100 |
+----------+-------------------+----------------+
```

If the ENCRYPTION_KEY_ID table option is not specified, then the table will be encrypted with the key identified by the innodb_default_encryption_key_id system variable. For example, you might create a table using a statement like this:

```
SET SESSION innodb_default_encryption_key_id=100;

CREATE TABLE tab1 (
   id int PRIMARY KEY,
   str varchar(50)
) ENCRYPTED=YES;

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME='db1/tab1';
+----------+-------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+-------------------+----------------+
| db1/tab1 |                 1 |            100 |
+----------+-------------------+----------------+
```

In the event that you have an existing table and you want to manually enable encryption for that table, then you can do the same with an ALTER TABLE statement. For example:

```
CREATE TABLE tab1 (
   id int PRIMARY KEY,
   str varchar(50)
) ENCRYPTED=NO;

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME='db1/tab1';
+----------+-------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+-------------------+----------------+
| db1/tab1 |                 0 |            100 |
+----------+-------------------+----------------+

ALTER TABLE tab1
   ENCRYPTED=YES ENCRYPTION_KEY_ID=100;

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME='db1/tab1';
+----------+-------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+-------------------+----------------+
| db1/tab1 |                 1 |            100 |
+----------+-------------------+----------------+
```

InnoDB does not permit manual encryption changes to tables in the system tablespace using ALTER TABLE. Encryption of the system tablespace can only be configured by setting the value of the innodb_encrypt_tables system variable. This means that when you want to encrypt or decrypt the system tablespace, you must also set a non-zero value for the innodb_encryption_threads system variable, and you must also set the innodb_system_rotate_key_age system variable to `1` to ensure that the system tablespace is properly encrypted or decrypted by the background threads. See MDEV-14398 for more information.

Enabling Encryption for Temporary Tablespaces

The innodb_encrypt_temporary_tables system variable controls the configuration of encryption for the temporary tablespace. It has the following possible values:

Option	Description
OFF	Disables temporary table encryption.
ON	Enables temporary table encryption.

This system variable can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
innodb_encrypt_temporary_tables=ON
```

Enabling Encryption for the Redo Log

InnoDB uses the Redo Log in crash recovery. By default, these events are written to file in an unencrypted state. In configuring MariaDB for data-at-rest encryption, ensure that you also enable encryption for the Redo Log.

To encrypt the Redo Log, first stop the server process. Then, set the innodb_encrypt_log to ON in a relevant server option group in an option file. For example:

```
[mariadb]
...
innodb_encrypt_log = ON
```

Then, start MariaDB. When the server starts back up, it checks to recover InnoDB in the event of a crash. Once it is back online, it begins writing encrypted data to the Redo Log.

> In MariaDB 10.3 and before, InnoDB does not support key rotation for the Redo Log. Key rotation for the Redo Log is supported in MariaDB 10.4 and later. See InnoDB Encryption Keys: Key Rotation for more information.

2.2.1.1.2.6.3 Disabling InnoDB Encryption

Contents

The process involved in safely disabling encryption for your InnoDB tables is a little more complicated than that of enabling encryption. Turning off the relevant system variables doesn't decrypt the tables. If you turn it off and remove the encryption key management plugin, it'll render the encrypted data inaccessible.

In order to safely disable encryption, you first need to decrypt the tablespaces and the Redo Log, then turn off the system variables. The specifics of this process depends on whether you are using automatic or manual encryption of the InnoDB tablespaces.

Disabling Encryption for Automatically Encrypted Tablespaces

When an InnoDB tablespace has the ENCRYPTED table option set to DEFAULT and the innodb_encrypt_tables system variable is set to ON or FORCE, the tablespace's encryption is automatically managed by the background encryption threads. When you want to disable encryption for these tablespaces, you must ensure that the background encryption threads decrypt the tablespaces before removing the encryption keys. Otherwise, the tablespace remains encrypted and becomes inaccessible once you've removed the keys.

To safely decrypt the tablespaces, first, set the innodb_encrypt_tables system variable to OFF:

```
SET GLOBAL innodb_encrypt_tables = OFF;
```

Next, set the innodb_encryption_threads system variable to a non-zero value:

```
SET GLOBAL innodb_encryption_threads = 4;
```

Then, set the innodb_encryption_rotate_key_age system variable to `1`:

```
SET GLOBAL innodb_encryption_rotate_key_age = 1;
```

Once set, any InnoDB tablespaces that have the ENCRYPTED table option set to `DEFAULT` will be decrypted in the background by the InnoDB background encryption threads.

Decryption Status

You can check the status of the decryption process using the INNODB_TABLESPACES_ENCRYPTION table in the information_schema database.

```
SELECT COUNT(*) AS "Number of Encrypted Tablespaces"
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE ENCRYPTION_SCHEME != 0
   OR ROTATING_OR_FLUSHING != 0;
```

This query shows the number of InnoDB tablespaces that currently using background encryption threads. Once the count reaches 0, then all of your InnoDB tablespaces are unencrypted. Be sure to also remove encryption on the Redo Log and the Aria storage engine before removing the encryption key management settings from your configuration file.

Disabling Encryption for Manually Encrypted Tablespaces

In the case of manually encrypted InnoDB tablespaces, (that is, those where the ENCRYPTED table option is set to `YES`), you must issue an ALTER TABLE statement to decrypt each tablespace before removing the encryption keys. Otherwise, the tablespace remains encrypted and becomes inaccessible without the keys.

First, query the Information Schema TABLES table to find the encrypted tables. This can be done with a `WHERE` clause filtering the `CREATE_OPTIONS` column.

```
SELECT TABLE_SCHEMA AS "Database", TABLE_NAME AS "Table"
FROM information_schema.TABLES
WHERE ENGINE='InnoDB'
      AND CREATE_OPTIONS LIKE '%`ENCRYPTED`=YES%';
```

For each table in the result-set, issue an ALTER TABLE statement, setting the ENCRYPTED table option to `NO`.

```
SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME='db1/tab1';
+----------+-------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+-------------------+----------------+
| db1/tab1 |                 1 |            100 |
+----------+-------------------+----------------+

ALTER TABLE tab1
   ENCRYPTED=NO;

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME='db1/tab1';
+----------+-------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+-------------------+----------------+
| db1/tab1 |                 0 |            100 |
+----------+-------------------+----------------+
```

Once you have removed encryption from all the tables, your InnoDB deployment is unencrypted. Be sure to also remove encryption from the Redo Log as well as Aria and any other storage engines that support encryption before removing the encryption key management settings from your configuration file.

> InnoDB does not permit manual encryption changes to tables in the system tablespace using ALTER TABLE.

Encryption of the system tablespace can only be configured by setting the value of the innodb_encrypt_tables system variable. This means that when you want to encrypt or decrypt the system tablespace, you must also set a non-zero value for the innodb_encryption_threads system variable, and you must also set the innodb_system_rotate_key_age system variable to `1` to ensure that the system tablespace is properly encrypted or decrypted by the background threads. See MDEV-14398 for more information.

Disabling Encryption for Temporary Tablespaces

The innodb_encrypt_temporary_tables system variable controls the configuration of encryption for the temporary tablespace. To disable it, remove the system variable from your server's option file, and then restart the server.

Disabling Encryption for the Redo Log

InnoDB uses the Redo Log in crash recovery. By default, these events are written to file in an unencrypted state. In removing data-at-rest encryption for InnoDB, be sure to also disable encryption for the Redo Log before removing encryption key settings. Otherwise the Redo Log can become inaccessible without the encryption keys.

First, check the value of the innodb_fast_shutdown system variable with the SHOW VARIABLES statement. For example:

```
SHOW VARIABLES LIKE 'innodb_fast_shutdown';
+----------------------+-------+
| Variable_name        | Value |
+----------------------+-------+
| innodb_fast_shutdown |     2 |
+----------------------+-------+
```

When the value is set to `2`, InnoDB performs an unclean shutdown, so it will need the Redo Log at the next server startup. Ensure that the variable is set to `0`, `1`, or `3`. For performance reasons, `1` is usually the best option. It can be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL innodb_fast_shutdown = 1;
```

Then, set the innodb_encrypt_log system variable to `OFF` in a server option group in an option file. Once this is done, restart the MariaDB Server. When the Server comes back online, it begins writing unencrypted data to the Redo Log.

2.2.1.1.2.6.4 InnoDB Background Encryption Threads

InnoDB performs some encryption and decryption operations with background encryption threads. The innodb_encryption_threads system variable controls the number of threads that the storage engine uses for encryption-related background operations, including encrypting and decrypting pages after key rotations or configuration changes, and scrubbing data to permanently delete it.

Contents

Background Operations

InnoDB performs the following encryption and decryption operations using background encryption threads:

- When rotating encryption keys, InnoDB's background encryption threads re-encrypt pages that use key versions older than innodb_encryption_rotate_key_age to the new key version.
- When changing the innodb_encrypt_tables system variable to `FORCE`, InnoDB's background encryption threads encrypt the system tablespace and any file-per-table tablespaces that have the `ENCRYPTED` table option set to `DEFAULT`.
- When changing the innodb_encrypt_tables system variable to `OFF`, InnoDB's background encryption threads decrypt the system tablespace and any file-per-table tablespacs that have the `ENCRYPTED` table option set to `DEFAULT`.

The innodb_encryption_rotation_iops system variable can be used to configure how many I/O operations you want to allow for the operations performed by InnoDB's background encryption threads.

Whenever you change the value on the innodb_encrypt_tables system variable, InnoDB's background encryption

threads perform the necessary encryption or decryption operations. Because of this, you must have a non-zero value set for the innodb_encryption_threads system variable. InnoDB also considers these operations to be key rotations internally. Because of this, you must have a non-zero value set for the innodb_encryption_rotate_key_age system variable. For more information, see disabling key rotations.

Non-background Operations

InnoDB performs the following encryption and decryption operations **without** using background encryption threads:

- When a file-per-table tablespaces and using ALTER TABLE to manually set the ENCRYPTED table option to `YES`, InnoDB does **not** use background threads to encrypt the tablespaces.
- Similarly, when using file-per-table tablespaces and using ALTER TABLE to manually set the ENCRYPTED table option to `NO`, InnoDB does **not** use background threads to decrypt the tablespaces.

In these cases, InnoDB performs the encryption or decryption operation using the server thread for the client connection that executes the statement. This means that you can update encryption on file-per-table tablespaces with an ALTER TABLE statement, even when the innodb_encryption_threads and/or the innodb_rotate_key_age system variables are set to `0`.

InnoDB does not permit manual encryption changes to tables in the system tablespace using ALTER TABLE. Encryption of the system tablespace can only be configured by setting the value of the innodb_encrypt_tables system variable. This means that when you want to encrypt or decrypt the system tablespace, you must also set a non-zero value for the innodb_encryption_threads system variable, and you must also set the innodb_system_rotate_key_age system variable to `1` to ensure that the system tablespace is properly encrypted or decrypted by the background threads. See MDEV-14398 for more information.

Checking the Status of Background Operations

InnoDB records the status of background encryption operations in the INNODB_TABLESPACES_ENCRYPTION table in the information_schema database.

For example, to see which InnoDB tablespaces are currently being decrypted or encrypted on by background encryption, you can check which InnoDB tablespaces have the `ROTATING_OR_FLUSHING` column set to `1`:

```
SELECT SPACE, NAME
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE ROTATING_OR_FLUSHING = 1;
```

And to see how many InnoDB tablespaces are currently being decrypted or encrypted by background encryption threads, you can call the COUNT() aggregate function.

```
SELECT COUNT(*) AS 'encrypting'
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE ROTATING_OR_FLUSHING = 1;
```

And to see how many InnoDB tablespaces are currently being decrypted or encrypted by background encryption threads, while comparing that to the total number of InnoDB tablespaces and the total number of encrypted InnoDB tablespaces, you can join the table with the INNODB_SYS_TABLESPACES table in the information_schema database:

```
/* information_schema.INNODB_TABLESPACES_ENCRYPTION does not always have rows for all
tablespaces,
  so let's join it with information_schema.INNODB_SYS_TABLESPACES */
WITH tablespace_ids AS (
   SELECT SPACE
   FROM information_schema.INNODB_SYS_TABLESPACES ist
   UNION
   /* information_schema.INNODB_SYS_TABLESPACES doesn't have a row for the system tablespace
(MDEV-20802) */
   SELECT 0 AS SPACE
)
SELECT NOW() as 'time',
   'tablespaces', COUNT(*) AS 'tablespaces',
   'encrypted', SUM(IF(ite.ENCRYPTION_SCHEME IS NOT NULL, ite.ENCRYPTION_SCHEME, 0)) AS
'encrypted',
   'encrypting', SUM(IF(ite.ROTATING_OR_FLUSHING IS NOT NULL, ite.ROTATING_OR_FLUSHING, 0)) AS
'encrypting'
FROM tablespace_ids
LEFT JOIN information_schema.INNODB_TABLESPACES_ENCRYPTION ite
   ON tablespace_ids.SPACE = ite.SPACE
```

2.2.1.1.2.6.5 InnoDB Encryption Keys

Contents

InnoDB uses encryption key management plugins to support the use of multiple encryption keys.

Encryption Keys

Each encryption key has a 32-bit integer that serves as a key identifier.

The default key is set using the innodb_default_encryption_key_id system variable.

Encryption keys can also be specified with the ENCRYPTION_KEY_ID table option for tables that use file-per-table tablespaces.

InnoDB encrypts the temporary tablespace using the encryption key with the ID `1`.

InnoDB encrypts the Redo Log using the encryption key with the ID `1`.

Keys with Manually Encrypted Tablespaces

With tables that use manually enabled encryption, one way to set the specific encryption key for the table is to use the ENCRYPTION_KEY_ID table option. For example:

```
CREATE TABLE tab1 (
   id int PRIMARY KEY,
   str varchar(50)
) ENCRYPTED=YES ENCRYPTION_KEY_ID=100;

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME='db1/tab1';
+----------+-------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+-------------------+----------------+
| db1/tab1 |                 1 |            100 |
+----------+-------------------+----------------+
```

If the ENCRYPTION_KEY_ID table option is not set for a table that uses manually enabled encryption, then it will inherit the value from the innodb_default_encryption_key_id system variable. For example:

```
SET SESSION innodb_default_encryption_key_id=100;

CREATE TABLE tab1 (
   id int PRIMARY KEY,
   str varchar(50)
) ENCRYPTED=YES;

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME='db1/tab1';
+----------+-------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+-------------------+----------------+
| db1/tab1 |                 1 |            100 |
+----------+-------------------+----------------+
```

Keys with Automatically Encrypted Tablespaces

With tables that use automatically enabled encryption, one way to set the specific encryption key for the table is to use the innodb_default_encryption_key_id system variable. For example:

```
SET GLOBAL innodb_encryption_threads=4;

SET GLOBAL innodb_encrypt_tables=ON;

SET SESSION innodb_default_encryption_key_id=100;

CREATE TABLE tab1 (
   id int PRIMARY KEY,
   str varchar(50)
);

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME='db1/tab1';
+----------+-------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+-------------------+----------------+
| db1/tab1 |                 1 |            100 |
+----------+-------------------+----------------+
```

InnoDB tables that are part of the system tablespace can only be encrypted using the encryption key set by the innodb_default_encryption_key_id system variable.

If the table is in a file-per-table tablespace, and if innodb_encrypt_tables is set to `ON` or `FORCE`, and if innodb_encryption_threads is set to a value greater than `0`, then you can also set the specific encryption key for the table by using the ENCRYPTION_KEY_ID table option. For example:

```
SET GLOBAL innodb_encryption_threads=4;

SET GLOBAL innodb_encrypt_tables=ON;

CREATE TABLE tab1 (
   id int PRIMARY KEY,
   str varchar(50)
) ENCRYPTION_KEY_ID=100;

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
    -> FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
    -> WHERE NAME='db1/tab1';
+----------+-------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+-------------------+----------------+
| db1/tab1 |                 1 |            100 |
+----------+-------------------+----------------+
```

However, if innodb_encrypt_tables is set to `OFF` or if innodb_encryption_threads is set to `0`, then this will not work. See InnoDB Encryption Troubleshooting: Setting Encryption Key ID For an Unencrypted Table for more information.

Key Rotation

Some key management and encryption plugins allow you to automatically rotate and version your encryption keys. If a plugin support key rotation, and if it rotates the encryption keys, then InnoDB's background encryption threads can re-encrypt InnoDB pages that use the old key version with the new key version.

You can set the maximum age for an encryption key using the innodb_encryption_rotate_key_age system variable. When this variable is set to a non-zero value, background encryption threads constantly check pages to determine if any page is encrypted with a key version that's too old. When the key version is too old, any page encrypted with the older version of the key is automatically re-encrypted in the background to use a more current version of the key. Bear in mind, this constant checking can sometimes result in high CPU usage.

Key rotation for the InnoDB Redo Log is only supported in MariaDB 10.4.0 and later. For more information, see MDEV-12041.

> In order for key rotation to work, both the backend key management service (KMS) and the corresponding key management and encryption plugin have to support key rotation. See Encryption Key Management: Support for Key Rotation in Encryption Plugins to determine which plugins currently support key rotation.

Disabling Background Key Rotation Operations

In the event that you encounter issues with background key encryption, you can disable it by setting the innodb_encryption_rotate_key_age system variable to `0`. You may find this useful when the constant key version checks lead to excessive CPU usage. It's also useful in cases where your encryption key management plugin does not support key rotation, (such as with the file_key_management plugin). For more information, see MDEV-14180.

There are, however, issues that can arise when the background key rotation is disabled.

Pending Encryption Operations

Prior to MariaDB 10.2.24, MariaDB 10.3.15, and MariaDB 10.4.5, when you update the value on the innodb_encrypt_tables system variable InnoDB internally treats the subsequent background operations to encrypt and decrypt tablespaces as background key rotations. See MDEV-14398 for more information.

In older versions of MariaDB, if you have recently changed the value of the innodb_encrypt_tables system variable, then you must ensure that any pending background encryption or decryption operations are complete before disabling key rotation. You can check the status of background encryption operations by querying the INNODB_TABLESPACES_ENCRYPTION table in the information_schema database.

See InnoDB Background Encryption Threads: Checking the Status of Background Operations for some example queries.

Otherwise, in older versions of MariaDB, if you disable key rotation while there are background encryption threads at work, it may result in unencrypted tables that you want encrypted or vice versa.

For more information, see MDEV-14398.

2.2.1.1.2.6.6 InnoDB Encryption Troubleshooting

Contents

Wrong Create Options

With InnoDB tables using encryption, there are several cases where a CREATE TABLE or ALTER TABLE statement can throw Error 1005, due to the InnoDB error 140, `Wrong create options`. For instance,

```
CREATE TABLE `test`.`table1` ( `id` int(4) primary key , `name` varchar(50));
ERROR 1005 (HY000): Can't create table `test`.`table1` (errno: 140 "Wrong create options")
```

When this occurs, you can usually get more information about the cause of the error by following it with a SHOW WARNINGS statement.

This error is known to occur in the following cases:

- Encrypting a table by setting the ENCRYPTED table option to `YES` when the innodb_file_per_table is set to `OFF` .In this case, SHOW WARNINGS would return the following:

```
SHOW WARNINGS;
+---------+------+-----------------------------------------------------------------------+
| Level   | Code | Message                                                               |
+---------+------+-----------------------------------------------------------------------+
| Warning |  140 | InnoDB: ENCRYPTED requires innodb_file_per_table                      |
| Error   | 1005 | Can't create table `db1`.`tab3` (errno: 140 "Wrong create options") |
| Warning | 1030 | Got error 140 "Wrong create options" from storage engine InnoDB     |
+---------+------+-----------------------------------------------------------------------+
3 rows in set (0.00 sec)
```

- Encrypting a table by setting the ENCRYPTED table option to `YES` , and the innodb_default_encryption_key_id system variable or the ENCRYPTION_KEY_ID table option refers to a non-existent key identifier. In this case, SHOW WARNINGS would return the following:

```
SHOW WARNINGS;
+---------+------+-----------------------------------------------------------------------+
| Level   | Code | Message                                                               |
+---------+------+-----------------------------------------------------------------------+
| Warning |  140 | InnoDB: ENCRYPTION_KEY_ID 500 not available                           |
| Error   | 1005 | Can't create table `db1`.`tab3` (errno: 140 "Wrong create options") |
| Warning | 1030 | Got error 140 "Wrong create options" from storage engine InnoDB     |
+---------+------+-----------------------------------------------------------------------+
3 rows in set (0.00 sec)
```

- In some versions, this could happen while creating a table with the ENCRYPTED table option set to `DEFAULT` while the innodb_encrypt_tables system variable is set to `OFF` , and the innodb_default_encryption_key_id system variable or the ENCRYPTION_KEY_ID table option are **not** set to `1` . In this case, SHOW WARNINGS would return the following:

```
SHOW WARNINGS;
+---------+------+-----------------------------------------------------------------------+
| Level   | Code | Message                                                               |
+---------+------+-----------------------------------------------------------------------+
| Warning |  140 | InnoDB: innodb_encrypt_tables=OFF only allows ENCRYPTION_KEY_ID=1   |
| Error   | 1005 | Can't create table `db1`.`tab3` (errno: 140 "Wrong create options") |
| Warning | 1030 | Got error 140 "Wrong create options" from storage engine InnoDB     |
+---------+------+-----------------------------------------------------------------------+
3 rows in set (0.00 sec)
```

Starting in MariaDB 10.1.39, MariaDB 10.2.23, and MariaDB 10.3.14, creating a table with the ENCRYPTED table option set to `DEFAULT` while the innodb_encrypt_tables system variable is set to `OFF` , and the innodb_default_encryption_key_id system variable or the ENCRYPTION_KEY_ID table option are **not** set to `1` will no longer fail, and it will no longer throw a warning.

For more information, see MDEV-18601.

Setting Encryption Key ID For an Unencrypted Table

If you set the ENCRYPTION_KEY_ID table option for a table that is unencrypted because the innodb_encrypt_tables system variable is set to `OFF` and the ENCRYPTED table option set to `DEFAULT` , then this encryption key ID will be saved in the table's `.frm` file, but the encryption key will not be saved to the table's `.ibd` file.

As a side effect, with the current encryption design, if the innodb_encrypt_tables system variable is later set to `ON` , and InnoDB goes to encrypt the table, then the InnoDB background encryption threads will not read this encryption key ID from the `.frm` file. Instead, the threads may encrypt the table with the encryption key with ID `1` , which is internally considered the default encryption key when no key is specified. For example:

```
SET GLOBAL innodb_encrypt_tables=OFF;

CREATE TABLE tab1 (
   id INT PRIMARY KEY,
   str VARCHAR(50)
) ENCRYPTION_KEY_ID=100;

SET GLOBAL innodb_encrypt_tables=ON;

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME='db1/tab1';
+----------+-------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+-------------------+----------------+
| db1/tab1 |                 1 |              1 |
+----------+-------------------+----------------+
```

A similar problem is that, if you set the ENCRYPTION_KEY_ID table option for a table that is unencrypted because the ENCRYPTED table option is set to `NO`, then this encryption key ID will be saved in the table's `.frm` file, but the encryption key will not be saved to the table's `.ibd` file.

Recent versions of MariaDB will throw warnings in the case where the ENCRYPTED table option is set to `NO`, but they will allow the operation to succeed. For example:

```
CREATE TABLE tab1 (
   id INT PRIMARY KEY,
   str VARCHAR(50)
) ENCRYPTED=NO ENCRYPTION_KEY_ID=100;
Query OK, 0 rows affected, 1 warning (0.01 sec)

SHOW WARNINGS;
+---------+------+-----------------------------------------------------+
| Level   | Code | Message                                             |
+---------+------+-----------------------------------------------------+
| Warning |  140 | InnoDB: ENCRYPTED=NO implies ENCRYPTION_KEY_ID=1 |
+---------+------+-----------------------------------------------------+
1 row in set (0.00 sec)
```

However, in this case, if you change the ENCRYPTED table option to `YES` or `DEFAULT` with ALTER TABLE, then it will actually use the proper key. For example:

```
SET GLOBAL innodb_encrypt_tables=ON;

ALTER TABLE tab1 ENCRYPTED=DEFAULT;

SELECT NAME, ENCRYPTION_SCHEME, CURRENT_KEY_ID
FROM information_schema.INNODB_TABLESPACES_ENCRYPTION
WHERE NAME = 'db1/tab1';
+----------+-------------------+----------------+
| NAME     | ENCRYPTION_SCHEME | CURRENT_KEY_ID |
+----------+-------------------+----------------+
| db1/tab1 |                 1 |            100 |
+----------+-------------------+----------------+
```

For more information, see MDEV-17230, MDEV-18601, and MDEV-19086.

Tablespaces Created on MySQL 5.1.47 or Earlier

MariaDB's data-at-rest encryption implementation re-used previously unused fields in InnoDB's buffer pool pages to identify the encryption key version and the post-encryption checksum. Prior to MySQL 5.1.48, these unused fields were not initialized in memory due to performance concerns. These fields still had zero values most of the time, but since they were not explicitly initialized, that means that these fields could have occasionally had non-zero values that could have been written into InnoDB's tablespace files. If MariaDB were to encounter an unencrypted page from a tablespace file that was created on an early version of MySQL that also had non-zero values in these fields, then it would mistakenly think that the page was encrypted.

The fix for MDEV-12112 that was included in MariaDB 10.1.38, MariaDB 10.2.20, and MariaDB 10.3.12 changed the way that MariaDB distinguishes between encrypted and unencrypted pages, so that it is less likely to mistake an

unencrypted page for an encrypted page.

In MariaDB 10.4.3 and later, if innodb_checksum_algorithm is set to `full_crc32` or `strict_full_crc32`, and if the table does not use ROW_FORMAT=COMPRESSED, then data files will be guaranteed to be zero-initialized.

For more information, see MDEV-18097.

Spatial Indexes

MariaDB 10.4.3 introduces support for encrypting spatial indexes. To enable, set the innodb_checksum_algorithm to `full_crc32` or to `strict_full_crc32`. Note that MariaDB only encrypts spatial indexes when the ROW_FORMAT table option is **not** set to COMPRESSED.

In older versions of MariaDB, spatial index encryption is unsupported. Tables that contain spatial indexes store them unencrypted.

For more information, see MDEV-12026.

2.2.1.1.3 TLS and Cryptography Libraries Used by MariaDB

Contents

When MariaDB Server is compiled with TLS and cryptography support, it is usually either statically linked with MariaDB's bundled TLS and cryptography library or dynamically linked with the system's OpenSSL library. MariaDB's bundled TLS library is either wolfSSL or yaSSL, depending on the server version.

When a MariaDB client or client library is compiled with TLS and cryptography support, it is usually either statically linked with MariaDB's bundled TLS and cryptography library or dynamically linked with the system's TLS and cryptography library, which might be OpenSSL, GnuTLS, or Schannel.

Checking Dynamically vs. Statically Linked

Dynamically linking MariaDB to the system's TLS and cryptography library can often be beneficial, since this allows you to fix bugs in the system's TLS and cryptography library independently of MariaDB. For example, when information on the Heartbleed Bug in OpenSSL was released in 2014, the bug could be mitigated by simply updating your system to use a fixed version of the OpenSSL library, and then restarting the MariaDB Server.

You can verify that `mysqld` is in fact dynamically linked to the OpenSSL shared library on your system by using the `ldd` command:

```
$ ldd $(which mysqld) | grep -E '(libssl|libcrypto)'
        libssl.so.10 => /lib64/libssl.so.10 (0x00007f8736386000)
        libcrypto.so.10 => /lib64/libcrypto.so.10 (0x00007f8735f25000)
```

If the command does not return any results, then either your `mysqld` is statically linked to the TLS and cryptography library on your system or your `mysqld` is not built with TLS and cryptography support at all.

Checking If the Server Uses OpenSSL

In MariaDB 10.0 and later, if you aren't sure whether your server is linked with OpenSSL or the bundled TLS library, then you can check the value of the `have_openssl` system variable. For example:

```
SHOW GLOBAL VARIABLES LIKE 'have_openssl';
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| have_openssl  | YES   |
+---------------+-------+
```

Checking the Server's OpenSSL Version

In MariaDB 10.1 and later, if you want to see what version of OpenSSL your server is using, then you can check the value of the `version_ssl_library` system variable. For example:

```
SHOW GLOBAL VARIABLES LIKE 'version_ssl_library';
+--------------------+--------------------------------+
| Variable_name      | Value                          |
+--------------------+--------------------------------+
| version_ssl_library | OpenSSL 1.0.1e-fips 11 Feb 2013 |
+--------------------+--------------------------------+
```

Note that the version returned by this system variable does not always necessarily correspond to the exact version of the OpenSSL package installed on the system. OpenSSL shared libraries tend to contain interfaces for multiple versions at once to allow for backward compatibility. Therefore, if the OpenSSL package installed on the system is newer than the OpenSSL version that the MariaDB Server binary was built with, then the MariaDB Server binary might use one of the interfaces for an older version. See MDEV-15848 for more information. For example:

```
$ cat /etc/redhat-release
Red Hat Enterprise Linux Server release 7.5 (Maipo)
$ rpm -q openssl
openssl-1.0.2k-12.el7.x86_64
$ mysql -u root --batch --execute="SHOW GLOBAL VARIABLES LIKE 'version_ssl_library';"
Variable_name   Value
version_ssl_library     OpenSSL 1.0.1e-fips 11 Feb 2013
$ ldd $(which mysqld) | grep libcrypto
        libcrypto.so.10 => /lib64/libcrypto.so.10 (0x00007f3dd3482000)
$ readelf -a /lib64/libcrypto.so.10 | grep SSLeay_version
  1374: 000000000006f5d0    21 FUNC    GLOBAL DEFAULT   13 SSLeay_version@libcrypto.so.10
  1375: 000000000006f5f0    21 FUNC    GLOBAL DEFAULT   13 SSLeay_version@OPENSSL_1.0.1
  1377: 000000000006f580    70 FUNC    GLOBAL DEFAULT   13 SSLeay_version@@OPENSSL_1.0.2
```

FIPS Certification

Federal Information Processing Standards (FIPS) are standards published by the U.S. federal government that are used to establish requirements for various aspects of computer systems. FIPS 140-2 is a set of standards for security requirements for cryptographic modules.

This standard is relevant when discussing the TLS and cryptography libraries used by MariaDB. Some of these libraries have been certified to meet the standards set by FIPS 140-2.

FIPS Certification by OpenSSL

The OpenSSL library has a special FIPS mode that has been certified to meet the FIPS 140-2 standard. In FIPS mode, only algorithms and key sizes that meet the FIPS 140-2 standard are enabled by the library.

MariaDB does not yet support enabling FIPS mode within the database server. See MDEV-20260 for more information. Therefore, if you would like to use OpenSSL's FIPS mode with MariaDB, then you would either need to enable FIPS mode at the kernel level or enable it via the OpenSSL configuration file, system-wide or only for the MariaDB process.. See the following resources for more information on how to do that:

- Red Hat Enterprise Linux 7: Security Guide: Chapter 8. Federal Standards and Regulations
- Ubuntu Security Certifications Documentation: FIPS for Ubuntu 16.04 and 18.04
- OpenSSL 1.0.2, configuration file method
- OpenSSL 3.0 configuration file method

FIPS Certification by wolfSSL

The standard version of the wolfSSL library has not been certified to meet the FIPS 140-2 standard, but a special "FIPS-ready" version has been certified. Unfortunately, the "FIPS-ready" version of wolfSSL uses a license that is incompatible with MariaDB's license, so it cannot be used with MariaDB.

FIPS Certification by yaSSL

The yaSSL library has not been certified to meet the FIPS 140-2 standard.

Libraries Used by Each Platform and Package

MariaDB Server

MariaDB Server on Windows

MariaDB starting with 10.4.6

MariaDB Server is statically linked with the bundled wolfSSL library in MSI and ZIP packages on Windows.

MariaDB until 10.4.5

MariaDB Server is statically linked with the bundled yaSSL library in MSI and ZIP packages on Windows.

MariaDB Server on Linux

MariaDB Server in Binary Tarballs

MariaDB starting with 10.4.6

In MariaDB 10.4.6 and later, MariaDB Server is statically linked with the bundled wolfSSL library in binary tarballs on Linux.

MariaDB until 10.4.5

In MariaDB 10.4.5 and before, MariaDB Server is statically linked with the bundled yaSSL library in binary tarballs on Linux.

MariaDB Server in DEB Packages

MariaDB Server is dynamically linked with the system's OpenSSL library in `.deb` packages.

MariaDB until 10.3

In MariaDB 10.3 and before, MariaDB Server is statically linked with the bundled yaSSL library in `.deb` packages provided by Debian's and Ubuntu's default repositories.

See Differences in MariaDB in Debian (and Ubuntu) for more information.

MariaDB Server in RPM Packages

MariaDB Server is dynamically linked with the system's OpenSSL library in `.rpm` packages.

MariaDB Clients and Utilities

In MariaDB 10.2 and later, MariaDB Connector/C has been included with MariaDB Server, and the bundled and the

clients and utilities are linked with it. On some platforms, MariaDB Connector/C and these clients and utilities may use a different TLS library than the one used by MariaDB Server and libmysqlclient.

MariaDB Clients and Utilities on Windows

MariaDB starting with 10.4.6

In MariaDB 10.4.6 and later, MariaDB's clients and utilities and MariaDB Connector/C are are dynamically linked with the system's Schannel libraries in MSI and ZIP packages on Windows. libmysqlclient is still statically linked with the bundled wolfSSL library.

MariaDB Clients and Utilities on Linux

MariaDB Clients and Utilities in Binary Tarballs

MariaDB starting with 10.4.6

In MariaDB 10.4.6 and later, MariaDB's clients and utilities and MariaDB Connector/C are statically linked with the GnuTLS library in binary tarballs on Linux. libmysqlclient is still statically linked with the bundled wolfSSL library.

MariaDB Clients and Utilities in DEB Packages

MariaDB's clients and utilities, libmysqlclient, and MariaDB Connector/C are dynamically linked with the system's OpenSSL library in `.deb` packages.

See Differences in MariaDB in Debian (and Ubuntu) for more information.

MariaDB Clients and Utilities in RPM Packages

MariaDB's clients and utilities, libmysqlclient, and MariaDB Connector/C are dynamically linked with the system's OpenSSL library in `.rpm` packages.

Updating Dynamically Linked OpenSSL Libraries on Linux

When the MariaDB Server or clients and utilities are dynamically linked to the system's OpenSSL library, it makes it very easy to update the libraries. The information below will show how to update these libraries for each platform.

Updating Dynamically Linked OpenSSL Libraries with yum/dnf

On RHEL, CentOS, Fedora, and other similar Linux distributions, it is highly recommended to update the libraries using `yum` or `dnf`. Starting with RHEL 8 and Fedora 22, `yum` has been replaced by `dnf`, which is the next major version of `yum`. However, `yum` commands still work on many systems that use `dnf`. For example:

Update the package by executing the following command:

```
sudo yum update openssl
```

And then restart MariaDB server and any clients or applications that use the library.

Updating Dynamically Linked OpenSSL Libraries with apt-get

On Debian, Ubuntu, and other similar Linux distributions, it is highly recommended to recommended to update the libraries using `apt-get`. For example:

First update the package cache by executing the following command:

```
sudo apt update
```

And then update the package by executing the following command:

```
sudo apt-get update openssl
```

And then restart MariaDB server and any clients or applications that use the library.

Updating Dynamically Linked OpenSSL Libraries with zypper

On SLES, OpenSUSE, and other similar Linux distributions, it is highly recommended to recommended to update the libraries using `zypper`. For example:

Update the package by executing the following command:

```
sudo zypper update openssl
```

And then restart MariaDB server and any clients or applications that use the library.

2.2.1.2 Running mysqld as root

MariaDB should never normally be run as the system's root user (this is unrelated to the MariaDB root user). If it is, any user with the FILE privilege can create or modify any files on the server as root.

MariaDB will normally return the error **Fatal error: Please read "Security" section of the manual to find out how to run mysqld as root!** if you attempt to run mysqld as root. If you need to override this restriction for some reason, start mysqld with the `user=root` option.

Better practice, and the default in most situations, is to use a separate user, exclusively used for MariaDB. In most distributions, this user is called `mysql`.

1.3.43.14 mysql_secure_installation

2.2.1.4 Security-Enhanced Linux with MariaDB

Contents

Security-Enhanced Linux (SELinux) is a Linux kernel module that provides a framework for configuring mandatory access control (MAC) system for many resources on the system. It is enabled by default on some Linux distributions, including RHEL, CentOS, Fedora, and other similar Linux distribution. SELinux prevents programs from accessing files, directories or ports unless it is configured to access those resources.

Verifying Whether SELinux Is Enabled

To verify whether SELinux is enabled, execute the `getenforce` command. For example:

```
getenforce
```

Temporarily Putting mysqld Into Permissive Mode

When you are troubleshooting issues that you think SELinux might be causing, it can help to temporarily put `mysqld_t` into permissive mode. This can be done by executing the `semanage` command. For example:

```
sudo semanage permissive -a mysqld_t
```

If that solved the problem, then it means that the current SELinux policy is the culprit. You need to adjust the SELinux policy or labels for MariaDB.

Configuring a MariaDB Server SELinux Policy

MariaDB Server should work with your default distribution policy (which is usually part of the `selinux-policy` or `selinux-policy-targeted` system package). If you use `mysqld_safe`, you will need an additional policy file, `mariadb.pp`, which is installed together with the MariaDB Server. It will be loaded automatically if you have `/usr/sbin/semodule` installed, but you can load it manually anytime with

```
/usr/sbin/semodule -i /usr/share/mysql/policy/selinux/mariadb.pp
```

Note that this policy file extends, but not replaces the system policy.

Setting File Contexts

SELinux uses file contexts as a way to determine who should be able to access that file.

File contexts are managed with the `semanage fcontext` and `restorecon` commands.

On many systems, the `semanage` utility is installed by the `policycoreutils-python` package, and the `restorecon` utility is installed by the `policycoreutils` package. You can install these with the following command:

```
sudo yum install policycoreutils policycoreutils-python
```

A file or directory's current context can be checked by executing `ls` with the `--context` or `--scontext` options.

Setting the File Context for the Data Directory

If you use a custom directory for `datadir`, then you may need to set the file context for that directory. The SELinux file context for MariaDB data files is `mysqld_db_t`. You can determine if this file context is present on your system and which files or directories it is associated with by executing the following command:

```
sudo semanage fcontext --list | grep mysqld_db_t
```

If you would like to set the file context for your custom directory for your `datadir`, then that can be done by executing the `semanage fcontext` and `restorecon` commands. For example:

```
sudo semanage fcontext -a -t mysqld_db_t "/mariadb/data(/.*)?"
sudo restorecon -Rv /mariadb/data
```

If you would like to check the current file context, you can do so by by executing `ls` with the `--context` or `--scontext` options. For example:

```
ls --directory --scontext /mariadb/data
```

Setting the File Context for Log Files

If you use a custom directory for log files, then you may need to set the file context for that directory. The SELinux file context for MariaDB log files is `mysqld_log_t`. You can determine if this file context is present on your system and which files or directories it is associated with by executing the following command:

```
sudo semanage fcontext --list | grep mysqld_log_t
```

If you would like to set the file context for your custom directory for log files, then that can be done by executing the `semanage fcontext` and `restorecon` commands. For example:

```
sudo semanage fcontext -a -t mysqld_log_t "/var/log/mysql(/.*)?"
sudo restorecon -Rv /var/log/mysql
```

If you would like to check the current file context, you can do so by by executing `ls` with the `--context` or `--scontext` options. For example:

```
ls --directory --scontext /var/log/mysql
```

Setting the File Context for Option Files

If you use a custom directory for option files, then you may need to set the file context for that directory. The SELinux file context for MariaDB option files is `mysqld_etc_t`. You can determine if this file context is present on your system and which files or directories it is associated with by executing the following command:

```
sudo semanage fcontext --list | grep mysqld_etc_t
```

If you would like to set the file context for your custom directory for option files, then that can be done by executing the `semanage fcontext` and `restorecon` commands. For example:

```
sudo semanage fcontext -a -t mysqld_etc_t "/etc/mariadb(/.*)?"
sudo restorecon -Rv /etc/mariadb
```

If you would like to check the current file context, you can do so by by executing `ls` with the `--context` or `--scontext` options. For example:

```
ls --directory --scontext /etc/mariadb
```

Allowing Access to the Tmpfs File Context

If you wanted to mount your `tmpdir` on a `tmpfs` file system or wanted to use a `tmpfs` file system on `/run/shm`, then you might need to allow `mysqld_t` to have access to a couple tmpfs-related file contexts. For example:

```
cd /usr/share/mysql/policy/selinux/
tee ./mysqld_tmpfs.te <<EOF
module mysqld_tmpfs 1.0;

require {
type tmpfs_t;
type mysqld_t;
class dir { write search read remove_name open getattr add_name };
class file { write getattr read lock create unlink open };
}

allow mysqld_t tmpfs_t:dir { write search read remove_name open getattr add_name };

allow mysqld_t tmpfs_t:file { write getattr read lock create unlink open }
EOF
sudo checkmodule -M -m mysqld_tmpfs.te -o mysqld_tmpfs.mod
sudo semodule_package -m mysqld_tmpfs.mod -o mysqld_tmpfs.pp
sudo semodule -i mysqld_tmpfs.pp
```

Troubleshooting SELinux Issues

You might need to troubleshoot SELinux-related issues in cases, such as:

- MariaDB is using a non-default port.
- MariaDB is reading from or writing to some files (datadir, log files, option files, etc.) located at non-default paths.
- MariaDB is using a plugin that requires access to resources that default installations do not use.

File System Permission Errors

If the file system permissions for some MariaDB directory look fine, but the MariaDB error log still has errors that look similar to the following:

```
130321 11:50:51 mysqld_safe Starting mysqld daemon with databases from /datadir
...
2013-03-21 11:50:52 2119 [Warning] Can't create test file /datadir/
2013-03-21 11:50:52 2119 [Warning] Can't create test file /datadir/
...
2013-03-21 11:50:52 2119 [ERROR] /usr/sbin/mysqld: Can't create/write to file
    '/datadir/boxy.pid' (Errcode: 13 - Permission denied)
2013-03-21 11:50:52 2119 [ERROR] Can't start server: can't create PID file:
    Permission denied
130321 11:50:52 mysqld_safe mysqld from pid file /datadir/boxy.pid ended
```

Then check SELinux's `/var/log/audit/audit.log` for log entries that look similar to the following:

```
type=AVC msg=audit(1363866652.030:24): avc:  denied  { write } for  pid=2119
    comm="mysqld" name="datadir" dev=dm-0 ino=394
    scontext=unconfined_u:system_r:mysqld_t:s0
    tcontext=unconfined_u:object_r:default_t:s0 tclass=dir
```

If you see any entries that look similar to this, then you most likely need to adjust the file contexts for some files or directories. See Setting File Contexts for more information on how to do that.

SELinux and MariaDB On a Different Port

TCP and UDP ports are enabled for permission to bind too. If you are using a different port, or some Galera ports, configure SELinux to be able to use those ports:

```
sudo semanage port -a -t mysqld_port_t -p tcp 3307
```

Generating SELinux Policies with audit2allow

In some cases, a MariaDB system might need non-standard policies. It is possible to create these policies from the SELinux audit log using the `audit2allow` utility. The `semanage` and `semodule` utilities will also be needed.

On many systems, the `audit2allow` and `semanage` utilities are installed by the `policycoreutils-python` package, and the `semodule` utility is installed by the `policycoreutils` package. You can install these with the following command:

```
sudo yum install policycoreutils policycoreutils-python
```

The following process can be used to generate a policy from the audit log:

- Remove dontaudits from the policy:

```
sudo semodule -DB
```

- Temporarily put `mysqld_t` into permissive mode. For example:

```
sudo semanage permissive -a mysqld_t
```

- Start MariaDB.
- Do whatever was causing SELinux errors.
- Use the generated audit log to create a policy:

```
sudo grep mysqld /var/log/audit/audit.log | audit2allow -M mariadb_local
sudo semodule -i mariadb_local.pp
```

- Pull `mysqld_t` out of permissive mode. For example:

```
sudo semanage permissive -d mysqld_t
```

- Restore dontaudits for the policy:

```
sudo setmodule -B
```

The same procedure can be used if MariaDB starts but SELinux prevents it from functioning correctly. For example, SELinux may prevent PAM plugin from authenticating users. The solution is the same — enable auditing, switch to permissive, do, whatever SELinux didn't allow you to, create a policy from the audit log.

When you discover any needed SELinux permissions, please report the needed permissions to your operating system bug tracking so all users can benefit from your work (e.g. Red Hat Bugzilla https://bugzilla.redhat.com/).

2.2.2 User Account Management

Account Management SQL Commands
CREATE/DROP USER, GRANT, REVOKE, SET PASSWORD etc.

Data-in-Transit Encryption
Data can be encrypted in transit using the Transport Layer Security (TLS) protocol.

Roles
Roles bundle privileges together to ease account management.

Catalogs
Catalogs permit several unrelated users or customers to share a single MariaDB Server instance.

Account Locking
Account locking permits privileged administrators to lock/unlock user accounts.

Authentication from MariaDB 10.4
Authentication changes from MariaDB 10.4.

User Password Expiry
Password expiry permits administrators to expire user passwords.

There are 3 related questions.

1.1.1.1 Account Management SQL Commands

2.2.1.1.1 Data-in-Transit Encryption

2.2.2.3 Roles

Roles bundle privileges together to ease account management

Roles Overview
Bundling privileges together.

CREATE ROLE
Add new roles.

DROP ROLE
Drop a role.

CURRENT_ROLE
Current role name.

SET ROLE
Enable a role.

SET DEFAULT ROLE
Sets a default role for a specified (or current) user.

GRANT
Create accounts and set privileges or roles.

REVOKE
Remove privileges or roles.

mysql.roles_mapping Table
MariaDB roles information.

Information Schema APPLICABLE_ROLES Table

Roles available to be used.

Information Schema ENABLED_ROLES Table

Enabled roles for the current session.

SecuRich

Library of security-related stored procedures.

There are 2 related questions.

2.2.2.3.1 Roles Overview

Contents

Description

A role bundles a number of privileges together. It assists larger organizations where, typically, a number of users would have the same privileges, and, previously, the only way to change the privileges for a group of users was by changing each user's privileges individually.

Alternatively, multiple external users could have been assigned the same user, and there would have been no way to see which actual user was responsible for which action.

With roles, managing this is easy. For example, there could be a number of users assigned to a journalist role, with identical privileges. Changing the privileges for all the journalists is a matter of simply changing the role's privileges, while the individual user is still linked with any changes that take place.

Roles are created with the CREATE ROLE statement, and dropped with the DROP ROLE statement. Roles are then assigned to a user with an extension to the GRANT statement, while privileges are assigned to a role in the regular way with GRANT. Similarly, the REVOKE statement can be used to both revoke a role from a user, or revoke a privilege from a role.

Once a user has connected, he can obtain all privileges associated with a role by **setting** a role with the SET ROLE statement. The CURRENT_ROLE function returns the currently set role for the session, if any.

Only roles granted directly to a user can be set, roles granted to other roles cannot. Instead the privileges granted to a role, which is, in turn, granted to another role (grantee), will be immediately available to any user who sets this second grantee role.

The SET DEFAULT ROLE statement allows one to set a default role for a user. A default role is automatically enabled when a user connects (an implicit SET ROLE statement is executed immediately after a connection is established).

Roles were implemented as a GSoC 2013 project by Vicentiu Ciorbaru.

System Tables

Information about roles and who they've been granted to can be found in the Information Schema APPLICABLE_ROLES table as well as the mysql.ROLES_MAPPING table.

The Information Schema ENABLED_ROLES table shows the enabled roles for the current session.

Examples

Creating a role and granting a privilege:

```
CREATE ROLE journalist;

GRANT SHOW DATABASES ON *.* TO journalist;

GRANT journalist to hulda;
```

Note, that hulda has no `SHOW DATABASES` privilege, even though she was granted the journalist role. She needs to **set** the role first:

```
SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| information_schema |
+--------------------+

SELECT CURRENT_ROLE;
+--------------+
| CURRENT_ROLE |
+--------------+
| NULL         |
+--------------+

SET ROLE journalist;

SELECT CURRENT_ROLE;
+--------------+
| CURRENT_ROLE |
+--------------+
| journalist   |
+--------------+

SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| ...                |
| information_schema |
| mysql              |
| performance_schema |
| test               |
| ...                |
+--------------------+

SET ROLE NONE;
```

Roles can be granted to roles:

```
CREATE ROLE writer;

GRANT SELECT ON data.* TO writer;

GRANT writer TO journalist;
```

But one does not need to set a role granted to a role. For example, hulda will automatically get all writer privileges when she sets the journalist role:

```
SELECT CURRENT_ROLE;
+--------------+
| CURRENT_ROLE |
+--------------+
| NULL         |
+--------------+

SHOW TABLES FROM data;
Empty set (0.01 sec)

SET ROLE journalist;

SELECT CURRENT_ROLE;
+--------------+
| CURRENT_ROLE |
+--------------+
| journalist   |
+--------------+

SHOW TABLES FROM data;
+-----------------------------+
| Tables_in_data              |
+-----------------------------+
| set1                        |
| ...                         |
+-----------------------------+
```

Roles and Views (and Stored Routines)

When a user sets a role, he, in a sense, has two identities with two associated sets of privileges. But a view (or a stored routine) can have only one definer. So, when a view (or a stored routine) is created with the `SQL SECURITY DEFINER`, one can specify whether the definer should be `CURRENT_USER` (and the view will have none of the privileges of the user's role) or `CURRENT_ROLE` (in this case, the view will use role's privileges, but none of the user's privileges). As a result, sometimes one can create a view that is impossible to use.

```
CREATE ROLE r1;

GRANT ALL ON db1.* TO r1;

GRANT r1 TO foo@localhost;

GRANT ALL ON db.* TO foo@localhost;

SELECT CURRENT_USER
+---------------+
| current_user  |
+---------------+
| foo@localhost |
+---------------+

SET ROLE r1;

CREATE TABLE db1.t1 (i int);

CREATE VIEW db.v1 AS SELECT * FROM db1.t1;

SHOW CREATE VIEW db.v1;
+------+-----------------------------------------------------------------------------------------------------------------+----------------------+----------------------+
| View | Create View                                                                                                     | character_set_client | collation_connection |
+------+-----------------------------------------------------------------------------------------------------------------+----------------------+----------------------+
| v1   | CREATE ALGORITHM=UNDEFINED DEFINER=`foo`@`localhost` SQL SECURITY DEFINER VIEW `db`.`v1` AS SELECT `db1`.`t1`.`i` AS `i` from `db1`.`t1` | utf8                 | utf8_general_ci      |
+------+-----------------------------------------------------------------------------------------------------------------+----------------------+----------------------+

CREATE DEFINER=CURRENT_ROLE VIEW db.v2 AS SELECT * FROM db1.t1;

SHOW CREATE VIEW db.b2;
+------+-----------------------------------------------------------------------------------------------------------------+----------------------+----------------------+
| View | Create View                                                                                                     | character_set_client | collation_connection |
+------+-----------------------------------------------------------------------------------------------------------------+----------------------+----------------------+
| v2   | CREATE ALGORITHM=UNDEFINED DEFINER=`r1` SQL SECURITY DEFINER VIEW `db`.`v2` AS select `db1`.`t1`.`a` AS `a` from `db1`.`t1` | utf8                 | utf8_general_ci      |
+------+-----------------------------------------------------------------------------------------------------------------+----------------------+----------------------+
```

2.2.2.4 Catalogs

Catalogs are an upcoming feature intended primarily for Cloud Service Providers with many customers, each having many MariaDB Server users and databases.

Catalogs will permit several unrelated users or customers to share a single MariaDB Server instance.

Catalogs Overview

Catalogs offer multi-tenancy.

Starting with Catalogs

Installing MariaDB with catalogs and adding new catalogs.

Catalog Status Variables

With catalogs enabled, status information is collected for the whole server...

DROP CATALOG

Deletes a catalog.

USE CATALOG

Changes to another catalog.

2.2.2.4.1 Catalogs Overview

Contents

Catalogs are an upcoming feature that will be included in a future release of MariaDB. The MariaDB catalogs will be a multi-tenancy feature where a single instance MariaDB server handles multiple independent tenants (customers), who have their own users, schemas etc. See MDEV-31542 "Add multi-tenancy catalogs to MariaDB" for details.

Background

For hosting providers, a common solution, to drive down cost, is to have one MariaDB server support several different customers by creating one named schema for each of them.

This has however a lot of limitations:

- The user cannot have exactly the same schema(s) on the cloud as they have on premise.
- The user cannot use multiple schemas.
- The user cannot take a backup of all their data (not even with mariadb-dump). This is because the 'mysql' schema, which includes users, stored procedures etc. cannot be copied as its data is shared among all server users.
- The user cannot access the general or error log.

The suggested solution to solve all of the above and thus create a better multi-tenant database is to add support for catalogs to MariaDB.

By each user having their own catalog, they will get very close to the same user experience as if they would have the MariaDB server for themselves.

Catalogs make it possible for hosting providers to have 10-100x more 'not that active' database users on a server compared to having a container or MariaDB server per customer (which limits a 192G server to about 100 customers with a 1G InnoDB buffer each).

User Experience With Catalogs

- Each user is assigned one catalog. The user can specify their catalog in their my.cnf file or as an argument to clients or when connecting to MariaDB server.
- Users can mariadb-dump of all their tables (including the 'mysql' database) and apply it on their own on premise MariaDB or to another 'MariaDB catalog' to duplicate their setup.
- Each catalog has its own privilege system. This allows a MariaDB admin to create users independently in their catalog to users in any other catalog. This also implies that the catalog has to be part of the connect information as otherwise the server does not know which user table to use.
- If the user is using applications that don't yet support catalogs, they can specify the catalog as part of the database when connecting to the server ('catalog.database') or by connecting to a specific port that is associated with a catalog.
- After logging in, a normal user can only see the objects (databases, tables, users etc) from their database. They cannot access other catalogs or change catalogs.
- A normal user cannot change the active catalog with a command. They need to logout from the current catalog and login to another.

For the end user, the MariaDB server will act as a normal a standalone server, with the following differences:

- When connecting to the server, a normal user must specify the catalog. If the connector software does not support catalogs, then the catalog should be specified in the database string. If the catalog is not specified, the 'def' catalog is assumed.
- LOAD DATA INFILE and SELECT … INTO OUTFILE can be configured to only be used with the catalog directory or a directory in it.
- SHUTDOWN command is only for the 'catalog root users'
- Replication (MASTER and SLAVE commands) are only for 'catalog root users'
- Errors from background task (like write error) will be logged into the system error log, not the catalog error log.
- SHOW STATUS will show status data for the whole server, not only for the active catalog.
- The server will handle legacy applications by extending the default database in the connection to contain the catalog in the form "catalog/database". See Appendix for details.
- Tables that are only read from the 'def.mysql' schema:
  - plugin
  - help_* tables
  - time_zone* tables
  - gtid_slave_pos (replication state)
  - innodb_index_stats (innodb internal)
  - servers (federated)
  - transaction_registry (innodb internal)
  - func (udf)
  - performance_schema

New 'catalog root user'

- The 'def' catalog is reserved to store permissions for 'catalog root users', which can access any catalog. * These are meant for admin users that need to do tasks like shutdown, upgrade, create/drop catalogs, managing primaries and replicas etc.
- Only the 'catalog root user' can change to another catalog with 'set catalog catalog_name'.
- A normal user can do 'set catalog current-catalog'. This will be needed to be able to execute a mariadb-dump that includes this command.

New Storage Layout

MariaDB server will be able to run either on 'original mode', where the data layout is exactly as it was before, or on 'catalog' mode, with a new data layout:

When running mariadb-install-db with --use-catalogs, it will create the following new data structure:

- data_directory/
  - engine system data files
  - system files
  - replication files
  - general.log
  - error.log
  - mariadb/
    - mysql/
    - privilege tables
  - catalog1
  - general.log
  - error.log
  - mysql/
    - privilege tables
  - database1/
    - tables for database1
  - database2/
    - tables for database2
  - catalog2/
    - general.log
    - error.log
  - mysql/
    - privilege tables
  - database1/
    - tables for database1
  - database2/
    - tables for database2

The disk structure when not using catalogs is:

- data_directory/
  - engine system data files
  - system files
  - replication files
  - general.log
  - error.log
  - mysql/
    - privilege tables
  - database1/
    - tables for database1
  - database2/
    - tables for database2

The above shows:

- There is a 'mariadb' catalog that stores admin users that can access all catalogs, shutdown servers, create new catalogs etc. The 'system root' user uses this when connecting.
- Each catalog has their own users, privilege tables, databases, error log and general logs

The MariaDB server will automatically start in catalog mode if it notices the new directory structure.

Catalog SQL Commands/Functions

- USE CATALOG catalog_name;
- CREATE CATALOG
- DROP CATALOG
- ALTER CATALOG
- SHOW CATALOGS (and also information_schema.catalogs)
- SHOW CREATE CATALOG catalog_name;
- SELECT CATALOG();

Changes Needed in MariaDB Codebase

Client changes:

- Add --catalog option to all standard MariaDB clients
- Add support for looping over all existing catalogs to:
  - mariadb-dump
  - mariadb-backup
  - mariadb-upgrade

Changes to mariadb-install-db:

- Allow one to create multiple catalogs at once: -–catalogs=”catalog1,catalog2”
- Init MariaDB with catalog support: —use-catalogs

Changes to mariadb (mysql client):

- Add support for 'USE CATALOG xxx'' (and later 'use database xxx').

Changes to mysql-test-run:

- Add support of running tests with catalogs (normal tests are run without catalogs)

Changes to MariaDB server (See MDEV-31542):

- Add support for 'catalog' in the connection string. For old clients, the user can specify the catalog as part of the database. If catalog is not specified, the 'def' catalog (like now) is assumed.
- Add CATALOG() function that returns the current catalog.
- Add ‘USE CATALOG xxx’
- Add 'USE DATABASE xxx'
- Create a global CATALOG object to hold all information related to the catalog.
- Add the current catalog to the 'thd' object.
- Add catalog argument to all functions that take 'database' as an argument.
- Add SHOW CATALOGS and information_schema.catalogs
- Move all relevant global variables (users, privileges, mdl-locks(?), open log files) to be stored in the CATALOG structure.
- Add 'catalog privilege', for ‘catalog super users’ to allow them to access data in any catalog.
- Add support for accessing tables with 'catalog.schema.table' (needed for catalog super users).
- For normal users, only show processes for the current catalog in 'show processlist'.
- Add loops over all catalogs for information schema for the 'catalog root user'.
- Update performance schema to take catalogs into account.
- Work with external connectors to get them to support connecting with a catalog.
- Check/update all storage engines to ensure they work also with catalogs.

Notes:

- The storage handler calls will probably not be changed. The storage engine will get the catalog name as part of the database name (catalog/database).
- We don't need a 'catalog' column for tables in the 'mysql' schema (like mysql.proc) as these are stored per catalog.

Some Implementation Ideas

- Instead of sending a catalog string to function, use a pointer to the global catalog object. Do the same later for databases. This allows use to precompute things like 'filename' for catalogs and databases and we don't have to do this for every table open. It also allows us to later support logging information at a catalog and database level.
- Don't take a MDL lock for the catalog for each table. The metadata lock for the catalog will be taken when a user logs in or changes catalog.
- Add system variables ‘current_catalog’ and ‘current_database’ and allow users to change these.
- Add support for ‘catalog ports’ that are connected to catalog. This allows users to connect to a specific catalog from any client software.

Limitations (in addition to limitations listed in “User experience with catalogs”)

- Database names cannot contain ‘.’ when connecting from clients without the new catalog connect option.
- One cannot refer to other catalogs in triggers, stored procedures, events etc. This is because a transaction cannot span catalogs.
- Only the catalog root user can use mariadb-backup. This is a normal restriction as one has to be system root to be able to use mariadb-backup.
- Events are global (to save resources). Catalog users can enable/disable events for their catalog.

Stage 2 (not in first release)

- Support usage statistics per catalog and whole server (the last for the ‘catalog root user’). This allows the DBA to see the number of queries, type of queries etc. Some ‘system’ and ‘global innodb’ statistics will only be shown globally (number of open files, number of sync calls etc).
- Support a my.cnf file in each catalog directory to handle catalog (customer) unique defaults.
- Add quotas per catalog for tables and temporary files.
- Add more support to limit users from overusing resources (cpu, tables, databases, number of connections etc)
- Support 'drop catalog'. (This is in Stage 2 as there may be some issues to drop already active CATALOG objects)
- Add optional catalog support to the S3 engine
- More things will be added later.

Stage 3

- Allow users to manage their own replication stream (maybe?).
- Allow users to have different options for the S3 engine
- More things will be added later.

Appendix

Legacy Connector Support

SQLALchemy test:

```
In [1]: from sqlalchemy.engine import make_url
In [2]: u = make_url('mariadb+mariadbconnector://app_user:Password123!@127.0.0.1:3306/catalog/com
In [3]: u.database
Out[3]: 'catalog/company'
```

The following tests ensured that inside the server (mysql_change_db), the “catalog/test” was picked up as the database.

PHP PDO test:

```
$ php -r '$db = new \PDO("mysql:host=localhost;user=dan;dbname=catalog/test;charset=utf8mb4;unix_
```

PHP mysqli test:

```
php -r '$dbcon = mysqli_connect("localhost","dan","nopass","catalog/test",3306,"/tmp/build-mariad
```

Nodejs test:

```
var mysql = require('mysql')
var con = mysql.createConnection({
  socketPath: "/tmp/build-mariadb-server-10.4.sock",
  user: "dan",
  password: "yourpassword",
  database: "catalog/test",
})
con.connect(function(err) {
  if (err) throw err;
  console.log("Connected!");
})
```

(need to map out a few other connectors here to make sure it’s supported well in this form).

Ref: https://mariadb.com/kb/en/connection/#handshake-response-packet

Migration of existing MariaDB original mode to the new catalog layout

As shared hosting services have a naming scheme from user/schema to database name in MariaDB, to provide a migration to the new catalog layout, the following steps will be required:

- Use mariadb-dump to dump the original data
- On the new server execute:
- mariadb-install-db –catalogs=’catalog_name’
- mariadb –catalog catalog_name < dump_file

This is needed as InnoDB needs to know where the new files are located.

Migration of one catalog user to another MariaDB server

Create a migration tool set / procedure that does the following

- Execute FLUSH TABLES FOR EXPORT for all tables in a catalog.
- Take a copy of the catalog directory
- Copy the data to a new catalog directory to the new server
- Run ALTER TABLE ... IMPORT TABLESPACE on each InnoDB table

Note that for partitioned tables the process will be a bit more complex, see above link.

This procedure will be a bit easier after an in-the-works patch for InnoDB related to IMPORT will be pushed. (Should happen before we start on the catalog project)

Other Things

- Drizzle's default catalog was called "local". MariaDB's default will be called 'def', as this is what we already have as the default catalog in information_schema, in current connectors and other places.
- CONNECT engine will need testing against catalogs and maybe a small code change to support them. It could also be a way to join from one catalog to another.

2.2.2.4.2 Starting with Catalogs

MariaDB starting with 11.3
Catalog support is planned for 11.3.

Contents

Background

mariadb-install-db initializes the MariaDB data directory and creates the system tables in the mysql database.

When used with the `--catalog` options it will initialize MariaDB server to use catalogs. The mariadbd server will automatically discover if catalogs are used or not.

Note that **one cannot change** a 'normal server' to a server with catalogs or a server with catalogs to a 'normal server'. In the future we will add tools that will allow one to easily move an existing server inside a catalog or move an server inside a catalog to a standalone server.

Initializing a New Server with Catalog Support

To initialize a server with 4 catalogs (the `def` catalog, that holds the catalog root user (CRU) is automatically created):

```
mariadb_install_db --catalogs="cat1 cat2 cat3" --datadir=/my/data/
```

The above will create a directory `/my/data` and the 4 directories under it, one for each catalog.

Adding More Catalogs to a Running Server

When adding more catalogs to an existing server, `mariadb_install_db` will start the mariadb client to execute the needed commands on the running server. This is why one has to supply user and password to `mariadb_install_db`.

```
mariadb_install_db --catalogs="cat4 cat5 cat6" --datadir=/my/data --catalog-user=monty --catalog-
```

2.2.2.4.3 Catalog Status Variables

When using a MariaDB Server with catalogs support, all status information is collected for the whole server, per catalog and per user.

```
SHOW SERVER STATUS;
```

shows the status for the whole server. Note that only the super user in the 'def' catalog has privileges for the above statement.

```
SHOW GLOBAL STATUS;
SHOW CATALOG STATUS;
```

Both commands show the status for the current catalog. The reason that `GLOBAL` shows catalog status is that because catalogs are 'multi-tenant', a catalog user should not be able to see the status from other users (for most things).

```
SHOW [SESSION] STATUS;
```

Shows the status for the current connection.

The main "new thing" is that catalogs enable SAS providers to see the status for a single tenant (catalog user). This makes it much easier to find 'bad neighbors' (tenants that cause problems for other tenants) so that they can be moved to other servers.

When the MariaDB server is not configured for catalogs, the following commands are equivalent:

```
SHOW GLOBAL STATUS
SHOW SERVER STATUS
SHOW CATALOG STATUS
```

2.2.2.4.4 DROP CATALOG

Syntax

```
DROP CATALOG catalog_name
```

Description

Deletes a catalog. Can only be performed by a super user in the 'def' catalog. If the current catalog is dropped, the user is moved to the 'def' catalog. 'def' catalog cannot be dropped.

Currently, there cannot be any databases in a catalog to be dropped. This will be fixed soon.

2.2.2.4.5 USE CATALOG

Syntax

```
USE CATALOG catalog_name
```

Description

Changes to another catalog. Can only be done by a super user in the 'def' catalog. Changing catalog will update catalog status and reset all session status.

A tenant (a user in any other catalog than 'def') cannot change to another catalog. However tenants can execute `USE CATALOG current_catalog`. This is to allow the user to import SQL scripts that use `USE CATALOG...`.

2.2.2.5 Account Locking

MariaDB starting with 10.4.2

Account locking was introduced in MariaDB 10.4.2.

Contents

Description

Account locking permits privileged administrators to lock/unlock user accounts. No new client connections will be permitted if an account is locked (existing connections are not affected).

User accounts can be locked at creation, with the CREATE USER statement, or modified after creation with the ALTER USER statement. For example:

```
CREATE USER 'lorin'@'localhost' ACCOUNT LOCK;
```

or

```
ALTER USER 'marijn'@'localhost' ACCOUNT LOCK;
```

The server will return an ER_ACCOUNT_HAS_BEEN_LOCKED error when locked users attempt to connect:

```
mysql -ulorin
  ERROR 4151 (HY000): Access denied, this account is locked
```

The ALTER USER statement is also used to unlock a user:

```
ALTER USER 'lorin'@'localhost' ACCOUNT UNLOCK;
```

The SHOW CREATE USER statement will show whether the account is locked:

```
SHOW CREATE USER 'marijn'@'localhost';
+-----------------------------------------------+
| CREATE USER for marijn@localhost              |
+-----------------------------------------------+
| CREATE USER 'marijn'@'localhost' ACCOUNT LOCK |
+-----------------------------------------------+
```

as well as querying the mysql.global_priv table:

```
SELECT CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv)) FROM mysql.global_priv
  WHERE user='marijn';
+-----------------------------------------------------------------------------------------+
| CONCAT(user, '@', host, ' => ', JSON_DETAILED(priv))                                    |
+-----------------------------------------------------------------------------------------+
| marijn@localhost => {
    "access": 0,
    "plugin": "mysql_native_password",
    "authentication_string": "",
    "account_locked": true,
    "password_last_changed": 1558017158
} |
+-----------------------------------------------------------------------------------------+
```

2.2.2.6 Authentication from MariaDB 10.4

MariaDB starting with 10.4

MariaDB 10.4 introduced a number of changes to the authentication process, intended to make things easier and more intuitive.

Contents

Overview

There are four **new main features in 10.4** relating to authentication:

- It is possible to use more than one authentication plugin for each user account. For example, this can be useful to slowly migrate users to the more secure ed25519 authentication plugin over time, while allowing the old mysql_native_password authentication plugin as an alternative for the transitional period.
- The `root@localhost` user account created by mariadb-install-db is created with the ability to use two authentication plugins.
    - First, it is configured to try to use the unix_socket authentication plugin. This allows the `root@localhost` user to login without a password via the local Unix socket file defined by the socket system variable, as long as the login is attempted from a process owned by the operating system `root` user account.
    - Second, if authentication fails with the unix_socket authentication plugin, then it is configured to try to use the mysql_native_password authentication plugin. However, an invalid password is initially set, so in order to authenticate this way, a password must be set with SET PASSWORD.
    - However, just using the unix_socket authentication plugin may be fine for many users, and it is very secure. You may want to try going without password authentication to see how well it works for you. Remember, the best way to keep your password safe is not to have one!
- All user accounts, passwords, and global privileges are now stored in the mysql.global_priv table. The mysql.user table still exists and has exactly the same set of columns as before, but it's now a view that references the mysql.global_priv table. Tools that analyze the mysql.user table should continue to work as before. From MariaDB 10.4.13, the dedicated `mariadb.sys` user is created as the definer of this view. Previously `root` was the definer, which resulted in privilege problems when this username was changed.
- MariaDB 10.4 adds supports for User Password Expiry, which is not active by default.

Description

As a result of the above changes, the open-for-everyone all-powerful root account is finally gone. And installation scripts will no longer demand that you "PLEASE REMEMBER TO SET A PASSWORD FOR THE MariaDB root USER !", because the root account is securely created automatically.

Two all-powerful accounts are created by default — root and the OS user that owns the data directory, typically mysql. They are created as:

```
CREATE USER root@localhost IDENTIFIED VIA unix_socket OR mysql_native_password USING 'invalid'
CREATE USER mysql@localhost IDENTIFIED VIA unix_socket OR mysql_native_password USING 'invalid'
```

Using unix_socket means that if you are the system root user, you can login as root@locahost without a password. This technique was pioneered by Otto Kekäläinen in Debian MariaDB packages and has been successfully used in Debian since as early as MariaDB 10.0.

It is based on a simple fact that asking the system root for a password adds no extra security — root has full access to all the data files and all process memory anyway. But not asking for a password means, there is no root password to forget (no need for the numerous tutorials on "how to reset MariaDB root password"). And if you want to script some tedious database work, there is no need to store the root password in plain text for the script to use (no need for debian-sys-maint user).

Still, some users may wish to log in as MariaDB root without using sudo. Hence the old authentication method — conventional MariaDB password — is still available. By default it is disabled ("invalid" is not a valid password hash), but one can set the password with a usual SET PASSWORD statement. And still retain the password-less access via sudo.

If you install MariaDB locally (say from a tarball), you would not want to use sudo to be able to login. This is why MariaDB creates a second all-powerful user with the same name as a system user that owns the data directory. In local (not system-wide) installations, this will be the user who installed MariaDB — they automatically get convenient password-less root-like access, because they can access all the data files anyway.

Even if MariaDB is installed system-wide, you may not want to run your database maintenance scripts as system root — now you can run them as system mysql user. And you will know that they will never destroy your entire system, even if you make a typo in a shell script.

However, seasoned MariaDB DBAs who are used to the old ways do need to make some changes. See the examples below for common tasks.

Cookbook

After installing MariaDB system-wide the first thing you've got used to doing is logging in into the unprotected root account and protecting it, that is, setting the root password:

```
$ sudo dnf install MariaDB-server
$ mysql -uroot
...
MariaDB> set password = password("XH4VmT3_jt");
```

This is not only unnecessary now, it will simply not work — there is no unprotected root account. To login as root use

```
$ sudo dnf install MariaDB-server
$ sudo mysql
```

Note that it implies you are connecting via the unix socket, not tcp. If you happen to have `protocol=tcp` in a system-wide `/etc/my.cnf` file, use `sudo mysql --protocol=socket`.

After installing MariaDB locally you've also used to connect to the unprotected root account using `mysql -uroot`. This will not work either, simply use `mysql` without specifying a username.

If you've forgotten your root password, no problem — you can still connect using sudo and change the password. And if you've also removed unix_socket authentication, to restore access do as follows:

- restart MariaDB with --skip-grant-tables
- login into the unprotected server
- run FLUSH PRIVILEGES (note, before 10.4 this would've been the last step, not anymore). This disables `--skip-grant-tables` and allows you to change the stored authentication method
- run SET PASSWORD FOR root@localhost to change the root password.

To view inside privilege tables, the old mysql.user table still exists. You can select from it as before, although you cannot update it anymore. It doesn't show alternative authentication plugins and this was one of the reasons for switching to the mysql.global_priv table — complex authentication rules did not fit into rigid structure of a relational table. You can select from the new table, for example:

```
select concat(user, '@', host, ' => ', json_detailed(priv)) from mysql.global_priv;
```

Reverting to the Previous Authentication Method for root@localhost

If you don't want the `root@localhost` user account created by mariadb-install-db to use unix_socket authentication by default, then there are a few ways to revert to the previous mysql_native_password authentication method for this user account.

Configuring mariadb-install-db to Revert to the Previous Authentication Method

One way to revert to the previous mysql_native_password authentication method for the `root@localhost` user account is to execute mariadb-install-db with a special option. If mariadb-install-db is executed while `--auth-root-authentication-method=normal` is specified, then it will create the default user accounts using the default behavior of MariaDB 10.3 and before.

This means that the `root@localhost` user account will use mysql_native_password authentication by default. There are some other differences as well. See mariadb-install-db: User Accounts Created by Default for more information.

For example, the option can be set on the command-line while running mariadb-install-db:

```
mariadb-install-db --user=mysql --datadir=/var/lib/mysql --auth-root-authentication-method=normal
```

The option can also be set in an option file in an option group supported by mariadb-install-db. For example:

```
[mysql_install_db]
auth_root_authentication_method=normal
```

If the option is set in an option file and if mariadb-install-db is executed, then mariadb-install-db will read this option from the option file, and it will automatically set this option.

Altering the User Account to Revert to the Previous Authentication Method

If you have already installed MariaDB, and if the `root@localhost` user account is already using unix_socket authentication, then you can revert to the old mysql_native_password authentication method for the user account by executing the following:

```
ALTER USER root@localhost IDENTIFIED VIA mysql_native_password USING PASSWORD("verysecret")
```

2.2.2.7 User Password Expiry

MariaDB starting with 10.4.3

User password expiry was introduced in MariaDB 10.4.3.

Contents

Password expiry permits administrators to expire user passwords, either manually or automatically.

System Variables

There are two system variables which affect password expiry: default_password_lifetime, which determines the amount of time between requiring the user to change their password. `0`, the default, means automatic password expiry is not active.

The second variable, disconnect_on_expired_password determines whether a client is permitted to connect if their password has expired, or whether they are permitted to connect in sandbox mode, able to perform a limited subset of queries related to resetting the password, in particular SET PASSWORD and SET.

Setting a Password Expiry Limit for a User

Besides automatic password expiry, as determined by default_password_lifetime, password expiry times can be set on an individual user basis, overriding the global using the CREATE USER or ALTER USER statements, for example:

```
CREATE USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY;
```

```
ALTER USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY;
```

Limits can be disabled by use of the `NEVER` keyword, for example:

```
CREATE USER 'monty'@'localhost' PASSWORD EXPIRE NEVER;
```

```
ALTER USER 'monty'@'localhost' PASSWORD EXPIRE NEVER;
```

A manually set limit can be restored the system default by use of `DEFAULT`, for example:

```
CREATE USER 'monty'@'localhost' PASSWORD EXPIRE DEFAULT;
```

```
ALTER USER 'monty'@'localhost' PASSWORD EXPIRE DEFAULT;
```

SHOW CREATE USER

The SHOW CREATE USER statement will display information about the password expiry status of the user. Unlike MySQL, it will not display if the user is unlocked, or if the password expiry is set to default.

```
CREATE USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY;
CREATE USER 'konstantin'@'localhost' PASSWORD EXPIRE NEVER;
CREATE USER 'amse'@'localhost' PASSWORD EXPIRE DEFAULT;

SHOW CREATE USER 'monty'@'localhost';
+-------------------------------------------------------------------+
| CREATE USER for monty@localhost                                   |
+-------------------------------------------------------------------+
| CREATE USER 'monty'@'localhost' PASSWORD EXPIRE INTERVAL 120 DAY |
+-------------------------------------------------------------------+

SHOW CREATE USER 'konstantin'@'localhost';
+-----------------------------------------------------------+
| CREATE USER for konstantin@localhost                      |
+-----------------------------------------------------------+
| CREATE USER 'konstantin'@'localhost' PASSWORD EXPIRE NEVER |
+-----------------------------------------------------------+

SHOW CREATE USER 'amse'@'localhost';
+--------------------------------+
| CREATE USER for amse@localhost |
+--------------------------------+
| CREATE USER 'amse'@'localhost' |
+--------------------------------+
```

Checking When Passwords Expire

The following query can be used to check when the current passwords expire for all users:

```
WITH password_expiration_info AS (
  SELECT User, Host,
  IF(
   IFNULL(JSON_EXTRACT(Priv, '$.password_lifetime'), -1) = -1,
   @@global.default_password_lifetime,
   JSON_EXTRACT(Priv, '$.password_lifetime')
  ) AS password_lifetime,
  JSON_EXTRACT(Priv, '$.password_last_changed') AS password_last_changed
  FROM mysql.global_priv
)
SELECT pei.User, pei.Host,
  pei.password_lifetime,
  FROM_UNIXTIME(pei.password_last_changed) AS password_last_changed_datetime,
  FROM_UNIXTIME(
   pei.password_last_changed +
   (pei.password_lifetime * 60 * 60 * 24)
  ) AS password_expiration_datetime
  FROM password_expiration_info pei
  WHERE pei.password_lifetime != 0
   AND pei.password_last_changed IS NOT NULL
UNION
SELECT pei.User, pei.Host,
  pei.password_lifetime,
  FROM_UNIXTIME(pei.password_last_changed) AS password_last_changed_datetime,
  0 AS password_expiration_datetime
  FROM password_expiration_info pei
  WHERE pei.password_lifetime = 0
   OR pei.password_last_changed IS NULL;
```

--connect-expired-password Client Option

The mariadb client `--connect-expired-password` option notifies the server that the client is prepared to handle expired password sandbox mode (even if the `--batch` option was specified).

2.3 Backing Up and Restoring Databases

There are a number of ways to backup a MariaDB server.

Backup and Restore Overview
Backing up and restoring MariaDB.

Replication as a Backup Solution
Replication can be used to support the backup strategy.

mariadb-dump
Dump a database or a collection of databases in a portable format.

Mariabackup
Physical backups, supports Data-at-Rest and InnoDB compression.

Backup and Restore via dbForge Studio
The fastest and easiest way to perform these operations with MariaDB databases.

mariadb-hotcopy
Fast backup program on local machine. Deprecated.

There are 13 related questions.

2.3.1 Backup and Restore Overview

Contents

This article briefly discusses the main ways to backup MariaDB. For detailed descriptions and syntax, see the individual pages. More detail is in the process of being added.

Logical vs Physical Backups

Logical backups consist of the SQL statements necessary to restore the data, such as CREATE DATABASE, CREATE TABLE and INSERT.

Physical backups are performed by copying the individual data files or directories.

The main differences are as follows:

- logical backups are more flexible, as the data can be restored on other hardware configurations, MariaDB versions or even on another DBMS, while physical backups cannot be imported on significantly different hardware, a different DBMS, or potentially even a different MariaDB version.
- logical backups can be performed at the level of database and table, while physical databases are the level of directories and files. In the MyISAM and InnoDB storage engines, each table has an equivalent set of files. (In versions prior to MariaDB 5.5, by default a number of InnoDB tables are stored in the same file, in which case it is not possible to backup by table. See innodb_file_per_table.)
- logical backups are larger in size than the equivalent physical backup.
- logical backups takes more time to both backup and restore than the equivalent physical backup.
- log files and configuration files are not part of a logical backup

Backup Tools

Mariadb-backup

Mariadb-backup is a fork of Percona XtraBackup with added support for MariaDB 10.1 compression and data-at-rest encryption. It is included with MariaDB 10.1.23 and later.

mariadb-dump

mariadb-dump (previously mysqldump) performs a logical backup. It is the most flexible way to perform a backup and restore, and a good choice when the data size is relatively small.

For large datasets, the backup file can be large, and the restore time lengthy.

mariadb-dump dumps the data into SQL format (it can also dump into other formats, such as CSV or XML) which can then easily be imported into another database. The data can be imported into other versions of MariaDB, MySQL, or even another DBMS entirely, assuming there are no version or DBMS-specific statements in the dump.

mariadb-dump dumps triggers along with tables, as these are part of the table definition. However, stored procedures, views, and events are not, and need extra parameters to be recreated explicitly (for example, `--routines` and `--events`). Procedures and functions are however also part of the system tables (for example mysql.proc).

InnoDB Logical Backups

InnoDB uses the buffer pool, which stores data and indexes from its tables in memory. This buffer is very important for performance. If InnoDB data doesn't fit the memory, it is important that the buffer contains the most frequently accessed data. However, last accessed data is candidate for insertion into the buffer pool. If not properly configured, when a table scan happens, InnoDB may copy the whole contents of a table into the buffer pool. The problem with logical backups is that they always imply full table scans.

An easy way to avoid this is by increasing the value of the innodb_old_blocks_time system variable. It represents the number of milliseconds that must pass before a recently accessed page can be put into the "new" sublist in the buffer pool. Data which is accessed only once should remain in the "old" sublist. This means that they will soon be evicted from the buffer pool. Since during the backup process the "old" sublist is likely to store data that is not useful, one could also consider resizing it by changing the value of the innodb_old_blocks_pct system variable.

It is also possible to explicitly dump the buffer pool on disk before starting a logical backup, and restore it after the process. This will undo any negative change to the buffer pool which happens during the backup. To dump the buffer pool, the innodb_buffer_pool_dump_now system variable can be set to ON. To restore it, the innodb_buffer_pool_load_now system variable can be set to ON.

Examples

Backing up a single database

```
shell> mariadb-dump db_name > backup-file.sql
```

Restoring or loading the database

```
shell> mariadb db_name < backup-file.sql
```

See the mariadb-dump page for detailed syntax and examples.

mariadb-hotcopy

> mariadb-hotcopy is deprecated.

mariadb-hotcopy performs a physical backup, and works only for backing up MyISAM and ARCHIVE tables. It can only be run on the same machine as the location of the database directories.

Examples

```
shell> mariadb-hotcopy db_name [/path/to/new_directory]
shell> mariadb-hotcopy db_name_1 ... db_name_n /path/to/new_directory
```

Percona XtraBackup

In MariaDB 10.1 and later, Mariabackup is the recommended backup method to use instead of Percona XtraBackup.

In MariaDB 10.3, Percona XtraBackup is **not supported**. See Percona XtraBackup Overview: Compatibility with MariaDB for more information.

In MariaDB 10.2 and MariaDB 10.1, Percona XtraBackup is only **partially supported**. See Percona XtraBackup Overview: Compatibility with MariaDB for more information.

Percona XtraBackup is a tool for performing fast, hot backups. It was designed specifically for XtraDB/InnoDB databases, but can be used with any storage engine (although not with MariaDB 10.1 encryption and compression). It is not included by default with MariaDB.

Filesystem Snapshots

Some filesystems, like Veritas, support snapshots. During the snapshot, the table must be locked. The proper steps to obtain a snapshot are:

- From the mariadb client, execute FLUSH TABLES WITH READ LOCK. The client must remain open.
- From a shell, execute `mount vxfs snapshot`
- The client can execute UNLOCK TABLES.
- Copy the snapshot files.
- From a shell, unmount the snapshot with `umount snapshot`.

LVM

Widely-used physical backup method, using a Perl script as a wrapper. See http://www.lenzg.net/mylvmbackup/.

Percona TokuBackup

For details, see:

- TokuDB Hot Backup – Part 1
- TokuDB Hot Backup – Part 2
- TokuDB Hot Backup Now a MySQL Plugin

dbForge Studio for MySQL

Besides the system utilities, it is possible to use third-party GUI tools to perform backup and restore operations. In this context, it is worth mentioning dbForge Studio for MySQL, a feature-rich database IDE that is fully compatible with MariaDB and delivers extensive backup functionality.

The backup and restore module of the Studio allows precise configuration and management of full and partial backups up to particular database objects. The feature of scheduling regular backups offers specific settings to handle errors and keep a log of them. Additionally, settings and configurations can be saved for later reuse.

These operations are wizard-aided allowing users to set up all tasks in a visual mode.

3.1.6 Replication as a Backup Solution

1.3.6.2 mysqldump

2.3.4 Mariabackup

Mariabackup is an open source tool provided by MariaDB for performing physical online backups of InnoDB, MyRocks, Aria and MyISAM tables.

Mariabackup Overview

The Mariabackup utility performs physical backups and supports Data-at-Rest...

Mariabackup Options
Options for Mariabackup.

Full Backup and Restore with Mariabackup
Taking complete backups of databases and restoring from a complete backup.

Incremental Backup and Restore with Mariabackup
Backing up incremental changes of a database

Partial Backup and Restore with Mariabackup
Taking partial backups of databases and restoring from a partial backup.

Restoring Individual Tables and Partitions with Mariabackup
Restoring individual tables and partitions from a backup.

Setting up a Replica with Mariabackup

2.3.4.1 Mariabackup Overview

Mariabackup is an open source tool provided by MariaDB for performing physical online backups of InnoDB, Aria and MyISAM tables. For InnoDB, “hot online” backups are possible. It was originally forked from Percona XtraBackup 2.3.8. It is available on Linux and Windows.

Contents

Backup Support for MariaDB-Exclusive Features

MariaDB 10.1 introduced features that are exclusive to MariaDB, such as InnoDB Page Compression and Data-at-Rest Encryption. These exclusive features have been very popular with MariaDB users. However, existing backup solutions from the MySQL ecosystem, such as Percona XtraBackup, did not support full backup capability for these features.

To address the needs of our users, we decided to develop a backup solution that would fully support these popular MariaDB-exclusive features. We did this by creating Mariabackup, which is based on the well-known and commonly used backup tool called Percona XtraBackup. Mariabackup was originally extended from version 2.3.8.

Supported Features

Mariabackup supports all of the main features of Percona XtraBackup 2.3.8, plus:

- Backup/Restore of tables using Data-at-Rest Encryption.
- Backup/Restore of tables using InnoDB Page Compression.
- mariabackup SST method with Galera Cluster.
- Microsoft Windows support.
- Backup/Restore of tables using the MyRocks storage engine starting with MariaDB 10.2.16 and MariaDB 10.3.8. See Files Backed up by Mariabackup: MyRocks Data Files for more information.

Supported Features in MariaDB Enterprise Backup

MariaDB Enterprise Backup supports some additional features, such as:

- Minimizes locks during the backup to permit more concurrency and to enable faster backups.
  - This relies on the usage of `BACKUP STAGE` commands and DDL logging.
  - This includes no locking during the copy phase of `ALTER TABLE` statements, which tends to be the longest phase of these statements.
- Provides optimal backup support for all storage engines that store things on local disk.

Differences Compared to Percona XtraBackup

- Percona XtraBackup copies its InnoDB redo log files to the file `xtrabackup_logfile`, while Mariabackup uses the

file `ib_logfile0`.

- Percona XtraBackup's libgcrypt-based encryption of backups is not supported by Mariabackup.
- There is no symbolic link from `mariabackup` to `innobackupex`, as there is for `xtrabackup`. Instead, `mariabackup` has the `--innobackupex` command-line option to enable innobackupex-compatible options.
- The `--compact` and `--rebuild_indexes` options are not supported.
- Support for `--stream=tar` was removed from Mariabackup in MariaDB 10.1.24.
- The `xbstream` utility has been renamed to `mbstream`. However, to select this output format when creating a backup, Mariabackup's `--stream` option still expects the `xbstream` value.
- Mariabackup does not support lockless binlog.

Difference in Versioning Schemes

Each Percona XtraBackup release has two version numbers--the Percona XtraBackup version number and the version number of the MySQL Server release that it is based on. For example:

```
xtrabackup version 2.2.8 based on MySQL server 5.6.22
```

Each Mariabackup release only has one version number, and it is the same as the version number of the MariaDB Server release that it is based on. For example:

```
mariabackup based on MariaDB server 10.2.15-MariaDB Linux (x86_64)
```

See Compatibility of Mariabackup Releases with MariaDB Server Releases for more information on Mariabackup versions.

Compatibility of Mariabackup Releases with MariaDB Server Releases

> It is not generally possible, or supported, to prepare a backup in a different MariaDB version than the database version at the time when backup was taken. For example, if you backup MariaDB 10.4, you should use mariabackup version 10.4, rather than e.g 10.5.

A MariaDB Server version can often be backed up with most other Mariabackup releases in the same release series. For example, MariaDB 10.2.21 and MariaDB 10.2.22 are both in the MariaDB 10.2 release series, so MariaDB Server from MariaDB 10.2.21 could be backed up by Mariabackup from MariaDB 10.2.22, or vice versa.

However, occasionally, a MariaDB Server or Mariabackup release will include bug fixes that will break compatibility with previous releases. For example, the fix for MDEV-13564 changed the InnoDB redo log format in MariaDB 10.2.19 which broke compatibility with previous releases. To be safest, a MariaDB Server release should generally be backed up with the Mariabackup release that has the same version number.

> Mariabackup from MariaDB 10.1 releases may also be able to back up MariaDB Server from MariaDB 5.5 and MariaDB 10.0 releases in many cases. However, this is not fully supported. See MDEV-14936 for more information.

Installing Mariabackup

Installing on Linux

The `mariabackup` executable is included in binary tarballs on Linux.

Installing with a Package Manager

Mariabackup can also be installed via a package manager on Linux. In order to do so, your system needs to be configured to install from one of the MariaDB repositories.

You can configure your package manager to install it from MariaDB Corporation's MariaDB Package Repository by using the MariaDB Package Repository setup script.

You can also configure your package manager to install it from MariaDB Foundation's MariaDB Repository by using the MariaDB Repository Configuration Tool.

Installing with yum/dnf

On RHEL, CentOS, Fedora, and other similar Linux distributions, it is highly recommended to install the relevant RPM package from MariaDB's repository using `yum` or `dnf`. Starting with RHEL 8 and Fedora 22, `yum` has been replaced by `dnf`, which is the next major version of `yum`. However, `yum` commands still work on many systems that use `dnf`. For example:

```
sudo yum install MariaDB-backup
```

Installing with apt-get

On Debian, Ubuntu, and other similar Linux distributions, it is highly recommended to install the relevant DEB package from MariaDB's repository using `apt-get`. For example:

```
sudo apt-get install mariadb-backup
```

Installing with zypper

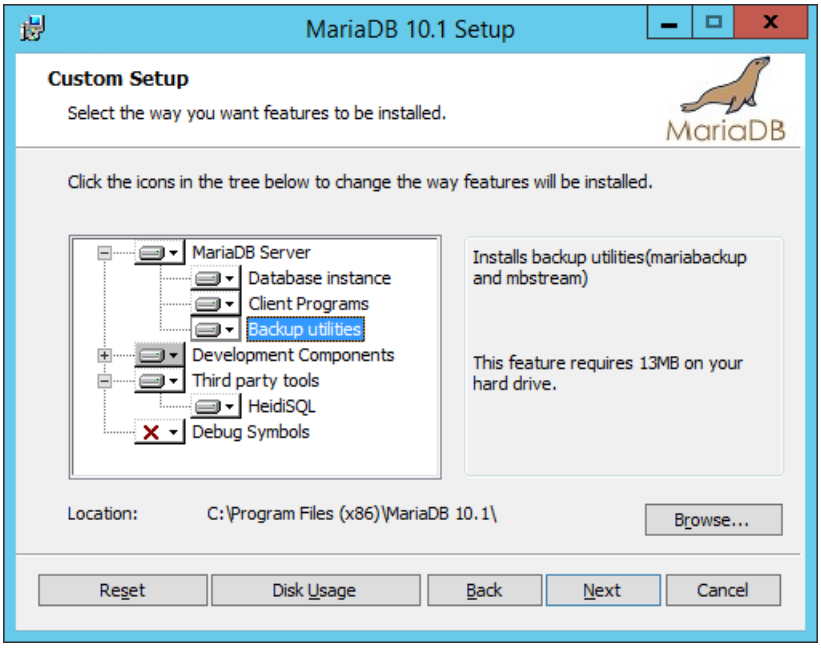
On SLES, OpenSUSE, and other similar Linux distributions, it is highly recommended to install the relevant RPM package from MariaDB's repository using `zypper`. For example:

```
sudo zypper install MariaDB-backup
```

Installing on Windows

The `mariabackup` executable is included in MSI and ZIP packages on Windows.

When using the Windows MSI installer, `mariabackup` can be installed by selecting *Backup utilities*:



Using Mariabackup

The command to use `mariabackup` and the general syntax is:

```
mariabackup <options>
```

For in-depth explanations on how to use Mariabackup, see:

- Full Backup and Restore with Mariabackup
- Incremental Backup and Restore with Mariabackup
- Partial Backup and Restore with Mariabackup
- Restoring Individual Tables and Partitions with Mariabackup
- Setting up a Replication Slave with Mariabackup
- Using Encryption and Compression Tools With Mariabackup

Options

Options supported by Mariabackup can be found here.

`mariabackup` will currently silently ignore unknown command-line options, so be extra careful about accidentally including typos in options or accidentally using options from later `mariabackup` versions. The reason for this is that `mariabackup` currently treats command-line options and options from option files equivalently. When it reads from these option files, it has to read a lot of options from the server option groups read by `mysqld`. However, `mariabackup` does not know about many of the options that it normally reads in these option groups. If `mariabackup` raised an error or warning when it encountered an unknown option, then this process would generate a large amount of log messages under normal use. Therefore, `mariabackup` is designed to silently ignore the unknown options instead. See MDEV-18215 about that.

Option Files

In addition to reading options from the command-line, Mariabackup can also read options from option files.

The following options relate to how MariaDB command-line tools handles option files. They must be given as the first argument on the command-line:

Option	Description
`--print-defaults`	Print the program argument list and exit.
`--no-defaults`	Don't read default options from any option file.
`--defaults-file=#`	Only read default options from the given option file.
`--defaults-extra-file=#`	Read this file after the global files are read.
`--defaults-group-suffix=#`	In addition to the default option groups, also read option groups with this suffix.

Server Option Groups

Mariabackup reads server options from the following option groups from option files:

Group	Description
`[mariabackup]`	Options read by Mariabackup. Available starting with MariaDB 10.1.31 and MariaDB 10.2.13.
`[mariadb-backup]`	Options read by Mariabackup. Available starting with MariaDB 10.4.14 and MariaDB 10.5.4.
`[xtrabackup]`	Options read by Mariabackup and Percona XtraBackup.
`[server]`	Options read by MariaDB Server. Available starting with MariaDB 10.1.38, MariaDB 10.2.22, and MariaDB 10.3.13.
`[mysqld]`	Options read by `mysqld`, which includes both MariaDB Server and MySQL Server.
`[mysqld-X.Y]`	Options read by a specific version of `mysqld`, which includes both MariaDB Server and MySQL Server. For example, `[mysqld-10.4]`. Available starting with MariaDB 10.1.38, MariaDB 10.2.22, and MariaDB 10.3.13.
`[mariadb]`	Options read by MariaDB Server. Available starting with MariaDB 10.1.38, MariaDB 10.2.22, and MariaDB 10.3.13.
`[mariadb-X.Y]`	Options read by a specific version of MariaDB Server. For example, `[mariadb-10.4]`. Available starting with MariaDB 10.1.38, MariaDB 10.2.22, and MariaDB 10.3.13.
`[mariadbd]`	Options read by MariaDB Server. Available starting with MariaDB 10.4.14 and MariaDB 10.5.4.
`[mariadbd-X.Y]`	Options read by a specific version of MariaDB Server. For example, `[mariadbd-10.4]`. Available starting with MariaDB 10.4.14 and MariaDB 10.5.4.
`[client-server]`	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients. Available starting with MariaDB 10.1.38, MariaDB 10.2.22, and MariaDB 10.3.13.
`[galera]`	Options read by MariaDB Server, but only if it is compiled with Galera Cluster support. In MariaDB 10.1 and later, all builds on Linux are compiled with Galera Cluster support. When using one of these builds, options from this option group are read even if the Galera Cluster functionality is not enabled. Available starting with MariaDB 10.1.38, MariaDB 10.2.22, and MariaDB 10.3.13 on systems compiled with Galera Cluster support.

Client Option Groups

Mariabackup reads client options from the following option groups from option files:

Group	Description
`[mariabackup]`	Options read by Mariabackup. Available starting with MariaDB 10.1.31 and MariaDB 10.2.13.
`[mariadb-backup]`	Options read by Mariabackup. Available starting with MariaDB 10.4.14 and MariaDB 10.5.4.
`[xtrabackup]`	Options read by Mariabackup and Percona XtraBackup.
`[client]`	Options read by all MariaDB and MySQL client programs, which includes both MariaDB and MySQL clients. For example, `mysqldump`.
`[client-server]`	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients. Available starting with MariaDB 10.1.38, MariaDB 10.2.22, and MariaDB 10.3.13.
`[client-mariadb]`	Options read by all MariaDB client programs. Available starting with MariaDB 10.1.38, MariaDB 10.2.22, and MariaDB 10.3.13.

Authentication and Privileges

Mariabackup needs to authenticate with the database server when it performs a backup operation (i.e. when the `--backup` option is specified). For most use cases, the user account that performs the backup needs to have the following global privileges on the database server.

In 10.5 and later the required privileges are:

```
CREATE USER 'mariabackup'@'localhost' IDENTIFIED BY 'mypassword';
GRANT RELOAD, PROCESS, LOCK TABLES, BINLOG MONITOR ON *.* TO 'mariabackup'@'localhost';
```

Prior to 10.5, the required privileges are:

```
CREATE USER 'mariabackup'@'localhost' IDENTIFIED BY 'mypassword';
GRANT RELOAD, PROCESS, LOCK TABLES, REPLICATION CLIENT ON *.* TO 'mariabackup'@'localhost';
```

If your database server is also using the MyRocks storage engine, then the user account that performs the backup will also need the `SUPER` global privilege. This is because Mariabackup creates a checkpoint of this data by setting the `rocksdb_create_checkpoint` system variable, which requires this privilege. See MDEV-20577 for more information.

To use the `--history` option, the backup user also needs to have the following privileges granted:

```
GRANT CREATE, INSERT ON mysql.* TO 'mariabackup'@'localhost';
```

Prior to MariaDB 10.11, the necessary permissions to use `--history` were:

```
GRANT CREATE, INSERT ON PERCONA_SCHEMA.* TO 'mariabackup'@'localhost';
```

If you're upgrading from an older version and you want to use the new default table without losing your backup history, you can move and rename the current table in this way:

```
RENAME TABLE PERCONA_SCHEMA.xtrabackup_history TO mysql.mariadb_backup_history;
```

The user account information can be specified with the `--user` and `--password` command-line options. For example:

```
$ mariabackup --backup \
   --target-dir=/var/mariadb/backup/ \
   --user=mariabackup --password=mypassword
```

The user account information can also be specified in a supported client option group in an option file. For example:

```
[mariabackup]
user=mariabackup
password=mypassword
```

Mariabackup does not need to authenticate with the database server when preparing or restoring a backup.

File System Permissions

Mariabackup has to read MariaDB's files from the file system. Therefore, when you run Mariabackup as a specific operating system user, you should ensure that user account has sufficient permissions to read those files.

If you are using Linux and if you installed MariaDB with a package manager, then MariaDB's files will probably be owned by the `mysql` user and the `mysql` group.

Using Mariabackup with Data-at-Rest Encryption

Mariabackup supports Data-at-Rest Encryption.

Mariabackup will query the server to determine which key management and encryption plugin is being used, and then it will load that plugin itself, which means that Mariabackup needs to be able to load the key management and encryption plugin's shared library.

Mariabackup will also query the server to determine which encryption keys it needs to use.

In other words, Mariabackup is able to figure out a lot of encryption-related information on its own, so normally one doesn't need to provide any extra options to backup or restore encrypted tables.

Mariabackup backs up encrypted and unencrypted tables as they are on the original server. If a table is encrypted, then the table will remain encrypted in the backup. Similarly, if a table is unencrypted, then the table will remain unencrypted in the backup.

The primary reason that Mariabackup needs to be able to encrypt and decrypt data is that it needs to apply InnoDB redo log records to make the data consistent when the backup is prepared. As a consequence, Mariabackup does not perform many encryption or decryption operations when the backup is initially taken. MariaDB performs more encryption and decryption operations when the backup is prepared. This means that some encryption-related problems (such as using the wrong encryption keys) may not become apparent until the backup is prepared.

Using Mariabackup for Galera SSTs

The `mariabackup` SST method uses the Mariabackup utility for performing SSTs. See mariabackup SST method for more information.

Files Backed up by Mariabackup

Mariabackup backs up many different files in order to perform its backup operation. See Files Backed up by Mariabackup for a list of these files.

Files Created by Mariabackup

Mariabackup creates several different types of files during the backup and prepare phases. See Files Created by Mariabackup for a list of these files.

Known Issues

Unsupported Server Option Groups

Prior to MariaDB 10.1.38, MariaDB 10.2.22, and MariaDB 10.3.13, Mariabackup doesn't read server options from all option groups supported by the server. In those versions, it only looks for server options in the following server option groups:

Group	Description
`[xtrabackup]`	Options read by Percona XtraBackup and Mariabackup.
`[mariabackup]`	Options read by Percona XtraBackup and Mariabackup. Available starting with MariaDB 10.1.31 and MariaDB 10.2.13.
`[mysqld]`	Options read by `mysqld`, which includes both MariaDB Server and MySQL Server.

Those versions do not read server options from the following option groups supported by the server:

Group	Description
`[server]`	Options read by MariaDB Server. Available starting with MariaDB 10.1.38, MariaDB 10.2.22, and MariaDB 10.3.13.
`[mysqld-X.Y]`	Options read by a specific version of `mysqld`, which includes both MariaDB Server and MySQL Server. For example, `[mysqld-5.5]` Available starting with MariaDB 10.1.38, MariaDB 10.2.22, and MariaDB 10.3.13.
`[mariadb]`	Options read by MariaDB Server. Available starting with MariaDB 10.1.38, MariaDB 10.2.22, and MariaDB 10.3.13.
`[mariadb-X.Y]`	Options read by a specific version of MariaDB Server. For example, `[mariadb-10.3]` Available starting with MariaDB 10.1.38, MariaDB 10.2.22, and MariaDB 10.3.13.
`[client-server]`	Options read by all MariaDB client programs and the MariaDB Server. This is useful for options like socket and port, which is common between the server and the clients. Available starting with MariaDB 10.1.38, MariaDB 10.2.22, and MariaDB 10.3.13.
`[galera]`	Options read by MariaDB Server, but only if it is compiled with Galera Cluster support. In MariaDB 10.1 and later, all builds on Linux are compiled with Galera Cluster support. When using one of these builds, options from this option group are read even if the Galera Cluster functionality is not enabled. Available starting with MariaDB 10.1.38, MariaDB 10.2.22, and MariaDB 10.3.13 on systems compiled with Galera Cluster support.

See MDEV-18347 for more information.

No Default Datadir

Prior to MariaDB 10.1.36, MariaDB 10.2.18, and MariaDB 10.3.10, if you were performing a `--copy-back` operation, and if you did not explicitly specify a value for the `datadir` option either on the command line or one of the supported server option groups in an option file, then Mariabackup would not default to the server's default `datadir`. Instead, Mariabackup would fail with an error. For example:

```
Error: datadir must be specified.
```

The solution is to explicitly specify a value for the `datadir` option either on the command line or in one of the supported server option groups in an option file. For example:

```
[mysqld]
datadir=/var/lib/mysql
```

In MariaDB 10.1.36, MariaDB 10.2.18, and MariaDB 10.3.10 and later, Mariabackup will default to the server's default `datadir` value.

See MDEV-12956 for more information.

Concurrent DDL and Backup Issues

Prior to MariaDB 10.2.19 and MariaDB 10.3.10, if concurrent DDL was executed while the backup was taken, then that could cause various kinds of problems to occur.

One example is that if DDL caused any tablespace IDs to change (such as `TRUNCATE TABLE` or `RENAME TABLE`), then that could cause the effected tables to be inconsistent in the backup. In this scenario, you might see errors about mismatched tablespace IDs when the backup is prepared.

For example, the errors might look like this:

```
2018-12-07 07:49:32 7f51b3184820  InnoDB: Error: table 'DB1/TAB_TEMP'
InnoDB: in InnoDB data dictionary has tablespace id 1355633,
InnoDB: but a tablespace with that id does not exist. There is
InnoDB: a tablespace of name DB1/TAB_TEMP and id 1354713, though. Have
InnoDB: you deleted or moved .ibd files?
InnoDB: Please refer to
InnoDB: http://dev.mysql.com/doc/refman/5.6/en/innodb-troubleshooting-datadict.html
InnoDB: for how to resolve the issue.
```

Or they might look like this:

```
2018-07-12 21:24:14 139666981324672 [Note] InnoDB: Ignoring data file 'db1/tab1.ibd' with space
ID 200485, since the redo log references db1/tab1.ibd with space ID 200484.
```

Some of the problems related to concurrent DDL are described below.

Problems solved by setting `--lock-ddl-per-table` (Mariabackup command-line option added in MariaDB 10.2.9):

- If a table is dropped during the backup, then it might still exists after the backup is prepared.
- If a table exists when the backup starts, but it is dropped before the backup copies it, then the tablespace file can't be copied, so the backup would fail.

Problems solved by setting `innodb_log_optimize_ddl=OFF` (MariaDB Server system variable added in MariaDB 10.2.17 and removed in 10.6.0):

- If the backup noticed concurrent DDL, then it might fail with "ALTER TABLE or OPTIMIZE TABLE was executed during backup".

Problems solved by `innodb_safe_truncate=ON` (MariaDB Server system variable in MariaDB 10.2.19 and removed in 10.3.0):

- If a table is created during the backup, then it might not exist in the backup after prepare.
- If a table is renamed during the backup after the tablespace file was copied, then the table may not exist after the backup is prepared.
- If a table is dropped and created under the same name during the backup after the tablespace file was copied, then the table will have the wrong tablespace ID when the backup is prepared.

Note that, with the removal of `innodb_log_optimize_ddl` and `innodb_safe_truncate`, the above problems were definitely solved.

Problems solved by other bug fixes:

- If `--lock-ddl-per-table` is used and if a table is concurrently being dropped or renamed, then Mariabackup can fail to acquire the MDL lock.

These problems are only fixed in MariaDB 10.2 and later, so it is not recommended to execute concurrent DDL when using Mariabackup with MariaDB 10.1.

See MDEV-13563, MDEV-13564, MDEV-16809, and MDEV-16791 for more information.

Manual Restore with Pre-existing InnoDB Redo Log files

Prior to MariaDB 10.2.10, Mariabackup users could run into issues if they restored a backup by manually copying the files from the backup into the `datadir` while the directory still contained pre-existing InnoDB redo log files. The backup itself did not contain InnoDB redo log files with the traditional `ib_logfileN` file names, so the pre-existing log files would remain in the `datadir`. If the server were started with these pre-existing log files, then it could perform crash recovery with them, which could cause the database to become inconsistent or corrupt.

In these MariaDB versions, this problem could be avoided by not restoring the backup by manually copying the files and instead restoring the backup by using Mariabackup and providing the `--copy-back` option, since Mariabackup deletes pre-existing InnoDB redo log files from the `datadir` during the restore process.

In MariaDB 10.2.10 and later, Mariabackup prevents this issue by creating an empty InnoDB redo log file called `ib_logfile0` as part of the `--prepare` stage. That way, if the backup is manually restored, any pre-existing InnoDB redo log files would get overwritten by the empty one.

See MDEV-13311 for more information.

Too Many Open Files

If Mariabackup uses more file descriptors than the system is configured to allow, then users can see errors like the following:

```
2019-02-12 09:48:38 7ffff7fdb820  InnoDB: Operating system error number 23 in a file operation.
InnoDB: Error number 23 means 'Too many open files in system'.
InnoDB: Some operating system error numbers are described at
InnoDB: http://dev.mysql.com/doc/refman/5.6/en/operating-system-error-codes.html
InnoDB: Error: could not open single-table tablespace file ./db1/tab1.ibd
InnoDB: We do not continue the crash recovery, because the table may become
InnoDB: corrupt if we cannot apply the log records in the InnoDB log to it.
InnoDB: To fix the problem and start mysqld:
InnoDB: 1) If there is a permission problem in the file and mysqld cannot
InnoDB: open the file, you should modify the permissions.
InnoDB: 2) If the table is not needed, or you can restore it from a backup,
InnoDB: then you can remove the .ibd file, and InnoDB will do a normal
InnoDB: crash recovery and ignore that table.
InnoDB: 3) If the file system or the disk is broken, and you cannot remove
InnoDB: the .ibd file, you can set innodb_force_recovery > 0 in my.cnf
InnoDB: and force InnoDB to continue crash recovery here.
```

Prior to MariaDB 10.1.39, MariaDB 10.2.24, and MariaDB 10.3.14, Mariabackup would actually ignore the error and continue the backup. In some of those cases, Mariabackup would even report a successful completion of the backup to the user. In later versions, Mariabackup will properly throw an error and abort when this error is encountered. See MDEV-19060 for more information.

When this error is encountered, one solution is to explicitly specify a value for the `open-files-limit` option either on the command line or in one of the supported server option groups in an option file. For example:

```
[mariabackup]
open_files_limit=65535
```

An alternative solution is to set the soft and hard limits for the user account that runs Mariabackup by adding new limits to `/etc/security/limits.conf`. For example, if Mariabackup is run by the `mysql` user, then you could add lines like the following:

```
mysql soft nofile 65535
mysql hard nofile 65535
```

After the system is rebooted, the above configuration should set new open file limits for the `mysql` user, and the user's `ulimit` output should look like the following:

```
$ ulimit -Sn
65535
$ ulimit -Hn
65535
```

Versions

Mariabackup/Server Version	Maturity
MariaDB 10.2.10+, MariaDB 10.1.26+	Stable
MariaDB 10.2.7+, MariaDB 10.1.25	Beta
MariaDB 10.1.23	Alpha

2.3.4.2 Mariabackup Options

There are a number of options available in `Mariabackup`.

List of Options

`--apply-log`

Prepares an existing backup to restore to the MariaDB Server. This is only valid in `innobackupex` mode, which can be enabled with the `--innobackupex` option.

Files that Mariabackup generates during `--backup` operations in the target directory are not ready for use on the Server. Before you can restore the data to MariaDB, you first need to prepare the backup.

In the case of full backups, the files are not point in time consistent, since they were taken at different times. If you try to restore the database without first preparing the data, InnoDB rejects the new data as corrupt. Running Mariabackup with the `--prepare` command readies the data so you can restore it to MariaDB Server. When working with incremental backups, you need to use the `--prepare` command and the `--incremental-dir` option to update the base backup with the deltas from an incremental backup.

```
$ mariabackup --innobackupex --apply-log
```

Once the backup is ready, you can use the `--copy-back` or the `--move-back` commands to restore the backup to the server.

--apply-log-only

If this option is used when preparing a backup, then only the redo log apply stage will be performed, and other stages of crash recovery will be ignored. This option is used with incremental backups.

This option is only supported in MariaDB 10.1. In MariaDB 10.2 and later, this option is not needed or supported.

--backup

Backs up your databases.

Using this command option, Mariabackup performs a backup operation on your database or databases. The backups are written to the target directory, as set by the `--target-dir` option.

```
$ mariabackup --backup
      --target-dir /path/to/backup \
      --user user_name --password user_passwd
```

Mariabackup can perform full and incremental backups. A full backup creates a snapshot of the database in the target directory. An incremental backup checks the database against a previously taken full backup, (defined by the `--incremental-basedir` option) and creates delta files for these changes.

In order to restore from a backup, you first need to run Mariabackup with the `--prepare` command option, to make a full backup point-in-time consistent or to apply incremental backup deltas to base. Then you can run Mariabackup again with either the `--copy-back` or `--move-back` commands to restore the database.

For more information, see Full Backup and Restore and Incremental Backup and Restore.

--binlog-info

Defines how Mariabackup retrieves the binary log coordinates from the server.

```
--binlog-info[=OFF | ON | LOCKLESS | AUTO]
```

The `--binlog-info` option supports the following retrieval methods. When no retrieval method is provided, it defaults to `AUTO`.

Option	Description
`OFF`	Disables the retrieval of binary log information
`ON`	Enables the retrieval of binary log information, performs locking where available to ensure consistency
`LOCKLESS`	Unsupported option
`AUTO`	Enables the retrieval of binary log information using `ON` or `LOCKLESS` where supported

Using this option, you can control how Mariabackup retrieves the server's binary log coordinates corresponding to the backup.

When enabled, whether using `ON` or `AUTO`, Mariabackup retrieves information from the binlog during the backup process. When disabled with `OFF`, Mariabackup runs without attempting to retrieve binary log information. You may find this useful when you need to copy data without metadata like the binlog or replication coordinates.

```
$ mariabackup --binlog-info --backup
```

Currently, the `LOCKLESS` option depends on features unsupported by MariaDB Server. See the description of the `xtrabackup_binlog_pos_innodb` file for more information. If you attempt to run Mariabackup with this option, then it causes the utility to exit with an error.

--close-files

Defines whether you want to close file handles.

Using this option, you can tell Mariabackup that you want to close file handles. Without this option, Mariabackup keeps files open in order to manage DDL operations. When working with particularly large tablespaces, closing the file can make the backup more manageable. However, it can also lead to inconsistent backups. Use at your own risk.

```
$ mariabackup --close-files --prepare
```

--compress

This option was deprecated starting with MariaDB 10.1.31 and 10.2.13 as it relies on the no longer maintained QuickLZ library. It is recommended to instead backup to a stream (stdout), and use a 3rd party compression library to compress the stream, as described in Using Encryption and Compression Tools With Mariabackup.

Defines the compression algorithm for backup files.

```
--compress[=compression_algorithm]
```

The `--compress` option only supports the now deprecated `quicklz` algorithm.

Option	Description
`quicklz`	Uses the QuickLZ compression algorithm

```
$ mariabackup --compress --backup
```

If a backup is compressed using this option, then Mariabackup will record that detail in the `xtrabackup_info` file.

--compress-chunk-size

Deprecated, for details see the `--compress` option.

Defines the working buffer size for compression threads.

```
--compress-chunk-size=#
```

Mariabackup can perform compression operations on the backup files before writing them to disk. It can also use multiple threads for parallel data compression during this process. Using this option, you can set the chunk size each thread uses during compression. It defaults to 64K.

```
$ mariabackup --backup --compress \
     --compress-threads=12 --compress-chunk-size=5M
```

To further configure backup compression, see the `--compress` and `--compress-threads` options.

--compress-threads

Deprecated, for details see the `--compress` option.

Defines the number of threads to use in compression.

```
--compress-threads=#
```

Mariabackup can perform compression operations on the backup files before writing them to disk. Using this option, you can define the number of threads you want to use for this operation. You may find this useful in speeding up the compression of particularly large databases. It defaults to single-threaded.

```
$ mariabackup --compress --compress-threads=12 --backup
```

To further configure backup compression, see the `--compress` and `--compress-chunk-size` options.

--copy-back

Restores the backup to the data directory.

Using this command, Mariabackup copies the backup from the target directory to the data directory, as defined by the `--datadir` option. You must stop the MariaDB Server before running this command. The data directory must be empty. If you want to overwrite the data directory with the backup, use the `--force-non-empty-directories` option.

Bear in mind, before you can restore a backup, you first need to run Mariabackup with the `--prepare` option. In the case of full backups, this makes the files point-in-time consistent. With incremental backups, this applies the deltas to the base backup. Once the backup is prepared, you can run `--copy-back` to apply it to MariaDB Server.

```
$ mariabackup --copy-back --force-non-empty-directories
```

Running the `--copy-back` command copies the backup files to the data directory. Use this command if you want to save the backup for later. If you don't want to save the backup for later, use the `--move-back` command.

--core-file

Defines whether to write a core file.

Using this option, you can configure Mariabackup to dump its core to file in the event that it encounters fatal signals. You may find this useful for review and debugging purposes.

```
$ mariabackup --core-file --backup
```

--databases

Defines the databases and tables you want to back up.

```
--databases="database[.table][ database[.table] ...]"
```

Using this option, you can define the specific database or databases you want to back up. In cases where you have a particularly large database or otherwise only want to back up a portion of it, you can optionally also define the tables on the database.

```
$ mariabackup --backup \
      --databases="example.table1 example.table2"
```

In cases where you want to back up most databases on a server or tables on a database, but not all, you can set the specific databases or tables you don't want to back up using the `--databases-exclude` option.

If a backup is a partial backup, then Mariabackup will record that detail in the `xtrabackup_info` file.

In `innobackupex` mode, which can be enabled with the `--innobackupex` option, the `--databases` option can be used as described above, or it can be used to refer to a file, just as the `--databases-file` option can in the normal mode.

--databases-exclude

Defines the databases you don't want to back up.

```
--databases-exclude="database[.table][ database[.table] ...]"
```

Using this option, you can define the specific database or databases you want to exclude from the backup process. You may find it useful when you want to back up most databases on the server or tables on a database, but would like to exclude a few from the process.

```
$ mariabackup --backup \
      --databases="example" \
      --databases-exclude="example.table1 example.table2"
```

To include databases in the backup, see the `--databases` option option

If a backup is a partial backup, then Mariabackup will record that detail in the `xtrabackup_info` file.

--databases-file

Defines the path to a file listing databases and/or tables you want to back up.

```
--databases-file="/path/to/database-file"
```

Format the databases file to list one element per line, with the following syntax:

```
database[.table]
```

In cases where you need to back up a number of databases or specific tables in a database, you may find the syntax for the `--databases` and `--databases-exclude` options a little cumbersome. Using this option you can set the path to a file listing the databases or databases and tables you want to back up.

For instance, imagine you list the databases and tables for a backup in a file called `main-backup`.

```
$ cat main-backup
example1
example2.table1
example2.table2

$ mariabackup --backup --databases-file=main-backup
```

If a backup is a partial backup, then Mariabackup will record that detail in the `xtrabackup_info` file.

-h, --datadir

Defines the path to the database root.

```
--datadir=PATH
```

Using this option, you can define the path to the source directory. This is the directory that Mariabackup reads for the data it backs up. It should be the same as the MariaDB Server `datadir` system variable.

```
$ mariabackup --backup -h /var/lib64/mysql
```

--debug-sleep-before-unlock

This is a debug-only option used by the Xtrabackup test suite.

--decompress

Deprecated, for details see the `--compress` option.

This option requires that you have the `qpress` utility installed on your system.

Defines whether you want to decompress previously compressed backup files.

When you run Mariabackup with the `--compress` option, it compresses the subsequent backup files, using the QuickLZ algorithm. Using this option, Mariabackup decompresses the compressed files from a previous backup.

For instance, run a backup with compression,

```
$ mariabackup --compress --backup
```

Then decompress the backup,

```
$ mariabackup --decompress
```

You can enable the decryption of multiple files at a time using the `--parallel` option. By default, Mariabackup does not remove the compressed files from the target directory. If you want to delete these files, use the `--remove-original` option.

--debug-sync

Defines the debug sync point. This option is only used by the Mariabackup test suite.

--defaults-extra-file

Defines the path to an extra default option file.

```
--defaults-extra-file=/path/to/config
```

Using this option, you can define an extra default option file for Mariabackup. Unlike `--defaults-file`, this file is read after the default option files are read, allowing you to only overwrite the existing defaults.

```
$ mariabackup --backup \
      --defaults-file-extra=addition-config.cnf \
      --defaults-file=config.cnf
```

--defaults-file

Defines the path to the default option file.

```
--defaults-file=/path/to/config
```

Using this option, you can define a default option file for Mariabackup. Unlike the `--defaults-extra-file` option, when this option is provided, it completely replaces all default option files.

```
$ mariabackup --backup \
     --defaults-file="config.cnf
```

--defaults-group

Defines the option group to read in the option file.

```
--defaults-group="name"
```

In situations where you find yourself using certain Mariabackup options consistently every time you call it, you can set the options in an option file. The `--defaults-group` option defines what option group Mariabackup reads for its options.

Options you define from the command-line can be set in the configuration file using minor formatting changes. For instance, if you find yourself perform compression operations frequently, you might set `--compress-threads` and `--compress-chunk-size` options in this way:

```
[mariabackup]
compress_threads = 12
compress_chunk_size = 64K
```

Now whenever you run a backup with the `--compress` option, it always performs the compression using 12 threads and 64K chunks.

```
$ mariabackup --compress --backup
```

See Mariabackup Overview: Server Option Groups and Mariabackup Overview: Client Option Groups for a list of the option groups read by Mariabackup by default.

--encrypted-backup

When this option is used with `--backup`, if Mariabackup encounters a page that has a non-zero `key_version` value, then Mariabackup assumes that the page is encrypted.

Use `--skip-encrypted-backup` instead to allow Mariabackup to copy unencrypted tables that were originally created before MySQL 5.1.48.

This option was added in MariaDB 10.2.22, MariaDB 10.3.13, and MariaDB 10.4.2.

--export

If this option is provided during the `--prepare` stage, then it tells Mariabackup to create `.cfg` files for each InnoDB file-per-table tablespace. These `.cfg` files are used to import transportable tablespaces in the process of restoring partial backups and restoring individual tables and partitions.

The `--export` option could require rolling back incomplete transactions that had modified the table. This will likely create a "new branch of history" that does not correspond to the server that had been backed up, which makes it impossible to apply another incremental backup on top of such additional changes. The option should only be applied when doing a `--prepare` of the last incremental.

```
$ mariabackup --prepare --export
```

MariaDB until 10.2.8

In MariaDB 10.2.8 and before, Mariabackup did not support the `--export` option. See MDEV-13466 about that. In earlier versions of MariaDB, this means that Mariabackup could not create `.cfg` files for InnoDB file-per-table tablespaces during the `--prepare` stage. You can still import file-per-table tablespaces without the `.cfg` files in many cases, so it may still be possible in those versions to restore partial backups or to restore individual tables and partitions with just the `.ibd` files. If you have a full backup and you need to create `.cfg` files for InnoDB file-per-table tablespaces, then you can do so by preparing the backup as usual without the `--export` option, and then restoring the backup, and then starting the server. At that point, you can use the server's built-in features to copy the transportable tablespaces.

--extra-lsndir

Saves an extra copy of the `xtrabackup_checkpoints` and `xtrabackup_info` files into the given directory.

```
--extra-lsndir=PATH
```

When using the `--backup` command option, Mariabackup produces a number of backup files in the target directory. Using this option, you can have Mariabackup produce additional copies of the `xtrabackup_checkpoints` and `xtrabackup_info` files in the given directory.

```
$ mariabackup --extra-lsndir=extras/ --backup
```

This is especially usefull when using `--stream` for streaming output, e.g. for compression and/or encryption using external tools in combination with incremental backups, as the `xtrabackup_checkpoints` file necessary to determine the LSN to continue the incremental backup from is still accessible without uncompressing / decrypting the backup file first. Simply pass in the `--extra-lsndir` of the previous backup as `--incremental-basedir`

--force-non-empty-directories

Allows `--copy-back` or `--move-back` command options to use non-empty target directories.

When using Mariabackup with the `--copy-back` or `--move-back` command options, they normally require a non-empty target directory to avoid conflicts. Using this option with either of command allows Mariabackup to use a non-empty directory.

```
$ mariabackup --force-on-empty-directories --copy-back
```

Bear in mind that this option does not enable overwrites. When copying or moving files into the target directory, if Mariabackup finds that the target file already exists, it fails with an error.

--ftwrl-wait-query-type

Defines the type of query allowed to complete before Mariabackup issues the global lock.

```
--ftwrl-wait-query-type=[ALL | UPDATE | SELECT]
```

The `--ftwrl-wait-query-type` option supports the following query types. The default value is `ALL`.

Option	Description
`ALL`	Waits until all queries complete before issuing the global lock
`SELECT`	Waits until `SELECT` statements complete before issuing the global lock
`UPDATE`	Waits until `UPDATE` statements complete before issuing the global lock

When Mariabackup runs, it issues a global lock to prevent data from changing during the backup process. When it encounters a statement in the process of executing, it waits until the statement is finished before issuing the global lock. Using this option, you can modify this default behavior to ensure that it waits only for certain query types, such as for `SELECT` and `UPDATE` statements.

```
$ mariabackup --backup  \
      --ftwrl-wait-query-type=UPDATE
```

`--ftwrl-wait-threshold`

Defines the minimum threshold for identifying long-running queries for FTWRL.

```
--ftwrl-wait-threshold=#
```

When Mariabackup runs, it issues a global lock to prevent data from changing during the backup process and ensure a consistent record. If it encounters statements still in the process of executing, it waits until they complete before setting the lock. Using this option, you can set the threshold at which Mariabackup engages FTWRL. When it `--ftwrl-wait-timeout` is not 0 and a statement has run for at least the amount of time given this argument, Mariabackup waits until the statement completes or until the `--ftwrl-wait-timeout` expires before setting the global lock and starting the backup.

```
$ mariabackup --backup \
     --ftwrl-wait-timeout=90 \
     --ftwrl-wait-threshold=30
```

`--ftwrl-wait-timeout`

Defines the timeout to wait for queries before trying to acquire the global lock. In MariaDB 10.4 and later, the global lock refers to `BACKUP STAGE BLOCK_COMMIT`. In MariaDB 10.3 and before, the global lock refers to `FLUSH TABLES WITH READ LOCK (FTWRL)`.

```
--ftwrl-wait-timeout=#
```

When Mariabackup runs, it acquires a global lock to prevent data from changing during the backup process and ensure a consistent record. If it encounters statements still in the process of executing, it can be configured to wait until the statements complete before trying to acquire the global lock.

If the `--ftwrl-wait-timeout` is set to 0, then Mariabackup tries to acquire the global lock immediately without waiting. This is the default value.

If the `--ftwrl-wait-timeout` is set to a non-zero value, then Mariabackup waits for the configured number of seconds until trying to acquire the global lock.

Starting in MariaDB 10.5.3, MariaDB 10.4.13, MariaDB 10.3.23, and MariaDB 10.2.32, Mariabackup will exit if it can't acquire the global lock after waiting for the configured number of seconds. In earlier versions, it could wait for the global lock indefinitely, even if `--ftwrl-wait-timeout` was set to a non-zero value.

```
$ mariabackup --backup \
      --ftwrl-wait-query-type=UPDATE \
      --ftwrl-wait-timeout=5
```

`--galera-info`

Defines whether you want to back up information about a Galera Cluster node's state.

When this option is used, Mariabackup creates an additional file called `xtrabackup_galera_info`, which records information about a Galera Cluster node's state. It records the values of the `wsrep_local_state_uuid` and `wsrep_last_committed` status variables.

You should only use this option when backing up a Galera Cluster node. If the server is not a Galera Cluster node, then this

option has no effect.

```
$ mariabackup --backup --galera-info
```

--history

Defines whether you want to track backup history in the `PERCONA_SCHEMA.xtrabackup_history` table.

```
--history[=name]
```

When using this option, Mariabackup records its operation in a table on the MariaDB Server. Passing a name to this option allows you group backups under arbitrary terms for later processing and analysis.

```
$ mariabackup --backup --history=backup_all
```

Currently, the table it uses by default is named `mysql.mariadb_backup_history`. Prior to MariaDB 10.11, the default table was `PERCONA_SCHEMA.xtrabackup_history`.

Mariabackup will also record this in the `xtrabackup_info` file.

-H, --host

Defines the host for the MariaDB Server you want to backup.

```
--host=name
```

Using this option, you can define the host to use when connecting to a MariaDB Server over TCP/IP. By default, Mariabackup attempts to connect to the local host.

```
$ mariabackup --backup \
      --host="example.com"
```

--include

This option is a regular expression to be matched against table names in databasename.tablename format. It is equivalent to the `--tables` option. This is only valid in `innobackupex` mode, which can be enabled with the `--innobackupex` option.

--incremental

Defines whether you want to take an increment backup, based on another backup. This is only valid in `innobackupex` mode, which can be enabled with the `--innobackupex` option.

```
mariabackup --innobackupex --incremental
```

Using this option with the `--backup` command option makes the operation incremental rather than a complete overwrite. When this option is specified, either the `--incremental-lsn` or `--incremental-basedir` options can also be given. If neither option is given, option `--incremental-basedir` is used by default, set to the first timestamped backup directory in the backup base directory.

```
$ mariabackup --innobackupex --backup --incremental \
     --incremental-basedir=/data/backups \
     --target-dir=/data/backups
```

If a backup is a incremental backup, then Mariabackup will record that detail in the `xtrabackup_info` file.

--incremental-basedir

Defines whether you want to take an incremental backup, based on another backup.

```
--incremental-basedir=PATH
```

Using this option with the `--backup` command option makes the operation incremental rather than a complete overwrite. Mariabackup will only copy pages from `.ibd` files if they are newer than the backup in the specified directory.

```
$ mariabackup --backup \
     --incremental-basedir=/data/backups \
     --target-dir=/data/backups
```

If a backup is a incremental backup, then Mariabackup will record that detail in the `xtrabackup_info` file.

`--incremental-dir`

Defines whether you want to take an incremental backup, based on another backup.

```
--increment-dir=PATH
```

Using this option with `--prepare` command option makes the operation incremental rather than a complete overwrite. Mariabackup will apply `.delta` files and log files into the target directory.

```
$ mariabackup --prepare \
      --increment-dir=backups/
```

If a backup is a incremental backup, then Mariabackup will record that detail in the `xtrabackup_info` file.

`--incremental-force-scan`

Defines whether you want to force a full scan for incremental backups.

When using Mariabackup to perform an incremental backup, this option forces it to also perform a full scan of the data pages being backed up, even when there's bitmap data on the changes. MariaDB 10.2 and later does not support changed page bitmaps, so this option is useless in those versions. See MDEV-18985 for more information.

```
$ mariabackup --backup \
     --incremental-basedir=/path/to/target \
     --incremental-force-scan
```

`--incremental-history-name`

Defines a logical name for the backup.

```
--incremental-history-name=name
```

Mariabackup can store data about its operations on the MariaDB Server. Using this option, you can define the logical name it uses in identifying the backup.

```
$ mariabackup --backup \
     --incremental-history-name=morning_backup
```

Currently, the table it uses by default is named `mysql.mariadb_backup_history`. Prior to MariaDB 10.11, the default table was `PERCONA_SCHEMA.xtrabackup_history`.

Mariabackup will also record this in the `xtrabackup_info` file.

`--incremental-history-uuid`

Defines a UUID for the backup.

```
--incremental-history-uuid=name
```

Mariabackup can store data about its operations on the MariaDB Server. Using this option, you can define the UUID it uses in identifying a previous backup to increment from. It checks `--incremental-history-name`, `--incremental-basedir`, and `--incremental-lsn`. If Mariabackup fails to find a valid lsn, it generates an error.

```
$ mariabackup --backup \
      --incremental-history-uuid=main-backup012345678
```

Currently, the table it uses is named `PERCONA_SCHEMA.xtrabackup_history`, but expect that name to change in future releases. See MDEV-19246 for more information.

Mariabackup will also record this in the `xtrabackup_info` file.

--incremental-lsn

Defines the sequence number for incremental backups.

```
--incremental-lsn=name
```

Using this option, you can define the sequence number (LSN) value for `--backup` operations. During backups, Mariabackup only copies `.ibd` pages newer than the specified values.

WARNING: Incorrect LSN values can make the backup unusable. It is impossible to diagnose this issue.

--innobackupex

> Deprecated in MariaDB 10.3.0.

Enables `innobackupex` mode, which is a compatibility mode.

```
$ mariabackup --innobackupex
```

In `innobackupex` mode, Mariabackup has the following differences:

- To prepare a backup, the `--apply-log` option is used instead of the `--prepare` option.
- To create an incremental backup, the `--incremental` option is supported.
- The `--no-timestamp` option is supported.
- To create a partial backup, the `--include` option is used instead of the `--tables` option.
- To create a partial backup, the `--databases` option can still be used, but it's behavior changes slightly.
- The `--target-dir` option is not used to specify the backup directory. The backup directory should instead be specified as a standalone argument.

The primary purpose of `innobackupex` mode is to allow scripts and tools to more easily migrate to Mariabackup if they were originally designed to use the `innobackupex` utility that is included with Percona XtraBackup. It is not recommended to use this mode in new scripts, since it is not guaranteed to be supported forever. See MDEV-20552 for more information.

--innodb

This option has no effect. Set only for MySQL option compatibility.

--innodb-adaptive-hash-index

Enables InnoDB Adaptive Hash Index.

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option you can explicitly enable the InnoDB Adaptive Hash Index. This feature is enabled by default for Mariabackup. If you want to disable it, use `--skip-innodb-adaptive-hash-index`.

```
$ mariabackup --backup \
      --innodb-adaptive-hash-index
```

--innodb-autoextend-increment

Defines the increment in megabytes for auto-extending the size of tablespace file.

```
--innodb-autoextend-increment=36
```

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option, you can set the increment in megabytes for automatically extending the size of tablespace data file in InnoDB.

```
$ mariabackup --backup \
     --innodb-autoextend-increment=35
```

--innodb-buffer-pool-filename

Using this option has no effect. It is available to provide compatibility with the MariaDB Server.

--innodb-buffer-pool-size

Defines the memory buffer size InnoDB uses the cache data and indexes of the table.

```
--innodb-buffer-pool-size=124M
```

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option, you can configure the buffer pool for InnoDB operations.

```
$ mariabackup --backup \
      --innodb-buffer-pool-size=124M
```

--innodb-checksum-algorithm

innodb_checksum_algorithm was deprecated in MariaDB 10.3.29, MariaDB 10.4.19, MariaDB 10.5.10 and removed in MariaDB 10.6.

In earlier versions, it is used to define the checksum algorithm.

```
--innodb-checksum-algorithm=crc32
                           | strict_crc32
                           | innodb
                           | strict_innodb
                           | none
                           | strict_none
```

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option, you can specify the algorithm Mariabackup uses when checksumming on InnoDB tables. Currently, MariaDB supports the following algorithms `CRC32`, `STRICT_CRC32`, `INNODB`, `STRICT_INNODB`, `NONE`, `STRICT_NONE`.

```
$ mariabackup --backup \
      ---innodb-checksum-algorithm=strict_innodb
```

--innodb-data-file-path

Defines the path to individual data files.

```
--innodb-data-file-path=/path/to/file
```

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option you can define the path to InnoDB data files. Each path is appended to the `--innodb-data-home-dir` option.

```
$ mariabackup --backup \
     --innodb-data-file-path=ibdata1:13M:autoextend \
     --innodb-data-home-dir=/var/dbs/mysql/data
```

--innodb-data-home-dir

Defines the home directory for InnoDB data files.

```
--innodb-data-home-dir=PATH
```

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option you can define the path to the directory containing InnoDB data files. You can specific the files using the `--innodb-data-file-path` option.

```
$ mariabackup --backup \
     --innodb-data-file-path=ibdata1:13M:autoextend \
     --innodb-data-home-dir=/var/dbs/mysql/data
```

--innodb-doublewrite

Enables doublewrites for InnoDB tables.

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. When using this option, Mariabackup improves fault tolerance on InnoDB tables with a doublewrite buffer. By default, this feature is enabled. Use this option to explicitly enable it. To disable doublewrites, use the `--skip-innodb-doublewrite` option.

```
$ mariabackup --backup \
     --innodb-doublewrite
```

--innodb-encrypt-log

Defines whether you want to encrypt InnoDB logs.

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option, you can tell Mariabackup that you want to encrypt logs from its InnoDB activity.

--innodb-file-io-threads

Defines the number of file I/O threads in InnoDB.

```
--innodb-file-io-threads=#
```

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option, you can define the number of file I/O threads Mariabackup uses on InnoDB tables.

```
$ mariabackup --backup \
     --innodb-file-io-threads=5
```

--innodb-file-per-table

Defines whether you want to store each InnoDB table as an `.ibd` file.

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option causes Mariabackup to store each InnoDB table as an `.ibd` file in the target directory.

--innodb-flush-method

Defines the data flush method. Ignored from MariaDB 11.0.

```
--innodb-flush-method=fdatasync
                     | O_DSYNC
                     | O_DIRECT
                     | O_DIRECT_NO_FSYNC
                     | ALL_O_DIRECT
```

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option, you can define the data flush method Mariabackup uses with InnoDB tables.

```
$ mariabackup --backup \
      --innodb-flush-method==_DIRECT_NO_FSYNC
```

Note, the `O_DIRECT_NO_FSYNC` method is only available with MariaDB 10.0 and later. The `ALL_O_DIRECT` method available with version 5.5 and later, but only with tables using the XtraDB storage engine.

--innodb-io-capacity

Defines the number of IOP's the utility can perform.

```
--innodb-io-capacity=#
```

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option, you can limit the I/O activity for InnoDB background tasks. It should be set around the number of I/O operations per second that the system can handle, based on drive or drives being used.

```
$ mariabackup --backup \
     --innodb-io-capacity=200
```

--innodb-log-checksums

Defines whether to include checksums in the InnoDB logs.

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option, you can explicitly set Mariabackup to include checksums in the InnoDB logs. The feature is enabled by default. To disable it, use the `--skip-innodb-log-checksums` option.

```
$ mariabackup --backup \
      --innodb-log-checksums
```

--innodb-log-buffer-size

This option has no functionality in Mariabackup. It exists for MariaDB Server compatibility.

--innodb-log-files-in-group

This option has no functionality in Mariabackup. It exists for MariaDB Server compatibility.

--innodb-log-group-home-dir

Defines the path to InnoDB log files.

```
--innodb-log-group-home-dir=PATH
```

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option, you can define the path to InnoDB log files.

```
$ mariabackup --backup \
     --innodb-log-group-home-dir=/path/to/logs
```

--innodb-max-dirty-pages-pct

Defines the percentage of dirty pages allowed in the InnoDB buffer pool.

```
--innodb-max-dirty-pages-pct=#
```

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option, you can define the maximum percentage of dirty, (that is, unwritten) pages that Mariabackup allows in the InnoDB buffer pool.

```
$ mariabackup --backup \
     --innodb-max-dirty-pages-pct=80
```

--innodb-open-files

Defines the number of files kept open at a time.

```
--innodb-open-files=#
```

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option, you can set the maximum number of files InnoDB keeps open at a given time during backups.

```
$ mariabackup --backup \
      --innodb-open-files=10
```

--innodb-page-size

Defines the universal page size.

```
--innodb-page-size=#
```

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option, you can define the universal page size in bytes for Mariabackup.

```
$ mariabackup --backup \
     --innodb-page-size=16k
```

--innodb-read-io-threads

Defines the number of background read I/O threads in InnoDB.

```
--innodb-read-io-threads=#
```

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option, you can set the number of I/O threads MariaDB uses when reading from InnoDB.

```
$ mariabackup --backup \
      --innodb-read-io-threads=4
```

--innodb-undo-directory

Defines the directory for the undo tablespace files.

```
--innodb-undo-directory=PATH
```

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option, you can define the path to the directory where you want MariaDB to store the undo tablespace on InnoDB tables. The path can be absolute.

```
$ mariabackup --backup \
     --innodb-undo-directory=/path/to/innodb_undo
```

--innodb-undo-tablespaces

Defines the number of undo tablespaces to use.

```
--innodb-undo-tablespaces=#
```

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option, you can define the number of undo tablespaces you want to use during the backup.

```
$ mariabackup --backup \
      --innodb-undo-tablespaces=10
```

--innodb-use-native-aio

Defines whether you want to use native AI/O.

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option, you can enable the use of the native asynchronous I/O subsystem. It is only available on Linux operating systems.

```
$ mariabackup --backup \
      --innodb-use-native-aio
```

--innodb-write-io-threads

Defines the number of background write I/O threads in InnoDB.

```
--innodb-write-io-threads=#
```

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option, you can set the number of background write I/O threads Mariabackup uses.

```
$ mariabackup --backup \
     --innodb-write-io-threads=4
```

--kill-long-queries-timeout

Defines the timeout for blocking queries.

```
--kill-long-queries-timeout=#
```

When Mariabackup runs, it issues a `FLUSH TABLES WITH READ LOCK` statement. It then identifies blocking queries. Using this option you can set a timeout in seconds for these blocking queries. When the time runs out, Mariabackup kills the queries.

The default value is 0, which causes Mariabackup to not attempt killing any queries.

```
$ mariabackup --backup \
      --kill-long-queries-timeout=10
```

--kill-long-query-type

Defines the query type the utility can kill to unblock the global lock.

```
--kill-long-query-type=ALL | UPDATE | SELECT
```

When Mariabackup encounters a query that sets a global lock, it can kill the query in order to free up MariaDB Server for the backup. Using this option, you can choose the types of query it kills: `SELECT`, `UPDATE`, or both set with `ALL`. The default is `ALL`.

```
$ mariabackup --backup \
      --kill-long-query-type=UPDATE
```

--lock-ddl-per-table

Prevents DDL for each table to be backed up by acquiring MDL lock on that. NOTE: Unless --no-lock option was also specified, conflicting DDL queries , will be killed at the end of backup This is done avoid deadlock between "FLUSH TABLE WITH READ LOCK", user's DDL query (ALTER, RENAME), and MDL lock on table. Only available in MariaDB 10.2.9 and later.

--log

This option has no functionality. It is set to ensure compatibility with MySQL.

--log-bin

Defines the base name for the log sequence.

```
--log-bin[=name]
```

Using this option you, you can set the base name for Mariabackup to use in log sequences.

--log-copy-interval

Defines the copy interval between checks done by the log copying thread.

```
--log-copy-interval=#
```

Using this option, you can define the copy interval Mariabackup uses between checks done by the log copying thread. The given value is in milliseconds.

```
$ mariabackup --backup \
      --log-copy-interval=50
```

--log-innodb-page-corruption

Continue backup if InnoDB corrupted pages are found. The pages are logged in `innodb_corrupted_pages` and backup is finished with error. --prepare will try to fix corrupted pages. If `innodb_corrupted_pages` exists after --prepare in base backup directory, backup still contains corrupted pages and can not be considered as consistent.

Added in MariaDB 10.2.37, MariaDB 10.3.28, MariaDB 10.4.18, MariaDB 10.5.9

--move-back

Restores the backup to the data directory.

Using this command, Mariabackup moves the backup from the target directory to the data directory, as defined by the `--datadir` option. You must stop the MariaDB Server before running this command. The data directory must be empty. If you want to overwrite the data directory with the backup, use the `--force-non-empty-directories` option.

Bear in mind, before you can restore a backup, you first need to run Mariabackup with the `--prepare` option. In the case of full backups, this makes the files point-in-time consistent. With incremental backups, this applies the deltas to the base backup. Once the backup is prepared, you can run `--move-back` to apply it to MariaDB Server.

```
$ mariabackup --move-back \
      --datadir=/var/mysql
```

Running the `--move-back` command moves the backup files to the data directory. Use this command if you don't want to save the backup for later. If you do want to save the backup for later, use the `--copy-back` command.

--mysqld

Used internally to prepare a backup.

--no-backup-locks

Mariabackup locks the database by default when it runs. This option disables support for Percona Server's backup locks.

When backing up Percona Server, Mariabackup would use backup locks by default. To be specific, backup locks refers to the `LOCK TABLES FOR BACKUP` and `LOCK BINLOG FOR BACKUP` statements. This option can be used to disable support for Percona Server's backup locks. This option has no effect when the server does not support Percona's backup locks.

This option may eventually be removed. See MDEV-19753 for more information.

```
$ mariabackup --backup --no-backup-locks
```

--no-lock

Disables table locks with the `FLUSH TABLE WITH READ LOCK` statement.

Using this option causes Mariabackup to disable table locks with the `FLUSH TABLE WITH READ LOCK` statement. Only use this option if:

- You are not executing DML statements on non-InnoDB tables during the backup. This includes the `mysql` database system tables (which are MyISAM).
- You are not executing any DDL statements during the backup.
- You are _not_ using the file "xtrabackup_binlog_info", which is not consistent with the data when --no-lock is used.

Use the file "xtrabackup_binlog_pos_innodb" [link] instead.
- **All** tables you're backing up use the InnoDB storage engine.

```
$ mariabackup --backup --no-lock
```

If you're considering `--no-lock` due to backups failing to acquire locks, this may be due to incoming replication events preventing the lock. Consider using the --safe-slave-backup option to momentarily stop the replica thread. This alternative may help the backup to succeed without resorting to `--no-lock`.

The --no-lock option only provides a consistent backup if the user ensures that no DDL or non-transactional table updates occur during the backup. The --no-lock option is not supported by MariaDB plc.

--no-timestamp

This option prevents creation of a time-stamped subdirectory of the BACKUP-ROOT-DIR given on the command line. When it is specified, the backup is done in BACKUP-ROOT-DIR instead. This is only valid in `innobackupex` mode, which can be enabled with the `--innobackupex` option.

--no-version-check

Disables version check.

Using this option, you can disable Mariabackup version check.

```
$ mariabackup --backup --no-version-check
```

--open-files-limit

Defines the maximum number of file descriptors.

```
--open-files-limit=#
```

Using this option, you can define the maximum number of file descriptors Mariabackup reserves with `setrlimit()`.

```
$ mariabackup --backup \
      --open-files-limit=
```

--parallel

Defines the number of threads to use for parallel data file transfer.

```
--parallel=#
```

Using this option, you can set the number of threads Mariabackup uses for parallel data file transfers. By default, it is set to 1.

-p, --password

Defines the password to use to connect to MariaDB Server.

```
--password=passwd
```

When you run Mariabackup, it connects to MariaDB Server in order to access and back up the databases and tables. Using this option, you can set the password Mariabackup uses to access the server. To set the user, use the `--user` option.

```
$ mariabackup --backup \
      --user=root \
      --password=root_password
```

--plugin-dir

Defines the directory for server plugins.

```
--plugin-dir=PATH
```

Using this option, you can define the path Mariabackup reads for MariaDB Server plugins. It only uses it during the `--prepare` phase to load the encryption plugin. It defaults to the `plugin_dir` server system variable.

```
$ mariabackup --backup \
      --plugin-dir=/var/mysql/lib/plugin
```

--plugin-load

Defines the encryption plugins to load.

```
--plugin-load=name
```

Using this option, you can define the encryption plugin you want to load. It is only used during the `--prepare` phase to load the encryption plugin. It defaults to the server `--plugin-load` option.

The option was removed starting from MariaDB 10.2.18

-P, --port

Defines the server port to connect to.

```
--port=#
```

When you run Mariabackup, it connects to MariaDB Server in order to access and back up your databases and tables. Using this option, you can set the port the utility uses to access the server over TCP/IP. To set the host, see the `--host` option. Use `mysql --help` for more details.

```
$ mariabackup --backup \
      --host=192.168.11.1 \
      --port=3306
```

--prepare

Prepares an existing backup to restore to the MariaDB Server.

Files that Mariabackup generates during `--backup` operations in the target directory are not ready for use on the Server. Before you can restore the data to MariaDB, you first need to prepare the backup.

In the case of full backups, the files are not point in time consistent, since they were taken at different times. If you try to restore the database without first preparing the data, InnoDB rejects the new data as corrupt. Running Mariabackup with the `--prepare` command readies the data so you can restore it to MariaDB Server. When working with incremental backups, you need to use the `--prepare` command and the `--incremental-dir` option to update the base backup with the deltas from an incremental backup.

```
$ mariabackup --prepare
```

Once the backup is ready, you can use the `--copy-back` or the `--move-back` commands to restore the backup to the server.

--print-defaults

Prints the utility argument list, then exits.

Using this argument, MariaDB prints the argument list to stdout and then exits. You may find this useful in debugging to see how the options are set for the utility.

```
$ mariabackup --print-defaults
```

--print-param

Prints the MariaDB Server options needed for copyback.

Using this option, Mariabackup prints to stdout the MariaDB Server options that the utility requires to run the `--copy-back` command option.

```
$ mariabackup --print-param
```

--rollback-xa

By default, Mariabackup will not commit or rollback uncommitted XA transactions, and when the backup is restored, any uncommitted XA transactions must be manually committed using `XA COMMIT` or manually rolled back using `XA ROLLBACK`.

In MariaDB 10.2, MariaDB 10.3, and MariaDB 10.4, Mariabackup's `--rollback-xa` option can be used to rollback uncommitted XA transactions while performing a `--prepare` operation, so that they do not need to be manually committed or rolled back when the backup is restored.

This option is not present from MariaDB 10.5, because the server has more robust ways of handling uncommitted XA transactions in later versions.

> This is an experimental option. Do not use this option in versions older than MariaDB 10.2.33, MariaDB 10.3.24, and MariaDB 10.4.14. Older implementation can cause corruption of InnoDB data.

--rsync

Defines whether to use rsync.

During normal operation, Mariabackup transfers local non-InnoDB files using a separate call to `cp` for each file. Using this option, you can optimize this process by performing this transfer with rsync, instead.

```
$ mariabackup --backup --rsync
```

This option is not compatible with the `--stream` option.

--safe-slave-backup

Stops replica SQL threads for backups.

When running Mariabackup on a server that uses replication, you may occasionally encounter locks that block backups. Using this option, it stops replica SQL threads and waits until the `Slave_open_temp_tables` in the `SHOW STATUS` statement is zero. If there are no open temporary tables, the backup runs, otherwise the SQL thread starts and stops until there are no open temporary tables.

```
$ mariabackup --backup \
      --safe-slave-backup \
      --safe-slave-backup-timeout=500
```

The backup fails if the `Slave_open_temp_tables` doesn't reach zero after the timeout period set by the --safe-slave-backup-timeout option.

--safe-slave-backup-timeout

Defines the timeout for replica backups.

```
--safe-slave-backup-timeout=#
```

When running Mariabackup on a server that uses replication, you may occasionally encounter locks that block backups. With the --safe-slave-backup option, it waits until the `Slave_open_temp_tables` in the `SHOW STATUS` statement reaches zero. Using this option, you set how long it waits. It defaults to 300.

```
$ mariabackup --backup \
      --safe-slave-backup \
      --safe-slave-backup-timeout=500
```

--secure-auth

Refuses client connections to servers using the older protocol.

Using this option, you can set it explicitly to refuse client connections to the server when using the older protocol, from before 4.1.1. This feature is enabled by default. Use the --skip-secure-auth option to disable it.

```
$ mariabackup --backup --secure-auth
```

--skip-innodb-adaptive-hash-index

Disables InnoDB Adaptive Hash Index.

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option you can explicitly disable the InnoDB Adaptive Hash Index. This feature is enabled by default for Mariabackup. If you want to explicitly enable it, use `--innodb-adaptive-hash-index`.

```
$ mariabackup --backup \
      --skip-innodb-adaptive-hash-index
```

--skip-innodb-doublewrite

Disables doublewrites for InnoDB tables.

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. When doublewrites are enabled, InnoDB improves fault tolerance with a doublewrite buffer. By default this feature is turned on. Using this option you can disable it for Mariabackup. To explicitly enable doublewrites, use the `--innodb-doublewrite` option.

```
$ mariabackup --backup \
     --skip-innodb-doublewrite
```

--skip-innodb-log-checksums

Defines whether to exclude checksums in the InnoDB logs.

Mariabackup initializes its own embedded instance of InnoDB using the same configuration as defined in the configuration file. Using this option, you can set Mariabackup to exclude checksums in the InnoDB logs. The feature is enabled by default. To explicitly enable it, use the `--innodb-log-checksums` option.

--skip-secure-auth

Refuses client connections to servers using the older protocol.

Using this option, you can set it accept client connections to the server when using the older protocol, from before 4.1.1. By default, it refuses these connections. Use the `--secure-auth` option to explicitly enable it.

```
$ mariabackup --backup --skip-secure-auth
```

--slave-info

Prints the binary log position and the name of the primary server.

If the server is a replica, then this option causes Mariabackup to print the hostname of the replica's replication primary and the binary log file and position of the replica's SQL thread to `stdout`.

This option also causes Mariabackup to record this information as a CHANGE MASTER command that can be used to set up a new server as a replica of the original server's primary after the backup has been restored. This information will be written to to the xtrabackup_slave_info file.

Mariabackup does **not** check if GTIDs are being used in replication. It takes a shortcut and assumes that if the gtid_slave_pos system variable is non-empty, then it writes the CHANGE MASTER command with the MASTER_USE_GTID option set to `slave_pos`. Otherwise, it writes the CHANGE MASTER command with the MASTER_LOG_FILE and MASTER_LOG_POS options using the primary's binary log file and position. See MDEV-19264 for more information.

```
$ mariabackup --slave-info
```

-S, --socket

Defines the socket for connecting to local database.

```
--socket=name
```

Using this option, you can define the UNIX domain socket you want to use when connecting to a local database server. The option accepts a string argument. For more information, see the `mysql --help` command.

```
$ mariabackup --backup \
      --socket=/var/mysql/mysql.sock
```

--ssl

Enables TLS. By using this option, you can explicitly configure Mariabackup to to encrypt its connection with TLS when communicating with the server. You may find this useful when performing backups in environments where security is extra important or when operating over an insecure network.

TLS is also enabled even without setting this option when certain other TLS options are set. For example, see the descriptions of the following options:

- `--ssl-ca`
- `--ssl-capath`
- `--ssl-cert`
- `--ssl-cipher`
- `--ssl-key`

--ssl-ca

Defines a path to a PEM file that should contain one or more X509 certificates for trusted Certificate Authorities (CAs) to use for TLS. This option requires that you use the absolute path, not a relative path. For example:

```
--ssl-ca=/etc/my.cnf.d/certificates/ca.pem
```

This option is usually used with other TLS options. For example:

```
$ mariabackup --backup \
   --ssl-cert=/etc/my.cnf.d/certificates/client-cert.pem \
   --ssl-key=/etc/my.cnf.d/certificates/client-key.pem \
   --ssl-ca=/etc/my.cnf.d/certificates/ca.pem
```

See Secure Connections Overview: Certificate Authorities (CAs) for more information.

This option implies the --ssl option.

--ssl-capath

Defines a path to a directory that contains one or more PEM files that should each contain one X509 certificate for a trusted Certificate Authority (CA) to use for TLS. This option requires that you use the absolute path, not a relative path. For example:

```
--ssl-capath=/etc/my.cnf.d/certificates/ca/
```

This option is usually used with other TLS options. For example:

```
$ mariabackup --backup \
   --ssl-cert=/etc/my.cnf.d/certificates/client-cert.pem \
   --ssl-key=/etc/my.cnf.d/certificates/client-key.pem \
   --ssl-ca=/etc/my.cnf.d/certificates/ca.pem \
   --ssl-capath=/etc/my.cnf.d/certificates/ca/
```

The directory specified by this option needs to be run through the openssl rehash command.

See Secure Connections Overview: Certificate Authorities (CAs) for more information

This option implies the --ssl option.

--ssl-cert

Defines a path to the X509 certificate file to use for TLS. This option requires that you use the absolute path, not a relative path. For example:

```
--ssl-cert=/etc/my.cnf.d/certificates/client-cert.pem
```

This option is usually used with other TLS options. For example:

```
$ mariabackup --backup \
   --ssl-cert=/etc/my.cnf.d/certificates/client-cert.pem \
   --ssl-key=/etc/my.cnf.d/certificates/client-key.pem \
   --ssl-ca=/etc/my.cnf.d/certificates/ca.pem
```

This option implies the --ssl option.

--ssl-cipher

Defines the list of permitted ciphers or cipher suites to use for TLS. For example:

```
--ssl-cipher=name
```

This option is usually used with other TLS options. For example:

```
$ mariabackup --backup \
   --ssl-cert=/etc/my.cnf.d/certificates/client-cert.pem \
   --ssl-key=/etc/my.cnf.d/certificates/client-key.pem \
   --ssl-ca=/etc/my.cnf.d/certificates/ca.pem
   --ssl-cipher=TLSv1.2
```

To determine if the server restricts clients to specific ciphers, check the ssl_cipher system variable.

This option implies the --ssl option.

--ssl-crl

Defines a path to a PEM file that should contain one or more revoked X509 certificates to use for TLS. This option requires that you use the absolute path, not a relative path. For example:

```
--ssl-crl=/etc/my.cnf.d/certificates/crl.pem
```

This option is usually used with other TLS options. For example:

```
$ mariabackup --backup \
   --ssl-cert=/etc/my.cnf.d/certificates/client-cert.pem \
   --ssl-key=/etc/my.cnf.d/certificates/client-key.pem \
   --ssl-ca=/etc/my.cnf.d/certificates/ca.pem \
   --ssl-crl=/etc/my.cnf.d/certificates/crl.pem
```

See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information.

This option is only supported if Mariabackup was built with OpenSSL. If Mariabackup was built with yaSSL, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

--ssl-crlpath

Defines a path to a directory that contains one or more PEM files that should each contain one revoked X509 certificate to use for TLS. This option requires that you use the absolute path, not a relative path. For example:

```
--ssl-crlpath=/etc/my.cnf.d/certificates/crl/
```

This option is usually used with other TLS options. For example:

```
$ mariabackup --backup \
   --ssl-cert=/etc/my.cnf.d/certificates/client-cert.pem \
   --ssl-key=/etc/my.cnf.d/certificates/client-key.pem \
   --ssl-ca=/etc/my.cnf.d/certificates/ca.pem \
   --ssl-crlpath=/etc/my.cnf.d/certificates/crl/
```

The directory specified by this option needs to be run through the openssl rehash command.

See Secure Connections Overview: Certificate Revocation Lists (CRLs) for more information.

This option is only supported if Mariabackup was built with OpenSSL. If Mariabackup was built with yaSSL, then this option is not supported. See TLS and Cryptography Libraries Used by MariaDB for more information about which libraries are used on which platforms.

--ssl-key

Defines a path to a private key file to use for TLS. This option requires that you use the absolute path, not a relative path. For example:

```
--ssl-key=/etc/my.cnf.d/certificates/client-key.pem
```

This option is usually used with other TLS options. For example:

```
$ mariabackup --backup \
   --ssl-cert=/etc/my.cnf.d/certificates/client-cert.pem \
   --ssl-key=/etc/my.cnf.d/certificates/client-key.pem \
   --ssl-ca=/etc/my.cnf.d/certificates/ca.pem
```

This option implies the --ssl option.

--ssl-verify-server-cert

Enables server certificate verification. This option is disabled by default.

This option is usually used with other TLS options. For example:

```
$ mariabackup --backup \
   --ssl-cert=/etc/my.cnf.d/certificates/client-cert.pem \
   --ssl-key=/etc/my.cnf.d/certificates/client-key.pem \
   --ssl-ca=/etc/my.cnf.d/certificates/ca.pem \
   --ssl-verify-server-cert
```

--stream

Streams backup files to stdout.

```
--stream=xbstream
```

Using this command option, you can set Mariabackup to stream the backup files to stdout in the given format. Currently, the supported format is `xbstream`.

```
$ mariabackup --stream=xbstream > backup.xb
```

To extract all files from the xbstream archive into a directory use the `mbstream` utility

```
$ mbstream  -x < backup.xb
```

If a backup is streamed, then Mariabackup will record the format in the xtrabackup_info file.

--tables

Defines the tables you want to include in the backup.

```
--tables=REGEX
```

Using this option, you can define what tables you want Mariabackup to back up from the database. The table values are defined using Regular Expressions. To define the tables you want to exclude from the backup, see the --tables-exclude option.

```
$ mariabackup --backup \
     --databases=example
     --tables=nodes_* \
     --tables-exclude=nodes_tmp
```

If a backup is a partial backup, then Mariabackup will record that detail in the xtrabackup_info file.

--tables-exclude

Defines the tables you want to exclude from the backup.

```
--tables-exclude=REGEX
```

Using this option, you can define what tables you want Mariabackup to exclude from the backup. The table values are defined using Regular Expressions. To define the tables you want to include from the backup, see the --tables option.

```
$ mariabackup --backup \
     --databases=example
     --tables=nodes_* \
     --tables-exclude=nodes_tmp
```

If a backup is a partial backup, then Mariabackup will record that detail in the xtrabackup_info file.

--tables-file

Defines path to file with tables for backups.

```
--tables-file=/path/to/file
```

Using this option, you can set a path to a file listing the tables you want to back up. Mariabackup iterates over each line in the file. The format is `database.table`.

```
$ mariabackup --backup \
     --databases=example \
     --tables-file=/etc/mysql/backup-file
```

If a backup is a partial backup, then Mariabackup will record that detail in the xtrabackup_info file.

--target-dir

Defines the destination directory.

```
--target-dir=/path/to/target
```

Using this option you can define the destination directory for the backup. Mariabackup writes all backup files to this directory. Mariabackup will create the directory, if it does not exist (but it will not create the full path recursively, i.e. at least parent directory if the --target-dir must exist=

```
$ mariabackup --backup \
       --target-dir=/data/backups
```

--throttle

Defines the limit for I/O operations per second in IOS values.

```
--throttle=#
```

Using this option, you can set a limit on the I/O operations Mariabackup performs per second in IOS values. It is only used during the --backup command option.

--tls-version

This option accepts a comma-separated list of TLS protocol versions. A TLS protocol version will only be enabled if it is present in this list. All other TLS protocol versions will not be permitted. For example:

```
--tls-version="TLSv1.2,TLSv1.3"
```

This option is usually used with other TLS options. For example:

```
$ mariabackup --backup \
   --ssl-cert=/etc/my.cnf.d/certificates/client-cert.pem \
   --ssl-key=/etc/my.cnf.d/certificates/client-key.pem \
   --ssl-ca=/etc/my.cnf.d/certificates/ca.pem \
   --tls-version="TLSv1.2,TLSv1.3"
```

This option was added in MariaDB 10.4.6.

See Secure Connections Overview: TLS Protocol Versions for more information.

-t, --tmpdir

Defines path for temporary files.

```
--tmpdir=/path/tmp[;/path/tmp...]
```

Using this option, you can define the path to a directory Mariabackup uses in writing temporary files. If you want to use more than one, separate the values by a semicolon (that is, `;`). When passing multiple temporary directories, it cycles through them using round-robin.

```
$ mariabackup --backup \
     --tmpdir=/data/tmp;/tmp
```

--use-memory

Defines the buffer pool size that is used during the prepare stage.

```
--use-memory=124M
```

Using this option, you can define the buffer pool size for Mariabackup. Use it instead of `buffer_pool_size`.

```
$ mariabackup --prepare \
      --use-memory=124M
```

--user

Defines the username for connecting to the MariaDB Server.

```
--user=name
-u name
```

When Mariabackup runs it connects to the specified MariaDB Server to get its backups. Using this option, you can define the database user uses for authentication.

```
$ mariabackup --backup \
      --user=root \
      --password=root_passwd
```

--version

Prints version information.

Using this option, you can print the Mariabackup version information to stdout.

```
$ mariabackup --version
```

2.3.4.3 Full Backup and Restore with Mariabackup

Contents

When using Mariabackup, you have the option of performing a full or an incremental backup. Full backups create a complete backup of the database server in an empty directory while incremental backups update a previous backup with whatever changes to the data have occurred since the backup. This page documents how to perform full backups.

Backing up the Database Server

In order to back up the database, you need to run Mariabackup with the `--backup` option to tell it to perform a backup and with the `--target-dir` option to tell it where to place the backup files. When taking a full backup, the target directory must be empty or it must not exist.

To take a backup, run the following command:

```
$ mariabackup --backup \
   --target-dir=/var/mariadb/backup/ \
   --user=mariabackup --password=mypassword
```

The time the backup takes depends on the size of the databases or tables you're backing up. You can cancel the backup if you need to, as the backup process does not modify the database.

Mariabackup writes the backup files the target directory. If the target directory doesn't exist, then it creates it. If the target directory exists and contains files, then it raises an error and aborts.

Here is an example backup directory:

```
$ ls /var/mariadb/backup/

aria_log.0000001  mysql                  xtrabackup_checkpoints
aria_log_control  performance_schema     xtrabackup_info
backup-my.cnf     test                   xtrabackup_logfile
ibdata1           xtrabackup_binlog_info
```

Preparing the Backup for Restoration

The data files that Mariabackup creates in the target directory are not point-in-time consistent, given that the data files are copied at different times during the backup operation. If you try to restore from these files, InnoDB notices the inconsistencies and crashes to protect you from corruption

Before you can restore from a backup, you first need to **prepare** it to make the data files consistent. You can do so with the `--prepare` option.

```
$ mariabackup --prepare \
   --target-dir=/var/mariadb/backup/
```

Restoring the Backup

Once the backup is complete and you have prepared the backup for restoration (previous step), you can restore the backup using either the `--copy-back` or the `--move-back` options. The `--copy-back` option allows you to keep the original backup files. The `--move-back` option actually moves the backup files to the `datadir`, so the original backup files are lost.

- First, stop the MariaDB Server process.
- Then, ensure that the `datadir` is empty.
- Then, run Mariabackup with one of the options mentioned above:

```
$ mariabackup --copy-back \
   --target-dir=/var/mariadb/backup/
```

- Then, you may need to fix the file permissions.

When Mariabackup restores a database, it preserves the file and directory privileges of the backup. However, it writes the files to disk as the user and group restoring the database. As such, after restoring a backup, you may need to adjust the owner of the data directory to match the user and group for the MariaDB Server, typically `mysql` for both. For example, to recursively change ownership of the files to the `mysql` user and group, you could execute:

```
$ chown -R mysql:mysql /var/lib/mysql/
```

- Finally, start the MariaDB Server process.

Restoring with Other Tools

Once a full backup is prepared, it is a fully functional MariaDB data directory. Therefore, as long as the MariaDB Server process is stopped on the target server, you can technically restore the backup using any file copying tool, such as `cp` or `rysnc`. For example, you could also execute the following to restore the backup:

```
$ rsync -avrP /var/mariadb/backup /var/lib/mysql/
$ chown -R mysql:mysql /var/lib/mysql/
```

2.3.4.4 Incremental Backup and Restore with Mariabackup

Contents

When using Mariabackup, you have the option of performing a full or incremental backup. Full backups create a complete copy in an empty directory while incremental backups update a previous backup with new data. This page documents incremental backups.

InnoDB pages contain log sequence numbers, or LSN's. Whenever you modify a row on any InnoDB table on the database, the storage engine increments this number. When performing an incremental backup, Mariabackup checks the most recent LSN for the backup against the LSN's contained in the database. It then updates any of the backup files that have fallen behind.

Backing up the Database Server

In order to take an incremental backup, you first need to take a full backup. In order to back up the database, you need to run Mariabackup with the `--backup` option to tell it to perform a backup and with the `--target-dir` option to tell it where to place the backup files. When taking a full backup, the target directory must be empty or it must not exist.

To take a backup, run the following command:

```
$ mariabackup --backup \
   --target-dir=/var/mariadb/backup/ \
   --user=mariabackup --password=mypassword
```

This backs up all databases into the target directory `/var/mariadb/backup`. If you look in that directory at the `xtrabackup_checkpoints` file, you can see the LSN data provided by InnoDB.

For example:

```
backup_type = full-backuped
from_lsn = 0
to_lsn = 1635102
last_lsn = 1635102
recover_binlog_info = 0
```

Backing up the Incremental Changes

Once you have created a full backup on your system, you can also back up the incremental changes as often as you would like.

In order to perform an incremental backup, you need to run Mariabackup with the `--backup` option to tell it to perform a backup and with the `--target-dir` option to tell it where to place the incremental changes. The target directory must be empty. You also need to run it with the `--incremental-basedir` option to tell it the path to the full backup taken above. For example:

```
$ mariabackup --backup \
   --target-dir=/var/mariadb/inc1/ \
   --incremental-basedir=/var/mariadb/backup/ \
   --user=mariabackup --password=mypassword
```

This command creates a series of delta files that store the incremental changes in `/var/mariadb/inc1` . You can find a similar `xtrabackup_checkpoints` file in this directory, with the updated LSN values.

For example:

```
backup_type = incremental
from_lsn = 1635102
to_lsn = 1635114
last_lsn = 1635114
recover_binlog_info = 0
```

To perform additional incremental backups, you can then use the target directory of the previous incremental backup as the incremental base directory of the next incremental backup. For example:

```
$ mariabackup --backup \
   --target-dir=/var/mariadb/inc2/ \
   --incremental-basedir=/var/mariadb/inc1/ \
   --user=mariabackup --password=mypassword
```

Combining with `--stream` output

When using `--stream` , e.g for compression or encryption using external tools, the `xtrabackup_checkpoints` file containing the information where to continue from on the next incremental backup will also be part of the compressed/encrypted backup file, and so not directly accessible by default.

A directory containing an extra copy of the file can be created using the `--extra-lsndir=...` option though, and this directory can then be passed to the next incremental backup `--incremental-basedir=...` , for example:

```
# initial full backup
$ mariabackup --backup --stream=mbstream \
  --user=mariabackup --password=mypassword \
  --extra-lsndir=backup_base | gzip > backup_base.gz

# incremental backup
$ mariabackup --backup --stream=mbstream \
  --incremental-basedir=backup_base \
  --user=mariabackup --password=mypassword \
  --extra-lsndir=backup_inc1 | gzip > backup-inc1.gz
```

Preparing the Backup

Following the above steps, you have three backups in `/var/mariadb` : The first is a full backup, the others are increments on this first backup. In order to restore a backup to the database, you first need to apply the incremental backups to the base full backup. This is done using the `--prepare` command option. In MariaDB 10.1, you would also have to use the the

`--apply-log-only` option.

In MariaDB 10.2 and later, perform the following process:

First, prepare the base backup:

```
$ mariabackup --prepare \
   --target-dir=/var/mariadb/backup
```

Running this command brings the base full backup, that is, `/var/mariadb/backup`, into sync with the changes contained in the InnoDB redo log collected while the backup was taken.

Then, apply the incremental changes to the base full backup:

```
$ mariabackup --prepare \
   --target-dir=/var/mariadb/backup \
   --incremental-dir=/var/mariadb/inc1
```

Running this command brings the base full backup, that is, `/var/mariadb/backup`, into sync with the changes contained in the first incremental backup.

For each remaining incremental backup, repeat the last step to bring the base full backup into sync with the changes contained in that incremental backup.

Restoring the Backup

Once you've applied all incremental backups to the base, you can restore the backup using either the `--copy-back` or the `--move-back` options. The `--copy-back` option allows you to keep the original backup files. The `--move-back` option actually moves the backup files to the `datadir`, so the original backup files are lost.

- First, stop the MariaDB Server process.
- Then, ensure that the `datadir` is empty.
- Then, run Mariabackup with one of the options mentioned above:

```
$ mariabackup --copy-back \
   --target-dir=/var/mariadb/backup/
```

- Then, you may need to fix the file permissions.

When Mariabackup restores a database, it preserves the file and directory privileges of the backup. However, it writes the files to disk as the user and group restoring the database. As such, after restoring a backup, you may need to adjust the owner of the data directory to match the user and group for the MariaDB Server, typically `mysql` for both. For example, to recursively change ownership of the files to the `mysql` user and group, you could execute:

```
$ chown -R mysql:mysql /var/lib/mysql/
```

- Finally, start the MariaDB Server process.

2.3.4.5 Partial Backup and Restore with Mariabackup

Contents

When using Mariabackup, you have the option of performing partial backups. Partial backups allow you to choose which databases or tables to backup, as long as the table or partition involved is in an InnoDB file-per-table tablespace.This page documents how to perform partial backups.

Backing up the Database Server

Just like with full backups, in order to back up the database, you need to run Mariabackup with the `--backup` option to tell it to perform a backup and with the `--target-dir` option to tell it where to place the backup files. The target directory must be empty or not exist.

For a partial backup, there are a few other arguments that you can provide as well:

- To tell it which databases to backup, you can provide the `--databases` option.
- To tell it which databases to exclude from the backup, you can provide the `--databases-exclude` option.
- To tell it to check a file for the databases to backup, you can provide the `--databases-file` option.
- To tell it which tables to backup, you can use the `--tables` option.
- To tell it which tables to exclude from the backup, you can provide the `--tables-exclude` option.
- To tell it to check a file for specific tables to backup, you can provide the `--tables-file` option.

The non-file partial backup options support regex in the database and table names.

For example, to take a backup of any database that starts with the string `app1_` and any table in those databases that start with the string `tab_`, run the following command:

```
$ mariabackup --backup \
   --target-dir=/var/mariadb/backup/ \
   --databases='app1_*' --tables='tab_*' \
   --user=mariabackup --password=mypassword
```

Mariabackup cannot currently backup a subset of partitions from a partitioned table. Backing up a partitioned table is currently an all-or-nothing selection. See MDEV-17132 about that. If you need to backup a subset of partitions, then one possibility is that instead of using Mariabackup, you can export the file-per-table tablespaces of the partitions.

The time the backup takes depends on the size of the databases or tables you're backing up. You can cancel the backup if you need to, as the backup process does not modify the database.

Mariabackup writes the backup files the target directory. If the target directory doesn't exist, then it creates it. If the target directory exists and contains files, then it raises an error and aborts.

Preparing the Backup

Just like with full backups, the data files that Mariabackup creates in the target directory are not point-in-time consistent, given that the data files are copied at different times during the backup operation. If you try to restore from these files, InnoDB notices the inconsistencies and crashes to protect you from corruption. In fact, for partial backups, the backup is not even a completely functional MariaDB data directory, so InnoDB would raise more errors than it would for full backups. This point will also be very important to keep in mind during the restore process.

Before you can restore from a backup, you first need to **prepare** it to make the data files consistent. You can do so with the `--prepare` command option.

Partial backups rely on InnoDB's transportable tablespaces. For MariaDB to import tablespaces like these, InnoDB looks for a file with a `.cfg` extension. For Mariabackup to create these files, you also need to add the `--export` option during the prepare step.

For example, you might execute the following command:

```
$ mariabackup --prepare --export \
   --target-dir=/var/mariadb/backup/
```

If this operation completes without error, then the backup is ready to be restored.

MariaDB until 10.2.8

In MariaDB 10.2.8 and before, Mariabackup did not support the `--export` option. See MDEV-13466 about that. In these versions of MariaDB, this means that Mariabackup could not create `.cfg` files for InnoDB file-per-table tablespaces during the `--prepare` stage. You can still import file-per-table tablespaces without the `.cfg` files in many cases, so it may still be possible in those versions to restore partial backups or to restore individual tables and partitions with just the `.ibd` files. If you have a full backup and you need to create `.cfg` files for InnoDB file-per-table tablespaces, then you can do so by preparing the backup as usual without the `--export` option, and then restoring the backup, and then starting the server. At that point, you can use the server's built-in features to copy the transportable tablespaces.

Restoring the Backup

The restore process for partial backups is quite different than the process for full backups. A partial backup is not a completely functional data directory. The data dictionary in the InnoDB system tablespace will still contain entries for the databases and tables that were not included in the backup.

Rather than using the `--copy-back` or the `--move-back`, each individual InnoDB file-per-table tablespace file will have to be manually imported into the target server. The process that is used to import the file will depend on whether partitioning is involved.

Restoring Individual Non-Partitioned Tables

To restore individual non-partitioned tables from a backup, find the `.ibd` and `.cfg` files for the table in the backup, and then import them using the Importing Transportable Tablespaces for Non-partitioned Tables process.

Restoring Individual Partitions and Partitioned Tables

To restore individual partitions or partitioned tables from a backup, find the `.ibd` and `.cfg` files for the partition(s) in the backup, and then import them using the Importing Transportable Tablespaces for Partitioned Tables process.

2.3.4.6 Restoring Individual Tables and Partitions with Mariabackup

Contents

When using Mariabackup, you don't necessarily need to restore every table and/or partition that was backed up. Even if you're starting from a full backup, it is certainly possible to restore only certain tables and/or partitions from the backup, as long as the table or partition involved is in an InnoDB file-per-table tablespace. This page documents how to restore individual tables and partitions.

Preparing the Backup

Before you can restore from a backup, you first need to **prepare** it to make the data files consistent. You can do so with the `--prepare` command option.

The ability to restore individual tables and partitions relies on InnoDB's transportable tablespaces. For MariaDB to import tablespaces like these, InnoDB looks for a file with a `.cfg` extension. For Mariabackup to create these files, you also need to add the `--export` option during the prepare step.

For example, you might execute the following command:

```
$ mariabackup --prepare --export \
   --target-dir=/var/mariadb/backup/ \
   --user=mariabackup --password=mypassword
```

If this operation completes without error, then the backup is ready to be restored.

MariaDB until 10.2.8

Before MariaDB 10.2.9, Mariabackup did not support the `--export` option. See MDEV-13466 about that. In earlier versions of MariaDB, this means that Mariabackup could not create `.cfg` files for InnoDB file-per-table tablespaces during the `--prepare` stage. You can still import file-per-table tablespaces without the `.cfg` files in many cases, so it may still be possible in those versions to restore partial backups or to restore individual tables and partitions with just the `.ibd` files. If you have a full backup and you need to create `.cfg` files for InnoDB file-per-table tablespaces, then you can do so by preparing the backup as usual without the `--export` option, and then restoring the backup, and then starting the server. At that point, you can use the server's built-in features to copy the transportable tablespaces.

Restoring the Backup

The restore process for restoring individual tables and/or partitions is quite different than the process for full backups.

Rather than using the `--copy-back` or the `--move-back`, each individual InnoDB file-per-table tablespace file will have to be manually imported into the target server. The process that is used to restore the backup will depend on whether partitioning is involved.

Restoring Individual Non-Partitioned Tables

To restore individual non-partitioned tables from a backup, find the `.ibd` and `.cfg` files for the table in the backup, and then import them using the Importing Transportable Tablespaces for Non-partitioned Tables process.

Restoring Individual Partitions and Partitioned Tables

To restore individual partitions or partitioned tables from a backup, find the `.ibd` and `.cfg` files for the partition(s) in the backup, and then import them using the Importing Transportable Tablespaces for Partitioned Tables process.

2.3.4.7 Setting up a Replica with Mariabackup

The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Contents

Mariabackup makes it very easy to set up a replica using a full backup. This page documents how to set up a replica from a backup.

If you are using MariaDB Galera Cluster, then you may want to try one of the following pages instead:

- Configuring MariaDB Replication between MariaDB Galera Cluster and MariaDB Server
- Configuring MariaDB Replication between Two MariaDB Galera Clusters

Backup the Database and Prepare It

The first step is to simply take and prepare a fresh full backup of a database server in the replication topology. If the source database server is the desired replication primary, then we do not need to add any additional options when taking the full backup. For example:

```
$ mariabackup --backup \
   --target-dir=/var/mariadb/backup/ \
   --user=mariabackup --password=mypassword
```

If the source database server is a replica of the desired primary, then we should add the --slave-info option, and possibly the --safe-slave-backup option. For example:

```
$ mariabackup --backup \
   --slave-info --safe-slave-backup \
   --target-dir=/var/mariadb/backup/ \
   --user=mariabackup --password=mypassword
```

And then we would prepare the backup as you normally would. For example:

```
$ mariabackup --prepare \
   --target-dir=/var/mariadb/backup/
```

Copy the Backup to the New Replica

Once the backup is done and prepared, we can copy it to the new replica. For example:

```
$ rsync -avP /var/mariadb/backup dbserver2:/var/mariadb/backup
```

Restore the Backup on the New Replica

At this point, we can restore the backup to the datadir, as you normally would. For example:

```
$ mariabackup --copy-back \
   --target-dir=/var/mariadb/backup/
```

And adjusting file permissions, if necessary:

```
$ chown -R mysql:mysql /var/lib/mysql/
```

Create a Replication User on the Primary

Before the new replica can begin replicating from the primary, we need to create a user account on the primary that the replica can use to connect, and we need to grant the user account the REPLICATION SLAVE privilege. For example:

```
CREATE USER 'repl'@'dbserver2' IDENTIFIED BY 'password';
GRANT REPLICATION SLAVE ON *.*  TO 'repl'@'dbserver2';
```

Configure the New Replica

Before we start the server on the new replica, we need to configure it. At the very least, we need to ensure that it has a unique server_id value. We also need to make sure other replication settings are what we want them to be, such as the various GTID system variables, if those apply in the specific environment.

Once configuration is done, we can start the MariaDB Server process on the new replica.

Start Replication on the New Replica

At this point, we need to get the replication coordinates of the primary from the original backup directory.

If we took the backup on the primary, then the coordinates will be in the xtrabackup_binlog_info file. If we took the backup on another replica and if we provided the --slave-info option, then the coordinates will be in the file xtrabackup_slave_info file.

Mariabackup dumps replication coordinates in two forms: GTID coordinates and binary log file and position coordinates, like the ones you would normally see from SHOW MASTER STATUS output. We can choose which set of coordinates we would like to use to set up replication.

For example:

```
mariadb-bin.000096 568 0-1-2
```

Regardless of the coordinates we use, we will have to set up the primary connection using CHANGE MASTER TO and then start the replication threads with START SLAVE.

GTIDs

If we want to use GTIDs, then we will have to first set gtid_slave_pos to the GTID coordinates that we pulled from either the xtrabackup_binlog_info file or the xtrabackup_slave_info file in the backup directory. For example:

```
$ cat xtrabackup_binlog_info
mariadb-bin.000096 568 0-1-2
```

And then we would set `MASTER_USE_GTID=slave_pos` in the CHANGE MASTER TO command. For example:

```
SET GLOBAL gtid_slave_pos = "0-1-2";
CHANGE MASTER TO
   MASTER_HOST="dbserver1",
   MASTER_PORT=3306,
   MASTER_USER="repl",
   MASTER_PASSWORD="password",
   MASTER_USE_GTID=slave_pos;
START SLAVE;
```

File and Position

If we want to use the binary log file and position coordinates, then we would set `MASTER_LOG_FILE` and `MASTER_LOG_POS` in the CHANGE MASTER TO command to the file and position coordinates that we pulled; either the xtrabackup_binlog_info file or the xtrabackup_slave_info file in the backup directory, depending on whether the backup was taken from the primary or from a replica of the primary. For example:

```
CHANGE MASTER TO
   MASTER_HOST="dbserver1",
   MASTER_PORT=3306,
   MASTER_USER="repl",
   MASTER_PASSWORD="password",
   MASTER_LOG_FILE='mariadb-bin.000096',
   MASTER_LOG_POS=568;
START SLAVE;
```

Check the Status of the New Replica

We should be done setting up the replica now, so we should check its status with SHOW SLAVE STATUS. For example:

```
SHOW SLAVE STATUS\G
```

2.3.4.8 Files Backed Up By Mariabackup

Contents

Files Included in Backup

Mariabackup backs up the files listed below.

InnoDB Data Files

Mariabackup backs up the following InnoDB data files:

- InnoDB system tablespace
- InnoDB file-per-table tablespaces

MyRocks Data Files

Starting with MariaDB 10.2.16 and MariaDB 10.3.8, Mariabackup will back up tables that use the MyRocks storage engine. This data data is located in the directory defined by the `rocksdb_datadir` system variable. Mariabackup backs this data up by performing a checkpoint using the `rocksdb_create_checkpoint` system variable.

Mariabackup does not currently support partial backups for MyRocks.

Other Data Files

Mariabackup also backs up files with the following extensions:

- frm
- isl
- MYD
- MYI
- MAD
- MAI
- MRG
- TRG
- TRN
- ARM
- ARZ
- CSM
- CSV
- opt
- par

Files Excluded From Backup

Mariabackup does **not** back up the files listed below.

- InnoDB Temporary Tablespaces
- Binary logs
- Relay logs

2.3.4.9 Files Created by Mariabackup

Contents

Mariabackup creates the following files:

backup-my.cnf

During the backup, any server options relevant to Mariabackup are written to the `backup-my.cnf` option file, so that they can be re-read later during the `--prepare` stage.

ib_logfile0

In MariaDB 10.2.10 and later, Mariabackup creates an empty InnoDB redo log file called `ib_logfile0` as part of the `--prepare` stage. This file has 3 roles:

1. In the source server, `ib_logfile0` is the first (and possibly the only) InnoDB redo log file.
2. In the non-prepared backup, `ib_logfile0` contains all of the InnoDB redo log copied during the backup. Previous versions of Mariabackup would use a file called `xtrabackup_logfile` for this.
3. During the `--prepare` stage, `ib_logfile0` would previously be deleted. Now during the `--prepare` stage, `ib_logfile0` is initialized as an empty InnoDB redo log file. That way, if the backup is manually restored, any pre-existing InnoDB redo log files would get overwritten by the empty one. This helps to prevent certain kinds of known issues. For example, see Mariabackup Overview: Manual Restore with Pre-existing InnoDB Redo Log files.

xtrabackup_logfile

In MariaDB 10.2.9 and before, Mariabackup creates `xtrabackup_logfile` to store the InnoDB redo log, In later versions, `ib_logfile0` is created instead.

xtrabackup_binlog_info

This file stores the binary log file name and position that corresponds to the backup.

This file also stores the value of the `gtid_current_pos` system variable that correspond to the backup.

For example:

```
mariadb-bin.000096 568 0-1-2
```

The values in this file are only guaranteed to be consistent with the backup if the `--no-lock` option was **not** provided when the backup was taken.

xtrabackup_binlog_pos_innodb

This file is created by mariabackup to provide the binary log file name and position when the --no-lock option is used. It can be used instead of the file "xtrabackup_binlog_info" to obtain transactionally consistent binlog coordinates from the backup of a master server with the --no-lock option to minimize the impact on a running server.

Whenever a transaction is committed inside InnoDB when the binary log is enabled, the corresponding binlog coordinates are written to the InnoDB redo log along with the transaction commit. This allows one to restore the binlog coordinates corresponding to the last commit done by InnoDB along with a backup.

The limitation of using "xtrabackup_binlog_pos_innodb" with the "--no-lock" option is that no DDL or modification of non-transactional tables should be done during the backup. If the last event in the binlog is a DDL/non-transactional update, the coordinates in the file "xtrabackup_binlog_pos_innodb" will be too old. But as long as only InnoDB updates are done during the backup, the coordinates will be correct.

xtrabackup_checkpoints

The `xtrabackup_checkpoints` file contains metadata about the backup.

For example:

```
backup_type = full-backuped
from_lsn = 0
to_lsn = 1635102
last_lsn = 1635102
recover_binlog_info = 0
```

See below for a description of the fields.

If the `--extra-lsndir` option is provided, then an extra copy of this file will be saved in that directory.

backup_type

If the backup is a non-prepared full backup or a non-prepared partial backup, then `backup_type` is set to `full-backuped`.

If the backup is a non-prepared incremental backup, then `backup_type` is set to `incremental`.

If the backup has already been prepared, then `backup_type` is set to `log-applied`.

from_lsn

If `backup_type` is `full-backuped`, then `from_lsn` has the value of `0`.

If `backup_type` is `incremental`, then `from_lsn` has the value of the log sequence number (LSN) at which the backup started reading from the InnoDB redo log. This is internally used by Mariabackup when preparing incremental backups.

This value can be manually set during an incremental backup with the `--incremental-lsn` option. However, it is generally better to let Mariabackup figure out the `from_lsn` automatically by specifying a parent backup with the `--incremental-basedir` option.

to_lsn

`to_lsn` has the value of the log sequence number (LSN) of the last checkpoint in the InnoDB redo log. This is internally used by Mariabackup when preparing incremental backups.

last_lsn

`last_lsn` has the value of the last log sequence number (LSN) read from the InnoDB redo log. This is internally used by Mariabackup when preparing incremental backups.

xtrabackup_info

The `xtrabackup_info` file contains information about the backup. The fields in this file are listed below.

If the `--extra-lsndir` option is provided, then an extra copy of this file will be saved in that directory.

uuid

If a UUID was provided by the `--incremental-history-uuid` option, then it will be saved here. Otherwise, this will be the empty string.

name

If a name was provided by the `--history` or the `---incremental-history-name` options, then it will be saved here. Otherwise, this will be the empty string.

tool_name

The name of the Mariabackup executable that performed the backup. This is generally `mariabackup`.

tool_command

The arguments that were provided to Mariabackup when it performed the backup.

tool_version

The version of Mariabackup that performed the backup.

ibbackup_version

The version of Mariabackup that performed the backup.

server_version

The version of MariaDB Server that was backed up.

start_time

The time that the backup started.

end_time

The time that the backup ended.

lock_time

The amount of time that Mariabackup held its locks.

binlog_pos

This field stores the binary log file name and position that corresponds to the backup.

This field also stores the value of the `gtid_current_pos` system variable that correspond to the backup.

The values in this field are only guaranteed to be consistent with the backup if the `--no-lock` option was **not** provided when the backup was taken.

innodb_from_lsn

This is identical to `from_lsn` in `xtrabackup_checkpoints`.

If the backup is a full backup, then `innodb_from_lsn` has the value of `0`.

If the backup is an incremental backup, then `innodb_from_lsn` has the value of the log sequence number (LSN) at which the backup started reading from the InnoDB redo log.

innodb_to_lsn

This is identical to `to_lsn` in `xtrabackup_checkpoints`.

`innodb_to_lsn` has the value of the log sequence number (LSN) of the last checkpoint in the InnoDB redo log.

partial

If the backup is a partial backup, then this value will be `Y`.

Otherwise, this value will be `N`.

incremental

If the backup is an incremental backup, then this value will be `Y`.

Otherwise, this value will be `N`.

format

This field's value is the format of the backup.

If the `--stream` option was set to `xbstream`, then this value will be `xbstream`.

If the `--stream` option was **not** provided, then this value will be `file`.

compressed

If the `--compress` option was provided, then this value will be `compressed`.

Otherwise, this value will be `N`.

xtrabackup_slave_info

If the `--slave-info` option is provided, then this file contains the `CHANGE MASTER` command that can be used to set up a new server as a slave of the original server's master after the backup has been restored.

Mariabackup does **not** check if GTIDs are being used in replication. It takes a shortcut and assumes that if the `gtid_slave_pos` system variable is non-empty, then it writes the `CHANGE MASTER` command with the `MASTER_USE_GTID` option set to `slave_pos`. Otherwise, it writes the `CHANGE MASTER` command with the `MASTER_LOG_FILE` and `MASTER_LOG_POS` options using the master's binary log file and position. See MDEV-19264 for more information.

xtrabackup_galera_info

If the `--galera-info` option is provided, then this file contains information about a Galera Cluster node's state.

The file contains the values of the `wsrep_local_state_uuid` and `wsrep_last_committed` status variables.

The values are written in the following format:

```
wsrep_local_state_uuid:wsrep_last_committed
```

For example:

```
d38587ce-246c-11e5-bcce-6bbd0831cc0f:1352215
```

<table>.delta

If the backup is an incremental backup, then this file contains changed pages for the table.

<table>.delta.meta

If the backup is an incremental backup, then this file contains metadata about `<table>.delta` files. The fields in this file are listed below.

page_size

This field contains either the value of `innodb_page_size` or the value of the `KEY_BLOCK_SIZE` table option for the table if the `ROW_FORMAT` table option for the table is set to `COMPRESSED`.

zip_size

If the `ROW_FORMAT` table option for this table is set to `COMPRESSED`, then this field contains the value of the compressed page size.

space_id

This field contains the value of the table's `space_id`.

2.3.4.10 Using Encryption and Compression Tools With Mariabackup

Contents

Mariabackup supports streaming to stdout with the `--stream=xbstream` option. This option allows easy integration with popular encryption and compression tools. Below are several examples.

Encrypting and Decrypting Backup With openssl

The following example creates an AES-encrypted backup, protected with the password "mypass" and stores it in a file "backup.xb.enc":

```
mariabackup --user=root --backup --stream=xbstream  | openssl  enc -aes-256-cbc -k mypass >
backup.xb.enc
```

To decrypt and unpack this backup into the current directory, the following command can be used:

```
openssl  enc -d -aes-256-cbc -k mypass -in backup.xb.enc | mbstream -x
```

Compressing and Decompressing Backup With gzip

This example compresses the backup without encrypting:

```
mariabackup --user=root --backup --stream=xbstream | gzip > backupstream.gz
```

We can decompress and unpack the backup as follows:

```
gunzip -c backupstream.gz | mbstream -x
```

Compressing and Encrypting Backup, Using gzip and openssl

This example adds a compression step before the encryption, otherwise looks almost identical to the previous example:

```
mariabackup --user=root --backup --stream=xbstream | gzip | openssl  enc -aes-256-cbc -k mypass
> backup.xb.gz.enc
```

We can decrypt, decompress and unpack the backup as follow (note `gzip -d` in the pipeline):

```
openssl  enc -d -aes-256-cbc -k mypass -in backup.xb.gz.enc |gzip -d| mbstream -x
```

Compressing and Encrypting with 7Zip

7zip archiver is a popular utility (especially on Windows) that supports reading from standard output, with the - `-si` option, and writing to stdout with the `-so` option, and can thus be used together with Mariabackup.

Compressing backup with the 7z command line utility works as follows:

```
mariabackup --user=root --backup --stream=xbstream | 7z a -si backup.xb.7z
```

Uncompress and unpack the archive with

```
7z e backup.xb.7z -so |mbstream -x
```

7z also has builtin AES-256 encryption. To encrypt the backup from the previous example using password SECRET, add `-pSECRET` to the 7z command line.

Encrypting With GPG

Encryption

```
mariabackup --user=root --backup --stream=xbstream | gpg -c --passphrase SECRET --batch --yes -o backup.xb.gpg
```

Decrypt, unpack

```
gpg --decrypt --passphrase SECRET --batch --yes  backup.xb.gpg | mbstream -x
```

Interactive Input for Passphrases

Most of the described tools also provide a way to enter a passphrase interactively (although 7zip does not seem to work well when reading input from stdin). Please consult documentation of the tools for more info.

Writing extra status files

By default files like `xtrabackup_checkpoints` are also written to the output stream only, and so would not be available for taking further incremental backups without prior extraction from the compressed or encrypted stream output file.

To avoid this these files can additionally be written to a directory that can then be used as input for further incremental backups using the `--extra-lsndir=...` option.

See also e.g: Combining incremental backups with streaming output

2.3.4.11 How Mariabackup Works

Contents

This is a description of the different stages in Mariabackup, what they do and why they are needed.

Note that a few items are marked with `TODO`; these are things we are working on and will be in next version of Mariabackup.

Execution Stages

Initialization Phase

- Connect to mysqld instance, find out important variables (datadir ,InnoDB pagesize, encryption keys, encryption plugin etc)
- Scan the database directory, `datadir`, looking for InnoDB tablespaces, load the tablespaces (basically, it is an “open” in InnoDB sense)
- If --lock-ddl-per-table is used:
  - Do MDL locks, for InnoDB tablespaces that we want to copy. This is to ensure that there are no ALTER, RENAME , TRUNCATE or DROP TABLE on any of the tables that we want to copy.
  - This is implemented with:

```
BEGIN
For each affected table
SELECT 1 from <table> LIMIT 0
```

- If lock-ddl-per-table is not done, then Mariabackup would have to know all tables that were created or altered during the backup. See MDEV-16791.

Redo Log Handling

Start a dedicated thread in Mariabackup to copy InnoDB redo log (`ib_logfile*`).

- This is needed to record all changes done while the backup is running. (The redo log logically is a single circular file, split into innodb_log_files_in_group files.)
- The log is also used to see detect if any truncate or online alter tables are used.
- The assumption is that the copy thread will be able to keep up with server. It should always be able keep up, if the redo log is big enough.

Copy-phase for InnoDB Tablespaces

- Copy all selected tablespaces, file by file, in dedicated threads in Mariabackup without involving the mysqld server.
- This is special “careful” copy, it looks for page-level consistency by checking the checksum.
- The files are not point-in-time consistent as data may change during copy.
- The idea is that InnoDB recovery would make it point-in-time consistent.
- Copy Aria log files (TODO)

Create a Consistent Backup Point

- Execute FLUSH TABLE WITH READ LOCK. This is default, but may be omitted with the `--no-lock` parameter. The reason why `FLUSH` is needed is to ensure that all tables are in a consistent state at the exact same point in time, independent of storage engine.
- If `--lock-ddl-per-table` is used and there is a user query waiting for MDL, the user query will be killed to resolve a deadlock. Note that these are only queries of type ALTER, DROP, TRUNCATE or RENAME TABLE. (MDEV-15636)

Last Copy Phase

- Copy `.frm`, `MyISAM`, `Aria` and other storage engine files
- If `MyRocks` is used, create rocksdb checkpoint via "set rocksdb_create_checkpoint=$rocksdb_data_dir/mariabackup_rocksdb_checkpoint " command. The result of it is a directory with hardlinks to MyRocks files. Copy the checkpoint directory to the backup (or create hardlinks in backup directory is on the same partition as data directory). Remove the checkpoint directory.
- Copy tables that were created while the backup was running and do rename files that were changed during backup (since MDEV-16791)
- Copy the rest of InnoDB redo log, stop redo-log-copy thread
- Copy changes to Aria log files (They are append only, so this is easy to do) (TODO)
- Write some metadata info (binlog position)

Release Locks

- If FLUSH TABLE WITH READ LOCK was done:
  - execute: `UNLOCK TABLES`
- If `--lock-ddl-per-table` was done:
  - execute `COMMIT`

Handle Log Tables (TODO)

- If log tables exists:
  - Take MDL lock for log tables
  - Copy part of log tables that wasn't copied before
  - Unlock log tables

Notes

- If FLUSH TABLE WITH READ LOCK is not used, then only InnoDB tables will be consistent (not the privilege tables in the mysql database or the binary log). The backup point depends on the content of the redo log within the backup itself.

2.3.4.12 Mariabackup and BACKUP STAGE Commands

MariaDB starting with 10.4.1

The `BACKUP STAGE` commands were introduced in MariaDB 10.4.1.

Contents

The `BACKUP STAGE` commands are a set of commands to make it possible to make an efficient external backup tool. How Mariabackup uses these commands depends on whether you are using the version that is bundled with MariaDB Community Server or the version that is bundled with MariaDB Enterprise Server.

Mariabackup and `BACKUP STAGE` Commands in MariaDB Community Server

MariaDB starting with 10.4.1

In MariaDB Community Server, Mariabackup first supported `BACKUP STAGE` commands in MariaDB 10.4.1.

In MariaDB 10.3 and before, the `BACKUP STAGE` commands are **not** supported, so Mariabackup executes the `FLUSH TABLES WITH READ LOCK` command to lock the database. When the backup is complete, it executes the `UNLOCK TABLES` command to unlock the database.

In MariaDB 10.4 and later, the `BACKUP STAGE` commands are supported. However, the version of Mariabackup that is bundled with MariaDB Community Server does not yet use the `BACKUP STAGE` commands in the most efficient way. Mariabackup simply executes the following `BACKUP STAGE` commands to lock the database:

```
BACKUP STAGE START;
BACKUP STAGE BLOCK_COMMIT;
```

When the backup is complete, it executes the following `BACKUP STAGE` command to unlock the database:

```
BACKUP STAGE END;
```

If you would like to use a version of Mariabackup that uses the `BACKUP STAGE` commands in the most efficient way, then your best option is to use MariaDB Enterprise Backup that is bundled with MariaDB Enterprise Server.

Tasks Performed Prior to `BACKUP STAGE` in MariaDB Community Server

- Copy some transactional tables.
  - InnoDB (i.e. `ibdataN` and file extensions `.ibd` and `.isl`)

- Copy the tail of some transaction logs.
  - The tail of the InnoDB redo log (i.e. `ib_logfileN` files) will be copied for InnoDB tables.

`BACKUP STAGE START` in MariaDB Community Server

Mariabackup from MariaDB Community Server does not currently perform any tasks in the `START` stage.

`BACKUP STAGE FLUSH` in MariaDB Community Server

Mariabackup from MariaDB Community Server does not currently perform any tasks in the `FLUSH` stage.

`BACKUP STAGE BLOCK_DDL` in MariaDB Community Server

Mariabackup from MariaDB Community Server does not currently perform any tasks in the `BLOCK_DDL` stage.

`BACKUP STAGE BLOCK_COMMIT` in MariaDB Community Server

Mariabackup from MariaDB Community Server performs the following tasks in the `BLOCK_COMMIT` stage:

- Copy other files.
  - i.e. file extensions `.frm`, `.isl`, `.TRG`, `.TRN`, `.opt`, `.par`
- Copy some transactional tables.
  - Aria (i.e. `aria_log_control` and file extensions `.MAD` and `.MAI`)
- Copy the non-transactional tables.
  - MyISAM (i.e. file extensions `.MYD` and `.MYI`)
  - MERGE (i.e. file extensions `.MRG`)
  - ARCHIVE (i.e. file extensions `.ARM` and `.ARZ`)
  - CSV (i.e. file extensions `.CSM` and `.CSV`)
- Create a MyRocks checkpoint using the `rocksdb_create_checkpoint` system variable.
- Copy the tail of some transaction logs.
  - The tail of the InnoDB redo log (i.e. `ib_logfileN` files) will be copied for InnoDB tables.
- Save the binary log position to `xtrabackup_binlog_info`.
- Save the Galera Cluster state information to `xtrabackup_galera_info`.

`BACKUP STAGE END` in MariaDB Community Server

Mariabackup from MariaDB Community Server performs the following tasks in the `END` stage:

- Copy the MyRocks checkpoint into the backup.

Mariabackup and `BACKUP STAGE` Commands in MariaDB Enterprise Server

MariaDB starting with 10.2.25

MariaDB Enterprise Backup first supported `BACKUP STAGE` commands in MariaDB Enterprise Server 10.4.6-1, MariaDB Enterprise Server 10.3.16-1, and MariaDB Enterprise Server 10.2.25-1.

The following sections describe how the MariaDB Enterprise Backup version of Mariabackup that is bundled with MariaDB Enterprise Server uses each `BACKUP STAGE` command in an efficient way.

`BACKUP STAGE START` in MariaDB Enterprise Server

Mariabackup from MariaDB Enterprise Server performs the following tasks in the `START` stage:

- Copy all transactional tables.
  - InnoDB (i.e. `ibdataN` and file extensions `.ibd` and `.isl`)
  - Aria (i.e. `aria_log_control` and file extensions `.MAD` and `.MAI`)
- Copy the tail of all transaction logs.
  - The tail of the InnoDB redo log (i.e. `ib_logfileN` files) will be copied for InnoDB tables.
  - The tail of the Aria redo log (i.e. `aria_log.N` files) will be copied for Aria tables.

`BACKUP STAGE FLUSH` in MariaDB Enterprise Server

Mariabackup from MariaDB Enterprise Server performs the following tasks in the `FLUSH` stage:

- Copy all non-transactional tables that are not in use. This list of used tables is found with `SHOW OPEN TABLES`.
  - MyISAM (i.e. file extensions `.MYD` and `.MYI`)
  - MERGE (i.e. file extensions `.MRG`)
  - ARCHIVE (i.e. file extensions `.ARM` and `.ARZ`)
  - CSV (i.e. file extensions `.CSM` and `.CSV`)
- Copy the tail of all transaction logs.
  - The tail of the InnoDB redo log (i.e. `ib_logfileN` files) will be copied for InnoDB tables.
  - The tail of the Aria redo log (i.e. `aria_log.N` files) will be copied for Aria tables.

`BACKUP STAGE BLOCK_DDL` in MariaDB Enterprise Server

Mariabackup from MariaDB Enterprise Server performs the following tasks in the `BLOCK_DDL` stage:

- Copy other files.
  - i.e. file extensions `.frm`, `.isl`, `.TRG`, `.TRN`, `.opt`, `.par`
- Copy the non-transactional tables that were in use during `BACKUP STAGE FLUSH`.
  - MyISAM (i.e. file extensions `.MYD` and `.MYI`)
  - MERGE (i.e. file extensions `.MRG`)
  - ARCHIVE (i.e. file extensions `.ARM` and `.ARZ`)
  - CSV (i.e. file extensions `.CSM` and `.CSV`)
- Check `ddl.log` for DDL executed before the `BLOCK DDL` stage.
  - The file names of newly created tables can be read from `ddl.log`.
  - The file names of dropped tables can also be read from `ddl.log`.
  - The file names of renamed tables can also be read from `ddl.log`, so the files can be renamed instead of re-copying them.
- Copy changes to system log tables.
  - `mysql.general_log`
  - `mysql.slow_log`
  - This is easy as these are append only.
- Copy the tail of all transaction logs.
  - The tail of the InnoDB redo log (i.e. `ib_logfileN` files) will be copied for InnoDB tables.
  - The tail of the Aria redo log (i.e. `aria_log.N` files) will be copied for Aria tables.

`BACKUP STAGE BLOCK_COMMIT` in MariaDB Enterprise Server

Mariabackup from MariaDB Enterprise Server performs the following tasks in the `BLOCK_COMMIT` stage:

- Create a MyRocks checkpoint using the `rocksdb_create_checkpoint` system variable.
- Copy changes to system log tables.
  - `mysql.general_log`
  - `mysql.slow_log`
  - This is easy as these are append only.
- Copy changes to statistics tables.
  - `mysql.table_stats`
  - `mysql.column_stats`
  - `mysql.index_stats`
- Copy the tail of all transaction logs.
  - The tail of the InnoDB redo log (i.e. `ib_logfileN` files) will be copied for InnoDB tables.
  - The tail of the Aria redo log (i.e. `aria_log.N` files) will be copied for Aria tables.
- Save the binary log position to `xtrabackup_binlog_info`.
- Save the Galera Cluster state information to `xtrabackup_galera_info`.

`BACKUP STAGE END` in MariaDB Enterprise Server

Mariabackup from MariaDB Enterprise Server performs the following tasks in the `END` stage:

- Copy the MyRocks checkpoint into the backup.

2.3.4.13 mariabackup SST Method

The `mariabackup` SST method uses the Mariabackup utility for performing SSTs. It is one of the methods that does not block the donor node. Mariabackup was originally forked from Percona XtraBackup, and similarly, the `mariabackup` SST method was originally forked from the `xtrabackup-v2` SST method.

Note that if you use the `mariabackup` SST method, then you also need to have `socat` installed on the server. This is needed to stream the backup from the donor node to the joiner node. This is a limitation that was inherited from the `xtrabackup-v2` SST method.

Contents

Choosing Mariabackup for SSTs

To use the `mariabackup` SST method, you must set the `wsrep_sst_method=mariabackup` on both the donor and joiner node. It can be changed dynamically with `SET GLOBAL` on the node that you intend to be a SST donor. For example:

```
SET GLOBAL wsrep_sst_method='mariabackup';
```

It can be set in a server option group in an option file prior to starting up a node:

```
[mariadb]
...
wsrep_sst_method = mariabackup
```

For an SST to work properly, the donor and joiner node must use the same SST method. Therefore, it is recommended to set `wsrep_sst_method` to the same value on all nodes, since any node will usually be a donor or joiner node at some point.

Major version upgrades

The InnoDB redo log format has been changed in MariaDB 10.5 and MariaDB 10.8 in a way that will not allow the crash recovery or the preparation of a backup from an older major version. Because of this, the `mariabackup` SST method cannot be used for some major version upgrades, unless you temporarily edit the `wsrep_sst_mariabackup` script so that the `--prepare` step on the newer-major-version joiner will be executed using the older-major-version `mariabackup` tool.

The default method `wsrep_sst_method=rsync` will work for major version upgrades; see MDEV-27437.

Authentication and Privileges

To use the `mariabackup` SST method, Mariabackup needs to be able to authenticate locally on the donor node, so that it can create a backup to stream to the joiner. You can tell the donor node what username and password to use by setting the `wsrep_sst_auth` system variable. It can be changed dynamically with `SET GLOBAL` on the node that you intend to be a SST donor. For example:

```
SET GLOBAL wsrep_sst_auth = 'mariabackup:mypassword';
```

It can also be set in a server option group in an option file prior to starting up a node:

```
[mariadb]
...
wsrep_sst_auth = mariabackup:mypassword
```

Some authentication plugins do not require a password. For example, the `unix_socket` and `gssapi` authentication plugins do not require a password. If you are using a user account that does not require a password in order to log in, then you can just leave the password component of `wsrep_sst_auth` empty. For example:

```
[mariadb]
...
wsrep_sst_auth = mariabackup:
```

The user account that performs the backup for the SST needs to have the same privileges as Mariabackup, which are the `RELOAD`, `PROCESS`, `LOCK TABLES` and `REPLICATION CLIENT` global privileges. To be safe, you should ensure that these privileges are set on each node in your cluster. Mariabackup connects locally on the donor node to perform the backup, so the following user should be sufficient:

```
CREATE USER 'mariabackup'@'localhost' IDENTIFIED BY 'mypassword';
GRANT RELOAD, PROCESS, LOCK TABLES, REPLICATION CLIENT ON *.* TO 'mariabackup'@'localhost';
```

Passwordless Authentication - Unix Socket

It is possible to use the `unix_socket` authentication plugin for the user account that performs SSTs. This would provide the benefit of not needing to configure a plain-text password in `wsrep_sst_auth`.

The user account would have to have the same name as the operating system user account that is running the `mysqld` process. On many systems, this is the user account configured as the `user` option, and it tends to default to `mysql`.

For example, if the `unix_socket` authentication plugin is already installed, then you could execute the following to create the user account:

```
CREATE USER 'mysql'@'localhost' IDENTIFIED VIA unix_socket;
GRANT RELOAD, PROCESS, LOCK TABLES, REPLICATION CLIENT ON *.* TO 'mysql'@'localhost';
```

And then to configure `wsrep_sst_auth`, you could set the following in a server option group in an option file prior to starting up a node:

```
[mariadb]
...
wsrep_sst_auth = mysql:
```

Passwordless Authentication - GSSAPI

It is possible to use the `gssapi` authentication plugin for the user account that performs SSTs. This would provide the benefit of not needing to configure a plain-text password in `wsrep_sst_auth`.

The following steps would need to be done beforehand:

- You need a KDC running MIT Kerberos or Microsoft Active Directory.
- You will need to create a keytab file for the MariaDB server.
- You will need to install the package containing the `gssapi` authentication plugin.
- You will need to install the plugin in MariaDB, so that the `gssapi` authentication plugin is available to use.
- You will need to configure the plugin.
- You will need to create a user account that authenticates with the `gssapi` authentication plugin, so that the user account can be used for SSTs. This user account will need to correspond with a user account that exists on the backend KDC.

For example, you could execute the following to create the user account in MariaDB:

```
CREATE USER 'mariabackup'@'localhost' IDENTIFIED VIA gssapi;
GRANT RELOAD, PROCESS, LOCK TABLES, REPLICATION CLIENT ON *.* TO 'mariabackup'@'localhost';
```

And then to configure `wsrep_sst_auth`, you could set the following in a server option group in an option file prior to starting up a node:

```
[mariadb]
...
wsrep_sst_auth = mariabackup:
```

Choosing a Donor Node

When Mariabackup is used to create the backup for the SST on the donor node, Mariabackup briefly requires a system-wide lock at the end of the backup. In MariaDB 10.3 and before, this is done with `FLUSH TABLES WITH READ LOCK`. In MariaDB 10.4 and later, this is done with `BACKUP STAGE BLOCK_COMMIT`.

If a specific node in your cluster is acting as the *primary* node by receiving all of the application's write traffic, then this node should not usually be used as the donor node, because the system-wide lock could interfere with the application. In this case, you can define one or more preferred donor nodes by setting the `wsrep_sst_donor` system variable.

For example, let's say that we have a 5-node cluster with the nodes `node1`, `node2`, `node3`, `node4`, and `node5`, and let's say that `node1` is acting as the *primary* node. The preferred donor nodes for `node2` could be configured by setting the following in a server option group in an option file prior to starting up a node:

```
[mariadb]
...
wsrep_sst_donor=node3,node4,node5,
```

The trailing comma tells the server to allow any other node as donor when the preferred donors are not available. Therefore, if `node1` is the only node left in the cluster, the trailing comma allows it to be used as the donor node.

Socat Dependency

During the SST process, the donor node uses socat to stream the backup to the joiner node. Then the joiner node prepares the backup before restoring it. The socat utility must be installed on both the donor node and the joiner node in order for this to work. Otherwise, the MariaDB error log will contain an error like:

```
WSREP_SST: [ERROR] socat not found in path:
/usr/sbin:/sbin:/usr//bin:/usr/local/sbin:/usr/local/bin:/usr/sbin:/usr/bin (20180122
14:55:32.993)
```

Installing Socat on RHEL/CentOS

On RHEL/CentOS, `socat` can be installed from the Extra Packages for Enterprise Linux (EPEL) repository.

TLS

This SST method supports two different TLS methods. The specific method can be selected by setting the `encrypt` option in the `[sst]` section of the MariaDB configuration file. The options are:

- TLS using OpenSSL encryption built into `socat` (`encrypt=2`)
- TLS using OpenSSL encryption with Galera-compatible certificates and keys (`encrypt=3`)

Note that `encrypt=1` refers to a TLS encryption method that has been deprecated and removed. `encrypt=4` refers to a TLS encryption method in `xtrabackup-v2` that has not yet been ported to `mariabackup`. See MDEV-18050 about that.

TLS Using OpenSSL Encryption Built into Socat

To generate keys compatible with this encryption method, you can follow these directions.

For example:

- First, generate the keys and certificates:

```
FILENAME=sst
openssl genrsa -out $FILENAME.key 1024
openssl req -new -key $FILENAME.key -x509 -days 3653 -out $FILENAME.crt
cat $FILENAME.key $FILENAME.crt >$FILENAME.pem
chmod 600 $FILENAME.key $FILENAME.pem
```

- On some systems, you may also have to add dhparams to the certificate:

```
openssl dhparam -out dhparams.pem 2048
cat dhparams.pem >> sst.pem
```

- Then, copy the certificate and keys to all nodes in the cluster.
- Then, configure the following on all nodes in the cluster:

```
[sst]
encrypt=2
tca=/etc/my.cnf.d/certificates/sst.crt
tcert=/etc/my.cnf.d/certificates/sst.pem
```

But replace the paths with whatever is relevant on your system.

This should allow your SSTs to be encrypted.

TLS Using OpenSSL Encryption with Galera-compatible Certificates and Keys

To generate keys compatible with this encryption method, you can follow these directions.

For example:

- First, generate the keys and certificates:

```
# CA
openssl genrsa 2048 > ca-key.pem
openssl req -new -x509 -nodes -days 365000 \
-key ca-key.pem -out ca-cert.pem

# server1
openssl req -newkey rsa:2048 -days 365000 \
-nodes -keyout server1-key.pem -out server1-req.pem
openssl rsa -in server1-key.pem -out server1-key.pem
openssl x509 -req -in server1-req.pem -days 365000 \
-CA ca-cert.pem -CAkey ca-key.pem -set_serial 01 \
-out server1-cert.pem
```

- Then, copy the certificate and keys to all nodes in the cluster.
- Then, configure the following on all nodes in the cluster:

```
[sst]
encrypt=3
tkey=/etc/my.cnf.d/certificates/server1-key.pem
tcert=/etc/my.cnf.d/certificates/server1-cert.pem
```

But replace the paths with whatever is relevant on your system.

This should allow your SSTs to be encrypted.

Logs

The `mariabackup` SST method has its own logging outside of the MariaDB Server logging.

Logging to SST Logs

MariaDB starting with 10.3.13

Starting with MariaDB 10.1.38, MariaDB 10.2.22, and MariaDB 10.3.13, logging for `mariabackup` SSTs works the following way.

By default, on the donor node, it logs to `mariabackup.backup.log`. This log file is located in the `datadir`.

By default, on the joiner node, it logs to `mariabackup.prepare.log` and `mariabackup.move.log` These log files are also located in the `datadir`.

By default, before a new SST is started, existing `mariabackup` SST log files are compressed and moved to `/tmp/sst_log_archive`. This behavior can be disabled by setting `sst-log-archive=0` in the `[sst]` option group

in an option file. Similarly, the archive directory can be changed by setting `sst-log-archive-dir`. For example:

```
[sst]
sst-log-archive=1
sst-log-archive-dir=/var/log/mysql/sst/
```

See MDEV-17973 for more information.

MariaDB until 10.3.13 MariaDB 10.2.22, and MariaDB 10.3.13, logging for `mariabackup` SSTs works the following way.

By default, on the donor node, it logs to `innobackup.backup.log`. This log file is located in the `datadir`.

By default, on the joiner node, it logs to `innobackup.prepare.log` and `innobackup.move.log`. These log files are located in the `.sst` directory, which is a hidden directory inside the `datadir`.

These log files are overwritten by each subsequent SST, so if an SST fails, it is best to copy them somewhere safe before starting another SST, so that the log files can be analyzed.

Logging to Syslog

You can redirect the SST logs to the syslog instead by setting the following in the `[sst]` option group in an option file:

```
[sst]
sst-syslog=1
```

You can also redirect the SST logs to the syslog by setting the following in the `[mysqld_safe]` option group in an option file:

```
[mysqld_safe]
syslog
```

Performing SSTs with IPv6 Addresses

If you are performing Mariabackup SSTs with IPv6 addresses, then the `socat` utility needs to be passed the `pf=ip6` option. This can be done by setting the `sockopt` option in the `[sst]` option group in an option file. For example:

```
[sst]
sockopt=",pf=ip6"
```

See MDEV-18797 for more information.

Manual SST with Mariabackup

In some cases, if Galera Cluster's automatic SSTs repeatedly fail, then it can be helpful to perform a "manual SST". See the following page on how to do that:

- Manual SST of Galera Cluster node with Mariabackup

3.2.8.3 Manual SST of Galera Cluster Node with Mariabackup

2.3.4.15 Individual Database Restores with MariaBackup from Full Backup

This method is to solve a flaw with Mariabackup; it cannot do single database restores from a full backup easily. There is a blog post that details a way to do this, but it's a manual process which is fine for a few tables but if you have hundreds or even thousands of tables then it would be impossible to do quickly.

Contents

We can't just move the data files to the datadir as the tables are not registered in the engines, so the database will error. Currently, the only effective method is to a do full restore in a test database and then dump the database that requires restoring or running a partial backup. **This has only been tested with InnoDB. Also, if you have stored procedures or triggers then these will need to be deleted and recreated.**

Some of the issues that this method overcomes:

- Tables not registered in the InnoDB engine so will error when you try to select from a table if you move the data files into the datadir
- Tables with foreign keys need to be created without keys, otherwise it will error when you discard the tablespace

Single Node

Below is the process to perform a single database restore.

Firstly, we will need the table structure from a mariadb-dump backup with the --no-data option. I recommend this is done at least once per day or every six hours via a cronjob. As it is just the structure, it will be very fast.

```
mariadb-dump -u root -p --all-databases --no-data > nodata.sql
```

Using SED to return only the table structure we require, then use vim or another text editor to make sure nothing is left.

```
sed -n '/Current Database: `DATABASENAME`/, /Current Database:/p' nodata.sql > trimednodata.sql
vim trimednodata.sql
```

I won't go over the backup process, as this is done earlier in other documents, such as full-backup-and-restore-with-mariabackup. Prepare the backup with any incremental-backup-and-restores that you have, and then run the following on the full backup folder using the --export option to generate files with .cfg extensions which InnoDB will look for.

```
Mariabackup --prepare --export --target-dir=/media/backups/fullbackupfolder
```

Once we have done these steps, we can then import the table structure. If you have used the --all-databases option, then you will need to either use SED or open it in a text editor and export out tables that you require. You will also need to log in to the database and create the database if the dump file doesn't. Run the following command below:

```
Mysql -u root -p schema_name < nodata.sql
```

Once the structure is in the database, we have now registered the tables to the engine. Next, we will run the following statements in the information_schema database, to export statements to import/discard table spaces and drop and create foreign keys which we will use later. (edit the CONSTRAINT_SCHEMA and TABLE_SCHEMA WHERE clause to the database you are restoring. Also, add the following lines after your SELECT and before the FROM to have MariaDB export the files to the OS)

```
SELECT ...
into outfile '/tmp/filename.sql'
FIELDS TERMINATED BY ','
LINES TERMINATED BY '\n'
FROM ...
```

The following are the statements that we will need later.

```
USE information_schema;
select concat("ALTER TABLE ",table_name," DISCARD TABLESPACE;")  AS discard_tablespace
from information_schema.tables
where TABLE_SCHEMA="DATABASENAME";

select concat("ALTER TABLE ",table_name," IMPORT TABLESPACE;") AS import_tablespace
from information_schema.tables
where TABLE_SCHEMA="DATABASENAME";

SELECT
concat ("ALTER TABLE ", rc.CONSTRAINT_SCHEMA, ".",rc.TABLE_NAME," DROP FOREIGN KEY ", rc.CONSTRAI
FROM REFERENTIAL_CONSTRAINTS AS rc
where CONSTRAINT_SCHEMA = 'DATABASENAME';

SELECT
CONCAT ("ALTER TABLE ",
KCU.CONSTRAINT_SCHEMA, ".",
KCU.TABLE_NAME,"
ADD CONSTRAINT ",
KCU.CONSTRAINT_NAME, "
FOREIGN KEY ", "
(`",KCU.COLUMN_NAME,"`)", "
REFERENCES `",REFERENCED_TABLE_NAME,"`
(`",REFERENCED_COLUMN_NAME,"`)" ,"
ON UPDATE " ,(SELECT UPDATE_RULE FROM REFERENTIAL_CONSTRAINTS WHERE CONSTRAINT_NAME = KCU.CONSTRA
ON DELETE ",(SELECT DELETE_RULE FROM REFERENTIAL_CONSTRAINTS WHERE CONSTRAINT_NAME = KCU.CONSTRAI
FROM KEY_COLUMN_USAGE AS KCU
WHERE KCU.CONSTRAINT_SCHEMA = 'DATABASENAME'
AND KCU.POSITION_IN_UNIQUE_CONSTRAINT >= 0
AND KCU.CONSTRAINT_NAME NOT LIKE 'PRIMARY';
```

Once we have run those statements, and they have been exported to a Linux directory or copied from a GUI interface.

Run the ALTER DROP KEYS statements in the database

```
ALTER TABLE schemaname.tablename DROP FOREIGN KEY key_name;
...
```

Once completed, run the DROP TABLE SPACE statements in the database

```
ALTER TABLE test DISCARD TABLESPACE;
...
```

Exit out the database and change into the directory of the full backup location. Run the following commands to copy all the .cfg and .ibd files to the datadir such as /var/lib/mysql/testdatabase (Change the datadir location if needed). Learn more about files that Mariabackup generates with files-created-by-mariabackup

```
cp *.cfg /var/lib/mysql
cp *.ibd /var/lib/mysql
```

After moving the files, it is very important that MySQL is the owner of the files, otherwise it won't have access to them and will error when we import the tablespaces.

```
sudo chown -R mysql:mysql /var/lib/mysql
```

Run the import table spaces statements in the database.

```
ALTER TABLE test IMPORT TABLESPACE;
...
```

Run the add key statements in the database

```
ALTER TABLE schmeaname.tablename ADD CONSTRAINT key_name FOREIGN KEY (`column_name`) REFERENCES `
...
```

We have successfully restored a single database. To test that this has worked, we can do a basic check on some tables.

```
use database
SELECT * from test limit 10;
```

Replica nodes

If you have a primary-replica set up, it would be best to follow the sets above for the primary node and then either take a full mariadb-dump or take a new full mariabackup and restore this to the replica. You can find more information about restoring a replica with mariabackup in Setting up a Replica with Mariabackup

After running the below command, copy to the replica and use the LESS linux command to grab the change master statement. Remember to follow this process: Stop replica > restore data > run CHANGE MASTER statement > start replica again.

```
mariadb-dump -u user -p --single-transaction --master-data=2 > fullbackup.sql
```

Please follow Setting up a Replica with Mariabackup on restoring a replica with Mariabackup

```
$ mariabackup --backup \
   --slave-info --safe-slave-backup \
   --target-dir=/var/mariadb/backup/ \
   --user=mariabackup --password=mypassword
```

Galera cluster

For this process to work with Galera cluster, we first need to understand that some statements are not replicated across Galera nodes. One of which is the DISCARD and IMPORT for ALTER TABLES statements, and these statements will need to be ran on all nodes. We also need to run the OS level steps on each server as seen below.

Run the ALTER DROP KEYS statements on ONE NODE as these are replicated.

```
ALTER TABLE schemaname.tablename DROP FOREIGN KEY key_name;
...
```

Once completed, run the DROP TABLE SPACE statements on EVERY NODE, as these are not replicated.

```
ALTER TABLE test DISCARD TABLESPACE;
...
```

Exit out the database and change into the directory of the full backup location. Run the following commands to copy all the .cfg and .ibd files to the datadir such as /var/lib/mysql/testdatabase (Change the datadir location if needed). Learn more about files that Mariabackup generates with files-created-by-mariabackup. This step needs to be done on all nodes. You will need to copy the backup files to each node, we can use the same backup on all nodes.

```
cp *.cfg /var/lib/mysql
cp *.ibd /var/lib/mysql
```

After moving the files, it is very important that MySQL is the owner of the files, otherwise it won't have access to them and will error when we import the tablespaces.

```
sudo chown -R mysql:mysql /var/lib/mysql
```

Run the import table spaces statements on EVERY NODE.

```
ALTER TABLE test IMPORT TABLESPACE;
...
```

Run the add key statements on ONE NODE

```
ALTER TABLE schmeaname.tablename ADD CONSTRAINT key_name FOREIGN KEY (`column_name`) REFERENCES `
...
```

1.3.6.3 mariadb-hotcopy

2.4 Server Monitoring & Logs

MariaDB can keep a number of log files, including the error log, the binary log, the general query log and the slow query log.

Overview of MariaDB Logs

What to log and what not to log.

Error Log

Record of critical errors that occurred during the server's operation.

Setting the Language for Error Messages

Specifying the language for the server error messages.

General Query Log

Log of every SQL query received from a client, as well as connects/disconnects.

Slow Query Log

Logging slow queries

Rotating Logs on Unix and Linux

Rotating logs on Unix and Linux with logrotate.

Binary Log

Contains a record of all changes to the databases, both data and structure

InnoDB Redo Log

The redo log is used by InnoDB during crash recovery.

InnoDB Undo Log

InnoDB Undo log.

MyISAM Log

Records all changes to MyISAM tables

Transaction Coordinator Log

The transaction coordinator log (tc_log) is used to coordinate transactions...

SQL Error Log Plugin

Records SQL-level errors to a log file.

Writing Logs Into Tables

The general query log and the slow query log can be written into system tables

Performance Schema

Monitoring server performance.

MariaDB Audit Plugin

Logging user activity with the MariaDB Audit Plugin.

There are 4 related questions.

2.4.1 Overview of MariaDB Logs

There are many variables in MariaDB that you can use to define what to log and when to log.

This article will give you an overview of the different logs and how to enable/disable logging to these.

Note that storage engines can have their logs too: for example, InnoDB keeps an Undo Log and a Redo Log which are used for rollback and crash recovery. However, this page only lists MariaDB server logs.

Error Log

- Always enabled
- Usually a file in the data directory, but some distributions may move this to other locations.
- All critical errors are logged here.
- One can get warnings to be logged by setting log_warnings.
- With the mysqld_safe `--syslog` option one can duplicate the messages to the system's syslog.

General Query Log

- Enabled with --general-log
- Logs all queries to a file or table.
- Useful for debugging or auditing queries.
- The super user can disable logging to it for a connection by setting SQL_LOG_OFF to 1.

Slow Query Log

- Enabled by starting mysqld with --slow-query-log
- Logs all queries to a file or table.
- Useful to find queries that causes performance problems.
- Logs all queries that takes more than long_query_time to run.
- One can decide what to log with the options --log-slow-admin-statements, --log-slow-slave-statements, log_slow_filter or log_slow_rate_limit.
- One can change what is logged by setting log_slow_verbosity.
- One can disable it globally by setting global.slow_query_log to 0
- In 10.1 one can disable it for a connection by setting local.slow_query_log to 0.

Binary Log

- Enabled by starting mysqld with --log-bin
- Used on machines that are, or may become, replication masters.
- Required for point-in-time recovery.
- Binary log files are mainly used by replication and can also be used with mariadb-binlog to apply on a backup to get the database up to date.
- One can decide what to log with --binlog-ignore-db=database_name or --binlog-do-db=database_name.
- The super user can disable logging for a connection by setting SQL_LOG_BIN to 0. However while this is 0, no changes done in this connection will be replicated to the slaves!
- For examples, see Using and Maintaining the Binary Log.

Examples

If you know that your next query will be slow and you don't want to log it in the slow query log, do:

```
SET LOCAL SLOW_QUERY_LOG=0;
```

If you are a super user running a log batch job that you don't want to have logged (for example mariadb-dump), do:

```
SET LOCAL SQL_LOG_OFF=1, LOCAL SLOW_QUERY_LOG=0;
```

mariadb-dump (previously mysqldump) since MariaDB 10.1 will add this automatically to your dump file if you run it with the `--skip-log-queries` option.

2.4.2 Error Log

Contents

The error log contains a record of critical errors that occurred during the server's operation, table corruption, start and stop information.

SQL errors can also be logged in a separate file using the SQL_ERROR_LOG plugin.

Configuring the Error Log Output Destination

MariaDB always writes its error log, but the destination is configurable.

Writing the Error Log to a File

To configure the error log to be written to a file, you can set the log_error system variable. You can configure a specific file name. However, if a specific file name is not configured, then the log will be written to the `${hostname}.err` file in the datadir directory by default.

The log_error system variable can be set in a server option group in an option file prior to starting up the server. For example, to write the error log to the default `${hostname}.err` file, you could configure the following:

```
[mariadb]
...
log_error
```

If you configure a specific file name as the log_error system variable, and if it is not an absolute path, then it will be relative to the datadir directory. For example, if you configured the following, then the error log would be written to `mariadb.err` in the datadir directory:

```
[mariadb]
...
log_error=mariadb.err
```

If it is a relative path, then the log_error is relative to the datadir directory.

However, the log_error system variable can also be an absolute path. For example:

```
[mariadb]
...
log_error=/var/log/mysql/mariadb.err
```

Another way to configure the error log file name is to set the log-basename option, which configures MariaDB to use a common prefix for all log files (e.g. general query log, slow query log, error log, binary logs, etc.). The error log file name will be built by adding a `.err` extension to this prefix. For example, if you configured the following, then the error log would still be written to `mariadb.err` in the datadir directory:

```
[mariadb]
...
log-basename=mariadb
log_error
```

The log-basename cannot be an absolute path. The log file name is relative to the datadir directory.

Writing the Error Log to Stderr on Unix

On Unix, if the log_error system variable is not set, then errors are written to `stderr`, which usually means that the log messages are output to the terminal that started `mysqld`.

If the log_error system variable was set in an option file or on the command-line, then it can still be unset by specifying `--skip-log-error`.

Writing the Error Log to Syslog on Unix

On Unix, the error log can also be redirected to the syslog. How this is done depends on how you start MariaDB.

Syslog with mysqld_safe

If you start MariaDB with mysqld_safe, then the error log can be redirected to the syslog. See mysqld_safe: Configuring MariaDB to Write the Error Log to Syslog for more information.

Syslog with Systemd

If you start MariaDB with systemd, then the error log can also be redirected to the syslog. See Systemd: Configuring MariaDB to Write the Error Log to Syslog for more information.

systemd also has its own logging system called the `journal`, and some errors may get logged there instead. See Systemd:Systemd Journal for more information.

Writing the Error Log to Console on Windows

On Windows, if the console option is specified, and if the log_error system variable is not used, then errors are written to the console. If both options are specified, then the last option takes precedence.

Writing the Error Log to the Windows Event Viewer

On Windows, error log messages are also written to the Windows Event Viewer. You can find MariaDB's error log messages by browsing **Windows Logs**, and then selecting **Application** or **Application Log**, depending on the Windows version.

In MariaDB 10.3 and before, you can find MariaDB's error log messages by searching for the **Source** `MySQL`.

In MariaDB 10.4 and later, you can find MariaDB's error log messages by searching for the **Source** `MariaDB`.

Finding the Error Log

To find where the error log is stored, one can find the options used for the error log with:

```
mariadbd --print-defaults
```

or

```
my_print_defaults --mysqld | grep log-error
```

If the above don't help, check also if your system is set to write to syslog, in which case you need to use journalctl to access it.

Configuring the Error Log Verbosity

The default value of the log_warnings system variable is `2`.

The log_warnings system variable can be used to configure the verbosity of the error log. It can be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL log_warnings=3;
```

It can also be set either on the command-line or in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
log_warnings=3
```

Some of the warnings included in each verbosity level are described below.

> The log_warnings system variable only has an effect on some log messages. Some log messages are **always** written to the error log, regardless of the error log verbosity. For example, most warnings from the InnoDB storage engine are not affected by log_warnings. For a complete list of log messages affected by log_warnings, see the description of the log_warnings system variable.

Verbosity Level 0

If log_warnings is `0`, then many optional warnings will not be logged. However, this does not prevent all warnings from being logged, because there are certain core warnings that will always be written to the error log. For example:

- If InnoDB strict mode is disabled, and if DDL is performed on a table that triggers a "Row size too large" error, then InnoDB will log a warning:

```
[Warning] InnoDB: Cannot add field col25 in table db1.tab because after
  adding it, the row size is 8477 which is greater than maximum allowed
  size (8126) for a record on index leaf page.
```

However, if InnoDB strict mode is enabled, then the same message will be logged as an error.

Verbosity Level 1

Default until MariaDB 10.2.3. If log_warnings is `1`, then many types of warnings are logged. Some useful warnings are:

- Replication-related messages:

```
[Note] Error reading relay log event: slave SQL thread was killed
[Note] Slave SQL thread exiting, replication stopped in log
  'dbserver-2-bin.000033'   at position 181420;
  GTID position '0-263316466-368886'
[Note] Slave I/O thread exiting, read up to log
  'dbserver-2-bin.000034', position 642;
  GTID position 0-263316466-368887
```

- Messages related to DNS lookup failures:

```
[Warning] IP address '192.168.1.193'
  could not be resolved: Name or service not known
```

- Messages related to the event scheduler:

```
[Note] Event Scheduler: Loaded 0 events
```

- Messages related to unsafe statements for statement-based replication:

```
[Warning] Unsafe statement written to the binary log using statement format since
  BINLOG_FORMAT = STATEMENT. The statement is unsafe because
  it uses a LIMIT clause. This
  is unsafe because the set of rows included cannot be predicted.
```

Frequent warnings about unsafe statements for statement-based replication can cause the error log to grow very large.

MariaDB will automatically detect frequent duplicate warnings about unsafe statements for statement-based replication. After 10 identical warnings are detected, MariaDB will prevent that same warning from being written to the error log again for the next 5 minutes.

Verbosity Level 2

Default from MariaDB 10.2.4. If log_warnings is `2`, then a couple other different kinds of warnings are printed. For example:

- Messages related to access denied errors:

```
[Warning] Access denied for user 'root'@'localhost' (using password: YES)
```

- Messages related to connections that are aborted due to errors or timeouts:

```
[Warning] Aborted connection 35 to db: 'unconnected' user:
  'user1@host1' host: '192.168.1.40' (Got an error writing communication packets)
[Warning] Aborted connection 36 to db: 'unconnected' user:
  'user1@host2' host: '192.168.1.230' (Got an error writing communication packets)
[Warning] Aborted connection 38 to db: 'db1' user:
  'user2' host: '192.168.1.60' (Unknown error)
[Warning] Aborted connection 51 to db: 'db1' user:
  'user2' host: '192.168.1.50' (Got an error reading communication packets)
[Warning] Aborted connection 52 to db: 'db1' user:
  'user3' host: '192.168.1.53' (Got timeout reading communication packets)
```

- Messages related to table handler errors:

```
[Warning] Can't find record in 'tab1'.
[Warning] Can't write; duplicate key in table 'tab1'.
[Warning] Lock wait timeout exceeded; try restarting transaction.
[Warning] The number of locks exceeds the lock table size.
[Warning] Update locks cannot be acquired during a READ UNCOMMITTED transaction.
```

- Messages related to the files used to persist replication state:
  - Either the default `master.info` file or the file that is configured by the master_info_file option.
  - Either the default `relay-log.info` file or the file that is configured by the relay_log_info_file system variable.

```
[Note] Reading Master_info: '/mariadb/data/master.info'
  Relay_info:'/mariadb/data/relay-log.info'
[Note] Initialized Master_info from '/mariadb/data/master.info'
[Note] Reading of all Master_info entries succeded
[Note] Deleted Master_info file '/mariadb/data/master.info'.
[Note] Deleted Master_info file '/mariadb/data/relay-log.info'.
```

- Messages about a master's binary log dump thread:

```
[Note] Start binlog_dump to slave_server(263316466), pos(, 4)
```

Verbosity Level 3

If log_warnings is `3`, then a couple other different kinds of warnings are printed. For example:

- Messages related to old-style language options:

```
[Warning] An old style --language value with language specific
  part detected: /usr/local/mysql/data/
[Warning] Use --lc-messages-dir without language specific part instead.
```

- Messages related to progress of InnoDB online DDL:

```
[Note] InnoDB: Online DDL : Start
[Note] InnoDB: Online DDL : Start reading clustered index of the table and
  create temporary files
[Note] InnoDB: Online DDL : End of reading clustered index of the table and
  create temporary files
[Note] InnoDB: Online DDL : Start merge-sorting index PRIMARY (1 / 3),
  estimated cost : 18.0263
[Note] InnoDB: Online DDL : merge-sorting has estimated 33 runs
[Note] InnoDB: Online DDL : merge-sorting current run 1 estimated 33 runs
[Note] InnoDB: Online DDL : merge-sorting current run 2 estimated 17 runs
[Note] InnoDB: Online DDL : merge-sorting current run 3 estimated 9 runs
[Note] InnoDB: Online DDL : merge-sorting current run 4 estimated 5 runs
[Note] InnoDB: Online DDL : merge-sorting current run 5 estimated 3 runs
[Note] InnoDB: Online DDL : merge-sorting current run 6 estimated 2 runs
[Note] InnoDB: Online DDL : End of  merge-sorting index PRIMARY (1 / 3)
[Note] InnoDB: Online DDL : Start building index PRIMARY (1 / 3),
  estimated cost : 27.0395
[Note] InnoDB: Online DDL : End of building index PRIMARY (1 / 3)
[Note] InnoDB: Online DDL : Completed
[Note] InnoDB: Online DDL : Start merge-sorting index ux1 (2 / 3),
  estimated cost : 5.7895
[Note] InnoDB: Online DDL : merge-sorting has estimated 2 runs
[Note] InnoDB: Online DDL : merge-sorting current run 1 estimated 2 runs
[Note] InnoDB: Online DDL : End of  merge-sorting index ux1 (2 / 3)
[Note] InnoDB: Online DDL : Start building index ux1 (2 / 3),
  estimated cost : 8.6842
[Note] InnoDB: Online DDL : End of building index ux1 (2 / 3)
[Note] InnoDB: Online DDL : Completed
[Note] InnoDB: Online DDL : Start merge-sorting index ix1 (3 / 3),
  estimated cost : 6.1842
[Note] InnoDB: Online DDL : merge-sorting has estimated 3 runs
[Note] InnoDB: Online DDL : merge-sorting current run 1 estimated 3 runs
[Note] InnoDB: Online DDL : merge-sorting current run 2 estimated 2 runs
[Note] InnoDB: Online DDL : End of  merge-sorting index ix1 (3 / 3)
[Note] InnoDB: Online DDL : Start building index ix1 (3 / 3),
  estimated cost : 9.2763
[Note] InnoDB: Online DDL : End of building index ix1 (3 / 3)
[Note] InnoDB: Online DDL : Completed
```

Verbosity Level 4

If log_warnings is `4`, then a couple other different kinds of warnings are printed. For example:

- Messages related to killed connections:

```
[Warning] Aborted connection 53 to db: 'db1' user:
  'user2' host: '192.168.1.50' (KILLED)
```

- Messages related to **all** closed connections:

```
[Warning] Aborted connection 56 to db: 'db1' user:
  'user2' host: '192.168.1.50' (CLOSE_CONNECTION)
```

- Messages related to released connections, such as when a transaction is committed and completion_type is set to `RELEASE`:

```
[Warning] Aborted connection 58 to db: 'db1' user:
  'user2' host: '192.168.1.50' (RELEASE)
```

Verbosity Level 9

If log_warnings is `9`, then some **very** verbose warnings are printed. For example:

- Messages about initializing plugins:

```
[Note] Initializing built-in plugins
[Note] Initializing plugins specified on the command line
[Note] Initializing installed plugins
```

MySQL's log_error_verbosity

MariaDB does not support the log_error_verbosity system variable added in MySQL 5.7.

Format

The format consists of the date (yyyy-mm-dd) and time, the thread ID, followed by the type of error (Note, Warning or Error) and the error message, for example:

```
2016-06-15 16:53:33 139651251140544 [Note] InnoDB:
  The InnoDB memory heap is disabled
```

Until MariaDB 10.1.4, the format only consisted of the date (yymmdd) and time, followed by the type of error (Note, Warning or Error) and the error message, for example:

```
160615 16:53:08 [Note] InnoDB: The InnoDB memory heap is disabled
```

Rotating the Error Log on Unix and Linux

Unix and Linux distributions offer the logrotate utility, which makes it very easy to rotate log files. See Rotating Logs on Unix and Linux for more information on how to use this utility to rotate the error log.

Error Messages File

Many error messages are ready from an error messages file that contains localized error messages. If the server can't find this file when it starts up, then you might see errors like the following:

```
[ERROR] Can't find messagefile '/usr/share/errmsg.sys'
```

If this error is occurring because the file is in a custom location, then you can configure this location by setting the lc_messages_dir system variable either on the command-line or in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
lc_messages_dir=/usr/share/mysql/
```

If you want to use a different locale for error messages, then you can also set the lc_messages system variable. For example:

```
[mariadb]
...
lc_messages_dir=/usr/share/mysql/
lc_messages=en_US
```

See Setting the Language for Error Messages for more information.

2.4.3 Setting the Language for Error Messages

Contents

MariaDB server error messages are by default in English. However, MariaDB server also supports error message localization in many different languages. Each supported language has its own version of the error message file called `errmsg.sys` in a dedicated directory for that language.

Supported Languages for Error Messages

Error message localization is supported for the following languages:

- Bulgarian
- Chinese (from MariaDB 10.4.25, 10.5.16, 10.6.8, 10.7.4, 10.8.3)
- Czech
- Danish
- Dutch
- English
- Estonian
- French
- Georgian (from MariaDB 10.11.3)
- German
- Greek
- Hindi
- Hungarian
- Italian
- Japanese
- Korean
- Norwegian
- Norwegian-ny (Nynorsk)
- Polish
- Portuguese
- Romanian
- Russian
- Serbian
- Slovak
- Spanish
- Swahili (from MariaDB 11.1.2)
- Swedish
- Ukrainian

Setting the `lc_messages` and `lc_messages_dir` System Variables

The lc_messages and lc_messages_dir system variables can be used to set the server locale used for error messages.

The lc_messages system variable can be specified as a locale name. The language of the associated locale will be used for error messages. See Server Locales for a list of supported locales and their associated languages.

The lc_messages system variable is set to `en_US` by default, which means that error messages are in English by default.

If the `lc_messages` system variable is set to a valid locale name, but the server can't find an error message file for the language associated with the locale, then the default language will be used instead.

This system variable can be specified as command-line arguments to mariadbd or it can be specified in a relevant server option group in an option file. For example:

```
[mariadb]
...
lc_messages=fr_CA
```

The lc_messages system variable can also be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL lc_messages='fr_CA';
```

If a server has the lc_messages system variable set to the `fr_CA` locale like the above example, then error messages would be in French. For example:

```
SELECT blah;
ERROR 1054 (42S22): Champ 'blah' inconnu dans field list
```

The lc_messages_dir system variable can be specified either as the path to the directory storing the server's error message files or as the path to the directory storing the specific language's error message file.

The server initially tries to interpret the value of the `lc_messages_dir` system variable as a path to the directory storing the server's error message files. Therefore, it constructs the path to the language's error message file by concatenating the value of the lc_messages_dir system variable with the language name of the locale specified by the lc_messages system

variable .

If the server does not find the error message file for the language, then it tries to interpret the value of the lc_messages_dir system variable as a direct path to the directory storing the specific language's error message file.

This system variable can be specified as command-line arguments to mariadbd or it can be specified in a relevant server option group in an option file.

For example, to specify the path to the directory storing the server's error message files:

```
[mariadb]
...
lc_messages_dir=/usr/share/mysql/
```

Or to specify the path to the directory storing the specific language's error message file:

```
[mariadb]
...
lc_messages_dir=/usr/share/mysql/french/
```

The `lc_messages_dir` system variable can not be changed dynamically.

Setting the --language Option

The --language option can also be used to set the server's language for error messages, but it is deprecated. It is recommended to set the lc_messages system variable instead.

The --language option can be specified either as a language name or as the path to the directory storing the language's error message file. See Server Locales for a list of supported locales and their associated languages.

This option can be specified as command-line arguments to mariadbd or it can be specified in a relevant server option group in an option file.

For example, to specify a language name:

```
[mariadb]
...
language=french
```

Or to specify the path to the directory storing the language's error message file:

```
[mariadb]
...
language=/usr/share/mysql/french/
```

Character Set

The character set that the error messages are returned in is determined by the character_set_results variable, which defaults to UTF8.

2.4.4 General Query Log

Contents

The general query log is a log of every SQL query received from a client, as well as each client connect and disconnect. Since it's a record of every query received by the server, it can grow large quite quickly.

However, if you only want a record of queries that change data, it might be better to use the binary log instead. One important difference is that the binary log only logs a query when the transaction is committed by the server, but the general

query log logs a query immediately when it is received by the server.

Enabling the General Query Log

The general query log is disabled by default.

To enable the general query log, set the `general_log` system variable to `1`. It can be changed dynamically with `SET GLOBAL`. For example:

```
SET GLOBAL general_log=1;
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
general_log
```

Configuring the General Query Log Filename

By default, the general query log is written to `${hostname}.log` in the `datadir` directory. However, this can be changed.

One way to configure the general query log filename is to set the `general_log_file` system variable. It can be changed dynamically with `SET GLOBAL`. For example:

```
SET GLOBAL general_log_file='mariadb.log';
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
general_log
general_log_file=mariadb.log
```

If it is a relative path, then the `general_log_file` is relative to the `datadir` directory.

However, the `general_log_file` system variable can also be an absolute path. For example:

```
[mariadb]
...
general_log
general_log_file=/var/log/mysql/mariadb.log
```

Another way to configure the general query log filename is to set the `log-basename` option, which configures MariaDB to use a common prefix for all log files (e.g. general query log, slow query log, error log, binary logs, etc.). The general query log filename will be built by adding a `.log` extension to this prefix. This option cannot be set dynamically. It can be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
log-basename=mariadb
general_log
```

The `log-basename` cannot be an absolute path. The log file name is relative to the `datadir` directory.

Choosing the General Query Log Output Destination

The general query log can either be written to a file on disk, or it can be written to the `general_log` table in the `mysql` database. To choose the general query log output destination, set the `log_output` system variable.

Writing the General Query Log to a File

The general query log is output to a file by default. However, it can be explicitly chosen by setting the `log_output` system variable to `FILE`. It can be changed dynamically with `SET GLOBAL`. For example:

```
SET GLOBAL log_output='FILE';
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
log_output=FILE
general_log
general_log_file=queries.log
```

Writing the General Query Log to a Table

The general query log can either be written to the `general_log` table in the `mysql` database by setting the `log_output` system variable to `TABLE`. It can be changed dynamically with `SET GLOBAL`. For example:

```
SET GLOBAL log_output='TABLE';
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
log_output=TABLE
general_log
```

Some rows in this table might look like this:

```
SELECT * FROM mysql.general_log\G
*************************** 1. row ***************************
  event_time: 2014-11-11 08:40:04.117177
   user_host: root[root] @ localhost []
   thread_id: 74
   server_id: 1
command_type: Query
    argument: SELECT * FROM test.s
*************************** 2. row ***************************
  event_time: 2014-11-11 08:40:10.501131
   user_host: root[root] @ localhost []
   thread_id: 74
   server_id: 1
command_type: Query
    argument: SELECT * FROM mysql.general_log
...
```

See Writing logs into tables for more information.

Disabling the General Query Log for a Session

A user with the SUPER privilege can disable logging to the general query log for a connection by setting the SQL_LOG_OFF system variable to `1`. For example:

```
SET SESSION SQL_LOG_OFF=1;
```

Disabling the General Query Log for Specific Statements

In MariaDB 10.3.1 and later, it is possible to disable logging to the general query log for specific types of statements by setting the `log_disabled_statements` system variable. This option cannot be set dynamically. It can be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
log_output=FILE
general_log
general_log_file=queries.log
log_disabled_statements='slave,sp'
```

Rotating the General Query Log on Unix and Linux

Unix and Linux distributions offer the logrotate utility, which makes it very easy to rotate log files. See Rotating Logs on Unix and Linux for more information on how to use this utility to rotate the general query log.

2.4.5 Slow Query Log

The slow query log is a record of SQL queries that took a long time to perform.

Slow Query Log Overview

A record of SQL queries that took a long time to perform.

Slow Query Log Extended Statistics

The slow query log makes extended statistics available.

mysqldumpslow

Symlink or old name for mariadb-dumpslow.

EXPLAIN in the Slow Query Log

EXPLAIN output in the slow query log.

mysql.slow_log Table

Contents of the slow query log if written to table.

There are 1 related questions.

2.4.5.1 Slow Query Log Overview

Contents

The slow query log is a record of SQL queries that took a long time to perform.

Note that, if your queries contain user's passwords, the slow query log may contain passwords too. Thus, it should be protected.

The number of rows affected by the slow query are also recorded in the slow query log.

Enabling the Slow Query Log

The slow query log is disabled by default.

To enable the slow query log, set the slow_query_log system variable to `1`. It can be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL slow_query_log=1;
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
slow_query_log
```

Configuring the Slow Query Log Filename

By default, the slow query log is written to `${hostname}-slow.log` in the datadir directory. However, this can be changed.

One way to configure the slow query log filename is to set the slow_query_log_file system variable. It can be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL slow_query_log_file='mariadb-slow.log';
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
slow_query_log
slow_query_log_file=mariadb-slow.log
```

If it is a relative path, then the slow_query_log_file is relative to the datadir directory.

However, the slow_query_log_file system variable can also be an absolute path. For example:

```
[mariadb]
...
slow_query_log
slow_query_log_file=/var/log/mysql/mariadb-slow.log
```

Another way to configure the slow query log filename is to set the log-basename option, which configures MariaDB to use a common prefix for all log files (e.g. slow query log, general query log, error log, binary logs, etc.). The slow query log filename will be built by adding `-slow.log` to this prefix. This option cannot be set dynamically. It can be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
log-basename=mariadb
slow_query_log
```

The log-basename cannot be an absolute path. The log file name is relative to the datadir directory.

Choosing the Slow Query Log Output Destination

The slow query log can either be written to a file on disk, or it can be written to the slow_log table in the mysql database. To choose the slow query log output destination, set the log_output system variable.

Writing the Slow Query Log to a File

The slow query log is output to a file by default. However, it can be explicitly chosen by setting the log_output system variable to `FILE`. It can be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL log_output='FILE';
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
log_output=FILE
slow_query_log
slow_query_log_file=slow-queries.log
```

Writing the Slow Query Log to a Table

The slow query log can either be written to the slow_log table in the mysql database by setting the log_output system variable to `TABLE`. It can be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL log_output='TABLE';
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
log_output=TABLE
slow_query_log
```

Some rows in this table might look like this:

```
SELECT * FROM mysql.slow_log\G
...
*************************** 2. row ***************************
    start_time: 2014-11-11 07:56:28.721519
     user_host: root[root] @ localhost []
    query_time: 00:00:12.000215
     lock_time: 00:00:00.000000
     rows_sent: 1
 rows_examined: 0
            db: test
last_insert_id: 0
     insert_id: 0
     server_id: 1
      sql_text: SELECT SLEEP(12)
     thread_id: 74
...
```

See Writing logs into tables for more information.

Disabling the Slow Query Log for a Session

A user can disable logging to the slow query log for a connection by setting the slow_query_log system variable to `0`. For example:

```
SET SESSION slow_query_log=0;
```

Disabling the Slow Query Log for Specific Statements

In MariaDB 10.3.1 and later, it is possible to disable logging to the slow query log for specific types of statements by setting the log_slow_disabled_statements system variable. This option cannot be set dynamically. It can be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
log_output=FILE
general_log
general_log_file=queries.log
log_slow_disabled_statements='admin,call,slave,sp'
```

Configuring the Slow Query Log Time

The time that defines a slow query can be configured by setting the long_query_time system variable. It uses a units of seconds, with an optional milliseconds component. The default value is `10`. It can be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL long_query_time=5.0;
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
log_output=FILE
slow_query_log
slow_query_log_file=slow-queries.log
long_query_time=5.0
```

Logging Queries That Don't Use Indexes

It can be beneficial to log queries that don't use indexes to the slow query log, since queries that don't use indexes can usually be optimized either by adding an index or by doing a slight rewrite. The slow query log can be configured to log queries that don't use indexes regardless of their execution time by setting the log_queries_not_using_indexes system variable. It can be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL log_queries_not_using_indexes=ON;
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
log_output=FILE
slow_query_log
slow_query_log_file=slow-queries.log
long_query_time=5.0
log_queries_not_using_indexes=ON
```

As a significant number of queries can run quickly even without indexes, you can use the min_examined_row_limit system variable with log_queries_not_using_indexes to limit the logged queries to those having a material impact on the server.

Logging Queries That Examine a Minimum Row Limit

It can be beneficial to log queries that examine a minimum number of rows. The slow query log can be configured to log queries that examine a minimum number of rows regardless of their execution time by setting the min_examined_row_limit system variable. It can be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL min_examined_row_limit=100000;
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
log_output=FILE
slow_query_log
slow_query_log_file=slow-queries.log
long_query_time=5.0
min_examined_row_limit=100000
```

Logging Slow Administrative Statements

By default, the Slow Query Log only logs slow non-administrative statements. To log administrative statements, set the log_slow_admin_statements system variable. The Slow Query Log considers the following statements administrative: ALTER TABLE, ANALYZE TABLE, CHECK TABLE, CREATE INDEX, DROP INDEX, OPTIMIZE TABLE, and REPAIR TABLE. In MariaDB 10.3 and later, this also includes ALTER SEQUENCE statements.

You can dynamically enable this feature using a SET GLOBAL statement. For example:

```
SET GLOBAL log_slow_admin_statements=ON;
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
log_output=FILE
slow_query_log
slow_query_log_file=slow-queries.log
long_query_time=5.0
log_slow_admin_statements=ON
```

Enabling the Slow Query Log for Specific Criteria

It is possible to enable logging to the slow query log for queries that meet specific criteria by configuring the log_slow_filter system variable. It can be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL log_slow_filter='filesort,filesort_on_disk,tmp_table,tmp_table_on_disk';
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
log_output=FILE
slow_query_log
slow_query_log_file=slow-queries.log
long_query_time=5.0
log_slow_filter=filesort,filesort_on_disk,tmp_table,tmp_table_on_disk
```

Throttling the Slow Query Log

The slow query log can create a lot of I/O, so it can be beneficial to throttle it in some cases. The slow query log can be throttled by configuring the log_slow_rate_limit system variable. It can be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL log_slow_rate_limit=5;
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
log_output=FILE
slow_query_log
slow_query_log_file=slow-queries.log
long_query_time=5.0
log_slow_rate_limit=5
```

Configuring the Slow Query Log Verbosity

There are a few optional pieces of information that can be included in the slow query log for each query. This optional information can be included by configuring the log_slow_verbosity system variable. It can be changed dynamically with SET GLOBAL. For example:

```
SET GLOBAL log_slow_verbosity='full';
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
log_output=FILE
slow_query_log
slow_query_log_file=slow-queries.log
long_query_time=5.0
log_slow_verbosity=query_plan,explain,engine
```

It is possible to have EXPLAIN output printed in the slow query log.

Viewing the Slow Query Log

Slow query logs written to file can be viewed with any text editor, or you can use the mariadb-dumpslow tool to ease the process by summarizing the information.

Queries that you find in the log are key queries to try to optimize by constructing a more efficient query or by making better use of indexes.

For queries that appear in the log that cannot be optimized in the above ways, perhaps because they are simply very large selects, due to slow hardware, or very high lock/cpu/io contention, using shard/clustering/load balancing solutions, better hardware, or stats tables may help to improve these queries.

Slow query logs written to table can be viewed by querying the slow_log table.

Variables Related to the Slow Query Log

- slow_query_log - enable/disable the slow query log. Renamed to log_slow_query from MariaDB 10.11.0.
- log_output - how the output will be written
- slow_query_log_file - name of the slow query log file. Renamed to log_slow_query_file_name from MariaDB 10.11.0.
- long_query_time - time in seconds/microseconds defining a slow query. Renamed to log_slow_query_time from MariaDB 10.11.0.
- log_queries_not_using_indexes - whether to log queries that don't use indexes
- log_slow_admin_statements - whether to log certain admin statements
- log_slow_disabled_statements - types of statements that should not be logged in the slow query log
- min_examined_row_limit - minimum rows a query must examine to be slow. Renamed to log_slow_min_examined_row_limit from MariaDB 10.11.0.
- log_slow_rate_limit - permits a fraction of slow queries to be logged
- log_slow_verbosity - amount of detail in the log
- log_slow_filter - limit which queries to log
- log_slow_slave_statements - log slow statements executed by replica thread to the slow log if it is open.

Rotating the Slow Query Log on Unix and Linux

Unix and Linux distributions offer the logrotate utility, which makes it very easy to rotate log files. See Rotating Logs on Unix and Linux for more information on how to use this utility to rotate the slow query log.

3.3.4.6.5 Slow Query Log Extended Statistics

1.3.43.3 mysqldumpslow

2.4.5.4 EXPLAIN in the Slow Query Log

Switching it On

EXPLAIN output can be switched on by specifying the " `explain` " keyword in the log_slow_verbosity system variable. Alternatively, you can set with the `log-slow-verbosity` command line argument.

```
[mysqld]
log-slow-verbosity=query_plan,explain
```

EXPLAIN output will only be recorded if the slow query log is written to a file (and not to a table - see Writing logs into tables). This limitation also applies to other extended statistics that are written into the slow query log.

What it Looks Like

When explain recording is on, slow query log entries look like this:

```
# Time: 131112 17:03:32
# User@Host: root[root] @ localhost []
# Thread_id: 2  Schema: dbt3sf1  QC_hit: No
# Query_time: 5.524103  Lock_time: 0.000337  Rows_sent: 1  Rows_examined: 65633
#
# explain: id   select_type     table   type    possible_keys   key     key_len ref     rows
Extra
# explain: 1    SIMPLE  nation  ref     PRIMARY,n_name  n_name  26      const   1       Using
where; Using index
# explain: 1    SIMPLE  customer        ref     PRIMARY,i_c_nationkey   i_c_nationkey   5
dbt3sf1.nation.n_nationkey      3145    Using index
# explain: 1    SIMPLE  orders  ref     i_o_custkey     i_o_custkey     5
dbt3sf1.customer.c_custkey      7       Using index
#
SET timestamp=1384261412;
select count(*) from customer, orders, nation where c_custkey=o_custkey and
c_nationkey=n_nationkey and n_name='GERMANY';
```

EXPLAIN lines start with `# explain:` .

1.1.1.2.9.3.22 mysqlslow_log Table

2.4.6 Rotating Logs on Unix and Linux

Contents

Unix and Linux distributions offer the `logrotate` utility, which makes it very easy to rotate log files. This page will describe how to configure log rotation for the error log, general query log, and the slow query log.

Configuring Locations and File Names of Logs

The first step is to configure the locations and file names of logs. To make the log rotation configuration easier, it can be best to put these logs in a dedicated log directory.

We will need to configure the following:

- The error log location and file name is configured with the `log_error` system variable.
- The general query log location and file name is configured with the `general_log_file` system variable.
- The slow query log location and file name is configured with the `slow_query_log_file` system variable.

If you want to enable the general query log and slow query log immediately, then you will also have to configure the following:

- The general query log is enabled with the `general_log` system variable.
- The slow query log is enabled with the `slow_query_log` system variable.

These options can be set in a server option group in an option file prior to starting up the server. For example, if we wanted to put our log files in `/var/log/mysql/` , then we could configure the following:

```
[mariadb]
...
log_error=/var/log/mysql/mariadb.err
general_log
general_log_file=/var/log/mysql/mariadb.log
slow_query_log
slow_query_log_file=/var/log/mysql/mariadb-slow.log
long_query_time=5
```

We will also need to create the relevant directory:

```
sudo mkdir /var/log/mysql/
sudo chown mysql:mysql /var/log/mysql/
sudo chmod 0770 /var/log/mysql/
```

If you are using SELinux, then you may also need to set the SELinux context for the directory. See SELinux: Setting the File Context for Log Files for more information. For example:

```
sudo semanage fcontext -a -t mysqld_log_t "/var/log/mysql(/.*)?"
sudo restorecon -Rv /var/log/mysql
```

After MariaDB is restarted, it will use the new log locations and file names.

Configuring Authentication for Logrotate

The `logrotate` utility needs to be able to authenticate with MariaDB in order to flush the log files.

The easiest way to allow the `logrotate` utility to authenticate with MariaDB is to configure the `root@localhost` user account to use `unix_socket` authentication.

MariaDB starting with 10.4

In MariaDB 10.4 and later, the `root@localhost` user account is configured to use `unix_socket` authentication by default, so this part can be skipped in those versions.

MariaDB until 10.3

In MariaDB 10.3 and before, a user account is only able to have one authentication method at a time. In these versions, this means that once you enable `unix_socket` authentication for the `root@localhost` user account, you will no longer be able to use a password to log in with that user account. The user account will only be able to use `unix_socket` authentication.

In MariaDB 10.3 and before, you need to install the unix_socket plugin before you can configure the `root@localhost` user account to use it. For example:

```
INSTALL SONAME 'auth_socket';
```

After the plugin is installed, the `root@localhost` user account can be configured to use `unix_socket` authentication. How this is done depends on the version of MariaDB.

The `root@localhost` user account can be altered to use unix_socket authentication with the ALTER USER statement. For example:

```
ALTER USER 'root'@'localhost' IDENTIFIED VIA unix_socket;
```

<</product>>

Configuring Logrotate

At this point, we can configure the `logrotate` utility to rotate the log files.

On many systems, the primary `logrotate` configuration file is located at the following path:

- `/etc/logrotate.conf`

And the `logrotate` configuration files for individual services are located in the following directory:

- `/etc/logrotate.d/`

We can create a `logrotate` configuration file for MariaDB by executing the following command in a shell:

```
$ sudo tee /etc/logrotate.d/mariadb <<EOF
/var/log/mysql/* {
        su mysql mysql
        missingok
        create 660 mysql mysql
        notifempty
        daily
        minsize 1M # only use with logrotate >= 3.7.4
        maxsize 100M # only use with logrotate >= 3.8.1
        rotate 30
        # dateext # only use if your logrotate version is compatible with below dateformat
        # dateformat .%Y-%m-%d-%H-%M-%S # only use with logrotate >= 3.9.2
        compress
        delaycompress
        sharedscripts
        olddir archive/
        createolddir 770 mysql mysql # only use with logrotate >= 3.8.9
    postrotate
        # just if mysqld is really running
        if test -x /usr/bin/mysqladmin && \
           /usr/bin/mysqladmin ping &>/dev/null
        then
           /usr/bin/mysqladmin --local flush-error-log \
              flush-engine-log flush-general-log flush-slow-log
        fi
    endscript
}
EOF
```

You may have to modify this configuration file to use it on your system, depending on the specific version of the `logrotate` utility that is installed. See the description of each configuration directive below to determine which `logrotate` versions support that configuration directive.

Each specific configuration directive does the following:

- **`missingok`** : This directive configures it to ignore missing files, rather than failing with an error.
- **`create 660 mysql mysql`** : This directive configures it to recreate the log files after log rotation with the specified permissions and owner.
- **`notifempty`** : This directive configures it to skip a log file during log rotation if it is empty.
- **`daily`** : This directive configures it to rotate each log file once per day.
- **`minsize 1M`** : This directive configures it to skip a log file during log rotation if it is smaller than 1 MB. This directive is only available with `logrotate` 3.7.4 and later.
- **`maxsize 100M`** : This directive configures it to rotate a log file more frequently than daily if it grows larger than 100 MB. This directive is only available with `logrotate` 3.8.1 and later.
- **`rotate 30`** : This directive configures it to keep 30 old copies of each log file.
- **`dateext`** : This directive configures it to use the date as an extension, rather than just a number. This directive is only available with `logrotate` 3.7.6 and later.
- **`dateformat .%Y-%m-%d-%H-%M-%S`** : This directive configures it to use this date format string (as defined by the format specification for `strftime`) for the date extension configured by the `dateext` directive. This directive is only available with `logrotate` 3.7.7 and later. Support for `%H` is only available with `logrotate` 3.9.0 and later. Support for `%M` and `%S` is only available with `logrotate` 3.9.2 and later.
- **`compress`** : This directive configures it to compress the log files with `gzip` .
- **`delaycompress`** : This directive configures it to delay compression of each log file until the next log rotation. If the log file is compressed at the same time that it is rotated, then there may be cases where a log file is being compressed while the MariaDB server is still writing to the log file. Delaying compression of a log file until the next log rotation can prevent race conditions such as these that can happen between the compression operation and the MariaDB server's log flush operation.
- **`olddir archive/`** : This directive configures it to archive the rotated log files in `/var/log/mysql/archive/` .
- **`createolddir 770 mysql mysql`** : This directive configures it to create the directory specified by the `olddir` directive with the specified permissions and owner, if the directory does not already exist. This directive is only available with `logrotate` 3.8.9 and later.
- **`sharedscripts`** : This directive configures it to run the `postrotate` script just once, rather than once for each rotated log file.
- **`postrotate`** : This directive configures it to execute a script after log rotation. This particular script executes the mariadb-admin utility, which executes the FLUSH statement, which tells the MariaDB server to flush its various log files. When MariaDB server flushes a log file, it closes its existing file handle and reopens a new one. This ensure

that MariaDB server does not continue writing to a log file after it has been rotated. This is an important component of the log rotation process.

If our system does not have `logrotate` 3.8.9 or later, which is needed to support the `createolddir` directive, then we will also need to create the relevant directory specified by the `olddir` directive:

```
sudo mkdir /var/log/mysql/archive/
sudo chown mysql:mysql /var/log/mysql/archive/
sudo chmod 0770 /var/log/mysql/archive/
```

Testing Log Rotation

We can test log rotation by executing the `logrotate` utility with the `--force` option. For example:

```
sudo logrotate --force /etc/logrotate.d/mariadb
```

Keep in mind that under normal operation, the `logrotate` utility may skip a log file during log rotation if the utility does not believe that the log file needs to be rotated yet. For example:

- If you set the `notifempty` directive mentioned above, then it will be configured to skip a log file during log rotation if the log file is empty.
- If you set the `daily` directive mentioned above, then it will be configured to only rotate each log file once per day.
- If you set the `minsize 1M` directive mentioned above, then it will be configured to skip a log file during log rotation if the log file size is smaller than 1 MB.

However, when running tests with the `--force` option, the `logrotate` utility does not take these options into consideration.

After a few tests, we can see that the log rotation is indeed working:

```
$ sudo ls -l /var/log/mysql/archive/
total 48
-rw-rw---- 1 mysql mysql  440 Mar 31 15:31 mariadb.err.1
-rw-rw---- 1 mysql mysql  138 Mar 31 15:30 mariadb.err.2.gz
-rw-rw---- 1 mysql mysql  145 Mar 31 15:28 mariadb.err.3.gz
-rw-rw---- 1 mysql mysql 1007 Mar 31 15:27 mariadb.err.4.gz
-rw-rw---- 1 mysql mysql 1437 Mar 31 15:32 mariadb.log.1
-rw-rw---- 1 mysql mysql  429 Mar 31 15:31 mariadb.log.2.gz
-rw-rw---- 1 mysql mysql  439 Mar 31 15:28 mariadb.log.3.gz
-rw-rw---- 1 mysql mysql  370 Mar 31 15:27 mariadb.log.4.gz
-rw-rw---- 1 mysql mysql 3915 Mar 31 15:32 mariadb-slow.log.1
-rw-rw---- 1 mysql mysql  554 Mar 31 15:31 mariadb-slow.log.2.gz
-rw-rw---- 1 mysql mysql  569 Mar 31 15:28 mariadb-slow.log.3.gz
-rw-rw---- 1 mysql mysql  487 Mar 31 15:27 mariadb-slow.log.4.gz
```

Logrotate in Ansible

Let's see an example of how to configure logrotate in Ansible.

First, we'll create a couple of tasks in our playbook:

```
- name: Create mariadb_logrotate_old_dir
  file:
    path: "{{ mariadb_logrotate_old_dir }}"
    owner: mysql
    group: mysql
    mode: '770'
    state: directory

- name: Configure logrotate
  template:
    src: "../templates/logrotate.j2"
    dest: "/etc/logrotate.d/mysql"
```

The first task creates a directory to store the old, compressed logs, and set proper permissions.

The second task uploads logrotate configuration file into the proper directory, and calls it `mysql`. As you can see the original name is different, and it ends with the `.j2` extension, because it is a Jinja 2 template.

The file will look like the following:

```
{{ mariadb_log_dir }}/* {
        su mysql mysql
        missingok
        create 660 mysql mysql
        notifempty
        daily
        minsize 1M {{ mariadb_logrotate_min_size }}
        maxsize 100M {{ mariadb_logrotate_max_size }}
        rotate {{ mariadb_logrotate_old_dir }}
        dateformat .%Y-%m-%d-%H-%M-%S # only use with logrotate >= 3.9.2
        compress
        delaycompress
        sharedscripts
        olddir archive/
        createolddir 770 mysql mysql # only use with logrotate >= 3.8.9
    postrotate
        # just if mysqld is really running
        if test -x /usr/bin/mysqladmin && \
           /usr/bin/mysqladmin ping &>/dev/null
        then
           /usr/bin/mysqladmin --local flush-error-log \
              flush-engine-log flush-general-log flush-slow-log
        fi
    endscript
}
```

The file is very similar to the file shown above, which is obvious because we're still uploading a logrotate configuration file. Ansible is just a tool we've chosen to do this.

However, both in the tasks and in the template, we used some variables. This allows to use different paths and rotation parameters for different hosts, or host groups.

If we have a group host called `mariadb` that contains the default configuration for all our MariaDB servers, we can define these variables in a file called `group_vars/mariadb.yml`:

```
# MariaDB writes its logs here
mariadb_log_dir: /var/lib/mysql/logs

# logrotate configuration

mariadb_logrotate_min_size: 500M
mariadb_logrotate_max_size: 1G
mariadb_logrotate_old_files: 7
mariadb_logrotate_old_dir: /var/mysql/old-logs
```

After setting up logrotate in Ansible, you may want to deploy it to a non-production server and test it manually as explained above. Once you're sure that it works fine on one server, you can be confident in the new Ansible tasks and deploy them on all servers.

For more information on how to use Ansible to automate MariaDB configuration, see Ansible and MariaDB.

2.4.11 Transaction Coordinator Log

Transaction Coordinator Log Overview

The transaction coordinator log (tc_log) is used to coordinate transactions...

2.4.11.1 Transaction Coordinator Log Overview

Contents

The transaction coordinator log (tc_log) is used to coordinate transactions that affect multiple XA-capable storage engines. If you have two or more XA-capable storage engines enabled, then a transaction coordinator log must be available.

Types of Transaction Coordinator Logs

There are currently two implementations of the transaction coordinator log:

- Binary log-based transaction coordinator log
- Memory-mapped file-based transaction coordinator log

If the binary log is enabled on a server, then the server will use the binary log-based transaction coordinator log. Otherwise, it will use the memory-mapped file-based transaction coordinator log.

Binary Log-Based Transaction Coordinator Log

This transaction coordinator uses the binary log, which is enabled by the `log_bin` server option.

Memory-Mapped File-Based Transaction Coordinator Log

This transaction coordinator uses the memory-mapped file defined by the `--log-tc` server option. The size is defined by the `log_tc_size` system variable.

Some facts about this log:

- The log consists of a memory-mapped file that is divided into pages of 8KB size.
- The usable size of the first page is smaller because of the log header. There is a PAGE control structure for each page.
- Each page (or rather its PAGE control structure) can be in one of the three states - active, syncing, pool.
- There could be only one page in the active or syncing state, but many in the pool state - pool is a fifo queue.
- The usual lifecycle of a page is pool->active->syncing->pool.
- The "active" page is a page where new xid's are logged.
- The page stays active as long as the syncing slot is taken.
- The "syncing" page is being synced to disk. no new xid can be added to it.
- When the syncing is done the page is moved to a pool and an active page becomes "syncing".

The result of such an architecture is a natural "commit grouping" - If commits are coming faster than the system can sync, they do not stall. Instead, all commits that came since the last sync are logged to the same "active" page, and they all are synced with the next - one - sync. Thus, thought individual commits are delayed, throughput is not decreasing.

When an xid is added to an active page, the thread of this xid waits for a page's condition until the page is synced. When a syncing slot becomes vacant one of these waiters is awakened to take care of syncing. It syncs the page and signals all waiters that the page is synced. The waiters are counted, and a page may never become active again until waiters==0, which means that is all waiters from the previous sync have noticed that the sync was completed.

Note that a page becomes "dirty" and has to be synced only when a new xid is added into it. Removing a xid from a page does not make it dirty - we don't sync xid removals to disk.

Monitoring the Memory-Mapped File-Based Transaction Coordinator Log

The memory-mapped transaction coordinator log can be monitored with the following status variables:

- `Tc_log_max_pages_used`
- `Tc_log_page_size`
- `Tc_log_page_waits`

Heuristic Recovery with the Transaction Coordinator Log

One of the main purposes of the transaction coordinator log is in crash recovery. See Heuristic Recovery with the Transaction Coordinator Log for more information about that.

Known Issues

You must enable exactly N storage engines

Prior to MariaDB 10.1.10, if you were using the memory-mapped file-based transaction coordinator log, and then if the server crashed and you changed the number of XA-capable storage engines that it loaded, then you could see errors like the following:

```
2018-11-30 23:08:49 140046048638848 [Note] Recovering after a crash using tc.log
2018-11-30 23:08:49 140046048638848 [ERROR] Recovery failed! You must enable exactly 3 storage
engines that support two-phase commit protocol
2018-11-30 23:08:49 140046048638848 [ERROR] Crash recovery failed. Either correct the problem
(if it's, for example, out of memory error) and restart, or delete tc log and start mysqld with
--tc-heuristic-recover={commit|rollback}
2018-11-30 23:08:49 140046048638848 [ERROR] Can't init tc log
2018-11-30 23:08:49 140046048638848 [ERROR] Aborting
```

To recover from this error, delete the file defined by the `--log-tc` server option, and then restart the server with the `--tc-heuristic-recover` option set.

See MDEV-9214 for more information.

Bad magic header in tc log

If you are using the memory-mapped file-based transaction coordinator log, then it is possible to see errors like the following:

```
2018-09-19  4:29:31 0 [Note] Recovering after a crash using tc.log
2018-09-19  4:29:31 0 [ERROR] Bad magic header in tc log
2018-09-19  4:29:31 0 [ERROR] Crash recovery failed. Either correct the problem (if it's, for
example, out of memory error) and restart, or delete tc log and start mysqld with --tc-
heuristic-recover={commit|rollback}
2018-09-19  4:29:31 0 [ERROR] Can't init tc log
2018-09-19  4:29:31 0 [ERROR] Aborting
```

This means that the header of the memory-mapped file-based transaction coordinator log is corrupt. To recover from this error, delete the file defined by the `--log-tc` server option, and then restart the server with the `--tc-heuristic-recover` option set.

This issue is known to occur when using docker. In that case, the problem may be caused by using a MariaDB container version with a data directory from a different MariaDB or MySQL version. Therefore, some potential fixes are:

- Pinning the docker instance to a specific MariaDB version in the docker compose file, so that it consistently uses the same version.
- Running mariadb-upgrade to ensure that the data directory is upgraded to match the server version.

See this docker issue for more information.

MariaDB Galera Cluster

MariaDB Galera Cluster builds include a built-in plugin called `wsrep`. Prior to MariaDB 10.4.3, this plugin was internally considered an XA-capable storage engine. Consequently, these MariaDB Galera Cluster builds have multiple XA-capable storage engines by default, even if the only "real" storage engine that supports external XA transactions enabled on these builds by default is InnoDB. Therefore, when using one these builds MariaDB would be forced to use a transaction coordinator log by default, which could have performance implications.

For example, MDEV-16509 describes performance problems where MariaDB Galera Cluster actually performs better when the binary log is enabled. It is possible that this is caused by the fact that MariaDB is forced to use the memory-

mapped file-based transaction coordinator log in this case, which may not perform as well.

This became a bigger issue in MariaDB 10.1 when the MySQL-wsrep patch that powers MariaDB Galera Cluster was enabled on most MariaDB builds on Linux by default. Consequently, this built-in `wsrep` plugin would exist on those MariaDB builds on Linux by default. Therefore, MariaDB users might pay a performance penalty, even if they never actually intended to use the MariaDB Galera Cluster features included in MariaDB 10.1.

In MariaDB 10.4.3 and later, the built-in `wsrep` plugin has been changed to a replication plugin. Therefore, it is no longer considered an XA-capable storage engine, so it no longer forces MariaDB to use a transaction coordinator log by default.

See MDEV-16442 for more information.

2.4.11.2 Heuristic Recovery with the Transaction Coordinator Log

Contents

The transaction coordinator log (tc_log) is used to coordinate transactions that affect multiple XA-capable storage engines. One of the main purposes of this log is in crash recovery.

Modes of Crash Recovery

There are two modes of crash recovery:

- Automatic crash recovery.
- Manual heuristic recovery when `--tc-heuristic-recover` is set to some value other than `OFF`.

Automatic Crash Recovery

Automatic crash recovery occurs during startup when MariaDB needs to recover from a crash and `--tc-heuristic-recover` is set to `OFF`, which is the default value.

Automatic Crash Recovery with the Binary Log-Based Transaction Coordinator Log

If MariaDB needs to perform automatic crash recovery and if the binary log is enabled, then the error log will contain messages like this:

```
[Note] Recovering after a crash using cmdb-mariadb-0-bin
[Note] InnoDB: Buffer pool(s) load completed at 190313 11:24:29
[Note] Starting crash recovery...
[Note] Crash recovery finished.
```

Automatic Crash Recovery with the Memory-Mapped File-Based Transaction Coordinator Log

If MariaDB needs to perform automatic crash recovery and if the binary log is **not** enabled, then the error log will contain messages like this:

```
[Note] Recovering after a crash using tc.log
[Note] InnoDB: Buffer pool(s) load completed at 190313 11:26:32
[Note] Starting crash recovery...
[Note] Crash recovery finished.
```

Manual Heuristic Recovery

Manual heuristic recovery occurs when `--tc-heuristic-recover` is set to some value other than `OFF`. This might be needed if the server finds prepared transactions during crash recovery that are not in the transaction coordinator log. For example, the error log might contain an error like this:

```
[ERROR] Found 1 prepared transactions! It means that mysqld was not shut down properly last
time and critical recovery information (last binlog or tc.log file) was manually deleted after
a crash. You have to start mysqld with --tc-heuristic-recover switch to commit or rollback
pending transactions.
```

When manual heuristic recovery is initiated, MariaDB will ignore information about transactions in the transaction coordinator log during the recovery process. Prepared transactions that are encountered during the recovery process will either be rolled back or committed, depending on the value of `--tc-heuristic-recover`.

When manual heuristic recovery is initiated, the error log will contain a message like this:

```
[Note] Heuristic crash recovery mode
```

Manual Heuristic Recovery with the Binary Log-Based Transaction Coordinator Log

If `--tc-heuristic-recover` is set to some value other than `OFF` and if the binary log is enabled, then MariaDB will ignore information about transactions in the binary log during the recovery process. Prepared transactions that are encountered during the recovery process will either be rolled back or committed, depending on the value of `--tc-heuristic-recover`.

After the recovery process is complete, MariaDB will create a new empty binary log file, so that the old corrupt ones can be ignored.

Manual Heuristic Recovery with the Memory-Mapped File-Based Transaction Coordinator Log

If `--tc-heuristic-recover` is set to some value other than `OFF` and if the binary log is **not** enabled, then MariaDB will ignore information about transactions in the the memory-mapped file defined by the `--log-tc` option during the recovery process. Prepared transactions that are encountered during the recovery process will either be rolled back or committed, depending on the value of `--tc-heuristic-recover`.

For time series (includes list of PARTITION uses)

Partitioning Limitations

Limitations applying to partitioning in MariaDB.

Partitions Files

A partitioned table is stored in multiple files

Partitions Metadata

How to obtain information about partitions definition

Information Schema PARTITIONS Table

Table partition information.

There are 2 related questions.

2.5.1 Partitioning Overview

Contents

In MariaDB, a table can be split in smaller subsets. Both data and indexes are partitioned.

Uses for Partitioning

There can be several reasons to use this feature:

- Very big tables and indexes can be slow even with optimized queries. But if the target table is partitioned, queries that read a small number of partitions can be much faster.
- Partitioning allows one to distribute files over multiple storage devices. For example, we can have historical data on slower, larger disks (historical data are not supposed to be frequently read); and current data can be on faster disks, or SSD devices.
- In case we separate historical data from recent data, we will probably need to take regular backups of one partition, not the whole table.

Partitioning for Specific Storage Engines

Some MariaDB storage engines allow more interesting uses for partitioning.

SPIDER allows one to:

- Move partitions of the same table on different servers. In this way, the workload can be distributed on more physical or virtual machines (*data sharding*).
- All partitions of a SPIDER table can also live on the same machine. In this case there will be a small overhead (SPIDER will use connections to localhost), but queries that read multiple partitions will use parallel threads.

CONNECT allows one to:

- Build a table whose partitions are tables using different storage engines (like InnoDB, MyISAM, or even engines that do not support partitioning).
- Build an indexable, writeable table on several data files. These files can be in different formats.

See also: Using CONNECT - Partitioning and Sharding

Partitioning Types

When partitioning a table, the use should decide:

- a *partitioning type*;
- a *partitioning expression*.

A partitioning type is the method used by MariaDB to decide how rows are distributed over existing partitions. Choosing the proper partitioning type is important to distribute rows over partitions in an efficient way.

With some partitioning types, a partitioning expression is also required. A partitioning function is an SQL expression returning an integer or temporal value, used to determine which row will contain a given row. The partitioning expression is used for all reads and writes on involving the partitioned table, thus it should be fast.

See Partioning Types for a detailed description.

Enabling Partitioning

By default, MariaDB permits partitioning. You can determine this by using the SHOW PLUGINS statement, for example:

```
SHOW PLUGINS;
...
| Aria                          | ACTIVE   | STORAGE ENGINE     | NULL    | GPL     |
| FEEDBACK                      | DISABLED | INFORMATION SCHEMA | NULL    | GPL     |
| partition                     | ACTIVE   | STORAGE ENGINE     | NULL    | GPL     |
+-------------------------------+----------+--------------------+---------+---------+
```

If partition is listed as DISABLED:

```
| partition                     | DISABLED | STORAGE ENGINE     | NULL    | GPL     |
+-------------------------------+----------+--------------------+---------+---------+
```

MariaDB has either been built without partitioning support, or has been started with the the --skip-partition option, or one of its variants:

```
--skip-partition
--disable-partition
--partition=OFF
```

and you will not be able to create partitions.

Using Partitions

It is possible to create a new partitioned table using CREATE TABLE.

ALTER TABLE allows one to:

- Partition an existing table;
- Remove partitions from a partitioned table (**with all data in the partition**);
- Add/remove partitions, or reorganize them, as long as the partitioning function allows these operations (see below);
- Exchange a partition with a table;
- Perform administrative operations on some or all partitions (analyze, optimize, check, repair).

Adding Partitions

```
ADD PARTITION [IF NOT EXISTS] (partition_definition)
```

`ALTER TABLE ... ADD PARTITION` can be used to add partitions to an existing table:

```
CREATE OR REPLACE TABLE t1 (
  timestamp DATETIME NOT NULL
)
  ENGINE = InnoDB
  PARTITION BY RANGE (YEAR(timestamp))
  (
  PARTITION p0 VALUES LESS THAN (2013),
  PARTITION p1 VALUES LESS THAN (2014),
  PARTITION p2 VALUES LESS THAN (2015),
  PARTITION p3 VALUES LESS THAN (2016)
);

ALTER TABLE t1 ADD PARTITION (
  PARTITION p4 VALUES LESS THAN (2017),
  p5 VALUES LESS THAN (2018)
);
```

Converting Partitions to Tables

MariaDB starting with 10.7

```
CONVERT PARTITION partition_name TO TABLE tbl_name
```

`ALTER TABLE ... CONVERT PARTITION` can, from MariaDB 10.7, be used to convert partitions in an existing table to a standalone table:

```
CREATE OR REPLACE TABLE t1 (
   timestamp DATETIME NOT NULL
 )
   ENGINE = InnoDB
   PARTITION BY RANGE (YEAR(timestamp))
   (
   PARTITION p0 VALUES LESS THAN (2013),
   PARTITION p1 VALUES LESS THAN (2014),
   PARTITION p2 VALUES LESS THAN (2015),
   PARTITION p3 VALUES LESS THAN (2016)
 );

INSERT INTO t1 VALUES ('2012-11-11'),('2013-11-11'),('2014-11-11');

SELECT * FROM t1;
+---------------------+
| timestamp           |
+---------------------+
| 2012-11-11 00:00:00 |
| 2013-11-11 00:00:00 |
| 2014-11-11 00:00:00 |
+---------------------+

ALTER TABLE t1 CONVERT PARTITION p0 TO TABLE t2;

SELECT * FROM t1;
+---------------------+
| timestamp           |
+---------------------+
| 2013-11-11 00:00:00 |
| 2014-11-11 00:00:00 |
+---------------------+

SELECT * FROM t2;
+---------------------+
| timestamp           |
+---------------------+
| 2012-11-11 00:00:00 |
+---------------------+

SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
       Table: t1
Create Table: CREATE TABLE `t1` (
  `timestamp` datetime NOT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1 COLLATE=latin1_swedish_ci
 PARTITION BY RANGE (year(`timestamp`))
(PARTITION `p1` VALUES LESS THAN (2014) ENGINE = InnoDB,
 PARTITION `p2` VALUES LESS THAN (2015) ENGINE = InnoDB,
 PARTITION `p3` VALUES LESS THAN (2016) ENGINE = InnoDB)

SHOW CREATE TABLE t2\G
*************************** 1. row ***************************
       Table: t2
Create Table: CREATE TABLE `t2` (
  `timestamp` datetime NOT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1 COLLATE=latin1_swedish_ci
```

An alternative (and the only method prior to MariaDB 10.7) to convert partitions to tables is to use `ALTER TABLE ... EXCHANGE PARTITION`. This requires having to manually do the following steps:

- create an empty table with the same structure as the partition
- exchange the table with the partition
- drop the empty partition

For example:

```
CREATE OR REPLACE TABLE t1 (
   timestamp DATETIME NOT NULL
 )
   ENGINE = InnoDB
   PARTITION BY RANGE (YEAR(timestamp))
   (
   PARTITION p0 VALUES LESS THAN (2013),
   PARTITION p1 VALUES LESS THAN (2014),
   PARTITION p2 VALUES LESS THAN (2015),
   PARTITION p3 VALUES LESS THAN (2016)
 );

INSERT INTO t1 VALUES ('2012-11-11'),('2013-11-11'),('2014-11-11');

SELECT * FROM t1;
+---------------------+
| timestamp           |
+---------------------+
| 2012-11-11 00:00:00 |
| 2013-11-11 00:00:00 |
| 2014-11-11 00:00:00 |
+---------------------+

CREATE OR REPLACE TABLE t2 LIKE t1;

ALTER TABLE t2 REMOVE PARTITIONING;

ALTER TABLE t1 EXCHANGE PARTITION p0 WITH TABLE t2;

ALTER TABLE t1 DROP PARTITION p0;

SELECT * FROM t1;
+---------------------+
| timestamp           |
+---------------------+
| 2013-11-11 00:00:00 |
| 2014-11-11 00:00:00 |
+---------------------+

SELECT * FROM t2;
+---------------------+
| timestamp           |
+---------------------+
| 2012-11-11 00:00:00 |
+---------------------+

SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
       Table: t1
Create Table: CREATE TABLE `t1` (
  `timestamp` datetime NOT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1 COLLATE=latin1_swedish_ci
 PARTITION BY RANGE (year(`timestamp`))
(PARTITION `p1` VALUES LESS THAN (2014) ENGINE = InnoDB,
 PARTITION `p2` VALUES LESS THAN (2015) ENGINE = InnoDB,
 PARTITION `p3` VALUES LESS THAN (2016) ENGINE = InnoDB)
1 row in set (0.001 sec)

SHOW CREATE TABLE t2\G
*************************** 1. row ***************************
       Table: t2
Create Table: CREATE TABLE `t2` (
  `timestamp` datetime NOT NULL
) ENGINE=InnoDB DEFAULT CHARSET=latin1 COLLATE=latin1_swedish_ci
```

Dropping Partitions

```
DROP PARTITION [IF EXISTS] partition_names
```

`ALTER TABLE ... DROP PARTITION` can be used to drop specific partitions (and discard all data within the specified partitions) for RANGE and LIST partitions. It cannot be used on `HASH` or `KEY` partitions. To rather remove all partitioning,

while leaving the data unaffected, see Removing Partitioning.

```
CREATE OR REPLACE TABLE t1 (
  timestamp DATETIME NOT NULL
)
  ENGINE = InnoDB
  PARTITION BY RANGE (YEAR(timestamp))
  (
  PARTITION p0 VALUES LESS THAN (2013),
  PARTITION p1 VALUES LESS THAN (2014),
  PARTITION p2 VALUES LESS THAN (2015),
  PARTITION p3 VALUES LESS THAN (2016)
);

INSERT INTO t1 VALUES ('2012-11-15');
SELECT * FROM t1;
+---------------------+
| timestamp           |
+---------------------+
| 2012-11-15 00:00:00 |
+---------------------+

ALTER TABLE t1 DROP PARTITION p0;

SELECT * FROM t1;
Empty set (0.002 sec)
```

Removing Partitioning

```
REMOVE PARTITIONING
```

`ALTER TABLE ... REMOVE PARTITIONING` will remove all partitioning from the table, while leaving the data unaffected. To rather drop a particular partition (and discard all of its data), see Dropping Partitions.

```
ALTER TABLE t1 REMOVE PARTITIONING;
```

Truncating Partitions

```
TRUNCATE PARTITION partition_names
```

`ALTER TABLE ... TRUNCATE PARTITION` will remove all data from the specified partition/s, leaving the table and partition structure unchanged. Partitions don't need to be contiguous.

```
CREATE OR REPLACE TABLE t1 (
  timestamp DATETIME NOT NULL
)
  ENGINE = InnoDB
  PARTITION BY RANGE (YEAR(timestamp))
  (
  PARTITION p0 VALUES LESS THAN (2013),
  PARTITION p1 VALUES LESS THAN (2014),
  PARTITION p2 VALUES LESS THAN (2015),
  PARTITION p3 VALUES LESS THAN (2016)
);

INSERT INTO t1 VALUES ('2012-11-01'),('2013-11-02'),('2014-11-03'),('2015-11-04');

SELECT * FROM t1;
+---------------------+
| timestamp           |
+---------------------+
| 2012-11-01 00:00:00 |
| 2013-11-02 00:00:00 |
| 2014-11-03 00:00:00 |
| 2015-11-04 00:00:00 |
+---------------------+

ALTER TABLE t1 TRUNCATE PARTITION p0,p2;

SELECT * FROM t1;
+---------------------+
| timestamp           |
+---------------------+
| 2013-11-02 00:00:00 |
| 2015-11-04 00:00:00 |
+---------------------+
```

2.5.2 Partitioning Types

Partitioning Types Overview

A partition type determines how a partitioned table rows are distributed across partitions

LIST Partitioning Type

LIST partitioning is used to assign each partition a list of values

RANGE Partitioning Type

The RANGE partitioning type is used to assign each partition a range of values.

HASH Partitioning Type

Form of partitioning in which the server takes care of the partition in which to place the data.

KEY Partitioning Type

Used to have the server assign the distribution of rows across partitions.

LINEAR HASH Partitioning Type

Form of partitioning, similar to HASH, in which the server takes care of th...

LINEAR KEY Partitioning Type

Form of partitioning similar to KEY partitioning.

RANGE COLUMNS and LIST COLUMNS Partitioning Types

Used to assign each partition a range or a list of values

2.5.2.1 Partitioning Types Overview

A partitioning type determines how a partitioned table's rows are distributed across partitions. Some partition types require the user to specify a partitioning expression that determines in which partition a row will be stored.

The size of individual partitions depends on the partitioning type. Read and write performance are affected by the

partitioning expression. Therefore, these choices should be made carefully.

MariaDB supports the following partitioning types:

- RANGE
- LIST
- RANGE COLUMNS and LIST COLUMNS
- HASH
- LINEAR HASH
- KEY
- LINEAR KEY
- SYSTEM_TIME

2.5.2.2 LIST Partitioning Type

LIST partitioning is conceptually similar to RANGE partitioning. In both cases you decide a partitioning expression (a column, or a slightly more complex calculation) and use it to determine which partitions will contain each row. However, with the RANGE type, partitioning is done by assigning a range of values to each partition. With the LIST type, we assign a set of values to each partition. This is usually preferred if the partitioning expression can return a limited set of values.

A variant of this partitioning method, LIST COLUMNS, allows us to use multiple columns and more datatypes.

Syntax

The last part of a CREATE TABLE statement can be the definition of the new table's partitions. In the case of LIST partitioning, the syntax is the following:

```
PARTITION BY LIST (partitioning_expression)
(
 PARTITION partition_name VALUES IN (value_list),
 [ PARTITION partition_name VALUES IN (value_list), ... ]
        [ PARTITION partition_name DEFAULT ]
)
```

PARTITION BY LIST indicates that the partitioning type is LIST.

The `partitioning_expression` is an SQL expression that returns a value from each row. In the simplest cases, it is a column name. This value is used to determine which partition should contain a row.

`partition_name` is the name of a partition.

`value_list` is a list of values. If `partitioning_expression` returns one of these values, the row will be stored in this partition. If we try to insert something that does not belong to any of these value lists, the row will be rejected with an error.

The `DEFAULT` partition catches all records which do not fit into other partitions. Only one `DEFAULT` partition is permitted. This option was added in MariaDB 10.2.

Use cases

LIST partitioning can be useful when we have a column that can only contain a limited set of values. Even in that case, RANGE partitioning could be used instead; but LIST partitioning allows us to equally distribute the rows by assigning a proper set of values to each partition.

2.5.2.3 RANGE Partitioning Type

Contents

The RANGE partitioning type is used to assign each partition a range of values generated by the partitioning expression. Ranges must be ordered, contiguous and non-overlapping. The minimum value is always included in the first range. The highest value may or may not be included in the last range.

A variant of this partitioning method, RANGE COLUMNS, allows us to use multiple columns and more datatypes.

Syntax

The last part of a CREATE TABLE statement can be definition of the new table's partitions. In the case of RANGE partitioning, the syntax is the following:

```
PARTITION BY RANGE (partitioning_expression)
(
 PARTITION partition_name VALUES LESS THAN (value),
 [ PARTITION partition_name VALUES LESS THAN (value), ... ]
)
```

PARTITION BY RANGE indicates that the partitioning type is RANGE.

The `partitioning_expression` is an SQL expression that returns a value from each row. In the simplest cases, it is a column name. This value is used to determine which partition should contain a row.

`partition_name` is the name of a partition.

`value` indicates the upper bound for that partition. The values must be ascending. For the first partition, the lower limit is NULL. When trying to insert a row, if its value is higher than the upper limit of the last partition, the row will be rejected (with an error, if the IGNORE keyword is not used).

If this is a problem, MAXVALUE can be specified as a value for the last partition. Note however that it is not possible to split partitions of an existing RANGE partitioned table. New partitions can be appended, but this will not be possible if the last partition's higher bound is MAXVALUE.

Use Cases

A typical use case is when we want to partition a table whose rows refer to a moment or period in time; for example commercial transactions, blog posts, or events of some kind. We can partition the table by year, to keep all recent data in one partition and distribute historical data in big partitions that are stored on slower disks. Or, if our queries always read rows which refer to the same month or week, we can partition the table by month or year week (in this case, historical data and recent data will be stored together).

AUTO_INCREMENT values also represent a chronological order. So, these values can be used to store old data in separate partitions. However, partitioning by id is not the best choice if we usually query a table by date.

Examples

In the following example, we will partition a log table by year.

```
CREATE TABLE log
(
 id INT UNSIGNED NOT NULL AUTO_INCREMENT,
 timestamp DATETIME NOT NULL,
 user INT UNSIGNED,
 ip BINARY(16) NOT NULL,
 action VARCHAR(20) NOT NULL,
 PRIMARY KEY (id, timestamp)
)
 ENGINE = InnoDB
PARTITION BY RANGE (YEAR(timestamp))
(
 PARTITION p0 VALUES LESS THAN (2013),
 PARTITION p1 VALUES LESS THAN (2014),
 PARTITION p2 VALUES LESS THAN (2015),
 PARTITION p3 VALUES LESS THAN (2016)
);
```

As an alternative, we can partition the table by both year and month:

```
CREATE TABLE log
(
 id INT UNSIGNED NOT NULL AUTO_INCREMENT,
 timestamp TIMESTAMP NOT NULL,
 user INT UNSIGNED,
 ip BINARY(16) NOT NULL,
 action VARCHAR(20) NOT NULL,
 PRIMARY KEY (id, timestamp)
)
 ENGINE = InnoDB
PARTITION BY RANGE (UNIX_TIMESTAMP(timestamp))
(
 PARTITION p0 VALUES LESS THAN (UNIX_TIMESTAMP('2014-08-01 00:00:00')),
 PARTITION p1 VALUES LESS THAN (UNIX_TIMESTAMP('2014-11-01 00:00:00')),
 PARTITION p2 VALUES LESS THAN (UNIX_TIMESTAMP('2015-01-01 00:00:00')),
 PARTITION p3 VALUES LESS THAN (UNIX_TIMESTAMP('2015-02-01 00:00:00'))
);
```

As you can see, we used the UNIX_TIMESTAMP function to accomplish the purpose. Also, the first two partitions cover longer periods of time (probably because the logged activities were less intensive).

In both cases, when our tables become huge and we don't need to store all historical data any more, we can drop the oldest partitions in this way:

```
 ALTER TABLE log DROP PARTITION p0;
```

We will still be able to drop a partition that does not contain the oldest data, but all rows stored in it will disappear.

Example of an error when inserting outside a defined partition range:

```
INSERT INTO log(id,timestamp) VALUES
  (1, '2016-01-01 01:01:01'),
  (2, '2015-01-01 01:01:01');
ERROR 1526 (HY000): Table has no partition for value 2016
```

Unless the IGNORE keyword is used:

```
INSERT IGNORE INTO log(id,timestamp) VALUES
  (1, '2016-01-01 01:01:01'),
  (2, '2015-01-01 01:01:01');

SELECT * FROM log;
+----+---------------------+------+------------------+--------+
| id | timestamp           | user | ip               | action |
+----+---------------------+------+------------------+--------+
|  2 | 2015-01-01 01:01:01 | NULL |                  |        |
+----+---------------------+------+------------------+--------+
```

An alternative definition with MAXVALUE as a catchall:

```
CREATE TABLE log
(
 id INT UNSIGNED NOT NULL AUTO_INCREMENT,
 timestamp DATETIME NOT NULL,
 user INT UNSIGNED,
 ip BINARY(16) NOT NULL,
 action VARCHAR(20) NOT NULL,
 PRIMARY KEY (id, timestamp)
)
 ENGINE = InnoDB
PARTITION BY RANGE (YEAR(timestamp))
(
 PARTITION p0 VALUES LESS THAN (2013),
 PARTITION p1 VALUES LESS THAN (2014),
 PARTITION p2 VALUES LESS THAN (2015),
 PARTITION p3 VALUES LESS THAN (2016),
 PARTITION p4 VALUES LESS THAN MAXVALUE
);
```

2.5.2.4 HASH Partitioning Type

Syntax

```
PARTITION BY HASH (partitioning_expression)
[PARTITIONS(number_of_partitions)]
```

Description

HASH partitioning is a form of partitioning in which the server takes care of the partition in which to place the data, ensuring an even distribution among the partitions.

It requires a column value, or an expression based on a column value, which is hashed, as well as the number of partitions into which to divide the table.

partitioning_expression needs to return a non-constant, deterministic integer. It is evaluated for each insert and update, so overly complex expressions can lead to performance issues. A hashing function operating on a single column, and where the value changes consistently with the column value, allows for easy pruning on ranges of partitions, and is usually a better choice. For this reason, using multiple columns in a hashing expression is not usually recommended.

number_of_partitions is a positive integer specifying the number of partitions into which to divide the table. If the `PARTITIONS` clause is omitted, the default number of partitions is one.

Determining the Partition

To determine which partition to use, the following calculation is performed: MOD(partitioning_expression, number_of_partitions)

For example, if the expression is TO_DAYS(datetime_column) and the number of partitions is 5, inserting a datetime value of '2023-11-15' would determine the partition as follows:

- TO_DAYS('2023-11-15') gives a value of 739204
- MOD(739204,5) returns 4 so the 4th partition is used.

HASH partitioning making use of the modulus of the hashing function's value. The LINEAR HASH partitioning type is similar, using a powers-of-two algorithm. Data is more likely to be evenly distributed over the partitions than with the LINEAR HASH partitioning type, however, adding, dropping, merging and splitting partitions is much slower.

Examples

```
CREATE OR REPLACE TABLE t1 (c1 INT, c2 DATETIME)
  PARTITION BY HASH(TO_DAYS(c2))
  PARTITIONS 5;
```

Using the Information Schema PARTITIONS Table for more information:

```
INSERT INTO t1 VALUES (1,'2023-11-15');

SELECT PARTITION_NAME,TABLE_ROWS FROM INFORMATION_SCHEMA.PARTITIONS
  WHERE TABLE_SCHEMA='test' AND TABLE_NAME='t1';
+----------------+------------+
| PARTITION_NAME | TABLE_ROWS |
+----------------+------------+
| p0             |          0 |
| p1             |          0 |
| p2             |          0 |
| p3             |          0 |
| p4             |          1 |
+----------------+------------+
```

2.5.2.5 KEY Partitioning Type

Syntax

```
PARTITION BY KEY ([column_names])
[PARTITIONS (number_of_partitions)]
```

Description

Partitioning by key is a type of partitioning that is similar to and can be used in a similar way as partitioning by hash.

KEY takes an optional list of *column_names*, and the hashing function is given by the server.

Just like HASH partitioning, in KEY partitioning the server takes care of the partition and ensures an even distribution among the partitions. However, the largest difference is that KEY partitioning makes use of *column_names*, and cannot accept a *partitioning_expression* which is based on *column_names*, in contrast to HASH partitioning, which can.

If no *column_names* are specified, the table's primary key is used if present, or not null unique key if no primary key is present. If neither of these keys are present, not specifying any *column_names* will result in `ERROR 1488 (HY000): Field in list of fields for partition function not found in table`

Unlike other partitioning types, columns used for partitioning by KEY are not limited to integer or NULL values.

KEY partitions do not support column index prefixes. Any columns in the partitioning key that make use of column prefixes are not used (see also MDEV-32727).

Example

```
CREATE OR REPLACE TABLE t1 (v1 INT)
  PARTITION BY KEY (v1)
  PARTITIONS 2;
```

```
CREATE OR REPLACE TABLE t1 (v1 INT, v2 INT)
  PARTITION BY KEY (v1,v2)
  PARTITIONS 2;
```

```
CREATE OR REPLACE TABLE t1 (
    id INT NOT NULL PRIMARY KEY,
    name VARCHAR(5)
)
PARTITION BY KEY()
PARTITIONS 2;
```

```
CREATE OR REPLACE TABLE t1 (
    id INT NOT NULL UNIQUE KEY,
    name VARCHAR(5)
)
PARTITION BY KEY()
PARTITIONS 2;
```

The unique key must be NOT NULL:

```
CREATE OR REPLACE TABLE t1 (
    id INT NULL UNIQUE KEY,
    name VARCHAR(5)
)
PARTITION BY KEY()
PARTITIONS 2;
ERROR 1488 (HY000): Field in list of fields for partition function not found in table
```

KEY requires *column_values* if no primary key or not null unique key is present:

```
CREATE OR REPLACE TABLE t1 (
    id INT NULL UNIQUE KEY,
    name VARCHAR(5)
)
PARTITION BY KEY()
PARTITIONS 2;
ERROR 1488 (HY000): Field in list of fields for partition function not found in table
```

```
CREATE OR REPLACE TABLE t1 (
    id INT NULL UNIQUE KEY,
    name VARCHAR(5)
)
PARTITION BY KEY(name)
PARTITIONS 2;
```

Primary key columns with index prefixes are silently ignored, so the following two queries are equivalent:

```
CREATE OR REPLACE TABLE t1 (
    a VARCHAR(10),
    b VARCHAR(10),
    c VARCHAR(10),
    PRIMARY KEY (a(5), b, c(5))
) PARTITION BY KEY() PARTITIONS 2;

CREATE OR REPLACE TABLE t1 (
    a VARCHAR(10),
    b VARCHAR(10),
    c VARCHAR(10),
    PRIMARY KEY (b)
) PARTITION BY KEY() PARTITIONS 2;
```

`a(5)` and `c(5)` are silently ignored in the former.

If all columns use index prefixes, the statement fails with a slightly misleading error:

```
CREATE OR REPLACE TABLE t1 (
    a VARCHAR(10),
    b VARCHAR(10),
    c VARCHAR(10),
    PRIMARY KEY (a(5), b(5), c(5))
) PARTITION BY KEY() PARTITIONS 2;
ERROR 1503 (HY000): A PRIMARY KEY must include all columns in the table's partitioning function
```

2.5.2.6 LINEAR HASH Partitioning Type

Syntax

```
PARTITION BY LINEAR HASH (partitioning_expression)
[PARTITIONS(number_of_partitions)]
```

Description

LINEAR HASH partitioning is a form of partitioning, similar to HASH partitioning, in which the server takes care of the partition in which to place the data, ensuring a relatively even distribution among the partitions.

LINEAR HASH partitioning makes use of a powers-of-two algorithm, while HASH partitioning uses the modulus of the hashing function's value. Adding, dropping, merging and splitting partitions is much faster than with the HASH partitioning type, however, data is less likely to be evenly distributed over the partitions.

Example

```
CREATE OR REPLACE TABLE t1 (c1 INT, c2 DATETIME)
  PARTITION BY LINEAR HASH(TO_DAYS(c2))
  PARTITIONS 5;
```

2.5.2.7 LINEAR KEY Partitioning Type

Syntax

```
LINEAR PARTITION BY KEY ([column_names])
[PARTITIONS (number_of_partitions)]
```

Description

LINEAR KEY partitioning is a form of partitioning, similar to KEY partitioning.

LINEAR KEY partitioning makes use of a powers-of-two algorithm, while KEY partitioning uses modulo arithmetic, to determine the partition number.

Adding, dropping, merging and splitting partitions is much faster than with the KEY partitioning type, however, data is less likely to be evenly distributed over the partitions.

Example

```
CREATE OR REPLACE TABLE t1 (v1 INT)
  PARTITION BY LINEAR KEY (v1)
  PARTITIONS 2;
```

2.5.2.8 RANGE COLUMNS and LIST COLUMNS Partitioning Types

RANGE COLUMNS and LIST COLUMNS are variants of, respectively, RANGE and LIST. With these partitioning types there is not a single partitioning expression; instead, a list of one or more columns is accepted. The following rules apply:

- The list can contain one or more columns.
- Columns can be of any integer, string, DATE, and DATETIME types.
- Only bare columns are permitted; no expressions.

All the specified columns are compared to the specified values to determine which partition should contain a specific row. See below for details.

Syntax

The last part of a CREATE TABLE statement can be definition of the new table's partitions. In the case of RANGE COLUMNS partitioning, the syntax is the following:

```
PARTITION BY RANGE COLUMNS (col1, col2, ...)
(
 PARTITION partition_name VALUES LESS THAN (value1, value2, ...),
 [ PARTITION partition_name VALUES LESS THAN (value1, value2, ...), ... ]
)
```

The syntax for LIST COLUMNS is the following:

```
PARTITION BY LIST COLUMNS (partitioning_expression)
(
 PARTITION partition_name VALUES IN (value1, value2, ...),
 [ PARTITION partition_name VALUES IN (value1, value2, ...), ... ]
        [ PARTITION partititon_name DEFAULT ]
)
```

`partition_name` is the name of a partition.

Comparisons

To determine which partition should contain a row, all specified columns will be compared to each partition definition.

With LIST COLUMNS, a row matches a partition if all row values are identical to the specified values. At most one partition can match the row.

With RANGE COLUMNS, a row matches a partition if all row values are less than the specified values. The first partition that matches the row values will be used.

The `DEFAULT` partition catches all records which do not fit in other partitions. Only one `DEFAULT` partition is allowed.

2.5.3 Partition Pruning and Selection

When a WHERE clause is related to the partitioning expression, the optimizer knows which partitions are relevant for the query. Other partitions will not be read. This optimization is called *partition pruning*.

EXPLAIN PARTITIONS can be used to know which partitions will be read for a given query. A column called `partitions` will contain a comma-separated list of the accessed partitions. For example:

```
EXPLAIN PARTITIONS SELECT * FROM orders WHERE id < 15000000;
+------+-------------+--------+------------+-------+---------------+---------+---------+-----
-+------+-------------+
| id   | select_type | table  | partitions | type  | possible_keys | key     | key_len | ref  |
rows | Extra       |
+------+-------------+--------+------------+-------+---------------+---------+---------+-----
-+------+-------------+
|    1 | SIMPLE      | orders | p0,p1      | range | PRIMARY       | PRIMARY | 4       | NULL
|    2 | Using where |
+------+-------------+--------+------------+-------+---------------+---------+---------+-----
-+------+-------------+
```

Sometimes the WHERE clause does not contain the necessary information to use partition pruning, or the optimizer cannot infer this information. However, we may know which partitions are relevant for the query. Since MariaDB 10.0, we can force MariaDB to only access the specified partitions by adding a PARTITION clause. This feature is called *partition selection*. For example:

```
SELECT * FROM orders PARTITION (p3) WHERE user_id = 50;
SELECT * FROM orders PARTITION (p2,p3) WHERE user_id >= 40;
```

The PARTITION clause is supported for all DML statements:

- SELECT
- INSERT
- UPDATE
- DELETE
- REPLACE

Partition Pruning and Triggers

In general, partition pruning is applied to statements contained in triggers.

However, note that if a `BEFORE INSERT` or `BEFORE UPDATE` trigger is defined on a table, MariaDB doesn't know in advance if the columns used in the partitioning expression will be changed. For this reason, it is forced to lock all partitions.

2.5.4 Partition Maintenance

Contents

Preface

This article covers

- PARTITIONing uses and non-uses
- How to Maintain a time-series PARTITIONed table
- AUTO_INCREMENT secrets

First, my Opinions on PARTITIONing

Taken from Rick's RoTs - Rules of Thumb

- #1: Don't use PARTITIONing until you know how and why it will help.
- Don't use PARTITION unless you will have >1M rows
- No more than 50 PARTITIONs on a table (open, show table status, etc, are impacted) (fixed in MySQL 5.6.6?; a better fix coming eventually in 5.7)
- PARTITION BY RANGE is the only useful method.
- SUBPARTITIONs are not useful.
- The partition field should not be the field first in any key.
- It is OK to have an AUTO_INCREMENT as the first part of a compound key, or in a non-UNIQUE index.

It is so tempting to believe that PARTITIONing will solve performance problems. But it is so often wrong.

PARTITIONing splits up one table into several smaller tables. But table size is rarely a performance issue. Instead, I/O time and indexes are the issues.

A common fallacy: "Partitioning will make my queries run faster". It won't. Ponder what it takes for a 'point query'. Without partitioning, but with an appropriate index, there is a BTree (the index) to drill down to find the desired row. For a billion rows, this might be 5 levels deep. With partitioning, first the partition is chosen and "opened", then a smaller BTree (of say 4 levels) is drilled down. Well, the savings of the shallower BTree is consumed by having to open the partition. Similarly, if you look at the disk blocks that need to be touched, and which of those are likely to be cached, you come to the conclusion that about the same number of disk hits is likely. Since disk hits are the main cost in a query, Partitioning does not gain any performance (at least for this typical case). The 2D case (below) gives the main contradiction to this discussion.

Use Cases for PARTITIONing

Use case #1 -- time series. Perhaps the most common use case where PARTITIONing shines is in a dataset where "old" data is periodically deleted from the table. RANGE PARTITIONing by day (or other unit of time) lets you do a nearly instantaneous DROP PARTITION plus REORGANIZE PARTITION instead of a much slower DELETE. Much of this blog is focused on this use case. This use case is also discussed in Big DELETEs

The big win for Case #1: DROP PARTITION is a lot faster than DELETEing a lot of rows.

Use case #2 -- 2-D index. INDEXes are inherently one-dimensional. If you need two "ranges" in the WHERE clause, try to migrate one of them to PARTITIONing.

Finding the nearest 10 pizza parlors on a map needs a 2D index. Partition pruning sort of gives a second dimension. See Latitude/Longitude Indexing That uses PARTITION BY RANGE(latitude) together with PRIMARY KEY(longitude, ...)

The big win for Case #2: Scanning fewer rows.

Use case #3 -- hot spot. This is a bit complicated to explain. Given this combination:

- A table's index is too big to be cached, but the index for one partition is cacheable, and
- The index is randomly accessed, and
- Data ingestion would normally be I/O bound due to updating the index Partitioning can keep all the index "hot" in RAM, thereby avoiding a lot of I/O.

The big win for Case #3: Improving caching to decrease I/O to speed up operations.

AUTO_INCREMENT in PARTITION

- For AUTO_INCREMENT to work (in any table), it must be the first field in some index. Period. There are no other requirements on indexing it.
- Being the first field in some index lets the engine find the 'next' value when opening the table.
- AUTO_INCREMENT need not be UNIQUE. What you lose: prevention of explicitly inserting a duplicate id. (This is rarely needed, anyway.)

Examples (where id is AUTO_INCREMENT):

- PRIMARY KEY (...), INDEX(id)
- PRIMARY KEY (...), UNIQUE(id, partition_key) -- not useful
- INDEX(id), INDEX(...) (but no UNIQUE keys)
- PRIMARY KEY(id), ... -- works only if id is the partition key (not very useful)

PARTITION maintenance for the time-series case

Let's focus on the maintenance task involved in Case #1, as described above.

You have a large table that is growing on one end and being pruned on the other. Examples include news, logs, and other

transient information. PARTITION BY RANGE is an excellent vehicle for such a table.

- DROP PARTITION is much faster than DELETE. (This is the big reason for doing this flavor of partitioning.)
- Queries often limit themselves to 'recent' data, thereby taking advantage of "partition pruning".

Depending on the type of data, and how long before it expires, you might have daily or weekly or hourly (etc) partitions.

There is no simple SQL statement to "drop partitions older than 30 days" or "add a new partition for tomorrow". It would be tedious to do this by hand every day.

High level view of the code

```
ALTER TABLE tbl
    DROP PARTITION from20120314;
ALTER TABLE tbl
    REORGANIZE PARTITION future INTO (
        PARTITION from20120415 VALUES LESS THAN (TO_DAYS('2012-04-16')),
        PARTITION future     VALUES LESS THAN MAXVALUE);
```

After which you have...

```
    CREATE TABLE tbl (
        dt DATETIME NOT NULL,  -- or DATE
        ...
        PRIMARY KEY (..., dt),
        UNIQUE KEY (..., dt),
        ...
    )
    PARTITION BY RANGE (TO_DAYS(dt)) (
        PARTITION start        VALUES LESS THAN (0),
        PARTITION from20120315 VALUES LESS THAN (TO_DAYS('2012-03-16')),
        PARTITION from20120316 VALUES LESS THAN (TO_DAYS('2012-03-17')),
        ...
        PARTITION from20120414 VALUES LESS THAN (TO_DAYS('2012-04-15')),
        PARTITION from20120415 VALUES LESS THAN (TO_DAYS('2012-04-16')),
        PARTITION future       VALUES LESS THAN MAXVALUE
    );
```

Why?

Perhaps you noticed some odd things in the example. Let me explain them.

- Partition naming: Make them useful.
- from20120415 ... 04-16: Note that the LESS THAN is the next day's date
- The "start" partition: See paragraph below.
- The "future" partition: This is normally empty, but it can catch overflows; more later.
- The range key (dt) must be included in any PRIMARY or UNIQUE key.
- The range key (dt) should be last in any keys it is in -- You have already "pruned" with it; it is almost useless in the index, especially at the beginning.
- DATETIME, etc -- I picked this datatype because it is typical for a time series. Newer MySQL versions allow TIMESTAMP. INT could be used; etc.
- There is an extra day (03-16 thru 04-16): The latest day is only partially full.

Why the bogus "start" partition? If an invalid datetime (Feb 31) were to be used, the datetime would turn into NULL. NULLs are put into the first partition. Since any SELECT could have an invalid date (yeah, this stretching things), the partition pruner always includes the first partition in the resulting set of partitions to search. So, if the SELECT must scan the first partition, it would be slightly more efficient if that partition were empty. Hence the bogus "start" partition. Longer discussion, by The Data Charmer 5.5 eliminates the bogus check, but only if you switch to a new syntax:

```
    PARTITION BY RANGE COLUMNS(dt) (
    PARTITION day_20100226 VALUES LESS THAN ('2010-02-27'), ...
```

More on the "future" partition. Sooner or later the cron/EVENT to add tomorrow's partition will fail to run. The worst that could happen is for tomorrow's data to be lost. The easiest way to prevent that is to have a partition ready to catch it, even if this partition is normally always empty.

Having the "future" partition makes the ADD PARTITION script a little more complex. Instead, it needs to take tomorrow's data from "future" and put it into a new partition. This is done with the REORGANIZE command shown. Normally nothing need be moved, and the ALTER takes virtually zero time.

When to do the ALTERs?

- DROP if the oldest partition is "too old".
- Add 'tomorrow' near the end of today, but don't try to add it twice.
- Do not count partitions -- there are two extra ones. Use the partition names or information_schema.PARTITIONS.PARTITION_DESCRIPTION.
- DROP/Add only once in the script. Rerun the script if you need more.
- Run the script more often than necessary. For daily partitions, run the script twice a day, or even hourly. Why? Automatic repair.

Variants

As I have said many times, in many places, BY RANGE is perhaps the only useful variant. And a time series is the most common use for PARTITIONing.

- (as discussed here) DATETIME/DATE with TO_DAYS()
- DATETIME/DATE with TO_DAYS(), but with 7-day intervals
- TIMESTAMP with TO_DAYS(). (version 5.1.43 or later)
- PARTITION BY RANGE COLUMNS(DATETIME) (5.5.0)
- PARTITION BY RANGE(TIMESTAMP) (version 5.5.15 / 5.6.3)
- PARTITION BY RANGE(TO_SECONDS()) (5.6.0)
- INT UNSIGNED with constants computed as unix timestamps.
- INT UNSIGNED with constants for some non-time-based series.
- MEDIUMINT UNSIGNED containing an "hour id": FLOOR(FROM_UNIXTIME(timestamp) / 3600)
- Months, Quarters, etc: Concoct a notation that works.

How many partitions?

- Under, say, 5 partitions -- you get very little of the benefits.
- Over, say, 50 partitions, and you hit inefficiencies elsewhere.
- Certain operations (SHOW TABLE STATUS, opening the table, etc) open every partition.
- MyISAM, before version 5.6.6, would lock all partitions before pruning!
- Partition pruning does not happen on INSERTs (until Version 5.6.7), so INSERT needs to open all the partitions.
- A possible 2-partition use case: http://forums.mysql.com/read.php?24,633179,633179
- 8192 partitions is a hard limit (1024 before MariaDB 10.0.4).
- Before "native partitions" (5.7.6), each partition consumed a chunk of memory.

Detailed code

Reference implementation, in Perl, with demo of daily partitions

The complexity of the code is in the discovery of the PARTITION names, especially of the oldest and the 'next'.

To run the demo,

- Install Perl and DBIx::DWIW (from CPAN).
- copy the txt file (link above) to demo_part_maint.pl
- execute perl demo_part_maint.pl to get the rest of the instructions

The program will generate and execute (when needed) either of these:

```
ALTER TABLE tbl REORGANIZE PARTITION
      future
INTO (
      PARTITION from20150606 VALUES LESS THAN (736121),
      PARTITION future VALUES LESS THAN MAXVALUE
)

ALTER TABLE tbl
                  DROP PARTITION from20150603
```

Postlog

Original writing -- Oct, 2012; Use cases added: Oct, 2014; Refreshed: June, 2015; 8.0: Sep, 2016

Slides from Percona Amsterdam 2015

PARTITIONing requires at least MySQL 5.1

The tips in this document apply to MySQL, MariaDB, and Percona.

- More on PARTITIONing
- LinkedIn discussion
- Why NOT Partition
- Geoff Montee's Stored Proc

Future (as envisioned in 2016):

- MySQL 5.7.6 has "native partitioning for InnoDB".
- FOREIGN KEY support, perhaps in a later 8.0.xx.
- "GLOBAL INDEX" -- this would avoid the need for putting the partition key in every unique index, but make DROP PARTITION costly. This will be farther into the future.

MySQL 8.0, released Sep, 2016, not yet GA)

- Only InnoDB tables can be partitioned -- MariaDB is likely to continue maintaining Partitioning on non-InnoDB tables, but Oracle is clearly not.
- Some of the problems having lots of partitions are lessened by the Data-Dictionary-in-a-table.

Native partitioning will give:

- This will improve performance slightly by combining two "handlers" into one.
- Decreased memory usage, especially when using a large number of partitions.

2.5.5 Partitioning Limitations with MariaDB

The following limitations apply to partitioning in MariaDB:

- Each table can contain a maximum of 8192 partitions. Until MariaDB 10.0.3, the limit was 1024.
- Queries are never parallelized, even when they involve multiple partitions.
- A table can only be partitioned if the storage engine supports partitioning.
- All partitions must use the same storage engine. For a workaround, see Using CONNECT - Partitioning and Sharding.
- A partitioned table cannot contain, or be referenced by, foreign keys.
- The query cache is not aware of partitioning and partition pruning. Modifying a partition will invalidate the entries related to the whole table.
- Updates can run more slowly when binlog_format=ROW and a partitioned table is updated than an equivalent update of a non-partitioned table.
- All columns used in the partitioning expression for a partitioned table must be part of every unique key that the table may have.

2.5.6 Partitions Files

A partitioned table is stored in multiple files. By default, these files are stored in the MariaDB (or InnoDB) data directory. It is possible to keep them in different paths by specifying DATA_DIRECTORY and INDEX_DIRECTORY table options. This is useful to store different partitions on different devices.

> Note that, if the innodb_file_per_table server system variable is set to 0 at the time of the table creation, all partitions will be stored in the system tablespace.

The following files exist for each partitioned tables:

File name	Notes
table_name.frm	Contains the table definition. Non-partitioned tables have this file, too.
table_name.par	Contains the partitions definitions.
table_name#P#partition_name.ext	Normal files created by the storage engine use this pattern for names. The extension depends on the storage engine.

For example, an InnoDB table with 4 partitions will have the following files:

```
orders.frm
orders.par
orders#P#p0.ibd
orders#P#p1.ibd
orders#P#p2.ibd
orders#P#p3.ibd
```

If we convert the table to MyISAM, we will have these files:

```
orders.frm
orders.par
orders#P#p0.MYD
orders#P#p0.MYI
orders#P#p1.MYD
orders#P#p1.MYI
orders#P#p2.MYD
orders#P#p2.MYI
orders#P#p3.MYD
orders#P#p3.MYI
```

2.5.7 Partitions Metadata

The PARTITIONS table in the INFORMATION_SCHEMA database contains information about partitions.

The SHOW TABLE STATUS statement contains a `Create_options` column, that contains the string 'partitioned' for partitioned tables.

The SHOW CREATE TABLE statement returns the CREATE TABLE statement that can be used to re-create a table, including the partitions definition.

1.1.1.2.9.1.1.32 Information Schema PARTITIONS Table

5.4.5 MariaDB Audit Plugin

2.7 Variables and Modes

The different variables and modes to use to affect how MariaDB works.

Full List of MariaDB Options, System and Status Variables

Complete alphabetical list of all MariaDB options as well as system and status variables.

Server Status Variables

List and description of the Server Status Variables.

Server System Variables

List of system variables.

OLD_MODE

Used to emulate behavior from older MariaDB and MySQL versions.

SQL_MODE

Used to emulate behavior from other SQL servers.

SQL_MODE=MSSQL

Microsoft SQL Server compatibility mode.

SQL_MODE=ORACLE

MariaDB understands a subset of Oracle's PL/SQL language.

There are 3 related questions.

2.7.1 Full List of MariaDB Options, System and Status Variables

Alphabetical list of all mariadbd Options, Server System Variables and Server Status Variables. The convention used is that variable names are listed with '_' and options with '-'. If a variable and option both exist, both versions are listed for easy searching.

About the Server System Variables

MariaDB has many system variables that can be changed to suit your needs.

The full list of server variables are listed in the contents on this page, and most are described on this page, but some are described elsewhere:

- Aria System Variables
- CONNECT System Variables
- Galera System Variables
- Global Transaction ID System Variables
- HandlerSocket Plugin System Variables
- InnoDB System Variables
- Mroonga System Variables
- MyRocks System Variables
- MyISAM System Variables
- Performance Schema System Variables
- Replication and Binary Log System Variables
- S3 Storage Engine System Variables
- Server_Audit System Variables
- Spider System Variables
- SQL_ERROR_LOG Plugin System Variables
- SSL System Variables
- Threadpool System Variables
- TokuDB System Variables

See also the Full list of MariaDB options, system and status variables.

Most of these can be set with command line options and many of them can be changed at runtime. Variables that can be changed at runtime (and therefore are not read-only) are described as "Dynamic" below, and elsewhere in the documentation.

There are a few ways to see the full list of server system variables:

- While in the mariadb client, run:

  ```
  SHOW VARIABLES;
  ```

  See SHOW VARIABLES for instructions on using this command.

- From your shell, run mariadbd like so:

  ```
  mariadbd --verbose --help
  ```

- View the Information Schema GLOBAL_VARIABLES, SESSION_VARIABLES, and SYSTEM_VARIABLES tables.

Setting Server System Variables

There are several ways to set server system variables:

- Specify them on the command line:

  ```
  shell> ./mysqld_safe --aria_group_commit="hard"
  ```

- Specify them in your my.cnf file (see Configuring MariaDB with my.cnf for more information):

  ```
  aria_group_commit = "hard"
  ```

- Set them from the mariadb client using the SET command. Only variables that are dynamic can be set at runtime in this way. Note that variables set in this way will not persist after a restart.

  ```
  SET GLOBAL aria_group_commit="hard";
  ```

By convention, server variables have usually been specified with an underscore in the configuration files, and a dash on the command line. You can however specify underscores as dashes - they are interchangeable.

Variables that take a numeric size can either be specified in full, or with a suffix for easier readability. Valid suffixes are:

Suffix	Description	Value
K	kilobytes	1024
M	megabytes	1024^2
G	gigabytes	1024^3
T	terabytes	1024^4 (from MariaDB 10.3.3)
P	petabytes	1024^5 (from MariaDB 10.3.3)
E	exabytes	1024^6 (from MariaDB 10.3.3)

The suffix can be upper or lower-case.

List of Server System Variables

allow_suspicious_udfs

- **Description:** Allows use of user-defined functions consisting of only one symbol `x()` without corresponding `x_init()` or `x_deinit()`. That also means that one can load any function from any library, for example `exit()` from `libc.so`. Not recommended unless you require old UDFs with one symbol that cannot be recompiled. Before MariaDB 10.10, available as an option only.
- **Commandline:** `--allow-suspicious-udfs`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `OFF`
- **Introduced:** MariaDB 10.10

---

alter_algorithm

- **Description:** The implied `ALGORITHM` for ALTER TABLE if no `ALGORITHM` clause is specified. The deprecated variable old_alter_table is an alias for this.
  - `COPY` corresponds to the pre-MySQL 5.1 approach of creating an intermediate table, copying data one row at a time, and renaming and dropping tables.
  - `INPLACE` requests that the operation be refused if it cannot be done natively inside a the storage engine.
  - `DEFAULT` (the default) chooses `INPLACE` if available, and falls back to `COPY`.
  - `NOCOPY` refuses to copy a table.
  - `INSTANT` refuses an operation that would involve any other than metadata changes.
- **Commandline:** `--alter-algorithm=default`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `enumerated`
- **Default Value:** `DEFAULT`
- **Valid Values:** `DEFAULT`, `COPY`, `INPLACE`, `NOCOPY`, `INSTANT`
- **Introduced:** MariaDB 10.3.7

analyze_sample_percentage

- **Description:** Percentage of rows from the table ANALYZE TABLE will sample to collect table statistics. Set to 0 to let MariaDB decide what percentage of rows to sample.
- **Commandline:** `--analyze-sample-percentage=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `100.000000`
- **Range:** `0` to `100`
- **Introduced:** MariaDB 10.4.3

autocommit

- **Description:** If set to 1, the default, all queries are committed immediately. The LOCK IN SHARE MODE and FOR UPDATE clauses therefore have no effect. If set to 0, they are only committed upon a COMMIT statement, or rolled

back with a ROLLBACK statement. If autocommit is set to 0, and then changed to 1, all open transactions are immediately committed.

- **Commandline:** `--autocommit[=#]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `1`

---

automatic_sp_privileges

- **Description:** When set to 1, the default, when a stored routine is created, the creator is automatically granted permission to ALTER (which includes dropping) and to EXECUTE the routine. If set to 0, the creator is not automatically granted these privileges.
- **Commandline:** `--automatic-sp-privileges` , `--skip-automatic-sp-privileges`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `1`

---

back_log

- **Description:** Connections take a small amount of time to start, and this setting determines the number of outstanding connection requests MariaDB can have, or the size of the listen queue for incoming TCP/IP requests. Requests beyond this will be refused. Increase if you expect short bursts of connections. Cannot be set higher than the operating system limit (see the Unix listen() man page). If not set, set to `0` , or the `--autoset-back-log` option is used, will be autoset to the lower of `900` and (50 + max_connections/5).
- **Commandline:** `--back-log=#`
- **Scope:** Global
- **Dynamic:** No
- **Type:** number
- **Default Value:**
  - The lower of `900` and (50 + max_connections/5)

---

basedir

- **Description:** Path to the MariaDB installation directory. Other paths are usually resolved relative to this base directory.
- **Commandline:** `--basedir=path` or `-b path`
- **Scope:** Global
- **Dynamic:** No
- **Type:** directory name

---

big_tables

- **Description:** If this system variable is set to 1, then temporary tables will be saved to disk intead of memory.
  - This system variable's original intention was to allow result sets that were too big for memory-based temporary tables and to avoid the resulting 'table full' errors.
  - This system variable is no longer needed, because the server can automatically convert large memory-based temporary tables into disk-based temporary tables when they exceed the value of the `tmp_memory_table_size` system variable.
  - To prevent memory-based temporary tables from being used at all, set the `tmp_memory_table_size` system variable to `0` .
  - In MariaDB 5.5 and earlier, `sql_big_tables` is a synonym.
  - In MariaDB 10.5, this system variable is deprecated.
- **Commandline:** `--big-tables`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `0`
- **Deprecated:** MariaDB 10.5.0

---

bind_address

- **Description:** By default, the MariaDB server listens for TCP/IP connections on all addresses. You can specify an alternative when the server starts using this option; either a host name, an IPv4 or an IPv6 address, "::" or "*" (all addresses). In some systems, such as Debian and Ubuntu, the bind_address is set to 127.0.0.1, which binds the server to listen on localhost only. `bind_address` has always been available as a mariadbd option; from MariaDB 10.3.3 its also available as a system variable. Before MariaDB 10.6.0 "::" implied listening additionally on IPv4 addresses like "*". From 10.6.0 onwards it refers to IPv6 stictly. Starting with MariaDB 10.11, a comma-separated list of addresses to bind to can be given. See also Configuring MariaDB for Remote Client Access.
- **Commandline:** `--bind-address=addr`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** (Empty string)
- **Valid Values:** Host name, IPv4, IPv6, ::, *
- **Introduced:** MariaDB 10.3.3 (as a system variable)

---

block_encryption_mode

- **Description:** Default block encryption mode for AES_ENCRYPT() and AES_DECRYPT() functions.
- **Commandline:** `--block-encryption-mode=val`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `aes-128-ecb`
- **Valid values:** `aes-128-ecb`, `aes-192-ecb`, `aes-256-ecb`, `aes-128-cbc`, `aes-192-cbc`, `aes-256-cbc`, `aes-128-ctr`, `aes-192-ctr`, `aes-256-ctr`
- **Introduced:** MariaDB 11.2.0

---

bulk_insert_buffer_size

- **Description:** Size in bytes of the per-thread cache tree used to speed up bulk inserts into MyISAM and Aria tables. A value of 0 disables the cache tree.
- **Commandline:** `--bulk-insert-buffer-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `8388608`
- **Range - 32 bit:** `0` to `4294967295`
- **Range - 64 bit:** `0` to `18446744073709547520`

---

character_set_client

- **Description:** Determines the character set for queries arriving from the client. It can be set per session by the client, although the server can be configured to ignore client requests with the `--skip-character-set-client-handshake` option. If the client does not request a character set, or requests a character set that the server does not support, the global value will be used. utf16, utf16le, utf32 and ucs2 cannot be used as client character sets. From MariaDB 10.6, the `utf8` character set (and related collations) is by default an alias for `utf8mb3` rather than the other way around. It can be set to imply `utf8mb4` by changing the value of the old_mode system variable.
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `utf8mb3` (>= MariaDB 10.6), `utf8` (<= MariaDB 10.5)

---

character_set_collations

- **Description:** Overrides for character set default collations. Takes a comma-delimited list of character set and collation settings, for example `SET @@character_set_collations = 'utf8mb4=uca1400_ai_ci, latin2=latin2_hungarian_ci';` The new variable will take effect in all cases where a character set is explicitly or implicitly specified without an explicit COLLATE clause, including but not limited to:
  - Column collation

    - Table collation
    - Database collation
    - CHAR(expr USING csname)
    - CONVERT(expr USING csname)
    - CAST(expr AS CHAR CHARACTER SET csname)
    - '' - character string literal
    - _utf8mb3'text' - a character string literal with an introducer
    - _utf8mb3 X'61' - a character string literal with an introducer with hex notation
    - _utf8mb3 0x61 - a character string literal with an introducer with hex hybrid notation
    - @@collation_connection after a SET NAMES without COLLATE
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** Empty
- **Introduced:** MariaDB 11.2

`character_set_connection`

- **Description:** Character set used for number to string conversion, as well as for literals that don't have a character set introducer. From MariaDB 10.6, the `utf8` character set (and related collations) is by default an alias for `utf8mb3` rather than the other way around. It can be set to imply `utf8mb4` by changing the value of the old_mode system variable.
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `utf8mb3` (>= MariaDB 10.6), `utf8` (<= MariaDB 10.5)

`character_set_database`

- **Description:** Character set used by the default database, and set by the server whenever the default database is changed. If there's no default database, character_set_database contains the same value as character_set_server. This variable is dynamic, but should not be set manually, only by the server.
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `latin1`

`character_set_filesystem`

- **Description:** The character set for the filesystem. Used for converting file names specified as a string literal from character_set_client to character_set_filesystem before opening the file. By default set to `binary`, so no conversion takes place. This could be useful for statements such as LOAD_FILE() or LOAD DATA INFILE on system where multi-byte file names are use.
- **Commandline:** `--character-set-filesystem=name`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `binary`

`character_set_results`

- **Description:** Character set used for results and error messages returned to the client. From MariaDB 10.6, the `utf8` character set (and related collations) is by default an alias for `utf8mb3` rather than the other way around. It can be set to imply `utf8mb4` by changing the value of the old_mode system variable.
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `utf8mb3` (>= MariaDB 10.6), `utf8` (<= MariaDB 10.5)

`character_set_server`

- **Description:** Default character set used by the server. See character_set_database for character sets used by the default database. Defaults may be different on some systems, see for example Differences in MariaDB in Debian.
- **Commandline:** `--character-set-server`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `latin1`

---

character_set_system

- **Description:** Character set used by the server to store identifiers, always set to utf8, or its synonym utf8mb3 starting with MariaDB 10.6. From MariaDB 10.6, the `utf8` character set (and related collations) is by default an alias for `utf8mb3` rather than the other way around. It can be set to imply `utf8mb4` by changing the value of the old_mode system variable.
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** `utf8mb3` (>= MariaDB 10.6), `utf8` (<= MariaDB 10.5)

---

character_sets_dir

- **Description:** Directory where the character sets are installed.
- **Commandline:** `--character-sets-dir=path`
- **Scope:** Global
- **Dynamic:** No
- **Type:** directory name

---

check_constraint_checks

- **Description:** If set to `0`, will disable constraint checks, for example when loading a table that violates some constraints that you plan to fix later.
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Type:** boolean
- **Default:** ON

---

collation_connection

- **Description:** Collation used for the connection character set.
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `string`

---

collation_database

- **Description:** Collation used for the default database. Set by the server if the default database changes, if there is no default database the value from the `collation_server` variable is used. This variable is dynamic, but should not be set manually, only by the server.
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `string`

---

collation_server

- **Description:** Default collation used by the server. This is set to the default collation for a given character set automatically when character_set_server is changed, but it can also be set manually. Defaults may be different on some systems, see for example Differences in MariaDB in Debian.
- **Commandline:** `--collation-server=name`
- **Scope:** Global, Session

- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `latin1_swedish_ci`

---

completion_type

- **Description:** The transaction completion type. If set to `NO_CHAIN` or `0` (the default), there is no effect on commits and rollbacks. If set to `CHAIN` or `1`, a COMMIT statement is equivalent to COMMIT AND CHAIN, while a ROLLBACK is equivalent to ROLLBACK AND CHAIN, so a new transaction starts straight away with the same isolation level as transaction that's just finished. If set to `RELEASE` or `2`, a COMMIT statement is equivalent to COMMIT RELEASE, while a ROLLBACK is equivalent to ROLLBACK RELEASE, so the server will disconnect after the transaction completes. Note that the transaction completion type only applies to explicit commits, not implicit commits.
- **Commandline:** `--completion-type=name`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `enumerated`
- **Default Value:** `NO_CHAIN`
- **Valid Values:** `0`, `1`, `2`, `NO_CHAIN`, `CHAIN`, `RELEASE`

---

concurrent_insert

- **Description:** If set to `AUTO` or `1`, the default, MariaDB allows concurrent INSERTs and SELECTs for MyISAM tables with no free blocks in the data (deleted rows in the middle). If set to `NEVER` or `0`, concurrent inserts are disabled. If set to `ALWAYS` or `2`, concurrent inserts are permitted for all MyISAM tables, even those with holes, in which case new rows are added at the end of a table if the table is being used by another thread.

  If the --skip-new option is used when starting the server, concurrent_insert is set to `NEVER`.

  Changing the variable only affects new opened tables. Use FLUSH TABLES If you want it to also affect cached tables.

  See Concurrent Inserts for more.
- **Commandline:** `--concurrent-insert[=value]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `enumerated`
- **Default Value:** `AUTO`
- **Valid Values:** `0`, `1`, `2`, `AUTO`, `NEVER`, `ALWAYS`

---

connect_timeout

- **Description:** Time in seconds that the server waits for a connect packet before returning a 'Bad handshake'. Increasing may help if clients regularly encounter 'Lost connection to MySQL server at 'X', system error: error_number' type-errors.
- **Commandline:** `--connect-timeout=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Type:** numeric
- **Default Value:** `10`

---

core_file

- **Description:** Write a core-file on crashes. The file name and location are system dependent. On Linux it is usually called `core.${PID}`, and it is usually written to the data directory. However, this can be changed.
  - See Enabling Core Dumps for more information.
  - Previously this system variable existed only as an option, but it was also made into a read-only system variable starting with MariaDB 10.3.9, MariaDB 10.2.17 and MariaDB 10.1.35.
  - On Windows >= MariaDB 10.4.3, this option is set by default.
  - Note that the option accepts no arguments; specifying `--core-file` sets the value to `ON`. It cannot be disabled in the case of Windows >= MariaDB 10.4.3.

- **Commandline:** `--core-file`
- **Scope:** Global
- **Dynamic:** No
- **Type:** boolean
- **Default Value:**
  - Windows >= MariaDB 10.4.3: `ON`
  - All other systems: `OFF`

---

datadir

- **Description:** Directory where the data is stored.
- **Commandline:** `--datadir=path` or `-h path`
- **Scope:** Global
- **Dynamic:** No
- **Type:** directory name

---

date_format

- **Description:** Unused.
- **Removed:** MariaDB 11.3.0

---

datetime_format

- **Description:** Unused.
- **Removed:** MariaDB 11.3.0

---

debug/debug_dbug

- **Description:** Available in debug builds only (built with -DWITH_DEBUG=1). Used in debugging through the DBUG library to write to a trace file. Just using `--debug` will write a trace of what mariadbd is doing to the default trace file.
- **Commandline:** `-#` , `--debug[=debug_options]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:**
  - <= MariaDB 10.4: `d:t:i:o,/tmp/mysqld.trace` (Unix) or `d:t:i:O,\mysqld.trace` (Windows)
  - >= MariaDB 10.5: `d:t:i:o,/tmp/mariadbd.trace` (Unix) or `d:t:i:O,\mariadbd.trace` (Windows)
- **Debug Options:** See the option flags on the mysql_debug page
- **Removed:** MariaDB 11.3.0

---

debug_no_thread_alarm

- **Description:** Disable system thread alarm calls. Disabling it may be useful in debugging or testing, never do it in production.
- **Commandline:** `--debug-no-thead-alarm=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `OFF`
- **Introduced:** MariaDB

---

debug_sync

- **Description:** Used in debugging to show the interface to the Debug Sync facility. MariaDB needs to be configured with -DENABLE_DEBUG_SYNC=1 for this variable to be available.
- **Scope:** Session
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `OFF` or `ON - current signal` *`signal name`*

default_password_lifetime

- **Description:** This defines the global password expiration policy. 0 means automatic password expiration is disabled. If the value is a positive integer N, the passwords must be changed every N days. This behavior can be overridden using the password expiration options in ALTER USER.
- **Commandline:** `--default-password-lifetime=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Type:** numeric
- **Default Value:** `0`
- **Range:** `0` to `4294967295`
- **Introduced:** MariaDB 10.4.3

default_regex_flags

- **Description:** Introduced to address remaining incompatibilities between PCRE and the old regex library. Accepts a comma-separated list of zero or more of the following values:

Value	Pattern equivalent	Meaning
DOTALL	(?s)	. matches anything including NL
DUPNAMES	(?J)	Allow duplicate names for subpatterns
EXTENDED	(?x)	Ignore white space and # comments
EXTRA	(?X)	extra features (e.g. error on unknown escape character)
MULTILINE	(?m)	^ and $ match newlines within data
UNGREEDY	(?U)	Invert greediness of quantifiers

- **Commandline:** `--default-regex-flags=value`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Type:** enumeration
- **Default Value:** empty
- **Valid Values:** `DOTALL`, `DUPNAMES`, `EXTENDED`, `EXTRA`, `MULTILINE`, `UNGREEDY`

default_storage_engine

- **Description:** The default storage engine. The default storage engine must be enabled at server startup or the server won't start.
- **Commandline:** `--default-storage-engine=name`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Type:** enumeration
- **Default Value:** `InnoDB`

default_table_type

- **Description:** A synonym for default_storage_engine. Removed in MariaDB 5.5.
- **Commandline:** `--default-table-type=name`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Removed:** MariaDB 5.5

default_tmp_storage_engine

- **Description:** Default storage engine that will be used for tables created with CREATE TEMPORARY TABLE where no engine is specified. For internal temporary tables see aria_used_for_temp_tables). The storage engine used must be active or the server will not start. See default_storage_engine for the default for non-temporary tables. Defaults to NULL, in which case the value from default_storage_engine is used. ROCKSDB temporary tables cannot be created. Before MariaDB 10.7, attempting to do so would silently fail, and a MyISAM table would instead be created. From MariaDB 10.7, an error is returned.

- **Commandline:** `--default-tmp-storage-engine=name`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `enumeration`
- **Default Value:** NULL

---

default_week_format

- **Description:** Default mode for the WEEK() function. See that page for details on the different modes
- **Commandline:** `--default-week-format=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` to `7`

---

delay_key_write

- **Description:** Specifies how MyISAM tables handles CREATE TABLE DELAY_KEY_WRITE. If set to `ON`, the default, any DELAY KEY WRITEs are honored. The key buffer is then flushed only when the table closes, speeding up writes. MyISAM tables should be automatically checked upon startup in this case, and --external locking should not be used, as it can lead to index corruption. If set to `OFF`, DELAY KEY WRITEs are ignored, while if set to `ALL`, all new opened tables are treated as if created with DELAY KEY WRITEs enabled.
- **Commandline:** `--delay-key-write[=name]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `enumeration`
- **Default Value:** `ON`
- **Valid Values:** `ON`, `OFF`, `ALL`

---

delayed_insert_limit

- **Description:** After this many rows have been inserted with INSERT DELAYED, the handler will check for and execute any waiting SELECT statements.
- **Commandline:** `--delayed-insert-limit=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `100`
- **Range:** `1` to `4294967295`

---

delayed_insert_timeout

- **Description:** Time in seconds that the INSERT DELAYED handler will wait for INSERTs before terminating.
- **Commandline:** `--delayed-insert-timeout=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `300`

---

delayed_queue_size

- **Description:** Number of rows, per table, that can be queued when performing INSERT DELAYED statements. If the queue becomes full, clients attempting to perform INSERT DELAYED's will wait until the queue has room available again.
- **Commandline:** `--delayed-queue-size=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Type:** numeric
- **Default Value:** `1000`

- **Range:** `1 to 4294967295`

---

disconnect_on_expired_password

- **Description:** When a user password has expired (see User Password Expiry), this variable controls how the server handles clients that are not aware of the sandbox mode. If enabled, the client is not permitted to connect, otherwise the server puts the client in a sandbox mode.
- **Commandline:** `--disconnect-on-expired-password[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Type:** boolean
- **Default Value:** `OFF`
- **Introduced:** MariaDB 10.4.3

---

div_precision_increment

- **Description:** The precision of the result of the decimal division will be the larger than the precision of the dividend by that number. By default it's `4`, so `SELECT 2/15` would return 0.1333 and `SELECT 2.0/15` would return 0.13333. After setting div_precision_increment to `6`, for example, the same operation would return 0.133333 and 0.1333333 respectively.

  From MariaDB 10.1.46, MariaDB 10.2.33, MariaDB 10.3.24, MariaDB 10.4.14 and MariaDB 10.5.5, `div_precision_increment` is taken into account in intermediate calculations. Previous versions did not, and the results were dependent on the optimizer, and therefore unpredictable.

  In MariaDB 10.1.46, MariaDB 10.1.47, MariaDB 10.2.33, MariaDB 10.2.34, MariaDB 10.2.35, MariaDB 10.3.24, MariaDB 10.3.25, MariaDB 10.4.14, MariaDB 10.4.15, MariaDB 10.5.5 and MariaDB 10.5.6 only, the fix truncated decimal values after every division, resulting in lower precision in some cases for those versions only.

  From MariaDB 10.1.48, MariaDB 10.2.35, MariaDB 10.3.26, MariaDB 10.4.16 and MariaDB 10.5.7, a different fix was implemented. Instead of truncating decimal values after every division, they are instead truncated for comparison purposes only.

  For example

  Versions other than MariaDB 10.1.46, MariaDB 10.1.47, MariaDB 10.2.33, MariaDB 10.2.34, MariaDB 10.2.35, MariaDB 10.3.24, MariaDB 10.3.25, MariaDB 10.4.14, MariaDB 10.4.15, MariaDB 10.5.5 and MariaDB 10.5.6:

```
SELECT (55/23244*1000);
+-----------------+
| (55/23244*1000) |
+-----------------+
|          2.3662 |
+-----------------
```

  MariaDB 10.1.46, MariaDB 10.1.47, MariaDB 10.2.33, MariaDB 10.2.34, MariaDB 10.2.35, MariaDB 10.3.24, MariaDB 10.3.25, MariaDB 10.4.14, MariaDB 10.4.15, MariaDB 10.5.5 and MariaDB 10.5.6 only:

```
SELECT (55/23244*1000);
+-----------------+
| (55/23244*1000) |
+-----------------+
|          2.4000 |
+-----------------+
```

  This is because the intermediate result, `SELECT 55/23244` takes into account `div_precision_increment` and results were truncated after every division in those versions only.

- **Commandline:** `--div-precision-increment=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `4`
- **Range:** `0` to `30`

---

encrypt_tmp_disk_tables

- **Description:** Enables automatic encryption of all internal on-disk temporary tables that are created during query execution if `aria_used_for_temp_tables=ON` is set. See Data at Rest Encryption and Enabling Encryption for Internal On-disk Temporary Tables.
- **Commandline:** `--encrypt-tmp-disk-tables[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

encrypt_tmp_files

- **Description:** Enables automatic encryption of temporary files, such as those created for filesort operations, binary log file caches, etc. See Data at Rest Encryption.
- **Commandline:** `--encrypt-tmp-files[={0|1}]`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

encryption_algorithm

- **Description:** Which encryption algorithm to use for table encryption. `aes_cbc` is the recommended one. See Table and Tablespace Encryption.
- **Commandline:** `--encryption-algorithm=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `enum`
- **Default Value:** `none`
- **Valid Values:** `none`, `aes_ecb`, `aes_cbc`, `aes_ctr`
- **Introduced:** MariaDB 10.1.3
- **Removed:** MariaDB 10.1.4

---

enforce_storage_engine

- **Description:** Force the use of a particular storage engine for new tables. Used to avoid unwanted creation of tables using another engine. For example, setting to InnoDB will prevent any MyISAM tables from being created. If another engine is specified in a CREATE TABLE statement, the outcome depends on whether the `NO_ENGINE_SUBSTITUTION` SQL_MODE has been set or not. If set, the query will fail, while if not set, a warning will be returned and the table created according to the engine specified by this variable. The variable has a session scope, but is only modifiable by a user with the SUPER privilege.
- **Commandline:** None
- **Scope:** Session
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `none`

---

engine_condition_pushdown

- **Description:** Deprecated in MariaDB 5.5 and removed and replaced by the optimizer_switch `engine_condition_pushdown={on|off}` flag in MariaDB 10.0.. Specifies whether the engine condition pushdown optimization is enabled. Since MariaDB 10.1.1, engine condition pushdown is enabled for all engines that support it.
- **Commandline:** `--engine-condition-pushdown`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`
- **Deprecated:** MariaDB 5.5
- **Removed:** MariaDB 10.0

eq_range_index_dive_limit

- **Description:** Limit used for speeding up queries listed by long nested INs. The optimizer will use existing index statistics instead of doing index dives for equality ranges if the number of equality ranges for the index is larger than or equal to this number. If set to `0` (unlimited, the default), index dives are always used.
- **Commandline:** `--eq-range-index-dive-limit=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `200` (>= MariaDB 10.4.3), `0` (<= MariaDB 10.4.2)
- **Range:** `0` to `4294967295`

error_count

- **Description:** Read-only variable denoting the number of errors from the most recent statement in the current session that generated errors. See SHOW_ERRORS().
- **Scope:** Session
- **Dynamic:** Yes
- **Data Type:** `numeric`

event_scheduler

- **Description:** Status of the Event Scheduler. Can be set to `ON` or `OFF`, while `DISABLED` means it cannot be set at runtime. Setting the variable will cause a load of events if they were not loaded at startup.
- **Commandline:** `--event-scheduler[=value]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `enumeration`
- **Default Value:** `OFF`
- **Valid Values:** `ON` (or `1`), `OFF` (or `0`), `DISABLED`

expensive_subquery_limit

- **Description:** Number of rows to be examined for a query to be considered expensive, that is, maximum number of rows a subquery may examine in order to be executed during optimization and used for constant optimization.
- **Commandline:** `--expensive-subquery-limit=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `100`
- **Range:** `0` upwards

explicit_defaults_for_timestamp

- **Description:** This option causes CREATE TABLE to create all TIMESTAMP columns as NULL with the DEFAULT NULL attribute, Without this option, TIMESTAMP columns are NOT NULL and have implicit DEFAULT clauses.
- **Commandline:** `--explicit-defaults-for-timestamp=[={0|1}]`
- **Scope:**
  - Global, Session (>= MariaDB 10.8.4, MariaDB 10.7.5, MariaDB 10.6.9, MariaDB 10.5.17)
  - Global (<= MariaDB 10.8.3, MariaDB 10.7.4, MariaDB 10.6.8, MariaDB 10.5.16)
- **Dynamic:**
  - Yes (>= MariaDB 10.8.4, MariaDB 10.7.5, MariaDB 10.6.9, MariaDB 10.5.17)
  - No (<= MariaDB 10.8.3, MariaDB 10.7.4, MariaDB 10.6.8, MariaDB 10.5.16)
- **Data Type:** `boolean`
- **Default Value:** `ON` (>= MariaDB 10.10), `OFF` (<= MariaDB 10.9)

external_user

- **Description:** External user name set by the plugin used to authenticate the client. `NULL` if native MariaDB

authentication is used.
- **Scope:** Session
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** `NULL`

---

flush

- **Description:** Usually, MariaDB writes changes to disk after each SQL statement, and the operating system handles synchronizing (flushing) it to disk. If set to `ON`, the server will synchronize all changes to disk after each statement.
- **Commandline:** `--flush`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

flush_time

- **Description:** Interval in seconds that tables are closed to synchronize (flush) data to disk and free up resources. If set to 0, the default, there is no automatic synchronizing tables and closing of tables. This option should not be necessary on systems with sufficient resources.
- **Commandline:** `--flush_time=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`

---

foreign_key_checks

- **Description:** If set to 1 (the default) foreign key constraints (including ON UPDATE and ON DELETE behavior) InnoDB tables are checked, while if set to 0, they are not checked. `0` is not recommended for normal use, though it can be useful in situations where you know the data is consistent, but want to reload data in a different order from that that specified by parent/child relationships. Setting this variable to 1 does not retrospectively check for inconsistencies introduced while set to 0.
- **Commandline:** None
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `1`

---

ft_boolean_syntax

- **Description:** List of operators supported by an IN BOOLEAN MODE full-text search. If you wish to change, note that each character must be ASCII and non-alphanumeric, the full string must be 14 characters and the first or second character must be a space. Positions 10, 13 and 14 are reserved for future extensions. Also, no duplicates are permitted except for the phrase quoting characters in positions 11 and 12, which may be the same.
- **Commandline:** `--ft-boolean-syntax=name`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `+ -><()*:""&|`

---

ft_max_word_len

- **Description:** Maximum length for a word to be included in the MyISAM full-text index. If this variable is changed, the full-text index must be rebuilt in order for the new value to take effect. The quickest way to do this is by issuing a `REPAIR TABLE table_name QUICK` statement. See innodb_ft_max_token_size for the InnoDB equivalent.
- **Commandline:** `--ft-max-word-len=#`
- **Scope:** Global
- **Dynamic:** No

- **Data Type:** `numeric`
- **Default Value:** `84`
- **Minimum Value:** `10`

---

ft_min_word_len

- **Description:** Minimum length for a word to be included in the MyISAM full-text index. If this variable is changed, the full-text index must be rebuilt in order for the new value to take effect. The quickest way to do this is by issuing a `REPAIR TABLE table_name QUICK` statement. See innodb_ft_min_token_size for the InnoDB equivalent.
- **Commandline:** `--ft-min-word-len=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `4`
- **Minimum Value:** `1`

---

ft_query_expansion_limit

- **Description:** For full-text searches, denotes the numer of top matches when using WITH QUERY EXPANSION.
- **Commandline:** `--ft-query-expansion-limit=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `20`
- **Range:** `0` to `1000`

---

ft_stopword_file

- **Description:** File containing a list of stopwords for use in MyISAM full-text searches. Unless an absolute path is specified the file will be looked for in the data directory. The file is not parsed for comments, so all words found become stopwords. By default, a built-in list of words (built from `storage/myisam/ft_static.c file`) is used. Stopwords can be disabled by setting this variable to `''` (an empty string). If this variable is changed, the full-text index must be rebuilt. The quickest way to do this is by issuing a `REPAIR TABLE table_name QUICK` statement. See innodb_ft_server_stopword_table for the InnoDB equivalent.
- **Commandline:** `--ft-stopword-file=file_name`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `file name`
- **Default Value:** `(built-in)`

---

general_log

- **Description:** If set to 0, the default unless the --general-log option is used, the general query log is disabled, while if set to 1, the general query log is enabled. See log_output for how log files are written. If that variable is set to `NONE`, no logs will be written even if general_query_log is set to `1`.
- **Commandline:** `--general-log`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `0`

---

general_log_file

- **Description:** Name of the general query log file. If this is not specified, the name is taken from the log-basename setting or from your system hostname with `.log` as a suffix.
- **Commandline:** `--general-log-file=file_name`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `file name`
- **Default Value:** *`host_name`*`.log`

group_concat_max_len

- **Description:** Maximum length in bytes of the returned result for the functions GROUP_CONCAT(), JSON_OBJECTAGG and JSON_ARRAYAGG.
- **Commandline:** `--group-concat-max-len=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:**
  - `1048576` (1M)
- **Range:** `4` to `4294967295`

.

have_compress

- **Description:** If the zlib compression library is accessible to the server, this will be set to `YES`, otherwise it will be `NO`. The COMPRESS() and UNCOMPRESS() functions will only be available if set to `YES`.
- **Scope:** Global
- **Dynamic:** No

have_crypt

- **Description:** If the crypt() system call is available this variable will be set to `YES`, otherwise it will be set to `NO`. If set to `NO`, the ENCRYPT() function cannot be used.
- **Scope:** Global
- **Dynamic:** No

have_csv

- **Description:** If the server supports CSV tables, will be set to `YES`, otherwise will be set to `NO`. Removed in MariaDB 10.0, use the Information Schema PLUGINS table or SHOW ENGINES instead.
- **Scope:** Global
- **Dynamic:** No
- **Removed:** MariaDB 10.0

have_dynamic_loading

- **Description:** If the server supports dynamic loading of plugins, will be set to `YES`, otherwise will be set to `NO`.
- **Scope:** Global
- **Dynamic:** No

have_geometry

- **Description:** If the server supports spatial data types, will be set to `YES`, otherwise will be set to `NO`.
- **Scope:** Global
- **Dynamic:** No

have_ndbcluster

- **Description:** If the server supports NDBCluster (disabled in MariaDB).
- **Scope:** Global
- **Dynamic:** No
- **Removed:** MariaDB 10.0

have_partitioning

- **Description:** If the server supports partitioning, will be set to `YES`, unless the `--skip-partition` option is used, in which case will be set to `DISABLED`. Will be set to `NO` otherwise. Removed in MariaDB 10.0 - SHOW PLUGINS should be used instead.
- **Scope:** Global
- **Dynamic:** No
- **Removed:** MariaDB 10.0

---

have_profiling

- **Description:** If statement profiling is available, will be set to `YES`, otherwise will be set to `NO`. See SHOW PROFILES() and SHOW PROFILE().
- **Scope:** Global
- **Dynamic:** No

---

have_query_cache

- **Description:** If the server supports the query cache, will be set to `YES`, otherwise will be set to `NO`.
- **Scope:** Global
- **Dynamic:** No

---

have_rtree_keys

- **Description:** If RTREE indexes (used for spatial indexes) are available, will be set to `YES`, otherwise will be set to `NO`.
- **Scope:** Global
- **Dynamic:** No

---

have_symlink

- **Description:** This system variable can be used to determine whether the server supports symbolic links (note that it has no meaning on Windows).
  - If symbolic links are supported, then the value will be `YES`.
  - If symbolic links are not supported, then the value will be `NO`.
  - If symbolic links are disabled with the --symbolic-links option and the `skip` option prefix (i.e. --skip-symbolic-links), then the value will be `DISABLED`.
  - Symbolic link support is required for the INDEX DIRECTORY and DATA DIRECTORY table options.
- **Scope:** Global
- **Dynamic:** No

---

histogram_size

- **Description:** Number of bytes used for a histogram, or, from MariaDB 10.7 when histogram_type is set to `JSON_HB`, number of buckets. If set to 0, no histograms are created by ANALYZE.
- **Commandline:** `--histogram-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `254` (>= MariaDB 10.4.3), `0` (<= MariaDB 10.4.2)
- **Range:** `0` to `255`

---

histogram_type

- **Description:** Specifies the type of histograms created by ANALYZE.
  - `SINGLE_PREC_HB` - single precision height-balanced.
  - `DOUBLE_PREC_HB` - double precision height-balanced.
  - `JSON_HB` - JSON histograms (from MariaDB 10.7)
- **Commandline:** `--histogram-type=value`
- **Scope:** Global, Session
- **Dynamic:** Yes

- **Data Type:** `enumeration`
- **Default Value:**
  - `JSON_HB` (>= MariaDB 11.0)
  - `DOUBLE_PREC_HB` (<= MariaDB 10.11, >= MariaDB 10.4.3)
  - `SINGLE_PREC_HB` (<= MariaDB 10.4.2)
- **Valid Values:**
  - `SINGLE_PREC_HB`, `DOUBLE_PREC_HB` (<= MariaDB 10.6)
  - `SINGLE_PREC_HB`, `DOUBLE_PREC_HB`, `JSON_HB` (>= MariaDB 10.7)

---

host_cache_size

- **Description:** Number of host names that will be cached to avoid resolving. Setting to `0` disables the cache. Changing the value while the server is running causes an implicit FLUSH HOSTS, clearing the host cache and truncating the performance_schema.host_cache table. If you are connecting from a lot of different machines you should consider increasing.
- **Commandline:** `--host-cache-size=#`.
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `128`
- **Range:** `0` to `65536`

---

hostname

- **Description:** When the server starts, this variable is set to the server host name.
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`

---

identity

- **Description:** A synonym for last_insert_id variable.

---

idle_readonly_transaction_timeout

- **Description:** Time in seconds that the server waits for idle read-only transactions before killing the connection. If set to `0`, the default, connections are never killed. See also idle_transaction_timeout, idle_write_transaction_timeout and Transaction Timeouts.
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` to `31536000`
- **Introduced:** MariaDB 10.3.0

---

idle_transaction_timeout

- **Description:** Time in seconds that the server waits for idle transactions before killing the connection. If set to `0`, the default, connections are never killed. See also idle_readonly_transaction_timeout, idle_write_transaction_timeout and Transaction Timeouts.
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` to `31536000`
- **Introduced:** MariaDB 10.3.0

---

idle_write_transaction_timeout

- **Description:** Time in seconds that the server waits for idle read-write transactions before killing the connection. If set to `0`, the default, connections are never killed. See also idle_transaction_timeout, idle_readonly_transaction_timeout and Transaction Timeouts. Called `idle_readwrite_transaction_timeout` until MariaDB 10.3.2.
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` to `31536000`
- **Introduced:** MariaDB 10.3.0

---

ignore_db_dirs

- **Description:** Tells the server that this directory can never be a database. That means two things - firstly it is ignored by the SHOW DATABASES command and INFORMATION_SCHEMA tables. And secondly, USE, CREATE DATABASE and SELECT statements will return an error if the database from the ignored list specified. Use this option several times if you need to ignore more than one directory. To make the list empty set the void value to the option as --ignore-db-dir=. If the option or configuration is specified multiple times, viewing this value will list the ignore directories separated by a period.
- **Commandline:** `--ignore-db-dirs=dir`.
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`

---

in_predicate_conversion_threshold

- **Description:** The minimum number of scalar elements in the value list of an IN predicate that triggers its conversion to an IN subquery. Set to 0 to disable the conversion. See Conversion of Big IN Predicates Into Subqueries.
- **Commandline:** `--in-predicate-conversion-threshold=#`
- **Scope:** Global, Session
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `1000`
- **Range:** `0` to `4294967295`
- **Introduced:** MariaDB 10.3.18 (previously debug builds only)

---

in_transaction

- **Description:** Session-only and read-only variable that is set to `1` if a transaction is in progress, `0` if not.
- **Commandline:** No
- **Scope:** Session
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `0`

---

init_connect

- **Description:** String containing one or more SQL statements, separated by semicolons, that will be executed by the server for each client connecting. If there's a syntax error in the one of the statements, the client will fail to connect. For this reason, the statements are not executed for users with the SUPER privilege or, from MariaDB 10.5.2, the CONNECTION ADMIN privilege, who can then still connect and correct the error. See also init_file.
- **Commandline:** `--init-connect=name`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string`

---

init_file

- **Description:** Name of a file containing SQL statements that will be executed by the server on startup. Each statement should be on a new line, and end with a semicolon. See also init_connect.
- **Commandline:** `init-file=file_name`

- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `file name`

---

insert_id

- **Description:** Value to be used for the next statement inserting a new AUTO_INCREMENT value.
- **Scope:** Session
- **Dynamic:** Yes
- **Data Type:** `numeric`

---

interactive_timeout

- **Description:** Time in seconds that the server waits for an interactive connection (one that connects with the mysql_real_connect() CLIENT_INTERACTIVE option) to become active before closing it. See also wait_timeout.
- **Commandline:** `--interactive-timeout=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `28800`
- **Range: (Windows):** `1` **to** `2147483`
- **Range: (Other):** `1` **to** `31536000`

---

join_buffer_size

- **Description:** Minimum size in bytes of the buffer used for queries that cannot use an index, and instead perform a full table scan. Increase to get faster full joins when adding indexes is not possible, although be aware of memory issues, since joins will always allocate the minimum size. Best left low globally and set high in sessions that require large full joins. In 64-bit platforms, Windows truncates values above 4GB to 4GB with a warning. See also Block-Based Join Algorithms - Size of Join Buffers.
- **Commandline:** `--join-buffer-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `262144` (256kB)
- **Range (non-Windows):** `128` to `18446744073709547520`
- **Range (Windows):** `8228` to `18446744073709547520`

---

join_buffer_space_limit

- **Description:** Maximum size in bytes of the query buffer, By default 1024*128*10. See Block-based join algorithms.
- **Commandline:** `--join-buffer-space-limit=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `2097152`
- **Range:** `2048` to `18446744073709551615`

---

join_cache_level

- **Description:** Controls which of the eight block-based algorithms can be used for join operations. See Block-based join algorithms for more information.
  - 1 – flat (Block Nested Loop) BNL
  - 2 – incremental BNL
  - 3 – flat Block Nested Loop Hash (BNLH)
  - 4 – incremental BNLH
  - 5 – flat Batch Key Access (BKA)
  - 6 – incremental BKA
  - 7 – flat Batch Key Access Hash (BKAH)
  - 8 – incremental BKAH

- **Commandline:** `--join-cache-level=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `2`
- **Range:** `0` to `8`

---

keep_files_on_create

- **Description:** If a MyISAM table is created with no DATA DIRECTORY option, the .MYD file is stored in the database directory. When set to `0`, the default, if MariaDB finds another .MYD file in the database directory it will overwrite it. Setting this variable to `1` means that MariaDB will return an error instead, just as it usually does in the same situation outside of the database directory. The same applies for .MYI files and no INDEX DIRECTORY option. Deprecated in MariaDB 10.8.0.
- **Commandline:** `--keep-files-on-create=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`
- **Deprecated:** MariaDB 10.8.0

---

large_files_support

- **Description:** ON if the server if was compiled with large file support or not, else OFF
- **Scope:** Global
- **Dynamic:** No

---

large_page_size

- **Description:** Indicates the size of memory page if large page support (Linux only) is enabled. The page size is determined from the Hugepagesize setting in `/proc/meminfo`. See large_pages. Deprecated and unused in MariaDB 10.5.3 since multiple page size support was added.
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** Autosized (see description)
- **Deprecated:** MariaDB 10.5.3

---

large_pages

- **Description:** Indicates whether large page support (prior to MariaDB 10.5, Linux only, by now supported Windows and BSD distros, also called huge pages) is used. This is set with `--large-pages` or disabled with `--skip-large-pages`. Large pages are used for the innodb buffer pool and for online DDL (of size 3* innodb_sort_buffer_size (or 6 when encryption is used)). To use large pages, the Linux `sysctl` variable `kernel.shmmax` must be large than the llocation. Also the `sysctl` variable `vm.nr_hugepages` multipled by large-page) must be larger than the usage. The ulimit for locked memory must be sufficient to cover the amount used (`ulimit -l` and equalivent in /etc/security/limits.conf / or in systemd LimitMEMLOCK). If these operating system controls or insufficient free huge pages are available, the allocation of large pages will fall back to conventional memory allocation and a warning will appear in the logs. Only allocations of the default `Hugepagesize` currently occur (see `/proc/meminfo`).
- **Commandline:** `--large-pages`, `--skip-large-pages`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

last_insert_id

- **Description:** Contains the same value as that returned by LAST_INSERT_ID(). Note that setting this variable doen't update the value returned by the underlying function.

- **Scope:** Session
- **Dynamic:** Yes
- **Data Type:** `numeric`

---

lc_messages

- **Description:** This system variable can be specified as a locale name. The language of the associated locale will be used for error messages. See Server Locales for a list of supported locales and their associated languages.
  - This system variable is set to `en_US` by default, which means that error messages are in English by default.
  - If this system variable is set to a valid locale name, but the server can't find an error message file for the language associated with the locale, then the default language will be used instead.
  - This system variable is used along with the `lc_messages_dir` system variable to construct the path to the error messages file.
  - See Setting the Language for Error Messages for more information.
- **Commandline:** `--lc-messages=name`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `en_us`

---

lc_messages_dir

- **Description:** This system variable can be specified either as the path to the directory storing the server's error message files or as the path to the directory storing the specific language's error message file. See Server Locales for a list of available locales and their related languages.
  - The server initially tries to interpret the value of this system variable as a path to the directory storing the server's error message files. Therefore, it constructs the path to the language's error message file by concatenating the value of this system variable with the language name of the locale specified by the `lc_messages` system variable .
  - If the server does not find the error message file for the language, then it tries to interpret the value of this system variable as a direct path to the directory storing the specific language's error message file.
  - See Setting the Language for Error Messages for more information.
- **Commandline:** `--lc-messages-dir=path`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `directory name`

---

lc_time_names

- **Description:** The locale that determines the language used for the date and time functions DAYNAME(), MONTHNAME() and DATE_FORMAT(). Locale names are language and region subtags, for example 'en_ZA' (English - South Africa) or 'es_US: Spanish - United States'. The default is always 'en-US' regardless of the system's locale setting. See server locale for a full list of supported locales.
- **Commandline:** `--lc-time-names=name`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `en_US`

---

license

- **Description:** Server license, for example `GPL` .
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`

---

local_infile

- **Description:** If set to `1` , LOCAL is supported for LOAD DATA INFILE statements. If set to `0` , usually for security reasons, attempts to perform a LOAD DATA LOCAL will fail with an error message.

- **Commandline:** `--local-infile=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `ON`

---

lock_wait_timeout

- **Description:** Timeout in seconds for attempts to acquire metadata locks. Statements using metadata locks include FLUSH TABLES WITH READ LOCK, LOCK TABLES, HANDLER and DML and DDL operations on tables, stored procedures and functions, and views. The timeout is separate for each attempt, of which there may be multiple in a single statement. `0` (from MariaDB 10.3.0) means no wait. See WAIT and NOWAIT.
- **Commandline:** `--lock-wait-timeout=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:**
  - `86400` (1 day)
- **Range:**
  - `0` to `31536000`

---

locked_in_memory

- **Description:** Indicates whether --memlock was used to lock mariadbd in memory.
- **Commandline:** `--memlock`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

log

- **Description:** Deprecated and removed in MariaDB 10.0, use general_log instead.
- **Commandline:** `-l [filename]` or `--log[=filename]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `OFF`
- **Removed:** MariaDB 10.0

---

log_disabled_statements

- **Description:** If set, the specified type of statements (slave and/or stored procedure statements) will not be logged to the general log. Multiple values are comma-separated, without spaces.
- **Commandline:** `--log-disabled_statements=value`
- **Scope:** Global, Session
- **Dynamic:** No
- **Data Type:** `set`
- **Default Value:** `sp`
- **Valid Values:** `slave` and/or `sp`, or empty string for none
- **Introduced:** MariaDB 10.3.1

---

log_error

- **Description:** Specifies the name of the error log. If --console is specified later in the configuration (Windows only) or this option isn't specified, errors will be logged to stderr. If no name is provided, errors will still be logged to `hostname.err` in the `datadir` directory by default. If a configuration file sets `--log-error`, one can reset it with `--skip-log-error` (useful to override a system wide configuration file). MariaDB always writes its error log, but the destination is configurable. See error log for details.
- **Commandline:** `--log-error[=name]`, `--skip-log-error`

- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `file name`
- **Default Value:** (empty string)

---

log_output

- **Description:** How the output for the general query log and the slow query log is stored. By default written to file (`FILE`), it can also be stored in the general_log and slow_log tables in the mysql database (`TABLE`), or not stored at all (`NONE`). More than one option can be chosen at the same time, with `NONE` taking precedence if present. Logs will not be written if logging is not enabled. See Writing logs into tables, and the slow_query_log and general_log server system variables.
- **Commandline:** `--log-output=name`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `set`
- **Default Value:** `FILE`
- **Valid Values:** `TABLE` , `FILE` or `NONE`

---

log_queries_not_using_indexes

- **Description:** Queries that don't use an index, or that perform a full index scan where the index doesn't limit the number of rows, will be logged to the slow query log (regardless of time taken). The slow query log needs to be enabled for this to have an effect. Mapped to `log_slow_filter='not_using_index'` from MariaDB 10.3.1.
- **Commandline:** `--log-queries-not-using-indexes`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

log_slow_admin_statements

- **Description:** Log slow OPTIMIZE, ANALYZE, ALTER and other administrative statements to the slow log if it is open. See also log_slow_disabled_statements and log_slow_filter. Deprecated, use log_slow_filter without `admin` .
- **Commandline:** `--log-slow-admin-statements`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:**
  - `ON`
- **Deprecated:** MariaDB 11.0.1

---

log_slow_disabled_statements

- **Description:** If set, the specified type of statements will not be logged to the slow query log. See also log_slow_admin_statements and log_slow_filter.
- **Commandline:** `--log-slow-disabled_statements=value`
- **Scope:** Global, Session
- **Dynamic:** No
- **Data Type:** `set`
- **Default Value:** `sp`
- **Valid Vales:** `admin` , `call` , `slave` and/or `sp`
- **Introduced:** MariaDB 10.3.1

---

log_slow_filter

- **Description:** Comma-delimited string (without spaces) containing one or more settings for filtering what is logged to the slow query log. If a query matches one of the types listed in the filter, and takes longer than long_query_time, it will be logged(except for 'not_using_index' which is always logged if enabled, regardless of the time). Sets log-slow-admin-statements to ON. See also log_slow_disabled_statements.

    - `admin` log administrative queries (create, optimize, drop etc...)
    - `filesort` logs queries that use a filesort.
    - `filesort_on_disk` logs queries that perform a a filesort on disk.
    - `filesort_priority_queue` (from MariaDB 10.3.2)
    - `full_join` logs queries that perform a join without indexes.
    - `full_scan` logs queries that perform full table scans.
    - `not_using_index` logs queries that don't use an index, or that perform a full index scan where the index doesn't limit the number of rows. Disregards long_query_time, unlike other options. log_queries_not_using_indexes maps to this option. From MariaDB 10.3.1.
    - `query_cache` log queries that are resolved by the query cache.
    - `query_cache_miss` logs queries that are not found in the query cache.
    - `tmp_table` logs queries that create an implicit temporary table.
    - `tmp_table_on_disk` logs queries that create a temporary table on disk.
- **Commandline:** `log-slow-filter=value1[,value2...]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `enumeration`
- **Default Value:**
    - `admin`, `filesort`, `filesort_on_disk`, `full_join`, `full_scan`, `query_cache`, `query_cache_miss`, `tmp_table`, `tmp_table_on_disk` (<= MariaDB 10.3.0)
    - `admin`, `filesort`, `filesort_on_disk`, `filesort_priority_queue`, `full_join`, `full_scan`, `query_cache`, `query_cache_miss`, `tmp_table`, `tmp_table_on_disk` (>= MariaDB 10.3.1)
- **Valid Values:** `admin`, `filesort`, `filesort_on_disk`, `filesort_priority_queue`, `full_join`, `full_scan`, `query_cache`, `query_cache_miss`, `tmp_table`, `tmp_table_on_disk`

---

log_slow_min_examined_row_limit

- **Description:** If a query examines more than this number of rows, it is logged to the slow query log. If set to `0`, the default, no row limit is used. `min_examined_row_limit` is an alias.
- **Commandline:** `--log-slow-min-examined-row-limit=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0-4294967295`
- **Introduced:** MariaDB 10.11.0

---

log_slow_queries

- **Description:** Deprecated and removed in MariaDB 10.0, use slow_query_log instead.
- **Commandline:** `--log-slow-queries[=name]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`
- **Removed:** MariaDB 10.0

---

log_slow_query

- **Description:** If set to 0, the default unless the --slow-query-log option is used, the slow query log is disabled, while if set to 1 (both global and session variables), the slow query log is enabled. Named slow_query_log before MariaDB 10.11.0, which is now an alias.
- **Commandline:** `--slow-query-log`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `0`
- **Introduced:** MariaDB 10.11.0
- **See also:** See log_output to see how log files are written. If that variable is set to `NONE`, no logs will be written even if log_slow_query is set to `1`.

---

log_slow_query_file

- **Description:** Name of the slow query log file. Before MariaDB 10.11, was named slow_query_log_file. This was named `log_slow_query_file_name` in the MariaDB 10.11.0 preview release.
- **Commandline:** `--log-slow-query-file=file_name`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `file name`
- **Default Value:** *`host_name`*`-slow.log`
- **Introduced:** MariaDB 10.11.0

---

log_slow_query_time

- **Description:** If a query takes longer than this many seconds to execute (microseconds can be specified too), the Slow_queries status variable is incremented and, if enabled, the query is logged to the slow query log. Before MariaDB 10.11, was named long_query_time.
- **Commandline:** `--log-slow-query-time=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `10.000000`
- **Range:** `0` to `31536000`
- **Introduced:** MariaDB 10.11.0

---

log_slow_rate_limit

- **Description:** The slow query log will log every this many queries. The default is `1`, or every query, while setting it to `20` would log every 20 queries, or five percent. Aims to reduce I/O usage and excessively large slow query logs. See also Slow Query Log Extended Statistics.
- **Commandline:** `log-slow-rate-limit=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `1`
- **Range:** `1` upwards

---

log_slow_verbosity

- **Description:** Controls information to be added to the slow query log. Options are added in a comma-delimited string. See also Slow Query Log Extended Statistics. log_slow_verbosity is not supported when log_output='TABLE'.
  - `query_plan` logs query execution plan information
  - `innodb` Alias to `engine` (from MariaDB 10.6.15 and MariaDB 10.11.5), previously ignored.
  - `explain` prints EXPLAIN output in the slow query log. See EXPLAIN in the Slow Query Log.
  - `engine` Logs engine statistics (from MariaDB 10.6.15 and MariaDB 10.11.5).
  - `warnings` Print all errors, warnings and notes for the statement to the slow query log. (from MariaDB 10.6.16).
  - `all` Enables all above options (From MariaDB 10.6.16)
  - `full` Enables all above options.
- **Commandline:** `log-slow-verbosity=value1[,value2...]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `enumeration`
- **Default Value:** (Empty)
- **Valid Values:**
  - >= MariaDB 10.6.16, MariaDB 10.11.6: (Empty), `query_plan`, `innodb`, `explain`, `engine`, `warnings`, `all`, `full`
  - >= MariaDB 10.6.15, MariaDB 10.11.5: (Empty), `query_plan`, `innodb`, `explain`, `engine`, `full`
  - <= MariaDB 10.6.14, MariaDB 10.11.4: (Empty), `query_plan`, `innodb`, `explain`

---

log_slow_max_warnings

- **Description:** Max numbers of warnings printed to slow query log per statement
- **Commandline:** `log-slow-max-warnings=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `10`
- **Range:** `0` to `1000`
- **Introduced:** MariaDB 10.6.16

log_tc_size

- **Description:** Defines the size in bytes of the memory-mapped file-based transaction coordinator log, which is only used if the binary log is disabled. If you have two or more XA-capable storage engines enabled, then a transaction coordinator log must be available. This size is defined in multiples of 4096. See Transaction Coordinator Log for more information. Also see the `--log-tc` server option and the `--tc-heuristic-recover` option.
- **Commandline:** `log-tc-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `24576`
- **Range:** `12288` to `18446744073709551615`

---

log_warnings

- **Description:** Determines which additional warnings are logged. Setting to `0` disables additional warning logging. Note that this does not prevent all warnings, there is a core set of warnings that will always be written to the error log. The additional warnings are as follows:
  - log_warnings >= 1
    - Event scheduler information.
    - System signals
    - Wrong usage of `--user`
    - Failed setrlimit() and mlockall()
    - Changed limits
    - Wrong values of lower_case_table_names and stack_size
    - Wrong values for command line options
    - Start log position and some master information when starting slaves
    - Slave reconnects
    - Killed slaves
    - Error reading relay logs
    - Unsafe statements for statement-based replication. If this warning occurs frequently, it is throttled to prevent flooding the log.
    - Disabled plugins that one tried to enable or use.
    - UDF files that didn't include the required init functions.
    - DNS lookup failures.
  - log_warnings >= 2
    - Access denied errors.
    - Connections aborted or closed due to errors or timeouts.
    - Table handler errors
    - Messages related to the files used to persist replication state:
      - Either the default `master.info` file or the file that is configured by the `master_info_file` option.
      - Either the default `relay-log.info` file or the file that is configured by the `relay_log_info_file` system variable.
    - Information about a master's binary log dump thread.
  - log_warnings >= 3
    - All errors and warnings during MyISAM repair and auto recover.
    - Information about old-style language options.
    - Information about progress of InnoDB online DDL.
  - log_warnings >=4
    - Connections aborted due to "Too many connections" errors.
    - Connections closed normally.
    - Connections aborted due to `KILL`.
    - Connections closed due to released connections, such as when `completion_type` is set to `RELEASE`.
  - log_warnings >=9
    - Information about initializing plugins.

- **Commandline:** `-W [level]` or `--log-warnings[=level]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:**
  - `2`
- **Range:** `0` to `4294967295`

---

long_query_time

- **Description:** If a query takes longer than this many seconds to execute (microseconds can be specified too), the Slow_queries status variable is incremented and, if enabled, the query is logged to the slow query log. From MariaDB 10.11.0, this is an alias for log_slow_query_time.
- **Commandline:** `--long-query-time=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `10.000000`
- **Range:** `0` upwards

---

low_priority_updates

- **Description:** If set to 1 (0 is the default), for storage engines that use only table-level locking (Aria, MyISAM, MEMORY and MERGE), all INSERTs, UPDATEs, DELETEs and LOCK TABLE WRITEs will wait until there are no more SELECTs or LOCK TABLE READs pending on the relevant tables. Set this to 1 if reads are prioritized over writes.
  - In MariaDB 5.5 and earlier, `sql_low_priority_updates` is a synonym.
- **Commandline:** `--low-priority-updates`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `0`

---

lower_case_file_system

- **Description:** Read-only variable describing whether the file system is case-sensitive. If set to `OFF`, file names are case-sensitive. If set to `ON`, they are not case-sensitive.
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `##`

---

lower_case_table_names

- **Description:** If set to `0` (the default on Unix-based systems), table names and aliases and database names are compared in a case-sensitive manner. If set to `1` (the default on Windows), names are stored in lowercase and not compared in a case-sensitive manner. If set to `2` (the default on Mac OS X), names are stored as declared, but compared in lowercase. This system variable's value cannot be changed after the datadir has been initialized. lower_case_table_names is set when a MariaDB instance starts, and it remains constant afterwards.
- **Commandline:** `--lower-case-table-names[=#]`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `0` (Unix), `1` (Windows), `2` (Mac OS X)
- **Range:** `0` to `2`

---

max_allowed_packet

- **Description:** Maximum size in bytes of a packet or a generated/intermediate string. The packet message buffer is

initialized with the value from net_buffer_length, but can grow up to max_allowed_packet bytes. Set as large as the largest BLOB, in multiples of 1024. If this value is changed, it should be changed on the client side as well. See slave_max_allowed_packet for a specific limit for replication purposes.

- **Commandline:** `--max-allowed-packet=#`
- **Scope:** Global, Session
- **Dynamic:** Yes (Global), No (Session)
- **Data Type:** `numeric`
- **Default Value:**
  - `16777216` (16M)
  - `1073741824` (1GB) (client-side)
- **Range:** `1024` to `1073741824`

---

max_connect_errors

- **Description:** Limit to the number of successive failed connects from a host before the host is blocked from making further connections. The count for a host is reset to zero if they successfully connect. To unblock, flush the host cache with a FLUSH HOSTS statement or mariadb-admin flush-hosts. The performance_schema.host_cache table contains the status of the current hosts.
- **Commandline:** `--max-connect-errors=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `100`
- **Range:** `1` to `4294967295`

---

max_connections

- **Description:** The maximum number of simultaneous client connections. See also Handling Too Many Connections. Note that this value affects the number of file descriptors required on the operating system. Minimum was changed from `1` to `10` to avoid possible unexpected results for the user (MDEV-18252). Note that MariaDB always has one reserved connection for a superuser. Additionally it can listen on a separate port, so will be available even when the max_connections limit is reached.
- **Commandline:** `--max-connections=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `151`
- **Range:** `10` to `100000`

---

max_delayed_threads

- **Description:** Limits to the number of INSERT DELAYED threads. Once this limit is reached, the insert is handled as if there was no DELAYED attribute. If set to `0`, DELAYED is ignored entirely. The session value can only be set to `0` or to the same as the global value.
- **Commandline:** `--max-delayed-threads=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `20`
- **Range:** `0` to `16384`

---

max_digest_length

- **Description:** Maximum length considered for computing a statement digest, such as used by the Performance Schema and query rewrite plugins. Statements that differ after this many bytes produce the same digest, and are aggregated for statistics purposes. The variable is allocated per session. Increasing will allow longer statements to be distinguished from each other, but increase memory use, while decreasing will reduce memory use, but more statements may become indistinguishable.
- **Commandline:** `--max-digest-length=#`
- **Scope:** Global,
- **Dynamic:** No

- **Data Type:** `numeric`
- **Default Value:** `1024`
- **Range:** `0` to `1048576`

---

max_error_count

- **Description:** Specifies the maximum number of messages stored for display by SHOW ERRORS and SHOW WARNINGS statements.
- **Commandline:** `--max-error-count=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `64`
- **Range:** `0` to `65535`

---

max_heap_table_size

- **Description:** Maximum size in bytes for user-created MEMORY tables. Setting the variable while the server is active has no effect on existing tables unless they are recreated or altered. The smaller of max_heap_table_size and tmp_table_size also limits internal in-memory tables. When the maximum size is reached, any further attempts to insert data will receive a "table ... is full" error. Temporary tables created with CREATE TEMPORARY will not be converted to Aria, as occurs with internal temporary tables, but will also receive a table full error.
- **Commandline:** `--max-heap-table-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `16777216`
- **Range :** `16384` to `4294966272`

---

max_insert_delayed_threads

- **Description:** Synonym for max_delayed_threads.

---

max_join_size

- **Description:** Statements will not be performed if they are likely to need to examine more than this number of rows, row combinations or do more disk seeks. Can prevent poorly-formatted queries from taking server resources. Changing this value to anything other the default will reset sql_big_selects to 0. If sql_big_selects is set again, max_join_size will be ignored. This limit is also ignored if the query result is sitting in the query cache. Previously named sql_max_join_size, which is still a synonym.
- **Commandline:** `--max-join-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `18446744073709551615`
- **Range:** `1` to `18446744073709551615`

---

max_length_for_sort_data

- **Description:** Used to decide which algorithm to choose when sorting rows. If the total size of the column data, not including columns that are part of the sort, is less than `max_length_for_sort_data` , then we add these to the sort key. This can speed up the sort as we don't have to re-read the same row again later. Setting the value too high can slow things down as there will be a higher disk activity for doing the sort.
- **Commandline:** `--max-length-for-sort-data=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `1024`
- **Range:** `4` to `8388608`

---

max_long_data_size

- **Description:** Maximum size for parameter values sent with mysql_stmt_send_long_data(). If not set, will default to the value of max_allowed_packet. Deprecated in MariaDB 5.5 and removed in MariaDB 10.5.0; use max_allowed_packet instead.
- **Commandline:** `--max-long-data-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:**
  - `16777216` (16M)
- **Range:** `1024` to `4294967295`
- **Deprecated:** MariaDB 5.5
- **Removed:** MariaDB 10.5.0

---

max_password_errors

- **Description:** The maximum permitted number of failed connection attempts due to an invalid password before a user is blocked from further connections. FLUSH_PRIVILEGES will permit the user to connect again. This limit is ignored for users with the SUPER privilege or, from MariaDB 10.5.2, the CONNECTION ADMIN privilege. The maximum also doesn't apply to users with a hostname of localhost, 127.0.0.1 or ::1.
- **Commandline:** `--max-password-errors=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `4294967295`
- **Range:** `1` to `4294967295`
- **Introduced:** MariaDB 10.4.2

---

max_prepared_stmt_count

- **Description:** Maximum number of prepared statements on the server. Can help prevent certain forms of denial-of-service attacks. If set to `0`, no prepared statements are permitted on the server.
- **Commandline:** `--max-prepared-stmt-count=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `16382`
- **Range:** `0` to `4294967295` (>= MariaDB 10.3.6), `0` to `1048576` (<= MariaDB 10.3.5)

---

max_recursive_iterations

- **Description:** Maximum number of iterations when executing recursive queries, used to prevent infinite loops in recursive CTEs.
- **Commandline:** `--max-recursive-iterations=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `1000` (>= MariaDB 10.6.0), `4294967295` (<= MariaDB 10.5)
- **Range:** `0` to `4294967295`

---

max_rowid_filter_size

- **Description:** The maximum size of the container of a rowid filter.
- **Commandline:** `--max-rowid-filter-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `131072`
- **Range:** `1024` to `18446744073709551615`
- **Introduced:** MariaDB 10.4.3

max_seeks_for_key

- **Description:** The optimizer assumes that the number specified here is the most key seeks required when searching with an index, regardless of the actual index cardinality. If this value is set lower than its default and maximum, indexes will tend to be preferred over table scans.
- **Commandline:** `--max-seeks-for-key=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `4294967295`
- **Range:** `1` to `4294967295`

max_session_mem_used

- **Description:** Amount of memory a single user session is allowed to allocate. This limits the value of the session variable Memory_used.
- **Commandline:** `--max-session-mem-used=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `9223372036854775807` (8192 PB)
- **Range:** `8192` to `18446744073709551615`

max_sort_length

- **Description:** Maximum size in bytes used for sorting data values - anything exceeding this is ignored. The server uses only the first `max_sort_length` bytes of each value and ignores the rest. Increasing this may require sort_buffer_size to be increased (especially if ER_OUT_OF_SORTMEMORY errors start appearing).
- **Commandline:** `--max-sort-length=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `1024`
- **Range:**
  - `4` to `8388608` (<= MariaDB 10.4.13, MariaDB 10.5.3)
  - `8` to `8388608` (>= MariaDB 10.4.14, MariaDB 10.5.4)

max_sp_recursion_depth

- **Description:** Permitted number of recursive calls for a stored procedure. `0`, the default, no recursion is permitted. Increasing this value increases the thread stack requirements, so you may need to increase thread_stack as well. This limit doesn't apply to stored functions.
- **Commandline:** `--max-sp-recursion-depth[=#]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` to `255`

max_statement_time

- **Description:** Maximum time in seconds that a query can execute before being aborted. This includes all queries, not just SELECT statements, but excludes statements in stored procedures. If set to 0, no limit is applied. See Aborting statements that take longer than a certain time to execute for details and limitations. Useful when combined with SET STATEMENT for limiting the execution times of individual queries. Replicas are not affected by this variable, however, from MariaDB 10.10, there's slave_max_statement_time that sets the limit to abort queries on a replica.
- **Commandline:** `--max-statement-time[=#]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`

- **Default Value:** `0.000000`
- **Range:** `0` to `31536000`

---

max_tmp_tables

- **Description:** Unused.
- **Removed:** MariaDB 11.3.0

---

max_user_connections

- **Description:** Maximum simultaneous connections permitted for each user account. When set to `0`, there is no per user limit. Setting it to `-1` stops users without the SUPER privilege or, from MariaDB 10.5.2, the CONNECTION ADMIN privilege, from connecting to the server. The session variable is always read-only and only privileged users can modify user limits. The session variable defaults to the global `max_user_connections` variable, unless the user's specific `MAX_USER_CONNECTIONS` resource option is non-zero. When both global variable and the user resource option are set, the user's MAX_USER_CONNECTIONS is used. Note: This variable does not affect users with the SUPER privilege or, from MariaDB 10.5.2, the CONNECTION ADMIN privilege.
- **Commandline:** `--max-user-connections=#`
- **Scope:** Global, Session
- **Dynamic:** Yes, (except when globally set to `0` or `-1`)
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `-1` to `4294967295`

---

max_write_lock_count

- **Description:** Read lock requests will be permitted for processing after this many write locks. Applies only to storage engines that use table level locks (thr_lock), so no effect with InnoDB or Archive.
- **Commandline:** `--max-write-lock-count=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `4294967295`
- **Range:** `0-4294967295`

---

metadata_locks_cache_size

- **Description:** Size of the metadata locks cache, used for reducing the need to create and destroy synchronization objects. It is particularly helpful on systems where this process is inefficient, such as Windows XP.
- **Commandline:** `--metadata-locks-cache-size=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `1024`
- **Range:** `1` to `1048576`

---

metadata_locks_hash_instances

- **Description:** Number of hashes used by the set of metadata locks. The metadata locks are partitioned into separate hashes in order to reduce contention.
- **Commandline:** `--metadata-locks-hash-instances=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `8`
- **Range:** `1` to `1024`

---

min_examined_row_limit

- **Description:** If a query examines more than this number of rows, it is logged to the slow query log. If set to `0`, the default, no row limit is used. From MariaDB 10.11.0, this is an alias for log_slow_min_examined_row_limit.
- **Commandline:** `--min-examined-row-limit=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0-4294967295`

---

mrr_buffer_size

- **Description:** Size of buffer to use when using multi-range read with range access. See Multi Range Read optimization for more information.
- **Commandline:** `--mrr-buffer-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `262144`
- **Range** `8192` to `2147483648`

---

multi_range_count

- **Description:** Ignored. Use mrr_buffer_size instead.
- **Commandline:** `--multi-range-count=#`
- **Default Value:** `256`
- **Removed:** MariaDB 10.5.1

---

mysql56_temporal_format

- **Description:** If set (the default), MariaDB uses the MySQL 5.6 low level formats for TIME, DATETIME and TIMESTAMP instead of the MariaDB 5.3 version. The version MySQL introduced in 5.6 requires more storage, but potentially allows negative dates and has some advantages in replication. There should be no reason to revert to the old MariaDB 5.3 microsecond format. See also MDEV-10723.
- **Commandline:** `--mysql56-temporal-format`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `ON`

---

named_pipe

- **Description:** On Windows systems, determines whether connections over named pipes are permitted.
- **Commandline:** `--named-pipe`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

net_buffer_length

- **Description:** The starting size, in bytes, for the connection and thread buffers for each client thread. The size can grow to max_allowed_packet. This variable's session value is read-only. Can be set to the expected length of client statements if memory is a limitation.
- **Commandline:** `--net-buffer-length=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `16384`
- **Range:** `1024` to `1048576`

---

net_read_timeout

- **Description:** Time in seconds the server will wait for a client connection to send more data before aborting the read. See also net_write_timeout and slave_net_timeout
- **Commandline:** `--net-read-timeout=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `30`
- **Range:** `1` upwards

---

net_retry_count

- **Description:** Permit this many retries before aborting when attempting to read or write on a communication port. On FreeBSD systems should be set higher as threads are sent internal interrupts..
- **Commandline:** `--net-retry-count=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `10`
- **Range:** `1` to `4294967295`

---

net_write_timeout

- **Description:** Time in seconds to wait on writing a block to a connection before aborting the write. See also net_read_timeout and slave_net_timeout.
- **Commandline:** `--net-write-timeout=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `60`
- **Range:** `1` upwards

---

note_verbosity

- **Description:** Verbosity level for note-warnings given to the user. Options are added in a comma-delimited string, except for `all`, which sets all options. See also Notes when an index cannot be used. Be aware that if the old sql_notes variable is 0, one will not get any notes. Setting `note_verbosity` to "" is the recommended way to disable notes.
  - `basic` All old notes.
  - `unusable_keys` Give warnings for unusable keys for SELECT, DELETE and UPDATE.
  - `explain` Give warnings for unusable keys for EXPLAIN.
  - `all` Enables all above options. This has to be given alone.
- **Commandline:** `note-verbosity=value1[,value2...]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `enumeration`
- **Default Value:** `basic,explain`
- **Valid Values:** `basic,explain,unusable_keys` or `all`.
- **Introduced:** MariaDB 10.6.16

old

- **Description:** Disabled by default, enabling it reverts index hints to those used before MySQL 5.1.17. Enabling may lead to replication errors. Deprecated and replaced by old_mode from MariaDB 10.9.
- **Commandline:** `--old`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`
- **Deprecated:** MariaDB 10.9

---

old_alter_table

- **Description:** From MariaDB 10.3.7, an alias for alter_algorithm. Prior to that, if set to `1` (`0` is default), MariaDB reverts to the non-optimized, pre-MySQL 5.1, method of processing ALTER TABLE statements. A temporary table is created, the data is copied over, and then the temporary table is renamed to the original.
- **Commandline:** `--old-alter-table`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `enumerated` (>=MariaDB 10.3.7), `boolean` (<= MariaDB 10.3.6)
- **Default Value:** See alter_algorithm (>= MariaDB 10.3.7), `0` (<= MariaDB 10.3.6)
- **Valid Values:** See alter_algorithm for the full list.
- **Deprecated:** MariaDB 10.3.7 (superceded by alter_algorithm)
- **Removed:** MariaDB 11.2.0

---

old_mode

- **Description:** Used for getting MariaDB to emulate behavior from an old version of MySQL or MariaDB. See OLD Mode. Fully replaces the old variable from MariaDB 10.9.
- **Commandline:** `--old-mode`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `UTF8_IS_UTF8MB3` (>= MariaDB 10.6) `(empty string)` (<= MariaDB 10.5)
- **Valid Values:** See OLD Mode for the full list.

---

old_passwords

- **Description:** If set to `1` (`0` is default), MariaDB reverts to using the `mysql_old_password` authentication plugin by default for newly created users and passwords, instead of the `mysql_native_password` authentication plugin.
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

open_files_limit

- **Description:** The number of file descriptors available to MariaDB. If you are getting the `Too many open files` error, then you should increase this limit. If set to 0, then MariaDB will calculate a limit based on the following:

  MAX(max_connections*5, max_connections +table_open_cache*2)

  MariaDB sets the limit with `setrlimit`. MariaDB cannot set this to exceed the hard limit imposed by the operating system. Therefore, you may also need to change the hard limit. There are a few ways to do so.
  - If you are using `mysqld_safe` to start `mariadbd`, then see the instructions at mysqld_safe: Configuring the Open Files Limit.
  - If you are using `systemd` to start `mysqld`, then see the instructions at systemd: Configuring the Open Files Limit.
  - Otherwise, you can change the hard limit for the `mysql` user account by modifying `/etc/security/limits.conf`. See Configuring Linux for MariaDB: Configuring the Open Files Limit for more details.
- **Commandline:** `--open-files-limit=count`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** Autosized (see description)
- **Range:** `0` to `4294967295`

---

optimizer_extra_pruning_depth

- **Description:**If the optimizer needs to enumerate a join prefix of this size or larger, then it will try aggressively prune away the search space.

- **Commandline:** `--optimizer-extra-pruning-depth1[=#]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `8`
- **Range:** `0` to `62`
- **Introduced:** MariaDB 10.10.1

---

optimizer_max_sel_args

- **Description:** The maximum number of SEL_ARG objects created when optimizing a range. If more objects would be needed, the range will not be used by the optimizer.
- **Commandline:** `--optimizer-max-sel-args=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `16000`
- **Range:** `0` to `4294967295`
- **Introduced:** MariaDB 10.6.16

---

optimizer_max_sel_arg_weight

- **Description:** The maximum weight of the SEL_ARG graph. Set to 0 for no limit.
- **Commandline:** `--optimizer-max-sel-arg-weight=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `32000`
- **Range:** `0` to `18446744073709551615`
- **Introduced:** MariaDB 10.5.9

---

optimizer_prune_level

- **Description:**Controls the heuristic(s) applied during query optimization to prune less-promising partial plans from the optimizer search space.
  - `0` : heuristics are disabled and an exhaustive search is performed
  - `1` : the optimizer will use heuristics to prune less-promising partial plans from the optimizer search space
  - `2` : tables using EQ_REF will be joined together as 'one entity' and the different combinations of these tables will not be considered (from MariaDB 10.10)
- **Commandline:** `--optimizer-prune-level[=#]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `2` (>= MariaDB 10.10), `1` (<= MariaDB 10.9)

---

optimizer_search_depth

- **Description:** Maximum search depth by the query optimizer. Smaller values lead to less time spent on execution plans, but potentially less optimal results. If set to `0`, MariaDB will automatically choose a reasonable value. Since the better results from more optimal planning usually offset the longer time spent on planning, this is set as high as possible by default. `63` is a valid value, but its effects (switching to the original find_best search) are deprecated.
- **Commandline:** `--optimizer-search-depth[=#]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `62`
- **Range:** `0` to `63`

---

optimizer_selectivity_sampling_limit

- **Description:** Controls number of record samples to check condition selectivity. Only used if `optimizer_use_condition_selectivity > 4`.
- **Commandline:** `optimizer-selectivity-sampling-limit[=#]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `100`
- **Range:** `10` upwards

---

optimizer_switch

- **Description:** A series of flags for controlling the query optimizer. See Optimizer Switch for defaults, and a comparison to MySQL.
- **Commandline:** `--optimizer-switch=value`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `string`
- **Valid Values:**
  - `condition_pushdown_for_derived={on|off}`
  - `condition_pushdown_for_subquery={on|off}` (>=MariaDB 10.4.0)
  - `condition_pushdown_from_having={on|off}` (>=MariaDB 10.4.3)
  - `default` - set all optimizations to their default values.
  - `derived_merge={on|off}` - see Derived table merge optimization
  - `derived_with_keys={on|off}` - see Derived table with key optimization
  - `engine_condition_pushdown={on|off}` . Deprecated in MariaDB 10.1.1 as engine condition pushdown is now automatically enabled for all engines that support it.
  - `exists_to_in={on|off}` - see EXISTS-to-IN optimization
  - `extended_keys={on|off}` - see Extended Keys
  - `firstmatch={on|off}` - see First Match Strategy
  - `hash_join_cardinality={on|off}` - see hash_join_cardinality-optimizer_switch-flag (>= MariaDB 11.0.2, MariaDB 10.11.3, MariaDB 10.6.13)
  - `index_condition_pushdown={on|off}` - see Index Condition Pushdown
  - `index_merge={on|off}`
  - `index_merge_intersection={on|off}`
  - `index_merge_sort_intersection={on|off}` - more details
  - `index_merge_sort_union={on|off}`
  - `index_merge_union={on|off}`
  - `in_to_exists={on|off}` - see IN-TO-EXISTS transformation
  - `join_cache_bka={on|off}` - see Block-Based Join Algorithms
  - `join_cache_hashed={on|off}` - see Block-Based Join Algorithms
  - `join_cache_incremental={on|off}` - see Block-Based Join Algorithms
  - `loosescan={on|off}` - see LooseScan strategy
  - `materialization={on|off}` - Semi-join and non semi-join materialization.
  - `mrr={on|off}` - see Multi Range Read optimization
  - `mrr_cost_based={on|off}` - see Multi Range Read optimization
  - `mrr_sort_keys={on|off}` - see Multi Range Read optimization
  - `not_null_range_scan={on|off}` - see not_null_range_scan optimization (>= MariaDB 10.5.0)
  - `optimize_join_buffer_size={on|off}` - see Block-Based Join Algorithms
  - `orderby_uses_equalities={on|off}` - if not set, the optimizer ignores equality propagation. See MDEV-8989.
  - `outer_join_with_cache={on|off}` - see Block-Based Join Algorithms
  - `partial_match_rowid_merge={on|off}` - see Non-semi-join subquery optimizations
  - `partial_match_table_scan={on|off}` - see Non-semi-join subquery optimizations
  - `rowid_filter={on|off}` - see Rowid Filtering Optimization (>= MariaDB 10.4.3)
  - `sargable_casefold={on|off}` (>= MariaDB 11.3.0)
  - `semijoin={on|off}` - see Semi-join subquery optimizations
  - `semijoin_with_cache={on|off}` - see Block-Based Join Algorithms
  - `split_materialized={on|off}`
  - `subquery_cache={on|off}` - see subquery cache.
  - `table_elimination={on|off}` - see Table Elimination User Interface

---

optimizer_trace

- **Description:** Controls tracing of the optimizer: optimizer_trace=option=val[,option=val...], where option is one of {enabled} and val is one of {on, off, default}
- **Commandline:** `--optimizer-trace=value`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `enum`
- **Default Value:** `enabled=off`
- **Valid Values:** `enabled={on|off|default}`
- **Introduced:** MariaDB 10.4.3

---

optimizer_trace_max_mem_size

- **Description:** Limits the memory used while tracing a query by specifying the maximum allowed cumulated size, in bytes, of stored optimizer traces.
- **Commandline:** `--optimizer-trace-max-mem-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `1048576`
- **Range:** `1` to `18446744073709551615`
- **Introduced:** MariaDB 10.4.3

---

optimizer_use_condition_selectivity

- **Description:** Controls which statistics can be used by the optimizer when looking for the best query execution plan.
  - `1` Use selectivity of predicates as in MariaDB 5.5.
  - `2` Use selectivity of all range predicates supported by indexes.
  - `3` Use selectivity of all range predicates estimated without histogram.
  - `4` Use selectivity of all range predicates estimated with histogram.
  - `5` Additionally use selectivity of certain non-range predicates calculated on record sample.
- **Commandline:** `--optimizer-use-condition-selectivity=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `4` (>= MariaDB 10.4.1), `1` (<= MariaDB 10.4.0)
- **Range:** `1` to `5`

---

pid_file

- **Description:** Full path of the process ID file.
- **Commandline:** `--pid-file=file_name`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `file name`

---

plugin_dir

- **Description:** Path to the plugin directory. For security reasons, either make sure this directory can only be read by the server, or set secure_file_priv.
- **Commandline:** `--plugin-dir=path`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `directory name`
- **Default Value:** `BASEDIR/lib/plugin`

---

plugin_maturity

- **Description:** The lowest acceptable plugin maturity. MariaDB will not load plugins less mature than the specified level.
- **Commandline:** `--plugin-maturity=level`

- **Scope:** Global
- **Dynamic:** No
- **Type:** enum
- **Default Value:** One less than the server maturity (>= MariaDB 10.3.3), `unknown` (<= MariaDB 10.3.2)
- **Valid Values:** `unknown`, `experimental`, `alpha`, `beta`, `gamma`, `stable`

---

port

- **Description:** Port to listen for TCP/IP connections. If set to `0`, will default to, in order of preference, my.cnf, the MYSQL_TCP_PORT environment variable, /etc/services, built-in default (3306).
- **Commandline:** `--port=#`, `-P`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `3306`
- **Range:** `0` to `65535`

---

preload_buffer_size

- **Description:** Size in bytes of the buffer allocated when indexes are preloaded.
- **Commandline:** `--preload-buffer-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `32768`
- **Range:** `1024` to `1073741824`

---

profiling

- **Description:** If set to `1` (`0` is default), statement profiling will be enabled. See SHOW PROFILES() and SHOW PROFILE().
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

profiling_history_size

- **Description:** Number of statements about which profiling information is maintained. If set to `0`, no profiles are stored. See SHOW PROFILES.
- **Commandline:** `--profiling-history-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `15`
- **Range:** `0` to `100`

---

progress_report_time

- **Description:** Time in seconds between sending progress reports to the client for time-consuming statements. If set to `0`, progress reporting will be disabled.
- **Commandline:** `--progress-report-time=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `5`
- **Range:** `0` to `4294967295`

---

protocol_version

- **Description:** The version of the client/server protocol used by the MariaDB server.
- **Commandline:** None
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `10`
- **Range:** `0` to `4294967295`

---

proxy_protocol_networks

- **Description:** Enable proxy protocol for these source networks. The syntax is a comma separated list of IPv4 and IPv6 networks. If the network doesn't contain a mask, it is considered to be a single host. "*" represents all networks and must be the only directive on the line. String "localhost" represents non-TCP local connections (Unix domain socket, Windows named pipe or shared memory). See Proxy Protocol Support.
- **Commandline:** `--proxy-protocol-networks=value`
- **Scope:** Global
- **Dynamic:** Yes (>= MariaDB 10.3.6), No (<= MariaDB 10.3.5)
- **Data Type:** `string`
- **Default Value:** (empty)
- **Introduced:** MariaDB 10.3.1

---

proxy_user

- **Description:** Set to the proxy user account name if the current client is a proxy, else `NULL`.
- **Scope:** Session
- **Dynamic:** No
- **Data Type:** `string`

---

pseudo_slave_mode

- **Description:** For internal use by the server.
- **Scope:** Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `OFF`

---

pseudo_thread_id

- **Description:** For internal use only.
- **Scope:** Session
- **Dynamic:** Yes
- **Data Type:** `numeric`

---

query_alloc_block_size

- **Description:** Size in bytes of the extra blocks allocated during query parsing and execution (after query_prealloc_size is used up).
- **Commandline:** `--query-alloc-block-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `16384`
- **Range - 32 bit:** `1024` to `4294967295`
- **Range - 64 bit:** `1024` to `18446744073709547520`

---

query_cache_limit

- **Description:** Size in bytes for which results larger than this are not stored in the query cache.
- **Commandline:** `--query-cache-limit=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `1048576` (1MB)
- **Range:** `0` to `4294967295`

---

query_cache_min_res_unit

- **Description:** Minimum size in bytes of the blocks allocated for query cache results.
- **Commandline:** `--query-cache-min-res-unit=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `4096` (4KB)
- **Range - 32 bit:** `1024` to `4294967295`
- **Range - 64 bit:** `1024` to `18446744073709547520`

---

query_cache_size

- **Description:** Size in bytes available to the query cache. About 40KB is needed for query cache structures, so setting a size lower than this will result in a warning. `0`, the default before MariaDB 10.1.7, effectively disables the query cache.

Warning: Starting from MariaDB 10.1.7, query_cache_type is automatically set to ON if the server is started with the query_cache_size set to a non-zero (and non-default) value. This will happen even if query_cache_type is explicitly set to OFF in the configuration.

- **Commandline:** `--query-cache-size=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `1M` (although frequently given a default value in some setups)
- **Valid Values:** `0` upwards in units of 1024.

---

query_cache_strip_comments

- **Description:** If set to `1` (`0` is default), the server will strip any comments from the query before searching to see if it exists in the query cache. Multiple space, line feeds, tab and other white space characters will also be removed.
- **Commandline:** `query-cache-strip-comments`
- **Scope:** Session, Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

query_cache_type

- **Description:** If set to `0`, the query cache is disabled (although a buffer of query_cache_size bytes is still allocated). If set to `1` all SELECT queries will be cached unless SQL_NO_CACHE is specified. If set to `2` (or `DEMAND`), only queries with the SQL CACHE clause will be cached. Note that if the server is started with the query cache disabled, it cannot be enabled at runtime.

Warning: Starting from MariaDB 10.1.7, query_cache_type is automatically set to ON if the server is started with the query_cache_size set to a non-zero (and non-default) value. This will happen even if query_cache_type is explicitly set to OFF in the configuration.

- **Commandline:** `--query-cache-type=#`
- **Scope:** Global, Session

- **Dynamic:** Yes
- **Data Type:** `enumeration`
- **Default Value:** `OFF`
- **Valid Values:** `0` or `OFF`, `1` or `ON`, `2` or `DEMAND`

---

query_cache_wlock_invalidate

- **Description:** If set to `0`, the default, results present in the query cache will be returned even if there's a write lock on the table. If set to `1`, the client will first have to wait for the lock to be released.
- **Commandline:** `--query-cache-wlock-invalidate`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

query_prealloc_size

- **Description:** Size in bytes of the persistent buffer for query parsing and execution, allocated on connect and freed on disconnect. Increasing may be useful if complex queries are being run, as this will reduce the need for more memory allocations during query operation. See also query_alloc_block_size.
- **Commandline:** `--query-prealloc-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `24576`
- **Range:** `1024` to `4294967295`

---

rand_seed1

- **Description:** `rand_seed1` and `rand_seed2` facilitate replication of the RAND() function. The master passes the value of these to the slaves so that the random number generator is seeded in the same way, and generates the same value, on the slave as on the master. Until MariaDB 10.1.4, the variable value could not be viewed, with the SHOW VARIABLES output always displaying zero.
- **Commandline:** None
- **Scope:** Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** Varies
- **Range:** `0` to `18446744073709551615`

---

rand_seed2

- **Description:** See rand_seed1.

---

range_alloc_block_size

- **Description:** Size in bytes of blocks allocated during range optimization. The unit size in 1024.
- **Commandline:** `--range-alloc-block-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `4096`
- **Range - 32 bit:** `4096` to `4294967295`
- **Range - 64 bit:** `4096` to `18446744073709547520`

---

read_buffer_size

- **Description:** Each thread performing a sequential scan (for MyISAM, Aria and MERGE tables) allocates a buffer of this size in bytes for each table scanned. Increase if you perform many sequential scans. If not in a multiple of 4KB,

will be rounded down to the nearest multiple. Also used in ORDER BY's for caching indexes in a temporary file (not temporary table), for caching results of nested queries, for bulk inserts into partitions, and to determine the memory block size of MEMORY tables.

- **Commandline:** `--read-buffer-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `131072`
- **Range:** `8200 to 2147479552`

---

read_only

- **Description:** When set to `1` (`0` is default), no updates are permitted except from users with the SUPER privilege or, from MariaDB 10.5.2, the READ ONLY ADMIN privilege, or replica servers updating from a primary. The `read_only` variable is useful for replica servers to ensure no updates are accidentally made outside of what are performed on the primary. Inserting rows to log tables, updates to temporary tables and OPTIMIZE TABLE or ANALYZE TABLE statements are excluded from this limitation. If `read_only` is set to `1`, then the SET PASSWORD statement is limited only to users with the SUPER privilege (<= MariaDB 10.5.1) or READ ONLY ADMIN privilege (>= MariaDB 10.5.2). Attempting to set this variable to `1` will fail if the current session has table locks or transactions pending, while if other sessions hold table locks, the statement will wait until these locks are released before completing. While the attempt to set `read_only` is waiting, other requests for table locks or transactions will also wait until `read_only` has been set. See Read-Only Replicas for more.
- **Commandline:** `--read-only`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

read_rnd_buffer_size

- **Description:** Size in bytes of the buffer used when reading rows from a MyISAM table in sorted order after a key sort. Larger values improve ORDER BY performance, although rather increase the size by SESSION where the need arises to avoid excessive memory use.
- **Commandline:** `--read-rnd-buffer-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `262144`
- **Range:** `8200` to `2147483647`

---

redirect_url

- **Description:** URL of another server to redirect clients to. Empty string means no redirection.
- **Commandline:** `--redirect_url=val`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** Empty
- **Introduced:** MariaDB 11.3.0

-

-

require_secure_transport

- **Description:** When this option is enabled, connections attempted using insecure transport will be rejected. Secure transports are SSL/TLS, Unix sockets or named pipes. Note that per-account requirements take precedence.
- **Commandline:** `--require-secure-transport[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`

- **Default Value:** `OFF`
- **Introduced:** MariaDB 10.5.2

---

rowid_merge_buff_size

- **Description:** The maximum size in bytes of the memory available to the Rowid-merge strategy. See Non-semi-join subquery optimizations for more information.
- **Commandline:** `--rowid-merge-buff-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `8388608`
- **Range:** `0` to `2147483647`

---

rpl_recovery_rank

- **Description:** Unused.
- **Removed:** MariaDB 10.1.2

---

safe_show_database

- **Description:** This variable was removed in MariaDB 5.5, and has been replaced by the more flexible SHOW DATABASES privilege.
- **Commandline:** `--safe-show-database` (until MySQL 4.1.1)
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Removed:** MariaDB 5.5

---

secure_auth

- **Description:** Connections will be blocked if they use the the `mysql_old_password` authentication plugin. The server will also fail to start if the privilege tables are in the old, pre-MySQL 4.1 format.
- **Commandline:** `--secure-auth`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `ON`

---

secure_file_priv

- **Description:** LOAD DATA, SELECT ... INTO and LOAD FILE() will only work with files in the specified path. If not set, the default, or set to empty string, the statements will work with any files that can be accessed.
- **Commandline:** `--secure-file-priv=path`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `path name`
- **Default Value:** None

---

secure_timestamp

- **Description:** Restricts direct setting of a session timestamp. Possible levels are:
  - YES - timestamp cannot deviate from the system clock
  - REPLICATION - replication thread can adjust timestamp to match the master's
  - SUPER - a user with this privilege and a replication thread can adjust timestamp
  - NO - historical behavior, anyone can modify session timestamp
- **Commandline:** `--secure-timestamp=value`
- **Scope:** Global
- **Dynamic:** No

- **Data Type:** `enum`
- **Default Value:** `NO`
- **Introduced:** MariaDB 10.3.7

---

session_track_schema

- **Description:** Whether to track changes to the default schema within the current session.
- **Commandline:** `--session-track-schema={0|1}`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `ON`

---

session_track_state_change

- **Description:** Whether to track changes to the session state.
- **Commandline:** `--session-track-state-change={0|1}`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

session_track_system_variables

- **Description:** Comma-separated list of session system variables for which to track changes. For compatibility with MySQL defaults, this variable should be set to "autocommit, character_set_client, character_set_connection, character_set_results, time_zone". The `*` character tracks all session variables.
- **Commandline:** `--session-track-system-variables=value`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:**
  - >= MariaDB 11.3: `autocommit,character_set_client,character_set_connection,character_set_results,redirect_ur`
  - <= MariaDB 11.2: `autocommit, character_set_client, character_set_connection, character_set_results, time_zone`

---

session_track_transaction_info

- **Description:** Track changes to the transaction attributes. OFF to disable; STATE to track just transaction state (Is there an active transaction? Does it have any data? etc.); CHARACTERISTICS to track transaction state and report all statements needed to start a transaction with the same characteristics (isolation level, read only/read write,snapshot - but not any work done / data modified within the transaction).
- **Commandline:** `--session-track-transaction-info=value`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `enum`
- **Default Value:** `OFF`
- **Valid Values:** `OFF`, `STATE`, `CHARACTERISTICS`

---

shared_memory

- **Description:** Windows only, determines whether the server permits shared memory connections. See also shared_memory_base_name.
- **Scope:** Global
- **Dynamic:** No

---

shared_memory_base_name

- **Description:** Windows only, specifies the name of the shared memory to use for shared memory connection. Mainly used when running more than one instance on the same physical machine. By default the name is `MYSQL` and is case sensitive. See also shared_memory.
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** `MYSQL`

---

skip_external_locking

- **Description:** If this system variable is set, then some kinds of external table locks will be disabled for some storage engines.
  - If this system variable is set, then the MyISAM storage engine will not use file-based locks. Otherwise, it will use the `fcntl()` function with the `F_SETLK` option to get file-based locks on Unix, and it will use the `LockFileEx()` function to get file-based locks on Windows.
  - If this system variable is set, then the Aria storage engine will not lock a table when it decrements the table's in-file counter that keeps track of how many connections currently have the table open. See MDEV-19393 for more information.
- **Commandline:** `--skip-external-locking`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `1`

---

skip_grant_tables

- **Description:** Start without grant tables. This gives all users FULL ACCESS to all tables. Before MariaDB 10.10, available as an option only. Use mariadb-admin flush-privileges, mariadb-admin reload or FLUSH PRIVILEGES to resume using the grant tables.
- **Commandline:** `--skip-grant-tables`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `OFF`
- **Introduced:** MariaDB 10.10

---

skip_name_resolve

- **Description:** If set to 1 (0 is the default), only IP addresses are used for connections. Host names are not resolved. All host values in the GRANT tables must be IP addresses (or localhost).
- **Commandline:** `--skip-name-resolve`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `0`

---

skip_networking

- **Description:** If set to 1, (0 is the default), the server does not listen for TCP/IP connections. All interaction with the server will be through socket files (Unix) or named pipes or shared memory (Windows). It's recommended to use this option if only local clients are permitted to connect to the server.
- **Commandline:** `--skip-networking`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `0`

---

skip_show_database

- **Description:** If set to 1, (0 is the default), only users with the SHOW DATABASES privilege can use the SHOW

DATABASES statement to see all database names.
- **Commandline:** `--skip-show-database`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `0`

---

slow_launch_time

- **Description:** Time in seconds. If a thread takes longer than this to launch, the `slow_launch_threads` server status variable is incremented.
- **Commandline:** `--slow-launch-time=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `2`

---

slow_query_log

- **Description:** If set to 0, the default unless the --slow-query-log option is used, the slow query log is disabled, while if set to 1 (both global and session variables), the slow query log is enabled. From MariaDB 10.11.0, an alias for log_slow_query.
- **Commandline:** `--slow-query-log`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Data Type:** `boolean`
- **Default Value:** `0`
- **See also:** See log_output to see how log files are written. If that variable is set to `NONE`, no logs will be written even if slow_query_log is set to `1`.

---

slow_query_log_file

- **Description:** Name of the slow query log file. From MariaDB 10.11, an alias for log_slow_query_file.
- **Commandline:** `--slow-query-log-file=file_name`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `file name`
- **Default Value:** *`host_name`*`-slow.log`

---

socket

- **Description:** On Unix-like systems, this is the name of the socket file used for local client connections, by default `/tmp/mysql.sock`, often changed by the distribution, for example `/var/lib/mysql/mysql.sock`. On Windows, this is the name of the named pipe used for local client connections, by default `MySQL`. On Windows, this is not case-sensitive.
- **Commandline:** `--socket=name`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `file name`
- **Default Value:** `/tmp/mysql.sock` (Unix), `MySQL` (Windows)

---

sort_buffer_size

- **Description:** Each session performing a sort allocates a buffer with this amount of memory. Not specific to any storage engine. If the status variable sort_merge_passes is too high, you may need to look at improving your query indexes, or increasing this. Consider reducing where there are many small sorts, such as OLTP, and increasing where needed by session. 16k is a suggested minimum.
- **Commandline:** `--sort-buffer-size=#`
- **Scope:** Global, Session

- **Dynamic:** Yes
- **Data Type:** `number`
- **Default Value:** `2M (2097152)` (some distributions increase the default)

---

sql_auto_is_null

- **Description:** If set to 1, the query `SELECT * FROM table_name WHERE auto_increment_column IS NULL` will return an auto-increment that has just been successfully inserted, the same as the LAST_INSERT_ID() function. Some ODBC programs make use of this IS NULL comparison.
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `0`

---

sql_big_selects

- **Description:** If set to 0, MariaDB will not perform large SELECTs. See max_join_size for details. If max_join_size is set to anything but DEFAULT, sql_big_selects is automatically set to 0. If sql_big_selects is again set, max_join_size will be ignored.
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `1`

---

sql_big_tables

- **Description:** Old variable, which if set to 1, allows large result sets by saving all temporary sets to disk, avoiding 'table full' errors. No longer needed, as the server now handles this automatically.
  - This is a synonym for `big_tables` .
- **Commandline:** `--sql-big-tables`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `0`
- **Removed:** MariaDB 10.0

---

sql_buffer_result

- **Description:** If set to 1 (0 is default), results from SELECT statements are always placed into temporary tables. This can help the server when it takes a long time to send the results to the client by allowing the table locks to be freed early.
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `0`

---

sql_if_exists

- **Description:** If set to 1, adds an implicit IF EXISTS to ALTER, RENAME and DROP of TABLES, VIEWS, FUNCTIONS and PACKAGES. This variable is mainly used in replication to tag DDLs that can be ignored on the slave if the target table doesn't exist.
- **Commandline:** `--sql-if-exists[={0|1}]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`
- **Introduced:** MariaDB 10.5.2

---

sql_log_off

- **Description:** If set to 1 (0 is the default), no logging to the general query log is done for the client. Only clients with the SUPER privilege can update this variable.
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `0`

---

sql_log_update

- **Description:** Removed. Use sql_log_bin instead.
- **Removed:** MariaDB/MySQL 5.5

---

sql_low_priority_updates

- **Description:** If set to 1 (0 is the default), for storage engines that use only table-level locking (Aria, MyISAM, MEMORY and MERGE), all INSERTs, UPDATEs, DELETEs and LOCK TABLE WRITEs will wait until there are no more SELECTs or LOCK TABLE READs pending on the relevant tables. Set this to 1 if reads are prioritized over writes.
  - This is a synonym for `low_priority_updates`.
- **Commandline:** `--sql-low-priority-updates`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `0`
- **Removed:** MariaDB 10.0

---

sql_max_join_size

- **Description:** Synonym for max_join_size, the preferred name.
- **Deprecated:** MariaDB 5.5
- **Removed:** MariaDB 10.0

---

sql_mode

- **Description:** Sets the SQL Mode. Multiple modes can be set, separated by a comma.
- **Commandline:** `--sql-mode=value[,value[,value...]]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:**
  - `STRICT_TRANS_TABLES,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION`
- **Valid Values:** See SQL Mode for the full list.

---

sql_notes

- **Description:** If set to 1, the default, warning_count is incremented each time a Note warning is encountered. If set to 0, Note warnings are not recorded. mariadb-dump has outputs to set this variable to 0 so that no unnecessary increments occur when data is reloaded. See also note_verbosity, which defines which notes should be given. The recommended way, as of MariaDB 10.6.16, to disable notes is to set `note_verbosity` to "".
- **Commandline:** None
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `1`

---

sql_quote_show_create

- **Description:** If set to 1, the default, the server will quote identifiers for SHOW CREATE DATABASE, SHOW CREATE TABLE and SHOW CREATE VIEW statements. Quoting is disabled if set to 0. Enable to ensure

replications works when identifiers require quoting.
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `1`

---

sql_safe_updates

- **Description:** If set to 1, UPDATEs and DELETEs must be executed by using an index (simply mentioning an indexed column in a WHERE clause is not enough, optimizer must actually use it) or they must mention an indexed column and specify a LIMIT clause. Otherwise a statement will be aborted. Prevents the common mistake of accidentally deleting or updating every row in a table. Until MariaDB 10.3.11, could not be set as a command-line option or in my.cnf.
- **Commandline:** `--sql-safe-updates[={0|1}]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

sql_select_limit

- **Description:** Maximum number of rows that can be returned from a SELECT query. Default is the maximum number of rows permitted per table by the server, usually 2^{32}-1 or 2^{64}-1. Can be restored to the default value after being changed by assigning it a value of DEFAULT.
- **Commandline:** None
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `18446744073709551615`

---

sql_warnings

- **Description:** If set to 1, single-row INSERTs will produce a string containing warning information if a warning occurs.
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF (0)`

---

storage_engine

- **Description:** See default_storage_engine.
- **Deprecated:** MariaDB 5.5

---

standard_compliant_cte

- **Description:** Allow only standard-compliant common table expressions. Prior to MariaDB 10.2.4, this variable was named `standards_compliant_cte`.
- **Commandline:** `--standard-compliant-cte={0|1}`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `ON`
- **Introduced:** MariaDB 10.2.2

---

stored_program_cache

- **Description:** Limit to the number of stored routines held in the stored procedures and stored functions caches. Each time a stored routine is executed, this limit is first checked, and if the number held in the cache exceeds this, that cache is flushed and memory freed.

- **Commandline:** `--stored-program-cache=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `256`
- **Range:** `256` to `524288`

---

strict_password_validation

- **Description:** When password validation plugins are enabled, reject passwords that cannot be validated (passwords specified as a hash). This excludes direct updates to the privilege tables.
- **Commandline:** `--strict-password-validation`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `ON`

---

sync_frm

- **Description:** If set to 1, the default, each time a non-temporary table is created, its .frm definition file is synced to disk. Fractionally slower, but safer in case of a crash.
- **Commandline:** `--sync-frm`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `TRUE`

---

system_time_zone

- **Description:** The system time zone is determined when the server starts. The system time zone is usually read from the operating system's environment but can be overridden by setting the 'TZ' environment variable before starting the server. See Time Zones: System Time Zone for the various ways to change the system time zone. This variable is not the same as the time_zone system variable, which is the variable that actually controls a session's active time zone. The system time zone is used for a session when `time_zone` is set to the special value `SYSTEM`.
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`

---

table_definition_cache

- **Description:** Number of table definitions that can be cached. Table definitions are taken from the .frm files, and if there are a large number of tables increasing the cache size can speed up table opening. Unlike the table_open_cache, as the table_definition_cache doesn't use file descriptors, and is much smaller.
- **Commandline:** `--table-definition-cache=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `400`
- **Range:**
  - `400` to `2097152` (>= MariaDB 10.4.2, MariaDB 10.3.13, MariaDB 10.2.22, MariaDB 10.1.38)
  - `400` to `524288` (<= MariaDB 10.4.1, MariaDB 10.3.12, MariaDB 10.2.21, MariaDB 10.1.37)

---

table_lock_wait_timeout

- **Description:** Unused, and removed.
- **Commandline:** `--table-lock-wait-timeout=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `50`

- **Range:** `1` to `1073741824`
- **Removed:** MariaDB 5.5

---

table_open_cache

- **Description:** Maximum number of open tables cached in one table cache instance. See Optimizing table_open_cache for suggestions on optimizing. Increasing table_open_cache increases the number of file descriptors required.
- **Commandline:** `--table-open-cache=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `2000`
- **Range:**
  - `1` to `1048576` (1024K)

---

table_open_cache_instances

- **Description:** This system variable specifies the maximum number of table cache instances. MariaDB Server initially creates just a single instance. However, whenever it detects contention on the existing instances, it will automatically create a new instance. When the number of instances has been increased due to contention, it does not decrease again. The default value of this system variable is `8`, which is expected to handle up to 100 CPU cores. If your system is larger than this, then you may benefit from increasing the value of this system variable.
  - Depending on the ratio of actual available file handles, and `table_open_cache` size, the max. instance count may be auto adjusted to a lower value on server startup.
  - The implementation and behavior of this feature is different than the same feature in MySQL 5.6.
  - See Optimizing table_open_cache: Automatic Creation of New Table Open Cache Instances for more information.
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `8` (>= MariaDB 10.2.2)
- **Range:** `1` to `64`
- **Introduced:** MariaDB 10.2.2

---

table_type

- **Description:** Removed and replaced by storage_engine. Use default_storage_engine instead.

---

tcp_keepalive_interval

- **Description:** The interval, in seconds, between when successive keep-alive packets are sent if no acknowledgement is received. If set to 0, the system dependent default is used.
- **Commandline:** `--tcp-keepalive-interval=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` to `2147483`
- **Introduced:** MariaDB 10.3.3

---

tcp_keepalive_probes

- **Description:** The number of unacknowledged probes to send before considering the connection dead and notifying the application layer. If set to 0, a system dependent default is used.
- **Commandline:** `--tcp-keepalive-probes=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`

- **Range:** `0` to `2147483`
- **Introduced:** MariaDB 10.3.3

---

tcp_keepalive_time

- **Description:** Timeout, in seconds, with no activity until the first TCP keep-alive packet is sent. If set to 0, a system dependent default is used.
- **Commandline:** `--tcp-keepalive-time=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` to `2147483`
- **Introduced:** MariaDB 10.3.3

---

tcp_nodelay

- **Description:** Set the TCP_NODELAY option (disable Nagle's algorithm) on socket.
- **Commandline:** `--tcp-nodelay={0|1}`
- **Scope:** Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `1`
- **Introduced:** MariaDB 10.4.0

---

thread_cache_size

- **Description:** Number of threads server caches for re-use. If this limit hasn't been reached, when a client disconnects, its threads are put into the cache, and re-used where possible. In MariaDB 10.2.0 and newer the threads are freed after 5 minutes of idle time. Normally this setting has little effect, as the other aspects of the thread implementation are more important, but increasing it can help servers with high volumes of connections per second so that most can use a cached, rather than a new, thread. The cache miss rate can be calculated as the server status variables threads_created/connections. If the thread pool is active, `thread_cache_size` is ignored. If `thread_cache_size` is set to greater than the value of max_connections, `thread_cache_size` will be set to the max_connections value.
- **Commandline:** `--thread-cache-size=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `256` (adjusted if thread pool is active)
- **Range:** `0` to `16384`

---

thread_concurrency

- **Description:** Allows applications to give the system a hint about the desired number of threads. Specific to Solaris only, invokes thr_setconcurrency(). Deprecated and has no effect from MariaDB 5.5.
- **Commandline:** `--thread-concurrency=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `10`
- **Range:** `1` to `512`
- **Deprecated:** MariaDB 5.5
- **Removed:** MariaDB 10.5.1

---

thread_stack

- **Description:** Stack size for each thread. If set too small, limits recursion depth of stored procedures and complexity of SQL statements the server can handle in memory. Also affects limits in the crash-me test.
- **Commandline:** `--thread-stack=#`

- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:**
  - `299008`
- **Range:** `131072` to `18446744073709551615`

---

time_format

- **Description:** Unused.
- **Removed:** MariaDB 11.3.0

---

time_zone

- **Description:** The global value determines the default time zone for sessions that connect. The session value determines the session's active time zone. When it is set to `SYSTEM`, the session's time zone is determined by the `system_time_zone` system variable.
- **Commandline:** `--default-time-zone=string`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `SYSTEM`

---

timed_mutexes

- **Description:** Determines whether InnoDB mutexes are timed. `OFF`, the default, disables mutex timing, while `ON` enables it. See also SHOW ENGINE for more on mutex statistics. Deprecated and has no effect.
- **Commandline:** `--timed-mutexes`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`
- **Deprecated:** MariaDB 5.5.39
- **Removed:** MariaDB 10.5.1

---

timestamp

- **Description:** Sets the time for the client. This will affect the result returned by the NOW() function, not the SYSDATE() function, unless the server is started with the --sysdate-is-now option, in which case SYSDATE becomes an alias of NOW, and will also be affected. Also used to get the original timestamp when restoring rows from the binary log.
- **Scope:** Session
- **Dynamic:** Yes
- **Valid Values:** `timestamp_value` (Unix epoch timestamp, not MariaDB timestamp), `DEFAULT`

---

tmp_disk_table_size

- **Description:** Max size for data for an internal temporary on-disk MyISAM or Aria table. These tables are created as part of complex queries when the result doesn't fit into the memory engine. You can set this variable if you want to limit the size of temporary tables created in your temporary directory tmpdir.
- **Commandline:** `--tmp-disk-table-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `18446744073709551615` (max unsigned integer, no limit)
- **Range:** `1024` to `18446744073709551615`
- **Introduced:** MariaDB 10.2.7

---

tmp_memory_table_size

- **Description:** An alias for tmp_table_size.
- **Commandline:** `--tmp-memory-table-size=#`
- **Introduced:** MariaDB 10.2.7

---

tmp_table_size

- **Description:** The largest size for temporary tables in memory (not MEMORY tables) although if max_heap_table_size is smaller the lower limit will apply. You can see if it's necessary to increase by comparing the status variables `Created_tmp_disk_tables` and `Created_tmp_tables` to see how many temporary tables out of the total created needed to be converted to disk. Often complex GROUP BY queries are responsible for exceeding the limit. Defaults may be different on some systems, see for example Differences in MariaDB in Debian. From MariaDB 10.2.7, tmp_memory_table_size is an alias.
- **Commandline:** `--tmp-table-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `16777216` (16MB)
- **Range:**
  - `1024` to `4294967295` (< MariaDB 10.5)
  - `0` to `4294967295` (>= MariaDB 10.5.0)

---

tmpdir

- **Description:** Directory for storing temporary tables and files. Can specify a list (separated by semicolons in Windows, and colons in Unix) that will then be used in round-robin fashion. This can be used for load balancing across several disks. Note that if the server is a replication replica, and slave_load_tmpdir, which overrides `tmpdir` for replicas, is not set, you should not set `tmpdir` to a directory that is cleared when the machine restarts, or else replication may fail.
- **Commandline:** `--tmpdir=path` or `-t path`
- **Scope:** Global
- **Dynamic:** No
- **Type:** directory name/s
- **Default:**
  - `$TMPDIR` (environment variable) if set
  - otherwise `$TEMP` if set and on Windows
  - otherwise `$TMP` if set and on Windows
  - otherwise `P_tmpdir` (`"/tmp"`) or `C:\TEMP` (unless overridden during buid time)

---

transaction_alloc_block_size

- **Description:** Size in bytes to increase the memory pool available to each transaction when the available pool is not large enough. See transaction_prealloc_size.
- **Commandline:** `--transaction-alloc-block-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Type:** numeric
- **Default Value:** `8192`
- **Range:** `1024` to `4294967295`
- **Block Size:** `1024`

---

transaction_isolation

- **Description:** The transaction isolation level. See also SET TRANSACTION ISOLATION LEVEL. Introduced in MariaDB 11.1.1 to replace the tx_isolation system variable and align the option and the system variable name.
- **Commandline:** `--transaction-isolation=name`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Type:** enumeration
- **Default Value:** `REPEATABLE-READ`

- **Valid Values:** `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, `SERIALIZABLE`
- **Introduced:** MariaDB 11.1.1

---

transaction_prealloc_size

- **Description:** Initial size of a memory pool available to each transaction for various memory allocations. If the memory pool is not large enough for an allocation, it is increased by transaction_alloc_block_size bytes, and truncated back to transaction_prealloc_size bytes when the transaction is completed. If set large enough to contain all statements in a transaction, extra malloc() calls are avoided.
- **Commandline:** `--transaction-prealloc-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Type:** numeric
- **Default Value:** `4096`
- **Range:** `1024` to `4294967295`
- **Block Size:** `1024`

---

transaction_read_only

- **Description:** Default transaction access mode. If set to `OFF`, the default, access is read/write. If set to `ON`, access is read-only. The `SET TRANSACTION` statement can also change the value of this variable. See SET TRANSACTION and START TRANSACTION.
- **Commandline:** `--transaction-read-only=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Type:** boolean
- **Default Value:** `OFF`
- **Introduced:** MariaDB 11.1

---

tx_isolation

- **Description:** The transaction isolation level. Setting this session variable via `set @@tx_isolation=` will take effect for only the subsequent transaction in the current session, much like SET TRANSACTION ISOLATION LEVEL. To set for a session, use `SET SESSION tx_isolation` or `SET @@session.tx_isolation`. See MDEV-31751. See also SET TRANSACTION ISOLATION LEVEL. In MariaDB 11.1, this system variable is deprecated and replaced by transaction_isolation.
- **Commandline:** `--transaction-isolation=name`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Type:** enumeration
- **Default Value:** `REPEATABLE-READ`
- **Valid Values:** `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, `SERIALIZABLE`
- **Deprecated:** MariaDB 11.1

---

tx_read_only

- **Description:** Default transaction access mode. If set to `OFF`, the default, access is read/write. If set to `ON`, access is read-only. The `SET TRANSACTION` statement can also change the value of this variable. See SET TRANSACTION and START TRANSACTION. In MariaDB 11.1, this system variable is deprecated and replaced by transaction_read_only.
- **Commandline:** `--transaction-read-only=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Type:** boolean
- **Default Value:** `OFF`
- **Deprecated:** MariaDB 11.1

---

unique_checks

- **Description:** If set to 0, storage engines can (but are not required to) assume that duplicate keys are not present in

input data. If set to 0, inserting duplicates into a `UNIQUE` index can succeed, causing the table to become corrupted. Set to 0 to speed up imports of large tables to InnoDB.
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Type:** boolean
- **Default Value:** `1`

---

updatable_views_with_limit

- **Description:** Determines whether view updates can be made with an UPDATE or DELETE statement with a LIMIT clause if the view does not contain all primary or not null unique key columns from the underlying table. `0` prohibits this, while `1` permits it while issuing a warning (the default).
- **Commandline:** `--updatable-views-with-limit=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Type:** boolean
- **Default Value:** `1`

---

use_stat_tables

- **Description:** Controls the use of engine-independent table statistics.
  - `never` : The optimizer will not use data from statistics tables.
  - `complementary` : The optimizer uses data from statistics tables if the same kind of data is not provided by the storage engine.
  - `preferably` : Prefer the data from statistics tables, if it's not available there, use the data from the storage engine.
  - `complementary_for_queries` : Same as `complementary` , but for queries only (to avoid needlessly collecting for ANALYZE TABLE). From MariaDB 10.4.1.
  - `preferably_for_queries` : Same as `preferably` , but for queries only (to avoid needlessly collecting for ANALYZE TABLE). From MariaDB 10.4.1.
- **Commandline:** `--use-stat-tables=mode`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `enum`
- **Default Value:** `preferably_for_queries` (>= MariaDB 10.4.1), `never` (<= MariaDB 10.4.0)

---

version

- **Description:** Server version number. It may also include a suffix with configuration or build information. `-debug` indicates debugging support was enabled on the server, and `-log` indicates at least one of the binary log, general log or slow query log are enabled, for example `10.0.1-MariaDB-mariadb1precise-log` . Can be set at startup in order to fake the server version.
- **Commandline:** `-V` , `--version[=name]`
- **Scope:** Global
- **Dynamic:** No
- **Type:** string

---

version_comment

- **Description:** Value of the COMPILATION_COMMENT option specified by CMake when building MariaDB, for example `mariadb.org binary distribution` .
- **Scope:** Global
- **Dynamic:** No
- **Type:** string

---

version_compile_machine

- **Description:** The machine type or architecture MariaDB was built on, for example `i686` .
- **Scope:** Global
- **Dynamic:** No

- **Type:** string

`version_compile_os`

- **Description:** Operating system that MariaDB was built on, for example `debian-linux-gnu`.
- **Scope:** Global
- **Dynamic:** No
- **Type:** string

`version_malloc_library`

- **Description:** Version of the used malloc library.
- **Commandline:** No
- **Scope:** Global
- **Dynamic:** No
- **Type:** string

`version_source_revision`

- **Description:** Source control revision id for MariaDB source code, enabling one to see exactly which version of the source was used for a build.
- **Commandline:** None
- **Scope:** Global
- **Dynamic:** No
- **Type:** string
- **Introduced:** MariaDB 10.3.2

`wait_timeout`

- **Description:** Time in seconds that the server waits for a connection to become active before closing it. The session value is initialized when a thread starts up from either the global value, if the connection is non-interactive, or from the interactive_timeout value, if the connection is interactive.
- **Commandline:** `--wait-timeout=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Type:** numeric
- **Default Value:** `28800`
- **Range: (Windows):** `1` **to** `2147483`
- **Range: (Other):** `1` **to** `31536000`

`warning_count`

- **Description:** Read-only variable indicating the number of warnings, errors and notes resulting from the most recent statement that generated messages. See SHOW WARNINGS for more. Note warnings will only be recorded if sql_notes is true (the default).
- **Scope:** Session
- **Dynamic:** No
- **Type:** numeric

2.7.3 OLD_MODE

The old_mode system variable was introduced in MariaDB 5.5.35 to replace the old variable with a new one with better granularity.

Contents

MariaDB supports several different modes which allow you to tune it to suit your needs.

The most important ways for doing this are with SQL_MODE and `OLD_MODE`.

SQL_MODE is used for getting MariaDB to emulate behavior from other SQL servers, while `OLD_MODE` is used for emulating behavior from older MariaDB or MySQL versions.

`OLD_MODE` is a string with different options separated by commas (' , ') without spaces. The options are case insensitive.

Normally `OLD_MODE` should be empty. It's mainly used to get old behavior when switching to MariaDB or to a new major version of MariaDB, until you have time to fix your application.

Between major versions of MariaDB various options supported by `OLD_MODE` may be removed. This is intentional as we assume that the application will be fixed to conform with the new MariaDB behavior between releases.

In other words, `OLD_MODE` options are by design deprecated from the day they were added and will eventually be removed as any other deprecated feature.

You can check the variable's local and global value with:

```
SELECT @@OLD_MODE, @@GLOBAL.OLD_MODE;
```

You can set the `OLD_MODE`
either from the command line (option `--old-mode`) or by setting the old_mode system variable.

Non-default old mode features are deprecated by design, and from MariaDB 11.3, a warning will be issued when set.

Modes

The different values of `OLD_MODE` are:

NO_DUP_KEY_WARNINGS_WITH_IGNORE

Don't print duplicate key warnings when using INSERT IGNORE.

NO_PROGRESS_INFO

Don't show progress information in SHOW PROCESSLIST.

UTF8_IS_UTF8MB3

From MariaDB 10.6.1, the main name of the previous 3 byte `utf` character set has been changed to `utf8mb3`. If set, the default, `utf8` is an alias for `utf8mb3`. If not set, `utf8` would be an alias for `utf8mb4`.

ZERO_DATE_TIME_CAST

When a TIME value is cast to a DATETIME, the date part will be `0000-00-00`, not CURRENT_DATE (as dictated by the SQL standard).

IGNORE_INDEX_ONLY_FOR_JOIN

From MariaDB 10.9, the --old option is deprecated. This option allows behaviour of the --old option for disabling the index only for joins, but allow it for ORDER BY.

COMPAT_5_1_CHECKSUM

From MariaDB 10.9, the --old option is deprecated. This option allows behaviour of the --old option for enabling the old-style checksum for `CHECKSUM TABLE` that MySQL 5.1 supports

LOCK_ALTER_TABLE_COPY

From MariaDB 11.2. The non-locking copy ALTER introduced in MDEV-16329 should be beneficial in the vast majority of cases, but scenarios can exist which significantly impact performance. For example, RBR on tables without a primary key. When non-locking ALTER is performed on such a table, and DML affecting a large number of records is run in parallel, the ALTER can become extremely slow, and further DML can also be affected. If there is a chance of such scenarios (and no possibility of improving the schema by immediately adding primary keys), ALTER should be performed with the explicit LOCK=SHARED clause. If this is also impossible, then LOCK_ALTER_TABLE_COPY flag should be added to the old_mode variable until the schema can be improved.

OLD_MODE and Stored Programs

In contrast to SQL_MODE, stored programs use the current user's `OLD_MODE` value.

Changes to `OLD_MODE` are not sent to replicas.

Examples

This example shows how to get a readable list of enabled OLD_MODE flags:

```
SELECT REPLACE(@@OLD_MODE, ',', '\n');
+-------------------------------------------------+
| REPLACE(@@OLD_MODE, ',', '\n')                  |
+-------------------------------------------------+
| NO_DUP_KEY_WARNINGS_WITH_IGNORE                 |
| NO_PROGRESS_INFO                                |
+-------------------------------------------------+
```

Adding a new flag:

```
SET @@OLD_MODE = CONCAT(@@OLD_MODE, ',NO_PROGRESS_INFO');
```

If the specified flag is already ON, the above example has no effect but does not produce an error.

How to unset a flag:

```
SET @@OLD_MODE = REPLACE(@@OLD_MODE, 'NO_PROGRESS_INFO', '');
```

How to check if a flag is set:

```
SELECT @@OLD_MODE LIKE '%NO_PROGRESS_INFO';
+-----------------------------------+
| @@OLD_MODE LIKE '%NO_PROGESS_INFO' |
+-----------------------------------+
|                                 1 |
+-----------------------------------+
```

From MariaDB 11.3:

```
SET @@OLD_MODE = CONCAT(@@OLD_MODE, ',NO_PROGRESS_INFO');
Query OK, 0 rows affected, 1 warning (0.000 sec)

SHOW WARNINGS;
+---------+------+-----------------------------------------------------------------------------+
| Level   | Code | Message                                                                     |
+---------+------+-----------------------------------------------------------------------------+
| Warning | 1287 | 'NO_PROGRESS_INFO' is deprecated and will be removed in a future release |
+---------+------+-----------------------------------------------------------------------------+
```

2.7.4 SQL_MODE

Contents

MariaDB supports several different modes which allow you to tune it to suit your needs.

The most important ways for doing this are using `SQL_MODE` (controlled by the sql_mode system variable) and OLD_MODE (the old_mode system variable). `SQL_MODE` is used for getting MariaDB to emulate behavior from other SQL servers, while OLD_MODE is used for emulating behavior from older MariaDB or MySQL versions.

`SQL_MODE` is a string with different options separated by commas (' , ') without spaces. The options are case insensitive.

You can check the local and global value of it with:

```
SELECT @@SQL_MODE, @@GLOBAL.SQL_MODE;
```

Setting SQL_MODE

Defaults

From version	Default sql_mode setting
MariaDB 10.2.4	STRICT_TRANS_TABLES, ERROR_FOR_DIVISION_BY_ZERO , NO_AUTO_CREATE_USER, NO_ENGINE_SUBSTITUTION

MariaDB 10.1.7	NO_ENGINE_SUBSTITUTION, NO_AUTO_CREATE_USER
<= MariaDB 10.1.6	No value

You can set the `SQL_MODE` either from the command line (the `--sql-mode` option) or by setting the sql_mode system variable.

```
SET sql_mode = 'modes';
SET GLOBAL sql_mode = 'modes';
```

The session value only affects the current client, and can be changed by the client when required. To set the global value, the SUPER privilege is required, and the change affects any clients that connect from that point on.

SQL_MODE Values

The different `SQL_MODE` values are:

ALLOW_INVALID_DATES

Allow any day between 1-31 in the day part. This is convenient when you want to read in all (including wrong data) into the database and then manipulate it there.

ANSI

Changes the SQL syntax to be closer to ANSI SQL.

Sets: REAL_AS_FLOAT, PIPES_AS_CONCAT, ANSI_QUOTES, IGNORE_SPACE.

It also adds a restriction: an error will be returned if a subquery uses an aggregating function with a reference to a column from an outer query in a way that cannot be resolved.

If set, SHOW CREATE TABLE output will not display MariaDB-specific table attributes.

ANSI_QUOTES

Changes `"` to be treated as `` ` ``, the identifier quote character. This may break old MariaDB applications which assume that `"` is used as a string quote character.

DB2

Same as: PIPES_AS_CONCAT, ANSI_QUOTES , IGNORE_SPACE, DB2, NO_KEY_OPTIONS, NO_TABLE_OPTIONS, NO_FIELD_OPTIONS

If set, SHOW CREATE TABLE output will not display MariaDB-specific table attributes.

EMPTY_STRING_IS_NULL

Oracle-compatibility option that translates Item_string created in the parser to Item_null, and translates binding an empty string as prepared statement parameters to binding NULL. For example, `SELECT '' IS NULL` returns TRUE, `INSERT INTO t1 VALUES ('')` inserts NULL. Since MariaDB 10.3.3

ERROR_FOR_DIVISION_BY_ZERO

If not set, division by zero returns NULL. If set returns an error if one tries to update a column with 1/0 and returns a warning as well. Also see MDEV-8319. Default since MariaDB 10.2.4.

HIGH_NOT_PRECEDENCE

Compatibility option for MySQL 5.0.1 and before; This changes `NOT a BETWEEN b AND c` to be parsed as `(NOT a) BETWEEN b AND c`

IGNORE_BAD_TABLE_OPTIONS

If this is set generate a warning (not an error) for wrong table option in CREATE TABLE. Also, since 10.0.13, do not comment out these wrong table options in SHOW CREATE TABLE.

IGNORE_SPACE

Allow one to have spaces (including tab characters and new line characters) between function name and '('. The drawback is that this causes built in functions to become reserved words.

MAXDB

Same as: PIPES_AS_CONCAT, ANSI_QUOTES, IGNORE_SPACE, MAXDB, NO_KEY_OPTIONS, NO_TABLE_OPTIONS, NO_FIELD_OPTIONS, NO_AUTO_CREATE_USER.

Also has the effect of silently converting TIMESTAMP fields into DATETIME fields when created or modified.

If set, SHOW CREATE TABLE output will not display MariaDB-specific table attributes.

MSSQL

Additionally implies the following: PIPES_AS_CONCAT, ANSI_QUOTES, IGNORE_SPACE, NO_KEY_OPTIONS, NO_TABLE_OPTIONS, NO_FIELD_OPTIONS.

Additionally from MariaDB 10.4.5, implements a limited subset of Microsoft SQL Server's language. See SQL_MODE=MSSQL for more.

If set, SHOW CREATE TABLE output will not display MariaDB-specific table attributes.

MYSQL323

Same as: NO_FIELD_OPTIONS, HIGH_NOT_PRECEDENCE.

MYSQL40

Same as: NO_FIELD_OPTIONS, HIGH_NOT_PRECEDENCE.

NO_AUTO_CREATE_USER

Don't automatically create users with `GRANT` unless authentication information is specified. If none is provided, will produce a 1133 error: "Can't find any matching row in the user table". Default since MariaDB 10.1.7.

NO_AUTO_VALUE_ON_ZERO

If set, don't generate an AUTO_INCREMENT on INSERT of zero in an `AUTO_INCREMENT` column, or when adding an AUTO_INCREMENT attribute with the ALTER TABLE statement. Normally both `zero` and `NULL` generate new `AUTO_INCREMENT` values.

NO_BACKSLASH_ESCAPES

Disables using the backslash character `\` as an escape character within strings, making it equivalent to an ordinary character.

NO_DIR_IN_CREATE

Ignore all INDEX DIRECTORY and DATA DIRECTORY directives when creating a table. Can be useful on slave replication servers.

NO_ENGINE_SUBSTITUTION

If not set, if the available storage engine specified by a CREATE TABLE is not available, a warning is given and the default storage engine is used instead. If set, generate a 1286 error when creating a table if the specified storage engine is not available. See also enforce_storage_engine. Default since MariaDB 10.1.7.

NO_FIELD_OPTIONS

Remove MariaDB-specific column options from the output of SHOW CREATE TABLE. This is also used by the portability mode of mariadb-dump.

NO_KEY_OPTIONS

Remove MariaDB-specific index options from the output of SHOW CREATE TABLE. This is also used by the portability mode of mariadb-dump.

NO_TABLE_OPTIONS

Remove MariaDB-specific table options from the output of SHOW CREATE TABLE. This is also used by the portability mode of mariadb-dump.

NO_UNSIGNED_SUBTRACTION

When enabled, subtraction results are signed even if the operands are unsigned.

NO_ZERO_DATE

Don't allow '0000-00-00' as a valid date in strict mode (produce a 1525 error). Zero dates can be inserted with IGNORE. If not in strict mode, a warning is generated.

NO_ZERO_IN_DATE

Don't allow dates where the year is not zero but the month or day parts of the date *are* zero (produce a 1525 error). For example, with this set, '0000-00-00' is allowed, but '1970-00-10' or '1929-01-00' are not. If the ignore option is used, MariaDB will insert '0000-00-00' for those types of dates. If not in strict mode, a warning is generated instead.

ONLY_FULL_GROUP_BY

For SELECT ... GROUP BY queries, disallow SELECTing columns which are not referred to in the GROUP BY clause, unless they are passed to an aggregate function like COUNT() or MAX(). Produce a 1055 error.

ORACLE

In all versions of MariaDB up to MariaDB 10.2, this sets `sql_mode` that is equivalent to: PIPES_AS_CONCAT, ANSI_QUOTES, IGNORE_SPACE, NO_KEY_OPTIONS, NO_TABLE_OPTIONS, NO_FIELD_OPTIONS, NO_AUTO_CREATE_USER

From MariaDB 10.3, this mode also sets SIMULTANEOUS_ASSIGNMENT and configures the server to understand a large subset of Oracle's PL/SQL language instead of MariaDB's traditional syntax for stored routines. See SQL_MODE=ORACLE From MariaDB 10.3.

If set, SHOW CREATE TABLE output will not display MariaDB-specific table attributes.

PAD_CHAR_TO_FULL_LENGTH

Trailing spaces in CHAR columns are by default trimmed upon retrieval. With PAD_CHAR_TO_FULL_LENGTH enabled, no trimming occurs. Does not apply to VARCHARs.

PIPES_AS_CONCAT

Allows using the pipe character (ASCII 124) as string concatenation operator. This means that `"A" || "B"` can be used in place of `CONCAT("A", "B")`.

POSTGRESQL

Same as: PIPES_AS_CONCAT, ANSI_QUOTES, IGNORE_SPACE, POSTGRESQL, NO_KEY_OPTIONS, NO_TABLE_OPTIONS, NO_FIELD_OPTIONS.

If set, SHOW CREATE TABLE output will not display MariaDB-specific table attributes.

REAL_AS_FLOAT

`REAL` is a synonym for FLOAT rather than DOUBLE.

SIMULTANEOUS_ASSIGNMENT

Setting this makes the SET part of the UPDATE statement evaluate all assignments simultaneously, not left-to-right. From MariaDB 10.3.5.

STRICT_ALL_TABLES

Strict mode. Statements with invalid or missing data are aborted and rolled back. For a non-transactional storage engine with a statement affecting multiple rows, this may mean a partial insert or update if the error is found in a row beyond the first.

STRICT_TRANS_TABLES

Strict mode. Statements with invalid or missing data are aborted and rolled back, except that for non-transactional storage engines and statements affecting multiple rows where the invalid or missing data is not the first row, MariaDB will convert the invalid value to the closest valid value, or, if a value is missing, insert the column default value. Default since MariaDB 10.2.4.

TIME_ROUND_FRACTIONAL

With this mode unset, MariaDB truncates fractional seconds when changing precision to smaller. When set, MariaDB will round when converting to TIME, DATETIME and TIMESTAMP, and truncate when converting to DATE. Since MariaDB 10.4.1

TRADITIONAL

Makes MariaDB work like a traditional SQL server. Same as: STRICT_TRANS_TABLES, STRICT_ALL_TABLES, NO_ZERO_IN_DATE, NO_ZERO_DATE, ERROR_FOR_DIVISION_BY_ZERO, TRADITIONAL, NO_AUTO_CREATE_USER.

Strict Mode

A mode where at least one of `STRICT_TRANS_TABLES` or `STRICT_ALL_TABLES` is enabled is called *strict mode*.

With strict mode set (default from MariaDB 10.2.4), statements that modify tables (either transactional for `STRICT_TRANS_TABLES` or all for `STRICT_ALL_TABLES`) will fail, and an error will be returned instead. The IGNORE keyword can be used when strict mode is set to convert the error to a warning.

With strict mode not set (default in version <= MariaDB 10.2.3), MariaDB will automatically adjust invalid values, for example, truncating strings that are too long, or adjusting numeric values that are out of range, and produce a warning.

Statements that don't modify data will return a warning when adjusted regardless of mode.

SQL_MODE and Stored Programs

Stored programs and views always use the SQL_MODE that was active when they were created. This means that users can safely change session or global SQL_MODE; the stored programs they use will still work as usual.

It is possible to change session SQL_MODE within a stored program. In this case, the new SQL_MODE will be in effect only in the body of the current stored program. If it calls some stored procedures, they will not be affected by the change.

Some Information Schema tables (such as ROUTINES) and SHOW CREATE statements such as SHOW CREATE PROCEDURE show the SQL_MODE used by the stored programs.

Examples

This example shows how to get a readable list of enabled SQL_MODE flags:

```
SELECT REPLACE(@@SQL_MODE, ',', '\n');
+--------------------------------------------------------------------------+
| REPLACE(@@SQL_MODE, ',', '\n')                                           |
+--------------------------------------------------------------------------+
| STRICT_TRANS_TABLES
NO_ZERO_IN_DATE
NO_ZERO_DATE
NO_ENGINE_SUBSTITUTION |
+--------------------------------------------------------------------------+
```

Adding a new flag:

```
SET @@SQL_MODE = CONCAT(@@SQL_MODE, ',NO_ENGINE_SUBSTITUTION');
```

If the specified flag is already ON, the above example has no effect but does not produce an error.

How to unset a flag:

```
SET @@SQL_MODE = REPLACE(@@SQL_MODE, 'NO_ENGINE_SUBSTITUTION', '');
```

How to check if a flag is set:

```
SELECT @@SQL_MODE LIKE '%NO_ZERO_DATE%';
+-----------------------------------+
| @@SQL_MODE LIKE '%NO_ZERO_DATE%' |
+-----------------------------------+
|                                 1 |
+-----------------------------------+
```

Without and with strict mode:

```
CREATE TABLE strict (s CHAR(5), n TINYINT);

INSERT INTO strict VALUES ('MariaDB', '128');
Query OK, 1 row affected, 2 warnings (0.14 sec)

SHOW WARNINGS;
+---------+------+--------------------------------------------+
| Level   | Code | Message                                    |
+---------+------+--------------------------------------------+
| Warning | 1265 | Data truncated for column 's' at row 1     |
| Warning | 1264 | Out of range value for column 'n' at row 1 |
+---------+------+--------------------------------------------+
2 rows in set (0.00 sec)

SELECT * FROM strict;
+-------+------+
| s     | n    |
+-------+------+
| Maria |  127 |
+-------+------+

SET sql_mode='STRICT_TRANS_TABLES';

INSERT INTO strict VALUES ('MariaDB', '128');
ERROR 1406 (22001): Data too long for column 's' at row 1
```

Overriding strict mode with the IGNORE keyword:

```
INSERT IGNORE INTO strict VALUES ('MariaDB', '128');
Query OK, 1 row affected, 2 warnings (0.15 sec)
```

2.1.14.2.14 SQL_MODE-MSSQL

2.8 Copying Tables Between Different MariaDB Databases and MariaDB Servers

Contents

With MariaDB it's very easy to copy tables between different MariaDB databases and different MariaDB servers. This works for tables created with the Archive, Aria, CSV, InnoDB, MyISAM, MERGE, and XtraDB engines.

The normal procedures to copy a table is:

```
FLUSH TABLES db_name.table_name FOR EXPORT

# Copy the relevant files associated with the table

UNLOCK TABLES;
```

The table files can be found in datadir/databasename (you can execute `SELECT @@datadir` to find the correct directory). When copying the files, you should copy all files with the same table_name + various extensions. For example, for an Aria table of name foo, you will have files foo.frm, foo.MAI, foo.MAD and possibly foo.TRG if you have triggers.

If one wants to distribute a table to a user that doesn't need write access to the table and one wants to minimize the storage size of the table, the recommended engine to use is Aria or MyISAM as one can pack the table with aria_pack or myisampack respectively to make it notablly smaller. MyISAM is the most portable format as it's not dependent on whether the server settings are different. Aria and InnoDB require the same block size on both servers.

Copying Tables When the MariaDB Server is Down

The following storage engines support export without `FLUSH TABLES ... FOR EXPORT`, assuming the source server is down and the receiving server is not accessing the files during the copy.

Engine	Comment
Archive	
Aria	Requires clean shutdown. Table will automatically be fixed on the receiving server if `aria_chk --zerofill` was not run. If `aria_chk --zerofill` is run, then the table is immediately usable without any delays
CSV	
MyISAM	
MERGE	.MRG files can be copied even while server is running as the file only contains a list of tables that are part of merge.

Copying Tables Live From a Running MariaDB Server

For all of the above storage engines (Archive, Aria, CSV, MyISAM and MERGE), one can copy tables even from a live server under the following circumstances:

- You have done a `FLUSH TABLES` or `FLUSH TABLE table_name` for the specific table.
- The server is not accessing the tables during the copy process.

The advantage of FLUSH TABLES table_name FOR EXPORT is that the table is read locked until UNLOCK TABLES is executed.

Warning: If you do the above live copy, you are doing this on **your own risk** as if you do something wrong, the copied table is very likely to be corrupted. The original table will of course be fine.

An Efficient Way to Give Someone Else Access to a Read Only Table

If you want to give a user access to some data in a table for the user to use in their MariaDB server, you can do the following:

First let's create the table we want to export. To speed up things, we create this without any indexes. We use `TRANSACTIONAL=0` `ROW_FORMAT=DYNAMIC` for Aria to use the smallest possible row format.

```
CREATE TABLE new_table ... ENGINE=ARIA TRANSACTIONAL=0;
ALTER TABLE new_table DISABLE_KEYS;
# Fill the table with data:
INSERT INTO new_table SELECT * ...
FLUSH TABLE new_table WITH READ LOCK;

# Copy table data to some external location, like /tmp with something
# like cp /my/data/test/new_table.* /tmp/

UNLOCK TABLES;
```

Then we pack it and generate the indexes. We use a big sort buffer to speed up generating the index.

```
> ls -l /tmp/new_table.*
-rw-rw---- 1 mysql my 42396148 Sep 21 17:58 /tmp/new_table.MAD
-rw-rw---- 1 mysql my     8192 Sep 21 17:58 /tmp/new_table.MAI
-rw-rw---- 1 mysql my     1039 Sep 21 17:58 /tmp/new_table.frm
> aria_pack /tmp/new_table
Compressing /tmp/new_table.MAD: (922666 records)
- Calculating statistics
- Compressing file
46.07%
> aria_chk -rq --ignore-control-file --sort_buffer_size=1G /tmp/new_table
Recreating table '/tmp/new_table'
- check record delete-chain
- recovering (with sort) Aria-table '/tmp/new_table'
Data records: 922666
- Fixing index 1
State updated
> ls -l /tmp/new_table.*
-rw-rw---- 1 mysql my 26271608 Sep 21 17:58 /tmp/new_table.MAD
-rw-rw---- 1 mysql my 10207232 Sep 21 17:58 /tmp/new_table.MAI
-rw-rw---- 1 mysql my     1039 Sep 21 17:58 /tmp/new_table.frm
```

The procedure for MyISAM tables is identical, except that myisamchk doesn't have the `--ignore-control-file` option.

Copying InnoDB's Transportable Tablespaces

InnoDB's file-per-table tablespaces are transportable, which means that you can copy a file-per-table tablespace from one MariaDB Server to another server. See Copying Transportable Tablespaces for more information.

Importing Tables

Tables that use most storage engines are immediately usable when their files are copied to the new `datadir`.

However, this is not true for tables that use InnoDB. InnoDB tables have to be imported with ALTER TABLE ... IMPORT TABLESPACE. See Copying Transportable Tablespaces for more information.

3 High Availability & Performance Tuning

There are 2 related questions.

3.1 MariaDB Replication

The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Replication is a feature allowing the contents of one or more primary servers to be mirrored on one or more replica servers.

Replication Overview
Allow the contents of one or more primary servers to be mirrored on one or more replicas.

Replication Commands

Obsolete Replication Information

This section is for replication-related items that are obsolete

There are 23 related questions.

3.1.1 Replication Overview

Contents

Replication is a feature allowing the contents of one or more servers (called primaries) to be mirrored on one or more servers (called replicas).

You can exert control over which data to replicate. All databases, one or more databases, or tables within a database can each be selectively replicated.

The main mechanism used in replication is the binary log. If binary logging is enabled, all updates to the database (data manipulation and data definition) are written into the binary log as binlog events. Replicas read the binary log from each primary in order to access the data to replicate. A relay log is created on the replica, using the same format as the binary log, and this is used to perform the replication. Old relay log files are removed when no longer needed.

A replica server keeps track of the position in the primary's binlog of the last event applied on the replica. This allows the replica server to re-connect and resume from where it left off after replication has been temporarily stopped. It also allows a replica to disconnect, be cloned and then have the new replica resume replication from the same primary.

Primaries and replicas do not need to be in constant communication with each other. It's quite possible to take servers offline or disconnect from the network, and when they come back, replication will continue where it left off.

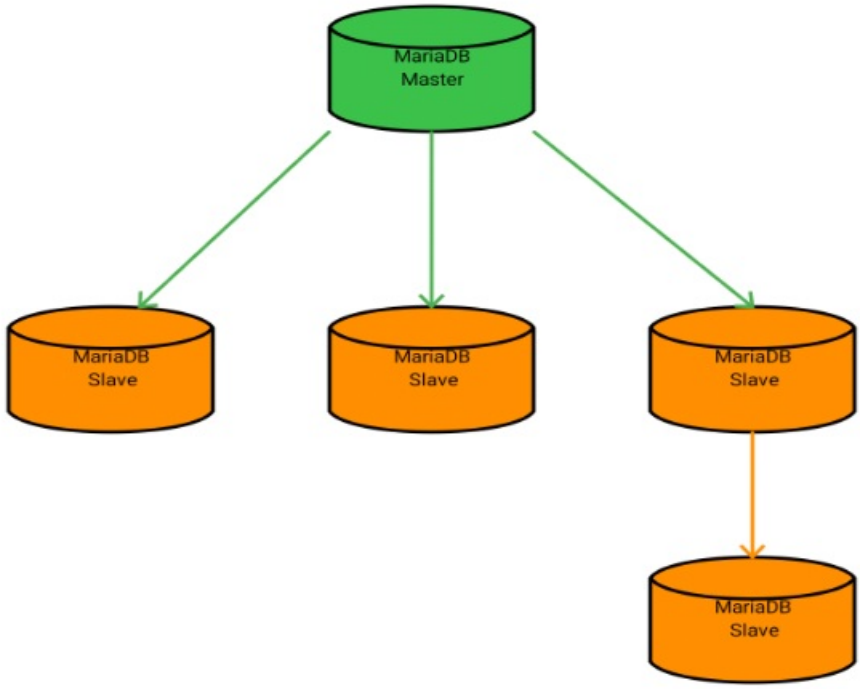
Replication Uses

Replication is used in a number of common scenarios. Uses include:

- Scalability. By having one or more replicas, reads can be spread over multiple servers, reducing the load on the primary. The most common scenario for a high-read, low-write environment is to have one primary, where all the writes occur, replicating to multiple replicas, which handle most of the reads.
- Data analysis. Analyzing data may have too much of an impact on a primary server, and this can similarly be handled on a replica, while the primary continues unaffected by the extra load.
- Backup assistance. Backups can more easily be run if a server is not actively changing the data. A common scenario is to replicate the data to a replica, which is then disconnected from the primary with the data in a stable state. Backup is then performed from this server. See Replication as a Backup Solution.
- Distribution of data. Instead of being connected to a remote primary, it's possible to replicate the data locally and work from this data instead.

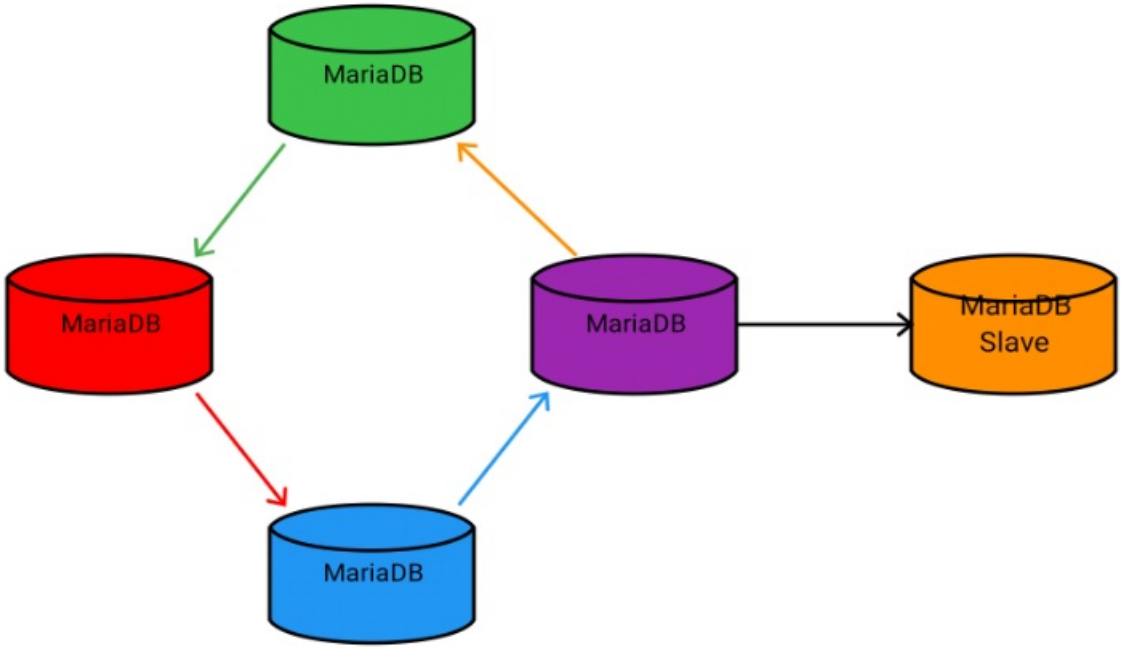
Common Replication Setups

Standard Replication



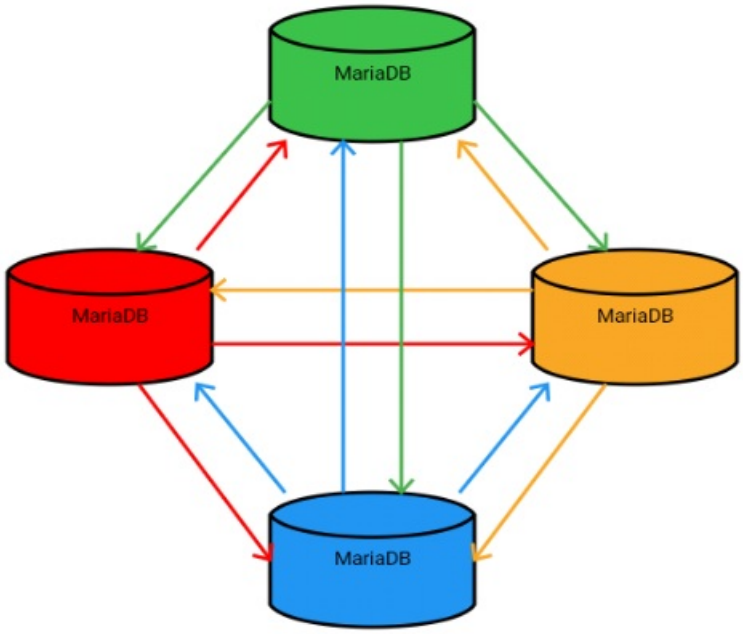
- Provides infinite read scale out.
- Provides high-availability by upgrading replica to primary.

Ring Replication



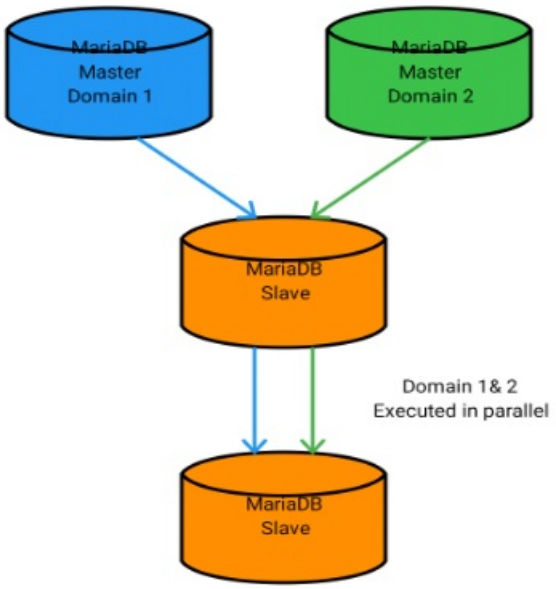
- Provides read and write scaling.
- Doesn’t handle conflicts.
- If one primary fails, replication stops.

Star Replication



- Provides read and write scaling.
- Doesn’t handle conflicts.
- Have to use replication filters to avoid duplication of data.

Multi-Source Replication



- Allows you to combine data from different sources.
- Different domains executed independently in parallel on all replicas.

Cross-Version Replication Compatibility

The following table describes replication compatibility between different MariaDB Server versions. In general, the replica should always be at least equivalent in version to the primary:

Primary→ / Replica ↓	MariaDB 10.3	MariaDB 10.4	MariaDB 10.5	MariaDB 10.6	MariaDB 10.11
MariaDB 10.3	✓	□	□	□	□
MariaDB 10.4	✓	✓	□	□	□
MariaDB 10.5	✓	✓	✓	□	□
MariaDB 10.6	✓	✓	✓	✓	□
MariaDB 10.11	✓	✓	✓	✓	✓

- ✓: This combination is supported.
- □: This combination is **not** supported.

For replication compatibility details between MariaDB and MySQL, see MariaDB versus MySQL - Compatibility: Replication Compatibility.

1.1.1.2.5 Replication Commands

3.1.3 Setting Up Replication

The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Contents

Getting replication working involves steps on both the master server/s and steps on the slave server/s.

MariaDB 10.0 introduced replication with global transaction IDs. These have a number of benefits, and it is generally recommended to use this feature from MariaDB 10.0.

Setting up a Replication Slave with Mariabackup

If you would like to use Mariabackup to set up a replication slave, then you might find the information at Setting up a Replication Slave with Mariabackup helpful.

Versions

In general, when replicating across different versions of MariaDB, it is best that the master is an older version than the slave. MariaDB versions are usually backward compatible, while of course older versions cannot always be forward compatible. See also Replicating from MySQL Master to MariaDB Slave.

Configuring the Master

- Enable binary logging if it's not already enabled. See Activating the Binary Log and Binary log formats for details.
- Give the master a unique server_id. All slaves must also be given a server_id. This can be a number from 1 to 2^{32}-1, and must be unique for each server in the replicating group.
- Specify a unique name for your replication logs with --log-basename. If this is not specified your host name will be used and there will be problems if the hostname ever changes.
- Slaves will need permission to connect and start replicating from a server. Usually this is done by creating a dedicated slave user, and granting that user permission only to replicate (REPLICATION SLAVE permission).

Example Enabling Replication for MariaDB

Add the following into your my.cnf file and restart the database.

```
[mariadb]
log-bin
server_id=1
log-basename=master1
binlog-format=mixed
```

The server id is a unique number for each MariaDB/MySQL server in your network. binlog-format specifies how your statements are logged. This mainly affects the size of the binary log that is sent between the Master and the Slaves.

Then execute the following SQL with the `mysql` command line client:

```
CREATE USER 'replication_user'@'%' IDENTIFIED BY 'bigs3cret';
GRANT REPLICATION SLAVE ON *.* TO 'replication_user'@'%';
```

Example Enabling Replication for MySQL

If you want to enable replication from MySQL to MariaDB, you can do it in almost the same way as between MariaDB servers. The main difference is that MySQL doesn't support `log-basename`.

```
[mysqld]
log-bin
server_id=1
```

Settings to Check

There are a number of options that may impact or break replication. Check the following settings to avoid problems.

- skip-networking. If `skip-networking=1`, the server will limit connections to localhost only, and prevent all remote slaves from connecting.
- bind-address. Similarly, if the address the server listens for TCP/IP connections is 127.0.0.1 (localhost), remote slaves connections will fail.

Configuring the Slave

- Give the slave a unique server_id. All servers, whether masters or slaves, are given a server_id. This can be a number from 1 to 2^{32}-1, and must be unique for each server in the replicating group. The server will need to be restarted in order for a change in this option to take effect.

Getting the Master's Binary Log Co-ordinates

Now you need prevent any changes to the data while you view the binary log position. You'll use this to tell the slave at exactly which point it should start replicating from.

- On the master, flush and lock all tables by running `FLUSH TABLES WITH READ LOCK`. Keep this session running - exiting it will release the lock.
- Get the current position in the binary log by running `SHOW MASTER STATUS`:

```
SHOW MASTER STATUS;
+--------------------+----------+--------------+------------------+
| File               | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+--------------------+----------+--------------+------------------+
| master1-bin.000096 |      568 |              |                  |
+--------------------+----------+--------------+------------------+
```

- Record the *File* and *Position* details. If binary logging has just been enabled, these will be blank.
- Now, with the lock still in place, copy the data from the master to the slave. See Backup, Restore and Import for details on how to do this.
- Note for live databases: You just need to make a local copy of the data, you don't need to keep the master locked until the slave has imported the data.
- Once the data has been copied, you can release the lock on the master by running UNLOCK TABLES.

```
UNLOCK TABLES;
```

Start the Slave

- Once the data has been imported, you are ready to start replicating. Begin by running a CHANGE MASTER TO, making sure that *MASTER_LOG_FILE* matches the file and *MASTER_LOG_POS* the position returned by the earlier SHOW MASTER STATUS. For example:

```
CHANGE MASTER TO
  MASTER_HOST='master.domain.com',
  MASTER_USER='replication_user',
  MASTER_PASSWORD='bigs3cret',
  MASTER_PORT=3306,
  MASTER_LOG_FILE='master1-bin.000096',
  MASTER_LOG_POS=568,
  MASTER_CONNECT_RETRY=10;
```

If you are starting a slave against a fresh master that was configured for replication from the start, then you don't have to specify `MASTER_LOG_FILE` and `MASTER_LOG_POS`.

Use Global Transaction Id (GTID)

MariaDB starting with 10.0

MariaDB 10.0 introduced global transaction IDs (GTIDs) for replication. It is generally recommended to use (GTIDs) from MariaDB 10.0, as this has a number of benefits. All that is needed is to add the `MASTER_USE_GTID` option to the `CHANGE MASTER` statement, for example:

```
CHANGE MASTER TO MASTER_USE_GTID = slave_pos
```

See Global Transaction ID for a full description.

- Now start the slave with the `START SLAVE` command:

```
START SLAVE;
```

- Check that the replication is working by executing the `SHOW SLAVE STATUS` command:

```
SHOW SLAVE STATUS \G
```

- If replication is working correctly, both the values of `Slave_IO_Running` and `Slave_SQL_Running` should be `Yes`:

```
Slave_IO_Running: Yes
Slave_SQL_Running: Yes
```

Replicating from MySQL Master to MariaDB Slave

- Replicating from MySQL 5.5 to MariaDB 5.5+ should just work. When using a MariaDB 10.2+ as a slave, it may be necessary to set binlog_checksum to NONE.
- Replicating from MySQL 5.6 without GTID to MariaDB 10+ should work.
- Replication from MySQL 5.6 with GTID, binlog_rows_query_log_events and ignorable events works starting from MariaDB 10.0.22 and MariaDB 10.1.8. In this case MariaDB will remove the MySQL GTIDs and other unneeded events and instead adds its own GTIDs.

2.3.4.7 Setting up a Replica with Mariabackup

3.1.5 Read-Only Replicas

Contents

1. Older MariaDB Versions

A common replication setup is to have the replicas read-only to ensure that no one accidentally updates them. If the replica has binary logging enabled and gtid_strict_mode is used, then any update that causes changes to the binary log will stop replication.

When the variable `read_only` is set to 1, no updates are permitted except from users with the SUPER privilege (<= MariaDB 10.5.1) or READ ONLY ADMIN privilege (>= MariaDB 10.5.2) or replica servers updating from a primary. Inserting rows to log tables, updates to temporary tables and OPTIMIZE TABLE or ANALYZE TABLE statements on temporary tables are excluded from this limitation.

If read_only is set to 1, then the SET PASSWORD statement is limited only to users with the SUPER privilege (<= MariaDB 10.5.1) or READ ONLY ADMIN privilege (>= MariaDB 10.5.2).

Attempting to set the `read_only` variable to 1 will fail if the current session has table locks or transactions pending.

The statement will wait for other sessions that hold table locks. While the attempt to set read_only is waiting, other requests for table locks or transactions will also wait until read_only has been set.

From MariaDB 10.3.19, some issues related to read only replicas are fixed:

- CREATE, DROP, ALTER, INSERT and DELETE of temporary tables are not logged to binary log, even in statement or mixed mode. With earlier MariaDB versions, one can avoid the problem with temporary tables by using binlog_format=ROW in which cases temporary tables are never logged.
- Changes to temporary tables created during `read_only` will not be logged even after `read_only` mode is disabled (for example if the replica is promoted to a primary).
- The admin statements ANALYZE, CHECK, OPTIMIZE and REPAIR will not be logged to the binary log under read-only.

Older MariaDB Versions

If you are using an older MariaDB version with read-only replicas and binary logging enabled on the replica, and you need to do some changes but don't want to have them logged to the binary log, the easiest way to avoid the logging is to disable binary logging while running as root during maintenance:

```
set sql_log_bin=0;
alter table test engine=rocksdb;
```

The above changes the test table on the replica to rocksdb without registering the change in the binary log.

3.1.6 Replication as a Backup Solution

Replication can be used to support the backup strategy.

Replication alone is *not* sufficient for backup. It assists in protecting against hardware failure on the primary server, but does not protect against data loss. An accidental or malicious `DROP DATABASE` or `TRUNCATE TABLE` statement will be replicated onto the replica as well. Care needs to be taken to prevent data getting out of sync between the primary and the replica.

The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Replication is most commonly used to support backups as follows:

- A primary server replicates to a replica
- Backups are then run off the replica without any impact on the primary.

Backups can have a significant effect on a server, and a high-availability primary may not be able to be stopped, locked or simply handle the extra load of a backup. Running the backup from a replica has the advantage of being able to shutdown or lock the replica and perform a backup without any impact on the primary server.

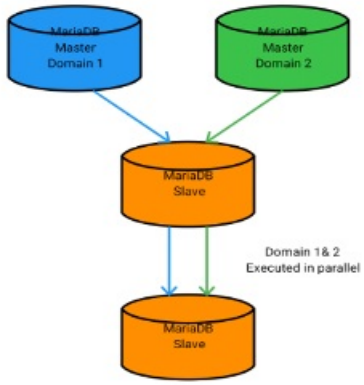
Note that when backing up off a replica server, it is important to ensure that the servers keep the data in sync. See for example Replication and Foreign Keys for a situation when identical statements can result in different data on a replica and a primary.

3.1.7 Multi-Source Replication

The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Contents

Multi-source replication means that one server has many primaries from which it replicates.



New Syntax

You specify which primary connection you want to work with by either specifying the connection name in the command or setting default_master_connection to the connection you want to work with.

The connection name may include any characters and should be less than 64 characters. Connection names are compared without regard to case (case insensitive). You should preferably keep the connection name short as it will be used as a suffix for relay logs and primary info index files.

The new syntax introduced to handle many connections:

- `CHANGE MASTER ['connection_name'] TO ...` . This creates or modifies a connection to a primary.
- `FLUSH RELAY LOGS ['connection_name']`
- `MASTER_POS_WAIT(....,['connection_name'])`
- `RESET SLAVE ['connection_name'] [ALL]` . This is used to reset a replica's replication position or to remove a replica permanently.
- `SHOW RELAYLOG ['connection_name'] EVENTS`
- `SHOW SLAVE ['connection_name'] STATUS`
- `SHOW ALL SLAVES STATUS`
- `START SLAVE ['connection_name'...]]`
- `START ALL SLAVES ...`
- `STOP SLAVE ['connection_name'] ...`
- `STOP ALL SLAVES ...`

The original old-style connection is an empty string `''` . You don't have to use this connection if you don't want to.

You create new primary connections with CHANGE MASTER.
You delete the connection permanently with RESET SLAVE 'connection_name' ALL.

Replication Variables for Multi-Source

The new replication variable default_master_connection specifies which connection will be used for commands and variables if you don't specify a connection. By default this is `''` (the default connection name).

The following replication variables are local for the connection. (In other words, they show the value for the `@@default_master_connection` connection). We are working on making all the important ones local for the connection.

Type	Name	Description
Variable	max_relay_log_size	Max size of relay log. Is set at startup to `max_binlog_size` if 0
Variable	replicate_do_db	Tell the replica to restrict replication to updates of tables whose names appear in the comma-separated list. For statement-based replication, only the default database (that is, the one selected by USE) is considered, not any explicitly mentioned tables in the query. For row-based replication, the actual names of table(s) being updated are checked.
Variable	replicate_do_table	Tells the replica to restrict replication to tables in the comma-separated list
Variable	replicate_ignore_db	Tell the replica to restrict replication to updates of tables whose names do not appear in the comma-separated list. For statement-based replication, only the default database (that is, the one selected by USE) is considered, not any explicitly mentioned tables in the query. For row-based replication, the actual names of table(s) being updated are checked.

Variable	replicate_ignore_table	Tells the replica thread to not replicate any statement that updates the specified table, even if any other tables might be updated by the same statement.
Variable	replicate_rewrite_db	From MariaDB 10.11. Allows one to configure a replica to rewrite database names. It uses the format primary_database->replica_database. If a replica encounters a binary log event in which the default database (i.e. the one selected by the USE statement) is primary_database, then the replica will apply the event in replica_database instead.
Variable	replicate_wild_do_table	Tells the replica thread to restrict replication to statements where any of the updated tables match the specified database and table name patterns.
Variable	replicate_wild_ignore_table	Tells the replica thread to not replicate to the tables that match the given wildcard pattern.
Status	Slave_heartbeat_period	How often to request a heartbeat packet from the primary (in seconds).
Status	Slave_received_heartbeats	How many heartbeats we have got from the primary.
Status	Slave_running	Shows if the replica is running. YES means that the sql thread and the IO thread are active. No means either one is not running. '' means that `@@default_master_connection` doesn't exist.
Variable	Sql_slave_skip_counter	How many entries in the replication log that should be skipped (mainly used in case of errors in the log).

You can access all of the above variables with either `SESSION` or `GLOBAL`.

Note that in contrast to MySQL, all variables always show the correct active value!

Example:

```
set @@default_master_connection='';
show status like 'Slave_running';
set @@default_master_connection='other_connection';
show status like 'Slave_running';
```

If `@@default_master_connection` contains a non existing name, you will get a warning.

All other primary-related variables are global and affect either only the '' connections or all connections. For example, Slave_retried_transactions now shows the total number of retried transactions over all replicas.

If you need to set gtid_slave_pos you need to set this for all primaries at the same time.

New status variables:

Name	Description
`Com_start_all_slaves`	Number of executed `START ALL SLAVES` commands.
`Com_start_slave`	Number of executed `START SLAVE` commands. This replaces `Com_slave_start`.
`Com_stop_slave`	Number of executed `STOP SLAVE` commands. This replaces `Com_slave_stop`.
`Com_stop_all_slaves`	Number of executed `STOP ALL SLAVES` commands.

`SHOW ALL SLAVES STATUS` has the following new columns:

Name	Description
`Connection_name`	Name of the primary connection. This is the first variable.
`Slave_SQL_State`	State of SQL thread.
`Retried_transactions`	Number of retried transactions for this connection.
`Max_relay_log_size`	Max relay log size for this connection.
`Executed_log_entries`	How many log entries the replica has executed.
`Slave_received_heartbeats`	How many heartbeats we have got from the primary.
`Slave_heartbeat_period`	How often to request a heartbeat packet from the primary (in seconds).

New Files

The basic principle of the new files used by multi source replication is that they have the same name as the original relay log files suffixed with `connection_name` before the extension. The main exception is the file that holds all connection is named as the normal `master-info-file` with a `multi-` prefix.

When you are using multi source, the following new files are created:

Name	Description
`multi-master-info-file`	The `master-info-file` (normally `master.info`) with a `multi-` prefix. This contains all primary connections in use.
`master-info-file`-connection_name`.extension`	Contains the current primary position for what's applied to in the replica. Extension is normally `.info`
`relay-log`-connection_name`.xxxxx`	The relay-log name with a connection_name suffix. The xxxxx is the relay log number. This contains the replication data read from the primary.
`relay-log-index`-connection_name`.extension`	Contains the name of the active `relay-log`-connection_name`.xxxxx` files. Extension is normally `.index`
`relay-log-info-file`-connection_name`.extension`	Contains the current primary position for the relay log. Extension is normally `.info`

When creating the file, the connection name is converted to lower case and all special characters in the connection name are converted, the same way as MySQL table names are converted. This is done to make the file name portable across different systems.

Hint:

Instead of specifying names for `mysqld` with --relay-log, --relay-log-index, --general-log-file, --slow-query-log-file, --log-bin and --log-bin-index, you can just specify --log-basename and all the other variables are set with this as a prefix.

Other Things

- All error messages from a replica with a connection name, that are written to the error log, are prefixed with `Master 'connection_name':`. This makes it easy to see from where an error originated.
- Errors `ER_MASTER_INFO` and `WARN_NO_MASTER_INFO` now includes connection_name.
- There is no conflict resolution. The assumption is that there are no conflicts in data between the different primaries.
- All executed commands are stored in the normal binary log (nothing new here).
- If the server variable `log_warnings` > 1 then you will get some information in the log about how the multi-master-info file is updated (mainly for debugging).
- The output of SHOW ALL SLAVES STATUS has one more column than `SHOW SLAVE STATUS`, since it includes the `connection_name` column.
- `RESET SLAVE` now deletes all relay-log files.

replicate-... Variables

- One can set the values for the `replicate-...` variables from the command line or in `my.cnf` for a given connection by prefixing the variable with the connection name.
- If one doesn't use any connection name prefix for a `replicate..` variable, then the value will be used as the default value for all connections that don't have a value set for this variable.

Example:

```
mysqld --main_connection.replicate_do_db=main_database --replicate_do_db=other_database
```

The have sets the `replicate_do_db` variable to `main_database` for the connection named `main_connection`. All other connections will use the value `other_database`.

One can also use this syntax to set `replicate-rewrite-db` for a given connection.

Typical Use Cases

- You are partitioning your data over many primaries and would like to get it all together on one machine to do analytical queries on all data.
- You have many databases spread over many MariaDB/MySQL servers and would like to have all of them on one machine as an extra backup.
- In a Galera cluster the default replication filter rules like `replicate-do-db` do not apply to replication connections,

but also to Galera write set applier threads. By using a named multi-primary replication connection instead, even when replicating from just one primary into the cluster, the primary-replica replication rules can be kept separate from the Galera intra-node replication traffic.

Limitations

- Each active connection will create 2 threads (as is normal for MariaDB replication).
- You should ensure that all primaries have different `server-id`'s. If you don't do this, you will get into trouble if you try to replicate from the multi-source replica back to your primaries.
- One can change max_relay_log_size for any active connection, but new connections will always use the server startup value for `max_relay_log_size`, which can't be changed at runtime.
- Option innodb-recovery-update-relay-log (xtradb feature to store and restore relay log position for replicas) only works for the default connection ''. As this option is not really safe and can easily cause loss of data if you use storage engines other than InnoDB, we don't recommend this option be used.
- slave_net_timeout affects all connections. We don't check anymore if it's less than Slave_heartbeat_period, as this doesn't make sense in a multi-source setup.

Incompatibilities with MariaDB/MySQL 5.5

- max_relay_log_size is now (almost) a normal variable and not automatically changed if max_binlog_size is changed. To keep things compatible with old config files, we set it to `max_binlog_size` at startup if its value is 0.
- You can now access replication variables that depend on the active connection with either `GLOBAL` or `SESSION`.
- We only write information about relay log positions for recovery if innodb-recovery-update-relay-log is set.
- Slave_retried_transactions now shows the total count of retried transactions over all replicas.
- The status variable `Com_slave_start` is replaced with Com_start_slave.
- The status variable `Com_slave_stop` is replaced with Com_stop_slave.
- `FLUSH RELAY LOGS` are not replicated anymore. This is not safe as connection names may be different on the replica.

3.1.8 Replication Threads

The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Contents

MariaDB's replication implementation requires several types of threads.

Threads on the Primary

The primary usually only has one type of replication-related thread: the binary log dump thread.

If semisynchronous replication is enabled, then the primary also has an ACK receiver thread.

Binary Log Dump Thread

The binary log dump thread runs on the primary and dumps the binary log to the replica. This thread can be identified by running the SHOW PROCESSLIST statement and finding the thread where the thread command is `"Binlog Dump"`.

The primary creates a separate binary log dump thread for each replica connected to the primary. You can identify which replicas are connected to the primary by executing the SHOW SLAVE HOSTS statement.

Binary Log Dump Threads and the Shutdown Process

When a primary server is shutdown and it goes through the normal shutdown process, the primary kills client threads in random order. By default, the primary also considers its binary log dump threads to be regular client threads. As a consequence, the binary log dump threads can be killed while client threads still exist, and this means that data can be written on the primary during a normal shutdown that won't be replicated. This is true even if semi-synchronous replication is being used. Data is not lost, it is stored in the primary server's binary log. The replicas on reconnection, after the primary server restarts, will resume at the exact position they where killed off during the primary shutdown. No data is lost.

In MariaDB 10.4 and later, this problem can be solved by shutting down the server using either the mariadb-admin utility or the SHUTDOWN command, and providing a special option.

For example, this problem can be solved by shutting down the server with the mariadb-admin utility and by providing the `--wait-for-all-slaves` option to the utility and by executing the `shutdown` command with the utility:

```
mariadb-admin --wait-for-all-slaves shutdown
```

Or this problem can be solved by shutting down the server with the SHUTDOWN command and by providing the `WAIT FOR ALL SLAVES` option to the command:

```
SHUTDOWN WAIT FOR ALL SLAVES;
```

When one of these special options is provided, the server only kills its binary log dump threads after all client threads have been killed, and it only completes the shutdown after the last binary log has been sent to all connected replicas.

In MariaDB 10.4 and later, it is still not possible to enable this behavior by default. This means that this behavior is currently inaccessible when shutting down the server using tools like systemd or sysVinit.

In MariaDB 10.3 and before, it is recommended to manually switchover replicas to a new primary before shutting down the old primary.

ACK Receiver Thread

When semisynchronous replication is enabled, semisynchronous replicas send acknowledgements (ACKs) to their primary to confirm that they have received some transaction. The primary creates an ACK receiver thread to receive these ACKs.

Threads on the Replica

The replica has three types of replication-related threads: the replica I/O thread, the replica SQL thread, and worker threads, which are only applicable when parallel replication is in use.

When multi-source replication is in use, each independent replication connection has its own replica threads of each type.

Replica I/O Thread

The replica's I/O thread receives the binary log events from the primary and writes them to its relay log.

Binary Log Position

The binary log position of the replica's I/O thread can be checked by executing the SHOW SLAVE STATUS statement. It will be shown as the `Master_Log_File` and `Read_Master_Log_Pos` columns.

The binary log position of the replica's I/O thread can be set by setting the MASTER_LOG_FILE and MASTER_LOG_POS options with the CHANGE MASTER statement.

The binary log position of the replica's I/O thread and the values of most other CHANGE MASTER options are written to either the default `master.info` file or the file that is configured by the master_info_file option. The replica's I/O thread keeps this binary log position updated as it downloads events only when the MASTER_USE_GTID option is set to `NO`. Otherwise the file is not updated on a per event basis. See CHANGE MASTER TO: Option Persistence for more information.

Replica SQL Thread

The replica's SQL thread reads events from the relay log. What it does with them depends on whether parallel replication is

in use. If parallel replication is not in use, then the SQL thread applies the events to its local copy of the data. If parallel replication is in use, then the SQL thread hands off the events to its worker threads to apply in parallel.

Relay Log Position

The relay log position of the replica's SQL thread can be checked by executing the SHOW SLAVE STATUS statement. It will be shown as the `Relay_Log_File` and `Relay_Log_Pos` columns.

The relay log position of the replica's SQL thread can be set by setting the RELAY_LOG_FILE and RELAY_LOG_POS options with the CHANGE MASTER statement.

The relay log position of the replica's SQL thread is written to either the default `relay-log.info` file or the file that is configured by the relay_log_info_file system variable. The replica's SQL thread keeps this relay log position updated as it applies events. See CHANGE MASTER TO: Option Persistence for more information.

Binary Log Position

The corresponding binary log position of the current relay log position of the replica's SQL thread can be checked by executing the SHOW SLAVE STATUS statement. It will be shown as the `Relay_Master_Log_File` and `Exec_Master_Log_Pos` columns.

GTID Position

If the replica is replicating binary log events that contain GTIDs, then the replica's's SQL thread will write every GTID that it applies to the mysql.gtid_slave_pos table. This GTID can be inspected and modified through the gtid_slave_pos system variable.

If the replica has the log_slave_updates system variable enabled and if the replica has the binary log enabled, then every write by the replica's SQL thread will also go into the replica's binary log. This means that GTIDs of replicated transactions would be reflected in the value of the gtid_binlog_pos system variable.

See CHANGE MASTER TO: GTID Persistence for more information.

Worker Threads

When parallel replication is in use, then the SQL thread hands off the events to its worker threads to apply in parallel.

3.1.9 Global Transaction ID

> The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Contents

Note that MariaDB and MySQL have different GTID implementations, and that these are not compatible with each other. MariaDB can be a replica for a MySQL primary but MySQL cannot be a replica for a MariaDB primary.

Overview

MariaDB replication in general works as follows (see Replication overview for more information):

On a master server, all updates to the database (DML and DDL) are written into the binary log as binlog events. A replica server connects to the primary and reads the binlog events, then applies the events locally to replicate the same changes as done on the primary. A server can be both a primary and a replica at the same time, and it is thus possible for binlog events to replicated through multiple levels of servers.

A replica server keeps track of the position in the primary's binlog of the last event applied on the replica. This allows the replica server to re-connect and resume from where it left off after replication has been temporarily stopped. It also allows a replica to disconnect, be cloned and then have the new replica resume replication from the same primary.

Global transaction ID introduces a new event attached to each event group in the binlog. (An event group is a collection of events that are always applied as a unit. They are best thought of as a "transaction", though they also include non-transactional DML statements, as well as DDL). As an event group is replicated from primary server to replica server, the global transaction ID is preserved. Since the ID is globally unique across the entire group of servers, this makes it easy to uniquely identify the same binlog events on different servers that replicate each other (this was not easily possible before MariaDB 10.0.2).

Benefits

Using global transaction ID provides two main benefits:

1. Easy to change a replica server to connect to and replicate from a different primary server.

The replica remembers the global transaction ID of the last event group applied from the old primary. This makes it easy to know where to resume replication on the new primary, since the global transaction IDs are known throughout the entire replication hierarchy. This is not the case when using old-style replication; in this case the replica knows only the specific file name and offset of the old primary server of the last event applied. There is no simple way to guess from this the correct file name and offset on a new primary.

2. The state of the replica is recorded in a crash-safe way.

The replica keeps track of its current position (the global transaction ID of the last transaction applied) in the mysql.gtid_slave_pos system table. If this table is using a transactional storage engine (such as InnoDB, which is the default), then updates to the state are done in the same transaction as the updates to the data. This makes the state crash-safe; if the replica server crashes, crash recovery on restart will make sure that the recorded replication position matches the changes that were actually replicated. This is not the case for old-style replication, where the state is recorded in a file relay-log.info, which is updated independently of the actual data changes and can easily get out of sync if the replica server crashes. (This works for DML to transactional tables; non-transactional tables and DDL in general are not crash-safe in MariaDB.)

Because of these two benefits, it is generally recommended to use global transaction ID for any replication setups based on MariaDB 10.0.2 or later. However, old-style replication continues to work as always, so there is no pressing need to change existing setups. Global transaction ID integrates smoothly with old-style replication, and the two can be used freely together in the same replication hierarchy. There is no special configuration needed of the server to start using global transaction ID. However, it must be explicitly set for a replica server with the appropriate CHANGE MASTER option; by default old-style replication is used by a replication replica, to maintain backwards compatibility.

Implementation

A global transaction ID, or GTID for short, consists of three numbers separated with dashes '-'. For example:

```
0-1-10
```

- The first number 0 is the domain ID, which is specific for global transaction ID (more on this below). It is a 32-bit unsigned integer.
- The second number is the server ID, the same as is also used in old-style replication. It is a 32-bit unsigned integer.
- The third number is the sequence number. This is a 64-bit unsigned integer that is monotonically increasing for each new event group logged into the binlog.

The server ID is set to the server ID of the server where the event group is first logged into the binlog. The sequence number is increased on a server for every event group logged. Since server IDs must be unique for every server, this makes the (server_id, sequence_number) pair, and hence the whole GTID, globally unique.

Using a 64-bit number provides ample range that there should be no risk of it overflowing in the foreseeable future. However, one should not artificially (by setting `gtid_seq_no`) inject a GTID with a very high sequence number close to the limit of 64-bit.

The Domain ID

When events are replicated from a primary server to a replica server, the events are always logged into the replica's binlog in the same order that they were read from the primary's binlog. Thus, if there is only ever a single primary server receiving (non-replication) updates at a time, then the binlog order will be identical on every server in the replication hierarchy.

This consistent binlog order is used by the replica to keep track of its current position in the replication. Basically, the replica remembers the GTID of the last event group replicated from the primary. When reconnecting to a primary, whether the same one or a new one, it sends this GTID position to the primary, and the primary starts sending events from the first event after the corresponding event group.

However, if user updates are done independently on multiple servers at the same time, then in general it is not possible for binlog order to be identical across all servers. This can happen when using multi-source replication, with multi-primary ring topologies, or just if manual updates are done on a replica that is replicating from active primary. If the binlog order is different on the new primary from the order on the old primary, then it is not sufficient for the replica to keep track of a single GTID to completely record the current state.

The domain ID, the first component of the GTID, is used to handle this.

In general, the binlog is not a single ordered stream. Rather, it consists of a number of different streams, each one identified by its own domain ID. Within each stream, GTIDs always have the same order in every server binlog. However, different streams can be interleaved in different ways on different servers.

A replica server then keeps track of its replication position by recording the last GTID applied within each replication stream. When connecting to a new primary, the replica can start replication from a different point in the binlog for each domain ID.

For more details on using multi-primary setups and multiple domain IDs, see Use with multi-source replication and other multi-primary setups.

Simple replication setups only have a single primary being updated by the application at any one time. In such setups, there is only a single replication stream needed. Then domain ID can be ignored, and left as the default of 0 on all servers.

Using Global Transaction IDs

Global transaction ID is enabled automatically. Each event group logged to the binlog receives a GTID event, as can be seen with mariadb-binlog or SHOW BINLOG EVENTS.

The replica automatically keeps track of the GTID of the last applied event group, as can be seen from the gtid_slave_pos variable:

```
SELECT @@GLOBAL.gtid_slave_pos
0-1-1
```

When a replica connects to a primary, it can use either global transaction ID or old-style filename/offset to decide where in the primary binlogs to start replicating from. To use global transaction ID, use the CHANGE MASTER *master_use_gtid* option:

```
CHANGE MASTER TO master_use_gtid = { slave_pos | current_pos | no }
```

A replica is configured to use GTID by `CHANGE MASTER TO master_use_gtid=slave_pos`. When the replica connects to the primary, it will start replication at the position of the last GTID replicated to the replica, which can be seen in the variable gtid_slave_pos. Since GTIDs are the same across all replication servers, the replica can then be pointed to a different primary, and the correct position will be determined automatically.

But suppose that we set up two servers A and B and let A be the primary and B the replica. It runs for a while. Then at some point we take down A, and B becomes the new primary. Then later we want to add A back, this time as a replica.

Since A was never a replica before, it does not have any prior replicated GTIDs, and gtid_slave_pos will be empty. To allow A to be added as a replica automatically, `master_use_gtid=current_pos` can be used. This will connect using the value of the variable gtid_current_pos instead of gtid_slave_pos, which also takes into account GTIDs written into the binlog when the server was a primary.

When using `master_use_gtid=current_pos` there is no need to consider whether a server was a primary or a replica prior to using CHANGE MASTER. But care must be taken not to inject extra transactions into the binlog on the replica server that are not intended to be replicated to other servers. If such an extra transaction is the most recent when the replica starts, it will be used as the starting point of replication. This will probably fail because that transaction is not present on the primary. To avoid local changes on a replica server to go into the binlog, set sql_log_bin to 0.

If it is undesirable that changes to the binlog on the replica affects the GTID replication position, then `master_use_gtid=slave_pos` should be used. Then the replica will always connect to the primary at the position of the last replicated GTID. This may avoid some surprises for users that expect behavior consistent with traditional replication, where the replication position is never changed by local changes done on a server.

When GTID strict mode is enabled (by setting `@@GLOBAL.gtid_strict_mode` to 1), it is normally best to use `current_pos`. In strict mode, extra transactions on the primary are disallowed.

If a replica is configured with the binlog disabled, `current_pos` and `slave_pos` are equivalent.

Even when a replica is configured to connect with the old-style binlog filename and offset (`CHANGE MASTER TO master_log_file=..., master_log_pos=...`), it will still keep track of the current GTID position in `@@GLOBAL.gtid_slave_pos`. This means that an existing replica previously configured and running can be changed to connect with GTID (to the same or a new master) simply with:

```
CHANGE MASTER TO master_use_gtid = slave_pos
```

The replica remembers that `master_use_gtid=slave_pos|master_pos` was specified and will use it also for subsequent connects, until it is explicitly changed by specifying `master_log_file/pos=...` or `master_use_gtid=no`. The current value can be seen as the field Using_Gtid of SHOW SLAVE STATUS:

```
SHOW SLAVE STATUS\G
...
Using_Gtid: Slave_pos
```

The replica server internally uses the mysql.gtid_slave_pos table to store the GTID position (and so preserve the value of `@@GLOBAL.gtid_slave_pos` across server restarts). After upgrading a server to 10.0, it is necessary to run mysql_upgrade (as always) to get the table created.

In order to be crash-safe, this table must use a transactional storage engine such as InnoDB. When MariaDB is first installed (or upgraded to 10.0.2+) the table is created using the default storage engine - which itself defaults to InnoDB. If there is a need to change the storage engine for this table (to make it transactional on a system configured with MyISAM as the default storage engine, for example), use ALTER TABLE:

```
ALTER TABLE mysql.gtid_slave_pos ENGINE = InnoDB
```

The mysql.gtid_slave_pos table should not be modified in any other way. In particular, do not try to update the rows in the table to change the replica's idea of the current GTID position; instead use

```
SET GLOBAL gtid_slave_pos = '0-1-1'
```

Starting from MariaDB 10.3.1, the server variable gtid_pos_auto_engines can preferably be set to make the server handle this automatically. See the description of the mysql.gtid_slave_pos table for details.

Using `current_pos` vs. `slave_pos`

When setting the MASTER_USE_GTID replication parameter, you have the option of enabling Global Transaction IDs to use either the `current_pos` or `slave_pos` values.

Using the value `current_pos` causes the replica to set its position based on the gtid_current_pos system variable, which is a union of gtid_binlog_pos and gtid_slave_pos. Using the value `slave_pos` causes the replica to instead set its position based on the gtid_slave_pos system variable.

You may run into issues when you use the value `current_pos` if you write any local transactions on the replica. For instance, if you issue an INSERT statement or otherwise write to a table while the replica threads are stopped, then new local GTIDs may be generated in gtid_binlog_pos, which will affect the replica's value of gtid_current_pos. This may cause errors when the replica threads are restarted, since the local GTIDs will be absent from the primary.

You can correct this issue by setting the MASTER_USE_GTID replication parameter to `slave_pos` instead of `current_pos`. For example:

```
CHANGE MASTER TO MASTER_USE_GTID = slave_pos;
START SLAVE;
```

Using GTIDs with Parallel Replication

If parallel replication is in use, then events that were logged with GTIDs with different gtid_domain_id values can be applied in parallel in an out-of-order manner.

Using GTIDs with MariaDB Galera Cluster

Starting with MariaDB 10.1.4, MariaDB Galera Cluster has limited support for GTIDs. See Using MariaDB GTIDs with MariaDB Galera Cluster for more information.

Setting up a New Replica Server with Global Transaction ID

Setting up a new replica server with global transaction ID is not much different from setting up an old-style replica. The basic steps are:

1. Setup the new server and load it with the initial data.

2. Start the replica replicating from the appropriate point in the primary's binlog.

Setting up a New Replica with an Empty Server

The simplest way for testing purposes is probably to setup a new, empty replica server and replicate all of the primary's binlogs from the start (this is usually not feasible in a realistic production setup, as the initial binlog files will probably have been purged or take too long to apply).

The replica server is installed in the normal way. By default, the GTID position for a newly installed server is empty, which makes the replica replicate from the start of the primary's binlogs. But if the replica was used for other purposes before, the initial position can be explicitly set to empty first:

```
SET GLOBAL gtid_slave_pos = "";
```

Next, point the replica to the master with CHANGE MASTER. Specify master_host etc. as usual. But instead of specifying master_log_file and master_log_pos manually, use `master_use_gtid=current_pos` (or `slave_pos` to have GTID do it

automatically:

```
CHANGE MASTER TO master_host="127.0.0.1", master_port=3310, master_user="root",
master_use_gtid=current_pos;
START SLAVE;
```

Setting up a New Replica From a Backup

The normal way to set up a new replication replica is to take a backup from an existing server (either a primary or replica in the replication topology), and then restore that backup on the server acting as the new replica, and the configure it to start replicating from the appropriate position in the primary's binary log.

It is important that the position at which replication is started corresponds exactly to the state of the data at the point in time that the backup was taken. Otherwise, the replica can end up with different data than the primary because of missing or duplicated transactions. Of course, if there are no writes to the server being backed up during the backup process, then a simple SHOW MASTER STATUS will give the correct position.

See the description of the specific backup tool to determine how to get the binary log position that corresponds to the backup.

Once the current binary log position for the backup has been obtained, in the form of a binary log file name and position, the corresponding GTID position can be obtained from BINLOG_GTID_POS() on the server that was backed up:

```
SELECT BINLOG_GTID_POS("master-bin.000001", 600);
```

The new replica can then start replicating from the primary by setting the correct value for gtid_slave_pos, and then executing CHANGE MASTER with the relevant values for the primary, and then starting the replica threads by executing START SLAVE. For example:

```
SET GLOBAL gtid_slave_pos = "0-1-2";
CHANGE MASTER TO master_host="127.0.0.1", master_port=3310, master_user="root",
master_use_gtid=slave_pos;
START SLAVE;
```

This method is particularly useful when setting up a new replica from a backup of the primary. Remember to ensure that the value of server_id configured on the new replica is different from that of any other server in the replication topology.

If the backup was taken of an existing replica server, then the new replica should already have the correct GTID position stored in the mysql.gtid_slave_pos table. This is assuming that this table was backed up and that it was backed up in a consistent manner with changes to other tables. In this case, there is no need to explicitly look up the GTID position on the old server and set it on the new replica - it will be already correctly loaded from the mysql.gtid_slave_pos table. This however does not work if the backup was taken from the primary - because then the current GTID position is contained in the binary log, not in the mysql.gtid_slave_pos table or any other table.

Setting up a New Replica with Mariabackup

A new replica can easily be set up with Mariabackup, which is a fork of Percona XtraBackup. See Setting up a Replica with Mariabackup for more information.

Setting up a New Replica with mariadb-dump

A new replica can also be set up with mariadb-dump.

mariadb-dump automatically includes the GTID position as a comment in the backup file if either the --master-data or --dump-slave option is used. It also automatically includes the commands to set gtid_slave_pos and execute CHANGE MASTER in the backup file if the --gtid option is used with either the --master-data or --dump-slave option.

Switching An Existing Old-Style Replica To Use GTID.

If there is already an existing replica running using old-style binlog filename/offset position, then this can be changed to use GTID directly. This can be useful for upgrades for example, or where there are already tools to setup new replica using old-style binlog positions.

When a replica connects to a primary using old-style binlog positions, and the primary supports GTID (i.e. is MariaDB 10.0.2 or later), then the replica automatically downloads the GTID position at connect and updates it during replication. Thus, once a replica has connected to the GTID-aware primary at least once, it can be switched to using GTID without any other actions needed;

```
STOP SLAVE;
CHANGE MASTER TO master_host="127.0.0.1", master_port=3310, master_user="root",
master_use_gtid=current_pos;
START SLAVE;
```

(A later version will probably add a way to setup the replica so that it will connect with old-style binlog file/offset the first time, and automatically switch to using GTID on subsequent connects.)

Changing a Replica to Replicate From a Different Primary

Once replication is running with GTID (master_use_gtid=current_pos|slave_pos), the replica can be pointed to a new primary simply by specifying in CHANGE MASTER the new master_host (and if required master_port, master_user, and master_password):

```
STOP SLAVE;
CHANGE MASTER TO master_host='127.0.0.1', master_port=3312;
START SLAVE;
```

The replica has a record of the GTID of the last applied transaction from the old primary, and since GTIDs are identical across all servers in a replication hierarchy, the replica will just continue from the appropriate point in the new primary's binlog.

It is important to understand how this change of primary work. The binlog is an ordered stream of events (or multiple streams, one per replication domain, (see Use with multi-source replication and other multi-primary setups). Events within the stream are always applied in the same order on every replica that replicates it. The MariaDB GTID relies on this ordering, so that it is sufficient to remember just a single point within the stream. Since event order is the same on every server, switching to the point of the same GTID in the binlog of another server will give the same result.

This translates into some responsibility for the user. The MariaDB GTID replication is fully asynchronous, and fully flexible in how it can be configured. This makes it possible to use it in ways where the assumption that binlog sequence is the same on all servers is violated. In such cases, when changing primary, GTID will still attempt to continue at the point of current GTID in the new binlog.

The most common way that binlog sequence gets different between servers is when the user/DBA does updates directly on a replica server (and these updates are written into the replica's binlog). This results in events in the replica's binlog that are not present on the primary or any other replicas. This can be avoided by setting the session variable sql_log_bin false while doing such updates, so they do not go into the binlog.

It is normally best to avoid any differences in binlogs between servers. That being said, MariaDB replication is designed for maximum flexibility, and there can be valid reasons for introducing such differences from time to time. It this case, it just needs to be understood that the GTID position is a single point in each binlog stream (one per replication domain), and how this affects the users particular setup.

Differences can also occur when two primary are active at the same time in a replication hierarchy. This happens when using a multi-primary ring. But it can also occur in a simple primary-replica setup, during switch to a new primary, if changes on the old primary is not allowed to fully replicate to all replica servers before switching primary. Normally, to switch primary, first writes to the old primary should be stopped, then one should wait for all changes to be replicated to the new primary, and only then should writes begin on the new primary. Deliberately using multiple active primary is also supported, this is described in the next section.

The GTID strict mode can be used to enforce identical binlogs across servers. When it is enabled, most actions that would cause differences are rejected with an error.

Use With Multi-Source Replication and Other Multi-Primary Setups

MariaDB global transaction ID supports having multiple primarys active at the same time. Typically this happens with either multi-source replication or multi-primary ring setups.

In such setups, each active primary must be configured with its own distinct replication domain ID, gtid_domain_id. The binlog will then in effect consists of multiple independent streams, one per active primary. Within one replication domain, binlog order is always the same on every server. But two different streams can be interleaved differently in different server binlogs.

The GTID position of a given replica is then not a single GTID. Rather, it becomes the GTID of the last event group applied for each value of domain ID, in effect the position reached in each binlog stream. When the replica connects to a primary, it can continue from one stream in a different binlog position than another stream. Since order within one stream is consistent across all servers, this is sufficient to always be able to continue replication at the correct point in any new primary

server(s).

Domain IDs are assigned by the DBA, according to the need of the application. The default value of @@GLOBAL.gtid_domain_id is 0. This is appropriate for most replication setups, where only a single primary is active at a time. The MariaDB server will never by itself introduce new domain_id values into the binlog.

When using multi-source replication, where a single replica connects to multiple primaries at the same time, each such primary should be configured with its own distinct domain ID.

Similarly, in a multi-primary ring topology, where all primary in the ring are updated by the application concurrently (with some mechanism to avoid conflicts), a distinct domain ID should be configured for each server (In a multi-primary ring where the application is careful to only do updates on one primary at a time, a single domain ID is sufficient).

Normally, a replica server should not receive direct updates (as this creates binlog differences compared to the primary). Thus it does not matter what value of gtid_domain_id is set on a replica, though it may make sense to make it the same as the primary (if not using multi-primary) to make it easy to promote the replica as a new primary. Of course, if a replica is itself an active primary, as in a multi-primary ring topology, the domain ID should be set according to the server's role as active primary.

Note that domain ID and server ID are distinct concepts. It is possible to use a different domain ID on each server, but this is normally not desirable. It makes the current GTID position (@@global.gtid_slave_pos) more complicated to understand and work with, and loses the concept of a single ordered binlog stream across all servers. It is recommended only to configure as many domain IDs as there are primary servers actively being updated by the application at the same time.

It is not an error in itself to configure domain IDs incorrectly (for example, not configuring them at all). For example, this will be typical in an upgrade scenario where a multi-primary ring using 5.5 is upgraded to 10.0. The ring will continue to work as before even though everything is configured to use the default domain ID 0. It is even possible to use GTID for replication between the servers. However, care must be taken when switching a replica to a different primary. If the binlog order between the old and the new primary differs, then a single GTID position to start replication from in the new primary's binlog may not be sufficient.

Multiple Redundant Replication Paths

Using GTID with multi-source replication, it is possible to set up multiple redundant replication paths. For example:

```
M1 <-> M2
M1 -> S1
M1 -> S2
M2 -> S1
M2 -> S2
```

Here, M1 and M2 are setup in a master-master ring. S1 and S2 both replicate from each of M1 and M2. Each event generated on M1 will now arrive twice at S1, through the paths M1->S1 and M1->M2->S1. This way, if the network connection between M1 and S1 is broken, the replication can continue uninterrupted through the alternate path through M2. Note that this is an advanced setup, and good familiarity with MariaDB replication is recommended to successfully operate it.

The option --gtid-ignore-duplicates must be enabled to use multiple redundant replication paths. This is necessary to avoid each event being applied twice on the replica as it arrives through each path. The GTID of every event will be compared against the sequence number of the current GTID replica position (within each domain), and will be skipped if less than or equal. Thus it is required that sequence numbers are strictly increasing within each domain for --gtid-ignore-duplicates to function correctly, and setting --gtid-strict-mode=1 to help enforce this is recommended.

The --gtid-ignore-duplicates options also relaxes the requirement for connection to the master. In the above example, when S1 connects to M2, it may connect at a GTID position from M1 that has not yet been applied on M2.

When --gtid-ignore-duplicates is enabled, the connection will be allowed, and S1 will start receiving events from M2 once the GTID has been replicated from M1 to M2. This can also be used to use replication filters in parts of a replication topology, to allow a replica to connect to a GTID position which was filtered on a master. When --gtid-ignore-duplicates is enabled, the connecting replica will start receiving events from the master at the first GTID sequence number that is larger than the connect-position.

Deleting Unused Domains

`FLUSH BINARY LOGS DELETE_DOMAIN_ID=(list-of-domains)` can be used to discard obsolete GTID domains from the server's binary log state. In order for this to be successful, no event group from the listed GTID domains can be present in existing binary log files. If some still exist, then they must be purged prior to executing this command.

If the command completes successfully, then it also rotates the binary log.

The old domains will still appear in gtid_io_pos. To get rid of these, you can stop the replica and execute on the replica:

```
SET gtid_slave_pos="<position with domains removed>"
```

New Syntax For Global Transaction ID

CHANGE MASTER

CHANGE MASTER has a new option, `master_use_gtid=[current_pos|slave_pos|no]`. When enabled (set to *current_pos* or *slave_pos*), the replica will connect to the master using the GTID position. When disabled (set to "no"), the old-style binlog filename/offset position is used to decide where to start replicating when connecting. Unlike in the old-style, when GTID is enabled, the values of the MASTER_LOG_FILE and MASTER_LOG_POS options are not updated per received event in master_info_file file.

The value of `master_use_gtid` is saved across server restarts (in master.info). The current value can be seen as the field Using_Gtid in the output of SHOW SLAVE STATUS.

For a detailed look at the difference between the *current_pos* and *slave_pos* options, see Using global transaction IDs

START SLAVE UNTIL master_gtid_pos=xxx

When starting replication with START SLAVE, it is possible to request the replica to run only until a specific GTID position is reached. Once that position is reached, the replica will stop.

The syntax for this is:

```
START SLAVE UNTIL master_gtid_pos = <GTID position>
```

The replica will start replication from the current GTID position, run up to and including the event with the GTID specified, and then stop. Note that this stops both the IO thread and the SQL thread (unlike START SLAVE UNTIL MASTER_LOG_FILE/MASTER_LOG_POS, which stops only the SQL thread).

If multiple GTIDs are specified, then they must be with distinct replication domain ID, for example:

```
START SLAVE UNTIL master_gtid_pos = "1-11-100,2-21-50"
```

With multiple domains in the UNTIL condition, each domain runs only up to and including the specified position, so it is possible for different domains to stop at different places in the binlog (each domain will resume from the stopped position when the replica is started the next time).

Not specifying a replication domain at all in the UNTIL condition means that the domain is stopped immediately, nothing is replicated from that domain. In particular, specifying the empty string will stop the replica immediately.

When using `START SLAVE UNTIL master_gtid_pos = XXX`, if the UNTIL position is present in the primary's binlog then it is permissible for the start position to be missing on the primary. In this case, replication for the associated domains stop immediately.

Both replica threads must be already stopped when using UNTIL master_gtid_pos, otherwise an error occurs. It is also an error if the replica is not configured to use GTID (`CHANGE MASTER TO master_use_gtid=current_pos|slave_pos`). And both threads must be started at the same time, the `IO_THREAD` or `SQL_THREAD` options can not be used to start only one of them.

`START SLAVE UNTIL master_gtid_pos=XXX` is particularly useful for promoting a new primary among a set of replicas when the old master goes away and replicas may have reached different positions in the old primary's binlog. The new primary needs to be ahead of all the other replicas to avoid losing events. This can be achieved by picking one server, say S1, and replicating any missing events from each other server S2, S3, ..., Sn:

```
CHANGE MASTER TO master_host="S2";
START SLAVE UNTIL master_gtid_pos = "<S2 GTID position>";
...
CHANGE MASTER TO master_host="Sn";
START SLAVE UNTIL master_gtid_pos = "<Sn GTID position>";
```

Once this is completed, S1 will have all events present on any of the servers. It can now be selected as the new primary, and all the other servers set to replicate from it.

MariaDB starting with 11.3.0

SQL_BEFORE_GTIDS|SQL_AFTER_GTIDS

MariaDB 11.3 extended the START SLAVE UNTIL command with the options `SQL_BEFORE_GTIDS` and `SQL_AFTER_GTIDS` to allow control of whether the replica stops before or after a provided GTID state. Its syntax is:

```
START SLAVE UNTIL (SQL_BEFORE_GTIDS|SQL_AFTER_GTIDS)="<gtid_list>"
```

When providing SQL_BEFORE_GTIDS="<gtid_list>", the replica will execute all transactions up to the first GTID found in the provided list, and stop immediately. In contrast to the default behavior of UNTIL, this will execute transactions from all domains on the primary until the replica stops due to seeing a GTID on the list.

START SLAVE UNTIL SQL_AFTER_GTIDS="<gtid_list>" is an alias to the default behavior of START SLAVE UNTIL master_gtid_pos="<gtid_list>". That is, the replica will only execute transactions originating from domain ids provided in the list, and will stop once all transactions provided in the UNTIL list have all been executed.

Example

If a primary server has a binary log consisting of the following GTIDs:

- 0-1-1
- 1-1-1
- 0-1-2
- 1-1-2
- 0-1-3
- 1-1-3

If a fresh replica (i.e. one with an empty GTID position, @@gtid_slave_pos='') is started with `SQL_BEFORE_GTIDS`, i.e. `START SLAVE UNTIL SQL_BEFORE_GTIDS="1-1-2"`, the resulting gtid_slave_pos of the replica will be "0-1-2,1-1-1". This is because the replica will execute all events until it sees the transaction with GTID 1-1-2 and immediately stop without executing it.

However, if a replica is started with `SQL_AFTER_GTIDS`, i.e. `START SLAVE UNTIL SQL_AFTER_GTIDS="1-1-2"` then the resulting gtid_slave_pos of the replica will be "1-1-2". This is because it will only execute events from domain 1 until it has executed the provided GTID.

BINLOG_GTID_POS().

The BINLOG_GTID_POS() function takes as input an old-style binary log position in the form of a file name and a file offset. It looks up the position in the current binlog, and returns a string representation of the corresponding GTID position. If the position is not found in the current binlog, NULL is returned.

MASTER_GTID_WAIT

The MASTER_GTID_WAIT function is useful in replication for controlling primary/replica synchronization, and blocks until the replica has read and applied all updates up to the specified position in the primary log. See MASTER_GTID_WAIT for details.

System Variables

`gtid_slave_pos`

This system variable contains the GTID of the last transaction applied to the database by the server's replica threads for each replication domain. This system variable's value is automatically updated whenever a replica thread applies an event group. This system variable's value can also be manually changed by users, so that the user can change the GTID position of the replica threads.

When using multi-source replication, the same GTID position is shared by all replica connections. In this case, different primaries should use different replication domains by configuring different gtid_domain_id values. If one primary was using a gtid_domain_id value of `1`, and if another primary was using a gtid_domain_id value of `2`, then any replicas replicating from both primaries would have GTIDs with both gtid_domain_id values in `gtid_slave_pos`.

This system variable's value can be manually changed by executing SET GLOBAL, but all replica threads to be stopped with STOP SLAVE first. For example:

```
STOP ALL SLAVES;
SET GLOBAL gtid_slave_pos = "1-10-100,2-20-500";
START ALL SLAVES;
```

This system variable's value can be reset by manually changing its value to the empty string. For example:

```
SET GLOBAL gtid_slave_pos = '';
```

The GTID position defined by `gtid_slave_pos` can be used as a replica's starting replication position by setting MASTER_USE_GTID=slave_pos when the replica is configured with the CHANGE MASTER TO statement. As an alternative, the gtid_current_pos system variable can also be used as a replica's starting replication position.

If a user sets the value of the `gtid_slave_pos` system variable, and gtid_binlog_pos contains later GTIDs for certain replication domains, then gtid_current_pos will contain the GTIDs from gtid_binlog_pos for those replication domains. To protect users in this scenario, if a user sets the `gtid_slave_pos` system variable to a GTID position that is behind the GTID position in gtid_binlog_pos, then the server will give the user a warning.

This can help protect the user when the replica is configured to use gtid_current_pos as its replication position. This can also help protect the user when a server has been rolled back to restart replication from an earlier point in time, but the user has forgotten to reset gtid_binlog_pos with RESET MASTER.

The mysql.gtid_slave_pos system table is used to store the contents of global.gtid_slave_pos and preserve it over restarts.

- **Commandline:** None
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default:** Null

`gtid_binlog_pos`

This variable is the GTID of the last event group written to the binary log, for each replication domain.

Note that when the binlog is empty (such as on a fresh install or after RESET MASTER), there are no event groups written in any replication domain, so in this case the value of `gtid_binlog_pos` will be the empty string.

The value is read-only, but it is updated whenever a DML or DDL statement is written to the binary log. The value can be reset by executing RESET MASTER, which will also delete all binary logs. However, note that RESET MASTER does not also reset gtid_slave_pos. Since gtid_current_pos is the union of gtid_slave_pos and `gtid_binlog_pos`, that means that new GTIDs added to `gtid_binlog_pos` can lag behind those in gtid_current_pos if gtid_slave_pos contains GTIDs in the same domain with higher sequence numbers. If you want to reset gtid_current_pos for a specific GTID domain in cases like this, then you will also have to change gtid_slave_pos in addition to executing RESET MASTER. See gtid_slave_pos for notes on how to change its value.

- **Commandline:** None
- **Scope:** Global
- **Dynamic:** Read-only
- **Data Type:** `string`
- **Default:** Null

`gtid_binlog_state`

The variable gtid_binlog_state holds the internal state of the binlog. The state consists of the last GTID ever logged to the binary log for every combination of domain_id and server_id. This information is used by the primary to determine whether a given GTID has been logged to the binlog in the past, even if it has later been deleted due to binlog purge. For each domain_id, the last entry in @@gtid_binlog_state is the last GTID logged into binlog, ie. this is the value that appears in @@gtid_binlog_pos.

Normally this internal state is not needed by users, as @@gtid_binlog_pos is more useful in most cases. The main usage of @@gtid_binlog_state is to restore the state of the binlog after RESET MASTER (or equivalently if the binlog files are lost). If the value of @@gtid_binlog_state is saved before RESET MASTER and restored afterwards, the primary will retain information about past history, same as if PURGE BINARY LOGS had been used (of course the actual events in the binary logs are still deleted).

Note that to set the value of @@gtid_binlog_state, the binary log must be empty, that is it must not contain any GTID events and the previous value of @@gtid_binlog_state must be the empty string. If not, then RESET MASTER must be used first to erase the binary log first.

The value of @@gtid_binlog_state is preserved by the server across restarts by writing a file MASTER-BIN.state, where MASTER-BIN is the base name of the binlog set with the --log-bin option. This file is written at server shutdown, and re-read at next server start. (In case of a server crash, the data in the MASTER-BIN.state is not correct, and the server instead recovers the correct value during binlog crash recovery by scanning the binlog files and recording each GTID found).

For completeness, note that setting @@gtid_binlog_state internally executes a RESET MASTER. This is normally not noticeable as it can only be changed when the binlog is empty of GTID events. However, if executed e.g. immediately after upgrading to MariaDB 10, it is possible that the binlog is non-empty but without any GTID events, in which case all such events will be deleted, just as if RESET MASTER had been run.

- **Commandline:** None
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default:** Null

`gtid_current_pos`

This system variable contains the GTID of the last transaction applied to the database for each replication domain.

The value of this system variable is constructed from the values of the gtid_binlog_pos and gtid_slave_pos system variables. It gets GTIDs of transactions executed locally from the value of the gtid_binlog_pos system variable. It gets GTIDs of replicated transactions from the value of the gtid_slave_pos system variable.

For each replication domain, if the server_id of the corresponding GTID in gtid_binlog_pos is equal to the servers own server_id, *and* the sequence number is higher than the corresponding GTID in gtid_slave_pos, then the GTID from gtid_binlog_pos will be used. Otherwise the GTID from gtid_slave_pos will be used for that domain.

GTIDs from gtid_binlog_pos in which the server_id of the GTID is **not** equal to the server's own server_id are effectively ignored. If gtid_binlog_pos contains a GTID for a given replication domain, but the server_id of the GTID is **not** equal to the server's own server_id, and gtid_slave_pos does **not** contain a GTID for that given replication domain, then `gtid_current_pos` will **not** contain any GTID for that replication domain.

Thus, `gtid_current_pos` contains the most recent GTID executed on the server, whether this was done as a primary or as a replica.

The GTID position defined by `gtid_current_pos` can be used as a replica's starting replication position by setting MASTER_USE_GTID=current_pos when the replica is configured with the CHANGE MASTER TO statement. As an alternative, the gtid_slave_pos system variable can also be used as a replica's starting replication position.

The value of `gtid_current_pos` is read-only, but it is updated whenever a transaction is written to the binary log and/or replicated by a replica thread, and that transaction's GTID is considered *newer* than the current GTID for that domain. See above for the rules on how to determine if a GTID would be considered *newer*.

If you need to reset the value, see the notes on resetting gtid_slave_pos and gtid_binlog_pos, since `gtid_current_pos` is formed from the values of those variables.

- **Commandline:** None
- **Scope:** Global
- **Dynamic:** Read-only
- **Data Type:** `string`
- **Default:** Null

`gtid_strict_mode`

The GTID strict mode is an optional setting that can be used to help the DBA enforce a strict discipline about keeping binlogs identical across multiple servers replicating using global transaction ID.

When GTID strict mode is enabled, some additional errors are enabled for situations that could otherwise cause differences between binlogs on different servers in a replication hierarchy:

1. If a replica server tries to replicate a GTID with a sequence number lower than what is already in the binlog for that replication domain, the SQL thread stops with an error (this indicates an extra transaction in the replica binlog not present on the primary).
2. Similarly, an attempt to manually binlog a GTID with a lower sequence number (by setting `@@SESSION.gtid_seq_no`) is rejected with an error.
3. If the replica tries to connect starting at a GTID that is missing in the primary's binlog, this is an error in GTID strict mode even if a GTID exists with a higher sequence number (this indicates a GTID on the replica missing on the primary). Note that this error is controlled by the setting of GTID strict mode on the connecting replica server.

GTID mode is off by default; this is needed to preserve backwards compatibility with existing replication setups (older versions of the server did not enforce any strict mode for binlog order). Global transaction ID is designed to work correctly even when strict mode is not enabled. However, with strict mode enforced, the semantics is simpler and thus easier to understand, because binlog order is always identical across servers and sequence numbers are always strictly increasing within each replication domain. This can also make automated scripting of large replication setups easier to implement correctly.

When GTID strict mode is enabled, the replica will stop with an error when a problem is encountered. This allows the DBA to become aware of the problem and take corrective actions to avoid similar issues in the future. One way to recover from such an error is to temporarily disable GTID strict mode on the offending replica, to be able to replicate past the problem

point (perhaps using `START SLAVE UNTIL master_gtid_pos=XXX`).

- **Commandline:** `--gtid-strict-mode[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default:** `Off`

---

gtid_domain_id

- **Description:** This variable is used to decide which replication domain new GTIDs are logged in for a primary server. See Use with multi-source replication and other multi-primary setups for details. This variable can also be set on the session level by a user with the SUPER privilege. This is used by mariadb-binlog to preserve the domain ID of GTID events.
- **Commandline:** `--gtid-domain-id=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric (32-bit unsigned integer)`
- **Default Value:** `0`
- **Range:** `0` to `4294967295`

---

last_gtid

- **Description:** Holds the GTID that was assigned to the last transaction, or statement that was logged to the binary log. If the binary log is disabled, or if no transaction or statement was executed in the session yet, then the value is an empty string.
- **Scope:** Session
- **Dynamic:** Read-only
- **Data Type:** `string`

---

server_id

- **Description:** Server_id can be set on the session level to change which server_id value is logged in binlog events (both GTID and other events). This is used by mariadb-binlog to preserve the server ID of GTID events.
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** numeric (32-bit unsigned integer)

---

gtid_seq_no

- **Description:** gtid_seq_no can be set on the session level to change which sequence number is logged in the following GTID event. The variable, along with @@gtid_domain_id and @@server_id, is typically used by mariadb-binlog to set up the gtid value of the transaction being decoded into the output.
- **Commandline:** None
- **Scope:** Session
- **Dynamic:** Yes
- **Data Type:** `numeric (64-bit unsigned integer)`
- **Default:** Null

---

gtid_ignore_duplicates

- **Description:** When set, different primary connections in multi-source replication are allowed to receive and process event groups with the same GTID (when using GTID mode). Only one will be applied, any others will be ignored. Within a given replication domain, just the sequence number will be used to decide whether a given GTID has been already applied; this means it is the responsibility of the user to ensure that GTID sequence numbers are strictly increasing. With gtid_ignore_duplicates=OFF, a duplicate event based on domain id and sequence number, will be executed. When --gtid-ignore-duplicate is set, a replica is allowed to connect at a GTID position that does not exist on the primary. The replica will start receiving events once a GTID with a higher sequence number is available on the primary (within that domain). This can be used to allow a replica to connect at a GTID position that was filtered on the primary, eg. using --replicate-ignore-table. See also Multiple Redundant Replication Paths
- **Commandline:** `--gtid-ignore-duplicates=#`

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default:** `OFF`

`gtid_pos_auto_engines`

This variable is used to enable multiple versions of the mysql.gtid_slave_pos table, one for each transactional storage engine in use. This can improve replication performance if a server is using multiple different storage engines in different transactions.

The value is a list of engine names, separated by commas (','). Replication of transactions using these engines will automatically create new versions of the mysql.gtid_slave_pos table in the same engine and use that for future transactions (table creation takes place in a background thread). This avoids introducing a cross-engine transaction to update the GTID position. Only transactional storage engines are supported for gtid_pos_auto_engines (this currently means InnoDB, TokuDB, or MyRocks).

The variable can be changed dynamically, but replica SQL threads should be stopped when changing it, and it will take effect when the replicas are running again.

When setting the variable on the command line or in a configuration file, it is possible to specify engines that are not enabled in the server. The server will then still start if, for example, that engine is no longer used. Attempting to set a non-enabled engine dynamically in a running server (with SET GLOBAL gtid_pos_auto_engines) will still result in an error.

Removing a storage engine from the variable will have no effect once the new tables have been created - as long as these tables are detected, they will be used.

- **Commandline:** `--gtid-pos-auto-engines=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string` (comma-separated list of engine names)
- **Default:** empty

`gtid_cleanup_batch_size`

- **Description:** Normally does not need tuning. How many old rows must accumulate in the mysql.gtid_slave_pos table before a background job will be run to delete them. Can be increased to reduce number of commits if using many different engines with gtid_pos_auto_engines, or to reduce CPU overhead if using a huge number of different gtid_domain_ids. Can be decreased to reduce number of old rows in the table.
- **Commandline:** `--gtid-cleanup-batch-size=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default:** `64`
- **Range:** `0` to `2147483647`
- **Introduced:** MariaDB 10.4.1

3.1.10 Parallel Replication

> The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Contents

Some writes, replicated from the primary can be executed in parallel (simultaneously) on the replica. Note that for parallel replication to work, both the primary and replica need to be MariaDB 10.0.5 or later.

Parallel Replication Overview

MariaDB replication in general takes place in three parts:

- Replication events are read from the primary by the IO thread and queued in the relay log.
- Replication events are fetched one at a time by the SQL thread from the relay log
- Each event is applied on the replica to replicate all changes done on the primary.

Before MariaDB 10, the third step was also performed by the SQL thread; this meant that only one event could execute at a time, and replication was essentially single-threaded. Since MariaDB 10, the third step can optionally be performed by a pool of separate replication worker threads, and thereby potentially increase replication performance by applying multiple events in parallel.

How to Enable Parallel Replica

To enable, specify slave-parallel-threads=# in your my.cnf file as an argument to mysql. Parallel replication can in addition be disabled on a per-multi-source connection by setting @@connection_name.slave-parallel-mode to "none".

The value (#) of slave_parallel_threads specifies how many threads will be created in a pool of worker threads used to apply events in parallel for *all* your replicas (this includes multi-source replication). If the value is zero, then no worker threads are created, and old-style replication is used where events are applied inside the SQL thread. Usually the value, if non-zero, should be at least two times the number of multi-source primary connections used. It makes little sense to use only a single worker thread for one connection; this will incur some overhead in inter-thread communication between the SQL thread and the worker thread, but with just a single worker thread events can not be applied in parallel anyway.

`slave-parallel-threads=#` is a dynamic variable that can be changed without restarting mysqld. All replicas connections must however be stopped when changing the value.

Configuring the Replica Parallel Mode

Parallel replication can be in-order or out-of-order:

- In-order executes transactions in parallel, but orders the commit step of the transactions to happen in the exact same order as on the primary. Transactions are only executed in parallel to the extent that this can be automatically verified to be possible without any conflicts. This means that the use of parallelism is completely transparent to the application.
- Out-of-order can execute and commit transactions in different order on the replica than originally on the primary. This means that the application must be tolerant to seeing updates occur in different order. The application is also responsible for ensuring that there are no conflicts between transactions that are replicated out-of-order. Out-of-order is only used in GTID mode and only when explicitly enabled by the application, using the replication domain that is part of the GTID.

In-Order Parallel Replication

Optimistic Mode of In-Order Parallel Replication

Optimistic mode of in-order parallel replication provides a lot of opportunities for parallel apply on the replica while still

preserving exact transaction semantics from the point of view of applications. It is the default mode from MariaDB 10.5.1.

Optimistic mode of in-order parallel replication can be configured by setting the slave_parallel_mode system variable to `optimistic` on the replica.

Any transactional DML (INSERT/UPDATE/DELETE) is allowed to run in parallel, up to the limit of @@slave_domain_parallel_threads. This may cause conflicts on the replica, eg. if two transactions try to modify the same row. Any such conflict is detected, and the latter of the two transactions is rolled back, allowing the former to proceed. The latter transaction is then re-tried once the former has completed.

The term "optimistic" is used for this mode, because the server optimistically assumes that few conflicts will occur, and that the extra work spent rolling back and retrying conflicting transactions is justified from the gain from running most transactions in parallel.

There are a few heuristics to try to avoid needless conflicts. If a transaction executed a row lock wait on the primary, it will not be run in parallel on the replica. Transactions can also be marked explicitly as potentially conflicting on the primary, by setting the variable @@skip_parallel_replication. More such heuristics may be added in later MariaDB versions. There is a further --slave-parallel-mode called "aggressive", where these heuristics are disabled, allowing even more transactions to be applied in parallel.

Non-transactional DML and DDL is not safe to optimistically apply in parallel, as it cannot be rolled back in case of conflicts. Thus, in optimistic mode, non-transactional (such as MyISAM) updates are not applied in parallel with earlier events (it is however possible to apply a MyISAM update in parallel with a later InnoDB update). DDL statements are not applied in parallel with any other transactions, earlier or later.

The different kind of transactions can be identified in the output of mariadb-binlog. For example:

```
#150324 13:06:26 server id 1  end_log_pos 6881  GTID 0-1-42 ddl
...
#150324 13:06:26 server id 1  end_log_pos 7816  GTID 0-1-47
...
#150324 13:06:26 server id 1  end_log_pos 8177  GTID 0-1-49 trans
/*!100101 SET @@session.skip_parallel_replication=1*//*!*/;
...
#150324 13:06:26 server id 1  end_log_pos 9836  GTID 0-1-59 trans waited
```

GTID 0-1-42 is marked as being DDL. GTID 0-1-47 is marked as being non-transactional DML, while GTID 0-1-49 is transactional DML (seen on the "trans" keyword). GTID 0-1-49 was additionally run with @@skip_parallel_replication set on the primary. GTID 0-1-59 is transactional DML that had a row lock wait when run on the primary (the "waited" keyword).

Aggressive Mode of In-Order Parallel Replication

Aggressive mode of in-order parallel replication is very similar to optimistic mode. The main difference is that the replica does not consider whether transactions conflicted on the primary when deciding whether to apply the transactions in parallel.

Aggressive mode of in-order parallel replication can be configured by setting the slave_parallel_mode system variable to `aggressive` on the replica.

Conservative Mode of In-Order Parallel Replication

Conservative mode of in-order parallel replication uses the group commit on the primary to discover potential for parallel apply of events on the replica. If two transactions commit together in a group commit on the primary, they are written into the binlog with the same commit id. Such events are certain to not conflict with each other, and they can be scheduled by the parallel replication to run in different worker threads.

Conservative mode of in-order parallel replication is the default mode until MariaDB 10.5.0, but it can also be configured by setting the slave_parallel_mode system variable to `conservative` on the replica.

Two transactions that were committed separately on the primary can potentially conflict (eg. modify the same row of a table). Thus, the worker that applies the second transaction will not start immediately, but wait until the first transaction begins the commit step; at this point it is safe to start the second transaction, as it can no longer disrupt the execution of the first one.

Here is example output from mariadb-binlog that shows how GTID events are marked with commit id. The GTID 0-1-47 has no commit id, and can not run in parallel. The GTIDs 0-1-48 and 0-1-49 have the same commit id 630, and can thus replicate in parallel with one another on a replica:

```
#150324 12:54:24 server id 1  end_log_pos 20052  GTID 0-1-47 trans
...
#150324 12:54:24 server id 1  end_log_pos 20212  GTID 0-1-48 cid=630 trans
...
#150324 12:54:24 server id 1  end_log_pos 20372  GTID 0-1-49 cid=630 trans
```

In either case, when the two transactions reach the point where the low-level commit happens and commit order is determined, the two commits are sequenced to happen in the same order as on the primary, so that operation is transparent to applications.

The opportunities for parallel replication on replicas can be highly increased if more transactions are committed in a group commit on the primary. This can be tuned using the binlog_commit_wait_count and binlog_commit_wait_usec variables. If for example the application can tolerate up to 50 milliseconds extra delay for transactions on the primary, one can set `binlog_commit_wait_usec=50000` and `binlog_commit_wait_count=20` to get up to 20 transactions at a time available for replication in parallel. Care must however be taken to not set `binlog_commit_wait_usec` too high, as this could cause significant slowdown for applications that run a lot of small transactions serially one after the other.

Note that even if there is no parallelism available from the primary group commit, there is still an opportunity for speedup from in-order parallel replication, since the actual commit steps of different transactions can run in parallel. This can be particularly effective on a replica with binlog enabled (log_slave_updates=1), and more so if replica is configured to be crash-safe (sync_binlog=1 and innodb_flush_log_at_trx_commit=1), as this makes group commit possible on the replica.

Minimal Mode of In-Order Parallel Replication

Minimal mode of in-order parallel replication *only* allows the commit step of transactions to be applied in parallel; all other steps are applied serially.

Minimal mode of in-order parallel replication can be configured by setting the slave_parallel_mode system variable to `minimal` on the replica.

Out-of-Order Parallel Replication

Out-of-order parallel replication happens (only) when using GTID mode, when GTIDs with different replication domains are used. The replication domain is set by the DBA/application using the variable `gtid_domain_id`.

Two transactions having GTIDs with different domain_id are scheduled to different worker threads by parallel replication, and are allowed to execute completely independently from each other. It is the responsibility of the application to only set different domain_ids for transactions that are truly independent, and are guaranteed to not conflict with each other. The application must also be able to work correctly even though the transactions with different domain_id are seen as committing in different order between the replica and the primary, and between different replicas.

Out-of-order parallel replication can potentially give more performance gain than in-order parallel replication, since the application can explicitly give more opportunities for running transactions in parallel than what the server can determine on its own automatically.

One simple but effective usage is to run long-running statements, such as ALTER TABLE, in a separate replication domain. This allows replication of other transactions to proceed uninterrupted:

```
SET SESSION gtid_domain_id=1
ALTER TABLE t ADD INDEX myidx(b)
SET SESSION gtid_domain_id=0
```

Normally, a long-running ALTER TABLE or other query will stall all following transactions, causing the replica to become behind the primary as least as long time as it takes to run the long-running query. By using out-of-order parallel replication by setting the replication domain id, this can be avoided. The DBA/application must ensure that no conflicting transactions will be replicated while the ALTER TABLE runs.

Another common opportunity for out-of-order parallel replication comes in connection with multi-source replication. Suppose we have two different primaries M1 and M2, and we are using multi-source replication to have S1 as a replica of both M1 and M2. S1 will apply events received from M1 in parallel with events received from M2. If we now have a third-level replica S2 that replicates from S1 as primary, we want S2 to also be able to apply events that originated on M1 in parallel with events that originated on M2. This can be achieved with out-of-order parallel replication, by setting `gtid_domain_id` different on M1 and M2.

Note that there are no special restrictions on what operations can be replicated in parallel using out-of-order; such operations can be on the same database/schema or even on the same table. The only restriction is that the operations must not conflict, that is they must be able to be applied in any order and still end up with the same result.

When using out-of-order parallel replication, the current replica position in the primary's binlog becomes multi-dimensional - each replication domain can have reached a different point in the primary binlog at any one time. The current position can be seen from the variable `gtid_slave_pos`. When the replica is stopped, restarted, or switched to replicate from a different primary using CHANGE MASTER, MariaDB automatically handles restarting each replication domain at the appropriate point in the binlog.

Out-of-order parallel replication is disabled when --slave-parallel-mode=minimal (or none).

Checking Worker Thread Status in SHOW PROCESSLIST

The worker threads will be listed as "system user" in SHOW PROCESSLIST. Their state will show the query they are currently working on, or it can show one of these:

- "Waiting for work from main SQL threads". This means that the worker thread is idle, no work is available for it at the moment.
- "Waiting for prior transaction to start commit before starting next transaction". This means that the previous batch of transactions that committed together on the primary primary has to complete first. This worker thread is waiting for that to happen before it can start working on the following batch.
- "Waiting for prior transaction to commit". This means that the transaction has been executed by the worker thread. In order to ensure in-order commit, the worker thread is waiting to commit until the previous transaction is ready to commit before it.

Expected Performance Gain

Here is an article showing up to ten times improvement when using parallel replication: http://kristiannielsen.livejournal.com/18435.html.

Configuring the Maximum Size of the Parallel Replica Queue

The slave_parallel_max_queued system variable can be used to configure the maximum size of the parallel replica queue. This system variable is only meaningful when parallel replication is configured (i.e. when slave_parallel_threads > `0`).

When parallel replication is used, the SQL thread will read ahead in the relay logs, queueing events in memory while looking for opportunities for executing events in parallel. The slave_parallel_max_queued system variable sets a limit for how much memory it will use for this.

The configured value of the slave_parallel_max_queued system variable is actually allocated for each worker thread, so the total allocation is actually equivalent to the following:

slave_parallel_max_queued * slave_parallel_threads

If this value is set too high, and the replica is far (eg. gigabytes of binlog) behind the primary, then the SQL thread can quickly read all of that and fill up memory with huge amounts of binlog events faster than the worker threads can consume them.

On the other hand, if set too low, the SQL thread might not have sufficient space for queuing enough events to keep the worker threads busy, which could reduce performance. In this case, the SQL thread will have the thread state that states `Waiting for room in worker thread event queue`. For example:

```
+----+-------------+-----------+------+---------+--------+----------------------------------
------------+------------------+----------+
| Id | User        | Host      | db   | Command | Time   | State
| Info             | Progress |
+----+-------------+-----------+------+---------+--------+----------------------------------
------------+------------------+----------+
|  3 | system user |           | NULL | Connect |    139 | closing tables
| NULL             |    0.000 |
|  4 | system user |           | NULL | Connect |    139 | Waiting for work from SQL thread
| NULL             |    0.000 |
|  6 | system user |           | NULL | Connect | 264274 | Waiting for master to send event
| NULL             |    0.000 |
| 10 | root        | localhost | NULL | Sleep   |     43 |
| NULL             |    0.000 |
| 21 | system user |           | NULL | Connect |     45 | Waiting for room in worker thread
event queue | NULL             |    0.000 |
| 54 | root        | localhost | NULL | Query   |      0 | init
| SHOW PROCESSLIST |    0.000 |
+----+-------------+-----------+------+---------+--------+----------------------------------
------------+------------------+----------+
```

The slave_parallel_max_queued system variable does not define a hard limit, since the binary log events that are currently executing always need to be held in-memory. This means that at least two events per worker thread can always be queued in-memory, regardless of the value of slave_parallel_threads.

Usually, the slave_parallel_threads system variable should be set large enough that the SQL thread is able to read far enough ahead in the binary log to exploit all possible parallelism. In normal operation, the replica will hopefully not be too far behind, so there will not be a need to queue much data in-memory. The slave_parallel_max_queued system variable could be set fairly high (eg. a few hundred kilobytes) to not limit throughput. It should just be set low enough that total allocation of the parallel replica queue will not cause the server to run out of memory.

Configuration Variable slave_domain_parallel_threads

The pool of replication worker threads is shared among all multi-source primary connections, and among all replication domains that can replicate in parallel using out-of-order.

If one primary connection or replication domain is currently processing a long-running query, it is possible that it will allocate all the worker threads in the pool, only to have them wait for the long-running query to complete, stalling any other primary connection or replication domain, which will have to wait for a worker thread to become free.

This can be avoided by setting slave_domain_parallel_threads to a number that is lower than `slave_parallel_threads`. When set different from zero, each replication domain in one primary connection can reserve at most that many worker threads at any one time, leaving the rest (up to the value of slave_parallel_threads) free for other primary connections or replication domains to use in parallel.

The `slave_domain_parallel_threads` variable is dynamic and can be changed without restarting the server; all replicas must be stopped while changing it, though.

Implementation Details

The implementation is described in MDEV-4506.

3.1.11 Replication and Binary Log System Variables

The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

This page lists system variables that are related to binary logging and replication.

See Server System Variables for a complete list of system variables and instructions on setting them, as well as System variables for global transaction ID.

Also see mariadbd replication options for related options that are not system variables (such as binlog_do_db and binlog_ignore_db).

See also the Full list of MariaDB options, system and status variables.

auto_increment_increment

- **Description:** The increment for all AUTO_INCREMENT values on the server, by default `1`. Intended for use in primary-to-primary replication.
- **Commandline:** `--auto-increment-increment[=#]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `1`
- **Range:** `1` to `65535`

---

auto_increment_offset

- **Description:** The offset for all AUTO_INCREMENT values on the server, by default `1`. Intended for use in primary-to-primary replication. Should be not be larger than auto_increment_increment. See AUTO_INCREMENT#Replication.
- **Commandline:** `--auto-increment-offset[=#]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `1`
- **Range:** `1` to `65535`

---

binlog_alter_two_phase

- **Description:** When set, split ALTER at binary logging into two statements: START ALTER and COMMIT/ROLLBACK ALTER. The ON setting is recommended for long-running ALTER-table so it could start on replica before its actual execution on primary.
- **Commandline:** `--binlog-alter-two-phase[={0|1}]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`
- **Introduced:** MariaDB 10.8.1

---

binlog_annotate_row_events

- **Description:** This option tells the primary to write annotate_rows_events to the binary log.
- **Commandline:** `--binlog-annotate-row-events[={0|1}]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** boolean
- **Default Value:**
  - `ON` (>= MariaDB 10.2.4)
  - `OFF` (<= MariaDB 10.2.3)

binlog_do_db

- **Description:** This option allows you to configure a replication primary to write statements and transactions affecting databases that match a specified name into its binary log. Since the filtered statements or transactions will not be present in the binary log, its replicas will not be able to replicate them.
  - This option will **not** work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.
  - Until MariaDB 11.2.0, only available as an option, not a system variable. This option can **not** be set

dynamically.
    - When setting it on the command-line or in a server option group in an option file, the option does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the option multiple times.
    - See Replication Filters for more information.
- **Commandline:** `--binlog-do-db=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** NULL
- **Introduced:** MariaDB 11.2.0 (as a system variable)

---

binlog_cache_size

- **Description:** If the binary log is active, this variable determines the size in bytes, per-connection, of the cache holding a record of binary log changes during a transaction. A separate variable, binlog_stmt_cache_size, sets the upper limit for the statement cache. The binlog_cache_disk_use and binlog_cache_use server status variables will indicate whether this variable needs to be increased (you want a low ratio of binlog_cache_disk_use to binlog_cache_use).
- **Commandline:** `--binlog-cache-size=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `32768`
- **Range - 32 bit:** `4096` to `4294967295`
- **Range - 64 bit:** `4096` to `18446744073709547520`

---

binlog_checksum

- **Description:** Specifies the type of BINLOG_CHECKSUM_ALG for log events in the binary log.
- **Commandline:**
    - `--binlog-checksum=name`
    - `--binlog-checksum=[0|1]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:**
    - `CRC32` (>= MariaDB 10.2.1)
    - `NONE` (<= MariaDB 10.2.0)
- **Valid Values:** `NONE` (`0`), `CRC32` (`1`)

---

binlog_commit_wait_count

- **Description:** Configures the behavior of group commit for the binary log, which can help increase transaction throughput and is used to enable conservative mode of in-order parallel replication . With group commit for the binary log, the server can delay flushing a committed transaction into binary log until the given number of transactions are ready to be flushed as a group. The delay will however not be longer than the value set by binlog_commit_wait_usec. The default value of 0 means that no delay is introduced. Setting this value can reduce I/O on the binary log and give an increased opportunity for parallel apply on the replica when conservative mode of in-order parallel replication is enabled, but too high a value will decrease the transaction throughput. By monitoring the status variable binlog_group_commit_trigger_count (>=MariaDB 10.1.5) it is possible to see how often this is occurring.
- Starting with MariaDB 10.0.18 and MariaDB 10.1.4: If the server detects that one of the committing transactions T1 holds an InnoDB row lock that another transaction T2 is waiting for, then the commit will complete immediately without further delay. This helps avoid losing throughput when many transactions need conflicting locks. This often makes it safe to use this option without losing throughput on a replica with conservative mode of in-order parallel replication, provided the value of slave_parallel_threads is sufficiently high.
- **Commandline:** `--binlog-commit-wait-count=#]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` to `18446744073709551615`

binlog_commit_wait_usec

- **Description:** Configures the behavior of group commit for the binary log, which can help increase transaction throughput and is used to enable conservative mode of in-order parallel replication. With group commit for the binary log, the server can delay flushing a committed transaction into binary log until the transaction has waited the configured number of microseconds. By monitoring the status variable binlog_group_commit_trigger_timeout (>=MariaDB 10.1.5) it is possible to see how often group commits are made due to `binlog_commit_wait_usec`. As soon as the number of pending commits reaches binlog_commit_wait_count, the wait will be terminated, though. Thus, this setting only takes effect if `binlog_commit_wait_count` is non-zero.
- **Commandline:** `--binlog-commit-wait-usec#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `100000`
- **Range:** `0` to `18446744073709551615`

binlog_direct_non_transactional_updates

- **Description:** Replication inconsistencies can occur due when a transaction updates both transactional and non-transactional tables and the updates to the non-transactional tables are visible before being written to the binary log. This is because, to preserve causality, the non-transactional statements are written to the transaction cache, which is only flushed on commit. Setting binlog_direct_non_transactional_updates to 1 (0 is default) will cause non-transactional tables to be written straight to the binary log, rather than the transaction cache. This setting has no effect when row-based binary logging is used, as it requires statement-based logging. See binlog_format. Use with care, and only in situations where no dependencies exist between the non-transactional and transactional tables, for example INSERTing into a non-transactional table based upon the results of a SELECT from a transactional table.
- **Commandline:** `--binlog-direct-non-transactional-updates[=value]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF (0)`

binlog_expire_logs_seconds

- **Description:** If non-zero, binary logs will be purged after `binlog_expire_logs_seconds` seconds. Possible purges happen at startup and at binary log rotation. From MariaDB 10.6.1, `binlog_expire_logs_seconds` and expire_logs_days are forms of aliases, such that changes to one automatically reflect in the other.
- **Commandline:** `--binlog-expire-logs-seconds=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` to `4294967295`
- **Introduced:** MariaDB 10.6.1

binlog_file_cache_size

- **Description:** Size of in-memory cache that is allocated when reading binary log and relay log files.
- **Commandline:** `--binlog-file-cache-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `16384`
- **Range:** `8192` to `18446744073709551615`
- **Introduced:** MariaDB 10.3.3

binlog_format

- **Description:** Determines whether replication is row-based, statement-based or mixed. Statement-based was the default until MariaDB 10.2.3. Be careful of changing the binary log format when a replication environment is

already running. See Binary Log Formats. Starting from MariaDB 10.0.22 a replica will apply any events it gets from the primary, regardless of the binary log format. `binlog_format` only applies to normal (not replicated) updates.

- **Commandline:** `--binlog-format=format`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `enumeration`
- **Default Value:**
  - `MIXED` (>= MariaDB 10.2.4)
  - `STATEMENT` (<= MariaDB 10.2.3)
- **Valid Values:** `ROW`, `STATEMENT` or `MIXED`

---

binlog_ignore_db

- **Description:** This option allows you to configure a replication primary to **not** write statements and transactions affecting databases that match a specified name into its binary log. Since the filtered statements or transactions will not be present in the binary log, its replicas will not be able to replicate them.
  - This option will **not** work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.
  - Until MariaDB 11.2.0, only available as an option, not a system variable. This option can **not** be set dynamically.
  - When setting it on the command-line or in a server option group in an option file, the option does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the option multiple times.
  - See Replication Filters for more information.
- **Commandline:** `--binlog-ignore-db=name`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** NULL
- **Introduced:** MariaDB 11.2.0

---

binlog_optimize_thread_scheduling

- **Description:** Run fast part of group commit in a single thread, to optimize kernel thread scheduling. On by default. Disable to run each transaction in group commit in its own thread, which can be slower at very high concurrency. This option is mostly for testing one algorithm versus another, and it should not normally be necessary to change it.
- **Commandline:** `--binlog-optimize-thread-scheduling` or `--skip-binlog-optimize-thread-scheduling`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `ON`

---

binlog_row_event_max_size

- **Description:** The maximum size of a row-based binary log event in bytes. Rows will be grouped into events smaller than this size if possible. The value has to be a multiple of 256. Until MariaDB 11.2.0, only available as an option, not a system variable.
- **Commandline:** `--binlog-row-event-max-size=val`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `8192`
- **Range:** `256` to `4294967040` (in multiples of 256)
- **Introduced:** MariaDB 11.2.0

---

binlog_row_image

- **Description:** Controls whether, in row-based replication, rows should be logged in 'FULL', 'NOBLOB' or 'MINIMAL' formats. In row-based replication (the variable has no effect with statement-based replication), each row change event contains an image for matching against when choosing the row to be updated, and another image containing the changes. Before the introduction of this variable, all columns were logged for both of these images. In certain circumstances, this is not necessary, and memory, disk and network resources can be saved by partial logging. Note

that to safely change this setting from the default, the table being replicated to must contain identical primary key definitions, and columns must be present, in the same order, and use the same data types as the original table. If these conditions are not met, matches may not be correctly determined and updates and deletes may diverge on the replica, with no warnings or errors returned.
    - `FULL` : All columns in the before and after image are logged. This is the default, and the only behavior in earlier versions.
    - `NOBLOB` : mariadbd avoids logging blob and text columns whenever possible (eg, blob column was not changed or is not part of primary key).
    - `MINIMAL` : A PK equivalent (PK columns or full row if there is no PK in the table) is logged in the before image, and only changed columns are logged in the after image.
- **Commandline:** `--binlog-row-image=value`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `enum`
- **Default Value:** `FULL`
- **Valid Values:** `FULL`, `NOBLOB` or `MINIMAL`

---

binlog_row_metadata

- **Description:** Controls the format used for binlog metadata logging.
    - `NO_LOG` : No metadata is logged (default).
    - `MINIMAL` : Only metadata required by a replica is logged.
    - `FULL` : All metadata is logged.
- **Commandline:** `--binlog-row-metadata=value`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `enum`
- **Default Value:** `NO_LOG`
- **Valid Values:** `NO_LOG`, `MINIMAL`, `FULL`
- **Introduced:** MariaDB 10.5.0

---

binlog_stmt_cache_size

- **Description:** If the binary log is active, this variable determines the size in bytes of the cache holding a record of binary log changes outside of a transaction. The variable binlog_cache_size, determines the cache size for binary log statements inside a transaction. The binlog_stmt_cache_disk_use and binlog_stmt_cache_use server status variables will indicate whether this variable needs to be increased (you want a low ratio of binlog_stmt_cache_disk_use to binlog_stmt_cache_use).
- **Commandline:** `--binlog-stmt-cache-size=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `32768`
- **Range - 32 bit:** `4096` to `4294967295`
- **Range - 64 bit:** `4096` to `18446744073709547520`

---

default_master_connection

- **Description:** In multi-source replication, specifies which connection will be used for commands and variables if you don't specify a connection.
- **Commandline:** None
- **Scope:** Session
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `''` (empty string)

---

encrypt_binlog

- **Description:** Encrypt binary logs (including relay logs). See Data at Rest Encryption and Encrypting Binary Logs.
- **Commandline:** `--encrypt-binlog[={0|1}]`
- **Scope:** Global

- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

expire_logs_days

- **Description:** Number of days after which the binary log can be automatically removed. By default 0, or no automatic removal. When using replication, should always be set higher than the maximum lag by any replica. Removals take place when the server starts up, when the binary log is flushed, when the next binary log is created after the previous one reaches the maximum size, or when running PURGE BINARY LOGS. Units are whole days (integer) until MariaDB 10.6.0, or 1/1000000 precision (double) from MariaDB 10.6.1.
  Starting from MariaDB 10.6.1, `expire_logs_days` and binlog_expire_logs_seconds are forms of aliases, such that changes to one automatically reflect in the other.
- **Commandline:** `--expire-logs-days=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0.000000` (>= MariaDB 10.6.1), `0` (<= MariaDB 10.6.0)
- **Range:** `0` to `99`

---

init_slave

- **Description:** Similar to init_connect, but the string contains one or more SQL statements, separated by semicolons, that will be executed by a replica server each time the SQL thread starts. These statements are only executed after the acknowledgement is sent to the replica and START SLAVE completes.
- **Commandline:** `--init-slave=name`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string`
- **Related variables:** `init_connect`

---

log_bin

- **Description:** Whether binary logging is enabled or not. If the --log-bin option is used, log_bin will be set to ON, otherwise it will be OFF. If no `name` option is given for `--log-bin`, `datadir/'log-basename'-bin` or `'datadir'/mysql-bin` will be used (the latter if --log-basename is not specified). We strongly recommend you use either `--log-basename` or specify a filename to ensure that replication doesn't stop if the real hostname of the computer changes. The name option can optionally include an absolute path. If no path is specified, the log will be written to the data directory. The name can optionally include the file extension; it will be stripped and only the file basename will be used.
- **Commandline:** `--log-bin[=name]`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `OFF`
- **Related variables:** `sql_log_bin`

---

log_bin_basename

- **Description:** The full path of the binary log file names, excluding the extension. Its value is derived from the rules specified in `log_bin` system variable. This is a read-only variable only, there is no corresponding configuration file setting or command line option by the same name, use `log_bin` to set the basename path instead.
- **Commandline:** `No commandline option`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** None
- **Dynamic:** `No`

---

log_bin_compress

- **Description:** Whether or not the binary log can be compressed. `0` (the default) means no compression. See Compressing Events to Reduce Size of the Binary Log.
- **Commandline:** `--log-bin-compress`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

log_bin_compress_min_len

- **Description:** Minimum length of sql statement (in statement mode) or record (in row mode) that can be compressed. See Compressing Events to Reduce Size of the Binary Log.
- **Commandline:** `--log-bin-compress-min-len`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `256`
- **Range:** `10` to `1024`

---

log_bin_index

- **Description:** File that holds the names for last binlog files.
- **Commandline:** `--log-bin-index=name`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** None

---

log_bin_trust_function_creators

- **Description:** Functions and triggers can be dangerous when used with replication. Certain types of functions and triggers may have unintended consequences when the statements are applied on a replica. For that reason, there are some restrictions on the creation of functions and triggers when the binary log is enabled by default, such as:
  - When `log_bin_trust_function_creators` is `OFF` and `log_bin` is `ON`, `CREATE FUNCTION` and `ALTER FUNCTION` statements will trigger an error if the function is defined with any of the `NOT DETERMINISTIC`, `CONTAINS SQL` or `MODIFIES SQL DATA` characteristics.
  - This means that when `log_bin_trust_function_creators` is `OFF` and `log_bin` is `ON`, `CREATE FUNCTION` and `ALTER FUNCTION` statements will only succeed if the function is defined with any of the `DETERMINISTIC`, `NO SQL`, or `READS SQL DATA` characteristics.
  - When `log_bin_trust_function_creators` is `OFF` and `log_bin` is `ON`, the `SUPER` privilege is also required to execute the following statements:
    - `CREATE FUNCTION`
    - `CREATE TRIGGER`
    - `DROP TRIGGER`
  - Setting `log_bin_trust_function_creators` to `ON` removes these requirements around functions characteristics and the `SUPER` privileges.
  - See Binary Logging of Stored Routines for more information.
- **Commandline:** `--log-bin-trust-function-creators[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

log_slow_slave_statements

- **Description:** Log slow statements executed by replica thread to the slow log if it is open. Before MariaDB 10.1.13, this was only available as a mariadbd option, not a server variable.
- **Commandline:** `--log-slow-slave-statements`
- **Scope:** Global

- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:**
  - `ON` (>= MariaDB 10.2.4)
  - `OFF` (<= MariaDB 10.2.3)

---

log_slave_updates

- **Description:** If set to `0`, the default, updates on a replica received from a primary during replication are not logged in the replica's binary log. If set to `1`, they are. The replica's binary log needs to be enabled for this to have an effect. Set to `1` if you want to daisy-chain the replicas.
- **Commandline:** `--log-slave-updates`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

master_verify_checksum

- **Description:** Verify binlog checksums when reading events from the binlog on the primary.
- **Commandline:** `--master-verify-checksum=[0|1]`
- **Scope:** Global
- **Access Type:** Can be changed dynamically
- **Data Type:** `bool`
- **Default Value:** `OFF (0)`

---

max_binlog_cache_size

- **Description:** Restricts the size in bytes used to cache a multi-transactional query. If more bytes are required, a `Multi-statement transaction required more than 'max_binlog_cache_size' bytes of storage` error is generated. If the value is changed, current sessions are unaffected, only sessions started subsequently. See max_binlog_stmt_cache_size and binlog_cache_size.
- **Commandline:** `--max-binlog-cache-size=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `18446744073709547520`
- **Range:** `4096` to `18446744073709547520`

---

max_binlog_size

- **Description:** If the binary log exceeds this size after a write, the server rotates it by closing it and opening a new binary log. Single transactions will always be stored in the same binary log, so the server will wait for open transactions to complete before rotating. This figure also applies to the size of relay logs if max_relay_log_size is set to zero.
- **Commandline:** `--max-binlog-size=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `1073741824` (1GB)
- **Range:** `4096 to 1073741824` (4KB to 1GB)

---

max_binlog_stmt_cache_size

- **Description:** Restricts the size used to cache non-transactional statements. See max_binlog_cache_size and binlog_stmt_cache_size.
- **Commandline:** `--max-binlog-stmt-cache-size=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`

- **Default Value:** `18446744073709547520` (64 bit), `4294963200` (32 bit)
- **Range:** `4096` to `18446744073709547520`

---

max_relay_log_size

- **Description:** Replica will rotate its relay log if it exceeds this size after a write. If set to 0, the max_binlog_size setting is used instead. Previously global only, since the implementation of multi-source replication, it can be set per session as well.
- **Commandline:** `--max-relay-log-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` , or `4096 to 1073741824` (4KB to 1GB)

---

read_binlog_speed_limit

- **Description:** Used to restrict the speed at which a replica can read the binlog from the primary. This can be used to reduce the load on a primary if many replicas need to download large amounts of old binlog files at the same time. The network traffic will be restricted to the specified number of kilobytes per second.
- **Commandline:** `--read-binlog-speed-limit=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0` (no limit)
- **Range:** `0` to `18446744073709551615`

---

relay_log

- **Description:** Relay log basename. If not set, the basename of the files will be `hostname-relay-bin` .
- **Commandline:** `--relay-log=file_name`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `filename`
- **Default Value:** `''` (none)

---

relay_log_basename

- **Description:** The full path of the relay log file names, excluding the extension. Its value is derived from the relay-log variable value.
- **Commandline:** `No commandline option`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** None
- **Dynamic:** `No`

---

relay_log_index

- **Description:** Name and location of the relay log index file, the file that keeps a list of the last relay logs. Defaults to *hostname*-relay-bin.index.
- **Commandline:** `--relay-log-index=name`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** None

---

relay_log_info_file

- **Description:** Name and location of the file where the `RELAY_LOG_FILE` and `RELAY_LOG_POS` options (i.e. the relay log position) for the CHANGE MASTER statement are written. The replica's SQL thread keeps this relay log position updated as it applies events.
  - See CHANGE MASTER TO: Option Persistence for more information.
- **Commandline:** `--relay-log-info-file=file_name`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** `relay-log.info`

---

relay_log_purge

- **Description:** If set to `1` (the default), relay logs will be purged as soon as they are no longer necessary.
- **Commandline:** `--relay-log-purge={0|1}`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `ON`
- **Note:** In MySQL and in MariaDB before version 10.0.8 this variable was silently changed if you did CHANGE MASTER.

---

relay_log_recovery

- **Description:** If set to `1` (`0` is default), on startup the replica will drop all relay logs that haven't yet been processed, and retrieve relay logs from the primary. Can be useful after the replica has crashed to prevent the processing of corrupt relay logs. relay_log_recovery should always be set together with relay_log_purge. Setting `relay-log-recovery=1` with `relay-log-purge=0` can cause the relay log to be read from files that were not purged, leading to data inconsistencies.
- **Commandline:** `--relay-log-recovery`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

relay_log_space_limit

- **Description:** Specifies the maximum space to be used for the relay logs. The IO thread will stop until the SQL thread has cleared the backlog. By default `0`, or no limit.
- **Commandline:** `--relay-log-space-limit=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range - 32 bit:** `0` to `4294967295`
- **Range - 64 bit:** `0` to `18446744073709547520`

---

replicate_annotate_row_events

- **Description:** Tells the replica to reproduce annotate_rows_events received from the primary in its own binary log. This option is sensible only when used in tandem with the log_slave_updates option.
- **Commandline:** `--replicate-annotate-row-events`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `boolean`
- **Default Value:**
  - `ON` (>= MariaDB 10.2.4)
  - `OFF` (<= MariaDB 10.2.3)

---

replicate_do_db

- **Description:** This system variable allows you to configure a replica to apply statements and transactions affecting databases that match a specified name.
  - This system variable will **not** work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.
  - When setting it dynamically with `SET GLOBAL`, the system variable accepts a comma-separated list of filters.
  - When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times.
  - See Replication Filters for more information.
- **Commandline:** `--replicate-do-db=name`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `''` (empty)

---

replicate_do_table

- **Description:** This system variable allows you to configure a replica to apply statements and transactions that affect tables that match a specified name. The table name is specified in the format: `dbname.tablename`.
  - This system variable will **not** work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.
  - When setting it dynamically with `SET GLOBAL`, the system variable accepts a comma-separated list of filters.
  - When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times.
  - See Replication Filters for more information.
- **Commandline:** `--replicate-do-table=name`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `''` (empty)

---

replicate_events_marked_for_skip

- **Description:** Tells the replica whether to replicate events that are marked with the `@@skip_replication` flag. See Selectively skipping replication of binlog events for more information.
- **Commandline:** `--replicate-events-marked-for-skip`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `enumeration`
- **Default Value:** `replicate`
- **Valid Values:** `REPLICATE`, `FILTER_ON_SLAVE`, `FILTER_ON_MASTER`

---

replicate_ignore_db

- **Description:** This system variable allows you to configure a replica to ignore statements and transactions affecting databases that match a specified name.
  - This system variable will **not** work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.
  - When setting it dynamically with `SET GLOBAL`, the system variable accepts a comma-separated list of filters.
  - When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times.
  - See Replication Filters for more information.
- **Commandline:** `--replicate-ignore-db=name`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `''` (empty)

---

replicate_ignore_table

- **Description:** This system variable allows you to configure a replica to ignore statements and transactions that affect tables that match a specified name. The table name is specified in the format: `dbname.tablename`.
  - This system variable will **not** work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.
  - When setting it dynamically with `SET GLOBAL`, the system variable accepts a comma-separated list of filters.
  - When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times.
  - See Replication Filters for more information.
- **Commandline:** `--replicate-ignore-table=name`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `''` (empty)

---

replicate_rewrite_db

- **Description:** This option allows you to configure a replica to rewrite database names. It uses the format `primary_database->replica_database`. If a replica encounters a binary log event in which the default database (i.e. the one selected by the `USE` statement) is `primary_database`, then the replica will apply the event in `replica_database` instead.
  - This option will **not** work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.
  - This option only affects statements that involve tables. This option does not affect statements involving the database itself, such as CREATE DATABASE, ALTER DATABASE, and DROP DATABASE.
  - When setting it on the command-line or in a server option group in an option file, the option does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the option multiple times.
  - See Replication Filters for more information.
  - Before MariaDB 10.11, `replicate_rewrite_db` was not available as a system variable, only as a mariadbd option, and could not be set dynamically. From MariaDB 10.11 it is available as a dynamic system variable
- **Commandline:** `--replicate-rewrite-db=primary_database->replica_database`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `''` (empty)
- **Introduced:** MariaDB 10.11.0

---

replicate_wild_do_table

- **Description:** This system variable allows you to configure a replica to apply statements and transactions that affect tables that match a specified wildcard pattern. The wildcard pattern uses the same semantics as the `LIKE` operator.
  - This system variable will work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.
  - When setting it dynamically with `SET GLOBAL`, the system variable accepts a comma-separated list of filters.
  - When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times.
  - See Replication Filters for more information.
- **Commandline:** `--replicate-wild-do-table=name`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `''` (empty)

---

replicate_wild_ignore_table

- **Description:** This system variable allows you to configure a replica to ignore statements and transactions that affect tables that match a specified wildcard pattern. The wildcard pattern uses the same semantics as the LIKE operator.
  - This system variable will work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.
  - When setting it dynamically with SET GLOBAL, the system variable accepts a comma-separated list of filters.
  - When setting it on the command-line or in a server option group in an option file, the system variable does not

accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times.
    - See Replication Filters for more information.
- **Commandline:** `--replicate-wild-ignore-table=name`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `string`
- **Default Value:** `''` (empty)

---

report_host

- **Description:** The host name or IP address the replica reports to the primary when it registers. If left unset, the replica will not register itself. Reported by SHOW SLAVE HOSTS. Note that it is not sufficient for the primary to simply read the IP of the replica from the socket once the replica connects. Due to NAT and other routing issues, that IP may not be valid for connecting to the replica from the primary or other hosts.
- **Commandline:** `--report-host=host_name`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`

---

report_password

- **Description:** Replica password reported to the primary when it registers. Reported by SHOW SLAVE HOSTS if `--show-slave-auth-info` is set. This password has no connection with user privileges or with the replication user account password.
- **Commandline:** `--report-password=password`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`

---

report_port

- **Description:** The commandline option sets the TCP/IP port for connecting to the replica that will be reported to the replicating primary during the replica's registration. Viewing the variable will show this value.
- **Commandline:** `--report-port=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` to `65535`

---

report_user

- **Description:** Replica's account user name reported to the primary when it registers. Reported by SHOW SLAVE HOSTS if `--show-slave-auth-info` is set. This username has no connection with user privileges or with the replication user account.
- **Commandline:** `--report-user=name`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`

---

server_id

- **Description:** This system variable is used with MariaDB replication to identify unique primary and replica servers in a topology. This system variable is also used with the binary log to determine which server a specific transaction originated on.
    - When MariaDB replication is used with standalone MariaDB Server, each server in the replication topology must have a unique `server_id` value.
    - When MariaDB replication is used with MariaDB Galera Cluster, see Using MariaDB Replication with MariaDB Galera Cluster: Setting server_id on Cluster Nodes for more information on how to set the `server_id` values.

    - In MariaDB 10.2.1 and below, the default `server_id` value is `0`. If a replica's `server_id` value is `0`, then all primary's will refuse its connection attempts. If a primary's `server_id` value is `0`, then it will refuse all replica connection attempts.
- **Commandline:** `--server-id =#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `1`
- **Range:** `1` to `4294967295`

---

skip_parallel_replication

- **Description:** If set when a transaction is written to the binlog, parallel apply of that transaction will be avoided on a replica where slave_parallel_mode is not `aggressive`. Can be used to avoid unnecessary rollback and retry for transactions that are likely to cause a conflict if replicated in parallel. See parallel replication.
- **Commandline:** None
- **Scope:** Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

skip_replication

- **Description:** Changes are logged into the binary log with the @@skip_replication flag set. Such events will not be replicated by replica that run with `--replicate-events-marked-for-skip` set different from its default of `REPLICATE`. See Selectively skipping replication of binlog events for more information.
- **Commandline:** None
- **Scope:** Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

slave_compressed_protocol

- **Description:** If set to 1 (0 is the default), will use compression for the replica/primary protocol if both primary and replica support this.
- **Commandline:** `--slave-compressed-protocol`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `0`

---

slave_ddl_exec_mode

- **Description:** Modes for how replication of DDL events should be executed. Legal values are `STRICT` and `IDEMPOTENT` (default). In `IDEMPOTENT` mode, the replica will not stop for failed DDL operations that would not cause a difference between the primary and the replica. In particular CREATE TABLE is treated as CREATE OR REPLACE TABLE and DROP TABLE is treated as `DROP TABLE IF EXISTS`.
- **Commandline:** `--slave-ddl-exec-mode=name`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `enumeration`
- **Default Value:** `IDEMPOTENT`
- **Valid Values:** `IDEMPOTENT`, `STRICT`

---

slave_domain_parallel_threads

- **Description:** When set to a non-zero value, each replication domain in one primary connection can reserve at most that many worker threads at any one time, leaving the rest (up to the value of slave_parallel_threads) free for other primary connections or replication domains to use in parallel. See Parallel Replication for details.

- **Commandline:** `--slave-domain-parallel-threads=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Valid Values:** `0` to `16383`

---

slave_exec_mode

- **Description:** Determines the mode used for replication error checking and conflict resolution. STRICT mode is the default, and catches all errors and conflicts. IDEMPOTENT mode suppresses duplicate key or no key errors, which can be useful in certain replication scenarios, such as when there are multiple primaries, or circular replication.
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `enumeration`
- **Default Value:** `IDEMPOTENT` (NDB), `STRICT` (All)
- **Valid Values:** `IDEMPOTENT`, `STRICT`

---

slave_load_tmpdir

- **Description:** Directory where the replica stores temporary files for replicating LOAD DATA INFILE statements. If not set, the replica will use tmpdir. Should be set to a disk-based directory that will survive restarts, or else replication may fail.
- **Commandline:** `--slave-load-tmpdir=path`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `file name`
- **Default Value:** `/tmp`

---

slave_max_allowed_packet

- **Description:** Maximum packet size in bytes for replica SQL and I/O threads. This value overrides max_allowed_packet for replication purposes. Set in multiples of 1024 (the minimum) up to 1GB
- **Commandline:** `--slave-max-allowed-packet=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `1073741824`
- **Range:** `1024` to `1073741824`

---

slave_max_statement_time

- **Description:** A query that has taken more than this in seconds to run on the replica will be aborted. The argument will be treated as a decimal value with microsecond precision. A value of 0 (default) means no timeout.
- **Commandline:** `--slave-max-statement-time=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0.000000`
- **Range:** `0` to `31536000`
- **Introduced:** MariaDB 10.10

---

slave_net_timeout

- **Description:** Time in seconds for the replica to wait for more data from the primary before considering the connection broken, after which it will abort the read and attempt to reconnect. The retry interval is determined by the MASTER_CONNECT_RETRY open for the CHANGE MASTER statement, while the maximum number of reconnection attempts is set by the master-retry-count option. The first reconnect attempt takes place immediately.
- **Commandline:** `--slave-net-timeout=#`
- **Scope:** Global

- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:**
  - `60 (1 minute)`
- **Range:** `1` to `31536000`

---

slave_parallel_max_queued

- **Description:** When parallel_replication is used, the SQL thread will read ahead in the relay logs, queueing events in memory while looking for opportunities for executing events in parallel. This system variable sets a limit for how much memory it will use for this.
  - The configured value of this system variable is actually allocated for each worker thread, so the total allocation is actually equivalent to the following:
    - `slave_parallel_max_queued * slave_parallel_threads`
  - This system variable is only meaningful when parallel replication is configured (i.e. when `slave_parallel_threads > 0`).
  - See Parallel Replication: Configuring the Maximum Size of the Parallel Slave Queue for more information.
- **Commandline:** `--slave-parallel-max-queued=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `131072`
- **Range:** `0` to `2147483647`

---

slave_parallel_mode

- **Description:** Controls what transactions are applied in parallel when using parallel replication.
  - `optimistic` : tries to apply most transactional DML in parallel, and handles any conflicts with rollback and retry. See optimistic mode.
  - `conservative` : limits parallelism in an effort to avoid any conflicts. See conservative mode.
  - `aggressive` : tries to maximize the parallelism, possibly at the cost of increased conflict rate.
  - `minimal` : only parallelizes the commit steps of transactions.
  - `none` disables parallel apply completely.
- **Commandline:** None
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `enum`
- **Default Value:** `optimistic` (>= MariaDB 10.5.1), `conservative` (<= MariaDB 10.5.0)
- **Valid Values:** `conservative`, `optimistic`, `none`, `aggressive` and `minimal`

---

slave_parallel_threads

- **Description:** This system variable is used to configure parallel replication.
  - If this system variable is set to a value greater than `0`, then its value will determine how many replica worker threads will be created to apply binary log events in parallel.
  - If this system variable is set to `0` (which is the default value), then no replica worker threads will be created. Instead, when replication is enabled, binary log events are applied by the replica's SQL thread.
  - The replica threads must be stopped in order to change this option's value dynamically.
  - Events that were logged with GTIDs with different `gtid_domain_id` values can be applied in parallel in an out-of-order manner. Each `gtid_domain_id` can use the number of threads configured by `slave_domain_parallel_threads`.
  - Events that were group-committed on the primary can be applied in parallel in an in-order manner, and the specific behavior can be configured by setting `slave_parallel_mode`.
- **Commandline:** `--slave-parallel-threads=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` to `16383`

---

slave_parallel_workers

- **Description:** Alias for slave_parallel_threads.
- **Commandline:** `--slave-parallel-workers=#`

---

slave_run_triggers_for_rbr

- **Description:** See Running triggers on the slave for Row-based events for a description and use-case for this setting.
- **Commandline:** `--slave-run-triggers-for-rbr=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `enum`
- **Default Value:** `NO`
- **Valid Values:** `NO`, `YES`, `LOGGING`, or `ENFORCE` (>= MariaDB 10.5.2)

---

slave_skip_errors

- **Description:** When an error occurs on the replica, replication usually halts. This option permits a list of error codes to ignore, and for which replication will continue. This option should never be needed in normal use, and careless use could lead to replica that are out of sync with primary's. Error codes are in the format of the number from the replica error log. Using `all` as an option permits the replica the keep replicating no matter what error it encounters, an option you would never normally need in production and which could rapidly lead to data inconsistencies. A count of these is kept in slave_skipped_errors.
- **Commandline:** `--slave-skip-errors=[error_code1,error_code2,...|all|ddl_exist_errors]`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:** `OFF`
- **Valid Values:** `[list of error codes]`, `ALL`, `OFF`

---

slave_sql_verify_checksum

- **Description:** Verify binlog checksums when the replica SQL thread reads events from the relay log.
- **Commandline:** `--slave-sql-verify-checksum=[0|1]`
- **Scope:** Global
- **Access Type:** Can be changed dynamically
- **Data Type:** `bool`
- **Default Value:** `ON (1)`

---

slave_transaction_retries

- **Description:** Number of times a replication replica retries to execute an SQL thread after it fails due to InnDB deadlock or by exceeding the transaction execution time limit. If after this number of tries the SQL thread has still failed to execute, the replica will stop with an error. See also the innodb_lock_wait_timeout system variable.
- **Commandline:** `--slave-transaction-retries=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `10`
- **Range - 32 bit:** `0` to `4294967295`
- **Range - 64 bit:** `0` to `18446744073709547520`

---

slave_transaction_retry_errors

- **Description:** When an error occurs during a transaction on the replica, replication usually halts. By default, transactions that caused a deadlock or elapsed lock wait timeout will be retried. One can add other errors to the the list of errors that should be retried by adding a comma-separated list of error numbers to this variable. This is particularly useful in some Spider setups. Some recommended errors to retry for Spider are 1158,1159,1160,1161,1429,2013,12701.(From MariaDB 10.4.5, these are in the default value)
- **Commandline:** `--slave-transaction_retry-errors=[error_code1,error_code2,...]`

- **Scope:** Global
- **Dynamic:** No
- **Data Type:** `string`
- **Default Value:**
  - `1158,1159,1160,1161,1205,1213,1429,2013,12701` (>= MariaDB 10.4.5)
  - `1213,1205` (>= MariaDB 10.3.3)
- **Valid Values:** `comma-separated list of error codes`
- **Introduced:** MariaDB 10.3.3

---

slave_transaction_retry_interval

- **Description:** Interval in seconds for the replica SQL thread to retry a failed transaction due to a deadlock, elapsed lock wait timeout or an error listed in slave_transaction_retry_errors. The interval is calculated as `max(slave_transaction_retry_interval, min(retry_count, 5))`.
- **Commandline:** `--slave-transaction-retry-interval=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` to `3600`
- **Introduced:** MariaDB 10.3.3

---

slave_type_conversions

- **Description:** Determines the type conversion mode on the replica when using row-based replication, including replications in MariaDB Galera cluster. Multiple options can be set, delimited by commas. If left empty, the default, type conversions are disallowed. The variable is dynamic and a change in its value takes effect immediately. This variable tells the server what to do if the table definition is different between the primary and replica (for example a column is 'int' on the primary and 'bigint' on the replica).
  - `ALL_NON_LOSSY` means that all safe conversions (no data loss) are allowed.
  - `ALL_LOSSY` means that all lossy conversions are allowed (for example 'bigint' to 'int'). This, however, does not imply that safe conversions (non-lossy) are allowed as well. In order to allow all conversions, one needs to allow both lossy as well as non-lossy conversions by setting this variable to ALL_NON_LOSSY,ALL_LOSSY.
  - Empty (default) means that the server should give an error and replication should stop if the table definition is different between the primary and replica.
- **Commandline:** `--slave-type-conversions=set`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `set`
- **Default Value:** `Empty variable`
- **Valid Values:** `ALL_LOSSY`, `ALL_NON_LOSSY`, empty

---

sql_log_bin

- **Description:** If set to 0 (1 is the default), no logging to the binary log is done for the client. Only clients with the SUPER privilege can update this variable. Does not affect the replication of events in a Galera cluster.
- **Scope:** Session
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `1`

---

sql_slave_skip_counter

- **Description:** Number of events that a replica skips from the primary. If this would cause the replica to begin in the middle of an event group, the replica will instead begin from the beginning of the next event group. See SET GLOBAL sql_slave_skip_counter.
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`

---

sync_binlog

- **Description:** MariaDB will synchronize its binary log file to disk after this many events. The default is 0, in which case the operating system handles flushing the file to disk. 1 is the safest, but slowest, choice, since the file is flushed after each write. If autocommit is enabled, there is one write per statement, otherwise there's one write per transaction. If the disk has cache backed by battery, synchronization will be fast and a more conservative number can be chosen.
- **Commandline:** `--sync-binlog=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` to `4294967295`

---

sync_master_info

- **Description:** A replication replica will synchronize its master.info file to disk after this many events. If set to 0, the operating system handles flushing the file to disk.
- **Commandline:** `--sync-master-info=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `10000`

---

sync_relay_log

- **Description:** The MariaDB server will synchronize its relay log to disk after this many writes to the log. The default until MariaDB 10.1.7 was 0, in which case the operating system handles flushing the file to disk. 1 is the safest, but slowest, choice, since the file is flushed after each write. If autocommit is enabled, there is one write per statement, otherwise there's one write per transaction. If the disk has cache backed by battery, synchronization will be fast and a more conservative number can be chosen.
- **Commandline:** `--sync-relay-log=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `10000`

---

sync_relay_log_info

- **Description:** A replication replica will synchronize its relay-log.info file to disk after this many transactions. The default until MariaDB 10.1.7 was 0, in which case the operating system handles flushing the file to disk. 1 is the most secure choice, because at most one event could be lost in the event of a crash, but it's also the slowest.
- **Commandline:** `--sync-relay-log-info=#`
- **Scope:** Global,
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `10000`
- **Range:** `0` to `4294967295`

3.1.12 Replication and Binary Log Status Variables

The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Contents

The following status variables are useful in binary logging and replication. See Server Status Variables for a complete list of status variables that can be viewed with SHOW STATUS.

See also the Full list of MariaDB options, system and status variables.

`Binlog_bytes_written`

- **Description:** The number of bytes written to the binary log.
- **Scope:** Global
- **Data Type:** `numeric`

`Binlog_cache_disk_use`

- **Description:** Number of transactions which used a temporary disk cache because they could not fit in the regular binary log cache, being larger than binlog_cache_size. The global value can be flushed by `FLUSH STATUS`.
- **Scope:** Global
- **Data Type:** `numeric`

`Binlog_cache_use`

- **Description:** Number of transaction which used the regular binary log cache, being smaller than binlog_cache_size. The global value can be flushed by `FLUSH STATUS`.
- **Scope:** Global

- **Data Type:** `numeric`

`Binlog_commits`

- **Description:** Total number of transactions committed to the binary log.
- **Scope:** Global
- **Data Type:** `numeric`

`Binlog_group_commit_trigger_count`

- **Description:** Total number of group commits triggered because of the number of binary log commits in the group reached the limit set by the variable binlog_commit_wait_count. See Group commit for the binary log.
- **Scope:** Global
- **Data Type:** `numeric`

`Binlog_group_commit_trigger_lock_wait`

- **Description:** Total number of group commits triggered because a binary log commit was being delayed because of a lock wait where the lock was held by a prior binary log commit. When this happens the later binary log commit is placed in the next group commit. See Group commit for the binary log.
- **Scope:** Global
- **Data Type:** `numeric`

`Binlog_group_commit_trigger_timeout`

- **Description:** Total number of group commits triggered because of the time since the first binary log commit reached the limit set by the variable binlog_commit_wait_usec. See Group commit for the binary log.
- **Scope:** Global
- **Data Type:** `numeric`

`Binlog_group_commits`

- **Description:** Total number of group commits done to the binary log. See Group commit for the binary log.
- **Scope:** Global
- **Data Type:** `numeric`

`Binlog_snapshot_file`

- **Description:** The binary log file. Unlike SHOW MASTER STATUS, can be queried in a transactionally consistent way, irrespective of which other transactions have been committed since the snapshot was taken. See Enhancements for START TRANSACTION WITH CONSISTENT SNAPSHOT.
- **Scope:** Global
- **Data Type:** `string`

`Binlog_snapshot_position`

- **Description:** The binary log position. Unlike SHOW MASTER STATUS, can be queried in a transactionally consistent way, irrespective of which other transactions have been committed since the snapshot was taken. See Enhancements for START TRANSACTION WITH CONSISTENT SNAPSHOT.
- **Scope:** Global
- **Data Type:** `numeric`

`Binlog_stmt_cache_disk_use`

- **Description:** Number of non-transaction statements which used a temporary disk cache because they could not fit in the regular binary log cache, being larger than binlog_stmt_cache_size. The global value can be flushed by `FLUSH STATUS` .

- **Scope:** Global
- **Data Type:** `numeric`

`Binlog_stmt_cache_use`

- **Description:** Number of non-transaction statement which used the regular binary log cache, being smaller than binlog_stmt_cache_size. The global value can be flushed by `FLUSH STATUS`.
- **Scope:** Global
- **Data Type:** `numeric`

`Com_change_master`

- **Description:** Number of CHANGE MASTER TO statements executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_show_binlog_status`

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.5.2

`Com_show_master_status`

- **Description:** Number of SHOW MASTER STATUS commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Removed:** MariaDB 10.5.2

`Com_show_new_master`

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Removed:** `MariaDB 5.5`

`Com_show_slave_hosts`

- **Description:** Number of SHOW SLAVE HOSTS commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_show_slave_status`

- **Description:** Number of SHOW SLAVE STATUS commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_slave_start`

- **Description:** Number of START SLAVE commands executed. Removed in MariaDB 10.0, see Com_start_slave.
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Removed:** `MariaDB 10.0`

Com_slave_stop

- **Description:** Number of STOP SLAVE commands executed. Removed in MariaDB 10.0, see Com_stop_slave.
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Removed:** `MariaDB 10.0`

Com_start_all_slaves

- **Description:** Number of START ALL SLAVES commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_start_slave

- **Description:** Number of START SLAVE commands executed. Replaces the old Com_slave_start.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_stop_all_slaves

- **Description:** Number of STOP ALL SLAVES commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_stop_slave

- **Description:** Number of STOP SLAVE commands executed. Replaces the old Com_slave_stop.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Master_gtid_wait_count

- **Description:** Number of times MASTER_GTID_WAIT called.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Master_gtid_wait_time

- **Description:** Total number of time spent in MASTER_GTID_WAIT.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Master_gtid_wait_timeouts

- **Description:** Number of timeouts occurring in MASTER_GTID_WAIT.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Rpl_status

- **Description:** For showing the status of fail-safe replication. Removed in MySQL 5.6, still present in MariaDB 10.0.

Rpl_transactions_multi_engine

- **Description:** Number of replicated transactions that involved changes in multiple (transactional) storage engines,

before considering the update of `mysql.gtid_slave_pos`. These are transactions that were already cross-engine, independent of the GTID position update introduced by replication. The global value can be flushed by `FLUSH STATUS`.

- **Scope:** Global
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.3.1

Slave_connections

- **Description:** Number of REGISTER_SLAVE attempts. In practice the number of times slaves has tried to connect to the master.
- **Scope:** Global
- **Data Type:** `numeric`

Slave_heartbeat_period

- **Description:** Time in seconds that a heartbeat packet is requested from the master by a slave.
- **Scope:** Global
- **Data Type:** `numeric`

Slave_open_temp_tables

- **Description:** Number of temporary tables the slave has open.
- **Scope:** Global
- **Data Type:** `numeric`

Slave_received_heartbeats

- **Description:** Number of heartbeats the slave has received from the master.
- **Scope:** Global
- **Data Type:** `numeric`

Slave_retried_transactions

- **Description:** Number of times the slave has retried transactions since the server started. The global value can be flushed by `FLUSH STATUS`.
- **Scope:** Global
- **Data Type:** `numeric`

Slave_running

- **Description:** Whether the default connection slave is running (both I/O and SQL threads are running) or not.
- **Scope:** Global
- **Data Type:** `numeric`

Slave_skipped_errors

- **Description:** The number of times a slave has skipped errors defined by slave-skip-errors.
- **Scope:** Global
- **Data Type:** `numeric`

Slaves_connected

- **Description:** Number of slaves connected.
- **Scope:** Global
- **Data Type:** `numeric`

`Slaves_running`

- **Description:** Number of slave SQL threads running.
- **Scope:** Global
- **Data Type:** `numeric`

`Transactions_gtid_foreign_engine`

- **Description:** Number of replicated transactions where the update of the `gtid_slave_pos` table had to choose a storage engine that did not otherwise participate in the transaction. This can indicate that setting gtid_pos_auto_engines might be useful. The global value can be flushed by `FLUSH STATUS`.
- **Scope:** Global
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.3.1

`Transactions_multi_engine`

- **Description:** Number of transactions that changed data in multiple (transactional) storage engines. If this is significantly larger than Rpl_transactions_multi_engine, it indicates that setting gtid_pos_auto_engines could reduce the need for cross-engine transactions. The global value can be flushed by `FLUSH STATUS`.
- **Scope:** Global
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.3.1

3.1.13 Binary Log

The binary log contains a record of all changes to the databases, both data and structure. It consists of a set of binary log files and an index.

It is necessary for replication, and can also be used to restore data after a backup.

Overview of the Binary Log

The binary log contains a record of all changes to the databases

Activating the Binary Log

Activating the Binary Log.

Using and Maintaining the Binary Log

Using and maintaining the binary log.

Binary Log Formats

The three binary logging formats.

Binary Logging of Stored Routines

Stored routines require extra consideration when binary logging.

SHOW BINARY LOGS

SHOW BINARY LOGS lists all binary logs on the server.

PURGE BINARY LOGS

PURGE BINARY LOGS removes all binary logs from the server, prior to the provided date or log file.

SHOW BINLOG EVENTS

Show events in the binary log.

SHOW MASTER STATUS

Status information about the binary log.

Binlog Event Checksums

Including a checksum in binlog events.

Binlog Event Checksum Interoperability

Replicating between servers with differing binlog checksum availability

Group Commit for the Binary Log

Optimization when the server is run with innodb_flush_logs_at_trx_commit or sync_binlog.

mariadb-binlog

mariadb-binlog utility for processing binary log files.

Transaction Coordinator Log

The transaction coordinator log (tc_log) is used to coordinate transactions...

Compressing Events to Reduce Size of the Binary Log

Binlog events can be compressed to save space on disk and in network transfers.

Encrypting Binary Logs

Data-at-rest encryption for binary logs and relay logs.

Flashback

Rollback instances/databases/tables to an old snapshot.

Relay Log

Event log created by the replica from the primary binary log.

Replication and Binary Log System Variables

Replication and binary log system variables.

There are 5 related questions.

3.1.13.1 Overview of the Binary Log

The binary log contains a record of all changes to the databases, both data and structure, as well as how long each statement took to execute. It consists of a set of binary log files and an index.

This means that statements such as CREATE, ALTER, INSERT, UPDATE and DELETE will be logged, but statements that have no effect on the data, such as SELECT and SHOW, will not be logged. If you want to log these (at a cost in performance), use the general query log.

If a statement may potentially have an effect, but doesn't, such as an UPDATE or DELETE that returns no rows, it will still be logged (this applies to the default statement-based logging, not to row-based logging - see Binary Log Formats).

The purpose of the binary log is to allow replication, where data is sent from one or more masters to one or more slave servers based on the contents of the binary log, as well as assisting in backup operations.

A MariaDB server with the binary log enabled will run slightly more slowly.

It is important to protect the binary log, as it may contain sensitive information, including passwords.

Binary logs are stored in a binary, not plain text, format, and so are not viewable with a regular editor. However, MariaDB includes mariadb-binlog, a commandline tool for plain text processing of binary logs.

3.1.13.2 Activating the Binary Log

Contents

To enable binary logging, start the server with the `--log-bin[=name]` option.

If you specify a filename with an extension (for example `.log`), the extension will be silently ignored.

If you don't provide a name (which can, optionally, include an absolute path), the default will be `datadir/log-basename-bin`, `datadir/mysql-bin` or `datadir/mariadb-bin` (the latter two if --log-basename is not specified, and dependent on server version). Datadir is determined by the value of the datadir system variable.

We strongly recommend you use either --log-basename or specify a filename to ensure that replication doesn't stop if the

hostname of the computer changes.

The directory storing the binary logs will contain a binary log index, as well as the individual binary log files.

The binary log files will have a series of numbers as filename extensions. Each additional binary log will increment the extension number, so the oldest binary logs will have lower numbers, the most recent, higher numbers.

A new binary log, with a new extension, is created every time the server starts, the logs are flushed, or the maximum size is reached (determined by max_binlog_size).

The binary log index file contains a master list of all the binary logs, in order.

A sample listing from a directory containing the binary logs:

```
shell> ls -l
total 100
...
-rw-rw---- 1 mysql adm 2098 Apr 19 00:46 mariadb-bin.000079
-rw-rw---- 1 mysql adm  332 Apr 19 00:56 mariadb-bin.000080
-rw-rw---- 1 mysql adm  347 Apr 19 07:36 mariadb-bin.000081
-rw-rw---- 1 mysql adm  306 Apr 20 07:15 mariadb-bin.000082
-rw-rw---- 1 mysql adm  332 Apr 20 07:41 mariadb-bin.000083
-rw-rw---- 1 mysql adm  373 Apr 21 07:56 mariadb-bin.000084
-rw-rw---- 1 mysql adm  347 Apr 21 09:09 mariadb-bin.000085
-rw-rw---- 1 mysql adm  398 Apr 21 21:24 mariadb-bin.000086
-rw-rw---- 1 mysql adm  816 Apr 21 17:05 mariadb-bin.index
```

The binary log index file will by default have the same name as the individual binary logs, with the extension .index. You can specify an alternative name with the `--log-bin-index[=filename]` option.

Clients with the SUPER privilege can disable and re-enable the binary log for the current session by setting the sql_log_bin variable.

```
SET sql_log_bin = 0;

SET sql_log_bin = 1;
```

Binary Log Format

There are three formats for the binary log. The default is mixed logging, which is a mix of statement-based and row-based logging. See Binary Log Formats for a full discussion.

3.1.13.3 Using and Maintaining the Binary Log

Contents

See Overview of the Binary Log for a general overview of what the binary log is, and Activating the Binary Log for how to make sure it's running on your system.

For details on using the binary log for replication, see the Replication section.

Purging Log Files

To delete all binary log files on the server, run the RESET MASTER command. To delete all binary logs before a certain datetime, or up to a certain number, use PURGE BINARY LOGS.

> If a replica is active but has yet to read from a binary log file you attempt to delete, the statement will fail with an error. However, if the replica is not connected and has yet to read from a log file you delete, the file will be deleted, but the replica will be unable to continue replicating once it connects again.

Log files can also be removed automatically with the expire_logs_days system variable. This is set to 0 by default (no removal), but can be set to a time, in days, after which a binary log file will be automatically removed. Log files will only be checked for being older than expire_logs_days upon log rotation, so if your binary log only fills up slowly and does not reach max_binlog_size on a daily basis, you may see older log files still being kept. You can also force log rotation, and so expiry deletes, by running FLUSH BINARY LOGS on a regular basis. Always set expire_logs_days higher than any possible replica lag.

From MariaDB 10.6, the binlog_expire_logs_seconds variable allows more precise control over binlog deletion, and takes precedence if both are non-zero.

> If the binary log index file has been removed, or incorrectly manually edited, all of the above forms of purging log files will fail. The .index file is a plain text file, and can be manually recreated or edited so that it lists only the binary log files that are present, in numeric/age order.

Examples

```
PURGE BINARY LOGS TO 'mariadb-bin.000063';
```

```
PURGE BINARY LOGS BEFORE '2013-04-22 09:55:22';
```

Safely Purging Binary Log Files While Replicating

To be sure replication is not broken while deleting log files, perform the following steps:

- Get a listing of binary log files on the primary by running SHOW BINARY LOGS.
- Go to each replica server and run SHOW SLAVE STATUS to check which binary log file each replica is currently reading.
- Find the earliest log file still being read by a replica. No log files before this one will be needed.
- If you wish, make a backup of the log files to be deleted
- Purge all log files before (not including) the file identified above.

Binary Log Format

There are three formats for the binary log. The default is statement-based logging, while row-based logging and a mix of the two formats are also possible. See Binary Log Formats for a full discussion.

Selectively Logging to the Binary Log

By default, all changes to data or data structure are logged. This behavior can be changed by starting the server with the `--binlog-ignore-db=database_name` or `--binlog-do-db=database_name` options.

`--binlog-ignore-db=database_name` specified a database to ignore for logging purposes, while `--binlog-do-db=database_name` will not log any statements unless they apply to the specified database.

> Neither option accepts comma-delimited lists of multiple databases as an option, since a database name can contain a comma. To apply to multiple databases, use the option multiple times.

`--binlog-ignore-db=database_name` behaves differently depending on whether statement-based or row-based logging is used. For statement-based logging, the server will not log any statement where the *default database* is database_name. The default database is set with the USE statement.

Similarly, `--binlog-do-db=database_name` also behaves differently depending on whether statement-based or row-based logging is used.

For statement-based logging, the server will only log statement where the *default database* is database_name. The default database is set with the USE statement.

For row-based logging, the server will log any updates to any tables in the named database/s, irrespective of the current database.

Examples

Assume the server has started with the option `--binlog-ignore-db=employees`. The following example *is* logged if

statement-based logging is used, and *is not* logged with row-based logging.

```
USE customers;
UPDATE employees.details SET bonus=bonus*1.2;
```

This is because statement-based logging examines the default database, in this case, `customers`. Since `customers` is not specified in the ignore list, the statement will be logged. If row-based logging is used, the example will not be logged as updates are written to the tables in the `employees` database.

Assume instead the server started with the option `--binlog-do-db=employees`. The following example *is not* logged if statement-based logging is used, and *is* logged with row-based logging.

```
USE customers;
UPDATE employees.details SET bonus=bonus*1.2;
```

This is again because statement-based logging examines the default database, in this case, `customers`. Since `customers` is not specified in the do list, the statement will not be logged. If row-based logging is used, the example will be logged as updates are written to the tables in the `employees` database.

Effects of Full Disk Errors on Binary Logging

If MariaDB encounters a full disk error while trying to write to a binary log file, then it will keep retrying the write every 60 seconds. Log messages will get written to the error log every 600 seconds. For example:

```
2018-11-27  2:46:46 140278181563136 [Warning] mysqld: Disk is full writing '/var/lib/mariadb-
bin.00001' (Errcode: 28 "No space left on device"). Waiting for someone to free space... (Expect
up to 60 secs delay for server to continue after freeing disk space)
2018-11-27  2:46:46 140278181563136 [Warning] mysqld: Retry in 60 secs. Message reprinted in 600
secs
```

However, if MariaDB encounters a full disk error while trying to open a new binary log file, then it will disable binary logging entirely. A log message like the following will be written to the error log:

```
2018-11-27  3:30:49 140278181563136 [ERROR] Could not open '/var/lib/mariadb-bin.00002 for
logging (error 28). Turning logging off for the whole duration of the MySQL server process. To
turn it on again: fix the cause, shutdown the MySQL server and restart it.
2018-11-27  3:30:49 140278181563136 [ERROR] mysqld: Error writing file '(null)' (errno: 9 "Bad
file descriptor")
2018-11-27  3:30:49 140278181563136 [ERROR] mysqld: Error writing file '(null)' (errno: 28 "No
space left on device")
```

3.1.13.4 Binary Log Formats

Contents

Supported Binary Log Formats

There are three supported formats for binary log events:

- Statement-Based Logging
- Row-Based Logging
- Mixed Logging

Regardless of the format, binary log events are always stored in a binary format, rather than in plain text. MariaDB includes the mariadb-binlog utility that can be used to output binary log events in a human-readable format.

You may want to set the binary log format in the following cases:

- If you execute single statements that update many rows, then statement-based logging will be more efficient than row-based logging for the replica to download.
- If you execute many statements that don't affect any rows, then row-based logging will be more efficient than statement-based logging for the replica to download.
- If you execute statements that take a long time to complete, but they ultimately only insert, update, or delete a few rows in the table, then row-based logging will be more efficient than statement-based logging for the replica to apply.

The default is mixed logging which is replication-safe and requires less storage space than row logging.

The storage engine API also allows storage engines to set or limit the logging format, which helps reduce errors with replicating between primaries and replicas with different storage engines.

Statement-Based Logging

In MariaDB 10.2.3 and before, statement-based logging was the default. Mixed logging is now the default.

When statement-based logging is enabled, statements are logged to the binary log exactly as they were executed. Temporary tables created on the primary will also be created on the replica. This mode is only recommended where one needs to keep the binary log as small as possible, the primary and replica have identical data (including using the same storage engines for all tables), and all functions being used are deterministic (repeatable with the same arguments). Statements and tables using timestamps or auto_increment are safe to use with statement-based logging.

This mode can be enabled by setting the binlog_format system variable to `STATEMENT`.

In certain cases when it would be impossible to execute the statement on the replica, the server will switch to row-based logging for the statement. Some cases of this are:

- When replication has been changed from row-based to statement-based and a statement uses data from a temporary table created during row-based mode. In this case, the temporary tables are not stored on the replica, so row logging is the only alternative.
- ALTER TABLE of a table using a storage engine that stores data remotely, such as the S3 storage engine, to another storage engine.
- One is using SEQUENCE's in the statement or the CREATE TABLE definition.

In certain cases, a statement may not be deterministic, and therefore not safe for replication. If MariaDB determines that an unsafe statement has been executed, then it will issue a warning. For example:

```
[Warning] Unsafe statement written to the binary log using statement format since
  BINLOG_FORMAT = STATEMENT. The statement is unsafe because it uses a LIMIT clause. This
  is unsafe because the set of rows included cannot be predicted.
```

See Unsafe Statements for Statement-based Replication for more information.

If you need to execute non-deterministic statements, then it is safer to use mixed logging or row-based.

Mixed Logging

Mixed logging is the default binary log format.

When mixed logging is enabled, the server uses a combination of statement-based logging and row-based logging. Statement-based logging is used where possible, but when the server determines a statement may not be safe for statement-based logging, it will use row-based logging instead. See Unsafe Statements for Statement-based Replication: Unsafe Statements for a list of unsafe statements.

During one transaction, some statements may be logged with row logging while others are logged with statement-based logging.

This mode can be enabled by setting the binlog_format system variable to `MIXED`.

Row-Based Logging

When row-based logging is enabled, DML statements are **not** logged to the binary log. Instead, each insert, update, or delete performed by the statement for each row is logged to the binary log separately. DDL statements are still logged to the binary log.

Row-based logging uses more storage than the other log formats but is the safest to use. In practice mixed logging should be as safe.

If one wants to be able to see the original query that was logged, one can enable annotated rows events, that is shown with mariadb-binlog, with --binlog-annotate-row-events. This option is on by default.

This mode can be enabled by setting the binlog_format system variable to `ROW`.

Compression of the Binary Log

Compression of the binary log can be used with any of the binary log formats, but the best results come from using mixed or row-based logging. You can enable compression by using the --log_bin_compress startup option.

Configuring the Binary Log Format

The format for binary log events can be configured by setting the binlog_format system variable. If you have the SUPER privilege, then you can change it dynamically with SET GLOBAL. For example:

```
SET GLOBAL binlog_format='ROW';
```

You can also change it dynamically for just a specific session with SET SESSION. For example:

```
SET SESSION binlog_format='ROW';
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
binlog_format=ROW
```

Be careful when changing the binary log format when using replication. When you change the binary log format on a server, it only changes the format for that server. Changing the binary log format on a primary has no effect on the replica's binary log format. This can cause replication to give inconsistent results or to fail.

Be careful changing the binary log format dynamically when the server is a replica and parallel replication is enabled. If you change the global value dynamically, then that does not also affect the session values of any currently running threads. This can cause problems with parallel replication, because the worker threads will remain running even after STOP SLAVE is executed. This can be worked around by resetting the slave_parallel_threads system variable. For example:

```
STOP SLAVE;
SET GLOBAL slave_parallel_threads=0;
SET GLOBAL binlog_format='ROW';
SET GLOBAL slave_parallel_threads=4;
START SLAVE
```

Effect of the Binary Log Format on Replicas

In MariaDB 10.0.22 and later, a replica will apply any events it gets from the primary, regardless of the binary log format. The binlog_format system variable only applies to normal (not replicated) updates.

If you are running MySQL or an older MariaDB than 10.0.22, you should be aware of that if you are running the replica in `binlog_format=STATEMENT` mode, the replica will stop if the primary is used with `binlog_format` set to anything else than `STATEMENT`.

The binary log format is upwards-compatible. This means replication should always work if the replica is the same or a newer version of MariaDB than the primary.

The mysql Database

Statements that affect the `mysql` database can be logged in a different way to that expected.

If the mysql database is edited directly, logging is performed as expected according to the binlog_format. Statements that directly edit the mysql database include INSERT, UPDATE, DELETE, REPLACE, DO, LOAD DATA INFILE, SELECT, and

TRUNCATE TABLE.

If the `mysql` database is edited indirectly, statement logging is used regardless of binlog_format setting. Statements editing the `mysql` database indirectly include GRANT, REVOKE, SET PASSWORD, RENAME USER, ALTER, DROP and CREATE (except for the situation described below).

CREATE TABLE ... SELECT can use a combination of logging formats. The CREATE TABLE portion of the statement is logged using statement-based logging, while the SELECT portion is logged according to the value of `binlog_format`.

3.1.13.5 Binary Logging of Stored Routines

Contents

Binary logging can be row-based, statement-based, or a mix of the two. See Binary Log Formats for more details on the formats. If logging is statement-based, it is possible that a statement will have different effects on the master and on the slave.

Stored routines are particularly prone to this, for two main reasons:

- stored routines can be non-deterministic, in other words non-repeatable, and therefore have different results each time they are run.
- the slave thread executing the stored routine on the slave holds full privileges, while this may not be the case when the routine was run on the master.

The problems with replication will only occur with statement-based logging. If row-based logging is used, since changes are made to rows based on the master's rows, there is no possibility of the slave and master getting out of sync.

By default, with row-based replication, triggers run on the master, and the effects of their executions are replicated to the slaves. However, starting from MariaDB 10.1.1, it is possible to run triggers on the slaves. See Running triggers on the slave for Row-based events.

How MariaDB Handles Statement-Based Binary Logging of Routines

If the following criteria are met, then there are some limitations on whether stored routines can be created:

- The binary log is enabled, and the `binlog_format` system variable is set to `STATEMENT`. See Binary Log Formats for more information.
- The `log_bin_trust_function_creators` is set to `OFF`, which is the default value.

If the above criteria are met, then the following limitations apply:

- When a stored function is created, it must be declared as either `DETERMINISTIC`, `NO SQL` or `READS SQL DATA`, or else an error will occur. MariaDB cannot check whether a function is deterministic, and relies on the correct definition being used.
- To create or modify a stored function, a user requires the `SUPER` privilege as well as the regular privileges. See Stored Routine Privileges for these details.
- Triggers work in the same way, except that they are always assumed to be deterministic for logging purposes, even if this is obviously not the case, such as when they use the UUID function.
- Triggers can also update data. The slave uses the DEFINER attribute to determine which user is taken to have created the trigger.
- Note that the above limitations do no apply to stored procedures or to events.

Examples

A deterministic function:

```
DELIMITER //

CREATE FUNCTION trust_me(x INT)
RETURNS INT
DETERMINISTIC
READS SQL DATA
BEGIN
   RETURN (x);
END //

DELIMITER ;
```

A non-deterministic function, since it uses the UUID_SHORT function:

```
DELIMITER //

CREATE FUNCTION dont_trust_me()
RETURNS INT
BEGIN
   RETURN UUID_SHORT();
END //

DELIMITER ;
```

1.1.1.2.8.4 SHOW BINARY LOGS

1.1.1.2.11 PURGE BINARY LOGS

1.1.1.2.8.5 SHOW BINLOG EVENTS

1.1.1.2.5.8 SHOW MASTER STATUS

3.1.19 Binlog Event Checksums

3.1.13.11 Binlog Event Checksum Interoperability

> The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

The introduction of checksums on binlog events changes the format that events are stored in binary log files and sent over the network to replicas. This raises the question on what happens when replicating between different versions of the server, where one server is a newer version that has the binlog checksum feature implemented, while the other server is an older version that does not know about binlog checksums.

When checksums are disabled on the primary (or the primary has the old version with no checksums implemented), there is no problem. In this case the binlog format is backwards compatible, and replication works fine.

When the primary is a newer version with checksums enabled in the binlog, but the replica is an old version that does not understand checksums, replication will fail. The primary will disconnect the replica with an error, and also log a warning in its own error log. This prevents sending events to the replica that it will be unable to interpret correctly, but means that binlog checksums can not be used with older replicas. (With the recommended upgrade path, where replicas are upgraded before primaries, this is not a problem of course).

Replicating from a new MySQL primary with checksums enabled to a new MariaDB which also understands checksums works, and the MariaDB replica will verify checksums on replicated events.

There is however a problem when a newer MySQL replica replicates against a newer MariaDB primary with checksums enabled. The replica server looks at the primary server version to know whether events include checksums or not, and MySQL has not yet been updated to learn that MariaDB does this already from version 5.3.0 (as of the time of writing,

MySQL 5.6.2). Thus, if MariaDB at least version 5.3.0 but less that 5.6.1 is used as a primary with binlog checksums enabled, a MySQL replica will interpret the received events incorrectly as it does not realise the last part of the events is the checksum. So replication will fail with an error about corrupt events or even silent corruption of replicated data in unlucky cases. This requires changes to the MySQL server to fix.

Here is a summary table of the status of replication between different combination of primary and replica servers and checksum enabled/disabled:

- **OLD:** MySQL <5.6.1 or MariaDB < 5.3.0 with no checksum capabilities
- **NEW-MARIA:** MariaDB >= 5.3.0 with checksum capabilities
- **NEW-MYSQL:** MySQL >= 5.6.1 with checksum capabilities

Primary mariadb-lbinlog	Replica / enabled?	Checksums	Status
OLD	OLD	-	Ok
OLD	NEW-MARIA	-	Ok
OLD	MYSQL	-	Ok
NEW-MARIA	OLD	No	Ok
NEW-MARIA	OLD	Yes	Primary will refuse with error
NEW-MARIA	NEW-MARIA	Yes/No	Ok
NEW-MARIA	NEW-MYSQL	No	Ok
NEW-MARIA	NEW-MYSQL	Yes	Fail. Requires changes in MySQL, otherwise it will not realise MariaDB < 5.6.1 does checksums and will be confused.
NEW-MYSQL	OLD	No	Ok
NEW-MYSQL	OLD	Yes	Primary will refuse with error
NEW-MYSQL	NEW-MARIA	Yes/No	Ok
NEW-MYSQL	NEW-MYSQL	Yes/No	Ok

Checksums and mariadb-binlog

When using the mariadb-binlog client program, there are similar issues.

A version of `mariadb-binlog` which understands checksums can read binlog files from either old or new servers, with or without checksums enabled.

An old version of `mariadb-binlog` can read binlog files produced by a new server version **if** checksums were disabled when the log was produced. Old versions of `mariadb-binlog` reading a new binlog file containing checksums will be confused, and output will be garbled, with the added checksums being interpreted as extra garbage at the end of query strings and similar entries. No error will be reported in this case, just wrong output.

A version of `mysqlbinlog` (the MySQL equivalent to mariadb-binlog and the old MariaDB name for the binary) from MySQL >= 5.6.1 will have similar problems as a replica until this is fixed in MySQL. When reading a binlog file with checksums produced by MariaDB >= 5.3.0 but < 5.6.1, it will not realise that checksums are included, and will produce garbled output just like an old version of `mysqlbinlog` . The MariaDB version of `mariadb-binlog` can read binlog files produced by either MySQL or MariaDB just fine.

3.1.13.12 Group Commit for the Binary Log

Contents

Overview

The server supports group commit. This is an important optimization that helps MariaDB reduce the number of expensive

disk operations that are performed.

Durability

In ACID terminology, the "D" stands for durability. In order to ensure durability with group commit, innodb_flush_log_at_trx_commit=1 and/or sync_binlog=1 should be set. These settings are needed to ensure that if the server crashes, then any transaction that was committed prior to the time of crash will still be present in the database after crash recovery.

Durable InnoDB Data and Binary Logs

Setting both innodb_flush_log_at_trx_commit=1 and sync_binlog=1 provides the most durability and the best guarantee of replication consistency after a crash.

Non-Durable InnoDB Data

If sync_binlog=1 is set, but innodb_flush_log_at_trx_commit is not set to `1` or `3`, then it is possible after a crash to end up in a state where a transaction present in a server's binary log is missing from the server's InnoDB redo log. If the server is a replication master, then that means that the server can become inconsistent with its slaves, since the slaves may have replicated transactions from the master's binary log that are no longer present in the master's local InnoDB data.

Non-Durable Binary Logs

If innodb_flush_log_at_trx_commit is set to `1` or `3`, but sync_binlog=1 is not set, then it is possible after a crash to end up in a state where a transaction present in a server's InnoDB redo log is missing from the server's binary log. If the server is a replication master, then that also means that the server can become inconsistent with its slaves, since the server's slaves would not be able to replicate the missing transactions from the server's binary log.

Non-Durable InnoDB Data and Binary Logs

Setting innodb_flush_log_at_trx_commit=1 when sync_binlog=1 is not set can also cause the transaction to be missing from the server's InnoDB redo log due to some optimizations added in those versions. In that case, it is recommended to always set sync_binlog=1. If you can't do that, then it is recommended to set innodb_flush_log_at_trx_commit to `3`, rather than `1`. See Non-durable Binary Log Settings for more information.

Amortizing Disk Flush Costs

After every transaction COMMIT, the server normally has to flush any changes the transaction made to the InnoDB redo log and the binary log to disk (i.e. by calling system calls such as `fsync()` or `fdatasync()` or similar). This helps ensure that the data changes made by the transaction are stored durably on the disk. Disk flushing is a time-consuming operation, and can easily impose limits on throughput in terms of the number of transactions-per-second (TPS) which can be committed.

The idea with group commit is to amortize the costs of each flush to disk over multiple commits from multiple parallel transactions. For example, if there are 10 transactions trying to commit in parallel, then we can force all of them to be flushed disk at once with a single system call, rather than do one system call for each commit. This can greatly reduce the need for flush operations, and can consequently greatly improve the throughput of transactions-per-second (TPS).

However, to see the positive effects of group commit, the workload must have sufficient parallelism. A good rule of thumb is that at least three parallel transactions are needed for group commit to be effective. For example, while the first transaction is waiting for its flush operation to complete, the other two transactions will queue up waiting for their turn to flush their changes to disk. When the first transaction is done, a single system call can be used to flush the two queued-up transactions, saving in this case one of the three system calls.

In addition to sufficient parallelism, it is also necessary to have enough transactions per second wanting to commit that the flush operations are a bottleneck. If no such bottleneck exists (i.e. transactions never or rarely need to wait for the flush of another to complete), then group commit will provide little to no improvement.

Changing Group Commit Frequency

The frequency of group commits can be changed by configuring the binlog_commit_wait_usec and binlog_commit_wait_count system variables.

Measuring Group Commit Ratio

Two status variables are available for checking how effective group commit is at reducing flush overhead. These are the Binlog_commits and Binlog_group_commits status variables. We can obtain those values with the following query:

```
SHOW GLOBAL STATUS WHERE Variable_name IN('Binlog_commits', 'Binlog_group_commits');
```

Binlog_commits is the total number of transactions committed to the binary log.

Binlog_group_commits is the total number of groups committed to the binary log. As explained in the previous sections of this page, a group commit is when a group of transactions is flushed to the binary log together by sharing a single flush system call. When sync_binlog=1 is set, then this is also the total number of flush system calls executed in the process of flushing commits to the binary log.

Thus the extent to which group commit is effective at reducing the number of flush system calls on the binary log can be determined by the ratio between these two status variables. Binlog_commits will always be as equal to or greater than Binlog_group_commits. The greater the difference is between these status variables, the more effective group commit was at reducing flush overhead.

To calculate the group commit ratio, we actually need the values of these status variables from two snapshots. Then we can calculate the ratio with the following formula:

`transactions/group commit` = (`Binlog_commits` (*snapshot2*) - `Binlog_commits` (*snapshot1*))/(`Binlog_group_commits` (*snapshot2*) - `Binlog_group_commits` (*snapshot1*))

For example, if we had the following first snapshot:

```
SHOW GLOBAL STATUS WHERE Variable_name IN('Binlog_commits', 'Binlog_group_commits');
+-----------------------+-------+
| Variable_name         | Value |
+-----------------------+-------+
| Binlog_commits        | 120   |
| Binlog_group_commits  | 120   |
+-----------------------+-------+
2 rows in set (0.00 sec)
```

And the following second snapshot:

```
SHOW GLOBAL STATUS WHERE Variable_name IN('Binlog_commits', 'Binlog_group_commits');
+-----------------------+-------+
| Variable_name         | Value |
+-----------------------+-------+
| Binlog_commits        | 220   |
| Binlog_group_commits  | 145   |
+-----------------------+-------+
2 rows in set (0.00 sec)
```

Then we would have:

`transactions/group commit` = (220 - 120) / (145 - 120) = 100 / 25 = 4 `transactions/group commit`

If your group commit ratio is too close to 1, then it may help to change your group commit frequency.

Use of Group Commit with Parallel Replication

Group commit is also used to enable conservative mode of in-order parallel replication .

Effects of Group Commit on InnoDB Performance

When both innodb_flush_log_at_trx_commit=1 (the default) is set and the binary log is enabled, there is now one less sync to disk inside InnoDB during commit (2 syncs shared between a group of transactions instead of 3). See Binary Log Group Commit and InnoDB Flushing Performance for more information.

Status Variables

Binlog_commits is the total number of transactions committed to the binary log.

Binlog_group_commits is the total number of groups committed to the binary log.

Binlog_group_commit_trigger_count is the total number of group commits triggered because of the number of binary log commits in the group reached the limit set by the system variable binlog_commit_wait_count.

Binlog_group_commit_trigger_lock_wait is the total number of group commits triggered because a binary log commit was being delayed because of a lock wait where the lock was held by a prior binary log commit. When this happens the later binary log commit is placed in the next group commit.

Binlog_group_commit_trigger_timeout is the total number of group commits triggered because of the time since the first binary log commit reached the limit set by the system variable binlog_commit_wait_usec.

To query these variables, use a statement such as:

```
SHOW GLOBAL STATUS LIKE 'Binlog_%commit%';
```

1.3.16 mariadb-binlog

2.4.11 Transaction Coordinator Log

3.1.13.15 Compressing Events to Reduce Size of the Binary Log

Selected events in the binary log can be optionally compressed, to save space in the binary log on disk and in network transfers.

The events that can be compressed are the events that normally can be of a significant size: Query events (for DDL and DML in statement-based replication), and row events (for DML in row-based replication).

Compression is fully transparent. Events are compressed on the primary before being written into the binary log, and are uncompressed by the I/O thread on the replica before being written into the relay log. The mariadb-binlog command will likewise uncompress events for its output.

Currently, the zlib compression algorithm is used to compress events.

Compression will have the most impact when events are of a non-negligible size, as each event is compressed individually. For example, batch INSERT statements that insert many rows or large values, or row-based events that touch a number of rows in one query.

The log_bin_compress option is used to enable compression of events. Only events with data (query text or row data) above a certain size are compressed; the limit is set with the log_bin_compress_min_len option.

2.2.1.1.2.4 Encrypting Binary Logs

3.1.13.17 Flashback

Contents

Flashback is a feature that allows instances, databases or tables to be rolled back to an old snapshot.

Flashback is currently supported only over DML statements (INSERT, DELETE, UPDATE). An upcoming version of MariaDB will add support for flashback over DDL statements (DROP, TRUNCATE, ALTER, etc.) by copying or moving the current table to a reserved and hidden database, and then copying or moving back when using flashback. See MDEV-10571.

Flashback is achieved in MariaDB Server using existing support for full image format binary logs (binlog_row_image=FULL), so it supports all engines.

The real work of Flashback is done by mariadb-binlog with `--flashback`. This causes events to be translated: INSERT to DELETE, DELETE to INSERT, and for UPDATEs, the before and after images are swapped.

When executing `mariadb-binlog` with `--flashback`, the Flashback events will be stored in memory. You should make sure your server has enough memory for this feature.

Arguments

- mariadb-binlog has the option `--flashback` or `-B` that will let it work in flashback mode.
- mariadbd / mysqld has the option --flashback that enables the binary log and sets `binlog_format=ROW`. It is not mandatory to use this option if you have already enabled those options directly.

Do not use `-v -vv` options, as this adds verbose information to the binary log which can cause problems when importing. See MDEV-12066 and MDEV-12067.

Example

With a table "mytable" in database "test", you can compare the output with `--flashback` and without.

```
mariadb-binlog /var/lib/mysql/mysql-bin.000001 -vv -d test -T mytable \
   --start-datetime="2013-03-27 14:54:00" > review.sql
```

```
mariadb-binlog /var/lib/mysql/mysql-bin.000001 -vv -d test -T mytable \
   --start-datetime="2013-03-27 14:54:00" --flashback > flashback.sql
```

If you know the exact position, `--start-position` can be used instead of `--start-datetime`.

Then, by importing the output file (`mysql < flashback.sql`), you can flash your database/table back to the specified time or position.

Common Use Case

A common use case for Flashback is the following scenario:

- You have one primary and two replicas, one started with `--flashback` (i.e. with binary logging enabled, using binlog_format=ROW, and binlog_row_image=FULL).
- Something goes wrong on the primary (like a wrong update or delete) and you would like to revert to a state of the database (or just a table) at a certain point in time.
- Remove the flashback-enabled replica from replication.
- Invoke mariadb-binlog to find the exact log position of the first offending operation after the state you want to revert to.
- Run `mariadb-binlog --flashback --start-position=xyz | mysql` to pipe the output of `mariadb-binlog` directly to the `mariadb` client, or save the output to a file and then direct the file to the command-line client.

3.1.13.18 Relay Log

Contents

The relay log is a set of log files created by a replica during replication.

It's the same format as the binary log, containing a record of events that affect the data or structure; thus, mariadb-binlog can be used to display its contents. It consists of a set of relay log files and an index file containing a list of all relay log files.

Events are read from the primary's binary log and written to the replica's relay log. They are then performed on the replica. Old relay log files are automatically removed once they are no longer needed.

Creating Relay Log Files

New relay log files are created by the replica at the following times:

- when the IO thread starts
- when the logs are flushed, with FLUSH LOGS or mariadb-admin flush-logs.
- when the maximum size, determined by the max_relay_log_size system variable, has been reached

Relay Log Names

By default, the relay log will be given a name `host_name-relay-bin.nnnnnn`, with `host_name` referring to the server's host name, and #nnnnnn `the sequence number.`

This will cause problems if the replica's host name changes, returning the error `Failed to open the relay log` and `Could not find target log during relay log initialization`. To prevent this, you can specify the relay log file name by setting the relay_log and relay_log_index system variables.

If you need to overcome this issue while replication is already underway,you can stop the replica, prepend the old relay log index file to the new relay log index file, and restart the replica.

For example:

```
shell> cat NEW_relay_log_name.index >> OLD_relay_log_name.index
shell> mv OLD_relay_log_name.index NEW_relay_log_name.index
```

Viewing Relay Logs

The SHOW RELAYLOG EVENTS shows events in the relay log, and, since relay log files are the same format as binary log files, they can be read with the mariadb-binlog utility.

Removing Old Relay Logs

Old relay logs are automatically removed once all events have been implemented on the replica, and the relay log file is no longer needed. This behavior can be changed by adjusting the relay_log_purge system variable from its default of `1` to `0`, in which case the relay logs will be left on the server.

Relay logs are also removed by the CHANGE MASTER statement unless a relay log option is used.

One can also flush the logs with the FLUSH RELAY LOGS commands.

If the relay logs are taking up too much space on the replica, the relay_log_space_limit system variable can be set to limit the size. The IO thread will stop until the SQL thread has cleared the backlog. By default there is no limit.

3.1.11 Replication and Binary Log System Variables

3.1.14 Unsafe Statements for Statement-based Replication

Contents

A safe statement is generally deterministic; in other words the statement will always produce the same result. For example, an INSERT statement producing a random number will most likely produce a different result on the primary than on the replica, and so cannot be replicated safely.

When an unsafe statement is run, the current binary logging format determines how the server responds.

- If the binary logging format is statement-based (the default until MariaDB 10.2.3), unsafe statements generate a warning and are logged normally.
- If the binary logging format is mixed (the default from MariaDB 10.2.4), unsafe statements are logged using the row-based format, while safe statements use the statement-based format.
- If the binary logging format is row-based, all statements are logged normally, and the distinction between safe and unsafe is not made.

MariaDB tries to detect unsafe statements. When an unsafe statement is issued, a warning similar to the following is produced:

```
Note (Code 1592): Unsafe statement written to the binary log using statement format since
  BINLOG_FORMAT = STATEMENT. The statement is unsafe because it uses a LIMIT clause. This
  is unsafe because the set of rows included cannot be predicted.
```

MariaDB also issues this warning for some classes of statements that are safe.

Unsafe Statements

The following statements are regarded as unsafe:

- INSERT ... ON DUPLICATE KEY UPDATE statements upon tables with multiple primary or unique keys, as the order that the keys are checked in, and which affect the rows chosen to update, is not deterministic. Before MariaDB 5.5.24, these statements were not regarded as unsafe. In MariaDB 10.0 this warning has been removed as we always check keys in the same order on the primary and replica if the primary and replica are using the same storage engine.
- INSERT-DELAYED. These statements are inserted in an indeterminate order.
- INSERTs on tables with a composite primary key that has an AUTO_INCREMENT column that isn't the first column of the composite key.
- When a table has an AUTO_INCREMENT column and a trigger or stored procedure executes an UPDATE statement against the table. Before MariaDB 5.5, all updates on tables with an AUTO_INCREMENT column were considered unsafe, as the order that the rows were updated could differ across servers.
- UPDATE statements that use LIMIT, since the order of the returned rows is unspecified. This applies even to statements using an ORDER BY clause, which are deterministic (a known bug). However, since MariaDB 10.0.11, `LIMIT 0` is an exception to this rule (see MDEV-6170), and these statements are safe for replication.
- When using a user-defined function.
- Statements using using any of the following functions, which can return different results on the replica:
  - CURRENT_ROLE()
  - CURRENT_USER()
  - FOUND_ROWS()
  - GET_LOCK()
  - IS_FREE_LOCK()
  - IS_USED_LOCK()
  - JSON_TABLE()
  - LOAD_FILE()
  - MASTER_POS_WAIT()
  - RAND()
  - RANDOM_BYTES()
  - RELEASE_ALL_LOCKS()
  - RELEASE_LOCK()
  - ROW_COUNT()
  - SESSION_USER()
  - SLEEP()
  - SYSDATE()
  - SYSTEM_USER()
  - USER()
  - UUID()
  - UUID_SHORT().
- Statements which refer to log tables, since these may differ across servers.
- Statements which refer to self-logging tables. Statements following a read or write to a self-logging table within a transaction are also considered unsafe.
- Statements which refer to system variables (there are a few exceptions).
- LOAD DATA INFILE statements (since MariaDB 5.5).
- Non-transactional reads or writes that execute after transactional reads within a transaction.
- If row-based logging is used for a statement, and the session executing the statement has any temporary tables, row-based logging is used for the remaining statements until the temporary table is dropped. This is because temporary tables can't use row-based logging, so if it is used due to one of the above conditions, all subsequent statements using that table are unsafe. The server deals with this situation by treating all statements in the session as unsafe for statement-based logging until the temporary table is dropped.

Safe Statements

The following statements are not deterministic, but are considered safe for binary logging and replication:

- CONNECTION_ID()
- CURDATE()
- CURRENT_DATE()
- CURRENT_TIME()
- CURRENT_TIMESTAMP()
- CURTIME()
- LAST_INSERT_ID()
- LOCALTIME()
- LOCALTIMESTAMP()
- NOW()
- UNIX_TIMESTAMP()

- UTC_DATE()
- UTC_TIME()
- UTC_TIMESTAMP()

Isolation Levels

Even when using safe statements, not all transaction isolation levels are safe with statement-based or mixed binary logging. The REPEATABLE READ and SERIALIZABLE isolation levels can only be used with the row-based format.

This restriction does not apply if only non-transactional storage engines are used.

3.1.15 Replication and Foreign Keys

> The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Replication is based upon the binary log. However, cascading deletes or updates based on foreign key relations are an internal mechanism, and are not written to the binary log.

Because of this, an identical statement run on the master and the slave may result in different outcomes if the foreign key relations are not identical on both master and slave This could be the case if the storage engine on one supports cascading deletes (e.g. InnoDB) and the storage engine on the other does not (e.g. MyISAM), or the one has specified a foreign key relation, and the other hasn't.

Take the following example:

```
CREATE TABLE employees (
    x INT PRIMARY KEY,
    name VARCHAR(10)
) ENGINE = InnoDB;

CREATE TABLE children (
    y INT PRIMARY KEY,
    f INT,
    name VARCHAR(10),
    FOREIGN KEY fk (f) REFERENCES employees (x)
        ON DELETE CASCADE
) ENGINE = InnoDB;
```

The slave, however, has been set up without InnoDB support, and defaults to MyISAM, so the foreign key restrictions are not in place.

```
INSERT INTO employees VALUES (1, 'Yaser'), (2, 'Prune');

INSERT INTO children VALUES (1, 1, 'Haruna'), (2, 1, 'Hera'), (3, 2, 'Eva');
```

At this point, the slave and the master are in sync:

```
SELECT * FROM employees;
+---+--------+
| x | name   |
+---+--------+
| 1 | Yaser |
| 2 | Prune |
+---+--------+
2 rows in set (0.00 sec)

SELECT * FROM children;
+---+------+---------+
| y | f    | name    |
+---+------+---------+
| 1 |    1 | Haruna |
| 2 |    1 | Hera    |
| 3 |    2 | Eva     |
+---+------+---------+
```

However, after:

```
DELETE FROM employees WHERE x=1;
```

there are different outcomes on the slave and the master.

On the master, the cascading deletes have taken effect:

```
SELECT * FROM children;
+---+------+------+
| y | f    | name |
+---+------+------+
| 3 |    2 | Eva  |
+---+------+------+
```

On the slave, the cascading deletes did not take effect:

```
SELECT * FROM children;
+---+------+--------+
| y | f    | name   |
+---+------+--------+
| 1 |    1 | Haruna |
| 2 |    1 | Hera   |
| 3 |    2 | Eva    |
+---+------+--------+
```

3.1.13.18 Relay Log

3.1.13.12 Group Commit for the Binary Log

3.1.18 Selectively Skipping Replication of Binlog Events

The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Contents

Normally, all changes that are logged as events in the binary log are also replicated to all replicas (though still subject to filtering by replicate-do-db, replicate-ignore-db, and similar options). However, sometimes it may be desirable to have certain events be logged into the binlog, but not be replicated to all or a subset of replicas, where the distinction between events that should be replicated or not is under the control of the application making the changes.

This could be useful if an application does some replication external to the server outside of the built-in replication, or if it has some data that should not be replicated for whatever reason.

This is possible with the following system variables.

Primary Session Variable: skip_replication

When the skip_replication variable is set to true, changes are logged into the binary log with the flag `@@skip_replication` set. Such events will not be replicated by replicas that run with `--replicate-events-marked-for-skip` set different from its default of `REPLICATE`.

Variable Name	skip_replication

Scope	Session only
Access Type	Dynamic
Data Type	`bool`
Default Value	`OFF`

The `skip_replication` option only has effect if binary logging is enabled and sql_log_bin is true.

Attempting to change `@@skip_replication` in the middle of a transaction will fail; this is to avoid getting half of a transaction replicated while the other half is not replicated. Be sure to end any current transaction with `COMMIT` / `ROLLBACK` before changing the variable.

Replica Option: --replicate-events-marked-for-skip

The replicate_events_marked_for_skip option tells the replica whether to replicate events that are marked with the `@@skip_replication` flag. Default is `REPLICATE`, to ensure that all changes are replicated to the replica. If set to `FILTER_ON_SLAVE`, events so marked will be skipped on the replica and not replicated. If set to `FILTER_ON_MASTER`, the filtering will be done on the primary, saving on network bandwidth as the events will not be received by the replica at all.

Variable Name	`replicate_events_marked_for_skip`
Scope	Global
Access Type	Dynamic
Data Type	enum: `REPLICATE` | `FILTER_ON_SLAVE` | `FILTER_ON_MASTER`
Default Value	`REPLICATE`

Note: `replicate_events_marked_for_skip` is a dynamic variable (it can be changed without restarting the server), however the replica threads must be stopped when it is changed, otherwise an error will be thrown.

When events are filtered due to `@@skip_replication`, the filtering happens on the primary side; in other words, the event is never sent to the replica. If many events are filtered like this, a replica can sit a long time without receiving any events from the primary. This is not a problem in itself, but must be kept in mind when inquiring on the replica about events that are filtered. For example `START SLAVE UNTIL <some position>` will stop when the first event that is **not** filtered is encountered at the given position or beyond. If the event at the given position is filtered, then the replica thread will only stop when the next non-filtered event is encountered. In effect, if an event is filtered, to the replica it appears that it was never written to the binlog on the primary.

Note that when events are filtered for a replica, the data in the database will be different on the replica and on the primary. It is the responsibility of the application to replicate the data outside of the built-in replication or otherwise ensure consistency of operation. If this is not done, it is possible for replication to encounter, for example, `UNIQUE` contraint violations or other problems which will cause replication to stop and require manual intervention to fix.

The session variable `@@skip_replication` can be changed without requiring special privileges. This makes it possible for normal applications to control it without requiring `SUPER` privileges. But it must be kept in mind when using replicas with `--replicate-events-marked-for-skip` set different from `REPLICATE`, as it allows any connection to do changes that are not replicated.

skip_replication and sql_log_bin

`@@sql_log_bin` and `@@skip_replication` are somewhat related, as they can both be used to prevent a change on the primary from being replicated to the replica. The difference is that with `@@skip_replication`, changes are still written into the binlog, and replication of the events is only skipped on replicas that explicitly are configured to do so, with `--replicate-events-marked-for-skip` different from `REPLICATE`. With `@@sql_log_bin`, events are not logged into the binlog, and so are not replicated by any replica.

skip_replication and the Binlog

When events in the binlog are marked with the `@@skip_replication` flag, the flag will be preserved if the events are dumped by the mariadb-binlog program and re-applied against a server with the mariadb client program. Similarly, the BINLOG statement will preserve the flag from the event being replayed. And a replica which runs with `--log-slave-updates` and does not filter events (`--replicate-events-marked-for-skip=REPLICATE`) will also preserve the flag in

the events logged into the binlog on the replica.

3.1.19 Binlog Event Checksums

> The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

MariaDB includes a feature to include a checksum in binary log events.

Checksums are enabled with the binlog_checksum option. Until MariaDB 10.2.1, this was disabled by default. From MariaDB 10.2.1, the option is set to `CRC32`.

The variable can be changed dynamically without restarting the server. Setting the variable in any way (even to the existing value) forces a rotation of the binary log (the intention is to avoid having a single binlog where some events are checksummed and others are not).

When checksums are enabled, replication slaves will check events received over the network for checksum errors, and will stop with an error if a corrupt event is detected.

In addition, the server can be configured to verify checksums in two other places.

One is when reading events from the binlog on the master, for example when sending events to a slave or for something like SHOW BINLOG EVENTS. This is controlled by option master_verify_checksum, and is thus used to detect file system corruption of the binlog files.

The other is when the slave SQL thread reads events from the relay log. This is controlled by the slave_sql_verify_checksum option, and is used to detect file system corruption of slave relay log files.

`master_verify_checksum`

- **Description:** Verify binlog checksums when reading events from the binlog on the master.
- **Commandline:** `--master_verify_checksum=[0|1]`
- **Scope:** Global
- **Access Type:** Can be changed dynamically
- **Data Type:** `bool`
- **Default Value:** `OFF (0)`

`slave_sql_verify_checksum`

- **Description:** Verify binlog checksums when the slave SQL thread reads events from the relay log.
- **Commandline:** `--slave_sql_verify_checksum=[0|1]`
- **Scope:** Global
- **Access Type:** Can be changed dynamically
- **Data Type:** `bool`
- **Default Value:** `ON (1)`

The mysqlbinlog client program by default does not verify checksums when reading a binlog file, however it can be instructed to do so with the option verify-binlog-checksum:

- **Variable Name:** `verify-binlog-checksum`
- **Data Type:** `bool`
- **Default Value:** `OFF`

1.3.16.3 Annotate_rows_log_event

3.1.21 Row-based Replication With No Primary Key

> The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

MariaDB improves on row-based replication (see binary log formats) of tables which have no primary key but do have some other index. This is based in part on the original Percona patch "row_based_replication_without_primary_key.patch", with some additional fixes and enhancements.

When row-based replication is used with UPDATE or DELETE, the slave needs to locate each replicated row based on the value in columns. If the table contains at least one index, an index lookup will be used (otherwise a table scan is needed for each row, which is extremely inefficient for all but the smallest table and generally to be avoided).

In MariaDB, the slave will try to choose a good index among any available:

- The primary key is used, if there is one.
- Else, the first unique index without NULL-able columns is used, if there is one.
- Else, a choice is made among any normal indexes on the table (e.g. a FULLTEXT index is not considered).

The choice of which of several non-unique indexes to use is based on the cardinality of indexes; the one that is most selective (has the smallest average number of rows per distinct tuple of column values) is preferred. Note that for this choice to be effective, for most storage engines (like MyISAM, InnoDB) it is necessary to make sure ANALYZE TABLE has been run on the slave, otherwise statistics about index cardinality will not be available. In the absence of index cardinality, the first unique index will be chosen, if any, else the first non-unique index.

Prior to MariaDB 5.3, the slave would always choose the first index without considering cardinality. The slave could even choose an unusable index (like FULLTEXT) if no other index was available (MySQL Bug #58997), causing row-based replication to break in this case; this was also fixed in MariaDB 5.3.

3.1.22 Replication Filters

The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Contents

Replication filters allow users to configure replicas to intentionally skip certain events.

Binary Log Filters for Replication Primaries

MariaDB provides options that can be used on a replication primary to restrict local changes to specific databases from getting written to the binary log, which also determines whether any replicas replicate those changes.

Binary Log Filter Options

The following options are available, and they are evaluated in the order that they are listed below. If there are conflicting settings, *binlog_do_db* prevails. Before MariaDB 11.2.0, they are only available as options; from MariaDB 11.2.0 they are also available as system variables.

binlog_do_db

The binlog_do_db option allows you to configure a replication primary to write statements and transactions affecting databases that match a specified name into its binary log. Since the filtered statements or transactions will not be present in the binary log, its replicas will not be able to replicate them.

This option will **not** work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.

This option can **not** be set dynamically.

When setting it on the command-line or in a server option group in an option file, the option does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the option multiple times. For example:

```
[mariadb]
...
binlog_do_db=db1
binlog_do_db=db2
```

This will tell the primary to do the following:

- Write statements and transactions affecting the database named *db1* into the binary log.
- Write statements and transactions affecting the database named *db2* into the binary log.
- Don't write statements and transactions affecting any other databases into the binary log.

binlog_ignore_db

The binlog_ignore_db option allows you to configure a replication primary to **not** write statements and transactions affecting databases that match a specified name into its binary log. Since the filtered statements or transactions will not be present in the binary log, its replicas will not be able to replicate them.

This option will **not** work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.

This option can **not** be set dynamically.

When setting it on the command-line or in a server option group in an option file, the option does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the option multiple times. For example:

```
[mariadb]
...
binlog_ignore_db=db1
binlog_ignore_db=db2
```

This will tell the primary to do the following:

- Don't write statements and transactions affecting the database named *db1* into the binary log.
- Don't write statements and transactions affecting the database named *db2* into the binary log.
- Write statements and transactions affecting any other databases into the binary log.

> The binlog_ignore_db option is effectively ignored if the binlog_do_db option is set, so those two options should not be set together.

Replication Filters for Replicas

MariaDB provides options and system variables that can be used on used on a replicas to filter events replicated in the binary log.

Replication Filter Options

The following options and system variables are available, and they are evaluated in the order that they are listed below. If there are conflicting settings, the respective *replicate_do_* prevails.

replicate_rewrite_db

The replicate_rewrite_db option (and, from MariaDB 10.11, system variable), allows you to configure a replica to rewrite database names. It uses the format `primary_database->replica_database`. If a replica encounters a binary log event in which the default database (i.e. the one selected by the USE statement) is `primary_database`, then the replica will apply the event in `replica_database` instead.

This option will **not** work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.

This option only affects statements that involve tables. This option does not affect statements involving the database itself, such as CREATE DATABASE, ALTER DATABASE, and DROP DATABASE.

This option's rewrites are evaluated *before* any other replication filters configured by the `replicate_*` system variables.

Statements that use table names qualified with database names do not work with other replication filters such as replicate_do_table.

Until MariaDB 10.11, this option could not be set dynamically.

When setting it on the command-line or in a server option group in an option file, the option does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the option multiple times. For example:

```
[mariadb]
...
replicate_rewrite_db=db1->db3
replicate_rewrite_db=db2->db4
```

This will tell the replica to do the following:

- If a binary log event is encountered in which the default database was *db1*, then apply the event in *db3* instead.
- If a binary log event is encountered in which the default database was *db2*, then apply the event in *db4* instead.

See Configuring Replication Filter Options with Multi-Source Replication for how to configure this system variable with multi-source replication.

`replicate_do_db`

The replicate_do_db system variable allows you to configure a replica to apply statements and transactions affecting databases that match a specified name.

This system variable will **not** work with cross-database updates with statement-based logging or when using mixed-based logging and the statement is logged statement based. For statement-based replication, only the default database (that is, the one selected by USE) is considered, not any explicitly mentioned tables in the query. See the Statement-Based Logging section for more information.

When setting it dynamically with SET GLOBAL, the system variable accepts a comma-separated list of filters.

When setting it dynamically, it is not possible to specify database names that contain commas. If you need to specify database names that contain commas, then you will need to specify them by either providing the command-line options or configuring them in a server option group in an option file when the server is started.

When setting it dynamically, the replica threads must be stopped. For example:

```
STOP SLAVE;
SET GLOBAL replicate_do_db='db1,db2';
START SLAVE;
```

When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times. For example:

```
[mariadb]
...
replicate_do_db=db1
replicate_do_db=db2
```

This will tell the replica to do the following:

- Replicate statements and transactions affecting the database named *db1*.
- Replicate statements and transactions affecting the database named *db2*.
- Ignore statements and transactions affecting any other databases.

See Configuring Replication Filter Options with Multi-Source Replication for how to configure this system variable with multi-source replication.

replicate_ignore_db

The replicate_ignore_db system variable allows you to configure a replica to ignore statements and transactions affecting databases that match a specified name.

This system variable will **not** work with cross-database updates with statement-based logging or when using mixed-based logging and the statement is logged statement based. For statement-based replication, only the default database (that is, the one selected by USE) is considered, not any explicitly mentioned tables in the query. See the Statement-Based Logging section for more information.

When setting it dynamically with SET GLOBAL, the system variable accepts a comma-separated list of filters.

When setting it dynamically, it is not possible to specify database names that contain commas. If you need to specify names or patterns that contain commas, then you will need to specify them by either providing the command-line options or configuring them in a server option group in an option file when the server is started.

When setting it dynamically, the replica threads must be stopped. For example:

```
STOP SLAVE;
SET GLOBAL replicate_ignore_db='db1,db2';
START SLAVE;
```

When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times. For example:

```
[mariadb]
...
replicate_ignore_db=db1
replicate_ignore_db=db2
```

This will tell the replica to do the following:

- Ignore statements and transactions affecting databases named *db1*.
- Ignore statements and transactions affecting databases named *db2*.
- Replicate statements and transactions affecting any other databases.

> The replicate_ignore_db system variable is effectively ignored if the replicate_do_db system variable is set, so those two system variables should not be set together.

See Configuring Replication Filter Options with Multi-Source Replication for how to configure this system variable with multi-source replication.

replicate_do_table

The replicate_do_table system variable allows you to configure a replica to apply statements and transactions that affect tables that match a specified name. The table name is specified in the format: `dbname.tablename`.

This system variable will **not** work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.

This option only affects statements that involve tables. This option does not affect statements involving the database itself, such as CREATE DATABASE, ALTER DATABASE, and DROP DATABASE.

When setting it dynamically with SET GLOBAL, the system variable accepts a comma-separated list of filters.

When setting it dynamically, it is not possible to specify database or table names or patterns that contain commas. If you need to specify database or table names that contain commas, then you will need to specify them by either providing the command-line options or configuring them in a server option group in an option file when the server is started.

When setting it dynamically, the replica threads must be stopped. For example:

```
STOP SLAVE;
SET GLOBAL replicate_do_table='db1.tab,db2.tab';
START SLAVE;
```

When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times. For example:

```
[mariadb]
...
replicate_do_table=db1.tab
replicate_do_table=db2.tab
```

This will tell the replica to do the following:

- Replicate statements and transactions affecting tables in databases named *db1* and which are named *tab*.
- Replicate statements and transactions affecting tables in databases named *db2* and which are named *tab*.
- Ignore statements and transactions affecting any other tables.

See Configuring Replication Filter Options with Multi-Source Replication for how to configure this system variable with multi-source replication.

replicate_ignore_table

The replicate_ignore_table system variable allows you to configure a replica to ignore statements and transactions that affect tables that match a specified name. The table name is specified in the format: `dbname.tablename`.

This system variable will **not** work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.

When setting it dynamically with SET GLOBAL, the system variable accepts a comma-separated list of filters.

When setting it dynamically, it is not possible to specify database or table names that contain commas. If you need to specify database or table names that contain commas, then you will need to specify them by either providing the command-line options or configuring them in a server option group in an option file when the server is started.

When setting it dynamically, the replica threads must be stopped. For example:

```
STOP SLAVE;
SET GLOBAL replicate_ignore_table='db1.tab,db2.tab';
START SLAVE;
```

When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times. For example:

```
[mariadb]
...
replicate_ignore_table=db1.tab
replicate_ignore_table=db2.tab
```

This will tell the replica to do the following:

- Ignore statements and transactions affecting tables in databases named *db1* and which are named *tab*.
- Ignore statements and transactions affecting tables in databases named *db2* and which are named *tab*.
- Replicate statements and transactions affecting any other tables.

The replicate_ignore_table system variable is effectively ignored if either the replicate_do_table system variable or the replicate_wild_do_table system variable is set, so the replicate_ignore_table system variable should not be used with those two system variables.

See Configuring Replication Filter Options with Multi-Source Replication for how to configure this system variable with multi-source replication.

replicate_wild_do_table

The replicate_wild_do_table system variable allows you to configure a replica to apply statements and transactions that affect tables that match a specified wildcard pattern.

The wildcard pattern uses the same semantics as the LIKE operator. This means that the the following characters have a special meaning:

- `_` - The `_` character matches any single character.
- `%` - The `%` character matches zero or more characters.
- `\` - The `\` character is used to escape the other special characters in cases where you need the literal character.

This system variable will work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.

The system variable does filter databases, tables, views and triggers.

The system variable does not filter stored procedures, stored functions, and events. The replicate_do_db system variable will need to be used to filter those.

If the table name pattern for a filter is just specified as `%`, then all tables in the database will be matched. In this case, the filter will also affect certain database-level statements, such as CREATE DATABASE, ALTER DATABASE and DROP DATABASE.

When setting it dynamically with SET GLOBAL, the system variable accepts a comma-separated list of filters.

When setting it dynamically, it is not possible to specify database or table names or patterns that contain commas. If you need to specify database or table names or patterns that contain commas, then you will need to specify them by either providing the command-line options or configuring them in a server option group in an option file when the server is started.

When setting it dynamically, the replica threads must be stopped. For example:

```
STOP SLAVE;
SET GLOBAL replicate_wild_do_table='db%.tab%,app1.%';
START SLAVE;
```

When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times. For example:

```
[mariadb]
...
replicate_wild_do_table=db%.tab%
replicate_wild_do_table=app1.%
```

This will tell the replica to do the following:

- Replicate statements and transactions affecting tables in databases that start with *db* and whose table names start with *tab*.
- Replicate statements and transactions affecting the database named *app1*.
- Ignore statements and transactions affecting any other tables and databases.

See Configuring Replication Filter Options with Multi-Source Replication for how to configure this system variable with multi-source replication.

replicate_wild_ignore_table

The replicate_wild_ignore_table system variable allows you to configure a replica to ignore statements and transactions that affect tables that match a specified wildcard pattern.

The wildcard pattern uses the same semantics as the LIKE operator. This means that the the following characters have a special meaning:

- `_` - The `_` character matches any single character.
- `%` - The `%` character matches zero or more characters.
- `\` - The `\` character is used to escape the other special characters in cases where you need the literal character.

This system variable will work with cross-database updates with statement-based logging. See the Statement-Based Logging section for more information.

The system variable does filter databases, tables, views and triggers.

The system variable does not filter stored procedures, stored functions, and events. The replicate_ignore_db system variable will need to be used to filter those.

If the table name pattern for a filter is just specified as `%`, then all tables in the database will be matched. In this case, the filter will also affect certain database-level statements, such as CREATE DATABASE, ALTER DATABASE and DROP DATABASE.

When setting it dynamically with SET GLOBAL, the system variable accepts a comma-separated list of filters.

When setting it dynamically, it is not possible to specify database or table names or patterns that contain commas. If you need to specify database or table names or patterns that contain commas, then you will need to specify them by either providing the command-line options or configuring them in a server option group in an option file when the server is started.

When setting it dynamically, the replica threads must be stopped. For example:

```
STOP SLAVE;
SET GLOBAL replicate_wild_ignore_table='db%.tab%,app1.%';
START SLAVE;
```

When setting it on the command-line or in a server option group in an option file, the system variable does not accept a comma-separated list. If you would like to specify multiple filters, then you need to specify the system variable multiple times. For example:

```
[mariadb]
...
replicate_wild_ignore_table=db%.tab%
replicate_wild_ignore_table=app1.%
```

This will tell the replica to do the following:

- Ignore statements and transactions affecting tables in databases that start with *db* and whose table names start with *tab*.
- Ignore statements and transactions affecting all the tables in the database named *app1*.
- Replicate statements and transactions affecting any other tables and databases.

> The replicate_ignore_table system variable is effectively ignored if either the replicate_do_table system variable or the replicate_wild_do_table system variable is set, so the replicate_ignore_table system variable should not be used with those two system variables.

See Configuring Replication Filter Options with Multi-Source Replication for how to configure this system variable with multi-source replication.

Configuring Replication Filter Options with Multi-Source Replication

How you configure replication filters with multi-source replication depends on whether you are configuring them dynamically or whether you are configuring them in a server option group in an option file.

Setting Replication Filter Options Dynamically with Multi-Source Replication

The usage of dynamic replication filters changes somewhat when multi-source replication is in use. By default, the variables are addressed to the default connection, so in a multi-source environment, the required connection needs to be specified. There are two ways to do this.

Prefixing the Replication Filter Option with the Connection Name

One way to change a replication filter for a multi-source connection is to explicitly specify the name when changing the filter. For example:

```
STOP SLAVE 'gandalf';
SET GLOBAL gandalf.replicate_do_table='database1.table1,database1.table2,database1.table3';
START SLAVE 'gandalf';
```

Changing the Default Connection

Alternatively, the default connection can be changed by setting the default_master_connection system variable, and then the replication filter can be changed in the usual fashion. For example:

```
SET default_master_connection = 'gandalf';
STOP SLAVE;
SET GLOBAL replicate_do_table='database1.table1,database1.table2,database1.table3';
START SLAVE;
```

Setting Replication Filter Options in Option Files with Multi-Source Replication

If you are using multi-source replication and if you would like to make this filter persist server restarts by adding it to a server option group in an option file, then the option file can also include the connection name that each filter would apply to. For example:

```
[mariadb]
...
gandalf.replicate_do_db=database1
saruman.replicate_do_db=database2
```

CHANGE MASTER Options

The CHANGE MASTER statement has a few options that can be used to filter certain types of binary log events.

`IGNORE_SERVER_IDS`

The IGNORE_SERVER_IDS option for `CHANGE MASTER` can be used to configure a replica to ignore binary log events that originated from certain servers. Filtered binary log events will not get logged to the replica's relay log, and they will not be applied by the replica.

`DO_DOMAIN_IDS`

The DO_DOMAIN_IDS option for `CHANGE MASTER` can be used to configure a replica to only apply binary log events if the transaction's GTID is in a specific gtid_domain_id value. Filtered binary log events will not get logged to the replica's relay log, and they will not be applied by the replica.

`IGNORE_DOMAIN_IDS`

The IGNORE_DOMAIN_IDS option for `CHANGE MASTER` can be used to configure a replica to ignore binary log events if the transaction's GTID is in a specific gtid_domain_id value. Filtered binary log events will not get logged to the replica's relay log, and they will not be applied by the replica.

Replication Filters and Binary Log Formats

The way that a replication filter is interpreted can depend on the binary log format.

Statement-Based Logging

When an event is logged in its statement-based format, many replication filters that affect a database will test the filter against the default database (i.e. the one selected by the USE statement). This applies to the following replication filters:

- binlog_do_db
- binlog_ignore_db
- replicate_rewrite_db
- replicate_do_db
- replicate_ignore_db

When an event is logged in its statement-based format, many replication filters that affect a table will test the filter against the table in the default database (i.e. the one selected by the USE statement). This applies to the following replication filters:

- replicate_do_table
- replicate_ignore_table

This means that cross-database updates **not** work with replication filters and statement-based binary logging. For example, if replicate_do_table=db2.tab were set, then the following would not replicate with statement-based binary logging:

```
USE db1;
INSERT INTO db2.tab VALUES (1);
```

If you need to be able to support cross-database updates with replication filters and statement-based binary logging, then you should use the following replication filters:

- replicate_wild_do_table
- replicate_wild_ignore_table

Row-Based Logging

When an event is logged in its row-based format, many replication filters that affect a database will test the filter against the database that is actually affected by the event.

Similarly, when an event is logged in its row-based format, many replication filters that affect a table will test the filter against the table in the the database that is actually affected by the event.

This means that cross-database updates work with replication filters and statement-based binary logging.

> Keep in mind that DDL statements are always logged to the binary log in statement-based format, even when the binlog_format system variable is set to `ROW`. This means that the notes mentioned in Statement-Based Logging

always apply to DDL.

Replication Filters and Galera Cluster

When using Galera cluster, replication filters should be used with caution. See Configuring MariaDB Galera Cluster: Replication Filters for more details.

3.1.23 Running Triggers on the Replica for Row-based Events

The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Contents

MariaDB can force the replica thread to run triggers for row-based binlog events.

The setting is controlled by the slave_run_triggers_for_rbr global variable. It can be also specified as a command-line option or in my.cnf.

Possible values are:

Value	Meaning
NO (Default)	Don't invoke triggers for row-based events
YES	Invoke triggers for row-based events, don't log their effect into the binary log
LOGGING	Invoke triggers for row-based events, and log their effect into the binary log
ENFORCE	From MariaDB 10.5.2 only. Triggers will always be run on the replica, even if there are triggers on the master. ENFORCE implies LOGGING.

Note that if you just want to use triggers together with replication, you most likely don't need this option. Read below for details.

When to Use slave_run_triggers_for_rbr

Background

Normally, MariaDB's replication system can replicate trigger actions automatically.

- When one uses statement-based replication, the binary log contains SQL statements. Replica server(s) execute the SQL statements. Triggers are run on the master and on each replica, independently.
- When one uses row-based replication, the binary log contains row changes. It will have both the changes made by the statement itself, and the changes made by the triggers that were invoked by the statement. Replica server(s) do not need to run triggers for row changes they are applying.

Target Usecase

One may want to have a setup where a replica has triggers that are not present on the master (Suppose the replica needs to update summary tables or perform some other ETL-like process).

If one uses statement-based replication, they can just create the required triggers on the replica. The replica will run the statements from the binary log, which will cause the triggers to be invoked.

However, there are cases where you have to use row-based replication. It could be because the master runs non-deterministic statements, or the master could be a node in a Galera cluster. In that case, you would want row-based events

to invoke triggers on the replica. This is what the `slave_run_triggers_for_rbr` option is for. Setting the option to `YES` will cause the SQL replica thread to invoke triggers for row-based events; setting it to `LOGGING` will also cause the changes made by the triggers to be written into the binary log.

The following triggers are invoked:

- Update_row_event runs an UPDATE trigger
- Delete_row_event runs a DELETE trigger
- Write_row_event runs an INSERT trigger. Additionally it runs a DELETE trigger if there was a conflicting row that had to be deleted.

Preventing Multiple Trigger Invocations

There is a basic protection against triggers being invoked both on the master and replica. If the master modifies a table that has triggers, it will produce row-based binlog events with the "triggers were invoked for this event" flag. The replica will not invoke any triggers for flagged events.

3.1.24 Semisynchronous Replication

Contents

Description

Standard MariaDB replication is asynchronous, but MariaDB also provides a semisynchronous replication option.

With regular asynchronous replication, replicas request events from the primary's binary log whenever the replicas are ready. The primary does not wait for a replica to confirm that an event has been received.

With fully synchronous replication, all replicas are required to respond that they have received the events. See Galera Cluster.

Semisynchronous replication waits for just one replica to acknowledge that it has received and logged the events.

Semisynchronous replication therefore comes with some negative performance impact, but increased data integrity. Since the delay is based on the roundtrip time to the replica and back, this delay is minimized for servers in close proximity over fast networks.

In MariaDB 10.3 and later, semisynchronous replication is built into the server, and is no longer a plugin so it can be enabled immediately in those versions. This removes some overhead and improves performance. See MDEV-13073 for more information.

In MariaDB 10.2 and before, semisynchronous replication requires the user to install a plugin on both the primary and the replica before it can be enabled.

Installing the Plugin

> **MariaDB starting with 10.3.3**
> In MariaDB 10.3.3 and later, the Semisynchronous Replication feature is built into MariaDB server and is no longer provided by a plugin. **This means that installing the plugin is not supported on those versions.** In MariaDB 10.3.3 and later, you can skip right to Enabling Semisynchronous Replication.

The semisynchronous replication plugin is actually two different plugins--one for the primary, and one for the replica. Shared libraries for both plugins are included with MariaDB. Although the plugins' shared libraries distributed with MariaDB by default, the plugin is not actually installed by MariaDB by default prior to MariaDB 10.3.3. There are two methods that can be used to install the plugin with MariaDB.

The first method can be used to install the plugin without restarting the server. You can install the plugin dynamically by executing INSTALL SONAME or INSTALL PLUGIN.

For example, if it's a primary:

```
INSTALL SONAME 'semisync_master';
```

Or if it's a replica:

```
INSTALL SONAME 'semisync_slave';
```

The second method can be used to tell the server to load the plugin when it starts up. The plugin can be installed this way by providing the --plugin-load or the --plugin-load-add options. This can be specified as a command-line argument to mysqld or it can be specified in a relevant server option group in an option file.

For example, if it's a primary:

```
[mariadb]
...
plugin_load_add = semisync_master
```

Or if it's a replica:

```
[mariadb]
...
plugin_load_add = semisync_slave
```

Uninstalling the Plugin

> **MariaDB starting with 10.3.3**
> In MariaDB 10.3.3 and later, the Semisynchronous Replication feature is built into MariaDB server and is no longer provided by a plugin. **This means that uninstalling the plugin is not supported on those versions.**

You can uninstall the plugin dynamically by executing UNINSTALL SONAME or UNINSTALL PLUGIN.

For example, if it's a primary:

```
UNINSTALL SONAME 'semisync_master';
```

Or if it's a replica:

```
UNINSTALL SONAME 'semisync_slave';
```

If you installed the plugin by providing the --plugin-load or the --plugin-load-add options in a relevant server option group in an option file, then those options should be removed to prevent the plugin from being loaded the next time the server is restarted.

Enabling Semisynchronous Replication

Semisynchronous replication can be enabled by setting the relevant system variables on the primary and the replica.

If a server needs to be able to switch between acting as a primary and a replica, then you can enable both the primary and

replica system variables on the server. For example, you might need to do this if MariaDB MaxScale is being used to enable auto-failover or switchover with MariaDB Monitor.

Enabling Semisynchronous Replication on the Primary

Semisynchronous replication can be enabled on the primary by setting the rpl_semi_sync_master_enabled system variable to `ON`. It can be set dynamically with SET GLOBAL. For example:

```
SET GLOBAL rpl_semi_sync_master_enabled=ON;
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
rpl_semi_sync_master_enabled=ON
```

Enabling Semisynchronous Replication on the Replica

Semisynchronous replication can be enabled on the replica by setting the rpl_semi_sync_slave_enabled system variable to `ON`. It can be set dynamically with SET GLOBAL. For example:

```
SET GLOBAL rpl_semi_sync_slave_enabled=ON;
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
rpl_semi_sync_slave_enabled=ON
```

When switching between semisynchronous replication and asynchronous replication on a replica with replica IO threads already running, the replica I/O thread will need to be restarted. For example:

```
STOP SLAVE IO_THREAD;
START SLAVE IO_THREAD;
```

If this is not done, and the replica IO thread will continue to use the previous setting.

Configuring the Primary Timeout

In semisynchronous replication, only after the events have been written to the relay log and flushed does the replica acknowledge receipt of a transaction's events. If the replica does not acknowledge the transaction before a certain amount of time has passed, then a timeout occurs and the primary switches to asynchronous replication. This will be reflected in the primary's error log with messages like the following:

```
[Warning] Timeout waiting for reply of binlog (file: mariadb-1-bin.000002, pos: 538), semi-sync
up to file , position 0.
[Note] Semi-sync replication switched OFF.
```

When this occurs, the Rpl_semi_sync_master_status status variable will be switched to `OFF`.

When at least one semisynchronous replica catches up, semisynchronous replication is resumed. This will be reflected in the primary's error log with messages like the following:

```
[Note] Semi-sync replication switched ON with replica (server_id: 184137206) at (mariadb-1-
bin.000002, 215076)
```

When this occurs, the Rpl_semi_sync_master_status status variable will be switched to `ON`.

The number of times that semisynchronous replication has been switched off can be checked by looking at the value of the Rpl_semi_sync_master_no_times status variable.

If you see a lot of timeouts like this in your environment, then you may want to change the timeout period. The timeout period can be changed by setting the rpl_semi_sync_master_timeout system variable. It can be set dynamically with SET GLOBAL. For example:

```
SET GLOBAL rpl_semi_sync_master_timeout=20000;
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
rpl_semi_sync_master_timeout=20000
```

To determine a good value for the rpl_semi_sync_master_timeout system variable, you may want to look at the values of the Rpl_semi_sync_master_net_avg_wait_time and Rpl_semi_sync_master_tx_avg_wait_time status variables.

Configuring the Primary Wait Point

In semisynchronous replication, there are two potential points at which the primary can wait for the replica acknowledge the receipt of a transaction's events. These two wait points have different advantages and disadvantages.

The wait point is configured by the rpl_semi_sync_master_wait_point system variable. The supported values are:

- `AFTER_SYNC`
- `AFTER_COMMIT`

It can be set dynamically with SET GLOBAL. For example:

```
SET GLOBAL rpl_semi_sync_master_wait_point='AFTER_SYNC';
```

It can also be set in a server option group in an option file prior to starting up the server. For example:

```
[mariadb]
...
rpl_semi_sync_master_wait_point=AFTER_SYNC
```

When this variable is set to `AFTER_SYNC`, the primary performs the following steps:

1. Prepares the transaction in the storage engine.
2. Syncs the transaction to the binary log.
3. Waits for acknowledgement from the replica.
4. Commits the transaction to the storage engine.
5. Returns an acknowledgement to the client.

The effects of the `AFTER_SYNC` wait point are:

- All clients see the same data on the primary at the same time; after acknowledgement by the replica and after being committed to the storage engine on the primary.
- If the primary crashes, then failover should be lossless, because all transactions committed on the primary would have been replicated to the replica.
- However, if the primary crashes, then its binary log may also contain events for transactions that were prepared by the storage engine and written to the binary log, but that were never actually committed by the storage engine. As part of the server's automatic crash recovery process, the server may recover these prepared transactions when the server is restarted. This could cause the "old" crashed primary to become inconsistent with its former replicas when they have been reconfigured to replace the old primary with a new one. The old primary in such a scenario can be re-introduced only as a semisync slave. The server post-crash recovery of the server configured with `rpl_semi_sync_slave_enabled = ON` ensures through MDEV-21117 that the server will not have extra transactions. The reconfigured as semisync replica server's binlog gets truncated to discard transactions proven not to be committed, in any of their branches if they are multi-engine. Truncation does not occur though when there exists a non-transactional group of events beyond the truncation position in which case recovery reports an error. When the semisync replica recovery can't be carried out, the crashed primary may need to be rebuilt.

When this variable is set to `AFTER_COMMIT`, the primary performs the following steps:

1. Prepares the transaction in the storage engine.
2. Syncs the transaction to the binary log.
3. Commits the transaction to the storage engine.
4. Waits for acknowledgement from the replica.
5. Returns an acknowledgement to the client.

The effects of the `AFTER_COMMIT` wait point are:

- Other clients may see the committed transaction before the committing client.

- If the primary crashes, then failover may involve some data loss, because the primary may have committed transactions that had not yet been acknowledged by the replicas.

Versions

Version	Status	Introduced
N/A	N/A	MariaDB 10.3.3
1.0	Stable	MariaDB 10.1.13
1.0	Gamma	MariaDB 10.0.13
1.0	Unknown	MariaDB 10.0.11
1.0	N/A	MariaDB 5.5

System Variables

`rpl_semi_sync_master_enabled`

- **Description:** Set to `ON` to enable semi-synchronous replication primary. Disabled by default.
- **Commandline:** `--rpl-semi-sync-master-enabled[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

`rpl_semi_sync_master_timeout`

- **Description:** The timeout value, in milliseconds, for semi-synchronous replication in the primary. If this timeout is exceeded in waiting on a commit for acknowledgement from a replica, the primary will revert to asynchronous replication.
  - When a timeout occurs, the Rpl_semi_sync_master_status status variable will also be switched to `OFF`.
  - See Configuring the Primary Timeout for more information.
- **Commandline:** `--rpl-semi-sync-master-timeout[=#]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `10000` (10 seconds)
- **Range:** `0` to `18446744073709551615`

`rpl_semi_sync_master_trace_level`

- **Description:** The tracing level for semi-sync replication. Four levels are defined:
  - `1`: General level, including for example time function failures.
  - `16`: More detailed level, with more verbose information.
  - `32`: Net wait level, including more information about network waits.
  - `64`: Function level, including information about function entries and exits.
- **Commandline:** `--rpl-semi-sync-master-trace-level[=#]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `32`
- **Range:** `0` to `18446744073709551615`

`rpl_semi_sync_master_wait_no_slave`

- **Description:** If set to `ON`, the default, the replica count (recorded by Rpl_semi_sync_master_clients) may drop to zero, and the primary will still wait for the timeout period. If set to `OFF`, the primary will revert to asynchronous replication as soon as the replica count drops to zero.
- **Commandline:** `--rpl-semi-sync-master-wait-no-slave[={0|1}]`

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `ON`

`rpl_semi_sync_master_wait_point`

- **Description:** Whether the transaction should wait for semi-sync acknowledgement after having synced the binlog (`AFTER_SYNC`), or after having committed in storage engine (`AFTER_COMMIT` , the default).
  - When this variable is set to `AFTER_SYNC` , the primary performs the following steps:
    1. Prepares the transaction in the storage engine.
    2. Syncs the transaction to the binary log.
    3. Waits for acknowledgement from the replica.
    4. Commits the transaction to the storage engine.
    5. Returns an acknowledgement to the client.
  - When this variable is set to `AFTER_COMMIT` , the primary performs the following steps:
    1. Prepares the transaction in the storage engine.
    2. Syncs the transaction to the binary log.
    3. Commits the transaction to the storage engine.
    4. Waits for acknowledgement from the replica.
    5. Returns an acknowledgement to the client.
  - In MariaDB 10.1.2 and before, this system variable does not exist. However, in those versions, the primary waits for the acknowledgement from replicas at a point that is equivalent to `AFTER_COMMIT` .
  - See Configuring the Primary Wait Point for more information.
- **Commandline:** `--rpl-semi-sync-master-wait-point=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `enum`
- **Default Value:** `AFTER_COMMIT`
- **Valid Values:** `AFTER_SYNC` , `AFTER_COMMIT`
- **Introduced:** MariaDB 10.1.3

`rpl_semi_sync_slave_delay_master`

- **Description:** Only write primary info file when ack is needed.
- **Commandline:** `--rpl-semi-sync-slave-delay-master[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`
- **Introduced:** MariaDB 10.3.3

`rpl_semi_sync_slave_enabled`

- **Description:** Set to `ON` to enable semi-synchronous replication replica. Disabled by default.
- **Commandline:** `--rpl-semi-sync-slave-enabled[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

`rpl_semi_sync_slave_kill_conn_timeout`

- **Description:** Timeout for the mysql connection used to kill the replica io_thread's connection on primary. This timeout comes into play when stop slave is executed.
- **Commandline:** `--rpl-semi-sync-slave-kill-conn-timeout[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `5`
- **Range:** `0` to `4294967295`

- **Introduced:** MariaDB 10.3.3

rpl_semi_sync_slave_trace_level

- **Description:** The tracing level for semi-sync replication. The levels are the same as for rpl_semi_sync_master_trace_level.
- **Commandline:** `--rpl-semi-sync-slave-trace_level[=#]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `32`
- **Range:** `0` to `18446744073709551615`

Options

rpl_semi_sync_master

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--rpl-semi-sync-master=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`
- **Removed:** MariaDB 10.3.3

rpl_semi_sync_slave

- **Description:** Controls how the server should treat the plugin when the server starts up.
  - Valid values are:
    - `OFF` - Disables the plugin without removing it from the mysql.plugins table.
    - `ON` - Enables the plugin. If the plugin cannot be initialized, then the server will still continue starting up, but the plugin will be disabled.
    - `FORCE` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error.
    - `FORCE_PLUS_PERMANENT` - Enables the plugin. If the plugin cannot be initialized, then the server will fail to start with an error. In addition, the plugin cannot be uninstalled with UNINSTALL SONAME or UNINSTALL PLUGIN while the server is running.
  - See Plugin Overview: Configuring Plugin Activation at Server Startup for more information.
- **Commandline:** `--rpl-semi-sync-slave=value`
- **Data Type:** `enumerated`
- **Default Value:** `ON`
- **Valid Values:** `OFF`, `ON`, `FORCE`, `FORCE_PLUS_PERMANENT`
- **Removed:** MariaDB 10.3.3

Status Variables

For a list of status variables added when the plugin is installed, see Semisynchronous Replication Plugin Status Variables.

3.1.25.1 Using MariaDB Replication with MariaDB Galera Cluster

Contents

MariaDB replication and MariaDB Galera Cluster can be used together. However, there are some things that have to be taken into account.

Tutorials

If you want to use MariaDB replication and MariaDB Galera Cluster together, then the following tutorials may be useful:

- Configuring MariaDB Replication between MariaDB Galera Cluster and MariaDB Server
- Configuring MariaDB Replication between Two MariaDB Galera Clusters

Configuring a Cluster Node as a Replication Master

If a Galera Cluster node is also a replication master, then some additional configuration may be needed.

Like with MariaDB replication, write sets that are received by a node with Galera Cluster's certification-based replication are not written to the binary log by default.

If the node is a replication master, then its replication slaves only replicate transactions which are in the binary log, so this means that the transactions that correspond to Galera Cluster write-sets would not be replicated by any replication slaves by default. If you would like a node to write its replicated write sets to the binary log, then you will have to set `log_slave_updates=ON`. If the node has any replication slaves, then this would also allow those slaves to replicate the transactions that corresponded to those write sets.

See Configuring MariaDB Galera Cluster: Writing Replicated Write Sets to the Binary Log for more information.

Configuring a Cluster Node as a Replication Slave

If a Galera Cluster node is also a replication slave, then some additional configuration may be needed.

If the node is a replication slave, then the node's slave SQL thread will be applying transactions that it replicates from its replication master. Transactions applied by the slave SQL thread will only generate Galera Cluster write-sets if the node has

`log_slave_updates=ON` set. Therefore, in order to replicate these transactions to the rest of the nodes in the cluster, `log_slave_updates=ON` must be set.

If the node is a replication slave, then it is probably also a good idea to enable `wsrep_restart_slave`. When this is enabled, the node will restart its slave threads whenever it rejoins the cluster.

Replication Filters

Both MariaDB replication and MariaDB Galera Cluster support replication filters, so extra caution must be taken when using all of these features together. See Configuring MariaDB Galera Cluster: Replication Filters for more details on how MariaDB Galera Cluster interprets replication filters.

Setting server_id on Cluster Nodes

Setting the Same server_id on Each Cluster Node

It is most common to set `server_id` to the same value on each node in a given cluster. Since MariaDB Galera Cluster uses a virtually synchronous certification-based replication, all nodes should have the same data, so in a logical sense, a cluster can be considered in many cases a single logical server for purposes related to MariaDB replication. The binary logs of each cluster node might even contain roughly the same transactions and GTIDs if `log_slave_updates=ON` is set and if wsrep GTID mode is enabled and if non-Galera transactions are not being executed on any nodes.

Setting a Different server_id on Each Cluster Node

There are cases when it might make sense to set a different `server_id` value on each node in a given cluster. For example, if `log_slave_updates=OFF` is set and if another cluster or a standard MariaDB Server is using multi-source replication to replicate transactions from each cluster node individually, then it would be required to set a different `server_id` value on each node for this to work.

Keep in mind that if replication is set up in a scenario where each cluster node has a different `server_id` value, and if the replication topology is set up in such a way that a cluster node can replicate the same transactions through Galera and through MariaDB replication, then you may need to configure the cluster node to ignore these transactions when setting up MariaDB replication. You can do so by setting `IGNORE_SERVER_IDS` to the server IDs of all nodes in the same cluster when executing `CHANGE MASTER TO`. For example, this might be required when circular replication is set up between two separate clusters, and each cluster node as a different `server_id` value, and each cluster has `log_slave_updates=ON` set.

3.1.25.2 Using MariaDB GTIDs with MariaDB Galera Cluster

Contents

MariaDB's global transaction IDs (GTIDs) are very useful when used with MariaDB replication, which is primarily what that feature was developed for. Galera Cluster, on the other hand, was developed by Codership for all MySQL and MariaDB variants, and the initial development of the technology pre-dated MariaDB's GTID implementation. As a side effect, MariaDB Galera Cluster (at least until MariaDB 10.5.1) only partially supports MariaDB's GTID implementation.

GTID Support for Write Sets Replicated by Galera Cluster

Galera Cluster has its own certification-based replication method that is substantially different from MariaDB replication. However, it would still be beneficial if MariaDB Galera Cluster was able to associate a Galera Cluster write set with a GTID that is globally unique, but that is also consistent for that write set on each cluster node.

Before MariaDB 10.5.1, MariaDB Galera Cluster did not replicate the original GTID with the write set except in cases where the transaction was originally applied by a slave SQL thread. Each node independently generated its own GTID for each write set in most cases. See MDEV-20720.

Wsrep GTID Mode

MariaDB supports wsrep_gtid_mode.

MariaDB has a feature called wsrep GTID mode. When this mode is enabled, MariaDB uses some tricks to try to associate each Galera Cluster write set with a GTID that is globally unique, but that is also consistent for that write set on each cluster node. These tricks work in some cases, but GTIDs can still become inconsistent among cluster nodes.

Enabling Wsrep GTID Mode

Several things need to be configured for wsrep GTID mode to work, such as:

- `wsrep_gtid_mode=ON` needs to be set on all nodes in the cluster.
- `wsrep_gtid_domain_id` needs to be set to the same value on all nodes in a given cluster, so that each cluster node uses the same domain when assigning GTIDs for Galera Cluster's write sets. When replicating between two clusters, each cluster should have this set to a different value, so that each cluster uses different domains when assigning GTIDs for their write sets.
- `log_slave_updates` needs to be enabled on all nodes in the cluster. See MDEV-9855.
- `log_bin` needs to be set to the same path on all nodes in the cluster. See MDEV-9856.

And as an extra safety measure:

- `gtid_domain_id` should be set to a different value on all nodes in a given cluster, and each of these values should be different than the configured `wsrep_gtid_domain_id` value. This is to prevent a node from using the same domain used for Galera Cluster's write sets when assigning GTIDs for non-Galera transactions, such as DDL executed with `wsrep_sst_method=RSU` set or DML executed with `wsrep_on=OFF` set.

For information on setting `server_id`, see Using MariaDB Replication with MariaDB Galera Cluster: Setting server_id on Cluster Nodes.

Known Problems with Wsrep GTID Mode

Until MariaDB 10.5.1, there were known cases where GTIDs could become inconsistent across the cluster nodes.

A known issue (fixed in MariaDB 10.5.1) is:

- Implicitly dropped temporary tables can make GTIDs inconsistent. See MDEV-14153 and MDEV-20720.

This does not necessarily imply that wsrep GTID mode works perfectly in all other situations. If you discover any other issues with it, please report a bug.

GTIDs for Transactions Applied by Slave Thread

If a Galera Cluster node is also a replication slave, then that node's slave SQL thread will be applying transactions that it replicates from its replication master. If the node has `log_slave_updates=ON` set, then each transaction that the slave SQL thread applies will also generate a Galera Cluster write set that is replicated to the rest of the nodes in the cluster.

In MariaDB 10.1.30 and earlier, the node acting as slave would apply the transaction with the original GTID that it received from the master, and the other Galera Cluster nodes would generate their own GTIDs for the transaction when they replicated the write set.

In MariaDB 10.1.31 and later, the node acting as slave will include the transaction's original `Gtid_Log_Event` in the replicated write set, so all nodes should associate the write set with its original GTID. See MDEV-13431 about that.

3.1.25.3 Configuring MariaDB Replication between MariaDB Galera Cluster and MariaDB Server

Contents

MariaDB replication can be used to replicate between MariaDB Galera Cluster and MariaDB Server. This article will discuss how to do that.

Configuring the Cluster

Before we set up replication, we need to ensure that the cluster is configured properly. This involves the following steps:

- Set `log_slave_updates=ON` on all nodes in the cluster. See Configuring MariaDB Galera Cluster: Writing Replicated Write Sets to the Binary Log and Using MariaDB Replication with MariaDB Galera Cluster: Configuring a Cluster Node as a Replication Master for more information on why this is important. This is also needed to enable wsrep GTID mode.
- Set `server_id` to the same value on all nodes in the cluster. See Using MariaDB Replication with MariaDB Galera Cluster: Setting server_id on Cluster Nodes for more information on what this means.

Configuring Wsrep GTID Mode

If you want to use GTID replication, then you also need to configure some things to enable wsrep GTID mode. For example:

- `wsrep_gtid_mode=ON` needs to be set on all nodes in the cluster.
- `wsrep_gtid_domain_id` needs to be set to the same value on all nodes in the cluster, so that each cluster node uses the same domain when assigning GTIDs for Galera Cluster's write sets.
- `log_slave_updates` needs to be enabled on all nodes in the cluster. See MDEV-9855 about that.
- `log_bin` needs to be set to the same path on all nodes in the cluster. See MDEV-9856 about that.

And as an extra safety measure:

- gtid_domain_id should be set to a different value on all nodes in a given cluster, and each of these values should be different than the configured wsrep_gtid_domain_id value. This is to prevent a node from using the same domain used for Galera Cluster's write sets when assigning GTIDs for non-Galera transactions, such as DDL executed with wsrep_sst_method=RSU set or DML executed with wsrep_on=OFF set.

Configuring the Replica

Before we set up replication, we also need to ensure that the MariaDB Server replica is configured properly. This involves the following steps:

- Set server_id to a different value than the one that the cluster nodes are using.
- Set gtid_domain_id to a value that is different than the wsrep_gtid_domain_id and gtid_domain_id values that the cluster nodes are using.
- Set log_bin and log_slave_updates=ON if you want the replica to log the transactions that it replicates.

Setting up Replication

Our process to set up replication is going to be similar to the process described at Setting up a Replication Slave with Mariabackup, but it will be modified a bit to work in this context.

Start the Cluster

The very first step is to start the nodes in the first cluster. The first node will have to be bootstrapped. The other nodes can be started normally.

Once the nodes are started, you need to pick a specific node that will act as the replication primary for the MariaDB Server.

Backup the Database on the Cluster's Primary Node and Prepare It

The first step is to simply take and prepare a fresh full backup of the node that you have chosen to be the replication primary. For example:

```
$ mariabackup --backup \
   --target-dir=/var/mariadb/backup/ \
   --user=mariabackup --password=mypassword
```

And then you would prepare the backup as you normally would. For example:

```
$ mariabackup --prepare \
   --target-dir=/var/mariadb/backup/
```

Copy the Backup to the Replica

Once the backup is done and prepared, you can copy it to the MariaDB Server that will be acting as replica. For example:

```
$ rsync -avrP /var/mariadb/backup dc2-dbserver1:/var/mariadb/backup
```

Restore the Backup on the Second Cluster's Replica

At this point, you can restore the backup to the datadir, as you normally would. For example:

```
$ mariabackup --copy-back \
   --target-dir=/var/mariadb/backup/
```

And adjusting file permissions, if necessary:

```
$ chown -R mysql:mysql /var/lib/mysql/
```

Start the New Replica

Now that the backup has been restored to the MariaDB Server replica, you can start the MariaDB Server process.

Create a Replication User on the Cluster's Primary

Before the MariaDB Server replica can begin replicating from the cluster's primary, you need to create a user account on the primary that the replica can use to connect, and you need to grant the user account the REPLICATION SLAVE privilege. For example:

```
CREATE USER 'repl'@'dc2-dbserver1' IDENTIFIED BY 'password';
GRANT REPLICATION SLAVE ON *.*  TO 'repl'@'dc2-dbserver1';
```

Start Replication on the New Replica

At this point, you need to get the replication coordinates of the primary from the original backup.

The coordinates will be in the xtrabackup_binlog_info file.

Mariabackup dumps replication coordinates in two forms: GTID strings and binary log file and position coordinates, like the

ones you would normally see from SHOW MASTER STATUS output. In this case, it is probably better to use the GTID coordinates.

For example:

```
mariadb-bin.000096 568 0-1-2
```

Regardless of the coordinates you use, you will have to set up the primary connection using CHANGE MASTER TO and then start the replication threads with START SLAVE.

GTIDs

If you want to use GTIDs, then you will have to first set gtid_slave_pos to the GTID coordinates that we pulled from the xtrabackup_binlog_info file, and we would set MASTER_USE_GTID=slave_pos in the CHANGE MASTER TO command. For example:

```
SET GLOBAL gtid_slave_pos = "0-1-2";
CHANGE MASTER TO
   MASTER_HOST="c1dbserver1",
   MASTER_PORT=3310,
   MASTER_USER="repl",
   MASTER_PASSWORD="password",
   MASTER_USE_GTID=slave_pos;
START SLAVE;
```

File and Position

If you want to use the binary log file and position coordinates, then you would set MASTER_LOG_FILE and MASTER_LOG_POS in the CHANGE MASTER TO command to the file and position coordinates that we pulled the xtrabackup_binlog_info file. For example:

```
CHANGE MASTER TO
   MASTER_HOST="c1dbserver1",
   MASTER_PORT=3310,
   MASTER_USER="repl",
   MASTER_PASSWORD="password",
   MASTER_LOG_FILE='mariadb-bin.000096',
   MASTER_LOG_POS=568,
START SLAVE;
```

Check the Status of the New Replica

You should be done setting up the replica now, so you should check its status with SHOW SLAVE STATUS. For example:

```
SHOW SLAVE STATUS\G
```

Now that the MariaDB Server is up, ensure that it does not start accepting writes yet if you want to set up circular replication between the cluster and the MariaDB Server.

Setting up Circular Replication

You can also set up circular replication between the cluster and MariaDB Server, which means that the MariaDB Server replicates from the cluster, and the cluster also replicates from the MariaDB Server.

Create a Replication User on the MariaDB Server Primary

Before circular replication can begin, you also need to create a user account on the MariaDB Server, since it will be acting as replication primary to the cluster's replica, and you need to grant the user account the REPLICATION SLAVE privilege. For example:

```
CREATE USER 'repl'@'c1dbserver1' IDENTIFIED BY 'password';
GRANT REPLICATION SLAVE ON *.*  TO 'repl'@'c1dbserver1';
```

Start Circular Replication on the Cluster

How this is done would depend on whether you want to use the GTID coordinates or the binary log file and position coordinates.

Regardless, you need to ensure that the second cluster is not accepting any writes other than those that it replicates from the cluster at this stage.

GTIDs

To get the GTID coordinates on the MariaDB Server you can check `gtid_current_pos` by executing:

```
SHOW GLOBAL VARIABLES LIKE 'gtid_current_pos';
```

Then on the node acting as replica in the cluster, you can set up replication by setting gtid_slave_pos to the GTID that was returned and then executing CHANGE MASTER TO:

```
SET GLOBAL gtid_slave_pos = "0-1-2";
CHANGE MASTER TO
   MASTER_HOST="c2dbserver1",
   MASTER_PORT=3310,
   MASTER_USER="repl",
   MASTER_PASSWORD="password",
   MASTER_USE_GTID=slave_pos;
START SLAVE;
```

File and Position

To get the binary log file and position coordinates on the MariaDB Server, you can execute SHOW MASTER STATUS:

```
SHOW MASTER STATUS
```

Then on the node acting as replica in the cluster, you would set `master_log_file` and `master_log_pos` in the CHANGE MASTER TO command. For example:

```
CHANGE MASTER TO
   MASTER_HOST="c2dbserver1",
   MASTER_PORT=3310,
   MASTER_USER="repl",
   MASTER_PASSWORD="password",
   MASTER_LOG_FILE='mariadb-bin.000096',
   MASTER_LOG_POS=568;
START SLAVE;
```

Check the Status of the Circular Replication

You should be done setting up the circular replication on the node in the first cluster now, so you should check its status with SHOW SLAVE STATUS. For example:

```
SHOW SLAVE STATUS\G
```

3.1.25.4 Configuring MariaDB Replication between Two MariaDB Galera Clusters

Contents

MariaDB replication can be used to replication between two MariaDB Galera Clusters. This article will discuss how to do that.

Configuring the Clusters

Before we set up replication, we need to ensure that the clusters are configured properly. This involves the following steps:

- Set `log_slave_updates=ON` on all nodes in both clusters. See Configuring MariaDB Galera Cluster: Writing Replicated Write Sets to the Binary Log and Using MariaDB Replication with MariaDB Galera Cluster: Configuring a Cluster Node as a Replication Master for more information on why this is important. This is also needed to enable wsrep GTID mode.
- Set `server_id` to the same value on all nodes in a given cluster, but be sure to use a different value in each cluster. See Using MariaDB Replication with MariaDB Galera Cluster: Setting server_id on Cluster Nodes for more information on what this means.

Configuring Wsrep GTID Mode

If you want to use GTID replication, then you also need to configure some things to enable wsrep GTID mode. For example:

- `wsrep_gtid_mode=ON` needs to be set on all nodes in each cluster.
- `wsrep_gtid_domain_id` needs to be set to the same value on all nodes in a given cluster, so that each cluster node uses the same domain when assigning GTIDs for Galera Cluster's write sets. Each cluster should have this set to a different value, so that each cluster uses different domains when assigning GTIDs for their write sets.
- `log_slave_updates` needs to be enabled on all nodes in the cluster. See MDEV-9855 about that.
- `log_bin` needs to be set to the same path on all nodes in the cluster. See MDEV-9856 about that.

And as an extra safety measure:

- `gtid_domain_id` should be set to a different value on all nodes in a given cluster, and each of these values should be different than the configured `wsrep_gtid_domain_id` value. This is to prevent a node from using the same domain used for Galera Cluster's write sets when assigning GTIDs for non-Galera transactions, such as DDL executed with `wsrep_sst_method=RSU` set or DML executed with `wsrep_on=OFF` set.

Setting up Replication

Our process to set up replication is going to be similar to the process described at Setting up a Replication Slave with Mariabackup, but it will be modified a bit to work in this context.

Start the First Cluster

The very first step is to start the nodes in the first cluster. The first node will have to be bootstrapped. The other nodes can be started normally.

Once the nodes are started, you need to pick a specific node that will act as the replication primary for the second cluster.

Backup the Database on the First Cluster's Primary Node and Prepare It

The first step is to simply take and prepare a fresh full backup of the node that you have chosen to be the replication primary. For example:

```
$ mariabackup --backup \
   --target-dir=/var/mariadb/backup/ \
   --user=mariabackup --password=mypassword
```

And then you would prepare the backup as you normally would. For example:

```
$ mariabackup --prepare \
   --target-dir=/var/mariadb/backup/
```

Copy the Backup to the Second Cluster's Replica

Once the backup is done and prepared, you can copy it to the node in the second cluster that will be acting as replica. For example:

```
$ rsync -avrP /var/mariadb/backup c2dbserver:/var/mariadb/backup
```

Restore the Backup on the Second Cluster's Replica

At this point, you can restore the backup to the datadir, as you normally would. For example:

```
$ mariabackup --copy-back \
   --target-dir=/var/mariadb/backup/
```

And adjusting file permissions, if necessary:

```
$ chown -R mysql:mysql /var/lib/mysql/
```

Bootstrap the Second Cluster's Replica

Now that the backup has been restored to the second cluster's replica, you can start the server by bootstrapping the node.

Create a Replication User on the First Cluster's Primary

Before the second cluster's replica can begin replicating from the first cluster's primary, you need to create a user account on the primary that the replica can use to connect, and you need to grant the user account the REPLICATION SLAVE privilege. For example:

```
CREATE USER 'repl'@'c2dbserver1' IDENTIFIED BY 'password';
GRANT REPLICATION SLAVE ON *.*  TO 'repl'@'c2dbserver1';
```

Start Replication on the Second Cluster's Replica

At this point, you need to get the replication coordinates of the primary from the original backup.

The coordinates will be in the xtrabackup_binlog_info file.

Mariabackup dumps replication coordinates in two forms: GTID strings and binary log file and position coordinates, like the ones you would normally see from SHOW MASTER STATUS output. In this case, it is probably better to use the GTID coordinates.

For example:

```
mariadb-bin.000096 568 0-1-2
```

Regardless of the coordinates you use, you will have to set up the primary connection using CHANGE MASTER TO and then start the replication threads with START SLAVE.

GTIDs

If you want to use GTIDs, then you will have to first set `gtid_slave_pos` to the GTID coordinates that we pulled from the `xtrabackup_binlog_info` file, and we would set `MASTER_USE_GTID=slave_pos` in the `CHANGE MASTER TO` command. For example:

```
SET GLOBAL gtid_slave_pos = "0-1-2";
CHANGE MASTER TO
   MASTER_HOST="c1dbserver1",
   MASTER_PORT=3310,
   MASTER_USER="repl",
   MASTER_PASSWORD="password",
   MASTER_USE_GTID=slave_pos;
START SLAVE;
```

File and Position

If you want to use the binary log file and position coordinates, then you would set `MASTER_LOG_FILE` and `MASTER_LOG_POS` in the `CHANGE MASTER TO` command to the file and position coordinates that we pulled the `xtrabackup_binlog_info` file. For example:

```
CHANGE MASTER TO
   MASTER_HOST="c1dbserver1",
   MASTER_PORT=3310,
   MASTER_USER="repl",
   MASTER_PASSWORD="password",
   MASTER_LOG_FILE='mariadb-bin.000096',
   MASTER_LOG_POS=568,
START SLAVE;
```

Check the Status of the Second Cluster's Replica

You should be done setting up the replica now, so you should check its status with `SHOW SLAVE STATUS`. For example:

```
SHOW SLAVE STATUS\G
```

Start the Second Cluster

If the replica is replicating normally, then the next step would be to start the MariaDB Server process on the other nodes in the second cluster.

Now that the second cluster is up, ensure that it does not start accepting writes yet if you want to set up circular replication between the two clusters.

Setting up Circular Replication

You can also set up circular replication between the two clusters, which means that the second cluster replicates from the first cluster, and the first cluster also replicates from the second cluster.

Create a Replication User on the Second Cluster's Primary

Before circular replication can begin, you also need to create a user account on the second cluster's primary that the first cluster's replica can use to connect, and you need to grant the user account the `REPLICATION SLAVE` privilege. For example:

```
CREATE USER 'repl'@'c1dbserver1' IDENTIFIED BY 'password';
GRANT REPLICATION SLAVE ON *.*  TO 'repl'@'c1dbserver1';
```

Start Circular Replication on the First Cluster

How this is done would depend on whether you want to use the GTID coordinates or the binary log file and position coordinates.

Regardless, you need to ensure that the second cluster is not accepting any writes other than those that it replicates from the first cluster at this stage.

GTIDs

To get the GTID coordinates on the second cluster, you can check `gtid_current_pos` by executing:

```
SHOW GLOBAL VARIABLES LIKE 'gtid_current_pos';
```

Then on the first cluster, you can set up replication by setting `gtid_slave_pos` to the GTID that was returned and then executing CHANGE MASTER TO:

```
SET GLOBAL gtid_slave_pos = "0-1-2";
CHANGE MASTER TO
   MASTER_HOST="c2dbserver1",
   MASTER_PORT=3310,
   MASTER_USER="repl",
   MASTER_PASSWORD="password",
   MASTER_USE_GTID=slave_pos;
START SLAVE;
```

File and Position

To get the binary log file and position coordinates on the second cluster, you can execute SHOW MASTER STATUS:

```
SHOW MASTER STATUS
```

Then on the first cluster, you would set `master_log_file` and `master_log_pos` in the CHANGE MASTER TO command. For example:

```
CHANGE MASTER TO
   MASTER_HOST="c2dbserver1",
   MASTER_PORT=3310,
   MASTER_USER="repl",
   MASTER_PASSWORD="password",
   MASTER_LOG_FILE='mariadb-bin.000096',
   MASTER_LOG_POS=568;
START SLAVE;
```

Check the Status of the Circular Replication

You should be done setting up the circular replication on the node in the first cluster now, so you should check its status with SHOW SLAVE STATUS. For example:

```
SHOW SLAVE STATUS\G
```

3.1.26 Delayed Replication

> The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Delayed replication allows specifying that a replica should lag behind the primary by (at least) a specified amount of time (specified in seconds). Before executing an event, the replica will first wait, if necessary, until the given time has passed since the event was created on the primary. The result is that the replica will reflect the state of the primary some time back in the past.

The default is zero, or no delay, and the maximum value is 2147483647, or about 68 years.

Delayed replication is enabled using the MASTER_DELAY option to CHANGE MASTER:

```
  CHANGE MASTER TO master_delay=3600;
```

A zero delay disables delayed replication. The replica must be stopped when changing the delay value.

Three fields in SHOW SLAVE STATUS are associated with delayed replication:

1. SQL_Delay: This is the value specified by MASTER_DELAY in CHANGE MASTER (or 0 if none).
2. SQL_Remaining_Delay. When the replica is delaying the execution of an event due to MASTER_DELAY, this is the number of seconds of delay remaining before the event will be applied. Otherwise, the value is NULL.
3. Slave_SQL_Running_State. This shows the state of the SQL driver threads, same as in SHOW PROCESSLIST. When the replica is delaying the execution of an event due to MASTER_DELAY, this fields displays: "Waiting until MASTER_DELAY seconds after master executed event".

When using older versions prior to MariaDB 10.2.3, a 3rd party tool called pt-slave-delay can be used. It is part of the Percona Toolkit. Note that pt-slave-delay does not support MariaDB multi-channel replication syntax.

3.1.27 Replication When the Primary and Replica Have Different Table Definitions

The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Contents

While replication is usually meant to take place between primaries and replicas with the same table definitions and this is recommended, in certain cases replication can still take place even if the definitions are identical.

Tables on the replica and the primary do not need to have the same definition in order for replication to take place. There can be differing numbers of columns, or differing data definitions and, in certain cases, replication can still proceed.

Different Column Definitions - Attribute Promotion and Demotion

It is possible in some cases to replicate to a replica that has a column of a different type on the replica and the primary. This process is called attribute promotion (to a larger type) or attribute demotion (to a smaller type).

The conditions differ depending on whether statement-based or row-based replication is used.

Statement-Based Replication

When using statement-based replication, generally, if a statement can run successfully on the replica, it will be replicated. If a column definition is the same or a larger type on the replica than on the primary, it can replicate successfully. For example a column defined as `VARCHAR(10)` will successfully be replicated on a replica with a definition of `VARCHAR(12)`.

Replicating to a replica where the column is defined as smaller than on the primary can also work. For example, given the following table definitions:

Master:

```
DESC r;
+-------+-------------+------+-----+---------+-------+
| Field | Type        | Null | Key | Default | Extra |
+-------+-------------+------+-----+---------+-------+
| id    | tinyint(4)  | YES  |     | NULL    |       |
| v     | varchar(10) | YES  |     | NULL    |       |
+-------+-------------+------+-----+---------+-------+
```

Slave

```
DESC r;
+-------+-------------+------+-----+---------+-------+
| Field | Type        | Null | Key | Default | Extra |
+-------+-------------+------+-----+---------+-------+
| id    | tinyint(4)  | YES  |     | NULL    |       |
| v     | varchar(8)  | YES  |     | NULL    |       |
+-------+-------------+------+-----+---------+-------+
```

the statement

```
INSERT INTO r VALUES (6,'hi');
```

would successfully replicate because the value inserted into the `v` field can successfully be inserted on both the primary and the smaller replica equivalent.

However, the following statement would fail:

```
INSERT INTO r VALUES (7,'abcdefghi')
```

In this case, the value fits in the primary definition, but is too long for the replica field, and so replication will fail.

```
SHOW SLAVE STATUS\G
*************************** 1. row ***************************
...
Slave_IO_Running: Yes
Slave_SQL_Running: No
...
Last_Errno: 1406
Last_Error: Error 'Data too long for column 'v' at row 1' on query.
   Default database: 'test'. Query: 'INSERT INTO r VALUES (7,'abcdefghi')'
...
```

Row-Based Replication

When using row-based replication, the value of the slave_type_conversions variable is important. The default value of this variable is empty, in which case MariaDB will not perform attribute promotion or demotion. If the column definitions do not match, replication will stop. If set to `ALL_NON_LOSSY`, safe replication is permitted. If set to `ALL_LOSSY` as well, replication will be permitted even if data loss takes place.

For example:

Master:

```
DESC r;
+-------+-------------+------+-----+---------+-------+
| Field | Type        | Null | Key | Default | Extra |
+-------+-------------+------+-----+---------+-------+
| id    | smallint(6) | YES  |     | NULL    |       |
| v     | varchar(10) | YES  |     | NULL    |       |
+-------+-------------+------+-----+---------+-------+
```

Slave:

```
SHOW VARIABLES LIKE 'slave_ty%';
+-------------------------+-------+
| Variable_name           | Value |
+-------------------------+-------+
| slave_type_conversions |       |
+-------------------------+-------+

 DESC r;
+-------+------------+------+-----+---------+-------+
| Field | Type       | Null | Key | Default | Extra |
+-------+------------+------+-----+---------+-------+
| id    | tinyint(4) | YES  |     | NULL    |       |
| v     | varchar(1) | YES  |     | NULL    |       |
+-------+------------+------+-----+---------+-------+
```

The following query will fail:

```
INSERT INTO r VALUES (3,'c');
```

```
SHOW SLAVE STATUS\G;
...
Slave_IO_Running: Yes
Slave_SQL_Running: No
...
Last_Errno: 1677
Last_Error: Column 0 of table 'test.r' cannot be converted from
  type 'smallint' to type 'tinyint(4)'
...
```

By changing the value of the slave_type_conversions, replication can proceed:

```
SET GLOBAL slave_type_conversions='ALL_NON_LOSSY,ALL_LOSSY';

START SLAVE;
```

```
SHOW SLAVE STATUS\G;
*************************** 1. row ***************************
...
             Slave_IO_Running: Yes
            Slave_SQL_Running: Yes
...
```

Supported Conversions

- Between TINYINT, SMALLINT, MEDIUMINT, INT and BIGINT. If lossy conversion is supported, the value from the primary will be converted to the maximum or minimum permitted on the replica, which non-lossy conversions require the replica column to be large enough. For example, SMALLINT UNSIGNED can be converted to MEDIUMINT, but not SMALLINT SIGNED.

Different Number or Order of Columns

Replication can also take place when the primary and replica have a different number of columns if the following criteria are met:

- columns must be in the same order on the primary and replica
- common columns must be defined with the same data type
- extra columns must be defined after the common columns

Row-Based

The following example replicates incorrectly (replication proceeds, but the data is corrupted), as the columns are not in the same order.

Master:

```
CREATE OR REPLACE TABLE r (i1 INT, i2 INT);
```

Slave:

```
ALTER TABLE r ADD i3 INT AFTER i1;
```

Master:

```
INSERT INTO r (i1,i2) VALUES (1,1);

SELECT * FROM r;
+------+------+
| i1   | i2   |
+------+------+
|    1 |    1 |
+------+------+
```

Slave:

```
SELECT * FROM r;
+------+------+------+
| i1   | i3   | i2   |
+------+------+------+
|    1 |    1 | NULL |
+------+------+------+
```

Statement-Based

Using statement-based replication, the same example may work, even though the columns are not in the same order.

Master:

```
CREATE OR REPLACE TABLE r (i1 INT, i2 INT);
```

Slave:

```
ALTER TABLE r ADD i3 INT AFTER i1;
```

Master:

```
INSERT INTO r (i1,i2) VALUES (1,1);

SELECT * FROM r;
+------+------+
| i1   | i2   |
+------+------+
|    1 |    1 |
+------+------+
```

Slave:

```
 SELECT * FROM r;
+------+------+------+
| i1   | i3   | i2   |
+------+------+------+
|    1 | NULL |    1 |
+------+------+------+
```

3.1.28 Restricting Speed of Reading Binlog from Primary by a Replica

When a replica starts after being stopped for some time, or a new replica starts that was created from a backup from some time back, a lot of old binlog events may need to be downloaded from the primary. If this happens from many replicas simultaneously, it can put a lot of load on the primary.

The **read_binlog_speed_limit** option can be used to reduce such load, by limiting the speed at which events are downloaded. The limit is given as maximum kilobytes per second to download on one replica connection.

With this option set, the replication I/O thread will limit the rate of download. Since the I/O thread is often much faster to download events than the SQL thread is at applying them, an appropriate value for **read_binlog_speed_limit** may reduce load spikes on the primary without much limit in the speed of the replica.

The option **read_binlog_speed_limit** is available starting from MariaDB 10.2.3.

`read_binlog_speed_limit`

- **Description:** Maximum speed(KB/s) to read binlog from primary.
- **Commandline:** `--read-binlog-speed-limit[=#]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` to `4294967295`
- **Introduced:** MariaDB 10.2.3

3.1.29 Changing a Replica to Become the Primary

The terms *master* and *slave* have historically been used in replication, but the terms terms *primary* and *replica* are now preferred. The old terms are used still used in parts of the documentation, and in MariaDB commands, although MariaDB 10.5 has begun the process of renaming. The documentation process is ongoing. See MDEV-18777 to follow progress on this effort.

Contents

This article describes how to change a replica to become a primary and optionally to set the old primary as a replica for the new primary.

A typical scenario of when this is useful is if you have set up a new version of MariaDB as a replica, for example for testing, and want to upgrade your primary to the new version.

In MariaDB replication, a replica should be of a version same or newer than the primary. Because of this, one should first upgrades all replicas to the latest version before changing a replica to be a primary. In some cases one can have a replica to be of an older version than the primary, as long as one doesn't execute on the primary any SQL commands that the replica doesn't understand. This is however not guaranteed between all major MariaDB versions.

Note that in the examples below, `[connection_name]` is used as the name of the connection. If you are not using named connections you can ignore this.

Stopping the Original Master.

First one needs to take down the original primary in such a way that the replica has all information on the primary.

If you are using Semisynchronous Replication you can just stop the server with the SHUTDOWN command as the replicas should be automatically up to date.

If you are using MariaDB MaxScale proxy, then you can use MaxScale to handle the whole process of taking down the primary and replacing it with one of the replicas.

If neither of the above is true, you have to do this step manually:

Manually Take Down the Primary

First we have to set the primary to read only to ensure that there are no new updates on the primary:

```
FLUSH TABLES WITH READ LOCK;
```

Note that you should not disconnect this session as otherwise the read lock will disappear and you have to start from the beginning.

Then you should check the current position of the primary:

```
SHOW MASTER STATUS;
+--------------------+----------+--------------+------------------+
| File               | Position | Binlog_Do_DB | Binlog_Ignore_DB |
+--------------------+----------+--------------+------------------+
| mariadb-bin.000003 |      343 |              |                  |
+--------------------+----------+--------------+------------------+
SELECT @@global.gtid_binlog_pos;
+---------------------------+
| @@global.gtid_binlog_pos |
+---------------------------+
| 0-1-2                     |
+---------------------------+
```

And wait until you have the same position on the replica: (The following should be excepted on the replica)

```
SHOW SLAVE [connection_name] STATUS;
+------------------+-------------------+
Master_Log_File     | narttu-bin.000003 +
Read_Master_Log_Pos | 343               +
Exec_Master_Log_Pos | 343               +
...
Gtid_IO_Pos          0-1-2              +
+------------------+-------------------+
```

The most important information to watch are `Master_Log_File` and `Exec_Master_Log_Pos` as when this matches the primary, it signals that all transactions has been committed on the replica.

Note that `Gtid_IO_Pos` on replica can contain many different positions separated with ',' if the replica has been connected to many different primaries. What is important is that all the sequences that are on the primary is also on the replica.

When replica is up to date, you can then take the **PRIMARY** down. This should be on the same connection where you executed FLUSH TABLES WITH READ LOCK.

```
SHUTDOWN;
```

Preparing the Replica to be a Primary

Stop all old connections to the old primary(s) and reset **read only mode**, if you had it enabled. You also want to save the values of SHOW MASTER STATUS and `gtid_binlog_pos`, as you may need these to setup new replicas.

```
STOP ALL SLAVES;
RESET SLAVE ALL;
SHOW MASTER STATUS;
SELECT @@global.gtid_binlog_pos;
SET @@global.read_only=0;
```

Reconnect Other Replicas to the New Primary

On the other replicas you have point them to the new primary (the replica you promoted to a primary).

```
STOP SLAVE [connection_name];
CHANGE MASTER [connection_name] TO MASTER_HOST="new_master_name",
MASTER_PORT=3306, MASTER_USER='root', MASTER_USE_GTID=current_pos,
MASTER_LOG_FILE="XXX", MASTER_LOG_POS=XXX;
START SLAVE;
```

The `XXX` values for `MASTER_LOG_FILE` and `MASTER_LOG_POS` should be the values you got from the `SHOW MASTER STATUS` command you did when you finished setting up the replica.

Changing the Old Primary to be a Replica

Now you can upgrade the new primary to a newer version of MariaDB and then follow the same procedure to connect it as a replica.

When starting the original primary, it's good to start the `mysqld` executable with the `--with-skip-slave-start` and `--read-only` options to ensure that no old replica configurations could cause any conflicts.

For the same reason it's also good to execute the following commands on the old primary (same as for other replicas, but with some extra security). The `read_only` option below is there to ensure that old applications doesn't by accident try to update the old primary by mistake. It only affects normal connections to the replica, not changes from the new primary.

```
set @@global.read_only=1;
STOP ALL SLAVES;
RESET MASTER;
RESET SLAVE ALL;
CHANGE MASTER [connection_name] TO MASTER_HOST="new_master_name",
MASTER_PORT=3306, MASTER_USER='root', MASTER_USE_GTID=current_pos,
MASTER_LOG_FILE="XXX", MASTER_LOG_POS=XXX;
START SLAVE;
```

Moving Applications to Use New Primary

You should now point your applications to use the new primary. If you are using the MariaDB MaxScale proxy, then you don't have to do this step as MaxScale will take care of sending write request to the new primary.

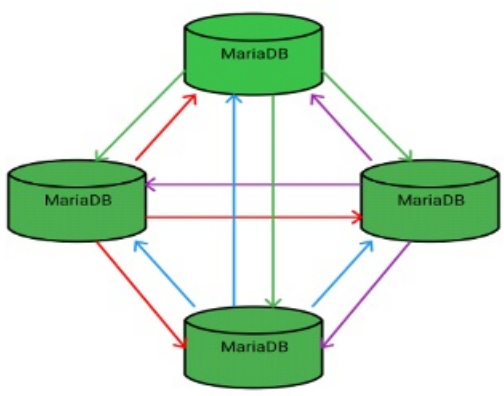
3.2.1 What is MariaDB Galera Cluster?

Contents

About



MariaDB Galera Cluster is a virtually synchronous multi-primary cluster for MariaDB. It is available on Linux only, and only supports the InnoDB storage engine (although there is experimental support for MyISAM and, from MariaDB 10.6, Aria. See

the wsrep_replicate_myisam system variable, or, from MariaDB 10.6, the wsrep_mode system variable).

Features

- Virtually synchronous replication
- Active-active multi-primary topology
- Read and write to any cluster node
- Automatic membership control, failed nodes drop from the cluster
- Automatic node joining
- True parallel replication, on row level
- Direct client connections, native MariaDB look & feel

Benefits

The above features yield several benefits for a DBMS clustering solution, including:

- No replica lag
- No lost transactions
- Read scalability
- Smaller client latencies

The Getting Started with MariaDB Galera Cluster page has instructions on how to get up and running with MariaDB Galera Cluster.

> A great resource for Galera users is Codership on Google Groups (`codership-team 'at' googlegroups (dot) com`) - If you use Galera it is recommended you subscribe.

Galera Versions

MariaDB Galera Cluster is powered by:

- MariaDB Server.
- The Galera wsrep provider library.

The functionality of MariaDB Galera Cluster can be obtained by installing the standard MariaDB Server packages and the Galera wsrep provider library package. The following Galera version corresponds to each MariaDB Server version:

- In MariaDB 10.4 and later, MariaDB Galera Cluster uses Galera 4. This means that the wsrep API version is 26 and the Galera wsrep provider library is version 4.X.
- In MariaDB 10.3 and before, MariaDB Galera Cluster uses Galera 3. This means that the wsrep API is version 25 and the Galera wsrep provider library is version 3.X.

See Deciphering Galera Version Numbers for more information about how to interpret these version numbers.

Galera 4 Versions

The following table lists each version of the Galera 4 wsrep provider, and it lists which version of MariaDB each one was first released in. If you would like to install Galera 4 using yum, apt, or zypper, then the package is called `galera-4` .

Galera Version	Released in MariaDB Version
26.4.14	10.10.3, 10.9.5, 10.8.7, 10.7.8, 10.6.12, 10.5.19, 10.4.28
26.4.13	10.10.2, 10.9.4, 10.8.6, 10.7.7, 10.6.11, 10.5.18, 10.4.27
26.4.12	10.10.1, 10.9.2, 10.8.4, 10.7.5, 10.6.9, 10.5.17, 10.4.26
26.4.11	10.8.1, 10.7.2, 10.6.6, 10.5.14, 10.4.22
26.4.9	10.6.4, 10.5.12, 10.4.21
26.4.8	10.6.1, 10.5.10, 10.4.19
26.4.7	10.5.9, 10.4.18
26.4.6	10.5.7, 10.4.16
26.4.5	10.5.4, 10.4.14
26.4.4	10.5.1, 10.4.13

26.4.3	10.5.0, 10.4.9
26.4.2	10.4.4
26.4.1	10.4.3
26.4.0	10.4.2

Galera 3 Versions

The following table lists each version of the Galera 3 wsrep provider, and it lists which version of MariaDB each one was first released in. If you would like to install Galera 3 using yum, apt, or zypper, then the package is called `galera`.

Galera Version	Released in MariaDB Version
25.3.37	MariaDB 10.3.36
25.3.35	MariaDB 10.3.33, MariaDB 10.2.42
25.3.34	MariaDB 10.3.31, MariaDB 10.2.40
25.3.33	MariaDB 10.3.29, MariaDB 10.2.38

3.2.2 About Galera Replication

Contents

In MariaDB Cluster, the Server replicates a transaction at commit time by broadcasting the write set associated with the transaction to every node in the cluster. The client connects directly to the DBMS and experiences behavior that is similar to native MariaDB in most cases. The wsrep API (write set replication API) defines the interface between Galera replication and MariaDB.

Synchronous vs. Asynchronous Replication

The basic difference between synchronous and asynchronous replication is that "synchronous" replication guarantees that if a change happened on one node in the cluster, then the change will happen on other nodes in the cluster "synchronously", or at the same time. "Asynchronous" replication gives no guarantees about the delay between applying changes on "master" node and the propagation of changes to "slave" nodes. The delay with "asynchronous" replication can be short or long. This also implies that if master node crashes in an "asynchronous" replication topology, then some of the latest changes may be lost.

Theoretically, synchronous replication has a number of advantages over asynchronous replication:

- Clusters utilizing synchronous replication are always highly available. If one of the nodes crashed, then there would be no data loss. Additionally, all cluster nodes are always consistent.
- Clusters utilizing synchronous replication allow transactions to be executed on all nodes in parallel.
- Clusters utilizing synchronous replication can guarantee causality across the whole cluster. This means that if a `SELECT` is executed on one cluster node after a transaction is executed on a cluster node, it should see the effects of that transaction.

However, in practice, synchronous database replication has traditionally been implemented via the so-called "2-phase commit" or distributed locking which proved to be very slow. Low performance and complexity of implementation of synchronous replication led to a situation where asynchronous replication remains the dominant means for database performance scalability and availability. Widely adopted open-source databases such as MySQL or PostgreSQL offer only asynchronous or semi-synchronous replication solutions.

Galera's replication is not completely synchronous. It is sometimes called **virtually synchronous** replication.

Certification-Based Replication Method

An alternative approach to synchronous replication that uses Group Communication and transaction ordering techniques was suggested by a number of researchers. For example:

- Database State Machine Approach
- Don't Be Lazy, Be Consistent

Prototype implementations have shown a lot of promise. We combined our experience in synchronous database replication and the latest research in the field to create the Galera Replication library and the wsrep API.

Galera replication is a **highly transparent**, **scalable**, and **virtually synchronous** replication solution for database clustering to achieve high availability and improved performance. Galera-based clusters are:

- Highly available
- Highly transparent
- Highly scalable (near linear scalability may be reached depending on the application)

Generic Replication Library

Galera replication functionality is implemented as a shared library and can be linked with any transaction processing system which implements the wsrep API hooks.

The Galera replication library is a protocol stack providing functionality for preparing, replicating and applying of transaction write sets. It consists of:

- **wsrep API** specifies the interface — responsibilities for DBMS and replication provider
- **wsrep hooks** is the wsrep integration in the DBMS engine.
- **Galera provider** implements the wsrep API for Galera library
- **certification** layer takes care of preparing write sets and performing certification
- **replication** manages replication protocol and provides total ordering capabilities
- **GCS framework** provides plugin architecture for group communication systems
- many gcs implementations can be adapted, we have experimented with spread and our in-house implementations: vsbes and gemini

Many components in the Galera replication library were redesigned and improved with the introduction of MariaDB 10.4, which includes Galera 4.

Galera Slave Threads

Although the **Galera provider** certifies the write set associated with a transaction at commit time on each node in the cluster, this write set is not necessarily applied on that cluster node immediately. Instead, the write set is placed in the cluster node's receive queue on the node, and it is eventually applied by one of the cluster node's Galera slave thread.

The number of Galera slave threads can be configured with the wsrep_slave_threads system variable.

The Galera slave threads are able to determine which write sets are safe to apply in parallel. However, if your cluster nodes seem to have frequent consistency problems, then setting the value to `1` will probably fix the problem.

When a cluster node's state, as seen by wsrep_local_state_comment, is `JOINED`, then increasing the number of slave threads may help the cluster node catch up with the cluster more quickly. In this case, it may be useful to set the number of threads to twice the number of CPUs on the system.

Streaming Replication

MariaDB starting with 10.4

Streaming replication was introduced in Galera 4, and so is only available from MariaDB 10.4.

In older versions of MariaDB Cluster there was a 2GB limit on the size of the transaction you could run. The node waits on the transaction commit before performing replication and certification. With large transactions, long running writes, and changes to huge data-sets, there was a greater possibility of a conflict forcing rollback on an expensive operation.

Using Streaming replication, the node breaks huge transactions up into smaller and more manageable fragments, it then replicates these fragments to the cluster as it works instead of waiting for the commit. Once certified, the fragment can no longer be aborted by conflicting transactions. As this can have performance consequences both during execution and in the event of rollback, it is recommended that you only use it with large transactions that are unlikely to experience conflict.

For more information on Streaming Replication, see the Galera documentation.

Group Commits

MariaDB starting with 10.4

Group Commit support for MariaDB Cluster was introduced in Galera 4, and so is only available from MariaDB 10.4.

In MariaDB Group Commit, groups of transactions are flushed together to disk to improve performance. Prior to MariaDB 10.4, this feature was not available in MariaDB Cluster as it interfered with the global-ordering of transactions for replication. Beginning in 10.4, MariaDB Cluster can take advantage of Group Commit.

For more information on Group Commit, see the Galera documentation.

3.2.3 Galera Use Cases

Here are some common use cases for Galera replication:

Read Master	Traditional MariaDB master-slave topology, but with Galera all "slave" nodes are capable masters at all times - it is just the application that treats them as slaves. Galera replication can guarantee zero slave lag for such installations and, due to parallel slave applying, much better throughput for the cluster.

WAN Clustering	Synchronous replication works fine over the WAN network. There will be a delay, which is proportional to the network round trip time (RTT), but it only affects the commit operation.
Disaster Recover	Disaster recovery is a sub-class of WAN replication. Here one data center is passive and only receives replication events, but does not process any client transactions. Such a remote data center will be up to date at all times and no data loss can happen. During recovery, the spare site is just nominated as primary and application can continue as normal with a minimal fail over delay.
Latency Eraser	With WAN replication topology, cluster nodes can be located close to clients. Therefore all read & write operations will be super fast with the local node connection. The RTT related delay will be experienced only at commit time, and even then it can be generally accepted by end user, usually the kill-joy for end user experiences is the slow browsing response time, and read operations are as fast as they possibly can be.

3.2.4 MariaDB Galera Cluster - Known Limitations

This article contains information on known problems and limitations of MariaDB Galera Cluster.

Limitations from codership.com:

- Currently replication works only with the InnoDB storage engine. Any writes to tables of other types, including system (mysql.*) tables are not replicated (this limitation excludes DDL statements such as CREATE USER, which implicitly modify the mysql.* tables — those are replicated). There is however experimental support for MyISAM - see the wsrep_replicate_myisam system variable)
- Unsupported explicit locking include LOCK TABLES, FLUSH TABLES {explicit table list} WITH READ LOCK, (GET_LOCK(), RELEASE_LOCK(),…). Using transactions properly should be able to overcome these limitations. Global locking operators like FLUSH TABLES WITH READ LOCK are supported.
- All tables should have a primary key (multi-column primary keys are supported). DELETE operations are unsupported on tables without a primary key. Also, rows in tables without a primary key may appear in a different order on different nodes.
- The general query log and the slow query log cannot be directed to a table. If you enable these logs, then you must forward the log to a file by setting `log_output=FILE`.
- XA transactions are not supported.
- Transaction size. While Galera does not explicitly limit the transaction size, a writeset is processed as a single memory-resident buffer and as a result, extremely large transactions (e.g. LOAD DATA) may adversely affect node performance. To avoid that, the wsrep_max_ws_rows and wsrep_max_ws_size system variables limit transaction rows to 128K and the transaction size to 2Gb by default. If necessary, users may want to increase those limits. Future versions will add support for transaction fragmentation.

Other observations, in no particular order:

- If you are using mysqldump for state transfer, and it failed for whatever reason (e.g. you do not have the database account it attempts to connect with, or it does not have necessary permissions), you will see an SQL SYNTAX error in the server error log. Don't let it fool you, this is just a fancy way to deliver a message (the pseudo-statement inside of the bogus SQL will actually contain the error message).
- Do not use transactions of any essential size. Just to insert 100K rows, the server might require additional 200-300 Mb. In a less fortunate scenario it can be 1.5 Gb for 500K rows, or 3.5 Gb for 1M rows. See MDEV-466 for some numbers (you'll see that it's closed, but it's not closed because it was fixed).
- Locking is lax when DDL is involved. For example, if your DML transaction uses a table, and a parallel DDL statement is started, in the normal MySQL setup it would have waited for the metadata lock, but in Galera context it will be executed right away. It happens even if you are running a single node, as long as you configured it as a cluster node. See also MDEV-468. This behavior might cause various side-effects, the consequences have not been investigated yet. Try to avoid such parallelism.
- Do not rely on auto-increment values to be sequential. Galera uses a mechanism based on autoincrement increment to produce unique non-conflicting sequences, so on every single node the sequence will have gaps. See http://codership.blogspot.com/2009/02/managing-auto-increments-with-multi.html
- A command may fail with `ER_UNKNOWN_COM_ERROR` producing 'WSREP has not yet prepared node for application use' (or 'Unknown command' in older versions) error message. It happens when a cluster is suspected to be split and the node is in a smaller part — for example, during a network glitch, when nodes temporarily lose each other. It can

also occur during state transfer. The node takes this measure to prevent data inconsistency. Its usually a temporary state which can be detected by checking wsrep_ready value. The node, however, allows SHOW and SET command during this period.

- After a temporary split, if the 'good' part of the cluster was still reachable and its state was modified, resynchronization occurs. As a part of it, nodes of the 'bad' part of the cluster drop all client connections. It might be quite unexpected, especially if the client was idle and did not even know anything wrong was happening. Please also note that after the connection to the isolated node is restored, if there is a flow on the node, it takes a long time for it to synchronize, during which the "good" node says that the cluster is already of the normal size and synced, while the rejoining node says it's only joined (but not synced). The connections keep getting 'unknown command'. It should pass eventually.
- While binlog_format is checked on startup and can only be ROW (see Binary Log Formats), it can be changed at runtime. Do NOT change binlog_format at runtime, it is likely not only cause replication failure, but make all other nodes crash.
- If you are using rsync for state transfer, and a node crashes before the state transfer is over, rsync process might hang forever, occupying the port and not allowing to restart the node. The problem will show up as 'port in use' in the server error log. Find the orphan rsync process and kill it manually.
- Performance: by design performance of the cluster cannot be higher than performance of the slowest node; however, even if you have only one node, its performance can be considerably lower comparing to running the same server in a standalone mode (without wsrep provider). It is particularly true for big enough transactions (even those which are well within current limitations on transaction size quoted above).
- Windows is not supported.
- Replication filters: When using Galera cluster, replication filters should be used with caution. See Configuring MariaDB Galera Cluster: Replication Filters for more details. See also MDEV-421 and MDEV-6229.
- Flashback isn't supported in Galera due to incompatible binary log format.
- `FLUSH PRIVILEGES` is not replicated.
- The query cache needed to be disabled by setting `query_cache_size=0` prior to MariaDB Galera Cluster 5.5.40, MariaDB Galera Cluster 10.0.14, and MariaDB 10.1.2..
- In an asynchronous replication setup where a master replicates to a galera node acting as slave, parallel replication (slave-parallel-threads > 1) on slave is currently not supported (see MDEV-6860).
- The disk-based Galera gcache is not encrypted (MDEV-8072).
- Nodes may have different table definitions, especially temporarily during rolling schema upgrade operations, but the same schema compatibility restrictions apply as they do for ROW based replication

3.2.5 Tips on Converting to Galera

Contents

These topics will be discussed in more detail below.

Dear Schema Designer:

- InnoDB only, always have PK.

Dear Developer:

- Check for errors, even after COMMIT.
- Moderate sized transactions.
- Don't make assumptions about AUTO_INCREMENT values.
- Handling of "critical reads" is quite different (arguably better).
- Read/Write split is not necessary, but is still advised in case the underlying structure changes in the future.

Dear DBA:

- Building the machines is quite different. (Not covered here)
- ALTERs are handled differently.
- TRIGGERs and EVENTs may need checking.
- Tricks in replication (eg, BLACKHOLE) may not work.
- Several variables need to be set differently.

Galera is available in many places

Galera's High Availability replication is available via:

- MariaDB 10.1 and later
- Percona XtraDB Cluster
- Codership's Galera Cluster for MySQL

Overview of cross-colo writing

(This overview is valid even for same-datacenter nodes, but the issues of latency vanish.)

Cross-colo latency is an 'different' than with traditional replication, but not necessarily better or worse with Galera. The latency happens at a very different time for Galera.

In 'traditional' replication, these steps occur:

- Client talks to Master. If Client and Master are in different colos, this has a latency hit.
- Each SQL to Master is another latency hit, including(?) the COMMIT (unless using autocommit).
- Replication to Slave(s) is asynchronous, so this does not impact the client writing to the Master.
- Since replication is asynchronous, a Client (same or subsequent) cannot be guaranteed to see that data on the Slave. This is a "critical read". The async Replication delay forces apps to take some evasive action.

In Galera-based replication:

- Client talks to any Master -- possibly with cross-colo latency. Or you could arrange to have Galera nodes co-located with clients to avoid this latency.
- At COMMIT time (or end of statement, in case of autocommit=1), galera makes one roundtrip to other nodes.
- The COMMIT usually succeeds, but could fail if some other node is messing with the same rows. (Galera retries on autocommit failures.)
- Failure of the COMMIT is reported to the Client, who should simply replay the SQL statements from the BEGIN.
- Later, the whole transaction will be applied (with possibility of conflict) on the other nodes.
- Critical Read -- details below

For an N-statement transaction: In a typical 'traditional' replication setup:

- 0 or N (N+2?) latency hits, depending on whether the Client is co-located with the Master.
- Replication latencies and delays lead to issues with "Critical Reads".

In Galera:

- 0 latency hits (assuming Client is 'near' some node)
- 1 latency hit for the COMMIT.
- 0 (usually) for Critical Read (details below)

Bottom line: Depending on where your Clients are, and whether you clump statements into BEGIN...COMMIT transacitons, Galera may be faster or slower than traditional replication in a WAN topology.

AUTO_INCREMENT

By using wsrep_auto_increment_control = ON, the values of auto_increment_increment and auto_increment_offset will be automatically adjusted as nodes come/go.

If you are building a Galera cluster by starting with one node as a Slave to an existing non-Galera system, and if you have multi-row INSERTs that depend on AUTO_INCREMENTs, the read this Percona blog

Bottom line: There may be gaps in AUTO_INCREMENT values. Consecutive rows, even on one connection, will not have

consecutive ids.

Beware of Proxies that try to implement a "read/write split". In some situations, a reference to LAST_INSERT_ID() will be sent to a "Slave".

InnoDB only

For effective replication of data, you must use only InnoDB. This eliminates

- FULLTEXT index (until 5.6)
- SPATIAL index
- MyISAM's PK as second column

You can use MyISAM and MEMORY for data that does not need to be replicated.

Also, you should use "START TRANSACTION READONLY" wherever appropriate.

Check after COMMIT

Check for errors after issuing COMMIT. A "deadlock" can occur due to writes on other node(s).

Possible exception (could be useful for legacy code without such checks): Treat the system as single-Master, plus Slaves. By writing only to one node, COMMIT should always succeed(?)

What about autocommit = 1? wsrep_retry_autocommit tells Galera to retry if a single statement that is autocommited N times. So, there is still a chance (very slim) of getting a deadlock on such a statement. The default setting of "1" retry is probably good.

Always have PRIMARY KEY

"Row Based Replication" will be used; this requires a PK on every table.

A non-replicated table (eg, MyISAM) does not have to have a PK.

Transaction "size"

(This section assumes you have Galera nodes in multiple colos.) Because of some of the issues discussed, it is wise to group your write statements into moderate sized BEGIN...COMMIT transactions. There is one latency hit per COMMIT or autocommit. So, combining statements will decrease those hits. On the other hand, it is unwise (for other reasons) to make huge transactions, such as inserting/modifying millions of rows in a single transaction.

To deal with failure on COMMIT, design your code so you can redo the SQL statements in the transaction without messing up other data. For example, move "normalization" statements out of the main transaction; there is arguably no compelling reason to roll them back if the main code rolls back.

In any case, doing what is "right" for the business logic overrides other considerations.

Galera's tx_isolation is between Serializable and Repeatable Read. tx_isolation variable is ignored.

Set wsrep_log_conflicts to get errors put in the regular MySQL mysqld.err.

XA transactions cannot be supported. (Galera is already doing a form of XA in order to do its thing.)

Critical reads

Here is a 'simple' (but not 'free') way to assure that a read-after-write, even from a different connection, will see the updated data.

SET SESSION wsrep_sync_wait = 1; SELECT ... SET SESSION wsrep_sync_wait = 0;

For non-SELECTs, use a different bit set for the first select. (TBD: Would 0xffff always work?) (Before Galera 3.6, it was wsrep_causal_reads = ON.) Doc for wsrep_sync_wait

This setting stalls the SELECT until all current updates have been applied to the node. That is sufficient to guarantee that a previous write will be visible. The time cost is usually zero. However, a large UPDATE could lead to a delay. Because of RBR and parallel application, delays are likely to be less than on traditional replication. Zaitsev's blog

It may be more practical (for a web app) to simply set wsrep_sync_wait right after connecting.

MyISAM and MEMORY

As said above, use InnoDB only. However, here is more info on the MyISAM (and hence FULLTEXT, SPATIAL, etc) issues.

MyISAM and MEMORY tables are not replicated.

Having MyISAM not replicated can be a big benefit -- You can "CREATE TEMPORARY TABLE ... ENGINE=MyISAM" and have it exist on only one node. RBR assures that any data transferred from that temp table into a 'real' table can still be replicated.

Replicating GRANTs

GRANTs and related operations act on the MyISAM tables in the database `mysql`. The GRANT statements will(?) be replicated, but the underlying tables will not.

ALTERs

Many DDL changes on Galera can be achieved without downtime, even if they take a long time.

RSU vs TOI:

- Rolling Schema Upgrade (RSU): manually execute the DDL on each node in the cluster. The node will desync while executing the DDL.
- Total Order Isolation (TOI): Galera automatically replicates the DDL to each node in the cluster, and it synchronizes each node so that the statement is executed at same time (in the replication sequence) on all nodes.

Caution: Since there is no way to synchronize the clients with the DDL, you must make sure that the clients are happy with either the old or the new schema. Otherwise, you will probably need to take down the entire cluster while simultaneously switching over both the schema and the client code.

Fast DDL operations can usually be executed in TOI mode:

- DDL operations that support the `NOCOPY` and `INSTANT` algorithms are usually very fast.
- DDL operations that support the `INPLACE` algorithm may be fast or slow, depending on whether the table needs to be rebuilt.
- DDL operations that only support the `COPY` algorithm are usually very slow.

For a list of which operations support which algorithms, see InnoDB Online DDL.

If you need to use RSU mode, then do the following separately for each node:

```
SET SESSION wsrep_OSU_method='RSU';
ALTER TABLE tab <alter options here>;
SET SESSION wsrep_OSU_method='TOI';
```

More discussion of RSU procedures

Single "Master" Configuration

You can 'simulate' Master + Slaves by having clients write only to one node.

- No need to check for errors after COMMIT.
- Lose the latency benefits.

DBA tricks

- Remove node from cluster; back it up; put it back in. Syncup is automatic.
- Remove node from cluster; use it for testing, etc; put it back in. Syncup is automatic.
- Rolling hardware/software upgrade: Remove; upgrade; put back in. Repeat.

Variables that may need to be different

- auto_increment_increment - If you are writing to multiple nodes, and you use AUTO_INCREMENT, then auto_increment_increment will automatically be equal the current number of nodes.
- binlog-do/ignore-db - Do not use.
- binlog_format - ROW is required for Galera.
- innodb_autoinc_lock_mode - 2
- innodb_doublewrite - ON: When an IST occurs, want there to be no torn pages? (With FusionIO or other drives that guarantee atomicity, OFF is better.)
- innodb_flush_log_at_trx_commit - 2 or 0. IST or SST will recover from loss if you have 1.

- query_cache_size - 0
- query_cache_type - 0: The Query cache cannot be used in a Galera context.
- wsrep_auto_increment_control - Normally want ON
- wsrep_on - ON
- wsrep_provider_options - Various settings may need tuning if you are using a WAN.
- wsrep_slave_threads - use for parallel replication
- wsrep_sync_wait (previously wsrep_causal_reads) - used transiently to dealing with "critical reads".

Miscellany

Until recently, FOREIGN KEYs were buggy.

LOAD DATA is auto-chunked. That is, it is passed to other nodes piecemeal, not all at once.

MariaDB's known issues with Galera

DROP USER may not replicate?

A slight difference in ROLLBACK for conflict: InnoDB rolls back smaller transaction; Galera rolls back last.

Slide Deck for Galera

SET GLOBAL wsrep_debug = 1; leads to a lot of debug info in the error log.

Large UPDATEs / DELETEs should be broken up. This admonition is valid for all databases, but there are additional issues in Galera.

WAN: May need to increase (from the defaults) wsrep_provider_options = evs...

MySQL/Perona 5.6 or MariaDB 10 is recommended when going to Galera.

Cluster limitations Slide show

GTIDs

See Using MariaDB GTIDs with MariaDB Galera Cluster.

How many nodes to have in a cluster

If all the servers are in the same 'vulnerability zone' -- eg, rack or data center -- Have an odd number (at least 3) of nodes.

When spanning colos, you need 3 (or more) data centers in order to be 'always' up, even during a colo failure. With only 2 data centers, Galera can automatically recover from one colo outage, but not the other. (You pick which.)

If you use 3 or 4 colos, these number of nodes per colo are safe:

- 3 nodes: 1+1+1 (1 node in each of 3 colos)
- 4 nodes: 1+1+1+1 (4 nodes won't work in 3 colos)
- 5 nodes: 2+2+1, 2+1+1+1 (5 nodes spread 'evenly' across the colos)
- 6 nodes: 2+2+2, 2+2+1+1
- 7 nodes: 3+2+2, 3+3+1, 2+2+2+1, 3+2+1+1 There may be a way to "weight" the nodes differently; that would allow a few more configurations. With "weighting", give each colo the same weight; then subdivide the weight within each colo evenly. Four nodes in 3 colos: (1/6+1/6) + 1/3 + 1/3 That way, any single colo failure cannot lead to "split brain".

3.2.6 Getting Started with MariaDB Galera Cluster

Galera 3.

For convenience, packages containing these libraries are included in the MariaDB YUM and APT repositories.

Currently, MariaDB Galera Cluster only supports the InnoDB storage engine (although there is experimental support for MyISAM and, from MariaDB 10.6, Aria).

A great resource for Galera users is the mailing list run by the developers at Codership. It can be found at Codership on Google Groups. If you use Galera, then it is recommended you subscribe.

Contents

Galera Cluster Support in MariaDB Server

MariaDB Galera Cluster is powered by:

- MariaDB Server.
- The MySQL-wsrep patch for MySQL Server and MariaDB Server developed by Codership. The patch currently supports only Unix-like operating systems.
- The Galera wsrep provider library.

In MariaDB 10.1 and later, the MySQL-wsrep patch has been merged into MariaDB Server. This means that the functionality of MariaDB Galera Cluster can be obtained by installing the standard MariaDB Server packages and the Galera wsrep provider library package. The following Galera version corresponds to each MariaDB Server version:

- In MariaDB 10.4 and later, MariaDB Galera Cluster uses Galera 4. This means that the MySQL-wsrep patch is version 26 and the Galera wsrep provider library is version 4.
- In MariaDB 10.3 and before, MariaDB Galera Cluster uses Galera 3. This means that the MySQL-wsrep patch is version 25 and the Galera wsrep provider library is version 3.

See Deciphering Galera Version Numbers for more information about how to interpret these version numbers.

See What is MariaDB Galera Cluster?: Galera Versions for more information about which specific Galera version is included in each release of MariaDB Server.

In supported builds, Galera Cluster functionality can be enabled by setting some configuration options that are mentioned below. Galera Cluster functionality is not enabled in a standard MariaDB Server installation unless explicitly enabled with these configuration options.

Prerequisites

Swap Size Requirements

During normal operation a MariaDB Galera node does not consume much more memory than a regular MariaDB server. Additional memory is consumed for the certification index and uncommitted writesets, but normally this should not be noticeable in a typical application. There is one exception though:

1. **Writeset caching during state transfer.** When a node is receiving a state transfer it cannot process and apply incoming writesets because it has no state to apply them to yet. Depending on a state transfer mechanism (e.g. mysqldump) the node that sends the state transfer may not be able to apply writesets as well. Thus they need to cache those writesets for a catch-up phase. Currently the writesets are cached in memory and, if the system runs out of memory either the state transfer will fail or the cluster will block waiting for the state transfer to end.

To control memory usage for writeset caching, check the Galera parameters: `gcs.recv_q_hard_limit`, `gcs.recv_q_soft_limit`, and `gcs.max_throttle`.

Limitations

Before using MariaDB Galera Cluster, we would recommend reading through the known limitations, so you can be sure that it is appropriate for your application.

Installing MariaDB Galera Cluster

To use MariaDB Galera Cluster, there are two primary packages that you need to install:

1. A MariaDB Server version that supports Galera Cluster.
2. The Galera wsrep provider library.

As mentioned in the previous section, in MariaDB 10.1 and above, Galera Cluster support is actually included in the standard MariaDB Server packages. That means that installing MariaDB Galera Cluster package is the same as installing standard MariaDB Server package in those versions. However, you will also have to install an additional package to obtain the Galera wsrep provider library.

Some SST methods may also require additional packages to be installed. The `mariabackup` SST method is generally the best option for large clusters that expect a lot of load.

Installing MariaDB Galera Cluster with a Package Manager

MariaDB Galera Cluster can be installed via a package manager on Linux. In order to do so, your system needs to be configured to install from one of the MariaDB repositories.

You can configure your package manager to install it from MariaDB Corporation's MariaDB Package Repository by using the MariaDB Package Repository setup script.

You can also configure your package manager to install it from MariaDB Foundation's MariaDB Repository by using the MariaDB Repository Configuration Tool.

Installing MariaDB Galera Cluster with yum/dnf

On RHEL, CentOS, Fedora, and other similar Linux distributions, it is highly recommended to install the relevant RPM packages from MariaDB's repository using `yum` or `dnf`. Starting with RHEL 8 and Fedora 22, `yum` has been replaced by `dnf`, which is the next major version of `yum`. However, `yum` commands still work on many systems that use `dnf`.

To install MariaDB Galera Cluster with `yum` or `dnf`, follow the instructions at Installing MariaDB Galera Cluster with yum.

Installing MariaDB Galera Cluster with apt-get

On Debian, Ubuntu, and other similar Linux distributions, it is highly recommended to install the relevant DEB packages from MariaDB's repository using `apt-get`.

To install MariaDB Galera Cluster with `apt-get`, follow the instructions at Installing MariaDB Galera Cluster with apt-get.

Installing MariaDB Galera Cluster with zypper

On SLES, OpenSUSE, and other similar Linux distributions, it is highly recommended to install the relevant RPM packages

from MariaDB's repository using `zypper`.

To install MariaDB Galera Cluster with `zypper`, follow the instructions at Installing MariaDB Galera Cluster with ZYpp.

Installing MariaDB Galera Cluster with a Binary Tarball

To install MariaDB Galera Cluster with a binary tarball, follow the instructions at Installing MariaDB Binary Tarballs.

MariaDB Galera Cluster starting with 10.0.24

To make the location of the `libgalera_smm.so` library in binary tarballs more similar to its location in other packages, the library is now found at `lib/galera/libgalera_smm.so` in the binary tarballs, and there is a symbolic link in the `lib` directory that points to it.

Installing MariaDB Galera Cluster from Source

To install MariaDB Galera Cluster by compiling it from source, you will have to compile both MariaDB Server and the Galera wsrep provider library. For some information on how to do this, see the pages at Installing Galera From Source. The pages at Compiling MariaDB From Source and Galera Cluster Documentation: Building Galera Cluster for MySQL may also be helpful.

Configuring MariaDB Galera Cluster

A number of options need to be set in order for Galera Cluster to work when using MariaDB. See Configuring MariaDB Galera Cluster for more information.

Bootstrapping a New Cluster

To first node of a new cluster needs to be bootstrapped by starting mariadbd on that node with the option `--wsrep-new-cluster` option. This option tells the node that there is no existing cluster to connect to. The node will create a new UUID to identify the new cluster.

Do not use the --wsrep-new-cluster option when connecting to an existing cluster. Restarting the node with this option set will cause the node to create new UUID to identify the cluster again, and the node won't reconnect to the old cluster. See the next section about how to reconnect to an existing cluster.

For example, if you were manually starting mariadbd on a node, then you could bootstrap it by executing the following:

```
$ mariadbd --wsrep-new-cluster
```

However, keep in mind that most users are not going to be starting mariadbd manually. Instead, most users will use a service manager to start mariadbd. See the following sections on how to bootstrap a node with the most common service managers.

Systemd and Bootstrapping

On operating systems that use systemd, a node can be bootstrapped in the following way:

```
$ galera_new_cluster
```

This wrapper uses systemd to run mariadbd with the --wsrep-new-cluster option.

If you are using the systemd service that supports the systemd service's method for interacting with multiple MariaDB Server processes, then you can bootstrap a specific instance by specifying the instance name as a suffix. For example:

```
$ galera_new_cluster mariadb@node1
```

Systemd support and the galera_new_cluster script were added in MariaDB 10.1.

SysVinit and Bootstrapping

On operating systems that use sysVinit, a node can be bootstrapped in the following way:

```
$ service mysql bootstrap
```

This runs mariadbd with the `--wsrep-new-cluster` option.

Adding Another Node to a Cluster

Once you have a cluster running and you want to add/reconnect another node to it, you must supply an address of one or more of the existing cluster members in the `wsrep_cluster_address` option. For example, if the first node of the cluster has the address 192.168.0.1, then you could add a second node to the cluster by setting the following option in a server option group in an option file:

```
[mariadb]
...
wsrep_cluster_address=gcomm://192.168.0.1  # DNS names work as well, IP is preferred for performa
```

The new node only needs to connect to one of the existing cluster nodes. Once it connects to one of the existing cluster nodes, it will be able to see all of the nodes in the cluster. However, it is generally better to list all nodes of the cluster in `wsrep_cluster_address`, so that any node can join a cluster by connecting to any of the other cluster nodes, even if one or more of the cluster nodes are down. It is even OK to list a node's own IP address in `wsrep_cluster_address`, since Galera Cluster is smart enough to ignore it.

Once all members agree on the membership, the cluster's state will be exchanged. If the new node's state is different from that of the cluster, then it will request an IST or SST to make itself consistent with the other nodes.

Restarting the Cluster

If you shut down all nodes at the same time, then you have effectively terminated the cluster. Of course, the cluster's data still exists, but the running cluster no longer exists. When this happens, you'll need to bootstrap the cluster again.

If the cluster is not bootstrapped and mariadbd on the first node is just started normally, then the node willl try to connect to at least one of the nodes listed in the `wsrep_cluster_address` option. If no nodes are currently running, then this will fail. Bootstrapping the first node solves this problem.

Determining the Most Advanced Node

In some cases Galera will refuse to bootstrap a node if it detects that it might not be the most advanced node in the cluster. Galera makes this determination if the node was not the last one in the cluster to be shut down or if the node crashed. In those cases, manual intervention is needed.

If you know for sure which node is the most advanced you can edit the `grastate.dat` file in the `datadir`. You can set `safe_to_bootstrap=1` on the most advanced node.

You can determine which node is the most advanced by checking `grastate.dat` on each node and looking for the node with the highest `seqno`. If the node crashed and `seqno=-1`, then you can find the most advanced node by recovering the `seqno` on each node with the `wsrep_recover` option. For example:

```
$ mariadbd --wsrep_recover
```

Systemd and Galera Recovery

On operating systems that use `systemd`, the position of a node can be recovered by running the `galera_recovery` script. For example:

```
$ galera_recovery
```

If you are using the `systemd` service that supports the systemd service's method for interacting with multiple MariaDB Server processes, then you can recover the position of a specific instance by specifying the instance name as a suffix. For example:

```
$ galera_recovery mariadb@node1
```

The `galera_recovery` script recovers the position of a node by running mariadbd with the `wsrep_recover` option.

When the `galera_recovery` script runs mariadbd, it does not write to the error log. Instead, it redirects mariadbd log output to a file named with the format `/tmp/wsrep_recovery.XXXXXX`, where `XXXXXX` is replaced with random characters.

When Galera is enabled, MariaDB's systemd service automatically runs the `galera_recovery` script prior to starting MariaDB, so that MariaDB starts with the proper Galera position.

Support for systemd and the `galera_recovery` script were added in MariaDB 10.1.

State Snapshot Transfers (SSTs)

In a State Snapshot Transfer (SST), the cluster provisions nodes by transferring a full data copy from one node to another. When a new node joins the cluster, the new node initiates a State Snapshot Transfer to synchronize its data with a node that is already part of the cluster.

See Introduction to State Snapshot Transfers (SSTs) for more information.

Incremental State Transfers (ISTs)

In an Incremental State Transfer (SST), the cluster provisions nodes by transferring a node's missing writesets from one node to another. When a new node joins the cluster, the new node initiates a Incremental State Transfer to synchronize its data with a node that is already part of the cluster.

If a node has only been out of a cluster for a little while, then an IST is generally faster than an SST.

Data at Rest Encryption

In MariaDB 10.1 and above, MariaDB Galera Cluster supports Data at Rest Encryption. See SSTs and Data at Rest Encryption for some disclaimers on how SSTs are affected when encryption is configured.

Some data still cannot be encrypted:

- The disk-based Galera gcache is not encrypted (MDEV-8072).

Monitoring

Status Variables

Galera Cluster's status variables can be queried with the standard `SHOW STATUS` command. For example:

```
SHOW GLOBAL STATUS LIKE 'wsrep_%';
```

Cluster Change Notifications

The cluster nodes can be configured to invoke a command when cluster membership or node status changes. This mechanism can also be used to communicate the event to some external monitoring agent. This is configured by setting `wsrep_notify_cmd`. See Galera Cluster documentation: Notification Command for more information.

3.2.7 Configuring MariaDB Galera Cluster

Contents

A number of options need to be set in order for Galera Cluster to work when using MariaDB. These should be set in the MariaDB option file.

Mandatory Options

Several options are mandatory, which means that they *must* be set in order for Galera Cluster to be enabled or to work properly with MariaDB. The mandatory options are:

- `wsrep_provider` — Path to the Galera library

- `wsrep_cluster_address` — See Galera Cluster address format and usage
- `binlog_format=ROW` — See Binary Log Formats
- `wsrep_on=ON` — Enable wsrep replication
- `default_storage_engine=InnoDB` — This is the default value, or alternately `wsrep_replicate_myisam=1` (before MariaDB 10.6) or `galera-cluster-system-variables/#wsrep_mode=REPLICATE_ARIA,REPLICATE_MYISAM` (MariaDB 10.6 and later)
- `innodb_doublewrite=1` — This is the default value, and should not be changed.

Performance-related Options

These are optional optimizations that can be made to improve performance.

- `innodb_flush_log_at_trx_commit=0` — This is not usually recommended in the case of standard MariaDB. However, it is a bit safer with Galera Cluster, since inconsistencies can always be fixed by recovering from another node.

Writing Replicated Write Sets to the Binary Log

Like with MariaDB replication, write sets that are received by a node with Galera Cluster's certification-based replication are not written to the binary log by default. If you would like a node to write its replicated write sets to the binary log, then you will have to set `log_slave_updates=ON`. This is especially helpful if the node is a replication master. See Using MariaDB Replication with MariaDB Galera Cluster: Configuring a Cluster Node as a Replication Master.

Replication Filters

Like with MariaDB replication, replication filters can be used to filter write sets from being replicated by Galera Cluster's certification-based replication. However, they should be used with caution because they may not work as you'd expect.

The following replication filters are honored for InnoDB DML, but not DDL:

- `binlog_do_db`
- `binlog_ignore_db`
- `replicate_wild_do_table`
- `replicate_wild_ignore_table`

The following replication filters are honored for DML and DDL for tables that use both the InnoDB and MyISAM storage engines:

- `replicate_do_table`
- `replicate_ignore_table`

However, it should be kept in mind that if replication filters cause inconsistencies that lead to replication errors, then nodes may abort.

See also MDEV-421 and MDEV-6229.

Network Ports

Galera Cluster needs access to the following ports:

- **Standard MariaDB Port** (default: 3306) - For MySQL client connections and State Snapshot Transfers that use the `mysqldump` method. This can be changed by setting `port`.
- **Galera Replication Port** (default: 4567) - For Galera Cluster replication traffic, multicast replication uses both UDP transport and TCP on this port. Can be changed by setting `wsrep_node_address`.
- **Galera Replication Listening Interface** (default: `0.0.0.0:4567`) needs to be set using gmcast.listen_addr, either
  - in wsrep_provider_options: `wsrep_provider_options='gmcast.listen_addr=tcp://<IP_ADDR>:<PORT>;'`
  - or in wsrep_cluster_address
- **IST Port** (default: 4568) - For Incremental State Transfers. Can be changed by setting `ist.recv_addr` in `wsrep_provider_options`.
- **SST Port** (default: 4444) - For all State Snapshot Transfer methods other than `mysqldump`. Can be changed by setting `wsrep_sst_receive_address`.

Mutiple Galera Cluster Instances on One Server

If you want to run multiple Galera Cluster instances on one server, then you can do so by starting each instance with

`mysqld_multi`, or if you are using systemd, then you can use the relevant systemd method for interacting with multiple MariaDB instances.

You need to ensure that each instance is configured with a different `datadir`.

You also need to ensure that each instance is configured with different network ports.

3.2.8 State Snapshot Transfers (SSTs) in Galera Cluster

Introduction to State Snapshot Transfers (SSTs)
In an SST, the cluster provisions nodes by transferring a full data copy from one node to another.

mariabackup SST Method
The mariabackup SST method uses the Mariabackup utility for performing SSTs.

Manual SST of Galera Cluster Node With Mariabackup
It can be helpful to perform a "manual SST" with Mariabackup when Galera's normal SSTs fail.

xtrabackup-v2 SST Method
The xtrabackup-v2 SST method uses the Percona XtraBackup utility for performing SSTs.

Manual SST of Galera Cluster Node With Percona XtraBackup
It can be helpful to perform a "manual SST" with Xtrabackup when Galera's normal SSTs fail.

3.2.8.1 Introduction to State Snapshot Transfers (SSTs)

Contents

In a State Snapshot Transfer (SST), the cluster provisions nodes by transferring a full data copy from one node to another. When a new node joins the cluster, the new node initiates a State Snapshot Transfer to synchronize its data with a node that is already part of the cluster.

Types of SSTs

There are two conceptually different ways to transfer a state from one MariaDB server to another:

1. **Logical**

The only SST method of this type is the `mysqldump` SST method, which actually uses the `mysqldump` utility to get a logical dump of the donor. This SST method requires the joiner node to be fully initialized and ready to accept connections before the transfer. This method is, by definition, blocking, in that it blocks the donor node from modifying its own state for the duration of the transfer. It is also the slowest of all, and that might be an issue in a cluster with a lot of load.

2. **Physical**

SST methods of this type physically copy the data files from the donor node to the joiner node. This requires that the joiner node is initialized after the transfer. The `mariabackup` SST method and a few other SST methods fall into this category.

These SST methods are much faster than the `mysqldump` SST method, but they have certain limitations. For example, they can be used only on server startup and the joiner node must be configured very similarly to the donor node (e.g. innodb_file_per_table should be the same and so on). Some of the SST methods in this category are non-blocking on the donor node, meaning that the donor node is still able to process queries while donating the SST (e.g. the `mariabackup` SST method is non-blocking).

SST Methods

SST methods are supported via a scriptable interface. New SST methods could potentially be developed by creating new SST scripts. The scripts usually have names of the form `wsrep_sst_<method>` where `<method>` is one of the SST methods listed below.

You can choose your SST method by setting the `wsrep_sst_method` system variable. It can be changed dynamically with `SET GLOBAL` on the node that you intend to be a SST donor. For example:

```
SET GLOBAL wsrep_sst_method='mariabackup';
```

It can also be set in a server option group in an option file prior to starting up a node:

```
[mariadb]
...
wsrep_sst_method = mariabackup
```

For an SST to work properly, the donor and joiner node must use the same SST method. Therefore, it is recommended to set `wsrep_sst_method` to the same value on all nodes, since any node will usually be a donor or joiner node at some point.

MariaDB Galera Cluster comes with the following built-in SST methods:

mariabackup

This SST method uses the Mariabackup utility for performing SSTs. It is one of the two non-locking methods. This is the recommended SST method if you require the ability to run queries on the donor node during the SST. Note that if you use the `mariabackup` SST method, then you also need to have `socat` installed on the server. This is needed to stream the backup from the donor to the joiner. This is a limitation inherited from the `xtrabackup-v2` SST method.

This SST method supports GTID.

This SST method supports Data at Rest Encryption.

This SST method is available from MariaDB 10.1.26 and MariaDB 10.2.10.

With this SST method, it is impossible to upgrade the cluster between some major versions; see MDEV-27437.

See mariabackup SST method for more information.

rsync / rsync_wan

`rsync` is the default method. This method uses the `rsync` utility to create a snapshot of the donor node. `rsync` should be available by default on all modern Linux distributions. The donor node is blocked with a read lock during the SST. This is the fastest SST method, especially for large datasets since it copies binary data. Because of that, this is the recommended SST method if you do not need to allow the donor node to execute queries during the SST.

The `rsync` method runs `rsync` in `--whole-file` mode, assuming that nodes are connected by fast local network links so that the default delta transfer mode would consume more processing time than it may save on data transfer bandwidth. When having a distributed cluster with slow links between nodes, the `rsync_wan` method runs `rsync` in the default delta transfer mode, which may reduce data transfer time substantially when an older datadir state is already present on the joiner node. Both methods are actually implemented by the same script, `wsrep_sst_rsync_wan` is just a symlink to the `wsrep_sst_rsync` script and the actual `rsync` mode to use is determined by the name the script was called by.

This SST method supports GTID.

This SST method supports Data at Rest Encryption.

The rsync SST method does not support tables created with the DATA DIRECTORY or INDEX DIRECTORY clause. Use the mariabackup SST method as an alternative to support this feature.

Use of this SST method **could result in data corruption** when using innodb_use_native_aio (the default) if the donor is older than MariaDB 10.3.35, MariaDB 10.4.25, MariaDB 10.5.16, MariaDB 10.6.8, or MariaDB 10.7.4; see MDEV-

25975. Starting with those donor versions, `wsrep_sst_method=rsync` is a reliable way to upgrade the cluster to a newer major version.

As of MariaDB 10.1.36, MariaDB 10.2.18, and MariaDB 10.3.10, `stunnel` can be used to encrypt data over the wire. Be sure to have `stunnel` installed. You will also need to generate certificates and keys. See the stunnel documentation for information on how to do that. Once you have the keys, you will need to add the `tkey` and `tcert` options to the `[sst]` option group in your MariaDB configuration file, such as:

```
[sst]
tkey = /etc/my.cnf.d/certificates/client-key.pem
tcert = /etc/my.cnf.d/certificates/client-cert.pem
```

You also need to run the certificate directory through `openssl rehash`.

mysqldump

This SST method runs mysqldump on the donor node and pipes the output to the mariadb client connected to the joiner node. The `mysqldump` SST method needs a username/password pair set in the wsrep_sst_auth variable in order to get the dump. The donor node is blocked with a read lock during the SST. This is the slowest SST method.

This SST method supports GTID.

This SST method supports Data at Rest Encryption.

xtrabackup-v2

In MariaDB 10.1 and later, Mariabackup is the recommended backup method to use instead of Percona XtraBackup.

In MariaDB 10.3, Percona XtraBackup is **not supported**. See Percona XtraBackup Overview: Compatibility with MariaDB for more information.

In MariaDB 10.2 and MariaDB 10.1, Percona XtraBackup is only **partially supported**. See Percona XtraBackup Overview: Compatibility with MariaDB for more information.

This SST method uses the Percona XtraBackup utility for performing SSTs. It is one of the two non-blocking methods. Note that if you use the `xtrabackup-v2` SST method, you also need to have `socat` installed on the server. Since Percona XtraBackup is a third party product, this SST method requires an additional installation some additional configuration. Please refer to Percona's xtrabackup SST documentation for information from the vendor.

This SST method does **not** support GTID.

This SST method does **not** support Data at Rest Encryption.

This SST method is available from MariaDB Galera Cluster 5.5.37 and MariaDB Galera Cluster 10.0.10.

See xtrabackup-v2 SST method for more information.

xtrabackup

In MariaDB 10.1 and later, Mariabackup is the recommended backup method to use instead of Percona XtraBackup.

In MariaDB 10.3, Percona XtraBackup is **not supported**. See Percona XtraBackup Overview: Compatibility with MariaDB for more information.

In MariaDB 10.2 and MariaDB 10.1, Percona XtraBackup is only **partially supported**. See Percona XtraBackup Overview: Compatibility with MariaDB for more information.

This SST method is an older SST method that uses the Percona XtraBackup utility for performing SSTs. The `xtrabackup-v2` SST method should be used instead of the `xtrabackup` SST method starting from MariaDB 5.5.33.

This SST method does **not** support GTID.

This SST method does **not** support Data at Rest Encryption.

Authentication

All SST methods except `rsync` require authentication via username and password. You can tell the client what username and password to use by setting the `wsrep_sst_auth` system variable. It can be changed dynamically with `SET GLOBAL` on the node that you intend to be a SST donor. For example:

```
SET GLOBAL wsrep_sst_auth = 'mariabackup:password';
```

It can also be set in a server option group in an option file prior to starting up a node:

```
[mariadb]
...
wsrep_sst_auth = mariabackup:password
```

Some authentication plugins do not require a password. For example, the `unix_socket` and `gssapi` authentication plugins do not require a password. If you are using a user account that does not require a password in order to log in, then you can just leave the password component of `wsrep_sst_auth` empty. For example:

```
[mariadb]
...
wsrep_sst_auth = mariabackup:
```

See the relevant description or page for each SST method to find out what privileges need to be granted to the user and whether the privileges are needed on the donor node or joiner node for that method.

SSTs and Systemd

MariaDB's `systemd` unit file has a default startup timeout of about 90 seconds on most systems. If an SST takes longer than this default startup timeout on a joiner node, then `systemd` will assume that `mysqld` has failed to startup, which causes `systemd` to kill the `mysqld` process on the joiner node. To work around this, you can reconfigure the MariaDB `systemd` unit to have an infinite timeout, such as by executing one of the following commands:

If you are using `systemd` 228 or older, then you can execute the following to set an infinite timeout:

```
sudo tee /etc/systemd/system/mariadb.service.d/timeoutstartsec.conf <<EOF
[Service]

TimeoutStartSec=0
EOF
sudo systemctl daemon-reload
```

Systemd 229 added the infinity option, so if you are using `systemd` 229 or later, then you can execute the following to set an infinite timeout:

```
sudo tee /etc/systemd/system/mariadb.service.d/timeoutstartsec.conf <<EOF
[Service]

TimeoutStartSec=infinity
EOF
sudo systemctl daemon-reload
```

See Configuring the Systemd Service Timeout for more details.

Note that systemd 236 added the `EXTEND_TIMEOUT_USEC` environment variable that allows services to extend the startup timeout during long-running processes. Starting with MariaDB 10.1.35, MariaDB 10.2.17, and MariaDB 10.3.8, on systems with systemd versions that support it, MariaDB uses this feature to extend the startup timeout during long SSTs. Therefore, if you are using `systemd` 236 or later, then you should not need to manually override `TimeoutStartSec`, even if your SSTs run for longer than the configured value. See MDEV-15607 for more information.

SST Failure

An SST failure generally renders the joiner node unusable. Therefore, when an SST failure is detected, the joiner node will abort.

Restarting a node after a `mysqldump` SST failure may require manual restoration of the administrative tables.

SSTs and Data at Rest Encryption

Look at the description of each SST method to determine which methods support Data at Rest Encryption.

For logical SST methods like `mysqldump`, each node should be able to have different encryption keys. For physical SST methods, all nodes need to have the same encryption keys, since the donor node will copy encrypted data files to the joiner node, and the joiner node will need to be able to decrypt them.

Minimal Cluster Size

In order to avoid a split-brain condition, the minimum recommended number of nodes in a cluster is 3.

When using an SST method that blocks the donor, there is yet another reason to require a minimum of 3 nodes. In a 3-node cluster, if one node is acting as an SST joiner and one other node is acting as an SST donor, then there is still one more node to continue executing queries.

Manual SSTs

In some cases, if Galera Cluster's automatic SSTs repeatedly fail, then it can be helpful to perform a "manual SST". See the following pages on how to do that:

- Manual SST of Galera Cluster node with Mariabackup
- Manual SST of Galera Cluster node with Percona XtraBackup

Known Issues

mysqld_multi

SST scripts can't currently read the `[mysqldN]` option groups in option files that are read by instances managed by `mysqld_multi`.

See MDEV-18863 for more information.

2.3.4.13 mariabackup SST Method

3.2.8.3 Manual SST of Galera Cluster Node With Mariabackup

Contents

Sometimes it can be helpful to perform a "manual SST" when Galera's normal SSTs fail. This can be especially useful when the cluster's `datadir` is very large, since a normal SST can take a long time to fail in that case.

A manual SST essentially consists of taking a backup of the donor, loading the backup on the joiner, and then manually editing the cluster state on the joiner node. This page will show how to perform this process with Mariabackup.

Process

- Check that the donor and joiner nodes have the same Mariabackup version.

```
mariabackup --version
```

- Create backup directory on donor.

```
MYSQL_BACKUP_DIR=/mysql_backup
mkdir $MYSQL_BACKUP_DIR
```

- Take a full backup the of the donor node with `mariabackup`. The `--galera-info` option should also be provided, so that the node's cluster state is also backed up.

```
DB_USER=sstuser
DB_USER_PASS=password
mariabackup --backup  --galera-info \
   --target-dir=$MYSQL_BACKUP_DIR \
   --user=$DB_USER \
   --password=$DB_USER_PASS
```

- Verify that the MariaDB Server process is stopped on the joiner node. This will depend on your service manager.

For example, on systemd systems, you can execute::

```
systemctl status mariadb
```

- Create the backup directory on the joiner node.

```
MYSQL_BACKUP_DIR=/mysql_backup
mkdir $MYSQL_BACKUP_DIR
```

- Copy the backup from the donor node to the joiner node.

```
OS_USER=dba
JOINER_HOST=dbserver2.mariadb.com
rsync -av $MYSQL_BACKUP_DIR/* ${OS_USER}@${JOINER_HOST}:${MYSQL_BACKUP_DIR}
```

- Prepare the backup on the joiner node.

```
mariabackup --prepare \
   --target-dir=$MYSQL_BACKUP_DIR
```

- Get the Galera Cluster version ID from the donor node's `grastate.dat` file.

```
MYSQL_DATADIR=/var/lib/mysql
cat $MYSQL_DATADIR/grastate.dat | grep version
```

For example, a very common version number is "2.1".

- Get the node's cluster state from the `xtrabackup_galera_info` file in the backup that was copied to the joiner node.

```
cat $MYSQL_BACKUP_DIR/xtrabackup_galera_info
```

The file contains the values of the `wsrep_local_state_uuid` and `wsrep_last_committed` status variables.

The values are written in the following format:

```
wsrep_local_state_uuid:wsrep_last_committed
```

For example:

```
d38587ce-246c-11e5-bcce-6bbd0831cc0f:1352215
```

- Create a `grastate.dat` file in the backup directory of the joiner node. The Galera Cluster version ID, the cluster uuid, and the seqno from previous steps will be used to fill in the relevant fields.

For example, with the example values from the last two steps, we could do:

```
sudo tee $MYSQL_BACKUP_DIR/grastate.dat <<EOF
# GALERA saved state
version: 2.1
uuid:    d38587ce-246c-11e5-bcce-6bbd0831cc0f
seqno:   1352215
safe_to_bootstrap: 0
EOF
```

- Remove the existing contents of the `datadir` on the joiner node.

```
MYSQL_DATADIR=/var/lib/mysql
rm -Rf $MYSQL_DATADIR/*
```

- Copy the contents of the backup directory to the `datadir` the on joiner node.

```
mariabackup --copy-back \
   --target-dir=$MYSQL_BACKUP_DIR
```

- Make sure the permissions of the `datadir` are correct on the joiner node.

```
chown -R mysql:mysql $MYSQL_DATADIR/
```

- Start the MariaDB Server process on the joiner node. This will depend on your service manager.

For example, on systemd systems, you can execute::

```
systemctl start mariadb
```

- Watch the MariaDB error log on the joiner node and verify that the node does not need to perform a normal SSTs due to the manual SST.

```
tail -f /var/log/mysql/mysqld.log
```

3.2.8.4 xtrabackup-v2 SST Method

Contents

In MariaDB 10.1 and later, Mariabackup is the recommended backup method to use instead of Percona XtraBackup.

In MariaDB 10.3, Percona XtraBackup is **not supported**. See Percona XtraBackup Overview: Compatibility with MariaDB for more information.

In MariaDB 10.2 and MariaDB 10.1, Percona XtraBackup is only **partially supported**. See Percona XtraBackup Overview: Compatibility with MariaDB for more information.

The `xtrabackup-v2` SST method uses the Percona XtraBackup utility for performing SSTs. It is one of the methods that does not block the donor node.

Note that if you use the `xtrabackup-v2` SST method, then you also need to have socat installed on the server. This is needed to stream the backup from the donor node to the joiner node.

Since Percona XtraBackup is a third party product, it may require additional installation and additional configuration. Please refer to Percona's xtrabackup SST documentation for information from the vendor.

Choosing Percona XtraBackup for SSTs

To use the `xtrabackup-v2` SST method, you must set the `wsrep_sst_method=xtrabackup-v2` on both the donor and joiner node. It can be changed dynamically with `SET GLOBAL` on the node that you intend to be a SST donor. For example:

```
SET GLOBAL wsrep_sst_method='xtrabackup-v2';
```

It can be set in a server option group in an option file prior to starting up a node:

```
[mariadb]
...
wsrep_sst_method = xtrabackup-v2
```

For an SST to work properly, the donor and joiner node must use the same SST method. Therefore, it is recommended to set `wsrep_sst_method` to the same value on all nodes, since any node will usually be a donor or joiner node at some point.

Authentication and Privileges

To use the `xtrabackup-v2` SST method, Percona XtraBackup needs to be able to authenticate locally on the donor node, so that it can create a backup to stream to the joiner. You can tell the donor node what username and password to use by setting the `wsrep_sst_auth` system variable. It can be changed dynamically with `SET GLOBAL` on the node that you intend to be a SST donor. For example:

```
SET GLOBAL wsrep_sst_auth = 'xtrabackup:mypassword';
```

It can also be set in a server option group in an option file prior to starting up a node:

```
[mariadb]
...
wsrep_sst_auth = xtrabackup:mypassword
```

Some authentication plugins do not require a password. For example, the `unix_socket` and `gssapi` authentication plugins do not require a password. If you are using a user account that does not require a password in order to log in, then you can just leave the password component of `wsrep_sst_auth` empty. For example:

```
[mariadb]
...
wsrep_sst_auth = xtrabackup:
```

The user account that performs the backup for the SST needs to have the same privileges as Percona XtraBackup, which are the `RELOAD` , `PROCESS` , `LOCK TABLES` and `REPLICATION CLIENT` global privileges. To be safe, you should ensure that these privileges are set on each node in your cluster. Percona XtraBackup connects locally on the donor node to perform the backup, so the following user should be sufficient:

```
CREATE USER 'xtrabackup'@'localhost' IDENTIFIED BY 'mypassword';
GRANT RELOAD, PROCESS, LOCK TABLES, REPLICATION CLIENT ON *.* TO 'xtrabackup'@'localhost';
```

Passwordless Authentication - Unix Socket

It is possible to use the `unix_socket` authentication plugin for the user account that performs SSTs. This would provide the benefit of not needing to configure a plain-text password in `wsrep_sst_auth` .

The user account would have to have the same name as the operating system user account that is running the `mysqld` process. On many systems, this is the user account configured as the `user` option, and it tends to default to `mysql`.

For example, if the `unix_socket` authentication plugin is already installed, then you could execute the following to create the user account:

```
CREATE USER 'mysql'@'localhost' IDENTIFIED VIA unix_socket;
GRANT RELOAD, PROCESS, LOCK TABLES, REPLICATION CLIENT ON *.* TO 'mysql'@'localhost';
```

And then to configure `wsrep_sst_auth`, you could set the following in a server option group in an option file prior to starting up a node:

```
[mariadb]
...
wsrep_sst_auth = mysql:
```

Passwordless Authentication - GSSAPI

It is possible to use the `gssapi` authentication plugin for the user account that performs SSTs. This would provide the benefit of not needing to configure a plain-text password in `wsrep_sst_auth`.

The following steps would need to be done beforehand:

- You need a KDC running MIT Kerberos or Microsoft Active Directory.
- You will need to create a keytab file for the MariaDB server.
- You will need to install the package containing the `gssapi` authentication plugin.
- You will need to install the plugin in MariaDB, so that the `gssapi` authentication plugin is available to use.
- You will need to configure the plugin.
- You will need to create a user account that authenticates with the `gssapi` authentication plugin, so that the user account can be used for SSTs. This user account will need to correspond with a user account that exists on the backend KDC.

For example, you could execute the following to create the user account in MariaDB:

```
CREATE USER 'xtrabackup'@'localhost' IDENTIFIED VIA gssapi;
GRANT RELOAD, PROCESS, LOCK TABLES, REPLICATION CLIENT ON *.* TO 'xtrabackup'@'localhost';
```

And then to configure `wsrep_sst_auth`, you could set the following in a server option group in an option file prior to starting up a node:

```
[mariadb]
...
wsrep_sst_auth = xtrabackup:
```

Choosing a Donor Node

When Percona XtraBackup is used to create the backup for the SST on the donor node, XtraBackup briefly requires a system-wide lock at the end of the backup. This is done with `FLUSH TABLES WITH READ LOCK`.

If a specific node in your cluster is acting as the *primary* node by receiving all of the application's write traffic, then this node should not usually be used as the donor node, because the system-wide lock could interfere with the application. In this case, you can define one or more preferred donor nodes by setting the `wsrep_sst_donor` system variable.

For example, let's say that we have a 5-node cluster with the nodes `node1`, `node2`, `node3`, `node4`, and `node5`, and let's say that `node1` is acting as the *primary* node.The preferred donor nodes for `node2` could be configured by setting the following in a server option group in an option file prior to starting up a node:

```
[mariadb]
...
wsrep_sst_donor=node3,node4,node5,
```

The trailing comma tells the server to allow any other node as donor when the preferred donors are not available. Therefore, if `node1` is the only node left in the cluster, the trailing comma allows it to be used as the donor node.

Socat Dependency

During the SST process, the donor node uses socat to stream the backup to the joiner node. Then the joiner node prepares the backup before restoring it. The socat utility must be installed on both the donor node and the joiner node in order for this to work. Otherwise, the MariaDB error log will contain an error like:

```
WSREP_SST: [ERROR] socat not found in path:
/usr/sbin:/sbin:/usr//bin:/usr/local/sbin:/usr/local/bin:/usr/sbin:/usr/bin (20180122
14:55:32.993)
```

Installing Socat on RHEL/CentOS

On RHEL/CentOS, `socat` can be installed from the Extra Packages for Enterprise Linux (EPEL) repository.

TLS

This SST method supports three different TLS methods. The specific method can be selected by setting the `encrypt` option in the `[sst]` section of the MariaDB configuration file. The options are:

- TLS using OpenSSL encryption built into `socat` (`encrypt=2`)
- TLS using OpenSSL encryption with Galera-compatible certificates and keys (`encrypt=3`)
- TLS using OpenSSL encryption with MariaDB-compatible certificates and keys (`encrypt=4`)

Note that `encrypt=1` refers to a TLS encryption method that has been deprecated and removed.

TLS Using OpenSSL Encryption Built into Socat

To generate keys compatible with this encryption method, you can follow these directions.

For example:

- First, generate the keys and certificates:

```
FILENAME=sst
openssl genrsa -out $FILENAME.key 1024
openssl req -new -key $FILENAME.key -x509 -days 3653 -out $FILENAME.crt
cat $FILENAME.key $FILENAME.crt >$FILENAME.pem
chmod 600 $FILENAME.key $FILENAME.pem
```

- On some systems, you may also have to add dhparams to the certificate:

```
openssl dhparam -out dhparams.pem 2048
cat dhparams.pem >> sst.pem
```

- Then, copy the certificate and keys to all nodes in the cluster.
- Then, configure the following on all nodes in the cluster:

```
[sst]
encrypt=2
tca=/etc/my.cnf.d/certificates/sst.crt
tcert=/etc/my.cnf.d/certificates/sst.pem
```

But replace the paths with whatever is relevant on your system.

This should allow your SSTs to be encrypted.

TLS Using OpenSSL Encryption with Galera-compatible Certificates and Keys

To generate keys compatible with this encryption method, you can follow these directions.

For example:

- First, generate the keys and certificates:

```
# CA
openssl genrsa 2048 > ca-key.pem
openssl req -new -x509 -nodes -days 365000 \
-key ca-key.pem -out ca-cert.pem

# server1
openssl req -newkey rsa:2048 -days 365000 \
-nodes -keyout server1-key.pem -out server1-req.pem
openssl rsa -in server1-key.pem -out server1-key.pem
openssl x509 -req -in server1-req.pem -days 365000 \
-CA ca-cert.pem -CAkey ca-key.pem -set_serial 01 \
-out server1-cert.pem
```

- Then, copy the certificate and keys to all nodes in the cluster.
- Then, configure the following on all nodes in the cluster:

```
[sst]
encrypt=3
tkey=/etc/my.cnf.d/certificates/server1-key.pem
tcert=/etc/my.cnf.d/certificates/server1-cert.pem
```

But replace the paths with whatever is relevant on your system.

This should allow your SSTs to be encrypted.

TLS Using OpenSSL Encryption with MariaDB-compatible Certificates and Keys

To generate keys compatible with this encryption method, you can follow these directions.

For example:

- First, generate the keys and certificates:

```
# CA
openssl genrsa 2048 > ca-key.pem
openssl req -new -x509 -nodes -days 365000 \
-key ca-key.pem -out ca-cert.pem

# server1
openssl req -newkey rsa:2048 -days 365000 \
-nodes -keyout server1-key.pem -out server1-req.pem
openssl rsa -in server1-key.pem -out server1-key.pem
openssl x509 -req -in server1-req.pem -days 365000 \
-CA ca-cert.pem -CAkey ca-key.pem -set_serial 01 \
-out server1-cert.pem
```

- Then, copy the certificate and keys to all nodes in the cluster.
- Then, configure the following on all nodes in the cluster:

```
[sst]
encrypt=4
ssl-ca=/etc/my.cnf.d/certificates/ca-cert.pem
ssl-cert=/etc/my.cnf.d/certificates/server1-cert.pem
ssl-key=/etc/my.cnf.d/certificates/server1-key.pem
```

But replace the paths with whatever is relevant on your system.

This should allow your SSTs to be encrypted.

Logs

The `xtrabackup-v2` SST method has its own logging outside of the MariaDB Server logging.

Logging to SST Logs

By default, on the donor node, it logs to `innobackup.backup.log`. This log file is located in the `datadir`.

By default, on the joiner node, it logs to `innobackup.prepare.log` and `innobackup.move.log`. These log files are located in the `.sst` directory, which is a hidden directory inside the `datadir`.

These log files are overwritten by each subsequent SST, so if an SST fails, it is best to copy them somewhere safe before starting another SST, so that the log files can be analyzed. See MDEV-17973 about that.

Logging to Syslog

You can redirect the SST logs to the syslog instead by setting the following in the `[sst]` option group in an option file:

```
[sst]
sst-syslog=1
```

You can also redirect the SST logs to the syslog by setting the following in the `[mysqld_safe]` option group in an option file:

```
[mysqld_safe]
syslog
```

Performing SSTs with IPv6 Addresses

If you are performing Percona XtraBackup SSTs with IPv6 addresses, then the `socat` utility needs to be passed the `pf=ip6` option. This can be done by setting the `sockopt` option in the `[sst]` option group in an option file. For example:

```
[sst]
sockopt=",pf=ip6"
```

See MDEV-18797 for more information.

Manual SST with Percona XtraBackup

In some cases, if Galera Cluster's automatic SSTs repeatedly fail, then it can be helpful to perform a "manual SST". See the following page on how to do that:

- Manual SST of Galera Cluster node with Percona XtraBackup

3.2.8.5 Manual SST of Galera Cluster Node With Percona XtraBackup

Contents

Mariabackup should be used instead of XtraBackup on all supported releases. See manual SST with Mariabackup.

In MariaDB 10.1 and later, Mariabackup is the recommended backup method to use instead of Percona XtraBackup.

In MariaDB 10.3, Percona XtraBackup is **not supported**. See Percona XtraBackup Overview: Compatibility with MariaDB for more information.

In MariaDB 10.2 and MariaDB 10.1, Percona XtraBackup is only **partially supported**. See Percona XtraBackup Overview: Compatibility with MariaDB for more information.

Sometimes it can be helpful to perform a "manual SST" when Galera's normal SSTs fail. This can be especially useful when the cluster's `datadir` is very large, since a normal SST can take a long time to fail in that case.

A manual SST essentially consists of taking a backup of the donor, loading the backup on the joiner, and then manually editing the cluster state on the joiner node. This page will show how to perform this process with Percona XtraBackup.

Process

- Check that the donor and joiner nodes have the same XtraBackup version.

```
innobackupex --version
```

- Create backup directory on donor.

```
MYSQL_BACKUP_DIR=/mysql_backup
mkdir $MYSQL_BACKUP_DIR
```

- Take a full backup the of the donor node with `innobackupex` . The `--galera-info` option should also be provided, so that the node's cluster state is also backed up.

```
DB_USER=sstuser
DB_USER_PASS=password
innobackupex --user=$DB_USER --password=$DB_USER_PASS --galera-info --no-timestamp $MYSQL_BACKUP_
```

- Verify that the MariaDB Server process is stopped on the joiner node. This will depend on your service manager.

For example, on systemd systems, you can execute::

```
systemctl status mariadb
```

- Create the backup directory on the joiner node.

```
MYSQL_BACKUP_DIR=/mysql_backup
mkdir $MYSQL_BACKUP_DIR
```

- Copy the backup from the donor node to the joiner node.

```
OS_USER=dba
JOINER_HOST=dbserver2.mariadb.com
rsync -av $MYSQL_BACKUP_DIR/* ${OS_USER}@${JOINER_HOST}:${MYSQL_BACKUP_DIR}
```

- Prepare the backup on the joiner node.

```
innobackupex --apply-log $MYSQL_BACKUP_DIR
```

- Get the Galera Cluster version ID from the donor node's `grastate.dat` file.

```
MYSQL_DATADIR=/var/lib/mysql
cat $MYSQL_DATADIR/grastate.dat | grep version
```

For example, a very common version number is "2.1".

- Get the node's cluster state from the `--xtrabackup_galera_info` file in the backup that was copied to the joiner node.

```
cat $MYSQL_BACKUP_DIR/xtrabackup_galera_info
```

Example output:

```
d38587ce-246c-11e5-bcce-6bbd0831cc0f:1352215
```

This output is in the format:

```
uuid:seqno
```

- Create a `grastate.dat` file in the backup directory of the joiner node. The Galera Cluster version ID, the cluster uuid, and the seqno from previous steps will be used to fill in the relevant fields.

For example, with the example values from the last two steps, we could do:

```
sudo tee $MYSQL_BACKUP_DIR/grastate.dat <<EOF
# GALERA saved state
version: 2.1
uuid:    d38587ce-246c-11e5-bcce-6bbd0831cc0f
seqno:   1352215
safe_to_bootstrap: 0
EOF
```

- Remove the existing contents of the `datadir` on the joiner node.

```
MYSQL_DATADIR=/var/lib/mysql
rm -Rf $MYSQL_DATADIR/*
```

- Copy the contents of the backup directory to the `datadir` the on joiner node.

```
cp -R $MYSQL_BACKUP_DIR/* $MYSQL_DATADIR/
```

- Make sure the permissions of the `datadir` are correct on the joiner node.

```
chown -R mysql:mysql $MYSQL_DATADIR/
```

- Start the MariaDB Server process on the joiner node. This will depend on your service manager.

For example, on systemd systems, you can execute::

```
systemctl start mariadb
```

- Watch the MariaDB error log on the joiner node and verify that the node does not need to perform a normal SSTs due to the manual SST.

```
tail -f /var/log/mysql/mysqld.log
```

3.2.9 Galera Cluster Status Variables

Contents

Viewing Galera Cluster Status Variables

Galera status variables can be viewed with the SHOW STATUS statement.

```
SHOW STATUS LIKE 'wsrep%';
```

See also the Full list of MariaDB options, system and status variables.

List of Galera Cluster status variables

MariaDB Galera Cluster has the following status variables:

wsrep_applier_thread_count

- **Description:** Stores current number of applier threads to make clear how many slave threads of this type there are.
- **Introduced:** MariaDB 10.2.26, MariaDB 10.3.17, MariaDB 10.4.7

---

wsrep_apply_oooe

- **Description:** How often writesets have been applied out of order, an indicators of parallelization efficiency.

---

wsrep_apply_oool

- **Description:** How often writesets with a higher sequence number were applied before ones with a lower sequence number, implying slow writesets.

---

wsrep_apply_window

- **Description:** Average distance between highest and lowest concurrently applied seqno.

---

wsrep_cert_deps_distance

- **Description:** Average distance between the highest and the lowest sequence numbers that can possibly be applied in parallel, or the potential degree of parallelization.

---

wsrep_cert_index_size

- **Description:** The number of entries in the certification index.

---

wsrep_cert_interval

- **Description:** Average number of transactions received while a transaction replicates.

---

wsrep_cluster_capabilities

- **Description:**

---

wsrep_cluster_conf_id

- **Description:** Total number of cluster membership changes that have taken place.

---

wsrep_cluster_size

- **Description:** Number of nodes currently in the cluster.

wsrep_cluster_state_uuid

- **Description:** UUID state of the cluster. If it matches the value in wsrep_local_state_uuid, the local and cluster nodes are in sync.

wsrep_cluster_status

- **Description:** Cluster component status. Possible values are `PRIMARY` (primary group configuration, quorum present), `NON_PRIMARY` (non-primary group configuration, quorum lost) or `DISCONNECTED` (not connected to group, retrying).

wsrep_cluster_weight

- **Description:** The total weight of the current members in the cluster. The value is counted as a sum of of pc.weight of the nodes in the current Primary Component.

wsrep_commit_oooe

- **Description:** How often a transaction was committed out of order.

wsrep_commit_oool

- **Description:** No meaning.

wsrep_commit_window

- **Description:** Average distance between highest and lowest concurrently committed seqno.

wsrep_connected

- **Description:** Whether or not MariaDB is connected to the wsrep provider. Possible values are `ON` or `OFF`.

wsrep_desync_count

- **Description:** Returns the number of operations in progress that require the node to temporarily desync from the cluster.

wsrep_evs_delayed

- **Description:** Provides a comma separated list of all the nodes this node has registered on its delayed list.

wsrep_evs_evict_list

- **Description:** Lists the UUID's of all nodes evicted from the cluster. Evicted nodes cannot rejoin the cluster until you restart their mysqld processes.

wsrep_evs_repl_latency

- **Description:** This status variable provides figures for the replication latency on group communication. It measures latency (in seconds) from the time point when a message is sent out to the time point when a message is received. As replication is a group operation, this essentially gives you the slowest ACK and longest RTT in the cluster. Format is min/avg/max/stddev

`wsrep_evs_state`

- **Description:** Shows the internal state of the EVS Protocol.

`wsrep_flow_control_paused`

- **Description:** The fraction of time since the last FLUSH STATUS command that replication was paused due to flow control.

`wsrep_flow_control_paused_ns`

- **Description:** The total time spent in a paused state measured in nanoseconds.

`wsrep_flow_control_recv`

- **Description:** Number of FC_PAUSE events received as well as sent since the most recent status query.

`wsrep_flow_control_sent`

- **Description:** Number of FC_PAUSE events sent since the most recent status query

---

`wsrep_gcomm_uuid`

- **Description:** The UUID assigned to the node.

`wsrep_incoming_addresses`

- **Description:** Comma-separated list of incoming server addresses in the cluster component.

`wsrep_last_committed`

- **Description:** Sequence number of the most recently committed transaction.

`wsrep_local_bf_aborts`

- **Description:** Total number of local transactions aborted by slave transactions while being executed

---

`wsrep_local_cached_downto`

- **Description:** The lowest sequence number, or seqno, in the write-set cache (GCache).

`wsrep_local_cert_failures`

- **Description:** Total number of local transactions that failed the certification test.

`wsrep_local_commits`

- **Description:** Total number of local transactions committed on the node.

`wsrep_local_index`

- **Description:** The node's index in the cluster. The index is zero-based.

`wsrep_local_recv_queue`

- **Description:** Current length of the receive queue, which is the number of writesets waiting to be applied.

`wsrep_local_recv_queue_avg`

- **Description:** Average length of the receive queue since the most recent status query. If this value is noticeably larger than zero, the node is likely to be overloaded, and cannot apply the writesets as quickly as they arrive, resulting in replication throttling.

`wsrep_local_recv_queue_max`

- **Description:** The maximum length of the recv queue since the last FLUSH STATUS command.

`wsrep_local_recv_queue_min`

- **Description:** The minimum length of the recv queue since the last FLUSH STATUS command.

`wsrep_local_replays`

- **Description:** Total number of transaction replays due to asymmetric lock granularity.

`wsrep_local_send_queue`

- **Description:** Current length of the send queue, which is the number of writesets waiting to be sent.

`wsrep_local_send_queue_avg`

- **Description:** Average length of the send queue since the most recent status query. If this value is noticeably larger than zero, there is most likely network throughput or replication throttling issues.

`wsrep_local_send_queue_max`

- **Description:** The maximum length of the send queue since the last FLUSH STATUS command.

`wsrep_local_send_queue_min`

- **Description:** The minimum length of the send queue since the last FLUSH STATUS command.

`wsrep_local_state`

- **Description:** Internal Galera Cluster FSM state number.

`wsrep_local_state_comment`

- **Description:** Human-readable explanation of the state.

`wsrep_local_state_uuid`

- **Description:** The node's UUID state. If it matches the value in wsrep_cluster_state_uuid, the local and cluster nodes are in sync.

`wsrep_open_connections`

- **Description:** The number of open connection objects inside the wsrep provider.

`wsrep_open_transactions`

- **Description:** The number of locally running transactions which have been registered inside the wsrep provider. This means transactions which have made operations which have caused write set population to happen. Transactions which are read only are not counted.

`wsrep_protocol_version`

- **Description:** The wsrep protocol version being used.

`wsrep_provider_name`

- **Description:** The name of the provider. The default is "Galera".

`wsrep_provider_vendor`

- **Description:** The vendor string.

`wsrep_provider_version`

- **Description:** The version number of the Galera wsrep provider

---

`wsrep_ready`

- **Description:** Whether or not the Galera wsrep provider is ready. Possible values are `ON` or `OFF`

`wsrep_received`

- **Description:** Total number of writesets received from other nodes.

`wsrep_received_bytes`

- **Description:** Total size in bytes of all writesets received from other nodes.

`wsrep_repl_data_bytes`

- **Description:** Total size of data replicated.

`wsrep_repl_keys`

- **Description:** Total number of keys replicated.

`wsrep_repl_keys_bytes`

- **Description:** Total size of keys replicated.

`wsrep_repl_other_bytes`

- **Description:** Total size of other bits replicated.

`wsrep_replicated`

- **Description:** Total number of writesets replicated to other nodes.

`wsrep_replicated_bytes`

- **Description:** Total size in bytes of all writesets replicated to other nodes.

`wsrep_rollbacker_thread_count`

- **Description:** Stores current number of rollbacker threads to make clear how many slave threads of this type there are.
- **Introduced:** MariaDB 10.2.26, MariaDB 10.3.17, MariaDB 10.4.7

`wsrep_thread_count`

- **Description:** Total number of wsrep (applier/rollbacker) threads.

3.2.10 Galera Cluster System Variables

Contents

This page documents system variables related to Galera Cluster. For options that are not system variables, see Galera Options.

See Server System Variables for a complete list of system variables and instructions on setting them.

Also see the Full list of MariaDB options, system and status variables.

`wsrep_allowlist`

- **Description:** Allowed IP addresses, comma delimited.
- **Commandline:** `--wsrep-allowlist=value1[,value2...]`
- **Scope:** Global

- **Dynamic:** No
- **Data Type:** String
- **Default Value:** None
- **Introduced:** MariaDB 10.10

---

wsrep_auto_increment_control

- **Description:** If set to `1` (the default), will automatically adjust the auto_increment_increment and auto_increment_offset variables according to the size of the cluster, and when the cluster size changes. This avoids replication conflicts due to auto_increment. In a primary-replica environment, can be set to `OFF`.
- **Commandline:** `--wsrep-auto-increment-control[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** Boolean
- **Default Value:** `ON`

---

wsrep_causal_reads

- **Description:** If set to `ON` (`OFF` is default), enforces read-committed characteristics across the cluster. In the case that a primary applies an event more quickly than a replica, the two could briefly be out-of-sync. With this variable set to `ON`, the replica will wait for the event to be applied before processing further queries. Setting to `ON` also results in larger read latencies. Deprecated by wsrep_sync_wait=1.
- **Commandline:** `--wsrep-causal-reads[={0|1}]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** Boolean
- **Default Value:** `OFF`
- **Deprecated:** MariaDB 10.1.3
- **Removed:** MariaDB 11.3.0

---

wsrep_certification_rules

- **Description:** Certification rules to use in the cluster. Possible values are:
  - `strict`: Stricter rules that could result in more certification failures. For example with foreign keys, certification failure could result if different nodes receive non-conflicting insertions at about the same time that point to the same row in a parent table
  - `optimized`: relaxed rules that allow more concurrency and cause less certification failures.
- **Commandline:** `--wsrep-certifcation-rules`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** Enumeration
- **Default Value:** `strict`
- **Valid Values:** `strict`, `optimized`
- **Introduced:** MariaDB 10.4.3, MariaDB 10.3.13, MariaDB 10.2.22, MariaDB 10.1.38

---

wsrep_certify_nonPK

- **Description:** When set to `ON` (the default), Galera will still certify transactions for tables with no primary key. However, this can still cause undefined behavior in some circumstances. It is recommended to define primary keys for every InnoDB table when using Galera.
- **Commandline:** `--wsrep-certify-nonPK[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** Boolean
- **Default Value:** `ON`

---

wsrep_cluster_address

- **Description:** The addresses of cluster nodes to connect to when starting up.
  - Good practice is to specify all possible cluster nodes, in the form `gcomm://<node1 or ip:port>,<node2 or`

ip2:port>,<node3 or ip3:port>.
    - Specifying an empty ip (`gcomm://`) will cause the node to start a new cluster (which should not be done in the my.cnf file, as after each restart the server will not rejoin the current cluster).
    - The variable can be changed at runtime in some configurations, and will result in the node closing the connection to any current cluster, and connecting to the new address.
    - If specifying a port, note that this is the Galera port, not the MariaDB port.
    - For example:
        - `gcomm://192.168.0.1,192.168.0.2,192.168.0.3`
        - `gcomm://192.168.0.1:1234,192.168.0.2:1234,192.168.0.3:1234?gmcast.listen_addr=tcp://0.0.0.0:1234`
    - See also gmcast.listen_addr
- **Commandline:** `--wsrep-cluster-address=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** String

---

wsrep_cluster_name

- **Description:** The name of the cluster. Nodes cannot connect to clusters with a different name, so needs to be identical on all nodes in the same cluster. The variable can be set dynamically, but note that doing so may be unsafe and cause an outage, and that the wsrep provider is unloaded and loaded.
- **Commandline:** `--wsrep-cluster-name=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** String
- **Default Value:** `my_wsrep_cluster`

---

wsrep_convert_LOCK_to_trx

- **Description:** Converts LOCK/UNLOCK TABLES statements to BEGIN and COMMIT. Used mainly for getting older applications to work with a multi-primary setup, use carefully, as can result in extremely large writesets.
- **Commandline:** `--wsrep-convert-LOCK-to-trx[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** Boolean
- **Default Value:** `OFF`

---

wsrep_data_home_dir

- **Description:** Directory where wsrep provider will store its internal files.
- **Commandline:** `--wsrep-data-home-dir=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** String
- **Default Value:** The datadir variable value.

---

wsrep_dbug_option

- **Description:** Unused. The mechanism to pass the DBUG options to the wsrep provider hasn't been implemented.
- **Commandline:** `--wsrep-dbug-option=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** String

---

wsrep_debug

- **Description:** WSREP debug level logging. Before MariaDB 10.4.3 was a boolean, which when set to `ON` (`OFF` was default), ensured debug messages would be logged to the error log as well. Before MariaDB 10.6.1, DDL logging was only logged on the originating node. From MariaDB 10.6.1, it is logged on other nodes as well.
- **Commandline:** `--wsrep-debug[={0|1}]`

- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** Enumeration (>= MariaDB 10.4.3), Boolean (<= MariaDB 10.4.2)
- **Default Value:** `NONE` (>= MariaDB 10.4.3), `OFF` (<= MariaDB 10.4.2)
- **Valid Values**: (>= MariaDB 10.4.3) `NONE`, `SERVER`, `TRANSACTION`, `STREAMING`, `CLIENT`

---

wsrep_desync

- **Description:** When a node receives more write-sets than it can apply, the transactions are placed in a received queue. If the node's received queue has too many write-sets waiting to be applied (as defined by the `gcs.fc_limit` WSREP provider option), then the node would usually engage Flow Control. However, when this option is set to `ON`, Flow Control will be disabled for the desynced node. The desynced node works through the received queue until it reaches a more manageable size. The desynced node continues to receive write-sets from the other nodes in the cluster. The other nodes in the cluster do not wait for the desynced node to catch up, so the desynced node can fall even further behind the other nodes in the cluster. You can check if a node is desynced by checking if the `wsrep_local_state_comment` status variable is equal to `Donor/Desynced`.
- **Commandline:** `--wsrep-desync[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** Boolean
- **Default Value:** `OFF`

---

wsrep_dirty_reads

- **Description:** By default, when not synchronized with the group (wsrep_ready=OFF) a node will reject all queries other than SET and SHOW. If `wsrep_dirty_reads` is set to `1`, queries which do not change data, like SELECT queries (dirty reads), creating of prepare statement, etc. will be accepted by the node.
- **Commandline:** `--wsrep-dirty-reads[={0|1}]`
- **Scope:** Global,Session
- **Dynamic:** Yes
- **Data Type:** Boolean
- **Default Value:** `OFF`
- **Valid Values:** `ON`, `OFF`

---

wsrep_drupal_282555_workaround

- **Description:** If set to `ON`, a workaround for Drupal/MySQL/InnoDB bug #282555 is enabled. This is a bug where, in some cases, when inserting a `DEFAULT` value into an AUTO_INCREMENT column, a duplicate key error may be returned.
- **Commandline:** `--wsrep-drupal-282555-workaround[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** Boolean
- **Default Value:** `OFF`

---

wsrep_forced_binlog_format

- **Description:** A binary log format that will override any session binlog format settings.
- **Commandline:** `--wsrep-forced-binlog-format=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Default Value:** `NONE`
- **Data Type:** Enum
- **Valid Values:** `STATEMENT`, `ROW`, `MIXED` or `NONE` (which resets the forced binlog format state).

---

wsrep_gtid_domain_id

- **Description:** This system variable defines the GTID domain ID that is used for wsrep GTID mode.
  - When `wsrep_gtid_mode` is set to `ON`, `wsrep_gtid_domain_id` is used in place of `gtid_domain_id` for all Galera Cluster write sets.

    - When `wsrep_gtid_mode` is set to `OFF`, `wsrep_gtid_domain_id` is simply ignored to allow for backward compatibility.
    - There are some additional requirements that need to be met in order for this mode to generate consistent GTIDs. For more information, see Using MariaDB GTIDs with MariaDB Galera Cluster.
- **Commandline:** `--wsrep-gtid-domain-id=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Default Value:** `0`
- **Range:** `0` to `4294967295`

---

wsrep_gtid_mode

- **Description:** Wsrep GTID mode attempts to keep GTIDs consistent for Galera Cluster write sets on all cluster nodes. GTID state is initially copied to a joiner node during an SST. If you are planning to use Galera Cluster with MariaDB replication, then wsrep GTID mode can be helpful.
    - When `wsrep_gtid_mode` is set to `ON`, `wsrep_gtid_domain_id` is used in place of `gtid_domain_id` for all Galera Cluster write sets.
    - When `wsrep_gtid_mode` is set to `OFF`, `wsrep_gtid_domain_id` is simply ignored to allow for backward compatibility.
    - There are some additional requirements that need to be met in order for this mode to generate consistent GTIDs. For more information, see Using MariaDB GTIDs with MariaDB Galera Cluster.
- **Commandline:** `--wsrep-gtid-mode[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`

---

wsrep_gtid_seq_no

- **Description:** Internal server usage, manually set WSREP GTID seqno.
- **Commandline:** None
- **Scope:** Session only
- **Dynamic:** Yes
- **Data Type:** `numeric`
- **Range:** `0` to `18446744073709551615`
- **Introduced:** MariaDB 10.5.1

---

wsrep_ignore_apply_errors

- **Description:** Bitmask determining whether errors are ignored, or reported back to the provider.
    - 0: No errors are skipped.
    - 1: Ignore some DDL errors (DROP DATABASE, DROP TABLE, DROP INDEX, ALTER TABLE).
    - 2: Skip DML errors (Only ignores DELETE errors).
    - 4: Ignore all DDL errors.
- **Commandline:** `--wsrep-ignore-apply-errors`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** Numeric
- **Default Value:** `7`
- **Range:** `0` to `7`
- **Introduced:** MariaDB 10.4.2

---

wsrep_load_data_splitting

- **Description:** If set to `ON` (the default for MariaDB 10.4.2 and before), LOAD DATA INFILE supports big data files by introducing transaction splitting. The setting has been deprecated in Galera 4, and defaults to `OFF` from MariaDB 10.4.3.
- **Commandline:** `--wsrep-load-data-splitting[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes

- **Data Type:** Boolean
- **Default Value:** `OFF` (>= MariaDB 10.4.3), `ON` (<= MariaDB 10.4.2)

---

wsrep_log_conflicts

- **Description:** If set to `ON` (`OFF` is default), details of conflicting MDL as well as InnoDB locks in the cluster will be logged.
- **Commandline:** `--wsrep-log-conflicts[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** Boolean
- **Default Value:** `OFF`

---

wsrep_max_ws_rows

- **Description:** Maximum permitted number of rows per writeset. Before MariaDB Galera 10.0.27 and MariaDB 10.1.17 this variable was ignored internally and had no effect on the node. From MariaDB Galera 10.0.27 and MariaDB 10.1.17 support for this variable has been added and in order to be backward compatible the default value has been changed to `0` , which essentially allows writesets to be any size.
- **Commandline:** `--wsrep-max-ws-rows=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** Numeric
- **Default Value:**
  - `0` (>= MariaDB Galera 10.0.27, MariaDB 10.1.17)
  - `131072` (<= MariaDB Galera 10.0.26, MariaDB 10.1.16)
- **Range:** `0` to `1048576`

---

wsrep_max_ws_size

- **Description:** Maximum permitted size in bytes per writeset. Writesets exceeding this will be rejected. Note that versions from and before MariaDB 10.1.17 and MariaDB Galera 10.0.27 permitted the maximum to be set beyond 2GB, which was rejected by Galera.
- **Commandline:** `--wsrep-max-ws-size=#`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** Numeric
- **Default Value:**
  - `2147483647` (2GB, >= MariaDB Galera 10.0.27, MariaDB 10.1.17)
  - `1073741824` (1GB, <= MariaDB Galera 10.0.26, MariaDB 10.1.16)
- **Range:** `1024` to `2147483647`

---

wsrep_mode

- **Description:** Turns on WSREP features which are not part of default behavior.
  - BINLOG_ROW_FORMAT_ONLY: Only ROW binlog format is supported.
  - DISALLOW_LOCAL_GTID: Nodes can have GTIDs for local transactions in a number of scenarios. If DISALLOW_LOCAL_GTID is set, these operations produce an error ERROR HY000: Galera replication not supported. Scenarios include:
    - A DDL statement is executed with wsrep_OSU_method=RSU set.
    - A DML statement writes to a non-InnoDB table.
    - A DML statement writes to an InnoDB table with wsrep_on=OFF set.
  - REPLICATE_ARIA: Whether or not DML updates for Aria tables will be replicated. This functionality is experimental and should not be relied upon in production systems.
  - REPLICATE_MYISAM: Whether or not DML updates for MyISAM tables will be replicated. This functionality is experimental and should not be relied upon in production systems.
  - REQUIRED_PRIMARY_KEY: Table should have PRIMARY KEY defined.
  - STRICT_REPLICATION: Same as the old wsrep_strict_ddl setting.
- **Commandline:** `--wsrep-mode=value`
- **Scope:** Global
- **Dynamic:** Yes

- **Data Type:** Enumeration
- **Default Value:** (Empty)
- **Valid Values:** `BINLOG_ROW_FORMAT_ONLY`, `DISALLOW_LOCAL_GTID`, `REQUIRED_PRIMARY_KEY`, `REPLICATE_ARIA`, `REPLICATE_MYISAM` and `STRICT_REPLICATION`
- **Introduced:** MariaDB 10.6.0

---

wsrep_mysql_replication_bundle

- **Description:** Determines the number of replication events that are grouped together. Experimental implementation aimed to assist with bottlenecks when a single replica faces a large commit time delay. If set to `0` (the default), there is no grouping.
- **Commandline:** `--wsrep-mysql-replication-bundle=#`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** Numeric
- **Default Value:** `0`
- **Range:** `0` to `1000`

---

wsrep_node_address

- **Description:** Specifies the node's network address, in the format `ip address[:port]`. As of MariaDB 10.1.8, supports IPv6. The default behavior is for the node to pull the address of the first network interface on the system and the default Galera port. This autoguessing can be unreliable, particularly in the following cases:
  - cloud deployments
  - container deployments
  - servers with multiple network interfaces.
  - servers running multiple nodes.
  - network address translation (NAT).
  - clusters with nodes in more than one region.
- **See also** wsrep_provider_options -> gmcast.listen_addr
- **Commandline:** `--wsrep-node-address=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** String
- **Default Value:** Primary network address, usually `eth0` with a default port of 4567, or `0.0.0.0` if no IP address.

---

wsrep_node_incoming_address

- **Description:** This is the address from which the node listens for client connections. If an address is not specified or it's set to `AUTO` (default), mysqld uses either --bind-address or --wsrep-node-address, or tries to get one from the list of available network interfaces, in the same order. See also wsrep_provider_options -> gmcast.listen_addr.
- **Commandline:** `--wsrep-node-incoming-address=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** String
- **Default Value:** `AUTO`

---

wsrep_node_name

- **Description:** Name of this node. This name can be used in wsrep_sst_donor as a preferred donor. Note that multiple nodes in a cluster can have the same name.
- **Commandline:** `--wsrep-node-name=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** String
- **Default Value:** The server's hostname.

---

wsrep_notify_cmd

- **Description:** Command to be executed each time the node state or the cluster membership changes. Can be used

for raising an alarm, configuring load balancers and so on. See the Codership Notification Script page for more details.

- **Commandline:** `--wsrep-notify-command=value`
- **Scope:** Global
- **Dynamic:**
  - No (>= MariaDB 10.5.9, MariaDB 10.4.18, MariaDB 10.3.28, MariaDB 10.2.37)
  - Yes (<= MariaDB 10.5.8, MariaDB 10.4.17, MariaDB 10.3.27, MariaDB 10.2.36)
- **Data Type:** String
- **Default Value:** Empty

---

wsrep_on

- **Description:** Whether or not wsrep replication is enabled. If the global value is set to `OFF` (the default since MariaDB 10.1), it is not possible to load the provider and join the node in the cluster. If only the session value is set to `OFF`, the operations from that particular session are not replicated in the cluster, but other sessions and applier threads will continue as normal. The session value of the variable does not affect the node's membership and thus, regardless of its value, the node keeps receiving updates from other nodes in the cluster. Before MariaDB 10.1, even though this variable is `ON` by default, its value gets automatically adjusted based on whether mandatory configurations to turn on Galera replication have been specified. Since MariaDB 10.1, it is set to `OFF` by default and must be turned on to enable Galera replication.
- **Commandline:** `--wsrep-on[={0|1}]`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** Boolean
- **Default Value:** `OFF` (>= MariaDB 10.1), `ON` (<= MariaDB Galera Cluster 10.0),
- **Valid Values:** `ON`, `OFF`

---

wsrep_OSU_method

- **Description:** Online schema upgrade method. The default is `TOI`, specifying the setting without the optional parameter will set to `RSU`.
  - `TOI`: Total Order Isolation. In each cluster node, DDL is processed in the same order regarding other transactions, guaranteeing data consistency. However, affected parts of the database will be locked for the whole cluster.
  - `RSU`: Rolling Schema Upgrade. DDL processing is only done locally on the node, and the user needs perform the changes manually on each node. The node is desynced from the rest of the cluster while the processing takes place to avoid the blocking other nodes. Schema changes *must* be backwards compatible in the same way as for ROW based replication to avoid breaking replication when the DDL processing is complete on the single node, and replication recommences.
- **Commandline:** `--wsrep-OSU-method[=value]`
- **Scope:** Global, Session (since MariaDB Galera 10.0.19)
- **Dynamic:** Yes
- **Data Type:** Enum
- **Default Value:** `TOI`
- **Valid Values:** `TOI`, `RSU`

---

wsrep_patch_version

- **Description:** Wsrep patch version, for example `wsrep_25.10`.
- **Commandline:** None
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** String
- **Default Value:** None

---

wsrep_provider

- **Description:** Location of the wsrep library, usually `/usr/lib/libgalera_smm.so` on Debian and Ubuntu, and `/usr/lib64/libgalera_smm.so` on Red Hat/CentOS.
- **Commandline:** `--wsrep-provider=value`
- **Scope:** Global

    - No (>= MariaDB 10.5.9, MariaDB 10.4.18, MariaDB 10.3.28, MariaDB 10.2.37)
    - Yes (<= MariaDB 10.5.8, MariaDB 10.4.17, MariaDB 10.3.27, MariaDB 10.2.36)
- **Data Type:** String
- **Default Value:** None

---

wsrep_provider_options

- **Description:** Semicolon (;) separated list of wsrep options (see wsrep_provider_options).
- **Commandline:** `--wsrep-provider-options=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** String
- **Default Value:** Empty

---

wsrep_recover

- **Description:** If set to `ON` when the server starts, the server will recover the sequence number of the most recent write set applied by Galera, and it will be output to `stderr`, which is usually redirected to the error log. At that point, the server will exit. This sequence number can be provided to the `wsrep_start_position` system variable.
- **Commandline:** `--wsrep-recover[={0|1}]`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** Boolean
- **Default Value:** `OFF`

---

wsrep_reject_queries

- **Description:** Variable to set to reject queries from client connections, useful for maintenance. The node continues to apply write-sets, but an `Error 1047: Unknown command` error is generated by a client query.
    - `NONE` - Not set. Queries will be processed as normal.
    - `ALL` - All queries from client connections will be rejected, but existing client connections will be maintained.
    - `ALL_KILL` All queries from client connections will be rejected, and existing client connections, including the current one, will be immediately killed.
- **Commandline:** `--wsrep-reject-queries[=value]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** Enum
- **Default Value:** `NONE`
- **Valid Values:** `NONE`, `ALL`, `ALL_KILL`
- **Introduced:** MariaDB 10.3.6, MariaDB 10.2.14, MariaDB 10.1.32

---

wsrep_replicate_myisam

- **Description:** Whether or not DML updates for MyISAM tables will be replicated. This functionality is still experimental and should not be relied upon in production systems. Deprecated in MariaDB 10.6, and removed in MariaDB 10.7, use wsrep_mode instead.
- **Commandline:** `--wsrep-replicate-myisam[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Default Value:** `OFF`
- **Data Type:** Boolean
- **Valid Values:** `ON`, `OFF`
- **Deprecated:** MariaDB 10.6.0
- **Removed:** MariaDB 10.7.0

---

wsrep_restart_slave

- **Description:** If set to ON, the replica is restarted automatically, when node joins back to cluster.
- **Commandline:** `--wsrep-restart-slave[={0|1}]`
- **Scope:** Global

- **Dynamic:** Yes
- **Default Value:** `OFF`
- **Data Type:** Boolean

---

wsrep_retry_autocommit

- **Description:** Number of times autocommited queries will be retried due to cluster-wide conflicts before returning an error to the client. If set to `0`, no retries will be attempted, while a value of `1` (the default) or more specifies the number of retries attempted. Can be useful to assist applications using autocommit to avoid deadlocks.
- **Commandline:** `--wsrep-retry-autocommit=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** Numeric
- **Default Value:** `1`
- **Range:** `0` to `10000`

---

wsrep_slave_FK_checks

- **Description:** If set to ON (the default), the applier replica thread performs foreign key constraint checks.
- **Commandline:** `--wsrep-slave-FK-checks[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** Boolean
- **Default Value:** ON

---

wsrep_slave_threads

- **Description:** Number of replica threads used to apply Galera write sets in parallel. The Galera replica threads are able to determine which write sets are safe to apply in parallel. However, if your cluster nodes seem to have frequent consistency problems, then setting the value to `1` will probably fix the problem. See About Galera Replication: Galera Replica Threads for more information.
- **Commandline:** `--wsrep-slave-threads=` #
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** Numeric
- **Default Value:** `1`
- **Range:** `1` to `512`

---

wsrep_slave_UK_checks

- **Description:** If set to ON, the applier replica thread performs secondary index uniqueness checks.
- **Commandline:** `--wsrep-slave-UK-checks[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** Boolean
- **Default Value:** OFF

---

wsrep_sr_store

- **Description:** Storage for streaming replication fragments.
- **Commandline:** `--wsrep-sr-store=val`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** Enum
- **Default Value:** `table`
- **Valid Values:** `table`, `none`
- **Introduced:** MariaDB 10.4.2

---

wsrep_sst_auth

- **Description:** Username and password of the user to use for replication. Unused if wsrep_sst_method is set to `rsync`, while for other methods it should be in the format `<user>:<password>`. The contents are masked in logs and when querying the value with SHOW VARIABLES. See Introduction to State Snapshot Transfers (SSTs) for more information.
- **Commandline:** `--wsrep-sst-auth=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** String
- **Default Value:** (Empty)

---

wsrep_sst_donor

- **Description:** Comma-separated list (from 5.5.33) or name (as per wsrep_node_name) of the servers as donors, or the source of the state transfer, in order of preference. The donor-selection algorithm, in general, prefers a donor capable of transferring only the missing transactions (IST) to the joiner node, instead of the complete state (SST). Thus, it starts by looking for an IST-capable node in the given donor list followed by rest of the nodes in the cluster. In case multiple candidate nodes are found outside the specified donor list, the node in the same segment (gmcast.segment) as the joiner is preferred. If none of the existing nodes in the cluster can serve the missing transactions through IST, the algorithm moves on to look for a suitable node to transfer the entire state (SST). It first looks at the nodes specified in the donor list (irrespective of their segment). If no suitable donor is still found, the rest of the donor nodes are checked for suitability only if the donor list has a "terminating-comma". Note that a stateless node (the Galera arbitrator) can never be a donor. See Introduction to State Snapshot Transfers (SSTs) for more information. [NOTE] Although the variable is dynamic, the node will not use the new value unless the node requiring SST or IST disconnects from the cluster. To force this, set wsrep_cluster_address to an empty string and back to the nodes list. After setting this variable dynamically, on startup the value from the configuration file will be used again.
- **Commandline:** `--wsrep-sst-donor=value`
- **Scope:** Global
- **Dynamic:** Yes (read note above)
- **Data Type:** String
- **Default Value:**

---

wsrep_sst_donor_rejects_queries

- **Description:** If set to `ON` (`OFF` is default), the donor node will reject incoming queries, returning an `UNKNOWN COMMAND` error code. Can be used for informing load balancers that a node is unavailable.
- **Commandline:** `--wsrep-sst-donor-rejects-queries[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** Boolean
- **Default Value:** `OFF`

---

wsrep_sst_method

- **Description:** Method used for taking the state snapshot transfer (SST). See Introduction to State Snapshot Transfers (SSTs): SST Methods for more information.
- **Commandline:** `--wsrep-sst-method=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** String
- **Default Value:** `rsync`
- **Valid Values:** `rsync`, `mysqldump`, `xtrabackup`, `xtrabackup-v2`, `mariabackup`

---

wsrep_sst_receive_address

- **Description:** This is the address where other nodes (donor) in the cluster connect to in order to send the state-transfer updates. If an address is not specified or its set to `AUTO` (default), mysqld uses --wsrep_node_address's value as the receiving address. However, if --wsrep_node_address is not set, it uses address from either --bind-address or tries to get one from the list of available network interfaces, in the same order. Note: setting it to `localhost` will make it impossible for nodes running on other hosts to reach this node. See Introduction to State Snapshot Transfers (SSTs) for more information.
- **Commandline:** `--wsrep-sst-receive-address=value`
- **Scope:** Global

- **Dynamic:** Yes
- **Data Type:** String
- **Default Value:** `AUTO`

---

wsrep_start_position

- **Description:** The start position that the node should use in the format: `UUID:seq_no`. The proper value to use for this position can be recovered with `wsrep_recover`.
- **Commandline:** `--wsrep-start-position=value`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** String
- **Default Value:** `00000000-0000-0000-0000-000000000000:-1`

---

wsrep_status_file

- **Description:** wsrep status output filename.
- **Commandline:** `--wsrep-status-file=value`
- **Scope:** Global
- **Dynamic:** No
- **Data Type:** String
- **Default Value:** None
- **Introduced:** MariaDB 10.9

---

wsrep_strict_ddl

- **Description:** If set, reject DDL statements on affected tables not supporting Galera replication. This is done by checking if the table is InnoDB, which is the only table currently fully supporting Galera replication. MyISAM tables will not trigger the error if the experimental wsrep_replicate_myisam setting is `ON`. If set, should be set on all tables in the cluster. Affected DDL statements include:
  CREATE TABLE (e.g. CREATE TABLE t1(a int) engine=Aria)
  ALTER TABLE
  TRUNCATE TABLE
  CREATE VIEW
  CREATE TRIGGER
  CREATE INDEX
  DROP INDEX
  RENAME TABLE
  DROP TABLE
  Statements in procedures, events, and functions are permitted as the affected tables are only known at execution. Furthermore, the various USER, ROLE, SERVER and DATABASE statements are also allowed as they do not have an affected table. Deprecated in MariaDB 10.6.0 and removed in MariaDB 10.7. Use wsrep_mode=STRICT_REPLICATION instead.
- **Commandline:** `--wsrep-strict-ddl[={0|1}]`
- **Scope:** Global
- **Dynamic:** Yes
- **Data Type:** `boolean`
- **Default Value:** `OFF`
- **Introduced:** MariaDB 10.5.1
- **Deprecated:** MariaDB 10.6.0
- **Removed:** MariaDB 10.7.0

---

wsrep_sync_wait

- **Description:** Setting this variable ensures causality checks will take place before executing an operation of the type specified by the value, ensuring that the statement is executed on a fully synced node. While the check is taking place, new queries are blocked on the node to allow the server to catch up with all updates made in the cluster up to the point where the check was begun. Once reached, the original query is executed on the node. This can result in higher latency. Note that when wsrep_dirty_reads is ON, values of wsrep_sync_wait become irrelevant. Sample usage (for a critical read that must have the most up-to-date data) `SET SESSION wsrep_sync_wait=1; SELECT ...; SET SESSION wsrep_sync_wait=0;`

    - `0` - Disabled (default)
    - `1` - READ (SELECT and BEGIN/START TRANSACTION). Up until MariaDB 10.2.8, MariaDB 10.1.26, MariaDB Galera 10.0.31 and MariaDB Galera 5.5.56, also SHOW). This is the same as wsrep_causal_reads=1.
    - `2` - UPDATE and DELETE;
    - `3` - READ, UPDATE and DELETE;
    - `4` - INSERT and REPLACE;
    - `5` - READ, INSERT and REPLACE;
    - `6` - UPDATE, DELETE, INSERT and REPLACE;
    - `7` - READ, UPDATE, DELETE, INSERT and REPLACE;
    - `8` - SHOW (from MariaDB 10.2.9, MariaDB 10.1.27, MariaDB Galera 10.0.32, MariaDB Galera 5.5.57)
    - `9` - READ and SHOW (from MariaDB 10.2.9, MariaDB 10.1.27, MariaDB Galera 10.0.32, MariaDB Galera 5.5.57)
    - `10` - UPDATE, DELETE and SHOW (from MariaDB 10.2.9, MariaDB 10.1.27, MariaDB Galera 10.0.32, MariaDB Galera 5.5.57)
    - `11` - READ, UPDATE, DELETE and SHOW (from MariaDB 10.2.9, MariaDB 10.1.27, MariaDB Galera 10.0.32, MariaDB Galera 5.5.57)
    - `12` - INSERT, REPLACE and SHOW (from MariaDB 10.2.9, MariaDB 10.1.27, MariaDB Galera 10.0.32, MariaDB Galera 5.5.57)
    - `13` - READ, INSERT, REPLACE and SHOW (from MariaDB 10.2.9, MariaDB 10.1.27, MariaDB Galera 10.0.32, MariaDB Galera 5.5.57)
    - `14` - UPDATE, DELETE, INSERT, REPLACE and SHOW (from MariaDB 10.2.9, MariaDB 10.1.27, MariaDB Galera 10.0.32, MariaDB Galera 5.5.57)
    - `15` - READ, UPDATE, DELETE, INSERT, REPLACE and SHOW (from MariaDB 10.2.9, MariaDB 10.1.27, MariaDB Galera 10.0.32, MariaDB Galera 5.5.57)
- **Commandline:** `--wsrep-sync-wait=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** Numeric
- **Default Value:** `0`
- **Range:**
    - `0` to `15`

---

wsrep_trx_fragment_size

- **Description:** Size of transaction fragments for streaming replication (measured in units as specified by wsrep_trx_fragment_unit)
- **Commandline:** `--wsrep-trx-fragment-size=#`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** numeric
- **Default Value:** `0`
- **Range:** `0` to `2147483647`
- **Introduced:** MariaDB 10.4.2

---

wsrep_trx_fragment_unit

- **Description:** Unit for streaming replication transaction fragments' size:
    - `bytes` : transaction's binlog events buffer size in bytes
    - `rows` : number of rows affected by the transaction
    - `statements` : number of SQL statements executed in the multi-statement transaction
- **Commandline:** `--wsrep-trx-fragment-unit=value`
- **Scope:** Global, Session
- **Dynamic:** Yes
- **Data Type:** enum
- **Default Value:** `bytes`
- **Valid Values:** `bytes`, `rows` or `statements`
- **Introduced:** MariaDB 10.4.2

3.2.11 Building the Galera wsrep Package on Ubuntu and Debian

The instructions on this page were used to create the *galera* package on the Ubuntu and Debian Linux distributions. This package contains the wsrep provider for MariaDB Galera Cluster.

MariaDB Galera Cluster starting with 5.5.35

Starting with MariaDB Galera Cluster 5.5.35, the version of the wsrep provider is **25.3.5**. We also provide **25.2.9** for those that need or want it.

Prior to that, the wsrep version was 23.2.7.

1. Install prerequisites:

```
sudo apt-get update
sudo apt-get upgrade
sudo apt-get -y install check debhelper libasio-dev libboost-dev libboost-program-options-dev libssl-dev scons
```

2. Clone galera.git from github.com/mariadb and checkout mariadb-3.x banch:

```
git init repo
cd repo
git clone -b mariadb-3.x https://github.com/MariaDB/galera.git
```

3. Build the packages by executing `build.sh` under scripts/ directory with `-p` switch:

```
cd galera
./scripts/build.sh -p
```

When finished, you will have the Debian packages for galera library and arbitrator in the parent directory.

Running galera test suite

If you want to run the `galera` test suite (`mysql-test-run --suite=galera`), you need to install the galera library as either `/usr/lib/galera/libgalera_smm.so` or `/usr/lib64/galera/libgalera_smm.so`

3.2.12 Building the Galera wsrep Package on Fedora

The instructions on this page were used to create the *galera* package on the Fedora Linux distribution. This package contains the wsrep provider for MariaDB Galera Cluster.

The following table lists each version of the Galera 4 wsrep provider, and it lists which version of MariaDB each one was first released in. If you would like to install Galera 4 using yum, apt, or zypper, then the package is called `galera-4` .

Galera Version	Released in MariaDB Version
26.4.14	10.10.3, 10.9.5, 10.8.7, 10.7.8, 10.6.12, 10.5.19, 10.4.28
26.4.13	10.10.2, 10.9.4, 10.8.6, 10.7.7, 10.6.11, 10.5.18, 10.4.27
26.4.12	10.10.1, 10.9.2, 10.8.4, 10.7.5, 10.6.9, 10.5.17, 10.4.26
26.4.11	10.8.1, 10.7.2, 10.6.6, 10.5.14, 10.4.22
26.4.9	10.6.4, 10.5.12, 10.4.21
26.4.8	10.6.1, 10.5.10, 10.4.19
26.4.7	10.5.9, 10.4.18
26.4.6	10.5.7, 10.4.16
26.4.5	10.5.4, 10.4.14
26.4.4	10.5.1, 10.4.13

26.4.3	10.5.0, 10.4.9
26.4.2	10.4.4
26.4.1	10.4.3
26.4.0	10.4.2

The following table lists each version of the Galera 3 wsrep provider, and it lists which version of MariaDB each one was first released in. If you would like to install Galera 3 using yum, apt, or zypper, then the package is called `galera`.

Galera Version	Released in MariaDB Version
25.3.37	MariaDB 10.3.36
25.3.35	MariaDB 10.3.33, MariaDB 10.2.42
25.3.34	MariaDB 10.3.31, MariaDB 10.2.40
25.3.33	MariaDB 10.3.29, MariaDB 10.2.38
25.3.32	MariaDB 10.3.28, MariaDB 10.2.37
25.3.31	MariaDB 10.3.26, MariaDB 10.2.35, MariaDB 10.1.48
25.3.30	MariaDB 10.3.25, MariaDB 10.2.34, MariaDB 10.1.47
25.3.29	MariaDB 10.3.23, MariaDB 10.2.32, MariaDB 10.1.45
25.3.28	MariaDB 10.3.19, MariaDB 10.2.28, MariaDB 10.1.42
25.3.27	MariaDB 10.3.18, MariaDB 10.2.27
25.3.26	MariaDB 10.3.14, MariaDB 10.2.23, MariaDB 10.1.39
25.3.25	MariaDB 10.3.12, MariaDB 10.2.20, MariaDB 10.1.38, MariaDB Galera Cluster 10.0.38, MariaDB Galera Cluster 5.5.63
25.3.24	MariaDB 10.4.0, MariaDB 10.3.10, MariaDB 10.2.18, MariaDB 10.1.37, MariaDB Galera Cluster 10.0.37, MariaDB Galera Cluster 5.5.62
25.3.23	MariaDB 10.3.5, MariaDB 10.2.13, MariaDB 10.1.32, MariaDB Galera Cluster 10.0.35, MariaDB Galera Cluster 5.5.60
25.3.22	MariaDB 10.3.3, MariaDB 10.2.11, MariaDB 10.1.29, MariaDB Galera Cluster 10.0.33, MariaDB Galera Cluster 5.5.59
25.3.21	N/A
25.3.20	MariaDB 10.3.1, MariaDB 10.2.6, MariaDB 10.1.23, MariaDB Galera Cluster 10.0.31, MariaDB Galera Cluster 5.5.56
25.3.19	MariaDB 10.3.0, MariaDB 10.2.3, MariaDB 10.1.20, MariaDB Galera Cluster 10.0.29, MariaDB Galera Cluster 5.5.54
25.3.18	MariaDB 10.2.2, MariaDB 10.1.18, MariaDB Galera Cluster 10.0.28, MariaDB Galera Cluster 5.5.53
25.3.17	MariaDB 10.1.17, MariaDB Galera Cluster 10.0.27, MariaDB Galera Cluster 5.5.51
25.3.16	N/A
25.3.15	MariaDB 10.2.0, MariaDB 10.1.13, MariaDB Galera Cluster 10.0.25, MariaDB Galera Cluster 5.5.49
25.3.14	MariaDB 10.1.12, MariaDB Galera Cluster 10.0.24, MariaDB Galera Cluster 5.5.48
25.3.12	MariaDB 10.1.11
25.3.11	N/A
25.3.10	N/A
25.3.9	MariaDB 10.1.3, MariaDB Galera Cluster 10.0.17, MariaDB Galera Cluster 5.5.42
25.3.8	N/A
25.3.7	N/A
25.3.6	N/A
25.3.5	MariaDB 10.1.1, MariaDB Galera Cluster 10.0.10, MariaDB Galera Cluster 5.5.37

25.3.4	N/A
25.3.3	N/A
25.3.2	MariaDB Galera Cluster 10.0.7, MariaDB Galera Cluster 5.5.35

The following table lists each version of the Galera 2 wsrep provider, and it lists which version of MariaDB each one was first released in.

Galera Version	Released in MariaDB Galera Cluster Version
25.2.9	10.0.10, 5.5.37
25.2.8	10.0.7, 5.5.35
23.2.7	5.5.34

For convenience, a *galera* package containing the **preferred** wsrep provider is included in the MariaDB YUM and APT repositories (the preferred versions are **bolded** in the table above).

See also Deciphering Galera Version Numbers.

1. Install the prerequisites:

```
sudo yum update
sudo yum -y install boost-devel check-devel glibc-devel openssl-devel scons
```

2. Clone galera.git from github.com/mariadb and checkout mariadb-3.x banch:

```
git init repo
cd repo
git clone -b mariadb-3.x https://github.com/MariaDB/galera.git
```

3. Build the packages by executing `build.sh` under scripts/ directory with `-p` switch:

```
cd galera
./scripts/build.sh -p
```

When finished, you will have an RPM package containing galera library, arbitrator and related files in the current directory. Note: The same set of instructions can be applied to other RPM based platforms to generate galera package.

3.2.13 Installing Galera from Source

Contents

There are binary installation packages available for RPM and Debian-based distributions, which will pull in all required Galera dependencies.

If these are not available, you will need to build Galera from source.

MariaDB starting with 10.1

Starting from MariaDB 10.1, the wsrep API for Galera Cluster is included by default. Follow the usual compiling-mariadb-from-source instructions

MariaDB until 10.0

MariaDB 10.0 and below are no longer supported. The instructions below have only historical significance.

Preparation

make cannot manage dependencies for the build process, so the following packages need to be installed first:

RPM-based:

```
yum-builddep MariaDB-server
```

Debian-based:

```
apt-get build-dep mariadb-server
```

If running on an alternative system, or the commands are available, the following packages are required. You will need to check the repositories for the correct package names on your distribution - these may differ between distributions, or require additional packages:

MariaDB Database Server with wsrep API

- Git, CMake (on Fedora, both cmake and cmake-fedora are required), GCC and GCC-C++, Automake, Autoconf, and Bison, as well as development releases of libaio and ncurses.

Building

You can use Git to download the source code, as MariaDB source code is available through GitHub. Clone the repository:

```
git clone https://github.com/mariadb/server mariadb
```

1. Checkout the branch (e.g. 10.0-galera or 5.5-galera), for example:

```
cd mariadb
git checkout 10.0-galera
```

Building the Database Server

The standard and Galera cluster database servers are the same, except that for Galera Cluster, the wsrep API patch is included. Enable the patch with the CMake configuration options `WITH_WSREP` and `WITH_INNODB_DISALLOW_WRITES`. To build the database server, run the following commands:

```
cmake -DWITH_WSREP=ON -DWITH_INNODB_DISALLOW_WRITES=ON .
make
make install
```

There are also some build scripts in the *BUILD/* directory which may be more convenient to use. For example, the following pre-configures the build options discussed above:

```
./BUILD/compile-pentium64-wsrep
```

There are several others as well, so you can select the most convenient.

Besides the server with the Galera support, you will also need a galera provider.

Preparation

make cannot manage dependencies itself, so the following packages need to be installed first:

```
apt-get install -y scons check
```

If running on an alternative system, or the commands are available, the following packages are required. You will need to check the repositories for the correct package names on your distribution - these may differ between distributions, or require additional packages:

Galera Replication Plugin

- SCons, as well as development releases of Boost (libboost_program_options, libboost_headers1), Check and OpenSSL.

Building

Run:

```
git clone -b mariadb-4.x https://github.com/MariaDB/galera.git
```

If you are using MariaDB 10.3 or earlier, you should checkout `mariadb-3.x` instead.

After this, the source files for the Galera provider will be in the `galera` directory.

Building the Galera Provider

The Galera Replication Plugin both implements the wsrep API and operates as the database server's wsrep Provider. To build, cd into the *galera/* directory and do:

```
git submodule init
git submodule update
./scripts/build.sh
mkdir /usr/lib64/galera
cp libgalera_smm.so /usr/lib64/galera
```

The path to `libgalera_smm.so` needs to be defined in the *my.cnf* configuration file.

> Building Galera Replication Plugin from source on FreeBSD runs into issues due to Linux dependencies. To overcome these, either install the binary package: `pkg install galera`, or use the ports build available at `/usr/ports/databases/galera`.

Configuration

After building, a number of other steps are necessary:

- Create the database server user and group:

```
groupadd mysql
useradd -g mysql mysql
```

- Install the database (the path may be different if you specified CMAKE_INSTALL_PREFIX):

```
cd /usr/local/mysql
./scripts/mariadb-install-db --user=mysql
```

- If you want to install the database in a location other than */usr/local/mysql/data*, use the *--basedir* or *--datadir* options.
- Change the user and group permissions for the base directory.

```
chown -R mysql /usr/local/mysql
chgrp -R mysql /usr/local/mysql
```

- Create a system unit for the database server.

```
cp /usr/local/mysql/supported-files/mysql.server /etc/init.d/mysql
chmod +x /etc/init.d/mysql
chkconfig --add mysql
```

- Galera Cluster can now be started using the service command, and is set to start at boot.

3.2.14 Galera Test Repositories

To facilitate development and QA, we have created some test repositories for the Galera wsrep provider.

> These are **test** repositories. There will be periods when they do not work at all, or work incorrectly, or possibly cause earthquakes, typhoons, and tornadoes. You have been warned.

Galera Test Repositories for YUM

Replace `${dist}`
in the code below for the YUM-based distribution you are testing. Valid distributions are:

- centos5-amd64
- centos5-x86
- centos6-amd64
- centos6-x86
- centos7-amd64
- rhel5-amd64
- rhel5-x86
- rhel6-amd64
- rhel6-x86
- rhel6-ppc64
- rhel7-amd64
- rhel7-ppc64
- rhel7-ppc64le
- fedora22-amd64
- fedora22-x86
- fedora23-amd64
- fedora23-x86
- fedora24-amd64
- fedora24-x86
- opensuse13-amd64
- opensuse13-x86
- sles11-amd64
- sles11-x86
- sles12-amd64
- sles12-ppc64le

```
# Place this code block in a file at /etc/yum.repos.d/galera.repo
[galera-test]
name = galera-test
baseurl = http://yum.mariadb.org/galera/repo/rpm/${dist}
gpgkey=https://yum.mariadb.org/RPM-GPG-KEY-MariaDB
gpgcheck=1
```

Galera Test Repositories for APT

Replace `${dist}`
in the code below for the APT-based distribution you are testing. Valid ones are:

- wheezy
- jessie
- sid
- precise
- trusty
- xenial

```
# run the following command:
sudo apt-key adv --recv-keys --keyserver keyserver.ubuntu.com 0xcbcb082a1bb943db 0xF1656F24C74CD1

# Add the following line to your /etc/apt/sources.list file:
deb http://yum.mariadb.org/galera/repo/deb ${dist} main
```

3.2.15 wsrep_provider_options

Contents

6. debug

71. repl.proto_max
72. socket.checksum
73. socket.dynamic

74. socket.recv_buf_size
75. socket.send_buf_size
76. socket.ssl
77. socket.ssl_ca
78. socket.ssl_cert
79. socket.ssl_cipher
80. socket.ssl_compression
81. socket.ssl_key
82. socket.ssl_password_file

wsrep_provider_options

The following options can be set as part of the Galera wsrep_provider_options variable. Dynamic options can be changed while the server is running.

Options need to be provided as a semicolon (;) separated list on a single line. Options that are not explicitly set are set to their default value.

Note that before Galera 3, the `repl` tag was named `replicator`.

`base_dir`

- **Description:** Specifies the data directory

`base_host`

- **Description:** For internal use. Should not be manually set.
- **Default:** `127.0.0.1` (detected network address)

`base_port`

- **Description:** For internal use. Should not be manually set.
- **Default:** `4567`

`cert.log_conflicts`

- **Description:** Certification failure log details.
- **Dynamic:** Yes
- **Default:** `no`

`cert.optimistic_pa`

- **Description:** Controls parallel application of actions on the replica. If set, the full range of parallelization as determined by the certification algorithm is permitted. If not set, the parallel applying window will not exceed that seen on the primary, and applying will start no sooner than after all actions it has seen on the master are committed.
- **Dynamic:** Yes
- **Default:** `yes`

`debug`

- **Description:** Enable debugging.
- **Dynamic:** Yes
- **Default:** `no`

`evs.auto_evict`

- **Description:** Number of entries the node permits for a given delayed node before triggering the Auto Eviction protocol. An entry is added to a delayed list for each delayed response from a node. If set to `0`, the default, the Auto Eviction protocol is disabled for this node. See Auto Eviction for more.
- **Dynamic:** No

- **Default:** `0`

`evs.causal_keepalive_period`

- **Description:** Used by the developers only, and not manually serviceable.
- **Dynamic:** No
- **Default:** The evs.keepalive_period.

`evs.debug_log_mask`

- **Description:** Controls EVS debug logging. Only effective when wsrep_debug is on.
- **Dynamic:** Yes
- **Default:** `0x1`

`evs.delay_margin`

- **Description:** Time that response times can be delayed before this node adds an entry to the delayed list. See evs.auto_evict. Must be set to a higher value than the round-trip delay time between nodes.
- **Dynamic:** No
- **Default:** `PT1S`

`evs.delayed_keep_period`

- **Description:** Time that this node requires a previously delayed node to remain responsive before being removed from the delayed list. See evs.auto_evict.
- **Dynamic:** No
- **Default:** `PT30S`

`evs.evict`

- **Description:** When set to the gcomm UUID of a node, that node is evicted from the cluster. When set to an empty string, the eviction list is cleared on the node where it is set. See evs.auto_evict.
- **Dynamic:** No
- **Default:** Empty string

`evs.inactive_check_period`

- **Description:** Frequency of checks for peer inactivity (looking for nodes with delayed responses), after which nodes may be added to the delayed list, and later evicted.
- **Dynamic:** No
- **Default:** `PT0.5S`

`evs.inactive_timeout`

- **Description:** Time limit that a node can be inactive before being pronounced as dead.
- **Dynamic:** No
- **Default:** `PT15S`

`evs.info_log_mask`

- **Description:** Controls extra EVS info logging. Bits:
  - 0x1 – extra view change information
  - 0x2 – extra state change information
  - 0x4 – statistics
  - 0x8 – profiling (only available in builds with profiling enabled)
- **Dynamic:** No
- **Default:** `0`

evs.install_timeout

- **Description:** Timeout on waits for install message acknowledgments. Replaces evs.consensus_timeout.
- **Dynamic:** Yes
- **Default:** `PT7.5S`

evs.join_retrans_period

- **Description:** Time period for how often retransmission of EVS join messages when forming cluster membership should occur.
- **Dynamic:** Yes
- **Default:** `PT1S`

evs.keepalive_period

- **Description:** How often keepalive signals should be transmitted when there's no other traffic.
- **Dynamic:** Yes
- **Default:** `PT1S`

evs.max_install_timeouts

- **Description:** Number of membership install rounds to attempt before timing out. The total rounds will be this value plus two.
- **Dynamic:** No
- **Default:** `3`

evs.send_window

- **Description:** Maximum number of packets that can be replicated at a time, Must be more than evs.user_send_window, which applies to data packets only (double is recommended). In WAN environments can be set much higher than the default, for example `512` .
- **Dynamic:** Yes
- **Default:** `4`

evs.stats_report_period

- **Description:** Reporting period for EVS statistics.
- **Dynamic:** No
- **Default:** `PT1M`

evs.suspect_timeout

- **Description:** A node will be suspected to be dead after this period of inactivity. If all nodes agree, the node is dropped from the cluster before evs.inactive_timeout is reached.
- **Dynamic:** No
- **Default:** `PT5S`

evs.use_aggregate

- **Description:** If set to `true` (the default), small packets will be aggregated into one where possible.
- **Dynamic:** No
- **Default:** `true`

evs.user_send_window

- **Description:** Maximum number of data packets that can be replicated at a time. Must be smaller than

evs.send_window (half is recommended). In WAN environments can be set much higher than the default, for example `512`.

- **Dynamic:** Yes
- **Default:** `2`

`evs.version`

- **Description:** EVS protocol version. Defaults to `0` for backward compatibility. Certain EVS features (e.g. auto eviction) require more recent versions.
- **Dynamic:** No
- **Default:** `0`

`evs.view_forget_timeout`

- **Description:** Time after which past views will be dropped from the view history.
- **Dynamic:** No
- **Default:** `P1D`

`gcache.dir`

- **Description:** Directory where GCache files are placed.
- **Dynamic:** No
- **Default:** The working directory

`gcache.keep_pages_size`

- **Description:** Total size of the page storage pages for caching. One page is always present if only page storage is enabled.
- **Dynamic:** No
- **Default:** `0`

`gcache.mem_size`

- **Description:** Maximum size of size of the malloc() store for setups that have spare RAM.
- **Dynamic:** No
- **Default:** `0`

`gcache.name`

- **Description:** Gcache ring buffer storage file name. By default placed in the working directory, changing to another location or partition can reduce disk IO.
- **Dynamic:** No
- **Default:** `./galera.cache` ---

`gcache.page_size`

- **Description:** Size of the page storage page files. These are prefixed by `gcache.page`. Can be set to as large as the disk can handle.
- **Dynamic:** No
- **Default:** `128M`

`gcache.recover`

- **Description:** Whether or not gcache recovery takes place when the node starts up. If it is possible to recover gcache, the node can then provide IST to other joining nodes, which assists when the whole cluster is restarted.
- **Dynamic:** No
- **Default:** `no`
- **Introduced:** MariaDB 10.1.20, MariaDB Galera 10.0.29, MariaDB Galera 5.5.54

gcache.size

- **Description:** Gcache ring buffer storage size (the space the node uses for caching write sets), preallocated on startup.
- **Dynamic:** No
- **Default:** `128M`

gcomm.thread_prio

- **Description:** Gcomm thread policy and priority (in the format `policy:priority`. Priority is an integer, while policy can be one of:
  - `fifo`: First-in, first-out scheduling. Always preempt other, batch or idle threads and can only be preempted by other `fifo` threads of a higher priority or blocked by an I/O request.
  - `rr`: Round-robin scheduling. Always preempt other, batch or idle threads. Runs for a fixed period of time after which the thread is stopped and moved to the end of the list, being replaced by another round-robin thread with the same priority. Otherwise runs until preempted by other `rr` threads of a higher priority or blocked by an I/O request.
  - `other`: Default scheduling on Linux. Threads run until preempted by a thread of a higher priority or a superior scheduling designation, or blocked by an I/O request.
- **Dynamic:** No
- **Default:** Empty string

gcs.fc_debug

- **Description:** If set to a value greater than zero (the default), debug statistics about SST flow control will be posted each time after the specified number of writesets.
- **Dynamic:** No
- **Default:** `0`

gcs.fc_factor

- **Description:**Fraction below gcs.fc_limit which if the recv queue drops below, replication resumes.
- **Dynamic:** Yes
- **Default:** `1.0`

gcs.fc_limit

- **Description:** If the recv queue exceeds this many writesets, replication is paused. Can increase greatly in master-slave setups. Replication will resume again according to the gcs.fc_factor setting.
- **Dynamic:** Yes
- **Default:** `16`

gcs.fc_master_slave

- **Description:** Whether to assume that the cluster only contains one master. Deprecated since Galera 4.10 (MariaDB 10.8.1, MariaDB 10.7.2, MariaDB 10.6.6, MariaDB 10.5.14, MariaDB 10.4.22) - see gcs.fc_single_primary
- **Dynamic:** No
- **Default:** `no`

gcs.fc_single_primary

- **Description:** Defines whether there is more than one source of replication. As the number of nodes in the cluster grows, the larger the calculated gcs.fc_limit gets. At the same time, the number of writes from the nodes increases. When this parameter value is set to NO (multi-primary), the gcs.fc_limit parameter is dynamically modified to give more margin for each node to be a bit further behind applying writes. The gcs.fc_limit parameter is modified by the square root of the cluster size, that is, in a four-node cluster it is two times higher than the base value. This is done to compensate for the increasing replication rate noise.
- **Dynamic:** No
- **Default:** `no`

gcs.max_packet_size

- **Description:** Maximum packet size, after which writesets become fragmented.
- **Dynamic:** No
- **Default:** `64500`

gcs.max_throttle

- **Description:** How much we can throttle replication rate during state transfer (to avoid running out of memory). Set it to 0.0 if stopping replication is acceptable for the sake of completing state transfer.
- **Dynamic:** No
- **Default:** `0.25`

gcs.recv_q_hard_limit

- **Description:** Maximum size of the recv queue. If exceeded, the server aborts. Half of available RAM plus swap is a recommended size.
- **Dynamic:** No
- **Default:** LLONG_MAX

gcs.recv_q_soft_limit

- **Description:** Fraction of gcs.recv_q_hard_limit after which replication rate is throttled. The rate of throttling increases linearly from zero (the regular, varying rate of replication) at and below `csrecv_q_soft_limit` to one (full throttling) at gcs.recv_q_hard_limit
- **Dynamic:** No
- **Default:** `0.25`

gcs.sync_donor

- **Description:** Whether or not the rest of the cluster should stay in sync with the donor. If set to `YES` (`NO` is default), if the donor is blocked by state transfer, the whole cluster is also blocked.
- **Dynamic:** No
- **Default:** `no`

gmcast.listen_addr

- **Description:** Address Galera listens for connections from other nodes. Can be used to override the default port to listen, which is obtained from the connection address.
- **Dynamic:** No
- **Default:** `tcp://0.0.0.0:4567`

gmcast.mcast_addr

- **Description:** Not set by default, but if set, UDP multicast will be used for replication. Must be identical on all nodes.For example, `gmcast.mcast_addr=239.192.0.11`
- **Dynamic:** No
- **Default:** None

gmcast.mcast_ttl

- **Description:** Multicast packet TTL (time to live) value.
- **Dynamic:** No
- **Default:** `1`

gmcast.peer_timeout

- **Description:** Connection timeout for initiating message relaying.
- **Dynamic:** No
- **Default:** `PT3S`

---

gmcast.segment

- **Description:** Defines the segment to which the node belongs. By default, all nodes are placed in the same segment (`0`). Usually, you would place all nodes in the same datacenter in the same segment. Galera protocol traffic is only redirected to one node in each segment, and then relayed to other nodes in that same segment, which saves cross-datacenter network traffic at the expense of some extra latency. State transfers are also, preferably but not exclusively, taken from the same segment. If there are no nodes available in the same segment, state transfer will be taken from a node in another segment.
- **Dynamic:** No
- **Default:** `0`
- **Range:** `0` to `255`

---

gmcast.time_wait

- **Description:** Waiting time before allowing a peer that was declared outside of the stable view to reconnect.
- **Dynamic:** No
- **Default:** `PT5S`

---

gmcast.version

- **Description:** Deprecated option. Gmcast version.
- **Dynamic:** No
- **Default:** `0`

---

ist.recv_addr

- **Description:** Address for listening for Incremental State Transfer.
- **Dynamic:** No
- **Default:** <address>:<port+1> from wsrep_node_address

---

ist.recv_bind

- **Description:**
- **Dynamic:** No
- **Default:** Empty string
- **Introduced:** MariaDB 10.1.17, MariaDB Galera 10.0.27, MariaDB Galera 5.5.51

---

pc.announce_timeout

- **Description:** Period of time for which cluster joining announcements are sent every 1/2 second.
- **Dynamic:** No
- **Default:** `PT3S`

---

pc.checksum

- **Description:** For debug purposes, by default `false` (`true` in earlier releases), indicates whether to checksum replicated messages on PC level. Safe to turn off.
- **Dynamic:** No
- **Default:** `false`

---

pc.ignore_quorum

- **Description:** Whether to ignore quorum calculations, for example when a master splits from several slaves, it will remain in operation if set to `true` (`false is default`). Use with care however, as in master-slave setups, slaves will not automatically reconnect to the master if set.
- **Dynamic:** Yes
- **Default:** `false`

`pc.ignore_sb`

- **Description:** Whether to permit updates to be processed even in the case of split brain (when a node is disconnected from its remaining peers). Safe in master-slave setups, but could lead to data inconsistency in a multi-master setup.
- **Dynamic:** Yes
- **Default:** `false`

`pc.linger`

- **Description:** Time that the PC protocol waits for EVS termination.
- **Dynamic:** No
- **Default:** `PT20S`

`pc.npvo`

- **Description:** If set to `true` (`false` is default), when there are primary component conficts, the most recent component will override the older.
- **Dynamic:** No
- **Default:** `false`

`pc.recovery`

- **Description:** If set to `true` (the default), the Primary Component state is stored on disk and in the case of a full cluster crash (e.g power outages), automatic recovery is then possible. Subsequent graceful full cluster restarts will require explicit bootstrapping for a new Primary Component.
- **Dynamic:** No
- **Default:** `true`

`pc.version`

- **Description:** Deprecated option. PC protocol version.
- **Dynamic:** No
- **Default:** `0`

`pc.wait_prim`

- **Description:** When set to `true` , the default, the node will wait for a primary component for the period of time specified by pc.wait_prim_timeout. Used to bring up non-primary components and make them primary using pc.bootstrap.
- **Dynamic:** No
- **Default:** `true`

`pc.wait_prim_timeout`

- **Description:** Ttime to wait for a primary component. See pc.wait_prim.
- **Dynamic:** No
- **Default:** `PT30S`

`pc.weight`

- **Description:** Node weight, used for quorum calculation. See the Codership article Weighted Quorum.
- **Dynamic:** Yes
- **Default:** `1`

`protonet.backend`

- **Description:** Deprecated option. Transport backend to use. Only ASIO is supported currently.
- **Dynamic:** No
- **Default:** `asio`

`protonet.version`

- **Description:** Deprecated option. Protonet version.
- **Dynamic:** No
- **Default:** `0`

`repl.causal_read_timeout`

- **Description:** Timeout period for causal reads.
- **Dynamic:** Yes
- **Default:** `PT30S`

`repl.commit_order`

- **Description:** Whether or not out-of-order committing is permitted, and under what conditions. By default it is not permitted, but setting this can improve parallel performance.
  - `0` BYPASS: No commit order monitoring is done (useful for measuring the performance penalty).
  - `1` OOOC: Out-of-order committing is permitted for all transactions.
  - `2` LOCAL_OOOC: Out-of-order committing is permitted for local transactions only.
  - `3` NO_OOOC: Out-of-order committing is not permitted at all.
- **Dynamic:** No
- **Default:** `3`

`repl.key_format`

- **Description:** Format for key replication. Can be one of:
  - `FLAT8` - shorter key with a higher probability of false positives when matching
  - `FLAT16` - longer key with a lower probability of false positives when matching
  - `FLAT8A` - shorter key with a higher probability of false positives when matching, includes annotations for debug purposes
  - `FLAT16A` - longer key with a lower probability of false positives when matching, includes annotations for debug purposes
- **Dynamic:** Yes
- **Default:** `FLAT8`

`repl.max_ws_size`

- **Description:**
- **Dynamic:**
- **Default:** `2147483647`

`repl.proto_max`

- **Description:**
- **Dynamic:**
- **Default:** `9`

---

socket.checksum

- **Description:** Method used for generating checksum. Note: If Galera 25.2.x and 25.3.x are both being used in the cluster, MariaDB with Galera 25.3.x must be started with `wsrep_provider_options='socket.checksum=1'` in order to make it backward compatible with Galera v2. Galera wsrep providers other than 25.3.x or 25.2.x are not supported.
- **Dynamic:** No
- **Default:** `2`

---

socket.dynamic

- **Description:** Allow both encrypted and unencrypted connections between nodes. Typically this should be set to `false` (the default), when set to `true` encrypted connections will still be preferred, but will fall back to unencrypted connections when encryption is not possible, e.g. not enabled on all nodes yet. Needs to be `true` on all nodes when wanting to enable or disable encryption via a rolling restart. As this can't be changed at runtime a rolling restart to enable or disable encryption may need three restarts per node in total: one to enable `socket.dynamic` on each node, one to change the actual encryption settings on each node, and a final round to change `socket.dynamic` back to `false`.
- **Dynamic:** No
- **Default:** `false`
- **Introduced:** MariaDB 10.4.19, MariaDB 10.5.10, MariaDB 10.6.0

---

socket.recv_buf_size

- **Description:** Size in bytes of the receive buffer used on the network sockets between nodes, passed on to the kernel via the SO_RCVBUF socket option.
- **Dynamic:** No
- **Default:**
  - >= MariaDB 10.3.23, MariaDB 10.2.32, MariaDB 10.1.45: Auto
  - < MariaDB 10.3.22: MariaDB 10.2.31, MariaDB 10.1.44: `212992`

---

socket.send_buf_size

- **Description:** Size in bytes of the send buffer used on the network sockets between nodes, passed on to the kernel via the SO_SNDBUF socket option.
- **Dynamic:** No
- **Default:**: Auto
- **Introduced:** MariaDB 10.3.23, MariaDB 10.2.32, MariaDB 10.1.45

---

socket.ssl

- **Description:** Explicitly enables TLS usage by the wsrep Provider.
- **Dynamic:** No
- **Default:** `NO`

---

socket.ssl_ca

- **Description:** Path to Certificate Authority (CA) file. Implicitly enables the `socket.ssl` option.
- **Dynamic:** No

---

socket.ssl_cert

- **Description:** Path to TLS certificate. Implicitly enables the `socket.ssl` option.
- **Dynamic:** No

---

socket.ssl_cipher

- **Description:** TLS cipher to use. Implicitly enables the `socket.ssl` option. Since MariaDB 10.2.18 defaults to the

value of the `ssl_cipher` system variable.
- **Dynamic:** No
- **Default:** system default, before MariaDB 10.2.18 defaults to `AES128-SHA`.

`socket.ssl_compression`

- **Description:** Compression to use on TLS connections. Implicitly enables the `socket.ssl` option.
- **Dynamic:** No

`socket.ssl_key`

- **Description:** Path to TLS key file. Implicitly enables the `socket.ssl` option.
- **Dynamic:** No

`socket.ssl_password_file`

- **Description:** Path to password file to use in TLS connections. Implicitly enables the `socket.ssl` option.
- **Dynamic:** No

3.2.16 Galera Cluster Address

URL's in Galera take a particular format:

```
<schema>://<cluster_address>[?option1=value1[&option2=value2]]
```

Contents

Schema

- `gcomm` - This is the option to use for a working implementation.
- `dummy` - Used for running tests and profiling, does not do any actual replication, and all following parameters are ignored.

Cluster address

- The cluster address shouldn't be empty like `gcomm://`. This should never be hardcoded into any configuration files.
- To connect the node to an existing cluster, the cluster address should contain the address of any member of the cluster you want to join.
- The cluster address can also contain a comma-separated list of multiple members of the cluster. It is good practice to list all possible members of the cluster, for example `gcomm:<node1 name or ip>,<node2 name or ip2>,<node3 name or ip>`. Alternately if multicast is use put the multicast address instead of the list of nodes. Each member address or multicast address can specify `<node name or ip>:<port>` if a non-default port is used.

Option list

- The wsrep_provider_options variable is used to set a list of options. These parameters can also be provided (and overridden) as part of the URL. Unlike options provided in a configuration file, they will not endure, and need to be resubmitted with each connection.

A useful option to set is `pc.wait_prim=no` to ensure the server will start running even if it can't determine a primary node. This is useful if all members go down at the same time.

Port

By default, gcomm listens on all interfaces. The port is either provided in the cluster address, or will default to 4567 if not set.

3.2.17 Galera Load Balancer

Galera Load Balancer is a simple Load Balancer specifically designed for Galera Cluster. Like Galera, it only runs on Linux. Galera Load Balancer is developed and mantained by Codership. Documentation is available on fromdual.com.

Galera Load Balancer is inspired by pen, which is a generic TCP load balancer. However, since pen is a generic TCP connections load balancer, the techniques it uses are not well-suited to the particular use case of database servers. Galera Load Balancer is optimized for this type of workload.

Several balancing policies are supported. Each node can be assigned a different weight. Nodes with a higher weight are preferred. Depending on the selected policy, other nodes can even be ignored, until the preferred nodes crash.

A lightweight daemon called glbd receives the connections from clients and it redirects them to nodes. No specific client exists for this demo: a generic TCP client, like nc, can be used to send administrative commands and read the usage statistics.

2.1.3.11 Upgrading Galera Cluster

3.1.25 Using MariaDB Replication with MariaDB Galera Cluster

2.2.1.1.1.5 Securing Communications in Galera Cluster

3.2.21 Installing MariaDB Galera on IBM Cloud

Contents

Get MariaDB Galera on IBM Cloud

You should have an IBM Cloud account, otherwise you can register here. At the end of the tutorial you will have a cluster with MariaDB up and running. IBM Cloud uses Bitnami charts to deploy MariaDB Galera on with helm

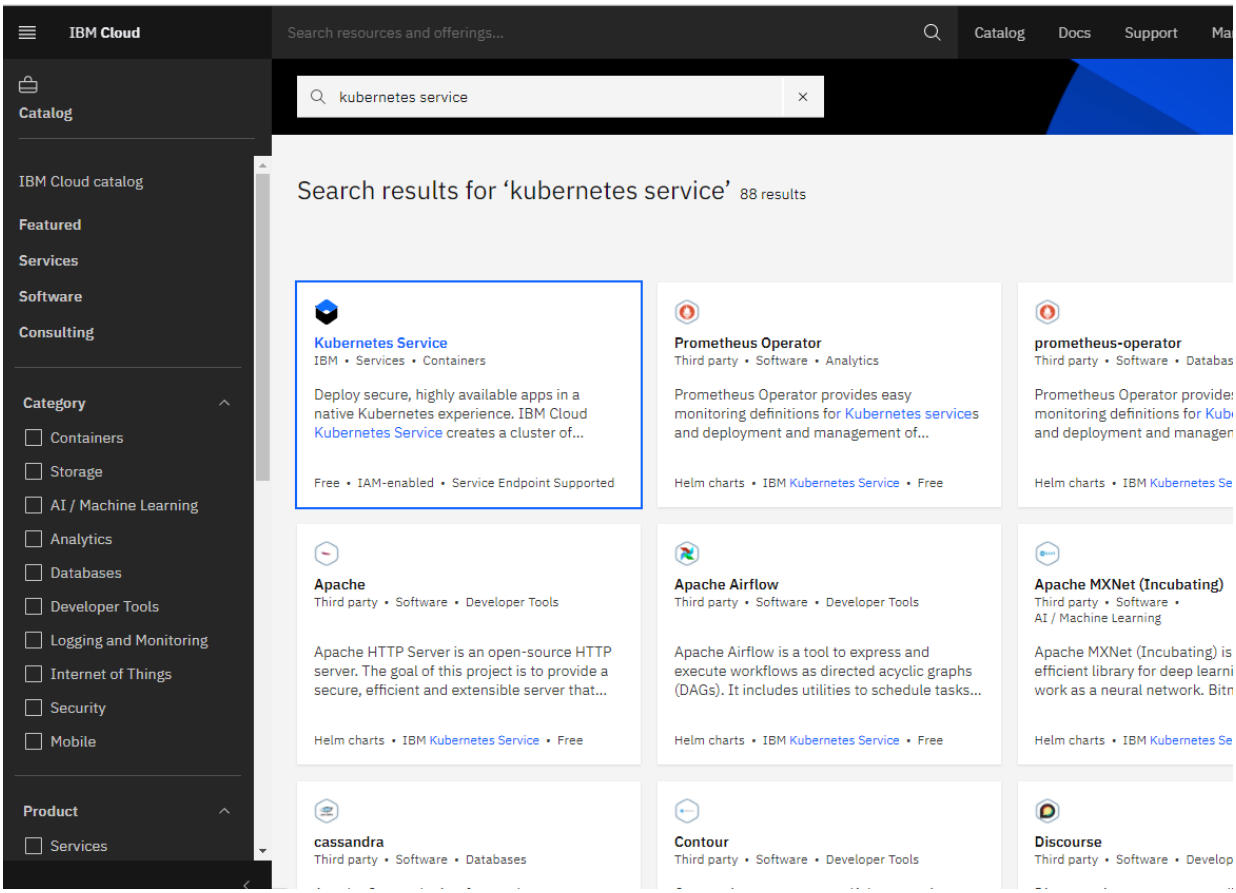
1. We will provision a new Kubernetes Cluster for you if, you already have one skip to step **2**

2. We will deploy the IBM Cloud Block Storage plug-in, if already have it skip to step **3**

3. MariaDB Galera deployment

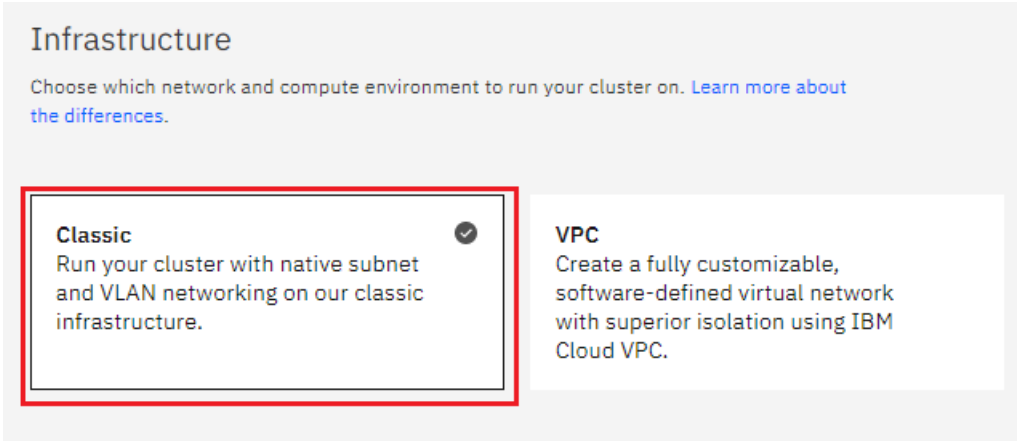
Step 1 provision Kubernetes Cluster

- Click the **Catalog** button on the top
- Select **Service** from the catalog
- Search for **Kubernetes Service** and click on it

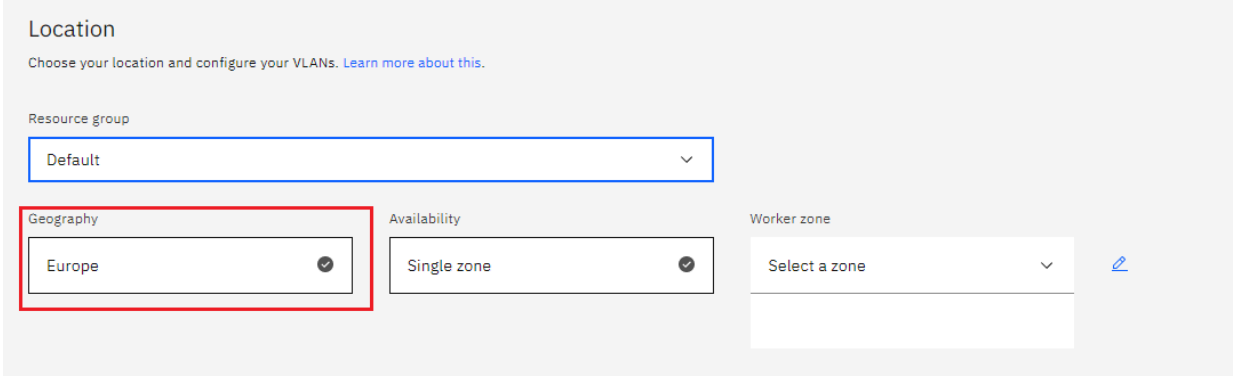


- You are now at the Kubernetes deployment page, you need to specify some details about the cluster
- Choose a plan **standard** or **free**, the free plan only has one worker node and no subnet, to provision a standard cluster, you will need to upgrade you account to Pay-As-You-Go
- To upgrade to a Pay-As-You-Go account, complete the following steps:

- In the console, go to Manage > Account.
- Select Account settings, and click Add credit card.
- Enter your payment information, click Next, and submit your information
- Choose **classic** or **VPC**, read the docs and choose the most suitable type for yourself

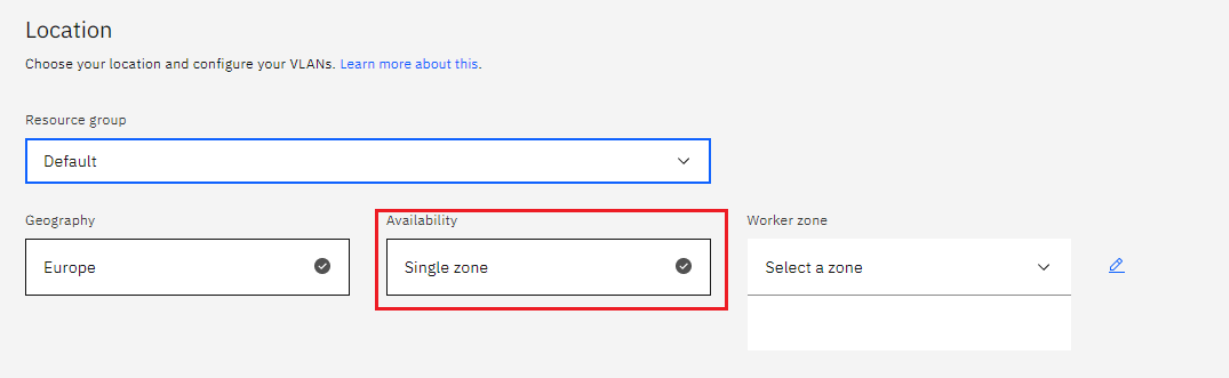


- Now choose your location settings, for more information please visit Locations
- Choose **Geography** (continent)

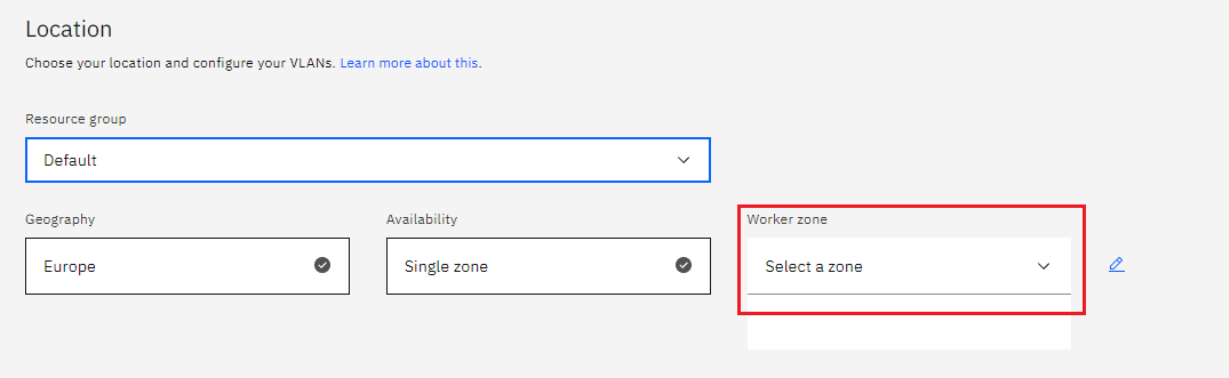


- Choose **Single** or **Multizone**, in single zone your data is only kept in on datacenter, on the other hand with Multizone

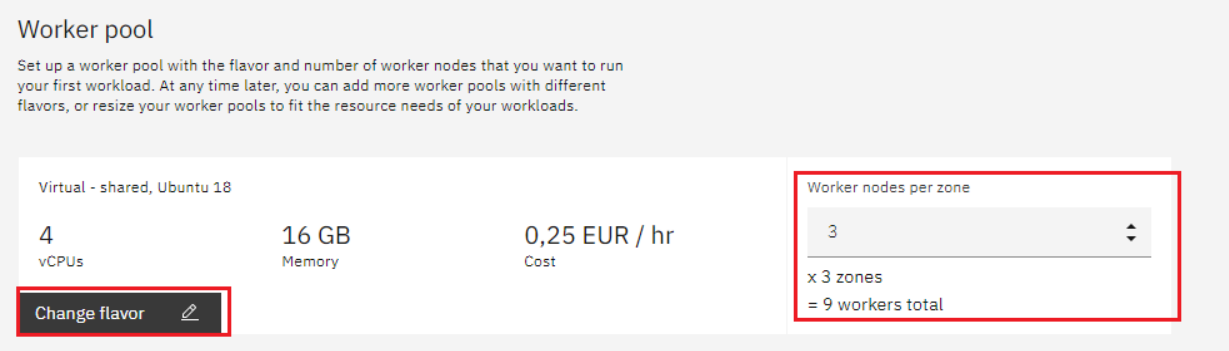
it is distributed to multiple zones, thus safer in an unforseen zone failure



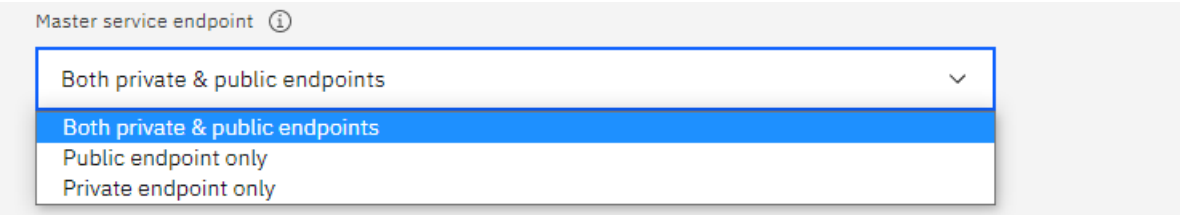
- Choose a **Worker Zone** if using Single zones or **Metro** if Multizone



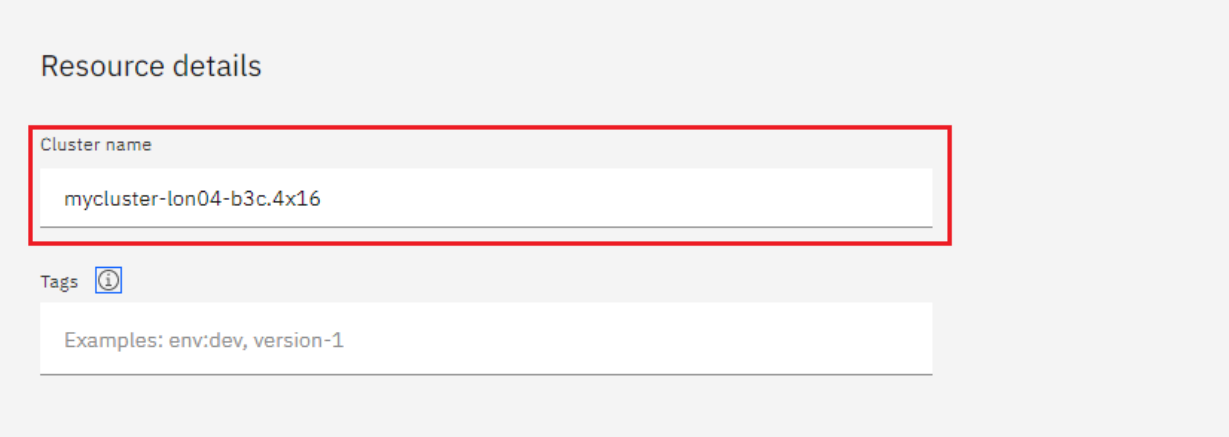
- If you wish to use Multizone please set up your account with VRF or enable Vlan spanning
- If at your current location selection, there is no available Virtual LAN, a new Vlan will be created for you
- Choose a **Worker node setup** or use the preselected one, set **Worker node amount per zone**



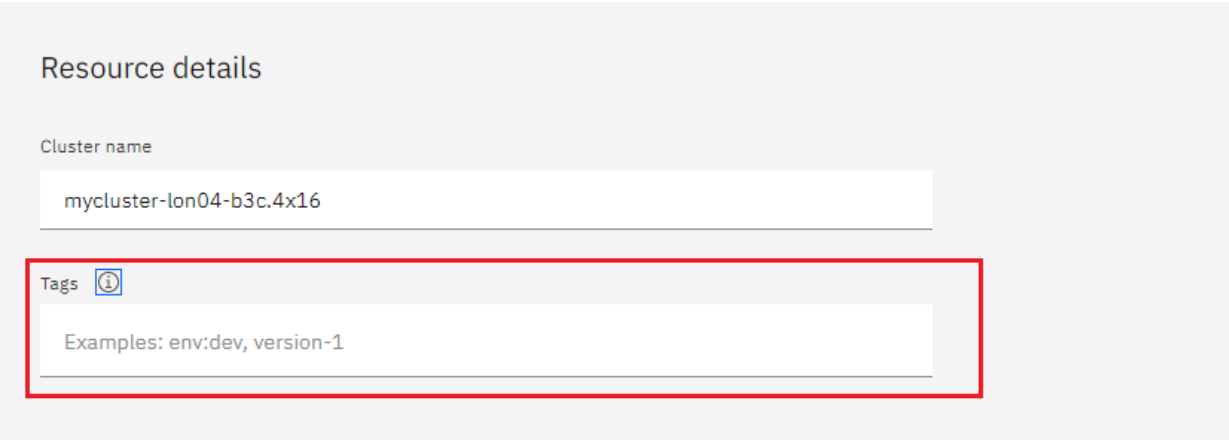
- Choose **Master Service Endpoint**, In VRF-enabled accounts, you can choose private-only to make your master accessible on the private network or via VPN tunnel. Choose public-only to make your master publicly accessible. When you have a VRF-enabled account, your cluster is set up by default to use both private and public endpoints. For more information visit endpoints.



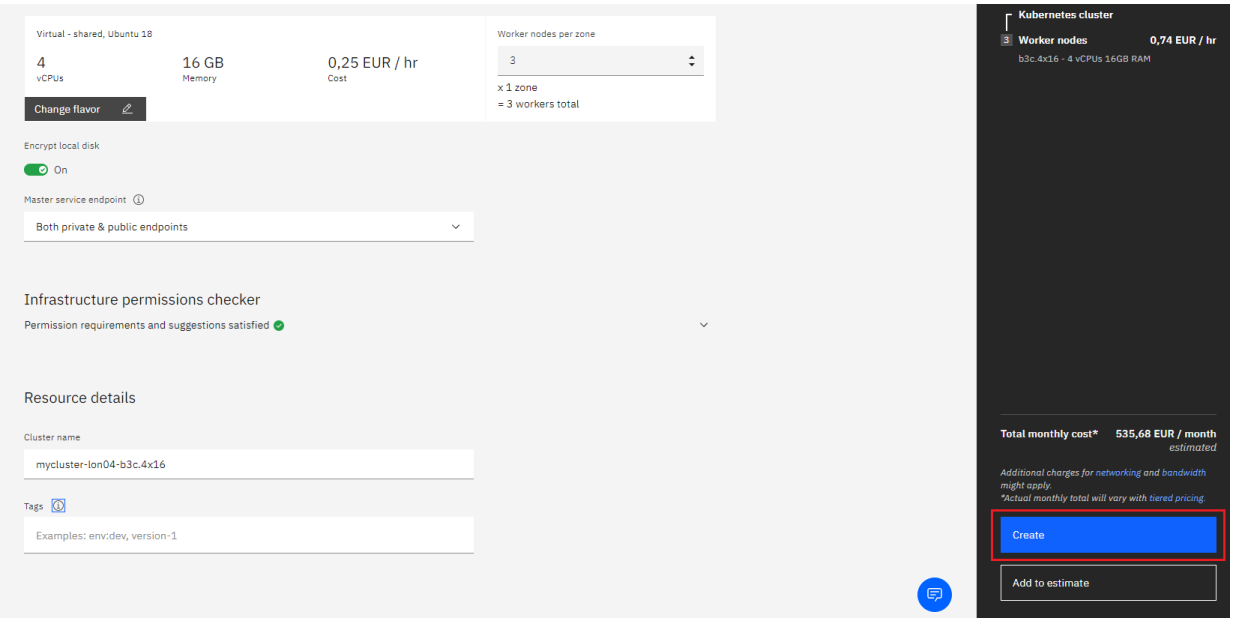
- Give cluster a **name**



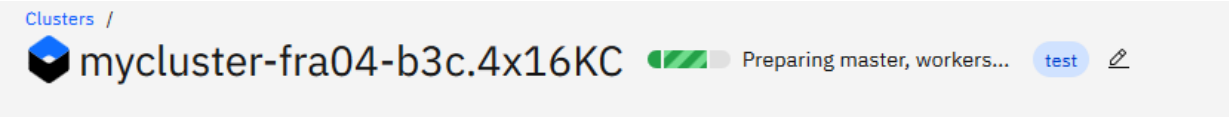
- Give desired **tags** to your cluster, for more information visit tags



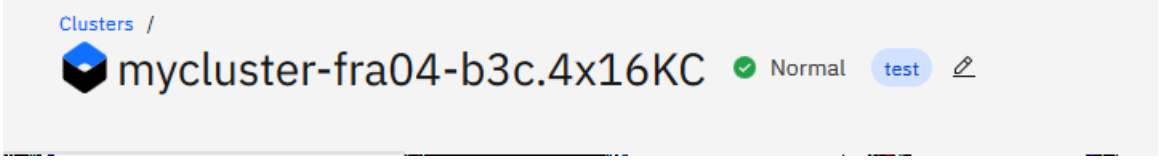
- Click **create**



- Wait for you cluster to be provisioned



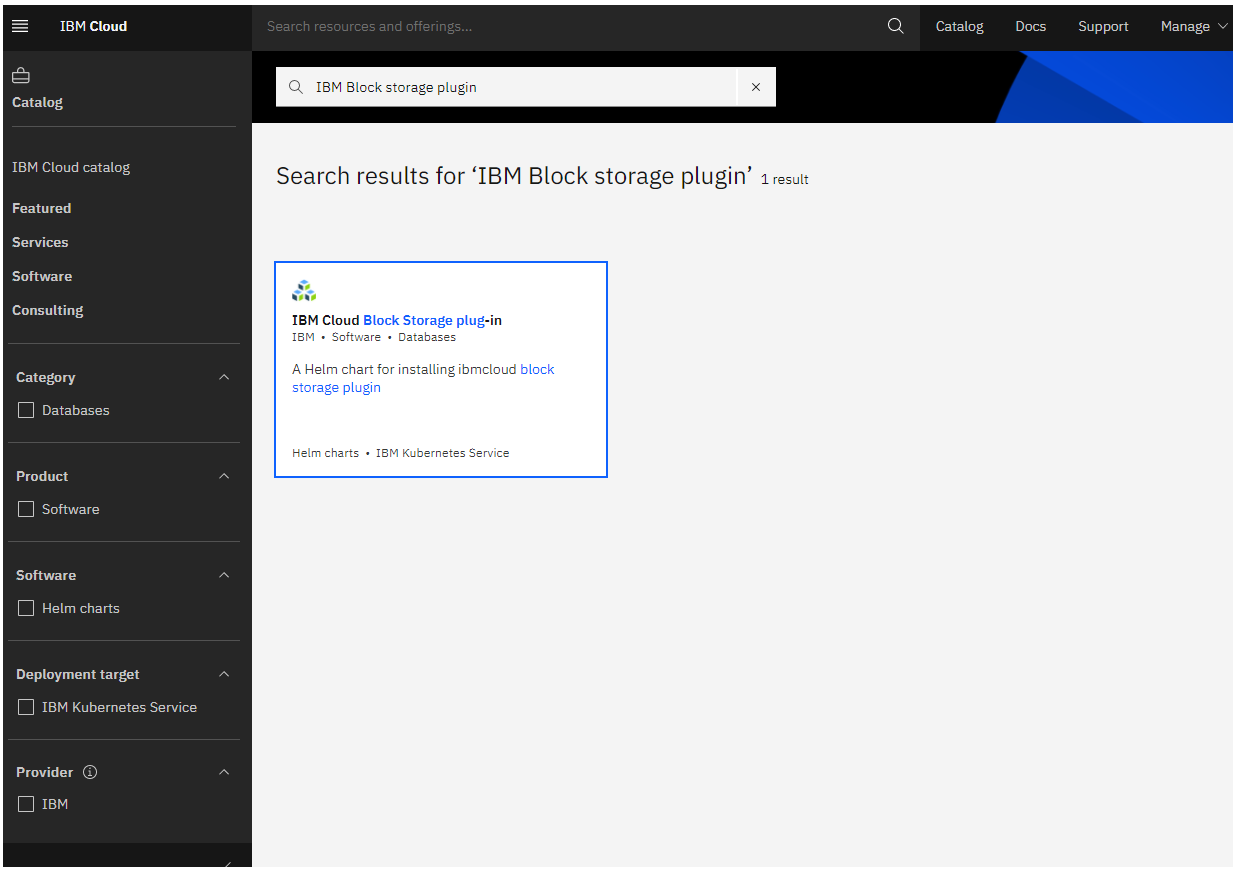
- Your cluster is ready for usage



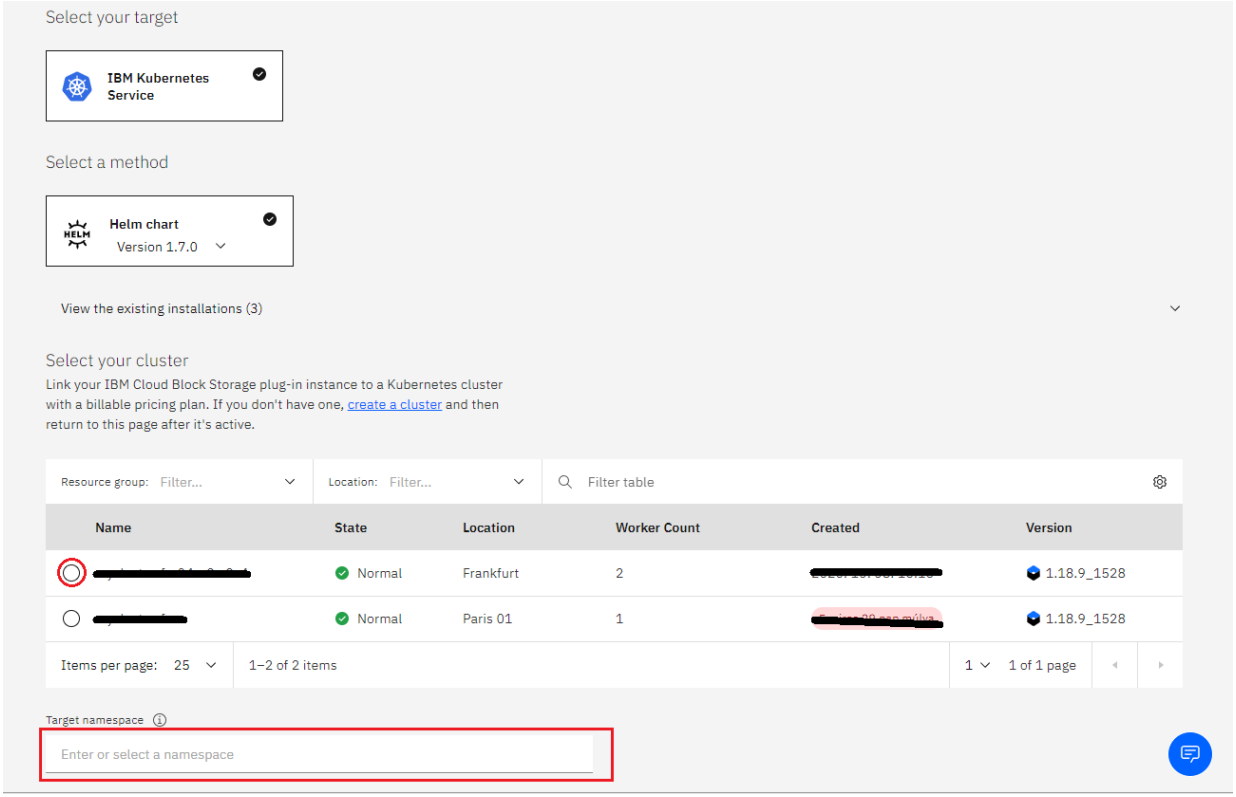
Step 2 deploy IBM Cloud Block Storage plug-in

The Block Storage plug-in is a persistent, high-performance iSCSI storage that you can add to your apps by using Kubernetes Persistent Volumes (PVs).

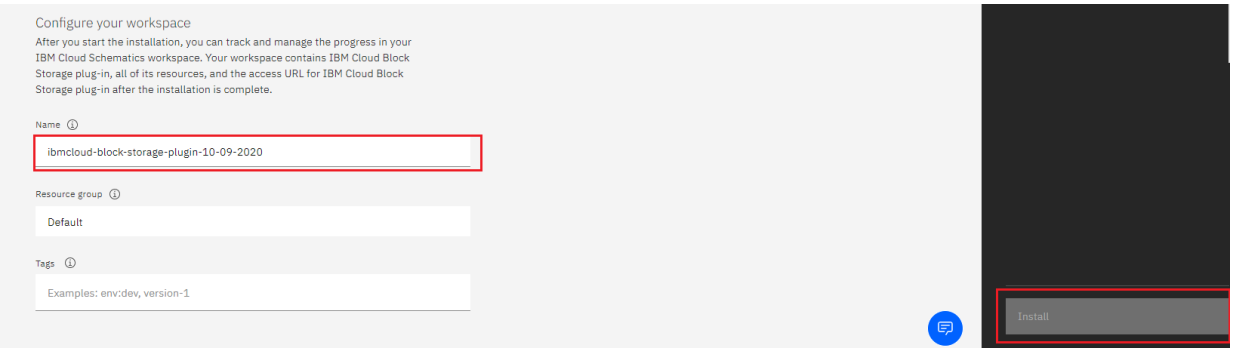
- Click the **Catalog** button on the top
- Select **Software** from the catalog
- Search for **IBM Cloud Block Storage plug-in** and click on it



- On the application page Click in the dot next to the cluster, you wish to use
- Click on **Enter or Select Namespace** and choose the default Namespace or use a custom one (if you get error please wait 30 minutes for the cluster to finalize)



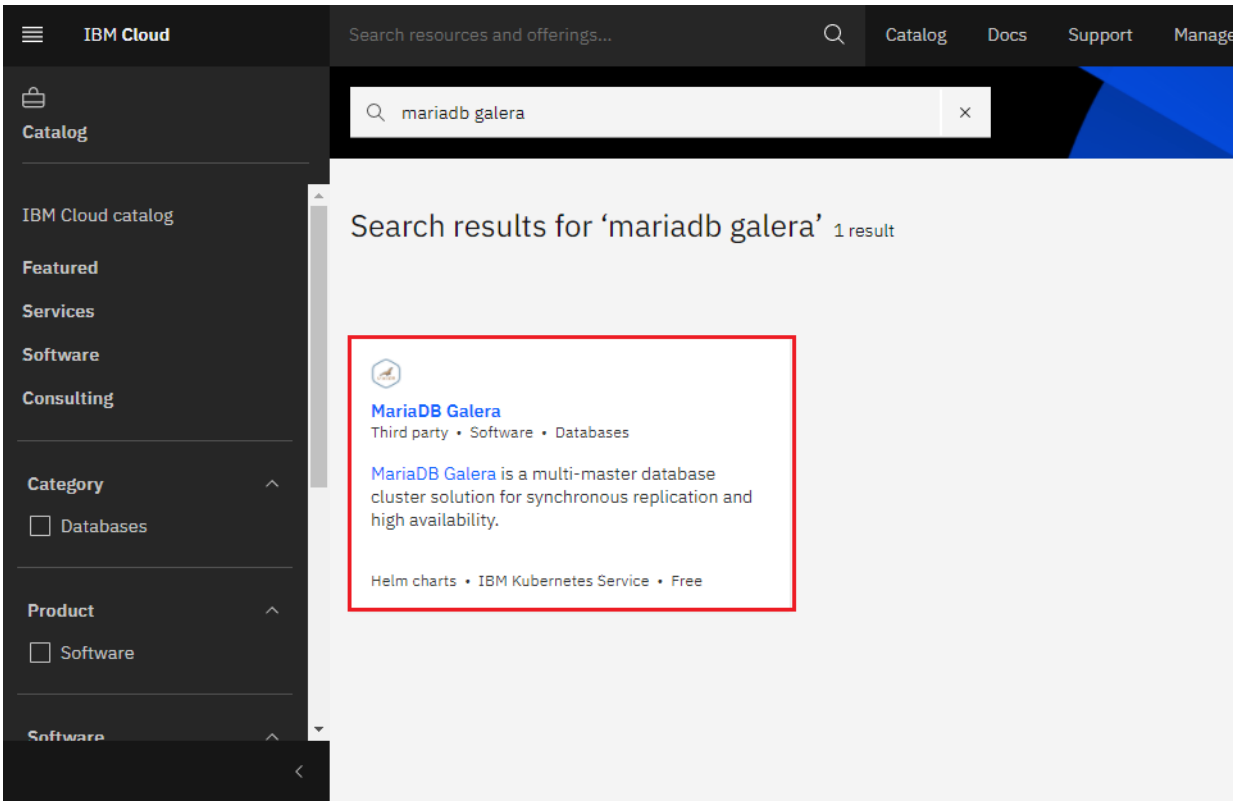
- Give a **name** to this workspace
- Click **install** and wait for the deployment



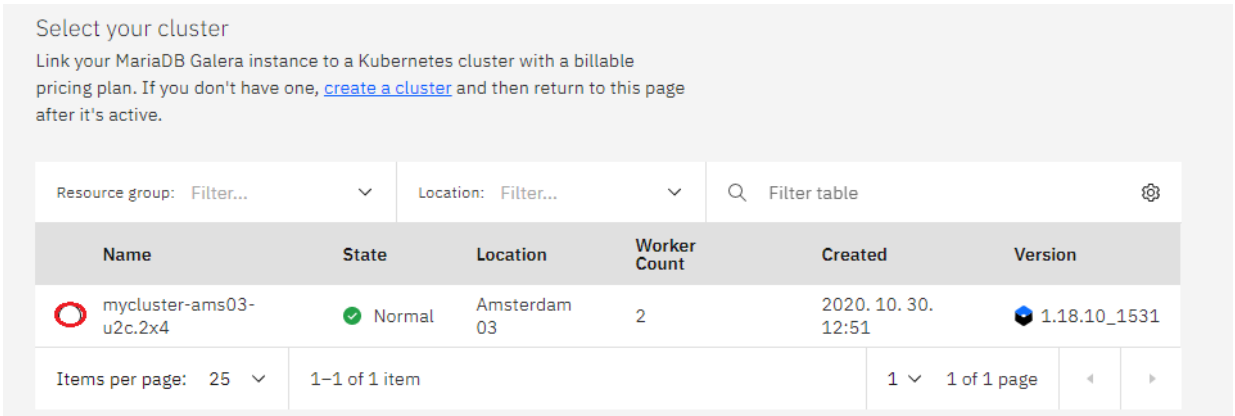
Step 3 deploy MariaDB Galera

We will deploy MariaDB on our cluster

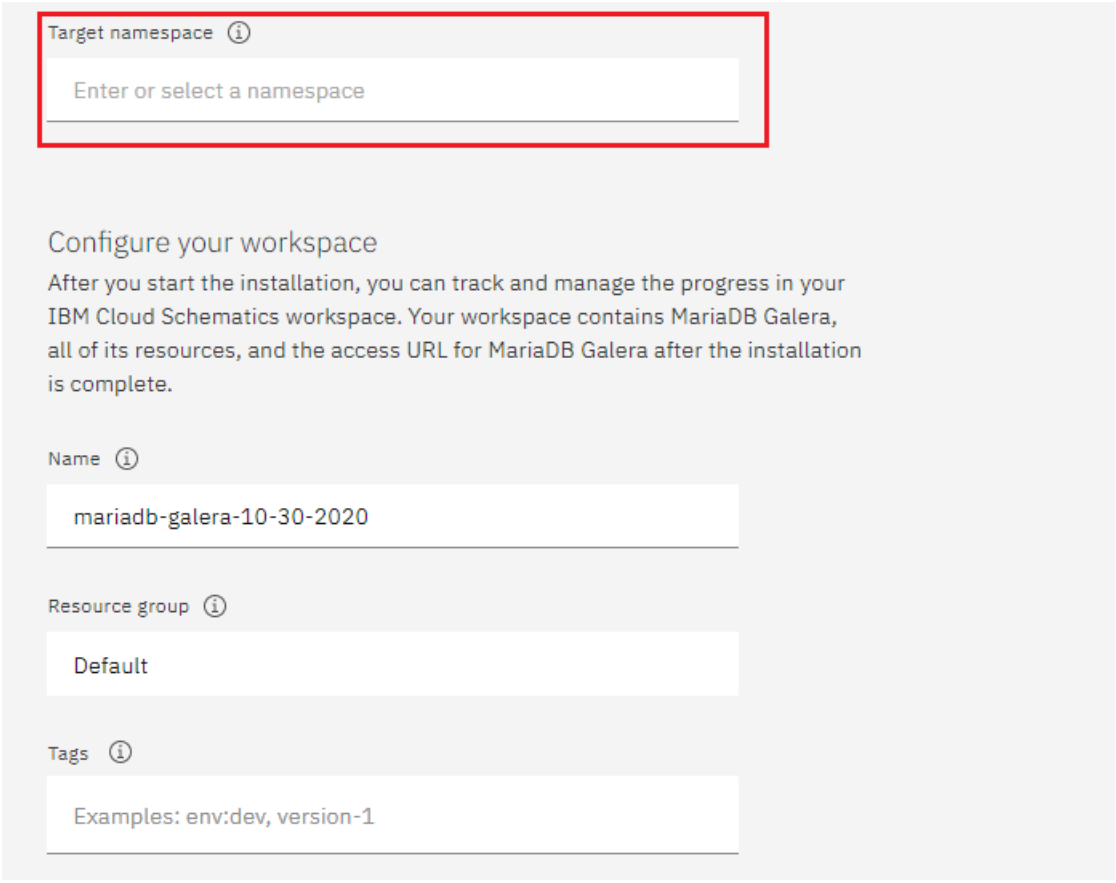
- Click the **Catalog** button on the top
- Select **Software** from the catalog
- Search for **MariaDB** and click on it



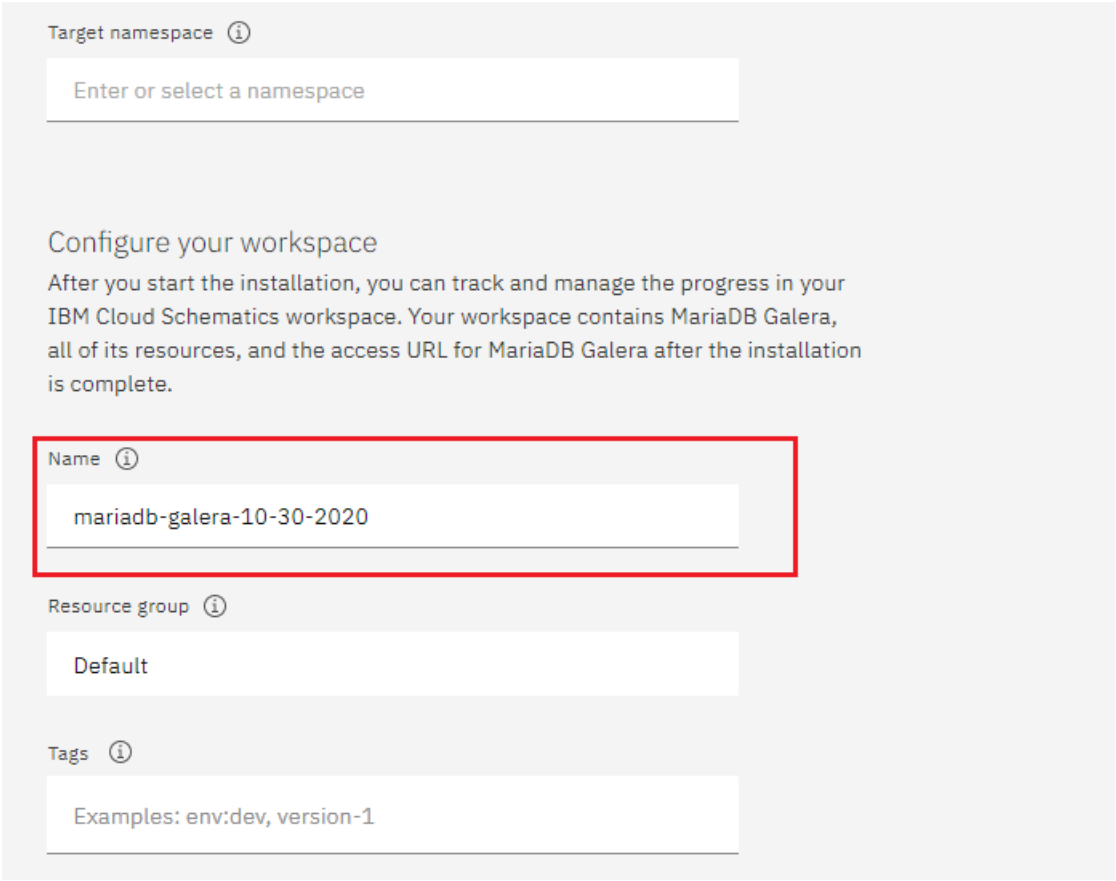
- On the application page Click in the dot next to the cluster, you wish to use



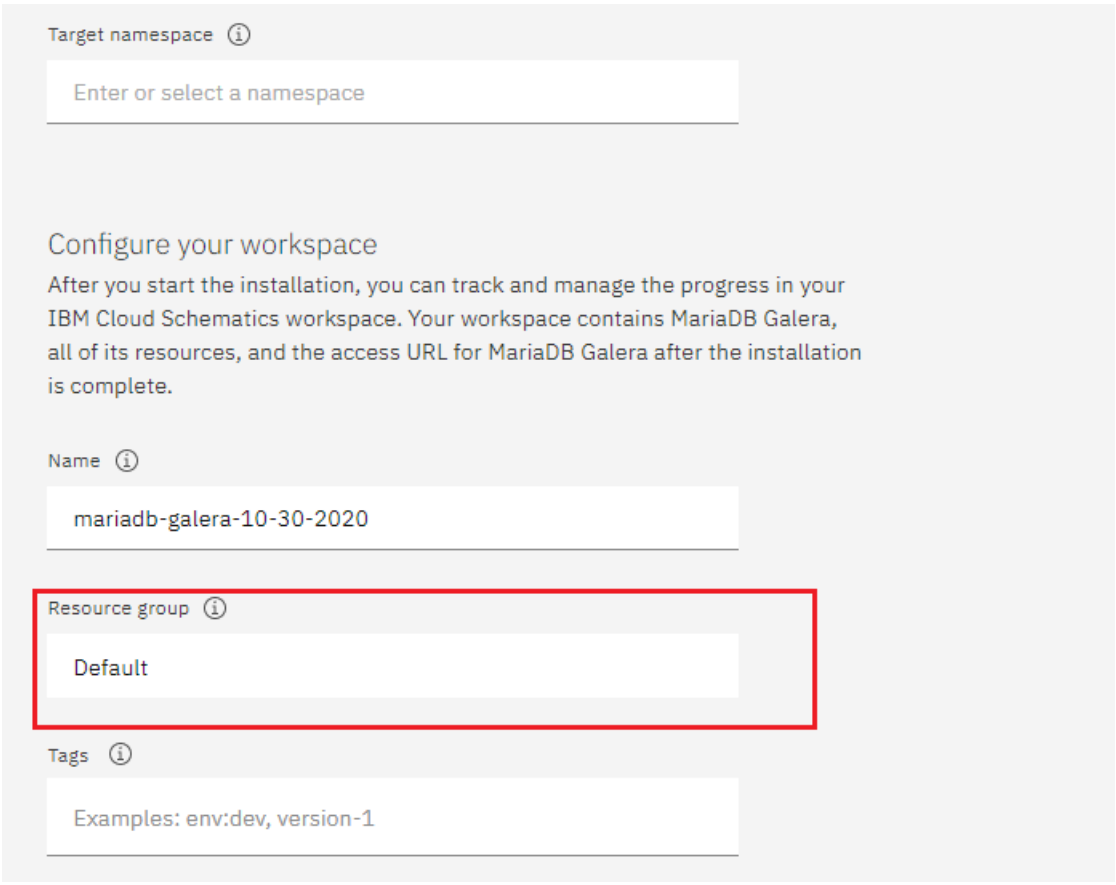
- Click on **Enter or Select Namespace** and choose the default Namespace or use a custom one



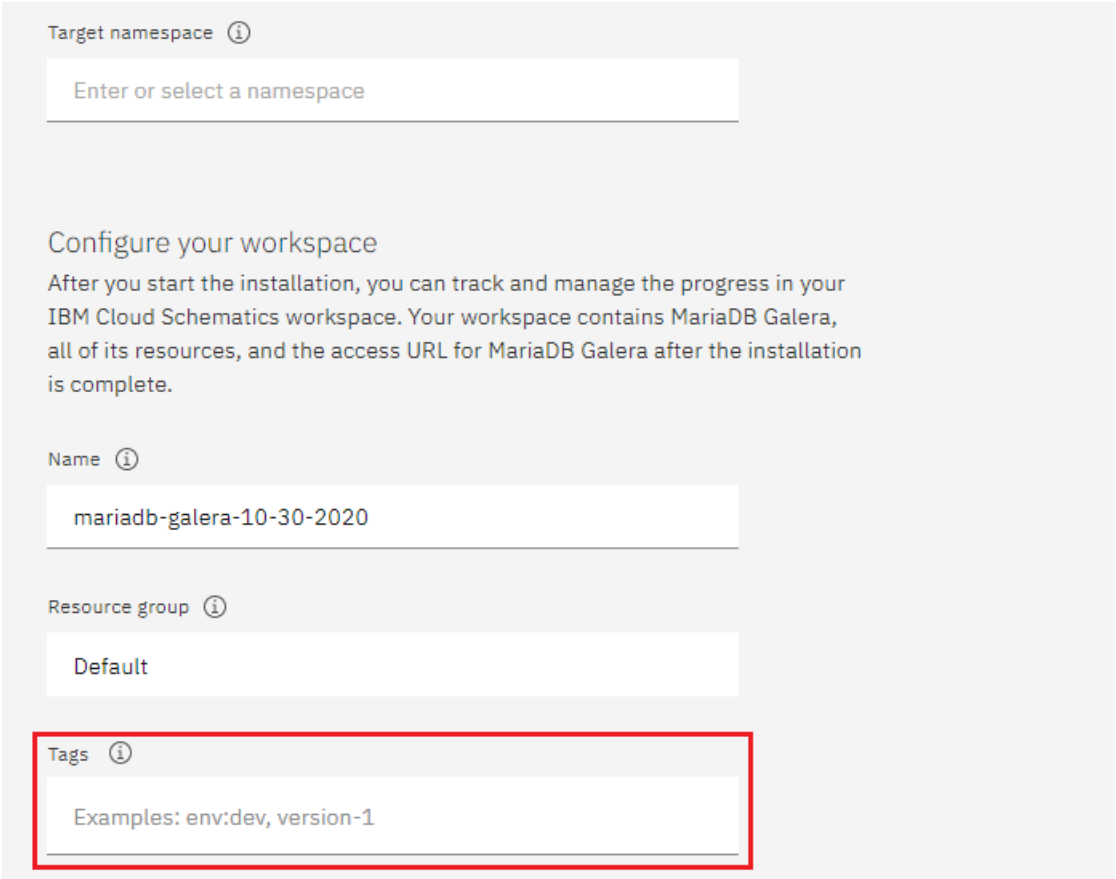
- Give a unique **name** to workspace, which you can easily recognize



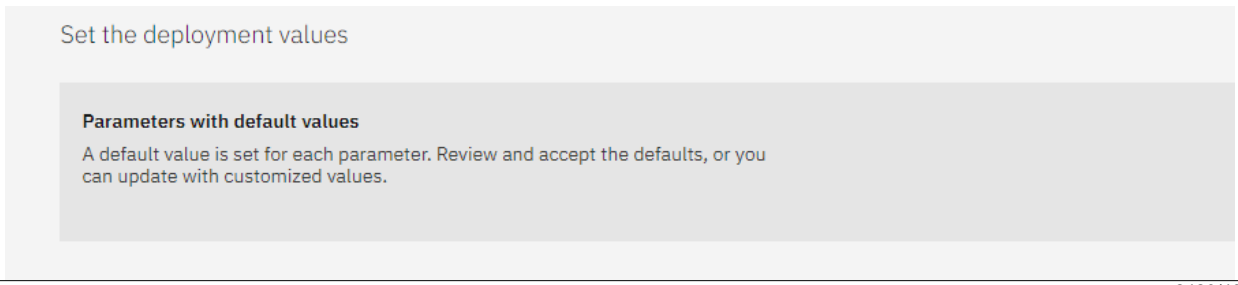
- Select which resource group you want to use, it's for access controll and billing purposes. For more information please visit resource groups



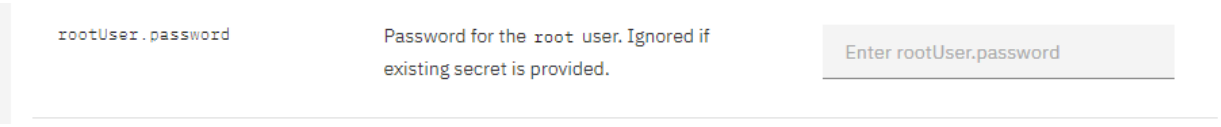
- Give **tags** to your MariaDB Galera, for more information visit tags



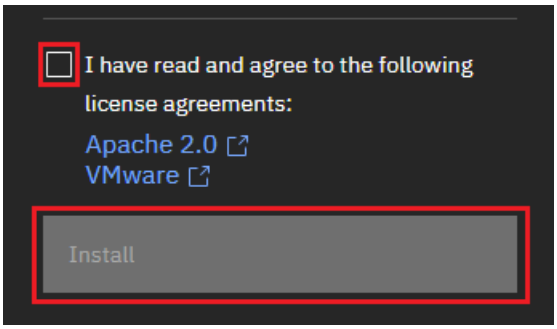
- Click on **Parameters with default values**, You can set deployment values or use the default ones



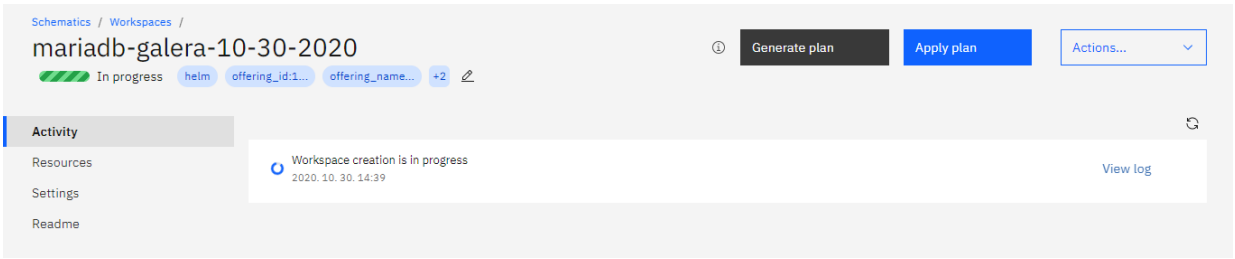
- Please set the MariaDB Galera root password in the parameters



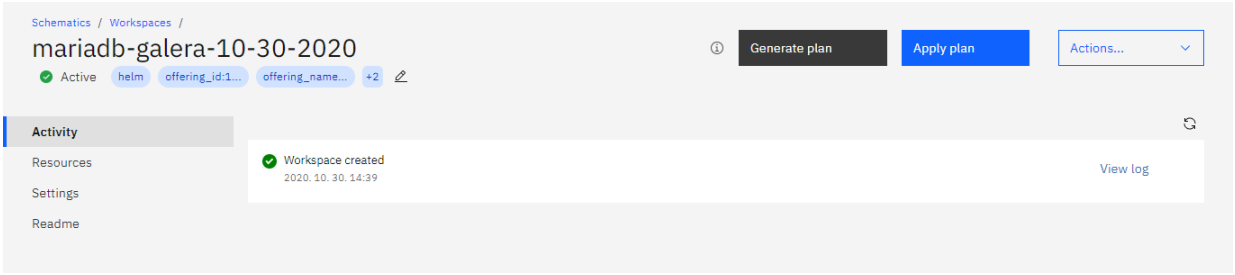
- After finishing everything, **tick** the box next to the agreements and click **install**



- The MariaDB Galera workspace will start installing, wait a couple of minutes

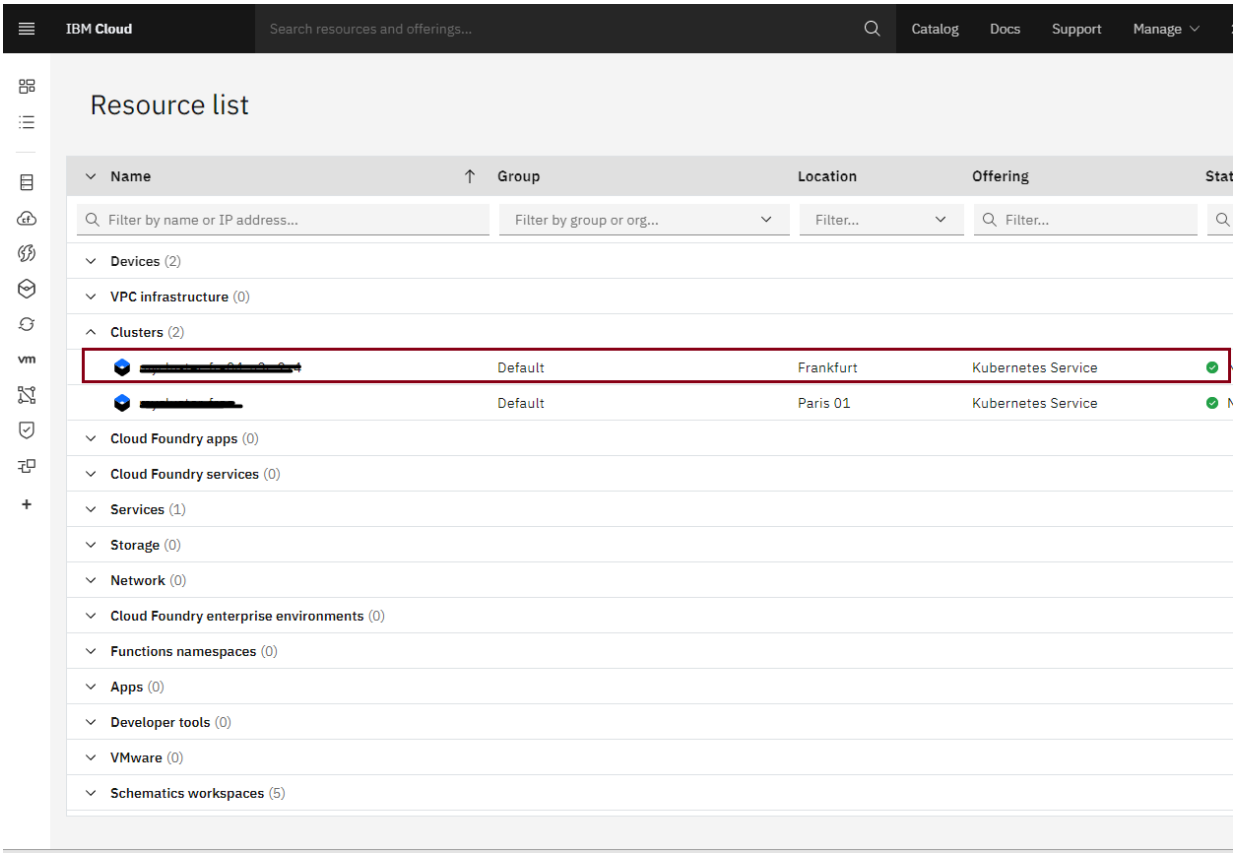


- Your MariaDB Galera workspace has been successfully deployed

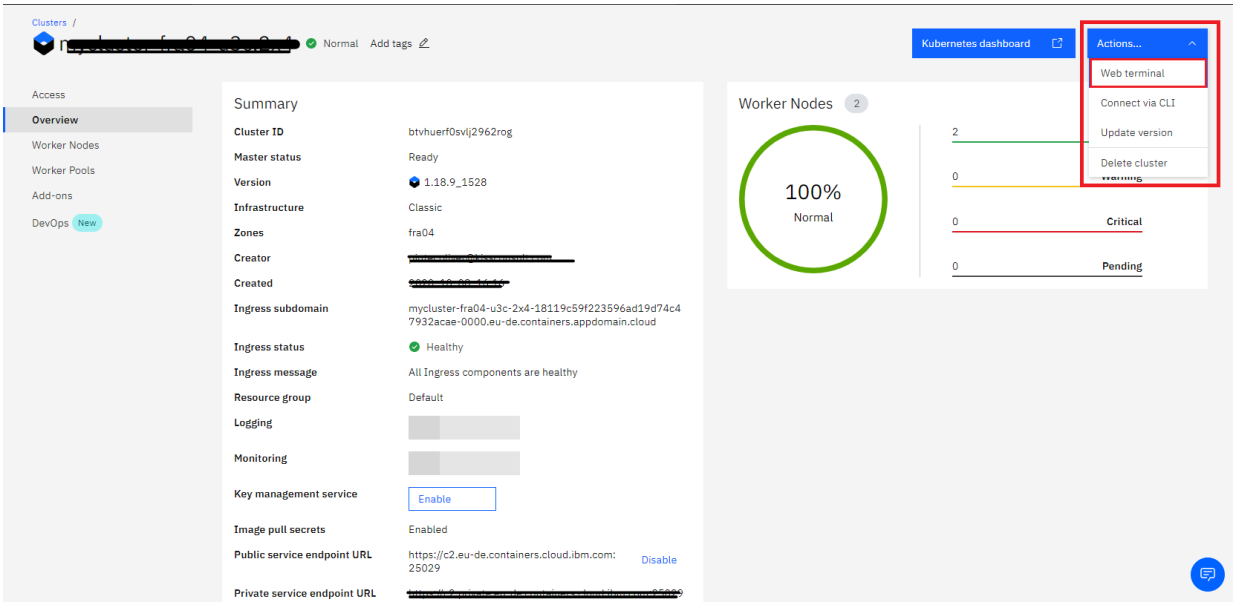


Verify MariaDB Galera installation

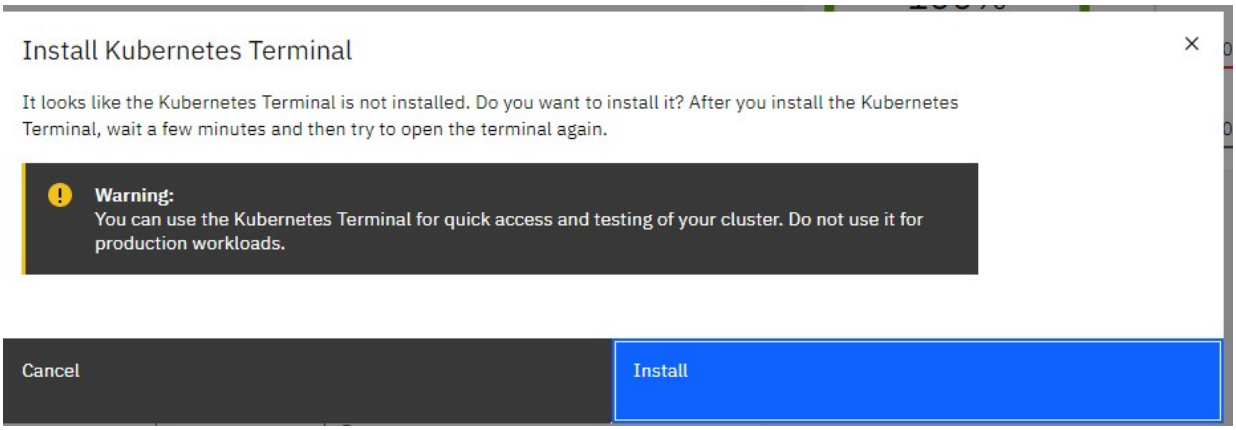
- Go to Resources in your browser
- Click on **Clusters**
- Click on your Cluster



- Now you are at you clusters overview, here Click on **Actions** and **Web terminal** from the dropdown menu



- Click **install** - wait couple of minutes



- Click on **Actions**
- Click **Web terminal** --> a terminal will open up
- **Type** in the terminal, please change NAMESPACE to the namespace you choose at the deployment setup:

```
$ kubectl get ns
```

```
tabatip@k8s-terminal ~ (⎈ mycluster-ams03-u2c.2x4/budvscbf0h42sg93uld0:default)$ kubectl get ns
NAME              STATUS   AGE
default           Active   103m
ibm-cert-store    Active   97m
ibm-operators     Active   98m
ibm-system        Active   102m
kube-node-lease   Active   103m
kube-public       Active   103m
kube-system       Active   103m
mariadb           Active   2m10s
mediawiki         Active   81m
mongodb           Active   67m
storage-plugin    Active   90m
tabatip@k8s-terminal ~ (⎈ mycluster-ams03-u2c.2x4/budvscbf0h42sg93uld0:default)$
```

```
$ kubectl get pod -n NAMESPACE -o wide
```

```
tabatip@k8s-terminal ~ (⎈ mycluster-ams03-u2c.2x4/budvscbf0h42sg93uld0:default)$ kubectl get pods -n mariadb -o wide
NAME                          READY   STATUS    RESTARTS   AGE     IP               NODE             NOMINATED NODE   READINESS GATES
mariadb-galera9a-b9ae-44-0    1/1     Running   0          121m    172.30.108.138   10.136.164.95    <none>           <none>
mariadb-galera9a-b9ae-44-1    1/1     Running   0          118m    172.30.42.205    10.136.164.79    <none>           <none>
mariadb-galera9a-b9ae-44-2    1/1     Running   0          116m    172.30.108.139   10.136.164.95    <none>           <none>
```

```
$ kubectl get service -n NAMESPACE
```

```
tabatip@k8s-terminal ~ (⎈ mycluster-ams03-u2c.2x4/budvscbf0h42sg93uld0:default)$ kubectl get svc -n mariadb
NAME                           TYPE        CLUSTER-IP      EXTERNAL-IP   PORT(S)                      AGE
mariadb-galera9a-b9ae-44       ClusterIP   172.21.86.90    <none>        3306/TCP                     122m
mariadb-galera9a-b9ae-44-headless   ClusterIP   None            <none>        4567/TCP,4568/TCP,4444/TCP   122m
```

- Enter your pod with bash , please replace PODNAME with your mariadb pod's name

```
$ kubectl exec --stdin --tty PODNAME -n NAMESPACE -- /bin/bash
```

```
tabatip@k8s-terminal ~ (⎈ mycluster-ams03-u2c.2x4/budvscbf0h42sg93uld0:default)$ kubectl exec --stdin  --tty mariadb-galera9a-b9ae-44-0 -n mariadb --
/bin/bash
```

- After you are in your pod , please verify that mariadb is running on your pods cluster. Please enter the root password after the prompt

```
mysql -u root -p -e "SHOW STATUS LIKE 'wsrep_cluster_size'"
```

```
I have no name!@mariadb-galera9a-b9ae-44-0:/$ mysql -u root -p -e "SHOW STATUS LIKE 'wsrep_cluster_size'"
Enter password:
+--------------------+-------+
| Variable_name      | Value |
+--------------------+-------+
| wsrep_cluster_size | 3     |
+--------------------+-------+
I have no name!@mariadb-galera9a-b9ae-44-0:/$
```

You have succesfully deployed MariaDB Galera on IBM Cloud!

3.3.1 Hardware Optimization

Better hardware is one of the easiest ways to improve performance.

As a general rule of thumb, hardware should be improved in the following order:

Memory

Memory is the most important factor as it allows you to adjust the Server System Variables. More memory means larger key and table caches can be stored in memory so that disk access, an order of magnitude slower, is reduced.

Simply adding more memory may not result in drastic improvements if the server variables are not set to make use of the extra available memory.

Using more RAM slots on the motherboard increases the bus frequency, and there will be more latency between the RAM and the CPU. So, using the highest RAM size per slot is preferable.

Disks

Fast disk access is critical, as ultimately it's where the data resides. The key figure is the disk seek time, a measurement of how fast the physical disk can move to access the data, so choose disks with as low a seek time as possible.

You can also add dedicated disks for temporary files and transaction logs.

Fast Ethernet

CPU

Although hardware bottlenecks often fall elsewhere, faster processors allow calculations to be performed more quickly, and the results sent back to the client more quickly. Besides processor speed, the processor's bus speed and cache size are also important factors to consider.

3.3.2 Operating System Optimizations

Between the hardware and MariaDB sits the operating system, and there are a number of optimizations that can be made at this level

3.3.2.3 Filesystem Optimizations

Contents

Which filesystem is best?

The filesystem is not the most important aspect of MariaDB performance. Far more important are available RAM, drive speed, the system variable settings (see Hardware Optimization and System Variables).

Optimizing the filesystem can however in some cases make a noticeable difference. Currently, the best Linux filesystems are generally regarded as ext4, XFS and Btrfs. They are all included in the mainline Linux kernel, and are widely supported and available on most Linux distributions. Red Hat though regards Brtfs as a technology preview, not yet ready for production systems.

The following theoretical file size and filesystem size limits apply to the three filesystems:

	ext4	XFS	Brtfs
Max file size	16TB	8EB	16EB
Max filesystem size	1 EB	8EB	16EB

Each has unique characteristics that are worth understanding to get the most from.

Disabling access time

It's unlikely you'll need to record file access time on a database server, and mounting your filesystem with this disabled can give an easy improvement in performance. To do so, use the `noatime` option.

If you want to keep access time for log files or other system files, these can be stored on a separate drive.

3.3.3 Optimization and Indexes

A critical way to improve table performance is by creating indexes on key columns.

The Essentials of an Index

Explains the basics of a table index.

Getting Started with Indexes

Extensive tutorial on creating indexes for tables.

Full-Text Indexes

MariaDB has support for full-text indexing and searching.

6.2.6 The Essentials of an Index

3.3.3.2 Getting Started with Indexes

Contents

For a very basic overview, see The Essentials of an Index.

There are four main kinds of indexes; primary keys (unique and not null), unique indexes (unique and can be null), plain indexes (not necessarily unique) and full-text indexes (for full-text searching).

The terms 'KEY' and 'INDEX' are generally used interchangeably, and statements should work with either keyword.

Primary Key

A primary key is unique and can never be null. It will always identify only one record, and each record must be represented. Each table can only have one primary key.

In InnoDB tables, all indexes contain the primary key as a suffix. Thus, when using this storage engine, keeping the primary key as small as possible is particularly important. If a primary key does not exist and there are no UNIQUE indexes, InnoDB creates a 6-bytes clustered index which is invisible to the user.

Many tables use a numeric ID field as a primary key. The AUTO_INCREMENT attribute can be used to generate a unique identity for new rows, and is commonly-used with primary keys.

Primary keys are usually added when the table is created with the CREATE TABLE statement. For example, the following creates a primary key on the ID field. Note that the ID field had to be defined as NOT NULL, otherwise the index could not have been created.

```
CREATE TABLE `Employees` (
  `ID` TINYINT(3) UNSIGNED NOT NULL AUTO_INCREMENT,
  `First_Name` VARCHAR(25) NOT NULL,
  `Last_Name` VARCHAR(25) NOT NULL,
  `Position` VARCHAR(25) NOT NULL,
  `Home_Address` VARCHAR(50) NOT NULL,
  `Home_Phone` VARCHAR(12) NOT NULL,
  PRIMARY KEY (`ID`)
) ENGINE=Aria;
```

You cannot create a primary key with the CREATE INDEX command. If you do want to add one after the table has already been created, use ALTER TABLE, for example:

```
ALTER TABLE Employees ADD PRIMARY KEY(ID);
```

Finding Tables Without Primary Keys

Tables in the information_schema database can be queried to find tables that do not have primary keys. For example, here is a query using the TABLES and KEY_COLUMN_USAGE tables that can be used:

```
SELECT t.TABLE_SCHEMA, t.TABLE_NAME
FROM information_schema.TABLES AS t
LEFT JOIN information_schema.KEY_COLUMN_USAGE AS c
ON t.TABLE_SCHEMA = c.CONSTRAINT_SCHEMA
   AND t.TABLE_NAME = c.TABLE_NAME
   AND c.CONSTRAINT_NAME = 'PRIMARY'
WHERE t.TABLE_SCHEMA != 'information_schema'
   AND t.TABLE_SCHEMA != 'performance_schema'
   AND t.TABLE_SCHEMA != 'mysql'
   AND c.CONSTRAINT_NAME IS NULL;
```

Unique Index

A Unique Index must be unique, but it can have columns that may be NULL. So each key value identifies only one record, but not each record needs to be represented.

MariaDB starting with 10.5

Unique, if index type is not specified, is normally a BTREE index that can also be used by the optimizer to find rows. If the key is longer than the max key length for the used storage engine and the storage engine supports long unique index, a HASH key will be created. This enables MariaDB to enforce uniqueness for any type or number of columns.

For example, to create a unique key on the Employee_Code field, as well as a primary key, use:

```
CREATE TABLE `Employees` (
  `ID` TINYINT(3) UNSIGNED NOT NULL,
  `First_Name` VARCHAR(25) NOT NULL,
  `Last_Name` VARCHAR(25) NOT NULL,
  `Position` VARCHAR(25) NOT NULL,
  `Home_Address` VARCHAR(50) NOT NULL,
  `Home_Phone` VARCHAR(12) NOT NULL,
  `Employee_Code` VARCHAR(25) NOT NULL,
  PRIMARY KEY (`ID`),
  UNIQUE KEY (`Employee_Code`)
) ENGINE=Aria;
```

Unique keys can also be added after the table is created with the CREATE INDEX command, or with the ALTER TABLE command, for example:

```
ALTER TABLE Employees ADD UNIQUE `EmpCode`(`Employee_Code`);
```

and

```
CREATE UNIQUE INDEX HomePhone ON Employees(Home_Phone);
```

Indexes can contain more than one column. MariaDB is able to use one or more columns on the leftmost part of the index, if it cannot use the whole index. (except for the HASH index type).

Take another example:

```
CREATE TABLE t1 (a INT NOT NULL, b INT, UNIQUE (a,b));

INSERT INTO t1 values (1,1), (2,2);

SELECT * FROM t1;
+---+------+
| a | b    |
+---+------+
| 1 |    1 |
| 2 |    2 |
+---+------+
```

Since the index is defined as unique over both columns *a* and *b*, the following row is valid, as while neither *a* nor *b* are unique on their own, the combination is unique:

```
INSERT INTO t1 values (2,1);

SELECT * FROM t1;
+---+------+
| a | b    |
+---+------+
| 1 |    1 |
| 2 |    1 |
| 2 |    2 |
+---+------+
```

The fact that a `UNIQUE` constraint can be `NULL` is often overlooked. In SQL any `NULL` is never equal to anything, not even to another `NULL`. Consequently, a `UNIQUE` constraint will not prevent one from storing duplicate rows if they contain null values:

```
INSERT INTO t1 values (3,NULL), (3, NULL);

SELECT * FROM t1;
+---+------+
| a | b    |
+---+------+
| 1 |    1 |
| 2 |    1 |
| 2 |    2 |
| 3 | NULL |
| 3 | NULL |
+---+------+
```

Indeed, in SQL two last rows, even if identical, are not equal to each other:

```
SELECT (3, NULL) = (3, NULL);

+----------------------+
| (3, NULL) = (3, NULL) |
+----------------------+
| 0                    |
+----------------------+
```

In MariaDB you can combine this with virtual columns to enforce uniqueness over a subset of rows in a table:

```
create table Table_1 (
  user_name varchar(10),
  status enum('Active', 'On-Hold', 'Deleted'),
  del char(0) as (if(status in ('Active', 'On-Hold'),'', NULL)) persistent,
  unique(user_name,del)
)
```

This table structure ensures that all *active* or *on-hold* users have distinct names, but as soon as a user is *deleted*, his name is no longer part of the uniqueness constraint, and another user may get the same name.

If a unique index consists of a column where trailing pad characters are stripped or ignored, inserts into that column where values differ only by the number of trailing pad characters will result in a duplicate-key error.

MariaDB starting with 10.5

For some engines, like InnoDB, `UNIQUE` can be used with any type of columns or any number of columns.

```
create table t1 (a int primary key,
b blob,
c1 varchar(1000),
c2 varchar(1000),
c3 varchar(1000),
c4 varchar(1000),
c5 varchar(1000),
c6 varchar(1000),
c7 varchar(1000),
c8 varchar(1000),
c9 varchar(1000),
unique key `b` (b),
unique key `all_c` (c1,c2,c3,c4,c6,c7,c8,c9)) engine=myisam;
```

If the key length is longer than the max key length supported by the engine, a HASH key will be created. This can be seen with `SHOW CREATE TABLE table_name` or `SHOW INDEX FROM table_name`:

```
show create table t1\G
*************************** 1. row ***************************
       Table: t1
Create Table: CREATE TABLE `t1` (
  `a` int(11) NOT NULL,
  `b` blob DEFAULT NULL,
  `c1` varchar(1000) DEFAULT NULL,
  `c2` varchar(1000) DEFAULT NULL,
  `c3` varchar(1000) DEFAULT NULL,
  `c4` varchar(1000) DEFAULT NULL,
  `c5` varchar(1000) DEFAULT NULL,
  `c6` varchar(1000) DEFAULT NULL,
  `c7` varchar(1000) DEFAULT NULL,
  `c8` varchar(1000) DEFAULT NULL,
  `c9` varchar(1000) DEFAULT NULL,
  PRIMARY KEY (`a`),
  UNIQUE KEY `b` (`b`) USING HASH,
  UNIQUE KEY `all_c` (`c1`,`c2`,`c3`,`c4`,`c6`,`c7`,`c8`,`c9`) USING HASH
) ENGINE=InnoDB DEFAULT CHARSET=latin1 COLLATE=latin1_swedish_ci
```

Plain Indexes

Indexes do not necessarily need to be unique. For example:

```
CREATE TABLE t2 (a INT NOT NULL, b INT, INDEX (a,b));

INSERT INTO t2 values (1,1), (2,2), (2,2);

SELECT * FROM t2;
+---+------+
| a | b    |
+---+------+
| 1 |    1 |
| 2 |    2 |
| 2 |    2 |
+---+------+
```

Full-Text Indexes

Full-text indexes support full-text indexing and searching. See the Full-Text Indexes section.

Choosing Indexes

In general you should only add indexes to match the queries your application uses. Any extra will waste resources. In an application with very small tables, indexes will not make much difference but as soon as your tables are larger than your buffer sizes the indexes will start to speed things up dramatically.

Using the EXPLAIN statement on your queries can help you decide which columns need indexing.

If you query contains something like `LIKE '%word%'`, without a fulltext index you are using a full table scan every time, which is very slow.

If your table has a large number of reads and writes, consider using delayed writes. This uses the db engine in a "batch" write mode, which cuts down on disk io, therefore increasing performance.

Use the CREATE INDEX command to create an index.

If you are building a large table then for best performance add the index after the table is populated with data. This is to increase the insert performance and remove the index overhead during inserts.

Viewing Indexes

You can view which indexes are present on a table, as well as details about them, with the SHOW INDEX statement.

If you want to know how to re-create an index, run `SHOW CREATE TABLE`.

When to Remove an Index

If an index is rarely used (or not used at all) then remove it to increase INSERT, and UPDATE performance.

If user statistics are enabled, the Information Schema INDEX_STATISTICS table stores the index usage.

If the slow query log is enabled and the `log_queries_not_using_indexes` server system variable is `ON`, the queries which do not use indexes are logged.

The initial version of this article was copied, with permission, from http://hashmysql.org/wiki/Proper_Indexing_Strategy on 2012-10-30.

3.3.3.3 Full-Text Indexes

MariaDB has support for full-text indexing and searching.

Full-Text Index Overview
Full-text indexing and searching overview.

Full-Text Index Stopwords
Default list of full-text stopwords used by MATCH...AGAINST.

MATCH AGAINST
Perform a fulltext search on a fulltext index.

3.3.3.3.1 Full-Text Index Overview

Contents

MariaDB has support for full-text indexing and searching:

- A full-text index in MariaDB is an index of type FULLTEXT, and it allows more options when searching for portions of text from a field.
- Full-text indexes can be used only with MyISAM, Aria, InnoDB and Mroonga tables, and can be created only for CHAR, VARCHAR, or TEXT columns.
- Partitioned tables cannot contain fulltext indexes, even if the storage engine supports them.
- A FULLTEXT index definition can be given in the CREATE TABLE statement when a table is created, or added later using ALTER TABLE or CREATE INDEX.
- For large data sets, it is much faster to load your data into a table that has no FULLTEXT index and then create the index after that, than to load data into a table that has an existing FULLTEXT index.

Full-text searching is performed using MATCH() ... AGAINST syntax. MATCH() takes a comma-separated list that names the columns to be searched. AGAINST takes a string to search for, and an optional modifier that indicates what type of search to perform. The search string must be a literal string, not a variable or a column name.

```
MATCH (col1,col2,...) AGAINST (expr [search_modifier])
```

Excluded Results

- Partial words are excluded.
- Words less than 4 (MyISAM) or 3 (InnoDB) characters in length will not be stored in the fulltext index. This value can be adjusted by changing the ft_min_word_length system variable (or, for InnoDB, innodb_ft_min_token_size).
- Words longer than 84 characters in length will also not be stored in the fulltext index. This values can be adjusted by changing the ft_max_word_length system variable (or, for InnoDB, innodb_ft_max_token_size).
- Stopwords are a list of common words such as "once" or "then" that do not reflect in the search results unless IN BOOLEAN MODE is used. The stopword list for MyISAM/Aria tables and InnoDB tables can differ. See stopwords for details and a full list, as well as for details on how to change the default list.
- For MyISAM/Aria fulltext indexes only, if a word appears in more than half the rows, it is also excluded from the results of a fulltext search.
- For InnoDB indexes, only committed rows appear - modifications from the current transaction do not apply.

Relevance

MariaDB calculates a relevance for each result, based on a number of factors, including the number of words in the index, the number of unique words in a row, the total number of words in both the index and the result, and the weight of the word. In English, 'cool' will be weighted less than 'dandy', at least at present! The relevance can be returned as part of a query simply by using the MATCH function in the field list.

Types of Full-Text search

IN NATURAL LANGUAGE MODE

IN NATURAL LANGUAGE MODE is the default type of full-text search, and the keywords can be omitted. There are no special operators, and searches consist of one or more comma-separated keywords.

Searches are returned in descending order of relevance.

IN BOOLEAN MODE

Boolean search permits the use of a number of special operators:

Operator	Description
+	The word is mandatory in all rows returned.
-	The word cannot appear in any row returned.
<	The word that follows has a lower relevance than other words, although rows containing it will still match
>	The word that follows has a higher relevance than other words.
()	Used to group words into subexpressions.
~	The word following contributes negatively to the relevance of the row (which is different to the '-' operator, which specifically excludes the word, or the '<' operator, which still causes the word to contribute positively to the relevance of the row.
*	The wildcard, indicating zero or more characters. It can only appear at the end of a word.
"	Anything enclosed in the double quotes is taken as a whole (so you can match phrases, for example).

Searches are not returned in order of relevance, and nor does the 50% limit apply. Stopwords and word minimum and maximum lengths still apply as usual.

WITH QUERY EXPANSION

A query expansion search is a modification of a natural language search. The search string is used to perform a regular natural language search. Then, words from the most relevant rows returned by the search are added to the search string and the search is done again. The query returns the rows from the second search. The IN NATURAL LANGUAGE MODE WITH QUERY EXPANSION or WITH QUERY EXPANSION modifier specifies a query expansion search. It can be useful when relying on implied knowledge within the data, for example that MariaDB is a database.

Examples

Creating a table, and performing a basic search:

```
CREATE TABLE ft_myisam(copy TEXT,FULLTEXT(copy)) ENGINE=MyISAM;

INSERT INTO ft_myisam(copy) VALUES ('Once upon a time'),
  ('There was a wicked witch'), ('Who ate everybody up');

SELECT * FROM ft_myisam WHERE MATCH(copy) AGAINST('wicked');
+--------------------------+
| copy                     |
+--------------------------+
| There was a wicked witch |
+--------------------------+
```

Multiple words:

```
SELECT * FROM ft_myisam WHERE MATCH(copy) AGAINST('wicked,witch');
+--------------------------------+
| copy                           |
+--------------------------------+
| There was a wicked witch       |
+--------------------------------+
```

Since 'Once' is a stopword, no result is returned:

```
SELECT * FROM ft_myisam WHERE MATCH(copy) AGAINST('Once');
Empty set (0.00 sec)
```

Inserting the word 'wicked' into more than half the rows excludes it from the results:

```
INSERT INTO ft_myisam(copy) VALUES ('Once upon a wicked time'),
  ('There was a wicked wicked witch'), ('Who ate everybody wicked up');

SELECT * FROM ft_myisam WHERE MATCH(copy) AGAINST('wicked');
Empty set (0.00 sec)
```

Using IN BOOLEAN MODE to overcome the 50% limitation:

```
SELECT * FROM ft_myisam WHERE MATCH(copy) AGAINST('wicked' IN BOOLEAN MODE);
+-------------------------------+
| copy                          |
+-------------------------------+
| There was a wicked witch      |
| Once upon a wicked time       |
| There was a wicked wicked witch |
| Who ate everybody wicked up   |
+-------------------------------+
```

Returning the relevance:

```
SELECT copy,MATCH(copy) AGAINST('witch') AS relevance
  FROM ft_myisam WHERE MATCH(copy) AGAINST('witch');
+-------------------------------+--------------------+
| copy                          | relevance          |
+-------------------------------+--------------------+
| There was a wicked witch      | 0.6775632500648499 |
| There was a wicked wicked witch | 0.5031757950782776 |
+-------------------------------+--------------------+
```

WITH QUERY EXPANSION. In the following example, 'MariaDB' is always associated with the word 'database', so it is returned when query expansion is used, even though not explicitly requested.

```
CREATE TABLE ft2(copy TEXT,FULLTEXT(copy)) ENGINE=MyISAM;

INSERT INTO ft2(copy) VALUES
 ('MySQL vs MariaDB database'),
 ('Oracle vs MariaDB database'),
 ('PostgreSQL vs MariaDB database'),
 ('MariaDB overview'),
 ('Foreign keys'),
 ('Primary keys'),
 ('Indexes'),
 ('Transactions'),
 ('Triggers');

SELECT * FROM ft2 WHERE MATCH(copy) AGAINST('database');
+-------------------------------+
| copy                          |
+-------------------------------+
| MySQL vs MariaDB database     |
| Oracle vs MariaDB database    |
| PostgreSQL vs MariaDB database |
+-------------------------------+
3 rows in set (0.00 sec)

SELECT * FROM ft2 WHERE MATCH(copy) AGAINST('database' WITH QUERY EXPANSION);
+-------------------------------+
| copy                          |
+-------------------------------+
| MySQL vs MariaDB database     |
| Oracle vs MariaDB database    |
| PostgreSQL vs MariaDB database |
| MariaDB overview              |
+-------------------------------+
4 rows in set (0.00 sec)
```

Partial word matching with IN BOOLEAN MODE:

```
SELECT * FROM ft2 WHERE MATCH(copy) AGAINST('Maria*' IN BOOLEAN MODE);
+-------------------------------+
| copy                          |
+-------------------------------+
| MySQL vs MariaDB database     |
| Oracle vs MariaDB database    |
| PostgreSQL vs MariaDB database |
| MariaDB overview              |
+-------------------------------+
```

Using boolean operators

```
SELECT * FROM ft2 WHERE MATCH(copy) AGAINST('+MariaDB -database'
  IN BOOLEAN MODE);
+------------------+
| copy             |
+------------------+
| MariaDB overview |
+------------------+
```

3.3.3.3.2 Full-Text Index Stopwords

Contents

Stopwords are used to provide a list of commonly-used words that can be ignored for the purposes of Full-text-indexes.

Full-text indexes built in MyISAM and InnoDB have different stopword lists by default.

MyISAM Stopwords

For full-text indexes on MyISAM tables, by default, the list is built from the file `storage/myisam/ft_static.c`, and searched using the server's character set and collation. The ft_stopword_file system variable allows the default list to be overridden with words from another file, or for stopwords to be ignored altogether.

If the stopword list is changed, any existing full-text indexes need to be rebuilt

The following table shows the default list of stopwords, although you should always treat `storage/myisam/ft_static.c` as the definitive list. See the Fulltext Index Overview for more details, and Full-text-indexes for related articles.

InnoDB Stopwords

Stopwords on full-text indexes are only enabled if the innodb_ft_enable_stopword system variable is set (by default it is) at the time the index was created.

The stopword list is determined as follows:

- If the innodb_ft_user_stopword_table system variable is set, that table is used as a stopword list.
- If `innodb_ft_user_stopword_table` is not set, the table set by innodb_ft_server_stopword_table is used.
- If neither variable is set, the built-in list is used, which can be viewed by querying the INNODB_FT_DEFAULT_STOPWORD table in the Information Schema.

In the first two cases, the specified table must exist at the time the system variable is set and the full-text index created. It must be an InnoDB table with a single column, a VARCHAR named VALUE.

The default InnoDB stopword list differs from the default MyISAM list, being much shorter, and contains the following words:

a	about	an	are
as	at	be	by
com	de	en	for
from	how	i	in
is	it	la	of

1.1.1.2.1.2 ANALYZE TABLE

3.3.3.5 Building the best INDEX for a given SELECT

Contents

The problem

You have a SELECT and you want to build the best INDEX for it. This blog is a "cookbook" on how to do that task.

- A short algorithm that works for many simpler SELECTs and helps in complex queries.
- Examples of the algorithm, plus digressions into exceptions and variants
- Finally a long list of "other cases".

The hope is that a newbie can quickly get up to speed, and his/her INDEXes will no longer smack of "newbie".

Many edge cases are explained, so even an expert may find something useful here.

Algorithm

Here's the way to approach creating an INDEX, given a SELECT. Follow the steps below, gathering columns to put in the INDEX in order. When the steps give out, you usually have the 'perfect' index.

1. Given a WHERE with a bunch of expressions connected by AND: Include the columns (if any), in any order, that are compared to a constant and not hidden in a function. 2. You get one more chance to add to the INDEX; do the first of these that applies:

- 2a. One column used in a 'range' -- BETWEEN, '>', LIKE w/o leading wildcard, etc.
- 2b. All columns, in order, of the GROUP BY.
- 2c. All columns, in order, of the ORDER BY if there is no mixing of ASC and DESC.

Digression

This blog assumes you know the basic idea behind having an INDEX. Here is a refresher on some of the key points.

Virtually all INDEXes in MySQL are structured as BTrees BTrees allow very efficient for

- Given a key, find the corresponding row(s);
- "Range scans" -- That is start at one value for the key and repeatedly find the "next" (or "previous") row.

A PRIMARY KEY is a UNIQUE KEY; a UNIQUE KEY is an INDEX. ("KEY" == "INDEX".)

InnoDB "clusters" the PRIMARY KEY with the data. Hence, given the value of the PK ("PRIMARY KEY"), after drilling down the BTree to find the index entry, you have all the columns of the row when you get there. A "secondary key" (any UNIQUE or INDEX other than the PK) in InnoDB first drills down the BTree for the secondary index, where it finds a copy of the PK. Then it drills down the PK to find the row.

Every InnoDB table has a PRIMARY KEY. While there is a default if you do not specify one, it is best to explicitly provide a PK.

For completeness: MyISAM works differently. All indexes (including the PK) are in separate BTrees. The leaf node of such BTrees have a pointer (usually a byte offset) into the data file.

All discussion here assumes InnoDB tables, however most statements apply to other Engines.

First, some examples

Think of a list of names, sorted by last_name, then first_name. You have undoubtedly seen such lists, and they often have other information such as address and phone number. Suppose you wanted to look me up. If you remember my full name ('James' and 'Rick'), it is easy to find my entry. If you remembered only my last name ('James') and first initial ('R'). You would quickly zoom in on the Jameses and find the Rs in them. There, you might remember 'Rick' and ignore 'Ronald'. But, suppose you remembered my first name ('Rick') and only my last initial ('J'). Now you are in trouble. You would be scanning all the Js -- Jones, Rick; Johnson, Rick; Jamison, Rick; etc, etc. That's much less efficient.

Those equate to

```
INDEX(last_name, first_name) -- the order of the list.
WHERE last_name = 'James' AND first_name = 'Rick'  -- best case
WHERE last_name = 'James' AND first_name LIKE 'R%' -- pretty good
WHERE last_name LIKE 'J%' AND first_name = 'Rick'  -- pretty bad
```

Think about this example as I talk about "=" versus "range" in the Algorithm, below.

Algorithm, step 1 (WHERE "column = const")

- `WHERE aaa = 123 AND ...` : an INDEX starting with aaa is good.
- `WHERE aaa = 123 AND bbb = 456 AND ...` : an INDEX starting with aaa and bbb is good. In this case, it does not matter whether aaa or bbb comes first in the INDEX.
- `xxx IS NULL` : this acts like "= const" for this discussion.
- `WHERE t1.aa = 123 AND t2.bb = 456` -- You must only consider columns in the current table.

Note that the expression must be of the form of `column_name` = (constant). These do not apply to this step in the Algorithm: DATE(dt) = '...', LOWER(s) = '...', CAST(s ...) = '...', x='...' COLLATE...

(If there are no "=" parts AND'd in the WHERE clause, move on to step 2 without any columns in your putative INDEX.)

Algorithm, step 2

Find the first of 2a / 2b / 2c that applies; use it; then quit. If none apply, then you are through gathering columns for the index.

In some cases it is optimal to do step 1 (all equals) plus step 2c (ORDER BY).

Algorithm, step 2a (one range)

A "range" shows up as

- `aaa >= 123` -- any of <, <=, >=, >; but not <>, !=
- `aaa BETWEEN 22 AND 44`
- `sss LIKE 'blah%'` -- but not `sss LIKE '%blah'`
- `xxx IS NOT NULL` Add the column in the range to your putative INDEX.

If there are more parts to the WHERE clause, you must stop now.

Complete examples (assume nothing else comes after the snippet)

- `WHERE aaa >= 123 AND bbb = 1 ⇒ INDEX(bbb, aaa)` (WHERE order does not matter; INDEX order does)
- `WHERE aaa >= 123 ⇒ INDEX(aaa)`
- `WHERE aaa >= 123 AND ccc > 'xyz' ⇒ INDEX(aaa) or INDEX(ccc)` (only one range)
- `WHERE aaa >= 123 ORDER BY aaa ⇒ INDEX(aaa)` -- Bonus: The ORDER BY will use the INDEX.
- `WHERE aaa >= 123 ORDER BY aaa ⇒ INDEX(aaa) DESC` -- Same Bonus.

Algorithm, step 2b (GROUP BY)

If there is a GROUP BY, all the columns of the GROUP BY should now be added, in the specified order, to the INDEX you are building. (I do not know what happens if one of the columns is already in the INDEX.)

If you are GROUPing BY an expression (including function calls), you cannot use the GROUP BY; stop.

Complete examples (assume nothing else comes after the snippet)

- `WHERE aaa = 123 AND bbb = 1 GROUP BY ccc ⇒ INDEX(bbb, aaa, ccc) or INDEX(aaa, bbb, ccc)` (='s first, in any order; then the GROUP BY)
- `WHERE aaa >= 123 GROUP BY xxx ⇒ INDEX(aaa)` (You should have stopped with Step 2a)
- `GROUP BY x,y ⇒ INDEX(x,y)` (no WHERE)
- `WHERE aaa = 123 GROUP BY xxx, (a+b) ⇒ INDEX(aaa)` -- expression in GROUP BY, so no use including even xxx.

Algorithm, step 2c (ORDER BY)

If there is a ORDER BY, all the columns of the ORDER BY should now be added, in the specified order, to the INDEX you are building.

If there are multiple columns in the ORDER BY, and there is a mixture of ASC and DESC, do not add the ORDER BY columns; they won't help; stop.

If you are ORDERing BY an expression (including function calls), you cannot use the ORDER BY; stop.

Complete examples (assume nothing else comes after the snippet)

- `WHERE aaa = 123 GROUP BY ccc ORDER BY ddd ⇒ INDEX(aaa, ccc)` -- should have stopped with Step 2b
- `WHERE aaa = 123 GROUP BY ccc ORDER BY ccc ⇒ INDEX(aaa, ccc)` -- the ccc will be used for both GROUP BY and ORDER BY
- `WHERE aaa = 123 ORDER BY xxx ASC, yyy DESC ⇒ INDEX(aaa)` -- mixture of ASC and DESC.

The following are especially good. Normally a LIMIT cannot be applied until after lots of rows are gathered and then sorted according to the ORDER BY. But, if the INDEX gets all they way through the ORDER BY, only (OFFSET + LIMIT) rows need to be gathered. So, in these cases, you win the lottery with your new index:

- `WHERE aaa = 123 GROUP BY ccc ORDER BY ccc LIMIT 10 ⇒ INDEX(aaa, ccc)`
- `WHERE aaa = 123 ORDER BY ccc LIMIT 10 ⇒ INDEX(aaa, ccc)`
- `ORDER BY ccc LIMIT 10 ⇒ INDEX(ccc)`
- `WHERE ccc > 432 ORDER BY ccc LIMIT 10 ⇒ INDEX(ccc)` -- This "range" is compatible with ORDER BY

(It does not make much sense to have a LIMIT without an ORDER BY, so I do not discuss that case.)

Algorithm end

You have collected a few columns; put them in INDEX and ADD that to the table. That will often produce a "good" index for the SELECT you have. Below are some other suggestions that may be relevant.

An example of the Algorithm being 'wrong':

```
    SELECT ... FROM t WHERE flag = true;
```

This would (according to the Algorithm) call for INDEX(flag). However, indexing a column that has two (or a small number of) values is almost always useless. This is called 'low cardinality'. The Optimizer would prefer to do a table scan than to bounce between the index BTree and the data.

On the other hand, the Algorithm is 'right' with

```
    SELECT ... FROM t WHERE flag = true AND date >= '2015-01-01';
```

That would call for a compound index starting with a flag: INDEX(flag, date). Such an index is likely to be very beneficial. And it is likely to be more beneficial than INDEX(date).

If your resulting INDEX include column(s) that are likely to be UPDATEd, note that the UPDATE will have extra work to remove a 'row' from one place in the INDEX's BTree and insert a 'row' back into the BTree. For example:

```
INDEX(x)
UPDATE t SET x = ... WHERE ...;
```

There are too many variables to say whether it is better to keep the index or to toss it.

In this case, shortening the index may may be beneficial:

```
INDEX(z, x)
UPDATE t SET x = ... WHERE ...;
```

Changing to INDEX(z) would make for less work for the UPDATE, but might hurt some SELECT. It depends on the frequency of each, plus many more factors.

Limitations

(There are exceptions to some of these.)

- You may not create an index bigger than 3KB.
- You may not include a column that equates to bigger than some value (767 bytes -- VARCHAR(255) CHARACTER SET utf8).
- You can deal with big fields using "prefix" indexing; but see below.
- You should not have more than 5 columns in an index. (This is just a Rule of Thumb; nothing prevents having more.)
- You should not have redundant indexes. (See below.)

Flags and low cardinality

`INDEX(flag)` is almost never useful if `flag` has very few values. More specifically, when you say WHERE flag = 1 and "1" occurs more than 20% of the time, such an index will be shunned. The Optimizer would prefer to scan the table instead of bouncing back and forth between the index and the data for more than 20% of the rows.

("20%" is really somewhere between 10% and 30%, depending on the phase of the moon.)

"Covering" indexes

A "Covering" index is an index that contains all the columns in the SELECT. It is special in that the SELECT can be completed by looking only at the INDEX BTree. (Since InnoDB's PRIMARY KEY is clustered with the data, "covering" is of no benefit when considering at the PRIMARY KEY.)

Mini-cookbook: 1. Gather the list of column(s) according to the "Algorithm", above. 2. Add to the end of the list the rest of the columns seen in the SELECT, in any order.

Examples:

- `SELECT x FROM t WHERE y = 5;` ⇒ `INDEX(y,x)` -- The algorithm said just INDEX(y)
- `SELECT x,z FROM t WHERE y = 5 AND q = 7;` ⇒ `INDEX(y,q,x,z)` -- y and q in either order (Algorithm), then x and z in either order (covering).
- `SELECT x FROM t WHERE y > 5 AND q > 7;` ⇒ `INDEX(y,q,x)` -- y or q first (that's as far as the Algorithm goes), then the other two fields afterwards.

The speedup you get might be minor, or it might be spectacular; it is hard to predict.

But...

- It is not wise to build an index with lots of columns. Let's cut it off at 5 (Rule of Thumb).
- Prefix indexes cannot 'cover', so don't use them anywhere in a 'covering' index.
- There are limits (3KB?) on how 'wide' an index can be, so "covering" may not be possible.

Redundant/excessive indexes

INDEX(a,b) can find anything that INDEX(a) could find. So you don't need both. Get rid of the shorter one.

If you have lots of SELECTs and they generate lots of INDEXes, this may cause a different problem. Each index must be updated (sooner or later) for each INSERT. More indexes ⇒ slower INSERTs. Limit the number of indexes on a table to about 6 (Rule of Thumb).

Notice in the cookbook how it says "in any order" in a few places. If, for example, you have both of these (in different SELECTs):

- `WHERE a=1 AND b=2` begs for either INDEX(a,b) or INDEX(b,a)
- `WHERE a>1 AND b=2` begs only for INDEX(b,a) Include only INDEX(b,a) since it handles both cases with only one INDEX.

Suppose you have a lot of indexes, including (a,b,c,dd) and (a,b,c,ee). Those are getting rather long. Consider either picking one of them, or having simply (a,b,c). Sometimes the selectivity of (a,b,c) is so good that tacking on 'dd' or 'ee' does make enough difference to matter.

Optimizer picks ORDER BY

The main cookbook skips over an important optimization that is sometimes used. The optimizer will sometimes ignore the WHERE and, instead, use an INDEX that matches the ORDER BY. This, of course, needs to be a perfect match -- all columns, in the same order. And all ASC or all DESC.

This becomes especially beneficial if there is a LIMIT.

But there is a problem. There could be two situations, and the Optimizer is sometimes not smart enough to see which case applies:

- If the WHERE does very little filtering, fetching the rows in ORDER BY order avoids a sort and has little wasted effort (because of 'little filtering'). Using the INDEX matching the ORDER BY is better in this case.
- If the WHERE does a lot of filtering, the ORDER BY is wasting a lot of time fetching rows only to filter them out. Using an INDEX matching the WHERE clause is better.

What should you do? If you think the "little filtering" is likely, then create an index with the ORDER BY columns in order and hope that the Optimizer uses it when it should.

OR

Cases...

- `WHERE a=1 OR a=2` -- This is turned into WHERE a IN (1,2) and optimized that way.
- `WHERE a=1 OR b=2` usually cannot be optimized.
- `WHERE x.a=1 OR y.b=2` This is even worse because of using two different tables.

A workaround is to use UNION. Each part of the UNION is optimized separately. For the second case:

```
( SELECT ... WHERE a=1 )   -- and have INDEX(a)
UNION DISTINCT -- "DISTINCT" is assuming you need to get rid of dups
( SELECT ... WHERE b=2 )   -- and have INDEX(b)
GROUP BY ... ORDER BY ...  -- whatever you had at the end of the original query
```

Now the query can take good advantage of two different indexes. Note: "Index merge" might kick in on the original query, but it is not necessarily any faster than the UNION. Sister blog on compound indexes, including 'Index Merge'

The third case (OR across 2 tables) is similar to the second.

If you originally had a LIMIT, UNION gets complicated. If you started with ORDER BY z LIMIT 190, 10, then the UNION needs to be

```
( SELECT ... LIMIT 200 )   -- Note: OFFSET 0, LIMIT 190+10
UNION DISTINCT -- (or ALL)
( SELECT ... LIMIT 200 )
LIMIT 190, 10              -- Same as originally
```

TEXT / BLOB

You cannot directly index a TEXT or BLOB or large VARCHAR or large BINARY column. However, you can use a "prefix" index: INDEX(foo(20)). This says to index the first 20 characters of `foo`. But... It is rarely useful.

Example of a prefix index:

```
    INDEX(last_name(2), first_name)
```

The index for me would contain 'Ja', 'Rick'. That's not useful for distinguishing between 'Jamison', 'Jackson', 'James', etc., so the index is so close to useless that the optimizer often ignores it.

Probably never do UNIQUE(foo(20)) because this applies a uniqueness constraint on the first 20 characters of the column, not the whole column!

More on prefix indexing

Dates

DATE, DATETIME, etc. are tricky to compare against.

Some tempting, but inefficient, techniques:

`date_col LIKE '2016-01%'` -- must convert date_col to a string, so acts like a function `LEFT(date_col, 4) = '2016-01'` -- hiding the column in function `DATE(date_col) = 2016` -- hiding the column in function

All must do a full scan. (On the other hand, it can handy to use GROUP BY LEFT(date_col, 7) for monthly grouping, but that is not an INDEX issue.)

This is efficient, and can use an index:

```
        date_col >= '2016-01-01'
    AND date_col  < '2016-01-01' + INTERVAL 3 MONTH
```

This case works because both right-hand values are converted to constants, then it is a "range". I like the design pattern with INTERVAL because it avoids computing the last day of the month. And it avoids tacking on '23:59:59', which is wrong if you have microsecond times. (And other cases.)

EXPLAIN Key_len

Perform EXPLAIN SELECT... (and EXPLAIN FORMAT=JSON SELECT... if you have 5.6.5). Look at the Key that it chose, and the Key_len. From those you can deduce how many columns of the index are being used for filtering. (JSON makes it easier to get the answer.) From that you can decide whether it is using as much of the INDEX as you thought. Caveat: Key_len only covers the WHERE part of the action; the non-JSON output won't easily say whether GROUP BY or ORDER BY was handled by the index.

IN

`IN (1,99,3)` is sometimes optimized as efficiently as "=", but not always. Older versions of MySQL did not optimize it as well as newer versions. (5.6 is possibly the main turning point.)

IN (SELECT ...)

From version 4.1 through 5.5, IN (SELECT ...) was very poorly optimized. The SELECT was effectively re-evaluated every time. Often it can be transformed into a JOIN, which works much faster. Heres is a pattern to follow:

```
SELECT  ...
    FROM  a
    WHERE  test_a
      AND  x IN (
        SELECT  x
            FROM  b
            WHERE  test_b
                );
⇒
SELECT  ...
    FROM  a
    JOIN  b USING(x)
    WHERE  test_a
      AND  test_b;
```

The SELECT expressions will need "a." prefixing the column names.

Alas, there are cases where the pattern is hard to follow.

5.6 does some optimizing, but probably not as good as the JOIN.

If there is a JOIN or GROUP BY or ORDER BY LIMIT in the subquery, that complicates the JOIN in new format. So, it might be better to use this pattern:

```
SELECT  ...
    FROM  a
    WHERE  test_a
      AND  x IN ( SELECT  x  FROM ... );
⇒
SELECT  ...
    FROM  a
    JOIN        ( SELECT  x  FROM ... ) b
        USING(x)
    WHERE  test_a;
```

Caveat: If you end up with two subqueries JOINed together, note that neither has any indexes, hence performance can be very bad. (5.6 improves on it by dynamically creating indexes for subqueries.)

There is work going on in MariaDB and Oracle 5.7, in relation to "NOT IN", "NOT EXISTS", and "LEFT JOIN..IS NULL"; here is an old discussion on the topic So, what I say here may not be the final word.

Explode/Implode

When you have a JOIN and a GROUP BY, you may have the situation where the JOIN exploded more rows than the original query (due to many:many), but you wanted only one row from the original table, so you added the GROUP BY to implode back to the desired set of rows.

This explode + implode, itself, is costly. It would be better to avoid them if possible.

Sometimes the following will work.

Using DISTINCT or GROUP BY to counteract the explosion

```
SELECT  DISTINCT
        a.*,
        b.y
    FROM a
    JOIN b
⇒
SELECT  a.*,
        ( SELECT GROUP_CONCAT(b.y) FROM b WHERE b.x = a.x ) AS ys
    FROM a
```

When using second table just to check for existence:

```
SELECT  a.*
    FROM a
    JOIN b  ON b.x = a.x
    GROUP BY a.id
⇒
SELECT  a.*,
    FROM a
    WHERE EXISTS ( SELECT *  FROM b  WHERE b.x = a.x )
```

Another variant

Many-to-many mapping table

Do it this way.

```
    CREATE TABLE XtoY (
        # No surrogate id for this table
        x_id MEDIUMINT UNSIGNED NOT NULL,   -- For JOINing to one table
        y_id MEDIUMINT UNSIGNED NOT NULL,   -- For JOINing to the other table
        # Include other fields specific to the 'relation'
        PRIMARY KEY(x_id, y_id),            -- When starting with X
        INDEX      (y_id, x_id)             -- When starting with Y
    ) ENGINE=InnoDB;
```

Notes:

- Lack of an AUTO_INCREMENT id for this table -- The PK given is the 'natural' PK; there is no good reason for a surrogate.
- "MEDIUMINT" -- This is a reminder that all INTs should be made as small as is safe (smaller ⇒ faster). Of course the declaration here must match the definition in the table being linked to.
- "UNSIGNED" -- Nearly all INTs may as well be declared non-negative
- "NOT NULL" -- Well, that's true, isn't it?
- "InnoDB" -- More effecient than MyISAM because of the way the PRIMARY KEY is clustered with the data in InnoDB.
- "INDEX(y_id, x_id)" -- The PRIMARY KEY makes it efficient to go one direction; this index makes the other direction efficient. No need to say UNIQUE; that would be extra effort on INSERTs.
- In the secondary index, saying justINDEX(y_id) would work because it would implicit include x_id. But I would rather make it more obvious that I am hoping for a 'covering' index.

To conditionally INSERT new links, use IODKU

Note that if you had an AUTO_INCREMENT in this table, IODKU would "burn" ids quite rapidly.

Subqueries and UNIONs

Each subquery SELECT and each SELECT in a UNION can be considered separately for finding the optimal INDEX.

Exception: In a "correlated" ("dependent") subquery, the part of the WHERE that depends on the outside table is not easily factored into the INDEX generation. (Cop out!)

JOINs

The first step is to decide what order the optimizer will go through the tables. If you cannot figure it out, then you may need to be pessimistic and create two indexes for each table -- one assuming the table will be used first, one assiming that it will come later in the table order.

The optimizer usually starts with one table and extracts the data needed from it. As it finds a useful (that is, matches the WHERE clause, if any) row, it reaches into the 'next' table. This is called NLJ ("Nested Loop Join"). The process of filtering and reaching to the next table continues through the rest of the tables.

The optimizer usually picks the "first" table based on these hints:

- STRAIGHT_JOIN forces the the table order.
- The WHERE clause limits which rows needed (whether indexed or not).
- The table to the "left" in a LEFT JOIN usually comes before the "right" table. (By looking at the table definitions, the optimizer may decide that "LEFT" is irrelevant.)
- The current INDEXes will encourage an order.
- etc.

Running EXPLAIN tells you the table order that the Optimizer is very likely to use today. After adding a new INDEX, the

optimizer may pick a different table order. You should anticipate the order changing, guess at what order makes the most sense, and build the INDEXes accordingly. Then rerun EXPLAIN to see if the Optimizer's brain was on the same wavelength you were on.

You should build the INDEX for the "first" table based on any parts of the WHERE, GROUP BY, and ORDER BY clauses that are relevant to it. If a GROUP/ORDER BY mentions a different table, you should ignore that clause.

The second (and subsequent) table will be reached into based on the ON clause. (Instead of using commajoin, please write JOINs with the JOIN keyword and ON clause!) In addition, there could be parts of the WHERE clause that are relevant. GROUP/ORDER BY are not to be considered in writing the optimal INDEX for subsequent tables.

PARTITIONing

PARTITIONing is rarely a substitute for a good INDEX.

PARTITION BY RANGE is a technique that is sometimes useful when indexing fails to be good enough. In a two-dimensional situation such as nearness in a geographical sense, one dimension can partially be handled by partition pruning; then the other dimension can be handled by a regular index (preferrably the PRIMARY KEY). This goes into more detail: Find nearest 10 pizza parlors.

FULLTEXT

FULLTEXT is now implemented in InnoDB as well as MyISAM. It provides a way to search for "words" in TEXT columns. This is much faster (when it is applicable) than col LIKE '%word%'.

```
    WHERE x = 1
      AND MATCH (...) AGAINST (...)
```

always(?) uses the FULLTEXT index first. That is, the whole Algorithm is invalidated when one of the ANDs is a MATCH.

Signs of a Newbie

- No "compound" (aka "composite") indexes
- No PRIMARY KEY
- Redundant indexes (especially blatant is PRIMARY KEY(id), KEY(id))
- Most or all columns individually indexes ("But I indexed everything")
- "Commajoin" -- That is `FROM a, b WHERE a.x=b.x` instead of `FROM a JOIN b ON a.x=b.x`

Speeding up wp_postmeta

The published table (see Wikipedia) is

```
    CREATE TABLE wp_postmeta (
      meta_id bigint(20) unsigned NOT NULL AUTO_INCREMENT,
      post_id bigint(20) unsigned NOT NULL DEFAULT '0',
      meta_key varchar(255) DEFAULT NULL,
      meta_value longtext,
      PRIMARY KEY (meta_id),
      KEY post_id (post_id),
      KEY meta_key (meta_key)
    ) ENGINE=InnoDB  DEFAULT CHARSET=utf8;
```

The problems:

- The AUTO_INCREMENT provides no benefit; in fact it slows down most queries and clutters disk.
- Much better is PRIMARY KEY(post_id, meta_key) -- clustered, handles both parts of usual JOIN.
- BIGINT is overkill, but that can't be fixed without changing other tables.
- VARCHAR(255) can be a problem in 5.6 with utf8mb4; see workarounds below.
- When would `meta_key` or `meta_value` ever be NULL?

The solutions:

```
    CREATE TABLE wp_postmeta (
        post_id BIGINT UNSIGNED NOT NULL,
        meta_key VARCHAR(255) NOT NULL,
        meta_value LONGTEXT NOT NULL,
        PRIMARY KEY(post_id, meta_key),
        INDEX(meta_key)
        ) ENGINE=InnoDB;
```

Postlog

Initial posting: March, 2015; Refreshed Feb, 2016; Add DATE June, 2016; Add WP example May, 2017.

The tips in this document apply to MySQL, MariaDB, and Percona.

3.3.3.6 Compound (Composite) Indexes

A mini-lesson in "compound indexes" ("composite indexes")

This document starts out trivial and perhaps boring, but builds up to more interesting information, perhaps things you did not realize about how MariaDB and MySQL indexing works.

This also explains EXPLAIN (to some extent).

(Most of this applies to other databases, too.)

The query to discuss

The question is "When was Andrew Johnson president of the US?".

The available table `Presidents` looks like:

```
+-----+------------+----------------+-----------+
| seq | last_name  | first_name     | term      |
+-----+------------+----------------+-----------+
|   1 | Washington | George         | 1789-1797 |
|   2 | Adams      | John           | 1797-1801 |
...
|   7 | Jackson    | Andrew         | 1829-1837 |
...
|  17 | Johnson    | Andrew         | 1865-1869 |
...
|  36 | Johnson    | Lyndon B.      | 1963-1969 |
...
```

("Andrew Johnson" was picked for this lesson because of the duplicates.)

What index(es) would be best for that question? More specifically, what would be best for

```
    SELECT  term
        FROM  Presidents
        WHERE  last_name = 'Johnson'
          AND  first_name = 'Andrew';
```

Some INDEXes to try...

- No indexes
- INDEX(first_name), INDEX(last_name) (two separate indexes)
- "Index Merge Intersect"
- INDEX(last_name, first_name) (a "compound" index)
- INDEX(last_name, first_name, term) (a "covering" index)
- Variants

No indexes

Well, I am fudging a little here. I have a PRIMARY KEY on `seq`, but that has no advantage on the query we are studying.

```
SHOW CREATE TABLE Presidents \G
CREATE TABLE `presidents` (
  `seq` tinyint(3) unsigned NOT NULL AUTO_INCREMENT,
  `last_name` varchar(30) NOT NULL,
  `first_name` varchar(30) NOT NULL,
  `term` varchar(9) NOT NULL,
  PRIMARY KEY (`seq`)
) ENGINE=InnoDB AUTO_INCREMENT=45 DEFAULT CHARSET=utf8

EXPLAIN  SELECT  term
   FROM  Presidents
   WHERE  last_name = 'Johnson'
   AND  first_name = 'Andrew';
+----+-------------+------------+------+---------------+------+---------+------+------+----------
| id | select_type | table      | type | possible_keys | key  | key_len | ref  | rows | Extra
+----+-------------+------------+------+---------------+------+---------+------+------+----------
|  1 | SIMPLE      | Presidents | ALL  | NULL          | NULL | NULL    | NULL |   44 | Using whe
+----+-------------+------------+------+---------------+------+---------+------+------+----------

# Or, using the other form of display:  EXPLAIN ... \G
           id: 1
  select_type: SIMPLE
        table: Presidents
         type: ALL        <-- Implies table scan
possible_keys: NULL
          key: NULL       <-- Implies that no index is useful, hence table scan
      key_len: NULL
          ref: NULL
         rows: 44         <-- That's about how many rows in the table, so table scan
        Extra: Using where
```

Implementation Details

First, let's describe how InnoDB stores and uses indexes.

- The data and the PRIMARY KEY are "clustered" together in on BTree.
- A BTree lookup is quite fast and efficient. For a million-row table there might be 3 levels of BTree, and the top two levels are probably cached.
- Each secondary index is in another BTree, with the PRIMARY KEY at the leaf.
- Fetching 'consecutive' (according to the index) items from a BTree is very efficient because they are stored consecutively.
- For the sake of simplicity, we can count each BTree lookup as 1 unit of work, and ignore scans for consecutive items. This approximates the number of disk hits for a large table in a busy system.

For MyISAM, the PRIMARY KEY is not stored with the data, so think of it as being a secondary key (over-simplified).

INDEX(first_name), INDEX(last_name)

The novice, once he learns about indexing, decides to index lots of columns, one at a time. But...

MariaDB rarely uses more than one index at a time in a query. So, it will analyze the possible indexes.

- first_name -- there are 2 possible rows (one BTree lookup, then scan consecutively)
- last_name -- there are 2 possible rows Let's say it picks last_name. Here are the steps for doing the SELECT: 1. Using INDEX(last_name), find 2 index entries with last_name = 'Johnson'. 2. Get the PRIMARY KEY (implicitly added to each secondary index in InnoDB); get (17, 36). 3. Reach into the data using seq = (17, 36) to get the rows for Andrew Johnson and Lyndon B. Johnson. 4. Use the rest of the WHERE clause filter out all but the desired row. 5. Deliver the answer (1865-1869).

```
EXPLAIN  SELECT  term
  FROM  Presidents
  WHERE  last_name = 'Johnson'
  AND  first_name = 'Andrew'  \G
  select_type: SIMPLE
        table: Presidents
         type: ref
possible_keys: last_name, first_name
          key: last_name
      key_len: 92                <-- VARCHAR(30) utf8 may need 2+3*30 bytes
          ref: const
         rows: 2                 <-- Two 'Johnson's
        Extra: Using where
```

"Index Merge Intersect"

OK, so you get really smart and decide that MariaDB should be smart enough to use both name indexes to get the answer. This is called "Intersect". 1. Using INDEX(last_name), find 2 index entries with last_name = 'Johnson'; get (7, 17) 2. Using INDEX(first_name), find 2 index entries with first_name = 'Andrew'; get (17, 36) 3. "And" the two lists together (7,17) & (17,36) = (17) 4. Reach into the data using seq = (17) to get the row for Andrew Johnson. 5. Deliver the answer (1865-1869).

```
           id: 1
  select_type: SIMPLE
        table: Presidents
         type: index_merge
possible_keys: first_name,last_name
          key: first_name,last_name
      key_len: 92,92
          ref: NULL
         rows: 1
        Extra: Using intersect(first_name,last_name); Using where
```

The EXPLAIN fails to give the gory details of how many rows collected from each index, etc.

INDEX(last_name, first_name)

This is called a "compound" or "composite" index since it has more than one column. 1. Drill down the BTree for the index to get to exactly the index row for Johnson+Andrew; get seq = (17). 2. Reach into the data using seq = (17) to get the row for Andrew Johnson. 3. Deliver the answer (1865-1869). This is much better. In fact this is usually the "best".

```
    ALTER TABLE Presidents
        (drop old indexes and...)
        ADD INDEX compound(last_name, first_name);

           id: 1
  select_type: SIMPLE
        table: Presidents
         type: ref
possible_keys: compound
          key: compound
      key_len: 184             <-- The length of both fields
          ref: const,const     <-- The WHERE clause gave constants for both
         rows: 1               <-- Goodie!  It homed in on the one row.
        Extra: Using where
```

"Covering": INDEX(last_name, first_name, term)

Surprise! We can actually do a little better. A "Covering" index is one in which _all_ of the fields of the SELECT are found in the index. It has the added bonus of not having to reach into the "data" to finish the task. 1. Drill down the BTree for the index to get to exactly the index row for Johnson+Andrew; get seq = (17). 2. Deliver the answer (1865-1869). The "data" BTree is not touched; this is an improvement over "compound".

```
    ... ADD INDEX covering(last_name, first_name, term);

           id: 1
  select_type: SIMPLE
        table: Presidents
         type: ref
possible_keys: covering
          key: covering
      key_len: 184
          ref: const,const
         rows: 1
        Extra: Using where; Using index   <-- Note
```

Everything is similar to using "compound", except for the addition of "Using index".

Variants

- What would happen if you shuffled the fields in the WHERE clause? Answer: The order of ANDed things does not matter.
- What would happen if you shuffled the fields in the INDEX? Answer: It may make a huge difference. More in a minute.
- What if there are extra fields on the the end? Answer: Minimal harm; possibly a lot of good (eg, 'covering').
- Reduncancy? That is, what if you have both of these: INDEX(a), INDEX(a,b)? Answer: Reduncy costs something on INSERTs; it is rarely useful for SELECTs.
- Prefix? That is, INDEX(last_name(5). first_name(5)) Answer: Don't bother; it rarely helps, and often hurts. (The details are another topic.)

More examples:

```
    INDEX(last, first)
    ... WHERE last = '...' -- good (even though `first` is unused)
    ... WHERE first = '...' -- index is useless

    INDEX(first, last), INDEX(last, first)
    ... WHERE first = '...' -- 1st index is used
    ... WHERE last = '...' -- 2nd index is used
    ... WHERE first = '...' AND last = '...' -- either could be used equally well

    INDEX(last, first)
    Both of these are handled by that one INDEX:
    ... WHERE last = '...'
    ... WHERE last = '...' AND first = '...'

    INDEX(last), INDEX(last, first)
    In light of the above example, don't bother including INDEX(last).
```

1.1.1.2.2.4 EXPLAIN

3.3.3.8 Foreign Keys

Contents

Overview

A foreign key is a constraint which can be used to enforce data integrity. It is composed by a column (or a set of columns) in a table called the child table, which references to a column (or a set of columns) in a table called the parent table. If foreign keys are used, MariaDB performs some checks to enforce that some integrity rules are always enforced. For a more exhaustive explanation, see Relational databases: Foreign Keys.

Foreign keys can only be used with storage engines that support them. The default InnoDB and the obsolete PBXT support foreign keys.

Partitioned tables cannot contain foreign keys, and cannot be referenced by a foreign key.

Syntax

Note: Until MariaDB 10.4, MariaDB accepts the shortcut format with a REFERENCES clause only in ALTER TABLE and CREATE TABLE statements, but that syntax does nothing. For example:

```
CREATE TABLE b(for_key INT REFERENCES a(not_key));
```

MariaDB simply parses it without returning any error or warning, for compatibility with other DBMS's. However, only the syntax described below creates foreign keys.

From MariaDB 10.5, MariaDB will attempt to apply the constraint. See the Examples below.

Foreign keys are created with CREATE TABLE or ALTER TABLE. The definition must follow this syntax:

```
[CONSTRAINT [symbol]] FOREIGN KEY
    [index_name] (index_col_name, ...)
    REFERENCES tbl_name (index_col_name,...)
    [ON DELETE reference_option]
    [ON UPDATE reference_option]

reference_option:
    RESTRICT | CASCADE | SET NULL | NO ACTION | SET DEFAULT
```

The `symbol` clause, if specified, is used in error messages and must be unique in the database.

The columns in the child table must be a BTREE (not HASH, RTREE, or FULLTEXT — see SHOW INDEX) index, or the leftmost part of a BTREE index. Index prefixes are not supported (thus, TEXT and BLOB columns cannot be used as foreign keys). If MariaDB automatically creates an index for the foreign key (because it does not exist and is not explicitly created), its name will be `index_name`.

The referenced columns in the parent table must be a an index or a prefix of an index.

The foreign key columns and the referenced columns must be of the same type, or similar types. For integer types, the size and sign must also be the same.

Both the foreign key columns and the referenced columns can be PERSISTENT columns. However, the ON UPDATE CASCADE, ON UPDATE SET NULL, ON DELETE SET NULL clauses are not allowed in this case.

The parent and the child table must use the same storage engine, and must not be `TEMPORARY` or partitioned tables. They can be the same table.

Constraints

If a foreign keys exists, each row in the child table must match a row in the parent table. Multiple child rows can match the same parent row. A child row *matches* a parent row if all its foreign key values are identical to a parent row's values in the parent table. However, if at least one of the foreign key values is `NULL`, the row has no parents, but it is still allowed.

MariaDB performs certain checks to guarantee that the data integrity is enforced:

- Trying to insert non-matching rows (or update matching rows in a way that makes them non-matching rows) in the child table produces a 1452 error (SQLSTATE '23000').
- When a row in the parent table is deleted and at least one child row exists, MariaDB performs an action which depends on the `ON DELETE` clause of the foreign key.
- When a value in the column referenced by a foreign key changes and at least one child row exists, MariaDB performs an action which depends on the `ON UPDATE` clause of the foreign key.
- Trying to drop a table that is referenced by a foreign key produces a 1217 error (SQLSTATE '23000').
- A TRUNCATE TABLE against a table containing one or more foreign keys is executed as a DELETE without

WHERE, so that the foreign keys are enforced for each row.

The allowed actions for `ON DELETE` and `ON UPDATE` are:

- `RESTRICT` : The change on the parent table is prevented. The statement terminates with a 1451 error (SQLSTATE '2300'). This is the default behavior for both `ON DELETE` and `ON UPDATE` .
- `NO ACTION` : Synonym for `RESTRICT` .
- `CASCADE` : The change is allowed and propagates on the child table. For example, if a parent row is deleted, the child row is also deleted; if a parent row's ID changes, the child row's ID will also change.
- `SET NULL` : The change is allowed, and the child row's foreign key columns are set to `NULL` .
- `SET DEFAULT` : Only worked with PBXT. Similar to `SET NULL` , but the foreign key columns were set to their default values. If default values do not exist, an error is produced.

The delete or update operations triggered by foreign keys do not activate triggers and are not counted in the Com_delete and Com_update status variables.

Foreign key constraints can be disabled by setting the foreign_key_checks server system variable to 0. This speeds up the insertion of large quantities of data.

Metadata

The Information Schema `REFERENTIAL_CONSTRAINTS` table contains information about foreign keys. The individual columns are listed in the `KEY_COLUMN_USAGE` table.

The InnoDB-specific Information Schema tables also contain information about the InnoDB foreign keys. The foreign key information is stored in the `INNODB_SYS_FOREIGN` . Data about the individual columns are stored in `INNODB_SYS_FOREIGN_COLS` .

The most human-readable way to get information about a table's foreign keys sometimes is the `SHOW CREATE TABLE` statement.

Limitations

Foreign keys have the following limitations in MariaDB:

- Currently, foreign keys are only supported by InnoDB.
- Cannot be used with views.
- The `SET DEFAULT` action is not supported.
- Foreign keys actions do not activate triggers.
- If ON UPDATE CASCADE recurses to update the same table it has previously updated during the cascade, it acts like RESTRICT.

Examples

Let's see an example. We will create an `author` table and a `book` table. Both tables have a primary key called `id` . `book` also has a foreign key composed by a field called `author_id` , which refers to the `author` primary key. The foreign key constraint name is optional, but we'll specify it because we want it to appear in error messages: `fk_book_author` .

```
CREATE TABLE author (
  id SMALLINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  name VARCHAR(100) NOT NULL
) ENGINE = InnoDB;

CREATE TABLE book (
  id MEDIUMINT UNSIGNED NOT NULL AUTO_INCREMENT PRIMARY KEY,
  title VARCHAR(200) NOT NULL,
  author_id SMALLINT UNSIGNED NOT NULL,
  CONSTRAINT `fk_book_author`
    FOREIGN KEY (author_id) REFERENCES author (id)
    ON DELETE CASCADE
    ON UPDATE RESTRICT
) ENGINE = InnoDB;
```

Now, if we try to insert a book with a non-existing author, we will get an error:

```
INSERT INTO book (title, author_id) VALUES ('Necronomicon', 1);
ERROR 1452 (23000): Cannot add or update a child row: a foreign key constraint fails
 (`test`.`book`, CONSTRAINT `fk_book_author` FOREIGN KEY (`author_id`)
  REFERENCES `author` (`id`) ON DELETE CASCADE)
```

The error is very descriptive.

Now, let's try to properly insert two authors and their books:

```
INSERT INTO author (name) VALUES ('Abdul Alhazred');
INSERT INTO book (title, author_id) VALUES ('Necronomicon', LAST_INSERT_ID());

INSERT INTO author (name) VALUES ('H.P. Lovecraft');
INSERT INTO book (title, author_id) VALUES
  ('The call of Cthulhu', LAST_INSERT_ID()),
  ('The colour out of space', LAST_INSERT_ID());
```

It worked!

Now, let's delete the second author. When we created the foreign key, we specified `ON DELETE CASCADE`. This should propagate the deletion, and make the deleted author's books disappear:

```
DELETE FROM author WHERE name = 'H.P. Lovecraft';

SELECT * FROM book;
+----+--------------+-----------+
| id | title        | author_id |
+----+--------------+-----------+
|  3 | Necronomicon |         1 |
+----+--------------+-----------+
```

We also specified `ON UPDATE RESTRICT`. This should prevent us from modifying an author's `id` (the column referenced by the foreign key) if a child row exists:

```
UPDATE author SET id = 10 WHERE id = 1;
ERROR 1451 (23000): Cannot delete or update a parent row: a foreign key constraint fails
 (`test`.`book`, CONSTRAINT `fk_book_author` FOREIGN KEY (`author_id`)
  REFERENCES `author` (`id`) ON DELETE CASCADE)
```

REFERENCES

Until MariaDB 10.4

```
CREATE TABLE a(a_key INT primary key, not_key INT);

CREATE TABLE b(for_key INT REFERENCES a(not_key));

SHOW CREATE TABLE b;
+-------+-----------------------------------------------------------------------------------------+
| Table | Create Table                                                                            |

+---------+
|      10 |
|       1 |
+---------+
```

From MariaDB 10.5

```
CREATE TABLE a(a_key INT primary key, not_key INT);

CREATE TABLE b(for_key INT REFERENCES a(not_key));
ERROR 1005 (HY000): Can't create table `test`.`b`
  (errno: 150 "Foreign key constraint is incorrectly formed")

CREATE TABLE c(for_key INT REFERENCES a(a_key));

SHOW CREATE TABLE c;
+-------+-----------------------------------------------------------------------------------------+
| Table | Create Table                                                                            |
+-------+-----------------------------------------------------------------------------------------+
| c     | CREATE TABLE `c` (
  `for_key` int(11) DEFAULT NULL,
  KEY `for_key` (`for_key`),
  CONSTRAINT `c_ibfk_1` FOREIGN KEY (`for_key`) REFERENCES `a` (`a_key`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1 |
+-------+-----------------------------------------------------------------------------------------+

INSERT INTO a VALUES (1,10);
Query OK, 1 row affected (0.004 sec)

INSERT INTO c VALUES (10);
ERROR 1452 (23000): Cannot add or update a child row: a foreign key constraint fails
  (`test`.`c`, CONSTRAINT `c_ibfk_1` FOREIGN KEY (`for_key`) REFERENCES `a` (`a_key`))

INSERT INTO c VALUES (1);
Query OK, 1 row affected (0.004 sec)

SELECT * FROM c;
+---------+
| for_key |
+---------+
|       1 |
+---------+
```

3.3.3.9 Ignored Indexes

MariaDB starting with 10.6.0

MariaDB starting with [illegible]
Ignored indexes were added in MariaDB 10.6.

Ignored indexes are indexes that are visible and maintained, but which are not used by the optimizer. MySQL 8 has a similar feature which they call "invisible indexes".

Syntax

By default, an index is not ignored. One can mark existing index as ignored (or not ignored) with an ALTER TABLE statement:

```
ALTER TABLE table_name ALTER {KEY|INDEX} [IF EXISTS] key_name [NOT] IGNORED;
```

It is also possible to specify IGNORED attribute when creating an index with a CREATE TABLE, or CREATE INDEX statement:

```
CREATE TABLE table_name (
  ...
  INDEX index_name ( ...) [NOT] IGNORED
  ...
```

```
CREATE INDEX index_name (...) [NOT] IGNORED ON tbl_name (...);
```

table's primary key cannot be ignored. This applies to both explicitly defined primary key, as well as implicit primary key - if there is no explicit primary key defined but the table has a unique key containing only NOT NULL columns, the first of such keys becomes the implicitly defined primary key.

Handling for ignored indexes

The optimizer will treats ignored indexes as if they didn't exist. They will not be used in the query plans, or as a source of statistical information. Also, an attempt to use an ignored index in a `USE INDEX`, `FORCE INDEX`, or `IGNORE INDEX` hint will result in an error - the same what would have if one used a name of a non-existent index.

Information about whether or not indexes are ignored can be viewed in the IGNORED column in the Information Schema STATISTICS table or the SHOW INDEX statement.

Intended Usage

The primary use case is as follows: a DBA sees an index that seems to have little or no usage and considers whether to remove it. Dropping the index is a risk as it may still be needed in a few cases. For example, the optimizer may rely on the estimates provided by the index without using the index in query plans. If dropping an index causes an issue, it will take a while to re-create the index. On the other hand, marking the index as ignored (or not ignored) is instant, so the suggested workflow is:

1. Mark the index as ignored
2. Check if everything continues to work
3. If not, mark the index as not ignored.
4. If everything continues to work, one can safely drop the index.

Examples

```
CREATE TABLE t1 (id INT PRIMARY KEY, b INT, KEY k1(b) IGNORED);
```

```
CREATE OR REPLACE TABLE t1 (id INT PRIMARY KEY, b INT, KEY k1(b));
ALTER TABLE t1 ALTER INDEX k1 IGNORED;
```

```
CREATE OR REPLACE TABLE t1 (id INT PRIMARY KEY, b INT);
CREATE INDEX k1 ON t1(b) IGNORED;
```

```
SELECT * FROM INFORMATION_SCHEMA.STATISTICS WHERE TABLE_NAME = 't1'\G
*************************** 1. row ***************************
TABLE_CATALOG: def
 TABLE_SCHEMA: test
   TABLE_NAME: t1
   NON_UNIQUE: 0
 INDEX_SCHEMA: test
   INDEX_NAME: PRIMARY
 SEQ_IN_INDEX: 1
  COLUMN_NAME: id
    COLLATION: A
  CARDINALITY: 0
     SUB_PART: NULL
       PACKED: NULL
     NULLABLE:
   INDEX_TYPE: BTREE
      COMMENT:
INDEX_COMMENT:

*************************** 2. row ***************************
TABLE_CATALOG: def
 TABLE_SCHEMA: test
   TABLE_NAME: t1
   NON_UNIQUE: 1
 INDEX_SCHEMA: test
   INDEX_NAME: k1
 SEQ_IN_INDEX: 1
  COLUMN_NAME: b
    COLLATION: A
  CARDINALITY: 0
     SUB_PART: NULL
       PACKED: NULL
     NULLABLE: YES
   INDEX_TYPE: BTREE
      COMMENT:
INDEX_COMMENT:
      IGNORED: YES
```

```
SHOW INDEXES FROM t1\G
*************************** 1. row ***************************
        Table: t1
   Non_unique: 0
     Key_name: PRIMARY
 Seq_in_index: 1
  Column_name: id
    Collation: A
  Cardinality: 0
     Sub_part: NULL
       Packed: NULL
         Null:
   Index_type: BTREE
      Comment:
Index_comment:
      Ignored: NO
*************************** 2. row ***************************
        Table: t1
   Non_unique: 1
     Key_name: k1
 Seq_in_index: 1
  Column_name: b
    Collation: A
  Cardinality: 0
     Sub_part: NULL
       Packed: NULL
         Null: YES
   Index_type: BTREE
      Comment:
Index_comment:
      Ignored: YES
```

The optimizer does not make use of an index when it is ignored, while if the index is not ignored (the default), the optimizer will consider it in the optimizer plan, as shown in the EXPLAIN output.

```
CREATE OR REPLACE TABLE t1 (id INT PRIMARY KEY, b INT, KEY k1(b) IGNORED);

EXPLAIN SELECT * FROM t1 ORDER BY b;
+------+-------------+-------+------+---------------+------+---------+------+------+-------------
| id   | select_type | table | type | possible_keys | key  | key_len | ref  | rows | Extra
+------+-------------+-------+------+---------------+------+---------+------+------+-------------
|    1 | SIMPLE      | t1    | ALL  | NULL          | NULL | NULL    | NULL | 1    | Using filesc
+------+-------------+-------+------+---------------+------+---------+------+------+-------------

ALTER TABLE t1 ALTER INDEX k1 NOT IGNORED;

EXPLAIN SELECT * FROM t1 ORDER BY b;
+------+-------------+-------+-------+---------------+------+---------+------+------+-------------

+------+-------------+-------+-------+---------------+------+---------+------+------+-------------
```

3.3.3.10 Index Statistics

Contents

How Index Statistics Help the Query Optimizer

The MariaDB query optimizer decides how best to execute each query based largely on the details of the indexes involved.

The index statistics help inform these decisions. Imagine yourself choosing whether to look up a number in a phone book, or in your personal address book. You'd choose the personal phone book if at all possible, as it would (usually!) contain far fewer records and be quicker to search.

Now imagine getting to your personal address book and finding it has twice the number of entries as the phone book. Your search would be slower. The same process applies to the query optimizer, so having access to up-to-date and accurate statistics is critical.

Value Groups

The statistics are mainly based on groups of index elements of the same value. In a primary key, every index is unique, so every group size is one. In a non-unique index, you may have multiple keys with the same value. A worst-case example would be having large groups with the same value, for example an index on a boolean field.

MariaDB makes heavy use of the average group size statistic. For example, if there are 100 rows, and twenty groups with the same index values, the average group size would be five.

However, averages can be skewed by extremes, and the usual culprit is NULL values. The row of 100 may have 19 groups with an average size of 1, while the other 81 values are all NULL. MariaDB may think five is a good average size and choose to use that index, and then end up having to read through 81 rows with identical keys, taking longer than an alternative.

Dealing with NULLs

There are three main approaches to the problem of NULLs. NULL index values can be treated as a single group (nulls_equal). This is usually fine, but if you have large numbers of NULLs the average group size is slanted higher, and the optimizer may miss using the index for ref accesses when it would be useful. This is the default used by XtraDB/InnoDB and MyISAM. Nulls_unequal is the opposite approach, with each NULL forming its own group of one. Conversely, the average group size is slanted lower, and the optimizer may use the index for ref accesses when not suitable. This is the default used by the Aria storage engine. A third options sees NULL's ignored altogether from index group calculations.

The default approaches can be changed by setting the aria_stats_method, myisam_stats_method and innodb_stats_method server variables.

Null-Safe and Regular Comparisons

The comparison operator used plays an important role. If two values are compared with <=> (see the null-safe-equal comparison operator), and both are null, 1 is returned. If the same values are compared with = (see the equal comparison operator) null is returned. For example:

```
SELECT 1 <=> 1, NULL <=> NULL, 1 <=> NULL;
+---------+---------------+-------------+
| 1 <=> 1 | NULL <=> NULL | 1 <=> NULL |
+---------+---------------+-------------+
|       1 |             1 |           0 |
+---------+---------------+-------------+

SELECT 1 = 1, NULL = NULL, 1 = NULL;
+-------+-------------+----------+
| 1 = 1 | NULL = NULL | 1 = NULL |
+-------+-------------+----------+
|     1 |        NULL |     NULL |
+-------+-------------+----------+
```

Engine-Independent Statistics

MariaDB 10.0.1 introduced a way to gather statistics independently of the storage engine. See Engine-independent table statistics.

Histogram-Based Statistics

Histogram-Based Statistics were introduced in MariaDB 10.0.2, and are collected by default from MariaDB 10.4.3.

3.3.3.11 Latitude/Longitude Indexing

Contents

The problem

You want to find the nearest 10 pizza parlors, but you cannot figure out how to do it efficiently in your huge database. Database indexes are good at one-dimensional indexing, but poor at two-dimensions.

You might have tried

- INDEX(lat), INDEX(lon) -- but the optimizer used only one
- INDEX(lat,lon) -- but it still had to work too hard
- Sometimes you ended up with a full table scan -- Yuck.

WHERE SQRT(...)< ... -- No chance of using any index.

WHERE lat BETWEEN ... AND lng BETWEEN... -- This has some chance of using such indexes.

The goal is to look only at records "close", in both directions, to the target lat/lng.

A solution -- first, the principles

PARTITIONs in MariaDB and MySQL sort of give you a way to have two clustered indexes. So, if we could slice up (partition) the globe in one dimension and use ordinary indexing in the other dimension, maybe we can get something approximating a 2D index. This 2D approach keeps the number of disk hits significantly lower than 1D approaches, thereby speeding up "find nearest" queries.

It works. Not perfectly, but better than the alternatives.

What to PARTITION on? It seems like latitude or longitude would be a good idea. Note that longitudes vary in width, from 69 miles (111 km) at the equator, to 0 at the poles. So, latitude seems like a better choice.

How many PARTITIONs? It does not matter a lot. Some thoughts:

- 90 partitions - 2 degrees each. (I don't like tables with too many partitions; 90 seems like plenty.)
- 50-100 - evenly populated. (This requires code. For 2.7M placenames, 85 partitions varied from 0.5 degrees to very wide partitions at the poles.)
- Don't have more than 100 partitions, there are inefficiencies in the partition implementation.

How to PARTITION? Well, MariaDB and MySQL are very picky. So FLOAT/DOUBLE are out. DECIMAL is out. So, we are stuck with some kludge. Essentially, we need to convert Lat/Lng to some size of INT and use PARTITION BY RANGE.

Representation choices

To get to a datatype that can be used in PARTITION, you need to "scale" the latitude and longitude. (Consider only the *INTs; the other datatypes are included for comparison)

```
Datatype           Bytes       resolution
------------------ -----  --------------------------------
Deg*100 (SMALLINT)     4  1570 m    1.0 mi  Cities
DECIMAL(4,2)/(5,2)     5  1570 m    1.0 mi  Cities
SMALLINT scaled        4   682 m    0.4 mi  Cities
Deg*10000 (MEDIUMINT)  6    16 m     52 ft  Houses/Businesses
DECIMAL(6,4)/(7,4)     7    16 m     52 ft  Houses/Businesses
MEDIUMINT scaled       6   2.7 m    8.8 ft
FLOAT                  8   1.7 m    5.6 ft
DECIMAL(8,6)/(9,6)     9    16cm    1/2 ft  Friends in a mall
Deg*10000000 (INT)     8    16mm    5/8 in  Marbles
DOUBLE                16   3.5nm     ...    Fleas on a dog
```

(Sorted by resolution)

What these mean...

Deg*100 (SMALLINT) -- you take the lat/lng, multiply by 100, round, and store into a SMALLINT. That will take 2 bytes for each dimension, for a total of 4 bytes. Two items might be 1570 meters apart, but register as having the same latitude and longitude.

DECIMAL(4,2) for latitude and DECIMAL(5,2) for longitude will take 2+3 bytes and have no better resolution than Deg*100.

SMALLINT scaled -- Convert latitude into a SMALLINT SIGNED by doing (degrees / 90 * 32767) and rounding; longitude by (degrees / 180 * 32767).

FLOAT has 24 significant bits; DOUBLE has 53. (They don't work with PARTITIONing but are included for completeness. Often people use DOUBLE without realizing how much an overkill it is, and how much space it takes.)

Sure, you could do DEG*1000 and other "in between" cases, but there is no advantage. DEG*1000 takes as much space as DEG*10000, but has less resolution.

So, go down the list to see how much resolution you need, then pick an encoding you are comfortable with. However, since we are about to use latitude as a "partition key", it must be limited to one of the INTs. For the sample code, I will use Deg*10000 (MEDIUMINT).

GCDist -- compute "great circle distance"

GCDist is a helper FUNCTION that correctly computes the distance between two points on the globe.

The code has been benchmarked at about 20 microseconds per call on a 2011-vintage PC. If you had to check a million points, that would take 20 seconds -- far too much for a web application. So, one goal of the Procedure that uses it will be to minimize the usage of this function. With the code presented here, the function need be called only a few dozen or few hundred times, except in pathological cases.

Sure, you could use the Pythagorean formula. And it would work for most applications. But it does not take extra effort to do the GC. Furthermore, GC works across a pole and across the dateline. And, a Pythagorean function is not that much faster.

For efficiency, GCDist understands the scaling you picked and has that stuff hardcoded. I am picking "Deg*10000", so the

function expects 350000 for representing 35 degrees. If you choose a different scaling, you will need to change the code.

GCDist() takes 4 scaled DOUBLEs -- lat1, lon1, lat2, lon2 -- and returns a scaled number of "degrees" representing the distance.

The table of representation choices says 52 feet of resolution for Deg*10000 and DECIMAL(x,4). Here is how it was calculated: To measuring a diagonal between lat/lng (0,0) and (0.0001,00001) (one 'unit in the last place'): GCDist(0,0,1,1) * 69.172 / 10000 * 5280 = 51.65, where

- 69.172 miles/degree of latitude
- 10000 units per degree for the scaling chosen
- 5280 feet / mile.

(No, this function does not compensate for the Earth being an oblate spheroid, etc.)

Required table structure

There will be one table (plus normalization tables as needed). The one table must be partitioned and indexed as indicated below.

Fields and indexes

- PARTITION BY RANGE(lat)
- lat -- scaled latitude (see above)
- lon -- scaled longitude
- PRIMARY KEY(lon, lat, ...) -- lon must be first; something must be added to make it UNIQUE
- id -- (optional) you may need to identify the rows for your purposes; AUTO_INCREMENT if you like
- INDEX(id) -- if `id` is AUTO_INCREMENT, then this plain INDEX (not UNIQUE, not PRIMARY KEY) is necessary
- ENGINE=InnoDB -- so the PRIMARY KEY will be "clustered"
- Other indexes -- keep to a minimum (this is a general performance rule for large tables)

For most of this discussion, lat is assumed to be MEDIUMINT -- scaled from -90 to +90 by multiplying by 10000. Similarly for lon and -180 to +180.

The PRIMARY KEY must

- start with `lon` since the algorithm needs the "clustering" that InnoDB will provide, and
- include `lat` somewhere, since it is the PARTITION key, and
- contain something to make the key UNIQUE (lon+lat is unlikely to be sufficient).

The FindNearest PROCEDURE will do multiple SELECTs something like this:

```
    WHERE lat    BETWEEN @my_lat - @dlat
                     AND @my_lat + @dlat   -- PARTITION Pruning and bounding box
      AND lon    BETWEEN @my_lon - @dlon
                     AND @my_lon + @dlon   -- first part of PK
      AND condition                        -- filter out non-pizza parlors
```

The query planner will

- Do PARTITION "pruning" based on the latitude; then
- Within a PARTITION (which is effectively a table), use lon do a 'clustered' range scan; then
- Use the "condition" to filter down to the rows you desire, plus recheck lat. This design leads to very few disk blocks needing to be read, which is the main goal of the design.

Note that this does not even call GCDist. That comes in the last pass when the ORDER BY and LIMIT are used.

The stored procedure has a loop. At least two SELECTs will be executed, but with proper tuning; usually no more than about 6 SELECTs will be performed. Because of searching by the PRIMARY KEY, each SELECT hits only one block, sometimes more, of the table. Counting the number of blocks hit is a crude, but effective way, of comparing the performance of multiple designs. By comparison, a full table scan will probably touch thousands of blocks. A simple INDEX(lat) probably leads to hitting hundreds of blocks.

Filtering... An argument to the FindNearest procedure includes a boolean expression ("condition") for a WHERE clause. If you don't need any filtering, pass in "1". To avoid "SQL injection", do not let web users put arbitrary expressions; instead, construct the "condition" from inputs they provide, thereby making sure it is safe.

The algorithm

The algorithm is embodied in a stored procedure because of its complexity.

- You feed it a starting width for a "square" and a number of items to find.
- It builds a "square" around where you are.

- A SELECT is performed to see how many items are in the square.
- Loop, doubling the width of the square, until enough items are found.
- Now, a 'last' SELECT is performed to get the exact distances, sort them (ORDER BY) and LIMIT to the desired number.
- If spanning a pole or the dateline, a more complex SELECT is used.

The next section ("Performance") should make this a bit clearer as it walks through some examples.

Performance

Because of all the variations, it is hard to get a meaningful benchmark. So, here is some hand-waving instead.

Each SELECT is constrained by a "square" defined by a latitude range and a longitude range. (See the WHERE clause mentioned above, or in the sample code below.) Because of the way longitude lines warp, the longitude range of the "square" will be more degrees than the latitude range. Let's say the latitude partitioning is 3 degrees wide in the area where you are searching. That is over 200 miles (over 300km), so you are very likely to have a latitude range smaller than the partition width. Still, if you are reaching from the edge of a latitude stripe, the square could span two partitions. After partition pruning down to one (sometimes more) partition, the query is then constrained by a longitude range. (Remember, the PRIMARY KEY starts with `lon`.) If an InnoDB data block contains 100 rows (a handy Rule of Thumb), the select will touch one (or a few) block. If the square spans two (or more) partitions, then the same logic applies to each partition.

So, scanning the square will involve as little as one block; rarely more than a few blocks. The number of blocks is mostly independent of the dataset size.

The primary use case for this algorithm is when the data is significantly larger than will fit into cache (the buffer_pool). Hence, the main goal is to minimize the number of disk hits.

Now let's look at some edge cases, and argue that the number of blocks is still better (usually) than with traditional indexing techniques.

What if you are looking for Starbucks in a dense city? There would be dozens, maybe hundreds per square mile. If you start the guess at 100 miles, the SELECTs would be hitting lots of blocks -- not efficient. In this case, the "starting distance" should be small, say, 2 miles. Let's say your app wants the closest 10 stores. In this example, you would probably find more than 10 Starbucks within 2 miles in 1 InnoDB block in one partition. Even though there is a second SELECT to finish off the query, it would be hitting the same block. Total: One block hit == cheap.

Let's say you start with a 5 mile square. Since there are upwards of 200 Starbucks within a 5-miles radius in some dense cities of the world, that might imply 300 in our "square". That maps to about 4 disk blocks, and a modest amount of CPU to chew through the 300 records. Still not bad.

Now, suppose you are on an ocean liner somewhere in the Pacific. And there is one Starbucks onboard, but you are looking for the nearest 10. If you again start with 2 miles, it will take several iterations to find 10 sites. But, let's walk through it anyway. The first probe will hit one partition (maybe 2), and find just one hit. The second probe doubles the width of the square; 4 miles will still give you one hit -- the same hit in the same block, which is now cached, so we won't count it as a second disk I/O. Eventually the square will be wide enough to span multiple partitions. Each extra partition will be one new disk hit to discover no sites in the square. Finally, the square will hit Chile or Hawaii or Fiji and find some more sites, perhaps enough to stop the iteration. Since the main criteria in determining the number of disk hits is the number of partitions hit, we do not want to split the world into too many partitions. If there are, say, 40 partitions, then I have just described a case where there might be 20 disk hits.

2-degree partitions might be good for a global table of stores or restaurants. A 5-mile starting distance might be good when filtering for Starbucks. 20 miles might be better for a department store.

Now, let's discuss the 'last' SELECT, wherein the square is expanded by SQRT(2) and it uses the Great Circle formula to precisely order the N results. The SQRT(2) is in case that the N items were all at the corners of the 'square'. Growing the square by this much allows us to catch any other sites that were just outside the old square.

First, note that this 'last' SELECT is hitting the same block(s) that the iteration hit, plus possibly hitting some more blocks. It is hard to predict how many extra blocks might be hit. Here's a pathological case. You are in the middle of a desert; the square grows and grows. Eventually it finds N sites. There is a big city just outside the final square from the iterating. Now the 'last' SELECT kicks in, and it includes lots of sites in this big city. "Lots of sites" --> lots of blocks --> lots of disk hits.

Discussion of reference code

Here's the gist of the stored procedure FindNearest().

- Make a guess at how close to "me" to look.
- See how many items are in a 'square' around me, after filtering.
- If not enough, repeat, doubling the width of the square.
- After finding enough, or giving up because we are looking "too far", make one last pass to get all the data, ORDERed and LIMITed

Note that the loop merely uses 'squares' of lat/lng ranges. This is crude, but works well with the partitioning and indexing, and avoids calling to GCDist (until the last step). In the sample code, I picked 15 miles as starting value. Adjusting this will have some impact on the Procedure's performance, but the impact will vary with the use cases. A rough way to set the radius is to guess what will find the desired LIMIT about half the time. (This value is hardcoded in the PROCEDURE.)

Parameters passed into FindNearest():

- your Latitude -- -90..90 (not scaled -- see hardcoded conversion in PROCEDURE)
- your Longitude -- -180..180 (not scaled)
- Start distance -- (miles or km) -- see discussion below
- Max distance -- in miles or km -- see hardcoded conversion in PROCEDURE
- Limit -- maximum number of items to return
- Condition -- something to put after 'AND' (more discussion above)

The function will find the nearest items, up to Limit that meet the Condition. But it will give up at Max distance. (If you are at the South Pole, why bother searching very far for the tenth pizza parlor?)

Because of the "scaling", "hardcoding", "Condition", the table name, etc, this PROCEDURE is not truly generic; the code must be modified for each application. Yes, I could have designed it to pass all that stuff in. But what a mess.

The "_start_dist" gives some control over the performance. Making this too small leads to extra iterations; too big leads to more rows being checked. If you choose to tune the Stored Procedure, do the following. "SELECT @iterations" after calling the SP for a number of typical values. If the value is usually 1, then decrease _start_dist. If it is usually 2 or more, then increase it.

Timing: Under 10ms for "typical" usage; any dataset size. Slower for pathological cases (low min distance, high max distance, crossing dateline, bad filtering, cold cache, etc)

End-cases:

- By using GC distance, not Pythagoras, distances are 'correct' even near poles.
- Poles -- Even if the "nearest" is almost 360 degrees away (longitude), it can find it.
- Dateline -- There is a small, 'contained', piece of code for crossing the Dateline. Example: you are at +179 deg longitude, and the nearest item is at -179.

The procedure returns one resultset, SELECT *, distance.

- Only rows that meet your Condition, within Max distance are returned
- At most Limit rows are returned
- The rows will be ordered, "closest" first.
- "dist" will be in miles or km (based on a hardcoded constant in the SP)

Reference code, assuming deg*10000 and 'miles'

This version is based on scaling "Deg*10000 (MEDIUMINT)".

Postlog

There is a "Haversine" algorithm that is twice as fast as the GCDist function here. But it has a fatal flaw of sometimes returning NULL for the distance between a point and itself. (This is because of computing a number slightly bigger than 1.0, then trying to take the ACOS of it.)

3.3.3.12 Primary Keys with Nullable Columns

MariaDB deals with primary keys over nullable columns according to the SQL standards.

Take the following table structure:

```
CREATE TABLE t1(
  c1 INT NOT NULL AUTO_INCREMENT,
  c2 INT NULL DEFAULT NULL,
  PRIMARY KEY(c1,c2)
);
```

Column c2 is part of a primary key, and thus it cannot be NULL.

Before MariaDB 10.1.7, MariaDB (as well as versions of MySQL before MySQL 5.7) would silently convert it into a NOT NULL column with a default value of *0*.

Since MariaDB 10.1.7, the column is converted to NOT NULL, but without a default value. If we then attempt to insert a record without explicitly setting *c2*, a warning (or, in strict mode, an error), will be thrown, for example:

```
INSERT INTO t1() VALUES();
Query OK, 1 row affected, 1 warning (0.00 sec)
Warning (Code 1364): Field 'c2' doesn't have a default value

SELECT * FROM t1;
+----+----+
| c1 | c2 |
+----+----+
|  1 |  0 |
+----+----+
```

MySQL, since 5.7, will abort such a CREATE TABLE with an error.

The MariaDB 10.1.7 behavior adheres to the SQL 2003 standard.

SQL-2003, Part II, “Foundation” says:

11.7 <unique constraint definition>
Syntax Rules

…

5) If the <unique specification> specifies PRIMARY KEY, then for each <column name> in the explicit or implicit <unique column list> for which NOT NULL is not specified, NOT NULL is implicit in the <column definition>.

Essentially this means that all PRIMARY KEY columns are automatically converted to NOT NULL. Furthermore:

11.5 <default clause>
General Rules

…

3) When a site S is set to its default value,

…

b) If the data descriptor for the site includes a <default option>, then S is set to the value specified by that <default option>.

…

e) Otherwise, S is set to the null value.

There is no concept of “no default value” in the standard. Instead, a column always has an implicit default value of NULL. On insertion it might however fail the NOT NULL constraint. MariaDB and MySQL instead mark such a column as “not having a default value”. The end result is the same — a value must be specified explicitly or an INSERT will fail.

MariaDB since 10.1.7 behaves in a standard compatible manner — being part of a PRIMARY KEY, the nullable column gets an automatic NOT NULL constraint, on insertion one must specify a value for such a column. MariaDB before 10.1.7 was automatically assigning a default value of 0 — this behavior was non-standard. Issuing an error at CREATE TABLE time is also non-standard.

1.1.1.2.2.7 SHOW EXPLAIN

1.1.3.15 Spatial Index

3.3.3.15 Storage Engine Index Types

Contents

This refers to the index_type definition when creating an index, i.e. BTREE, HASH or RTREE.

For more information on general types of indexes, such as primary keys, unique indexes etc, go to Getting Started with Indexes.

Storage Engine	Permitted Indexes
Aria	BTREE, RTREE
MyISAM	BTREE, RTREE
InnoDB	BTREE
MEMORY/HEAP	HASH, BTREE

BTREE is generally the default index type. For MEMORY tables, HASH is the default. TokuDB uses a particular data structure called *fractal trees*, which is optimized for data that do not entirely fit memory.

Understanding the B-tree and hash data structures can help predict how different queries perform on different storage engines that use these data structures in their indexes, particularly for the MEMORY storage engine that lets you choose B-tree or hash indexes. B-Tree Index Characteristics

B-tree Indexes

B-tree indexes are used for column comparisons using the >, >=, =, >=, < or BETWEEN operators, as well as for LIKE comparisons that begin with a constant.

For example, the query `SELECT * FROM Employees WHERE First_Name LIKE 'Maria%';` can make use of a B-tree index, while `SELECT * FROM Employees WHERE First_Name LIKE '%aria';` cannot.

B-tree indexes also permit leftmost prefixing for searching of rows.

If the number or rows doesn't change, hash indexes occupy a fixed amount of memory, which is lower than the memory occupied by BTREE indexes.

Hash Indexes

Hash indexes, in contrast, can only be used for equality comparisons, so those using the = or <=> operators. They cannot be used for ordering, and provide no information to the optimizer on how many rows exist between two values.

Hash indexes do not permit leftmost prefixing - only the whole index can be used.

R-tree Indexes

See SPATIAL for more information.

3.3.4 Query Optimizations

Different query optimizations and how you can use and tune them to get better performance.

Index Hints: How to Force Query Plans

Using hints to get the optimizer to use another query plan.

Subquery Optimizations

Articles about subquery optimizations in MariaDB.

Optimization Strategies

Various optimization strategies used by the query optimizer.

Optimizations for Derived Tables

Optimizations for derived tables, or subqueries in the FROM clause

Table Elimination
Resolving queries without accessing some of the tables the query refers to

Statistics for Optimizing Queries
Different statistics provided by MariaDB to help you optimize your queries

Filesort with Small LIMIT Optimization
Filesort with small LIMIT optimization.

LIMIT ROWS EXAMINED
Means to terminate execution of SELECTs that examine too many rows.

index_merge sort_intersection
Operation to allow the use of index_merge in a broader number of cases.

MariaDB 5.3 Optimizer Debugging
MariaDB 5.3's optimizer debugging patch

optimizer_switch
Server variable for enabling specific optimizations.

How to Quickly Insert Data Into MariaDB
Techniques for inserting data quickly into MariaDB.

Index Condition Pushdown
Index Condition Pushdown optimization.

Query Limits and Timeouts
Different methods MariaDB provides to limit/timeout a query.

Aborting Statements that Exceed a Certain Time to Execute
Aborting statements that take longer than a certain time to execute.

Partition Pruning and Selection
Partition pruning is when the optimizer knows which partitions are relevant for the query.

Big DELETEs
How to DELETE lots of rows from a large table

Data Sampling: Techniques for Efficiently Finding a Random Row
Fetching random rows from a table (beyond ORDER BY RAND())

Creation and maintenance of summary tables

Data Warehousing Techniques
Improving performance for data-warehouse-like tables

Equality propagation optimization
Basic idea Consider a query with a WHERE clause: WHERE col1=col2 AND ... t...

FORCE INDEX
Similar to USE INDEX, but tells the optimizer to regard a table scan as very expensive.

Groupwise Max in MariaDB
Finding the largest row for each group.

GUID/UUID Performance
GUID/UUID performance (type 1 only).

hash_join_cardinality optimizer_switch Flag

MariaDB starting with <a href="#https://mariadb.com/kb/en/mariadb-10-6-13-release-notes/">10.6.13...

IGNORE INDEX

Tell the optimizer to not consider a particular index.

not_null_range_scan Optimization

Enables constructing range scans from NOT NULL conditions inferred from the WHERE clause.

Optimizing for "Latest News"-style Queries

Optimizing the schema and code for "Latest News"-style queries

Pagination Optimization

Pagination, not with OFFSET, LIMIT

Pivoting in MariaDB

Pivoting data so a linear list of values with two keys becomes a spreadsheet-like array.

Rollup Unique User Counts

Technique for counting unique users

Rowid Filtering Optimization

Rowid filtering is an optimization available from MariaDB 10.4.

Sargable UPPER

Starting from MariaDB 11.3, expressions in the form UPPER(key_col) = expr ...

USE INDEX

Find rows in the table using only one of the named indexes.

There are 2 related questions.

3.3.4.1 Index Hints: How to Force Query Plans

Contents

The optimizer is largely cost-based and will try to choose the optimal plan for any query. However in some cases it does not have enough information to choose a perfect plan and in these cases you may have to provide hints to force the optimizer to use another plan.

You can examine the query plan for a SELECT by writing EXPLAIN before the statement. SHOW EXPLAIN shows the output of a running query. In some cases, its output can be closer to reality than `EXPLAIN`.

For the following queries, we will use the world database for the examples.

Setting up the World Example Database

Download it from ftp://ftp.askmonty.org/public/world.sql.gz

Install it with:

```
mariadb-admin create world
zcat world.sql.gz | ../client/mysql world
```

or

```
mariadb-admin create world
gunzip world.sql.gz
../client/mysql world < world.sql
```

Forcing Join Order

You can force the join order by using STRAIGHT_JOIN either in the SELECT or JOIN part.

The simplest way to force the join order is to put the tables in the correct order in the `FROM` clause and use `SELECT STRAIGHT_JOIN` like so:

```
SELECT STRAIGHT_JOIN SUM(City.Population) FROM Country,City WHERE
City.CountryCode=Country.Code AND Country.HeadOfState="Volodymyr Zelenskyy";
```

If you only want to force the join order for a few tables, use `STRAIGHT_JOIN` in the `FROM` clause. When this is done, only tables connected with `STRAIGHT_JOIN` will have their order forced. For example:

```
SELECT SUM(City.Population) FROM Country STRAIGHT_JOIN City WHERE
City.CountryCode=Country.Code AND Country.HeadOfState="Volodymyr Zelenskyy";
```

In both of the above cases `Country` will be scanned first and for each matching country (one in this case) all rows in `City` will be checked for a match. As there is only one matching country this will be faster than the original query.

The output of EXPLAIN for the above cases is:

id	select_type	table	type	possible_keys	key	key_len	ref	rows	Extra
1	SIMPLE	Country	ALL	PRIMARY	NULL	NULL	NULL	239	Using where
1	SIMPLE	City	ALL	NULL	NULL	NULL	NULL	4079	Using where; Using join buffer (flat, BNL join)

This is one of the few cases where `ALL` is ok, as the scan of the `Country` table will only find one matching row.

Forcing Usage of a Specific Index for the WHERE Clause

In some cases the optimizer may choose a non-optimal index or it may choose to not use an index at all, even if some index could theoretically be used.

In these cases you have the option to either tell the optimizer to only use a limited set of indexes, ignore one or more indexes, or force the usage of some particular index.

USE INDEX: Use a Limited Set of Indexes

You can limit which indexes are considered with the USE INDEX option.

```
USE INDEX [{FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
```

The default is '`FOR JOIN`', which means that the hint only affects how the `WHERE` clause is optimized.

`USE INDEX` is used after the table name in the `FROM` clause.

Example:

```
CREATE INDEX Name ON City (Name);
CREATE INDEX CountryCode ON City (Countrycode);
EXPLAIN SELECT Name FROM City USE INDEX (CountryCode)
WHERE name="Helsingborg" AND countrycode="SWE";
```

This produces:

id	select_type	table	type	possible_keys	key	key_len	ref	rows	Extra
1	SIMPLE	City	ref	CountryCode	CountryCode	3	const	14	Using where

If we had not used USE INDEX, the `Name` index would have been in `possible keys`.

IGNORE INDEX: Don't Use a Particular Index

You can tell the optimizer to not consider some particular index with the IGNORE INDEX option.

```
IGNORE INDEX [{FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
```

This is used after the table name in the `FROM` clause:

```
CREATE INDEX Name ON City (Name);
CREATE INDEX CountryCode ON City (Countrycode);
EXPLAIN SELECT Name FROM City IGNORE INDEX (Name)
WHERE name="Helsingborg" AND countrycode="SWE";
```

This produces:

id	select_type	table	type	possible_keys	key	key_len	ref	rows	Extra
1	SIMPLE	City	ref	CountryCode	CountryCode	3	const	14	Using where

The benefit of using `IGNORE_INDEX` instead of `USE_INDEX` is that it will not disable a new index which you may add later.

Also see Ignored Indexes for an option to specify in the index definition that indexes should be ignored.

FORCE INDEX: Forcing an Index

Forcing an index to be used is mostly useful when the optimizer decides to do a table scan even if you know that using an index would be better. (The optimizer could decide to do a table scan even if there is an available index when it believes that most or all rows will match and it can avoid the overhead of using the index).

```
CREATE INDEX Name ON City (Name);
EXPLAIN SELECT Name,CountryCode FROM City FORCE INDEX (Name)
WHERE name>="A" and CountryCode >="A";
```

This produces:

id	select_type	table	type	possible_keys	key	key_len	ref	rows	Extra
1	SIMPLE	City	range	Name	Name	35	NULL	4079	Using where

`FORCE_INDEX` works by only considering the given indexes (like with `USE_INDEX`) but in addition it tells the optimizer to regard a table scan as something very expensive. However if none of the 'forced' indexes can be used, then a table scan will be used anyway.

Index Prefixes

When using index hints (USE, FORCE or IGNORE INDEX), the index name value can also be an unambiguous prefix of an index name.

Forcing an Index to be Used for ORDER BY or GROUP BY

The optimizer will try to use indexes to resolve ORDER BY and GROUP BY.

You can use USE INDEX, IGNORE INDEX and FORCE INDEX as in the `WHERE` clause above to ensure that some specific index used:

```
USE INDEX [{FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
```

This is used after the table name in the `FROM` clause.

Example:

```
CREATE INDEX Name ON City (Name);
EXPLAIN SELECT Name,Count(*) FROM City
FORCE INDEX FOR GROUP BY (Name)
WHERE population >= 10000000 GROUP BY Name;
```

This produces:

id	select_type	table	type	possible_keys	key	key_len	ref	rows	Extra
1	SIMPLE	City	index	NULL	Name	35	NULL	4079	Using where

Without the FORCE INDEX option we would have ' `Using where; Using temporary; Using filesort` ' in the 'Extra' column, which means that the optimizer would created a temporary table and sort it.

Help the Optimizer Optimize GROUP BY and ORDER BY

The optimizer uses several strategies to optimize GROUP BY and ORDER BY:

- Resolve with an index:
  - Scan the table in index order and output data as we go. (This only works if the ORDER BY / GROUP BY can be resolved by an index after constant propagation is done).
- Filesort:
  - Scan the table to be sorted and collect the sort keys in a temporary file.
  - Sort the keys + reference to row (with filesort)
  - Scan the table in sorted order
- Use a temporary table for ORDER BY:
  - Create a temporary (in memory) table for the 'to-be-sorted' data. (If this gets bigger than `max_heap_table_size` or contains blobs then an Aria or MyISAM disk based table will be used)
  - Sort the keys + reference to row (with filesort)
  - Scan the table in sorted order

A temporary table will always be used if the fields which will be sorted are not from the first table in the JOIN order.

- Use a temporary table for GROUP BY:
  - Create a temporary table to hold the GROUP BY result with an index that matches the GROUP BY fields.
  - Produce a result row
  - If a row with the GROUP BY key exists in the temporary table, add the new result row to it. If not, create a new row.
  - Before sending the results to the user, sort the rows with filesort to get the results in the GROUP BY order.

Forcing/Disallowing TemporaryTables to be Used for GROUP BY:

Using an in-memory table (as described above) is usually the fastest option for GROUP BY if the result set is small. It is not optimal if the result set is very big. You can tell the optimizer this by using `SELECT SQL_SMALL_RESULT` or `SELECT SQL_BIG_RESULT`.

For example:

```
EXPLAIN SELECT SQL_SMALL_RESULT Name,Count(*) AS Cities FROM City GROUP BY Name HAVING Cities > 2
```

produces:

id	select_type	table	type	possible_keys	key	key_len	ref	rows	Extra
1	SIMPLE	City	ALL	NULL	NULL	NULL	NULL	4079	Using temporary; Using filesort

while:

```
EXPLAIN SELECT SQL_BIG_RESULT Name,Count(*) AS Cities FROM City
GROUP BY Name HAVING Cities > 2;
```

produces:

id	select_type	table	type	possible_keys	key	key_len	ref	rows	Extra

1	SIMPLE	City	ALL	NULL	NULL	NULL	NULL	4079	Using filesort

The difference is that with `SQL_SMALL_RESULT` a temporary table is used.

Forcing Usage of Temporary Tables

In some cases you may want to force the use of a temporary table for the result to free up the table/row locks for the used tables as quickly as possible.

You can do this with the `SQL_BUFFER_RESULT` option:

```
CREATE INDEX Name ON City (Name);
EXPLAIN SELECT SQL_BUFFER_RESULT Name,Count(*) AS Cities FROM City
GROUP BY Name HAVING Cities > 2;
```

This produces:

id	select_type	table	type	possible_keys	key	key_len	ref	rows	Extra
1	SIMPLE	City	index	NULL	Name	35	NULL	4079	Using index; Using temporary

Without `SQL_BUFFER_RESULT`, the above query would not use a temporary table for the result set.

Optimizer Switch

In MariaDB 5.3 we added an optimizer switch which allows you to specify which algorithms will be considered when optimizing a query.

See the optimizer section for more information about the different algorithms which are used.

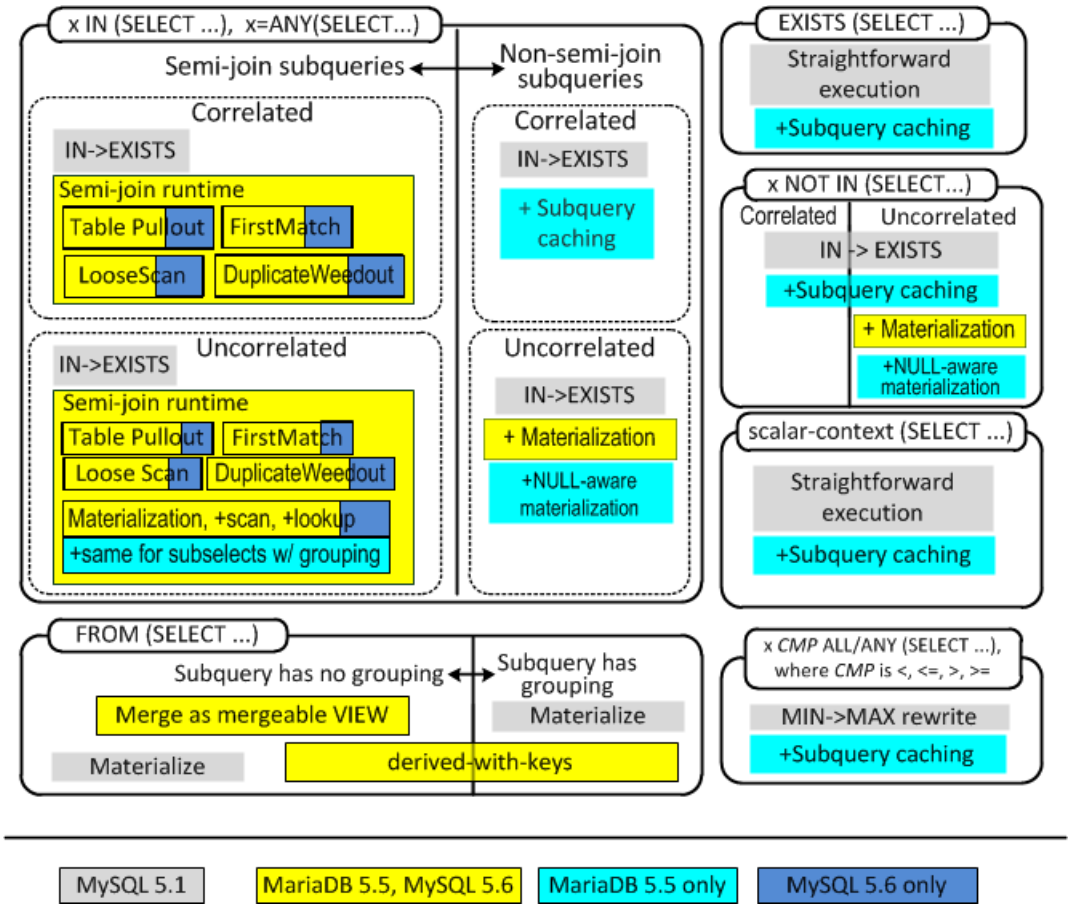
Optimizing GROUP BY and DISTINCT Clauses in Subqueries
MariaDB removes DISTINCT and GROUP BY without HAVING in certain cases

3.3.4.2.1 Subquery Optimizations Map

Below is a map showing all types of subqueries allowed in the SQL language, and the optimizer strategies available to handle them.

- Uncolored areas represent different kinds of subqueries, for example:
  - Subqueries that have form `x IN (SELECT ...)`
  - Subqueries that are in the `FROM` clause
  - .. and so forth
- The size of each uncolored area roughly corresponds to how important (i.e. frequently used) that kind of subquery is. For example, `x IN (SELECT ...)` queries are the most important, and `EXISTS (SELECT ...)` are relatively unimportant.
- Colored areas represent optimizations/execution strategies that are applied to handle various kinds of subqueries.
- The color of optimization indicates which version of MySQL/MariaDB it was available in (see legend below)



Some things are not on the map:

- MariaDB doesn't evaluate expensive subqueries when doing optimization (this means, EXPLAIN is always fast). MySQL 5.6 has made a progress in this regard but its optimizer will still evaluate certain kinds of subqueries (for example, scalar-context subqueries used in range predicates)

- Non-semi-join Materialization (including NULL-aware and partial matching)
- Derived table optimizations
  - Derived table merge
  - Derived table with keys

3.3.4.2.2 Semi-join Subquery Optimizations

Contents

MariaDB has a set of optimizations specifically targeted at *semi-join subqueries*.

What is a Semi-Join Subquery

A semi-join subquery has a form of

```
SELECT ... FROM outer_tables WHERE expr IN (SELECT ... FROM inner_tables ...) AND ...
```

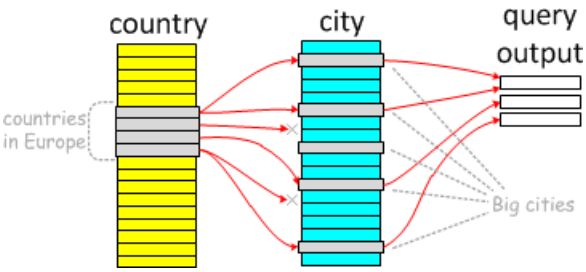
that is, the subquery is an IN-subquery and it is located in the WHERE clause. The most important part here is

with semi-join subquery, we're only interested in records of outer_tables that have matches in the subquery

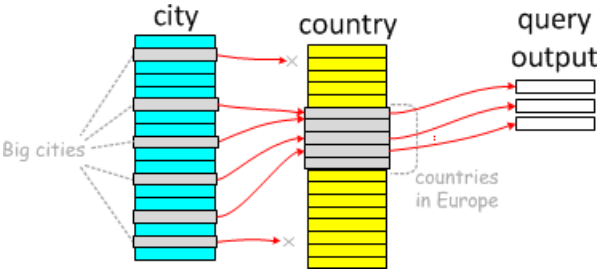
Let's see why this is important. Consider a semi-join subquery:

```
select * from Country
where
  Continent='Europe' and
  Country.Code in (select City.country
                   from City
                   where City.Population>1*1000*1000);
```

One can execute it "naturally", by starting from countries in Europe and checking if they have populous Cities:



The semi-join property also allows "backwards" execution: we can start from big cities, and check which countries they are in:

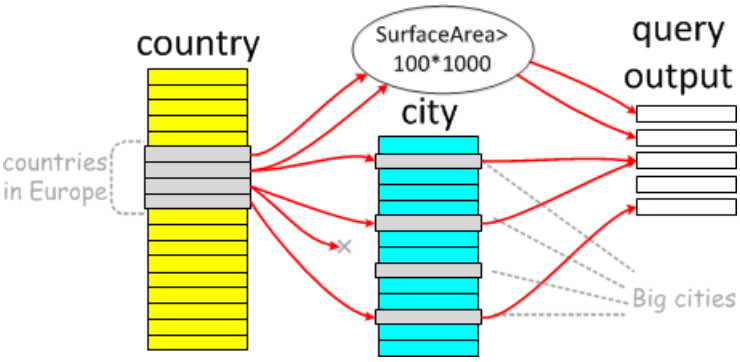


To contrast, let's change the subquery to be non-semi-join:

```
select * from Country
where
   Country.Continent='Europe' and
   (Country.Code in (select City.country
                     from City where City.Population>1*1000*1000)
    or Country.SurfaceArea > 100*1000  -- Added this part
   );
```

It is still possible to start from countries, and then check

- if a country has any big cities
- if it has a large surface area:



The opposite, city-to-country way is not possible. This is not a semi-join.

Difference from Inner Joins

Semi-join operations are similar to regular relational joins. There is a difference though: with semi-joins, you don't care how many matches an inner table has for an outer row. In the above countries-with-big-cities example, Germany will be returned once, even if it has three cities with populations of more than one million each.

Semi-Join Optimizations in MariaDB

MariaDB uses semi-join optimizations to run IN subqueries.The optimizations are enabled by default. You can disable them by turning off their optimizer_switch like so:

```
SET optimizer_switch='semijoin=off'
```

MariaDB has five different semi-join execution strategies:

- Table pullout optimization
- FirstMatch execution strategy
- Semi-join Materialization execution strategy
- LooseScan execution strategy
- DuplicateWeedout execution strategy

3.3.4.2.3 Table Pullout Optimization

Contents

Table pullout is an optimization for Semi-join subqueries.

The idea of Table Pullout

Sometimes, a subquery can be re-written as a join. For example:

```
select *
from City
where City.Country in (select Country.Code
                       from Country
                       where Country.Population < 100*1000);
```

If we know that there can be, at most, one country with with a given value of `Country.Code` (we can tell that if we see that table Country has a primary key or unique index over that column), we can re-write this query as:

```
select City.*
from
  City, Country
where
 City.Country=Country.Code AND Country.Population < 100*1000;
```

Table pullout in action

If one runs EXPLAIN for the above query in MySQL 5.1-5.6 or MariaDB 5.1-5.2, they'll get this plan:

```
MySQL [world]> explain select * from City where City.Country in (select Country.Code from
Country where Country.Population < 100*1000);
+----+--------------------+---------+----------------+-------------------+---------+-------
--+------+-------------+
| id | select_type        | table   | type           | possible_keys     | key     | key_len
| ref  | rows | Extra       |
+----+--------------------+---------+----------------+-------------------+---------+-------
--+------+-------------+
|  1 | PRIMARY            | City    | ALL            | NULL              | NULL    | NULL
| NULL | 4079 | Using where |
|  2 | DEPENDENT SUBQUERY | Country | unique_subquery | PRIMARY,Population | PRIMARY | 3
| func |    1 | Using where |
+----+--------------------+---------+----------------+-------------------+---------+-------
--+------+-------------+
2 rows in set (0.00 sec)
```

It shows that the optimizer is going to do a full scan on table `City`, and for each city it will do a lookup in table `Country`.

If one runs the same query in MariaDB 5.3, they will get this plan:

```
MariaDB [world]> explain select * from City where City.Country in (select Country.Code from
Country where Country.Population < 100*1000);
+----+-------------+---------+-------+-------------------+------------+---------+-----------
---------+------+-----------------------+
| id | select_type | table   | type  | possible_keys     | key        | key_len | ref
| rows | Extra                 |
+----+-------------+---------+-------+-------------------+------------+---------+-----------
---------+------+-----------------------+
|  1 | PRIMARY     | Country | range | PRIMARY,Population | Population | 4       | NULL
|   37 | Using index condition |
|  1 | PRIMARY     | City    | ref   | Country           | Country    | 3       |
world.Country.Code |   18 |                       |
+----+-------------+---------+-------+-------------------+------------+---------+-----------
---------+------+-----------------------+
2 rows in set (0.00 sec)
```

The interesting parts are:

- Both tables have `select_type=PRIMARY`, and `id=1` as if they were in one join.
- The `Country` table is first, followed by the `City` table.

Indeed, if one runs EXPLAIN EXTENDED; SHOW WARNINGS, they will see that the subquery is gone and it was replaced with a join:

```
MariaDB [world]> show warnings\G
*************************** 1. row ***************************
  Level: Note
   Code: 1003
Message: select `world`.`City`.`ID` AS `ID`,`world`.`City`.`Name` AS
`Name`,`world`.`City`.`Country` AS `Country`,`world`.`City`.`Population` AS
`Population`

   from `world`.`City` join `world`.`Country` where

((`world`.`City`.`Country` = `world`.`Country`.`Code`) and (`world`.`Country`.
`Population` < (100 * 1000)))
1 row in set (0.00 sec)
```

Changing the subquery into a join allows feeding the join to the join optimizer, which can make a choice between two possible join orders:

1. City -> Country
2. Country -> City

as opposed to the single choice of

1. City->Country

which we had before the optimization.

In the above example, the choice produces a better query plan. Without pullout, the query plan with a subquery would read `(4079 + 1*4079)=8158` table records. With table pullout, the join plan would read `(37 + 37 * 18) = 703` rows. Not all row reads are equal, but generally, reading `10` times fewer table records is faster.

Table pullout fact sheet

- Table pullout is possible only in semi-join subqueries.
- Table pullout is based on `UNIQUE` / `PRIMARY` key definitions.
- Doing table pullout does not cut off any possible query plans, so MariaDB will always try to pull out as much as possible.
- Table pullout is able to pull individual tables out of subqueries to their parent selects. If all tables in a subquery have been pulled out, the subquery (i.e. its semi-join) is removed completely.
- One common bit of advice for optimizing MySQL has been "If possible, rewrite your subqueries as joins". Table pullout does exactly that, so manual rewrites are no longer necessary.

Controlling table pullout

There is no separate @@optimizer_switch flag for table pullout. Table pullout can be disabled by switching off all semi-join optimizations with `SET @@optimizer_switch='semijoin=off'` command.

3.3.4.2.4 Non-semi-join Subquery Optimizations

Contents

Certain kinds of IN-subqueries cannot be flattened into semi-joins. These subqueries can be both correlated or non-correlated. In order to provide consistent performance in all cases, MariaDB provides several alternative strategies for these types of subqueries. Whenever several strategies are possible, the optimizer chooses the optimal one based on cost estimates.

The two primary non-semi-join strategies are materialization (also called outside-in materialization), and in-to-exists transformation. Materialization is applicable only for non-correlated subqueries, while in-to-exist can be used both for correlated and non-correlated subqueries.

Applicability

An IN subquery cannot be flattened into a semi-join in the following cases. The examples below use the *World* database from the MariaDB regression test suite.

Subquery in a disjunction (OR)

The subquery is located directly or indirectly under an OR operation in the WHERE clause of the outer query.

Query pattern:

```
SELECT ... FROM ... WHERE (expr1, ..., exprN) [NOT] IN (SELECT ... ) OR expr;
```

Example:

```
SELECT Name FROM Country
WHERE (Code IN (select Country from City where City.Population > 100000) OR
       Name LIKE 'L%') AND
      surfacearea > 1000000;
```

Negated subquery predicate (NOT IN)

The subquery predicate itself is negated.

Query pattern:

```
SELECT ... FROM ... WHERE ... (expr1, ..., exprN) NOT IN (SELECT ... ) ...;
```

Example:

```
SELECT Country.Name
FROM Country, CountryLanguage
WHERE Code NOT IN (SELECT Country FROM CountryLanguage WHERE Language = 'English')
  AND CountryLanguage.Language = 'French'
  AND Code = Country;
```

Subquery in the SELECT or HAVING clause

The subquery is located in the SELECT or HAVING clauses of the outer query.

Query pattern:

```
SELECT field1, ..., (SELECT ...)  WHERE ...;
SELECT ...  WHERE ... HAVING (SELECT ...);
```

Example:

```
select Name, City.id in (select capital from Country where capital is not null) as is_capital
from City
where City.population > 10000000;
```

Subquery with a UNION

The subquery itself is a UNION, while the IN predicate may be anywhere in the query where IN is allowed.

Query pattern:

```
... [NOT] IN (SELECT ... UNION SELECT ...)
```

Example:

```
SELECT * from City where (Name, 91) IN
(SELECT Name, round(Population/1000) FROM City WHERE Country = "IND" AND Population > 2500000
UNION
 SELECT Name, round(Population/1000) FROM City WHERE Country = "IND" AND Population < 100000);
```

Materialization for non-correlated IN-subqueries

Materialization basics

The basic idea of subquery materialization is to execute the subquery and store its result in an internal temporary table indexed on all its columns. Naturally, this is possible only when the subquery is non-correlated. The IN predicate tests whether its left operand is present in the subquery result. Therefore it is not necessary to store duplicate subquery result rows in the temporary table. Storing only unique subquery rows provides two benefits - the size of the temporary table is smaller, and the index on all its columns can be unique.

If the size of the temporary table is less than the tmp_table_size system variable, the table is a hash-indexed in-memory HEAP table. In the rare cases when the subquery result exceeds this limit, the temporary table is stored on disk in an ARIA

or MyISAM B-tree indexed table (ARIA is the default).

Subquery materialization happens on demand during the first execution of the IN predicate. Once the subquery is materialized, the IN predicate is evaluated very efficiently by index lookups of the outer expression into the unique index of the materialized temporary table. If there is a match, IN is TRUE, otherwise IN is FALSE.

NULL-aware efficient execution

An IN predicate may produce a NULL result if there is a NULL value in either of its arguments. Depending on its location in a query, a NULL predicate value is equivalent to FALSE. These are the cases when substituting NULL with FALSE would reject exactly the same result rows. A NULL result of IN is indistinguishable from a FALSE if the IN predicate is:

- not negated,
- not a function argument,
- inside a WHERE or ON clause.

In all these cases the evaluation of IN is performed as described in the previous paragraph via index lookups into the materialized subquery. In all remaining cases when NULL cannot be substituted with FALSE, it is not possible to use index lookups. This is not a limitation in the server, but a consequence of the NULL semantics in the ANSI SQL standard.

Suppose an IN predicate is evaluated as

```
NULL IN (select
not_null_col from t1)
```

, that is, the left operand of IN is a NULL value, and there are no NULLs in the subquery. In this case the value of IN is neither FALSE, nor TRUE. Instead it is NULL. If we were to perform an index lookup with the NULL as a key, such a value would not be found in not_null_col, and the IN predicate would incorrectly produce a FALSE.

In general, an NULL value on either side of an IN acts as a "wildcard" that matches any value, and if a match exists, the result of IN is NULL. Consider the following example:

If the left argument of IN is the row: `(7, NULL, 9)`
, and the result of the right subquery operand of IN is the table:

```
(7, 8, 10)
(6, NULL, NULL)
(7, 11, 9)
```

The the IN predicate matches the row `(7, 11, 9)`
, and the result of IN is NULL. Matches where the differing values on either side of the IN arguments are matched by a NULL in the other IN argument, are called *partial matches*.

In order to efficiently compute the result of an IN predicate in the presence of NULLs, MariaDB implements two special algorithms for partial matching, described here in detail.

- Rowid-merge partial matching
  This technique is used when the number of rows in the subquery result is above a certain limit. The technique creates special indexes on some of the columns of the temporary table, and merges them by alternative scanning of each index thus performing an operation similar to set-intersection.
- Table scan partial matching
  This algorithm is used for very small tables when the overhead of the rowid-merge algorithm is not justifiable. Then the server simply scans the materialized subquery, and checks for partial matches. Since this strategy doesn't need any in-memory buffers, it is also used when there is not enough memory to hold the indexes of the rowid-merge strategy.

Limitations

In principle the subquery materialization strategy is universal, however, due to some technical limitations in the MariaDB server, there are few cases when the server cannot apply this optimization.

- BLOB fields
  Either the left operand of an IN predicate refers to a BLOB field, or the subquery selects one or more BLOBs.
- Incomparable fields
  TODO

In the above cases, the server reverts to the IN-TO-EXISTS transformation.

The IN-TO-EXISTS transformation

This optimization is the only subquery execution strategy that existed in older versions of MariaDB and MySQL prior to MariaDB 5.3. We have made various changes and fixed a number of bugs in this code as well, but in essence it remains the same.

Performance discussion

Example speedup over MySQL 5.x and MariaDB 5.1/5.2

Depending on the query and data, either of the two strategies described here may result in orders of magnitude better/worse plan than the other strategy.

Older versions of MariaDB and any current MySQL version (including MySQL 5.5, and MySQL 5.6 DMR as of July 2011) implement only the IN-TO-EXISTS transformation. As illustrated below, this strategy is inferior in many common cases to subquery materialization.

Consider the following query over the data of the DBT3 benchmark scale 10. Find customers with top balance in their nations:

```
SELECT * FROM part
WHERE p_partkey IN
      (SELECT l_partkey FROM lineitem
       WHERE l_shipdate between '1997-01-01' and '1997-02-01')
ORDER BY p_retailprice DESC LIMIT 10;
```

The times to run this query is as follows:

- Execution time in MariaDB 5.2/MySQL 5.x (any MySQL): **> 1 h**
  The query takes more than one hour (we didn't wait longer), which makes it impractical to use subqueries in such cases. The EXPLAIN below shows that the subquery was transformed into a correlated one, which indicates an IN-TO-EXISTS transformation.

```
+--+------------------+--------+--------------+------------------+----+------+--------------
-------------+
|id|select_type       |table   |type          |key               |ref |rows  |Extra
|
+--+------------------+--------+--------------+------------------+----+------+--------------
-------------+
| 1|PRIMARY           |part    |ALL           |NULL              |NULL|199755|Using where;
Using filesort|
| 2|DEPENDENT SUBQUERY|lineitem|index_subquery|i_l_suppkey_partkey|func|    14|Using where
|
+--+------------------+--------+--------------+------------------+----+------+--------------
-------------+
```

- Execution time in MariaDB 5.3: **43 sec**
  In MariaDB 5.3 it takes less than a minute to run the same query. The EXPLAIN shows that the subquery remains uncorrelated, which is an indication that it is being executed via subquery materialization.

```
+--+------------+-----------+------+------------------+----+------+------------------------------
|id|select_type |table      |type  |key               |ref |rows  |Extra
+--+------------+-----------+------+------------------+----+------+------------------------------
| 1|PRIMARY     |part       |ALL   |NULL              |NULL|199755|Using temporary; Using filesor
| 1|PRIMARY     |<subquery2>|eq_ref|distinct_key      |func|     1|
| 2|MATERIALIZED|lineitem   |range |l_shipdate_partkey|NULL|160060|Using where; Using index
+--+------------+-----------+------+------------------+----+------+------------------------------
```

The speedup here is practically infinite, because both MySQL and older MariaDB versions cannot complete the query in any reasonable time.

In order to show the benefits of partial matching we extended the *customer* table from the DBT3 benchmark with two extra columns:

- c_pref_nationkey - preferred nation to buy from,
- c_pref_brand - preferred brand.

Both columns are prefixed with the percent NULL values in the column, that is, c_pref_nationkey_05 contains 5% NULL

values.

Consider the query "Find all customers that didn't buy from a preferred country, and from a preferred brand withing some date ranges":

```
SELECT count(*)
FROM customer
WHERE (c_custkey, c_pref_nationkey_05, c_pref_brand_05) NOT IN
  (SELECT o_custkey, s_nationkey, p_brand
   FROM orders, supplier, part, lineitem
   WHERE l_orderkey = o_orderkey and
         l_suppkey = s_suppkey and
         l_partkey = p_partkey and
         p_retailprice < 1200 and
         l_shipdate >= '1996-04-01' and l_shipdate < '1996-04-05' and
         o_orderdate >= '1996-04-01' and o_orderdate < '1996-04-05');
```

- Execution time in MariaDB 5.2/MySQL 5.x (any MySQL): **40 sec**
- Execution time in MariaDB 5.3: **2 sec**

The speedup for this query is 20 times.

Performance guidelines

TODO

Optimizer control

In certain cases it may be necessary to override the choice of the optimizer. Typically this is needed for benchmarking or testing purposes, or to mimic the behavior of an older version of the server, or if the optimizer made a poor choice.

All the above strategies can be controlled via the following switches in optimizer_switch system variable.

- materialization=on/off
  In some very special cases, even if materialization was forced, the optimizer may still revert to the IN-TO-EXISTS strategy if materialization is not applicable. In the cases when materialization requres partial matching (because of the presense of NULL values), there are two subordinate switches that control the two partial matching strategies:
  - partial_match_rowid_merge=on/off
    This switch controls the Rowid-merge strategy. In addition to this switch, the system variable rowid_merge_buff_size controls the maximum memory available to the Rowid-merge strategy.
  - partial_match_table_scan=on/off
    Controls the alternative partial match strategy that performs matching via a table scan.
- in_to_exists=on/off
  This switch controls the IN-TO-EXISTS transformation.
- tmp_table_size and max_heap_table_size system variables
  The *tmp_table_size* system variable sets the upper limit for internal MEMORY temporary tables. If an internal temporary table exceeds this size, it is converted automatically into a Aria or MyISAM table on disk with a B-tree index. Notice however, that a MEMORY table cannot be larger than *max_heap_table_size*.

The two main optimizer switches - *materialization* and *in_to_exists* cannot be simultaneously off. If both are set to off, the server will issue an error.

3.3.4.2.5 Subquery Cache

Contents

The goal of the subquery cache is to optimize the evaluation of correlated subqueries by storing results together with correlation parameters in a cache and avoiding re-execution of the subquery in cases where the result is already in the cache.

Administration

The cache is on by default. One can switch it off using the optimizer_switch `subquery_cache` setting, like so:

```
SET optimizer_switch='subquery_cache=off';
```

The efficiency of the subquery cache is visible in 2 statistical variables:

- Subquery_cache_hit - Global counter for all subquery cache hits.
- Subquery_cache_miss - Global counter for all subquery cache misses.

The session variables tmp_table_size and max_heap_table_size influence the size of in-memory temporary tables in the table used for caching. It cannot grow more than the minimum of the above variables values (see the Implementation section for details).

Visibility

Your usage of the cache is visible in `EXTENDED EXPLAIN` output (warnings) as `"<expr_cache><//list of parameters//>(//cached expression//)"`. For example:

```
EXPLAIN EXTENDED SELECT * FROM t1 WHERE a IN (SELECT b FROM t2);
+----+--------------------+-------+------+---------------+------+---------+------+------+----
------+-------------+
| id | select_type        | table | type | possible_keys | key  | key_len | ref  | rows |
filtered | Extra       |
+----+--------------------+-------+------+---------------+------+---------+------+------+----
------+-------------+
|  1 | PRIMARY            | t1    | ALL  | NULL          | NULL | NULL    | NULL |    2 |
100.00 | Using where |
|  2 | DEPENDENT SUBQUERY | t2    | ALL  | NULL          | NULL | NULL    | NULL |    2 |
100.00 | Using where |
+----+--------------------+-------+------+---------------+------+---------+------+------+----
------+-------------+
2 rows in set, 1 warning (0.00 sec)

SHOW WARNINGS;
+-------+------+-----------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------
---------------------------------+
| Level | Code | Message
|
+-------+------+-----------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------
---------------------------------+
| Note  | 1003 | SELECT `test`.`t1`.`a` AS `a` from `test`.`t1` WHERE <expr_cache>
<`test`.`t1`.`a`>(<in_optimizer>(`test`.`t1`.`a`,<exists>(SELECT 1 FROM `test`.`t2` WHERE
(<cache>(`test`.`t1`.`a`) = `test`.`t2`.`b`))) |
+-------+------+-----------------------------------------------------------------------------------
-----------------------------------------------------------------------------------------------
---------------------------------+
1 row in set (0.00 sec)
```

In the example above the presence of `"<expr_cache><`test`.`t1`.`a`>(...)"` is how you know you are using the subquery cache.

Implementation

Every subquery cache creates a temporary table where the results and all parameters are stored. It has a unique index over all parameters. First the cache is created in a MEMORY table (if doing this is impossible the cache becomes disabled for that expression). When the table grows up to the minimum of `tmp_table_size` and `max_heap_table_size`, the hit rate will be checked:

- if the hit rate is really small (<0.2) the cache will be disabled.
- if the hit rate is moderate (<0.7) the table will be cleaned (all records deleted) to keep the table in memory
- if the hit rate is high the table will be converted to a disk table (for 5.3.0 it can only be converted to a disk table).

```
hit rate = hit / (hit + miss)
```

Performance Impact

Here are some examples that show the performance impact of the subquery cache (these tests were made on a 2.53 GHz Intel Core 2 Duo MacBook Pro with dbt-3 scale 1 data set).

example	cache on	cache off	gain	hit	miss	hit rate
1	1.01sec	1 hour 31 min 43.33sec	5445x	149975	25	99.98%
2	0.21sec	1.41sec	6.71x	6285	220	96.6%
3	2.54sec	2.55sec	1.00044x	151	461	24.67%
4	1.87sec	1.95sec	0.96x	0	23026	0%

Example 1

Dataset from DBT-3 benchmark, a query to find customers with balance near top in their nation:

```
select count(*) from customer
where
   c_acctbal > 0.8 * (select max(c_acctbal)
                      from customer C
                      where C.c_nationkey=customer.c_nationkey
                      group by c_nationkey);
```

Example 2

DBT-3 benchmark, Query #17

```
select sum(l_extendedprice) / 7.0 as avg_yearly
from lineitem, part
where
  p_partkey = l_partkey and
  p_brand = 'Brand#42' and p_container = 'JUMBO BAG' and
  l_quantity < (select 0.2 * avg(l_quantity) from lineitem
                where l_partkey = p_partkey);
```

Example 3

DBT-3 benchmark, Query #2

```
select
        s_acctbal, s_name, n_name, p_partkey, p_mfgr, s_address, s_phone, s_comment
from
        part, supplier, partsupp, nation, region
where
        p_partkey = ps_partkey and s_suppkey = ps_suppkey and p_size = 33
        and p_type like '%STEEL' and s_nationkey = n_nationkey
        and n_regionkey = r_regionkey and r_name = 'MIDDLE EAST'
        and ps_supplycost = (
                select
                        min(ps_supplycost)
                from
                        partsupp, supplier, nation, region
                where
                        p_partkey = ps_partkey and s_suppkey = ps_suppkey
                        and s_nationkey = n_nationkey and n_regionkey = r_regionkey
                        and r_name = 'MIDDLE EAST'
        )
order by
        s_acctbal desc, n_name, s_name, p_partkey;
```

Example 4

DBT-3 benchmark, Query #20

```
select
        s_name, s_address
from
        supplier, nation
where
        s_suppkey in (
                select
                        distinct (ps_suppkey)
                from
                        partsupp, part
                where
                        ps_partkey=p_partkey
                        and p_name like 'indian%'
                        and ps_availqty > (
                                select
                                        0.5 * sum(l_quantity)
                                from
                                        lineitem
                                where
                                        l_partkey = ps_partkey
                                        and l_suppkey = ps_suppkey
                                        and l_shipdate >= '1995-01-01'
                                        and l_shipdate < date_ADD('1995-01-01',interval 1 year)
                                )
        )
        and s_nationkey = n_nationkey and n_name = 'JAPAN'
order by
        s_name;
```

3.3.4.2.6 Condition Pushdown Into IN subqueries

This article describes Condition Pushdown into IN subqueries as implemented in MDEV-12387.

optimizer_switch flag name: `condition_pushdown_for_subquery`.

3.3.4.2.7 Conversion of Big IN Predicates Into Subqueries

Starting from MariaDB 10.3, the optimizer converts certain big IN predicates into IN subqueries.

That is, an IN predicate in the form

```
column [NOT] IN (const1, const2, .... )
```

is converted into an equivalent IN-subquery:

```
column [NOT] IN (select ... from temporary_table)
```

which opens new opportunities for the query optimizer.

The conversion happens if the following conditions are met:

- the IN list has more than 1000 elements (One can control it through the in_predicate_conversion_threshold parameter).
- the [NOT] IN condition is at the top level of the WHERE/ON clause.

Controlling the Optimization

- The optimization is on by default. MariaDB 10.3.18 (and debug builds prior to that) introduced the in_predicate_conversion_threshold variable. Set to `0` to disable the optimization.

Benefits of the Optimization

If `column` is a key-prefix, MariaDB optimizer will process the condition

```
column [NOT] IN (const1, const2, .... )
```

by trying to construct a range access. If the list is large, the analysis may take a lot of memory and CPU time. The problem gets worse when `column` is a part of a multi-column index and the query has conditions on other parts of the index.

Conversion of IN predicates into a subqueries bypass the range analysis, which means the query optimization phase will use less CPU and memory.

Possible disadvantages of the conversion are are:

- The optimization may convert 'IN LIST elements' key accesses to a table scan (if there is no other usable index for the table)
- The estimates for the number of rows matching the `IN (...)` are less precise.

3.3.4.2.8 EXISTS-to-IN Optimization

Contents

MySQL (including MySQL 5.6) has only one execution strategy for EXISTS subqueries. The strategy is essentially the straightforward, "naive" execution, without any rewrites.

MariaDB 5.3 introduced a rich set of optimizations for IN subqueries. Since then, it makes sense to convert an EXISTS subquery into an IN so that the new optimizations can be used.

`EXISTS` will be converted into `IN` in two cases:

1. Trivially correlated EXISTS subqueries
2. Semi-join EXISTS

We will now describe these two cases in detail

Trivially-correlated EXISTS subqueries

Often, EXISTS subquery is correlated, but the correlation is trivial. The subquery has form

```
EXISTS (SELECT ...  FROM ... WHERE outer_col= inner_col AND inner_where)
```

and "outer_col" is the only place where the subquery refers to outside fields. In this case, the subquery can be re-written into uncorrelated IN:

```
outer_col IN (SELECT inner_col FROM ... WHERE inner_where)
```

(`NULL` values require some special handling, see below). For uncorrelated IN subqueries, MariaDB is able a cost-based choice between two execution strategies:

- IN-to-EXISTS (basically, convert back into EXISTS)
- Materialization

That is, converting trivially-correlated `EXISTS` into uncorrelated `IN` gives query optimizer an option to use Materialization strategy for the subquery.

Currently, EXISTS->IN conversion works only for subqueries that are at top level of the WHERE clause, or are under NOT operation which is directly at top level of the WHERE clause.

Semi-join EXISTS subqueries

If `EXISTS` subquery is an AND-part of the `WHERE` clause:

```
SELECT ... FROM outer_tables WHERE EXISTS (SELECT ...) AND ...
```

then it satisfies the main property of semi-join subqueries:

with semi-join subquery, we're only interested in records of outer_tables that have matches in the subquery

Semi-join optimizer offers a rich set of execution strategies for both correlated and uncorrelated subqueries. The set includes FirstMatch strategy which is an equivalent of how EXISTS suqueries are executed, so we do not lose any opportunities when converting an EXISTS subquery into a semi-join.

In theory, it makes sense to convert all kinds of EXISTS subqueries: convert both correlated and uncorrelated ones, convert irrespectively of whether the subquery has inner=outer equality.

In practice, the subquery will be converted only if it has inner=outer equality. Both correlated and uncorrelated subqueries are converted.

Handling of NULL values

TODO: rephrase this:

- IN has complicated NULL-semantics. NOT EXISTS doesn't.
- EXISTS-to-IN adds IS NOT NULL before the subquery predicate, when required

Control

The optimization is controlled by the `exists_to_in` flag in optimizer_switch. Before MariaDB 10.0.12, the optimization was OFF by default. Since MariaDB 10.0.12, it has been ON by default.

Limitations

EXISTS-to-IN doesn't handle

- subqueries that have GROUP BY, aggregate functions, or HAVING clause
- subqueries are UNIONs
- a number of degenerate edge cases

3.3.4.2.9 Optimizing GROUP BY and DISTINCT Clauses in Subqueries

A DISTINCT clause and a GROUP BY without a corresponding HAVING clause have no meaning in IN/ALL/ANY/SOME/EXISTS subqueries. The reason is that IN/ALL/ANY/SOME/EXISTS only check if an outer row satisfies some condition with respect to all or any row in the subquery result. Therefore is doesn't matter if the subquery has duplicate result rows or not - if some condition is true for some row of the subquery, this condition will be true for all duplicates of this row. Notice that GROUP BY without a corresponding HAVING clause is equivalent to a DISTINCT.

MariaDB 5.3 and later versions automatically remove DISTINCT and GROUP BY without HAVING if these clauses appear in an IN/ALL/ANY/SOME/EXISTS subquery. For instance:

```
select * from t1
where t1.a > ALL(select distinct b from t2 where t2.c > 100)
```

is transformed to:

```
select * from t1
where t1.a > ALL(select b from t2 where t2.c > 100)
```

Removing these unnecessary clauses allows the optimizer to find more efficient query plans because it doesn't need to take care of post-processing the subquery result to satisfy DISTINCT / GROUP BY.

3.3.4.3 Optimization Strategies

Various optimization strategies used by the query optimizer.

DuplicateWeedout Strategy

DuplicateWeedout is an execution strategy for Semi-join subqueries.

FirstMatch Strategy
FirstMatch is an execution strategy for Semi-join subqueries

LooseScan Strategy
LooseScan is an execution strategy for Semi-join subqueries

Semi-join Materialization Strategy
Semi-join Materialization is a subquery materialization used for Semi-join subqueries.

Improvements to ORDER BY Optimization
Several Improvements to the ORDER BY Optimizer in Version 10.1 of MariaDB.

3.3.4.3.1 DuplicateWeedout Strategy

`DuplicateWeedout` is an execution strategy for Semi-join subqueries.

Contents

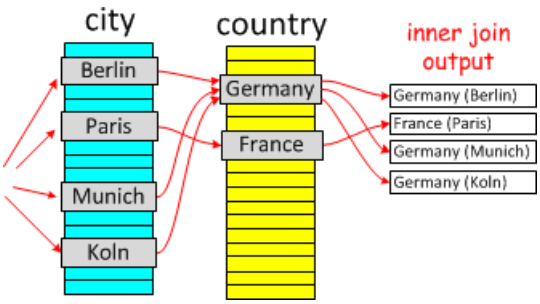
The idea

The idea is to run the semi-join (a query with uses `WHERE X IN (SELECT Y FROM ...)`) as if it were a regular inner join, and then eliminate the duplicate record combinations using a temporary table.

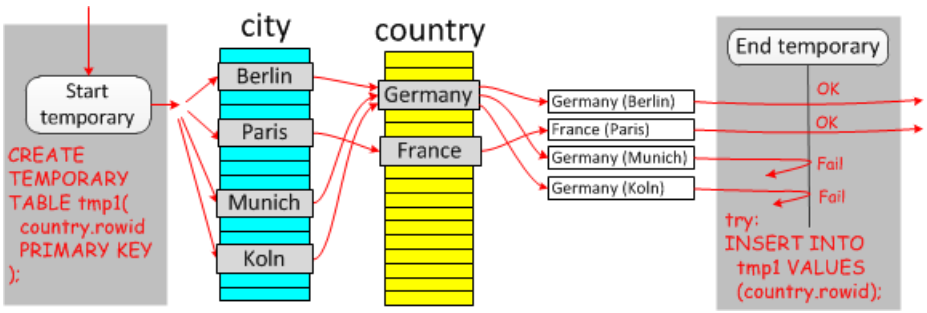
Suppose, you have a query where you're looking for countries which have more than 33% percent of their population in one big city:

```
select *
from Country
where
   Country.code IN (select City.Country
                    from City
                    where
                      City.Population > 0.33 * Country.Population and
                      City.Population > 1*1000*1000);
```

First, we run a regular inner join between the `City` and `Country` tables:



The Inner join produces duplicates. We have Germany three times, because it has three big cities. Now, lets put `DuplicateWeedout` into the picture:



Here one can see that a temporary table with a primary key was used to avoid producing multiple records with 'Germany'.

DuplicateWeedout in action

The `Start temporary` and `End temporary` from the last diagram are shown in the `EXPLAIN` output:

```
explain select * from Country where Country.code IN
  (select City.Country from City where City.Population > 0.33 * Country.Population
   and City.Population > 1*1000*1000)\G
*************************** 1. row ***************************
           id: 1
  select_type: PRIMARY
        table: City
         type: range
possible_keys: Population,Country
          key: Population
      key_len: 4
          ref: NULL
         rows: 238
        Extra: Using index condition; Start temporary
*************************** 2. row ***************************
           id: 1
  select_type: PRIMARY
        table: Country
         type: eq_ref
possible_keys: PRIMARY
          key: PRIMARY
      key_len: 3
          ref: world.City.Country
         rows: 1
        Extra: Using where; End temporary
2 rows in set (0.00 sec)
```

This query will read 238 rows from the `City` table, and for each of them will make a primary key lookup in the `Country` table, which gives another 238 rows. This gives a total of 476 rows, and you need to add 238 lookups in the temporary table (which are typically *much* cheaper since the temporary table is in-memory).

If we run the same EXPLAIN in MySQL, we'll get:

```
explain select * from Country where Country.code IN
  (select City.Country from City where City.Population > 0.33 * Country.Population
    and City.Population > 1*1000*1000)\G
*************************** 1. row ***************************
           id: 1
  select_type: PRIMARY
        table: Country
         type: ALL
possible_keys: NULL
          key: NULL
      key_len: NULL
          ref: NULL
         rows: 239
        Extra: Using where
*************************** 2. row ***************************
           id: 2
  select_type: DEPENDENT SUBQUERY
        table: City
         type: index_subquery
possible_keys: Population,Country
          key: Country
      key_len: 3
          ref: func
         rows: 18
        Extra: Using where
2 rows in set (0.00 sec)
```

This plan will read `(239 + 239*18) = 4541` rows, which is much slower.

Factsheet

- `DuplicateWeedout` is shown as "Start temporary/End temporary" in `EXPLAIN`.
- The strategy can handle correlated subqueries.
- But it cannot be applied if the subquery has meaningful `GROUP BY` and/or aggregate functions.
- `DuplicateWeedout` allows the optimizer to freely mix a subquery's tables and the parent select's tables.

- There is no separate @@optimizer_switch flag for `DuplicateWeedout`. The strategy can be disabled by switching off all semi-join optimizations with `SET @@optimizer_switch='optimizer_semijoin=off'` command.

3.3.4.3.2 FirstMatch Strategy

Contents

`FirstMatch` is an execution strategy for Semi-join subqueries.

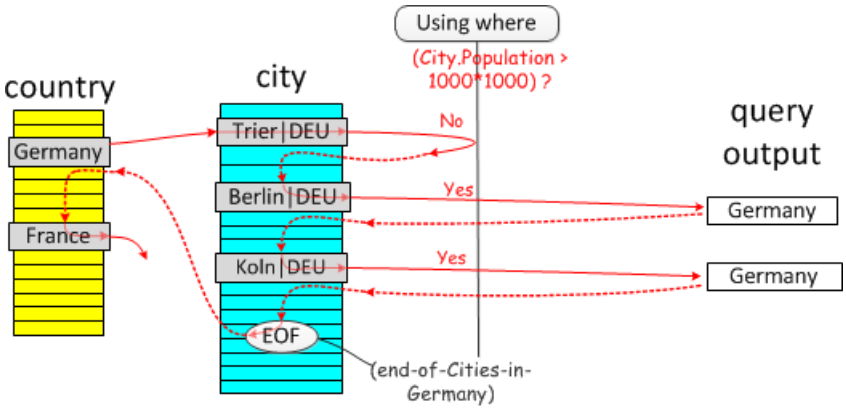
The idea

It is very similar to how `IN/EXISTS` subqueries were executed in MySQL 5.x.

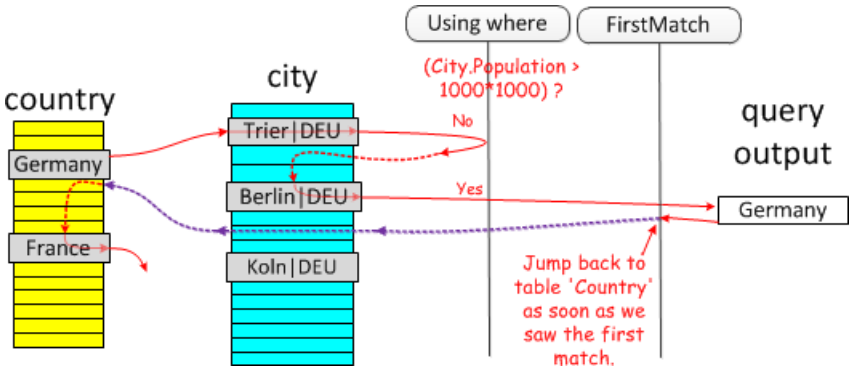
Let's take the usual example of a search for countries with big cities:

```
select * from Country
where Country.code IN (select City.Country
                       from City
                       where City.Population > 1*1000*1000)
      and Country.continent='Europe'
```

Suppose, our execution plan is to find countries in Europe, and then, for each found country, check if it has any big cities. Regular inner join execution will look as follows:



Since Germany has two big cities (in this diagram), it will be put into the query output twice. This is not correct, `SELECT ... FROM Country` should not produce the same country record twice. The `FirstMatch` strategy avoids the production of duplicates by short-cutting execution as soon as the first genuine match is found:



Note that the short-cutting has to take place after "Using where" has been applied. It would have been wrong to short-cut after we found Trier.

FirstMatch in action

The `EXPLAIN` for the above query will look as follows:

```
MariaDB [world]> explain select * from Country where Country.code IN
  (select City.Country from City where City.Population > 1*1000*1000)
   and Country.continent='Europe';
+----+-------------+---------+------+-------------------+-----------+---------+-------------
-------+------+-----------------------------------+
| id | select_type | table   | type | possible_keys     | key       | key_len | ref
| rows | Extra                             |
+----+-------------+---------+------+-------------------+-----------+---------+-------------
-------+------+-----------------------------------+
|  1 | PRIMARY     | Country | ref  | PRIMARY,continent | continent | 17      | const
|   60 | Using index condition            |
|  1 | PRIMARY     | City    | ref  | Population,Country | Country   | 3       |
world.Country.Code |   18 | Using where; FirstMatch(Country) |
+----+-------------+---------+------+-------------------+-----------+---------+-------------
-------+------+-----------------------------------+
2 rows in set (0.00 sec)
```

`FirstMatch(Country)` in the Extra column means that *as soon as we have produced one matching record combination, short-cut the execution and jump back to the Country* table.

`FirstMatch` 's query plan is very similar to one you would get in MySQL:

```
MySQL [world]> explain select * from Country  where Country.code IN
  (select City.Country from City where City.Population > 1*1000*1000)
   and Country.continent='Europe';
+----+--------------------+---------+----------------+--------------------+-----------+------
---+--------+------+-----------------------------------------+
| id | select_type        | table   | type           | possible_keys      | key       |
key_len | ref    | rows | Extra                                   |
+----+--------------------+---------+----------------+--------------------+-----------+------
---+--------+------+-----------------------------------------+
|  1 | PRIMARY            | Country | ref            | continent          | continent | 17
| const |   60 | Using index condition; Using where |
|  2 | DEPENDENT SUBQUERY | City    | index_subquery | Population,Country | Country   | 3
| func  |   18 | Using where                        |
+----+--------------------+---------+----------------+--------------------+-----------+------
---+--------+------+-----------------------------------------+
2 rows in set (0.01 sec)
```

and these two particular query plans will execute in the same time.

Difference between FirstMatch and IN->EXISTS

The general idea behind the `FirstMatch` strategy is the same as the one behind the `IN->EXISTS` transformation, however, `FirstMatch` has several advantages:

- Equality propagation works across semi-join bounds, but not subquery bounds. Therefore, converting a subquery to semi-join and using `FirstMatch` can still give a better execution plan. (TODO example)
- There is only one way to apply the `IN->EXISTS` strategy and MySQL will do it unconditionally. With `FirstMatch` , the optimizer can make a choice between whether it should run the `FirstMatch` strategy as soon as all tables used in the subquery are in the join prefix, or at some later point in time. (TODO: example)

FirstMatch factsheet

- The `FirstMatch` strategy works by executing the subquery and short-cutting its execution as soon as the first match is found.
- This means, subquery tables must be after all of the parent select's tables that are referred from the subquery predicate.
- `EXPLAIN` shows `FirstMatch` as " `FirstMatch(tableN)` ".
- The strategy can handle correlated subqueries.
- But it cannot be applied if the subquery has meaningful `GROUP BY` and/or aggregate functions.
- Use of the `FirstMatch` strategy is controlled with the `firstmatch=on|off` flag in the optimizer_switch variable.

3.3.4.3.3 LooseScan Strategy

LooseScan is an execution strategy for Semi-join subqueries.

Contents

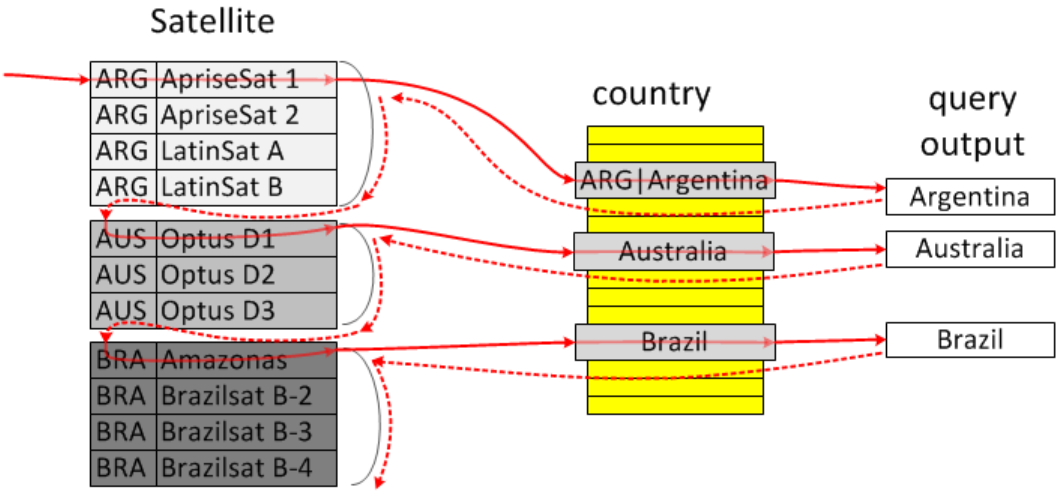
The idea

We will demonstrate the `LooseScan` strategy by example. Suppose, we're looking for countries that have satellites. We can get them using the following query (for the sake of simplicity we ignore satellites that are owned by consortiums of multiple countries):

```
select * from Country
where
  Country.code in (select country_code from Satellite)
```

Suppose, there is an index on `Satellite.country_code`. If we use that index, we will get satellites in the order of their owner country:

The `LooseScan` strategy doesn't really need ordering, what it needs is grouping. In the above figure, satellites are grouped by country. For instance, all satellites owned by Australia come together, without being mixed with satellites of other countries. This makes it easy to select just one satellite from each group, which you can join with its country and get a list of countries without duplicates:



LooseScan in action

The `EXPLAIN` output for the above query looks as follows:

```
MariaDB [world]> explain select * from Country where Country.code in
  (select country_code from Satellite);
+----+-------------+-----------+--------+---------------+-------------+---------+-----------
------------------+------+---------------------------------------+
| id | select_type | table     | type   | possible_keys | key         | key_len | ref
| rows | Extra                                 |
+----+-------------+-----------+--------+---------------+-------------+---------+-----------
------------------+------+---------------------------------------+
|  1 | PRIMARY     | Satellite | index  | country_code  | country_code | 9       | NULL
|  932 | Using where; Using index; LooseScan |
|  1 | PRIMARY     | Country   | eq_ref | PRIMARY       | PRIMARY      | 3       |
world.Satellite.country_code |    1 | Using index condition                 |
+----+-------------+-----------+--------+---------------+-------------+---------+-----------
------------------+------+---------------------------------------+
```

Factsheet

- LooseScan avoids the production of duplicate record combinations by putting the subquery table first and using its index to select one record from multiple duplicates
- Hence, in order for LooseScan to be applicable, the subquery should look like:

```
expr IN (SELECT tbl.keypart1 FROM tbl ...)
```

or

```
expr IN (SELECT tbl.keypart2 FROM tbl WHERE tbl.keypart1=const AND ...)
```

- LooseScan can handle correlated subqueries
- LooseScan can be switched off by setting the `loosescan=off` flag in the optimizer_switch variable.

3.3.4.3.4 Semi-join Materialization Strategy

Contents

Semi-join Materialization is a special kind of subquery materialization used for Semi-join subqueries. It actually includes two strategies:

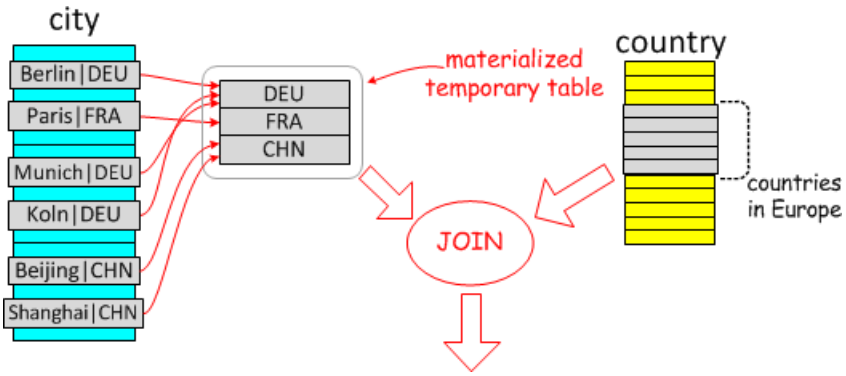
- Materialization/lookup
- Materialization/scan

The idea

Consider a query that finds countries in Europe which have big cities:

```
select * from Country
where Country.code IN (select City.Country
                       from City
                       where City.Population > 7*1000*1000)
      and Country.continent='Europe'
```

The subquery is uncorrelated, that is, we can run it independently of the upper query. The idea of semi-join materialization is to do just that, and fill a temporary table with possible values of the City.country field of big cities, and then do a join with countries in Europe:



The join can be done in two directions:

1. From the materialized table to countries in Europe
2. From countries in Europe to the materialized table

The first way involves doing a full scan on the materialized table, so we call it "Materialization-scan".

If you run a join from Countries to the materialized table, the cheapest way to find a match in the materialized table is to make a lookup on its primary key (it has one: we used it to remove duplicates). Because of that, we call the strategy "Materialization-lookup".

Semi-join materialization in action

Materialization-Scan

If we chose to look for cities with a population greater than 7 million, the optimizer will use Materialization-Scan and `EXPLAIN` will show this:

```
MariaDB [world]> explain select * from Country where Country.code IN
  (select City.Country from City where  City.Population > 7*1000*1000);
+----+--------------+-------------+--------+--------------------+------------+---------+-----
--------------+------+-----------------------+
| id | select_type  | table       | type   | possible_keys      | key        | key_len | ref
| rows | Extra                  |
+----+--------------+-------------+--------+--------------------+------------+---------+-----
--------------+------+-----------------------+
|  1 | PRIMARY      | <subquery2> | ALL    | distinct_key       | NULL       | NULL    | NULL
|   15 |                        |
|  1 | PRIMARY      | Country     | eq_ref | PRIMARY            | PRIMARY    | 3       |
world.City.Country |    1 |                        |
|  2 | MATERIALIZED | City        | range  | Population,Country | Population | 4       | NULL
|   15 | Using index condition |
+----+--------------+-------------+--------+--------------------+------------+---------+-----
--------------+------+-----------------------+
3 rows in set (0.01 sec)
```

Here, you can see:

- There are still two `SELECT` s (look for columns with `id=1` and `id=2`)
- The second select (with `id=2`) has `select_type=MATERIALIZED` . This means it will be executed and its results will be stored in a temporary table with a unique key over all columns. The unique key is there to prevent the table from containing any duplicate records.
- The first select received the table name `<subquery2>` . This is the table that we got as a result of the materialization of the select with `id=2` .

The optimizer chose to do a full scan over the materialized table, so this is an example of a use of the Materialization-Scan strategy.

As for execution costs, we're going to read 15 rows from table City, write 15 rows to materialized table, read them back (the optimizer assumes there won't be any duplicates), and then do 15 eq_ref accesses to table Country. In total, we'll do 45 reads and 15 writes.

By comparison, if you run the `EXPLAIN` in MySQL, you'll get this:

```
MySQL [world]> explain select * from Country where Country.code IN
  (select City.Country from City where  City.Population > 7*1000*1000);
+----+--------------------+---------+-------+--------------------+------------+---------+----
--+------+-----------------------------------+
| id | select_type        | table   | type  | possible_keys      | key        | key_len | ref
| rows | Extra                              |
+----+--------------------+---------+-------+--------------------+------------+---------+----
--+------+-----------------------------------+
|  1 | PRIMARY            | Country | ALL   | NULL               | NULL       | NULL    | NULL
|  239 | Using where                        |
|  2 | DEPENDENT SUBQUERY | City    | range | Population,Country | Population | 4       | NULL
|   15 | Using index condition; Using where |
+----+--------------------+---------+-------+--------------------+------------+---------+----
--+------+-----------------------------------+
```

...which is a plan to do `(239 + 239*15) = 3824` table reads.

Materialization-Lookup

Let's modify the query slightly and look for countries which have cities with a population over one millon (instead of seven):

```
MariaDB [world]> explain select * from Country where Country.code IN
  (select City.Country from City where  City.Population > 1*1000*1000) ;
+----+-------------+-------------+--------+--------------------+-------------+---------+---
---+------+-----------------------+
| id | select_type  | table       | type   | possible_keys      | key         | key_len | ref
| rows | Extra                 |
+----+-------------+-------------+--------+--------------------+-------------+---------+---
---+------+-----------------------+
|  1 | PRIMARY      | Country     | ALL    | PRIMARY            | NULL        | NULL    |
NULL |  239 |                       |
|  1 | PRIMARY      | <subquery2> | eq_ref | distinct_key       | distinct_key | 3       |
func |    1 |                       |
|  2 | MATERIALIZED | City        | range  | Population,Country | Population  | 4       |
NULL |  238 | Using index condition |
+----+-------------+-------------+--------+--------------------+-------------+---------+---
---+------+-----------------------+
3 rows in set (0.00 sec)
```

The `EXPLAIN` output is similar to the one which used Materialization-scan, except that:

- the `<subquery2>` table is accessed with the `eq_ref` access method
- the access uses an index named `distinct_key`

This means that the optimizer is planning to do index lookups into the materialized table. In other words, we're going to use the Materialization-lookup strategy.

In MySQL (or with `optimizer_switch='semijoin=off,materialization=off'`), one will get this `EXPLAIN` :

```
MySQL [world]> explain select * from Country where Country.code IN
  (select City.Country from City where  City.Population > 1*1000*1000) ;
+----+--------------------+---------+----------------+--------------------+---------+--------
-+------+------+-------------+
| id | select_type        | table   | type           | possible_keys      | key     | key_len
| ref  | rows | Extra       |
+----+--------------------+---------+----------------+--------------------+---------+--------
-+------+------+-------------+
|  1 | PRIMARY            | Country | ALL            | NULL               | NULL    | NULL
| NULL |  239 | Using where |
|  2 | DEPENDENT SUBQUERY | City    | index_subquery | Population,Country | Country | 3       |
func |   18 | Using where |
+----+--------------------+---------+----------------+--------------------+---------+--------
-+------+------+-------------+
```

One can see that both plans will do a full scan on the `Country` table. For the second step, MariaDB will fill the materialized table (238 rows read from table City and written to the temporary table) and then do a unique key lookup for each record in table `Country` , which works out to 238 unique key lookups. In total, the second step will cost `(239+238) = 477` reads and `238` temp.table writes.

MySQL's plan for the second step is to read 18 rows using an index on `City.Country` for each record it receives for table

`Country`. This works out to a cost of `(18*239) = 4302` reads. Had there been fewer subquery invocations, this plan would have been better than the one with Materialization. By the way, MariaDB has an option to use such a query plan, too (see FirstMatch Strategy), but it did not choose it.

Subqueries with grouping

MariaDB is able to use Semi-join materialization strategy when the subquery has grouping (other semi-join strategies are not applicable in this case).

This allows for efficient execution of queries that search for the best/last element in a certain group.

For example, let's find cities that have the biggest population on their continent:

```
explain
select * from City
where City.Population in (select max(City.Population) from City, Country
                          where City.Country=Country.Code
                          group by Continent)
+------+--------------+-------------+------+---------------+------------+---------+----------
------------------------+------+-----------------+
| id   | select_type  | table       | type | possible_keys | key        | key_len | ref
| rows | Extra           |
+------+--------------+-------------+------+---------------+------------+---------+----------
------------------------+------+-----------------+
|    1 | PRIMARY      | <subquery2> | ALL  | distinct_key  | NULL       | NULL    | NULL
|  239 |                 |
|    1 | PRIMARY      | City        | ref  | Population    | Population | 4       |
<subquery2>.max(City.Population) |    1 |                |
|    2 | MATERIALIZED | Country     | ALL  | PRIMARY       | NULL       | NULL    | NULL
|  239 | Using temporary |
|    2 | MATERIALIZED | City        | ref  | Country       | Country    | 3       |
world.Country.Code               |   18 |                |
+------+--------------+-------------+------+---------------+------------+---------+----------
------------------------+------+-----------------+
4 rows in set (0.00 sec)
```

the cities are:

```
+------+-------------------+---------+------------+
| ID   | Name              | Country | Population |
+------+-------------------+---------+------------+
| 1024 | Mumbai (Bombay)   | IND     |   10500000 |
| 3580 | Moscow            | RUS     |    8389200 |
| 2454 | Macao             | MAC     |     437500 |
|  608 | Cairo             | EGY     |    6789479 |
| 2515 | Ciudad de México | MEX     |    8591309 |
|  206 | São Paulo        | BRA     |    9968485 |
|  130 | Sydney            | AUS     |    3276207 |
+------+-------------------+---------+------------+
```

Factsheet

Semi-join materialization

- Can be used for uncorrelated IN-subqueries. The subselect may use grouping and/or aggregate functions.
- Is shown in `EXPLAIN` as `type=MATERIALIZED` for the subquery, and a line with `table=<subqueryN>` in the parent subquery.
- Is enabled when one has both `materialization=on` and `semijoin=on` in the optimizer_switch variable.
- The `materialization=on|off` flag is shared with Non-semijoin materialization.

3.3.4.3.5 Improvements to ORDER BY Optimization

MariaDB starting with 10.1

MariaDB 10.1 includes several improvements to the ORDER BY optimizer.

The fixes were made as a response to complaints by MariaDB customers, so they fix real-world optimization problems. The fixes are a bit hard to describe (as the `ORDER BY` optimizer is complicated), but here's a short description:

The ORDER BY optimizer in MariaDB 10.1:

- Doesn't make stupid choices when several multi-part keys and potential range accesses are present (MDEV-6402).
  - This also fixes MySQL Bug#12113.
- Always uses "range" and (not full "index" scan) when it switches to an index to satisfy `ORDER BY … LIMIT` (MDEV-6657).
- Tries hard to be smart and use cost/number of records estimates from other parts of the optimizer (MDEV-6384, MDEV-465).
  - This change also fixes MySQL Bug#36817.
- Takes full advantage of InnoDB's Extended Keys feature when checking if filesort() can be skipped (MDEV-6796).

Extra optimizations

Starting from MariaDB 10.1.15

- The ORDER BY optimizer takes multiple-equalities into account (MDEV-8989). This optimization is not enabled by default in MariaDB 10.1. You need to explicitly switch it ON by setting the optimizer_switch system variable, as follows:

```
optimizer_switch='orderby_uses_equalities=on'
```

Setting the switch ON is considered safe. It is off by default in MariaDB 10.1 in order to avoid changing query plans in a stable release. It is on by default from MariaDB 10.2

Comparison with MySQL 5.7

In MySQL 5.7 changelog, one can find this passage:

> Make switching of index due to small limit cost-based (WL#6986) : We have made the decision in make_join_select() of whether to switch to a new index in order to support "ORDER BY ... LIMIT N" cost-based. This work fixes Bug#73837.

MariaDB is not using Oracle's fix (we believe `make_join_select` is not the right place to do ORDER BY optimization), but the effect is the same: this case is covered by MariaDB 10.1's optimizer.

3.3.4.4 Optimizations for Derived Tables

Derived tables are subqueries in the `FROM` clause. Prior to MariaDB 5.3/MySQL 5.6, they were too slow to be usable. In MariaDB 5.3/MySQL 5.6, there are two optimizations which provide adequate performance:

Condition Pushdown into Derived Table Optimization

If a query uses a derived table (or a view), the first action that the que...

Derived Table Merge Optimization

MariaDB 5.3 introduced the derived table merge optimization.

Derived Table with Key Optimization

Since MariaDB 5.3, the optimizer can create an index and use it for joins with other tables.

Lateral Derived Optimization

Lateral Derived optimization, also referred to as "Split Grouping Optimization".

3.3.4.4.1 Condition Pushdown into Derived Table Optimization

Contents

If a query uses a derived table (or a view), the first action that the query optimizer will attempt is to apply the derived-table-merge-optimization and merge the derived table into its parent select. However, that optimization is only applicable when

the select inside the derived table has a join as the top-level operation. If it has a GROUP-BY, DISTINCT, or uses window functions, then derived-table-merge-optimization is not applicable.

In that case, the Condition Pushdown optimization is applicable.

Introduction to Condition Pushdown

Consider an example

```
create view OCT_TOTALS as
select
  customer_id,
  SUM(amount) as TOTAL_AMT
from orders
where  order_date BETWEEN '2017-10-01' and '2017-10-31'
group by customer_id;

select * from OCT_TOTALS where customer_id=1
```

The naive way to execute the above is to

1. Compute the OCT_TOTALS contents (for all customers).
2. The, select the line with customer_id=1

This is obviously inefficient, if there are 1000 customers, then one will be doing up to 1000 times more work than necessary.

However, the optimizer can take the condition `customer_id=1` and push it down into the OCT_TOTALS view.

(TODO: elaborate here)

Condition Pushdown Properties

- Condition Pushdown has been available since MariaDB 10.2.
- The Jira task for it was MDEV-9197.
- The optimization is enabled by default. One can disable it by setting `@@optimizer_switch` flag `condition_pushdown_for_derived` to OFF.

3.3.4.4.2 Derived Table Merge Optimization

Contents

Background

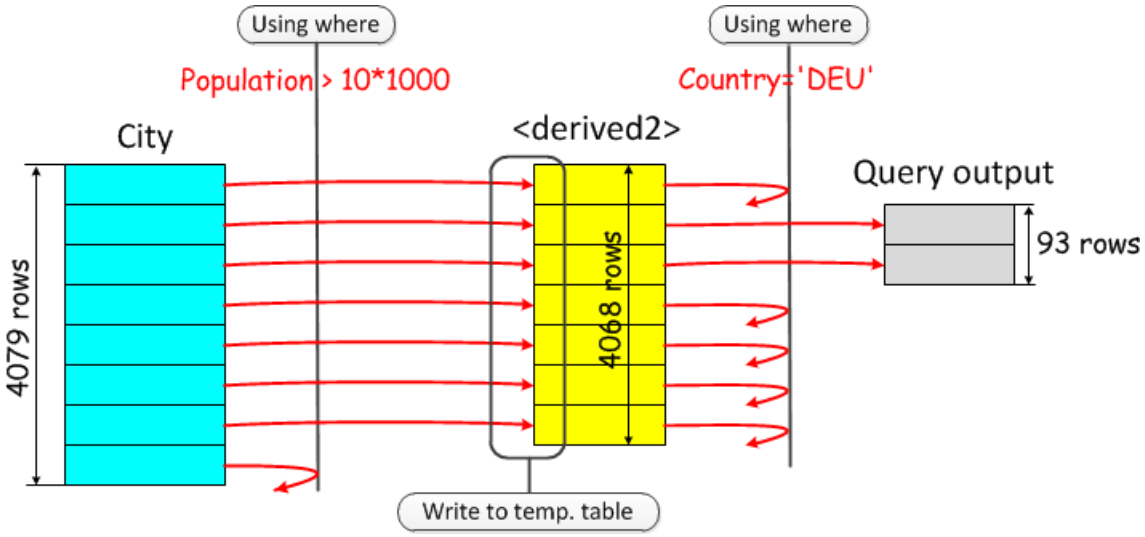
Users of "big" database systems are used to using `FROM` subqueries as a way to structure their queries. For example, if one's first thought was to select cities with population greater than 10,000 people, and then that from these cities to select those that are located in Germany, one could write this SQL:

```
SELECT *
FROM
  (SELECT * FROM City WHERE Population > 10*1000) AS big_city
WHERE
  big_city.Country='DEU'
```

For MySQL, using such syntax was taboo. If you run EXPLAIN for this query, you can see why:

```
mysql> EXPLAIN SELECT * FROM (SELECT * FROM City WHERE Population > 1*1000)
  AS big_city WHERE big_city.Country='DEU' ;
+----+-------------+------------+------+---------------+------+---------+------+------+------
-------+
| id | select_type | table      | type | possible_keys | key  | key_len | ref  | rows | Extra
|
+----+-------------+------------+------+---------------+------+---------+------+------+------
-------+
|  1 | PRIMARY     | <derived2> | ALL  | NULL          | NULL | NULL    | NULL | 4068 | Using
where |
|  2 | DERIVED     | City       | ALL  | Population    | NULL | NULL    | NULL | 4079 | Using
where |
+----+-------------+------------+------+---------------+------+---------+------+------+------
-------+
2 rows in set (0.60 sec)
```

It plans to do the following actions:



From left to right:

1. Execute the subquery: `(SELECT * FROM City WHERE Population > 1*1000)` , exactly as it was written in the query.
2. Put result of the subquery into a temporary table.
3. Read back, and apply a `WHERE` condition from the upper select, `big_city.Country='DEU'`

Executing a subquery like this is very inefficient, because the highly-selective condition from the parent select, (`Country='DEU'`) is not used when scanning the base table `City` . We read too many records from the `City` table, and then we have to write them into a temporary table and read them back again, before finally filtering them out.

Derived table merge in action

If one runs this query in MariaDB/MySQL 5.6, they get this:

```
MariaDB [world]> EXPLAIN SELECT * FROM (SELECT * FROM City WHERE Population > 1*1000)
  AS big_city WHERE big_city.Country='DEU';
+----+-------------+------+------+-----------------+---------+---------+-------+------+--
-----------------------------------+
| id | select_type | table | type | possible_keys   | key     | key_len | ref   | rows |
Extra                              |
+----+-------------+------+------+-----------------+---------+---------+-------+------+--
-----------------------------------+
|  1 | SIMPLE      | City  | ref  | Population,Country | Country | 3       | const |   90 |
Using index condition; Using where |
+----+-------------+------+------+-----------------+---------+---------+-------+------+--
-----------------------------------+
1 row in set (0.00 sec)
```

From the above, one can see that:

1. The output has only one line. This means that the subquery has been merged into the top-level `SELECT` .
2. Table `City` is accessed through an index on the `Country` column. Apparently, the `Country='DEU'` condition was used to construct `ref` access on the table.

3. The query will read about 90 rows, which is a big improvement over the 4079 row reads plus 4068 temporary table reads/writes we had before.

Factsheet

- Derived tables (subqueries in the `FROM` clause) can be merged into their parent select when they have no grouping, aggregates, or `ORDER BY ... LIMIT` clauses. These requirements are the same as requirements for `VIEW` s to allow `algorithm=merge` .
- The optimization is enabled by default. It can be disabled with:

```
set @@optimizer_switch='derived_merge=OFF'
```

- Versions of MySQL and MariaDB which do not have support for this optimization will execute subqueries even when running `EXPLAIN` . This can result in a well-known problem (see e.g. MySQL Bug #44802) of `EXPLAIN` statements taking a very long time. Starting from MariaDB 5.3+ and MySQL 5.6+ `EXPLAIN` commands execute instantly, regardless of the `derived_merge` setting.

3.3.4.4.3 Derived Table with Key Optimization

Contents

The idea

If a derived table cannot be merged into its parent SELECT, it will be materialized in a temporary table, and then parent select will treat it as a regular base table.

Before MariaDB 5.3/MySQL 5.6, the temporary table would never have any indexes, and the only way to read records from it would be a full table scan. Starting from the mentioned versions of the server, the optimizer has an option to create an index and use it for joins with other tables.

Example

Consider a query: we want to find countries in Europe, that have more than one million people living in cities. This is accomplished with this query:

```
select *
from
   Country,
   (select
       sum(City.Population) as urban_population,
       City.Country
    from City
    group by City.Country
    having
    urban_population > 1*1000*1000
   ) as cities_in_country
where
  Country.Code=cities_in_country.Country and Country.Continent='Europe';
```

The EXPLAIN output for it will show:

```
+----+-------------+------------+------+-----------------+-----------+---------+-----------
---------+------+-----------------------------------+
| id | select_type | table      | type | possible_keys     | key       | key_len | ref
| rows | Extra                             |
+----+-------------+------------+------+-----------------+-----------+---------+-----------
---------+------+-----------------------------------+
|  1 | PRIMARY     | Country    | ref  | PRIMARY,continent | continent | 17      | const
|   60 | Using index condition           |
|  1 | PRIMARY     | <derived2> | ref  | key0              | key0      | 3       |
world.Country.Code |   17 |                                  |
|  2 | DERIVED     | City       | ALL  | NULL              | NULL      | NULL    | NULL
| 4079 | Using temporary; Using filesort |
+----+-------------+------------+------+-----------------+-----------+---------+-----------
---------+------+-----------------------------------+
```

One can see here that

- table `<derived2>` is accessed through `key0`.
- `ref` column shows `world.Country.Code`
- if we look that up in the original query, we find the equality that was used to construct `ref` access: `Country.Code=cities_in_country.Country`.

Factsheet

- The idea of "derived table with key" optimization is to let the materialized derived table have one key which is used for joins with other tables.
- The optimization is applied then the derived table could not be merged into its parent SELECT
  - which happens when the derived table doesn't meet criteria for mergeable VIEW
- The optimization is ON by default, it can be switched off like so:

```
set optimizer_switch='derived_with_keys=off'
```

3.3.4.4.4 Lateral Derived Optimization

Contents

MariaDB supports the Lateral Derived optimization, also referred to as "Split Grouping Optimization" or "Split Materialized Optimization" in some sources.

Description

The optimization's use case is

- The query uses a derived table (or a VIEW, or a non-recursive CTE)
- The derived table/View/CTE has a GROUP BY operation as its top-level operation
- The query only needs data from a few GROUP BY groups

An example of this: consider a VIEW that computes totals for each customer in October:

```
create view OCT_TOTALS as
select
  customer_id,
  SUM(amount) as TOTAL_AMT
from orders
where
  order_date BETWEEN '2017-10-01' and '2017-10-31'
group by
  customer_id;
```

And a query that does a join with the customer table to get October totals for "Customer#1" and Customer#2:

```
select *
from
  customer, OCT_TOTALS
where
  customer.customer_id=OCT_TOTALS.customer_id and
  customer.customer_name IN ('Customer#1', 'Customer#2')
```

Before Lateral Derived optimization, MariaDB would execute the query as follows:

1. Materialize the view OCT_TOTALS. This essentially computes OCT_TOTALS for all customers.
2. Join it with table customer.

The EXPLAIN would look like so:

```
+------+-------------+------------+-------+---------------+-----------+---------+------------
--------------+-------+--------------------------+
| id   | select_type | table      | type  | possible_keys | key       | key_len | ref
| rows  | Extra                     |
+------+-------------+------------+-------+---------------+-----------+---------+------------
--------------+-------+--------------------------+
|    1 | PRIMARY     | customer   | range | PRIMARY,name  | name      | 103     | NULL
| 2     | Using where; Using index |
|    1 | PRIMARY     | <derived2> | ref   | key0          | key0      | 4       |
test.customer.customer_id | 36    |                           |
|    2 | DERIVED     | orders     | index | NULL          | o_cust_id | 4       | NULL
| 36738 | Using where              |
+------+-------------+------------+-------+---------------+-----------+---------+------------
--------------+-------+--------------------------+
```

It is obvious that Step #1 is very inefficient: we compute totals for all customers in the database, while we will only need them for two customers. (If there are 1000 customers, we are doing 500x more work than needed here)

Lateral Derived optimization addresses this case. It turns the computation of OCT_TOTALS into what SQL Standard refers to as "LATERAL subquery": a subquery that may have dependencies on the outside tables. This allows pushing the equality `customer.customer_id=OCT_TOTALS.customer_id` down into the derived table/view, where it can be used to limit the computation to compute totals only for the customer of interest.

The query plan will look as follows:

1. Scan table `customer` and find `customer_id` for Customer#1 and Customer#2.
2. For each customer_id, compute the October totals, for this specific customer.

The EXPLAIN output will look like so:

```
+------+-----------------+------------+-------+---------------+-----------+---------+--------
------------------+------+--------------------------+
| id   | select_type     | table      | type  | possible_keys | key       | key_len | ref
| rows | Extra                     |
+------+-----------------+------------+-------+---------------+-----------+---------+--------
------------------+------+--------------------------+
|    1 | PRIMARY         | customer   | range | PRIMARY,name  | name      | 103     | NULL
| 2    | Using where; Using index |
|    1 | PRIMARY         | <derived2> | ref   | key0          | key0      | 4       |
test.customer.customer_id | 2    |                           |
|    2 | LATERAL DERIVED | orders     | ref   | o_cust_id     | o_cust_id | 4       |
test.customer.customer_id | 1    | Using where               |
+------+-----------------+------------+-------+---------------+-----------+---------+--------
------------------+------+--------------------------+
```

Note the line with `id=2` : select_type is `LATERAL DERIVED` . And table customer uses ref access referring to `customer.customer_id` , which is normally not allowed for derived tables.

In `EXPLAIN FORMAT=JSON` output, the optimization is shown like so:

```
...
        "table": {
          "table_name": "<derived2>",
          "access_type": "ref",
...
          "materialized": {
            "lateral": 1,
```

Note the `"lateral": 1` member.

Controlling the Optimization

Lateral Derived is enabled by default, the optimizer will make a cost-based decision whether the optimization should be used.

If you need to disable the optimization, it has an optimizer_switch flag. It can be disabled like so:

```
set optimizer_switch='split_materialized=off'
```

3.3.4.5 Table Elimination

Articles about Table Elimination, the idea that it is sometimes possible to resolve a query without accessing some of the tables the query refers to.

What is Table Elimination?
Resolving a query without accessing some of the tables that the query refers to.

Table Elimination in MariaDB
Table elimination in the MariaDB optimizer.

Table Elimination User Interface
Table Elimination User Interface and EXPLAIN.

Table Elimination in Other Databases
Table Elimination in SQL Server and Oracle.

Table Elimination External Resources
an example of how to do this in MariaDB

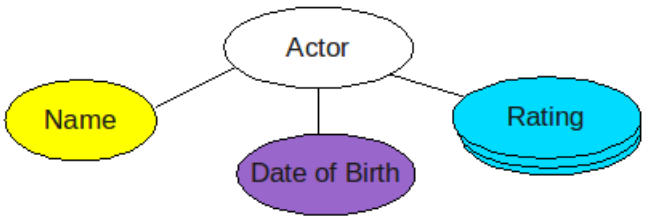
There are 2 related questions.

3.3.4.5.1 What is Table Elimination?

The basic idea behind table elimination is that sometimes it is possible to resolve a query without even accessing some of the tables that the query refers to. One can invent many kinds of such cases, but in Table Elimination we targeted only a certain class of SQL constructs that one ends up writing when they are querying highly-normalized data.

The sample queries were drawn from “Anchor Modeling”, a database modeling technique which takes normalization to the extreme. The slides at the anchor modeling website have an in-depth explanation of Anchor modeling and its merits, but the part that's important for table elimination can be shown with an example.

Suppose the database stores information about actors, together with their names, birthdays, and ratings, where ratings can change over time:



According to anchor modeling, each attribute should go into its own table:

- the 'anchor' table which only has a synthetic primary key:

```
create table  ac_anchor(AC_ID int primary key);
```

- a table for the 'name' attribute:

```
create table ac_name(AC_ID int, ACNAM_name char(N),
                     primary key(AC_ID));
```

- a table for the 'birthdate' attribute:

```
create table ac_dob(AC_ID int,
                    ACDOB_birthdate date,
                    primary key(AC_ID));
```

- a table for the ‘rating’ attribute, which is historized:

```
create table ac_rating(AC_ID int,
                       ACRAT_rating int,
                       ACRAT_fromdate date,
                       primary key(AC_ID, ACRAT_fromdate));
```

With this approach it becomes easy to add/change/remove attributes, but this comes at a cost of added complexity in querying the data: in order to answer the simplest, select-star question of displaying actors and their current ratings one has to write outer joins:

Display actors, with their names and current ratings:

```
select
  ac_anchor.AC_ID, ACNAM_Name, ACDOB_birthdate, ACRAT_rating
from
  ac_anchor
  left join ac_name on ac_anchor.AC_ID=ac_name.AC_ID
  left join ac_dob on ac_anchor.AC_ID=ac_dob.AC_ID
  left join ac_rating on (ac_anchor.AC_ID=ac_rating.AC_ID and
                          ac_rating.ACRAT_fromdate =
                            (select max(sub.ACRAT_fromdate)
                             from ac_rating sub where sub.AC_ID = ac_rating.AC_ID))
```

We don't want to write the joins every time we need to access an actor's properties, so we’ll create a view:

```
create view actors as
  select  ac_anchor.AC_ID, ACNAM_Name,  ACDOB_birthdate, ACRAT_rating
  from <see the select above>
```

This will allow us to access the data as if it was stored in a regular way:

```
select ACRAT_rating from actors where ACNAM_name='Gary Oldman'
```

And this is where table elimination will be needed.

3.3.4.5.2 Table Elimination in MariaDB

The first thing the MariaDB optimizer does is to merge the `VIEW` definition into the query to obtain:

```
select ACRAT_rating
from
  ac_anchor
  left join ac_name on ac_anchor.AC_ID=ac_name.AC_ID
  left join ac_dob on ac_anchor.AC_ID=ac_dob.AC_ID
  left join ac_rating on (ac_anchor.AC_ID=ac_rating.AC_ID and
                          ac_rating.ACRAT_fromdate =
                            (select max(sub.ACRAT_fromdate)
                             from ac_rating sub where sub.AC_ID = ac_rating.AC_ID))
where
 ACNAM_name='Gary Oldman'
```

It's important to realize that the obtained query has a useless part:

- `left join ac_dob on ac_dob.AC_ID=...` will produce exactly one matching record:
  - `primary key(ac_dob.AC_ID)` guarantees that there will be at most one match for any value of `ac_anchor.AC_ID`,
  - and if there won't be a match, `LEFT JOIN` will generate a NULL-complemented "row"
- and we don't care what the matching record is, as table `ac_dob` is not used anywhere else in the query.

This means that the `left join ac_dob on ...` part can be removed from the query and this is what Table Elimination module does. The detection logic is rather smart, for example it would be able to remove the `left join ac_rating on ...` part as well, together with the subquery (in the above example it won't be removed because ac_rating used in the selection list of the query). The Table Elimination module can also handle nested outer joins and multi-table outer joins.

3.3.4.5.3 Table Elimination User Interface

One can check that table elimination is working by looking at the output of `EXPLAIN [EXTENDED]` and not finding there the tables that were eliminated:

```
explain select ACRAT_rating from actors where ACNAM_name='Gary Oldman';
+----+--------------------+-----------+--------+---------------+---------+---------+---------
------------+------+-------------+
| id | select_type        | table     | type   | possible_keys | key     | key_len | ref
| rows | Extra       |
+----+--------------------+-----------+--------+---------------+---------+---------+---------
------------+------+-------------+
|  1 | PRIMARY            | ac_anchor | index  | PRIMARY       | PRIMARY | 4       | NULL
|    2 | Using index |
|  1 | PRIMARY            | ac_name   | eq_ref | PRIMARY       | PRIMARY | 4       |
test.ac_anchor.AC_ID |    1 | Using where |
|  1 | PRIMARY            | ac_rating | ref    | PRIMARY       | PRIMARY | 4       |
test.ac_anchor.AC_ID |    1 |             |
|  3 | DEPENDENT SUBQUERY | sub       | ref    | PRIMARY       | PRIMARY | 4       |
test.ac_rating.AC_ID |    1 | Using index |
+----+--------------------+-----------+--------+---------------+---------+---------+---------
------------+------+-------------+
```

Note that `ac_dob` table is not in the output. Now let's try getting birthdate instead:

```
explain select ACDOB_birthdate from actors where ACNAM_name='Gary Oldman';
+----+-------------+-----------+--------+---------------+---------+---------+----------------
------+------+-------------+
| id | select_type | table     | type   | possible_keys | key     | key_len | ref
| rows | Extra       |
+----+-------------+-----------+--------+---------------+---------+---------+----------------
------+------+-------------+
|  1 | PRIMARY     | ac_anchor | index  | PRIMARY       | PRIMARY | 4       | NULL
|    2 | Using index |
|  1 | PRIMARY     | ac_name   | eq_ref | PRIMARY       | PRIMARY | 4       |
test.ac_anchor.AC_ID |    1 | Using where |
|  1 | PRIMARY     | ac_dob    | eq_ref | PRIMARY       | PRIMARY | 4       |
test.ac_anchor.AC_ID |    1 |             |
+----+-------------+-----------+--------+---------------+---------+---------+----------------
------+------+-------------+
3 rows in set (0.01 sec)
```

The `ac_dob` table is there while `ac_rating` and the subquery are gone. Now, if we just want to check the name of the actor:

```
explain select count(*) from actors where ACNAM_name='Gary Oldman';
+----+-------------+-----------+--------+---------------+---------+---------+---------------
------+------+-------------+
| id | select_type | table     | type   | possible_keys | key     | key_len | ref
| rows | Extra       |
+----+-------------+-----------+--------+---------------+---------+---------+---------------
------+------+-------------+
|  1 | PRIMARY     | ac_anchor | index  | PRIMARY       | PRIMARY | 4       | NULL
|    2 | Using index |
|  1 | PRIMARY     | ac_name   | eq_ref | PRIMARY       | PRIMARY | 4       |
test.ac_anchor.AC_ID |    1 | Using where |
+----+-------------+-----------+--------+---------------+---------+---------+---------------
------+------+-------------+
2 rows in set (0.01 sec)
```

In this case it will eliminate both the `ac_dob` and `ac_rating` tables.

Removing tables from a query does not make the query slower, and it does not cut off any optimization opportunities, so table elimination is unconditional and there are no plans on having any kind of query hints for it.

For debugging purposes there is a `table_elimination=on|off` switch in debug builds of the server.

3.3.4.5.4 Table Elimination in Other Databases

In addition to MariaDB, Table Elimination is found in both Microsoft SQL Server 2005/2008 and Oracle 11g. Of the two, Microsoft SQL Server 2005/2008 seems to have the most advanced implementation. Oracle 11g has been confirmed to use table elimination but not to the same extent.

To compare the two, we will look at the following query:

```
select
 A.colA
from
 tableA A
left outer join
 tableB B
on
 B.id = A.id;
```

When using A as the left table we ensure that the query will return at least as many rows as there are in that table. For rows where the join condition (B.id = A.id) is not met the selected column (A.colA) will still contain its original value. The not seen B.* row would contain all NULL:s.

However, the result set could actually contain more rows than what is found in tableA if there are duplicates of the column B.id in tableB. If A contains a row [1, "val1"] and B the rows [1, "other1a"],[1, "other1b"] then two rows will match in the join condition. The only way to know what the result will look like is to actually touch both tables during execution.

Instead, let's say tableB contains rows that make it possible to place a unique constraint on the column B.id, for example, which is often the case with a primary key. In this situation we know that we will get exactly as many rows as there are in tableA, since joining with tableB cannot introduce any duplicates. Furthermore, as in the example query, if we do not select any columns from tableB, touching that table during execution is unnecessary. We can remove the whole join operation from the execution plan.

Both SQL Server 2005/2008 and Oracle 11g deploy table elimination in the case described above. Let us look at a more advanced query, where Oracle fails.

```
select
 A.colA
from
 tableA A
left outer join
 tableB B
on
 B.id = A.id
and
 B.fromDate = (
   select
     max(sub.fromDate)
   from
     tableB sub
   where
     sub.id = A.id
 );
```

In this example we have added another join condition, which ensures that we only pick the matching row from tableB having the latest fromDate. In this case tableB will contain duplicates of the column B.id, so in order to ensure uniqueness the primary key has to contain the fromDate column as well. In other words the primary key of tableB is (B.id, B.fromDate).

Furthermore, since the subselect ensures that we only pick the latest B.fromDate for a given B.id we know that at most one row will match the join condition. We will again have the situation where joining with tableB cannot affect the number of rows in the result set. Since we do not select any columns from tableB, the whole join operation can be eliminated from the execution plan.

SQL Server 2005/2008 will deploy table elimination in this situation as well. We have not found a way to make Oracle 11g use it for this type of query. Queries like these arise in two situations. Either when you have a denormalized model consisting of a fact table with several related dimension tables, or when you have a highly normalized model where each attribute is stored in its own table. The example with the subselect is common whenever you store historized/versioned data.

3.3.4.5.5 Table Elimination External Resources

- an example of how to do this in MariaDB

3.3.4.6 Statistics for Optimizing Queries

Different statistics provided by MariaDB to help you optimize your queries

Engine-Independent Table Statistics

Table statistics independent of the storage engine.

Histogram-Based Statistics

Histogram-based statistics can improve the optimizer query plan in certain situations.

Index Statistics

Index statistics and the query optimizer.

InnoDB Persistent Statistics

InnoDB persistent statistics are stored on disk, leading to more consistent query plans.

Slow Query Log Extended Statistics

The slow query log makes extended statistics available.

User Statistics

User Statistics.

3.3.4.6.1 Engine-Independent Table Statistics

MariaDB starting with 10.4

The engine-independent table statistics feature was first implemented in MariaDB 10.0.1 and was first enabled for queries by default in MariaDB 10.4.

Contents

Introduction

Before MariaDB 10.0, the MySQL/MariaDB optimizer relied on storage engines (e.g. InnoDB) to provide statistics for the query optimizer. This approach worked; however it had some deficiencies:

- Storage engines provided poor statistics (this was fixed to some degree with the introduction of Persistent Statistics).
- The statistics were supplied through the MySQL Storage Engine Interface, which puts a lot of restrictions on what kind of data is supplied (for example, there is no way to get any data about value distribution in a non-indexed column)
- There was little control of the statistics. There was no way to "pin" current statistic values, or provide some values on your own, etc.

Engine-independent table statistics lift these limitations.

- Statistics are stored in regular tables in the `mysql` database.
  - it is possible for a DBA to read and update the values.
- More data is collected/used.

Statistics are stored in three tables, mysql.table_stats, mysql.column_stats and mysql.index_stats.

Use or update of data from these tables is controlled by use_stat_tables variable. Possible values are listed below:

Value	Meaning
'never'	The optimizer doesn't use data from statistics tables. Default for MariaDB 10.4.0 and below.
'complementary'	The optimizer uses data from statistics tables if the same kind of data is not provided by the storage engine.
'preferably'	Prefer the data from statistics tables, if it's not available there, use the data from the storage engine.
'complementary_for_queries'	Same as `complementary`, but for queries only (to avoid needlessly collecting for ANALYZE TABLE). From MariaDB 10.4.1.
'preferably_for_queries'	Same as `preferably`, but for queries only (to avoid needlessly collecting for ANALYZE TABLE). Available and default from MariaDB 10.4.1.

Collecting Statistics with the ANALYZE TABLE Statement

The ANALYZE TABLE statement can be used to collect table statistics. For example:

```
ANALYZE TABLE table_name;
```

When the ANALYZE TABLE statement is executed, MariaDB makes a call to the table's storage engine, and the storage engine collects its own statistics for the table. The specific behavior depends on the storage engine. For InnoDB, see InnoDB Persistent Statistics for more information.

When the ANALYZE TABLE statement is executed, MariaDB may also collect engine-independent statistics for the table. The specific behavior depends on the value of the use_stat_tables system variable. Engine-independent statistics will only be collected by the ANALYZE TABLE statement if one of the following is true:

- The use_stat_tables system variable is set to `complementary` or `preferably`.
- The ANALYZE TABLE statement includes the `PERSISTENT FOR` clause.

MariaDB starting with 10.4

In MariaDB 10.4 and later, the use_stat_tables system variable is set to `preferably_for_queries` by default. With this value, engine-independent statistics are used by default, but they are not collected by default. If you want to use engine-independent statistics with the default configuration, then you will have to collect them by executing the ANALYZE TABLE statement and by specifying the `PERSISTENT FOR` clause. It is recommended to collect engine-independent statistics on as-needed basis, so typically one will not have engine-independent statistics for all indexes/all columns.

Engine-independent statistics are collected by doing full table and full index scans, and this process can be quite expensive.

Collecting Statistics for Specific Columns or Indexes

The syntax for the ANALYZE TABLE statement has been extended with the `PERSISTENT FOR` clause. This clause allows one to collect engine-independent statistics only for particular columns or indexes. This clause also allows one to collect engine-independent statistics, regardless of the value of the use_stat_tables system variable. For example:

```
ANALYZE TABLE table_name PERSISTENT FOR ALL;
```

Statistics for columns using the BLOB and TEXT data types are not collected. If a column using one of these types is explicitly specified, then a warning is returned.

Examples of Statistics Collection

```
-- update all engine-independent statistics for all columns and indexes
ANALYZE TABLE tbl PERSISTENT FOR ALL;

-- update specific columns and indexes:
ANALYZE TABLE tbl PERSISTENT FOR COLUMNS (col1,col2,...) INDEXES (idx1,idx2,...);

-- empty lists are allowed:
ANALYZE TABLE tbl PERSISTENT FOR COLUMNS (col1,col2,...) INDEXES ();
ANALYZE TABLE tbl PERSISTENT FOR COLUMNS () INDEXES (idx1,idx2,...);

-- the following will only update mysql.table_stats fields:
ANALYZE TABLE tbl PERSISTENT FOR COLUMNS () INDEXES ();

-- when use_stat_tables is set to 'COMPLEMENTARY' or 'PREFERABLY',
-- a simple ANALYZE TABLE  collects engine-independent statistics for all columns and indexes.
SET SESSION use_stat_tables='COMPLEMENTARY';
ANALYZE TABLE tbl;
```

Manual Updates to Statistics Tables

Statistics are stored in three tables, mysql.table_stats, mysql.column_stats and mysql.index_stats.

It is possible to update statistics tables manually. One should modify the table(s) with regular INSERT/UPDATE/DELETE statements. Statistics data will be re-read when the tables are re-opened. One way to force all tables to be re-opened is to issue FLUSH TABLES command.

A few scenarios where one might need to update statistics tables manually:

- Deleting the statistics. Currently, the ANALYZE TABLE command will collect the statistics, but there is no special command to delete statistics.
- Running ANALYZE on a different server. ANALYZE TABLE does a full table scan, which can put too much load on the server. It is possible to run ANALYZE on the slave, and then take the data from statistics tables on the slave and apply it on the master.
- In some cases, knowledge of the database allows one to compute statistics manually in a more efficient way than ANALYZE does. One can compute the statistics manually and put it into the database.

3.3.4.6.2 Histogram-Based Statistics

MariaDB starting with 10.4.3

Histograms are collected by default from MariaDB 10.4.3.

Contents

Histogram-based statistics are a mechanism to improve the query plan chosen by the optimizer in certain situations. Before their introduction, all conditions on non-indexed columns were ignored when searching for the best execution plan. Histograms can be collected for both indexed and non-indexed columns, and are made available to the optimizer.

Histogram statistics are stored in the mysql.column_stats table, which stores data for engine-independent table statistics, and so are essentially a subset of engine-independent table statistics.

Consider this example, using the following query:

```
SELECT * FROM t1,t2 WHERE t1.a=t2.a and t2.b BETWEEN 1 AND 3;
```

Let's assume that

- table t1 contains 100 records
- table t2 contains 1000 records
- there is a primary index on t1(a)
- there is a secondary index on t2(a)
- there is no index defined on column t2.b
- the selectivity of the condition t2.b BETWEEN (1,3) is high (~ 1%)

Before histograms were introduced, the optimizer would choose the plan that:

- accesses t1 using a table scan
- accesses t2 using index t2(a)
- checks the condition t2.b BETWEEN 1 AND 3

This plan examines all rows of both tables and performs 100 index look-ups.

With histograms available, the optimizer can choose the following, more efficient plan:

- accesses table t2 in a table scan
- checks the condition t2.b BETWEEN 1 AND 3
- accesses t1 using index t1(a)

This plan also examine all rows from t2, but it performs only 10 look-ups to access 10 rows of table t1.

System Variables

There are a number of system variables that affect histograms.

histogram_size

The histogram_size variable determines the size, in bytes, from 0 to 255, used for a histogram. This is effectively the number of bins for `histogram_type=SINGLE_PREC_HB` or number of bins/2 for `histogram_type=DOUBLE_PREC_HB`. If it is set to 0 (the default for MariaDB 10.4.2 and below), no histograms are created when running an ANALYZE TABLE.

histogram_type

The histogram_type variable determines whether single precision (`SINGLE_PREC_HB`) or double precision (`DOUBLE_PREC_HB`) height-balanced histograms are created. From MariaDB 10.4.3, double precision is the default. For MariaDB 10.4.2 and below, single precision is the default.

From MariaDB 10.8, `JSON_HB` , JSON-format histograms, are accepted.

optimizer_use_condition_selectivity

The optimizer_use_condition_selectivity controls which statistics can be used by the optimizer when looking for the best query execution plan.

- `1` Use selectivity of predicates as in MariaDB 5.5.
- `2` Use selectivity of all range predicates supported by indexes.
- `3` Use selectivity of all range predicates estimated without histogram.

- `4` Use selectivity of all range predicates estimated with histogram.
- `5` Additionally use selectivity of certain non-range predicates calculated on record sample.

From MariaDB 10.4.1, the default is `4`. Until MariaDB 10.4.0, the default is `1`.

3.3.3.10 Index Statistics

3.3.4.6.4 InnoDB Persistent Statistics

Before MariaDB 10.0, InnoDB statistics were not stored on disk, meaning that on server restarts the statistics would need to be recalculated, which is both needless computation, as well as leading to inconsistent query plans.

There are a number of variables that control persistent statistics:

- innodb_stats_persistent - when set (the default) enables InnoDB persistent statistics.
- innodb_stats_auto_recalc - when set (the default), persistent statistics are automatically recalculated when the table changes significantly (more than 10% of the rows)
- innodb_stats_persistent_sample_pages - Number of index pages sampled (default 20) when estimating cardinality and statistics for indexed columns. Increasing this value will increases index statistics accuracy, but use more I/O resources when running ANALYZE TABLE.

These settings can be overwritten on a per-table basis by use of the STATS_PERSISTENT, STATS_AUTO_RECALC and STATS_SAMPLE_PAGES clauses in a CREATE TABLE or ALTER TABLE statement.

Details of the statistics are stored in two system tables in the mysql database:

- innodb_table_stats
- innodb_index_stats

3.3.4.6.5 Slow Query Log Extended Statistics

Contents

Overview

- Added extra logging to slow log of 'Thread_id, Schema, Query Cache hit, Rows sent and Rows examined'
- Added optional logging to slow log, through log_slow_verbosity, of query plan statistics
- Added new session variables log_slow_rate_limit, log_slow_verbosity, log_slow_filter
- Added log-slow-file as synonym for 'slow-log-file', as most slow-log variables starts with 'log-slow'
- Added log-slow-time as synonym for long-query-time.

Session Variables

log_slow_verbosity

You can set the verbosity of what's logged to the slow query log by setting the the log_slow_verbosity variable to a combination of the following values:

- `All` (From MariaDB 10.6.16)
  - Enable all verbosity options.
- `Query_plan`
  - For select queries, log information about the query plan. This includes "Full_scan", "Full_join", "Tmp_table", "Tmp_table_on_disk", "Filesort", "Filesort_on_disk" and number of "Merge_passes during sorting"
- `explain`
  - EXPLAIN output is logged in the slow query log. See explain-in-the-slow-query-log for details.
- `Innodb` (From MariaDB 10.6.15. Before that this option did nothing)
  - Kept for compatibility. Same as `engine`.
- `engine` (From MariaDB 10.6.15)

- Writes statistics from the storage engine. This includes:

Option	Description	Engine
`Pages_accessed`	Number of pages accessed from page buffer (innodb-buffer-pool / key cache)	InnoDB
`Pages_updated`	Number of pages updated in memory	InnoDB
`Pages_read_time`	Milliseconds spend reading pages from storage	InnoDB
`Old_rows_read`	Number of retrieval of old versions of rows in the engine (versioning)	InnoDB
`Engine_time`	Milliseconds spent inside engine calls (read_row / read_next_row etc)	All

- `Warnings` (From MariaDB 10.6.16)
  - Print all errors, warnings and notes related to statement, up to `log_slow_max_warnings` lines.
- `full`.
  - Old shortcut to enable all the verbosity options

The default value for `log_slow_verbosity` is ' ', to be compatible with MySQL 5.1.

The possible values for `log_slow_verbosity are` innodb,query_plan,explain,engine,warnings. `Multiple options are separated by ','.`

log_slow_verbosity is not supported when log_output='TABLE'.

In the future we will add more `engine` statistics and also support for other engines.

log_slow_filter

You can define which queries to log to the slow query log by setting the variable log_slow_filter to a combination of the following values:

- `admin`
  - Log administrative statements (create, optimize, drop etc...)
- `filesort`
  - Log statement if it uses filesort
- `filesort_on_disk`
  - Log statement if it uses filesort that needs temporary tables on disk
- `full_join`
  - Log statements that doesn't uses indexes to join tables
- `full_scan`
  - Log statements that uses full table scans
- `query_cache`
  - Log statements that are resolved by the query cache
- `query_cache_miss`
  - Log statements that are not resolved by the query cache
- `tmp_table`
  - Log statements that uses in memory temporary tables
- `tmp_table_on_disk`
  - Log statements that uses temporary tables on disk

Multiple options are separated by ','. If you don't specify any options everything will be logged.

log_slow_rate_limit

The log_slow_rate_limit variable limits logging to the slow query log by not logging every query (only one query / log_slow_rate_limit is logged). This is mostly useful when debugging and you get too much information to the slow query log.

Note that in any case, only queries that takes longer than **log_slow_time** or **long_query_time'** are logged (as before).

log_slow_max_warnings

MariaDB starting with 10.6.16

If one enables the warning option for `log_slow_verbosity`, all notes and warnings for a slow query will also be added to the slow query log. This is very usable when one has enabled warnings for Notes when an index cannot be used. `log_slow_max_warnings` limits the number of warnings printed to the slow query log per query. The default value is 10.

Credits

Part of this addition is based on the microslow patch from Percona.

3.3.4.6.6 User Statistics

The User Statistics feature was first released in MariaDB 5.2.0, and moved to the `userstat` plugin in MariaDB 10.1.1.

The `userstat` plugin creates the USER_STATISTICS, CLIENT_STATISTICS, the INDEX_STATISTICS, and the TABLE_STATISTICS tables in the INFORMATION_SCHEMA database. As an alternative to these tables, the plugin also adds the SHOW USER_STATISTICS, the SHOW CLIENT_STATISTICS, the SHOW INDEX_STATISTICS, and the SHOW TABLE_STATISTICS statements.

These tables and commands can be used to understand the server activity better and to identify the sources of your database's load.

The plugin also adds the FLUSH USER_STATISTICS, FLUSH CLIENT_STATISTICS, FLUSH INDEX_STATISTICS, and FLUSH TABLE_STATISTICS statements.

The MariaDB implementation of this plugin is based on the userstatv2 patch from Percona and Ourdelta. The original code comes from Google (Mark Callaghan's team) with additional work from Percona, Ourdelta, and Weldon Whipple. The MariaDB implementation provides the same functionality as the userstatv2 patch but a lot of changes have been made to make it faster and to better fit the MariaDB infrastructure.

Contents

How it Works

The `userstat` plugin works by keeping several hash tables in memory. All variables are incremented while the query is running. At the end of each statement the global values are updated.

Enabling the Plugin

By default statistics are not collected. This is to ensure that statistics collection does not cause any extra load on the server unless desired.

Set the userstat=ON system variable in a relevant server option group in an option file to enable the plugin. For example:

```
[mariadb]
...
userstat = 1
```

The value can also be changed dynamically. For example:

```
SET GLOBAL userstat=1;
```

Using the Plugin

Using the Information Schema Table

The `userstat` plugin creates the USER_STATISTICS, CLIENT_STATISTICS, the INDEX_STATISTICS, and the TABLE_STATISTICS tables in the INFORMATION_SCHEMA database.

```
SELECT * FROM INFORMATION_SCHEMA.USER_STATISTICS\G
*************************** 1. row ***************************
                  USER: root
     TOTAL_CONNECTIONS: 1

    DENIED_CONNECTIONS: 0
      LOST_CONNECTIONS: 0
         ACCESS_DENIED: 0
         EMPTY_QUERIES: 1
```

```
SELECT * FROM INFORMATION_SCHEMA.CLIENT_STATISTICS\G
*************************** 1. row ***************************
                CLIENT: localhost
     TOTAL_CONNECTIONS: 3
CONCURRENT_CONNECTIONS: 0
        CONNECTED_TIME: 4883
             BUSY_TIME: 0.009722
              CPU_TIME: 0.0102131
        BYTES_RECEIVED: 841
            BYTES_SENT: 13897
  BINLOG_BYTES_WRITTEN: 0
             ROWS_READ: 0
             ROWS_SENT: 214
          ROWS_DELETED: 0
         ROWS_INSERTED: 207
          ROWS_UPDATED: 0
       SELECT_COMMANDS: 10
       UPDATE_COMMANDS: 0
        OTHER_COMMANDS: 13
   COMMIT_TRANSACTIONS: 0
 ROLLBACK_TRANSACTIONS: 0
    DENIED_CONNECTIONS: 0
      LOST_CONNECTIONS: 0
         ACCESS_DENIED: 0
         EMPTY_QUERIES: 1
1 row in set (0.00 sec)
```

```
SELECT * FROM INFORMATION_SCHEMA.INDEX_STATISTICS WHERE TABLE_NAME = "author";
+--------------+------------+------------+-----------+
| TABLE_SCHEMA | TABLE_NAME | INDEX_NAME | ROWS_READ |
+--------------+------------+------------+-----------+
| books        | author     | by_name    |        15 |
+--------------+------------+------------+-----------+
```

```
SELECT * FROM INFORMATION_SCHEMA.TABLE_STATISTICS WHERE TABLE_NAME='user';
+--------------+------------+-----------+--------------+-----------------------+
| TABLE_SCHEMA | TABLE_NAME | ROWS_READ | ROWS_CHANGED | ROWS_CHANGED_X_INDEXES |
+--------------+------------+-----------+--------------+-----------------------+
| mysql        | user       |         5 |            2 |                     2 |
+--------------+------------+-----------+--------------+-----------------------+
```

Using the SHOW Statements

As an alternative to the INFORMATION_SCHEMA tables, the `userstat` plugin also adds the SHOW USER_STATISTICS, the SHOW CLIENT_STATISTICS, the SHOW INDEX_STATISTICS, and the SHOW TABLE_STATISTICS statements.

These commands are another way to display the information stored in the information schema tables. WHERE clauses are accepted. LIKE clauses are accepted but ignored.

```
SHOW USER_STATISTICS
SHOW CLIENT_STATISTICS
SHOW INDEX_STATISTICS
SHOW TABLE_STATISTICS
```

Flushing Plugin Data

The `userstat` plugin also adds the FLUSH USER_STATISTICS, FLUSH CLIENT_STATISTICS, FLUSH INDEX_STATISTICS, and FLUSH TABLE_STATISTICS statements, which discard the information stored in the specified information schema table.

```
FLUSH USER_STATISTICS
FLUSH CLIENT_STATISTICS
FLUSH INDEX_STATISTICS
FLUSH TABLE_STATISTICS
```

Versions

USER_STATISTICS

Version	Status	Introduced
2.0	Stable	MariaDB 10.1.18
2.0	Gamma	MariaDB 10.1.1

CLIENT_STATISTICS

Version	Status	Introduced
2.0	Stable	MariaDB 10.1.13
2.0	Gamma	MariaDB 10.1.1

INDEX_STATISTICS

Version	Status	Introduced
2.0	Stable	MariaDB 10.1.13
2.0	Gamma	MariaDB 10.1.1

TABLE_STATISTICS

Version	Status	Introduced
2.0	Stable	MariaDB 10.1.18
2.0	Gamma	MariaDB 10.1.1

System Variables

`userstat`

- **Description:** If set to `1`, user statistics will be activated.
- **Commandline:** `--userstat=1`
- **Scope:** Global
- **Dynamic:** Yes

- **Data Type:** `boolean`
- **Default Value:** `OFF`

3.3.4.7 MIN/MAX optimization

Contents

Min/Max optimization without GROUP BY

MariaDB and MySQL can optimize the MIN() and MAX() functions to be a single row lookup in the following cases:

- There is only one table used in the `SELECT`.
- You only have constants, `MIN()` and `MAX()` in the `SELECT` part.
- The argument to `MIN()` and `MAX()` is a simple column reference that is part of a key.
- There is no `WHERE` clause or the `WHERE` is used with a constant for all prefix parts of the key before the argument to `MIN()` / `MAX()`.
- If the argument is used in the `WHERE` clause, it can be be compared to a constant with `<` or `<=` in case of `MAX()` and with `>` or `>=` in case of `MIN()`.

Here are some examples to clarify this. In this case we assume there is an index on columns `(a,b,c)`

```
SELECT MIN(a),MAX(a) from t1
SELECT MIN(b) FROM t1 WHERE a=const
SELECT MIN(b),MAX(b) FROM t1 WHERE a=const
SELECT MAX(c) FROM t1 WHERE a=const AND b=const
SELECT MAX(b) FROM t1 WHERE a=const AND b<const
SELECT MIN(b) FROM t1 WHERE a=const AND b>const
SELECT MIN(b) FROM t1 WHERE a=const AND b BETWEEN const AND const
SELECT MAX(b) FROM t1 WHERE a=const AND b BETWEEN const AND const
```

- Instead of `a=const` the condition `a IS NULL` can be used.

The above optimization also works for subqueries:

```
SELECT x from t2 where y= (SELECT MIN(b) FROM t1 WHERE a=const)
```

Cross joins, where there is no join condition for a table, can also be optimized to a few key lookups:

```
select min(t1.key_part_1), max(t2.key_part_1) from t1, t2
```

Min/Max optimization with GROUP BY

MariaDB and MySQL support loose index scan, which can speed up certain `GROUP BY` queries. The basic idea is that when scanning a `BTREE` index (the most common index type for the MariaDB storage engines) we can jump over identical values for any prefix of a key and thus speed up the scan significantly.

Loose scan is possible in the following cases:

- The query uses only one table.
- The `GROUP BY` part only uses indexed columns in the same order as in the index.
- The only aggregated functions in the `SELECT` part are `MIN()` and `MAX()` functions and all of them using the same column which is the next index part after the used `GROUP BY` columns.
- Partial indexed columns cannot be used (like only indexing 10 characters of a `VARCHAR(20)` column).

Loose scan will apply for your query if `EXPLAIN` shows `Using index for group-by` in the `Extra` column. In this case the optimizer will do only one extra row fetch to calculate the value for `MIN()` or `MAX()` for every unique key prefix.

The following examples assume that the table `t1` has an index on `(a,b,c)`.

```
SELECT a, b, MIN(c),MAX(c) FROM t1 GROUP BY a,b
```

3.3.4.8 Filesort with Small LIMIT Optimization

Contents

Optimization Description

When `n` is sufficiently small, the optimizer will use a priority queue for sorting. Before the optimization's porting to MariaDB 10.0, the alternative was, roughly speaking, to sort the entire output and then pick only first `n` rows.

Optimization Visibility in MariaDB

There are two ways to check whether filesort has used a priority queue.

Status Variable

The first way is to check the Sort_priority_queue_sorts status variable. It shows the number of times that sorting was done through a priority queue. (The total number of times sorting was done is a sum Sort_range and Sort_scan).

Slow Query Log

The second way is to check the slow query log. When one uses Extended statistics in the slow query log and specifies log_slow_verbosity=query_plan, slow query log entries look like this

```
# Time: 140714 18:30:39
# User@Host: root[root] @ localhost []
# Thread_id: 3  Schema: test  QC_hit: No
# Query_time: 0.053857  Lock_time: 0.000188  Rows_sent: 11  Rows_examined: 100011
# Full_scan: Yes  Full_join: No  Tmp_table: No  Tmp_table_on_disk: No
# Filesort: Yes  Filesort_on_disk: No  Merge_passes: 0  Priority_queue: Yes
SET timestamp=1405348239;SET timestamp=1405348239;
select * from t1 where col1 between 10 and 20 order by col2 limit 100;
```

Note the "Priority_queue: Yes" on the last comment line. (`pt-query-digest` is able to parse slow query logs with the Priority_queue field)

As for `EXPLAIN` , it will give no indication whether filesort uses priority queue or the generic quicksort and merge algorithm. `Using filesort` will be shown in both cases, by both MariaDB and MySQL.

3.3.4.9 LIMIT ROWS EXAMINED

Syntax

```
SELECT ... FROM ... WHERE ...
[group_clause] [order_clause]
LIMIT [[offset,] row_count] ROWS EXAMINED rows_limit;
```

Similar to the parameters of `LIMIT` , *`rows_limit`* can be both a prepared statement parameter, or a stored program parameter.

Description

The purpose of this optimization is to provide the means to terminate the execution of `SELECT` statements which examine too many rows, and thus use too many resources. This is achieved through an extension of the `LIMIT` clause — `LIMIT ROWS EXAMINED number_of_rows` . Whenever possible the semantics of `LIMIT ROWS EXAMINED` is the same as that of normal `LIMIT` (for instance for aggregate functions).

The `LIMIT ROWS EXAMINED` clause is taken into account by the query engine only during query execution. Thus the clause

is ignored in the following cases:

- If a query is `EXPLAIN` -ed.
- During query optimization.
- During auxiliary operations such as writing to system tables (e.g. logs).

The clause is not applicable to `DELETE` or `UPDATE` statements, and if used in those statements produces a syntax error.

The effects of this clause are as follows:

- The server counts the number of read, inserted, modified, and deleted rows during query execution. This takes into account the use of temporary tables, and sorting for intermediate query operations.
- Once the counter exceeds the value specified in the LIMIT ROWS EXAMINED clause, query execution is terminated as soon as possible.
- The effects of terminating the query because of LIMIT ROWS EXAMINED are as follows:
  - The result of the query is a subset of the complete query, depending on when the query engine detected that the limit was reached. The result may be empty if no result rows could be computed before reaching the limit.
  - A warning is generated of the form: "Query execution was interrupted. The query examined at least 100 rows, which exceeds LIMIT ROWS EXAMINED (20). The query result may be incomplete."
  - If query processing was interrupted during filesort, an error is returned in addition to the warning.
  - If a UNION was interrupted during execution of one of its queries, the last step of the UNION is still executed in order to produce a partial result.
  - Depending on the join and other execution strategies used for a query, the same query may produce no result at all, or a different subset of the complete result when terminated due to LIMIT ROWS EXAMINED.
  - If the query contains a GROUP BY clause, the last group where the limit was reached will be discarded.

The `LIMIT ROWS EXAMINED` clause cannot be specified on a per-subquery basis. There can be only one `LIMIT ROWS EXAMINED` clause for the whole `SELECT` statement. If a `SELECT` statement contains several subqueries with `LIMIT ROWS EXAMINED`, the one that is parsed last is taken into account.

Examples

A simple example of the clause is:

```
SELECT * from t1, t2 LIMIT 10 ROWS EXAMINED 10000;
```

The `LIMIT ROWS EXAMINED` clause is global for the whole statement.

If a composite query (such as `UNION`, or query with derived tables or with subqueries) contains more than one `LIMIT ROWS EXAMINED`, the last one parsed is taken into account. In this manner either the last or the outermost one is taken into account. For instance, in the query:

```
SELECT * FROM t1
WHERE c1 IN (SELECT * FROM t2 WHERE c2 > ' ' LIMIT ROWS EXAMINED 0)
LIMIT ROWS EXAMINED 11;
```

The limit that is taken into account is 11, not 0.

3.3.4.10 Block-Based Join Algorithms

Contents

In the versions of MariaDB/MySQL before 5.3 only one block-based join algorithm was implemented: the Block Nested Loops (BNL) join algorithm which could only be used for inner joins.

MariaDB 5.3 enhanced the implementation of BNL joins and provides a variety of block-based join algorithms that can be used for inner joins, outer joins, and semi-joins. Block-based join algorithms in MariaDB employ a join buffer to accumulate records of the first join operand before they start looking for matches in the second join operand.

This page documents the various block-based join algorithms.

- Block Nested Loop (BNL) join
- Block Nested Loop Hash (BNLH) join
- Block Index join known as Batch Key Access (BKA) join
- Block Index Hash join known as Batch Key Access Hash (BKAH) join

Block Nested Loop Join

The major difference between the implementation of BNL join in MariaDB 5.3 compared to earlier versions of MariaDB/MySQL is that the former uses a new format for records written into join buffers. This new format allows:

- More efficient use of buffer space for null field values and field values of flexible length types (like the varchar type)
- Support for so-called *incremental* join buffers saving buffer space for multi-way joins
- Use of the algorithm for outer joins and semi-joins

How Block Nested Loop Join Works

The algorithm performs a join operation of tables t1 and t2 according to the following schema.
The records of the first operand are written into the join buffer one by one until the buffer is full.
The records of the second operand are read from the base/temporary table one by one. For every read record r2 of table t2 the join buffer is scanned, and, for any record r1 from the buffer such that r2 matches r1 the concatenation of the interesting fields of r1 and r2 is sent to the result stream of the corresponding partial join.
To read the records of t2 a full table scan, a full index scan or a range index scan is performed. Only the records that meet the condition pushed to table t2 are checked for a match of the records from the join buffer.
When the scan of the table t2 is finished a new portion of the records of the first operand fills the buffer and matches for these records are looked for in t2.
The buffer refills and scans of the second operand that look for matches in the join buffer are performed again and again until the records of first operand are exhausted.
In total the algorithm scans the second operand as many times as many refills of the join buffer occur.

More Efficient Usage of Join Buffer Space

No join buffer space is used for null field values.
Any field value of a flexible length type is not padded by 0 up to the maximal field size anymore.

Incremental Join Buffers

If we have a query with a join of three tables t1, t2, t3 such that table t1 is joined with table t2 and the result of this join operation is joined with table t3 then two join buffers can be used to execute the query. The first join buffer B1 is used to store the records comprising interesting fields of table t1, while the second join buffer B2 contains the records with fields from the partial join of t1 and t2. The interesting fields of any record r1 from B1 are copied into B2 for any record record r1,r2 from the partial join of t1 and t2. One could suggest storing in B2 just a pointer to the position of the r1 fields in B1 together with the interesting fields from t2. So for any record r2 matching the record r1 the buffer B2 would contain a reference to the fields of r1 in B1 and the fields of r2. In this case the buffer B2 is called incremental. Incremental buffers allow to avoid copying field values from one buffer into another. They also allow to save a significant amount of buffer space if for a record from t1 several matches from t2 are expected.

Using Join Buffers for Simple Outer Joins and Semi-joins

If a join buffer is used for a simple left outer join of tables t1 and t1 t1 LEFT JOIN t2 ON P(t1,t2) then each record r1 stored in the buffer is provided with a match flag. Initially this flag is set off. As soon as the first match for r1 is found this flag is set on. When all matching candidates from t2 have been check, the record the join buffer are scanned and for those of them that still have there match flags off null-complemented rows are generated. The same match flag is used for any record in the join buffer is a semi-join operation t1 SEMI JOIN t2 ON P(t1,t2) is performed with a block based join algorithm. When this match flag is set to on for a record r1 in the buffer no matches from table t2 for record r1 are looked for anymore.

Block Hash Join

Block based hash join algorithm is a new option to be used for join operations in MariaDB 5.3. It can be employed in the cases when there are equi-join sub-condition for the joined tables, in the other words when equalities of the form t2.f1=

e1(t1),...,t2.fn=en(t1) can be extracted from the full join condition. As any block based join algorithm this one used a join buffer filled with the records of the first operand and looks through the records of the second operand to find matches for the records in the buffer.

How Block Hash Join Works

For each refill of the join buffer and each record r1 from it the algorithm builds a hash table with the keys constructed over the values e1(r1),...en(r1). Then the records of t2 are looked through. For each record r2 from t2 that the condition pushed to the table t2 a hash key over the fields r2.f1,..., r2.fn is calculated to probe into the hash table. The probing returns those records from the buffer to which r2 matches. As for BNL join algorithm this algorithm scans the second operand as many time as many refills of the buffer occur. Yet it has to look only through the records of one bucket in the hash table when looking for the records to which a record from t2 matches, not through all records in the join buffer as BNL join algorithm does. The implementation of this algorithm in MariaDB builds the hash table with hash keys at the very end of the join buffer. That's why the number of records written into the buffer at one refill is less then for BNL join algorithms. However a much shorter list of possible matching candidates makes this the block hash join algorithm usually much faster then BNL join.

Batch Key Access Join

Batch Keys Access join algorithm performs index look-ups when looking for possible matching candidates provided by the second join operand. With this respect the algorithm behave itself as the regular join algorithm. Yet BKA performs index look-ups for a batch of the records from the join buffer. For conventional database engines like InnoDB/MyISAM it allows to fetch matching candidates in an optimal way. For the engines with remote data store such as FederateX/Spider the algorithm allows to save on transfers between the MySQL node and the data store nodes.

How Batch Keys Access Join Works

The implementation of the algorithm in 5.3 heavily exploits the multi-range-read interface and its properties. The interface hides the actual mechanism of fetching possible candidates for matching records from the table to be joined. As any block based join algorithm the BKA join repeatedly fills the join buffer with records of the first operand and for each refill it finds records from the join table that could match the records in the buffer. To find such records it asks the MRR interface to perform index look-ups with the keys constructed over all records from the buffer. Together with each key the interface receives a return address - a reference to the record over which this key has been constructed. The actual implementation functions of the MRR interface organize and optimize somehow the process of fetching the records of the joined table by the received keys. Each fetched record r2 is appended with the return address associated with the key by which the record has been found and the result is passed to the BKA join procedure. The procedure takes the record r1 from the join buffer by the return address, joins it with r2 and checks the join condition. If the condition is evaluated to true the joined records is sent to the result stream of the join operation. So for each record returned by the MRR interface only one record from the join buffer is accessed. The number of records from table t2 fetched by the BKA join is exactly the same as for the regular nested loops join algorithm. Yet BKA join allows to optimize the order in which the records are fetched.

Interaction of BKA Join With the MRR Functions

BKA join interacts with the MRR functions respecting the following contract. The join procedure calls the MRR function multi_range_read_init passing it the callback functions that allows to initialize reading keys for the records in the join buffer and to iterate over these keys. It also passes the parameters of the buffer for MRR needs allocated within the join buffer space. Then BKA join repeatedly calls the MRR function multi_range_read_next. The function works as an iterator function over the records fetched by index look-ups with the keys produced by a callback function set in the call of multi_range_read_init. A call of the function multi_range_read_next returns the next fetched record through the dedicated record buffer, and the associated reference to the matched record from the join buffer as the output parameter of the function.

Managing Usage of Block-Based Join Algorithms

Currently 4 different types of block-based join algorithms are supported. For a particular join operation each of them can be employed with a regular (flat) join buffer or with an incremental join buffer.

Three optimizer switches - `join_cache_incremental` , `join_cache_hashed` , `join_cache_bka` – and the system variable join_cache_level control which of the 8 variants of the block-based algorithms will be used for join operations.

If `join_cache_bka` is off then BKA and BKAH join algorithms are not allowed. If `join_cache_hashed` is off then BNLH and BKAH join algorithms are not allowed. If `join_cache_incremental` is off then no incremental variants of the block-based join algorithms are allowed.

By default the switches `join_cache_incremental` , `join_cache_hashed` , `join_cache_bka` are set to 'on'. However it

does not mean that by default any of block-based join algorithms is allowed to be used. All of them are allowed only if the system variable join_cache_level is set to 8. This variable can take an integer value in the interval from 0 to 8.

If the value is set to 0 no block-based algorithm can be used for a join operation. The values from 1 to 8 correspond to the following variants of block-based join algorithms :

- 1 – Flat BNL
- 2 – Incremental BNL
- 3 – Flat BNLH
- 4 – Incremental BNLH
- 5 – Flat BKA
- 6 – Incremental BKA
- 7 – Flat BKAH
- 8 – Incremental BKAH

If the value of join_cache_level is set to N, any of block-based algorithms with the level greater than N is disallowed.

So if join_cache_level is set to 5, no usage of BKAH is allowed and usage of incremental BKA is not allowed either while usage of all remaining variants are controlled by the settings of the optimizer switches `join_cache_incremental`, `join_cache_hashed`, `join_cache_bka`.

By default join_cache_level is set to 2. In other words only usage of flat or incremental BNL is allowed.

By default block-based algorithms can be used only for regular (inner) join operations. To allow them for outer join operations (left outer joins and right outer joins) the optimizer switch `outer_join_with_cache` has to be set to 'on'. Setting the optimizer switch `semijoin_with_cache` to 'on' allows using these algorithms for semi-join operations.

Currently, only incremental variants of the block-based join algorithms can be used for nested outer joins and nested semi-joins.

Size of Join Buffers

The maximum size of join buffers used by block-based algorithms is controlled by setting the join_buffer_size system variable. This value must be large enough in order for the join buffer employed for a join operation to contain all relevant fields for at least one joined record.

MariaDB 5.3 introduced the system variable join_buffer_space_limit that limits the total memory used for join buffers in a query.

To optimize the usage of the join buffers within the limit set by `join_buffer_space_limit`, one should use the optimizer switch `optimize_join_buffer_size=on`. When this flag is set to 'off' (default until MariaDB 10.4.2), the size of the used join buffer is taken directly from the join_buffer_size system variable. When this flag is set to 'on' (default from MariaDB 10.4.3) then the size of the buffer depends on the estimated number of rows in the partial join whose records are to be stored in the buffer.

Related MRR Settings

To use BKA/BKAH join algorithms for InnoDB/MyISAM, one must set the optimizer switch `mrr` to 'on'. When using these algorithms for InnoDB/MyISAM the overall performance of the join operations can be dramatically improved if the optimizer switch `mrr_sort_keys` is set 'on'.

3.3.4.11 index_merge sort_intersection

Prior to MariaDB 5.3, the `index_merge` access method supported `union`, `sort-union`, and `intersection` operations. Starting from MariaDB 5.3, the `sort-intersection` operation is also supported. This allows the use of `index_merge` in a broader number of cases.

This feature is disabled by default. To enable it, turn on the optimizer switch `index_merge_sort_intersection` like so:

```
SET optimizer_switch='index_merge_sort_intersection=on'
```

Limitations of index_merge/intersection

Prior to MariaDB 5.3, the `index_merge` access method had one intersection strategy called `intersection`. That strategy can only be used when merged index scans produced rowid-ordered streams. In practice this means that an `intersection` could only be constructed from equality (=) conditions.

For example, the following query will use `intersection`:

```
MySQL [ontime]> EXPLAIN SELECT AVG(arrdelay) FROM ontime WHERE depdel15=1 AND OriginState
='CA';
+--+-----------+------+-----------+-------------------+-------------------+-------+----+---
--+-----------------------------------------------+
|id|select_type|table |type       |possible_keys      |key                |key_len|ref |rows
|Extra                                          |
+--+-----------+------+-----------+-------------------+-------------------+-------+----+---
--+-----------------------------------------------+
| 1|SIMPLE     |ontime|index_merge|OriginState,DepDel15|OriginState,DepDel15|3,5
|NULL|76952|Using intersect(OriginState,DepDel15);Using where|
+--+-----------+------+-----------+-------------------+-------------------+-------+----+---
--+-----------------------------------------------+
```

but if you replace `OriginState ='CA'` with `OriginState IN ('CA', 'GB')` (which matches the same number of records), then `intersection` is not usable anymore:

```
MySQL [ontime]> explain select avg(arrdelay) from ontime where depdel15=1 and OriginState IN
('CA', 'GB');
+--+-----------+------+----+-------------------+--------+-------+-----+-----------+
|id|select_type|table |type|possible_keys      |key     |key_len|ref  |rows |Extra      |
+--+-----------+------+----+-------------------+--------+-------+-----+-----------+
| 1|SIMPLE     |ontime|ref |OriginState,DepDel15|DepDel15|5      |const|36926|Using where|
+--+-----------+------+----+-------------------+--------+-------+-----+-----+-----------+
```

The latter query would also run 5.x times slower (from 2.2 to 10.8 seconds) in our experiments.

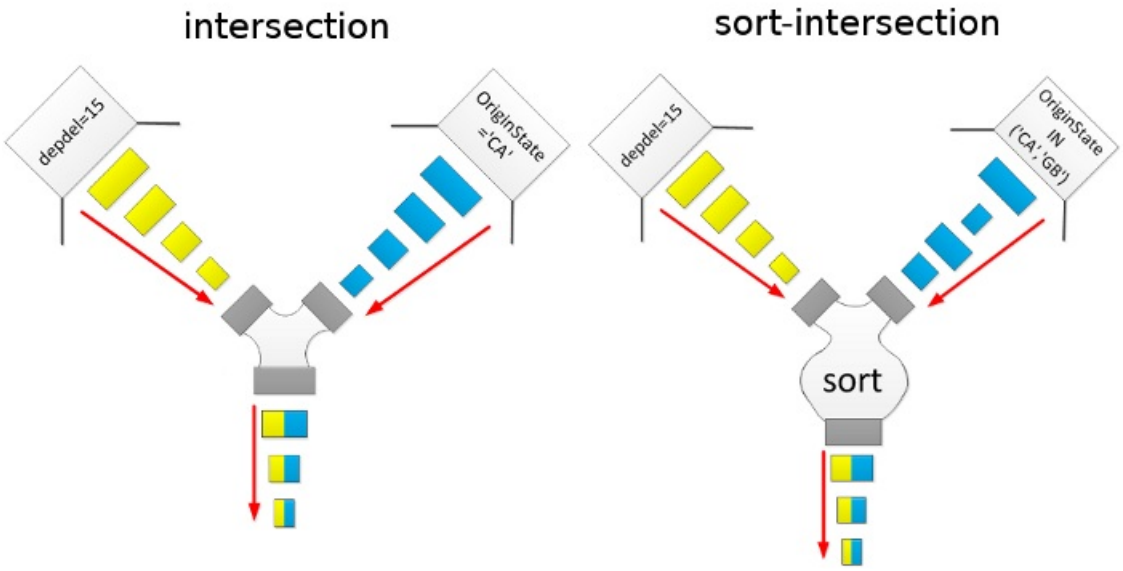
How index_merge/sort_intersection improves the situation

In MariaDB 5.3, when `index_merge_sort_intersection` is enabled, `index_merge` intersection plans can be constructed from non-equality conditions:

```
MySQL [ontime]> explain select avg(arrdelay) from ontime where depdel15=1 and OriginState IN
('CA', 'GB');
+--+-----------+------+-----------+-------------------+-------------------+-------+----+---
--+-------------------------------------------------------+
|id|select_type|table |type       |possible_keys      |key                |key_len|ref |rows
|Extra                                                    |
+--+-----------+------+-----------+-------------------+-------------------+-------+----+---
--+-------------------------------------------------------+
| 1|SIMPLE     |ontime|index_merge|OriginState,DepDel15|DepDel15,OriginState|5,3
|NULL|60754|Using sort_intersect(DepDel15,OriginState); Using where |
+--+-----------+------+-----------+-------------------+-------------------+-------+----+---
--+-------------------------------------------------------+
```

In our tests, this query ran in 3.2 seconds, which is not as good as the case with two equalities, but still much better than 10.8 seconds we were getting without `sort_intersect`.

The `sort_intersect` strategy has higher overhead than `intersect` but is able to handle a broader set of `WHERE` conditions.



When to Use

`index_merge/sort_intersection` works best on tables with lots of records and where intersections are sufficiently large (but still small enough to make a full table scan overkill).

The benefit is expected to be bigger for io-bound loads.

3.3.4.12 optimizer_switch

Contents

optimizer_switch is a server variable that one can use to enable/disable specific optimizations.

Syntax

To set or unset the various optimizations, use the following syntax:

```
SET [GLOBAL|SESSION] optimizer_switch='cmd[,cmd]...';
```

The *cmd* takes the following format:

Syntax	Description
default	Reset all optimizations to their default values.
optimization_name=default	Set the specified optimization to its default value.
optimization_name=on	Enable the specified optimization.
optimization_name=off	Disable the specified optimization.

There is no need to list all flags - only those that are specified in the command will be affected.

Available Flags

Below is a list of all *optimizer_switch* flags available in MariaDB:

Flag and MariaDB default	Supported in MariaDB since	Supported in MySQL since
condition_pushdown_for_derived=on	MariaDB 10.2.2	-
condition_pushdown_for_subquery=on	MariaDB 10.4.0	-

condition_pushdown_from_having=on	MariaDB 10.4.3	-
derived_merge=on	MariaDB 5.3	MySQL 5.7
derived_with_keys=on	MariaDB 5.3	-
default	MariaDB 5.1	MySQL 5.1
engine_condition_pushdown=off	MariaDB 5.5 (deprecated in 10.1)	MySQL 5.5
exists_to_in=on	MariaDB 10.0	-
extended_keys=on	MariaDB 5.5.21	-
firstmatch=on	MariaDB 5.3	MySQL 5.6
index_condition_pushdown=on	MariaDB 5.3	MySQL 5.6
hash_join_cardinality=off	MariaDB 10.6.13 (MDEV-30812)	-
index_merge=on	MariaDB 5.1	MySQL 5.1
index_merge_intersection=on	MariaDB 5.1	MySQL 5.1
index_merge_sort_intersection=off	MariaDB 5.3	-
index_merge_sort_union=on	MariaDB 5.1	MySQL 5.1
index_merge_union=on#	MariaDB 5.1	MySQL 5.1
in_to_exists=on	MariaDB 5.3	-
join_cache_bka=on	MariaDB 5.3	-
join_cache_hashed=on	MariaDB 5.3	-
join_cache_incremental=on	MariaDB 5.3	-
loosescan=on	MariaDB 5.3	MySQL 5.6
materialization=on (semi-join, non-semi-join)	MariaDB 5.3	MySQL 5.6

3.3.4.13 Extended Keys

Syntax

Enable:

```
set optimizer_switch='extended_keys=on';
```

Disable:

```
set optimizer_switch='extended_keys=off';
```

Description

Extended Keys is an optimization set with the optimizer_switch system variable, which makes use of existing components of InnoDB keys to generate more efficient execution plans. Using these components in many cases allows the server to generate execution plans which employ index-only look-ups. It is set by default.

Extended keys can be used with:

- ref and eq-ref accesses
- range scans
- index-merge scans
- loose scans
- min/max optimizations

Examples

An example of how extended keys could be employed for a query built over a DBT-3/TPC-H database with one added index defined on `p_retailprice`:

```
select o_orderkey
from part, lineitem, orders
where p_retailprice > 2095 and o_orderdate='1992-07-01'
      and o_orderkey=l_orderkey and p_partkey=l_partkey;
```

The above query asks for the `orderkeys` of the orders placed on 1992-07-01 which contain parts with a retail price greater than $2095.

Using Extended Keys, the query could be executed by the following execution plan:

1. Scan the entries of the index `i_p_retailprice` where `p_retailprice>2095` and read `p_partkey` values from the extended keys.
2. For each value `p_partkey` make an index look-up into the table lineitem employing index `i_l_partkey` and fetch the values of `l_orderkey` from the extended index.
3. For each fetched value of `l_orderkey`, append it to the date `'1992-07-01'` and use the resulting key for an index look-up by index `i_o_orderdate` to fetch the values of `o_orderkey` from the found index entries.

All access methods of this plan do not touch table rows, which results in much better performance.

Here is the explain output for the above query:

```
MariaDB [dbt3sf10]> explain
   -> select o_orderkey
   ->   from part, lineitem, orders
   ->   where p_retailprice > 2095 and o_orderdate='1992-07-01'
   ->         and o_orderkey=l_orderkey and p_partkey=l_partkey\G

3.3.4.14 How to Quickly Insert Data Into MariaDB

Contents

This article describes different techniques for inserting data quickly into MariaDB.

Background

When inserting new data into MariaDB, the things that take time are: (in order of importance):

- Syncing data to disk (as part of the end of transactions)
- Adding new keys. The larger the index, the more time it takes to keep keys updated.
- Checking against foreign keys (if they exist).
- Adding rows to the storage engine.
- Sending data to the server.

The following describes the different techniques (again, in order of importance) you can use to quickly insert data into a table.

Disabling Keys

You can temporarily disable updating of non unique indexes. This is mostly useful when there are zero (or very few) rows in the table into which you are inserting data.

```
ALTER TABLE table_name DISABLE KEYS;
BEGIN;
... inserting data with INSERT or LOAD DATA ....
COMMIT;
ALTER TABLE table_name ENABLE KEYS;
```

In many storage engines (at least MyISAM and Aria), `ENABLE KEYS` works by scanning through the row data and collecting keys, sorting them, and then creating the index blocks. This is an order of magnitude faster than creating the index one row at a time and it also uses less key buffer memory.

> **Note:** When you insert into an **empty table** with INSERT or LOAD DATA, MariaDB **automatically** does an DISABLE KEYS before and an ENABLE KEYS afterwards.

When inserting big amounts of data, integrity checks are sensibly time-consuming. It is possible to disable the `UNIQUE` indexes and the foreign keys checks using the unique_checks and the foreign_key_checks system variables:

```
SET @@session.unique_checks = 0;
SET @@session.foreign_key_checks = 0;
```

For InnoDB tables, the AUTO_INCREMENT lock mode can be temporarily set to 2, which is the fastest setting:

```
SET @@global.innodb_autoinc_lock_mode = 2;
```

Also, if the table has INSERT triggers or PERSISTENT columns, you may want to drop them, insert all data, and recreate them.

Loading Text Files

The **fastest way** to insert data into MariaDB is through the LOAD DATA INFILE command.

The simplest form of the command is:

```
LOAD DATA INFILE 'file_name' INTO TABLE table_name;
```

You can also read a file locally on the machine where the client is running by using:

```
LOAD DATA LOCAL INFILE 'file_name' INTO TABLE table_name;
```

This is not as fast as reading the file on the server side, but the difference is not that big.

`LOAD DATA INFILE` is very fast because:

1. there is no parsing of SQL.
2. data is read in big blocks.
3. if the table is empty at the beginning of the operation, all non unique indexes are disabled during the operation.
4. the engine is told to cache rows first and then insert them in big blocks (At least MyISAM and Aria support this).
5. for empty tables, some transactional engines (like Aria) do not log the inserted data in the transaction log because one can rollback the operation by just doing a TRUNCATE on the table.

Because of the above speed advantages there are many cases, when you need to insert **many** rows at a time, where it may be faster to create a file locally, add the rows there, and then use `LOAD DATA INFILE` to load them; compared to using `INSERT` to insert the rows.

You will also get progress reporting for `LOAD DATA INFILE` .

mariadb-import

You can import many files in parallel with mariadb-import (`mysqlimport` before MariaDB 10.5). For example:

```
mariadb-import --use-threads=10 database text-file-name [text-file-name...]
```

Internally mariadb-import uses LOAD DATA INFILE to read in the data.

Inserting Data with INSERT Statements

Using Big Transactions

When doing many inserts in a row, you should wrap them with `BEGIN / END` to avoid doing a full transaction (which includes a disk sync) for every row. For example, doing a begin/end every 1000 inserts will speed up your inserts by almost 1000 times.

```
BEGIN;
INSERT ...
INSERT ...
END;
BEGIN;
INSERT ...
INSERT ...
END;
...
```

The reason why you may want to have many `BEGIN/END` statements instead of just one is that the former will use up less transaction log space.

Multi-Value Inserts

You can insert many rows at once with multi-value row inserts:

```
INSERT INTO table_name values(1,"row 1"),(2, "row 2"),...;
```

The limit for how much data you can have in one statement is controlled by the max_allowed_packet server variable.

Inserting Data Into Several Tables at Once

If you need to insert data into several tables at once, the best way to do so is to enable multi-row statements and send many inserts to the server at once:

```
INSERT INTO table_name_1 (auto_increment_key, data) VALUES (NULL,"row 1");
INSERT INTO table_name_2 (auto_increment, reference, data) values (NULL, LAST_INSERT_ID(), "row 2
```

LAST_INSERT_ID() is a function that returns the last `auto_increment` value inserted.

By default, the command line `mariadb` client will send the above as multiple statements.

To test this in the `mariadb` client you have to do:

```
delimiter ;;
select 1; select 2;;
delimiter ;
```

Note: for multi-query statements to work, your client must specify the `CLIENT_MULTI_STATEMENTS` flag to `mysql_real_connect()`.

Server Variables That Can be Used to Tune Insert Speed

Option	Description
innodb_buffer_pool_size	Increase this if you have many indexes in InnoDB/XtraDB tables

key_buffer_size	Increase this if you have many indexes in MyISAM tables
max_allowed_packet	Increase this to allow bigger multi-insert statements
read_buffer_size	Read block size when reading a file with `LOAD DATA`

See Server System Variables for the full list of server variables.

3.3.4.15 Index Condition Pushdown

Contents

Index Condition Pushdown is an optimization that is applied for access methods that access table data through indexes: `range`, `ref`, `eq_ref`, `ref_or_null`, and Batched Key Access.

The idea is to check part of the WHERE condition that refers to index fields (we call it *Pushed Index Condition*) as soon as we've accessed the index. If the *Pushed Index Condition* is not satisfied, we won't need to read the whole table record.

Index Condition Pushdown is **on** by default. To disable it, set its optimizer_switch flag like so:

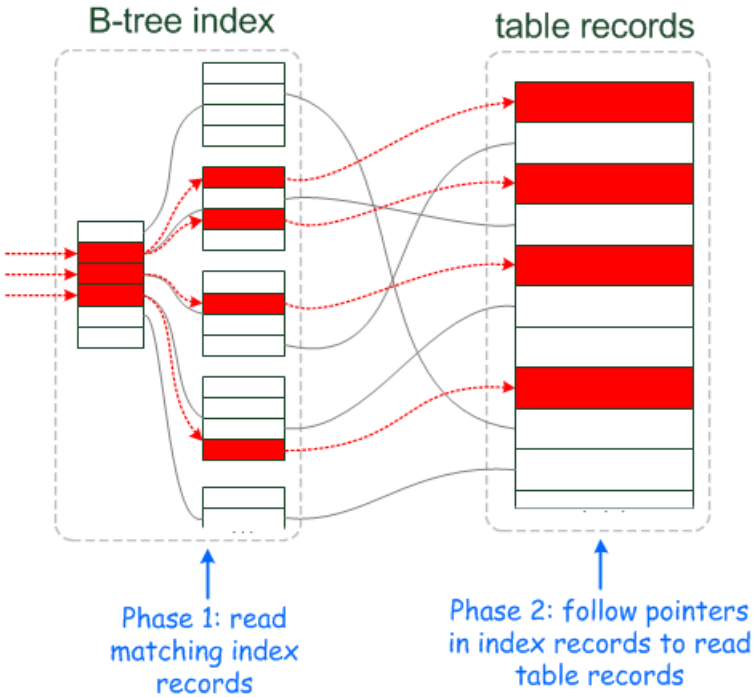
```
SET optimizer_switch='index_condition_pushdown=off'
```

When Index Condition Pushdown is used, EXPLAIN will show "Using index condition":

```
MariaDB [test]> explain select * from tbl where key_col1 between 10 and 11 and key_col2 like
'%foo%';
+----+-------------+-------+-------+---------------+----------+---------+------+------+------
-----------------+
| id | select_type | table | type  | possible_keys | key      | key_len | ref  | rows | Extra
|
+----+-------------+-------+-------+---------------+----------+---------+------+------+------
-----------------+
|  1 | SIMPLE      | tbl   | range | key_col1      | key_col1 | 5       | NULL |    2 | Using
index condition |
+----+-------------+-------+-------+---------------+----------+---------+------+------+------
-----------------+
```

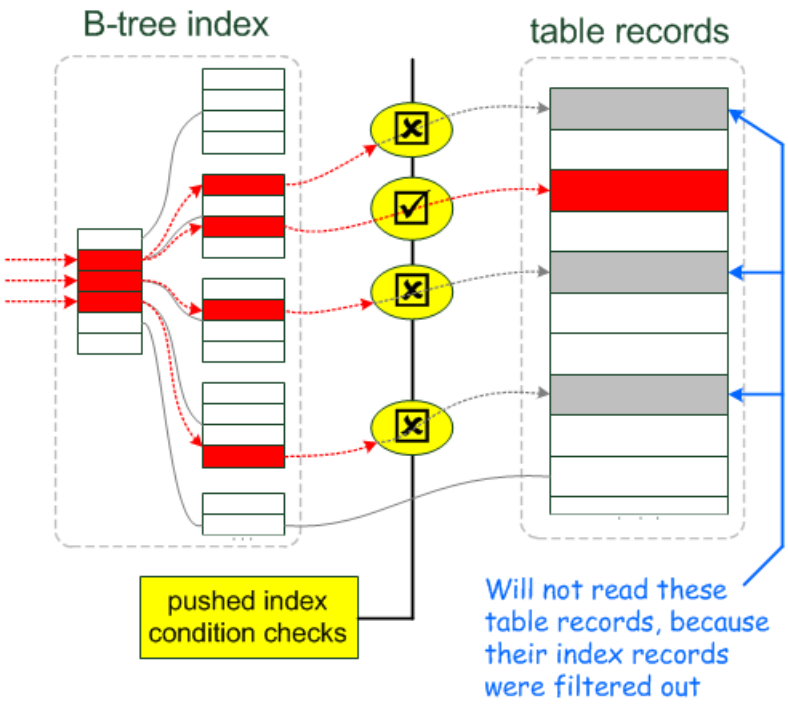
The Idea Behind Index Condition Pushdown

In disk-based storage engines, making an index lookup is done in two steps, like shown on the picture:



Index Condition Pushdown optimization tries to cut down the number of full record reads by checking whether index records

satisfy part of the WHERE condition that can be checked for them:



How much speed will be gained depends on - How many records will be filtered out - How expensive it was to read them

The former depends on the query and the dataset. The latter is generally bigger when table records are on disk and/or are big, especially when they have blobs.

Example Speedup

I used DBT-3 benchmark data, with scale factor=1. Since the benchmark defines very few indexes, we've added a multi-column index (index condition pushdown is usually useful with multi-column indexes: the first component(s) is what index access is done for, the subsequent have columns that we read and check conditions on).

```
alter table lineitem add index s_r (l_shipdate, l_receiptdate);
```

The query was to find big (l_quantity > 40) orders that were made in January 1993 that took more than 25 days to ship:

```
select count(*) from lineitem
where
  l_shipdate between '1993-01-01' and '1993-02-01' and
  datediff(l_receiptdate,l_shipdate) > 25 and
  l_quantity > 40;
```

EXPLAIN without Index Condition Pushdown:

```
-+----------+-------+----------------------+-----+---------+------+--------+-------------+
 | table    | type | possible_keys         | key | key_len | ref | rows    | Extra       |
-+----------+-------+----------------------+-----+---------+------+--------+-------------+
 | lineitem | range | s_r                   | s_r | 4       | NULL | 152064 | Using where |
-+----------+-------+----------------------+-----+---------+------+--------+-------------+
```

with Index Condition Pushdown:

```
-+----------+-------+---------------+-----+---------+------+--------+-----------------------
-------------+
 | table     | type | possible_keys | key | key_len | ref | rows     | Extra
|
-+----------+-------+---------------+-----+---------+------+--------+-----------------------
-------------+
 | lineitem | range | s_r           | s_r | 4       | NULL | 152064 | Using index condition;
Using where |
-+----------+-------+---------------+-----+---------+------+--------+-----------------------
-------------+
```

The speedup was:

- Cold buffer pool: from 5 min down to 1 min
- Hot buffer pool: from 0.19 sec down to 0.07 sec

Status Variables

There are two server status variables:

Variable name	Meaning
Handler_icp_attempts	Number of times pushed index condition was checked.
Handler_icp_match	Number of times the condition was matched.

That way, the value `Handler_icp_attempts - Handler_icp_match` shows the number records that the server did not have to read because of Index Condition Pushdown.

3.3.4.16 Query Limits and Timeouts

This article describes the different methods MariaDB provides to limit/timeout a query:

Contents

LIMIT

```
SELECT ... LIMIT row_count
or
SELECT ... LIMIT offset, row_count
or
SELECT ... LIMIT row_count OFFSET offset
```

The LIMIT clause restricts the number of returned rows.

LIMIT ROWS EXAMINED

```
SELECT ... LIMIT ROWS EXAMINED rows_limit;
```

Stops the query after 'rows_limit' number of rows have been examined.

sql_safe_updates

If the sql_safe_updates variable is set, one can't execute an UPDATE or DELETE statement unless one specifies a key constraint in the `WHERE` clause or provide a `LIMIT` clause (or both).

```
SET @@SQL_SAFE_UPDATES=1
UPDATE tbl_name SET not_key_column=val;
-> ERROR 1175 (HY000): You are using safe update mode
  and you tried to update a table without a WHERE that uses a KEY column
```

sql_select_limit

sql_select_limit acts as an automatic `LIMIT row_count` to any SELECT query.

```
SET @@SQL_SELECT_LIMIT=1000
SELECT * from big_table;
```

The above is the same as:

```
SELECT * from big_table LIMIT 1000;
```

max_join_size

If the max_join_size variable (also called `sql_max_join_size`) is set, then it will limit any SELECT statements that probably need to examine more than `MAX_JOIN_SIZE` rows.

```
SET @@MAX_JOIN_SIZE=1000;
SELECT count(null_column) from big_table;
->ERROR 1104 (42000): The SELECT would examine more than MAX_JOIN_SIZE rows;
  check your WHERE and use SET SQL_BIG_SELECTS=1 or SET MAX_JOIN_SIZE=# if the SELECT is okay
```

max_statement_time

If the max_statement_time variable is set, any query (excluding stored procedures) taking longer than the value of `max_statement_time` (specified in seconds) to execute will be aborted. This can be set globally, by session, as well as per user and per query. See Aborting statements that take longer than a certain time to execute.

3.3.4.17 Aborting Statements that Exceed a Certain Time to Execute

Contents

Overview

MariaDB 10.1.1 introduced the max_statement_time system variable. When set to a non-zero value, any queries taking longer than this time in seconds will be aborted. The default is zero, and no limits are then applied. The aborted query has no effect on any larger transaction or connection contexts. The variable is of type double, thus you can use subsecond timeout. For example you can use value 0.01 for 10 milliseconds timeout.

The value can be set globally or per session, as well as per user or per query (see below). Replicas are not affected by this variable, however from MariaDB 10.10, there is slave_max_statement_time which serves the same purpose on replicas only.

An associated status variable, max_statement_time_exceeded, stores the number of queries that have exceeded the execution time specified by max_statement_time, and a `MAX_STATEMENT_TIME_EXCEEDED` column was added to the CLIENT_STATISTICS and USER STATISTICS Information Schema tables.

The feature was based upon a patch by Davi Arnaut.

User max_statement_time

max_statement_time can be stored per user with the GRANT ... MAX_STATEMENT_TIME syntax.

Per-query max_statement_time

By using max_statement_time in conjunction with SET STATEMENT, it is possible to limit the execution time of individual queries. For example:

```
SET STATEMENT max_statement_time=100 FOR
  SELECT field1 FROM table_name ORDER BY field1;
```

Limitations

- max_statement_time does not work in embedded servers.
- max_statement_time does not work for COMMIT statements in a Galera cluster (see MDEV-18673 for discussion).

Differences Between the MariaDB and MySQL Implementations

MySQL 5.7.4 introduced similar functionality, but the MariaDB implementation differs in a number of ways.

- The MySQL version of max_statement_time (`max_execution_time`) is defined in millseconds, not seconds
- MySQL's implementation can only kill SELECTs, while MariaDB's can kill any queries (excluding stored procedures).
- MariaDB only introduced the max_statement_time_exceeded status variable, while MySQL also introduced a number of other variables which were not seen as necessary in MariaDB.
- The `SELECT MAX_STATEMENT_TIME = N ...` syntax is not valid in MariaDB. In MariaDB one should use `SET STATEMENT MAX_STATEMENT_TIME=N FOR....`

2.5.3 Partition Pruning and Selection

3.3.4.19 Big DELETEs

Contents

The problem

How to DELETE lots of rows from a large table? Here is an example of purging items older than 30 days:

```
DELETE FROM tbl WHERE
  ts < CURRENT_DATE() - INTERVAL 30 DAY
```

If there are millions of rows in the table, this statement may take minutes, maybe hours.

Any suggestions on how to speed this up?

Why it is a problem

- MyISAM will lock the table during the entire operation, thereby nothing else can be done with the table.
- InnoDB won't lock the table, but it will chew up a lot of resources, leading to sluggishness.
- InnoDB has to write the undo information to its transaction logs; this significantly increases the I/O required.
- Replication, being asynchronous, will effectively be delayed (on Slaves) while the DELETE is running.

InnoDB and undo

To be ready for a crash, a transactional engine such as InnoDB will record what it is doing to a log file. To make that somewhat less costly, the log file is sequentially written. If the log files you have (there are usually 2) fill up because the delete is really big, then the undo information spills into the actual data blocks, leading to even more I/O.

Deleting in chunks avoids some of this excess overhead.

Limited benchmarking of total delete elapsed time show two observations:

- Total delete time approximately doubles above some 'chunk' size (as opposed to below that threshold). I do not have a formula relating the log file size with the threshold cutoff.
- Chunk size below several hundred rows is slower. This is probably because the overhead of starting/ending each

chunk dominates the timing.

Solutions

- PARTITION -- Requires some careful setup, but is excellent for purging a time-base series.
- DELETE in chunks -- Carefully walk through the table N rows at a time.

PARTITION

The idea here is to have a sliding window of partitions. Let's say you need to purge news articles after 30 days. The "partition key" would be the datetime (or timestamp) that is to be used for purging, and the PARTITIONs would be "range". Every night, a cron job would come along and build a new partition for the next day, and drop the oldest partition.

Dropping a partition is essentially instantaneous, much faster than deleting that many rows. However, you must design the table so that the entire partition can be dropped. That is, you cannot have some items living longer than others.

PARTITION tables have a lot of restrictions, some are rather weird. You can either have no UNIQUE (or PRIMARY) key on the table, or every UNIQUE key must include the partition key. In this use case, the partition key is the datetime. It should not be the first part of the PRIMARY KEY (if you have a PRIMARY KEY).

You can PARTITION InnoDB or MyISAM tables.

Since two news articles could have the same timestamp, you cannot assume the partition key is sufficient for uniqueness of the PRIMARY KEY, so you need to find something else to help with that.

Reference implementation for Partition maintenance

MariaDB docs on PARTITION

Deleting in chunks

Although the discussion in this section talks about DELETE, it can be used for any other "chunking", such as, say, UPDATE, or SELECT plus some complex processing.

(This discussion applies to both MyISAM and InnoDB.)

When deleting in chunks, be sure to avoid doing a table scan. The code below is good at that; it scans no more than 1001 rows in any one query. (The 1000 is tunable.)

Assuming you have news articles that need to be purged, and you have a schema something like

```
CREATE TABLE tbl
   id INT UNSIGNED NOT NULL AUTO_INCREMENT,
   ts TIMESTAMP,
   ...
   PRIMARY KEY(id)
```

Then, this pseudo-code is a good way to delete the rows older than 30 days:

```
@a = 0
LOOP
   DELETE FROM tbl
      WHERE id BETWEEN @a AND @a+999
        AND ts < DATE_SUB(CURRENT_DATE(), INTERVAL 30 DAY)
   SET @a = @a + 1000
   sleep 1  -- be a nice guy
UNTIL end of table
```

Notes (Most of these caveats will be covered later):

- It uses the PK instead of the secondary key. This gives much better locality of disk hits, especially for InnoDB.
- You could (should?) do something to avoid walking through recent days but doing nothing. Caution -- the code for this could be costly.
- The 1000 should be tweaked so that the DELETE usually takes under, say, one second.
- No INDEX on ts is needed. (This helps INSERTs a little.)
- If your PRIMARY KEY is compound, the code gets messier.
- This code will not work without a numeric PRIMARY or UNIQUE key.
- Read on, we'll develop messier code to deal with most of these caveats.

If there are big gaps in `id` values (and there will after the first purge), then

```
@a = SELECT MIN(id) FROM tbl
LOOP
   SELECT @z := id FROM tbl WHERE id >= @a ORDER BY id LIMIT 1000,1
   If @z is null
      exit LOOP  -- last chunk
   DELETE FROM tbl
      WHERE id >= @a
        AND id <  @z
        AND ts < DATE_SUB(CURRENT_DATE(), INTERVAL 30 DAY)
   SET @a = @z
   sleep 1  -- be a nice guy, especially in replication
ENDLOOP
# Last chunk:
DELETE FROM tbl
   WHERE id >= @a
     AND ts < DATE_SUB(CURRENT_DATE(), INTERVAL 30 DAY)
```

That code works whether id is numeric or character, and it mostly works even if id is not UNIQUE. With a non-unique key, the risk is that you could be caught in a loop whenever @z==@a. That can be detected and fixed thus:

```
...
   SELECT @z := id FROM tbl WHERE id >= @a ORDER BY id LIMIT 1000,1
   If @z == @a
      SELECT @z := id FROM tbl WHERE id > @a ORDER BY id LIMIT 1
...
```

The drawback is that there could be more than 1000 items with a single id. In most practical cases, that is unlikely.

If you do not have a primary (or unique) key defined on the table, and you have an INDEX on ts, then consider

```
LOOP
   DELETE FROM tbl
      WHERE ts < DATE_SUB(CURRENT_DATE(), INTERVAL 30 DAY)
      ORDER BY ts   -- to use the index, and to make it deterministic
      LIMIT 1000
UNTIL no rows deleted
```

This technique is NOT recommended because the LIMIT leads to a warning on replication about it being non-deterministic (discussed below).

InnoDB chunking recommendation

- Have a 'reasonable' size for innodb_log_file_size.
- Use AUTOCOMMIT=1 for the session doing the deletions.
- Pick about 1000 rows for the chunk size.
- Adjust the row count down if asynchronous replication (Statement Based) causes too much delay on the Slaves or hogs the table too much.

Iterating through a compound key

To perform the chunked deletes recommended above, you need a way to walk through the PRIMARY KEY. This can be difficult if the PK has more than one column in it.

To efficiently to do compound 'greater than':

Assume that you left off at ($g, $s) (and have handled that row):

```
INDEX(Genus, species)
SELECT/DELETE ...
   WHERE Genus >= '$g' AND ( species  > '$s' OR Genus > '$g' )
   ORDER BY Genus, species
   LIMIT ...
```

Addenda: The above AND/OR works well in older versions of MySQL; this works better in MariaDB and newer versions of MySQL:

```
      WHERE ( Genus = '$g' AND species  > '$s' ) OR Genus > '$g' )
```

A caution about using @variables for strings. If, instead of '$g', you use @g, you need to be careful to make sure that @g has the same CHARACTER SET and COLLATION as `Genus`, else there could be a charset/collation conversion on the fly that prevents the use of the INDEX. Using the INDEX is vital for performance. It may require a COLLATE clause on SET NAMES and/or the @g in the SELECT.

Reclaiming the disk space

This is costly. (Switch to the PARTITION solution if practical.)

MyISAM leaves gaps in the table (.MYD file); OPTIMIZE TABLE will reclaim the freed space after a big delete. But it may take a long time and lock the table.

InnoDB is block-structured, organized in a BTree on the PRIMARY KEY. An isolated deleted row leaves a block less full. A lot of deleted rows can lead to coalescing of adjacent blocks. (Blocks are normally 16KB - see innodb_page_size.)

In InnoDB, there is no practical way to reclaim the freed space from ibdata1, other than to reuse the freed blocks eventually.

The only option with innodb_file_per_table = 0 is to dump ALL tables, remove ibdata*, restart, and reload. That is rarely worth the effort and time.

InnoDB, even with innodb_file_per_table = 1, won't give space back to the OS, but at least it is only one table to rebuild with. In this case, something like this should work:

```
CREATE TABLE new LIKE main;
INSERT INTO new SELECT * FROM main;  -- This could take a long time
RENAME TABLE main TO old, new TO main;   -- Atomic swap
DROP TABLE old;   -- Space freed up here
```

You do need enough disk space for both copies. You must not write to the table during the process.

Deleting more than half a table

The following technique can be used for any combination of

- Deleting a large portion of the table more efficiently
- Add PARTITIONing
- Converting to innodb_file_per_table = ON
- Defragmenting

This can be done by chunking, or (if practical) all at once:

```
-- Optional:  SET GLOBAL innodb_file_per_table = ON;
CREATE TABLE New LIKE Main;
-- Optional:  ALTER TABLE New ADD PARTITION BY RANGE ...;
-- Do this INSERT..SELECT all at once, or with chunking:
INSERT INTO New
   SELECT * FROM Main
      WHERE ...;  -- just the rows you want to keep
RENAME TABLE main TO Old, New TO Main;
DROP TABLE Old;   -- Space freed up here
```

Notes:

- You do need enough disk space for both copies.
- You must not write to the table during the process. (Changes to Main may not be reflected in New.)

Non-deterministic replication

Any UPDATE, DELETE, etc with LIMIT that is replicated to slaves (via Statement Based Replication) *may* cause inconsistencies between the Master and Slaves. This is because the actual order of the records discovered for updating/deleting may be different on the slave, thereby leading to a different subset being modified. To be safe, add ORDER BY to such statements. Moreover, be sure the ORDER BY is deterministic -- that is, the fields/expressions in the ORDER BY are unique.

An example of an ORDER BY that does not quite work: Assume there are multiple rows for each 'date':

```
DELETE * FROM tbl ORDER BY date LIMIT 111
```

Given that id is the PRIMARY KEY (or UNIQUE), this will be safe:

```
DELETE * FROM tbl ORDER BY date, id LIMIT 111
```

Unfortunately, even with the ORDER BY, MySQL has a deficiency that leads to a bogus warning in mysqld.err. See Spurious "Statement is not safe to log in statement format." warnings

Some of the above code avoids this spurious warning by doing

```
SELECT @z := ... LIMIT 1000,1;   -- not replicated
DELETE ... BETWEEN @a AND @z;    -- deterministic
```

That pair of statements guarantees no more than 1000 rows are touched, not the whole table.

Replication and KILL

If you KILL a DELETE (or any? query) on the master in the middle of its execution, what will be replicated?

If it is InnoDB, the query should be rolled back. (Exceptions??)

In MyISAM, rows are DELETEd as the statement is executed, and there is no provision for ROLLBACK. Some of the rows will be deleted, some won't. You probably have no clue of how much was deleted. In a single server, simply run the delete again. The delete is put into the binlog, but with error 1317. Since replication is supposed to keep the master and slave in sync, and since it has no clue of how to do that, replication stops and waits for manual intervention. In a HA (High Available) system using replication, this is a minor disaster. Meanwhile, you need to go to each slave(s) and verify that it is stuck for this reason, then do

```
SET GLOBAL SQL_SLAVE_SKIP_COUNTER = 1;
START SLAVE;
```

Then (presumably) re-executing the DELETE will finish the aborted task.

(That is yet another reason to move all your tables from MyISAM to InnoDB.)

SBR vs RBR; Galera

TBD -- "Row Based Replication" may impact this discussion.

Postlog

The tips in this document apply to MySQL, MariaDB, and Percona.

3.3.4.20 Data Sampling: Techniques for Efficiently Finding a Random Row

Contents

Fetching random rows from a table (beyond ORDER BY RAND())

The problem

One would like to do "SELECT ... ORDER BY RAND() LIMIT 10" to get 10 rows at random. But this is slow. The optimizer does

- Fetch all the rows -- this is costly

- Append RAND() to the rows
- Sort the rows -- also costly
- Pick the first 10.

All the algorithms given below are "fast", but most introduce flaws:

- Bias -- some rows are more like to be fetched than others.
- Repetitions -- If two random sets contain the same row, they are likely to contain other dups.
- Sometimes failing to fetch the desired number of rows.

"Fast" means avoiding reading all the rows. There are many techniques that require a full table scan, or at least an index scan. They are not acceptable for this list. There is even a technique that averages half a scan; it is relegated to a footnote.

Metrics

Here's a way to measure performance without having a big table.

```
    FLUSH STATUS;
    SELECT ...;
    SHOW SESSION STATUS LIKE 'Handler%';
```

If some of the "Handler" numbers look like the number of rows in the table, then there was a table scan.

None of the queries presented here need a full table (or index) scan. Each has a time proportional to the number of rows returned.

Virtually all published algorithms involve a table scan. The previously published version of this blog had, embarrassingly, several algorithms that had table scans.

Sometimes the scan can be avoided via a subquery. For example, the first of these will do a table scan; the second will not.

```
SELECT *  FROM RandTest AS a
  WHERE id = FLOOR(@min + (@max - @min + 1) * RAND());  -- BAD: table scan
SELECT *
 FROM RandTest AS a
 JOIN (
   SELECT FLOOR(@min + (@max - @min + 1) * RAND()) AS id -- Good; single eval.
      ) b  USING (id);
```

Case: Consecutive AUTO_INCREMENT without gaps, 1 row returned

- Requirement: AUTO_INCREMENT id
- Requirement: No gaps in id

```
  SELECT r.*
      FROM (
          SELECT FLOOR(mm.min_id + (mm.max_id - mm.min_id + 1) * RAND()) AS id
              FROM (
                  SELECT MIN(id) AS min_id,
                         MAX(id) AS max_id
                      FROM RandTest
                   ) AS mm
           ) AS init
      JOIN  RandTest AS r  ON r.id = init.id;
```

(Of course, you might be able to simplify this. For example, min_id is likely to be 1. Or precalculate limits into @min and @max.)

Case: Consecutive AUTO_INCREMENT without gaps, 10 rows

- Requirement: AUTO_INCREMENT id
- Requirement: No gaps in id
- Flaw: Sometimes delivers fewer than 10 rows

```
-- First select is one-time:
SELECT @min := MIN(id),
       @max := MAX(id)
    FROM RandTest;
SELECT DISTINCT *
    FROM RandTest AS a
    JOIN (
        SELECT FLOOR(@min + (@max - @min + 1) * RAND()) AS id
            FROM RandTest
            LIMIT 11     -- more than 10 (to compensate for dups)
         ) b  USING (id)
    LIMIT 10;            -- the desired number of rows
```

The FLOOR expression could lead to duplicates, hence the inflated inner LIMIT. There could (rarely) be so many duplicates that the inflated LIMIT leads to fewer than the desired 10 different rows. One approach to that Flaw is to rerun the query if it delivers too few rows.

A variant:

```
SELECT r.*
    FROM (
        SELECT FLOOR(mm.min_id + (mm.max_id - mm.min_id + 1) * RAND()) AS id
            FROM (
                SELECT MIN(id) AS min_id,
                       MAX(id) AS max_id
                    FROM RandTest
                 ) AS mm
            JOIN ( SELECT id dummy FROM RandTest LIMIT 11 ) z
         ) AS init
    JOIN  RandTest AS r  ON r.id = init.id
    LIMIT 10;
```

Again, ugly but fast, regardless of table size.

Case: AUTO_INCREMENT with gaps, 1 or more rows returned

- Requirement: AUTO_INCREMENT, possibly with gaps due to DELETEs, etc
- Flaw: Only semi-random (rows do not have an equal chance of being picked), but it does partially compensate for the gaps
- Flaw: The first and last few rows of the table are less likely to be delivered.

This gets 50 "consecutive" ids (possibly with gaps), then delivers a random 10 of them.

```
-- First select is one-time:
SELECT @min := MIN(id),
       @max := MAX(id)
    FROM RandTest;
SELECT a.*
    FROM RandTest a
    JOIN ( SELECT id FROM
            ( SELECT id
                FROM ( SELECT @min + (@max - @min + 1 - 50) * RAND()
                  AS start FROM DUAL ) AS init
                JOIN RandTest y
                WHERE    y.id > init.start
                ORDER BY y.id
                LIMIT 50          -- Inflated to deal with gaps
            ) z ORDER BY RAND()
           LIMIT 10               -- number of rows desired (change to 1 if looking for a single r
         ) r ON a.id = r.id;
```

Yes, it is complex, but yes, it is fast, regardless of the table size.

Case: Extra FLOAT column for randomizing

(Unfinished: need to check these.)

Assuming `rnd` is a FLOAT (or DOUBLE) populated with RAND() and INDEXed:

- Requirement: extra, indexed, FLOAT column
- Flaw: Fetches 10 adjacent rows (according to `rnd`), hence not good randomness
- Flaw: Near 'end' of table, can't find 10 rows.

```
SELECT r.*
    FROM ( SELECT RAND() AS start FROM DUAL ) init
    JOIN RandTest r
    WHERE r.rnd >= init.start
    ORDER BY r.rnd
    LIMIT 10;
```

- These two variants attempt to resolve the end-of-table flaw:

```
SELECT r.*
    FROM ( SELECT RAND() * ( SELECT rnd
                    FROM RandTest
                    ORDER BY rnd DESC
                    LIMIT 10,1 ) AS start
         ) AS init
    JOIN RandTest r
    WHERE r.rnd > init.start
    ORDER BY r.rnd
    LIMIT 10;

SELECT @start := RAND(),
       @cutoff := CAST(1.1 * 10 + 5 AS DECIMAL(20,8)) / TABLE_ROWS
    FROM information_schema.TABLES
    WHERE TABLE_SCHEMA = 'dbname'
      AND TABLE_NAME = 'RandTest'; -- 0.0030
SELECT d.*
    FROM (
        SELECT a.id
            FROM RandTest a
            WHERE rnd BETWEEN @start AND @start + @cutoff
         ) sample
    JOIN RandTest d USING (id)
    ORDER BY rand()
    LIMIT 10;
```

Case: UUID or MD5 column

- Requirement: UUID/GUID/MD5/SHA1 column exists and is indexed.
- Similar code/benefits/flaws to AUTO_INCREMENT with gaps.
- Needs 7 random HEX digits:

```
RIGHT( HEX( (1<<24) * (1+RAND()) ), 6)
```

can be used as a `start` for adapting a gapped AUTO_INCREMENT case. If the field is BINARY instead of hex, then

```
UNHEX(RIGHT( HEX( (1<<24) * (1+RAND()) ), 6))
```

3.3.4.21 Data Warehousing High Speed Ingestion

Contents

The problem

You are ingesting lots of data. Performance is bottlenecked in the INSERT area.

This will be couched in terms of Data Warehousing, with a huge `Fact` table and Summary (aggregation) tables.

Overview of solution

- Have a separate staging table.
- Inserts go into `Staging`.
- Normalization and Summarization reads Staging, not Fact.
- After normalizing, the data is copied from Staging to Fact.

`Staging` is one (or more) tables in which the data lives only long enough to be handed off to Normalization, Summary, and the Fact tables.

Since we are probably talking about a billion-row table, shrinking the width of the Fact table by normalizing (as mentioned here). Changing an INT to a MEDIUMINT will save a GB. Replacing a string by an id (normalizing) saves many GB. This helps disk space and cacheability, hence speed.

Injection speed

Some variations:

- Big dump of data once an hour, versus continual stream of records.
- The input stream could be single-threaded or multi-threaded.
- You might have 3rd party software tying your hands.

Generally the fastest injection rate can be achieved by "staging" the INSERTs in some way, then batch processing the staged records. This blog discusses various techniques for staging and batch processing.

Normalization

Let's say your Input has a VARCHAR `host_name` column, but you need to turn that into a smaller MEDIUMINT `host_id` in the Fact table. The "Normalization" table, as I call it, looks something like

```
CREATE TABLE Hosts (
    host_id  MEDIUMINT UNSIGNED  NOT NULL AUTO_INCREMENT,
    host_name VARCHAR(99) NOT NULL,
    PRIMARY KEY (host_id),      -- for mapping one direction
    INDEX(host_name, host_id)   -- for mapping the other direction
) ENGINE=InnoDB;                -- InnoDB works best for Many:Many mapping table
```

Here's how you can use `Staging` as an efficient way achieve the swap from name to id.

Staging has two fields (for this normalization example):

```
    host_name VARCHAR(99) NOT NULL,     -- Comes from the insertion proces
    host_id  MEDIUMINT UNSIGNED  NULL,  -- NULL to start with; see code below
```

Meawhile, the Fact table has:

```
    host_id  MEDIUMINT UNSIGNED NOT NULL,
```

SQL #1 (of 2):

```
# This should not be in the main transaction, and it should be done with autocommit = ON
# In fact, it could lead to strange errors if this were part
#    of the main transaction and it ROLLBACKed.
INSERT IGNORE INTO Hosts (host_name)
    SELECT DISTINCT s.host_name
        FROM Staging AS s
        LEFT JOIN Hosts AS n  ON n.host_name = s.host_name
        WHERE n.host_id IS NULL;
```

By isolating this as its own transaction, we get it finished in a hurry, thereby minimizing blocking. By saying IGNORE, we don't care if other threads are 'simultaneously' inserting the same host_names.

There is a subtle reason for the LEFT JOIN. If, instead, it were INSERT IGNORE..SELECT DISTINCT, then the INSERT would preallocate auto_increment ids for as many rows as the SELECT provides. This is very likely to "burn" a lot of ids, thereby leading to overflowing MEDIUMINT unnecessarily. The LEFT JOIN leads to finding just the new ids that are needed (except for the rare possibility of a 'simultaneous' insert by another thread). More rationale: Mapping table

SQL #2:

```
# Also not in the main transaction, and it should be with autocommit = ON
# This multi-table UPDATE sets the ids in Staging:
UPDATE   Hosts AS n
    JOIN Staging AS s  ON s.host_name = n host_name
    SET s.host_id = n.host_id
```

This gets the IDs, whether already existing, set by another thread, or set by SQL #1.

If the size of `Staging` changes depending on the busy versus idle times of the day, this pair of SQL statements has another comforting feature. The more rows in `Staging`, the more efficient the SQL runs, thereby helping compensate for the "busy" times.

The companion Data Warehouse article folds SQL #2 into the INSERT INTO Fact. But you may need host_id for further normalization steps and/or Summarization steps, so this explicit UPDATE shown here is often better.

Flip-flop staging

The simple way to stage is to ingest for a while, then batch-process what is in `Staging`. But that leads to new records piling up waiting to be staged. To avoid that issue, have 2 processes:

- one process (or set of processes) for INSERTing into `Staging`;
- one process (or set of processes) to do the batch processing (normalization, summarization).

To keep the processes from stepping on each other, we have a pair of staging tables:

- `Staging` is being INSERTed into;
- `StageProcess` is one being processed for normalization, summarization, and moving to the Fact table. A separate process does the processing, then swaps the tables:

```
DROP   TABLE StageProcess;
CREATE TABLE StageProcess LIKE Staging;
RENAME TABLE Staging TO tmp, StageProcess TO Staging, tmp TO StageProcess;
```

This may not seem like the shortest way to do it, but has these features:

- The DROP + CREATE might be faster than TRUNCATE, which is the desired effect.
- The RENAME is atomic, so the INSERT process(es) never find that `Staging` is missing.

A variant on the 2-table flip-flop is to have a separate `Staging` table for each Insertion process. The Processing process would run around to each Staging in turn.

A variant on that would be to have a separate processing process for each Insertion process.

The choice depends on which is faster (insertion or processing). There are tradeoffs; a single processing thread avoids some locks, but lacks some parallelism.

Engine choice

`Fact` table -- InnoDB, if for no other reason than that a system crash would not need a REPAIR TABLE. (REPAIRing a billion-row MyISAM table can take hours or days.)

Normalization tables -- InnoDB, primarily because it can be done efficiently with 2 indexes, whereas, MyISAM would need 4 to achieve the same efficiency.

`Staging` -- Lots of options here.

- If you have multiple Inserters and a single Staging table, InnoDB is desirable due to row-level, not table-level, locking.
- MEMORY may be the fastest and it avoids I/O. This is good for a single staging table.
- For multiple Inserters, a separate Staging table for each Inserter is desired.
- For multiple Inserters into a single Staging table, InnoDB may be faster. (MEMORY does table-level locking.)
- With one non-InnoDB Staging table per Inserter, using an explicit LOCK TABLE avoids repeated implicit locks on each INSERT.
- But, if you are doing LOCK TABLE and the Processing thread is separate, an UNLOCK is necessary periodically to let the RENAME grab the table.
- "Batch INSERTs" (100-1000 rows per SQL) eliminates much of the issues of the above bullet items.

Confused? Lost? There are enough variations in applications that make it impractical to predict what is best. Or, simply good enough. Your ingestion rate may be low enough that you don't hit the brick walls that I am helping you avoid.

Should you do "CREATE TEMPORARY TABLE"? Probably not. Consider `Staging` as part of the data flow, not to be DROPped.

Summarization

This is mostly covered here: Summary Tables
Summarize from the Staging table instead of the Fact table.

Replication Issues

Row Based Replication (RBR) is probably the best option.

The following allows you to keep more of the Ingestion process in the Master, thereby not bogging down the Slave(s) with writes to the Staging table.

- RBR
- `Staging` is in a separate database
- That database is not replicated (binlog-ignore-db on Master)
- In the Processing steps, USE that database, reach into the main db via syntax like "MainDb.Hosts". (Otherwise, the binlog-ignore-db does the wrong thing.)

That way

- Writes to `Staging` are not replicated.
- Normalization sends only the few updates to the normalization tables.
- Summarization sends only the updates to the summary tables.
- Flip-flop does not replicate the DROP, CREATE or RENAME.

Sharding

You could possibly spread the data you are trying ingest across multiple machines in a predictable way (sharding on hash, range, etc). Running "reports" on a sharded Fact table is a challenge unto itself. On the other hand, Summary Tables rarely get too big to manage on a single machine.

For now, Sharding is beyond the scope of this blog.

Push me vs pull me

I have implicitly assumed the data is being pushed into the database. If, instead, you are "pulling" data from some source(s), then there are some different considerations.

Case 1: An hourly upload; run via cron

1. Grab the upload, parse it 2. Put it into the Staging table 3. Normalize -- each SQL in its own transaction (autocommit) 4. BEGIN 5. Summarize 6. Copy from Staging to Fact. 7. COMMIT

If you need parallelism in Summarization, you will have to sacrifice the transactional integrity of steps 4-7.

Caution: If these steps add up to more than an hour, you are in deep dodo.

Case 2: You are polling for the data

It is probably reasonable to have multiple processes doing this, so it will be detailed about locking.

0. Create a Staging table for this polling processor. Loop: 1. With some locked mechanism, decide which 'thing' to poll. 2. Poll for the data, pull it in, parse it. (Potentially polling and parsing are significantly costly) 3. Put it into the process-specific Staging table 4. Normalize -- each SQL in its own transaction (autocommit) 5. BEGIN 6. Summarize 7. Copy from Staging to Fact. 8. COMMIT 9. Declare that you are finished with this 'thing' (see step 1) EndLoop.

iblog_file_size should be larger than the change in the STATUS "Innodb_os_log_written" across the BEGIN...COMMIT transaction (for either Case).

3.3.4.22 Data Warehousing Summary Tables

Contents

Preface

This document discusses the creation and maintenance of "Summary Tables". It is a companion to the document on Data Warehousing Techniques.

The basic terminology ("Fact Table", "Normalization", etc) is covered in that document.

Summary tables for data warehouse "reports"

Summary tables are a performance necessity for large tables. MariaDB and MySQL do not provide any automated way to create such, so I am providing techniques here.

(Other vendors provide something similar with "materialized views".)

When you have millions or billions of rows, it takes a long time to summarize the data to present counts, totals, averages, etc, in a size that is readily digestible by humans. By computing and saving subtotals as the data comes in, one can make "reports" run much faster. (I have seen 10x to 1000x speedups.) The subtotals go into a "summary table". This document guides you on efficiency in both creating and using such tables.

General structure of a summary table

A summary table includes two sets of columns:

- Main KEY: date + some dimension(s)
- Subtotals: COUNT(*), SUM(...), ...; but not AVG()

The "date" might be a DATE (a 3-byte native datatype), or an hour, or some other time interval. A 3-byte MEDIUMINT UNSIGNED 'hour' can be derived from a DATETIME or TIMESTAMP via

```
FLOOR(UNIX_TIMESTAMP(dt) / 3600)
FROM_UNIXTIME(hour * 3600)
```

The "dimensions" (a DW term) are some of the columns of the "Fact" table. Examples: Country, Make, Product, Category, Host Non-dimension examples: Sales, Quantity, TimeSpent

There would be one or more indexes, usually starting with some dimensions and ending with the date field. By ending with the date, one can efficiently get a range of days/weeks/etc. even when each row summarizes only one day.

There will typically be a "few" summary tables. Often one summary table can serve multiple purposes sufficiently efficiently.

As a rule of thumb, a summary table will have one-tenth the number of rows as the Fact table. (This number is very loose.)

Example

Let's talk about a large chain of car dealerships. The Fact table has all the sales with columns such as datetime, salesman_id, city, price, customer_id, make, model, model_year. One Summary table might focus on sales:

```
    PRIMARY KEY(city, datetime),
    Aggregations: ct, sum_price

    # Core of INSERT..SELECT:
    DATE(datetime) AS date, city, COUNT(*) AS ct, SUM(price) AS sum_price

    # Reporting average price for last month, broken down by city:
    SELECT city,
           SUM(sum_price) / SUM(ct) AS 'AveragePrice'
       FROM SalesSummary
       WHERE datetime BETWEEN ...
       GROUP BY city;

    # Monthly sales, nationwide, from same summary table:
    SELECT MONTH(datetime) AS 'Month',
           SUM(ct)         AS 'TotalSalesCount'
           SUM(sum_price)  AS 'TotalDollars'
       FROM SalesSummary
       WHERE datetime BETWEEN ...
       GROUP BY MONTH(datetime);
    # This might benefit from a secondary INDEX(datetime)
```

When to augment the summary table(s)?

"Augment" in this section means to add new rows into the summary table or increment the counts in existing rows.

Plan A: "While inserting" rows into the Fact table, augment the summary table(s). This is simple, and workable for a smaller DW database (under 10 Fact table rows per second). For larger DW databases, Plan A likely to be too costly to be practical.

Plan B: "Periodically", via cron or an EVENT.

Plan C: "As needed". That is, when someone asks for a report, the code first updates the summary tables that will be needed.

Plan D: "Hybrid" of B and C. C, by itself, can led to long delays for the report. By also doing B, those delays can be kept low.

Plan E: (This is not advised.) "Rebuild" the entire summary table from the entire Fact table. The cost of this is prohibitive for large tables. However, Plan E may be needed when you decide to change the columns of a Summary Table, or discover a flaw in the computations. To lessen the impact of an entire build, adapt the chunking techniques in Deleting in chunks .

Plan F: "Staging table". This is primarily for very high speed ingestion. It is mentioned briefly in this blog, and discussed more thoroughly in the companion blog: High Speed Ingestion

Summarizing while Inserting (one row at a time)

```
    INSERT INTO Fact ...;
    INSERT INTO Summary (..., ct, foo, ...) VALUES (..., 1, foo, ...)
        ON DUPLICATE KEY UPDATE ct = ct+1, sum_foo = sum_foo + VALUES(foo), ...;
```

IODKU (Insert On Duplicate Key Update) will update an existing row or create a new row. It knows which to do based on the Summary table's PRIMARY KEY.

Caution: This approach is costly, and will not scale to an ingestion rate of over, say, 10 rows per second (Or maybe 50/second on SSDs). More discussion later.

Summarizing periodically vs as-needed

If your reports need to be up-to-the-second, you need "as needed" or "hybrid". If your reports have less urgency (eg, weekly reports that don't include 'today'), then "periodically" might be best.

For a daily summaries, augmenting the summary tables could be done right after midnight. But, beware of data coming "late".

For both "periodic" and "as needed", you need a definitive way of keeping track of where you "left off".

Case 1: You insert into the Fact table first and it has an AUTO_INCREMENT id: Grab MAX(id) as the upper bound for summarizing and put it either into some other secure place (an extra table), or put it into the row(s) in the Summary table as you insert them. (Caveat: AUTO_INCREMENT ids do not work well in multi-master, including Galera, setups.)

Case 2: If you are using a 'staging' table, there is no issue. (More on staging tables later.)

Summarizing while batch inserting

This applies to multi-row (batch) INSERT and LOAD DATA.

The Fact table needs an AUTO_INCREMENT id, and you need to be able to find the exact range of ids inserted. (This may be impractical in any multi-master setup.)

Then perform bulk summarization using

```
    FROM Fact
    WHERE id BETWEEN min_id and max_id
```

Summarizing when using a staging table

Load the data (via INSERTs or LOAD DATA) en masse into a "staging table". Then perform batch summarization from the Staging table. And batch copy from the Staging table to the Fact table. Note that the Staging table is handy for batching "normalization" during ingestion. See also [[data-warehousing-high-speed-ingestion|High Speed Ingestion

Summary table: PK or not?

Let's say your summary table has a DATE, `dy`, and a dimension, `foo`. The question is: Should (foo, dy) be the PRIMARY KEY? Or a non-UNIQUE index?

Case 1: PRIMARY KEY (foo, dy) and summarization is in lock step with, say, changes in `dy`.

This case is clean and simple -- until you get to endcases. How will you handle the case of data arriving 'late'? Maybe you will need to recalculate some chunks of data? If so, how?

Case 2: (foo, dy) is a non-UNIQUE INDEX.

This case is clean and simple, but it can clutter the summary table because multiple rows can occur for a given (foo, dy) pair. The report will always have to SUM() up values because it cannot assume there is only one row, even when it is reporting on a single `foo` for a single `dy`. This forced-SUM is not really bad -- you should do it anyway; that way all your reports are written with one pattern.

Case 3: PRIMARY KEY (foo, dy) and summarization can happen anytime.

Since you should be using InnoDB, there needs to be an explicit PRIMARY KEY. One approach when you do not have a 'natural' PK is this:

```
    id INT UNSIGNED AUTO_INCREMENT NOT NULL,
    ...
    PRIMARY KEY(foo, dy, id),   -- `id` added to make unique
    INDEX(id)                   -- sufficient to keep AUTO_INCREMENT happy
```

This case pushes the complexity onto the summarization by doing a IODKU.

Advice? Avoid Case 1; too messy. Case 2 is ok if the extra rows are not too common. Case 3 may be the closest to "once size fits all".

Averages, etc.

When summarizing, include `COUNT(*) AS ct and SUM(foo) AS sum_foo`. When reporting, the "average" is computed as SUM(sum_foo) / SUM(ct). That is mathematically correct.

Exception... Let's say you are looking at weather temperatures. And you monitoring station gets the temp periodically, but unreliably. That is, the number of readings for a day varies. Further, you decide that the easiest way to compensate for the inconsistency is to do something like: Compute the avg temp for each day, then average those across the month (or other timeframe).

Formula for Standard Deviation:

```
    SQRT( SUM(sum_foo2)/SUM(ct) - POWER(SUM(sum_foo)/SUM(ct), 2) )
```

Where sum_foo2 is SUM(foo * foo) from the summary table. sum_foo and sum_foo2 should be FLOAT. FLOAT gives you about 7 significant digits, which is more than enough for things like average and standard deviation. FLOAT occupies 4 bytes. DOUBLE would give you more precision, but occupies 8 bytes. INT and BIGINT are not practical because they may lead to complaints about overflow.

Staging table

The idea here is to first load a set of Fact records into a "staging table", with the following characteristics (at least):

- The table is repeatedly populated and truncated
- Inserts could be individual or batched, and from one or many clients
- SELECTs will be table scans, so no indexes needed
- Inserting will be fast (InnoDB may be the fastest)
- Normalization can be done in bulk, hence efficiently
- Copying to the Fact table will be fast
- Summarization can be done in bulk, hence efficiently
- "Bursty" ingestion is smoothed by this process
- Flip-flop a pair of Staging tables

If you have bulk inserts (Batch INSERT or LOAD DATA) then consider doing the normalization and summarization immediately after each bulk insert.

More details: High Speed Ingestion

Extreme design

Here is a more complex way to design the system, with the goal of even more scaling.

- Use master-slave setup: ingest into master; report from slave(s).
- Feed ingestion through a staging table (as described above)
- Single-source of data: ENGINE=MEMORY; multiple sources: InnoDB
- binlog_format = ROW
- Use binlog_ignore_db to avoid replicating staging -- necessitating putting it in a separate database.
- Do the summarization from Staging
- Load Fact via INSERT INTO Fact ... SELECT FROM Staging ...

Explanation and comments:

- ROW + ignore_db avoids replicating Staging, yet replicates the INSERTs based on it. Hence, it lightens the write load on the Slaves
- If using MEMORY, remember that it is volatile -- recover from a crash by starting the ingestion over.
- To aid with debugging, TRUNCATE or re-CREATE Staging at the start of the next cycle.
- Staging needs no indexes -- all operations read all rows from it.

Stats on the system that this 'extreme design' came from: Fact Table: 450GB, 100M rows/day (batch of 4M/hour), 60 day retention (60+24 partitions), 75B/row, 7 summary tables, under 10 minutes to ingest and summarize the hourly batch. The INSERT..SELECT handled over 20K rows/sec going into the Fact table. Spinning drives (not SSD) with RAID-10.

"Left Off"

One technique involves summarizing some of the data, then recording where you "left off", so that next time, you can start there. There are some subtle issues with "left off" that you should be cautious of.

If you use a DATETIME or TIMESTAMP as "left off", beware of multiple rows with the same value.

- Plan A: Use a compound "left off" (eg, TIMESTAMP + ID). This is messy, error prone, etc.
- Plan B: WHERE ts >= $left_off AND ts < $max_ts -- avoids dups, but has other problems (below)
- Separate threads could COMMIT TIMESTAMPs out of order.

If you use an AUTO_INCREMENT as "left off" beware of:

- In InnoDB, separate threads could COMMIT ids in the 'wrong' order.
- Multi-master (including Galera and InnoDB Cluster), could lead to ordering issues.

So, nothing works, at least not in a multi-threaded environment?

If you can live with an occasional hiccup (skipped record), then maybe this is 'not a problem' for you.

The "Flip-Flop Staging" is a safe alternative, optionally combined with the "Extreme Design".

Flip-flop staging

If you have many threads simultaneously INSERTing into one staging table, then here is an efficient way to handle a large load: Have a process that flips that staging table with another, identical, staging table, and performs bulk normalization, Fact insertion, and bulk summarization.

The flipping step uses a fast, atomic, RENAME.

Here is a sketch of the code:

```
    # Prep for flip:
    CREATE TABLE new LIKE Staging;

    # Swap (flip) Staging tables:
    RENAME TABLE Staging TO old, new TO Staging;

    # Normalize new `foo`s:
    # (autocommit = 1)
    INSERT IGNORE INTO Foos SELECT fpp FROM old LEFT JOIN Foos ...

    # Prep for possible deadlocks, etc
    while...
    START TRANSACTION;

    # Add to Fact:
    INSERT INTO Fact ... FROM old JOIN Foos ...

    # Summarize:
    INSERT INTO Summary ... FROM old ... GROUP BY ...

    COMMIT;
    end-while

    # Cleanup:
    DROP TABLE old;
```

Meanwhile, ingestion can continue writing to `Staging`. The ingestion INSERTs will conflict with the RENAME, but will be resolved gracefully and silently and quickly.

How fast should you flip-flop? Probably the best scheme is to

- Have a job that flip-flops in a tight loop (no delay, or a small delay, between iterations), and
- Have a CRON that serves only as a "keep-alive" to restart the job if it dies.

If Staging is 'big', an iteration will take longer, but run more efficiently. Hence, it is self-regulating.

In a Galera (or InnoDB Cluster?) environment, each node could be receiving input. If can afford to loose a few rows, have `Staging` be a non-replicated MEMORY table. Otherwise, have one `Staging` per node and be InnoDB; it will be more secure, but slower and not without problems. In particular, if a node dies completely, you somehow need to process its `Staging` table.

Multiple summary tables

- Look at the reports you will need.
- Design a summary table for each.
- Then look at the summary tables -- you are likely to find some similarities.
- Merge similar ones.

To look at what a report needs, look at the WHERE clause that would provide the data. Some examples, assuming data about service records for automobiles: The GROUP BY to gives a clue of what the report might be about.

1. WHERE make = ? AND model_year = ? GROUP BY service_date, service_type 2. WHERE make = ? AND model = ? GROUP BY service_date, service_type 3. WHERE service_type = ? GROUP BY make, model, service_date 4. WHERE service_date between ? and ? GROUP BY make, model, model_year

You need to allow for 'ad hoc' queries? Well, look at all the ad hoc queries -- they all have a date range, plus nail down one or two other things. (I rarely see something as ugly as '%CL%' for nailing down another dimension.) So, start by thinking of date plus one or two other dimensions as the 'key' into a new summary table. Then comes the question of what data might be desired -- counts, sums, etc. Eventually you have a small set of summary tables. Then build a front end to allow them to pick only from those possibilities. It should encourage use of the existing summary tables, not not be truly 'open ended'.

Later, another 'requirement' may surface. So, build another summary table. Of course, it may take a day to initially populate it.

Games on summary tables

Does one ever need to summarize a summary table? Yes, but only in extreme situations. Usually a 'weekly' report can be derived from a 'daily' summary table; building a separate weekly summary table not being worth the effort.

Would one ever PARTITION a Summary Table? Yes, in extreme situations, such as the table being large, and

- Need to purge old data (unlikely), or
- Recent' data is usually requested, and the index(es) fail to prevent table scans (rare). ("Partition pruning" to the rescue.)

3.3.4.23 Data Warehousing Techniques

Contents

Preface

This document discusses techniques for improving performance for data-warehouse-like tables in MariaDB and MySQL.

- How to load large tables.
- Normalization.
- Developing 'summary tables' to make 'reports' efficient.
- Purging old data.

Details on summary tables is covered in the companion document: Summary Tables.

Terminology

This list mirrors "Data Warehouse" terminology.

- Fact table -- The one huge table with the 'raw' data.
- Summary table -- a redundant table of summarized data that could -- use for efficiency
- Dimension -- columns that identify aspects of the dataset (region, country, user, SKU, zipcode, ...)
- Normalization table (dimension table) -- mapping between strings an ids; used for space and speed.
- Normalization -- The process of building the mapping ('New York City' <-> 123)

Fact table

Techniques that should be applied to the huge Fact table.

- id INT/BIGINT UNSIGNED NOT NULL AUTO_INCREMENT
- PRIMARY KEY (id)
- Probably no other INDEXes
- Accessed only via id
- All VARCHARs are "normalized"; ids are stored instead
- ENGINE = InnoDB
- All "reports" use summary tables, not the Fact table
- Summary tables may be populated from ranges of id (other techniques described below)

There are exceptions where the Fact table must be accessed to retrieve multiple rows. However, you should minimize the number of INDEXes on the table because they are likely to be costly on INSERT.

Why keep the Fact table?

Once you have built the Summary table(s), there is not much need for the Fact table. One option that you should seriously consider is to not have a Fact table. Or, at least, you could purge old data from it sooner than you purge the Summary tables. Maybe even keep the Summary tables forever.

Case 1: You need to find the raw data involved in some event. But how will you find those row(s)? This is where a secondary index may be required.

If a secondary index is bigger than can be cached in RAM, and if the column(s) being indexed is random, then each row inserted may cause a disk hit to update the index. This limits insert speed to something like 100 rows per second (on ordinary disks). Multiple random indexes slow down insertion further. RAID striping and/or SSDs speed up insertion. Write caching helps, but only for bursts.

Case 2: You need some event, but you did not plan ahead with the optimal INDEX. Well, if the data is PARTITIONed on date, so even if you have a clue of when the event occurred, "partition pruning" will keep the query from being too terribly slow.

Case 3: Over time, the application is likely to need new 'reports', which may lead to a new Summary table. At this point, it would be handy to scan through the old data to fill up the new table.

Case 4: You find a flaw in the summarization, and need to rebuild an existing Summary table.

Cases 3 and 4 both need the "raw" data. But they don't necessarily need the data sitting in a database table. It could be in the pre-database format (such as log files). So, consider not building the Fact table, but simply keep the raw data, comressed, on some file system.

Batching the load of the Fact table

When talking about billions of rows in the Fact table, it is essentially mandatory that you "batch" the inserts. There are two main ways:

- INSERT INTO Fact (.,.,.) VALUES (.,.,.), (.,.,.), ...; -- "Batch insert"
- LOAD DATA ...;

A third way is to INSERT or LOAD into a Staging table, then

- INSERT INTO Fact SELECT * FROM Staging; This INSERT..SELECT allows you to do other things, such as normalization. More later.

Batched INSERT Statement

Chunk size should usually be 100-1000 rows.

- 100-1000 an insert will run 10 times as fast as single-row inserts.
- Beyond 100, you may be interfering replication and SELECTs.
- Beyond 1000, you are into diminishing returns -- virtually no further performance gains.
- Don't go past, say, 1MB for the constructed INSERT statement. This deals with packet sizes, etc. (1MB is unlikely to be hit for a Fact table.) Decide whether your application should lean toward the 100 or the 1000.

If your data is coming in continually, and you are adding a batching layer, let's do some math. Compute your ingestion rate -- R rows per second.

- If R < 10 (= 1M/day = 300M/year) -- single-row INSERTs would probably work fine (that is, batching is optional)
- If R < 100 (3B records per year) -- secondary indexes on Fact table may be ok
- If R < 1000 (100M records/day) -- avoid secondary indexes on Fact table.
- If R > 1000 -- Batching may not work. Decide how long (S seconds) you can stall loading the data in order to collect a batch of rows.
- If S < 0.1s -- May not be able to keep up

If batching seems viable, then design the batching layer to gather for S seconds or 100-1000 rows, whichever comes first.

(Note: Similar math applies to rapid UPDATEs of a table.)

Normalization (Dimension) table

Normalization is important in Data Warehouse applications because it significantly cuts down on the disk footprint and improves performance. There are other reasons for normalizing, but space is the important one for DW.

Here is a typical pattern for a Dimension table:

```
CREATE TABLE Emails (
    email_id MEDIUMINT UNSIGNED NOT NULL AUTO_INCREMENT,  -- don't make bigger than needed
    email VARCHAR(...) NOT NULL,
    PRIMARY KEY (email),  -- for looking up one way
    INDEX(email_id)  -- for looking up the other way (UNIQUE is not needed)
) ENGINE = InnoDB;  -- to get clustering
```

Notes:

- MEDIUMINT is 3 bytes with UNSIGNED range of 0..16M; pick SMALLINT, INT, etc, based on a conservative estimate of how many 'foo's you will eventually have.
- datatype sizes
- There may be more than one VARCHAR in the table. Example: For cities, you might have City and Country.
- InnoDB is better than MyISAM because of way the two keys are structured.
- The secondary key is effectively (email_id, email), hence 'covering' for certain queries.
- It is OK to not specify an AUTO_INCREMENT to be UNIQUE.

Batched normalization

I bring this up as a separate topic because of some of the subtle issues that can happen.

You may be tempted to do

```
INSERT IGNORE INTO Foos
    SELECT DISTINCT foo FROM Staging;  -- not wise
```

It has the problem of "burning" AUTO_INCREMENT ids. This is because MariaDB pre-allocates ids before getting to "IGNORE". That could rapidly increase the AUTO_INCREMENT values beyond what you expected.

Better is this...

```
INSERT IGNORE INTO Foos
    SELECT DISTINCT foo
        FROM Staging
        LEFT JOIN Foos ON Foos.foo = Staging.foo
        WHERE Foos.foo_id IS NULL;
```

Notes:

- The LEFT JOIN .. IS NULL finds the `foo`s that are not yet in Foos.
- This INSERT..SELECT must not be done inside the transaction with the rest of the processing. Otherwise, you add to deadlock risks, leading to burned ids.
- IGNORE is used in case you are doing the INSERT from multiple processes simultaneously.

Once that INSERT is done, this will find all the foo_ids it needs:

```
INSERT INTO Fact (..., foo_id, ...)
    SELECT ..., Foos.foo_id, ...
        FROM Staging
        JOIN Foos ON Foos.foo = Staging.foo;
```

An advantage of "Batched Normalization" is that you can summarize directly from the Staging table. Two approaches:

Case 1: PRIMARY KEY (dy, foo) and summarization is in lock step with, say, changes in `dy`.

- This approach can have troubles if new data arrives after you have summarized the day's data.

```
INSERT INTO Summary (dy, foo, ct, blah_total)
    SELECT  DATE(dt) as dy, foo,
            COUNT(*) as ct, SUM(blah) as blah_total)
        FROM Staging
        GROUP BY 1, 2;
```

Case 2: (dy, foo) is a non-UNIQUE INDEX.

- Same code as Case 1.
- By having the index be non-UNIQUE, delayed data simply shows up as extra rows.
- You need to take care to avoid summarizing the data twice. (The id on the Fact table may be a good tool for that.)

Case 3: PRIMARY KEY (dy, foo) and summarization can happen anytime.

```
    INSERT INTO Summary (dy, foo, ct, blah_total)
        ON DUPLICATE KEY UPDATE
            ct = ct + VALUE(ct),
            blah_total = blah_total + VALUE(bt)
        SELECT  DATE(dt) as dy, foo,
                COUNT(*) as ct, SUM(blah) as bt)
            FROM Staging
            GROUP BY 1, 2;
```

Too many choices?

This document lists a number of ways to do things. Your situation may lead to one approach being more/less acceptable. But, if you are thinking "Just tell me what to do!", then here:

- Batch load the raw data into a temporary table (`Staging`).
- Normalize from `Staging` -- use code in Case 3.
- INSERT .. SELECT to move the data from `Staging` into the Fact table
- Summarize from `Staging` to Summary table(s) via IODKU (Insert ... On Duplicate Key Update).
- Drop the Staging

Those techniques should perform well and scale well in most cases. As you develop your situation, you may discover why I described alternative solutions.

Purging old data

Typically the Fact table is PARTITION BY RANGE (10-60 ranges of days/weeks/etc) and needs purging (DROP PARTITION) periodically. This discusses a safe/clean way to design the partitioning and do the DROPs: Purging PARTITIONs

Master / slave

For "read scaling", backup, and failover, use master-slave replication or something fancier. Do ingestion only on a single active master; it replicate to the slave(s). Generate reports on the slave(s).

Sharding

"Sharding" is the splitting of data across multiple servers. (In contrast, replication and Galera have the same data on all servers, requiring all data to be written to all servers.)

With the non-sharding techniques described here, terabyte(s) of data can be handled by a single machine. Tens of terabytes probably requires sharding.

Sharding is beyond the scope of this document.

How fast? How big?

With the techniques described here, you may be able to achieve the following performance numbers. I say "may" because every data warehouse situation is different, and you may require performance-hurting deviations from what I describe here. I give multiple options for some aspects; these may cover some of your deviations.

One big performance killer is UUID/GUID keys. Since they are very 'random', updates of them (at scale) are limited to 1 row = 1 disk hit. Plain disks can handle only 100 hits/second. RAID and/or SSD can increase that to something like 1000 hits/sec. Huge amounts of RAM (for caching the random index) are a costly solution. It is possible to turn type-1 UUIDs into roughly-chronological keys, thereby mittigating the performance problems if the UUIDs are written/read with some chronological clustering. UUID discussion

Hardware, etc:

- Single SATA drive: 100 IOPs (Input/Output operations per second)
- RAID with N physical drives -- 100*N IOPs (roughly)
- SSD -- 5 times as fast as rotating media (in this context)
- Batch INSERT -- 100-1000 rows is 10 times as fast as INSERTing 1 row at a time (see above)
- Purge "old" data -- Do not use DELETE or TRUNCATE, design so you can use DROP PARTITION (see above)
- Think of each INDEX (except the PRIMARY KEY on InnoDB) as a separate table
- Consider access patterns of each table/index: random vs at-the-end vs something in between

"Count the disk hits" -- back-of-envelope performance analysis

- Random accesses to a table/index -- count each as a disk hit.
- At-the-end accesses (INSERT chronologically or with AUTO_INCREMENT; range SELECT) -- count as zero hits.
- In between (hot/popular ids, etc) -- count as something in between
- For INSERTs, do the analysis on each index; add them up.
- For SELECTs, do the analysis on the one index used, plus the table. (Use of 2 indexes is rare.) Insert cost, based on datatype of first column in an index:
- AUTO_INCREMENT -- essentially 0 IOPs
- DATETIME, TIMESTAMP -- essentially 0 for 'current' times
- UUID/GUID -- 1 per insert (terrible)
- Others -- depends on their patterns SELECT cost gets a little tricky:
- Range on PRIMARY KEY -- think of it as getting 100 rows per disk hit.
- IN on PRIMARY KEY -- 1 disk hit per item in IN
- "=" -- 1 hit (for 1 row)
- Secondary key -- First compute the hits for the index, then...
- Think of each row as needing 1 disk hit.
- However, if the rows are likely to be 'near' each other (based on the PRIMARY KEY), then it could be < 1 disk hit/row.

More on Count the Disk Hits

How fast?

Look at your data; compute raw rows per second (or hour or day or year). There are about 30M seconds in a year; 86,400 seconds per day. Inserting 30 rows per second becomes a billion rows per year.

10 rows per second is about all you can expect from an ordinary machine (after allowing for various overheads). If you have less than that, you don't have many worries, but still you should probably create Summary tables. If more than 10/sec, then batching, etc, becomes vital. Even on spiffy hardware, 100/sec is about all you can expect without utilizing the techniques here.

Not so fast?

Let's say your insert rate is only one-tenth of your disk IOPs (eg, 10 rows/sec vs 100 IOPs). Also, let's say your data is not "bursty"; that is, the data comes in somewhat soothly throughout the day.

Note that 10 rows/sec (300M/year) implies maybe 30GB for data + indexes + normalization tables + summary tables for 1 year. I would call this "not so big".

Still, the normalization and summarization are important. Normalization keeps the data from being, say, twice as big. Summarization speeds up the reports by orders of magnitude.

Let's design and analyse a "simple ingestion scheme" for 10 rows/second, without 'batching'.

```
    # Normalize:
    $foo_id = SELECT foo_id FROM Foos WHERE foo = $foo;
    if no $foo_id, then
        INSERT IGNORE INTO Foos ...

    # Inserts:
    BEGIN;
        INSERT INTO Fact ...;
        INSERT INTO Summary ... ON DUPLICATE KEY UPDATE ...;
    COMMIT;
    # (plus code to deal with errors on INSERTs or COMMIT)
```

Depending on the number and randomness of your indexes, etc, 10 Fact rows may (or may not) take less than 100 IOPs.

Also, note that as the data grows over time, random indexes will become less and less likely to be cached. That is, even if runs fine with 1 year's worth of data, it may be in trouble with 2 year's worth.

For those reasons, I started this discussion with a wide margin (10 rows versus 100 IOPs).

3.3.4.24 Equality propagation optimization

Contents

Basic idea

Consider a query with a WHERE clause:

```
WHERE col1=col2 AND ...
```

the WHERE clause will compute to true only if `col1=col2`. This means that in the rest of the WHERE clause occurrences of `col1` can be substituted with `col2` (with some limitations which are discussed in the next section). This allows the optimizer to infer additional restrictions.

For example:

```
WHERE col1=col2 AND col1=123
```

allows to infer a new equality: `col2=123`

```
WHERE col1=col2 AND col1 < 10
```

allows to infer that `col2<10`.

Identity and comparison substitution

There are some limitations to where one can do the substitution, though.

The first and obvious example is the string datatype and collations. Most commonly-used collations in SQL are "case-insensitive", that is `'A'='a'`. Also, most collations have a "PAD SPACE" attribute, which means that comparison ignores the spaces at the end of the value, `'a'='a  '`.

Now, consider a query:

```
INSERT INTO t1 (col1, col2) VALUES ('ab', 'ab   ');
SELECT * FROM t1 WHERE col1=col2 AND LENGTH(col1)=2
```

Here, `col1=col2`, the values are "equal". At the same time `LENGTH(col1)=2`, while `LENGTH(col2)=4`, which means one can't perform the substiution for the argument of LENGTH(...).

It's not only collations. There are similar phenomena when equality compares columns of different datatypes. The exact criteria of when thy happen are rather convoluted.

The take-away is: **sometimes, X=Y does not mean that one can replace any reference to X with Y**. What one CAN do is still replace the occurrence in the comparisons `<`, `>`, `>=`, `<=`, etc.

This is how we get two kinds of substitution:

- **Identity substitution**: X=Y, and any occurrence of X can be replaced with Y.
- **Comparison substitution**: X=Y, and an occurrence of X in a comparison (X<Z) can be replaced with Y (Y<Z).

Place in query optimization

(A draft description): Let's look at how Equality Propagation is integrated with the rest of the query optimization process.

- First, multiple-equalities are built (TODO example from optimizer trace)
  - If multiple-equality includes a constant, fields are substituted with a constant if possible.
- From this point, all optimizations like range optimization, ref access, etc make use of multiple equalities: when they see a reference to `tableX.columnY` somewhere, they also look at all the columns that tableX.columnY is equal to.
- After the join order is picked, the optimizer walks through the WHERE clause and substitutes each field reference with the "best" one - the one that can be checked as soon as possible.
  - Then, the parts of the WHERE condition are attached to the tables where they can be checked.

Interplay with ORDER BY optimization

Consider a query:

```
SELECT ... FROM ... WHERE col1=col2 ORDER BY col2
```

Suppose, there is an `INDEX(col1)`. MariaDB optimizer is able to figure out that it can use an index on `col1` (or sort by the value of `col1`) in order to resolve `ORDER BY col2`.

Optimizer trace

Look at these elements:

- `condition_processing`
- `attaching_conditions_to_tables`

More details

Equality propagation doesn't just happen at the top of the WHERE clause. It is done "at all levels" where a level is:

- A top level of the WHERE clause.
- If the WHERE clause has an OR clause, each branch of the OR clause.
- The top level of any ON expression
- (the same as above about OR-levels)

3.3.4.25 FORCE INDEX

Contents

Description

Forcing an index to be used is mostly useful when the optimizer decides to do a table scan even if you know that using an index would be better. (The optimizer could decide to do a table scan even if there is an available index when it believes that most or all rows will match and it can avoid the overhead of using the index).

FORCE INDEX works by only considering the given indexes (like with USE_INDEX) but in addition it tells the optimizer to regard a table scan as something very expensive. However if none of the 'forced' indexes can be used, then a table scan will be used anyway.

FORCE INDEX cannot force an ignored index to be used - it will be treated as if it doesn't exist.

Example

```
CREATE INDEX Name ON City (Name);
EXPLAIN SELECT Name,CountryCode FROM City FORCE INDEX (Name)
WHERE name>="A" and CountryCode >="A";
```

This produces:

```
id select_type table type possible_keys key key_len ref rows Extra
1 SIMPLE City range Name Name 35 NULL 4079 Using where
```

Index Prefixes

When using index hints (USE, FORCE or IGNORE INDEX), the index name value can also be an unambiguous prefix of an index name.

3.3.4.26 Groupwise Max in MariaDB

Contents

The problem

You want to find the largest row in each group of rows. An example is looking for the largest city in each state. While it is easy to find the MAX(population) ... GROUP BY state, it is hard to find the name of the `city` associated with that `population`. Alas, MySQL and MariaDB do not have any syntax to provide the solution directly.

This article is under construction, mostly for cleanup. The content is reasonably accurate during construction.

The article presents two "good" solutions. They differ in ways that make neither of them 'perfect'; you should try both and weigh the pros and cons.

Also, a few "bad" solutions will be presented, together with why they were rejected.

MySQL manual gives 3 solutions; only the "Uncorrelated" one is "good", the other two are "bad".

Sample data

To show how the various coding attempts work, I have devised this simple task: Find the largest city in each Canadian province. Here's a sample of the source data (5493 rows):

```
+------------------+----------------+------------+
| province         | city           | population |
+------------------+----------------+------------+
| Saskatchewan     | Rosetown       |       2309 |
| British Columbia | Chilliwack     |      51942 |
| Nova Scotia      | Yarmouth       |       7500 |
| Alberta          | Grande Prairie |      41463 |
| Quebec           | Sorel          |      33591 |
| Ontario          | Moose Factory  |       2060 |
| Ontario          | Bracebridge    |       8238 |
| British Columbia | Nanaimo        |      84906 |
| Manitoba         | Neepawa        |       3151 |
| Alberta          | Grimshaw       |       2560 |
| Saskatchewan     | Carnduff       |        950 |
...
```

Here's the desired output (13 rows):

```
+--------------------------+---------------+------------+
| province                 | city          | population |
+--------------------------+---------------+------------+
| Alberta                  | Calgary       |     968475 |
| British Columbia         | Vancouver     |    1837970 |
| Manitoba                 | Winnipeg      |     632069 |
| New Brunswick            | Saint John    |      87857 |
| Newfoundland and Labrador | Corner Brook  |      18693 |
| Northwest Territories    | Yellowknife   |      15866 |
| Nova Scotia              | Halifax       |     266012 |
| Nunavut                  | Iqaluit       |       6124 |
| Ontario                  | Toronto       |    4612187 |
| Prince Edward Island     | Charlottetown |      42403 |
| Quebec                   | Montreal      |    3268513 |
| Saskatchewan             | Saskatoon     |     198957 |
| Yukon                    | Whitehorse    |      19616 |
+--------------------------+---------------+------------+
```

Duplicate max

One thing to consider is whether you want -- or do not want -- to see multiple rows for tied winners. For the dataset being used here, that would imply that the two largest cities in a province had identical populations. For this case, a duplicate would be unlikely. But there are many groupwise-max use cases where duplictes are likely.

The two best algorithms differ in whether they show duplicates.

Using an uncorrelated subquery

Characteristics:

- Superior performance or medium performance
- It will show duplicates
- Needs an extra index
- Probably requires 5.6
- If all goes well, it will run in O(M) where M is the number of output rows.

An 'uncorrelated subquery':

```
SELECT  c1.province, c1.city, c1.population
    FROM  Canada AS c1
    JOIN
      ( SELECT  province, MAX(population) AS population
            FROM  Canada
            GROUP BY  province
      ) AS c2 USING (province, population)
    ORDER BY c1.province;
```

But this also 'requires' an extra index: INDEX(province, population). In addition, MySQL has not always been able to use that index effectively, hence the "requires 5.6". (I am not sure of the actual version.)

Without that extra index, you would need 5.6, which has the ability to create indexes for subqueries. This is indicated by <auto_key0> in the EXPLAIN. Even so, the performance is worse with the auto-generated index than with the manually generated one.

With neither the extra index, nor 5.6, this 'solution' would belong in 'The Duds' because it would run in O(N*N) time.

Using @variables

Characteristics:

- Good performance
- Does not show duplicates (picks one to show)
- Consistent O(N) run time (N = number of input rows)
- Only one scan of the data

```
SELECT
        province, city, population   -- The desired columns
    FROM
      ( SELECT  @prev := '' ) init
    JOIN
      ( SELECT  province != @prev AS first,  -- `province` is the 'GROUP BY'
                @prev := province,           -- The 'GROUP BY'
                province, city, population   -- Also the desired columns
            FROM  Canada           -- The table
            ORDER BY
                province,          -- The 'GROUP BY'
                population DESC    -- ASC for MIN(population), DESC for MAX
      ) x
    WHERE  first
    ORDER BY  province;     -- Whatever you like
```

For your application, change the lines with comments.

The duds

*** 'correlated subquery' (from MySQL doc):**

```
SELECT  province, city, population
    FROM  Canada AS c1
    WHERE  population =
      ( SELECT  MAX(c2.population)
            FROM  Canada AS c2
            WHERE  c2.province= c1.province
      )
    ORDER BY  province;
```

O(N*N) (that is, terrible) performance

*** LEFT JOIN (from MySQL doc):**

```
SELECT  c1.province, c1.city, c1.population
    FROM  Canada AS c1
    LEFT JOIN  Canada AS c2 ON c2.province = c1.province
      AND  c2.population > c1.population
    WHERE  c2.province IS NULL
    ORDER BY province;
```

Medium performance (2N-3N, depending on join_buffer_size).

For O(N*N) time,... It will take one second to do a groupwise-max on a few thousand rows; a million rows could take hours.

Top-N in each group

This is a variant on "groupwise-max" wherein you desire the largest (or smallest) N items in each group. Do these substitutions for your use case:

- province --> your 'GROUP BY'
- Canada --> your table
- 3 --> how many of each group to show
- population --> your numeric field for determining "Top-N"
- city --> more field(s) you want to show
- Change the SELECT and ORDER BY if you desire
- DESC to get the 'largest'; ASC for the 'smallest'

```
SELECT
        province, n, city, population
    FROM
      ( SELECT  @prev := '', @n := 0 ) init
    JOIN
      ( SELECT  @n := if(province != @prev, 1, @n + 1) AS n,
                @prev := province,
                province, city, population
            FROM  Canada
            ORDER BY
                province   ASC,
                population DESC
      ) x
    WHERE  n <= 3
    ORDER BY  province, n;
```

Output:

```
+--------------------------+------+------------------+------------+
| province                 | n    | city             | population |
+--------------------------+------+------------------+------------+
| Alberta                  |    1 | Calgary          |     968475 |
| Alberta                  |    2 | Edmonton         |     822319 |
| Alberta                  |    3 | Red Deer         |      73595 |
| British Columbia         |    1 | Vancouver        |    1837970 |
| British Columbia         |    2 | Victoria         |     289625 |
| British Columbia         |    3 | Abbotsford       |     151685 |
| Manitoba                 |    1 | ...
```

The performance of this is O(N), actually about 3N, where N is the number of source rows.

EXPLAIN EXTENDED gives

```
+----+-------------+------------+--------+---------------+------+---------+------+------+----
------+----------------+
| id | select_type | table      | type   | possible_keys | key  | key_len | ref  | rows |
filtered | Extra          |
+----+-------------+------------+--------+---------------+------+---------+------+------+----
------+----------------+
|  1 | PRIMARY     | <derived2> | system | NULL          | NULL | NULL    | NULL |    1 |
100.00 | Using filesort |
|  1 | PRIMARY     | <derived3> | ALL    | NULL          | NULL | NULL    | NULL | 5484 |
100.00 | Using where    |
|  3 | DERIVED     | Canada     | ALL    | NULL          | NULL | NULL    | NULL | 5484 |
100.00 | Using filesort |
|  2 | DERIVED     | NULL       | NULL   | NULL          | NULL | NULL    | NULL | NULL |
NULL | No tables used |
+----+-------------+------------+--------+---------------+------+---------+------+------+----
------+----------------+
```

Explanation, shown in the same order as the EXPLAIN, but numbered chronologically: 3. Get the subquery id=2 (init) 4. Scan the the output from subquery id=3 (x) 2. Subquery id=3 -- the table scan of Canada 1. Subquery id=2 -- `init` for simply initializing the two @variables Yes, it took two sorts, though probably in RAM.

Main Handler values:

```
| Handler_read_rnd           | 39    |
| Handler_read_rnd_next      | 10971 |
| Handler_write              | 5485  |  -- #rows in Canada (+1)
```

Top-n in each group, take II

This variant is faster than the previous, but depends on `city` being unique across the dataset. (from openark.org)

```
SELECT  province, city, population
    FROM  Canada
    JOIN
      ( SELECT  GROUP_CONCAT(top_in_province) AS top_cities
            FROM
              ( SELECT  SUBSTRING_INDEX(
                            GROUP_CONCAT(city ORDER BY  population DESC),
                        ',', 3) AS top_in_province
                    FROM  Canada
                    GROUP BY  province
              ) AS x
      ) AS y
    WHERE  FIND_IN_SET(city, top_cities)
    ORDER BY  province, population DESC;
```

Output. Note how there can be more than 3 cities per province:

```
| Alberta                  | Calgary          |     968475 |
| Alberta                  | Edmonton         |     822319 |
| Alberta                  | Red Deer         |      73595 |
| British Columbia         | Vancouver        |    1837970 |
| British Columbia         | Victoria         |     289625 |
| British Columbia         | Abbotsford       |     151685 |
| British Columbia         | Sydney           |          0 | -- Nova Scotia's second largest is
| Manitoba                 | Winnipeg         |     632069 |
```

Main Handler values:

```
| Handler_read_next          | 5484  | -- table size
| Handler_read_rnd_next      | 5500  | -- table size + number of provinces
| Handler_write              | 14    | -- number of provinces (+1)
```

Top-n using MyISAM

(This does not need your table to be MyISAM, but it does need MyISAM tmp table for its 2-column PRIMARY KEY feature.) See previous section for what changes to make for your use case.

```
    -- build tmp table to get numbering
    -- (Assumes auto_increment_increment = 1)
    CREATE TEMPORARY TABLE t (
        nth MEDIUMINT UNSIGNED NOT NULL AUTO_INCREMENT,
        PRIMARY KEY(province, nth)
    ) ENGINE=MyISAM
        SELECT province, NULL AS nth, city, population
            FROM Canada
            ORDER BY population DESC;
    -- Output the biggest 3 cities in each province:
    SELECT province, nth, city, population
        FROM t
        WHERE nth <= 3
        ORDER BY province, nth;

+--------------------------+-----+-----------------+------------+
| province                 | nth | city            | population |
+--------------------------+-----+-----------------+------------+
| Alberta                  |   1 | Calgary         |     968475 |
| Alberta                  |   2 | Edmonton        |     822319 |
| Alberta                  |   3 | Red Deer        |      73595 |
| British Columbia         |   1 | Vancouver       |    1837970 |
| British Columbia         |   2 | Victoria        |     289625 |
| British Columbia         |   3 | Abbotsford      |     151685 |
| Manitoba                 |  ...

SELECT for CREATE:
+----+-------------+--------+------+---------------+------+---------+------+------+--------------
| id | select_type | table  | type | possible_keys | key  | key_len | ref  | rows | Extra
+----+-------------+--------+------+---------------+------+---------+------+------+--------------
|  1 | SIMPLE      | Canada | ALL  | NULL          | NULL | NULL    | NULL | 5484 | Using filesor
+----+-------------+--------+------+---------------+------+---------+------+------+--------------
Other SELECT:
+----+-------------+-------+-------+---------------+---------+---------+------+------+-----------
| id | select_type | table | type  | possible_keys | key     | key_len | ref  | rows | Extra
+----+-------------+-------+-------+---------------+---------+---------+------+------+-----------
|  1 | SIMPLE      | t     | index | NULL          | PRIMARY | 104     | NULL |   22 | Using wher
+----+-------------+-------+-------+---------------+---------+---------+------+------+-----------
```

The main handler values (total of all operations):

```
| Handler_read_rnd_next      | 10970 |
| Handler_write              | 5484  |  -- number of rows in Canada (write tmp table)
```

Both "Top-n" formulations probably take about the same amount of time.

Windowing functions

Hot off the press from Percona Live... MariaDB 10.2 has "windowing functions", which make "groupwise max" much more straightforward.

The code:

TBD

Postlog

Developed an first posted, Feb, 2015; Add MyISAM approach: July, 2015; Openark's method added: Apr, 2016; Windowing: Apr 2016

I did not include the technique(s) using GROUP_CONCAT. They are useful in some situations with small datasets. They can be found in the references below.

3.3.4.27 GUID/UUID Performance

Contents

The problem

GUIDs/UUIDs (Globally/Universally Unique Identifiers) are very random. Therefore, INSERTing into an index means jumping around a lot. Once the index is too big to be cached, most INSERTs involve a disk hit. Even on a beefy system, this limits you to a few hundred INSERTs per second.

MariaDB's UUID function.

This blog is mostly eliminated in MySQL 8.0 with the advent of the following function: UUID_TO_BIN(str, swap_flag).

Why it is a problem

A 'standard' GUID/UUID is composed of the time, machine identification and some other stuff. The combination should be unique, even without coordination between different computers that could be generating UUIDs simultaneously.

The top part of the GUID/UUID is the bottom part of the current time. The top part is the primary part of what would be used for placing the value in an ordered list (INDEX). This cycles in about 7.16 minutes.

Some math... If the index is small enough to be cached in RAM, each insert into the index is CPU only, with the writes being delayed and batched. If the index is 20 times as big as can be cached, then 19 out of 20 inserts will be a cache miss. (This math applies to any "random" index.)

Second problem

36 characters is bulky. If you are using that as a PRIMARY KEY in InnoDB and you have secondary keys, remember that each secondary key has an implicit copy of the PK, thereby making it bulky.

It is tempting to declare the UUID VARCHAR(36). And, since you probably are thinking globally, so you have CHARACTER SET utf8 (or utf8mb4). For utf8:

- 2 - Overhead for VAR
- 36 - chars
- 3 (or 4) bytes per character for utf8 (or utf8mb4) So, max length = 2+3*36 = 110 (or 146) bytes. For temp tables 108 (or 144) is actually used if a MEMORY table is used.

To compress

- utf8 is unnecessary (ascii would do); but this is obviated by the next two steps
- Toss dashes
- UNHEX Now it will fit in 16 bytes: BINARY(16)

Combining the problems and crafting a solution

But first, a caveat. This solution only works for "Time based" / "Version 1" UUIDs They are recognizable by the "1" at the beginning of the third clump.

The manual's sample: 6ccd780c-baba-1026-9564-0040f4311e29 . A more current value (after a few years): 49ea2de3-17a2-11e2-8346-001eecac3efa . Notice how the 3rd part has slowly changed over time? Let's data is rearranged, thus:

```
1026-baba-6ccd780c-9564-0040f4311e29
11e2-17a2-49ea2de3-8346-001eecac3efa
11e2-17ac-106762a5-8346-001eecac3efa -- after a few more minutes
```

Now we have a number that increases nicely over time. Multiple sources won't be quite in time order, but they will be close. The "hot" spot for inserting into an INDEX(uuid) will be rather narrow, thereby making it quite cacheable and efficient.

If your SELECTs tend to be for "recent" uuids, then they, too, will be easily cached. If, on the other hand, your SELECTs often reach for old uuids, they will be random and not well cached. Still, improving the INSERTs will help the system overall.

Code to do it

Let's make Stored Functions to do the messy work of the two actions:

- Rearrange fields
- Convert to/from BINARY(16)

```
DELIMITER //

CREATE FUNCTION UuidToBin(_uuid BINARY(36))
    RETURNS BINARY(16)
    LANGUAGE SQL  DETERMINISTIC  CONTAINS SQL  SQL SECURITY INVOKER
RETURN
    UNHEX(CONCAT(
        SUBSTR(_uuid, 15, 4),
        SUBSTR(_uuid, 10, 4),
        SUBSTR(_uuid,  1, 8),
        SUBSTR(_uuid, 20, 4),
        SUBSTR(_uuid, 25) ));
//
CREATE FUNCTION UuidFromBin(_bin BINARY(16))
    RETURNS BINARY(36)
    LANGUAGE SQL  DETERMINISTIC  CONTAINS SQL  SQL SECURITY INVOKER
RETURN
    LCASE(CONCAT_WS('-',
        HEX(SUBSTR(_bin,  5, 4)),
        HEX(SUBSTR(_bin,  3, 2)),
        HEX(SUBSTR(_bin,  1, 2)),
        HEX(SUBSTR(_bin,  9, 2)),
        HEX(SUBSTR(_bin, 11))
             ));

//
DELIMITER ;
```

Then you would do things like

```
-- Letting MySQL create the UUID:
INSERT INTO t (uuid, ...) VALUES (UuidToBin(UUID()), ...);

-- Creating the UUID elsewhere:
INSERT INTO t (uuid, ...) VALUES (UuidToBin(?), ...);

-- Retrieving (point query using uuid):
SELECT ... FROM t WHERE uuid = UuidToBin(?);

-- Retrieving (other):
SELECT UuidFromBin(uuid), ... FROM t ...;
```

Do not flip the WHERE; this will be inefficent because it won't use INDEX(uuid):

```
WHERE UuidFromBin(uuid) = '1026-baba-6ccd780c-9564-0040f4311e29' -- NO
```

TokuDB

> TokuDB has been deprecated by its upstream maintainer. It is disabled from MariaDB 10.5 and has been been removed in MariaDB 10.6 - MDEV-19780. We recommend MyRocks as a long-term migration path.

TokuDB is a viable engine if you must have UUIDs (even non-type-1) in a huge table. TokuDB is available in MariaDB as a 'standard' engine, making the barrier to entry very low. There are a small number of differences between InnoDB and TokuDB; I will not go into them here.

Tokudb, with its “fractal” indexing strategy builds the indexes in stages. In contrast, InnoDB inserts index entries “immediately” — actually that indexing is buffered by most of the size of the buffer_pool. To elaborate…

When adding a record to an InnoDB table, here are (roughly) the steps performed to write the data (and PK) and secondary indexes to disk. (I leave out logging, provision for rollback, etc.) First the PRIMARY KEY and data:

- Check for UNIQUEness constraints

- Fetch the BTree block (normally 16KB) that should contain the row (based on the PRIMARY KEY).
- Insert the row (overflow typically occurs 1% of the time; this leads to a block split).
- Leave the page “dirty” in the buffer_pool, hoping that more rows are added before it is bumped out of cache (buffer_pool).. Note that for AUTO_INCREMENT and TIMESTAMP-based PKs, the “last” block in the data will be updated repeatedly before splitting; hence, this delayed write adds greatly to the efficiency. OTOH, a UUID will be very random; when the table is big enough, the block will almost always be flushed before a second insert occurs in that block. <– This is the inefficiency in UUIDs. Now for any secondary keys:
- All the steps are the same, since an index is essentially a "table" except that the "data" is a copy of the PRIMARY KEY.
- UNIQUEness must be checked immediately — cannot delay the read.
- There are (I think) some other "delays" that avoid some I/O.

Tokudb, on the other hand, does something like

- Write data/index partially sorted records to disk before finding out exactly where it belongs.
- In the background, combine these partially digested blocks. Repeat as needed.
- Eventually move the info into the real table/indexes.

If you are familiar with how sort-merge works, consider the parallels to Tokudb. Each "sort" does some work of ordering things; each "merge" is quite efficient.

To summarize:

- In the extreme (data/index much larger than buffer_pool), InnoDB must read-modify-write one 16KB disk block for each UUID entry.
- Tokudb makes each I/O "count" by merging several UUIDs for each disk block. (Yeah, Toku rereads blocks, but it comes out ahead in the long run.)
- Tokudb excels when the table is really big, which implies high ingestion rate.

Wrapup

This shows three thing for speeding up usage of GUIDs/UUIDs:

- Shrink footprint (Smaller -> more cacheable -> faster).
- Rearrange uuid to make a "hot spot" to improve cachability.
- Use TokuDB (MyRocks shares some architectural traits which may also be beneficial in handling UUIDs, but this is hypothetical and hasn't been tested)

Note that the benefit of the "hot spot" is only partial:

- Chronologically ordered (or approximately ordered) INSERTs benefit; random ones don't.
- SELECTs/UPDATEs by "recent" uuids benefit; old ones don't benefit.

Postlog

Thanks to Trey for some of the ideas here.

The tips in this document apply to MySQL, MariaDB, and Percona.

Written Oct, 2012. Added TokuDB, Jan, 2015.

3.3.4.28 IGNORE INDEX

Syntax

```
IGNORE INDEX [{FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
```

Contents

Description

You can tell the optimizer to not consider a particular index with the IGNORE INDEX option.

The benefit of using IGNORE_INDEX instead of USE_INDEX is that it will not disable a new index which you may add later.

Also see Ignored Indexes for an option to specify in the index definition that indexes should be ignored.

Index Prefixes

When using index hints (USE, FORCE or IGNORE INDEX), the index name value can also be an unambiguous prefix of an index name.

Example

This is used after the table name in the FROM clause:

```
CREATE INDEX Name ON City (Name);
CREATE INDEX CountryCode ON City (Countrycode);
EXPLAIN SELECT Name FROM City IGNORE INDEX (Name)
WHERE name="Helsingborg" AND countrycode="SWE";
```

This produces:

```
id select_type table type possible_keys key key_len ref rows Extra
1 SIMPLE City ref CountryCode CountryCode 3 const 14 Using where
```

3.3.4.29 not_null_range_scan Optimization

Contents

The NOT NULL range scan optimization enables the optimizer to construct range scans from NOT NULL conditions that it was able to infer from the WHERE clause.

The optimization appeared in MariaDB 10.5.0. It is not enabled by default; one needs to set an `optimizer_switch` flag to enable it.

Description

A basic (but slightly artificial) example:

```
create table items (
  price  decimal(8,2),
  weight decimal(8,2),
  ...
  index(weight)
);
```

```
-- Find items that cost more than 1000 $currency_units per kg:
set optimizer_switch='not_null_range_scan=on';
explain
select * from items where items.price > items.weight / 1000;
```

The WHERE condition in this form cannot be used for range scans. However, one can infer that it will reject rows that NULL for `weight`. That is, infer an additional condition that

```
weight IS NOT NULL
```

and pass it to the range optimizer. The range optimizer can, in turn, evaluate whether it makes sense to construct range access from the condition:

```
+------+-------------+-------+-------+---------------+--------+---------+------+------+----------
| id   | select_type | table | type  | possible_keys | key    | key_len | ref  | rows | Extra
+------+-------------+-------+-------+---------------+--------+---------+------+------+----------
|    1 | SIMPLE      | items | range | NULL          | weight | 5       | NULL | 1    | Using whe
+------+-------------+-------+-------+---------------+--------+---------+------+------+----------
```

Here's another example that's more complex but is based on a real-world query. Consider a join query

```
-- Find orders that were returned
select * from current_orders as O, order_returns as RET
where
  O.return_id= RET.id;
```

Here, the optimizer can infer the condition "return_id IS NOT NULL". If most of the orders are not returned (and so have NULL for return_id), one can use range access to scan only those orders that had a return.

Controlling the Optimization

The optimization is not enabled by default. One can enable it like so

```
set optimizer_switch='not_null_range_scan=on';
```

Optimizer Trace

TODO.

3.3.4.30 Optimizing for "Latest News"-style Queries

Contents

The problem space

Let's say you have "news articles" (rows in a table) and want a web page showing the latest ten articles about a particular topic.

Variants on "topic":

- Category
- Tag
- Provider (of news article)
- Manufacturer (of item for sale)
- Ticker (financial stock)

Variants on "news article"

- Item for sale
- Blog comment
- Blog thread

Variants on "latest"

- Publication date (unix_timestamp)
- Most popular (keep the count)
- Most emailed (keep the count)
- Manual ranking (1..10 -- 'top ten')

Variants on "10" - there is nothing sacred about "10" in this discussion.

The performance issues

Currently you have a table (or a column) that relates the topic to the article. The SELECT statement to find the latest 10 articles has grown in complexity, and performance is poor. You have focused on what index to add, but nothing seems to work.

- If there are multiple topics for each article, you need a many-to-many table.
- You have a flag "is_deleted" that needs filtering on.
- You want to "paginate" the list (ten articles per page, for as many pages as necessary).

The solution

First, let me give you the solution, then I will elaborate on why it works well.

- One new table called, say, Lists.
- Lists has _exactly_ 3 columns: topic, article_id, sequence
- Lists has _exactly_ 2 indexes: PRIMARY KEY(topic, sequence, article_id), INDEX(article_id)
- Only viewable articles are in Lists. (This avoids the filtering on "is_deleted", etc)
- Lists is InnoDB. (This gets "clustering".)
- "sequence" is typically the date of the article, but could be some other ordering.
- "topic" should probably be normalized, but that is not critical to this discussion.
- "article_id" is a link to the bulky row in another table(s) that provide all the details about the article.

The queries

Find the latest 10 articles for a topic:

```
SELECT  a.*
    FROM  Articles a
    JOIN  Lists s ON s.article_id = a.article_id
    WHERE  s.topic = ?
    ORDER BY  s.sequence DESC
    LIMIT  10;
```

You must *not* have any WHERE condition touching columns in Articles.

When you mark an article for deletion; you *must* remove it from Lists:

```
DELETE  FROM  Lists
    WHERE  article_id = ?;
```

I emphasize "must" because flags and other filtering is often the root of performance issues.

Why it works

By now, you may have discovered why it works.

The big goal is to minimize the disk hits. Let's itemize how few disk hits are needed. When finding the latest articles with 'normal' code, you will probably find that it is doing significant scans of the Articles table, failing to quickly home in on the 10 rows you want. With this design, there is only one extra disk hit:

- 1 disk hit: 10 adjacent, narrow, rows in Lists -- probably in a single "block".
- 10 disk hits: The 10 articles. (These hits are unavoidable, but may be cached.) The PRIMARY KEY, and using InnoDB, makes these quite efficient.

OK, you pay for this by removing things that you should avoid.

- 1 disk hit: INDEX(article_id) - finding a few ids
- A few more disk hits to DELETE rows from Lists. This is a small price to pay -- and you are not paying it while the user is waiting for the page to render.

3.3.4.31 Pagination Optimization

Contents

The Desire

You have a website with news articles, or a blog, or some other thing with a list of things that might be too long for a single page. So, you decide to break it into chunks of, say, 10 items and provide a [Next] button to go the next "page".

You spot OFFSET and LIMIT in MariaDB and decide that is the obvious way to do it.

```
SELECT  *
    FROM  items
    WHERE  messy_filtering
    ORDER BY  date DESC
    OFFSET  $M  LIMIT $N
```

Note that the problem requirement needs a [Next] link on each page so that the user can 'page' through the data. He does not really need "GoTo Page #". Jump to the [First] or [Last] page may be useful.

The Problem

All is well -- until you have 50,000 items in a list. And someone tries to walk through all 5000 pages. That 'someone' could be a search engine crawler.

Where's the problem? Performance. Your web page is doing "SELECT ... OFFSET 49990 LIMIT 10" (or the equivalent "LIMIT 49990,10"). MariaDB has to find all 50,000 rows, step over the first 49,990, then deliver the 10 for that distant page.

If it is a crawler ('spider') that read all the pages, then it actually touched about 125,000,000 items to read all 5,000 pages.

Reading the entire table, just to get a distant page, can be so much I/O that it can cause timeouts on the web page. Or it can interfere with other activity, causing other things to be slow.

Other Bugs

In addition to a performance problem, ...

- If an item is inserted or deleted between the time you look at one page and the next, you could miss an item, or see an item duplicated.
- The pages are not easily bookmarked or sent to someone else because the contents shift over time.
- The WHERE clause and the ORDER BY may even make it so that all 50,000 items have to be read, just to find the 10 items for page 1!

What to Do?

Hardware? No, that's just a bandaid. The data will continue to grow and even the new hardware won't handle it.

Better INDEX? No. You must get away from reading the entire table to get the 5000th page.

Build another table saying where the pages start? Get real! That would be a maintenance nightmare, and expensive.

Bottom line: Don't use OFFSET; instead remember where you "left off".

```
First page (latest 10 items):
    SELECT ... WHERE ... ORDER BY id DESC LIMIT 10
Next page (second 10):
    SELECT ... WHERE ... AND id < $left_off ORDER BY id DESC LIMIT 10
```

With INDEX(id), this suddenly becomes very efficient.

Implementation -- Getting Rid of OFFSET

You are probably doing this now: ORDER BY datetime DESC LIMIT 49990,10 You probably have some unique id on the table. This can probably be used for "left off".

Currently, the [Next] button probably has a url something like ?topic=xyz&page=4999&limit=10 The 'topic' (or 'tag' or 'provider' or 'user' or etc) says which set of items are being displayed. The product of page*limit gives the OFFSET. (The "limit=10" might be in the url, or might be hard-coded; this choice is not relevant to this discussion.)

The new variant would be ?topic=xyz&id=12345&limit=10. (Note: the 12345 is not computable from 4999.) By using INDEX(topic, id) you can efficiently say

```
    WHERE topic = 'xyz'
      AND id >= 1234
    ORDER BY id
    LIMIT 10
```

That will hit only 10 rows. This is a huge improvement for later pages. Now for more details.

Implementation -- "Left Off"

What if there are exactly 10 rows left when you display the current page? It would make the UI nice if you grayed out the [Next] button, wouldn't it. (Or you could suppress the button all together.)

How to do that? Instead of LIMIT 10, use LIMIT 11. That will give you the 10 items needed for the current page, plus an indication of whether there is another page. And the id for that page.

So, take the 11th id for the [Next] button: Next

Implementation -- Links Beyond [Next]

Let's extend the 11 trick to also find the next 5 pages and build links for them.

Plan A is to say LIMIT 51. If you are on page 12, that would give you links for pages 13 (using 11th id) through pages 17 (51st).

Plan B is to do two queries, one to get the 10 items for the current page, the other to get the next 41 ids (LIMIT 10, 41) for the next 5 pages.

Which plan to pick? It depends on many things, so benchmark.

A Reasonable Set of Links

Reaching forward and backward by 5 pages is not too much work. It would take two separate queries to find the ids in both directions. Also, having links that take you to the First and Last pages would be easy to do. No id is needed; they can be something like

```
    <a href=?topic=xyz&id=FIRST&limit=10>First</a>
    <a href=?topic=xyz&id=LAST&limit=10>Last</a>
```

The UI would recognize those, then generate a SELECT with something like

```
    WHERE topic = 'xyz'
    ORDER BY id ASC -- ASC for First; DESC for Last
    LIMIT 10
```

The last items would be delivered in reverse order. Either deal with that in the UI, or make the SELECT more complex:

```
    ( SELECT ...
        WHERE topic = 'xyz'
        ORDER BY id DESC
        LIMIT 10
    ) ORDER BY id ASC
```

Let's say you are on page 12 of lots of pages. It could show these links:

```
    [First] ... [7] [8] [9] [10] [11] 12 [13] [14] [15] [16] [17] ... [Last]
```

where the ellipsis is really used. Some end cases:

```
Page one of three:
    First [2] [3]
Page one of many:
    First [2] [3] [4] [5] ... [Last]
Page two of many:
    [First] 2 [3] [4] [5] ... [Last]
If you jump to the Last page, you don't know what page number it is.
So, the best you can do is perhaps:
    [First] ... [Prev] Last
```

Why it Works

The goal is to touch only the relevant rows, not all the rows leading up to the desired rows. This is nicely achieved, except for building links to the "next 5 pages". That may (or may not) be efficiently resolved by the simple SELECT id, discussed above. The reason that may not be efficient deals with the WHERE clause.

Let's discuss the optimal and suboptimal indexes.

For this discussion, I am assuming

- The datetime field might have duplicates -- this can cause troubles
- The id field is unique
- The id field is close enough to datetime-ordered to be used instead of datetime.

Very efficient -- it does all the work in the index:

```
    INDEX(topic, id)
    WHERE topic = 'xyz'
      AND id >= 876
    ORDER BY id ASC
    LIMIT 10,41
<</code??
That will hit 51 consecutive index entries, 0 data rows.

Inefficient -- it must reach into the data:
<<code>>
    INDEX(topic, id)
    WHERE topic = 'xyz'
      AND id >= 876
      AND is_deleted = 0
    ORDER BY id ASC
    LIMIT 10,41
```

That will hit at least 51 consecutive index entries, plus at least 51 _randomly_ located data rows.

Efficient -- back to the previous degree of efficiency:

```
    INDEX(topic, is_deleted, id)
    WHERE topic = 'xyz'
      AND id >= 876
      AND is_deleted = 0
    ORDER BY id ASC
    LIMIT 10,41
```

Note how all the '=' parts of the WHERE come first; then comes both the '>=' and 'ORDER BY', both on id. This means that the INDEX can be used for all the WHERE, plus the ORDER BY.

"Items 11-20 Out of 12345"

You lose the "out of" except when the count is small. Instead, say something like

```
    Items 11-20 out of Many
```

Alternatively... Only a few searches will have too many items to count. Keep another table with the search criteria and a count. This count can be computed daily (or hourly) by some background script. When discovering that the topic is a busy one, look it up in the table to get

```
    Items 11-20 out of about 49,000
```

The background script would round the count off.

The quick way to get an _estimated_ number of rows for an InnoDB table is

```
    SELECT  table_rows
        FROM  information_schema.TABLES
        WHERE  TABLE_SCHEMA = 'database_name'
          AND  TABLE_NAME = 'table_name'
```

However, it does not allow for the WHERE clause that you probably have.

Complex WHERE, or JOIN

If the search criteria cannot be confined to an INDEX in a single table, this technique is doomed. I have another paper that discusses "Lists", which solves that (which extra development work), and even improves on what is discussed here.

How Much Faster?

This depends on

- How many rows (total)
- Whether the WHERE clause prevented the efficient use of the ORDER BY
- Whether the data is bigger than the cache. This last one kicks in when building one page requires reading more data from disk can be cached. At that point, the problem goes from being CPU-bound to being I/O-bound. This is likely to suddenly slow down the loading of a pages by a factor of 10.

What is Lost

- Cannot "jump to Page N", for an arbitrary N. Why do you want to do that?
- Walking backward from the end does not know the page numbers.
- The code is more complex.

3.3.4.32 Pivoting in MariaDB

Contents

The problem

You want to "pivot" the data so that a linear list of values with two keys becomes a spreadsheet-like array. See examples, below.

A solution

The best solution is probably to do it in some form of client code (PHP, etc). MySQL and MariaDB do not have a syntax for SELECT that will do the work for you. The code provided here uses a stored procedure to generate code to pivot the data, and then runs the code.

You can edit the SQL generated by the stored procedure to tweak the output in a variety of ways. Or you can tweak the stored procedure to generate what you would prefer.

Reference code for solution

'Source' this into the mysql commandline tool:

```
DELIMITER //
DROP   PROCEDURE IF EXISTS Pivot //
CREATE PROCEDURE Pivot(
    IN tbl_name VARCHAR(99),       -- table name (or db.tbl)
    IN base_cols VARCHAR(99),      -- column(s) on the left, separated by commas
    IN pivot_col VARCHAR(64),      -- name of column to put across the top
    IN tally_col VARCHAR(64),      -- name of column to SUM up
    IN where_clause VARCHAR(99),   -- empty string or "WHERE ..."
    IN order_by VARCHAR(99)        -- empty string or "ORDER BY ..."; usually the base_cols
    )
    DETERMINISTIC
    SQL SECURITY INVOKER
BEGIN
    -- Find the distinct values
    -- Build the SUM()s
    SET @subq = CONCAT('SELECT DISTINCT ', pivot_col, ' AS val ',
                    ' FROM ', tbl_name, ' ', where_clause, ' ORDER BY 1');
    -- select @subq;

    SET @cc1 = "CONCAT('SUM(IF(&p = ', &v, ', &t, 0)) AS ', &v)";
    SET @cc2 = REPLACE(@cc1, '&p', pivot_col);
    SET @cc3 = REPLACE(@cc2, '&t', tally_col);
    -- select @cc2, @cc3;
    SET @qval = CONCAT("'\"', val, '\"'");
    -- select @qval;
    SET @cc4 = REPLACE(@cc3, '&v', @qval);
    -- select @cc4;

    SET SESSION group_concat_max_len = 10000;   -- just in case
    SET @stmt = CONCAT(
            'SELECT  GROUP_CONCAT(', @cc4, ' SEPARATOR ",\n")  INTO @sums',
            ' FROM ( ', @subq, ' ) AS top');
     select @stmt;
    PREPARE _sql FROM @stmt;
    EXECUTE _sql;                       -- Intermediate step: build SQL for columns
    DEALLOCATE PREPARE _sql;
    -- Construct the query and perform it
    SET @stmt2 = CONCAT(
            'SELECT ',
                base_cols, ',\n',
                @sums,
                ',\n SUM(', tally_col, ') AS Total'
            '\n FROM ', tbl_name, ' ',
            where_clause,
            ' GROUP BY ', base_cols,
            '\n WITH ROLLUP',
            '\n', order_by
        );
    select @stmt2;                      -- The statement that generates the result
    PREPARE _sql FROM @stmt2;
    EXECUTE _sql;                       -- The resulting pivot table ouput
    DEALLOCATE PREPARE _sql;
    -- For debugging / tweaking, SELECT the various @variables after CALLing.
END;
//
DELIMITER ;
```

Then do a CALL, like in the examples, below.

Variants

I thought about having several extra options for variations, but decided that would be too messy. Instead, here are instructions for implementing the variations, either by capturing the SELECT that was output by the Stored Procedure, or by modifying the SP, itself.

- The data is strings (not numeric) -- Remove "SUM" (but keep the expression); remove the SUM...AS TOTAL line.
- If you want blank output instead of 0 -- Currently the code says "SUM(IF(... 0))"; change the 0 to NULL, then wrap the SUM: IFNULL(SUM(...), ''). Note that this will distinguish between a zero total (showing '0') and no data (blank).
- Fancier output -- Use PHP/VB/Java/etc.
- No Totals at the bottom -- Remove the WITH ROLLUP line from the SELECT.
- No Total for each row -- Remove the SUM...AS Total line from the SELECT.
- Change the order of the columns -- Modify the ORDER BY 1 ('1' meaning first column) in the SELECT DISTINCT in the SP.
- Example: ORDER BY FIND_IN_SET(DAYOFWEEK(...), 'Sun,Mon,Tue,Wed,Thu,Fri,Sat')

Notes about "base_cols":

- Multiple columns on the left, such as an ID and its meaning -- This is already handled by allowing base_cols to be a commalist like 'id, meaning'
- You cannot call the SP with "foo AS 'blah'" in hopes of changing the labels, but you could edit the SELECT to achieve that goal.

Notes about the "Totals":

- If "base_cols" is more than one column, WITH ROLLUP will be subtotals as well as a grand total.
- NULL shows up in the Totals row in the "base_cols" column; this can be changed via something like IFNULL(..., 'Totals').

Example 1 - Population vs Latitude in US

```
-- Sample input:
+-------+----------------------+---------+------------+
| state | city                 | lat     | population |
+-------+----------------------+---------+------------+
| AK    | Anchorage            | 61.2181 |     276263 |
| AK    | Juneau               | 58.3019 |      31796 |
| WA    | Monroe               | 47.8556 |      15554 |
| WA    | Spanaway             | 47.1042 |      25045 |
| PR    | Arecibo              | 18.4744 |      49189 |
| MT    | Kalispell            | 48.1958 |      18018 |
| AL    | Anniston             | 33.6597 |      23423 |
| AL    | Scottsboro           | 34.6722 |      14737 |
| HI    | Kaneohe              | 21.4181 |      35424 |
| PR    | Candelaria           | 18.4061 |      17632 |
...

-- Call the Stored Procedure:
CALL Pivot('World.US', 'state', '5*FLOOR(lat/5)', 'population', '', '');

-- SQL generated by the SP:
SELECT state,
SUM(IF(5*FLOOR(lat/5) = "15", population, 0)) AS "15",
SUM(IF(5*FLOOR(lat/5) = "20", population, 0)) AS "20",
SUM(IF(5*FLOOR(lat/5) = "25", population, 0)) AS "25",
SUM(IF(5*FLOOR(lat/5) = "30", population, 0)) AS "30",
SUM(IF(5*FLOOR(lat/5) = "35", population, 0)) AS "35",
SUM(IF(5*FLOOR(lat/5) = "40", population, 0)) AS "40",
SUM(IF(5*FLOOR(lat/5) = "45", population, 0)) AS "45",
SUM(IF(5*FLOOR(lat/5) = "55", population, 0)) AS "55",
SUM(IF(5*FLOOR(lat/5) = "60", population, 0)) AS "60",
SUM(IF(5*FLOOR(lat/5) = "70", population, 0)) AS "70",
 SUM(population) AS Total
 FROM World.US  GROUP BY state
 WITH ROLLUP

-- Output from that SQL (also comes out of the SP):
+-------+---------+--------+----------+----------+----------+----------+---------+-------+---
-----+------+-----------+
| state | 15      | 20     | 25       | 30       | 35       | 40       | 45      | 55    | 60
| 70   | Total     |
+-------+---------+--------+----------+----------+----------+----------+---------+-------+---
-----+------+-----------+
| AK    |       0 |      0 |        0 |        0 |        0 |        0 |       0 | 60607 |
360765 | 4336 |    425708 |
| AL    |       0 |      0 |        0 |  1995225 |        0 |        0 |       0 |     0 |
0 |    0 |   1995225 |
| AR    |       0 |      0 |        0 |   595537 |   617361 |        0 |       0 |     0 |
0 |    0 |   1212898 |
| AZ    |       0 |      0 |        0 |  4708346 |   129989 |        0 |       0 |     0 |
0 |    0 |   4838335 |
...
| FL    |       0 |  34706 |  9096223 |  1440916 |        0 |        0 |       0 |     0 |
0 |    0 |  10571845 |
| GA    |       0 |      0 |        0 |  2823939 |        0 |        0 |       0 |     0 |
0 |    0 |   2823939 |
| HI    |   43050 | 752983 |        0 |        0 |        0 |        0 |       0 |     0 |
0 |    0 |    796033 |
...
| WY    |       0 |      0 |        0 |        0 |        0 |   277480 |       0 |     0 |
0 |    0 |    277480 |
| NULL  | 1792991 | 787689 | 16227033 | 44213344 | 47460670 | 61110822 | 7105143 | 60607 |
360765 | 4336 | 179123400 |
+-------+---------+--------+----------+----------+----------+----------+---------+-------+---
-----+------+-----------+
```

Notice how Alaska (AK) has populations in high latitudes and Hawaii (HI) in low latitudes.

Example 2 - Home Solar Power Generation

This give the power (KWh) generated by hour and month for 2012.

```
-- Sample input:
+---------------------+------+
| ts                  | enwh |
+---------------------+------+
| 2012-06-06 11:00:00 |  523 |
| 2012-06-06 11:05:00 |  526 |
| 2012-06-06 11:10:00 |  529 |
| 2012-06-06 11:15:00 |  533 |
| 2012-06-06 11:20:00 |  537 |
| 2012-06-06 11:25:00 |  540 |
| 2012-06-06 11:30:00 |  542 |
| 2012-06-06 11:35:00 |  543 |
Note that it is a reading in watts for each 5 minutes.
So, summing is needed to get the breakdown by month and hour.

-- Invoke the SP:
CALL Pivot('details',    -- Table
           'MONTH(ts)',  -- `base_cols`, to put on left; SUM up over the month
           'HOUR(ts)',   -- `pivot_col` to put across the top; SUM up entries across the hour
           'enwh/1000',  -- The data -- watts converted to KWh
           "WHERE ts >= '2012-01-01' AND ts < '2012-01-01' + INTERVAL 1 year",  -- Limit to one
year
           '');          -- assumes that the months stay in order

-- The SQL generated:
SELECT MONTH(ts),
SUM(IF(HOUR(ts) = "5", enwh/1000, 0)) AS "5",
SUM(IF(HOUR(ts) = "6", enwh/1000, 0)) AS "6",
SUM(IF(HOUR(ts) = "7", enwh/1000, 0)) AS "7",
SUM(IF(HOUR(ts) = "8", enwh/1000, 0)) AS "8",
SUM(IF(HOUR(ts) = "9", enwh/1000, 0)) AS "9",
SUM(IF(HOUR(ts) = "10", enwh/1000, 0)) AS "10",
SUM(IF(HOUR(ts) = "11", enwh/1000, 0)) AS "11",
SUM(IF(HOUR(ts) = "12", enwh/1000, 0)) AS "12",
SUM(IF(HOUR(ts) = "13", enwh/1000, 0)) AS "13",
SUM(IF(HOUR(ts) = "14", enwh/1000, 0)) AS "14",
SUM(IF(HOUR(ts) = "15", enwh/1000, 0)) AS "15",
SUM(IF(HOUR(ts) = "16", enwh/1000, 0)) AS "16",
SUM(IF(HOUR(ts) = "17", enwh/1000, 0)) AS "17",
SUM(IF(HOUR(ts) = "18", enwh/1000, 0)) AS "18",
SUM(IF(HOUR(ts) = "19", enwh/1000, 0)) AS "19",
SUM(IF(HOUR(ts) = "20", enwh/1000, 0)) AS "20",
 SUM(enwh/1000) AS Total
 FROM details WHERE ts >= '2012-01-01' AND ts < '2012-01-01' + INTERVAL 1 year GROUP BY
MONTH(ts)
 WITH ROLLUP

-- That generated decimal places that I did like:
| MONTH(ts) | 5      | 6       | 7        | 8        | 9         | 10        | 11        | 12
| 13        | 14
     | 15        | 16       | 17       | 18       | 19      | 20     | Total      |
+-----------+--------+---------+----------+----------+-----------+-----------+-----------+---
--------+-----------+------
-----+-----------+----------+----------+----------+---------+--------+------------+
|         1 | 0.0000 |  0.0000 |   1.8510 |  21.1620 |   52.3190 |   73.0420 |   89.3220 |
97.0190 |   88.9720 |   75.
4970 |   50.9270 |  12.5130 |   0.5990 |   0.0000 |  0.0000 | 0.0000 |   563.2230 |
|         2 | 0.0000 |  0.0460 |   5.9560 |  35.6330 |   72.4710 |   96.5130 |  112.7770 |
126.0850 |  117.1540 |   96.
7160 |   72.5900 |  33.6230 |   4.7650 |   0.0040 |  0.0000 | 0.0000 |   774.3330 |
```

Other variations made the math go wrong. (Note that there is no CAST to FLOAT.)

While I was at it, I gave an alias to change "MONTH(ts)" to just "Month".

So, I edited the SQL to this and ran it:

```
SELECT MONTH(ts) AS 'Month',
ROUND(SUM(IF(HOUR(ts) = "5", enwh, 0))/1000) AS "5",
...
ROUND(SUM(IF(HOUR(ts) = "20", enwh, 0))/1000) AS "20",
 ROUND(SUM(enwh)/1000) AS Total
 FROM details WHERE ts >= '2012-01-01' AND ts < '2012-01-01' + INTERVAL 1 year
 GROUP BY MONTH(ts)
 WITH ROLLUP;
```

-- Which gave cleaner output:

```
+-------+------+------+------+------+------+------+------+------+------+------+------+------
+------+------+------+------+--------+
| Month | 5    | 6    | 7    | 8    | 9    | 10   | 11   | 12   | 13   | 14   | 15   | 16   |
17   | 18   | 19   | 20   | Total |
+-------+------+------+------+------+------+------+------+------+------+------+------+------
+------+------+------+------+--------+
|     1 |    0 |    0 |    2 |   21 |   52 |   73 |   89 |   97 |   89 |   75 |   51 |   13 |
1 |    0 |    0 |    0 |   563 |
|     2 |    0 |    0 |    6 |   36 |   72 |   97 |  113 |  126 |  117 |   97 |   73 |   34 |
5 |    0 |    0 |    0 |   774 |
|     3 |    0 |    0 |    9 |   46 |   75 |  105 |  121 |  122 |  128 |  126 |  105 |   71 |
33 |   10 |    0 |    0 |   952 |
|     4 |    0 |    1 |   14 |   63 |  111 |  146 |  171 |  179 |  177 |  158 |  141 |  105 |
65 |   26 |    3 |    0 |  1360 |
|     5 |    0 |    4 |   21 |   78 |  128 |  162 |  185 |  199 |  196 |  187 |  166 |  130 |
81 |   36 |    8 |    0 |  1581 |
|     6 |    0 |    4 |   17 |   71 |  132 |  163 |  182 |  191 |  193 |  182 |  161 |  132 |

3.3.4.33 Rollup Unique User Counts

Contents

The Problem

The normal way to count "Unique Users" is to take large log files, sort by userid, dedup, and count. This requires a rather large amount of processing. Furthermore, the count derived cannot be rolled up. That is, daily counts cannot be added to get weekly counts -- some users will be counted multiple times.

So, the problem is to store the counts is such a way as to allow rolling up.

The solution

Let's think about what we can do with a hash of the userid. The hash could map to a bit in a bit string. A BIT_COUNT of the bit string would give the 1-bits, representing the number of users. But that bit string would have to be huge. What if we could use shorter bit strings? Then different userids would be folded into the same bit. Let's assume we can solve that.

Meanwhile, what about the rollup? The daily bit strings can be OR'd together to get a similar bit string for the week.

We have now figured out how to do the rollup, but have created another problem -- the counts are too low.

Inflating the BIT_COUNT

A sufficiently random hash (eg MD5) will fold userids into the same bits with a predictable frequency. We need to figure this out, and work backwards. That is, given that X percent of the bits are set, we need a formula that says approximately how many userids were used to get those bits.

I simulated the problem by generating random hashes and calculated the number of bits that would be set. Then, with the help of Eureqa software, I derived the formula:

Y = 0.5456*X + 0.6543*tan(1.39*X*X*X)

How good is it?

The formula is reasonably precise. It is usually within 1% of the correct value; rarely off by 2%.

Of course, if virtually all the bits are set, the forumla can't be very precise. Hence, you need to plan to have the bit strings big enough to handle the expected number of Uniques. In practice, you can use less than 1 bit per Unique. This would be a huge space savings over trying to save all the userids.

Another suggestion... If you are rolling up over a big span of time (eg hourly -> monthly), the bit strings must all be the same length, and the monthly string must be big enough to handle the expected count. This is likely to lead to very sparse hourly bit strings. Hence, it may be prudent to compress the hourly stings.

Postlog

Invented Nov, 2013; published Apr, 2014

Future: Rick is working on actual code (Sep, 2016) It is complicated by bit-wise operations being limited to BIGINT. However, with MySQL 8.0 (freshly released), the desired bit-wise operations can be applied to BLOB, greatly simplifying my code. I hope to publish the pre-8.0 code soon; 8.0 code later.

3.3.4.34 Rowid Filtering Optimization

MariaDB starting with 10.4

Rowid filtering is an optimization available from MariaDB 10.4.

Contents

The target use case for rowid filtering is as follows:

- a table uses ref access on index IDX1
- but it also has a fairly restrictive range predicate on another index IDX2.

In this case, it is advantageous to:

- Do an index-only scan on index IDX2 and collect rowids of index records into a data structure that allows filtering (let's call it $FILTER).
- When doing ref access on IDX1, check $FILTER before reading the full record.

Example

Consider a query

```
SELECT ...
FROM orders JOIN lineitem ON o_orderkey=l_orderkey
WHERE
  l_shipdate BETWEEN '1997-01-01' AND '1997-01-31' AND
  o_totalprice between 200000 and 230000;
```

Suppose the condition on `l_shipdate` is very restrictive, which means lineitem table should go first in the join order. Then, the optimizer can use `o_orderkey=l_orderkey` equality to do an index lookup to get the order the line item is from. On the other hand `o_totalprice between ...` can also be rather selective.

With filtering, the query plan would be:

```
*************************** 1. row ***************************
           id: 1
  select_type: SIMPLE
        table: lineitem
         type: range
possible_keys: PRIMARY,i_l_shipdate,i_l_orderkey,i_l_orderkey_quantity
          key: i_l_shipdate
      key_len: 4
          ref: NULL
         rows: 98
        Extra: Using index condition
*************************** 2. row ***************************
           id: 1
  select_type: SIMPLE
        table: orders
         type: eq_ref|filter
possible_keys: PRIMARY,i_o_totalprice
          key: PRIMARY|i_o_totalprice
      key_len: 4|9
          ref: dbt3_s001.lineitem.l_orderkey
         rows: 1 (5%)
        Extra: Using where; Using rowid filter
```

Note that table `orders` has "Using rowid filter". The `type` column has `"|filter"`, the `key` column shows the index that is used to construct the filter. `rows` column shows the expected filter selectivity, it is 5%.

ANALYZE FORMAT=JSON output for table orders will show

```
    "table": {
      "table_name": "orders",
      "access_type": "eq_ref",
      "possible_keys": ["PRIMARY", "i_o_totalprice"],
      "key": "PRIMARY",
      "key_length": "4",
      "used_key_parts": ["o_orderkey"],
      "ref": ["dbt3_s001.lineitem.l_orderkey"],
      "rowid_filter": {
        "range": {
          "key": "i_o_totalprice",
          "used_key_parts": ["o_totalprice"]
        },
        "rows": 69,
        "selectivity_pct": 4.6,
        "r_rows": 71,
        "r_selectivity_pct": 10.417,
        "r_buffer_size": 53,
        "r_filling_time_ms": 0.0716
      }
```

Note the `rowid_filter` element. It has a `range` element inside it. `selectivity_pct` is the expected selectivity, accompanied by the `r_selectivity_pct` showing the actual observed selectivity.

Details

- The optimizer makes a cost-based decision about when the filter should be used.
- The filter data structure is currently an ordered array of rowids. (a Bloom filter would be better here and will probably be introduced in the future versions).

- The optimization needs to be supported by the storage engine. At the moment, it is supported by InnoDB and MyISAM. It is not supported in partitioned tables.

Control

Rowid filtering can be switched on/off using `rowid_filter` flag in the optimizer_switch variable. By default, the optimization is enabled.

3.3.4.35 Sargable UPPER

Starting from MariaDB 11.3, expressions in the form

```
UPPER(key_col) = expr
UPPER(key_col) IN (constant-list)
```

are sargable if `key_col` uses either the `utf8mb3_general_ci` or `utf8mb4_general_ci` collation.

`UCASE` is a synonym for UPPER so is covered as well.

Sargable means that the optimizer is able to use such conditions to construct access methods, estimate their selectivity, or perform partition pruning.

Example

```
create table t1 (
  key1 varchar(32) collate utf8mb4_general_ci,
  ...
  key(key1)
);
```

```
explain select * from t1 where UPPER(key1)='ABC'
+------+-------------+-------+------+---------------+------+---------+-------+------+-------------
| id   | select_type | table | type | possible_keys | key  | key_len | ref   | rows | Extra
+------+-------------+-------+------+---------------+------+---------+-------+------+-------------
|    1 | SIMPLE      | t1    | ref  | key1          | key1 | 131     | const | 1    | Using where
+------+-------------+-------+------+---------------+------+---------+-------+------+-------------
```

Note that `ref` access is used.

An example with join:

```
explain select * from t0,t1 where upper(t1.key1)=t0.col;
+------+-------------+-------+------+---------------+------+---------+-------------+------+------
| id   | select_type | table | type | possible_keys | key  | key_len | ref         | rows | Extra
+------+-------------+-------+------+---------------+------+---------+-------------+------+------
|    1 | SIMPLE      | t0    | ALL  | NULL          | NULL | NULL    | NULL        | 10   | Using
|    1 | SIMPLE      | t1    | ref  | key1          | key1 | 131     | test.t0.col | 1    | Using
+------+-------------+-------+------+---------------+------+---------+-------------+------+------
```

Here, the optimizer was able to construct `ref` access.

Controlling the Optimization

The optimizer_switch variable has the flag `sargable_casefold` to turn the optimization on and off. The default is ON.

Optimizer Trace

The optimization is implemented as a rewrite for a query's WHERE/ON conditions. It uses the `sargable_casefold_removal` object name in the trace:

```
      "join_optimization": {
        "select_id": 1,
        "steps": [
          {
            "sargable_casefold_removal": {
              "before": "ucase(t1.key1) = t0.col",
              "after": "t1.key1 = t0.col"
            }
          },
```

References

- MDEV-31496: Make optimizer handle UCASE(varchar_col)=...
- An analog for LCASE is not possible. See MDEV-31955: Make optimizer handle LCASE(varchar_col)=... for details.

3.3.4.36 USE INDEX

You can limit which indexes are considered with the `USE INDEX` option.

Syntax

```
USE INDEX [{FOR {JOIN|ORDER BY|GROUP BY}] ([index_list])
```

Contents

Description

The default is 'FOR JOIN', which means that the hint only affects how the WHERE clause is optimized.

USE INDEX is used after the table name in the FROM clause.

USE INDEX cannot use an ignored index - it will be treated as if it doesn't exist.

Index Prefixes

When using index hints (USE, FORCE or IGNORE INDEX), the index name value can also be an unambiguous prefix of an index name.

Example

```
CREATE INDEX Name ON City (Name);
CREATE INDEX CountryCode ON City (Countrycode);
EXPLAIN SELECT Name FROM City USE INDEX (CountryCode)
WHERE name="Helsingborg" AND countrycode="SWE";
```

This produces:

```
id select_type table type possible_keys key key_len ref rows Extra
1 SIMPLE City ref CountryCode CountryCode 3 const 14 Using where
```

If we had not used USE INDEX, the Name index would have been in possible keys.

3.3.5 Optimizing Tables

Different ways to optimize tables and data on disk

OPTIMIZE TABLE
Reclaim unused space and defragment data.

ANALYZE TABLE
Store key distributions for a table.

Choosing the Right Storage Engine
Quickly choose the most suitable storage engine for your needs.

Converting Tables from MyISAM to InnoDB
Issues when converting tables from MyISAM to InnoDB.

Histogram-Based Statistics
Histogram-based statistics can improve the optimizer query plan in certain situations.

Defragmenting InnoDB Tablespaces
MariaDB 10.1.1 introduced a feature to defragment InnoDB tablespaces.

Entity-Attribute-Value Implementation
A common, poorly performing, design pattern (EAV); plus an alternative

IP Range Table Performance
IP Range Table Performance Improvements

There are 1 related questions.

3.3.4.6.2 Histogram-Based Statistics

3.3.5.6 Defragmenting InnoDB Tablespaces

Contents

Overview

When rows are deleted from an InnoDB table, the rows are simply marked as deleted and not physically deleted. The free space is not returned to the operating system for re-use.

The purge thread will physically delete index keys and rows, but the free space introduced is still not returned to operating system. This can lead to gaps in the pages. If you have variable length rows, new rows may be larger than old rows and cannot make use of the available space.

You can run OPTIMIZE TABLE or ALTER TABLE <table> ENGINE=InnoDB to reconstruct the table. Unfortunately running `OPTIMIZE TABLE` against an InnoDB table stored in the shared table-space file `ibdata1` does two things:

- Makes the table's data and indexes contiguous inside `ibdata1` .
- Increases the size of `ibdata1` because the contiguous data and index pages are appended to `ibdata1` .

InnoDB Defragmentation

> The feature described below has been deprecated in MariaDB 11.0 and was removed in MariaDB 11.1.0. See MDEV-30544 and MDEV-30545.

MariaDB 10.1 merged Facebook's defragmentation code prepared for MariaDB by Matt, Seong Uck Lee from Kakao. The only major difference to Facebook's code and Matt's patch is that MariaDB does not introduce new literals to SQL and makes no changes to the server code. Instead, OPTIMIZE TABLE is used and all code changes are inside the InnoDB/XtraDB storage engines.

The behaviour of `OPTIMIZE TABLE` is unchanged by default, and to enable this new feature, you need to set the innodb_defragment system variable to `1`.

```
[mysqld]
...
innodb-defragment=1
```

No new tables are created and there is no need to copy data from old tables to new tables. Instead, this feature loads `n` pages (determined by innodb-defragment-n-pages) and tries to move records so that pages would be full of records and then frees pages that are fully empty after the operation.

Note that tablespace files (including ibdata1) will not shrink as the result of defragmentation, but one will get better memory utilization in the InnoDB buffer pool as there are fewer data pages in use.

A number of new system and status variables for controlling and monitoring the feature are introduced.

System Variables

- innodb_defragment: Enable InnoDB defragmentation.
- innodb_defragment_n_pages: Number of pages considered at once when merging multiple pages to defragment.
- innodb_defragment_stats_accuracy: Number of defragment stats changes there are before the stats are written to persistent storage.
- innodb_defragment_fill_factor_n_recs: Number of records of space that defragmentation should leave on the page.
- innodb_defragment_fill_factor: Indicates how full defragmentation should fill a page.
- innodb_defragment_frequency: Maximum times per second for defragmenting a single index.

Status Variables

- Innodb_defragment_compression_failures: Number of defragment re-compression failures
- Innodb_defragment_failures: Number of defragment failures.
- Innodb_defragment_count: Number of defragment operations.

Example

```
set @@global.innodb_file_per_table = 1;
set @@global.innodb_defragment_n_pages = 32;
set @@global.innodb_defragment_fill_factor = 0.95;
CREATE TABLE tb_defragment (
pk1 bigint(20) NOT NULL,
pk2 bigint(20) NOT NULL,
fd4 text,
fd5 varchar(50) DEFAULT NULL,
PRIMARY KEY (pk1),
KEY ix1 (pk2)
) ENGINE=InnoDB;

delimiter //
create procedure innodb_insert_proc (repeat_count int)
begin
  declare current_num int;
  set current_num = 0;
  while current_num < repeat_count do
    INSERT INTO tb_defragment VALUES (current_num, 1, REPEAT('Abcdefg', 20),
REPEAT('12345',5));
    INSERT INTO tb_defragment VALUES (current_num+1, 2, REPEAT('HIJKLM', 20),
REPEAT('67890',5));
    INSERT INTO tb_defragment VALUES (current_num+2, 3, REPEAT('HIJKLM', 20),
REPEAT('67890',5));
    INSERT INTO tb_defragment VALUES (current_num+3, 4, REPEAT('HIJKLM', 20),
REPEAT('67890',5));
    set current_num = current_num + 4;
  end while;
end//
delimiter ;
commit;

set autocommit=0;
call innodb_insert_proc(50000);
commit;
set autocommit=1;
```

After these CREATE and INSERT operations, the following information can be seen from the INFORMATION SCHEMA:

```
select count(*) as Value from information_schema.innodb_buffer_page
  where table_name like '%tb_defragment%' and index_name = 'PRIMARY';
Value
313

select count(*) as Value from information_schema.innodb_buffer_page
  where table_name like '%tb_defragment%' and index_name = 'ix1';
Value
72

select count(stat_value) from mysql.innodb_index_stats
  where table_name like '%tb_defragment%' and stat_name in ('n_pages_freed');
count(stat_value)
0

select count(stat_value) from mysql.innodb_index_stats
  where table_name like '%tb_defragment%' and stat_name in ('n_page_split');
count(stat_value)
0

select count(stat_value) from mysql.innodb_index_stats
  where table_name like '%tb_defragment%' and stat_name in ('n_leaf_pages_defrag');
count(stat_value)
0

SELECT table_name, data_free/1024/1024 AS data_free_MB, table_rows FROM
information_schema.tables
  WHERE engine LIKE 'InnoDB' and table_name like '%tb_defragment%';
table_name data_free_MB table_rows
tb_defragment 4.00000000 50051

SELECT table_name, index_name, sum(number_records), sum(data_size) FROM
information_schema.innodb_buffer_page
  where table_name like '%tb_defragment%' and index_name like 'PRIMARY';
table_name index_name sum(number_records) sum(data_size)
`test`.`tb_defragment` PRIMARY 25873 4739939

SELECT table_name, index_name, sum(number_records), sum(data_size) FROM
information_schema.innodb_buffer_page
  where table_name like '%tb_defragment%' and index_name like 'ix1';
table_name index_name sum(number_records) sum(data_size)
`test`.`tb_defragment` ix1 50071 1051775
```

Deleting three-quarters of the records, leaving gaps, and then optimizing:

```
delete from tb_defragment where pk2 between 2 and 4;

optimize table tb_defragment;
Table Op Msg_type Msg_text
test.tb_defragment optimize status OK
show status like '%innodb_def%';
Variable_name Value
Innodb_defragment_compression_failures 0
Innodb_defragment_failures 1
Innodb_defragment_count 4
```

Now some pages have been freed, and some merged:

```
select count(*) as Value from information_schema.innodb_buffer_page
  where table_name like '%tb_defragment%' and index_name = 'PRIMARY';
Value
0

select count(*) as Value from information_schema.innodb_buffer_page
  where table_name like '%tb_defragment%' and index_name = 'ix1';
Value
0

select count(stat_value) from mysql.innodb_index_stats
  where table_name like '%tb_defragment%' and stat_name in ('n_pages_freed');
count(stat_value)
2

select count(stat_value) from mysql.innodb_index_stats
  where table_name like '%tb_defragment%' and stat_name in ('n_page_split');
count(stat_value)
2

select count(stat_value) from mysql.innodb_index_stats
  where table_name like '%tb_defragment%' and stat_name in ('n_leaf_pages_defrag');
count(stat_value)
2

SELECT table_name, data_free/1024/1024 AS data_free_MB, table_rows FROM
information_schema.tables
  WHERE engine LIKE 'InnoDB';
table_name data_free_MB table_rows
innodb_index_stats 0.00000000 8
innodb_table_stats 0.00000000 0
tb_defragment 4.00000000 12431

SELECT table_name, index_name, sum(number_records), sum(data_size) FROM
information_schema.innodb_buffer_page
  where table_name like '%tb_defragment%' and index_name like 'PRIMARY';
table_name index_name sum(number_records) sum(data_size)
`test`.`tb_defragment` PRIMARY 690 102145

SELECT table_name, index_name, sum(number_records), sum(data_size) FROM
information_schema.innodb_buffer_page
  where table_name like '%tb_defragment%' and index_name like 'ix1';
table_name index_name sum(number_records) sum(data_size)
`test`.`tb_defragment` ix1 5295 111263
```

See Defragmenting unused space on InnoDB tablespace on the Mariadb.org blog for more details.

3.3.5.7 Entity-Attribute-Value Implementation

Contents

The desires

- Open-ended set of "attributes" (key=value) for each "entity". That is, the list of attributes is not known at development time, and will grow in the future. (This makes one column per attribute impractical.)
- "ad hoc" queries testing attributes.
- Attribute values come in different types (numbers, strings, dates, etc.)
- Scale to lots of entities, yet perform well.

It goes by various names

- EAV -- Entity - Attribute - Value
- key-value
- RDF -- This is a flavor of EAV
- MariaDB has dynamic columns that look something like the solution below, with the added advantage of being able to index the columns otherwise hidden in the blob. (There are caveats.)
- MySQL 5.7 Has JSON datatype, plus functions to access parts
- MongoDB, CouchDB -- and others -- Not SQL-based.

Bad solution

- Table with 3 columns: entity_id, key, value
- The "value" is a string, or maybe multiple columns depending on datatype or other kludges.
- a JOIN b ON a.entity=b.entity AND b.key='x' JOIN c ON ... WHERE a.value=... AND b.value=...

The problems

- The SELECTs get messy -- multiple JOINs
- Datatype issues -- It's clumsy to be putting numbers into strings
- Numbers stored in VARCHAR do not compare 'correctly', especially for range tests.
- Bulky.
- Dedupping the values is clumsy.

A solution

Decide which columns need to be searched/sorted by SQL queries. No, you don't need all the columns to be searchable or sortable. Certain columns are frequently used for selection; identify these. You probably won't use all of them in all queries, but you will use some of them in every query.

The solution uses one table for all the EAV stuff. The columns include the searchable fields plus one BLOB. Searchable fields are declared appropriately (INT, TIMESTAMP, etc). The BLOB contains JSON-encoding of all the extra fields.

The table should be InnoDB, hence it should have a PRIMARY KEY. The entitity_id is the 'natural' PK. Add a small number of other indexes (often 'composite') on the searchable fields. PARTITIONing is unlikely to be of any use, unless the Entities should purged after some time. (Example: News Articles)

But what about the ad hoc queries?

You have included the most important fields to search on -- date, category, etc. These should filter the data down significantly. When you also need to filter on something more obscure, that will be handled differently. The application code will look at the BLOB for that; more on this later.

Why it works

- You are not really going to search on more than a few fields.
- The disk footprint is smaller; Smaller --> More cacheable --> Faster
- It needs no JOINs
- The indexes are useful
- The one table has one row per entity, and can grow as needed. (EAV needs many rows per entity.)
- Performance is as good as the indexes you have on the 'searchable fields'.
- Optionally, you can duplicate the indexed fields in the BLOB.
- Values missing from 'searchable fields' would need to be NULL (or whatever), and the code would need to deal with such.

Details on the BLOB/JSON

- Build the extra (or all) key-value pairs in a hash (associative array) in your application. Encode it. COMPRESS it. Insert that string into the BLOB.
- JSON is recommended, but not mandatory; it is simpler than XML. Other serializations (eg, YAML) could be used.
- COMPRESS the JSON and put it into a BLOB (or MEDIUMBLOB) instead of a TEXT field. Compression gives about 3x shrinkage.
- When SELECTing, UNCOMPRESS the blob. Decode the string into a hash. You are now ready to interrogate/display any of the extra fields.
- If you choose to use the JSON features of MariaDB or 5.7, you will have to forgo the compression feature described.

- MySQL 5.7.8's JSON native JSON datatype uses a binary format for more efficient access.

Conclusions

- Schema is reasonably compact (compression, real datatypes, less redundancy, etc, than EAV)
- Queries are fast (since you have picked 'good' indexes)
- Expandable (JSON is happy to have new fields)
- Compatible (No 3rd party products, just supported products)
- Range tests work (unlike storing INTs in VARCHARs)
- (Drawback) Cannot use the non-indexed attributes in WHERE or ORDER BY clauses, must deal with that in the app. (MySQL 5.7 partially alleviates this.)

Postlog

Posted Jan, 2014; Refreshed Feb, 2016.

- MariaDB's Dynamic Columns
- MySQL 5.7's JSON

This looks very promising; I will need to do more research to see how much of this article is obviated by it: Using MySQL as a Document Store in 5.7, more DocStore discussion

If you insist on EAV, set optimizer_search_depth=1.

3.3.5.8 IP Range Table Performance

Contents

The situation

Your data includes a large set of non-overlapping 'ranges'. These could be IP addresses, datetimes (show times for a single station), zipcodes, etc.

You have pairs of start and end values; one 'item' belongs to each such 'range'. So, instinctively, you create a table with start and end of the range, plus info about the item. Your queries involve a WHERE clause that compares for being between the start and end values.

The problem

Once you get a large set of items, performance degrades. You play with the indexes, but find nothing that works well. The indexes fail to lead to optimal functioning because the database does not understand that the ranges are non-overlapping.

The solution

I will present a solution that enforces the fact that items cannot have overlapping ranges. The solution builds a table to take advantage of that, then uses Stored Routines to get around the clumsiness imposed by it.

Performance

The instinctive solution often leads to scanning half the table to do just about anything, such as finding the item containing an 'address'. In complexity terms, this is Order(N).

The solution here can usually get the desired information by fetching a single row, or a small number of rows. It is Order(1).

In a large table, "counting the disk hits" is the important part of performance. Since InnoDB is used, and the PRIMARY KEY (clustered) is used, most operations hit only 1 block.

Finding the 'block' where a given IP address lives:

- For start of block: One single-row fetch using the PRIMARY KEY
- For end of block: Ditto. The record containing this will be 'adjacent' to the other record.

For allocating or freeing a block:

- 2-7 SQL statements, hitting the clustered PRIMARY KEY for the rows containing and immediately adjacent to the block.
- One SQL statement is a DELETE; if hits as many rows as are needed for the block.
- The other statements hit one row each.

Design decisions

This is crucial to the design and its performance:

- Having just one address in the row. These were alternative designs; they seemed to be no better, and possibly worse:
- That one address could have been the 'end' address.
- The routine parameters for a 'block' could have be start of this block and start of next block.
- The IPv4 parameters could have been dotted quads; I chose to keep the reference implemetation simpler instead.
- The IPv6 parameters are 32-digit hex because it was the simpler that BINARY(16) or IPv5 for a reference implementation.

The interesting work is in the Ips, not the second table, so I focus on it. The inconvenience of JOINing to the second table is small compared to the performance gains.

Details

Two, not one, tables will be used. The first table (`Ips` in the reference implementations) is carefully designed to be optimal for all the basic operations needed. The second table contains other infomation about the 'owner' of each 'item'. In the reference implementations `owner` is an id used to JOIN the two tables. This discussion centers around `Ips` and how to efficiently map IP(s) to/from owner(s). The second table has "PRIMARY KEY(owner)".

In addition to the two-table schema, there are a set of Stored Routines to encapsulate the necessary code.

One row of Ips represents one 'item' by specifying the starting IP address and the 'owner'. The next row gives the starting IP address of the next "address block", thereby indirectly providing the ending address for the current block.

This lack of explicitly stating the "end address" leads to some clumsiness. The stored routines hide it from the user.

A special owner (indicated by '0') is reserved for "free" or "not-owned" blocks. Hence, sparse allocation of address blocks is no problem. Also, the 'free' owner is handled no differently than real owners, so there are no extra Stored Routines for such.

Links below give "reference" implementations for IPv4 and IPv6. You will need to make changes for non-IP situations, and may need to make changes even for IP situations.

These are the main stored routines provided:

- IpIncr, IpDecr -- for adding/subtracting 1
- IpStore -- for allocating/freeing a range
- IpOwner, IpRangeOwners, IpFindRanges, Owner2IpStarts, Owner2IpRanges -- for lookups
- IpNext, IpEnd -- IP of start of next block, or end of current block

None of the provided routines JOIN to the other table; you may wish to develop custom queries based on the given reference Stored Procedures.

The Ips table's size is proportional to the number of blocks. A million 'owned' blocks may be 20-50MB. This varies due to

- number of 'free' gaps (between zero and the number of owned blocks)
- datatypes used for `ip` and `owner`
- InnoDB overhead Even 100M blocks is quite manageable in today's hardware. Once things are cached, most operations would take only a few milliseconds. A trillion blocks would work, but most operations would hit the disk a few times -- only a few times.

Reference implementation of IPv4

This specific to IPv4 (32 bit, a la '196.168.1.255'). It can handle anywhere from 'nothing assigned' (1 row) to 'everything assigned' (4B rows) 'equally' well. That is, to ask the question "who owns '11.22.33.44'" is equally efficient regardless of how many blocks of IP addresses exist in the table. (OK, caching, disk hits, etc may make a slight difference.) The one function that can vary is the one that reassigns a range to a new owner. Its speed is a function of how many existing ranges need to be consumed, since those rows will be DELETEd. (It helps that they are, by schema design, 'clustered'.)

Notes on the Reference implementation for IPv4 :

- Externally, the user may use the dotted quad notation (11.22.33.44), but needs to convert to INT UNSIGNED for calling the Stored Procs.
- The user is responsible for converting to/from the calling datatype (INT UNSIGNED) when accessing the stored routine; suggest INET_ATON/INET_NTOA.
- The internal datatype for addresses is the same as the calling datatype (INT UNSIGNED).
- Adding and subtracting 1 (simple arithmetic).
- The datatype of an 'owner' (MEDIUMINT UNSIGNED: 0..16M) -- adjust if needed.
- The address "Off the end" (255.255.255.255+1 - represented as NULL).
- The table is initialized to one row: (ip=0, owner=0), meaning "all addresses are free See the comments in the code for more details.

(The reference implementation does not handle CDRs. Such should be easy to add on, by first turning it into an IP range.)

Reference implementation of IPv6

The code for handling IP address is more complex, but the overall structure is the same as for IPv4. Launch into it only if you need IPv6.

Notes on the reference implementation for IPv6:

- Externally, IPv6 has a complex string, VARCHAR(39) CHARACTER SET ASCII. The Stored Procedure IpStr2Hex() is provided.
- The user is responsible for converting to/from the calling datatype (BINARY(16)) when accessing the stored routine; suggest INET6_ATON/INET6_NTOA.
- The internal datatype for addresses is the same as the calling datatype (BINARY(16)).
- Communication with the Stored routines is via 32-char hex strings.
- Inside the Procedures, and in the Ips table, an address is stored as BINARY(16) for efficiency. HEX() and UNHEX() are used at the boundaries.
- Adding/subtracting 1 is rather complex (see the code).
- The datatype of an 'owner' (MEDIUMINT UNSIGNED: 0..16M); 'free' is represented by 0. You may need a bigger datatype.
- The address "Off the end" (ffff.ffff.ffff.ffff.ffff.ffff.ffff.ffff+1 is represented by NULL).
- The table is initialized to one row: (UNHEX('00000000000000000000000000000000'), 0), meaning "all addresses are free.
- You may need to decide on a canonical representation of IPv4 in IPv6. See the comments in the code for more details.

The INET6* functions were first available in MySQL 5.6.3 and MariaDB 10.0.3

Adapting to a different non-IP 'address range' data

- The external datatype for an 'address' should be whatever is convenient for the application.
- The datatype for the 'address' in the table must be ordered, and should be as compact as possible.
- You must write the Stored functions (IpIncr, IpDecr) for incrementing/decrementing an 'address'.
- An 'owner' is an id of your choosing, but smaller is better.
- A special value (such as 0 or '') must be provided for 'free'.
- The table must be initialized to one row: (SmallestAddress, Free)

"Owner" needs a special value to represent "not owned". The reference implementations use "=" and "!=" to compare two 'owners'. Numeric values and strings work nicely with those operators; NULL does not. Hence, please do not use NULL for "not owned".

Since the datatypes are pervasive in the stored routines, adapting a reference implementation to a different concept of 'address' would require multiple minor changes.

The code enforces that consecutive blocks never have the same 'owner', so the table is of 'minimal' size. Your application can assume that such is always the case.

3.3.6 MariaDB Memory Allocation

Contents

Allocating RAM for MariaDB - The Short Answer

If only using MyISAM, set key_buffer_size to 20% of **available** RAM. (Plus innodb_buffer_pool_size=0)

If only using InnoDB, set innodb_buffer_pool_size to 70% of **available** RAM. (Plus key_buffer_size = 10M, small, but not zero.)

Rule of thumb for tuning:

- Start with released copy of my.cnf / my.ini.
- Change key_buffer_size and innodb_buffer_pool_size according to engine usage and RAM.
- Slow queries can usually be 'fixed' via indexes, schema changes, or SELECT changes, not by tuning.
- Don't get carried away with the query cache until you understand what it can and cannot do.
- Don't change anything else unless you run into trouble (eg, max connections).
- Be sure the changes are under the [mysqld] section, not some other section.

The 20%/70% assumes you have at least 4GB of RAM. If you have a tiny antique, or a tiny VM, then those percentages are too high.

Now for the gory details.

How to troubleshoot out-of-memory issues

If the MariaDB server is crashing because of 'out-of-memory' then it is probably wrongly configured.

There are two kind of buffers in MariaDB:

- Global ones that are only allocated once during the lifetime of the server:
  - Storage engine buffers (innodb_buffer_pool_size, key_buffer_size, aria_pagecache_buffer_size, etc)
  - Query cache query_cache_size.
- Global caches onces that grow and shrink dynamically on demand up to max limit:
  - max_user_connections
  - table_open_cache
  - table_definition_cache
  - thread_cache_size
- Local buffers that are allocated on demand whenever needed
  - Internal ones used during engine index creation (myisam_sort_buffer_size, aria_sort_buffer_size).
  - Internal buffers for storing blobs.
    - Some storage engine will keep a temporary cache to store the largest blob seen so far when scanning a table. This will be freed at end of query. Note that temporary blob storage is **not** included in the memory information in information_schema.processlist but only in the total memory used (`show global status like "memory_used"`).

- Buffers and caches used during query execution:

Variable	Description
join_buffer_size	Used when no keys can be used to find a row in next table
mrr_buffer_size	Size of buffer to use when using multi-range read with range access
net_buffer_length	Max size of network packet
read_buffer_size	Used by some storage engines when doing bulk insert
sort_buffer_size	When doing ORDER BY or GROUP BY
max_heap_table_size	Used to store temporary tables in memory. See Optimizing memory tables

If any variables in the last group is very large and you have a lot of simultaneous users that are executing queries that are using these buffers then you can run into trouble.

In a default MariaDB installation the default of most of the above variables are quite small to ensure that one does not run out of memory.

You can check which variables that have been changed in your setup by executing the following sql statement. If you are running into out-of-memory issues, it is very likely that the problematic variable is in this list!

```
select information_schema.system_variables.variable_name,
information_schema.system_variables.default_value,
global_variables.variable_value from
information_schema.system_variables,information_schema.global_variables where
system_variables.variable_name=global_variables.variable_name and
system_variables.default_value <> global_variables.variable_value and
system_variables.default_value <> 0
```

What is the Key Buffer?

MyISAM does two different things for caching.

- Index blocks (1KB each, BTree structured, from .MYI file) live in the "key buffer".
- Data block caching (from .MYD file) is left to the OS, so be sure to leave a bunch of free space for this. Caveat: Some flavors of OS always claim to be using over 90%, even when there is really lots of free space.

```
SHOW GLOBAL STATUS LIKE 'Key%';
```

then calculate Key_read_requests / Key_reads. If it is high (say, over 10), then the key buffer is big enough, otherwise you should adjust the key_buffer_size value.

What is the Buffer Pool?

InnoDB does all its caching in a the buffer pool, whose size is controlled by innodb_buffer_pool_size. By default it contains 16KB data and index blocks from the open tables (see innodb_page_size), plus some maintenance overhead.

From MariaDB 5.5, multiple buffer pools are permitted; this can help because there is one mutex per pool, thereby relieving some of the mutex bottleneck.

More on InnoDB tuning

Another Algorithm

This will set the main cache settings to the minimum; it could be important to systems with lots of other processes and/or RAM is 2GB or smaller.

Do SHOW TABLE STATUS for all the tables in all the databases.

Add up Index_length for all the MyISAM tables. Set key_buffer_size no larger than that size.

Add up Data_length + Index_length for all the InnoDB tables. Set innodb_buffer_pool_size to no more than 110% of that total.

If that leads to swapping, cut both settings back. Suggest cutting them down proportionately.

Run this to see the values for your system. (If you have a lot of tables, it can take minute(s).)

```
SELECT  ENGINE,
        ROUND(SUM(data_length) /1024/1024, 1) AS "Data MB",
        ROUND(SUM(index_length)/1024/1024, 1) AS "Index MB",
        ROUND(SUM(data_length + index_length)/1024/1024, 1) AS "Total MB",
        COUNT(*) "Num Tables"
    FROM  INFORMATION_SCHEMA.TABLES
    WHERE  table_schema not in ("information_schema", "PERFORMANCE_SCHEMA", "SYS_SCHEMA", "ndbinf
    GROUP BY  ENGINE;
```

Query Memory Allocation

There are two variables that dictates how memory are allocated by MariaDB while parsing and executing a query. query_prealloc_size defines the standard buffer for memory used for query execution and query_alloc_block_size that is size of memory blocks if `query_prealloc_size` was not big enough. Getting these variables right will reduce memory fragmentation in the server.

Mutex Bottleneck

MySQL was designed in the days of single-CPU machines, and designed to be easily ported to many different architectures. Unfortunately, that lead to some sloppiness in how to interlock actions. There are a small number (too small) of "mutexes" to gain access to several critical processes. Of note:

- MyISAM's key_buffer
- The Query Cache
- InnoDB's buffer_pool With multi-core boxes, the mutex problem is causing performance problems. In general, past 4-8 cores, MySQL gets slower, not faster. MySQL 5.5 and Percona's XtraDB made that somewhat better in InnoDB; the practical limit for cores is more like 32, and performance tends plateaus after that rather than declining. 5.6 claims to scale up to about 48 cores.

HyperThreading and Multiple Cores (CPUs)

Short answers (for older versions of MySQL and MariaDB):

- Turn off HyperThreading
- Turn off any cores beyond 8
- HyperThreading is mostly a thing of the past, so this section may not apply.

HyperThreading is great for marketing, lousy for performance. It involves having two processing units sharing a single hardware cache. If both units are doing the same thing, the cache will be reasonably useful. If the units are doing different things, they will be clobbering each other's cache entries.

Furthermore MySQL is not great on using multiple cores. So, if you turn off HT, the remaining cores run a little faster.

- 32-bit OS and MariaDB

First, the OS (and the hardware?) may conspire to not let you use all 4GB, if that is what you have. If you have more than 4GB of RAM, the excess beyond 4GB is _totally_ inaccessable and unusable on a 32-bit OS.

Secondly, the OS probably has a limit on how much RAM it will allow any process to use.

Example: FreeBSD's maxdsiz, which defaults to 512MB.

Example:

```
$ ulimit -a
...
max memory size (kbytes, -m) 524288
```

So, once you have determined how much RAM is available to mysqld, then apply the 20%/70%, but round down some.

If you get an error like `[ERROR] /usr/libexec/mysqld: Out of memory (Needed xxx bytes)` , it probably means that MySQL exceeded what the OS is willing to give it. Decrease the cache settings.

- 64-bit OS with 32-bit MariaDB

The OS is not limited by 4GB, but MariaDB is.

If you have at least 4GB of RAM, then maybe these would be good:

- key_buffer_size = 20% of _all_ of RAM, but not more than 3G
- innodb_buffer_pool_size = 3G

You should probably upgrade MariaDB to 64-bit.

- 64-bit OS and MariaDB

MyISAM only: key_buffer_size: Use about 20% of RAM. Set (in my.cnf / my.ini) innodb_buffer_pool_size=0 = 0.

InnoDB only: innodb_buffer_pool_size=0 = 70% of RAM. If you have lots of RAM and are using 5.5 (or later), then consider having multiple pools. Recommend 1-16 innodb_buffer_pool_instances, such that each one is no smaller than 1GB. (Sorry, no metric on how much this will help; probably not a lot.)

Meanwhile, set key_buffer_size = 20M (tiny, but non-zero)

If you have a mixture of engines, lower both numbers.

max_connections, thread_stack Each "thread" takes some amount of RAM. This used to be about 200KB; 100 threads would be 20MB, not a significant size. If you have max_connections = 1000, then you are talking about 200MB, maybe more. Having that many connections probably implies other issues that should be addressed.

In 5.6 (or MariaDB 5.5), optional thread pooling interacts with max_connections. This is a more advanced topic.

Thread stack overrun rarely happens. If it does, do something like thread_stack=256K

More on max_connections, wait_timeout, connection pooling, etc

table_open_cache

(In older versions this was called table_cache)

The OS has some limit on the number of open files it will let a process have. Each table needs 1 to 3 open files. Each PARTITION is effectively a table. Most operations on a partitioned table open _all_ partitions.

In *nix, ulimit tells you what the file limit is. The maximum value is in the tens of thousands, but sometimes it is set to only 1024. This limits you to about 300 tables. More discussion on ulimit

(This paragraph is in disputed.) On the other side, the table cache is (was) inefficiently implemented -- lookups were done with a linear scan. Hence, setting table_cache in the thousands could actually slow down mysql. (Benchmarks have shown this.)

You can see how well your system is performing via SHOW GLOBAL STATUS; and computing the opens/second via Opened_files / Uptime If this is more than, say, 5, table_open_cache should be increased. If it is less than, say, 1, you might get improvement by decreasing table_open_cache.

From MariaDB 10.1, table_open_cache defaults to 2000.

Query Cache

Short answer: query_cache_type = OFF and query_cache_size = 0

The Query Cache (QC) is effectively a hash mapping SELECT statements to resultsets.

Long answer... There are many aspects of the "Query cache"; many are negative.

- Novice Alert! The QC is totally unrelated to the key_buffer and buffer_pool.
- When it is useful, the QC is blazingly fast. It would not be hard to create a benchmark that runs 1000x faster.
- There is a single mutex controlling the QC.
- The QC, unless it is OFF & 0, is consulted for _every_ SELECT.
- Yes, the mutex is hit even if query_cache_type = DEMAND (2).
- Yes, the mutex is hit even for SQL_NO_CACHE.
- Any change to a query (even adding a space) leads (potentially) to a different entry in the QC.
- If my.cnf says type=ON and you later turn it OFF, it is not fully OFF. Ref: https://bugs.mysql.com/bug.php?id=60696

"Pruning" is costly and frequent:

- When _any_ write happens on a table, _all_ entries in the QC for _that_ table are removed.
- It happens even on a readonly Slave.
- Purges are performed with a linear algorithm, so a large QC (even 200MB) can be noticeably slow.

To see how well your QC is performing, SHOW GLOBAL STATUS LIKE 'Qc%'; then compute the read hit rate: Qcache_hits / Qcache_inserts If it is over, say, 5, the QC might be worth keeping.

If you decide the QC is right for you, then I recommend

- query_cache_size = no more than 50M
- query_cache_type = DEMAND
- SQL_CACHE or SQL_NO_CACHE in all SELECTs, based on which queries are likely to benefit from caching.

- Why to turn off the QC
- Discussion about size

thread_cache_size

It is not necessary to tune thread_cache_size from MariaDB 10.2.0. Previously, it was minor tunable variable. Zero will slow down thread (connection) creation. A small (say, 10), non-zero number is good. The setting has essentially no impact on RAM usage.

It is the number of extra processes to hang onto. It does not restrict the number of threads; max_connections does.

Binary Logs

If you have turned on binary logging (via log_bin) for replication and/or point-in-time recovery, the system will create binary logs forever. That is, they can slowly fill up the disk. Suggest setting expire_logs_days = 14 to keep only 14 days' worth of logs.

Swappiness

RHEL, in its infinite wisdom, decided to let you control how aggressively the OS will pre-emptively swap RAM. This is good in general, but lousy for MariaDB.

MariaDB would love for RAM allocations to be reasonably stable -- the caches are (mostly) pre-allocated; the threads, etc, are (mostly) of limited scope. ANY swapping is likely to severely hurt performance of MariaDB.

With a high value for swappiness, you lose some RAM because the OS is trying to keep a lot of space free for future allocations (that MySQL is not likely to need).

With swappiness = 0, the OS will probably crash rather than swap. I would rather have MariaDB limping than die. The latest recommendation is swappiness = 1. (2015)

More confirmation

Somewhere in between (say, 5?) might be a good value for a MariaDB-only server.

NUMA

OK, it's time to complicate the architecture of how a CPU talks to RAM. NUMA (Non-Uniform Memory Access) enters the picture. Each CPU (or maybe socket with several cores) has a part of the RAM hanging off each. This leads to memory access being faster for local RAM, but slower (tens of cycles slower) for RAM hanging off other CPUs.

Then the OS enters the picture. In at least one case (RHEL?), two things seem to be done:

- OS allocations are pinned to the 'first' CPU's RAM.]
- Other allocations go by default to the first CPU until it is full.

Now for the problem.

- The OS and MariaDB have allocated all the 'first' RAM.
- MariaDB has allocated some of the second RAM.
- The OS needs to allocate something. Ouch -- it is out of room in the one CPU where it is willing to allocate its stuff, so it swaps out some of MariaDB. Bad.

dmesg | grep -i numa # to see if you have numa

Probable solution: Configure the BIOS to "interleave" the RAM allocations. This should prevent the premature swapping, at the cost of off-CPU RAM accesses half the time. Well, you have the costly accesses anyway, since you really want to use all of RAM. Older MySQL versions: numactl --interleave=all. Or: innodb_numa_interleave=1

Another possible solution: Turn numa off (if the OS has a way of doing that)

Overall performance loss/gain: A few percent.

Huge Pages

This is another hardware performance gimmick.

For a CPU to access RAM, especially mapping a 64-bit address to somewhere in, say, 128GB or 'real' RAM, the TLB is used. (TLB = Translation Lookup Buffer.) Think of the TLB as a hardware associative memory lookup table; given a 64-bit virtual address, what is the real address.

Because it is an associative memory of finite size, sometimes there will be "misses" that require reaching into real RAM to resolve the lookup. This is costly, so should be avoided.

Normally, RAM is 'paged' in 4KB pieces; the TLB actually maps the top (64-12) bits into a specific page. Then the bottom 12 bits of the virtual address are carried over intact.

For example, 128GB of RAM broken 4KB pages means 32M page-table entries. This is a lot, and probably far exceeds the capacity of the TLB. So, enter the "Huge page" trick.

With the help of both the hardware and the OS, it is possible to have some of RAM in huge pages, of say 4MB (instead of 4KB). This leads to far fewer TLB entries, but it means the unit of paging is 4MB for such parts of RAM. Hence, huge pages tend to be non-pagable.

Now RAM is broken into pagable and non pagable parts; what parts can reasonably be non pagable? In MariaDB, the Innodb Buffer Pool is a perfect candidate. So, by correctly configuring these, InnoDB can run a little faster:

- Huge pages enabled
- Tell the OS to allocate the right amount (namely to match the buffer_pool)
- Tell MariaDB to use huge pages
- innodb memory usage vs swap

That thread has more details on what to look for and what to set.

Overall performance gain: A few percent. Yawn. Too much hassle for too little benefit.

Jumbo Pages? Turn off.

ENGINE=MEMORY

The Memory Storage Engine is a little-used alternative to MyISAM and InnoDB. The data is not persistent, so it has limited uses. The size of a MEMORY table is limited to max_heap_table_size, which defaults to 16MB. I mention it in case you have changed the value to something huge; this would stealing from other possible uses of RAM.

How to Set Variables

In the text file my.cnf (my.ini on Windows), add or modify a line to say something like

innodb_buffer_pool_size = 5G

That is, VARIABLE name, "=", and a value. Some abbreviations are allowed, such as M for million (1048576), G for billion.

For the server to see it, the settings must be in the "[mysqld]" section of the file.

The settings in my.cnf or my.ini will not take effect until you restart the server.

Most settings can be changed on the live system by connecting as user root (or other user with SUPER privilege) and doing something like

```
SET @@global.key_buffer_size = 77000000;
```

Note: No M or G suffix is allowed here.

To see the setting a global VARIABLE do something like

```
SHOW GLOBAL VARIABLES LIKE "key_buffer_size";
+-----------------+----------+
| Variable_name   | Value    |
+-----------------+----------+
| key_buffer_size | 76996608 |
+-----------------+----------+
```

Note that this particular setting was rounded down to some multiple that MariaDB liked.

You may want to do both (SET, and modify my.cnf) in order to make the change immediately and have it so that the next restart (for whatever reason) will again get the value.

Web Server

A web server like Apache runs multiple threads. If each thread opens a connection to MariaDB, you could run out of connections. Make sure MaxClients (or equivalent) is set to some civilized number (under 50).

Tools

- MySQLTuner
- TUNING-PRIMER

There are several tools that advise on memory. One misleading entry they come up with

Maximum possible memory usage: 31.3G (266% of installed RAM)

Don't let it scare you -- the formulas used are excessively conservative. They assume all of max_connections are in use and active, and doing something memory-intensive.

Total fragmented tables: 23 This implies that OPTIMIZE TABLE _might_ help. I suggest it for tables with either a high percentage of "free space" (see SHOW TABLE STATUS) or where you know you do a lot of DELETEs and/or UPDATEs. Still, don't bother to OPTIMIZE too often. Once a month might suffice.

MySQL 5.7

5.7 stores a lot more information in RAM, leading to the footprint being perhaps half a GB more than 5.6. See Memory increase in 5.7.

Postlog

Created 2010; Refreshed Oct, 2012, Jan, 2014

The tips in this document apply to MySQL, MariaDB, and Percona.

3.3.7 System Variables

System and Status Variables Added By Major Release

Lists of status and system variables added in MariaDB major releases.

Full List of MariaDB Options, System and Status Variables

Complete alphabetical list of all MariaDB options as well as system and status variables.

Server Status Variables

List and description of the Server Status Variables.

Server System Variables

List of system variables.

Aria Status Variables

Aria-related server status variables.

Aria System Variables

Aria-related system variables.

Cassandra Status Variables

Cassandra-related status variables

Cassandra System Variables

Cassandra system variables

CONNECT System Variables

System variables related to the CONNECT storage engine.

Galera Cluster Status Variables

Galera Cluster status variables.

Galera Cluster System Variables

Listing and description of Galera Cluster system variables.

InnoDB Server Status Variables

List and description of InnoDB status variables.

InnoDB System Variables

List and description of InnoDB-related server system variables.

MariaDB Audit Plugin Options and System Variables

Description of Server_Audit plugin options and system variables.

MariaDB Audit Plugin - Status Variables

Server Audit plugin status variables

Mroonga Status Variables

Mroonga-related status variables.

Mroonga System Variables

Mroonga-related system variables.

MyISAM System Variables

MyISAM system variables.

MyRocks Status Variables

MyRocks-related status variables.

MyRocks System Variables

MyRocks server system variables.

OQGRAPH System and Status Variables

List and description of OQGRAPH system and status variables.

Performance Schema Status Variables

Performance Schema status variables.

Performance Schema System Variables

Performance Schema system variables.

Replication and Binary Log Status Variables

Replication and binary log status variables.

Replication and Binary Log System Variables

Replication and binary log system variables.

Semisynchronous Replication Plugin Status Variables

Semisynchronous Replication plugin status variables

Semisynchronous Replication

Semisynchronous replication.

Sphinx Status Variables

Sphinx status variables.

Spider Status Variables

Spider server status variables.

Spider System Variables

System variables for the Spider storage engine.

SQL_ERROR_LOG Plugin System Variables

SQL_ERROR_LOG plugin-related system variables.

SSL/TLS Status Variables

List and description of Transport Layer Security (TLS)-related status variables.

SSL/TLS System Variables

List and description of Transport Layer Security (TLS)-related system variables.

Thread Pool System and Status Variables

System and status variables related to the MariaDB thread pool.

The full list of status variables are listed in the contents on this page; most are described on this page, but some are described elsewhere:

- Aria Status Variables
- Galera Status Variables
- InnoDB Status Variables
- Mroonga Status Variables
- MyRocks Status Variables
- Performance Scheme Status Variables
- Replication and Binary Log Status Variables
- S3 Storage Engine Status Variables
- Server_Audit Status Variables
- Sphinx Status Variables
- Spider Status Variables
- TokuDB Status Variables

See also the Full list of MariaDB options, system and status variables.

Use the SHOW STATUS statement to view status variables. This information also can be obtained using the mariadb-admin

extended-status command, or by querying the Information Schema GLOBAL_STATUS and SESSION_STATUS tables.

Issuing a FLUSH STATUS will reset many status variables to zero.

List of Server Status Variables

`Aborted_clients`

- **Description:** Number of aborted client connections. This can be due to the client not calling mysql_close() before exiting, the client sleeping without issuing a request to the server for more seconds than specified by wait_timeout or interactive_timeout, or by the client program ending in the midst of transferring data. The global value can be flushed by `FLUSH STATUS`.
- **Scope:** Global
- **Data Type:** `numeric`

`Aborted_connects`

- **Description:** Number of failed server connection attempts. This can be due to a client using an incorrect password, a client not having privileges to connect to a database, a connection packet not containing the correct information, or if it takes more than connect_timeout seconds to get a connect packet. The global value can be flushed by `FLUSH STATUS`.
- **Scope:** Global
- **Data Type:** `numeric`

`Aborted_connects_preauth`

- **Description:** Number of connection attempts that were aborted prior to authentication (regardless of whether or not an error occured).
- **Scope:** Global
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.4.5

`Access_denied_errors`

- **Description:** Number of access denied errors.
- **Scope:** Global
- **Data Type:** `numeric`

`Acl_column_grants`

- **Description:** Number of column permissions granted (rows in the mysql.columns_priv table).
- **Scope:** Global
- **Data Type:** `numeric`

`Acl_database_grants`

- **Description:** Number of database permissions granted (rows in the mysql.db table).
- **Scope:** Global
- **Data Type:** `numeric`

`Acl_function_grants`

- **Description:** Number of function permissions granted (rows in the mysql.procs_priv table with a routine type of `FUNCTION`).
- **Scope:** Global
- **Data Type:** `numeric`

Acl_package_body_grants

- **Description:**
- **Scope:** Global
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.3.5

Acl_package_spec_grants

- **Description:**
- **Scope:** Global
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.3.5

Acl_procedure_grants

- **Description:** Number of procedure permissions granted (rows in the mysql.procs_priv table with a routine type of `PROCEDURE`).
- **Scope:** Global
- **Data Type:** `numeric`

Acl_proxy_users

- **Description:** Number of proxy permissions granted (rows in the mysql.proxies_priv table).
- **Scope:** Global
- **Data Type:** `numeric`

Acl_role_grants

- **Description:** Number of role permissions granted (rows in the mysql.roles_mapping table).
- **Scope:** Global
- **Data Type:** `numeric`

Acl_roles

- **Description:** Number of roles (rows in the mysql.user table where `is_role='Y'`).
- **Scope:** Global
- **Data Type:** `numeric`

Acl_table_grants

- **Description:** Number of table permissions granted (rows in the mysql.tables_priv table).
- **Scope:** Global
- **Data Type:** `numeric`

Acl_users

- **Description:** Number of users (rows in the mysql.user table where `is_role='N'`).
- **Scope:** Global
- **Data Type:** `numeric`

Busy_time

- **Description:** Cumulative time in seconds of activity on connections.
- **Scope:** Global
- **Data Type:** `numeric`

Bytes_received

- **Description:** Total bytes received from all clients.
- **Scope:** Global
- **Data Type:** `numeric`

Bytes_sent

- **Description:** Total bytes sent to all clients.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_admin_commands

- **Description:** Number of admin commands executed. These include table dumps, change users, binary log dumps, shutdowns, pings and debugs.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_alter_db

- **Description:** Number of ALTER DATABASE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_alter_db_upgrade

- **Description:** Number of ALTER DATABASE ... UPGRADE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_alter_event

- **Description:** Number of ALTER EVENT commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_alter_function

- **Description:** Number of ALTER FUNCTION commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_alter_procedure

- **Description:** Number of ALTER PROCEDURE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_alter_sequence

- **Description:** Number of ALTER SEQUENCE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.3.1

Com_alter_server

- **Description:** Number of ALTER SERVER commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_alter_table

- **Description:** Number of ALTER TABLE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_alter_tablespace

- **Description:** Number of ALTER TABLESPACE commands executed (unsupported by MariaDB).
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Removed:** MariaDB 10.7.0

Com_alter_user

- **Description:** Number of ALTER USER commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.2.0

Com_analyze

- **Description:** Number of ANALYZE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_assign_to_keycache

- **Description:** Number of assign to keycache commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_backup

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Removed:** MariaDB 10.4.1

Com_backup_lock

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Removed:** MariaDB 10.4.2

Com_backup_table

- **Description:** Removed in MariaDB 5.5. In older versions, Com_backup_table contains the number of BACKUP TABLE commands executed.
- **Scope:** Global, Session

- **Data Type:** `numeric`
- **Removed:** MariaDB 5.5

`Com_begin`

- **Description:** Number of BEGIN or START TRANSACTION statements executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_binlog`

- **Description:** Number of BINLOG commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_call_procedure`

- **Description:** Number of CALL procedure_name statements executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_change_db`

- **Description:** Number of USE database_name commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_check`

- **Description:** Number of CHECK TABLE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_checksum`

- **Description:** Number of CHECKSUM TABLE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_commit`

- **Description:** Number of COMMIT commands executed. Differs from Handler_commit, which counts internal commit statements.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_compound_sql`

- **Description:** Number of compund sql statements.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_create_db`

- **Description:** Number of CREATE DATABASE commands executed.
- **Scope:** Global, Session

- **Data Type:** `numeric`

Com_create_event

- **Description:** Number of CREATE EVENT commands executed. Differs from Executed_events in that it is incremented when the CREATE EVENT is run, and not when the event executes.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_create_function

- **Description:** Number of CREATE FUNCTION commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_create_index

- **Description:** Number of CREATE INDEX commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_create_package

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.3.5

Com_create_package_body

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.3.5

Com_create_procedure

- **Description:** Number of CREATE PROCEDURE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_create_role

- **Description:** Number of CREATE ROLE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_create_sequence

- **Description:** Number of CREATE SEQUENCE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.3.0

Com_create_server

- **Description:** Number of CREATE SERVER commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_create_table

- **Description:** Number of CREATE TABLE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_create_temporary_table

- **Description:** Number of CREATE TEMPORARY TABLE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_create_trigger

- **Description:** Number of CREATE TRIGGER commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_create_udf

- **Description:** Number of CREATE UDF commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_create_user

- **Description:** Number of CREATE USER commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_create_view

- **Description:** Number of CREATE VIEW commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_dealloc_sql

- **Description:** Number of DEALLOCATE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_delete

- **Description:** Number of DELETE commands executed. Differs from Handler_delete, which counts the number of times rows have been deleted from tables.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_delete_multi

- **Description:** Number of multi-table DELETE commands executed.

- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_do

- **Description:** Number of DO commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_drop_db

- **Description:** Number of DROP DATABASE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_drop_event

- **Description:** Number of DROP EVENT commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_drop_function

- **Description:** Number of DROP FUNCTION commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_drop_index

- **Description:** Number of DROP INDEX commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_drop_package

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.3.5

Com_drop_package_body

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.3.5

Com_drop_procedure

- **Description:** Number of DROP PROCEDURE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_drop_role

- **Description:** Number of DROP ROLE commands executed.

- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_drop_sequence`

- **Description:** Number of DROP SEQUENCE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.3.0

`Com_drop_server`

- **Description:** Number of DROP SERVER commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_drop_table`

- **Description:** Number of DROP TABLE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_drop_temporary_table`

- **Description:** Number of DROP TEMPORARY TABLE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_drop_trigger`

- **Description:** Number of DROP TRIGGER commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_drop_user`

- **Description:** Number of DROP USER commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_drop_view`

- **Description:** Number of DROP VIEW commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_empty_query`

- **Description:** Number of queries to the server that do not produce SQL queries. An SQL query simply returning no results does not increment `Com_empty_query` - see Empty_queries instead. An example of an empty query sent to the server is `mariadb --comments -e '-- sql comment'`
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_execute_immediate`

- **Description:** Number of EXECUTE IMMEDIATE statements executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.2.3

`Com_execute_sql`

- **Description:** Number of EXECUTE statements executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_flush`

- **Description:** Number of FLUSH commands executed. This differs from Flush_commands, which also counts internal server flush requests.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_get_diagnostics`

- **Description:** Number of GET DIAGNOSTICS commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_grant`

- **Description:** Number of GRANT commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_grant_role`

- **Description:** Number of GRANT role commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_ha_close`

- **Description:** Number of HANDLER table_name CLOSE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_ha_open`

- **Description:** Number of HANDLER table_name OPEN commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_ha_read`

- **Description:** Number of HANDLER table_name READ commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_help`

- **Description:** Number of HELP commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_insert`

- **Description:** Number of INSERT commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_insert_select`

- **Description:** Number of INSERT ... SELECT commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_install_plugin`

- **Description:** Number of INSTALL PLUGIN commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_kill`

- **Description:** Number of KILL commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_load`

- **Description:** Number of LOAD commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

`Com_load_master_data`

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Removed:** MariaDB 5.5

`Com_load_master_table`

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Removed:** MariaDB 5.5

`Com_multi`

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.2.0

Com_lock_tables

- **Description:** Number of [lock-tables|LOCK TABLES]] commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_optimize

- **Description:** Number of OPTIMIZE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_preload_keys

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_prepare_sql

- **Description:** Number of PREPARE statements executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_purge

- **Description:** Number of PURGE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_purge_before_date

- **Description:** Number of PURGE BEFORE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_release_savepoint

- **Description:** Number of RELEASE SAVEPOINT commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_rename_table

- **Description:** Number of RENAME TABLE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_rename_user

- **Description:** Number of RENAME USER commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_repair

- **Description:** Number of REPAIR TABLE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_replace

- **Description:** Number of REPLACE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_replace_select

- **Description:** Number of REPLACE ... SELECT commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_reset

- **Description:** Number of RESET commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_resignal

- **Description:** Number of RESIGNAL commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_restore_table

- **Description:** Removed in MariaDB 5.5. In older versions, Com_restore_table contains the number of RESTORE TABLE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Removed:** MariaDB 5.5

Com_revoke

- **Description:** Number of REVOKE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_revoke_all

- **Description:** Number of REVOKE ALL commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_revoke_grant

- **Description:** Number of REVOKE role commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_rollback

- **Description:** Number of ROLLBACK commands executed. Differs from Handler_rollback, which is the number of transaction rollback requests given to a storage engine.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_rollback_to_savepoint

- **Description:** Number of ROLLBACK ... TO SAVEPOINT commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_savepoint

- **Description:** Number of SAVEPOINT commands executed. Differs from Handler_savepoint, which is the number of transaction savepoint creation requests.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_select

- **Description:** Number of SELECT commands executed. Also includes queries that make use of the query cache.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_set_option

- **Description:** Number of SET OPTION commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_signal

- **Description:** Number of SIGNAL statements executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_show_authors

- **Description:** Number of SHOW AUTHORS commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_show_binlog_events

- **Description:** Number of SHOW BINLOG EVENTS statements executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_show_binlogs

- **Description:** Number of SHOW BINARY LOGS commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_show_charsets

- **Description:** Number of SHOW CHARACTER SET commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_show_client_statistics

- **Description:** Number of SHOW CLIENT STATISTICS commands executed. Removed in MariaDB 10.1.1 when that statement was replaced by the generic SHOW information_schema_table.
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Removed:** MariaDB 10.1.1

Com_show_collations

- **Description:** Number of SHOW COLLATION commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_show_column_types

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Removed:** MariaDB 5.5

Com_show_contributors

- **Description:** Number of SHOW CONTRIBUTORS commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_show_create_db

- **Description:** Number of SHOW CREATE DATABASE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_show_create_event

- **Description:** Number of SHOW CREATE EVENT commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_show_create_func

- **Description:** Number of SHOW CREATE FUNCTION commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_show_create_package

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.3.5

Com_show_create_package_body

- **Description:**
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.3.5

Com_show_create_proc

- **Description:** Number of SHOW CREATE PROCEDURE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_show_create_table

- **Description:** Number of SHOW CREATE TABLE commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_show_create_trigger

- **Description:** Number of SHOW CREATE TRIGGER commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_show_create_user

- **Description:** Number of SHOW CREATE USER commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`
- **Introduced:** MariaDB 10.2.0

Com_show_databases

- **Description:** Number of SHOW DATABASES commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_show_engine_logs

- **Description:** Number of SHOW ENGINE LOGS commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_show_engine_mutex

- **Description:** Number of SHOW ENGINE MUTEX commands executed.
- **Scope:** Global, Session
- **Data Type:** `numeric`

Com_show_engine_status

- **Description:** Number of SHOW ENGINE STATUS commands executed.
