What Is MATLAB Builder for Java?

MATLAB Builder for Java (also called Java Builder) is an extension to MATLAB Compiler. Use Java Builder to wrap MATLAB functions into one or more Java classes that make up a Java component, or package. Each MATLAB function is encapsulated as a method of a Java class and can be invoked from within a Java application.

When you package and distribute the application to your users, you must include supporting files generated by Java Builder as well as the MATLAB Component Runtime (MCR), which is provided by the product. Your users do not have to purchase and install MATLAB.

Note MATLAB Builder for Java is also referred to in this documentation as Java Builder, for ease of use.

Support for MATLAB Features in Java

Java Builder provides robust data conversion, indexing, and array formatting capabilities to preserve the flexibility of MATLAB when called from Java code. To support the MATLAB data types, Java Builder provides the `MWArray` class hierarchy. You can use `MWArray` and other Java class members in your application to convert native arrays to MATLAB arrays and vice versa. Java Builder also provides automatic data conversion for passing arguments that are Java types.

Known Issue in Data Returned by `toArray` Referencing Sparse Format

There is a known issue where the data returned by calling `toArray` on a `MWNumericArray` or `MWLogicalArray` object that references a MATLAB array stored in sparse format may be incorrect or corrupted. If this use case applies to your work, see “Version 1.0 (R2006b) MATLAB Builder for Java” in the Release Notes for a link to information and a patch to fix this problem.

Using the Deployment Tool

The Deployment Tool provides a graphical user interface to Java Builder. While you are still in MATLAB, issue the following command to open the Deployment Tool:

```
deploytool
```

Use the Deployment Tool to perform the following tasks:

Creating a Java Component

To create a component you need to write M-code (or use existing code) and then create a project in MATLAB Builder for Java that encapsulates the code. In general, the steps are as follows:

- 1** Write, test, and save the MATLAB code to be used as the basis for the Java component.
- 2** Set the environment variables that are required on a development machine. See “Settings for Environment Variables (Development Machine)” on page 6-2.
- 3** While you are still in MATLAB, issue the following command to open the Deployment Tool:

```
deploytool
```

- 4** Use the Deployment Tool to create a project that contains one or more classes.
 - a. Create the project by clicking the New Project icon  in the toolbar.
 - b. Specify the project name and location.

By default the project name is assigned to be the name of the package to be created. You can change the default.

- c. Add class names for classes that you want to create as part of the Java package.
 - d. Add one or more M-files that you want to encapsulate in each class.
 - e. Add helper files as needed to support the classes.
 - f. Save the project.
- 5** Build the package.

The build process for a project copies a Java wrapper class in the `\src` subdirectory of your project directory. It also copies a `.jar` file and `.ctf` file in the `\distrib` subdirectory of your project directory. The files in the `\distrib` directory define your Java component.

The `.ctf` is a *component technology file*, which is required to support components that encapsulate MATLAB functions when running them on a user machine that does not have the MATLAB desktop installed.

6 Test the component and rebuild it as needed.

You probably want to test your component before using it in an application or before preparing it for use by others. After testing the component on your development platform, you can reopen the project if necessary and proceed to the next step.

7 Optionally, create a package to distribute the component and the required files to developers. This step is necessary only if you want to make the component available to other application developers on a different development machine.

Note On Windows platforms, the Deployment Tool creates a self-extracting executable. On non-Windows platforms, the package is a `.zip` file rather than a self-extracting executable.

8 Save the project.

Java Builder saves the project in a `.prj` file.

Using the Command-Line Interface

You can use the MATLAB command-line interface (or the operating system command line) instead of the GUI to create Java objects. Do this by issuing the `mcc` command with options. If you use `mcc`, you do not create a project.

Note See the MATLAB Compiler documentation for a complete description of the `mcc` command and its options.

The following table provides an overview of some `mcc` options related to creating Java components, along with syntax and examples of their usage.

Using the Command Line to Create Java Components

Action to Perform	mcc Option to Use	Description
Create a class encapsulating one or more M-files.	-W java:	Tells Java Builder to generate a Java component that contains a class that encapsulates the specified files.
	<p>Syntax</p> <pre>mcc -W 'java:component_name[,class_name]' file1 [file2...fileN]</pre> <p><i>component_name</i> is a fully qualified package name for your component. The name is a period-separated list.</p> <p><i>class_name</i> is the name for the Java class to be created. The default <i>class_name</i> is the last item in the list specified by <i>component_name</i>.</p> <p><i>file1</i> [<i>file2...fileN</i>] are M-files to be encapsulated as methods in <i>class_name</i>.</p>	
	<p>Example</p> <pre>mcc -W 'java:com.mycompany.mycomponent,myclass' foo.m bar.m</pre> <p>The example creates a Java component that has a fully qualified package name, <code>com.mycompany.mycomponent</code>. The component contains a single Java class, <code>myclass</code>, which contains methods <code>foo</code> and <code>bar</code>.</p> <p>To use <code>myclass</code>, place the following statement in your code:</p> <pre>import com.mycompany.mycomponent.myclass;</pre>	

Using the Command Line to Create Java Components (Continued)

Action to Perform	mcc Option to Use	Description
Add additional classes to a Java component.	<code>class{...}</code>	Used with <code>-W java:.</code> . Tells Java Builder to create <i>class_name</i> , which encapsulates one or more M-files that are specified in a comma-separated list.
	Syntax <code>class{class_name:file1 [file2...fileN]}</code>	
	Example <pre> mcc -W 'java:com.mycompany.mycomponent,myclass' foo.m bar.m class{myclass2:foo2.m,bar2.m} </pre> <p>The example creates a Java component named <code>mycomponent</code> with two classes:</p> <p><code>myclass</code> has methods <code>foo</code> and <code>bar</code>.</p> <p><code>myclass2</code> has methods <code>foo2</code> and <code>bar2</code>.</p>	

Using the Command Line to Create Java Components (Continued)

Action to Perform	mcc Option to Use	Description
Simplify the command-line input for components.	-B	Tells Java Builder to replace a specified file with the command-line information it contains.
	<p>Syntax</p> <pre>mcc -B 'bundlefile'[:arg1, arg2, ..., argN]</pre>	
	<p>Example</p> <p>Suppose a myoptions file contains</p> <pre>-W 'java:mycomponent,myclass'</pre> <p>In this case,</p> <pre>mcc -B 'myoptions' foo.m bar.m</pre> <p>produces the same results as</p> <pre>mcc -W 'java:[mycomponent,myclass]' foo.m bar.m</pre> <p>See “Using Bundle Files” for more information.</p>	

Using the Command Line to Create Java Components (Continued)

Action to Perform	mcc Option to Use	Description
Control how each Java class uses the MCR.	-S	<p>Tells Java Builder to create a single MCR when the first Java class is instantiated. This MCR is reused and shared among all subsequent class instances within the component, resulting in more efficient memory usage and eliminating the MCR startup cost in each subsequent class instantiation.</p> <p>By default, a new MCR instance is created for each instance of each Java class in the component. Use -S to change the default.</p> <p>When using -S, note that all class instances share a single MATLAB workspace and share global variables in the M-files used to build the component. This makes properties of a Java class behave as static properties instead of instance-wise properties.</p>
		<p>Example</p> <pre>mcc -S 'java:mycomponent,myclass' foo.m bar.m</pre> <p>The example creates a Java component called mycomponent containing a single Java class named myclass with methods foo and bar. (See the first example in this table).</p> <p>If and when multiple instances of myclass are instantiated in an application, only one MCR is initialized, and it is shared by all instances of myclass.</p>
Specify a directory for output	-d <i>directoryname</i>	Tells Java Builder to create a directory and copy the output files to it. (If you use mcc instead of the GUI, the <i>project_directory</i> \src and <i>project_directory</i> \distrib directories are not automatically created.)

Note All of these command-line examples produce the following files:

`mycomponent.jar` (component jar file)

`mycomponent.ctf` (component ctf file)

Notice that the component name used to create these files is derived from the last item on the period-separated list that specifies the fully qualified name of the class.

Developing an Application

- 1** If the component is not already installed on the machine where you want to develop your application, unpack and install the component as follows:
 - a. Copy the package that was created in the last step in “Creating a Java Component” on page 1-5.
 - b. If the package is a self-extracting executable, paste the package in a directory on the development machine, and run it. If the package is a .zip file, unzip and extract the contents to the development machine.

Note You must repeat these steps for each development machine where you want to use the components.

The first step is not necessary if you are developing your application on the same machine where you created the Java component.

- 2** If you have not already done so, set the environment variables that are required on a development machine. See “Settings for Environment Variables (Development Machine)” on page 6-2.
- 3** Import the MATLAB libraries and the component classes into your code with the Java `import` function. For example:

```
import com.mathworks.toolbox.javabuilder.*;
import componentname.classname; or import componentname.*;
```
- 4** Use the new function in your Java code to create an instance of each class you want to use in the application.
- 5** Call the class methods as you would do with any Java class.
- 6** Handle data conversion as needed.

When you invoke a method on a Java Builder component, the input parameters received by the method must be in the MATLAB internal array format. You can either (manually) convert them yourself within the calling program, or pass the parameters as Java data types.

- To manually convert to one of the standard MATLAB data types, use `MWArray` classes in the package `com.mathworks.toolbox.javabuilder`. See Chapter 4, “Using `MWArray` Classes” for an introduction to the classes and see `com.mathworks.toolbox.javabuilder.MWArray` (available online only) for reference information for this class library.
 - If you pass them as Java data types, they are automatically converted.
- 7** Build and test the Java application as you would any application.

Deploying an Application

To deploy your application you must make sure that the installer you create for the application takes care of supporting the components created by MATLAB Builder for Java. In general, this means that the MCR must be installed on the target machine, in addition to the application files.

Users must also set paths and environment variables correctly. See “Deploying to End Users” in the MATLAB Compiler documentation.

Example: Magic Square

This example shows you how to:

- Access the online examples provided with MATLAB Builder for Java.
- Use MATLAB Builder for Java to encapsulate a simple MATLAB function in a Java component.
- Use the MWArray class library to handle data conversion in a sample application.

About the Examples The examples for MATLAB Builder for Java are in `matlabroot\toolbox\javabuilder\Examples`.

The Magic Square example shows you how to create `magicsquare`, a Java component, which contains the `magic` class. The class encapsulates a MATLAB function, `makesqr`, which computes a magic square. It represents the magic square as a two-dimensional array.

The sample application, `getmagic`, does the following:

- Displays the array returned by the `makesqr` method
- Converts the array returned by `makesqr` to a native array and displays it

When you run the `getmagic` application from the command line, you can pass the dimension for the magic square as a command-line argument.

Magic Square Example: Step-by-Step Procedure

- 1 If you have not already done so, set the environment variables that are required on a development machine. See “Settings for Environment Variables (Development Machine)” on page 6-2.
- 2 If you have not already done so, copy the files for this example as follows:
 - a. Copy the following directory that ships with MATLAB to your work directory:

```
matlabroot\toolbox\javabuilder\Examples\MagicSquareExample
```

This procedure assumes that you are working on Windows and your work directory is D:\Work.

- b. At the MATLAB command prompt, change directory to the new MagicSquareExample subdirectory in your work directory.
- 3** Write the makesqr function as you would any MATLAB function.

Here is the code for the makesqr function:

```
function y = makesqr(x)
    y = magic(x);
```

This code is already in your directory in MagicSquareExample\MagicDemoComp\makesqr.m.

- 4** While in MATLAB, issue the following command to open the Deployment Tool:

```
deploytool
```

- 5** Create a new project

- a. Click the New Deployment Project button  in the Deployment Tool toolbar.

Alternatively you can select **File > New Deployment Project** from the MATLAB menu bar.

- b. In the navigation pane, select **MATLAB Builder for Java** as the product you want to use to create the deployment project.
- c. From the component list, select **Java** as the kind of component you want to create.
- d. Click **Browse** to drill and select the location for your project.
- e. Type the project name as `magicsquare` and click **OK**.

Note By default, the project name is also the component name.

When you create a new project, the Deployment Tool dialog box shows the folders that are part of the project. By default the top folder represents a Java class belonging to the component. By default the class name is the same as the project name.

Note When a new project first opens, the folders in the project are empty.

- 6 Enter the settings for the project.
 - a. Right-click the top folder, which represents the Java class you are going to create, and select **Rename Class**.
 - b. In the Rename Class dialog box, enter magic and click **OK**.
 - c. Add the makesqr.m file to the project by dragging the file from the **Current Directory** pane in the MATLAB desktop to the magic folder in the Deployment Tool dialog box.
 - d. Select **Generate Verbose Output**.
 - e. Save the project by clicking  (Save) in the Deployment Tool toolbar.
- 7 Build the project by clicking  (Build) in the Deployment Tool toolbar.

The build process begins, and a log of the build is created. The files that are needed for the component are generated in two newly created directories, `src` and `distrib`, in the project directory. A copy of the build log is placed in the `src` directory.

Note To create and build the `magicsquare` component without using the Deployment Tool to create a project, issue the following command at the MATLAB prompt:

```
mcc -W 'java:magicsquare,magic' makesqr.m
```

If you build your component using the `mcc` command, Java Builder does not create the `src` and `distrib` subdirectories.

See “What Happens in the Build Process?” on page 2-9 for more information.

- 8** Access the component in a Java application. The sample application for this example is in `MagicSquareExample\MagicDemoJavaApp\getmagic.java`.

getmagic.java

```
/* getmagic.java
 * This file is used as an example for the MATLAB
 * Builder for Java product.
 *
 * Copyright 2001-2006 The MathWorks, Inc.
 */

/* Necessary package imports */
import com.mathworks.toolbox.javabuilder.*;
import magicsquare.*;

/*
 * getmagic class computes a magic square of order N. The
 * positive integer N is passed on the command line.
 */
class getmagic
{
    public static void main(String[] args)
    {
        MWNumericArray n = null; /* Stores input value */
        Object[] result = null; /* Stores the result */
        magic theMagic = null; /* Stores magic class instance */

        try
        {
            /* If no input, exit */
            if (args.length == 0)
            {
                System.out.println("Error: must input a positive integer");
                return;
            }

            /* Convert and print input value*/
            n = new MWNumericArray(Double.valueOf(args[0]),MWClassID.DOUBLE);
```

```

        System.out.println("Magic square of order " + n.toString());

        /* Create new magic object */
        theMagic = new magic();

        /* Compute magic square and print result */
        result = theMagic.makesqr(1, n);
        System.out.println(result[0]);
    }
    catch (Exception e)
    {
        System.out.println("Exception: " + e.toString());
    }
}

finally
{
    /* Free native resources */
    MWArray.disposeArray(n);
    MWArray.disposeArray(result);
    if (theMagic != null)
        theMagic.dispose();
}
}
}

```

In this sample application, the following code imports the libraries and classes that are needed:

```

import com.mathworks.toolbox.javabuilder.*;
import magicsquare.*;

```

The following line instantiates the magic class:

```

theMagic = new magic();

```

The following line calls the makesqr method:

```

result = theMagic.makesqr(1, n);

```

In this method call, the first input argument specifies the number of outputs the method is to return. This input is equivalent in value to the

MATLAB function, `nargout`, in the method being called. The second input argument is the input specified in the function declaration statement of the `makesqr` M-file.

Note The previous calling syntax is not the only way that you can call the `makesqr` method. When Java Builder encapsulates `makesqr.m`, it overloads the function, creating several signatures by which you can call the `makesqr` method. This lets you specify optional arguments when calling from Java. See “Understanding Function Signatures Generated by Java Builder” on page 2-6 for more details.

Note that the program uses a try-catch block to catch and handle any exceptions.

9 Compile the application.

Compile the `getmagic` application using the `javac -classpath` command at the DOS or UNIX command prompt.

The compile yields a `getmagic.class` file.

Note For `matlabroot` substitute the MATLAB root directory on your system. Type `matlabroot` to see this directory name.

- a. On Windows, execute the following command:

```
javac -classpath
.;matlabroot\toolbox\javabuilder\jar\javabuilder.jar;
.\distrib\magicsquare.jar getmagic.java
```

Note If you created the component using `mcc`, Java Builder does not create a `\distrib` directory to contain the `.java` file.

b. On UNIX, execute this command:

```
javac -classpath
.:matlabroot/toolbox/javabuilder/jar/javabuilder.jar:
./distrib/magicsquare.jar getmagic.java
```

10 Run the application.

If you used the Deployment Tool to create it, you can use the following commands to run the `getmagic.class` file:

On Windows, type

```
java -classpath
.;matlabroot\toolbox\javabuilder\jar\javabuilder.jar;
.\distrib\magicsquare.jar
-Djava.library.path=matlabroot\bin\win32;.\distrib
getmagic 5
```

On UNIX, type

```
java -classpath
.:matlabroot/toolbox/javabuilder/jar/javabuilder.jar:
./distrib/magicsquare.jar
-Djava.library.path=matlabroot/bin/arch:./distrib
getmagic 5
```

Note If you set your system path to include a directory pointed by `java.library.path`, you do not need to use the `-D` option.

See “Settings for Environment Variables (Development Machine)” on page 6-2 and for more information about setting paths correctly.

Note The supported JRE version is 1.5.0. To find out what JRE you are using, refer to the output of `'version - java'` in MATLAB or refer to the `jre.cfg` file in `matlabroot/sys/java/jre/<arch>` or `mcroot/sys/java/jre/<arch>`.

When you run the program you pass an argument representing the dimension for the magic square. In this example, the value for the dimension is 5.

The program converts the number passed on the command line to a scalar double value, creates an instance of class `magic`, and calls the `makesqr` method on that object. The method computes the square using the MATLAB `magic` function.

The `getmagic` program should display the following output:

Magic square of order 5

17	24	1	8	15
23	5	7	14	16
4	6	13	20	22
10	12	19	21	3
11	18	25	2	9

Understanding the Magic Square Example

The Magic Square example shows the following aspects of writing an application using components created by MATLAB Builder for Java:

- “Importing Classes” on page 1-23
- “Creating an Instance of the Class” on page 1-23
- “Calling Class Methods from Java” on page 1-23

Importing Classes

You must import the MATLAB libraries and your own Java classes into your code. Use the Java `import` function to do this.

For the `magicsquare` example, the following statements perform the necessary actions:

```
import com.mathworks.toolbox.javabuilder.*;
import magicsquare.*;
```

Creating an Instance of the Class

As with all Java classes, you must use the `new` function to create an instance of a class. To create an object (`theMagic`) from the magic class, the example application uses the following code:

```
theMagic = new magic();
```

Calling Class Methods from Java

Once you have instantiated the class, you can call a class method as you do with any Java object. In the Magic Square example, the `makesqr` method is called as shown:

```
result = theMagic.makesqr(1, n);
```

where `n` is an instance of an `MWArray` class. See the following code fragment for the declaration of `n`:

```
n = new MWNumericArray(Double.valueOf(args[0],  
                        MWClassID.DOUBLE);
```

For More Information

Understanding concepts needed to use MATLAB Builder for Java	Chapter 2, “Concepts”
Writing Java applications that can access Java methods that encapsulate M-code	Chapter 3, “Programming”
Using the MWArray API to handle data conversion	Chapter 4, “Using MWArray Classes”
Sample applications that access methods developed in MATLAB	Chapter 5, “Sample Applications (Java)”

Concepts

A component created by MATLAB Builder for Java is a stand-alone Java package (.jar file). The package contains one or more Java classes that encapsulate M-code. The classes provide methods that are callable directly from Java code.

To use MATLAB Builder for Java you create a project, which specifies the M-code to be used in the components that you want to create. Java Builder supports data conversion between Java types and MATLAB types.

Note When you use Java Builder to create classes, you must create those classes on the same operating system to which you are deploying them for development (or for use by end users running an application). For example, if your goal is to deploy an application to end users to run on Windows, you must create the Java classes with Java Builder running on Windows.

The reason for this limitation is that although the .jar file itself might be platform-independent, the .jar file is dependent on the .ctf file, which is not platform-independent.

For more information about these concepts and about how the product works, see the following topics:

What Is a Project? (p. 2-3)

How MATLAB Builder for Java uses the specifications in a project

How Does Component Deployment Work? (p. 2-11)	Details about deploying to an end user

What Is a Project?

A Java Builder project contains information about the files and settings needed by MATLAB Builder for Java to create a deployable Java component. A project specifies information about classes and methods, including the MATLAB functions to be included.

- “Classes and Methods” on page 2-3
- “Naming Conventions” on page 2-3

Classes and Methods

Java Builder transforms MATLAB functions that are specified in the component’s project to methods belonging to a Java class.

When creating a component, you must provide one or more class names as well as a component name. The class name denotes the name of the class that encapsulates MATLAB functions.

To access the features and operations provided by the MATLAB functions, instantiate the Java class generated by Java Builder, and then call the methods that encapsulate the MATLAB functions.

Note When you add files to a project, you do not have to add any M-files for functions that are called by the functions that you add. When Java Builder builds a component, it automatically includes any M functions called by the functions that you explicitly specify for the component. See “Spectral Analysis Example” on page 5-8 for a sample application that illustrates this feature.

Naming Conventions

Typically you should specify names for components and classes that will be clear to programmers who use your components. For example, if you are encapsulating many MATLAB functions, it helps to determine a scheme of function categories and to create a separate class for each category. Also, the name of each class should be descriptive of what the class does.

How Does MATLAB Builder for Java Handle Data?

To enable Java applications to exchange data with MATLAB methods they invoke, Java Builder provides an API, which is implemented as the `com.mathworks.toolbox.javabuilder.MWArray` package. This package provides a set of data conversion classes derived from the abstract class, `MWArray`. Each class represents a MATLAB data type.

- “Understanding the API Data Conversion Classes” on page 2-4
- “Automatic Conversion to MATLAB Types” on page 2-5
- “Understanding Function Signatures Generated by Java Builder” on page 2-6
- “Returning Data from MATLAB to Java” on page 2-7

Understanding the API Data Conversion Classes

When writing your Java application, you can represent your data using objects of any of the data conversion classes. Alternatively, you can use standard Java data types and objects.

The data conversion classes are built as a class hierarchy that represents the major MATLAB array types.

Note This discussion provides conceptual information about the classes.

For usage information, see Chapter 4, “Using MWArray Classes”.

For reference information, see `com.mathworks.toolbox.javabuilder`.

This discussion assumes you have a working knowledge of the Java programming language and the Java Software Development Kit (SDK). This is not intended to be a discussion on how to program in Java. Refer to the documentation that came with your Java SDK for general programming information.

Overview of Classes and Methods in the Data Conversion Class Hierarchy

The root of the data conversion class hierarchy is the `MWArray` abstract class. The `MWArray` class has the following subclasses representing the major MATLAB types: `MWNumericArray`, `MWLogicalArray`, `MWCharArray`, `MWCellArray`, and `MWStructArray`.

Each subclass stores a reference to a native MATLAB array of that type. Each class provides constructors and a basic set of methods for accessing the underlying array's properties and data. To be specific, `MWArray` and the classes derived from `MWArray` provide the following:

- Constructors and finalizers to instantiate and dispose of MATLAB arrays
- `get` and `set` methods to read and write the array data
- Methods to identify properties of the array
- Comparison methods to test the equality or order of the array
- Conversion methods to convert to other data types

Advantage of Using Data Conversion Classes

The `MWArray` data conversion classes let you pass native type parameters directly without using explicit data conversion. If you pass the same array frequently, you might improve the performance of your program by storing the array in an instance of one of the `MWArray` subclasses.

Automatic Conversion to MATLAB Types

Note Because the conversion process is automatic (in most cases), you do not need to understand the conversion process to pass and return arguments with MATLAB Builder for Java components.

When you pass an `MWArray` instance as an input argument, the encapsulated MATLAB array is passed directly to the method being called.

In contrast, if your code uses a native Java primitive or array as an input parameter, Java Builder converts it to an instance of the appropriate `MWArray`

class before it is passed to the method. Java Builder can convert any Java string, numeric type, or any multidimensional array of these types to an appropriate `MWArray` type, using its data conversion rules. See “Data Conversion Rules” on page 6-10 for a list of all the data types that are supported along with their equivalent types in MATLAB.

The conversion rules apply not only when calling your own methods, but also when calling constructors and factory methods belonging to the `MWArray` classes.

Note There are some data types commonly used in MATLAB that are not available as native Java types. Examples are cell arrays and arrays of complex numbers. Represent these array types as instances of `MWCellArray` and `MWNumericArray`, respectively.

Understanding Function Signatures Generated by Java Builder

The Java programming language does not support optional function arguments in the way that MATLAB does with `varargin` and `varargout`. To support this feature of MATLAB, Java Builder always generates a basic set of overloaded Java methods when it encapsulates each MATLAB function. Each of these overloaded Java methods has the same name as the original M-function, but has a different number or type of arguments. Each overloaded function corresponds to one of the possible signatures in MATLAB.

In general, a function with N input arguments in MATLAB generates $N+3$ overloaded methods in Java. There is an overloaded method for each input argument (N). The additional three methods handle (1) the case of no input arguments and (2) the `mlx` function signature.

Note In addition to handling optional function arguments, the overloaded Java methods that wrap MATLAB functions handle data conversion. See “Automatic Conversion to MATLAB Types” on page 2-5 for more details.

Understanding MATLAB Function Signatures

As background, recall that the generic MATLAB function has the following structure:

```
function [Out1, Out2, ..., varargout]=foo(In1, In2, ..., varargin)
```

To the *left* of the equal sign, the function specifies a set of explicit and optional return arguments.

To the *right* of the equal sign, the function lists explicit *input* arguments followed by one or more optional arguments.

Each argument represents a MATLAB type. When you include the `varargin` or `varargout` argument, you can specify an arbitrary number of inputs or outputs beyond the ones that are explicitly declared.

Overloaded Methods in Java That Encapsulate M-Code

When MATLAB Builder for Java encapsulates your M-code, it creates a set of overloaded methods that implement the MATLAB functions. Each of these overloaded methods corresponds to a call to the generic MATLAB function for each combination of the possible number and type of input arguments.

In addition to these methods encapsulating input arguments, Java Builder creates another method, which represents the output arguments, or return values, of the MATLAB function. This additional overloaded method takes care of return values for the encapsulated MATLAB function. This method of encapsulating the information about return values simulates the `mlx` interface in the MATLAB Compiler.

These overloaded methods are called the standard interface (encapsulating input arguments) and the `mlx` interface (encapsulating return values). See “Programming Interfaces Generated by Java Builder” on page 6-14 for details.

Returning Data from MATLAB to Java

All data returned from a method coded in MATLAB is passed as an instance of the appropriate `MWArray` subclass. For example, a MATLAB cell array is returned to the Java application as an `MWCellArray` object.

Return data is *not* converted to a Java type. If you choose to use a Java type, you must convert to that type using the `toArray` method of the `MWArray` subclass to which the return data belongs.

What Happens in the Build Process?

Note MATLAB Builder for Java uses the `JAVA_HOME` variable to locate the Java Software Development Kit (SDK) on your system. The compiler uses this variable to set the version of the `javac.exe` command it uses during compilation.

To create a component, Java Builder does the following:

- 1 Generates Java code to implement your component. The files are as follows:

<code>myclass.java</code>	Contains a Java class with methods encapsulating the M-functions specified in the project for that class.
<code>mycomponentMCR.java</code>	Contains the CTF decryption keys and code to initialize the MCR for the component.

- 2 Compiles the Java code produced in step 1.
- 3 Generates `/distrib` and `/src` subdirectories.
- 4 Creates a component technology file (`.ctf`) which contains encrypted MATLAB files generated by Java Builder.
- 5 Invokes the Jar utility to package the Java class files it has created into a Java archive file (`mycomponent.jar`).

What Happens in the Package Process?

The packaging process creates a self-extracting executable (on Windows platforms) or a `.zip` file (on non-Windows platforms). The package contains at least the following:

- The Java Builder component
- The `.ctf` file for the component
- The MCR Installer (if the **Install MCR** option was selected when the component was built)

Note The packaging process is not available when using `mcc` directly.

Note When you use Java Builder to create classes, you must create those classes on the same operating system to which you are deploying them for development (or for use by end users running an application). That is, for example, if your goal is to deploy an application to end users to run on Windows, you must create the Java classes with Java Builder running on Windows.

The reason for this limitation is as follows: although the `.jar` file itself might be platform-independent, the `.jar` file is dependent on the `.ctf` file, which is not platform-independent.

How Does Component Deployment Work?

There are two kinds of deployment:

- Installing components and setting up support for them on a development machine so that they can be accessed by a developer who seeks to use them in writing a Java application.

To accomplish this kind of deployment, create a package, using the GUI, as described in “Creating a Java Component” on page 1-5.

- Deploying support for the components when they are accessed at run time on an end-user machine.

To accomplish this kind of deployment, you must make sure that the installer you create for the application takes care of supporting the Java components on the target machine. In general, this means the MCR must be installed, on the target machine. You must also install the Java Builder component and its `.ctf` file.

For more information about the deployment process, see “Deploying to End Users” in the MATLAB Compiler documentation.

Programming

To access a Java component built and packaged by MATLAB Builder for Java, you must first unpack and install components so you can use them on a particular machine.

Then you perform the following programming tasks:

Import Classes (p. 3-2)	How to reference the classes
Creating an Instance of the Class (p. 3-3)	Sample code for instantiating a class that encapsulates MATLAB code
Passing Arguments to and from Java (p. 3-6)	How to match up data types between MATLAB and Java
Handling Errors (p. 3-19)	How to handle an error generated by MATLAB
Managing Native Resources (p. 3-25)	How to free memory used by the mxArray data conversion classes
Handling Data Conversion Between Java and MATLAB (p. 3-28)	Call signatures for passing arguments and returning output

Note For conceptual information that might help you in approaching these tasks, see Chapter 2, “Concepts”.

For examples of these tasks, see Chapter 5, “Sample Applications (Java)”.

For information about deploying your application after you complete these tasks, see “How Does Component Deployment Work?” on page 2-11.

Import Classes

To use a component generated by MATLAB Builder for Java, you must do the following:

- Import MATLAB libraries with the Java `import` function, for example:

```
import com.mathworks.toolbox.javabuilder.*;
```

- Import the component classes created by Java Builder, for example:

```
import componentname.*; or import componentname.classname;
```

Note When you use Java Builder to create classes, you must create those classes on the same operating system to which you are deploying them for development (or for use by end users running an application). That is, for example, if your goal is to deploy an application to end users to run on Windows, you must create the Java classes with Java Builder running on Windows.

The reason for this limitation is as follows: although the `.jar` file itself might be platform-independent, the `.jar` file is dependent on the `.ctf` file, which is not platform-independent.

Creating an Instance of the Class

As with any Java class, you need to instantiate the classes you create with MATLAB Builder for Java before you can use them in your program.

Suppose you build a component named `MyComponent` with a class named `MyClass`. Here is an example of creating an instance of the `MyClass` class:

```
MyClass ClassInstance = new MyClass();
```

Code Fragment: Instantiating a Java Class

The following Java code shows how to create an instance of a class that was built with MATLAB Builder for Java. The application uses a Java class that encapsulates a MATLAB function, `myprimes`.

```
/*
 * usemyclass.java uses myclass
 */

/* Import all com.mathworks.toolbox.javabuilder classes */
import com.mathworks.toolbox.javabuilder.*;

/* Import all com.mycompany.mycomponent classes */
import com.mycompany.mycomponent.*;

/*
 * usemyclass class
 */
public class usemyclass
{
    /** Constructs a new usemyclass */
    public usemyclass()
    {
        super();
    }

    /* Returns an array containing the primes between 0 and n */
    public double[] getprimes(int n) throws MWException
    {
        myclass cls = null;
```

```
Object[] y = null;

try
{
    cls = new myclass();
    y = cls.myprimes(1, new Double((double)n));
    return (double[])((MWArray)y[0]).getData();
}

finally
{
    MWArray.disposeArray(y);
    if (cls != null)
        cls.dispose();
}
}
```

The import statements at the beginning of the program import packages that define all the classes that the program requires. These classes are defined in `javabuilder.*` and `mycomponent.*`; the latter defines the class `myclass`.

The following statement instantiates the class `myclass`:

```
cls = new myclass();
```

The following statement calls the class method `myprimes`:

```
y = cls.myprimes(1, new Double((double)n));
```

The sample code passes a `java.lang.Double` to the `myprimes` method. The `java.lang.Double` is automatically converted to the `double` data type required by the encapsulated MATLAB `myprimes` function.

When `myprimes` executes, it finds all prime numbers between 0 and the input value and returns this in a MATLAB double array. This array is returned to the Java program as an `MWNumericArray` with its `MWClassID` property set to `MWClassID.DOUBLE`.

The `myprimes` method encapsulates the `myprimes` function.

myprimes Function

The code for myprimes is as follows:

```
function p = myprimes(n)
% MYPRIMES Returns the primes between 0 and n.
% P = MYPRIMES(N) Returns the primes between 0 and n.
% This file is used as an example for the MATLAB
% Builder for Java product.

% Copyright 2001-2006 The MathWorks, Inc.

if length(n) ~= 1
    error('N must be a scalar');
end

if n < 2
    p = zeros(1,0);
    return
end

p = 1:2:n;
q = length(p);
p(1) = 2;

for k = 3:2:sqrt(n)
    if p((k+1)/2)
        p(((k*k+1)/2):k:q) = 0;
    end
end

p = (p(p>0));
```

Passing Arguments to and from Java

When you invoke a method on a MATLAB Builder for Java component, the input arguments received by the method must be in the MATLAB internal array format. You can either convert them yourself within the calling program, or pass the arguments as Java data types, which are then automatically converted by the calling mechanism.

To convert them yourself, use instances of the `MWArray` classes; in this case you are using *manual conversion*. Storing your data using the classes and data types defined in the Java language means that you are relying on *automatic conversion*. Most likely, you will use a combination of manual and automatic conversion.

- “Manual Conversion of Data Types” on page 3-6
- “Automatic Conversion to a MATLAB Type” on page 3-7
- “Specifying Optional Arguments” on page 3-9
- “Handling Return Values” on page 3-14

Manual Conversion of Data Types

To manually convert to one of the standard MATLAB data types, use the `MWArray` data conversion classes provided by Java Builder. For class reference information, see the `com.mathworks.toolbox.javabuilder` package. For extensive usage information, see Chapter 4, “Using `MWArray` Classes”.

Code Fragment: Using `MWNumericArray`

The `getmagic` example shows manual conversion. The following code fragment from that program shows a `java.lang.Double` argument that is converted to an `MWNumericArray` type that can be used by the M-function without further conversion.

```
MWNumericArray dims = null;
dims = new MWNumericArray(Double.valueOf(args[0]),
                          MWClassID.DOUBLE);

result = theMagic.makesqr(1, dims);
```

Code Fragment: Passing an MWArray. This example constructs an `MWNumericArray` of type `MWClassID.DOUBLE`. The call to `myprimes` passes the number of outputs, 1, and the `MWNumericArray`, `x`:

```
x = new MWNumericArray(n, MWClassID.DOUBLE);
cls = new myclass();
y = cls.myprimes(1, x);
```

Java Builder converts the `MWNumericArray` object to a MATLAB scalar double to pass to the M-function.

Automatic Conversion to a MATLAB Type

When passing an argument only a small number of times, it is usually just as efficient to pass a primitive Java type or object. In this case, the calling mechanism converts the data for you into an equivalent MATLAB type.

For instance, either of the following Java types would be automatically converted to the MATLAB double type:

- A Java double primitive
- An object of class `java.lang.Double`

For reference information about data conversion (tables showing each Java type along with its converted MATLAB type, and each MATLAB type with its converted Java type), see “Data Conversion Rules” on page 6-10.

Code Fragment: Automatic Data Conversion

When calling the `makesqr` method used in the `getmagic` application, you could construct an object of type `MWNumericArray`. Doing so would be an example of manual conversion. Instead, you could rely on automatic conversion, as shown in the following code fragment:

```
result = M.makesqr(1, arg[0]);
```

In this case, a Java double is passed as `arg[0]`.

Here is another example:

```
result = theFourier.plotfft(3, data, new Double(interval));
```

In this Java statement, the third argument is of type `java.lang.Double`. According to conversion rules, the `java.lang.Double` automatically converts to a MATLAB 1-by-1 double array.

Code Fragment: Passing a Java Double Object

The example calls the `myprimes` method with two arguments. The first specifies the number of arguments to return. The second is an object of class `java.lang.Double` that passes the one data input to `myprimes`.

```
cls = new myclass();  
y = cls.myprimes(1, new Double((double)n));
```

This second argument is converted to a MATLAB 1-by-1 double array, as required by the M-function. This is the default conversion rule for `java.lang.Double`.

Code Fragment: Passing an MWArray

This example constructs an `MWNumericArray` of type `MWClassID.DOUBLE`. The call to `myprimes` passes the number of outputs, 1, and the `MWNumericArray`, `x`.

```
x = new MWNumericArray(n, MWClassID.DOUBLE);  
cls = new myclass();  
y = cls.myprimes(1, x);
```

Java Builder converts the `MWNumericArray` object to a MATLAB scalar double to pass to the M-function.

Code Fragment: Calling MWArray Methods

The conversion rules apply not only when calling your own methods, but also when calling constructors and factory methods belonging to the `MWArray` classes.

For example, the following code fragment calls the constructor for the `MWNumericArray` class with a Java double as the input argument:

```
double Adata = 24;
MWNumericArray A = new MWNumericArray(Adata);
System.out.println("Array A is of type " + A.classID());
```

Java Builder converts the input argument to an instance of `MWNumericArray`, with a `ClassID` property of `MWClassID.DOUBLE`. This `MWNumericArray` object is the equivalent of a MATLAB 1-by-1 double array.

When you run this example, the results are as follows:

```
Array A is of type double
```

Changing the Default by Specifying the Type

When calling an `MWArray` class method constructor, supplying a specific data type causes Java Builder to convert to that type instead of the default.

For example, in the following code fragment, the code specifies that `A` should be constructed as a MATLAB 1-by-1 16-bit integer array:

```
double Adata = 24;
MWNumericArray A = new MWNumericArray(Adata, MWClassID.INT16);
System.out.println("Array A is of type " + A.classID());
```

When you run this example, the results are as follows:

```
Array A is of type int16
```

Specifying Optional Arguments

So far, the examples have not used M-functions that have `varargin` or `varargout` arguments. Consider the following M-function:

```
function y = mysum(varargin)
%   MYSUM Returns the sum of the inputs.
%   Y = MYSUM(VARARGIN) Returns the sum of the inputs.
%   This file is used as an example for the MATLAB
%   Builder for Java product.

%   Copyright 2001-2006 The MathWorks, Inc.
```

```
y = sum([varargin{:}]);
```

This function returns the sum of the inputs. The inputs are provided as a `varargin` argument, which means that the caller can specify any number of inputs to the function. The result is returned as a scalar double.

Code Fragment: Passing Variable Numbers of Inputs

Java Builder generates a Java interface to this function as follows:

```
/* mlx interface - List version*/
public void mysum(List lhs, List rhs)
                throws MWException
{
    (implementation omitted)
}
/* mlx interface - Array version*/
public void mysum(Object[] lhs, Object[] rhs)
                throws MWException
{
    (implementation omitted)
}

/* standard interface - no inputs */
public Object[] mysum(int nargout) throws MWException
{
    (implementation omitted)
}

/* standard interface - variable inputs */
public Object[] mysum(int nargout, Object varargin)
                throws MWException
{
    (implementation omitted)
}
```

In all cases, the `varargin` argument is passed as type `Object`. This lets you provide any number of inputs in the form of an array of `Object`, that is `Object[]`, and the contents of this array are passed to the compiled

M-function in the order in which they appear in the array. Here is an example of how you might use the `mysum` method in a Java program:

```
public double getsum(double[] vals) throws MWException
{
    myclass cls = null;
    Object[] x = {vals};
    Object[] y = null;

    try
    {
        cls = new myclass();
        y = cls.mysum(1, x);
        return ((MWNumericArray)y[0]).getDouble(1);
    }

    finally
    {
        MWArray.disposeArray(y);
        if (cls != null)
            cls.dispose();
    }
}
```

In this example, an `Object` array of length 1 is created and initialized with a reference to the supplied `double` array. This argument is passed to the `mysum` method. The result is known to be a scalar `double`, so the code returns this `double` value with the statement:

```
return ((MWNumericArray)y[0]).getDouble(1);
```

Cast the return value to `MWNumericArray` and invoke the `getDouble(int)` method to return the first element in the array as a primitive `double` value.

Code Fragment: Passing Array Inputs. The next example performs a more general calculation:

```
public double getsum(Object[] vals) throws MWException
{
    myclass cls = null;
    Object[] x = null;
```

```
Object[] y = null;

try
{
    x = new Object[vals.length];
    for (int i = 0; i < vals.length; i++)
        x[i] = new MWNumericArray(vals[i], MWClassID.DOUBLE);

    cls = new myclass();
    y = cls.mysum(1, x);
    return ((MWNumericArray)y[0]).getDouble(1);
}
finally
{
    MWArray.disposeArray(x);
    MWArray.disposeArray(y);
    if (cls != null)
        cls.dispose();
}
}
```

This version of `getsum` takes an array of `Object` as input and converts each value to a double array. The list of double arrays is then passed to the `mysum` function, where it calculates the total sum of each input array.

Code Fragment: Passing a Variable Number of Outputs

When present, `varargout` arguments are handled in the same way that `varargin` arguments are handled. Consider the following M-function:

```
function varargout = randvectors
% RANDVECTORS Returns a list of random vectors.
% VARARGOUT = RANDVECTORS Returns a list of random
% vectors such that the length of the ith vector = i.
% This file is used as an example for the MATLAB
% Builder for Java product.

% Copyright 2001-2006 The MathWorks, Inc.

for i=1:nargout
```

```

    varargout{i} = rand(1, i);
end

```

This function returns a list of random double vectors such that the length of the *i*th vector is equal to *i*. The MATLAB Compiler generates a Java interface to this function as follows:

```

/* mlx interface - List version */
public void randvectors(List lhs, List rhs) throws MWException
{
    (implementation omitted)
}
/* mlx interface Array version */
public void randvectors(Object[] lhs, Object[] rhs) throws MWException
{
    (implementation omitted)
}
/* Standard interface no inputs*/
public Object[] randvectors(int nargsout) throws MWException
{
    (implementation omitted)
}

```

Code Fragment: Passing Optional Arguments with the Standard Interface. Here is one way to use the `randvectors` method in a Java program:

```

public double[][] getrandvectors(int n) throws MWException
{
    myclass cls = null;
    Object[] y = null;

    try
    {
        cls = new myclass();
        y = cls.randvectors(n);
        double[][] ret = new double[y.length][];

        for (int i = 0; i < y.length; i++)
            ret[i] = (double[])((MWArray)y[i]).getData();
    }
}

```

```
        return ret;
    }

    finally
    {
        MArray.disposeArray(y);
        if (cls != null)
            cls.dispose();
    }
}
```

The `getrandvectors` method returns a two-dimensional double array with a triangular structure. The length of the *i*th row equals *i*. Such arrays are commonly referred to as *jagged* arrays. Jagged arrays are easily supported in Java because a Java matrix is just an array of arrays.

Handling Return Values

The previous examples used the fact that you knew the type and dimensionality of the output argument. In the case that this information is unknown, or can vary (as is possible in M-programming), the code that calls the method might need to query the type and dimensionality of the output arguments.

There are two basic ways to do this. You can do one of the following:

- Use reflection support in the Java language to query any object for its type.
- Use several methods provided by the `MArray` class to query information about the underlying MATLAB array.

Code Fragment: Using Java Reflection

This code sample calls the `myprimes` method, and then determines the type using reflection. The example assumes that the output is returned as a numeric matrix but the exact numeric type is unknown.

```
public void getprimes(int n) throws MWException
{
    myclass cls = null;
    Object[] y = null;
```

```
try
{
    cls = new myclass();
    y = cls.myprimes(1, new Double((double)n));
    Object a = ((MArray)y[0]).toArray();

    if (a instanceof double[][])
    {
        double[][] x = (double[][])a;

        /* (do something with x...) */
    }

    else if (a instanceof float[][])
    {
        float[][] x = (float[][])a;

        /* (do something with x...) */
    }

    else if (a instanceof int[][])
    {
        int[][] x = (int[][])a;

        /* (do something with x...) */
    }

    else if (a instanceof long[][])
    {
        long[][] x = (long[][])a;

        /* (do something with x...) */
    }

    else if (a instanceof short[][])
    {
        short[][] x = (short[][])a;

        /* (do something with x...) */
    }
}
```

```
    }

    else if (a instanceof byte[][])
    {
        byte[][] x = (byte[][])a;

        /* (do something with x...) */
    }

    else
    {
        throw new MWException(
            "Bad type returned from myprimes");
    }
}
```

This example uses the `toArray` method (see “Methods to Copy, Convert, and Compare MWArrays” on page 4-49) to return a Java primitive array representing the underlying MATLAB array. The `toArray` method works just like `getData` in the previous examples, except that the returned array has the same dimensionality as the underlying MATLAB array.

Code Fragment: Using MWArray Query

The next example uses the `MWArray classID` method (see “Methods to Return Information About an MWArray” on page 4-40) to determine the type of the underlying MATLAB array. It also checks the dimensionality by calling `numberOfDimensions`. If any unexpected information is returned, an exception is thrown. It then checks the `MWClassID` and processes the array accordingly.

```
public void getprimes(int n) throws MWException
{
    myclass cls = null;
    Object[] y = null;

    try
    {
        cls = new myclass();
        y = cls.myprimes(1, new Double((double)n));
    }
}
```

```
MWClassID clsid = ((MWArray)y[0]).classID();

if (!clsid.isNumeric() ||
    ((MWArray)y[0]).numberOfDimensions() != 2)
{
    throw new MWException("Bad type returned from myprimes");
}

if (clsid == MWClassID.DOUBLE)
{
    double[][] x = (double[][])((MWArray)y[0]).toArray();

    /* (do something with x...) */
}

else if (clsid == MWClassID.SINGLE)
{
    float[][] x = (float[][])((MWArray)y[0]).toArray();

    /* (do something with x...) */
}

else if (clsid == MWClassID.INT32 ||
         clsid == MWClassID.UINT32)
{
    int[][] x = (int[][])((MWArray)y[0]).toArray();

    /* (do something with x...) */
}

else if (clsid == MWClassID.INT64 ||
         clsid == MWClassID.UINT64)
{
    long[][] x = (long[][])((MWArray)y[0]).toArray();

    /* (do something with x...) */
}

else if (clsid == MWClassID.INT16 ||
         clsid == MWClassID.UINT16)
```

```
    {
        short[][] x = (short[][])((MArray)y[0]).toArray();

        /* (do something with x...) */
    }

    else if (clsid == MWCClassID.INT8 ||
            clsid == MWCClassID.UINT8)
    {
        byte[][] x = (byte[][])((MArray)y[0]).toArray();

        /* (do something with x...) */
    }
}
finally
{
    MArray.disposeArray(y);
    if (cls != null)
        cls.dispose();
}
}
```

Handling Errors

Errors that occur during execution of an M-function or during data conversion are signaled by a standard Java exception. This includes MATLAB run-time errors as well as errors in your M-code.

In general, there are two types of exceptions in Java: checked exceptions and unchecked exceptions.

Handling Checked Exceptions

Checked exceptions must be declared as thrown by a method using the Java language throws clause. Java Builder components support one checked exception: `com.mathworks.toolbox.javabuilder.MWException`. This exception class inherits from `java.lang.Exception` and is thrown by every MATLAB Compiler generated Java method to signal that an error has occurred during the call. All normal MATLAB run-time errors, as well as user-created errors (e.g., a calling error in your M-code) are manifested as `MWExceptions`.

The Java interface to each M-function declares itself as throwing an `MWException` using the throws clause. For example, the `myprimes` M-function shown previously has the following interface:

```
/* mlx interface List version */
public void myprimes(List lhs, List rhs) throws MWException
{
    (implementation omitted)
}
/* mlx interface Array version */
public void myprimes(Object[] lhs, Object[] rhs) throws MWException
{
    (implementation omitted)
}
/* Standard interface no inputs*/
public Object[] myprimes(int nargout) throws MWException
{
    (implementation omitted)
}
/* Standard interface one input*/
```

```
public Object[] myprimes(int nargout, Object n) throws MWException
{
    (implementation omitted)
}
```

Any method that calls `myprimes` must do one of two things:

- Catch and handle the `MWException`.
- Allow the calling program to catch it.

The following two sections provide examples of each.

Code Fragment: Handling an Exception in the Called Function

The `getprimes` example shown here uses the first of these methods. This method handles the exception itself, and does not need to include a `throws` clause at the start.

```
public double[] getprimes(int n)
{
    myclass cls = null;
    Object[] y = null;

    try
    {
        cls = new myclass();
        y = cls.myprimes(1, new Double((double)n));
        return (double[])((MWArray)y[0]).getData();
    }

    /* Catches the exception thrown by myprimes */
    catch (MWException e)
    {
        System.out.println("Exception: " + e.toString());
        return new double[0];
    }

    finally
    {
        MWArray.disposeArray(y);
    }
}
```

```
        if (cls != null)
            cls.dispose();
    }
}
```

Note that in this case, it is the programmer's responsibility to return something reasonable from the method in case of an error.

The `finally` clause in the example contains code that executes after all other processing in the `try` block is executed. This code executes whether or not an exception occurs or a control flow statement like `return` or `break` is executed. It is common practice to include any cleanup code that must execute before leaving the function in a `finally` block. The documentation examples use `finally` blocks in all the code samples to free native resources that were allocated in the method.

For more information on freeing resources, see “Managing Native Resources” on page 3-25.

Code Fragment: Handling an Exception in the Calling Function

In this next example, the method that calls `myprimes` declares that it throws an `MWException`:

```
public double[] getprimes(int n) throws MWException
{
    myclass cls = null;
    Object[] y = null;

    try
    {
        cls = new myclass();
        y = cls.myprimes(1, new Double((double)n));
        return (double[])((MWArray)y[0]).getData();
    }

    finally
    {
        MWArray.disposeArray(y);
        if (cls != null)
```

```
        cls.dispose();
    }
}
```

Handling Unchecked Exceptions

Several types of unchecked exceptions can also occur during the course of execution. Unchecked exceptions are Java exceptions that do not need to be explicitly declared with a throws clause. The MWArray API classes all throw unchecked exceptions.

All unchecked exceptions thrown by MWArray and its subclasses are subclasses of `java.lang.RuntimeException`. The following exceptions can be thrown by MWArray:

- `java.lang.RuntimeException`
- `java.lang.ArrayStoreException`
- `java.lang.NullPointerException`
- `java.lang.IndexOutOfBoundsException`
- `java.lang.NegativeArraySizeException`

This list represents the most likely exceptions. Others might be added in the future. For information on the exceptions that can occur for each method of MWArray and its subclasses, see [Using MWArray Classes](#).

Code Fragment: Catching General Exceptions

You can easily rewrite the `getprimes` example to catch any exception that can occur during the method call and data conversion. Just change the catch clause to catch a general `java.lang.Exception`.

```
public double[] getprimes(int n)
{
    myclass cls = null;
    Object[] y = null;

    try
    {
        cls = new myclass();
    }
}
```

```

        y = cls.myprimes(1, new Double((double)n));
        return (double[])((MWArray)y[0]).getData();
    }

    /* Catches the exception thrown by anyone */
    catch (Exception e)
    {
        System.out.println("Exception: " + e.toString());
        return new double[0];
    }

    finally
    {
        MWArray.disposeArray(y);
        if (cls != null)
            cls.dispose();
    }
}

```

Code Fragment: Catching Multiple Exception Types

This second, and more general, variant of this example differentiates between an exception generated in a compiled method call and all other exception types by introducing two catch clauses as follows:

```

public double[] getprimes(int n)
{
    myclass cls = null;
    Object[] y = null;

    try
    {
        cls = new myclass();
        y = cls.myprimes(1, new Double((double)n));
        return (double[])((MWArray)y[0]).getData();
    }

    /* Catches the exception thrown by myprimes */
    catch (MWException e)
    {

```

```
        System.out.println("Exception in MATLAB call: " +
            e.toString());
        return new double[0];
    }

    /* Catches all other exceptions */
    catch (Exception e)
    {
        System.out.println("Exception: " + e.toString());
        return new double[0];
    }

    finally
    {
        MWArray.disposeArray(y);
        if (cls != null)
            cls.dispose();
    }
}
```

The order of the catch clauses here is important. Because `MWException` is a subclass of `Exception`, the catch clause for `MWException` must occur before the catch clause for `Exception`. If the order is reversed, the `MWException` catch clause will never execute.

Managing Native Resources

When your code accesses Java classes created by MATLAB Builder for Java, your program uses native resources, which exist outside the control of the Java Virtual Machine (JVM).

Specifically, each `MWArray` data conversion class is a wrapper class that encapsulates a MATLAB `mxArray`. The encapsulated MATLAB array allocates resources from the native memory heap.

Note Because the Java wrapper is small and the `mxArray` is relatively large, the JVM memory manager may not call the garbage collector before the native memory becomes exhausted or badly fragmented. This means that *native arrays should be explicitly freed*.

You can use any of the following techniques to free memory:

- “Using Garbage Collection Provided by the JVM” on page 3-25
- “Using the dispose Method” on page 3-26
- “Overriding the Object.Finalize Method” on page 3-27

Using Garbage Collection Provided by the JVM

When you create a new instance of a Java class, the JVM allocates and initializes the new object. When this object goes out of scope, or becomes otherwise unreachable, it becomes eligible for garbage collection by the JVM. The memory allocated by the object is eventually freed when the garbage collector is run.

When you instantiate `MWArray` classes, the encapsulated MATLAB also allocates space for native resources, but these resources are not visible to the JVM and are not eligible for garbage collection by the JVM. These resources are not released by the class finalizer until the JVM determines that it is appropriate to run the garbage collector.

The resources allocated by `MWArray` objects can be quite large and can quickly exhaust your available memory. To avoid exhausting the native memory

heap, `MWArray` objects should be explicitly freed as soon as possible by the application that creates them.

Using the `dispose` Method

The best technique for freeing resources for classes created by MATLAB Builder for Java is to call the `dispose` method explicitly. Any Java object, including an `MWArray` object, has a `dispose` method.

The `MWArray` classes also have a `finalize` method, called a finalizer, that calls `dispose`. Although you can think of the `MWArray` finalizer as a kind of safety net for the cases when you do not call `dispose` explicitly, keep in mind that you cannot determine exactly when JVM calls the finalizer, and the JVM might not discover memory that should be freed.

Code Fragment: Using `dispose`

The following example allocates an approximate 8 MB native array. To the JVM, the size of the wrapped object is just a few bytes (the size of an `MWNumericArray` instance) and thus not of significant size to trigger the garbage collector. This example shows why it is good practice to free the `MWArray` explicitly.

```
/* Allocate a huge array */
int[] dims = {1000, 1000};
MWNumericArray a = MWNumericArray.newInstance(dims,
    MWClassID.DOUBLE, MWComplexity.REAL);
    .
    . (use the array)
    .

/* Dispose of native resources */
a.dispose();

/* Make it eligible for garbage collection */
a = null;
```

The statement `a.dispose()` frees the memory allocated by both the managed wrapper and the native MATLAB array.

The `MWArray` class provides two disposal methods: `dispose` and `disposeArray`. The `disposeArray` method is more general in that it disposes of either a single `MWArray` or an array of arrays of type `MWArray`.

Code Fragment: Use try-finally to Ensure Resources Are Freed

Typically, the best way to call the `dispose` method is from a `finally` clause in a `try-finally` block. This technique ensures that all native resources are freed before exiting the method, even if an exception is thrown at some point before the cleanup code.

Code Fragment: Using dispose in a finally Clause.

This example shows the use of `dispose` in a `finally` clause:

```
/* Allocate a huge array */
try
{
    int[] dims = {1000, 1000};
    MWNumericArray a = MWNumericArray.newInstance(dims,
        MWClassID.DOUBLE, MWComplexity.REAL);
    .
    . (use the array)
    .
}

/* Dispose of native resources */
finally
{
    a.dispose();
    /* Make it eligible for garbage collection */
    a = null;
}
```

Overriding the Object.Finalize Method

You can also override the `Object.Finalize` method to help clean up native resources just before garbage collection of the managed object. Refer to your Java language reference documentation for detailed information on how to override this method.

Handling Data Conversion Between Java and MATLAB

The call signature for a method that encapsulates a MATLAB function uses one of the MATLAB data conversion classes to pass arguments and return output. When you call any such method, all input arguments not derived from one of the `MWArray` classes are converted by Java Builder to the correct `MWArray` type before being passed to the MATLAB method.

For example, consider the following Java statement:

```
result = theFourier.plotfft(3, data, new Double(interval));
```

The third argument is of type `java.lang.Double`, which converts to a MATLAB 1-by-1 double array.

Calling MWArray Methods

The conversion rules apply not only when calling your own methods, but also when calling constructors and factory methods belonging to the `MWArray` classes. For example, the following code calls the constructor for the `MWNumericArray` class with a Java double input. Java Builder converts the Java double input to an instance of `MWNumericArray` having a `ClassID` property of `MWClassID.DOUBLE`. This is the equivalent of a MATLAB 1-by-1 double array.

```
double Adata = 24;  
MWNumericArray A = new MWnumericArray(Adata);  
System.out.println("Array A is of type " + A.classID());
```

When you run this example, the results are as follows:

```
Array A is of type double
```

Specifying the Type

There is an exception: if you supply a specific data type in the same constructor, Java Builder converts to that type rather than following the default conversion rules. Here, the code specifies that `A` should be constructed as a MATLAB 1-by-1 16-bit integer array:

```
double Adata = 24;
```

```
MWNumericArray A = new MWnumericArray(Adata, MWClassID.INT16);  
System.out.println("Array A is of type " + A.classID());
```

When you run this example, the results are as follows:

```
Array A is of type int16
```

Using MWArray Classes

The following topics explain how to use the data conversion classes in the `com.mathworks.toolbox.javabuilder.MWArray` package.

Guidelines for Working with
MWArray Classes (p. 4-2)

Using Class Methods (p. 4-38)

How to use the MWArray API to
handle various kinds of data

How to use each class in the
MWArray API

Guidelines for Working with MWArray Classes

Overview of the MWArray API

The MWArray Java API is a class hierarchy that represents the major MATLAB array types. The root class is MWArray, which has the following subclasses:

- MWNumericArray
- MWLogicalArray
- MWCharArray
- MWCellArray
- MWStructArray

These subclasses provide constructors and factory methods for creating new MATLAB arrays from standard Java types and objects. You can use these MATLAB arrays as arguments in method calls.

Note To improve performance, MWArrays are designed so that they cannot be resized or reshaped once they are created.

Understanding the MWArray Base Class

MWArray stores a reference to a native MATLAB array and provides a set of methods for accessing the array's properties and data. MWArray also provides methods for converting the MATLAB array to standard Java types from the outputs of a Java class method call.

Accessing Elements of the Arrays

You cannot access the underlying MATLAB array's data buffers directly. Instead use set and get methods to retrieve or modify an element of the array. The set and get methods support simple indexing through a single subscript (value at offset) or you can supply an array of int representing the indices of the requested value. In the case of structure arrays, indexing by field name is also supported.

Method Overrides Implemented by MWArray

To ensure integration with Java programs, MWArray provides overrides for `java.lang.Object` methods and implements the required Java interfaces as needed. The following table provides more information about the overrides.

Overrides

Method in MWArray Base Class	Override Description
<code>equals</code>	Overrides <code>Object.equals</code> to provide a logical equality test for two MWArrays. Internally, this method does a byte-wise comparison of the native buffer. Therefore, two MWArray instances are logically equal when they are of the same MATLAB type and have identical size, shape, and content.
<code>hashCode</code>	Overrides <code>Object.hashCode</code> to allow MWArray to function properly with hash-based collections.
<code>toString</code>	Overrides <code>Object.toString</code> so that MWArray objects will print properly. This method formats a new <code>java.lang.String</code> from the underlying MATLAB array so that calls to <code>System.out.println</code> with an MWArray as an argument will produce the same output as displaying the array in MATLAB.
<code>finalize</code>	Overrides <code>Object.finalize</code> so that the underlying MATLAB array is destroyed when the garbage collector reclaims the containing MWArray object. This method has protected access and is not user callable.

Java Interfaces Implemented by MWArray

MWArray implements the standard Java interfaces shown in the following table.

Java Interfaces Implemented by MArray

Interface	Method in MArray Base Class	Description of Method
Cloneable	clone (public method)	Produces a new MArray object that contains a deep copy of the underlying MATLAB array.
Comparable	compareTo (public method)	Allows comparisons of MArrays for order. Internally, this method does a byte-wise comparison of the native buffer. Therefore, MArray has a natural ordering that is based on a combination of the array's MATLAB type, size, and shape.
Serializable	writeObject readObject (private methods)	Provides serialization support is as required by the Serializable interface.

Additional MArray Methods

MArray

MArray also implements several base class methods that are common to all MArray subclasses. These methods are shown in the following table.

Method	Usage
MArray()	Constructs an empty array.
classID()	Returns the MATLAB type of the array.

Method	Usage
<code>columnIndex()</code>	Returns the column index (second dimension) of each element in the array. Call this method to get an array of column indices for the nonzero elements of a sparse array.
<code>dispose()</code>	Frees the native resources associated with the underlying MATLAB array.
<code>disposeArray(Object)</code>	Calls <code>dispose</code> on all MWArray instances contained in the input.
<code>get(int)</code>	Returns the elements at the specified one-based offset.
<code>get(int[])</code>	Returns the elements at the specified one-based index array.
<code>getData()</code>	<p>Returns a one-dimensional array containing a copy of the data in the underlying MATLAB array as an array of Java types. The elements in the returned array are arranged in column-wise order. The different kinds of arrays are returned as follows:</p> <ul style="list-style-type: none"> • If the underlying MATLAB array is complex, the real part is returned. • If the underlying array is sparse, an array containing the nonzero elements is returned. • If the underlying array is a cell or struct array, <code>toArray</code> is recursively called on each element.
<code>getDimensions()</code>	Returns an array of dimensions for the array.
<code>isEmpty()</code>	Tests if the array is empty.
<code>isSparse()</code>	Tests if the array is sparse.

Method	Usage
<code>maximumNonZeros()</code>	Returns the current allocated capacity of nonzero elements for a sparse array.
<code>numberOfDimensions()</code>	Returns the number of dimensions in the array.
<code>numberOfElements()</code>	Returns the number of elements in the array.
<code>numberOfNonZeros()</code>	Returns the current number of nonzero elements for a sparse array.
<code>rowIndex()</code>	Returns the row index (first dimension) of each element in the array. Call this method to get an array of row indices for the nonzero elements of a sparse array.
<code>set(int, Object)</code>	Replaces the element at the one-based index with the supplied value.
<code>set(int[], Object)</code>	Replaces the element at the one-based index array with the supplied value.

Method	Usage
sharedCopy()	Creates a new MWArray instance that represents a shared copy of the underlying MATLAB array. A shared copy points to the same underlying MATLAB array as the original. Changing the data in a shared copy also changes the original array.
toArray()	Returns an array containing a copy of the data in the underlying MATLAB array as an array of Java types. The returned array has the same dimensionality as the underlying MATLAB array. The different kinds of arrays are returned as follows: <ul style="list-style-type: none"> • If the underlying MATLAB array is complex, the real part is returned. • If the underlying array is sparse, a full representation of the array is returned. • If the underlying array is a cell or struct array, toArray is recursively called on each element.

Constructing Numeric Arrays

The MWNumericArray class provides a Java interface to a numeric MATLAB array. An instance of this class can store a reference to a MATLAB array of type double, single, int8, uint8, int16, int32, uint32, int64, and uint64. MWNumericArrays can be real or complex, dense or sparse (sparse is supported for double type only).

Overview of Constructors and Data Types

The following table lists MWNumericArray class constructors.

Constructor	Usage
MWNumericArray()	Empty double array
MWNumericArray (MWClassID)	Empty array of type specified by MWClassID
MWNumericArray(<i>type</i> , MWClassID)	Real array of type specified by MWClassID
MWNumericArray(<i>type</i>)	Real array with type determined from default conversion rules
MWNumericArray(<i>type</i> , <i>type</i> , MWClassID)	Complex array of type specified by MWClassID
MWNumericArray(<i>type</i> , <i>type</i>)	Complex array with type determined from default conversion rules

Supported Data Types. In the previous table, *type* represents supported Java types. `MWNumericArray` supports the following Java primitive types:

- `double`
- `float`
- `byte`
- `short`
- `int`
- `long`
- `boolean`

The following object types are also supported:

- Subclasses of `java.lang.Number`
- Subclasses of `java.lang.String`
- Subclasses of `java.lang.Boolean`

In addition to supporting scalar values of the types listed, general N-dimensional arrays of each type are also supported.

Constructing Different Types of Numeric Arrays

Here are some examples showing how to construct different types of numeric arrays with the various forms of the `MWNumericArray` constructor.

Constructing Complex Arrays

The following four statements all construct a complex scalar `int32` array with a value of $1+2i$:

```
MWNumericArray a1 = new MWNumericArray(1, 2);
MWNumericArray a2 = new MWNumericArray(1.0, 2.0,
    MWClassID.INT32);
MWNumericArray a3 = new MWNumericArray(new Double(1.0),
```

```
New Integer(2), MWClassID.INT32);
MWNumericArray a4 = new MWNumericArray("1.0", "2.0",
MWClassID.INT32);
```

Constructing Matrices

The next group of statements constructs a 2-by-2 double matrix with the following values:

```
[1  2
 3  4]
```

```
double[][] x1 = {{1.0, 2.0}, {3.0, 4.0}};
int[][] x2 = {{1, 2}, {3, 4}};
Double[][] x3 = {{new Double(1.0), new Double(2.0)},
                 {new Double(3.0), new Double(4.0)}};
String[][] x4 = {{"1.0", "2.0"}, {"3.0", "4.0"}};

MWNumericArray a1 = new MWNumericArray(x1, MWClassID.DOUBLE);
MWNumericArray a2 = new MWNumericArray(x2, MWClassID.DOUBLE);
MWNumericArray a3 = new MWNumericArray(x3, MWClassID.DOUBLE);
MWNumericArray a4 = new MWNumericArray(x4, MWClassID.DOUBLE);
```

Constructing N-Dimensional Arrays

The MWNumericArray constructors also support multidimensional arrays of all supported types. For example, you can construct a 2-by-3-by-2 double array with the following two statements:

```
Double[][][] x1 = {
    {{ 1.0, 2.0, 3.0},
     { 4.0, 5.0, 6.0}},
    {{ 7.0, 8.0, 9.0},
     {10.0, 11.0, 12.0}}
};

MWNumericArray a1 = new MWNumericArray(x1);
```

Constructing Jagged Arrays

The previous examples constructed rectangular Java arrays and used these arrays to initialize MATLAB arrays. Multidimensional arrays in Java are implemented as arrays of arrays, which means that it is possible to construct a Java array in which each row can have a different number of columns. Such arrays are commonly referred to as *jagged* arrays.

MWNumericArray constructors support jagged arrays by constructing a rectangular array and padding with zeros any missing elements. The resulting MATLAB array will have a column count equal to the largest column count in any row of the input array. For example, the following two statements construct a 5-by-5 double matrix from a 5-by-5 Java double array in which the number of columns in the *i*th row equals *i*:

```
double[][] pascalsTriangle = {
    {1.0},
    {1.0, 1.0},
    {1.0, 2.0, 1.0},
    {1.0, 3.0, 3.0, 1.0},
    {1.0, 4.0, 6.0, 4.0, 1.0}
};
```

```
MWNumericArray a1 = new MWNumericArray(pascalsTriangle);
```

The resulting MATLAB array has the following structure:

```
[1 0 0 0 0
 1 1 0 0 0
 1 2 1 0 0
 1 3 3 1 0
 1 4 6 4 1]
```

Passing Arguments to Constructors as MWClassID. In some cases, the constructor converts the input to the specified type passed as an MWClassID value. When this value is omitted, the inputs are converted according to default conversion rules.

For example, each of the following statements creates a real scalar double array with a value of 1.0:

```
MWNumericArray a1 = new MWNumericArray(1.0);
MWNumericArray a2 = new MWNumericArray(1, MWClassID.DOUBLE);
MWNumericArray a3 = new MWNumericArray(new Double(1.0),
    MWClassID.DOUBLE);
MWNumericArray a4 = new MWNumericArray("1.0", MWClassID.DOUBLE);
```

In general, it is most efficient to supply an argument that causes the desired array to be created using the default conversion rules.

Some types require coercion to produce the correct MATLAB array. If you supply an unsupported type to an `MWNumericArray` constructor, an exception is thrown and the array is not created.

The following example constructs a real 1-by-3 double array with the values [1 2 3]:

```
double[] x1 = {1.0, 2.0, 3.0};
int[] x2 = {1, 2, 3};
Double[] x3 = {new Double(1.0), new Double(2.0),
    new Double(3.0)};
String[] x4 = {"1.0", "2.0", "3.0"};

MWNumericArray a1 = new MWNumericArray(x1, MWClassID.DOUBLE);
MWNumericArray a2 = new MWNumericArray(x2, MWClassID.DOUBLE);
MWNumericArray a3 = new MWNumericArray(x3, MWClassID.DOUBLE);
MWNumericArray a4 = new MWNumericArray(x4, MWClassID.DOUBLE);
```

Using Static Factory Methods to Construct MWNumericArrays

An alternative method for constructing numeric arrays is to use the static factory methods of the `MWNumericArray` class. The following table lists such methods.

Factory Method	Usage
<code>newInstance(int[], MWClassID, MWComplexity)</code>	Numeric array of specified type and complexity. Values are initialized to 0.

Factory Method	Usage
<code>newInstance(int[], Object, MWClassID)</code>	Real numeric array of specified type. Values are initialized with supplied arrays.
<code>newInstance(int[], Object, Object, MWClassID)</code>	Complex numeric array of specified type. Values are initialized with supplied arrays.
<code>newSparse(int[], int[], Object, int, int, int, MWClassID)</code>	Real sparse numeric matrix of specified type, dimensions, and maximum nonzeros. Values are initialized with supplied row, column, and data arrays.
<code>newSparse(int[], int[], Object, int, int, MWClassID)</code>	Real sparse numeric matrix of specified type and dimensions. Values are initialized with supplied row, column, and data arrays. Maximum nonzeros are computed from input data.
<code>newSparse(int[], int[], Object, MWClassID)</code>	Real sparse numeric matrix of specified type. Values are initialized with supplied row, column, and data arrays. Maximum nonzeros and dimensions are computed from input data.
<code>newSparse(int[], int[], Object, Object, int, int, int, MWClassID)</code>	Complex sparse numeric matrix of specified type, dimensions, and maximum nonzeros. Values are initialized with supplied row, column, and data arrays.
<code>newSparse(int[], int[], Object, Object, int, int, MWClassID)</code>	Complex sparse numeric matrix of specified type and dimensions. Values are initialized with supplied row, column, and data arrays. Maximum nonzeros are computed from input data.

Factory Method	Usage
newSparse(int[], int[], Object, Object, MWClassID)	Complex sparse numeric matrix of specified type. Values are initialized with supplied row, column, and data arrays. Maximum nonzeros and dimensions are computed from input data.
newSparse(int, int, int, MWClassID, MWComplexity)	Sparse numeric matrix with specified type, complexity, dimensions, and maximum nonzeros. Values are initialized to 0.
newSparse(Object, MWClassID)	Real sparse numeric matrix of specified type. Values are initialized from the supplied full matrix.
newSparse(Object, Object, MWClassID)	Complex sparse numeric matrix of specified type. Values are initialized from the supplied full matrix.

Data Arrangement in the Array. Each of the static factory methods for `MWNumericArray` returns a new `MWNumericArray` instance constructed from the input information. The methods can be used to construct and initialize an array with supplied data, or to construct an array of a specified size and initialize all values to zero. The main difference is that (with exception of the last two `newSparse` methods) data is supplied to the factory methods in one-dimensional arrays with the data arranged in column-wise order.

The following example rewrites the previous one-dimensional array constructor example:

```
double[] x1 = {1.0, 2.0, 3.0};
int[] x2 = {1, 2, 3};
Double[] x3 = {new Double(1.0),
               new Double(2.0),
               new Double(3.0)};
String[] x4 = {"1.0", "2.0", "3.0"};

int[] dims = {1, 3};
MWNumericArray a1 =
```

```

        MWNumericArray.newInstance(dims, x1, MWClassID.DOUBLE);
    MWNumericArray a2 =
        MWNumericArray.newInstance(dims, x2, MWClassID.DOUBLE);
    MWNumericArray a3 =
        MWNumericArray.newInstance(dims, x3, MWClassID.DOUBLE);
    MWNumericArray a4 =
        MWNumericArray.newInstance(dims, x4, MWClassID.DOUBLE);

```

Similarly, the 2-by-2 matrix example can be rewritten as follows:

```

double[] x1 = {1.0, 3.0, 2.0, 4.0};
int[] x2 = {1, 3, 2, 4};
Double[] x3 = {new Double(1.0),
               new Double(3.0),
               new Double(2.0),
               new Double(4.0)};
String[] x4 = {"1.0", "3.0", "2.0", "4.0"};

int[] dims = {2, 2};
MWNumericArray a1 =
    MWNumericArray.newInstance(dims, x1, MWClassID.DOUBLE);
MWNumericArray a2 =
    MWNumericArray.newInstance(dims, x2, MWClassID.DOUBLE);
MWNumericArray a3 =
    MWNumericArray.newInstance(dims, x3, MWClassID.DOUBLE);
MWNumericArray a4 =
    MWNumericArray.newInstance(dims, x4, MWClassID.DOUBLE);

```

Note the order of the data in the input buffers. The matrix elements are entered in column-wise order, which is the internal storage order used by MATLAB.

Constructing Sparse Arrays

An efficient way to construct sparse matrices is to use the `newSparse` constructor methods. The examples shown here create a 4-by-4 sparse matrix with the following values:

$$x = \begin{bmatrix} 2 & -1 & 0 & 0 \\ -1 & 2 & -1 & 0 \\ 0 & -1 & 2 & -1 \end{bmatrix}$$

```
0 0 -1 2 ]
```

Calling newSparse. The call to `newSparse` passes three arrays: an array of matrix data (`x`), an array containing the row indices of `x` (`rowindex`), and an array of column indices of `x` (`colindex`). The number of rows (4) and columns (4) are also passed, as well as the type (`MWClassID.DOUBLE`):

```
double[] x = { 2.0, -1.0, -1.0, 2.0, -1.0,
              -1.0, 2.0, -1.0, -1.0, 2.0 };
int[] rowindex = {1, 2, 1, 2, 3, 2, 3, 4, 3, 4};
int[] colindex = {1, 1, 2, 2, 2, 3, 3, 3, 4, 4};

MWNumericArray a =
    MWNumericArray.newSparse(rowindex, colindex, x, 4, 4,
                             MWClassID.DOUBLE);
```

Constructing the Array Without Setting Rows and Columns. You could have passed just the row and column arrays and let the `newSparse` method determine the number of rows and columns from the maximum values of `rowindex` and `colindex` as follows:

```
MWNumericArray a = MWNumericArray.newSparse(rowindex, colindex,
                                             x, MWClassID.DOUBLE);
```

Constructing the Array from a Full Matrix. You can also construct a sparse array from a full matrix using `newSparse`. The next example rewrites the previous example using a full matrix:

```
double[][] x = {{ 2.0, -1.0, 0.0, 0.0},
                {-1.0, 2.0, -1.0, 0.0},
                { 0.0 -1.0, 2.0, -1.0},
                { 0.0, 0.0, -1.0, 2.0 }};

MWNumericArray a = MWNumericArray.newSparse(x,
                                             MWClassID.DOUBLE);
```

Note Numeric sparse matrices are supported only for type `double`. Attempting to construct a sparse numeric matrix with any other type results in an exception being thrown.

Accessing MWNumericArray Elements

The `MWNumericArray` class provides methods for accessing and modifying array data in the form of `get` and `set` methods. The following table lists the `get` and `set` methods.

Method	Usage
<code>gettype(int)</code>	Returns the real part of the element at the one-based index. Return value is of the type specified (e.g., <code>getDouble</code> returns a <code>double</code>).
<code>gettype(int[])</code>	Returns the real part of the element at the one-based index array. Return value is of the type specified (e.g., <code>getDouble</code> returns a <code>double</code>).
<code>getImagtype(int)</code>	Returns the imaginary part of the element at the one-based index. Return value is of the type specified (e.g., <code>getImagDouble</code> returns a <code>double</code>).
<code>getImagtype(int[])</code>	Returns the imaginary part of the element at the one-based index array. Return value is of the type specified (e.g., <code>getDouble</code> returns a <code>double</code>).
<code>set(int, type)</code>	Replaces the real part of the element at the one-based index with the supplied value
<code>set(int[], type)</code>	Replaces the real part of the element at the one-based index array with the supplied value

Method	Usage
<code>setImag(int, type)</code>	Replaces the imaginary part of the element at the one-based index with the supplied value
<code>setImag(int[], type)</code>	Replaces the imaginary part of the element at the one-based index array with the supplied value

In these method calls, *type* represents one of the following supported Java types of `MWNumericArray`:

- `double`
- `float`
- `byte`
- `short`
- `int`
- `long`
- `Boolean`
- Subclass of `java.lang.Number`
- Subclass of `java.lang.String`
- Subclass of `java.lang.Boolean`

The `get` and `set` methods access a single element at a specified index. An index is passed to these accessor methods in the form of a single offset or as an array of indices.

Note All indexing is one-based, which is the MATLAB convention, as opposed to zero-based, which is the Java convention.

Examples of Using set. The following examples construct the 2-by-2 matrix of the previous example using the set method. The first example uses a single index:

```
int[] dims = {2, 2};
MWNumericArray a =
    MWNumericArray.newInstance(dims, MWClassID.DOUBLE,
        MWComplexity.REAL);
int index = 0;
double[] values = {1.0, 3.0, 2.0, 4.0};

for (int index = 1; index <= 4; index++)
    a.set(index, values[index-1]);
```

Here is the same example, but this time using an index array:

```
int[] dims = {2, 2};
MWNumericArray a =
    MWNumericArray.newInstance(dims, MWClassID.DOUBLE,
        MWComplexity.REAL);
int[] index = new int[2];
int k = 0;

for (index[0] = 1; index[0] <= 2; index[0]++)
{
    for (index[1] = 1; index[1] <= 2; index[1]++)
        a.set(index, ++k);
}
```

The sparse array example can likewise be rewritten using set as follows:

```
MWNumericArray a =
    MWNumericArray.newSparse(4, 4, 10, MWClassID.DOUBLE,
        MWComplexity.REAL);
int[] index = {1, 1};

for (index[0] = 1; index[0] <= 4; index[0]++)
{
    for (index[1] = 1; index[1] <= 4; index[1]++)
    {
        if (index[1] == index[0])
```

```
        a.set(index, 2.0);
    else if (index[1] == index[0]+1 || index[1] == index[0]-1)
        a.set(index, -1.0);
    }
}
```

The example allocates the 4-by-4 sparse matrix with a capacity of 10 nonzero elements. Initially, the array has no nonzero elements. The for loops set the array's values using an index array.

Sparse arrays allocate storage only for the nonzero elements that are assigned. This example preallocates the array with a capacity of 10 elements because it is known in advance that this many nonzeros are needed. If you set additional zero elements to nonzero values, the allocated capacity is automatically increased to accommodate the new values.

Examples of Using get. The get methods work like the set methods. The get methods support indexing through one-based offset or index array. The next example displays the elements of an N-dimensional array where all indices are equal:

```
public void printDiagonals(MWNumericArray a)
{
    int[] dims = a.getDimensions();
    int n = dims[0];

    for (int i = 1; i < dims.length; i++)
    {
        if (dims[i] < n)
            n = dims[i];
    }

    for (int i = 1; i <= n; i++)
    {
        for (int j = 0; j < dims.length; j++)
            dims[j] = n;
        System.out.print("[");

        for (int j = 0; j < dims.length; j++)
            System.out.print(i + (j!=dims.length-1?", ":""));
    }
}
```

```

        System.out.print("] = " + a.getDouble(dims));

        if (a.complexity() == MWComplexity.COMPLEX)
            System.out.print(" + "+a.getImagDouble(dims)+"i");
        System.out.print("\n");
    }
}

```

The next example sums the real parts of all the elements in a numeric array and returns the result as a double value:

```

public double sumElements(MWNumericArray a)
{
    double sum = 0.0;
    int n = a.numberOfElements();

    for (int i = 1; i <= n; i++)
        sum = sum + a.getDouble(i);

    return sum;
}

```

This example multiplies a Java double[][] with an MWNumericArray and returns the result as a Java double[][]:

```

public double[][] matrixMult(double[][] a, MWNumericArray b)
{
    int[] dims = b.getDimensions();
    double[][] result = new double[a.length][dims[1]];
    int[] index = new int[2];

    for (int i = 0; i < result.length; i++)
    {
        double[] row = a[i];
        if (row.length != dims[0])
            throw new IllegalArgumentException("Incompatible dims");

        for (index[1] = 1; index[1] <= result[0].length; index[1]++)
        {
            double sum = 0.0;

```

```

        for (index[0] = 1; index[0] <= dims[0]; index[0]++)
            sum += row[index[0]-1]*b.getDouble(index);
        result[i][index[0]] = sum;
    }
}
return result;
}

```

Working with Logical Arrays

The `MWLogicalArray` class provides a Java interface to a MATLAB logical array. `MWLogicalArrays` can be dense or sparse.

Constructing an `MWLogicalArray`

The `MWLogicalArray` class provides a set of constructors and factory methods for creating logical arrays. The following table lists the supplied constructors.

Constructor	Usage
<code>MWLogicalArray()</code>	Empty logical array
<code>MWLogicalArray(<i>type</i>)</code>	Logical array with values initialized with supplied data

Here, *type* represents supported Java types. `MWLogicalArray` supports the following Java primitive types: `double`, `float`, `byte`, `short`, `int`, `long`, and `boolean`. The following object types are also supported: subclasses of `java.lang.Number`, `java.lang.String`, and `java.lang.Boolean`. In addition to supporting scalar values of the types listed, general N-dimensional arrays of each type are also supported.

When numeric types are used, the values in the logical array are set to `true` if the input value is nonzero, and `false` otherwise. The following examples create a scalar logical array with its value initialized to `true`:

```

MWLogicalArray a1 = new MWLogicalArray(true);
MWLogicalArray a2 = new MWLogicalArray(1);
MWLogicalArray a3 = new MWLogicalArray("true");
MWLogicalArray a4 = new MWLogicalArray(new Boolean(true));

```

These examples construct a scalar logical array initialized to false:

```
MWLogicalArray a1 = new MWLogicalArray(false);
MWLogicalArray a2 = new MWLogicalArray(0);
MWLogicalArray a3 = new MWLogicalArray("false");
MWLogicalArray a4 = new MWLogicalArray(new Boolean(false));
```

As with MWNumericArray, MWLogicalArrays can be constructed with multidimensional Java arrays. Here are some examples:

```
boolean[][] x1 = {{true, false}, {false, true}};
int[][] x2 = {{1, 0}, {0, 1}};

Boolean[][] x3 = {{new Boolean(true), new Boolean(false)},
                 {new Boolean(false), new Boolean(true)}};
String[][] x4 = {"true", "false"},
               {"false", "true"};
boolean[][][] x5 = {
    {{ true,  false, true},
     { false, true,  false}},
    {{ true,  false, true},
     { false, true,  false}}
};

MWLogicalArray a1 = new MWLogicalArray(x1);
MWLogicalArray a2 = new MWLogicalArray(x2);
MWLogicalArray a3 = new MWLogicalArray(x3);
MWLogicalArray a4 = new MWLogicalArray(x4);
MWLogicalArray a5 = new MWLogicalArray(x5);
```

Using Static Factory Methods to Create MWLogicalArrays

The following table lists the static factory methods of MWLogicalArray.

Factory Method	Usage
<code>newInstance(int[])</code>	New logical array. Values are initialized to false.

Factory Method	Usage
<code>newInstance(int[], Object)</code>	New logical array. Values are initialized with supported data.
<code>newSparse(int[], int[], Object, int, int, int)</code>	Sparse logical matrix of specified dimensions and maximum nonzeros. Values are initialized with supplied row, column, and data arrays.
<code>newSparse(int[], int[], Object, int, int)</code>	Sparse logical matrix of specified dimensions. Values are initialized with supplied row, column, and data arrays. Maximum nonzeros are computed from input data.
<code>newSparse(int[], int[], Object)</code>	Sparse logical matrix. Values are initialized with supplied row, column, and data arrays. Maximum nonzeros and dimensions are computed from input data.
<code>newSparse(Object)</code>	Sparse logical matrix. Values are initialized from supplied full matrix.

These methods all return a new `MWLogicalArray` instance constructed from the input information. You can use these methods to construct and initialize an array with supplied data, or to construct an array of a specified size and initialize all values to false. The main difference is that, exception for the last `newSparse` method, data is supplied to the factory methods in one-dimensional arrays with the data arranged in column-wise order.

The following examples rewrite the two-dimensional array constructor examples using `newInstance`:

```
boolean[] x1 = {true, false, false, true};
int[] x2 = {1, 0, 0, 1};
Boolean[] x3 = {new Boolean(true), new Boolean(false),
               new Boolean(false), new Boolean(true)};
String[] x4 = {"true", "false", "false", "true"};

int[] dims = {2, 2};
```

```

MWLogicalArray a1 = MWLogicalArray.newInstance(dims, x1);
MWLogicalArray a2 = MWLogicalArray.newInstance(dims, x2);
MWLogicalArray a3 = MWLogicalArray.newInstance(dims, x3);
MWLogicalArray a4 = MWLogicalArray.newInstance(dims, x4);

```

Accessing MWLogicalArray Elements

The `MWLogicalArray` class provides methods for accessing and modifying array data in the form of `get` and `set` methods. The following table lists the `get` and `set` methods.

Method	Usage
<code>get(int)</code>	Returns the element at the one-based index as type <code>java.lang.Boolean</code> (inherited from <code>MWArray</code>).
<code>get(int[])</code>	Returns the element at the one-based index array as type <code>java.lang.Boolean</code> (inherited from <code>MWArray</code>).
<code>getBoolean(int)</code>	Returns the element at the one-based index as type <code>boolean</code> .
<code>getBoolean(int[])</code>	Returns the element at the one-based index array as type <code>boolean</code> .
<code>set(int, Object)</code>	Replaces the element at the one-based index with the supplied value (inherited from <code>MWArray</code>).
<code>set(int[], Object)</code>	Replaces the element at the one-based index array with the supplied value (inherited from <code>MWArray</code>).
<code>set(int, boolean)</code>	Replaces the element at the one-based index with the supplied <code>boolean</code> value.
<code>set(int[], boolean)</code>	Replaces element at the one-based index array with the supplied <code>boolean</code> value.

The `get` methods return a `java.lang.Boolean` representing the value at the specified index. The `getBoolean` methods do the same thing, except they return a primitive `boolean` value. The `set` methods replace the value at the specified index with the supplied value. These methods collectively support the same types as the `MWLogicalArray` constructors: `boolean`,

double, float, byte, short, int, long, java.lang.Boolean, subclasses of java.lang.Number, and java.lang.String.

Examples of Using set and get Methods. This example constructs a random sparse logical matrix with a specified fraction of nonzero elements:

```
MWLogicalArray getRandomSparse(int m, int n, double fillFactor)
{
    if (m < 0 || n < 0)
        throw new IllegalArgumentException(
            "Dimensions must be positive");

    if (fillFactor < 0.0 || fillFactor > 1.0)
        throw new IllegalArgumentException(
            "Fill factor must be between 0.0 and 1.0");

    int nsize = (int)(m*n*fillFactor);
    MWLogicalArray a = newSparse(m, n, nsize);
    if (nsize == 0)
        return a;

    while (a.numberOfNonZeros() < nsize)
    {
        int k = (int)(m*n*java.lang.Math.random());
        a.set((k != 0 ? k : 1), true);
    }
    return a;
}
```

This example toggles all elements of a logical array from true/false to false/true:

```
void toggleArray(MWLogicalArray a)
{
    for (int k = 1; k <= a.numberOfElements(); k++)
        a.set(k, !getBoolean(k));
}
```

Working with Character Arrays

The MWCharArray class provides a Java interface to a MATLAB char array.

Constructing an MWCharArray

The MWCharArray class provides a set of constructors and factory methods for creating logical arrays. The following table lists the supplied constructors.

Constructor	Usage
MWCharArray()	Empty char array
MWCharArray(<i>type</i>)	char array with values initialized with supplied data

Here, *type* represents supported Java types. MWCharArray supports the following Java types: char, java.lang.Character, and java.lang.String. In addition to supporting scalar values of the types listed, general N-dimensional arrays of each type are also supported. The following examples create scalar char arrays:

```
MWCharArray a1 = new MWCharArray('a');
MWCharArray a2 = new MWCharArray(new Character('a'));
```

Constructing Strings. You can use the MWCharArray class to create character strings, as shown in these examples:

```
char[] x1 = {'A', ' ', 'S', 't', 'r', 'i', 'n', 'g'};
String x2 = "A String";
Character[] x3 = {
    new Character('A'),
    new Character(' '),
    new Character('S'),
    new Character('t'),
    new Character('r'),
    new Character('i'),
    new Character('n'),
    new Character('g')};

MWCharArray a1 = new MWCharArray(x1);
MWCharArray a2 = new MWCharArray(x2);
MWCharArray a3 = new MWCharArray(x3);
```

Constructing an N-Dimensional Character Array. You can create a multidimensional char array using a multidimensional array of either char or java.lang.Character, or by using an array of java.lang.String, as shown in these examples:

```
char[][] x1 = {{'A', ' ', 'S', 't', 'r', 'i', 'n', 'g'}
               {'A', 'n', 'o', 't', 'h', 'e', 'r', ' ',
                'S', 't', 'r', 'i', 'n', 'g'}};
String[] x2 = {"A String",
               "Another String"};
Character[][] x3 = {
    {new Character('A'),
     new Character(' '),
     new Character('S'),
     new Character('t'),
     new Character('r'),
     new Character('i'),
     new Character('n'),
     new Character('g')},

    {new Character('A'),
     new Character('n'),
     new Character('o'),
     new Character('t'),
     new Character('h'),
     new Character('e'),
     new Character('r'),
     new Character(' '),
     new Character('S'),
     new Character('t'),
     new Character('r'),
     new Character('i'),
     new Character('n'),
     new Character('g')}
};

MWCharArray a1 = new MWCharArray(x1);
MWCharArray a2 = new MWCharArray(x2);
MWCharArray a3 = new MWCharArray(x3);
```

The `a1`, `a2`, and `a3` arrays constructed all contain a 2-by-14 MATLAB char array. The column count of the array is equal to the largest string length in the input array. Rows with fewer characters than the maximum are `Null` padded. Arrays with larger numbers of dimensions are handled similarly. This behavior parallels the way that `MWNumericArray` and `MWLogicalArray` handle jagged arrays.

Using Static Factory Methods for Constructing MWCharArrays

The following table lists the factory methods of `MWCharArray`.

Factory Method	Usage
<code>newInstance(int[])</code>	New char array. Values are initialized to <code>Null</code> .
<code>newInstance(int[] Object)</code>	New char array. Values are initialized with supported data.

These methods all return a new `MWCharArray` instance constructed from the input information. You can use these methods to construct and initialize an array with supplied data, or to construct an array of a specified size and initialize all values to zero. The main difference is that data is supplied to the factory methods in one-dimensional arrays with the data arranged in column-wise order. The input data array must be either a one-dimensional array of `char`, a one-dimensional array of `java.lang.Character`, or a single `java.lang.String`.

Rewriting Strings Using the `newInstance` Method. The following examples rewrite the character string examples using `newInstance`:

```
char[] x1 = {'A', ' ', 'S', 't', 'r', 'i', 'n', 'g'};
String x2 = "A String";
Character[] x3 =
{
    new Character('A'),
    new Character(' '),
    new Character('S'),
    new Character('t'),
    new Character('r'),
    new Character('i'),
    new Character('n'),
    new Character('g')
}
```

```

        new Character('g')
    };

    int[] dims = {1, 8};
    MWCharArray a1 = MWCharArray.newInstance(dims, x1);
    MWCharArray a2 = MWCharArray.newInstance(dims, x2);
    MWCharArray a3 = MWCharArray.newInstance(dims, x3);

```

Constructing a Two-Dimensional Character Array. This example constructs the two-dimensional char array of the previous example:

```

char[] x1 = ('A', 'A', ' ', 'n', 'S', 'o', 't', 't', 'r', 'h',
            'i', 'e', 'n', 'r', 'g', ' ', '\0', 'S', '\0', 't',
            '\0', 'r', '\0', 'i', '\0', 'n', '\0', 'g');

int[] dims = {2, 14};
MWCharArray a1 = MWCharArray.newInstance(dims, x1);

```

Note that the array of characters supplied to initialize the array is arranged in column-wise order, and the end of the shorter string is padded with Null characters ('\0'). Higher dimensional character arrays can be constructed using the same procedure.

Accessing MWCharArray Elements

The MWCharArray class provides methods for accessing and modifying array data in the form of get and set methods. The following table lists the get and set methods.

Method	Usage
get(int)	Returns the element at the one-based index as type <code>java.lang.Character</code> (inherited from <code>MWArray</code>).
get(int[])	Returns the element at the one-based index array as type <code>java.lang.Character</code> (inherited from <code>MWArray</code>).
getChar(int)	Returns the element at the one-based index as type <code>char</code> .
getChar(int[])	Returns the element at the one-based index array as type <code>char</code> .

Method	Usage
<code>set(int, Object)</code>	Replaces the element at the one-based index with the supplied value (inherited from MWArray).
<code>set(int[], Object)</code>	Replaces the element at the one-based index array with the supplied value (inherited from MWArray).
<code>set(int, char)</code>	Replaces the element at the one-based index with the supplied char value.
<code>set(int[], char)</code>	Replaces element at the one-based index array with the supplied char value.

The `get` methods return a `java.lang.Character` representing the character at the specified index. The `getChar` methods do the same thing, except they return a primitive `char` value. The `set` methods replace the character at the specified index with the supplied value. These methods collectively support types `char`, `java.lang.Character`, and `java.lang.String` (use a `String` of length 1 to pass a character to replace).

Replacing Character Occurrences Using MWCharArray Methods. This example replaces every occurrence of a given character in an `MWCharArray` with a specified new character:

```
void replaceWithChar(MWCharArray a, char ch, char newch)
{
    if (a == null)
        return;

    for (int k = 1; k <= a.numberOfElements(); k++)
    {
        if (a.getChar(k) == ch)
            a.setChar(k, newch);
    }
}
```

Working with Cell Arrays

The `MWCellArray` class provides a Java interface to a MATLAB cell array.

Using MWCellArray Constructors

The MWCellArray class provides the following constructors:

Constructor	Usage
MWCellArray()	Empty cell array.
MWCellArray(int[])	New cell array with specified dimensions. All cells are initialized to empty.
MWCellArray(gint, int)	New cell matrix with specified number of rows and columns.

Constructing a cell array is a two-step process. First, allocate the array using one of the constructors in the previous table, then assign values to each cell using one of the set methods.

Constructing an MWCellArray. For simple arrays, passing a Java array directly is the most convenient approach. When you want to assign a more complicated type to a cell (i.e., a complex array or another cell array), you must create a temporary MWArray for the input value. You should dispose of any temporary arrays after assigning them to a cell.

This example creates and initializes a 2-by-2 cell array:

```
String x11 = "A String";
double[][] x12 = {{1.0, 2.0},
                 {3.0, 4.0}};
int[][] x21 = {{1, 2},
              {3, 4}};
boolean[][] x22 = {{true, false},
                  {false, true}};

int[] index = {1, 1};
a.set(index, x11);
index[1] = 2;
a.set(index, x12);
index[0] = 2;
a.set(index, x22);
index[1] = 1;
a.set(index, x21);
```

Here, each cell is initialized with a Java array, and default conversion rules are used to create the MATLAB array for each cell.

Constructing an MWCellArray Containing Complex Arrays. The next example creates a helper function that constructs a cell array containing a list of complex double arrays. The real and imaginary parts of each cell are passed in the `re` and `im` arrays, respectively. The new cell array has dimensions 1-by-N, where N is the length of the input arrays, which must be the same.

```
MWCellArray createNumericCell(Object[] re, Object[] im)
    throws MWException
{
    if (re == null || im == null)
        throw new MWException("Invalid input");
    if (re.length != im.length)
        throw new MWException(
            "Input arrays must be the same length");

    MWCellArray a = null;
    MWNumericArray x = null;

    try
    {
        a = new MWCellArray(1, re.length);
        for (int k = 1; k <= re.length; k++)
        {
            x = new MWNumericArray(re[k-1], im[k-1],
                MWClassID.DOUBLE);
            a.set(k, x);
            x.dispose();
            x = null;
        }
        return a;
    }

    catch (Exception e)
    {
        if (a != null)
            a.dispose();
    }
}
```

```
        if (x != null)
            x.dispose();
        throw new MWException(e.getMessage());
    }
}
```

This method creates a new `MWCellArray` of the necessary size. Next, the code loops over the number of elements in the supplied arrays. For each loop iteration, a temporary `MWNumericArray`, `x`, is created for the current cell and initialized with the contents of `re[k-1]` and `im[k-1]` (the loop variable, `k`, is one-based). A shared copy of the temporary numeric array is then assigned to the cell at `k` using the `set` method.

The native resources associated with `x` are freed when you call `dispose`. If an exception is thrown during the construction phase, the partially constructed cell array and the temporary numeric array are disposed of, if necessary. The exception is then rethrown as an `MWException`. If everything goes well, the `MWCellArray` is returned.

Accessing MWCellArray Elements

The `MWCellArray` class provides methods for accessing and modifying array data in the form of `get` and `set` methods. The following table lists the `get` and `set` methods.

Method	Usage
<code>get(int)</code>	Returns the element at the one-based index as a Java array (inherited from <code>MWArray</code>).
<code>get(int)</code>	Returns the element at the one-based index array as a Java array (inherited from <code>MWArray</code>).
<code>getCell(int)</code>	Returns the element at the one-based index as an <code>MWArray</code> instance.
<code>getCell(int[])</code>	Returns the element at the one-based index array as an <code>MWArray</code> instance.

Method	Usage
<code>set(int, Object)</code>	Replaces the element at the one-based index with the supplied value (inherited from <code>MWArray</code>).
<code>set(int[], Object)</code>	Replaces the element at the one-based index array with the supplied value (inherited from <code>MWArray</code>).

The `set` methods replace the cell at the specified index with the supplied value. The cell value can be passed as any supported Java type or as an `MWArray` instance. When the cell value is passed as a Java type, the value is converted to a MATLAB array using default conversion rules. When the value is passed as an `MWArray`, the cell is assigned a shared copy of the underlying MATLAB array.

Using `getCell`. The `getCell` methods return an `MWArray` instance of the proper subclass type representing a shared copy of the underlying cell. The array returned by `getCell` should be disposed of when it is no longer needed. This is the most efficient way of accessing a cell, because an `MWArray` object is created to encapsulate a shared copy of the underlying array. This process is significantly more efficient than converting the entire array to a Java array each time you access the cell. The next example prints information about a cell array to standard output:

```
void printCellInfo(MWCellArray a)
{
    if (a == null)
        return;
    MWArray c = null;
    int n = a.numberOfElements();
    System.out.println("Number of elements: " + n);

    try
    {
        for (int k = 1; k <= n; k++)
        {
            c = a.getCell(k);
            System.out.println("cell: " + k + " type: " +
                a.classID());
            c.dispose();
            c = null;
        }
    }
}
```

```
        }  
    }  
  
    finally  
    {  
        if (c != null)  
            c.dispose();  
    }  
}
```

This method loops through the array and prints the type of each cell. The temporary array returned by `getCell` is disposed of after it is used. The `finally` clause ensures that the array is disposed of before exiting, in the case of an exception. `MWCellArray` also overrides the `MWArray.get` methods. In this case, a Java array is returned that represents a conversion of the underlying cell, as would be returned by `toArray`.

Using get. You can think of `get` as being implemented as follows:

```
Object get(int index)  
{  
    MWArray a = null;  
    try  
    {  
        a = this.getCell(index);  
        return a.toArray();  
    }  
  
    finally  
    {  
        if (a != null)  
            a.dispose();  
    }  
}
```

Using `get`, you can retrieve the cells from the first `MWCellArray` example as Java arrays.

```
int[] index = {1, 1};  
String x11 = (String)a.get(index);
```

```
index[1] = 2;
double[][] x12 = (double[][])a.get(index);
index[0] = 2;
boolean[][] x22 = (boolean[][])a.get(index);
index[1] = 1;
int[][] x21 = (int[][])a.get(index);
```

As with `set`, default conversion rules are applied (same rules as apply to `toArray`). In this example, the default rules are fine. In the case where complex arrays, other cell arrays, or struct arrays are stored in the cell array, it is recommended to use `getCell` to return an `MWArray` instance.

toArray and getData Methods

In addition to `get` and `getCell`, the `toArray` and `getData` methods are implemented on `MWCellArray` to return a conversion of the entire cell array. These methods provide a bulk conversion to an array of Java arrays, although the output can be difficult to dissect in some cases (particularly in the case of nested cell arrays).

The `getData` method returns a one-dimensional array of type `Object`. Each element of the return cell array is converted by calling `toArray` on the corresponding cell.

The `toArray` method returns the same array, except that it has the same dimensionality as the underlying cell array.

Using Class Methods

Use mxArray classes to construct data types as needed in your Java code. You can use the following classes to create objects that correspond to the basic MATLAB data types:

- Using mxArray
- Using mxNumericArray
- Using mxLogicalArray
- Using mxCharArray
- Using mxStructArray
- Using mxCellArray
- mxClassID
- Using mxComplexity

Using mxArray

This section covers topics on mxArray:

- “Constructing an mxArray” on page 4-38
- “Methods to Create and Destroy an mxArray” on page 4-39
- “Methods to Return Information About an mxArray” on page 4-40
- “Methods to Get and Set Data in the mxArray” on page 4-44
- “Methods to Copy, Convert, and Compare mxArray” on page 4-49
- “Methods to Use on Sparse mxArray” on page 4-54

Constructing an mxArray

Use this constructor to create an empty two-dimensional mxArray object:

```
mxArray()
```

The type given to this object is mxClassID.UNKNOWN.

Example. Construct an empty `MWArray` object:

```
MWArray A = new MWArray();
```

Methods to Create and Destroy an `MWArray`

Use these methods to destroy an object of class `MWArray` or any of its child classes.

Method	Description
“dispose” on page 4-39	Frees the native MATLAB array contained by this array.
“disposeArray” on page 4-40	Frees all native MATLAB arrays contained in the input object.

dispose. This method destroys the native MATLAB array contained by the array object and frees the memory occupied by the array.

The prototype for the `dispose` method is as follows:

```
public void dispose()
```

Input Parameters

None

Example — Constructing an `MWArray` Object

Construct and then destroy an `MWArray` object:

```
MWArray A = new MWArray();

A.dispose();
```

disposeArray. This method destroys any native MATLAB arrays contained in the input object and frees the memory occupied by them. This is a static method of the class and thus does not need to be invoked in reference to an instance of the class.

The prototype for the `disposeArray` method is as follows:

```
public static void disposeArray(Object arr)
```

Input Parameters

`arr`

Object to be disposed of

If the input object represents a single `MWArray` instance, then that instance is freed when you call its `dispose()` method.

If the input object represents an array of `MWArray` instances, each object in the array is disposed of.

If the input object represents an array of `Object` or a multidimensional array, the array is recursively processed to free each `MWArray` contained in the array.

Example — Constructing an `MWNumericArray` Object

Construct and then destroy an array of numeric objects:

```
MWArray[] MArr = new MWArray[10];  
for (int i = 0; i < 10; i++)  
    MArr[i] = new MWNumericArray();  
  
MWArray.disposeArray(MArr);
```

Methods to Return Information About an `MWArray`

Use these methods to return information about an object of class `MWArray` or any of its child classes.

Method	Description
“classID” on page 4-41	Returns the MATLAB type of the array.
“getDimensions” on page 4-42	Returns the size of each dimension of the array.
“isEmpty” on page 4-42	Tests if the array has no elements.
“numberOfDimensions” on page 4-43	Returns the number of dimensions of the array.
“numberOfElements” on page 4-43	Returns the total number of elements in the array.

The examples in the following sections use a 3-by-6 `MWNumericArray` object `A`, as constructed by this Java code:

```
int[][] Adata = {{ 1, 2, 3, 4, 5, 6},
                 { 7, 8, 9, 10, 11, 12},
                 {13, 14, 15, 16, 17, 18}};
```

```
MWNumericArray A = new MWNumericArray(Adata, MWClassID.INT32);
```

classID. This method returns the MATLAB type of the `MWArray` object. The return type is a field defined by the `MWClassID` class.

The prototype for the `classID` method is as follows:

```
public MWClassID classID()
```

Input Parameters

None

Example — Getting the Class ID of an `MWArray`

Return the class ID for an `MWNumericArray` object created previously:

```
System.out.println("Class of A is " + A.classID());
```

When run, the example displays this output:

```
Class of A is int32
```

getDimensions. This method returns a one-dimensional `int` array containing the size of each dimension of the `MWArray` object.

The prototype for the `getDimensions` method is as follows:

```
public int[] getDimensions()
```

Input Parameters

None

Example — Getting Array Dimensions of an `MWArray`

```
int[] dimA = A.getDimensions();  
  
System.out.println("Dimensions of A are " +  
    dimA[0] + " x " + dimA[1]);
```

When run, the example displays this output:

```
Dimensions of A are 3 x 6
```

isEmpty. This method returns `true` if the array object contains no elements, and `false` otherwise.

The prototype for the `isEmpty` method is as follows:

```
public boolean isEmpty()
```

Input Parameters

None

Example — Testing for an Empty MWArray

Display a message if array object A is an empty array. Otherwise, display the contents of A:

```
if (A.isEmpty())
    System.out.println("Matrix A is empty");
else
    System.out.println("A = " + A.toString());
```

When run, the example displays the contents of A:

```
A =   1     2     3     4     5     6
      7     8     9    10    11    12
     13    14    15    16    17    18
```

numberOfDimensions. This method returns the number of dimensions of the array object.

The prototype for the `numberOfDimensions` method is as follows:

```
public int numberOfDimensions()
```

Input Parameters

None

Example — Getting the Number of Dimensions of an MWArray

Display the number of dimensions for array object A:

```
System.out.println("Matrix A has " + A.numberOfDimensions() +
    " dimensions");
```

When run, the example displays this output:

```
Matrix A has 2 dimensions
```

numberOfElements. This method returns the total number of elements in the array object.

The prototype for the `numberOfElements` method is as follows:

```
public int numberOfElements()
```

Input Parameters

None

Example — Getting the Number of MWArray Elements

Display the number of elements in array object A:

```
System.out.println("Matrix A has " + A.numberOfElements() +  
    " elements");
```

When run, the example displays this output:

```
Matrix A has 18 elements
```

Methods to Get and Set Data in the MWArray

Use these methods to get and set values in an object of class `MWArray` or any of its child classes.

Method	Description
“get” on page 4-45	Returns the element at the specified one-based offset or index array as an <code>Object</code> .
“getData” on page 4-46	Returns a one-dimensional array containing a copy of the data in the underlying MATLAB array. The array is in column-wise order.
“set” on page 4-47	Replaces the element at the specified one-based offset, or index array, in this array with the specified element.
“toArray” on page 4-48	Returns an array containing a copy of the data in the underlying MATLAB array. The returned array has the same dimensionality as the MATLAB array.

get. This method returns the element located at the specified one-based offset or index array in the array object. The element is returned as an `Object`.

To get the element at a specific index, use one of the following:

```
public Object get(int index)
public Object get(int[] index)
```

Use the first syntax (`int index`) to return the element at the specified one-based offset in the array, accessing elements in column-wise order. Use the second syntax (`int[] index`) to return the element at the specified array of one-based indices. The first syntax offers better performance than the second.

Input Parameters

`index`

Index of the requested element in the `MWArray`

In the case where `index` is of type `int`, the valid range for `index` is $1 \leq \text{index} \leq N$, where N is the total number of elements in the array.

In the case where `index` is of type `int[]`, each element of the `index` vector is an index along one dimension of the `MWArray` object. The valid range for any `index` is $1 \leq \text{index}[i] \leq N[i]$, where $N[i]$ is the size of the i th dimension.

Exceptions

The `get` method throws the following exception:

`IndexOutOfBoundsException`

The specified `index` parameter is invalid.

Example — Getting an MWArray Value with get

Retrieve element (2, 4) from array object A:

```
int[] index = {2, 4};

Object d_out = A.get(index);
System.out.println("Data read from A(2,4) is " +
    d_out.toString());
```

When run, the example displays this output:

```
Data read from A(2,4) is 10
```

getData. This method returns all elements of the MWArray object. Elements are returned in a one-dimensional array, in column-wise order. Elements are returned as type Object.

The prototype for the getData method is as follows:

```
public Object getData()
```

Input Parameters

None

The elements of the returned array are converted according to default conversion rules. If the underlying MATLAB array is a complex numeric type, getData returns the real part.

Example — Getting an MWArray Value with getData

Get the data from MWArray object A, casting the type from Object to int:

```
System.out.println("Data read from matrix A is:");

int[] x = (int[]) A.getData();
for (int i = 0; i < x.length; i++)
    System.out.print(" " + x[i]);
```

```
System.out.println();
```

When run, the example displays this output:

```
Data read from matrix A is:  
1 7 13 2 8 14 3 9 15 4 10 16 5 11 17 6 12 18
```

set. This method replaces the element at a specified index in the `MWArray` object with the input element.

To set the element at a specific index, use one of the following:

```
public void set(int index, Object element)  
public void set(int[] index, Object element)
```

Use the first syntax (`int index`) to return the element at the specified one-based offset in the array, accessing elements in column-wise order. Use the second syntax (`int[] index`) to return the element at the specified array of one-based indices. The first syntax offers better performance than the second.

Input Parameters

`element`

New element to replace at `index`

`index`

Index of the requested element in the `MWArray`.

In the case where `index` is of type `int`, the valid range for `index` is $1 \leq \text{index} \leq N$, where N is the total number of elements in the array.

In the case where `index` is of type `int[]`, each element of the `index` vector is an index along one dimension of the `MWArray` object. The valid range for any `index` is $1 \leq \text{index}[i] \leq N[i]$, where $N[i]$ is the size of the i th dimension.

Exceptions

The set method throws the following exception:

`IndexOutOfBoundsException`

The specified index parameter is invalid.

Example — Setting an MWArray Value

Modify the data in element (2, 4) of MWArray object A:

```
int[] index = {2, 4};
A.set(index, 555);

Object d_out = A.get(index);
System.out.println("Data read from A(2,4) is " +
    d_out.toString());
```

When run, the example displays this output:

```
Data read from A(2,4) is 555
```

toArray. This method creates an array with the same dimensionality as the MATLAB array.

The prototype for the toArray method is as follows:

```
public Object[] toArray()
```

The elements of the returned array are converted according to default conversion rules. If the underlying MATLAB array is a complex numeric type, toArray returns the real part.

Input Parameters

None

Example — Getting an MWArray with toArray

Create and display a copy of MWArray object A:

```
int[][] x = (int[][]) A.toArray();
int[] dimA = A.getDimensions();

System.out.println("Matrix A is:");
for (int i = 0; i < dimA[0]; i++)
{
    for (int j = 0; j < dimA[1]; j++)
        System.out.print(" " + x[i][j]);
    System.out.println();
}
```

When run, the example displays this output:

```
Matrix A is:
 1 2 3 4 5 6
 7 8 9 10 11 12
13 14 15 16 17 18
```

Methods to Copy, Convert, and Compare MWArrays

Use these methods to copy, convert, and compare objects of class MWArray or any of its child classes.

Method	Description
“clone” on page 4-50	Creates and returns a deep copy of this array.
“compareTo” on page 4-51	Compares this array with the specified array for order.
“equals” on page 4-52	Indicates whether some other array is equal to this one.
“hashCode” on page 4-52	Returns a hash code value for the array.

Method	Description
“sharedCopy” on page 4-53	Creates and returns a shared copy of this array.
“toString” on page 4-54	Returns a string representation of the array.

clone. This method creates and returns a deep copy of the MWArray object. Because clone allocates a new array, any changes made to this new array are not reflected in the original.

The prototype for the clone method is as follows:

```
public Object clone()
```

Input Parameters

None

Exceptions

The clone method throws the following exception:

```
java.lang.CloneNotSupportedException
```

The object’s class does not implement the Cloneable interface.

Example — Cloning an MWArray Object

Create a clone of MWArray object A:

```
Object C = A.clone();  
  
System.out.println("Clone of matrix A is:");  
System.out.println(C.toString());
```

When run, the example displays this output:

```
Clone of matrix A is:
  1   2   3   4   5   6
  7   8   9  10  11  12
 13  14  15  16  17  18
```

compareTo. This method compares the `MWArray` object with the input object. It returns a negative integer, zero, or a positive integer if the `MWArray` object is less than, equal to, or greater than the specified object, respectively.

The prototype for the `compareTo` method is as follows:

```
public int compareTo(Object obj)
```

See the `compareTo` method in interface `java.lang.Comparable` for a full description of the return value.

Input Parameters

`obj`

Array to compare this `MWArray` object to

Example — Comparing `MWArrays` with `compareTo`

Create a shared copy of the `MWArray` object and then compare it to the original object. A return value of zero indicates that the two objects are equal:

```
Object S = A.sharedCopy();

if (A.compareTo(S) == 0)
    System.out.println("Matrix S is equal to matrix A");
```

When run, the example displays this output:

```
Matrix S is equal to matrix A
```

equals. This method indicates the MWArray object is equal to the input object. The equals method of the MWArray class overrides the equals method of class Object.

The prototype for the equals method is as follows:

```
public boolean equals(Object object)
```

Input Parameters

object

Array to compare this MWArray object to

Example — Comparing MWArrays with equals

Create a shared copy of the MWArray object and then compare it to the original object. A return value of true indicates that the two objects are equal:

```
Object S = A.sharedCopy();  
  
if (A.equals(S))  
    System.out.println("Matrix S is equal to matrix A");
```

When run, the example displays this output:

```
Matrix S is equal to matrix A
```

hashCode. This method returns a hash code value for the MWArray object. The hashCode method of the MWArray class overrides the hashCode method of class Object.

The prototype for the hashCode method is as follows:

```
public int hashCode()
```

Input Parameters

None

Example — Getting an MArray Hash Code

Obtain the hash code for MArray object A:

```
System.out.println("Hash code for matrix A is " + A.hashCode());
```

When run, the example displays this output:

```
Hash code for matrix A is 456687478
```

sharedCopy. This method creates and returns a shared copy of the array. The shared copy points to the underlying original MATLAB array. Any changes made to the copy are reflected in the original.

The prototype for the sharedCopy method is as follows:

```
public Object sharedCopy()
```

Input Parameters

None

Example — Making a Shared Copy of an MArray

Create a shared copy of MArray object A:

```
Object S = A.sharedCopy();  
  
System.out.println("Shared copy of matrix A is:");  
System.out.println(S.toString());
```

When run, the example displays this output:

```
Shared copy of matrix A is:  
  1   2   3   4   5   6  
  7   8   9  10  11  12  
 13  14  15  16  17  18
```

toString. This method returns a string representation of the array. The toString method of the MWArray class overrides the toString method of class Object.

The prototype for the toString method is as follows:

```
public java.lang.String toString()
```

Input Parameters

None

Example — Converting an MWArray to a String

Display the contents of MWArray object A:

```
System.out.println("A = " + A.toString());
```

When run, the example displays the contents of A:

```
A =   1     2     3     4     5     6
      7     8     9    10    11    12
     13    14    15    16    17    18
```

Methods to Use on Sparse MWArrays

Use these methods to return information on sparse arrays of type MWArray or any of its child classes.

Method	Description
“isSparse” on page 4-55	Tests whether the array is sparse.
“columnIndex” on page 4-56	Returns an array containing the column index of each nonzero element in the underlying MATLAB array.
“rowIndex” on page 4-57	Returns an array containing the row index of each nonzero element in the underlying MATLAB array.

Method	Description
“maximumNonZeros” on page 4-57	Returns the allocated capacity of a sparse array. If the underlying array is nonsparse, this method returns the same value as <code>numberOfElements()</code> .
“numberOfNonZeros” on page 4-58	Returns the number of nonzero elements in a sparse array. If the underlying array is nonsparse, this method returns the same value as <code>numberOfElements()</code> .

The examples that follow use the sparse `MWArray` object constructed below using the “`newSparse`” on page 4-66 method of `MWNumericArray`:

```
double[] Adata = { 0, 10, 0, 0, 40, 50, 60, 0, 0, 90};

int[] ri = {1, 1, 1, 1, 1, 2, 2, 2, 2, 2};
int[] ci = {1, 2, 3, 4, 5, 1, 2, 3, 4, 5};

MWNumericArray A = MWNumericArray.newSparse(ri, ci,
                                             Adata, MWClassID.DOUBLE);

System.out.println(A.toString());
```

Here are the contents of the sparse `MWArray`:

```
(2,1)      50
(1,2)      10
(2,2)      60
(1,5)      40
(2,5)      90
```

isSparse. This method returns `true` if the `MWArray` object is sparse, and `false` otherwise.

The prototype for the `isSparse` method is as follows:

```
public boolean isSparse()
```

Input Parameters

None

Example — Testing an MWArray for Sparseness

Test the MWArray object A created previously for sparseness:

```
if (A.isSparse())
    System.out.println("Matrix A is sparse");
```

When run, the example displays this output:

```
Matrix A is sparse
```

columnIndex. This method returns an array containing the column index of each element in the underlying MATLAB array.

The prototype for the columnIndex method is as follows:

```
public int[] columnIndex()
```

Input Parameters

None

Example — Getting the Column Indices of a Sparse MWArray

Get the column indices of the elements of the sparse array:

```
System.out.print("Column indices are: ");
int[] colidx = A.columnIndex();
for (int i = 0; i < 5; i++)
    System.out.print(colidx[i] + " ");
System.out.println();
```

When run, the example displays this output:

```
Column indices are:  1 2 2 5 5
```

rowIndex. This method returns an array containing the row index of each element in the underlying MATLAB array.

The prototype for the `rowIndex` method is as follows:

```
public int[] rowIndex()
```

Input Parameters

None

Example — Getting the Row Indices of a Sparse MArray

Get the row indices of the elements of the sparse array:

```
System.out.print("Row indices are: ");
int[] rowidx = A.rowIndex();
for (int i = 0; i < 5; i++)
    System.out.print(rowidx[i] + " ");
System.out.println();
```

When run, the example displays this output:

```
Row indices are:  2 1 2 1 2
```

maximumNonZeros. This method returns the allocated capacity of a sparse array. If the underlying array is nonsparse, this method returns the same value as `numberOfElements`.

The prototype for the `maximumNonZeros` method is as follows:

```
public int maximumNonZeros()
```

Input Parameters

None

Example — Getting the Maximum Number of Nonzeros in an MWArray

Display the maximum number of nonzeros for this array:

```
System.out.println("Maximum number of nonzeros for matrix A is "
    + A.maximumNonZeros());
```

When run, the example displays this output:

```
Maximum number of nonzeros for matrix A is 10
```

numberOfNonZeros. This method returns the number of nonzero elements in a sparse array. If the underlying array is nonsparse, this method returns the same value as `numberOfElements`.

The prototype for the `numberOfNonZeros` method is as follows:

```
public int numberOfNonZeros()
```

Input Parameters.

None

Example — Getting the Number of Nonzeros in an MWArray

Display the number of nonzero values in this array:

```
System.out.println("The number of nonzeros for matrix A is " +
    A.numberOfNonZeros());
```

When run, the example displays this output:

```
The number of nonzeros for matrix A is 5
```

Using MWNumericArray

This section covers the following topics:

- “Constructing an `MWNumericArray`” on page 4-59

- “Methods to Create and Destroy an `MWNumericArray`” on page 4-63
- “Methods to Get and Set the Real Parts of an `MWNumericArray`” on page 4-75
- “Methods to Get and Set the Imaginary Parts of an `MWNumericArray`” on page 4-79
- “Methods to Copy, Convert, and Compare `MWNumericArrays`” on page 4-87
- “Methods to Use on Sparse `MWNumericArrays`” on page 4-90
- “Methods to Return Special Constant Values” on page 4-90

Constructing an `MWNumericArray`

Use the tables in this section to construct an `MWNumericArray` from a particular Java data type. See the examples at the end of this section for more help.

- “Constructing an Empty Scalar” on page 4-59
- “Constructing a Real or Complex Numeric Scalar” on page 4-60
- “Constructing a Real or Complex Numeric Array” on page 4-61

In addition to using the `MWNumericArray` constructor, you can also use “`newSparse`” on page 4-66 to construct an `MWNumericArray`. These two methods provide better performance than the constructor.

Constructing an Empty Scalar. Use either of the following constructors to create an empty scalar `MWNumericArray`:

To construct an empty scalar of type `MWClassID.DOUBLE`, use the following:

```
MWNumericArray()
```

To construct an empty scalar of type `classid`, use the following:

```
MWNumericArray(MWClassID classid)
```

Example — Constructing an Empty Numeric Array Object

Create an empty scalar of type int64:

```
MWNumericArray A = new MWNumericArray(MWClassID.INT64);  
System.out.println("A = " + A);
```

When you run this example, the results are as follows:

```
A = []
```

Constructing a Real or Complex Numeric Scalar. Use this constructor syntax to create a real scalar `MWNumericArray` from a primitive Java type:

```
MWNumericArray(javatype realValue)
```

Or use this syntax to create a complex scalar `MWNumericArray` from a primitive Java type:

```
MWNumericArray(javatype realValue, javatype imagValue)
```

The class ID for the returned `MWNumericArray` is shown in the following table:

javatype Input	Class ID of MWNumericArray
double	MWClassID.DOUBLE
float	MWClassID.SINGLE
long	MWClassID.INT64
int	MWClassID.INT32
short	MWClassID.INT16
byte	MWClassID.INT8

Exceptions

The `MWNumericArray` constructor throws the following exception:

`ArrayStoreException`

A nonnumeric array type was specified.

Example — Constructing an Integer Array Object

Construct a scalar numeric array of type `MWClassID.INT16`:

```
double AReal = 24;

MWNumericArray A = new MWNumericArray(AReal, MWClassID.INT16);
System.out.println("Array A of type " + A.classID() + " = \n" + A);
```

When you run this example, the results are as follows:

```
Array A of type int16 =
  24
```

Example — Constructing a Complex Array Object

Construct a numeric scalar having real and imaginary parts:

```
double AReal = 24;
double AImag = 5;

MWNumericArray A = new MWNumericArray(AReal, AImag);
System.out.println("Array A of type " + A.classID() + " = \n" + A);
```

When you run this example, the results are as follows:

```
Array A of type double =
  24.0000 + 5.0000i
```

Constructing a Real or Complex Numeric Array. Use this constructor syntax to create a real nonscalar `MWNumericArray` from a primitive Java type:

```
MWNumericArray(javatype realValue, MWClassID classid)
```

Or use this syntax to create a complex nonscalar `MWNumericArray` from a primitive Java type:

```
MWNumericArray(javatype realValue, javatype imagValue,
```

MWClassID classid)

The type *javatype* can be any of the following:

- double
- float
- long
- int
- short
- byte
- boolean
- Object

Example — Constructing a Real Array of a Specific Type

Construct a 3-by-6 real array of type MWClassID.SINGLE:

```
double[][] AData = {{ 1, 2, 3, 4, 5, 6},
                    { 7, 8, 9, 10, 11, 12},
                    {13, 14, 15, 16, 17, 18}};
```

```
MWNumericArray A = new MWNumericArray(AData, MWClassID.SINGLE);
System.out.println("Array A = \n" + A);
```

When run, the example displays this output:

```
A =   1     2     3     4     5     6
      7     8     9    10    11    12
     13    14    15    16    17    18
```

Example — Constructing a Complex Array of a Specific Type

Construct a 1-by-3 complex array of MWClassID.DOUBLE:

```
double[] AReal = {24.2, -7, 113};
double[] AImag = {5, 31, 27};
```

```
MWNumericArray A =
    new MWNumericArray(AReal, AImag, MWClassID.DOUBLE);

System.out.println("Array A of type " + A.classID() + " = \n" + A);
```

When run, the example displays this output:

```
Array A of type double =
  1.0e+002 *
  0.2420 + 0.0500i -0.0700 + 0.3100i   1.1300 + 0.2700i
```

Methods to Create and Destroy an MWNumericArray

In addition to the `MWNumericArray` constructor, you can use the `newInstance` and `newSparse` methods to construct a numeric array. These two methods offer better performance than using the class constructor. To destroy the arrays, use either `dispose` or `disposeArray`, inherited from class `MWArray`.

Method	Description
“newInstance” on page 4-63	Constructs an array with the specified dimensions and complexity.
“newSparse” on page 4-66	Constructs a real sparse numeric matrix with the specified number of rows and columns and maximum nonzero elements, and initializes the array with the supplied data.
“dispose” on page 4-71	Frees the native MATLAB array contained by this array.
“disposeArray” on page 4-71	Frees all native MATLAB arrays contained in the input object.

newInstance. This method constructs a real or complex array, specifying the array dimensions, type, and complexity. This is a static method of the class and thus does not need to be invoked in reference to an instance of the class.

Note This method offers better performance than using the class constructor.

To construct an uninitialized real or complex numeric array, use the following:

```
newInstance(int[] dims, MWClassID classid, MWComplexity cmplx)
```

To construct and initialize a real numeric array, use

```
newInstance(int[] dims, Object rData, MWClassID classid)
```

To construct and initialize a complex numeric array, use

```
newInstance(int[] dims, Object rData, Object iData,  
            MWClassID classid)
```

Input Parameters

`dims`

Array of nonnegative dimension sizes

`classId`

MWClassID representing the MATLAB type of the array

`rData`

Data to initialize the real part of the array. You must format the `rData` array in column-wise order.

`iData`

Data to initialize the imaginary part of the array. You must format the `iData` array in column-wise order.

Valid types for `realData` and `imagData` are as follows:

- `double[]`
- `float[]`
- `long[]`
- `int[]`

- `short[]`
- `byte[]`
- `boolean[]`
- One-dimensional arrays of any subclass of `java.lang.Number`
- One-dimensional arrays of `java.lang.Boolean`

Exceptions

The `newInstance` method throws the following exceptions:

`NegativeArraySizeException`

The specified `dims` parameter is negative.

`ArrayStoreException`

The array type is nonnumeric.

Example — Constructing a Numeric Array Object with `newInstance`

Construct a 3-by-6 real numeric array using the `newInstance` method. Note that data in the Java array must be stored in column-wise order so that it will be in the correct order in the final `MWNumericArray` object.

```
int[] dims = {3, 6};
double[] Adata = { 1,  7, 13,
                  2,  8, 14,
                  3,  9, 15,
                  4, 10, 16,
                  5, 11, 17,
                  6, 12, 18};
```

```
MWNumericArray A =
    MWNumericArray.newInstance(dims, Adata, MWClassID.DOUBLE);
```

```
System.out.println("A = " + A);
```

When run, the example displays this output:

```
A =  1   2   3   4   5   6
     7   8   9  10  11  12
    13  14  15  16  17  18
```

newSparse. This method constructs a real or complex sparse `MWNumericArray`, with the specified number of rows and columns and maximum nonzero elements, and initializes the array with the supplied data. This is a static method of the class and thus does not need to be invoked in reference to an instance of the class.

Constructing a Sparse Matrix with No Nonzero Elements

To construct a sparse matrix with no nonzero elements, use

```
newSparse(int rows, int cols, int nzmax, MWClassID classid,
          MWComplexity cplx)
```

Constructing a Sparse Matrix of Real Numbers

To construct a real sparse array from an existing nonsparse two-dimensional array, use

```
newSparse(Object realData, MWClassID classid)
```

To construct and initialize a new real sparse array, use

```
newSparse(int[] rowindex, int[] colindex, Object realData,
          MWClassID classid)
```

To construct and initialize a new real sparse array, specifying its dimensions. use

```
newSparse(int[] rowindex, int[] colindex, Object realData,
          int rows, int cols, MWClassID classid)
```

To construct and initialize a new real sparse array, specifying its dimensions and maximum number of nonzeros, use

```
newSparse(int[] rowindex, int[] colindex, Object realData,  
          int rows, int cols, int nzmax, MWClassID classid)
```

Constructing a Sparse Matrix of Complex Numbers

To construct a complex sparse array from an existing nonsparse two-dimensional array, use

```
newSparse(Object realData, Object imagData, MWClassID classid)
```

To construct and initialize a new complex sparse array, use

```
newSparse(int[] rowindex, int[] colindex, Object realData,  
          Object imagData, MWClassID classid)
```

To construct and initialize a new complex sparse array, specifying its dimensions, use

```
newSparse(int[] rowindex, int[] colindex, Object realData,  
          Object imagData, int rows, int cols, MWClassID classid)
```

To construct and initialize a new complex sparse array, specifying its dimensions and maximum number of nonzeros, use

```
newSparse(int[] rowindex, int[] colindex, Object realData,  
          Object imagData, int rows, int cols, int nzmax,  
          MWClassID classid)
```

Input Parameters

`realData` and `imagData`

Data to initialize the real and imaginary parts of the array. See information on valid data types below.

`rowIndex` and `colIndex`

Arrays of one-based row and column indices

Row and column index arrays are used to construct the sparse array such that the following holds true, with space allocated for `nzmax` nonzeros:

$$S(\text{rowIndex}(k), \text{columnIndex}(k)) = \text{realData}(k) + \text{imagData}(k)*i$$

If you assign multiple values to a single `rowIndex` and `colIndex` pair, then the element at that index is assigned the sum of these values.

`rows` and `cols`

Number of rows and columns in the matrix

`nzmax`

Maximum number of nonzero elements

`classID`

MWClassID representing the MATLAB type of the array. The only `classID` currently supported is `MWClassID.DOUBLE`.

Valid types for the `realData` and `imagData` parameters are as follows:

- `double[]`
- `float[]`
- `long[]`
- `int[]`
- `short[]`
- `byte[]`
- `boolean[]`
- One-dimensional arrays of any subclass of `java.lang.Number`
- One-dimensional arrays of `java.lang.Boolean`
- One-dimensional arrays of `java.lang.String`

Exceptions

The `newSparse` method throws the following exceptions:

`NegativeArraySizeException`

Row or column size is negative.

`IndexOutOfBoundsException`

The specified index parameter is invalid.

`ArrayStoreException`

Incompatible array type or invalid array data

Example — Constructing a Sparse Array Object with `newSparse`

Creating a sparse complex `MWNumericArray`:

Construct a two-dimensional complex sparse `MWNumericArray` from the real and imaginary double vectors:

```
double[][] rData = {{ 0, 0, 0, 16, 0},
                    {71, 63, 32, 0, 0}};

double[][] iData = {{ 0, 0, 0, 41, 0},
                    { 0, 0, 32, 0, 2}};

MWNumericArray A =
    MWNumericArray.newSparse(rData, iData, MWClassID.DOUBLE);

System.out.println("A = " + A.toString());
```

When run, the example displays this output:

```
A =      (2,1)      71.0000
          (2,2)      63.0000
          (2,3)      32.0000 +32.0000i
```

```
(1,4)    16.0000 +41.0000i
(2,5)           0 + 2.0000i
```

Example — Using newSparse with Row and Column Indices

Construct a sparse MWNumericArray from vector Adata:

```
double[] Adata = { 0, 10, 0, 0, 40, 50, 60, 0, 0, 90};

int[] ri = {1, 1, 1, 1, 1, 2, 2, 2, 2, 2};
int[] ci = {1, 2, 3, 4, 5, 1, 2, 3, 4, 5};

MWNumericArray A = MWNumericArray.newSparse(ri, ci,
                                             Adata, MWClassID.DOUBLE);

System.out.println("A = " + A.toString());
```

When run, the example displays this output:

```
(2,1)    50
(1,2)    10
(2,2)    60
(1,5)    40
(2,5)    90
```

Example — Assigning Multiple Values to a Single Array Element

Create a sparse MWNumericArray using the rowindex and colindex arguments, specifying multiple values for the array element at index (2, 5). The result is that this element stores the sum of the values from Adata(1), Adata(7), Adata(8), and Adata(9), which is equal to 250.

```
double[] Adata = { 0, 10, 0, 0, 40, 50, 60, 70, 80, 90};

int[] ri = {1, 2, 1, 1, 1, 2, 2, 2, 2, 2};
int[] ci = {1, 5, 2, 3, 5, 1, 2, 5, 5, 5};

MWNumericArray A =
    MWNumericArray.newSparse(ri, ci, Adata, 4, 5,
                             MWClassID.DOUBLE);
```

```
System.out.println("A = " + A.toString());
```

When run, the example displays this output:

```
(2,1)      50
(2,2)      60
(1,5)      40
(2,5)      250
```

dispose. `MWNumericArray` inherits this method from the `MWArray` class.

disposeArray. `MWNumericArray` inherits this method from the `MWArray` class.

Methods to Return Information About an `MWNumericArray`

Use these methods to return information about an object of class `MWNumericArray`.

Method	Description
“classID” on page 4-72	Returns the MATLAB type of this array.
“complexity” on page 4-72	Returns the complexity of this array.
“getDimensions” on page 4-72	Returns an array containing the size of each dimension of this array.
“isEmpty” on page 4-72	Tests whether the array has no elements.
“isFinite” on page 4-72	Tests for finiteness in a machine-independent manner.
“isInf” on page 4-73	Tests for infinity in a machine-independent manner.
“isNaN” on page 4-74	Tests for NaN (not a number) in a machine-independent manner.
“numberOfDimensions” on page 4-75	Returns the number of dimensions of this array.
“numberOfElements” on page 4-75	Returns the total number of elements in this array.

classID. MWNumericArray inherits this method from the MWArray class.

complexity. This method returns the complexity of the MWNumericArray object as either MWComplexity.REAL for a real array, or MWComplexity.COMPLEX for a complex array.

The prototype for the complexity method is

```
public MWComplexity complexity()
```

Input Parameters

None

Example — Testing for a Complex Array

Determine whether matrix A is real or complex:

```
double AReal = 24;
double AImag = 5;

MWNumericArray A = new MWNumericArray(AReal, AImag);
System.out.println("A is a " + A.complexity() + " matrix");
```

When run, the example displays this output:

```
A is a complex matrix
```

getDimensions. MWNumericArray inherits this method from the MWArray class.

isEmpty. MWNumericArray inherits this method from the MWArray class.

isFinite. This method tests for finiteness in a machine-independent manner. This is a static method of the class and does not need to be invoked in reference to an instance of the class.

The prototype for the isFinite method is as follows:

```
public static boolean isFinite(double value)
```

Input Parameters

value

double value to test for finiteness

Example — Testing for Finite Array Values

Test x for finiteness:

```
double x = 25;

if (MWNumericArray.isFinite(x))
    System.out.println("The input value is finite");
```

When run, the example displays this output:

```
The input value is finite
```

isInf. This method tests for infinity in a machine-independent manner. This is a static method of the class and does not need to be invoked in reference to an instance of the class.

The prototype for the `isInf` method is as follows:

```
public static boolean isInf(double value)
```

Input Parameters

value

double value to test for infinity

Example — Testing for Infinite Array Values

Test x for infinity:

```
double x = 1.0 / 0.0;

if (MWNumericArray.isInf(x))
    System.out.println("The input value is infinite");
```

When run, the example displays this output:

```
The input value is infinite
```

isNaN. This method tests for NaN (Not a Number) in a machine-independent manner. This is a static method of the class and does not need to be invoked in reference to an instance of the class.

The prototype for the `isNaN` method is

```
public static boolean isNaN(double value)
```

Input Parameters

value

double value to test for NaN

Example — Testing for NaN Array Values

Test x for NaN:

```
double x = 0.0 / 0.0;

if (MWNumericArray.isNaN(x))
    System.out.println("The input value is not a number.");
```

When run, the example displays this output:

```
The input value is not a number.
```

numberOfDimensions. MWNumericArray inherits this method from the MWArray class.

numberOfElements. MWNumericArray inherits this method from the MWArray class.

Methods to Get and Set the Real Parts of an MWNumericArray

Use these methods to get and set real values in an object of class MWNumericArray.

Method	Description
“get” on page 4-76	Returns the element at the specified offset as an Object.
“getData” on page 4-76	Returns a one-dimensional array containing a copy of the data in the underlying MATLAB array.
“getDouble” on page 4-76	Returns the real part at the specified offset as a double value.
“getFloat” on page 4-77	Returns the real part at the specified offset as a float value.
“getLong” on page 4-77	Returns the real part at the specified offset as a long value.
“getInt” on page 4-77	Returns the real part at the specified offset as an int value.
“getShort” on page 4-77	Returns the real part at the specified offset as a short value.
“getBytes” on page 4-78	Returns the real part at the specified offset as a byte value.
“set” on page 4-79	Replaces the real part at the specified offset with the specified value.
“toArray” on page 4-79	Returns an array containing a copy of the data in the underlying MATLAB array. The returned array has the same dimensionality as the MATLAB array.

The following syntax applies to all the above methods except `getData` and `toArray`.

Calling Syntax. To get the element at a specific index, use one of the following:

```
public type getType(int index)
public type getType(int[] index)
```

To set the element at a specific index, use one of the following:

```
public void set(int index, type element)
public void set(int[] index, type element)
```

Use the first syntax (`int index`) to return the element at the specified one-based offset in the array, accessing elements in column-wise order. Use the second syntax (`int[] index`) to return the element at the specified array of one-based indices. The first syntax offers better performance than the second.

In the case where `index` is of type `int`, the valid range for `index` is $1 \leq \text{index} \leq N$, where N is the total number of elements in the array.

In the case where `index` is of type `int[]`, each element of the `index` vector is an index along one dimension of the `MWNumericArray` object. The valid range for any `index` is $1 \leq \text{index}[i] \leq N[i]$, where $N[i]$ is the size of the i th dimension.

Exceptions. The `MWNumericArray` constructor throws the following exception:

`IndexOutOfBoundsException`

The specified `index` parameter is invalid.

get. `MWNumericArray` inherits this method from the `MWArray` class.

getData. `MWNumericArray` inherits this method from the `MWArray` class.

getDouble. This method returns the real part of the `MWNumericArray` element located at the specified one-based index or index array. The return value is given type `double`.

Use either of the following prototypes for the `getDouble` method, where `index` can be of type `int` or `int[]`:

```
public double getDouble(int index)
public double getDouble(int[] index)
```

getFloat. This method returns the real part of the `MWNumericArray` element located at the specified one-based index or index array. The return value is given type `float`.

Use either of the following prototypes for the `getFloat` method, where `index` can be of type `int` or `int[]`:

```
public float getFloat(int index)
public float getFloat(int[] index)
```

getLong. This method returns the real part of the `MWNumericArray` element located at the specified one-based index or index array. The return value is given type `long`.

Use either of the following prototypes for the `getLong` method, where `index` can be of type `int` or `int[]`:

```
public long getLong(int index)
public long getLong(int[] index)
```

getInt. This method returns the real part of the `MWNumericArray` element located at the specified one-based index or index array. The return value is given type `int`.

Use either of the following prototypes for the `getInt` method, where `index` can be of type `int` or `int[]`:

```
public int getInt(int index)
public int getInt(int[] index)
```

getShort. This method returns the real part of the `MWNumericArray` element located at the specified one-based index or index array. The return value is given type `short`.

Use either of the following prototypes for the `getShort` method, where `index` can be of type `int` or `int[]`:

```
public short getShort(int index)
public short getShort(int[] index)
```

getByte. This method returns the real part of the `MWNumericArray` element located at the specified one-based index or index array. The return value is given type `byte`.

Use either of the following prototypes for the `getByte` method, where `index` can be of type `int` or `int[]`:

```
public byte getByte(int index)
public byte getByte(int[] index)
```

Example — Getting a Short Value from a Numeric Array

The following examples use this array:

```
short[][] Adata = {{ 1, 2, 3, 4, 5, 6},
                  { 7, 8, 9, 10, 11, 12},
                  {13, 14, 15, 16, 17, 18}};

MWNumericArray A = new MWNumericArray(Adata, MWClassID.INT16);
int[] index = {2, 4};
System.out.println("A(2,4) = " + A.getShort(index));
```

When run, the example displays this output:

```
A(2,4) = 10
```

Example — Using get and set on a Numeric Array

Given the same `MWNumericArray` used in the previous example, get and then modify the value of element (2, 3):

```
int[] idx = {2, 3};

System.out.println("A(2, 3) is " + A.get(idx).toString());
System.out.println("");
```

```

System.out.println("Setting A(2, 3) to a new value ...");
A.set(idx, 555);
System.out.println("");

System.out.println("A(2, 3) is now " + A.get(idx).toString());

```

When run, the example displays this output:

```

A(2, 3) is 9.0

Setting A(2, 3) to a new value ...

A(2, 3) is now 555.0

```

set. `MWNumericArray` inherits the following methods from the `MWArray` class.

```

set(int index, type element)
set(int[] index, type element)

```

`MWNumericArray` also overloads `set` for primitive byte, short, int, long, float, and double types.

toArray. `MWNumericArray` inherits this method from the `MWArray` class.

Methods to Get and Set the Imaginary Parts of an `MWNumericArray`

Use these methods to get and set imaginary values in an object of class `MWNumericArray`.

Method	Description
“getImag” on page 4-81	Returns the imaginary part at the specified index array in this array.
“getImagData” on page 4-82	Returns a one-dimensional array containing a copy of the imaginary data in the underlying MATLAB array.
“getImagDouble” on page 4-83	Returns the imaginary part at the specified offset as a double value.

Method	Description
“getImagFloat” on page 4-84	Returns the imaginary part at the specified offset as a float value.
“getImagLong” on page 4-84	Returns the imaginary part at the specified offset as a long value.
“getImagInt” on page 4-84	Returns the imaginary part at the specified offset as an int value.
“getImagShort” on page 4-84	Returns the imaginary part at the specified offset as a short value.
“getImagByte” on page 4-85	Returns the imaginary part at the specified offset as a byte value.
“setImag” on page 4-85	Replaces the imaginary part at the specified index array in this array with the specified double value.
“toImagArray” on page 4-86	Returns an array containing a copy of the imaginary data in the underlying MATLAB array. The returned array has the same dimensionality as the MATLAB array.

The following syntax applies to all the above methods except getImagData.

Calling Syntax. To get the element at a specific index, use one of the following:

```
public type getImagType(int index)
public type getImagType(int[] index)
```

To set the element at a specific index, use one of the following:

```
public void setImag(int index, type element)
public void setImag(int[] index, type element)
```

Use the first syntax (`int index`) to return the element at the specified one-based offset in the array, accessing elements in column-wise order. Use the second syntax (`int[] index`) to return the element at the specified array of one-based indices. The first syntax offers better performance than the second.

In the case where `index` is of type `int`, the valid range for `index` is $1 \leq \text{index} \leq N$, where N is the total number of elements in the array.

In the case where `index` is of type `int[]`, each element of the `index` vector is an index along one dimension of the `MWNumericArray` object. The valid range for any index is $1 \leq \text{index}[i] \leq N[i]$, where $N[i]$ is the size of the i th dimension.

Exceptions. These methods throw the following exception:

`IndexOutOfBoundsException`

The specified `index` parameter is invalid.

getImag. This method returns the imaginary part of the `MWNumericArray` element located at the specified one-based index or index array. The type of the return value is `Object`.

Use either of the following prototypes for the `getImag` method, where `index` can be of type `int` or `int[]`:

```
public Object getImag(int index)
public Object getImag(int[] index)
```

Example — Getting the Real and Imaginary Parts of an Array

Start by creating a two-dimensional array of complex values:

```
double[][] Rdata = {{ 2, 3, 4},
                   { 8, 9, 10},
                   {14, 15, 16}};

double[][] Idata = {{ 6, 5, 14},
                   { 7, 1, 23},
                   { 1, 1, 9}};

MWNumericArray A = new MWNumericArray(Rdata, Idata,
                                       MWClassID.DOUBLE);

System.out.println("Complex matrix A =");
```

```
System.out.println(A.toString());
```

Here is the complex array that is displayed:

```
2.0000 + 6.0000i   3.0000 + 5.0000i   4.0000 + 14.0000i
8.0000 + 7.0000i   9.0000 + 1.0000i   10.0000 + 23.0000i
14.0000 + 1.0000i  15.0000 + 1.0000i   16.0000 + 9.0000i
```

Now, use `get` and `getImag` to read the real and imaginary parts of the element at index (2, 3):

```
int[] index = {2, 3};
System.out.println("The real part of A(2,3) = " +
    A.get(index));
System.out.println("The imaginary part of A(2,3) = " +
    A.getImag(index));
```

When run, the example displays this output:

```
The real part of A(2,3) = 10.0
The imaginary part of A(2,3) = 23.0
```

getImagData. This method returns a one-dimensional `MWNumericArray` containing a copy of the imaginary data in the underlying MATLAB array.

The prototype for the `getImagData` method is as follows:

```
public Object getImagData()
```

`getImagData` returns the array of elements in column-wise order. The elements are converted according to default conversion rules.

Example — Getting Data from a Complex Array

Using the same array as in the example for “`getImag`” on page 4-81, get the entire contents of the complex array:

```
int[] index = {2, 3};
double[] x;
```

```

System.out.println("The real data in matrix A is:");
x = (double[]) A.getData();
for (int i = 0; i < x.length; i++)
    System.out.print(" " + x[i]);
System.out.println();

System.out.println();

System.out.println("The imaginary data in matrix A is:");
x = (double[]) A.getImagData();
for (int i = 0; i < x.length; i++)
    System.out.print(" " + x[i]);
System.out.println();

```

When run, the example displays this output:

```

The real data in matrix A is:
 2.0 8.0 14.0 3.0 9.0 15.0 4.0 10.0 16.0

The imaginary data in matrix A is:
 6.0 7.0 1.0 5.0 1.0 1.0 14.0 23.0 9.0

```

getImagDouble. This method returns the imaginary part of the `MWNumericArray` element located at the specified one-based index or index array. The return value is given type `double`.

Use either of the following prototypes for the `getImagDouble` method, where `index` can be of type `int` or `int[]`:

```

public double getImagDouble(int index)
public double getImagDouble(int[] index)

```

Example — Getting Complex Data of a Specific Type

Using the same array as in the example for “`getImag`” on page 4-81, get the real and imaginary parts of one element of the `MWNumericArray`:

```

int[] index = {2, 3};
System.out.println("The real part of A(2,3) = " +
    A.getDouble(index));

```

```
System.out.println("The imaginary part of A(2,3) = " +  
A.getImagDouble(index));
```

When run, the example displays this output:

```
The real part of A(2,3) = 10.0  
The imaginary part of A(2,3) = 23.0
```

getImagFloat. This method returns the imaginary part of the `MWNumericArray` element located at the specified one-based index or index array. The return value is given type `float`.

Use either of the following prototypes for the `getImagFloat` method, where `index` can be of type `int` or `int[]`:

```
public float getImagFloat(int index)  
public float getImagFloat(int[] index)
```

getImagLong. This method returns the imaginary part of the `MWNumericArray` element located at the specified one-based index or index array. The return value is given type `long`.

Use either of the following prototypes for the `getImagLong` method, where `index` can be of type `int` or `int[]`:

```
public long getImagLong(int index)  
public long getImagLong(int[] index)
```

getImagInt. This method returns the imaginary part of the `MWNumericArray` element located at the specified one-based index or index array. The return value is given type `int`.

Use either of the following prototypes for the `getImagInt` method, where `index` can be of type `int` or `int[]`:

```
public int getImagInt(int index)  
public int getImagInt(int[] index)
```

getImagShort. This method returns the imaginary part of the `MWNumericArray` element located at the specified one-based index or index array. The return value is given type `short`.

Use either of the following prototypes for the `getImagShort` method, where `index` can be of type `int` or `int[]`:

```
public short getImagShort(int index)
public short getImagShort(int[] index)
```

getImagByte. This method returns the imaginary part of the `MWNumericArray` element located at the specified one-based index or index array. The return value is given type `byte`.

Use either of the following prototypes for the `getImagByte` method, where `index` can be of type `int` or `int[]`:

```
public byte getImagByte(int index)
public byte getImagByte(int[] index)
```

setImag. This method replaces the imaginary part at the specified one-based index array in this array with the specified byte value.

Use either of the following prototypes for the `setImag` method, where `index` can be of type `int` or `int[]`:

```
public void setImag(int index, javatype element)
public void setImag(int[] index, javatype element)
```

The type *javatype* can be any of the following:

- `double`
- `float`
- `long`
- `int`
- `short`
- `byte`
- `Object`

Exceptions

These methods throw the following exception:

`IndexOutOfBoundsException`

The specified index parameter is invalid.

toImagArray. This method returns an array containing a copy of the imaginary data in the underlying MATLAB array.

The prototype for the `toImagArray` method is

```
public Object toImagArray()
```

The array that is returned has the same dimensionality as the MATLAB array. The elements of this array are converted according to default conversion rules.

Input Parameters

None

Example — Getting Complex Data with `toImagArray`

Using the same array as in the example for “`getImag`” on page 4-81, get and display a copy of the imaginary part of that array:

```
double[][] x = (double[][]) A.toImagArray();
int[] dimA = A.getDimensions();

System.out.println("The imaginary part of matrix A is:");
for (int i = 0; i < dimA[0]; i++)
{
    for (int j = 0; j < dimA[1]; j++)
        System.out.print(" " + x[i][j]);
    System.out.println();
}
```

When run, the example displays this output:

```
The imaginary part of matrix A is:
6.0 5.0 14.0
7.0 1.0 23.0
1.0 1.0 9.0
```

Methods to Copy, Convert, and Compare MWNumericArrays

Use these methods to copy, convert, and compare objects of class MWNumericArray.

Method	Description
“clone” on page 4-87	Creates and returns a deep copy of this array.
“compareTo” on page 4-88	Compares this array with the specified array for order.
“equals” on page 4-89	Indicates whether some other array is equal to this one.
“hashCode” on page 4-89	Returns a hash code value for the array.
“sharedCopy” on page 4-89	Creates and returns a shared copy of this array.
“toString” on page 4-89	Returns a string representation of the array.

clone. This method creates and returns a deep copy of this array. Because clone allocates a new array, any changes made to this new array are not reflected in the original.

The clone method of MWNumericArray overrides the clone method of class MWArray.

The prototype for the clone method is

```
public Object clone()
```

Input Parameters

None

Exceptions

The clone method throws the following exception:

```
java.lang.CloneNotSupportedException
```

The object's class does not implement the Cloneable interface.

Example — Cloning a Numeric Array Object

Create a 3-by-6 array of type double:

```
double[][] AData = {{ 1, 2, 3, 4, 5, 6},  
                    { 7, 8, 9, 10, 11, 12},  
                    {13, 14, 15, 16, 17, 18}};
```

```
MWNumericArray A = new MWNumericArray(AData, MWClassID.DOUBLE);
```

Create a clone of the MWNumericArray object A:

```
Object C = A.clone();
```

```
System.out.println("Clone of matrix A is:");  
System.out.println(C.toString());
```

When run, the example displays this output:

```
Clone of matrix A is:  
  1   2   3   4   5   6  
  7   8   9  10  11  12  
 13  14  15  16  17  18
```

compareTo. MWNumericArray inherits this method from the MWArray class.

equals. MWNumericArray inherits this method from the MWArray class.

hashCode. MWNumericArray inherits this method from the MWArray class.

sharedCopy. This method creates and returns a shared copy of the MWNumericArray object. The shared copy points to the underlying original MATLAB array. Any changes made to the copy are reflected in the original.

The sharedCopy method of MWNumericArray overrides the sharedCopy method of class MWArray.

The prototype for the sharedCopy method is as follows:

```
public Object sharedCopy()
```

Input Parameters

None

Example — Making a Shared Copy of a Numeric Array Object

Create a shared copy of MWArray object A:

```
Object S = A.sharedCopy();  
  
System.out.println("Shared copy of matrix A is:");  
System.out.println(S.toString());
```

When run, the example displays this output:

```
Shared copy of matrix A is:  
  1    2    3    4    5    6  
  7    8    9   10   11   12  
 13   14   15   16   17   18
```

toString. MWNumericArray inherits this method from the MWArray class.

Methods to Use on Sparse MWNumericArrays

Use these methods to return information on sparse arrays of type `MWNumericArray`. All are inherited from class `MWArray`.

Operations on sparse arrays of type `MWNumericArray` are currently supported only for the double type.

Method	Description
“newSparse” on page 4-66	Constructs a real sparse numeric matrix with the specified number of rows and columns and maximum nonzero elements, and initializes the array with the supplied data.
“isSparse” on page 4-55	Tests whether the array is sparse.
“columnIndex” on page 4-56	Returns an array containing the column index of each nonzero element in the underlying MATLAB array.
“rowIndex” on page 4-57	Returns an array containing the row index of each nonzero element in the underlying MATLAB array.
“maximumNonZeros” on page 4-57	Returns the allocated capacity of a sparse array. If the underlying array is nonsparse, this method returns the same value as <code>numberOfElements()</code> .
“numberOfNonZeros” on page 4-58	Returns the number of nonzero elements in a sparse array. If the underlying array is nonsparse, this method returns the same value as <code>numberOfElements()</code> .

`MWNumericArray` inherits all the above methods from the `MWArray` class.

Methods to Return Special Constant Values

Use these methods to return the values symbolized by `EPS`, `Inf`, and `NaN` in MATLAB.

Method	Description
“getEps” on page 4-91	Get the value represented by EPS (floating-point relative accuracy) in MATLAB.
“getInf” on page 4-91	Get the value represented by INF (infinity) in MATLAB.
“getNaN” on page 4-92	Get the value represented by NaN (Not a Number) in MATLAB.

getEps. This method returns the MATLAB concept of EPS, which stands for the floating-point relative accuracy.

The prototype for the getEps method is

```
public static double getEps()
```

Input Parameters

None

Exceptions

None

getInf. This method returns the MATLAB concept of Inf, which stands for infinity.

The prototype for the getInf method is

```
public static double getInf()
```

Input Parameters

None

Exceptions

None

getNaN. This method returns the MATLAB concept of NaN, which stands for "Not a Number".

The prototype for the getNaN method is

```
public static double getNaN()
```

Input Parameters

None

Exceptions

None

Using MWLogicalArray

This section covers the following topics:

- “Constructing an MWLogicalArray” on page 4-92
- “Methods to Create and Destroy an MWLogicalArray” on page 4-93
- “Methods to Return Information About an MWLogicalArray” on page 4-98
- “Methods to Get and Set Data in an MWLogicalArray” on page 4-100
- “Methods to Copy, Convert, and Compare MWLogicalArrays” on page 4-104
- “Methods to Use on Sparse MWLogicalArrays” on page 4-107

Constructing an MWLogicalArray

You can construct two types of MWLogicalArray objects – an empty logical scalar or an initialized logical scalar or array.

Constructing an Empty Logical Scalar. To construct an empty scalar logical of type MWClassID.LOGICAL, use

```
MWLogicalArray()
```

Constructing an Initialized Logical Scalar or Array. Use this constructor syntax to create a `MWLogicalArray` scalar or array that represents the primitive Java type *javatype*:

```
MWLogicalArray(javatype array)
```

The value of *array* is set to `true` if the argument is nonzero, and `false` otherwise.

The type *javatype* can be any of the following:

- `double`
- `float`
- `long`
- `int`
- `short`
- `byte`
- `boolean`
- `Object`

Example — Constructing an Initialized Logical Array Object

```
boolean[][] Adata = {{true, false, false},  
                    {false, true, false}};  
  
MWLogicalArray A = new MWLogicalArray(Adata);
```

Methods to Create and Destroy an MWLogicalArray

In addition to the `MWLogicalArray` constructor, you can use the `newInstance` and `newSparse` methods to construct a logical array. These two methods offer better performance than using the class constructor. To destroy the arrays, use either `dispose` or `disposeArray`.

Method	Description
“newInstance” on page 4-94	Constructs a logical array with the specified dimensions.
“newSparse” on page 4-95	Constructs a sparse logical matrix from the supplied full matrix.
“dispose” on page 4-98	Frees the native MATLAB array contained by this array.
“disposeArray” on page 4-98	Frees all native MATLAB arrays contained in the input object.

newInstance. This method constructs a real or complex array, specifying the array dimensions, type, and complexity. This is a static method of the class and thus does not need to be invoked in reference to an instance of the class.

Note This method offers better performance than using the class constructor.

To construct a logical array with specified dimensions and all elements initialized to false, use the following:

```
public static MWLogicalArray newInstance(int[] dims)
```

To construct a logical array with specified dimensions and initialized to the supplied data, use the following:

```
public static MWLogicalArray newInstance(int[] dims,  
    Object data)
```

Input Parameters

dims

Array of nonnegative dimension sizes

data

Data to initialize the array

Exceptions

The `newInstance` method throws the following exceptions:

`NegativeArraySizeException`

The specified `dims` parameter is negative.

`ArrayStoreException`

The specified data is nonnumeric or non-Boolean.

Example — Constructing a Logical Array Object with `newInstance`

Construct a 1-by-5 logical array using the `newInstance` method. Note that data in the Java array must be stored in a column-wise order so that it will be in row-wise order in the final `MWLogicalArray` object.

```
boolean[] Adata = { true, true, false, false, true};
int[] dims = {1, 5};

MWLogicalArray A = MWLogicalArray.newInstance(dims, Adata);
System.out.println("Array A: " + A.toString());
```

When run, the example displays this output:

```
Array A:      1      1      0      0      1
```

`newSparse`. This method constructs a sparse `MWLogicalArray` with the specified number of rows and columns and maximum nonzero elements, and initializes the array with the supplied data. This is a static method of the class and thus does not need to be invoked in reference to an instance of the class.

Supported Prototypes

Supported prototypes for `newSparse` are as follows. All input parameters shown here are described under Input Parameters on page 96. Any parameters not specified are given their default values.

To construct a sparse logical matrix with no nonzero elements, use the following:

```
public static MWLogicalArray newSparse(int rows, int cols,
                                       int nzmax)
```

To construct a sparse logical matrix from a supplied full matrix, use the following:

```
public static MWLogicalArray newSparse(Object data)
```

To specify what data is assigned to each element, use the following:

```
public static MWLogicalArray newSparse(int[] rowindex,
                                       int[] colindex, Object data)
```

To specify the number of rows and columns in the array, use the following:

```
public static MWLogicalArray newSparse(int[] rowindex,
                                       int[] colindex, Object data, int rows, int cols)
```

To specify the maximum number of nonzero elements in the array, use the following:

```
public static MWLogicalArray newSparse(int[] rowindex,
                                       int[] colindex, Object data, int rows, int cols,
                                       int nzmax)
```

Input Parameters

`data`

Data to initialize the array. See the list of valid data types below.

`rowIndex` and `colIndex`

Arrays of one-based row and column indices

Row and column index arrays are used to construct the sparse array such that the following holds true, with space allocated for `nzmax` nonzeros:

$S(\text{rowIndex}(k), \text{colIndex}(k)) = \text{data}(k)$

rows and cols

Number of rows and columns in the matrix

nzmax

Maximum number of nonzero elements

Valid types for the data parameter are as follows:

- double[]
- float[]
- long[]
- int[]
- short[]
- byte[]
- boolean[]
- One-dimensional arrays of any subclass of `java.lang.Number`
- One-dimensional arrays of `java.lang.Boolean`
- One-dimensional arrays of `java.lang.String`

rowIndex and colIndex Parameters

Exceptions

The `newSparse` method throws the following exceptions:

`NegativeArraySizeException`

Row or column size is negative.

`IndexOutOfBoundsException`

The specified index parameter is invalid.

ArrayStoreException

Incompatible array type or invalid array data

Example — Constructing a Sparse Logical Array Object

Create a sparse array of logical values using the `newSparse` method:

```
boolean[] Adata = {true, true, false, false, true};

int[] ri = {1, 1, 1, 1, 1};
int[] ci = {1, 2, 3, 4, 5};

MWLogicalArray A = MWLogicalArray.newSparse(ri, ci, Adata);

System.out.println(A.toString());
```

When run, the example displays this output:

```
(1,1)      1
(1,2)      1
(1,5)      1
```

dispose. `MWLogicalArray` inherits this method from the `MWArray` class.

disposeArray. `MWLogicalArray` inherits this method from the `MWArray` class.

Methods to Return Information About an `MWLogicalArray`

Use these methods to return information about an object of class `MWLogicalArray`.

Method	Description
“classID” on page 4-99	Returns the MATLAB type of this array.

Method	Description
“getDimensions” on page 4-100	Returns an array containing the size of each dimension of this array.
“isEmpty” on page 4-100	Tests whether the array has no elements.
“numberOfDimensions” on page 4-100	Returns the number of dimensions of this array.
“numberOfElements” on page 4-100	Returns the total number of elements in this array.

classID. This method returns the MATLAB type of the `MWLogicalArray` object. The `classID` method of `MWLogicalArray` overrides the `classID` method of class `MWArray`.

The prototype for the `classID` method is

```
public MWClassID classID()
```

`classID` returns a field defined by the `MWClassID` class. For an `MWLogicalArray`, `classID` returns the value `MWClassID.LOGICAL`.

Input Parameters

None

Example — Getting the Class ID for a Logical Array Object

Return the class ID for `MWLogicalArray` object `Adata`:

```
boolean[][] Adata = {{true, false, false},
                    {false, true, false}};

MWLogicalArray A = new MWLogicalArray(Adata);

System.out.println("Class of A is " + A.classID());
```

When run, the example displays this output:

Class of A is logical

getDimensions. MWLogicalArray inherits this method from the MWArray class.

isEmpty. MWLogicalArray inherits this method from the MWArray class.

numberOfDimensions. MWLogicalArray inherits this method from the MWArray class.

numberOfElements. MWLogicalArray inherits this method from the MWArray class.

Methods to Get and Set Data in an MWLogicalArray

Use these methods to get and set values in an object of class MWLogicalArray.

Method	Description
“get” on page 4-100	Returns the element at the specified offset as an Object.
“getData” on page 4-100	Returns a one-dimensional array containing a copy of the data in the underlying MATLAB array.
“getBoolean” on page 4-101	Returns the boolean at the specified one-based offset.
“set” on page 4-102	Replaces the element at the specified one-based offset in this array with the specified element.
“toArray” on page 4-104	Returns an array containing a copy of the data in the underlying MATLAB array. The returned array has the same dimensionality as the MATLAB array.

get. MWLogicalArray inherits this method from the MWArray class.

getData. MWLogicalArray inherits this method from the MWArray class.

getBoolean. This method returns the element located at the specified one-based index of the `MWLogicalArray` object.

To get the element at a specific index, use one of the following:

```
public boolean getBoolean(int index)
public boolean getBoolean(int[] index)
```

Use the first syntax (`int index`) to return the element at the specified one-based offset in the array, accessing elements in column-wise order. Use the second syntax (`int[] index`) to return the element at the specified array of one-based indices. The first syntax offers better performance than the second.

Input Parameters

`index`

Index of the requested element in the `MWLogicalArray`

In the case where `index` is of type `int`, the valid range for `index` is $1 \leq \text{index} \leq N$, where N is the total number of elements in the array.

In the case where `index` is of type `int[]`, each element of the `index` vector is an index along one dimension of the `MWLogicalArray` object. The valid range for any `index` is $1 \leq \text{index}[i] \leq N[i]$, where $N[i]$ is the size of the i th dimension.

Exceptions

The `getBoolean` method throws the following exception:

`IndexOutOfBoundsException`

The specified `index` parameter is invalid.

Example — Getting a Boolean Value from a Logical Array

```
boolean[][] Adata = {{true, false, false},
                    {false, true, false}};

MWLogicalArray A = new MWLogicalArray(Adata);

int[] index = {2, 2};
System.out.println("A(2,2) is " + A.getBoolean(index));
```

When run, the example displays this output:

```
A(2,2) = true
```

set. This method returns the element located at the specified one-based index of the `MWLogicalArray` object.

To set the element at a specific index, use one of the following:

```
public void set(int index, boolean element)
public void set(int[] index, boolean element)
```

Use the first syntax (`int index`) to return the element at the specified one-based offset in the array, accessing elements in column-wise order. Use the second syntax (`int[] index`) to return the element at the specified array of one-based indices. The first syntax offers better performance than the second.

Input Parameters

`element`

New element to replace at `index`

`index`

Index of the requested element in the `MWLogicalArray`

In the case where `index` is of type `int`, the valid range for `index` is $1 \leq \text{index} \leq N$, where N is the total number of elements in the array.

In the case where `index` is of type `int[]`, each element of the `index` vector is an index along one dimension of the `MWLogicalArray` object. The valid range for any index is $1 \leq \text{index}[i] \leq N[i]$, where $N[i]$ is the size of the i th dimension.

Exceptions

The `set` method throws the following exception:

`IndexOutOfBoundsException`

The specified `index` parameter is invalid.

Example — Setting a Value in a Logical Array

Get and modify the value at `A(2,3)`:

```
boolean[][] Adata = {{true, false, false},
                    {false, true, false}};

MWLogicalArray A = new MWLogicalArray(Adata);

int[] index = {2, 3};
Object d_out = A.get(index);
System.out.println("Array element A(2,3) is " +
                  d_out.toString() + "\n");

System.out.println("Setting A(2,3) to true\n");
A.set(index, true);

d_out = A.get(index);
System.out.println("Array element A(2,3) is " +
                  d_out.toString() + "\n");
```

When run, the example displays this output:

```
Array element A(2,3) is false
```

```
Setting A(2,3) to true
```

```
Array element A(2,3) is true
```

toArray. NSMutableArray inherits this method from the NSMutableArray class.

Methods to Copy, Convert, and Compare NSMutableArray

Use these methods to copy, convert, and compare objects of class NSMutableArray.

Method	Description
“clone” on page 4-104	Creates and returns a deep copy of this array.
“compareTo” on page 4-105	Compares this array with the specified array for order.
“equals” on page 4-105	Indicates whether some other array is equal to this one.
“hashCode” on page 4-106	Returns a hash code value for the array.
“sharedCopy” on page 4-106	Creates and returns a shared copy of this array.
“toString” on page 4-106	Returns a string representation of the array.

clone. This method creates and returns a deep copy of this array. Because clone allocates a new array, any changes made to this new array are not reflected in the original.

The clone method of NSMutableArray overrides the clone method of class NSMutableArray.

The prototype for the clone method is

```
public Object clone()
```

Input Parameters

None

Exceptions

The clone method throws the following exception:

```
java.lang.CloneNotSupportedException
```

The object's class does not implement the Cloneable interface.

Example — Cloning a Logical Array Object

Create a clone of MWLogicalArray object A:

```
boolean[][] Adata = {{true, false, false},
                    {false, true, false}};

MWLogicalArray A = new MWLogicalArray(Adata);

Object C = A.clone();

System.out.println("Clone of logical matrix A is:");
System.out.println(C.toString());
```

When run, the example displays this output:

```
Clone of logical matrix A is:
  1   0   0
  0   1   0
```

compareTo. MWLogicalArray inherits this method from the MWArray class.

equals. MWLogicalArray inherits this method from the MWArray class.

hashCode. MWLogicalArray inherits this method from the MWArray class.

sharedCopy. This method creates and returns a shared copy of the MWLogicalArray object. The shared copy points to the underlying original MATLAB array. Any changes made to the copy are reflected in the original.

The sharedCopy method of MWLogicalArray overrides the sharedCopy method of class MWArray.

The prototype for the sharedCopy method is

```
public Object sharedCopy()
```

Input Parameters

None

Example — Making a Shared Copy of a Logical Array Object

Create a shared copy of MWLogicalArray object A:

```
boolean[][] Adata = {{true, false, false},
                    {false, true, false}};

MWLogicalArray A = new MWLogicalArray(Adata);

Object C = A.sharedCopy();

System.out.println("Shared copy of logical matrix A is:");
System.out.println(C.toString());
```

When run, the example displays this output:

```
Shared copy of logical matrix A is:
  1   0   0
  0   1   0
```

toString. MWLogicalArray inherits this method from the MWArray class.

Methods to Use on Sparse MWLogicalArrays

Use these methods to return information on sparse arrays of type `MWLogicalArray`. All are inherited from class `MWArray`.

Method	Description
“isSparse” on page 4-55	Tests whether the array is sparse.
“columnIndex” on page 4-56	Returns an array containing the column index of each nonzero element in the underlying MATLAB array.
“rowIndex” on page 4-57	Returns an array containing the row index of each nonzero element in the underlying MATLAB array.
“maximumNonZeros” on page 4-57	Returns the allocated capacity of a sparse array. If the underlying array is nonsparse, this method returns the same value as <code>numberOfElements()</code> .
“numberOfNonZeros” on page 4-58	Returns the number of nonzero elements in a sparse array. If the underlying array is nonsparse, this method returns the same value as <code>numberOfElements()</code> .

`MWLogicalArray` inherits all the above methods from the `MWArray` class.

Using MWCharArray

This section covers the following topics:

- “Constructing an `MWCharArray`” on page 4-108
- “Methods to Create and Destroy an `MWCharArray`” on page 4-109
- “Methods to Return Information About an `MWCharArray`” on page 4-111
- “Methods to Get and Set Data in the `MWCharArray`” on page 4-112
- “Methods to Copy, Convert, and Compare `MWCharArrays`” on page 4-116

Constructing an MWCharArray

Use the tables in this section to construct an MWCharArray from a particular Java data type. See the examples in this section for more help.

Constructing an Empty Character Array. To construct an empty MWCharArray, use

```
MWCharArray()
```

To construct a MWCharArray object from a primitive Java char scalar, use the following prototype:

```
MWCharArray(char value)
```

To construct a MWCharArray object from a Java Object, use

```
MWCharArray(Object value)
```

Input Parameters

value

Value to initialize the array

Valid argument types for value are as follows:

- N-dimensional primitive char arrays
- java.lang.String
- N-dimensional arrays of java.lang.String
- java.lang.Character
- N-dimensional arrays of java.lang.Character

Example — Constructing an Initialized Character Array Object

Construct one MWCharArray object from a primitive character array:

```
char[] chArray1 = {'H', 'e', 'l', 'l', 'o'};
```

```
char[] chArray2 = {'W', 'o', 'r', 'l', 'd'};
MWCharArray A = new MWCharArray(chArray1);

System.out.println("The string in MWCharArray1 is \"" + A + "\"");
```

Construct a second MWCharArray from a String object:

```
String str = new String(chArray2);
MWCharArray A2 = new MWCharArray(str);

System.out.println("The string in MWCharArray2 is \"" +
    A2 + "\"");
```

When run, the example displays this output:

```
The string in MWCharArray1 is "Hello"

The string in MWCharArray2 is "World"
```

Methods to Create and Destroy an MWCharArray

In addition to the MWCharArray constructor, you can use the `newInstance` method to construct a character array. This method offers better performance than using the class constructor. To destroy the array, use either `dispose` or `disposeArray`.

Method	Description
“newInstance” on page 4-109	Constructs a char array with the specified dimensions.
“dispose” on page 4-110	Frees the native MATLAB array contained by this array.
“disposeArray” on page 4-111	Frees all native MATLAB arrays contained in the input object.

newInstance. This method constructs a char array with the specified dimensions and initializes the array with the supplied data. The input array must be of type `char[]` or `java.lang.String`. The characters in the array are assumed to be stored in column-major order.

To construct a `MWCharArray` object with the specified dimensions, use

```
public static MWCharArray newInstance(int[] dims)
```

The elements of the array are all initialized to zero.

To construct a `MWCharArray` object with the specified dimensions and initialized with the supplied data, use

```
public static MWCharArray newInstance(int[] dims,  
    Object data)
```

Input Parameters

`dims`

Array of dimension sizes. Each dimension size must be nonnegative.

`data`

Data to initialize the array

Example — Constructing a Character Array Object with `newInstance`

Create an `MWCharArray` object containing the text Hello:

```
int[] dims = {1, 5};  
char[] chArray = {'H', 'e', 'l', 'l', 'o'};  
String str = new String(chArray);  
  
MWCharArray A =  
    MWCharArray.newInstance(dims, str);  
  
System.out.println("The array string is \" + A + "\"");
```

When run, the example displays this output:

```
The array string is "Hello"
```

dispose. `MWCharArray` inherits this method from the `MWArray` class.

disposeArray. `MWCharArray` inherits this method from the `MWArray` class.

Methods to Return Information About an `MWCharArray`

Use these methods to return information about an object of class `MWCharArray`.

Method	Description
“classID” on page 4-111	Returns the MATLAB type of this array.
“getDimensions” on page 4-112	Returns an array containing the size of each dimension of this array.
“isEmpty” on page 4-112	Tests whether the array has no elements.
“numberOfDimensions” on page 4-112	Returns the number of dimensions of this array.
“numberOfElements” on page 4-112	Returns the total number of elements in this array.

classID. This method returns the MATLAB type of the `MWCharArray` object. The `classID` method of `MWCharArray` overrides the `classID` method of class `MWArray`.

The prototype for the `classID` method is

```
public MWClassID classID()
```

Input Parameters

None

Example — Getting the Class ID of a Character Array

Create an `MWCharArray` object and then display the class ID:

```
char[] chArray1 = {'H', 'e', 'l', 'l', 'o'};
MWCharArray A = new MWCharArray(chArray1);

System.out.println("The class of A is " + A.classID());
```

When run, the example displays this output:

The class of A is char

getDimensions. MWCharArray inherits this method from the MWArray class.

isEmpty. MWCharArray inherits this method from the MWArray class.

numberOfDimensions. MWCharArray inherits this method from the MWArray class.

numberOfElements. MWCharArray inherits this method from the MWArray class.

Methods to Get and Set Data in the MWCharArray

Use these methods to get and set values in an object of class MWCharArray.

Method	Description
“get” on page 4-112	Returns the element at the specified offset as an Object.
“getData” on page 4-112	Returns a one-dimensional array containing a copy of the data in the underlying MATLAB array.
“getChar” on page 4-113	Returns the character at the specified one-based offset.
“set” on page 4-114	Replaces the element at the specified one-based offset in this array with the specified element.
“toArray” on page 4-116	Returns an array containing a copy of the data in the underlying MATLAB array. The returned array has the same dimensionality as the MATLAB array.

get. MWCharArray inherits this method from the MWArray class.

getData. MWCharArray inherits this method from the MWArray class.

getChar. This method returns the character located at the specified one-based index of the `MWCharArray` object.

To get the element at a specific index, use one of

```
public char getChar(int index)
public char getChar(int[] index)
```

Use the first syntax (`int index`) to return the element at the specified one-based offset in the array, accessing elements in column-wise order. Use the second syntax (`int[] index`) to return the element at the specified array of one-based indices. The first syntax offers better performance than the second.

Input Parameters

`index`

Index of the requested element in the `MWCharArray`

In the case where `index` is of type `int`, the valid range for `index` is $1 \leq \text{index} \leq N$, where N is the total number of elements in the array.

In the case where `index` is of type `int[]`, each element of the `index` vector is an index along one dimension of the `MWCharArray` object. The valid range for any `index` is $1 \leq \text{index}[i] \leq N[i]$, where $N[i]$ is the size of the i th dimension.

Exceptions

The `getChar` method throws the following exception:

`IndexOutOfBoundsException`

The specified `index` parameter is invalid.

Example — Getting Character Array Data with getChar

Use getChar to display the string stored in MWCharArray object A:

```
char[] chArray = {'H', 'e', 'l', 'l', 'o'};
MWCharArray A = new MWCharArray(chArray);

for (int i = 1; i <= 5; i++)
    System.out.print(A.getChar(i));
```

When run, the example displays this output:

```
Hello
```

set. This method replaces the character located at the specified one-based offset in the MWCharArray object with the specified char value.

To set the element at a specific index, use one of

```
public void set(int index, char element);
public void set(int[] index, char element);
```

Use the first syntax (int index) to return the element at the specified one-based offset in the array, accessing elements in column-wise order. Use the second syntax (int[] index) to return the element at the specified array of one-based indices. The first syntax offers better performance than the second.

Input Parameters

element

New element to replace at index

index

Index of the requested element in the MWCharArray

In the case where index is of type int, the valid range for index is $1 \leq \text{index} \leq N$, where N is the total number of elements in the array.

In the case where `index` is of type `int[]`, each element of the `index` vector is an index along one dimension of the `MWCharArray` object. The valid range for any `index` is $1 \leq \text{index}[i] \leq N[i]$, where $N[i]$ is the size of the i th dimension.

Exceptions

The `set` method throws the following exception:

`IndexOutOfBoundsException`

The specified `index` parameter is invalid.

Example — Setting Values in a Character Array

Display a phrase stored in `MWCharArray` object `A`, change one of the characters, and then display the modified phrase:

```
char[] chArray = {'G', 'a', 'r', 'y'};
MWCharArray A = new MWCharArray(chArray);

System.out.println(" I think " + A + " lives here." + "\n");

System.out.println("Changing the first character to M ...\n");
int[] index = {1, 1};
A.set(index, 'M');

System.out.println(" I think " + A + " lives here." + "\n");
```

When run, the example displays this output:

```
I think Gary lives here.
```

```
Changing the first character to M ...
```

```
I think Mary lives here.
```

toArray. MWCharArray inherits this method from the MWArray class.

Methods to Copy, Convert, and Compare MWCharArrays

Use these methods to copy, convert, and compare objects of class MWCharArray.

Method	Description
“clone” on page 4-116	Creates and returns a deep copy of this array.
“compareTo” on page 4-117	Compares this array with the specified array for order.
“equals” on page 4-117	Indicates whether some other array is equal to this one.
“hashCode” on page 4-117	Returns a hash code value for the array.
“sharedCopy” on page 4-117	Creates and returns a shared copy of this array.
“toString” on page 4-118	Returns a string representation of the array.

clone. This method creates and returns a deep copy of this array. Because clone allocates a new array, any changes made to this new array are not reflected in the original.

The clone method of MWCharArray overrides the clone method of class MWArray.

The prototype for the clone method is

```
public Object clone()
```

Input Parameters

None

Example — Cloning a Character Array Object

Create a clone of MWCharArray object A:

```
char[] chArray = {'H', 'e', 'l', 'l', 'o'};
MWCharArray A = new MWCharArray(chArray);

Object C = A.clone();

System.out.println("Clone of matrix A is:");
System.out.println(C.toString());
```

When run, the example displays this output:

```
Clone of matrix A is:
Hello
```

compareTo. MWCharArray inherits this method from the MWArray class.

equals. MWCharArray inherits this method from the MWArray class.

hashCode. MWCharArray inherits this method from the MWArray class.

sharedCopy. This method creates and returns a shared copy of the MWCharArray object. The shared copy points to the underlying original MATLAB array. Any changes made to the copy are reflected in the original.

The sharedCopy method of MWCharArray overrides the sharedCopy method of class MWArray.

The prototype for the sharedCopy method is

```
public Object sharedCopy();
```

Input Parameters

None

Example — Making a Shared Copy of a Character Array Object

Create a shared copy of MWCharArray object A:

```
char[] chArray = {'H', 'e', 'l', 'l', 'o'};
MWCharArray A = new MWCharArray(chArray);

Object S = A.sharedCopy();

System.out.print("Shared copy of matrix A is \"" +
    S.toString() + "\"");
```

When run, the example displays this output:

```
Shared copy of matrix A is "Hello"
```

toString. MWCharArray inherits this method from the MWArray class.

Using MWStructArray

This section covers the following topics:

- “Constructing an MWStructArray” on page 4-118
- “Methods to Destroy an MWStructArray” on page 4-120
- “Methods to Return Information About an MWStructArray” on page 4-121
- “Methods to Get and Set Data in the MWStructArray” on page 4-124
- “Methods to Copy, Convert, and Compare MWStructArrays” on page 4-132

Constructing an MWStructArray

Use the tables in this section to construct an MWStructArray from a particular Java data type. See the examples at the end of this section for more help.

Constructing an Empty Structure Array. To construct an empty 0-by-0 MATLAB structure array, use

```
MWStructArray()
```

To construct an `MWStructArray` object with the specified dimensions and field names, use

```
MWStructArray(int[] dims, java.lang.String[] fieldnames)
```

To construct an `MWStructArray` object with the specified number of rows and columns, and field names, use

```
MWStructArray(int rows, int cols, java.lang.String[] fieldnames)
```

Input Parameters

`dims`

Array of dimension sizes. Each dimension size must be nonnegative.

`fieldnames`

Array of field names

`rows`

Number of rows in the array. This number must be nonnegative.

`cols`

Number of columns in the array. This number must be nonnegative.

Example — Constructing a Structure Array Object

This first example creates a 0-by-0 `MWStructArray` object:

```
MWStructArray S = new MWStructArray();  
System.out.println("Structure array S: " + S);
```

When run, the example displays this output:

```
Structure array S: []
```

The second example creates a 1-by-2 MWStructArray object with fields f1, f2, and f3:

```
int[] sdims = {1, 2};
String[] sfields = {"f1", "f2", "f3"};

MWStructArray S = new MWStructArray(sdims, sfields);

System.out.println("Structure array S: " + S);
```

When run, the example displays this output:

```
Structure array S: 1x2 struct array with fields:
    f1
    f2
    f3
```

Methods to Destroy an MWStructArray

To destroy the arrays, use either `dispose` or `disposeArray`.

Method	Description
“dispose” on page 4-120	Frees the native MATLAB array contained by this array.
“disposeArray” on page 4-121	Frees all native MATLAB arrays contained in the input object.

dispose. The `dispose` method of `MWStructArray` overrides the `dispose` method of class `MWArray`.

The prototype for the `dispose` method is

```
public void dispose()
```

Input Parameters

None

Example — Disposing of a Structure Array Object

```
int[] sdims = {1, 2};
String[] sfields = {"f1", "f2", "f3"};

MWStructArray S = new MWStructArray(sdims, sfields);

System.out.println("Structure array S: " + S);
System.out.println("Now disposing of array S\n");
S.dispose();

System.out.println("Structure array S: " + S);
```

When run, the example displays this output:

```
Structure array S: 1x2 struct array with fields:
    f1
    f2
    f3

Now disposing of array S

Structure array S: []
```

disposeArray. MWStructArray inherits this method from the MWArray class.

Methods to Return Information About an MWStructArray

Use these methods to return information about an object of class MWStructArray.

Method	Description
“classID” on page 4-122	Returns the MATLAB type of this array.
“fieldNames” on page 4-122	Returns the field names in this array.
“getDimensions” on page 4-123	Returns an array containing the size of each dimension of this array.
“isEmpty” on page 4-123	Tests whether the array has no elements.

Method	Description
“numberOfDimensions” on page 4-123	Returns the number of dimensions of this array.
“numberOfElements” on page 4-123	Returns the total number of elements in this array.
“numberOfFields” on page 4-123	Returns the number of fields in this array.

classID. This method returns the MATLAB type of this array. The `classID` method of `MWStructArray` overrides the `classID` method of class `MWArray`.

The prototype for the `classID` method is

```
public MWClassID classID()
```

Input Parameters

None

Example — Getting the Class ID of a Structure Array

Create an `MWStructArray` object and display the class ID:

```
int[] sdims = {1, 2};
String[] sfields = {"f1", "f2", "f3"};

MWStructArray S = new MWStructArray(sdims, sfields);

System.out.println("The class of S is " + S.classID());
```

When run, the example displays this output:

```
The class of S is struct
```

fieldNames. This method returns the field names in this array.

The prototype for the `fieldNames` method is

```
public java.lang.String[] fieldNames()
```

Input Parameters

None

Example — Getting the Field Names of a Structure Array

Create an `MWStructArray` object with three fields and display the field names:

```
int[] sdims = {1, 2};
String[] sfields = {"f1", "f2", "f3"};
MWStructArray S = new MWStructArray(sdims, sfields);

String[] str = S.fieldNames();

System.out.print("The structure has the fields: ");
for (int i=0; i<S.numberOfFields(); i++)
    System.out.print(" " + str[i]);
```

When run, the example displays this output:

```
The structure has the fields:  f1 f2 f3
```

getDimensions. `MWStructArray` inherits this method from the `MWArray` class.

isEmpty. `MWStructArray` inherits this method from the `MWArray` class.

numberOfDimensions. `MWStructArray` inherits this method from the `MWArray` class.

numberOfElements. `MWStructArray` inherits this method from the `MWArray` class.

numberOfFields. This method returns the number of fields in this array.

The prototype for the `numberOfFields` method is

```
public int numberOfFields()
```

Input Parameters

None

Example — Getting the Number of Fields in a Structure Array

Create an `MWStructArray` object with three fields and display the number of fields:

```
int[] sdims = {1, 2};  
String[] sfields = {"f1", "f2", "f3"};  
MWStructArray S = new MWStructArray(sdims, sfields);  
  
String[] str = S.fieldNames();  
  
System.out.println("There are " + S.numberOfFields() +  
    " fields in this structure.");
```

When run, the example displays this output:

```
There are 3 fields in this structure.
```

Methods to Get and Set Data in the `MWStructArray`

Use these methods to get and set values in an object of class `MWStructArray`.

Method	Description
“get” on page 4-125	Returns the element at the specified offset as an <code>Object</code> .
“getData” on page 4-127	Returns a one-dimensional array containing a copy of the data in the underlying MATLAB array.

Method	Description
“getField” on page 4-128	Returns a shared copy of the element at the specified one-based offset and field name in this array as an MArray instance.
“set” on page 4-129	Replaces the element at the specified one-based offset in this array with the specified element.
“toArray” on page 4-131	Returns an array containing a copy of the data in the underlying MATLAB array. The returned array has the same dimensionality as the MATLAB array.

get. This method returns the element at the specified one-based offset in this array. The returned element is converted to a Java array using default conversion rules.

To get the element at a specific index, use one of the following. Calling this method is equivalent to calling `getField(index).toArray()`.

```
public Object get(int index)
public Object get(int[] index)
```

To get the element at a specific index and structure field, use one of the following. Calling this method is equivalent to calling `getField(fieldname, index).toArray()`.

```
public Object get(String fieldname, int index)
public Object get(String fieldname, int[] index)
```

Use the first syntax (`int index`) to return the element at the specified one-based offset in the array, accessing elements in column-wise order. Use the second syntax (`int[] index`) to return the element at the specified array of one-based indices. The first syntax offers better performance than the second.

Input Parameters

`fieldname`

Field name of the requested element

`index`

Index of the requested element in the `MWStructArray`

In the case where `index` is of type `int`, the valid range for `index` is $1 \leq \text{index} \leq N$, where N is the total number of elements in the array.

In the case where `index` is of type `int[]`, each element of the `index` vector is an index along one dimension of the `MWStructArray` object. The valid range for any `index` is $1 \leq \text{index}[i] \leq N[i]$, where $N[i]$ is the size of the i th dimension.

Exceptions

The `get` method throws the following exception:

`IndexOutOfBoundsException`

The specified `index` parameter is invalid.

Example — Getting Structure Array Data with `get`

Get the data stored in field `f2` at index `(1, 1)` of `MWStructArray` object `S`:

```
int[] sdims = {1, 2};
String[] sfields = {"f1", "f2", "f3"};
Integer val = new Integer(555);

MWStructArray S = new MWStructArray(sdims, sfields);

int[] index = {1, 1};
S.set(sfields[2], index, val);

Object d_out = S.get(sfields[2], index);
System.out.println("Structure data S(1,1).f2 is " +
    d_out.toString());
```

When run, the example displays this output:

Structure data S(1,1).f2 is 555

getData. This method returns a one-dimensional array containing a copy of the data in the underlying MATLAB array. The `getData` method of `MWStructArray` overrides the `getData` method of class `MWArray`.

The prototype for the `getData` method is

```
public Object getData()
```

`getData` returns a one-dimensional array of elements stored in column-wise order. Before converting, a new array is derived by transforming the struct array into a cell array such that an N-by-M-by-... struct array with P fields is transformed into a P-by-N-by-M-by-... cell array. Each element in the returned array is converted to a Java array when you call `MWArray.toArray()` on the corresponding cell.

Input Parameters

None

Example — Getting Structure Array Data with `getData`

Get the data stored in all fields and indices of `MWStructArray` object S:

```
int[] sdims = {1, 2};
String[] sfields = {"f1", "f2", "f3"};
MWStructArray S = new MWStructArray(sdims, sfields);

int count = S.numberOfElements() * S.numberOfFields();

// Initialize the structure.
Integer[] val = new Integer[6];
for (int i = 0; i < count; i++)
    val[i] = new Integer((i+1) * 15);

// Use getData to get data from the structure.
System.out.println("Data read from structure array S: \n");
```

```
MWArray[] x = (MWArray[]) S.getData();
for (int i = 0; i < x.length; i++)
    System.out.print(" " + x[i]);
```

When run, the example displays this output:

```
Data read from structure array S:
```

```
15
30
45
60
75
90
```

getField. This method returns a shared copy of the element at the specified one-based index array and field name in this array as an MWArray instance.

To get the element at a specific index, use one of

```
public MWArray getField(int index)
public MWArray getField(int[] index)
```

To get the element at a specific index and structure field, use one of

```
public MWArray getField(String fieldname, int index)
public MWArray getField(String fieldname, int[] index)
```

Use the first syntax (`int index`) to return the element at the specified one-based offset in the array, accessing elements in column-wise order. Use the second syntax (`int[] index`) to return the element at the specified array of one-based indices. The first syntax offers better performance than the second.

Dispose of the returned MWArray reference by calling `MWArray.dispose()`.

Input Parameters

`fieldname`

Field name of the requested element

`index`

Index of the requested element in the `MWStructArray`

In the case where `index` is of type `int`, the valid range for `index` is $1 \leq \text{index} \leq N$, where N is the total number of elements in the array.

In the case where `index` is of type `int[]`, each element of the `index` vector is an index along one dimension of the `MWStructArray` object. The valid range for any `index` is $1 \leq \text{index}[i] \leq N[i]$, where $N[i]$ is the size of the i th dimension.

Exceptions

The `get` method throws the following exception:

`IndexOutOfBoundsException`

The specified `index` parameter is invalid

set. This method returns the element at the specified one-based offset in this array. The `set` method of `MWStructArray` overrides the `set` method of class `MWArray`.

To set the element at a specific index, use one of

```
public void set(int index, Object element)
public void set(int[] index, Object element)
```

To set the element at a specific index and structure field, use one of

```
public void set(String fieldname, int index, Object element)
public void set(String fieldname, int[] index, Object element)
```

Use the first syntax (`int index`) to return the element at the specified one-based offset in the array, accessing elements in column-wise order. Use the

second syntax (`int[] index`) to return the element at the specified array of one-based indices. The first syntax offers better performance than the second.

Input Parameters

`fieldname`

Field name of the requested element

`index`

Index of the requested element in the `MWStructArray`

In the case where `index` is of type `int`, the valid range for `index` is $1 \leq \text{index} \leq N$, where N is the total number of elements in the array.

In the case where `index` is of type `int[]`, each element of the `index` vector is an index along one dimension of the `MWStructArray` object. The valid range for any index is $1 \leq \text{index}[i] \leq N[i]$, where $N[i]$ is the size of the i th dimension.

`element`

New element to replace at `index`

If `element` is of type `MWArray`, the cell at `index` is set to a shared copy of the underlying MATLAB array. Otherwise, a new MATLAB array is created from `element` using default conversion rules and assigned to the cell at `index`.

Exceptions

The `set` method throws the following exception:

`IndexOutOfBoundsException`

The specified `index` parameter is invalid.

Example — Setting Values in a Structure Array

```
int[] sdims = {1, 2};
String[] sfields = {"f1", "f2", "f3"};
MWStructArray S = new MWStructArray(sdims, sfields);

Integer[] val = new Integer[25];
for (int i = 0; i < 6; i++)
    val[i] = new Integer(i * 15);

for (int i = 0; i < 2; i++)
    for (int j = 0; j < sfields.length; j++)
        S.set(sfields[j], i+1, val[j + (i * 3)]);

// Use getData to get data from the structure.
System.out.println("Data read from structure array S: \n");
Object[] x = (Object[]) S.getData();
for (int i = 0; i < x.length; i++)
    System.out.print(" " + ((int[][][]) x[i])[0][0]);
```

When run, the example displays this output:

```
Data read from structure array S:
```

```
0 15 30 45 60 75
```

toArray. This method returns an array containing a copy of the data in the underlying MATLAB array.

The prototype for the `toArray` method is

```
public Object[] toArray()
```

`toArray` returns an array with the same dimensionality as the MATLAB array. Before converting, a new array is derived by transforming the struct array into a cell array such that an N-by-M-by-... struct array with P fields is transformed into a P-by-N-by-M-by-... cell array. Each element in the returned array is converted to a Java array when you call `MWArray.toArray()` on the corresponding cell.

Input Parameters

None

Example — Getting Structure Array Data with toArray

```
int[] sdims = {1, 2};
String[] sfields = {"f1", "f2", "f3"};
MWStructArray S = new MWStructArray(sdims, sfields);

Integer[] val = new Integer[25];
for (int i = 0; i < 6; i++)
    val[i] = new Integer(i * 15);

for (int i = 0; i < 2; i++)
    for (int j = 0; j < sfields.length; j++)
        S.set(sfields[j], i+1, val[j + (i * 3)]);

Object[][][] x = (Object[][][]) S.toArray();
System.out.println();

System.out.println("Data read from structure array S \n");
for (int j = 0; j < 2; j++)
    for (int i = 0; i < x.length; i++)
        System.out.print(" " + ((int[][] x[i][0][j])[0][0]));
```

When run, the example displays this output:

```
Data read from structure array S

0 15 30 45 60 75
```

Methods to Copy, Convert, and Compare MWStructArrays

Use these methods to copy, convert, and compare objects of class MWStructArray.

Method	Description
“clone” on page 4-133	Creates and returns a deep copy of this array.
“compareTo” on page 4-134	Compares this array with the specified array for order.
“equals” on page 4-134	Indicates whether some other array is equal to this one.
“hashCode” on page 4-134	Returns a hash code value for the array.
“sharedCopy” on page 4-134	Creates and returns a shared copy of this array.
“toString” on page 4-135	Returns a string representation of the array.

clone. This method creates and returns a deep copy of this array. Because clone allocates a new array, any changes made to this new array are not reflected in the original.

The clone method of `MWStructArray` overrides the clone method of class `MWArray`.

The prototype for the clone method is

```
public Object clone()
```

Input Parameters

None

Exceptions

The clone method throws the following exception:

`IndexOutOfBoundsException`

The specified index parameter is invalid.

Example — Cloning a Structure Array Object

Create an MWStructArray object and then a clone of that object:

```
int[] sdims = {1, 2};
String[] sfields = {"f1", "f2", "f3"};
MWStructArray S = new MWStructArray(sdims, sfields);

Object C = S.clone();

System.out.println("Clone of structure S is:");
System.out.println(C.toString());
```

When run, the example displays this output:

```
Clone of structure S is:
1x2 struct array with fields:
    f1
    f2
    f3
```

compareTo. MWStructArray inherits this method from the MWArray class.

equals. MWStructArray inherits this method from the MWArray class.

hashCode. MWStructArray inherits this method from the MWArray class.

sharedCopy. This method creates and returns a shared copy of the MWStructArray object. The shared copy points to the underlying original MATLAB array. Any changes made to the copy are reflected in the original.

The sharedCopy method of MWStructArray overrides the sharedCopy method of class MWArray.

The prototype for the sharedCopy method is

```
public Object sharedCopy()
```

Input Parameters

None

Example — Making a Shared Copy of a Structure Array Object

Create an `MWStructArray` object and then a shared copy of that object:

```
int[] sdims = {1, 2};
String[] sfields = {"f1", "f2", "f3"};
MWStructArray S = new MWStructArray(sdims, sfields);

Object C = S.sharedCopy();

System.out.println("Shared copy of structure S is:");
System.out.println(C.toString());
```

When run, the example displays this output:

```
Shared copy of structure S is:
1x2 struct array with fields:
    f1
    f2
    f3
```

toString. `MWStructArray` inherits this method from the `MWArray` class.

Using `MWCellArray`

This section covers the following topics:

- “Constructing an `MWCellArray`” on page 4-136
- “Methods to Destroy an `MWCellArray`” on page 4-137
- “Methods to Return Information About an `MWCellArray`” on page 4-138
- “Methods to Get and Set Data in the `MWCellArray`” on page 4-140
- “Methods to Copy, Convert, and Compare `MWCellArrays`” on page 4-147

Constructing an MWCellArray

Use the tables in this section to construct an `MWCellArray` from a particular Java data type. See the examples at the end of this section for more help:

Constructing an Empty Cell Array. To construct an empty 0-by-0 MATLAB cell array, use

```
MWCellArray();
```

To construct an `MWCellArray` object with the specified dimensions, use

```
MWCellArray(int[] dims);
```

To construct an `MWCellArray` object with the specified number of rows and columns, use

```
MWCellArray(int rows, int cols);
```

Input Parameters

`dims`

Array of dimension sizes

`rows`

Number of rows

`cols`

Number of columns

Exceptions

The `MWCellArray` constructor throws the following exception:

`NegativeArraySizeException`

The specified `dims` parameter is negative.

Example — Constructing an Empty Cell Array Object

This first example creates an empty `MWCellArray` object:

```
MWCellArray C = new MWCellArray();
System.out.println("C = " + C.toString());
```

When run, the example displays this output:

```
C = []
```

Example — Constructing an Initialized Cell Array Object

The second example constructs and initializes a 2-by-3 `MWCellArray` object:

```
int[] cdims = {2, 3};
MWCellArray C = new MWCellArray(cdims);

Integer[] val = new Integer[6];
for (int i = 0; i < 6; i++)
    val[i] = new Integer(i * 15);

for (int i = 0; i < 2; i++)
    for (int j = 0; j < 3; j++)
    {
        int[] idx = {i+1, j+1};
        C.set(idx, val[j + (i * 3)]);
    }

System.out.println("C = " + C.toString());
```

When run, the example displays this output:

```
C =      [ 0]    [15]    [30]
         [45]    [60]    [75]
```

Methods to Destroy an `MWCellArray`

To destroy the arrays, use either `dispose` or `disposeArray`.

Method	Description
“dispose” on page 4-138	Frees the native MATLAB array contained by this array.
“disposeArray” on page 4-138	Frees all native MATLAB arrays contained in the input object.

dispose. This method frees the native MATLAB array contained by this array. The dispose method of MWCellArray overrides the dispose method of class MWArray.

The prototype for the dispose method is as follows:

```
public void dispose()
```

All MWArray references returned by `get(int)`, `toArray()`, or `getData()` are also disposed of.

Input Parameters

None

Example — Disposing of a Cell Array Object

Create a 2-by-3 MWCellArray object and then dispose of it.

```
int[] cdims = {2, 3};  
MWCellArray C = new MWCellArray(cdims);  
  
C.dispose();
```

disposeArray. MWCellArray inherits this method from the MWArray class.

Methods to Return Information About an MWCellArray

Use these methods to return information about an object of class MWCellArray.

Method	Description
“classID” on page 4-139	Returns the MATLAB type of this array.
“getDimensions” on page 4-139	Returns an array containing the size of each dimension of this array.
“isEmpty” on page 4-140	Tests whether the array has no elements.
“numberOfDimensions” on page 4-140	Returns the number of dimensions of this array.
“numberOfElements” on page 4-140	Returns the total number of elements in this array.

classID. This method returns the MATLAB type of this array. The `classID` method of `MWCellArray` overrides the `classID` method of class `MWArray`.

The prototype for the `classID` method is

```
public MWClassID classID()
```

Input Parameters

None

Example — Getting the Class ID of a Cell Array

Create an `MWCellArray` object and display its class:

```
int[] cdims = {2, 3};
MWCellArray C = new MWCellArray(cdims);

System.out.println("Class of C is " + C.classID());
```

When run, the example displays this output:

```
Class of C is cell
```

getDimensions. `MWCellArray` inherits this method from the `MWArray` class.

isEmpty. MWCellArray inherits this method from the MWArray class.

numberOfDimensions. MWCellArray inherits this method from the MWArray class.

numberOfElements. MWCellArray inherits this method from the MWArray class.

Methods to Get and Set Data in the MWCellArray

Use these methods to get and set values in an object of class MWCellArray.

Method	Description
“get” on page 4-140	Returns the element at the specified offset as an Object.
“getCell” on page 4-142	Returns a shared copy of the element at the specified one-based offset in this array as an MWArray instance.
“getData” on page 4-143	Returns a one-dimensional array containing a copy of the data in the underlying MATLAB array.
“set” on page 4-144	Replaces the element at the specified one-based offset in this array with the specified element.
“toArray” on page 4-146	Returns an array containing a copy of the data in the underlying MATLAB array. The returned array has the same dimensionality as the MATLAB array.

get. This method returns the element at the specified one-based offset in this array. The returned element is converted to a Java array using default conversion rules. Calling this method is equivalent to calling `getCell(index).toArray()`.

The `get` method of MWCellArray overrides the `get` method of class MWArray.

To get the element at a specific index, use one of the following:

```
public Object get(int index)
public Object get(int[] index)
```

Use the first syntax (`int index`) to return the element at the specified one-based offset in the array, accessing elements in column-wise order. Use the second syntax (`int[] index`) to return the element at the specified array of one-based indices. The first syntax offers better performance than the second.

Input Parameters

`index`

Index of the requested element in the `MWCellArray`

In the case where `index` is of type `int`, the valid range for `index` is $1 \leq \text{index} \leq N$, where N is the total number of elements in the array.

In the case where `index` is of type `int[]`, each element of the `index` vector is an index along one dimension of the `MWCellArray` object. The valid range for any `index` is $1 \leq \text{index}[i] \leq N[i]$, where $N[i]$ is the size of the i th dimension.

Exceptions

The `get` method throws the following exception:

`IndexOutOfBoundsException`

The specified `index` parameter is invalid.

Example — Getting Data from a Cell Array with `get`

Use `get` to read index (1,3) of `MWCellArray` object `C`:

```
int[] cdims = {1, 3};
MWCellArray C = new MWCellArray(cdims);

Integer val = new Integer(15);
int[] index = {1, 3};
```

```
C.set(index, val);

Object x = C.get(index);
System.out.println("Cell data C(1,3) is " + x.toString());
```

When run, the example displays this output:

```
Cell data C(1,3) is      15
```

getCell. This method returns a shared copy of the element at the specified one-based offset in this array as an MWArray instance.

To get the element at a specific index, use one of the following:

```
public MWArray getCell(int index)
public MWArray getCell(int[] index)
```

Use the first syntax (`int index`) to return the element at the specified one-based offset in the array, accessing elements in column-wise order. Use the second syntax (`int[] index`) to return the element at the specified array of one-based indices. The first syntax offers better performance than the second.

`getCell` returns an MWArray instance representing the requested cell. When you are done using this instance, call `MWArray.dispose()` to dispose of it.

Input Parameters

`index`

Index of the requested element in the MWCellArray

In the case where `index` is of type `int`, the valid range for `index` is $1 \leq \text{index} \leq N$, where N is the total number of elements in the array.

In the case where `index` is of type `int[]`, each element of the `index` vector is an index along one dimension of the MWCellArray object. The valid range for any `index` is $1 \leq \text{index}[i] \leq N[i]$, where $N[i]$ is the size of the i th dimension.

Exceptions

The `getCell` method throws the following exception:

`IndexOutOfBoundsException`

The specified index parameter is invalid.

getData. This method returns a one-dimensional array containing a copy of the data in the underlying MATLAB array. The `getData` method of `MWCellArray` overrides the `getData` method of class `MWArray`.

The prototype for the `getData` method is as follows:

```
public Object getData()
```

`getData` returns a one-dimensional array of elements stored in column-wise order. Each element in the returned array is converted to a Java array when you call `MWArray.toArray()` on the corresponding cell.

Input Parameters

None

Example — Getting Cell Array Data with `getData`

Use `getData` to read data from `MWCellArray` object `C`:

```
int[] cdims = {1, 3};
MWCellArray C = new MWCellArray(cdims);

Integer[] val = new Integer[3];
for (int i = 0; i < 3; i++)
    val[i] = new Integer(i * 15);

for (int i = 1; i <= 3; i++)
    C.set(i, val[i-1]);
```

```
System.out.println("Data read from cell array C: \n");
MWArray[] x = (MWArray[]) C.getData();

for (int i = 0; i < x.length; i++)
    System.out.println(x[i]);

System.out.println();
```

When run, the example displays this output:

```
Data read from cell array C:
  0
  0
  0
```

set. This method replaces the element at the specified one-based offset in this array with the specified element. The `set` method of `MWCellArray` overrides the `set` method of class `MWArray`.

To get the element at a specific index, use one of the following:

```
public void set(int index, Object element)
public void set(int[] index, Object element)
```

Use the first syntax (`int index`) to return the element at the specified one-based offset in the array, accessing elements in column-wise order. Use the second syntax (`int[] index`) to return the element at the specified array of one-based indices. The first syntax offers better performance than the second.

Input Parameters

element

New element to replace at index

If `element` is of type `MWArray`, the cell at `index` is set to a shared copy of the underlying MATLAB array. Otherwise, a new MATLAB array is created from `element` using default conversion rules and assigned to the cell at `index`.

`index`

Index of the requested element in the `MWCellArray`

In the case where `index` is of type `int`, the valid range for `index` is $1 \leq \text{index} \leq N$, where N is the total number of elements in the array.

In the case where `index` is of type `int[]`, each element of the `index` vector is an index along one dimension of the `MWCellArray` object. The valid range for any `index` is $1 \leq \text{index}[i] \leq N[i]$, where $N[i]$ is the size of the i th dimension.

Exceptions

The `set` method throws the following exception:

`IndexOutOfBoundsException`

The specified `index` parameter is invalid.

Example — Setting Values in a Cell Array

Set the value of the `MWCellArray` object `C` at index `(1,3)`:

```
int[] cdims = {1, 3};
MWCellArray C = new MWCellArray(cdims);

Integer val = new Integer(15);
int[] index = {1, 3};

C.set(index, val);

Object x = C.get(index);
System.out.println("Cell data C(1,3) is " + x.toString());
```

When run, the example displays this output:

```
Cell data C(1,3) is      15
```

toArray. This method returns an array containing a copy of the data in the underlying MATLAB array.

The prototype for the `toArray` method is as follows:

```
public Object[] toArray()
```

`toArray` returns an array with the same dimensionality as the MATLAB array. Each element in the returned array is converted to a Java array when you call `MWArray.toArray()` on the corresponding cell.

Input Parameters

None

Example — Getting Cell Array Data with `toArray`

```
int[] cdims = {1, 3};
MWCellArray C = new MWCellArray(cdims);

System.out.println("Data read from cell array C \n");
Object x = (Object) C.toArray();
System.out.println();

for (int i = 0; i < x[0].length; i++)
    System.out.println(x[0][i]);
```

When run, the example displays this output:

```
Data read from cell array C
[]
[]
[]
```

Methods to Copy, Convert, and Compare MWCellArrays

Use these methods to copy, convert, and compare objects of class MWCellArray.

Method	Description
“clone” on page 4-147	Creates and returns a deep copy of this array.
“compareTo” on page 4-148	Compares this array with the specified array for order.
“equals” on page 4-148	Indicates whether some other array is equal to this one.
“hashCode” on page 4-148	Returns a hash code value for the array.
“sharedCopy” on page 4-148	Creates and returns a shared copy of this array.
“toString” on page 4-149	Returns a string representation of the array.

clone. This method creates and returns a deep copy of this array. Because clone allocates a new array, any changes made to this new array are not reflected in the original.

The clone method of MWCellArray overrides the clone method of class MWArray.

The prototype for the clone method is as follows:

```
public Object clone()
```

Input Parameters

None

Exceptions

The clone method throws the following exception:

`IndexOutOfBoundsException`

The specified index parameter is invalid.

Example — Cloning a Cell Array Object

Create an `MWCellArray` object and then a clone of that object:

```
int[] cdims = {1, 3};
MWCellArray C = new MWCellArray(cdims);

Object X = C.clone();

System.out.println("Clone of cell array C is:");
System.out.println(X.toString());
```

When run, the example displays this output:

```
Clone of cell array C is:
    []    []    []
```

compareTo. `MWCellArray` inherits this method from the `MWArray` class.

equals. `MWCellArray` inherits this method from the `MWArray` class.

hashCode. `MWCellArray` inherits this method from the `MWArray` class.

sharedCopy. This method creates and returns a shared copy of the `MWCellArray` object. The shared copy points to the underlying original MATLAB array. Any changes made to the copy are reflected in the original.

The `sharedCopy` method of `MWCellArray` overrides the `sharedCopy` method of class `MWArray`.

The prototype for the `sharedCopy` method is

```
public Object sharedCopy()
```

Input Parameters

None

Example — Making a Shared Copy of a Cell Array Object

Create an `MWCellArray` object and then a shared copy of that object:

```
int[] cdims = {1, 3};
MWCellArray C = new MWCellArray(cdims);

Object X = C.sharedCopy();

System.out.println("Shared copy of cell array C is:");
System.out.println(X.toString());
```

When run, the example displays this output:

```
Shared copy of cell array C is:
[] [] []
```

toString. `MWCellArray` inherits this method from the `MWArray` class.

Using MWClassID

The `MWClassID` class enumerates all MATLAB array types. This class contains no public constructors. A set of public static `MWClassID` instances is provided, one for each MATLAB array type.

`MWClassID` extends class `java.lang.Object`.

`MWClassID` implements interface `java.io.Serializable`.

Fields of MWClassID

CELL. `CELL` represents MATLAB array type `cell`.

CHAR. CHAR represents MATLAB array type char.

DOUBLE. DOUBLE represents MATLAB array type double.

FUNCTION. FUNCTION represents MATLAB array type function.

Note MATLAB function arrays are not supported in the current release.

INT8. INT8 represents MATLAB array type int8.

INT16. INT16 represents MATLAB array type int16.

INT32. INT32 represents MATLAB array type int32.

INT64. INT64 represents MATLAB array type int64.

LOGICAL. LOGICAL represents MATLAB array type logical.

OBJECT. OBJECT represents MATLAB array type object.

Note MATLAB object arrays are not supported in the current release.

OPAQUE. OPAQUE represents MATLAB array type opaque.

Note MATLAB opaque arrays are not supported in the current release.

SINGLE. SINGLE represents MATLAB array type single.

STRUCT. STRUCT represents MATLAB array type struct.

UINT8. UINT8 represents MATLAB array type uint8.

UINT16. UINT16 represents MATLAB array type uint16.

UINT32. UINT32 represents MATLAB array type uint32.

UINT64. UINT64 represents MATLAB array type uint64.

UNKNOWN. UNKNOWN represents MATLAB empty array type.

Example — Specifying an MWClassID Value

Construct a scalar numeric array of type MWClassID.INT16:

```
double AReal = 24;

MWNumericArray A = new MWNumericArray(AReal, MWClassID.INT16);
System.out.println("Array A of type " + A.classID() + " = \n" + A);
```

When you run this example, the results are as follows:

```
Array A of type int16 =
    24
```

Methods of MWClassID

equals. This method indicates whether some other MWClassID is equal to this one. The equals method of MWClassID overrides the equals method of class java.lang.Object.

The prototype for equals is as follows:

```
public final boolean equals(java.lang.Object obj)
```

getSize. This method returns the size in bytes of an array element of this type.

The prototype for getSize is as follows:

```
public final int getSize()
```

hashCode. This method returns a hash code value for the type. The hashCode method of MWClassID overrides the hashCode method of class java.lang.Object.

The prototype for hashCode is as follows:

```
public final int hashCode()
```

isNumeric. This method tests if this type is numeric.

The prototype for isNumeric is as follows:

```
public boolean isNumeric()
```

toString. This method returns a string representation of the property. The toString method of MWClassID overrides the toString method of class java.lang.Object.

The prototype for toString is as follows:

```
public final java.lang.String toString()
```

Using MWComplexity

The MWComplexity class enumerates the MATLAB real/complex array property. This class contains no public constructors. A set of public static MWComplexity instances is provided, one to represent real and one for complex.

MWComplexity extends class java.lang.Object.

MWComplexity implements interface java.io.Serializable.

Fields of MWComplexity

REAL. REAL represents a real numeric value. The prototype for REAL is as follows:

```
public static final MWComplexity REAL
```

COMPLEX. COMPLEX represents a complex numeric value containing both real and imaginary parts. The prototype for COMPLEX is as follows:

```
public static final MWComplexity COMPLEX
```

Example – Determining the Complexity of an Array

Determine whether matrix A is real or complex. The complexity method of `MWNumericArray` returns an enumeration of type `MWComplexity`.

```
double AReal = 24;
double AImag = 5;

MWNumericArray A = new MWNumericArray(AReal, AImag);
System.out.println("A is a " + A.complexity() + " matrix");
```

When run, the example displays this output:

```
A is a complex matrix
```

Methods of `MWComplexity`

toString. This method returns a string representation of the property. The `toString` method of `MWComplexity` overrides the `toString` method of class `java.lang.Object`.

The prototype for the `toString` method is as follows:

```
public java.lang.String toString()
```

Sample Applications (Java)

Note The examples for MATLAB Builder for Java are in `matlabroot\toolbox\javabuilder\Examples`.

In addition to these examples, see “Example: Magic Square” on page 1-15 for a simple example that gets you started using MATLAB Builder for Java.

Plot Example (p. 5-2)

How to encapsulate a MATLAB function that draws a plot given two input arguments

Spectral Analysis Example (p. 5-8)

How to create a class that has two methods

Matrix Math Example (p. 5-16)

How to create and use a class with three methods that encapsulate MATLAB functions

Plot Example

The purpose of the example is to show you how to do the following:

- Use MATLAB Builder for Java to convert a MATLAB function (`drawplot`) to a method of a Java class (`plotter`) and wrap the class in a Java component (`plotdemo`).
- Access the component in a Java application (`createplot.java`) by instantiating the `plotter` class and using the `MWArray` class library to handle data conversion.

Note For complete reference information about the `MWArray` class hierarchy, see the `com.mathworks.toolbox.javabuilder` package.

- Build and run the `createplot.java` application.

The `drawplot` function displays a plot of input parameters `x` and `y`.

Plot Example: Step-by-Step Procedure

- 1 If you have not already done so, copy the files for this example as follows:
 - a. Copy the following directory that ships with MATLAB to your work directory:

```
matlabroot\toolbox\javabuilder\Examples\PlotExample
```
 - b. At the MATLAB command prompt, `cd` to the new `PlotExample` subdirectory in your work directory.
- 2 If you have not already done so, set the environment variables that are required on a development machine. See “Settings for Environment Variables (Development Machine)” on page 6-2.
- 3 Write the `drawplot` function as you would any MATLAB function.

The following code defines the `drawplot` function:

```
function drawplot(x,y)
```

```
plot(x,y);
```

This code is already in your work directory in `PlotExample\PlotDemoComp\drawplot.m`.

4 Specify a Java component as follows:

- a. While in MATLAB, issue the following command to open the Deployment Tool dialog box:

```
deploytool
```

- b. Create a new project with these settings:

Field	Value
Component name	plotdemo
Class name	plotter
Show verbose output	Selected

- c. Add the `computefft.m` and `plotfft.m` M-files to the project.
- d. Save the project.

5 Build the component.

6 Write source code for an application that accesses the component.

The sample application for this example is in `matlabroot\toolbox\javabuilder\Examples\PlotExample\PlotDemoJavaApp\createplot.java`.

The program graphs a simple parabola from the equation $y = x^2$

The program listing is shown here.

createplot.java

```
/* createplot.java
 * This file is used as an example for the MATLAB
 * Builder for Java product.
 *
 * Copyright 2001-2006 The MathWorks, Inc.
 */

/* Necessary package imports */
import com.mathworks.toolbox.javabuilder.*;
import plotdemo.*;

/*
 * createplot class demonstrates plotting x-y data into
 * a MATLAB figure window by graphing a simple parabola.
 */
class createplot
{
    public static void main(String[] args)
    {
        MWNumericArray x = null; /* Array of x values */
        MWNumericArray y = null; /* Array of y values */
        plotter thePlot = null; /* Plotter class instance */
        int n = 20; /* Number of points to plot */

        try
        {
            /* Allocate arrays for x and y values */
            int[] dims = {1, n};
            x = MWNumericArray.newInstance(dims,
                MWClassID.DOUBLE, MWComplexity.REAL);
            y = MWNumericArray.newInstance(dims,
                MWClassID.DOUBLE, MWComplexity.REAL);

            /* Set values so that y = x^2 */
            for (int i = 1; i <= n; i++)
            {
```

```
        x.set(i, i);
        y.set(i, i*i);
    }

    /* Create new plotter object */
    thePlot = new plotter();

    /* Plot data */
    thePlot.drawplot(x, y);
}

catch (Exception e)
{
    System.out.println("Exception: " + e.toString());
}

finally
{
    /* Free native resources */
    MWArray.disposeArray(x);
    MWArray.disposeArray(y);
    if (thePlot != null)
        thePlot.dispose();
}
}
}
```

The program does the following:

- Creates two arrays of double values, using `MWNumericArray` to represent the data needed to plot the equation.
- Instantiates the plotter class as `thePlot` object, as shown:

```
thePlot = new plotter();
```

- Calls the `drawplot` method to plot the equation using the MATLAB plot function, as shown:

```
thePlot.drawplot(x,y);
```

- Uses a try-catch block to catch and handle any exceptions.

7 Compile the createplot application using javac.

- a. On Windows, execute the following command:

```
javac -classpath
    .;matlabroot\java\jar\toolbox\javabuilder.jar;
    .\distrib\plotdemo.jar createplot.java
```

- b. On UNIX, execute this command:

```
javac -classpath
    .:matlabroot/java/jar/toolbox/javabuilder.jar:
    ./distrib/plotdemo.jar createplot.java
```

8 Run the application.

To run the createplot.class file, do one of the following:

On Windows, type

```
java -classpath
    .;matlabroot\java\jar\toolbox\javabuilder.jar;
    .\distrib\plotdemo.jar
    -Djava.library.path=matlabroot\bin\win32;.\distrib
    createplot
```

On UNIX, type

```
java -classpath
    .:matlabroot/java/jar/toolbox/javabuilder.jar:
    ./distrib/plotdemo.jar
    -Djava.library.path=matlabroot/bin/<Arch>./distrib
    createplot
% where <Arch> = glux86 gluxa64 sol2
```

Note The supported JRE version is 1.5.0. To find out what JRE you are using, refer to the output of 'version - java' in MATLAB or refer to the jre.cfg file in *matlabroot/sys/java/jre/<arch>* or *mcrroot/sys/java/jre/<arch>*.

The createplot program should display the output:

Spectral Analysis Example

The purpose of the example is to show you the following:

- How to use MATLAB Builder for Java to create a component (spectralanalysis) containing a class that has a private method that is automatically encapsulated.
- How to access the component in a Java application (powerspect.java), including use of the MWArray class hierarchy to represent data.

Note For complete reference information about the MWArray class hierarchy, see the `com.mathworks.toolbox.javabuilder` package.

- How to build and run the application

The component spectralanalysis analyzes a signal and graphs the result. The class, `fourier`, performs a Fast Fourier Transform (FFT) on an input data array. A method of this class, `computefft`, returns the results of that FFT as two output arrays — an array of frequency points and the power spectral density. The second method, `plotfft`, graphs the returned data. These two methods, `computefft` and `plotfft`, encapsulate MATLAB functions.

The MATLAB code for these two methods is in `computefft.m` and `plotfft.m`, which can be found in `matlabroot\toolbox\javabuilder\Examples\SpectraExample\SpectraDemoComp`.

computefft.m

```
function [fftData, freq, powerSpect] = ComputeFFT(data, interval)
% COMPUTEFFT Computes the FFT and power spectral density.
% [FFTDATA, FREQ, POWERSPECT] = COMPUTEFFT(DATA, INTERVAL)
% Computes the FFT and power spectral density of the input data.
% This file is used as an example for the .NET Builder
% product.
% Copyright 2001-2006 The MathWorks, Inc.
if (isempty(data))
    fftdata = [];
    freq = [];
```

```

        powerspect = [];
        return;
    end
    if (interval <= 0)
        error('Sampling interval must be greater than zero');
        return;
    end
    fftData = fft(data);
    freq = (0:length(fftData)-1)/(length(fftData)*interval);
    powerSpect = abs(fftData)/(sqrt(length(fftData)));

```

plotfft.m

```

function PlotFFT(fftData, freq, powerSpect)
%PLOTFFT Computes and plots the FFT and power spectral density.
% [FFTDATA, FREQ, POWERSPECT] = PLOTFFT(DATA, INTERVAL)
% Computes the FFT and power spectral density of the input data.
% This file is used as an example for the .NET Builder
% product.
% Copyright 2001-2006 The MathWorks, Inc.
len = length(fftData);
    if (len <= 0)
        return;
    end
    plot(freq(1:floor(len/2)), powerSpect(1:floor(len/2)))
    xlabel('Frequency (Hz)'), grid on
    title('Power spectral density')

```

Spectral Analysis Example: Step-by-Step Procedure

- 1 If you have not already done so, copy the files for this example as follows:
 - a. Copy the following directory that ships with MATLAB to your work directory:

```
matlabroot\toolbox\javabuilder\Examples\SpectraExample
```

- b. At the MATLAB command prompt, cd to the new SpectraExample subdirectory in your work directory.

- 2** If you have not already done so, set the environment variables that are required on a development machine. See “Settings for Environment Variables (Development Machine)” on page 6-2.
- 3** Write the M-code that you want to access.

This example uses `computefft.m` and `plotfft.m`, which are already in your work directory in `SpectraExample\SpectraDemoComp`.

- 4** Specify a Java component as follows:
 - a. While in MATLAB, issue the following command to open the Deployment Tool dialog box:

```
deploytool
```

- b. Create a new project with these settings:

Field	Value
Component name	spectralanalysis
Class name	fourier
Show verbose output	Selected

- c. Add the `plotfft.m` M-file to the project.

Note In this example, the application that uses the `fourier` class does not need to call `computefft` directly. The `computefft` method is required only by the `plotfft` method. Thus, when creating the component, you do not need to add the `computefft` function, although doing so does no harm.

- d. Save the project. Make note of the project directory because you will refer to it later when you build the program that will use it.
- 5** Build the component.

6 Write source code for an application that accesses the component.

The sample application for this example is in
SpectraExample\SpectraDemoJavaApp\powerspect.java.

The program listing is shown here.

powerspect.java

```
/* powerspect.java
 * This file is used as an example for the MATLAB
 * Builder for Java product.
 *
 * Copyright 2001-2006 The MathWorks, Inc.
 */

/* Necessary package imports */
import com.mathworks.toolbox.javabuilder.*;
import spectralanalysis.*;

/*
 * powerspect class computes and plots the power
 * spectral density of an input signal.
 */
class powerspect
{
    public static void main(String[] args)
    {
        double interval = 0.01;    /* Sampling interval */
        int nSamples = 1001;      /* Number of samples */
        MWNumericArray data = null; /* Stores input data */
        Object[] result = null;    /* Stores result */
        fourier theFourier = null; /* Fourier class instance */

        try
        {
            /*
             * Construct input data as sin(2*PI*15*t) +
             * sin(2*PI*40*t) plus a random signal.
             * Duration = 10
            */

```

```
        *   Sampling interval = 0.01
        */
int[] dims = {1, nSamples};
data = MWNumericArray.newInstance(dims, MWClassID.DOUBLE,
                                MWComplexity.REAL);

for (int i = 1; i <= nSamples; i++)
{
    double t = (i-1)*interval;
    double x = Math.sin(2.0*Math.PI*15.0*t) +
        Math.sin(2.0*Math.PI*40.0*t) +
        Math.random();
    data.set(i, x);
}

/* Create new fourier object */
theFourier = new fourier();

/* Compute power spectral density and plot result */
result = theFourier.plotfft(3, data,
    new Double(interval));
}

catch (Exception e)
{
    System.out.println("Exception: " + e.toString());
}

finally
{
    /* Free native resources */
    MWArray.disposeArray(data);
    MWArray.disposeArray(result);
    if (theFourier != null)
        theFourier.dispose();
}
}
}
```

The program does the following:

- Constructs an input array with values representing a random signal with two sinusoids at 15 and 40 Hz embedded inside of it
- Creates an `MWNumericArray` array that contains the data, as shown:

```
data = MWNumericArray.newInstance(dims, MWClassID.DOUBLE, MWComplexity.REAL);
```

- Instantiates a fourier object
- Calls the `plotfft` method, which calls `computefft` and plots the data
- Uses a `try/catch` block to handle exceptions
- Frees native resources using `MWArray` methods

7 Compile the `powerspect.java` application using `javac`.

- a. Open a Command Prompt window and `cd` to the `matlabroot\work\spectralanalysis` directory.
- b. On Windows, execute the following command:

```
javac -classpath  
.;matlabroot\java\jar\toolbox\javabuilder.jar;  
.\distrib\spectralanalysis.jar powerspect.java
```

- c. On UNIX, execute the following command:

```
javac -classpath  
.:matlabroot/java/jar/toolbox/javabuilder.jar:  
./distrib/spectralanalysis.jar powerspect.java
```

Note For `matlabroot` substitute the MATLAB root directory on your system. Type `matlabroot` to see this directory name.

8 Run the application

- On Windows, execute the `powerspect` class file as follows:

```
java -classpath
```

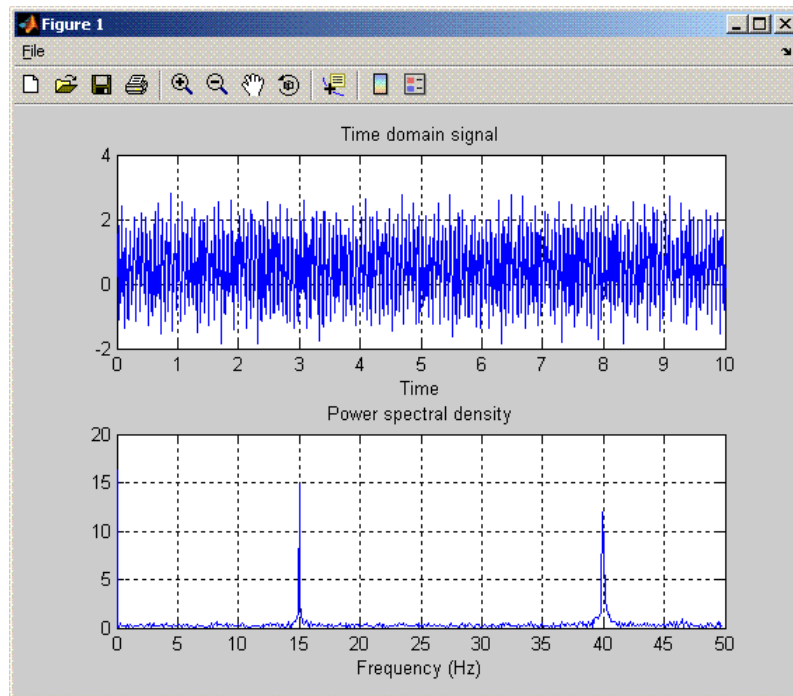

```
.;matlabroot\java\jar\toolbox\javabuilder.jar;  
.\distrib\spectralanalysis.jar  
-Djava.library.path=matlabroot\bin\win32;.\distrib  
powerspect
```

- On UNIX, execute the powerspect class file as follows:

```
java -classpath  
.:matlabroot/java/jar/toolbox/javabuilder.jar:  
./distrib/spectralanalysis.jar  
-Djava.library.path=matlabroot/bin/<Arch>./distrib  
powerspect  
% where <Arch> = glux86 gluxa64 sol2
```

Note The supported JRE version is 1.5.0. To find out what JRE you are using, refer to the output of 'version -java' in MATLAB or refer to the jre.cfg file in *matlabroot/sys/java/jre/<arch>* or *mcrrroot/sys/java/jre/<arch>*.

The powerspect program should display the output:

Matrix Math Example

The purpose of the example is to show you the following:

- How to assign more than one MATLAB function to a component class.
- How to manually handle native memory management.
- How to access the component in a Java application (`getfactor.java`) by instantiating `Factor` and using the `MWArray` class library to handle data conversion.

Note For complete reference information about the `MWArray` class hierarchy, see the `com.mathworks.toolbox.javabuilder` package.

- How to build and run the `MatrixMathDemoApp` application

This example builds a Java component to perform matrix math. The example creates a program that performs Cholesky, LU, and QR factorizations on a simple tridiagonal matrix (finite difference matrix) with the following form:

$$A = \begin{bmatrix} 2 & -1 & 0 & 0 & 0 \\ -1 & 2 & -1 & 0 & 0 \\ 0 & -1 & 2 & -1 & 0 \\ 0 & 0 & -1 & 2 & -1 \\ 0 & 0 & 0 & -1 & 2 \end{bmatrix}$$

You supply the size of the matrix on the command line, and the program constructs the matrix and performs the three factorizations. The original matrix and the results are printed to standard output. You may optionally perform the calculations using a sparse matrix by specifying the string "sparse" as the second parameter on the command line.

MATLAB Functions to Be Encapsulated

The following code defines the MATLAB functions used in the example.

`cholesky.m`

```
function [L] = cholesky(A)
```

```
%CHOLSKY Cholesky factorization of A.
% L = CHOLSKY(A) returns the Cholesky factorization of A.
% This file is used as an example for the MATLAB
% Builder for Java product.

% Copyright 2001-2006 The MathWorks, Inc.

L = chol(A);
```

ludecomp.m

```
function [L,U] = ludecomp(A)
%LUDECOMP LU factorization of A.
% [L,U] = LUDECOMP(A) returns the LU factorization of A.
% This file is used as an example for the MATLAB
% Builder for Java product.

% Copyright 2001-2006 The MathWorks, Inc.

[L,U] = lu(A);
```

qrdecomp.m

```
function [Q,R] = qrdecomp(A)
%QRDECOMP QR factorization of A.
% [Q,R] = QRDECOMP(A) returns the QR factorization of A.
% This file is used as an example for the MATLAB
% Builder for Java product.

% Copyright 2001-2006 The MathWorks, Inc.

[Q,R] = qr(A);
```

Matrix Math Example: Step-by-Step Procedure

- 1 If you have not already done so, copy the files for this example as follows:
 - a. Copy the following directory that ships with MATLAB to your work directory:

matlabroot\toolbox\javabuilder\Examples\MatrixMathExample

- b. At the MATLAB command prompt, `cd` to the new `MatrixMathExample` subdirectory in your work directory.
- 2** If you have not already done so, set the environment variables that are required on a development machine. See “Settings for Environment Variables (Development Machine)” on page 6-2.
- 3** Write the MATLAB functions as you would any MATLAB function.

The code for the `cholesky`, `ludcomp`, and `qrdecomp` functions is already in your work directory in `MatrixMathExample\MatrixMathDemoComp\`.

- 4** While in MATLAB, issue the following command to open the Deployment Tool dialog box:

```
deploytool
```

- 5** Specify a Java component as follows:

Field	Value
Component name	factormatrix
Class name	factor
Show verbose output	Selected

- 6** Add the `cholesky.m`, `ludcomp.m` and `qrdecomp.m` M-files to the project.
- 7** Save the project.
- 8** Build the component.
- 9** Write source code for an application that accesses the component.

The sample application for this example is in `MatrixMathExample\MatrixMathDemoJavaApp\getfactor.java`.

The program listing is shown here.

getfactor.java

```
/* getfactor.java
 * This file is used as an example for the MATLAB
 * Builder for Java product.
 *
 * Copyright 2001-2006 The MathWorks, Inc.
 */

/* Necessary package imports */
import com.mathworks.toolbox.javabuilder.*;
import factormatrix.*;

/*
 * getfactor class computes cholesky, LU, and QR
 * factorizations of a finite difference matrix
 * of order N. The value of N is passed on the
 * command line. If a second command line arg
 * is passed with the value of "sparse", then
 * a sparse matrix is used.
 */
class getfactor
{
    public static void main(String[] args)
    {
        MWNumericArray a = null; /* Stores matrix to factor */
        Object[] result = null; /* Stores the result */
        factor theFactor = null; /* Stores factor class instance */

        try
        {
            /* If no input, exit */
            if (args.length == 0)
            {
                System.out.println("Error: must input a positive integer");
                return;
            }

            /* Convert input value */
            int n = Integer.valueOf(args[0]).intValue();

```

```
if (n <= 0)
{
    System.out.println("Error: must input a positive integer");
    return;
}

/*
 * Allocate matrix. If second input is "sparse"
 * allocate a sparse array
 */
int[] dims = {n, n};

if (args.length > 1 && args[1].equals("sparse"))
    a = MWNumericArray.newSparse(dims[0], dims[1], n+2*(n-1), MWClassID.DOUBLE, MWComplexity.REAL);
else
    a = MWNumericArray.newInstance(dims, MWClassID.DOUBLE, MWComplexity.REAL);

/* Set matrix values */
int[] index = {1, 1};

for (index[0] = 1; index[0] <= dims[0]; index[0]++)
{
    for (index[1] = 1; index[1] <= dims[1]; index[1]++)
    {
        if (index[1] == index[0])
            a.set(index, 2.0);
        else if (index[1] == index[0]+1 || index[1] == index[0]-1)
            a.set(index, -1.0);
    }
}

/* Create new factor object */
theFactor = new factor();

/* Print original matrix */
System.out.println("Original matrix:");
System.out.println(a);

/* Compute cholesky factorization and print results. */
```

```

        result = theFactor.cholesky(1, a);
        System.out.println("Cholesky factorization:");
        System.out.println(result[0]);
        MWArray.disposeArray(result);

        /* Compute LU factorization and print results. */
        result = theFactor.ludecomp(2, a);
        System.out.println("LU factorization:");
        System.out.println("L matrix:");
        System.out.println(result[0]);
        System.out.println("U matrix:");
        System.out.println(result[1]);
        MWArray.disposeArray(result);

        /* Compute QR factorization and print results. */
        result = theFactor.qrdecomp(2, a);
        System.out.println("QR factorization:");
        System.out.println("Q matrix:");
        System.out.println(result[0]);
        System.out.println("R matrix:");
        System.out.println(result[1]);
    }

    catch (Exception e)
    {
        System.out.println("Exception: " + e.toString());
    }

    finally
    {
        /* Free native resources */
        MWArray.disposeArray(a);
        MWArray.disposeArray(result);
        if (theFactor != null)
            theFactor.dispose();
    }
}
}

```

The statement `theFactor = new factor();`

creates an instance of the class `factor`.

The following statements call the methods that encapsulate the MATLAB functions:

```
result = theFactor.cholesky(1, a);  
...  
result = theFactor.ludecomp(2, a);  
...  
result = theFactor.qrdecomp(2, a);  
...
```

10 Compile the `getfactor` application using `javac`.

cd to the `matlabroot\work\factormatrix` directory.

- On Windows, execute the following command:

```
javac -classpath  
.;matlabroot\java\jar\toolbox\javabuilder.jar;  
.\distrib\factormatrix.jar getfactor.java
```

- On UNIX, execute the following command:

```
javac -classpath  
.:matlabroot/java/jar/toolbox/javabuilder.jar:  
./distrib/factormatrix.jar getfactor.java
```

11 Run the application.

Run `getfactor` using a nonsparse matrix

- On Windows, execute the `getfactor` class file as follows:

```
java -classpath  
.;matlabroot\java\jar\toolbox\javabuilder.jar;  
.\distrib\factormatrix.jar  
-Djava.library.path=matlabroot\bin\win32;.\distrib  
getfactor 4
```

- On UNIX, execute the getfactor class file as follows:

```
java -classpath
.:matlabroot/java/jar/toolbox/javabuilder.jar:
./distrib/factormatrix.jar
-Djava.library.path=matlabroot/bin/<Arch>./distrib
getfactor 4
% where <Arch> = glux86 gluxa64 sol2
```

Note The supported JRE version is 1.5.0. To find out what JRE you are using, refer to the output of 'version -java' in MATLAB or refer to the jre.cfg file in *matlabroot/sys/java/jre/<arch>* or *mcrroot/sys/java/jre/<arch>*.

Output for the Matrix Math Example

Original matrix:

```
 2   -1   0   0
-1   2  -1   0
 0   -1   2  -1
 0   0  -1   2
```

Cholesky factorization:

```
1.4142  -0.7071   0   0
 0   1.2247  -0.8165   0
 0   0   1.1547  -0.8660
 0   0   0   1.1180
```

LU factorization:

L matrix:

```
1.0000   0   0   0
-0.5000  1.0000   0   0
 0  -0.6667  1.0000   0
 0   0   -0.7500  1.0000
```

U matrix:

```
2.0000  -1.0000   0   0
```

```
      0    1.5000  -1.0000    0
      0      0    1.3333  -1.0000
      0      0      0    1.2500
```

QR factorization:

Q matrix:

```
-0.8944  -0.3586  -0.1952   0.1826
 0.4472  -0.7171  -0.3904   0.3651
 0      0.5976  -0.5855   0.5477
 0      0      0.6831   0.7303
```

R matrix:

```
-2.2361   1.7889  -0.4472    0
 0    -1.6733   1.9124  -0.5976
 0      0    -1.4639   1.9518
 0      0      0    0.9129
```

To run the same program for a sparse matrix, use the same command and add the string `sparse` to the command line:

```
java (... same arguments) getfactor 4 sparse
```

Output for a Sparse Matrix

Original matrix:

```
(1,1)    2
(2,1)   -1
(1,2)   -1
(2,2)    2
(3,2)   -1
(2,3)   -1
(3,3)    2
(4,3)   -1
(3,4)   -1
(4,4)    2
```

Cholesky factorization:

(1,1)	1.4142
(1,2)	-0.7071
(2,2)	1.2247
(2,3)	-0.8165
(3,3)	1.1547
(3,4)	-0.8660
(4,4)	1.1180

LU factorization:

L matrix:

(1,1)	1.0000
(2,1)	-0.5000
(2,2)	1.0000
(3,2)	-0.6667
(3,3)	1.0000
(4,3)	-0.7500
(4,4)	1.0000

U matrix:

(1,1)	2.0000
(1,2)	-1.0000
(2,2)	1.5000
(2,3)	-1.0000
(3,3)	1.3333
(3,4)	-1.0000
(4,4)	1.2500

QR factorization:

Q matrix:

(1,1)	0.8944
(2,1)	-0.4472
(1,2)	0.3586
(2,2)	0.7171
(3,2)	-0.5976
(1,3)	0.1952
(2,3)	0.3904
(3,3)	0.5855

```
(4,3)      -0.6831
(1,4)      0.1826

(3,4)      0.5477
(4,4)      0.7303
```

R matrix:

```
(1,1)      2.2361
(1,2)     -1.7889
(2,2)      1.6733
(1,3)      0.4472
(2,3)     -1.9124
(3,3)      1.4639
(2,4)      0.5976
(3,4)     -1.9518
(4,4)      0.9129
```

Understanding the `getfactor` Program

The `getfactor` program takes one or two arguments from standard input. The first argument is converted to the integer order of the test matrix. If the string `sparse` is passed as the second argument, a sparse matrix is created to contain the test array. The Cholesky, LU, and QR factorizations are then computed and the results are displayed to standard output.

The main method has three parts:

- The first part sets up the input matrix, creates a new factor object, and calls the `cholesky`, `ludcomp`, and `qrdecomp` methods. This part is executed inside of a `try` block. This is done so that if an exception occurs during execution, the corresponding catch block will be executed.
- The second part is the catch block. The code prints a message to standard output to let the user know about the error that has occurred.
- The third part is a `finally` block to manually clean up native resources before exiting.

Requirements for MATLAB Builder for Java

- “System Requirements” on page 6-2
- “Limitations and Restrictions” on page 6-2
- “Settings for Environment Variables (Development Machine)” on page 6-2

System Requirements

System requirements and restrictions on use for MATLAB Builder for Java are as follows:

- All requirements for the MATLAB Compiler; see “Installation and Configuration” in the MATLAB Compiler documentation.
- Java Development Kit (JDK) 1.4 or later must be installed.
- Java Runtime Environment (JRE) that is used by MATLAB and MCR.

Note The supported JRE version is 1.5.0. To find out what JRE you are using, refer to the output of 'version - java' in MATLAB or refer to the `jre.cfg` file in `matlabroot/sys/java/jre/<arch>` or `mcrroot/sys/java/jre/<arch>`.

Limitations and Restrictions

In general, limitations and restrictions on the use of Java Builder are the same as those for the MATLAB Compiler. See “Limitations and Restrictions” in the MATLAB Compiler documentation for details.

Settings for Environment Variables (Development Machine)

Before starting to program, you must set the environment on your development machine to be compatible with MATLAB Builder for Java.

Specify the following environment variables:

- “JAVA_HOME Variable” on page 6-3

- “Java CLASSPATH Variable” on page 6-4
- “Native Library Path Variables” on page 6-6

JAVA_HOME Variable

Java Builder uses the `JAVA_HOME` variable to locate the Java Software Development Kit (SDK) on your system. It also uses this variable to set the versions of the `javac.exe` and `jar.exe` files it uses during the build process.

Note If you do not set `JAVA_HOME`, Java Builder assumes that `\jdk\bin` is on the system path.

Setting JAVA_HOME on Windows (Development Machine). If you are working on Windows, set your `JAVA_HOME` variable by entering the following command in your DOS command window. (In this example, your Java SDK is installed in directory `C:\java\jdk\j2sdk1.5.0`.)

```
set JAVA_HOME=C:\java\jdk\j2sdk1.5.0
```

Alternatively, you can add `jdk_directory/bin` to the system path. For example:

```
set PATH=%PATH%;c:\java\jdk\j2sdk1.5.0\bin
```

You can also set these variables globally using the Windows Control Panel. Consult your Windows documentation for instructions on setting system variables.

Note The supported JRE version is 1.5.0. To find out what JRE you are using, refer to the output of `'version -java'` in MATLAB or refer to the `jre.cfg` file in `matlabroot/sys/java/jre/<arch>` or `mcrroot/sys/java/jre/<arch>`.

Setting JAVA_HOME on UNIX (Development Machine). If you are working on a UNIX system, set your `JAVA_HOME` variable by entering the following commands at the command prompt. (In this example, your Java SDK is installed in directory `/java/jdk/j2sdk1.5.0`.)

```
setenv JAVA_HOME /java/jdk/j2sdk1.5.0
```

Alternatively, you can add *jdk_directory*\bin to the system path.

Java CLASSPATH Variable

To build and run a Java application that encapsulates MATLAB the system needs to find .jar files containing the MATLAB libraries and the class and method definitions that you have developed and built with Java Builder. To tell the system how to locate the .jar files it needs, specify a classpath either in the javac command or in your system environment variables.

Java uses the CLASSPATH variable to locate user classes needed to compile or run a given Java class. The class path contains directories where all the .class and/or .jar files needed by your program reside. These .jar files contain any classes that your Java class depends on.

When you compile a Java class that uses classes contained in the com.mathworks.toolbox.javabuilder package, you need to include a file called javabuilder.jar on the Java class path. This file comes with Java Builder; you can find it in the following directory:

```
matlabroot/toolbox/javabuilder/jar % (development machine)
mcrroot/toolbox/javabuilder/jar % (end-user machine)
```

where *matlabroot* refers to the root directory into which the MATLAB installer has placed the MATLAB files, and *mcrroot* refers to the root directory under which mcr is installed. Java Builder automatically includes this .jar file on the class path when it creates the component. To use a class generated by Java Builder, you need to add this *matlabroot/toolbox/javabuilder/jar/javabuilder.jar* to the class path.

In addition, you need to add to the class path the .jar file created by Java Builder for your compiled .class files.

Example: Setting CLASSPATH on Windows. Suppose your MATLAB libraries are installed in C:*matlabroot*\bin\win32, and your component .jar files are in C:\mycomponent.

Note For *matlabroot* substitute the MATLAB root directory on your system. Type *matlabroot* to see this directory name.

To set your CLASSPATH variable on your development machine, enter the following command at the DOS command prompt:

```
set CLASSPATH=.;C:\matlabroot\toolbox\javabuilder\jar\javabuilder.jar;  
C:\mycomponent\mycomponent.jar
```

Alternatively, if the Java SDK is installed, you can specify the class path on the Java command line as follows.

```
javac  
-classpath .;C:\matlabroot\toolbox\javabuilder\jar\javabuilder.jar;  
C:\mycomponent\mycomponent.jar usemyclass.java
```

where *usemyclass.java* is the file to be compiled.

It is recommended that you globally add any frequently used class paths to the CLASSPATH system variable via the Windows Control Panel.

Example: Setting CLASSPATH on UNIX (Development Machine).

Suppose your UNIX environment is as follows:

- Your MATLAB libraries are installed in */matlabroot/bin/arch*, (where *arch* is either *glnx86*, *glnxa64*, *mac*, or *sol2*, depending on the operating system of the machine.
- Your component *.jar* files are in */mycomponent*.

To set your CLASSPATH variable, enter the following command at the prompt:

```
setenv CLASSPATH ./matlabroot/toolbox/javabuilder/jar/javabuilder.jar:  
/mycomponent/mycomponent.jar
```

Like Windows, you can specify the class path directly on the Java command line. To compile *usemyclass.java*, type the following:

```
javac -classpath
./matlabroot/toolbox/javabuilder/jar/javabuilder.jar:
/mycomponent/mycomponent.jar usemyclass.java
```

where `usemyclass.java` is the file to be compiled.

Native Library Path Variables

The operating system uses the native library path to locate native libraries that are needed to run your Java class. See the following list of variable names according to operating system:

Windows	PATH
Linux	LD_LIBRARY_PATH
Solaris	LD_LIBRARY_PATH
Macintosh	DYLD_LIBRARY_PATH

For information on how to set these path variables, see the following topics in the “Stand-Alone Applications” section of the MATLAB Compiler documentation:

- See “Testing the Application” for information on setting your path on a development machine.
- See “Running the Application” for information on setting your path on an end-user machine.

MATLAB Builder for Java Graphical User Interface

Use the MATLAB Builder for Java graphical user interface (GUI) to create Java classes that encapsulate your M-file functions. You can build and package Javacomponents that support the classes you create.

To start the application, run the following command at the MATLAB prompt:

```
deploytool
```

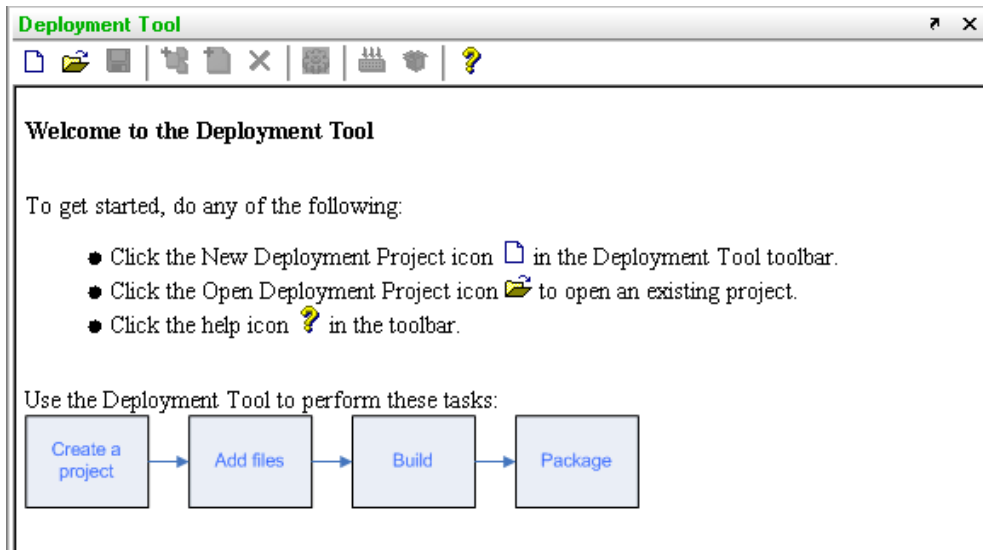

Use the GUI to perform the following tasks:

- Create projects that define your Java components
- Name the classes to contain the M-file methods you want to use and associate the classes with a component in the project.

Associate the appropriate methods with each class

- Build Java class files and methods from the M-files you specify.
- Create a component installer, a package you can use to install the components on another machine for development.

The Deployment Tool opens as shown.

Note that the Deployment Tool window can be docked or undocked.

The Deployment Tool toolbar has the following icons.

Toolbar Icons

Name of Toolbar Icon	Icon	Click to...
New Project		Create a new deployment project.
Open Project		View projects and select one to open.
Save Project		Save the current project, including all files and settings.
Add Class (only for components that contain classes)		Open the Add Class dialog box, where you can specify the name of a new class to be created as part of the current project.

Toolbar Icons (Continued)

Name of Toolbar Icon	Icon	Click to...
Remove		Remove the selected class folder or the selected files from the project.
Build		Build the components specified by the project, displaying the build process in the Deployment Tool Output pane.
Package		Create a self-extracting executable (Windows) or .zip file (UNIX) that contains the files needed to use the component in an application.
Settings		Change settings for the project. You can improve performance by changing settings, such as whether to exclude the MCR or change the search path when building.
Help		View a quick start and steps for using the Deployment Tool.

Data Conversion Rules

- “Java to MATLAB Conversion” on page 6-10
- “MATLAB to Java Conversion” on page 6-12
- “Unsupported MATLAB Array Types” on page 6-13

Java to MATLAB Conversion

The following table lists the data conversion rules for converting Java data types to MATLAB types.

Note The conversion rules apply to scalars, vectors, matrices, and multidimensional arrays of the types listed.

The conversion rules apply not only when calling your own methods, but also when calling constructors and factory methods belonging to the `MWArray` classes.

When calling an `MWArray` class method constructor, supplying a specific data type causes Java Builder to convert to that type instead of the default.

Java to MATLAB Conversion Rules

Java Type	MATLAB Type
<code>double</code>	<code>double</code>
<code>float</code>	<code>single</code>
<code>byte</code>	<code>int8</code>
<code>int</code>	<code>int32</code>
<code>short</code>	<code>int16</code>
<code>long</code>	<code>int64</code>
<code>char</code>	<code>char</code>
<code>boolean</code>	<code>logical</code>
<code>java.lang.Double</code>	<code>double</code>

Java to MATLAB Conversion Rules (Continued)

Java Type	MATLAB Type
java.lang.Float	single
java.lang.Byte	int8
java.lang.Integer	int32
java.lang.Long	int64
java.lang.Short	int16
java.lang.Number	double Note Subclasses of java.lang.Number not listed above are converted to double.
java.lang.Boolean	logical
java.lang.Character	char
java.lang.String	char Note A Java string is converted to a 1-by-N array of char with N equal to the length of the input string. An array of Java strings (String[]) is converted to an M-by-N array of char, with M equal to the number of elements in the input array and N equal to the maximum length of any of the strings in the array. Higher dimensional arrays of String are converted similarly. In general, an N-dimensional array of String is converted to an N+1 dimensional array of char with appropriate zero padding where supplied strings have different lengths.

MATLAB to Java Conversion

The following table lists the data conversion rules for converting MATLAB data types to Java types.

Note The conversion rules apply to scalars, vectors, matrices, and multidimensional arrays of the types listed.

MATLAB to Java Conversion Rules

MATLAB Type	Java Type (Primitive)	Java Type (Object)
cell	N/A	Object Note Cell arrays are constructed and accessed as arrays of MWArray.
structure	N/A	Object Note Structure arrays are constructed and accessed as arrays of MWArray.
char	char	java.lang.Character
double	double	java.lang.Double
single	float	java.lang.Float
int8	byte	java.lang.Byte
int16	short	java.lang.Short
int32	int	java.lang.Integer
int64	long	java.lang.Long
uint8	byte	java.lang.Byte Java has no unsigned type to represent the uint8 used in MATLAB. Construction of and access to MATLAB arrays of an unsigned type requires conversion.

MATLAB to Java Conversion Rules (Continued)

MATLAB Type	Java Type (Primitive)	Java Type (Object)
uint16	short	java.lang.ShortJava has no unsigned type to represent the uint16 used in MATLAB. Construction of and access to MATLAB arrays of an unsigned type requires conversion.
uint32	int	java.lang.IntegerJava has no unsigned type to represent the uint32 used in MATLAB. Construction of and access to MATLAB arrays of an unsigned type requires conversion.
uint64	long	java.lang.LongJava has no unsigned type to represent the uint64 used in MATLAB. Construction of and access to MATLAB arrays of an unsigned type requires conversion.
logical	boolean	java.lang.Boolean
Function handle	Not supported	
Java class	Not supported	
User class	Not supported	

Unsupported MATLAB Array Types

Java has no unsigned types to represent the uint8, uint16, uint32, and uint64 types used in MATLAB. Construction of and access to MATLAB arrays of an unsigned type requires conversion.

Programming Interfaces Generated by Java Builder

- “APIs Based on MATLAB Function Signatures” on page 6-14
- “Standard API” on page 6-15
- “mlx API” on page 6-17
- “Code Fragment: Signatures Generated for myprimes Example” on page 6-17

APIs Based on MATLAB Function Signatures

Java Builder generates two kinds of interfaces to handle MATLAB function signatures.

- A *standard* signature in Java.

This interface specifies input arguments for each overloaded method as one or more input arguments of class `java.lang.Object` or any subclass (including subclasses of `MWArray`). The standard interface specifies return values, if any, as a subclass of `MWArray`.

- `mlx` API

This interface allows the user to specify the inputs to a function as an `Object` array, where each array element is one input argument. Similarly, the user also gives the `mlx` interface a pre-allocated `Object` array to hold the outputs of the function. The allocated length of the output array determines the number of desired function outputs.

The `mlx` interface may also be accessed using `java.util.List` containers in place of `Object` arrays for the inputs and outputs. Note that if `List` containers are used, the output `List` passed in must contain a number of elements equal to the desired number of function outputs.

For example, this would be incorrect usage:

```
java.util.List outputs = new ArrayList(3);
myclass.myfunction(outputs, inputs); // outputs contains 0 elements!
```

And this would be the correct usage:

```
java.util.List outputs = Arrays.asList(new Object[3]);
myclass.myfunction(outputs, inputs); // ok, list contains 3 elements
```

Typically you use the standard interface when you want to call MATLAB functions that return a single array. In other cases you probably need to use the `mlx` interface.

Standard API

The standard calling interface returns an array of one or more `MWArray` objects.

The standard API for a generic function with none, one, more than one, or a variable number of arguments, is shown in the following table.

Arguments	API to Use
Generic MATLAB function	<code>function [Out1, Out2, ..., varargout] = foo(In1, In2, ..., InN, varargin)</code>
API if there are no input arguments	<code>public Object[] foo(int numArgsOut)</code>
API if there is one input argument	<code>public Object[] foo(int numArgsOut, Object In1)</code>
API if there are two to N input arguments	<code>public Object[] foo(int numArgsOut, Object In1, Object In2, ... Object InN)</code>
API if there are optional arguments, represented	<code>public Object[] foo(int numArgsOut, Object in1,</code>

by the varargin argument	Object <i>in2</i> , ..., Object <i>InN</i> , Object <i>varargin</i>)
--------------------------------	---

Details about the arguments for these samples of standard signatures are shown in the following table.

Argument	Description	Details About this Argument
<i>numArgsOut</i>	Number of outputs	<p>An integer indicating the number of outputs you want the method to return. To return no arguments, omit this argument.</p> <p>The value of <i>numArgsOut</i> must be less than or equal to the MATLAB function <i>nargout</i>.</p> <p>The <i>numArgsOut</i> argument must always be the first argument in the list.</p>
<i>In1, In2, ...InN</i>	Required input arguments	<p>All arguments that follow <i>numArgsOut</i> in the argument list are inputs to the method being called.</p> <p>Specify all required inputs first. Each required input must be of class <i>MWArray</i> or any class derived from <i>MWArray</i>.</p>
<i>varargin</i>	Optional inputs	<p>You can also specify optional inputs if your M-code uses the <i>varargin</i> input: list the optional inputs, or put them in an <code>Object[]</code> argument, placing the array last in the argument list.</p>
<i>Out1, Out2, ...OutN</i>	Output arguments	<p>With the standard calling interface, all output arguments are returned as an array of <i>MWArrays</i>.</p>

mlx API

For a function with the following structure:

```
function [Out1, Out2, ..., varargout] =
    foo(In1, In2, ..., InN, varargin)
```

Java Builder generates the following API, as the mlx interface:

```
public void foo (List outputs, List inputs) throws MWException;
public void foo (Object[] outputs, Object[] inputs) throws MWException;
```

Code Fragment: Signatures Generated for myprimes Example

For a specific example, look at the myprimes method. This method has one input argument, so Java Builder generates three overloaded methods in Java.

When you add myprimes to the class myclass and build the component, Java Builder generates the myclass.java file. A fragment of myclass.java is listed to show the three overloaded implementations of the myprimes method in the Java code. The first implementation shows the interface to be used if there are no input arguments, the second shows the implementation to be used if there is one input argument, and the third shows the feval interface.

```
/* mlx interface List version */
public void myprimes(List lhs, List rhs) throws MWException
{
    (implementation omitted)
}
/* mlx interface Array version */
public void myprimes(Object[] lhs, Object[] rhs) throws MWException
{
    (implementation omitted)
}
/* Standard interface no inputs*/
public Object[] myprimes(int nargout) throws MWException
{
    (implementation omitted)
}
/* Standard interface one input*/
public Object[] myprimes(int nargout, Object n) throws MWException
```

```
{  
    (implementation omitted)  
}
```

The standard interface specifies inputs to the function within the argument list and outputs as return values.

Rather than returning function outputs as a return value, the `feval` interface includes both input and output arguments in the argument list. Output arguments are specified first, followed by input arguments.

See “APIs Based on MATLAB Function Signatures” on page 6-14 for details about the interfaces.

MWArray Class Specification

For complete reference information about the MWArray class hierarchy, see `com.mathworks.toolbox.javabuilder.MWArray`, which is in the `matlabroot/help/toolbox/javabuilder/MWArrayAPI/` directory.

Note For `matlabroot` substitute the MATLAB root directory on your system. Type `matlabroot` to see this directory name.

Functions — Alphabetical List

deploytool

Purpose	Open GUI for MATLAB Builder for Java and MATLAB Compiler
Syntax	<code>deploytool</code>
Description	<p>The <code>deploytool</code> command opens the Deployment Tool dialog box, which is the graphical user interface (GUI) for MATLAB Builder for Java and for MATLAB Compiler.</p> <p>See “Creating a Java Component” on page 1-5 to get started using the Deployment Tool to create Java components, and see “Using the GUI to Create and Package a Deployable Component” in the MATLAB Compiler documentation for information about using the Deployment Tool to create standalone applications and libraries.</p>

Examples

Use this list to find examples in the documentation.

Quick Start

“Example: Magic Square” on page 1-15

Handling Data

“Code Fragment: Passing an MWArray” on page 3-7

“Code Fragment: Passing a Java Double Object” on page 3-8

“Code Fragment: Passing an MWArray” on page 3-8

“Code Fragment: Passing Variable Numbers of Inputs” on page 3-10

“Code Fragment: Passing Array Inputs” on page 3-11

“Code Fragment: Passing a Variable Number of Outputs” on page 3-12

“Code Fragment: Passing Optional Arguments with the Standard Interface” on page 3-13

“Code Fragment: Using MWArray Query” on page 3-16

“Handling Data Conversion Between Java and MATLAB” on page 3-28

“Examples of Using set” on page 4-19

“Examples of Using get” on page 4-20

“Examples of Using set and get Methods” on page 4-26

“Code Fragment: Signatures Generated for myprimes Example” on page 6-17

Handling Errors

“Code Fragment: Handling an Exception in the Called Function” on page 3-20

“Code Fragment: Handling an Exception in the Calling Function” on page 3-21

“Code Fragment: Catching General Exceptions” on page 3-22

“Code Fragment: Catching Multiple Exception Types” on page 3-23

Handling Memory

“Code Fragment: Use try-finally to Ensure Resources Are Freed” on page 3-27

Sample Applications (Java)

“Plot Example” on page 5-2

“Spectral Analysis Example” on page 5-8

“Matrix Math Example” on page 5-16
