What Is Financial Toolbox?

MATLAB® and Financial Toolbox provide a complete integrated computing environment for financial analysis and engineering. The toolbox has everything you need to perform mathematical and statistical analysis of financial data and display the results with presentation-quality graphics. You can quickly ask, visualize, and answer complicated questions.

In traditional or spreadsheet programming, you must deal with all sorts of housekeeping details: declaring, data typing, sizing, and so on, MATLAB does all that for you. You just write expressions the way you think of problems. There is no need to switch tools, convert files, or rewrite applications.

With MATLAB and Financial Toolbox, you can do the following:

- Compute and analyze prices, yields, and sensitivities for derivatives and other securities, and for portfolios of securities.
- Perform Securities Industry Association (SIA) compatible fixed-income pricing, yield, and sensitivity analysis.
- Analyze or manage portfolios.
- Design and evaluate hedging strategies.
- Identify, measure, and control risk.
- Analyze and compute cash flows, including rates of return and depreciation streams.
- Analyze and predict economic activity.
- Visualize and analyze financial time series data
- Create structured financial instruments, including foreign-exchange instruments.
- Teach or conduct academic research.

This chapter uses MATLAB to review the fundamentals of matrix algebra you need for financial analysis and engineering applications. It contains these sections:

- “Using Matrix Functions for Finance” on page 1-4

Reviews “Key Definitions” on page 1-4 and some matrix algebra fundamentals, such as “Referencing Matrix Elements” on page 1-5 and “Transposing Matrices” on page 1-6.

- “Matrix Algebra Refresher” on page 1-7

Provides a brief refresher on using matrix functions in financial analysis and engineering

- “Function Input and Output Arguments” on page 1-18

Describes acceptable formats for providing data to MATLAB and the resulting output from computations on the supplied data.

This material explains some MATLAB concepts and operations using financial examples to help get you started.

Using Matrix Functions for Finance

- “Key Definitions” on page 1-4
- “Referencing Matrix Elements” on page 1-5
- “Transposing Matrices” on page 1-6

Many financial analysis procedures involve *sets* of numbers; for example, a portfolio of securities at various prices and yields. Matrices, matrix functions, and matrix algebra are the most efficient ways to analyze sets of numbers and their relationships. Spreadsheets focus on individual cells and the relationships between cells. While you can think of a set of spreadsheet cells (a range of rows and columns) as a matrix, a matrix-oriented tool like MATLAB manipulates sets of numbers more quickly, easily, and naturally.

Key Definitions

Matrix. A rectangular array of numeric or algebraic quantities subject to mathematical operations; the regular formation of elements into rows and columns. Described as a “*m*-by-*n*” matrix, with *m* the number of rows and *n* the number of columns. The description is always “row-by-column.” For example, here is a 2-by-3 matrix of two bonds (the rows) with different par values, coupon rates, and coupon payment frequencies per year (the columns) entered using MATLAB notation:

```
Bonds = [1000    0.06    2
          500    0.055   4]
```

Vector. A matrix with only one row or column. Described as a “1-by-*n*” or “*m*-by-1” matrix. The description is always “row-by-column.” Here is a 1-by-4 vector of cash flows in MATLAB notation:

```
Cash = [1500    4470    5280    -1299]
```

Scalar. A 1-by-1 matrix; that is, a single number.

Referencing Matrix Elements

To reference specific matrix elements, use (row, column) notation. For example:

```
Bonds(1,2)
```

```
ans =
```

```
0.06
```

```
Cash(3)
```

```
ans =
```

```
5280.00
```

You can enlarge matrices using small matrices or vectors as elements. For example,

```
AddBond = [1000 0.065 2];
```

```
Bonds = [Bonds; AddBond]
```

adds another row to the matrix and creates

```
Bonds =
```

```
1000 0.06 2
```

```
500 0.055 4
```

```
1000 0.065 2
```

Likewise,

```
Prices = [987.50
```

```
475.00
```

```
995.00]
```

```
Bonds = [Prices, Bonds]
```

adds another column and creates

```
Bonds =
```

```
987.50  1000  0.06  2
475.00   500  0.055  4
995.00  1000  0.065  2
```

Finally, the colon (:) is important in generating and referencing matrix elements. For example, to reference the par value, coupon rate, and coupon frequency of the second bond.

```
BondItems = Bonds(2, 2:4)
```

```
BondItems =
```

```
500.00  0.055  4
```

Transposing Matrices

Sometimes matrices are in the wrong configuration for an operation. In MATLAB, the apostrophe or prime character (') transposes a matrix: columns become rows, rows become columns. For example,

```
Cash = [1500  4470  5280  -1299]'
```

produces

```
Cash =
```

```
1500
4470
5280
-1299
```

Matrix Algebra Refresher

Matrix algebra and matrix operations are fundamental to using MATLAB in financial analysis and engineering. The topics discussed in this section include:

- “Adding and Subtracting Matrices” on page 1-7
- “Multiplying Matrices” on page 1-8
- “Dividing Matrices” on page 1-13
- “Solving Simultaneous Linear Equations” on page 1-13
- “Operating Element by Element” on page 1-17

These explanations should help refresh your skills.

William Sharpe’s *Macro-Investment Analysis* also provides an excellent explanation of matrix algebra operations using MATLAB. It is available on the Web at

<http://www.stanford.edu/~wfsharpe/mia/mia.htm>

Note When you are setting up a problem, it helps to “talk through” the units and dimensions associated with each input and output matrix. In the example under “Multiplying Matrices” on page 1-8, one input matrix has “five days’ closing prices for three stocks,” the other input matrix has “shares of three stocks in two portfolios,” and the output matrix therefore has “five days’ closing values for two portfolios.” It also helps to name variables using descriptive terms.

Adding and Subtracting Matrices

Matrix addition and subtraction operate element-by-element. The two input matrices must have the same dimensions. The result is a new matrix of the same dimensions where each element is the sum or difference of each corresponding input element. For example, consider combining portfolios of different quantities of the same stocks (“shares of stocks A, B, and C [the rows] in portfolios P and Q [the columns] plus shares of A, B, and C in portfolios R and S”).

```
Portfolios_PQ = [100  200
                 500  400
                 300  150];

Portfolios_RS = [175  125
                 200  200
                 100  500];

NewPortfolios = Portfolios_PQ + Portfolios_RS

NewPortfolios =

    275.00    325.00
    700.00    600.00
    400.00    650.00
```

Adding or subtracting a scalar and a matrix is allowed and also operates element-by-element.

```
SmallerPortf = NewPortfolios-10

SmallerPortf =

    265.00    315.00
    690.00    590.00
    390.00    640.00
```

Multiplying Matrices

Matrix multiplication does *not* operate element-by-element. It operates according to the rules of linear algebra. In multiplying matrices, it helps to remember this key rule: the inner dimensions must be the same. That is, if the first matrix is m -by- n , the second must be n -by- p . The resulting matrix is m -by- p . It also helps to “talk through” the units of each matrix, as mentioned in “Using Matrix Functions for Finance” on page 1-4.

Matrix multiplication also is *not* commutative; that is, it is not independent of order. $A*B$ does *not* equal $B*A$. The dimension rule illustrates this property. If A is 1-by-3 and B is 3-by-1, $A*B$ yields a scalar (1-by-1) but $B*A$ yields a 3-by-3 matrix.

Multiplying Vectors

Vector multiplication follows the same rules and helps illustrate the principles. For example, a stock portfolio has three different stocks and their closing prices today are

$$\text{ClosePrices} = [42.5 \quad 15 \quad 78.875]$$

The portfolio contains these numbers of shares of each stock.

$$\text{NumShares} = \begin{bmatrix} 100 \\ 500 \\ 300 \end{bmatrix}$$

To find the value of the portfolio, simply multiply the vectors

$$\text{PortfValue} = \text{ClosePrices} * \text{NumShares}$$

which yields

$$\text{PortfValue} = 35412.50$$

The vectors are 1-by-3 and 3-by-1; the resulting vector is 1-by-1, a scalar. Multiplying these vectors thus means multiplying each closing price by its respective number of shares and summing the result.

To illustrate order dependence, switch the order of the vectors

$$\text{Values} = \text{NumShares} * \text{ClosePrices}$$

$$\text{Values} = \begin{bmatrix} 4250.00 & 1500.00 & 7887.50 \\ 21250.00 & 7500.00 & 39437.50 \\ 12750.00 & 4500.00 & 23662.50 \end{bmatrix}$$

which shows the closing values of 100, 500, and 300 shares of each stock, not the portfolio value, and meaningless for this example.

Computing Dot Products of Vectors

In matrix algebra, if X and Y are vectors of the same length

$$Y = [y_1, y_2, \dots, y_n]$$

$$X = [x_1, x_2, \dots, x_n]$$

then the dot product

$$X \bullet Y = x_1y_1 + x_2y_2 + \dots + x_ny_n$$

is the scalar product of the two vectors. It is an exception to the commutative rule. To compute the dot product in MATLAB, use `sum(X .* Y)` or `sum(Y .* X)`. Just be sure the two vectors have the same dimensions. To illustrate, use the previous vectors.

```
Value = sum(NumShares .* ClosePrices')
```

```
Value =
```

```
35412.50
```

```
Value = sum(ClosePrices .* NumShares')
```

```
Value =
```

```
35412.50
```

As expected, the value in these cases matches the `PortfValue` computed previously.

Multiplying Vectors and Matrices

Multiplying vectors and matrices follows the matrix multiplication rules and process. For example, a portfolio matrix contains closing prices for a week. A second matrix (vector) contains the stock quantities in the portfolio.

```
WeekClosePr = [42.5      15      78.875
                42.125   15.5     78.75
                42.125   15.125   79
```

```

          42.625   15.25   78.875
          43      15.25   78.625];
PortQuan = [100
            500
            300];

```

To see the closing portfolio value for each day, simply multiply

```
WeekPortValue = WeekClosePr * PortQuan
```

```
WeekPortValue =
```

```

35412.50
35587.50
35475.00
35550.00
35512.50

```

The prices matrix is 5-by-3, the quantity matrix (vector) is 3-by-1, so the resulting matrix (vector) is 5-by-1.

Multiplying Two Matrices

Matrix multiplication also follows the rules of matrix algebra. In matrix algebra notation, if A is an m -by- n matrix and B is an n -by- p matrix

$$A = \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ \vdots & \vdots & & \vdots \\ a_{i1} & a_{i2} & \dots & a_{in} \\ \vdots & \vdots & & \vdots \\ a_{m1} & a_{m2} & \dots & a_{mn} \end{bmatrix}, \quad B = \begin{bmatrix} b_{11} & \dots & b_{1j} & \dots & b_{1p} \\ b_{21} & \dots & b_{2j} & \dots & b_{2p} \\ \vdots & & \vdots & & \vdots \\ b_{n1} & & b_{nj} & & b_{np} \end{bmatrix}$$

then $C = A*B$ is an m -by- p matrix; and the element c_{ij} in the i th row and j th column of C is

$$c_{ij} = a_{i1}b_{1j} + a_{i2}b_{2j} + \dots + a_{in}b_{nj}$$

To illustrate, assume there are two portfolios of the same three stocks above but with different quantities.

```
Portfolios = [100  200
              500  400
              300  150];
```

Multiplying the 5-by-3 week's closing prices matrix by the 3-by-2 portfolios matrix yields a 5-by-2 matrix showing each day's closing value for both portfolios.

```
PortfolioValues = WeekClosePr * Portfolios
```

```
PortfolioValues =
    35412.50    26331.25
    35587.50    26437.50
    35475.00    26325.00
    35550.00    26456.25
    35512.50    26493.75
```

Monday's values result from multiplying each Monday closing price by its respective number of shares and summing the result for the first portfolio, then doing the same for the second portfolio. Tuesday's values result from multiplying each Tuesday closing price by its respective number of shares and summing the result for the first portfolio, then doing the same for the second portfolio. And so on through the rest of the week. With one simple command, MATLAB quickly performs many calculations.

Multiplying a Matrix by a Scalar

Multiplying a matrix by a scalar is an exception to the dimension and commutative rules. It just operates element-by-element.

```
Portfolios = [100  200
              500  400
              300  150];
```

```
DoublePort = Portfolios * 2
```

```
DoublePort =
```

200.00	400.00
1000.00	800.00
600.00	300.00

Dividing Matrices

Matrix division is useful primarily for solving equations, and especially for solving simultaneous linear equations (see “Solving Simultaneous Linear Equations” on page 1-13). For example, you want to solve for X in $A*X = B$.

In ordinary algebra, you would simply divide both sides of the equation by A , and X would equal B/A . However, since matrix algebra is not commutative ($A*X \neq X*A$), different processes apply. In formal matrix algebra, the solution involves matrix inversion. MATLAB, however, simplifies the process by providing two matrix division symbols, left and right (\backslash and $/$). In general,

$X = A \backslash B$ solves for X in $A*X = B$ and

$X = B / A$ solves for X in $X*A = B$.

In general, matrix A must be a nonsingular square matrix; that is, it must be invertible and it must have the same number of rows and columns. (Generally, a matrix is invertible if the matrix times its inverse equals the identity matrix. To understand the theory and proofs, consult a textbook on linear algebra such as *Elementary Linear Algebra* by Hill listed in Appendix A, “Bibliography”.) MATLAB gives a warning message if the matrix is singular or nearly so.

Solving Simultaneous Linear Equations

Matrix division is especially useful in solving simultaneous linear equations. Consider this problem: given two portfolios of mortgage-based instruments, each with certain yields depending on the prime rate, how do you weight the portfolios to achieve certain annual cash flows? The answer involves solving two linear equations.

A linear equation is any equation of the form

$$a_1x + a_2y = b$$

where a_1 , a_2 , and b are constants (with a_1 and a_2 not both 0), and x and y are variables. (It's a linear equation because it describes a line in the xy -plane. For example the equation $2x + y = 8$ describes a line such that if $x = 2$ then $y = 4$.)

A system of linear equations is a set of linear equations that you usually want to solve at the same time; that is, simultaneously. A basic principle for exact answers in solving simultaneous linear equations requires that there be as many equations as there are unknowns. To get exact answers for x and y there must be two equations. For example, to solve for x and y in the system of linear equations

$$2x + y = 13$$

$$x - 3y = -18$$

there must be two equations, which there are. Matrix algebra represents this system as an equation involving three matrices: A for the left-side constants, X for the variables, and B for the right-side constants

$$A = \begin{bmatrix} 2 & 1 \\ 1 & -3 \end{bmatrix} \quad X = \begin{bmatrix} x \\ y \end{bmatrix} \quad B = \begin{bmatrix} 13 \\ -18 \end{bmatrix}$$

where $A * X = B$.

Solving the system simultaneously simply means solving for X . Using MATLAB,

$$A = [2 \ 1 \\ 1 \ -3];$$

$$B = [13 \\ -18];$$

$$X = A \setminus B$$

solves for X in $A * X = B$.

$$X = [3 \\ 7]$$

So $x = 3$ and $y = 7$ in this example. In general, you can use matrix algebra to solve any system of linear equations such as

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n &= b_1 \\ a_{21}x_1 + a_{22}x_2 + \dots + a_{2n}x_n &= b_2 \\ &\vdots \\ a_{m1}x_1 + a_{m2}x_2 + \dots + a_{mn}x_n &= b_m \end{aligned}$$

by representing them as matrices

$$A = \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \vdots & \vdots \\ a_{m1} & a_{m2} & \dots & a_{mn} \end{bmatrix} \quad X = \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_n \end{bmatrix} \quad B = \begin{bmatrix} b_1 \\ b_2 \\ \vdots \\ b_m \end{bmatrix}$$

and solving for X in $A * X = B$.

To illustrate, consider this situation. There are two portfolios of mortgage-based instruments, M1 and M2. They have current annual cash payments of \$100 and \$70 per unit, respectively, based on today's prime rate. If the prime rate moves down one percentage point, their payments would be \$80 and \$40. An investor holds 10 units of M1 and 20 units of M2. The investor's receipts equal cash payments times units, or $R = C * U$, for each prime-rate scenario. As word equations:

	M1	M2
Prime flat:	\$100 * 10 units	+ \$70 * 20 units = \$2400 receipts
Prime down:	\$80 * 10 units	+ \$40 * 20 units = \$1600 receipts

As MATLAB matrices:

```
Cash = [100 70
        80 40];
```

```
Units =[10
        20];
```

```
Receipts = Cash * Units
```

```
Receipts =
        2400.00
        1600.00
```

Now the investor asks the question: given these two portfolios and their characteristics, how many units of each should I hold to receive \$7000 if the prime rate stays flat and \$5000 if the prime drops one percentage point? Find the answer by solving two linear equations.

	M1	M2
Prime flat:	\$100 * x units	+ \$70 * y units = \$7000 receipts
Prime down:	\$80 * x units	+ \$40 * y units = \$5000 receipts

In other words, solve for U (units) in the equation R (receipts) = C (cash) * U (units). Using MATLAB left division

```
Cash = [100 70
        80 40];
```

```
Receipts = [7000
            5000];
```

```
Units = Cash \ Receipts
Units =
```

```
43.75
```

37.50

The investor should hold 43.75 units of portfolio M1 and 37.5 units of portfolio M2 to achieve the annual receipts desired.

Operating Element by Element

Finally, element-by-element arithmetic operations are called *array* operations. To indicate an array operation in MATLAB, precede the operator with a period (.). Addition and subtraction, and matrix multiplication and division by a scalar, are already array operations so no period is necessary. When using array operations on two matrices, the dimensions of the matrices must be the same. For example, given vectors of stock dividends and closing prices

```
Dividends = [1.90  0.40  1.56  4.50];  
Prices = [25.625  17.75  26.125  60.50];
```

```
Yields = Dividends ./ Prices
```

```
Yields =
```

```
    0.0741    0.0225    0.0597    0.0744
```

Function Input and Output Arguments

- “Input Arguments” on page 1-18
- “Output Arguments” on page 1-20
- “Interest Rate Arguments” on page 1-21

MATLAB was designed to be a large-scale array (vector or matrix) processor. In addition to its linear algebra applications, the general array-based processing facility has the capability to perform repeated operations on collections of data. When MATLAB code is written to operate simultaneously on collections of data stored in arrays, the code is said to be vectorized. Vectorized code is not only clean and concise, but is also efficiently processed by the underlying MATLAB engine.

Input Arguments

Matrix Input

Because MATLAB can process vectors and matrices easily, most functions in Financial Toolbox allow vector or matrix input arguments, rather than just single (scalar) values. For example, the `irr` function computes the internal rate of return of a cash flow stream. It accepts a vector of cash flows and returns a scalar-valued internal rate of return. However, it also accepts a matrix of cash flow streams, a column in the matrix representing a different cash flow stream. In this case, `irr` returns a vector of internal rates of return, each entry in the vector corresponding to a column of the input matrix. Many other toolbox functions work similarly.

As an example, suppose you make an initial investment of \$100, from which you then receive by a series of annual cash receipts of \$10, \$20, \$30, \$40, and \$50. This cash flow stream may be stored in a vector

```
CashFlows = [-100 10 20 30 40 50]'
```

which MATLAB displays as

```
CashFlows =  
-100  
 10
```

```
20
30
40
50
```

The `irr` function can compute the internal rate of return of this stream.

```
Rate = irr(CashFlows)
```

The internal rate of return of this investment is

```
Rate =
```

```
0.1201
```

or 12.01%.

In this case, a single cash flow stream (written as an input vector) produces a scalar output – the internal rate of return of the investment.

Extending this example, if you process a matrix of identical cash flow streams

```
Rate = irr([CashFlows CashFlows CashFlows])
```

you should expect to see identical internal rates of return for each of the three investments.

```
Rate =
```

```
0.1201    0.1201    0.1201
```

This simple example illustrates the power of vectorized programming. The example shows how to collect data into a matrix and then use a toolbox function to compute answers for the entire collection. This feature can be useful in portfolio management, for example, where you might want to organize multiple assets into a single collection. Place data for each asset in a different column or row of a matrix, then pass the matrix to a Financial Toolbox function. MATLAB performs the same computation on all of the assets at once.

Matrices of String Input

Enter strings in MATLAB surrounded by single quotes ('string').

Strings are stored as character arrays, one ASCII character per element. Thus the date string

```
DateString = '9/16/2001'
```

is actually a 1-by-9 vector. Strings making up the rows of a matrix or vector all must have the same length. To enter several date strings, therefore, use a column vector and be sure all strings are the same length. Fill in with spaces or zeros. For example, to create a vector of dates corresponding to irregular cash flows

```
DateFields = ['01/12/2001'  
              '02/14/2001'  
              '03/03/2001'  
              '06/14/2001'  
              '12/01/2001'];
```

DateFields actually becomes a 5-by-10 character array.

Don't mix numbers and strings in a matrix. If you do, MATLAB treats all entries as characters. For example,

```
Item = [83 90 99 '14-Sep-1999']
```

becomes a 1-by-14 character array, not a 1-by-4 vector, and it contains

```
Item =  
  
SZc14-Sep-1999
```

Output Arguments

Some functions return no arguments, some return just one, and some return multiple arguments. Functions that return multiple arguments use the syntax

```
[A, B, C] = function(variables...)
```

to return arguments A, B, and C. If you omit all but one, the function returns the first argument. Thus, for this example if you use the syntax

```
X = function(variables...)
```

function returns a value for A, but not for B or C.

Some functions that return vectors accept only scalars as arguments. Why could such functions not accept vectors as arguments and return matrices, where each column in the output matrix corresponds to an entry in the input vector? The answer is that the output vectors can be variable length and thus will not fit in a matrix without some convention to indicate that the shorter columns are missing data.

Functions that require asset life as an input, and return values corresponding to different periods over that life, cannot generally handle vectors or matrices as input arguments. Those functions are

<code>amortize</code>	Amortization
<code>depxdb</code>	Fixed declining-balance depreciation
<code>depxdb</code>	General declining-balance depreciation
<code>depxdb</code>	Sum of years' digits depreciation

For example, suppose you have a collection of assets such as automobiles and you want to compute the depreciation schedules for them. The function `depxdb` computes a stream of declining-balance depreciation values for an asset. You might want to set up a vector where each entry is the initial value of each asset. `depxdb` also needs the lifetime of an asset. If you were to set up such a collection of automobiles as an input vector, and the lifetimes of those automobiles varied, the resulting depreciation streams would differ in length according to the life of each automobile, and the output column lengths would vary. A matrix must have the same number of rows in each column.

Interest Rate Arguments

One common argument, both as input and output, is interest rate. All Financial Toolbox functions expect and return interest rates as decimal fractions. Thus an interest rate of 9.5% is indicated as 0.095.

Performing Common Financial Tasks

Introduction (p. 2-2)

Pricing and Analyzing Equity Derivatives (p. 2-36)

Black-Scholes and binomial models.

Introduction

Financial Toolbox contains functions that perform many common financial tasks, including:

- “Handling and Converting Dates” on page 2-4

Calendar functions convert dates among different formats (including Excel formats), determine future or past dates, find dates of holidays and business days, compute time differences between dates, find coupon dates and coupon periods for coupon bonds, and compute time periods based on 360-, 365-, or 366-day years.

- “Formatting Currency” on page 2-12

The toolbox includes functions for handling decimal values in bank (currency) formats and as fractional prices.

- “Charting Financial Data” on page 2-13

Charting functions produce a variety of financial charts including Bollinger bands, high-low-close charts, candlestick plots, point and figure plots, and moving-average plots.

- “Analyzing and Computing Cash Flows” on page 2-17

Cash-flow evaluation and financial accounting functions compute interest rates, rates of return, payments associated with loans and annuities, future and present values, depreciation, and other standard accounting calculations associated with cash-flow streams.

- “Pricing and Computing Yields for Fixed-Income Securities” on page 2-21, analyzing the term structure of interest rates.

Securities Industry Association (SIA) compliant fixed-income functions compute prices, yields, accrued interest, and sensitivities for securities such as bonds, zero-coupon bonds, and Treasury bills. They handle odd first and last periods in price/yield calculations, compute accrued interest and discount rates, and calculate convexity and duration. Another set of functions analyzes term structure of interest rates, including pricing bonds from yield curves and bootstrapping yield curves from market prices.

- “Pricing and Analyzing Equity Derivatives” on page 2-36

Derivatives analysis functions compute prices, yields, and sensitivities for derivative securities. They deal with both European and American options.

Black-Scholes functions work with European options. They compute delta, gamma, lambda, rho, theta, and vega, as well as values of call and put options.

Binomial functions work with American options, computing put and call prices.

- “Analyzing Portfolios” on page 3-2

Portfolio analysis functions provide basic utilities to compute variances and covariance of portfolios, find combinations to minimize variance, compute Markowitz efficient frontiers, and calculate combined rates of return.

- Modeling volatility in time series.

Generalized Autoregressive Conditional Heteroskedasticity (GARCH) functions model the volatility of univariate economic time series. (GARCH Toolbox provides a more comprehensive and integrated computing environment. For information, see the GARCH Toolbox User’s Guide documentation or the financial products Web page at <http://www.mathworks.com/products/finprod>.)

Handling and Converting Dates

Since virtually all financial data is dated or derives from a time series, financial functions must have extensive date-handling capabilities. This section discusses date handling in Financial Toolbox, specifically the topics:

- “Date Formats” on page 2-4
- “Date Conversions” on page 2-5
- “Current Date and Time” on page 2-8
- “Determining Dates” on page 2-9

Date Formats

You most often work with date strings (14-Sep-1999) when dealing with dates. Financial Toolbox works internally with *serial date numbers* (for example, 730377). A serial date number represents a calendar date as the number of days that has passed since a fixed base date. In MATLAB, serial date number 1 is January 1, 0000 A.D. MATLAB also uses serial time to represent fractions of days beginning at midnight; for example, 6 p.m. equals 0.75 serial days. So 6:00 p.m. on 14-Sep-1999, in MATLAB, is date number 730377.75.

Note If you specify a two-digit year, MATLAB assumes that the year lies within the 100-year period centered about the current year. See the function `datenum` for specific information. MATLAB internal date handling and calculations generate no ambiguous values. However, whenever possible, programmers should use serial date numbers or date strings containing four-digit years.

Many toolbox functions that require dates accept either date strings or serial date numbers. If you are dealing with a few dates at the MATLAB command-line level, date strings are more convenient. If you are using toolbox functions on large numbers of dates, as in analyzing large portfolios or cash flows, performance improves if you use date numbers.

The toolbox provides functions that convert date strings to serial date numbers, and vice versa.

Date Conversions

Functions that convert between date formats are

<code>datedisp</code>	Displays a numeric matrix with date entries formatted as date strings
<code>datenum</code>	Converts a date string to a serial date number
<code>datestr</code>	Converts a serial date number to a date string
<code>m2xdate</code>	Converts MATLAB serial date number to Excel serial date number
<code>x2mdate</code>	Converts Excel serial date number to MATLAB serial date number

Another function, `datevec`, converts a date number or date string to a date vector whose elements are [Year Month Day Hour Minute Second]. Date vectors are mostly an internal format for some MATLAB functions; you would not often use them in financial calculations.

Input Conversions

The `datenum` function is important for using Financial Toolbox efficiently. `datenum` takes an input string in any of several formats, with `'dd-mmm-yyyy'`, `'mm/dd/yyyy'` or `'dd-mmm-yyyy, hh:mm:ss.ss'` most common. The input string can have up to six fields formed by letters and numbers separated by any other characters:

- The day field is an integer from 1 through 31.
- The month field is either an integer from 1 through 12 or an alphabetic string with at least three characters.
- The year field is a nonnegative integer: if only two numbers are specified, then the year is assumed to lie within the 100-year period centered about the current year; if the year is omitted, the current year is used as the default.
- The hours, minutes, and seconds fields are optional. They are integers separated by colons or followed by `'am'` or `'pm'`.

For example, if the current year is 1999, then these are all equivalent

```
'17-May-1999'  
'17-May-99'  
'17-may'  
'May 17, 1999'  
'5/17/99'  
'5/17'
```

and both of these represent the same time.

```
'17-May-1999, 18:30'  
'5/17/99/6:30 pm'
```

Note that the default format for numbers-only input follows the American convention. Thus 3/6 is March 6, not June 3.

With `datenum` you can convert dates into serial date format, store them in a matrix variable, then later pass the variable to a function. Alternatively, you can use `datenum` directly in a function input argument list.

For example, consider the function `bndprice` that computes the price of a bond given the yield-to-maturity. First set up variables for the yield-to-maturity, coupon rate, and the necessary dates.

```
Yield      = 0.07;  
CouponRate = 0.08;  
Settle     = datenum('17-May-2000');  
Maturity   = datenum('01-Oct-2000');
```

Then call the function with the variables

```
bndprice(Yield, CouponRate, Settle, Maturity)
```

Alternatively, convert date strings to serial date numbers directly in the function input argument list.

```
bndprice(0.07, 0.08, datenum('17-May-2000'), ...  
        datenum('01-Oct-2000'))
```

`bndprice` is an example of a function designed to detect the presence of date strings and make the conversion automatically. For these functions date strings may be passed directly.

```
bndprice(0.07, 0.08, '17-May-2000', '01-Oct-2000')
```

The decision to represent dates as either date strings or serial date numbers is often a matter of convenience. For example, when formatting data for visual display or for debugging date-handling code, it is often much easier to view dates as date strings because serial date numbers are difficult to interpret. Alternatively, serial date numbers are just another type of numeric data, and can be placed in a matrix along with any other numeric data for convenient manipulation.

Remember that if you create a vector of input date strings, use a column vector and be sure all strings are the same length. Fill with spaces or zeros. See “Matrices of String Input” on page 1-20.

Output Conversions

The function `datestr` converts a serial date number to one of 19 different date string output formats showing date, time, or both. The default output for dates is a day-month-year string, for example, 24-Aug-2000. This function is quite useful for preparing output reports.

Format	Description
01-Mar-2000 15:45:17	day-month-year hour:minute:second
01-Mar-2000	day-month-year
03/01/00	month/day/year
Mar	month, three letters
M	month, single letter
3	month
03/01	month/day
1	day of month
Wed	day of week, three letters
W	day of week, single letter
2000	year, four numbers
99	year, two numbers

Format	Description
Mar01	month year
15:45:17	hour:minute:second
03:45:17 PM	hour:minute:second AM or PM
15:45	hour:minute
03:45 PM	hour:minute AM or PM
Q1-99	calendar quarter-year
Q1	calendar quarter

Current Date and Time

The functions `today` and `now` return serial date numbers for the current date, and the current date and time, respectively.

```
today
```

```
ans =  
    730693
```

```
now
```

```
ans =  
    730693.48
```

The MATLAB function `date` returns a string for today's date.

```
date
```

```
ans =  
    26-Jul-2000
```

Determining Dates

The toolbox provides many functions for determining specific dates, including functions which account for holidays and other nontrading days. For example, you schedule an accounting procedure for the last Friday of every month. The `lweekdate` function returns those dates for 2000; the 6 specifies Friday.

```
Fridates = lweekdate(6, 2000, 1:12);
```

```
Fridays = datestr(Fridates)
```

```
Fridays =
```

```
28-Jan-2000
```

```
25-Feb-2000
```

```
31-Mar-2000
```

```
28-Apr-2000
```

```
26-May-2000
```

```
30-Jun-2000
```

```
28-Jul-2000
```

```
25-Aug-2000
```

```
29-Sep-2000
```

```
27-Oct-2000
```

```
24-Nov-2000
```

```
29-Dec-2000
```

Or your company closes on Martin Luther King Jr. Day, which is the third Monday in January. The `nweekdate` function determines those dates for 2001 through 2004.

```
MLKDates = nweekdate(3, 2, 2001:2004, 1);
```

```
MLKDays = datestr(MLKDates)
```

```
MLKDays =
```

```
15-Jan-2001
```

```
21-Jan-2002
```

```
20-Jan-2003
```

```
19-Jan-2004
```

Accounting for holidays and other nontrading days is important when examining financial dates. The toolbox provides the `holidays` function, which contains holidays and special nontrading days for the New York Stock Exchange between 1950 and 2030, inclusive. You can edit the `holidays.m` file to customize it with your own holidays and nontrading days. In this example, use it to determine the standard holidays in the last half of 2000.

```
LHHDates = holidays('1-Jul-2000', '31-Dec-2000');  
  
LHHDays = datestr(LHHDates)  
  
LHHDays =  
  
04-Jul-2000  
04-Sep-2000  
23-Nov-2000  
25-Dec-2000
```

Now use the toolbox `busdate` function to determine the next business day after these holidays.

```
LHNNextDates = busdate(LHHDates);  
  
LHNNextDays = datestr(LHNNextDates)  
  
LHNNextDays =  
  
05-Jul-2000  
05-Sep-2000  
24-Nov-2000  
26-Dec-2000
```

The toolbox also provides the `cfdates` function to determine cash-flow dates for securities with periodic payments. This function accounts for the coupons per year, the day-count basis, and the end-of-month rule. For example, to determine the cash-flow dates for a security that pays four coupons per year on the last day of the month, on an actual/365 day-count basis, just enter the settlement date, the maturity date, and the parameters.

```
PayDates = cfdates('14-Mar-2000', '30-Nov-2001', 4, 3, 1);
```

```
PayDays = datestr(PayDates)
```

```
PayDays =
```

```
31-May-2000
```

```
31-Aug-2000
```

```
30-Nov-2000
```

```
28-Feb-2001
```

```
31-May-2001
```

```
31-Aug-2001
```

```
30-Nov-2001
```

Formatting Currency

Financial Toolbox provides several functions to format currency and chart financial data. The currency formatting functions are

<code>cur2frac</code>	Converts decimal currency values to fractional values
<code>cur2str</code>	Converts a value to Financial Toolbox bank format
<code>frac2cur</code>	Converts fractional currency values to decimal values

These examples show their use.

```
Dec = frac2cur('12.1', 8)
```

returns `Dec = 12.125`, which is the decimal equivalent of $12\frac{1}{8}$. The second input variable is the denominator of the fraction.

```
Str = cur2str(-8264, 2)
```

returns the string `($8264.00)`. For this toolbox function, the output format is a numerical format with dollar sign prefix, two decimal places, and negative numbers in parentheses; for example, `($123.45)` and `$6789.01`. The standard MATLAB bank format uses two decimal places, no dollar sign, and a minus sign for negative numbers; for example, `-123.45` and `6789.01`.

Charting Financial Data

- “High-Low-Close Chart Example” on page 2-14
- “Bollinger Chart Example” on page 2-15

The following toolbox financial charting functions plot financial data and produce presentation-quality figures quickly and easily.

<code>bolling</code>	Bollinger band chart
<code>bollinger</code>	Time series Bollinger band
<code>candle</code>	Candlestick chart
<code>candle</code>	Time series candle plot
<code>pointfig</code>	Point and figure chart
<code>highlow</code>	High, low, open, close chart
<code>highlow</code>	Time series High-Low plot
<code>movavg</code>	Leading and lagging moving averages chart

These functions work with standard MATLAB functions that draw axes, control appearance, and add labels and titles. The toolbox also provides a comprehensive set of charting functions that work with financial time series objects. For lists of these, see “Charting Financial Data” on page 12-6 and “Financial Time Series Indicator” on page 12-21.

Here are two plotting examples: a high-low-close chart of sample IBM stock price data, and a Bollinger band chart of the same data. These examples load data from an external file (`ibm.dat`), then call the functions using subsets of the data. The MATLAB variable `ibm`, which is created by loading `ibm.dat`, is a six-column matrix where each row is a trading day’s data and where columns 2, 3, and 4 contain the high, low, and closing prices, respectively.

Note The data in `ibm.dat` is fictional and for illustrative use only.

High-Low-Close Chart Example

First load the data and set up matrix dimensions. `load` and `size` are standard MATLAB functions.

```
load ibm.dat;  
[ro, co] = size(ibm);
```

Open a figure window for the chart. Use Financial Toolbox `highlow` function to plot high, low, and close prices for the last 50 trading days in the data file.

```
figure;  
highlow(ibm(ro-50:ro,2),ibm(ro-50:ro,3),ibm(ro-50:ro,4),[], 'b');
```

Add labels and title, and set axes with standard MATLAB functions. Use Financial Toolbox `dateaxis` function to provide dates for the x -axis ticks.

```
xlabel('');  
ylabel('Price ($)');  
title('International Business Machines, 941231 - 950219');  
axis([0 50 -inf inf]);  
dateaxis('x',6,'31-Dec-1994')
```

MATLAB produces a figure like this. The plotted data and axes you see may differ. Viewed online, the high-low-close bars are blue.

Bollinger Chart Example

The `bolling` function in Financial Toolbox produces a Bollinger band chart using all the closing prices in the same IBM stock price matrix. A Bollinger band chart plots actual data along with three other bands of data. The upper band is two standard deviations above a moving average; the lower band is two standard deviations below that moving average; and the middle band is the moving average itself. This example uses a 15-day moving average.

Assuming the previous IBM data is still loaded, simply execute the function.

```
bolling(ibm(:,4), 15, 0);
```

Specify the axes, labels, and titles. Again, use `dateaxis` to add the x -axis dates.

```
axis([0 ro min(ibm(:,4)) max(ibm(:,4))]);
ylabel('Price ($)');
title(['International Business Machines']);
```

```
dateaxis('x', 6, '31-Dec-1994')
```

For help using MATLAB plotting functions, see “Creating Plots” in the MATLAB documentation. See the MATLAB documentation for details on the axis, title, xlabel, and ylabel functions.

Analyzing and Computing Cash Flows

Financial Toolbox cash-flow functions compute interest rates and rates of return, present or future values, depreciation streams, and annuities.

- “Interest Rates/Rates of Return” on page 2-17
- “Present or Future Values” on page 2-18
- “Depreciation” on page 2-19
- “Annuities” on page 2-19

Some examples in this section use this income stream: an initial investment of \$20,000 followed by three annual return payments, a second investment of \$5,000, then four more returns. Investments are negative cash flows, return payments are positive cash flows.

```
Stream = [-20000, 2000, 2500, 3500, -5000, 6500, ...
          9500, 9500, 9500];
```

Interest Rates/Rates of Return

Several functions calculate interest rates involved with cash flows. To compute the internal rate of return of the cash stream, simply execute the toolbox function `irr`

```
ROR = irr(Stream)
```

which gives a rate of return of 11.72%.

Note that the internal rate of return of a cash flow may not have a unique value. Every time the sign changes in a cash flow, the equation defining `irr` can give up to two additional answers. An `irr` computation requires solving a polynomial equation, and the number of real roots of such an equation can depend on the number of sign changes in the coefficients. The equation for internal rate of return is

$$\frac{cf_1}{(1+r)} + \frac{cf_2}{(1+r)^2} + \dots + \frac{cf_n}{(1+r)^n} + Investment = 0$$

where *Investment* is a (negative) initial cash outlay at time 0, cf_n is the cash flow in the n th period, and n is the number of periods. Basically, `irr` finds the rate r such that the net present value of the cash flow equals the initial investment. If all of the cf_n s are positive there is only one solution. Every time there is a change of sign between coefficients, up to two additional real roots are possible. There is usually only one answer that makes sense, but it is possible to get returns of both 5% and 11% (for example) from one income stream.

Another toolbox rate function, `effrr`, calculates the effective rate of return given an annual interest rate (also known as nominal rate or annual percentage rate, APR) and number of compounding periods per year. To find the effective rate of a 9% APR compounded monthly, simply enter

```
Rate = effrr(0.09, 12)
```

The answer is 9.38%.

A companion function `nomrr` computes the nominal rate of return given the effective annual rate and the number of compounding periods.

Present or Future Values

The toolbox includes functions to compute the present or future value of cash flows at regular or irregular time intervals with equal or unequal payments: `fvfix`, `fvvar`, `pvfix`, and `pvar`. The `-fix` functions assume equal cash flows at regular intervals, while the `-var` functions allow irregular cash flows at irregular periods.

Now compute the net present value of the sample income stream for which you computed the internal rate of return. This exercise also serves as a check on that calculation because the net present value of a cash stream at its internal rate of return should be zero. Enter

```
NPV = pvar(Stream, ROR)
```

which returns an answer very close to zero. The answer usually is not *exactly* zero due to rounding errors and the computational precision of the computer.

Note Other toolbox functions behave similarly. The functions that compute a bond's yield, for example, often must solve a nonlinear equation. If you then use that yield to compute the net present value of the bond's income stream, it usually does not *exactly* equal the purchase price, but the difference is negligible for practical applications.

Depreciation

The toolbox includes functions to compute standard depreciation schedules: straight line, general declining-balance, fixed declining-balance, and sum of years' digits. Functions also compute a complete amortization schedule for an asset, and return the remaining depreciable value after a depreciation schedule has been applied.

This example depreciates an automobile worth \$15,000 over five years with a salvage value of \$1,500. It computes the general declining balance using two different depreciation rates: 50% (or 1.5), and 100% (or 2.0, also known as double declining balance). Enter

```
Decline1 = depreddb(15000, 1500, 5, 1.5)
Decline2 = depreddb(15000, 1500, 5, 2.0)
```

which returns

```
Decline1 =
    4500.00    3150.00    2205.00    1543.50    2101.50
Decline2 =
    6000.00    3600.00    2160.00    1296.00    444.00
```

These functions return the actual depreciation amount for the first four years and the remaining depreciable value as the entry for the fifth year.

Annuities

Several toolbox functions deal with annuities. This first example shows how to compute the interest rate associated with a series of loan payments when only the payment amounts and principal are known. For a loan whose original value was \$5000.00 and which was paid back monthly over four years at \$130.00/month

```
Rate = annurate(4*12, 130, 5000, 0, 0)
```

The function returns a rate of 0.0094 monthly, or approximately 11.28% annually.

The next example uses a present-value function to show how to compute the initial principal when the payment and rate are known. For a loan paid at \$300.00/month over four years at 11% annual interest

```
Principal = pvfix(0.11/12, 4*12, 300, 0, 0)
```

The function returns the original principal value of \$11,607.43.

The final example computes an amortization schedule for a loan or annuity. The original value was \$5000.00 and was paid back over 12 months at an annual rate of 9%.

```
[Prpmt, Intpmt, Balance, Payment] = ...  
    amortize(0.09/12, 12, 5000, 0, 0);
```

This function returns vectors containing the amount of principal paid,

```
Prpmt = [399.76 402.76 405.78 408.82 411.89 414.97  
         418.09 421.22 424.38 427.56 430.77 434.00]
```

the amount of interest paid,

```
Intpmt = [37.50 34.50 31.48 28.44 25.37 22.28  
         19.17 16.03 12.88 9.69 6.49 3.26]
```

the remaining balance for each period of the loan,

```
Balance = [4600.24 4197.49 3791.71 3382.89 2971.01  
          2556.03 2137.94 1716.72 1292.34 864.77  
          434.00 0.00]
```

and a scalar for the monthly payment.

```
Payment = 437.26
```

Pricing and Computing Yields for Fixed-Income Securities

- “Terminology” on page 2-21
- “SIA Framework” on page 2-26
- “SIA Default Parameter Values” on page 2-27
- “SIA Coupon Date Calculations” on page 2-29
- “SIA Semiannual Yield Conventions” on page 2-30
- “Pricing Functions” on page 2-30
- “Yield Functions” on page 2-31
- “Fixed-Income Sensitivities” on page 2-32
- “Term Structure of Interest Rates” on page 2-33

The Securities Industry Association (SIA) has established conventions regarding bond pricing, yield calculation and quotation, time factors and accrued interest, coupon and quasi-coupon dates, and duration and convexity sensitivity measures. Financial Toolbox includes SIA-compliant functions to compute accrued interest, determine prices and yields, as well as calculate convexity and duration of fixed-income securities. It also includes a set of functions to generate and analyze term structure of interest rates.

SIA-compliant functions can be used with U.S. Treasury bills, bonds, and notes; corporate bonds; and municipal bonds. Bonds can have long, normal, or short first or last coupon periods.

Chapter 12, “Functions — By Category” identifies SIA-compliant functions. These functions have been thoroughly tested against the benchmarks in Jan Mayle’s *Standard Securities Calculation Methods*, in Appendix A, “Bibliography”.

Terminology

Since terminology varies among texts on this subject, here are some basic definitions that apply to these Financial Toolbox functions. The “Glossary” on page Glossary-1 contains additional definitions.

The *settlement date* of a bond is the date when money first changes hands; that is, when a buyer pays for a bond. It need not coincide with the *issue date*, which is the date a bond is first offered for sale.

The *first coupon date* and *last coupon date* are the dates when the first and last coupons are paid, respectively. Although bonds typically pay periodic annual or semiannual coupons, the length of the first and last coupon periods may differ from the standard coupon period. The toolbox includes price and yield functions that handle these odd first and/or last periods.

Successive *quasi-coupon dates* determine the length of the standard coupon period for the fixed income security of interest, and do not necessarily coincide with actual coupon payment dates. The toolbox includes functions that calculate both actual and quasi-coupon dates for bonds with odd first and/or last periods.

Fixed-income securities can be purchased on dates that do not coincide with coupon payment dates. In this case, the bond owner is not entitled to the full value of the coupon for that period. When a bond is purchased between coupon dates, the buyer must compensate the seller for the pro-rata share of the coupon interest earned from the previous coupon payment date. This pro-rata share of the coupon payment is called *accrued interest*. The *purchase price*, the price actually paid for a bond, is the quoted market price plus accrued interest.

The *maturity date* of a bond is the date when the issuer returns the final face value, also known as the *redemption value* or *par value*, to the buyer. The *yield-to-maturity* of a bond is the nominal compound rate of return that equates the present value of all future cash flows (coupons and principal) to the current market price of the bond.

The *period* of a bond refers to the frequency with which the issuer of a bond makes coupon payments to the holder.

Period of a Bond

Period Value	Payment Schedule
0	No coupons (Zero coupon bond)
1	Annual

Period of a Bond (Continued)

Period Value	Payment Schedule
2	Semiannual
3	Tri-annual
4	Quarterly
6	Bi-monthly
12	Monthly

The *basis* of a bond refers to the basis or day-count convention for a bond. Basis is normally expressed as a fraction in which the numerator determines the number of days between two dates, and the denominator determines the number of days in the year. For example, the numerator of *actual/actual* means that when determining the number of days between two dates, count the actual number of days; the denominator means that you use the actual number of days in the given year in any calculations (either 365 or 366 days depending on whether the given year is a leap year).

Basis of a Bond

Basis Value	Meaning	Description
0 (default)	actual/actual	Actual days held over actual days in coupon period. Denominator is 365 in most years and 366 in a leap year.
1	30/360 (SIA)	Each month contains 30 days; a year contains 360 days. Payments are adjusted for bonds that pay coupons on the last day of February.
2	actual/360	Actual days held over 360.

Basis of a Bond (Continued)

Basis Value	Meaning	Description
3	actual/365	Actual days held over 365, even in leap years.
4	30/360 PSA (Public Securities Association)	Each month contains 30 days; a year contains 360 days. If the last date of the period is the last day of February, the month is extended to 30 days.
5	30/360 ISDA (International Swap Dealers Association)	Variant of 30/360 with slight differences for calculating number of days in a month.
6	30/360 European	Variant of 30/360 used primarily in Europe.
7	actual/365 Japanese	All years contain 365 days. Leap days are ignored.
8	actual/actual (ISMA)	Actual days held over actual days in coupon period. Denominator is 365 in most years and 366 in a leap year. This basis assumes an annual compounding period.

Basis of a Bond (Continued)

Basis Value	Meaning	Description
9	actual/360 (ISMA)	Actual days held over 360. This basis assumes an annual compounding period.
10	actual/365 (ISMA)	Actual days held over 365, even in leap years. This basis assumes an annual compounding period.

Note Although the concept of day count sounds deceptively simple, the actual calculation of day counts can be quite complex. You can find a good discussion of day counts and the formulas for calculating them in Chapter 5 of Stigum and Robinson, *Money Market and Bond Calculations* in Appendix A, “Bibliography”.

The *end-of-month rule* affects a bond’s coupon payment structure. When the rule is in effect, a security that pays a coupon on the last actual day of a month will always pay coupons on the last day of the month. This means, for example, that a semiannual bond that pays a coupon on February 28 in nonleap years will pay coupons on August 31 in all years and on February 29 in leap years.

End-of-Month Rule

End-of-Month Rule Value	Meaning
1 (default)	Rule in effect.
0	Rule not in effect.

SIA Framework

Many of the fixed-income related functions in Financial Toolbox comply with the Securities Industry Association (SIA) conventions. Although not all SIA-compliant functions require the same input arguments, they all accept the following common set of input arguments.

SIA Common Input Arguments

Input	Meaning
Settle	Settlement date
Maturity	Maturity date
Period	Coupon payment period
Basis	Day-count basis
EndMonthRule	End-of-month payment rule
IssueDate	Bond issue date
FirstCouponDate	First coupon payment date
LastCouponDate	Last coupon payment date

Of the common input arguments, only `Settle` and `Maturity` are required. All others are optional. They will be set to the default values if you do not explicitly set them. Note that, by default, the `FirstCouponDate` and `LastCouponDate` are nonapplicable. In other words, if you do not specify `FirstCouponDate` and `LastCouponDate`, the bond is assumed to have no odd first or last coupon periods. In this case, the bond is simply a standard bond with a coupon payment structure based solely on the maturity date.

SIA Default Parameter Values

To illustrate the use of default values in SIA-compliant functions, consider the `cfdates` function, which computes actual cash flow payment dates for a portfolio of fixed income securities regardless of whether the first and/or last coupon periods are normal, long, or short.

The complete calling syntax with the full input argument list is

```
CFlowDates = cfdates(Settle, Maturity, Period, Basis, ...
    EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate)
```

while the minimal calling syntax requires only settlement and maturity dates

```
CFlowDates = cfdates(Settle, Maturity)
```

Single Bond Example

As an example, suppose you have a bond with these characteristics

```
Settle          = '20-Sep-1999'
Maturity        = '15-Oct-2007'
Period          = 2
Basis           = 0
EndMonthRule    = 1
IssueDate       = NaN
FirstCouponDate = NaN
LastCouponDate  = NaN
```

Note that `Period`, `Basis`, and `EndMonthRule` are set to their default values, and `IssueDate`, `FirstCouponDate`, and `LastCouponDate` are set to `NaN`.

Formally, a `NaN` is an IEEE arithmetic standard for *Not-a-Number* and is used to indicate the result of an undefined operation (for example, zero divided by zero). However, `NaN` is also a very convenient placeholder. In the SIA functions of Financial Toolbox, `NaN` indicates the presence of a nonapplicable value. It tells the SIA fixed-income functions to ignore the input value and apply the default. Setting `IssueDate`, `FirstCouponDate`, and `LastCouponDate` to `NaN` in this example tells `cfdates` to assume that the bond has been issued prior to settlement and that no odd first or last coupon periods exist.

Having set these values, all these calls to `cfdates` produce the same result.

```
cfdates(Settle, Maturity)
cfdates(Settle, Maturity, Period)
cfdates(Settle, Maturity, Period, [])
cfdates(Settle, Maturity, [], Basis)
cfdates(Settle, Maturity, [], [])
cfdates(Settle, Maturity, Period, [], EndMonthRule)
cfdates(Settle, Maturity, Period, [], NaN)
cfdates(Settle, Maturity, Period, [], [], IssueDate)
cfdates(Settle, Maturity, Period, [], [], IssueDate, [], [])
cfdates(Settle, Maturity, Period, [], [], [], [], LastCouponDate)
cfdates(Settle, Maturity, Period, Basis, EndMonthRule, ...
IssueDate, FirstCouponDate, LastCouponDate)
```

Thus, leaving a particular input unspecified has the same effect as passing an empty matrix (`[]`) or passing a `NaN` – all three tell `cfdates` (and other SIA-compliant functions) to use the default value for a particular input parameter.

Bond Portfolio Example

Since the previous example included only a single bond, there was no difference between passing an empty matrix or passing a `NaN` for an optional input argument. For a portfolio of bonds, however, using `NaN` as a placeholder is the only way to specify default acceptance for some bonds while explicitly setting nondefault values for the remaining bonds in the portfolio.

Now suppose you have a portfolio of two bonds.

```
Settle    = '20-Sep-1999'
Maturity  = ['15-Oct-2007'; '15-Oct-2010']
```

These calls to `cfdates` all set the coupon period to its default value (`Period = 2`) for both bonds.

```
cfdates(Settle, Maturity, 2)
cfdates(Settle, Maturity, [2 2])
cfdates(Settle, Maturity, [])
cfdates(Settle, Maturity, NaN)
cfdates(Settle, Maturity, [NaN NaN])
```

```
cfdates(Settle, Maturity)
```

The first two calls explicitly set `Period = 2`. Since `Maturity` is a 2-by-1 vector of maturity dates, `cfdates` knows you have a two-bond portfolio.

The first call specifies a single (that is, scalar) 2 for `Period`. Passing a scalar tells `cfdates` to apply the scalar-valued input to all bonds in the portfolio. This is an example of implicit scalar-expansion. Note that the settlement date has been implicit scalar-expanded as well.

The second call also applies the default coupon period by explicitly passing a two-element vector of 2's. The third call passes an empty matrix, which `cfdates` interprets as an invalid period, for which the default value will be used. The fourth call is similar, except that a NaN has been passed. The fifth call passes two NaN's, and has the same effect as the third. The last call passes the minimal input set.

Finally, consider the following calls to `cfdates` for the same two-bond portfolio.

```
cfdates(Settle, Maturity, [4 NaN])
cfdates(Settle, Maturity, [4 2])
```

The first call explicitly sets `Period = 4` for the first bond and implicitly sets the default `Period = 2` for the second bond. The second call has the same effect as the first but explicitly sets the periodicity for both bonds.

The optional input `Period` has been used for illustrative purpose only. The default-handling process illustrated in the examples applies to any of the optional input arguments.

SIA Coupon Date Calculations

Calculating coupon dates, either actual or quasi dates, is notoriously complicated. Financial Toolbox follows the SIA conventions in coupon date calculations.

The first step in finding the coupon dates associated with a bond is to determine the reference, or synchronization date (the *sync date*). Within the SIA framework, the order of precedence for determining the sync date is:

- 1 The first coupon date
- 2 The last coupon date
- 3 The maturity date

In other words, an SIA-compliant function in Financial Toolbox first examines the `FirstCouponDate` input. If `FirstCouponDate` is specified, coupon payment dates and quasi-coupon dates are computed with respect to `FirstCouponDate`; if `FirstCouponDate` is unspecified, empty (`[]`), or `NaN`, then the `LastCouponDate` is examined. If `LastCouponDate` is specified, coupon payment dates and quasi-coupon dates are computed with respect to `LastCouponDate`. If both `FirstCouponDate` and `LastCouponDate` are unspecified, empty (`[]`), or `NaN`, the `Maturity` (a required input argument) serves as the sync date.

SIA Semiannual Yield Conventions

Within the SIA framework, all yields and time factors for price-to-yield conversion are quoted on a semiannual bond basis (see `bndprice`, `bndyield`, and `cfamounts`) regardless of the period of the bond's coupon payments (including zero-coupon bonds). In addition, any yield-related sensitivity (that is, duration and convexity), when quoted on a periodic basis, assumes semiannual coupon periods. (See `bndconvp`, `bndconvy`, `bnddurp`, and `bnddury`.)

Pricing Functions

This example shows how easily you can compute the price of a bond with an odd first period using the SIA-compliant function `bndprice`. Assume you have a bond with these characteristics:

```
Settle           = '11-Nov-1992';  
Maturity         = '01-Mar-2005';  
IssueDate       = '15-Oct-1992';  
FirstCouponDate = '01-Mar-1993';  
CouponRate      = 0.0785;  
Yield           = 0.0625;
```

Allow coupon payment period (`Period = 2`), day-count basis (`Basis = 0`), and end-of-month rule (`EndMonthRule = 1`) to assume the default values. Also, assume there is no odd last coupon date and that the face value of the bond is \$100. Calling the function

```
[Price, AccruedInt] = bndprice(Yield, CouponRate, Settle, ...
    Maturity, [], [], [], IssueDate, FirstCouponDate)
```

returns a price of \$113.60 and accrued interest of \$0.59.

Similar functions compute prices with regular payments, odd first and last periods, as well as prices of Treasury bills and discounted securities such as zero-coupon bonds.

Note `bndprice` and other SIA-compliant functions use nonlinear formulas to compute the price of a security. For this reason, Financial Toolbox uses Newton's method when solving for an independent variable within a formula. See any elementary numerical methods textbook for the mathematics underlying Newton's method.

Yield Functions

To illustrate toolbox yield functions, compute the yield of a bond that has odd first and last periods and settlement in the first period. First set up variables for settlement, maturity date, issue, first coupon, and a last coupon date.

```
Settle          = '12-Jan-2000';
Maturity        = '01-Oct-2001';
IssueDate       = '01-Jan-2000';
FirstCouponDate = '15-Jan-2000';
LastCouponDate  = '15-Apr-2000';
```

Assume a face value of \$100. Specify a purchase price of \$95.70, a coupon rate of 4%, quarterly coupon payments, and a 30/360 day-count convention (`Basis = 1`).

```
Price          = 95.7;
CouponRate     = 0.04;
```

```
Period      = 4;  
Basis       = 1;  
EndMonthRule = 1;
```

Calling the function

```
Yield = bndyield(Price, CouponRate, Settle, Maturity, Period,...  
Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate)
```

returns

```
Yield = 0.0659 (6.60%).
```

Fixed-Income Sensitivities

The toolbox includes SIA-compliant functions to perform sensitivity analysis such as convexity and the Macaulay and modified durations for fixed-income securities. The Macaulay duration of an income stream, such as a coupon bond, measures how long, on average, the owner waits before receiving a payment. It is the weighted average of the times payments are made, with the weights at time T equal to the present value of the money received at time T . The modified duration is the Macaulay duration discounted by the per-period interest rate; that is, divided by $(1+\text{rate}/\text{frequency})$.

To illustrate, the following example computes the annualized Macaulay and modified durations, and the periodic Macaulay duration for a bond with settlement (12-Jan-2000) and maturity (01-Oct-2001) dates as above, a 5% coupon rate, and a 4.5% yield to maturity. For simplicity, any optional input arguments assume default values (that is, semiannual coupons, and day-count basis = 0 (actual/actual), coupon payment structure synchronized to the maturity date, and end-of-month payment rule in effect).

```
CouponRate = 0.05;  
Yield = 0.045;
```

```
[ModDuration, YearDuration, PerDuration] = bnddury(Yield,...  
CouponRate, Settle, Maturity)
```

The durations are

```

ModDuration = 1.6107 (years)
YearDuration = 1.6470 (years)
PerDuration = 3.2940 (semiannual periods)

```

Note that the semiannual periodic Macaulay duration (PerDuration) is twice the annualized Macaulay duration (YearDuration).

Term Structure of Interest Rates

The toolbox contains several functions to derive and analyze interest rate curves, including data conversion and extrapolation, bootstrapping, and interest-rate curve conversion functions.

One of the first problems in analyzing the term structure of interest rates is dealing with market data reported in different formats. Treasury bills, for example, are quoted with bid and asked bank-discount rates. Treasury notes and bonds, on the other hand, are quoted with bid and asked prices based on \$100 face value. To examine the full spectrum of Treasury securities, analysts must convert data to a single format. Toolbox functions ease this conversion. This brief example uses only one security each; analysts often use 30, 100, or more of each.

First, capture Treasury bill quotes in their reported format

```

%      Maturity      Days Bid    Ask    AskYield
TBill = [datenum('12/26/2000') 53    0.0503 0.0499 0.0510];

```

then capture Treasury bond quotes in their reported format

```

%      Coupon Maturity      Bid    Ask    AskYield
TBond = [0.08875 datenum(2001,11,5) 103+4/32 103+6/32 0.0564];

```

and note that these quotes are based on a November 3, 2000 settlement date.

```

Settle = datenum('3-Nov-2000');

```

Next use the toolbox `tb12bond` function to convert the Treasury bill data to Treasury bond format.

```

TBTBond = tb12bond(TBill)

```

```
TBTBond =  
        0      730846      99.26      99.27      0.05
```

(The second element of TBTBond is the serial date number for December 26, 2000.)

Now combine short-term (Treasury bill) with long-term (Treasury bond) data to set up the overall term structure.

```
TBondsAll = [TBTBond; TBond]
```

```
TBondsAll =  
        0      730846      99.26      99.27      0.05  
    0.09      731160      103.13      103.19      0.06
```

The toolbox provides a second data-preparation function, `tr2bonds`, to convert the bond data into a form ready for the bootstrapping functions. `tr2bonds` generates a matrix of bond information sorted by maturity date, plus vectors of prices and yields.

```
[Bonds, Prices, Yields] = tr2bonds(TBondsAll);
```

With this market data, you are now ready to use one of the toolbox bootstrapping functions to derive an implied zero curve. Bootstrapping is a process whereby you begin with known data points and solve for unknown data points using an underlying arbitrage theory. Every coupon bond can be valued as a package of zero-coupon bonds which mimic its cash flow and risk characteristics. By mapping yields-to-maturity for each theoretical zero-coupon bond, to the dates spanning the investment horizon, you can create a theoretical zero-rate curve. The toolbox provides two bootstrapping functions: `zbtprice` derives a zero curve from bond data and *prices*, and `zbtyield` derives a zero curve from bond data and *yields*. Using `zbtprice`

```
[ZeroRates, CurveDates] = zbtprice(Bonds, Prices, Settle)
```

```
ZeroRates =  
        0.05  
        0.06
```

```
CurveDates =
```

```
    730846  
    731160
```

CurveDates gives the investment horizon.

```
datestr(CurveDates)
```

```
ans =
```

```
26-Dec-2000  
05-Nov-2001
```

Additional toolbox functions construct discount, forward, and par yield curves from the zero curve, and vice versa.

```
[DiscRates, CurveDates] = zero2disc(ZeroRates, CurveDates,...  
Settle);  
[FwdRates, CurveDates] = zero2fwd(ZeroRates, CurveDates, Settle);  
[PYldRates, CurveDates] = zero2pyld(ZeroRates, CurveDates,...  
Settle);
```

Pricing and Analyzing Equity Derivatives

- “Sensitivity Measures” on page 2-36
- “Analysis Models” on page 2-37

These toolbox functions compute prices, sensitivities, and profits for portfolios of options or other equity derivatives. They use the Black-Scholes model for European options and the binomial model for American options. Such measures are useful for managing portfolios and for executing collars, hedges, and straddles.

Sensitivity Measures

There are six basic sensitivity measures associated with option pricing: delta, gamma, lambda, rho, theta, and vega — the “greeks.” The toolbox provides functions for calculating each sensitivity and for implied volatility.

Delta

Delta of a derivative security is the rate of change of its price relative to the price of the underlying asset. It is the first derivative of the curve that relates the price of the derivative to the price of the underlying security. When delta is large, the price of the derivative is sensitive to small changes in the price of the underlying security.

Gamma

Gamma of a derivative security is the rate of change of delta relative to the price of the underlying asset; that is, the second derivative of the option price relative to the security price. When gamma is small, the change in delta is small. This sensitivity measure is important for deciding how much to adjust a hedge position.

Lambda

Lambda, also known as the elasticity of an option, represents the percentage change in the price of an option relative to a 1% change in the price of the underlying security.

Rho

Rho is the rate of change in option price relative to the risk-free interest rate.

Theta

Theta is the rate of change in the price of a derivative security relative to time. Theta is usually very small or negative since the value of an option tends to drop as it approaches maturity.

Vega

Vega is the rate of change in the price of a derivative security relative to the volatility of the underlying security. When vega is large the security is sensitive to small changes in volatility. For example, options traders often must decide whether to buy an option to hedge against vega or gamma. The hedge selected usually depends upon how frequently one rebalances a hedge position and also upon the standard deviation of the price of the underlying asset (the volatility). If the standard deviation is changing rapidly, balancing against vega is usually preferable.

Implied Volatility

The implied volatility of an option is the standard deviation that makes an option price equal to the market price. It helps determine a market estimate for the future volatility of a stock and provides the input volatility (when needed) to the other Black-Scholes functions.

Analysis Models

Toolbox functions for analyzing equity derivatives use the Black-Scholes model for European options and the binomial model for American options. The Black-Scholes model makes several assumptions about the underlying securities and their behavior. The binomial model, on the other hand, makes far fewer assumptions about the processes underlying an option. For further explanation, see Options, Futures, and Other Derivatives by John Hull in Appendix A, “Bibliography”.

Black-Scholes Model

Using the Black-Scholes model entails several assumptions:

- The prices of the underlying asset follow an Ito process. (See Hull, page 222.)
- The option can be exercised only on its expiration date (European option).
- Short selling is permitted.
- There are no transaction costs.
- All securities are divisible.
- There is no riskless arbitrage.
- Trading is a continuous process.
- The risk-free interest rate is constant and remains the same for all maturities.

If any of these assumptions is untrue, Black-Scholes may not be an appropriate model.

To illustrate toolbox Black-Scholes functions, this example computes the call and put prices of a European option and its delta, gamma, lambda, and implied volatility. The asset price is \$100.00, the exercise price is \$95.00, the risk-free interest rate is 10%, the time to maturity is 0.25 years, the volatility is 0.50, and the dividend rate is 0. Simply executing the toolbox functions

```
[OptCall, OptPut] = blsprice(100, 95, 0.10, 0.25, 0.50, 0);  
[CallVal, PutVal] = blsdelta(100, 95, 0.10, 0.25, 0.50, 0);  
GammaVal = blsgamma(100, 95, 0.10, 0.25, 0.50, 0);  
VegaVal = blsvega(100, 95, 0.10, 0.25, 0.50, 0);  
[LamCall, LamPut] = blslambda(100, 95, 0.10, 0.25, 0.50, 0);
```

yields:

- The option call price OptCall = \$13.70
- The option put price OptPut = \$6.35
- delta for a call CallVal = 0.6665 and delta for a put PutVal = -0.3335
- gamma GammaVal = 0.0145
- vega VegaVal = 18.1843
- lambda for a call LamCall = 4.8664 and lambda for a put LamPut = -5.2528

Now as a computation check, find the implied volatility of the option using the call option price from `blsprice`.

```
Volatility = blsimpv(100, 95, 0.10, 0.25, OptCall);
```

The function returns an implied volatility of 0.500, the original `blsprice` input.

Binomial Model

The binomial model for pricing options or other equity derivatives assumes that the probability over time of each possible price follows a binomial distribution. The basic assumption is that prices can move to only two values, one up and one down, over any short time period. Plotting the two values, and then the subsequent two values each, and then the subsequent two values each, and so on over time, is known as “building a binomial tree.” This model applies to American options, which can be exercised any time up to and including their expiration date.

This example prices an American call option using a binomial model. Again, the asset price is \$100.00, the exercise price is \$95.00, the risk-free interest rate is 10%, and the time to maturity is 0.25 years. It computes the tree in increments of 0.05 years, so there are $0.25/0.05 = 5$ periods in the example. The volatility is 0.50, this is a call (`flag = 1`), the dividend rate is 0, and it pays a dividend of \$5.00 after three periods (an ex-dividend date). Executing the toolbox function

```
[StockPrice, OptionPrice] = binprice(100, 95, 0.10, 0.25,...
0.05, 0.50, 1, 0, 5.0, 3);
```

returns the tree of prices of the underlying asset

```
StockPrice =
```

100.00	111.27	123.87	137.96	148.69	166.28
0	89.97	100.05	111.32	118.90	132.96
0	0	81.00	90.02	95.07	106.32
0	0	0	72.98	76.02	85.02
0	0	0	0	60.79	67.98
0	0	0	0	0	54.36

and the tree of option values.

OptionPrice =

12.10	19.17	29.35	42.96	54.17	71.28
0	5.31	9.41	16.32	24.37	37.96
0	0	1.35	2.74	5.57	11.32
0	0	0	0	0	0
0	0	0	0	0	0
0	0	0	0	0	0

The output from the binomial function is a binary tree. Read the StockPrice matrix this way: column 1 shows the price for period 0, column 2 shows the up and down prices for period 1, column 3 shows the up-up, up-down, and down-down prices for period 2, and so on. Ignore the zeros. The OptionPrice matrix gives the associated option value for each node in the price tree. Ignore the zeros that correspond to a zero in the price tree.

Analyzing Portfolios

Portfolio managers concentrate their efforts on achieving the best possible trade-off between risk and return. For portfolios constructed from a fixed set of assets, the risk/return profile varies with the portfolio composition. Portfolios that maximize the return, given the risk, or, conversely, minimize the risk for the given return, are called *optimal*. Optimal portfolios define a line in the risk/return plane called the *efficient frontier*.

A portfolio may also have to meet additional requirements to be considered. Different investors have different levels of risk tolerance. Selecting the adequate portfolio for a particular investor is a difficult process. The portfolio manager can hedge the risk related to a particular portfolio along the efficient frontier with partial investment in risk-free assets. The definition of the capital allocation line, and finding where the final portfolio falls on this line, if at all, is a function of:

- The risk/return profile of each asset
- The risk-free rate
- The borrowing rate
- The degree of risk aversion characterizing an investor

Financial Toolbox includes a set of portfolio optimization functions designed to find the portfolio that best meets investor requirements.

Portfolio Optimization Functions

The portfolio optimization functions assist portfolio managers in constructing portfolios that optimize risk and return.

Capital Allocation	Description
portalloc	Computes the optimal risky portfolio on the efficient frontier, based on the risk-free rate, the borrowing rate, and the investor's degree of risk aversion. Also generates the capital allocation line, which provides the optimal allocation of funds between the risky portfolio and the risk-free asset.

Efficient Frontier Computation	Description
frontcon	Computes portfolios along the efficient frontier for a given group of assets. The computation is based on sets of constraints representing the maximum and minimum weights for each asset, and the maximum and minimum total weight for specified groups of assets.
frontier	Computes portfolios along the efficient frontier for a given group of assets. Generates a surface of efficient frontiers showing how asset allocation influences risk and return over time.
portopt	Computes portfolios along the efficient frontier for a given group of assets. The computation is based on a set of user-specified linear constraints. Typically, these constraints are generated using the constraint specification functions described below.

Constraint Specification	Description
portcons	Generates the portfolio constraints matrix for a portfolio of asset investments using linear inequalities. The inequalities are of the type $A \cdot Wts' \leq b$, where Wts is a row vector of weights. The capabilities of portcons are also provided individually by the following functions.
pcalims	Asset minimum and maximum allocation. Generates a constraint set to fix the minimum and maximum weight for each individual asset.
pcgcomp	Group-to-group ratio constraint. Generates a constraint set specifying the maximum and minimum ratios between pairs of groups.
pcglims	Asset group minimum and maximum allocation. Generates a constraint set to fix the minimum and maximum total weight for each defined group of assets.
pcpval	Total portfolio value. Generates a constraint set to fix the total value of the portfolio.

Constraint Conversion	Description
abs2active	Transforms a constraint matrix expressed in absolute weight format to an equivalent matrix expressed in active weight format.
active2abs	Transforms a constraint matrix expressed in active weight format to an equivalent matrix expressed in absolute weight format.

Portfolio Construction Examples

The efficient frontier computation functions require information about each asset in the portfolio. This data is entered into the function via two matrices: an expected return vector and a covariance matrix. The expected return vector contains the average expected return for each asset in the portfolio. The covariance matrix is a square matrix representing the interrelationships between pairs of assets. This information can be directly specified or can be estimated from an asset return time series with the function `ewstats`.

Efficient Frontier Example

This example computes the efficient frontier of portfolios consisting of three different assets using the function `frontcon`. To visualize the efficient frontier curve clearly, consider 10 different evenly spaced portfolios.

Assume that the expected return of the first asset is 10%, the second is 20%, and the third is 15%. The covariance is defined in the matrix `ExpCovariance`.

```
ExpReturn = [0.1 0.2 0.15];
```

```
ExpCovariance = [ 0.005   -0.010    0.004;  
                 -0.010    0.040   -0.002;  
                 0.004   -0.002    0.023];
```

```
NumPorts = 10;
```

Since there are no constraints, you can call `frontcon` directly with the data you already have. If you call `frontcon` without specifying any output arguments, you get a graph representing the efficient frontier curve.

```
frontcon (ExpReturn, ExpCovariance, NumPorts);
```

Calling `frontcon` while specifying the output arguments returns the corresponding vectors and arrays representing the risk, return, and weights for each of the 10 points computed along the efficient frontier.

```
[PortRisk, PortReturn, PortWts] = frontcon(ExpReturn,...  
ExpCovariance, NumPorts)
```

```
PortRisk =  
    0.0392  
    0.0445  
    0.0559  
    0.0701  
    0.0858  
    0.1023  
    0.1192  
    0.1383  
    0.1661  
    0.2000
```

```
PortReturn =
```

0.1231
 0.1316
 0.1402
 0.1487
 0.1573
 0.1658
 0.1744
 0.1829
 0.1915
 0.2000

PortWts =

0.7692	0.2308	0.0000
0.6667	0.2991	0.0342
0.5443	0.3478	0.1079
0.4220	0.3964	0.1816
0.2997	0.4450	0.2553
0.1774	0.4936	0.3290
0.0550	0.5422	0.4027
0	0.6581	0.3419
0	0.8291	0.1709
0	1.0000	0.0000

The output data is represented row-wise. Each portfolio's risk, rate of return, and associated weights are identified as corresponding rows in the vectors and matrix.

For example, you can see from these results that the second portfolio has a risk of 0.0445, an expected return of 13.16%, and allocations of about 67% in the first asset, 30% in the second, and 3% in the third.

Portfolio Selection and Risk Aversion

One of the factors to consider when selecting the optimal portfolio for a particular investor is degree of risk aversion. This level of aversion to risk can be characterized by defining the investor's indifference curve. This curve consists of the family of risk/return pairs defining the trade-off between the expected return and the risk. It establishes the increment in return that a particular investor will require in order to make an increment in risk worthwhile. Typical risk aversion coefficients range between 2.0 and 4.0, with the higher number representing lesser tolerance to risk. The equation used to represent risk aversion in Financial Toolbox is

$$U = E(r) - 0.005 * A * sig^2$$

where:

U is the utility value.

E(r) is the expected return.

A is the index of investor's aversion.

sig is the standard deviation.

Optimal Risky Portfolio Example

This example computes the optimal risky portfolio on the efficient frontier based upon the risk-free rate, the borrowing rate, and the investor's degree of risk aversion. You do this with the function `portalloc`.

First generate the efficient frontier data using either `portopt` or `frontcon`. This example uses `portopt` and the same asset data from the previous example.

```
ExpReturn = [0.1 0.2 0.15];

ExpCovariance = [ 0.005   -0.010   0.004;
                 -0.010   0.040   -0.002;
                  0.004   -0.002   0.023];
```

This time consider 20 different points along the efficient frontier.

```
NumPorts = 20;
```

```
[PortRisk, PortReturn, PortWts] = portopt(ExpReturn,...
ExpCovariance, NumPorts);
```

As with `frontcon`, calling `portopt` while specifying output arguments returns the corresponding vectors and arrays representing the risk, return, and weights for each of the portfolios along the efficient frontier. Use them as the first three input arguments to the function `portalloc`.

Now find the optimal risky portfolio and the optimal allocation of funds between the risky portfolio and the risk-free asset, using these values for the risk-free rate, borrowing rate and investor's degree of risk aversion.

```
RisklessRate = 0.08
BorrowRate = 0.12
RiskAversion = 3
```

Calling `portalloc` without specifying any output arguments gives a graph displaying the critical points.

```
portalloc (PortRisk, PortReturn, PortWts, RisklessRate,...
BorrowRate, RiskAversion);
```

Calling `portalloc` while specifying the output arguments returns the variance (`RiskyRisk`), the expected return (`RiskyReturn`), and the weights (`RiskyWts`) allocated to the optimal risky portfolio. It also returns the fraction (`RiskyFraction`) of the complete portfolio allocated to the risky portfolio, and the variance (`OverallRisk`) and expected return (`OverallReturn`) of the optimal overall portfolio. The overall portfolio combines investments in the risk-free asset and in the risky portfolio. The actual proportion assigned to each of these two investments is determined by the degree of risk aversion characterizing the investor.

```
[RiskyRisk, RiskyReturn, RiskyWts, RiskyFraction, OverallRisk, ...  
OverallReturn] = portalloc (PortRisk, PortReturn, PortWts, ...  
RisklessRate, BorrowRate, RiskAversion)
```

```
RiskyRisk = 0.1288  
RiskyReturn = 0.1791  
RiskyWts = 0.0057 0.5879 0.4064  
RiskyFraction = 1.1869  
OverallRisk = 0.1529  
OverallReturn = 0.1902
```

The value of `RiskyFraction` exceeds 1 (100%), implying that the risk tolerance specified allows borrowing money to invest in the risky portfolio, and that no money will be invested in the risk-free asset. This borrowed capital is added to the original capital available for investment. In this example the customer will tolerate borrowing 18.69% of the original capital amount.

Constraint Specification

- “Linear Constraint Equations” on page 3-14
- “Specifying Additional Constraints” on page 3-17

This example computes the efficient frontier of portfolios consisting of three different assets, INTC, XON, and RD, given a list of constraints. The expected returns for INTC, XON, and RD are respectively as follows:

```
ExpReturn = [0.1 0.2 0.15];
```

The covariance matrix is

```
ExpCovariance = [ 0.005  -0.010  0.004;
                  -0.010  0.040  -0.002;
                  0.004  -0.002  0.023];
```

- Constraint 1
 - Allow short selling up to 10% of the portfolio value in any asset, but limit the investment in any one asset to 110% of the portfolio value.
- Constraint 2
 - Consider two different sectors, technology and energy, with the following table indicating the sector each asset belongs to.

Asset	INTC	XON	RD
Sector	Technology	Energy	Energy

Constrain the investment in the Energy sector to 80% of the portfolio value, and the investment in the Technology sector to 70%.

To solve this problem, use `frontcon`, passing in a list of asset constraints. Consider eight different portfolios along the efficient frontier:

```
NumPorts = 8;
```

To introduce the asset bounds constraints specified in Constraint 1, create the matrix `AssetBounds`, where each column represents an

asset. The upper row represents the lower bounds, and the lower row represents the upper bounds.

```
AssetBounds = [-0.10, -0.10, -0.10;
               1.10,  1.10,  1.10];
```

Constraint 2 needs to be entered in two parts, the first part defining the groups, and the second part defining the constraints for each group. Given the information above, you can build a matrix of 1s and 0s indicating whether a specific asset belongs to a group. Each column represents an asset, and each row represents a group. This example has two groups: the technology group, and the energy group. Create the matrix `Groups` as follows.

```
Groups = [0  1  1;
          1  0  0];
```

The `GroupBounds` matrix allows you to specify an upper and lower bound for each group. Each row in this matrix represents a group. The first column represents the minimum allocation, and the second column represents the maximum allocation to each group. Since the investment in the Energy sector is capped at 80% of the portfolio value, and the investment in the Technology sector is capped at 70%, create the `GroupBounds` matrix using this information.

```
GroupBounds = [0  0.80;
               0  0.70];
```

Now use `frontcon` to obtain the vectors and arrays representing the risk, return, and weights for each of the eight portfolios computed along the efficient frontier.

```
[PortRisk, PortReturn, PortWts] = frontcon(ExpReturn,...
ExpCovariance, NumPorts, [], AssetBounds, Groups, GroupBounds)
```

```
PortRisk =
```

```
0.0416
0.0499
0.0624
0.0767
```

0.0920
0.1100
0.1378
0.1716

PortReturn =

0.1279
0.1361
0.1442
0.1524
0.1605
0.1687
0.1768
0.1850

PortWts =

0.7000	0.2582	0.0418
0.6031	0.3244	0.0725
0.4864	0.3708	0.1428
0.3696	0.4172	0.2132
0.2529	0.4636	0.2835
0.2000	0.5738	0.2262
0.2000	0.7369	0.0631
0.2000	0.9000	-0.1000

The output data is represented row-wise, where each portfolio's risk, rate of return, and associated weight is identified as corresponding rows in the vectors and matrix.

Linear Constraint Equations

While `frontcon` allows you to enter a fixed set of constraints related to minimum and maximum values for groups and individual assets, you often need to specify a larger and more general set of constraints when finding the optimal risky portfolio. The function `portopt` addresses this need, by accepting an arbitrary set of constraints as an input matrix.

The auxiliary function `portcons` can be used to create the matrix of constraints, with each row representing an inequality. These inequalities are of the type $A * Wts' \leq b$, where A is a matrix, b is a vector, and Wts is a row vector of asset allocations. The number of columns of the matrix A , and the length of the vector Wts correspond to the number of assets. The number of rows of the matrix A , and the length of vector b correspond to the number of constraints. This method allows you to specify any number of linear inequalities to the function `portopt`.

In actuality, `portcons` is an entry point to a set of functions that generate matrices for specific types of constraints. `portcons` allows you to specify all the constraints data at once, while the specific portfolio constraint functions allow you to build the constraints incrementally. These constraint functions are `pcpval`, `pcalims`, `pcglims`, and `pcgcomp`.

Consider an example to help understand how to specify constraints to `portopt` while bypassing the use of `portcons`. This example requires specifying the minimum and maximum investment in various groups.

Maximum and Minimum Group Exposure

Group	Minimum Exposure	Maximum Exposure
North America	0.30	0.75
Europe	0.10	0.55
Latin America	0.20	0.50
Asia	0.50	0.50

Note that the minimum and maximum exposure in Asia is the same. This means that you require a fixed exposure for this group.

Also assume that the portfolio consists of three different funds. The correspondence between funds and groups is shown in the table below.

Group Membership

Group	Fund 1	Fund 2	Fund 3
North America	X	X	
Europe			X
Latin America	X		
Asia		X	X

Using the information in these two tables, build a mathematical representation of the constraints represented. Assume that the vector of weights representing the exposure of each asset in a portfolio is called $Wts = [W1 \ W2 \ W3]$.

Specifically

- | | | | |
|----|-----------|--------|------|
| 1. | $W1 + W2$ | \geq | 0.30 |
| 2. | $W1 + W2$ | \leq | 0.75 |
| 3. | $W3$ | \geq | 0.10 |
| 4. | $W3$ | \leq | 0.55 |
| 5. | $W1$ | \geq | 0.20 |
| 6. | $W1$ | \leq | 0.50 |
| 7. | $W2 + W3$ | $=$ | 0.50 |

Since you need to represent the information in the form $A*Wts \leq b$, multiply equations 1, 3 and 5 by -1 . Also turn equation 7 into a set of two inequalities: $W2 + W3 \geq 0.50$ and $W2 + W3 \leq 0.50$. (The intersection of these two inequalities is the equality itself.) Thus

- | | | | |
|----|------------|--------|-------|
| 1. | $-W1 - W2$ | \leq | -0.30 |
| 2. | $W1 + W2$ | \leq | 0.75 |
| 3. | $-W3$ | \leq | -0.10 |

4.	$W3$	\leq	0.55
5.	$-W1$	\leq	-0.20
6.	$W1$	\leq	0.50
7.	$-W2 - W3$	\leq	-0.50
8.	$W2 + W3$	\leq	0.50

Bringing these equations into matrix notation gives

$$A = \begin{bmatrix} -1 & -1 & 0; \\ 1 & 1 & 0; \\ 0 & 0 & -1; \\ 0 & 0 & 1; \\ -1 & 0 & 0; \\ 1 & 0 & 0; \\ 0 & -1 & -1; \\ 0 & 1 & 1 \end{bmatrix}$$

$$b = \begin{bmatrix} -0.30; \\ 0.75; \\ -0.10; \\ 0.55; \\ -0.20; \\ 0.50; \\ -0.50; \\ 0.50 \end{bmatrix}$$

Build the constraint matrix ConSet by concatenating the matrix A to the vector b.

$$\text{ConSet} = [A, b]$$

Specifying Additional Constraints

The example above defined a constraints matrix that specified a set of typical scenarios. It defined groups of assets, specified upper and lower bounds for total allocation in each of these groups, and it set the total allocation of one of the groups to a fixed value. Constraints like these are common occurrences.

The function `portcons` was created to simplify the creation of the constraint matrix for these and other common portfolio requirements. `portcons` takes as input arguments a list of constraint-specifier strings, followed by the data necessary to build the constraint specified by the strings.

Assume that you need to add more constraints to the previous example. Specifically, add a constraint indicating that the sum of weights in any portfolio should be equal to 1, and another set of constraints (one per asset) indicating that the weight for each asset must be greater than 0. This translates into five more constraint rows: two for the new equality, and three indicating that each weight must be greater or equal to 0. The total number of inequalities in the example is now 13. Clearly, creating the constraint matrix can turn into a tedious task.

To create the new constraint matrix using `portcons`, use two separate constraint-specifier strings:

- 'Default', which indicates that each weight is greater than 0 and that the total sum of the weights adds to 1
- 'GroupLims', which defines the minimum and maximum allocation on each group

The only data requirement for the constraint-specifier string 'Default' is `NumAssets` (the total number of assets). The constraint-specifier string 'GroupLims' requires three different arguments: a `Groups` matrix indicating the assets that belong to each group, the `GroupMin` vector indicating the minimum bounds for each group, and the `GroupMax` vector indicating the maximum bounds for each group. Based on the table Group Membership on page 3-16, build the `Group` matrix, with each row representing a group, and each column representing an asset.

```
Group = [1    1    0;
         0    0    1;
         1    0    0;
         0    1    1]
```

The table Maximum and Minimum Group Exposure on page 3-15 has the information to build `GroupMin` and `GroupMax`.

```
GroupMin = [0.30  0.10  0.20  0.50];
```

```
GroupMax = [0.75 0.55 0.50 0.50];
```

Given that the number of assets is three, build the constraint matrix by calling `portcons`.

```
ConSet = portcons('Default', 3, 'GroupLims', Group, GroupMin,...  
GroupMax);
```

In most cases, `portcons('Default')` returns the minimal set of constraints required for calling `portopt`. If `ConSet` is not specified in the call to `portopt`, the function calls `portcons` passing 'Default' as its only specifier.

Now use `portopt` to obtain the vectors and arrays representing the risk, return, and weights for the portfolios computed along the efficient frontier.

```
[PortRisk, PortReturn, PortWts] = portopt(ExpReturn,...  
ExpCovariance, [], [], ConSet)
```

```
PortRisk = 0.0586  
Port Return = 0.1375  
PortWts = 0.5 0.25 0.25
```

In this case, the constraints allow only one optimum portfolio.

Active Returns and Tracking Error Efficient Frontier

Suppose you wish to identify an efficient set of portfolios that minimize the variance of the difference in returns with respect to a given target portfolio, subject to a given expected excess return. The mean and standard deviation of this excess return are often called the active return and active risk, respectively. Active risk is sometimes referred to as the tracking error. Since the objective is to track a given target portfolio as closely as possible, the resulting set of portfolios is sometimes referred to as the tracking error efficient frontier.

Specifically, assume that the target portfolio is expressed as an index weight vector, such that the index return series may be expressed as a linear combination of the available assets. This example illustrates how to construct a frontier that minimizes the active risk (tracking error) subject to attaining a given level of return. That is, it computes the tracking error efficient frontier.

One way to construct the tracking error efficient frontier is to explicitly form the target return series and subtract it from the return series of the individual assets. In this manner, you specify the expected mean and covariance of the active returns, and compute the efficient frontier subject to the usual portfolio constraints.

This example works directly with the mean and covariance of the absolute (unadjusted) returns but converts the constraints from the usual absolute weight format to active weight format.

Consider a portfolio of five assets with the following expected returns, standard deviations, and correlation matrix based on absolute weekly asset returns.

```

NumAssets      = 5;

ExpReturn      = [0.2074  0.1971  0.2669  0.1323  0.2535]/100;

Sigmas         = [2.6570  3.6297  3.9916  2.7145  2.6133]/100;

Correlations   = [1.0000  0.6092  0.6321  0.5833  0.7304
                  0.6092  1.0000  0.8504  0.8038  0.7176
                  0.6321  0.8504  1.0000  0.7723  0.7236

```

```

0.5833  0.8038  0.7723  1.0000  0.7225
0.7304  0.7176  0.7236  0.7225  1.0000];

```

Convert the correlations and standard deviations to a covariance matrix.

```
ExpCovariance = corr2cov(Sigmas, Correlations);
```

Next, assume that the target index portfolio is simply an equally-weighted portfolio formed from the five assets. Note that the sum of index weights equals 1, satisfying the standard full investment budget equality constraint.

```
Index = ones(NumAssets, 1)/NumAssets;
```

Generate an asset constraint matrix via `portcons`. The constraint matrix `AbsConSet` is expressed in absolute format (unadjusted for the index), and is formatted as `[A b]`, corresponding to constraints of the form $A*w \leq b$. Each row of `AbsConSet` corresponds to a constraint, and each column corresponds to an asset. Allow no short-selling and full investment in each asset (lower and upper bounds of each asset are 0 and 1, respectively). In particular, note that the first two rows correspond to the budget equality constraint; the remaining rows correspond to the upper/lower investment bounds.

```
AbsConSet = portcons('PortValue', 1, NumAssets, ...
'AssetLims', zeros(NumAssets,1), ones(NumAssets,1));
```

Now transform the absolute constraints to active constraints with `abs2active`.

```
ActiveConSet = abs2active(AbsConSet, Index);
```

An examination of the absolute and active constraint matrices reveals that they differ only in the last column (the columns corresponding to the b in $A*w \leq b$).

```
[AbsConSet(:,end) ActiveConSet(:,end)]
```

```
ans =
```

```

1.0000      0
-1.0000      0
1.0000    0.8000

```

```
1.0000    0.8000
1.0000    0.8000
1.0000    0.8000
1.0000    0.8000
         0    0.2000
         0    0.2000
         0    0.2000
         0    0.2000
         0    0.2000
```

In particular, note that the sum-to-one absolute budget constraint becomes a sum-to-zero active budget constraint. The general transformation is as follows:

$$b_{active} = b_{absolute} - A \cdot Index$$

Now construct and plot the tracking error efficient frontier with 21 portfolios.

```
[ActiveRisk, ActiveReturn, ActiveWeights] = ...
portopt(ExpReturn,ExpCovariance, 21, [], ActiveConSet);
ActiveRisk = real(ActiveRisk);
plot(ActiveRisk*100, ActiveReturn*100, 'blue')
grid('on')
xlabel('Active Risk (Standard Deviation in Percent)')
ylabel('Active Return (Percent)')
title('Tracking Error Efficient Frontier')
```

Of particular interest is the lower-left portfolio along the frontier. This zero-risk/zero-return portfolio has a practical economic significance. It represents a full investment in the index portfolio itself. Note that each tracking error efficient portfolio (each row in the array `ActiveWeights`) satisfies the active budget constraint, and thus represents portfolio investment allocations with respect to the index portfolio. To convert these allocations to absolute investment allocations, add the index to each efficient portfolio.

```
AbsoluteWeights = ActiveWeights + repmat(Index', 21, 1);
```

Investment Performance Metrics

Overview of Performance Metrics
(p. 4-2)

Overview for performance metrics supported by Financial Toolbox

Using the Sharpe Ratio (p. 4-5)

Use the Sharpe ratio to calculate the ratio of an asset's excess return divided by the asset's standard deviation of returns

Using the Information Ratio (p. 4-6)

Use the information ratio to calculate the ratio of relative return to relative risk

Tracking Error (p. 4-7)

Use tracking error to measure the variation of a portfolio's return relative to its benchmark index

Risk-Adjusted Return (p. 4-8)

Use the risk-adjusted return to shift the risk of a portfolio to match the risk of a market portfolio or fund

Sample and Expected Lower Partial Moments (p. 4-10)

Use sample and expected lower partial moments to model moments of asset returns that fall below a minimum acceptable level of return

Maximum and Expected Maximum Drawdown (p. 4-13)

Use maximum drawdown to calculate drop from maximum to minimum return over a period of time and expected maximum drawdown of a linear Brownian motion with drift

Overview of Performance Metrics

Sharpe first proposed a ratio of excess return to total risk as an investment performance metric. Subsequent work by Sharpe, Lintner, and Mossin extended these ideas to entire asset markets in what is called the Capital Asset Pricing Model (CAPM). Since the development of the CAPM, a variety of investment performance metrics has evolved.

This chapter presents four classes of investment performance metrics:

- The first class of metrics are absolute investment performance metrics that can be called “classic” metrics since they are based on the CAPM. They include the Sharpe ratio, the information ratio, and tracking error. To compute the Sharpe ratio from data, use the function `sharpe` to calculate the ratio for one or more asset return series. To compute the information ratio and associated tracking error, use the function `inforatio` to calculate these quantities for one or more asset return series.
- The second class of metrics are relative investment performance metrics to compute risk-adjusted returns. These metrics are also based on the CAPM and include Beta, Jensen’s Alpha, the Security Market Line (SML), Modigliani and Modigliani Risk-Adjusted Return, and the Graham-Harvey measures. To calculate risk-adjusted alpha and return, use `portalpha`.
- The third class of metrics are alternative investment performance metrics based on lower partial moments. To calculate lower partial moments, use the functions `lpm` for sample lower partial moments and `elpm` for expected lower partial moments.
- The fourth class of metrics are performance metrics based on maximum drawdown and expected maximum drawdown. To calculate maximum or expected maximum drawdowns, use the functions `maxdrawdown` and `emaxdrawdown`.

Illustrative Example

To illustrate the functions for investment performance metrics, you will work with three financial time series objects using performance data for:

- An actively managed, large-cap value mutual fund
- A large-cap market index
- 90-day Treasury bills

The data is monthly total return prices that cover a span of 5 years.

The following plot illustrates the performance of each series in terms of total returns to an initial \$1 invested at the start of this 5-year period:

```
load FundMarketCash
plot(TestfData)
hold all
title('\bfive-Year Total Return Performance');
legend('Fund','Market','Cash','Location','SouthEast');
hold off
```

The mean (Mean) and standard deviation (Sigma) of returns for each series are

```
Returns = tick2ret(TestData);  
Assets  
Mean = mean>Returns)  
Sigma = std>Returns, 1)
```

which gives the following result:

```
Assets =  
  'Fund'    'Market'    'Cash'  
Mean =  
  0.0038    0.0030    0.0017  
Sigma =  
  0.0229    0.0389    0.0009
```

In this chapter, you will work with this data to demonstrate that the example fund has done quite well in absolute, relative, and risk-adjusted terms with respect to the investment performance metrics.

Note Functions for investment performance metrics use total return price and total returns. To convert between total return price and total returns, use `ret2tick` and `tick2ret`.

Using the Sharpe Ratio

The Sharpe ratio is the ratio of the excess return of an asset divided by the asset's standard deviation of returns. The Sharpe ratio has the form:

$$(\text{Mean} - \text{Riskless}) / \text{Sigma}$$

Here Mean is the mean of asset returns, Riskless is the return of a riskless asset, and Sigma is the standard deviation of asset returns. A higher Sharpe ratio is better than a lower Sharpe ratio. A negative Sharpe ratio indicates “anti-skill” since the performance of the riskless asset is superior.

Sharpe Ratio Example

To compute the Sharpe ratio, the mean return of the cash asset will be used as the return for the riskless asset. Thus, given asset return data and the riskless asset return, the Sharpe ratio is calculated with

```
Riskless = mean>Returns(:,3))
Sharpe = sharpe>Returns, Riskless)
```

which gives the following result:

```
Riskless =
    0.0017
Sharpe =
    0.0886    0.0315    0
```

The Sharpe ratio of the example fund is significantly higher than the Sharpe ratio of the market. As will be demonstrated with `portalpha`, this translates into a strong risk-adjusted return. Since the Cash asset is the same as Riskless, it makes sense that its Sharpe ratio is 0. The Sharpe ratio was calculated with the mean of cash returns. It can also be calculated with the cash return series as input for the riskless asset

```
Sharpe = sharpe>Returns, Returns(:,3))
```

which gives the following result:

```
Sharpe =
    0.0886    0.0315    0
```

Using the Information Ratio

Although originally called the “appraisal ratio” by Treynor and Black, the information ratio is the ratio of relative return to relative risk (known as “tracking error”). Whereas the Sharpe ratio looks at returns relative to a riskless asset, the information ratio is based on returns relative to a risky benchmark which is known colloquially as a “bogey.” Given an asset or portfolio of assets with random returns designated by *Asset* and a benchmark with random returns designated by *Benchmark*, the information ratio has the form:

$$\text{Mean}(\text{Asset} - \text{Benchmark}) / \text{Sigma}(\text{Asset} - \text{Benchmark})$$

Here $\text{Mean}(\text{Asset} - \text{Benchmark})$ is the mean of *Asset* minus *Benchmark* returns, and $\text{Sigma}(\text{Asset} - \text{Benchmark})$ is the standard deviation of *Asset* minus *Benchmark* returns. A higher information ratio is considered better than a lower information ratio.

Information Ratio Example

To calculate the information ratio using the example data, the mean return of the market series will be used as the return of the benchmark. Thus, given asset return data and the riskless asset return, compute the information ratio with

```
Benchmark = Returns(:,2);
InfoRatio = inforatio>Returns, Benchmark)
```

which gives the following result:

```
InfoRatio =
    0.0432      NaN    -0.0315
```

Since the market series has no risk relative to itself, the information ratio for the second series is undefined (which is represented as NaN in MATLAB). Its standard deviation of relative returns in the denominator is 0.

Tracking Error

Given an asset or portfolio of assets and a benchmark, the relative standard deviation of returns between the asset or portfolio of assets and the benchmark is called tracking error.

Tracking Error Example

The function `inforatio` computes tracking error and returns it as a second argument

```
Benchmark = Returns(:,2);  
[InfoRatio, TrackingError] = inforatio>Returns, Benchmark)
```

which gives the following results:

```
InfoRatio =  
    0.0432      NaN   -0.0315  
TrackingError =  
    0.0187         0    0.0390
```

Tracking error is a useful measure of performance relative to a benchmark since it is in units of asset returns. For example, the tracking error of 1.87% for the fund relative to the market in this example is reasonable for an actively managed, large-cap value fund.

Risk-Adjusted Return

Risk-adjusted return either shifts the risk (which is the standard deviation of returns) of a portfolio to match the risk of a market portfolio or shifts the risk of a market portfolio to match the risk of a fund. According to the Capital Asset Pricing Model (CAPM), the market portfolio and a riskless asset are points on a Security Market Line (SML). The return of the resultant shifted portfolio, levered or unlevered, to match the risk of the market portfolio, is the risk-adjusted return. The SML provides another measure of risk-adjusted return, since the difference in return between the fund and the SML, return at the same level of risk.

Risk-Adjusted Return Example

Given our example data with a fund, a market, and a cash series, you can calculate the risk-adjusted return and compare it with the fund and market's mean returns

```
Fund = Returns(:,1);
Market = Returns(:,2);
Cash = Returns(:,3);
MeanFund = mean(Fund)
MeanMarket = mean(Market)

[MM, aMM] = portalpha(Fund, Market, Cash)
[GH1, aGH1] = portalpha(Fund, Market, Cash, 'gh1')
[GH2, aGH2] = portalpha(Fund, Market, Cash, 'gh2')
[SML, aSML] = portalpha(Fund, Market, Cash, 'sml')
```

which gives the following results:

```
MeanFund =
    0.0038
MeanMarket =
    0.0030
MM =
    0.0052
aMM =
    0.0022
GH1 =
```

0.0025
aGH1 =
0.0013
GH2 =
0.0052
aGH2 =
0.0022
SML =
0.0025
aSML =
0.0013

Since the fund's risk is much less than the market's risk, the risk-adjusted return of the fund is much higher than both the nominal fund and market returns.

Sample and Expected Lower Partial Moments

- “Sample Lower Partial Moments Example” on page 4-10
- “Expected Lower Partial Moments Example” on page 4-11

Use lower partial moments to examine what is colloquially known as “downside risk.” The main idea of the lower partial moment framework is to model moments of asset returns that fall below a minimum acceptable level of return. To compute lower partial moments from data, use `lpm` to calculate lower partial moments for multiple asset return series and for multiple moment orders. To compute expected values for lower partial moments under several assumptions about the distribution of asset returns, use `elpm` to calculate lower partial moments for multiple assets and for multiple orders.

Sample Lower Partial Moments Example

The following example demonstrates `lpm` to compute the zero-order, first-order, and second-order lower partial moments for the three time series, where the mean of the third time series is used to compute MAR (with the so-called risk-free rate).

```
Assets
MAR = mean>Returns(:,3)
LPM = lpm>Returns, MAR, [0 1 2])
```

which gives the following results:

```
Assets =
  'Fund'   'Market'   'Cash'
MAR =
  0.0017
LPM =
  0.4333    0.4167    0.6167
  0.0075    0.0140    0.0004
  0.0003    0.0008    0.0000
```

The first row of LPM contains zero-order lower partial moments of the three series. The fund and market index fall below MAR about 40% of the time and cash returns fall below its own mean about 60% of the time.

The second row contains first-order lower partial moments of the three series. The fund and market have large expected shortfall returns relative to MAR by 75 and 140 basis points per month. On the other hand, cash underperforms MAR by about only 4 basis points per month on the downside.

The third row contains second-order lower partial moments of the three series. The square root of these quantities provides an idea of the dispersion of returns that fall below the MAR. The market index has a much larger variation on the downside when compared with the fund.

Expected Lower Partial Moments Example

To compare realized values with expected values, use `elpm` to compute expected lower partial moments based on the mean and standard deviations of normally distributed asset returns. The `elpm` function works with the mean and standard deviations for multiple assets and multiple orders

```
Assets
ELPM = elpm(Mean, Sigma, MAR, [0 1 2])
```

which gives the following results:

```
Assets =
  'Fund'      'Market'      'Cash'
ELPM =
  0.4647      0.4874      0.5000
  0.0082      0.0149      0.0004
  0.0002      0.0007      0.0000
```

Based on the moments of each asset, the expected values for lower partial moments imply better than expected performance for the fund and market and worse than expected performance for cash. Note that this function works with either degenerate or nondegenerate normal random variables. For example, if cash were truly riskless, its standard deviation would be 0. You can examine the difference in expected shortfall.

```
RisklessCash = elpm(Mean(3), 0, MAR, 1)
```

which gives the following result:

$$\text{RisklessCash} = 0$$

Maximum and Expected Maximum Drawdown

- “Maximum Drawdown Example” on page 4-13
- “Expected Maximum Drawdown Example” on page 4-14

Although additional metrics exist that are used in the hedge fund and commodity trading communities (see Pederson and Rudholm-Alfvén in Appendix A, “Bibliography”), the original definition and subsequent implementation of these metrics is not yet standardized. The “traditional” return form for maximum drawdown is the drop from maximum to minimum return over a period of time. Given returns that have been transformed into a linear Brownian motion with drift, it is possible to compute the expected maximum drawdown (see Magdon-Ismail, Atiya, Pratap, and Abu-Mostafa in Appendix A, “Bibliography”). Use `maxdrawdown` and `emaxdrawdown` to calculate the maximum and expected maximum drawdowns.

Maximum Drawdown Example

This example demonstrates computing `MaxDD` for three types of returns: fund, market, and cash

```
load FundMarketCash
MaxDD = maxdrawdown(FundMarketCash)
```

which gives the following results:

```
MaxDD =
    0.1658    0.3381    0
```

Most academic research on maximum drawdown focuses on the underlying stochastic processes that generate asset returns. Convert price data to geometric Brownian motion and compute maximum drawdown

```
Returns = TestData(2:end,:) ./ TestData(1:end - 1,:);
MaxDD = maxdrawdown>Returns, 'geometric')
```

which gives the following results:

```
MaxDD =
    0.1007    0.1890    0.0137
```

Convert price data to arithmetic Brownian motion and compute maximum drawdown (the answer should match the previous result).

```
Returns = log>Returns);  
MaxDD = maxdrawdown>Returns,'arithmetic')
```

which gives the following results:

```
MaxDD =  
    0.1007    0.1890    0.0137
```

The maximum drawdown function has been enhanced to return the indices of the maximum drawdown periods for each series

```
[MaxDD, Start, End] = drawdown(FundMarketCash)
```

which gives the following results:

```
MaxDD =  
    0.1658    0.3381         0  
Start =  
     2     2    NaN  
End =  
    18    18    NaN
```

The first two series have the same periods for maximum drawdown from the 2nd to the 18th month in the data. Note that the third series never has a drawdown, so that the indices are NaNs.

Expected Maximum Drawdown Example

This example demonstrates using the return moments of the fund to compute the expected MaxDD and then compare it with the realized MaxDD

```
load FundMarketCash  
Returns = TestData(2:end,:) ./ TestData(1:end - 1,:);  
Returns = log>Returns);  
MaxDD = maxdrawdown>Returns(:,1),'arithmetic')  
Mu = mean>Returns(:,1));  
Sigma = std>Returns(:,1),1);
```

```
EMaxDD = emaxdrawdown(Mu, Sigma, 100)
```

which gives the following results:

```
MaxDD =  
    0.1007  
EMaxDD =  
    0.1852
```

This section focuses using likelihood-based methods for multivariate normal regression with missing data. The parameters of the regression model are estimated via maximum likelihood estimation. For multiple series, this requires iteration until convergence. The complication due to the possibility of missing data is incorporated into the analysis with a variant of the EM algorithm known as the ECM algorithm.

The underlying theory of maximum likelihood estimation and the definition and significance of the Fisher information matrix can be found in Caines [1] and Cramér [2]. The underlying theory of the ECM algorithm can be found in Meng and Rubin [8] and Sexton and Swensen [9].

In addition, these two examples of maximum likelihood estimation are presented:

- “Example of Portfolios with Missing Data” on page 5-26
- “Estimation of Some Technology Stock Betas” on page 5-36

Multivariate Normal Linear Regression

Suppose you have a multivariate normal linear regression model in the form

$$\begin{bmatrix} \mathbf{Z}_1 \\ \vdots \\ \mathbf{Z}_m \end{bmatrix} \sim N \left(\begin{bmatrix} \mathbf{H}_1 \mathbf{b} \\ \vdots \\ \mathbf{H}_m \mathbf{b} \end{bmatrix}, \begin{bmatrix} \mathbf{C} \cdots \mathbf{0} \\ \vdots \quad \vdots \\ \mathbf{0} \cdots \mathbf{C} \end{bmatrix} \right)$$

where the model has m observations of n -dimensional random variables $\mathbf{Z}_1, \dots, \mathbf{Z}_m$ with a linear regression model that has a p -dimensional model parameter vector \mathbf{b} . In addition, the model has a sequence of m design matrices $\mathbf{H}_1, \dots, \mathbf{H}_m$, where each design matrix is a known n -by- p matrix.

Given a parameter vector \mathbf{b} and a collection of design matrices, the collection of m independent variables \mathbf{Z}_k is assumed to have independent identically distributed multivariate normal residual errors $\mathbf{Z}_k - \mathbf{H}_k \mathbf{b}$ with n -vector mean $\mathbf{0}$ and n -by- n covariance matrix \mathbf{C} for each $k = 1, \dots, m$.

A concise way to write this model is

$$\mathbf{Z}_k \sim N(\mathbf{H}_k \mathbf{b}, \mathbf{C})$$

for $k = 1, \dots, m$.

The goal of multivariate normal regression is to obtain maximum likelihood estimates for \mathbf{b} and \mathbf{C} given a collection of m observations $\mathbf{z}_1, \dots, \mathbf{z}_m$ of the random variables $\mathbf{Z}_1, \dots, \mathbf{Z}_m$. The parameters to be estimated are the p distinct elements of \mathbf{b} and the $n(n+1)/2$ distinct elements of \mathbf{C} (the lower-triangular elements of \mathbf{C}).

Note Quasi-maximum likelihood estimation works with the same models but with a relaxation of the assumption of normally distributed residuals. In this case, however, the parameter estimates are asymptotically optimal.

Maximum Likelihood Estimation

To estimate the parameters of the multivariate normal linear regression model using maximum likelihood estimation, it is necessary to maximize the

log-likelihood function over the estimation parameters given observations $\mathbf{z}_1, \dots, \mathbf{z}_m$.

Given the multivariate normal model to characterize residual errors in the regression model, the log-likelihood function is

$$L(\mathbf{z}_1, \dots, \mathbf{z}_m; \mathbf{b}, \mathbf{C}) = \frac{1}{2} mn \log(2\pi) + \frac{1}{2} m \log(\det(\mathbf{C})) + \frac{1}{2} \sum_{k=1}^m (\mathbf{z}_k - \mathbf{H}_k \mathbf{b})^T \mathbf{C}^{-1} (\mathbf{z}_k - \mathbf{H}_k \mathbf{b})$$

Although the cross-sectional residuals must be independent, you can use this log-likelihood function for quasi-maximum likelihood estimation. In this case, the estimates for the parameters \mathbf{b} and \mathbf{C} provide estimates to characterize the first and second moments of the residuals. See Caines [1] for details.

Except for a special case (see “Special Case of a Multiple Linear Regression Model” on page 5-5), if both the model parameters in \mathbf{b} and the covariance parameters in \mathbf{C} are to be estimated, the estimation problem is intractably nonlinear and a solution must use iterative methods. Denote estimates for the parameters \mathbf{b} and \mathbf{C} for iteration $t = 0, 1, \dots$ with the superscript notation $\mathbf{b}^{(t)}$ and $\mathbf{C}^{(t)}$.

Given initial estimates $\mathbf{b}^{(0)}$ and $\mathbf{C}^{(0)}$ for the parameters, the maximum likelihood estimates for \mathbf{b} and \mathbf{C} are obtained using a two-stage iterative process with

$$\mathbf{b}^{(t+1)} = \left(\sum_{k=1}^m \mathbf{H}_k^T (\mathbf{C}^{(t)})^{-1} \mathbf{H}_k \right)^{-1} \left(\sum_{k=1}^m \mathbf{H}_k^T (\mathbf{C}^{(t)})^{-1} \mathbf{z}_k \right)$$

and

$$\mathbf{C}^{(t+1)} = \frac{1}{m} \sum_{k=1}^m (\mathbf{z}_k - \mathbf{H}_k \mathbf{b}^{(t+1)}) (\mathbf{z}_k - \mathbf{H}_k \mathbf{b}^{(t+1)})^T$$

for $t = 0, 1, \dots$

Special Case of a Multiple Linear Regression Model

The special case mentioned in “Maximum Likelihood Estimation” on page 5-3 occurs if $n = 1$ so that the sequence of observations is a sequence of scalar observations. This model is known as a multiple linear regression model. In this case, the covariance matrix \mathbf{C} is a 1-by-1 matrix that drops out of the maximum likelihood iterates so that a single-step estimate for \mathbf{b} and \mathbf{C} can be obtained with converged estimates $\mathbf{b}^{(1)}$ and $\mathbf{C}^{(1)}$.

Least-Squares Regression

Another simplification of the general model is called least-squares regression. If $\mathbf{b}^{(0)} = \mathbf{0}$ and $\mathbf{C}^{(0)} = \mathbf{I}$, then $\mathbf{b}^{(1)}$ and $\mathbf{C}^{(1)}$ from the two-stage iterative process are least squares estimates for \mathbf{b} and \mathbf{C} , where

$$\mathbf{b}^{LS} = \left(\sum_{k=1}^m \mathbf{H}_k^T \mathbf{H}_k \right)^{-1} \left(\sum_{k=1}^m \mathbf{H}_k^T \mathbf{z}_k \right)$$

and

$$\mathbf{C}^{LS} = \frac{1}{m} \sum_{k=1}^m (\mathbf{z}_k - \mathbf{H}_k \mathbf{b}^{LS}) (\mathbf{z}_k - \mathbf{H}_k \mathbf{b}^{LS})^T$$

Mean and Covariance Estimation

A final simplification of the general model is to estimate the mean and covariance of a sequence of n -dimensional observations $\mathbf{z}_1, \dots, \mathbf{z}_m$. In this case, the number of series is equal to the number of model parameters with $n = p$ and the design matrices are identity matrices with $\mathbf{H}_k = \mathbf{I}$ for $i = 1, \dots, m$ so that \mathbf{b} is an estimate for the mean and \mathbf{C} is an estimate of the covariance of the collection of observations $\mathbf{z}_1, \dots, \mathbf{z}_m$.

Convergence

If the iterative process continues until the log-likelihood function increases by no more than a specified amount, the resultant estimates are said to be maximum likelihood estimates \mathbf{b}^{ML} and \mathbf{C}^{ML} .

Note that if $n = 1$ (which implies a single data series), convergence occurs after only one iterative step, which, in turn, implies that the least-squares and maximum likelihood estimates are identical. If, however, $n > 1$, the least-squares and maximum likelihood estimates are usually distinct.

In Financial Toolbox, both the changes in the log-likelihood function and the norm of the change in parameter estimates are monitored. Whenever both changes fall below specified tolerances (which should be something between machine precision and its square root), the toolbox functions terminate under an assumption that convergence has been achieved.

Fisher Information

Since maximum likelihood estimates are formed from samples of random variables, their estimators are random variables; an estimate derived from such samples has an uncertainty associated with it. To characterize these uncertainties, which are called standard errors, two quantities are derived from the total log-likelihood function.

The Hessian of the total log-likelihood function is

$$\nabla^2 L(\mathbf{z}_1, \dots, \mathbf{z}_m; \theta)$$

and the Fisher information matrix is

$$\mathbf{I}(\theta) = -E[\nabla^2 L(\mathbf{z}_1, \dots, \mathbf{z}_m; \theta)]$$

where the partial derivatives of the ∇^2 operator are taken with respect to the combined parameter vector θ that contains the distinct components of \mathbf{b} and \mathbf{C} with a total of $q = p + n(n + 1)/2$ parameters.

Since maximum likelihood estimation is concerned with large-sample estimates, the central limit theorem applies to the estimates and the Fisher

information matrix plays a key role in the sampling distribution of the parameter estimates. Specifically, maximum likelihood parameter estimates are asymptotically normally distributed such that

$$(\boldsymbol{\theta}^{(t)} - \boldsymbol{\theta}) \sim N(\mathbf{0}, \mathbf{I}^{-1}(\boldsymbol{\theta}^{(t)})) \text{ as } t \rightarrow \infty$$

where $\boldsymbol{\theta}$ is the combined parameter vector and $\boldsymbol{\theta}^{(t)}$ is the estimate for the combined parameter vector at iteration $t = 0, 1, \dots$.

The Fisher information matrix provides a lower bound, called a Cramér-Rao lower bound, for the standard errors of estimates of the model parameters.

Statistical Tests

Given an estimate for the combined parameter vector $\boldsymbol{\theta}$, the squared standard errors are the diagonal elements of the inverse of the Fisher information matrix

$$s^2(\hat{\theta}_i) = (\mathbf{I}^{-1}(\hat{\boldsymbol{\theta}}))_{ii}$$

for $i = 1, \dots, q$.

Since the standard errors are estimates for the standard deviations of the parameter estimates, you can construct confidence intervals so that, for example, a 95% interval for each parameter estimate is approximately

$$\hat{\theta}_i \pm 1.96 s(\hat{\theta}_i)$$

for $i = 1, \dots, q$.

Error ellipses at a level-of-significance $\alpha \in [0, 1]$ for the parameter estimates satisfy the inequality

$$(\boldsymbol{\theta} - \hat{\boldsymbol{\theta}})^T \mathbf{I}(\hat{\boldsymbol{\theta}}) (\boldsymbol{\theta} - \hat{\boldsymbol{\theta}}) \leq \chi^2_{1-\alpha, q}$$

and follow a χ^2 distribution with q degrees-of-freedom. Note that similar inequalities can be formed for any subcollection of the parameters.

In general, given parameter estimates, the computed Fisher information matrix, and the log-likelihood function, you can perform numerous statistical tests on the parameters, the model, and the regression.

Maximum Likelihood Estimation with Missing Data

- “ECM Algorithm” on page 5-10
- “Standard Errors” on page 5-10
- “Data Augmentation” on page 5-11
- “Multivariate Normal Regression Functions” on page 5-12
- “Multivariate Normal Regression Without Missing Data” on page 5-14
- “Multivariate Normal Regression with Missing Data” on page 5-14
- “Least-Squares Regression with Missing Data” on page 5-15
- “Multivariate Normal Parameter Estimation with Missing Data” on page 5-15
- “Support Functions” on page 5-16

Suppose that a portion of the sample data is missing, where missing values are represented as NaNs. If the missing values are missing-at-random and ignorable, where Little and Rubin [7] have precise definitions for these terms, it is possible to employ a version of the Expectation Maximization, or EM, algorithm of Dempster, Laird, and Rubin [3] to estimate the parameters of the multivariate normal regression model. The algorithm used in Financial Toolbox is the ECM (Expectation Conditional Maximization) algorithm of Meng and Rubin [8] with enhancements by Sexton and Swensen [9].

Each sample \mathbf{z}_k for $k = 1, \dots, m$, is either complete with no missing values, empty with no observed values, or incomplete with both observed and missing values. Empty samples are ignored since they contribute no information.

To understand the missing-at-random and ignorability conditions, consider an example of stock price data before an IPO. For a counterexample, censored data, in which all values greater than some cutoff are replaced with NaNs, does not satisfy these conditions.

In sample k , let \mathbf{x}_k represent the missing values in \mathbf{z}_k , and \mathbf{y}_k represent the observed values. Define a permutation matrix \mathbf{P}_k so that

$$\mathbf{z}_k = \mathbf{P}_k \begin{bmatrix} \mathbf{x}_k \\ \mathbf{y}_k \end{bmatrix}$$

for $k = 1, \dots, m$.

ECM Algorithm

The ECM algorithm has two steps – an E, or expectation step, and a CM, or conditional maximization, step. As with maximum likelihood estimation, the parameter estimates evolve according to an iterative process, where estimates for the parameters after t iterations are denoted as $\mathbf{b}^{(t)}$ and $\mathbf{C}^{(t)}$.

The E step forms conditional expectations for the elements of missing data with

$$E[\mathbf{X}_k \mid \mathbf{Y}_k = \mathbf{y}_k; \mathbf{b}^{(t)}, \mathbf{C}^{(t)}]$$

$$cov[\mathbf{X}_k \mid \mathbf{Y}_k = \mathbf{y}_k; \mathbf{b}^{(t)}, \mathbf{C}^{(t)}]$$

for each sample $k \in \{1, \dots, m\}$ that has missing data.

The CM step proceeds in the same manner as the maximum likelihood procedure without missing data. The main difference is that missing data moments are imputed from the conditional expectations obtained in the E step.

The E and CM steps are repeated until the log-likelihood function ceases to increase. One of the important properties of the ECM algorithm is that it is always guaranteed to find a maximum of the log-likelihood function and, under suitable conditions, this maximum can be a global maximum.

Standard Errors

The negative of the expected Hessian of the log-likelihood function and the Fisher information matrix are identical if no data is missing. However, if data is missing, the Hessian, which is computed over available samples,

accounts for the loss of information due to missing data. Consequently, the Fisher information matrix provides standard errors that are a Cramér-Rao lower bound whereas the Hessian matrix provides standard errors that may be greater if there is missing data.

Data Augmentation

The ECM functions do not “fill in” missing values as they estimate model parameters. In some cases, you may want to fill in the missing values. Although you can fill in the missing values in your data with conditional expectations, you would get optimistic and unrealistic estimates because conditional estimates are not random realizations.

Several approaches are possible, including resampling methods and multiple imputation (see Little and Rubin [7] and Shafer [10] for details). A somewhat informal sampling method for data augmentation is to form random samples for missing values based on the conditional distribution for the missing values. Given parameter estimates for $\hat{\mathbf{b}}$ and $\hat{\mathbf{C}}$, each observation has moments

$$E[\mathbf{Z}_k] = \mathbf{H}_k \hat{\mathbf{b}}$$

and

$$\text{cov}(\mathbf{Z}_k) = \mathbf{H}_k^T \hat{\mathbf{C}} \mathbf{H}_k$$

for $k = 1, \dots, m$, where you have dropped the parameter dependence on the left sides for notational convenience.

For observations with missing values partitioned into missing values \mathbf{X}_k and observed values $\mathbf{Y}_k = \mathbf{y}_k$, you can form conditional estimates for any subcollection of random variables within a given observation. Thus, given estimates $E[\mathbf{Z}_k]$ and $\text{cov}(\mathbf{Z}_k)$ based on the parameter estimates, you can create conditional estimates

$$E[\mathbf{X}_k | \mathbf{y}_k]$$

and

$$\text{COV}(\mathbf{X}_k | \mathbf{y}_k)$$

using standard multivariate normal distribution theory. Given these conditional estimates, you can simulate random samples for the missing values from the conditional distribution

$$\mathbf{X}_k \sim N(E[\mathbf{X}_k | \mathbf{y}_k], \text{COV}(\mathbf{X}_k | \mathbf{y}_k))$$

The samples from this distribution reflect the pattern of missing and nonmissing values for observations $k = 1, \dots, m$. You must sample from conditional distributions for each observation to preserve the correlation structure with the nonmissing values at each observation.

If you follow this procedure, the resultant filled-in values are random and generate mean and covariance estimates that are asymptotically equivalent to the ECM-derived mean and covariance estimates. Note, however, that the filled-in values are random and reflect likely samples from the distribution estimated over all the data and may not reflect “true” values for a particular observation.

Multivariate Normal Regression Functions

Financial Toolbox has a number of functions for multivariate normal regression with or without missing data. The toolbox functions solve four classes of regression problems with functions to estimate parameters, standard errors, log-likelihood functions, and Fisher information matrices. The four classes of regression problems are:

- “Multivariate Normal Regression Without Missing Data” on page 5-14
- “Multivariate Normal Regression with Missing Data” on page 5-14
- “Least-Squares Regression with Missing Data” on page 5-15
- “Multivariate Normal Parameter Estimation with Missing Data” on page 5-15

Additional support functions are also provided, see “Support Functions” on page 5-16.

In all functions, the MATLAB representation for the number of observations (or samples) is `NumSamples = m`, the number of data series is `NumSeries = n`, and the number of model parameters is `NumParams = p`. Note that the moment estimation functions have `NumSeries = NumParams`.

The collection of observations (or samples) is stored in a MATLAB matrix `Data` such that

$$\mathbf{Data}(k, :) = \mathbf{z}_k^T$$

for $k = 1, \dots, \text{NumSamples}$, where `Data` is a `NumSamples`-by-`NumSeries` matrix.

For the multivariate normal regression or least-squares functions, an additional required input is the collection of design matrices that is stored as either a MATLAB matrix or a vector of cell arrays denoted as `Design`.

If `Numseries = 1`, `Design` can be a `NumSamples`-by-`NumParams` matrix. This is the “standard” form for regression on a single data series.

If `Numseries = 1`, `Design` can be either a cell array with a single cell or a cell array with `NumSamples` cells. Each cell in the cell array contains a `NumSeries`-by-`NumParams` matrix such that

$$\mathbf{Design}\{k\} = \mathbf{H}_k$$

for $k = 1, \dots, \text{NumSamples}$. If `Design` has a single cell, it is assumed to be the same `Design` matrix for each sample such that

$$\mathbf{Design}\{1\} = \mathbf{H}_1 = \dots = \mathbf{H}_m$$

Otherwise, `Design` must contain individual design matrices for each and every sample.

The main distinction among the four classes of regression problems depends upon how missing values are handled and where missing values are represented as the MATLAB value `NaN`. If a sample is to be ignored given any missing values in the sample, the problem is said to be a problem “without missing data.” If a sample is to be ignored if and only if every element of the

sample is missing, the problem is said to be a problem “with missing data” since the estimation must account for possible NaN values in the data.

In general, Data may or may not have missing values and Design should have no missing values. In some cases, however, if an observation in Data is to be ignored, the corresponding elements in Design are also ignored. Consult the function reference pages for details.

Multivariate Normal Regression Without Missing Data

You can use the following functions for multivariate normal regression without missing data.

<code>mvnrml</code>	Estimate model parameters, residuals, and the residual covariance.
<code>mvnrstd</code>	Estimate standard errors of model and covariance parameters.
<code>mvnrfish</code>	Estimate the Fisher information matrix.
<code>mvnrobj</code>	Calculate the log-likelihood function.

The first two functions are the main estimation functions. The second two are supporting functions that can be used for more detailed analyses.

Multivariate Normal Regression with Missing Data

You can use the following functions for multivariate normal regression with missing data.

<code>ecmmvnrml</code>	Estimate model parameters, residuals, and the residual covariance.
<code>ecmmvnrstd</code>	Estimate standard errors of model and covariance parameters.
<code>ecmmvnrfish</code>	Estimate the Fisher information matrix.
<code>ecmmvnrobj</code>	Calculate the log-likelihood function.

The first two functions are the main estimation functions. The second two are supporting functions used for more detailed analyses.

Least-Squares Regression with Missing Data

You can use the following functions for least-squares regression with missing data or for covariance-weighted least-squares regression with a fixed covariance matrix.

<code>ecmlsrml</code>	Estimate model parameters, residuals, and the residual covariance.
<code>ecmlsrobj</code>	Calculate the least-squares objective function (pseudo log-likelihood).

To compute standard errors and estimates for the Fisher information matrix, the multivariate normal regression functions with missing data are used.

<code>ecmmvnrstd</code>	Estimate standard errors of model and covariance parameters.
<code>ecmmvnrfish</code>	Estimate the Fisher information matrix.

Multivariate Normal Parameter Estimation with Missing Data

You can use the following functions to estimate the mean and covariance of multivariate normal data.

<code>ecmnml</code>	Estimate the mean and covariance of the data.
<code>ecmnstd</code>	Estimate standard errors of the mean and covariance of the data.
<code>ecmnfish</code>	Estimate the Fisher information matrix.
<code>ecmnhess</code>	Estimate the Fisher information matrix using the Hessian.
<code>ecmnobj</code>	Calculate the log-likelihood function.

These functions behave slightly differently from the more general regression functions since they solve a specialized problem. Consult the function reference pages for details.

Support Functions

Two support functions are included.

<code>convert2sur</code>	Convert a multivariate normal regression model into an SUR model.
<code>ecmncinit</code>	Obtain initial estimates for the mean and covariance of a Data matrix.

The `convert2sur` function converts a multivariate normal regression model into a seemingly unrelated regression, or SUR, model. The second function `ecmncinit` is a specialized function to obtain initial ad hoc estimates for the mean and covariance of a Data matrix with missing data. (If there are no missing values, the estimates are the maximum likelihood estimates for the mean and covariance.)

Regressions

Each regression function has a specific operation. This section shows how to use these functions to perform specific types of regressions. To illustrate use of the functions for various regressions, “typical” usage is shown with optional arguments kept to a minimum. For a typical regression, you estimate model parameters and residual covariance matrices with the `mle` functions and estimate the standard errors of model parameters with the `std` functions. The regressions “without missing data” essentially ignore samples with any missing values, and the regressions “with missing data” ignore samples with every value missing.

Multivariate Normal Regression

Multivariate normal regression, or MVNR, is the “standard” implementation of the regression functions in Financial Toolbox.

Multivariate Normal Regression Without Missing Data

Estimate Parameters

```
[Parameters, Covariance] = mvnrml(Data, Design);
```

Estimate Standard Errors

```
StdParameters = mvnrstd(Data, Design, Covariance);
```

Multivariate Normal Regression with Missing Data

Estimate Parameters

```
[Parameters, Covariance] = ecmmvnrml(Data, Design);
```

Estimate Standard Errors

```
StdParameters = ecmmvnrstd(Data, Design, Covariance);
```

Least-Squares Regression

Least-squares regression, or LSR, sometimes called ordinary least-squares or multiple linear regression, is the simplest linear regression model. It also enjoys the property that, independent of the underlying distribution, it is a best linear unbiased estimator (BLUE).

Given $m = \text{NumSamples}$ observations, the typical least-squares regression model seeks to minimize the objective function

$$\sum_{k=1}^m (\mathbf{Z}_k - \mathbf{H}_k \mathbf{b})^T (\mathbf{Z}_k - \mathbf{H}_k \mathbf{b})$$

which, within the maximum likelihood framework of the multivariate normal regression routine `mvnrml`, is equivalent to a single-iteration estimation of just the parameters to obtain `Parameters` with the initial covariance matrix `Covariance` held fixed as the identity matrix. In the case of missing data, however, the internal algorithm to handle missing data requires a separate routine `ecmlsrml` to do least-squares instead of multivariate normal regression.

Least-Squares Regression Without Missing Data

Estimate Parameters

```
[Parameters, Covariance] = mvnrml(Data, Design, 1);
```

Estimate Standard Errors

```
StdParameters = mvnrstd(Data, Design, Covariance);
```

Least-Squares Regression with Missing Data

Estimate Parameters

```
[Parameters, Covariance] = ecmlsrml(Data, Design);
```

Estimate Standard Errors

```
StdParameters = ecmmvnrstd(Data, Design, Covariance);
```

Covariance-Weighted Least Squares

Given $m = \text{NUMSAMPLES}$ observations, the typical covariance-weighted least squares, or CWLS, regression model seeks to minimize the objective function

$$\sum_{k=1}^m (\mathbf{Z}_k - \mathbf{H}_k \mathbf{b})^T \mathbf{C}_0 (\mathbf{Z}_k - \mathbf{H}_k \mathbf{b})$$

with fixed covariance \mathbf{C}_0 .

In most cases, \mathbf{C}_0 is a diagonal matrix. The inverse matrix $\mathbf{W} = \mathbf{C}_0^{-1}$ has diagonal elements that can be considered relative “weights” for each series. Thus, CWLS is a form of weighted least squares with the weights applied across series.

Covariance-Weighted Least Squares Without Missing Data

Estimate Parameters

```
[Parameters, Covariance] = mvnrml(Data, Design, 1, [], [], [],  
Covar0);
```

Estimate Standard Errors

```
StdParameters = mvnrstd(Data, Design, Covariance);
```

Covariance-Weighted Least Squares with Missing Data

Estimate Parameters

```
[Parameters, Covariance] = ecmlsrml(Data, Design, [], [], [], [],  
                                     Covar0);
```

Estimate Standard Errors

```
StdParameters = ecmmvnrstd(Data, Design, Covariance);
```

Feasible Generalized Least Squares

A somewhat ad hoc form of least squares that has surprisingly good properties for misspecified or nonnormal models is known as feasible generalized least squares, or FGLS. The basic procedure is to do least-squares regression and then to do covariance-weighted least-squares regression with the resultant residual covariance from the first regression.

Feasible Generalized Least Squares Without Missing Data

Estimate Parameters

```
[Parameters, Covariance] = mvnrml(Data, Design, 2, 0, 0);
```

or (to illustrate the FGLS process explicitly)

```
[Parameters, Covar0] = mvnrml(Data, Design, 1);  
[Parameters, Covariance] = mvnrml(Data, Design, 1, [], [], [],  
                                   Covar0);
```

Estimate Standard Errors

```
StdParameters = mvnrstd(Data, Design, Covariance);
```

Feasible Generalized Least Squares with Missing Data

Estimate Parameters

```
[Parameters, Covar0] = ecmlsrml(Data, Design);  
[Parameters, Covariance] = ecmlsrml(Data, Design, [], [], [], [],
```

```
Covar0);
```

Estimate Standard Errors

```
StdParameters = ecmvnrstd(Data, Design, Covariance);
```

Seemingly Unrelated Regression

Given a multivariate normal regression model in standard form with a `Data` matrix and a `Design` array, it is possible to convert the problem into a seemingly unrelated regression (SUR) problem by a simple transformation of the `Design` array. The main idea of SUR is that instead of having a common parameter vector over all data series, you have a separate parameter vector associated with each separate series or with distinct groups of series that, nevertheless, share a common residual covariance. It is this ability to aggregate and disaggregate series and to perform comparative tests on each design that is the power of SUR.

To make the transformation, use the function `convert2sur`, which converts a standard-form design array into an equivalent design array to do SUR with a specified mapping of the series into `NUMGROUPS` groups. The regression functions are used in the usual manner, but with the SUR design array instead of the original design array. Instead of having `NUMPARAMS` elements, the SUR output parameter vector has `NUMGROUPS` of stacked parameter estimates, where the first `NUMPARAMS` elements of `Parameters` contain parameter estimates associated with the first group of series, the next `NUMPARAMS` elements of `Parameters` contain parameter estimates associated with the second group of series, and so on. If the model has only one series, for example, `NUMSERIES = 1`, then the SUR design array is the same as the original design array since SUR requires two or more series to generate distinct parameter estimates.

Given `NUMPARAMS` parameters and `NUMGROUPS` groups with a parameter vector `Parameters` with `NUMGROUPS * NUMPARAMS` elements from any of the regression routines, the following MATLAB code fragment shows how to print a table of SUR parameter estimates with rows that correspond to each parameter and columns that correspond to each group or series:

```
fprintf(1, 'Seemingly Unrelated Regression Parameter
        Estimates\n');
fprintf(1, '    %7s ', ' ');
```

```
fprintf(1,' Group(%3d) ',1:NumGroups);
fprintf(1,'\n');
for i = 1:NumParams
    fprintf(1,' %7d ',i);
    ii = i;
    for j = 1:NumGroups
        fprintf(1,'%12g ',Param(ii));
        ii = ii + NumParams;
    end
    fprintf(1,'\n');
end
fprintf(1,'\n');
```

Seemingly Unrelated Regression Without Missing Data

Form an SUR Design

```
DesignSUR = convert2sur(Design, Group);
```

Estimate Parameters

```
[Parameters, Covariance] = mvnrmlc(Data, DesignSUR);
```

Estimate Standard Errors

```
StdParameters = mvnrstd(Data, DesignSUR, Covariance);
```

Seemingly Unrelated Regression with Missing Data

Form an SUR Design

```
DesignSUR = convert2sur(Design, Group);
```

Estimate Parameters

```
[Parameters, Covariance] = ecmmvnrmlc(Data, DesignSUR);
```

Estimate Standard Errors

```
StdParameters = ecmmvnrstd(Data, DesignSUR, Covariance);
```

Mean and Covariance Parameter Estimation

Without missing data, you can estimate the mean of your Data with the function `mean` and the covariance with the function `cov`. Nevertheless, the function `ecmmle` does this for you if it detects an absence of missing values. Otherwise, it uses the ECM algorithm to handle missing values.

Estimate Parameters

```
[Mean, Covariance] = ecmmle(Data);
```

Estimate Standard Errors

```
StdMean = ecmnstd(Data, Mean, Covariance);
```

Troubleshooting Multivariate Normal Regression

This section provides a few pointers to handle various technical and operational difficulties that might occur.

Biased Estimates

If samples are ignored, the number of samples used in the estimation is less than `NumSamples`. Clearly the actual number of samples used must be sufficient to obtain estimates. In addition, although the model parameters `Parameters` (or mean estimates `Mean`) are unbiased maximum likelihood estimates, the residual covariance estimate `Covariance` is biased. To convert to an unbiased covariance estimate, multiply `Covariance` by

$$\text{Count}/(\text{Count} - 1)$$

where `Count` is the actual number of samples used in the estimation with `Count ≤ NumSamples`. Note that none of the regression functions perform this adjustment.

Requirements

The regression functions, particularly the estimation functions, have several requirements. First, they must have consistent values for `NumSamples`, `NumSeries`, and `NumParams`. As a general rule, the multivariate normal regression functions require

$$\text{Count} * \text{NumSeries} \leq \max\{\text{NumParams}, \text{NumSeries} * (\text{NumSeries} + 1) / 2\}$$

and the least-squares regression functions require

$$\text{Count} * \text{NumSeries} \leq \text{NumParams}$$

where Count is the actual number of samples used in the estimation with

$$\text{Count} \leq \text{NumSamples}$$

Second, they must have enough nonmissing values to converge. Third, they must have a nondegenerate covariance matrix.

Although some necessary and sufficient conditions can be found in the references, general conditions for existence and uniqueness of solutions in the missing-data case do not exist. Nonconvergence is usually due to an ill-conditioned covariance matrix estimate, which is discussed in greater detail in “Nonconvergence” on page 5-25.

Slow Convergence

Since worst-case convergence of the ECM algorithm is linear, it is possible to execute hundreds and even thousands of iterations before termination of the algorithm. If you are estimating with the ECM algorithm on a regular basis with regular updates, you can use prior estimates as initial guesses for the next period’s estimation. This approach often speeds things up since the default initialization in the regression functions sets the initial parameters **b** to zero and the initial covariance **C** to be the identity matrix.

Other ad hoc approaches are possible although most approaches are problem-dependent. In particular, for mean and covariance estimation, the estimation function `ecmmle` uses a function `ecmninit` to obtain an initial estimate.

Nonrandom Residuals

Simultaneous estimates for parameters **b** and covariances **C** require **C** to be positive-definite. Consequently, the general multivariate normal regression routines require nondegenerate residual errors. If you are faced with a model that has exact results, the least-squares routine `ecmlsrml` still

works, although it provides a least-squares estimate with a singular residual covariance matrix. The other regression functions will fail.

Nonconvergence

Although the regression functions are robust and work for most “typical” cases, they can fail to converge. The main failure mode is an ill-conditioned covariance matrix, where failures are either soft or hard. A soft failure wanders endlessly toward a nearly singular covariance matrix and can be spotted if the algorithm fails to converge after about 100 iterations. If `MaxIterations` is increased to 500 and display mode is initiated (with no output arguments), a typical soft failure looks like this.

This case, which is based on 20 observations of 5 assets with 30% of data missing, shows that the log-likelihood goes somewhat linearly to infinity as the likelihood function goes to 0. In this case, the function converges but

the covariance matrix is effectively singular with a smallest eigenvalue on the order of machine precision (`eps`).

For the function `ecmmle`, a hard error looks like this:

```
> In ecmmle at 60
  In ecmmle at 140
??? Error using ==> ecmmle
Full covariance not positive-definite in iteration 218.
```

From a practical standpoint, if in doubt, test your residual covariance matrix from the regression routines to ensure that it is positive-definite. This is important because a soft error has a matrix that appears to be positive-definite but actually has a near-zero-valued eigenvalue to within machine precision. To do this with a covariance estimate `Covariance`, use `cond(Covariance)`, where any value greater than $1/\text{eps}$ should be considered suspect.

If either type of failure occurs, however, note that the regression routine is indicating that something is probably wrong with the data. (Even with no missing data, two time series that are proportional to one another will produce a singular covariance matrix.)

Example of Portfolios with Missing Data

This example illustrates how to use the missing data algorithms for portfolio optimization and for valuation. This example works with 5 years of daily total return data for 12 computer technology stocks, with 6 hardware and 6 software companies. The example estimates the mean and covariance matrix for these stocks, forms efficient frontiers with both a naïve approach and the ECM approach, and compares results.

You can run the example directly with the M-file `ecmtechdemo.m`.

1 Load the following data file:

```
load ecmtechdemo
```

This file contains these three quantities:

- `Assets` is a cell array of the tickers for the twelve stocks in the example.

- Data is a 1254-by-12 matrix of 1254 daily total returns for each of the 12 stocks.
- Dates is a 1254-by-1 column vector of the dates associated with the data.

The time period for the data extends from April 19, 2000 to April 18, 2005.

The sixth stock in Assets is Google (GOOG), which started trading on August 19, 2004. Consequently, all returns before August 20, 2004 are missing and represented as NaNs. Also, Amazon (AMZN) had a few days with missing values scattered throughout the past 5 years.

- 2** A naïve approach to the estimation of the mean and covariance for these 12 assets is to eliminate all days that have missing values for any of the 12 assets. Use the function `ecmninit` with the `nanskip` option to accomplish this.

```
[NaNMean, NaNCovar] = ecmninit(Data, 'nanskip');
```

- 3** Contrast the result of this approach with using all available data and the function `ecmmle` to compute the mean and covariance. First, call `ecmmle` with no output arguments to establish that sufficient data is available to obtain meaningful estimates.

```
ecmmle(Data);
```

The following figure shows that, even with almost 87% of the Google data being NaN values, the algorithm converges after only four iterations.

4 Estimate the mean and covariance as computed by ecmmle.

```
>> [ECMMean, ECMCovar] = ecmmle(Data)
```

```
ECMMean =

The naïve portfolios in NaNWts tend to favor Apple Computer (AAPL), which happened to do well over the period from the Google IPO to the end of the estimation period, while the ECM portfolios in ECMWts tend to underweight Apple and to recommend increased weights in Google relative to the naïve weights.

- 8** To evaluate the impact of estimation error and, in particular, the effect of missing data, use `ecmnstd` to calculate standard errors. Although it is possible to estimate the standard errors for both the mean and covariance, the standard errors for the mean estimates alone are usually the main quantities of interest.

```
StdMeanF = ecmnstd(Data,ECMMean,ECMCovar,'fisher');
```

- 9 Calculate standard errors that use the data-generated Hessian matrix (which accounts for the possible loss of information due to missing data) with the option HESSIAN.

```
StdMeanH = ecmnstd(Data,ECMMean,ECMCovar,'hessian');
```

The difference in the standard errors shows the increase in uncertainty of estimation of asset expected returns due to missing data. This can be viewed by entering

```
Assets  
StdMeanH'  
StdMeanF'  
StdMeanH' - StdMeanF'
```

The two assets with missing data, AMZN and GOOG, are the only assets to have differences due to missing information.

Valuation with Missing Data

- “Capital Asset Pricing Model” on page 5-34
- “Estimation of the CAPM” on page 5-35
- “Estimation with Missing Data” on page 5-36
- “Estimation of Some Technology Stock Betas” on page 5-36
- “Grouped Estimation of Some Technology Stock Betas” on page 5-39
- “References” on page 5-42

The Capital Asset Pricing Model (CAPM) is a venerable but often maligned tool to characterize comovements between asset and market prices. Although many issues arise in CAPM implementation and interpretation, one problem that practitioners face is to estimate the coefficients of the CAPM with incomplete stock price data.

This example shows how to use the missing data regression functions to estimate the coefficients of the CAPM. You can run the example directly with the M-file `CAPMdemo.m`.

Capital Asset Pricing Model

Given a host of assumptions that can be found in the references (see Sharpe [11], Lintner [6], Jarrow [5], and Sharpe, et. al. [12]), the CAPM concludes that asset returns have a linear relationship with market returns. Specifically, given the return of all stocks that constitute a market denoted as M and the return of a riskless asset denoted as C , the CAPM states that the return of each asset R_i in the market has the expectational form

$$E[R_i] = C + \beta_i (E[M] - C)$$

for assets $i = 1, \dots, n$, where β_i is a parameter that specifies the degree of comovement between a given asset and the underlying market. In other words, the expected return of each asset is equal to the return on a riskless asset plus a risk-adjusted expected market return net of riskless asset returns. The collection of parameters β_1, \dots, β_n is called asset betas.

Note that the beta of an asset has the form

$$\beta_i = \frac{\text{cov}(R_i, M)}{\text{var}(M)}$$

which is the ratio of the covariance between asset and market returns divided by the variance of market returns. If an asset has a beta = 1, the asset is said to move with the market; if an asset has a beta > 1, the asset is said to be more volatile than the market. Conversely, if an asset has a beta < 1, the asset is said to be less volatile than the market.

Estimation of the CAPM

The standard CAPM model is a linear model with additional parameters for each asset to characterize residual errors. For each of n assets with m samples of observed asset returns $R_{k,i}$, market returns M_k , and riskless asset returns C_k , the estimation model has the form

$$R_{k,i} = \alpha + C_k + \beta_i (M_k - C_k) + V_{k,i}$$

for samples $k = 1, \dots, m$ and assets $i = 1, \dots, n$, where α_i is a parameter that specifies the nonsystematic return of an asset, β_i is the asset beta, and $V_{k,i}$ is the residual error for each asset with associated random variable V_i .

The collection of parameters $\alpha_1, \dots, \alpha_n$ are called asset alphas. The strict form of the CAPM specifies that alphas must be zero and that deviations from zero are the result of temporary disequilibria. In practice, however, assets may have nonzero alphas, where much of active investment management is devoted to the search for assets with exploitable nonzero alphas.

To allow for the possibility of nonzero alphas, the estimation model generally seeks to estimate alphas and to perform tests to determine if the alphas are statistically equal to zero.

The residual errors V_i are assumed to have moments

$$E[V_i] = 0$$

and

$$E[V_i V_j] = S_{ij}$$

for assets $i, j = 1, \dots, n$, where the parameters S_{11}, \dots, S_{nn} are called residual or nonsystematic variances/covariances.

The square root of the residual variance of each asset, for example, $\sqrt{S_{ii}}$ for $i = 1, \dots, n$, is said to be the residual or nonsystematic risk of the asset since it characterizes the residual variation in asset prices that are not explained by variations in market prices.

Estimation with Missing Data

Although betas can be estimated for companies with sufficiently long histories of asset returns, it is extremely difficult to estimate betas for recent IPOs. However, if a collection of sufficiently observable companies exists that can be expected to have some degree of correlation with the new company's stock price movements, that is, companies within the same industry as the new company, it is possible to obtain imputed estimates for new company betas with the missing-data regression routines.

Estimation of Some Technology Stock Betas

To illustrate how to use the missing-data regression routines, estimate betas for 12 technology stocks, where a single stock (GOOG) is an IPO.

- 1 Load dates, total returns, and ticker symbols for the 12 stocks from the MAT-file CAPMuniverse.

```
load CAPMuniverse
whos Assets Data Dates
```

Name	Size	Bytes	Class
Assets	1x14	952	cell array
Data	1471x14	164752	double array
Dates	1471x1	11768	double array

```
Grand total is 22135 elements using 177472 bytes
```

The assets in the model have the following symbols, where the last two series are proxies for the market and the riskless asset:

```
Assets(1:7)
Assets(8:14)

ans =

    'AAPL'    'AMZN'    'CSCO'    'DELL'    'EBAY'    'GOOG'    'HPQ'

ans =

    'IBM'    'INTC'    'MSFT'    'ORCL'    'YHOO'    'MARKET'    'CASH'
```

The data covers the period from January 1, 2000 to November 7, 2005 with daily total returns. Two stocks in this universe have missing values that are represented by NaNs. One of the two stocks had an IPO during this period and, consequently, has significantly less data than the other stocks.

- 2 Compute separate regressions for each stock, where the stocks with missing data will have estimates that reflect their reduced observability.

```
[NumSamples, NumSeries] = size(Data);
NumAssets = NumSeries - 2;

StartDate = Dates(1);
EndDate = Dates(end);

fprintf(1,'Separate regressions with ');
fprintf(1,'daily total return data from %s to %s ...\n', ...
    datestr(StartDate,1),datestr(EndDate,1));
fprintf(1,'  %4s %-20s %-20s %-20s\n', '', 'Alpha', 'Beta', 'Sigma');
fprintf(1,'  ---- -\n');
fprintf(1,'-----\n');

for i = 1:NumAssets
% Set up separate asset data and design matrices
    TestData = zeros(NumSamples,1);
    TestDesign = zeros(NumSamples,2);
```

```

    TestData(:) = Data(:,i) - Data(:,14);
    TestDesign(:,1) = 1.0;
    TestDesign(:,2) = Data(:,13) - Data(:,14);

% Estimate CAPM for each asset separately
[Param, Covar] = ecmmvnrmlc(TestData, TestDesign);

% Estimate ideal standard errors for covariance parameters
[StdParam, StdCovar] = ecmmvnrstd(TestData, TestDesign, ...
    Covar, 'fisher');

% Estimate sample standard errors for model parameters
StdParam = ecmmvnrstd(TestData, TestDesign, Covar, 'hessian');

% Set up results for output
Alpha = Param(1);
Beta = Param(2);
Sigma = sqrt(Covar);

StdAlpha = StdParam(1);
StdBeta = StdParam(2);
StdSigma = sqrt(StdCovar);

% Display estimates
fprintf(' %4s %9.4f (%8.4f) %9.4f (%8.4f) %9.4f (%8.4f)\n', ...
    Assets{i}, Alpha(1), abs(Alpha(1)/StdAlpha(1)), ...
    Beta(1), abs(Beta(1)/StdBeta(1)), Sigma(1), StdSigma(1));
end

```

This code fragment generates the following table.

Separate regressions with daily total return data from 03-Jan-2000
to 07-Nov-2005 ...

YHOO	0.0001 (0.1282)	1.6543 (19.3838)	0.0384 (0.0074)

The Alpha column contains alpha estimates for each stock that are near zero as expected. In addition, the t-statistics (which are enclosed in parentheses) generally reject the hypothesis that the alphas are nonzero at the 99.5% level of significance.

The Beta column contains beta estimates for each stock that also have t-statistics enclosed in parentheses. For all stocks but GOOG, the hypothesis that the betas are nonzero is accepted at the 99.5% level of significance. It seems, however, that GOOG does not have enough data to obtain a meaningful estimate for beta since its t-statistic would imply rejection of the hypothesis of a nonzero beta.

The Sigma column contains residual standard deviations, that is, estimates for nonsystematic risks. Instead of t-statistics, the associated standard errors for the residual standard deviations are enclosed in parentheses.

Grouped Estimation of Some Technology Stock Betas

To estimate stock betas for all 12 stocks, set up a joint regression model that groups all 12 stocks within a single design. (Since each stock has the same design matrix, this model is actually an example of seemingly unrelated regression.) The routine to estimate model parameters is `emcmvnrml`, and the routine to estimate standard errors is `ecmmvnrstd`.

Because GOOG has a significant number of missing values, a direct use of the missing data routine `ecmmvnrml` takes 482 iterations to converge. This can take a long time to compute. For the sake of brevity, the parameter and covariance estimates after the first 480 iterations are contained in a MAT-file and are used as initial estimates to compute stock betas.

```
load CAPMgroupparam
whos Param0 Covar0
```

Name	Size	Bytes	Class
Covar0	12x12	1152	double array
Param0	24x1	192	double array

Grand total is 168 elements using 1344 bytes

Now estimate the parameters for the collection of 12 stocks.

```
fprintf(1, '\n');
fprintf(1, 'Grouped regression with ');
fprintf(1, 'daily total return data from %s to %s ... \n', ...
    datestr(StartDate,1), datestr(EndDate,1));
fprintf(1, ' %4s %-20s %-20s %-20s \n', '', 'Alpha', 'Beta', 'Sigma');
fprintf(1, ' ----- ');
fprintf(1, '----- \n');

NumParams = 2 * NumAssets;

% Set up grouped asset data and design matrices
TestData = zeros(NumSamples, NumAssets);
TestDesign = cell(NumSamples, 1);
Design = zeros(NumAssets, NumParams);

for k = 1:NumSamples
    for i = 1:NumAssets
        TestData(k,i) = Data(k,i) - Data(k,14);
        Design(i,2*i - 1) = 1.0;
        Design(i,2*i) = Data(k,13) - Data(k,14);
    end
    TestDesign{k} = Design;
end

% Estimate CAPM for all assets together with initial parameter
% estimates
[Param, Covar] = ecmvnrmls(TestData, TestDesign, [], [], [], ...
    Param0, Covar0);

% Estimate ideal standard errors for covariance parameters
```

```

[StdParam, StdCovar] = ecmmvnrstd(TestData, TestDesign, Covar,...
    'fisher');

% Estimate sample standard errors for model parameters
StdParam = ecmmvnrstd(TestData, TestDesign, Covar, 'hessian');

% Set up results for output
Alpha = Param(1:2:end-1);
Beta = Param(2:2:end);
Sigma = sqrt(diag(Covar));

StdAlpha = StdParam(1:2:end-1);
StdBeta = StdParam(2:2:end);
StdSigma = sqrt(diag(StdCovar));

% Display estimates
for i = 1:NumAssets
    fprintf(' %4s %9.4f (%8.4f) %9.4f (%8.4f) %9.4f (%8.4f)\n', ...
        Assets{i},Alpha(i),abs(Alpha(i)/StdAlpha(i)), ...
        Beta(i),abs(Beta(i)/StdBeta(i)),Sigma(i),StdSigma(i));
end

```

This code fragment generates the following table.

Grouped regression with daily total return data from 03-Jan-2000
to 07-Nov-2005 ...

	Alpha	Beta	Sigma

AAPL	0.0012 (1.3882)	1.2294 (17.1839)	0.0322 (0.0062)
AMZN	0.0007 (0.6086)	1.3673 (13.6427)	0.0450 (0.0086)
CSCO	-0.0002 (0.2878)	1.5653 (23.6085)	0.0298 (0.0057)
DELL	-0.0000 (0.0368)	1.2594 (22.2164)	0.0255 (0.0049)
EBAY	0.0014 (1.4326)	1.3441 (16.0732)	0.0376 (0.0072)
GOOG	0.0041 (2.8907)	0.6173 (3.1100)	0.0337 (0.0065)
HPQ	0.0001 (0.1747)	1.3745 (24.2390)	0.0255 (0.0049)
IBM	-0.0000 (0.0312)	1.0807 (28.7576)	0.0169 (0.0032)
INTC	0.0001 (0.1608)	1.6002 (27.3684)	0.0263 (0.0050)
MSFT	-0.0002 (0.4871)	1.1765 (27.4554)	0.0193 (0.0037)
ORCL	0.0000 (0.0389)	1.5010 (21.1855)	0.0319 (0.0061)
YHOO	0.0001 (0.1282)	1.6543 (19.3838)	0.0384 (0.0074)

Although the results for complete-data stocks are the same, note that the beta estimates for AMZN and GOOG (the two stocks with missing values) are different from the estimates derived for each stock separately. Since AMZN has few missing values, the differences in the estimates are small. With GOOG, however, the differences are more pronounced.

The t-statistic for the beta estimate of GOOG is now significant at the 99.5% level of significance. Note, however, that the t-statistics for beta estimates are based on standard errors from the sample Hessian which, in contrast to the Fisher information matrix, accounts for the increased uncertainty in an estimate due to missing values. If the t-statistic is obtained from the more optimistic Fisher information matrix, the t-statistic for GOOG is 8.25. Thus, despite the increase in uncertainty due to missing data, GOOG nonetheless has a statistically significant estimate for beta.

Finally, note that the beta estimate for GOOG is 0.62—a value that may require some explanation. Although the market has been volatile over this period with sideways price movements, GOOG has steadily appreciated in value. Consequently, it is less tightly correlated with the market, implying that it is less volatile than the market ($\beta < 1$).

Problems involving bond portfolios
and equity options

Producing Graphics with the Toolbox
(p. 6-20)

Use of MATLAB graphics to
illustrate financial data

Introduction

This section shows how Financial Toolbox functions solve real-world problems. The examples ship with the toolbox as M-files. Try them by entering the commands directly or by executing the M-files.

This chapter contains two major topics:

- “Common Problems in Finance” on page 6-3

Shows how the toolbox solves real-world financial problems, specifically:

- “Sensitivity of Bond Prices to Changes in Interest Rates” on page 6-3
 - “Constructing a Bond Portfolio to Hedge Against Duration and Convexity” on page 6-6
 - “Sensitivity of Bond Prices to Parallel Shifts in the Yield Curve” on page 6-9
 - “Constructing Greek-Neutral Portfolios of European Stock Options” on page 6-12
 - “Term Structure Analysis and Interest Rate Swap Pricing” on page 6-16
- “Producing Graphics with the Toolbox” on page 6-20

Shows how the toolbox produces presentation-quality graphics by solving these problems:

- “Plotting an Efficient Frontier” on page 6-20
- “Plotting Sensitivities of an Option” on page 6-23
- “Plotting Sensitivities of a Portfolio of Options” on page 6-25

Common Problems in Finance

- “Sensitivity of Bond Prices to Changes in Interest Rates” on page 6-3
- “Constructing a Bond Portfolio to Hedge Against Duration and Convexity” on page 6-6
- “Sensitivity of Bond Prices to Parallel Shifts in the Yield Curve” on page 6-9
- “Constructing Greek-Neutral Portfolios of European Stock Options” on page 6-12
- “Term Structure Analysis and Interest Rate Swap Pricing” on page 6-16

Sensitivity of Bond Prices to Changes in Interest Rates

Macaulay and *modified duration* measure the sensitivity of a bond’s price to changes in the level of interest rates. *Convexity* measures the change in duration for small shifts in the yield curve, and thus measures the second-order price sensitivity of a bond. Both measures can gauge the vulnerability of a bond portfolio’s value to changes in the level of interest rates.

Alternatively, analysts can use duration and convexity to construct a bond portfolio that is partly hedged against small shifts in the term structure. If you combine bonds in a portfolio whose duration is zero, the portfolio is insulated, to some extent, against interest rate changes. If the portfolio convexity is also zero, this insulation is even better. However, since hedging costs money or reduces expected return, you need to know how much protection results from hedging duration alone compared with hedging both duration and convexity.

This example demonstrates a way to analyze the relative importance of duration and convexity for a bond portfolio using some of the SIA-compliant bond functions in Financial Toolbox. Using duration, it constructs a first-order approximation of the change in portfolio price to a level shift in interest rates. Then, using convexity, it calculates a second-order approximation. Finally, it compares the two approximations with the true price change resulting from a change in the yield curve. The example M-file is `ftspex1.m`.

Step 1. Define three bonds using values for the settlement date, maturity date, face value, and coupon rate. For simplicity, accept default values for the coupon payment periodicity (semiannual), end-of-month payment rule (rule in effect), and day-count basis (actual/actual). Also, synchronize the coupon payment structure to the maturity date (no odd first or last coupon dates). Any inputs for which defaults are accepted are set to empty matrices ([]) as placeholders where appropriate.

```
Settle      = '19-Aug-1999';  
Maturity    = ['17-Jun-2010'; '09-Jun-2015'; '14-May-2025'];  
Face        = [100; 100; 1000];  
CouponRate = [0.07; 0.06; 0.045];
```

Also, specify the yield curve information.

```
Yields = [0.05; 0.06; 0.065];
```

Step 2. Use Financial Toolbox functions to calculate the price, modified duration in years, and convexity in years of each bond.

The true price is quoted (clean) price plus accrued interest.

```
[CleanPrice, AccruedInterest] = bndprice(Yields, CouponRate,...  
Settle, Maturity, 2, 0, [], [], [], [], [], Face);  
  
Durations = bnddury(Yields, CouponRate, Settle, Maturity, 2,  
0,... [], [], [], [], [], Face);  
  
Convexities = bndconvy(Yields, CouponRate, Settle, Maturity, 2,  
0,... [], [], [], [], [], Face);  
  
Prices = CleanPrice + AccruedInterest;
```

Step 3. Choose a hypothetical amount by which to shift the yield curve (here, 0.2 percentage point or 20 basis points).

```
dY = 0.002;
```

Weight the three bonds equally, and calculate the actual quantity of each bond in the portfolio, which has a total value of \$100,000.

```

PortfolioPrice = 100000;
PortfolioWeights = ones(3,1)/3;
PortfolioAmounts = PortfolioPrice * PortfolioWeights ./ Prices;

```

Step 4. Calculate the modified duration and convexity of the portfolio. Note that the portfolio duration or convexity is a weighted average of the durations or convexities of the individual bonds. Calculate the first- and second-order approximations of the percent price change as a function of the change in the level of interest rates.

```

PortfolioDuration = PortfolioWeights' * Durations;
PortfolioConvexity = PortfolioWeights' * Convexities;
PercentApprox1 = -PortfolioDuration * dY * 100;

PercentApprox2 = PercentApprox1 + ...
PortfolioConvexity*dY^2*100/2.0;

```

Step 5. Estimate the new portfolio price using the two estimates for the percent price change.

```

PriceApprox1 = PortfolioPrice + ...
PercentApprox1 * PortfolioPrice/100;

PriceApprox2 = PortfolioPrice + ...
PercentApprox2 * PortfolioPrice/100;

```

Step 6. Calculate the true new portfolio price by shifting the yield curve.

```

[CleanPrice, AccruedInterest] = bndprice(Yields + dY,...
CouponRate, Settle, Maturity, 2, 0, [], [], [], [], [],...
Face);

NewPrice = PortfolioAmounts' * (CleanPrice + AccruedInterest);

```

Step 7. Compare the results. The analysis results are as follows (verify these results by running the example M-file `ftspex1.m`):

- The original portfolio price was \$100,000.
- The yield curve shifted up by 0.2 percentage point or 20 basis points.

- The portfolio duration and convexity are 10.3181 and 157.6346, respectively. These will be needed for “Constructing a Bond Portfolio to Hedge Against Duration and Convexity” on page 6-6.
- The first-order approximation, based on modified duration, predicts the new portfolio price ($Price_{Approx1}$) will be \$97,936.37.
- The second-order approximation, based on duration and convexity, predicts the new portfolio price ($Price_{Approx2}$) will be \$97,967.90.
- The true new portfolio price ($NewPrice$) for this yield curve shift is \$97,967.51.
- The estimate using duration and convexity is quite good (at least for this fairly small shift in the yield curve), but only slightly better than the estimate using duration alone. The importance of convexity increases as the magnitude of the yield curve shift increases. Try a larger shift (dY) to see this effect.

The approximation formulas in this example consider only parallel shifts in the term structure, because both formulas are functions of dY , the change in yield. The formulas are not well-defined unless each yield changes by the same amount. In actual financial markets, changes in yield curve level typically explain a substantial portion of bond price movements. However, other changes in the yield curve, such as slope, may also be important and are not captured here. Also, both formulas give local approximations whose accuracy deteriorates as dY increases in size. You can demonstrate this by running the program with larger values of dY .

Constructing a Bond Portfolio to Hedge Against Duration and Convexity

This example constructs a bond portfolio to hedge the portfolio of “Sensitivity of Bond Prices to Changes in Interest Rates” on page 6-3. It assumes a long position in (holding) the portfolio, and that three other bonds are available for hedging. It chooses weights for these three other bonds in a new portfolio so that the duration and convexity of the new portfolio match those of the original portfolio. Taking a short position in the new portfolio, in an amount equal to the value of the first portfolio, partially hedges against parallel shifts in the yield curve.

Recall that portfolio duration or convexity is a weighted average of the durations or convexities of the individual bonds in a portfolio. As in the previous example, this example uses modified duration in years and convexity in years. The hedging problem therefore becomes one of solving a system of linear equations, which is an easy to do in MATLAB. The M-file for this example is `ftspex2.m`.

Step 1. Define three bonds available for hedging the original portfolio. Specify values for the settlement date, maturity date, face value, and coupon rate. For simplicity, accept default values for the coupon payment periodicity (semiannual), end-of-month payment rule (rule in effect), and day-count basis (actual/actual). Also, synchronize the coupon payment structure to the maturity date (that is, no odd first or last coupon dates). Set any inputs for which defaults are accepted to empty matrices (`[]`) as placeholders where appropriate. The intent is to hedge against duration and convexity as well as constrain total portfolio price.

```
Settle      = '19-Aug-1999';
Maturity    = ['15-Jun-2005'; '02-Oct-2010'; '01-Mar-2025'];
Face        = [500; 1000; 250];
CouponRate  = [0.07; 0.066; 0.08];
```

Also, specify the yield curve for each bond.

```
Yields = [0.06; 0.07; 0.075];
```

Step 2. Use Financial Toolbox functions to calculate the price, modified duration in years, and convexity in years of each bond.

The true price is quoted (clean price plus accrued interest).

```
[CleanPrice, AccruedInterest] = bndprice(Yields, CouponRate, ...
    Settle, Maturity, 2, 0, [], [], [], [], [], Face);

Durations = bnddury(Yields, CouponRate, Settle, Maturity, ...
    2, 0, [], [], [], [], [], Face);

Convexities = bndconvy(Yields, CouponRate, Settle, ...
    Maturity, 2, 0, [], [], [], [], [], Face);

Prices = CleanPrice + AccruedInterest;
```

Step 3. Set up and solve the system of linear equations whose solution is the weights of the new bonds in a new portfolio with the same duration and convexity as the original portfolio. In addition, scale the weights to sum to 1; that is, force them to be portfolio weights. You can then scale this unit portfolio to have the same price as the original portfolio. Recall that the original portfolio duration and convexity are 10.3181 and 157.6346, respectively. Also, note that the last row of the linear system ensures the sum of the weights is unity.

```
A = [ Durations'  
      Convexities'  
      1 1 1];
```

```
b = [ 10.3181  
      157.6346  
      1];
```

```
Weights = A\b;
```

Step 4. Compute the duration and convexity of the hedge portfolio, which should now match the original portfolio.

```
PortfolioDuration = Weights' * Durations;  
PortfolioConvexity = Weights' * Convexities;
```

Step 5. Finally, scale the unit portfolio to match the value of the original portfolio and find the number of bonds required to insulate against small parallel shifts in the yield curve.

```
PortfolioValue = 100000;  
HedgeAmounts = Weights ./ Prices * PortfolioValue;
```

Step 6. Compare the results. (Verify the analysis results by running the example M-file `ftspex2.m`.)

- As required, the duration and convexity of the new portfolio are 10.3181 and 157.6346, respectively.
- The hedge amounts for bonds 1, 2, and 3 are -57.37, 71.70, and 216.27, respectively.

Notice that the hedge matches the duration, convexity, and value (\$100,000) of the original portfolio. If you are holding that first portfolio, you can hedge by taking a short position in the new portfolio.

Just as the approximations of the first example are appropriate only for small parallel shifts in the yield curve, the hedge portfolio is appropriate only for reducing the impact of small level changes in the term structure.

Sensitivity of Bond Prices to Parallel Shifts in the Yield Curve

Often bond portfolio managers want to consider more than just the sensitivity of a portfolio's price to a small shift in the yield curve, particularly if the investment horizon is long. This example shows how MATLAB can visualize the price behavior of a portfolio of bonds over a wide range of yield curve scenarios, and as time progresses toward maturity.

This example uses Financial Toolbox bond pricing functions to evaluate the impact of time-to-maturity and yield variation on the price of a bond portfolio. It plots the portfolio value and shows the behavior of bond prices as yield and time vary. This example M-file is `ftspex3.m`.

Step 1. Specify values for the settlement date, maturity date, face value, coupon rate, and coupon payment periodicity of a four-bond portfolio. For simplicity, accept default values for the end-of-month payment rule (rule in effect) and day-count basis (actual/actual). Also, synchronize the coupon payment structure to the maturity date (no odd first or last coupon dates). Any inputs for which defaults are accepted are set to empty matrices (`[]`) as placeholders where appropriate.

```
Settle      = '15-Jan-1995';
Maturity    = datenum(['03-Apr-2020'; '14-May-2025'; ...
                    '09-Jun-2019'; '25-Feb-2019']);
Face        = [1000; 1000; 1000; 1000];
CouponRate  = [0; 0.05; 0; 0.055];
Periods     = [0; 2; 0; 2];
```

Also, specify the points on the yield curve for each bond.

```
Yields = [0.078; 0.09; 0.075; 0.085];
```

Step 2. Use Financial Toolbox functions to calculate the true bond prices as the sum of the quoted price plus accrued interest.

```
[CleanPrice, AccruedInterest] = bndprice(Yields,...
CouponRate,Settle, Maturity, Periods,...
[], [], [], [], [], [], Face);

Prices = CleanPrice + AccruedInterest;
```

Step 3. Assume the value of each bond is \$25,000, and determine the quantity of each bond such that the portfolio value is \$100,000.

```
BondAmounts = 25000 ./ Prices;
```

Step 4. Compute the portfolio price for a rolling series of settlement dates over a range of yields. The evaluation dates occur annually on January 15, beginning on 15-Jan-1995 (settlement) and extending out to 15-Jan-2018. Thus, this step evaluates portfolio price on a grid of time of progression (dT) and interest rates (dY).

```
dy = -0.05:0.005:0.05;           % Yield changes

D = datevec(Settle);             % Get date components
dt = datenum(D(1):2018, D(2), D(3)); % Get evaluation dates

[dT, dY] = meshgrid(dt, dy); % Create grid

NumTimes = length(dt);          % Number of time steps
NumYields = length(dy);         % Number of yield changes
NumBonds = length(Maturity);    % Number of bonds

% Preallocate vector
Prices = zeros(NumTimes*NumYields, NumBonds);
```

Now that the grid and price vectors have been created, compute the price of each bond in the portfolio on the grid one bond at a time.

```
for i = 1:NumBonds

    [CleanPrice, AccruedInterest] = bndprice(Yields(i)+...
```

```

    dY(:), CouponRate(i), dT(:), Maturity(i), Periods(i),...
    [], [], [], [], [], [], Face(i));

    Prices(:,i) = CleanPrice + AccruedInterest;

```

```
end
```

Scale the bond prices by the quantity of bonds.

```
Prices = Prices * BondAmounts;
```

Reshape the bond values to conform to the underlying evaluation grid.

```
Prices = reshape(Prices, NumYields, NumTimes);
```

Step 5. Plot the price of the portfolio as a function of settlement date and a range of yields, and as a function of the change in yield (dY). This plot illustrates the interest rate sensitivity of the portfolio as time progresses (dT), under a range of interest rate scenarios. With the following graphics commands, you can visualize the three-dimensional surface relative to the current portfolio value (that is, \$100,000).

```

figure                                % Open a new figure window
surf(dt, dy, Prices)                  % Draw the surface

```

Add the base portfolio value to the existing surface plot.

```

hold on                                % Add the current value for reference
basemesh = mesh(dt, dy, 100000*ones(NumYields, NumTimes));

```

Make it transparent, plot it so the price surface shows through, and draw a box around the plot.

```

set(basemesh, 'facecolor', 'none');
set(basemesh, 'edgecolor', 'm');
set(gca, 'box', 'on');

```

Plot the x -axis using two-digit year (YY format) labels for ticks.

```
dateaxis('x', 11);
```

Add axis labels and set the three-dimensional viewpoint. MATLAB produces the figure.

```
xlabel('Evaluation Date (YY Format)');
ylabel('Change in Yield');
zlabel('Portfolio Price');
hold off
view(-25,25);
```

MATLAB three-dimensional graphics allow you to visualize the interest rate risk experienced by a bond portfolio over time. This example assumed parallel shifts in the term structure, but it might similarly have allowed other components to vary, such as the level and slope.

Constructing Greek-Neutral Portfolios of European Stock Options

The option sensitivity measures familiar to most option traders are often referred to as the *greeks*: *delta*, *gamma*, *vega*, *lambda*, *rho*, and *theta*. Delta is

the price sensitivity of an option with respect to changes in the price of the underlying asset. It represents a first-order sensitivity measure analogous to duration in fixed income markets. Gamma is the sensitivity of an option's delta to changes in the price of the underlying asset, and represents a second-order price sensitivity analogous to convexity in fixed income markets. Vega is the price sensitivity of an option with respect to changes in the volatility of the underlying asset. See "Pricing and Analyzing Equity Derivatives" on page 2-36 or the "Glossary" on page Glossary-1 for other definitions.

The greeks of a particular option are a function of the model used to price the option. However, given enough different options to work with, a trader can construct a portfolio with any desired values for its greeks. For example, to insulate the value of an option portfolio from small changes in the price of the underlying asset, one trader might construct an option portfolio whose delta is zero. Such a portfolio is then said to be "delta neutral." Another trader may wish to protect an option portfolio from larger changes in the price of the underlying asset, and so might construct a portfolio whose delta and gamma are both zero. Such a portfolio is both delta and gamma neutral. A third trader may wish to construct a portfolio insulated from small changes in the volatility of the underlying asset in addition to delta and gamma neutrality. Such a portfolio is then delta, gamma, and vega neutral.

Using the Black-Scholes model for European options, this example creates an equity option portfolio that is simultaneously delta, gamma, and vega neutral. The value of a particular greek of an option portfolio is a weighted average of the corresponding greek of each individual option. The weights are the quantity of each option in the portfolio. Hedging an option portfolio thus involves solving a system of linear equations, an easy process in MATLAB. This example M-file is `ftspex4.m`.

Step 1. Create an input data matrix to summarize the relevant information. Each row of the matrix contains the standard inputs to Financial Toolbox Black-Scholes suite of functions: column 1 contains the current price of the underlying stock; column 2 the strike price of each option; column 3 the time to-expiry of each option in years; column 4 the annualized stock price volatility; and column 5 the annualized dividend rate of the underlying asset. Note that rows 1 and 3 are data related to call options, while rows 2 and 4 are data related to put options.

```
DataMatrix = [100.000  100  0.2  0.3  0          % Call
```

```

119.100  125  0.2  0.2  0.025  % Put
 87.200   85  0.1  0.23  0      % Call
301.125  315  0.5  0.25  0.0333] % Put

```

Also, assume the annualized risk-free rate is 10% and is constant for all maturities of interest.

```
RiskFreeRate = 0.10;
```

For clarity, assign each column of `DataMatrix` to a column vector whose name reflects the type of financial data in the column.

```

StockPrice = DataMatrix(:,1);
StrikePrice = DataMatrix(:,2);
ExpiryTime = DataMatrix(:,3);
Volatility  = DataMatrix(:,4);
DividendRate = DataMatrix(:,5);

```

Step 2. Based on the Black-Scholes model, compute the prices, as well as the delta, gamma, and vega sensitivity greeks of each of the four options. Note that the functions `blsprice` and `blsdelta` have two outputs, while `blsgamma` and `blsvega` have only one. The price and delta of a call option differ from the price and delta of an otherwise equivalent put option, in contrast to the gamma and vega sensitivities, which are valid for both calls and puts.

```

[CallPrices, PutPrices] = blsprice(StockPrice, StrikePrice,...
RiskFreeRate, ExpiryTime, Volatility, DividendRate);

[CallDeltas, PutDeltas] = blsdelta(StockPrice,...
StrikePrice, RiskFreeRate, ExpiryTime, Volatility,...
DividendRate);

Gammas = blsgamma(StockPrice, StrikePrice, RiskFreeRate,...
ExpiryTime, Volatility , DividendRate)';

Vegas = blsvega(StockPrice, StrikePrice, RiskFreeRate,...
ExpiryTime, Volatility , DividendRate)';

```

Extract the prices and deltas of interest to account for the distinction between call and puts.

```
Prices = [CallPrices(1) PutPrices(2) CallPrices(3)...
PutPrices(4)];
```

```
Deltas = [CallDeltas(1) PutDeltas(2) CallDeltas(3)...
PutDeltas(4)];
```

Step 3. Now, assuming an arbitrary portfolio value of \$17,000, set up and solve the linear system of equations such that the overall option portfolio is simultaneously delta, gamma, and vega-neutral. The solution computes the value of a particular greek of a portfolio of options as a weighted average of the corresponding greek of each individual option in the portfolio. The system of equations is solved using the backslash (\) operator discussed in “Solving Simultaneous Linear Equations” on page 1-13.

```
A = [Deltas; Gammas; Vegas; Prices];
b = [0; 0; 0; 17000];
OptionQuantities = A\b; % Quantity (number) of each option.
```

Step 4. Finally, compute the market value, delta, gamma, and vega of the overall portfolio as a weighted average of the corresponding parameters of the component options. The weighted average is computed as an inner product of two vectors.

```
PortfolioValue = Prices * OptionQuantities;
PortfolioDelta = Deltas * OptionQuantities;
PortfolioGamma = Gammas * OptionQuantities;
PortfolioVega = Vegas * OptionQuantities;
```

The example `ftspex4.m` performs these computations and displays the output on the screen.

Option	Price	Delta	Gamma	Vega	Quantity
1	6.3441	0.5856	0.0290	17.4293	22332.6131
2	6.6035	-0.6255	0.0353	20.0347	6864.0731
3	4.2993	0.7003	0.0548	9.5837	-15654.8657
4	22.7694	-0.4830	0.0074	83.5225	-4510.5153

```
Portfolio Value: $17000.00
Portfolio Delta:      0.00
Portfolio Gamma:     -0.00
```

Portfolio Vega : 0.00

You can verify that the portfolio value is \$17,000 and that the option portfolio is indeed delta, gamma, and vega neutral, as desired. Hedges based on these measures are effective only for small changes in the underlying variables.

Term Structure Analysis and Interest Rate Swap Pricing

This example illustrates some of the term-structure analysis functions found in Financial Toolbox. Specifically, it illustrates how to derive implied zero (*spot*) and forward curves from the observed market prices of coupon-bearing bonds. The zero and forward curves implied from the market data are then used to price an interest rate swap agreement.

In an interest rate swap, two parties agree to a periodic exchange of cash flows. One of the cash flows is based on a fixed interest rate held constant throughout the life of the swap. The other cash flow stream is tied to some variable index rate. Pricing a swap at inception amounts to finding the fixed rate of the swap agreement. This fixed rate, appropriately scaled by the notional principle of the swap agreement, determines the periodic sequence of fixed cash flows.

In general, interest rate swaps are priced from the forward curve such that the variable cash flows implied from the series of forward rates and the periodic sequence of fixed-rate cash flows have the same present value. Thus, interest rate swap pricing and term structure analysis are intimately related.

Step 1. Specify values for the settlement date, maturity dates, coupon rates, and market prices for 10 U.S. Treasury Bonds. This data allows you to price a five-year swap with net cash flow payments exchanged every six months. For simplicity, accept default values for the end-of-month payment rule (rule in effect) and day-count basis (actual/actual). To avoid issues of accrued interest, assume that all Treasury Bonds pay semiannual coupons and that settlement occurs on a coupon payment date.

```
Settle = datenum('15-Jan-1999');  
  
BondData = {'15-Jul-1999' 0.06000 99.93  
            '15-Jan-2000' 0.06125 99.72
```

```

'15-Jul-2000' 0.06375 99.70
'15-Jan-2001' 0.06500 99.40
'15-Jul-2001' 0.06875 99.73
'15-Jan-2002' 0.07000 99.42
'15-Jul-2002' 0.07250 99.32
'15-Jan-2003' 0.07375 98.45
'15-Jul-2003' 0.07500 97.71
'15-Jan-2004' 0.08000 98.15};

```

BondData is an instance of a MATLAB *cell array*, indicated by the curly braces ({}).

Next assign the date stored in the cell array to Maturity, CouponRate, and Prices vectors for further processing.

```

Maturity = datenum(strvcat(BondData{:},1));
CouponRate = [BondData{:},2]';
Prices = [BondData{:},3]';
Period = 2; % semiannual coupons

```

Step 2. Now that the data has been specified, use the term structure function `zbtprice` to bootstrap the zero curve implied from the prices of the coupon-bearing bonds. This implied zero curve represents the series of zero-coupon Treasury rates consistent with the prices of the coupon-bearing bonds such that arbitrage opportunities will not exist.

```
ZeroRates = zbtprice([Maturity CouponRate], Prices, Settle);
```

The zero curve, stored in `ZeroRates`, is quoted on a semiannual bond basis (the periodic, six-month, interest rate is doubled to annualize). The first element of `ZeroRates` is the annualized rate over the next six months, the second element is the annualized rate over the next 12 months, and so on.

Step 3. From the implied zero curve, find the corresponding series of implied forward rates using the term structure function `zero2fwd`.

```
ForwardRates = zero2fwd(ZeroRates, Maturity, Settle);
```

The forward curve, stored in `ForwardRates`, is also quoted on a semiannual bond basis. The first element of `ForwardRates` is the annualized rate applied

to the interval between settlement and six months after settlement, the second element is the annualized rate applied to the interval from six months to 12 months after settlement, and so on. This implied forward curve is also consistent with the observed market prices such that arbitrage activities will be unprofitable. Since the first forward rate is also a zero rate, the first element of `ZeroRates` and `ForwardRates` are the same.

Step 4. Now that you have derived the zero curve, convert it to a sequence of discount factors with the term structure function `zero2disc`.

```
DiscountFactors = zero2disc(ZeroRates, Maturity, Settle);
```

Step 5. From the discount factors, compute the present value of the variable cash flows derived from the implied forward rates. For plain interest rate swaps, the notional principle remains constant for each payment date and cancels out of each side of the present value equation. The next line assumes unit notional principle.

```
PresentValue = sum((ForwardRates/Period) .* DiscountFactors);
```

Step 6. Compute the swap's price (the fixed rate) by equating the present value of the fixed cash flows with the present value of the cash flows derived from the implied forward rates. Again, since the notional principle cancels out of each side of the equation, it is simply assumed to be 1.

```
SwapFixedRate = Period * PresentValue / sum(DiscountFactors);
```

The example `ftspex5.m` performs these computations and displays the output on the screen.

Zero Rates	Forward Rates
0.0614	0.0614
0.0642	0.0670
0.0660	0.0695
0.0684	0.0758
0.0702	0.0774
0.0726	0.0846
0.0754	0.0925
0.0795	0.1077
0.0827	0.1089
0.0868	0.1239

Swap Price (Fixed Rate) = 0.0845

All rates are in decimal format. The swap price, 8.45%, would likely be the mid-point between a market-maker's bid/ask quotes.

Producing Graphics with the Toolbox

- “Plotting an Efficient Frontier” on page 6-20
- “Plotting Sensitivities of an Option” on page 6-23
- “Plotting Sensitivities of a Portfolio of Options” on page 6-25

Financial Toolbox and MATLAB graphics functions work together to produce presentation quality graphics, as these examples show. The examples ship with the toolbox as M-files. Try them by entering the commands directly or by executing the M-files. For help using MATLAB plotting functions, see “Creating Line Plots” in the MATLAB documentation.

Plotting an Efficient Frontier

This example plots the efficient frontier of a hypothetical portfolio of three assets. It illustrates how to specify the expected returns, standard deviations, and correlations of a portfolio of assets, how to convert standard deviations and correlations into a covariance matrix, and how to compute and plot the efficient frontier from the returns and covariance matrix. The example also illustrates how to randomly generate a set of portfolio weights, and how to add the random portfolios to an existing plot for comparison with the efficient frontier. The example M-file is `ftgex1.m`.

First, specify the expected returns, standard deviations, and correlation matrix for a hypothetical portfolio of three assets.

```
Returns      = [0.1 0.15 0.12];  
STDs         = [0.2 0.25 0.18];
```

```
Correlations = [ 1  0.3  0.4  
                0.3  1  0.3  
                0.4 0.3  1  ];
```

Convert the standard deviations and correlation matrix into a variance-covariance matrix with the Financial Toolbox function `corr2cov`.

```
Covariances = corr2cov(STDs, Correlations);
```

Evaluate and plot the efficient frontier at 20 points along the frontier, using the function `portopt` and the expected returns and corresponding covariance matrix. Although rather elaborate constraints can be placed on the assets in a portfolio, for simplicity accept the default constraints and scale the total value of the portfolio to 1 and constrain the weights to be positive (no short-selling).

```
portopt>Returns, Covariances, 20)
```

Now that the efficient frontier is displayed, randomly generate the asset weights for 1000 portfolios starting from the MATLAB initial state.

```
rand('state', 0)
Weights = rand(1000, 3);
```

The previous line of code generates three columns of uniformly distributed random weights, but does not guarantee they sum to 1. The following code segment normalizes the weights of each portfolio so that the total of the three weights represent a valid portfolio.

```
Total = sum(Weights, 2);    % Add the weights
Total = Total(:,ones(3,1)); % Make size-compatible matrix
Weights = Weights./Total;  % Normalize so sum = 1
```

Given the 1000 random portfolios just created, compute the expected return and risk of each portfolio associated with the weights.

```
[PortRisk, PortReturn] = portstats>Returns, Covariances, ...
                             Weights);
```

Finally, hold the current graph, and plot the returns and risks of each portfolio on top of the existing efficient frontier for comparison. After plotting, annotate the graph with a title and return the graph to default holding status (any subsequent plots will erase the existing data). The efficient frontier appears in blue, while the 1000 random portfolios appear as a set of red dots on or below the frontier.

```
hold on
plot (PortRisk, PortReturn, '.r')
title('Mean-Variance Efficient Frontier and Random Portfolios')
hold off
```

Plotting Sensitivities of an Option

This example creates a three-dimensional plot showing how gamma changes relative to price for a Black-Scholes option. Recall that gamma is the second derivative of the option price relative to the underlying security price. The plot shows a three-dimensional surface whose z -value is the gamma of an option as price (x -axis) and time (y -axis) vary. It adds yet a fourth dimension by showing option delta (the first derivative of option price to security price) as the color of the surface. This example M-file is `ftgex2.m`.

First set the price range of the options, and set the time range to one year divided into half-months and expressed as fractions of a year.

```
Range = 10:70;
Span = length(Range);
j = 1:0.5:12;
Newj = j(ones(Span,1),:)' / 12;
```

For each time period create a vector of prices from 10 to 70 and create a matrix of all ones.

```
JSpan = ones(length(j),1);  
NewRange = Range(JSpan,:);  
Pad = ones(size(Newj));
```

Calculate the toolbox gamma and delta sensitivity functions (greeks). (Recall that gamma is the second derivative of the option price with respect to the stock price, and delta is the first derivative of the option price with respect to the stock price.) The exercise price is \$40, the risk-free interest rate is 10%, and volatility is 0.35 for all prices and periods.

```
ZVal = blsgamma(NewRange, 40*Pad, 0.1*Pad, Newj, 0.35*Pad);  
Color = blsdelta(NewRange, 40*Pad, 0.1*Pad, Newj, 0.35*Pad);
```

Display the greeks as a function of price and time. Gamma is the z -axis; delta is the color.

```
mesh(Range, j, ZVal, Color);  
xlabel('Stock Price ($)');  
ylabel('Time (months)');  
zlabel('Gamma');  
title('Call Option Price Sensitivity');  
axis([10 70 1 12 -inf inf]);  
view(-40, 50);  
colorbar('horiz');
```

Plotting Sensitivities of a Portfolio of Options

This example plots gamma as a function of price and time for a portfolio of 10 Black-Scholes options. The plot shows a three-dimensional surface. For each point on the surface, the height (z -value) represents the sum of the gammas for each option in the portfolio weighted by the amount of each option. The x -axis represents changing price, and the y -axis represents time. The plot adds a fourth dimension by showing delta as surface color. This has applications in hedging.

This example M-file is `ftgex3.m`.

First set up the portfolio with arbitrary data. Current prices range from \$20 to \$90 for each option. Set corresponding exercise prices for each option.

```
Range = 20:90;
PLen = length(Range);
ExPrice = [75 70 50 55 75 50 40 75 60 35];
```

Set all risk-free interest rates to 10%, and set times to maturity in days. Set all volatilities to 0.35. Set the number of options of each instrument, and allocate space for matrices.

```
Rate = 0.1*ones(10,1);
Time = [36 36 36 27 18 18 18 9 9 9];
Sigma = 0.35*ones(10,1);
NumOpt = 1000*[4 8 3 5 5.5 2 4.8 3 4.8 2.5];
ZVal = zeros(36, PLen);
Color = zeros(36, PLen);
```

For each instrument, create a matrix (of size Time by PLen) of prices for each period.

```
for i = 1:10
    Pad = ones(Time(i),PLen);
    NewR = Range(ones(Time(i),1),:);
```

Create a vector of time periods 1 to Time; and a matrix of times, one column for each price.

```
T = (1:Time(i))';
NewT = T(:,ones(PLen,1));
```

Call the toolbox gamma and delta sensitivity functions to compute gamma and delta.

```
ZVal(36-Time(i)+1:36,:) = ZVal(36-Time(i)+1:36,:) ...
    + NumOpt(i) * blsgamma(NewR, ExPrice(i)*Pad, ...
    Rate(i)*Pad, NewT/36, Sigma(i)*Pad);

Color(36-Time(i)+1:36,:) = Color(36-Time(i)+1:36,:) ...
    + NumOpt(i) * blsdelta(NewR, ExPrice(i)*Pad, ...
    Rate(i)*Pad, NewT/36, Sigma(i)*Pad);

end
```

Draw the surface as a mesh, set the viewpoint, and reverse the x -axis because of the viewpoint. The axes range from 20 to 90, 0 to 36, and $-\infty$ to ∞ .

```
mesh(Range, 1:36, ZVal, Color);
view(60,60);
```

```
set(gca, 'xdir','reverse', 'tag', 'mesh_axes_3');  
axis([20 90 0 36 -inf inf]);
```

Add a title and axis labels and draw a box around the plot. Annotate the colors with a bar and label the colorbar.

```
title('Call Option Portfolio Sensitivity');  
xlabel('Stock Price ($)');  
ylabel('Time (months)');  
zlabel('Gamma');  
set(gca, 'box', 'on');  
colorbar('horiz');
```

Analyzing Financial Time Series

Financial Toolbox provides a collection of tools for the analysis of time series data in the financial markets. The toolbox contains a financial time series object constructor and several methods that operate on and analyze the object. Financial engineers working with time series data, such as equity prices or daily interest fluctuations, can use these tools for more intuitive data management than by using regular vectors or matrices.

This chapter discusses how to create a financial time series object in one of two ways:

- “Using the Constructor” on page 7-3
- “Transforming a Text File” on page 7-14

The chapter also discusses `chartfts`, a graphical tool for visualizing financial time series objects. You can find this discussion in “Visualizing Financial Time Series Objects” on page 7-18.

Creating Financial Time Series Objects

- “Using the Constructor” on page 7-3
- “Transforming a Text File” on page 7-14

Financial Toolbox provides two ways to create a financial time series object:

- At the command line using the object constructor `fints`
- From a text data file through the function `ascii2fts`

The structure of the object minimally consists of a description field, a frequency indicator field, the date vector field, and at least one data series vector. The names for the fields are fixed for the first three fields: `desc`, `freq`, and `dates`. You can specify names of your choice for any data series vectors. If you do not specify names, the object uses the default names `series1`, `series2`, `series3`, and so on.

If time-of-day information is incorporated in the date vector, the object contains an additional field named `times`.

Using the Constructor

The object constructor function `fints` has five different syntaxes. These forms exist to simplify object construction. The syntaxes vary according to the types of input arguments presented to the constructor. The syntaxes are

- Single Matrix Input
 - See “Time-of-Day Information Excluded” on page 7-4.
 - See “Time-of-Day Information Included” on page 7-7.
- Separate Vector Input
 - See “Time-of-Day Information Excluded” on page 7-7.
 - See “Time-of-Day Information Included” on page 7-9.
- See “Data Name Input” on page 7-10.
- See “Frequency Indicator Input” on page 7-12.
- See “Description Field Input” on page 7-13.

Single Matrix Input

The date information provided with this syntax must be in serial date number format. The date number may or may not include time-of-day information.

Note If you are unfamiliar with the concepts of date strings and serial date numbers, consult “Handling and Converting Dates” on page 2-4.

Time-of-Day Information Excluded.

```
fts = fints(dates_and_data)
```

In this simplest form of syntax, the input must be at least a two-column matrix. The first column contains the dates in serial date format; the second column is the data series. The input matrix can have more than two columns, each additional column representing a different data series or set of observations.

If the input is a two-column matrix, the output object contains four fields: `desc`, `freq`, `dates`, and `series1`. The description field, `desc`, defaults to blanks `' '`, and the frequency indicator field, `freq`, defaults to 0. The dates field, `dates`, contains the serial dates from the first column of the input matrix, while the data series field, `series1`, has the data from the second column of the input matrix.

The first example makes two financial time series objects. The first one has only one data series, while the other has more than one. A random vector provides the values for the data series. The range of dates is arbitrarily chosen using the `today` function:

```
date_series = (today:today+100)';  
data_series = exp(randn(1, 101))';  
dates_and_data = [date_series data_series];  
fts1 = fints(dates_and_data);
```

Examine the contents of the object `fts1` just created. The actual date series you observe will vary according to the day when you run the example (the value of `today`). Also, your values in `series1` will differ from those shown, depending upon the sequence of random numbers generated:

```

fts1 =

    desc: (none)
    freq: Unknown (0)

    'dates: (101)'      'series1: (101)'
    '12-Jul-1999'      [         0.3124]
    '13-Jul-1999'      [         3.2665]
    '14-Jul-1999'      [         0.9847]
    '15-Jul-1999'      [         1.7095]
    '16-Jul-1999'      [         0.4885]
    '17-Jul-1999'      [         0.5192]
    '18-Jul-1999'      [         1.3694]
    '19-Jul-1999'      [         1.1127]
    '20-Jul-1999'      [         6.3485]
    '21-Jul-1999'      [         0.7595]
    '22-Jul-1999'      [         9.1390]
    '23-Jul-1999'      [         4.5201]
    '24-Jul-1999'      [         0.1430]
    '25-Jul-1999'      [         0.1863]
    '26-Jul-1999'      [         0.5635]
    '27-Jul-1999'      [         0.8304]
    '28-Jul-1999'      [         1.0090]...

```

The output is truncated for brevity. There are actually 101 data points in the object.

Note that the desc field displays as (none) instead of ' ', and that the contents of the object display as cell array elements. Although the object displays as such, it should be thought of as a MATLAB structure containing the default field names for a single data series object: desc, freq, dates, and series1.

Now create an object with more than one data series in it:

```

date_series = (today:today+100)';
data_series1 = exp(randn(1, 101))';
data_series2 = exp(randn(1, 101))';
dates_and_data = [date_series data_series1 data_series2];
fts2 = fints(dates_and_data);

```

Now look at the object created (again in abbreviated form):

```
fts2 =  
  
desc: (none)  
freq: Unknown (0)  
  
'dates: (101)'      'series1: (101)'      'series2: (101)'  
'12-Jul-1999'      [          0.5816]      [          1.2816]  
'13-Jul-1999'      [          5.1253]      [          0.9262]  
'14-Jul-1999'      [          2.2824]      [          5.6869]  
'15-Jul-1999'      [          1.2596]      [          5.0631]  
'16-Jul-1999'      [          1.9574]      [          1.8709]  
'17-Jul-1999'      [          0.6017]      [          1.0962]  
'18-Jul-1999'      [          2.3546]      [          0.4459]  
'19-Jul-1999'      [          1.3080]      [          0.6304]  
'20-Jul-1999'      [          1.8682]      [          0.2451]  
'21-Jul-1999'      [          0.3509]      [          0.6876]  
'22-Jul-1999'      [          4.6444]      [          0.6244]  
'23-Jul-1999'      [          1.5441]      [          5.7621]  
'24-Jul-1999'      [          0.1470]      [          2.1238]  
'25-Jul-1999'      [          1.5999]      [          1.0671]  
'26-Jul-1999'      [          3.5764]      [          0.7462]  
'27-Jul-1999'      [          1.8937]      [          1.0863]  
'28-Jul-1999'      [          3.9780]      [          2.1516]...
```

The second data series name defaults to `series2`, as expected.

Before you can perform any operations on the object, you must set the frequency indicator field `freq` to the valid frequency of the data series contained in the object. You can leave the description field `desc` blank.

To set the frequency indicator field to a daily frequency, enter

```
fts2.freq = 1, or
```

```
fts2.freq = 'daily'
```

See the `fints` function description in Chapter 12, “Functions — By Category” or Chapter 13, “Functions — Alphabetical List”.

Time-of-Day Information Included. The serial date number used with this form of the `fints` function can incorporate time-of-day information. When time-of-day information is present, the output of the function contains a field `times` that indicates the time of day.

If you recode the previous example to include time-of-day information, you can see the additional column present in the output object:

```
time_series = (now:now+100)';
data_series = exp(randn(1, 101))';
times_and_data = [time_series data_series];
fts1 = fints(times_and_data);

fts1 =

    desc: (none)
    freq: Unknown (0)

    'dates: (101)'    'times: (101)'    'series1: (101)'
    '29-Nov-2001'    '14:57'          [    0.5816]
    '30-Nov-2001'    '14:57'          [    5.1253]
    '01-Dec-2001'    '14:57'          [    2.2824]
    '02-Dec-2001'    '14:57'          [    1.2596]...
```

Separate Vector Input

The date information provided with this syntax can be in serial date number or date string format. The date information may or may not include time-of-day information.

Time-of-Day Information Excluded.

```
fts = fints(dates, data)
```

In this second syntax the dates and data series are entered as separate vectors to `fints`, the financial time series object constructor function. The `dates` vector must be a column vector, while the data series `data` can be a column vector (if there is only one data series) or a column-oriented matrix (for multiple data series). A column-oriented matrix, in this context, indicates

that each column is a set of observations. Different columns are different sets of data series.

Here is an example:

```
dates = (today:today+100)';
data_series1 = exp(randn(1, 101))';
data_series2 = exp(randn(1, 101))';
data = [data_series1 data_series2];
fts = fints(dates, data)

desc: (none)
freq: Unknown (0)

'dates: (101)'    'series1: (101)'    'series2: (101)'
'12-Jul-1999'    [    0.5816]        [    1.2816]
'13-Jul-1999'    [    5.1253]        [    0.9262]
'14-Jul-1999'    [    2.2824]        [    5.6869]
'15-Jul-1999'    [    1.2596]        [    5.0631]
'16-Jul-1999'    [    1.9574]        [    1.8709]
'17-Jul-1999'    [    0.6017]        [    1.0962]
'18-Jul-1999'    [    2.3546]        [    0.4459]
'19-Jul-1999'    [    1.3080]        [    0.6304]
'20-Jul-1999'    [    1.8682]        [    0.2451]
'21-Jul-1999'    [    0.3509]        [    0.6876]
'22-Jul-1999'    [    4.6444]        [    0.6244]
'23-Jul-1999'    [    1.5441]        [    5.7621]
'24-Jul-1999'    [    0.1470]        [    2.1238]
'25-Jul-1999'    [    1.5999]        [    1.0671]
'26-Jul-1999'    [    3.5764]        [    0.7462]
'27-Jul-1999'    [    1.8937]        [    1.0863]
'28-Jul-1999'    [    3.9780]        [    2.1516]...
```

The result is exactly the same as the first syntax. The only difference between the first and second syntax is the way the inputs are entered into the constructor function.

Time-of-Day Information Included. With this form of the function you can enter the time-of-day information either as a serial date number or as a date string. If more than one serial date and time are present, the entry must be in the form of a column-oriented matrix. If more than one string date and time are present, the entry must be a column-oriented cell array of dates and times.

With date string input the dates and times can initially be separate column-oriented date and time series, but you must concatenate them into a single column-oriented cell array before entering them as the first input to `fints`.

For date string input the allowable formats are

- 'ddmmyy hh:mm' or 'ddmmyyyy hh:mm'
- 'mm/dd/yy hh:mm' or 'mm/dd/yyyy hh:mm'
- 'dd-mmm-yy hh:mm' or 'dd-mmm-yyyy hh:mm'
- 'mmm.dd,yy hh:mm' or 'mmm.dd,yyyy hh:mm'

The next example shows time-of-day information input as serial date numbers in a column-oriented matrix:

```
f = fints([now;now+1],(1:2)')

f =

    desc: (none)
    freq: Unknown (0)

    'dates: (2)'    'times: (2)'    'series1: (2)'
    '29-Nov-2001'  '15:22'          [          1]
    '30-Nov-2001'  '15:22'          [          2]
```

If the time-of-day information is in date string format, you must provide it to `fints` as a column-oriented cell array:

```
f = fints({'01-Jan-2001 12:00';'02-Jan-2001 12:00'},(1:2)')

f =
```

```
desc: (none)
freq: Unknown (0)

'dates: (2)'      'times: (2)'      'series1: (2)'
'01-Jan-2001'    '12:00'           [          1]
'02-Jan-2001'    '12:00'           [          2]
```

If the dates and times are in date string format and contained in separate matrices, you must concatenate them before using the date and time information as input to `fints`:

```
dates = ['01-Jan-2001'; '02-Jan-2001'; '03-Jan-2001'];
times = ['12:00'; '12:00'; '12:00'];
dates_time = cellstr([dates, repmat(' ', size(dates,1),1), times]);
f = fints(dates_time, (1:3)')
```

```
f =
```

```
desc: (none)
freq: Unknown (0)

'dates: (3)'      'times: (3)'      'series1: (3)'
'01-Jan-2001'    '12:00'           [          1]
'02-Jan-2001'    '12:00'           [          2]
'03-Jan-2001'    '12:00'           [          3]
```

Data Name Input

```
fts = fints(dates, data, datanames)
```

The third syntax lets you specify the names for the data series with the argument `datanames`. The `datanames` argument can be a MATLAB string for a single data series. For multiple data series names, it must be a cell array of strings.

Look at two examples, one with a single data series and a second with two. The first example sets the data series name to the specified name `First`:

```
dates = (today:today+100)';
```

```

data = exp(randn(1, 101))';
fts1 = fints(dates, data, 'First')

fts1 =

    desc: (none)
    freq: Unknown (0)

    'dates: (101)'    'First: (101)'
    '12-Jul-1999'    [      0.4615]
    '13-Jul-1999'    [      1.1640]
    '14-Jul-1999'    [      0.7140]
    '15-Jul-1999'    [      2.6400]
    '16-Jul-1999'    [      0.8983]
    '17-Jul-1999'    [      2.7552]
    '18-Jul-1999'    [      0.6217]
    '19-Jul-1999'    [      1.0714]
    '20-Jul-1999'    [      1.4897]
    '21-Jul-1999'    [      3.0536]
    '22-Jul-1999'    [      1.8598]
    '23-Jul-1999'    [      0.7500]
    '24-Jul-1999'    [      0.2537]
    '25-Jul-1999'    [      0.5037]
    '26-Jul-1999'    [      1.3933]
    '27-Jul-1999'    [      0.3687]...

```

The second example provides two data series named First and Second:

```

dates = (today:today+100)';
data_series1 = exp(randn(1, 101))';
data_series2 = exp(randn(1, 101))';
data = [data_series1 data_series2];
fts2 = fints(dates, data, {'First', 'Second'})

fts2 =

    desc: (none)
    freq: Unknown (0)

    'dates: (101)'    'First: (101)'    'Second: (101)'
    '12-Jul-1999'    [      1.2305]    [      0.7396]

```

```
'13-Jul-1999' [ 1.2473] [ 2.6038]
'14-Jul-1999' [ 0.3657] [ 0.5866]
'15-Jul-1999' [ 0.6357] [ 0.4061]
'16-Jul-1999' [ 4.0530] [ 0.4096]
'17-Jul-1999' [ 0.6300] [ 1.3214]
'18-Jul-1999' [ 1.0333] [ 0.4744]
'19-Jul-1999' [ 2.2228] [ 4.9702]
'20-Jul-1999' [ 2.4518] [ 1.7758]
'21-Jul-1999' [ 1.1479] [ 1.3780]
'22-Jul-1999' [ 0.1981] [ 0.8595]
'23-Jul-1999' [ 0.1927] [ 1.3713]
'24-Jul-1999' [ 1.5353] [ 3.8332]
'25-Jul-1999' [ 0.4784] [ 0.1067]
'26-Jul-1999' [ 1.7593] [ 3.6434]
'27-Jul-1999' [ 0.2505] [ 0.6849]
'28-Jul-1999' [ 1.5845] [ 1.0025]...
```

Note Data series names must be valid MATLAB variable names. The only allowed nonalphanumeric character is the underscore (`_`) character.

Because `freq` for `fts2` has not been explicitly indicated, the frequency indicator for `fts2` is set to `Unknown`. Set the frequency indicator field `freq` before you attempt any operations on the object. You will not be able to use the object until the frequency indicator field is set to a valid indicator.

Frequency Indicator Input

```
fts = fints(dates, data, datanames, freq)
```

With the fourth syntax you can set the frequency indicator field when you create the financial time series object. The frequency indicator field `freq` is set as the fourth input argument. You will not be able to use the financial time series object until `freq` is set to a valid indicator. Valid frequency indicators are

```
UNKNOWN, Unknown, unknown, U, u,0
DAILY, Daily, daily, D, d,1
WEEKLY, Weekly, weekly, W, w,2
```

```

MONTHLY, Monthly, monthly, M, m,3
QUARTERLY, Quarterly, quarterly, Q, q,4
SEMIANNUAL, Semiannual, semiannual, S, s,5
ANNUAL, Annual, annual, A, a,6

```

The previous example contained sets of daily data. The `freq` field displayed as `Unknown (0)` because the frequency indicator was not explicitly set. The command

```
fts = fints(dates, data, {'First', 'Second'}, 1);
```

sets the `freq` indicator to `Daily(1)` when creating the financial time series object:

```

fts =
  desc: (none)
  freq: Daily (1)

  'dates: (101)'   'First: (101)'   'Second: (101)'
  '12-Jul-1999'   [      1.2305]   [      0.7396]
  '13-Jul-1999'   [      1.2473]   [      2.6038]
  '14-Jul-1999'   [      0.3657]   [      0.5866]
  '15-Jul-1999'   [      0.6357]   [      0.4061]
  '16-Jul-1999'   [      4.0530]   [      0.4096]
  '17-Jul-1999'   [      0.6300]   [      1.3214]
  '18-Jul-1999'   [      1.0333]   [      0.4744]...

```

When you create the object using this syntax, you can use the other valid frequency indicators for a particular frequency. For a daily data set you can use `DAILY`, `Daily`, `daily`, `D`, or `d`. Similarly, with the other frequencies, you can use the valid string indicators or their numeric counterparts.

Description Field Input

```
fts = fints(dates, data, datanames, freq, desc)
```

With the fifth syntax, you can explicitly set the description field as the fifth input argument. The description can be anything you want. It is not used in any operations performed on the object.

This example sets the desc field to 'Test TS'.

```
dates = (today:today+100)';
data_series1 = exp(randn(1, 101))';
data_series2 = exp(randn(1, 101))';
data = [data_series1 data_series2];
fts = fints(dates, data, {'First', 'Second'}, 1, 'Test TS')

fts =
  desc: Test TS
  freq: Daily (1)

  'dates: (101)'      'First: (101)'      'Second: (101)'
  '12-Jul-1999'      [      0.5428]      [      1.2491]
  '13-Jul-1999'      [      0.6649]      [      6.4969]
  '14-Jul-1999'      [      0.2428]      [      1.1163]
  '15-Jul-1999'      [      1.2550]      [      0.6628]
  '16-Jul-1999'      [      1.2312]      [      1.6674]
  '17-Jul-1999'      [      0.4869]      [      0.3015]
  '18-Jul-1999'      [      2.1335]      [      0.9081]...
```

Now the description field is filled with the specified string 'Test TS' when the constructor is called.

Transforming a Text File

The function `ascii2fts` creates a financial time series object from a text (ASCII) data file provided that the data file conforms to a general format. The general format of the text data file is as follows:

- Can contain header text lines.
- Can contain column header information. The column header information must immediately precede the data series columns unless the `skiprows` argument (see below) is specified.
- Leftmost column must be the date column.
- Dates must be in a valid date string format.
 - 'ddmmyy' or 'ddmmyyyy'
 - 'mm/dd/yy' or 'mm/dd/yyyy'

- 'dd-mmm-yy' or 'dd-mmm-yyyy'
- 'mmm.dd,yy' or 'mmm.dd,yyyy'
- Each column must be separated either by spaces or a tab.

Several example text data files are included with the toolbox. These files are in the `ftsdata` subdirectory within the directory `<matlab>/toolbox/ftseries`.

The syntax of the function

```
fts = ascii2fts(filename, descrow, colheadrow, skiprows);
```

takes in the data filename (`filename`), the row number where the text for the description field is (`descrow`), the row number of the column header information (`colheadrow`), and the row numbers of rows to be skipped (`skiprows`). For example, rows need to be skipped when there are intervening rows between the column head row and the start of the time series data.

Look at the beginning of the ASCII file `disney.dat` in the `ftsdata` subdirectory:

```
Walt Disney Company (DIS)
Daily prices (3/29/96 to 3/29/99)
DATE      OPEN      HIGH      LOW      CLOSE     VOLUME
3/29/99   33.0625   33.188    32.75    33.063    6320500
3/26/99   33.3125   33.375    32.75    32.938    5552800
3/25/99   33.5      33.625    32.875   33.375    7936000
3/24/99   33.0625   33.25     32.625   33.188    6025400...
```

The command line

```
disfts = ascii2fts('disney.dat', 1, 3, 2)
```

uses `disney.dat` to create time series object `disfts`. This example

- Reads the text data file `disney.dat`
- Uses the first line in the file as the content of the description field
- Skips the second line
- Parses the third line in the file for column header (or data series names)

- Parses the rest of the file for the date vector as well as the data series values

The resulting financial time series object looks like this.

```
disfts =  
  
desc: Walt Disney Company (DIS)  
freq: Unknown (0)  
  
'dates: (782)'   'OPEN: (782)'   'HIGH: (782)'   'LOW: (782)'  
'29-Mar-1996'   [ 21.1938]      [ 21.6250]      [ 21.2920]  
'01-Apr-1996'   [ 21.1120]      [ 21.6250]      [ 21.4170]  
'02-Apr-1996'   [ 21.3165]      [ 21.8750]      [ 21.6670]  
'03-Apr-1996'   [ 21.4802]      [ 21.8750]      [ 21.7500]  
'04-Apr-1996'   [ 21.4393]      [ 21.8750]      [ 21.5000]  
'05-Apr-1996'   [      NaN]      [      NaN]      [      NaN]  
'09-Apr-1996'   [ 21.1529]      [ 21.5420]      [ 21.2080]  
'10-Apr-1996'   [ 20.7387]      [ 21.1670]      [ 20.2500]  
'11-Apr-1996'   [ 20.0829]      [ 20.5000]      [ 20.0420]  
'12-Apr-1996'   [ 19.9189]      [ 20.5830]      [ 20.0830]  
'15-Apr-1996'   [ 20.2878]      [ 20.7920]      [ 20.3750]  
'16-Apr-1996'   [ 20.3698]      [ 20.9170]      [ 20.1670]  
'17-Apr-1996'   [ 20.4927]      [ 20.9170]      [ 20.7080]  
'18-Apr-1996'   [ 20.4927]      [ 21.0420]      [ 20.7920]
```

There are 782 data points in this object. Only the first few lines are shown here. Also, this object has two other data series, the CLOSE and VOLUME data series, that are not shown here. Note that in creating the financial time series object, `ascii2fts` sorts the data into ascending chronological order.

The frequency indicator field, `freq`, is set to 0 for Unknown frequency. You can manually reset it to the appropriate frequency using structure syntax `disfts.freq = 1` for Daily frequency.

With a slightly different syntax, the function `ascii2fts` can create a financial time series object when time-of-day data is present in the ASCII file. The new syntax has the form

```
fts = ascii2fts(filename, timedata, descrow, colheadrow,  
skiprows);
```

Set `timedata` to 'T' when time-of-day data is present and to 'NT' when there is no time data. For an example using this function with time-of-day data, see the reference page for `ascii2fts`.

Visualizing Financial Time Series Objects

- “Using chartfts” on page 7-18
- “Zoom Tool” on page 7-21
- “Combine Axes Tool” on page 7-24

Financial Toolbox contains the function `chartfts`, which provides a visual representation of a financial time series object. `chartfts` is an interactive charting and graphing utility for financial time series objects. With this function, you can observe time series values on the entire range of dates covered by the time series.

Note Interactive charting is also available from the **Graphs** menu of the graphical user interface. See “Interactive Chart” on page 10-17 for additional information.

Using `chartfts`

`chartfts` requires a single input argument, `tobj`, where `tobj` is the name of the financial time series object you want to explore. Most equity financial time series objects contain four price series, such as opening, closing, highest, and lowest prices, plus an additional series containing the volume traded. However, `chartfts` is not limited to a time series of equity prices and volume traded. It can be used to display any time series data you may have.

To illustrate the use of `chartfts`, use the equity price and volume traded data for the Walt Disney Corporation (NYSE: DIS) provided in the file `disney.mat`:

```
load disney.mat
```

```
whos
```

Name	Size	Bytes	Class
<code>dis</code>	782x5	39290	fints object
<code>dis_CLOSE</code>	782x1	6256	double array
<code>dis_HIGH</code>	782x1	6256	double array

```

dis_LOW      782x1      6256  double array
dis_OPEN    782x1      6256  double array
dis_VOLUME  782x1      6256  double array
dis_nv      782x4      32930  fints object
q_dis       13x4        2196  fints object

```

For charting purposes look only at the objects `dis` (daily equity data including volume traded) and `dis_nv` (daily data without volume traded). Both objects contain the series `OPEN`, `HIGH`, `LOW`, and `CLOSE`, but only `dis` contains the additional `VOLUME` series.

Use `chartfts(dis)` to observe the values.

The chart contains five plots, each representing one of the series in the time series object. Boxes indicate the value of each individual plot. The date box is always on the left. The number of data boxes on the right depends upon the number of data series in the time series object, five in this case. The order in which these boxes are arranged (left to right) matches the plots from

top to bottom. With more than eight data series in the object, the scroll bar on the right is activated so that additional data from the other series can be brought into view.

Slide the mouse cursor over the chart. A vertical bar appears across all plots. This bar selects the set of data shown in the boxes below. Move this bar horizontally and the data changes accordingly.

Click the plot. A small information box displays the data at the point where you click the mouse button.

Zoom Tool

The zoom feature of `chartfts` enables a more detailed look at the data during a selected time frame. The Zoom tool is found under the **Chart Tools** menu.

Note Due to the specialized nature of this feature, do not use the MATLAB zoom command or **Zoom In** and **Zoom Out** from the **Tools** menu.

When the feature is turned on, you will see two inactive buttons (**ZOOM In** and **Reset ZOOM**) above the boxes. The buttons become active later after certain actions have been performed.

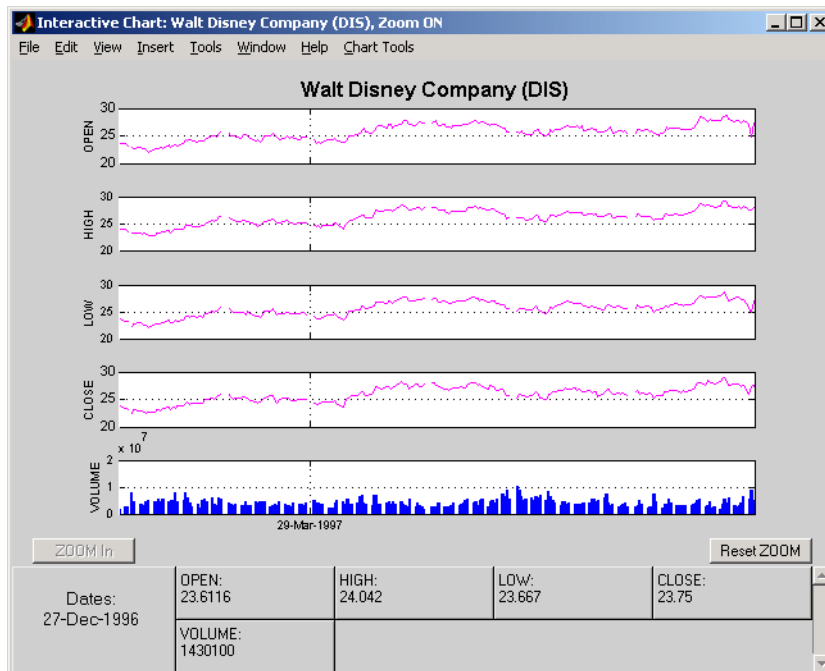

The window title bar displays the status of the chart tool that you are using. With the Zoom tool turned on, you see **Zoom ON** in the title bar in addition to the name of the time series you are working with. When the tool is off, no status is displayed.

To zoom into the chart, you need to define the starting and ending dates. Define the starting date by moving the cursor over the chart until the desired date appears at the bottom-left box and click the mouse button. A blue vertical line indicates the starting date you have selected. Next, again move the cursor over the chart until the desired ending date appears in the box and click the mouse once again. This time, a red vertical line appears and the **ZOOM In** button is activated.

To zoom into the chart, click the **ZOOM In** button.

The chart is zoomed in. Note that the **Reset ZOOM** button now becomes active while the **ZOOM In** button becomes inactive again. To return the chart

to its original state (not zoomed), click the **Reset ZOOM** button. To zoom into the chart even further, repeat the steps above for zooming into the chart.

Turn the Zoom tool off by going back to the **Chart Tools** menu and choosing **Zoom Off**.

With the tool turned off, the chart stays at the last state that it was in. If you turn it off when the chart is zoomed in, the chart stays zoomed in. If you reset the zoom before turning it off, the chart becomes the original (not zoomed).

Combine Axes Tool

The Combine Axes tool allows you to combine all axes or specific axes into one. With axes combined, you can visually spot any trends that can occur among the data series in a financial time series object.

To illustrate this tool, use `dis_nv`, the financial time series object that does not contain volume traded data:

```
chartfts(dis_nv)
```

To combine axes, choose the **Chart Tools** menu, followed by **Combine Axes** and **On**.

When the Combine Axes tool is on, check boxes appear beside each individual plot. An additional check box enables the combination of all plots.

Combining All Axes

To combine all plots, select the **Select all plots** check box.

Now click the **Combine Selected Graphs** button to combine the chosen plots. In this case, all plots are combined.

The combined plots have a single plot axis with all data series traced. The background of each data box has changed to the color corresponding to the color of the trace that represents the data series. After the axes are combined, the tool is turned off.

Combining Selected Axes

You can choose any combination of the available axes to combine. For example, combine the HIGH and LOW price series of the Disney time series. Click the check boxes next to the corresponding plots. The **Combine Selected Graphs** button appears and is active.

Click the **Combine Selected Graphs** button. The chart with the combined plots looks like the next figure.

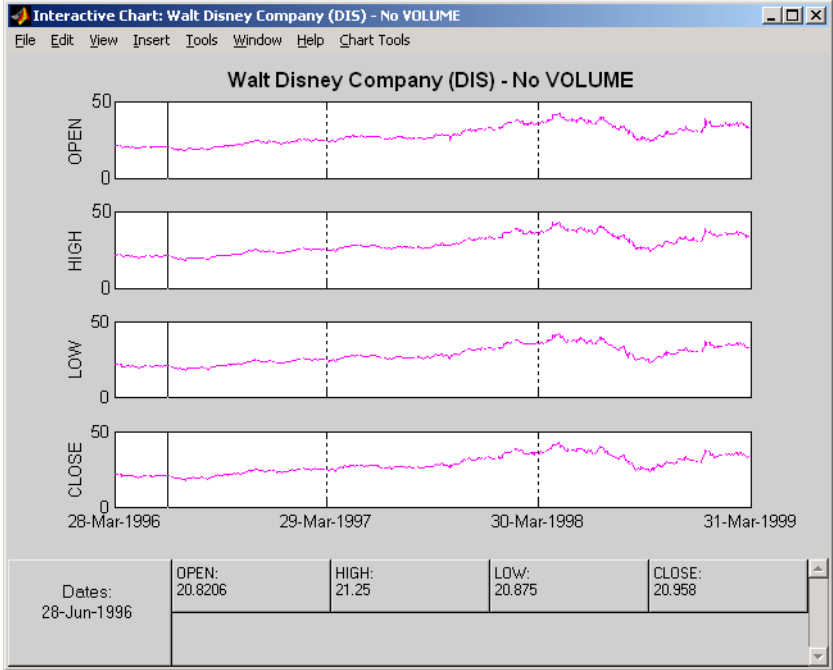

The plot with the combined axes is located at the top of the chart while the remaining plots follow it. The data boxes have also been changed. The boxes that correspond to the combined axes are relocated to the beginning, and the background colors are set to the color of the respective traces. The data boxes for the remaining axes retain their original formats.

Resetting Axes

If you have altered the chart by combining axes, you must reset the axes before you can visualize additional combinations. Reset the axes with the **Reset Axes** menu item under **Chart Tools > Combine Axes**. Note that now the **On** and **Off** features are turned off.

With axes reset, the interactive chart appears in its original format, and you can proceed with additional axes combinations.

Using Financial Time Series

Introduction (p. 8-2)

How to manipulate and analyze financial time series data

Working with Financial Time Series Objects (p. 8-3)

Extracting time series data and performing operations on time series

Demonstration Program (p. 8-25)

A comprehensive example illustrating the use of the toolbox to predict the return on an equity

Introduction

This chapter discusses how to manipulate and analyze financial time series data. The major topics discussed include

- “Financial Time Series Object Structure” on page 8-3
- “Data Extraction” on page 8-4
- “Object-to-Matrix Conversion” on page 8-6
- “Indexing a Financial Time Series Object” on page 8-7
- “Operations” on page 8-15
- “Data Transformation and Frequency Conversion” on page 8-19

Much of this information is summarized in the “Demonstration Program” on page 8-25.

Working with Financial Time Series Objects

- “Financial Time Series Object Structure” on page 8-3
- “Data Extraction” on page 8-4
- “Object-to-Matrix Conversion” on page 8-6
- “Indexing a Financial Time Series Object” on page 8-7
- “Operations” on page 8-15
- “Data Transformation and Frequency Conversion” on page 8-19

A financial time series object is designed to be used as if it were a MATLAB structure. (See the MATLAB documentation for a description of MATLAB structures or how to use MATLAB in general.)

This part of the tutorial assumes that you know how to use MATLAB and are familiar with MATLAB structures. The terminology is similar to that of a MATLAB structure. The financial time series object term *component* is interchangeable with the MATLAB structure term *field*.

Financial Time Series Object Structure

A financial time series object always contains three component names: `desc` (description field), `freq` (frequency indicator field), and `dates` (date vector). If you build the object using the constructor `fints`, the default value for the description field is a blank string (' '). If you build the object from a text data file using `ascii2fts`, the default is the name of the text data file. The default for the frequency indicator field is 0 (Unknown frequency). Objects created from operations can default the setting to 0. For example, if you decide to pick out values selectively from an object, the frequency of the new object might not be the same as that of the object from which it came.

The date vector `dates` does not have a default set of values. When you create an object, you have to supply the date vector. You can change the date vector afterwards but, at object creation time, you must provide a set of dates.

The final component of a financial time series object is one or more data series vectors. If you do not supply a name for the data series, the default name is `series1`. If you have multiple data series in an object and do not supply the

names, the default is the name series followed by a number, for example, series1, series2, and series3.

Data Extraction

Here is an exercise on how to extract data from a financial time series object. As mentioned before, you can think of the object as a MATLAB structure. Highlight each line in the exercise in the MATLAB Help browser, press the right mouse button, and select **Evaluate Selection** to execute it.

To begin, create a financial time series object called myfts:

```
dates = (datenum('05/11/99'):datenum('05/11/99')+100)';
data_series1 = exp(randn(1, 101))';
data_series2 = exp(randn(1, 101))';
data = [data_series1 data_series2];
myfts = fints(dates, data);
```

The myfts object looks like this:

```
myfts =

  desc: (none)
  freq: Unknown (0)

  'dates: (101)'      'series1: (101)'      'series2: (101)'
  '11-May-1999'      [      2.8108]        [      0.9323]
  '12-May-1999'      [      0.2454]        [      0.5608]
  '13-May-1999'      [      0.3568]        [      1.5989]
  '14-May-1999'      [      0.5255]        [      3.6682]
  '15-May-1999'      [      1.1862]        [      5.1284]
  '16-May-1999'      [      3.8376]        [      0.4952]
  '17-May-1999'      [      6.9329]        [      2.2417]
  '18-May-1999'      [      2.0987]        [      0.3579]
  '19-May-1999'      [      2.2524]        [      3.6492]
  '20-May-1999'      [      0.8669]        [      1.0150]
  '21-May-1999'      [      0.9050]        [      1.2445]
  '22-May-1999'      [      0.4493]        [      5.5466]
  '23-May-1999'      [      1.6376]        [      0.1251]
  '24-May-1999'      [      3.4472]        [      1.1195]
```

```
'25-May-1999' [ 3.6545] [ 0.3374]...
```

There are more dates in the object; only the first few lines are shown here.

Note The actual data in your `series1` and `series2` will differ from the above because of the use of random numbers.

Now create another object with only the values for `series2`:

```
srs2 = myfts.series2

srs2 =

desc: (none)
freq: Unknown (0)

'dates: (101)' 'series2: (101)'
'11-May-1999' [ 0.9323]
'12-May-1999' [ 0.5608]
'13-May-1999' [ 1.5989]
'14-May-1999' [ 3.6682]
'15-May-1999' [ 5.1284]
'16-May-1999' [ 0.4952]
'17-May-1999' [ 2.2417]
'18-May-1999' [ 0.3579]
'19-May-1999' [ 3.6492]
'20-May-1999' [ 1.0150]
'21-May-1999' [ 1.2445]
'22-May-1999' [ 5.5466]
'23-May-1999' [ 0.1251]
'24-May-1999' [ 1.1195]
'25-May-1999' [ 0.3374]...
```

The new object `srs2` contains all the dates in `myfts`, but the only data series is `series2`. The name of the data series retains its name from the original object, `myfts`.

Note The output from referencing a data series field or indexing a financial time series object is always another financial time series object. The exceptions are referencing the description, frequency indicator, and dates fields, and indexing into the dates field.

Object-to-Matrix Conversion

The function `fts2mat` extracts the dates and/or the data series values from an object and places them into a vector or a matrix. The default behavior extracts just the values into a vector or a matrix. Look at the next example:

```
srs2_vec = fts2mat(myfts.series2)

srs2_vec =
    0.9323
    0.5608
    1.5989
    3.6682
    5.1284
    0.4952
    2.2417
    0.3579
    3.6492
    1.0150
    1.2445
    5.5466
    0.1251
    1.1195
    0.3374...
```

If you want to include the dates in the output matrix, provide a second input argument and set it to 1. This results in a matrix whose first column is a vector of serial date numbers:

```
format long g

srs2_mtx = fts2mat(myfts.series2, 1)
```

```

srs2_mtx =

    730251    0.932251754559576
    730252    0.560845677519876
    730253    1.59888712183914
    730254    3.6681500883527
    730255    5.12842215360269
    730256    0.49519254119977
    730257    2.24174134286213
    730258    0.357918065917634
    730259    3.64915665824198
    730260    1.01504236943148
    730261    1.24446420606078
    730262    5.54661849025711
    730263    0.12507959735904
    730264    1.11953883096805
    730265    0.337398214166607

```

The vector `srs2_vec` contains just `series2` values. The matrix `srs2_mtx` contains dates in the first column and the values of the `series2` data series in the second. Dates in the first column are in serial date format. Serial date format is a representation of the date string format (for example, serial date = 1 is equivalent to 01-Jan-0000). (The serial date vector can include time-of-day information.)

The long `g` display format displays the numbers without exponentiation. (To revert to the default display format, use `format short`. (See the `format` command in the MATLAB documentation for a description of MATLAB display formats.) Remember that both the vector and the matrix have 101 rows of data as in the original object `myfts` but are shown truncated here.

Indexing a Financial Time Series Object

You can also index into the object as with any other MATLAB variable or structure. A financial time series object lets you use a date string, a cell array of date strings, a date string range, or normal integer indexing. *You cannot, however, index into the object using serial dates.* If you have serial dates, you must first use the MATLAB `datestr` command to convert them into date strings.

When indexing by date string, note that

- Each date string must contain the day, month, and year. Valid formats are
 - 'ddmmyy hh:mm' or 'ddmmyyyy hh:mm'
 - 'mm/dd/yy hh:mm' or 'mm/dd/yyyy hh:mm'
 - 'dd-mmm-yy hh:mm' or 'dd-mmm-yyyy hh:mm'
 - 'mmm.dd,yy hh:mm' or 'mmm.dd,yyyy hh:mm'
- All data falls at the end of the indicated time period, that is, weekly data falls on Fridays, monthly data falls on the end of each month, and so on, whenever the data has gone through a frequency conversion.

Indexing with Date Strings

With date string indexing you get the values in a financial time series object for a specific date using a date string as the index into the object. Similarly, if you want values for multiple dates in the object, you can put those date strings into a cell array and use the cell array as the index to the object. Here are some examples.

This example extracts all values for May 11, 1999 from `myfts`:

```
format short
myfts('05/11/99')

ans =

    desc: (none)
    freq: Unknown (0)

    'dates: (1)'    'series1: (1)'    'series2: (1)'
    '11-May-1999' [      2.8108]    [      0.9323]
```

The next example extracts only `series2` values for May 11, 1999 from `myfts`:

```
myfts.series2('05/11/99')

ans =
```

```

desc: (none)
freq: Unknown (0)

'dates: (1)'      'series2: (1)'
'11-May-1999'    [      0.9323]

```

The third example extracts all values for three different dates:

```

myfts({'05/11/99', '05/21/99', '05/31/99'})

ans =

desc: (none)
freq: Unknown (0)

'dates: (3)'      'series1: (3)'      'series2: (3)'
'11-May-1999'    [      2.8108]      [      0.9323]
'21-May-1999'    [      0.9050]      [      1.2445]
'31-May-1999'    [      1.4266]      [      0.6470]

```

The next example extracts only series2 values for the same three dates:

```

myfts.series2({'05/11/99', '05/21/99', '05/31/99'})

ans =

desc: (none)
freq: Unknown (0)

'dates: (3)'      'series2: (3)'
'11-May-1999'    [      0.9323]
'21-May-1999'    [      1.2445]
'31-May-1999'    [      0.6470]

```

Indexing with Date String Range

A financial time series is unique because it allows you to index into the object using a date string range. A date string range consists of two date strings separated by two colons (::). In MATLAB this separator is called the double-colon operator. An example of a MATLAB date string range is

'05/11/99::05/31/99'. The operator gives you all data points available between those dates, including the start and end dates.

Here are some date string range examples:

```
myfts ('05/11/99::05/15/99')

ans =

    desc: (none)
    freq: Unknown (0)

    'dates: (5)'    'series1: (5)'    'series2: (5)'
    '11-May-1999'  [      2.8108]    [      0.9323]
    '12-May-1999'  [      0.2454]    [      0.5608]
    '13-May-1999'  [      0.3568]    [      1.5989]
    '14-May-1999'  [      0.5255]    [      3.6682]
    '15-May-1999'  [      1.1862]    [      5.1284]
```

```
myfts.series2('05/11/99::05/15/99')
```

```
ans =

    desc: (none)
    freq: Unknown (0)

    'dates: (5)'    'series2: (5)'
    '11-May-1999'  [      0.9323]
    '12-May-1999'  [      0.5608]
    '13-May-1999'  [      1.5989]
    '14-May-1999'  [      3.6682]
    '15-May-1999'  [      5.1284]
```

As with any other MATLAB variable or structure, you can assign the output to another object variable:

```
nfts = myfts.series2('05/11/99::05/20/99');
```

nfts is the same as ans in the second example.

If one of the dates does not exist in the object, an error message indicates that one or both date indexes are out of the range of the available dates in the object. You can either display the contents of the object or use the command `ftsbound` to determine the first and last dates in the object.

Indexing with Integers

Integer indexing is the normal form of indexing in MATLAB. Indexing starts at 1 (not 0); index = 1 corresponds to the first element, index = 2 to the second element, index = 3 to the third element, and so on. Here are some examples with and without data series reference.

Get the first item in `series2`:

```
myfts.series2(1)

ans =

    desc: (none)
    freq: Unknown (0)

    'dates: (1)'    'series2: (1)'
    '11-May-1999'  [      0.9323]
```

Get the first, third, and fifth items in `series2`:

```
myfts.series2([1, 3, 5])

ans =

    desc: (none)
    freq: Unknown (0)

    'dates: (3)'    'series2: (3)'
    '11-May-1999'  [      0.9323]
    '13-May-1999'  [      1.5989]
    '15-May-1999'  [      5.1284]
```

Get items 16 through 20 in `series2`:

```
myfts.series2(16:20)
```

```
ans =
```

```
desc: (none)
freq: Unknown (0)

'dates: (5)'      'series2: (5)'
```

'26-May-1999'	[0.2105]
'27-May-1999'	[1.8916]
'28-May-1999'	[0.6673]
'29-May-1999'	[0.6681]
'30-May-1999'	[1.0877]

Get items 16 through 20 in the financial time series object myfts:

```
myfts(16:20)
```

```
ans =
```

```
desc: (none)
freq: Unknown (0)

'dates: (5)'      'series1: (5)'      'series2: (5)'
```

'26-May-1999'	[0.7571]	[0.2105]
'27-May-1999'	[1.2425]	[1.8916]
'28-May-1999'	[1.8790]	[0.6673]
'29-May-1999'	[0.5778]	[0.6681]
'30-May-1999'	[1.2581]	[1.0877]

Get the last item in myfts:

```
myfts(end)
```

```
ans =
```

```
desc: (none)
freq: Unknown (0)

'dates: (1)'      'series1: (1)'      'series2: (1)'
```

'19-Aug-1999'	[1.4692]	[3.4238]
---------------	---	---------	---	---------

This example uses the MATLAB special variable `end`, which points to the last element of the object when used as an index. The example returns an object whose contents are the values in the object `myfts` on the last date entry.

Indexing When Time-of-Day Data Is Present

Both integer and date string indexing are permitted when time-of-day information is present in the financial time series object. You can index into the object with both date and time specifications, but not with time of day alone. To show how indexing works with time-of-day data present, create a financial time series object called `timeday` containing a time specification:

```

dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
         '02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
dates_times = cellstr([dates, repmat(' ', size(dates,1),1), ...
                       times]);
timeday = fints(dates_times, (1:6)', {'Data1'}, 1, 'My first FINTS')

timeday =

    desc: My first FINTS
    freq: Daily (1)

    'dates: (6)'      'times: (6)'      'Data1: (6)'
    '01-Jan-2001'    '11:00'          [          1]
    '    "          '12:00'          [          2]
    '02-Jan-2001'    '11:00'          [          3]
    '    "          '12:00'          [          4]
    '03-Jan-2001'    '11:00'          [          5]
    '    "          '12:00'          [          6]

```

Use integer indexing to extract the second and third data items from `timeday`:

```

timeday(2:3)

ans =

    desc: My first FINTS
    freq: Daily (1)

```

```
'dates: (2)'      'times: (2)'      'Data1: (2)'  
'01-Jan-2001'    '12:00'           [          2]  
'02-Jan-2001'    '11:00'           [          3]
```

For date string indexing, enclose the date and time string in one pair of quotation marks. If there is one date with multiple times, indexing with only the date returns the data for all the times for that specific date. For example, the command `timeday('01-Jan-2001')` returns the data for all times on January 1, 2001:

```
ans =  
  
desc: My first FINTS  
freq: Daily (1)  
  
'dates: (2)'      'times: (2)'      'Data1: (2)'  
'01-Jan-2001'    '11:00'           [          1]  
'      "      '    '12:00'           [          2]
```

You can also indicate a specific date and time:

```
timeday('01-Jan-2001 12:00')  
  
ans =  
  
desc: My first FINTS  
freq: Daily (1)  
  
'dates: (1)'      'times: (1)'      'Data1: (1)'  
'01-Jan-2001'    '12:00'           [          2]
```

Use the double-colon operator `::` to specify a range of dates and times:

```
timeday('01-Jan-2001 12:00::03-Jan-2001 11:00')  
  
ans =  
  
desc: My first FINTS  
freq: Daily (1)
```

```

'dates: (4)'   'times: (4)'   'Data1: (4)'
'01-Jan-2001' '12:00'       [         2]
'02-Jan-2001' '11:00'       [         3]
'   "   "   '12:00'       [         4]
'03-Jan-2001' '11:00'       [         5]

```

Treat `timeday` as a MATLAB structure if you want to obtain the contents of a specific field. For example, to find the times of day included in this object, enter

```
datestr(timeday.times)
```

```
ans =
```

```

11:00 AM
12:00 PM
11:00 AM
12:00 PM
11:00 AM
12:00 PM

```

Operations

Several MATLAB functions have been overloaded to work with financial time series objects. The overloaded functions include basic arithmetic functions such as addition, subtraction, multiplication, and division as well as other functions such as arithmetic average, filter, and difference. Also, specific methods have been designed to work with the financial time series object. For a list of functions grouped by type, refer to Chapter 12, “Functions — By Category” or enter

```
help ftseries
```

at the MATLAB command prompt.

Basic Arithmetic

Financial time series objects permit you to do addition, subtraction, multiplication, and division, either on the entire object or on specific object fields. This is a feature that MATLAB structures do not allow. You cannot

do arithmetic operations on entire MATLAB structures, only on specific fields of a structure.

You can perform arithmetic operations on two financial time series objects as long as they are compatible. (All contents are the same except for the description and the values associated with the data series.)

Note *Compatible* time series are not the same as *equal* time series. Two time series objects are equal when everything but the description fields is the same.

Here are some examples of arithmetic operations on financial time series objects.

Load a MAT-file that contains some sample financial time series objects:

```
load dji30short
```

One of the objects in `dji30short` is called `myfts1`:

```
myfts1 =  
  
desc: DJI30MAR94.dat  
freq: Daily (1)  
  
'dates: (20)' 'Open: (20)' 'High: (20)' 'Low: (20)' 'Close: (20)'  
'04-Mar-1994' [ 3830.90] [ 3868.04] [ 3800.50] [ 3832.30]  
'07-Mar-1994' [ 3851.72] [ 3882.40] [ 3824.71] [ 3856.22]  
'08-Mar-1994' [ 3858.48] [ 3881.55] [ 3822.45] [ 3851.72]  
'09-Mar-1994' [ 3853.97] [ 3874.52] [ 3817.95] [ 3853.41]  
'10-Mar-1994' [ 3852.57] [ 3865.51] [ 3801.63] [ 3830.62]...
```

Create another financial time series object that is identical to `myfts1`:

```
newfts = fints(myfts1.dates, fts2mat(myfts1)/100,...  
{'Open','High','Low','Close'}, 1, 'New FTS')  
  
newfts =  
  
desc: New FTS
```

```
freq: Daily (1)
```

```
'dates: (20)' 'Open: (20)' 'High: (20)' 'Low: (20)' 'Close: (20)'  
'04-Mar-1994' [ 38.31] [ 38.68] [ 38.01] [ 38.32]  
'07-Mar-1994' [ 38.52] [ 38.82] [ 38.25] [ 38.56]  
'08-Mar-1994' [ 38.58] [ 38.82] [ 38.22] [ 38.52]  
'09-Mar-1994' [ 38.54] [ 38.75] [ 38.18] [ 38.53]  
'10-Mar-1994' [ 38.53] [ 38.66] [ 38.02] [ 38.31]...
```

Perform an addition operation on both time series objects:

```
addup = myfts1 + newfts
```

```
addup =
```

```
desc: DJI30MAR94.dat
```

```
freq: Daily (1)
```

```
'dates: (20)' 'Open: (20)' 'High: (20)' 'Low: (20)' 'Close: (20)'  
'04-Mar-1994' [ 3869.21] [ 3906.72] [ 3838.51] [ 3870.62]  
'07-Mar-1994' [ 3890.24] [ 3921.22] [ 3862.96] [ 3894.78]  
'08-Mar-1994' [ 3897.06] [ 3920.37] [ 3860.67] [ 3890.24]  
'09-Mar-1994' [ 3892.51] [ 3913.27] [ 3856.13] [ 3891.94]  
'10-Mar-1994' [ 3891.10] [ 3904.17] [ 3839.65] [ 3868.93]...
```

Now, perform a subtraction operation on both time series objects:

```
subout = myfts1 - newfts
```

```
subout =
```

```
desc: DJI30MAR94.dat
```

```
freq: Daily (1)
```

```
'dates: (20)' 'Open: (20)' 'High: (20)' 'Low: (20)' 'Close: (20)'  
'04-Mar-1994' [ 3792.59] [ 3829.36] [ 3762.49] [ 3793.98]  
'07-Mar-1994' [ 3813.20] [ 3843.58] [ 3786.46] [ 3817.66]  
'08-Mar-1994' [ 3819.90] [ 3842.73] [ 3784.23] [ 3813.20]  
'09-Mar-1994' [ 3815.43] [ 3835.77] [ 3779.77] [ 3814.88]  
'10-Mar-1994' [ 3814.04] [ 3826.85] [ 3763.61] [ 3792.31]...
```

Operations with Objects and Matrices

You can also perform operations involving a financial time series object and a matrix or scalar:

```
addscalar = myfts1 + 10000

addscalar =

desc: DJI30MAR94.dat
freq: Daily (1)

'dates: (20)' 'Open: (20)' 'High: (20)' 'Low: (20)' 'Close: (20)'
'04-Mar-1994' [ 13830.90] [ 13868.04] [ 13800.50] [ 13832.30]
'07-Mar-1994' [ 13851.72] [ 13882.40] [ 13824.71] [ 13856.22]
'08-Mar-1994' [ 13858.48] [ 13881.55] [ 13822.45] [ 13851.72]
'09-Mar-1994' [ 13853.97] [ 13874.52] [ 13817.95] [ 13853.41]
'10-Mar-1994' [ 13852.57] [ 13865.51] [ 13801.63] [ 13862.70]...
```

For operations with both an object and a matrix, the size of the matrix must match the size of the object. For example, a matrix to be subtracted from `myfts1` must be 20-by-4, since `myfts1` has 20 dates and four data series:

```
submtx = myfts1 - randn(20, 4)

submtx =

desc: DJI30MAR94.dat
freq: Daily (1)

'dates: (20)' 'Open: (20)' 'High: (20)' 'Low: (20)' 'Close: (20)'
'04-Mar-1994' [ 3831.33] [ 3867.75] [ 3802.10] [ 3832.63]
'07-Mar-1994' [ 3853.39] [ 3883.74] [ 3824.45] [ 3857.06]
'08-Mar-1994' [ 3858.35] [ 3880.84] [ 3823.51] [ 3851.22]
'09-Mar-1994' [ 3853.68] [ 3872.90] [ 3816.53] [ 3851.92]
'10-Mar-1994' [ 3853.72] [ 3866.20] [ 3802.44] [ 3831.17]...
```

Arithmetic Operations with Differing Data Series Names

Arithmetic operations on two objects that have the same size but contain different data series names require the function `fts2mat`. This function extracts the values in an object and puts them into a matrix or vector, whichever is appropriate.

To see an example, create another financial time series object the same size as `myfts1` but with different values and data series names:

```
newfts2 = fints(myfts1.dates, fts2mat(myfts1/10000), ...
               {'Rat1', 'Rat2', 'Rat3', 'Rat4'}, 1, 'New FTS')
```

If you attempt to add (or subtract, and so on) this new object to `myfts1`, an error indicates that the objects are not identical. Although they contain the same dates, number of dates, number of data series, and frequency, the two time series objects do not have the same data series names. Use `fts2mat` to bypass this problem:

```
addother = myfts1 + fts2mat(newfts2);
```

This operation adds the matrix that contains the contents of the data series in the object `newfts2` to `myfts1`. You should carefully consider the effects on your data before deciding to combine financial time series objects in this manner.

Other Arithmetic Operations

In addition to the basic arithmetic operations, several other mathematical functions operate directly on financial time series objects. These functions include exponential (`exp`), natural logarithm (`log`), common logarithm (`log10`), and many more. See Chapter 12, “Functions — By Category” for more details.

Data Transformation and Frequency Conversion

The data transformation and the frequency conversion functions convert a data series into a different format.

Data Transformation Functions

Function	Purpose
boxcox	Box-Cox transformation
diff	Differencing
filllts	Fill missing values
filter	Filter
lagts	Lag time series object
leadts	Lead time series object
peravg	Periodic average
smoothts	Smooth data
tsmovavg	Moving average

Frequency Conversion Functions

Function	New Frequency
convertto	As specified
resamplets	As specified
toannual	Annual
todayly	Daily
tomonthly	Monthly
toquarterly	Quarterly
tosemi	Semiannually
toweekly	Weekly

As an example look at `boxcox`, the Box-Cox transformation function. This function transforms the data series contained in a financial time series object into another set of data series with relatively normal distributions.

First create a financial time series object from the supplied `whirlpool.dat` data file.

```
whr1 = ascii2fts('whirlpool.dat', 1, 2, []);
```

Fill any missing values denoted with NaNs in `whr1` with values calculated using the linear method:

```
f_whr1 = fillts(whr1);
```

Transform the nonnormally distributed filled data series `f_whr1` into a normally distributed one using Box-Cox transformation:

```
bc_whr1 = boxcox(f_whr1);
```

Compare the result of the `Close` data series with a normal (Gaussian) probability distribution function as well as the nonnormally distributed `f_whr1`:

```
subplot(2, 1, 1);  
hist(f_whr1.Close);  
grid; title('Nonnormally Distributed Data');  
subplot(2, 1, 2);  
hist(bc_whr1.Close);  
grid; title('Box-Cox Transformed Data');
```

Box-Cox Transformation

The bar chart on the top represents the probability distribution function of the filled data series, `f_whr1`, which is the original data series `whr1` with the missing values interpolated using the linear method. The distribution is skewed towards the left (not normally distributed). The bar chart on the bottom is less skewed to the left. If you plot a Gaussian probability distribution function (PDF) with similar mean and standard deviation, the distribution of the transformed data is very close to normal (Gaussian).

When you examine the contents of the resulting object `bc_whr1`, you find an identical object to the original object `whr1` but the contents are the transformed data series. If you have the Statistics Toolbox, you can generate a Gaussian PDF with mean and standard deviation equal to those of the transformed data series and plot it as an overlay to the second bar chart. In the next figure, you can see that it is an approximately normal distribution.

Overlay of Gaussian PDF

The next example uses the `smoothts` function to smooth a time series.

To begin, transform `ibm9599.dat`, a supplied data file, into a financial time series object:

```
ibm = ascii2fts('ibm9599.dat', 1, 3, 2);
```

Fill the missing data for holidays with data interpolated using the `fillts` function and the Spline fill method:

```
f_ibm = fillts(ibm, 'Spline');
```

Smooth the filled data series using the default Box (rectangular window) method:

```
sm_ibm = smoothts(f_ibm);
```

Now, plot the original and smoothed closing price series for IBM:

```
plot(f_ibm.CLOSE('11/01/97::02/28/98'), 'r')
datetick('x', 'mmyy')
hold on
plot(sm_ibm.CLOSE('11/01/97::02/28/98'), 'b')
hold off
datetick('x', 'mmyy')
legend('Filled', 'Smoothed')
```

```
title('Filled IBM Close Price vs. Smoothed Series')
```

Smoothed Data Series

These examples give you an idea of what you can do with a financial time series object. This toolbox provides some MATLAB functions that have been overloaded to work directly with the these objects. The overloaded functions are those most commonly needed to work with time series data.

Demonstration Program

- “Loading the Data” on page 8-26
- “Create Financial Time Series Objects” on page 8-26
- “Create Closing Prices Adjustment Series” on page 8-27
- “Adjust Closing Prices and Make Them Spot Prices” on page 8-28
- “Create Return Series” on page 8-28
- “Regress Return Series Against Metric Data” on page 8-28
- “Plot the Results” on page 8-29
- “Calculate the Dividend Rate” on page 8-30

This example demonstrates a practical use of financial time series objects, predicting the return of a stock from a given set of data. The data is a series of closing stock prices, a series of dividend payments from the stock, and an explanatory series (in this case a market index). Additionally, the example calculates the dividend rate from the stock data provided.

Note You can find a script M-file for this demonstration program in the directory `matlabroot/toolbox/ftseries/ftsdemos` on your MATLAB path. The script is named `predict_ret.m`.

To perform these computations:

- 1 Load the data.
- 2 Create financial time series objects from the loaded data.
- 3 Create the series from dividend payment for adjusting the closing prices.
- 4 Adjust the closing prices and make them the spot prices.
- 5 Create the return series.
- 6 Regress the return series against the metric data (for example, a market index) using the MATLAB `\` operator.

7 Plot the results.

8 Calculate the dividend rate.

Loading the Data

The data for this demonstration is found in the MAT-file `predict_ret_data.mat`:

```
load predict_ret_data.mat
```

The MAT-file contains six vectors:

- Dates corresponding to the closing stock prices, `sdates`
- Closing stock prices, `sdata`
- Dividend dates, `divdates`
- Dividend paid, `divdata`
- Dates corresponding to the metric data, `expdates`
- Metric data, `expdata`

Use the `whos` command to see the variables in your MATLAB workspace.

Create Financial Time Series Objects

It is advantageous to work with financial time series objects rather than with the vectors now in the workspace. By using objects, you can easily keep track of the dates. Also, you can easily manipulate the data series based on dates because the object keeps track of the administration of time series for you.

Use the object constructor `fints` to construct three financial time series objects.

```
t0 = fints(sdates, sdata, {'Close'}, 'd', 'Inc');  
d0 = fints(divdates, divdata, {'Dividends'}, 'u', 'Inc');  
x0 = fints(expdates, expdata, {'Metric'}, 'w', 'Index');
```

The variables `t0`, `d0`, and `x0` are financial time series objects containing the stock closing prices, dividend payments, and the explanatory data,

respectively. To see the contents of an object, type its name at the MATLAB command prompt and press **Enter**. For example:

```
d0
d0 =
    'desc:'          'Inc'
    'freq:'          'Unknown (0)'
           ''
    'dates: (4)'     'Dividends: (4)'
    '04/15/99'      '0.2000'
    '06/30/99'      '0.3500'
    '10/02/99'      '0.2000'
    '12/30/99'      '0.1500'
```

Create Closing Prices Adjustment Series

The price of a stock is affected by the dividend payment. On the day before the dividend payment date, the stock price reflects the amount of dividend to be paid the next day. On the dividend payment date, the stock price is decreased by the amount of dividend paid. Create a time series that reflects this adjustment factor:

```
dadj1          = d0;
dadj1.dates    = dadj1.dates-1;
```

Now create the series that adjust the prices at the day of dividend payment; this is an adjustment of 0. You also need to add the previous dividend payment date since the stock price data reflect the period subsequent to that day; the previous dividend date was December 31, 1998:

```
dadj2          = d0;
dadj2.Dividends = 0;
dadj2          = fillts(dadj2,'linear','12/31/98');
dadj2('12/31/98') = 0;
```

Combining the two objects above gives the data needed to adjust the prices. However, since the stock price data is daily data and the effect of the dividend is linearly divided during the period, use the `fillts` function to make a daily time series from the adjustment data. Use the dates from the stock price data to make the dates of the adjustment the same:

```
dadj3 = [dadj1; dadj2];  
dadj3 = fillts(dadj3, 'linear', t0.dates);
```

Adjust Closing Prices and Make Them Spot Prices

The stock price recorded already reflects the dividend effect. To obtain the “correct” price, subtract the dividend amount from the closing prices. Put the result inside the same object `t0` with the data series name `Spot`.

To make sure that adjustments correspond, index into the adjustment series using the dates from the stock price series `t0`. Use the `datestr` command because `t0.dates` returns the dates in serial date format. Also, since the data series name in the adjustment series `dadj3` does not match the one in `t0`, use the function `fts2mat`:

```
t0.Spot = t0.Close - fts2mat(dadj3(datestr(t0.dates)));
```

Create Return Series

Now calculate the return series from the stock price data. A stock return is calculated by dividing the difference between the current closing price and the previous closing price by the previous closing price.

```
tret = (t0.Spot - lagts(t0.Spot, 1)) ./ lagts(t0.Spot, 1);  
tret = chfield(tret, 'Spot', 'Return');
```

Ignore any warnings you receive during this sequence. Since the operation on the first line above preserves the data series name `Spot`, it has to be changed with the `chfield` command to reflect the contents correctly.

Regress Return Series Against Metric Data

The explanatory (metric) data set is a weekly data set while the stock price data is a daily data set. The frequency needs to be the same. Use `todayly` to convert the weekly series into a daily series. The constant needs to be included here to get the constant factor from the regression:

```
x1 = todayly(x0);  
x1.Const = 1;
```

Get all the dates common to the return series calculated above and the explanatory (metric) data. Then combine the contents of the two series that have dates in common into a new time series:

```
dcommon = intersect(tret.dates, x1.dates);
regts0 = [tret(datestr(dcommon)), x1(datestr(dcommon))];
```

Remove the contents of the new time series that are not finite:

```
finite_regts0 = find(all(isfinite(fts2mat(regts0)), 2));
regts1 = regts0( finite_regts0 );
```

Now, place the data to be regressed into a matrix using the function `fts2mat`. The first column of the matrix corresponds to the values of the first data series in the object, the second column to the second data series, and so on. In this case, the first column is regressed against the second and third column:

```
DataMatrix = fts2mat(regts1);
XCoeff = DataMatrix(:, 2:3) \ DataMatrix(:, 1);
```

Using the regression coefficients, calculate the predicted return from the stock price data. Put the result into the return time series `tret` as the data series `PredReturn`:

```
RetPred = DataMatrix(:,2:3) * XCoeff;
tret.PredReturn(datestr(regts1.dates)) = RetPred;
```

Plot the Results

Plot the results in a single figure window. The top plot in the window has the actual closing stock prices and the dividend-adjusted stock prices (spot prices). The bottom plot shows the actual return of the stock and the predicted stock return through regression:

```
subplot(2, 1, 1);
plot(t0);
title('Spot and Closing Prices of Stock');
subplot(2, 1, 2);
plot(tret);
title('Actual and Predicted Return of Stock');
```

Closing Prices and Returns

Calculate the Dividend Rate

The last part of the task is to calculate the dividend rate from the stock price data. Calculate the dividend rate by dividing the dividend payments by the corresponding closing stock prices.

First check to see if you have the stock price data on all the dividend dates:

```
datestr(d0.dates, 2)
ans =

04/15/99
06/30/99
10/02/99
12/30/99
t0(datestr(d0.dates))
ans =

      'desc:'          'Inc'          ''
      'freq:'          'Daily (1)'   ''
           ''          ''          ''
```

```
'dates: (3)'      'Close: (3)'      'Spot: (3)'
'04/15/99'        '10.3369'         '10.3369'
'06/30/99'        '11.4707'         '11.4707'
'12/30/99'        '11.2244'         '11.2244'
```

Note that stock price data for October 2, 1999 does not exist. The `fillts` function can overcome this situation; `fillts` allows you to insert a date and interpolate a value for the date from the existing values in the series. There are a number of interpolation methods. See `fillts` in Chapter 12, “Functions — By Category” for details.

Use `fillts` to create a new time series containing the missing date from the original data series. Then set the frequency indicator to daily:

```
t1 = fillts(t0, 'nearest', d0.dates);
t1.freq = 'd';
```

Calculate the dividend rate:

```
tdr = d0./fts2mat(t1.Close(datestr(d0.dates)))
tdr =
```

```
'desc:'          'Inc'
'freq:'          'Unknown (0)'
      , ,
'prices: (4)'    'Dividends: (4)'
'04/15/99'      '0.0193'
'06/30/99'      '0.0305'
'10/02/99'      '0.0166'
'12/30/99'      '0.0134'
```

Financial Time Series Tool (FTSTool)

What Is the Financial Time Series Tool? (p. 9-2)	Explains the purpose of the Financial Time Series Tool (FTSTool)
Getting Started with FTSTool (p. 9-4)	Explains how to get started with FTSTool
Loading Data with FTSTool (p. 9-5)	Explains how to use FTSTool to load data
Using FTSTool for Supported Tasks (p. 9-10)	Explains tasks supported by FTSTool
Using FTSTool with Other Time Series GUIs (p. 9-18)	Explains how to use FTSTool with other Time Series GUIs

What Is the Financial Time Series Tool?

The Financial Time Series Tool (`ftstool`) provides a graphical user interface to create and manage financial time series (`fints`) objects. `ftstool` interoperates with the Financial Time Series Graphical User Interface (`ftsgui`) and Interactive Chart (`chartfts`). In addition, you can use Datafeed Toolbox or Database Toolbox to connect to external data sources.

A financial time series object minimally consists of:

- `Desc`, which is the description field.
- `Freq`, which is a frequency indicator field.
- `Dates`, which is a date vector field. If the date vector incorporates time-of-day information, the object contains an additional field named `times`.
- In addition, you can have at least one data series vector. You can specify names for any data series vectors. If you do not specify names, the object uses the default names `series1`, `series2`, `series3`, and so on.

In general, the workflow for using FTSTool is:

- 1** Acquire data.
- 2** Create a variable.
- 3** Convert the variable to `fints`.
- 4** Convert `fints` to a MATLAB double object.

To obtain the data for `ftstool`, you need to use a MATLAB double object or a financial time series (`fints`) object. You can use previously stored internal data on your computer or you can connect to external data sources using Datafeed Toolbox or Database Toolbox.

Note You must obtain a license for these products from The MathWorks before you can use either of these toolboxes.

After creating a financial time series object, you can use `ftstool` to change the characteristics of the time series object, including merging with other financial time series objects, removing rows or columns, and changing the frequency. You can also use `ftstool` to generate various forms of plotted output and you can reconvert a `fints` object to a MATLAB double-precision matrix.

Getting Started with FTSTool

To start the Financial Time Series Tool:

- 1 At the MATLAB command prompt, enter

```
ftstool
```

The Financial Time Series Tool opens.

- 2 If you plan to load data from Database Toolbox or Datafeed Toolbox, ensure you have a license. For more information on using these toolboxes, see the Database Toolbox User's Guide and Datafeed Toolbox User's Guide documentation.

Loading Data with FTSTool

- “Obtaining External Data” on page 9-5
- “Obtaining Internal Data” on page 9-7
- “Viewing the MATLAB Workspace” on page 9-8

The **Data source** pane in the Financial Time Series Tool window lets you do the following:

- Obtain live data from various external data servers using either Datafeed Toolbox or Database Toolbox.
- Load data you previously obtained and stored in a file.
- View data contained within the MATLAB workspace.

Obtaining External Data

You can obtain external data using Datafeed Toolbox or Database Toolbox. Datafeed Toolbox lets you obtain data from several financial data servers, including:

- Bloomberg
- Thomson Datastream
- FactSet
- Hyperfeed
- FT Interactive Data
- Kx Systems kdb+ database
- Haver Analytics financial data
- Federal Reserve Economic Data
- Yahoo!

Except for Federal Reserve Economic Data and Yahoo!, these data servers require that you obtain a license from the vendor before you can access their data.

Note If you open Datafeed Toolbox or Database Toolbox before starting FTSTool, FTSTool is unable to recognize the toolboxes. When working with FTSTool, select **File > Load** to open these toolboxes.

Obtaining Data with Datafeed Toolbox

To obtain external data with Datafeed Toolbox:

- 1 From the Financial Time Series Tool window, select **File > Load > Datafeed Toolbox** to open the toolbox.
- 2 Click the **Connection** tab in Datafeed Toolbox to select the data source you want to load into FTSTool.
- 3 Click the **Data** tab in Datafeed Toolbox to select the security and the associated data that you want to load into FTSTool.
- 4 After using Datafeed Toolbox to define the connection, security, data, and **MATLAB variable** name, click **Get Data** and then, using FTSTool, click **Refresh variable list**. The **Data source** field in FTSTool displays the name of the security you selected from the **Data** tab in Datafeed Toolbox. The FTSTool **Active variable** field indicates the name of the MATLAB workspace variable you chose for this security.
- 5 Click **Close** to exit Datafeed Toolbox. FTSTool clears the **Data source** and **Active variable** fields.

Obtaining Data with Database Toolbox

To obtain external data with Database Toolbox:

- 1 From the Financial Time Series Tool window, select **File > Load > Database Toolbox** to open the toolbox.
- 2 From the Visual Query Builder window, select the data you want to load into FTSTool.

- 3** After using Database Toolbox to select data and name the **MATLAB workspace variable**, click **Execute** and then, using FTSTool, click **Refresh variable list**. The **Data source** field in FTSTool displays the name of the highlighted data source that you selected from the **Data** list box in the Visual Query Builder window. The FTSTool **Active variable** field indicates the name of the MATLAB workspace variable you chose for the security in the Visual Query Builder window.
- 4** From Database Toolbox, select **Query > Close Visual Query Builder**, FTSTool clears the **Data source** and **Active variable** fields.

Obtaining Internal Data

You can use FTSTool to load data from files previously stored on your computer. The types of data files you can load are as follows:

- MATLAB `.mat` files
- ASCII text files (`.dat` or `.txt` suffixes)
- Excel `.xls` files

To obtain internal data:

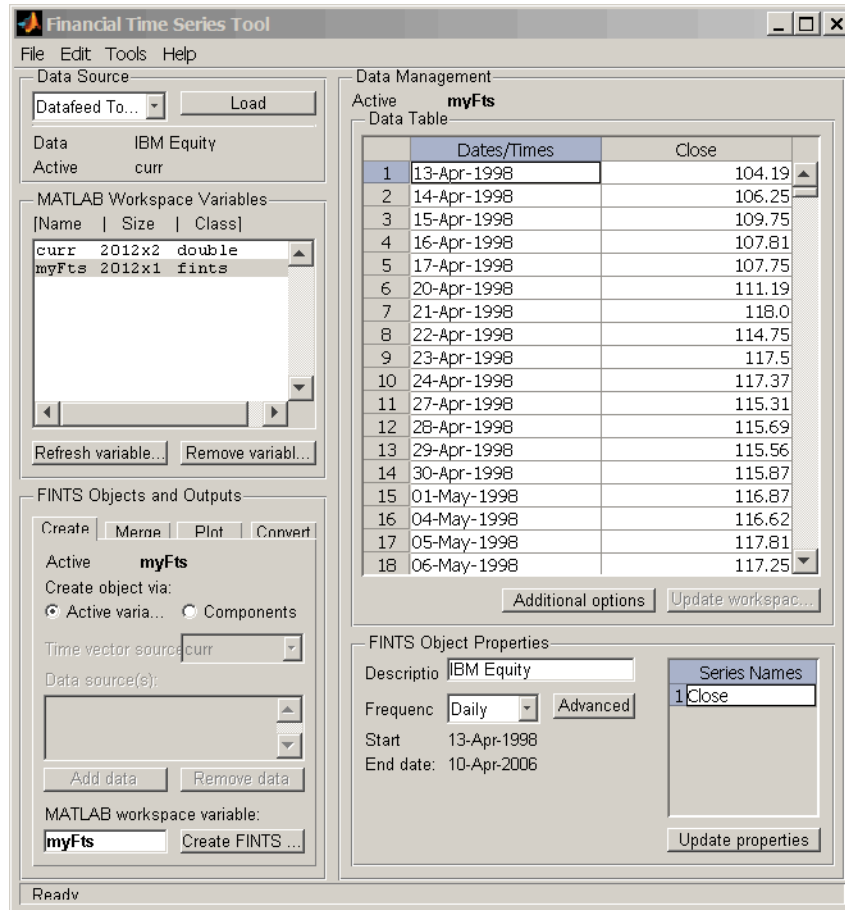

- 1** From the Financial Time Series Tool window, select **File > Load > File** to open the Load a MAT, ASCII, .XLS File dialog box.
- 2** Select the data you want to load into FTSTool.
 - If you load a MATLAB MAT-file, the variables in the file are placed into the MATLAB workspace. The **MATLAB Workspace Variables** list box shows the variables that have been added to the workspace. For example, if you load the file `disney.mat`, which is distributed with the toolbox, the **MATLAB Workspace Variables** list box displays the variables in that MAT-file.

Note FTSTool automatically generates a line plot for each workspace variables unless you disable this feature by resetting the default action under **File > Preferences > Generate line plot on load**.

- If you load a .dat or an ASCII .txt file, the ASCII File Parameters dialog box opens. Use this dialog box to transform a text data file into a MATLAB financial time series `fints` object. (See the reference page for `ascii2fts` for further explanation of the fields in the ASCII File Parameters dialog box.
 - If you load an Excel .xls file, the Excel File Parameters dialog box opens. Use this dialog box to transform Excel worksheet data into a MATLAB financial time series (`fints`) object.
- 3** From the Financial Time Series Tool window, select **File > Save** to save the data you gave loaded from an internal file.

Viewing the MATLAB Workspace

The **MATLAB Workspace Variables** list box displays all existing MATLAB workspace variables. Double-click any variable to display the data in the **Data Table**. You can only display financial time series (`fints`) objects, MATLAB doubles, and cell arrays of double data in the **Data Table**.

In addition, you can click **Refresh variable list** to refresh the **MATLAB Workspace Variables** list box. You need to refresh this list periodically because it is refreshed automatically only for operations performed with FTSTool, not for operations performed within MATLAB itself.

Click **Remove variable(s)** to remove variable from the **MATLAB Workspace Variables** list and from the MATLAB workspace.

Using FTSTool for Supported Tasks

- “Creating a Financial Time Series Object” on page 9-10
- “Merging Financial Time Series Objects” on page 9-11
- “Converting a Financial Time Series Object to a MATLAB Double-Precision Matrix” on page 9-12
- “Plotting the Output in Several Formats” on page 9-12
- “Viewing Data for a Financial Time Series Object in the Data Table” on page 9-13
- “Modifying Data for a Financial Time Series Object in the Data Table” on page 9-14
- “Viewing and Modifying the Properties for a FINTS Object” on page 9-16

Creating a Financial Time Series Object

Using the **Create** tab in the **FINTS Objects and Outputs** pane for FTSTool, you can create a financial time series (`fints`) object from one or more selected variables.

Note When you first start FTSTool, the **Create** tab appears on top, unless you reset the default using **File > Preferences > Show Create tab when ftstool starts**.

To create a financial time series (`fints`) object from one or more selected variables:

- 1 Load data into FTSTool from either an external data source using Datafeed Toolbox or Database Toolbox or an internal data source using **File > Load > File**.
- 2 Select one or more variables from the **MATLAB Workspace Variables** list.
- 3 Click the **Create** tab and then click **Active variable**.

When combining multiple variables, you can type a new variable name for the combined variables in the **MATLAB workspace variable** box. The new variable name is added to the **MATLAB Workspace Variables** list. (If you do not choose a name for the **MATLAB workspace variable**, FTSTool uses the default name myFts.)

4 Click **Create FINTS object** to display the result in the **Data Table**.

Merging Financial Time Series Objects

Using the **Create** tab in the **FINTS Objects and Outputs** pane for FTSTool, you can create a new financial time series object by merging (joining) multiple existing financial time series objects.

Note When you first start FTSTool, the **Create** tab appears on top, unless you reset the default using **File > Preferences**.

To create a financial time series (fints) object by merging two or more existing financial time series objects:

- 1** Load data into FTSTool from either an external data source using Datafeed Toolbox or Database Toolbox or an internal data source using **File > Load > File**.
- 2** To merge two or more existing financial time series objects, click the **Create** tab, click **Components**, and then select a value for the **Time vector source** and one or more items from the **Data sources** list.

Note You can merge at once multiple financial time series objects. For more information on merging fints objects, see merge.

3 Click **Create FINTS object** to display the result in the **Data Table**.

Converting a Financial Time Series Object to a MATLAB Double-Precision Matrix

Using the **Convert** tab in the **FINTS Objects and Outputs** pane for FTSTool, you can convert a financial time series (`fints`) object to a MATLAB double-precision matrix.

To create a financial time series object from one or more selected variables:

- 1 Load data into FTSTool from either an external data source using Datafeed Toolbox or Database Toolbox or an internal data source using **File > Load > File**.
- 2 Select a variable from the **MATLAB Workspace Variables** list box.
- 3 Click the **Convert** tab and then determine whether to include or exclude dates in the conversion by clicking **Include dates** or **Exclude dates**.
- 4 Type a variable name in the **Output variable name** box. (If you do not choose a variable name, FTSTool uses the default name `myDb1`.)
- 5 Click **Convert FINTS to double matrix**. (This operation is equivalent to performing `fts2mat` on a financial time series object.)

Plotting the Output in Several Formats

Using the **Plot** tab in the **FINTS Objects and Outputs** pane for FTSTool, you can create several forms of plotted output by using a selection list. You can create four types of bar charts, candle plots, high-low plots, line plots, and interactive charts (the latter is created by using the interoperation of FTSTool with the function `chartfts`).

The set of plots supported by FTSTool are identical to the set provided by the **Graphs** menu of the Financial Time Series GUI. (See “Graphs Menu” on page 10-15.) You can find more detailed information for the supported plots by consulting the reference page for each individual type of plot.

To create a plotted output:

- 1 Load data into FTSTool from either an external data source using Datafeed Toolbox or Database Toolbox or an internal data source using **File > Load > File**.
- 2 Select a variable from the **MATLAB Workspace Variables** list box or select data from the **Data Table**.
- 3 Click the **Plot** tab and indicate whether you are plotting based on a workspace variable or data from the **Data Table**.
- 4 From the **Type** drop-down list, select the type of plot.
- 5 Click **Plot**. The plot is displayed.

Note If the selected workspace variable that you are plotting is not a `fints` object, a `fints` object is created when you click **Plot**. The new `fints` object uses the name designated by the **MATLAB workspace variable** box on the **Create** tab.

Viewing Data for a Financial Time Series Object in the Data Table

Once a financial time series (`fints`) object is created, the FTSTool **Data Table** displays user-designated data, including financial time series objects, MATLAB double-precision variables, and cell arrays of doubles. (Cell arrays of doubles is often the resulting format when using Database Toolbox.)

When displaying double variables (or a cell array of doubles) in the **Data Table**, the column headings for a double variable or cell array of doubles displayed in the **Data Table** are labeled **A**, **B**, **C**, and so on.

Overwriting Data in the Data Table Display

If you use the command line to overwrite data previously retrieved using Datafeed Toolbox or Database Toolbox, two events could occur:

- If the new data contains the same number of columns as before, the headers remain unchanged when you attempt to create a financial time series (`fints`) object using the modified data.

- If the data contains a different number of columns, a warning dialog box appears.

For example, assume that you use Datafeed Toolbox to obtain Close, High, Low, and Volume data for the equity GlaxoSmithkline. You store the data in the MATLAB workspace with the variable name `glaxo`. From the command line, if you redefine the variable `glaxo`, eliminating the second column (Close)

```
glaxo(:,2) = [ ]
```

and then return to FTSTool and attempt to create a financial time series object, a warning dialog box appears.

Modifying Data for a Financial Time Series Object in the Data Table

FTSTool lets you update your data displayed in the **Data Table** by adding or removing rows or columns.

Note Modifying data in the **Data Table** will not update the MATLAB workspace variable. To update the workspace variable after modifying the **Data Table**, click **Update workspace variable**.

Adding and Removing Rows

To add a row of data displayed in the **Data Table**:

- 1 Select a row from the **Data Table** display where you want to add a row. Click **Additional options** to open the Data Table Options dialog box.
- 2 Click **Add row**. The default is to add the row up. To add a row down, select **Insertion option** and then click **Add down**. In addition, you can select the **Insertion option of Date** to designate a specific date. (If a date is not specified, the added row will contain a date that is chronologically in order with respect to the initial row.)

When you add rows, the **Data Table** display is immediately updated.

To remove a row of data from the **Data Table**:

- 1 Select one or more rows in the **Data Table** display that you want to remove. Click **Additional options** to open the Data Table Options dialog box.
- 2 Click **Remove row(s)**. The default is to remove the selected rows. In addition, to remove selected rows, select **Removal options** and then select other options for row removal from the **Remove rows** list box. You can specify a **Start** and **End** date or you can click the **Non-uniform range setting** option to designate a range.

When you remove rows, the **Data Table** display is updated immediately.

Adding and Removing Columns

To add a column of data displayed in the **Data Table**:

- 1 Select a column from the **Data Table** display where you want to add a column. Click **Additional options** to open the Data Table Options dialog box.

- 2 Click **Add column**. The default is to add the column to the left of the selected column.

Note For time series objects, you cannot add a column to the left of the Date/Times column; there is no restriction for double data.

To add a column to the right, select **Insertion option** and then click **Add right**. In addition, you can use the **Insertion option** of **New Column Name** to designate a specific column name. (If a **New Column Name** is not specified, an added column will contain a column name of series1, series2, and so on.)

When you add columns, the **Data Table** display is updated immediately.

To remove a column of data displayed in the **Data Table**:

- 1 Select one or more columns in the **Data Table** display that you want to remove. Click **Additional options** to open the Data Table Options dialog box.
- 2 Click **Remove column(s)**. The default is to remove the selected rows. In addition, to remove selected columns, select **Removal options** and then select columns for removal from the **Remove columns** list box.

When you remove columns, the **Data Table** display is updated immediately.

Viewing and Modifying the Properties for a FINTS Object

The **FINTS Object Properties** pane in FTSTool lets you modify financial time series (fints) object properties. This area becomes active whenever the **Data Table** displays a financial time series object.

To modify the properties for a fints object:

- 1 After you create a fints object, double-click the object name in the **MATLAB Workspace Variables** list box to open the **Data Table** and display the fints object properties.

- 2 Click to modify the **Description**, **Frequency**, or **Series Names** fields.

The Frequency drop-down list supports the following conversion functions:

Function	New Frequency
toannual	Annual
todayly	Daily
tomonthly	Monthly
toquarterly	Quarterly
tosemi	Semiannually
toweekly	Weekly

- 3 Click **Update properties** to save the changes. This action also updates the associated workspace variable.

Using FTSTool with Other Time Series GUIs

FTSTool works with Datafeed Toolbox and Database Toolbox to load data. In addition, FTSTool interoperates with `chartfts` to display an interactive plot and `ftsgui` to perform further time series data analysis.

The workflow for using FTSTool with `chartfts` is:

- 1 After loading data from either Datafeed Toolbox or Database Toolbox or an internal file, select a variable from the **MATLAB Workspace Variables** list box.
- 2 Click the **Plot** tab, click **Type**, and then select **Interactive Chart**.
- 3 Click **Plot**. The interactive plot is displayed in `chartfts`. You can then use `chartfts` menu items for further display options.

For more information on `chartfts`, select **Help > Graphics Help**.

The workflow for using FTSTool with the Financial Time Series GUI (`ftsgui`) is:

- 1 After loading data from either Datafeed Toolbox or Database Toolbox or an internal file, select a variable from the **MATLAB Workspace Variables** list box.
- 2 Select **Tools > FTSGUI** to open the Financial Time Series GUI window.
- 3 Select a variable from the **MATLAB Workspace Variables** list box. Click the **Plot** tab and then select one of the following from the **Type** drop-down list: Line Plot, High-Low Plot, or Candlestick Plot.
- 4 Click **Plot**. The plot is displayed in a MATLAB graphic window. In addition, the Financial Time Series GUI window displays an entry for the plotted `fints` object. You can then use the menu items in the Financial Time Series GUI window to perform further analysis.

For more information on `ftsgui`, select **Help > Help on Financial Time Series GUI**.

Note If the selected workspace variable that you are plotting is not a `fints` object, a `fints` object is created when you click **Plot**. The new `fints` object uses the name designated by the **MATLAB workspace variable** box on the **Create** tab.

Financial Time Series Graphical User Interface

Introduction (p. 10-2)

Using the Financial Time Series
GUI (p. 10-7)

Menus available on the main window
of the financial time series GUI

A more in-depth exploration of the
capabilities of the financial time
series GUI

Introduction

Use the financial time series graphical user interface (GUI) to analyze your time series data and display the results graphically without resorting to the command line. The GUI lets you visualize the data and the results at the same time.

“Using the Financial Time Series GUI” on page 10-7 discusses how to use this GUI.

Main Window

Start the financial time series GUI with the command

```
ftsgui
```

The main financial time series GUI window appears.

The title bar acts as an active time series object indicator (indicates the currently active financial time series object). For example, if you load the file `disney.mat` and want to use the time series data in the file `dis`, the title bar on the main GUI would read as shown.

The menu bar consists of six menu items: **File**, **Data**, **Analysis**, **Graphs**, **Window**, and **Help**. Under the menu bar is a status box that displays the steps you are doing.

File Menu

The **File** menu contains the commands for input and output. You can read and save (**Load**, **Save**, and **Save As**) MATLAB MAT-files, ASCII (text) data files, as well as import (**Import**) Microsoft Excel XLS files. MATLAB does not support the export of XLS files at this time.

The **File** menu also contains the printing suite (**Page Setup**, **Print Preview**, and **Print**). Lastly, from this menu you can close the GUI itself (**Close FTS GUI**) and quit MATLAB (**Exit MATLAB**).

Data Menu

The **Data** menu provides a collection of data manipulation functions and data conversion functions.

To use any of the functions here, make sure that the correct financial time series object is displayed in the title bar of the main GUI window.

Analysis Menu

The **Analysis** menu provides

- A set of exponentiation and logarithmic functions.
- Statistical tools (**Basic Statistics**), which calculate and display the minimum, maximum, average (mean), standard deviation, and variance of the current (active) time series object; these basic statistics numbers are displayed in a dialog window.
- Data difference (**Difference**) and periodic average (**Periodic Average**) calculations. Data difference generates a vector of data that is the difference between the first data point and the second, the second and the third, and so on. The periodic average function calculates the average per defined length period, for example, averages of every five days.
- Technical analysis functions. See Chapter 11, “Technical Analysis” for a list of the provided technical analysis functions.

As with the **Data** menu, to use any of the **Analysis** menu functions, make sure that the correct financial time series object is displayed in the title bar of the main GUI window.

Graphs Menu

The **Graphs** menu contains functions that graphically display the current (active) financial time series object. You can also invoke the interactive charting function (`chartfts`) from this menu.

Window Menu

The **Window** menu lists open windows under the current MATLAB session.

Help Menu

The **Help** menu provides a standard set of Help menu links.

Using the Financial Time Series GUI

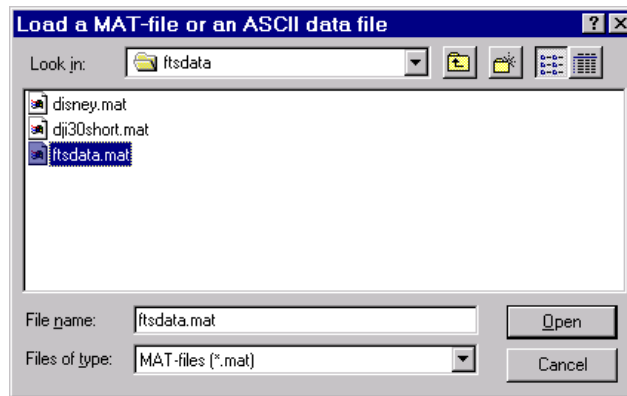

- “Getting Started” on page 10-7
- “Data Menu” on page 10-9
- “Analysis Menu” on page 10-13
- “Graphs Menu” on page 10-15
- “Saving Time Series Data” on page 10-19

Getting Started

To use the Financial Time Series GUI, first start the financial time series GUI with the command `ftsgui`. Then load (or import) the time series data.

For example, if your data is in a MATLAB MAT-file, select **Load** from the **File** menu.

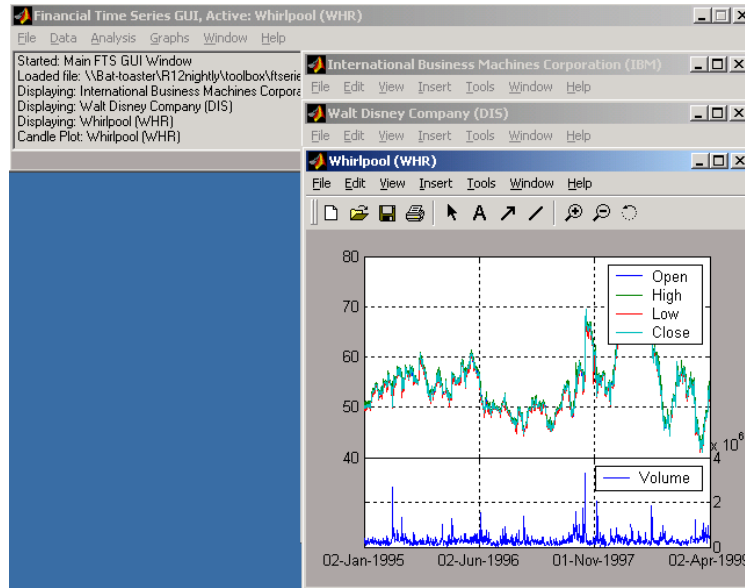

For illustration purposes, choose the file `ftsddata.mat` from the dialog presented.

If you don't see the MAT-file, look in the directory `matlabroot\toolbox\finance\findemos`, where `matlabroot` is the MATLAB root directory (the directory where MATLAB is installed).

Note Data loaded through the Financial Time Series GUI is not available in the MATLAB workspace. You can access this data only through the GUI itself, not with any MATLAB command-line functions.

Each financial time series object inside the MAT-file is presented as a line plot in a separate window. The status window is updated accordingly.

Whirlpool (WHR) is the last plot displayed, as indicated on the title bar of the main window.

Data Menu

The **Data** menu provides functions that manipulate time series data.

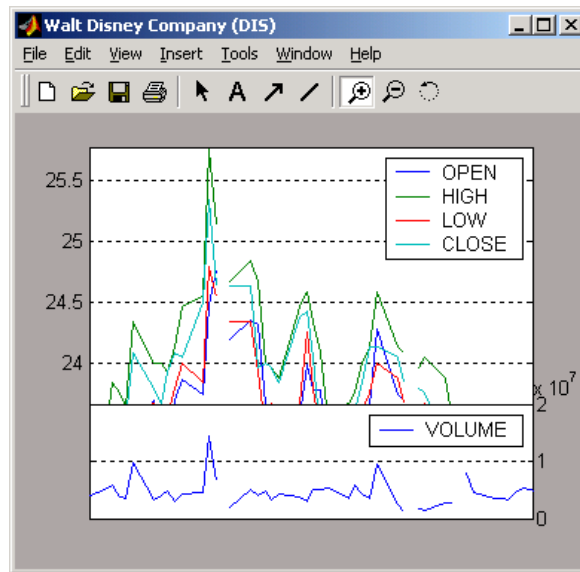

Here are some example tasks that illustrate the use of the functions on this menu.

Fill Missing Data

First, look at filling missing data. The **Fill Missing Data** item uses the toolbox function `fillts`. With the data loaded from the file `ftsdata`, you have three time series: IBM Corp. (IBM), Walt Disney Co. (DIS), and Whirlpool Co. (DIS).

To view any missing data in this time series data set, zoom into the plot using the Zoom tool (the magnifying glass icon with the plus sign) from the toolbar and select a region.

The gaps represent the missing data in the series. To fill these gaps, select **Data > Fill Missing Data**. This selection automatically fills the gaps and generates a new plot that displays the filled time series data.

You cannot see the filled gaps when you display the entire data set. However, when you zoom into the plot, you see that the gaps have been eliminated. Note that the title bar has changed; the title has been prefixed with the word **Filled** to reflect the filled time series data.

Frequency Conversion

The **Data** menu also provides access to frequency conversion functions.

This example changes the DIS time series data frequency from daily to monthly. Close the Filled Walt Disney Company (DIS) window, and click the Walt Disney Company (DIS) window to make it active (current) again. Then, from the **Data** menu, select **Convert Data Frequency To** and **To Monthly**.

Active variable: telephone

Data Table Show data

Dates/Ti...	Close	High	Low	Open	Volume
1 31-Jan-20	22.875	23.16399...	20.719	21.30600...	8848257.0
2 28-Feb-20	18.4	18.935	17.3975	18.0475	5077970.0
3 31-Mar-20	17.215	17.655	16.3475	16.82249...	4722830.0
4 30-Apr-20	15.07500...	16.00999...	13.915	14.94250...	9589337.5
5 30-May-20	17.33000...	18.398	16.855	18.028	8308132.0
6 30-Jun-20	20.20999...	20.9025	19.2425	20.0075	5226625.0
7 31-Jul-2003	19.6	19.83	19.02	19.25	3797700.0

Remove rows: via row #'s via dates Remove columns: via column #'s via series names

Start: Columns:

A new figure window displays the result of this conversion.

The title reflects that the data displayed had its frequency changed to monthly.

Analysis Menu

The **Analysis** menu provides functions that analyze time series data, including the technical analysis functions. (See Chapter 11, “Technical Analysis” for a complete list of the technical analysis functions and several usage examples.)

For example, you can use the **Analysis** menu to calculate the natural logarithm (\log) of the data contained within the data set `ftsdata.mat`. This data file provides time series data for IBM (IBM), Walt Disney (DIS), and Whirlpool (WHR). Click the window displaying the data for IBM Corporation (IBM) to make it active (current). Then select the **Analysis** menu, followed by **Log(...)**. The result appears in its own window.

Close the above window and click again on the IBM data window to make it active (current).

Note Before proceeding with any time series analysis, make certain that the title bar confirms that the active data series is the correct one.

From the **Analysis** menu on the main window, select **Technical Analysis** and **MACD**. The result, again, is displayed in its own window.

Other analysis functions work similarly.

Graphs Menu

The **Graphs** menu displays time series data using the provided graphics functions. Included in the **Graphs** menu are several types of bar charts (`bar`, `barh` and `bar3`, `bar3h`), line plot (`plot`), candle plot (`candle`), and High-Low plot (`highlow`). The **Graphs** menu also provides access to the interactive charting function, `chartfts`.

Candle Plot

For example, you can display the candle plot of a set of time series data and invoke the interactive chart on the same data set.

Load the `ftsdata.mat` data set, and click the window that displays the Whirlpool (WHR) time series data to make it active (current). From the main window, select the **Graphs** menu and then **Candle Plot**.

The result is shown below.

This does not look much like a candle plot because there are too many data points in the data set. All the candles are too compressed for effective

viewing. However, when you zoom into a region of this plot, the candles become apparent.

Interactive Chart

To create an interactive chart (chartfts) on the Whirlpool data, click the window that displays the Whirlpool (WHR) data to make it active (current). Then, go to the **Graphs** menu and select **Interactive Chart**.

The chart that results is shown below.

You can use this interactive chart as if you had invoked it with the `chartfts` command from the MATLAB command line. For a tutorial on the use of `chartfts`, see “Visualizing Financial Time Series Objects” on page 7-18.

Saving Time Series Data

The **Save** and **Save As** items on the main window **File** menu let you save the time series data that results from your analyses and computations. These items save *all* time series data that has been loaded or processed during the current session, even if the window displaying the results of a computation has previously been dismissed.

Note The **Save** and **Save As** items on the **File** menu of individual plot windows are not available for use.

You can save your time series data in two ways:

- Into the latest MAT-file loaded (**Save**)
- Into a MAT-file chosen (or named) from the window (**Save As**)

To illustrate this, start by loading the data file `testftstdata.mat` (located in `matlabroot/toolbox/finance/findemos`). Then, convert the Disney (DIS) data from daily (the original frequency) to monthly data. Next, run the MACD analysis on the Whirlpool (WHR) data. You now have a set of five open figure windows.

Saving into the Original File (Save)

To save the data back into the original file (`testftstdata.mat`), select **Save** from the **File** menu.

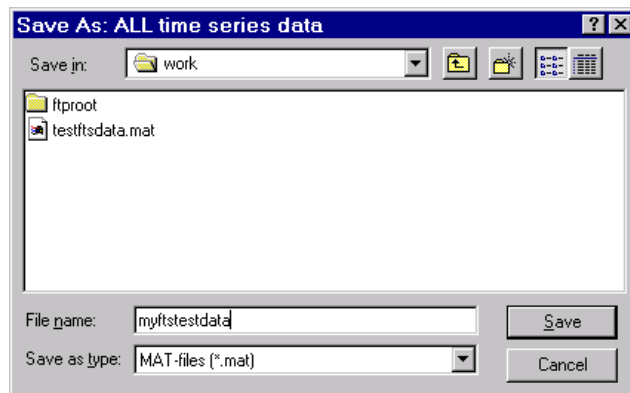

A confirmation window appears. It confirms that the data has been saved in the latest MAT-file loaded (`testftstdata.mat` in this example).

Saving into a New File (Save As)

To save the data in a different file, choose **Save As** from the **File** menu.

The dialog box that appears lets you choose an existing MAT-file from a list or type in the name of a new MAT-file you want to create.

After you click the **Save** button, another confirmation window appears.

This confirmation window indicates that the data has been saved in a new file named `myftstestdata.mat`.

Technical Analysis

Introduction (p. 11-2)

Examples (p. 11-4)

Tables of technical analysis functions
listed by category

Examples showing the use of several
technical analysis functions

Introduction

Technical analysis (or charting) is used by some investment managers to help manage portfolios. Technical analysis relies heavily on the availability of historical data. Investment managers calculate different indicators from available data and plot them as charts. Observations of price, direction, and volume on the charts assist managers in making decisions on their investment portfolios.

The technical analysis functions in this toolbox are tools to help analyze your investments. The functions in themselves will not make any suggestions or perform any qualitative analysis of your investment.

Technical Analysis: Oscillators

Function	Type
adosc	Accumulation/distribution oscillator
chaikosc	Chaikin oscillator
macd	Moving Average Convergence/Divergence
stochosc	Stochastic oscillator
tsaccel	Acceleration
tsmom	Momentum

Technical Analysis: Stochastics

Function	Type
chaikvolat	Chaikin volatility
fpctkd	Fast stochastics

Technical Analysis: Stochastics (Continued)

Function	Type
spctkd	Slow stochastics
willpctr	Williams %R

Technical Analysis: Indexes

Function	Type
negvolidx	Negative volume index
posvolidx	Positive volume index
rsindex	Relative strength index

Technical Analysis: Indicators

Function	Type
adline	Accumulation/distribution line
bollinger	Bollinger band
hhigh	Highest high
llow	Lowest low
medprice	Median price
onbalvol	On balance volume
prcroc	Price rate of change
pvtrend	Price-volume trend
typprice	Typical price
volroc	Volume rate of change
wclose	Weighted close
willad	Williams accumulation/distribution

Examples

The section provides examples for several types of technical analysis:

- “Moving Average Convergence/Divergence (MACD)” on page 11-4
- “Williams %R” on page 11-6
- “Relative Strength Index (RSI)” on page 11-7
- “On-Balance Volume (OBV)” on page 11-8

To illustrate some of the technical analysis functions, this section uses the IBM stock price data contained in the supplied file `ibm9599.dat`. First create a financial time series object from the data using `ascii2fts`:

```
ibm = ascii2fts('ibm9599.dat', 1, 3, 2);
```

The time series data contains the open, close, high, and low prices, as well as the volume traded on each day. The time series dates start on January 3, 1995, and end on April 1, 1999, with some values missing for weekday holidays; weekend dates are not included.

Moving Average Convergence/Divergence (MACD)

Moving Average Convergence/Divergence (MACD) is an oscillator function used by technical analysts to spot overbought and oversold conditions. Look at the portion of the time series covering the 3-month period between October 1, 1995 and December 31, 1995. At the same time fill any missing values due to holidays within the time period specified:

```
part_ibm = fillts(ibm('10/01/95::12/31/95'));
```

Now calculate the MACD, which when plotted produces two lines; the first line is the MACD line itself and the second is the nine-period moving average line:

```
macd_ibm = macd(part_ibm);
```

Note When you call `macd` without giving it a second input argument to specify a particular data series name, it searches for a closing price series named `Close` (in all combinations of letter cases).

Plot the MACD lines and the High-Low plot of the IBM stock prices in two separate plots in one window.

```
subplot(2, 1, 1);  
plot(macd_ibm);  
title('MACD of IBM Close Stock Prices, 10/01/95-12/31/95');  
datetick('x', 'mm/dd/yy');  
subplot(2, 1, 2);  
highlow(part_ibm);  
title('IBM Stock Prices, 10/01/95-12/31/95');  
datetick('x', 'mm/dd/yy')
```

The following figure shows the result.

Williams %R

Williams %R is an indicator that measures overbought and oversold levels. The function `willpctr` is from the `stochastics` category. All the technical analysis functions can accept a different name for a required data series. If, for example, a function needs the high, low, and closing price series but your time series object does not have the data series names exactly as `High`, `Low`, and `Close`, you can specify the correct names as follows.

```
wpr = willpctr(tsobj, 14, 'HighName', 'Hi', 'LowName', 'Lo', ...
  'CloseName', 'Closing')
```

The function `willpctr` now assumes that your high price series is named `Hi`, low price series is named `Lo`, and closing price series is named `Closing`.

Since the time series object `part_ibm` has its data series names identical to the required names, name adjustments are not needed. The input argument to the function is only the name of the time series object itself.

Calculate and plot the Williams %R indicator for IBM along with the price range using these commands:

```
wpctr_ibm = willpctr(part_ibm);
subplot(2, 1, 1);
plot(wpctr_ibm);
title('Williams %R of IBM stock, 10/01/95-12/31/95');
datetick('x', 'mm/dd/yy');
hold on;
plot(wpctr_ibm.dates, -80*ones(1, length(wpctr_ibm)), ...
  'color', [0.5 0 0], 'linewidth', 2)
plot(wpctr_ibm.dates, -20*ones(1, length(wpctr_ibm)), ...
  'color', [0 0.5 0], 'linewidth', 2)
subplot(2, 1, 2);
highlow(part_ibm);
title('IBM Stock Prices, 10/01/95-12/31/95');
datetick('x', 'mm/dd/yy');
```

The next figure shows the results. The top plot has the Williams %R line plus two lines at -20% and -80%. The bottom plot is the High-Low plot of the IBM stock price for the corresponding time period.

Relative Strength Index (RSI)

The Relative Strength Index (RSI) is a momentum indicator that measures an equity's price relative to itself and its past performance. The function name is `rsindex`.

The `rsindex` function needs a series that contains the closing price of a stock. The default period length for the RSI calculation is 14 periods. This length can be changed by providing a second input argument to the function. Similar to the previous commands, if your closing price series is not named `Close`, you can provide the correct name.

Calculate and plot the RSI for IBM along with the price range using these commands:

```
rsi_ibm = rsindex(part_ibm);
subplot(2, 1, 1);
plot(rsi_ibm);
title('RSI of IBM stock, 10/01/95-12/31/95');
```

```

datetick('x', 'mm/dd/yy');
hold on;
plot(rsi_ibm.dates, 30*ones(1, length(wpctr_ibm)),...
'color', [0.5 0 0], 'linewidth', 2)
plot(rsi_ibm.dates, 70*ones(1, length(wpctr_ibm)),...
'color', [0 0.5 0], 'linewidth', 2)
subplot(2, 1, 2);
highlow(part_ibm);
title('IBM Stock Prices, 10/01/95-12/31/95');
datetick('x', 'mm/dd/yy');

```

The next figure shows the result.

On-Balance Volume (OBV)

On-Balance Volume (OBV) relates volume to price change. The function `onbalvol` requires you to have the closing price (`Close`) series as well as the volume traded (`Volume`) series.

Calculate and plot the OBV for IBM along with the price range using these commands:

```
obv_ibm = onbalvol(part_ibm);
subplot(2, 1, 1);
plot(obv_ibm);
title('On-Balance Volume of IBM Stock, 10/01/95-12/31/95');
datetick('x', 'mm/dd/yy');
subplot(2, 1, 2);
highlow(part_ibm);
title('IBM Stock Prices, 10/01/95-12/31/95');
datetick('x', 'mm/dd/yy');
```

The next figure shows the result.

Functions — By Category

Handling and Converting Dates (p. 12-2)	Work with dates
Formatting Currency and Price (p. 12-6)	Work with currency and price data
Charting Financial Data (p. 12-6)	Create charts
Analyzing and Computing Cash Flows (p. 12-7)	Work with cash flows
Fixed-Income Securities (p. 12-9)	Work with fixed-income securities
Analyzing Portfolios (p. 12-11)	Analyze and measure performance for portfolios
Financial Statistics (p. 12-14)	Perform statistical analysis of financial data
Pricing and Analyzing Derivatives (p. 12-16)	Price and analyze derivatives
GARCH Processes (p. 12-17)	Introduce GARCH analysis
Financial Time Series Object and File Construction (p. 12-18)	Functions for creating financial time series
Financial Time Series Arithmetic (p. 12-18)	Arithmetic in financial time series
Financial Time Series Mathematical (p. 12-19)	Mathematical calculations in financial time series
Financial Time Series Utility (p. 12-19)	Utility work with financial time series

Financial Time Series Data Transformation (p. 12-20)	Data transformations of financial time series
Financial Time Series Indicator (p. 12-21)	Work with indicators for financial time series
Financial Time Series Graphical User Interface (p. 12-22)	Work with Financial Time series GUI

Handling and Converting Dates

Current Time and Date (p. 12-2)	Work with current date and time
Date and Time Components (p. 12-2)	Compute dates and times
Date Conversion (p. 12-3)	Convert dates
Financial Dates (p. 12-4)	Compute financial dates
Coupon Bond Dates (p. 12-5)	Compute coupon bond dates

Current Time and Date

now	Current date and time
today	Current date

Date and Time Components

datefind	Indices of date numbers in matrix
datevec	Date components
day	Day of month
eomdate	Last date of month
eomday	Last day of month
hour	Hour of date or time

<code>lweekdate</code>	Date of last occurrence of weekday in month
<code>minute</code>	Minute of date or time
<code>month</code>	Month of date
<code>months</code>	Number of whole months between dates
<code>nweekdate</code>	Date of specific occurrence of weekday in month
<code>second</code>	Seconds of date or time
<code>weekday</code>	Day of week
<code>year</code>	Year of date
<code>yeardays</code>	Number of days in year

Date Conversion

<code>date2time</code>	Time and frequency from dates
<code>datedisp</code>	Display date entries
<code>datenum</code>	Create date number
<code>datestr</code>	Create date string
<code>dec2thirtytwo</code>	Decimal to thirty-second quotation
<code>m2xdate</code>	MATLAB serial date number to Excel serial date number
<code>thirtytwo2dec</code>	Thirty-second quotation to decimal
<code>time2date</code>	Dates from time and frequency
<code>x2mdate</code>	Excel serial date number to MATLAB serial date number

Financial Dates

busdate	Next or previous business day
busdays	Business days in serial date format
datemnth	Date of day in future or past month
datewrkdy	Date of future or past workday
days360	Days between dates based on 360-day year
days360e	Days between dates based on 360-day year (European)
days360isda	Days between dates based on 360-day year (International Swap Dealer Association (ISDA) compliant)
days360psa	Days between dates based on 360-day year (Public Securities Association (PSA) compliant)
days365	Days between dates based on 365-day year
daysact	Actual number of days between dates
daysadd	Date away from starting date for any day-count basis
daysdif	Days between dates for any day-count basis
fbusdate	First business date of month
holidays	Holidays and nontrading days
isbusday	True for dates that are business days
lbusdate	Last business date of month
thirdwednesday	Find third Wednesday of month

wrkdydif	Number of working days between dates
yearfrac	Fraction of year between dates

Coupon Bond Dates

accfrac	Fraction of coupon period before settlement
cfamounts	Cash flow and time mapping for bond portfolio
cfdates	Cash flow dates for fixed-income security
cfport	Portfolio form of cash flow amounts
cftimes	Time factors corresponding to bond cash flow dates
cpncount	Coupon payments remaining until maturity
cpndaten	Next coupon date for fixed-income security
cpndatenq	Next quasi coupon date for fixed income security
cpndatep	Previous coupon date for fixed-income security
cpndatepq	Previous quasi coupon date for fixed income security
cpndaysn	Number of days to next coupon date
cpndaysp	Number of days since previous coupon date
cpnpersz	Number of days in coupon period

Formatting Currency and Price

<code>cur2frac</code>	Decimal currency values to fractional values
<code>cur2str</code>	Bank-formatted text
<code>dec2thirtytwo</code>	Decimal to thirty-second quotation
<code>frac2cur</code>	Fractional currency value to decimal value
<code>thirtytwo2dec</code>	Thirty-second quotation to decimal

Charting Financial Data

<code>bar, barh</code>	Bar chart
<code>bar3, bar3h</code>	3-D bar chart
<code>bolling</code>	Bollinger band chart
<code>candle</code>	Time series candle plot
<code>candle</code>	Candlestick chart
<code>chartfts</code>	Interactive display
<code>dateaxis</code>	Convert serial-date axis labels to calendar-date axis labels
<code>highlow</code>	Time series High-Low plot
<code>highlow</code>	High, low, open, close chart
<code>movavg</code>	Leading and lagging moving averages chart
<code>plot</code>	Plot data series
<code>pointfig</code>	Point and figure chart

Analyzing and Computing Cash Flows

Annuities (p. 12-7)	Work with annuities
Amortization and Depreciation (p. 12-7)	Work with amortization and depreciation
Present Value (p. 12-8)	Work with present values
Future Value (p. 12-8)	Work with future values
Payment Calculations (p. 12-8)	Work with payment calculations
Rates of Return (p. 12-8)	Work with rates of return
Cash Flow Sensitivities (p. 12-9)	Work with cash flow sensitivities

Annuities

annurate	Periodic interest rate of annuity
annuterm	Number of periods to obtain value

Amortization and Depreciation

amortize	Amortization schedule
depxfdb	Fixed declining-balance depreciation schedule
depxendb	General declining-balance depreciation schedule
deprdv	Remaining depreciable value
depxoyd	Sum of years' digits depreciation
depxtln	Straight-line depreciation schedule

Present Value

pvfix	Present value with fixed periodic payments
pvvar	Present value of varying cash flow

Future Value

fvdisc	Future value of discounted security
fvfix	Future value with fixed periodic payments
fvvar	Future value of varying cash flow

Payment Calculations

payadv	Periodic payment given number of advance payments
payodd	Payment of loan or annuity with odd first period
payper	Periodic payment of loan or annuity
payuni	Uniform payment equal to varying cash flow

Rates of Return

effrr	Effective rate of return
elpm	Compute expected lower partial moments for normal asset returns
irr	Internal rate of return
mirr	Modified internal rate of return
nomrr	Nominal rate of return

taxedrr	After-tax rate of return
xirr	Internal rate of return for nonperiodic cash flow

Cash Flow Sensitivities

cfconv	Cash flow convexity
cfdur	Cash-flow duration and modified duration

Fixed-Income Securities

Accrued Interest (p. 12-9)	Work with accrued interest
Prices (p. 12-10)	Work with prices
Term Structure of Interest Rates (p. 12-10)	Work with term structure of interest rates
Yields (p. 12-11)	Work with yields
Spreads (p. 12-11)	Work with spreads
Interest Rate Sensitivities (p. 12-11)	Work with interest rate sensitivities

Accrued Interest

acrubond	Accrued interest of security with periodic interest payments
acrudisc	Accrued interest of discount security paying at maturity

Prices

bndprice	Price fixed income security from yield to maturity
prdisc	Price of discounted security
prmat	Price with interest at maturity
prtbill	Price of Treasury bill

Term Structure of Interest Rates

disc2zero	Zero curve given discount curve
fwd2zero	Zero curve given forward curve
prbyzero	Price bonds in portfolio by set of zero curves
pyld2zero	Zero curve given par yield curve
tbl2bond	Treasury bond parameters given Treasury bill parameters
tr2bonds	Term-structure parameters given Treasury bond parameters
zbtprice	Zero curve bootstrapping from coupon bond data given price
zbtyield	Zero curve bootstrapping from coupon bond data given yield
zero2disc	Discount curve given zero curve
zero2fwd	Forward curve given zero curve
zero2pyld	Par yield curve given zero curve

Yields

beytbill	Bond equivalent yield for Treasury bill
bndyield	Yield to maturity for fixed income security
discrate	Bank discount rate of money market security
ylddisc	Yield of discounted security
yldmat	Yield with interest at maturity
yldtbill	Yield of Treasury bill

Spreads

bndspread	Static spread over spot curve
-----------	-------------------------------

Interest Rate Sensitivities

bndconvp	Bond convexity given price
bndconvy	Bond convexity given yield
bnddurp	Bond duration given price
bnddury	Bond duration given yield

Analyzing Portfolios

Portfolio Analysis (p. 12-12)	Perform portfolio analysis
Performance Metrics (p. 12-13)	Calculate performance metrics

Portfolio Analysis

abs2active	Convert constraints from absolute to active format
active2abs	Convert constraints from active to absolute format
corr2cov	Convert standard deviation and correlation to covariance
cov2corr	Convert covariance to standard deviation and correlation coefficient
ewstats	Expected return and covariance from return time series
frontcon	Mean-variance efficient frontier
frontier	Rolling efficient frontier
holdings2weights	Portfolio holdings into weights
pcalims	Linear inequalities for individual asset allocation
pcgcomp	Linear inequalities for asset group comparison constraints
pcglims	Linear inequalities for asset group minimum and maximum allocation
pcpval	Linear inequalities for fixing total portfolio value
periodicreturns	Periodic total returns from total return prices
portalloc	Optimal capital allocation to efficient frontier portfolios
portcons	Portfolio constraints
portopt	Portfolios on constrained efficient frontier
portrand	Randomized portfolio risks, returns, and weights

portsim	Monte Carlo simulation of correlated asset returns
portstats	Portfolio expected return and risk
portvrisk	Portfolio value at risk
ret2tick	Convert return series to price series
selectreturn	Portfolio configurations from 3-D efficient frontier
targetreturn	Portfolio weight accuracy
tick2ret	Convert price series to return series
totalreturnprice	Total return price time series
weights2holdings	Portfolio values and weights into holdings

Performance Metrics

emaxdrawdown	Compute expected maximum drawdown for Brownian motion
inforatio	Calculate information ratio for one or more assets
lpm	Compute sample lower partial moments of data
maxdrawdown	Compute maximum drawdown for one or more price series
portalpha	Compute risk-adjusted alphas and returns for one or more assets
sharpe	Compute Sharpe ratio for one or more assets

Financial Statistics

Expectation Conditional Maximization (p. 12-14)	Work with expectation conditional maximization
Multivariate Normal Regression (p. 12-15)	Work with multivariate normal regression
Expectation Conditional Maximization – Multivariate Normal Regression (p. 12-15)	Work with expectation conditional maximization and multivariate normal regression
Expectation Conditional Maximization – Least Squares Regression (p. 12-16)	Work with least squares regression
Seemingly Unrelated Regression (p. 12-16)	Work with unrelated regression

Expectation Conditional Maximization

ecmnfish	Fisher information matrix
ecmnhess	Hessian of negative log-likelihood function
ecmninit	Initial mean and covariance
ecmnmlc	Mean and covariance of incomplete multivariate normal data
ecmnobj	Multivariate normal negative log-likelihood function
ecmnstd	Standard errors for mean and covariance of incomplete data

Multivariate Normal Regression

<code>mvnrfish</code>	Fisher information matrix for multivariate normal or least-squares regression
<code>mvnrml</code>	Multivariate normal regression (ignore missing data)
<code>mvnrobj</code>	Log-likelihood function for multivariate normal regression without missing data
<code>mvnrstd</code>	Evaluate standard errors for multivariate normal regression model

Expectation Conditional Maximization – Multivariate Normal Regression

<code>ecmmvnrfish</code>	Fisher information matrix for multivariate normal regression model
<code>ecmmvnrml</code>	Multivariate normal regression with missing data
<code>ecmmvnrobj</code>	Log-likelihood function for multivariate normal regression with missing data
<code>ecmmvrstd</code>	Evaluate standard errors for multivariate normal regression model

Expectation Conditional Maximization – Least Squares Regression

ecmlsrmlle	Least-squares regression with missing data
ecmlsrobj	Log-likelihood function for least-squares regression with missing data

Seemingly Unrelated Regression

convert2sur	Convert multivariate normal regression model to seemingly unrelated regression (SUR) model
-------------	--

Pricing and Analyzing Derivatives

Option Valuation and Sensitivity (p. 12-16)	Work with option valuation and sensitivity
---	--

Option Valuation and Sensitivity

binprice	Binomial put and call pricing
blkimpv	Implied volatility for futures options from Black's model
blkprice	Black's model for pricing futures options
blsdelta	Black-Scholes sensitivity to underlying price change
blsgamma	Black-Scholes sensitivity to underlying delta change

blsimpv	Black-Scholes implied volatility
blslambda	Black-Scholes elasticity
blsprice	Black-Scholes put and call option pricing
blsrho	Black-Scholes sensitivity to interest rate change
blstheta	Black-Scholes sensitivity to time-until-maturity change
blsvega	Black-Scholes sensitivity to underlying price volatility
opprofit	Option profit

GARCH Processes

Univariate GARCH Processes
(p. 12-17)

Work with univariate GARCH processes

Univariate GARCH Processes

ugarch	Univariate GARCH(P,Q) parameter estimation with Gaussian innovations
ugarchllf	Log-likelihood objective function of univariate GARCH(P,Q) processes with Gaussian innovations
ugarchpred	Forecast conditional variance of univariate GARCH(P,Q) processes
ugarchsim	Simulate univariate GARCH(P,Q) process with Gaussian innovations

Financial Time Series Object and File Construction

ascii2fts	Create financial time series object from ASCII data file
fints	Construct financial time series object
fts2ascii	Write elements of time-series data into ASCII file
fts2mat	Convert to matrix
merge	Merge multiple financial time series objects

Financial Time Series Arithmetic

end	Last date entry
horzcat	Concatenate financial time series objects horizontally
length	Get number of dates (rows)
minus	Financial time series subtraction
mrdivide	Financial time series matrix division
mtimes	Financial time series matrix multiplication
plus	Financial time series addition
power	Financial time series power
rdivide	Financial time series division
size	Number of dates and data series
subsasgn	Content assignment
subsref	Subscripted reference
times	Financial time series multiplication

uminus	Unary minus of financial time series object
uplus	Unary plus of financial time series object
vertcat	Concatenate financial time series objects vertically

Financial Time Series Mathematical

cumsum	Cumulative sum
exp	Exponential values
hist	Histogram
log	Natural logarithm
log10	Common logarithm
log2	Base 2 logarithm
max	Maximum value
mean	Arithmetic average
min	Minimum value
std	Standard deviation

Financial Time Series Utility

chfield	Change data series name
extfield	Data series extraction
fetch	Data from financial time series object
fieldnames	Get names of fields

freqnum	Convert string frequency indicator to numeric frequency indicator
freqstr	Convert numeric frequency indicator to string representation
ftsbound	Start and end dates
ftsinfo	Financial time series object information
ftsuniq	Determine uniqueness
getfield	Content of specific field
getnameidx	Find name in list
iscompatible	Structural equality
isequal	Multiple object equality
isfield	Check whether string is field name
issorted	Check whether dates and times are monotonically increasing
rmfield	Remove data series
setfield	Set content of specific field
sortfts	Sort financial time series

Financial Time Series Data Transformation

boxcox	Box-Cox transformation
convert2sur	Convert multivariate normal regression model to seemingly unrelated regression (SUR) model
convertto	Convert to specified frequency
diff	Differencing
fillts	Fill missing values in time series

filter	Linear filtering
lagts	Lag time series object
leadts	Lead time series object
peravg	Periodic average of a FINTS object
resamplets	Downsample data
smoothts	Smooth data
toannual	Convert to annual
todayly	Convert to daily
todecimal	Fractional to decimal conversion
tomonthly	Convert to monthly
toquarterly	Convert to quarterly
toquoted	Decimal to fractional conversion
tosemi	Convert to semiannual
toweekly	Convert to weekly
tsmovavg	Moving average

Financial Time Series Indicator

adline	Accumulation/Distribution line
adosc	Accumulation/Distribution oscillator
bollinger	Time series Bollinger band
chaikosc	Chaikin oscillator
chaikvolat	Chaikin volatility
fpctkd	Fast stochastics
hhigh	Highest high
llow	Lowest low

macd	Moving Average Convergence/Divergence (MACD)
medprice	Median price
negvolidx	Negative volume index
onbalvol	On-Balance Volume (OBV)
posvolidx	Positive volume index
prcroc	Price rate of change
pvtrend	Price and Volume Trend (PVT)
rsindex	Relative Strength Index (RSI)
spctkd	Slow stochastics
stochosc	Stochastic oscillator
tsaccel	Acceleration between periods
tsmom	Momentum between periods
typprice	Typical price
volroc	Volume rate of change
wclose	Weighted close
willad	Williams Accumulation/Distribution line
willpctr	Williams %R

Financial Time Series Graphical User Interface

ftsgui

Financial time series GUI

Functions — Alphabetical List

Purpose Convert constraints from absolute to active format

Syntax `ActiveConSet = abs2active(AbsConSet, Index)`

Arguments

AbsConSet	Portfolio linear inequality constraint matrix expressed in absolute weight format. AbsConSet is formatted as $[A \ b]$ such that $A*w \leq b$, where A is a number of constraints (NCONSTRAINTS) by number of assets (NASSETS) weight coefficient matrix, and b and w are column vectors of length NASSETS. The value w represents a vector of absolute asset weights whose elements sum to the total portfolio value. See the output ConSet from portcons for additional details about constraint matrices.
Index	NASSETS-by-1 vector of index portfolio weights. The sum of the index weights must equal the total portfolio value (for example, a standard portfolio optimization imposes a sum-to-one budget constraint).

Description `ActiveConSet = abs2active(AbsConSet, Index)` transforms a constraint matrix to an equivalent matrix expressed in active weight format (relative to the index). The transformation equation is

$$Aw_{absolute} = A(w_{active} + w_{index}) \leq b_{absolute}$$

Therefore

$$Aw_{active} \leq b_{absolute} - Aw_{index} = b_{active}$$

The initial constraint matrix consists of NCONSTRAINTS portfolio linear inequality constraints expressed in absolute weight format. The index portfolio vector contains NASSETS assets.

ActiveConSet is the transformed portfolio linear inequality constraint matrix expressed in active weight format, also of the form $[A \ b]$ such that $A*w \leq b$. The value w represents a vector of active asset weights (relative to the index portfolio) whose elements sum to zero.

See Also

active2abs, pcalims, pcgcomp, pcglims, pcpval, portcons

accrfrac

Purpose Fraction of coupon period before settlement

Syntax Fraction = accrfrac(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate)

Arguments

Settle	Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than or equal to Maturity.
Maturity	Maturity date. A vector of serial date numbers or date strings.
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
Basis	(Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)

EndMonthRule	(Optional) End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.
IssueDate	(Optional) Date when a bond was issued.
FirstCouponDate	(Optional) Date when a bond makes its first coupon payment. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.
LastCouponDate	(Optional) Last coupon date of a bond prior to the maturity date. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate regardless of where it falls and will be followed only by the bond's maturity cash flow date.
StartDate	(Future implementation; optional) Date when a bond actually starts (the date from which a bond's cash flows can be considered). To make an instrument forward-starting, specify this date as a future date. If StartDate is not explicitly specified, the effective start date is the settlement date.

Vector arguments must have consistent dimensions, or they must be scalars.

accrfrac

Description

Fraction = accrfrac(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate) returns the fraction of the coupon period before settlement. This function is used for computing accrued interest.

Examples

Given data for three bonds

```
Settle = '14-Mar-1997';
Maturity = ['30-Nov-2000'
            '31-Dec-2000'
            '31-Jan-2001'];
Period = 2;
Basis = 0;
EndMonthRule = 1;
```

Execute the function.

```
Fraction = accrfrac(Settle, Maturity, Period, Basis,...
                    EndMonthRule)

Fraction =
    0.5714
    0.4033
    0.2320
```

Purpose Accrued interest of security with periodic interest payments

Syntax `AccruInterest = acrubond(IssueDate, Settle, FirstCouponDate, Face, CouponRate, Period, Basis)`

Arguments

IssueDate	Enter as serial date number or date string.
Settle	Enter as serial date number or date string.
FirstCouponDate	Enter as serial date number or date string.
Face	Redemption (par, face) value.
CouponRate	Enter as decimal fraction.
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
Basis	(Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none"> • 0 = actual/actual (default) • 1 = 30/360 (SIA) • 2 = actual/360 • 3 = actual/365 • 4 = 30/360 (PSA) • 5 = 30/360 (ISDA) • 6 = 30/360 (European) • 7 = actual/365 (Japanese) • 8 = actual/actual (ISMA) • 9 = actual/360 (ISMA)

acrubond

- 10 = actual/365 (ISMA)

Description

AccruInterest = acrubond(IssueDate, Settle, FirstCouponDate, Face, CouponRate, Period, Basis)
returns the accrued interest for a security with periodic interest payments. This function computes the accrued interest for securities with standard, short, and long first coupon periods.

Note cfamounts or accrfrac is recommended when calculating accrued interest beyond the first period.

Examples

```
AccruInterest = acrubond('31-jan-1983', '1-mar-1993', ...  
                        '31-jul-1983', 100, 0.1, 2, 0)
```

```
AccruInterest =  
0.8011
```

See Also

accrfrac, acrudisc, bndprice, bndyield, cfamounts, datenum

Purpose Accrued interest of discount security paying at maturity

Syntax `AccruInterest = acrudisc(Settle, Maturity, Face, Discount, Period, Basis)`

Arguments

Settle	Enter as serial date number or date string. Settle must be earlier than or equal to Maturity.
Maturity	Enter as serial date number or date string.
Face	Redemption (par, face) value.
Discount	Discount rate of the security. Enter as decimal fraction.
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
Basis	(Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none"> • 0 = actual/actual (default) • 1 = 30/360 (SIA) • 2 = actual/360 • 3 = actual/365 • 4 = 30/360 (PSA) • 5 = 30/360 (ISDA) • 6 = 30/360 (European) • 7 = actual/365 (Japanese) • 8 = actual/actual (ISMA) • 9 = actual/360 (ISMA)

acrudisc

- 10 = actual/365 (ISMA)

Description `AccruInterest = acrudisc(Settle, Maturity, Face, Discount, Period, Basis)` returns the accrued interest of a discount security paid at maturity.

Examples `AccruInterest = acrudisc('05/01/1992', '07/15/1992', ...
 100, 0.1, 2, 0)`

`AccruInterest =`
 2.0604 (or \$2.06)

Purpose Convert constraints from active to absolute format

Syntax `AbsConSet = active2abs(ActiveConSet, Index)`

Arguments

ActiveConSet	Portfolio linear inequality constraint matrix expressed in active weight format. ActiveConSet is formatted as [A b] such that $A*w \leq b$, where A is a number of constraints (NCONSTRAINTS) by number of assets (NASSETS) weight coefficient matrix, and b and w are column vectors of length NASSETS. The value w represents a vector of active asset weights (relative to the index portfolio) whose elements sum to 0. See the output ConSet from portcons for additional details about constraint matrices.
Index	NASSETS-by-1 vector of index portfolio weights. The sum of the index weights must equal the total portfolio value (for example, a standard portfolio optimization imposes a sum-to-one budget constraint).

Description

`AbsConSet = active2abs(ActiveConSet, Index)` transforms a constraint matrix to an equivalent matrix expressed in absolute weight format. The transformation equation is

$$Aw_{active} = A(w_{absolute} - w_{index}) \leq b_{active}$$

Therefore

$$Aw_{absolute} \leq b_{active} + Aw_{index} = b_{absolute}$$

active2abs

The initial constraint matrix consists of NCONSTRAINTS portfolio linear inequality constraints expressed in active weight format (relative to the index portfolio). The index portfolio vector contains NASSETS assets.

AbsConSet is the transformed portfolio linear inequality constraint matrix expressed in absolute weight format, also of the form $[A \ b]$ such that $A*w \leq b$. The value w represents a vector of active asset weights (relative to the index portfolio) whose elements sum to the total portfolio value.

Purpose Accumulation/Distribution line

Syntax

```
adln = adline(highp, lowp, closep, tvolume)
adln = adline([highp lowp closep tvolume])
adlnts = adline(tsobj)
adlnts = adline(tsobj, ParameterName, ParameterValue, ...)
```

Arguments

highp	High price (vector)
lowp	Low price (vector)
closep	Closing price (vector)
tvolume	Volume traded (vector)
tsobj	Time series object

Description

`adln = adline(highp, lowp, closep, tvolume)` computes the Accumulation/Distribution line for a set of stock price and volume traded data. The prices required for this function are the high (`highp`), low (`lowp`), and closing (`closep`) prices.

`adln = adline([highp lowp closep tvolume])` accepts a four-column matrix as input. The first column contains the high prices, the second contains the low prices, the third contains the closing prices, and the fourth contains the volume traded.

`adlnts = adline(tsobj)` computes the Williams Accumulation/Distribution line for a set of stock price data contained in the financial time series object `tsobj`. The object must contain the high, low, and closing prices plus the volume traded. The function assumes that the series are named `High`, `Low`, `Close`, and `Volume`. All are required. `adlnts` is a financial time series object with the same dates as `tsobj` but with a single series named `ADLine`.

adline

`adlnts = adline(tsoobj, ParameterName, ParameterValue, ...)`
accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

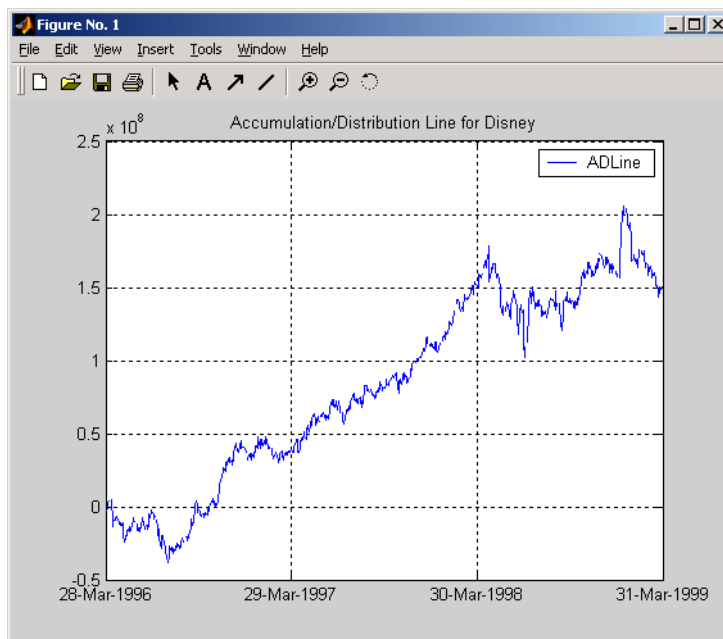

- HighName: high prices series name
- LowName: low prices series name
- CloseName: closing prices series name
- VolumeName: volume traded series name

Parameter values are the strings that represent the valid parameter names.

Examples

Compute the Accumulation/Distribution line for Disney stock and plot the results:

```
load disney.mat
dis_ADLine = adline(dis)
plot(dis_ADLine)
title('Accumulation/Distribution Line for Disney')
```

References

Achelis, Steven B., *Technical Analysis from A to Z*, Second Edition, McGraw-Hill, 1995, pp. 56-58.

adosc, willad, willpctr

adosc

Purpose Accumulation/Distribution oscillator

Syntax

```
ado = adosc(highp, lowp, openp, closep)
ado = adosc([highp lowp openp closep])
adots = adosc(tsobj)
adots = adosc(tsobj, ParameterName, ParameterValue, ...)
```

Arguments

highp	High price (vector)
lowp	Low price (vector)
openp	Opening price (vector)
closep	Closing price (vector)
tsobj	Time series object

Description

`ado = adosc(highp, lowp, openp, closep)` returns a vector, `ado`, that represents the Accumulation/Distribution (A/D) oscillator. The A/D oscillator is calculated based on the high, low, opening, and closing prices of each period. Each period is treated individually.

`ado = adosc([highp lowp openp closep])` accepts a four-column matrix as input. The order of the columns must be high, low, opening, and closing prices.

`adots = adosc(tsobj)` calculates the Accumulation/Distribution (A/D) oscillator, `adots`, for the set of stock price data contained in the financial time series object `tsobj`. The object must contain the high, low, opening, and closing prices. The function assumes that the series are named High, Low, Open, and Close. All are required. `adots` is a financial time series object with similar dates to `tsobj` and only one series named `ADosc`.

`adots = adosc(tsobj, ParameterName, ParameterValue, ...)` accepts parameter name-parameter value pairs as input. These pairs

specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

- HighName: high prices series name
- LowName: low prices series name
- OpenName: opening prices series name
- CloseName: closing prices series name

Parameter values are the strings that represents the valid parameter names.

Examples

Compute the Accumulation/Distribution oscillator for Disney stock and plot the results:

```
load disney.mat
dis_ADOsc = adosc(dis)
plot(dis_ADOsc)
title('A/D Oscillator for Disney')
```

See Also [adline](#), [willad](#)

Purpose Amortization schedule

Syntax [Principal, Interest, Balance, Payment] = amortize(Rate, NumPeriods, PresentValue, FutureValue, Due)

Arguments

Rate	Interest rate per period, as a decimal fraction.
NumPeriods	Number of payment periods.
PresentValue	Present value of the loan.
FutureValue	(Optional) Future value of the loan. Default = 0.
Due	(Optional) When payments are due: 0 = end of period (default), or 1 = beginning of period.

Description

[Principal, Interest, Balance, Payment] = amortize(Rate, NumPeriods, PresentValue, FutureValue, Due) returns the principal and interest payments of a loan, the remaining balance of the original loan amount, and the periodic payment.

Principal	Principal paid in each period. A 1-by-NumPeriods vector.
Interest	Interest paid in each period. A 1-by-NumPeriods vector.
Balance	Remaining balance of the loan in each payment period. A 1-by-NumPeriods vector.
Payment	Payment per period. A scalar.

Examples

Compute an amortization schedule for a conventional 30-year, fixed-rate mortgage with fixed monthly payments. Assume a fixed rate of 12% APR and an initial loan amount of \$100,000.

```
Rate          = 0.12/12;    % 12 percent APR = 1 percent per month
NumPeriods    = 30*12;     % 30 years = 360 months
PresentValue  = 100000;
```

```
[Principal, Interest, Balance, Payment] = amortize(Rate,
NumPeriods, PresentValue);
```

The output argument `Payment` contains the fixed monthly payment.

```
format bank
```

```
Payment
```

```
Payment =
```

```
1028.61
```

Finally, summarize the amortization schedule graphically by plotting the current outstanding loan balance, the cumulative principal, and the interest payments over the life of the mortgage. In particular, note that total interest paid over the life of the mortgage exceeds \$270,000, far in excess of the original loan amount.

```
plot(Balance, 'b'), hold('on')
plot(cumsum(Principal), '--k')
plot(cumsum(Interest), ':r')

xlabel('Payment Month')
ylabel('Dollars')
grid('on')
title('Outstanding Balance, Cumulative Principal & Interest')
legend('Outstanding Balance', 'Cumulative Principal', ...
'Cumulative Interest', 'TL')
```

The solid blue line represents the declining principal over the 30-year period. The dotted red line indicates the increasing cumulative interest payments. Finally, the dashed black line represents the cumulative principal payments, reaching \$100,000 after 30 years.

See Also

annurate, annuterm, payadv, payodd, payer

annurate

Purpose Periodic interest rate of annuity

Syntax Rate = annurate(NumPeriods, Payment, PresentValue, FutureValue, Due)

Arguments

NumPeriods	Number of payment periods.
Payment	Payment per period.
PresentValue	Present value of the loan or annuity.
FutureValue	(Optional) Future value of the loan or annuity. Default = 0.
Due	(Optional) When payments are due: 0 = end of period (default), or 1 = beginning of period.

Description Rate = annurate(NumPeriods, Payment, PresentValue, FutureValue, Due) returns the periodic interest rate paid on a loan or annuity.

Examples Find the periodic interest rate of a four-year, \$5000 loan with a \$130 monthly payment made at the end of each month.

```
Rate = annurate(4*12, 130, 5000, 0, 0)
```

```
Rate =  
0.0094
```

(Rate multiplied by 12 gives an annual interest rate of 11.32% on the loan.)

See Also amortize, annueterm, bndyield, irr

Purpose Number of periods to obtain value

Syntax NumPeriods = annuterm(Rate, Payment, PresentValue, FutureValue, Due)

Arguments

Rate	Interest rate per period, as a decimal fraction.
Payment	Payment per period.
PresentValue	Present value.
FutureValue	(Optional) Future value. Default = 0.
Due	(Optional) When payments are due: 0 = end of period (default), or 1 = beginning of period.

Description NumPeriods = annuterm(Rate, Payment, PresentValue, FutureValue, Due) calculates the number of periods needed to obtain a future value. To calculate the number of periods needed to pay off a loan, enter the payment or the present value as a negative value.

Examples A savings account has a starting balance of \$1500. \$200 is added at the end of each month and the account pays 9% interest, compounded monthly. How many years will it take to save \$5,000?

```
NumPeriods = annuterm(0.09/12, 200, 1500, 5000, 0)
```

```
NumPeriods =  
15.68 months or 1.31 years.
```

See Also annurate, amortize, fvfix, pvfix

Purpose Create financial time series object from ASCII data file

Syntax

```
tsobj = ascii2fts(filename, descrow, colheadrow, skiprows)
tsobj = ascii2fts(filename, timedata, descrow, colheadrow, skiprows)
```

Arguments

filename	ASCII data file
descrow	(Optional) Row number in the data file that contains the description to be used for the description field of the financial time series object
colheadrow	(Optional) Row number that has the column headers/names
skiprows	(Optional) Scalar or vector of row numbers to be skipped in the data file
timedata	Set to 'T' if time-of-day data is present in the ASCII data file or to 'NT' if no time-of-day data is present.

Description

`tsobj = ascii2fts(filename, descrow, colheadrow, skiprows)` creates a financial time series object `tsobj` from the ASCII file named `filename`. This form of the function can only read a data file without time-of-day information and create a financial time series object without time information. If time information is present in the ASCII file, an error message appears.

The general format of the text data file is

- Can contain header text lines.
- Can contain column header information. The column header information must immediately precede the data series columns unless `skiprows` is specified.

- Leftmost column must be the date column.
- Dates must be in a valid date string format:
 - 'ddmmyy' or 'ddmmyyyy'
 - 'mm/dd/yy' or 'mm/dd/yyyy'
 - 'dd-mmm-yy' or 'dd-mmm-yyyy'
 - 'mmm.dd,yy' or 'mmm.dd,yyyy'
- Each column must be separated either by spaces or a tab.

`tsobj = ascii2fts(filename, timedata, descrow, colheadrow, skiprows)` creates a financial time series object containing time-of-day data. Set `timedata` to 'T' to create a financial time series object containing time-of-day data.

Examples

Example 1. If your data file contains no description or column header rows,

```
1/3/95  36.75  36.9063  36.6563  36.875  1167900
1/4/95  37     37.2813  36.625  37.1563  1994700  ...
```

you can create a financial time series object from it with the simplest form of the `ascii2fts` function:

```
myinc = ascii2fts('my_inc.dat');

myinc =

desc:  my_inc.dat
freq:  Unknown (0)

'dates: (2)' 'series1: (2)' 'series2: (2)' 'series3: (2)'...
'03-Jan-1995' [ 36.7500] [ 36.9063] [ 36.6563]
'04-Jan-1995' [      37] [ 37.2813] [ 36.6250]
```

Example 2: If your data file contains description and column header information with the data series immediately following the column header row,

```
International Business Machines Corporation (IBM)
Daily prices (1/3/95 to 4/5/99)
DATE      OPEN      HIGH      LOW      CLOSE      VOLUME
1/3/95    36.75    36.9063   36.6563   36.875    1167900
1/4/95    37       37.2813   36.625    37.1563   1994700 ...
```

you must specify the row numbers containing the description and column headers:

```
ibm = ascii2fts('ibm9599.dat', 1, 3);

ibm =

desc: International Business Machines Corporation (IBM)
freq: Unknown (0)
'dates: (2)' 'OPEN: (2)' 'HIGH: (2)' 'LOW: (2)' ...
'03-Jan-1995' [ 36.7500] [ 36.9063] [ 36.6563]
'04-Jan-1995' [ 37] [ 37.2813] [ 36.6250]
```

Example 3: If your data file contains rows between the column headers and the data series, for example,

```
Staples, Inc. (SPLS)
Daily prices
DATE      OPEN      HIGH      LOW      CLOSE      VOLUME
Starting date: 04/08/1996
Ending date: 04/07/1999
4/8/96    19.50    19.75    19.25    19.375    548500
4/9/96    19.75    20.125   19.375    20        1135900 ...
```

you need to indicate to `ascii2fts` the rows in the file that must be skipped. Assume that you have called the data file containing the Staples data above `staples.dat`. The command

```
spls = ascii2fts('staples.dat', 1, 3, [4 5]);
```

indicates that the fourth and fifth rows in the file should be skipped in creating the financial time series object:

```
spls =

desc: Staples, Inc. (SPLS)
freq: Unknown (0)

'dates: (2)'  'OPEN: (2)'  'HIGH: (2)'  'LOW: (2)'
'08-Apr-1996' [ 19.5000]  [ 19.7500]  [19.2500]
'09-Apr-1996' [ 19.7500]  [ 20.1250]  [19.3750]
```

Example 4. Create a financial time series object containing time-of-day information.

First create a data file with time information:

```
dates = ['01-Jan-2001';'01-Jan-2001'; '02-Jan-2001'; ...
'02-Jan-2001'; '03-Jan-2001';'03-Jan-2001'];
times = ['11:00';'12:00';'11:00';'12:00';'11:00';'12:00'];
serial_dates_times = [datenum(dates), datenum(times)];
data = round(10*rand(6,2));
stat = fts2ascii('myfts_file2.txt',serial_dates_times,data, ...
{'dates';'times';'Data1';'Data2'},'My FTS with Time');
```

Now read the data file back and create a financial time series object:

```
MyFts = ascii2fts('myfts_file2.txt','t',1,2,1)

MyFts =

desc: My FTS with Time
freq: Unknown (0)

'dates: (6)'  'times: (6)'  'Data1: (6)'  'Data2: (6)'
'01-Jan-2001'  '11:00'  [ 9]  [ 4]
```

ascii2fts

```
'      ' '12:00' [ 7] [ 9]
'02-Jan-2001' '11:00' [ 2] [ 1]
'      ' '12:00' [ 4] [ 4]
'03-Jan-2001' '11:00' [ 9] [ 8]
'      ' '12:00' [ 9] [ 0]
```

See Also `fints, fts2ascii`

Purpose Bar chart

Syntax

```
bar(tsoj)
bar(tsoj, width)
bar(..., 'style')
hbar = bar(...)
```

```
barh(...)
hbarh = barh(...)
```

Arguments

<code>tsoj</code>	Financial time series object.
<code>width</code>	Width of the bars and separation of bars within a group. (Default = 0.8.) If width is 1, the bars within a group touch one another. Values > 1 produce overlapping bars.
<code>style</code>	'grouped' (default) or 'stacked'.

Description

`bar`, `barh` draw vertical and horizontal bar charts.

`bar(tsoj)` draws the columns of data series of the object `tsoj`. The number of data series dictates the number of vertical bars per group. Each group is the data for one particular date.

`bar(tsoj, width)` specifies the width of the bars.

`bar(..., 'style')` changes the style of the bar chart.

`hbar = bar(...)` returns a vector of bar handles.

Use the MATLAB command `shading faceted` to put edges on the bars. Use `shading flat` to turn edges off.

bar, barh

Examples

Create bar charts for Disney stock showing high, low, opening, and closing prices.

```
load disney
bar(q_dis)
title('Bar Chart of Disney Prices')
```

```
load disney
```

```
bar(q_dis)  
title('Horizontal Bar Chart of Disney Prices')
```

See Also [bar3](#), [bar3h](#), [candle](#), [highlow](#)

bar3, bar3h

Purpose 3-D bar chart

Syntax

```
bar3(tsobj)
bar3(tsobj, width)
bar3(..., 'style')
hbar3 = bar3(...)

bar3h(...)
hbar3h = bar3h(...)
```

Arguments

<code>tsobj</code>	Financial time series object.
<code>width</code>	Width of the bars and separation of bars within a group. (Default = 0.8.) If width is 1, the bars within a group touch one another. Values > 1 produce overlapping bars.
<code>style</code>	'detached' (default), 'grouped', or 'stacked'.

Description

`bar3`, `bar3h` draw three-dimensional vertical and horizontal bar charts.

`bar3(tsobj)` draws the columns of data series of the object `tsobj`. The number of data series dictates the number of vertical bars per group. Each group is the data for one particular date.

`bar3(tsobj, width)` specifies the width of the bars.

`bar3(..., 'style')` changes the style of the bar chart.

`hbar3 = bar3(...)` returns a vector of bar handles.

Use the MATLAB command `shading faceted` to put edges on the bars. Use `shading flat` to turn edges off.

Examples

Create three-dimensional bar charts for Disney stock showing high, low, opening, and closing prices.

```
load disney
bar3(q_dis, 'stacked')
title('Three-Dimensional Bar Chart of Disney Prices')
```

bar3, bar3h

```
load disney
bar3(q_dis, 'stacked')
title('Three-Dimensional Bar Chart of Disney Prices (Stacked)')
```

Purpose Bond equivalent yield for Treasury bill

Syntax `Yield = beytbill(Settle, Maturity, Discount)`

Arguments

Settle	Enter as serial date numbers or date strings. Settle must be earlier than or equal to Maturity.
Maturity	Enter as serial date numbers or date strings.
Discount	Discount rate of the Treasury bill. Enter as decimal fraction.

Description `Yield = beytbill(Settle, Maturity, Discount)` returns the bond equivalent yield for a Treasury bill.

Examples The settlement date of a Treasury bill is February 11, 2000, the maturity date is August 7, 2000, and the discount rate is 5.77%. The bond equivalent yield is

```
Yield = beytbill('2/11/2000', '8/7/2000', 0.0577)
```

```
Yield =  
0.0602
```

See Also `datenum`, `prtbill`, `yltdbill`

binprice

Purpose Binomial put and call pricing

Syntax [AssetPrice, OptionValue] = binprice(Price, Strike, Rate, Time, Increment, Volatility, Flag, DividendRate, Dividend, ExDiv)

Arguments

Price	Underlying asset price. A scalar.
Strike	Option exercise price. A scalar.
Rate	Risk-free interest rate. A scalar. Enter as a decimal fraction.
Time	Option's time until maturity in years. A scalar.
Increment	Time increment. A scalar. Increment is adjusted so that the length of each interval is consistent with the maturity time of the option. (Increment is adjusted so that Time divided by Increment equals an integer number of increments.)
Volatility	Asset's volatility. A scalar.
Flag	Specifies whether the option is a call (Flag = 1) or a put (Flag = 0). A scalar.
DividendRate	(Optional) The dividend rate, as a decimal fraction. A scalar. Default = 0. If you enter a value for DividendRate, set Dividend and ExDiv = 0 or do not enter them. If you enter values for Dividend and ExDiv, set DividendRate = 0.

Dividend	(Optional) The dividend payment at an ex-dividend date, ExDiv. A row vector. For each dividend payment, there must be a corresponding ex-dividend date. Default = 0. If you enter values for Dividend and ExDiv, set DividendRate = 0.
ExDiv	(Optional) Ex-dividend date, specified in number of periods. A row vector. Default = 0.

Description

[AssetPrice, OptionValue] = binprice(Price, Strike, Rate, Time, Increment, Volatility, Flag, DividendRate, Dividend, ExDiv) prices an option using the Cox-Ross-Rubinstein binomial pricing model.

Examples

For a put option, the asset price is \$52, option exercise price is \$50, risk-free interest rate is 10%, option matures in 5 months, volatility is 40%, and there is one dividend payment of \$2.06 in 3-1/2 months.

```
[Price, Option] = binprice(52, 50, 0.1, 5/12, 1/12, 0.4, 0, 0, ...
2.06, 3.5)
```

returns the asset price and option value at each node of the binary tree.

Price =

52.0000	58.1367	65.0226	72.7494	79.3515	89.0642
0	46.5642	52.0336	58.1706	62.9882	70.6980
0	0	41.7231	46.5981	49.9992	56.1192
0	0	0	37.4120	39.6887	44.5467
0	0	0	0	31.5044	35.3606
0	0	0	0	0	28.0688

Option =

4.4404	2.1627	0.6361	0	0	0

blkprice, blsprice

Purpose Implied volatility for futures options from Black's model

Syntax `Volatility = blsimpv(Price, Strike, Rate, Time, Value, Limit, ...
Tolerance, Class)`

Arguments

Price	Current price of the underlying asset (a futures contract).
Strike	Exercise price of the futures option.
Rate	Annualized, continuously compounded risk-free rate of return over the life of the option, expressed as a positive decimal number.
Time	Time to expiration of the option, expressed in years.
Value	Price of a European futures option from which the implied volatility of the underlying asset is derived.
Limit	(Optional) Positive scalar representing the upper bound of the implied volatility search interval. If Limit is empty or unspecified, the default = 10, or 1000% per annum.
Tolerance	(Optional) Implied volatility termination tolerance. A positive scalar. Default = 1e-6.
Class	(Optional) Option class (call or put) indicating the option type from which the implied volatility is derived. May be either a logical indicator or a cell array of characters. To specify call options, set <code>Class = true</code> or <code>Class = {'call'}</code> ; to specify put options, set <code>Class = false</code> or <code>Class = {'put'}</code> . If Class is empty or unspecified, the default is a call option.

Description

Volatility = blkimpv(Price, Strike, Rate, Time, CallPrice, MaxIterations, Tolerance) computes the implied volatility of a futures price from the market value of European futures options using Black's model.

Volatility is the implied volatility of the underlying asset derived from European futures option prices, expressed as a decimal number. If no solution is found, blkimpv returns NaN.

Any input argument may be a scalar, vector, or matrix. When a value is a scalar, that value is used to compute the implied volatility of all the options. If more than one input is a vector or matrix, the dimensions of all nonscalar inputs must be identical.

Rate and Time must be expressed in consistent units of time.

Examples

Consider a European call futures option that expires in four months, trading at \$1.1166, with an exercise price of \$20. Assume that the current underlying futures price is also \$20 and that the risk-free rate is 9% per annum. Furthermore, assume that you are interested in implied volatilities no greater than 0.5 (50% per annum). Under these conditions, the following commands all return an implied volatility of 0.25, or 25% per annum:

```
Volatility = blkimpv(20, 20, 0.09, 4/12, 1.1166, 0.5)
Volatility = blkimpv(20, 20, 0.09, 4/12, 1.1166, 0.5, [],
{'Call'})
Volatility = blkimpv(20, 20, 0.09, 4/12, 1.1166, 0.5, [], true)
```

blkprice, blsimpv, blsprice

Purpose Black's model for pricing futures options

Syntax [Call, Put] = blkprice(Price, Strike, Rate, Time, Volatility)

Arguments

Price	Current price of the underlying asset (a futures contract).
Strike	Strike or exercise price of the futures option.
Rate	Annualized, continuously compounded, risk-free rate of return over the life of the option, expressed as a positive decimal number.
Time	Time until expiration of the option, expressed in years. Must be greater than 0.
Volatility	Annualized futures price volatility, expressed as a positive decimal number.

Description

[Call, Put] = blkprice(ForwardPrice, Strike, Rate, Time, Volatility) uses Black's model to compute European put and call futures option prices.

Any input argument may be a scalar, vector, or matrix. When a value is a scalar, that value is used to compute the implied volatility from all options. If more than one input is a vector or matrix, the dimensions of all non-scalar inputs must be identical.

Rate, Time, and Volatility must be expressed in consistent units of time.

Examples

Consider European futures options with exercise prices of \$20 that expire in four months. Assume that the current underlying futures price is also \$20 with a volatility of 25% per annum. The risk-free rate is 9% per annum. Using this data

blkprice

```
[Call, Put] = blkprice(20, 20, 0.09, 4/12, 0.25)
```

returns equal call and put prices of \$1.1166.

binprice, blsprice

Purpose Black-Scholes sensitivity to underlying price change

Syntax [CallDelta, PutDelta] = blsdelta(Price, Strike, Rate, Time, Volatility, Yield)

Arguments

Price	Current price of the underlying asset.
Strike	Exercise price of the option.
Rate	Annualized, continuously compounded risk-free rate of return over the life of the option, expressed as a positive decimal number.
Time	Time to expiration of the option, expressed in years.
Volatility	Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), expressed as a positive decimal number.
Yield	(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, expressed as a decimal number. (Default = 0.) For example, for options written on stock indices, Yield could represent the dividend yield. For currency options, Yield could be the foreign risk-free interest rate.

Description [CallDelta, PutDelta] = blsdelta(Price, Strike, Rate, Time, Volatility, Yield) returns delta, the sensitivity in option value to change in the underlying asset price. Delta is also known as the hedge ratio.

Examples [CallDelta, PutDelta] = blsdelta(50, 50, 0.1, 0.25, 0.3, 0)

blsdelta

CallDelta =
0.5955

PutDelta =
-0.4045

Purpose Black-Scholes sensitivity to underlying delta change

Syntax `Gamma = blsgamma(Price, Strike, Rate, Time, Volatility, Yield)`

Arguments

Price	Current price of the underlying asset.
Strike	Exercise price of the option.
Rate	Annualized, continuously compounded risk-free rate of return over the life of the option, expressed as a positive decimal number.
Time	Time to expiration of the option, expressed in years.
Volatility	Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), expressed as a positive decimal number.
Yield	(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, expressed as a decimal number. (Default = 0.) For example, for options written on stock indices, Yield could represent the dividend yield. For currency options, Yield could be the foreign risk-free interest rate.

Description `Gamma = blsgamma(Price, Strike, Rate, Time, Volatility, Yield)` returns gamma, the sensitivity of delta to change in the underlying asset price.

Examples `Gamma = blsgamma(50, 50, 0.12, 0.25, 0.3, 0)`

`Gamma =`

blsgamma

0.0512

Purpose Black-Scholes implied volatility

Syntax Volatility = blsimpv(Price, Strike, Rate, Time, Value, Limit, ...
Yield, Tolerance, Class)

Arguments

Price	Current price of the underlying asset.
Strike	Exercise price of the option.
Rate	Annualized, continuously compounded risk-free rate of return over the life of the option, expressed as a positive decimal number.
Time	Time to expiration of the option, expressed in years.
Value	Price of a European option from which the implied volatility of the underlying asset is derived.
Limit	(Optional) Positive scalar representing the upper bound of the implied volatility search interval. If Limit is empty or unspecified, the default = 10, or 1000% per annum.
Yield	(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, expressed as a decimal number. (Default = 0.) For example, for options written on stock indices, Yield could represent the dividend yield. For currency options, Yield could be the foreign risk-free interest rate.

Tolerance	(Optional) Implied volatility termination tolerance. A positive scalar. Default = 1e-6.
Class	(Optional) Option class (call or put) indicating the option type from which the implied volatility is derived. May be either a logical indicator or a cell array of characters. To specify call options, set <code>Class = true</code> or <code>Class = {'call'}</code> ; to specify put options, set <code>Class = false</code> or <code>Class = {'put'}</code> . If <code>Class</code> is empty or unspecified, the default is a call option.

Description

`Volatility = blsimpv(Price, Strike, Rate, Time, Value, Limit, Yield, Tolerance, Class)` using a Black-Scholes model computes the implied volatility of an underlying asset from the market value of European call and put options.

`Volatility` is the implied volatility of the underlying asset derived from European option prices, expressed as a decimal number. If no solution is found, `blsimpv` returns NaN.

Any input argument may be a scalar, vector, or matrix. When a value is a scalar, that value is used to price all the options. If more than one input is a vector or matrix, the dimensions of all non-scalar inputs must be identical.

`Rate`, `Time`, and `Yield` must be expressed in consistent units of time.

Examples

Consider a European call option trading at \$10 with an exercise price of \$95 and three months until expiration. Assume that the underlying stock pays no dividend and trades at \$100. The risk-free rate is 7.5% per annum. Furthermore, assume that you are interested in implied volatilities no greater than 0.5 (50% per annum).

Under these conditions, the following statements all compute an implied volatility of 0.3130, or 31.30% per annum.

```
Volatility = blsimpv(100, 95, 0.075, 0.25, 10, 0.5)
```

```
Volatility = blsimpv(100, 95, 0.075, 0.25, 10, 0.5, 0, [], {'Call'})  
Volatility = blsimpv(100, 95, 0.075, 0.25, 10, 0.5, 0, [], true)
```

blsdelta, blsgamma, blslambda, blsprice, blsrho, blstheta

blslambda

Purpose Black-Scholes elasticity

Syntax [CallEl, PutEl] = blslambda(Price, Strike, Rate, Time, Volatility, Yield)

Arguments

Price	Current price of the underlying asset.
Strike	Exercise price of the option.
Rate	Annualized, continuously compounded risk-free rate of return over the life of the option, expressed as a positive decimal number.
Time	Time to expiration of the option, expressed in years.
Volatility	Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), expressed as a positive decimal number.
Yield	(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, expressed as a decimal number. (Default = 0.) For example, for options written on stock indices, Yield could represent the dividend yield. For currency options, Yield could be the foreign risk-free interest rate.

Description [CallEl, PutEl] = blslambda(Price, Strike, Rate, Time, Volatility, yield) returns the elasticity of an option. CallEl is the call option elasticity or leverage factor, and PutEl is the put option elasticity or leverage factor. Elasticity (the leverage of an option position) measures the percent change in an option price per one percent change in the underlying asset price.

Examples

```
[CallE1, PutE1] = blslambda(50, 50, 0.12, 0.25, 0.3)
```

```
CallE1 =  
    8.1274
```

```
PutE1 =  
   -8.6466
```

blsprice

Purpose Black-Scholes put and call option pricing

Syntax [Call, Put] = blsprice(Price, Strike, Rate, Time, Volatility, Yield)

Arguments

Price	Current price of the underlying asset.
Strike	Exercise price of the option.
Rate	Annualized, continuously compounded risk-free rate of return over the life of the option, expressed as a positive decimal number.
Time	Time to expiration of the option, expressed in years.
Volatility	Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), expressed as a positive decimal number.
Yield	(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, expressed as a decimal number. (Default = 0.) For example, for options written on stock indices, Yield could represent the dividend yield. For currency options, Yield could be the foreign risk-free interest rate.

Description [Call, Put] = blsprice(Price, Strike, Rate, Time, Volatility, Yield) computes European put and call option prices using a Black-Scholes model.

Any input argument may be a scalar, vector, or matrix. When a value is a scalar, that value is used to price all the options. If more than one input is a vector or matrix, the dimensions of all non-scalar inputs must be identical.

Rate, Time, Volatility, and Yield must be expressed in consistent units of time.

Examples

Consider European stock options that expire in three months with an exercise price of \$95. Assume that the underlying stock pays no dividend, trades at \$100, and has a volatility of 50% per annum. The risk-free rate is 10% per annum. Using this data

```
[Call, Put] = blsprice(100, 95, 0.1, 0.25, 0.5)
```

returns call and put prices of \$13.70 and \$6.35, respectively.

blsrho

Purpose Black-Scholes sensitivity to interest rate change

Syntax [CallRho, PutRho]= blsrho(Price, Strike, Rate, Time, Volatility, Yield)

Arguments

Price	Current price of the underlying asset.
Strike	Exercise price of the option.
Rate	Annualized, continuously compounded risk-free rate of return over the life of the option, expressed as a positive decimal number.
Time	Time to expiration of the option, expressed in years.
Volatility	Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), expressed as a positive decimal number.
Yield	(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, expressed as a decimal number. (Default = 0.) For example, for options written on stock indices, Yield could represent the dividend yield. For currency options, Yield could be the foreign risk-free interest rate.

Description [CallRho, PutRho]= blsrho(Price, Strike, Rate, Time, Volatility, Yield) returns the call option rho CallRho, and the put option rho PutRho. Rho is the rate of change in value of derivative securities with respect to interest rates.

Examples [CallRho, PutRho] = blsrho(50, 50, 0.12, 0.25, 0.3, 0)

CallRho =
6.6686

PutRho =
-5.4619

blstheta

Purpose Black-Scholes sensitivity to time-until-maturity change

Syntax [CallTheta, PutTheta] = blstheta(Price, Strike, Rate, Time, Volatility, Yield)

Arguments

Price	Current price of the underlying asset.
Strike	Exercise price of the option.
Rate	Annualized, continuously compounded risk-free rate of return over the life of the option, expressed as a positive decimal number.
Time	Time to expiration of the option, expressed in years.
Volatility	Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), expressed as a positive decimal number.
Yield	(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, expressed as a decimal number. (Default = 0.) For example, for options written on stock indices, Yield could represent the dividend yield. For currency options, Yield could be the foreign risk-free interest rate.

Description [CallTheta, PutTheta] = blstheta(Price, Strike, Rate, Time, Volatility, Yield) returns the call option theta CallTheta, and the put option theta PutTheta. Theta is the sensitivity in option value with respect to time.

Examples

```
[CallTheta, PutTheta] = blstheta(50, 50, 0.12, 0.25, 0.3, 0)
```

```
CallTheta =  
-8.9630
```

```
PutTheta =  
-3.1404
```

blsvega

Purpose Black-Scholes sensitivity to underlying price volatility

Syntax `Vega = blsvega(Price, Strike, Rate, Time, Volatility, Yield)`

Arguments

Price	Current price of the underlying asset.
Strike	Exercise price of the option.
Rate	Annualized, continuously compounded risk-free rate of return over the life of the option, expressed as a positive decimal number.
Time	Time to expiration of the option, expressed in years.
Volatility	Annualized asset price volatility (annualized standard deviation of the continuously compounded asset return), expressed as a positive decimal number.
Yield	(Optional) Annualized, continuously compounded yield of the underlying asset over the life of the option, expressed as a decimal number. (Default = 0.) For example, for options written on stock indices, Yield could represent the dividend yield. For currency options, Yield could be the foreign risk-free interest rate.

Description `Vega = blsvega(Price, Strike, Rate, Time, Volatility, Yield)` returns vega, the rate of change of the option value with respect to the volatility of the underlying asset.

Examples `Vega = blsvega(50, 50, 0.12, 0.25, 0.3, 0)`

`Vega =`

9.6035

bndconvp

Purpose Bond convexity given price

Syntax [YearConvexity, PerConvexity] = bndconvp(Price, CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face)

Arguments

Price	Clean price (excludes accrued interest).
CouponRate	Decimal number indicating the annual percentage rate used to determine the coupons payable on a bond.
Settle	Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than or equal to Maturity.
Maturity	Maturity date. A vector of serial date numbers or date strings.
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
Basis	(Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)

	<ul style="list-style-type: none">• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)
EndMonthRule	(Optional) End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.
IssueDate	(Optional) Date when a bond was issued.
FirstCouponDate	(Optional) Date when a bond makes its first coupon payment. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.
LastCouponDate	(Optional) Last coupon date of a bond prior to the maturity date. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate regardless of where it falls and will be followed only by the bond's maturity cash flow date.

StartDate	(Future implementation; optional) Date when a bond actually starts (the date from which a bond's cash flows can be considered). To make an instrument forward-starting, specify this date as a future date. If StartDate is not explicitly specified, the effective start date is the settlement date.
Face	(Optional) Face or par value. Default = 100.

All specified arguments must be number of bonds (NUMBONDS) by 1 or 1-by-NUMBONDS conforming vectors or scalar arguments. Use an empty matrix ([]) as a placeholder for an optional argument. Fill unspecified entries in input vectors with NaN. Dates can be serial date numbers or date strings.

Description

[YearConvexity, PerConvexity] = bndconvp(Price, CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face) computes the convexity of NUMBONDS fixed income securities given a clean price for each bond. This function determines the convexity for a bond whether or not the first or last coupon periods in the coupon structure are short or long (that is, whether or not the coupon structure is synchronized to maturity). This function also determines the convexity of a zero coupon bond.

YearConvexity is the yearly (annualized) convexity; PerConvexity is the periodic convexity reported on a semiannual bond basis (in accordance with SIA convention). Both outputs are NUMBONDS-by-1 vectors.

Examples

Find the convexity of three bonds given their prices.

```
Price = [106; 100; 98];  
CouponRate = 0.055;  
Settle = '02-Aug-1999';  
Maturity = '15-Jun-2004';
```

```
Period = 2;  
Basis = 0;  
  
[YearConvexity, PerConvexity] = bndconvp(Price,...  
CouponRate,Settle, Maturity, Period, Basis)  
  
YearConvexity =  
  
    21.4447  
    21.0363  
    20.8951  
  
PerConvexity =  
  
    85.7788  
    84.1454  
    83.5803
```

bndconvy

Purpose Bond convexity given yield

Syntax [YearConvexity, PerConvexity] = bndconvy(Yield, CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face)

Arguments

Yield	Yield to maturity on a semiannual basis.
CouponRate	Decimal number indicating the annual percentage rate used to determine the coupons payable on a bond.
Settle	Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than or equal to Maturity.
Maturity	Maturity date. A vector of serial date numbers or date strings.
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
Basis	(Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)

	<ul style="list-style-type: none">• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)
EndMonthRule	(Optional) End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.
IssueDate	(Optional) Date when a bond was issued.
FirstCouponDate	(Optional) Date when a bond makes its first coupon payment. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.
LastCouponDate	(Optional) Last coupon date of a bond prior to the maturity date. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate regardless of where it falls and will be followed only by the bond's maturity cash flow date.

StartDate	(Future implementation; optional) Date when a bond actually starts (the date from which a bond's cash flows can be considered). To make an instrument forward-starting, specify this date as a future date. If StartDate is not explicitly specified, the effective start date is the settlement date.
Face	(Optional) Face or par value. Default = 100.

All specified arguments must be number of bonds (NUMBONDS) by 1 or 1-by-NUMBONDS conforming vectors or scalar arguments. Use an empty matrix ([]) as a placeholder for an optional argument. Fill unspecified entries in input vectors with NaN. Dates can be serial date numbers or date strings.

Description

[YearConvexity, PerConvexity] = bndconvy(Yield, CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face) computes the convexity of NUMBONDS fixed income securities given the yield to maturity for each bond. This function determines the convexity for a bond whether or not the first or last coupon periods in the coupon structure are short or long (that is, whether or not the coupon structure is synchronized to maturity). This function also determines the convexity of a zero coupon bond.

YearConvexity is the yearly (annualized) convexity; PerConvexity is the periodic convexity reported on a semiannual bond basis (in accordance with SIA convention). Both outputs are NUMBONDS-by-1 vectors.

Examples

Find the convexity of a bond at three different yield values.

```
Yield = [0.04; 0.055; 0.06];  
CouponRate = 0.055;  
Settle = '02-Aug-1999';  
Maturity = '15-Jun-2004';
```

```

bnddurp

Purpose Bond duration given price

Syntax [ModDuration, YearDuration, PerDuration] = bnddurp(Price, CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face)

Arguments

Price	Clean price (excludes accrued interest).
CouponRate	Decimal number indicating the annual percentage rate used to determine the coupons payable on a bond.
Settle	Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than or equal to Maturity.
Maturity	Maturity date. A vector of serial date numbers or date strings.
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
Basis	(Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)

	<ul style="list-style-type: none"> • 7 = actual/365 (Japanese) • 8 = actual/actual (ISMA) • 9 = actual/360 (ISMA) • 10 = actual/365 (ISMA)
EndMonthRule	(Optional) End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.
IssueDate	(Optional) Date when a bond was issued.
FirstCouponDate	(Optional) Date when a bond makes its first coupon payment. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.
LastCouponDate	(Optional) Last coupon date of a bond prior to the maturity date. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate regardless of where it falls and will be followed only by the bond's maturity cash flow date.

StartDate	(Future implementation; optional) Date when a bond actually starts (the date from which a bond's cash flows can be considered). To make an instrument forward-starting, specify this date as a future date. If StartDate is not explicitly specified, the effective start date is the settlement date.
Face	(Optional) Face or par value. Default = 100.

All specified arguments must be number of bonds (NUMBONDS) by 1 or 1-by-NUMBONDS conforming vectors or scalar arguments. Use an empty matrix ([]) as a placeholder for an optional argument. Fill unspecified entries in input vectors with NaN. Dates can be serial date numbers or date strings.

Description

[ModDuration, YearDuration, PerDuration] = bnddurp(Price, CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face) computes the duration of NUMBONDS fixed income securities given a clean price for each bond. This function determines the Macaulay and modified duration for a bond whether or not the first or last coupon periods in the coupon structure are short or long (this is, whether or not the coupon structure is synchronized to maturity). This function also determines the Macaulay and modified duration for a zero coupon bond.

ModDuration is the modified duration in years, reported on a semiannual bond basis (in accordance with SIA convention); YearDuration is the Macaulay duration in years; PerDuration is the periodic Macaulay duration reported on a semiannual bond basis (in accordance with SIA convention). Outputs are NUMBONDS-by-1 vectors.

Examples

Find the duration of three bonds given their prices.

```
Price = [106; 100; 98];  
CouponRate = 0.055;  
Settle = '02-Aug-1999';
```

```
Maturity = '15-Jun-2004';
Period = 2;
Basis = 0;

[ModDuration, YearDuration, PerDuration] = bnddurp(Price,...
CouponRate, Settle, Maturity, Period, Basis)

ModDuration =

    4.2400
    4.1925
    4.1759

YearDuration =

    4.3275
    4.3077
    4.3007

PerDuration =

    8.6549
    8.6154
    8.6014
```

bnddury

Purpose Bond duration given yield

Syntax [ModDuration, YearDuration, PerDuration] = bnddury(Yield, CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face)

Arguments

Yield	Yield to maturity on a semiannual basis.
CouponRate	Decimal number indicating the annual percentage rate used to determine the coupons payable on a bond.
Settle	Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than or equal to Maturity.
Maturity	Maturity date. A vector of serial date numbers or date strings.
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
Basis	(Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)

	<ul style="list-style-type: none"> • 7 = actual/365 (Japanese) • 8 = actual/actual (ISMA) • 9 = actual/360 (ISMA) • 10 = actual/365 (ISMA)
EndMonthRule	<p>(Optional) End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.</p>
IssueDate	<p>(Optional) Date when a bond was issued.</p>
FirstCouponDate	<p>(Optional) Date when a bond makes its first coupon payment. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.</p>
LastCouponDate	<p>(Optional) Last coupon date of a bond prior to the maturity date. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate regardless of where it falls and will be followed only by the bond's maturity cash flow date.</p>

bndprice

Purpose Price fixed income security from yield to maturity

Syntax [Price, AccruedInt] = bndprice(Yield, CouponRate, Settle, Maturity)
[Price, AccruedInt] = bndprice(Yield, CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face)

Arguments Required and optional inputs can be number of bonds (NUMBONDS) by 1 or 1-by-NUMBONDS conforming vectors or scalar arguments. Optional inputs can also be passed as empty matrices ([]) or omitted at the end of the argument list. The value NaN in any optional input invokes the default value for that entry. Dates can be serial date numbers or date strings.

Yield	Bond yield to maturity on a semiannual basis.
CouponRate	Decimal number indicating the annual percentage rate used to determine the coupons payable on a bond.
Settle	Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than or equal to Maturity.
Maturity	Maturity date. A vector of serial date numbers or date strings.
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.

Basis	<p>(Optional) Day-count basis of the instrument. A vector of integers.</p> <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)
EndMonthRule	<p>(Optional) End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.</p>
IssueDate	<p>(Optional) Date when a bond was issued.</p>
FirstCouponDate	<p>(Optional) Date when a bond makes its first coupon payment. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.</p>

bndprice

LastCouponDate	(Optional) Last coupon date of a bond prior to the maturity date. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate regardless of where it falls and will be followed only by the bond's maturity cash flow date.
StartDate	(Future implementation; optional) Date when a bond actually starts (the date from which a bond's cash flows can be considered). To make an instrument forward-starting, specify this date as a future date. If StartDate is not explicitly specified, the effective start date is the settlement date.
Face	(Optional) Face or par value. Default = 100.

Description

[Price, AccruedInt] = bndprice(Yield, CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face) given bonds with SIA date parameters and semiannual yields to maturity, returns the clean prices and accrued interest due.

Price is the clean price of the bond (current price without accrued interest).

AccruedInt is the accrued interest payable at settlement.

Price and Yield are related by the formula

$$\text{Price} + \text{Accrued_Interest} = \text{sum}(\text{Cash_Flow} * (1 + \text{Yield}/2)^{-\text{Time}})$$

where the sum is over the bonds' cash flows and corresponding times in units of semiannual coupon periods.

Examples

Price a treasury bond at three different yield values.

```
Yield = [0.04; 0.05; 0.06];
CouponRate = 0.05;
Settle = '20-Jan-1997';
Maturity = '15-Jun-2002';
Period = 2;
Basis = 0;

[Price, AccruedInt] = bndprice(Yield, CouponRate, Settle,...
Maturity, Period, Basis)

Price =

    104.8106
     99.9951
     95.4384

AccruedInt =

     0.4945
     0.4945
     0.4945
```

cfamounts, bndyield

bndspread

Purpose Static spread over spot curve

Syntax Spread = bndspread(SpotInfo, Price, Coupon, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate)

Arguments

SpotInfo	Two-column matrix: [SpotDates ZeroRates] Zero rates correspond to maturities on the spot dates, continuously compounded. You will obtain the best results if you choose evenly spaced rates close together, for example, by using the three-month deposit rates.
Price	Price for every \$100 notional amount of bonds whose spreads are computed.
CouponRate	Decimal number indicating the annual percentage rate used to determine the coupons payable on a bond.
Settle	Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than or equal to Maturity.
Maturity	Maturity date. A vector of serial date numbers or date strings.
Period	(Optional) Coupons per year of the bond. A scalar or vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.

Basis	<p>(Optional) Day-count basis of the instrument. A vector of integers.</p> <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)
EndMonthRule	<p>(Optional) End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.</p>
IssueDate	<p>(Optional) Date when a bond was issued.</p>

bndspread

FirstCouponDate	(Optional) Date when a bond makes its first coupon payment. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.
LastCouponDate	(Optional) Last coupon date of a bond prior to the maturity date. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate regardless of where it falls and will be followed only by the bond's maturity cash flow date.

Description

Spread = bndspread(SpotInfo, Price, Coupon, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate) computes the static spread to benchmark in basis points.

Examples

Compute a FNMA 4 3/8 spread over a Treasury spot-curve.

```
% Build spot curve.

RefMaturity = [datenum('02/27/2003');
               datenum('05/29/2003');
               datenum('10/31/2004');
               datenum('11/15/2007');
               datenum('11/15/2012');
               datenum('02/15/2031')];

RefCpn = [0;
          0;
          2.125;
          3;
          4;
```

```

        5.375] / 100;

RefPrices = [99.6964;
            99.3572;
            100.3662;
            99.4511;
            99.4299;
            106.5756];

RefBonds = [RefPrices, RefMaturity, RefCpn];
Settle    = datenum('26-Nov-2002');
[ZeroRates, CurveDates] = zbtprice(RefBonds(:, 2:end), ...
RefPrices, Settle)

% FNMA 4 3/8 maturing 10/06 at 4.30 pm Tuesday, Nov 26, 2002
Price     = 105.484;
Coupon    = 0.04375;
Maturity  = datenum('15-Oct-2006');

% All optional inputs are supposed to be accounted by default,
% except the accrued interest under 30/360 (SIA), so:
Period    = 2;
Basis     = 1;
SpotInfo  = [CurveDates, ZeroRates];

% Compute static spread over treasury curve, taking into account
% the shape of curve as derived by bootstrapping method embedded
% within bndspread.

SpreadInBP = bndspread(SpotInfo, Price, Coupon, Settle, ...
Maturity, Period, Basis)

plot(CurveDates, ZeroRates*100, 'b', CurveDates, ...
ZeroRates*100+SpreadInBP/100, 'r--')

bndyield

Purpose Yield to maturity for fixed income security

Syntax Yield = bndyield(Price, CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face)

Arguments Required and optional inputs can be number of bonds (NUMBONDS) by 1 or 1-by-NUMBONDS conforming vectors or scalar arguments. Optional inputs can also be passed as empty matrices ([]) or omitted at the end of the argument list. The value NaN in any optional input invokes the default value for that entry. Dates can be serial date numbers or date strings.

Price	Clean price of the bond (current price without accrued interest).
CouponRate	Decimal number indicating the annual percentage rate used to determine the coupons payable on a bond.
Settle	Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than or equal to Maturity.
Maturity	Maturity date. A vector of serial date numbers or date strings.
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.

Basis (Optional) Day-count basis of the instrument. A vector of integers.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ISMA)
- 9 = actual/360 (ISMA)
- 10 = actual/365 (ISMA)

EndMonthRule (Optional) End-of-month rule. A vector. This rule applies only when **Maturity** is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.

IssueDate (Optional) Date when a bond was issued.

FirstCouponDate (Optional) Date when a bond makes its first coupon payment. When **FirstCouponDate** and **LastCouponDate** are both specified, **FirstCouponDate** takes precedence in determining the coupon payment structure.

bndyield

LastCouponDate	(Optional) Last coupon date of a bond prior to the maturity date. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate regardless of where it falls and will be followed only by the bond's maturity cash flow date.
StartDate	(Future implementation; optional) Date when a bond actually starts (the date from which a bond's cash flows can be considered). To make an instrument forward-starting, specify this date as a future date. If StartDate is not explicitly specified, the effective start date is the settlement date.
Face	(Optional) Face or par value. Default = 100.

Description

Yield = bndyield(Price, CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face) given NUMBONDS bonds with SIA date parameters and clean prices (excludes accrued interest), returns the bond equivalent yields to maturity.

Yield is a NUMBONDS-by-1 vector of the bond equivalent yields to maturity with semiannual compounding.

Price and Yield are related by the formula

$$\text{Price} + \text{Accrued_Interest} = \text{sum}(\text{Cash_Flow} * (1 + \text{Yield}/2)^{-\text{Time}})$$

where the sum is over the bonds' cash flows and corresponding times in units of semiannual coupon periods.

Examples

Compute the yield of a treasury bond at three different price values.

```
Price = [95; 100; 105];  
CouponRate = 0.05;  
Settle = '20-Jan-1997';  
Maturity = '15-Jun-2002';  
Period = 2;  
Basis = 0;
```

```
Yield = bndyield(Price, CouponRate, Settle,...  
Maturity, Period, Basis)
```

```
Yield =
```

```
    0.0610  
    0.0500  
    0.0396
```

bndprice, cfamounts

bolling

Purpose Bollinger band chart

Syntax `bolling(Asset, Samples, Alpha)`
`[Movavgv, UpperBand, LowerBand] = bolling(Asset, Samples, Alpha, Width)`

Arguments

Asset	Vector of asset data.
Samples	Number of samples to use in computing the moving average.
Alpha	(Optional) Exponent used to compute the element weights of the moving average. Default = 0 (simple moving average).
Width	(Optional) Number of standard deviations to include in the envelope. A multiplicative factor specifying how tight the bands should be around the simple moving average. Default = 2.

Description `bolling(Asset, Samples, Alpha, Width)` plots Bollinger bands for given Asset data. This form of the function does not return any data.

`[Movavgv, UpperBand, LowerBand] = bolling(Asset, Samples, Alpha, Width)` returns Movavgv with the moving average of the Asset data, UpperBand with the upper band data, and LowerBand with the lower band data. This form of the function does not plot any data.

Note The standard deviations are normalized by N-1, where N = the sequence length.

Examples

If `Asset` is a column vector of closing stock prices

```
bollinger(Asset, 20, 1)
```

plots linear 20-day moving average Bollinger bands based on the stock prices.

```
[Movavgv, UpperBand, LowerBand] = bollinger(Asset, 20, 1)
```

returns `Movavgv`, `UpperBand`, and `LowerBand` as vectors containing the moving average, upper band, and lower band data, without plotting the data.

`candle`, `dateaxis`, `highlow`, `movavg`, `pointfig`

bollinger

Purpose Time series Bollinger band

Syntax
`[mid, uppr, lowr] = bollinger(data, wsize, wts, nstd)`
`[midfts, upprfts, lowrfts] = bollinger(tsobj, wsize, wts, nstd)`

Arguments

<code>data</code>	Data vector.
<code>wsize</code>	(Optional) Window size. Default = 20.
<code>wts</code>	(Optional) Weight factor. Determines the type of moving average used. Default = 0 (box). 1 = linear.
<code>nstd</code>	(Optional) Number of standard deviations for upper and lower bands. Default = 2.
<code>tsobj</code>	Financial time series object.

Description

`[mid, uppr, lowr] = bollinger(data, wsize, wts, nstd)` calculates the middle, upper, and lower bands that make up the Bollinger bands from the vector `data`.

`mid` is the vector that represents the middle band, a simple moving average with default window size of 20. `uppr` and `lowr` are vectors that represent the upper and lower bands. These bands are +2 times and -2 times moving standard deviations away from the middle band.

`[midfts, upprfts, lowrfts] = bollinger(tsobj, wsize, wts, nstd)` calculates the middle, upper, and lower bands that make up the Bollinger bands from a financial time series object `tsobj`.

`midfts` is a financial time series object that represents the middle band for all series in `tsobj`. Both `upprfts` and `lowrfts` are financial time series objects that represent the upper and lower bands of all series, which are +2 times and -2 times moving standard deviations away from the middle band.

Examples

Compute the Bollinger bands for Disney stock closing prices and plot the results:

```
load disney.mat
[dis_Mid,dis_Uppr,dis_Lowr]= bollinger(dis);
dis_CloseBolling = [dis_Mid.CLOSE, dis_Uppr.CLOSE,...
dis_Lowr.CLOSE];
plot(dis_CloseBolling)
title('Bollinger Bands for Disney Closing Prices')
```

tsmovavg

Purpose Box-Cox transformation

Syntax

```
[transdat, lambda] = boxcox(data)
[transfts, lambdas] = boxcox(tsobj)
transdat = boxcox(lambda, data)
transfts = boxcox(lambda, tsobj)
```

Arguments

`data` Data vector. Must be positive.
`tsobj` Financial time series object.

Description

`boxcox` transforms nonnormally distributed data to a set of data that has approximately normal distribution. The Box-Cox transformation is a family of power transformations defined by

$$data(\lambda) = \begin{cases} \frac{data^\lambda - 1}{\lambda} & \text{if } \lambda \neq 0 \\ \log(data) & \text{if } \lambda = 1 \end{cases}$$

The logarithm is the natural logarithm (log base e). The algorithm calls for finding the λ value that maximizes the Log-Likelihood Function (LLF). The search is conducted using `fminsearch`.

`[transdat, lambda] = boxcox(data)` transforms the data vector `data` using the Box-Cox transformation method into `transdat`. It also calculates the transformation parameter λ .

`[transfts, lambda] = boxcox(tsobj)` transforms the financial time series object `tsobj` using the Box-Cox transformation method into `transfts`. It also calculates the transformation parameter λ .

If the input data is a vector, `lambda` is a scalar. If the input is a financial time series object, `lambda` is a structure with fields similar to the

components of the object; for example, if the object contains series names `Open` and `Close`, `lambda` has fields `lambda.Open` and `lambda.Close`.

`transdat = boxcox(lambda, data)` and `transfts = boxcox(lambda, tsobj)` transform the data using a certain specified λ for the Box-Cox transformation. This syntax does not find the optimum λ that maximizes the LLF.

`fminsearch`

busdate

Purpose Next or previous business day

Syntax Busday = busdate(Date, Direction, Holiday, Weekend)

Arguments

Date	Reference date. Enter scalar, vector, or matrix of reference business dates as serial date numbers or date strings.
Direction	(Optional) Scalar, vector, or matrix of search directions. 1 = next (default) or -1 = previous business day.
Holiday	(Optional) Vector of holidays and nontrading-day dates. All dates in Holiday must be the same format: either serial date numbers or date strings. (Using serial date numbers improves performance.) If Holiday is not specified, the non-trading day default vector is determined by the routine holidays function.
Weekend	(Optional) Vector of length 7, containing 0 and 1, the value 1 indicating weekend days. The first element of this vector corresponds to Sunday. Thus, when Saturday and Sunday form the weekend (default), Weekend = [1 0 0 0 0 0 1].

Description Busday = busdate(Date, Direction, Holiday, Weekend) returns the scalar, vector, or matrix of the next or previous business day(s), depending on Holiday.

Use the function datestr to convert serial date numbers to formatted date strings.

Examples

Example 1.

```
Busday = busdate('3-Jul-2001', 1)
```

```
Busday =
```

```
731037
```

```
datestr(Busday)
```

```
ans =
```

```
05-Jul-2001
```

Example 2. You can indicate that Saturday is a business day by appropriately setting the Weekend argument.

```
Weekend = [1 0 0 0 0 0 0];
```

July 4, 2003 falls on a Friday. Use busdate to verify that Saturday, July 5, is actually a business day.

```
Date = datestr(busdate('3-Jul-2003', 1, , Weekend))
```

See Also

holidays, isbusday

busdays

Purpose Business days in serial date format

Syntax
`bdates = busdays(sdate, edate, bdmode)`
`bdates = busdays(sdate, edate, bdmode, holvec)`

Arguments

<code>sdate</code>	Start date in string or serial date format.
<code>edate</code>	End date in string or serial date format.
<code>bdmode</code>	(Optional) Frequency of business days: <ul style="list-style-type: none">• DAILY, Daily, daily, D, d, 1 (default)• WEEKLY, Weekly, weekly, W, w, 2• MONTHLY, Monthly, monthly, M, m, 3• QUARTERLY, Quarterly, quarterly, Q, q, 4• SEMIANNUAL, Semiannual, semiannual, S, s, 5• ANNUAL, Annual, annual, A, a, 6
<code>holvec</code>	Strings must be enclosed in single quotation marks. (Optional) Holiday dates vector in string or serial date format.

Description `bdates = busdays(sdate, edate, bdmode)` generates a vector of business days, `bdates`, in serial date format between the last business date of the period that contains the start date, and the last business date of period that contains the end date. If `holvec` is not supplied, the dates are generated based on United States holidays. If you do not supply `bdmode`, `busdays` generates a daily vector.

For example:

```
vec = datestr(busdays('1/2/01','1/9/01','weekly'))
vec =
05-Jan-2001
12-Jan-2001
```

The end of the week is considered to be a Friday. Between 1/2/01 (Monday) and 1/9/01 (Tuesday) there is only one end-of-week day, 1/5/01 (Friday).

Because 1/9/01 is part of following week, the following Friday (1/12/01) is also reported.

`bdates = busdays(sdate, edate, bdmode, holvec)` lets you supply a vector of holidays, `holvec`, used to generate business days. `holvec` can either be in serial date format or date string format. If you use this syntax, you need to supply the frequency `bdmode`.

The output, `bdates`, is a column vector of business dates in serial date format.

If you want a weekday vector without the holidays, set `holvec` to `''` (empty string) or `[]` (empty vector).

candle

Purpose Candlestick chart

Syntax `candle(High, Low, Close, Open, Color)`

Arguments

High	High prices for a security. A column vector.
Low	Low prices for a security. A column vector.
Close	Closing prices for a security. A column vector.
Open	Opening prices for a security. A column vector.
Color	(Optional) Candlestick color. A string. MATLAB supplies a default color if none is specified. The default color differs depending on the background color of the figure window. See <code>ColorSpec</code> in the MATLAB documentation for color names.

Description `candle(High, Low, Close, Open, Color)` plots a candlestick chart given column vectors with the high, low, closing, and opening prices of a security.

If the closing price is greater than the opening price, the body (the region between the opening and closing price) is unfilled.

If the opening price is greater than the closing price, the body is filled.

Examples Given High, Low, Close, and Open as equal-size vectors of stock price data

```
candle(High, Low, Close, Open, 'cyan')
```

plots a candlestick chart with cyan candles.

See Also `bolling`, `dateaxis`, `highlow`, `movavg`, `pointfig`

Purpose Time series candle plot

Syntax

```
candle(tsobj)
candle(tsobj, color)
candle(tsobj, color, dateform)
candle(tsobj, color, dateform, ParameterName, ParameterValue, ...)
hcdl = candle(tsobj, color, dateform, ParameterName,
ParameterValue, ...)
```

Arguments

<code>tsobj</code>	Financial time series object
<code>color</code>	(Optional) A three-element row vector representing RGB or a color identifier. (See <code>plot</code> in the MATLAB documentation.)
<code>dateform</code>	(Optional) Date string format used as the <i>x</i> -axis tick labels. (See <code>datetick</code> in the MATLAB documentation.) You can specify a <code>dateform</code> only when <code>tsobj</code> does not contain time-of-day data. If <code>tsobj</code> contains time-of-day data, <code>dateform</code> is restricted to <code>'dd-mmm-yyyy HH:MM'</code> .

Description

`candle(tsobj)` generates a candle plot of the data in the financial time series object `tsobj`. `tsobj` must contain at least four data series representing the high, low, open, and closing prices. These series must have the names High, Low, Open, and Close (case-insensitive).

`candle(tsobj, color)` additionally specifies the color of the candle box.

`candle(tsobj, color, dateform)` additionally specifies the date string format used as the *x*-axis tick labels. See `datestr` for a list of date string formats.

candle

`candle(tsoobj, color, dateform, ParameterName, ParameterValue, ...)` indicates the actual name(s) of the required data series if the data series do not have the default names. `ParameterName` can be

- `HighName`: high prices series name
- `LowName`: low prices series name
- `OpenName`: open prices series name
- `CloseName`: closing prices series name

`hcdl = candle(tsoobj, color, dateform, ParameterName, ParameterValue, ...)` returns the handle to the patch objects and the line object that make up the candle plot. `hcdl` is a three-element column vector representing the handles to the two patches and one line that forms the candle plot.

Examples

Create a candle plot for Disney stock for the dates March 31, 1998 through April 30, 1998:

```
load disney.mat
candle(dis('3/31/98::4/30/98'))
title('Disney 3/31/98 to 4/30/98')
```

See Also `chartfts`, `highlow`, `plot`

cfamounts

Purpose Cash flow and time mapping for bond portfolio

Syntax [CFlowAmounts, CFlowDates, TFactors, CFlowFlags] =
cfamounts(CouponRate, Settle, Maturity, Period, Basis,
EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate,
StartDate, Face)

Arguments

CouponRate	Decimal number indicating the annual percentage rate used to determine the coupons payable on a bond.
Settle	Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than or equal to Maturity.
Maturity	Maturity date. A vector of serial date numbers or date strings.
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
Basis	(Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)

	<ul style="list-style-type: none">• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)
EndMonthRule	(Optional) End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.
IssueDate	(Optional) Date when a bond was issued.
FirstCouponDate	(Optional) Date when a bond makes its first coupon payment. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.
LastCouponDate	(Optional) Last coupon date of a bond prior to the maturity date. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate regardless of where it falls and will be followed only by the bond's maturity cash flow date.

StartDate	(Future implementation; optional) Date when a bond actually starts (the date from which a bond's cash flows can be considered). To make an instrument forward-starting, specify this date as a future date. If StartDate is not explicitly specified, the effective start date is the settlement date.
Face	(Optional) Face or par value. Default = 100.

Required arguments must be number of bonds (NUMBONDS) by 1 or 1-by-NUMBONDS conforming vectors or scalars. Optional arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices.

Description

[CFlowAmounts, CFlowDates, TFactors, CFlowFlags] = cfamounts(CouponRate, Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate, Face) returns matrices of cash flow amounts, cash flow dates, time factors, and cash flow flags for a portfolio of NUMBONDS fixed income securities. The elements contained in the cash flow matrix, time factor matrix, and cash flow flag matrix correspond to the cash flow dates for each security. The first element of each row in the cash flow matrix is the accrued interest payable on each bond. This is zero in the case of all zero coupon bonds. This function determines all cash flows and time mappings for a bond whether or not the coupon structure contains odd first or last periods. All output matrices are padded with NaNs as necessary to ensure that all rows have the same number of elements.

CFlowAmounts is the cash flow matrix of a portfolio of bonds. Each row represents the cash flow vector of a single bond. Each element in a column represents a specific cash flow for that bond.

CFlowDates is the cash flow date matrix of a portfolio of bonds. Each row represents a single bond in the portfolio. Each element in a column represents a cash flow date of that bond.

TFactors is the matrix of time factors for a portfolio of bonds. Each row corresponds to the vector of time factors for each bond. Each element in a column corresponds to the specific time factor associated with each cash flow of a bond. Time factors are useful in determining the present value of a stream of cash flows. The term “time factor” refers to the exponent TF in the discounting equation

$$PV = CF / (1 + z/2)^{TF}$$

where:

PV = Present value of a cash flow.

CF = The cash flow amount.

z = The risk-adjusted annualized rate or yield corresponding to given cash flow. The yield is quoted on a semiannual basis.

TF = Time factor for a given cash flow. Time is measured in semiannual periods from the settlement date to the cash flow date. In computing time factors, you use SIA actual/actual day count conventions for all time factor calculations.

CFlowFlags is the matrix of cash flow flags for a portfolio of bonds. Each row corresponds to the vector of cash flow flags for each bond. Each element in a column corresponds to the specific flag associated with each cash flow of a bond. Flags identify the type of each cash flow (for example, nominal coupon cash flow, front or end partial or “stub” coupon, maturity cash flow). Possible values are shown in the table.

Flag	Cash Flow Type
0	Accrued interest due on a bond at settlement.

Flag	Cash Flow Type
1	Initial cash flow amount smaller than normal due to “stub” coupon period. A stub period is created when the time from issue date to first coupon is shorter than normal.
2	Larger than normal initial cash flow amount because first coupon period is longer than normal.
3	Nominal coupon cash flow amount.
4	Normal maturity cash flow amount (face value plus the nominal coupon amount).
5	End “stub” coupon amount (last coupon period abnormally short and actual maturity cash flow is smaller than normal).
6	Larger than normal maturity cash flow because last coupon period longer than normal.
7	Maturity cash flow on a coupon bond when the bond has less than one coupon period to maturity.
8	Smaller than normal maturity cash flow when bond has less than one coupon period to maturity.
9	Larger than normal maturity cash flow when bond has less than one coupon period to maturity.
10	Maturity cash flow on a zero coupon bond.

Examples

Consider a portfolio containing a corporate bond paying interest quarterly and a treasury bond paying interest semiannually. Compute the cash flow structure and the time factors for each bond.

```
Settle = '01-Nov-1993';  
Maturity = ['15-Dec-1994'; '15-Jun-1995'];  
CouponRate = [0.06; 0.05];  
Period = [4; 2];
```

```
Basis = [1; 0];
[CFlowAmounts, CFlowDates, TFactors, CFlowFlags] = ...
cfamounts(CouponRate,Settle, Maturity, Period, Basis)
```

CFlowAmounts =

```
-0.7667    1.5000    1.5000    1.5000    1.5000  101.5000
-1.8989    2.5000    2.5000    2.5000  102.5000      NaN
```

CFlowDates =

```
728234    728278    728368    728460    728552    728643
728234    728278    728460    728643    728825      NaN
```

TFactors =

```
0    0.2404    0.7403    1.2404    1.7403    2.2404
0    0.2404    1.2404    2.2404    3.2404      NaN
```

CFlowFlags =

```
0    3    3    3    3    4
0    3    3    3    4  NaN
```

cfconv

Purpose Cash flow convexity

Syntax `CFlowConvexity = cfconv(CashFlow, Yield)`

Arguments

CashFlow A vector of real numbers.

Yield Periodic yield. A scalar. Enter as a decimal fraction.

Description `CFlowConvexity = cfconv(CashFlow, Yield)` returns the convexity of a cash flow in periods.

Examples Given a cash flow of nine payments of \$2.50 and a final payment \$102.50, with a periodic yield of 2.5%

```
CashFlow = [2.5 2.5 2.5 2.5 2.5 2.5 2.5 2.5 2.5 102.5];
```

```
Convex = cfconv(CashFlow, 0.025)
```

```
Convex =
```

```
90.4493 (periods)
```

See Also `bndconvp`, `bndconvy`, `bnddurp`, `bnddury`, `cfdur`

Purpose

Cash flow dates for fixed-income security

Syntax

CFlowDates = cfdates(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate)

Arguments

Settle	Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than or equal to Maturity.
Maturity	Maturity date. A vector of serial date numbers or date strings.
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
Basis	(Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none"> • 0 = actual/actual (default) • 1 = 30/360 (SIA) • 2 = actual/360 • 3 = actual/365 • 4 = 30/360 (PSA) • 5 = 30/360 (ISDA) • 6 = 30/360 (European) • 7 = actual/365 (Japanese) • 8 = actual/actual (ISMA) • 9 = actual/360 (ISMA) • 10 = actual/365 (ISMA)

EndMonthRule	(Optional) End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.
IssueDate	(Optional) Date when a bond was issued.
FirstCouponDate	(Optional) Date when a bond makes its first coupon payment. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.
LastCouponDate	(Optional) Last coupon date of a bond prior to the maturity date. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate regardless of where it falls and will be followed only by the bond's maturity cash flow date.
StartDate	(Future implementation; optional) Date when a bond actually starts (the date from which a bond's cash flows can be considered). To make an instrument forward-starting, specify this date as a future date. If StartDate is not explicitly specified, the effective start date is the settlement date.

Required arguments must be number of bonds (NUMBONDS) by 1 or 1-by-NUMBONDS conforming vectors or scalars. Optional arguments must

be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices.

Any input can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all. For example, if Maturity contains N dates, then Settle must contain N dates or a single date.

Description

CFlowDates = cfdates(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate) returns a matrix of cash flow dates for a bond or set of bonds. cfdates determines all cash flow dates for a bond whether or not the coupon payment structure is normal or the first and/or last coupon period is long or short.

CFlowDates is an N-row matrix of serial date numbers, padded with NaNs as necessary to ensure that all rows have the same number of elements. Use the function datestr to convert serial date numbers to formatted date strings.

Note The cash flow flags for a portfolio of bonds were formerly available as the cfdates second output argument, CFlowFlags. You can now use cfamounts to get these flags. If you specify a CFlowFlags argument, cfdates displays a message directing you to use cfamounts.

Examples

```
CFlowDates = cfdates('14 Mar 1997', '30 Nov 1998', 2, 0, 1)
CFlowDates =
    729541    729724    729906    730089
datestr(CFlowDates)
ans =
31-May-1997
30-Nov-1997
31-May-1998
30-Nov-1998
```

Given three securities with different maturity dates and the same default arguments

```
Maturity = ['30-Sep-1997'; '31-Oct-1998'; '30-Nov-1998'];
CFlowDates = cfdates('14-Mar-1997', Maturity)
CFlowDates =
    729480    729663         NaN         NaN
    729510    729694    729875    730059
    729541    729724    729906    730089
```

Look at the cash-flow dates for the last security.

```
datestr(CFlowDates(3,:))
ans =
31-May-1997
30-Nov-1997
31-May-1998
30-Nov-1998
```

Purpose Cash-flow duration and modified duration

Syntax [Duration, ModDuration] = cfdur(CashFlow, Yield)

Arguments

CashFlow A vector of real numbers.

Yield Periodic yield. A scalar. Enter as a decimal fraction.

Description [Duration, ModDuration] = cfdur(CashFlow, Yield) calculates the duration and modified duration of a cash flow in periods.

Examples Given a cash flow of nine payments of \$2.50 and a final payment \$102.50, with a periodic yield of 2.5%

```
CashFlow=[2.5 2.5 2.5 2.5 2.5 2.5 2.5 2.5 2.5 102.5];
```

```
[Duration, ModDuration] = cfdur(CashFlow, 0.025)
```

```
Duration =
    8.9709 (periods)
```

```
ModDuration =
    8.7521 (periods)
```

See Also bndconvp, bndconvy, bnddurp, bnddury, cfconv

Purpose Portfolio form of cash flow amounts

Syntax [CFBondDate, AllDates, AllTF, IndByBond] = cfport(CFlowAmounts, CFlowDates, TFactors)

Arguments

CFlowAmounts	Number of bonds (NUMBONDS) by number of cash flows (NUMCFS) matrix with entries listing cash flow amounts corresponding to each date in CFlowDates.
CFlowDates	NUMBONDS-by-NUMCFS matrix with rows listing cash flow dates for each bond and padded with NaNs.
TFactors	(Optional) NUMBONDS-by-NUMCFS matrix with entries listing the time between settlement and the cash flow date measured in semiannual coupon periods.

Description [CFBondDate, AllDates, AllTF, IndByBond] = cfport(CFlowAmounts, CFlowDates, TFactors) computes a vector of all cash flow dates of a bond portfolio, and a matrix mapping the cash flows of each bond to those dates. Use the matrix for pricing the bonds against a curve of discount factors.

CFBondDate is a NUMBONDS by number of dates (NUMDATES) matrix of cash flows indexed by bond and by date in AllDates. Each row contains a bond's cash flow values at the indices corresponding to entries in AllDates. Other indices in the row contain zeros.

AllDates is a NUMDATES-by-1 list of all dates that have any cash flow from the bond portfolio.

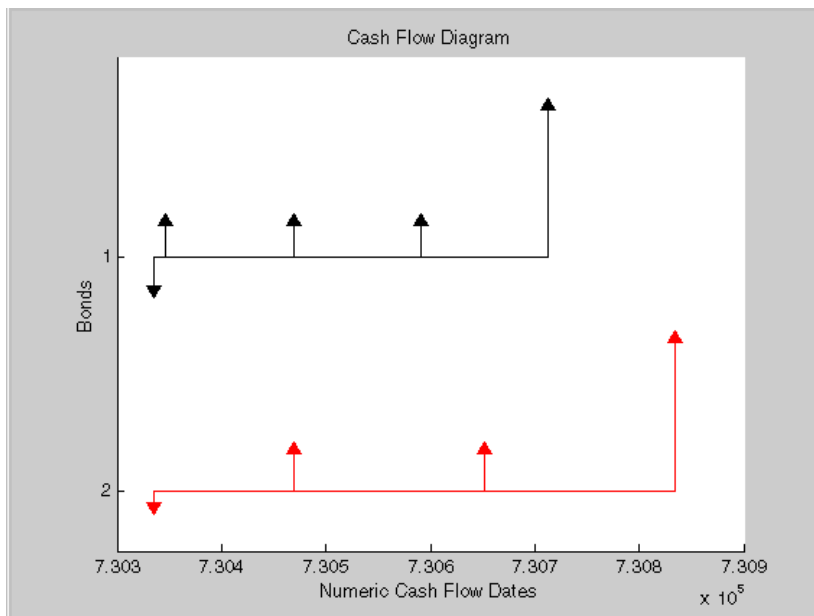

AllTF is a NUMDATES-by-1 list of time factors corresponding to the dates in AllDates. If TFactors is not entered, AllTF contains the number of days from the first date in AllDates.

IndByBond is a NUMBONDS-by-NUMCFS matrix of indices. The *ith* row contains a list of indices into AllDates where the *ith* bond has cash flows. Since some bonds have more cash flows than others, the matrix is padded with NaNs.

Examples

Use cfamounts to calculate the cash flow amounts, cash flow dates, and time factors for each of two bonds. Then use cfplot to plot the cash flow diagram.

```
Settle = '03-Aug-1999';
Maturity = ['15-Aug-2000'; '15-Dec-2000'];
CouponRate = [0.06; 0.05];
Period = [3; 2];
Basis = [1; 0];
[CFlowAmounts, CFlowDates, TFactors] = cfamounts(CouponRate, ...
Settle, Maturity, Period, Basis);
cfplot(CFlowDates, CFlowAmounts)
xlabel('Numeric Cash Flow Dates')
ylabel('Bonds')
title('Cash Flow Diagram')
```

Finally, call `cfport` to map the cash flow amounts to the cash flow dates.

Each row in the resultant `CFBondDate` matrix represents a bond. Each column represents a date on which one or more of the bonds has a cash flow. A 0 means the bond did not have a cash flow on that date. The dates associated with the columns are listed in `AllDates`. For example, the first bond had a cash flow of 2.000 on 730347. The second bond had no cash flow on this date.

For each bond, `IndByBond` indicates the columns of `CFBondDate`, or dates in `AllDates`, for which a bond has a cash flow.

```
[CFBondDate, AllDates, AllTF, IndByBond] = ...
cfport(CFlowAmounts, CFlowDates, TFactors)
```

`CFBondDate =`

```
-1.8000  2.0000  2.0000  2.0000      0 102.0000      0
```

```
-0.6694      0  2.5000      0  2.5000      0 102.5000
```

```
AllDates =
```

```
730335  
730347  
730469  
730591  
730652  
730713  
730835
```

```
AllTF =
```

```
0  
0.0663  
0.7322  
1.3989  
1.7322  
2.0663  
2.7322
```

```
IndByBond =
```

```
1  2  3  4  6  
1  3  5  7 NaN
```

cfamounts

cftimes

Purpose Time factors corresponding to bond cash flow dates

Syntax `TFactors = cftimes(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate)`

Arguments

Settle	Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than or equal to Maturity.
Maturity	Maturity date. A vector of serial date numbers or date strings.
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
Basis	(Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)

EndMonthRule	(Optional) End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.
IssueDate	(Optional) Date when a bond was issued.
FirstCouponDate	(Optional) Date when a bond makes its first coupon payment. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.
LastCouponDate	(Optional) Last coupon date of a bond prior to the maturity date. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate regardless of where it falls and will be followed only by the bond's maturity cash flow date.
StartDate	(Future implementation; optional) Date when a bond actually starts (the date from which a bond's cash flows can be considered). To make an instrument forward-starting, specify this date as a future date. If StartDate is not explicitly specified, the effective start date is the settlement date.

Description

TFactors = cftimes(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate,

cftimes

StartDate) determines the time factors corresponding to the cash flows of a bond or set of bonds. The time factor of a cash flow is the difference between the settlement date and the cash flow date in units of semiannual coupon periods. In computing time factors, you use SIA actual/actual day count conventions for all time factor calculations.

Examples

```
Settle = '15-Mar-1997';  
Maturity = '01-Sep-1999';  
Period = 2;  
TFactors = cftimes(Settle, Maturity, Period)
```

```
TFactors =
```

```
    0.9239    1.9239    2.9239    3.9239    4.9239
```

Purpose

Chaikin oscillator

Syntax

```
chosc = chaikosc(highp, lowp, closep, tvolume)
chosc = chaikosc([highp lowp closep tvolume])
choscts = chaikosc(tsobj)
choscts = chaikosc(tsobj, ParameterName, ParameterValue, ... )
```

Arguments

highp	High price (vector)
lowp	Low price (vector)
closep	Closing price (vector)
tvolume	Volume traded (vector)
tsobj	Financial time series object

Description

The Chaikin oscillator is calculated by subtracting the 10-period exponential moving average of the Accumulation/Distribution (A/D) line from the three-period exponential moving average of the A/D line.

`chosc = chaikosc(highp, lowp, closep, tvolume)` calculates the Chaikin oscillator (vector), `chosc`, for the set of stock price and volume traded data (`tvolume`). The prices that must be included are the high (`highp`), low (`lowp`), and closing (`closep`) prices.

`chosc = chaikosc([highp lowp closep tvolume])` accepts a four-column matrix as input.

`choscts = chaikosc(tsobj)` calculates the Chaikin Oscillator, `choscts`, from the data contained in the financial time series object `tsobj`. `tsobj` must at least contain data series with names High, Low, Close, and Volume. These series must represent the high, low, and closing prices, plus the volume traded. `choscts` is a financial time series object with the same dates as `tsobj` but only one series named `ChaikOsc`.

chaikosc

`choscts = chaikosc(tsobj, ParameterName, ParameterValue, ...)` accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

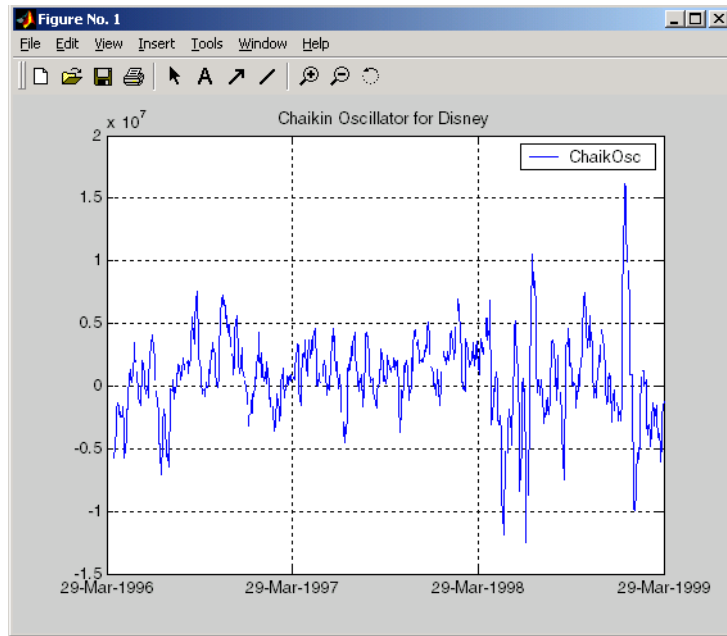

- HighName: high prices series name
- LowName: low prices series name
- CloseName: closing prices series name
- VolumeName: volume traded series name

Parameter values are the strings that represent the valid parameter names.

Examples

Compute the Chaikin oscillator for Disney stock and plot the results.

```
load disney.mat
dis_CHAIKosc = chaikosc(dis)
plot(dis_CHAIKosc)
title('Chaikin Oscillator for Disney')
```

chaikvolat

Purpose Chaikin volatility

Syntax

```
chvol = chaikvolat(highp, lowp)
chvol = chaikvolat([highp lowp])
chvol = chaikvolat(high, lowp, nperdiff, manper)
chvol = chaikvolat([high lowp], nperdiff, manper)
chvts = chaikvolat(tsobj)
chvts = chaikvolat(tsobj, nperdiff, manper, ParameterName,
ParameterValue, ...)
```

Arguments

highp	High price (vector).
lowp	Low price (vector).
nperdiff	Period difference (vector). Default = 10.
manper	Length of exponential moving average in periods (vector). Default = 10.
tsobj	Financial time series object.

Description `chvol = chaikvolat(highp, lowp)` calculates the Chaikin volatility from the series of stock prices, `highp` and `lowp`. The vector `chvol` contains the Chaikin volatility values, calculated on a 10-period exponential moving average and 10-period difference.

`chvol = chaikvolat([highp lowp])` accepts a two-column matrix as the input.

`chvol = chaikvolat(high, lowp, nperdiff, manper)` manually sets the period difference `nperdiff` and the length of the exponential moving average `manper` in periods.

`chvol = chaikvolat([high lowp], nperdiff, manper)` accepts a two-column matrix as the first input.

`chvts = chaikvolat(tsoobj)` calculates the Chaikin volatility from the financial time series object `tsoobj`. The object must contain at least two series named `High` and `Low`, representing the high and low prices per period. `chvts` is a financial time series object containing the Chaikin volatility values, based on a 10-period exponential moving average and 10-period difference. `chvts` has the same dates as `tsoobj` and a series called `ChaikVol`.

`chvts = chaikvolat(tsoobj, nperdiff, manper, ParameterName, ParameterValue, ...)` accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

- `HighName`: high prices series name
- `LowName`: low prices series name

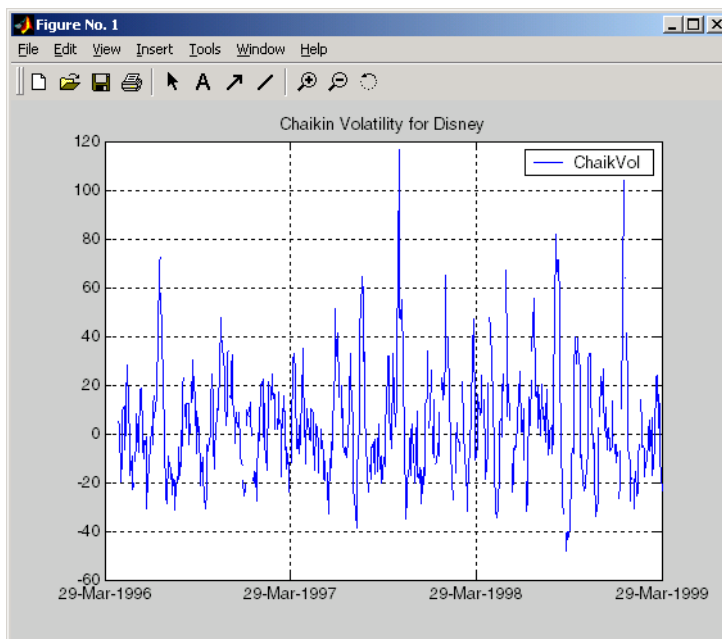

Parameter values are the strings that represent the valid parameter names.

`nperdiff`, the period difference, and `manper`, the length of the exponential moving average in periods, can also be set with this form of `chaikvolat`.

Examples

Compute the Chaikin volatility for Disney stock and plot the results:

```
load disney.mat
dis_CHAIKvol = chaikvolat(dis)
plot(dis_CHAIKvol)
title('Chaikin Volatility for Disney')
```

Purpose Interactive display

Syntax `chartfts(tsobj)`

Description `chartfts(tsobj)` produces a figure window that contains one or more plots. You can use the mouse to observe the data at a particular time point of the plot.

Examples Create a financial time series object from the supplied data file `ibm9599.dat`:

```
ibmfts = ascii2fts('ibm9599.dat', 1, 3, 2);
```

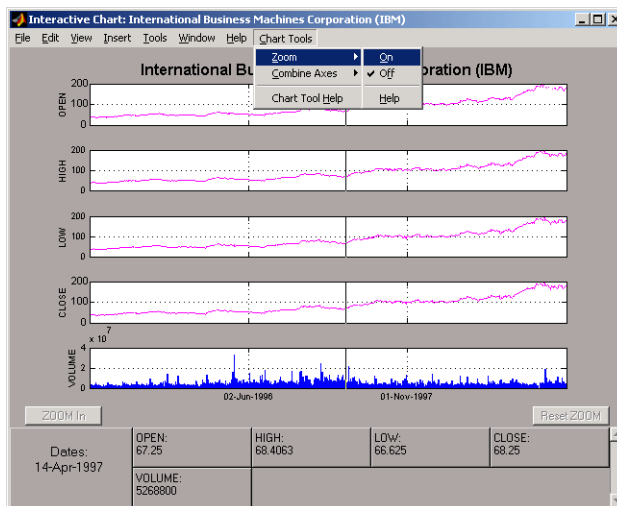

Chart the financial time series object `ibmfts`:

```
chartfts(ibmfts)
```

With the **Zoom** feature set off, a mouse click on the indicator line displays object data in a pop-up box.

With the **Zoom** feature set on, mouse clicks indicate the area of the chart to zoom.

You can find a tutorial on using chartfts in “Visualizing Financial Time Series Objects” on page 7-18. See “Zoom Tool” on page 7-21 for details on performing the zoom. Also see “Combine Axes Tool” on page 7-24 for information about combining axes for specified plots.

candle, highlow, plot

chfield

Purpose Change data series name

Syntax `newfts = chfield(oldfts, oldname, newname)`

Arguments

<code>oldfts</code>	Name of an existing financial time series object.
<code>oldname</code>	Name of the existing component in <code>oldfts</code> . A MATLAB string or column cell array.
<code>newname</code>	New name for the component in <code>oldfts</code> . A MATLAB string or column cell array.

Description

`newfts = chfield(oldfts, oldname, newname)` changes the name of the financial time series object component from `oldname` to `newname`.

Set `newfts = oldfts` to change the name of an existing component without changing the name of the financial time series object.

To change the names of several components at once, specify the series of old and new component names in corresponding column cell arrays.

You cannot change the names of the object components `desc`, `freq`, and `dates`.

`fieldnames`, `isfield`, `rmfield`

Purpose Convert multivariate normal regression model to seemingly unrelated regression (SUR) model

Syntax DesignSUR = convert2sur(Design, Group)

Arguments

Design A matrix or a cell array that depends on the number of data series NUMSERIES.

- If NUMSERIES = 1, convert2sur simply returns the Design matrix.
- If NUMSERIES > 1, Design is a cell array with NUMSAMPLES cells, where each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.

Group Contains information about how data series are to be grouped, with separate parameters for each group. Specify groups either by series or by groups:

- To identify groups by series, construct an index vector that has NUMSERIES elements. Element $i = 1, \dots, \text{NUMSERIES}$ in the vector, and has the index $j = 1, \dots, \text{NUMGROUPS}$ of the group in which series i is a member.
- To identify groups by groups, construct a cell array with NUMGROUPS elements. Each cell contains a vector with the indexes of the series that populate a given group.

In either case, the number of series is NUMSERIES and the number of groups is NUMGROUPS, with $1 \leq \text{NUMGROUPS} \leq \text{NUMSERIES}$.

Description

`DesignSUR = convert2sur(Design, Group)` converts a multivariate normal regression model into a seemingly unrelated regression model with a specified grouping of the data series. `DesignSUR` is either a matrix or a cell array that depends on the value of `NUMSERIES`:

- If `NUMSERIES = 1`, `DesignSUR = Design`, which is a `NUMSAMPLES-by-NUMPARAMS` matrix.
- If `NUMSERIES > 1` and `NUMGROUPS` groups are to be formed, `Design` is a cell array with `NUMSAMPLES` cells, where each cell contains a `NUMSERIES-by-(NUMGROUPS * NUMPARAMS)` matrix of known values.

The original collection of parameters that are common to all series are replicated to form collections of parameters for each group.

Examples

This example has ten series in three groups, and two model parameters. Suppose

Group 1 has series 1, 3, 4, 8.

Group 2 has series 2, 6, 10.

Group 3 has series 5, 7, 9.

Either:

```
Group = [ 1, 2, 1, 1, 3, 2, 3, 1, 3, 2];
```

or

```
Group = cell(3,1);  
Group{1} = [1, 3, 4, 8];  
Group{2} = [2, 6, 10];  
Group{3} = [5, 7, 9];
```

A regression with `DesignSUR` would have $3 \times 2 = 6$ model parameters.

Purpose Convert to specified frequency

Syntax
`newfts = convertto(oldfts, newfreq)`
`newfts = convertto(oldfts, newfreq, 'param1', 'value1', 'param2', 'value2')`

Arguments

<code>oldfts</code>	Name of an existing financial time series object.
<code>newfreq</code>	1, DAILY, Daily, daily, D, d 2, WEEKLY, Weekly, weekly, W, w 3, MONTHLY, Monthly, monthly, M, m 4, QUARTERLY, Quarterly, quarterly, Q, q 5, SEMIANNUAL, Semiannual, semiannual, S, s 6, ANNUAL, Annual, annual, A, a

Description `convertto` converts a financial time series of any frequency to one of a specified frequency.

`newfts = convertto(oldfts, newfreq)` converts the object `oldfts` to the new time series object `newfts` with the frequency `newfreq`.

Refer to the documentation for each frequency conversion function to determine the valid parameter/value pairs.

See Also `toannual`, `todayly`, `tomonthly`, `toquarterly`, `tosemi`, `toweekly`

Purpose Convert standard deviation and correlation to covariance

Syntax `ExpCovariance = corr2cov(ExpSigma, ExpCorrC)`

Arguments

`ExpSigma` Vector of length n with the standard deviations of each process. n is the number of random processes.

`ExpCorrC` (Optional) n -by- n correlation coefficient matrix. If `ExpCorrC` is not specified, the processes are assumed to be uncorrelated, and the identity matrix is used.

Description `corr2cov` converts standard deviation and correlation to covariance. `ExpCovariance` is an n -by- n covariance matrix, where n is the number of processes.

$$\text{ExpCov}(i,j) = \text{ExpCorrC}(i,j) * (\text{ExpSigma}(i) * \text{ExpSigma}(j))$$

Examples

```
ExpSigma = [0.5 2.0];
```

```
ExpCorrC = [1.0 -0.5  
            -0.5 1.0];
```

```
ExpCovariance = corr2cov(ExpSigma, ExpCorrC)
```

Expected results:

```
ExpCovariance =  
  
    0.2500    -0.5000  
   -0.5000    4.0000
```

See Also `corrcoef`, `cov`, `cov2corr`, `ewstats`, `std`

Purpose Convert covariance to standard deviation and correlation coefficient

Syntax `[ExpSigma, ExpCorrC] = cov2corr(ExpCovariance)`

Arguments

`ExpCovariance` *n*-by-*n* covariance matrix; for example, from `cov` or `ewstats`. *n* is the number of random processes.

Description

`[ExpSigma, ExpCorrC] = cov2corr(ExpCovariance)` converts covariance to standard deviations and correlation coefficients.

`ExpSigma` is a 1-by-*n* vector with the standard deviation of each process.

`ExpCorrC` is an *n*-by-*n* matrix of correlation coefficients.

```
ExpSigma(i) = sqrt(ExpCovariance(i,i))
ExpCorrC(i,j) = ExpCovariance(i,j)/(ExpSigma(i)*ExpSigma(j))
```

Examples

```
ExpCovariance = [0.25 -0.5
                 -0.5  4.0];
```

```
[ExpSigma, ExpCorrC] = cov2corr(ExpCovariance)
```

Expected results:

```
ExpSigma =
    0.5000    2.0000
```

```
ExpCorrC =
    1.0000   -0.5000
   -0.5000    1.0000
```

cov2corr

Purpose Coupon payments remaining until maturity

Syntax NumCouponsRemaining = cpncount(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate)

Arguments

Settle	Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than or equal to Maturity.
Maturity	Maturity date. A vector of serial date numbers or date strings.
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
Basis	(Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)

	<ul style="list-style-type: none">• 10 = actual/365 (ISMA)
EndMonthRule	(Optional) End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.
IssueDate	(Optional) Date when a bond was issued.
FirstCouponDate	(Optional) Date when a bond makes its first coupon payment. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.
LastCouponDate	(Optional) Last coupon date of a bond prior to the maturity date. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate regardless of where it falls and will be followed only by the bond's maturity cash flow date.
StartDate	(Future implementation; optional) Date when a bond actually starts (the date from which a bond's cash flows can be considered). To make an instrument forward-starting, specify this date as a future date. If StartDate is not explicitly specified, the effective start date is the settlement date.

Required arguments must be number of bonds (NUMBONDS) by 1 or 1-by-NUMBONDS conforming vectors or scalars. Optional arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices.

Description

NumCouponsRemaining = cpncount(Settle, Maturity, Period, Basis, EndMonthRule) returns the whole number of coupon payments between the settlement and maturity dates for a coupon bond or set of bonds.

Examples

```
NumCouponsRemaining = cpncount('14 Mar 1997', '30 Nov 2000',...
2, 0, 0)
```

```
n =
    8
```

Given three coupon bonds with different maturity dates and the same default arguments

```
Maturity = ['30 Sep 2000'; '31 Oct 2001'; '30 Nov 2002'];
```

```
NumCouponsRemaining = cpncount('14 Sep 1997', Maturity)
```

```
NumCouponsRemaining =
```

```
    7
    9
   11
```

cpndaten

Purpose Next coupon date for fixed-income security

Syntax `NextCouponDate = cpndaten(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate)`

Arguments

Settle	Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than or equal to Maturity.
Maturity	Maturity date. A vector of serial date numbers or date strings.
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
Basis	(Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)

EndMonthRule	(Optional) End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.
IssueDate	(Optional) Date when a bond was issued.
FirstCouponDate	(Optional) Date when a bond makes its first coupon payment. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.
LastCouponDate	(Optional) Last coupon date of a bond prior to the maturity date. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate regardless of where it falls and will be followed only by the bond's maturity cash flow date.

Required arguments must be number of bonds (NUMBONDS) by 1 or 1-by-NUMBONDS conforming vectors or scalars. Optional arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices.

Description

NextCouponDate = cpndaten(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate) returns the next coupon date after the settlement date. This function finds the next coupon date whether or not the coupon structure is synchronized with the maturity date.

NextCouponDate is returned as a serial date number. The function datestr converts a serial date number to a formatted date string.

Examples

```
NextCouponDate = cpndaten('14 Mar 1997', '30 Nov 2000', 2, 0, 0);
```

```
datestr(NextCouponDate)
```

```
ans =
```

```
30-May-1997
```

```
NextCouponDate = cpndaten('14 Mar 1997', '30 Nov 2000', 2, 0, 1);
```

```
datestr(NextCouponDate)
```

```
ans =
```

```
31-May-1997
```

```
Maturity = ['30 Sep 2000'; '31 Oct 2000'; '30 Nov 2000'];
```

```
NextCouponDate = cpndaten('14 Mar 1997', Maturity);
```

```
datestr(NextCouponDate)
```

```
ans =
```

```
31-Mar-1997
```

```
30-Apr-1997
```

```
31-May-1997
```

Purpose Next quasi coupon date for fixed income security

Syntax NextQuasiCouponDate = cpndatenq(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate)

Arguments

Settle	Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than or equal to Maturity.
Maturity	Maturity date. A vector of serial date numbers or date strings.
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
Basis	(Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)

EndMonthRule	(Optional) End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.
IssueDate	(Optional) Date when a bond was issued.
FirstCouponDate	(Optional) Date when a bond makes its first coupon payment. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.
LastCouponDate	(Optional) Last coupon date of a bond prior to the maturity date. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate regardless of where it falls and will be followed only by the bond's maturity cash flow date.

Required arguments must be number of bonds (NUMBONDS) by 1 or 1-by-NUMBONDS conforming vectors or scalars. Optional arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices. Fill unspecified entries in input vectors with the value NaN. Dates can be serial date numbers or date strings.

Description

NextQuasiCouponDate = cpndatenq(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate) determines the next quasi coupon date for a portfolio of NUMBONDS fixed income securities whether or not the first or last

coupon is normal, short, or long. For zero coupon bonds `cpndatenq` returns quasi coupon dates as if the bond had a semiannual coupon structure. Successive quasi coupon dates determine the length of the standard coupon period for the fixed income security of interest and do not necessarily coincide with actual coupon payment dates.

Outputs are `NUMBONDS-by-1` vectors.

If `Settle` is a coupon date, this function never returns the settlement date. It returns the quasi coupon date strictly after settlement.

`NextQuasiCouponDate` is returned as a serial date number. The function `datestr` converts a serial date number to a formatted date string.

Examples

Given a pair of bonds with the characteristics

```
Settle = char('30-May-1997', '10-Dec-1997');
Maturity = char('30-Nov-2002', '10-Jun-2004');
```

Compute `NextCouponDate` for this pair of bonds.

```
NextCouponDate = cpndaten(Settle, Maturity);
```

```
datestr(NextCouponDate)
```

```
ans =
```

```
31-May-1997
```

```
10-Jun-1998
```

Compute the next quasi coupon dates for these two bonds.

```
NextQuasiCouponDate = cpndatenq(Settle, Maturity);
```

```
datestr(NextQuasiCouponDate)
```

```
ans =
```

```
31-May-1997
```

10-Jun-1998

Because no `FirstCouponDate` has been specified, the results are identical.

Now supply an explicit `FirstCouponDate` for each bond.

```
FirstCouponDate = char('30-Nov-1997', '10-Dec-1998');
```

Compute the next coupon dates.

```
NextCouponDate = cpndaten(Settle, Maturity, 2, 0, 1, [], ...  
FirstCouponDate);
```

```
datestr(NextCouponDate)
```

```
ans =
```

```
30-Nov-1997
```

```
10-Dec-1998
```

The next coupon dates are identical to the specified first coupon dates.

Now recompute the next quasi coupon dates.

```
NextQuasiCouponDate = cpndatenq(Settle, Maturity, 2, 0, 1, [], ...  
FirstCouponDate);
```

```
datestr(NextQuasiCouponDate)
```

```
ans =
```

```
31-May-1997
```

```
10-Jun-1998
```

These results illustrate the distinction between actual coupon payment dates and quasi coupon dates. `FirstCouponDate` (and `LastCouponDate`, as well), when specified, is associated with an actual coupon payment

and also serves as the synchronization date for determining all quasi coupon dates. Since each bond in this example pays semiannual coupons, and the first coupon date occurs more than six months after settlement, each will have an intermediate quasi coupon date before the actual first coupon payment occurs.

cpndatep

Purpose Previous coupon date for fixed-income security

Syntax PreviousCouponDate = cpndatep(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate)

Arguments

Settle	Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than or equal to Maturity.
Maturity	Maturity date. A vector of serial date numbers or date strings.
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
Basis	(Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)

EndMonthRule	(Optional) End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.
IssueDate	(Optional) Date when a bond was issued.
FirstCouponDate	(Optional) Date when a bond makes its first coupon payment. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.
LastCouponDate	(Optional) Last coupon date of a bond prior to the maturity date. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate regardless of where it falls and will be followed only by the bond's maturity cash flow date.

Required arguments must be number of bonds (NUMBONDS) by 1 or 1-by-NUMBONDS conforming vectors or scalars. Optional arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices.

Description

PreviousCouponDate = cpndatep(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate) returns the previous coupon date on or before settlement for a portfolio of bonds. This function finds the previous

coupon date whether or not the coupon structure is synchronized with the maturity date.

For zero coupon bonds the previous coupon date is the issue date, if available. However, if the issue date is not supplied, the previous coupon date for zero coupon bonds is the previous quasi coupon date calculated as if the frequency is semiannual.

PreviousCouponDate is returned as a serial date number. The function datestr converts a serial date number to a formatted date string.

Examples

```
PreviousCouponDate = cpndatep('14 Mar 1997', '30 Jun 2000',...  
2, 0, 0);
```

```
datestr(PreviousCouponDate)
```

```
ans =
```

```
30-Dec-1996
```

```
PreviousCouponDate = cpndatep('14 Mar 1997', '30 Jun 2000',...  
2, 0, 1);
```

```
datestr(PreviousCouponDate)
```

```
ans =
```

```
31-Dec-1996
```

```
Maturity = ['30 Apr 2000'; '31 May 2000'; '30 Jun 2000'];
```

```
PreviousCouponDate = cpndatep('14 Mar 1997', Maturity);
```

```
datestr(PreviousCouponDate)
```

```
ans =
```

```
31-Oct-1996
```

```
30-Nov-1996
```

cpndatepq

Purpose Previous quasi coupon date for fixed income security

Syntax PreviousQuasiCouponDate = cpndatepq(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate)

Arguments

Settle	Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than or equal to Maturity.
Maturity	Maturity date. A vector of serial date numbers or date strings.
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
Basis	(Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)

EndMonthRule	(Optional) End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.
IssueDate	(Optional) Date when a bond was issued.
FirstCouponDate	(Optional) Date when a bond makes its first coupon payment. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.
LastCouponDate	(Optional) Last coupon date of a bond prior to the maturity date. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate regardless of where it falls and will be followed only by the bond's maturity cash flow date.

Required arguments must be number of bonds (NUMBONDS) by 1 or 1-by-NUMBONDS conforming vectors or scalars. Optional arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices. Fill unspecified entries in input vectors with the value NaN. Dates can be serial date numbers or date strings.

Description

PreviousQuasiCouponDate = cpndatepq(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate) determines the previous quasi coupon date on or before settlement for a set of NUMBONDS fixed income securities. This

function finds the previous quasi coupon date for a bond with a coupon structure in which the first or last period is either normal, short, or long (whether or not the coupon structure is synchronized to maturity). For zero coupon bonds this function returns quasi coupon dates as if the bond had a semiannual coupon structure.

The term “previous quasi coupon date” refers to the previous coupon date for a bond calculated as if no issue date were specified. Although the issue date is not actually a coupon date, when issue date is specified, the previous actual coupon date for a bond is normally calculated as being either the previous coupon date or the issue date, whichever is greater. This function always returns the previous quasi coupon date regardless of issue date. If the settlement date is a coupon date, this function returns the settlement date.

PreviousQuasiCouponDate is returned as a serial date number. The function datestr converts a serial date number to a formatted date string.

Examples

Given a pair of bonds with the characteristics

```
Settle = char('30-May-1997','10-Dec-1997');  
Maturity = char('30-Nov-2002','10-Jun-2004');
```

With no FirstCouponDate explicitly supplied, compute the PreviousCouponDate for this pair of bonds.

```
PreviousCouponDate = cpndatepq(Settle, Maturity);  
  
datestr(PreviousCouponDate)  
  
ans =  
  
30-Nov-1996  
10-Dec-1997
```

Note that since the settlement date for the second bond is also a coupon date, cpndatepq returns this date as the previous coupon date.

Now establish a FirstCouponDate and IssueDate for this pair of bonds.

```
FirstCouponDate = char('30-Nov-1997', '10-Dec-1998');
IssueDate = char('30-May-1996', '10-Dec-1996');
```

Recompute the PreviousCouponDate for this pair of bonds.

```
PreviousCouponDate = cpndatep(Settle, Maturity, 2, 0, 1, ...
IssueDate, FirstCouponDate);
```

```
datestr(PreviousCouponDate)
```

```
ans =
```

```
30-May-1996
10-Dec-1996
```

Since both of these bonds settled before the first coupon had been paid, cpndatep returns the IssueDate as the PreviousCouponDate.

Using the same data, compute PreviousQuasiCouponDate.

```
PreviousQuasiCouponDate = cpndatepq(Settle, Maturity, 2, 0, 1, ...
IssueDate, FirstCouponDate);
```

```
datestr(PreviousQuasiCouponDate)
```

```
ans =
```

```
30-Nov-1996
10-Dec-1997
```

For the first bond the settlement date is not a normal coupon date. The PreviousQuasiCouponDate is the coupon date prior to or on the settlement date. Since the coupon structure is synchronized to FirstCouponDate, the previous quasi coupon date is 30-Nov-1996. PreviousQuasiCouponDate disregards IssueDate and FirstCouponDate in this case. For the second bond the settlement date

cpndatepq

(10-Dec-1997) occurs on a date when a coupon would normally be paid in the absence of an explicit FirstCouponDate. cpndatepq returns this date as PreviousQuasiCouponDate.

Purpose Number of days to next coupon date

Syntax NumDaysNext = cpndaysn(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate)

Arguments

- | | |
|----------|---|
| Settle | Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than or equal to Maturity. |
| Maturity | Maturity date. A vector of serial date numbers or date strings. |
| Period | (Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12. |
| Basis | (Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none"> • 0 = actual/actual (default) • 1 = 30/360 (SIA) • 2 = actual/360 • 3 = actual/365 • 4 = 30/360 (PSA) • 5 = 30/360 (ISDA) • 6 = 30/360 (European) • 7 = actual/365 (Japanese) • 8 = actual/actual (ISMA) • 9 = actual/360 (ISMA) |

	<ul style="list-style-type: none">• 10 = actual/365 (ISMA)
EndMonthRule	(Optional) End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.
IssueDate	(Optional) Date when a bond was issued.
FirstCouponDate	(Optional) Date when a bond makes its first coupon payment. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.
LastCouponDate	(Optional) Last coupon date of a bond prior to the maturity date. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate regardless of where it falls and will be followed only by the bond's maturity cash flow date.
StartDate	(Future implementation; optional) Date when a bond actually starts (the date from which a bond's cash flows can be considered). To make an instrument forward-starting, specify this date as a future date. If StartDate is not explicitly specified, the effective start date is the settlement date.

Required arguments must be number of bonds (NUMBONDS) by 1 or 1-by-NUMBONDS conforming vectors or scalars. Optional arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices.

Description

NumDaysNext = cpndaysn(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate) returns the number of days from the settlement date to the next coupon date for a bond or set of bonds. For zero coupon bonds coupon dates are computed as if the bonds have a semiannual coupon structure.

Examples

```
NumDaysNext = cpndaysn('14 Sep 2000', '30 Jun 2001', 2, 0, 0)
```

```
NumDaysNext =
```

```
107
```

```
NumDaysNext = cpndaysn('14 Sep 2000', '30 Jun 2001', 2, 0, 1)
```

```
NumDaysNext =
```

```
108
```

```
Maturity = ['30 Apr 2001'; '31 May 2001'; '30 Jun 2001'];
```

```
NumDaysNext = cpndaysn('14 Sep 2000', Maturity)
```

```
NumDaysNext =

cpndaysp

Purpose Number of days since previous coupon date

Syntax NumDaysPrevious = cpndaysp(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate)

Arguments

Settle	Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than or equal to Maturity.
Maturity	Maturity date. A vector of serial date numbers or date strings.
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
Basis	(Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)

	<ul style="list-style-type: none"> • 10 = actual/365 (ISMA)
EndMonthRule	(Optional) End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.
IssueDate	(Optional) Date when a bond was issued.
FirstCouponDate	(Optional) Date when a bond makes its first coupon payment. When FirstCouponDate and LastCouponDate are both specified, FirstCouponDate takes precedence in determining the coupon payment structure.
LastCouponDate	(Optional) Last coupon date of a bond prior to the maturity date. In the absence of a specified FirstCouponDate, a specified LastCouponDate determines the coupon structure of the bond. The coupon structure of a bond is truncated at the LastCouponDate regardless of where it falls and will be followed only by the bond's maturity cash flow date.
StartDate	(Future implementation; optional) Date when a bond actually starts (the date from which a bond's cash flows can be considered). To make an instrument forward-starting, specify this date as a future date. If StartDate is not explicitly specified, the effective start date is the settlement date.

cpndaysp

Required arguments must be a number of bonds (NUMBONDS) by 1 or 1-by-NUMBONDS conforming vectors or scalars. Optional arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices.

Description

NumDaysPrevious = cpndaysp(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate) returns the number of days between the previous coupon date and the settlement date for a bond or set of bonds. When the coupon frequency is 0 (a zero coupon bond), the previous coupon date is calculated as if the frequency were semiannual.

Examples

```
NumDaysPrevious = cpndaysp('14 Mar 2000', '30 Jun 2001', 2, 0, 0)
```

```
NumDaysPrevious =
```

```
75
```

```
NumDaysPrevious = cpndaysp('14 Mar 2000', '30 Jun 2001', 2, 0, 1)
```

```
NumDaysPrevious =
```

```
74
```

```
Maturity = ['30 Apr 2001'; '31 May 2001'; '30 Jun 2001'];
```

```
NumDaysPrevious = cpndaysp('14 Mar 2000', Maturity)
```

```
NumDaysPrevious =
```

```

Purpose Number of days in coupon period

Syntax NumDaysPeriod = cpnpersz(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate)

Arguments

Settle	Settlement date. A vector of serial date numbers or date strings. Settle must be earlier than or equal to Maturity.
Maturity	Maturity date. A vector of serial date numbers or date strings.
Period	(Optional) Coupons per year of the bond. A vector of integers. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.
Basis	(Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)

	<ul style="list-style-type: none">• 10 = actual/365 (ISMA)
EndMonthRule	(Optional) End-of-month rule. A vector. This rule applies only when <code>Maturity</code> is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.
IssueDate	(Optional) Date when a bond was issued.
FirstCouponDate	(Optional) Date when a bond makes its first coupon payment. When <code>FirstCouponDate</code> and <code>LastCouponDate</code> are both specified, <code>FirstCouponDate</code> takes precedence in determining the coupon payment structure.
LastCouponDate	(Optional) Last coupon date of a bond prior to the maturity date. In the absence of a specified <code>FirstCouponDate</code> , a specified <code>LastCouponDate</code> determines the coupon structure of the bond. The coupon structure of a bond is truncated at the <code>LastCouponDate</code> regardless of where it falls and will be followed only by the bond's maturity cash flow date.
StartDate	(Future implementation; optional) Date when a bond actually starts (the date from which a bond's cash flows can be considered). To make an instrument forward-starting, specify this date as a future date. If <code>StartDate</code> is not explicitly specified, the effective start date is the settlement date.

Required arguments must be a number of bonds (NUMBONDS) by 1 or 1-by-NUMBONDS conforming vectors or scalars. Optional arguments must be either NUMBONDS-by-1 or 1-by-NUMBONDS conforming vectors, scalars, or empty matrices.

Description

NumDaysPeriod = cpnpersz(Settle, Maturity, Period, Basis, EndMonthRule, IssueDate, FirstCouponDate, LastCouponDate, StartDate) returns the number of days in the coupon period containing the settlement date. For zero coupon bonds coupon dates are computed as if the bonds have a semiannual coupon structure.

Examples

```
NumDaysPeriod = cpnpersz('14 Sep 2000', '30 Jun 2001', 2, 0, 0)
```

```
NumDaysPeriod =
```

```
183
```

```

cumsum

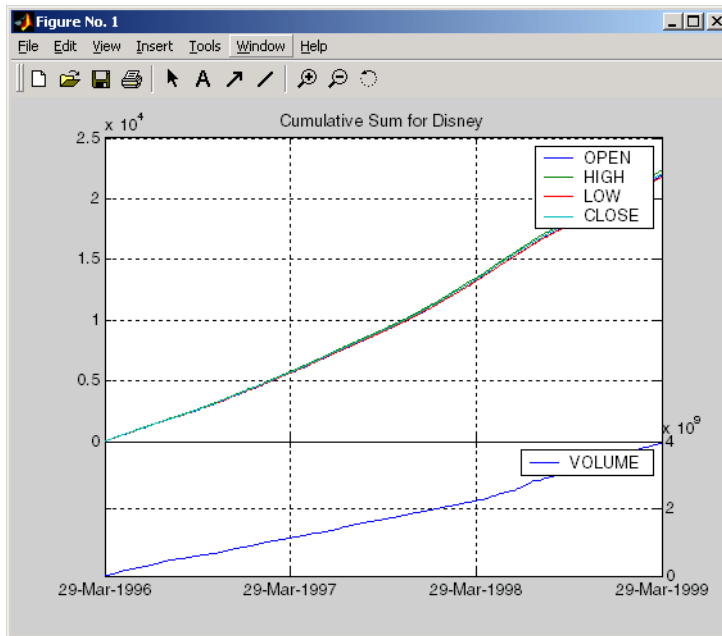

Purpose Cumulative sum

Syntax `newfts = cumsum(oldfts)`

Description `newfts = cumsum(oldfts)` calculates the cumulative sum of each individual time series data series in the financial time series object `oldfts` and returns the result in another financial time series object `newfts`. `newfts` contains the same data series names as `oldfts`.

Examples Compute the cumulative sum for Disney stock and plot the results:

```
load disney.mat
cs_dis = cumsum(fillfts(dis));
plot(cs_dis)
title('Cumulative Sum for Disney')
```

See Also [cumsum](#) in the MATLAB documentation

cur2frac

Purpose Decimal currency values to fractional values

Syntax `Fraction = cur2frac(Decimal, Denominator)`

Description `Fraction = cur2frac(Decimal, Denominator)` converts decimal currency values to fractional values. `Fraction` is returned as a string.

Examples `Fraction = cur2frac(12.125, 8)`

returns `Fraction = 12.1`, a string.

See Also `cur2str`, `frac2cur`

Purpose Bank-formatted text

Syntax `String = cur2str(Value, Digits)`

Description `String = cur2str(Value, Digits)` returns the given value in bank format. By default, `Digits = 2`. A negative `Digits` rounds the value to the left of the decimal point. `String` is returned as a string with a leading dollar sign (\$). Negative numbers are displayed in parentheses.

Examples `String = cur2str(-8264, 2)`

returns `String = ($8264.00)`

See Also `cur2frac, frac2cur`

date2time

Purpose Time and frequency from dates

Syntax [TFactors, F] = date2time(Settle, Maturity, Compounding, Basis, EndMonthRule)

Arguments

Settle	Settlement date. A vector of serial date numbers or date strings.
Maturity	A vector of serial maturity dates.
Compounding	Scalar value representing the rate at which the input zero rates were compounded when annualized. This argument determines the formula for the discount factors: <ul style="list-style-type: none">• Compounding = 1, 2, 3, 4, 6, 12• $\text{Disc} = (1 + Z/F)^{-T}$, where F is the compounding frequency, Z is the zero rate, and T is the time in periodic units, for example, $T = F$ is one year.• Compounding = 365• $\text{Disc} = (1 + Z/F)^{-T}$, where F is the number of days in the basis year and T is a number of days elapsed computed by basis.• Compounding = -1• $\text{Disc} = \exp(-T*Z)$, where T is time in years.

Basis	<p>(Optional) Day-count basis of the instrument. A vector of integers.</p> <ul style="list-style-type: none"> • 0 = actual/actual (default) • 1 = 30/360 (SIA) • 2 = actual/360 • 3 = actual/365 • 4 = 30/360 (PSA) • 5 = 30/360 (ISDA) • 6 = 30/360 (European) • 7 = actual/365 (Japanese) • 8 = actual/actual (ISMA) • 9 = actual/360 (ISMA) • 10 = actual/365 (ISMA)
EndMonthRule	<p>(Optional) End-of-month rule. A vector. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.</p>

Description

[TFactors, F] = date2time(Settle, Maturity, Compounding, Basis, EndMonthRule) computes time factors appropriate to compounded rate quotes between the settlement and maturity dates.

TFactors is a vector of time factors.

F is a scalar of related compounding frequencies.

date2time

date2time is the inverse of time2date.

See Also

cftimes, disc2rate, rate2disc, time2date

Purpose Convert serial-date axis labels to calendar-date axis labels

Syntax `dateaxis(Aksis, DateForm, StartDate)`

Arguments

<code>Aksis</code>	(Optional) Determines which axis tick labels— <i>x</i> , <i>y</i> , or <i>z</i> —to replace. Enter as a string. Default = 'x'.
<code>DateForm</code>	(Optional) Specifies which date format to use. Enter as an integer from 0 to 17. If no <code>DateForm</code> argument is entered, this function determines the date format based on the span of the axis limits. For example, if the difference between the axis minimum and maximum is less than 15, the tick labels are converted to three-letter day-of-the-week abbreviations (<code>DateForm</code> = 8). See <code>DateForm</code> format descriptions below.
<code>StartDate</code>	(Optional) Assigns the date to the first axis tick value. Enter as a string. The tick values are treated as serial date numbers. The default <code>StartDate</code> is the lower axis limit converted to the appropriate date number. For example, a tick value of 1 is converted to the date 01-Jan-0000. Entering <code>StartDate</code> as '06-apr-1999' assigns the date April 6, 1999 to the first tick value and the axis tick labels are set accordingly.

Description `dateaxis(Aksis, DateForm, StartDate)` replaces axis tick labels with date labels on a graphic figure.

See the MATLAB `set` command for information on modifying the axis tick values and other axis parameters.

dateaxis

DateForm	Format	Description
0	01-Mar-1999 15:45:17	day-month-year hour:minute:second
1	01-mar-1999	day-month-year
2	03/01/99	month/day/year
3	Mar	month, three letters
4	M	month, single letter
5	3	month
6	03/01	month/day
7	1	day of month
8	Wed	day of week, three letters
9	W	day of week, single letter
10	1999	year, four digits
11	99	year, two digits
12	Mar99	month year
13	15:45:17	hour:minute:second
14	03:45:17 PM	hour:minute:second AM or PM
15	15:45	hour:minute
16	03:45 PM	hour:minute AM or PM
17	95/03/01	year month day

Examples

```
dateaxis('x') or dateaxis
```

converts the *x*-axis labels to an automatically determined date format.

```
dateaxis('y', 6)
```

converts the *y*-axis labels to the month/day format.

```
dateaxis('x', 2, '03/03/1999')
```

converts the *x*-axis labels to the month/day/year format. The minimum *x*-tick value is treated as March 3, 1999.

datedisp

Purpose Display date entries

Syntax `datedisp(NumMat, DateForm)`
`CharMat = datedisp(NumMat, DateForm)`

Arguments

`NumMat` Numeric matrix to display.
`DateForm` (Optional) Date format. See `datestr` for available and default format flags.

Description

`datedisp(NumMat, DateForm)` displays a matrix with the serial dates formatted as date strings, using a matrix with mixed numeric entries and serial date number entries. Integers between `datenum('01-Jan-1900')` and `datenum('01-Jan-2200')` are assumed to be serial date numbers, while all other values are treated as numeric entries.

`CharMat` is a character array representing `NumMat`. If no output variable is assigned, the function prints the array to the display.

Examples

```
NumMat = [730730, 0.03, 1200 730100;  
          730731, 0.05, 1000 NaN]
```

```
NumMat =
```

```
1.0e+05 *
```

```
7.3073    0.0000    0.0120    7.3010  
7.3073    0.0000    0.0100         NaN
```

```
datedisp(NumMat)
```

```
01-Sep-2000    0.03    1200    11-Dec-1998
```

02-Sep-2000 0.05 1000 NaN

See Also

datestr

datefind

Purpose Indices of date numbers in matrix

Syntax `Indices = datefind(Subset, Superset, Tolerance)`

Arguments

Subset	Subset matrix of date numbers used to find matching date numbers in Superset. These date numbers must be a nonrepeating subset of those in Superset.
Superset	Superset matrix of nonrepeating date numbers whose elements are sought.
Tolerance	(Optional) Tolerance (+/-) for matching the date numbers in Superset. A positive integer. Default = 0.

Description `Indices = datefind(Subset, Superset, Tolerance)` returns a vector of indices to the date numbers in Superset that are present in Subset, plus or minus the Tolerance. If no date numbers match, `Indices = []`.

Although this function was designed for use with sequential date numbers, you can use it with any nonrepeating integers.

Examples

```
Superset = datenum(1999, 7, 1:31);  
Subset = [datenum(1999, 7, 10); datenum(1999, 7, 20)];  
Indices = datefind(Subset, Superset, 1)  
  
Indices =  
  
     9  
    10
```

11
19
20
21

See Also datenum

datemnth

Purpose Date of day in future or past month

Syntax TargetDate = datemnth(StartDate, NumberMonths, DayFlag, Basis, EndMonthRule)

Arguments

StartDate	Enter as serial date numbers or date strings.
NumberMonths	Vector containing number of months in future (positive) or past (negative). Values must be in integer form.
DayFlag	(Optional) Vector containing values that specify how the actual day number for the target date in future or past month is determined. 0 (default) = day number should be the day in the future or past month corresponding to the actual day number of the start date. 1 = day number should be the first day of the future or past month. 2 = day number should be the last day of the future or past month. This flag has no effect if EndMonthRule is set to 1.
Basis	(Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)

- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ISMA)
- 9 = actual/360 (ISMA)
- 10 = actual/365 (ISMA)

EndMonthRule (Optional) End-of-month rule. A vector. 1 = rule in effect, meaning that if you are beginning on the last day of a month, and the month has 30 or fewer days, you will end on the last actual day of the future or past month regardless of whether that month has 28, 29, 30 or 31 days) 0 = rule off (default), meaning that the rule is not in effect.

Any input can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all. For example, if `StartDate` is an n-row character array of date strings, then `NumberMonths` must be an n-by-1 vector of integers or a single integer. `TargetDate` is then an n-by-1 vector of date numbers.

Description

`TargetDate = datemnth(StartDate, NumberMonths, DayFlag, Basis, EndMonthRule)` returns the serial date number of the target date in the future or past.

Use `datestr` to convert serial date numbers to formatted date strings.

Examples

```
Day = datemnth('3 jun 2001', 6, 0, 0, 0)
Day =
    731188
datestr(Day)
ans =
    03-Dec-2001
```

datemnth

```
Day = datemnth('3 jun 2001', 6, 1, 0, 1); datestr(Day)
ans =
01-Dec-2001
```

```
Day = datemnth('31 jan 2001', 5, 0, 0, 0); datestr(Day)
ans =
30-Jun-2001
```

```
Day = datemnth('31 jan 2001', 5, 1, 0, 0); datestr(Day)
ans =
01-Jun-2001
```

```
Day = datemnth('31 jan 2001', 5, 1, 0, 1); datestr(Day)
ans =
30-Jun-2001
```

```
Day = datemnth('31 jan 2001', 5, 2, 0, 1); datestr(Day)
ans =
30-Jun-2001
```

```
Months = [1; 3; 5; 7; 9];
Day = datemnth('31 jan 2001', Months); datestr(Day)
ans =
28-Feb-2001
30-Apr-2001
30-Jun-2001
31-Aug-2001
31-Oct-2001
```

datestr, datevec, days360, days365, daysact, daysdif, wrkdydif

Purpose Create date number

Syntax

```
DateNumber = datenum(DateString)
DateNumber = datenum(DateString, Pivot)
DateNumber = datenum(Year, Month, Day)
DateNumber = datenum(Year, Month, Day, Hour, Minute, Second)
```

Description `DateNumber = datenum(DateString)` returns a serial date number given a date string. Date numbers are the number of days that has passed since a base date. *In MATLAB, date number 1 is January 1, 0000 A.D.* If the input includes time components, the date number includes a fractional component.

The date string can be any of several forms.

```
'19-may-1999'
'may 19, 1999'
'19-may-99'
'19-may' (current year assumed)
'5/19/99'
'5/19' (current year assumed)
'19-may-1999, 18:37'
'19-may-1999, 6:37 pm'
'5/19/99/18:37'
'5/19/99/6:37 pm'
```

Certain formats may not contain enough information to compute a date number. In these cases, missing values default to 0 for hours, minutes, and seconds; January for the month; and 1 for the day of month. The year defaults to the current year. Unless you specify a pivot year, date strings with two-character years; for example, 12-june-12, are assumed to lie within the 100-year period centered about the current year.

`DateNumber = datenum(DateString, Pivot)` assumes that two-character years lie within the 100-year period beginning with the pivot year. The default pivot year is the current year minus 50 years.

datenum

`DateNumber = datenum(Year, Month, Day)` returns a serial date number given year, month, and day integers.

`DateNumber = datenum(Year, Month, Day, Hour, Minute, Second)` returns a serial date number given year, month, day, hour, minute, and second integers.

Note This function now ships with basic MATLAB. It originally shipped only with Financial Toolbox. This description remains here for your convenience.

Examples

Example 1.

```
DateNumber = datenum('19-may-1999')  
DateNumber = 730259
```

```
DateNumber = datenum('5/19/99')  
DateNumber = 730259
```

```
DateNumber = datenum('19-may-1999, 6:37 pm')  
DateNumber = 730259.78
```

```
DateNumber = datenum('5/19/99/18:37')  
DateNumber = 730259.78
```

```
DateNumber = datenum(1999, 5, 19)  
DateNumber = 730259
```

```
DateNumber = datenum(1999, 1:6, 19)  
DateNumber = [730139 730170 730198 730229 730259 730290]
```

```
DateNumber = datenum(1999, 5, 19, 18, 37, 0)  
DateNumber = 730259.78
```

```
DateNumber = datenum(730259)
```

```
DateNumber = 730259
```

Example 2. The next example demonstrates the use of the pivot year in interpreting date strings with two-character years.

```
DateNumber = datenum('12-june-12')
DateNumber =
    735032
datestr(735032)
ans =
    12-Jun-2012
```

```
DateNumber = datenum('12-june-12',1900)
DateNumber =
    698507
datestr(698507)
ans =
    12-Jun-1912
```

datestr

Purpose Create date string

Syntax
DateString = datestr(Date, DateForm)
DateString = datestr(Date, DateForm, Pivot)
DateString = datestr(Date)

Description DateString = datestr(Date, DateForm) converts a date number or a date string to a date string. DateForm specifies the format of DateString. Date strings with two-character years; for example, 12-june-12, are assumed to lie within the 100-year period centered about the current year.

DateString = datestr(Date, DateForm, Pivot) assumes that two-character years lie within the 100-year period beginning with the pivot year. The default pivot year is the current year minus 50 years.

Note MATLAB internal date handling and calculations generate no ambiguous values. However, whenever possible, programmers should use date strings containing four-digit years or serial date numbers.

DateString = datestr(Date) assumes DateForm is 1, 16, or 0 depending on whether the date number Date contains a date, time, or both, respectively. If Date is a date string, the function assumes DateForm is 1.

DateForm	Format	Example
0	'dd-mmm-yyyy HH:MM:SS'	01-Mar-2000 15:45:17
1	'dd-mmm-yyyy'	01-Mar-2000
2	'mm/dd/yy'	03/01/00
3	'mmm'	Mar
4	'm'	M

DateForm	Format	Example
5	'mm'	03
6	'mm/dd'	03/01
7	'dd'	01
8	'ddd'	Wed
9	'd'	W
10	'yyyy'	2000
11	'yy'	00
12	'mmyy'	Mar00
13	'HH:MM:SS'	15:45:17
14	'HH:MM:SS PM'	3:45:17 PM
15	'HH:MM'	15:45
16	'HH:MM PM'	3:45 PM
17	'QQ-YY'	Q1 01
18	'QQ'	Q1
19	'dd/mm'	01/03
20	'dd/mm/yy'	01/03/00
21	'mmm.dd.yyyy HH:MM:SS'	Mar.01,2000 15:45:17
22	'mmm.dd.yyyy'	Mar.01.2000
23	'mm/dd/yyyy'	03/01/2000
24	'dd/mm/yyyy'	01/03/2000
25	'yy/mm/dd'	00/03/01
26	'yyyy/mm/dd'	2000/03/01
27	'QQ-YYYY'	Q1-2001
28	'mmyyyy'	Mar2000

Note This function now ships with basic MATLAB. It originally shipped only with Financial Toolbox. This description remains here for your convenience.

Examples

```
DateString = datestr(730123, 1)
DateString = 03-Jan-1999
```

```
DateString = datestr(730123, 2)
DateString = 01/03/99
```

```
DateString = datestr(730123, 12)
DateString = Jan99
```

```
DateString = datestr(730123.776, 0)
DateString = 03-Jan-1999 18:37:26
```

```
DateString = datestr('1/03', 1) (assuming the current year is 1999)
DateString = 03-Jan-1999
```

```
DateString = datestr(730123)
DateString = 03-Jan-1999
```

```
DateString = datestr([730123 730154 730182 730213 730243 730274])
DateString =
03-Jan-1999
03-Feb-1999
03-Mar-1999
03-Apr-1999
03-May-1999
03-Jun-1999
```

```
DateString = datestr('1/03')
DateString = 03-Jan-1999 (assuming the current year is 1999)
```

See Also dateaxis, datedisp, datenum, datevec, daysact, now, today

datevec

Purpose Date components

Syntax DateVector = datevec(Date)
DateVector = datevec(Date, Pivot)
[Year, Month, Day, Hour, Minute, Second] = datevec(Date)

Description DateVector = datevec(Date) converts a date number or a date string to a date vector whose elements are [Year Month Day Hour Minute Second]. The first five elements are integers, the sixth is a floating-point number. Date strings with two-character years; for example, 12-june-12, are assumed to lie within the 100-year period centered about the current year.

DateVector = datevec(Date, Pivot) assumes that two-character years lie within the 100-year period beginning with the pivot year. The default pivot year is the current year minus 50 years.

Note MATLAB internal date handling and calculations generate no ambiguous values. However, whenever possible, programmers should use date strings containing four-digit years or serial date numbers.

[Year, Month, Day, Hour, Minute, Second] = datevec(Date) converts a date number or a date string to a date vector and returns the components of the date vector as individual variables.

Note This function now ships with basic MATLAB. It originally shipped only with Financial Toolbox. This description remains here for your convenience.

Examples

```
DateVec = datevec('28-Jul-00')
DateVec =
    2000     7     28     0     0     0
```

```
DateVec = datevec(730695)
DateVec =
    2000     7     28     0     0     0
DateVec = datevec(730695.776)

DateVec =
    2000     7     28     18     37     26.4

[Year, Month, Day, Hour, Minute, Second] = datevec(730695.776)

Year =
    2000

Month =
     7

Day =
    28

Hour =
    18

Minute =
    37

Second =
    26.4

[Year, Month, Day] = datevec(730695:730697)

Year =
    2000    2000    2000

Month =
     7     7     7
```

datevec

Day =
28 29 30

See Also datenum, datestr, now, today

Purpose Date of future or past workday

Syntax `EndDate = datewrkdy(StartDate, NumberWorkDays, NumberHolidays)`

Arguments

StartDate	Start date vector. Enter as serial date numbers or date strings.
NumberWorkDays	Vector containing number of work or business days in future (positive) or past (negative), including the starting date.
NumberHolidays	Vector containing values for the number of holidays within NumberWorkDays. NumberHolidays and NumberWorkDays must have the same sign.

Any input can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all. For example, if StartDate is an n-row character array of date strings, then NumberWorkDays must be an n-by-1 vector of integers or a single integer. EndDate is then an n-by-1 vector of date numbers.

Description

`EndDate = datewrkdy(StartDate, NumberWorkDays, NumberHolidays)` returns the serial number of the date a given number of workdays before or after the start date.

Use `datestr` to convert serial date numbers to formatted date strings.

Examples

```
Workday = datewrkdy('12-dec-2000', 16, 2);  
datestr(Workday)  
ans =  
04-Jan-2001  
NumDays = [16; 20; 44];
```

datewrkdy

```
Workdays = datewrkdy('12-dec-2000', NumDays, 2);  
datestr(Workdays)  
ans =  
4-Jan-2001  
10-Jan-2001  
13-Feb-2001
```

busdate, holidays, isbusday, wrkdydif

Purpose Day of month

Syntax DayMonth = day(Date)

Description DayMonth = day(Date) returns the day of the month given a serial date number or date string.

Examples DayMonth = day(730544)

or

DayMonth = day('2/28/00')

returns DayMonth = 28

See Also datevec, eomday, month, year

days360

Purpose Days between dates based on 360-day year

Syntax NumDays = days360(StartDate, EndDate)

Arguments

StartDate Enter as serial date numbers or date strings.

EndDate Enter as serial date numbers or date strings.

Either input can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if StartDate is an n-row character array of date strings, then EndDate must be an n-by-1 vector of integers or a single integer. NumDays is then an n-by-1 vector of date numbers.

Description NumDays = days360(StartDate, EndDate) returns the number of days between StartDate and EndDate based on a 360-day year (that is, all months contain 30 days). If EndDate is earlier than StartDate, NumDays is negative.

Examples

```
NumDays = days360('15-jan-2000', '15-mar-2000')
```

```
NumDays =
```

```
60
```

```
MoreDays = ['15-mar-2000'; '15-apr-2000'; '15-jun-2000'];
```

```
NumDays = days360('15-jan-2000', MoreDays)
```

```
NumDays =
```

```
60
```

```
90
```

days365, daysact, daysdif, wrkdydif, yearfrac

days360e

Purpose Days between dates based on 360-day year (European)

Syntax NumDays = days360e(StartDate, EndDate)

Arguments

StartDate Row vector, column vector, or scalar value in serial date number or date string format.

EndDate Row vector, column vector, or scalar value in serial date number or date string format.

Either input can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all.

Description NumDays = days360e(StartDate, EndDate) returns a vector or scalar value representing the number of days between StartDate and EndDate based on a 360-day year (that is, all months contain 30 days). If EndDate is earlier than StartDate, NumDays is negative.

This day count convention is used primarily in Europe. Under this convention all months contain 30 days.

Examples Example 1. Use this convention to find the number of days in the month of January.

```
StartDate = '1-Jan-2002';  
EndDate = '1-Feb-2002';  
NumDays = days360e(StartDate, EndDate)
```

```
NumDays =
```

```
30
```

Example 2. Use this convention to find the number of days in February during a leap year.

```
StartDate = '1-Feb-2000';  
EndDate = '1-Mar-2000';  
NumDays = days360e(StartDate, EndDate)
```

```
NumDays =
```

```
30
```

Example 3. Use this convention to find the number of days in February of a non-leap year.

```
StartDate = '1-Feb-2002';  
EndDate = '1-Mar-2002';  
  
NumDays = days360e(StartDate, EndDate)
```

```
NumDays =
```

```
30
```

See Also

days360, days360isda, days360psa

days360isda

Purpose Days between dates based on 360-day year (International Swap Dealer Association (ISDA) compliant)

Syntax NumDays = days360isda(StartDate, EndDate)

Arguments

StartDate Row vector, column vector, or scalar value in serial date number or date string format.

EndDate Row vector, column vector, or scalar value in serial date number or date string format.

Either input can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all.

Description NumDays = days360isda(StartDate, EndDate) returns a vector or scalar value representing the number of days between StartDate and EndDate based on a 360-day year (that is, all months contain 30 days). If EndDate is earlier than StartDate, NumDays is negative.

Under this convention all months contain 30 days.

Examples Example 1. Use this convention to find the number of days in the month of January.

```
StartDate = '1-Jan-2002';  
EndDate = '1-Feb-2002';  
NumDays = days360isda(StartDate, EndDate)
```

```
NumDays =
```

```
30
```

Example 2. Use this convention to find the number of days in February during a leap year.

```
StartDate = '1-Feb-2000';  
EndDate = '1-Mar-2000';  
NumDays = days360isda(StartDate, EndDate)
```

```
NumDays =
```

```
30
```

Example 3. Use this convention to find the number of days in February of a non leap year.

```
StartDate = '1-Feb-2002';  
EndDate = '1-Mar-2002';  
NumDays = days360isda(StartDate, EndDate)
```

```
NumDays =
```

```
30
```

See Also

days360, days360e, days360psa

days360psa

Purpose Days between dates based on 360-day year (Public Securities Association (PSA) compliant)

Syntax NumDays = days360psa(StartDate, EndDate)

Arguments

StartDate Row vector, column vector, or scalar value in serial date number or date string format.

EndDate Row vector, column vector, or scalar value in serial date number or date string format.

Either input can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all.

Description NumDays = days360psa(StartDate, EndDate) returns a vector or scalar value representing the number of days between StartDate and EndDate based on a 360-day year (that is, all months contain 30 days). If EndDate is earlier than StartDate, NumDays is negative.

Under this payment convention all months contain 30 days. In both leap and non-leap years, if the StartDate is the last day of February, this day is considered to be day 30 of the month.

Examples Example 1. Use this convention to find the number of days in between the last day of February and the first day of March during a leap year.

```
StartDate = '29-Feb-2000';  
EndDate = '1-Mar-2000';  
NumDays = days360psa(StartDate, EndDate)
```

```
NumDays =
```

```
1
```

Example 2. Use this convention to find the number of days in between the last day of February and the first day of March during a non-leap year.

```
StartDate = '28-Feb-2002';  
EndDate = '1-Mar-2002';  
NumDays = days360psa(StartDate, EndDate)
```

```
NumDays =
```

```
1
```

As expected, the number of days in both cases is the same. The convention always assumes that the last day of February is the 30th day.

See Also

days360, days360e, days360isda

days365

Purpose Days between dates based on 365-day year

Syntax NumDays = days365(StartDate, EndDate)

Arguments

StartDate Enter as serial date numbers or date strings.

EndDate Enter as serial date numbers or date strings.

Either input can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if StartDate is an n-row character array of date strings, then EndDate must be an n-by-1 vector of integers or a single integer. NumDays is then an n-by-1 vector of date numbers.

Description NumDays = days365(StartDate, EndDate) returns the number of days between dates StartDate and EndDate based on a 365-day year. (All months contain their actual number of days. February always contains 28 days.) If EndDate is earlier than StartDate, NumDays is negative. Enter dates as serial date numbers or date strings.

Examples

```
NumDays = days365('15-jan-2000', '15-mar-2000')
```

```
NumDays =
```

```
59
```

```
MoreDays = ['15-mar-2000'; '15-apr-2000'; '15-jun-2000'];
```

```
NumDays = days365('15-jan-2000', MoreDays)
```

```
NumDays =
```

```
59
```

90

See Also

days360, daysact, daysdif, wrkdydif, yearfrac

daysact

Purpose Actual number of days between dates

Syntax NumDays = daysact(StartDate, EndDate)

Arguments

StartDate Enter as serial date numbers or date strings.

EndDate (Optional) Enter as serial date numbers or date strings.

Either input can contain multiple values, but if so, the other must contain the same number of values or a single value that applies to all. For example, if StartDate is an n -row character array of date strings, then EndDate must be an n -row character array of date strings or a single date. NumDays is then an n -by-1 vector of numbers.

Description

NumDays = daysact(StartDate, EndDate) returns the actual number of days between two dates. Enter dates as serial date numbers or date strings. NumDays is negative if EndDate is earlier than StartDate.

NumDays = daysact(StartDate) returns the actual number of days between the MATLAB base date and StartDate. In MATLAB, the base date 1 is 1-Jan-0000 A.D. See datenum for a similar function.

Examples

```
NumDays = daysact('7-sep-2002', '25-dec-2002')
NumDays =
    109
```

```
NumDays = daysact('9/7/2002')
NumDays =
    731466
```

```
MoreDays = ['09/07/2002'; '10/22/2002'; '11/05/2002'];
NumDays = daysact(MoreDays, '12/25/2002')
```

```
NumDays =  
    109  
     64  
     50
```

See Also

datenum, datevec, days360, days365, daysdif

daysadd

Purpose Date away from starting date for any day-count basis

Syntax NumDays = daysadd(StartDate, NumDays, Basis)

Arguments

StartDate Start date. Enter as serial date numbers or date strings.

NumDays Integer number of days from start date. Enter a negative integer for dates before start date.

Basis (Optional) Day-count basis of the instrument. A vector of integers.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ISMA)
- 9 = actual/360 (ISMA)
- 10 = actual/365 (ISMA)

Note When using the 30/360 day-count basis, it is not always possible to find the exact date NumDays number of days away because of a known discontinuity in the method of counting days. A warning is displayed if this occurs.

Description

NumDays = daysadd(StartDate, NumDays, Basis) returns a date NumDays number of days away from StartDate, using the given day-count basis.

Examples

```
NewDate = daysadd('01-Feb-2004', 31)
```

```
NewDate =
```

```
732009
```

```
datestr(NewDate)
```

```
ans =
```

```
03-Mar-2004
```

```
NewDate = daysadd('01-Feb-2004', 31, 1)
```

```
NewDate =
```

```
732008
```

```
datestr(NewDate)
```

```
ans =
```

```
02-Mar-2004
```

daysadd

daysdif

Purpose Days between dates for any day-count basis

Syntax NumDays = daysdif(StartDate, EndDate, Basis)

Arguments

StartDate Enter as serial date numbers or date strings.
EndDate Enter as serial date numbers or date strings.
Basis (Optional) Day-count basis of the instrument. A vector of integers.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ISMA)
- 9 = actual/360 (ISMA)
- 10 = actual/365 (ISMA)

Any input argument can contain multiple values, but if so, the other inputs must contain the same number of values or a single value that applies to all. For example, if StartDate is an n-row character array of date strings, then EndDate must be an n-row character array of date strings or a single date. NumDays is then an n-by-1 vector of numbers.

daysdif

Description

NumDays = daysdif(StartDate, EndDate, Basis) returns the number of days between dates StartDate and EndDate using the given day-count basis. Enter dates as serial date numbers or date strings. Enter dates as serial date numbers or date strings. The first date (StartDate) is not included when determining the number of days between first and last date.

This function is a helper function for the bond pricing and yield functions. It is designed to make the code more readable and to eliminate redundant calls within if statements.

Examples

```
NumDays = daysdif('3/1/99', '3/1/00', 1)
NumDays =
    360
```

```
MoreDays = ['3/1/2001'; '3/1/2002'; '3/1/2003'];
NumDays = daysdif('3/1/98', MoreDays)
NumDays =
    1096
    1461
    1826
```

Purpose Decimal to thirty-second quotation

Syntax [OutNumber, Fractions] = dec2thirtytwo(InNumber, Accuracy)

Arguments

InNumber	Input number as a decimal fraction.
Accuracy	(Optional) Rounding. Default = 1, round down to nearest thirty second. Other values are 2 (nearest half), 4 (nearest quarter) and 10 (nearest decile).

Description

[OutNumber, Fractions] = dec2thirtytwo(InNumber, Accuracy) changes a decimal price quotation for a bond or bond future to a fraction with a denominator of 32.

OutNumber is InNumber rounded downward to the closest integer.

Fractions is the fractional part in units of thirty-second with accuracy as prescribed by the input Accuracy.

Examples

Two bonds are quoted with decimal prices of 101.78 and 102.96. Convert these prices to fractions with a denominator of 32.

```
InNumber = [101.78; 102.96];
```

```
[OutNumber, Fractions] = dec2thirtytwo(InNumber)
```

```
OutNumber =
```

```
101
```

```
102
```

```
Fractions =
```

```
25
```

dec2thirtytwo

Purpose Fixed declining-balance depreciation schedule

Syntax Depreciation = depfixdb(Cost, Salvage, Life, Period, Month)

Arguments

Cost	Scalar for the initial value of the asset.
Salvage	Scalar for the salvage value of the asset.
Life	Scalar value for the life of the asset in years.
Period	Scalar integer for the number of years to calculate.
Month	(Optional) Scalar value for the number of months in the first year of asset life. Default = 12.

Description Depreciation = depfixdb(Cost, Salvage, Life, Period, Month) calculates the fixed declining-balance depreciation for each period.

Examples A car is purchased for \$11,000 with a salvage value of \$1500 and a lifetime of eight years. To calculate the depreciation for the first five years

```
Depreciation = depfixdb(11000, 1500, 8, 5)
```

returns

```
Depreciation =
    2425.08    1890.44    1473.67    1148.78    895.52
```

See Also depgenb, deprdv, depsoyd, depstln

depgendb

Purpose General declining-balance depreciation schedule

Syntax Depreciation = depgendb(Cost, Salvage, Life, Factor)

Arguments

Cost	Cost of the asset.
Salvage	Estimated salvage value of the asset.
Life	Number of periods over which the asset is depreciated.
Factor	Depreciation factor. Factor = 2 uses the double-declining-balance method.

Description Depreciation = depgendb(Cost, Salvage, Life, Factor) calculates the declining-balance depreciation for each period.

Examples A car is purchased for \$11,000 and is to be depreciated over five years. The estimated salvage value is \$1000. Using the double-declining-balance method, the function calculates the depreciation for each year and returns the remaining depreciable value at the end of the life of the car.

```
Depreciation = depgendb(11000, 1000, 5, 2)
```

returns

```
Depreciation =  
4400.00    2640.00    1584.00    950.40    425.60
```

See Also depfixdb, deprdv, depsoyd, depstln

Purpose Remaining depreciable value

Syntax Value = deprdv(Cost, Salvage, Accum)

Arguments

Cost	Cost of the asset.
Salvage	Salvage value of the asset.
Accum	Accumulated depreciation of the asset for prior periods.

Description Value = deprdv(Cost, Salvage, Accum) returns the remaining depreciable value for an asset.

Examples The cost of an asset is \$13,000 with a life of 10 years. The salvage value is \$1000. First find the accumulated depreciation with the straight-line depreciation function, depstln. Then find the remaining depreciable value after six years.

```
Accum = depstln(13000, 1000, 10) * 6
```

```
Accum =  
    7200.00
```

```
Value = deprdv(13000, 1000, 7200)
```

```
Value =  
    4800.00
```

See Also depfixdb, depgendb, depsoyd, depstln

depsyod

Purpose Sum of years' digits depreciation

Syntax Sum = depsoyd(Cost, Salvage, Life)

Arguments

Cost	Cost of the asset.
Salvage	Salvage value of the asset.
Life	Depreciable life of the asset in years.

Description Sum = depsoyd(Cost, Salvage, Life) calculates the depreciation for an asset using the sum of years' digits method. Sum is a 1-by-Life vector of depreciation values with each element corresponding to a year of the asset's life.

Examples The cost of an asset is \$13,000 with a life of 10 years. The salvage value of the asset is \$1000.

```
Sum = depsoyd(13000, 1000, 10)'
```

returns

```
Sum =  
    2181.82  
    1963.64  
    1745.45  
    1527.27  
    1309.09  
    1090.91  
     872.73  
     654.55  
     436.36  
     218.18
```

See Also

depfixdb, depgendb, deprdv, depstln

depstln

Purpose Straight-line depreciation schedule

Syntax Depreciation = depstln(Cost, Salvage, Life)

Arguments

Cost	Cost of the asset.
Salvage	Salvage value of the asset.
Life	Depreciable life of the asset in years.

Description Depreciation = depstln(Cost, Salvage, Life) calculates straight-line depreciation for an asset.

Examples The cost of an asset is \$13,000 with a life of 10 years. The salvage value of the asset is \$1000.

```
Depreciation = depstln(13000, 1000, 10)
```

returns

```
Depreciation =  
1200
```

See Also depfixdb, depgendb, deprdv, depsoyd

Purpose Differencing

Syntax `newfts = diff(oldfts)`

Description `diff` computes the differences of the data series in a financial time series object. It returns another time series object containing the difference.

`newfts = diff(oldfts)` computes the difference of all the data in the data series of the object `oldfts` and returns the result in the object `newfts`. `newfts` is a financial time series object containing the same data series (names) as the input `oldfts`.

See Also `diff` in the MATLAB documentation

disc2zero

Purpose Zero curve given discount curve

Syntax [ZeroRates, CurveDates] = disc2zero(DiscRates, CurveDates, Settle, Compounding, Basis)

Arguments

DiscRates	Column vector of discount factors, as decimal fractions. In aggregate, the factors in DiscRates constitute a discount curve for the investment horizon represented by CurveDates.														
CurveDates	Column vector of maturity dates (as serial date numbers) that correspond to the discount factors in DiscRates.														
Settle	Serial date number that is the common settlement date for the discount rates in DiscRates.														
Compounding	(Optional) Output compounding. A scalar that sets the compounding frequency per year for annualizing the output zero rates. Allowed values are: <table><tr><td>1</td><td>Annual compounding</td></tr><tr><td>2</td><td>Semiannual compounding (default)</td></tr><tr><td>3</td><td>Compounding three times per year</td></tr><tr><td>4</td><td>Quarterly compounding</td></tr><tr><td>6</td><td>Bimonthly compounding</td></tr><tr><td>12</td><td>Monthly compounding</td></tr><tr><td>365</td><td>Daily compounding</td></tr></table>	1	Annual compounding	2	Semiannual compounding (default)	3	Compounding three times per year	4	Quarterly compounding	6	Bimonthly compounding	12	Monthly compounding	365	Daily compounding
1	Annual compounding														
2	Semiannual compounding (default)														
3	Compounding three times per year														
4	Quarterly compounding														
6	Bimonthly compounding														
12	Monthly compounding														
365	Daily compounding														

	-1	Continuous compounding
Basis		(Optional) Day-count basis for annualizing the output zero rates.
		<ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)

Description

[ZeroRates, CurveDates] = disc2zero(DiscRates, CurveDates, Settle, Compounding, Basis) returns a zero curve given a discount curve and its maturity dates.

ZeroRates Column vector of decimal fractions. In aggregate, the rates in **ZeroRates** constitute a zero curve for the investment horizon represented by **CurveDates**. The zero rates are the yields to maturity on theoretical zero-coupon bonds.

CurveDates Column vector of maturity dates (as serial date numbers) that correspond to the zero rates. This vector is the same as the input vector **CurveDates**.

Examples

Given discount factors **DiscRates** over a set of maturity dates **CurveDates**, and a settlement date **Settle**

```
DiscRates = [0.9996
             0.9947
             0.9896
             0.9866
             0.9826
             0.9786
             0.9745
             0.9665
             0.9552
             0.9466];

CurveDates = [datenum('06-Nov-2000')
             datenum('11-Dec-2000')
             datenum('15-Jan-2001')
             datenum('05-Feb-2001')
             datenum('04-Mar-2001')
             datenum('02-Apr-2001')
             datenum('30-Apr-2001')
             datenum('25-Jun-2001')
             datenum('04-Sep-2001')
             datenum('12-Nov-2001')];

Settle = datenum('03-Nov-2000');
```

Set daily compounding for the output zero curve, on an actual/365 basis.

```
Compounding = 365;  
Basis = 3;
```

Execute the function

```
[ZeroRates, CurveDates] = disc2zero(DiscRates, CurveDates,...  
Settle, Compounding, Basis)
```

which returns the zero curve ZeroRates at the maturity dates CurveDates.

```
ZeroRates =  
    0.0487  
    0.0510  
    0.0523  
    0.0524  
    0.0530  
    0.0526  
    0.0530  
    0.0532  
    0.0549  
    0.0536
```

```
CurveDates =  
    730796  
    730831  
    730866  
    730887  
    730914  
    730943  
    730971  
    731027  
    731098  
    731167
```

disc2zero

For readability, `DiscRates` and `ZeroRates` are shown here only to the basis point. However, MATLAB computed them at full precision. If you enter `DiscRates` as shown, `ZeroRates` may differ due to rounding.

`zero2disc` and other functions for “Term Structure of Interest Rates” on page 2-33

Purpose Bank discount rate of money market security

Syntax `DiscRate = discrater(Settle, Maturity, Face, Price, Basis)`

Arguments

Settle	Enter as serial date numbers or date strings. Settle must be earlier than or equal to Maturity.
Maturity	Enter as serial date numbers or date strings.
Face	Redemption (par, face) value.
Price	Price of the security.
Basis	(Optional) Day-count basis of the instrument. A vector of integers.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ISMA)
- 9 = actual/360 (ISMA)
- 10 = actual/365 (ISMA)

discrate

Description

`DiscRate = discrate(Settle, Maturity, Face, Price, Basis)` finds the bank discount rate of a security. The bank discount rate normalizes by the face value of the security (for example, U. S. Treasury Bills) and understates the true yield earned by investors.

Examples

```
DiscRate = discrate('12-jan-2000', '25-jun-2000', 100, 97.74, 0)
```

returns

```
DiscRate =
```

```
0.0501
```

a discount rate of 5.01%.

Purpose

Least-squares regression with missing data

Syntax

```
[Parameters, Covariance, Resid, Info] = ecmlsrmlle(Data, Design,  
MaxIterations, TolParam, TolObj, Param0, Covar0)
```

Arguments

Data

NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. Missing values are represented as NaNs. Only samples that are entirely NaNs are ignored. (To ignore samples with at least one NaN, use `mvnrmlle`.)

Design

A matrix or a cell array that handles two model structures:

- If `NUMSERIES = 1`, `Design` is a `NUMSAMPLES-by-NUMPARAMS` matrix with known values. This structure is the standard form for regression on a single series.
- If `NUMSERIES ≥ 1`, `Design` is a cell array. The cell array contains either one or `NUMSAMPLES` cells. Each cell contains a `NUMSERIES-by-NUMPARAMS` matrix of known values.

If `Design` has a single cell, it is assumed to have the same `Design` matrix for each sample. If `Design` has more than one cell, each cell contains a `Design` matrix for each sample.

MaxIterations (Optional) Maximum number of iterations for the estimation algorithm. Default value is 100.

TolParam (Optional) Convergence tolerance for estimation algorithm based on changes in model parameter estimates. Default value is $\sqrt{\text{eps}}$ which is about $1.0\text{e-}8$ for double precision. The convergence test for changes in model parameters is

$$\|\text{Param}_k - \text{Param}_{k-1}\| < \text{TolParam} \times (1 + \|\text{Param}_k\|)$$

where Param represents the output Parameters, and iteration $k = 2, 3, \dots$. Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both TolParam ≤ 0 and TolObj ≤ 0 , do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests.

TolObj (Optional) Convergence tolerance for estimation algorithm based on changes in the objective function. Default value is $\text{eps}^{3/4}$ which is about $1.0\text{e-}12$ for double precision. The convergence test for changes in the objective function is

$$|\text{Obj}_k - \text{Obj}_{k-1}| < \text{TolObj} \times (1 + |\text{Obj}_k|)$$

for iteration $k = 2, 3, \dots$. Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both TolParam ≤ 0 and TolObj ≤ 0 , do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests.

Param0	(Optional) NUMPARAMS-by-1 column vector that contains a user-supplied initial estimate for the parameters of the regression model. Default is a zero vector.
Covar0	(Optional) NUMSERIES-by-NUMSERIES matrix that contains a user-supplied initial or known estimate for the covariance matrix of the regression residuals. Default is an identity matrix. For covariance-weighted least-squares calculations, this matrix corresponds with weights for each series in the regression. The matrix also serves as an initial guess for the residual covariance in the expectation conditional maximization (ECM) algorithm.

Description

[Parameters, Covariance, Resid, Info] = ecmlsrml(Data, Design, MaxIterations, TolParam, TolObj, Param0, Covar0) estimates a least-squares regression model with missing data. The model has the form

$$\text{Data}_k \sim N(\text{Design}_k \times \text{Parameters}, \text{Covariance})$$

for samples $k = 1, \dots, \text{NUMSAMPLES}$.

ecmlsrml estimates a NUMPARAMS-by-1 column vector of model parameters called Parameters, and a NUMSERIES-by-NUMSERIES matrix of covariance parameters called Covariance.

ecmlsrml(Data, Design) with no output arguments plots the log-likelihood function for each iteration of the algorithm.

To summarize the outputs of ecmlsrml:

- Parameters is a NUMPARAMS-by-1 column vector of estimates for the parameters of the regression model.

- Covariance is a NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the regression model's residuals. For least-squares models, this estimate may not be a maximum likelihood estimate except under special circumstances.
- Resid is a NUMSAMPLES-by-NUMSERIES matrix of residuals from the regression.

Another output, Info, is a structure that contains additional information from the regression. The structure has these fields:

- Info.Obj – A variable-extent column vector, with no more than MaxIterations elements, that contains each value of the objective function at each iteration of the estimation algorithm. The last value in this vector, Obj(end), is the terminal estimate of the objective function. If you do least-squares, the objective function is the least-squares objective function.
- Info.PrevParameters – NUMPARAMS-by-1 column vector of estimates for the model parameters from the iteration just prior to the terminal iteration.
- Info.PrevCovariance – NUMSERIES-by-NUMSERIES matrix of estimates for the covariance parameters from the iteration just prior to the terminal iteration.

Notes

If doing covariance-weighted least-squares, Covar0 should usually be a diagonal matrix. Series with greater influence should have smaller diagonal elements in Covar0 and series with lesser influence should have larger diagonal elements.

You can configure Design as a matrix if NUMSERIES = 1 or as a cell array if NUMSERIES ≥ 1.

- If Design is a cell array and NUMSERIES = 1, each cell contains a NUMPARAMS row vector.
- If Design is a cell array and NUMSERIES > 1, each cell contains a NUMSERIES-by-NUMPARAMS matrix.

These points concern how Design handles missing data:

- Although Design should not have NaN values, ignored samples due to NaN values in Data are also ignored in the corresponding Design array.
- If Design is a 1-by-1 cell array, which has a single Design matrix for each sample, no NaN values are permitted in the array. A model with this structure must have $\text{NUMSERIES} \geq \text{NUMPARAMS}$ with $\text{rank}(\text{Design}\{1\}) = \text{NUMPARAMS}$.
- ecmlsrmlle is more strict than mvnrmlle about the presence of NaN values in the Design array.

Use the estimates in the optional output structure Info for diagnostic purposes.

Parameters	NUMPARAMS-by-1 column vector of estimates for the parameters of the regression model.
Covariance	(Optional) NUMSERIES-by-NUMSERIES matrix that contains a user-supplied estimate for the covariance matrix of the residuals of the regression. Default is an identity matrix.

Description

Objective = ecmlsrobj(Data, Design, Parameters, Covariance) computes a least-squares objective function based on current parameter estimates with missing data. Objective is a scalar that contains the least-squares objective function.

Notes

ecmlsrobj requires that Covariance be positive-definite.

Note that

```
ecmlsrobj(Data, Design, Parameters) = ecmmvnrobj(Data, ...  
Design, Parameters, IdentityMatrix)
```

where IdentityMatrix is a NUMSERIES-by-NUMSERIES identity matrix.

You can configure Design as a matrix if NUMSERIES = 1 or as a cell array if NUMSERIES ≥ 1.

- If Design is a cell array and NUMSERIES = 1, each cell contains a NUPPARAMS row vector.
- If Design is a cell array and NUMSERIES > 1, each cell contains a NUMSERIES-by-NUPPARAMS matrix.

Examples

See “Multivariate Normal Regression” on page 5-17, “Least-Squares Regression” on page 5-18, “Covariance-Weighted Least Squares” on page 5-19, “Feasible Generalized Least Squares” on page 5-20, and “Seemingly Unrelated Regression” on page 5-21.

Covariance	NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the residuals of the regression.
Method	(Optional) String that identifies method of calculation for the information matrix: <ul style="list-style-type: none"> • <code>hessian</code> - Default method. Use the expected Hessian matrix of the observed log-likelihood function. This method is recommended since the resultant standard errors incorporate the increased uncertainties due to missing data. • <code>fisher</code> - Use the Fisher information matrix.
MatrixFormat	(Optional) String that identifies parameters to be included in the Fisher information matrix: <ul style="list-style-type: none"> • <code>full</code> - Default format. Compute the full Fisher information matrix for both model and covariance parameter estimates. • <code>paramonly</code> - Compute only components of the Fisher information matrix associated with the model parameter estimates.

Description

`Fisher = ecmmvnrfish(Data, Design, Covariance, Method, MatrixFormat)` computes a Fisher information matrix based on current maximum likelihood or least-squares parameter estimates that account for missing data.

Fisher is a NUMPARAMS-by-NUMPARAMS Fisher information matrix or Hessian matrix. The size of NUMPARAMS depends on MatrixFormat and on current parameter estimates. If MatrixFormat = 'full',

$$\text{NUMPARAMS} = \text{NUMSERIES} * (\text{NUMSERIES} + 3) / 2$$

ecmmvnrfish

```
If MatrixFormat = 'paramonly',
```

```
NUMPARAMS = NUMSERIES
```

Note ecmmvnrfish operates slowly if you calculate the full Fisher information matrix.

Examples

See “Multivariate Normal Regression” on page 5-17, “Least-Squares Regression” on page 5-18, “Covariance-Weighted Least Squares” on page 5-19, “Feasible Generalized Least Squares” on page 5-20, and “Seemingly Unrelated Regression” on page 5-21.

Purpose

Multivariate normal regression with missing data

Syntax

```
[Parameters, Covariance, Resid, Info] = ecmmvnrmlc(Data, Design,  
MaxIterations, TolParam, TolObj, Param0, Covar0)
```

Arguments

Data

NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. Missing values are represented as NaNs. Only samples that are entirely NaNs are ignored. (To ignore samples with at least one NaN, use `mvnrmlc`.)

Design

A matrix or a cell array that handles two model structures:

- If `NUMSERIES = 1`, Design is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.
- If `NUMSERIES ≥ 1`, Design is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.

If Design has a single cell, it is assumed to have the same Design matrix for each sample. If Design has more than one cell, each cell contains a Design matrix for each sample.

MaxIterations (Optional) Maximum number of iterations for the estimation algorithm. Default value is 100.

TolParam (Optional) Convergence tolerance for estimation algorithm based on changes in model parameter estimates. Default value is $\text{sqrt}(\text{eps})$ which is about $1.0\text{e-}8$ for double precision. The convergence test for changes in model parameters is

$$\|\text{Param}_k - \text{Param}_{k-1}\| < \text{TolParam} \times (1 + \|\text{Param}_k\|)$$

where Param represents the output Parameters, and iteration $k = 2, 3, \dots$. Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both $\text{TolParam} \leq 0$ and $\text{TolObj} \leq 0$, do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests.

TolObj (Optional) Convergence tolerance for estimation algorithm based on changes in the objective function. Default value is $\text{eps}^{3/4}$ which is about $1.0\text{e-}12$ for double precision. The convergence test for changes in the objective function is

$$|\text{Obj}_k - \text{Obj}_{k-1}| < \text{TolObj} \times (1 + |\text{Obj}_k|)$$

for iteration $k = 2, 3, \dots$. Convergence is assumed when both the TolParam and TolObj conditions are satisfied. If both $\text{TolParam} \leq 0$ and $\text{TolObj} \leq 0$, do the maximum number of iterations (MaxIterations), whatever the results of the convergence tests.

Param0	(Optional) NUMPARAMS-by-1 column vector that contains a user-supplied initial estimate for the parameters of the regression model.
Covar0	(Optional) NUMSERIES-by-NUMSERIES matrix that contains a user-supplied initial or known estimate for the covariance matrix of the regression residuals.

Description

[Parameters, Covariance, Resid, Info] = ecmmvnrmlc(Data, Design, MaxIterations, TolParam, TolObj, Param0, Covar0) estimates a multivariate normal regression model with missing data. The model has the form

$$\text{Data}_k \sim N(\text{Design}_k \times \text{Parameters}, \text{Covariance})$$

for samples $k = 1, \dots, \text{NUMSAMPLES}$.

ecmmvnrmlc estimates a NUMPARAMS-by-1 column vector of model parameters called Parameters, and a NUMSERIES-by-NUMSERIES matrix of covariance parameters called Covariance.

ecmmvnrmlc(Data, Design) with no output arguments plots the log-likelihood function for each iteration of the algorithm.

To summarize the outputs of ecmmvnrmlc:

- Parameters is a NUMPARAMS-by-1 column vector of estimates for the parameters of the regression model.
- Covariance is a NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the regression model's residuals.
- Resid is a NUMSAMPLES-by-NUMSERIES matrix of residuals from the regression. For any missing values in Data, the corresponding residual is the difference between the conditionally imputed value for Data and the model, that is, the imputed residual.

Note The covariance estimate `Covariance` cannot be derived from the residuals.

Another output, `Info`, is a structure that contains additional information from the regression. The structure has these fields:

- `Info.Obj` – A variable-extent column vector, with no more than `MaxIterations` elements, that contains each value of the objective function at each iteration of the estimation algorithm. The last value in this vector, `Obj(end)`, is the terminal estimate of the objective function. If you do maximum likelihood estimation, the objective function is the log-likelihood function.
- `Info.PrevParameters` – `NUMPARAMS`-by-1 column vector of estimates for the model parameters from the iteration just prior to the terminal iteration.
`Info.PrevCovariance` – `NUMSERIES`-by-`NUMSERIES` matrix of estimates for the covariance parameters from the iteration just prior to the terminal iteration.

Notes

`ecmmvnrml` does not accept an initial parameter vector, since the parameters are estimated directly from the first iteration onward.

You can configure `Design` as a matrix if `NUMSERIES = 1` or as a cell array if `NUMSERIES ≥ 1`.

- If `Design` is a cell array and `NUMSERIES = 1`, each cell contains a `NUMPARAMS` row vector.
- If `Design` is a cell array and `NUMSERIES > 1`, each cell contains a `NUMSERIES`-by-`NUMPARAMS` matrix.

These points concern how `Design` handles missing data:

- Although `Design` should not have NaN values, ignored samples due to NaN values in `Data` are also ignored in the corresponding `Design` array.

- If `Design` is a 1-by-1 cell array, which has a single `Design` matrix for each sample, no NaN values are permitted in the array. A model with this structure must have `NUMSERIES ≥ NUMPARAMS` with `rank(Design{1}) = NUMPARAMS`.
- `ecmmvnrmlc` is more strict than `mvnrmlc` about the presence of NaN values in the `Design` array.

Use the estimates in the optional output structure `Info` for diagnostic purposes.

ecmmvnrobj

Purpose Log-likelihood function for multivariate normal regression with missing data

Syntax `Objective = ecmmvnrobj(Data, Design, Parameters, Covariance)`

Arguments

Data	NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. Missing values are represented as NaNs. Only samples that are entirely NaNs are ignored. (To ignore samples with at least one NaN, use <code>mvnrml</code> .)
Design	<p>A matrix or a cell array that handles two model structures:</p> <ul style="list-style-type: none">• If <code>NUMSERIES = 1</code>, <code>Design</code> is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.• If <code>NUMSERIES ≥ 1</code>, <code>Design</code> is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values. <p>If <code>Design</code> has a single cell, it is assumed to have the same <code>Design</code> matrix for each sample. If <code>Design</code> has more than one cell, each cell contains a <code>Design</code> matrix for each sample.</p>
Parameters	NUMPARAMS-by-1 column vector of estimates for the parameters of the regression model.
Covariance	NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the residuals of the regression.

Description

Objective = ecmmvnobj(Data, Design, Parameters, Covariance) computes a log-likelihood function based on current maximum likelihood parameter estimates with missing data. Objective is a scalar that contains the least-squares objective function.

Notes

You can configure Design as a matrix if NUMSERIES = 1 or as a cell array if NUMSERIES ≥ 1.

- If Design is a cell array and NUMSERIES = 1, each cell contains a NUPARAMS row vector.
- If Design is a cell array and NUMSERIES > 1, each cell contains a NUMSERIES-by-NUPARAMS matrix.

Examples

See “Multivariate Normal Regression” on page 5-17, “Least-Squares Regression” on page 5-18, “Covariance-Weighted Least Squares” on page 5-19, “Feasible Generalized Least Squares” on page 5-20, and “Seemingly Unrelated Regression” on page 5-21.

ecmmvnrmls, mvnrmls, mvnrobj

ecmmvnrstd

Purpose Evaluate standard errors for multivariate normal regression model

Syntax [StdParameters, StdCovariance] = ecmmvnrstd(Data, Design, Covariance, Method)

Arguments

Data NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. Missing values are represented as NaNs. Only samples that are entirely NaNs are ignored. (To ignore samples with at least one NaN, use mvnrstd.)

Design A matrix or a cell array that handles two model structures:

- If NUMSERIES = 1, Design is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.
- If NUMSERIES ≥ 1, Design is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.

If Design has a single cell, it is assumed to have the same Design matrix for each sample. If Design has more than one cell, each cell contains a Design matrix for each sample.

Covariance	NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the regression residuals.
Method	(Optional) String that identifies method of calculation for the information matrix: <ul style="list-style-type: none"> • hessian - Default method. Use the expected Hessian matrix of the observed log-likelihood function. This method is recommended since the resultant standard errors incorporate the increased uncertainties due to missing data. • fisher - Use the Fisher information matrix.

Description

[StdParameters, StdCovariance] = ecmmvnstd(Data, Design, Covariance, Method) evaluates standard errors for a multivariate normal regression model with missing data. The model has the form

$$\text{Data}_k \sim N(\text{Design}_k \times \text{Parameters}, \text{Covariance})$$

for samples $k = 1, \dots, \text{NUMSAMPLES}$.

ecmmvnstd computes two outputs:

- StdParameters is a NUMPARAMS-by-1 column vector of standard errors for each element of Parameters, the vector of estimated model parameters.
- StdCovariance is a NUMSERIES-by-NUMSERIES matrix of standard errors for each element of Covariance, the matrix of estimated covariance parameters.

Note ecmmvnstd operates slowly when you calculate the standard errors associated with the covariance matrix Covariance.

Notes

You can configure `Design` as a matrix if `NUMSERIES = 1` or as a cell array if `NUMSERIES ≥ 1`.

- If `Design` is a cell array and `NUMSERIES = 1`, each cell contains a `NUMPARAMS` row vector.
- If `Design` is a cell array and `NUMSERIES > 1`, each cell contains a `NUMSERIES`-by-`NUMPARAMS` matrix.

`ecmmvnrmlc`, `ecmmvnrstd`, `mvnrmlc`

Purpose Fisher information matrix

Syntax `Fisher = ecmnfish(Data, Covariance, InvCovariance, MatrixFormat)`

Arguments

Data	NUMSAMPLES-by-NUMSERIES matrix of observed multivariate normal data
Covariance	NUMSERIES-by-NUMSERIES matrix with covariance estimate of Data
InvCovariance	(Optional) Inverse of covariance matrix: <code>inv(Covariance)</code>
MatrixFormat	(Optional) String that identifies parameters included in the Fisher information matrix. If <code>MatrixFormat = []</code> or <code>''</code> , the default method <code>full</code> is used. The parameter choices are <ul style="list-style-type: none"> <code>full</code> — (Default) Compute full Fisher information matrix. <code>meanonly</code> — Compute only components of the Fisher information matrix associated with the mean.

Description `Fisher = ecmnfish(Data, Covariance, InvCovariance, MatrixFormat)` computes a NUMPARAMS-by-NUMPARAMS Fisher information matrix based on current parameter estimates, where

$$\text{NUMPARAMS} = \text{NUMSERIES} * (\text{NUMSERIES} + 3) / 2$$

if `MatrixFormat = 'full'` and

$$\text{NUMPARAMS} = \text{NUMSERIES}$$

```
if MatrixFormat = 'meanonly'.
```

This routine is very slow for `NUMSERIES > 10` or `NUMSAMPLES > 1000`.

The data matrix has NaNs for missing observations. The multivariate normal model has

```
NUMPARAMS = NUMSERIES + NUMSERIES*(NUMSERIES + 1)/2
```

distinct parameters. Therefore, the full Fisher information matrix is of size `NUMPARAMS-by-NUMPARAMS`. The first `NUMSERIES` parameters are estimates for the mean of the data in `Mean`, and the remaining `NUMSERIES*(NUMSERIES + 1)/2` parameters are estimates for the lower-triangular portion of the covariance of the data in `Covariance`, in row-major order.

If `MatrixFormat = 'meanonly'`, the number of parameters is reduced to `NUMPARAMS = NUMSERIES`, where the Fisher information matrix is computed for the mean parameters only. In this format, the routine executes fastest.

This routine expects the inverse of the covariance matrix as an input. If you do not pass in the inverse, the routine computes it. You can obtain an approximation for the lower-bound standard errors of estimation of the parameters from

```
Stderr = (1.0/sqrt(NumSamples)) .* sqrt(diag(inv(Fisher)));
```

Because of missing information, these standard errors may be smaller than the estimated standard errors derived from the expected Hessian matrix. To see the difference, compare with standard errors calculated with `ecmnhess`.

`ecmnhess`, `ecmnmle`

Purpose Hessian of negative log-likelihood function

Syntax `Hessian = ecmhess(Data, Covariance, InvCovariance, MatrixFormat)`

Arguments

Data	NUMSAMPLES-by-NUMSERIES matrix of observed multivariate normal data
Covariance	NUMSERIES-by-NUMSERIES matrix with covariance estimate of Data
InvCovariance	(Optional) Inverse of covariance matrix: <code>inv(Covariance)</code>
MatrixFormat	(Optional) String that identifies parameters included in the Hessian matrix. If <code>MatrixFormat = []</code> or <code>''</code> , the default method <code>full</code> is used. The parameter choices are <ul style="list-style-type: none"> <code>full</code> — (Default) Compute full Hessian matrix. <code>meanonly</code> — Compute only components of the Hessian matrix associated with the mean.

Description `Hessian = ecmhess(Data, Covariance, InvCovariance, MatrixFormat)` computes a `NUMPARAMS`-by-`NUMPARAMS` Hessian matrix of the observed negative log-likelihood function based upon current parameter estimates, where

$$\text{NUMPARAMS} = \text{NUMSERIES} * (\text{NUMSERIES} + 3) / 2$$

if `MatrixFormat = 'full'` and

```
NUMPARAMS = NUMSERIES
```

```
if MatrixFormat = 'meanonly'.
```

This routine is very slow for $\text{NUMSERIES} > 10$ or $\text{NUMSAMPLES} > 1000$.

The data matrix has NaNs for missing observations. The multivariate normal model has

```
NUMPARAMS = NUMSERIES + NUMSERIES*(NUMSERIES + 1)/2
```

distinct parameters. Therefore, the full Hessian is a NUMPARAMS -by- NUMPARAMS matrix.

The first NUMSERIES parameters are estimates for the mean of the data in `Mean` and the remaining $\text{NUMSERIES}*(\text{NUMSERIES} + 1)/2$ parameters are estimates for the lower-triangular portion of the covariance of the data in `Covariance`, in row-major order.

If `MatrixFormat = 'meanonly'`, the number of parameters is reduced to $\text{NUMPARAMS} = \text{NUMSERIES}$, where the Hessian is computed for the mean parameters only. In this format, the routine executes fastest.

This routine expects the inverse of the covariance matrix as an input. If you do not pass in the inverse, the routine computes it.

The equation

```
Stderr = (1.0/sqrt(NumSamples)) .* sqrt(diag(inv(Hessian)));
```

provides an approximation for the observed standard errors of estimation of the parameters.

Because of the additional uncertainties introduced by missing information, these standard errors may be larger than the estimated standard errors derived from the Fisher information matrix. To see the difference, compare with standard errors calculated from `ecmnfish`.

Purpose Initial mean and covariance

Syntax [Mean, Covariance] = ecmninit(Data, InitMethod)

Arguments

- | | |
|------------|---|
| Data | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. Missing values are indicated by NaNs. |
| InitMethod | <p>(Optional) String that identifies one of three defined initialization methods to compute initial estimates for the mean and covariance of the data. If InitMethod = [] or '', the default method nanskip is used. The initialization methods are</p> <ul style="list-style-type: none"> • nanskip — (Default) Skip all records with NaNs. • twostage — Estimate mean. Fill NaNs with the mean. Then estimate the covariance. • diagonal — Form a diagonal covariance. |

Description [Mean, Covariance] = ecmninit(Data, InitMethod) creates initial mean and covariance estimates for the function ecmnmle. Mean is a NUMSERIES-by-1 column vector estimate for the mean of Data. Covariance is a NUMSERIES-by-NUMSERIES matrix estimate for the covariance of Data.

Algorithm **Model**

The general model is

$$Z \sim N(\text{Mean}, \text{Covariance})$$

where each row of `Data` is an observation of Z .

Each observation of Z is assumed to be iid (independent, identically distributed) multivariate normal, and missing values are assumed to be missing at random (MAR).

Initialization Methods

This routine has three initialization methods that cover most cases, each with its advantages and disadvantages.

nanskip

The `nanskip` method works well with small problems (fewer than 10 series or with monotone missing data patterns). It skips over any records with NaNs and estimates initial values from complete-data records only. This initialization method tends to yield fastest convergence of the ECM algorithm. This routine switches to the `twostage` method if it determines that significant numbers of records contain NaN.

twostage

The `twostage` method is the best choice for large problems (more than 10 series). It estimates the mean for each series using all available data for each series. It then estimates the covariance matrix with missing values treated as equal to the mean rather than as NaNs. This initialization method is quite robust but tends to result in slower convergence of the ECM algorithm.

diagonal

The `diagonal` method is a worst-case approach that deals with problematic data, such as disjoint series and excessive missing data (more than 33% missing data). Of the three initialization methods, this method causes the slowest convergence of the ECM algorithm.

See Also

`ecmnmle`

Purpose Mean and covariance of incomplete multivariate normal data

Syntax [Mean, Covariance] = ecmmle(Data, InitMethod, MaxIterations, Tolerance, Mean0, Covar0)

Arguments

Data NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. Missing values are indicated by NaNs. A sample is also called an *observation* or a *record*.

InitMethod (Optional) String that identifies one of three defined initialization methods to compute initial estimates for the mean and covariance of the data. If InitMethod = [] or ' ', the default method nanskip is used. The initialization methods are:

- nanskip — (Default) Skip all records with NaNs.
- twostage — Estimate mean. Fill NaNs with mean. Then estimate covariance.
- diagonal — Form a diagonal covariance.

Note If you supply Mean0 and Covar0, InitMethod is not executed.

MaxIterations (Optional) Maximum number of iterations for the expectation conditional maximization (ECM) algorithm. Default = 50.

Tolerance	(Optional) Convergence tolerance for the ECM algorithm (Default = $1.0e-8$.) If $Tolerance \leq 0$, perform maximum iterations specified by <code>MaxIterations</code> and do not evaluate the objective function at each step unless in display mode, as described below.
Mean0	(Optional) Initial NUMSERIES-by-1 column vector estimate for the mean. If you leave <code>Mean0</code> unspecified (<code>[]</code>), the method specified by <code>InitMethod</code> is used. If you specify <code>Mean0</code> , you must also specify <code>Covar0</code> .
Covar0	(Optional) Initial NUMSERIES-by-NUMSERIES matrix estimate for the covariance, where the input matrix must be positive-definite. If you leave <code>Covar0</code> unspecified (<code>[]</code>), the method specified by <code>InitMethod</code> is used. If you specify <code>Covar0</code> , you must also specify <code>Mean0</code> .

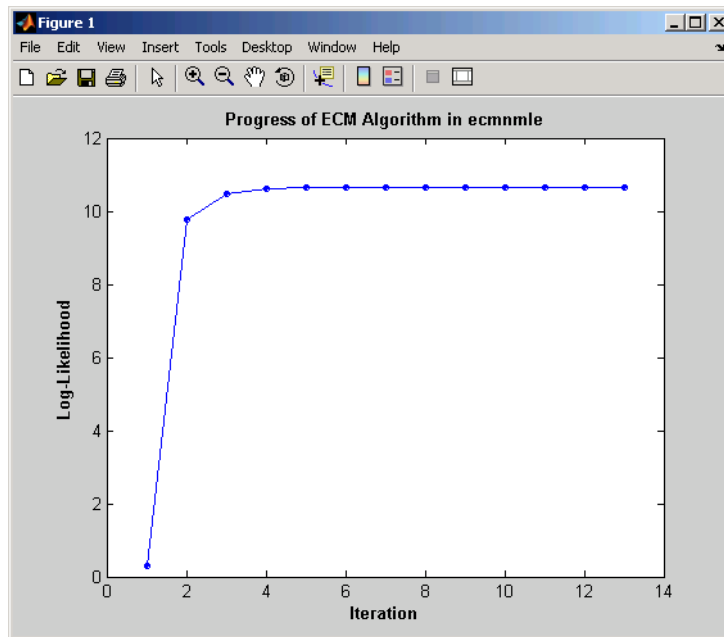

Description

`[Mean, Covariance] = ecmmle(Data, InitMethod, MaxIterations, Tolerance, Mean0, Covar0)` estimates the mean and covariance of a data set. If the data set has missing values, this routine implements the ECM algorithm of Meng and Rubin [2] with enhancements by Sexton and Swensen [3]. ECM stands for *expectation conditional maximization*, a conditional maximization form of the EM algorithm of Dempster, Laird, and Rubin [4].

This routine has two operational modes.

Display Mode

With no output arguments, this mode displays the convergence of the ECM algorithm. It estimates and plots objective function values for each iteration of the ECM algorithm until termination, as shown in the following plot.

Display mode can determine `MaxIter` and `Tolerance` values or serve as a diagnostic tool. The objective function is the negative log-likelihood function of the observed data and convergence to a maximum likelihood estimate corresponds with minimization of the objective.

Estimation Mode

With output arguments, this mode estimates the mean and covariance via the ECM algorithm.

Examples

To see an example of how to use `ecmmle`, run the demo program `ecmguidemo`.

Algorithm

Model

The general model is

$Z \sim N(\text{Mean}, \text{Covariance})$

where each row of Data is an observation of Z .

Each observation of Z is assumed to be iid (independent, identically distributed) multivariate normal, and missing values are assumed to be missing at random (MAR). See Little and Rubin [1] for a precise definition of MAR.

This routine estimates the mean and covariance from given data. If data values are missing, the routine implements the ECM algorithm of Meng and Rubin [2] with enhancements by Sexton and Swensen [3].

If a record is empty (every value in a sample is NaN), this routine ignores the record because it contributes no information. If such records exist in the data, the number of nonempty samples used in the estimation is $\leq \text{NumSamples}$.

The estimate for the covariance is a biased maximum likelihood estimate (MLE). To convert to an unbiased estimate, multiply the covariance by $\text{Count}/\text{Count} - 1$, where Count is the number of nonempty samples used in the estimation.

Requirements

This routine requires consistent values for NUMSAMPLES and NUMSERIES with NUMSAMPLES > NUMSERIES. It must have enough nonmissing values to converge. Finally, it must have a positive-definite covariance matrix. Although the references provide some necessary and sufficient conditions, general conditions for existence and uniqueness of solutions in the missing-data case do not exist. The main failure mode is an ill-conditioned covariance matrix estimate. Nonetheless, this routine works for most cases that have less than 15% missing data (a typical upper bound for financial data).

Initialization Methods

This routine has three initialization methods that cover most cases, each with its advantages and disadvantages. The ECM algorithm always converges to a minimum of the observed negative log-likelihood

function. If you override the initialization methods, you must ensure that the initial estimate for the covariance matrix is positive-definite.

The following is a guide to the supported initialization methods.

nanskip

The `nanskip` method works well with small problems (fewer than 10 series or with monotone missing data patterns). It skips over any records with NaNs and estimates initial values from complete-data records only. This initialization method tends to yield fastest convergence of the ECM algorithm. This routine switches to the `twostage` method if it determines that significant numbers of records contain NaN.

twostage

The `twostage` method is the best choice for large problems (more than 10 series). It estimates the mean for each series using all available data for each series. It then estimates the covariance matrix with missing values treated as equal to the mean rather than as NaNs. This initialization method is quite robust but tends to result in slower convergence of the ECM algorithm.

diagonal

The `diagonal` method is a worst-case approach that deals with problematic data, such as disjoint series and excessive missing data (more than 33% of data missing). Of the three initialization methods, this method causes the slowest convergence of the ECM algorithm. If problems occur with this method, use `display` mode to examine convergence and modify either `MaxIterations` or `Tolerance`, or try alternative initial estimates with `Mean0` and `Covar0`. If all else fails, try

```
Mean0 = zeros(NumSeries);  
Covar0 = eye(NumSeries,NumSeries);
```

Given estimates for mean and covariance from this routine, you can estimate standard errors with the companion routine `ecmstd`.

Convergence

The ECM algorithm does not work for all patterns of missing values. Although it works in most cases, it can fail to converge if the covariance becomes singular. If this occurs, plots of the log-likelihood function tend to have a constant upward slope over many iterations as the log of the negative determinant of the covariance goes to zero. In some cases, the objective fails to converge due to machine precision errors. No general theory of missing data patterns exists to determine these cases. An example of a known failure occurs when two time series are proportional wherever both series contain nonmissing values.

Purpose

Multivariate normal negative log-likelihood function

Syntax

Objective = ecmnojb(Data, Mean, Covariance, CholCovariance)

Arguments

Data	NUMSAMPLES-by-NUMSERIES matrix of observed multivariate normal data
Mean	NUMSERIES-by-1 column vector with mean estimate of Data
Covariance	NUMSERIES-by-NUMSERIES matrix with covariance estimate of Data
CholCovariance	(Optional) Cholesky decomposition of covariance matrix: chol(Covariance)

Description

Objective = ecmnojb(Data, Mean, Covariance, CholCovariance) computes the value of the observed negative log-likelihood function over the data given current estimates for the mean and covariance of the data.

The data matrix has NaNs for missing observations. The inputs Mean and Covariance are current estimates for model parameters.

This routine expects the Cholesky decomposition of the covariance matrix as an input. The routine computes the Cholesky decomposition if you do not explicitly specify it.

See Also

chol, ecmnmle

Purpose Standard errors for mean and covariance of incomplete data

Syntax [StdMean, StdCovariance] = ecmnstd(Data, Mean, Covariance, Method)

Arguments

Data	NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. Missing values are indicated by NaNs.
Mean	NUMSERIES-by-1 column vector of maximum-likelihood parameter estimates for the mean of Data using the expectation conditional maximization (ECM) algorithm
Covariance	NUMSERIES-by-NUMSERIES matrix of maximum-likelihood covariance estimates for the covariance of Data using the ECM algorithm
Method	(Optional) String indicating method of estimation for standard error calculations. The methods are: <ul style="list-style-type: none">• <code>hessian</code> — (Default) Hessian of the observed negative log-likelihood function.• <code>fisher</code> — Fisher information matrix.

Description [StdMean, StdCovariance] = ecmnstd(Data, Mean, Covariance, Method) computes standard errors for mean and covariance of incomplete data.

StdMean is a NUMSERIES-by-1 column vector of standard errors of estimates for each element of the mean vector Mean.

StdCovariance is a NUMSERIES-by-NUMSERIES matrix of standard errors of estimates for each element of the covariance matrix Covariance.

Use this routine after estimating the mean and covariance of Data with `ecmnml`. If the mean and distinct covariance elements are treated as the parameter θ in a complete-data maximum-likelihood estimation, then as the number of samples increases, θ attains asymptotic normality such that

$$\theta - E[\theta] \sim N(0, I^{-1}(\theta))$$

where $E[\theta]$ is the mean and $I(\theta)$ is the Fisher information matrix.

With missing data, the Hessian $H(\theta)$ is a good approximation for the Fisher information (which can only be approximated when data is missing).

It is usually advisable to use the default Method since the resultant standard errors incorporate the increased uncertainty due to missing data. In particular, standard errors calculated with the Hessian are generally larger than standard errors calculated with the Fisher information matrix.

Note This routine is very slow for `NUMSERIES > 10` or `NUMSAMPLES > 1000`.

`ecmnml`

effrr

Purpose Effective rate of return

Syntax Return = effrr(Rate, NumPeriods)

Arguments

Rate Annual percentage rate. Enter as a decimal fraction.

NumPeriods Number of compounding periods per year, an integer.

Description Return = effrr(Rate, NumPeriods) calculates the annual effective rate of return. Compounding continuously returns Return equivalent to $(e^{\text{Rate}} - 1)$.

Examples Find the effective annual rate of return based on an annual percentage rate of 9% compounded monthly.

Return = effrr(0.09, 12)

returns

Return =

0.0938 or 9.38%

Purpose Compute expected lower partial moments for normal asset returns

Syntax

```
elpm(Mean, Sigma)
    elpm(Mean, Sigma, MAR)
    elpm(Mean, Sigma, MAR, Order)
Moment = elpm(Mean, Sigma, MAR, Order)
```

Arguments

Mean	NUMSERIES vector with mean returns for a collection of NUMSERIES assets.
Sigma	NUMSERIES vector with standard deviation of returns for a collection of NUMSERIES assets.
MAR	(Optional) Scalar minimum acceptable return (default MAR = 0). This is a cutoff level of return such that all returns above MAR contribute nothing to the lower partial moment.
Order	(Optional) Either a scalar or a NUMORDERS vector of nonnegative integer moment orders. If no order specified, default Order = 0, which is the shortfall probability. This function will not work for negative or noninteger orders.

Description

Given NUMSERIES asset returns with a vector of mean returns in a NUMSERIES vector Mean, a vector of standard deviations of returns in a NUMSERIES vector Sigma, a scalar minimum acceptable return MAR, and one or more nonnegative integer moment orders in a NUMORDERS vector Order, compute expected lower partial moments (elpm) relative to MAR for each asset in a NUMORDERS-by-NUMSERIESmatrix Moment.

The output, Moment, is a NUMORDERS-by-NUMSERIES matrix of expected lower partial moments with NUMORDERS Orders and NUMSERIES series,

that is, each row contains expected lower partial moments for a given order.

Note To compute upper partial moments, just reverse the signs of both the input Mean and MAR (do not reverse the signs of either Sigma or the output). This function computes expected lower partial moments with the mean and standard deviation of normally distributed asset returns. To compute sample lower partial moments from asset returns which have no distributional assumptions, use lpm.

Example

See “Expected Lower Partial Moments Example” on page 4-11.

lpm

Purpose Compute expected maximum drawdown for Brownian motion

Syntax EDD = emaxdrawdown(Mu, Sigma, T)

Arguments

Mu	Scalar. Drift term of a Brownian motion with drift.
Sigma	Scalar. Diffusion term of a Brownian motion with drift.
T	A time period of interest or a vector of times.

Description

EDD = emaxdrawdown(Mu, Sigma, T) computes the expected maximum drawdown for a Brownian motion for each time period in T using the following equation:

$$dX(t) = \mu dt + \sigma dW(t)$$

If the Brownian motion is geometric with the stochastic differential equation

$$dS(t) = \mu_0 S(t) dt + \sigma_0 S(t) dW(t)$$

then use Ito's lemma with $X(t) = \log(S(t))$ such that

$$\mu = \mu_0 - 0.5\sigma_0^2$$

$$\sigma = \sigma_0$$

converts it to the form used here.

The output argument ExpDrawdown is computed using an interpolation method. Values are accurate to a fraction of a basis point. Maximum drawdown is nonnegative since it is the change from a peak to a trough.

emaxdrawdown

Note To compare the actual results from maxdrawdown with the expected results of emaxdrawdown, set the Format input argument of maxdrawdown to either of the nondefault values ('arithmetic' or 'geometric'). These are the only two formats emaxdrawdown supports.

Example

See “Expected Maximum Drawdown Example” on page 4-14.

maxdrawdown

Purpose Last date entry

Syntax end

Description end returns the index to the last date entry in a financial time series object.

Examples Consider a financial time series object called fts:

```
fts =
```

```
desc: DJI30MAR94.dat  
freq: Daily (1)
```

```
'dates: (20) '    'Open: (20) '  
'04-Mar-1994 '    [      3830.9]  
'07-Mar-1994 '    [      3851.7]  
'08-Mar-1994 '    [      3858.5]  
'09-Mar-1994 '    [        3854]  
'10-Mar-1994 '    [      3852.6]  
'11-Mar-1994 '    [      3832.6]  
'14-Mar-1994 '    [      3870.3]  
'16-Mar-1994 '    [        3851]  
'17-Mar-1994 '    [      3853.6]  
'18-Mar-1994 '    [      3865.4]  
'21-Mar-1994 '    [      3878.4]  
'22-Mar-1994 '    [      3865.7]  
'23-Mar-1994 '    [      3868.9]  
'24-Mar-1994 '    [      3849.9]  
'25-Mar-1994 '    [      3827.1]  
'28-Mar-1994 '    [      3776.5]  
'29-Mar-1994 '    [      3757.2]  
'30-Mar-1994 '    [      3688.4]  
'31-Mar-1994 '    [      3639.7]
```

The command `fts(15:end)` returns

end

```
ans =
```

```
desc: DJI30MAR94.dat
```

```
freq: Daily (1)
```

```
'dates: (6)'      'Open: (6)'
```

end in the MATLAB documentation

Purpose Last date of month

Syntax DayMonth = eomdate(Year, Month)

Description DayMonth = eomdate(Year, Month) returns the serial date number of the last date of the month for the given year and month. Enter Year as a four-digit integer; enter Month as an integer from 1 through 12.

Either input argument can contain multiple values, but if so, the other input must contain the same number of values or a single value that applies to all. For example, if Year is a 1-by-*n* vector of integers, then Month must be a 1-by-*n* vector of integers or a single integer. DayMonth is then a 1-by-*n* vector of date numbers.

Use the function `datestr` to convert serial date numbers to formatted date strings.

Examples

```
DayMonth = eomdate(2001, 2)
DayMonth =
    730910
datestr(DayMonth)

ans =
    28-Feb-2001

Year = [2002 2003 2004 2005];
DayMonth = eomdate(Year, 2)
DayMonth =
    731275    731640    732006    732371

datestr(DayMonth)

ans =
    28-Feb-2002
    28-Feb-2003
    29-Feb-2004
```

eomdate

28-Feb-2005

See Also

day, eomday, lbusdate, month, year

Purpose Last day of month

Syntax Day = eomday(Year, Month)

Description Day = eomday(Year, Month) returns the last day of the month for the given year and month. Enter Year as a four-digit integer; enter Month as an integer from 1 through 12.

Either input argument can contain multiple values, but if so, the other input must contain the same number of values or a single value that applies to all. For example, if Year is a 1-by-*n* vector of integers, then Month must be a 1-by-*n* vector of integers or a single integer. Day is then a 1-by-*n* vector of days.

Note This function now ships with basic MATLAB. It originally shipped only with Financial Toolbox. This description remains here for your convenience.

Examples Day = eomday(2000, 2)

Day =

29

See Also day, eomdate, month

ewstats

Purpose Expected return and covariance from return time series

Syntax `[ExpReturn, ExpCovariance, NumEffObs] = ewstats(RetSeries, DecayFactor, WindowLength)`

Arguments

- RetSeries** Return Series: number of observations (NUMOBS) by number of assets (NASSETS) matrix of equally spaced incremental return observations. The first row is the oldest observation, and the last row is the most recent.
- DecayFactor** (Optional) Controls how much less each observation is weighted than its successor. The k th observation back in time has weight DecayFactor^k . DecayFactor must lie in the range: $0 < \text{DecayFactor} \leq 1$.
Default = 1, the equally weighted linear moving average model (BIS).
- WindowLength** (Optional) Number of recent observations in the computation. Default = NUMOBS.

Description

`[ExpReturn, ExpCovariance, NumEffObs] = ewstats(RetSeries, DecayFactor, WindowLength)` computes estimated expected returns, estimated covariance matrix, and the number of effective observations.

ExpReturn is a 1-by-NASSETS vector of estimated expected returns.

ExpCovariance is an NASSETS-by-NASSETS estimated covariance matrix. The standard deviations of the asset return processes are given by

$$\text{STDVec} = \text{sqrt}(\text{diag}(\text{ExpCovariance}))$$

The correlation matrix is

```
CorrMat = ExpCovariance./( STDVec*STDVec' )
```

NumEffObs is the number of effective observations =
(1-DecayFactor^WindowLength)/(1-DecayFactor).

A smaller DecayFactor or WindowLength emphasizes recent data more strongly but uses less of the available data set.

Examples

```
RetSeries = [ 0.24 0.08  
             0.15 0.13  
             0.27 0.06  
             0.14 0.13 ];
```

```
DecayFactor = 0.98;
```

```
[ExpReturn, ExpCovariance] = ewstats(RetSeries, DecayFactor)
```

```
ExpReturn =
```

```
0.1995    0.1002
```

```
ExpCovariance =
```

```
0.0032    -0.0017  
-0.0017    0.0010
```

See Also

cov, mean

exp

Purpose Exponential values

Syntax `newfts = exp(tsobj)`

Description `newfts = exp(tsobj)` calculates the natural exponential (base e) of all the data in the data series of the financial time series object `tsobj` and returns the result in the object `newfts`.

See Also `log`, `log2`, `log10`

Purpose Data series extraction

Syntax `ftse = extfield(tsoobj, fieldnames)`

Arguments

<code>tsoobj</code>	Financial time series object
<code>fieldnames</code>	Data series to be extracted. A cell array if a list of data series names (<code>fieldnames</code>) is supplied. A string if only one is wanted.

Description `ftse = extfield(tsoobj, fieldnames)` extracts from `tsoobj` the dates and data series specified by `fieldnames` into a new financial time series object `ftse`. `ftse` has all the dates in `tsoobj` but contains a smaller number of data series.

Examples `extfield` is identical to referencing a field in the object. For example,

```
ftse = extfield(fts, 'Close')
```

is the same as

```
ftse = fts.Close
```

This function is the complement of the function `rmfield`.

See Also `rmfield`

fbusdate

Purpose First business date of month

Syntax `Date = fbusdate(Year, Month, Holiday, Weekend)`

Arguments

Year	Enter as four-digit integer.
Month	Enter as integer from 1 to 12.
Holiday	(Optional) Vector of holidays and nontrading-day dates. All dates in <code>Holiday</code> must be the same format: either serial date numbers or date strings. (Using date numbers improves performance.) The <code>holidays</code> function supplies the default vector.
Weekend	(Optional) Vector of length 7, containing 0 and 1, the value 1 indicating weekend days. The first element of this vector corresponds to Sunday. Thus, when Saturday and Sunday form the weekend (default), then <code>Weekend = [1 0 0 0 0 0 1]</code> .

Description

`Date = fbusdate(Year, Month, Holiday, Weekend)` returns the serial date number for the first business date of the given year and month. `Holiday` specifies nontrading days.

`Year` and `Month` can contain multiple values. If one contains multiple values, the other must contain the same number of values or a single value that applies to all. For example, if `Year` is a 1-by-n vector of integers, then `Month` must be a 1-by-n vector of integers or a single integer. `Date` is then a 1-by-n vector of date numbers.

Use the function `datestr` to convert serial date numbers to formatted date strings.

Examples

Example 1:

```
Date = fbusdate(2001, 11); datestr(Date)
ans =
01-Nov-2001
```

```
Year = [2002 2003 2004];
Date = fbusdate(Year, 11); datestr(Date)
```

```
ans =
01-Nov-2002
03-Nov-2003
01-Nov-2004
```

Example 2: You can indicate that Saturday is a business day by appropriately setting the Weekend argument.

```
Weekend = [1 0 0 0 0 0 0];
```

March 1, 2003, is a Saturday. Use `fbusdate` to check that this Saturday is actually the first business day of the month.

```
Date = datestr(fbusdate(2003, 3, [], Weekend))
```

```
Date =
```

```
01-Mar-2003
```

See Also`busdate, eomdate, holidays, isbusday, lbusdate`

fetch

Purpose Data from financial time series object

Syntax `newfts = fetch(oldfts, StartDate, StartTime, EndDate, EndTime, delta, dmy_specifier, time_ref)`

Arguments

<code>oldfts</code>	Existing financial time series object.
<code>StartDate</code>	First date in the range from which data is to be extracted.
<code>StartTime</code>	Beginning time on each day. If you do not require specific times or <code>oldfts</code> does not contain time information, use <code>[]</code> . If you specify <code>StartTime</code> , you must also specify <code>EndTime</code> .
<code>EndDate</code>	Last date in the range from which data is to be extracted.
<code>EndTime</code>	Ending time on each day. If you do not require specific times or <code>oldfts</code> does not contain time information, use <code>[]</code> . If you specify <code>EndTime</code> , you must also specify <code>StartTime</code> .
<code>delta</code>	Skip interval. Can be any positive integer. Units for the skip interval specified by <code>dmy_specifier</code> .
<code>dmy_specifier</code>	Specifies the units for <code>delta</code> . Can be <ul style="list-style-type: none">• D, d (Days)• M, m (Months)• Y, y (Years)
<code>time_ref</code>	Time reference intervals or specific times. Valid time reference intervals are 1, 5, 15, or 60 minutes. Enter specific times as <code>'hh:mm'</code> .

Description

`newfts = fetch(oldfts, StartDate, StartTime, EndDate, EndTime, delta, dmy_specifier, time_ref)` requests data from a financial time series object beginning from the start date and/or start time to the end date and/or end time, skipping a specified number of days, months, or years.

Note If time information is present in `oldfts`, using `[]` for start or end times results in `fetch` returning all instances of a specific date.

Examples

Example 1. Create a financial time series object containing both dates and times:

```
dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
         '02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
dates_times = cellstr([dates, repmat(' ', size(dates,1),1), ...
                       times]);
myFts = fints(dates_times, (1:6)', {'Data1'}, 1, 'My first FINTS')
```

myFts =

```
desc: My first FINTS
freq: Daily (1)
```

```
'dates: (6)'      'times: (6)'      'Data1: (6)'
'01-Jan-2001'    '11:00'          [          1]
'      "      '  '12:00'          [          2]
'02-Jan-2001'    '11:00'          [          3]
'      "      '  '12:00'          [          4]
'03-Jan-2001'    '11:00'          [          5]
'      "      '  '12:00'          [          6]
```

To fetch all dates and times from this financial time series, enter

```
fetch(myFts, '01-Jan-2001', [], '03-Jan-2001', [], 1, 'd')
```

or

```
fetch(myFts, '01-Jan-2001', '11:00', '03-Jan-2001', '12:00', 1, 'd')
```

These commands reproduce the entire time series shown above.

To fetch every other day's data, enter

```
fetch(myFts, '01-Jan-2001', [], '03-Jan-2001', [], 2, 'd')
```

This produces

```
ans =
```

```
desc: My first FINTS
```

```
freq: Daily (1)
```

```
'dates: (4)'      'times: (4)'      'Data1: (4)'
'01-Jan-2001'    '11:00'          [          1]
'      "      '  '12:00'          [          2]
'03-Jan-2001'    '11:00'          [          5]
'      "      '  '12:00'          [          6]
```

Example 2. Create a financial time series object with time intervals of less than 1 hour:

```
dates2 = ['01-Jan-2001'; '01-Jan-2001'; '01-Jan-2001'; ...
'02-Jan-2001'; '02-Jan-2001'; '02-Jan-2001'];
times2 = ['11:00'; '11:05'; '11:06'; '12:00'; '12:05'; '12:06'];
dates_times2 = cellstr([dates2, repmat(' ', size(dates2,1),1), ...
times2]);
myFts2 = fints(dates_times2, (1:6)', {'Data1'}, 1, 'My second
FINTS')

myFts2 =
```

```

desc: My second FINTS
freq: Daily (1)

'dates: (6)'   'times: (6)'   'Data1: (6)'
'01-Jan-2001' '11:00'   [      1]
'   "   "   '11:05'   [      2]
'   "   "   '11:06'   [      3]
'02-Jan-2001' '12:00'   [      4]
'   "   "   '12:05'   [      5]
'   "   "   '12:06'   [      6]

```

Use fetch to extract data from this time series object at 5-minute intervals for each day starting at 11:00 o'clock on January 1, 2001.

```
fetch(myFts2, '01-Jan-2001', [], '02-Jan-2001', [], 1, 'd', 5)
```

```

desc: My second FINTS
freq: Daily (1)

'dates: (4)'   'times: (4)'   'Data1: (4)'
'01-Jan-2001' '11:00'   [      1]
'   "   "   '11:05'   [      2]
'02-Jan-2001' '12:00'   [      4]
'   "   "   '12:05'   [      5]

```

You can use this version of fetch to extract data at specific times. For example, to fetch data only at 11:06 and 12:06 from myFts2, enter

```
fetch(myFts2, '01-Jan-2001', [], '02-Jan-2001', [], 1, 'd', ...
{'11:06'; '12:06'})
```

ans =

```

desc: My second FINTS
freq: Daily (1)

'dates: (2)'   'times: (2)'   'Data1: (2)'

```

fetch

'01-Jan-2001'	'11:06'	[3]
'02-Jan-2001'	'12:06'	[6]

See Also extfield, ftsbound, getfield, subsref

Purpose Get names of fields

Syntax

```
fnames = fieldnames(tsobj)
fnames = fieldnames(tsobj, srsnameonly)
```

Arguments

<code>tsobj</code>	Financial time series object
<code>srsnameonly</code>	Field names returned: 0 = All field names (default). 1 = Data series names only.

Description `fieldnames` gets field names in a financial time series object.

`fnames = fieldnames(tsobj)` returns the field names associated with the financial time series object `tsobj` as a cell array of strings, including the common fields: `desc`, `freq`, `dates` (and `times` if present).

`fnames = fieldnames(tsobj, srsnameonly)` returns field names depending upon the setting of `srsnameonly`. If `srsnameonly` is 0, the function returns all field names, including the common fields: `desc`, `freq`, `dates`, and `times`. If `srsnameonly` is set to 1, `fieldnames` returns only the data series in `fnames`.

See Also `chfield`, `getfield`, `isfield`, `rmfield`, `setfield`

Purpose Fill missing values in time series

Syntax

```
newfts = fillts(oldfts, fill_method)
newfts = fillts(oldfts, fill_method, newdates)
newfts = fillts(oldfts, fill_method, newdates, {'T1','T2',...})
newfts = fillts(oldfts, fill_method, newdates, 'SPAN', {'TS','TE'},
delta)
newfts = fillts(... sortmode)
```

Arguments

<code>oldfts</code>	Financial time series object.
<code><i>fill_method</i></code>	(Optional) Replaces missing values (NaN) in <code>oldfts</code> using an interpolation process, a constant, or a zero-order hold. Valid fill methods (interpolation methods) are: <ul style="list-style-type: none">• linear - 'linear' - 'l' (default)• linear with extrapolation - 'linearExtrap' - 'le'• cubic - 'cubic' - 'c'• cubic with extrapolation - 'cubicExtrap' - 'ce'• spline - 'spline' - 's'• spline with extrapolation - 'splineExtrap' - 'se'• nearest - 'nearest' - 'n'• nearest with extrapolation - 'nearestExtrap' - 'ne'• pchip - 'pchip' - 'p'

- pchip with extrapolation - 'pchipExtrap'
- 'pe'

(See `interp1` for a discussion of extrapolation.)

To fill with a constant, enter that constant.

A zero-order hold ('zero') fills a missing value with the value immediately preceding it. If the first value in the time series is missing, it remains a NaN.

<code>newdates</code>	(Optional) Column vector of serial dates, a date string, or a column cell array of date strings. If <code>oldfts</code> contains time of day information, <code>newdates</code> must be accompanied by a time vector (<code>newtimes</code>). Otherwise, <code>newdates</code> is assumed to have times of '00:00'.
<code>T1, T2, TS, TE</code>	First time, second time, start time, end time
<code>delta</code>	Time interval in minutes to span between the start time and end time
<code>sortmode</code>	(Optional) Default = 0 (unsorted). 1 = sorted.

Description

`newfts = fillts(oldfts, fill_method)` replaces missing values (represented by NaN) in the financial time series object `oldfts` with real values, using either a constant or the interpolation process indicated by `fill_method`.

`newfts = fillts(oldfts, fill_method, newdates)` replaces all the missing values on the specified dates `newdates` added to the financial time series `oldfts` with new values. The values can be a single constant or values obtained through the interpolation process designated by `fill_method`. If any of the dates in `newdates` exists in `oldfts`, the existing one has precedence.

`newfts = fillts(olddfts, fill_method, newdates, {'T1', 'T2', ...})` additionally allows the designation of specific times of day for addition or replacement of data.

`newfts = fillts(olddfts, fill_method, newdates, 'SPAN', {'TS', 'TE'}, delta)` is similar to the previous format except that you designate only a start time and an end time. You follow these times with a spanning time interval, `delta`.

If you specify only one date for `newdates`, specifying a start and end time generates only times for that specific date.

`newfts = fillts(... sortmode)` additionally denotes whether you want the order of the dates in the output object to stay the same as in the input object or to be sorted chronologically.

`sortmode = 0` (unsorted) appends any new dates to the end. The interpolation and zero-order processes that calculate the values for the new dates work on a sorted object. Upon completion, the existing dates are reordered as they were originally, and the new dates are appended to the end.

`sortmode = 1` sorts the output. After interpolation, no reordering of the date sequence occurs.

Examples

Example 1. Create a financial time series object with missing data in the fourth and fifth rows.

```
dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
         '02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
dates_times = cellstr([dates, repmat(' ', size(dates,1),1), ...
                       times]);
OpenFts = fints(dates_times, [(1:3)'; nan; nan; 6], {'Data1'}, 1, ...
               'Open Financial Time Series');
```

`OpenFts` looks like this:

```
OpenFts =
```

```

desc: Open Financial Time Series
freq: Daily (1)

'dates: (6)'   'times: (6)'   'Data1: (6)'
'01-Jan-2001' '11:00'         [          1]
'   "   "   '12:00'         [          2]
'02-Jan-2001' '11:00'         [          3]
'   "   "   '12:00'         [         NaN]
'03-Jan-2001' '11:00'         [         NaN]
'   "   "   '12:00'         [          6]

```

Example 2. Fill the missing data in OpenFts using cubic interpolation.

```
FilledFts = fillts(OpenFts,'cubic')
```

```
FilledFts =
```

```

desc: Filled Open Financial Time Series
freq: Unknown (0)

'dates: (6)'   'times: (6)'   'Data1: (6)'
'01-Jan-2001' '11:00'         [          1]
'   "   "   '12:00'         [          2]
'02-Jan-2001' '11:00'         [          3]
'   "   "   '12:00'         [    3.0663]
'03-Jan-2001' '11:00'         [    5.8411]
'   "   "   '12:00'         [    6.0000]

```

Example 3. Fill the missing data in OpenFts with a constant value.

```
FilledFts = fillts(OpenFts,0.3)
```

```
FilledFts =
```

```

desc: Filled Open Financial Time Series
freq: Unknown (0)

```

```
'dates: (6)'      'times: (6)'      'Data1: (6)'  
'01-Jan-2001'    '11:00'           [          1]  
'    "    '    '12:00'           [          2]  
'02-Jan-2001'    '11:00'           [          3]  
'    "    '    '12:00'           [    0.3000]  
'03-Jan-2001'    '11:00'           [    0.3000]  
'    "    '    '12:00'           [          6]
```

Example 3. You can use `fillts` to identify a specific time on a specific day for the replacement of missing data. This example shows how to replace missing data at 12:00 on January 2 and 11:00 on January 3.

```
FilltimeFts = fillts(OpenFts,'c',...  
{'02-Jan-2001';'03-Jan-2001'}, {'12:00';'11:00'},0)
```

```
FilltimeFts =
```

```
desc: Filled Open Financial Time Series  
freq: Unknown (0)
```

```
'dates: (6)'      'times: (6)'      'Data1: (6)'  
'01-Jan-2001'    '11:00'           [          1]  
'    "    '    '12:00'           [          2]  
'02-Jan-2001'    '11:00'           [          3]  
'    "    '    '12:00'           [    3.0663]  
'03-Jan-2001'    '11:00'           [    5.8411]  
'    "    '    '12:00'           [    6.0000]
```

Example 4. Use a spanning time interval to add an additional day to `OpenFts`.

```
SpanFts = fillts(OpenFts,'c','04-Jan-2001','span',...  
{'11:00';'12:00'},60,0)
```

```
SpanFts =
```

```
desc: Filled Open Financial Time Series
```

```
freq: Unknown (0)
```

```
'dates: (8)'      'times: (8)'      'Data1: (8)'  
'01-Jan-2001'    '11:00'           [          1]  
'    "          '12:00'           [          2]  
'02-Jan-2001'    '11:00'           [          3]  
'    "          '12:00'           [    3.0663]  
'03-Jan-2001'    '11:00'           [    5.8411]  
'    "          '12:00'           [    6.0000]  
'04-Jan-2001'    '11:00'           [    9.8404]  
'    "          '12:00'           [    9.9994]
```

`interp1` in the MATLAB documentation

filter

Purpose Linear filtering

Syntax `newfts = filter(B, A, oldfts)`

Description `filter` filters an entire financial time series object with certain filter specifications. The filter is specified in a transfer function expression. `newfts = filter(B, A, oldfts)` filters the data in the financial time series object `oldfts` with the filter described by vectors `A` and `B` to create the new financial time series object `newfts`. The filter is a “Direct Form II Transposed” implementation of the standard difference equation. `newfts` is a financial time series object containing the same data series (names) as the input `oldfts`.

See Also `filter`, `filter2` in the MATLAB documentation

Purpose

Construct financial time series object

Syntax

```
tsobj = fints(dates_and_data)
tsobj = fints(dates, data)
tsobj = fints(dates, data, datanames)
tsobj = fints(dates, data, datanames, freq)
tsobj = fints(dates, data, datanames, freq, desc)
```

Arguments

`dates_and_data` Column-oriented matrix containing one column of dates and a single column for each series of data. In this format, dates must be entered in serial date number format. If the input serial date numbers encode time-of-day information, the output object contains a column labeled 'dates' containing the date information and another labeled 'times' containing the time information.

You can use the function `today` to enter date information or the function `now` to enter date with time information.

`dates` Column vector of dates. Dates can be date strings or serial date numbers and can include time of day information. When entering time-of-day information as serial date numbers, the entry must be a column-oriented matrix when multiple entries are present. If the time-of-day information is in string format, the entry must be a column-oriented cell array of dates and times when multiple entries are present.

Valid date and time string formats are:

- 'ddmmyy hh:mm' or 'ddmmyyyy hh:mm'
- 'mm/dd/yy hh:mm' or 'mm/dd/yyyy hh:mm'
- 'dd-mmm-yy hh:mm' or 'dd-mmm-yyyy hh:mm'
- 'mmm.dd,yy hh:mm' or 'mmm.dd,yyyy hh:mm'

Dates and times can initially be separate column-oriented vectors, but they must be concatenated into a single column-oriented matrix before being passed to `fints`. You can use the MATLAB functions `today` and `now` to assist in entering date and time information.

`data`

Column-oriented matrix containing a column for each series of data. The number of values in each data series must match the number of dates. If a mismatch occurs, MATLAB does not generate the financial time series object, and you receive an error message.

`datanames`

Cell array of data series names. Overrides the default data series names. Default data series names are `series1`, `series2`,

<code>freq</code>	Frequency indicator. Allowed values are: UNKNOWN, Unknown, unknown, U, u, 0 DAILY, Daily, daily, D, d, 1 WEEKLY, Weekly, weekly, W, w, 2 MONTHLY, Monthly, monthly, M, m, 3 QUARTERLY, Quarterly, quarterly, Q, q, 4 SEMIANNUAL, Semiannual, semiannual, S, s, 5 ANNUAL, Annual, annual, A, a, 6 Default = Unknown.
<code>desc</code>	String providing descriptive name for financial time series object. Default = ''.

Note The toolbox supports only hourly and minute time series. Seconds are disregarded when the object is created (for example, 01-jan-2001 12:00:01 is considered to be 01-jan-2001 12:00). If there are duplicate dates and times, `fints` sorts the dates and times and chooses the first instance of the duplicate dates and times. The other duplicate dates and times are removed from the object along with their corresponding data.

Description

`fints` constructs a financial time series object. A financial time series object is a MATLAB object that contains a series of dates and one or more series of data. Before you perform an operation on the data, you must set the frequency indicator (`freq`). You can optionally provide a description (`desc`) for the time series.

`tsobj = fints(dates_and_data)` creates a financial time series object containing the dates and data from the matrix `dates_and_data`. If the dates contain time-of-day information, the object contains an additional series of times. The date series and each data series must

each be a column in the input matrix. The names of the data series default to `series1`, ..., `seriesn`. The `desc` and `freq` fields are set to their defaults.

`tsobj = fints(dates, data)` generates a financial time series object containing dates from the `dates` column vector of dates and data from the matrix `data`. If the dates contain time-of-day information, the object contains an additional series of times. The data matrix must be column-oriented, that is, each column in the matrix is a data series. The names of the series default to `series1`, ..., `seriesn`, where `n` is the total number of columns in `data`. The `desc` and `freq` fields are set to their defaults.

`tsobj = fints(dates, data, datanames)` additionally allows you to rename the data series. The names are specified in the `datanames` cell array. The number of strings in `datanames` must correspond to the number of columns in `data`. The `desc` and `freq` fields are set to their defaults.

`tsobj = fints(dates, data, datanames, freq)` additionally sets the frequency when you create the object. The `desc` field is set to its default `''`.

`tsobj = fints(dates, data, datanames, freq, desc)` provides a description string for the financial time series object.

Examples

Example 1. Create a financial time series containing days and data only.

```
data = [1:6]'  
  
data =  
  
    1  
    2  
    3  
    4  
    5  
    6
```

```
dates = [today:today+5]'

dates =

    731132
    731133
    731134
    731135
    731136
    731137

tsobjkt = fints(dates, data)

tsobjkt =

    desc: (none)
    freq: Unknown (0)

    'dates: (6)'      'series1: (6)'
    '08-Oct-2001'    [          1]
    '09-Oct-2001'    [          2]
    '10-Oct-2001'    [          3]
    '11-Oct-2001'    [          4]
    '12-Oct-2001'    [          5]
    '13-Oct-2001'    [          6]
```

Example 2. Expand Example 1 to include time-of-day information>

```
dates = [now:now+5]';

tsobjkt = fints(dates, data)

tsobjkt =

    desc: (none)
    freq: Unknown (0)
```

```
'dates: (6)'      'times: (6)'      'series1: (6)'  
'08-Oct-2001'    '14:51'           [          1]  
'09-Oct-2001'    '14:51'           [          2]  
'10-Oct-2001'    '14:51'           [          3]  
'11-Oct-2001'    '14:51'           [          4]  
'12-Oct-2001'    '14:51'           [          5]  
'13-Oct-2001'    '14:51'           [          6]
```

Example 3. Create a financial time series object when dates and times are located in separate vectors.

Step 1. Create a column vector of times in date number format:

```
times = datenum(datestr(now:1/24+1/24/60:now+6/24+1/24/60,15))  
  
times =  
  
    0.43750000000000  
    0.47986111111111  
    0.52222222222222  
    0.56458333333333  
    0.60694444444444  
    0.64930555555556
```

Step 2. Create a column vector of dates:

```
dates = [today:today+5]'  
  
dates =  
  
    731133  
    731134  
    731135  
    731136  
    731137  
    731138
```

Step 3. Concatenate dates and times into a single matrix:

```

dates_times = [dates, times]

dates_times =

1.0e+005 *

7.311330000000000  0.000004375000000
7.311340000000000  0.000004798611111
7.311350000000000  0.000005222222222
7.311360000000000  0.000005645833333
7.311370000000000  0.000006069444444
7.311380000000000  0.000006493055556

```

Step 4. Create column vector of data:

```
data = [1:6]'
```

Step 5. Create the financial time series object:

```
tsobj = fints(dates_times, data)
```

```
tsobj =
```

```

desc: (none)
freq: Unknown (0)

'dates: (6)'   'times: (6)'   'series1: (6)'
'09-Oct-2001' '10:30'       [          1]
'10-Oct-2001' '11:31'       [          2]
'11-Oct-2001' '12:32'       [          3]
'12-Oct-2001' '13:33'       [          4]
'13-Oct-2001' '14:34'       [          5]
'14-Oct-2001' '15:35'       [          6]

```

datenum, datestr

Purpose Fast stochastics

Syntax

```
[pctk, pctd] = fpctkd(highp, lowp, closep)
[pctk, pctd] = fpctkd([highp lowp closep])
[pctk, pctd] = fpctkd(highp, lowp, closep, kperiods, dperiods,
dmamethod)
[pctk, pctd] = fpctkd([highp lowp closep], kperiods, dperiods,
dmamethod)
pkdts = fpctkd(tsobj, kperiods, dperiods, dmamethod)
pkdts = fpctkd(tsobj, kperiods, dperiods, dmamethod, ParameterName,
ParameterValue, ...)
```

Arguments

highp	High price (vector).
lowp	Low price (vector).
closep	Closing price (vector).
kperiods	(Optional) %K periods. Default = 10.
dperiods	(Optional) %D periods. Default = 3.
damethod	(Optional) %D moving average method. Default = 'e' (exponential).
tsobj	Financial time series object.
ParameterName	Valid parameter names are:

- HighName: high prices series name
- LowName: low prices series name
- CloseName: closing prices series name

ParameterValue Parameter values are the strings that represent the valid parameter names.

Description

fpctkd calculates the stochastic oscillator.

[pctk, pctd] = fpctkd(highp, lowp, closep) calculates the fast stochastics F%K and F%D from the stock price data highp (high prices), lowp (low prices), and closep (closing prices).

[pctk, pctd] = fpctkd([highp lowp closep]) accepts a three-column matrix of high (highp), low (lowp), and closing prices (closep), in that order.

[pctk, pctd] = fpctkd(highp, lowp, closep, kperiods, dperiods, dmamethod) calculates the fast stochastics F%K and F%D from the stock price data highp (high prices), lowp (low prices), and closep (closing prices). kperiods sets the %K period. dperiods sets the %D period.

dmamethod specifies the %D moving average method. Valid moving average methods for %D are Exponential ('e') and Triangular ('t'). See tsmovavg for explanations of these methods.

[pctk, pctd]= fpctkd([highp lowp closep], kperiods, dperiods, dmamethod) accepts a three-column matrix of high (highp), low (lowp), and closing prices (closep), in that order.

pkdts = fpctkd(tsobj, kperiods, dperiods, dmamethod) calculates the fast stochastics F%K and F%D from the stock price data in the financial time series object tsobj. tsobj must minimally contain the series High (high prices), Low (low prices), and Close (closing prices). pkdts is a financial time series object with similar dates to tsobj and two data series named PercentK and PercentD.

pkdts = fpctkd(tsobj, kperiods, dperiods, dmamethod, ParameterName, ParameterValue, ...) accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Parameter values are the strings that represent the valid parameter names.

Examples

Compute the stochastic oscillator for Disney stock and plot the results:

```
load disney.mat
dis_FastStoc = fpctkd(dis)
plot(dis_FastStoc)
title('Stochastic Oscillator for Disney')
```

Purpose Fractional currency value to decimal value

Syntax `Decimal = frac2cur(Fraction, Denominator)`

Description `Decimal = frac2cur(Fraction, Denominator)` converts a fractional currency value to a decimal value. `Fraction` is the fractional currency value input as a string, and `Denominator` is the denominator of the fraction.

Examples `Decimal = frac2cur('12.1', 8)`

returns

```
Decimal =  
12.1250
```

freqnum

Purpose Convert string frequency indicator to numeric frequency indicator

Syntax `nfreq = freqnum(sfreq)`

Arguments

`sfreq` UNKNOWN, Unknown, unknown, U, u
DAILY, Daily, daily, D, d
WEEKLY, Weekly, weekly, W, w
MONTHLY, Monthly, monthly, M, m
QUARTERLY, Quarterly, quarterly, Q, q
SEMIANNUAL, Semiannual, semiannual, S, s
ANNUAL, Annual, annual, A, a

Description `nfreq = freqnum(sfreq)` converts a string frequency indicator into a numeric value.

String Frequency Indicator	Numeric Representation
UNKNOWN, Unknown, unknown, U, u	0
DAILY, Daily, daily, D, d	1
WEEKLY, Weekly, weekly, W, w	2
MONTHLY, Monthly, monthly, M, m	3
QUARTERLY, Quarterly, quarterly, Q, q	4
SEMIANNUAL, Semiannual, semiannual, S, s	5
ANNUAL, Annual, annual, A, a	6

Purpose Mean-variance efficient frontier

Syntax [PortRisk, PortReturn, PortWts] = frontcon(ExpReturn, ExpCovariance, NumPorts, PortReturn, AssetBounds, Groups, GroupBounds)

Arguments

ExpReturn	1 by number of assets (NASSETS) vector specifying the expected (mean) return of each asset.
ExpCovariance	NASSETS-by-NASSETS matrix specifying the covariance of asset returns.
NumPorts	(Optional) Number of portfolios generated along the efficient frontier. Returns are equally spaced between the maximum possible return and the minimum risk point. If NumPorts is empty (entered as []), frontcon computes 10 equally spaced points. When entering a target rate of return (PortReturn), enter NumPorts as an empty matrix [].
PortReturn	(Optional) Vector of length equal to the number of portfolios (NPORTS) containing the target return values on the frontier. If PortReturn is not entered or [], NumPorts equally spaced returns between the minimum and maximum possible values are used.
AssetBounds	(Optional) 2-by-NASSETS matrix containing the lower and upper bounds on the weight allocated to each asset in the portfolio. Default lower bound = all 0s (no short-selling). Default upper bound = all 1s (any asset may constitute the entire portfolio).

Groups	(Optional) Number of groups (NGROUPS)-by-NASSETS matrix specifying NGROUPS asset groups or classes. Each row specifies a group. $\text{Groups}(i, j) = 1$ (j th asset belongs in the i th group). $\text{Groups}(i, j) = 0$ (j th asset not a member of the i th group).
GroupBounds	(Optional) NGROUPS-by-2 matrix specifying, for each group, the lower and upper bounds of the total weights of all assets in that group. Default lower bound = all 0s. Default upper bound = all 1s.

Description

`[PortRisk, PortReturn, PortWts] = frontcon(ExpReturn, ExpCovariance, NumPorts, PortReturn, AssetBounds, Groups, GroupBounds)` returns the mean-variance efficient frontier with user-specified asset constraints, covariance, and returns. For a collection of NASSETS risky assets, computes a portfolio of asset investment weights that minimize the risk for given values of the expected return. The portfolio risk is minimized subject to constraints on the asset weights or on groups of asset weights.

PortRisk is an NPORTS-by-1 vector of the standard deviation of each portfolio.

PortReturn is a NPORTS-by-1 vector of the expected return of each portfolio.

PortWts is an NPORTS-by-NASSETS matrix of weights allocated to each asset. Each row represents a portfolio. The total of all weights in a portfolio is 1.

frontcon generates a plot of the efficient frontier if you invoke it without output arguments.

The asset returns are assumed to be jointly normal, with expected mean returns of ExpReturn and return covariance ExpCovariance. The variance of a portfolio with 1-by-NASSETS weights PortWts is given by

$\text{PortVar} = \text{PortWts} * \text{ExpCovariance} * \text{PortWts}'$. The portfolio expected return is $\text{PortReturn} = \text{dot}(\text{ExpReturn}, \text{PortWts})$.

Examples

Given three assets with expected returns of

```
ExpReturn = [0.1 0.2 0.15];
```

and expected covariance of

```
ExpCovariance = [ 0.0100  -0.0061  0.0042
                  -0.0061  0.0400  -0.0252
                   0.0042  -0.0252  0.0225];
```

compute the mean-variance efficient frontier for four points.

```
NumPorts = 4;
[PortRisk, PortReturn, PortWts] = frontcon(ExpReturn,...
ExpCovariance, NumPorts)
```

```

See Also ewstats, portopt, portstats

Purpose Rolling efficient frontier

Syntax [PortWts, AllMean, AllCovariance] = frontier(Universe, Window, Offset, NumPorts, ActiveMap, ConSet, NumNonNan)

Arguments

Universe	Number of observations (NUMOBS) by number of assets plus one (NASSETS + 1) time series array containing total return data for a group of securities. Each row represents an observation. Column 1 contains MATLAB serial date numbers. The remaining columns contain the total return data for each security.
Window	Number of data periods used to calculate each frontier.
Offset	Increment in number of periods between each frontier.
NumPorts	Number of portfolios to calculate on each frontier.
ActiveMap	(Optional) Number of observations (NUMOBS) by number of assets (NASSETS) matrix with Boolean elements corresponding to the Universe. Each element indicates if the asset is part of the Universe on the corresponding date. Default = NUMOBS-by-NASSETS matrix of 1's (all assets active on all dates).

Conset	(Optional) Constraint matrix for a portfolio of asset investments, created using portcons with the 'Default' constraint type. This single constraint matrix is applied to each frontier.
NumNonNan	(Optional) Minimum number of nonNaN points for each active asset in each window of data needed to perform the optimization. The default value is Window - NASSETS.

Description

`[PortWts, AllMean, AllCovariance] = frontier(Universe, Window, Offset, NumPorts, ActiveMap, ConSet, NumNonNan)` generates a surface of efficient frontiers showing how asset allocation influences risk and return over time.

PortWts is a number of curves (NCURVES) by 1 cell array, where each element is a NPORTS-by-NASSETS matrix of weights allocated to each asset.

AllMean is a NCURVES-by-1 cell array, where each element is a 1-by-NASSETS vector of the expected asset returns used to generate each curve on the surface.

AllCovariance is a NCURVES-by-1 cell array, where each element is a NASSETS-by-NASSETS vector of the covariance matrix used to generate each curve on the surface.

fts2ascii

Purpose Write elements of time-series data into ASCII file

Syntax

```
stat = fts2ascii(filename, tsoj, exttext)
stat = fts2ascii(filename, dates, data, colheads, desc, exttext)
```

Arguments

filename	Name of an ASCII file
tsoj	Financial time series object
exttext	(Optional) Extra text. A string written after the description line (line 2 in the file).
dates	Column vector containing dates. Dates must be in serial date number format and can specify time of day.
data	Column-oriented matrix. Each column is a series.
colheads	(Optional) Cell array of column headers (names); first cell must always be the one for the dates column. colheads will be written to the file just before the data.
desc	(Optional) Description string, which will be the first line in the file.

Description `stat = fts2ascii(filename, tsoj, exttext)` writes the financial time series object `tsoj` into an ASCII file `filename`. The data in the file is tab delimited.

`stat = fts2ascii(filename, dates, data, colheads, desc, exttext)` writes into an ASCII file `filename` the dates, times, and data contained in the column vector `dates` and the column-oriented matrix `data`. The first column in `filename` contains the dates, followed by times (if specified). Subsequent columns contain the data. The data in the file is tab delimited.

stat indicates whether file creation is successful (1) or not (0).

ascii2fts

fts2mat

Purpose Convert to matrix

Syntax

```
tsmat = fts2mat(tsoobj)
tsmat = fts2mat(tsoobj, datesflag)
tsmat = fts2mat(tsoobj, seriesnames)
tsmat = fts2mat(tsoobj, datesflag, seriesnames)
```

Arguments

<code>tsoobj</code>	Financial time series object
<code>datesflag</code>	(Optional) Specifies inclusion of dates vector: <code>datesflag = 0</code> (default) excludes dates. <code>datesflag = 1</code> includes dates vector.
<code>seriesnames</code>	(Optional) Specifies the data series to be included in the matrix. Can be a cell array of strings.

Description

`tsmat = fts2mat(tsoobj)` takes the data series in the financial time series object `tsoobj` and puts them into the matrix `tsmat` as columns. The order of the columns is the same as the order of the data series in the object `tsoobj`.

`tsmat = fts2mat(tsoobj, datesflag)` specifies whether or not you want the dates vector included. The dates vector will be the first column. The dates are represented as serial date numbers. Dates can include time-of-day information.

`tsmat = fts2mat(tsoobj, seriesnames)` extracts the data series named in `seriesnames` and puts its values into `tsmat`. The `seriesnames` argument can be a cell array of strings.

`tsmat = fts2mat(tsoobj, datesflag, seriesnames)` puts into `tsmat` the specific data series named in `seriesnames`. The `datesflag` argument must be specified. If `datesflag` is set to 1, the dates vector

is included. If you specify an empty matrix ([]) for datesflag, the default behavior is adopted.

See Also

subsref

ftsbound

Purpose Start and end dates

Syntax
`datesbound = ftsbound(tsoj)`
`datesbound = ftsbound(tsoj, dateform)`

Arguments

`tsoj` Financial time series object
`dateform` `dateform` is an integer representing the format of a date string. See `datestr` for a description of these formats.

Description

`ftsbound` returns the start and end dates of a financial time series object. If the object contains time-of-day data, `ftsbound` additionally returns the starting time on the first date and the ending time on the last date.

`datesbound = ftsbound(tsoj)` returns the start and end dates contained in `tsoj` as serial dates in the column matrix `datesbound`. The first row in `datesbound` corresponds to the start date, and the second corresponds to the end date.

`datesbound = ftsbound(tsoj, dateform)` returns the starting and ending dates contained in the object, `tsoj`, as date strings in the column matrix, `datesbound`. The first row in `datesbound` corresponds to the start date, and the second corresponds to the end date. The `dateform` argument controls the format of the output dates.

See Also

`datestr`

Purpose Financial time series GUI

Syntax ftsgui

Description ftsgui displays the financial time series graphical user interface (GUI) main window.

The use of the financial time series GUI is described in Chapter 10, “Financial Time Series Graphical User Interface”.

Examples ftsgui

ftsinfo

Purpose Financial time series object information

Syntax `ftsinfo(tsoobj)`
`infofts = ftsinfo(tsoobj)`

Arguments

`tsoobj` Financial time series object.

Description `ftsinfo(tsoobj)` displays information about the financial time series object `tsoobj`.

`infofts = ftsinfo(tsoobj)` stores information about the financial time series object `tsoobj` in the structure `infofts`.

`infofts` has these fields.

Field	Contents
<code>version</code>	Financial time series object version.
<code>desc</code>	Description of the time series object (<code>tsoobj.desc</code>).
<code>freq</code>	Numeric representation of the time series data frequency (<code>tsoobj.freq</code>). See <code>freqstr</code> for list of numeric frequencies and what they represent.
<code>startdate</code>	Earliest date in the time series.
<code>enddate</code>	Latest date in the time series.
<code>seriesnames</code>	Cell array containing the time series data column names.
<code>ndata</code>	Number of data points in the time series.
<code>nseries</code>	Number of columns of time series data.

Examples

Convert the supplied file `disney.dat` into a financial time series object named `dis`:

```
dis = ascii2fts('disney.dat', 1, 3);
```

Now use `ftsinfo` to obtain information about `dis`:

```
ftsinfo(dis)

FINTS version: 2.0
Description: Walt Disney Company (DIS)
Frequency: Unknown
Start date: 29-Mar-1996
End date: 29-Mar-1999
Series names: OPEN
              HIGH
              LOW
              CLOSE
              VOLUME
# of data: 782
# of series: 5
```

Then, executing

```
infodis = ftsinfo(dis)
```

creates the structure `infodis` containing the values

```
infodis =

    ver: '2.0'
   desc: 'Walt Disney Company (DIS)'
   freq: 0
startdate: '29-Mar-1996'
  enddate: '29-Mar-1999'
seriesnames: {5x1 cell}
   ndata: 782
  nseries: 5
```

ftsinfo

fints, freqnum, freqstr, ftsbound

Purpose

Determine uniqueness

Syntax

```
uniq = ftsuniq(dates_and_times)
[uniq, dup] = ftsuniq(dates_and_times)
```

Arguments

`dates_and_times` A single column vector of serial date numbers. The serial date numbers can include time-of-day information.

Description

`uniq = ftsuniq(dates_and_times)` returns 1 if the dates and times within the financial time series object are unique and 0 if duplicates exist.

`[uniq, dup] = ftsuniq(dates_and_times)` additionally returns a structure `dup`. In the structure

- `dup.dt` contains the strings of the duplicate dates and times and their locations in the object.
- `dup.intidx` contains the integer indices of duplicate dates and times in the object.

`fints`

fvdisc

Purpose Future value of discounted security

Syntax FutureVal = fvdisc(Settle, Maturity, Price, Discount, Basis)

Arguments

Settle	Settlement date. Enter as serial date number or date string. Settle must be earlier than or equal to Maturity.
Maturity	Maturity date. Enter as serial date number or date string.
Price	Price (present value) of the security.
Discount	Bank discount rate of the security. Enter as decimal fraction.
Basis	(Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)

Description

FutureVal = fvdisc(Settle, Maturity, Price, Discount, Basis) finds the amount received at maturity for a fully vested security.

Examples

Using this data

```
Settle = '02/15/2001';  
Maturity = '05/15/2001';  
Price = 100;  
Discount = 0.0575;  
Basis = 2;
```

```
FutureVal = fvdisc(Settle, Maturity, Price, Discount, Basis)
```

returns

```
FutureVal =  
          101.44
```

Purpose Future value with fixed periodic payments

Syntax `FutureVal = fvfix(Rate, NumPeriods, Payment, PresentVal, Due)`

Arguments

Rate	Periodic interest rate, as a decimal fraction.
NumPeriods	Number of periods.
Payment	Periodic payment.
PresentVal	(Optional) Initial value. Default = 0.
Due	(Optional) When payments are due or made: 0 = end of period (default), or 1 = beginning of period.

Description `FutureVal = fvfix(Rate, NumPeriods, Payment, PresentVal, Due)` returns the future value of a series of equal payments.

Examples A savings account has a starting balance of \$1500. \$200 is added at the end of each month for 10 years and the account pays 9% interest compounded monthly. Using this data

```
FutureVal = fvfix(0.09/12, 12*10, 200, 1500, 0)
```

returns

```
FutureVal =  
42379.89
```

See Also `fvvar`, `pvfix`, `pvvar`

Purpose Future value of varying cash flow

Syntax `FutureVal = fvvar(CashFlow, Rate, IrrCFDates)`

Arguments

CashFlow	A vector of varying cash flows. Include the initial investment as the initial cash flow value (a negative number).
Rate	Periodic interest rate. Enter as a decimal fraction.
IrrCFDates	(Optional) For irregular (nonperiodic) cash flows, a vector of dates on which the cash flows occur. Enter dates as serial date numbers or date strings. Default assumes CashFlow contains regular (periodic) cash flows.

Description `FutureVal = fvvar(CashFlow, Rate, IrrCFDates)` returns the future value of a varying cash flow.

Examples This cash flow represents the yearly income from an initial investment of \$10,000. The annual interest rate is 8%.

Year 1	\$2000
Year 2	\$1500
Year 3	\$3000
Year 4	\$3800
Year 5	\$5000

For the future value of this regular (periodic) cash flow

```
FutureVal = fvvar([-10000 2000 1500 3000 3800 5000], 0.08)
```

returns

```
FutureVal =
```

```
2520.47
```

An investment of \$10,000 returns this irregular cash flow. The original investment and its date are included. The periodic interest rate is 9%.

Cash Flow	Dates
(\$10000)	January 12, 2000
\$2500	February 14, 2001
\$2000	March 3, 2001
\$3000	June 14, 2001
\$4000	December 1, 2001

To calculate the future value of this irregular (nonperiodic) cash flow

```
CashFlow = [-10000, 2500, 2000, 3000, 4000];
```

```
IrrCFDates = ['01/12/2000'  
              '02/14/2001'  
              '03/03/2001'  
              '06/14/2001'  
              '12/01/2001'];
```

```
FutureVal = fvvar(CashFlow, 0.09, IrrCFDates)
```

returns

```
FutureVal =
```

170.66

fwd2zero

Purpose Zero curve given forward curve

Syntax [ZeroRates, CurveDates] = fwd2zero(ForwardRates, CurveDates, Settle, Compounding, Basis)

Arguments

ForwardRates	A number of bonds (NUMBONDS)-by-1 vector of annualized implied forward rates, as decimal fractions. In aggregate, the rates in ForwardRates constitute an implied forward curve for the investment horizon represented by CurveDates. The first element pertains to forward rates from the settlement date to the first curve date.
CurveDates	A NUMBONDS-by-1 vector of maturity dates (as serial date numbers) that correspond to the forward rates.
Settle	A serial date number that is the common settlement date for the forward rates.
Compounding	(Optional) Output compounding. A scalar that sets the compounding frequency per year for annualizing the output zero rates. Allowed values are: 1 Annual compounding 2 Semiannual compounding (default) 3 Compounding three times per year 4 Quarterly compounding 6 Bimonthly compounding 12 Monthly compounding 365 Daily compounding

	- 1	Continuous compounding
Basis	(Optional)	Output day-count basis for annualizing the output zero rates.
		<ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)

Description

[ZeroRates, CurveDates] = fwd2zero(ForwardRates, CurveDates, Settle, Compounding, Basis) returns a zero curve given an implied forward rate curve and its maturity dates.

ZeroRates A NUMBONDS-by-1 vector of decimal fractions. In aggregate, the rates in ZeroRates constitute a zero curve for the investment horizon represented by CurveDates.

CurveDates A NUMBONDS-by-1 vector of maturity dates (as serial date numbers) that correspond to the zero rates in ZeroRates. This vector is the same as the input vector CurveDates.

Examples

Given an implied forward rate curve over a set of maturity dates, a settlement date, and a compounding rate, compute the zero curve.

```
ForwardRates = [0.0469
                0.0519
                0.0549
                0.0535
                0.0558
                0.0508
                0.0560
                0.0545
                0.0615
                0.0486];

CurveDates = [datenum('06-Nov-2000')
              datenum('11-Dec-2000')
              datenum('15-Jan-2001')
              datenum('05-Feb-2001')
              datenum('04-Mar-2001')
              datenum('02-Apr-2001')
              datenum('30-Apr-2001')
              datenum('25-Jun-2001')
              datenum('04-Sep-2001')
              datenum('12-Nov-2001')];

Settle = datenum('03-Nov-2000');
```

```
Compounding = 1;
```

Execute the function

```
[ZeroRates, CurveDates] = fwd2zero(ForwardRates, CurveDates,...  
Settle, Compounding)
```

which returns the zero curve ZeroRates at the maturity dates CurveDates.

```
ZeroRates =
```

```
0.0469  
0.0515  
0.0531  
0.0532  
0.0538  
0.0532  
0.0536  
0.0539  
0.0556  
0.0543
```

```
CurveDates =
```

```
730796  
730831  
730866  
730887  
730914  
730943  
730971  
731027  
731098  
731167
```

For readability, `ForwardRates` and `ZeroRates` are shown here only to the basis point. However, MATLAB computed them at full precision. If you enter `ForwardRates` as shown, `ZeroRates` may differ due to rounding.

`zero2fwd` and other functions for “Term Structure of Interest Rates” on page 2-33

Purpose Content of specific field

Syntax

```
fieldval = getfield(tsoobj, field)
fieldval = getfield(tsoobj, field, {dates})
```

Arguments

<code>tsoobj</code>	Financial time series object.
<code>field</code>	Field name within <code>tsoobj</code> .
<code>dates</code>	Date range. Dates can be expanded to include time-of-day information.

Description

`getfield` treats the contents of a financial times series object `tsoobj` as fields in a structure.

`fieldval = getfield(tsoobj, field)` returns the contents of the specified field. This is equivalent to the syntax `fieldval = tsoobj.field`.

`fieldval = getfield(tsoobj, field, {dates})` returns the contents of the specified field for the specified dates. `dates` can be individual cells of date strings or a cell of a date string range using the `::` operator, such as `'03/01/99::03/31/99'`.

Examples

Create a financial time series object containing both date and time-of-day information:

```
dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
         '02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
dates_times = cellstr([dates, repmat(' ', size(dates,1),1), ...
                      times]);
AnFts = fints(dates_times, [(1:4)'; nan; 6], {'Data1'}, 1, ...
             'Yet Another Financial Time Series')
```

```
AnFts =  
  
desc: Yet Another Financial Time Series  
freq: Daily (1)  
  
'dates: (6)' 'times: (6)' 'Data1: (6)'  
'01-Jan-2001' '11:00' [ 1]  
' ' " '12:00' [ 2]  
'02-Jan-2001' '11:00' [ 3]  
' ' " '12:00' [ 4]  
'03-Jan-2001' '11:00' [ NaN]  
' ' " '12:00' [ 6]
```

Example 1. Get the contents of the times field in AnFts:

```
F = datestr(getfield(AnFts, 'times'))
```

```
F =
```

```
11:00 AM  
12:00 PM  
11:00 AM  
12:00 PM  
11:00 AM  
12:00 PM
```

Example 2. Extract the contents of specific data fields within AnFts:

```
FF = getfield(AnFts, 'Data1', ...  
             '01-Jan-2001 12:00::02-Jan-2001 12:00')
```

```
FF =
```

```
2  
3  
4
```

getnameidx

Purpose Find name in list

Syntax `nameidx = getnameidx(list, name)`

Arguments

<code>list</code>	Cell array of name strings.
<code>name</code>	String or cell array of name strings.

Description

`nameidx = getnameidx(list, name)` finds the occurrence of a name or set of names in a list. It returns an index (order number) indicating where the specified names are located within the list. If name is not found, `nameidx` returns 0.

If `name` is a cell array of names, `getnameidx` returns a vector containing the indices (order number) of the name strings within `list`. If none of the names in the `name` cell array is in `list`, it returns zero. If some of the names in `name` are not found, the indices for these names will be zeros.

`getnameidx` finds only the first occurrence of the name in the list of names. This function is meant to be used on a list of unique names (strings) only. It does not find multiple occurrences of a name or a list of names within `list`.

Examples

Given

```
poultry = {'duck', 'chicken'}
animals = {'duck', 'cow', 'sheep', 'horse', 'chicken'}
nameidx = getnameidx(animals, poultry)
ans =
     1     5
```

Given

```
poultry = {'duck', 'goose', 'chicken'}
```

```
animals = {'duck', 'cow', 'sheep', 'horse', 'chicken'}
nameidx = getnameidx(animals, poultry)
ans =
    1  0  5
```

See Also

findstr, strcmp, strfind

hhigh

Purpose Highest high

Syntax

```
hhv = hhigh(data)
hhv = hhigh(data, nperiods, dim)
hhvts = hhigh(tsobj, nperiods)
hhvts = hhigh(tsobj, nperiods, ParameterName, ParameterValue)
```

Arguments

<code>data</code>	Data series matrix.
<code>nperiods</code>	(Optional) Number of periods. Default = 14.
<code>dim</code>	(Optional) Dimension.
<code>tsobj</code>	Financial time series object.
<code>ParameterName</code>	The valid parameter name is: <ul style="list-style-type: none">• <code>HighName</code>: high prices series name
<code>ParameterValue</code>	The parameter value is a string that represents the valid parameter name.

Description `hhv = hhigh(data)` generates a vector of highest high values the past 14 periods from the matrix data.

`hhv = hhigh(data, nperiods, dim)` generates a vector of highest high values the past `nperiods` periods. `dim` indicates the direction in which the highest high is to be searched. If you input `[]` for `nperiods`, the default is 14.

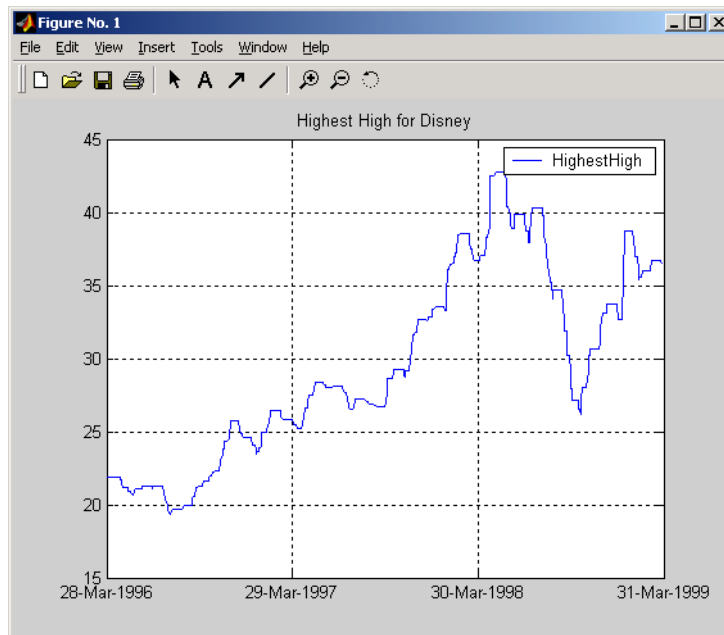

`hhvts = hhigh(tsobj, nperiods)` generates a vector of highest high values from `tsobj`, a financial time series object. `tsobj` must include at least the series `High`. The output `hhvts` is a financial time series object with the same dates as `tsobj` and data series named `HighestHigh`. If `nperiods` is specified, `hhigh` generates a financial time series object of highest high values for the past `nperiods` periods.

`hhvts = hhigh(tsoobj, nperiods, ParameterName, ParameterValue)` specifies the name for the required data series when it is different from the default name. The valid parameter name is `isHighName`. The parameter value is a string that represents the valid parameter name.

Example

Compute the highest high prices for Disney stock and plot the results:

```
load disney.mat
dis_HHigh = hhigh(dis)
plot(dis_HHigh)
title('Highest High for Disney')
```

See Also

`l1low`

highlow

Purpose Time series High-Low plot

Syntax

```
highlow(tsoobj)
highlow(tsoobj, color)
highlow(tsoobj, color, dateform)
highlow(tsoobj, color, dateform, ParameterName, ParameterValue, ...)
hhll = highlow(tsoobj, color, dateform, ParameterName,
ParameterValue, ...)
```

Arguments

<code>tsoobj</code>	Financial time series object.
<code>color</code>	(Optional) A three-element row vector representing RGB or a color identifier. (See <code>plot</code> in the MATLAB documentation.)
<code>dateform</code>	(Optional) Date string format used as the <i>x</i> -axis tick labels. (See <code>datetick</code> in the MATLAB documentation.) You can specify a <code>dateform</code> only when <code>tsoobj</code> does not contain time-of-day data. If <code>tsoobj</code> contains time-of-day data, <code>dateform</code> is restricted to <code>'dd-mmm-yyyy HH:MM'</code> .
<code>ParameterName</code>	<code>ParameterName</code> can be: <ul style="list-style-type: none">• <code>HighName</code>: high prices series name• <code>LowName</code>: low prices series name• <code>OpenName</code>: open prices series name• <code>CloseName</code>: closing prices series name
<code>ParameterValue</code>	The parameter value is a string that represents the valid parameter name.

Description

`highlow(tsobj)` generates a High-Low plot of the data in the financial time series object `tsobj`. `tsobj` must contain at least four data series representing the high, low, open, and closing prices. These series must have the names High, Low, Open, and Close (case-insensitive).

`highlow(tsobj, color)` additionally specifies the color of the plot.

`highlow(tsobj, color, dateform)` additionally specifies the date string format used as the *x*-axis tick labels. See `datestr` for a list of date string formats.

`highlow(tsobj, color, dateform, ParameterName, ParameterValue, ...)` indicates the actual name(s) of the required data series if the data series do not have the default names.

You can specify open prices as optional by providing the parameter name 'OpenName' and the parameter value '' (empty string).

```
highlow(tsobj, color, dateform, 'OpenName', '')
```

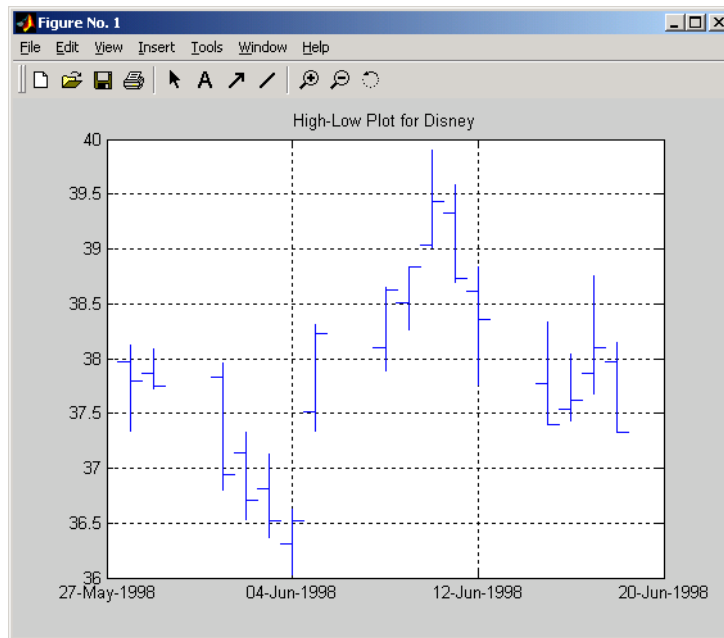

`hhll = highlow(tsobj, color, dateform, ParameterName, ParameterValue, ...)` returns the handle to the line object that makes up the High-Low plot.

Examples

Generate a High-Low plot for Disney stock for the dates from May 28 to June 18, 1998:

```
load disney.mat
highlow(dis('28-May-1998'::18-Jun-1998'))
title('High-Low Plot for Disney')
```

highlow

See Also

candle

Purpose High, low, open, close chart

Syntax `highlow(High, Low, Close, Open, Color)`
`Handles = highlow(High, Low, Close, Open, Color)`

Arguments

High	High prices for a security. A column vector.
Low	Low prices for a security. A column vector.
Close	Closing prices for a security. A column vector.
Open	(Optional) Opening prices for a security. A column vector. To specify Color when Open is unknown, enter Open as an empty matrix [].
Color	(Optional) Vertical line color. A string. MATLAB supplies a default color if none is specified. The default color differs depending on the background color of the figure window. See ColorSpec in the MATLAB documentation for color names.

Description

`highlow(High, Low, Close, Open, Color)` plots the high, low, opening, and closing prices of an asset. Plots are vertical lines whose top is the high, bottom is the low, open is a short horizontal tick to the left, and close is a short horizontal tick to the right.

`Handles = highlow(High, Low, Close, Open, Color)` plots the figure and returns the handles of the lines.

Examples

The high, low, and closing prices for an asset are stored in equal-length vectors `AssetHi`, `AssetLo`, and `AssetCl` respectively.

```
highlow(AssetHi, AssetLo, AssetCl, [], 'cyan')
```

plots the price data using cyan lines.

highlow

Purpose

Histogram

Syntax

```
hist(tsoobj, numbins)
ftshist = hist(tsoobj, numbins)
[ftshist, binpos] = hist(tsoobj, numbins)
```

Arguments

tsoobj	Financial time series object.
numbins	(Optional) Number of histogram bins. Default = 10.

Description

`hist(tsoobj, numbins)` calculates and displays the histogram of the data series contained in the financial time series object `tsoobj`.

`ftshist = hist(tsoobj, numbins)` calculates, but does not display, the histogram of the data series contained in the financial time series object `tsoobj`. The output `ftshist` is a structure with field names similar to the data series names of `tsoobj`.

`[ftshist, binpos] = hist(tsoobj, numbins)` additionally returns the bin positions `binpos`. The positions are the centers of each bin. `binpos` is a column vector.

Example

Create a histogram of Disney open, high, low, and close prices:

```
load disney.mat

hist in the MATLAB documentation

Purpose Portfolio holdings into weights

Syntax `Weights = holdings2weights(Holdings, Prices, Budget)`

Arguments

Holdings	Number of portfolios (NPORTS) by number of assets (NASSETS) matrix with the holdings of NPORTS portfolios containing NASSETS assets.
Prices	NASSETS vector of asset prices.
Budget	(Optional) Scalar or NPORTS vector of nonzero budget constraints. Default = 1.

Description

`Weights = holdings2weights(Holdings, Prices, Budget)` converts portfolio holdings into portfolio weights. The weights must satisfy a budget constraint such that the weights sum to Budget for each portfolio.

Weights is a NPORTS by NASSETS matrix containing the normalized weights of NPORTS portfolios containing NASSETS assets.

Notes

- Holdings may be negative to indicate a short position, but the overall portfolio weights must satisfy a nonzero budget constraint.
 - The weights in each portfolio sum to the Budget value (which is 1 if Budget is unspecified.)
-

`weights2holdings`

holidays

Purpose Holidays and nontrading days

Syntax Holidays = holidays(StartDate, EndDate)

Arguments

StartDate	Start date vector. Enter as serial date numbers or date strings.
EndDate	End date vector. Enter as serial date numbers or date strings.

Description

Holidays = holidays(StartDate, EndDate) returns a vector of serial date numbers corresponding to the holidays and nontrading days between StartDate and EndDate, inclusive.

Holidays = holidays returns a vector of serial date numbers corresponding to all holidays and nontrading days.

As shipped, this function contains all holidays and special nontrading days for the New York Stock Exchange between 1950 and 2050. You can edit the holidays.m file to contain your own holidays and nontrading days. By definition, holidays and nontrading days are those that occur on weekdays.

Examples

```
Holidays = holidays('jan 1 2001', 'jun 23 2001')
returns
Holidays =

    730852
    730901
    730954
    730999
```

which are the serial date numbers for

01-Jan-2001 (New Year's Day)
19-Feb-2001 (President's Day)
13-Apr-2001 (Good Friday)
28-May-2001 (Memorial Day)

horzcat

Purpose

Concatenate financial time series objects horizontally

Description

`horzcat` implements horizontal concatenation of financial time series objects. `horzcat` essentially merges the data columns of the financial time series objects. The time series objects must contain the exact same dates and times.

When multiple instances of a data series name occur, concatenation adds a suffix to the current names of the data series. The suffix has the format `_objectname<n>`, where `n` is a number indicating the position of the time series, from left to right, in the concatenation command. The `n` part of the suffix appears only when there is more than one instance of a particular data series name.

The description fields are concatenated as well. They are separated by two forward slashes (`//`).

Examples

Construct three financial time series, each containing a data series named `DataSeries`:

```
firstfts = fints((today:today+4)', (1:5)', 'DataSeries', 'd');
secondfts = fints((today:today+4)', (11:15)', 'DataSeries', 'd');
thirdfts = fints((today:today+4)', (21:25)', 'DataSeries', 'd');
```

Concatenate the time series horizontally into a new financial time series `newfts`:

```
newfts = [firstfts secondfts thirdfts secondfts];
```

The resulting object `newfts` has data series names `DataSeries_firstfts`, `DataSeries_secondfts2`, `DataSeries_thirdfts`, and `DataSeries_secondfts4`.

Verify this with the command

```
fieldnames(newfts)
```

```
ans =
```

```
'desc'  
'freq'  
'dates'  
'DataSeries_firstfts'  
'DataSeries_secondfts2'  
'DataSeries_thirdfts'  
'DataSeries_secondfts4'  
'times'
```

Use `chfield` to change the data series names.

Note If all input objects have the same frequency, the new object has that frequency as well. However, if one of the objects concatenated has a different frequency from the others, the frequency indicator of the resulting object is set to Unknown (0).

`vertcat`

hour

Purpose Hour of date or time

Syntax Hour = hour(Date)

Description Hour = hour(Date) returns the hour of the day given a serial date number or a date string.

Examples Hour = hour(730473.5584278936)

or

Hour = hour('19-dec-1999, 13:24:08.17')

returns

Hour =
13

See Also datevec, minute, second

Purpose Calculate information ratio for one or more assets

Syntax

```
inforatio(Asset, Benchmark)
Ratio = inforatio(Asset, Benchmark)
[Ratio, TE] = inforatio(Asset, Benchmark)
```

Arguments

Asset	NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES observations of asset returns for NUMSERIES asset return series.
Benchmark	NUMSAMPLES vector of returns for a benchmark asset. The periodicity must be the same as the periodicity of Asset. For example, if Asset is monthly data, then Benchmark must be monthly returns.

Description

Given NUMSERIES assets with NUMSAMPLES returns for each asset in a NUMSAMPLES x NUMSERIES matrix Asset and given a NUMSAMPLES vector of benchmark returns in Benchmark, inforatio computes the information ratio and tracking error for each asset relative to the Benchmark.

To summarize the outputs of inforatio:

- Ratio is a 1 x NUMSERIES row vector of information ratios for each series in Asset. Any series in Asset with a tracking error of 0 will have a NaN value for its information ratio.
- TE is a 1 x NUMSERIES row vector of tracking errors, that is, the standard deviation of Asset relative to Benchmark returns, for each series.

Note NaN values in the data are ignored. If the Asset and Benchmark series are identical, the information ratio will be NaN since the tracking error is 0. The information ratio and the Sharpe ratio of an Asset versus a riskless Benchmark (a Benchmark with standard deviation of returns equal to 0) are equivalent. This equivalence is not necessarily true if the Benchmark is risky.

Examples

See “Information Ratio Example” on page 4-6.

portalalpha, sharpe

Purpose Internal rate of return

Syntax Return = irr(CashFlow)

Description Return = irr(CashFlow) calculates the internal rate of return for a series of periodic cash flows. CashFlow is the cash flow vector. The first entry in CashFlow is the initial investment. If the initial investment is negative, irr generates a unique result only if all subsequent cash flows are positive. If some future cash flows are negative, irr generates nonunique solutions (multiple solutions that are each valid).

If the cash flow payments are monthly, multiply the resulting rate of return by 12 for the annual rate of return. This function calculates only positive rates of return; for nonpositive rates of return, Return = NaN.

Examples This cash flow represents the yearly income from an initial investment of \$100,000:

Year 1	\$10,000
Year 2	\$20,000
Year 3	\$30,000
Year 4	\$40,000
Year 5	\$50,000

To calculate the internal rate of return on the investment

```
Return = irr([-100000 10000 20000 30000 40000 50000])
```

returns

```
Return =
```

```
0.1201 (12.01%)
```

Purpose True for dates that are business days

Syntax `Busday = isbusday(Date, Holiday, Weekend)`

Arguments

Date	Date(s) being checked. Enter as a serial date number or date string. Date can contain multiple dates, but they must all be in the same format.
Holiday	(Optional) Vector of holidays and nontrading-day dates. All dates in Holiday must be the same format: either serial date numbers or date strings. (Using date numbers improves performance.) The holidays function supplies the default vector.
Weekend	(Optional) Vector of length 7, containing 0 and 1, the value 1 indicating weekend days. The first element of this vector corresponds to Sunday. Thus, when Saturday and Sunday form the weekend (default), then <code>Weekend = [1 0 0 0 0 0 1]</code> .

Description `Busday = isbusday(Date, Holiday, Weekend)` returns logical true (1) if Date is a business day and logical false (0) otherwise.

Examples

Example 1:

```
Busday = isbusday('16 jun 2001')
```

```
Busday =
```

```
0
```

```
Date = ['15 feb 2001'; '16 feb 2001'; '17 feb 2001'];
```

isbusday

```
Busday = isbusday(Date)
```

```
Busday =
```

```
    1  
    1  
    0
```

Example 2: Set June 21, 2003 (a Saturday) as a business day.

```
Weekend = [1 0 0 0 0 0 0];
```

```
isbusday('June 21, 2003', [], Weekend)
```

```
ans =
```

```
    1
```

Purpose Structural equality

Syntax `iscomp = iscompatible(tsoobj_1, tsoobj_2)`

Arguments

`tsoobj_1, tsoobj_2` A pair of financial time series objects.

Description

`iscomp = iscompatible(tsoobj_1, tsoobj_2)` returns 1 if both financial time series objects `tsoobj_1` and `tsoobj_2` have the same dates and data series names. It returns 0 if any component is different.

`iscomp = 1` indicates that the two objects contain the same number of data points as well as equal number of data series. However, the values contained in the data series can be different.

Note Data series names are case sensitive.

See Also `isequal`

isequal

Purpose Multiple object equality

Syntax `iseq = isequal(tsobj_1, tsobj_2, ...)`

Arguments

`tsobj_1 ...` A list of financial time series objects.

Description

`iseq = isequal(tsobj_1, tsobj_2, ...)` returns 1 if all listed financial time series objects have the same dates, data series names, and values contained in the data series. It returns 0 if any of those components is different.

Note Data series names are case sensitive.

`iseq = 1` implies that each object contains the same number of dates and the same data. Only the descriptions can differ.

See Also

`iscompatible`

Purpose Check whether string is field name

Syntax `F = isfield(tsoobj, name)`

Description `F = isfield(tsoobj, name)` returns true (1) if name is the name of a data series in tsoobj. Otherwise, `isfield` returns false (0).

See Also `fieldnames`, `getfield`, `setfield`

issorted

Purpose Check whether dates and times are monotonically increasing

Syntax `monod = issorted(tsobj)`

Arguments

`tsobj` Financial time series object

Description `monod = issorted(tsobj)` returns 1 if the dates and times in `tsobj` are monotonically increasing or 0 if they are not.

See Also `sortfts`

Purpose Lag time series object

Syntax

```
newfts = lagts(oldfts)
newfts = lagts(oldfts, lagperiod)
newfts = lagts(oldfts, lagperiod, padmode)
```

Arguments

<code>oldfts</code>	Financial time series object
<code>lagperiod</code>	Number of lag periods expressed in the frequency of the time series object
<code>padmode</code>	Data padding value

Description

`lagts` delays a financial time series object by a specified time step.

`newfts = lagts(oldfts)` delays the data series in `oldfts` by one time series date entry and returns the result in the object `newfts`. The end will be padded with zeros, by default.

`newfts = lagts(oldfts, lagperiod)` shifts time series values to the right on an increasing time scale. `lagts` delays the data series to happen at a later time. `lagperiod` is the number of lag periods expressed in the frequency of the time series object `oldfts`. For example, if `oldfts` is a daily time series, `lagperiod` is specified in days. `lagts` pads the data with zeros (default).

`newfts = lagts(oldfts, lagperiod, padmode)` lets you pad the data with an arbitrary value, NaN, or Inf rather than zeros by setting `padmode` to the desired value.

See Also

`leadts`

lbusdate

Purpose Last business date of month

Syntax `Date = lbusdate(Year, Month, Holiday, Weekend)`

Arguments

Year	Enter as four-digit integer.
Month	Enter as integer from 1 through 12.
Holiday	(Optional) Vector of holidays and nontrading-day dates. All dates in <code>Holiday</code> must be the same format: either serial date numbers or date strings. (Using date numbers improves performance.) The <code>holidays</code> function supplies the default vector.
Weekend	(Optional) Vector of length 7, containing 0 and 1, the value 1 indicating weekend days. The first element of this vector corresponds to Sunday. Thus, when Saturday and Sunday form the weekend (default), then <code>Weekend = [1 0 0 0 0 0 1]</code> .

Description

`Date = lbusdate(Year, Month, Holiday, Weekend)` returns the serial date number for the last business date of the given year and month. `Holiday` specifies nontrading days.

`Year` and `Month` can contain multiple values. If one contains multiple values, the other must contain the same number of values or a single value that applies to all. For example, if `Year` is a 1-by-n vector of integers, then `Month` must be a 1-by-n vector of integers or a single integer. `Date` is then a 1-by-n vector of date numbers.

Use the function `datestr` to convert serial date numbers to formatted date strings.

Examples

Example 1.

```
Date = lbusdate(2001, 5)
```

```
Date =
```

```
731002
```

```
datestr(Date)
```

```
ans =
```

```
31-May-2001
```

```
c
```

```
ans =
```

```
31-May-2001
```

```
31-May-2002
```

```
30-May-2003
```

Example 2. You can indicate that Saturday is a business day by appropriately setting the Weekend argument.

```
Weekend = [1 0 0 0 0 0 0];
```

May 31, 2003, is a Saturday. Use lbusdate to check that this Saturday is actually the last business day of the month.

```
Date = datestr(lbusdate(2003, 5, [], Weekend))
```

```
Date =
```

```
31-May-2003
```

See Also

busdate, eomdate, fbusdate, holidays, isbusday

leadts

Purpose Lead time series object

Syntax

```
newfts = leadts(oldfts)
newfts = leadts(oldfts, leadperiod)
newfts = leadts(oldfts, leadperiod, padmode)
```

Arguments

<code>oldfts</code>	Financial time series object.
<code>leadperiod</code>	Number of lead periods expressed in the frequency of the time series object.
<code>padmode</code>	Data padding value.

Description

`leadts` advances a financial time series object by a specified time step.

`newfts = leadts(oldfts)` advances the data series in `oldfts` by one time series date entry and returns the result in the object `newfts`. The end will be padded with zeros, by default.

`newfts = leadts(oldfts, leadperiod)` shifts time series values to the left on an increasing time scale. `leadts` advances the data series to happen at an earlier time. `leadperiod` is the number of lead periods expressed in the frequency of the time series object `oldfts`. For example, if `oldfts` is a daily time series, `leadperiod` is specified in days. `leadts` pads the data with zeros (default).

`newfts = leadts(oldfts, leadperiod, padmode)` lets you pad the data with an arbitrary value, NaN, or Inf rather than zeros by setting `padmode` to the desired value.

See Also

`lagts`

Purpose Get number of dates (rows)

Syntax `lenfts = length(tsobj)`

Description `lenfts = length(tsobj)` returns the number of dates (rows) in the financial time series object `tsobj`. This is the same as issuing `lenfts = size(tsobj, 1)`.

See Also `size`
`length` in the MATLAB documentation

Purpose Lowest low

Syntax

```
llv = llo(data)
llv = llo(data, nperiods, dim)
llvts = llo(tsoobj, nperiods)
llvts = llo(tsoobj, nperiods, ParameterName, ParameterValue)
```

Arguments

<code>data</code>	Data series matrix.
<code>nperiods</code>	(Optional) Number of periods. Default = 14.
<code>dim</code>	Dimension.
<code>tsoobj</code>	Financial time series object.
<code>ParameterName</code>	The valid parameter name is: <ul style="list-style-type: none">• <code>LowName</code>: low prices series name
<code>ParameterValue</code>	The parameter value is a string that represents the valid parameter name.

Description `llv = llo(data)` generates a vector of lowest low values for the past 14 periods from the matrix data.

`llv = llo(data, nperiods, dim)` generates a vector of lowest low values for the past `nperiods` periods. `dim` indicates the direction in which the lowest low is to be searched. If you input `[]` for `nperiods`, the default is 14.

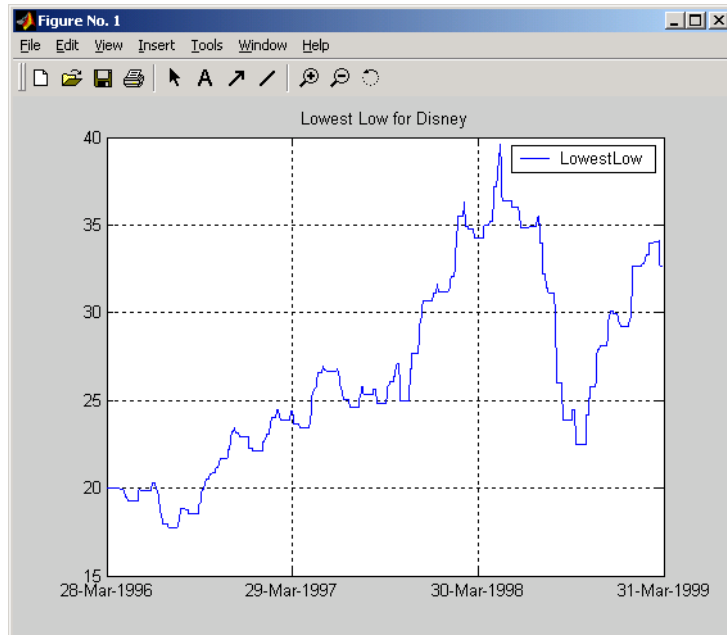

`llvts = llo(tsoobj, nperiods)` generates a vector of lowest low values from `tsoobj`, a financial time series object. `tsoobj` must include at least the series `Low`. The output `llvts` is a financial time series object with the same dates as `tsoobj` and data series named `LowestLow`. If `nperiods` is specified, `llo` generates a financial time series object of lowest low values for the past `nperiods` periods.

`llvts = l1ow(tsobj, nperiods, ParameterName, ParameterValue)` specifies the name for the required data series when it is different from the default name. The parameter value is a string that represents the valid parameter name.

Examples

Compute the lowest low prices for Disney stock and plot the results.

```
load disney.mat
dis_LLow = l1ow(dis)
plot(dis_LLow)
title('Lowest Low for Disney')
```

See Also

`hhigh`

log

Purpose Natural logarithm

Syntax `newfts = log(tsobj)`

Description `newfts = log(tsobj)` calculates the natural logarithm (log base e) of the data series in a financial time series object `tsobj`. It returns another time series object `newfts` containing the natural logarithms.

See Also `exp`, `log2`, `log10`

Purpose Common logarithm

Syntax `newfts = log10(tsobj)`

Description `newfts = log10(tsobj)` calculates the common logarithm (base 10) of all the data in the data series of the financial time series object `tsobj` and returns the result in the object `newfts`.

See Also `exp`, `log`, `log2`

log2

Purpose Base 2 logarithm

Syntax `newfts = log2(tsobj)`

Description `newfts = log2(tsobj)` calculates the base 2 logarithm of the data series in a financial time series object `tsobj`. It returns another time series object `newfts` containing the logarithms.

See Also `exp`, `log`, `log10`

Purpose Compute sample lower partial moments of data

Syntax

```
lpm(Data)
lpm(Data, MAR)
lpm(Data, MAR, Order)
Moment = lpm(Data, MAR, Order)
```

Arguments

Data	NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES observations of NUMSERIES asset returns.
MAR	(Optional) Scalar minimum acceptable return (default MAR = 0). This is a cutoff level of return such that all returns above MAR contribute nothing to the lower partial moment.
Order	(Optional) Either a scalar or a NUMORDERS-vector of nonnegative integer moment orders. If no order specified, default Order = 0, which is the shortfall probability. Although this function will work for noninteger orders and, in some cases, for negative orders, this falls outside customary usage.

Description

Given NUMSERIES assets with NUMSAMPLES returns in a NUMSAMPLES-by-NUMSERIES matrix `Data`, a scalar minimum acceptable return `MAR`, and one or more nonnegative moment orders in a NUMORDERS vector `Order`, `lpm` computes lower partial moments relative to `MAR` for each asset in a NUMORDERS \times NUMSERIES matrix `Moment`.

The output `Moment` is a NUMORDERS \times NUMSERIES matrix of lower partial moments with NUMORDERS `Orders` and NUMSERIES series, that is, each row contains lower partial moments for a given order.

Note To compute upper partial moments, just reverse the signs of both Data and MAR (do not reverse the sign of the output). This function computes sample lower partial moments from data. To compute expected lower partial moments for multivariate normal asset returns with a specified mean and covariance, use `elpm`. With `lpm`, you can compute various investment ratios such as Omega, Sortino, and Upside Potential, where:

- $\text{Omega} = \text{lpm}(-\text{Data}, -\text{MAR}, 1) / \text{lpm}(\text{Data}, \text{MAR}, 1)$
 - $\text{Sortino} = (\text{mean}(\text{Data}) - \text{MAR}) / \text{sqrt}(\text{lpm}(\text{Data}, \text{MAR}, 2))$
 - $\text{Upside} = \text{lpm}(-\text{Data}, -\text{MAR}, 1) / \text{sqrt}(\text{lpm}(\text{Data}, \text{MAR}, 2))$
-

Example

See “Sample Lower Partial Moments Example” on page 4-10.

`elpm`

Purpose Date of last occurrence of weekday in month

Syntax `LastDate = lweekdate(Weekday, Year, Month, NextDay)`

Arguments

Weekday	Weekday whose date you seek. Enter as an integer from 1 through 7:
1	Sunday
2	Monday
3	Tuesday
4	Wednesday
5	Thursday
6	Friday
7	Saturday
Year	Year. Enter as a four-digit integer.
Month	Month. Enter as an integer from 1 through 12.
NextDay	(Optional) Weekday that must occur after Weekday in the same week. Enter as an integer from 0 through 7, where 0 = ignore (default) and 1 through 7 are the same as for Weekday.

Any input can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all. For example, if `Year` is a 1-by-n vector of integers, then `Month` must be a 1-by-n vector of integers or a single integer. `LastDate` is then a 1-by-n vector of date numbers.

lweekdate

Description

LastDate = lweekdate(Weekday, Year, Month, NextDay) returns the serial date number for the last occurrence of Weekday in the given year and month and in a week that also contains NextDay.

Use the function datestr to convert serial date numbers to formatted date strings.

Examples

Example 1. To find the last Monday in June 2001

```
LastDate = lweekdate(2, 2001, 6); datestr>LastDate)
```

```
ans =
```

```
25-Jun-2001
```

Example 2. To find the last Monday in a week that also contains a Friday in June 2001

```
LastDate = lweekdate(2, 2001, 6, 6); datestr>LastDate)
```

```
ans =
```

```
25-Jun-2001
```

Example 3. To find the last Monday in May for 2001, 2002, and 2003

```
Year = [2001:2003];
```

```
LastDate = lweekdate(2, Year, 5)
```

```
LastDate =
```

```
          730999      731363      731727  
datestr>LastDate)
```

```
ans =
```

```
28-May-2001
```

27-May-2002

26-May-2003

eomdate, lbusdate, nweekdate

m2xdate

Purpose MATLAB serial date number to Excel serial date number

Syntax `DateNum = m2xdate(MATLABDateNumber, Convention)`

Arguments

MATLABDateNumber A vector or scalar of MATLAB serial date numbers.

Convention (Optional) Excel date system. A vector or scalar. When `Convention = 0` (default), the Excel 1900 date system is in effect. When `Convention = 1`, the Excel 1904 date system is used.

In the Excel 1900 date system, the Excel serial date number 1 corresponds to January 1, 1900 A.D. In the Excel 1904 date system, date number 0 is January 1, 1904 A.D.

Due to a software limitation in Excel, the year 1900 is considered a leap year. As a result, all DATEVALUE's reported by Excel between Jan. 1, 1900 and Feb. 28, 1900 (inclusive) differs from the values reported by 1. For example:

- In Excel, Jan. 1, 1900 = 1
- In MATLAB, Jan. 1, 1900 = 2

Vector arguments must have consistent dimensions.

Description

`DateNum = m2xdate(MATLABDateNumber, Convention)` converts MATLAB serial date numbers to Excel serial date numbers. MATLAB date numbers start with 1 = January 1, 0000 A.D., hence there is a difference of 693961 relative to the 1900 date system, or 695422 relative

to the 1904 date system. This function is useful with MATLAB Excel Link.

Examples

Given MATLAB date numbers for Christmas 2001 through 2004

```
DateNum = datenum(2001:2004, 12, 25)
```

```
DateNum =
```

```
       731210       731575       731940       732306
```

convert them to Excel date numbers in the 1904 system

```
ExDate = m2xdate(DateNum, 1)
```

```
ExDate =
```

```
       35788       36153       36518       36884
```

or the 1900 system

```
ExDate = m2xdate(DateNum)
```

```
ExDate =
```

```
       37250       37615       37980       38346
```

See Also

`datenum`, `datestr`, `x2mdate`

macd

Purpose Moving Average Convergence/Divergence (MACD)

Syntax

```
[macdvec, nineperma] = macd(data)
[macdvec, nineperma] = macd(data, dim)
macdts = macd(tsoobj, series_name)
```

Arguments

<code>data</code>	Data matrix
<code>dim</code>	Dimension. Default = 1 (column orientation).
<code>tsoobj</code>	Financial time series object
<code>series_name</code>	Data series name

Description

`[macdvec, nineperma] = macd(data)` calculates the Moving Average Convergence/Divergence (MACD) line, `macdvec`, from the data matrix, `data`, as well as the nine-period exponential moving average, `nineperma`, from the MACD line.

When the two lines are plotted, they can give you an indication of whether to buy or sell a stock, when an overbought or oversold condition is occurring, and when the end of a trend might occur.

The MACD is calculated by subtracting the 26-period (7.5%) exponential moving average from the 12-period (15%) moving average. The 9-day (20%) exponential moving average of the MACD line is used as the *signal* line. For example, when the MACD and the 20% moving average line have just crossed and the MACD line falls below the other line, it is time to sell.

`[macdvec, nineperma] = macd(data, dim)` lets you specify the orientation direction for the input. If the input data is a matrix, you need to indicate whether each row is a set of observations (`dim = 2`) or each column is a set of observations (`dim = 1`, the default).

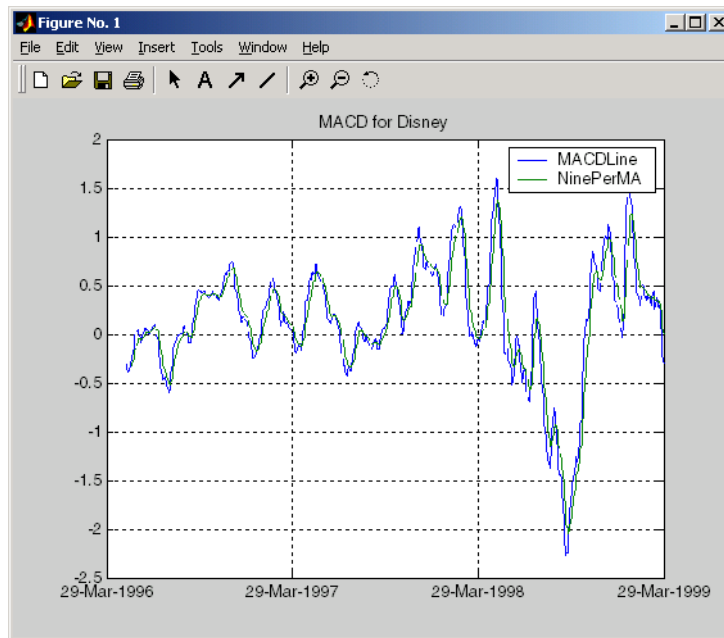

`macdts = macd(tsobj, series_name)` calculates the MACD line from the financial time series `tsobj`, as well as the nine-period exponential moving average from the MACD line. The MACD is calculated for the closing price series in `tsobj`, presumed to have been named `Close`. The result is stored in the financial time series object `macdts`. The `macdts` object has the same dates as the input object `tsobj` and contains only two series, named `MACDLine` and `NinePerMA`. The first series contains the values representing the MACD line and the second is the nine-period exponential moving average of the MACD line.

Examples

Compute the MACD for Disney stock and plot the results:

```
load disney.mat
dis_CloseMACD = macd(dis);
dis_OpenMACD = macd(dis, 'OPEN');
plot(dis_CloseMACD);
plot(dis_OpenMACD);
title('MACD for Disney')
```

macd

See Also [adline](#), [willad](#)

Purpose Maximum value

Syntax `tymax = max(tsobj)`

Description `tymax = max(tsobj)` finds the maximum value in each data series in the financial time series object `tsobj` and returns it in a structure `tymax`. The `tymax` structure contains field name(s) identical to the data series name(s).

Note `tymax` returns only the values and does not return the dates associated with the values. The maximum values are not necessarily from the same date.

See Also `min`

maxdrawdown

Purpose Compute maximum drawdown for one or more price series

Syntax
MaxDD = maxdrawdown(Data)
MaxDD = maxdrawdown(Data, *Format*)
[MaxDD, MaxDDIndex] = maxdrawdown(Data, *Format*)

Arguments

Data T-by-N matrix with T samples of N total return price series (also known as total equity).

Format (Optional) MATLAB string indicating format of data. Possible values are:

- 'return' (default): Maximum drawdown in terms of maximum percentage drop from a peak.
- 'arithmetic': Maximum drawdown of an arithmetic Brownian motion with drift (differences of data from peak to trough) using the equation
$$dX(t) = \mu dt + \sigma dW(t)$$
- 'geometric': Maximum drawdown of a geometric Brownian motion with drift (differences of log of data from peak to trough) using the equation
$$dS(t) = \mu_0 S(t) dt + \sigma_0 S(t) dW(t)$$

Description MaxDD = maxdrawdown(Data, *Format*) computes maximum drawdown for each series in an N-vector MaxDD and identifies start and end indexes of maximum drawdown periods for each series in a 2 x N matrix MaxDDIndex.

To summarize the outputs of maxdrawdown:

- MaxDD is a 1-by-N vector with maximum drawdown for each of N time series.

- MaxDDIndex is a 2-by-N vector of start and end indexes for each maximum drawdown period for each total equity time series, where the first row contains the start indexes and the second row contains the end indexes of each maximum drawdown period.

Notes

- Drawdown is the percentage drop in total returns from the start to the end of a period. If the total equity time series is increasing over an entire period, drawdown is 0. Otherwise, it is a negative number. Maximum drawdown is an ex-ante proxy for downside risk that computes the largest drawdown over all intervals of time that can be formed within a specified interval of time.
- Maximum drawdown is sensitive to quantization error.

Example

See “Maximum Drawdown Example” on page 4-13.

emaxdrawdown

mean

Purpose Arithmetic average

Syntax `tsmean = mean(tsobj)`

Description `tsmean = mean(tsobj)` computes the arithmetic mean of all data in all series in `tsobj` and returns it in a structure `tsmean`. The `tsmean` structure contains field name(s) identical to the data series name(s).

See Also `peravg`, `tsmovavg`

Purpose

Median price

Syntax

```
mprc = medprice(highp, lowp)
mprc = medprice([highp lowp])
mprcts = medprice(tsobj)
mprcts = medprice(tsobj, ParameterName, ParameterValue, ...)
```

Arguments

highp	High price (vector)
lowp	Low price (vector)
tsobj	Financial time series object
ParameterName	Valid parameter names are: <ul style="list-style-type: none"> • HighName: high prices series name • LowName: low prices series name
ParameterValue	Parameter values are the strings that represent the valid parameter names.

Description

`mprc = medprice(highp, lowp)` calculates the median prices `mprc` from the high (`highp`) and low (`lowp`) prices. The median price is the average of the high and low price for each period.

`mprc = medprice([highp lowp])` accepts a two-column matrix as the input rather than two individual vectors. The columns of the matrix represent the high and low prices, in that order.

`mprcts = medprice(tsobj)` calculates the median prices of a financial time series object `tsobj`. The object must minimally contain the series High and Low. The median price is the average of the high and low price each period. `mprcts` is a financial time series object with the same dates as `tsobj` and the data series `MedPrice`.

medprice

`mprcts = medprice(tsoobj, ParameterName, ParameterValue, ...)` accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Parameter values are the strings that represent the valid parameter names.

Examples

Compute the median price for Disney stock and plot the results:

```
load disney.mat
dis_MedPrice = medprice(dis)
plot(dis_MedPrice)
title('Median Price for Disney')
```

References

Achelis, Steven B., *Technical Analysis from A to Z*, Second printing, McGraw-Hill, 1995, pp. 177 -178.

Purpose

Merge multiple financial time series objects

Syntax

```
newfts = merge(fts1, fts2)
newfts = merge(fts1, fts2, ..., ftsx)
newfts = merge(fts1, fts2, ..., ftsx, 'PARAM1', VALUE1, 'PARAM2',
VALUE2, ...)
```

Arguments

fts1, fts2, ... Comma-separated list of financial time series objects to merge.

Note Multiple Financial Time Series objects can be merged at once. The merged objects must appear in a comma separated list before the optional inputs. The order of the inputs is significant.

'DateSetMethod' (Optional) Merge *method*. Valid merge values are: 'union' or 'u': (Default) Returns the combined values of all merged objects. 'intersection' or 'i': Returns the values common to all merged objects. RefObj: Maps all values to a reference time contained in a Financial Time Series object (RefObj) or vector of date numbers.

'DataSetMethod' (Optional) Merge *method*. Valid merge values are: 'closest': (Default) Returns data based on the order of the inputs. However, the first missing data point (NaN value) of a date will be replaced by the closest non-NaN data point that appears on the same date of subsequent merged objects.

merge

'order': Returns data based strictly on the order of the inputs.

Description

`newfts = merge(fts1, fts2, ..., ftsx, 'PARAM1', VALUE1, 'PARAM2', VALUE2, ...)` merges multiple financial time series objects. The optional parameter and value pair argument specifies the values contained in the output financial time series object `ftsout`.

Examples

Create three financial time series objects and merge them into a single object.

```
dates = {'jan-01-2001'; 'jan-02-2001'; 'jan-03-2001'; ...
         'jan-04-2001'; 'jan-06-2001'};
data = [1; 1; 1; 1; 1];
t1 = fints(dates, data);
```

```
dates = {'jan-02-2001'; 'jan-03-2001'; 'jan-04-2001';
         'jan-05-2001'};
data = [2; 2; 2; 2];
t2 = fints(dates, data);
```

```
dates = {'jan-03-2001'; 'jan-04-2001'; 'jan-05-2001';
         'jan-06-2001'};
data = [3; 3; 3; 3];
t3 = fints(dates, data);
```

```
t123 = merge(t1, t2, t3)
```

```
ans =
```

```
desc:  ||  ||
freq:  Unknown (0)
```

```
'dates: (6)'      'series1: (6)'  
'01-Jan-2001'    [          1]
```

```
'02-Jan-2001' [ 1]
'03-Jan-2001' [ 1]
'04-Jan-2001' [ 1]
'05-Jan-2001' [ 2]
'06-Jan-2001' [ 1]
```

If you change the order of input time series, the output may contain different data when duplicate dates exist. Here, for example, is the result of using the same three time series defined above but with the order changed.

```
merge(t3, t2, t1)

ans =

desc:  ||  ||
freq: Unknown (0)

'dates: (6)'   'series1: (6)'
'01-Jan-2001' [ 1]
'02-Jan-2001' [ 2]
'03-Jan-2001' [ 3]
'04-Jan-2001' [ 3]
'05-Jan-2001' [ 3]
'06-Jan-2001' [ 3]%
```

Note t123 contains all 1s except on '05-Jan-2001' because t1 appears first in the list of inputs and takes precedence. The same logic can be applied to t321.

By changing the order of inputs, you can overwrite old financial time series data with new data by placing the new time series ahead of the old one in the list of inputs to the merge function.

horzcat, vertcat

min

Purpose Minimum value

Syntax `tmin = min(tsobj)`

Description `tmin = min(tsobj)` finds the minimum value in each data series in the financial time series object `tsobj` and returns it in the structure `tmin`. The `tmin` structure contains field name(s) identical to the data series name(s).

Note `tmin` returns only the values and does not return the dates associated with the values. The minimum values are not necessarily from the same date.

See Also `max`

Purpose Financial time series subtraction

Syntax

```
newfts = tsoj_1 - tsoj_2
newfts = tsoj - array
newfts = array - tsoj
```

Arguments

`tsoj_1`, `tsoj_2` A pair of financial time series objects .

`array` A scalar value or array with the number of rows equal to the number of dates in `tsoj` and the number of columns equal to the number of data series in `tsoj`.

Description

`minus` is an element-by-element subtraction of the components.

`newfts = tsoj_1 - tsoj_2` subtracts financial time series objects. If an object is to be subtracted from another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when one financial time series object is subtracted from another, follows the order of the first object.

`newfts = tsoj - array` subtracts an array element by element from a financial time series object.

`newfts = array - tsoj` subtracts a financial time series object element by element from an array.

See Also

`rdivide`, `plus`, `times`

minute

Purpose Minute of date or time

Syntax Minute = minute(Date)

Description Minute = minute(Date) returns the minute given a serial date number or a date string.

Examples Minute = minute(731204.5591223380)

or

```
Minute = minute('19-dec-2001, 13:25:08.17')
```

returns

```
Minute =
```

```
25
```

See Also datevec, hour, second

Purpose Modified internal rate of return

Syntax `Return = mirr(CashFlow, FinRate, Reinvest)`

Arguments

CashFlow	Vector of cash flows. The first entry is the initial investment.
FinRate	Finance rate for negative cash flow values. Enter as a decimal fraction.
Reinvest	Reinvestment rate for positive cash flow values, as a decimal fraction.

Description

`Return = mirr(CashFlow, FinRate, Reinvest)` calculates the modified internal rate of return for a series of periodic cash flows. This function calculates only positive rates of return; for nonpositive rates of return, `Return = 0`.

Examples

This cash flow represents the yearly income from an initial investment of \$100,000. The finance rate is 9% and the reinvestment rate is 12%.

Year 1	\$20,000
Year 2	(\$10,000)
Year 3	\$30,000
Year 4	\$38,000
Year 5	\$50,000

To calculate the modified internal rate of return on the investment

```
Return = mirr([-100000 20000 -10000 30000 38000 50000], 0.09,...  
0.12)
```

returns

```
Return =  
0.0832 (8.32%)
```

annurate, effrr, irr, nomrr, pvar, xirr

Purpose Month of date

Syntax [MonthNum, MonthString] = month(Date)

Description [MonthNum, MonthString] = month(Date) returns the month in numeric and string form given a serial date number or a date string.

Examples [MonthNum, MonthString] = month(730368)

or

[MonthNum, MonthString] = month('05-Sep-1999')

returns

MonthNum =

9

MonthString =

Sep

See Also datevec, day, year

months

Purpose Number of whole months between dates

Syntax Months = months(StartDate, EndDate, EndMonthFlag)

Arguments

StartDate Enter as serial date numbers or date strings.

EndDate Enter as serial date numbers or date strings.

EndMonthFlag (Optional) end-of-month flag. If StartDate and EndDate are end-of-month dates and EndDate has fewer days than StartDate, EndMonthFlag = 1 (default) treats EndDate as the end of a whole month, while EndMonthFlag = 0 does not.

Description Months = months(StartDate, EndDate, EndMonthFlag) returns the number of whole months between StartDate and EndDate. If EndDate is earlier than StartDate, Months is negative. Enter dates as serial date numbers or date strings.

Any input argument can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all. For example, if StartDate is an n -row character array of date strings, then EndDate must be an n -row character array of date strings or a single date. Months is then an n -by-1 vector of numbers.

Examples

```
Months = months('may 31 2000', 'jun 30 2000', 1)
Months =
    1
```

```
Months = months('may 31 2000', 'jun 30 2000', 0)
Months =
    0
```

```
Dates = ['mar 31 2002'; 'apr 30 2002'; 'may 31 2002'];  
Months = months(Dates, 'jun 30 2002')  
Months =  
      3  
      2  
      1
```

See Also [yearfrac](#)

movavg

Purpose Leading and lagging moving averages chart

Syntax `movavg(Asset, Lead, Lag, Alpha)`
`[Short, Long] = movavg(Asset, Lead, Lag, Alpha)`

Arguments

Asset	Security data, usually a vector of time-series prices.
Lead	Number of samples to use in leading average calculation. A positive integer. Lead must be less than or equal to Lag.
Lag	Number of samples to use in the lagging average calculation. A positive integer.
Alpha	(Optional) Control parameter that determines the type of moving averages. 0 = simple moving average (default), 0.5 = square root weighted moving average, 1 = linear moving average, 2 = square weighted moving average, and so on. To calculate the exponential moving average, set Alpha = 'e'.

Description `movavg(Asset, Lead, lag, Alpha)` plots leading and lagging moving averages.

`[Short, Long] = movavg(Asset, Lead, lag, Alpha)` returns the leading Short and lagging Long moving average data without plotting it.

Notes

- Moving averages smooth data via a sliding window to engender a better view of trends. Starting at the first element, the function slides along the input vector (*Asset*), capturing all data within the size of the window. The first window - 1 elements contain invalid information because there is insufficient data to compute an average until the *N*th element is reached, where *N* = the size of the window. The simple moving average ($\text{Alpha} = 0$) retains the window - 1 invalid points of data in its computation, while the exponential moving average ($\text{Alpha} = e$) removes them. For a window of size $n = \text{Lead}$ or $n = \text{Lag}$ the data points $\text{Asset}(i - n + 1 : i)$ (provided *Asset* is a vector) are used to compute the *i*-th element of the moving average data vector.
- The size of the *Short* and *Long* output matrices depends upon the type of moving average you are computing, as determined by the *Alpha* input argument. For all forms of moving average, except exponential, the size of the output matrices is number of observations (*NUMOBS*) by number of assets (*NUMASSETS*). For the exponential moving average only, the size of the *Short* and *Long* output matrices is $\text{NUMOBS} - (N - 1)$ by *NUMASSETS*.

Examples

If asset A is a vector of stock price data from 01/01/2006 to 02/01/2006

```
>> A(:,2)
```

```
ans =
```

mrdivide

Purpose Financial time series matrix division

Syntax
`newfts = tsobj_1 / tsobj_2`
`newfts = tsobj / array`
`newfts = array / tsobj`

Arguments

`tsobj_1, tsobj_2` A pair of financial time series objects.
`array` A scalar value or array with number of rows equal to the number of dates in `tsobj` and number of columns equal to the number of data series in `tsobj`.

Description

The `mrdivide` method divides element by element the components of one financial time series object by the components of the other. You can also divide the whole object by an array or divide a financial time series object into an array.

If an object is to be divided by another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when an object is divided by another object, follows the order of the first object.

`newfts = tsobj_1 / tsobj_2` divides financial time series objects element by element.

`newfts = tsobj / array` divides a financial time series object element by element by an array.

`newfts = array / tsobj` divides an array element by element by a financial time series object.

For financial time series objects, the `mrdivide` operation is identical to the `rdivide` operation.

See Also minus, plus, rdivide, times

mtimes

Purpose Financial time series matrix multiplication

Syntax
`newfts = tsobj_1 * tsobj_2`
`newfts = tsobj * array`
`newfts = array * tsobj`

Arguments

`tsobj_1, tsobj_2` A pair of financial time series objects.
`array` A scalar value or array with number of rows equal to the number of dates in `tsobj` and number of columns equal to the number of data series in `tsobj`.

Description

The `mtimes` method multiplies element by element the components of one financial time series object by the components of the other. You can also multiply the entire object by an array.

If an object is to be multiplied by another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when an object is multiplied by another object, follows the order of the first object.

`newfts = tsobj_1 * tsobj_2` multiplies financial time series objects element by element.

`newfts = tsobj * array` multiplies a financial time series object element by element by an array.

`newfts = array * tsobj` `newfts = array / tsobj` multiplies an array element by element by a financial time series object.

For financial time series objects, the `mtimes` operation is identical to the `times` operation.

See Also

`minus`, `mrdivide`, `plus`, `times`

Purpose Fisher information matrix for multivariate normal or least-squares regression

Syntax `Fisher = mvnrfish(Data, Design, Covariance, MatrixFormat)`

Arguments

- | | |
|--------|---|
| Data | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. If a data sample has missing values, represented as NaNs, the sample is ignored. |
| Design | <p>A matrix or a cell array that handles two model structures:</p> <ul style="list-style-type: none">• If NUMSERIES = 1, Design is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.• If NUMSERIES ≥ 1, Design is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values. <p>If Design has a single cell, it is assumed to have the same Design matrix for each sample. If Design has more than one cell, each cell contains a Design matrix for each sample.</p> |

Covariance	NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the residuals of the regression.
MatrixFormat	(Optional) String that identifies parameters to be included in the Fisher information matrix: <ul style="list-style-type: none">• full - Default format. Compute the full Fisher information matrix for both model and covariance parameter estimates.• paramonly - Compute only components of the Fisher information matrix associated with the model parameter estimates.

Description

Fisher = mvnrfish(Data, Design, Covariance, MatrixFormat) computes a Fisher information matrix based on current maximum likelihood or least-squares parameter estimates.

Fisher is a TOTALPARAMS-by-TOTALPARAMS Fisher information matrix. The size of TOTALPARAMS depends on MatrixFormat and on current parameter estimates. If MatrixFormat = 'full',

$$\text{TOTALPARAMS} = \text{NUMPARAMS} + \text{NUMSERIES} * (\text{NUMSERIES} + 1)/2$$

If MatrixFormat = 'paramonly',

$$\text{TOTALPARAMS} = \text{NUMPARAMS}$$

Note mvnrfish operates slowly if you calculate the full Fisher information matrix.

Example See “Multivariate Normal Linear Regression” on page 5-2.

See Also mvnrstd, mvnrmlc

mvnrml

Purpose Multivariate normal regression (ignore missing data)

Syntax [Parameters, Covariance, Resid, Info] = mvnrml(Data, Design, MaxIterations, TolParam, TolObj, Covar0)

Arguments

Data	NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. If a data sample has missing values, represented as NaNs, the sample is ignored. (Use <code>ecmmvnrml</code> to handle missing data.)
Design	Matrix or a cell array that handles two model structures: <ul style="list-style-type: none">• If <code>NUMSERIES = 1</code>, <code>Design</code> is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.• If <code>NUMSERIES ≥ 1</code>, <code>Design</code> is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values. If <code>Design</code> has a single cell, it is assumed to have the same <code>Design</code> matrix for each sample. If <code>Design</code> has more than one cell, each cell contains a <code>Design</code> matrix for each sample.
MaxIterations	(Optional) Maximum number of iterations for the estimation algorithm. Default value is 100.

TolParam (Optional) Convergence tolerance for estimation algorithm based on changes in model parameter estimates. Default value is $\sqrt{\text{eps}}$ which is about $1.0\text{e-}8$ for double precision. The convergence test for changes in model parameters is

$$\|\text{Param}_k - \text{Param}_{k-1}\| < \text{TolParam} \times (1 + \|\text{Param}_k\|)$$

where Param represents the output Parameters, and iteration $k = 2, 3, \dots$. Convergence is assumed when both the **TolParam** and **TolObj** conditions are satisfied. If both $\text{TolParam} \leq 0$ and $\text{TolObj} \leq 0$, do the maximum number of iterations (**MaxIterations**), whatever the results of the convergence tests.

TolObj (Optional) Convergence tolerance for estimation algorithm based on changes in the objective function. Default value is $\text{eps}^{3/4}$ which is about $1.0\text{e-}12$ for double precision. The convergence test for changes in the objective function is

$$|\text{Obj}_k - \text{Obj}_{k-1}| < \text{TolObj} \times (1 + |\text{Obj}_k|)$$

for iteration $k = 2, 3, \dots$. Convergence is assumed when both the **TolParam** and **TolObj** conditions are satisfied. If both $\text{TolParam} \leq 0$ and $\text{TolObj} \leq 0$, do the maximum number of iterations (**MaxIterations**), whatever the results of the convergence tests.

Covar0 (Optional) NUMSERIES-by-NUMSERIES matrix that contains a user-supplied initial or known estimate for the covariance matrix of the regression residuals.

Description

[Parameters, Covariance, Resid, Info] = mvnrml(Data, Design, MaxIterations, TolParam, TolObj, Covar0) estimates a multivariate normal regression model without missing data. The model has the form

$$\text{Data}_k \sim N(\text{Design}_k \times \text{Parameters}, \text{Covariance})$$

for samples $k = 1, \dots, \text{NUMSAMPLES}$.

mvnrml estimates a NUPARAMS-by-1 column vector of model parameters called Parameters, and a NUMSERIES-by-NUMSERIES matrix of covariance parameters called Covariance.

mvnrml(Data, Design) with no output arguments plots the log-likelihood function for each iteration of the algorithm.

To summarize the outputs of mvnrml:

- Parameters is a NUPARAMS-by-1 column vector of estimates for the parameters of the regression model.
- Covariance is a NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the regression model's residuals.
- Resid is a NUMSAMPLES-by-NUMSERIES matrix of residuals from the regression. For any row with missing values in Data, the corresponding row of residuals is represented as all NaN missing values, since this routine ignores rows with NaN values.

Another output, Info, is a structure that contains additional information from the regression. The structure has these fields:

- Info.Obj – A variable-extent column vector, with no more than MaxIterations elements, that contains each value of the objective function at each iteration of the estimation algorithm. The last value in this vector, Obj(end), is the terminal estimate of the objective function. If you do maximum likelihood estimation, the objective function is the log-likelihood function.

- `Info.PrevParameters` – NUMPARAMS-by-1 column vector of estimates for the model parameters from the iteration just prior to the terminal iteration.
- `Info.PrevCovariance` – NUMSERIES-by-NUMSERIES matrix of estimates for the covariance parameters from the iteration just prior to the terminal iteration.

Notes

`mvnrmlc` does not accept an initial parameter vector, because the parameters are estimated directly from the first iteration onward.

You can configure `Design` as a matrix if `NUMSERIES = 1` or as a cell array if `NUMSERIES ≥ 1`.

- If `Design` is a cell array and `NUMSERIES = 1`, each cell contains a NUMPARAMS row vector.
- If `Design` is a cell array and `NUMSERIES > 1`, each cell contains a NUMSERIES-by-NUMPARAMS matrix.

These points concern how `Design` handles missing data:

- Although `Design` should not have NaN values, ignored samples due to NaN values in `Data` are also ignored in the corresponding `Design` array.
- If `Design` is a 1-by-1 cell array, which has a single `Design` matrix for each sample, no NaN values are permitted in the array. A model with this structure must have `NUMSERIES ≥ NUMPARAMS` with `rank(Design{1}) = NUMPARAMS`.
- Two functions for handling missing data, `ecmmvnrmlc` and `ecmlsrmlc`, are stricter about the presence of NaN values in `Design`.

Use the estimates in the optional output structure `Info` for diagnostic purposes.

Examples

See “Multivariate Normal Regression” on page 5-17, “Least-Squares Regression” on page 5-18, “Covariance-Weighted Least Squares” on

page 5-19, “Feasible Generalized Least Squares” on page 5-20, and “Seemingly Unrelated Regression” on page 5-21.

ecmmvnrml, mvnrstd, mvnrobj

Purpose Log-likelihood function for multivariate normal regression without missing data

Syntax Objective = mvnrobj(Data, Design, Parameters, Covariance)

Arguments

- | | |
|------------|--|
| Data | NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. If a data sample has missing values, represented as NaNs, the sample is ignored. (Use <code>ecmmvnrmle</code> to handle missing data.) |
| Design | <p>A matrix or a cell array that handles two model structures:</p> <ul style="list-style-type: none"> • If <code>NUMSERIES = 1</code>, Design is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series. • If <code>NUMSERIES ≥ 1</code>, Design is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values. <p>If Design has a single cell, it is assumed to have the same Design matrix for each sample. If Design has more than one cell, each cell contains a Design matrix for each sample.</p> |
| Parameters | NUMPARAMS-by-1 column vector of estimates for the parameters of the regression model. |
| Covariance | NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the residuals of the regression. |

Description

Objective = mvnrobj(Data, Design, Parameters, Covariance) computes the log-likelihood function based on current maximum likelihood parameter estimates without missing data. Objective is a scalar that contains the log-likelihood function.

Notes

You can configure Design as a matrix if NUMSERIES = 1 or as a cell array if NUMSERIES ≥ 1.

- If Design is a cell array and NUMSERIES = 1, each cell contains a NUMPARAMS row vector.
- If Design is a cell array and NUMSERIES > 1, each cell contains a NUMSERIES-by-NUMPARAMS matrix.

Although Design should not have NaN values, ignored samples due to NaN values in Data are also ignored in the corresponding Design array.

Examples

See “Multivariate Normal Regression” on page 5-17, “Least-Squares Regression” on page 5-18, “Covariance-Weighted Least Squares” on page 5-19, “Feasible Generalized Least Squares” on page 5-20, and “Seemingly Unrelated Regression” on page 5-21.

ecmmvnrmlc, ecmmvnrobj, mvnrmlc

Purpose Evaluate standard errors for multivariate normal regression model

Syntax [StdParameters, StdCovariance] = mvnrstd(Data, Design, Covariance)

Arguments

Data NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES samples of a NUMSERIES-dimensional random vector. If a data sample has missing values, represented as NaNs, the sample is ignored. (Use `ecmmvnrmlc` to handle missing data.)

Design A matrix or a cell array that handles two model structures:

- If `NUMSERIES = 1`, `Design` is a NUMSAMPLES-by-NUMPARAMS matrix with known values. This structure is the standard form for regression on a single series.
- If `NUMSERIES ≥ 1`, `Design` is a cell array. The cell array contains either one or NUMSAMPLES cells. Each cell contains a NUMSERIES-by-NUMPARAMS matrix of known values.

If `Design` has a single cell, it is assumed to have the same `Design` matrix for each sample. If `Design` has more than one cell, each cell contains a `Design` matrix for each sample.

Covariance NUMSERIES-by-NUMSERIES matrix of estimates for the covariance of the regression residuals.

Description

`[StdParameters, StdCovariance] = mvnrstd(Data, Design, Covariance)` evaluates standard errors for a multivariate normal regression model without missing data. The model has the form

$$\text{Data}_k \sim N(\text{Design}_k \times \text{Parameters}, \text{Covariance})$$

for samples $k = 1, \dots, \text{NUMSAMPLES}$.

`mvnrstd` computes two outputs:

- `StdParameters` is a `NUMPARAMS`-by-1 column vector of standard errors for each element of `Parameters`, the vector of estimated model parameters.
- `StdCovariance` is a `NUMSERIES`-by-`NUMSERIES` matrix of standard errors for each element of `Covariance`, the matrix of estimated covariance parameters.

Note `mvnrstd` operates slowly when you calculate the standard errors associated with the covariance matrix `Covariance`.

Notes

You can configure `Design` as a matrix if `NUMSERIES = 1` or as a cell array if `NUMSERIES ≥ 1`.

- If `Design` is a cell array and `NUMSERIES = 1`, each cell contains a `NUMPARAMS` row vector.
- If `Design` is a cell array and `NUMSERIES > 1`, each cell contains a `NUMSERIES`-by-`NUMPARAMS` matrix.

Examples

See “Multivariate Normal Regression” on page 5-17, “Least-Squares Regression” on page 5-18, “Covariance-Weighted Least Squares” on page 5-19, “Feasible Generalized Least Squares” on page 5-20, and “Seemingly Unrelated Regression” on page 5-21.

negvalidx

Purpose Negative volume index

Syntax

```
nvi = negvalidx(closep, tvolume, initnvi)
nvi = negvalidx([closep tvolume], initnvi)
nvits = negvalidx(tsoobj)
nvits = negvalidx(tsoobj, initnvi, ParameterName, ParameterValue,
...)
```

Arguments

closep	Closing price (vector).
tvolume	Volume traded (vector).
initnvi	(Optional) Initial value for negative volume index (Default = 100).
tsoobj	Financial time series object.
ParameterName	Valid parameter names are: <ul style="list-style-type: none">• CloseName: closing prices series name• VolumeName: volume traded series name
ParameterValue	Parameter values are the strings that represent the valid parameter names.

Description `nvi = negvalidx(closep, tvolume, initnvi)` calculates the negative volume index from a set of stock closing prices (`closep`) and volume traded (`tvolume`) data. `nvi` is a vector representing the negative volume index. If `initnvi` is specified, `negvalidx` uses that value instead of the default (100).

`nvi = negvalidx([closep tvolume], initnvi)` accepts a two-column matrix, the first column representing the closing prices (`closep`) and the second representing the volume traded (`tvolume`). If `initnvi` is specified, `negvalidx` uses that value instead of the default (100).

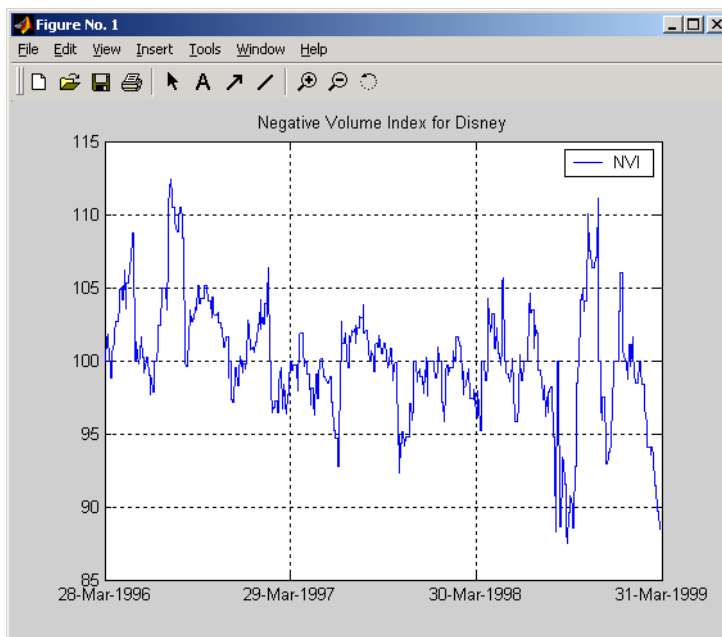

`nvits = negvalidx(tsoobj)` calculates the negative volume index from the financial time series object `tsoobj`. The object must contain, at least, the series `Close` and `Volume`. The `nvits` output is a financial time series object with dates similar to `tsoobj` and a data series named `NVI`. The initial value for the negative volume index is arbitrarily set to 100.

`nvits = negvalidx(tsoobj, initnvi, ParameterName, ParameterValue, ...)` accepts parameter name/ parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Parameter values are the strings that represent the valid parameter names.

Examples

Compute the negative volume index for Disney stock and plot the results:

```
load disney.mat
dis_NegVol = negvalidx(dis)
plot(dis_NegVol)
title('Negative Volume Index for Disney')
```

onbalvol, posvolidx

Purpose Nominal rate of return

Syntax Return = nomrr(Rate, NumPeriods)

Arguments

Rate Effective annual percentage rate. Enter as a decimal fraction.

NumPeriods Number of compounding periods per year, an integer.

Description Return = nomrr(Rate, NumPeriods) calculates the nominal rate of return.

Examples To find the nominal annual rate of return based on an effective annual percentage rate of 9.38% compounded monthly

```
Return = nomrr(0.0938, 12)
```

```
returns
```

```
Return =  
0.0900 (9.0%)
```

now

Purpose Current date and time

Syntax Datenum = now

Description Datenum = now returns the current date and time as a serial date number.

Note This function now ships with basic MATLAB. It originally shipped only with Financial Toolbox. This description remains here for your convenience.

Examples

```
Datenum = now

Datenum =

    730695.5942469908 (on July 28, 2000 at 2:15 PM)
```

See Also date, datenum, today

Purpose Date of specific occurrence of weekday in month

Syntax Date = nweekdate(n, Weekday, Year, Month, Same)

Arguments

n	Nth occurrence of the weekday in a month. Enter as integer from 1 through 5.
Weekday	Weekday whose date you seek. Enter as integer from 1 through 7.
	1 Sunday
	2 Monday
	3 Tuesday
	4 Wednesday
	5 Thursday
	6 Friday
	7 Saturday
Year	Year. Enter as a four-digit integer.
Month	Month. Enter as an integer from 1 through 12.
Same	(Optional) Weekday that must occur in the same week with Weekday. Enter as an integer from 0 through 7, where 0 = ignore (default) and 1 through 7 are as for Weekday.

Description Date = nweekdate(n, Weekday, Year, Month, Same) returns the serial date number for the specific occurrence of the weekday in the given year and month, and in a week that also contains the weekday Same.

nweekdate

If n is larger than the last occurrence of `Weekday`, `Date = 0`.

Any input can contain multiple values, but if so, all other inputs must contain the same number of values or a single value that applies to all. For example, if `Year` is a 1-by- n vector of integers, then `Month` must be a 1-by- n vector of integers or a single integer. `Date` is then a 1-by- n vector of date numbers.

Use the function `datestr` to convert serial date numbers to formatted date strings.

Examples

To find the first Thursday in May 2001

```
Date = nweekdate(1, 5, 2001, 5); datestr(Date)
```

```
ans =
```

```
03-May-2001
```

To find the first Thursday in a week that also contains a Wednesday in May 2001

```
Date = nweekdate(2, 5, 2001, 5, 4); datestr(Date)
```

```
ans =
```

```
10-May-2001
```

To find the third Monday in February for 2001, 2002, and 2003

```
Year = [2001:2003];
```

```
Date = nweekdate(3, 2, Year, 2)
```

```
Date =
```

```
730901      731265      731629
```

```
datestr(Date)
```

ans =

19-Feb-2001

18-Feb-2002

17-Feb-2003

fbusdate, lbusdate, lweekdate

onbalvol

Purpose On-Balance Volume (OBV)

Syntax

```
obv = onbalvol(closep, tvolume)
obv = onbalvol([closep tvolume])
obvts = onbalvol(tsobj)
obvts = onbalvol(tsobj, ParameterName, ParameterValue, ...)
```

Arguments

<code>closep</code>	Closing price (vector)
<code>tvolume</code>	Volume traded
<code>tsobj</code>	Financial time series object

Description

`obv = onbalvol(closep, tvolume)` calculates the On-Balance Volume (OBV) from the stock closing price (`closep`) and volume traded (`tvolume`) data.

`obv = onbalvol([closep tvolume])` accepts a two-column matrix representing the closing price (`closep`) and volume traded (`tvolume`), in that order.

`obvts = onbalvol(tsobj)` calculates the OBV from the stock data in the financial time series object `tsobj`. The object must minimally contain series names `Close` and `Volume`. The `obvts` output is a financial time series object with the same dates as `tsobj` and a series named `OnBalVol`.

`obvts = onbalvol(tsobj, ParameterName, ParameterValue, ...)` accepts parameter name/ parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

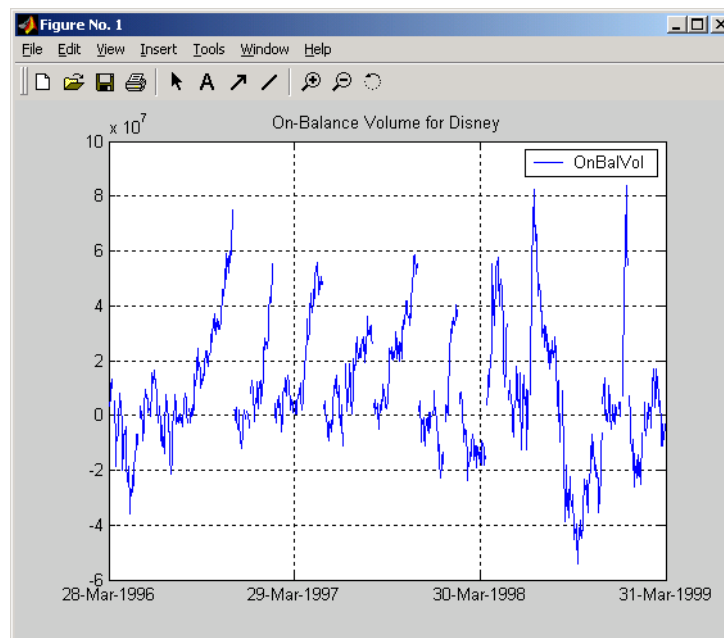

- `CloseName`: closing prices series name
- `VolumeName`: volume traded series name

Parameter values are the strings that represent the valid parameter names.

Examples

Compute the OBV for Disney stock and plot the results:

```
load disney.mat
dis_OnBalVol = onbalvol(dis)
plot(dis_OnBalVol)
title('On-Balance Volume for Disney')
```

opprofit

Purpose Option profit

Syntax Profit = opprofit(AssetPrice, Strike, Cost, PosFlag, OptType)

Arguments

AssetPrice	Asset price.
Strike	Strike or exercise price.
Cost	Cost of the option.
PosFlag	Option position. 0 = long, 1 = short.
OptType	Option type. 0 = call option, 1 = put option.

Description Profit = opprofit(AssetPrice, Strike, Cost, PosFlag, OptType) returns the profit of an option.

Examples Buying (going long on) a call option with a strike price of \$90 on an underlying asset with a current price of \$100 for a cost of \$4

```
Profit = opprofit(100, 90, 4, 0, 0)
```

returns

```
Profit =  
      6.00
```

a profit of \$6 if the option is exercised under these conditions.

Purpose Periodic payment given number of advance payments

Syntax `Payment = payadv(Rate, NumPeriods, PresentValue, FutureValue, Advance)`

Arguments

- Rate Lending or borrowing rate per period. Enter as a decimal fraction. Must be greater than or equal to 0.
- NumPeriods Number of periods in the life of the instrument.
- PresentValue Present value of the instrument.
- FutureValue Future value or target value to be attained after NumPeriods periods.
- Advance Number of advance payments. If the payments are made at the beginning of the period, add 1 to Advance.

Description `Payment = payadv(Rate, NumPeriods, PresentValue, FutureValue, Advance)` returns the periodic payment given a number of advance payments.

Examples The present value of a loan is \$1000.00 and it will be paid in full in 12 months. The annual interest rate is 10% and three payments are made at closing time. Using this data

$$\text{Payment} = \text{payadv}(0.1/12, 12, 1000, 0, 3)$$

returns

$$\text{Payment} =$$

85.94

for the periodic payment.

See Also amortize, payodd, payper

Purpose Payment of loan or annuity with odd first period

Syntax `Payment = payodd(Rate, NumPeriods, PresentValue, FutureValue, Days)`

Arguments

rate	Interest rate per period. Enter as a decimal fraction.
NumPeriods	Number of periods in the life of the instrument.
PresentValue	Present value of the instrument.
FutureValue	Future value or target value to be attained after NumPeriods periods.
Days	Actual number of days until the first payment is made.

Description `Payment = payodd(Rate, NumPeriods, PresentValue, FutureValue, Days)` returns the payment for a loan or annuity with an odd first period.

Examples A two-year loan for \$4000 has an annual interest rate of 11%. The first payment will be made in 36 days. To find the monthly payment

```
Payment = payodd(0.11/12, 24, 4000, 0, 36)
```

returns

```
Payment =
```

```
186.77
```

See Also `amortize`, `payadv`, `payper`

payper

Purpose Periodic payment of loan or annuity

Syntax `Payment = payper(Rate, NumPeriods, PresentValue, FutureValue, Due)`

Arguments

Rate	Interest rate per period. Enter as a decimal fraction.
NumPeriods	Number of payment periods in the life of the instrument.
PresentValue	Present value of the instrument.
FutureValue	(Optional) Future value or target value to be attained after NumPeriods periods. Default = 0.
Due	(Optional) When payments are due: 0 = end of period (default), or 1 = beginning of period.

Description `Payment = payper(Rate, NumPeriods, PresentValue, FutureValue, Due)` returns the periodic payment of a loan or annuity.

Examples Find the monthly payment for a three-year loan of \$9000 with an annual interest rate of 11.75%

```
Payment = payper(0.1175/12, 36, 9000, 0, 0)
```

returns

```
Payment =
```

```
297.86
```

See Also `amortize, fvfix, payadv, payodd, pvfix`

Purpose Uniform payment equal to varying cash flow

Syntax `Series = payuni(CashFlow, Rate)`

Arguments

CashFlow	A vector of varying cash flows. Include the initial investment as the initial cash flow value (a negative number).
Rate	Periodic interest rate. Enter as a decimal fraction.

Description `Series = payuni(CashFlow, Rate)` returns the uniform series value of a varying cash flow.

Examples This cash flow represents the yearly income from an initial investment of \$10,000. The annual interest rate is 8%.

Year 1	\$2000
Year 2	\$1500
Year 3	\$3000
Year 4	\$3800
Year 5	\$5000

To calculate the uniform series value

```
Series = payuni([-10000 2000 1500 3000 3800 5000], 0.08)
```

returns

```
Series =
```

payuni

fvfix, fvvar, irr, pvfix, pvvar

Purpose Linear inequalities for individual asset allocation

Syntax `[A,b] = pcalims(AssetMin, AssetMax, NumAssets)`

Arguments

- AssetMin Scalar or NASSETS vector of minimum allocations in each asset. NaN indicates no constraint.
- AssetMax Scalar or NASSETS vector of maximum allocations in each asset. NaN indicates no constraint.
- NumAssets (Optional) Number of assets. Default = length of AssetMin or AssetMax.

Description

`[A,b] = pcalims(AssetMin, AssetMax, NumAssets)` specifies the lower and upper bounds of portfolio allocations in each of NumAssets available asset investments.

A is a matrix and b is a vector such that $A * PortWts' \leq b$, where PortWts is a 1-by-NASSETS vector of asset allocations.

If pcalims is called with fewer than two output arguments, the function returns A concatenated with b [A,b].

Examples

Set the minimum weight in every asset to 0 (no short-selling), and set the maximum weight of IBM to 0.5 and CSCO to 0.8, while letting the maximum weight in INTC float.

Asset	IBM	INTC	CSCO
Min. Wt.	0	0	0
Max. Wt.	0.5		0.8

pcalims

```
AssetMin = 0
AssetMax = [0.5 NaN 0.8]
[A,b] = pcalims(AssetMin, AssetMax)
```

```
A =
    1     0     0
    0     0     1
   -1     0     0
    0    -1     0
    0     0    -1
```

```
b =
    0.5000
    0.8000
         0
         0
         0
```

Portfolio weights of 50% in IBM and 50% in INTC satisfy the constraints.
Set the minimum weight in every asset to 0 and the maximum weight to 1.

Asset	IBM	INTC	CSCO
Min. Wt.	0	0	0
Max. Wt.	1	1	1

```
AssetMin = 0
AssetMax = 1
NumAssets = 3
```

```
[A,b] = pcalims(AssetMin, AssetMax, NumAssets)
```

```
A =
```

```

    1    0    0
    0    1    0
    0    0    1
   -1    0    0
    0   -1    0
    0    0   -1

```

b =

```

    1
    1
    1
    0
    0
    0

```

Portfolio weights of 50% in IBM and 50% in INTC satisfy the constraints.

See Also

pcgcomp, pcglims, pcpval, portcons, portopt

Purpose Linear inequalities for asset group comparison constraints

Syntax `[A,b] = pcgcomp(GroupA, AtoBmin, AtoBmax, GroupB)`

Arguments

GroupA	Number of groups (NGROUPS) by number of assets (NASSETS) specifications of groups to compare.
GroupB	Each row specifies a group. For a specific group, $\text{Group}(i,j) = 1$ if the group contains asset j ; otherwise, $\text{Group}(i,j) = 0$.
AtoBmin	Scalar or NGROUPS-long vectors of minimum and maximum ratios of allocations in GroupA to allocations in GroupB. NaN indicates no constraint between the two groups. Scalar bounds are applied to all group pairs. The total number of assets allocated to GroupA divided by the total number of assets allocated to GroupB is $\geq \text{AtoBmin}$ and $\leq \text{AtoBmax}$.
AtoBmax	

Description

`[A,b] = pcgcomp(GroupA, AtoBmin, AtoBmax, GroupB)` specifies that the ratio of allocations in one group to allocations in another group is at least `AtoBmin` to 1 and at most `AtoBmax` to 1. Comparisons can be made between an arbitrary number of group pairs `NGROUPS` comprising subsets of `NASSETS` available investments.

A is a matrix and b a vector such that $A * \text{PortWts} \leq b$, where PortWts is a 1-by-`NASSETS` vector of asset allocations.

If `pcgcomp` is called with fewer than two output arguments, the function returns A concatenated with b `[A,b]`.

Examples

Asset	INTC	XOM	RD
Region	North America	North America	Europe
Sector	Technology	Energy	Energy

Group	Min. Exposure	Max. Exposure
North America	0.30	0.75
Europe	0.10	0.55
Technology	0.20	0.50
Energy	0.20	0.80

Make the North American energy sector compose exactly 20% of the North American investment.

```
%
      INTC  XOM  RD
GroupA = [  0   1   0 ]; % North American Energy
GroupB = [  1   1   0 ]; % North America
```

```
AtoBmin = 0.20;
AtoBmax = 0.20;
```

```
[A,b] = pcgcomp(GroupA, AtoBmin, AtoBmax, GroupB)
```

```
A =
```

```
    0.2000    -0.8000     0
   -0.2000     0.8000     0
```

```
b =
```

```
    0
    0
```

Portfolio weights of 40% for INTC, 10% for XOM, and 50% for RD satisfy the constraints.

See Also

pcalims, pcglims, pcpval, portcons, portopt

Purpose Linear inequalities for asset group minimum and maximum allocation

Syntax `[A,b] = pcglims(Groups, GroupMin, GroupMax)`

Arguments

Groups	Number of groups (NGROUPS) by number of assets (NASSETS) specification of which assets belong to which group. Each row specifies a group. For a specific group, $Group(i, j) = 1$ if the group contains asset j ; otherwise, $Group(i, j) = 0$.
GroupMin	Scalar or NGROUPS-long vectors of minimum and maximum combined allocations in each group. NaN indicates no constraint. Scalar bounds are applied to all groups.
GroupMax	

Description `[A,b] = pcglims(Groups, GroupMin, GroupMax)` specifies minimum and maximum allocations to groups of assets. An arbitrary number of groups, NGROUPS, comprising subsets of NASSETS investments, is allowed.

A is a matrix and b a vector such that $A * PortWts' \leq b$, where PortWts is a 1-by-NASSETS vector of asset allocations.

If pcglims is called with fewer than two output arguments, the function returns A concatenated with b `[A,b]`.

Examples

Asset	INTC	XOM	RD
Region	North America	North America	Europe
Sector	Technology	Energy	Energy

Group	Min. Exposure	Max. Exposure
North America	0.30	0.75
Europe	0.10	0.55
Technology	0.20	0.50
Energy	0.50	0.50

Set the minimum and maximum investment in various groups.

```
%          INTC  XOM  RD
Groups = [  1    1   0 ; % North America
           0    0   1 ; % Europe
           1    0   0 ; % Technology
           0    1   1 ]; % Energy
```

```
GroupMin = [0.30
            0.10
            0.20
            0.50];
```

```
GroupMax = [0.75
            0.55

Purpose Linear inequalities for fixing total portfolio value

Syntax `[A,b] = pcpval(PortValue, NumAssets)`

Arguments

PortValue	Scalar total value of asset portfolio (sum of the allocations in all assets). PortValue = 1 specifies weights as fractions of the portfolio and return and risk numbers as rates instead of value.
NumAssets	Number of available asset investments.

Description

`[A,b] = pcpval(PortValue, NumAssets)` scales the total value of a portfolio of NumAssets assets to PortValue. All portfolio weights, bounds, return, and risk values except ExpReturn and ExpCovariance (see portopt) are in terms of PortValue.

A is a matrix and b a vector such that $A * \text{PortWts}' \leq b$, where PortWts is a 1-by-NumAssets vector of asset allocations.

If pcpval is called with fewer than two output arguments, the function returns A concatenated with b [A,b].

Examples

Scale the value of a portfolio of three assets = 1, so all return values are rates and all weight values are in fractions of the portfolio.

```
PortValue = 1;  
NumAssets = 3;
```

```
[A,b] = pcpval(PortValue, NumAssets)
```

```
A =
```

```
1 1 1
```

$$\begin{matrix} -1 & -1 & -1 \end{matrix}$$
$$b =$$
$$\begin{matrix} 1 \\ -1 \end{matrix}$$

Portfolio weights of 40%, 10%, and 50% in the three assets satisfy the constraints.

Purpose Periodic average of a FINTS object

Syntax

```
avgfts = peravg(tsobj)
avgfts = peravg(tsobj, numperiod)
avgfts = peravg(tsobj, daterange)
```

Arguments

<code>tsobj</code>	Financial time series object
<code>numperiod</code>	(Optional) Integer specifying the number of data points over which each periodic average should be averaged
<code>daterange</code>	(Optional) Time period over which the data is averaged

Description

`peravg` calculates periodic averages of a financial time series object. Periodic averages are calculated from the values per period defined. If the period supplied is a string, it is assumed as a range of date string. If the period is entered as numeric, the number represents the number of data points (financial time series periods) to be included in a period for the calculation. For example, if you enter `'01/01/98::01/01/99'` as the period input argument, `peravg` returns the average of the time series between those dates, inclusive. However, if you enter the number 5 as the period input, `peravg` returns a series of averages from the time series data taken 5 date points (financial time series periods) at a time.

`avgfts = peravg(tsobj, numperiod)` returns a structure `avgfts` that contains the periodic (per `numperiod` periods) average of the financial time series object. `avgfts` has field names identical to the data series names of `tsobj`.

`avgfts = peravg(tsobj, daterange)` returns a structure `avgfts` that contains the periodic (as specified by `daterange`) average of the

financial time series object. `avgfts` has field names identical to the data series names of `tsobj`.

Note `peravg` calculates periodic averages of a FINTS object. Periodic averages are calculated from the values per period defined. If the period supplied is a string, it is assumed as a range of date strings. If the period is entered as numeric, the number represents the number of data points to be included in a period for the calculation.

Examples

If you enter `01-Jan-2001::03-Jan-2001` as the period input argument, `peravg` returns the average of the time series between those dates, inclusive. However, if you enter the number 5 as the period input, `peravg` returns a series of averages from the time series data, taken 5 date points at a time.

```
%% Create the FINTS object %%
dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
'02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
dates_times = cellstr([dates, repmat(' ', size(dates, 1), 1), times]);
data = [(1:6)', 2*(1:6)'];
myFts = fints(dates_times, data, {'Data1', 'Data2'}, 1, 'My first FINTS')

mean, tsmovavg

mean in the MATLAB documentation

Purpose Periodic total returns from total return prices

Syntax `TotalReturn = periodicreturns(TotalReturnPrices, Period)`

Arguments

`TotalReturnPrices` Number of observations (NUMOBS) by number of assets (NASSETS) matrix of total return prices for a given security. Column 1 contains MATLAB serial date numbers. The remaining columns contain total return price data.

`Period` (Optional) Periodicity flag used to compute total returns:

'd' = daily values

'm' = monthly values

Description `TotalReturn = periodicreturns(TotalReturnPrices)` calculates the daily total returns from a daily total return price series.

`TotalReturn = periodicreturns(TotalReturnPrices, Period)` calculates the total returns for a periodicity you specify from a daily total return price series.

`TotalReturn` is a NUMOBS-by-NASSETS matrix containing month-end dates and return values. Each row represents an observation. Column 1 contains month-end dates in MATLAB serial date number format. The remaining columns contain monthly return values.

See Also `totalreturnprice`

plot

Purpose Plot data series

Syntax

```
plot(tsobj)
hp = plot(tsobj)
plot(tsobj, linefmt)
hp = plot(tsobj, linefmt)
plot(..., volumename, bar)
hp = plot(..., volumename, bar)
```

Arguments

<code>tsobj</code>	Financial time series object.
<code>linefmt</code>	(Optional) Line format.
<code>volumename</code>	(Optional) Specifies which data series is the volume series. <code>volumename</code> must be the exact data series name for the volume column (case sensitive).
<code>bar</code>	(Optional) <ul style="list-style-type: none">• <code>bar = 0</code> (default). Plot volume as a line.• <code>bar = 1</code>. Plot volume as a bar chart. The width of each bar is the same as the default in <code>bar</code>, <code>barh</code>.

Description `plot(tsobj)` plots the data series contained in the object `tsobj`. Each data series will be a line. `plot` automatically generates a legend as well as dates on the *x*-axis. Grid is turned on by default. `plot` uses the default color order as if plotting a matrix.

The `plot` command automatically creates subplots when multiple time series are encountered, and they differ greatly on their decimal scales. For example, subplots are generated if one time series data set is in the 10s and another is in the 10,000s.

`hp = plot(tsobj)` additionally returns the handle(s) to the object(s) inside the plot figure. If there are multiple lines in the plot, `hp` is a vector of multiple handles.

`plot(tsobj, linefmt)` plots the data series in `tsobj` using the line format specified. For a list of possible line formats, see `plot` in the MATLAB documentation. The plot legend is not generated, but the dates on the *x*-axis and the plot grid are. The specified line format is applied to all data series; that is, all data series will have the same line type.

`hp = plot(tsobj, linefmt)` plots the data series in `tsobj` using the format specified. The plot legend is not generated, but the dates on the *x*-axis and the plot grid are. The specified line format is applied to all data series, that is, all data series can have the same line type. If there are multiple lines in the plot, `hp` is a vector of multiple handles.

`plot(..., volumename, bar)` additionally specifies which data series is the volume. The volume is plotted in a subplot below the other data series. If `bar = 1`, the volume is plotted as a bar chart. Otherwise, a line plot is used.

`hp = plot(..., volumename, bar)` returns handles for each line. If `bar = 1`, the handle to the patch for the bars is also returned.

Note To turn the legend off, enter `legend off` at the MATLAB command line. Once you turn it off, the legend is essentially deleted. To turn it back on, recreate it using the `legend` command as if you are creating it for the first time. To turn the grid off, enter `grid off`. To turn it back on, enter `grid on`.

`grid`, `legend`, and `plot` in the MATLAB documentation

plus

Purpose Financial time series addition

Syntax
`newfts = tsobj_1 + tsobj_2`
`newfts = tsobj + array`
`newfts = array + tsobj`

Arguments

`tsobj_1, tsobj_2` A pair of financial time series objects.
`array` A scalar value or array with the number of rows equal to the number of dates in `tsobj` and the number of columns equal to the number of data series in `tsobj`.

Description

`plus` is an element-by-element addition of the components.

`newfts = tsobj_1 + tsobj_2` adds financial time series objects. If an object is to be added to another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when one financial time series object is added to another, follows the order of the first object.

`newfts = tsobj + array` adds an array element by element to a financial time series object.

`newfts = array + tsobj` adds a financial time series object element by element to an array.

Purpose	Point and figure chart
Syntax	<code>pointfig(Asset)</code>
Description	<code>pointfig(Asset)</code> plots a point and figure chart for a vector of price data <code>Asset</code> . Upward price movements are plotted as <code>X</code> 's and downward price movements are plotted as <code>O</code> 's.
See Also	<code>bolling</code> , <code>candle</code> , <code>dateaxis</code> , <code>highlow</code> , <code>movavg</code>

Purpose Optimal capital allocation to efficient frontier portfolios

Syntax [RiskyRisk, RiskyReturn, RiskyWts, RiskyFraction, OverallRisk, OverallReturn] = portalloc(PortRisk, PortReturn, PortWts, RisklessRate, BorrowRate, RiskAversion)

Arguments

PortRisk	Standard deviation of each risky asset efficient frontier portfolio. A number of portfolios (NPORTS) by 1 vector.
PortReturn	Expected return of each risky asset efficient frontier portfolio. An NPORTS-by-1 vector.
PortWts	Weights allocated to each asset. An NPORTS by number of assets (NASSETS) matrix of weights allocated to each asset. Each row represents an efficient frontier portfolio of risky assets. Total of all weights in a portfolio is 1.
RisklessRate	Risk-free lending rate. A decimal number.
BorrowRate	(Optional) Borrowing rate. A decimal number. If borrowing is not desired, or not an option, set to NaN (default).
RiskAversion	(Optional) Coefficient of investor's degree of risk aversion. Higher numbers indicate greater risk aversion. Typical coefficients range between 2.0 and 4.0 (Default = 3).

Description [RiskyRisk, RiskyReturn, RiskyWts, RiskyFraction, OverallRisk, OverallReturn] = portalloc(PortRisk, PortReturn, PortWts, RisklessRate, BorrowRate, RiskAversion) computes the optimal risky portfolio, and the optimal allocation of funds between the risky portfolio and the risk-free asset.

RiskyRisk is the standard deviation of the optimal risky portfolio.

RiskyReturn is the expected return of the optimal risky portfolio.

RiskyWts is a 1-by-NASSETS vector of weights allocated to the optimal risky portfolio. The total of all weights in the portfolio is 1.

RiskyFraction is the fraction of the complete portfolio allocated to the risky portfolio.

OverallRisk is the standard deviation of the optimal overall portfolio.

OverallReturn is the expected rate of return of the optimal overall portfolio.

portalloc generates a plot of the optimal capital allocation if you invoke it without output arguments.

Examples

Generate the efficient frontier from the asset data.

```
ExpReturn = [0.1 0.2 0.15];

ExpCovariance = [0.005   -0.010   0.004
                 -0.010   0.040  -0.002
                  0.004  -0.002   0.023];
[PortRisk, PortReturn, PortWts] = portopt(ExpReturn,...
ExpCovariance);
```

Find the optimal risky portfolio and allocate capital. The risk free investment return is 8%, and the borrowing rate is 12%.

```
RisklessRate = 0.08;
BorrowRate   = 0.12;
RiskAversion = 3;

[RiskyRisk, RiskyReturn, RiskyWts, RiskyFraction, ...
OverallRisk, OverallReturn] = portalloc(PortRisk, PortReturn,...
PortWts, RisklessRate, BorrowRate, RiskAversion)

RiskyRisk =
```

frontcon, portrand, portstats

Purpose Compute risk-adjusted alphas and returns for one or more assets

Syntax

```
portalalpha(Asset, Benchmark)
portalalpha(Asset, Benchmark, Cash)
portalalpha(Asset, Benchmark, Cash, Choice)
Alpha = portalalpha(Asset, Benchmark, Cash, Choice)
[Alpha, RAReturn] = portalalpha(Asset, Benchmark, Cash, Choice)
```

Arguments

Asset	NUMSAMPLES × NUMSERIES matrix with NUMSAMPLES observations of asset returns for NUMSERIES asset return series.
Benchmark	NUMSAMPLES vector of returns for a benchmark asset. The periodicity must be the same as the periodicity of Asset. For example, if Asset is monthly data, then Benchmark should be monthly returns.
Cash	(Optional) Either a scalar return for a riskless asset or a vector of asset returns to be a proxy for a “riskless” asset. In either case, the periodicity must be the same as the periodicity of Asset. For example, if Asset is monthly data, then Cash must be monthly returns. If no value is supplied, the default value for Cash returns is 0.
Choice	(Optional) A number, string, or cell array of numbers or strings to indicate one or more measures to be computed from among a number of risk-adjusted alphas and return measures. The number of choices selected in Choice is NUMCHOICES. The current list of choices is given in the following table:

Code	Description
'xs'	Excess Return (no risk adjustment)
'sm1'	Security Market Line
'capm'	Jensen's Alpha
'mm'	Modigliani & Modigliani
'gh1'	Graham-Harvey 1
'gh2'	Graham-Harvey 2
'all'	Compute all measures

Choice is specified by using the code from the table (for example, to select the Modigliani & Modigliani measure, `Choice = 'mm'`). A single choice is either a string or a scalar cell array with a single code from the table.

Multiple choices can be selected with a cell array of choice codes (for example, to select both Graham-Harvey measures, `Choice = {'gh1', 'gh2'}`). To select all choices, specify `Choice = 'all'`. If no value is supplied, the default choice is to compute the excess return with `Choice = 'xs'`. Choice is not case sensitive.

Description

Given `NUMSERIES` assets with `NUMSAMPLES` returns in a `NUMSAMPLES`-by-`NUMSERIES` matrix `Asset`, a `NUMSAMPLES` vector of `Benchmark` returns, and either a scalar `Cash` return or a `NUMSAMPLES` vector of `Cash` returns, compute risk-adjusted alphas and returns for one or more methods specified by `Choice`.

To summarize the outputs of `portal α` :

- Alpha is a NUMCHOICES-by-NUMSERIES matrix of risk-adjusted alphas for each series in Asset with each row corresponding to a specified measure in Choice.
- RAReturn is a NUMCHOICES-by-NUMSERIES matrix of risk-adjusted returns for each series in Asset with each row corresponding to a specified measure in Choice.

Note NaN values in the data are ignored and, if NaNs are present, some results could be unpredictable. Although the alphas are comparable across measures, risk-adjusted returns depend on whether the Asset or Benchmark is levered or unlevered to match its risk with the alternative. If Choice = 'all', the order of rows in Alpha and RAReturn follows the order in the table. In addition, Choice = 'all' overrides all other choices.

Examples

See “Risk-Adjusted Return Example” on page 4-8.

Purpose Portfolio constraints

Syntax ConSet = portcons(varargin)

Description Using linear inequalities, portcons generates a matrix of constraints for a portfolio of asset investments. The matrix ConSet is defined as $\text{ConSet} = [A \ b]$. A is a matrix and b a vector such that $A * \text{PortWts}' \leq b$ sets the value, where PortWts is a 1-by-number of assets (NASSETS) vector of asset allocations.

`ConSet = portcons('ConstType', Data1, ..., DataN)` creates a matrix ConSet, based on the constraint type ConstType, and the constraint parameters Data1, ..., DataN.

`ConSet = portcons('ConstType1', Data11, ..., Data21, ..., Data2N, ...)` creates a matrix ConSet, based on the constraint types ConstTypeN, and the corresponding constraint parameters DataN1, ..., DataNN.

Constraint Type	Description	Values
Default	All allocations are ≥ 0 ; no short selling allowed. Combined value of portfolio allocations normalized to 1.	NumAssets (required). Scalar representing number of assets in portfolio.
PortValue	Fix total value of portfolio to PVal.	PVal (required). Scalar representing total value of portfolio. NumAssets (required). Scalar representing number of assets in portfolio. See pcpval.

Constraint Type	Description	Values
AssetLims	Minimum and maximum allocation per asset.	AssetMin (required). Scalar or vector of length NASSETS, specifying minimum allocation per asset. AssetMax (required). Scalar or vector of length NASSETS, specifying maximum allocation per asset. NumAssets (optional). See pcalims.
GroupLims	Minimum and maximum allocations to asset group.	Groups (required). NGROUPS-by-NASSETS matrix specifying which assets belong to each group. GroupMin (required). Scalar or a vector of length NGROUPS, specifying minimum combined allocations in each group. GroupMax (required). Scalar or a vector of length NGROUPS, specifying maximum combined allocations in each group. See pcglims.

Constraint Type	Description	Values
GroupComparison	Group-to-group comparison constraints.	<p>GroupA (required). NGROUPS-by-NASSETS matrix specifying first group in the comparison.</p> <p>AtoBmin (required). Scalar or vector of length NGROUPS specifying minimum ratios of allocations in GroupA to allocations in GroupB.</p> <p>AtoBmax (required). Scalar or vector of length NGROUPS specifying maximum ratios of allocations in GroupA to allocations in GroupB.</p> <p>GroupB (required). NGROUPS-by-NASSETS matrix specifying second group in the comparison.</p> <p>See pcgcomp.</p>
Custom	Custom linear inequality constraints $A * PortWts' \leq b$.	<p>A (required). NCONSTRAINTS-by-NASSETS matrix, specifying weights for each asset in each inequality equation.</p> <p>b (required). Vector of length NCONSTRAINTS specifying the right hand sides of the inequalities.</p> <hr/> <p>Note For more information using Custom, see “Specifying Additional Constraints” on page 3-17.</p> <hr/>

Examples

Constrain a portfolio of three assets:

Asset	IBM	HPQ	XOM
Group	A	A	B

Min. Wt.	0	0	0
Max. Wt.	0.5	0.9	0.8

```
NumAssets = 3;
PVal = 1; % Scale portfolio value to 1.
AssetMin = 0;
AssetMax = [0.5 0.9 0.8];
GroupA = [1 1 0];
GroupB = [0 0 1];
AtoBmax = 1.5 % Value of assets in Group A at most 1.5 times value
              % in group B.
```

```
ConSet = portcons('PortValue', PVal, NumAssets, 'AssetLims', ...
AssetMin, AssetMax, NumAssets, 'GroupComparison', GroupA, NaN, ...
AtoBmax, GroupB)
```

```
ConSet =
```

```
1.0000 1.0000 1.0000 1.0000
-1.0000 -1.0000 -1.0000 -1.0000
1.0000 0 0 0.5000
0 1.0000 0 0.9000
0 0 1.0000 0.8000
-1.0000 0 0 0
0 -1.0000 0 0
0 0 -1.0000 0
1.0000 1.0000 -1.5000 0
```

Portfolio weights of 30% in IBM, 30% in HPQ, and 40% in XOM satisfy the constraints.

Purpose Portfolios on constrained efficient frontier

Syntax [PortRisk, PortReturn, PortWts] = portopt(ExpReturn, ExpCovariance, NumPorts, PortReturn, ConSet)

Arguments

- ExpReturn 1 by number of assets (NASSETS) vector specifying the expected (mean) return of each asset.
- ExpCovariance NASSETS-by-NASSETS matrix specifying the covariance of the asset returns.
- NumPorts (Optional) Number of portfolios generated along the efficient frontier. Returns are equally spaced between the maximum possible return and the minimum risk point. If NumPorts is empty (entered as []), computes 10 equally spaced points.
- PortReturn (Optional) Expected return of each portfolio. A number of portfolios (NPORTS) by 1 vector. If not entered or empty, NumPorts equally spaced returns between the minimum and maximum possible values are used.
- ConSet (Optional) Constraint matrix for a portfolio of asset investments, created using portcons. If not specified, a default is created.

Description [PortRisk, PortReturn, PortWts] = portopt(ExpReturn, ExpCovariance, NumPorts, PortReturn, ConSet) returns the mean-variance efficient frontier with user-specified covariance, returns, and asset constraints (ConSet). Given a collection of NASSETS risky assets, computes a portfolio of asset investment weights that minimize

the risk for given values of the expected return. The portfolio risk is minimized subject to constraints on the total portfolio value, the individual asset minimum and maximum allocation, the asset group minimum and maximum allocation, or the asset group-to-group comparison.

PortRisk is an NPORTS-by-1 vector of the standard deviation of each portfolio.

PortReturn is an NPORTS-by-1 vector of the expected return of each portfolio.

PortWts is an NPORTS-by-NASSETS matrix of weights allocated to each asset. Each row represents a portfolio. The total of all weights in a portfolio is 1.

If portopt is invoked without output arguments, it returns a plot of the efficient frontier.

Examples

Plot the risk-return efficient frontier of portfolios allocated among three assets. Connect 20 portfolios along the frontier having evenly spaced returns. By default, choose among portfolios without short-selling and scale the value of the portfolio to 1.

```
ExpReturn = [0.1 0.2 0.15];
```

```
ExpCovariance = [0.005   -0.010   0.004  
                -0.010   0.040   -0.002  
                0.004   -0.002   0.023];
```

```
NumPorts = 20;
```

```
portopt(ExpReturn, ExpCovariance, NumPorts)
```

Return the two efficient portfolios that have returns of 16% and 17%. Limit to portfolios that have at least 20% of the allocation in the first asset, and cap the total value in the first and third assets at 50% of the portfolio.

```
ExpReturn = [0.1 0.2 0.15];

ExpCovariance = [0.005  -0.010  0.004
                 -0.010  0.040  -0.002
                 0.004  -0.002  0.023];

PortReturn = [0.16
              0.17];

NumAssets = 3;

AssetMin = [0.20 NaN NaN];

Group = [1  0  1];
```

portopt

```
GroupMax = 0.50;

ConSet = portcons('Default', NumAssets, 'AssetLims', AssetMin,...
NaN,'GroupLims', Group, NaN, GroupMax);

[PortRisk, PortReturn, PortWts] = portopt(ExpReturn,...
ExpCovariance, [], PortReturn, ConSet)

PortRisk =

    0.0919
    0.1138

PortReturn =

    0.1600
    0.1700

PortWts =

    0.3000    0.5000    0.2000
    0.2000    0.6000    0.2000
```

Purpose Randomized portfolio risks, returns, and weights

Syntax [PortRisk, PortReturn, PortWts] = portrand(Asset, Return, Points)
 portrand(Asset, Return, Points)

Arguments

- Asset Matrix of time series data. Each row is an observation and each column represents a single security.
- Return (Optional) Row vector where each column represents the rate of return for the corresponding security in Asset. By default, Return is computed by taking the average value of each column of Asset.
- Points (Optional) Scalar that specifies how many random points should be generated. Default = 1000.

Description [PortRisk, PortReturn, PortWts] = portrand(Asset, Return, Points) returns the risks, rates of return, and weights of random portfolio configurations.

- PortRisk Points-by-1 vector of standard deviations.
- PortReturn Points-by-1 vector of expected rates of return.
- PortWts Points by number of securities matrix of asset weights. Each row of PortWts is a different portfolio configuration.

portrand(Asset, Return, Points) plots the points representing each portfolio configuration. It does not return any data to the MATLAB workspace.

Purpose Monte Carlo simulation of correlated asset returns

Syntax `RetSeries = portsim(ExpReturn, ExpCovariance, NumObs, RetIntervals, NumSim, Method)`

Arguments

- ExpReturn 1 by number of assets (NASSETS) vector specifying the expected (mean) return of each asset.
- ExpCovariance NASSETS-by-NASSETS matrix of asset return covariances. ExpCovariance must be symmetric and positive semidefinite (no negative eigenvalues). The standard deviations of the returns are `ExpSigma = sqrt(diag(ExpCovariance))`.
- NumObs Positive scalar integer indicating the number of consecutive observations in the return time series. If NumObs is entered as the empty matrix `[]`, the length of RetIntervals is used.
- RetIntervals (Optional) Positive scalar or number of observations (NUMOBS) by 1 vector of interval times between observations. If RetIntervals is not specified, all intervals are assumed to have length 1.

<i>NumSim</i>	(Optional) Positive scalar integer indicating the number of simulated sample paths (realizations) of NUMOBS observations. Default = 1 (single realization of NUMOBS correlated asset returns).
<i>Method</i>	(Optional) String indicating the type of Monte Carlo simulation: 'Exact' (default) generates correlated asset returns in which the sample mean and covariance match the input mean (ExpReturn) and covariance (ExpCovariance) specifications. 'Expected' generates correlated asset returns in which the sample mean and covariance are statistically equal to the input mean and covariance specifications. (The expected value of the sample mean and covariance are equal to the input mean (ExpReturn) and covariance (ExpCovariance) specifications.) For either method the sample mean and covariance returned are appropriately scaled by RetIntervals.

Description

portsim simulates correlated returns of NASSETS assets over NUMOBS consecutive observation intervals. Asset returns are simulated as the proportional increments of constant drift, constant volatility stochastic processes, thereby approximating continuous-time geometric Brownian motion.

RetSeries is a NUMOBS-by-NASSETS-by-NUMSIM three-dimensional array of correlated, normally distributed, proportional asset returns. Asset returns over an interval of length dt are given by

$$\frac{dS}{S} = \mu dt + \sigma dz = \mu dt + \sigma \epsilon \sqrt{dt}$$

where S is the asset price, μ is the expected rate of return, σ is the volatility of the asset price, and ϵ represents a random drawing from a standardized normal distribution.

Notes

- When *Method* is 'Exact', the sample mean and covariance of all realizations (scaled by *RetIntervals*) match the input mean and covariance. When the returns are subsequently converted to asset prices, all terminal prices for a given asset are in close agreement. Although all realizations are drawn independently, they produce similar terminal asset prices. Set *Method* to 'Expected' to avoid this behavior.
- The returns from the portfolios in *PortWts* are given by `PortReturn = PortWts * RetSeries(:, :, 1)'`, where *PortWts* is a matrix in which each row contains the asset allocations of a portfolio. Each row of *PortReturn* corresponds to one of the portfolios identified in *PortWts*, and each column corresponds to one of the observations taken from the first realization (the first plane) in *RetSeries*. See `portopt` and `portstats` for portfolio specification and optimization.

Examples

Example 1. Distinction Between Simulation Methods

This example highlights the distinction between the Exact and Expected methods of simulation.

Consider a portfolio of five assets with the following expected returns, standard deviations, and correlation matrix based on daily asset returns:

```
ExpReturn    = [0.0246  0.0189  0.0273  0.0141  0.0311]/100;
Sigmas       = [0.9509  1.4259  1.5227  1.1062  1.0877]/100;
```

```
Correlations = [1.0000 0.4403 0.4735 0.4334 0.6855
               0.4403 1.0000 0.7597 0.7809 0.4343
               0.4735 0.7597 1.0000 0.6978 0.4926
               0.4334 0.7809 0.6978 1.0000 0.4289
               0.6855 0.4343 0.4926 0.4289 1.0000];
```

Convert the correlations and standard deviations to a covariance matrix.

```
ExpCovariance = corr2cov(Sigmas, Correlations);
```

```
ExpCovariance =
```

```
1.0e-003 *
```

```
    0.0904    0.0597    0.0686    0.0456    0.0709
    0.0597    0.2033    0.1649    0.1232    0.0674
    0.0686    0.1649    0.2319    0.1175    0.0816
    0.0456    0.1232    0.1175    0.1224    0.0516
    0.0709    0.0674    0.0816    0.0516    0.1183
```

Assume that there are 252 trading days in a calendar year, and simulate two sample paths (realizations) of daily returns over a two-year period. Since `ExpReturn` and `ExpCovariance` are expressed on a daily basis, set `RetIntervals = 1`.

```
StartPrice = 100;
NumObs = 504; % two calendar years of daily returns
NumSim = 2;
RetIntervals = 1; % one trading day
NumAssets = 5;
```

To illustrate the distinction between methods, simulate two paths by each method, starting with the same random number state.

```
randn('state',0);
RetExact = portsim(ExpReturn, ExpCovariance, NumObs, ...
RetIntervals, NumSim, 'Exact');
```

```

randn('state',0);
RetExpected = portsim(ExpReturn, ExpCovariance, NumObs, ...
RetIntervals, NumSim, 'Expected');

```

If you compare the mean and covariance of `RetExact` with the inputs (`ExpReturn` and `ExpCovariance`), you will observe that they are almost identical.

At this point, `RetExact` and `RetExpected` are both 504-by-5-by-2 arrays. Now assume an equally weighted portfolio formed from the five assets and create arrays of portfolio returns in which each column represents the portfolio return of the corresponding sample path of the simulated returns of the five assets. The portfolio arrays `PortRetExact` and `PortRetExpected` are 504-by-2 matrices.

```

Weights          = ones(NumAssets, 1)/NumAssets;
PortRetExact     = zeros(NumObs, NumSim);
PortRetExpected  = zeros(NumObs, NumSim);

for i = 1:NumSim
    PortRetExact(:,i) = RetExact(:, :, i) * Weights;
    PortRetExpected(:,i) = RetExpected(:, :, i) * Weights;
end

```

Finally, convert the simulated portfolio returns to prices and plot the data. In particular, note that since the `Exact` method matches expected return and covariance, the terminal portfolio prices are virtually identical for each sample path. This is not true for the `Expected` simulation method.

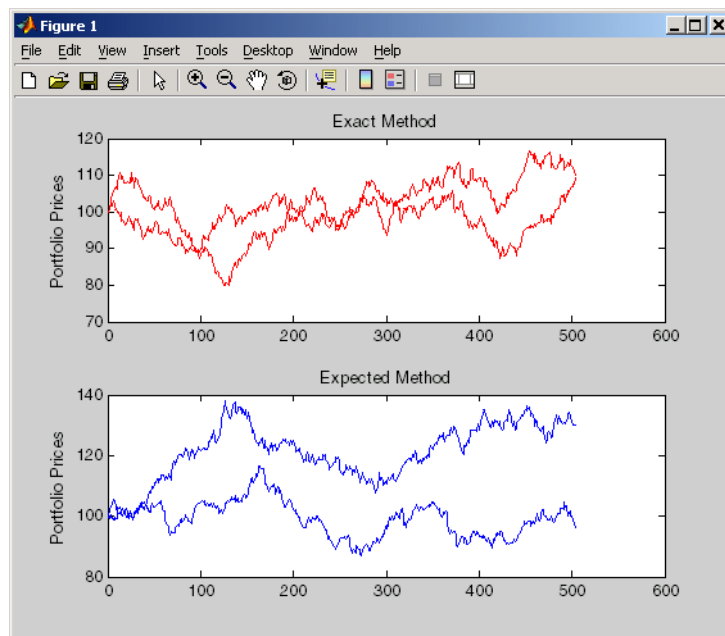

Although this example examines portfolios, the same methods apply to individual assets as well. Thus, `Exact` simulation is most appropriate when unique paths are required to reach the same terminal prices.

```

PortExact = ret2tick(PortRetExact, ...
repmat(StartPrice,1,NumSim));
PortExpected = ret2tick(PortRetExpected, ...
repmat(StartPrice,1,NumSim));

```

```
subplot(2,1,1), plot(PortExact, '-r')  
ylabel('Portfolio Prices')  
title('Exact Method')  
subplot(2,1,2), plot(PortExpected, '-b')  
ylabel('Portfolio Prices')  
title('Expected Method')
```

Example 2. Interaction Between ExpReturn, ExpCovariance and RetIntervals

Recall that `portsim` simulates correlated asset returns over an interval of length dt , given by the equation

$$\frac{dS}{S} = \mu dt + \sigma dz = \mu dt + \sigma \epsilon \sqrt{dt}$$

where S is the asset price, μ is the expected rate of return, σ is the volatility of the asset price, and ϵ represents a random drawing from a standardized normal distribution.

The time increment dt is determined by the optional input `RetIntervals`, either as an explicit input argument or as a unit time increment by default. Regardless, the periodicity of `ExpReturn`, `ExpCovariance` and `RetIntervals` must be consistent. For example, if `ExpReturn` and `ExpCovariance` are annualized, then `RetIntervals` must be in years. This point is often misunderstood.

To illustrate the interplay among `ExpReturn`, `ExpCovariance`, and `RetIntervals`, consider a portfolio of five assets with the following expected returns, standard deviations, and correlation matrix based on daily asset returns.

```
ExpReturn      = [0.0246  0.0189  0.0273  0.0141  0.0311]/100;

Sigmas         = [0.9509  1.4259  1.5227  1.1062  1.0877]/100;

Correlations   = [1.0000  0.4403  0.4735  0.4334  0.6855
                  0.4403  1.0000  0.7597  0.7809  0.4343
                  0.4735  0.7597  1.0000  0.6978  0.4926
                  0.4334  0.7809  0.6978  1.0000  0.4289
                  0.6855  0.4343  0.4926  0.4289  1.0000];
```

Convert the correlations and standard deviations to a covariance matrix of daily returns.

```
ExpCovariance = corr2cov(Sigmas, Correlations);
```

Assume 252 trading days per calendar year, and simulate a single sample path of daily returns over a four-year period. Since the `ExpReturn` and `ExpCovariance` inputs are expressed on a daily basis, set `RetIntervals = 1`.

```
StartPrice     = 100;
NumObs         = 1008;    % four calendar years of daily returns
RetIntervals   = 1;      % one trading day
```

```
NumAssets      = length(ExpReturn);
randn('state',0);
RetSeries1 = portsim(ExpReturn, ExpCovariance, NumObs, ...
RetIntervals, 1, 'Expected');
```

Now annualize the daily data, thereby changing the periodicity of the data, by multiplying `ExpReturn` and `ExpCovariance` by 252 and dividing `RetIntervals` by 252 (`RetIntervals = 1/252` of a year).

Resetting the random number generator to its initial state, you can reproduce the results.

```
randn('state',0);
RetSeries2 = portsim(ExpReturn*252, ExpCovariance*252, ...
NumObs, RetIntervals/252, 1, 'Expected');
```

Assume an equally weighted portfolio and compute portfolio returns associated with each simulated return series.

```
Weights = ones(NumAssets, 1)/NumAssets;

PortRet1 = RetSeries2 * Weights;
PortRet2 = RetSeries2 * Weights;
```

Comparison of the data reveals that `PortRet1` and `PortRet2` are identical.

Example 3. Univariate Geometric Brownian Motion

This example simulates a univariate geometric Brownian motion process. It is based on an example found in Hull, *Options, Futures, and Other Derivatives*, 5th Edition (see example 12.2 on page 236). In addition to verifying Hull's example, it also graphically illustrates the lognormal property of terminal stock prices by a rather large Monte Carlo simulation.

First, assume you own a stock with an initial price of \$20, an annualized expected return of 20% and volatility of 40%. Simulate the daily price

process for this stock over the course of one full calendar year (252 trading days).

```

StartPrice    = 20;
ExpReturn     = 0.2;
ExpCovariance = 0.4^2;
NumObs        = 252;
NumSim        = 10000;
RetIntervals  = 1/252;

```

Note that RetIntervals is expressed in years, consistent with the fact that ExpReturn and ExpCovariance are annualized. Also, note that ExpCovariance is entered as a variance rather than the more familiar standard deviation (volatility).

Now set the random number generator state, and simulate 10,000 trials (realizations) of stock returns over a full calendar year of 252 trading days.

```

randn('state',10);
RetSeries = squeeze(portsim(ExpReturn, ExpCovariance, NumObs, ...
RetIntervals, NumSim, 'Expected'));

```

The squeeze function simply reformats the output array of simulated returns from a 252-by-1-by-10000 array to more convenient 252-by-10000 array. (Recall that portsim is fundamentally a multivariate simulation engine).

In accordance with Hull's equations 12.4 and 12.5 on page 236

$$E(S_T) = S_0 e^{\mu T}$$

$$var(S_T) = S_0^2 e^{2\mu T} (e^{\sigma^2 T} - 1)$$

convert the simulated return series to a price series and compute the sample mean and the variance of the terminal stock prices.

```

StockPrices = ret2tick(RetSeries, repmat(StartPrice, 1, NumSim));

```

```
SampMean = mean(StockPrices(end,:))
```

```
SampMean =
```

```
24.4587
```

```
SampVar = var(StockPrices(end,:))
```

```
SampVar =
```

```
104.2016
```

Compare these values with the values you obtain by using Hull's equations.

```
ExpValue = StartPrice*exp(ExpReturn)
```

```
ExpValue =
```

```
24.4281
```

```
ExpVar = ...
```

```
StartPrice*StartPrice*exp(2*ExpReturn)*(exp((ExpCovariance)) - 1)
```

```
ExpVar =
```

```
103.5391
```

These results are very close to the results shown in Hull's example 12.2.

Next, display the sample density function of the terminal stock price after one calendar year. From the sample density function, the lognormal distribution of terminal stock prices is apparent.

```
[count, BinCenter] = hist(StockPrices(end,:), 30);
```

```
figure
```

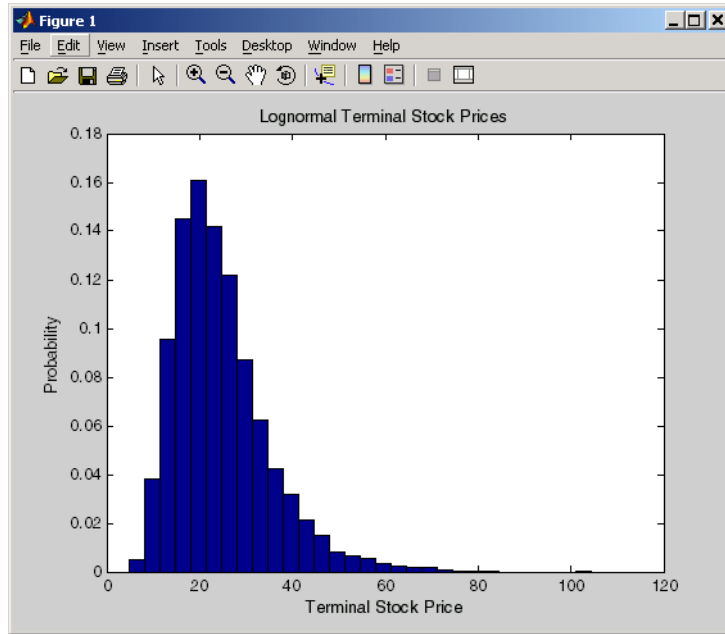

```
bar(BinCenter, count/sum(count), 1, 'r')
```

```

xlabel('Terminal Stock Price')
ylabel('Probability')
title('Lognormal Terminal Stock Prices')

```

portstats

Purpose Portfolio expected return and risk

Syntax [PortRisk, PortReturn] = portstats(ExpReturn, ExpCovariance, PortWts)

Arguments

ExpReturn	1-by-number of assets (NASSETS) vector specifying the expected (mean) return of each asset.
ExpCovariance	NASSETS-by-NASSETS matrix specifying the covariance of the asset returns.
PortWts	(Optional) Number of portfolios (NPORTS) by NASSETS matrix of weights allocated to each asset. Each row represents a different weighting combination. Default = 1/NASSETS (equally weighted).

Description [PortRisk, PortReturn] = portstats(ExpReturn, ExpCovariance, PortWts) computes the expected rate of return and risk for a portfolio of assets.

PortRisk is an NPORTS-by-1 vector of the standard deviation of each portfolio.

PortReturn is an NPORTS-by-1 vector of the expected return of each portfolio.

Examples

```
ExpReturn = [0.1 0.2 0.15];
```

```
ExpCovariance = [0.0100  -0.0061  0.0042  
                -0.0061  0.0400  -0.0252  
                0.0042  -0.0252  0.0225 ];
```

```
PortWts=[0.4 0.2 0.4; 0.2 0.4 0.2];

[PortRisk, PortReturn] = portstats(ExpReturn, ExpCovariance,...
PortWts)

PortRisk =

    0.0560
    0.0550

PortReturn =

    0.1400
    0.1300
```

portvrisk

Purpose Portfolio value at risk

Syntax ValueAtRisk = portvrisk(PortReturn, PortRisk, RiskThreshold, PortValue)

Arguments

PortReturn	Number of portfolios (NPORTS) by 1 vector or scalar of the expected return of each portfolio over the period.
PortRisk	NPORTS-by-1 vector or scalar of the standard deviation of each portfolio over the period.
RiskThreshold	(Optional) NPORTS-by-1 vector or scalar specifying the loss probability. Default = 0.05 (5%).
PortValue	(Optional) NPORTS-by-1 vector or scalar specifying the total value of asset portfolio. Default = 1.

Description

ValueAtRisk = portvrisk(PortReturn, PortRisk, RiskThreshold, PortValue) returns the maximum potential loss in the value of a portfolio over one period of time, given the loss probability level RiskThreshold.

ValueAtRisk is an NPORTS-by-1 vector of the estimated maximum loss in the portfolio, predicted with a confidence probability of 1-RiskThreshold.

If PortValue is not given, ValueAtRisk is presented on a per-unit basis. A value of 0 indicates no losses.

Examples

This example computes ValueAtRisk on a per-unit basis.

```
PortReturn = 0.29/100;
```

```

PortRisk = 3.08/100;
RiskThreshold = [0.01;0.05;0.10];
PortValue = 1;
ValueAtRisk = portvrisk(PortReturn,PortRisk,...
RiskThreshold,PortValue)
ValueAtRisk =

    0.0688
    0.0478
    0.0366

```

This example computes ValueAtRisk with actual values.

```

PortReturn = [0.29/100;0.30/100];
PortRisk = [3.08/100;3.15/100];
RiskThreshold = 0.10;
PortValue = [1000000000;500000000];
ValueAtRisk = portvrisk(PortReturn,PortRisk,...
RiskThreshold,PortValue)
ValueAtRisk =

    1.0e+007 *
    3.6572
    1.8684

frontcon, portopt

posvalidx

Purpose Positive volume index

Syntax

```
pvi = posvalidx(closep, tvolume, initpvi)
pvi = posvalidx([closep tvolume], initpvi)
pvits = posvalidx(tsobj)
pvits = posvalidx(tsobj, initpvi, ParameterName, ParameterValue, ...)
```

Arguments

<code>closep</code>	Closing price (vector).
<code>tvolume</code>	Volume traded (vector).
<code>initpvi</code>	(Optional) Initial value for positive volume index. Default = 100.
<code>tsobj</code>	Financial time series object.

Description

`pvi = posvalidx(closep, tvolume, initpvi)` calculates the positive volume index from a set of stock closing prices (`closep`) and volume traded (`tvolume`) data. `pvi` is a vector representing the positive volume index. If `initpvi` is specified, `posvalidx` uses that value instead of the default (100).

`pvi = posvalidx([closep tvolume], initpvi)` accepts a two-column matrix, the first column representing the closing prices (`closep`) and the second representing the volume traded (`tvolume`). If `initpvi` is specified, `posvalidx` uses that value instead of the default (100).

`pvits = posvalidx(tsobj)` calculates the positive volume index from the financial time series object `tsobj`. The object must contain, at least, the series `Close` and `Volume`. The `pvits` output is a financial time series object with dates similar to `tsobj` and a data series named `PVI`. The initial value for the positive volume index is arbitrarily set to 100.

`pvits = posvalidx(tsobj, initpvi, ParameterName, ParameterValue, ...)` accepts parameter name/parameter value pairs

as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

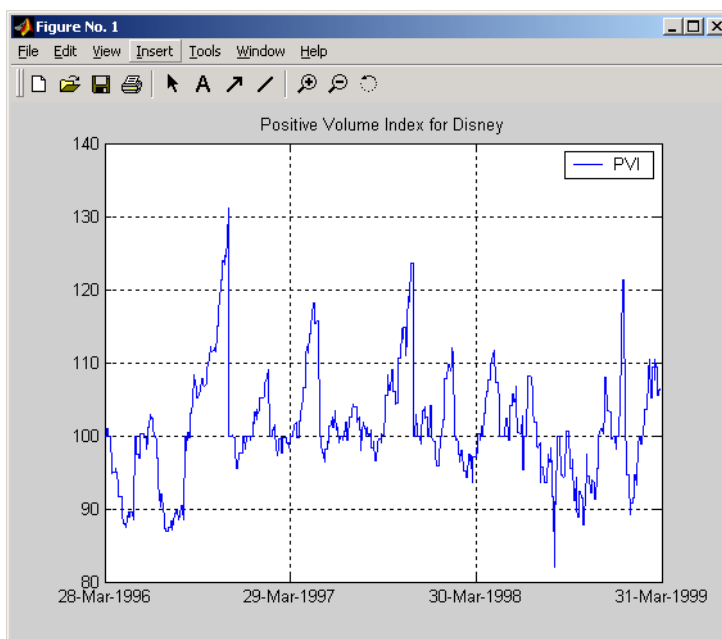

- CloseName: closing prices series name
- VolumeName: volume traded series name

Parameter values are the strings that represent the valid parameter names.

Examples

Compute the positive volume index for Disney stock and plot the results:

```
load disney.mat
dis_PosVol = posvalidx(dis)
plot(dis_PosVol)
title('Positive Volume Index for Disney')
```

onbalvol, negvalidx

Purpose Financial time series power

Syntax

```
newfts = tsoj .^ array
newfts = array .^tsoj
newfts = tsoj_1 .^ tsoj_2
```

Arguments

tsoj	Financial time series object.
array	Scalar value or array with the number of rows equal to the number of dates in tsoj and the number of columns equal to the number of data series in tsoj.
tsoj_1, tsoj_2	Pair of financial time series objects.

Description

`newfts = tsoj .^ array` raises all values in the data series of the financial time series object `tsoj` element by element to the power indicated by the array value. The results are stored in another financial time series object `newfts`. The `newfts` object contains the same data series names as `tsoj`.

`newfts = array .^ tsoj` raises the array values element by element to the values contained in the data series of the financial time series object `tsoj`. The results are stored in another financial time series object `newfts`. The `newfts` object contains the same data series names as `tsoj`.

`newfts = tsoj_1 .^ tsoj_2` raises the values in the object `tsoj_1` element by element to the values in the object `tsoj_2`. The data series names, the dates, and the number of data points in both series must be identical. `newfts` contains the same data series names as the original time series objects.

See Also `minus`, `plus`, `rdivide`, `times`

prbyzero

Purpose Price bonds in portfolio by set of zero curves

Syntax BondPrices = prbyzero(Bonds, Settle, ZeroRates, ZeroDates)

Arguments

Bonds	Coupon bond information used to compute prices. A number of bonds (NUMBONDS)-by-6 matrix where each row describes a bond. The first two columns are required; the rest are optional but must be added in order. All rows in Bonds must have the same number of columns. Columns are [Maturity CouponRate Face Period Basis EndMonthRule] where:
Maturity	Maturity date as a serial date number or date string.
CouponRate	Decimal number indicating the annual percentage rate used to determine the coupons payable on a bond.
Face	(Optional) Face or par value of the bond. Default = 100.
Period	(Optional) Coupons per year of the bond. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.

Basis	<p>(Optional) Day-count basis of the instrument. A vector of integers.</p> <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)
EndMonthRule	<p>(Optional) End-of-month rule. This rule applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.</p>
Settle	<p>Serial date number of the settlement date.</p>

ZeroRates NUMDATES-by-NUMCURVES matrix of observed zero rates, as decimal fractions. Each column represents a rate curve. Each row represents an observation date.

ZeroDates NUMDATES-by-1 column of dates for observed zeros

Description

`BondPrices = prbyzero(Bonds, Settle, ZeroRates, ZeroDates)` computes the bond prices in a portfolio using a set of zero curves.

`BondPrices` is a NUMBONDS-by-NUMCURVES matrix of clean bond prices. Each column is derived from the corresponding zero curve in `ZeroRates`.

Examples

This example uses `zbtprice` to compute a zero curve given a portfolio of coupon bonds and their prices. It then reverses the process, using the zero curve as input to `prbyzero` to compute the prices.

```
Bonds = [datenum('6/1/1998') 0.0475 100 2 0 0;  
         datenum('7/1/2000') 0.06 100 2 0 0;  
         datenum('7/1/2000') 0.09375 100 6 1 0;  
         datenum('6/30/2001') 0.05125 100 1 3 1;  
         datenum('4/15/2002') 0.07125 100 4 1 0;  
         datenum('1/15/2000') 0.065 100 2 0 0;  
         datenum('9/1/1999') 0.08 100 3 3 0;  
         datenum('4/30/2001') 0.05875 100 2 0 0;  
         datenum('11/15/1999') 0.07125 100 2 0 0;  
         datenum('6/30/2000') 0.07 100 2 3 1;  
         datenum('7/1/2001') 0.0525 100 2 3 0;  
         datenum('4/30/2002') 0.07 100 2 0 0];
```

```
Prices = [ 99.375;  
         99.875;  
         105.75 ;  
         96.875;  
         103.625;  
         101.125;
```

```
103.125;  
99.375;  
101.0 ;  
101.25 ;  
96.375;  
102.75 ];
```

```
Settle = datenum('12/18/1997');
```

Set semiannual compounding for the zero curve, on an actual/365 basis.
Derive the zero curve within 50 iterations.

```
OutputCompounding = 2;  
OutputBasis = 3;  
MaxIterations = 50;
```

Execute `zbtprice`

```
[ZeroRates, ZeroDates] = zbtprice(Bonds, Prices, Settle,...  
OutputCompounding, OutputBasis, MaxIterations)
```

which returns the zero curve at the maturity dates.

```
ZeroRates =

0.0590  
0.0648  
0.0655  
0.0606  
0.0601  
0.0642  
0.0621  
0.0627
```

prbyzero

ZeroDates =

729907
730364
730439
730500
730667
730668
730971
731032
731033
731321
731336

Now execute prbyzero

BondPrices = prbyzero(Bonds, Settle, ZeroRates, ZeroDates)

which returns

BondPrices =

99.38
98.80
106.83
96.88
103.62
101.13
103.12
99.36
101.00
101.25
96.37
102.74

In this example zbtprice and prbyzero do not exactly reverse each other. Many of the bonds have the end-of-month rule off (EndMonthRule

= 0). The rule subtly affects the time factor computation. If you set the rule on (`EndMonthRule = 1`) everywhere in the Bonds matrix, then `prbyzero` returns the original prices, except when the two incompatible prices fall on the same maturity date.

See Also

`tr2bonds`, `zbtprice`

Purpose Price rate of change

Syntax

```
proc = prcroc(closep, nperiods)
procts = prcroc(tsobj, nperiods)
procts = prcroc(tsobj, nperiods, ParameterName, ParameterValue)
```

Arguments

<code>closep</code>	Closing price
<code>nperiods</code>	(Optional) Period difference. Default = 12.
<code>tsobj</code>	Financial time series object

Description

`proc = prcroc(closep, nperiods)` calculates the price rate of change `proc` from the closing price `closep`. If `nperiods` periods is specified, the price rate of change is calculated between the current closing price and the closing price `nperiods` ago.

`procts = prcroc(tsobj, nperiods)` calculates the price rate of change `procts` from the financial time series object `tsobj`. `tsobj` must contain a data series named `Close`. The output `procts` is a financial time series object with similar dates as `tsobj` and a data series named `PriceROC`. If `nperiods` is specified, the price rate of change is calculated between the current closing price and the closing price `nperiods` ago.

`procts = prcroc(tsobj, nperiods, ParameterName, ParameterValue)` specifies the name for the required data series when it is different from the default name. The valid parameter name is

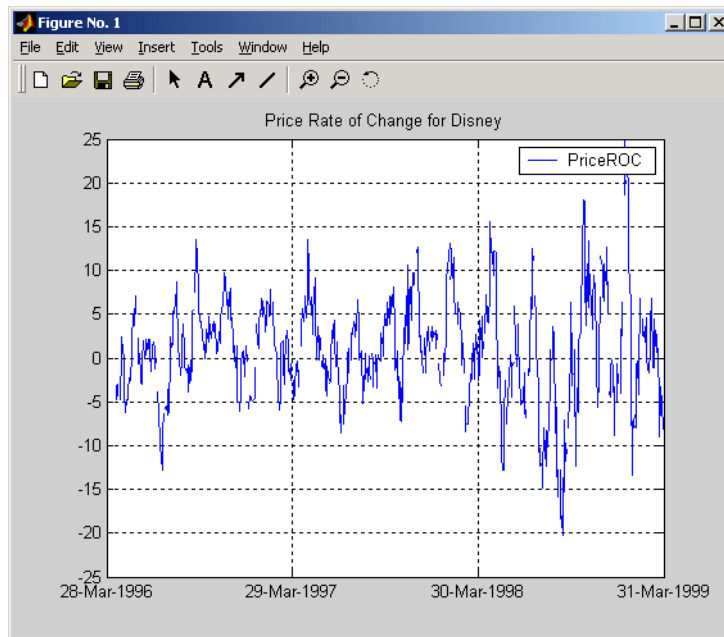

- `CloseName`: closing price series name

The parameter value is a string that represents the valid parameter name.

Examples

Compute the price rate of change for Disney stock and plot the results:

```
load disney.mat
dis_PriceRoc = prcroc(dis)
plot(dis_PriceRoc)
title('Price Rate of Change for Disney')
```

prdisc

Purpose Price of discounted security

Syntax Price = prdisc(Settle, Maturity, Face, Discount, Basis)

Arguments

Settle	Enter as serial date number or date string. Settle must be earlier than or equal to Maturity.
Maturity	Enter as serial date number or date string.
Face	Redemption (par, face) value.
Discount	Bank discount rate of the security. Enter as decimal fraction.
Basis	(Optional) Day-count basis of the instrument. A vector of integers.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ISMA)
- 9 = actual/360 (ISMA)
- 10 = actual/365 (ISMA)

Description

Price = prdisc(Settle, Maturity, Face, Discount, Basis)
returns the price of a security whose yield is quoted as a bank discount rate (for example, U. S. Treasury bills).

Examples

Using this data

```
Settle = '10/14/2000';  
Maturity = '03/17/2001';  
Face = 100;  
Discount = 0.087;  
Basis = 2;
```

```
Price = prdisc(Settle, Maturity, Face, Discount, Basis)
```

returns

```
Price =
```

```
96.2783
```

prmat

Purpose Price with interest at maturity

Syntax [Price, AccruInterest] = prmat(Settle, Maturity, Issue, Face, CouponRate, Yield, Basis)

Arguments

Settle	Enter as serial date number or date string. Settle must be earlier than or equal to Maturity.
Maturity	Enter as serial date number or date string.
Issue	Enter as serial date number or date string.
Face	Redemption (par, face) value.
CouponRate	Enter as decimal fraction.
Yield	Annual yield. Enter as decimal fraction.
Basis	(Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)

Description

[Price, AccruInterest] = prmat(Settle, Maturity, Issue, Face, CouponRate, Yield, Basis) returns the price and accrued interest of a security that pays interest at maturity. This function also applies to zero-coupon bonds or pure discount securities by setting CouponRate = 0.

Examples

Using this data

```
Settle = '02/07/2002';  
Maturity = '04/13/2002';  
Issue = '10/11/2001';  
Face = 100;  
CouponRate = 0.0608;  
Yield = 0.0608;  
Basis = 1;
```

```
[Price, AccruInterest] = prmat(Settle, Maturity, Issue, Face,...  
    CouponRate, Yield, Basis)
```

returns

```
Price =
```

```
    99.9784
```

```
AccruInterest =
```

```
    1.9591
```

prtbill

Purpose Price of Treasury bill

Syntax Price = prtbill(Settle, Maturity, Face, Discount)

Arguments

Settle	Enter as serial date number or date string. Settle must be earlier than or equal to Maturity.
Maturity	Enter as serial date number or date string.
Face	Redemption (par, face) value.
Discount	Discount rate of the Treasury bill. Enter as decimal fraction.

Description Price = prtbill(Settle, Maturity, Face, Discount) returns the price for a Treasury bill.

Examples The settlement date of a Treasury bill is February 10, 2002, the maturity date is August 6, 2002, the discount rate is 3.77%, and the par value is \$1000. Using this data

```
Price = prtbill('2/10/2002', '8/6/2002', 1000, 0.0377)
```

returns

```
Price =  
981.4642
```

References Bodie, Kane, and Marcus, *Investments*, pages 41-43.

Purpose Present value with fixed periodic payments

Syntax PresentVal = pvfix(Rate, NumPeriods, Payment, ExtraPayment, Due)

Arguments

- rate Periodic interest rate, as a decimal fraction.
- NumPeriods Number of periods.
- Payment Periodic payment.
- ExtraPayment (Optional) Payment received other than Payment in the last period. Default = 0.
- Due (Optional) When payments are due or made: 0 = end of period (default), or 1 = beginning of period.

Description PresentVal = pvfix(Rate, NumPeriods, Payment, ExtraPayment, Due) returns the present value of a series of equal payments.

Examples \$200 is paid monthly into a savings account earning 6%. The payments are made at the end of the month for five years. To find the present value of these payments

```
PresentVal = pvfix(0.06/12, 5*12, 200, 0, 0)
```

returns

```
PresentVal =
10345.11
```

See Also fvfix, fvvar, payper, pvvar

pvtrend

Purpose Price and Volume Trend (PVT)

Syntax

```
pvt = pvtrend(closep, tvolume)
pvt = pvtrend([closep tvolume])
pvttts = pvtrend(tsobj)
pvttts = pvtrend(tsobj, ParameterName, ParameterValue, ...)
```

Arguments

<code>closep</code>	Closing price.
<code>tvolume</code>	Volume traded.
<code>tsobj</code>	Financial time series object.
<code>ParameterName</code>	Valid parameter names are: <ul style="list-style-type: none">• <code>CloseName</code>: closing prices series name• <code>VolumeName</code>: volume traded series name
<code>ParameterValue</code>	Parameter values are the strings that represent the valid parameter names.

Description `pvt = pvtrend(closep, tvolume)` calculates the Price and Volume Trend (PVT) from the stock closing price (`closep`) data and the volume traded (`tvolume`) data.

`pvt = pvtrend([closep tvolume])` accepts a two-column matrix in which the first column contains the closing prices (`closep`) and the second contains the volume traded (`tvolume`).

`pvttts = pvtrend(tsobj)` calculates the PVT from the stock data contained in the financial time series object `tsobj`. The object `tsobj` must contain the closing price series `Close` and the volume traded series `Volume`. The output `pvttts` is a financial time series object with dates similar to `tsobj` and a data series named `PVT`.

`pvtts = pvtrend(tsoobj, ParameterName, ParameterValue, ...)`
accepts parameter name/ parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Parameter values are the strings that represent the valid parameter names.

Examples

Compute the PVT for Disney stock and plot the results:

```
load disney.mat
dis_PVTrend = pvtrend(dis)
plot(dis_PVTrend)
title('Price and Volume Trend for Disney')
```

pvvar

Purpose Present value of varying cash flow

Syntax PresentVal = pvvar(CashFlow, Rate, IrrCFDates)

Arguments

CashFlow A vector of varying cash flows. Include the initial investment as the initial cash flow value (a negative number).

Rate Periodic interest rate. Enter as a decimal fraction.

IrrCFDates (Optional) For irregular (nonperiodic) cash flows, a vector of dates on which the cash flows occur. Enter dates as serial date numbers or date strings. Default assumes CashFlow contains regular (periodic) cash flows.

Description PresentVal = pvvar(CashFlow, Rate, IrrCFDates) returns the net present value of a varying cash flow.

Examples This cash flow represents the yearly income from an initial investment of \$10,000. The annual interest rate is 8%.

Year 1	\$2000
Year 2	\$1500
Year 3	\$3000
Year 4	\$3800
Year 5	\$5000

To calculate the net present value of this regular cash flow

```
PresentVal = pvvar([-10000 2000 1500 3000 3800 5000], 0.08)
```

returns

```
PresentVal =
```

```
1715.39
```

An investment of \$10,000 returns this irregular cash flow. The original investment and its date are included. The periodic interest rate is 9%.

Cash Flow	Dates
(\$10000)	January 12, 1987
\$2500	February 14, 1988
\$2000	March 3, 1988
\$3000	June 14, 1988
\$4000	December 1, 1988

To calculate the net present value of this irregular cash flow

```
CashFlow = [-10000, 2500, 2000, 3000, 4000];
```

```
IrrCFDates = ['01/12/1987'
               '02/14/1988'
               '03/03/1988'
               '06/14/1988'
               '12/01/1988'];
```

```
PresentVal = pvvar(CashFlow, 0.09, IrrCFDates)
```

returns

```
PresentVal =
```

fvfix, fvvar, irr, payuni, pvfix

Purpose Zero curve given par yield curve

Syntax [ZeroRates, CurveDates] = pyld2zero(ParRates, CurveDates, Settle, Compounding, Basis, OutputCompounding)

Arguments

ParRates	Column vector of annualized implied par yield rates, as decimal fractions. (Par yields = coupon rates.) In aggregate, the yield rates in ParRates constitute an implied par yield curve for the investment horizon represented by CurveDates.
CurveDates	Column vector of maturity dates (as serial date numbers) that correspond to the par rates.
Settle	Serial date number that is the common settlement date for the par rates.
Compounding	(Optional) Scalar that sets the rate at which the par rates are compounded when annualized. Allowed values are: 1 Annual compounding 2 Semiannual compounding (default) 3 Compounding three times per year 4 Quarterly compounding 6 Bimonthly compounding 12 Monthly compounding 365 Daily compounding

Basis	(Optional) Day-count basis used to annualize the zero rates. <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)
OutputCompounding	(Optional) Value representing the rate at which the zero rates are compounded. Default = Compounding.

Description

[ZeroRates, CurveDates] = pyld2zero(ParRates, CurveDates, Settle, Compounding, Basis, OutputCompounding) returns a zero curve given a par yield curve and its maturity dates.

ZeroRates Column vector of decimal fractions. In aggregate, the rates in **ZeroRates** constitute a zero curve for the investment horizon represented by **CurveDates**.

CurveDates Column vector of maturity dates (as serial date numbers) corresponding to the zero rates. This vector is the same as the input vector **CurveDates**.

Examples

Given

- A par yield curve over a set of maturity dates
- A settlement date
- Annual compounding for the input par rates and monthly compounding for the output zero curve

compute a zero yield curve.

```
ParRates = [0.0479
            0.0522
            0.0540
            0.0540
            0.0536
            0.0532
            0.0532
            0.0539
            0.0558
            0.0543];

CurveDates = [datenum('06-Nov-2000')
              datenum('11-Dec-2000')
              datenum('15-Jan-2001')
              datenum('05-Feb-2001')
              datenum('04-Mar-2001')
              datenum('02-Apr-2001')
              datenum('30-Apr-2001')]
```

```
        datenum('25-Jun-2001')
        datenum('04-Sep-2001')
        datenum('12-Nov-2001')];

Settle = datenum('03-Nov-2000');
Compounding = 1;
OutputCompounding = 12;

[ZeroRates, CurveDates] = pyld2zero(ParRates, CurveDates,...
Settle, Compounding, [], OutputCompounding)

ZeroRates =

    0.0484
    0.0529
    0.0549
    0.0550
    0.0547
    0.0544
    0.0545
    0.0551
    0.0572
    0.0557

CurveDates =

    730796
    730831
    730866
    730887
    730914
    730943
    730971
    731027
    731098
    731167
```

For readability, `ParRates` and `ZeroRates` are shown only to the basis point. However, MATLAB computes them at full precision. If you enter `ParRates` as shown, `ZeroRates` may differ due to rounding.

`zero2py1d` and other functions for “Term Structure of Interest Rates” on page 2-33

rdivide

Purpose Financial time series division

Syntax
`newfts = tsoj_1 ./ tsoj_2`
`newfts = tsoj ./ array`
`newfts = array ./ tsoj`

Arguments

`tsoj_1, tsoj_2` Pair of financial time series objects.
`array` Scalar value or array with the number of rows equal to the number of dates in `tsoj` and the number of columns equal to the number of data series in `tsoj`.

Description

The `rdivide` method divides, element by element, the components of one financial time series object by the components of the other. You can also divide the whole object by an array or divide a financial time series object into an array.

If an object is to be divided by another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when an object is divided by another object, follows the order of the first object.

`newfts = tsoj_1 ./ tsoj_2` divides financial time series objects element by element.

`newfts = tsoj ./ array` divides a financial time series object element by element by an array.

`newfts = array ./ tsoj` divides an array element by element by a financial time series object.

For financial time series objects, the `rdivide` operation is identical to the `mrdivide` operation.

See Also minus, mrdivide, plus, times

resamplets

Purpose Downsample data

Syntax `newfts = resamplets(oldfts, samplestep)`

Description `newfts = resamplets(oldfts, samplestep)` downsamples the data contained in the financial time series object `oldfts` every `samplestep` periods. For example, to have the new financial time series object contain every other data element from `oldfts`, set `samplestep` to 2.

`newfts` is a financial time series object containing the same data series (names) as the input `oldfts`.

See Also `filter`

Purpose

Convert return series to price series

Syntax

```
[TickSeries, TickTimes] = ret2tick(RetSeries, StartPrice,  
RetIntervals, StartTime, Method)
```

Arguments

RetSeries	Number of observations (NUMOBS) by number of assets (NASSETS) time series array of asset returns associated with the prices in TickSeries. The <i>i</i> th return is quoted for the period TickTimes(<i>i</i>) to TickTimes(<i>i</i> +1) and is not normalized by the time increment between successive price observations.
StartPrice	(Optional) 1-by-NASSETS vector of initial asset prices or a single scalar initial price applied to all assets. Prices start at 1 if StartPrice is not specified.
RetIntervals	(Optional) Scalar or NUMOBS-by-1 vector of interval times between observations. If this argument is not specified, all intervals are assumed to have length 1.
StartTime	(Optional) Starting time for first observation, applied to the price series of all assets. The default is zero.
Method	(Optional) Character string indicating the method to convert asset returns to prices. Must be 'Simple' (default) or 'Continuous'. If Method is 'Simple', ret2tick uses simple periodic returns. If Method is 'Continuous', the function uses continuously compounded returns. Case is ignored for Method.

Description

`[TickSeries, TickTimes] = ret2tick(RetSeries, StartPrice, RetIntervals, StartTime, Method)` generates price values from the starting prices of NASSETS investments and NUMOBS incremental return observations.

`TickSeries` is a `NUMOBS+1`-by-`NASSETS` times series array of equity prices. The first row contains the oldest observations and the last row the most recent. Observations across a given row occur at the same time for all columns. Each column is a price series of an individual asset. If `Method` is unspecified or 'Simple', the prices are

$$\text{TickSeries}(i+1) = \text{TickSeries}(i) * [1 + \text{RetSeries}(i)]$$

If `Method` is 'Continuous', the prices are

$$\text{TickSeries}(i+1) = \text{TickSeries}(i) * \exp[\text{RetSeries}(i)]$$

`TickTimes` is a `NUMOBS+1` column vector of monotonically increasing observation times associated with the prices in `TickSeries`. The initial time is zero unless specified in `StartTime`, and sequential observation times occur at unit increments unless specified in `RetIntervals`.

Examples

Compute the price increase of two stocks over a year's time based on three incremental return observations.

```
RetSeries = [0.10 0.12
             0.05 0.04
            -0.05 0.05];
```

```
RetIntervals = [182
                 91
                 92];
```

```
StartTime = datenum('18-Dec-2000');
```

```
[TickSeries, TickTimes] = ret2tick(RetSeries, [], RetIntervals, ...
    StartTime)
```

```
TickSeries =  
  
    1.0000    1.0000  
    1.1000    1.1200  
    1.1550    1.1648  
    1.0973    1.2230
```

```
TickTimes =
```

```
    730838  
    731020  
    731111  
    731203
```

```
datestr(TickTimes)
```

```
ans =
```

```
18-Dec-2000  
18-Jun-2001  
17-Sep-2001  
18-Dec-2001
```

portsim, tick2ret

rmfield

Purpose Remove data series

Syntax `fts = rmfield(tsobj, fieldname)`

Arguments

<code>tsobj</code>	Financial time series object.
<code>fieldname</code>	String array containing the data series name to remove a single series from the object. Cell array of data series names to remove multiple data series from the object at the same time.

Description `fts = rmfield(tsobj, fieldname)` removes the data series `fieldname` and its contents from the financial time series object `tsobj`.

See Also `chfield`, `extfield`, `fieldnames`, `getfield`, `isfield`

Purpose Relative Strength Index (RSI)

Syntax

```
rsi = rsindex(closep, nperiods)
rsits = rsindex(tsobj, nperiods)
rsits = rsindex(tsobj, nperiods, ParameterName, ParameterValue)
```

Arguments

closep	Vector of closing prices.
nperiods	(Optional) Number of periods. Default = 14.
tsobj	Financial time series object.

Description

`rsi = rsindex(closep, nperiods)` calculates the Relative Strength Index (RSI) from the closing price vector `closep`.

`rsits = rsindex(tsobj, nperiods)` calculates the RSI from the closing price series in the financial time series object `tsobj`. The object `tsobj` must contain at least the series `Close`, representing the closing prices. The output `rsits` is a financial time series object whose dates are the same as `tsobj` and whose data series name is `RSI`.

`rsits = rsindex(tsobj, nperiods, ParameterName, ParameterValue)` accepts a parameter name/parameter value pair as input. This pair specifies the name for the required data series if it is different from the expected default name. The valid parameter name is `CloseName`: closing prices series name

The parameter value is the string that represents the valid parameter name.

- 1 The relative strength factor is calculated by dividing the average of the gains by the average of the losses within a specified time period:
$$RS = (\text{average gains}) / (\text{average losses}).$$

2 The first value of RSI, $RSI(1)$, is set as NaN to preserve the dimensions of CLOSEP.

Examples

Compute the RSI for Disney stock and plot the results:

```
load disney.mat
dis_RSI = rsindex(dis)
plot(dis_RSI)
title('Relative Strength Index for Disney')
```

negvolidx, posvolidx

Purpose Seconds of date or time

Syntax Seconds = second(Date)

Description Seconds = second(Date) returns the seconds given a serial date number or a date string.

Examples Seconds = second(738647.558427893)

or

Seconds = second('06-May-2022, 13:24:08.17')

returns

Seconds =

8.1700

See Also datevec, hour, minute

selectreturn

Purpose Portfolio configurations from 3-D efficient frontier

Syntax `PortConfigs = selectreturn(AllMean, All Covariance, Target)`

Arguments

AllMean	Number of curves (NCURVES) by 1 cell array where each element is a 1-by-NASSETS (number of assets) vector of the expected asset returns used to generate each curve on the surface.
AllCovariance	NCURVES-by-1 cell array where each element is an NASSETS-by-NASSETS vector of the covariance matrix used to generate each curve on the surface.
Target	Target return value for each curve in the frontier.

Description `PortConfigs = selectreturn(AllMean, All Covariance, Target)` returns the portfolio configurations for a target return given the average return and covariance for a rolling efficient frontier.

`PortConfigs` is a NASSETS-by-NCURVES matrix of asset allocation weights needed to obtain the target rate of return.

See Also `frontier`

Purpose

Set content of specific field

Syntax

```
newfts = setfield(tsobj, field, V)
newfts = setfield(tsobj, field, {dates}, V)
```

Description

setfield treats the contents of fields in a time series object (tsobj) as fields in a structure.

newfts = setfield(tsobj, field, V) sets the contents of the specified field to the value V. This is equivalent to the syntax S.field = V.

newfts = setfield(tsobj, field, {dates}, V) sets the contents of the specified field for the specified dates. dates can be individual cells of date strings or a cell of a date string range using the :: operator, for example, '03/01/99::03/31/99'. Dates can contain time-of-day information.

Examples

Example 1. Set the closing value for all days to 3890.

```
load dji30short
format bank
myfts1 = setfield(myfts1, 'Close', 3890);
```

Example 2. Set values for specific times on specific days.

First create a financial time series containing time-of-day data.

```
dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
         '02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
dates_times = cellstr([dates, repmat(' ', size(dates,1),1), ...
                      times]);
myfts = fints(dates_times, [(1:4)'; nan; 6], {'Data1'}, 1, ...
             'My FINTS')

myfts =
```

setfield

```
desc: My FINTS
freq: Daily (1)

'dates: (6)' 'times: (6)' 'Data1: (6)'
'01-Jan-2001' '11:00' [ 1]
' ' '12:00' [ 2]
'02-Jan-2001' '11:00' [ 3]
' ' '12:00' [ 4]
'03-Jan-2001' '11:00' [ NaN]
' ' '12:00' [ 6]
```

Now use `setfield` to replace the data in `myfts` with new data starting at 12:00 on January 1, 2001 and ending at 11:00 on January 3, 2001.

```
S = setfield(myfts, 'Data1', ...
            {'01-Jan-2001 12:00::03-Jan-2001 11:00'}, (102:105)')
```

S =

```
desc: My FINTS
freq: Daily (1)

'dates: (6)' 'times: (6)' 'Data1: (6)'
'01-Jan-2001' '11:00' [ 1.00]
' ' '12:00' [ 102.00]
'02-Jan-2001' '11:00' [ 103.00]
' ' '12:00' [ 104.00]
'03-Jan-2001' '11:00' [ 105.00]
' ' '12:00' [ 6.00]
```

Purpose Compute Sharpe ratio for one or more assets

Syntax

```
sharpe(Asset)
sharpe(Asset, Cash)
Ratio = sharpe(Asset, Cash)
```

Arguments

Asset	NUMSAMPLES-by-NUMSERIES matrix with NUMSAMPLES observations of asset returns for NUMSERIES asset return series.
Cash	(Optional) Either a scalar return for a riskless asset or a vector of asset returns to be a proxy for a riskless asset. In either case, the return periodicity must be the same as the periodicity of Asset. For example, if Asset is monthly data, then Cash must be monthly returns. If no value is supplied, the default value for Cash returns is 0.

Description Given NUMSERIES assets with NUMSAMPLES returns for each asset in a NUMSAMPLES-by-NUMSERIES matrix Asset and given either a scalar Cash asset return or a vector of Cash asset returns, the Sharpe ratio is computed for each asset.

The output is Ratio, a 1-by-NUMSERIES row vector of Sharpe ratios for each series in Asset. Any series in Asset with standard deviation of returns equal to 0 will have a NaN value for its Sharpe ratio.

sharpe

Note If Cash is a vector, Asset and Cash need not have the same number of returns but must have the same periodicity of returns. The classic Sharpe ratio assumes that Cash is riskless. In reality, a short-term cash rate is not necessarily riskless. NaN values in the data are ignored.

Example

See “Sharpe Ratio Example” on page 4-5.

Purpose Number of dates and data series

Syntax `szfts = size(tsobj)`
`szfts = size(tsobj, dim)`

Arguments

<code>tsobj</code>	Financial time series object.
<code>dim</code>	Dimension: <code>dim = 1</code> returns number of dates (rows). <code>dim = 2</code> returns number of data series (columns).

Description `szfts = size(tsobj)` returns the number of dates (rows) and the number of data series (columns) in the financial time series object `tsobj`. The result is returned in the vector `szfts`, whose first element is the number of dates and second is the number of data series.

`szfts = size(tsobj, dim)` specifies the dimension you want to extract.

See Also `length`
`size` in the MATLAB documentation

smoothts

Purpose Smooth data

Syntax

```
output = smoothts(input)
output = smoothts(input, 'b', wsize)
output = smoothts(input, 'g', wsize, stdev)
output = smoothts(input, 'e', n)
```

Arguments

input	Financial time series object or a row-oriented matrix. In a row-oriented matrix, each row represents an individual set of observations.
'b', 'g', or 'e'	Smoothing method (essentially the type of filter used). Can be Exponential (e), Gaussian (g), or Box (b). Default = b.
wsize	Window size (scalar). Default = 5.
stdev	Scalar that represents the standard deviation of the Gaussian window. Default = 0.65.
n	For Exponential method, specifies window size or exponential factor, depending upon value. <ul style="list-style-type: none">• $n > 1$ (window size) or period length• $n < 1$ and > 0 (exponential factor: alpha)• $n = 1$ (either window size or alpha) If n is not supplied, the defaults are wsize = 5 and alpha = 0.3333.

Description

`smoothts` smooths the input data using the specified method.

`output = smoothts(input)` smooths the input data using the default Box method with window size, `wsize`, of 5.

`output = smoothts(input, 'b', wsize)` smooths the input data using the Box (simple, linear) method. `wsize` specifies the width of the box to be used.

`output = smoothts(input, 'g', wsize, stdev)` smooths the input data using the Gaussian window method.

`output = smoothts(input, 'e', n)` smooths the input data using the Exponential method. `n` can represent the window size (period length) or alpha. If $n > 1$, `n` represents the window size. If $0 < n < 1$, `n` represents alpha, where

$$\alpha = \frac{2}{wsize + 1}$$

If `input` is a financial time series object, `output` is a financial time series object identical to `input` except for contents. If `input` is a row-oriented matrix, `output` is a row-oriented matrix of the same length.

`tsmovavg`

sortfts

Purpose Sort financial time series

Syntax

```
sfts = sortfts(tsoobj)
sfts = sortfts(tsoobj, flag)
sfts = sortfts(tsoobj, seriesnames, flag)
[sfts, sidx] = sortfts(...)
```

Arguments

<code>tsoobj</code>	Financial time series object.
<code>flag</code>	(Optional) Sort order: <code>flag = 1</code> ; increasing order (default) <code>flag = -1</code> ; decreasing order
<code>seriesnames</code>	(Optional) String containing a data series name or cell array containing a list of data series names.

Description

`sfts = sortfts(tsoobj)` sorts the financial time series object `tsoobj` in increasing order based only upon the 'dates' vector if `tsoobj` does not contain time-of-day information. If the object includes time-of-day information, the sort is based upon a combination of the 'dates' and 'times' vectors. The 'times' vector cannot be sorted individually.

`sfts = sortfts(tsoobj, flag)` sets the order of the sort. `flag = 1`: increasing date and time order. `flag = -1`: decreasing date and time order.

`sfts = sortfts(tsoobj, seriesnames, flag)` sorts the financial time series object `tsoobj` based upon the data series name(s) `seriesnames`. The `seriesnames` argument can be a single string containing a data series name or a cell array containing a list of data series names. If the optional `flag` is set to `-1`, the sort is in decreasing order.

[sfts, sidx] = sortfts(...) additionally returns the index of the original object tsoj sorted based on 'dates' or specified data series name(s).

sort and sortrows in the MATLAB documentation

Purpose Slow stochastics

Syntax

```
[spctk, spctd] = spctkd(fastpctk, fastpctd)
[spctk, spctd] = spctkd([fastpctk fastpctd])
[spctk, spctd] = spctkd(fastpctk, fastpctd, dperiods, dmamethod)
[spctk, spctd] = spctkd([fastpctk fastpctd], dperiods, dmamethod)
skdts = spctkd(tsobj)
skdts = spctkd(tsobj, dperiods, dmamethod)
skdts = spctkd(tsobj, dperiods, dmamethod, ParameterName,
ParameterValue, ...)
```

Arguments

fastpctk	Fast stochastic F%K (vector).
fastpctd	Fast stochastic F%D (vector).
dperiods	(Optional) %D periods. Default = 3.
dmamethod	(Optional) %D moving average method. Default = 'e' (exponential).
tsobj	Financial time series object.

Description

[spctk, spctd] = spctkd(fastpctk, fastpctd) calculates the slow stochastics S%K and S%D. spctk and spctd are column vectors representing the respective slow stochastics. The inputs must be single column-oriented vectors containing the fast stochastics F%K and F%D.

[spctk, spctd] = spctkd([fastpctk fastpctd]) accepts a two-column matrix as input. The first column contains the fast stochastic F%K values, and the second contains the fast stochastic F%D values.

[spctk, spctd] = spctkd(fastpctk, fastpctd, dperiods, dmamethod) calculates the slow stochastics, S%K and S%D, using the value of dperiods to set the number of periods and dmamethod

to indicate the moving average method. The inputs `fastpctk` and `fastpctd` must contain the fast stochastics, `F%K` and `F%D`, in column orientation. `spctk` and `spctd` are column vectors representing the respective slow stochastics.

Valid moving average methods for `%D` are exponential (`'e'`), triangular (`'t'`), and modified (`'m'`). See `tsmovavg` for explanations of these methods.

`[spctk, spctd] = spctkd([fastpctk fastpctd], dperiods, dmamethod)` accepts a two-column matrix rather than two separate vectors. The first column contains the `F%K` values, and the second contains the `F%D` values.

`skdts = spctkd(tsobj)` calculates the slow stochastics, `S%K` and `S%D`. `tsobj` must contain the fast stochastics, `F%K` and `F%D`, in data series named `PercentK` and `PercentD`. The `skdts` output is a financial time series object with the same dates as `tsobj`. Within `tsobj` the two series `SlowPctK` and `SlowPctD` represent the respective slow stochastics.

`skdts = spctkd(tsobj, dperiods, dmamethod)` lets you specify the length and the method of the moving average used to calculate `S%D` values.

`skdts = spctkd(tsobj, dperiods, dmamethod, ParameterName, ParameterValue, ...)` accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

- `KName`: `F%K` series name
- `DName`: `F%D` series name

Parameter values are the strings that represent the valid parameter names.

Examples

Compute the slow stochastics for Disney stock and plot the results:

```
load disney.mat
```

```
dis_FastStoch = fpctkd(dis);  
dis_SlowStoch = spctkd(dis_FastStoch);  
plot(dis_SlowStoch)  
title('Slow Stochastics for Disney')
```

Purpose Standard deviation

Syntax `tsstd = std(tsobj)`
`tsstd = std(tsobj, flag)`

Arguments

`tsobj` Financial time series object.
`flag` (Optional) Normalization factor:
`flag = 1` normalizes by `n` (number of observations).
`flag = 0` normalizes by `n-1`.

Description `tsstd = std(tsobj)` computes the standard deviation of each data series in the financial time series object `tsobj` and returns the results in `tsstd`. The `tsstd` output is a structure with field name(s) identical to the data series name(s).
`tsstd = std(tsobj, flag)` normalizes the data as indicated by `flag`.

See Also `hist`, `mean`

stochosc

Purpose Stochastic oscillator

Syntax

```
stosc = stochosc(highp, lowp, closep)
stosc = stochosc([highp lowp closep])
stosc = stochosc(highp, lowp, closep, kperiods, dperiods, dmamethod)
stosc = stochosc([highp lowp closep], kperiods, dperiods, dmamethod)
stoscts = stochosc(tsobj, kperiods, dperiods, dmamethod)
stoscts = stochosc(tsobj, kperiods, dperiods, dmamethod,
ParameterName, ParameterValue, ...)
```

Arguments

highp	High price (vector).
lowp	Low price (vector).
closep	Closing price (vector).
kperiods	(Optional) %K periods. Default = 10.
dperiods	(Optional) %D periods. Default = 3.
damethod	(Optional) %D moving average method. Default = 'e' (exponential).
tsobj	Financial time series object.

Description

`stosc = stochosc(highp, lowp, closep)` calculates the fast stochastics F%K and F%D from the stock price data `highp` (high prices), `lowp` (low prices), and `closep` (closing prices). `stosc` is a two-column matrix whose first column is the F%K values and second is the F%D values.

`stosc = stochosc([highp lowp closep])` accepts a three-column matrix of high (`highp`), low (`lowp`), and closing prices (`closep`), in that order.

`stosc = stochosc(highp, lowp, closep, kperiods, dperiods, dmamethod)` calculates the fast stochastics $F\%K$ and $F\%D$ from the stock price data `highp` (high prices), `lowp` (low prices), and `closep` (closing prices). `kperiods` sets the $\%K$ period. `dperiods` sets the $\%D$ period. `damethod` specifies the $\%D$ moving average method. Valid moving average methods for $\%D$ are exponential ('e') and triangular ('t'). See `tsmovavg` for explanations of these methods.

`stosc = stochosc([highp lowp closep], kperiods, dperiods, dmamethod)` accepts a three-column matrix of high (`highp`), low (`lowp`), and closing prices (`closep`), in that order.

`stoscts = stochosc(tsoobj, kperiods, dperiods, dmamethod)` calculates the fast stochastics $F\%K$ and $F\%D$ from the stock price data in the financial time series object `tsoobj`. `tsoobj` must minimally contain the series `High` (high prices), `Low` (low prices), and `Close` (closing prices). `stoscts` is a financial time series object with similar dates to `tsoobj` and two data series named `SOK` and `SOD`.

`stoscts = stochosc(tsoobj, kperiods, dperiods, dmamethod, ParameterName, ParameterValue, ...)` accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

- `HighName`: high prices series name
- `LowName`: low prices series name
- `CloseName`: closing prices series name

Parameter values are the strings that represent the valid parameter names.

Examples

Compute the stochastic oscillator for Disney stock and plot the results:

```
load disney.mat
dis_StochOsc = stochosc(dis)
plot(dis_StochOsc)
```

```
title('Stochastic Oscillator for Disney')
```

fpctkd, spctkd

Purpose Content assignment

Description subasgn assigns content to a component within a financial time series object. subasgn supports integer indexing or date string indexing into the time series object with values assigned to the designated components. *Serial date numbers cannot be used as indices.* To use date string indexing, enclose the date string(s) in a pair of single quotation marks ' '.

You can use integer indexing on the object as in any other MATLAB matrix. It will return the appropriate entry(ies) from the object.

You must specify the component to which you want to assign values. An assigned value must be either a scalar or a column vector.

Examples Given a time series myfts with a default data series name of series1,

```
myfts.series1('07/01/98::07/03/98') = [1 2 3]';
```

assigns the values 1, 2, and 3 corresponding to the first three days of July, 1998.

```
myfts('07/01/98::07/05/98')
```

```
ans =
```

```
desc: Data Assignment
```

```
freq: Daily (1)
```

```
'dates: (5)'    'series1: (5)'
```

'01-Jul-1998'	[1]
'02-Jul-1998'	[2]
'03-Jul-1998'	[3]
'04-Jul-1998'	[4561.2]
'05-Jul-1998'	[5612.3]

When the financial time series object contains a time-of-day specification, you can assign data to a specific time on a specific day. For

example, create a financial time series object called `timeday` containing both dates and times:

```
dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
'02-Jan-2001'; '03-Jan-2001'; '03-Jan-2001'];
times = ['11:00'; '12:00'; '11:00'; '12:00'; '11:00'; '12:00'];
dates_times = cellstr([dates, repmat(' ', size(dates,1),1), ...
times]);
timeday = fints(dates_times, (1:6)', {'Data1'}, 1, 'My first FINTS')
```

```
timeday =
```

```
desc: My first FINTS
freq: Daily (1)

'dates: (6)' 'times: (6)' 'Data1: (6)'
'01-Jan-2001' '11:00' [ 1]
' ' '12:00' [ 2]
'02-Jan-2001' '11:00' [ 3]
' ' '12:00' [ 4]
'03-Jan-2001' '11:00' [ 5]
' ' '12:00' [ 6]
```

Use integer indexing to assign the value 999 to the first item in the object.

```
timeday(1) = 999
```

```
timeday =
```

```
desc: My first FINTS
freq: Daily (1)

'dates: (6)' 'times: (6)' 'Data1: (6)'
'01-Jan-2001' '11:00' [ 999]
' ' '12:00' [ 2]
'02-Jan-2001' '11:00' [ 3]
```

```
'      "      '      '12:00'      [      4]
'03-Jan-2001'      '11:00'      [      5]
'      "      '      '12:00'      [      6]
```

For value assignment using date strings, enclose the string in single quotation marks. If a date has multiple times, designating only the date and assigning a value results in every element of that date taking on the assigned value. For example, to assign the value 0.5 to all times-of-day on January 1, 2001, enter

```
timedata('01-Jan-2001') = 0.5
```

The result is

```
timedata =

desc: My first FINTS
freq: Daily (1)

'dates: (6)'      'times: (6)'      'Data1: (6)'
'01-Jan-2001'      '11:00'      [      0.5000]
'      "      '      '12:00'      [      0.5000]
'02-Jan-2001'      '11:00'      [      3]
'      "      '      '12:00'      [      4]
'03-Jan-2001'      '11:00'      [      5]
'      "      '      '12:00'      [      6]
```

To access the individual components of the financial time series object, use the structure syntax. For example, to assign a range of data to all the data items in the series Data1, you can use

```
timedata.Data1 = (0: .1 : .5)'
```

```
timedata =

desc: My first FINTS
freq: Daily (1)
```

subsasgn

```
'dates: (6)'      'times: (6)'      'Data1: (6)'  
'01-Jan-2001'    '11:00'           [          0]  
'    "    '      '12:00'           [    0.1000]  
'02-Jan-2001'    '11:00'           [    0.2000]  
'    "    '      '12:00'           [    0.3000]  
'03-Jan-2001'    '11:00'           [    0.4000]  
'    "    '      '12:00'           [    0.5000]
```

See Also datestr, subsref

Purpose Subscripted reference

Description `subsref` implements indexing for a financial time series object. Integer indexing or date (and time) string indexing is allowed. *Serial date numbers cannot be used as indices.*

To use date string indexing, enclose the date string(s) in a pair of single quotation marks ' '.

You can use integer indexing on the object as in any other MATLAB matrix. It returns the appropriate entry(ies) from the object.

Additionally, `subsref` lets you access the individual components of the object using the structure syntax.

Examples Create a time series named `myfts`:

```
myfts = fints((datenum('07/01/98'):datenum('07/01/98')+4)',...
[1234.56; 2345.61; 3456.12; 4561.23; 5612.34], [], 'Daily',...
'Data Reference');
```

Extract the data for the single day July 1, 1998:

```
myfts('07/01/98')

ans =

    desc: Data Reference
    freq: Daily (1)

    'dates: (1)'    'series1: (1)'
    '01-Jul-1998'  [      1234.6]
```

Now, extract the data for the range of dates July 1, 1998, through July 5, 1998:

```
myfts('07/01/98::07/03/98')
ans =

    desc: Data Reference
```

```
freq: Daily (1)
'dates: (3)'    'series1: (3)'
'01-Jul-1998'  [      1234.6]
'02-Jul-1998'  [      2345.6]
'03-Jul-1998'  [      3456.1]
```

You can use the MATLAB structure syntax to access the individual components of a financial time series object. To get the description field of `myfts`, enter

```
myfts.desc
```

at the command line, which returns

```
ans =
Data Reference
```

Similarly

```
myfts.series1
```

returns

```
ans =
desc: Data Reference
freq: Daily (1)
'dates: (5)'    'series1: (5)'
'01-Jul-1998'  [      1234.6]
'02-Jul-1998'  [      2345.6]
'03-Jul-1998'  [      3456.1]
'04-Jul-1998'  [      4561.2]
'05-Jul-1998'  [      5612.3]
```

The syntax for integer indexing is the same as for any other MATLAB matrix. Create a new financial time series object containing both dates and times:

```
dates = ['01-Jan-2001'; '01-Jan-2001'; '02-Jan-2001'; ...
```

```

        '02-Jan-2001'; '03-Jan-2001';'03-Jan-2001'];
times = ['11:00';'12:00';'11:00';'12:00';'11:00';'12:00'];
dates_times = cellstr([dates, repmat(' ',size(dates,1),1),...
                        times]);
anewfts = fints(dates_times,(1:6),'',{'Data1'},1,'Another FinTs');

```

Use integer indexing to extract the second and third data items from the object.

```

anewfts(2:3)

ans =

    desc: Another FinTs
    freq: Daily (1)

    'dates: (2)'    'times: (2)'    'Data1: (2)'
    '01-Jan-2001'    '12:00'         [         2]
    '02-Jan-2001'    '11:00'         [         3]

```

For date or string enclose the indexing string in a pair of single quotation marks.

If there is one date with multiple times, indexing with only the date returns all the times for that specific date:

```

anewfts('01-Jan-2001')

ans =

    desc: Another FinTs
    freq: Daily (1)

    'dates: (2)'    'times: (2)'    'Data1: (2)'
    '01-Jan-2001'    '11:00'         [         1]
    '      "      '    '12:00'         [         2]

```

To specify one specific date and time, index with that date and time:

```
anewfts('01-Jan-2001 12:00')  
  
ans =  
  
desc: Another FinTs  
freq: Daily (1)  
  
'dates: (1)' 'times: (1)' 'Data1: (1)'  
'01-Jan-2001' '12:00' [ 2]
```

To specify a range of dates and times, use the double colon (: :) operator:

```
anewfts('01-Jan-2001 12:00::03-Jan-2001 11:00')  
  
ans =  
  
desc: Another FinTs

Purpose Portfolio weight accuracy

Syntax `return = targetreturn(Universe, Window, Offset, Weights)`

Arguments

Universe	Number of observations (NUMOBS) by number of assets plus one (NASSETS + 1) array containing total return data for a group of securities. Each row represents an observation. Column 1 contains MATLAB serial date numbers. The remaining columns contain the total return data for each security.
Window	Number of data periods used to calculate frontier.
Offset	Increment in number of periods at which each frontier is generated.
Weights	Number of assets (NASSETS) by number of curves (NCURVES) matrix of asset allocation weights needed to obtain the target rate of return.

Description `return = targetreturn(Universe, Window, Offset, Weights)` computes target return values for each window of data and given portfolio weights. These values should match the input target return used with `selectreturn`.

See Also `frontier`, `portopt`, `selectreturn`

taxedrr

Purpose After-tax rate of return

Syntax `Return = taxedrr(PreTaxReturn, TaxRate)`

Arguments

`PreTaxReturn` Nominal rate of return. Enter as a decimal fraction.

`TaxRate` Tax rate. Enter as a decimal fraction.

Description `Return = taxedrr(PreTaxReturn, TaxRate)` calculates the after-tax rate of return.

Examples An investment has a 12% nominal rate of return and is taxed at a 30% rate. The after-tax rate of return is

`Return = taxedrr(0.12, 0.30)`

`Return =`
`0.0840`

or 8.4%

See Also `effrr`, `irr`, `mirr`, `nomrr`, `xirr`

Purpose Treasury bond parameters given Treasury bill parameters

Syntax [TBondMatrix, Settle] = tbl2bond(TBillMatrix)

Arguments

TBillMatrix	Treasury bill parameters. An n-by-5 matrix where each row describes a Treasury bill. n is the number of Treasury bills. Columns are [Maturity DaysMaturity Bid Asked AskYield] where:
Maturity	Maturity date, as a serial date number. Use datenum to convert date strings to serial date numbers.
DaysMaturity	Days to maturity, as an integer. Days to maturity is quoted on a skip-day basis; the actual number of days from settlement to maturity is DaysMaturity + 1.
Bid	Bid bank-discount rate: the percentage discount from face value at which the bill could be bought, annualized on a simple-interest basis. A decimal fraction.
Asked	Asked bank-discount rate, as a decimal fraction.
AskYield	Asked yield: the bond-equivalent yield from holding the bill to maturity, annualized on a simple-interest basis and assuming a 365-day year. A decimal fraction.

Description [TBondMatrix, Settle] = tbl2bond(TBillMatrix) restates U.S. Treasury bill market parameters in U.S. Treasury bond form as zero-coupon bonds. This function makes Treasury bills directly comparable to Treasury bonds and notes.

TBondMatrix	Treasury bond parameters. An N-by-5 matrix where each row describes an equivalent Treasury (zero-coupon) bond. Columns are [CouponRate Maturity Bid Asked AskYield] where
CouponRate	Coupon rate, which is always 0.
Maturity	Maturity date, as a serial date number. This date is the same as the Treasury bill Maturity date.
Bid	Bid price based on \$100 face value.
Asked	Asked price based on \$100 face value.
AskYield	Asked yield to maturity: the effective return from holding the bond to maturity, annualized on a compound-interest basis.

Examples

Given published Treasury bill market parameters for December 22, 1997

```
TBill = [datenum('jan 02 1998') 10 0.0526 0.0522 0.0530  
         datenum('feb 05 1998') 44 0.0537 0.0533 0.0544  
         datenum('mar 05 1998') 72 0.0529 0.0527 0.0540];
```

Execute the function.

```
TBond = tbl2bond(TBill)  
  
TBond =  
      0  729760      99.854      99.855      0.053  
      0  729790      99.344      99.349      0.0544  
      0  729820      98.942      98.946      0.054
```

(Example output has been formatted for readability.)

thirdwednesday

Purpose Find third Wednesday of month

Syntax [BeginDates, EndDates] = thirdwednesday(Month, Year)

Arguments

Month	Month of delivery for Eurodollar futures.
Year	Four-digit year of delivery for Eurodollar futures, in sequence corresponding to a month in the Month input argument.

Inputs can be scalars or n-by-1 vectors.

Description

[BeginDates, EndDates] = thirdwednesday(Month, Year) computes the beginning and end period date for a LIBOR contract (third Wednesdays of delivery months).

BeginDates is the beginning of three-month period contract as specified by Month and Year.

EndDates is the end of three-month period contract as specified by Month and Year.

Notes

1. All dates are returned as serial date numbers. Convert to strings using datestr.
 2. The function returns duplicates if you supply identical months and years.
 3. The function supports dates from January 2000 to December 2099.
-

Examples

Find the third Wednesday dates for swaps commencing in the month of October in the years 2002, 2003, and 2004.

```
Months = [10; 10; 10];  
Year = [2002; 2003; 2004];  
[BeginDates, EndDates] = thirdwednesday(Months, Year);
```

```

```

```
16-Jan-2003
```

```
15-Jan-2004
```

```
20-Jan-2005
```

thirtytwo2dec

Purpose Thirty-second quotation to decimal

Syntax `OutNumber = thirtytwo2dec(InNumber, InFraction)`

Arguments

InNumber	Scalar or vector of input numbers without fractional component.
InFraction	Scalar or vector of fractional portions of each element in InNumber.

Description `OutNumber = thirtytwo2dec(InNumber, InFraction)` changes the price quotation for a bond or bond future from a fraction with a denominator of 32 to a decimal.

`OutNumber` represents the sum of `InNumber` and `InFraction` expressed as a decimal.

Examples Two bonds are quoted as 101-25 and 102-31. Convert these prices to decimal.

```
InNumber = [101; 102];
InFraction = [25; 31]

OutNumber = thirtytwo2dec(InNumber, InFraction)

OutNumber =

    101.7813
    102.9688
```

See Also `dec2thirtytwo`

Purpose

Convert price series to return series

Syntax

```
[RetSeries, RetIntervals] = tick2ret(TickSeries,  
TickTimes, Method)
```

Arguments

TickSeries	Number of observations (NUMOBS) by number of assets (NASSETS) matrix of prices of equity assets. Each column is a price series of an individual asset. First row is oldest observation. Last row is most recent. Observations across a given row occur at the same time for all columns.
TickTimes	(Optional) NUMOBS-by-1 increasing vector of observation times associated with the prices in TickSeries. Times are serial date numbers (day units) or decimal numbers in arbitrary units (for example, yearly). If TickTimes is empty or missing, sequential observation times from 1, 2, ... NUMOBS are assumed.
Method	(Optional) Character string indicating the method to convert prices to asset returns. Must be 'Simple' (default) or 'Continuous'. If Method is 'Simple', tick2ret computes simple periodic returns. If Method is 'Continuous', returns are continuously compounded. Case is ignored for Method.

Description

[RetSeries, RetIntervals] = tick2ret(TickSeries, TickTimes, Method) computes the asset returns realized between NUMOBS observations of prices of NASSETS assets.

RetSeries is a (NUMOBS - 1)-by-NASSETS time series array of asset returns associated with the prices in TickSeries. The *i*th return is quoted for the period TickTimes(*i*) to TickTimes(*i*+1) and is not normalized by

the time increment between successive price observations. If *Method* is unspecified or 'Simple', the returns are:

$$\text{RetSeries}(i) = \text{TickSeries}(i+1)/\text{TickSeries}(i) - 1$$

If *Method* is 'Continuous', the returns are:

$$\text{RetSeries}(i) = \log[\text{TickSeries}(i+1)/\text{TickSeries}(i)]$$

RetIntervals is a (NUMOBS-1)-by-1 column vector of interval times between observations. If TickTimes is empty or unspecified, all intervals are assumed to have length 1.

Examples

Compute the periodic returns of two stocks observed in the first, second, third, and fourth quarters.

```
TickSeries = [100 80
              110 90
              115 88
              110 91];
```

```
TickTimes = [0
             6
             9
            12];
```

```
[RetSeries, RetIntervals] = tick2ret(TickSeries, TickTimes)
```

```
RetSeries =
    0.1000    0.1250
    0.0455   -0.0222
   -0.0435    0.0341
```

```
RetIntervals =
```

```
6
```

time2date

Purpose Dates from time and frequency

Syntax `Dates = time2date(Settle, TFactors, Compounding, Basis, EndMonthRule)`

Arguments

Settle	Settlement date. A vector of serial date numbers or date strings.
TFactors	A vector of time factors corresponding to the compounding value. TFactors must be equal to or greater than zero.
Compounding	(Optional) Scalar value representing the rate at which the input zero rates were compounded when annualized. Default = 2. This argument determines the formula for the discount factors: Compounding = 1, 2, 3, 4, 6, 12 Disc = $(1 + Z/F)^{-T}$, where F is the compounding frequency, Z is the zero rate, and T is the time in periodic units; for example, T = F is one year. Compounding = 365 Disc = $(1 + Z/F)^{-T}$, where F is the number of days in the basis year and T is a number of days elapsed computed by basis. Compounding = -1 Disc = $\exp(-T*Z)$, where T is time in years.

Basis (Optional) Day-count basis of the instrument. A vector of integers.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ISMA)
- 9 = actual/360 (ISMA)
- 10 = actual/365 (ISMA)

EndMonthRule (Optional) End-of-month rule. A vector. This rule applies only when `Maturity` is an end-of-month date for a month having 30 or fewer days. 0 = ignore rule, meaning that a bond's coupon payment date is always the same numerical day of the month. 1 = set rule on (default), meaning that a bond's coupon payment date is always the last actual day of the month.

Description

`Dates = time2date(Settle, TFactors, Compounding, Basis, EndMonthRule)` computes dates corresponding to the times occurring beyond the settlement date.

The `time2date` function is the inverse of `date2time`.

Examples

Show that `date2time` and `time2date` are the inverse of each other. First compute the time factors using `date2time`.

```
Settle = '1-Sep-2002';
Dates = datenum(['31-Aug-2005'; '28-Feb-2006'; '15-Jun-2006';
                '31-Dec-2006']);
Compounding = 2;
Basis = 0;
EndMonthRule = 1;
TFactors = date2time(Settle, Dates, Compounding, Basis,...
                    EndMonthRule)

TFactors =

    5.9945
    6.9945
    7.5738
    8.6576
```

Now use the calculated `TFactors` in `time2date` and compare the calculated dates with the original set.

```
Dates_calc = time2date(Settle, TFactors, Compounding, Basis,...
                      EndMonthRule)

Dates_calc =

    732555
    732736
    732843
    733042

datestr(Dates_calc)

ans =

    31-Aug-2005
```

28-Feb-2006

15-Jun-2006

31-Dec-2006

`cftimes`, `date2time`

Purpose Financial time series multiplication

Syntax

```
newfts = tsobj_1 .* tsobj_2  
newfts = tsobj .* array  
newfts = array .* tsobj
```

Arguments

`tsobj_1`, `tsobj_2` Pair of financial time series objects.

`array` A scalar value or array with the number of rows equal to the number of dates in `tsobj` and the number of columns equal to the number of data series in `tsobj`.

Description

The `times` method multiplies element by element the components of one financial time series object by the components of the other. You can also multiply the entire object by an array.

If an object is to be multiplied by another object, both objects must have the same dates and data series names, although the order need not be the same. The order of the data series, when an object is multiplied by another object, follows the order of the first object.

`newfts = tsobj_1 .* tsobj_2` multiplies financial time series objects element by element.

`newfts = tsobj .* array` multiplies a financial time series object element by element by an array.

`newfts = array .* tsobj` multiplies an array element by element by a financial time series object.

For financial time series objects, the `times` operation is identical to the `mtimes` operation.

See Also

`minus`, `mtimes`, `plus`, `rdivide`

Purpose Convert to annual

Syntax

```
newfts = toannual(oldfts)
newfts = toannual(oldfts, ParameterName, ParameterValue, ...)
```

Arguments

oldfts Financial time series object.

Description

`newfts = toannual(oldfts)` converts a financial time series of any frequency to one of an annual frequency. The default end-of-year is the last business day of the December.

Note If `oldfts` contains time-of-day information, `newfts` displays the time-of-day as '00:00' for those days that did not previously exist in `oldfts`.

Empty ([]) passed as inputs for parameter pair values for `toannual` will trigger the use of the defaults.

`newfts = toannual(oldfts, ParameterName, ParameterValue, ...)` accepts parameter name/parameter value pairs as input, as specified in the following table.

Parameter Name	Parameter Value	Description
CalcMethod	CumSum	Returns the cumulative sum of the values within each year. Data for missing dates are given the value 0.
	Exact	Returns the exact value at the end-of-year date. No data manipulation occurs.

Parameter Name	Parameter Value	Description
	Nearest	(Default) Returns the values located at the end-of-year dates. If there is missing data, Nearest returns the nearest data point preceding the end-of-year date.
	SimpAvg	Returns an averaged annual value that only takes into account dates with data (nonNaN) within each year.
	v21x	This mode is compatible with previous versions of this function (Version 2.1.x and earlier). It returns an averaged end-of-year value using a previous toannual algorithm. This algorithm takes into account all dates and data. For dates that do not contain any data, the data is assumed to be 0.
<hr/> <p>Note If you set CalcMethod to v21x, settings for all of the following parameter name/parameter value pairs are not supported.</p> <hr/>		
BusDays	0	Returns a financial time series that ranges from (or between) the first date to the last date in oldfts (includes NYSE nonbusiness days and holidays).
	1	(Default) Returns a financial time series that includes only NYSE business days.
DateFilter	Absolute	(Default) Returns all annual dates between the start and end dates of oldfts. Some dates may be disregarded if BusDays = 1.

Parameter Name	Parameter Value	Description
	Relative	Returns only the annual dates that exist in oldfts. Some dates may be disregarded if BusDays = 1.
ED	0	Annual period ends on the last day or last business day of the month.
	1 - 31	Specifies a particular annual day. Months that do not contain the specified day return the last day (or last business day) of the month (for example, ED = 31 does not exist for February.)
EM	1 - 12	(Default) The annual period ends on the last day (or last business day) of the specified month All subsequent annual dates are calculated from this month. Default annual month is December (12).

Parameter Name	Parameter Value	Description
EndPtTol	[Begin, End]	<p>Denotes the minimum number of days that constitute an odd annual period at the end points of the time series (before the first time series date and after the last end-of-year date).</p> <p>Begin and End must be -1 or any positive integer greater than or equal to 0.</p> <p>A single value input for 'EndPtTol' is the same as specifying that single value for Begin and End.</p> <p>-1 Exclude odd annual period dates and data from calculations.</p> <p>0 (Default) Include odd annual period dates and data in calculations.</p> <p>n Number of days (any positive integer) that constitute an odd annual period. If there are insufficient days for a complete year, the end point data is ignored.</p>

The following diagram is a general depiction of the factors involved in the determination of end points for this function.

Parameter Name	Parameter Value	Description
TimeSpec	First	Returns only the observation that occurs at the first (earliest) time for a specific date.
	Last	(Default) Returns only the observation that occurs at the last (latest) time for a specific date.

todayly

Purpose Convert to daily

Syntax
`newfts = todayly(oldfts)`
`newfts = todayly(oldfts, ParameterName, ParameterValue, ...)`

Arguments

`oldfts` Financial time series object

Description `newfts = todayly(oldfts)` converts a financial time series of any frequency to a daily frequency.

Note If `oldfts` contains time-of-day information, `newfts` displays the time-of-day as '00:00' for those days that did not previously exist in `oldfts`.

Empty ([]) passed as inputs for parameter pair values for `todayly` will trigger the use of the defaults.

`newfts = todayly(oldfts, ParameterName, ParameterValue, ...)` accepts parameter name/parameter value pairs as input, as specified in the following table.

Parameter Name	Parameter Value	Description
CalcMethod	Exact	Returns the value located at specific dates/times. No data manipulation occurs.

Parameter Name	Parameter Value	Description
	v21x	This mode is compatible with previous versions of this function (Version 2.1.x and earlier). It returns a five-day business week that starts on Monday and ends on Friday.
<p>Note If you set CalcMethod to v21x, settings for all of the following parameter name/parameter value pairs are not supported.</p>		
BusDays	0	Generates a financial time series that ranges from (or between) the first date to the last date in oldfts (includes NYSE nonbusiness days and holidays).
	1	(Default) Generates a financial time series that includes only NYSE business days.
DateFilter	Absolute	(Default) Displays all daily dates between the start and end dates of oldfts. Some dates may be disregarded if BusDays = 1.
	Relative	Displays only dates that exist in oldfts. Some dates may be disregarded if BusDays = 1.
TimeSpec	First	Returns only the observation that occurs at the first (earliest) time for a specific date.
	Last	(Default) Returns only the observation that occurs at the last (latest) time for a specific date.

todayly

Purpose Current date

Syntax Datenum = today

Description Datenum = today returns the current date as a serial date number.

Examples Datenum = today

returns

Datenum =

730695

on July 28, 2000.

See Also datenum, datestr, now

todecimal

Purpose Fractional to decimal conversion

Syntax `usddec = todecimal(quote, fracpart)`

Description `usddec = todecimal(quote, fracpart)` returns the decimal equivalent, `usddec`, of a security whose price is normally quoted as a whole number and a fraction (`quote`). `fracpart` indicates the fractional base (denominator) with which the security is normally quoted (default = 32).

Examples In the *Wall Street Journal*, bond prices are quoted in fractional form based on a denominator of 32. For example, if you see the quoted price is 100:05 it means 100 5/32. To find the equivalent decimal value, enter

```
usddec = todecimal(100.05)
```

```
usddec =  
100.1563
```

```
usddec = todecimal(97.04, 16)
```

```
usddec =  
97.2500
```

Note The convention of using . (period) as a substitute for : (colon) in the input is adopted from Microsoft Excel.

See Also `toquoted`

Purpose Convert to monthly

Syntax
`newfts = tomonthly(oldfts)`
`newfts = tomonthly(oldfts, ParameterName, ParameterValue, ...)`

Arguments

`oldfts` Financial time series object.

Description

`newfts = tomonthly(oldfts)` converts a financial time series of any frequency to a monthly frequency. The default end-of-month day is the last business day of the month.

Note If `oldfts` contains time-of-day information, `newfts` displays the time-of-day as 00:00 for those days that did not previously exist in `oldfts`.

Empty (`[]`) passed as inputs for parameter pair values for `tomonthly` will trigger the use of the defaults.

`newfts = tomonthly(oldfts, ParameterName, ParameterValue, ...)` accepts parameter name/parameter value pairs as input, as specified in the following table.

Parameter Name	Parameter Value	Description
CalcMethod	CumSum	Returns the cumulative sum of the values within each month. Data for missing dates are given the value 0.

Parameter Name	Parameter Value	Description
	Exact	Returns the exact value at the end-of-month date. No data manipulation occurs.
	Nearest	(Default) Returns the values located at the end-of-month date. If there is missing data, 'Nearest' returns the nearest data point preceding the end-of-month date.
	SimpAvg	Returns an averaged monthly value that only takes into account dates with data (nonNaN) within each month.
	v21x	This mode is compatible with previous versions of this function (Version 2.1.x and earlier). It returns an averaged end-of-month value using a previous tomonthly algorithm. This algorithm takes into account all dates and data. For dates that do not contain any data, the data is assumed to be 0.
<hr/> <p>Note If you set CalcMethod to v21x, settings for all of the following parameter name/parameter value pairs are not supported.</p> <hr/>		
BusDays	0	Generates a monthly financial time series that ranges from the first date to the last date in oldfts (includes NYSE nonbusiness days and holidays).

Parameter Name	Parameter Value	Description
	1	(Default) Generates a monthly financial time series that ranges from the first date to the last date in oldfts (excludes NYSE nonbusiness days and holidays). If an end-of-month date falls on a nonbusiness day or NYSE holiday, returns the last business day of the month.
DateFilter	Absolute	(Default) Returns all monthly dates between the start and end dates of oldfts. Some dates may be disregarded if BusDays = 1.
	Relative	Returns only monthly dates that exist in oldfts. Some dates may be disregarded if BusDays = 1.
ED	0	(Default) The end-of-month date is the last day (or last business day) of the month.
	1 - 31	Returns values on the specified end-of-month day. Months that do not contain the specified end-of-month day return the last day of the month instead (for example, ED = 31 does not exist for February). If end-of-month falls on a NYSE non-business day or holiday, the previous business day is returned if BusDays = 1.

Parameter Name	Parameter Value	Description
EndPtTol	[Begin, End]	<p>Denotes the minimum number of days that constitute an odd month at the end points of the time series (before the first whole period and after the last whole period).</p> <p>Begin and End must be -1 or any positive integer greater than or equal to 0.</p> <p>A single value input for EndPtTol is the same as specifying that single value for Begin and End.</p> <p>-1 Do not include odd month dates and data in calculations.</p> <p>0 (Default) Include all odd month dates and data in calculations.</p> <p>n Number of days that constitute an odd month. If the minimum number of days is not met, the odd month dates and data are ignored.</p>

The following diagram is a general depiction of the factors involved in the determination of end points for this function.

Parameter Name	Parameter Value	Description
TimeSpec	First	Returns only the observation that occurs at the first (earliest) time for a specific date.
	Last	(Default) Returns only the observation that occurs at the last (latest) time for a specific date.

convertto, toannual, todaily, toquarterly, tosemi, toweekly

toquarterly

Purpose Convert to quarterly

Syntax
`newfts = toquarterly(oldfts)`
`newfts = toquarterly(oldfts, ParameterName, ParameterValue, ...)`

Arguments

`oldfts` Financial time series object

Description `newfts = toquarterly(oldfts)` converts a financial time series of any frequency to a quarterly frequency. The default quarterly days are the last business day of March, June, September, and December.

Note If `oldfts` contains time-of-day information, `newfts` displays the time-of-day as 00:00 for those days that did not previously exist in `oldfts`.

Empty (`[]`) passed as inputs for parameter pair values for `toquarterly` will trigger the use of the defaults.

`newfts = toquarterly(oldfts, ParameterName, ParameterValue, ...)` accepts parameter name/parameter value pairs as input, as specified in the following table.

Parameter Name	Parameter Value	Description
CalcMethod	CumSum	Returns the cumulative sum of the values between each quarter. Data for missing dates are given the value 0.

Parameter Name	Parameter Value	Description
	Exact	Returns the exact value at the end-of-quarter date. No data manipulation occurs.
	Nearest	(Default) Returns the values located at the end-of-quarter date. If there is missing data, Nearest returns the nearest data point preceding the end-of-quarter date.
	SimpAvg	Returns an averaged quarterly value that only takes into account dates with data (nonNaN) within each quarter.
	v21x	This mode is compatible with previous versions of this function (Version 2.1.x and earlier). It returns an averaged end-of-quarter value using a previous toquarterly algorithm. This algorithm takes into account all dates and data. For dates that do not contain any data, the data is assumed to be 0.
<hr/> <p>Note If you set CalcMethod to v21x, settings for all of the following parameter name/parameter value pairs are not supported.</p> <hr/>		
BusDays	0	Generates a financial time series that ranges from (or between) the first date to the last date in oldfts (includes NYSE nonbusiness days and holidays).

Parameter Name	Parameter Value	Description
	1	(Default) Generates a financial time series that ranges from the first date to the last date in oldfts (excludes NYSE nonbusiness days and holidays). If an end-of-quarter date falls on a nonbusiness day or NYSE holiday, returns the last business day of the quarter.
DateFilter	Absolute	(Default) Returns all quarterly dates between the start and end dates of oldfts. Some dates may be disregarded if BusDays = 1.
	Relative	Returns only quarterly dates that exist in oldfts. Some dates may be disregarded if BusDays = 1.
ED	0	(Default) The end-of-quarter date is the last day (or last business day) of the quarter.
	1 - 31	Specifies a particular end-of-quarter day. Months that do not contain the specified end-of-quarter day return the last day of the quarter instead (for example, ED = 31 does not exist for February).
EM	1 - 12	Last month of the first quarter. All subsequent quarterly dates are based on this month. The default end-of-first-quarter month is March (3).

Parameter Name	Parameter Value	Description
EndPtTol	[Begin, End]	<p>Denotes the minimum number of days that constitute a odd quarter at the end points of the time series (before the first whole period and after the last whole period).</p> <p>Begin and End must be -1 or any positive integer greater than or equal to 0.</p> <p>A single value input for EndPtTol is the same as specifying that single value for Begin and End.</p> <p>-1 Do not include odd quarter dates and data in calculations.</p> <p>0 (Default) Include all odd quarter dates and data in calculations.</p> <p>n Number of days (any positive integer) that constitute an odd quarter. If there are insufficient days for a complete quarter, the odd quarter dates and data are ignored.</p>

The following diagram is a general depiction of the factors involved in the determination of end points for this function.

toquarterly

Parameter Name	Parameter Value	Description
TimeSpec	First	Returns only the observation that occurs at the first (earliest) time for a specific date.
	Last	(Default) Returns only the observation that occurs at the last (latest) time for a specific date.

See Also

convertto, toannual, todaily, tomonthly, tosemi, toweekly

Purpose Decimal to fractional conversion

Syntax `quote = toquoted(usddec, fracpart)`

Description `quote = toquoted(usddec, fracpart)` returns the fractional equivalent, `quote`, of the decimal figure, `usddec`, based on the fractional base (denominator), `fracpart`. The fractional bases are the ones used for quoting equity prices in the United States (denominator 2, 4, 8, 16, or 32). If `fracpart` is not entered, the denominator 32 is assumed.

Examples A United States equity price in decimal form is 101.625. To convert this to fractional form in eighths of a dollar:

```
quote = toquoted(101.625, 8)
```

```
quote =  
101.05
```

The answer is interpreted as 101 5/8.

Note The convention of using . (period) as a substitute for : (colon) in the output is adopted from Microsoft Excel.

See Also `todecimal`

tosemi

Purpose Convert to semiannual

Syntax
`newfts = tosemi(oldfts)`
`newfts = tosemi(oldfts, ParameterName, ParameterValue, ...)`

Arguments

`oldfts` Financial time series object.

Description `newfts = tosemi(oldfts)` converts a financial time series of any frequency to a semiannual frequency. The default semiannual days are the last business day of June and December.

Note If `oldfts` contains time-of-day information, `newfts` displays the time-of-day as 00:00 for those days that did not previously exist in `oldfts`.

Empty (`[]`) passed as inputs for parameter pair values for `tosemi` will trigger the use of the defaults.

`newfts = tosemi(oldfts, ParameterName, ParameterValue, ...)` accepts parameter name/parameter value pairs as input, as specified in the following table.

Parameter Name	Parameter Value	Description
CalcMethod	CumSum	Returns the cumulative sum of the values within each semiannual period. Data for missing dates are given the value 0.

Parameter Name	Parameter Value	Description
	Exact	Returns the exact value at the end-of-period date. No data manipulation occurs.
	Nearest	(Default) Returns the values located at the end-of-period date. If there is missing data, Nearest returns the nearest data point preceding the end-of-period date.
	SimpAvg	Returns an averaged semiannual value that only takes into account dates with data (nonNaN) within each semiannual period.
	v21x	This mode is compatible with previous versions of this function (Version 2.1.x and earlier). It returns an averaged end-of-period value using a previous tosemi algorithm. This algorithm takes into account all dates and data. For dates that do not contain any data, the data is assumed to be 0.
<hr/> <p>Note If you set CalcMethod to v21x, settings for all of the following parameter name/parameter value pairs are not supported.</p> <hr/>		
BusDays	0	Generates a financial time series that ranges from (or between) the first date to the last date in oldfts (includes NYSE nonbusiness days and holidays).

Parameter Name	Parameter Value	Description
	1	(Default) Generates a financial time series that ranges from the first date to the last date in oldfts (excludes NYSE nonbusiness days and holidays). If an end-of-period date falls on a nonbusiness day or NYSE holiday, returns the last business day of the period.
DateFilter	Absolute	(Default) Returns all semiannual dates between the start and end dates of oldfts. Some dates may be disregarded if BusDays = 1.
	Relative	Returns only semiannual dates that exist in oldfts. Some dates may be disregarded if BusDays = 1.
ED	0	(Default) The end-of-period date is the last day (or last business day) of the semiannual period.
	1 - 31	Specifies a particular end-of-period day. Months that do not contain the specified end-of-period day return the last day of the semiannual period instead (for example, ED = 31 does not exist for February).
EM	1 - 12	End month of the first semiannual period. All subsequent period dates are based on this month. The default end of period months are June (6) and December (12).

Parameter Name	Parameter Value	Description
EndPtTol	[Begin, End]	<p>Denotes the minimum number of days that constitute an odd semiannual period at the end points of the time series (before the first whole period and after the last whole period).</p> <p>Begin and End must be -1 or any positive integer greater than or equal to 0.</p> <p>A single value input for EndPtTol is the same as specifying that single value for Begin and End.</p> <p>-1 Do not include odd period dates and data in calculations.</p> <p>0 (Default) Include all odd period dates and data in calculations.</p> <p>n Number of days (any positive integer) that constitute an odd period. If there are insufficient days for a complete semiannual period, the odd period dates and data are ignored.</p>

The following diagram is a general depiction of the factors involved in the determination of end points for this function.

Parameter Name	Parameter Value	Description
TimeSpec	First	Returns only the observation that occurs at the first (earliest) time for a specific date.
	Last	(Default) Returns only the observation that occurs at the last (latest) time for a specific date.

convertto, toannual, todaily, tomonthly, toquarterly, toweekly

Purpose Total return price time series

Syntax Return = totalreturnprice(Price, Action, Dividend)

Arguments

Price	Number of observations (NUMOBS) by 2 matrix of price data. Column 1 contains MATLAB serial date numbers. Column 2 contains price values.
Action	NUMOBS-by-2 matrix of price data. Column 1 contains MATLAB serial date numbers. Column 2 contains split ratios.
Dividend	NUMOBS-by-2 matrix of price data. Column 1 contains MATLAB serial date numbers. Column 2 contains dividend payouts.

The number of observations (NUMOBS) for the three input arguments will differ from each other.

Description

Return = totalreturnprice(Price, Action, Dividend) generates a total return price time series given price data, action or split data, and dividend data.

Return is NUMOBS-by-2 array of price data, where NUMOBS reflects the number of observations of price data. Column 1 contains MATLAB serial date numbers. Column 2 contains total return price values.

See Also periodicreturns

toweekly

Purpose Convert to weekly

Syntax
`newfts = toweekly(oldfts)`
`newfts = toweekly(oldfts, ParameterName, ParameterValue, ...)`

Arguments

`oldfts` Financial time series object.

Description

`newfts = toweekly(oldfts)` converts a financial time series of any frequency to a weekly frequency. The default weekly days are Fridays or the last business day of the week.

Note If `oldfts` contains time-of-day information, `newfts` displays the time-of-day as 00:00 for those days that did not previously exist in `oldfts`.

Empty (`[]`) passed as inputs for parameter pair values for `toweekly` will trigger the use of the defaults.

`newfts = toweekly(oldfts, ParameterName, ParameterValue, ...)` accepts parameter name/parameter value pairs as input, as specified in the following table.

Parameter Name	Parameter Value	Description
CalcMethod	CumSum	Returns the cumulative sum of the values within each week. Data for missing dates are given the value 0.

Parameter Name	Parameter Value	Description
	Exact	Returns the exact value at the end-of-week dates. No data manipulation occurs.
	Nearest	(Default) Returns the values located at the end-of-week dates. If there is missing data, Nearest returns the nearest data point preceding the end-of-week date.
	SimpAvg	Returns an averaged weekly value that only takes into account dates with data (nonNaN) within each week.
	v21x	This mode is compatible with previous versions of this function (Version 2.1.x and earlier). It returns an averaged end-of-weekly value using a previous toquarterly algorithm. This algorithm takes into account all dates and data. For dates that do not contain any data, the data is assumed to be 0.
<hr/> <p>Note If you set CalcMethod to v21x, settings for all of the following parameter name/parameter value pairs are not supported.</p> <hr/>		
BusDays	0	Generates a financial time series that ranges from (or between) the first date to the last date in oldfts (includes NYSE nonbusiness days and holidays).

Parameter Name	Parameter Value	Description
	1	(Default) Generates a financial time series that ranges from the first date to the last date in oldfts (excludes NYSE nonbusiness days and holidays). If an end-of-week date falls on a nonbusiness day or NYSE holiday, returns the previous business day.
DateFilter	Absolute	(Default) Returns all weekly dates between the start and end dates of oldfts. Some dates may be disregarded if BusDays = 1.
	Relative	Returns only end-of-week dates that exist in oldfts. Some dates may be disregarded if BusDays = 1.
EndPtTol	[Begin, End]	Denotes the minimum number of days that constitute a odd week at the end points of the time series (before the first whole period and after the last whole period). Begin and End must be -1 or any positive integer greater than or equal to 0. A single value input for EndPtTol is the same as specifying that single value for Begin and End. -1 Do not include odd week dates and data in calculations. 0 (Default) Include all odd week dates and data in calculations. n Number of days (any positive integer) that constitute an odd week. If there are insufficient days for a complete week, the odd week dates and data are ignored.

Parameter Name	Parameter Value	Description
----------------	-----------------	-------------

The following diagram is a general depiction of the factors involved in the determination of end points for this function.

EOW	0 - 6	<p>Specifies the end-of-week day:</p> <ul style="list-style-type: none"> • 0 Friday (default) • 1 Saturday • 2 Sunday • 3 Monday • 4 Tuesday • 5 Wednesday • 6 Thursday
TimeSpec	First	Returns only the observation that occurs at the first (earliest) time for a specific date.
	Last	(Default) Returns only the observation that occurs at the last (latest) time for a specific date.

Purpose Term-structure parameters given Treasury bond parameters

Syntax [Bonds, Prices, Yields] = tr2bonds(TreasuryMatrix, Settle)

Arguments

TreasuryMatrix	Treasury bond parameters. An n-by-5 matrix, where each row describes a Treasury bond. Columns are [CouponRate Maturity Bid Asked AskYield] where:
CouponRate	Coupon rate, as a decimal fraction.
Maturity	Maturity date, as a serial date number. Use datenum to convert date strings to serial date numbers.
Bid	Bid price based on \$100 face value.
Asked	Asked price based on \$100 face value.
AskYield	Asked yield to maturity, as a decimal fraction.
Settle	(Optional) Date string or serial date number of the settlement date for the analysis.

Description [Bonds, Prices, Yields] = tr2bonds(TreasuryMatrix, Settle) returns term-structure parameters (bond information, prices, and yields) sorted by ascending maturity date, given Treasury bond parameters. The formats of the output matrix and vectors meet requirements for input to the zbtprice and zbtyield zero-curve bootstrapping functions.

Bonds	Coupon bond information. An n-by-6 matrix where each row describes a bond. Columns are [Maturity CouponRate Face Period Basis EndMonthRule] where:
Maturity	Maturity date of the bond, as a serial date number. Use <code>datestr</code> to convert serial date numbers to date strings.
CouponRate	Coupon rate of the bond, as a decimal fraction.
Face	Redemption or face value of the bond, always 100.
Period	Coupons per year of the bond, always 2.
Basis	Day-count basis of the bond, possible values include: <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365
EndMonthRule	End-of-month flag, always 1, meaning that a bond's coupon payment date is always the last day of the month.

Prices	Prices. Column vector containing the price of each bond in bonds, respectively. The number of rows (n) matches the number of rows in bonds.
Yields	Yields. Column vector containing the yield to maturity of each bond in bonds, respectively. The number of rows (n) matches the number of rows in bonds. If <code>Settle</code> is input, <code>Yields</code> is computed as a semiannual yield to maturity. If <code>Settle</code> is not input, the quoted input yields will be used.

Examples

Given published Treasury bond market parameters for December 22, 1997

```
Matrix =[0.0650 datenum('15-apr-1999') 101.03125 101.09375 0.0564
         0.05125 datenum('17-dec-1998') 99.4375 99.5 0.0563
         0.0625 datenum('30-jul-1998') 100.3125 100.375 0.0560
         0.06125 datenum('26-mar-1998') 100.09375 100.15625 0.0546];
```

Execute the function.

```
[Bonds, Prices, Yields] = tr2bonds(Matrix)
```

Bonds =

```
729840 0.06125 100 2 0 1
729966 0.0625 100 2 0 1
730106 0.05125 100 2 0 1
730225 0.065 100 2 0 1
```

Prices =

```
100.1563
100.3750
```

tr2bonds

```
99.5000  
101.0938
```

```
Yields =
```

```
0.0546  
0.056  
0.0563  
0.0564
```

(Example output has been formatted for readability.)

Purpose Acceleration between periods

Syntax

```
acc = tsaccel(data, nperiods, datatype)
accts = tsaccel(tsobj, nperiods, datatype)
```

Arguments

<code>data</code>	Data series.
<code>nperiods</code>	(Optional) Number of periods. Default = 12.
<code>datatype</code>	(Optional) Indicates whether data contains the data itself or the momentum of the data: 0 = Data contains the data itself (default). 1 = Data contains the momentum of the data.
<code>tsobj</code>	Name of an existing financial time series object.

Description Acceleration is the difference of two momentums separated by some number of periods.

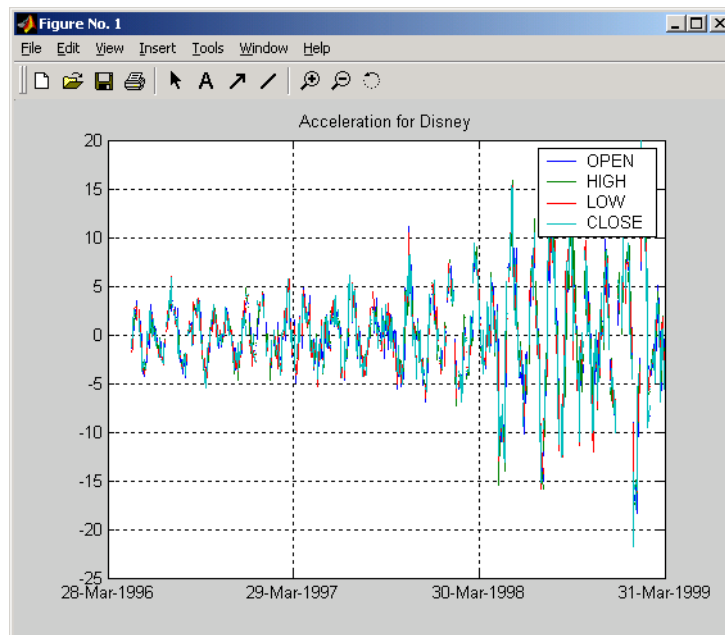

`acc = tsaccel(data, nperiods, datatype)` calculates the acceleration of a data series, essentially the difference of the current momentum with the momentum some number of periods ago. If `nperiods` is specified, `tsaccel` calculates the acceleration of a data series data with time distance of `nperiods` periods.

`accts = tsaccel(tsobj, nperiods, datatype)` calculates the acceleration of the data series in the financial time series object `tsobj`, essentially the difference of the current momentum with the momentum some number of periods ago. Each data series in `tsobj` is treated individually. `accts` is a financial time series object with similar dates and data series names as `tsobj`.

Examples

Compute the acceleration for Disney stock and plot the results:

```
load disney.mat
dis = rmfield(dis,'VOLUME') % remove VOLUME field
dis_Accel = tsaccel(dis);
plot(dis_Accel)
title('Acceleration for Disney')
```

References

See Also

tsmom

Purpose Momentum between periods

Syntax

```
mom = tsmom(data, nperiods)
momts = tsmom(tsobj, nperiods)
```

Arguments

data	Data series. Column-oriented vector or matrix.
nperiods	(Optional) Number of periods. Default = 12.
tsobj	Financial time series object.

Description Momentum is the difference between two prices (data points) separated by a number of periods.

`mom = tsmom(data, nperiods)` calculates the momentum of a data series `data`. If `nperiods` is specified, `tsmom` uses that value instead of the default 12.

`momts = tsmom(tsobj, nperiods)` calculates the momentum of all data series in the financial time series object `tsobj`. Each data series in `tsobj` is treated individually. `momts` is a financial time series object with similar dates and data series names as `tsobj`. If `nperiods` is specified, `tsmom` uses that value instead of the default 12.

Examples Compute the momentum for Disney stock and plot the results:

```
load disney.mat
dis = rmfield(dis, 'VOLUME') % remove VOLUME field
dis_Mom = tsmom(dis);
plot(dis_Mom)
title('Momentum for Disney')
```

tsaccel

Purpose

Moving average

Syntax

```

output = tsmovavg(tsobj, 's', lag)                (Simple)
output = tsmovavg(vector, 's', lag, dim)
output = tsmovavg(tsobj, 'e', timeperiod)        (Exponential)
output = tsmovavg(vector, 'e', timeperiod, dim)
output = tsmovavg(tsobj, 't', numperiod)         (Triangular)
output = tsmovavg(vector, 't', numperiod, dim)
output = tsmovavg(tsobj, 'w', weights)           (Weighted)
output = tsmovavg(vector, 'w', weights, dim)
output = tsmovavg(tsobj, 'm', numperiod)         (Modified)
output = tsmovavg(vector, 'm', numperiod, dim)

```

Arguments

tsobj	Financial time series object.
lag	Number of previous data points.
vector	Row vector or row-oriented matrix. Each row is a set of observations.
dim	(Optional) Specifies dimension when input is a vector or matrix. Default = 2 (row-oriented matrix: each row is a variable, and each column is an observation). If dim = 1, input is assumed to be a column vector or column-oriented matrix (each column is a variable and each row an observation). output is identical in format to input.
timeperiod	Length of time period.
numperiod	Number of periods considered.
weights	Weights for each element in the window.

Description

`output = tsmovavg(tsobj, 's', lag)` and
`output = tsmovavg(vector, 's', lag, dim)` compute the simple moving average. `lag` indicates the number of previous data points used in conjunction with the current data point when calculating the moving average.

`output = tsmovavg(tsobj, 'e', timeperiod)` and
`output = tsmovavg(vector, 'e', timeperiod, dim)` compute the exponential weighted moving average. The exponential moving average is a weighted moving average, where `timeperiod` specifies the time period. Exponential moving averages reduce the lag by applying more weight to recent prices. For example, a 10-period exponential moving average weights the most recent price by 18.18%. ($2/(timeperiod + 1)$).

`output = tsmovavg(tsobj, 't', numperiod)` and
`output = tsmovavg(vector, 't', numperiod, dim)` compute the triangular moving average. The triangular moving average double-smooths the data. `tsmovavg` calculates the first simple moving average with window width of $\text{ceil}(\text{numperiod} + 1)/2$. Then it calculates a second simple moving average on the first moving average with the same window size.

`output = tsmovavg(tsobj, 'w', weights)` and
`output = tsmovavg(vector, 'w', weights, dim)` calculate the weighted moving average by supplying weights for each element in the moving window. The length of the weight vector determines the size of the window. If larger weight factors are used for more recent prices and smaller factors for previous prices, the trend is more responsive to recent changes.

`output = tsmovavg(tsobj, 'm', numperiod)` and
`output = tsmovavg(vector, 'm', numperiod, dim)` calculate the modified moving average. The modified moving average is similar to the simple moving average. Consider the argument `numperiod` to be the lag of the simple moving average. The first modified moving average is calculated like a simple moving average. Subsequent values are calculated by adding the new price and subtracting the last average from the resulting sum.

mean, peravg

typprice

Purpose Typical price

Syntax

```
tprc = typprice(highp, lowp, closep)
tprc = typprice([highp lowp closep])
tprcts = typprice(tsobj)
tprcts = typprice(tsobj, ParameterName, ParameterValue, ...)
```

Arguments

highp	High price (vector).
lowp	Low price (vector).
closep	Closing price (vector).
tsobj	Financial time series object.

Description

`tprc = typprice(highp, lowp, closep)` calculates the typical prices `tprc` from the high (`highp`), low (`lowp`), and closing (`closep`) prices. The typical price is the average of the high, low, and closing prices for each period.

`tprc = typprice([highp lowp closep])` accepts a three-column matrix as the input rather than two individual vectors. The columns of the matrix represent the high, low, and closing prices, in that order.

`tprcts = typprice(tsobj)` calculates the typical prices from the stock data contained in the financial time series object `tsobj`. The object must contain, at least, the High, Low, and Close data series. The typical price is the average of the closing price plus the high and low prices. `tprcts` is a financial time series object of the same dates as `tsobj` containing the data series `TypPrice`.

`tprcts = typprice(tsobj, ParameterName, ParameterValue, ...)` accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

- HighName: high prices series name
- LowName: low prices series name
- CloseName: closing prices series name

Parameter values are the strings that represent the valid parameter names.

Examples

Compute the typical price for Disney stock and plot the results:

```
load disney.mat
dis_Typ = typprice(dis);
plot(dis_Typ)
title('Typical Price for Disney')
```

medprice, wclose

Purpose Univariate GARCH(P,Q) parameter estimation with Gaussian innovations

Syntax [Kappa, Alpha, Beta] = ugarch(U, P, Q)

Arguments

- U Single column vector of random disturbances, that is, the residuals or innovations (ϵ_t), of an econometric model representing a mean-zero, discrete-time stochastic process. The innovations time series U is assumed to follow a GARCH(P,Q) process.
- P Nonnegative, scalar integer representing a model order of the GARCH process. P is the number of lags of the conditional variance. P can be zero; when P = 0, a GARCH(0,Q) process is actually an ARCH(Q) process.
- Q Positive, scalar integer representing a model order of the GARCH process. Q is the number of lags of the squared innovations.

Description

[Kappa, Alpha, Beta] = ugarch(U, P, Q) computes estimated univariate GARCH(P,Q) parameters with Gaussian innovations.

Kappa is the estimated scalar constant term ([[KAPPA]]) of the GARCH process.

Alpha is a P-by-1 vector of estimated coefficients, where P is the number of lags of the conditional variance included in the GARCH process.

Beta is a Q-by-1 vector of estimated coefficients, where Q is the number of lags of the squared innovations included in the GARCH process.

The time-conditional variance, σ_t^2 , of a GARCH(P,Q) process is modeled as

$$\sigma_t^2 = \kappa + \sum_{i=1}^P \alpha_i \sigma_{t-i}^2 + \sum_{j=1}^Q \beta_j \varepsilon_{t-j}^2$$

where α represents the argument Alpha, β represents Beta, and the GARCH(P, Q) coefficients $\{\kappa, \alpha, \beta\}$ are subject to the following constraints.

$$\sum_{i=1}^P \alpha_i + \sum_{j=1}^Q \beta_j < 1$$

$$\kappa > 0$$

$$\alpha_i \geq 0 \quad i = 1, 2, \dots, P$$

$$\beta_j \geq 0 \quad j = 1, 2, \dots, Q$$

Note that U is a vector of residuals or innovations (ε_t) of an econometric model, representing a mean-zero, discrete-time stochastic process.

Although σ_t^2 is generated using the equation above, ε_t and σ_t^2 are related as

$$\varepsilon_t = \sigma_t v_t$$

where $\{v_t\}$ is an independent, identically distributed (iid) sequence $\sim N(0,1)$.

Note `ugarch` corresponds generally to the GARCH Toolbox function `garchfit`. The GARCH Toolbox provides a comprehensive and integrated computing environment for the analysis of volatility in time series. For information, see the GARCH Toolbox User's Guide documentation or the financial products Web page at <http://www.mathworks.com/products/finprod/>.

Examples

See `ugarchsim` for an example of a GARCH(P,Q) process.

References

James D. Hamilton, *Time Series Analysis*, Princeton University Press, 1994

`ugarchpred`, `ugarchsim`, and the GARCH Toolbox function `garchfit`

ugarchllf

Purpose Log-likelihood objective function of univariate GARCH(P,Q) processes with Gaussian innovations

Syntax `LogLikelihood = ugarchllf(Parameters, U, P, Q)`

Arguments

Parameters (1 + P + Q)- by-1 column vector of GARCH(P,Q) process parameters. The first element is the scalar constant term $[\text{KAPPA}]$ of the GARCH process; the next P elements are coefficients associated with the P lags of the conditional variance terms; the next Q elements are coefficients associated with the Q lags of the squared innovations terms.

U Single column vector of random disturbances, that is, the residuals or innovations (ϵ_t), of an econometric model representing a mean-zero, discrete-time stochastic process. The innovations time series U is assumed to follow a GARCH(P,Q) process.

P Nonnegative, scalar integer representing a model order of the GARCH process. P is the number of lags of the conditional variance. P can be zero; when P = 0, a GARCH(0,Q) process is actually an ARCH(Q) process.

Q Positive, scalar integer representing a model order of the GARCH process. Q is the number of lags of the squared innovations.

Description `LogLikelihood = ugarchllf(Parameters, U, P, Q)` computes the log-likelihood objective function of univariate GARCH(P,Q) processes with Gaussian innovations.

LogLikelihood is a scalar value of the GARCH(P,Q) log-likelihood objective function given the input arguments. This function is meant to be optimized via the `fmincon` function of the Optimization Toolbox.

`fmincon` is a minimization routine. To maximize the log-likelihood function, the LogLikelihood output parameter is actually the negative of what is formally presented in most time series or econometrics references.

The time-conditional variance, σ_t^2 , of a GARCH(P,Q) process is modeled as

$$\sigma_t^2 = \kappa + \sum_{i=1}^P \alpha_i \sigma_{t-i}^2 + \sum_{j=1}^Q \beta_j \varepsilon_{t-j}^2$$

where α represents the argument Alpha, and β represents Beta.

U is a vector of residuals or innovations (ε_t) representing a mean-zero, discrete time stochastic process. Although σ_t^2 is generated via the equation above, ε_t and σ_t^2 are related as

$$\varepsilon_t = \sigma_t u_t$$

where $\{u_t\}$ is an independent, identically distributed (iid) sequence $\sim N(0,1)$.

Since `ugarch11f` is really just a helper function, no argument checking is performed. This function is not meant to be called directly from the command line.

Note The GARCH Toolbox provides a comprehensive and integrated computing environment for the analysis of volatility in time series. For information, see the GARCH Toolbox User's Guide documentation or the financial products Web page at <http://www.mathworks.com/products/finprod/>.

ugarchllf

See Also

ugarch, ugarchpred, ugarchsim

Purpose Forecast conditional variance of univariate GARCH(P,Q) processes

Syntax [VarianceForecast, H] = ugarchpred(U, Kappa, Alpha, Beta, NumPeriods)

Arguments

- U Single column vector of random disturbances, that is, the residuals or innovations (ϵ_t), of an econometric model representing a mean-zero, discrete-time stochastic process. The innovations time series U is assumed to follow a GARCH(P,Q) process.
- Kappa Scalar constant term [[KAPPA]] of the GARCH process.
- Alpha P-by-1 vector of coefficients, where P is the number of lags of the conditional variance included in the GARCH process. Alpha can be an empty matrix, in which case P is assumed 0; when P = 0, a GARCH(0,Q) process is actually an ARCH(Q) process.
- Beta Q-by-1 vector of coefficients, where Q is the number of lags of the squared innovations included in the GARCH process.
- NumPeriods Positive, scalar integer representing the forecast horizon of interest, expressed in periods compatible with the sampling frequency of the input innovations column vector U.

Description [VarianceForecast, H] = ugarchpred(U, Kappa, Alpha, Beta, NumPeriods) forecasts the conditional variance of univariate GARCH(P,Q) processes.

VarianceForecast is a number of periods (NUMPERIODS)-by-1 vector of the minimum mean-square error forecast of the conditional variance of the innovations time series vector U (that is, ε_t). The first element contains the 1-period-ahead forecast, the second element contains the 2-period-ahead forecast, and so on. Thus, if a forecast horizon greater than 1 is specified (NUMPERIODS > 1), the forecasts of all intermediate horizons are returned as well. In this case, the last element contains the variance forecast of the specified horizon, NumPeriods from the most recent observation in U .

H is a vector of the conditional variances (σ_t^2) corresponding to the innovations vector U . It is inferred from the innovations U , and is a reconstruction of the “past” conditional variances, whereas the VarianceForecast output represents the projection of conditional variances into the “future.” This sequence is based on setting pre-sample values of σ_t^2 to the unconditional variance of the $\{\varepsilon_t\}$ process. H is a single column vector of the same length as the input innovations vector U .

The time-conditional variance, σ_t^2 , of a GARCH(P,Q) process is modeled as

$$\sigma_t^2 = \kappa + \sum_{i=1}^P \alpha_i \sigma_{t-i}^2 + \sum_{j=1}^Q \beta_j \varepsilon_{t-j}^2$$

where α represents the argument Alpha, β represents Beta, and the GARCH(P,Q) coefficients $\{\kappa, \alpha, \beta\}$ are subject to the following constraints.

$$\sum_{i=1}^P \alpha_i + \sum_{j=1}^Q \beta_j < 1$$

$$\kappa > 0$$

$$\alpha_i \geq 0 \quad i = 1, 2, \dots, P$$

$$\beta_j \geq 0 \quad j = 1, 2, \dots, Q$$

Note that U is a vector of residuals or innovations (ε_t) of an econometric model, representing a mean-zero, discrete-time stochastic process.

Although σ_t^2 is generated using the equation above, ε_t and σ_t^2 are related as

$$\varepsilon_t = \sigma_t v_t$$

where $\{v_t\}$ is an independent, identically distributed (iid) sequence $\sim N(0,1)$.

Note `ugarchpred` corresponds generally to the GARCH Toolbox function `garchpred`. The GARCH Toolbox provides a comprehensive and integrated computing environment for the analysis of volatility in time series. For information, see the GARCH Toolbox User's Guide documentation or the financial products Web page at <http://www.mathworks.com/products/finprod/>.

Examples

See `ugarchsim` for an example of forecasting the conditional variance of a univariate GARCH(P,Q) process.

`ugarch`, `ugarchsim`, and the GARCH Toolbox function `garchpred`

ugarchsim

Purpose Simulate univariate GARCH(P,Q) process with Gaussian innovations

Syntax [U, H] = ugarchsim(Kappa, Alpha, Beta, NumSamples)

Arguments

Kappa	Scalar constant term [[KAPPA]] of the GARCH process.
Alpha	P-by-1 vector of coefficients, where P is the number of lags of the conditional variance included in the GARCH process. Alpha can be an empty matrix, in which case P is assumed 0; when P = 0, a GARCH(0,Q) process is actually an ARCH(Q) process.
Beta	Q-by-1 vector of coefficients, where Q is the number of lags of the squared innovations included in the GARCH process.
NumSamples	Positive, scalar integer indicating the number of samples of the innovations U and conditional variance H (see below) to simulate.

Description [U, H] = ugarchsim(Kappa, Alpha, Beta, NumSamples) simulates a univariate GARCH(P,Q) process with Gaussian innovations.

U is a number of samples (NUMSAMPLES)-by-1 vector of innovations (ϵ_t), representing a mean-zero, discrete-time stochastic process. The innovations time series U is designed to follow the GARCH(P,Q) process specified by the inputs Kappa, Alpha, and Beta.

H is a NUMSAMPLES-by-1 vector of the conditional variances (σ_t^2) corresponding to the innovations vector U. Note that U and H are the same length, and form a “matching” pair of vectors. As shown in the following equation, σ_t^2 (that is, H(t)) represents the time series inferred from the innovations time series $\{\epsilon_t\}$ (that is, U).

The time-conditional variance, σ_t^2 , of a GARCH(P,Q) process is modeled as

$$\sigma_t^2 = \kappa + \sum_{i=1}^P \alpha_i \sigma_{t-i}^2 + \sum_{j=1}^Q \beta_j \varepsilon_{t-j}^2$$

where α represents the argument Alpha, β represents Beta, and the GARCH(P,Q) coefficients $\{\kappa, \alpha, \beta\}$ are subject to the following constraints.

$$\sum_{i=1}^P \alpha_i + \sum_{j=1}^Q \beta_j < 1$$

$$\kappa > 0$$

$$\alpha_i \geq 0 \quad i = 1, 2, \dots, P$$

$$\beta_j \geq 0 \quad j = 1, 2, \dots, Q$$

Note that U is a vector of residuals or innovations (ε_t) of an econometric model, representing a mean-zero, discrete-time stochastic process.

Although σ_t^2 is generated using the equation above, ε_t and σ_t^2 are related as

$$\varepsilon_t = \sigma_t v_t$$

where $\{v_t\}$ is an independent, identically distributed (iid) sequence $\sim N(0,1)$.

The output vectors U and H are designed to be steady-state sequences in which transients have arbitrarily small effect. The (arbitrary) metric used by `ugarchsim` strips the first N samples of U and H such that the sum of the GARCH coefficients, excluding κ , raised to the N th power, does not exceed 0.01.

$$0.01 = (\text{sum}(\text{Alpha}) + \text{sum}(\text{Beta}))^N$$

Thus

$$N = \log(0.01) / \log((\text{sum}(\text{Alpha}) + \text{sum}(\text{Beta})))$$

Note `ugarchsim` corresponds generally to the GARCH Toolbox function `garchsim`. The GARCH Toolbox provides a comprehensive and integrated computing environment for the analysis of volatility in time series. For information see the GARCH Toolbox User's Guide documentation or the financial products Web page at <http://www.mathworks.com/products/finprod/>.

Examples

This example simulates a GARCH(P,Q) process with $P = 2$ and $Q = 1$.

```
% Set the random number generator seed for reproducibility.

randn('seed', 10)

% Set the simulation parameters of GARCH(P,Q) = GARCH(2,1) process.

Kappa = 0.25;      %a positive scalar.
Alpha = [0.2 0.1]'; %a column vector of nonnegative numbers (P = 2).
Beta = 0.4;       % Q = 1.
NumSamples = 500; % number of samples to simulate.

% Now simulate the process.

[U , H] = ugarchsim(Kappa, Alpha, Beta, NumSamples);

% Estimate the process parameters.

P = 2; % Model order P (P = length of Alpha).
Q = 1; % Model order Q (Q = length of Beta).
[k, a, b] = ugarch(U , P , Q);
disp(' ')
```

```

disp(' Estimated Coefficients:')
disp(' -----')
disp([k; a; b])
disp(' ')

% Forecast the conditional variance using the estimated
%coefficients.

NumPeriods = 10; % Forecast out to 10 periods.
[VarianceForecast, H1] = ugarchpred(U, k, a, b, NumPeriods);
disp(' Variance Forecasts:')
disp(' -----')
disp(VarianceForecast)
disp(' ')

```

When the above code is executed, the screen output looks like the display shown.

```

vertcat

Purpose Concatenate financial time series objects vertically

Description `vertcat` implements vertical concatenation of financial time series objects. `vertcat` essentially adds data points to a time series object. Objects to be vertically concatenated must not have any duplicate dates and/or times or any overlapping dates and/or times. The description fields are concatenated as well. They are separated by `||`.

Examples Create two financial time series objects with daily frequencies:

```
myfts = fints((today:today+4)', (1:5)', 'DataSeries', 'd');
yourfts = fints((today+5:today+9)', (11:15)', 'DataSeries', 'd');
```

Use `vertcat` to concatenate them vertically:

```
newfts1 = [myfts; yourfts]
```

```
newfts1 =
```

```
desc:  ||
freq:  Daily (1)

'dates: (10)'   'DataSeries: (10)'
'11-Dec-2001'  [          1]
'12-Dec-2001'  [          2]
'13-Dec-2001'  [          3]
'14-Dec-2001'  [          4]
'15-Dec-2001'  [          5]
'16-Dec-2001'  [         11]
'17-Dec-2001'  [         12]
'18-Dec-2001'  [         13]
'19-Dec-2001'  [         14]
'20-Dec-2001'  [         15]
```

Create two financial time series objects with different frequencies:

```
myfts = fints((today:today+4)', (1:5)', 'DataSeries', 'd');
```

```
hisfts = fints((today+5:7:today+34)', (11:15)', 'DataSeries',...
'w');
```

Concatenate these two objects vertically:

```
newfts2 = [myfts; hisfts]
```

```
newfts2 =
```

```
desc:  ||
freq:  Unknown (0)

'dates: (10)'      'DataSeries: (10)'
'11-Dec-2001'     [          1]
'12-Dec-2001'     [          2]
'13-Dec-2001'     [          3]
'14-Dec-2001'     [          4]
'15-Dec-2001'     [          5]
'16-Dec-2001'     [         11]
'23-Dec-2001'     [         12]
'30-Dec-2001'     [         13]
'06-Jan-2002'     [         14]
'13-Jan-2002'     [         15]
```

If all frequency indicators are the same, the new object has the same frequency indicator. However, if one of the concatenated objects has a different `freq` from the other(s), the frequency of the resulting object is set to `Unknown (0)`. In these examples, `newfts1` has `Daily` frequency, while `newfts2` has `Unknown (0)` frequency.

volroc

Purpose Volume rate of change

Syntax

```
vroc = volroc(tvolume nperiods)
vrocts = volroc(tsobj, nperiods)
vrocts = volroc(tsobj, nperiods, ParameterName, ParameterValue)
```

Arguments

tvolume	Volume traded.
nperiods	(Optional) Period difference. Default = 12.
tsobj	Financial time series object.

Description

`vroc = volroc(tvolume nperiods)` calculates the volume rate of change, `vroc`, from the volume traded data `tvolume`. If `nperiods` is specified, the volume rate of change is calculated between the current volume and the volume `nperiods` ago.

`vrocts = volroc(tsobj, nperiods)` calculates the volume rate of change, `vrocts`, from the financial time series object `tsobj`. The `vrocts` output is a financial time series object with similar dates as `tsobj` and a data series named `VolumeROC`. If `nperiods` is specified, the volume rate of change is calculated between the current volume and the volume `nperiods` ago.

`vrocts = volroc(tsobj, nperiods, ParameterName, ParameterValue)` specifies the name for the required data series when it is different from the default name. The valid parameter name is

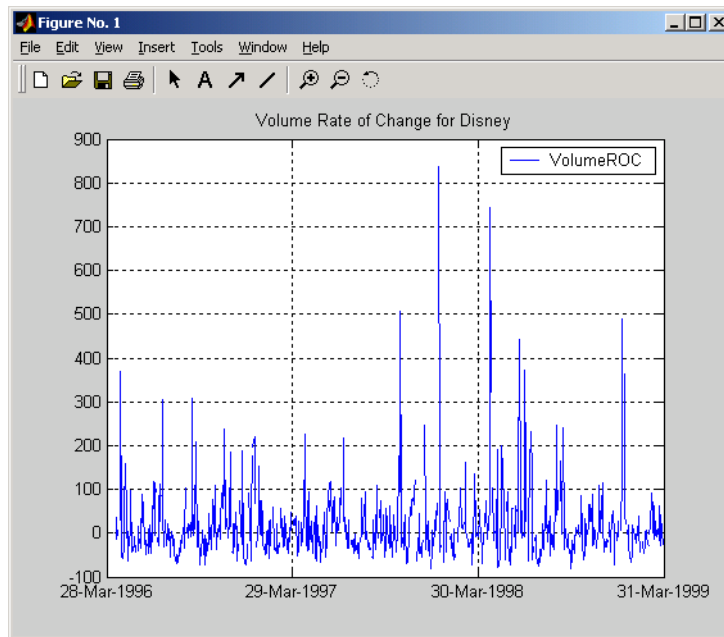

- `VolumeName`: volume traded series name

The parameter value is a string that represents the valid parameter name.

Examples

Compute the volume rate of change for Disney stock and plot the results:

```
load disney.mat
dis_VolRoc = volroc(dis)
plot(dis_VolRoc)
title('Volume Rate of Change for Disney')
```

wclose

Purpose Weighted close

Syntax

```
wcls = wclose(highp, lowp, closep)
wcls = wclose([highp lowp closep])
wclsts = wclose(tsoobj)
wclsts = wclose(tsoobj, ParameterName, ParameterValue, ...)
```

Arguments

highp	High price (vector).
lowp	Low price (vector).
closep	Closing price (vector).
tsoobj	Financial time series object.

Description The weighted close price is the average of twice the closing price plus the high and low prices.

`wcls = wclose(highp, lowp, closep)` calculates the weighted close prices `wcls` based on the high (`highp`), low (`lowp`), and closing (`closep`) prices per period.

`wcls = wclose([highp lowp closep])` accepts a three-column matrix consisting of the high, low, and closing prices, in that order.

`wclsts = wclose(tsoobj)` computes the weighted close prices for a set of stock price data contained in the financial time series object `tsoobj`. The object must contain the high, low, and closing prices needed for this function. The function assumes that the series are named `High`, `Low`, and `Close`. All three are required. `wclsts` is a financial time series object of the same dates as `tsoobj` and contains the data series named `WCclose`.

`wclsts = wclose(tsoobj, ParameterName, ParameterValue, ...)` accepts parameter name/parameter value pairs as input. These pairs

specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

- HighName: high prices series name
- LowName: low prices series name
- CloseName: closing prices series name

Parameter values are the strings that represent the valid parameter names.

Examples

Compute the weighted closing prices for Disney stock and plot the results:

```
load disney.mat
dis_Wclose = wclose(dis)
plot(dis_Wclose)
title('Weighted Closing Prices for Disney')
```

Purpose Day of week

Syntax [DayNum, DayString] = weekday(Date)

Description [DayNum, DayString] = weekday(Date) returns the day of the week in numeric and string form given the date as a serial date number or date string. The days of the week have these values.

DayNum	DayString
1	Sun
2	Mon
3	Tue
4	Wed
5	Thu
6	Fri
7	Sat

Note This function now ships with basic MATLAB. It originally shipped only with Financial Toolbox. This description remains here for your convenience.

Examples [DayNum, DayString] = weekday(730845)

or

[DayNum, DayString] = weekday('25-Dec-2000')

returns

weekday

DayNum =

2

DayString =

Mon

Purpose Portfolio values and weights into holdings

Syntax `Holdings = weights2holdings(Values, Weights, Prices)`

Arguments

Values	Scalar or number of portfolios (NPORTS) vector containing portfolio values.
Weights	NPORTS by number of assets (NASSETS) matrix with portfolio weights. The weights sum to the value of a Budget constraint, which is usually 1. (See <code>holdings2weights</code> for information about budget constraints.)
Prices	NASSETS vector of prices.

Description `Holdings = weights2holdings(Values, Weights, Prices)` converts portfolio values and weights into portfolio holdings.

Holdings is a NPORTS-by-NASSETS matrix containing the holdings of NPORTS portfolios that contain NASSETS assets.

Note This function does not create round-lot positions. Holdings are floating-point values.

See Also `holdings2weights`

willad

Purpose Williams Accumulation/Distribution line

Syntax

```
wadl = willad(highp, lowp, closep)
wadl = willad([highp lowp closep])
wadlts = willad(tsobj)
wadlts = willad(tsobj, ParameterName, ParameterValue, ...)
```

Arguments

highp	High price (vector)
lowp	Low price (vector)
closep	Closing price (vector)
tsobj	Time series object

Description

`wadl = willad(highp, lowp, closep)` computes the Williams Accumulation/Distribution line for a set of stock price data. The prices needed for this function are the high (`highp`), low (`lowp`), and closing (`closep`) prices. All three are required.

`wadl = willad([highp lowp closep])` accepts a three-column matrix of prices as input. The first column contains the high prices, the second contains the low prices, and the third contains the closing prices.

`wadlts = willad(tsobj)` computes the Williams Accumulation/Distribution line for a set of stock price data contained in the financial time series object `tsobj`. The object must contain the high, low, and closing prices needed for this function. The function assumes that the series are named `High`, `Low`, and `Close`. All three are required. `wadlts` is a financial time series object with the same dates as `tsobj` and a single data series named `WillAD`.

`wadlts = willad(tsobj, ParameterName, ParameterValue, ...)` accepts parameter name/parameter value pairs as input. These pairs

specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

- HighName: high prices series name
- LowName: low prices series name
- CloseName: closing prices series name

Parameter values are the strings that represent the valid parameter names.

Examples

Compute the Williams A/D line for Disney stock and plot the results:

```
load disney.mat
dis_Willad = willad(dis)
plot(dis_Willad)
title('Williams A/D Line for Disney')
```

adline, adosc, willpctr

Purpose

Williams %R

Syntax

```

wpctr = willpctr(highp, lowp, closep, nperiods)
wpctr = willpctr([highp, lowp, closep], nperiods)
wpctrts = willpctr(tsobj)
wpctrts = willpctr(tsobj, nperiods)
wpctrts = willpctr(tsobj, nperiods, ParameterName, ParameterValue,
... )

```

Arguments

highp	High price (vector)
lowp	Low price (vector)
closep	Closing price (vector)
nperiods	Number of periods (scalar). Default = 14.
tsobj	Financial time series object

Description

`wpctr = willpctr(highp, lowp, closep, nperiods)` calculates the Williams %R values for the given set of stock prices for a specified number of periods `nperiods`. The stock prices needed are the high (`highp`), low (`lowp`), and closing (`closep`) prices. `wpctr` is a vector that represents the Williams %R values from the stock data.

`wpctr = willpctr([highp, lowp, closep], nperiods)` accepts the price input as a three-column matrix representing the high, low, and closing prices, in that order.

`wpctrts = willpctr(tsobj)` calculates the Williams %R values for the financial time series object `tsobj`. The object must contain at least three data series named `High` (high prices), `Low` (low prices), and `Close` (closing prices). `wpctrts` is a financial time series object with the same dates as `tsobj` and a single data series named `WillPctr`.

willpctr

`wpctrts = willpctr(tsoobj, nperiods)` calculates the Williams %R values for the financial time series object `tsoobj` for `nperiods` periods.

`wpctrts = willpctr(tsoobj, nperiods, ParameterName, ParameterValue, ...)` accepts parameter name/parameter value pairs as input. These pairs specify the name(s) for the required data series if it is different from the expected default name(s). Valid parameter names are

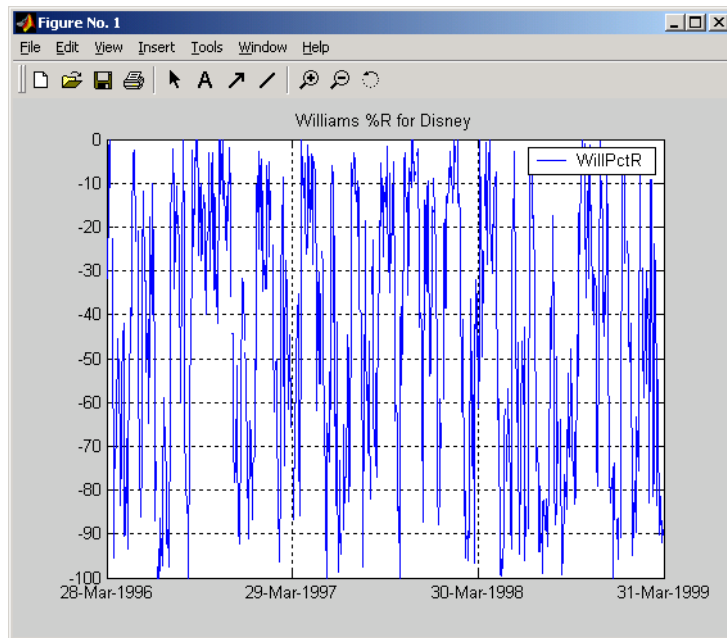

- `HighName`: high prices series name
- `LowName`: low prices series name
- `CloseName`: closing prices series name

Parameter values are the strings that represent the valid parameter names.

Examples

Compute the Williams %R values for Disney stock and plot the results:

```
load disney.mat
dis_Wpctr = willpctr(dis)
plot(dis_Wpctr)
title('Williams %R for Disney')
```

wrkdydif

Purpose Number of working days between dates

Syntax Days = wrkdydif(StartDate, EndDate, Holidays)

Arguments

StartDate Enter as serial date numbers or date strings.

EndDate Enter as serial date numbers or date strings.

Holidays A vector containing values for the number of Holidays between the two dates.

Description Days = wrkdydif(StartDate, EndDate, Holidays) returns the number of working days between dates StartDate and EndDate inclusive. Holidays is the number of holidays between the given dates, an integer. Enter dates as serial date numbers or date strings.

Examples Days = wrkdydif('9/1/2000', '9/11/2000', 1)

or

Days = wrkdydif(730730, 730740, 1)

returns

Days =
6

See Also busdate, datewrkdy, days360, days365, daysact, daysdif, holidays, yearfrac

Purpose Excel serial date number to MATLAB serial date number

Syntax `MATLABDate = x2mdate(ExcelDateNumber, Convention)`

Arguments

`ExcelDateNumber` A vector or scalar of Excel serial date numbers.

`Convention` (Optional) Excel date system. A vector or scalar. When `Convention = 0` (default), the Excel 1900 date system is in effect. When `Convention = 1`, the Excel 1904 date system is used.

In the Excel 1900 date system, the Excel serial date number 1 corresponds to January 1, 1900 A.D. In the Excel 1904 date system, date number 0 is January 1, 1904 A.D.

Due to a software limitation in Excel, the year 1900 is considered a leap year. As a result, all DATEVALUES reported by Excel between Jan. 1, 1900 and Feb. 28, 1900 (inclusive) differ from the values reported by 1. For example:

- In Excel, Jan. 1, 1900 = 1
- In MATLAB, Jan. 1, 1900 = 2

Vector arguments must have consistent dimensions.

Description

`DateNumber = x2mdate(ExcelDateNumber, Convention)` converts Excel serial date numbers to MATLAB serial date numbers. MATLAB date numbers start with 1 = January 1, 0000 A.D., hence there is a difference of 693961 relative to the 1900 date system, or 695422 relative

x2mdate

to the 1904 date system. This function is useful with MATLAB Excel Link.

Examples

Given Excel date numbers in the 1904 system

```
ExDates = [35423 35788 36153];
```

convert them to MATLAB date numbers

```
MATLABDate = x2mdate(ExDates, 1)
```

```
MATLABDate =
```

```
730845    731210    731575
```

and then to date strings.

```
datestr(MATLABDate)
```

```
ans =
```

```
25-Dec-2000
```

```
25-Dec-2001
```

```
25-Dec-2002
```

Purpose Internal rate of return for nonperiodic cash flow

Syntax Return = xirr(CashFlow, CashFlowDates, Guess, MaxIterations)

Arguments

- CashFlow Vector of nonperiodic cash flows. Include the initial investment as the initial cash flow value (a negative number).
- CashFlowDates Vector of dates on which the cash flows occur. Enter dates as serial date numbers or date strings.
- Guess (Optional) Initial estimate of the expected return. Default = 0.1 (10%).
- MaxIterations (Optional) Number of iterations used by Newton's method to solve for Return. Default = 50.

Description Return = xirr(CashFlow, CashFlowDates, Guess, MaxIterations) returns the internal rate of return for a schedule of nonperiodic cash flows.

Examples An investment of \$10,000 returns this nonperiodic cash flow. The original investment and its date are included.

Cash Flow	Dates
(\$10000)	January 12, 2000
\$2500	February 14, 2001
\$2000	March 3, 2001

Cash Flow	Dates
\$3000	June 14, 2001
\$4000	December 1, 2001

To calculate the internal rate of return for this nonperiodic cash flow

```
CashFlow = [-10000, 2500, 2000, 3000, 4000];
CashFlowDates = ['01/12/2000'
                 '02/14/2001'
                 '03/03/2001'
                 '06/14/2001'
                 '12/01/2001'];
Return = xirr(CashFlow, CashFlowDates)
```

returns

```
Return =
    0.1009 (or 10.09%)
```

fvvar, irr, mirr, pvvar

Purpose Year of date

Syntax Year = year(Date)

Description Year = year(Date) returns the year of a serial date number or a date string.

Examples Year = year(731798.776)

or

Year = year('05-Aug-2003')

returns

Year =

2003

See Also datevec, day, month, yeardays

yeardays

Purpose Number of days in year

Syntax Days = yeardays(Year, Basis)

Arguments

Year Enter as a four-digit integer.

Basis (Optional) Day-count basis of the instrument. A vector of integers.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ISMA)
- 9 = actual/360 (ISMA)
- 10 = actual/365 (ISMA)

Description Days = yeardays(Year, Basis) returns the number of days in the given year, based upon the day-count basis.

Examples Days = yeardays(2000)

Days =

Days = $\frac{366}{\text{yeardays}(2000, 1)}$

Days =

360

See Also

days360, days365, daysact, year, yearfrac

yearfrac

Purpose Fraction of year between dates

Syntax YearFraction = yearfrac(StartDate, EndDate, Basis)

Arguments

StartDate Enter as serial date numbers or date strings.
EndDate Enter as serial date numbers or date strings.
Basis (Optional) Day-count basis of the instrument. A vector of integers.

- 0 = actual/actual (default)
- 1 = 30/360 (SIA)
- 2 = actual/360
- 3 = actual/365
- 4 = 30/360 (PSA)
- 5 = 30/360 (ISDA)
- 6 = 30/360 (European)
- 7 = actual/365 (Japanese)
- 8 = actual/actual (ISMA)
- 9 = actual/360 (ISMA)
- 10 = actual/365 (ISMA)

All specified arguments must be number of instruments (NUMINST)-by-1 or 1-by-NUMINST conforming vectors or scalar arguments.

Description YearFraction = yearfrac(StartDate, EndDate, Basis) returns a fraction based on the number of days between dates StartDate and

EndDate using the given day-count basis. If EndDate is earlier than StartDate, Fraction is negative.

Examples

```
YearFraction = yearfrac('14 mar 01', '14 sep 01', 0)
```

```
YearFraction =
```

```
0.5041
```

```
YearFraction = yearfrac('14 mar 01', '14 sep 01', 1)
```

```
YearFraction =
```

```
0.5000
```

ylddisc

Purpose Yield of discounted security

Syntax Yield = ylddisc(Settle, Maturity, Face, Price, Basis)

Arguments

Settle	Settlement date. Enter as serial date number or date string. Settle must be earlier than or equal to Maturity.
Maturity	Maturity date. Enter as serial date number or date string.
Face	Redemption (par, face) value.
Price	Discounted price of the security.
Basis	(Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)

Description Yield = ylddisc(Settle, Maturity, Face, Price, Basis) finds the yield of a discounted security.

Examples Using the data

```
Settle = '10/14/2000';  
Maturity = '03/17/2001';  
Face = 100;  
Price = 96.28;  
Basis = 2;
```

```
Yield = ylddisc(Settle, Maturity, Face, Price, Basis)
```

returns

```
Yield =
```

```
0.0903 (or 9.03%)
```

Purpose Yield with interest at maturity

Syntax `Yield = yldmat(Settle, Maturity, Issue, Face, Price, CouponRate, Basis)`

Arguments

Settle	Settlement date. Enter as serial date number or date string. Settle must be earlier than or equal to Maturity.
Maturity	Maturity date. Enter as serial date number or date string.
Issue	Issue date. Enter as serial date number or date string.
Face	Redemption (par, face) value.
Price	Price of the security.
CouponRate	Coupon rate. Enter as decimal fraction.
Basis	(Optional) Day-count basis of the instrument. A vector of integers. <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)

- 9 = actual/360 (ISMA)
- 10 = actual/365 (ISMA)

Description

Yield = yldmat(Settle, Maturity, Issue, Face, Price, CouponRate, Basis) returns the yield of a security paying interest at maturity.

Examples

Using the data

```
Settle = '02/07/2000';  
Maturity = '04/13/2000';  
Issue = '10/11/1999';  
Face = 100;  
Price = 99.98;  
CouponRate = 0.0608;  
Basis = 1;
```

```
Yield = yldmat(Settle, Maturity, Issue, Face, Price,...  
CouponRate, Basis)
```

returns

```
Yield =  
0.0607 (or 6.07%)
```

yldtbill

Purpose Yield of Treasury bill

Syntax Yield = yldtbill(Settle, Maturity, Face, Price)

Arguments

Settle	Settlement date. Enter as serial date number or date string. Settle must be earlier than or equal to Maturity.
Maturity	Maturity date. Enter as serial date number or date string.
Face	Redemption (par, face) value.
Price	Price of the Treasury bill.

Description Yield = yldtbill(Settle, Maturity, Face, Price) returns the yield for a Treasury bill.

Examples The settlement date of a Treasury bill is February 10, 2000, the maturity date is August 6, 2000, the par value is \$1000, and the price is \$981.36. Using this data

```
Yield = yldtbill('2/10/2000', '8/6/2000', 1000, 981.36)
```

returns

```
Yield =
```

```
0.0384 (or 3.84%)
```

Purpose Zero curve bootstrapping from coupon bond data given price

Syntax [ZeroRates, CurveDates] = zbtprice(Bonds, Prices, Settle, OutputCompounding)

Arguments

Bonds

Coupon bond information used to generate the zero curve. An n-by-2 to n-by-6 matrix where each row describes a bond. The first two columns are required; the rest are optional but must be added in order. All rows in Bonds must have the same number of columns.

Columns are

[Maturity CouponRate Face Period Basis EndMonthRule] where

Maturity Maturity date of the bond, as a serial date number. Use datenum to convert date strings to serial date numbers.

CouponRate Coupon rate of the bond, as a decimal fraction.

Face (Optional) Redemption or face value of the bond. Default = 100.

Period (Optional) Coupons per year of the bond, as an integer. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.

Basis	<p>(Optional) Day-count basis of the bond:</p> <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)
EndMonthRule	<p>(Optional) End-of-month flag. This flag applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore flag, meaning that a bond's coupon payment date is always the same day of the month. 1 = set flag (default), meaning that a bond's coupon payment date is always the last day of the month.</p>
Prices	<p>Column vector containing the clean price (price without accrued interest) of each bond in Bonds, respectively. The number of rows (n) must match the number of rows in Bonds.</p>

Settle	Settlement date, as a scalar serial date number. This represents time zero for deriving the zero curve, and it is normally the common settlement date for all the bonds.														
OutputCompounding	(Optional) Scalar that sets the compounding frequency per year for the output zero rates in ZeroRates. Allowed values are: <table> <tr> <td>1</td> <td>Annual compounding</td> </tr> <tr> <td>2</td> <td>Semiannual compounding (default)</td> </tr> <tr> <td>3</td> <td>Compounding three times per year</td> </tr> <tr> <td>4</td> <td>Quarterly compounding</td> </tr> <tr> <td>6</td> <td>Bimonthly compounding</td> </tr> <tr> <td>12</td> <td>Monthly compounding</td> </tr> <tr> <td>-1</td> <td>Continuous compounding</td> </tr> </table>	1	Annual compounding	2	Semiannual compounding (default)	3	Compounding three times per year	4	Quarterly compounding	6	Bimonthly compounding	12	Monthly compounding	-1	Continuous compounding
1	Annual compounding														
2	Semiannual compounding (default)														
3	Compounding three times per year														
4	Quarterly compounding														
6	Bimonthly compounding														
12	Monthly compounding														
-1	Continuous compounding														

Description

[ZeroRates, CurveDates] = zbtprice(Bonds, Prices, Settle, OutputCompounding) uses the bootstrap method to return a zero curve given a portfolio of coupon bonds and their prices. A zero curve consists of the yields to maturity for a portfolio of theoretical zero-coupon bonds that are derived from the input Bonds portfolio. The bootstrap method that this function uses does *not* require alignment among the cash-flow dates of the bonds in the input portfolio. It uses theoretical par bond arbitrage and yield interpolation to derive all zero rates. For best results, use a portfolio of at least 30 bonds evenly spaced across the investment horizon.

ZeroRates An m-by-1 vector of decimal fractions that are the implied zero rates for each point along the investment horizon represented by CurveDates; m is the number of bonds of unique maturity dates. In aggregate, the rates in ZeroRates constitute a zero curve.

If more than one bond has the same maturity date, zbtprice returns the mean zero rate for that maturity.

CurveDates An m-by-1 vector of unique maturity dates (as serial date numbers) that correspond to the zero rates in ZeroRates; m is the number of bonds of different maturity dates. These dates begin with the earliest maturity date and end with the latest maturity date Maturity in the Bonds matrix.

Examples

Given data and prices for 12 coupon bonds, two with the same maturity date; and given the common settlement date

```
Bonds = [datenum('6/1/1998') 0.0475 100 2 0 0;  
         datenum('7/1/2000') 0.06 100 2 0 0;  
         datenum('7/1/2000') 0.09375 100 6 1 0;  
         datenum('6/30/2001') 0.05125 100 1 3 1;  
         datenum('4/15/2002') 0.07125 100 4 1 0;  
         datenum('1/15/2000') 0.065 100 2 0 0;  
         datenum('9/1/1999') 0.08 100 3 3 0;  
         datenum('4/30/2001') 0.05875 100 2 0 0;  
         datenum('11/15/1999') 0.07125 100 2 0 0;  
         datenum('6/30/2000') 0.07 100 2 3 1;  
         datenum('7/1/2001') 0.0525 100 2 3 0;  
         datenum('4/30/2002') 0.07 100 2 0 0];
```

```
Prices = [99.375;
```

```
    99.875;  
    105.75 ;  
    96.875;  
    103.625;  
    101.125;  
    103.125;  
    99.375;  
    101.0  ;  
    101.25 ;  
    96.375;  
    102.75 ];
```

```
Settle = datenum('12/18/1997');
```

Set semiannual compounding for the zero curve.

```
OutputCompounding = 2;
```

Execute the function

```
[ZeroRates, CurveDates] = zbtprice(Bonds, Prices, Settle,...  
OutputCompounding)
```

which returns the zero curve at the maturity dates. Note the mean zero rate for the two bonds with the same maturity date*.

```
ZeroRates =
```

```
    0.0616  
    0.0609  
    0.0658

zbtyield and other functions for Term Structure of Interest Rates

Purpose Zero curve bootstrapping from coupon bond data given yield

Syntax [ZeroRates, CurveDates] = zbyield(Bonds, Yields, Settle, OutputCompounding)

Arguments

Bonds	Coupon bond information used to generate the zero curve. An n-by-2 to n-by-6 matrix where each row describes a bond. The first two columns are required; the rest are optional but must be added in order. All rows in Bonds must have the same number of columns. Columns are [Maturity CouponRate Face Period Basis EndMonthRule] where
Maturity	Maturity date of the bond, as a serial date number. Use datenum to convert date strings to serial date numbers.
CouponRate	Coupon rate of the bond, as a decimal fraction.
Face	(Optional) Redemption or face value of the bond. Default = 100.
Period	(Optional) Coupons per year of the bond, as an integer. Allowed values are 0, 1, 2 (default), 3, 4, 6, and 12.

Basis	<p>(Optional) Day-count basis of the bond.</p> <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)
EndMonthRule	<p>(Optional) End-of-month flag. This flag applies only when Maturity is an end-of-month date for a month having 30 or fewer days. 0 = ignore flag, meaning that a bond's coupon payment date is always the same day of the month. 1 = set flag (default), meaning that a bond's coupon payment date is always the last day of the month.</p>

Yields	Column vector containing the yield to maturity of each bond in Bonds, respectively. The number of rows (n) must match the number of rows in Bonds. Yield to maturity must be compounded semiannually.
Settle	Settlement date, as a scalar serial date number. This represents time zero for deriving the zero curve, and it is normally the common settlement date for all the bonds.
OutputCompounding	(Optional) Scalar that sets the compounding frequency per year for the output zero rates in ZeroRates. Allowed values are: <ul style="list-style-type: none"> 1 Annual compounding 2 Semiannual compounding (default) 3 Compounding three times per year 4 Quarterly compounding 6 Bimonthly compounding 12 Monthly compounding -1 Continuous compounding

Description

[ZeroRates, CurveDates] = zbtyield(Bonds, Yields, Settle, OutputCompounding) uses the bootstrap method to return a zero curve given a portfolio of coupon bonds and their yields. A zero curve consists of the yields to maturity for a portfolio of theoretical zero-coupon bonds that are derived from the input Bonds portfolio. The bootstrap method that this function uses does *not* require alignment among the cash-flow dates of the bonds in the input portfolio. It uses theoretical par bond arbitrage and yield interpolation to derive all zero rates. For best

results, use a portfolio of at least 30 bonds evenly spaced across the investment horizon.

ZeroRates	<p>An m-by-1 vector of decimal fractions that are the implied zero rates for each point along the investment horizon represented by CurveDates; m is the number of bonds of different maturity dates. In aggregate, the rates in ZeroRates constitute a zero curve.</p> <p>If more than one bond has the same maturity date, zbyield returns the mean zero rate for that maturity.</p>
CurveDates	<p>An m-by-1 vector of unique maturity dates (as serial date numbers) that correspond to the zero rates in ZeroRates; m is the number of bonds of different maturity dates. These dates begin with the earliest maturity date and end with the latest maturity date Maturity in the Bonds matrix. Use datestr to convert serial date numbers to date strings.</p>

Examples

Given data and yields to maturity for 12 coupon bonds, two with the same maturity date; and given the common settlement date

```
Bonds = [datenum('6/1/1998') 0.0475 100 2 0 0;  
         datenum('7/1/2000') 0.06 100 2 0 0;  
         datenum('7/1/2000') 0.09375 100 6 1 0;  
         datenum('6/30/2001') 0.05125 100 1 3 1;  
         datenum('4/15/2002') 0.07125 100 4 1 0;  
         datenum('1/15/2000') 0.065 100 2 0 0;  
         datenum('9/1/1999') 0.08 100 3 3 0;  
         datenum('4/30/2001') 0.05875 100 2 0 0;

zbtprice and other functions for "Term Structure of Interest Rates" on page 2-33

Purpose Discount curve given zero curve

Syntax [DiscRates, CurveDates] = zero2disc(ZeroRates, CurveDates, Settle, Compounding, Basis)

Arguments

ZeroRates	Number of bonds (NUMBONDS) by 1 vector of annualized zero rates, as decimal fractions. In aggregate, the rates constitute an implied zero curve for the investment horizon represented by CurveDates.
CurveDates	NUMBONDS-by-1 vector of maturity dates (as serial date numbers) that correspond to the zero rates.
Settle	Serial date number that is the common settlement date for the zero rates; that is, the settlement date for the bonds from which the zero curve was bootstrapped.
Compounding	(Optional) Scalar that indicates the compounding frequency per year used for annualizing the input zero rates in ZeroRates. Allowed values are: <ul style="list-style-type: none"> 1 Annual compounding 2 Semiannual compounding (default) 3 Compounding three times per year 4 Quarterly compounding 6 Bimonthly compounding 12 Monthly compounding 365 Daily compounding

zero2disc

	- 1	Continuous compounding
Basis		(Optional) Day-count basis used for annualizing the input zero rates.
		<ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)

Description

[DiscRates, CurveDates] = zero2disc(ZeroRates, CurveDates, Settle, Compounding, Basis) returns a discount curve given a zero curve and its maturity dates.

DiscRates	A NUMBONDS-by-1 vector of discount factors, as decimal fractions. In aggregate, the factors in constitute a discount curve for the investment horizon represented by CurveDates.
CurveDates	A NUMBONDS-by-1 vector of maturity dates (as serial date numbers) that correspond to the discount rates. This vector is the same as the input vector CurveDates.

Examples

Given a zero curve over a set of maturity dates and a settlement date

```
ZeroRates = [0.0464
             0.0509
             0.0524
             0.0525
             0.0531
             0.0525
             0.0530
             0.0531
             0.0549
             0.0536];

CurveDates = [datenum('06-Nov-2000')
             datenum('11-Dec-2000')
             datenum('15-Jan-2001')
             datenum('05-Feb-2001')
             datenum('04-Mar-2001')
             datenum('02-Apr-2001')
             datenum('30-Apr-2001')
             datenum('25-Jun-2001')
             datenum('04-Sep-2001')
             datenum('12-Nov-2001')];

Settle = datenum('03-Nov-2000');
```

The zero curve was compounded daily on an actual/365 basis.

```
InputCompounding = 365;  
InputBasis = 3;
```

Execute the function

```
[DiscRates, CurveDates] = zero2disc(ZeroRates, CurveDates,...  
Settle, Compounding, Basis)
```

which returns the discount curve DiscRates at the maturity dates CurveDates.

```
DiscRates =
```

```
0.9996  
0.9947  
0.9896

zero2fwd

Purpose Forward curve given zero curve

Syntax [ForwardRates, CurveDates] = zero2fwd(ZeroRates, CurveDates, Settle, Compounding, Basis)

Arguments

ZeroRates	Number of bonds (NUMBONDS) by 1 vector of annualized zero rates, as decimal fractions. In aggregate, the rates constitute an implied zero curve for the investment horizon represented by CurveDates. The first element pertains to forward rates from the settlement date to the first curve date.														
CurveDates	NUMBONDS-by-1 vector of maturity dates (as serial date numbers) that correspond to the zero rates.														
Settle	Serial date number that is the common settlement date for the zero rates.														
Compounding	(Optional) Scalar that sets the compounding frequency per year used to annualize the input zero rates and the output implied forward rates. Allowed values are: <table><tr><td>1</td><td>Annual compounding</td></tr><tr><td>2</td><td>Semiannual compounding (default)</td></tr><tr><td>3</td><td>Compounding three times per year</td></tr><tr><td>4</td><td>Quarterly compounding</td></tr><tr><td>6</td><td>Bimonthly compounding</td></tr><tr><td>12</td><td>Monthly compounding</td></tr><tr><td>365</td><td>Daily compounding</td></tr></table>	1	Annual compounding	2	Semiannual compounding (default)	3	Compounding three times per year	4	Quarterly compounding	6	Bimonthly compounding	12	Monthly compounding	365	Daily compounding
1	Annual compounding														
2	Semiannual compounding (default)														
3	Compounding three times per year														
4	Quarterly compounding														
6	Bimonthly compounding														
12	Monthly compounding														
365	Daily compounding														

	- 1	Continuous compounding
Basis		(Optional) Day-count basis used to construct the input zero and output implied forward rate curves.
		<ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)

Description

[ForwardRates, CurveDates] = zero2fwd(ZeroRates, CurveDates, Settle, Compounding, Basis) returns an implied forward rate curve given a zero curve and its maturity dates.

ForwardRates A NUMBONDS-by-1 vector of decimal fractions. In aggregate, the rates in **ForwardRates** constitute a forward curve over the dates in **CurveDates**.

CurveDates A NUMBONDS-by-1 vector of maturity dates (as serial date numbers) that correspond to the forward rates in. This vector is the same as the input vector **CurveDates**.

Examples

Given a zero curve over a set of maturity dates, a settlement date, and a compounding rate, compute the forward rate curve.

```
ZeroRates = [0.0458
             0.0502
             0.0518
             0.0519
             0.0524
             0.0519
             0.0523
             0.0525
             0.0541
             0.0529];

CurveDates = [datenum('06-Nov-2000')
             datenum('11-Dec-2000')
             datenum('15-Jan-2001')
             datenum('05-Feb-2001')
             datenum('04-Mar-2001')
             datenum('02-Apr-2001')
             datenum('30-Apr-2001')
             datenum('25-Jun-2001')
             datenum('04-Sep-2001')
             datenum('12-Nov-2001')];

Settle = datenum('03-Nov-2000');
Compounding = 1;
```

Execute the function

```
[ForwardRates, CurveDates] = zero2fwd(ZeroRates, CurveDates,...  
Settle, Compounding)
```

which returns the forward rate curve `ForwardRates` at the maturity dates `CurveDates`.

`ForwardRates =`

```
0.0458  
0.0506  
0.0535  
0.0522  
0.0541  
0.0498  
0.0544  
0.0531  
0.0594  
0.0476
```

`CurveDates =`

```
730796  
730831  
730866  
730887  
730914

fwd2zero and other functions for “Term Structure of Interest Rates” on page 2-33

Purpose Par yield curve given zero curve

Syntax [ParRates, CurveDates] = zero2pyld(ZeroRates, CurveDates, Settle, Compounding, Basis, OutputCompounding)

Arguments

ZeroRates	A number of bonds (NUMBONDS) by 1 vector of annualized zero rates, as decimal fractions. In aggregate, the rates constitute an implied zero curve for the investment horizon represented by CurveDates.														
CurveDates	A NUMBONDS-by-1 vector of maturity dates (as serial date numbers) that correspond to the zero rates.														
Settle	A serial date number that is the common settlement date for the zero rates.														
Compounding	(Optional) A scalar that sets the rate at which the implied zero rates are compounded when annualized. Allowed values are: <table><tr><td>1</td><td>Annual compounding</td></tr><tr><td>2</td><td>Semiannual compounding (default)</td></tr><tr><td>3</td><td>Compounding three times per year</td></tr><tr><td>4</td><td>Quarterly compounding</td></tr><tr><td>6</td><td>Bimonthly compounding</td></tr><tr><td>12</td><td>Monthly compounding</td></tr><tr><td>365</td><td>Daily compounding</td></tr></table>	1	Annual compounding	2	Semiannual compounding (default)	3	Compounding three times per year	4	Quarterly compounding	6	Bimonthly compounding	12	Monthly compounding	365	Daily compounding
1	Annual compounding														
2	Semiannual compounding (default)														
3	Compounding three times per year														
4	Quarterly compounding														
6	Bimonthly compounding														
12	Monthly compounding														
365	Daily compounding														

Basis	(Optional) Day-count basis used to annualize the implied zero rates. <ul style="list-style-type: none">• 0 = actual/actual (default)• 1 = 30/360 (SIA)• 2 = actual/360• 3 = actual/365• 4 = 30/360 (PSA)• 5 = 30/360 (ISDA)• 6 = 30/360 (European)• 7 = actual/365 (Japanese)• 8 = actual/actual (ISMA)• 9 = actual/360 (ISMA)• 10 = actual/365 (ISMA)
OutputCompounding	(Optional) Value representing the rate at which the par rates are compounded. Default = Compounding.

Description

[ParRates, CurveDates] = zero2pyld(ZeroRates, CurveDates, Settle, Compounding, Basis, OutputCompounding) returns a par yield curve given a zero curve and its maturity dates.

ParRates	A NUMBONDS-by-1 vector of annualized par yields, as decimal fractions. (Par yields = coupon rates.) In aggregate, the yield rates in ParRates constitute a par yield curve for the investment horizon represented by CurveDates.
CurveDates	A NUMBONDS-by-1 vector of maturity dates (as serial date numbers) that correspond to the par yield rates. This vector is the same as the input vector CurveDates.

Examples

Given

- A zero curve over a set of maturity dates and
- A settlement date
- Annual compounding for the input zero curve and monthly compounding for the output par rates

compute a par yield curve.

```
ZeroRates = [0.0457
             0.0487
             0.0506
             0.0507
             0.0505
             0.0504
             0.0506
             0.0516
             0.0539
             0.0530];

CurveDates = [datenum('06-Nov-2000')
              datenum('11-Dec-2000')
              datenum('15-Jan-2001')
              datenum('05-Feb-2001')]
```

```
    datenum('04-Mar-2001')
    datenum('02-Apr-2001')

Note For the well-known algorithms and formulas used in Financial Toolbox (such as how to compute a loan payment given principal, interest rate, and length of the loan), no references are given here. The references here pertain to less common formulas.

Bond Pricing and Yields

The pricing and yield formulas for fixed-income securities come from:

[1] Mayle, Jan, *Standard Securities Calculation Methods*. New York: Securities Industry Association, Inc. Vol. 1, 3rd ed., 1993, ISBN 1-882936-01-9. Vol. 2, 1994, ISBN 1-882936-02-7.

In many cases these formulas compute the price of a security given yield, dates, rates, and other data. These formulas are nonlinear, however; so when solving for an independent variable within a formula, Financial Toolbox uses Newton's method. See any elementary numerical methods textbook for the mathematics underlying Newton's method.

Term Structure of Interest Rates

The formulas and methodology for term structure functions come from:

[2] Fabozzi, Frank J., “The Structure of Interest Rates.” Ch. 6 in Fabozzi, Frank J. and T. Dossa Fabozzi, eds. *The Handbook of Fixed Income Securities*. 4th ed. New York: Irwin Professional Publishing, 1995, ISBN 0-7863-0001-9.

[3] McEnally, Richard W. and James V. Jordan, “The Term Structure of Interest Rates.” Ch. 37 in Fabozzi and Fabozzi, *ibid*.

[4] Das, Satyajit, “Calculating Zero Coupon Rates.” *Swap and Derivative Financing*. Appendix to Ch. 8, pp. 219-225, New York: Irwin Professional Publishing., 1994, ISBN 1-55738-542-4.

Derivatives Pricing and Yields

The pricing and yield formulas for derivative securities come from:

[5] Chriss, Neil A., “Black-Scholes and Beyond: Option Pricing Models,” Chicago: Irwin Professional Publishing, 1997, ISBN 0-7863-1025-1.

[6] Cox, J., S. Ross, and M. Rubenstein, “Option Pricing: A Simplified Approach”, *Journal of Financial Economics* 7, Sept. 1979, pp. 229 - 263.

[7] Hull, John C., *Options, Futures, and Other Derivatives*, Prentice Hall, 5th edition, 2003, ISBN 0-13-009056-5.

Portfolio Analysis

The Markowitz model is used for portfolio analysis computations. For a discussion of this model see Chapter 7 of:

[8] Bodie, Zvi, Alex Kane, and Alan J. Marcus, *Investments*, Burr Ridge, IL: Irwin. 2nd. ed., 1993, ISBN 0-256-08342-8.

To solve the quadratic minimization problem associated with finding the efficient frontier, the toolbox uses the `fmincon` function (finds the constrained minimum of a function of several variables) in the Optimization Toolbox documentation. See that toolbox documentation for more details.

Investment Performance Metrics

The risk and ratio formulas for investment performance metrics come from:

Daniel Bernoulli, "Exposition of a New Theory on the Measurement of Risk," *Econometrica*, Vol. 22, No 1, January 1954, pp. 23-36 (English translation of "Specimen Theoriae Novae de Mensura Sortis," *Commentarii Academiae Scientiarum Imperialis Petropolitanae*, Tomus V, 1738, pp. 175-192).

Martin Eling and Frank Schuhmacher, *Does the Choice of Performance Measure Influence the Evaluation of Hedge Funds?*, Working Paper, November 2005.

John Lintner, "The Valuation of Risk Assets and the Selection of Risky Investments in Stocks Portfolios and Capital Budgets," *Review of Economics and Statistics*, Vol. 47, No. 1, February 1965, pp. 13-37.

Malik Magdon-Ismail, Amir F. Atiya, Amrit Pratap, and Yaser S. Abu-Mostafa, "On the Maximum Drawdown of a Brownian Motion," *Journal of Applied Probability*, Volume 41, Number 1, March 2004, pp. 147-161.

Malik Magdon-Ismail, "Maximum Drawdown," www.risk.net, October 2004.

active return

Amount of return achieved in excess of the return produced by an appropriate benchmark (for example, an index portfolio).

active risk

Standard deviation of the active return. Also known as the **tracking error** on page Glossary-12.

American option

An option that can be exercised any time until its expiration date. Contrast with European option.

amortization

Reduction in value of an asset over some period for accounting purposes. Generally used with intangible assets. Depreciation is the term used with fixed or tangible assets.

annuity

A series of payments over a period of time. The payments are usually in equal amounts and usually at regular intervals such as quarterly, semi-annually, or annually.

arbitrage

The purchase of securities on one market for immediate resale on another market in order to profit from a price or currency discrepancy.

basis point

One hundredth of one percentage point, or 0.0001.

beta

The price volatility of a financial instrument relative to the price volatility of a market or index as a whole. Beta is most commonly used with respect to equities. A high-beta instrument is riskier than a low-beta instrument.

binomial model

A method of pricing options or other equity derivatives in which the probability over time of each possible price follows a binomial

distribution. The basic assumption is that prices can move to only two values (one higher and one lower) over any short time period.

Black-Scholes model

The first complete mathematical model for pricing options, developed by Fischer Black and Myron Scholes. It examines market price, strike price, volatility, time to expiration, and interest rates. It is limited to only certain kinds of options.

Bollinger band chart

A financial chart that plots actual asset data along with three other bands of data: the upper band is two standard deviations above a user-specified moving average; the lower band is two standard deviations below that moving average; and the middle band is the moving average itself.

bootstrapping, bootstrap method

An arithmetic method for backing an implied zero curve out of the par yield curve.

building a binomial tree

For a binomial option model: plotting the two possible short-term price-changes values, and then the subsequent two values each, and then the subsequent two values each, and so on over time, is known as “building a binomial tree.” See also **binomial model** on page Glossary-1.

call

a. An option to buy a certain quantity of a stock or commodity for a specified price within a specified time. See also **put** on page Glossary-9.
b. A demand to submit bonds to the issuer for redemption before the maturity date. **c.** A demand for payment of a debt. **d.** A demand for payment due on stock bought on margin.

callable bond

A bond that allows the issuer to buy back the bond at a predetermined price at specified future dates. The bond contains an embedded call option; that is, the holder has sold a call option to the issuer. See also **puttable bond** on page Glossary-10.

candlestick chart

A financial chart usually used to plot the high, low, open, and close price of a security over time. The body of the “candle” is the region between the open and close price of the security. Thin vertical lines extend up to the high and down to the low, respectively. If the open price is greater than the close price, the body is empty. If the close price is greater than the open price, the body is filled. See also **high-low-close chart** on page Glossary-6.

cap

Interest-rate option that guarantees that the rate on a floating-rate loan will not exceed a certain level.

cash flow

Cash received and paid over time.

collar

Interest-rate option that guarantees that the rate on a floating-rate loan will not exceed a certain upper level nor fall below a lower level. It is designed to protect an investor against wide fluctuations in interest rates.

convexity

A measure of the rate of change in duration; measured in time. The greater the rate of change, the more the duration changes as yield changes.

correlation

The simultaneous change in value of two random numeric variables.

correlation coefficient

A statistic in which the covariance is scaled to a value between minus one (perfect negative correlation) and plus one (perfect positive correlation).

coupon

Detachable certificate attached to a bond that shows the amount of interest payable at regular intervals, usually semi-annually. Originally coupons were actually attached to the bonds and had to be cut off or “clipped” to redeem them and receive the interest payment.

coupon dates

The dates when the coupons are paid. Typically a bond pays coupons annually or semi-annually.

coupon rate

The nominal interest rate that the issuer promises to pay the buyer of a bond.

covariance

A measure of the degree to which returns on two assets move in tandem. A positive covariance means that asset returns move together; a negative covariance means they vary inversely.

delta

The rate of change of the price of a derivative security relative to the price of the underlying asset; that is, the first derivative of the curve that relates the price of the derivative to the price of the underlying security.

depreciation

Reduction in value of fixed or tangible assets over some period for accounting purposes. See also **amortization** on page Glossary-1.

derivative

A financial instrument that is based on some underlying asset. For example, an option is a derivative instrument based on the right to buy or sell an underlying instrument.

discount curve

The curve of discount rates versus maturity dates for bonds.

drawdown

The peak to trough decline during a specific record period of an investment or fund.

duration

The expected life of a fixed-income security considering its coupon yield, interest payments, maturity, and call features. As market interest rates rise, the duration of a financial instrument decreases. See also **Macaulay duration** on page Glossary-7.

efficient frontier

A graph representing a set of portfolios that maximizes expected return at each level of portfolio risk. See also **Markowitz model** on page Glossary-7.

elasticity

See **Lambda** on page Glossary-7.

European option

An option that can be exercised only on its expiration date. Contrast with American option.

ex-ante

Referring to future events, such as the future price of a stock.

ex-post

Referring to past events, when uncertainty of the result has been eliminated.

exercise price

The price set for buying an asset (call) or selling an asset (put). The strike price.

face value

The maturity value of a security. Also known as par value, principal value, or redemption value.

fixed-income security

A security that pays a specified cash flow over a specific period. Bonds are typical fixed-income securities.

floor

Interest-rate option that guarantees that the rate on a floating-rate loan will not fall below a certain level.

forward curve

The curve of forward interest rates versus maturity dates for bonds.

forward rate

The future interest rate of a bond inferred from the term structure, especially from the yield curve of zero-coupon bonds, calculated from the growth factor of an investment in a zero held until maturity.

future value

The value that a sum of money (the present value) earning compound interest will have in the future.

gamma

The rate of change of delta for a derivative security relative to the price of the underlying asset; that is, the second derivative of the option price relative to the security price.

greeks

Collectively, “greeks” refer to the financial measures beta, delta, gamma, lambda, rho, theta, and vega, which are sensitivity measures used in evaluating derivatives.

hedge

A securities transaction that reduces or offsets the risk on an existing investment position.

high-low-close chart

A financial chart usually used to plot the high, low, open, and close price of a security over time. Plots are vertical lines whose top is the high, bottom is the low, open is a short horizontal tick to the left, and close is a short horizontal tick to the right.

implied volatility

For an option, the variance that makes a call option price equal to the market price. Given the option price, strike price, and other factors, the Black-Scholes model computes implied volatility.

information ratio

The ratio of relative return to relative risk.

internal rate of return

a. The average annual yield earned by an investment during the period held. **b.** The effective rate of interest on a loan. **c.** The discount rate

in discounted cash flow analysis. **d.** The rate that adjusts the value of future cash receipts earned by an investment so that interest earned equals the original cost. See also **yield** on page Glossary-13.

issue date

The date a security is first offered for sale. That date usually determines when interest payments, known as coupons, are made.

Ito process

Statistical assumptions about the behavior of security prices. For details, see the book by Hull in “Derivatives Pricing and Yields” on page A-4.

Lambda

The percentage change in the price of an option relative to a 1% change in the price of the underlying security. Also known as elasticity.

long position

Outright ownership of a security or financial instrument. The owner expects the price to rise in order to make a profit on some future sale.

long rate

The yield on a zero-coupon Treasury bond.

lower partial moment

A model for the moments of asset returns that fall below a minimum acceptable level of return.

Macaulay duration

A widely used measure of price sensitivity to yield changes developed by Frederick Macaulay in 1938. It is measured in years and is a weighted average-time-to-maturity of an instrument. The Macaulay duration of an income stream, such as a coupon bond, measures how long, on average, the owner waits before receiving a payment. It is the weighted average of the times payments are made, with the weights at time T equal to the present value of the money received at time T .

Markowitz model

A model for selecting an optimum investment portfolio, devised by H. M. Markowitz. It uses a discrete-time, continuous-outcome approach

for modeling investment problems, often called the mean-variance paradigm. See also **efficient frontier** on page Glossary-5.

maturity date

The date when the issuer returns the final face value of a bond to the buyer.

mean

a. A number that typifies a set of numbers, such as a geometric mean or an arithmetic mean. **b.** The average value of a set of numbers.

modified duration

The Macaulay duration discounted by the per-period interest rate; that is, divided by $(1 + \text{rate}/\text{frequency})$.

Monte-Carlo simulation

A mathematical modeling process. For a model that has several parameters with statistical properties, pick a set of random values for the parameters and run a simulation. Then pick another set of values, and run it again. Run it many times (often 10,000 times) and build up a statistical distribution of outcomes of the simulation. This distribution of outcomes is then used to answer whatever question you are asking.

moving average

A price average that is adjusted by adding other parametrically determined prices over some time period.

moving-averages chart

A financial chart that plots leading and lagging moving averages for prices or values of an asset.

normal (bell-shaped) distribution

In statistics, a theoretical frequency distribution for a set of variable data, usually represented by a bell-shaped curve symmetrical about the mean.

odd first or last period

Fixed-income securities may be purchased on dates that do not coincide with coupon or payment dates. The length of the first and last periods may differ from the regular period between coupons, and thus the bond

owner is not entitled to the full value of the coupon for that period. Instead, the coupon is prorated according to how long the bond is held during that period.

option

A right to buy or sell specific securities or commodities at a stated price (exercise or strike price) within a specified time. An option is a type of derivative.

par value

The maturity or face value of a security or other financial instrument.

par yield curve

The yield curve of bonds selling at par, or face, value.

point and figure chart

A financial chart usually used to plot asset price data. Upward price movements are plotted as X's and downward price movements are plotted as O's.

present value

Today's value of an investment that yields some future value when invested to earn compounded interest at a known interest rate; that is, the future value at a known period in time discounted by the interest rate over that time period.

principal value

See **par value** on page Glossary-9.

purchase price

Price actually paid for a security. Typically the purchase price of a bond is not the same as the redemption value.

put

An option to sell a stipulated amount of stock or securities within a specified time and at a fixed exercise price. See also **call** on page Glossary-2.

puttable bond

A bond that allows the holder to redeem the bond at a predetermined price at specified future dates. The bond contains an embedded put option; that is, the holder has bought a put option. See also **callable bond** on page Glossary-2.

Quant

A quantitative analyst; someone who does numerical analysis of financial information in order to detect relationships, disparities, or patterns that can lead to making money.

redemption value

See **par value** on page Glossary-9.

regression analysis

Statistical analysis techniques that quantify the relationship between two or more variables. The intent is quantitative prediction or forecasting, particularly using a small population to forecast the behavior of a large population.

rho

The rate of change in a derivative's price relative to the underlying security's risk-free interest rate.

sensitivity

The "what if" relationship between variables; the degree to which changes in one variable cause changes in another variable. A specific synonym is volatility.

settlement date

The date when money first changes hands; that is, when a buyer actually pays for a security. It need not coincide with the issue date.

Sharpe ratio

The ratio of the excess return of an asset divided by the asset's standard deviation of returns.

short rate

The annualized one-period interest rate.

short sale, short position

The sale of a security or financial instrument not owned, in anticipation of a price decline and making a profit by purchasing the instrument later at a lower price, and then delivering the instrument to complete the sale. See also **long position** on page Glossary-7.

spot curve, spot yield curve

See **zero curve, zero-coupon yield curve** on page Glossary-13.

spot rate

The current interest rate appropriate for discounting a cash flow of some given maturity.

spread

For options, a combination of call or put options on the same stock with differing exercise prices or maturity dates.

standard deviation

A measure of the variation in a distribution, equal to the square root of the arithmetic mean of the squares of the deviations from the arithmetic mean; the square root of the variance.

stochastic

Involving or containing a random variable or variables; involving chance or probability.

straddle

A strategy used in trading options or futures. It involves simultaneously purchasing put and call options with the same exercise price and expiration date, and it is most profitable when the price of the underlying security is very volatile.

strike

Exercise a put or call option.

strike price

See **exercise price** on page Glossary-5.

swap

A contract between two parties to exchange cash flows in the future according to some formula.

swaption

A swap option; an option on an interest-rate swap. The option gives the holder the right to enter into a contracted interest-rate swap at a specified future date. See also **swap** on page Glossary-12.

term structure

The relationship between the yields on fixed-interest securities and their maturity dates. Expectation of changes in interest rates affects term structure, as do liquidity preferences and hedging pressure. A yield curve is one representation in the term structure.

theta

The rate of change in the price of a derivative security relative to time. Theta is usually very small or negative since the value of an option tends to drop as it approaches maturity.

tracking error

See **active risk** on page Glossary-1.

Treasury bill

Short-term U.S. government security issued at a discount from the face value and paying the face value at maturity.

Treasury bond

Long-term debt obligation of the U.S. government that makes coupon payments semi-annually and is sold at or near par value in \$1000 denominations or higher. Face value is paid at maturity.

variance

The dispersion of a variable. The square of the standard deviation.

vega

The rate of change in the price of a derivative security relative to the volatility of the underlying security. When vega is large, the security is sensitive to small changes in volatility.

volatility

a. Another general term for sensitivity. **b.** The standard deviation of the annualized continuously compounded rate of return of an asset. **c.** A measure of uncertainty or risk.

yield

a. Measure of return on an investment, stated as a percentage of price. Yield can be computed by dividing return by purchase price, current market value, or other measure of value. **b.** Income from a bond expressed as an annualized percentage rate. **c.** The nominal annual interest rate that gives a future value of the purchase price equal to the redemption value of the security. Any coupon payments determine part of that yield.

yield curve

Graph of yields (vertical axis) of a particular type of security versus the time to maturity (horizontal axis). This curve usually slopes upward, indicating that investors usually expect to receive a premium for securities that have a longer time to maturity. The benchmark yield curve is for U.S. Treasury securities with maturities ranging from three months to 30 years. See also **term structure** on page Glossary-12.

yield to maturity

A measure of the average rate of return that will be earned on a bond if held to maturity.

zero curve, zero-coupon yield curve

A yield curve for zero-coupon bonds; zero rates versus maturity dates. Since the maturity and duration (Macaulay duration) are identical for zeros, the zero curve is a pure depiction of supply/demand conditions for loanable funds across a continuum of durations and maturities. Also known as spot curve or spot yield curve.

zero-coupon bond, or zero

A bond that, instead of carrying a coupon, is sold at a discount from its face value, pays no interest during its life, and pays the principal only at maturity.
