- Set the block parameters to match the current settings in the GUI.

Here is the code for the `model_open` subfunction.

```
function model_open(handles)
if  isempty(find_system('Name','f14')),
 open_system('f14'); open_system('f14/Controller')
 set_param('f14/Controller/Gain','Position',[275 14 340 56])
 figure(handles.F14ControllerEditor)
 set_param('f14/Controller Gain','Gain',...
  get(handles.KfCurrentValue,'String'))
 set_param(...
      'f14/Controller/Proportional plus integral compensator',...
      'Numerator',...
      get(handles.KiCurrentValue,'String'))
end
```

Programming the Slider and Edit Text Components

This GUI employs a useful combination of components in its design. Each slider is coupled to an edit text component so that:

- The edit text displays the current value of the slider.
- The user can enter a value into the edit text box and cause the slider to update to that value.

- Both components update the appropriate model parameters when activated by the user.

Slider Callback

The GUI uses two sliders to specify block gains since these components enable the selection of continuous values within a specified range. When a user changes the slider value, the callback executes the following steps:

- Calls model_open to ensure that the Simulink model is open so that simulation parameters can be set.
- Gets the new slider value.
- Sets the value of the **Current value** edit text component to match the slider.
- Sets the appropriate block parameter to the new value (`set_param`).

Here is the callback for the **Proportional (Kf)** slider.

```
function KfValueSlider_Callback(hObject, eventdata, handles)
% Ensure model is open.
model_open(handles)
% Get the new value for the Kf Gain from the slider.
NewVal = get(hObject, 'Value');
% Set the value of the KfCurrentValue to the new value
% set by slider.
set(handles.KfCurrentValue,'String',NewVal)
% Set the Gain parameter of the Kf Gain Block to the new value.
set_param('f14/Controller/Gain','Gain',num2str(NewVal))
```

Note that, while a slider returns a number and the edit text requires a string, uicontrols automatically convert the values to the correct type.

The callback for the **Integral (Ki)** slider follows a similar approach.

Current Value Edit Text Callback

The edit text box enables users to type in a value for the respective parameter. When the user clicks on another component in the GUI after typing into the text box, the edit text callback executes the following steps:

- Calls model_open to ensure that the Simulink model is open so that it can set simulation parameters.
- Converts the string returned by the edit box `String` property to a double (`str2double`).
- Checks whether the value entered by the user is within the range of the slider:

  If the value is out of range, the edit text `String` property is set to the value of the slider (rejecting the number typed in by the user).

  If the value is in range, the slider `Value` property is updated to the new value.
- Sets the appropriate block parameter to the new value (`set_param`).

Here is the callback for the Kf **Current value** text box.

```
function KfCurrentValue_Callback(hObject, eventdata, handles)
% Ensure model is open.
model_open(handles)
% Get the new value for the Kf Gain.
NewStrVal = get(hObject, 'String');
NewVal = str2double(NewStrVal);
% Check that the entered value falls within the allowable range.
if  isempty(NewVal) || (NewVal< -5) || (NewVal>0),
   % Revert to last value, as indicated by KfValueSlider.
   OldVal = get(handles.KfValueSlider,'Value');
   set(hObject, 'String',OldVal)
else % Use new Kf value
   % Set the value of the KfValueSlider to the new value.
   set(handles.KfValueSlider,'Value',NewVal)
   % Set the Gain parameter of the Kf Gain Block
   % to the new value.
   set_param('f14/Controller/Gain','Gain',NewStrVal)
end
```

The callback for the Ki **Current value** follows a similar approach.

Running the Simulation from the GUI

The GUI **Simulate and store results** button callback runs the model simulation and stores the results in the `handles` structure. Storing data in the `handles` structure simplifies the process of passing data to other subfunction since this structure can be passed as an argument.

When a user clicks on the **Simulate and store results** button, the callback executes the following steps:

- Calls `sim`, which runs the simulation and returns the data that is used for plotting.
- Creates a structure to save the results of the simulation, the current values of the simulation parameters set by the GUI, and the run name and number.
- Stores the structure in the `handles` structure.
- Updates the list box `String` to list the most recent run.

Here is the **Simulate and store results** button callback.

```
function SimulateButton_Callback(hObject, eventdata, handles)
[timeVector,stateVector,outputVector] = sim('f14');
% Retrieve old results data structure
if isfield(handles,'ResultsData') &
~isempty(handles.ResultsData)
 ResultsData = handles.ResultsData;
 % Determine the maximum run number currently used.
 maxNum = ResultsData(length(ResultsData)).RunNumber;
 ResultNum = maxNum+1;
else % Set up the results data structure
 ResultsData = struct('RunName',[],'RunNumber',[],...
               'KiValue',[],'KfValue',[],'timeVector',[],...
               'outputVector',[]);
 ResultNum = 1;
end
if isequal(ResultNum,1),
 % Enable the Plot and Remove buttons
 set([handles.RemoveButton,handles.PlotButton],'Enable','on')
end
```

```
% Get Ki and Kf values to store with the data and put in the
results list.
Ki = get(handles.KiValueSlider,'Value');
Kf = get(handles.KfValueSlider,'Value');
ResultsData(ResultNum).RunName = ['Run',num2str(ResultNum)];
ResultsData(ResultNum).RunNumber = ResultNum;
ResultsData(ResultNum).KiValue = Ki;
ResultsData(ResultNum).KfValue = Kf;
ResultsData(ResultNum).timeVector = timeVector;
ResultsData(ResultNum).outputVector = outputVector;
% Build the new results list string for the listbox
ResultsStr = get(handles.ResultsList,'String');
if isequal(ResultNum,1)
 ResultsStr = {['Run1',num2str(Kf),' ',num2str(Ki)]};
else
 ResultsStr = [ResultsStr;...
 {['Run',num2str(ResultNum),' ',num2str(Kf),' ', ...
 num2str(Ki)]}];
end
set(handles.ResultsList,'String',ResultsStr);
% Store the new ResultsData
handles.ResultsData = ResultsData;
guidata(hObject, handles)
```

Removing Results from the List Box

The GUI **Remove** button callback deletes any selected item from the **Results list** list box. It also deletes the corresponding run data from the `handles` structure. When a user clicks on the **Remove** button, the callback executes the following steps:

- Determines which list box items are selected when a user clicks on the **Remove** button and removes these items from the list box `String` property by setting each item to the empty matrix `[]`.
- Removes the deleted data from the `handles` structure.
- Displays the string `<empty>` and disables the **Remove** and **Plot** buttons (using the `Enable` property), if all the items in the list box are removed.
- Save the changes to the `handles` structure (`guidata`).

Here is the **Remove** button callback.

```
function RemoveButton_Callback(hObject, eventdata, handles)
currentVal = get(handles.ResultsList,'Value');
resultsStr = get(handles.ResultsList,'String');
numResults = size(resultsStr,1);
% Remove the data and list entry for the selected value
resultsStr(currentVal) =[];
handles.ResultsData(currentVal)=[];
% If there are no other entries, disable the Remove and Plot
button
% and change the list string to <empty>
if isequal(numResults,length(currentVal)),
 resultsStr = {'<empty>'};
 currentVal = 1;

set([handles.RemoveButton,handles.PlotButton],'Enable','off')
end
% Ensure that list box Value is valid, then reset Value and String
currentVal = min(currentVal,size(resultsStr,1));
set(handles.ResultsList,'Value',currentVal,'String',resultsStr)
% Store the new ResultsData
guidata(hObject, handles)
```

Plotting the Results Data

The GUI **Plot** button callback creates a plot of the run data and adds a legend. The data to plot is passed to the callback in the `handles` structure, which also contains the gain settings used when the simulation ran. When a user clicks on the **Plot** button, the callback executes the following steps:

- Collects the data for each run selected in the **Results list**, including two variables (time vector and output vector) and a color for each result run to plot.
- Generates a string for the legend from the stored data.
- Creates the figure and axes for plotting and saves the handles for use by the **Close** button callback.
- Plots the data, adds a legend, and makes the figure visible.

Plotting Into the Hidden Figure

The figure that contains the plot is created invisible and then made visible after adding the plot and legend. To prevent this figure from becoming the target for plotting commands issued at the command line or by other GUIs, its `HandleVisibility` and `IntegerHandle` properties are set to `off`. However, this means the figure is also hidden from the `plot` and `legend` commands.

Use the following steps to plot into a hidden figure:

- Save the handle of the figure when you create it.
- Create an axes, set its `Parent` property to the figure handle, and save the axes handle.
- Create the plot (which is one or more line objects), save these line handles, and set their `Parent` properties to the handle of the axes.
- Make the figure visible.

Plot Button Callback Listing

Here is the **Plot** button callback.

```
function PlotButton_Callback(hObject, eventdata, handles)
currentVal = get(handles.ResultsList,'Value');
% Get data to plot and generate command string with color
% specified
legendStr = cell(length(currentVal),1);
plotColor = {'b','g','r','c','m','y','k'};
for ctVal = 1:length(currentVal);
 PlotData{(ctVal*3)-2} =
handles.ResultsData(currentVal(ctVal)).timeVector;
 PlotData{(ctVal*3)-1} =
handles.ResultsData(currentVal(ctVal)).outputVector;
 numColor = ctVal - 7*( floor((ctVal-1)/7) );
 PlotData{ctVal*3} = plotColor{numColor};
 legendStr{ctVal} = ...
      [handles.ResultsData(currentVal(ctVal)).RunName,'; Kf=',...
      num2str(handles.ResultsData(currentVal(ctVal)).KfValue),...
      ';  Ki=', ...
      num2str(handles.ResultsData(currentVal(ctVal)).KiValue)];
end
```

```
% If necessary, create the plot figure and store in handles
% structure
if ~isfield(handles,'PlotFigure') ||...
   ~ishandle(handles.PlotFigure),
 handles.PlotFigure = ...
        figure('Name','F14 Simulation Output',...
        'Visible','off','NumberTitle','off',...
        'HandleVisibility','off','IntegerHandle','off');
 handles.PlotAxes = axes('Parent',handles.PlotFigure);
 guidata(hObject, handles)
end
% Plot data
pHandles = plot(PlotData{:},'Parent',handles.PlotAxes);
% Add a legend, and bring figure to the front
legend(pHandles(1:2:end),legendStr{:})
% Make the figure visible and bring it forward
figure(handles.PlotFigure)
```

The GUI Help Button

The GUI **Help** button callback displays an HTML file in the MATLAB Help browser. It uses two commands:

- The `which` command returns the full path to the file when it is on the MATLAB path
- The `web` command displays the file in the Help browser.

This is the **Help** button callback.

```
function HelpButton_Callback(hObject, eventdata, handles)
HelpPath = which('f14ex_help.html');
web(HelpPath);
```

You can also display the help document in a Web browser or load an external URL. See the Web documentation for a description of these options.

Closing the GUI

The GUI **Close** button callback closes the plot figure, if one exists and then closes the GUI. The handle of the plot figure and the GUI figure are available from the `handles` structure. The callback executes two steps:

- Checks to see if there is a `PlotFigure` field in the `handles` structure and if it contains a valid figure handle (the user could have closed the figure manually).
- Closes the GUI figure

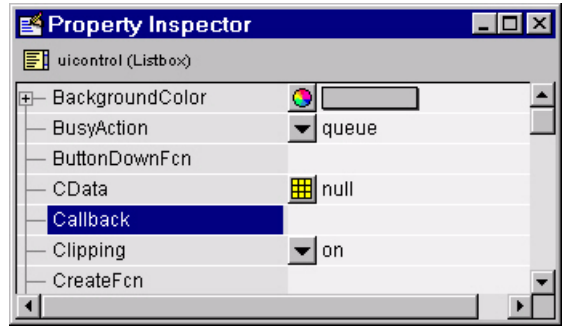
This is the **Close** button callback.

```
function CloseButton_Callback(hObject, eventdata, handles)
% Close the GUI and any plot window that is open
if isfield(handles,'PlotFigure') && ...
      ishandle(handles.PlotFigure),
   close(handles.PlotFigure);
end
close(handles.F14ControllerEditor);
```

The List Box Callback and Create Function

This GUI does not use the list box callback since the actions performed on list box items are carried out by push buttons (**Simulate and store results**, **Remove**, and **Plot**). However, GUIDE automatically inserts a callback stub when you add the list box and automatically sets the `Callback` property to execute this subfunction whenever the callback is triggered (which happens when users select an item in the list box).

In this case, there is no need for the list box callback to execute, so you should delete it from the GUI M-file. It is important to remember to also delete the `Callback` property string so MATLAB does not attempt to execute the callback. You can do this using the property inspector:



See the description of list box for more information on how to trigger the list box callback.

Setting the Background to White

The list box create function enables you to determine the background color of the list box. The following code shows the create function for the list box that is tagged `ResultsList`.

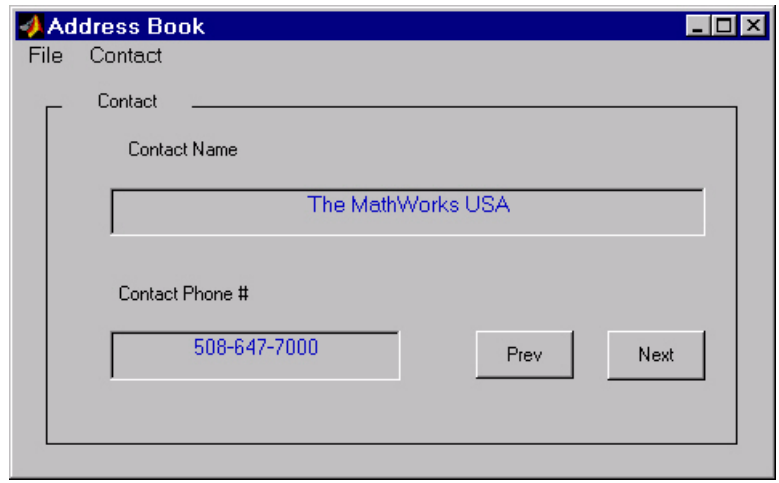
```
function ResultsList_CreateFcn(hObject, eventdata, handles)
% Hint: listbox controls usually have a white background, change
%       'usewhitebg' to 0 to use default. See ISPC and COMPUTER.
usewhitebg = 1;
if usewhitebg
    set(hObject,'BackgroundColor','white');
else
set(hObject,'BackgroundColor',...
    get(0,'defaultUicontrolBackgroundColor'));
end
```

An Address Book Reader

In this section...

Address Book Reader Example Outcome

This example shows how to implement a GUI that displays names and phone numbers, which it reads from a MAT-file.



Techniques Used in This Example

This example demonstrates the following GUI programming techniques:

- Uses open and save dialogs to provide a means for users to locate and open the address book MAT-files and to save revised or new address book MAT-files.
- Defines callbacks written for GUI menus.
- Uses the GUI's `handles` structure to save and recall shared data.
- Uses a GUI figure resize function.

Managing Shared Data

One of the key techniques illustrated in this example is how to keep track of information and make it available to the various subfunctions. This information includes

- The name of the current MAT-file
- The names and phone numbers stored in the MAT-file
- An index pointer that indicates the current name and phone number, which must be updated as the user pages through the address book

- The figure position and size
- The handles of all GUI components

The descriptions of the subfunctions that follow illustrate how to save and retrieve information from the `handles` structure. See “handles Structure” on page 8-15 for background information on this structure.

View Completed Layout and Its GUI M-File

If you are reading this in the MATLAB Help browser, you can click the following links to display the GUIDE Layout Editor and the MATLAB Editor with a completed version of this example. This enables you to see the values of all component properties and to understand how the components are assembled to create the GUI. You can also see a complete listing of the code that is discussed in the following sections.

Note The following links execute MATLAB commands and are designed to work within the MATLAB Help browser. If you are reading this online or in PDF, you should go to the corresponding section in the MATLAB Help Browser to use the links.

- Click here to display this GUI in the Layout Editor.
- Click here to display the GUI M-file in the MATLAB Editor.

Running the GUI

The GUI is nonblocking and nonmodal since it is designed to be displayed while you perform other MATLAB tasks.

GUI Option Settings

This GUI uses the following GUI option settings:

- Resize behavior: **User-specified**
- Command-line accessibility: **Off**
- GUI M-file options selected:

- Generate callback function prototypes
- Application allows only one instance to run

Calling the GUI

You can call the GUI M-file with no arguments, in which case the GUI uses the default address book MAT-file, or you can specify an alternate MAT-file from which the GUI reads information. In this example, the user calls the GUI with a pair of arguments, `address_book('book', 'my_list.mat')`. The first argument, `'book'`, is a key word that the M-file looks for in the opening function. If the M-file finds the key word, it knows to use the second argument as the MAT-file for the address book. Calling the GUI with this syntax is analogous to calling it with a valid property-value pair, such as `('color', 'red')`. However, since `'book'` is not a valid figure property, in this example the opening function in the M-file includes code to recognize the pair `('book', 'my_list.mat')`.

Note that it is not necessary to use the key word `'book'`. You could program the M-file to accept just the MAT-file as an argument, using the syntax `address_book('my_list.mat')`. The advantage of calling the GUI with the pair `('book', 'my_list.mat')` is that you can program the GUI to accept other user arguments, as well as valid figure properties, using the property-value pair syntax. The GUI can then identify which property the user wants to specify from the property name.

The following code shows how to program the opening function to look for the key word `'book'`, and if it finds the key word, to use the MAT-file specified by the second argument as the list of contacts.

```
function address_book_OpeningFcn(hObject, eventdata,...
    handles, varargin)
% Choose default command line output for address_book
handles.output = hObject;
% Update handles structure
guidata(hObject, handles);
% User added code follows
if nargin < 4
    % Load the default address book
    Check_And_Load([],handles);
    % If the first element in varargin is 'book' and
```

```
    & the second element is a MATLAB file, then load that file
elseif (length(varargin) == 2 && ...
       strcmpi(varargin{1},'book') && ...
       (2 == exist(varargin{2},'file')))
    Check_And_Load(varargin{2},handles);
else
    errordlg('File Not Found','File Load Error')
    set(handles.Contact_Name,'String','')
    set(handles.Contact_Phone,'String','')
end
```

Loading an Address Book Into the Reader

There are two ways in which an address book (i.e., a MAT-file) is loaded into the GUI:

- When running the GUI, you can specify a MAT-file as an argument. If you do not specify an argument, the GUI loads the default address book (`addrbook.mat`).
- The user can select **Open** under the **File** menu to browse for other MAT-files.

Validating the MAT-file

To be a valid address book, the MAT-file must contain a structure called `Addresses` that has two fields called `Name` and `Phone`. The `Check_And_Load` subfunction validates and loads the data with the following steps:

- Loads (`load`) the specified file or the default if none is specified.
- Determines if the MAT-file is a valid address book.
- Displays the data if it is valid. If it is not valid, displays an error dialog (`errordlg`).
- Returns `1` for valid MAT-files and `0` if invalid (used by the **Open** menu callback)
- Saves the following items in the `handles` structure:
  - The name of the MAT-file
  - The `Addresses` structure

- An index pointer indicating which name and phone number are currently displayed

Check_And_Load Code Listing

This is the `Check_And_Load` function.

```
function pass = Check_And_Load(file,handles)
% Initialize the variable "pass" to determine if this is
% a valid file.
pass = 0;
% If called without any file then set file to the default
% filename.
% Otherwise, if the file exists then load it.
if isempty(file)
 file = 'addrbook.mat';
 handles.LastFile = file;
 guidata(handles.Address_Book,handles)
end
if exist(file) == 2
 data = load(file);
end
% Validate the MAT-file
% The file is valid if the variable is called "Addresses"
% and it has fields called "Name" and "Phone"
flds = fieldnames(data);
if (length(flds) == 1) && (strcmp(flds{1},'Addresses'))
 fields = fieldnames(data.Addresses);
 if (length(fields) == 2) && ...
         (strcmp(fields{1},'Name')) && ...
         (strcmp(fields{2},'Phone'))
       pass = 1;
 end
end
% If the file is valid, display it
if pass
 % Add Addresses to the handles structure
 handles.Addresses = data.Addresses;
 guidata(handles.Address_Book,handles)
 % Display the first entry
```

```
 set(handles.Contact_Name,'String',data.Addresses(1).Name)
 set(handles.Contact_Phone,'String',data.Addresses(1).Phone)
 % Set the index pointer to 1 and save handles
 handles.Index = 1;
 guidata(handles.Address_Book,handles)
else
 errordlg('Not a valid Address Book','Address Book Error')
end
```

The Open Menu Callback

The address book GUI contains a **File** menu that has an **Open** submenu for loading address book MAT-files. When selected, **Open** displays a dialog (`uigetfile`) that enables the user to browse for files. The dialog displays only MAT-files, but users can change the filter to display all files.

The dialog returns both the filename and the path to the file, which is then passed to `fullfile` to ensure the path is properly constructed for any platform. `Check_And_Load` validates and load the new address book.

Open_Callback Code Listing

```
function Open_Callback(hObject, eventdata, handles)
[filename, pathname] = uigetfile( ...
 {'*.mat', 'All MAT-Files (*.mat)'; ...
  '*.*','All Files (*.*)'}, ...
 'Select Address Book');
% If "Cancel" is selected then return
if isequal([filename,pathname],[0,0])
 return
% Otherwise construct the fullfilename and Check and load
% the file
else
 File = fullfile(pathname,filename);
 % if the MAT-file is not valid, do not save the name
 if Check_And_Load(File,handles)
  handles.LastFIle = File;
  guidata(hObject, handles)
 end
end
```

See the “Creating Menus” on page 6-70 section for information on creating the menu.

The Contact Name Callback

The **Contact Name** text box displays the name of the address book entry. If you type in a new name and press enter, the callback performs these steps:

- If the name exists in the current address book, the corresponding phone number is displayed.
- If the name does not exist, a question dialog (`questdlg`) asks you if you want to create a new entry or cancel and return to the name previously displayed.
- If you create a new entry, you must save the MAT-file with the **File > Save** menu.

Storing and Retrieving Data

This callback makes use of the `handles` structure to access the contents of the address book and to maintain an index pointer (`handles.Index`) that enables the callback to determine what name was displayed before it was changed by the user. The index pointer indicates what name is currently displayed. The address book and index pointer fields are added by the `Check_And_Load` function when the GUI is run.

If the user adds a new entry, the callback adds the new name to the address book and updates the index pointer to reflect the new value displayed. The updated address book and index pointer are again saved (`guidata`) in the `handles` structure.

Contact Name Callback

```
function Contact_Name_Callback(hObject, eventdata, handles)
% Get the strings in the Contact Name and Phone text box
Current_Name = get(handles.Contact_Name,'string');
Current_Phone = get(handles.Contact_Phone,'string');
% If empty then return
if isempty(Current_Name)
 return
```

```
end
% Get the current list of addresses from the handles structure
Addresses = handles.Addresses;
% Go through the list of contacts
% Determine if the current name matches an existing name
for i = 1:length(Addresses)
 if strcmp(Addresses(i).Name,Current_Name)
  set(handles.Contact_Name,'string',Addresses(i).Name)
  set(handles.Contact_Phone,'string',Addresses(i).Phone)
  handles.Index = i;
  guidata(hObject, handles)
  return
 end
end
% If it's a new name, ask to create a new entry
Answer=questdlg('Do you want to create a new entry?', ...
 'Create New Entry', ...
 'Yes','Cancel','Yes');
switch Answer
case 'Yes'
 Addresses(end+1).Name = Current_Name; % Grow array by 1
 Addresses(end).Phone = Current_Phone;
 index = length(Addresses);
 handles.Addresses = Addresses;
 handles.Index = index;
 guidata(hObject, handles)
 return
case 'Cancel'
 % Revert back to the original number

set(handles.Contact_Name,'String',Addresses(handles.Index).Name
)

set(handles.Contact_Phone,'String',Addresses(handles.Index).Pho
ne)
 return
end
```

The Contact Phone Number Callback

The **Contact Phone #** text box displays the phone number of the entry listed in the **Contact Name** text box. If you type in a new number click one of the push buttons, the callback opens a question dialog that asks you if you want to change the existing number or cancel your change.

Like the **Contact Name** text box, this callback uses the index pointer (`handles.Index`) to update the new number in the address book and to revert to the previously displayed number if the user selects **Cancel** from the question dialog. Both the current address book and the index pointer are saved in the `handles` structure so that this data is available to other callbacks.

If you create a new entry, you must save the MAT-file with the **File > Save** menu.

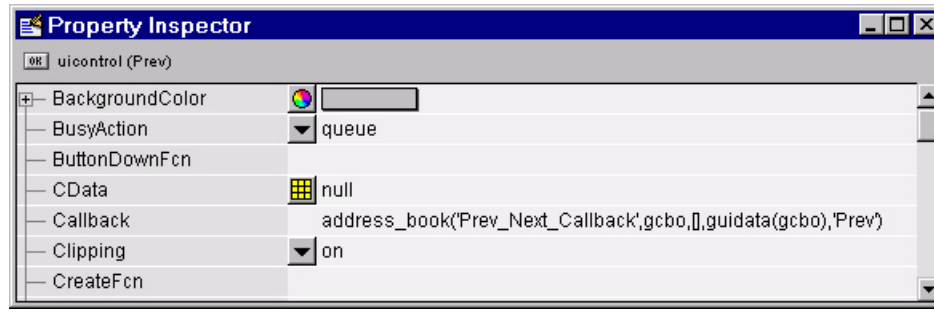
Code Listing

```
function Contact_Phone_Callback(hObject, eventdata, handles)
Current_Phone = get(handles.Contact_Phone,'string');
% If either one is empty then return
if isempty(Current_Phone)
 return
end
% Get the current list of addresses from the handles structure
Addresses = handles.Addresses;
Answer=questdlg('Do you want to change the phone number?', ...
 'Change Phone Number', ...
 'Yes','Cancel','Yes');
switch Answer
case 'Yes'
 % If no name match was found create a new contact
 Addresses(handles.Index).Phone = Current_Phone;
 handles.Addresses = Addresses;
 guidata(hObject, handles)
 return
case 'Cancel'
 % Revert back to the original number
 set(handles.Contact_Phone,...
       'String',Addresses(handles.Index).Phone)
```

```
    return
end
```

Paging Through the Address Book — Prev/Next

The **Prev** and **Next** buttons page back and forth through the entries in the address book. Both push buttons use the same callback, `Prev_Next_Callback`. You must set the `Callback` property of both push buttons to call this subfunction, as the following illustration of the **Prev** push button `Callback` property setting shows.



Determining Which Button Is Clicked

The callback defines an additional argument, `str`, that indicates which button, **Prev** or **Next**, was clicked. For the **Prev** button `Callback` property (illustrated above), the `Callback` string includes `'Prev'` as the last argument. The **Next** button `Callback` string includes `'Next'` as the last argument. The value of `str` is used in `case` statements to implement each button's functionality (see the code listing below).

Paging Forward or Backward

`Prev_Next_Callback` gets the current index pointer and the addresses from the `handles` structure and, depending on which button the user presses, the index pointer is decremented or incremented and the corresponding address and phone number are displayed. The final step stores the new value for the index pointer in the `handles` structure and saves the updated structure using `guidata`.

Code Listing

```
function Prev_Next_Callback(hObject, eventdata,handles,str)
% Get the index pointer and the addresses
index = handles.Index;
Addresses = handles.Addresses;
% Depending on whether Prev or Next was clicked,
% change the display
switch str
case 'Prev'
 % Decrease the index by one
 i = index - 1;
 % If the index is less than one then set it equal to the index
   %  of the last element in the Addresses array
 if i < 1
  i = length(Addresses);
 end
case 'Next'
 % Increase the index by one
 i = index + 1;
 % If the index is greater than the size of the array then
 % point to the first item in the Addresses array
 if i > length(Addresses)
  i = 1;
 end
end
% Get the appropriate data for the index in selected
Current_Name = Addresses(i).Name;
Current_Phone = Addresses(i).Phone;
set(handles.Contact_Name,'string',Current_Name)
set(handles.Contact_Phone,'string',Current_Phone)
% Update the index pointer to reflect the new index
handles.Index = i;
guidata(hObject, handles)
```

Saving Changes to the Address Book from the Menu

When you make changes to an address book, you need to save the current MAT-file, or save it as a new MAT-file. The **File** submenus **Save** and **Save As** enable you to do this. These menus, created with the Menu Editor, use the same callback, `Save_Callback`.

The callback uses the menu `Tag` property to identify whether **Save** or **Save As** is the callback object (i.e., the object whose handle is passed in as the first argument to the callback function). You specify the menu's `Tag` property with the Menu Editor.

Saving the Addresses Structure

The `handles` structure contains the `Addresses` structure, which you must save (`handles.Addresses`) as well as the name of the currently loaded MAT-file (`handles.LastFile`). When the user makes changes to the name or number, the `Contact_Name_Callback` or the `Contact_Phone_Callback` updates `handles.Addresses`.

Saving the MAT-File

If the user selects **Save**, the `save` command is called to save the current MAT-file with the new names and phone numbers.

If the user selects **Save As**, a dialog is displayed (`uiputfile`) that enables the user to select the name of an existing MAT-file or specify a new file. The dialog returns the selected filename and path. The final steps include

- Using `fullfile` to create a platform-independent pathname.
- Calling `save` to save the new data in the MAT-file.
- Updating the `handles` structure to contain the new MAT-file name.
- Calling `guidata` to save the `handles` structure.

Save_Callback Code Listing

```
function Save_Callback(hObject, eventdata, handles)
% Get the Tag of the menu selected
Tag = get(hObject, 'Tag');
% Get the address array
Addresses = handles.Addresses;
% Based on the item selected, take the appropriate action
switch Tag
case 'Save'
 % Save to the default addrbook file
 File = handles.LastFile;
```

```
 save(File,'Addresses')
case 'Save_As'
 % Allow the user to select the file name to save to
 [filename, pathname] = uiputfile( ...
  {'*.mat';'*.*'}, ...
  'Save as');
 % If 'Cancel' was selected then return
 if isequal([filename,pathname],[0,0])
  return
 else
  % Construct the full path and save
  File = fullfile(pathname,filename);
  save(File,'Addresses')
  handles.LastFile = File;
  guidata(hObject, handles)
 end
end
```

The Create New Menu

The **Create New** menu simply clears the **Contact Name** and **Contact Phone #** text fields to facilitate adding a new name and number. After making the new entries, the user must then save the address book with the **Save** or **Save As** menus. This callback sets the text `String` properties to empty strings:

```
function New_Callback(hObject, eventdata, handles)
set(handles.Contact_Name,'String','')
set(handles.Contact_Phone,'String','')
```

The Address Book Resize Function

The address book defines its own resize function. To use this resize function, you must set the Application Options dialog **Resize behavior** to `User-specified`, which in turn sets the figure's `ResizeFcn` property to:

```
address_book('ResizeFcn',gcbo,[],guidata(gcbo))
```

Whenever the user resizes the figure, MATLAB calls the `ResizeFcn` subfunction in the address book M-file (`address_book.m`)

Behavior of the Resize Function

The `resize` function allows users to make the figure wider, to accommodate long names and numbers, but does not allow the figure to be made narrower than its original width. Also, users cannot change the height. These restrictions do not limit the usefulness of the GUI and simplify the `resize` function, which must maintain the proper proportions between the figure size and the components in the GUI.

When the user resizes the figure and releases the mouse, the resize function executes. At that point, the resized figure's dimensions are saved. The following sections describe how the `resize` function handles the various possibilities.

Changing the Width

If the new width is greater than the original width, set the figure to the new width.

The size of the **Contact Name** text box changes in proportion to the new figure width. This is accomplished by:

- Changing the `Units` of the text box to `normalized`.
- Resetting the width of the text box to be 78.9% of the figure's width.
- Returning the `Units` to `characters`.

If the new width is less than the original width, use the original width.

Changing the Height

If the user attempts to change the height, use the original height. However, because the resize function is triggered when the user releases the mouse button after changing the size, the resize function cannot always determine the original position of the GUI on screen. Therefore, the resize function applies a compensation to the vertical position (second element in the figure `Position` vector) by adding the vertical position when the mouse is released to the height when mouse is released and subtracting the original height.

When the figure is resized from the bottom, it stays in the same position. When resized from the top, the figure moves to the location where the mouse button is released.

Ensuring the Resized Figure Is On Screen

The `resize` function calls `movegui` to ensure that the resized figure is on screen regardless of where the user releases the mouse.

When the GUI is first run, it is displayed at the size and location specified by the figure `Position` property. You can set this property with the Property Inspector when you create the GUI.

Code Listing

```
function ResizeFcn(hObject, eventdata, handles)
% Get the figure size and position
Figure_Size = get(hObject, 'Position');
% Set the figure's original size in character units
Original_Size = [ 0 0 94 19.230769230769234];
% If the resized figure is smaller than the
% original figure size then compensate.
if (Figure_Size(3)<Original_Size(3)) | ...
   (Figure_Size(4) ~= Original_Size(4))
   if Figure_Size(3) < Original_Size(3)
       % If the width is too small then reset to origianl width.
       set(hObject, 'Position',...
           [Figure_Size(1), Figure_Size(2), ...
            Original_Size(3), Original_Size(4)])
       Figure_Size = get(hObject, 'Position');
   end
   if Figure_Size(4) ~= Original_Size(4)
       % Do not allow the height to change.
       set(hObject, 'Position',...
           [Figure_Size(1),...
            Figure_Size(2)+Figure_Size(4)-Original_Size(4),...
            Figure_Size(3), Original_Size(4)])
   end
end
% Adjust the size of the Contact Name text box.
```

```
% Set the units of the Contact Name field to 'Normalized'.
set(handles.Contact_Name,'units','normalized')
% Get its Position.
C_N_pos = get(handles.Contact_Name,'Position');
% Reset it so that it's width remains normalized.
% relative to figure.
set(handles.Contact_Name,'Position',...
 [C_N_pos(1) C_N_pos(2)  0.789 C_N_pos(4)])
% Return the units to 'Characters'.
set(handles.Contact_Name,'units','characters')
% Reposition GUI on screen.
movegui(hObject, 'onscreen')
```

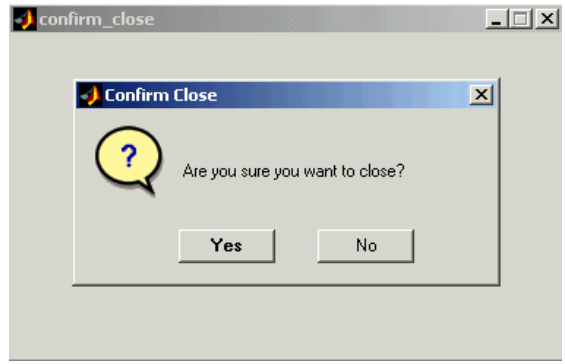
Using a Modal Dialog to Confirm an Operation

In this section...

Modal Dialog Example Outcome

This example illustrates how to use the modal dialog GUI together with another GUI that has a **Close** button. Clicking the **Close** button displays the modal dialog, which asks users to confirm that they really want to proceed with the close operation.

The following figure illustrates the dialog positioned over the GUI application, awaiting the user's response.



View Completed Layouts and Their GUI M-Files

If you are reading this in the MATLAB Help Browser, you can click the following links to display the GUIDE Layout Editor and the MATLAB Editor

with a completed version of this example. This enables you to see the values of all component properties and to understand how the components are assembled to create the GUI. You can also see a complete listing of the code that is discussed in the following sections.

Note The following links execute MATLAB commands and are designed to work within the MATLAB Help browser. If you are reading this online or in PDF, you should go to the corresponding section in the MATLAB Help Browser to use the links.

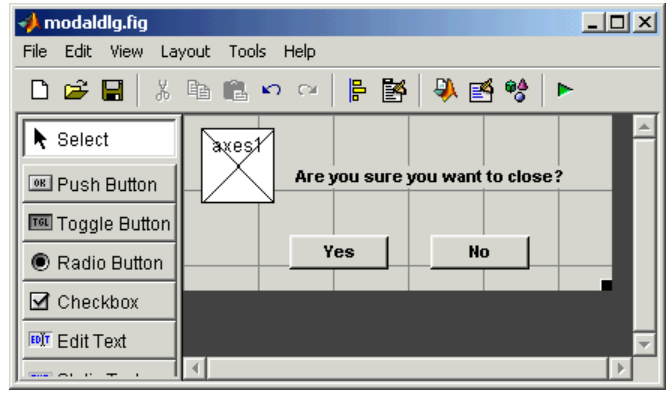
- Click here to display the GUIs in the Layout Editor.
- Click here to display the GUI M-files in the editor.

Setting Up the Close Confirmation Dialog

To set up the dialog, do the following:

1. Select **New** from the **File** menu in the GUIDE Layout Editor.
2. In the **GUIDE Quick Start** dialog, select the **Modal Question Dialog** template and click **OK**.
3. Right-click the static text, `Do you want to create a question dialog?`, in the Layout Editor and select **Property Inspector** from the pop-up menu.
4. Scroll down to `String` in the Property Inspector and change the `String` property to `Are you sure you want to close?`
5. Select **Save** from the **File** menu and type `modaldlg.fig` in the **File name** field.

The GUI should now appear as in the following figure.



Setting Up the GUI with the Close Button

To set up the second GUI with a **Close** button, do the following:

1. Select **New** from the **File** menu in the GUIDE Layout Editor.
2. In the **GUIDE Quick Start** dialog, select **Blank GUI (Default)** and click **OK**. This opens the blank GUI in a new Layout Editor window.
3. Drag a push button from the Component palette of the Layout Editor into the layout area.
4. Right-click the push button and select **Property Inspector** from the pop-up menu.
5. Change the `String` property to `Close`.
6. Change the `Tag` property to `close_pushbutton`.
7. Click the M-file Editor icon on the toolbar of the Layout Editor.
8. Click the Show functions icon on the toolbar of the M-file editor and select `close_pushbutton_Callback` from the menu.

   The following generated code for the **Close** button callback should appear in the M-file editor:

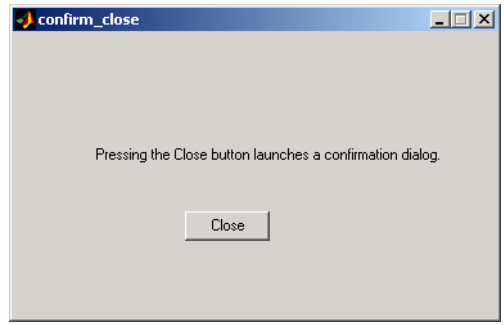
```
% --- Executes on button press in close_pushbutton.
function close_pushbutton_Callback(hObject, eventdata, handles)
% hObject    handle to close_pushbutton (see GCBO)
% eventdata  reserved - to be defined in a future version of MATLAB
% handles    structure with handles and user data (see GUIDATA)
```

9 After these comments, add the following code:

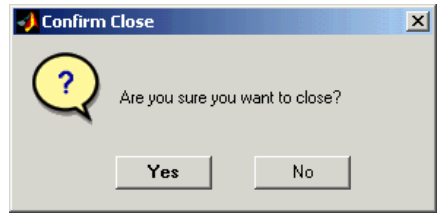
```
% Get the current position of the GUI from the handles structure
% to pass to the modal dialog.
pos_size = get(handles.figure1,'Position');
% Call modaldlg with the argument 'Position'.
user_response = modaldlg('Title','Confirm Close');
switch user_response
case {'No'}
 % take no action
case 'Yes'
 % Prepare to close GUI application window
 %                  .
 %                  .
 %                  .
 delete(handles.figure1)
end
```

Running the GUI with the Close Button

Run the GUI with the **Close** button by clicking the **Run** button on the Layout Editor toolbar. The GUI appears as in the following figure:



When you click the **Close** button on the GUI, the modal dialog appears as shown in the following figure:



Clicking the **Yes** button closes both the close dialog and the GUI that calls it. Clicking the **No** button closes just the dialog.

How the GUI and Dialog Work

This section describes what occurs when you click the **Close** button on the GUI:

1. User clicks the **Close** button. Its callback then
   - Gets the current position of the GUI from the `handles` structure with the command

     ```
     pos_size = get(handles.figure1,'Position')
     ```

   - Calls the modal dialog with the command

     ```
     user_response = modaldlg('Title','Confirm Close');
     ```

     This is an example of calling a GUI with a property value pair. In this case, the figure property is `'Title'`, and its value is the string `'Confirm Close'`. Opening `modaldlg` with this syntax displays the text "Confirm Close" at the top of the dialog.
2. The modal dialog opens with the `'Position'` obtained from the GUI that calls it.
3. The opening function in the modal dialog M-file:
   - Makes the dialog modal.

- Executes the `uiwait` command, which causes the dialog to wait for the user to click the **Yes** button or the **No** button, or click the close box (`X`) on the window border.

4 When a user clicks one of the two push buttons, the callback for the push button

- Updates the output field in the `handles` structure
- Executes `uiresume` to return control to the opening function where `uiwait` is called.

5 The output function is called, which returns the string `Yes` or `No` as an output argument, and deletes the dialog with the command

```
delete(handles.figure1)
```

6 When the GUI with the **Close** button regains control, it receives the string `Yes` or `No`. If the answer is `'No'`, it does nothing. If the answer is `'Yes'`, the **Close** button callback closes the GUI with the command

```
delete(handles.figure1)
```

Creating GUIs Programmatically

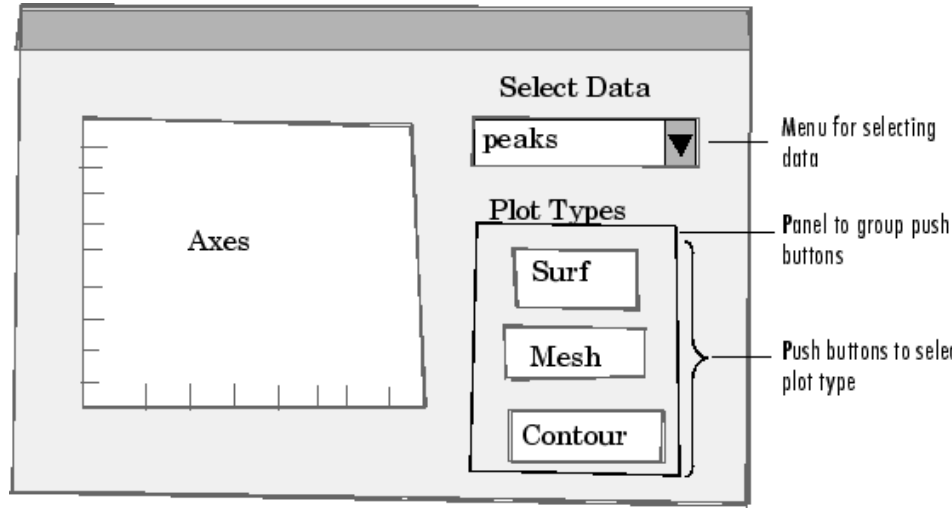
Laying Out a GUI

Designing a GUI

Before creating the actual GUI, it is important to decide what it is you want your GUI to do and how you want it to work. It is helpful to draw your GUI on paper and envision what the user sees and what actions the user takes.

Note MATLAB provides a selection of standard dialog boxes that you can create with a single function call. For information about these dialog boxes and the functions used to create them, see "Predefined Dialog Boxes" in the MATLAB Function Reference documentation.

The GUI used in this example contains an axes component that displays either a surface, mesh, or contour plot of data selected from the pop-up menu. The following picture shows a sketch that you might use as a starting point for the design.



A panel contains three push buttons that enable you to choose the type of plot you want. The pop-up menu contains three strings—`peaks`, `membrane`, and `sinc`, which correspond to MATLAB functions and generate data to plot. You can select the data to plot from this menu.

Many Web sites and commercial publications such as the following provide guidelines for designing GUIs:

- AskTog — Essays on good design and a list of First Principles for good user interface design. The author, Tognazzini, is a well-respected user interface designer. `http://www.asktog.com/basics/firstPrinciples.html`.
- Galitz, Wilbert, O., *Essential Guide to User Interface Design*. Wiley, New York, NY, 2002.
- GUI Design Handbook — A detailed guide to the use of GUI controls. `http://www.fast-consulting.com/GUI%20Design%20Handbook/GDH_FRNTMTR.htm`.
- Johnson, J., *GUI Bloopers: Don'ts and Do's for Software Developers and Web Designers*. Morgan Kaufmann, San Francisco, CA, 2000.
- Usability Glossary — An extensive glossary of terms related to GUI design, usability, and related topics. `http://www.usabilityfirst.com/glossary/main.cgi`.
- UsabilityNet — Covers design principles, user-centered design, and other usability and design-related topics. `http://www.usabilitynet.org/management/b_design.htm`.

Creating and Running the GUI M-File

In this section...

Note For an example of creating an M-file, see Chapter 3, "Creating a Simple GUI Programmatically" in the "Getting Started" part of this document.

File Organization

Typically, a GUI M-file has the following ordered sections. You can help to maintain the organization by adding comments that name the sections when you first create them.

1. Comments displayed in response to the MATLAB `help` command.
2. Initialization tasks such as data creation and any processing that is needed to construct the components. See "Initializing the GUI" on page 12-4 for more information.
3. Construction of figure and components. For more information, see "Creating the GUI Figure" on page 11-7 and "Adding Components to the GUI" on page 11-10.
4. Initialization tasks that require the components to exist, and output return. See "Initializing the GUI" on page 12-4 for more information.
5. Callbacks for the components. Callbacks are the routines that execute in response to user-generated events such as mouse clicks and key strokes. See Chapter 12, "Programming the GUI" for more information.
6. Utility functions.

File Template

This is a template for a GUI M-file:

```
function varargout = mygui(varargin)
% MYGUI Brief description of GUI.
%       Comments displayed at the command line in response
%       to the help command.

% (Leave a blank line following the help.)

%  Initialization tasks

%  Construct the components

%  Initialization tasks

%  Callbacks for MYGUI

%  Utility functions for MYGUI

end
```

The `end` statement that matches the `function` statement is necessary because this document treats GUI creation using nested functions. Chapter 12, “Programming the GUI” addresses this topic.

Save the file in your current directory or at a location that is on your MATLAB path.

Running the GUI

You can display your GUI at any time by executing its M-file. For example, if your GUI M-file is `mygui.m`, type

```
mygui
```

at the command line. Provide run-time arguments as appropriate. The files must reside on your path or in your current directory.

When you execute the GUI M-file, a fully functional copy of the GUI displays on the screen. You can manipulate components that it contains, but nothing happens unless the M-file includes code to initialize the GUI and callbacks

to service the components. Chapter 12, “Programming the GUI” tells you how to do this.

Creating the GUI Figure

In MATLAB, a GUI is a figure. Before you add components to it, create the figure explicitly and obtain a handle for it. In the initialization section of your file, use a statement such as the following to create the figure:

```
fh = figure;
```

where `fh` is the figure handle.

Note If you create a component when there is no figure, MATLAB creates a figure automatically but you do not know the figure handle.

When you create the figure, you can also specify properties for the figure. The most commonly used figure properties are shown in the following table:

Property	Values	Description
`MenuBar`	`figure`, `none`. Default is `figure`.	Display or hide the MATLAB standard menu bar menus. If `none` and there are no user-created menus, the menu bar itself is removed.
`Name`	String	Title displayed in the figure window. If `NumberTitle` is `on`, this string is appended to the figure number.
`NumberTitle`	`on`, `off`. Default is `on`.	Determines whether the string 'Figure `n`' (where `n` is the figure number) is prefixed to the figure window title specified by `Name`.
`Position`	4-element vector: [distance from left, distance from bottom, width, height].	Size of the GUI figure and its location relative to the lower-left corner of the screen.

Property	Values	Description
`Resize`	`on`, `off`. Default is `on`.	Determines if the user can resize the figure window with the mouse.
`Toolbar`	`auto`, `none`, `figure`. Default is `auto`.	Display or hide the default figure toolbar. • `none` — do not display the figure toolbar. • `auto` — display the figure toolbar, but remove it if a user interface control (`uicontrol`) is added to the figure. • `figure` — display the figure toolbar.
`Units`	`pixels`, `centimeters`, `characters`, `inches`, `normalized`, `points`, Default is `pixels`.	Units of measurement used to interpret position vector
`Visible`	`on`, `off`. Default is `on`.	Determines whether a figure is displayed on the screen.

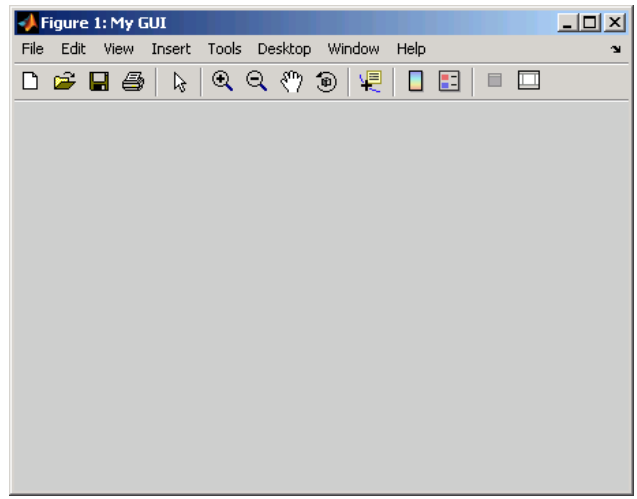
For a complete list of properties and for more information about the properties listed in the table, see the Figure Properties reference page in the MATLAB reference documentation.

The following statement names the figure My GUI, positions the figure on the screen, and makes the GUI invisible so that the user cannot see the components as they are added or initialized. All other properties assume their defaults.

```
f = figure('Visible','off','Name','My GUI',...
           'Position',[360,500,450,285]);
```

The `Position` property is a four-element vector that specifies the location of the GUI on the screen and its size: [distance from left, distance from bottom, width, height]. Default units are pixels.

If the figure were visible, it would look like this:



The next topic, “Adding Components to the GUI” on page 11-10, shows you how to add push buttons, axes, and other components to the GUI. “Creating Menus” on page 11-45 shows you how to create toolbar and context menus. “Creating Toolbars” on page 11-56 shows you how to add your own toolbar to a GUI.

Adding Components to the GUI

In this section...

Available Components

Components include user interface controls such as push buttons and sliders, containers such as panels and button groups, axes, and ActiveX controls. This topic tells you how to populate your GUI with these components.

Note MATLAB provides a selection of standard dialog boxes that you can create with a single function call. For information about these dialog boxes and the functions used to create them, see "Predefined Dialog Boxes" in the MATLAB Function Reference documentation.

The following table describes the available components and the function used to create each. Subsequent topics provide specific information about adding the components.

Component	Function	Description
ActiveX	`actxcontrol`	ActiveX components enable you to display ActiveX controls in your GUI. They are available only on the Microsoft Windows platform.
"Axes" on page 11-35	`axes`	Axes enable your GUI to display graphics such as graphs and images.

Component	Function	Description
"Button Group" on page 11-32	`uibuttongroup`	Button groups are like panels, but are used to manage exclusive selection behavior for radio buttons and toggle buttons.
"Check Box" on page 11-16	`uicontrol`	Check boxes can generate an action when checked and indicate their state as checked or not checked. Check boxes are useful when providing the user with a number of independent choices, for example, displaying a toolbar.
"Edit Text" on page 11-17	`uicontrol`	Edit text components are fields that enable users to enter or modify text strings. Use an edit text when you want text as input. Users can enter numbers, but you must convert them to their numeric equivalents.
"List Box" on page 11-18	`uicontrol`	List boxes display a list of items and enable users to select one or more items.
"Panel" on page 11-30	`uipanel`	Panels arrange GUI components into groups. By visually grouping related controls, panels can make the user interface easier to understand. A panel can have a title and various borders. Panel children can be user interface controls and axes, as well as button groups and other panels. The position of each component within a panel is interpreted relative to the panel. If you move the panel, its children move with it and maintain their positions on the panel.

Component	Function	Description
"Pop-Up Menu" on page 11-20	`uicontrol`	Pop-up menus open to display a list of choices when users click the arrow.
"Push Button" on page 11-21	`uicontrol`	Push buttons generate an action when clicked. For example, an *OK* button might apply settings and close a dialog box. When you click a push button, it appears depressed; when you release the mouse button, the push button appears raised.
"Radio Button" on page 11-23	`uicontrol`	Radio buttons are similar to check boxes, but radio buttons are typically mutually exclusive within a group of related radio buttons. That is, when you select one button the previously selected button is deselected. To activate a radio button, click the mouse button on the object. The display indicates the state of the button. Use a button group to manage mutually exclusive radio buttons.
"Slider" on page 11-24	`uicontrol`	Sliders accept numeric input within a specified range by enabling the user to move a sliding bar, which is called a slider or thumb. Users move the slider by clicking the slider and dragging it, by clicking in the trough, or by clicking an arrow. The location of the slider indicates the relative location within the specified range.

Component	Function	Description
"Static Text" on page 11-26	`uicontrol`	Static text controls display lines of text. Static text is typically used to label other controls, provide directions to the user, or indicate values associated with a slider. Users cannot change static text interactively.
"Toggle Button" on page 11-27	`uicontrol`	Toggle buttons generate an action and indicate whether they are turned on or off. When you click a toggle button, it appears depressed, showing that it is on. When you release the mouse button, the toggle button remains depressed until you click it a second time. When you do so, the button returns to the raised state, showing that it is off. Use a button group to manage mutually exclusive radio buttons.

Components are sometimes referred to by the name of the function used to create them. For example, a push button is created using the `uicontrol` function, and it is sometimes referred to as a uicontrol. A panel is created using the `uipanel` function and may be referred to as a uipanel.

Adding User Interface Controls

Use the `uicontrol` function to create user interface controls. These include push buttons, toggle buttons, sliders, radio buttons, edit text controls, static text controls, pop-up menus, check boxes, and list boxes.

Note See "Available Components" on page 11-10 for descriptions of these components. See "Programming User Interface Controls" on page 12-15 for basic examples of programming these components.

A syntax for the `uicontrol` function is

```
uich = uicontrol(parent,'PropertyName',PropertyValue,...)
```

where `uich` is the handle of the resulting user interface control. If you do not specify `parent`, the component parent is the current figure as specified by the root `CurrentFigure` property. See the `uicontrol` reference page for other valid syntaxes.

Subsequent topics describe commonly used properties of user interface controls and offer a simple example for each kind of control:

Commonly Used Properties

The most commonly used properties needed to describe a user interface control are shown in the following table:

Property	Values	Description
`Max`	Scalar. Default is 1.	Maximum value. Interpretation depends on the `Style` property.
`Min`	Scalar. Default is 0.	Minimum value. Interpretation depends on the `Style` property.

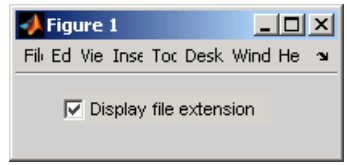
Property	Values	Description
`Position`	4-element vector: [distance from left, distance from bottom, width, height]. Default is [20, 20, 60, 20].	Size of the component and its location relative to its parent.
`String`	String. Can be a cell array or character array or strings.	Component label. For list boxes and pop-up menus it is a list of the items. To display the & character in a label, use two & characters in the string. The words `remove`, `default`, and `factory` (case sensitive) are reserved. To use one of these as a label, prepend a backslash (`\`) to the string. For example, `\remove` yields **remove**.
`Style`	`pushbutton`, `togglebutton`, `radiobutton`, `checkbox`, `edit`, `text`, `slider`, `listbox`, `popupmenu`. Default is `pushbutton`.	Type of user interface control object.
`Units`	`pixels`, `centimeters`, `characters`, `inches`, `normalized`, `points`, Default is `pixels`.	Units of measurement used to interpret position vector
`Value`	Scalar or vector	Value of the component. Interpretation depends on the `Style` property.

For a complete list of properties and for more information about the properties listed in the table, see Uicontrol Properties in the MATLAB Function Reference documentation. Properties needed to control GUI behavior are discussed in Chapter 12, “Programming the GUI” .

Check Box

The following statement creates a check box with handle `cbh`.

```
cbh = uicontrol(fh,'Style','checkbox',...
                'String','Display file extension',...
                'Value',1,'Position',[30 20 130 20]);
```



The first argument, `fh`, specifies the handle of the parent figure. You can also specify the parent as a panel or button group. See “Panel” on page 11-30 and “Button Group” on page 11-32 for more information.

The `Style` property, `checkbox`, specifies the user interface control as a check box.

The `String` property labels the check box as **Display file extension**. The check box accommodates only a single line of text. If you specify a component width that is too small to accommodate the specified `String`, MATLAB truncates the string with an ellipsis.

The `Value` property specifies whether the box is checked. Set `Value` to the value of the `Max` property (default is `1`) to create the component with the box checked. Set `Value` to `Min` (default is `0`) to leave the box unchecked. Correspondingly, when the user clicks the check box, MATLAB sets `Value` to `Max` when the user checks the box and to `Min` when the user unchecks it.

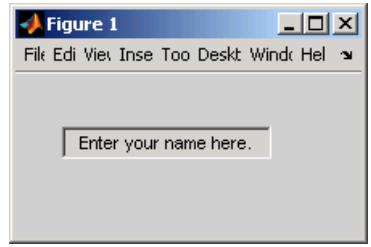
The `Position` property specifies the location and size of the list box. In this example, the list box is 130 pixels wide and 20 high. It is positioned 30 pixels from the left of the figure and 20 pixels from the bottom. The statement assumes the default value of the `Units` property, which is `pixels`.

Note You can also use an image as a label. See “Adding an Image to a Push Button” on page 11-22 for more information.

Edit Text

The following statement creates an edit text component with handle `eth`:

```
eth = uicontrol(fh,'Style','edit',...
                'String','Enter your name here.',...
                'Position',[30 50 130 20]);
```



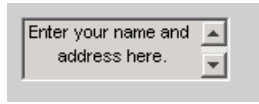
The first argument, `fh`, specifies the handle of the parent figure. You can also specify the parent as a panel or button group. See “Panel” on page 11-30 and “Button Group” on page 11-32 for more information.

The `Style` property, `edit`, specifies the user interface control as an edit text component.

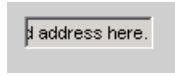
The `String` property defines the text that appears in the component.

To enable multiple-line input, `Max - Min` must be greater than 1, as in the following statement. MATLAB wraps the string if necessary.

```
eth = uicontrol(fh,'Style','edit',...
                'String','Enter your name and address here.',...
                'Max',2,'Min',0,...
                'Position',[30 20 130 80]);
```



If `Max-Min` is less than or equal to 1, the edit text component admits only a single line of input. If you specify a component width that is too small to accommodate the specified string, MATLAB displays only part of the string. The user can use the arrow keys to move the cursor over the entire string.

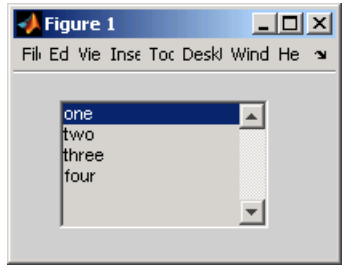


The `Position` property specifies the location and size of the edit text component. In this example, the edit text is 130 pixels wide and 20 high. It is positioned 30 pixels from the left of the figure and 50 pixels from the bottom. The statement assumes the default value of the `Units` property, which is `pixels`.

List Box

The following statement creates a list box with handle `lbh`:

```
lbh = uicontrol(fh,'Style','listbox',...
                'String',{'one','two','three','four'},...
                'Value',1,'Position',[30 80 130 20]);
```



The first argument, `fh`, specifies the handle of the parent figure. You can also specify the parent as a panel or button group. See “Panel” on page 11-30 and “Button Group” on page 11-32 for more information.

The `Style` property, `listbox`, specifies the user interface control as a list box.

The `String` property defines the list items. You can specify the items in any of the formats shown in the following table.

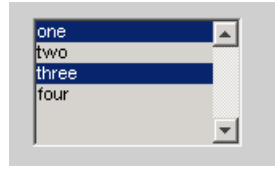
String Property Format	Example
Cell array of strings	`{'one' 'two' 'three'}`
Padded string matrix	`['one ';'two ';'three']`
String vector separated by vertical slash (`|`) characters	`['one|two|three']`

If you specify a component width that is too small to accommodate one or more of the specified strings, MATLAB truncates those strings with an ellipsis.

The `Value` property specifies the item or items that are selected when the component is created. To select a single item, set `Value` to a scalar that indicates the index of the selected list item, where 1 corresponds to the first item in the list.

To select more than one item, set `Value` to a vector of indices of the selected items. To enable selection of more than one item, `Max - Min` must be greater than 1, as in the following statement:

```
lbh = uicontrol(fh,'Style','listbox',...
                'String',{'one','two','three','four'},...
                'Max',2,'Min',0,'Value',[1 3],,...
                'Position',[30 20 130 80]);
```



If you want no initial selection:

1. Set the `Max` and `Min` properties to enable multiple selection
2. Set the `Value` property to an empty matrix `[]`.

If the list box is not large enough to display all list entries, you can set the `ListBoxTop` property to the index of the item you want to appear at the top when the component is created.

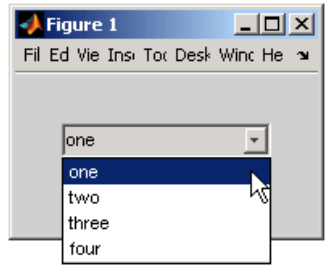
The `Position` property specifies the location and size of the list box. In this example, the list box is 130 pixels wide and 80 high. It is positioned 30 pixels from the left of the figure and 20 pixels from the bottom. The statement assumes the default value of the `Units` property, which is `pixels`.

The list box does not provide for a label. Use a static text component to label the list box.

Pop-Up Menu

The following statement creates a pop-up menu (also known as a drop-down menu or combo box) with handle `pmh`:

```
pmh = uicontrol(fh,'Style','popupmenu',...
                'String',{'one','two','three','four'},...
                'Value',1,'Position',[30 80 130 20]);
```



The first argument, `fh`, specifies the handle of the parent figure. You can also specify the parent as a panel or button group. See “Panel” on page 11-30 and “Button Group” on page 11-32 for more information.

The `Style` property, `popupmenu`, specifies the user interface control as a pop-up menu.

The `String` property defines the menu items. You can specify the items in any of the formats shown in the following table.

String Property Format	Example
Cell array of strings	`{'one' 'two' 'three'}`
Padded string matrix	`['one ';'two ';'three']`
String vector separated by vertical slash (`|`) characters	`['one|two|three']`

If you specify a component width that is too small to accommodate one or more of the specified strings, MATLAB truncates those strings with an ellipsis.

The `Value` property specifies the index of the item that is selected when the component is created. Set `Value` to a scalar that indicates the index of the selected menu item, where 1 corresponds to the first item in the list. In the statement, if `Value` is 2, the menu looks like this when it is created:

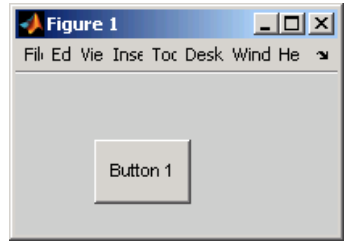
The `Position` property specifies the location and size of the pop-up menu. In this example, the pop-up menu is 130 pixels wide. It is positioned 30 pixels from the left of the figure and 80 pixels from the bottom. The height of a pop-up menu is determined by the font size; the height you set in the position vector is ignored. The statement assumes the default value of the `Units` property, which is `pixels`.

The pop up menu does not provide for a label. Use a static text component to label the pop-up menu.

Push Button

The following statement creates a push button with handle `pbh`:

```
pbh = uicontrol(fh,'Style','pushbutton','String','Button 1',...
                'Position',[50 20 60 40]);
```



The first argument, `fh`, specifies the handle of the parent figure. You can also specify the parent as a panel or button group. See “Panel” on page 11-30 and “Button Group” on page 11-32 for more information.

The `Style` property, `pushbutton`, specifies the user interface control as a push button. Because `pushbutton` is the default style, you can omit the `'Style'` property from the statement.

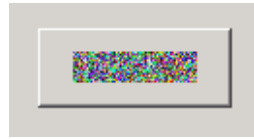
The `String` property labels the push button as **Button 1**. The push button allows only a single line of text. If you specify more than one line, only the first line is shown. If you specify a component width that is too small to accommodate the specified `String`, MATLAB truncates the string with an ellipsis.

The `Position` property specifies the location and size of the push button. In this example, the push button is 60 pixels wide and 40 high. It is positioned 50 pixels from the left of the figure and 20 pixels from the bottom. This statement assumes the default value of the `Units` property, which is `pixels`.

Adding an Image to a Push Button. To add an image to a push button, assign the button's `CData` property an m-by-n-by-3 array of RGB values that defines a truecolor image. For example, the array `img` defines 16-by-64 truecolor image using random values between 0 and 1 (generated by `rand`).

```
img(:,:,1) = rand(16,64);
img(:,:,2) = rand(16,64);
img(:,:,3) = rand(16,64);
```

```
pbh = uicontrol(fh,'Style','pushbutton',...
                'Position',[50 20 100 45],...
                'CData',img);
```

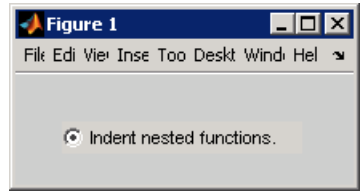


Note Create your own icon with the icon editor described in "Icon Editor" on page 15-29. See `ind2rgb` for information on converting a matrix `X` and corresponding colormap, i.e., an `(X, MAP)` image, to RGB (truecolor) format.

Radio Button

The following statement creates a radio button with handle `rbh`:

```
rbh = uicontrol(fh,'Style','radiobutton',...
                'String','Indent nested functions.',...
                'Value',1,'Position',[30 20 150 20]);
```



The first argument, `fh`, specifies the handle of the parent figure. You can also specify the parent as a panel or button group. Use a button group to manage exclusive selection of radio buttons and toggle buttons. See "Panel" on page 11-30 and "Button Group" on page 11-32 for more information.

The `Style` property, `radiobutton`, specifies the user interface control as a radio button.

The `String` property labels the radio button as **Indent nested functions**. The radio button allows only a single line of text. If you specify more than

one line, only the first line is shown. If you specify a component width that is too small to accommodate the specified `String`, MATLAB truncates the string with an ellipsis.

The `Value` property specifies whether the radio button is selected when the component is created. Set `Value` to the value of the `Max` property (default is `1`) to create the component with the radio button selected. Set `Value` to `Min` (default is `0`) to leave the radio button unselected.

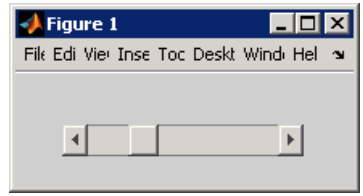
The `Position` property specifies the location and size of the radio button. In this example, the radio button is 150 pixels wide and 20 high. It is positioned 30 pixels from the left of the figure and 20 pixels from the bottom. The statement assumes the default value of the `Units` property, which is `pixels`.

Note You can also use an image as a label. See "Adding an Image to a Push Button" on page 11-22 for more information.

Slider

The following statement creates a slider with handle `sh`:

```
sh = uicontrol(fh,'Style','slider',...
                  'Max',100,'Min',0,'Value',25,...
                  'SliderStep',[0.05 0.2],...
                  'Position',[30 20 150 30]);
```



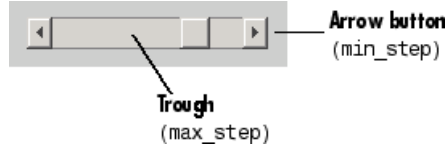
The first argument, `fh`, specifies the handle of the parent figure. You can also specify the parent as a panel or button group. See “Panel” on page 11-30 and “Button Group” on page 11-32 for more information.

The `Style` property, `slider`, specifies the user interface control as a slider.

The `Max` property is the maximum value of the slider. The `Min` property is the minimum value of the slider and must be less than `Max`.

The `Value` property specifies the value indicated by the slider when it is created. Set `Value` to a number that is less than or equal to `Max` and greater than or equal to `Min`. If you specify `Value` outside the specified range, the slider is not rendered.

The `SliderStep` property controls the amount the slider `Value` changes when a user clicks the arrow button to produce a minimum step or the slider trough to produce a maximum step. Specify `SliderStep` as a two-element vector, `[min_step,max_step]`, where each value is in the range [0, 1].



The example provides a 5 percent minimum step and a 20 percent maximum step. The default, `[0.01 0.10]`, provides a 1 percent minimum step and a 10 percent maximum step.

The `Position` property specifies the location and size of the slider. In this example, the slider is 150 pixels wide and 30 high. It is positioned 30 pixels from the left of the figure and 20 pixels from the bottom. The statement assumes the default value of the `Units` property, which is `pixels`.

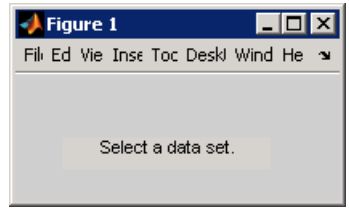
Note On Mac platforms, the height of a horizontal slider is constrained. If the height you set in the position vector exceeds this constraint, the displayed height of the slider is the maximum allowed. The height element of the position vector is not changed.

The slider component provides no text description. Use static text components to label the slider.

Static Text

The following statement creates a static text component with handle `sth`:

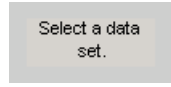
```
sth = uicontrol(fh,'Style','text',...
                'String','Select a data set.',...
                'Position',[30 50 130 20]);
```



The first argument, `fh`, specifies the handle of the parent figure. You can also specify the parent as a panel or button group. See “Panel” on page 11-30 and “Button Group” on page 11-32 for more information.

The `Style` property, `text`, specifies the user interface control as a static text component.

The `String` property defines the text that appears in the component. If you specify a component width that is too small to accommodate the specified `String`, MATLAB wraps the string.

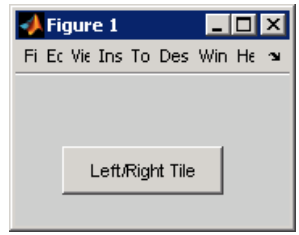


The `Position` property specifies the location and size of the static text component. In this example, the static text is 130 pixels wide and 20 high. It is positioned 30 pixels from the left of the figure and 50 pixels from the bottom. The statement assumes the default value of the `Units` property, which is `pixels`.

Toggle Button

The following statement creates a toggle button with handle `tbh`:

```
tbh = uicontrol(fh,'Style','togglebutton',...
                'String','Left/Right Tile',...
                'Value',0,'Position',[30 20 100 30]);
```



The first argument, `fh`, specifies the handle of the parent figure. You can also specify the parent as a panel or button group. Use a button group to manage exclusive selection of radio buttons and toggle buttons. See “Panel” on page 11-30 and “Button Group” on page 11-32 for more information.

The `Style` property, `togglebutton`, specifies the user interface control as a toggle button.

The `String` property labels the toggle button as **Left/Right Tile**. The toggle button allows only a single line of text. If you specify more than one line, only the first line is shown. If you specify a component width that is too small to accommodate the specified `String`, MATLAB truncates the string with an ellipsis.

The `Value` property specifies whether the toggle button is selected when the component is created. Set `Value` to the value of the `Max` property (default is `1`) to create the component with the toggle button selected (depressed). Set `Value` to `Min` (default is `0`) to leave the toggle button unselected (raised). The following figure shows the toggle button in the depressed position.

The `Position` property specifies the location and size of the toggle button. In this example, the toggle button is 100 pixels wide and 30 high. It is positioned 30 pixels from the left of the figure and 20 pixels from the bottom. The statement assumes the default value of the `Units` property, which is `pixels`.

Note You can also use an image as a label. See "Adding an Image to a Push Button" on page 11-22 for more information.

Adding Panels and Button Groups

Panels and button groups are containers that arrange GUI components into groups. If you move the panel or button group, its children move with it and maintain their positions relative to the panel or button group.

Note See "Available Components" on page 11-10 for descriptions of these components.

Use the `uipanel` and `uibuttongroup` functions to create these components.

A syntax for panels is

```
ph = uipanel(fh,'PropertyName',PropertyValue,...)
```

where `ph` is the handle of the resulting panel. The first argument, `fh`, specifies the handle of the parent figure. You can also specify the parent as a panel or button group. See the `uipanel` reference page for other valid syntaxes.

A syntax for button groups is

```
bgh = uibuttongroup('PropertyName',PropertyValue,...)
```

where `bgh` is the handle of the resulting button group. For button groups, you must use the `Parent` property to specify the component parent. See the `uibuttongroup` reference page for other valid syntaxes.

For both panels and button groups, if you do not specify a parent, the component parent is the current figure as specified by the root `CurrentFigure` property.

Subsequent topics describe commonly used properties of panels and button groups and offer a simple example for each component.

- "Commonly Used Properties" on page 11-29
- "Panel" on page 11-30
- "Button Group" on page 11-32

Commonly Used Properties

The most commonly used properties needed to describe a panel or button group are shown in the following table:

Property	Values	Description
`Parent`	Handle	Handle of the component's parent figure, panel, or button group.
`Position`	4-element vector: [distance from left, distance from bottom, width, height]. Default is [0, 0, 1, 1].	Size of the component and its location relative to its parent.

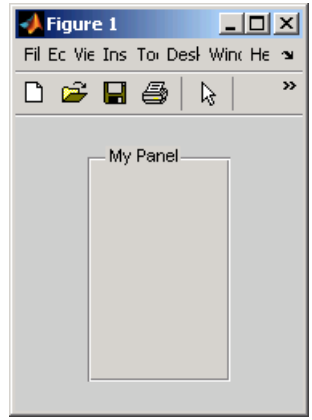
Property	Values	Description
`Title`	String	Component label. To display the & character in a label, use two & characters in the string. The words `remove`, `default`, and `factory` (case sensitive) are reserved. To use one of these as a label, prepend a backslash (`\`) to the string. For example, `\remove` yields **remove**.
`TitlePosition`	`lefttop`, `centertop`, `righttop`, `leftbottom`, `centerbottom`, `rightbottom`. Default is `lefttop`.	Location of title string in relation to the panel or button group.
`Units`	`normalized`, `centimeters`, `characters`, `inches`, `pixels`, `points`. Default is `normalized`.	Units of measurement used to interpret position vector

For a complete list of properties and for more information about the properties listed in the table, see Uipanel Properties and Uibuttongroup Properties in the MATLAB Function Reference documentation. Properties needed to control GUI behavior are discussed in Chapter 12, “Programming the GUI”.

Panel

The following statement creates a panel with handle `ph`. Use a panel to group components in the GUI.

```
ph = uipanel('Parent',fh,'Title','My Panel',...
             'Position',[.25 .1 .5 .8]);
```



The `Parent` property specifies the handle `fh` of the parent figure. You can also specify the parent as a panel or button group.

The `Title` property labels the panel as **My Panel**.

The statement assumes the default `TitlePosition` property, which is `lefttop`.

The `Units` property is used to interpret the `Position` property. This panel assumes the default `Units` property, `normalized`. This enables the panel to resize automatically if the figure is resized.

The `Position` property specifies the location and size of the panel. In this example, the panel is 50 percent of the width of the figure and 80 percent of its height. It is positioned 25 percent of the figure width from the left of the figure and 10 percent of the figure height from the bottom. As the figure is resized the panel retains these proportions.

The following statements add two push buttons to the panel with handle `ph`. The `Position` property of each component within a panel is interpreted relative to the panel.

```
pbh1 = uicontrol(ph,'Style','pushbutton','String','Button 1',...
                 'Units','normalized',...
                 'Position',[.1 .55 .8 .3]);
pbh2 = uicontrol(ph,'Style','pushbutton','String','Button 2',...
```

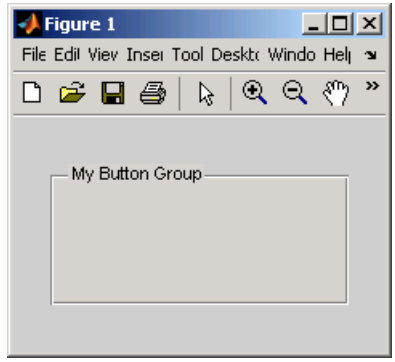
```
                'Units','normalized',...
                'Position',[.1 .15 .8 .3]);
```

See “Push Button” on page 11-21 for more information about adding push buttons.

Button Group

The following statement creates a button group with handle `bgh`. Use a button group to exclusively manage radio buttons and toggle buttons.

```
bgh = uibuttongroup('Parent',fh,'Title','My Button Group',...
            'Position',[.1 .2 .8 .6]);
```



The `Parent` property specifies the handle `fh` of the parent figure. You can also specify the parent as a panel or button group.

The `Title` property labels the button group as **My Button Group**.

The statement assumes the default `TitlePosition` property, which is `lefttop`.

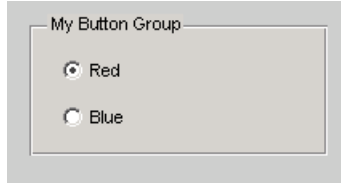
The `Units` property is used to interpret the `Position` property. This button group assumes the default `Units` property, `normalized`. This enables the button group to resize automatically if the figure is resized.

The `Position` property specifies the location and size of the button group. In this example, the button group is 80 percent of the width of the figure and 60 percent of its height. It is positioned 10 percent of the figure width from the left of the figure and 20 percent of the figure height from the bottom. As the figure is resized the button group retains these proportions.

The following statements add two radio buttons to the button group with handle `bgh`.

```
rbh1 = uicontrol(bgh,'Style','radiobutton','String','Red',...
                 'Units','normalized',...
                 'Position',[.1 .6 .3 .2]);
rbh2 = uicontrol(bgh,'Style','radiobutton','String','Blue',...
                 'Units','normalized',...
                 'Position',[.1 .2 .3 .2]);
```

By default, MATLAB automatically selects the first radio button added to a button group. You can use the radio button `Value` property to explicitly specify the initial selection. See “Radio Button” on page 11-23 for information.



Adding Axes

Axes enable your GUI to display graphics such as graphs and images using commands such as: `plot`, `surf`, `line`, `bar`, `polar`, `pie`, `contour`, and `mesh`.

Note See "Available Components" on page 11-10 for a description of this component.

Use the `axes` function to create an axes. A syntax for this function is

```
ah = axes('PropertyName',PropertyValue,...)
```

where `ah` is the handle of the resulting axes. You must use the `Parent` property to specify the axes parent. If you do not specify `Parent`, the parent is the current figure as specified by the root `CurrentFigure` property. See the `axes` reference page for other valid syntaxes.

Subsequent topics describe commonly used properties of axes and offer a simple example.

- "Commonly Used Properties" on page 11-34
- "Axes" on page 11-35

Commonly Used Properties

The most commonly used properties needed to describe an axes are shown in the following table:

Property	Values	Description
`HandleVisibility`	`on`, `callback`, `off`. Default is `on`.	Determines if an object's handle is visible in its parent's list of children. For axes, set `HandleVisibility` to `callback` to protect them from command line operations.
`Parent`	Handle	Handle of the component's parent figure, panel, or button group.

Property	Values	Description
`Position`	4-element vector: [distance from left, distance from bottom, width, height].	Size of the component and its location relative to its parent.
`Units`	`normalized`, `centimeters`, `characters`, `inches`, `pixels`, `points`. Default is `normalized`.	Units of measurement used to interpret position vector

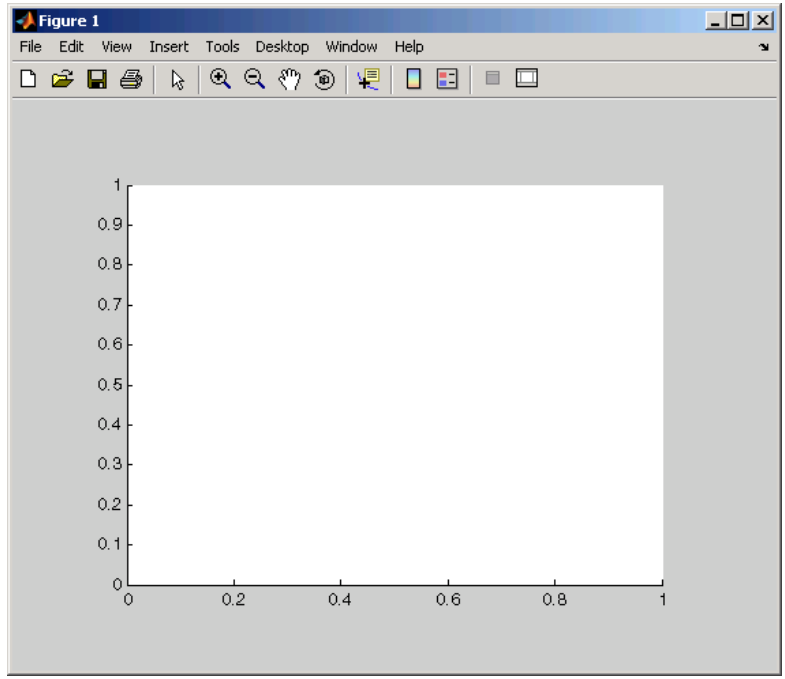
For a complete list of properties and for more information about the properties listed in the table, see Axes Properties in the MATLAB Function Reference documentation. Properties needed to control GUI behavior are discussed in Chapter 12, "Programming the GUI".

See commands such as the following for more information on axes objects: `plot`, `surf`, `line`, `bar`, `polar`, `pie`, `contour` and `mesh`. See "Functions — By Category" in the MATLAB Function Reference documentation for a complete list.

Axes

The following statement creates an axes with handle `ah`:

```
ah = axes('Parent',fh,'Position',[.15 .15 .7 .7]);
```



The `Parent` property specifies the handle `fh` of the parent figure. You can also specify the parent as a panel or button group.

The `Units` property is used to interpret the `Position` property. This axes assumes the default `Units` property, `normalized`. This enables the axes to resize automatically if the figure is resized.

The `Position` property specifies the location and size of the axes. In this example, the axes is 70 percent of the width of the figure and 70 percent of its height. It is positioned 15 percent of the figure width from the left of the figure and 15 percent of the figure height from the bottom. As the figure is resized the axes retains these proportions.

MATLAB automatically adds the tick marks. Most functions that draw in the axes update the tick marks appropriately.

Adding ActiveX Controls

ActiveX components enable you to display ActiveX controls in your GUI. They are available only on the Microsoft Windows platform.

An ActiveX control can be the child only of a figure, i.e., of the GUI itself. It cannot be the child of a panel or button group.

See “Creating an ActiveX Control” in the MATLAB External Interfaces documentation for information about adding an ActiveX control to a figure. See “MATLAB COM Client Support” in the MATLAB External Interfaces documentation for general information about ActiveX controls.

Aligning Components

In this section...

Using the `Align` Function

Use the `align` function to align user interface controls and axes. This function enables you to align the components vertically and horizontally. You can also distribute the components evenly, or specify a fixed distance between them.

A syntax for the `align` function is

```
align(HandleList,'HorizontalAlignment',...
                 'VerticalAlignment')
```

where *`HorizontalAlignment`* can be `None`, `Left`, `Center`, `Right`, `Distribute`, or `Fixed` and *`VerticalAlignment`* can be `None`, `Top`, `Middle`, `Bottom`, `Distribute`, or `Fixed`. All handles in `HandleList` must have the same parent. See the `align` reference page for information about other syntaxes.

The following code creates three push buttons that are somewhat randomly placed. Each subsequent example starts with these same three push buttons and aligns them in different ways. Components are aligned with reference to their bounding box, shown as a blue dashed line in the figures.

```
b1 = uicontrol(fh,'Posit',[30 10 60 30],'String','Button 1');
b2 = uicontrol(fh,'Posit',[50 50 60 30],'String','Button 2');
b3 = uicontrol(fh,'Posit',[10 80 60 30],'String','Button 3');
```

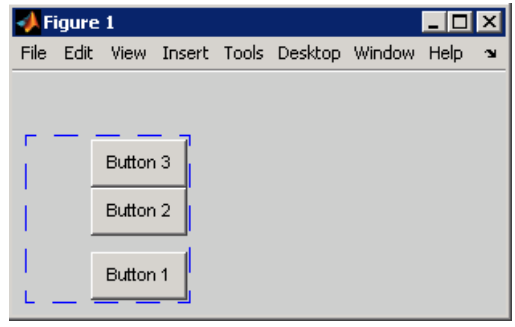
Button 1
Bounding box

Examples

Aligning Components Horizontally

The following statement moves the push buttons horizontally to the right of their bounding box. It does not alter their vertical positions. The figure shows the original bounding box.

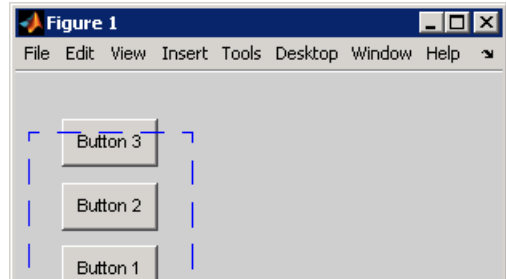
```
align([b1 b2 b3],'Right','None');
```



Aligning Components Horizontally While Distributing Them Vertically

The following statement moves the push buttons horizontally to the center of their bounding box and adjusts their vertical placement to create a fixed distance of 7 points between the boxes. The push buttons appear in the center of the original bounding box. The bottom push button remains at the bottom of the original bounding box.

```
align([b1 b2 b3],'Center','Fixed',7);
```



Setting Tab Order

In this section...

How Tabbing Works

A GUI's tab order is the order in which components of the GUI acquire focus when a user presses the keyboard **Tab** key. Focus is generally denoted by a border or a dotted border.

Tab order is determined separately for the children of each parent. For example, child components of the GUI figure have their own tab order. Child components of each panel or button group also have their own tab order.

If, in tabbing through the components at one level, a user tabs to a panel or button group, then the tabbing sequences through the components of the panel or button group before returning to the level from which the panel or button group was reached. For example, if a GUI figure contains a panel that contains three push buttons and the user tabs to the panel, then the tabbing sequences through the three push buttons before returning to the figure.

Note You cannot tab to axes and static text components. You cannot determine programmatically which component has focus.

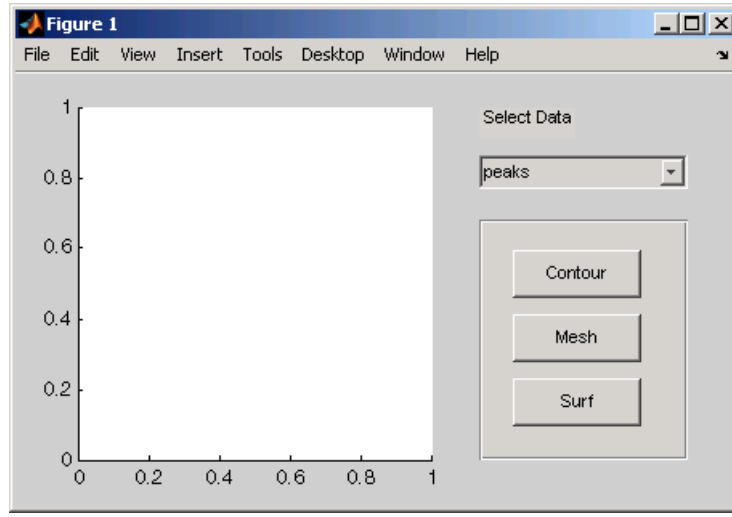
Default Tab Order

The default tab order for each level is the order in which you create the components at that level.

The following code creates a GUI that contains a pop-up menu with a static text label, a panel with three push buttons, and an axes.

```
fh = figure('Position',[200 200 450 270]);
pmh = uicontrol(fh,'Style','popupmenu',...
```

```
            'String',{'peaks','membrane','sinc'},...
            'Position',[290 200 130 20]);
sth = uicontrol(fh,'Style','text','String','Select Data',...
            'Position',[290 230 60 20]);
ph = uipanel('Parent',fh,'Units','pixels',...
            'Position',[290 30 130 150]);
ah = axes('Parent',fh,'Units','pixels',...
            'Position',[40 30 220 220]);
bh1 = uicontrol(ph,'Style','pushbutton',...
            'String','Contour','Position',[20 20 80 30]);
bh2 = uicontrol(ph,'Style','pushbutton',...
            'String','Mesh','Position',[20 60 80 30]);
bh3 = uicontrol(ph,'Style','pushbutton',...
            'String','Surf','Position',[20 100 80 30]);
```



You can obtain the default tab order for a figure, panel, or button group by retrieving its `Children` property. For the example, the statement is

```
ch = get(ph,'Children')
```

where `ph` is the handle of the panel. This statement returns a vector containing the handles of the children, the three push buttons.

```
ch =
```

```
4.0076
3.0076
2.0076
```

These handles correspond to the push buttons as shown in the following table:

Handle	Handle Variable	Push Button
4.0076	bh3	**Surf**
3.0076	bh2	**Mesh**
2.0076	bh1	**Contour**

The default tab order of the push buttons is the reverse of the order of the child vector: **Contour > Mesh > Surf**.

Note The `get` function returns only those children whose handles are visible, i.e., those with their `HandleVisibility` property set to `on`. Use `allchild` to retrieve children regardless of their handle visibility.

In the example GUI figure, the default order is pop-up menu followed by the panel's **Contour**, **Mesh**, and **Surf** push buttons (in that order), and then back to the pop-up menu. You cannot tab to the axes component or the static text component.

Try modifying the code to create the pop-up menu following the creation of the **Contour** push button and before the **Mesh** push button. Now execute the code to create the GUI and tab through the components. This code change does not alter the default tab order. This is because the pop-up menu does not have the same parent as the push buttons. The figure is the parent of the panel and the pop-up menu.

Changing the Tab Order

Use the `uistack` function to change the tab order of components that have the same parent. A convenient syntax for `uistack` is

```
uistack(h,stackopt,step)
```

where `h` is a vector of handles of the components whose tab order is to be changed.

`stackopt` represents the direction of the move. It must be one of the strings: `up`, `down`, `top`, or `bottom`, and is interpreted relative to the column vector returned by the statement:

```
ch = get(ph,'Children')

ch =
   4.0076
   3.0076
   2.0076
```

If the tab order is currently **Contour > Mesh > Surf**, the statement

```
uistack(bh2,up,1)
```

moves `bh2` (**Surf**) up one place in the vector of children and changes the tab order to **Contour > Surf > Mesh**.

```
ch = get(ph,'Children')
```

now returns

```
ch =
   3.0076
   4.0076
   2.0076
```

`step` is the number of levels changed. The default is 1.

Note Tab order also affects the stacking order of components. If components overlap, those that appear lower in the child order, are drawn on top of those that appear higher in the order. If the push buttons in the example overlapped, the **Contour** push button would be on top.

Creating Menus

In this section...

Adding Menu Bar Menus

Use the `uimenu` function to add a menu bar menu to your GUI. A syntax for `uimenu` is

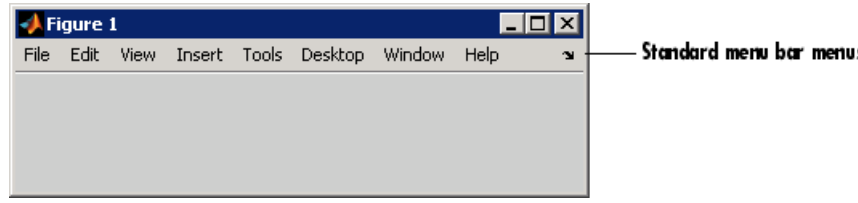
```
mh = uimenu(parent,'PropertyName',PropertyValue,...)
```

Where `mh` is the handle of the resulting menu or menu item. See the `uimenu` reference page for other valid syntaxes.

These topics discuss use of the MATLAB standard menu bar menus and describe commonly used menu properties and offer some simple examples.

Displaying Standard Menu Bar Menus

Displaying the standard menu bar menus is optional.



If you use the standard menu bar menus, any menus you create are added to it. If you choose not to display the standard menu bar menus, the menu bar contains only the menus that you create. If you display no standard menus and you create no menus, the menu bar itself is not displayed.

Use the figure `MenuBar` property to display or hide the MATLAB standard menus shown in the preceding figure. Set `MenuBar` to `figure` (the default) to display the standard menus. Set `MenuBar` to `none` to hide them.

```
set(fh,'MenuBar','figure');  % Display standard menu bar menus.
set(fh,'MenuBar','none');    % Hide standard menu bar menus.
```

In these statements, `fh` is the handle of the figure.

Commonly Used Properties

The most commonly used properties needed to describe a menu bar menu are shown in the following table.

Property	Values	Description
`Accelerator`	Alphabetic character	Keyboard equivalent. Available for menu items that do not have submenus.
`Checked`	`off`, `on`. Default is `off`.	Menu check indicator
`Enable`	`on`, `off`. Default is `on`.	Controls whether a menu item can be selected. When set to `off`, the menu label appears dimmed.
`HandleVisibility`	`on`, `off`. Default is `on`.	Determines if an object's handle is visible in its parent's list of children. For menus, set `HandleVisibility` to `off` to protect menus from operations not intended for them.

Property	Values	Description
`Label`	String	Menu label. To display the `&` character in a label, use two `&` characters in the string. The words `remove`, `default`, and `factory` (case sensitive) are reserved. To use one of these as a label, prepend a backslash (`\`) to the string. For example, `\remove` yields **remove**.
`Position`	Scalar. Default is `1`.	Position of a menu item in the menu.
`Separator`	`off`, `on`. Default is `off`.	Separator line mode

For a complete list of properties and for more information about the properties listed in the table, see Uimenu Properties in the MATLAB Function Reference documentation. Properties needed to control GUI behavior are discussed in Chapter 12, “Programming the GUI”.

Menu Bar Menu

The following statements create a menu bar menu with two menu items.

```
mh = uimenu(fh,'Label','My menu');
eh1 = uimenu(mh,'Label','Item 1');
eh2 = uimenu(mh,'Label','Item 2','Checked','on');
```

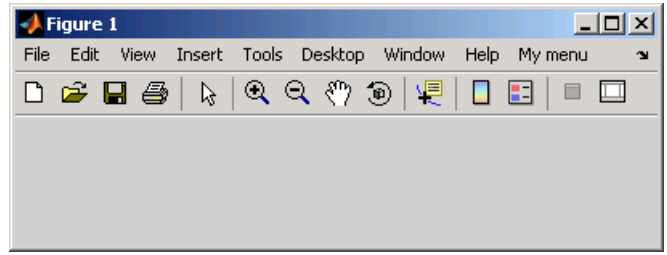
`fh` is the handle of the parent figure.

`mh` is the handle of the parent menu.

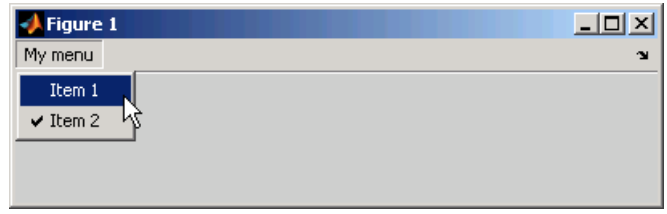
The `Label` property specifies the text that appears in the menu.

The `Checked` property specifies that this item is displayed with a check next to it when the menu is created.

If your GUI displays the standard menu bar, the new menu is added to it.

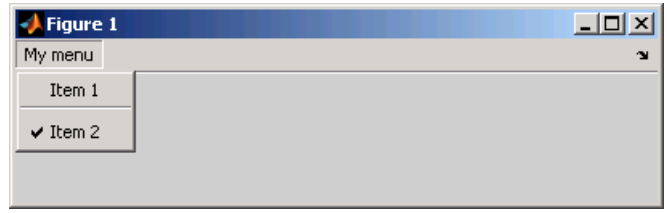


If your GUI does not display the standard menu bar, MATLAB creates a menu bar if none exists and then adds the menu to it.



The following statement adds a separator line preceding the second menu item.

```
set(eh2,'Separator','on');
```



The following statements add two menu subitems to **Item 1**, assign each subitem a keyboard accelerator, and disable the first subitem.

```
seh1 = uimenu(eh1,'Label','Choice 1','Accelerator','C',...
              'Enable','off');
seh2 = uimenu(eh1,'Label','Choice 2','Accelerator','H');
```

The `Accelerator` property adds keyboard accelerators to the menu items. Some accelerators may be used for other purposes on your system and other actions may result.

The `Enable` property disables the first subitem **Choice 1** so a user cannot select it when the menu is first created. The item appears dimmed.

Note After you have created all menu items, set their `HandleVisibility` properties `off` by executing the following statements:

```
menuhandles = findall(figurehandle,'type','uimenu');
set(menuhandles,'HandleVisibility','off')
```

See “Programming Menu Items” on page 12-28 for information about programming menu items.

Adding Context Menus

Context menus appear when the user right-clicks on a figure or GUI component. Follow these steps to add a context menu to your GUI:

1. Create the context menu object using the `uicontextmenu` function.
2. Add menu items to the context menu using the `uimenu` function.
3. Associate the context menu with a graphics object using the object’s `UIContextMenu` property.

Subsequent topics describe commonly used context menu properties and explain each of these steps:

Commonly Used Properties

The most commonly used properties needed to describe a context menu object are shown in the following table. These properties apply only to the menu object and not to the individual menu items.

Property	Values	Description
`HandleVisibility`	`on`, `off`. Default is `on`.	Determines if an object's handle is visible in its parent's list of children. For menus, set `HandleVisibility` to `off` to protect menus from operations not intended for them.
`Parent`	Figure handle	Handle of the context menu's parent figure.
`Position`	2-element vector: [distance from left, distance from bottom]. Default is `[0 0]`.	Distances from the bottom left corner of the parent figure to the top left corner of the context menu. This property is used only when you programmatically set the context menu `Visible` property to `on`.
`Visible`	`off`, `on`. Default is `off`	• Indicates whether the context menu is currently displayed. While the context menu is displayed, the property value is `on`; when the context menu is not displayed, its value is `off`. • Setting the value to `on` forces the posting of the context menu. Setting to `off` forces the context menu to be removed. The `Position` property determines the location where the context menu is displayed.

For a complete list of properties and for more information about the properties listed in the table, see the Uicontextmenu Properties reference page in the MATLAB Function Reference documentation. Properties needed to control GUI behavior are discussed in Chapter 12, “Programming the GUI”.

Creating the Context Menu Object

Use the `uicontextmenu` function to create a context menu object. The syntax is

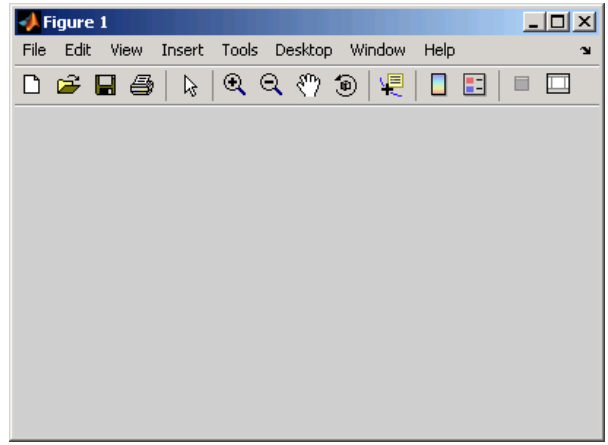
```
handle = uicontextmenu('PropertyName',PropertyValue,...)
```

The parent of a context menu must always be a figure. Use the context menu `Parent` property to specify its parent. If you do not specify `Parent`, the parent is the current figure as specified by the root `CurrentFigure` property.

The following code creates a figure and a context menu whose parent is the figure.

```
fh = figure('Position',[300 300 400 225]);
cmenu = uicontextmenu('Parent',fh,'Position',[10 215]);
```

At this point, the figure is visible, but not the menu.



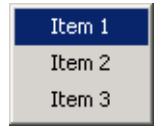
Note "Forcing Display of the Context Menu" on page 11-54 explains the use of the `Position` property.

Adding Menu Items to the Context Menu

Use the `uimenu` function to add items to the context menu. The items appear on the menu in the order in which you add them. The following code adds three items to the context menu created above.

```
mh1 = uimenu(cmenu,'Label','Item 1');
mh2 = uimenu(cmenu,'Label','Item 2');
mh3 = uimenu(cmenu,'Label','Item 3');
```

If you could see the context menu, it would look like this:



You can use any applicable Uimenu Properties such as `Checked` or `Separator` when you define context menu items. See the `uimenu` reference page and "Adding Menu Bar Menus" on page 11-45 for information about using `uimenu` to create menu items. Note that context menus do not have an `Accelerator` property.

Note After you have created the context menu and all its items, set their `HandleVisibility` properties to `off` by executing the following statements:

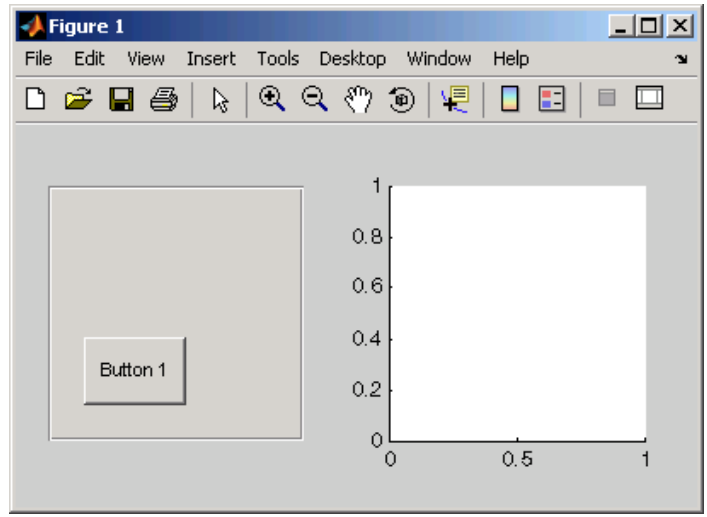
```
cmenuhandles = findall(figurehandle,'type','uicontextmenu');
set(cmenuhandles,'HandleVisibility','off')
menuitemhandles = findall(cmenuhandles,'type','uimenu');
set(menuitemhandles,'HandleVisibility','off')
```

Associating the Context Menu with Graphics Objects

You can associate a context menu with the figure itself and with all components that have a `UIContextMenu` property. This includes axes, panel, button group, all user interface controls (uicontrols).

The following code adds a panel and an axes to the figure. The panel contains a single push button.

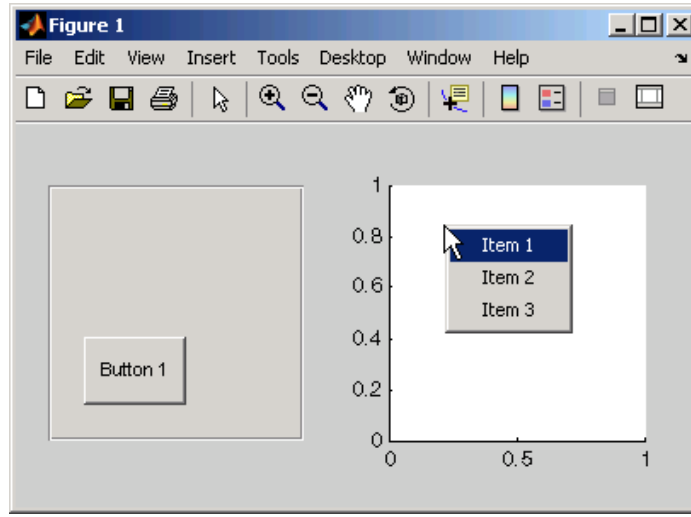
```
ph = uipanel('Parent',fh,'Units','pixels',...
             'Position',[20 40 150 150]);
bh1 = uicontrol(ph,'String','Button 1',...
             'Position',[20 20 60 40]);
ah = axes('Parent',fh,'Units','pixels',...
             'Position',[220 40 150 150]);
```



This code associates the context menu with the figure and with the axes by setting the `UIContextMenu` property of the figure and the axes to the handle `cmenu` of the context menu.

```
set(fh,'UIContextMenu',cmenu);   % Figure
set(ah,'UIContextMenu',cmenu);   % Axes
```

Right-click on the figure or on the axes. The context menu appears with its upper-left corner at the location you clicked. Right-click on the panel or its push button. The context menu does not appear.

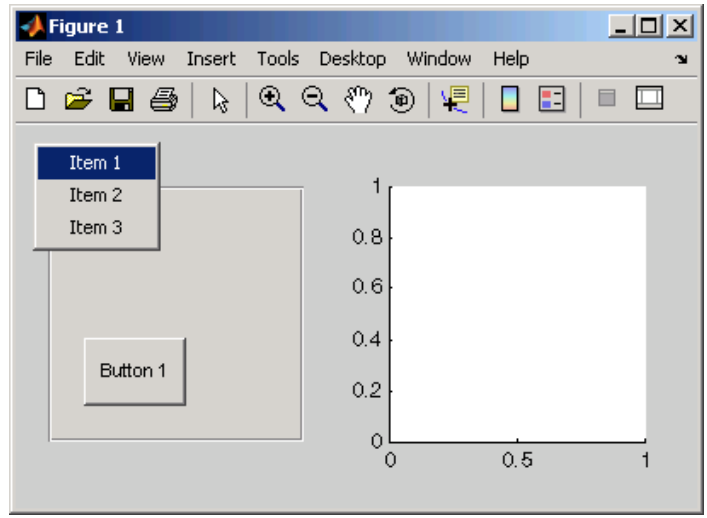


Forcing Display of the Context Menu

If you set the context menu `Visible` property `on`, the context menu is displayed at the location specified by the `Position` property, without the user taking any action. In this example, the context menu `Position` property is [10 215].

```
set(cmenu,'Visible','on');
```

The context menu is displayed 10 pixels from the left of the figure and 215 pixels from the bottom.



If you set the context menu `Visible` property to `off`, or if the user clicks the GUI outside the context menu, the context menu disappears.

Creating Toolbars

In this section...

Using the `uitoolbar` Function

Use the `uitoolbar` function to add a custom toolbar to your GUI. Use the `uipushtool` and `uitoggletool` functions to add push tools and toggle tools to a toolbar. A push tool functions as a push button. A toggle tool functions as a toggle button. You can add push tools and toggle tools to the standard toolbar or to a custom toolbar.

Syntaxes for the `uitoolbar`, `uipushtool`, and `uitoggletool` functions include

```
tbh = uitoolbar(h,'PropertyName',PropertyValue,...)
pth = uipushtool(h,'PropertyName',PropertyValue,...)
tth = uitoggletool(h,'PropertyName',PropertyValue,...)
```

where `tbh`, `pth`, and `tth` are the handles, respectively, of the resulting toolbar, push tool, and toggle tool. See the `uitoolbar`, `uipushtool`, and `uitoggletool` reference pages for other valid syntaxes.

Subsequent topics describe commonly used properties of toolbars and toolbar tools, offer a simple example, and discuss use of the MATLAB standard toolbar:

Commonly Used Properties

The most commonly used properties needed to describe a toolbar and its tools are shown in the following table.

Property	Values	Description
`CData`	3-D array of values between 0.0 and 1.0	n-by-m-by-3 array of RGB values that defines a truecolor image displayed on either a push button or toggle button.
`HandleVisibility`	`on`, `off`. Default is `on`.	Determines if an object's handle is visible in its parent's list of children. For toolbars and their tools, set `HandleVisibility` to `off` to protect them from operations not intended for them.
`Separator`	`off`, `on`. Default is `off`.	Draws a dividing line to left of the push tool or toggle tool
`State`	`off`, `on`. Default is `off`.	Toggle tool state. `on` is the down, or depressed, position. `off` is the up, or raised, position.
`TooltipString`	String	Text of the tooltip associated with the push tool or toggle tool.

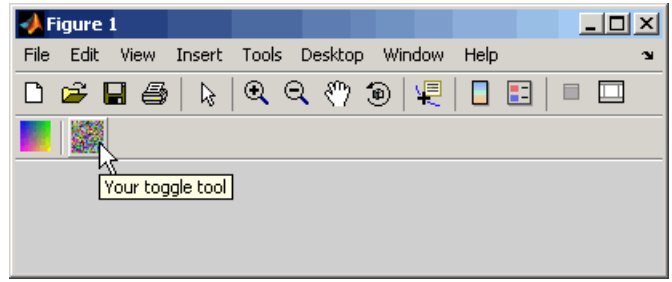
For a complete list of properties and for more information about the properties listed in the table, see the Uitoolbar Properties, Uipushtool Properties, and Uitoggletool Properties reference pages in the MATLAB Function Reference documentation. Properties needed to control GUI behavior are discussed in Chapter 12, "Programming the GUI".

Toolbars

The following statements add a toolbar to a figure, and then add a push tool and a toggle tool to the toolbar. By default, the tools are added to the toolbar, from left to right, in the order they are created.

```
% Create the toolbar
th = uitoolbar(fh);
```

```
% Add a push tool to the toolbar
a = [.20:.05:0.95]
img1(:,:,1) = repmat(a,16,1)'
img1(:,:,2) = repmat(a,16,1);
img1(:,:,3) = repmat(flipdim(a,2),16,1);
pth = uipushtool(th,'CData',img1,...
           'TooltipString','My push tool',...
           'HandleVisibility','off')
% Add a toggle tool to the toolbar
img2 = rand(16,16,3);
tth = uitoggletool(th,'CData',img2,'Separator','on',...
           'TooltipString','Your toggle tool',...
           'HandleVisibility','off')
```



`fh` is the handle of the parent figure.

`th` is the handle of the parent toolbar.

`CData` is a 16-by-16-by-3 array of values between 0 and 1. It defines the truecolor image that is displayed on the tool. If your image is larger than 16 pixels in either dimension, it may be clipped or cause other undesirable effects. If the array is clipped, only the center 16-by-16 part of the array is used.

Note Create your own icon with the icon editor described in "Icon Editor" on page 15-29. See the `ind2rgb` reference page for information on converting a matrix `X` and corresponding colormap, i.e., an `(X, MAP)` image, to RGB (truecolor) format.

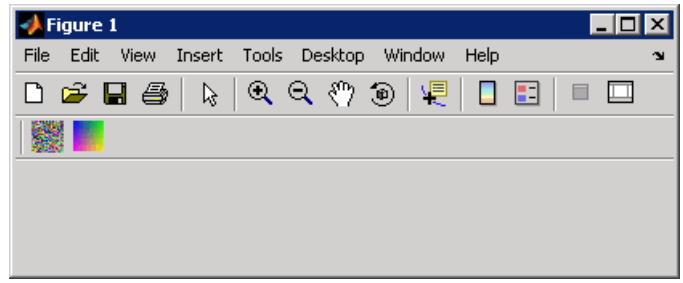
`TooltipString` specifies the tooltips for the push tool and the toggle tool as `My push tool` and `Your toggle tool`, respectively.

In this example, setting the toggle tool `Separator` property to `on` creates a dividing line to the left of the toggle tool.

You can change the order of the tools by modifying the child vector of the parent toolbar. For this example, execute the following code to reverse the order of the tools.

```
oldOrder = allchild(th);
newOrder = flipud(oldOrder);
set(th,'Children',newOrder);
```

This code uses `flipud` because the `Children` property is a column vector.



Use the `delete` function to remove a tool from the toolbar. The following statement removes the  toggle tool from the toolbar. The toggle tool handle is `tth`.

```
delete(tth)
```

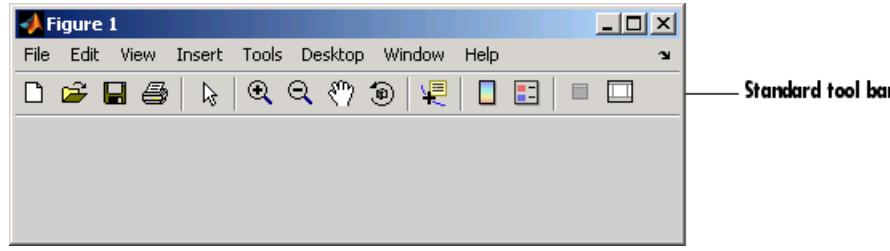
If necessary, you can use the `findall` function to determine the handles of the tools on a particular toolbar.

Note After you have created a toolbar and its tools, set their `HandleVisibility` properties `off` by executing statements similar to the following:

```
set(toolbarhandle,'HandleVisibility','off')
toolhandles = get(toolbarhandle,'Children');
set(toolhandles,'HandleVisibility','off')
```

Displaying and Modifying the Standard Toolbar

You can choose whether or not to display the MATLAB standard toolbar on your GUI. You can also add or delete tools from the standard toolbar.



Displaying the Standard Toolbar

Use the figure `Toolbar` property to display or hide the MATLAB standard toolbar. Set `Toolbar` to `figure` to display the standard toolbar. Set `Toolbar` to `none` to hide it.

```
set(fh,'Toolbar','figure');  % Display the standard toolbar
set(fh,'Toolbar','none');    % Hide the standard toolbar
```

In these statements, `fh` is the handle of the figure.

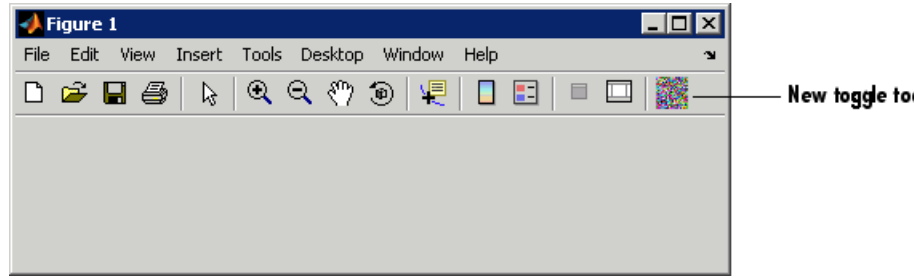
The default figure `Toolbar` setting is `auto`. This setting displays the figure toolbar, but removes it if you add a user interface control (uicontrol) to the figure.

Modifying the Standard Toolbar

Once you have the handle of the standard toolbar, you can add tools, delete tools, and change the order of the tools.

Add a tool the same way you would add it to a custom toolbar. The following code retrieves the handle of the MATLAB standard toolbar and adds to the toolbar a toggle tool similar to the one defined in “Toolbars” on page 11-57. `fh` is the handle of the figure.

```
tbh = findall(fh,'Type','uitoolbar');
tth = uitoggletool(tbh,'CData',rand(20,20,3),...
            'Separator','on',...
            'HandleVisibility','off');
```



To remove a tool from the standard toolbar, determine the handle of the tool to be removed, and then use the `delete` function to remove it. The following code deletes the toggle tool that was added to the standard toolbar above.

```
delete(tth)
```

If necessary, you can use the `findall` function to determine the handles of the tools on the standard toolbar.

Designing for Cross-Platform Compatibility

In this section...

Default System Font

By default, user interface controls (uicontrols) use the default font for the platform on which they are running. For example, when displaying your GUI on PCs, user interface controls use MS San Serif. When your GUI runs on a different platform, they use that computer's default font. This provides a consistent look with respect to your GUI and other application GUIs on the same platform.

If you have set the `FontName` property to a named font and want to return to the default value, you can set the property to the string `default`. This ensures that MATLAB uses the system default at run-time.

You can use the `set` command to set this property. For example, if there is a push button with handle `pbh1` in your GUI, then the statement

```
set(pbh1,'FontName','default')
```

sets the `FontName` property to use the system default.

Specifying a Fixed-Width Font

If you want to use a fixed-width font for a user interface control, set its `FontName` property to the string `fixedwidth`. This special identifier ensures that your GUI uses the standard fixed-width font for the target platform.

You can find the name of the fixed-width font that is used on a given platform by querying the root `FixedWidthFontName` property.

```
get(0,'FixedWidthFontName')
```

Using a Specific Font Name

You can specify an actual font name (such as Times or Courier) for the `FontName` property. However, doing so may cause your GUI to appear differently than you intended when run on a different computer. If the target computer does not have the specified font, it substitutes another font that may not look good in your GUI or may not be the standard font used for GUIs on that system. Also, different versions of the same named font may have different size requirements for a given set of characters.

Standard Background Color

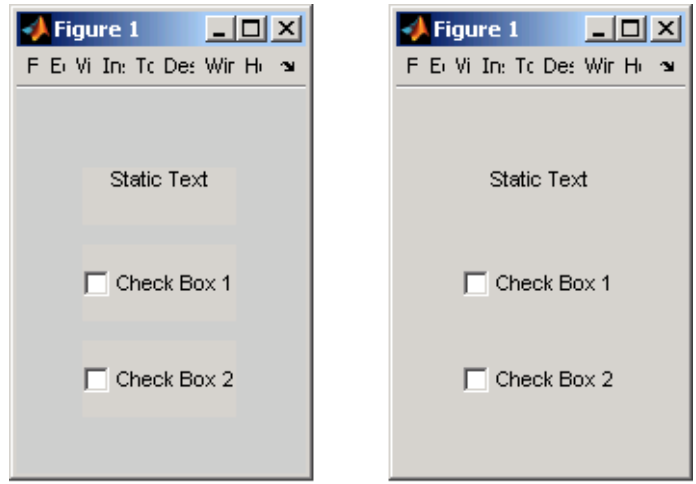
MATLAB uses the standard system background color of the system on which the GUI is running as the default component background color. This color varies on different computer systems, e.g., the standard shade of gray on the PC differs from that on UNIX, and may not match the default GUI background color.

You can make the GUI background color match the default component background color. The following statements retrieve the default component background color and assign it to the figure.

```
defaultBackground = get(0,'defaultUicontrolBackgroundColor');
set(figurehandle,'Color',defaultBackground)
```

The figure `Color` property specifies the figure's background color.

The following figures illustrate the results with and without system color matching.



Without system color matching

With system color matching

Cross-Platform Compatible Units

Cross-platform compatible GUIs should look correct on computers having different screen sizes and resolutions. Since the size of a pixel can vary on different computer displays, using the default figure `Units` of `pixels` does not produce a GUI that looks the same on all platforms. Setting the figure and components `Units` properties appropriately can help to determine how well the GUI transports to different platforms.

Units and Resize Behavior

The choice of units is also tied to the GUI's resize behavior. The figure `Resize` and `ResizeFcn` properties control the resize behavior of your GUI.

`Resize` determines if you can resize the figure window with the mouse. The `on` setting means you can resize the window, `off` means you cannot. When you set `Resize` to `off`, the figure window does not display any resizing controls to indicate that it cannot be resized.

`ResizeFcn` enables you to customize the GUI's resize behavior and is valid only if you set `Resize` to `on`. `ResizeFcn` is the handle of a user-written callback that is executed when a user resizes the GUI. It controls the resizing of all components in the GUI.

The following table shows appropriate `Units` settings based on the resize behavior of your GUI. These settings enable your GUI to automatically adjust the size and relative spacing of components as the GUI displays on different computers and when the GUI is resized.

Component	Default Units	Resize = on ResizeFcn = []	Resize = off
Figure	`pixels`	`characters`	`characters`
User interface controls (uicontrol) such as push buttons, sliders, and edit text components	`pixels`	`normalized`	characters
Axes	`normalized`	`normalized`	`characters`
Panel	`normalized`	`normalized`	`characters`
Button group	`normalized`	`normalized`	`characters`

Note The default settings shown in the table above are not the same as the GUIDE default settings. GUIDE default settings depend on the GUIDE **Resize behavior** option and are the same as those shown in the last two columns of the table.

About Some Units Settings

Characters. Character units are defined by characters from the default system font. The width of a character unit equals the width of the letter `x` in the system font. The height of a character unit is the distance between the baselines of two lines of text. Note that character units are not square.

Normalized. Normalized units represent a percentage of the size of the parent. The value of normalized units lies between 0 and 1. For example, if a panel contains a push button and the button units setting is `normalized`, then the push button `Position` setting [.2 .2 .6 .25] means that the left side of the push button is 20 percent of the panel width from the left side of the panel; the bottom of the button is 20 percent of the panel height from the bottom of the panel; the button itself is 60 percent of the width of the panel and 25 percent of its height.

Using Familiar Units of Measure. At times, it may be convenient to use a more familiar unit of measure, e.g., inches or centimeters, when you are laying out the GUI. However, to preserve the look of your GUI on different computers, remember to change the figure `Units` property back to `characters`, and the components' `Units` properties to `characters` (nonresizable GUIs) or `normalized` (resizable GUIs) before you save the M-file.

12

Programming the GUI

Introduction

After you have laid out your GUI, you need to program its behavior. This chapter addresses the programming of GUIs created programmatically. Specifically, it discusses data creation, GUI initialization, and the use of callbacks to control GUI behavior.

The following ordered list shows these topics within the organization of the typical GUI M-file.

1. Comments displayed in response to the MATLAB `help` command.
2. Initialization tasks such as data creation and any processing that is needed to construct the components. See "Initializing the GUI" on page 12-4 for information.
3. Construction of figure and components. See Chapter 11, "Laying Out a GUI" for information.
4. Initialization tasks that require the components to exist, and output return. See "Initializing the GUI" on page 12-4 for information.
5. Callbacks for the components. Callbacks are the routines that execute in response to user-generated events such as mouse clicks and key strokes. See "Callbacks: An Overview" on page 12-9 and "Examples: Programming GUI Components" on page 12-15 for information.
6. Utility functions.

Discussions in this chapter assume the use of nested functions. For information about using nested functions, see "Nested Functions" in the MATLAB Programming documentation.

See "Functions — By Category" in the MATLAB Function Reference documentation for a list of functions that are provided for GUI creation.

Note MATLAB provides a selection of standard dialog boxes that you can create with a single function call. For information about these dialog boxes and the functions used to create them, see “Predefined Dialog Boxes” in the MATLAB Function Reference documentation.

Initializing the GUI

Many kinds of tasks can be thought of as initialization tasks. This is a sampling of some of them:

- Define variables for supporting input and output arguments. See "Declaring Variables for Input and Output Arguments" on page 12-5.
- Define default values for input and output arguments.
- Define custom property values used for constructing the components. See "Defining Custom Property/Value Pairs" on page 12-5.
- Process command line input arguments.
- Create variables and data to be used by functions that are nested below the initialization section of the M-file. See "Nested Functions" in the MATLAB Programming documentation.
- Define variables for data to be shared between GUIs.
- Return user output if it is requested.
- Update or initialize components.
- Make changes needed to refine the look and feel of the GUI.
- Make changes needed for cross-platform compatibility. See "Designing for Cross-Platform Compatibility" on page 11-62.
- Make the GUI invisible while the components are being created and initialized. See "Making the Figure Invisible" on page 12-6.
- Make the GUI visible when you are ready for the user to see it.

Group these tasks together rather than scattering them throughout the code. If an initialization task is long or complex, consider creating a utility function to do the work.

Typically, some initialization tasks appear in the M-file before the components are constructed. Others appear after the components are constructed. Initialization tasks that require the components must appear following their construction.

Examples

These are some initialization examples taken from the examples discussed in Chapter 15, “Examples of GUIs Created Programmatically”. If MATLAB is running on your system, you can use these links to see the complete M-files:

- Color Palette
- Icon Editor

Declaring Variables for Input and Output Arguments

These are typical declarations for input and output arguments. They are taken from example “Icon Editor” on page 15-29.

```
mInputArgs = varargin; % Command line arguments when invoking
                       % the GUI
mOutputArgs = {};      % Variable for storing output when GUI
                       % returns
```

See the `varargin` reference page and the Icon Editor M-file for more information.

Defining Custom Property/Value Pairs

The example “Icon Editor” on page 15-29 defines property value pairs to be used as input arguments.

The example defines the properties in a cell array, `mPropertyDefs`, and then initializes the properties.

```
mPropertyDefs = {...
                'iconwidth',  @localValidateInput, 'mIconWidth';
                'iconheight', @localValidateInput, 'mIconHeight';
                'iconfile',   @localValidateInput, 'mIconFile'};
mIconWidth = 16;   % Use input property 'iconwidth' to initialize
mIconHeight = 16;  % Use input property 'iconheight' to initialize
mIconFile = fullfile(matlabroot,'toolbox/matlab/icons/');
                  % Use input property 'iconfile' to initialize
```

Each row of the cell array defines one property. It specifies, in order, the name of the property, the routine that is called to validate the input, and the name of the variable that holds the property value.

The `fullfile` function builds a full filename from parts.

The following statements each start the Icon Editor. The first one could be used to create a new icon. The second one could be used to edit an existing icon file.

```
cdata = iconEditor('iconwidth',16,'iconheight',25)
cdata = iconEditor('iconfile','eraser.gif');
```

`iconEditor` calls a routine, `processUserIputs`, during the initialization to

- Identify each property by matching it to the first column of the cell array
- Call the routine named in the second column to validate the input
- Assign the value to the variable named in the third column

See the complete Icon Editor M-file for more information.

Making the Figure Invisible

When you create the GUI figure, make it invisible so that you can display it for the user only when it is complete. Making it invisible during creation also enhances performance.

To make the GUI invisible, set the figure `Visible` property to `off`. This makes the entire figure window invisible. The statement that creates the figure might look like this:

```
hMainFigure = figure(...
              'Units','characters',...
              'MenuBar','none',...
              'Toolbar','none',...
              'Position',[71.8 34.7 106 36.15],...
              'Visible','off');
```

Just before returning to the caller, you can make the figure visible with a statement like the following:

```
set(hMainFigure,'Visible','on')
```

Most components have `Visible` properties. You can also use these properties to make individual components invisible.

Returning Output to the User

If your GUI function provides for an argument to the left of the equal sign, and the user specifies such an argument, then you want to return the expected output. The code that provides this output usually appears just before the GUI returns.

In the example shown here, taken from the Icon Editor example M-file,

1. A call to `uiwait` blocks execution until `uiresume` is called or the current figure is deleted.
2. While execution is blocked, the GUI user creates the desired icon.
3. When the user signals completion of the icon by clicking **OK**, the routine that services the **OK** push button calls `uiresume` and control returns to the statement following the call to `uiwait`.
4. The GUI then returns the completed icon to the user as output of the GUI.

```
% Make the GUI blocking.
uiwait(hMainFigure);

% Return the edited icon CData if it is requested.
mOutputArgs{1} = mIconCData;
if nargout>0
    [varargout{1:nargout}] = mOutputArgs{:};
end
```

`mIconData` contains the icon that the user created or edited. `mOutputArgs` is a cell array defined to hold the output arguments. `nargout` indicates how many output arguments the user has supplied. `varargout` contains the optional

output arguments returned by the GUI. See the complete Icon Editor M-file for more information.

Callbacks: An Overview

In this section...

What Is a Callback?

The callback functions you provide control how the GUI responds to events such as button clicks, slider movement, menu item selection, or the creation and deletion of components. There is a set of callbacks for each component and for the GUI figure itself.

The callback routines usually appear in the M-file following the initialization code and the creation of the components. See "File Organization" on page 11-4 for more information.

A callback is a function that you write and associate with a specific component in the GUI or with the GUI figure itself. The callbacks control GUI or component behavior by performing some action in response to an event for its component. The event can be a mouse click on a push button, menu selection, key press, etc. This kind of programming is often called event-driven programming.

When an event occurs for a component, MATLAB invokes the component callback that is associated with that event. As an example, suppose a GUI has a push button that triggers the plotting of some data. When the user clicks the button, MATLAB calls the callback you associated with clicking that button, and then the callback, which you have programmed, gets the data and plots it.

A component can be any control device such as an axes, push button, list box, or slider. For purposes of programming, it can also be a menu, toolbar tool, or a container such as a panel or button group. See "Available Components" on page 11-10 for a list and descriptions of components.

Kinds of Callbacks

The GUI figure and each type of component has specific kinds of callbacks with which you can associate it. The callbacks that are available for each component are defined as properties of that component. For example, a push button has five callback properties: `ButtonDownFcn`, `Callback`, `CreateFcn`, `DeleteFcn`, and `KeyPressFcn`. A panel has four callback properties: `ButtonDownFcn`, `CreateFcn`, `DeleteFcn`, and `ResizeFcn`. You can, but are not required to, create a callback function for each of these properties. The GUI itself, which is a figure, also has certain kinds of callbacks with which it can be associated.

Each kind of callback has a triggering mechanism or event that causes it to be called. The following table lists the callback properties that are available, their triggering events, and the components to which they apply.

Callback Property	Triggering Event	Components
`ButtonDownFcn`	Executes when the user presses a mouse button while the pointer is on or within five pixels of a component or figure.	Axes, figure, button group, panel, user interface controls
`Callback`	Control action. Executes, for example, when a user clicks a push button or selects a menu item.	Context menu, menu user interface controls
`ClickedCallback`	Control action. Executes when the push tool or toggle tool is clicked. For the toggle tool, this is independent of its state.	Push tool, toggle tool
`CloseRequestFcn`	Executes when the figure closes.	Figure

Callback Property	Triggering Event	Components
`CreateFcn`	Initializes the component when it is created. It executes after the component or figure is created, but before it is displayed.	Axes, button group, context menu, figure, menu, panel, push tool, toggle tool, toolbar, user interface controls
`DeleteFcn`	Performs cleanup operations just before the component or figure is destroyed.	Axes, button group, context menu, figure, menu, panel, push tool, toggle tool, toolbar, user interface controls
`KeyPressFcn`	Executes when the user presses a keyboard key and the callback's component or figure has focus.	Figure, user interface controls
`KeyReleaseFcn`	Executes when the user releases a keyboard key and the figure has focus.	Figure
`OffCallback`	Control action. Executes when the state of a toggle tool is changed to off.	Toggle tool
`OnCallback`	Control action. Executes when the state of a toggle tool is changed to on.	Toggle tool
`ResizeFcn`	Executes when a user resizes a panel, button group, or figure whose figure `Resize` property is set to `On`.	Figure, button group, panel

Callback Property	Triggering Event	Components
`SelectionChangeFcn`	Executes when a user selects a different radio button or toggle button in a button group component.	Button group
`WindowButtonDownFcn`	Executes when you press a mouse button while the pointer is in the figure window.	Figure
`WindowButtonMotionFcn`	Executes when you move the pointer within the figure window.	Figure
`WindowButtonUpFcn`	Executes when you release a mouse button.	Figure
`WindowScrollWheelFcn`	Executes when the mouse wheel is scrolled while the figure has focus.	Figure

Note User interface controls include push buttons, sliders, radio buttons, check boxes, editable text boxes, static text boxes, list boxes, and toggle buttons. They are sometimes referred to as uicontrols.

Check the properties reference page for your component, e.g., Uicontrol Properties, to get specific information for a given callback property.

Associating Callbacks with Components

A GUI can have many components and each component's properties provide a way of specifying which callback should run in response to a particular event for that component. The callback that runs when the user clicks a **Yes** button is not the one that runs for the **No** button. Each menu item also performs a different function and needs its own callback.

You associate a callback with a specific component by setting the value of the appropriate component callback property to the callback. This is usually done in the component definition.

You can specify a component callback property value as any of the following:

- **String** that is a valid MATLAB expression or the name of an M-file.
- **Cell array of strings**. This example uses a cell array of strings to specify `pushbutton_callback` as the callback routine to be executed when a user clicks **Button 1**.

  ```
  pbh = uicontrol(fh,'Style','pushbutton','String','Button 1',...
                  'Position',[50 20 60 40],...
                  'Callback',{'pushbutton_callback',width,...});
  ```

  `Callback` is the name of the callback property. The first element of the cell array is the name of the callback routine, subsequent elements are input arguments to the callback.

  The corresponding function definition would look like this:

  ```
  function pushbutton_callback(width,...)
  ```

  See “Defining Callbacks as a Cell Array of Strings — Special Case” in the MATLAB Graphics documentation for more information.

- **Function handle or cell array** containing a function handle and additional arguments. This example uses a function handle to specify `pushbutton_callback` as the callback routine to be executed when a user clicks **Button 1**.

  ```
  pbh = uicontrol(fh,'Style','pushbutton','String','Button 1',...
                  'Position',[50 20 60 40],...
                  'Callback',{@pushbutton_callback,width,...});
  ```

  `Callback` is the name of the callback property. The first element of the cell array is the handle of the callback routine, subsequent elements are input arguments to the callback.

  Because the callback is specified as a handle, MATLAB automatically passes two additional arguments, the handle of the component for which the event was triggered and `eventdata`, as the first two arguments of the

callback. The second element of the cell array, `width` in the example above, becomes the third argument of the callback.

The corresponding function definition would contain these two additional arguments:

```
function pushbutton_callback(hObject,eventdata,width,...)
```

See “Introduction” in the MATLAB Graphics documentation for more information.

When an appropriate event occurs, it triggers execution of the MATLAB expression, the script or function contained in the M-file, the specified function, or the function associated with the function handle. The same is true for menus, toolbar tools, and for the figure itself.

See “Kinds of Callbacks” on page 12-10 for a list of the available callbacks for each component. See the component property pages for information about specific callback properties.

Examples: Programming GUI Components

In this section...

Programming User Interface Controls

The examples assume that callback properties are specified using function handles, enabling MATLAB to pass arguments `hObject`, which is the handle of the component for which the event was triggered, and `eventdata`. See "Associating Callbacks with Components" on page 12-12 for more information.

- "Check Box" on page 12-16
- "Edit Text" on page 12-16
- "List Box" on page 12-18
- "Pop-Up Menu" on page 12-19
- "Push Button" on page 12-20
- "Radio Button" on page 12-21
- "Slider" on page 12-21
- "Toggle Button" on page 12-22

Note See "Available Components" on page 11-10 for descriptions of these components. See "Adding User Interface Controls" on page 11-13 for information about adding these components to your GUI.

Check Box

You can determine the current state of a check box from within any of its callbacks by querying the state of its `Value` property, as illustrated in the following example:

```
function checkbox1_Callback(hObject,eventdata)
if (get(hObject,'Value') == get(hObject,'Max'))
   % Checkbox is checked-take approriate action
else
   % Checkbox is not checked-take approriate action
end
```

`hObject` is the handle of the component for which the event was triggered.

You can also change the state of a check box by programmatically by setting the check box `Value` property to the value of the `Max` or `Min` property. For example,

```
set(cbh,'Value','Max')
```

puts the check box with handle `cbh` in the checked state.

Edit Text

To obtain the string a user types in an edit box, use any of its callbacks to get the value of the `String` property. This example uses the `Callback` callback.

```
function edittext1_Callback(hObject,eventdata)
user_string = get(hObject,'String');

% Proceed with callback
```

If the edit text `Max` and `Min` properties are set such that `Max - Min > 1`, the user can enter multiple lines. For example, setting `Max` to `2`, with the default value of `0` for `Min`, enables users to enter multiple lines. If you originally specify `String` as a character string, multiline user input is returned as a 2-D character array with each row containing a line. If you originally specify `String` as a cell array, multiline user input is returned as a 2-D cell array of strings.

`hObject` is the handle of the component for which the event was triggered.

Retrieving Numeric Data from an Edit Text Component. MATLAB returns the value of the edit text `String` property as a character string. If you want users to enter numeric values, you must convert the characters to numbers. You can do this using the `str2double` command, which converts strings to doubles. If the user enters nonnumeric characters, `str2double` returns `NaN`.

You can use code similar to the following in an edit text callback. It gets the value of the `String` property and converts it to a double. It then checks whether the converted value is `NaN` (`isnan`), indicating the user entered a nonnumeric character and displays an error dialog box (`errordlg`).

```
function edittext1_Callback(hObject,eventdata)
user_entry = str2double(get(hObject,'string'));
if isnan(user_entry)
 errordlg('You must enter a numeric value','Bad Input','modal')
 return
end

% Proceed with callback...
```

Triggering Callback Execution. If the contents of the edit text component have been changed, clicking inside the GUI, but outside the edit text, causes the edit text callback to execute. The user can also press **Enter** for an edit text that allows only a single line of text, or **Ctrl+Enter** for an edit text that allows multiple lines.

Available Keyboard Accelerators. GUI users can use the following keyboard accelerators to modify the content of an edit text. These accelerators are not modifiable.

- **Ctrl+X** – Cut
- **Ctrl+C** – Copy
- **Ctrl+V** – Paste
- **Ctrl+H** – Delete last character
- **Ctrl+A** – Select all

List Box

When the list box `Callback` callback is triggered, the list box `Value` property contains the index of the selected item, where `1` corresponds to the first item in the list. The `String` property contains the list as a cell array of strings.

This example retrieves the selected string. Note that it is necessary to convert the value of the `String` property from a cell array to a string.

```
function listbox1_Callback(hObject,eventdata)
index_selected = get(hObject,'Value');
list = get(hObject,'String');
item_selected = list{index_selected}; % Convert from cell array
                                      % to string
```

`hObject` is the handle of the component for which the event was triggered.

You can also select a list item programmatically by setting the list box `Value` property to the index of the desired item. For example,

```
set(lbh,'Value',2)
```

selects the second item in the list box with handle `lbh`.

Triggering Callback Execution. MATLAB executes the list box `Callback` callback after the mouse button is released or after certain key press events:

- The arrow keys change the `Value` property, trigger callback execution, and set the figure `SelectionType` property to `normal`.
- The **Enter** key and space bar do not change the `Value` property, but trigger callback execution and set the figure `SelectionType` property to `open`.

If the user double-clicks, the callback executes after each click. MATLAB sets the figure `SelectionType` property to `normal` on the first click and to `open` on the second click. The callback can query the figure `SelectionType` property to determine if it was a single or double click.

List Box Examples. See the following examples for more information on using list boxes:

- "List Box Directory Reader" on page 10-9 — Shows how to creates a GUI that displays the contents of directories in a list box and enables users to open a variety of file types by double-clicking the filename.
- "Accessing Workspace Variables from a List Box" on page 10-16 — Shows how to access variables in the MATLAB base workspace from a list box GUI.

Pop-Up Menu

When the pop-up menu `Callback` callback is triggered, the pop-up menu `Value` property contains the index of the selected item, where `1` corresponds to the first item on the menu. The `String` property contains the menu items as a cell array of strings.

Note A pop-up menu is sometimes referred to as a drop-down menu or combo box.

Using Only the Index of the Selected Menu Item. This example retrieves only the index of the item selected. It uses a switch statement to take action based on the value. If the contents of the pop-up menu are fixed, then you can use this approach. Else, you can use the index to retrieve the actual string for the selected item.

```
function popupmenu1_Callback(hObject,eventdata)
val = get(hObject,'Value');
switch val
case 1   % User selected the first item
case 2   % User selected the second item

% Proceed with callback...
```

`hObject` is the handle of the component for which the event was triggered.

You can also select a menu item programmatically by setting the pop-up menu `Value` property to the index of the desired item. For example,

```
set(pmh,'Value',2)
```

selects the second item in the pop-up menu with handle `pmh`.

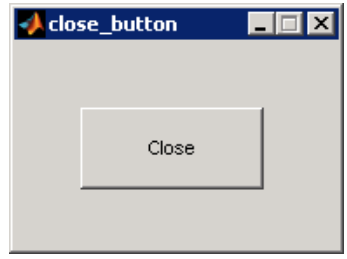
Using the Index to Determine the Selected String. This example retrieves the actual string selected in the pop-up menu. It uses the pop-up menu `Value` property to index into the list of strings. This approach may be useful if your program dynamically loads the contents of the pop-up menu based on user action and you need to obtain the selected string. Note that it is necessary to convert the value returned by the `String` property from a cell array to a string.

```
function popupmenu1_Callback(hObject,eventdata)
val = get(hObject,'Value');
string_list = get(hObject,'String');
selected_string = string_list{val}; % Convert from cell array
                                    % to string
% Proceed with callback...
```

`hObject` is the handle of the component for which the event was triggered.

Push Button

This example contains only a push button. Clicking the button, closes the GUI.



This is the push button's `Callback` callback. It displays the string `Goodbye` at the command line and then closes the GUI.

```
function pushbutton1_Callback(hObject,eventdata)
display Goodbye
close(gcbf)
```

`gcbf` returns the handle of the figure containing the object whose callback is executing.

Radio Button

You can determine the current state of a radio button from within its `Callback` callback by querying the state of its `Value` property, as illustrated in the following example:

```
function radiobutton_Callback(hObject,eventdata)
if (get(hObject,'Value') == get(hObject,'Max'))
 % Radio button is selected-take approriate action
else
 % Radio button is not selected-take approriate action
end
```

Radio buttons set `Value` to `Max` when they are on (when selected) and `Min` when off (not selected). `hObject` is the handle of the component for which the event was triggered.

You can also change the state of a radio button programmatically by setting the radio button `Value` property to the value of the `Max` or `Min` property. For example,

```
set(rbh,'Value','Max')
```

puts the radio button with handle `rbh` in the selected state.

Note You can use a button group to manage exclusive selection behavior for radio buttons. See “Button Group” on page 12-23 for more information.

Slider

You can determine the current value of a slider from within its `Callback` callback by querying its `Value` property, as illustrated in the following example:

```
function slider1_Callback(hObject,eventdata)
slider_value = get(hObject,'Value');

% Proceed with callback...
```

The Max and Min properties specify the slider's maximum and minimum values. The slider's range is Max - Min. hObject is the handle of the component for which the event was triggered.

Toggle Button

The callback for a toggle button needs to query the toggle button to determine what state it is in. MATLAB sets the Value property equal to the Max property when the toggle button is pressed (Max is 1 by default). It sets the Value property equal to the Min property when the toggle button is not pressed (Min is 0 by default).

The following code illustrates how to program the callback in the GUI M-file.

```
function togglebutton1_Callback(hObject,eventdata)
button_state = get(hObject,'Value');
if button_state == get(hObject,'Max')
 % Toggle button is pressed-take approperiate action
   ...
elseif button_state == get(hObject,'Min')
 % Toggle button is not pressed-take appropriate action
    ...
end
```

hObject is the handle of the component for which the event was triggered.

You can also change the state of a toggle button programmatically by setting the toggle button Value property to the value of the Max or Min property. For example,

```
set(tbh,'Value','Max')
```

puts the toggle button with handle tbh in the pressed state.

Note You can use a button group to manage exclusive selection behavior for toggle buttons. See "Button Group" on page 12-23 for more information.

Programming Panels and Button Groups

These topics provide basic code examples for panels and button group callbacks.

The examples assume that callback properties are specified using function handles, enabling MATLAB to pass arguments `hObject`, which is the handle of the component for which the event was triggered, and `eventdata`. See "Associating Callbacks with Components" on page 12-12 for more information.

Panel

Panels group GUI components and can make a GUI easier to understand by visually grouping related controls. A panel can contain panels and button groups, as well as axes and user interface controls such as push buttons, sliders, pop-up menus, etc. The position of each component within a panel is interpreted relative to the lower-left corner of the panel.

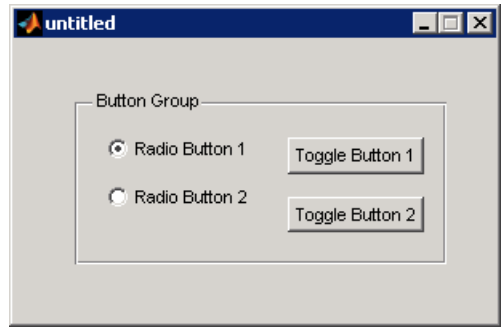
Generally, if the GUI is resized, the panel and its components are also resized. However, you can control the size and position of the panel and its components. You can do this by setting the GUI `Resize` property to `on` and providing a `ResizeFcn` callback for the panel.

Note See "Cross-Platform Compatible Units" on page 11-64 for information about the effect of units on resize behavior.

Button Group

Button groups are like panels except that they manage exclusive selection behavior for radio buttons and toggle buttons. If a button group contains a set of radio buttons, toggle buttons, or both, the button group allows only one of them to be selected. When a user clicks a button, that button is selected and all other buttons are deselected.

The following figure shows a button group with two radio buttons and two toggle buttons. **Radio Button 1** is selected.



If a user clicks the other radio button or one of the toggle buttons, it becomes selected and **Radio Button 1** is deselected. The following figure shows the result of clicking **Toggle Button 2**.

The button group `SelectionChangeFcn` callback is called whenever a selection is made. If you have a button group that contains a set of radio buttons and toggle buttons and you want:

- An immediate action to occur when a radio button or toggle button is selected, you must include the code to control the radio and toggle buttons in the button group's `SelectionChangeFcn` callback function, not in the individual toggle button `Callback` functions. "Color Palette" on page 15-17 provides a practical example of a `SelectionChangeFcn` callback.

- Another component such as a push button to base its action on the selection, then that component's `Callback` callback can get the handle of the selected radio button or toggle button from the button group's `SelectedObject` property.

This example of a `SelectionChangeFcn` callback uses the `Tag` property of the selected object to choose the appropriate code to execute. The `Tag` property of each component is a string that identifies that component and must be unique in the GUI.

```
function uibuttongroup1_SelectionChangeFcn(hObject,eventdata)
switch get(eventdata.NewValue,'Tag') % Get Tag of selected object.
    case 'radiobutton1'
        % Code for when radiobutton1 is selected.
    case 'radiobutton2'
        % Code for when radiobutton2 is selected.
    case 'togglebutton1'
        % Code for when togglebutton1 is selected.
    case 'togglebutton2'
        % Code for when togglebutton2 is selected.
    % Continue with more cases as necessary.
    otherwise
        % Code for when there is no match.
end
```

The `hObject` and `eventdata` arguments are available to the callback only if the value of the callback property is specified as a function handle. See the`SelectionChangeFcn` property on the Uibuttongroup Properties reference page for information about `eventdata`. See the `uibuttongroup` reference page and "Color Palette" on page 15-17 for other examples.

Programming Axes

Axes components enable your GUI to display graphics, such as graphs and images. This topic briefly tells you how to plot to an axes in your GUI.

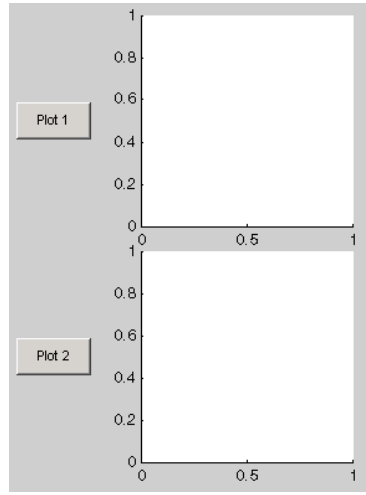
In most cases, you create a plot in an axes from a callback that belongs to some other component in the GUI. For example, pressing a button might trigger the plotting of a graph to an axes. In this case, the button's `Callback` callback contains the code that generates the plot.

The following example contains two axes and two push buttons. Clicking the first button generates a `contour` plot in one axes and clicking the other button generates a `surf` plot in the other axes. The example generates data for the plots using the `peaks` function, which returns a square matrix obtained by translating and scaling Gaussian distributions.

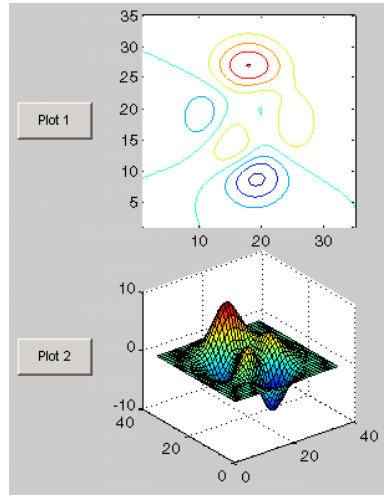
1 Save this code in an M-file named `two_axes.m`.

```
function two_axes
fh = figure;
bh1 = uicontrol(fh,'Position',[20 290 60 30],...
                'String','Plot 1',...
                'Callback',@button1_plot);
bh2 = uicontrol(fh,'Position',[20 100 60 30],...
                'String','Plot 2',...
                'Callback',@button2_plot);
ah1 = axes('Parent',fh,'units','pixels',...
           'Position',[120 220 170 170]);
ah2 = axes('Parent',fh,'units','pixels',...
           'Position',[120 30 170 170]);
   %-----------------------------------------------
   function button1_plot(hObject,eventdata)
      contour(ah1,peaks(35));
   end
   %-----------------------------------------------
   function button2_plot(hObject,eventdata)
      surf(ah2,peaks(35));
   end
end
```

2 Run the GUI by typing `two_axes` at the command line. This is what the example looks like before you click the push buttons.



3 Click the **Plot 1** button to display the contour plot in the first axes. Click the **Plot 2** button to display the surf plot in the second axes.



See “GUI with Multiple Axes” on page 10-2 for a more complex example that uses two axes.

If your GUI contains axes, you should ensure that their `HandleVisibility` properties are set to `callback`. This allows callbacks to change the contents of the axes and prevents command line operations from doing so. The default is `on`.

For more information about:

- Properties that you can set to control many aspects of axes behavior and appearance, see “Axes Properties” in the MATLAB Graphics documentation.
- Creating axes in a tiled pattern, see the `subplot` function reference page.
- Plotting in general, see “Plots and Plotting Tools” in the MATLAB Graphics documentation.

Programming ActiveX Controls

For information about programming ActiveX controls, see the following topics in the MATLAB External Interfaces documentation.

- “Control and Server Events”
- “Writing Event Handlers”

See “MATLAB COM Client Support” in the MATLAB External Interfaces documentation for general information.

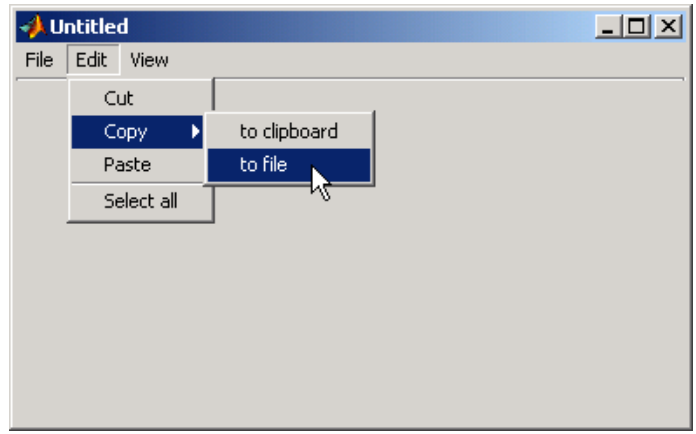
Programming Menu Items

Programming a Menu Title

Because clicking a menu title automatically displays the menu below it, you may not need to program callbacks at the title level. However, the callback

associated with a menu title can be a good place to enable or disable menu items below it.

Consider the example illustrated in the following picture.



When a user selects **Edit > Copy > to file**, no **Copy** callback is needed to perform the action. Only the `Callback` callback associated with the **to file** item is required.

Suppose, however, that only certain objects can be copied to a file. You can use the **Copy** item `Callback` callback to enable or disable the **to file** item, depending on the type of object selected.

The following code disables the **to file** item by setting its `Enable` property `off`. The menu item would then appear dimmed.

```
set(tofilehandle,'Enable','off')
```

Setting `Enable` to `on`, would then enable the menu item.

Opening a Dialog Box from a Menu Callback

The `Callback` callback for the **to file** menu item could contain code such as the following to display the standard dialog box for saving files.

```
[file,path] = uiputfile('animinit.m','Save file name');
```

'Save file name' is the dialog box title. In the dialog box, the filename field is set to animinit.m, and the filter set to M-files (*.m). For more information, see the uiputfile reference page.

Note MATLAB provides a selection of standard dialog boxes that you can create with a single function call. For information about these dialog boxes and the functions used to create them, see "Predefined Dialog Boxes" in the MATLAB Function Reference documentation.

Updating a Menu Item Check

A check is useful to indicate the current state of some menu items. If you set the Checked property to on when you create the menu item, the item initially appears checked. Each time the user selects the menu item, the callback for that item must turn the check on or off. The following example shows you how to do this by changing the value of the menu item's Checked property.

```
function menu_copyfile(hObject,eventdata)
if strcmp(get(hObject,'Checked'),'on')
    set(hObject,'Checked','off');
else
    set(hObject,'Checked','on');
end
```

hObject is the handle of the component for which the event was triggered. Its use here assumes the menu item's Callback property specifies the callback as a function handle. See "Associating Callbacks with Components" on page 12-12 for more information.

The strcmp function compares two strings and returns logical 1 (true) if the two are identical, and logical 0 (false) otherwise.

Use of checks when the GUI is first displayed should be consistent with the display. For example, if your GUI has an axes that is visible when a user first opens it and the GUI has a **Show axes** menu item, be sure to set the menu item's Checked property on when you create it so that a check appears next to the **Show axes** menu item initially.

Programming Toolbar Tools

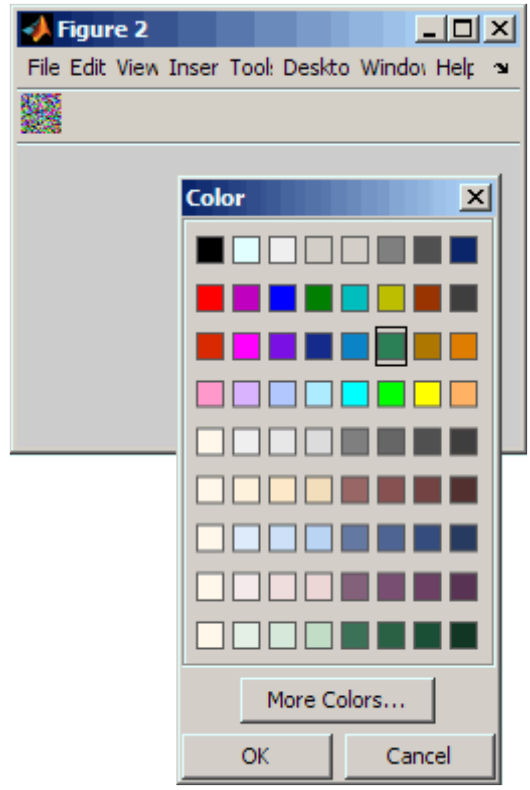
Push Tool

The push tool `ClickedCallback` property specifies the push tool control action. The following example creates a push tool and programs it to open a standard color selection dialog box. You can use the dialog box to set the background color of the GUI.

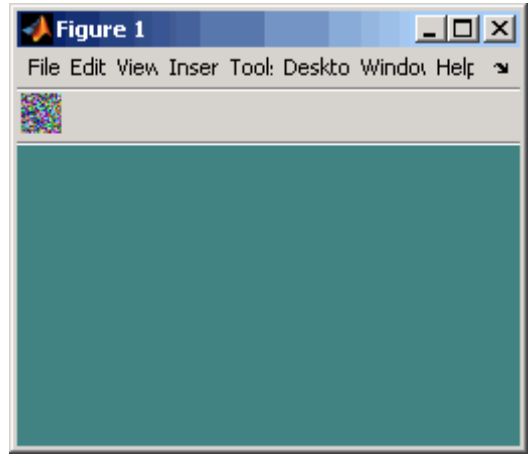
1 Copy the following code into an M-file and save it in your current directory or on your path as `color_gui.m`. Run the script by typing `color_gui` at the command line.

```
function color_gui
fh = figure('Position',[250 250 250 150],'Toolbar','none');
th = uitoolbar('Parent',fh);
pth = uipushtool('Parent',th,'Cdata',rand(20,20,3),...
                 'ClickedCallback',@color_callback);
%-------------------------------------------------------
    function color_callback(hObject,eventdata)
    color = uisetcolor(fh,'Pick a color');
    end
end
```

2 Click the push tool to display the color selection dialog box and click a color to select it.



3 Click **OK** on the color selection dialog box. The GUI background color changes to the color you selected—in this case, green.



Note Create your own icon with the icon editor described in "Icon Editor" on page 15-29. See the `ind2rgb` reference page for information on converting a matrix `X` and corresponding colormap, i.e., an `(X, MAP)` image, to RGB (truecolor) format.

Toggle Tool

The toggle tool `OnCallback` and `OffCallback` properties specify the toggle tool control actions that occur when the toggle tool is clicked and its `State` property changes to `on` or `off`. The toggle tool `ClickedCallback` property specifies a control action that takes place whenever the toggle tool is clicked, regardless of state.

The following example uses a toggle tool to toggle a plot between surface and mesh views of the `peaks` data. The example also counts the number of times you have clicked the toggle tool.

The `surf` function produces a 3-D shaded surface plot. The `mesh` function creates a wireframe parametric surface. `peaks` returns a square matrix obtained by translating and scaling Gaussian distributions

1 Copy the following code into an M-file and save it in your current directory or on your path as `toggle_plots.m`. Run the script by typing `toggle_plots` at the command line.

```
function toggle_plots
counter = 0;
fh = figure('Position',[250 250 300 340],'Toolbar','none');
ah = axes('Parent',fh,'Units','pixels',...
          'Position',[35 85 230 230]);
th = uitoolbar('Parent',fh);
tth = uitoggletool('Parent',th,'Cdata',rand(20,20,3),...
                 'OnCallback',@surf_callback,...
                 'OffCallback',@mesh_callback,...
                 'ClickedCallback',@counter_callback);
sth = uicontrol('Style','text','String','Counter: ',...
                'Position',[35 20 45 20]);
cth = uicontrol('Style','text','String',num2str(counter),...
                'Position',[85 20 30 20]);
%-------------------------------------------------------
    function counter_callback(hObject,eventdata)
    counter = counter + 1;
    set(cth,'String',num2str(counter))
    end
%-------------------------------------------------------
    function surf_callback(hObject,eventdata)
    surf(ah,peaks(35));
    end

Managing Application-Defined Data

Mechanisms for Managing Data

In this section...

Nested Functions

Use nested function to create your GUI M-files. They enable callback functions to share data freely without it having to be passed as arguments.

1. Construct components, define variables, and generate data in the initialization segment of your code.
2. Nest the GUI callbacks and utility functions at a level below the initialization.

The callbacks and utility functions automatically have access to the data and the component handles because they are defined at a higher level.

Note For information about using nested functions, see "Nested Functions" in the MATLAB Programming documentation.

GUI Data

Most GUIs generate or use data that is specific to the application. These mechanisms provide a way for applications to save and retrieve data stored with the GUI.

The GUI data and application data mechanisms are similar, but GUI data can be simpler to use. The figure and component `UserData` properties can also hold application-defined data.

GUI data is managed using the `guidata` function. This function can store a single variable as GUI data. It is also used to retrieve the value of that variable.

Note If your M-file was originally created by GUIDE, see "Changing GUI Data in an M-File Generated by GUIDE" on page 9-4.

About GUI Data

GUI data is always associated with the GUI figure. It is available to all callbacks of all components of the GUI. If you specify a component handle when you save or retrieve GUI data, MATLAB automatically associates the data with the component's parent figure.

GUI data can contain only one variable at any time. Writing GUI data with a different variable overwrites the existing GUI data. For this reason, GUI data is usually defined to be a structure to which you can add fields as you need them.

You can access the data from within a callback routine using the component's handle, without having to find the figure handle. If you specify a component's callback properties as function handles, the component handle is automatically passed to each callback as `hObject`. See "Associating Callbacks with Components" on page 12-12 for more information.

Because there can be only one GUI data variable and it is associated with the figure, you do not need to create and maintain a hard-coded name for the data throughout your source code.

Creating and Updating GUI Data

1 Create a structure and add to it the fields you want. For example,

```
mydata.iteration_counter = 0;
mydata.number_errors = 0;
```

2 Save the structure as GUI data. MATLAB associates GUI data with the figure, but you can use the handle of any component in the figure to retrieve or save it.

```
guidata(figurehandle,mydata);
```

3 To change GUI data from a callback, get a copy of the structure, update the desired field, and then save the GUI data.

```
mydata = guidata(hObject);      % Get the GUI data.
mydata.iteration_counter = mydata.iteration_counter +1;
guidata(hObject,mydata);        % Save the GUI data.
```

Note To use `hObject`, you must specify a component's callback properties as function handles. When you do, the component handle is automatically passed to each callback as `hObject`. See "Associating Callbacks with Components" on page 12-12 for more information.

Adding Fields to a GUI Data Structure

To add a field to a GUI data structure:

1 Get a copy of the structure with a command similar to the following where `hObject` is the handle of the component for which the callback was triggered.

```
mydata = guidata(hObject)
```

2 Assign a value to the new field. This adds the field to the structure. For example,

```
mydata.iteration_state = 0;
```

adds the field `iteration_state` to the structure `mydata` and sets it to `0`.

3 Use the following command to save the data.

```
guidata(hObject,mydata)
```

where `hObject` is the handle of the component for which the callback was triggered. MATLAB associates a new copy of the `mydata` structure with the component's parent figure.

Application Data

Application data provides a way for applications to save and retrieve data associated with a specified object. For a GUI, this is usually the GUI figure but can also be any component. The data is stored as name/value pairs. Application data enables you to create what are essentially user-defined properties for an object.

The following table summarizes the functions that provide access to application data. For more detailed information, see the individual function reference pages.

Functions for Managing Application Data

Function	Purpose
`setappdata`	Specify named application data for an object. The object does not have to be a figure. You can specify more than one named application data for an object. However, each name must be unique for that object and can be associated with only one value, usually a structure.
`getappdata`	Retrieve named application data. To retrieve named application data, you must know the name associated with the application data and the handle of the object with which it is associated.

Functions for Managing Application Data (Continued)

Function	Purpose
`isappdata`	True if the named application data exists on the specified object.
`rmappdata`	Remove named application data from the specified object.

Creating Application Data

Use the `setappdata` function to create application data. This example generates a 35-by-35 matrix of normally distributed random numbers and creates application data `mydata`, associated with the figure, to manage it.

```
matrices.rand_35 = randn(35);
setappdata(figurehandle,'mydata',matrices);
```

By using nested functions and creating the figure at the top level, the figure handle is accessible to all callbacks and utility functions nested at lower levels. For information about using nested functions, see “Nested Functions” in the MATLAB Programming documentation.

Adding Fields to an Application Data Structure

Application data is usually defined as a structure to enable you to add fields as necessary. This example adds a field to the application data structure `mydata` created in the previous topic.

1. Use `getappdata` to retrieve the structure.

   From the example in the previous topic, the name of the application data structure is `mydata`. It is associated with the figure.

   ```
   matrices = getappdata(figurehandle,'mydata');
   ```

2 Create a new field and assign it a value. For example

```
matrices.randn_50 = randn(50);
```

adds the field `randn_50` to the `matrices` structure and sets it to a 50-by-50 matrix of normally distributed random numbers.

3 Use `setappdata` to save the data. This example uses `setappdata` to save the `matrices` structure as the application data structure `mydata`.

```
setappdata(figurehandle,'mydata',matrices);
```

UserData Property

Each GUI component and the figure itself has a `UserData` property. You can assign any valid MATLAB value to a `UserData` property. To retrieve the data, a callback must know the handle of the component with which the data is associated.

1 In this example, an edit text component stores the user-entered string in its `UserData` property.

```
function edittext1_callback(hObject,eventdata)
mystring = get(hObject,'String');
set(hObject,'UserData',mystring);
```

2 A push button retrieves the string from the edit text component `UserData` property.

```
function pushbutton1_callback(hObject,eventdata)
string = get(edittexthandle,'UserData');
```

Specify `UserData` as a structure if you want to store multiple fields.

Note By using nested functions and creating the figure and the components at the top level, their handles are accessible to all callbacks and utility functions nested at lower levels. For information about using nested functions, see "Nested Functions" in the MATLAB Programming documentation. To use `hObject`, you must specify a component's callback properties as function handles. When you do, the component handle is automatically passed to each callback as `hObject`. See "Associating Callbacks with Components" on page 12-12 for more information.

Sharing Data Among a GUI's Callbacks

In this section...

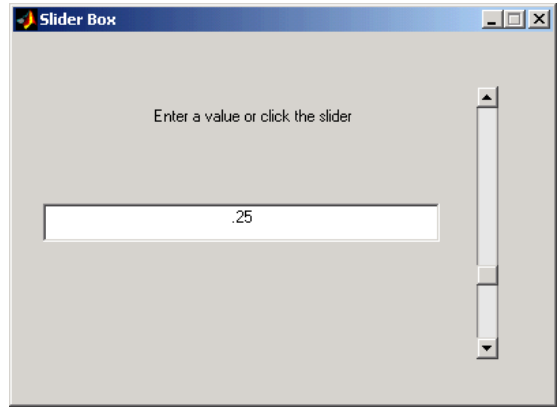
See "Mechanisms for Managing Data" on page 13-2 for general information about these methods.

Nested Functions

You can use GUI data, application data, and the `UserData` property to share data among a GUI's callbacks. In many cases nested functions enables you to share data among callbacks without using the other data forms.

Nested Functions Example: Passing Data Between Components

This example uses a GUI that contains a slider and an edit text component as shown in the following figure. A static text component instructs the user to enter a value in the edit text or click the slider. The example initializes and maintains an error counter as well as the old and new values of the slider in a nested functions environment.

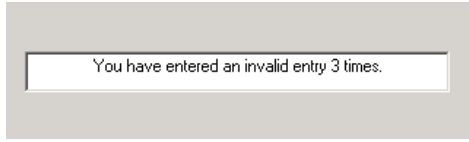


The GUI behavior is as follows:

- When a user moves the slider, the edit text component displays the slider's current value and prints a message to the command line, similar to the following, indicating how many units the slider moved.

  ```
  You moved the slider 25 units.
  ```

- When a user types a value into the edit text component and then presses **Enter** or clicks outside the component, the slider updates to this value an d the edit text component prints a message to the command line indicating how many units the slider moved.
- If a user enters a value in the edit text component that is out of range for the slider—that is, a value that is not between the slider's `Min` and `Max` properties—the application returns a message in the edit text indicating how many times the user has entered an erroneous value.



The following code constructs the components, initializes the error counter and the previous and new slider values in the initialization section of the function, and uses two callbacks to implement the interchange between the slider and the edit text component. Copy this code into an M-file and save it in your current directory or on your path as `slider_gui.m`. Run the script by typing `slider_gui` at the command line.

```
function slider_gui
fh = figure('Position',[250 250 350 350]);
sh = uicontrol(fh,'Style','slider',...
               'Max',100,'Min',0,'Value',25,...
               'SliderStep',[0.05 0.2],...
               'Position',[300 25 20 300],...
               'Callback',@slider_callback);
eth = uicontrol(fh,'Style','edit',...
               'String',num2str(get(sh,'Value')),...
               'Position',[30 175 240 20],...
```

```
               'Callback',@edittext_callback);
sth = uicontrol(fh,'Style','text',...
               'String','Enter a value or click the slider.',...
               'Position',[30 215 240 20]);
number_errors = 0;
previous_val = 0;
val = 0;
% --------------------------------------------------
% Set the value of the edit text component String property
% to the value of the slider.
   function slider_callback(hObject,eventdata)
      previous_val = val;
      val = get(hObject,'Value');
      set(eth,'String',num2str(val));
      sprintf('You moved the slider %d units.',abs(val - previous_val))
   end
% --------------------------------------------------
% Set the slider value to the number the user types in
% the edit text or display an error message.
   function edittext_callback(hObject,eventdata)
      previous_val = val;
      val = str2double(get(hObject,'String'));
      % Determine whether val is a number between the
      % slider's Min and Max. If it is, set the slider Value.
      if isnumeric(val) && length(val) == 1 && ...
         val >= get(sh,'Min') && ...
         val <= get(sh,'Max')
         set(sh,'Value',val);
         sprintf('You moved the slider %d units.',abs(val - previous_val)
      else
      % Increment the error count, and display it.
         number_errors = number_errors+1;
         set(hObject,'String',...
             ['You have entered an invalid entry ',...
             num2str(number_errors),' times.']);
         val = previous_val;
      end
   end
end
```

Because the components are constructed at the top level, their handles are immediately available to the callbacks that are nested at a lower level of the routine. The same is true of the error counter `number_errors`, the previous slider value `previous_val`, and the new slider value `val`. There is no need to pass these variables as arguments.

Both callbacks use the input argument `hObject` to get and set properties of the component that triggered execution of the callback. This argument is available to the callbacks because the components' `Callback` properties are specified as function handles. See "Associating Callbacks with Components" on page 12-12 for more information.

Slider Callback. The slider callback, `slider_callback`, uses the edit text component handle, `eth`, to set the edit text `'String'` property to the value the user typed.

The slider `Callback` saves the previous value, `val`, of the slider in `previous_val` before assigning the new value to `val`. These variables are known to both callbacks because they are initialized at a higher level. They can be retrieved and set by either callback.

```
previous_val = val;
val = get(hObject,'Value');
```

The following statements in the slider `Callback` update the value displayed in the edit text component when a user moves the slider and releases the mouse button.

```
val = get(hObject,'Value');
set(eth,'String',num2str(val));
```

The code combines three commands:

- The `get` command obtains the current value of the slider.
- The `num2str` command converts the value to a string.
- The `set` command sets the `String` property of the edit text component to the updated value.

Edit Text Callback. The edit text `Callback`, `edittext_callback`, uses the slider handle, `sh`, to determine the slider's `Max` and `Min` properties and to set the slider `Value` property, which determine's the position of the slider thumb.

The edit text `Callback` uses the following code to set the slider's value to the number the user types in, after checking to see if it is a single numeric value within the allowed range.

```
if isnumeric(val) && length(val) == 1 && ...
   val >= get(sh,'Min') && ...
   val <= get(sh,'Max')
   set(sh,'Value',val);
```

If the value is out of range, the `if` statement continues by incrementing the error counter, `number_errors`, and displaying a message telling the user how many times they have entered an invalid number.

```
else
   number_errors = number_errors+1;
   set(hObject,'String',...
   ['You have entered an invalid entry ',...
   num2str(number_errors),' times.']);
end
```

GUI Data

GUI data, which you manage with the `guidata` function, is accessible to all callbacks of the GUI. A callback for one component can set a value in GUI data, which can then be read by a callback for another component. See "GUI Data" on page 13-2 for more information.

GUI Data Example: Passing Data Between Components

The previous topic, "Nested Functions Example: Passing Data Between Components" on page 13-9, uses nested function capabilities to initialize and maintain an error counter as well as the old and new values of the slider. This example shows you how to initialize and maintain the old and new values of the slider using GUI data and make them available to the both callbacks. Refer to the previous topic for details of the example.

The following code is similar to the previous topic but uses GUI data to initialize and maintain the old and new slider values in the edit text and slider `Callbacks`. Copy this code into an M-file and save it in your current directory or on your path as `slider_gui.m`. Run the script by typing `slider_gui` at the command line.

```
function slider_gui
fh = figure('Position',[250 250 350 350]);
sh = uicontrol(fh,'Style','slider',...
               'Max',100,'Min',0,'Value',25,...
               'SliderStep',[0.05 0.2],...
               'Position',[300 25 20 300],...
               'Callback',@slider_callback);
eth = uicontrol(fh,'Style','edit',...
               'String',num2str(get(sh,'Value')),...
               'Position',[30 175 240 20],...
               'Callback',@edittext_callback);
sth = uicontrol(fh,'Style','text',...
               'String','Enter a value or click the slider.',...
               'Position',[30 215 240 20]);
number_errors = 0;
slider.val = 25;
guidata(fh,slider);
% --------------------------------------------------
% Set the value of the edit text component String property
% to the value of the slider.
   function slider_callback(hObject,eventdata)
        slider = guidata(fh);  % Get GUI data.
        slider.previous_val = slider.val;
        slider.val = get(hObject,'Value');
        set(eth,'String',num2str(slider.val));
        sprintf('You moved the slider %d units.',...
                 abs(slider.val - slider.previous_val))
        guidata(fh,slider) % Save GUI data before returning.
   end
% --------------------------------------------------
% Set the slider value to the number the user types in
% the edit text or display an error message.
   function edittext_callback(hObject,eventdata)
        slider = guidata(fh);   % Get GUI data.
```

```
            slider.previous_val = slider.val;
            slider.val = str2double(get(hObject,'String'));
         % Determine whether slider.val is a number between the
         % slider's Min and Max. If it is, set the slider Value.
         if isnumeric(slider.val) && length(slider.val) == 1 && ...
            slider.val >= get(sh,'Min') && ...
            slider.val <= get(sh,'Max')
            set(sh,'Value',slider.val);
            sprintf('You moved the slider %d units.',...
                    abs(slider.val - slider.previous_val))
         else
         % Increment the error count, and display it.
            number_errors = number_errors+1;
            set(hObject,'String',...
                ['You have entered an invalid entry ',...
                num2str(number_errors),' times.']);
            slider.val = slider.previous_val;
         end
         guidata(fh,slider); % Save the changes as GUI data.
      end
   end
```

Slider Values. In this example, both the slider callback`slider_callback` and the edit text callback `edittext_callback` retrieve the GUI data structure `slider` which hold previous and current values of the slider. They then save the value, `slider.val` to `slider.previous_val` before retrieving the new value and assigning it to `slider.val`. Before returning, each callback saves the `slider` structure to GUI data.

```
slider = guidata(fh);   % Get GUI data.
slider.previous_val = slider.val;
slider.val = ...;
...

guidata(fh,slider)  % Save GUI data before returning.
```

Both callbacks use the `guidata` function to retrieve and save the `slider` structure as GUI data.

Application Data

Application data can be associated with any object—a component, menu, or the figure itself. To access application data, a callback must know the name of the data and the handle of the component with which it is associated. Use the functions `setappdata`, `getappdata`, `isappdata`, and `rmappdata` to manage application data.

See "Application Data" on page 13-5 for more information about application data.

Application Data Example: Passing Data Between Components

The earlier topic, "Nested Functions Example: Passing Data Between Components" on page 13-9, uses nested function capabilities to initialize and maintain an error counter as well as the old and new values of the slider. This example shows you how to initialize and maintain the old and new values of the slider using application data (appdata) and make them available to the both callbacks. Refer to the earlier topic for details of the example.

The following code is similar to the earlier topic but uses application data to initialize and maintain the old and new slider values in the edit text and slider `Callbacks`. Copy this code into an M-file and save it in your current directory or on your path as `slider_gui.m`. Run the script by typing `slider_gui` at the command line.

```
function slider_gui
fh = figure('Position',[250 250 350 350]);
sh = uicontrol(fh,'Style','slider',...
               'Max',100,'Min',0,'Value',25,...
               'SliderStep',[0.05 0.2],...
               'Position',[300 25 20 300],...
               'Callback',@slider_callback);
eth = uicontrol(fh,'Style','edit',...
               'String',num2str(get(sh,'Value')),...
               'Position',[30 175 240 20],...
               'Callback',@edittext_callback);
sth = uicontrol(fh,'Style','text',...
               'String','Enter a value or click the slider.',...
               'Position',[30 215 240 20]);
number_errors = 0;
```

```
slider_data.val = 25;
% Create appdata with name 'slider'.
setappdata(fh,'slider',slider_data);
% --------------------------------------------------
% Set the value of the edit text component String property
% to the value of the slider.
   function slider_callback(hObject,eventdata)
      % Get 'slider' appdata.
      slider_data = getappdata(fh,'slider');
      slider_data.previous_val = slider_data.val;
      slider_data.val = get(hObject,'Value');
      set(eth,'String',num2str(get(slider_data.val)));
      sprintf('You moved the slider %d units.',...
              abs(slider_data.val - slider_data.previous_val))
      % Save 'slider' appdata before returning.
      setappdata(fh,'slider',slider_data)
end
% --------------------------------------------------
% Set the slider value to the number the user types in
% the edit text or display an error message.
   function edittext_callback(hObject,eventdata)
      % Get 'slider' appdata.
      slider_data = getappdata(fh,'slider');
      slider_data.previous_val = slider_data.val;
      slider_data.val = str2double(get(hObject,'String'));
      % Determine whether val is a number between the
      % slider's Min and Max. If it is, set the slider Value.
      if isnumeric(slider_data.val) && ...
            length(slider_data.val) == 1 && ...
         slider_data.val >= get(sh,'Min') && ...
         slider_data.val <= get(sh,'Max')
         set(sh,'Value',slider_data.val);
      else
      % Increment the error count, and display it.
         number_errors = number_errors+1;
         set(hObject,'String',...
             ['You have entered an invalid entry ',...
             num2str(number_errors),' times.']);
         slider_data.val = slider_data.previous_val;
      end
```

```
        % Save appdata before returning.
        setappdata(fh,'slider',slider_data);
    end
end
```

Slider Values. In this example, both the slider callbacks`slider_callback` and the edit text callback `edittext_callback` retrieve the application data structure `slider_data` which holds previous and current values of the slider. They then save the value, `slider_data.val` to `slider_data.previous_val` before retrieving the new value and assigning it to `slider_data.val`. Before returning, each callback saves the `slider_data` structure in the `slider` application data.

```
% Get 'slider' appdata.
slider_data = getappdata(fh,'slider');
slider_data.previous_val = slider_data.val;
slider_data.val = ...;
...
% Save 'slider' appdata before returning.
setappdata(fh,'slider',slider_data)
```

Both callbacks use the `getappdata` and `setappdata` functions to retrieve and save the `slider_data` structure as `slider` application data.

UserData Property

Every GUI component, and the figure itself, has a `UserData` property that you can use to store application-defined data. To access `UserData`, a callback must know the handle of the component with which a specific `UserData` property is associated.

Use the `get` function to retrieve `UserData`, and the `set` function to set it.

UserData Property Example: Passing Data Between Components

The previous topic, “Nested Functions Example: Passing Data Between Components” on page 13-9, uses nested function capabilities to initialize and maintain an error counter. This example shows you how to do the same thing using the edit text component’s `UserData` property to store the error count. Refer to the earlier example for example details.

The following code is the same as in the earlier topic but uses the `UserData` property to initialize and increment the error counter.

```
function slider_gui
fh = figure('Position',[250 250 350 350]);
sh = uicontrol(fh,'Style','slider',...
               'Max',100,'Min',0,'Value',25,...
               'SliderStep',[0.05 0.2],...
               'Position',[300 25 20 300],...
               'Callback',@slider_callback);
eth = uicontrol(fh,'Style','edit',...
               'String',num2str(get(sh,'Value')),...
               'Position',[30 175 240 20],...
               'Callback',@edittext_callback);
sth = uicontrol(fh,'Style','text',...
               'String','Enter a value or click the slider.',...
               'Position',[30 215 240 20]);
number_errors = 0;
slider.val = 25;
% Set edit text UserData property to slider structure.
set(eth,'UserData',slider)
% ------------------------------------------------------
% Set the value of the edit text component String property
% to the value of the slider.
   function slider_callback(hObject,eventdata)
      % Get slider from edit text UserData.
      slider = get(eth,'UserData');
      slider.previous_val = slider.val;
      slider.val = get(hObject,'Value');
      set(eth,'String',num2str(slider.val));
      sprintf('You moved the slider %d units.',...
              abs(slider.val - slider.previous_val))
      % Save slider in UserData before returning.
      set(eth,'UserData',slider)
   end
% ------------------------------------------------------
% Set the slider value to the number the user types in
% the edit text or display an error message.
   function edittext_callback(hObject,eventdata)
      % Get slider from edit text UserData.
```

```
        slider = get(eth,'UserData');
        slider.previous_val = slider.val;
        slider.val = str2double(get(hObject,'String'));
        % Determine whether slider.val is a number between the
        % slider's Min and Max. If it is, set the slider Value.
        if isnumeric(slider.val) && ...
              length(slider.val) == 1 && ...
           slider.val >= get(sh,'Min') && ...
           slider.val <= get(sh,'Max')
           set(sh,'Value',slider.val);
           sprintf('You moved the slider %d units.',...
                   abs(slider.val - slider.previous_val))
        else
        % Increment the error count, and display it.
           data = get(hObject,'UserData');
           data.number_errors = data.number_errors+1;
           set(hObject,'UserData',data);     % Save the changes.
           set(hObject,'String',...
              ['You have entered an invalid entry ',...
              num2str(number_errors),' times.']);
           slider.val = slider.previous_val;
        end
        % Save slider structure in UserData before returning.
        set(eth,'UserData',slider)
     end
  end
```

Slider Values. In this example, both the slider callbacks`slider_callback` and the edit text callback `edittext_callback` retrieve the structure `slider` from the edit text `UserData` property. The `slider` structure holds previous and current values of the slider. The callbacks then save the value `slider.val` to `slider.previous_val` before retrieving the new value and assigning it to `slider.val`. Before returning, each callback saves the `slider` structure in the edit text`UserData` property.

```
% Get slider structure from edit text UserData.
slider = get(eth,'UserData',slider);
slider.previous_val = slider.val;
slider.val = ...;
...
```

```
% Save slider structure in UserData before returning.
set(eth,'UserData',slider)
```

Both callbacks use the `get` and `set` functions to retrieve and save the `slider` structure in the edit text `UserData` property.

14

Managing Callback Execution

Callback Interruption

In this section...

Callback Execution

Callback execution is event driven and callbacks from different GUIs share the same event queue. In general, callbacks are triggered by user events such as a mouse click or key press. Because of this, you cannot predict, when a callback is requested, whether or not another callback is executing or, if one is, which callback it is.

If a callback is executing and the user triggers an event for which a callback is defined, that callback attempts to interrupt the callback that is already executing. When this occurs, MATLAB processes the callbacks according to these factors:

- The `Interruptible` property of the object whose callback is already executing. The `Interruptible` property specifies whether the executing callback can be interrupted.
- The `BusyAction` property of the object whose callback has just been triggered and wants to execute. The `BusyAction` property specifies whether a callback should be queued to await execution or be canceled.

How the Interruptible Property Works

An object's `Interruptible` property can be either `on` (the default) or `off`.

If the`Interruptible` property of the object whose callback is executing is `on`, the callback can be interrupted. However, it is interrupted only when it, or a function it triggers, calls `drawnow`, `figure`, `getframe`, `pause`, or `waitfor`. Before performing their defined tasks, these functions process any events in the event queue, including any waiting callbacks. If the executing callback, or

a function it triggers, calls none of these functions, it cannot be interrupted regardless of the value of its object's `Interruptible` property.

If the `Interruptible` property of the object whose callback is executing is `off`, the callback cannot be interrupted with the following exceptions. If the interrupting callback is a `DeleteFcn` or `CreateFcn` callback or a figure's `CloseRequest` or `ResizeFcn` callback, it interrupts an executing callback regardless of the value of the executing callback object's `Interruptible` property. These callbacks too can interrupt only when a `drawnow`, `figure`, `getframe`, `pause`, or `waitfor` function executes.

The callback properties to which `Interruptible` can apply depend on the objects for which the callback properties are defined:

- For figures, only callback routines defined for the `ButtonDownFcn`, `KeyPressFcn`, `KeyReleaseFcn`, `WindowButtonDownFcn`, `WindowButtonMotionFcn`, `WindowButtonUpFcn`, and `WindowScrollWheelFcn` are affected by the `Interruptible` property.
- For GUI components, `Interruptible` is applies to the `ButtonDownFcn`, `Callback`, `KeyPressFcn`, `SelectionChangeFcn`, `ClickedCallback`, `OffCallback`, and `OnCallback` properties, for the components for which these properties are defined.

How the Busy Action Property Works

An object's `BusyAction` property can be either `queue` (the default) or `cancel`. The `BusyAction` property of the interrupting callback's object is taken into account only if the `Interruptible` property of the executing callback's object is `off`, i.e., the executing callback is not interruptible.

If a noninterruptible callback is executing and an event (such as a mouse click) triggers a new callback, MATLAB uses the value of the new callback object's `BusyAction` property to decide whether to queue the requested callback or cancel it.

- If the `BusyAction` value is `queue`, the requested callback is added to the event queue and executes in its turn when the executing callback finishes execution.

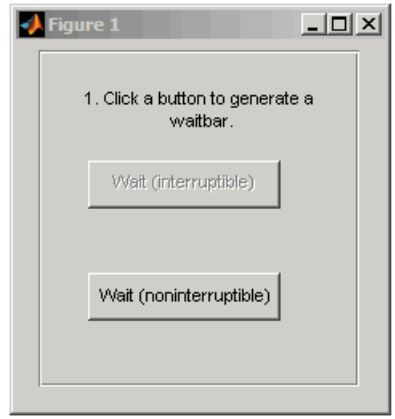
- If the value is `cancel`, the event is discarded and the requested callback does not execute.

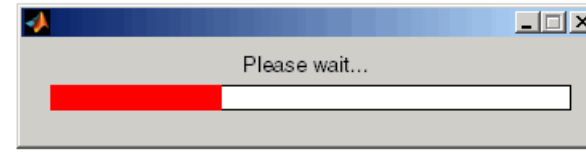
If an interruptible callback is executing, the requested callback runs when the executing callback terminates or calls `drawnow`, `figure`, `getframe`, `pause`, or `waitfor`. The `BusyAction` property of the requested callback's object has no effect.

Example

This example demonstrates control of callback interruption using the `Interruptible` and `BusyAction` properties. It creates two GUIs:

- The first GUI contains two push buttons, **Wait (interruptible)** whose `Interruptible` property is set to `on`, and **Wait (noninterruptible)**whose `Interruptible` property is set to `off`. Clicking either button triggers the button's `Callback` callback, which creates and updates a waitbar.



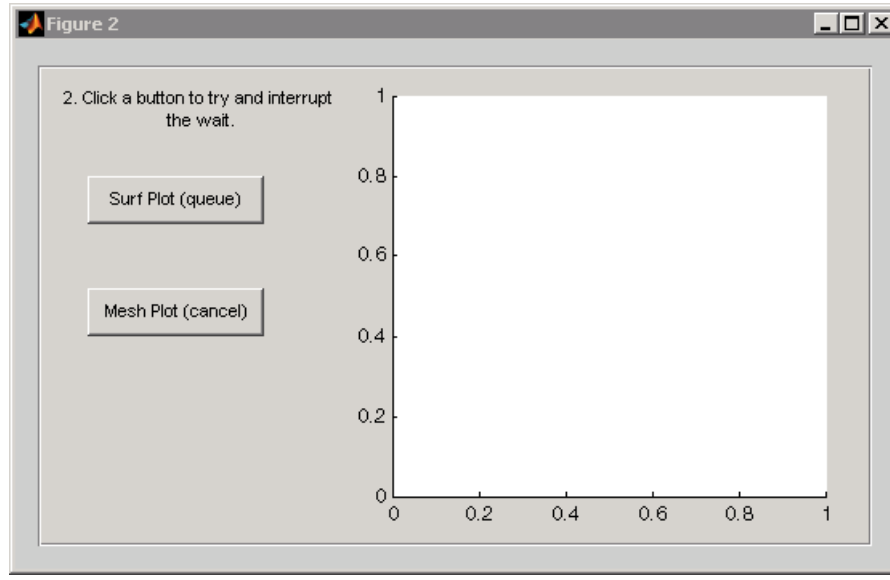


This code creates the two **Wait** buttons and specifies the callbacks that service them.

```
h_interrupt = uicontrol(h_panel1,'Style','pushbutton',...
                        'Position',[30,110,120,30],...
                        'String','Wait (interruptible)',...
                        'Interruptible','on',...
                        'Callback',@wait_interruptible);
```

```
h_noninterrupt = uicontrol(h_panel1,'Style','pushbutton',...
                           'Position',[30,40,120,30],...
                           'String','Wait (noninterruptible)',...
                           'Interruptible','off',...
                           'Callback',@wait_noninterruptible);
```

- The second GUI contains two push buttons, **Surf Plot (queue)** whose `BusyAction` property is set to `queue`, and **Mesh Plot (cancel)**whose `BusyAction` property is set to `cancel`. Clicking either button triggers the button's `Callback` callback to generate a plot in the axes.



This code creates the two plot buttons and specifies the callbacks that service them.

```
hsurf_queue = uicontrol(h_panel2,'Style','pushbutton',...
                           'Position',[30,200,110,30],...
                           'String','Surf Plot (queue)',...
                           'TooltipString','BusyAction = queue',...
                           'BusyAction','queue',...
                           'Callback',@surf_queue);
hmesh_cancel = uicontrol(h_panel2,'Style','pushbutton',...
                           'Position',[30,130,110,30],...
```

```
'String','Mesh Plot (cancel)',...
'BusyAction','cancel',...
'TooltipString','BusyAction = cancel',...
'Callback',@mesh_cancel);
```

Using the Example GUIs

Click here to run the example GUIs.

Note This link executes MATLAB commands and is designed to work within the MATLAB Help browser. If you are reading this online or in PDF, you should go to the corresponding section in the MATLAB Help Browser to use the link.

To see the interplay of the `Interruptible` and `BusyAction` properties:

1. Click one of the **Wait** buttons in the first GUI. Both buttons create and update a waitbar.
2. While the waitbar is active, click either the **Surf Plot** or the **Mesh Plot** button in the second GUI. The **Surf Plot** button creates a `surf` plot using `peaks` data. The **Mesh Plot** button creates a `mesh` plot using the same data.

The following topics describe what happens when you click specific combinations of buttons:

- "Clicking a Wait Button" on page 14-6
- "Clicking a Plot Button" on page 14-7

Clicking a Wait Button.

The **Wait** buttons are the same except for their `Interruptible` properties. Their `Callback` callbacks, which are essentially the same, call the utility function `create_update_waitbar` which calls `waitbar` to create and update a waitbar. The **Wait (Interruptible)** button `Callback` callback,`wait_interruptible`, can be interrupted each time `waitbar` calls `drawnow`. The **Wait (Noninterruptible)** button `Callback`

callback,`wait_noninterruptible`, cannot be interrupted (except by specific callbacks listed in "How the Interruptible Property Works" on page 14-2).

This is the **Wait (Interruptible)** button `Callback` callback,`wait_interruptible`:

```
function wait_interruptible(hObject,eventdata)
    % Disable the other push button.
    set(h_noninterrupt,'Enable','off')
    % Clear the axes in the other GUI.
    cla(h_axes2,'reset')
    % Create and update the waitbar.
    create_update_waitbar
    % Enable the other push button
    set(h_noninterrupt,'Enable','on')
end
```

The callback first disables the other push button and clears the axes in the second GUI. It then calls the utility function `create_update_waitbar` to create and update a waitbar. When `create_update_waitbar` returns, it enables the other button.

Clicking a Plot Button. What happens when you click a **Plot** button depends on which **Wait** button you clicked first and the `BusyAction` property of the **Plot** button.

- If you click **Surf Plot**, whose `BusyAction` property is `queue`, MATLAB queues the **Surf Plot** callback `surf_queue`.

  If you clicked the **Wait (interruptible)** button first, `surf_queue` runs and displays the surf plot when the waitbar issues a call to `drawnow`, terminates, or is destroyed.

  If you clicked the **Wait (noninterruptible)** button first, `surf_queue` runs only when the waitbar terminates or is destroyed.

  This is the `surf_queue` callback:

  ```
  function surf_queue(hObject,eventdata)
          h_plot = surf(h_axes2,peaks_data);
     end
  ```

- If you click **Mesh Plot** , whose `BusyAction` property is `cancel`, after having clicked **Wait (noninterruptible)**, MATLAB discards the button click event and does not queue the `mesh_cancel` callback.

  If you click **Mesh Plot** after having clicked **Wait (interruptible)**, the **Mesh Plot** `BusyAction` property has no effect. MATLAB queues the **Mesh Plot** callback, `mesh_cancel`. It runs and displays the mesh plot when the waitbar issues a call to `drawnow`, terminates, or is destroyed.

  This is the `mesh_plot` callback:

```
function mesh_cancel(hObject,eventdata)
        h_plot = surf(h_axes2,peaks_data);
    end
```

View the Complete GUI M-File

If you are reading this in the MATLAB Help browser, you can click here to display a complete listing of the code used in this example in the MATLAB Editor.

Note This link executes MATLAB commands and is designed to work within the MATLAB Help browser. If you are reading this online or in PDF, you should go to the corresponding section in the MATLAB Help Browser to use the links.

15

Examples of GUIs Created Programmatically

Introduction

This chapter provides three examples that illustrate the application of certain techniques in programmatically created GUIs.

Each example lists the techniques it illustrates. These techniques include:

- Creation of a dialog that does not return until the user makes a choice
- Passing input arguments to the GUI when it is opened
- Obtaining output from the GUI when it returns
- Shielding the GUI from accidental changes
- Running the GUI across multiple platforms
- Making a GUI modal
- Sharing data among multiple GUIs
- Creating menus and context menus
- Creating toolbars
- Using an external utility function
- Achieving proper resize behavior

The examples all use nested functions. For information about using nested functions, see "Nested Functions" in the MATLAB Programming documentation.

GUI with Axes, Menu, and Toolbar

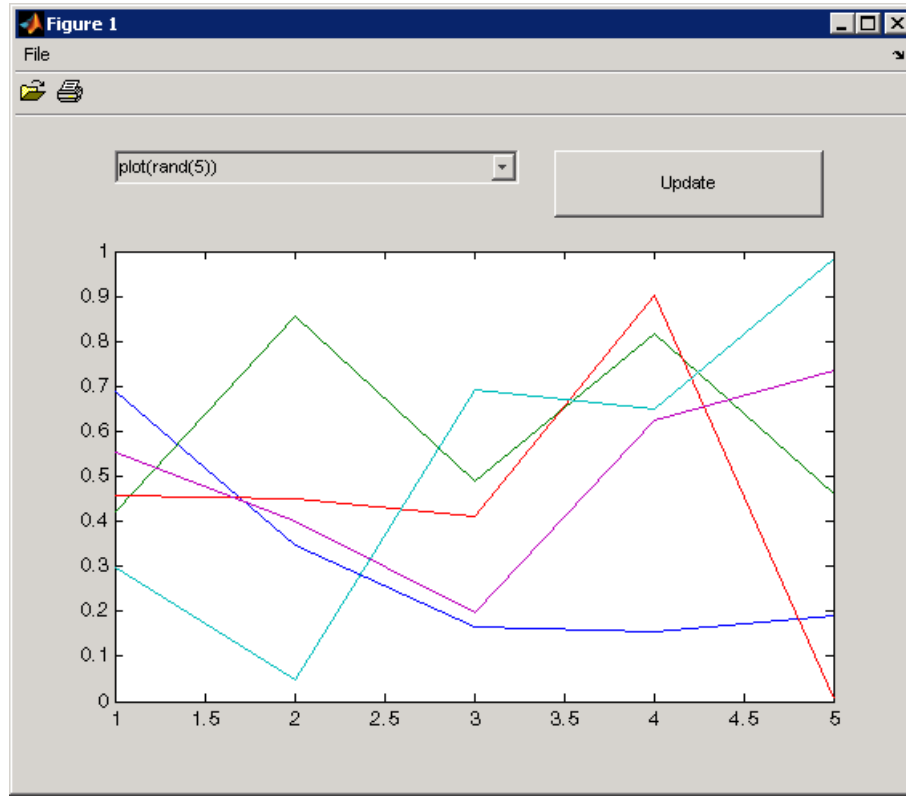
In this section...

The Example

This example creates a GUI that displays a user-selected plot in an axes. The GUI contains the following components:

- Axes
- Pop-up menu with a list of five plots
- Push button for updating the contents of the axes
- Menu bar File menu with three items: Open, Print, and Close
- Toolbar with two buttons that enable a user to open files and print the plot.

When you run the GUI, it initially displays a plot of five random numbers generated by the MATLAB `rand(5)` command, as shown in the following figure.



You can select other plots in the pop-up menu. Clicking the **Update** button displays the currently selected plot on the axes.

The GUI **File** menu has three items:

- **Open** displays a dialog from which you can open files on your computer.
- **Print** opens the Print dialog. Clicking **Yes** in the Print dialog prints the plot.
- **Close** closes the GUI.

The GUI toolbar has two buttons:

- The Open button  performs the same function as the **Open** menu item. It displays a dialog from which you can open files on your computer.
- The Print button  performs the same function as the **Print** menu item. It opens the Print dialog. Clicking **Yes** in the Print dialog prints the plot.

Techniques Used in the Example

This example illustrates the following techniques:

- Passing input arguments to the GUI when it is opened
- Obtaining output from the GUI when it returns
- Shielding the GUI from accidental changes
- Running the GUI across multiple platforms
- Creating menus
- Creating toolbars
- Achieving proper resize behavior

Note This example uses nested functions. For information about using nested functions, see “Nested Functions” in the MATLAB Programming documentation.

View and Run the Completed GUI M-Files

If you are reading this in the MATLAB Help browser, you can click the following links to display the MATLAB Editor with complete listings of the code used in this example.

Note The following links execute MATLAB commands and are designed to work within the MATLAB Help browser. If you are reading this online or in PDF, you should go to the corresponding section in the MATLAB Help Browser to use the links.

- Click here to display the main GUI M-file in the MATLAB Editor.
- Click here to display the utility `iconRead` M-file in the MATLAB Editor.
- Click here to run the GUI with axes, menu, and toolbar.

Creating the Data

The example defines two variables `mOutputArgs` and `mPlotTypes`.

`mOutputArgs` is a cell array that holds output values should the user request them. The example later assigns a default value to this argument.

```
mOutputArgs = {};  % Variable for storing output when GUI returns
```

`mPlotTypes` is a 5-by-2 cell array that holds the data to be plotted in the axes. The first column contains the strings that are used to populate the pop-up menu. The second column contains the functions, as anonymous function handles, that create the plots.

```
mPlotTypes = {...      % Example plot types shown by this GUI
              'plot(rand(5))',        @(a)plot(a,rand(5));
              'plot(sin(1:0.01:25))', @(a)plot(a,sin(1:0.01:25));
              'bar(1:.5:10)',         @(a)bar(a,1:.5:10);
              'plot(membrane)',       @(a)plot(a,membrane);
              'surf(peaks)',          @(a)surf(a,peaks)};
```

Because the data is created at the top level of the GUI function, it is available to all callbacks and other functions in the GUI.

See “Anonymous Functions” in the MATLAB Programming documentation for information about using anonymous functions.

Creating the GUI and Its Components

Like the data, the components are created at the top level so that their handles are available to all callbacks and other functions in the GUI.

- “The Main Figure” on page 15-7
- “The Axes” on page 15-7
- “The Pop-Up Menu” on page 15-8

The Main Figure

The following statement creates the figure for GUI.

```
hMainFigure = figure(...       % The main GUI figure
                     'MenuBar','none', ...
                     'Toolbar','none', ...
                     'HandleVisibility','callback', ...
                     'Color', get(0,...
                              'defaultuicontrolbackgroundcolor'));
```

- The `figure` function creates the GUI figure.
- Setting the `MenuBar` and `Toolbar` properties to `none`, prevents the standard menu bar and toolbar from displaying.
- Setting the `HandleVisibility` property to `callback` ensures that the figure can be accessed only from within a GUI callback, and cannot be drawn into or deleted from the command line.
- The `Color` property defines the background color of the figure. In this case, it is set to be the same as the default background color of `uicontrol` objects, such as the **Update** push button. The factory default background color of `uicontrol` objects is the system default and can vary from system to system. This statement ensures that the figure's background color matches the background color of the components.

See the Figure Properties reference page for information about figure properties and their default values.

The Axes

The following statement creates the axes.

```
hPlotAxes = axes(...    % Axes for plotting the selected plot
                 'Parent', hMainFigure, ...
                 'Units', 'normalized', ...
                 'HandleVisibility','callback', ...
```

```
                    'Position',[0.11 0.13 0.80 0.67]);
```

- The `axes` function creates the axes. Setting the axes `Parent` property to `hMainFigure` makes it a child of the main figure.
- Setting the `Units` property to `normalized` ensures that the axes resizes proportionately when the GUI is resized.
- The `Position` property is a 4-element vector that specifies the location of the axes within the figure and its size: [distance from left, distance from bottom, width, height]. Because the units are normalized, all values are between 0 and 1.

Note If you specify the `Units` property, then the `Position` property, and any other properties that depend on the value of the `Units` property, should follow the `Units` property specification.

See the Axes Properties reference page for information about axes properties and their default values.

The Pop-Up Menu

The following statement creates the pop-up menu.

```
hPlotsPopupmenu = uicontrol(... % List of available types of plot
                      'Parent', hMainFigure, ...
                      'Units','normalized',...
                      'Position',[0.11 0.85 0.45 0.1],...
                      'HandleVisibility','callback', ...
                      'String',mPlotTypes(:,1),...
                      'Style','popupmenu');
```

- The `uicontrol` function creates various user interface controls based on the value of the `Style` property. Here the `Style` property is set to `popupmenu`.
- For a pop-up menu, the `String` property defines the list of items in the menu. Here it is defined as a 5-by-1 cell array of strings derived from the cell array `mPlotTypes`.

See the Uicontrol Properties reference page for information about properties of `uicontrol` objects and their default values.

The Update Push Button

This statement creates the **Update** push button as a uicontrol object.

```
hUpdateButton = uicontrol(... % Button for updating selected plot
                  'Parent', hMainFigure, ...
                  'Units','normalized',...
                  'HandleVisibility','callback', ...
                  'Position',[0.6 0.85 0.3 0.1],...
                  'String','Update',...
                  'Callback', @hUpdateButtonCallback);
```

- The `uicontrol` function creates various user interface controls based on the value of the `Style` property. This statement does not set the `Style` property because its default is `pushbutton`.
- For a push button, the `String` property defines the label on the button. Here it is defined as the string `Update`.
- Setting the `Callback` property to `@hUpdateButtonCallback` defines the name of the callback function that services the push button. That is, clicking the push button triggers the execution of the named callback. This callback function is defined later in the script.

See the Uicontrol Properties reference page for information about properties of `uicontrol` objects and their default values.

The File Menu and Its Menu Items

These statements define the **File** menu and the three items it contains.

```
hFileMenu      =   uimenu(...       % File menu
                       'Parent',hMainFigure,...
                       'HandleVisibility','callback', ...
                       'Label','File');
hOpenMenuitem  =   uimenu(...       % Open menu item
                       'Parent',hFileMenu,...
                       'Label','Open',...
                       'HandleVisibility','callback', ...
```

```
                        'Callback', @hOpenMenuitemCallback);
hPrintMenuitem  =  uimenu(...       % Print menu item
                        'Parent',hFileMenu,...
                        'Label','Print',...
                        'HandleVisibility','callback', ...
                        'Callback', @hPrintMenuitemCallback);
hCloseMenuitem  =  uimenu(...       % Close menu item
                        'Parent',hFileMenu,...
                        'Label','Close',...
                        'Separator','on',...
                        'HandleVisibility','callback', ...
                        'Callback', @hCloseMenuitemCallback');
```

- The `uimenu` function creates both the main menu, **File**, and the items it contains. For the main menu and each of its items, set the `Parent` property to the handle of the desired parent to create the menu hierarchy you want. Here, setting the `Parent` property of the **File** menu to `hMainFigure` makes it the child of the main figure. This statement creates a menu bar in the figure and puts the **File** menu on it.

  For each of the menu items, setting its `Parent` property to the handle of the parent menu, `hFileMenu`, causes it to appear on the **File** menu.

- For the main menu and each item on it, the `Label` property defines the strings that appear in the menu.
- Setting the `Separator` property to `on` for the **Close** menu item causes a separator line to be drawn above this item.
- For each of the menu items, the `Callback` property specifies the callback that services that item. In this example, no callback services the **File** menu itself. These callbacks are defined later in the script.

See the Uicontrol Properties reference page for information about properties of `uicontrol` objects and their default values.

The Toolbar and Its Tools

These statements define the toolbar and the two buttons it contains.

```
hToolbar = uitoolbar(...    % Toolbar for Open and Print buttons
                  'Parent',hMainFigure, ...
                  'HandleVisibility','callback');
```

```
hOpenPushtool  =  uipushtool(...   % Open toolbar button
                   'Parent',hToolbar,...
                   'TooltipString','Open File',...
                   'CData',iconRead(fullfile(matlabroot,...
                       'toolbox\matlab\icons\opendoc.mat')),...
                   'HandleVisibility','callback', ...
                   'ClickedCallback', @hOpenMenuitemCallback);
hPrintPushtool = uipushtool(...    % Print toolbar button
                    'Parent',hToolbar,...
                    'TooltipString','Print Figure',...
                    'CData',iconRead(fullfile(matlabroot,...
                        'toolbox\matlab\icons\printdoc.mat')),...
                    'HandleVisibility','callback', ...
                    'ClickedCallback', @hPrintMenuitemCallback);
```

- The `uitoolbar` function creates the toolbar on the main figure.
- The `uipushtool` function creates the two push buttons on the toolbar.
- The uipushtool `TooltipString` property assigns a tool tip that displays when the GUI user moves the mouse pointer over the button and leaves it there.
- The `CData` property specifies a truecolor image that displays on the button. For these two buttons, the utility `iconRead` function supplies the image. If you are reading this in the MATLAB Help browser, click here to display this utility M-file in the MATLAB Editor.
- For each of the uipushtools, the `ClickedCallback` property specifies the callback that executes when the GUI user clicks the button. Note that the Open push button and the Print push button use the same callbacks as their counterpart menu items.

See “Creating Toolbars” on page 11-56 for more information.

Initializing the GUI

These statements create the plot that appears in the GUI when it first displays, and, if the user provides an output argument when running the GUI, define the output that is returned to the user .

```
% Update the plot with the initial plot type
```

```
localUpdatePlot();

% Define default output and return it if it is requested by users
mOutputArgs{1} = hMainFigure;
if nargout>0
    [varargout{1:nargout}] = mOutputArgs{:};
end
```

- The `localUpdatePlot` function plots the selected plot type in the axes. For a pop-up menu, the uicontrol `Value` property specifies the index of the selected menu item in the `String` property. Since the default value is 1, the initial selection is `'plot(rand(5))'`. The `localUpdatePlot` function is a helper function that is defined later in the script, at the same level as the callbacks.
- The default output is the handle of the main figure.

Defining the Callbacks

This topic defines the callbacks that service the components of the GUI. Because the callback definitions are at a lower level than the component definitions and the data created for the GUI, they have access to all data and component handles.

Although the GUI has six components that are serviced by callbacks, there are only four callback functions. This is because the **Open** menu item and the Open toolbar button share the same callbacks. Similarly, the **Print** menu item and the Print toolbar button share the same callbacks.

- "Update Button Callback" on page 15-13
- "Open Menu Item Callback" on page 15-13
- "Print Menu Item Callback" on page 15-14
- "Close Menu Item Callback" on page 15-15

Note These are the callbacks that were specified in the component definitions, "Creating the GUI and Its Components" on page 15-6.

Update Button Callback

The `hUpdateButtonCallback` function services the **Update** push button. Clicking the **Update** button triggers the execution of this callback function.

```
function hUpdateButtonCallback(hObject, eventdata)
  % Callback function run when the Update button is pressed
      localUpdatePlot();
  end
```

The `localUpdatePlot` function is a helper function that plots the selected plot type in the axes. It is defined later in the script, "Helper Function: Plotting the Plot Types" on page 15-16.

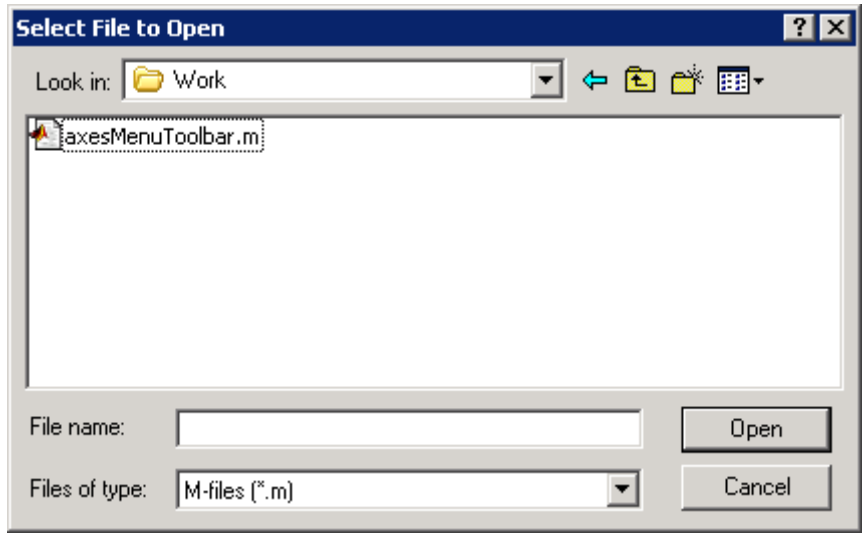
Note MATLAB automatically passes `hUpdateButtonCallback` two arguments, `hObject` and `eventdata`, because the **Update** push button component `Callback` property, `@hUpdateButtonCallback`, is defined as a function handle. `hObject` contains the handle of the component that triggered execution of the callback. `eventdata` is reserved for future use. The function definition line for your callback must account for these two arguments.

Open Menu Item Callback

The `hOpenMenuitemCallback` function services the **Open** menu item and the Open toolbar button  . Selecting the menu item or clicking the toolbar button triggers the execution of this callback function.

```
function hOpenMenuitemCallback(hObject, eventdata)
% Callback function run when the Open menu item is selected
    file = uigetfile('*.m');
    if ~isequal(file, 0)
        open(file);
    end
end
```

The `hOpenMenuitemCallback` function first calls the `uigetfile` function to open the standard dialog box for retrieving files. This dialog box lists all M-files. If `uigetfile` returns a filename, the function then calls the `open` function to open it.

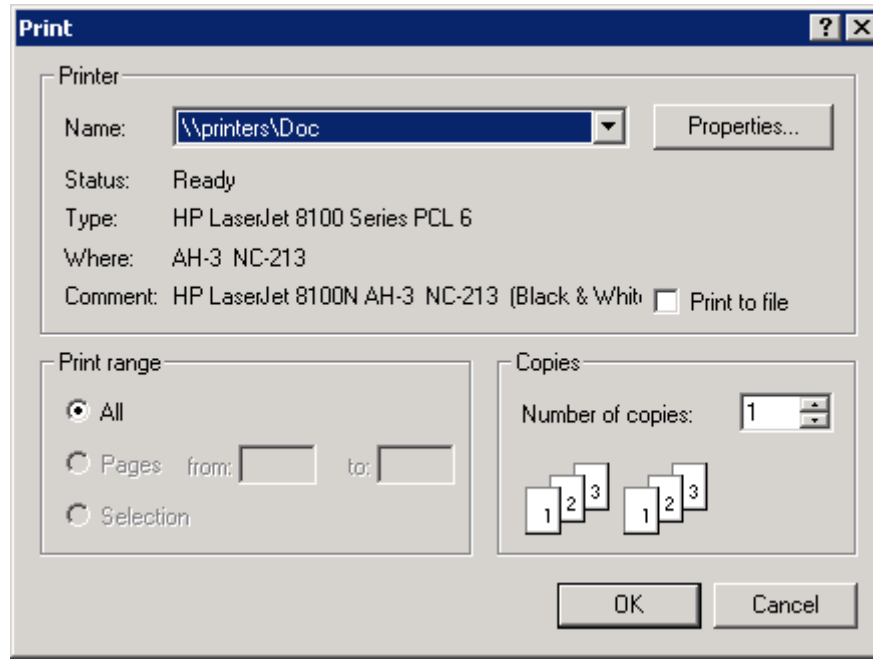


Print Menu Item Callback

The `hPrintMenuitemCallback` function services the **Print** menu item and the Print toolbar button. Selecting the menu item or clicking the toolbar button triggers the execution of this callback function.

```
function hPrintMenuitemCallback(hObject, eventdata)
% Callback function run when the Print menu item is selected
    printdlg(hMainFigure);
end
```

The `hPrintMenuitemCallback` function calls the `printdlg` function. This function opens the standard dialog box for printing the current figure.



Close Menu Item Callback

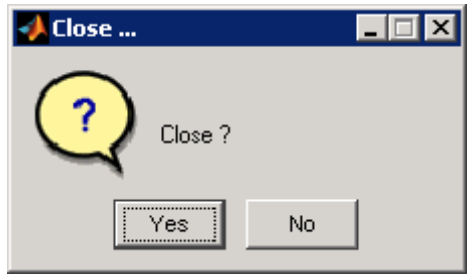
The `hCloseMenuitemCallback` function services the **Close** menu item. It executes when the GUI user selects **Close** from the **File** menu.

```
function hCloseMenuitemCallback(hObject, eventdata)
% Callback function run when the Close menu item is selected
    selection = ...
       questdlg(['Close ' get(hMainFigure,'Name') '?'],...
                ['Close ' get(hMainFigure,'Name') '...'],...
                'Yes','No','Yes');
    if strcmp(selection,'No')
        return;
    end

    delete(hMainFigure);
```

```
end
```

The `hCloseMenuitemCallback` function calls the `questdlg` function to create and open the question dialog box shown in the following figure.



If the user clicks the **No** button, the callback returns. If the user clicks the **Yes** button, the callback deletes the GUI.

See “Helper Function: Plotting the Plot Types” on page 15-16 for a description of the `localUpdatePlot` function.

Helper Function: Plotting the Plot Types

The example defines the `localUpdatePlot` function at the same level as the callback functions. Because of this, `localUpdatePlot` has access to the same data and component handles.

```
function localUpdatePlot
% Helper function for plotting the selected plot type
    mPlotTypes{get(hPlotsPopupmenu, 'Value'), 2}(hPlotAxes);
end
```

The `localUpdatePlot` function uses the pop-up menu `Value` property to identify the selected menu item from the first column of the `mPlotTypes` 5-by-2 cell array, then calls the corresponding anonymous function from column two of the cell array to create the plot in the axes.

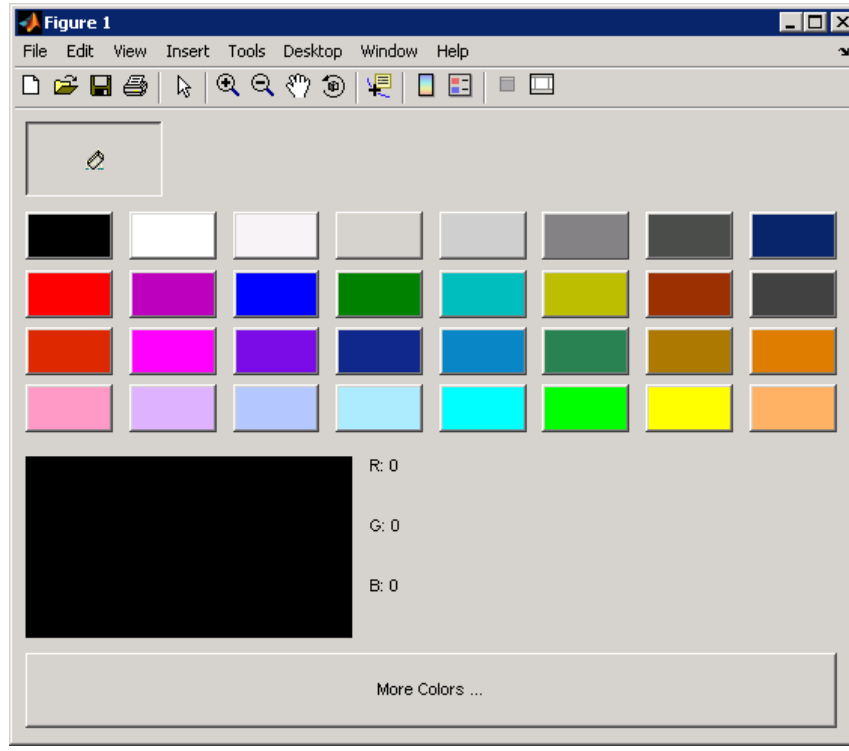
Color Palette

In this section...

The Example

This example creates a GUI, colorPalette, that enables a user to select a color from a color palette or display the standard color selection dialog box. Another example, "Icon Editor" on page 15-29, embeds the colorPalette, as the child of a panel, in a GUI you can use to design an icon.

The `colorPalette` function populates a GUI figure or panel with a color palette. The figure below shows the palette as the child of a figure.



The Components

The colorPalette includes the following components:

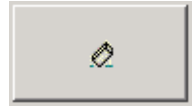
- An array of color cells defined as toggle buttons
- An Eraser toggle button with the  icon
- A button group that contains the array of color cells and the eraser button. The button group provides exclusive management of these toggle buttons.
- A **More Colors** push button
- A preview of the selected color, below the color cells, defined as a text component

- Text components to specify the red, blue, and green color values

Using the Color Palette

These are the basic steps for using the color palette.

1. Clicking a color cell toggle button:
   - Displays the selected color in the preview area.
   - The red, green, and blue values for the newly selected color are displayed in the **R**, **G**, and **B** fields to the right of the preview area.
   - Causes `colorPalette` to return a function handle that the host GUI can use to get the currently selected color.
2. Clicking the Eraser toggle button, causes `colorPalette` to return a value, `NaN`, that the host GUI can use to remove color from a data point.



3. Clicking the **More Colors** button displays the standard dialog box for setting a color.

Calling the colorPalette Function

You can call the `colorPalette` function with a statement such as

```
mGetColorFcn = colorPalette('Parent',hPaletteContainer)
```

The `colorPalette` function accepts property value pairs as input arguments. Only the custom property `Parent` is supported. This property specifies the handle of the parent figure or panel that contains the color palette. If the call to `colorPalette` does not specify a parent, it uses the current figure, `gcf`. Unrecognized property names or invalid values are ignored.

`colorPalette` returns a function handle that the host GUI can call to get the currently selected color. The host GUI can use the returned function handle at any time before the color palette is destroyed. For more information, see “Sharing Data Between Two GUIs” on page 15-26 for implementation details. “Icon Editor” on page 15-29 is an example of a host GUI that uses the colorPalette.

Techniques Used in the Example

This example illustrates the following techniques:

- Retrieving output from the GUI when it returns.
- Supporting custom input property/value pairs with data validation.
- Sharing data between two GUIs

See “Icon Editor” on page 15-29 for examples of these and other programming techniques.

Note This example uses nested functions. For information about using nested functions, see “Nested Functions” in the MATLAB Programming documentation.

View and Run the Completed GUI M-File

If you are reading this in the MATLAB Help browser, you can click the following link to display the MATLAB Editor with a complete listing of the code that is discussed in the following sections.

Note The following link executes MATLAB commands and is designed to work within the MATLAB Help browser. If you are reading this online or in PDF, you should go to the corresponding section in the MATLAB Help Browser to use the link.

- Click here to display the main GUI M-file in the MATLAB Editor.
- Click here to run the colorPalette GUI.

Subfunction Summary

The color palette example includes the callbacks listed in the following table.

Function	Description
`colorCellCallback`	Called by `hPalettePanelSelectionChanged` when any color cell is clicked.
`eraserToolCallback`	Called by `hPalettePanelSelectionChanged` when the Eraser button is clicked.
`hMoreColorButtonCallback`	Executes when the **More Colors** button is clicked. It calls `uisetcolor` to open the standard color-selection dialog box, and calls `localUpdateColor` to update the preview.
`hPalettePanelSelectionChanged`	Executes when the GUI user clicks on a new color. This is the `SectionChangeFcn` callback of the `uibuttongroup` that exclusively manages the tools and color cells that it contains. It calls the appropriate callback to service each of the tools and color cells.

Note Three `eventdata` fields are defined for use with button groups (`uibuttongroup`). These fields enable you to determine the previous and current radio or toggle button selections maintained by the button group. See `SelectionChangeFcn` in the Uibuttongroup Properties reference page for more information.

The example also includes the helper functions listed in the following table.

Function	Description
`layoutComponent`	Dynamically creates the Eraser tool and the color cells in the palette. It calls `localDefineLayout`.
`localUpdateColor`	Updates the preview of the selected color.
`getSelectedColor`	Returns the currently selected color which is then returned to the `colorPalette` caller.
`localDefineLayout`	Calculates the preferred color cell and tool sizes for the GUI. It calls `localDefineColors` and `localDefineTools`
`localDefineTools`	Defines the tools shown in the palette. In this example, the only tool is the **Eraser** button.
`localDefineColors`	Defines the colors that are shown in the array of color cells.
`processUserInputs`	Determines if the property in a property/value pair is supported. It calls `localValidateInput`.
`localValidateInput`	Validates the value in a property/value pair.

M-File Structure

The colorPalette is programmed using nested functions. Its M-file is organized in the following sequence:

1. Comments displayed in response to the `help` command.
2. Data creation. Because the example uses nested functions, defining this data at the top level makes the data accessible to all functions without having to pass them as arguments.
3. Command line input processing.
4. GUI figure and component creation.
5. GUI initialization.
6. Return output if it is requested.

7 Callback definitions. These callbacks, which service the GUI components, are subfunctions of the `colorPalette` function and so have access to the data and component handles created at the top level, without their having to be passed as arguments.

8 Helper function definitions. These helper functions are subfunctions of the `colorPalette` function and so have access to the data and component handles created at the top level, without their having to be passed as arguments.

Note For information about using nested functions, see "Nested Functions" in the MATLAB Programming documentation.

GUI Programming Techniques

This topic explains the following GUI programming techniques as they are used in the creation of the colorPalette.

- "Passing Input Arguments to a GUI" on page 15-24
- "Passing Output to a Caller on Returning" on page 15-26
- "Sharing Data Between Two GUIs" on page 15-26

See "Icon Editor" on page 15-29 for additional examples of these and other programming techniques.

Passing Input Arguments to a GUI

Inputs to the GUI are custom property/value pairs. `colorPalette` allows one such property: `Parent`. The names are case insensitive. The `colorPalette` syntax is

```
mGetColorFcn = colorPalette('Parent',hPaletteContainer)
```

Definition and Initialization of the Properties. The `colorPalette` function first defines a variable `mInputArgs` as `varargin` to accept the user input arguments.

```
mInputArgs = varargin;  % Command line arguments when invoking
                        % the GUI
```

The `colorPalette` function then defines the valid custom properties in a 3-by-3 cell array.

```
mPropertyDefs = {...    % The supported custom property/value
                        % pairs of this GUI
              'parent',   @localValidateInput, 'mPaletteParent';
```

- The first column contains the property name.
- The second column contains a function handle for the function, `localValidateInput`, that validates the input property values.
- The third column is the local variable that holds the value of the property.

`colorPalette` then initializes the properties with default values.

```
mPaletteParent = [];  % Use input property 'parent' to initialize
```

Processing the Input Arguments. The `processUserInputs` helper function processes the input property/value pairs. `colorPalette` calls `processUserInputs` before it creates the components, to determine the parent of the components.

```
% Process the command line input arguments supplied when
% the GUI is invoked
processUserInputs();
```

1. `processUserInputs` sequences through the inputs, if any, and tries to match each property name to a string in the first column of the `mPropertyDefs` cell array.
2. If it finds a match, `processUserInputs` assigns the value that was input for the property to its variable in the third column of the `mPropertyDefs` cell array.
3. `processUserInputs` then calls the helper function specified in the second column of the `mPropertyDefs` cell array to validate the value that was passed in for the property.

Passing Output to a Caller on Returning

If a host GUI calls the `colorPalette` function with an output argument, it returns a function handle that the host GUI can call to get the currently selected color.

The host GUI calls `colorPalette` only once. The call creates the color palette in the specified parent and then returns the function handle. The host GUI can call the returned function at any time before the color palette is destroyed.

The data definition section of the `colorPalette` M-file creates a cell array to hold the output:

```
mOutputArgs = {};  % Variable for storing output when GUI returns
```

Just before returning, `colorPalette` assigns the function handle, `mgetSelectedColor`, to the cell array `mOutputArgs` and then assigns `mOutputArgs` to `varargout` to return the arguments.

```
mOutputArgs{} = @getSelectedColor;
if nargout>0
    [varargout{1:nargout}] = mOutputArgs{:};
end
```

Sharing Data Between Two GUIs

The iconEditor embeds a GUI, the colorPalette, to enable the user to select colors for the icon cells. The colorPalette returns a function handle the iconEditor. The iconEditor can then call the returned function at any time to get the selected color.

The colorPalette GUI. The `colorPalette` function defines a cell array, `mOutputArgs`, to hold its output arguments.

```
mOutputArgs = {};  % Variable for storing output when GUI returns
```

Just before returning, `colorPalette` assigns `mOutputArgs` the function handle for its `getSelectedColor` helper function and then assigns `mOutputArgs` to `varargout` to return the arguments.

```
% Return user defined output if it is requested
mOutputArgs{1} =@getSelectedColor;
if nargout>0
    [varargout{1:nargout}] = mOutputArgs{:};
end
```

The iconEditor executes the colorPalette's `getSeclectedColor` function whenever it invokes the function that colorPalette returns to it.

```
function color = getSelectedColor
% function returns the currently selected color in this
% colorPlatte
    color = mSelectedColor;
```

The iconEditor GUI. The `iconEditor` function calls `colorPalette` only once and specifies its parent to be a panel in the iconEditor.

```
% Host the ColorPalette in the PaletteContainer and keep the
% function handle for getting its selected color for editing
% icon.
mGetColorFcn = colorPalette('parent', hPaletteContainer);
```

This call creates the colorPalette as a component of the iconEditor and then returns a function handle that `iconEditor` can call to get the currently selected color.

The iconEditor's `localEditColor` helper function calls `mGetColorFcn`, the function returned by `colorPalette`, to execute the colorPalette's `getSelectedColor` function.

```
function localEditColor
% helper function that changes the color of an icon data
% point to that of the currently selected color in
% colorPalette
    if mIsEditingIcon
        pt = get(hIconEditAxes,'currentpoint');
        x = ceil(pt(1,1));
```

```
            y = ceil(pt(1,2));
            color = mGetColorFcn();

            % update color of the selected block
            mIconCData(y, x,:) = color;

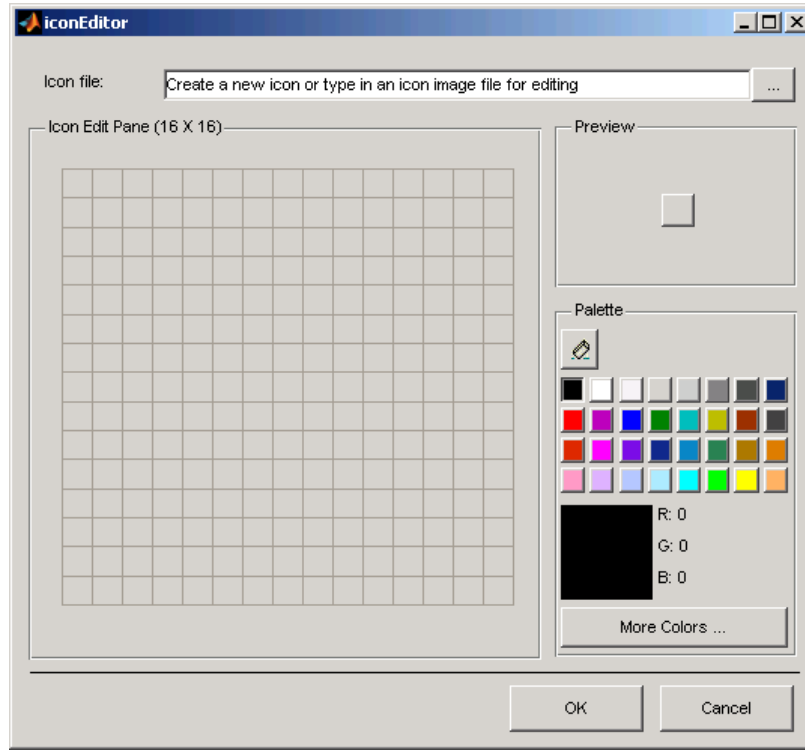
            localUpdateIconPlot();
        end
    end
```

Icon Editor

In this section...

The Example

This example creates a GUI that enables the user to create or edit an icon. The figure below shows the editor.



The Components

The GUI includes the following components:

- A edit text that instructs the user or contains the name of the file to be edited. The edit text is labeled using a static text.
- A push button to the right of the edit text enables the user to select an existing icon file for editing.
- A panel containing an axes. The axes displays a 16-by-16 grid for drawing an icon.
- A panel containing a button that shows a preview of the icon as it is being created.
- A color palette that is created in a separate script and embedded in this GUI. See “Color Palette” on page 15-17.

- A panel, configured as a line, that separates the icon editor from the **OK** and **Cancel** buttons.
- An **OK** push button that causes the GUI to return the icon as an m-by-n-by-3 array and closes the GUI.
- A **Cancel** push button that closes the GUI without returning the icon.

Using the Icon Editor

These are the basic steps to create an icon:

1. Start the icon editor with a command such as

   ```
   myicon = iconEditor('iconwidth',32,'iconheight',56);
   ```

   where the `iconwidth` and `iconheight` properties specify the icon size in pixels.

2. Color the squares in the grid.
   - Click a color cell in the palette. That color is then displayed in the palette preview.
   - Click in specific squares of the grid to transfer the selected color to those squares.
   - Hold down the left mouse button and drag the mouse over the grid to transfer the selected color to the squares that you touch.
   - Change a color by writing over it with another color.

3. Erase the color in some squares.
   - Click the **Eraser** button on the palette.
   - Click in specific squares to erase those squares.
   - Click and drag the mouse to erase the squares that you touch.
   - Click a color cell to disable the Eraser.

4. Click **OK** to close the GUI and return, in `myicon`, the icon you created – as a 32-by-65-by-3 array. Click **Cancel** to close the GUI and return an empty array `[]` in `myicon`.

Techniques Used in the Example

This example illustrates the following GUI programming techniques:

- Creating a GUI that does not return a value until the user makes a choice.
- Retrieving output from the GUI when it returns.
- Supporting custom input property/value pairs with data validation.
- Protecting a GUI from being changed from the command line.
- Creating a GUI that runs on multiple platforms
- Sharing data between two GUIs
- Achieving the proper resize behavior

Note This example uses nested functions. For information about using nested functions, see "Nested Functions" in the MATLAB Programming documentation.

View and Run the Completed GUI M-Files

If you are reading this in the MATLAB Help browser, you can click the following links to display the MATLAB Editor with a complete listing of the code that is discussed in the following sections.

Note The following links execute MATLAB commands and are designed to work within the MATLAB Help browser. If you are reading this online or in PDF, you should go to the corresponding section in the MATLAB Help Browser to use the links.

- Click here to display the main GUI M-file in the MATLAB Editor.
- Click here to display the utility iconRead M-file in the MATLAB Editor.
- Click here to run the iconEditor GUI.

Subfunction Summary

The icon editor example includes the callbacks listed in the following table.

Function	Description
`hMainFigureWindowButtonDownFcn`	Executes when the user clicks a mouse button anywhere in the GUI figure. It calls `localEditColor`.
`hMainFigureWindowButtonUpFcn`	Executes when the user releases the mouse button.
`hMainFigureWindowButtonMotionFcn`	Executes when the user drags the mouse anywhere in the figure with a button pressed. It calls `localEditColor`.
`hIconFileEditCallback`	Executes after the user manually changes the filename of the icon to be edited. It calls `localUpdateIconPlot`.
`hIconFileEditButtondownFcn`	Executes the first time the user clicks the **Icon file** edit box.
`hOKButtonCallback`	Executes when the user clicks the **OK** push button.
`hCancelButtonCallback`	Executes when the user clicks the **Cancel** push button.
`hIconFileButtonCallback`	Executes when the user clicks the **Icon file** push button  . It calls `localUpdateIconPlot`.

The example also includes the helper functions listed in the following table.

Function	Description
`localEditColor`	Changes the color of an icon data point to the currently selected color. Call the function `mGetColorFcn` returned by the `colorPalette` function. It also calls `localUpdateIconPlot`.
`localUpdateIconPlot`	Updates the icon preview. It also updates the axes when an icon is read from a file.
`processUserInputs`	Determines if the property in a property/value pair is supported. It calls `localValidateInput`.
`localValidateInput`	Validates the value in a property/value pair.
`prepareLayout`	Makes changes needed for look and feel and for running on multiple platforms.

M-File Structure

The iconEditor is programmed using nested functions. Its M-file is organized in the following sequence:

1. Comments displayed in response to the `help` command.
2. Data creation. Because the example uses nested functions, defining this data at the top level makes the data accessible to all functions without having to pass them as arguments.
3. GUI figure and component creation.
4. Command line input processing.
5. GUI initialization.
6. Block execution of the program until the GUI user clicks **OK** or **Cancel**.
7. Return output if requested.
8. Callback definitions. These callbacks, which service the GUI components, are subfunctions of the `iconEditor` function and so have access to the data and component handles created at the top level, without their having to be passed as arguments.
9. Helper function definitions. These helper functions are subfunctions of the `iconEditor` function and so have access to the data and component handles created at the top level, without their having to be passed as arguments.

Note For information about using nested functions, see "Nested Functions" in the MATLAB Programming documentation.

GUI Programming Techniques

This topic explains the following GUI programming techniques as they are used in the creation of the iconEditor.

- "Returning Only After the User Makes a Choice" on page 15-36
- "Passing Input Arguments to a GUI" on page 15-37

Returning Only After the User Makes a Choice

At the end of the initialization code, and just before returning, iconEditor calls `uiwait` with the handle of the main figure to make the GUI blocking.

```
% Make the GUI blocking
uiwait(hMainFigure);

% Return the edited icon CData if it is requested
mOutputArgs{1} =hMainFigure;
mOutputArgs{2} =mIconCData;
if nargout>0
    [varargout{1:nargout}] = mOutputArgs{:};
end
```

Placement of the call to `uiwait` is important. Calling `uiwait` stops the sequential execution of the `iconEdit` M-file after the GUI is initialized and just before the file would return the edited icon data.

When the user clicks the **OK** button, its callback, `hOKButtonCallback`, calls `uiresume` which enables the M-file to resume execution where it stopped and return the edited icon data.

```
function hOKButtonCallback(hObject, eventdata)
% Callback called when the OK button is pressed
    uiresume;
    delete(hMainFigure);
end
```

When the user clicks the **Cancel** button, its callback, `hOCancelButtonCallback`, effectively deletes the icon data then calls `uiresume`. This enables the M-file to resume execution where it stopped but it returns a null matrix.

```
function hCancelButtonCallback(hObject, eventdata)
% Callback called when the Cancel button is pressed
    mIconCData =[];
    uiresume;
    delete(hMainFigure);
end
```

Passing Input Arguments to a GUI

Inputs to the GUI are custom property/value pairs. `iconEdit` allows three such properties: `IconWidth`, `IconHeight`, and `IconFile`. The names are caseinsensitive.

Definition and Initialization of the Properties. The `iconEdit` first defines a variable `mInputArgs` as `varargin` to accept the user input arguments.

```
mInputArgs = varargin;  % Command line arguments when invoking
                        % the GUI
```

The `iconEdit` function then defines the valid custom properties in a 3-by-3 cell array.

```
mPropertyDefs = {...    % Supported custom property/value
                        % pairs of this GUI
              'iconwidth',   @localValidateInput, 'mIconWidth';
              'iconheight',  @localValidateInput, 'mIconHeight';
              'iconfile',    @localValidateInput, 'mIconFile'};
```

- The first column contains the property name.
- The second column contains a function handle for the function, `localValidateInput`, that validates the input property values.
- The third column is the local variable that holds the value of the property.

`iconEdit` then initializes the properties with default values.

```
mIconWidth = 16;   % Use input property 'iconwidth' to initialize
mIconHeight = 16;  % Use input property 'iconheight' to initialize
mIconFile = fullfile(matlabroot,'/toolbox/matlab/icons/');
```

The values of `mIconWidth` and `mIconHeight` are interpreted as pixels. The `fullfile` function builds a full filename from parts.

Processing the Input Arguments. The `processUserInputs` helper function processes the input property/value pairs. `iconEdit` calls `processUserInputs` after the layout is complete and just before it needs the inputs to initialize the GUI.

```
% Process the command line input arguments supplied when
% the GUI is invoked
processUserInputs();
```

1. `processUserInputs` sequences through the inputs, if any, and tries to match each property name to a string in the first column of the `mPropertyDefs` cell array.
2. If it finds a match, `processUserInputs` assigns the value that was input for the property to its variable in the third column of the `mPropertyDefs` cell array.
3. `processUserInputs` then calls the helper function specified in the second column of the `mPropertyDefs` cell array to validate the value that was passed in for the property.

Retrieving Output on Return from a GUI

If you call `iconEditor` with an output argument, it returns a truecolor image as an n-by-m-by-3 array.

The data definition section of the M-file creates a cell array to hold the output:

```
mOutputArgs = {};  % Variable for storing output when GUI returns
```

Following the call to `uiwait`, which stops the sequential execution of the M-file, iconEdit assigns the constructed icon array, `mIconEdit`, to the cell array `mOutputArgs` and then assigns `mOutputArgs` to `varargout` to return the arguments.

```
mOutputArgs{} =mIconCData;
if nargout>0
    [varargout{1:nargout}] = mOutputArgs{:};
end
```

This code is the last that iconEditor executes before returning. It executes only after clicking the **OK** or **Cancel** button triggers execution of `hOKButtonCallback` or `hCancelButtonCallback`, which call `uiresume` to resume execution.

Protecting a GUI from Inadvertent Access

The `prepareLayout` utility function protects the iconEditor from inadvertently being altered from the command line by setting the `HandleVisibility` properties of all the components. The iconEditor calls `prepareLayout` with the handle of the main figure, in the initialization section of the M-file.

```
% Make changes needed for proper look and feel and running on
% different platforms
prepareLayout(hMainFigure);
```

`prepareLayout` first uses `findall` to retrieve the handles of all objects contained in the figure. The list of retrieved handles includes the `colorPalette`, which is embedded in the `iconEditor`, and its children. The figure's handle is passed to `prepareLayout` as the input argument `topContainer`.

```
allObjects = findall(topContainer);
```

`prepareLayout` then sets the `HandleVisibility` properties of all those objects that have one to `Callback`.

```
% Make GUI objects available to callbacks so that they cannot
% be changed accidentally by other MATLAB commands
set(allObjects(isprop(allObjects,'HandleVisibility')),...
    'HandleVisibility','Callback');
```

Setting `HandleVisibility` to `Callback` causes the GUI handles to be visible from within callback routines or functions invoked by callback routines, but not from within functions invoked from the command line. This ensures that command-line users cannot inadvertently alter the GUI when it is the current figure.

Running a GUI on Multiple Platforms

The `prepareLayout` utility function sets various properties of all the GUI components to enable the GUI to retain the correct look and feel on multiple platforms. The iconEditor calls `prepareLayout` with the handle of the main figure, in the initialization section of the M-file.

```
% Make changes needed for proper look and feel and running on
% different platforms
prepareLayout(hMainFigure);
```

First, `prepareLayout` uses `findall` to retrieve the handles of all objects contained in the figure. The list of retrieved handles also includes the `colorPalette`, which is embedded in the `iconEditor`, and its children. The figure's handle is passed to `findall` as the input argument `topContainer`.

```
function prepareLayout(topContainer)
   ...
   allObjects = findall(topContainer);
```

Background Color. The default component background color is the standard system background color on which the GUI is running. This color varies on different computer systems, e.g., the standard shade of gray on the PC differs from that on UNIX, and may not match the default GUI background color.

The `prepareLayout` function sets the background color of the GUI to be the same as the default component background color. This provides a consistent look within the GUI, as well as with other application GUIs.

It first retrieves the default component background color from the root object. Then sets the GUI background color using the figure's `Color` property.

```
defaultColor = get(0,'defaultuicontrolbackgroundcolor');
if isa(handle(topContainer),'figure')

    ...

    % Make figure color match that of GUI objects
    set(topContainer, 'Color',defaultColor);
end
```

Selecting Units. The `prepareLayout` function decides what units to use based on the GUI's resizability. It uses `strcmpi` to determine the value of the GUI's Resize property. Depending on the outcome, it sets the `Units` properties of all the objects to either `Normalized` or `Characters`.

```
% Make the GUI run properly across multiple platforms by using
% the proper units
if strcmpi(get(topContainer, 'Resize'),'on')
    set(allObjects(isprop(allObjects,'Units')),...
        'Units','Normalized');
else
    set(allObjects(isprop(allObjects,'Units')),...
        'Units','Characters');
end
```

For a resizable figure, normalized units map the lower-left corner of the figure and of each component to (0,0) and the upper-right corner to (1.0,1.0). Because of this, component size is automatically adjusted to its parent's size when the GUI is displayed.

For a nonresizable figure, character units automatically adjusts the size and relative spacing of components as the GUI displays on different computers.

Character units are defined by characters from the default system font. The width of a character unit equals the width of the letter `x` in the system font. The height of a character unit is the distance between the baselines of two lines of text. Note that character units are not square.

Making a GUI Modal

iconEditor is a modal figure. Modal figures remain stacked above all normal figures and the MATLAB command window. This forces the user to respond without being able to interact with other windows. iconEditor makes the main figure modal by setting its `WindowStyle` property to `modal`.

```
hMainFigure = figure(...
 ...
              'WindowStyle','modal',...
```

See the Figure Properties in the MATLAB Function Reference documentation for more information about using the `WindowStyle` property.

Sharing Data Between Two GUIs

The iconEditor embeds a GUI, the colorPalette, to enable the user to select colors for the icon cells. The colorPalette returns the selected color to the iconEditor via a function handle.

The colorPalette GUI. Like the iconEditor, the colorPalette defines a cell array, `mOutputArgs`, to hold its output arguments.

```
mOutputArgs = {};  % Variable for storing output when GUI returns
```

Just before returning, `colorPalette` assigns `mOutputArgs` the function handle for its `getSelectedColor` helper function and then assigns `mOutputArgs` to `varargout` to return the arguments.

```
% Return user defined output if it is requested
mOutputArgs{1} =@getSelectedColor;
if nargout>0
    [varargout{1:nargout}] = mOutputArgs{:};
end
```

The iconEditor executes the colorPalette's `getSeclectedColor` function whenever it invokes the function that colorPalette returns to it.

```
function color = getSelectedColor
% function returns the currently selected color in this
% colorPlatte
    color = mSelectedColor;
```

The iconEditor GUI. The `iconEditor` function calls `colorPalette` only once and specifies its parent to be a panel in the iconEditor.

```
% Host the ColorPalette in the PaletteContainer and keep the
% function handle for getting its selected color for editing
% icon.
mGetColorFcn = colorPalette('parent', hPaletteContainer);
```

This call creates the colorPalette as a component of the iconEditor and then returns a function handle that `iconEditor` can call to get the currently selected color.

The iconEditor's `localEditColor` helper function calls `mGetColorFcn`, the function returned by `colorPalette`, to execute the colorPalette's `getSelectedColor` function.

```
function localEditColor
% helper function that changes the color of an icon data
% point to that of the currently selected color in
% colorPalette
    if mIsEditingIcon
        pt = get(hIconEditAxes,'currentpoint');
        x = ceil(pt(1,1));
        y = ceil(pt(1,2));
        color = mGetColorFcn();
        % update color of the selected block
        mIconCData(y, x,:) = color;
        localUpdateIconPlot();
    end
end
```

Achieving Proper Resize Behavior

The `prepareLayout` utility function sets the `Units` properties of all the GUI components to enable the GUI to resize correctly on multiple platforms. The iconEditor calls `prepareLayout` with the handle of the main figure, in the initialization section of the M-file.

```
prepareLayout(hMainFigure);
```

First, `prepareLayout` uses `findall` to retrieve the handles of all objects contained in the figure. The list of retrieved handles includes the `colorPalette`, which is embedded in the `iconEditor`, and its children. The figure's handle is passed to `findall` as the input argument `topContainer`.

```
function prepareLayout(topContainer)
   ...
   allObjects = findall(topContainer);
```

Then, `prepareLayout` uses `strcmpi` to determine if the GUI is resizable. Depending on the outcome, it sets the `Units` properties of all the objects to either `Normalized` or `Characters`.

```
if strcmpi(get(topContainer, 'Resize'),'on')
    set(allObjects(isprop(allObjects,'Units')),...
        'Units','Normalized');
else
    set(allObjects(isprop(allObjects,'Units')),...
        'Units','Characters');
end
```

Note The iconEditor is resizable because it accepts the default value, `on`, of the figure `Resize` property.

Resizable Figure. Normalized units map the lower-left corner of the figure and of each component to (0,0) and the upper-right corner to (1.0,1.0). Because of this, when the GUI is resized, component size is automatically changed relative its parent's size.

Nonresizable Figure. Character units automatically adjusts the size and relative spacing of components as the GUI displays on different computers.

Character units are defined by characters from the default system font. The width of a character unit equals the width of the letter `x` in the system font. The height of a character unit is the distance between the baselines of two lines of text. Note that character units are not square.

Preparing Data for Analysis

The following sections summarize MATLAB® data-analysis capabilities, and provide information about preparing your data for analysis.

MATLAB for Data Analysis (p. 1-3)	Provides an overview of data analysis using MATLAB
Importing and Exporting Data (p. 1-7)	Explains where to get information about importing and exporting data
Plotting Data (p. 1-8)	Provides information about MATLAB plots, and includes an example of loading data from a text file and creating a time plot
Removing and Interpolating Missing Values (p. 1-11)	Describes using `NaN`s to represent missing data, as well as removing or interpolating these values
Removing Outliers (p. 1-14)	Describes how to identify and remove values that seem inconsistent with the majority of the data
Filtering Data (p. 1-16)	Describes how to smooth and shape data using filters
Detrending Data (p. 1-21)	Describes how to remove the mean or a best-fit line from the data

MATLAB for Data Analysis

In this section...

Introduction

MATLAB provides functions and GUIs to perform a variety of common data-analysis tasks, such as plotting data, computing descriptive statistics, and performing linear correlation analysis, data fitting, and Fourier analysis.

Typically, the first step to any data analysis is to plot the data. After examining the plot, you can determine which portions of the data to include in the analysis. You can also use the plot to evaluate if your data contains any features that might distort or confuse the analysis results, and then process your data to work only with the regions of interest.

This chapter describes the common techniques you can use to ready your data for analysis. When you work with empirical data, it is often necessary to treat it by doing the following:

- Removing or interpolating missing values. For more information, see "Removing and Interpolating Missing Values" on page 1-11.
- Removing outliers. For more information, see "Removing Outliers" on page 1-14.
- Smoothing the data using a first-order filter, a transfer function, or an ideal filter. For more information, see "Filtering Data" on page 1-16.
- Removing the mean or a linear trend (*detrending*). For more information, see "Detrending Data" on page 1-21.
- Differencing the data. For more information, see "Finite Differences" on page 1-25.

After isolating the data of interest, you can proceed with the core data-analysis tasks, which might include basic data fitting (see Chapter 2, "Linear Regression Analysis") and Fourier analysis (see Chapter 3, "Fourier Analysis"). If your data analysis requires more advanced or specialized functionality, see "Related Toolboxes" on page 1-5 to learn about the toolboxes available from The MathWorks.

If you are working with time series data, MATLAB provides the `timeseries` and `tscollection` objects and methods that enable you to efficiently represent and manipulate time series data. For more information about creating and working with these objects, see Chapter 4, "Time Series Objects and Methods". Alternatively, you can use the MATLAB Time Series Tools graphical user interface (GUI) to import, plot, and analyze time series. For more information, see Chapter 5, "Time Series Tools".

Calculations on Vectors and Matrices

Whereas some MATLAB functions support only vector inputs, others accept matrices.

When your data is a vector, the result is the same whether the vector has a rowwise or columnwise orientation.

However, when your data is a matrix, MATLAB performs calculations independently for each column. This means that when you pass a matrix as an argument to the function `max`, for example, the result is a row vector containing maximum data values for each column in the matrix.

Note When your data is a matrix where each row contains a data set, you must transpose the matrix before proceeding with the data-analysis tasks to make the data sets have a columnwise orientation. For example, to transpose a real matrix `A`, use the syntax `A'`.

MATLAB GUIs for Data Analysis

In addition to the various MATLAB functions for performing data analysis, MATLAB provides four graphical user interfaces (GUIs) that facilitate

common data-analysis tasks. The following table lists these GUIs and tells you how to get more information about each one.

MATLAB GUIs for Data Analysis

GUI	Description	More Information
MATLAB Figure window	For plotting variables in the MATLAB workspace and editing plot properties	MATLAB Graphics documentation
Data Statistics dialog box	For calculating and plotting descriptive statistics	"Example — Using MATLAB Data Statistics" on page 1-29
Basic Fitting dialog box	For basic data fitting using polynomial and spline models, as well as plotting fitted data and residuals	"Interactive Fitting" on page 2-9
Time Series Tools	For plotting and manipulating time series data	Chapter 5, "Time Series Tools"

Related Toolboxes

The following table summarizes the toolboxes that extend MATLAB data-analysis capabilities. For the latest information about these and other MathWorks products, point your Web browser to

www.mathworks.com

Toolboxes That Extend MATLAB Data Analysis

Toolbox	Description
Bioinformatics Toolbox	Import, analyze, and visualize genomic, proteomic, and microarray data.
Curve Fitting Toolbox	Interactively model one-dimensional data.
Financial Toolbox	Analyze financial data and develop financial algorithms.

Toolboxes That Extend MATLAB Data Analysis (Continued)

Toolbox	Description
Image Processing Toolbox	Perform image processing, analysis, and algorithm development.
Model-Based Calibration Toolbox	Calibrate complex powertrain systems.
Neural Network Toolbox	Design and simulate neural networks.
Optimization Toolbox	Fit nonlinear models to data.
Signal Processing Toolbox	Perform signal processing, analysis, and algorithm development.
Spline Toolbox	Create and manipulate spline approximation models of data.
Statistics Toolbox	Analyze and model data, simulate systems, and develop statistical algorithms.
System Identification Toolbox	Create linear dynamic models from measured input-output data.
Wavelet Toolbox	Analyze and synthesize signals and images using wavelet techniques.

Importing and Exporting Data

The first step in analyzing data is to import it into MATLAB. The MATLAB Programming documentation provides detailed information about supported data formats and the functions for bringing data into MATLAB.

The easiest way to import data into MATLAB is to use the MATLAB Import Wizard, as described in the MATLAB Programming documentation. With the Import Wizard, you can import the following types of data sources:

- Text files, such as `.txt` and `.dat`
- MAT-files
- Spreadsheet files, such as `.xls`
- Graphics files, such as `.gif` and `.jpg`
- Audio and video files, such as `.avi` and `.wav`

The MATLAB Import Wizard processes the data source and recognizes data delimiters, as well as row or column headers, to facilitate the process of data selection.

After you finish analyzing your data, you might have created new variables. You can export these variables to a variety of file formats. For more information about exporting data from the MATLAB workspace, see the MATLAB Programming documentation.

When working with time series data, it is easiest to use the Time Series Tools GUI to import the data and create `timeseries` objects. The Import Wizard in Time Series Tools also makes it easy to import or define a time vector for your data. For more information, see “Importing and Exporting Data” on page 5-7.

Plotting Data

In this section...

Introduction

After you import data into MATLAB, it is a good idea to plot the data so that you can explore its features. An exploratory plot of your data enables you to identify discontinuities and potential outliers, as well as the regions of interest.

The MATLAB Graphics documentation fully describes the MATLAB figure window, which displays the plot. It also discusses the various plot tools that are available in MATLAB to help you annotate and edit plot properties.

If you are working with time series data, see Chapter 5, "Time Series Tools", for detailed information about working with time series plots.

Example — Loading and Plotting Data

In this example, you perform the following tasks on the data in a space-delimited text file:

This example uses sample data in `count.dat` that consists of three sets of hourly traffic counts, recorded at three different town intersections over a 24-hour period. Each data column in the file represents data for one intersection.

Loading the Data

Import data into MATLAB using the `load` function:

```
load count.dat
```

Loading this data creates a 24-by-3 matrix called `count` in the MATLAB workspace.

You can get the size of the data matrix by

```
[n,p] = size(count)
n =
    24
p =
     3
```

where `n` represents the number of rows, and `p` represents the number of columns.

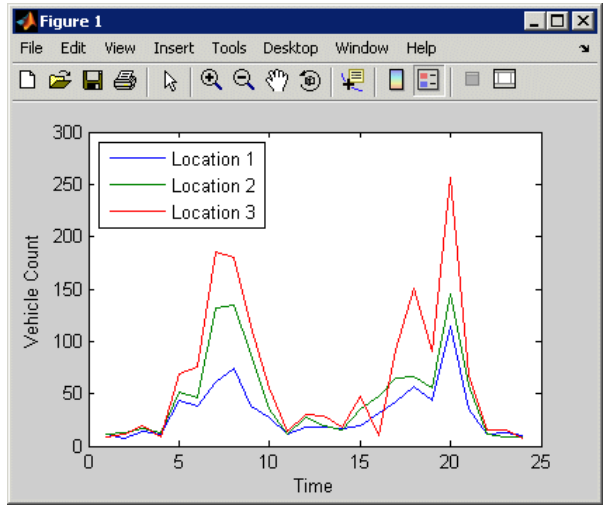
Plotting the Data

Create a time vector, `t`, containing integers from `1` to `n`:

```
t = 1:n;
```

Use the following commands to plot the data as a function of time, and to annotate the plot:

```
plot(t,count),
legend('Location 1','Location 2','Location 3',2)
xlabel('Time'), ylabel('Vehicle Count')
```



Traffic Counts at Three Intersections

Removing and Interpolating Missing Values

In this section...

Representing Missing Data Values

In MATLAB, missing or unavailable data values are represented by the special value `NaN`, which stands for *Not-a-Number*.

The IEEE floating-point arithmetic convention defines `NaN` as the result of an undefined operation, such as 0/0.

Calculating with NaNs

When you perform calculations on a MATLAB variable that contains `NaN`s, the `NaN` values are propagated to the final result. This might render the result useless.

For example, consider a matrix containing the 3-by-3 magic square with its center element replaced with `NaN`:

```
a = magic(3); a(2,2) = NaN

a =
     8     1     6
     3   NaN     7
     4     9     2
```

Compute the sum for each column in the matrix:

```
sum(a)

ans =
    15   NaN    15
```

Notice that the sum of the elements in the middle column is a `NaN` value because that column contains a `NaN`.

If you do not want to have `NaN`s in your final results, you must remove these values from your data. For more information, see "Removing NaNs from the Data" on page 1-12.

Removing NaNs from the Data

You can use the MATLAB function `isnan` to identify `NaN`s in the data, and then remove them using the techniques in the following table.

Note You must use the function `isnan` to identify `NaN`s because, by IEEE arithmetic convention, the logical comparison `NaN == NaN` always produces `0` (i.e., it never evaluates to `true`). Therefore, you *cannot* use `x(x==NaN) = []` to remove `NaN`s from your data.

Code	Description
`i = find(~isnan(x));` `x = x(i)`	Find the indices of elements in a vector `x` that are not `NaN`s. Keep only the non-`NaN` elements.
`x = x(~isnan(x));`	Remove `NaN`s from a vector `x`.
`x(isnan(x)) = [];`	Remove `NaN`s from a vector `x` (alternative method).
`X(any(isnan(X),2),:)  = [];`	Remove any rows containing `NaN`s from a matrix `X`.

If you frequently need to remove NaNs, you might want to write a short M-file function that you can call:

```
function X = exciseRows(X)
X(any(isnan(X),2),:) = [];
```

The following command computes the correlation coefficients of X after all rows containing NaNs are removed:

```
C = corrcoef(excise(X));
```

For more information about correlation coefficients, see “Correlation Analysis” on page 2-5.

Interpolating Missing Data

You can use interpolation to find intermediate points in your data. The simplest function for performing interpolation is `interp1`, which is a 1-D interpolation function.

By default, the interpolation method is `'linear'`, which fits a straight line between a pair of existing data points to calculate the intermediate value. The complete set of available methods, which you can specify as arguments in the `interp1` function, includes the following:

- `'nearest'` — Nearest neighbor interpolation
- `'linear'` — Linear interpolation
- `'spline'` — Piecewise cubic spline interpolation
- `'pchip'` or `'cubic'` — Shape-preserving piecewise cubic interpolation
- `'v5cubic'` — Cubic interpolation from MATLAB 5, which does not use `'extrapolate'` and uses `'spline'` when `X` is not equally spaced

For more information about `interp1`, see the MATLAB documentation or type at the MATLAB prompt

```
help interp1
```

Removing Outliers

When you examine a data plot, you might find that some points appear to dramatically differ from the rest of the data. In some cases, it is reasonable to consider such points *outliers*, or data values that do not appear to be consistent with the rest of the data.

The following example illustrates how to remove outliers from three data sets in the 24-by-3 matrix `count`. In this case, an outlier is defined as a value that is more than three standard deviations away from the mean.

Caution Be cautious about changing data unless you are confident that you understand the source of the problem you want to correct. Removing an outlier has a greater effect on the standard deviation than on the mean of the data. Deleting one such point leads to a smaller new standard deviation, which might result in making some remaining points appear to be outliers!

```
% Import the sample data
load count.dat;
% Calculate the mean and the standard deviation
% of each data column in the matrix
mu = mean(count)
sigma = std(count)
```

MATLAB displays

```
mu =
       32.0000   46.5417   65.5833

sigma =
       25.3703   41.4057   68.0281
```

When an *outlier* is considered to be more than three standard deviations away from the mean, you can use the following syntax to determine the number of outliers in each column of the `count` matrix:

```
[n,p] = size(count);
% Create a matrix of mean values by
% replicating the mu vector for n rows
MeanMat = repmat(mu,n,1);
% Create a matrix of standard deviation values by
% replicating the sigma vector for n rows
SigmaMat = repmat(sigma,n,1);
% Create a matrix of zeros and ones, where ones indicate
% the location of outliers
outliers = abs(count - MeanMat) > 3*SigmaMat;
% Calculate the number of outliers in each column
nout = sum(outliers)
```

MATLAB returns the following number of outliers in each column:

```
nout =
       1    0    0
```

There is one outlier in the first data column of `count` and none in the other two columns.

To remove an entire row of data containing the outlier, type

```
count(any(outliers,2),:) = [];
```

Here, `any(outliers,2)` returns a `1` when any of the elements in the `outliers` vector is a nonzero number, and the argument `2` specifies that `any` works down the second dimension of the count matrix—its columns.

Filtering Data

In this section...

Introduction

MATLAB provides functions for working with difference equations and filters to shape the variations in the raw data. These functions operate on both vectors and matrices. You can filter data to smooth out high-frequency fluctuations or remove periodic trends of a specific frequency.

A vector input represents a single, sampled data signal (or *sequence*). For a matrix input, each signal corresponds to a column in the matrix and each data sample is a row.

Filter Function

The function

```
y = filter(b,a,x)
```

creates filtered data `y` by processing the data in vector `x` with the filter described by vectors `a` and `b`.

The `filter` function is a general tapped delay-line filter, described by the difference equation

$$\begin{aligned} a(1)y(n) = b(1)x(n) + b(2)x(n-1) + \ldots + b(N_b)x(n-N_b+1) \\ - a(2)y(n-1) - \ldots - a(N_a)y(n-N_a+1) \end{aligned}$$

Here, n is the index of the current sample, N_a is the order of the polynomial described by vector a, and N_b is the order of the polynomial described by

vector b. The output $y(n)$ is a linear combination of current and previous inputs, $x(n)$ $x(n-1)$..., and previous outputs, $y(n-1)$ $y(n-2)$... .

Example 1 — Moving Average Filter

You can smooth the data in `count.dat` using a moving-average filter to see the average traffic flow over a 4-hour window (covering the current hour and the previous 3 hours). This is represented by the following difference equation:

$$y(n) = \frac{1}{4}x(n) + \frac{1}{4}x(n-1) + \frac{1}{4}x(n-2) + \frac{1}{4}x(n-3)$$

The corresponding vectors are

```
a = 1;
b = [1/4 1/4 1/4 1/4];
```

Enter the following syntax to load the sample data:

```
load count.dat
```

This adds the matrix `count` to the workspace.

Extract the first column of `count` and assign it to the vector `x`:

```
x = count(:,1);
```

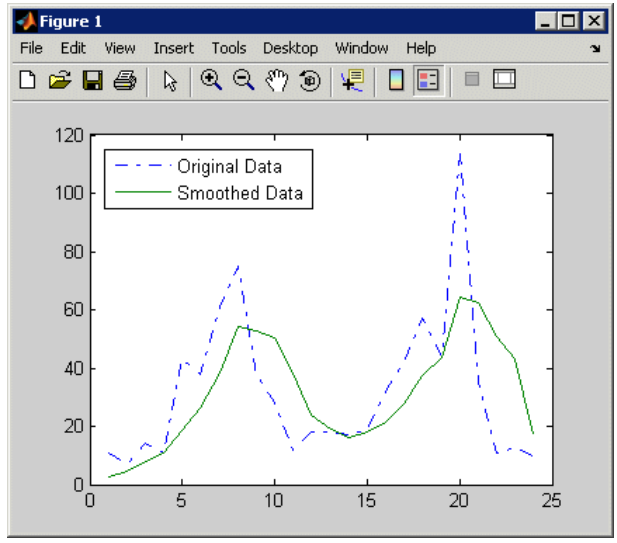
The 4-hour moving average of the data is calculated by

```
y = filter(b,a,x);
```

Compare the original data and the smoothed data with an overlaid plot of the two curves:

```
t = 1:length(x);
plot(t,x,'-.',t,y,'-'), grid on
legend('Original Data','Smoothed Data',2)
```

The filtered data, represented by the solid line in the plot, is the 4-hour moving average of the `count` data. The original data is represented by the dashed line.



Plot of Original and Smoothed Data

Example 2 — Discrete Filter

You use the discrete filter to shape the data by applying a transfer function to the input signal.

Depending on your objectives, the transfer function you choose might alter both the amplitude and the phase of the variations in the data at different frequencies to produce either a smoother or a rougher output.

Taking the z-transform of the following difference equation

$$a(1)y(n) = b(1)x(n) + b(2)x(n-1) + \ldots + b(N_b)x(n-N_b+1) - a(2)y(n-1) - \ldots - a(N_a)x(n-N_a+1)$$

results in the following transfer function:

$$Y(z) = H(z^{-1})X(z) = \frac{b(1) + b(2)z^{-1} + \ldots b(N_b)z^{-N_b+1}}{a(1) + a(2)z^{-1} + \ldots a(N_a)z^{-N_a+1}}X(z)$$

Here $Y(z)$ is the z-transform of the filtered output $y(n)$. The coefficients b and a are unchanged by the z-transform.

In digital signal processing (DSP), it is customary to write transfer functions as rational expressions in z^{-1} and to order the numerator and denominator terms in ascending powers of z^{-1}.

Consider the following transfer function:

$$H(z^{-1}) = \frac{b(z^{-1})}{a(z^{-1})} = \frac{2 + 3z^{-1}}{1 + 0.2z^{-1}}$$

To apply this transfer function to the data in `count.dat`:

1 Load the matrix count into the workspace:

```
load count.dat;
```

2 Extract the first column and assign it to `x`:

```
x = count(:,1);
```

3 Enter the coefficients of the denominator ordered in ascending powers of z^{-1} to represent $1 + 0.2z^{-1}$:

```
a = [1 0.2];
```

4 Enter the coefficients of the numerator to represent $2+2z^{-1}$:

```
b = [2 3];
```

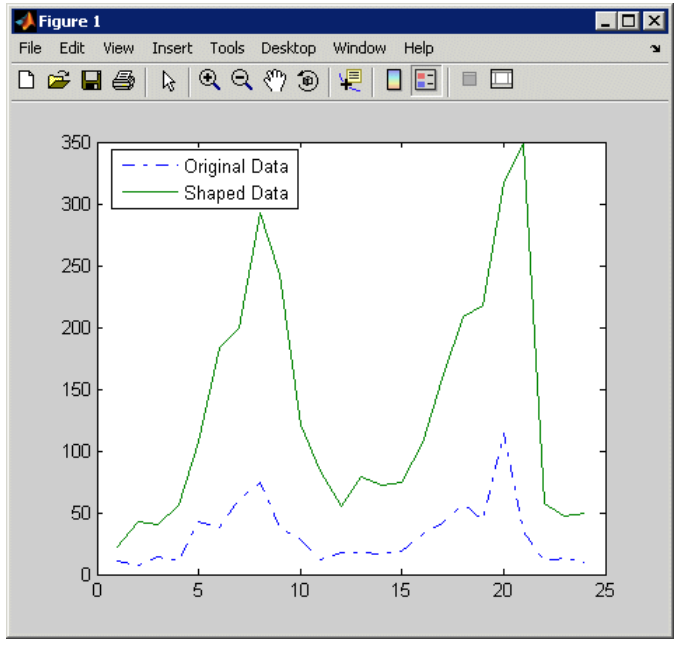
5 Call the filter function:

```
y = filter(b,a,x);
```

6 Compare the original data and the shaped data with an overlaid plot of the two curves:

```
t = 1:length(x);
plot(t,x,'-.',t,y,'-'), grid on
legend('Original Data','Shaped Data',2)
```

As you can see from the plot, this filter primarily modifies the amplitude of the original data.



Plot of Original and Shaped Data

Detrending Data

In this section...

Introduction

The MATLAB function `detrend` subtracts the mean or a best-fit line (in the least-squares sense) from your data. If your data contains several data columns, MATLAB detrends each data column separately.

Removing a trend from the data enables you to focus your analysis on the fluctuations in the data about the trend. A linear trend typically indicates a systematic increase or decrease in the data. This might be caused by sensor drift, for example.

You must decide whether it makes sense to remove trend effects in the data based on the objectives of your analysis.

Example — Removing Linear Trends from Data

This example shows how to remove a linear trend from daily closing stock prices to emphasize the price fluctuations about the overall increase. This data is available in the `predict_ret_data.mat` file.

You can follow along with the steps in this example to perform the following tasks:

- "Loading and Plotting Data" on page 1-22
- "Detrending Data and Plotting Results" on page 1-23

Loading and Plotting Data

1. Load the sample data:

   ```
   load predict_ret_data.mat
   ```

   This adds the variable `sdata` to the workspace, which contains the daily stock prices.

2. View the contents of the column vector `sdata`:

   ```
   sdata
   ```

   The last data value is a `NaN`, which must be removed before detrending the data.

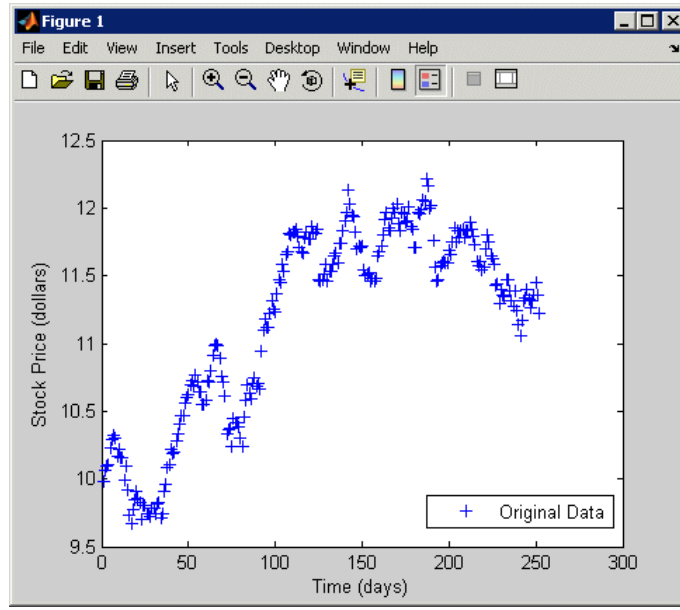
3. Identify and remove the `NaN` value from `sdata`:

   ```
   sdata(any(isnan(sdata),2),:) = []
   ```

   For more information about removing `NaN`s, see “Removing NaNs from the Data” on page 1-12.

4. Plot the data:

   ```
   plot(t, sdata,'+')
   legend('Original Data',1);
   xlabel('Time (days)');
   ylabel('Stock Price (dollars)');
   ```



Daily Closing Stock Prices

Notice the systematic increase in the stock prices when this data was collected.

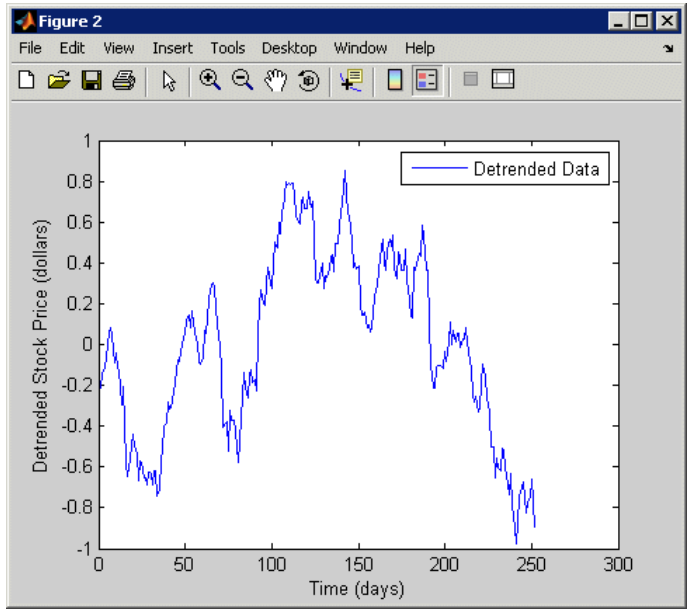
Detrending Data and Plotting Results

1. Remove a best-fit line (in the least-squares sense) from `sdata` and save the results to a new variable, `detrend_sdata`:

   ```
   detrend_sdata=detrend(sdata);
   ```

2. Plot the detrended data in a new MATLAB Figure window:

   ```
   figure
   plot(detrend_sdata,'-')
   legend('Detrended Data',2)
   xlabel('Time (days)');
   ylabel('Detrended Stock Price (dollars)');
   ```



Stock Prices with the Removed Linear Trend

Notice that the data is now centered about 0 and the linear drift is removed from the data.

Finite Differences

MATLAB provides three functions for finite difference calculations.

Function	Description
`del2`	Discrete Laplacian of a matrix
`diff`	Differences between successive elements of a vector; numerical partial derivatives of a vector
`gradient`	Numerical partial derivatives of a matrix

The `diff` function computes the difference between successive elements in a numeric vector. That is, `diff(X)` is `[X(2)-X(1) X(3)-X(2)...X(n)-X(n-1)]`. You might want to perform this operation on your data if you are more interested in analyzing the changes in the values, rather than the absolute values.

For a vector `A`,

```
A = [9 -2 3 0 1 5 4];
diff(A)

ans =
   -11     5    -3     1     4    -1
```

Besides computing the first difference, you can use `diff` to determine certain characteristics of vectors. For example, you can use `diff` to determine whether the vector values are monotonically increasing or decreasing, or whether a vector has equally spaced elements.

The following table provides examples for using `diff` with a vector `x`.

Test	Description
`any(diff(x)==0)`	Tests whether there are any repeated elements in X
`all(diff(x)>0)`	Tests whether the values are monotonically increasing
`all(diff(diff(x))==0)`	Tests for equally spaced vector elements

Descriptive Statistics

In this section...

If you need more advanced statistics functionality, you might want to use the Statistics Toolbox. For more information see the Statistics Toolbox documentation.

Functions for Calculating Descriptive Statistics

You can use the following MATLAB functions to calculate the descriptive statistics for your data.

Note For matrix data, MATLAB calculates descriptive statistics for each column independently.

Statistics Function Summary

Function	Description
`max`	Maximum value
`mean`	Average or mean value
`median`	Median value
`min`	Smallest value
`mode`	Most frequent value

Statistics Function Summary (Continued)

Function	Description
`std`	Standard deviation
`var`	Variance, which measures the spread or dispersion of the values

The following examples apply MATLAB functions to calculate descriptive statistics:

- "Example 1 — Calculating Maximum, Mean, and Standard Deviation" on page 1-27
- "Example 2 — Subtracting the Mean" on page 1-29

Example 1 — Calculating Maximum, Mean, and Standard Deviation

This example shows how to use MATLAB functions to calculate the maximum, mean, and standard deviation values for a 24-by-3 matrix called `count`. MATLAB computes these statistics independently for each column in the matrix.

```
% Load the sample data
load count.dat
% Find the maximum value in each column
mx = max(count)
% Calculate the mean of each column
mu = mean(count)
% Calculate the standard deviation of each column
sigma = std(count)
```

MATLAB responds with

```
mx =
          114           145           257

mu =
      32.0000       46.5417       65.5833

sigma =
      25.3703       41.4057       68.0281
```

To get the row numbers where the maximum data values occur in each data column, you can specify a second output parameter `indx` to return the row index. For example:

```
[mx,indx] = max(count)
```

MATLAB responds with this result:

```
mx =
      114     145     257

indx =
      20    20    20
```

Here, the variable `mx` is a row vector that contains the maximum value in each of the three data columns. The variable `indx` contains the row indices in each column that correspond to the maximum values.

To find the minimum value in the entire `count` matrix, you can reshape this 24-by-3 matrix into a 72-by-1 column vector by using the syntax `count(:)`. Then, to find the minimum value in the single column, you can use the following syntax:

```
min(count(:))

ans =
      7
```

Example 2 — Subtracting the Mean

You can subtract the mean from each column of the matrix by using the following syntax:

```
% Get the size of the count matrix
[n,p] = size(count)
% Compute the mean of each column
mu = mean(count)
% Create a matrix of mean values by
% replicating the mu vector for n rows
MeanMat = repmat(mu,n,1)
% Subtract the column mean from each element
% in that column
x = count - MeanMat
```

Note Subtracting the mean from the data is also called *detrending*. For more information about removing the mean or the best-fit line from the data, see "Detrending Data" on page 1-21.

Example — Using MATLAB Data Statistics

MATLAB provides the Data Statistics dialog box to help you calculate and plot descriptive statistics with the data. This example shows how to use MATLAB Data Statistics to calculate and plot statistics for a 24-by-3 matrix, called `count`.

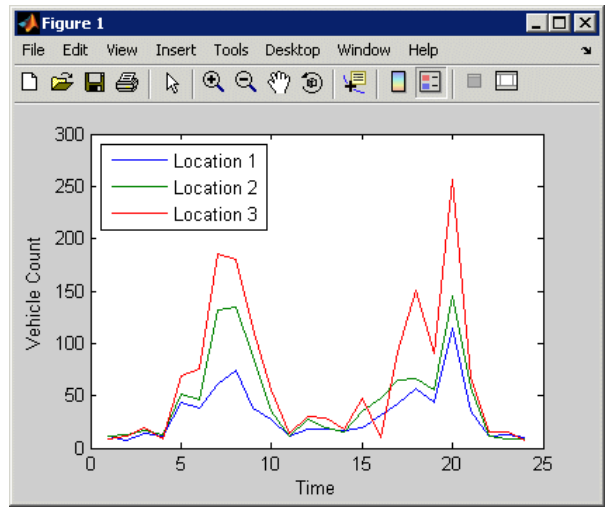
This section contains the following topics:

Note MATLAB Data Statistics is available only for 2-D plots.

Calculating and Plotting Descriptive Statistics

1 Load and plot the data:

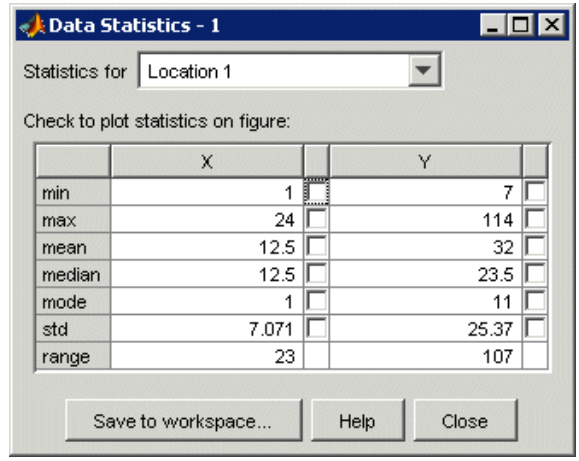
```
load count.dat
[n,p] = size(count);
% Define the x-values
t = 1:n;
% Plot the data and annotate the graph
plot(t,count)
legend('Location 1','Location 2','Location 3',2)
xlabel('Time'), ylabel('Vehicle Count')
```



Note The legend contains the name of each data set, as specified by the `legend` function: `Location 1`, `Location 2`, and `Location 3`. A *data set* refers to each column of data in the array you plotted. If you do not name the data sets, MATLAB assigns them default names: `data 1`, `data 2`, and so on.

2 In the Figure window, select **Tools > Data Statistics** .

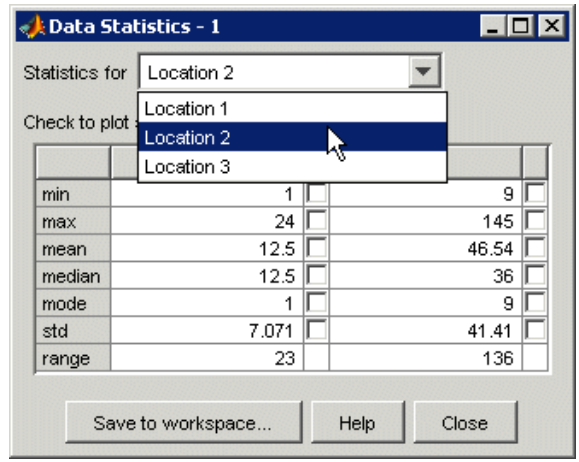
This opens the Data Statistics dialog box, which displays descriptive statistics for the `X`- and `Y`-data of the `Location 1` data set.



Note The Data Statistics GUI calculates the *range*, which is the difference between the minimum and maximum values in the selected data set. The Data Statistics GUI does not display the range on the plot.

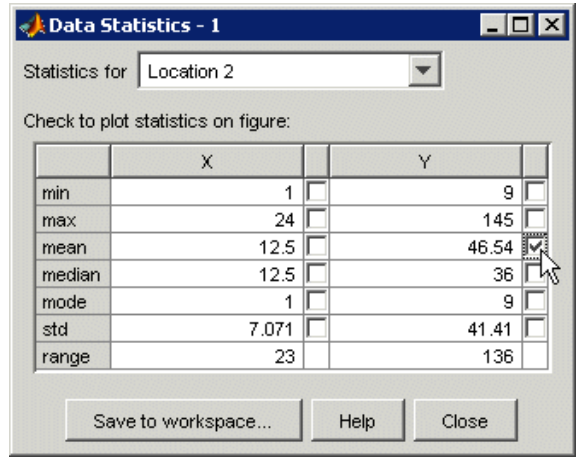
3 Select a different data set in the **Statistics for** list: `Location 2`.

This displays the statistics for the `X` and `Y` data of the `Location 2` data set.

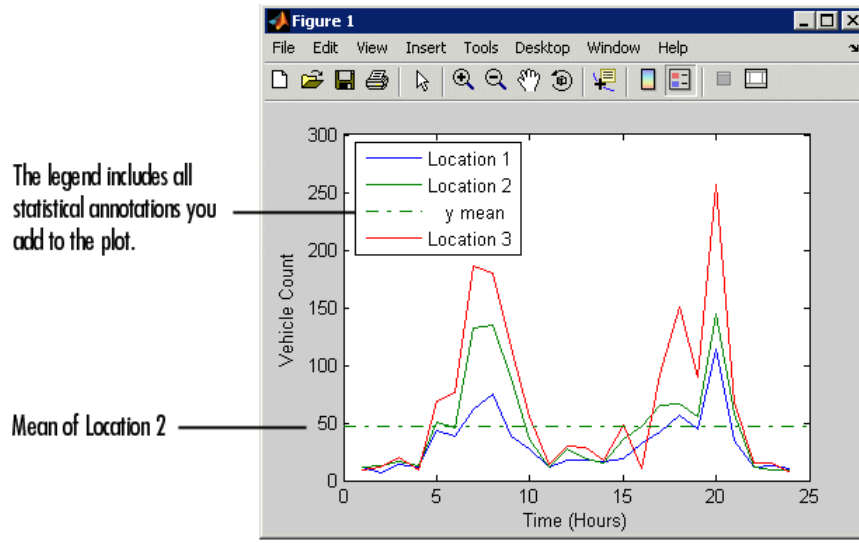


4 Select the check box for each statistic you want to display on the plot.

For example, to plot the mean of `Location 2`, select the **mean** check box in the **Y** column.



This plots a horizontal line to represent the mean of `Location 2` and updates the plot legend to include this statistic.



Formatting Data Statistics on Plots

The Data Statistics GUI uses colors and line styles to distinguish statistics from the data on the plot. This portion of the example shows how to customize the display of descriptive statistics on a plot, such as the color, line width, line style, or marker.

Note Do not edit display properties of statistics until you finish plotting all the statistics with the data. If you add or remove statistics after editing plot properties, the changes to plot properties are lost.

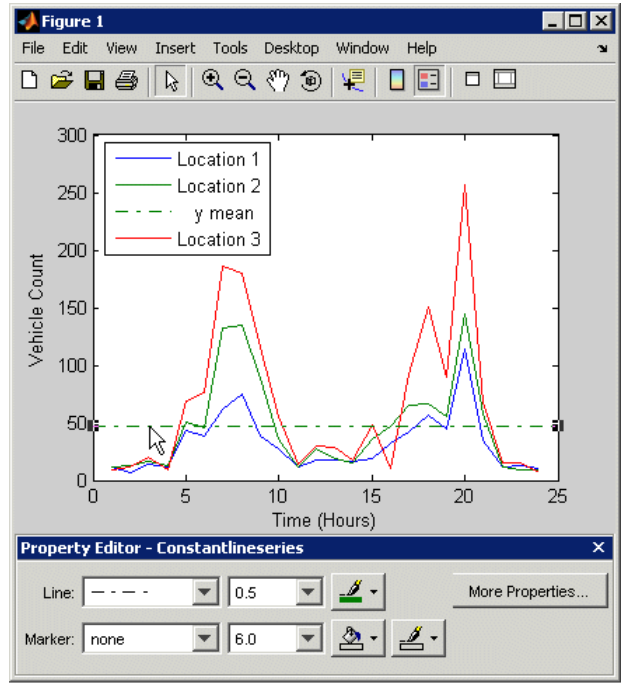
To modify the display of data statistics on a plot:

1. In the MATLAB Figure window, click the  (**Edit Plot**) button in the toolbar.

   This enables plot editing.

2 Double-click the statistic on the plot for which you want to edit display properties. For example, double-click the horizontal line representing the mean of `Location 2`.

This opens the Property Editor below the MATLAB Figure window, where you can modify the appearance of the line used to represent this statistic.



3 In the Property Editor, specify the **Line** and **Marker** styles, sizes, and colors.

Tip Alternatively, right-click the statistic on the plot, and select an option from the shortcut menu.

Saving Statistics to the MATLAB Workspace

This portion of the example shows how to save statistics in the Data Statistics GUI to the MATLAB workspace.

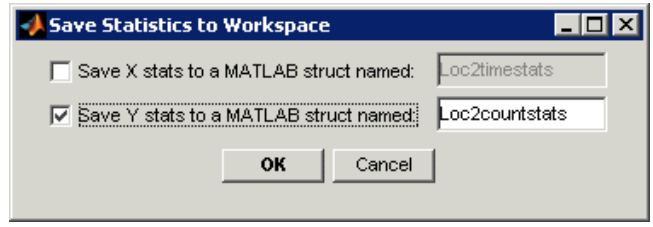
Note When your plot contains multiple data sets, you must save statistics for each data set individually. To display statistics for a different data set, select it from the **Statistics for** list in the Data Statistics GUI.

---

1. In the Data Statistics dialog box, click the **Save to workspace** button.

2. In the Save Statistics to Workspace dialog box, specify to save statistics for either `X` data, `Y` data, or both. Then, enter the corresponding variable names.

   In this example, save only the `Y` data. Enter the variable name as `Loc2countstats`.



3. Click **OK**.

   This saves the descriptive statistics to a structure. The new variable is added to the MATLAB workspace.

To view the new structure variable, type the variable name at the MATLAB prompt:

```
Loc2countstats

Loc2countstats =

       min: 9
       max: 145
      mean: 46.5417
    median: 36
      mode: 9
       std: 41.4057
     range: 136
```

Generating an M-file

This portion of the example shows how to generate an M-file that reproduces the format of the plot and the plotted statistics with new data.

1. In the Figure window, select **File > Generate M-File**.

   This creates a function M-file and displays it in the MATLAB Editor. The code in the M-file shows you how to programmatically reproduce what you did interactively with the Data Statistics GUI and the Property Editor.

2. Change the name of the function on the first line of the M-file from `createfigure` to something more specific, like `countplot`. Save the file to your current directory with the file name `countplot.m`.

3. Generate some new, random count data:

   ```
   randcount = 300*rand(24,3);
   ```

4. Reproduce the plot with the new data and the recomputed statistics:

   ```
   countplot(t,randcount)
   ```

Linear Regression Analysis

Linear Regression

In this section...

Introduction

MATLAB allows you to model your data using linear regression. A *model* is a relationship between independent and dependent variables. Linear regression produces a model that is linear in the model coefficients. The most common type of linear regression is a *least-squares fit*, which can fit both lines and polynomials.

Before you model the relationship between pairs of quantities, it is a good idea to perform correlation analysis to establish if a relationship exists between these quantities. For more information, see "Correlation Analysis" on page 2-5.

MATLAB provides the Basic Fitting GUI for fitting your data, which enables you to calculate model coefficients and plot the model on top of the data. For an example of using this GUI, see "Example — Using Basic Fitting GUI" on page 2-11. You can also use the MATLAB functions `polyfit` and `polyval` to fit your data to a model that is linear in the coefficients. For an example of using these functions, see "Example — Data Fitting Using MATLAB Functions" on page 2-29.

If you need to fit nonlinear data using MATLAB, you can try transforming the variables in your model to make the model linear, use the nonlinear algorithm `fminsearch`, or use the Curve Fitting Toolbox (see the Curve Fitting Toolbox documentation).

In this chapter, you learn how to do the following:

- Use correlation analysis to determine whether two quantities are related to justify fitting the data.

- Fit a linear model to the data.
- Plot the model and the data on the same plot.
- Evaluate the goodness of fit using a plot of the residuals.

Residuals and Goodness of Fit

Residuals are defined as the difference between the *observed* values of the dependent variable and the values that are *predicted* by the model. When you fit a model that is appropriate for your data, the residuals approximate independent random errors.

To calculate fit parameters for a linear model, MATLAB minimizes the sum of the squares of the residuals to produce a good fit. This is called a least-squares fit.

You can gain insight into the "goodness" of a fit by visually examining a plot of the residuals: if the residual plot has a pattern, this indicates that the model does not properly fit the data.

Notice that the "goodness" of a fit must be determined in the context of your data. For example, if your goal of fitting the data is to extract coefficients that have physical meaning, then it is important that your model reflect the physics of the data. In this case, understanding what your data represents and how it was measured is just as important as evaluating the goodness of fit.

When to Use the Curve Fitting Toolbox

The Curve Fitting Toolbox extends core MATLAB functionality by enabling the following data-fitting capabilities:

- Linear and nonlinear parametric fitting, including standard linear least squares, nonlinear least squares, weighted least squares, constrained least squares, and robust fitting procedures
- Nonparametric fitting
- Statistics for determining the goodness of fit
- Extrapolation, differentiation, and integration
- GUI that facilitates data sectioning and smoothing

- Saving fit results in various formats, including M-files, MAT-files, and workspace variables

For more information, see the Curve Fitting Toolbox documentation.

Correlation Analysis

In this section...

Introduction

Before you fit a function to model the relationship between two measured quantities, it is a good idea to determine if a relationship exists between these quantities.

Correlation is a method for establishing the degree of probability that a linear relationship exists between two measured quantities. When there is no correlation between the two quantities, then there is no tendency for the values of one quantity to increase or decrease with the values of the second quantity.

MATLAB provides the following three functions for computing correlation coefficients and covariance. In typical data analysis applications, where you are mostly interested in the degree of relationship between variables, you need only to calculate correlation coefficients. That is, it is not necessary to calculate the covariance independently.

Function	Description
`corrcoef`	Correlation coefficient matrix
`cov`	Covariance matrix
`xcorr` (in Signal Processing Toolbox)	Cross-correlation sequence of a random process (includes autocorrelation)

Covariance

Use the MATLAB `cov` function to explicitly calculate the covariance matrix for a data matrix (where each column represents a separate quantity).

In typical data analysis applications, where you are mostly interested in the degree of relationship between variables, you can calculate the correlation coefficients directly without calculating the covariance first.

The covariance matrix has the following properties:

- `cov(X)` is symmetrical.
- `diag(cov(X))` is a vector of variances for each data column, which represent a measure of the spread or dispersion of data in the corresponding column.
- `sqrt(diag(cov(X)))` is a vector of standard deviations.
- The off-diagonal elements of the covariance matrix represent the covariance between the individual data columns.

Here, `X` can be a vector or a matrix. For an *m*-by-*n* matrix, the covariance matrix is *n*-by-*n*.

For an example of calculating the covariance, load the sample data in `count.dat` that contains a 24-by-3 matrix:

```
load count.dat
```

Calculate the covariance matrix for this data:

```
cov(count)
```

MATLAB responds with the following result:

```
ans =
    1.0e+003 *
       0.6437  0.9802  1.6567
       0.9802  1.7144  2.6908
       1.6567  2.6908  4.6278
```

The covariance matrix for this data has the following form:

$$\begin{bmatrix} \sigma^2_{11} & \sigma^2_{12} & \sigma^2_{13} \\ \sigma^2_{21} & \sigma^2_{22} & \sigma^2_{23} \\ \sigma^2_{31} & \sigma^2_{32} & \sigma^2_{33} \end{bmatrix}$$

$$\sigma^2 ij = \sigma^2_{ji}$$

Here, σ^2_{ij} is the covariance between column i and column j of the data. Because the `count` matrix contains three columns, the covariance matrix is 3-by-3.

Note In the special case when a vector is the argument of `cov`, the function returns the variance.

Correlation Coefficients

The correlation coefficient matrix represents the normalized measure of the strength of linear relationship between variables.

Correlation coefficients r_k are given by

$$r_k = \frac{\sum_{t=1}^{N} (x_t - \bar{x})(x_{t+k} - \bar{x})}{\sum_{t=1}^{N} (x_t - \bar{x})^2}$$

where x_t is a data value at time step t, k is the lag, and the overall mean is given by

$$\bar{x} = \sum_{t=1}^{N} \frac{x_t}{N}$$

The MATLAB function `corrcoef` produces a matrix of correlation coefficients for a data matrix (where each column represents a separate quantity). The correlation coefficients range from -1 to 1, where

- Values close to 1 suggest that there is a positive linear relationship between the data columns.
- Values close to -1 suggest that one column of data has a negative linear relationship to another column of data (*anticorrelation*).
- Values close to or equal to 0 suggest there is no linear relationship between the data columns.

For an *m*-by-*n* matrix, the correlation-coefficient matrix is *n*-by-*n*. The arrangement of the elements in the correlation coefficient matrix corresponds to the location of the elements in the covariance matrix, as described in "Covariance" on page 2-6.

For an example of calculating correlation coefficients, load the sample data in `count.dat` that contains a 24-by-3 matrix:

```
load count.dat
```

Type the following syntax to calculate the correlation coefficients:

```
corrcoef(count)
```

This results in the following 3-by-3 matrix of correlation coefficients:

```
ans =
    1.0000    0.9331    0.9599
    0.9331    1.0000    0.9553
    0.9599    0.9553    1.0000
```

Because all correlation coefficients are close to 1, there is a strong correlation between each pair of data columns in the `count` matrix.

Interactive Fitting

In this section...

The Basic Fitting GUI

The MATLAB Basic Fitting GUI allows you to interactively:

- Model data using a spline interpolant, a shape-preserving interpolant, or a polynomial up to the tenth degree
- Plot one or more fits together with data
- Plot the residuals of the fits
- Compute model coefficients
- Compute the norm of the residuals (a measure of the goodness of fit)
- Use the model to interpolate or extrapolate outside of the data
- Save coefficients and computed values to the MATLAB workspace for use outside of the GUI
- Generate an M-file to recompute fits and reproduce plots with new data

---

Note The Basic Fitting GUI is only available for 2-D plots. For more advanced fitting and regression analysis, see the Curve Fitting Toolbox and the Statistics Toolbox.

Preparing for Basic Fitting

The Basic Fitting GUI sorts your data in ascending order before fitting. If your data set is large and the values are not sorted in ascending order, it will take longer for the Basic Fitting GUI to preprocess your data before fitting.

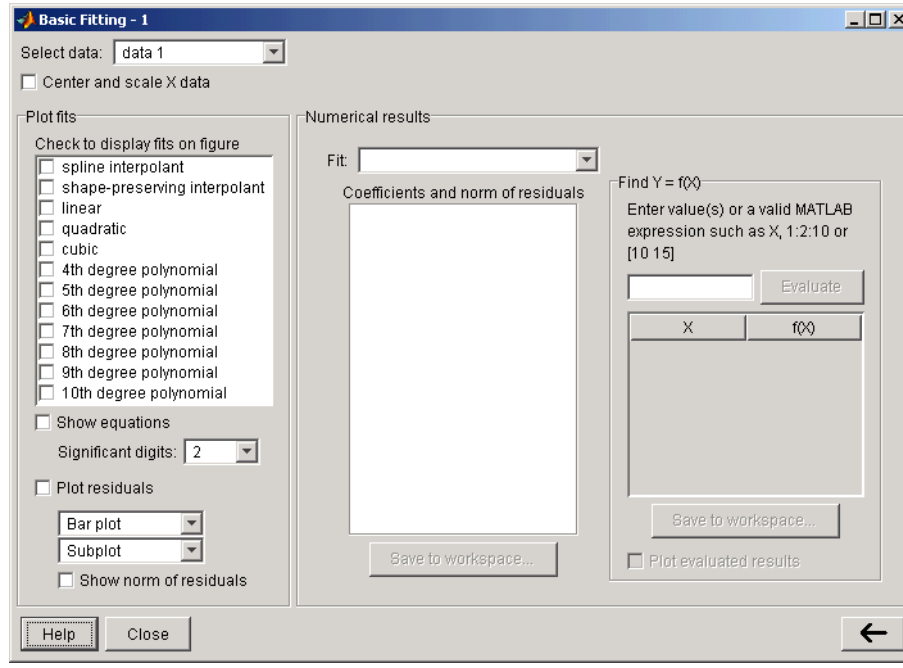
You can speed up the Basic Fitting GUI by first sorting your data in MATLAB. To create sorted vectors `x_sorted` and `y_sorted` from data vectors `x` and `y`, use the MATLAB `sort`function:

```
[x_sorted, i] = sort(x);
y_sorted = y(i);
```

Opening the Basic Fitting GUI

To use the Basic Fitting GUI, you must first plot your data in a figure window, using any MATLAB plotting command that produces (only) *x* and *y* data.

To open the Basic Fitting GUI, select **Tools > Basic Fitting** from the menus at the top of the figure window.



The GUI consists of three panels:

- For selecting a model and plotting options

- For examining and exporting model coefficients and norms of residuals
- For examining and exporting interpolated and extrapolated values

To expand or collapse the panels, use the arrow button in the lower right corner of the interface.

Example — Using Basic Fitting GUI

The example in this section shows you how to use the Basic Fitting GUI.

Loading and Plotting Data

The file `census.mat` contains U.S. population data for the years 1790 through 1990.

To load and plot the data, type the following commands at the MATLAB prompt:

```
load census
plot(cdate,pop,'ro')
```

The `load` command adds the following two variables to the MATLAB workspace:

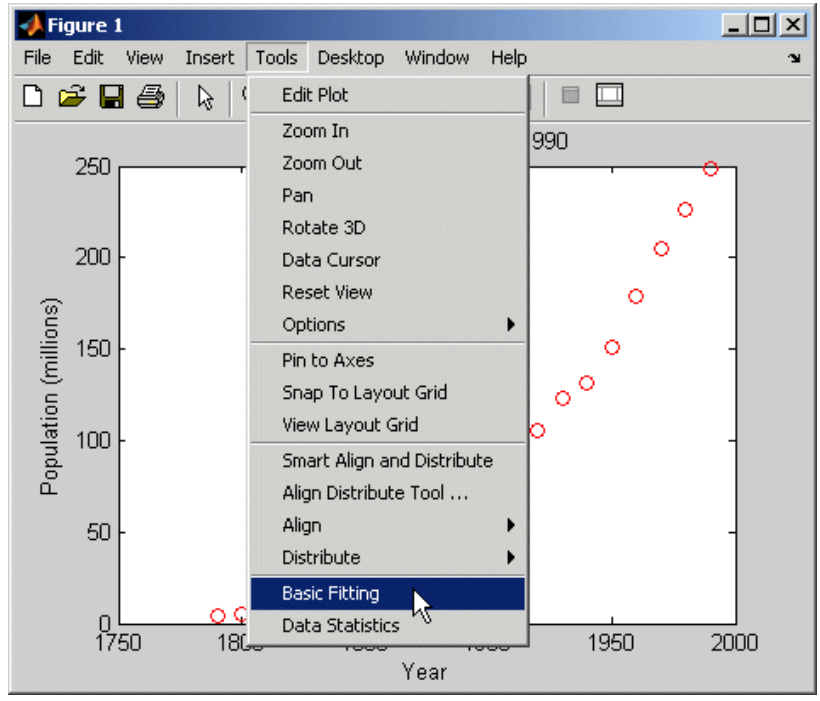
- `cdate` is a column vector containing the years from 1790 to 1990 in increments of 10. This is the predictor variable.
- `pop` is a column vector with U.S. population for each year in `cdate`. This is the response variable.

The data vectors are sorted in ascending order, by year. The plot shows the population as a function of year.

Now you are ready to fit the data.

Fitting Data

1 Open the Basic Fitting dialog box by selecting **Tools > Basic Fitting** in the Figure window.



2 In the **Plot fits** area of the Basic Fitting dialog box, select the **cubic** check box to fit a cubic polynomial to the data.

MATLAB displays the following warning:

```
Polynomial is badly conditioned. Removing
repeated data points or centering and scaling
may improve results.
```

The warning indicates that the computed coefficients for the model will be highly sensitive to random errors in the response (in this case, the measured population). To improve model accuracy, it is helpful to transform the predictors (in this case, the dates) by normalizing their center and scale. This is done by computing the *z-scores*:

$$z = \frac{x - \mu}{\sigma}$$

where x is the predictor data, μ is the mean of x, and σ is the standard deviation of x. This centers the data at 0, with a standard deviation of 1.

To perform this transformation on the predictor data, select the **Center and scale x data** check box.

After centering and scaling, model coefficients are computed for the y data as a function of z. These are different (and more robust) than the coefficients computed for y as a function of x. The form of the model, and the norm of the residuals, is unchanged. The Basic Fitting GUI automatically rescales the z-scores so that the fit is displayed on the same scale as the original x data.

The Basic Fitting GUI calls the MATLAB functions `polyfit` and `polyval` to compute and display the fit. To understand the way in which the centered and scaled data is used as an intermediary to create the final plot, type the following at the MATLAB command prompt:

```
load census
x = cdate;
y = pop;
z = (x-mean(x))/std(x); % Compute z-scores of x data

plot(x,y,'ro') % Plot data
hold on

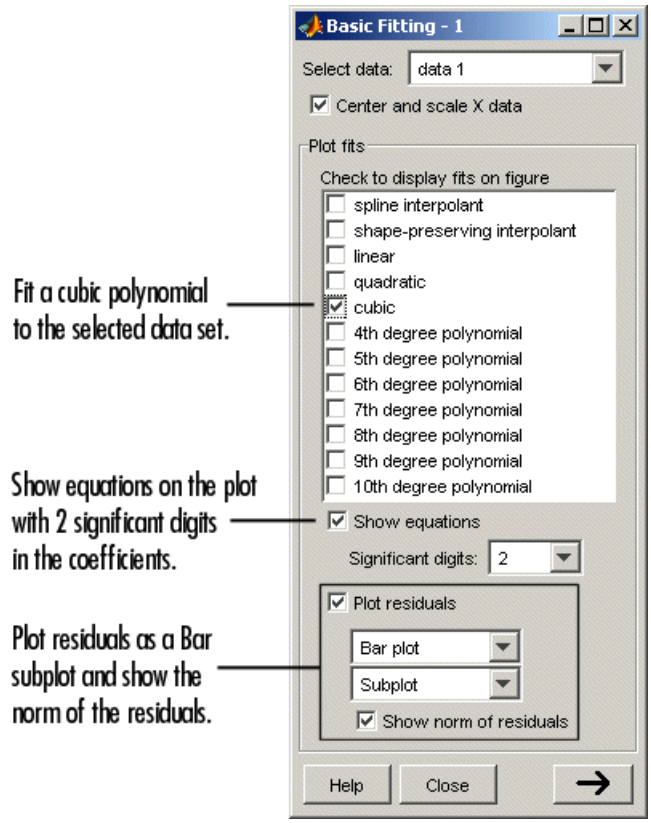
zfit = linspace(z(1),z(end),100);
pz = polyfit(z,y,3); % Compute conditioned fit
yfit = polyval(pz,zfit);

xfit = linspace(x(1),x(end),100);
```

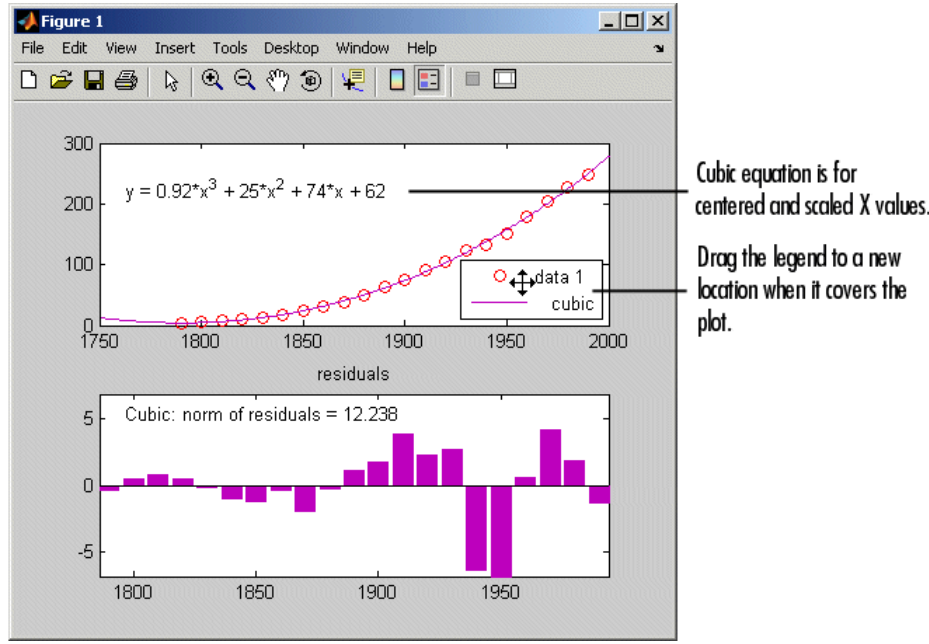
```
plot(xfit,yfit,'b-') % Plot conditioned fit vs. x data
```

3 Select the following options:

- Display the model equation in the plot
- Display the residuals as a subplot
- Display the norm of the residuals in the plot



The resulting display is shown in the following figure:



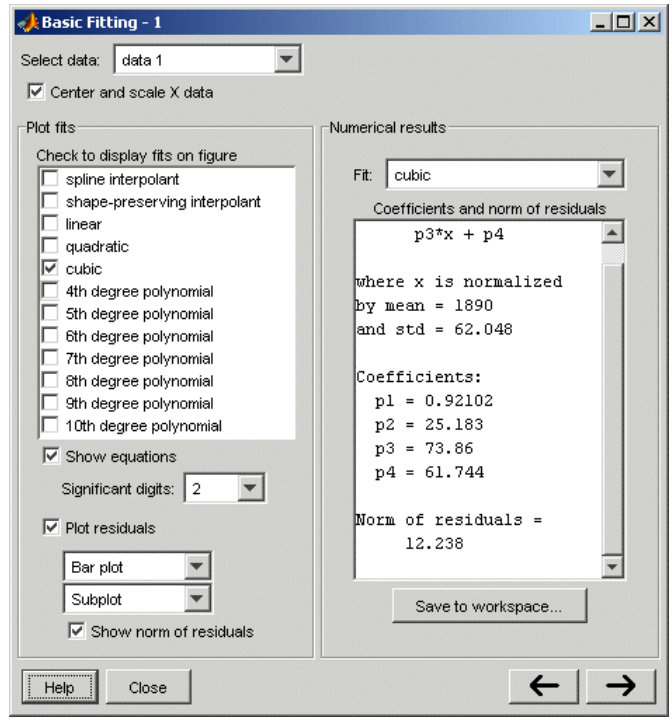
The cubic fit is a poor predictor before the year 1790, where it indicates a decreasing population. The model seems to approximate the data reasonably well after 1790, but a pattern in the residuals shows that the model does not meet the assumption of normal error, which is a basis for the least-squares fitting carried out by the Basic Fitting GUI.

For comparison, try fitting another equation to the census data by selecting it in the **Plot fits** area.

Tip You can change the default plot settings or rename data sets with the Property Editor.

Viewing and Saving Fit Parameters

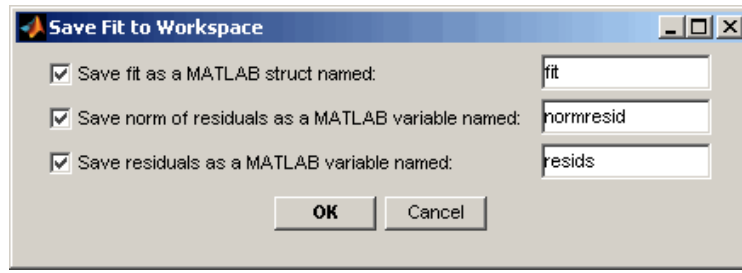
In the Basic Fitting dialog box, click the arrow button → to display the estimated coefficients and the norm of the residuals in the **Numerical results** panel.



To view a specific fit, select it from the **Fit** list. This displays the coefficients in the Basic Fitting dialog box, but does not plot the fit in the figure window.

Note If you also want to display a fit on the plot, you must select the corresponding **Plot fits** check box.

Save the fit data to the MATLAB workspace by clicking the **Save to workspace** button on the **Numerical results** panel. This opens the following dialog box:



Click **OK** to save the fit parameters as a MATLAB structure:

```
fit
fit =
     type: 'polynomial degree 3'
    coeff: [0.9210 25.1834 73.8598 61.7444]
```

You can now use the fit results in MATLAB programming, outside of the Basic Fitting GUI.

Interpolating and Extrapolating Values

Suppose you wish to use the cubic model to interpolate the U.S. population in 1965 (not in the original data).

In the Basic Fitting dialog box, click the → button to specify a vector of x values at which to evaluate the current fit.

1 In the **Enter value(s)...** field, type the following value:

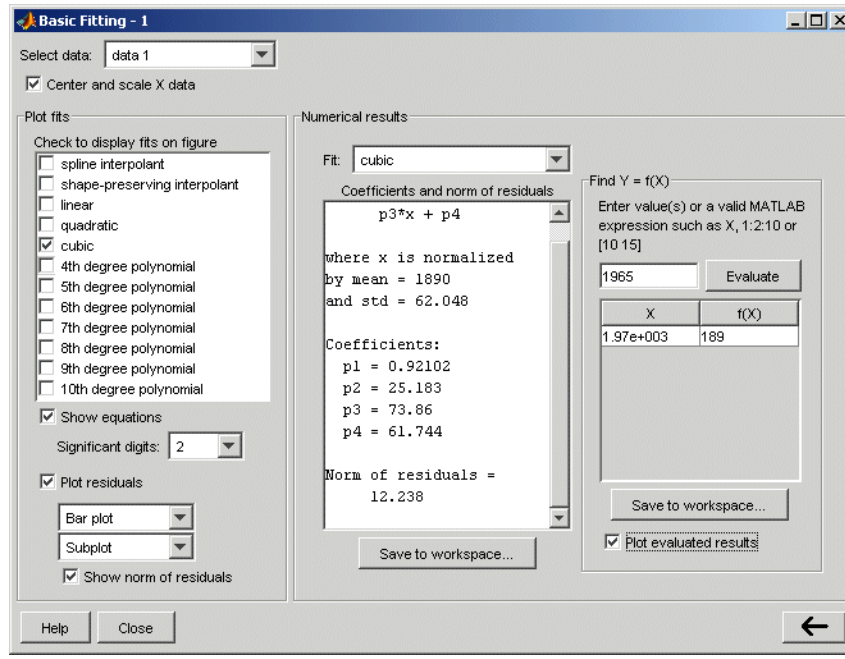
```
1965
```

Note Use unscaled and uncentered `x` values. You do not need to center and scale first, even though you selected to scale `x` values to obtain the coefficients in "Fitting Data" on page 2-12. Basic Fitting makes the necessary adjustments behind the scenes.

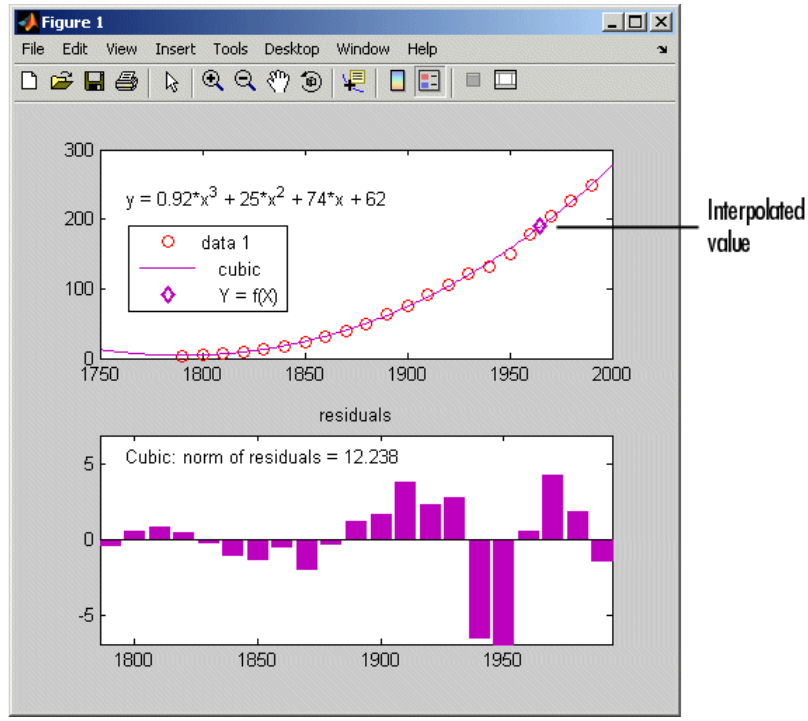
---

2 Click **Evaluate**.

The `x` values and the corresponding values for `f(x)` computed from the fit and displayed in a table, as shown below:

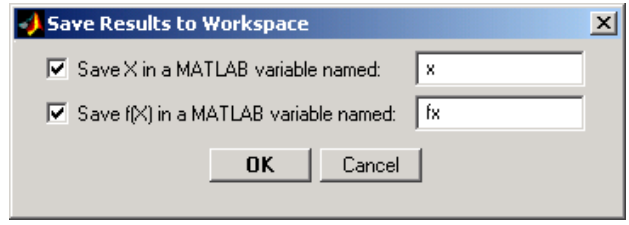


3 Select the **Plot evaluated results** check box to display the interpolated value:



4 Save the interpolated population in 1965 to the MATLAB workspace by clicking **Save to workspace**.

This opens the following dialog box, where you specify the variable names:



Generating an M-file

After completing a Basic Fitting session, you can generate an M-file that recomputes fits and reproduces plots with new data.

1. In the Figure window, select **File > Generate M-File**.

   This creates a function M-file and displays it in the MATLAB Editor. The code in the M-file shows you how to programmatically reproduce what you did interactively with the Basic Fitting dialog box.

2. Change the name of the function on the first line of the M-file from `createfigure` to something more specific, like `censusplot`. Save the file to your current directory with the file name `censusplot.m`

3. Generate some new, randomly perturbed census data:

   ```
   randpop = pop + 10*randn(size(pop));
   ```

4. Reproduce the plot with the new data and recompute the fit:

   ```
   censusplot(cdate,randpop,1965)
   ```

Programmatic Fitting

In this section...

MATLAB Functions for Polynomial Models

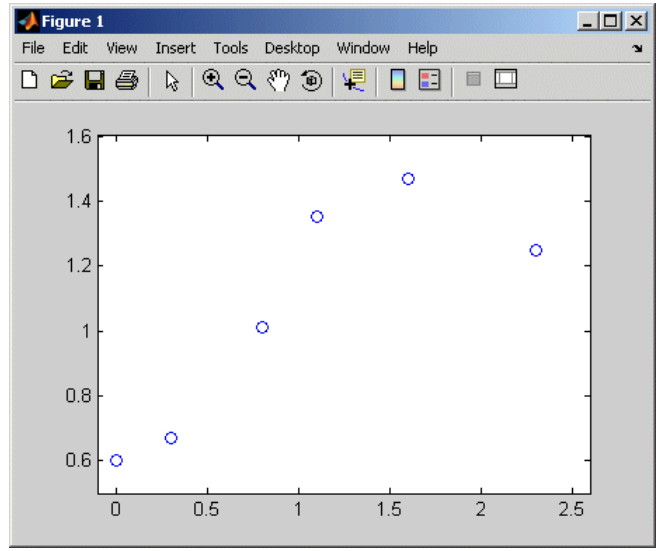
MATLAB provides two functions for modeling your data with a polynomial.

Polynomial Fit Functions

Function	Description
`polyfit`	`polyfit(x,y,n)` finds the coefficients of a polynomial `p(x)` of degree `n` that fits the `y` data by minimizing the sum of the squares of the deviations of the data from the model (least-squares fit).
`polyval`	`polyval(p,x)` returns the value of a polynomial of degree `n` that was determined by `polyfit`, evaluated at `x`.

For example, suppose you measure a quantity `y` at several values of time `t`:

```
t = [0 0.3 0.8 1.1 1.6 2.3];
y = [0.6 0.67 1.01 1.35 1.47 1.25];
plot(t,y,'o')
```



Plot of y Versus t

You can try modeling this data using a second-degree polynomial function:

$$y = a_2 t^2 + a_1 t + a_0$$

The unknown coefficients a_0, a_1, and a_2 are computed by minimizing the sum of the squares of the deviations of the data from the model (least-squares fit).

To find the polynomial coefficients, type the following at the MATLAB prompt:

```
p=polyfit(t,y,2)
```

MATLAB calculates the polynomial coefficients in descending powers:

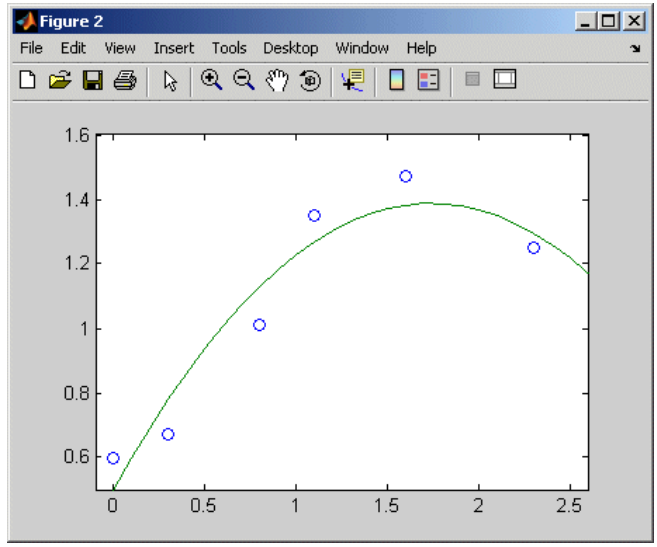
```
p =
   -0.2942    1.0231    0.4981
```

The second-degree polynomial model of the data is given by the following equation:

$$y = -0.2942t^2 + 1.0231t + 0.4981$$

To plot the model with the data, evaluate the polynomial at uniformly spaced times `t2` and overlay the original data on a plot:

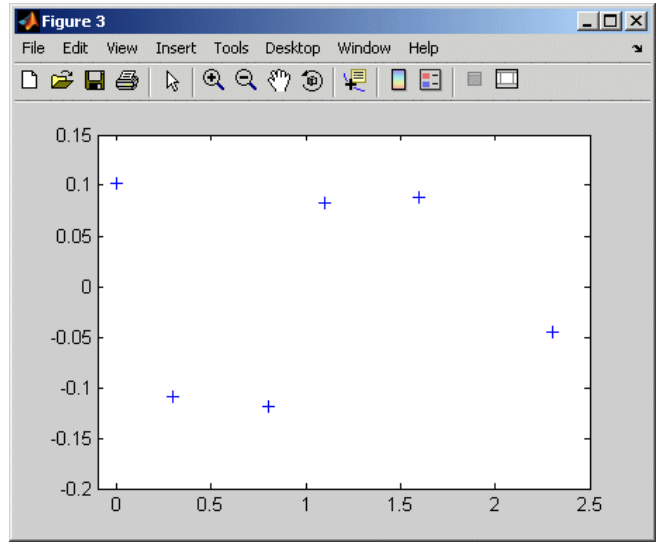
```
t2 = 0:0.1:2.8;     % Define a uniformly spaced time vector
y2=polyval(p,t2);   % Evaluate the polynomial at t2
figure
plot(t,y,'o',t2,y2) % Plot the fit on top of the data
                    % in a new Figure window
```



Plot of Data (Points) and Model (Line)

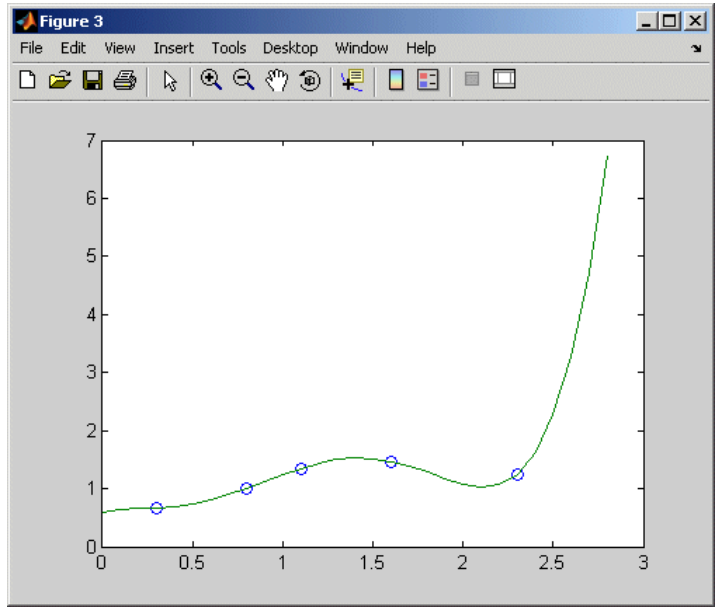
Use the following syntax to calculate the residuals:

```
y2=polyval(p,t); % Evaluate model at the data time vector
res=y-y2; % Calculate the residuals by subtracting
figure, plot(t,res,'+') % Plot the residuals
```



Plot of the Residuals

Notice that the second-degree fit roughly follows the basic shape of the data, but does not capture the smooth curve on which the data seems to lie. There appears to be a pattern in the residuals, which indicates that a different model might be necessary. A fifth-degree polynomial (shown next) does a better job of following the fluctuations in the data.



Fifth-Degree Polynomial Fit

Note If you are trying to model a physical situation, it is always important to consider whether a model of a specific order is meaningful in your situation.

Linear Model with Nonpolynomial Terms

When a polynomial function does not produce a satisfactory model of your data, you can try using a linear model with nonpolynomial terms. For example, consider the following function that is linear in the parameters a_0, a_1, and a_2, but nonlinear in the t data:

$$y = a_0 + a_1 e^{-t} + a_2 t e^{-t}$$

You can compute the unknown coefficients a_0, a_1, and a_2 by constructing and solving a set of simultaneous equations and solving for the parameters. The following syntax accomplishes this by forming a *design matrix*, where each column represents a variable used to predict the response (a term in the model) and each row corresponds to one observation of those variables:

```
% Enter t and y as columnwise vectors
t = [0 0.3 0.8 1.1 1.6 2.3]';
y = [0.6 0.67 1.01 1.35 1.47 1.25]';

% Form the design matrix
X = [ones(size(t))  exp(-t)  t.*exp(-t)];

% Calculate model coefficients
a = X\y

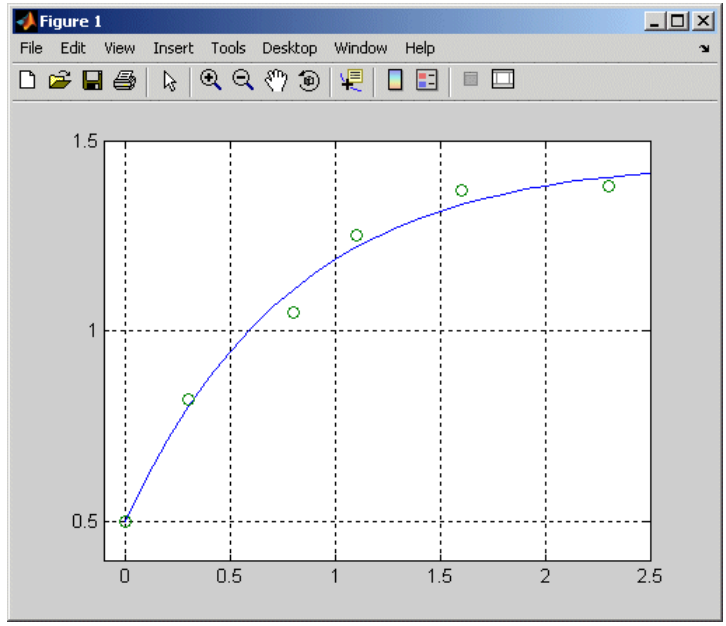
a =
    1.3983
  - 0.8860
    0.3085
```

Therefore, the model of the data is given by

$$y = 1.3983 - 0.8860e^{-t} + 0.3085te^{-t}$$

Now evaluate the model at regularly spaced points and plot the model with the original data, as follows:

```
T = (0:0.1:2.5)';
Y = [ones(size(T))  exp(-T)  T.*exp(-T)]*a;
plot(T,Y,'-',t,y,'o'), grid on
```



Linear Fit with Nonpolynomial Terms

Multiple Regression

When y is a function of more than one independent variable, the matrix equations that express the relationships among the variables must be expanded to accommodate the additional data. This is called *multiple regression*.

Suppose you measure a quantity y for several values of x_1 and x_2. Enter these variables in the MATLAB Command Window, as follows:

```
x1 = [.2 .5 .6 .8 1.0 1.1]';
x2 = [.1 .3 .4 .9 1.1 1.4]';
y  = [.17 .26 .28 .23 .27 .24]';
```

A model of this data is of the form

$$y = a_0 + a_1 x_1 + a_2 x_2$$

Multiple regression solves for unknown coefficients a_0, a_1, and a_2 by minimizing the sum of the squares of the deviations of the data from the model (least-squares fit).

Construct and solve the set of simultaneous equations by forming a design matrix, `X`, and solving for the parameters by using the backslash operator:

```
X = [ones(size(x1))  x1  x2];
a = X\y

a =
    0.1018
    0.4844
   -0.2847
```

The least-squares fit model of the data is

$$y = 0.1018 + 0.4844x_1 - 0.2847x_2$$

To validate the model, find the maximum of the absolute value of the deviation of the data from the model:

```
Y = X*a;
MaxErr = max(abs(Y - y))

MaxErr =
     0.0038
```

This value is much smaller than any of the data values, indicating that this model accurately follows the data.

Example — Data Fitting Using MATLAB Functions

In this example, you use MATLAB functions to accomplish the following:

This example uses the data in `census.mat`, which contains U.S. population data for the years 1790 to 1990.

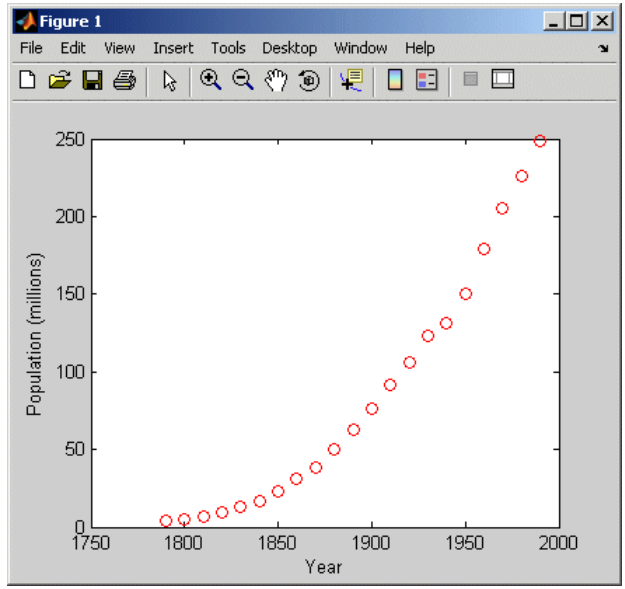
To load and plot the data, type the following commands at the MATLAB prompt:

```
load census
plot(cdate,pop,'ro')
```

This adds the following two variables to the MATLAB workspace:

- `cdate` is a column vector containing the years 1790 to 1990 in increments of 10.
- `pop` is a column vector with the U.S. population numbers corresponding to each year in `cdate`.

The following plot of the data shows a strong pattern, which indicates a high correlation between the variables.



U.S. Population from 1790 to 1990

Calculating Correlation Coefficients

In this portion of the example, you determine the statistical correlation between the variables `cdate` and `pop` to justify modeling the data. For more information about correlation coefficients, see “Correlation Analysis” on page 2-5.

Type the following syntax at the MATLAB prompt:

```
corrcoef(cdate,pop)
```

MATLAB calculates the following correlation-coefficient matrix:

```
ans =

    1.0000    0.9597
    0.9597    1.0000
```

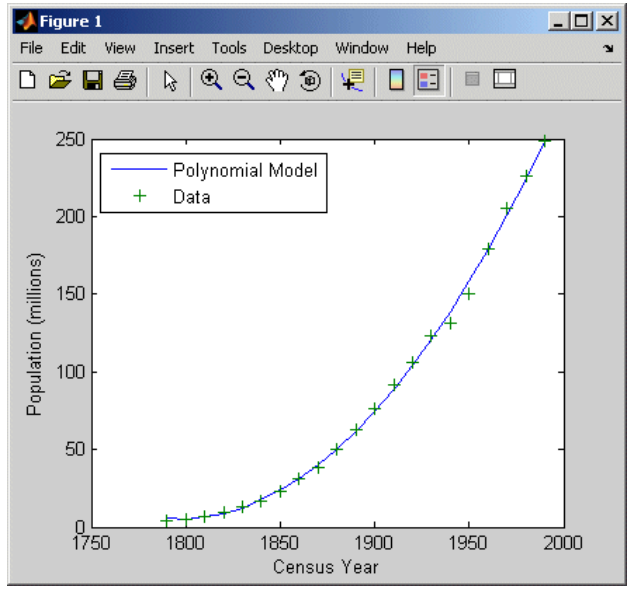
The diagonal matrix elements represent the perfect correlation of each variable with itself and are equal to 1. The off-diagonal elements are very close to 1, indicating that there is a strong statistical correlation between the variables `cdate` and `pop`.

Fitting a Polynomial to the Data

This portion of the example applies the `polyfit` and `polyval` MATLAB functions to model the data:

```
% Calculate fit parameters
[p,ErrorEst] = polyfit(cdate,pop,2);
% Evaluate the fit
pop_fit = polyval(p,cdate,ErrorEst);
% Plot the data and the fit
plot(cdate,pop_fit,'-',cdate,pop,'+');
% Annotate the plot
legend('Polynomial Model','Data');
xlabel('Census Year');
ylabel('Population (millions)');
```

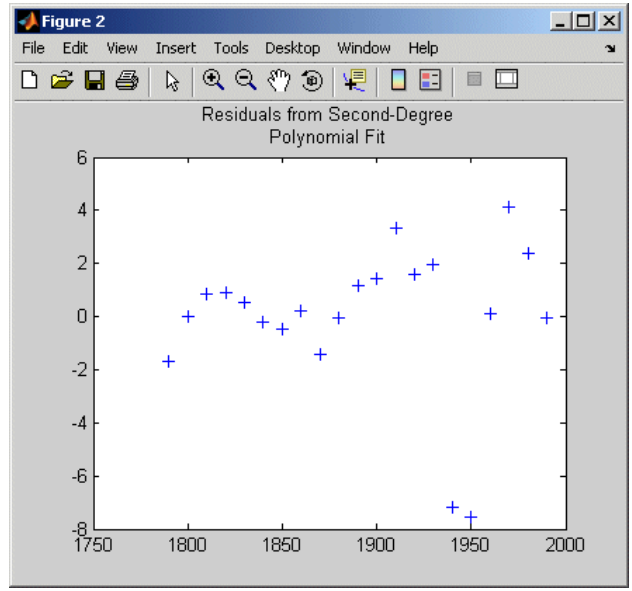
The following figure shows that the quadratic-polynomial fit provides a good approximation to the data:



Quadratic Polynomial Fit to the Census Data

To calculate the residuals for this fit, type the following syntax at the MATLAB prompt:

```
res = pop - pop_fit;
figure, plot(cdate,res,'+')
```



Residuals for the Quadratic Polynomial Model

Notice that the plot of the residuals exhibits a pattern, which indicates that a second-degree polynomial might not be appropriate for modeling this data.

Plot and Calculate Confidence Bounds

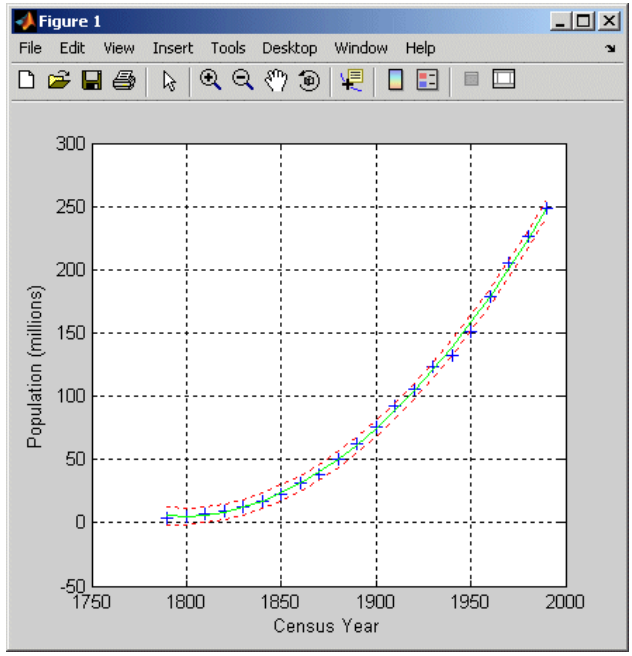
Confidence bounds are confidence intervals for a predicted response. The width of the interval indicates the degree of certainty of the fit.

This example applies `polyfit` and `polyval` to the `census` sample data to produce confidence bounds for a second-order polynomial model.

The following syntax uses an interval of $\pm 2\Delta$, which corresponds to a 95% confidence interval for large samples:

```
% Evaluate the fit and the prediction error estimate (delta)
[pop_fit,delta] = polyval(p,cdate,ErrorEst);
% Plot the data, the fit, and the confidence bounds
plot(cdate,pop,'+',...
     cdate,pop_fit,'g-',...
     cdate,pop_fit+2*delta,'r:',...
     cdate,pop_fit-2*delta,'r:');
% Annotate the plot
xlabel('Census Year');
ylabel('Population (millions)');
grid on
```

The 95% interval indicates that you have a 95% chance that a new observation will fall within the bounds.



Quadratic Polynomial Fit with Confidence Bounds

3

Fourier Analysis

The following sections describe how to perform Fourier analysis in MATLAB for gaining insight into periodic signals.

Introduction

Fourier analysis is particularly useful in areas such as signal and image processing, filtering, convolution, frequency analysis, and power spectrum estimation.

Fourier analysis provides insight into the periodicities in data by representing the data using a linear combination of sinusoidal components with different frequencies. The amplitude and phase of each sinusoidal component in the sum determines the relative contribution of that frequency component to the entire signal.

For discretely-sampled data, Fourier analysis is performed using the discrete Fourier transform (DFT). MATLAB calculates the DFT of a data sequence by applying the fast Fourier transform (FFT) algorithms; the FFT is an efficient computational method and not a different kind of transform.

To learn about more advanced power-spectrum methods, see the Signal Processing Toolbox documentation.

Function Summary

MATLAB provides the following functions for computing and working with Fourier transforms.

FFT Function Summary

Function	Description
`abs`	Absolute value and complex magnitude
`angle`	Phase angle
`cplxpair`	Sort numbers into complex conjugate pairs
`fft`	One-dimensional discrete Fourier transform, computed with a fast Fourier transform (FFT) algorithm
`fft2`	Two-dimensional discrete Fourier transform
`fftn`	N-dimensional discrete Fourier transform
`fftshift`	Shift DC component of the discrete Fourier transform to the center of spectrum
`ifft`	Inverse one-dimensional discrete Fourier transform
`ifft2`	Inverse two-dimensional discrete Fourier transform
`ifftn`	Inverse N-dimensional discrete Fourier transform
`ifftshift`	Inverse FFT shift
`nextpow2`	Next higher power of 2
`unwrap`	Unwrap phase angle in radians

Calculating Fourier Transforms

In this section...

Introduction

MATLAB performs Fourier analysis by computing the discrete Fourier transform (DFT) using the fast Fourier transform (FFT) algorithms, which improve computational performance.

Consider an input sequence $x(n)$ of length N. The DFT of this sequence is given by the vector $X(k)$, as follows:

$$X(k) = \sum_{n=1}^{N} x(n) e^{-j2\pi(k-1)\left(\frac{n-1}{N}\right)} \qquad 1 \le k \le N$$

You use the `fft` function in MATLAB to compute the spectrum. The length of $X(k)$ is the same as the length of $x(n)$. Notice that the value of $X(1)$ equals the sum of the data values in $x(n)$.

Note Traditional Fourier equations have summations from 0 to $N - 1$. However, because the first element of a MATLAB vector has the index of 1, the summations in the above equations are from 1 to N and are equivalent to traditional equations.

For a discrete input sequence, there is an upper limit on the frequency at which you can get meaningful information about the periodicities in the data. The highest frequency that can be uniquely fit to the data, called the *Nyquist frequency*, equals one cycle every two successive measurements. This makes sense because you cannot get information about the variations in the data at frequencies higher than the sampling rate—the rate at which you measured successive data values. For example, suppose that your data consists of daily temperature measurements in your town; here, 1 cycle (the time between

two successive measurements) equals 1 day and the Nyquist frequency is 0.5 cycle/day. In this situation, you can only determine variations in the temperature from one day to the next. If you want to study temperature fluctuations during the day, you must collect the data at more frequent intervals.

The lowest frequency that can be uniquely fit to the data, called the *fundamental frequency*, is one cycle for the entire length of the data vector.

The inverse DFT of a transformed sequence is given by:

$$x(n) = \frac{1}{N}\sum_{k=1}^{N} X(k)e^{j2\pi(k-1)\left(\frac{n-1}{N}\right)} \qquad 1 \le \mathrm{n} \le \mathrm{N}$$

You use the `ifft` function in MATLAB to synthesize the signal from its spectrum.

When $x(n)$ is real, you can rewrite the synthesis equation as a sum of sine and cosine functions with real coefficients:

$$x(n) = \frac{1}{N}\sum_{k=1}^{N} a(k)\cos\left(\frac{2\pi(k-1)(n-1)}{N}\right) + b(k)\sin\left(\frac{2\pi(k-1)(n-1)}{N}\right)$$

where

$a(k) = \mathrm{real}[\mathrm{X(k)}]$
$b(k) = -\mathrm{imag}[X(k)]$
$1 \le n \le N$

Example — FFT of a Column Vector

Consider the following column vector:

```
x = [4 3 7 -9 1 0 0 0]';
```

In this example, the length of the input sequence $N = 8$. The Nyquist frequency is 1 cycle every 2 observations, or 0.5. The index of the component

k at the Nyquist frequency is determined by setting the frequency to the Nyquist frequency value:

$$f = \frac{\omega}{2\pi} = \frac{k-1}{N} = 0.5$$

Compute the FFT of `x` as follows:

```
y = fft(x)
```

MATLAB responds with the following FFT vector:

```
y =
6.0000
11.4853 - 2.7574i
-2.0000 -12.0000i
-5.4853 +11.2426i
18.0000
-5.4853 -11.2426i
-2.0000 +12.0000i
11.4853 + 2.7574i
```

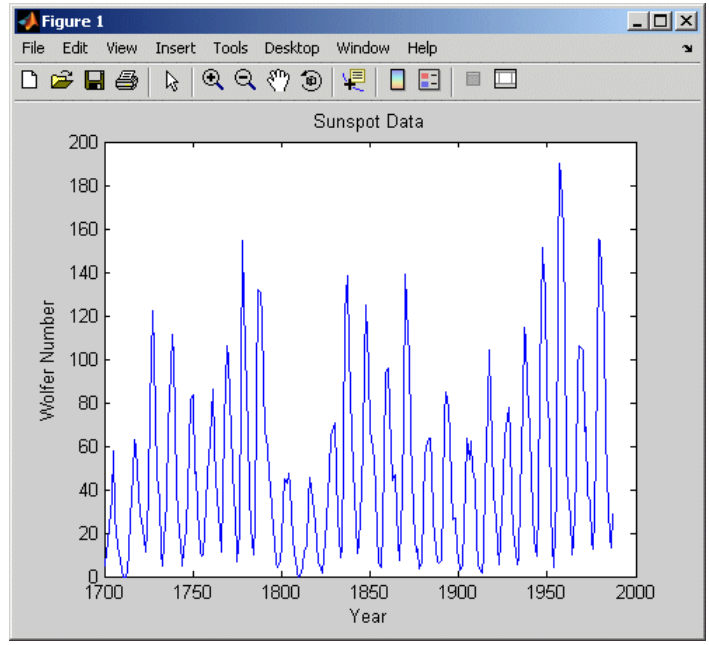
Notice that although the input sequence `x` is real, `y` is complex. The first element of `y` is the sum of the data values. The fifth element corresponds to the contribution at the Nyquist frequency. The last three values of `y` correspond to negative frequencies and, for the real sequence `x`, they are complex conjugates of three components in the first half of `y`.

Example — Sunspot Periodicity

In this example, you use the MATLAB `fft` function to analyze the variations in sunspot activity. You will use data collected by astronomers for almost 300 years of a quantity called the Wolfer number, which measures both the number and the size of sunspots.

Load and plot the sunspot data:

```
load sunspot.dat
year = sunspot(:,1);
wolfer = sunspot(:,2);
plot(year,wolfer)
title('Sunspot Data')
```



Sunspot Data

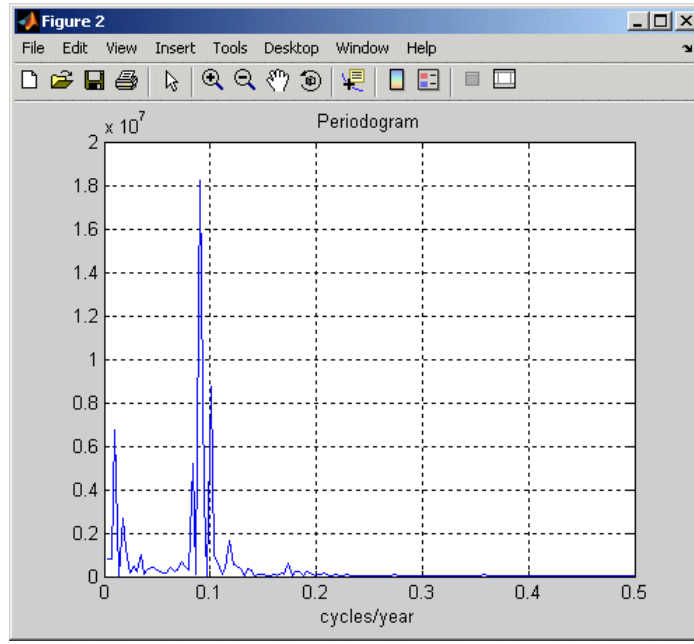
Take the FFT of the sunspot data:

```
Y = fft(wolfer);
```

The result of this transform is the complex vector `Y`. The magnitude of `Y` squared is called the estimated power spectrum. A plot of the estimated power spectrum versus frequency is called a *periodogram*.

Because the first component of `Y`, which is simply the sum of the data, has a large magnitude, the following syntax removes it before generating the periodogram:

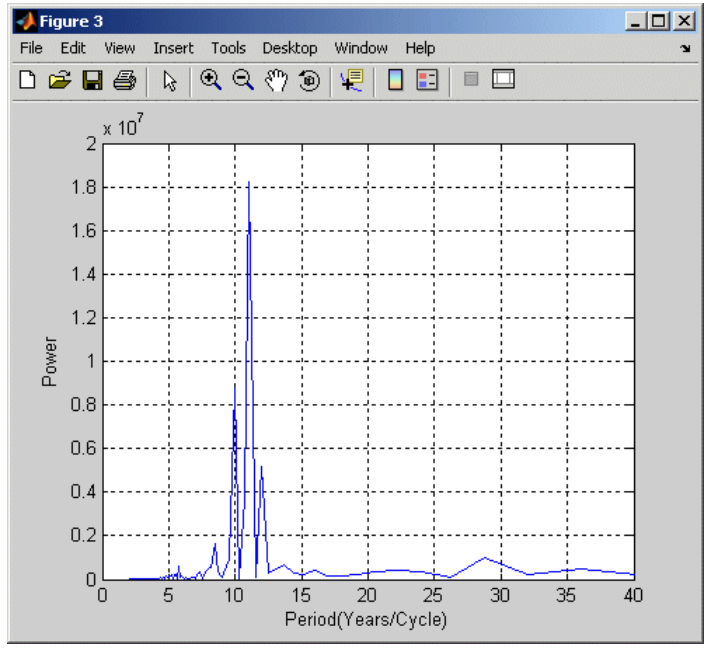
```
N = length(Y);
Y(1) = [];
power = abs(Y(1:N/2)).^2;
nyquist = 1/2;
freq = (1:N/2)/(N/2)*nyquist;
plot(freq,power), grid on
xlabel('cycles/year')
title('Periodogram')
```



Periodogram of Sunspot Data

The frequency scale is in cycles/year, which is inconvenient because for estimating the period of one cycle in years. Therefore, plot the power versus period (where `period = 1./freq`) from 0 to 40 years/cycle:

```
period = 1./freq;
plot(period,power), axis([0 40 0 2e7]), grid on
ylabel('Power')
xlabel('Period(Years/Cycle)')
```



Power Spectrum Versus Period of Sunspot Data

In order to determine the cycle more precisely, use the following syntax:

```
[mp,index] = max(power);
period(index)

ans =
      11.0769
```

This plot confirms the cyclical nature of sunspot activity, which reaches a maximum about every 11 years.

Magnitude and Phase of Transformed Data

Important information about a transformed data sequence includes its magnitude and phase. The MATLAB functions `abs` and `angle` calculate this information.

To try this, create a time vector `t`, and use this vector to create a sequence `x` consisting of two sinusoids at different frequencies:

```
t = 0:1/100:10-1/100;
x = sin(2*pi*15*t) + sin(2*pi*40*t);
```

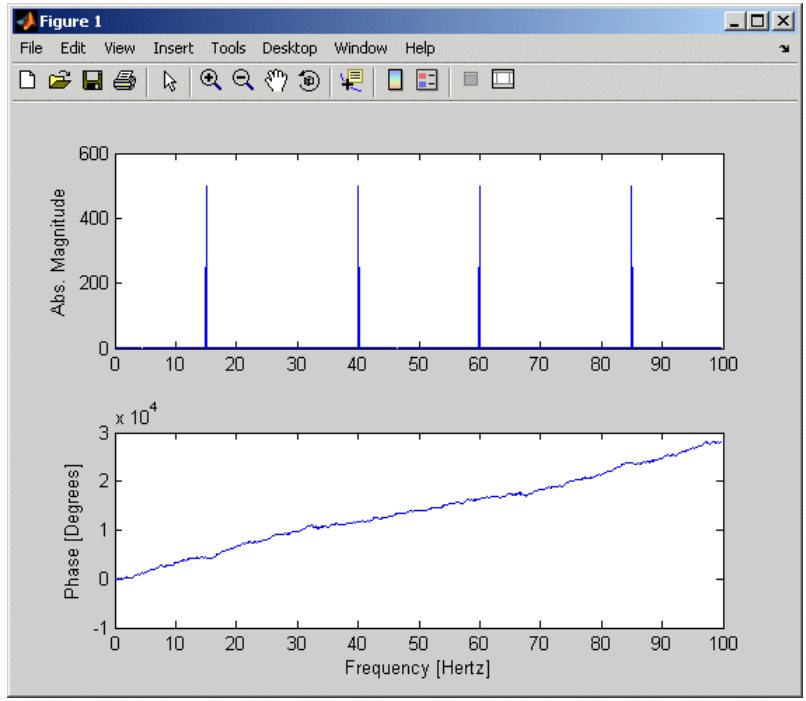
Now use the `fft` function to compute the DFT of the sequence. The following code calculates the magnitude and phase of the transformed sequence. It also uses the `abs` function to obtain the magnitude of the data, the `angle` function to obtain the phase information, and the `unwrap` function to remove phase jumps greater than π to their `2*pi` complement:

```
y = fft(x);
m = abs(y);
p = unwrap(angle(y));
```

Now create a frequency vector for the *x*-axis and plot the magnitude and phase:

```
f = (0:length(y)-1)'*100/length(y);
subplot(2,1,1), plot(f,m),
ylabel('Abs. Magnitude'), grid on
subplot(2,1,2), plot(f,p*180/pi)
ylabel('Phase [Degrees]'), grid on
xlabel('Frequency [Hertz]')
```

The magnitude plot is perfectly symmetrical about the Nyquist frequency of 50 Hz. The useful information in the signal is found in the range 0 to 50 Hz. For more information about the Nyquist frequency, see “Calculating Fourier Transforms” on page 3-4.



Magnitude and Phase Information in Transformed Data

FFT Length Versus Performance

The execution time for the `fft` depends on the length of the transform.

You can add a second argument to `fft` to specify a number of points `n` in the transform:

```
y = fft(x,n)
```

With this syntax, `fft` pads `x` with `0`s if it is shorter than `n`, or truncates it if it is longer than `n`. If you do not specify `n`, `fft` defaults to the length of the input sequence. `fft` is fastest for powers of 2. It is almost as fast for lengths that have only small prime factors. It is typically several times slower for lengths that are prime or have large prime factors.

The inverse FFT function `ifft` also accepts a transform length argument.

4

Time Series Objects and Methods

The following sections describe how to analyze time series data using MATLAB objects and methods.

Introduction

MATLAB provides methods for analyzing time series data. These methods operate on the following MATLAB objects:

- `timeseries` — Stores data and time values, as well as the metadata information that includes units, events, data quality, and interpolation method
- `tscollection` — Stores a collection of `timeseries` objects that share a common time vector, convenient for performing operations on synchronized time series with different units

In this chapter, you learn how to

- Use time series constructors to instantiate time series classes
- Modify object properties using `set` methods or dot notation
- Call time series functions and methods

To get a quick overview of programming with `timeseries` and `tscollection` objects, follow the steps in "Example — Time Series Objects and Methods" on page 4-6.

If you prefer to work with a graphical user interface (GUI), use MATLAB Time Series Tools to work with time series data. For more information about Time Series Tools, see Chapter 5, "Time Series Tools".

Note If you are new to programming with `timeseries` and `tscollection` objects, you might want to start by working with Time Series Tools and enabling the **Record M-Code** feature. This generates reusable M-code based on the operations you perform in the GUI. For more information, see "Generating Reusable M-Code" on page 5-6.

Time Series Data Sample

To properly understand the description of `timeseries` object properties and methods in this documentation, it is important to clarify some terms related to storing data in a `timeseries` object—the difference between a *data value* and a *data sample*.

A *data value* is a single, scalar value recorded at a specific time. A *data sample* consists of one or more values associated with a specific time in the `timeseries` object. The number of data samples in a time series is the same as the length of the time vector.

For example, consider data that consists of three sensor signals: two signals represent the position of an object in meters, and the third represents its velocity in meters/second.

To enter the data matrix, type the following at the MATLAB prompt:

```
x = [-0.2 -0.3 13;
     -0.1 -0.4 15;
      NaN  2.8 17;
      0.5 0.3 NaN;
     -0.3 -0.1 15]
```

The `NaN` value represents a missing data value. MATLAB displays the following 5-by-3 matrix:

```
x=
   -0.2000   -0.3000   13.0000
   -0.1000   -0.4000   15.0000
    NaN       2.8000   17.0000
    0.5000    0.3000       NaN
   -0.3000   -0.1000   15.0000
```

The first two columns of `x` contain quantities with the same units and you can create a multivariate `timeseries` object to store these two time series. For more information about creating `timeseries` objects, see “Time Series Constructor Syntax” on page 4-22. The following command creates a `timeseries` object `ts_pos` to store the position values:

```
ts_pos = timeseries(x(:,1:2), 1:5, 'name', 'Position')
```

MATLAB responds by displaying the following properties of ts_pos:

```
Time Series Object: Position

Time vector characteristics

      Length                5
      Start time            1 seconds
      End time              5 seconds

Data characteristics

      Interpolation method  linear
      Size                  [5  2]
      Data type             double
```

The Length of the time vector, which is 5 in this example, equals the number of data samples in the timeseries object. Find the size of the data sample in ts_pos by typing the following at the MATLAB prompt:

```
getdatasamplesize(ts_pos)

ans =

     1     2
```

Similarly, you can create a second timeseries object to store the velocity data:

```
ts_vel = timeseries(x(:,3), 1:5, 'name', 'Velocity');
```

Find the size of each data sample in ts_vel by typing the following:

```
getdatasamplesize(ts_vel)

ans =

     1     1
```

Notice that ts_vel has one data value in each data sample and ts_pos has two data values in each data sample.

Note In general, when the time series data is an *M*-by-*N*-by-*P*-by-... multidimensional array with *M* samples, the size of each data sample is *N*-by-*P*-by-... .

If you want to perform operations on the `ts_pos` and `ts_vel` `timeseries` objects while keeping them synchronized, group them in a time series collection. For more information, see "Time Series Collection Constructor Syntax" on page 4-36.

Example — Time Series Objects and Methods

In this section...

Creating Time Series Objects

This portion of the example illustrates how to create several `timeseries` objects from an array. For more information about the `timeseries` object, see "Time Series Constructor" on page 4-21.

The sample data provided with this example consists of a 24-by-3 matrix of double values, where each column represents the hourly traffic counts at three town intersections.

This adds the variable `count` to the MATLAB workspace:

```
%% Import the sample data
load count.dat
```

To view the `count` matrix, type

```
count
```

MATLAB responds by displaying the following 24-by-3 matrix:

```
    11    11     9
     7    13    11
    14    17    20
    11    13     9
    43    51    69
    38    46    76
    61   132   186
    75   135   180
    38    88   115
    28    36    55
    12    12    14
    18    27    30
    18    19    29
    17    15    18
    19    36    48
    32    47    10
    42    65    92
    57    66   151
    44    55    90
   114   145   257
    35    58    68
    11    12    15
    13     9    15
    10     9     7
```

Create three `timeseries` objects to store the data collected at each intersection:

```
count1 = timeseries(count(:,1), 1:24,'name', 'intersection1');
count2 = timeseries(count(:,2), 1:24,'name', 'intersection2');
count3 = timeseries(count(:,3), 1:24,'name', 'intersection3');
```

Note In the above construction, `timeseries` objects have both a variable name (e.g., `count1`) and an internal object name (e.g., `intersection1`). The variable name is used with MATLAB functions. The object name is a property of the object, accessed with object methods. For more information on `timeseries` object properties and methods, see "Time Series Properties" on page 4-24 and "Time Series Methods" on page 4-31.

Each time series has a time vector in units of seconds, starting at 1 second and increasing up to 24 seconds in 1-second increments. The software assumes this increment when you do not explicitly specify one. You will change the time units to hours in "Modifying Time Series Units and Interpolation Method" on page 4-11.

Note If you want to create a `timeseries` object that groups the three data columns in `count`, use the following syntax:

```
count_ts = timeseries(count, 1:24,'name','traffic_counts')
```

This is useful when all time series have the same units and you want to keep them synchronized during calculations.

Viewing Time Series Objects

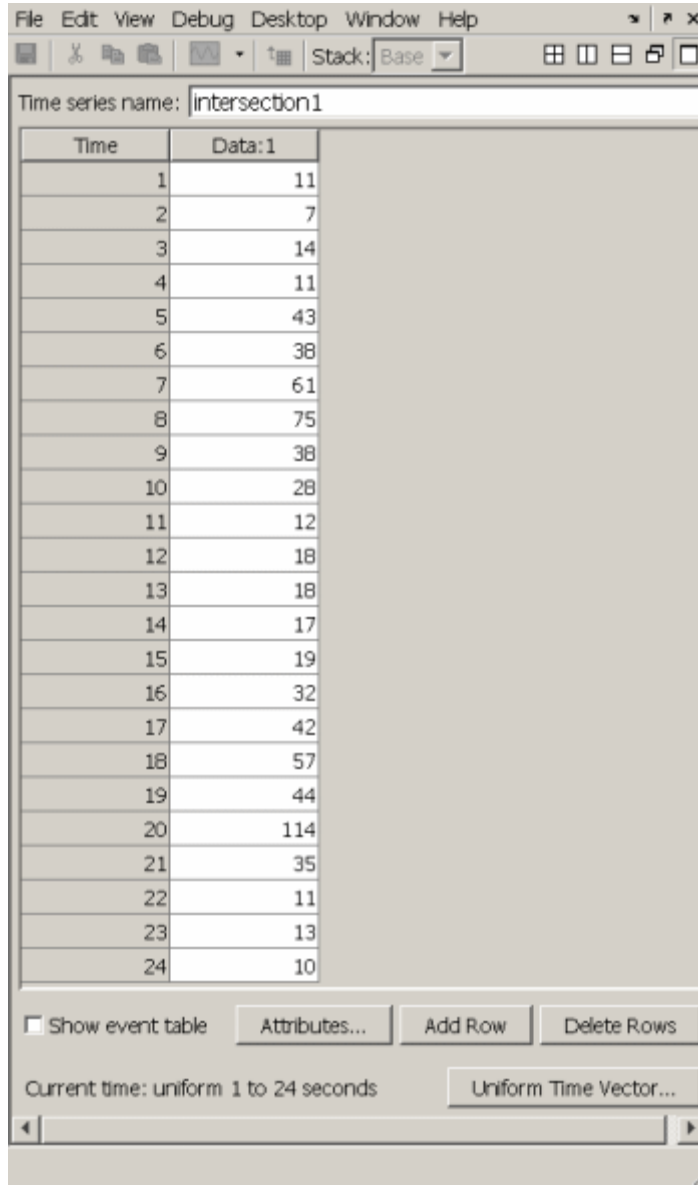
After creating a `timeseries` object, as described in "Creating Time Series Objects" on page 4-6, you can view it in either the Array Editor or Time Series Tools.

To view a `timeseries` object like `count1` in the Array Editor, use any one of several methods:

- Type `open('count1')` at the command prompt.
- Select `count1` in the Workspace Browser and click the **Open selection** button  .
- Double-click `count1` in the Workspace Browser.
- Right-click `count1` in the Workspace Browser and select **Open selection** from the context menu.

To view `count1` in Time Series Tools, right-click `count1` in the Workspace Browser and choose **Open in Time Series Tools** from the context menu.

When a `timeseries` object is opened in either the Array Editor or Time Series Tools, it is displayed with the Time Series Editor:



For information on using the Time Series Editor, see “Editing Data, Time, Attributes, and Events” on page 5-31.

Modifying Time Series Units and Interpolation Method

After creating a `timeseries` object, as described in "Creating Time Series Objects" on page 4-6, you can modify its units and interpolation method using dot notation.

To view the current properties of `count1`, type

```
get(count1)
```

MATLAB responds by displaying the current property values of the `count1` `timeseries` object:

```
Events: []
Name: 'intersection1'
Data: [24x1 double]
DataInfo: [1x1 tsdata.datametadata]
Time: [24x1 double]
TimeInfo: [1x1 tsdata.timemetadata]
Quality: []
QualityInfo: [1x1 tsdata.qualmetadata]
IsTimeFirst: true
TreatNaNasMissing: true
```

To view the current `DataInfo` properties, use dot notation:

```
count1.DataInfo
```

Change the data units and the default interpolation method for `count1`, as follows:

```
count1.DataInfo.Units = 'cars';
        % Specify new data units
count1.DataInfo.Interpolation = tsdata.interpolation('zoh');
        % Set the interpolation method to zero-order hold
```

To verify that the `DataInfo` properties have been modified, type

```
count1.DataInfo
```

MATLAB confirms the change by displaying

```
Time Series Data Meta Data Object
      Unit                 cars
      Interpolation Method  zoh
```

Modify the time units to be `'hours'` for the three time series:

```
count1.TimeInfo.Units = 'hours';
count2.TimeInfo.Units = 'hours';
count3.TimeInfo.Units = 'hours';
```

Defining Events

This portion of the example illustrates how to define events for a `timeseries` object by using the `tsdata.event` auxiliary object. Events mark the data at specific times. When you plot the data, event markers are displayed on the plot. Events also provide a convenient way to synchronize multiple time series.

Use the following syntax to add two events to the data that mark the times of the AM commute and PM commute:

```
%% Construct and add the first event to all time series
e1 = tsdata.event('AMCommute',8);
                          % Construct the first event at 8 AM
e1.Units = 'hours';       % Specify the time units of the time
count1 = addevent(count1,e1);  % Add the event to count1
count2 = addevent(count2,e1);  % Add the event to count2
count3 = addevent(count3,e1);  % Add the event to count3
%% Construct and add the second event to all time series
e2 = tsdata.event('PMCommute',18);
                          % Construct the first event at 6 PM
e2.Units = 'hours';       % Specify the time units of the time
count1 = addevent(count1,e2);  % Add the event to count1
count2 = addevent(count2,e2);  % Add the event to count2
count3 = addevent(count3,e2);  % Add the event to count3
```

Creating Time Series Collection Objects

This portion of the example illustrates how to create a `tscollection` object. Each individual time series in a collection is called a *member*. For more

information about the tscollection object, see “Time Series Collection Constructor” on page 4-36.

Note Typically, you use the tscollection object to group synchronized time series that have different units. In this simple example, all time series have the same units and the tscollection object does not provide an advantage over grouping the three time series in a single timeseries object. For an example of how to group several time series in one timeseries object, see “Creating Time Series Objects” on page 4-6.

Use the following syntax to create a tscollection object named count_coll and use the constructor syntax to immediately add two of the three time series currently in the MATLAB workspace (you will add the third time series later):

```
tsc = tscollection({count1 count2},'name', 'count_coll')
```

MATLAB responds with

```
Time Series Collection Object: count_coll
Time vector characteristics
Start time            1 hours
End time              24 hours
Member Time Series Objects:
      intersection1
      intersection2
```

Note The time vectors of the timeseries objects you are adding to the tscollection must match.

Notice that the Name property of the timeseries objects is used to name the collection members as intersection1 and intersection2.

Add the third timeseries object in the workspace to the tscollection by using the following syntax:

```
tsc = addts(tsc, count3)
```

MATLAB now lists all three members in the collection:

```
Time Series Collection Object: count_coll
Time vector characteristics
Start time            1 hours
End time              24 hours
Member Time Series Objects:
      intersection1
      intersection2
      intersection3
```

Resampling a Time Series Collection Object

This portion of the example illustrates how to resample each member in a `tscollection` using a new time vector. The resampling operation is used to either select existing data at specific time values, or to interpolate data at finer intervals. If the new time vector contains time values that did not exist in the previous time vector, the new data values are calculated using the default interpolation method you associated with the time series.

To resample the time series to include data values every 2 hours instead of every hour and save it as a new `tscollection` object, enter the following syntax:

```
tsc1 = resample(tsc,1:2:24)
```

In some cases you might need a finer sampling of information than you currently have and it is reasonable to obtain it by interpolating data values. For example, the following syntax interpolates values at each half-hour mark:

```
tsc1 = resample(tsc,1:0.5:24)
```

To add values at each half-hour mark, the default interpolation method of a time series is used. For example, the new data points in `intersection1` are calculated by using the zero-order hold interpolation method, which holds the value of the previous sample constant. You set the interpolation method for `intersection1` as described in “Modifying Time Series Units and Interpolation Method” on page 4-11.

The new data points in `intersection2` and `intersection3` are calculated using linear interpolation, which is the default method.

Adding a Data Sample to a Time Series Collection Object

This portion of the example illustrates how to add a data sample to a `tscollection`.

You can use the following syntax to add a data sample to the `intersection1` collection member at 3.25 hours (i.e., 15 minutes after the hour):

```
tsc1 = addsampletocollection(tsc1,'time',3.25,...
       'intersection1',5)
```

There are three members in the `tsc1` collection, and adding a data sample to one member adds a data sample to the other two members at 3.25 hours. However, because you did not specify the data values for `intersection2` and `intersection3` in the new sample, the missing values are represented by `NaN`s for these members. To learn how to remove or interpolate missing data values, see "Removing and Interpolating Missing Data" on page 4-16.

`tsc1` Data from 2.0 to 3.5 Hours

Hours	Intersection 1	Intersection 2	Intersection 3
2.0	7	13	11
2.5	7	15	15.5
3.0	14	17	20
3.25	5	`NaN`	`NaN`
3.5	14	15	14.5

To view all `intersection1` data (including the new sample at 3.25 hours), type

```
tsc1.intersection1
```

Similarly, to view all `intersection2` data (including the new sample at 3.25 hours containing a `NaN` value), type

```
tsc1.intersection2
```

Removing and Interpolating Missing Data

MATLAB uses NaNs to represent missing data in a time series. This portion of the example illustrates how to either remove the missing data or interpolate it by using the interpolation method you specified for that time series. In "Adding a Data Sample to a Time Series Collection Object" on page 4-15, you added a new data sample to the tsc1 collection at 3.25 hours.

There are three members in the tsc1 collection, and adding a data sample to one member adds a data sample to the other two members at 3.25 hours. However, because you did not specify the data values for the intersection2 and intersection3 members at 3.25 hours, they currently contain missing values that are represented by NaNs.

Removing Missing Data

You can use the following syntax to find and remove the data samples containing NaN values in the tsc1 collection:

```
tsc1 = delsamplefromcollection(tsc1,'index',...
       find(isnan(tsc1.intersection2.Data)));
```

This command searches one tscollection member at a time—in this case, intersection2. When a missing value is located in intersection2, the data at that time is removed from *all* members of the tscollection.

Note You can use the following dot-notation syntax to access the Data property of the intersection2 member in the tsc1 collection:

```
tsc1.intersection2.Data
```

For a complete list of timeseries properties, see "Time Series Properties" on page 4-24.

Interpolating Missing Data

For the sake of this example, you must reintroduce `NaN` values in `intersection2` and `intersection3` (which you removed):

```
tsc1 = addsampletocollection(tsc1,'time',3.25,...
       'intersection1',5);
```

To interpolate the missing values in `tsc1` using the current time vector (`tsc1.Time`), type the following syntax:

```
tsc1 = resample(tsc1,tsc1.Time)
```

This replaces the `NaN` values in `intersection2` and `intersection3` by using linear interpolation—the default interpolation method for these time series.

Note Dot notation `tsc1.Time` is used to access the `Time` property of the `tsc1` collection. For a complete list of `tscollection` properties, see "Time Series Collection Properties" on page 4-38.

To view `intersection2` data after interpolation, for example, type

```
tsc1.intersection2
```

New tsc1 Data from 2.0 to 3.5 Hours

Hours	Intersection 1	Intersection 2	Intersection 3
2.0	7	13	11
2.5	7	15	15.5
3.0	14	17	20

New tsc1 Data from 2.0 to 3.5 Hours (Continued)

Hours	Intersection 1	Intersection 2	Intersection 3
3.25	5	16	17.3
3.5	14	15	14.5

Removing a Time Series from a Time Series Collection

To remove the `intersection3` time series from the `tscollection` object `tsc1`, type:

```
tsc1 = removets(tsc1,'intersection3')
```

MATLAB now lists two time series as members in the collection:

```
Time Series Collection Object: count_coll
Time vector characteristics
Start time            1 hours
End time              24 hours
Member Time Series Objects:
      intersection1
      intersection2
```

Changing a Numerical Time Vector to Date Strings

This portion of the example illustrates how to convert the display format of a numerical time vector to MATLAB date strings. For a complete list of the MATLAB date-string formats supported for `timeseries` and `tscollection` objects, see “Time Vector Format” on page 4-21.

To convert a numerical time vector to date strings, you must set the `StartDate` field of the `TimeInfo` property. All values in the time vector are converted to date strings using `StartDate` as a reference date.

For example, suppose the reference date occurs on December 25, 2004:

```
tsc1.TimeInfo.StartDate = 'DEC-25-2004 00:00:00';
```

To verify that the time vector now uses date strings, type the following command to look at the sixth element of the `intersection2` member:

```
tsc1.intersection2(6)
```

MATLAB responds with

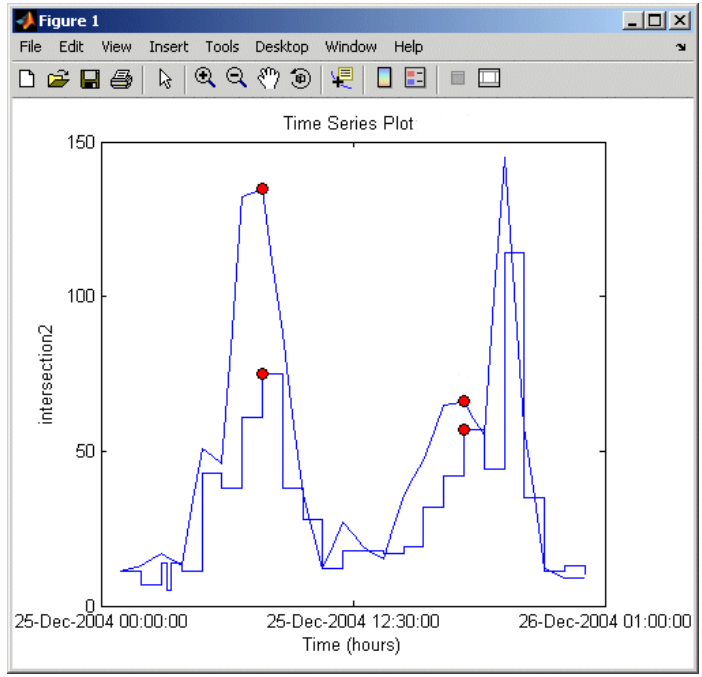
```
Time Series Object: unnamed
Time vector characteristics
      Length                1
      Start date            25-Dec-2004 03:15:00
      End date              25-Dec-2004 03:15:00
Data characteristics
      Interpolation method  linear
      Size                  [1  1]
      Data type             double
Time                              Data                  Quality
------------------------------------------------------------
25-Dec-2004 03:15:00              16
```

This result shows that the sixth element of `intersection2` has an interpolated data value of 16 cars at 3.25 hours (or 3:15:00).

Plotting Time Series Collection Members

You can plot the two remaining members in the `tsc1` collection by using the following command sequence:

```
plot(tsc1.intersection1); hold on;
plot(tsc1.intersection2)
```



Time Plot of Two Time Series in a Collection

This plot shows the two time series in the collection: `intersection1` and `intesection2`. `intersection1` uses the zero-order hold interpolation method and therefore has a jagged curve. In contrast, `intersection2` uses a linear interpolation method. The vertical axis is labeled as `intersection2` because this was the last time series plotted.

The filled circles on the plot indicate events, as specified in “Defining Events” on page 4-12.

Time Series Constructor

In this section...

Time Vector Format

You can specify the time vector of the `timeseries` object either as numerical (double) values or as valid MATLAB date strings.

When the `timeseries` `TimeInfo.StartDate` property is empty, the numerical `Time` values are measured relative to 0 (or another numerical value) in specified units. In this case, the time vector is described as *relative* (that is, it contains time values that are not associated with a specific start date).

When `TimeInfo.StartDate` is nonempty, the time values are date strings measured relative to `StartDate` in specified units. In this case, the time vector is described as *absolute* (that is, it contains time values that are associated with a specific calendar date). For more information, see "Time Series Properties" on page 4-24.

MATLAB supports the following date-string formats for time series applications.

Date-String Format	Usage Example
`dd-mmm-yyyy HH:MM:SS`	`01-Mar-2000 15:45:17`
`dd-mmm-yyyy`	`01-Mar-2000`
`mm/dd/yy`	`03/01/00`
`mm/dd`	`03/01`
`HH:MM:SS`	`15:45:17`
`HH:MM:SS PM`	`3:45:17 PM`
`HH:MM`	`15:45`

Date-String Format	Usage Example
HH:MM PM	3:45 PM
mmm.dd,yyyy HH:MM:SS	Mar.01,2000 15:45:17
mmm.dd,yyyy	Mar.01,2000
mm/dd/yyyy	03/01/2000

For an example of how to represent a numerical time vector relative to calendar dates, see "Changing a Numerical Time Vector to Date Strings" on page 4-18.

Time Series Constructor Syntax

Before implementing the various MATLAB functions and methods specifically designed to handle time series data, you must create a `timeseries` object to store the data.

The following table summarizes the syntax when using the `timeseries` constructor. For an example of using the constructor, see "Creating Time Series Objects" on page 4-6.

Time Series Syntax Descriptions

Syntax	Description
`ts = timeseries`	Creates an empty `timeseries` object. The size of this object is 0-by-1.
`ts = timeseries(Data)`	Creates a `timeseries` object with the specified `Data`. `ts` has a default time vector ranging from `0` to `N-1` with 1-second increments, where `N` is the number of samples. The default name of the `timeseries` object is `'unnamed'`.

Time Series Syntax Descriptions (Continued)

Syntax	Description
`ts = timeseries('Name')`	Creates an empty `timeseries` object with the name specified by a string `Name`. This name can differ from the `timeseries` variable name.
`ts = timeseries(Data,Time)`	Creates a `timeseries` object with the specified `Data` array and `Time`. When time values are date strings, you must specify `Time` as a cell array of date strings.

Time Series Syntax Descriptions (Continued)

Syntax	Description
`ts = timeseries(Data,Time,Quality)`	The `Quality` attribute is an integer vector containing values `-128` to `127` that specifies the quality in terms of codes defined by `QualityInfo.Code`. For more information about `QualityInfo`, see "Time Series Properties" on page 4-24.
`ts = timeseries(Data,..., 'Parameter',Value,...)`	Optionally enter the following parameter-value pairs after the `Data`, `Time`, and `Quality` arguments. You can specify the following parameters: • `Name` • `IsTimeFirst` • `IsDatenum` `Name` and `IsTimeFirst` are described in "Time Series Properties" on page 4-24. When set to `true`, `IsDatenum` specifies that `Time` values are dates in the format of MATLAB serial dates.

Time Series Properties

The following table lists the properties of the `timeseries` object. You can specify the `Data`, `IsTimeFirst`, `Name`, `Quality`, and `Time` properties as input arguments in the constructor. To assign other properties, use the `set` function or dot notation.

Note To get property information from the command line, type `help timeseries/tsprops` at the MATLAB prompt.

For an example of editing `timeseries` object properties, see "Modifying Time Series Units and Interpolation Method" on page 4-11.

Time Series Property Descriptions

Property	Description
`Data`	Time series data, where each data sample corresponds to a specific time. The data can be a scalar, a vector, or a multidimensional array. Either the first or last dimension of the data must align with `Time`. By default, `NaN`s represent missing or unspecified data. Set the `TreatNaNasMissing` property to determine how missing data is treated in calculations.

Time Series Property Descriptions (Continued)

Property	Description
`DataInfo`	Contains fields for storing contextual information about `Data`: • `Unit` — String that specifies data units. • `Interpolation` — A `tsdata.interpolation` object that specifies the interpolation method for this time series. Fields in the `tsdata.interpolation` object include: - `Fhandle`: Function handle to a user-defined interpolation function. - `Name`: String that specifies the name of the interpolation method. Predefined interpolation methods include `'linear'` and `'zoh'` (zero-order hold). `'linear'` is the default. • `UserData` — Any user-defined information entered as a string.

Time Series Property Descriptions (Continued)

Property	Description
`Events`	An array of `tsdata.event` objects that stores event information for this `timeseries` object. You add events using the `addevent` method. Fields in the `tsdata.event` object include the following: • `EventData` — Any user-defined information about the event • `Name` — String that specifies the name of the event • `Time` — Time value when this event occurs, specified as a real number or a date string relative to `StartDate` • `Units` — Time units • `StartDate` — A reference date specified in MATLAB date string format. `StartDate` is empty when you have a numerical time vector.

Time Series Property Descriptions (Continued)

Property	Description
`IsTimeFirst`	Logical value (`true` or `false`) that specifies whether the first or last dimension of the `Data` array aligns with the time vector. You can set this property when the `Data` array is square and it is ambiguous which dimension aligns with time. By default, the first `Data` dimension that matches the length of the time vector is aligned with `Time`. When you set this property to • `true`, the first dimension of the data array is aligned with the time vector. • `false`, the last dimension of the data array is aligned with the time vector. After a time series is created, this property is read-only.
`Name`	`timeseries` object name entered as a string. This name can differ from the name of the `timeseries` variable in the MATLAB workspace.
`Quality`	An integer vector or array containing values `-128` to `127` that specifies the quality in terms of codes defined by the `QualityInfo.Code` field. When `Quality` is a vector, it must have the same length as the time vector. In this case, each `Quality` value applies to the corresponding data sample. When `Quality` is an array, it must have the same size as the data array. In this case, each `Quality` value applies to the corresponding value of the data array.

Time Series Property Descriptions (Continued)

Property	Description
`QualityInfo`	Provides a lookup table that converts numerical `Quality` codes to readable descriptions. `QualityInfo` fields include the following: • `Code` — Integer vector containing values `-128` to `127` that defines the "dictionary" of quality codes, which you can assign to each `Data` value by using the `Quality` property • `Description` — Cell vector of strings, where each element provides a readable description of the associated quality `Code` • `UserData` — Stores any additional user-defined information The length of `Code` and `Description` must match.
`Time`	Vector of time values. When `TimeInfo.StartDate` is empty, the numerical `Time` values are measured relative to `0` in specified units. When `TimeInfo.StartDate` is defined, the time values are date strings measured relative to `StartDate` in specified units. The length of `Time` must match either the first or the last dimension of `Data`.

Time Series Property Descriptions (Continued)

Property	Description
`TimeInfo`	Uses the following fields to store contextual information about `Time`: • `Units` — Time units with the following values: `'weeks'`, `'days'`, `'hours'`, `'minutes'`, `'seconds'`, `'milliseconds'`, `'microseconds'`, and `'nanoseconds'` • `Start` — Start time • `End` — End time (read-only) • `Increment` — Interval between two subsequent time values • `Length` — Length of the time vector (read-only) • `Format` — String defining the date string display format. See the MATLAB `datestr` function reference page for more information. • `StartDate` — Date string defining the reference date. See the MATLAB `setabstime (timeseries)` function reference page for more information. • `UserData` — Stores any additional user-defined information
`TreatNaNasMissing`	Logical value that specifies how to treat `NaN` values in `Data`: • `true` — (Default) Treat all `NaN` values as missing data except during statistical calculations. • `false` — Include `NaN` values in statistical calculations, in which case `NaN` values are propagated to the result.

Time Series Methods

In this section...

General Methods

Use the following methods to query and set object properties, and plot the data.

Methods for Querying Properties

Method	Description
`get (timeseries)`	Query `timeseries` object property values.
`getdatasamplesize`	Return the size of each data sample in a `timeseries` object.
`getqualitydesc`	Return data quality descriptions based on the `Quality` property values assigned to a `timeseries` object.
`isempty (timeseries)`	Evaluate to `true` for an empty `timeseries` object.
`length (timeseries)`	Return the length of the time vector.
`plot (timeseries)`	Plot the `timeseries` object.
`set (timeseries)`	Set `timeseries` property values.

Methods for Querying Properties (Continued)

Method	Description
`size (timeseries)`	Return the `size` property of a `timeseries` object.
`tstool`	Open the Time Series Tools GUI.

Data and Time Manipulation Methods

Use the following methods to add or delete data samples, and manipulate the `timeseries` object.

Methods for Manipulating Data and Time

Method	Description
`addsample`	Add a data sample to a `timeseries` object.
`ctranspose (timeseries)`	Transpose a `timeseries` object.
`delsample`	Delete a sample from a `timeseries` object.
`detrend (timeseries)`	Subtract the mean or best-fit line and remove all `NaN`s from time series data.
`filter (timeseries)`	Shape frequency content of time series data using a 1-D digital filter.
`getabstime (timeseries)`	Extract a date-string time vector from a `timeseries` object into a cell array.
`getinterpmethod`	Get the interpolation method for a `timeseries` object.
`getsampleusingtime (timeseries)`	Extract specified data samples from an existing `timeseries` object into a new `timeseries` object.
`idealfilter (timeseries)`	Apply an ideal pass or notch (noncausal) filter to a `timeseries` object.

Methods for Manipulating Data and Time (Continued)

Method	Description
`resample (timeseries)`	Select or interpolate data in a `timeseries` object using a new time vector.
`setabstime (timeseries)`	Set the time values in the time vector as date strings.
`setinterpmethod`	Set interpolation method for a `timeseries` object.
`synchronize`	Synchronize and resample two `timeseries` objects using a common time vector.
`transpose (timeseries)`	Transpose a `timeseries` object.
`vertcat (timeseries)`	Vertical concatenation for `timeseries` objects.

Event Methods

To construct an event object, use the constructor `tsdata.event`. For an example of defining events for a time series, see “Defining Events” on page 4-12.

Methods That Define and Use Events

Method	Description
`addevent`	Add one or more events to a `timeseries` object.
`delevent`	Delete one or more events from a `timeseries` object.
`gettsafteratevent`	Create a new `timeseries` object by extracting the samples from an existing time series that occur after or at a specified event.
`gettsafterevent`	Create a new `timeseries` object by extracting the samples that occur after a specified event from an existing time series.

Methods That Define and Use Events (Continued)

Method	Description
`gettsatevent`	Create a new `timeseries` object by extracting the samples that occur at the same time as a specified event from an existing time series.
`gettsbeforeatevent`	Create a new `timeseries` object by extracting the samples that occur before or at a specified event from an existing time series.
`gettsbeforeevent`	Create a new `timeseries` object by extracting the samples that occur before a specified event from an existing time series.
`gettsbetweenevents`	Create a new `timeseries` object by extracting the samples that occur between two specified events from an existing time series.

Arithmetic Operation Methods

Use the following operators to arithmetically combine `timeseries` objects.

Methods to Arithmetically Combine Time Series

Operation	Description
`+`	Add the corresponding data values of `timeseries` objects.
`-`	Subtract the corresponding data values of `timeseries` objects.
`.*`	Element-by-element multiplication of `timeseries` data.
`*`	Matrix-multiply `timeseries` data.
`./`	Right element-by-element division of `timeseries` data.
`/`	Right matrix division of `timeseries` data.

Methods to Arithmetically Combine Time Series (Continued)

Operation	Description
`.\`	Element-by-element left-array divide of `timeseries` data.
`\`	Left matrix division of `timeseries` data.

Statistical Methods

Use the following methods to calculate descriptive statistics for a `timeseries` object.

Methods for Calculating Descriptive Statistics

Method	Description
`iqr (timeseries)`	Return the interquartile range of `timeseries` data.
`max (timeseries)`	Return the maximum value of `timeseries` data.
`mean (timeseries)`	Return the mean of `timeseries` data.
`median (timeseries)`	Return the median of `timeseries` data.
`min (timeseries)`	Return the minimum of `timeseries` data.
`std (timeseries)`	Return the standard deviation of `timeseries` data.
`sum (timeseries)`	Return the sum of `timeseries` data.
`var (timeseries)`	Return the variance of `timeseries` data.

Time Series Collection Constructor

In this section...

Introduction

The MATLAB object, called `tscollection`, is a MATLAB variable that groups several time series with a common time vector. The `timeseries` objects that you include in the `tscollection` object are called *members* of this collection.

MATLAB provides several methods for convenient analysis and manipulation of `timeseries` in a `tscollection` object.

Time Series Collection Constructor Syntax

Before you implement the MATLAB methods specifically designed to operate on a collection of `timeseries` objects, you must create a `tscollection` object to store the data.

The following table summarizes the syntax for using the `tscollection` constructor. For an example of using this constructor, see "Creating Time Series Collection Objects" on page 4-12.

Time Series Collection Syntax Descriptions

Syntax	Description
`tsc = tscollection(ts)`	Creates a `tscollection` object `tsc` that includes one or more `timeseries` objects. The `ts` argument can be one of the following: • Single `timeseries` object in the MATLAB workspace • Cell array of `timeseries` objects in the MATLAB workspace The `timeseries` objects share the same time vector in the `tscollection`.
`tsc = tscollection(Time)`	Creates an empty `tscollection` object with the time vector `Time`. When time values are date strings, you must specify `Time` as a cell array of date strings.
`tsc = tscollection(Time, TimeSeries, 'Parameter', Value, ...)`	Optionally enter the following parameter-value pairs after the `Time` and `TimeSeries` arguments: • `Name` (see "Time Series Collection Properties" on page 4-38) • `IsDatenum` When set to `true`, `IsDatenum` specifies that `Time` values are dates in the format of MATLAB serial dates.

Time Series Collection Properties

This table lists the properties of the `tscollection` object. You can specify the `Name`, `Time`, and `TimeInfo` properties as input arguments in the `tscollection` constructor.

Time Series Collection Property Descriptions

Property	Description
`Name`	`tscollection` object name entered as a string. This name can differ from the name of the `tscollection` variable in the MATLAB workspace.

Time Series Collection Property Descriptions (Continued)

Property	Description
`Time`	A vector of time values. When `TimeInfo.StartDate` is empty, the numerical `Time` values are measured relative to 0 in specified units. When `TimeInfo.StartDate` is defined, the time values represent date strings measured relative to `StartDate` in specified units. The length of `Time` must match either the first or the last dimension of the `Data` property of each `tscollection` member.
`TimeInfo`	Uses the following fields to store contextual information about `Time`: • `Units` — Time units with the following values: `'weeks'`, `'days'`, `'hours'`, `'minutes'`, `'seconds'`, `'milliseconds'`, `'microseconds'`, and `'nanoseconds'` • `Start` — Start time • `End` — End time (read-only) • `Increment` — Interval between two subsequent time values. The increment is `NaN` when times are not uniformly sampled. • `Length` — Length of the time vector (read-only) • `Format` — String defining the date string display format. See the MATLAB `datestr` function reference page for more information. • `StartDate` — Date string defining the reference date. See the MATLAB `setabstime (timeseries)` function reference page for more information. • `UserData` — Stores any additional user-defined information

Time Series Collection Methods

In this section...

General Time Series Collection Methods

Use the following methods to query and set object properties, and plot the data.

Methods for Querying Properties

Method	Description
`get (tscollection)`	Query `tscollection` object property values.
`isempty (tscollection)`	Evaluate to `true` for an empty `tscollection` object.
`length (tscollection)`	Return the length of the time vector.
`plot (timeseries)`	Plot the time series in a collection.
`set (tscollection)`	Set `tscollection` property values.
`size (tscollection)`	Return the size of a `tscollection` object.
`tstool`	Open the Time Series Tools GUI.

Data and Time Manipulation Methods

Use the following methods to add or delete data samples, and manipulate the `tscollection` object.

Methods for Manipulating Data and Time

Method	Description
`addts`	Add a `timeseries` object to a `tscollection` object.
`addsampletocollection`	Add data samples to a `tscollection` object.
`delsamplefromcollection`	Delete one or more data samples from a `tscollection` object.
`getabstime (tscollection)`	Extract a date-string time vector from a `tscollection` object into a cell array.
`getsampleusingtime (tscollection)`	Extract data samples from an existing `tscollection`object into a new `tscollection` object.
`gettimeseriesnames`	Return a cell array of time series names in a `tscollection` object.
`horzcat (tscollection)`	Horizontal concatenation of `tscollection` objects. Combines several `timeseries` objects with the same time vector into one time series collection.
`removets`	Remove one or more `timeseries` objects from a `tscollection` object.
`resample (tscollection)`	Select or interpolate data in a `tscollection` object using a new time vector.
`setabstime (tscollection)`	Set the time values in the time vector of a `tscollection` object as date strings.
`settimeseriesnames`	Change the name of the selected `timeseries` object in a `tscollection` object.
`vertcat (tscollection)`	Vertical concatenation of `tscollection` objects. Joins several `tscollection` objects along the time dimension.

5

Time Series Tools

The following sections describe how to use the MATLAB Time Series Tools graphical user interface (GUI) for analyzing time series data.

Introduction (p. 5-2)	Summarizes the Time Series Tools window and workflow
Importing and Exporting Data (p. 5-7)	Describes supported data sources and instructions for importing and exporting data in Time Series Tools
Plotting Time Series (p. 5-13)	Describes how to work with time plots, histograms, spectral plots, correlation plots, and *XY* plots
Selecting Data for Analysis (p. 5-28)	Provides instructions for selecting data on which to focus your analysis
Editing Data, Time, Attributes, and Events (p. 5-31)	Describes how to edit data, time, units, interpolation method, quality codes, and events for time series
Processing and Manipulating Time Series (p. 5-41)	Provides instructions for processing time series, including filtering, interpolating, resampling, and algebraically manipulating data
Example — Time Series Tools (p. 5-42)	Provides an example of importing, plotting, and analyzing time series

Introduction

In this section...

Opening Time Series Tools

To open Time Series Tools, type the following at the MATLAB prompt:

```
tstool
```

You can also open Time Series Tools using the MATLAB **Start** button by selecting **Start > MATLAB > Time Series Tools**.

For a description of the Time Series Tools GUI, see "Time Series Tools Window" on page 5-3.

To learn how to import data into Time Series Tools, see "Importing and Exporting Data" on page 5-7.

You can also start Time Series Tools and simultaneously import the following kinds of objects from the MATLAB workspace:

- `timeseries`
- `tscollection`
- Simulink® logged signals

Note You cannot import Simulink logged signals that contain a `/` in their `Name` property at any point in the signal hierarchy.

Syntax for Loading Data from the MATLAB Workspace

MATLAB Object	Syntax	Description
`timeseries`	`tstool(tsname)`	`tsname` is the name of a `timeseries` object.
`tscollection`	`tstool(tscname)`	`tscname` is the name of a `tscollection` object.
Simulink logged-signal data	`tstool(sldata)`	`sldata` is the name of a signal logged in a Simulink model.

Getting Help

Time Series Tools provides extensive context-sensitive help directly from the GUI.

In the Time Series Tools window, the context-sensitive help pane is available on the right to assist you with the primary tasks. To toggle between displaying or hiding the help pane, click the  (**Help**) button in the toolbar. You can resize the help pane by dragging the vertical divider to the left or to the right.

Context-sensitive help is also available via the **Help** button in Time Series Tools dialog boxes.

Time Series Tools Window

The Time Series Tools window consists of the following three areas:

- Time Series Session tree

  Organizes time series data and plots (or **Views**).

  The **Simulink Time Series** node is shown only when you have installed Simulink.

- Options and Settings pane

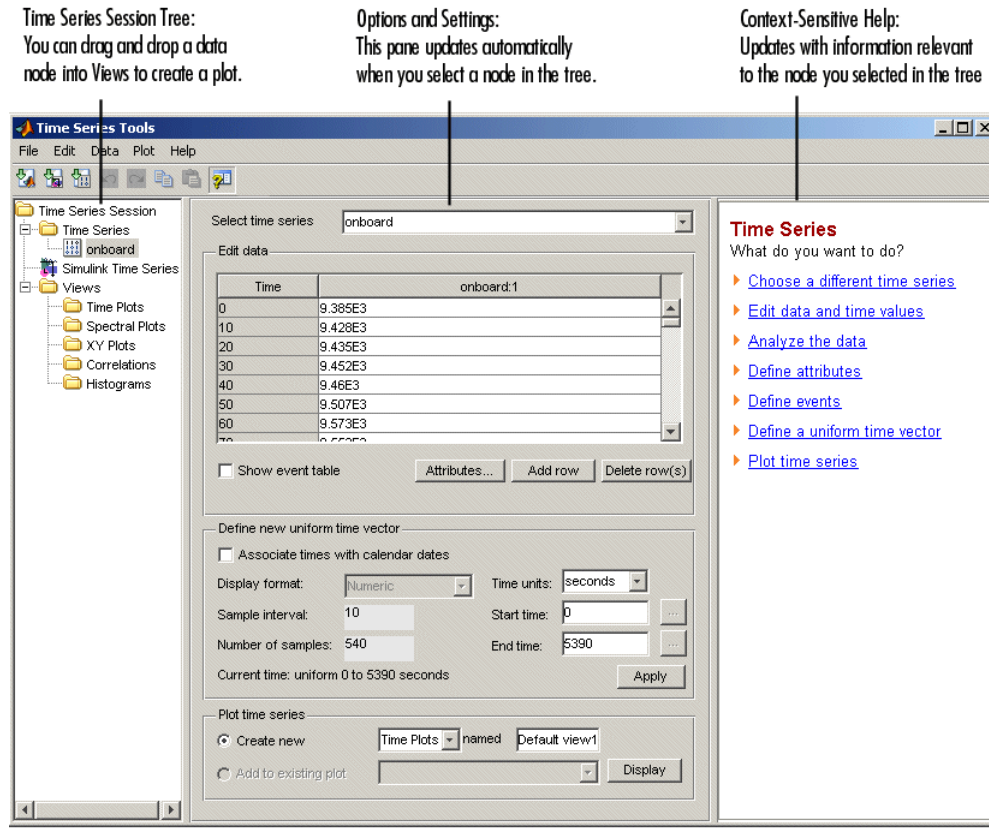
  After you select a node in the tree, this pane displays options and settings pertaining to the node you selected in the tree.

- Context-Sensitive Help pane

Provides information and instructions about entering the options and settings currently shown in Time Series Tools. You can toggle between displaying or hiding this help by clicking the button in the toolbar. You can change the width of the help pane by dragging the vertical divider to the left or to the right.

To learn about other help available in Time Series Tools, see “Getting Help” on page 5-3.

The following figure shows the three main areas of the Time Series Tools GUI:



Time Series Tools Workflow

When you analyze data using Time Series Tools, your workflow might include the following tasks:

1. Import data from an Excel workbook, MAT-file, or MATLAB workspace.

   For more information, see “Importing and Exporting Data” on page 5-7.

2. Create a time plot to gain insight into the data features.

   For more information, see “Creating a Plot” on page 5-14.

3. Select data subset for analysis.

   For more information, see “Selecting Data for Analysis” on page 5-28.

4. Edit the data by

   - Identifying and removing outliers or “dead time” (see “Selecting Data Using Rules” on page 5-28).
   - Manually correcting errors (see “Editing Data, Time, Attributes, and Events” on page 5-31).

5. Process the data by

   - Interpolating or removing missing values.
   - Detrending data by subtracting a mean value or a linear trend.
   - Filtering to smooth and shape the data.
   - Algebraically manipulating existing time series to create a new time series.
   - Resampling data using a specified time vector by selecting or interpolating values.

   For more information, see “Processing and Manipulating Time Series” on page 5-41.

6. Generating correlation plots, spectral plots, histograms, and *XY* plots.

   For more information, see “Plotting Time Series” on page 5-13.

7 Exporting data from Time Series Tools to the MATLAB workspace or to a file.

For more information, see “Exporting Data from Time Series Tools” on page 5-12.

Generating Reusable M-Code

You can enable automatic generation of reusable M-code while you perform operations that modify data in Time Series Tools. To do this, select **File > Record M-Code** in the Time Series Tools window.

If you are new to programming with MATLAB `timeseries` methods, you can use the generated M-code to get syntax examples. For more information about programming with MATLAB `timeseries` objects, see Chapter 4, “Time Series Objects and Methods”.

For an example of automatically generating and viewing M-code, see “Example — Time Series Tools” on page 5-42.

Note The scope of the **Record M-Code** feature is restricted to recording actions on the time series data itself. It does not generate code to import data or reproduce time series plots.

Importing and Exporting Data

In this section...

Types of Data You Can Import

You can import data into Time Series Tools from

- A Microsoft Excel workbook, a text file, or a MAT-file.
- An array in the MATLAB workspace.
- A `timeseries` or `tscollection` object in the MATLAB workspace.

  For more information about creating these objects, see Chapter 4, "Time Series Objects and Methods".
- Simulink logged-signal data from a Simulink model.

Note You cannot import a `timeseries` or `tscollection` object from a MAT-file.

How to Import Data

This section includes the following topics:

- "Importing Time Series and Time Series Collection Objects" on page 5-8
- "Importing Data from External Files" on page 5-8
- "Using the Import Wizard" on page 5-8

Importing Time Series and Time Series Collection Objects

If you have already encapsulated time series data in a `timeseries` or `tscollection` object in the MATLAB workspace, you can open Time Series Tools and import the data in a single operation. Simply right-click the object name in the Workspace Browser and choose **Open in Time Series Tools** from the context menu.

Importing Data from External Files

Once you have opened Time Series Tools, use the following commands to import data from external files. Each command opens a dialog box. You can get detailed information about options by clicking **Help**.

Data Source	Import Command
Microsoft Excel worksheet (`.xls`)	Select **File > Create Time Series from File** to open the Import Wizard.
Text file (`.csv`, `.txt`, `.dat`)	Select **File > Create Time Series from File** to open the Import Wizard.
MAT-file array (`.mat`)	Select **File > Create Time Series from File** to open the Import Wizard.
MATLAB workspace array	Select **File > Import from Workspace > Array Data** to open the Import Wizard.
`timeseries` or `tscollection` object in the MATLAB workspace	Select **File > Import from Workspace > Time Series Objects or Collections**.
Simulink logged signal	Select **File > Import from Workspace > Simulink Data Logs**.

Using the Import Wizard

When in Time Series Tools, you import data from the MATLAB workspace or an external file using the Import Wizard. The Import Wizard lets you select the data to import when analyzing a portion of an Excel worksheet or specific columns or rows in a MATLAB array.

After you select the data, you can specify to import time values from a file or define a uniformly spaced time vector in the Import Wizard. For an example

of importing data from an Excel worksheet, see “Importing Data into Time Series Tools” on page 5-43.

Each time series you import is added as a data node to the **Time Series Session** tree.

Note The Import Wizard in Time Series Tools imports data as `timeseries` objects. This is different from the Import Wizard you access from the MATLAB Command Window, which imports data as MATLAB vectors and matrices.

For instructions about working with the Import Wizard, click **Help** in the Import Wizard window. You can also get help on specific fields in the Wizard as follows:

1. Right-click the text label of a field for which you want to get help.
2. Select **What's This** from the shortcut menu.

Changes to Data Representation During Import

When you import data into Time Series Tools, a copy of the data is imported without affecting the original data source.

The data copy is changed during import, as follows:

- Rowwise data is transposed to become columnwise with the time vector in the first column.
- Data with more than two dimensions is reshaped to two dimensions such that dimensions three and higher become additional columns. For example, a 2-by-3-by-5 data array becomes a 2-by-15 data array.
- Non-`double` data, such as `int`, `logical`, and `fixed-point`, is converted to `double`.
- Missing data values are replaced by `NaN`s.
- A sparse matrix is converted to a full matrix.

Caution When you export data from Time Series Tools to a file or to the MATLAB workspace, please note that its representation might differ from what you imported into Time Series Tools. For more information about exporting data, see "Exporting Data from Time Series Tools" on page 5-12.

Importing Multivariate Data

When your data consists of several related variables measured at the same time, you might want to group this data so that you can plot variables together or perform calculations on all variables simultaneously.

There are two ways to represent multivariate data in Time Series Tools:

- Create a time series collection with a common time vector, where each time series is a member of the collection.
- Import a data array into a single `timeseries` object, where each time series is stored as a column.

Choosing How to Represent Multivariate Data

How you choose to represent your data depends on whether the variables have the same or different units.

When your data contains different measurements of the same quantity (same units), you can store all measurements as separate columns in a single time series. Plotting such a time series displays all columns on the same axes and distinguishes the data sets by line and marker styles. For more information, see "Customizing Line and Marker Styles" on page 5-15.

When your data contains different quantities, measured in different units, you might want to distinguish these quantities on plots and during analysis. In this case, we recommend that you store each quantity as a separate time series and then group them into a time series collection. For example, if you are working with stock-price data in a portfolio, you might represent each stock as a separate time series and group them in a collection. When you plot this collection, each member is plotted on separate axes. However, when you perform data-analysis operations on the collection, such as filtering or

interpolation, these operations are applied to all time series in the collection simultaneously.

Creating a Time Series Collection

You can create a time series collection in the MATLAB Command Window, as described in Chapter 4, "Time Series Objects and Methods", and then import the collection into Time Series Tools. Alternatively, you can use the Import Wizard to facilitate creating the `timeseries` objects and then group them into a collection in the MATLAB Command Window.

The following procedure describes one way to create a time series collection using data from a file.

Note At each step, you can click the **Help** button in the GUI to access context-sensitive help.

---

1. To import each variable in the Microsoft Excel worksheet or MATLAB array as a separate time series in Time Series Tools, select **File > Import from Workspace > Array Data**. This opens the Import Wizard.
2. After importing the data, select the **Time Series** node in the tree and export these time series to the MATLAB workspace.
3. In the MATLAB Command Window, combine individual time series into a time series collection object. For an example of creating a time series collection, see "Creating Time Series Collection Objects" on page 4-12.
4. In Time Series Tools, select **File > Import from Workspace > Time Series Objects or Collections** and import the collection from the MATLAB workspace.

Importing Data with Missing Values

When you import data from a Microsoft Excel worksheet into Time Series Tools that contains missing values, the missing data is automatically replaced with `NaN`s. `NaN`s are ignored in Time Series Tools calculations.

To remove or interpolate missing values:

1. Select a time series or a collection in the **Time Series Session** tree containing missing values.
2. Select **Data > Interpolate** or **Data > Remove Missing Data**, depending on the operation you want to perform. This opens the Process Data dialog box.
3. Click **Help** to access context-sensitive help on specific options in the dialog box.

Exporting Data from Time Series Tools

Importing data into Time Series Tools creates a copy of the original data. After you finish analyzing the data in Time Series Tools, you must export it to a file or to the MATLAB workspace to make it available for other processing in MATLAB.

To export a time series or a collection, select the desired node in the **Time Series Session** tree. Then, do one of the following:

- Export to a file (Microsoft Excel worksheet or MAT-file):

  Select **File > Export > To File**.

  When you export a time series collection, the individual time series are extracted into separate Microsoft Excel worksheets.

- Export to the MATLAB workspace:

  Select **File > Export > To Workspace**.

Plotting Time Series

In this section...

Types of Plots in Time Series Tools

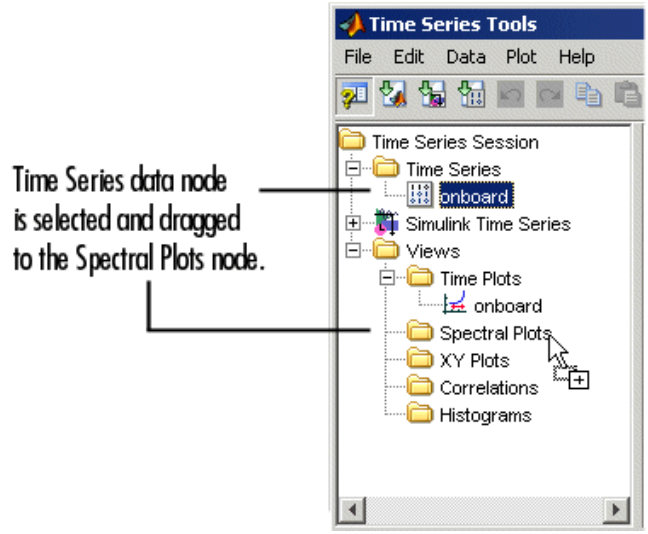
You can generate the following types of plots in Time Series Tools.

Plot Type	Description
Time Plot	Plots data as a function of time to help you see important features, such as outliers, discontinuities, trends, and periodicities.
Histogram	Plots the number of data values that occur in specified data ranges, called *bins*.
Spectral Plot	Shows data periodicities by plotting the estimated power spectral density as a function of frequency.
Correlation Plot	Shows the autocorrelation of a time series or cross-correlation between two time series.
XY Plot	Shows the relationship between two time series by plotting the data values of one on the x-axis and the data values of the other on the y-axis.

Creating a Plot

You can create a plot in Time Series Tools is by dragging and dropping a **Time Series** data node in the **Time Series Session** tree onto a **Views** node.

The following figure shows an example of how to create a spectral plot by dragging the `onboard` time series onto the **Spectral Plots** node:



This opens the spectral plot in the Time Series Plots window and adds a tree node under **Spectral Plots**. The Time Series Plots window is similar to the MATLAB Figure window but includes additional commands in the toolbar and the **Tools** menu.

Tip To change the default plot name, right-click the plot node and select **Rename** and enter the new name.

Subplots. To create subplots in a single figure window, drag several time series onto the same plot node. If a time series contains several columns of data, all data columns are plotted on the same axes. See “Editing Plot Appearance” on page 5-15 for information on interactively modifying the appearance of subplots.

***XY* and cross-correlation plots.** These plots require two time series. To create these plots, drag one time series onto a plot node and then drag a second time series onto the same plot node.

Customizing Line and Marker Styles

When you plot several time series on the same axes, or a single `timeseries` object that contains multiple columns of data, you can specify how to visually distinguish between the different sets of data in the plot.

To distinguish data by color, type of marker, or line style, select **Plot > Set Line Properties** in the Time Series Tools window. This opens the Line Styles dialog box. Click **Help** to learn how to work with this dialog box.

Note Your changes are applied to all open plots.

For an example of setting line styles, see "Creating a Time Plot" on page 5-46.

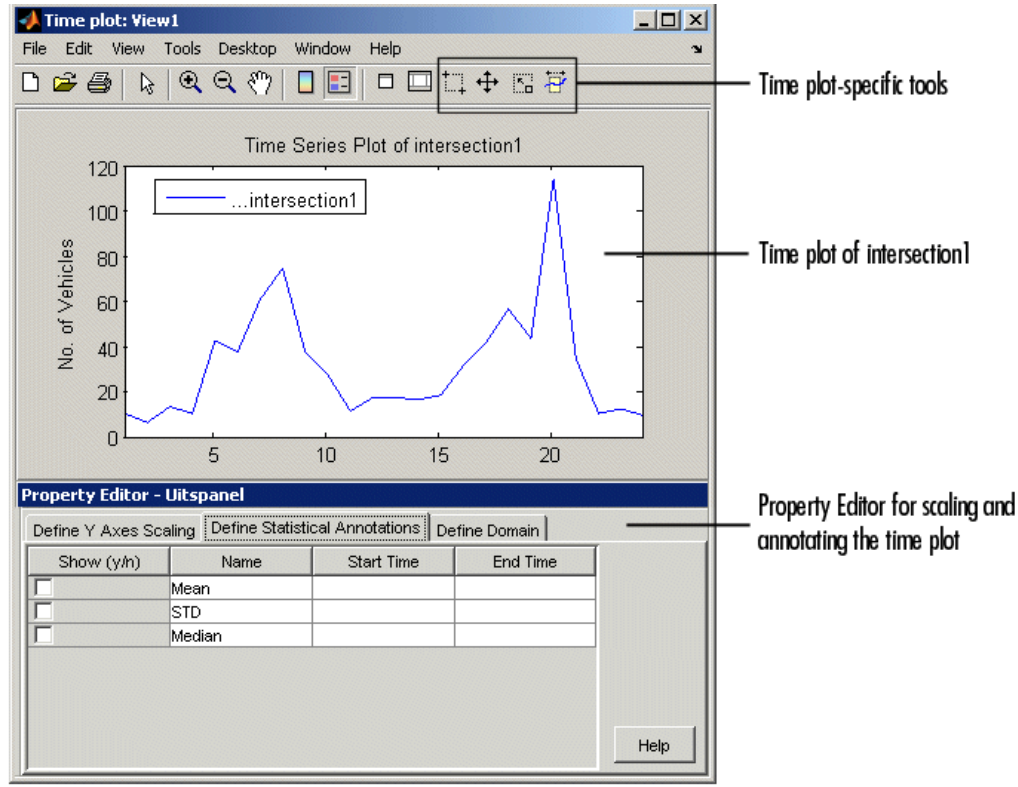
Editing Plot Appearance

After you create a plot, you can modify the plot appearance using the Property Editor as follows:

- Change the range of the horizontal and vertical axes.
- Show statistical annotations on the plot, such as the mean and standard deviation.

  The kinds of statistical quantities you can display vary depending on the type of plot.

The following figure shows the location of the Property Editor relative to the plot window:



To display the Property Editor for any Time Series Tools plot:

1. Select the plot in the **Time Series Session** tree.
2. In Time Series Tools, click the **Edit Plot** button. This displays the plot window on top with the Property Editor below the plot.
3. In the Property Editor, click **Help** to get information about options and settings.

Note The Property Editor options change depending on the type of plot and the plot item you select, such as lines or plot legends.

Subplots. You can change subplot indices interactively. To do so, click on a plotted line in a time series view and drag and drop it from one subplot to another. To create a new subplot, drag and drop the plotted line below the bottom axes.

Time Plots

By plotting data as a function of time, you can quickly gain insight into the following data features:

- Outliers, or values that do not appear to be consistent with the rest of the data
- Discontinuities
- Trends
- Periodicities
- Time intervals containing the data of interest

These features, when considered in the context of the data, enable you to plan your analysis strategy. For more information about creating a time plot, see “Creating a Plot” on page 5-14.

After you create the plot, you can use the Property Editor to

- Define Y-axis scale.
- Display statistical annotations on the plot, such as mean, standard deviation, and median.
- Define X-axis scale (or domain).

In the Property Editor, click **Help** to get information about options and settings.

The Time Plot window contains the following toolbar commands specific to working with time series data.

Time Plot Commands

Button	Description
	Select Data — Enables you to click and drag a rectangular region on the time plot to select the data inside the region.
	Move Time Series — Enables you to click and drag a time series to translate a time series on the plot and recalculate the data and time values. When you translate a time series in time, its time vector is shifted by a constant offset. If you had associated any events with this time series, the events are not shifted with the time series. For more information about editing event times, see “Defining Events” on page 5-37.
	Rescale Time Series — Rescales both axes of the time plot to the original view.
	Select Interval — Enables you to click and drag to select data corresponding to one or more time intervals. You can select multiple disconnected intervals.

Spectral Plots

You use a spectral plot (or periodogram) to determine the frequencies of the periodic variations in the data and to filter the data. For more information about creating a periodogram, see “Creating a Plot” on page 5-14.

The periodogram is the unbiased estimate of the power spectral density of a time series, calculated as the scaled absolute value of the $(FFT)^2$ of the time series. The corresponding frequency vector is computed in cycles per unit time and has the same length as the power vector. The periodogram is scaled so that the variance equals the mean of the periodogram.

The periodogram is useful for picking out periodic components in the presence of noise; a peak in the periodogram indicates an important contribution to variance frequencies near the value that corresponds to the peak.

After you create the plot, you can use the Property Editor to

- Define Y-axis scale.
- Display the variance for a selected frequency range on the plot.

  The periodogram is scaled so that the variance equals the mean of the periodogram.
- Define frequency scale.

In the Property Editor, click **Help** to get information about options and settings.

Filtering the Data

You can use the spectral plot to apply an ideal pass or stop filter to the data.

You use the *ideal notch (stop) filter* when you want to attenuate the variations in the data for a specific frequency range. Alternatively, you use the *ideal pass filter* to allow only the variations in a specific frequency range. These filters are "ideal" in the sense that they are not realizable; an ideal filter is noncausal and the ends of the filter amplitude are perfectly flat in the frequency domain.

To apply an ideal filter:

1. In the Spectral Plot window, click the **Select Frequency Interval(s)**  button in the toolbar.
2. Click and drag on the plot to select a frequency interval. The selected interval appears in a different color.
3. Decide if you want to select another frequency interval.
   - If yes, repeat step 2. The previously selected remains selected.
   - If no, go to step 4.
4. Right-click a selected region on the plot and select one of the following from the shortcut menu:
   - To allow only the variations in the selected frequency range, select **Pass**.
   - To remove the variations in the selected frequency range, select **Notch**.

Histograms

The histogram plot shows the distribution of data by counting the number of data values within a specific range of values and displaying each range as a rectangular bin. The heights of the bins represent the numbers of values that fall within each range. For more information about creating a histogram, see “Creating a Plot” on page 5-14.

You can use a histogram plot to select data values that fall in a specific range to exclude or include them in your analysis. If you want to interpolate specific data values, you can select them in a histogram plot first, and then replace them with `NaN`s. For more information, see “Removing or Replacing Data with NaNs” on page 5-21. Then, you can interpolate all values tagged as `NaN`s using the selected interpolation method. For more information about specifying an interpolation method, see “Defining Data Attributes” on page 5-34.

Note Time Series Tools generates a histogram plot of a time series by applying the MATLAB `hist` function.

After you create the plot, you can use the Property Editor to

- Define Y-axis scale.
- Display statistical annotations on the plot, including the mean and the median.
- Define data bins.

In the Property Editor, click **Help** to get information about options and settings.

Selecting Data

1. In the Histogram window, click the **Select Y Range Interval**  button in the toolbar.
2. Click and drag a rectangular region on the plot to select a data interval. The selected interval appears in a different color.

3 Decide if you want to select another data range.

- If yes, repeat step 2. The previously selected remains selected.
- If no, you are done.

Removing or Replacing Data with NaNs

After you select the data, as described in "Selecting Data" on page 5-20, you can delete it or replace it with `NaN`s. If you want to interpolate specific data values, you must replace the selected data with `NaN`s first.

To delete data, right-click the selected region and select **Remove Selection** from the shortcut menu.

To replace data with `NaN`s, right-click the selected region and select **Replace with NaNs** from the shortcut menu.

Correlation Plots

You can create autocorrelation plots (*correlograms*) and cross-correlation plots in Time Series Tools. A correlation plot shows correlation coefficients on the vertical axis, and lag values on the horizontal axis.

A *lag* is defined as the number of time steps by which a time series is shifted relative to itself (when autocorrelated), or relative to the corresponding time values of another time series (when crosscorrelated). Notice that a lag is not a time shift (in specified time units). However, you can interpret a lag as a time shift when the time series is uniformly sampled (autocorrelation), or when both time series are uniformly sampled with the same time interval (cross-correlation).

This section includes the following topics:

Note If your data is sampled at irregular time intervals, resample it on a uniform time vector before creating correlation plots. This is because correlation analysis only considers the number of time steps between data values, and not the actual time elapsed between successive measurements. For more information about resampling time series, see "Processing and Manipulating Time Series" on page 5-41.

Autocorrelation of a Time Series

The *autocorrelation* function is an important diagnostic tool for analyzing time series in the time domain. You use the autocorrelation plot, or *correlogram*, to better understand the evolution of a process through time by the probability of relationship between data values separated by a specific number of time steps.

The correlogram plots correlation coefficients on the vertical axis, and lag values on the horizontal axis. To learn more about correlation coefficients, see "Correlation Coefficients" on page 2-7.

To create a correlogram, drag and drop a time series into a **Correlations** node. Then explore the plot by editing the lag range in the Property Editor.

If a time series contains multiple data columns, your plot contains cross-correlations of the various data columns. For more information, see "Cross-Correlation of Time Series" on page 5-23.

Note A correlogram is not useful when the data contains a trend; data at all lags will appear to be correlated because a data value on one side of the mean tends to be followed by a large number of values on the same side of the mean. You must remove any trend in the data before you create a correlogram. For more information about accessing detrending functionality, see "Processing and Manipulating Time Series" on page 5-41.

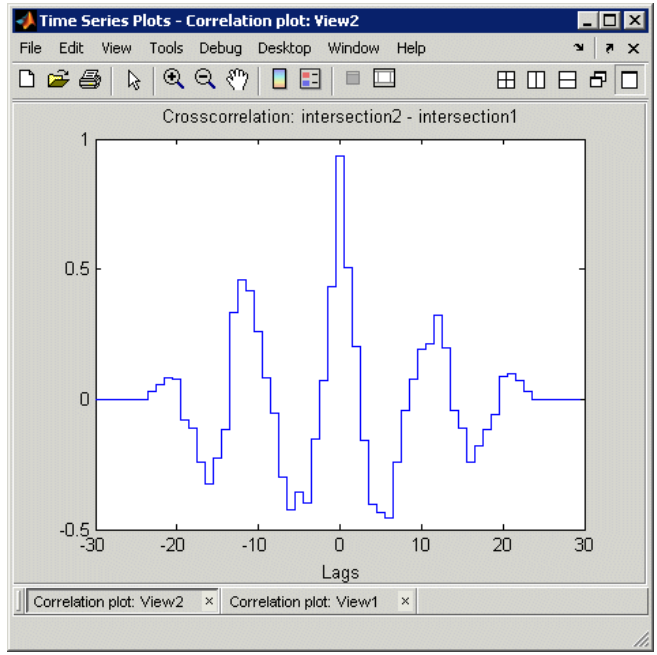
Cross-Correlation of Time Series

Cross-correlation is a measure of the degree of the linear relationship between two time series. A high correlation between time series at a specific lag might indicate a time delay in the system.

Note Before creating a cross-correlation plot, make sure that both time series have the same uniform time vector.

To create a cross-correlation plot, successively drag and drop the first time series and the second time series into the same **Correlations** node in the **Time Series Session** tree. Then explore the plot by varying the lag range in the Property Editor.

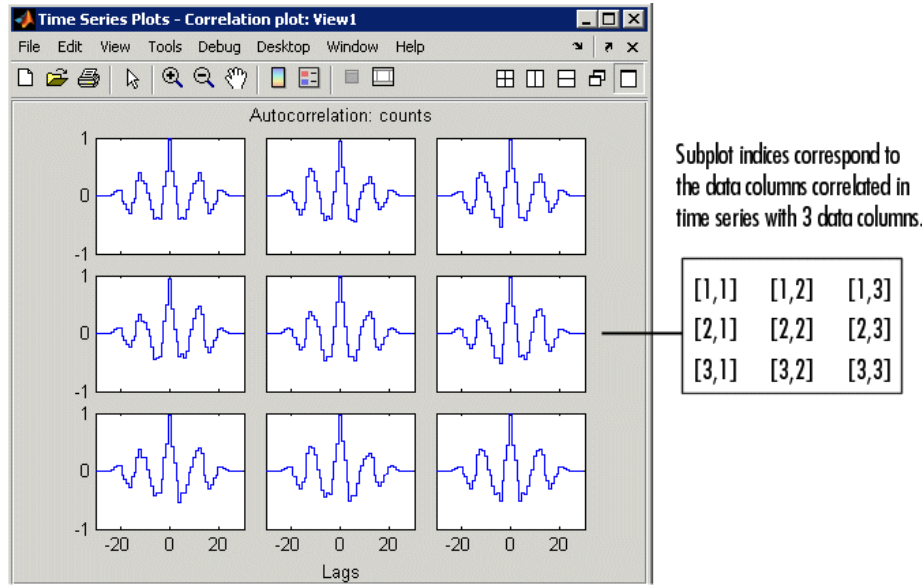
A cross-correlation plot of two time series, where each contains a single column of data, shows the degree of linear relationship between the data values in the two time series at various lags. For example, the following figure shows a cross-correlation plot of two time series, `intersection1` and `intersection2`. There is a high correlation when there is no lag in the data, as well as for lags of about `-11` and `11`.



Cross-Correlation of Two Time Series

A cross-correlation plot of two time series, where each contains multiple data columns, is displayed as a grid of subplots. The number of subplots equals the number of columns of data in the first time series multiplied by the number of columns of data in the second time series.

When you autocorrelate a time series with multiple data columns, the resulting plot also contains subplots. The diagonal of the subplot is the autocorrelation of a specific data column. The off-diagonal subplots are cross-correlation plots of the various columns. The subplot indices correspond to the indices of the data columns being correlated. For example, the figure below shows a correlation plot of the time series `counts` with three data columns.



Cross-Correlation of Multiple Data Columns in a Time Series

Interpreting Correlation Plots

The following table describes the degree of relationship between the data values at a given lag for various correlation values.

Correlation Value	Meaning
Close to 1	There is a relationship between data values at a specific lag: an increase in one corresponds to an increase in the other.
0	The variations in the data show no relationships at this lag.
Close to -1	There is an anticorrelation between the data values at a specific lag: a decrease in one data value corresponds to an increase in the other data value.

Cross-Correlation Algorithm

When computing the cross-correlation of two vector-valued time series `x` and `y`, Time Series Tools uses an algorithm that is functionally equivalent to calling `xcorr` from Signal Processing Toolbox with the `'biased'` option, after the time series means have been removed. Unlike `xcorr`, however, the cross-correlation estimate in Time Series Tools also works for matrix-valued time series `X` and `Y`, where it computes the cross-correlation of `X(:,i)` against `Y(:,j)` for all combinations of columns `i` and `j`. Note that Time Series Tools do not actually use the `xcorr` code, but rather a simplified version which works under these restricted assumptions.

XY Plots

An *XY* plot plots the data values of one time series against the data values of another time series at corresponding times. Any relationship between the two time series is evident from a pattern on the plot. For example, when the points on the *XY* plot form a straight line, there is a linear relationship between the data values of the two time series plotted. The *XY* plot does not show any time information.

Note To generate an *XY* plot, both time series must have the same time vectors.

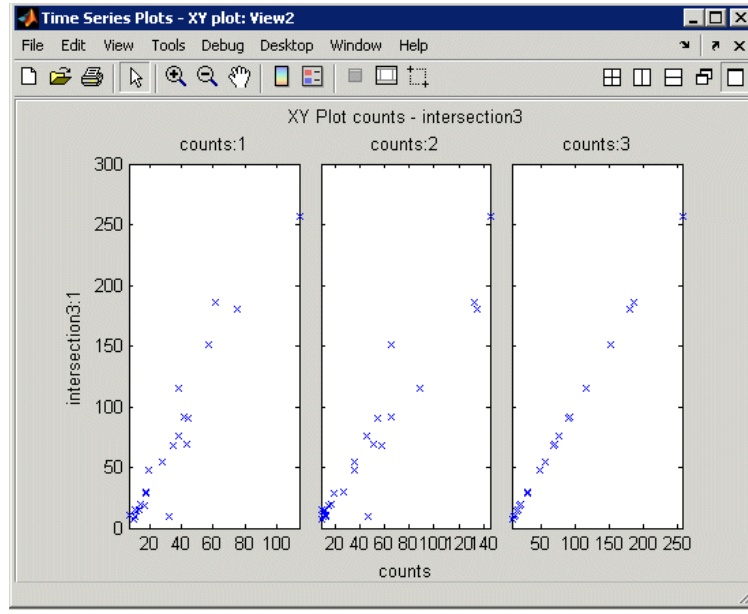
To create an *XY* plot, successively drag and drop the first time series and the second time series into the same **XY Plots** node in the **Time Series Session** tree.

When you are plotting two time series where each contains a single column of data, the *XY* plot includes a single set of axes. The pairs of data values from the same position in the column of data; that is, the third data point from one column is plotted against the third data point from the other column. For an example of generating such an *XY* plot, see “Comparing Data on an *XY* Plot” on page 5-53.

An *XY* plot of two time series, where each contains one or multiple data columns, is displayed as a grid of subplots. The number of subplots equals the number of columns of data in the first time series multiplied by the number

of columns of data in the second time series. The subplot indices correspond to the indices of the data columns.

The following figure shows an *XY* plot, where the data values in time series `count` are plotted on the *X*-axis against the corresponding data values of `intersection1` on the *Y*-axis. Because `count` contains three data columns and `intersection1` contains one data column, the *XY* plot window shows three subplots.



***XY* Plot Where One Time Series Contains Three Data Columns**

Selecting Data for Analysis

In this section...

Selecting Data Using Rules

You can select data using logical expressions in the Select Data Using Rules dialog box, which you access from a time plot. For more information about creating a time plot, see “Creating a Plot” on page 5-14.

To open the Select Data Using Rules dialog box, right-click inside the time plot and choose **Select Data** from the shortcut menu. Click **Help** in the dialog box to get information about specific options.

You can define up to four kinds of data-selection conditions:

- Bounds — Upper and lower bounds for time and data values
- Outliers — Condition for detecting outliers, or data values that are outside a specified confidence level
- MATLAB expression — A logical MATLAB expression that selects specific data values
- Flatlines – Condition for detecting a specified number of successive data points with a constant value

---

Tip To learn how to exclude data from analysis based on your selection, see “Excluding Data from Analysis” on page 5-30.

Selecting Data Graphically

This section describes how to select data in a time plot by using the mouse. For more information on creating a time plot, see “Creating a Plot” on page 5-14.

You can select data using two modes:

- Data mode — Enables you to select data values in a rectangular region on the time plot.

  For more information, see “Selecting Data in a Rectangular Region” on page 5-29.

- Time mode — Enables you to select data values in one or more time intervals on the time plot.

  For more information, see “Selecting Data in a Time Interval” on page 5-29.

Tip To learn how you can select specific data values in a histogram plot, see “Selecting Data” on page 5-20.

Selecting Data in a Rectangular Region

1. In the Time Plot window, click the **Select Data** button in the toolbar.
2. Click and drag a rectangular region on the plot that encloses the data you want to select.

   The data values are selected when you release the mouse button.
3. Decide if you want to select another region.

   - If yes, repeat step 2. This does not clear the previous selection.
   - If no, you can continue by excluding data from analysis (see “Excluding Data from Analysis” on page 5-30).

Selecting Data in a Time Interval

1. In the Time Plot window, click the **Select Time Interval(s)** button in the toolbar.

2 Click the start of a region that encloses the time interval where you want to select data, and then drag it. The selected time interval appears in a different color.

3 Decide if you want to select another time interval.

- If yes, repeat step 2. This does not clear the previous selection.
- If no, you can continue by excluding data from analysis (see "Excluding Data from Analysis" on page 5-30).

Excluding Data from Analysis

After you select the data, you can either exclude or keep the selected values. The following table summarizes how to do this.

Task	Operation
Exclude selected data from analysis	Right-click the selected data in the time plot and select **Remove Observations** from the shortcut menu. When there are multiple data columns in a single time series, this removes the entire data sample at that time.
Exclude unselected data from analysis	Right-click the selected data in the time plot and select **Keep Observations** from the shortcut menu.

Editing Data, Time, Attributes, and Events

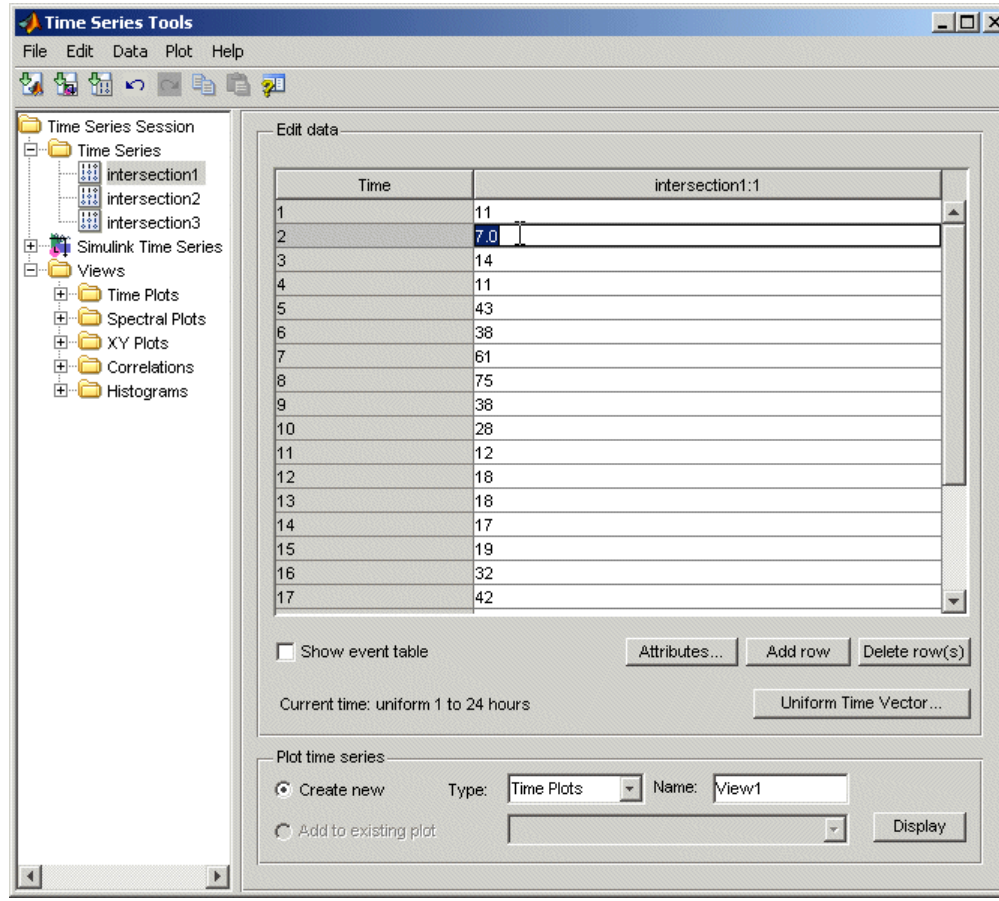
In this section...

Displaying the Data Table

To display the time series in an editable table, select the time series node in the Time Series Session tree.

In the following figure, the time series `intersection1` is selected in the tree and its data table is shown on the right. The **Time** column contains time values and the **intersection1:1** column contains the corresponding data values in the first column and only data column of `intersection1`.

If `intersection1` had multiple data columns, they would appear in the table and numbered as **intersection1:2**, **intersection1:3**, and so on. The data column headers are also used as plot labels to distinguish time series in plots. For more information about creating plots, see “Plotting Time Series” on page 5-13.



Note To toggle between displaying and hiding the help pane in Time Series Tools, click the button in the toolbar.

Editing Data and Time

After you display the time series data, as described in “Displaying the Data Table” on page 5-31, you can edit specific data and time values, define a uniform time vector, and add or remove data samples.

Edit Time or Data Values

To edit a specific time or data value, double-click that cell in the table and enter the new value. Press **Enter**.

Note When entering time values, you must use the current display format of your time vector. For more information, see "Time Vector Format" on page 4-21.

Define a Uniform Time Vector

To define a uniformly-increasing time vector, click **Uniform Time Vector** below the data table. This opens the Define Uniform Time Vector dialog box.

Here, you specify the start and end time of the time vector, the time units, and the display format. The time interval is calculated automatically by dividing the total time range by the number of data samples. You can get more instructions by clicking **Help** in the Define Uniform Time Vector dialog box.

When you are done specifying the time vector, the new time values replace the previous time values in the data table.

Add Data Samples

To insert a row in the data table, click any cell in a row and click the **Add Row** button. Enter the time and the corresponding data values.

Delete Data Samples

To delete a row in the data table, select one or more rows with the mouse and click the **Delete Row(s)** button.

Defining Data Attributes

The following attributes are defined for time series:

- Units — Stored as metadata for each time series.
- Interpolation method — Default method used to fill in missing data or to resample data on a new time vector.
- Quality codes — Used to annotate the quality of each value in the data table.

Click the **Attributes** button below the data table to open the Define Data Attributes dialog box. For information about displaying the data table, see "Displaying the Data Table" on page 5-31.

Units and Interpolation Method

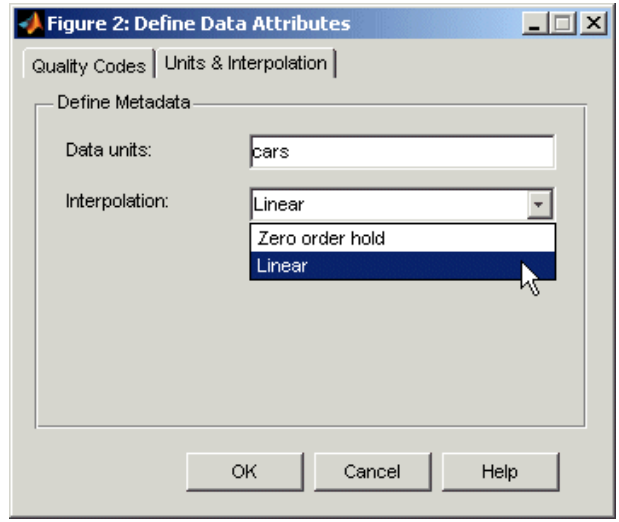
Data units are stored as metadata for the currently selected time series. If this time series contains multiple data columns, all data is assigned the same units.

In the **Units & Interpolation** tab, enter a string in the **Data units** field. For example, enter `N/m^2`.

The interpolation method you select here is used by default for this time series to fill in missing data or to resample the data on a new time vector.

In the **Units & Interpolation** tab, select one of the following **Interpolation** methods:

- `Linear` — A 1-D interpolation method that implements the MATLAB function `interp1` to fit a straight line between a pair of existing data points to calculate the missing value.
- `Zero-order hold` — Calculates the missing value by setting it equal to the last available data value. In other words, this methods "holds" the last value constant until the next available measurement.



Quality Codes

You can define quality codes to annotate the quality of each value in the data table. Each quality attribute consists of a numerical code and a brief description. For information about assigning quality codes to specific data values, see “Assigning Quality Codes to Data” on page 5-36.

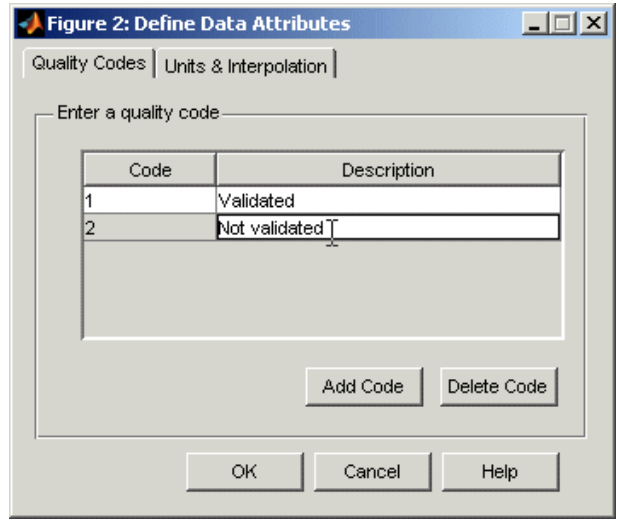
Tip To save time, first define the quality attribute that applies to most of your data values. It is automatically assigned to all data values. Then, define the attributes that occur less frequently and set them manually in the **Quality** column of the data table.

---

1. In the Define Data Attributes dialog box, click the **Quality Codes** tab.
2. Click the **Add Code** button. This adds an empty row in the Quality Codes table.
3. Click the empty cell in the **Code** column and type an integer from 0 to 127.
4. Press the **Tab** key. This highlights the cell in the **Description**. Type one or two words that briefly describe the numerical code, such as `Validated`.

5 To add another quality code, repeat steps 2 to 4. Or click **OK** to close the dialog box. This also assigns the first quality code you defined to all data values in the table.

The following figure shows two quality codes: `Validated` and `Not validated`.

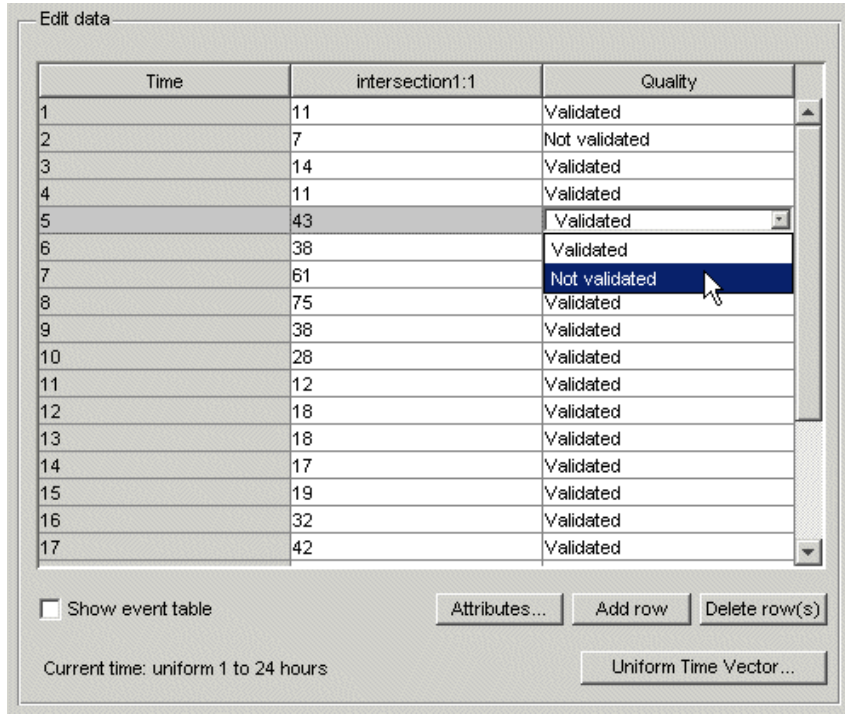


Note To delete a quality attribute, select it and click **Delete Code**.

Assigning Quality Codes to Data

After you define quality codes, as described in "Quality Codes" on page 5-35, the quality code you defined first is automatically assigned to all data values in the data table. For information about displaying the data table, see "Displaying the Data Table" on page 5-31.

To assign a different quality code to a specific data value, click the corresponding cell in the **Quality** column and select a different value from the drop-down list.



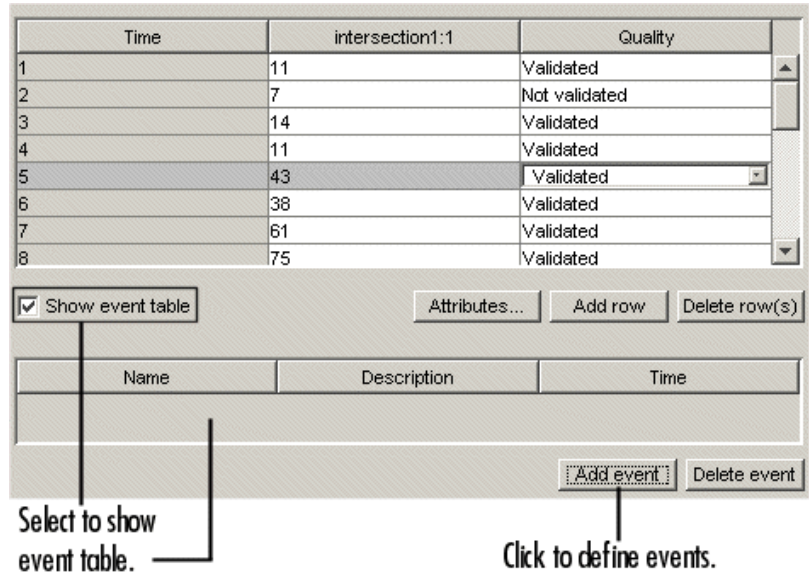
Defining Events

Events are stored as metadata for each time series. Time series events mark the data at a specific time in the data table and on a plot. For information about displaying the data table, see “Displaying the Data Table” on page 5-31.

You can also use events as reference points when shifting time series in time. For more information about synchronizing time series, see “Processing and Manipulating Time Series” on page 5-41.

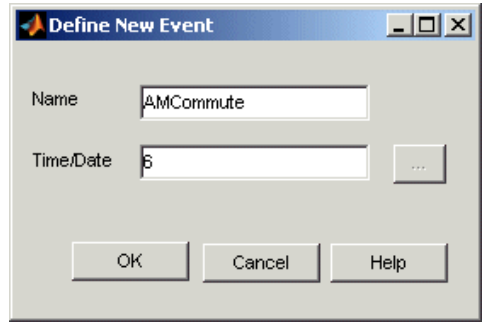
To define events for the selected time series:

1 Make sure that the **Show event table** check box is selected. This check box is located below the data table:



2 Click the **Add event** button below the event table. This opens the Define New Event dialog box.

3 In the **Name** field, enter the name of the event, such as `AMCommute`.

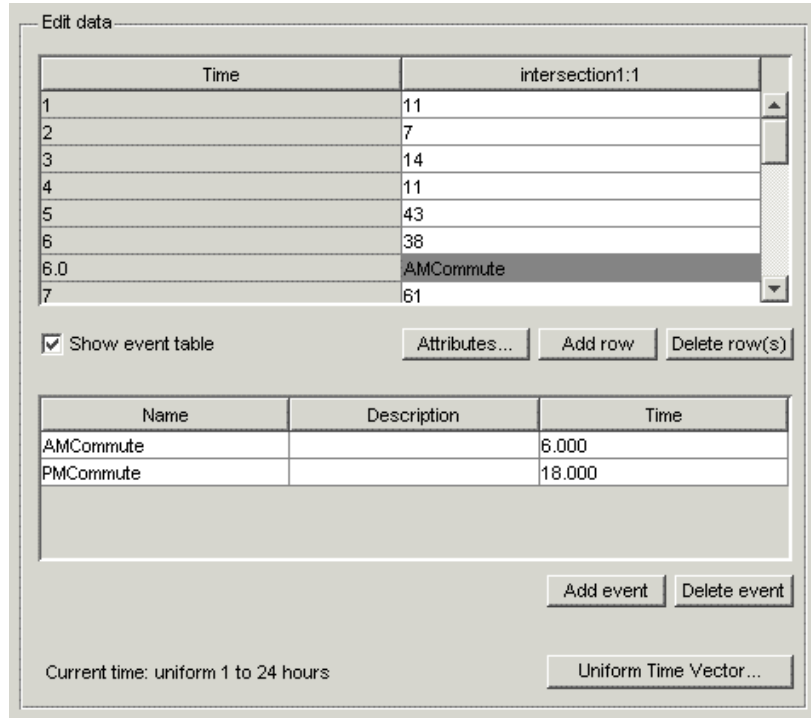


4 In the **Time/Date** field, enter or edit the time of the event in the appropriate display format. For information about time-vector formats, see “Time Vector Format” on page 4-21.

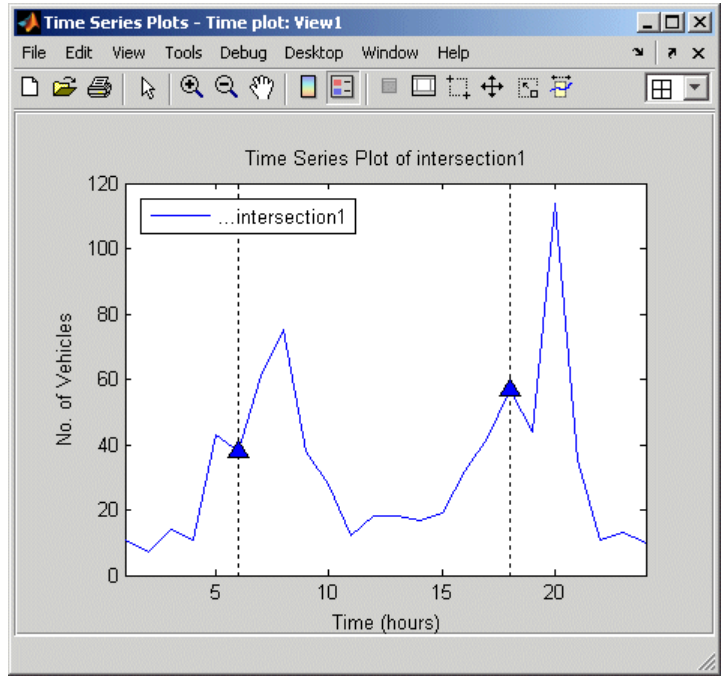
Tip To facilitate entering a date string, click the ... (**Browse**) button to open the Specify Date/Time dialog box. Select the month, year, and day. Then enter the **Time** in HH:MM:SS format.

5 Click **OK**.

The following figure shows two events in the event table: `AMCommute` and `PMCommute`. The data table also contains both events and `AMCommute` is shown at 6.0 hours.



Events are displayed as markers on time series plots. The following figure shows the `AMCommute` marker (at 6.0 hours) and `PMCommute` marker (at 18.0 hours) on a time plot.



Time Plot with Event Markers

Processing and Manipulating Time Series

The following table summarizes the operations you can perform on individual time series or time series collection. These commands are available from the **Data** menu in Time Series Tools after you select a time series or collection node in the Time Series Session tree.

Note If you are viewing a time plot, these operations are available by right-clicking inside the time plot and selecting a command from the shortcut menu. For more information about plotting data, see "Plotting Time Series" on page 5-13.

Each command opens a dialog box where you can get detailed instructions by clicking the **Help** button.

Data Analysis Commands

Command	Description
Data > Remove Missing Data	Delete the times that contain missing data.
Data > Detrend	Subtract a constant or a linear trend from the data.
Data > Filter	Smooth and shape the time series data.
Data > Interpolate	Interpolate missing values.
Data > Resample	Select or interpolate data values using a specified time vector.
Data > Transform Algebraically	Create a new time series by algebraically manipulating existing time series. This command is available only when you select an individual time series in the tree.
Data > Descriptive Statistics	Get summary statistics for each time series.

Example — Time Series Tools

In this section...

Loading Data into the MATLAB Workspace

Type the following command at the MATLAB prompt to load the hourly traffic counts at three road intersections, collected over a 24-hour period:

```
load count.dat
```

This adds the variable `count` to the MATLAB workspace.

Starting Time Series Tools

To start Time Series Tools, type

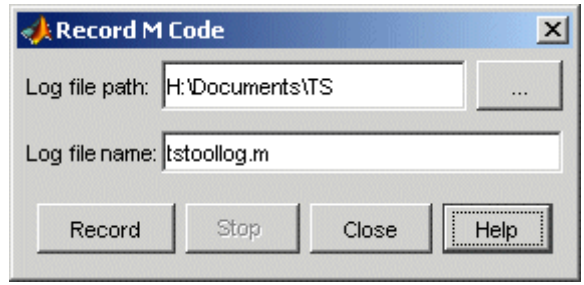
```
tstool
```

This opens the Time Series Tools window. For more information about this GUI, see "Time Series Tools Window" on page 5-3.

Enabling M-Code Generation

In this portion of the example, you will enable automatic M-code generation in Time Series Tools to capture reusable M-code as a MATLAB function.

1 In the Time Series Tools window, select **File > Record M-Code**. This opens the Record M-Code dialog box.



2 Click the ... button and select the folder where you want to store the M-file.

3 In the **Log file name** field, either select the name of a recently used file, or type a new name. The file name creates the function name you call in your M-code to reuse this function.

4 To begin capturing M-code, click **Record**. The M-code is recorded until you stop recording, as described in "Viewing Generated M-Code" on page 5-55.

Tip You can close this dialog box without interrupting the recording operation by clicking **Close**. To reopen the dialog box, select **File > Record M-Code** in the Time Series Tools window.

Note The scope of the **Record M-Code** feature is restricted to recording actions on the time series data itself. It does not generate code to import data or reproduce time series plots.

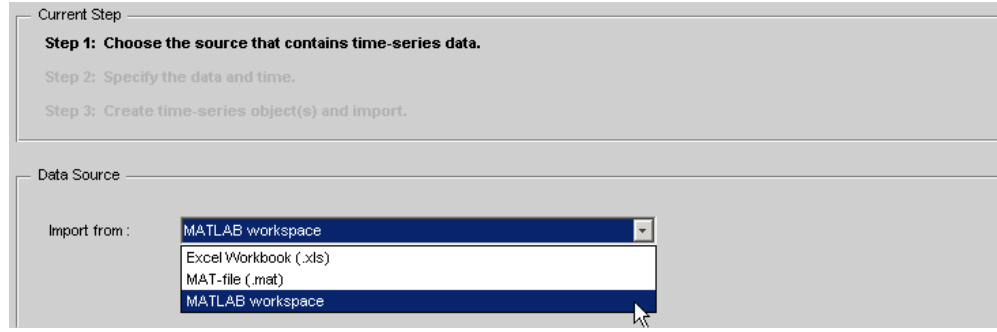
Importing Data into Time Series Tools

This portion of the example shows how to create three time series from the 24-by-3 count array you loaded into the MATLAB workspace.

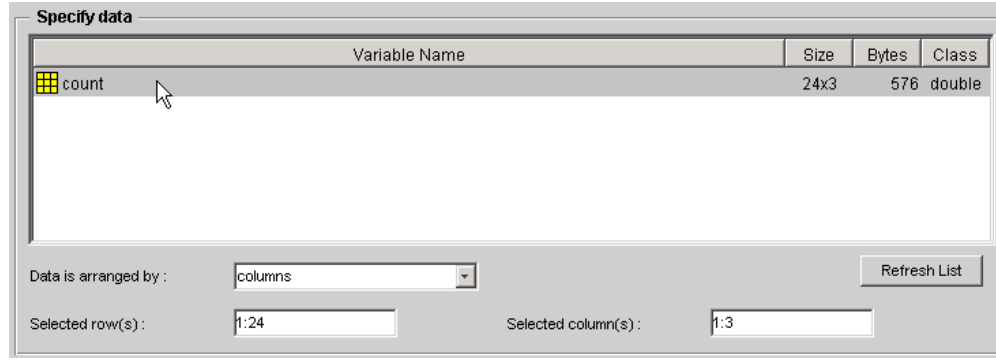
Note To get help on a specific field in the Import Wizard, right-click the field label and select **What's This** from the shortcut menu.

1 In the Time Series Tools window, select **File > Import from Workspace > Array Data**. This opens the Import Wizard.

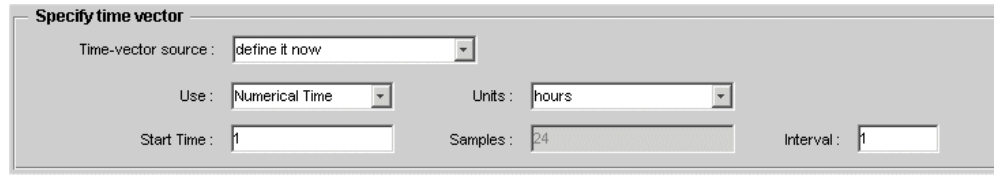
2 In the **Import from** list, select **MATLAB workspace** and click **Next**.



3 In **Step 2** of the Import Wizard, select the `count` variable. The Import Wizard infers from the data that it is arranged in columns.

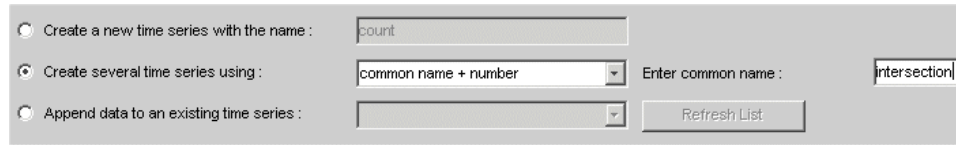


4 In the **Specify Time Vector** area, select `hours` from the **Units** list. In the **Start Time** field, type `1` to start the time vector at 1 hour. The Import Wizard has already filled in the remaining options to define a uniformly spaced time vector with a length of `24` and an interval of `1`.

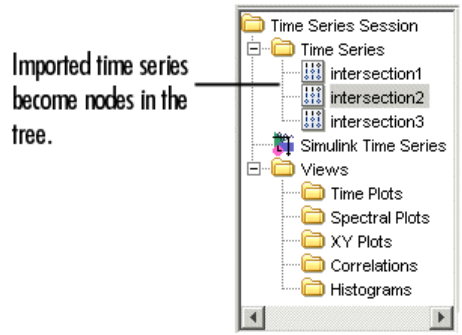


5 Click **Next**.

6 In **Step 3** of the Import Wizard, select **Create several time series using:** `common name+number`. In the **Enter common name** field, type `intersection`.



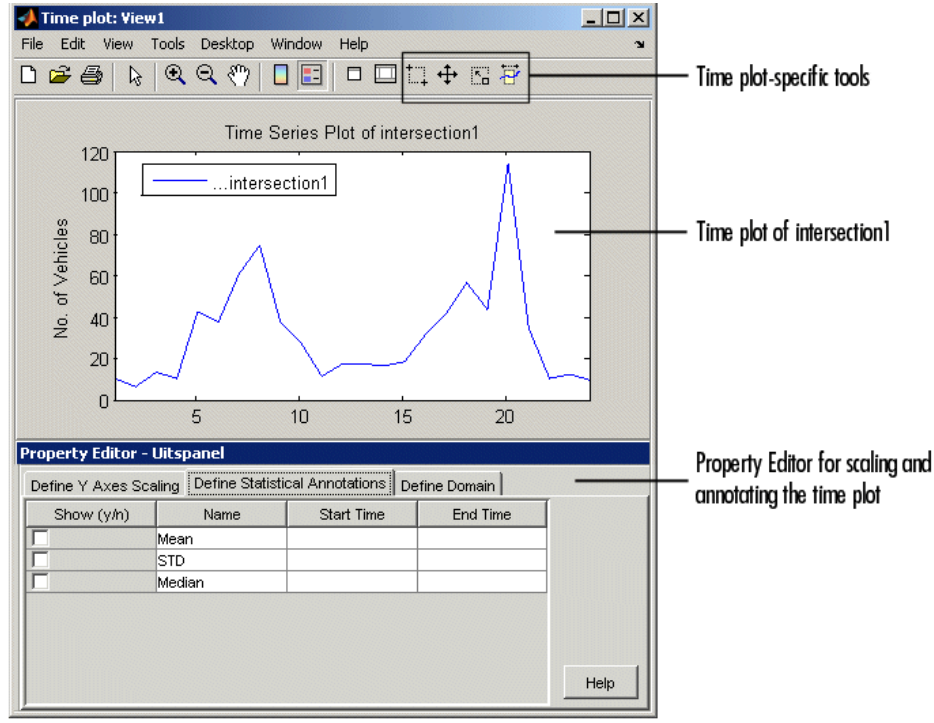
7 Click **Finish**. This adds three time series to the Time Series Session tree: `intersection1`, `intersection2`, and `intersection3` (as shown below).



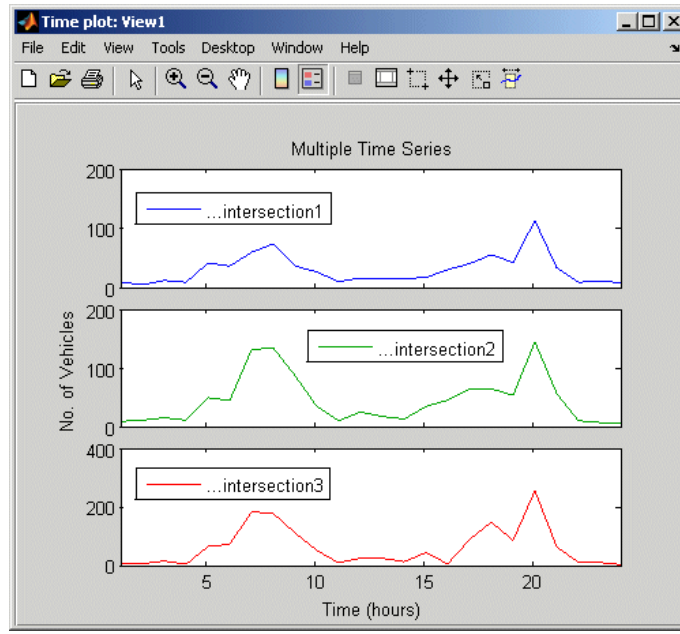
Creating a Time Plot

To explore the data, you can create a time plot of the three time series in the Time Series Tools window.

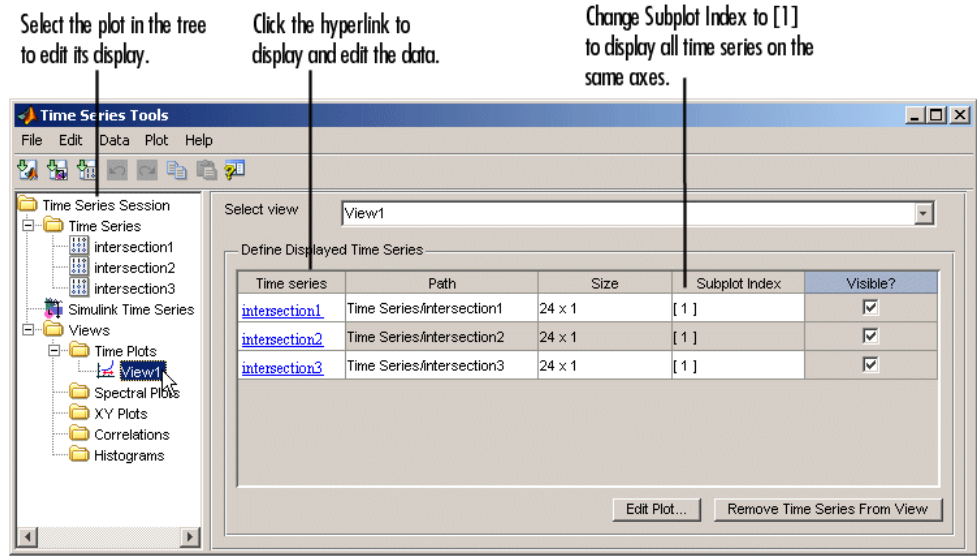
1 In the **Time Series Session** tree, drag and drop the `intersection1` time series into the **Time Plots** node. This creates a time plot in a new window with the default name **View1**.



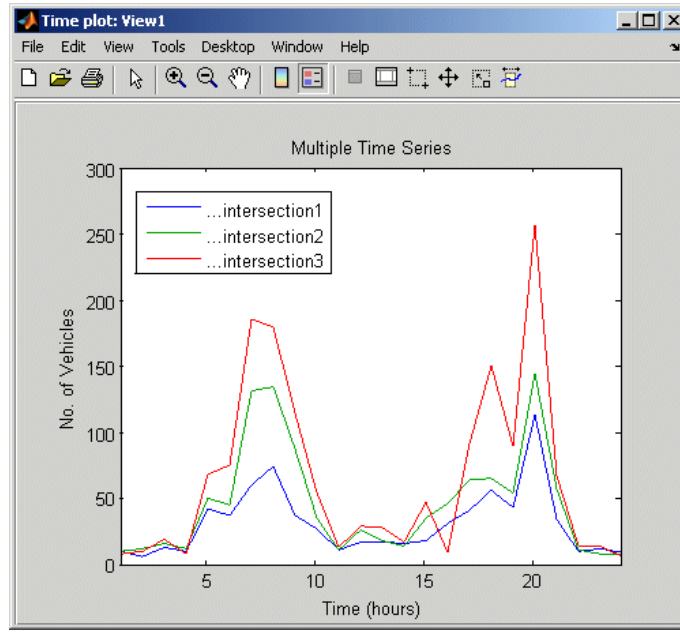
2 In the **Time Series Session** tree, drag and drop the `intersection2` and `intersection3` time series into **View1** to add them to the plot.



3 To display all three time series on the same axes, click the **View1** node in the Time Series Tools window. Change the subplot indices for `intersection2` and `intersection3` to `[1]` and press **Enter**.

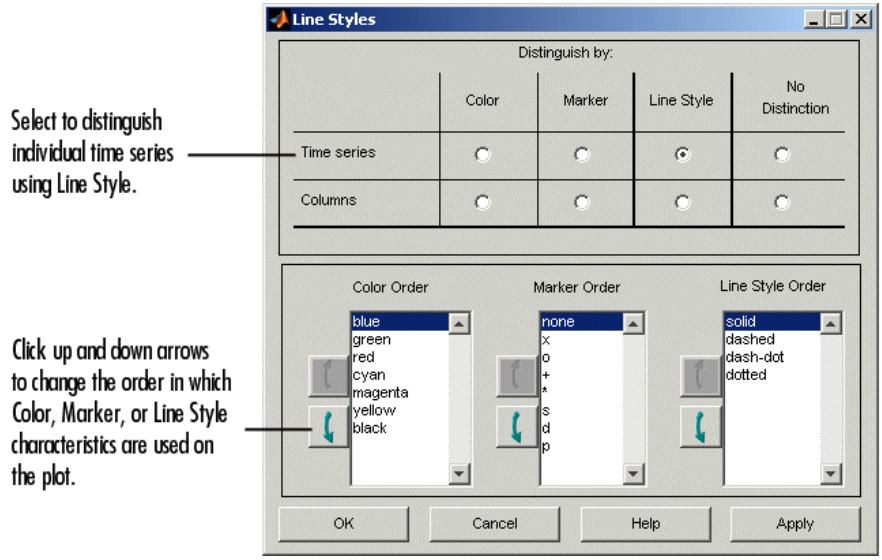


This displays all time series on the same axes, as follows:

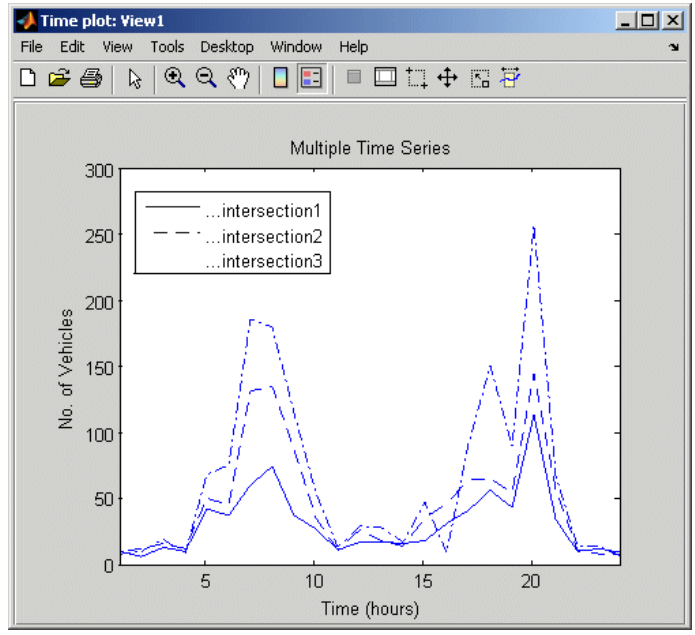


4 To change the appearance of the time series in the plot, go to the main Time Series Tools window and select **Plot > Set Line Properties**. This opens the Line Styles dialog box.

5 In the Line Styles dialog box, click **Line Style** to distinguish the time series, shown as follows.



The plot now looks like this.



Resampling Time Series

You can select or interpolate time series data using a specified time vector. When the new time vector contains time values that are not present in the original time vector, the intermediate data values are calculated using the interpolation method you associated with this time series. Linear interpolation is used by default. For more information about specifying the interpolation method, see “Defining Data Attributes” on page 5-34.

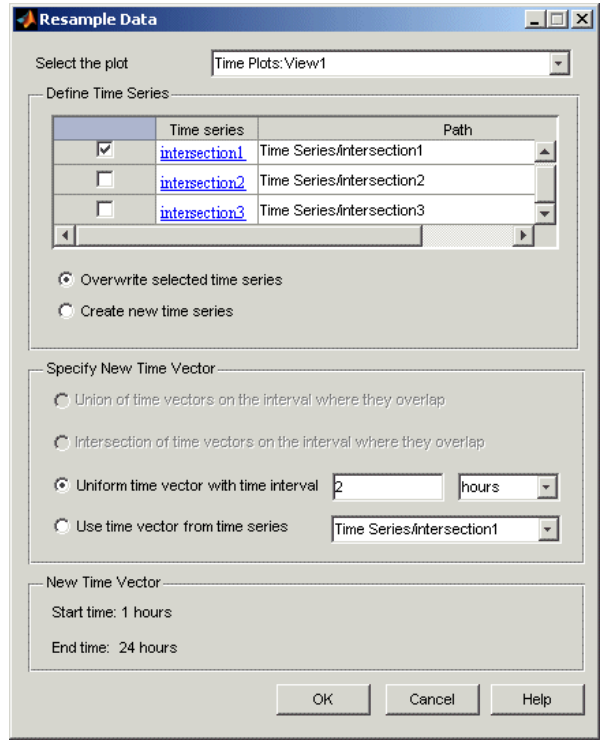
This portion of the example shows

Note You can only resample one time series at a time.

Resampling on a Uniform Time Vector

First, you resample the time series `intersection1` to include values every 2 hours.

1 Right-click inside the time plot you created in “Creating a Time Plot” on page 5-46 and select **Resample Data** from the shortcut menu. This opens the Resample Data dialog box.



2 In the **Define Time Series** area, select only `intersection1` and clear the rest.

3 In the **Specify New Time Vector** area, click **Uniform time vector with time interval** and specify the time interval as 2 hours. Click **OK**.

Tip To verify that `intersection1` is resampled, select it in the **Time Series Session** tree and examine the data table. It should have a time vector that starts at 1 hour and increases in increments of 2 hours.

Resampling by Finding a Common Time Vector

In some cases, you might want one time series to have the same time vector as another time series on the overlapping region of time values. This is especially useful when you want a specific time series to inherit a nonuniformly spaced time vector.

In this example, you resample `intersection2` on the same time vector as `intersection1`.

1. Right-click inside the time plot you created in "Creating a Time Plot" on page 5-46 and select **Resample Data** from the shortcut menu. This opens the Resample Data dialog box.

2. In the **Define Time Series** area, select only `intersection2` and clear the rest.

3. In the **Specify New Time Vector** area, click **Use time vector from time series** and select `intersection1` from the list. Click **OK**.

To verify that `intersection2` is resampled, select it in the **Time Series Session** tree and examine the data table. It should have a time vector that starts at 1 hour and increases in increments of 2 hours.

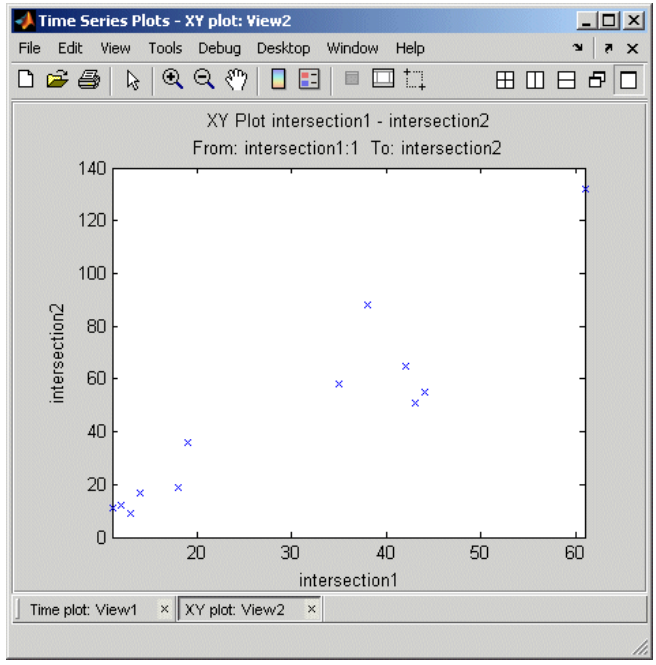
Comparing Data on an *XY* Plot

The *XY* plot is useful for visually determining a relationship between the data values of time series at corresponding times. For example, when the points on an *XY* plot form a straight line, there is a linear relationship between the two time series.

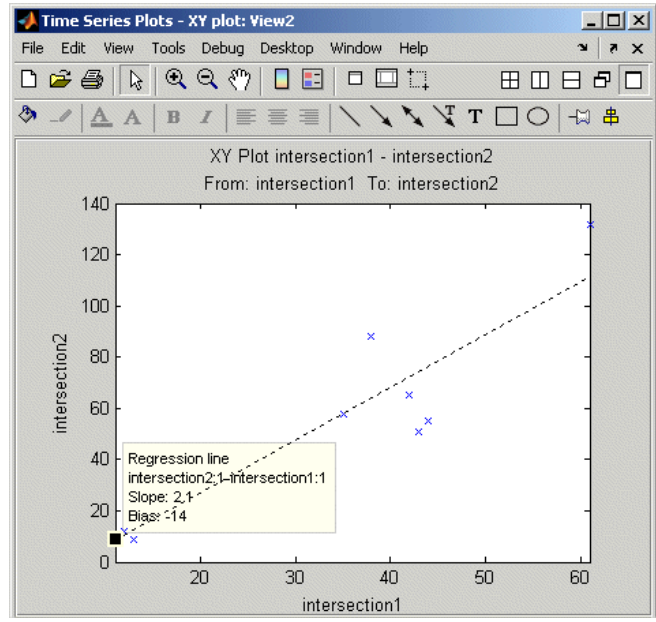
In this portion of the example, you examine the relationship between the corresponding data values of `intersection1` and `intersection2` by using an *XY* plot.

1. In the Time Series Session tree, drag and drop the **intersection1** time series into the **XY Plots** node. This creates a new plot node with the default name **View2**.

2 Drag and drop the **intersection2** time series into the **View2** node. This creates the following *XY* plot.



3 To show the best-fit line on the *XY* plot, click the **Define Statistical Annotations** tab in the Property Editor and select the **Best fit line** check box. Then, click the line to display the line equation on the plot.



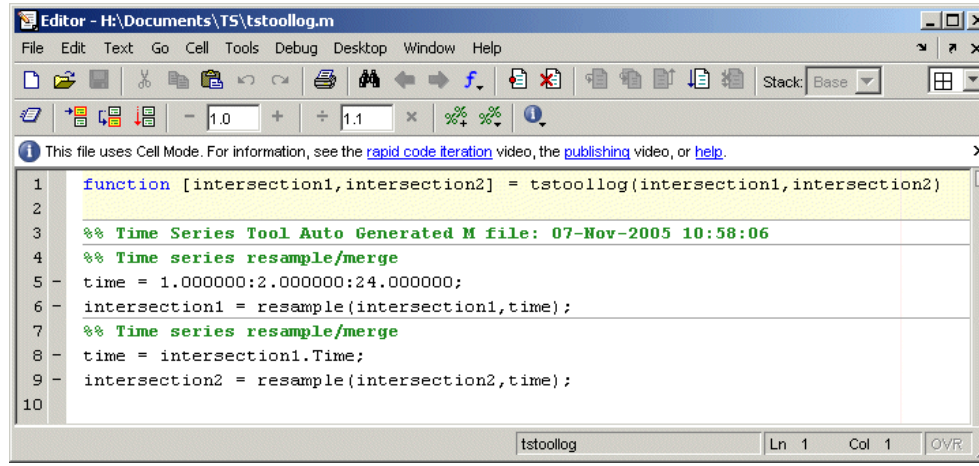
Viewing Generated M-Code

You can now view the M-code that Time Series Tools generated while you performed the previous steps in this example.

To view the M-file:

1 In the Time Series Tools window, select **File > Record M-Code** to open the Record M-Code dialog box.

2 Click **Stop** to open the M-file with the generated M-code in the MATLAB Editor.



Automatically Generated M-Code

You can reuse this M-code by calling the `tstoollog` function, which has the same name as this M-file. You specified the file name when you enabled M-code generation in this example, as described in “Enabling M-Code Generation” on page 5-42.

Examine the code of the `tstoollog` function to confirm that it takes two time series as input arguments and resamples them using a uniform time vector with the range 1 to 24 and intervals of 2.

Note The scope of the **Record M-Code** feature is restricted to recording actions on the time series data itself. It does not generate code to import data or reproduce time series plots.

Exporting Time Series to the Workspace

You can export individual time series, as well as time series collections, from Time Series Tools to the MATLAB workspace. You can also export time series to a Microsoft Excel worksheet or a MAT-file.

In this portion of the example, you will export the time series `intersection1` as a variable to the MATLAB workspace. This time series differs from the original data you imported into Time Series Tools because it has been resampled, as described in "Resampling Time Series" on page 5-51.

1. Click the **interesection1** node in the Time Series Session tree to select it.
2. Select **File > Export > To Workspace**. The variable `intersection1` is now listed in the MATLAB workspace.

Note If the MATLAB workspace is hidden, select **Desktop > Workspace** from the MATLAB window to display it.

Startup and Shutdown

This set of topics includes options for customizing the startup and shutdown.

Starting MATLAB on Windows Platforms (p. 1-2)	Ways to start MATLAB®, including from a desktop icon, or from a file in Windows Explorer. Associating file types with MATLAB.
Starting MATLAB on UNIX Platforms (p. 1-6)	MATLAB startup on UNIX.
Starting MATLAB on Macintosh Platforms (p. 1-7)	Ways to start MATLAB on a Macintosh, including from a MATLAB file type in the Finder.
Startup Directory for MATLAB (p. 1-8)	Ways to change the directory in which MATLAB starts.
Startup Options (p. 1-12)	Instruct MATLAB to perform operations upon startup via a `startup` file or the `matlab` function.
Toolbox Path Caching in MATLAB (p. 1-17)	About the cache file and updating the cache file.
Other Startup Topics (p. 1-21)	Error Log Reporter, passing Perl variables, and calling Java from MATLAB.
Quitting MATLAB (p. 1-23)	End a MATLAB session. Instruct MATLAB to perform specified operations upon shutdown.

Starting MATLAB on Windows Platforms

In this section...

Starting MATLAB from the Windows Desktop or a DOS Window

To start MATLAB on a Microsoft Windows platform, select the **Start > Programs > MATLAB > R2007b > MATLAB R2007b**, or double-click the MATLAB R2007b shortcut icon on your Windows desktop. The shortcut was automatically created when you installed MATLAB. If you have trouble starting MATLAB, see troubleshooting information in the Installation Guide for Windows.

To start MATLAB from a DOS window, `cd` to the directory in which you want to start MATLAB and type `matlab` at the DOS prompt.

After starting MATLAB, the desktop opens. Desktop components that were open when you last shut down MATLAB will be opened on startup. For more information, see Chapter 2, "Desktop".

Starting MATLAB from an M-File or Other File Type in Windows

On Windows platforms, you can start MATLAB from a Windows Explorer window by double-clicking a file with one of these extensions: `.fig`, `.m`, `.mat`, and `.mdl`. MATLAB starts and opens in an appropriate tool. If MATLAB is already running, the file opens in an appropriate tool in the existing session.

This startup feature is based on your Windows file type associations. When you installed MATLAB for Windows, you specified the file types to

associate with MATLAB. For example, if you accepted the default options, double-clicking an M-file in Windows Explorer opens the file in the MATLAB Editor/Debugger.

Other default options associate MEX-files and P-files with MATLAB in Windows Explorer, which assigns the file types a MATLAB icon. However, double-clicking a file with a `.mex` (`.mexw32` or `.mexw64`), or `.p` extension does not run or open the file in MATLAB.

File Type and Resulting Action

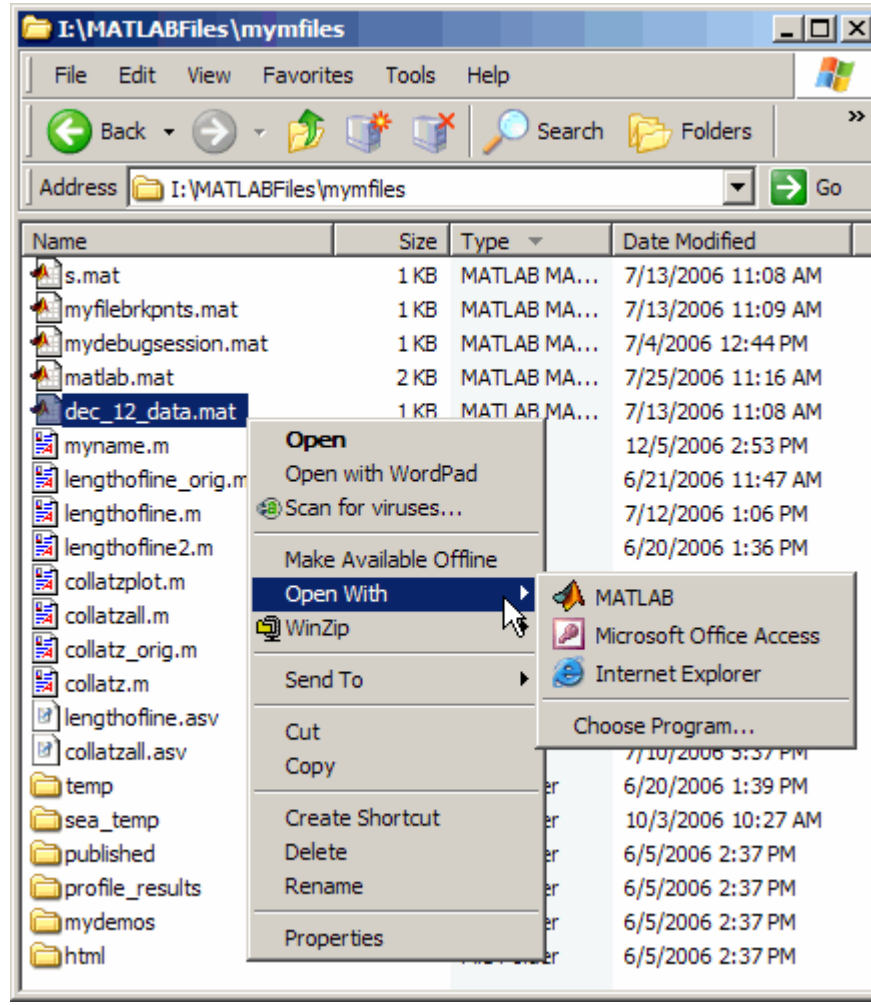
File Type	Result
FIG-file	Opens file in figure window
M-file	Opens file in Editor/Debugger
MAT-file	Opens Import Wizard to load the data into the MATLAB workspace
MDL-file	Opens file in Simulink® model window
MEX-file	Displays MATLAB icon in Windows Explorer
P-file	Displays MATLAB icon in Windows Explorer

Other applications you use can change Windows file associations. For example, Microsoft Access might associate files having a `.mat` extension. Then, double-clicking a MAT-file opens Access rather than MATLAB.

If you double-click a FIG-file, M-file, MAT-file, or MDL-file and it does not open in MATLAB, try this instead:

1. In Windows Explorer, right-click a file with one of the extensions listed in the preceding table, for example, `myfile.mat`.
2. From the context menu, select **Open With**. If MATLAB is one of the choices, select it to open `myfile.mat` in MATLAB. If MATLAB is not one of the choices, you will need to associate the file type with MATLAB using one of these techniques:
   - “Utility to Change Windows File Associations” on page 1-5
   - “Changing File Associations for MATLAB from Windows” on page 1-5

After associating a file type with MATLAB, you can open other applications using that file type via the context menu. For example, right-click `myfile.mat`, and from the context menu, select **Open With**. Microsoft Access will be one of the options.



File associations for Windows Explorer do not affect what happens when you open one of these file types from *within* MATLAB. MATLAB acts on the file

using the MATLAB tool associated with that file type. For example, even if you associate `.mat` files with Microsoft Access, when you open a MAT-file from within MATLAB, it opens the Import Wizard to load the data.

Utility to Change Windows File Associations

If you are viewing this topic in the MATLAB Help browser, you can run one of the utilities provided here to create Windows associations for common MATLAB file types. This requires you to have permission to write to the `HKEY_CLASSES_ROOT` registry key, which typically requires power user or administrator privileges.

- Run utility to associate MATLAB with FIG-files
- Run utility to associate MATLAB with M-files
- Run utility to associate MATLAB with MAT-files
- Run utility to associate MATLAB with MDL-files
- Run utility to associate MATLAB with MEX-files
- Run utility to associate MATLAB with P-files
- Run utility to associate MATLAB with all of these file types: FIG, M, MAT, MDL. MEX, and P

The file type icon in Windows Explorer might not reflect the change immediately.

Changing File Associations for MATLAB from Windows

You can associate file types with MATLAB from Windows Explorer. This is useful if you want associate file types other than those offered by the above utilities. For example, you can double-click `.xml` files to open them in the MATLAB Editor/Debugger.

The following examples show one way to change file associations in Windows. Note that these instructions might not exactly apply to your version of Windows. If you encounter differences or problems, try to delete the association before using these instructions, or see your Windows documentation.

Assume that when you double-click a `.mat` file in Windows Explorer, it opens in Microsoft Access, but you want the file to open in MATLAB.

1. In Windows Explorer, select **Tools > Folder Options**.
2. In the resulting Folder Options dialog box, select the **File Types** tab. From the **Registered file types** list, select the `MAT` extension. (If you do not see `MAT` in the list, click **New** to add it.)

   Under **Details for 'MAT' extension**, click **Change**.
3. In the resulting Open With dialog box, select `MATLAB` from the list.

   If MATLAB is not listed, click **Browse**. Then look for and select `matlab.exe`, and click **Open**. The file is located in the folder in which you installed MATLAB. An example of the default location is `C:\Program Files\MATLAB\R2007b\bin`.
4. In the Open With dialog box, click **OK**. In the Folder Options dialog box, click **Close**.

Starting MATLAB on UNIX Platforms

To start MATLAB on a UNIX platform, type `MATLAB` at the operating system prompt.

If you did not set up symbolic links in the installation procedure, you must enter the full pathname to start MATLAB, *`matlabroot`*`/bin/matlab`, where *`matlabroot`* is the name of your MATLAB installation directory. If you have trouble starting MATLAB, see troubleshooting information in the Installation Guide for UNIX.

After starting MATLAB, the desktop opens. Desktop components that were open when you last shut down MATLAB will be opened on startup. For more information, see Chapter 2, "Desktop". If the `DISPLAY` environment variable is not set or is invalid, the desktop will not display.

Starting MATLAB on Macintosh Platforms

In this section...

Starting MATLAB from the Macintosh Desktop

To start MATLAB on Macintosh platforms, double-click the MATLAB icon on the desktop. If there isn't a MATLAB icon on the desktop, you can find it in the MATLAB folder within the Applications folder. MATLAB starts, assuming you accepted the defaults for the license manager to automatically start at system startup.

Note On Macintosh systems, you cannot perform a remote login, that is, you cannot run MATLAB remotely. For example, you cannot `rlogin`.

Starting MATLAB from an M-File or Other File Type on Macintosh Platforms

On Macintosh platforms, you can start MATLAB from the Finder by double-clicking a file with one of these extensions: `.fig`, `.m`, `.mat`, and `.mdl`. MATLAB starts and opens in an appropriate tool. If MATLAB is already running, the file opens in an appropriate tool in the existing session—see File Type and Resulting Action on page 1-3.

Startup Directory for MATLAB

In this section...

What Is the Startup Directory?

The *startup directory* is the current directory in MATLAB when it starts. The default startup directory depends on your platform and installation. You can specify a different startup directory.

Startup Directory (Folder) on Windows Platforms

When you start MATLAB from a Windows shortcut icon, MATLAB sets the default startup directory to `My Documents\MATLAB` or `Documents\MATLAB` on Vista. This is a location where you can conveniently work with your personal MATLAB files. It offers these features:

- Because the `MATLAB` subfolder is the default startup directory, the current directory is automatically the one containing the files your work with.
- So that the files you work with are on the search path, MATLAB automatically adds the `MATLAB` subfolder to the top of the search path upon startup. If the `MATLAB` subfolder does not exist, MATLAB creates it.
- This location also utilizes the benefits provided by the Windows (or Vista) standard location for storing personal files, `My Documents` (or `Documents`). Files in the `MATLAB` subfolder are available to you when you use other machines, if your profile is set to roam. Because each user has their own `My Documents` or `Documents` folder, other users, even those using your machine, cannot access files in your `MATLAB` subfolder.
- When you upgrade to a newer version of MATLAB, MATLAB automatically continues to use the same `MATLAB` subfolder and your existing files, with all of the above benefits.

Startup Directory on UNIX Platforms

On UNIX platforms, the default startup directory is the directory you are in on your UNIX file system when you start MATLAB, for example, `/home/$user/matlab`. MATLAB automatically adds this `matlab` directory to the top of the MATLAB search path upon startup.

Changing the Startup Directory

You can start MATLAB in a directory other than the default.

For Windows Platforms Only

To change the startup directory on Windows platforms,

1. Right-click the MATLAB shortcut icon and select **Properties** from the context menu.

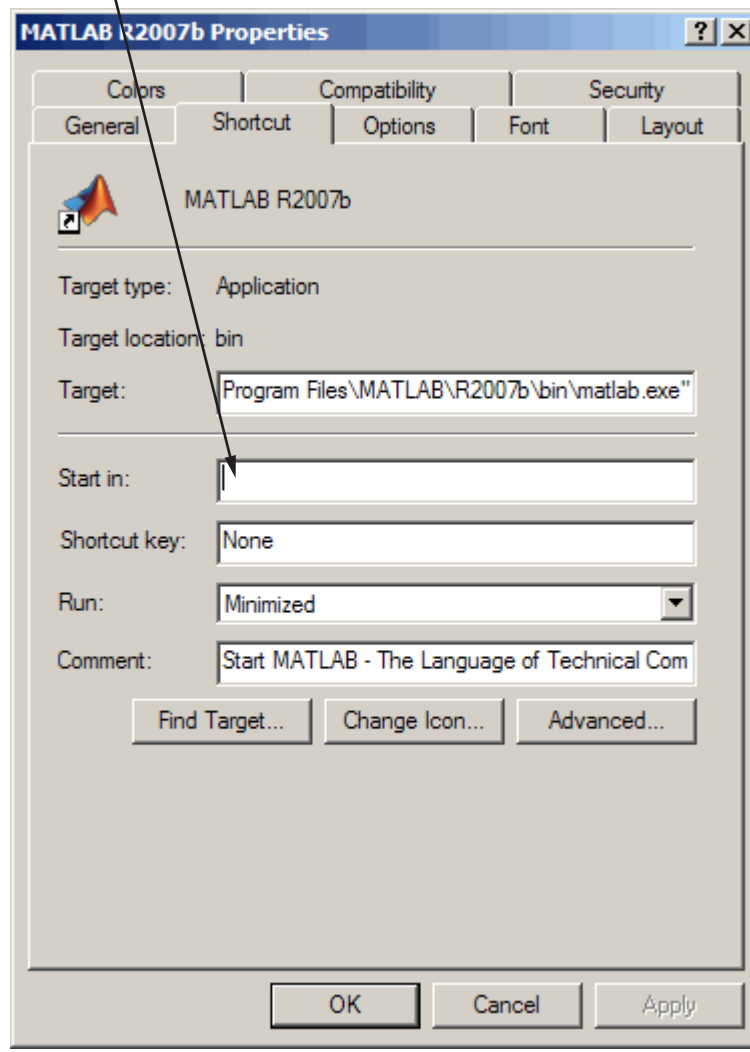
   The Properties dialog box for MATLAB opens to the **Shortcut** pane.

2. The **Target** field contains the full path to start MATLAB.

   By default, the startup directory is `My Documents\MATLAB` or `Documents\MATLAB` on Vista; for more information, see “Startup Directory (Folder) on Windows Platforms” on page 1-8.

   In the **Start in** field, specify the full path to the directory in which you want MATLAB to start, and click **OK**.

In the **Start in** field, enter the full path to the directory in which you want MATLAB to the start. For example, `I:\my_matlab_files`.



The next time you start MATLAB using that shortcut icon, the current directory will be the one you specified in step 2.

You can make multiple shortcuts to start MATLAB, each with its own startup directory, and with each startup directory having different startup options.

For All Platforms

To change the startup directory,

1. Create a `startup.m` file — see "Using the Startup File for MATLAB, startup.m" on page 1-12.
2. In the `startup.m` file, include the `cd` function to change to the new directory.
3. Put the `startup.m` file in the default startup directory for your platform, as noted in "Startup Directory (Folder) on Windows Platforms" on page 1-8 or "Startup Directory on UNIX Platforms" on page 1-9. Alternatively, put `startup.m` in the current startup directory.

Startup Options

In this section...

About Startup Options

You can define startup options that instruct MATLAB to perform certain operations when you start it. You specify these options using a startup file (`startup.m`) or as options to the `matlab` startup command.

Using the Startup File for MATLAB, startup.m

At startup, MATLAB automatically executes the master M-file `matlabrc.m` and, if it exists, `startup.m`. The file `matlabrc.m`, which is in the *`matlabroot`*`/toolbox/local` directory, is reserved for use by The MathWorks and by the system manager on multiuser systems.

The file `startup.m` is for you to specify startup options. For example, you can modify the default search path, predefine variables in your workspace, or define Handle Graphics® defaults. Creating a `startup.m` file with the lines

```
addpath /home/$user/mytools
cd /home/$user/mytools
```

adds `/home/`*`$user`*`/mytools` to your default search path and makes `mytools` the current directory upon startup.

Location of startup.m

Place the `startup.m` file in the default or current startup directory, which is where MATLAB first looks for it. For more information, see "Startup Directory for MATLAB" on page 1-8.

Adding Startup Options for Windows Platforms

You can add selected startup options (also called command flags or switches for the command line) to the target path for your Windows shortcut for MATLAB. Or you can add them to the command line when you start MATLAB in a DOS window. On Windows systems a startup option is preceded by either a hyphen (-) or a slash (/). For example, `-nosplash` and `/nosplash` are equivalent ways of specifying the `nosplash` option for Windows users.

Startup Options in Windows Shortcut

To use startup options in the Windows shortcut for MATLAB, follow these steps:

1. Right-click the MATLAB shortcut icon and select **Properties** from the context menu. The Properties dialog box for MATLAB opens to the **Shortcut** pane.
2. In the **Target** field, after the target path for `matlab.exe`, add the startup option, and click **OK**. For example, adding `-r "filename"` runs the M-file `filename` after startup.

This example instructs MATLAB to automatically run the file `results` after startup, where `results.m` is in the startup directory or on the MATLAB search path. The statement in the **Target** field might appear as

```
C:\Program Files\MATLAB\bin\matlab.exe -r "results"
```

Include the statement in double quotation marks (`"`*`statement`*`"`). Use only the filename, not the file extension or pathname. For example, MATLAB produces an error when you run

```
... matlab.exe -r "D:\results.m"
```

Use semicolons or commas to separate multiple statements. This example changes the format to `short`, and then runs the M-file `results`:

```
... matlab.exe -r "format('short');results"
```

Separate multiple options with spaces. This example starts MATLAB without displaying the splash screen, and then runs the M-file `results`:

```
... matlab.exe -nosplash -r "results"
```

Startup Options in DOS Window

When you start MATLAB in a DOS window, include startup options after the `matlab` command.

This example uses the `nosplash` startup option to start MATLAB without the splash screen, and adds the `-r` option to run the `results` function located in the startup directory, after starting MATLAB in a DOS window:

```
matlab -nosplash -r "results"
```

Adding Startup Options for UNIX Platforms

Include startup options (also called command flags or command line switches) after the `matlab` command. On UNIX systems a startup option is preceded by a hyphen (-). For example, to start MATLAB without the splash screen, type

```
matlab -nosplash
```

Commonly Used Startup Options

The following table provides a list of some commonly used startup options for both Windows and UNIX platforms. For more information, including a complete list of startup options, see the `matlab (Windows)` reference page or the `matlab (UNIX)` reference page.

Platform	Option	Description
All	`-c licensefile`	Set `LM_LICENSE_FILE` to `licensefile`. It can have the form `port@host`.
All	`-h or -help`	Display startup options (without starting MATLAB).
All	`-logfile "logfilename"`	Automatically write output from MATLAB to the specified log file.

Platform	Option	Description
UNIX	`-nodesktop`	Start MATLAB without bringing up the MATLAB desktop. Use this option to run without an X-window, for example, in VT100 mode, or in batch processing mode. Note that if you pipe to MATLAB using the > constructor, the `nodesktop` option is used automatically. With `nodesktop`, you can still use most development environment tools by starting them via a function. For example, use `preferences` to open the Preferences dialog box and `helpbrowser` to open the Help browser. Do not use `nodesktop` to provide a command-line interface. If you prefer a command-line interface, select **Desktop > Desktop Layout > Command Window > Only**.
Windows	`-minimize`	Start MATLAB with the desktop minimized. Any desktop tools or documents that were undocked when MATLAB was last closed will not be minimized upon startup.
UNIX	`-nojvm`	Start MATLAB without loading the Java VM. This minimizes memory usage and improves initial startup speed, but restricts functionality. With `nojvm`, you cannot use the desktop, or any tools that require Java. For example, you cannot set preferences if you start MATLAB with the `-nojvm` option. However, you can start MATLAB once *without* the `-nojvm` option, set the preference, and quit MATLAB. MATLAB remembers that preference when you start it again, even if you use the `-nojvm` option.

Platform	Option	Description
All	`-nosplash`	Start MATLAB without displaying the MATLAB splash screen.
All	`-r "statement"`	Automatically run the specified MATLAB statement immediately after MATLAB starts. This is sometimes referred to as calling MATLAB in batch mode. Files you run must be in the MATLAB startup directory or on the MATLAB search path. Do not include pathnames or file extensions. Enclose the statement in double quotation marks (`"statement"`).

Toolbox Path Caching in MATLAB

In this section...

About Toolbox Path Caching

For performance reasons, MATLAB caches toolbox directory information across sessions. The caching features are mostly transparent to you. However, if MATLAB does not see the latest versions of your M-files or if you receive warnings about the toolbox path cache, you might need to update the cache.

Using the Cache File Upon Startup

Upon startup, MATLAB gets information from a cache file to build the toolbox directory cache. Because of the cache file, startup is faster, especially if you run MATLAB from a network server or if you have many toolbox directories. When you end a session, MATLAB updates the cache file.

MATLAB does not use the cache file at startup if you clear the **Enable toolbox path cache** check box in **File > Preferences > General**. Instead, it creates the cache by reading from the operating system directories, which is slower than using the cache file.

Updating the Cache and Cache File

How the Toolbox Path Cache Works

MATLAB caches (essentially, stores in a known files list) the names and locations of files in *`matlabroot`*`/toolbox` directories. These directories are for MathWorks supplied files that should not change except for product installations and updates. Caching those directories provides better performance during a session because MATLAB does not actively monitor those directories.

We strongly recommend that you save any M-files you create and any MathWorks supplied M-files that you edit in a directory that is *not* in the *matlabroot*/toolbox directory tree. If you keep your files in *matlabroot*/toolbox directories, they may be overwritten when you install a new version of MATLAB.

When to Update the Cache

When you add files to *matlabroot*/toolbox directories, the cache and the cache file need to be updated. MATLAB updates the cache and cache file automatically when you install toolboxes or toolbox updates using the MATLAB installer. MATLAB also updates the cache and cache file automatically when you use MATLAB tools, such as when you save files from the MATLAB Editor/Debugger to *matlabroot*/toolbox directories.

When you add or remove files in *matlabroot*/toolbox directories by some other means, MATLAB might not recognize those changes. For example, when you

- Save new files in *matlabroot*/toolbox directories using an external editor
- Use operating system features and commands to add or remove files in *matlabroot*/toolbox directories

MATLAB displays this message:

```
Undefined function or variable
```

You need to update the cache so MATLAB will recognize the changes you made in *matlabroot*/toolbox directories.

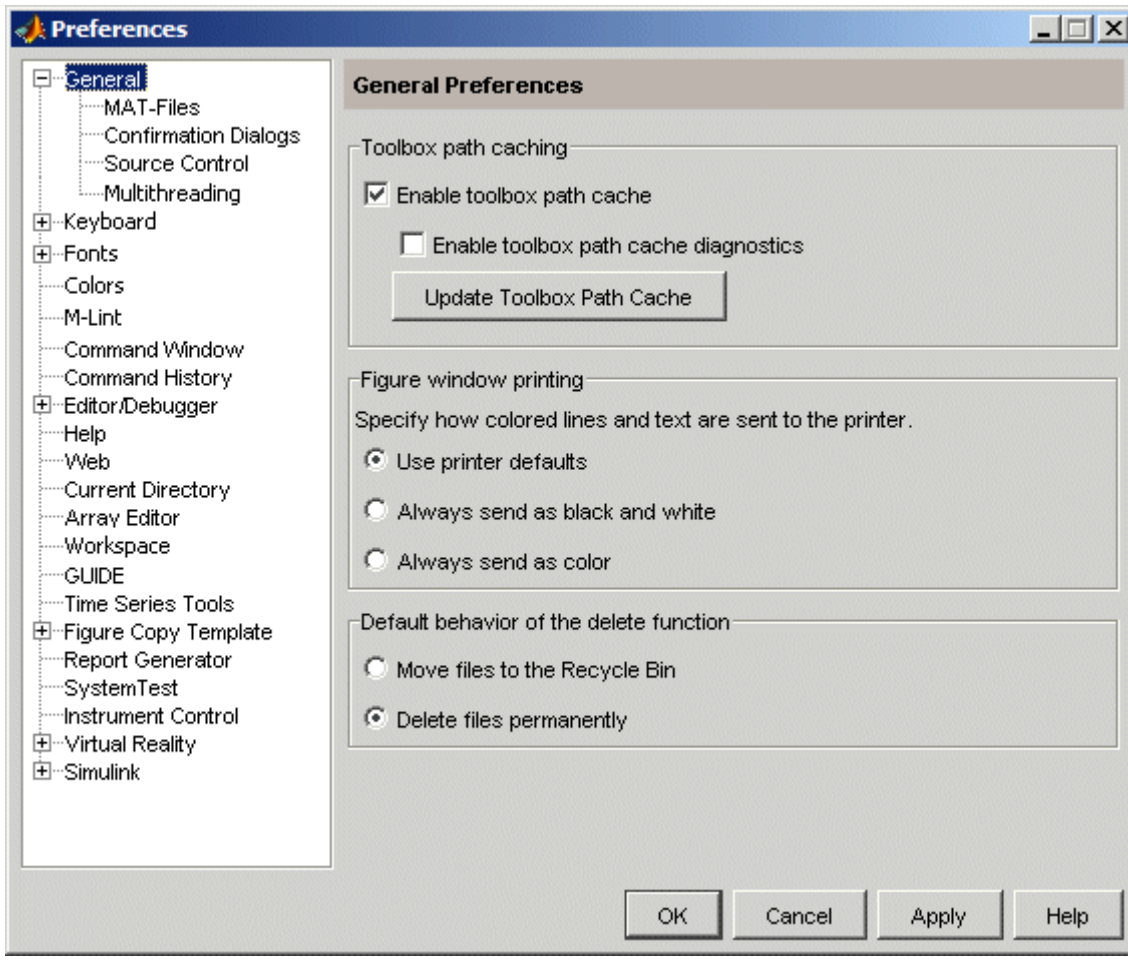
Steps to Update the Cache

To update the cache and the cache file,

1. Select **File > Preferences > General**.

   The **General Preferences** pane is displayed.

2. Click **Update Toolbox Path Cache** and click **OK**.



Function Alternative

To update the cache, use `rehash toolbox`. To also update the cache file, use `rehash toolboxcache`. For more information, see `rehash`.

Additional Diagnostics with Toolbox Path Caching

To display information about startup time when you start MATLAB, select the **Enable toolbox path cache diagnostics** check box in **General Preferences**.

Other Startup Topics

In this section...

Error Log Reporter

Upon startup, if MATLAB detects an error log generated by a serious problem encountered during the *previous* session, an Error Log Reporter prompts you to e-mail the log to The MathWorks for analysis. Click **Send Report** to e-mail the log, or click **Help** for more information. After sending the log, a confirmation message appears in the Command Window. For more information, see “Abnormal Termination” on page 1-24.

Passing Perl Variables on Startup

You can pass Perl variables to MATLAB on startup by using the `-r` option of the `matlab` function. For example, assume a MATLAB function `test` that takes one input variable:

```
function test(x)
```

To start MATLAB with the function `test`, use the command

```
matlab -r "test(10)"
```

On some platforms, you might need to use double quotation marks:

```
matlab -r "test(10)"
```

This command starts MATLAB and runs `test` with the input argument `10`.

To pass a Perl variable instead of a constant as the input parameter, follow these steps.

1 Create a Perl script such as

```
#!/usr/local/bin/perl
$val = 10;
system('matlab -r "test(' . ${val} . ')"');
```

2 Invoke the Perl script at the prompt using a Perl interpreter.

For more information, see the `matlab (Windows)` or `matlab (UNIX)` reference page.

Startup and Calling Java from MATLAB

When MATLAB starts, it constructs the Java class path using `librarypath.txt` as well as `classpath.txt`. If you call Java from MATLAB, see more about this in “The Java Class Path” and “Locating Native Method Libraries” in the MATLAB External Interfaces documentation.

Quitting MATLAB

In this section...

Ways to Quit MATLAB

To quit MATLAB at any time, do one of the following:

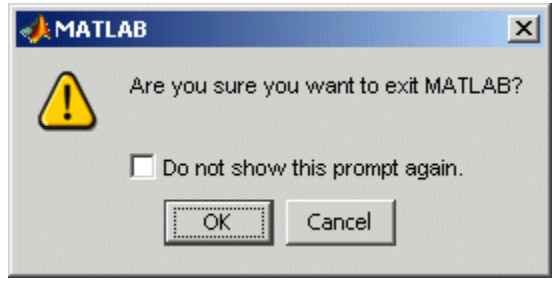
- Click the Close box in the MATLAB desktop.
- Select **Exit MATLAB** from the desktop **File** menu.
- Type `quit` at the Command Window prompt.

MATLAB closes after

- Prompting you to confirm quitting, if that preference is specified (see "Confirm Quitting MATLAB" on page 1-23)
- Prompting you to save any unsaved files
- Running the `finish.m` script, if it exists in the current directory or on the MATLAB path (see "Running a Script When Quitting MATLAB" on page 1-24)

Confirm Quitting MATLAB

To set a preference that displays a confirmation dialog box when you quit MATLAB, select **File > Preferences > General > Confirmation Dialogs**, select the **Confirm before quitting** check box, and click **OK**. MATLAB then displays the following dialog box when you quit.



For more information, see “Confirmation Dialogs Preferences” on page 2-81.

You can also display your own quitting confirmation dialog box using a `finish.m` script, as described in the following section.

Running a Script When Quitting MATLAB

When MATLAB quits, it runs the script `finish.m`, if `finish.m` exists in the current directory or anywhere on the MATLAB search path. You create the file `finish.m`. It contains statements to run when MATLAB terminates, such as saving the workspace or displaying a confirmation dialog box. There are two sample files in *`matlabroot`*`/toolbox/local` that you can use as the basis for your own `finish.m` file:

- `finishsav.m` — Includes a `save` function so the workspace is saved to a MAT-file when MATLAB quits.
- `finishdlg.m` — Displays a confirmation dialog box that allows you to cancel quitting.

For more information, see the `finish` reference page.

Abnormal Termination

In the event MATLAB experiences a segmentation violation (segv) or another serious problem, save your files and workspace if possible, exit MATLAB, and restart.

Upon startup, if MATLAB detects an error log generated by a serious problem during the *previous* session, an Error Log Reporter prompts you to e-mail the log to The MathWorks for analysis. If the problem occurs repeatedly,

make note of what seems to cause it and look for information about it in the MathWorks Bug Reports database.

There are some situations where the Error Log Reporter will not open, for example, when you start MATLAB with a `-r` option or run in deployed mode. If you experience segmentation violations but do not see the Error Log Reporter on subsequent startups, you can instead e-mail the reports by following the instructions at the end of the segmentation violation message in the Command Window.

Crash Recovery and Multithreading

When multithreaded computation is enabled, if MATLAB experiences a segmentation violation or other serious problem, it cannot try to return control to the Command Window. You do not have an opportunity to view a segmentation violation message in the Command Window as you might when multithreaded computation is *not* enabled. Instead, your platform's vendor, for example, Microsoft or Apple, provides an error dialog box. MATLAB then terminates.

Upon the next MATLAB startup after a fatal problem, the "Error Log Reporter" on page 1-21 prompts you to e-mail the log to The MathWorks.

2

Desktop

If you have an active Internet connection, you can watch the Working in the Development Environment video demo for an overview of the major functionality. The easiest way to learn to use the desktop is just by working with it. If you have problems or questions, refer to the following sections.

Overview of the Desktop (p. 2-3)	Basic summary of the desktop and its tools.
Arranging the Desktop (p. 2-6)	Open and arrange desktop tools and documents to suit your needs.
Examples of Desktop Arrangements (p. 2-15)	Scan the examples to see various ways to arrange the desktop.
Shortcuts for MATLAB — Easily Run a Group of Statements (p. 2-32)	Use MATLAB shortcuts, an easy way to run a group of MATLAB functions from the desktop.
Keyboard Shortcuts (p. 2-40)	Use the keyboard as an alternative to a mouse or other pointing device to access desktop features.
Other Desktop Features (p. 2-44)	Use the **Start** button, toolbars, menus and context menus, and status bar. Select multiple items, cut, copy, and paste, set up pages for printing, use a MATLAB Web browser, and access the MathWorks Web site from MATLAB.
Preferences (p. 2-59)	Specify options for tools such as fonts, colors, and more.

Fonts Preferences for Desktop Tools (p. 2-62)	Use desktop font preferences to specify the font characteristics for MATLAB desktop tools.
Colors Preferences for Desktop Tools (p. 2-70)	Set desktop color preferences for desktop tools, including syntax highlighting.
General Preferences for MATLAB (p. 2-76)	Set options for toolbox path caching, figure window printing, delete function behavior, MAT-file save format, confirmation dialogs, source control system, and multithreaded computation.
Accessibility (p. 2-85)	Use assistive technologies and accessibility features when working with MathWorks software.

Overview of the Desktop

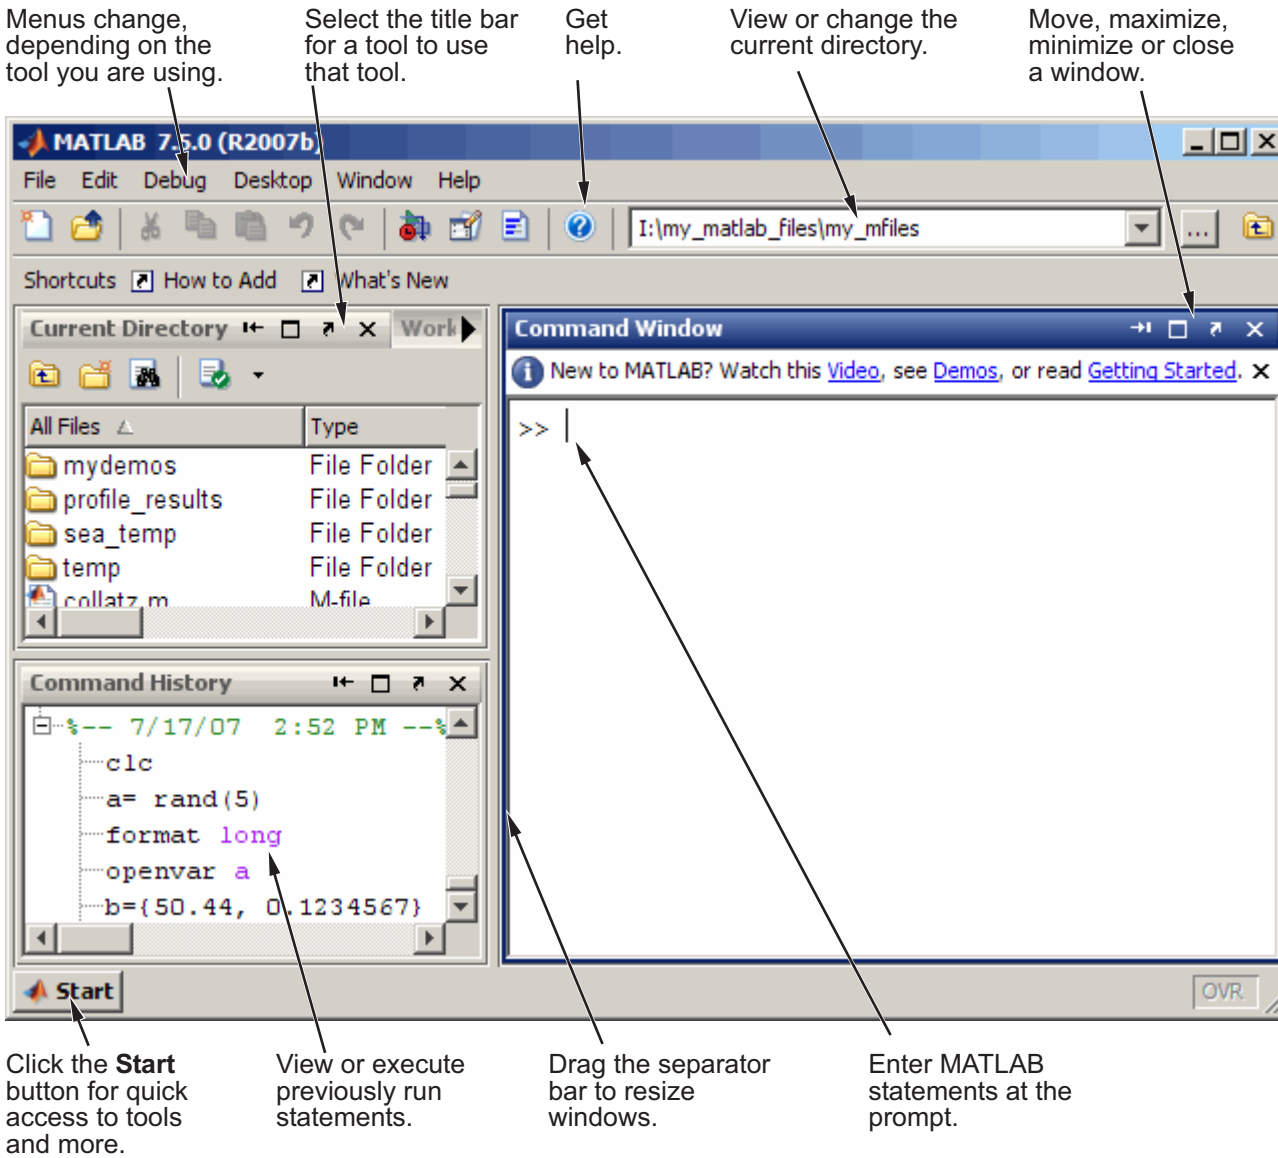
In this section...

About the Desktop

In general, when you start MATLAB, it displays the MATLAB desktop, a set of tools (graphical user interfaces or GUIs) for managing files, variables, and applications associated with MATLAB.

The first time you start MATLAB, the desktop appears with the default layout, as shown in the following illustration. You can change the desktop arrangement to meet your needs, including resizing, moving, and closing tools. For details, see "Arranging the Desktop" on page 2-6.

Some tools, such as the Editor/Debugger and Array Editor, support multiple document windows within them. Similarly, you can group multiple figure windows together. For information about working with documents in the desktop, see "Opening and Arranging Documents" on page 2-8.



Menus change, depending on the tool you are using.
Select the title bar for a tool to use that tool.
Get help.
View or change the current directory.
Move, maximize, minimize or close a window.

Click the Start button for quick access to tools and more.
View or execute previously run statements.
Drag the separator bar to resize windows.
Enter MATLAB statements at the prompt.

Summary of Desktop Tools

The following tools are managed by the MATLAB desktop, although not all of them appear by default when you first start. If you prefer a command-line interface, you can often use equivalent functions to accomplish the same result. To perform the equivalent of the GUI tasks in M-files, you must use the equivalent function. Instructions for using equivalent functions to perform the task are provided with the documentation for each tool and are typically labeled as Function Alternatives.

Desktop Tool	Description
Array Editor	View array contents in a table format and edit the values.
Command History	View a log of or search for the statements you entered in the Command Window, copy them, execute them, and more.
Command Window	Run MATLAB statements.
Current Directory Browser	View files, perform file operations such as open, find files and file content, and manage and tune your files.
Editor/Debugger	Create, edit, debug, and analyze M-files (files containing MATLAB statements).
Figures	Create, modify, view, and print MATLAB figures.
File Comparisons	View line-by-line differences between two files.
Help Browser	View and search the documentation and demos for all your MathWorks products.
Profiler	Improve the performance of your M-files.
Start Button	Run tools and access documentation for all your MathWorks products, and create and use MATLAB shortcuts.
“Web Browser” on page 2-55	View HTML and related files produced by MATLAB.
Workspace Browser	View and make changes to the contents of the workspace.

Arranging the Desktop

In this section...

See also "Examples of Desktop Arrangements" on page 2-15.

Modifying the Desktop Configuration

You can modify the desktop configuration to best meet your needs. Because the desktop uses many standard graphical user interface (GUI) conventions, it is easy to learn about arranging the desktop just by using it.

The desktop manages tools differently from documents. The Command History and Editor/Debugger are examples of tools, and an M-file is an example of a document, which appears in the Editor/Debugger tool.

Opening and Arranging Tools

This table summarizes actions for arranging desktop tools. For further information, click the "see more details online" links.

Tool Action	Steps to Perform
Opening desktop tools	To maximize your work area, keep open only those tools you use. To open a tool, select the tool name from the **Desktop** menu. Opened tools have a check mark before them in the menu. The tool appears in the location it occupied the last time it was open. The sizes of other tools adjust to accommodate the newly opened tool. See more details online.

Tool Action	Steps to Perform
Navigating among desktop tools	The **Window** menu displays all open desktop tools and documents, as well as opened tools for other MathWorks products. Select an entry in the **Window** menu to go directly to that tool or document. Another way to access an undocked desktop tool is by selecting its entry in the Windows task bar, or the equivalent for your platform. See also "Keyboard Shortcuts" on page 2-40 and more details online.
Closing desktop tools	To close a desktop tool, select the item in the **Desktop** menu, which clears the check mark in the menu and closes the tool. Or click the Close box (X) in the title bar for the tool, or select **File > Close** for the tool. See more details online.
Resizing tools	To resize tools in the MATLAB desktop, drag the separator bar, which is the bar between tools. You can hide the title bars for tools in the desktop so the tools use less space—select **Desktop > Titles**, and then hover over a title bar to see a tooltip containing the name of the tool. See more details online.
Moving tools within the desktop	To move a tool in the MATLAB desktop, drag the title bar of the tool toward where you want the tool to be located. As you drag the tool, an outline of it appears. When the outline nears a position where you can keep it, the outline snaps to that location. Release the mouse button. The tool stays at the new location. Other tools in the desktop resize to accommodate the new configuration. The inside edges of the desktop container and tools all act as if they are "sticky," so you can position a tool along any inside edge. See more details online.
Moving tools out of the desktop (undocking)	Move a tool out of the desktop to make it larger or easier to work with. To move a tool outside the MATLAB desktop (called *undocking*), select the tool to make it active, and then select **Desktop > Undock > Toolname**. The tool appears outside the MATLAB desktop and an entry for it appears in the Windows task bar or the equivalent for your platform. Tools within the desktop resize accordingly. Another way to undock is by using the Undock button  in the tool's title bar. See more details online.
Moving tools into the desktop (docking)	To move a tool that is outside the MATLAB desktop into the desktop, click the Dock button  in the tool's menu bar, or select **Desktop > Dock Toolname**. See more details online.

Tool Action	Steps to Perform
Grouping tools together	You can group tools so that they overlay each other in the MATLAB desktop. To group tools together, drag the title bar of one tool in the desktop on top of the title bar of another tool in the desktop. To make a tool active, click its name in the title bar. See more details online.
Maximizing tools in the desktop	To resize the active tool so it occupies the entire MATLAB desktop, double-click the tool's title bar; to return to the layout prior to maximizing, double-click the title bar of the maximized tool. Alternatively, use the menus: select **Desktop > Maximize Toolname**. To return to the layout prior to maximizing, select **Desktop > Restore Toolname**. You can also use the Maximize button and Restore button in the tool's title bar. This feature is not supported on Macintosh platforms.
Minimizing tools in the desktop	You can minimize any tool in the desktop, which creates a button along an edge of the desktop that represents the tool. Select **Desktop > Minimize Toolname**. You can also use the Minimize button in the tool's title bar. The tool's button appears along the edge indicated by the minimize arrow in the menu item or on the button. To move the tool's button to a different edge, right-click the button, and from the context menu, select an edge. To view or use a minimized tool, hover over or click the button—this temporarily opens the tool in the desktop. Once you are finished using the tool, click the button or another tool and the tool is again shown only as a button along the edge. To return the tool to the desktop layout position it occupied before being minimized, double-click the button. Alternatively, restore it by right-clicking the button and selecting **Restore > Toolname**, or use the Restore button in the tool's title bar. This feature is not supported on Macintosh platforms.

Opening and Arranging Documents

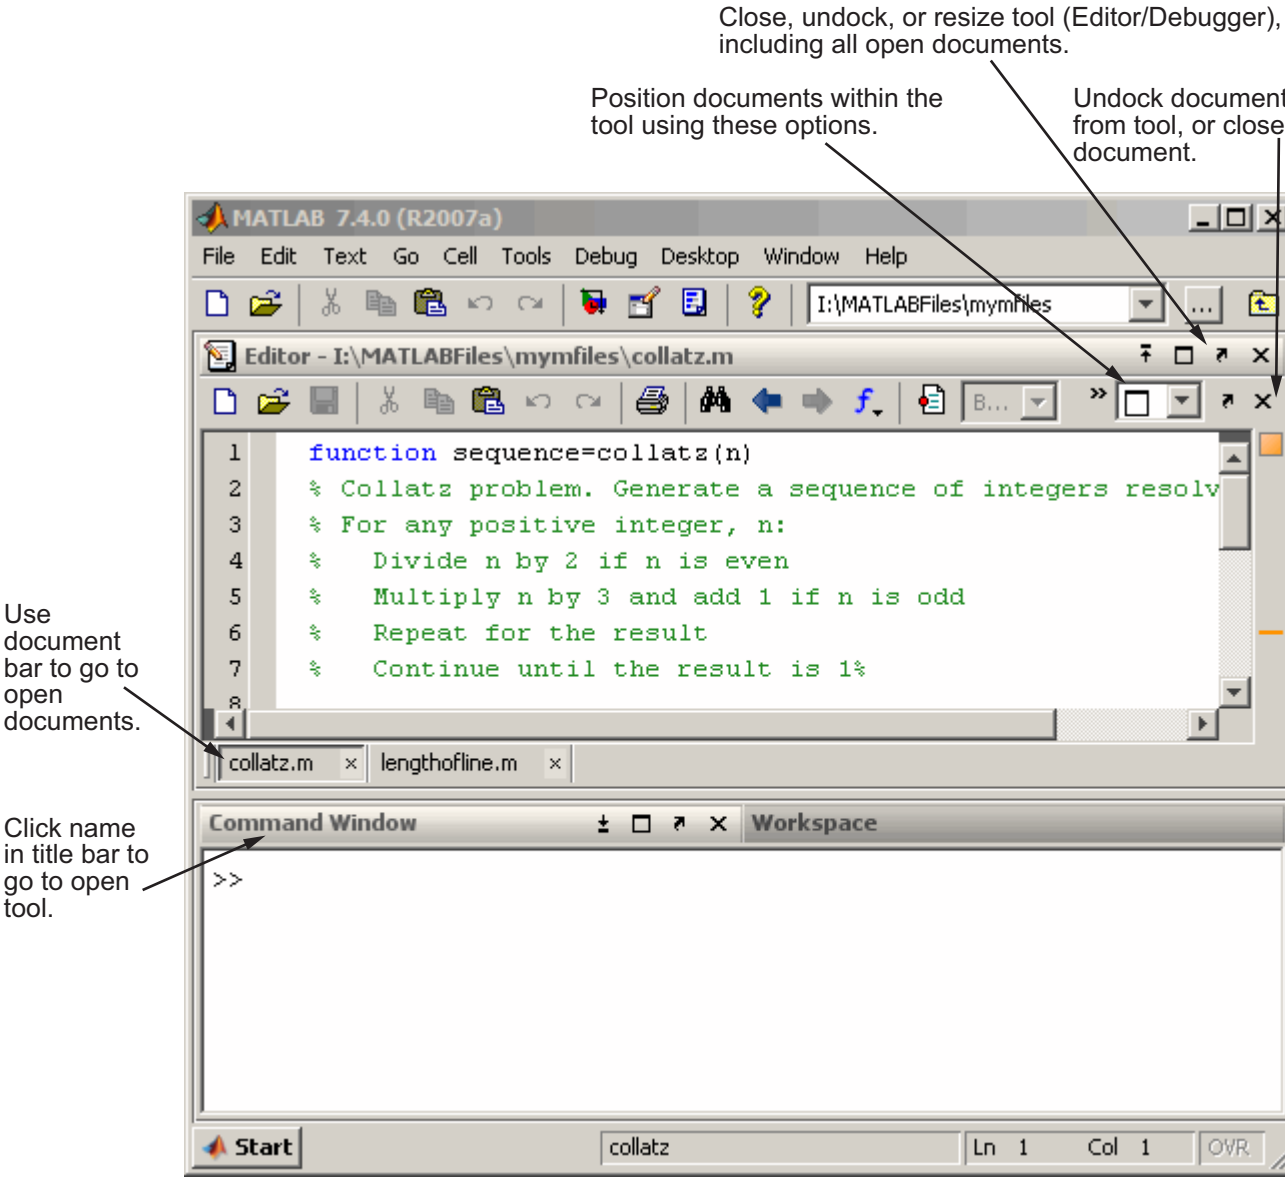
Open a document, such as an M-file or a variable, and it opens in its tool, for example, the Editor/Debugger or Array Editor. The following example illustration shows a desktop arrangement that includes Editor/Debugger and Array Editor documents. See instructions in "Summary of Actions for Arranging Documents" on page 2-11.

Example of Documents in the Desktop

Some common actions for working with documents in the desktop are

- Use the document bar to go to open documents.
- Use the **Window** menu or equivalent toolbar buttons to position documents.
- Close or undock a tool, including all documents in the tool.
- Undock a document from its tool.
- Use the document Close box with the **Ctrl** key to close the document without saving it and without displaying the unsaved document dialog box.

See also “Examples of Desktop Arrangements” on page 2-15.



Close, undock, or resize tool (Editor/Debugger), including all open documents.
Position documents within the tool using these options.
Undock document from tool, or close document.
Use document bar to go to open documents.
Click name in title bar to go to open tool.

Summary of Actions for Arranging Documents

This table summarizes actions for arranging documents in their tool. For further information, click the click the “see more details online” links.

Document Action	Overview
Opening documents	When you open a MATLAB document, it opens in the associated tool. If the tool is not already open, it opens when you open the document and appears in the position it occupied when last used. Figures open undocked, regardless of the last position occupied. How to open a document depends on the document type: • M-file: Select **File > Open** and select the M-file. It opens in the Editor/Debugger. • Workspace variable: In the Workspace browser, double-click the variable. It opens in the Array Editor. • HTML file: In the Current Directory browser, double-click the file. It opens in the MATLAB Web Browser. • Figure: Type `plot` or use another graphics function. The plot appears in a figure window. There are many additional ways to open documents. See more details online.

Document Action	Overview
Navigating among documents — the document bar	When more than one document is open within a tool, each document is either maximized (the default), or arranged so that multiple documents are visible at once. Click a document that is in view to make it the active document. See also "Keyboard Shortcuts" on page 2-40. Use the document bar to go to a document that is open but not in view. The names of all open documents appear in the document bar. Select a document name in the document bar to make that document active. To show the document bar if it is not open, select **Desktop > Document Bar > Bar Position** and select the position for it, for example, **Right**. See more details online. Entries for undocked documents appear in the Windows task bar, or the equivalent for your platform. Click the task bar entry for a document to make that document active.
Positioning, moving, and resizing documents	To position open documents within their tool, select an arrangement from the **Window** menu when the tool is active, or by using the equivalent toolbar button for **Maximize**, **Float**, **Left/Right Tile**, **Top/Bottom Tile**, and **Tile**. You can also define a specific grid arrangement using **Window > Tile...**. On the Macintosh platform, the tile option might not be available in the **Window** menu so use the Tile button ⊞ instead. With the tile arrangements, you refine the document position by moving the pointer over the handle (▪) on the separator bar. A Close box then appears. When you click the Close box between two open documents, both documents stay open, but one moves on top of the other. When you click the Close box between a document and an empty tile, the empty tile closes. To move a document in a tiled arrangement, drag the title bar of a document to another tile. To resize tiled documents, drag the separator bar between the documents. See also the Editor/Debugger's "Split Screen Display" on page 6-38, which allows you to view two different parts of the same file simultaneously. To move or resize maximized documents, you move or resize their tool. See more details online.

Document Action	Overview
Closing documents	To close a document, click the Close box in the document's title bar. After closing all the documents in a tool, the tool remains open with no documents in it. If you select the Close box for the tool, all documents in that tool close. In the Editor/Debugger, when you close a file that has unsaved changes, a prompt appears asking if you want to save the document. To close a file without saving changes and without seeing the save prompt, use **Ctrl** when you click the document's Close box. See more details online.
Moving documents and tools out of the desktop (undocking)	To undock all documents in a tool from the desktop, click the Undock button in the tool's title bar. The tool and its documents move outside of the desktop. See more details online. To undock a document from its tool, click the Undock button for the document. The Undock button is either in the document's title bar, menu bar, or toolbar, depending on the document type and whether or not the document is within the desktop or is in its tool outside of the desktop. Undocked documents have entries in the Windows task bar (or the equivalent for your platform).
Docking documents and tools	When you dock a document, it moves to the position in the tool that it occupied before you undocked the document. To dock a document, click the Dock button in the document's menu bar. See more details online.
Grouping documents in a tool outside the desktop	To group all of the documents for a tool together outside of the desktop, undock the tool from the desktop, not just the documents. If you have already undocked all of the documents and closed the empty tool that had contained them, select **Desktop > Dock All in Editor**, for example. This moves all the documents into the tool in the desktop. Then undock the tool.

Saving Desktop Layouts

When you end a session, MATLAB saves the desktop layout. The next time you start MATLAB, the desktop is restored to the way you last had it.

To use a predefined layout, select **Desktop > Desktop Layout**, and choose a configuration. See more details in the online documentation.

To save your own layouts for later reuse, select **Desktop > Save Layout** and provide a name. To reuse a saved layout, select the name from **Desktop > Desktop Layout**. See more details in the online documentation.

Examples of Desktop Arrangements

In this section...

About These Examples

Scan the illustrations in the following examples for a desktop arrangement similar to what you want, and then follow the brief instructions to achieve the arrangement. There are many different ways to accomplish the result; these instructions present just one way. The instructions might not apply exactly, depending on how your desktop looks before you start.

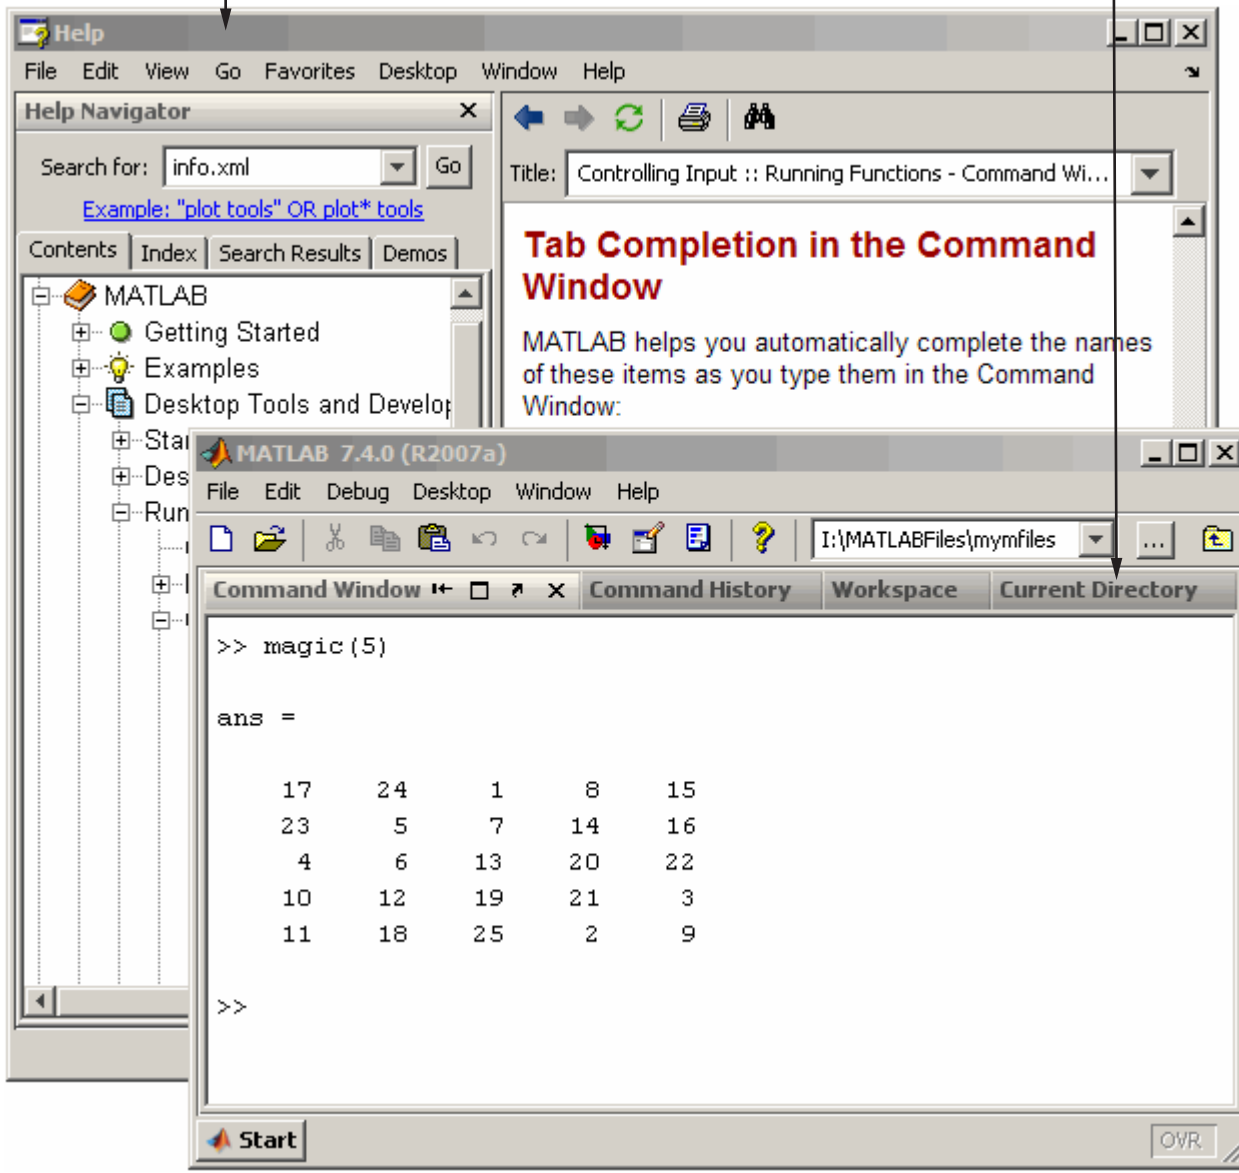
Tool Outside of Desktop and Other Tools Grouped Inside Desktop Example

This example shows two ways you can increase the size of a tool. One way is to move a tool outside of the desktop to increase its size. Here, the Help browser was moved outside of the desktop and made larger. To move a tool outside of the desktop, click the Undock button in the tool's title bar when the tool is in the desktop.

Another way to increase the size of a tool is by grouping tools together inside the desktop, and then accessing a tool via the tool's name in the title bar. Here the Command Window, Command History, Workspace browser, and Current Directory browser are grouped together. To achieve this, drag the title bar of one tool on top of the title bar of the tool(s) you want to group it with.

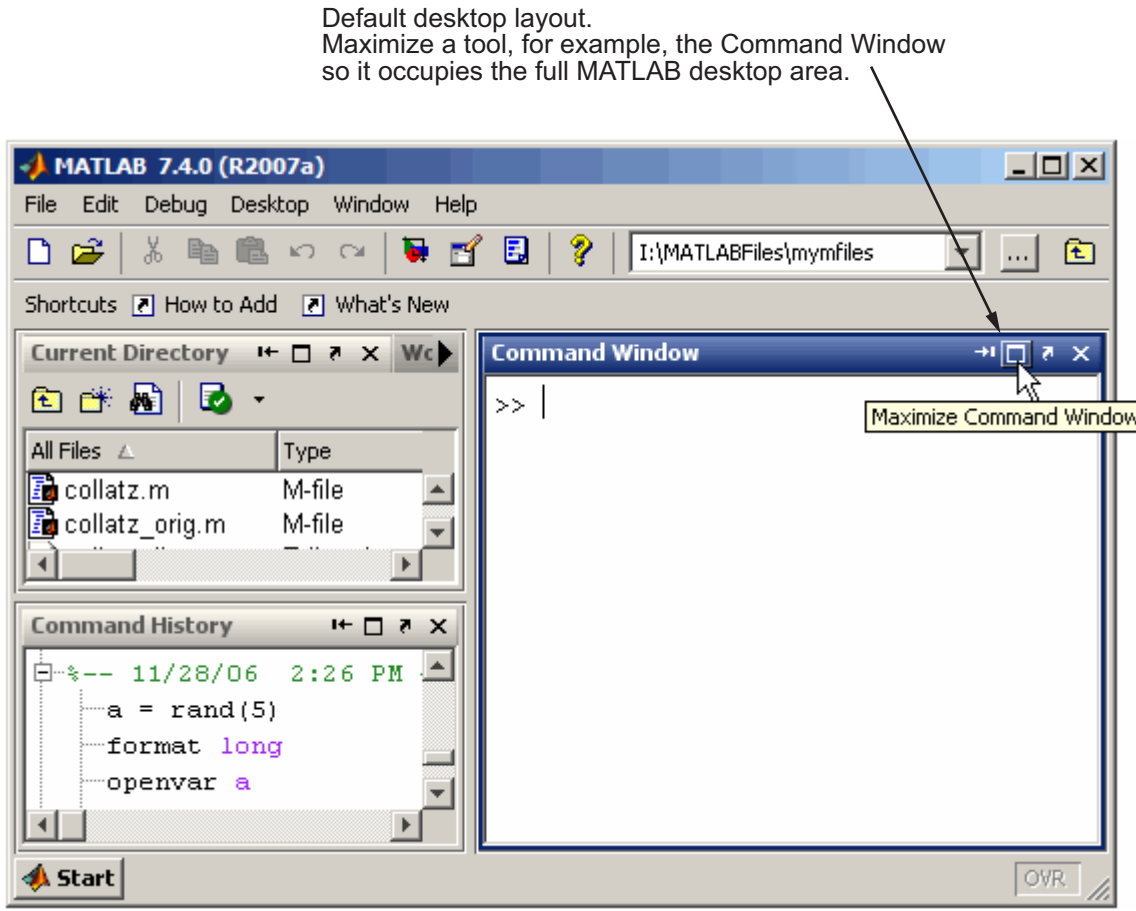
Help browser is undocked from desktop to provide a large area for viewing documentation when needed.

Four tools in the desktop are grouped together, providing a large area for working with a given tool. Click a tool's name in the title bar to make that tool active.



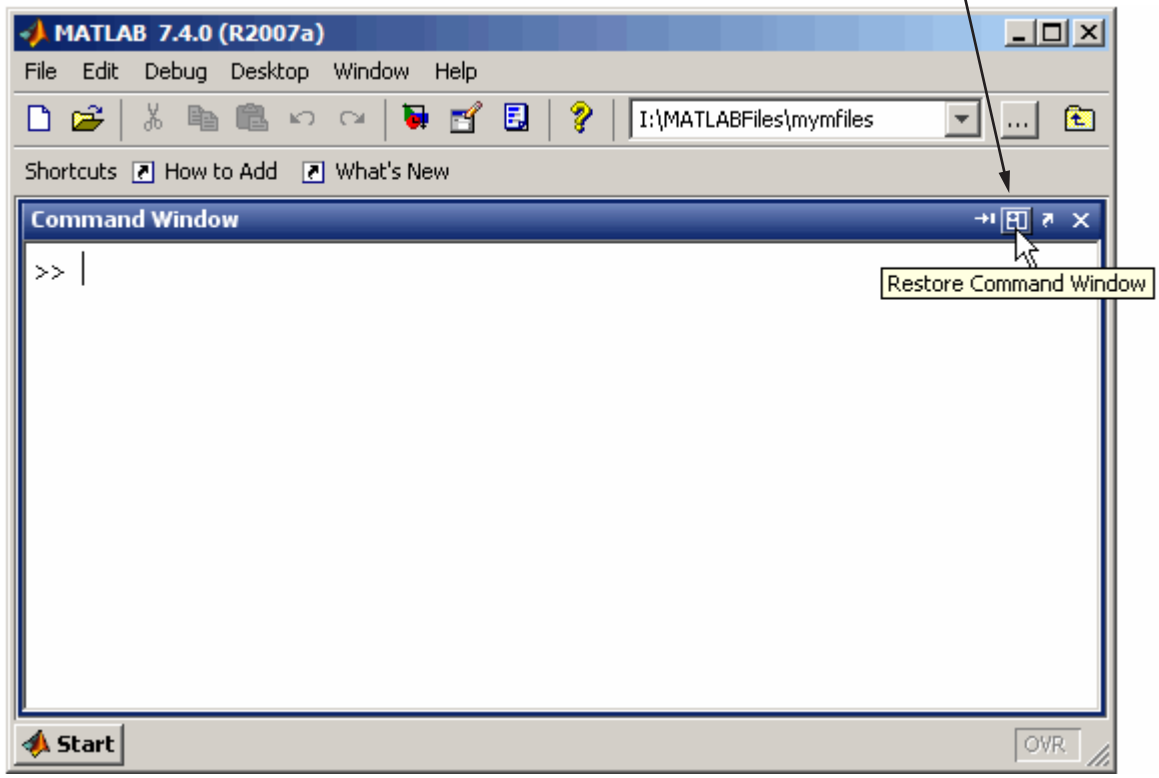
Maximized Tool in Desktop Example

This example shows a way you can temporarily increase the size of a tool so that it occupies the entire area of the desktop. In this example, the Command Window in the default desktop layout is temporarily maximized by clicking the Maximize button in the tool's title bar.



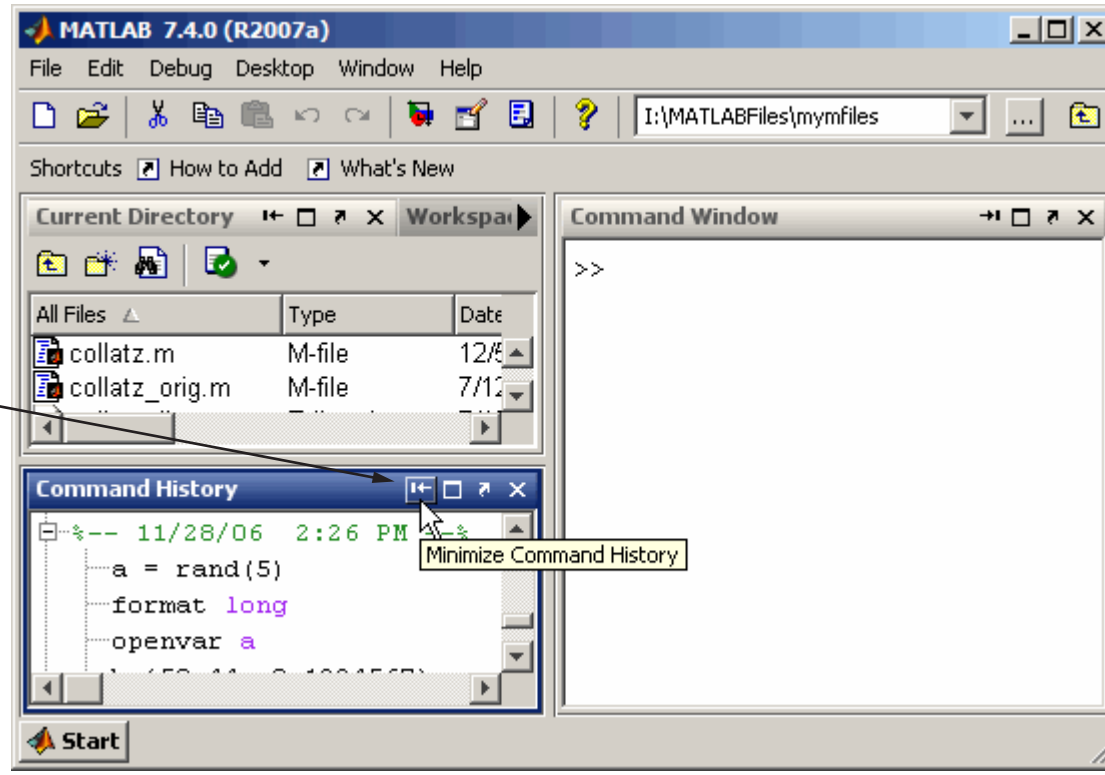
In this example, the maximized Command Window is being returned to its size and position in the default desktop layout by clicking the Restore button in the title bar.

Maximized, the Command Window now occupies the full desktop area. Restoring the Command Window returns it to its original size and location in the desktop.



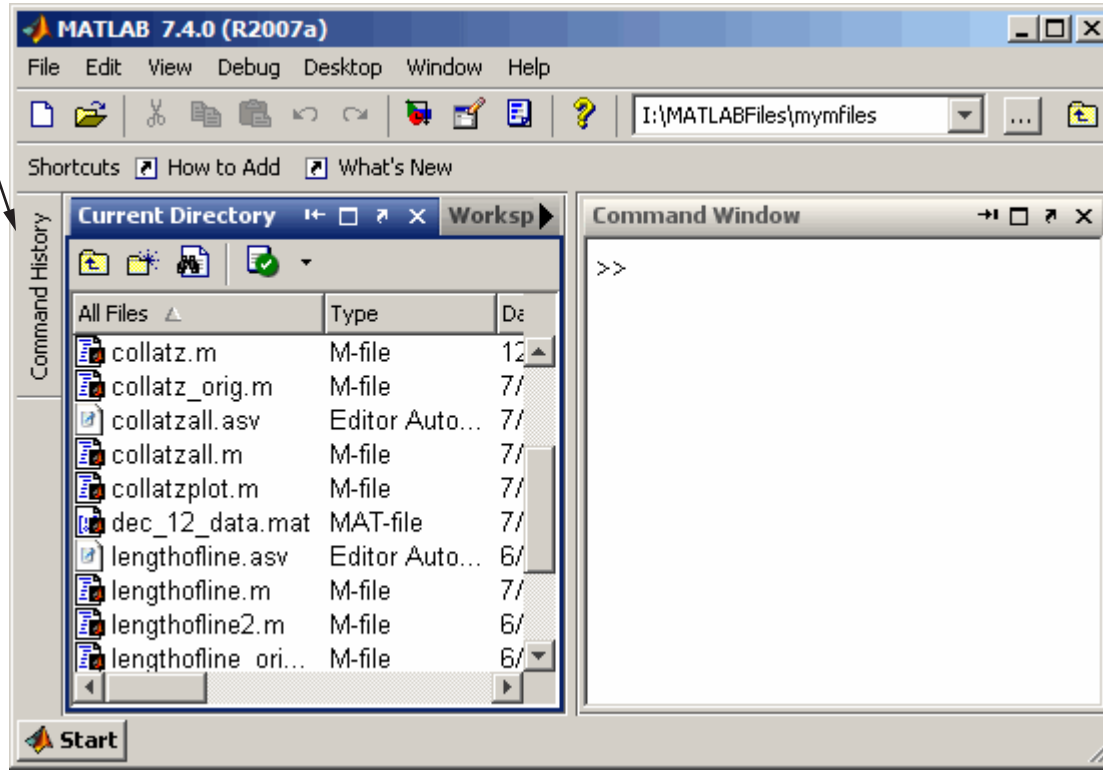
Minimized Tools in Desktop Example

Minimize a tool in the desktop to give the remaining desktop tools more space in the desktop. Minimizing is available on Windows and UNIX platforms. In this example, the Command History in the default layout is being minimized to the left edge of the desktop.



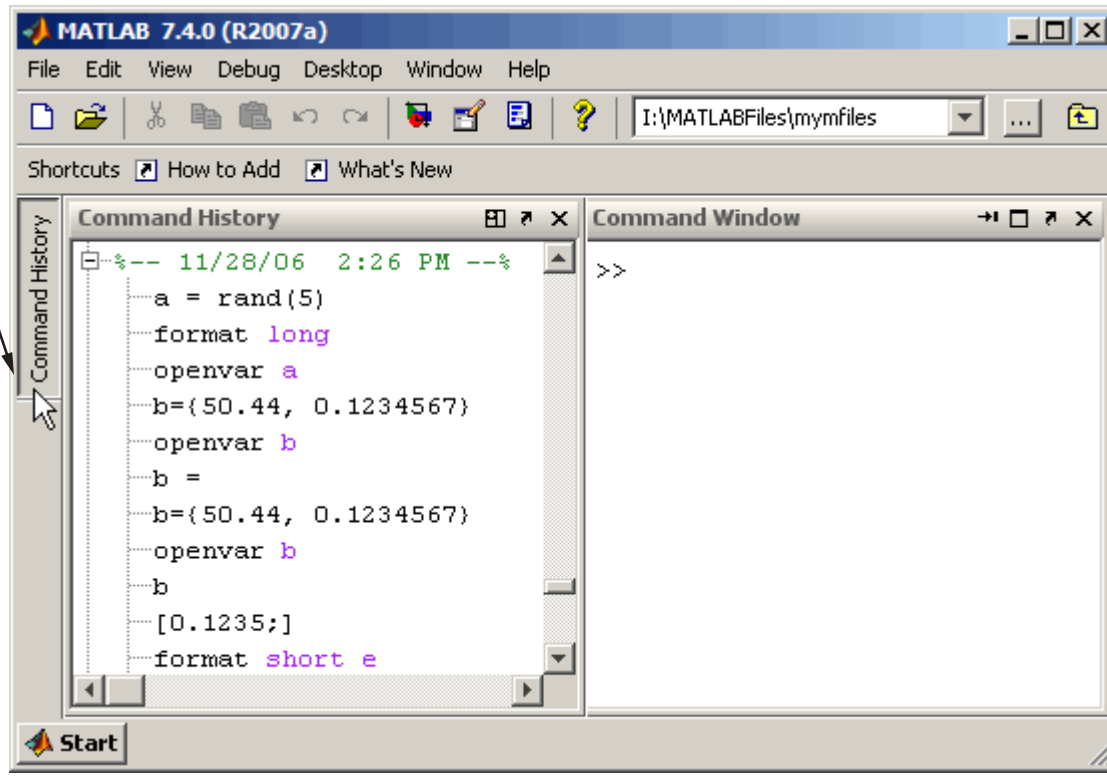
In this illustration, the Command History has been minimized and appears as a button along the left edge.

When minimized, a tool, such as the Command Window in this example, is represented by a button on the desktop border.



This illustration shows the minimized Command History being temporarily opened, as a result of clicking or hovering over the button.

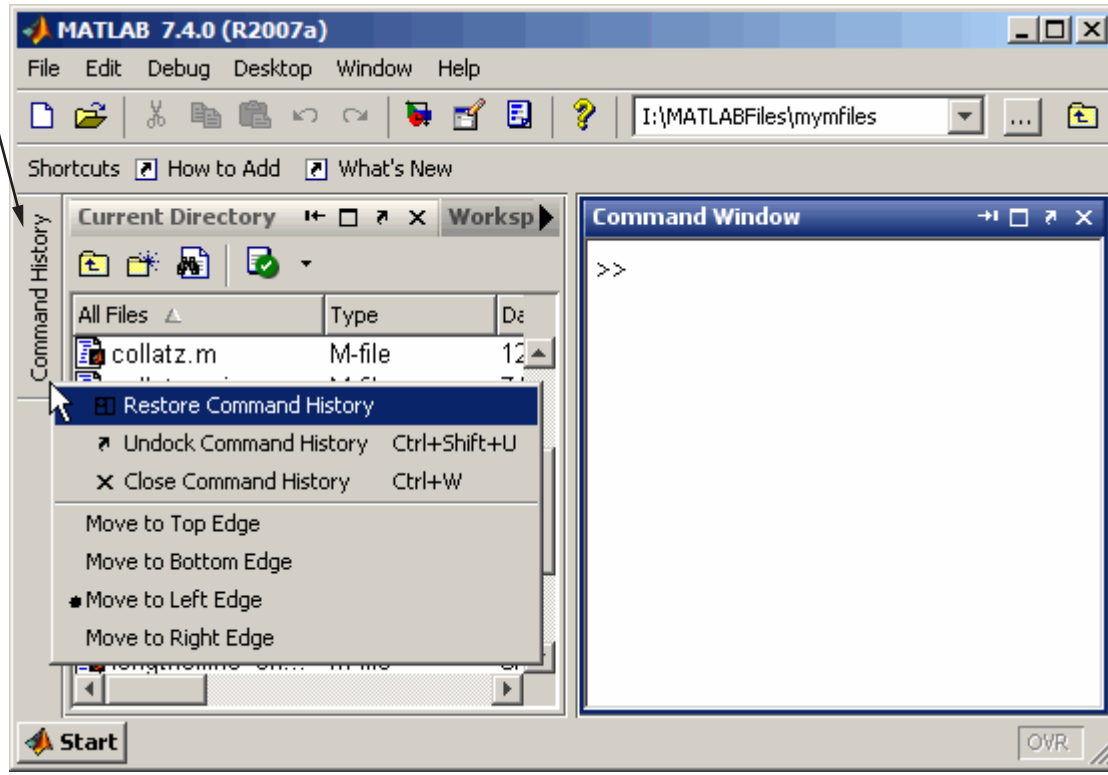
Hover over or click the button for a minimized tool to temporarily view or use the tool.
The tool is temporarily displayed until you select another tool.
Then the tool becomes minimized again.



After using the Command History and clicking the button, or moving on to another tool, the Command History again becomes minimized as a button along the left edge.

This illustration shows the Command History being returned to the position and size it occupied in the desktop prior to being minimized by clicking the Restore button .

On the button for a minimized tool, right-click, and from the context menu,select **Restore**. The tool resumes the size and position it had in the desktop before it was minimized.



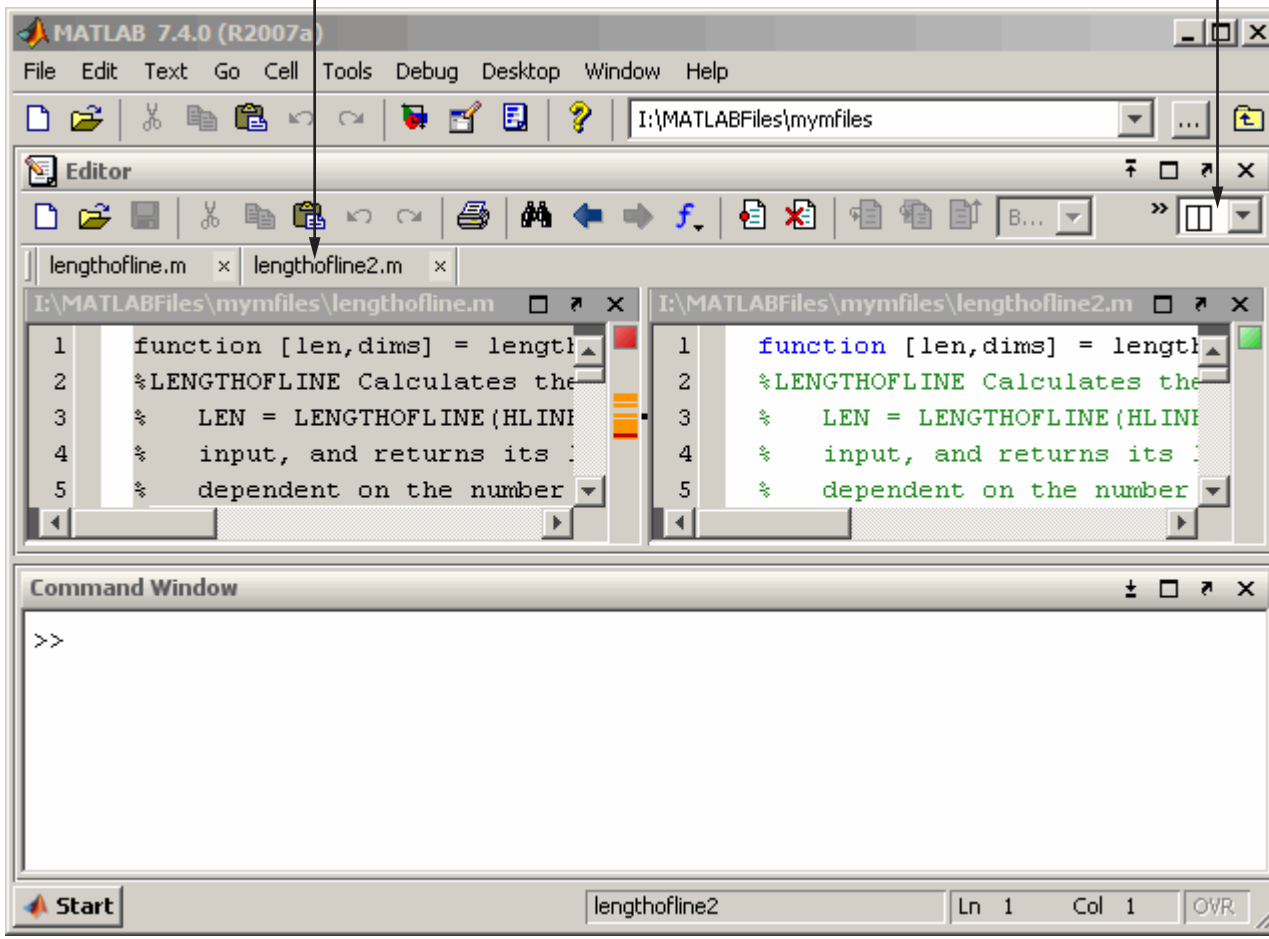
Tiled Documents in Desktop Example

When you open a document (for example, an M-file), it also opens the tool (for example, the Editor/Debugger) if the tool is not already opened. Subsequent documents of the same type open in the tool and you can then arrange the documents within the tool. You can move a document on top of another document, so that the one on top hides the one(s) beneath it, or you can show multiple documents at once. This example shows two M-files side-by-side, as a result of selecting **Window > Left/Right Tile** (or the ◫ toolbar button).

When tools and documents are docked, you might want to save space by hiding toolbars and document bars. In this illustration, the desktop shortcuts toolbar is hidden. Select **Desktop > Toolbar name** to hide (or show) a toolbar. To see or move the document bar, select **Desktop > Document Bar > Bar Position**, and choose its location, for example, **Top**.

The shortcuts toolbar is hidden. The document bar is at the top edge of the Editor/Debugger.

Select a button from the list to arrange the documents, such as Left/Right Tile.



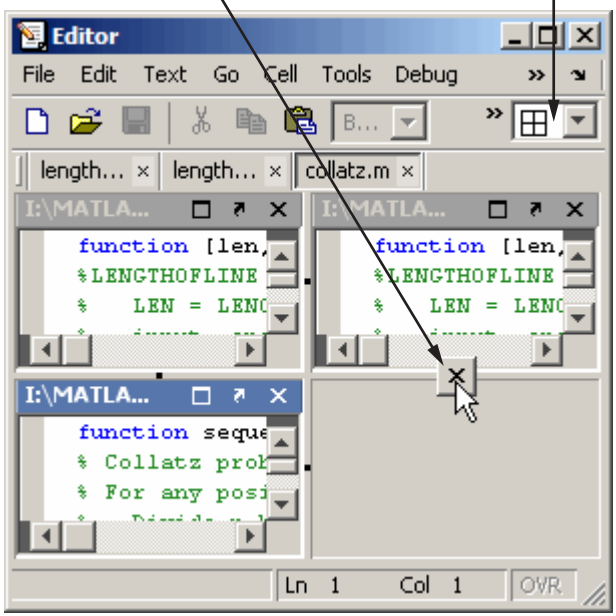
No Empty Document Tiles Example

To see more than two documents at once, select the Tile button and move the pointer across the gird that appears to select the number of tiles you want. The following “Before” illustration has four tiles, but only three documents are open. (The empty tile is gray.) You can move a document to any empty tile by dragging its title bar to the new location. To close an empty tile, position the pointer over the handle on the separator bar. It becomes a Close box, as shown here, which you click to close the empty tile. After clicking the Close box, the empty tile closes and the neighboring document expands as shown in the following “After” illustration. Similarly, click the Close box between two tiles containing documents, and one document becomes hidden. Note that preferences to show line numbers and M-Lint indicators have been cleared to provide more horizontal space.

Before

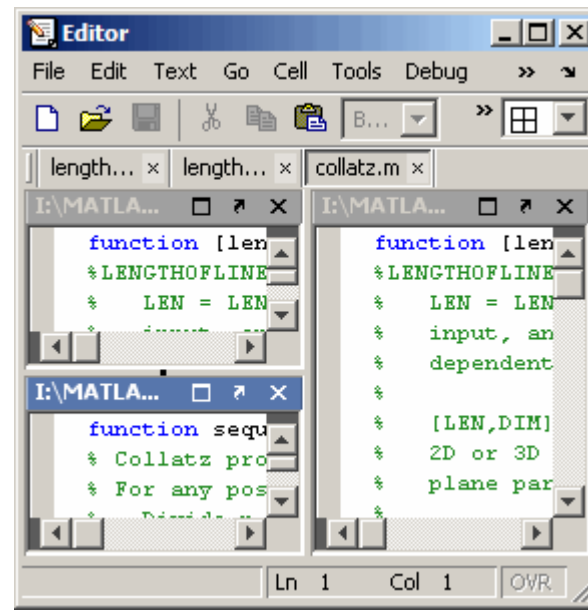
Close the empty tile using the handle on the separator bar.

Tile more than two documents with the Tile button.



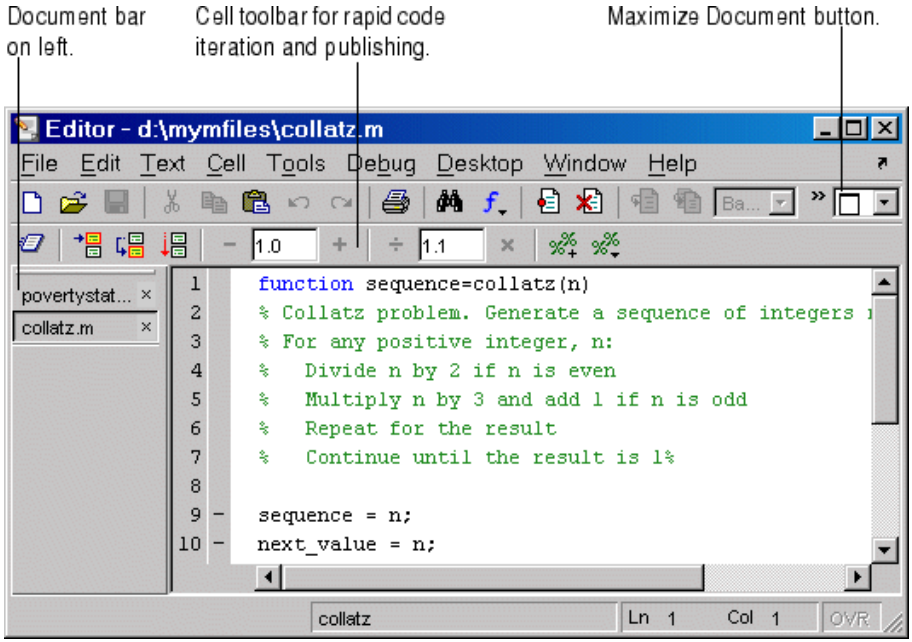
After

There are only three tiles.



Maximized Documents Outside of the Desktop Example

This example illustrates a way to provide a large area for multiple documents, in this case, M-files maximized in the undocked Editor/Debugger.



Some common actions for working with documents outside of the desktop are

- Group all Editor/Debugger documents together — select **Desktop > Dock All in Editor** from any Editor/Debugger document.
- Move all Editor/Debugger documents outside of the desktop — select **Desktop > Undock Editor** when the Editor/Debugger is the active window.
- Make a document occupy the full area in the Editor/Debugger — click the Maximize button in the Editor/Debugger toolbar, or select **Window > Maximize**.
- Display the cell toolbar — select **Desktop > Cell Toolbar**. This menu item is available only when the current document is an M-file.

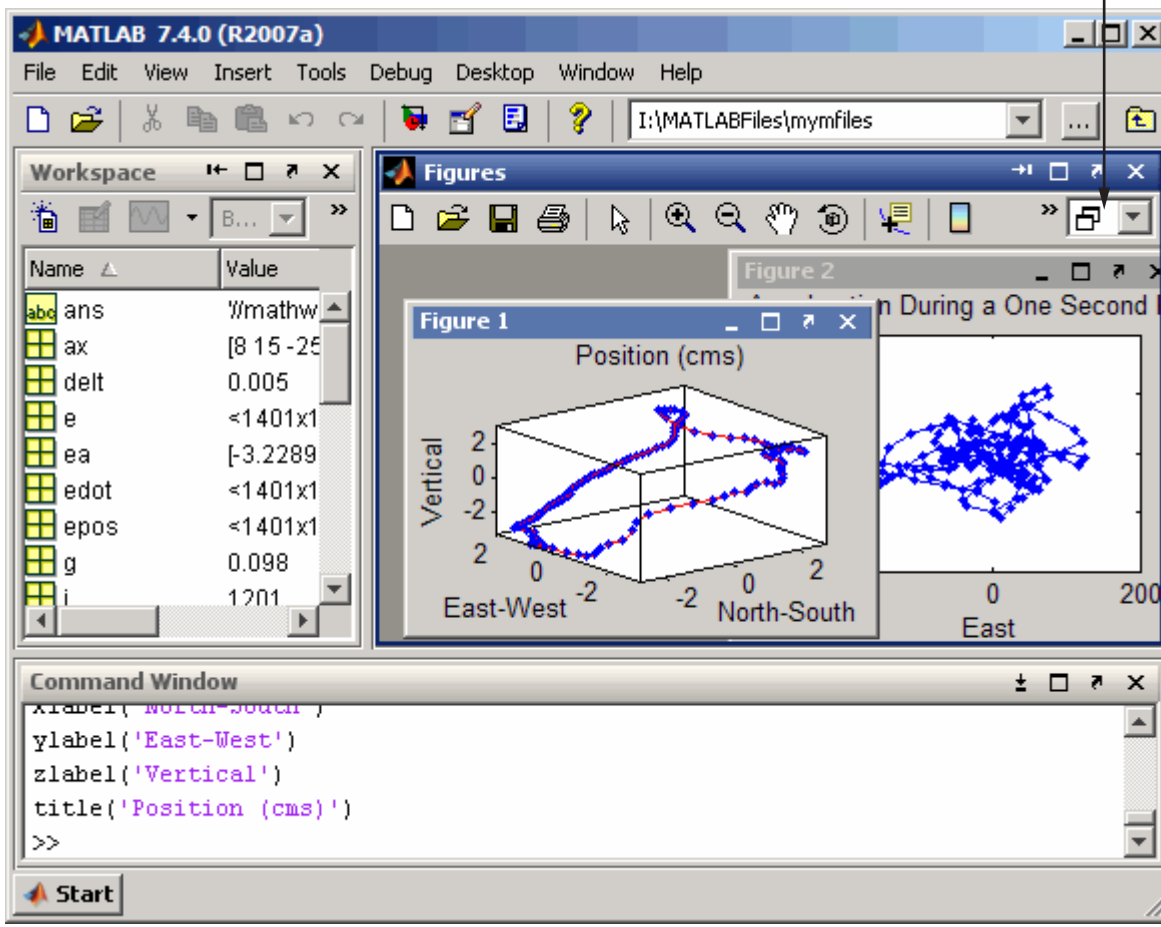
- Access any document in the Editor/Debugger using the document bar. To show the document bar on the left side of the Editor/Debugger, select **Desktop > Bar Position > Document Bar > Left** from the Editor/Debugger.

Floating (Cascaded) Figures in Desktop Example

This example illustrates multiple figures in the desktop. By default, figures open outside the desktop. Click the Dock button in each figure's menu bar to move the figures into the desktop.

You can float (also called cascade) the figures by selecting **Window > Float**, or clicking the Float button. To get even more screen area for the figures, hide the document bar as shown in this example — select **Desktop > Document Bar > Bar Position > Hide**.

Dock figures in the desktop and use the float option to arrange them within a Figures group. The document bar is hidden.



Undocked Tools and Documents Example

You can use tools and documents outside of the desktop. One way to achieve this is to first undock the tool from the desktop by selecting **Desktop > Undock Toolname**. Then undock documents from the undocked tool by selecting **Desktop > Undock Documentname** from the tool. If you undock all documents from a tool, an "empty" tool window remains.

In this example, one of the Editor/Debugger documents, `collatz.m`, includes the name of the tool with it; the other Editor/Debugger document, `lengthofline.m`, does not. Contrast this with the Array Editor documents, where neither document window includes the name of the tool. This is because the Array Editor was undocked from the desktop, the variables were undocked from the Array Editor, and the "empty" Array Editor window was closed. The tool's undocked documents remain open. If you closed the Editor/Debugger, the `lengthofline.m` document would remain open. To close all undocked documents and their tools at once, select **Window > Close All Documents** from an undocked document window.

Shortcuts for MATLAB — Easily Run a Group of Statements

In this section...

What Is a Shortcut?

A MATLAB shortcut is an easy way to run a group of MATLAB statements that you use regularly. First you create a shortcut that contains all the statements. Then you select and run the shortcut to execute all the statements it contains. Create, run, and organize shortcuts from the **Start > Shortcuts** menu or the desktop **Shortcuts** toolbar.

Differences Between Shortcuts and M-Files

A shortcut is like an M-file script, but unlike an M-file, a shortcut does not have to be on the MATLAB search path or in the current directory when you run it. In addition, you can run the shortcut by selecting it from the **Start** button or desktop **Shortcuts** toolbar, which are readily accessible.

Although shortcuts run MATLAB statements, they are not M-files and are not stored as M-files.

Examples of Useful Shortcuts

These are some examples of useful types of shortcuts:

- If you frequently run the same group of functions, consider creating a shortcut for them. An example of this is setting up your environment when you start working if you do not use a `startup` file, or if there are statements you do not want to include in the `startup` file. Some users

create a shortcut for even a single function they use frequently, such as `clc` to clear the Command Window.

- Create a shortcut to set the same properties for figures you create, such as adding a legend and setting the background color.
- Create a shortcut for a long statement, such as changing the current directory (`cd`) when the pathnames are long.
- Create a shortcut for a statement you do not easily remember but need to use.

Creating Shortcuts

This is an example of a shortcut you might create for a project you work on, the Sea Temperature project. When you work on that project, you might want to set up your environment in a certain way by running a series of statements. You create a shortcut called `sea_temp_env`, which contains the statements. Then when you work on the project, you run the shortcut to execute all of the statements with a single click. The statements are

```
more on
format long e
cd d:/mymfiles/sea_temp_project
clear
workspace
filebrowser
clc
```

To create a shortcut, perform the following steps:

1. From the **Start** button, select **Shortcuts > New Shortcut**.

   The Shortcut Editor dialog box appears.

2. Create the shortcut by completing the dialog box.

   a. Provide a shortcut name in the **Label** field, for example, `sea_temp_environment`.

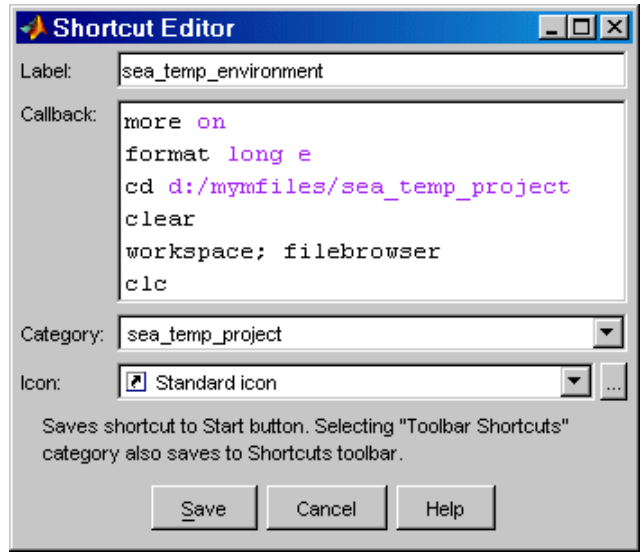
   b. Put the MATLAB statements in the **Callback** field as shown in the following illustration. Either type them in, or copy and paste or drag them from a desktop tool. Edit the statements as needed. The field uses

the Editor/Debugger preferences for key bindings, colors, and fonts. Note that if you copy the statements from the Command Window, the prompt appears in the shortcut, but MATLAB removes the prompt when you save the shortcut.

c Assign a category, which is like a directory for organizing shortcuts. Specify `sea_temp_project`. To add the shortcut to the shortcuts toolbar, select the `Toolbar Shortcuts` category.

d Use the default shortcuts icon, or select your own.

e Click **Save**. MATLAB automatically removes any Command Window prompts (>>) in the **Callback** field upon saving the shortcuts.



3 MATLAB adds the shortcut to the **Shortcuts** entry in the **Start** button, and to the **Shortcuts** toolbar, if you selected that **Category**.

After creating a shortcut, run it by selecting it from its category in the **Start** button. You can also run it from the **Shortcuts** toolbar if you selected the `Toolbar Shortcuts` category.

MATLAB maintains shortcut information in the file `shortcuts.xml`. Type `prefdir`, and MATLAB displays the location of the file. Most likely, you will not need to access this file, as MATLAB updates the file automatically.

For more information on the options in the Shortcut Editor dialog box, click the **Help** button.

Additional Ways to Create Shortcuts

You can also use these methods to create shortcuts:

- Add shortcuts to and run them from the desktop **Shortcuts** toolbar. See "Shortcuts Toolbar" on page 2-35.
- From the Command History window, create a shortcut by selecting statements, right-clicking, and selecting **Create Shortcut** from the context menu. By default, shortcuts created from the Command History window are assigned to the `Toolbar Shortcuts` category, meaning they will appear on the **Shortcuts** toolbar.
- From the Help browser, select **Favorites > Add to Favorites**, complete the Favorites Editor dialog box, and the shortcut appears in the shortcuts `Help Browser Favorites` category. You can also access `Help Browser Favorites` shortcuts from the Help browser **Favorites** menu.
- Drag statements from a desktop tool, such as the Command History, onto the **Start** button.

Running Shortcuts

To run a shortcut, select the shortcut name, for example, **sea_temp_environment**, from the **Start > Shortcuts** menu or from one of its category submenus. All of the statements in the shortcut **Callback** field execute. It is as if you ran those statements from the Command Window, although they are not reflected in the Command History window.

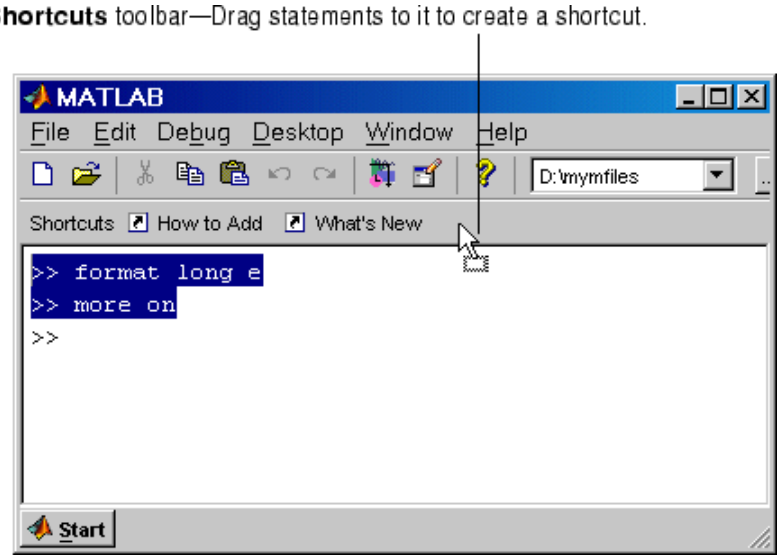
If you added a shortcut to the **Shortcuts** toolbar, you can run it by clicking its icon on the shortcuts toolbar.

Shortcuts Toolbar

The **Shortcuts** toolbar is an alternative to creating and running shortcuts via the **Start** button. To show or hide the shortcuts toolbar, use **Desktop > Shortcuts Toolbar**. To create and run shortcuts via the desktop **Shortcuts** toolbar, perform these steps:

1 Select statements from the Command History window, the Command Window, or an M-file.

2 Drag the selection to the desktop **Shortcuts** toolbar. The following illustration shows two statements being dragged from the Command Window.

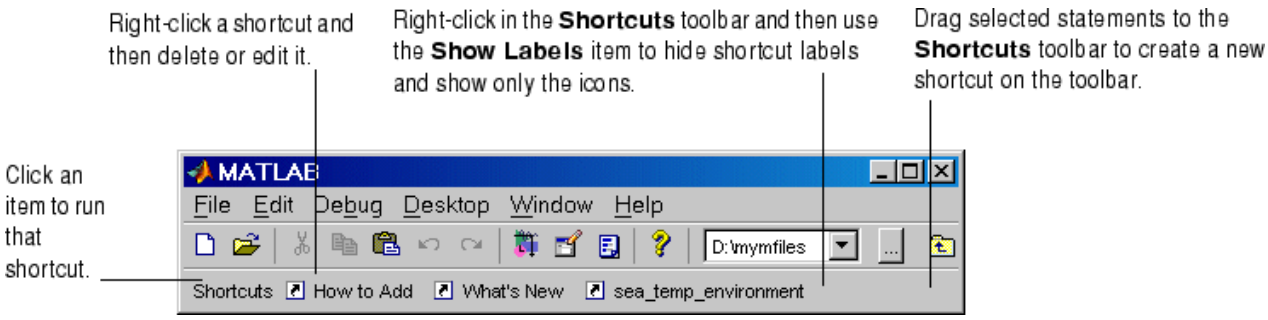


3 The Shortcut Editor dialog box appears. The **Callback** field contains the selected statements, which you can edit as needed. If prompts (>>) from the Command Window appear, note that MATLAB automatically removes them when you save the shortcut. The **Category** field is `Toolbar Shortcuts`, which you must retain in order for the shortcut to appear on the toolbar.

Provide the **Label**, select an **Icon**, and click **Save**.

The shortcut icon and label appear on the toolbar. If you have more shortcuts on the toolbar than can be displayed at once, use the drop-down list to access all of them. For more information, click the **Help** button in the Shortcut Editor dialog box.

4 Click the icon on the **Shortcuts** toolbar to run the shortcut. You can also run the shortcut from the **Start** button by selecting it in the `Toolbar Shortcuts` category.



You can also add a shortcut to the desktop **Shortcuts** toolbar by right-clicking the toolbar and selecting **New Shortcut**. Complete the resulting Shortcut Editor dialog box. Assuming you maintain the `Toolbar Shortcuts` category, the shortcut appears on the toolbar. To change the order of the shortcuts on the toolbar, select **Start > Shortcuts > Organize Shortcuts** and move the shortcuts within the `Toolbar Shortcuts` category.

How to Add and What's New Shortcuts

The **Shortcuts** toolbar includes two shortcuts provided with MATLAB. The **How to Add** shortcut provides help about shortcuts and adding them to the **Shortcuts** toolbar. **What's New** displays the Release Notes documentation.

To remove the **How to Add** or **What's New** shortcut from the **Shortcuts** toolbar, choose a different category. For instructions, see "Organizing and Editing Shortcuts" on page 2-38.

If you do not want to keep these shortcuts, remove each one by right-clicking its toolbar shortcut button and selecting **Delete** from the context menu. Click **OK** in the confirmation dialog box to remove the shortcut.

Shortcut Labels on Toolbar

You can hide the shortcut labels on the toolbar. Right-click in the **Shortcuts** toolbar. From the context menu, select **Show Labels**, which clears the check mark next to the item. The shortcut icons appear on the toolbar without labels.

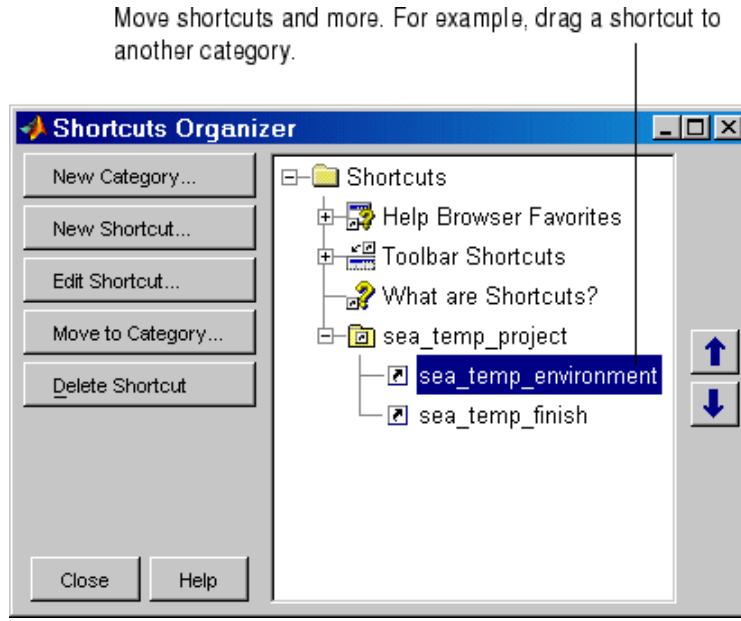
When you move the mouse over a shortcut icon, its label appears as a tooltip. To make labels display in the toolbar, right-click the toolbar and select **Show Labels**, which adds a check mark next to the item and displays the labels.

Organizing and Editing Shortcuts

To create categories for shortcuts, and to move, edit, and delete shortcuts, perform these steps:

1 Select **Shortcuts > Organize Shortcuts** from the **Start** button. Alternatively, access it via the shortcuts toolbar context menu.

The Shortcuts Organizer dialog box appears. When a shortcut category is selected in the dialog box, the **Edit Shortcut** button is replaced by the **Rename Category** button.



2 Use the buttons in the dialog box to edit and organize shortcuts and categories. You can also right-click an item and select an action from the context menu.

Changes take effect immediately.

3 Click **Close**.

For more information about using the Shortcuts Organizer dialog box, click the **Help** button.

Keyboard Shortcuts

In this section...

Keyboard Shortcuts (Accelerators or Hot Keys) and Mnemonics

You can access many of the menu items using shortcut keys (sometimes called accelerators or hot keys) for your platform. For example, use the **Ctrl+X** shortcut to perform a cut on Windows platforms. Many of the menu items show the shortcuts. Additional standard shortcuts for your platform usually work but only one is listed with each menu item.

See additional shortcuts for the Command Window at "Keyboard Shortcuts in the Command Window" on page 3-26, and for the Editor/Debugger at "Keyboard Shortcuts in the Editor/Debugger" on page 6-59.

Instructions in the documentation specify shortcuts using the Windows **Ctrl+** key convention, but with Macintosh key bindings selected, you can use the Command key instead. On the Macintosh, to make full use of all keyboard shortcuts, you need to select the **Full Access** system preference for **Keyboard Shortcuts**.

You can also use mnemonics to access menu items and buttons, such as **Alt+F** to open the **File** menu. This is not supported on the Macintosh platform. Mnemonics are listed with the menu item or button. For example, on the **File** menu, the **F** in **File** is underlined, which indicates that **Alt+F** opens the menu. In the Profiler, the **R** in the **Run this code** toolbar field is underlined, indicating that **Alt+R** moves the cursor to this field.

Note that some versions of Windows do not automatically show the mnemonics on the menu. For example, you might need to hold down the **Alt** key while the tool is selected in order to see the mnemonics on the menus and buttons. In

Windows 2000, go to **Display Control Panel**, select **Effects**, and clear the item **Hide keyboard navigation indicators until I use the Alt key**. See your Windows documentation for details.

Following are some general shortcuts that are not listed on menu items.

Key	Result
Enter	The equivalent of double-clicking, **Enter** performs the default action for a selection. For example, press **Enter** while a statement in the Command History window is selected to run that statement in the Command Window. For buttons in tools and dialog boxes, **Enter** executes the default button (the button with a border around it). If there is no default button, press the **space bar** to execute the active button (the button with a dotted outline inside it). See "Default Button and Active Button (Button with Focus)" on page 2-42 for an illustration.
Esc (escape)	Cancels the current action. For example, if you select the **Edit** menu, the menu items display. Pressing **Esc** retracts the menu items. Pressing **Esc** in a dialog box is the same as selecting the **Cancel** button.
Tab	Advances to the next button or field in a tool or dialog box. In the Command Window, completes a statement if the tab completion preference is selected.
Space bar	For buttons in tools and dialog boxes, activates the active button. See "Default Button and Active Button (Button with Focus)" on page 2-42 for an illustration of selecting default and active buttons using keys.
+ or **-** or * on numeric keypad	Use these keys on the numeric keypad to expand and collapse items in tree views. The Help browser **Help Navigator** pane and the Command History window use tree views. Use **+** to expand the selected item, use **-** to collapse the selected item, and use * to recursively expand it, meaning open all items contained in the selected item.
Alt+S	Displays the **Start** button menu (except on Macintosh platforms).
Alt+Y	Provides access to the current directory field in the toolbar (except on Macintosh platforms).
Ctrl+Tab	Moves to the next open tool in the desktop, or to the next open group of tools tabbed together.

Key	Result
Ctrl+Shift+Tab	Moves to the previous open tool or group of tabbed tools in the desktop.
Ctrl+Page Down	Moves to the next tool within a group of tools tabbed together. In a group of documents, moves to next document.
Ctrl+Page Up	Moves to the previous tool within a group of tools tabbed together. In a group of documents, moves to previous document.
Ctrl+F6	Moves to the next tool or document (only for Windows and Solaris platforms).
Ctrl+Shift+F6	Moves to the previous tool or document (only for Windows and Solaris platforms).
Alt+F4	Closes the desktop, thereby quitting MATLAB. Or outside the desktop, closes the active window (except on Macintosh platforms).

For additional shortcuts available in the various desktop tools, see the documentation for each tool. For example, see "Keyboard Shortcuts in the Command Window" on page 3-26 and "Keyboard Shortcuts in the Editor/Debugger" on page 6-59.

Go To First Letter (Type Ahead) Feature in Desktop Tool Lists

In the Current Directory browser and Command History window, you can type a letter to move directly to the next item in the list that starts with the letter you typed. This is sometimes referred to as *type ahead*.

Default Button and Active Button (Button with Focus)

These illustrations demonstrate the default versus active button in a dialog box.

The default button has a border around it. Here, **Save** is the default button. Press the **Enter** key to execute the default button.

The active button (the button with focus) has a dotted outline inside it. Here, **Cancel** is the active button. Press the space bar to execute the active button.

Here, the **Help** button is both the default button and the active button. In some cases, the default always changes to match the active button. You can press either **Enter** or the space bar to execute the **Help** button

Other Desktop Features

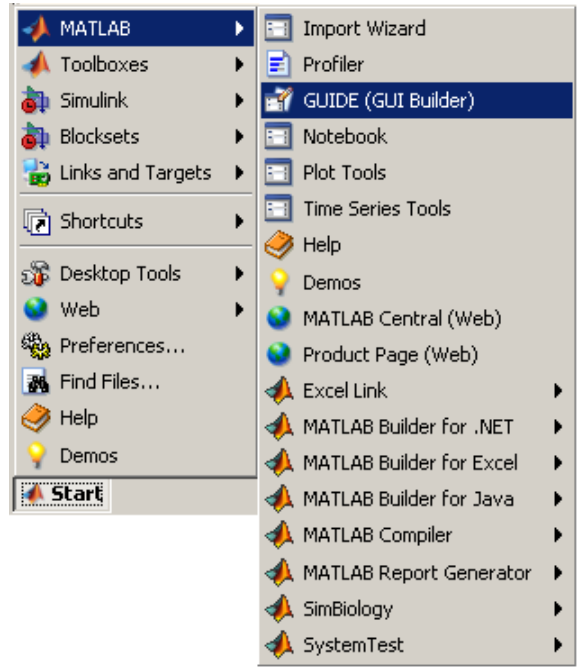
In this section...

Start Button for Accessing Tools

The MATLAB **Start** button provides easy access to tools, demos, and documentation for all your MathWorks products. From it, you can also create and run MATLAB shortcuts, which are groups of MATLAB statements.

Using the Start Button

1 Click the **Start** button to view a menu of product categories and desktop tools installed on your system. As an alternative, press **Alt+S** to view the **Start** button contents (except on Macintosh platforms). In the following illustration, MATLAB is selected.



2 From the menu and submenu items, select an item to open it. Use the icons to quickly locate a type of product or tool — see the following description of icons.

For example, select **Start > MATLAB > GUIDE (GUI Builder)** to open that tool.

Icons in the Start Button. Icons help you quickly locate a particular type of product or tool. This table describes the action performed when you select an entry with one of these icons in the **Start** button.

Icon	Description of Action When Opened
	Documentation for that product opens in the Help browser.
	Demos for the product are listed in the Help browser **Demos** pane.
	Selected tool opens.

Icon	Description of Action When Opened
	Block library opens.
	Document opens in your system Web browser.

Customizing the Start Button

You can add your own toolboxes to the **Start** button. Select **Start > Desktop Tools > View Source Files** to open the Start Button Configuration Files dialog box. For more information, click the **Help** button in the dialog box.

Menus and Context Menus

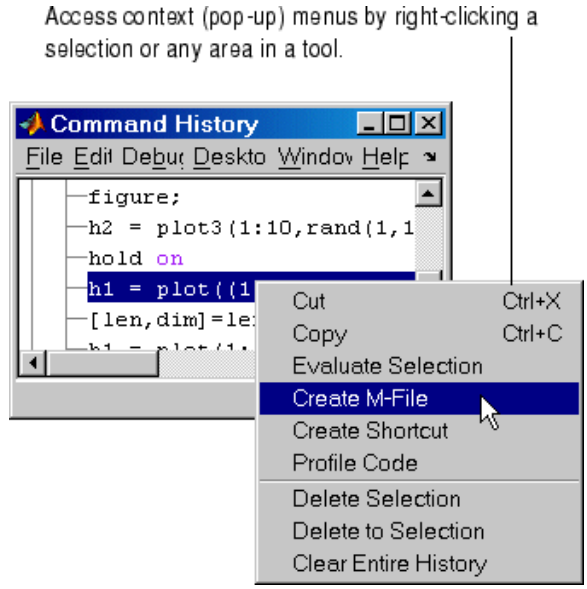
Merged Menus

When you use a tool in the desktop, its menu appears at the top of the desktop. When you work in a different tool in the desktop, you still use the menu at the top of the desktop, but the menu content changes to support that tool. When you undock a tool from the desktop, access its menu at the top of the undocked tool.

Context Menus

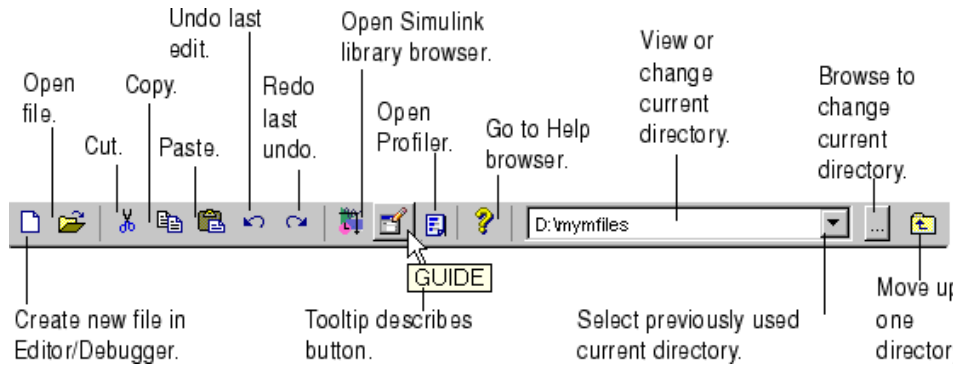
Many of the features in MATLAB desktop tools are available from context menus, also known as pop-up or right-click menus. To access a context menu, right-click a selection or an area, or press **Ctrl+Shift+F10**. The context menu for the selection or tool appears, presenting the available actions. For example, following is the context menu for a selection in the Command History window.

If a context menu does not appear, try right-clicking in a different part of the tool. When a context menu item is gray, the item does not apply to the current selection or area.



Toolbars

The toolbar in the desktop provides easy access to frequently used operations. Position the pointer over a button for a second or two and a tooltip appears that describes the item.



Some tools also have their own toolbars, which are located within the tool's own window. For example, the Current Directory browser has its own toolbar. When you undock one of these tools, the undocked tool includes the toolbar.

To hide a toolbar, or to show it again after hiding it, use the appropriate toolbar item in the **Desktop** menu. As an alternative, right-click a toolbar or menu bar and select a toolbar from the context menu to hide or show it.

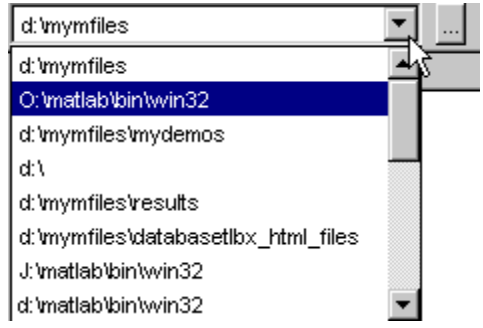
For figure windows, use the toolbar item in its **View** menu.

Current Directory Field

The current directory field in the desktop toolbar shows the MATLAB current working directory. You can change the current directory using this field and any of these methods:

- Type the new current directory directly in the field.
- Use the drop-down list to change to a previously used current directory. To specify the number of entries maintained each session, use the **History** preference you access via **File > Preferences > Current Directory**.
- Use the Browse for folder button **...** to select a new current directory.
- Use the Go Up One Level button to move the current directory up one level.

The same current directory field also appears in the Current Directory browser when the Current Directory browser is undocked from the desktop. Use the Current Directory browser to perform many additional file operations. For more information, see "File Management Operations" on page 5-35.



Status Bar

Along the bottom of the desktop is the status bar. It displays messages, such as when MATLAB is busy executing statements or when the Profiler is on. Some tools, such as the Editor/Debugger, display additional status information, such as the current line number. Not all status information appears on the status bar — many MATLAB functions and tools provide status information that is not reported to the status bar.

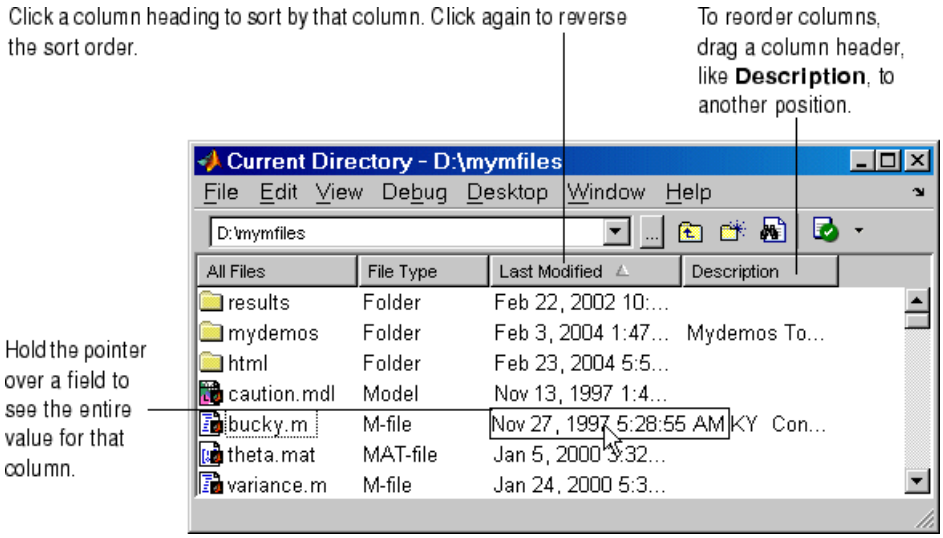
You can construct your own functions to provide status information. See the `timer` function, and search for other specific terms describing the status of interest.

Sizing, Arranging, and Sorting Columns in Tools

Some desktop tools present information in columns, such as the Current Directory browser.

To change the column width, drag the separator bar between two column headings in a tool. When a column is too narrow to show all the information in it, position the pointer over an item and the full value for that item displays like a tooltip.

To rearrange the columns in a tool, drag the column header to a different position. To sort the information by a particular column, click the column header. For example, in the Current Directory browser, click the **Last Modified** date to sort the items in date order. Some columns also allow you to reverse the sort order by clicking the column header again. A small gray arrow in the header indicates the current sort order — for example, an up arrow in the **Last Modified Date** column header indicates an ascending sort order, meaning the oldest files are at the top of the list.



Selecting Multiple Items

In many desktop tools, you can select multiple items and then select an action to perform on all the selected items. Select multiple items using the standard practices for your platform.

For example, if your platform is Windows, do the following to select multiple items:

1. Click the first item you want to select.
2. Hold the **Ctrl** key and then click the next item you want to select. Repeat this step until you have selected all the items you want. To select contiguous items, select the first item, hold the **Shift** key, and then select the last item.

Now you can perform an action on the selected items, such as delete.

To clear one of multiple selected items, use **Ctrl**+click. To clear all selected items, click outside of the selection.

Cut, Copy, Paste, and Move

You can cut and copy a selection from a desktop tool to the clipboard and then paste it from the clipboard into another tool or application. Use the **Edit** menu, toolbar, context menus, or standard keyboard shortcuts. For example, you can copy a selection of statements from the Command History window and paste them into some MATLAB desktop tools.

Use **Paste** to move items copied to the clipboard from other applications. The **Paste to Workspace** item in the **Edit** menu opens the selection on the clipboard in the Import Wizard. You can use this to copy data from another application, such as Excel, into MATLAB. For details, see the "Using the Import Wizard".

When editing in the Command Window and Editor/Debugger, to move text to a new location, select the text and drag it. To copy text, press **Ctrl** and drag the selected text to the new location.

To undo the most recent cut, copy, or paste command, select **Undo** from the **Edit** menu. Use **Redo** to reverse the **Undo**. For some tools, you can undo multiple times in succession.

See also the `clipboard` function.

Drag and Drop

You can also move or copy a selection from one tool to another by dragging the selection. For example, make a selection in the Command History window and drag it to the Command Window, which pastes it there. Edit the lines in the Command Window, if needed, and then press the **Enter** key to run the lines from the Command Window.

Another example is to drag a filename from the Current Directory browser to the Editor/Debugger to open that file in the Editor/Debugger. If you drag editable text, for example, text in the Editor/Debugger, the text is cut rather than copied. Use **Ctrl** and drag to copy rather than cut editable text.

On Windows platforms, you can drag items from external applications into MATLAB. For example, dragging text from a Microsoft Word document into the Editor/Debugger cuts and pastes it into the open file. Dragging an M-file from Windows Explorer to the Command Window runs the file. Similarly, you

can drag selections from desktop tools to other applications. For example, you can drag text from the Editor/Debugger to Microsoft Word.

Macintosh Differences in the Desktop

MATLAB on the Macintosh platform sometimes uses Macintosh GUI conventions, which might be different from what is stated in the MATLAB documentation, but the intended action should be clear. For example, if you select **File > Save** on the Macintosh, the Save dialog box that appears presents the options **Don't Save** and **Save**. On Windows and UNIX platforms, the Save dialog box presents the options **Yes**, **No**, and **Cancel**.

The standard Macintosh mouse is a single-button device. Other platforms use a mouse with more than one button. MATLAB takes advantage of these buttons. The documentation does not usually present the equivalent Macintosh instruction. When the documentation instruction is right-click, use **Ctrl**+click on the Macintosh. When the documentation instruction is middle-click, use **Command**+click on the Macintosh.

Printing and Page Setup Options for Desktop Tools

You can print from all desktop tools except the Current Directory browser, but there are some differences in usage.

To print, select **File > Print** from the tool. A Print dialog box opens. The **Properties** button in the Print dialog box is enabled for the Web and Help browsers and the Profiler, but is not enabled for the other desktop tools.

To specify standard page setup options for your platform when you print from the Command History, Workspace browser, and Array Editor, select **File > Page Setup**. A standard page setup dialog box for your platform opens.

MATLAB provides special page setup options for printing from the Command Window and Editor/Debugger. The setup options are essentially the same for both tools, with minor variations. This section covers their use:

- "Specifying Page Setup Options" on page 2-53
- "Layout Options for Page Setup" on page 2-54
- "Header Options for Page Setup" on page 2-54

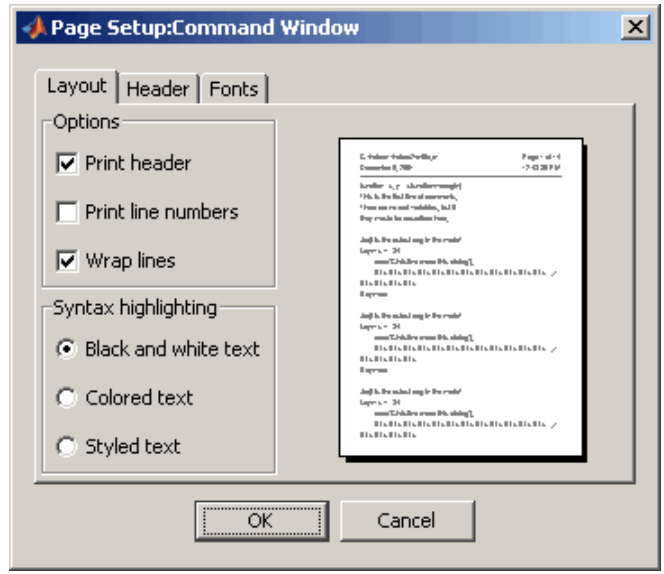
- "Fonts Options for Page Setup" on page 2-54

Specifying Page Setup Options

To specify page setup options, perform these steps:

1. In the tool you want to print from, for example, the Command Window, select **File > Page Setup**.

   The Page Setup dialog box opens for that tool.



2. Click the **Layout**, **Header**, or **Fonts** tab in the dialog box and set those options for that tool, as detailed in subsequent sections.

3. Click **OK**.

4. After specifying the options, select **File > Print** in the tool you want to print from, for example, the Command Window.

   The contents from the tool are printed, using the options you specified in Page Setup.

Layout Options for Page Setup

You can specify the following layout options. A preview area shows you the effects of your selections:

- **Print header** — Print the header specified in the **Header** pane.
- **Print line numbers** — Print line numbers.
- **Wrap lines** — Wrap any lines that are longer than the printed page width.
- **Syntax highlighting** — For keywords and comments that are highlighted in the Command Window, specify how they are to appear in print. Options are black and white text (that is, no highlighting), colored text (for use with a color printer), or styled text. For styled text, keywords appear in bold, comments appear in italics, and all other text appears in the normal style. Only keywords and comments you input in the Command Window are highlighted; output is not highlighted.

Header Options for Page Setup

If you want to print a header, select the **Layout** tab and then select **Print header**. Then select the **Header** tab and specify how the elements of the header are to appear. A preview area shows you the effects of your selections:

- **Page number** — Format for the page number, for example `# of n`
- **Border** — Border style for the header, for example, `Shaded box`
- **Layout** — Layout style for the header. For example, `Standard one line` includes the date, time, and page number all on one line

Fonts Options for Page Setup

Specify the font to be used for the printed contents:

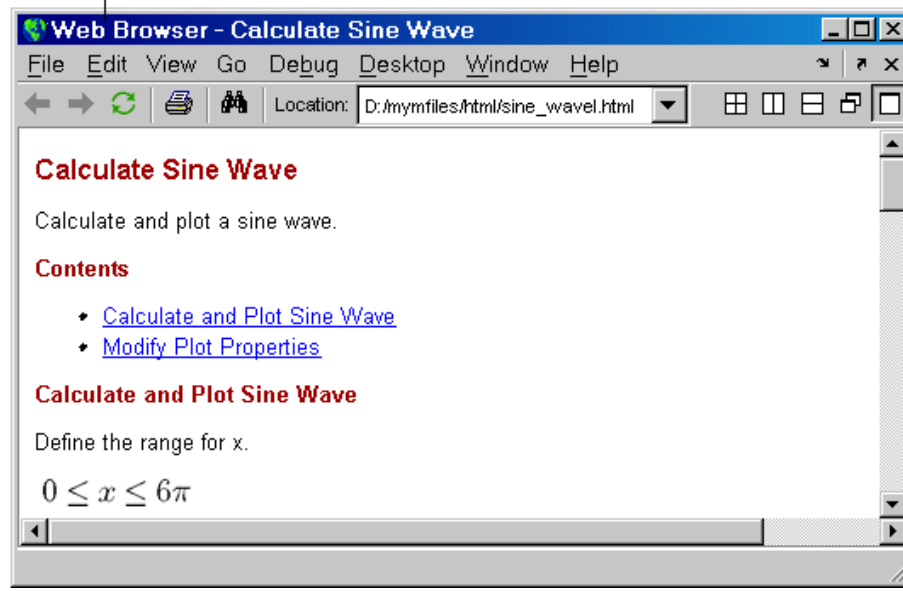
1. From **Choose font**, select the element, either `Body` or `Header`, where `Body` text is everything except the `Header`.
2. Select the font to use for that element. For example, select **Use Command Window font** for `Body` text if you want the printed text to be the same as the font that appears in the Command Window. This is the font specified in **File > Preferences > Fonts > Custom** for the `Command Window`.

3 Repeat for the other element. If you did not select **Print header** on the **Layout** pane, you do not need to specify the `Header` font. As an example, for `Header` text, select **Use custom font** and then specify the font characteristics — type, style, and size. After you specify a custom font, the **Sample** area shows how the font will look.

Web Browser

Some tools in MATLAB and related products display HTML documents in the MATLAB Web Browser. For example, after using the Editor/Debugger's cell features to publish an M-file to HTML, you view the HTML file in the MATLAB Web Browser. Because the MATLAB Web Browser is a desktop tool, you can dock it and perform other desktop operations on it.

Example of Web browser displaying results of M-file published to HTML format.



To display an HTML document in the Web Browser, double-click the document name in the Current Directory browser or use the `web` function. The `web` function supports arguments that display documents in your system browser, for example, Netscape, or in the Help browser.

The toolbar buttons and menu items in the Web Browser are similar to those found in the Help browser display pane. For more information, see “Viewing Documentation in the Help Browser” on page 4-26.

One feature of the Web Browser not found in the Help browser is the **Location** field. In the Web Browser, type a URL in the field to display that Web page.

Like any Web browser, the MATLAB Web Browser might not support all of the HTML or related features used in a particular Web site or HTML page. For example, the MATLAB Web Browser does not support the display of `.bmp` (bitmap) image files. Instead use `.gif` or `.jpeg` formats for image files in HTML pages. As another example, it does not support HTML pages you generate directly from Microsoft Word and PowerPoint.

Internet Connection and Fonts for Web Browser — Web Preferences

To specify a proxy server to connect from the MATLAB Web Browser to the Internet, use Web preferences. You might need to specify this preference if you have a firewall, for example. If you have a firewall and do not specify the proxy settings, links from the Web Browser to URLs will not work.

Select **File > Preferences > Web**. By default, the check box **Use a proxy server to connect to the Internet** is not selected. This is for when you have a direct connection to the Internet.

To specify a proxy server, select the check box and specify the **Proxy host** and **Proxy port**. See your system administrator for the information you need to specify the proxy settings. As an example, `172.16.10.8` illustrates the format for host, and `3128` is the type of value you enter for port.

Fonts for Web Browser. To modify the font used in the Web Browser, select **File > Preferences > Fonts**. The Web Browser uses the font settings you specify for HTML Proportional Text tool. For more information about setting fonts, click the **Help** button in the preference pane for **Fonts**.

Accessing The MathWorks on the Web

You can access popular MathWorks Web pages from the MATLAB desktop. Select one of the following items from the **Help > Web Resources** menu.

For most items, the selected Web page then opens in your default system Web browser, for example, Netscape:

- **The MathWorks Web Site** — Home page of the MathWorks Web site (`http://www.mathworks.com`).
- **Products & Services** — MathWorks Products and Services page (`http://www.mathworks.com/products/`) with information about the full family of products.
- **Support** — MathWorks Support page (`http://www.mathworks.com/support`) where you can look for solutions to problems you are having, or report new problems.
- **MathWorks Account**
  - **Login in or Create Account** — Login page for MathWorks Account (`http://www.mathworks.com/accesslogin/`). If you are registered, your main account page displays. Otherwise, you are directed to a page where you register online. Registration allows you to view your product registration and license information and helps you stay up to date on the latest MATLAB developments.
  - **Get Passcodes and Manage Licenses** — If you have a MathWorks Account, displays your Licenses page.
  - **Get Product Trials** — If you have a MathWorks Account, provides access to trial versions of products.
- **MATLAB Central** — MATLAB Central Web site (`http://www.mathworks.com/matlabcentral/`) for the MATLAB user community. It includes MATLAB contest entries and results, a MATLAB screen saver, and these technical resources:
  - **MATLAB File Exchange** — Code library of files contributed by MathWorks customers and employees, available for free download and use with MathWorks products.
  - **MATLAB Newsgroup Access** — Provides access to the Usenet newsgroup for MATLAB and related products, `comp.soft-sys.matlab`, where you can post and answer questions, as well as view the archives.
- **MATLAB Newsletters** — Access to online versions of News and Notes and MATLAB Digest. News and Notes is published twice a year and contains feature articles, technical notes, and product information for MATLAB

users. MATLAB Digest, an electronic bulletin consisting of technical notes, solutions, and timely announcements to the user community, is issued more frequently. See `http://www.mathworks.com/company/newsletters`.

Check for Updates

This features allows you to easily determine if more recent versions of your MathWorks products are available. Select **Help > Check for Updates**. A dialog box appears, listing the version numbers of all MathWorks products installed on your system. Click **Check for Updates** in the dialog box, which accesses the MathWorks Web site and reports back for each product if a newer version is available or if your version is the latest.

Terms of Use and Patents

Access the terms of use and patent information for MathWorks products.

Preferences

In this section...

Setting Preferences

Use preferences to specify options for MATLAB tools, as follows:

1. Select **File > Preferences**.
2. In the left pane of the Preferences dialog box, preferences appear for MATLAB tools as well as for any other MathWorks products installed on your system.

   Choose a tool and click the **+** to display more preferences for that tool. From the expanded list, select the entry you want. The right pane shows the preferences for that item.
3. Change settings. Click **Apply** or **OK** to set the preferences. Preferences take effect immediately. They remain persistent across MATLAB sessions.

Note that some tools allow you to control these settings from within the tool without setting a preference. Use that method if you only want the change to apply to the current session.

Function Alternative

Open the Preferences dialog box using the `preferences` function.

Summary of Preferences

Preference	What You Can Specify
General Preferences	Toolbox path caching, figure window printing, `delete` function behavior, MAT-file save formats, confirmation dialogs, source control, and multithreaded computation.
Keyboard	Key bindings, tab completion, and delimiter matching for the Command Window and the Editor/Debugger.
Fonts	Font type, style, and size for desktop tools. Customize for any tool.
Colors	Colors for text, background, syntax highlighting, and hyperlinks in desktop tools.
M-Lint	Show or hide M-Lint messages in the Editor/Debugger M-Lint automatic code analyzer and in the M-Lint Code Check Report.
Command Window	Numeric format and display, accessibility, and tab size.
Command History	Display, filtering, and saving.
Editor/Debugger	Editor type, startup options, display, tab size and indenting, language, including M-Lint messages, publishing, and autosave.
Help	Product filter and synchronization.
Web	Internet proxy server settings.
Current Directory	Number of entries in history and display options.
Array Editor	Numeric format, use of **Enter** key, and decimal separator.
Workspace	Statistical calculation options.
GUIDE	Display options for GUI-building tool.
Time Series Tools	Property Editor dialog and x-axes warning dialog.
Figure Copy Template	Application, text, line, uicontrols, axis, format, background color, and size.
Other products	Preferences for other installed MathWorks products.

Preferences File — matlab.prf

Preferences are stored in a preferences file, `matlab.prf`. Type `prefdir` in the Command Window to see the full pathname for the preferences directory that contains `matlab.prf`. The preference directory also contains related files.

On Macintosh platforms, the directory might be in a hidden folder, for example, `myname/.matlab/R2007b`. To access the directory, select **Go > Go to Folder** in the Mac OS Finder. In the resulting dialog box, type the path returned by `prefdir` and press **Enter**.

The `matlab.prf` file is loaded when MATLAB starts and is overwritten when you close MATLAB.

The exact name of the preferences directory that MATLAB uses depends on the release. When you install a new version of MATLAB, MATLAB tries to use your existing preferences from the previous version, where possible. For more information on the preference directory filename and the preference migration process, see the reference page for `prefdir`.

Fonts Preferences for Desktop Tools

In this section...

Setting Desktop Fonts

Use desktop font preferences to specify the font characteristics for MATLAB desktop tools. The font characteristics are

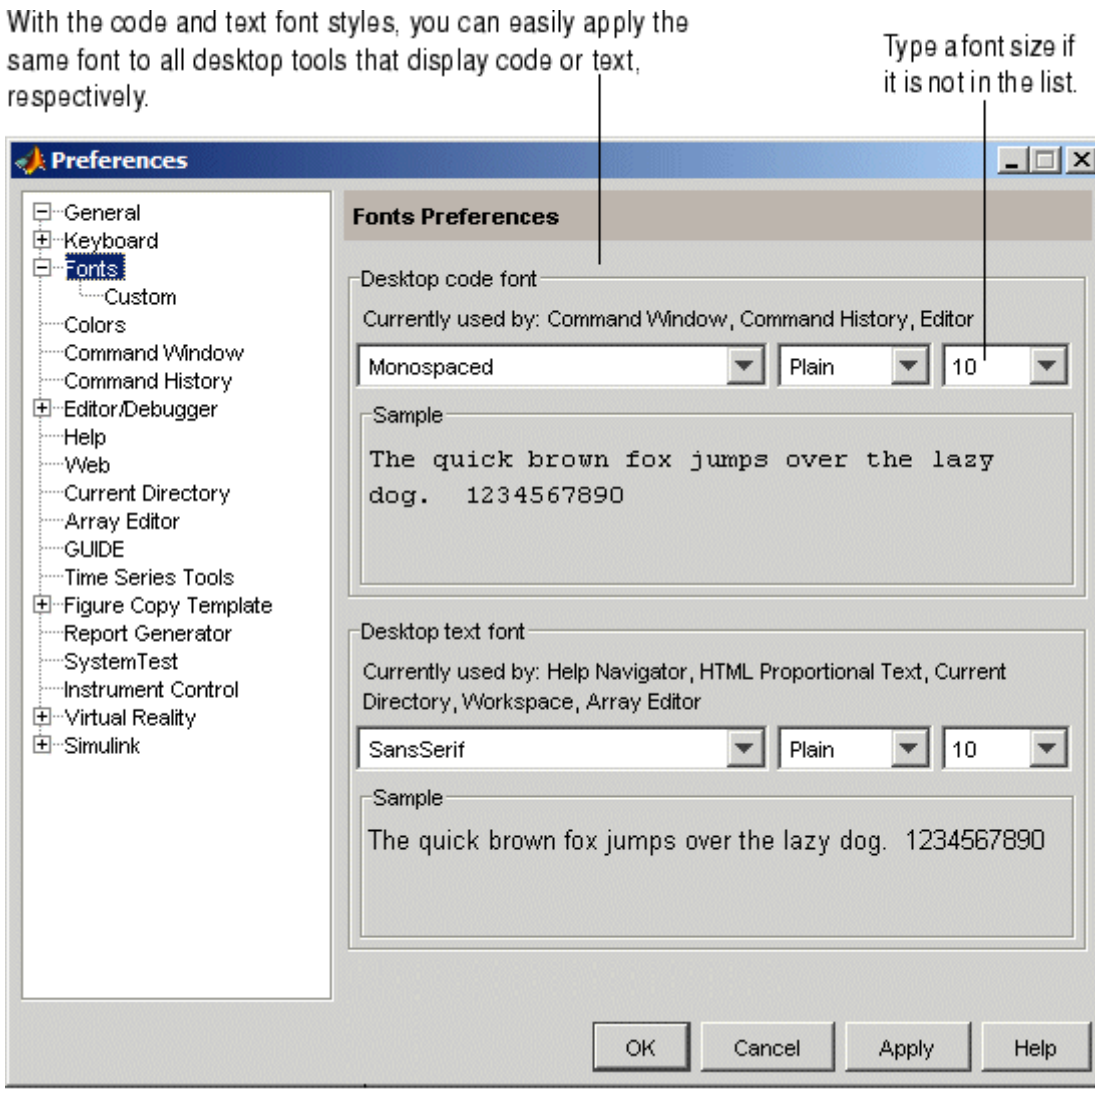
- Name (also called family or type), for example, select SansSerif
- Style, for example, select bold
- Size in points, for example, type 11 points

Select **File > Preferences > Fonts** to set fonts for desktop tools. You can specify the font to be used by all tools that primarily display code such as the Command Window, and specify the font to be used by all other desktop tools. Or you can separately specify the font for any desktop tool.

Select the font characteristics from the lists shown. For font size, not all entries are shown. You can type in a size, including one not shown.

You can set some font options differently for printing — see "Printing and Page Setup Options for Desktop Tools" on page 2-52.

For information about making additional fonts available to MATLAB, see "Making Fonts Available to MATLAB" on page 2-69.



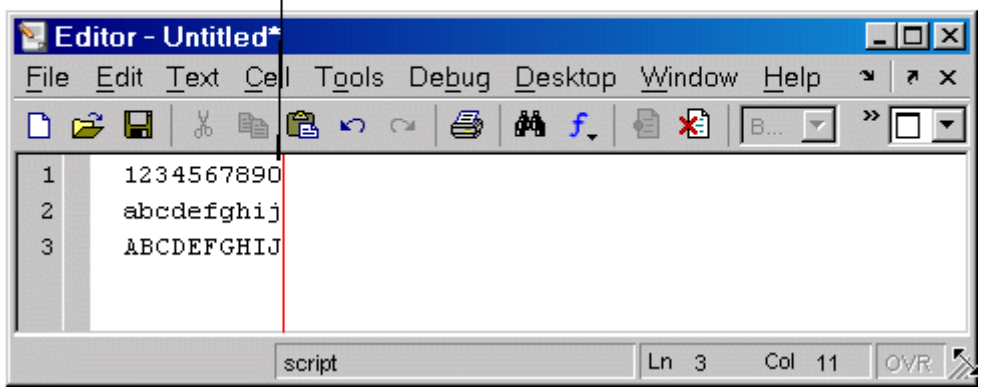
Desktop Code Font and Desktop Text Font

You specify separate font characteristics for tools that primarily display code (**Desktop code font**), such as the Command Window, and tools that primarily display text (**Desktop text font**), such as the Current Directory

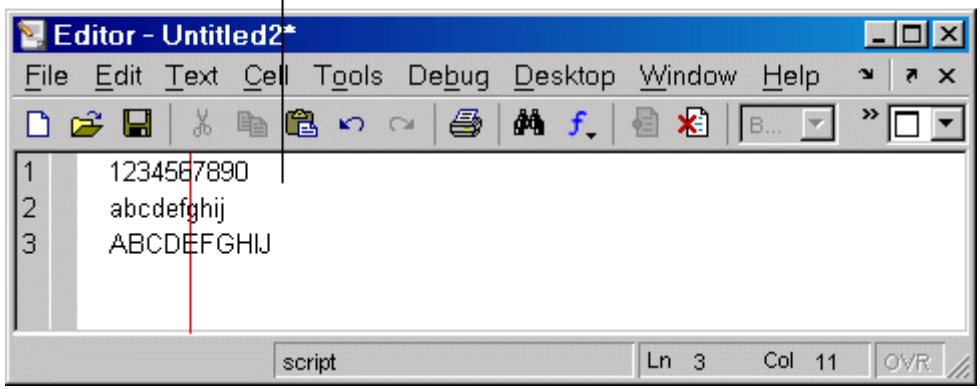
browser. Many users prefer that code display in a monospace font to provide better alignment, and prefer a more narrow font style for text information. With the desktop code font preference, you set just one preference to apply a monospace style to all tools that display code (except the Help and Web Browsers). Similarly, you can set just one preference to apply a text font to all desktop tools that display text.

The following illustrations show how the Editor/Debugger would look using a monospace font and a proportional font. Note that a monospace font is useful when you care about alignment, but a proportional font uses less space.

With a monospaced font, all characters are the same width. Here, the font is 10 pt. Monospace. Note the 10th character in each line aligns with the Editor/Debugger's right-hand text limit, which is set to column 10.



With a proportional font, characters are different widths. Here, the font is 10 pt. SansSerif. Each line contains 10 characters but the length of each line differs. The Editor/Debugger's right-hand text limit is not relevant.



Default Font Settings

Default settings are listed in the following table. Note that Lucida Console approximates the `fixedsys` font available in earlier versions of MATLAB.

Font Type	Default Characteristics and Sample	Tools Using Font Type by Default
Desktop code font	Monospaced, Plain, 10 point `Sample code font`	• Command History • Command Window • Editor/Debugger (which also applies to the Shortcuts Editor)
Desktop text font	SansSerif, Plain, 10 point Sample text font	• Array Editor • Current Directory browser (which also applies to the Path browser) • Help Navigator • HTML Proportional Text. This is the font used for noncode text in the Web browser (including, for example, HTML reports generated from cell publishing), Profiler, and Help browser display pane. While you can select the font name, you cannot change the font style (for example, to bold or italic) for HTML Proportional Text. Changes to size affect noncode and code text. • Workspace browser

When you change a font characteristic for **Desktop code font**, the characteristic takes effect for all tools that use the desktop code font. The same is true when you change a font characteristic for **Desktop text font**.

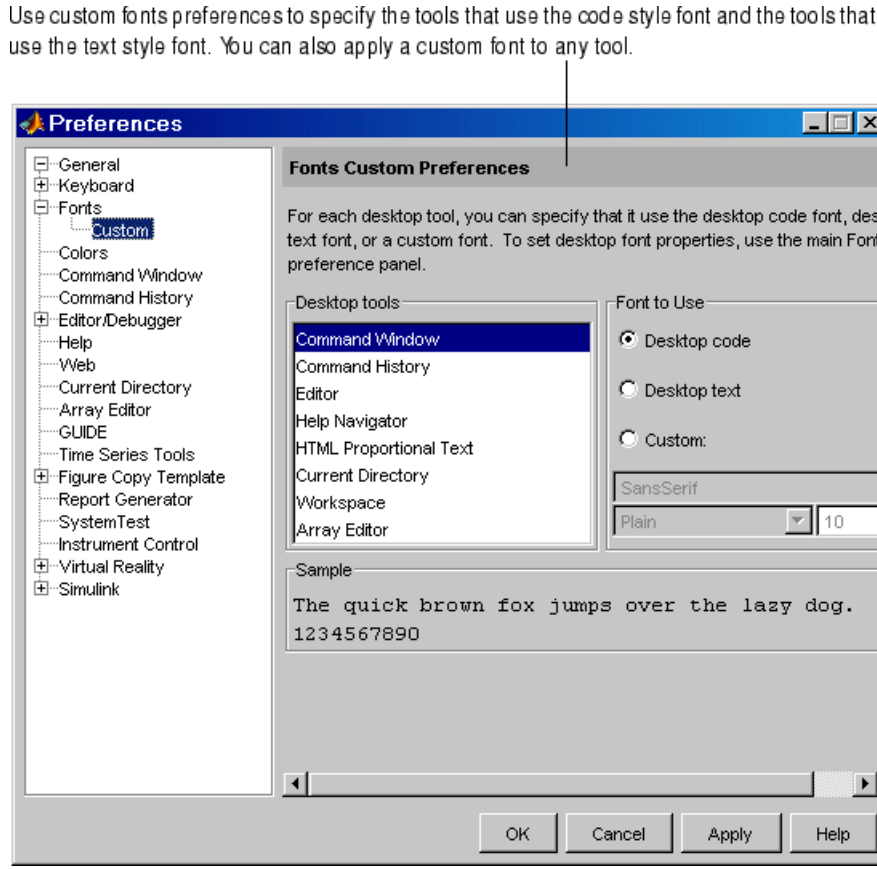
After changing a characteristic, a sample in the dialog box shows how it will look. Click **Apply** or **OK** to make the change take effect in the desktop tools.

See Also

"Preferences" on page 2-59

Custom Fonts Preferences

If you do not want to use the current settings for "Desktop Code Font and Desktop Text Font" on page 2-63, you can specify that a tool use the code font, the text font, or a different font. Select **File > Preferences > Fonts**. Click **+** and select **Custom**. The **Fonts Custom Preferences** pane appears.



Select a tool from the **Desktop tools** list. The type of font it uses, code or text, appears under **Font to Use**. In the illustration shown, the Command Window uses the **Desktop code font**, which is defined in the **Fonts** pane as described in the previous section.

To change the font characteristics the selected tool uses, select a different radio button. For **Custom**, you then specify the font characteristics for that tool.

Changing the Font — Example

This example changes the default settings (see "Default Font Settings" on page 2-65) for the desktop code font, changes the Command History font preference so that it uses the desktop text font instead of the code font, and specifies a custom font for the Current Directory browser:

1. Change the characteristics for the desktop code font. On the **Fonts** pane, set the **Desktop code font** to `Times New Roman`, `Plain`, `14` point. Use the default for the **Desktop text font**, `SansSerif`, `Plain`, `10` point. Click **Apply**.

2. Make the Command History window use the desktop text font. Select **Fonts**, click **+**, select **Custom**, and then select `Command History` from **Desktop tools**. Select the **Desktop text** radio button.

3. Apply a custom font to the Current Directory browser. Select `Current Directory` from **Desktop tools.** Select the **Custom** radio button. Select `Arial Narrow` and `Plain`, and type `11` in the size field. Click **OK**.

The following table details the results of the changes.

Tool	Font Type	Font Characteristics
Command Window	Desktop code	Times New Roman, Plain, 14 point
Command History	Desktop text	SansSerif, Plain, 10 point
Editor/Debugger	Desktop code	Times New Roman, Plain, 14 point
Help Navigator	Desktop text	SansSerif, Plain, 10 point
HTML Proportional Text	Desktop text	SansSerif, Plain, 10 point
Current Directory	Custom	Arial Narrow, Plain, 11 point

Tool	Font Type	Font Characteristics
Workspace	Desktop text	SansSerif, Plain, 10 point
Array Editor	Desktop text	SansSerif, Plain, 10 point

See Also

For help about how MATLAB stores preferences and help for other preferences, see “Preferences” on page 2-59.

Antialiasing for Desktop Fonts on Linux/UNIX

To give the desktop a smoother appearance in Linux/UNIX, select the antialiasing preference on the **Preference > Fonts** pane. The preference apply to all fonts.

Note The antialiasing option is not necessary on Windows or Mac, because MATLAB follows the operating system’s font settings on these platforms.

Making Fonts Available to MATLAB

On Windows platforms, desktop components (such as the Command Window and Workspace browser), figure windows, and uicontrols support only TrueType and OpenType fonts. Some graphics objects can render bitmapped fonts as well, such as `xlabel`, `ylabel`, `title`, and `text`.

To make a new compatible font available to MATLAB, install the font by selecting **Start > Control Panel > Fonts** in the Windows desktop, and then selecting **File > Install New Font**. Restart MATLAB so that it can use the font.

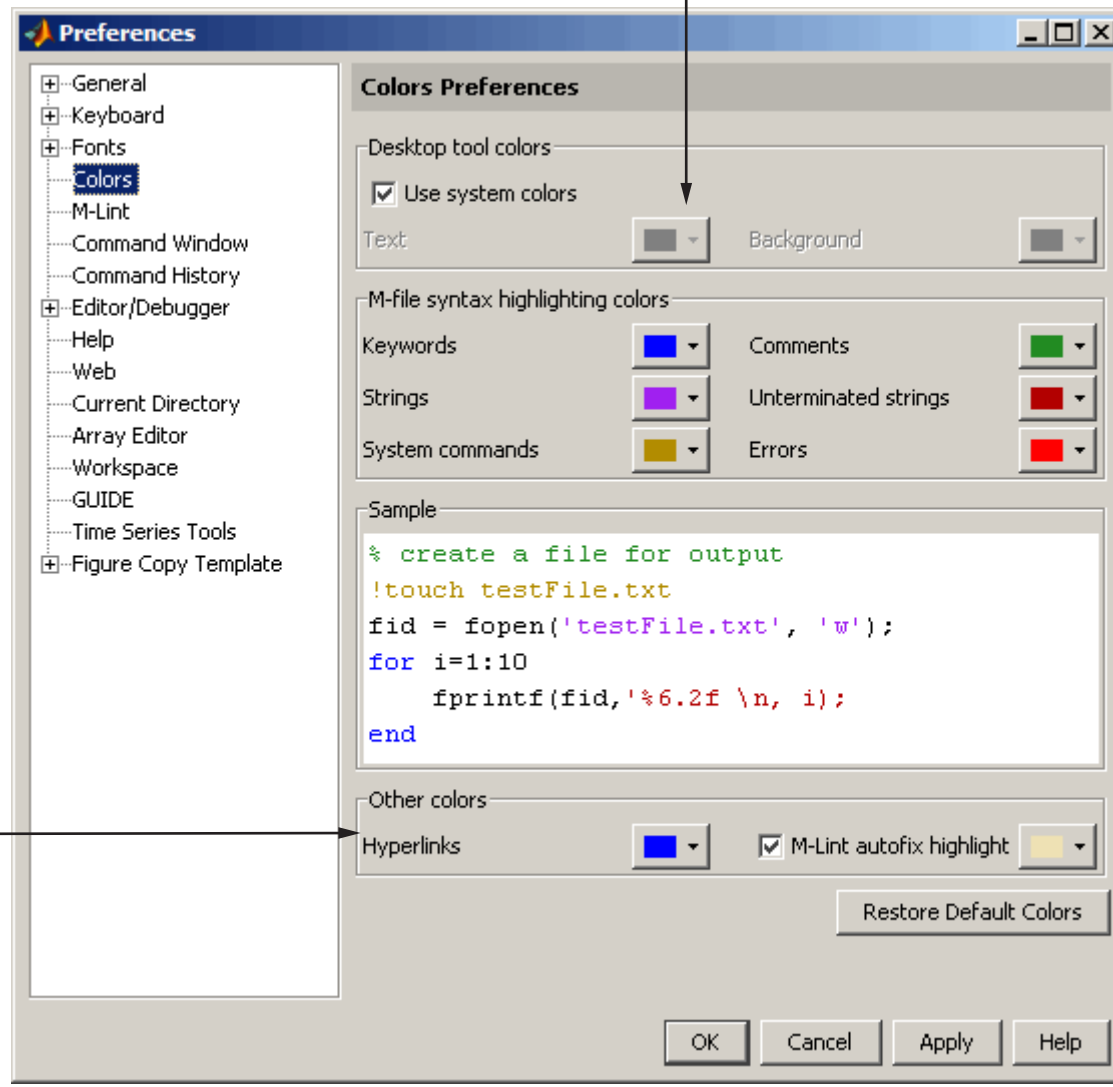
Colors Preferences for Desktop Tools

In this section...

Setting Colors Used in Desktop Tools

Desktop color preferences specify the colors used in MATLAB desktop tools and the colors that convey syntax highlighting. Select **File > Preferences > Colors** to set color preferences for desktop tools. You can set some color options differently for printing — see "Printing and Page Setup Options for Desktop Tools" on page 2-52.

To set colors for text and the background, clear the **Use system colors** check box and then select colors from the palettes.



Specify the color of hyperlinks in the Command Window and Help browser Index pane.

Desktop Tool Colors

Use **Desktop tool colors** to change the color of the text and background in the desktop tools. The colors also apply to the Import Wizard. The colors do not apply to the HTML display pane nor to the Web Browser.

Select the check box **Use system colors** if you want the desktop to use the same text and background colors that your platform (for example, Windows) uses for other applications.

To specify different text and background colors, follow these steps:

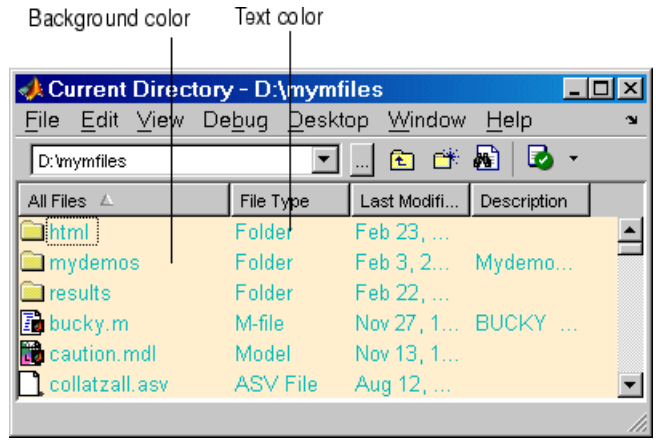
1. Clear the **Use system colors** check box.
2. Click the arrow next to the **Text** color and choose a new color from the palette shown.

   When you choose a color, the **Sample** area in the dialog box updates to show you how it will look.
3. Click the arrow next to the **Background** color and choose a new color.

   If you use a gray background color, a selection in an inactive window will not be visible.
4. Click **Apply** or **OK** to see the changes in the desktop tools.

Click **Restore Default Colors** to return to the default settings for desktop tool colors, as well as for syntax highlighting colors.

The following illustration shows how the Current Directory browser looks with blue-green text and a beige background. These colors are only discernible in the online version of this documentation.



Gray Background Color

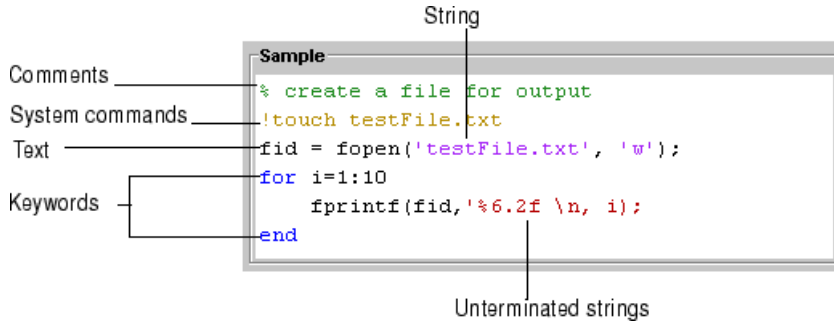
For some UNIX platforms, there is a gray background color for desktop tools, such as the Editor/Debugger. This occurs when the preference for **Desktop tool colors** is set to **Use system colors**, and the system's window manager uses gray as the background color default. To change the color, clear the check box for **Use system colors** and then select a new **Background** color from the palette.

Syntax Highlighting Colors

In the Command Window, Command History, Editor/Debugger, and Shortcuts callback area, MATLAB conveys syntax information via different colors to help you easily identify elements, such as `if/else` statements. This is known as syntax highlighting.

In the Command Window, only the input you type is highlighted; output from running MATLAB functions is not highlighted. In the Editor/Debugger, you can specify syntax highlighting preferences for use with files in M, C/C++, Java, and HTML. For details, click the **Help** button in the Preferences dialog box for the Editor/Debugger to see Language Preferences in the online documentation.

Use preferences to specify the syntax highlighting colors. When you choose a color, the **Sample** area in the dialog box updates to show you how it will look.



The default colors are listed here:

- **Keywords** — Flow control functions, such as `for` and `if`, as well as the continuation ellipsis (`...`), are colored blue.
- **Comments** — All lines beginning with a `%`, designating the lines as comments in MATLAB, are colored green. Similarly, the block comment symbols, `%{` and `%}`, as well as the code in between, appear in green. Text following the continuation ellipsis on a line is also green because it is a comment.
- **Strings** — Type a string and it is colored maroon. When you complete the string with the closing quotation mark (`'`), it becomes purple. Note that for functions you enter using command syntax instead of function syntax, the arguments are highlighted as strings. This is to alert you that in command notation, variables are passed as literal strings rather than as their values. For more information, see “MATLAB Command Syntax” in the MATLAB Programming documentation.
- **Unterminated strings** — A single quote without a matching single quote, and whatever follows the quote, are colored maroon. This might alert you to a possible error.
- **System commands** — Commands such as `!` (shell escape) are colored gold.
- **Errors** — Error text that appears after you run code, including any hyperlinks, is colored red.

Click **Restore Default Colors** to return to the default settings for syntax highlighting colors and desktop tool colors.

Other Colors

Specify the color for **Hyperlinks**, which applies to links in the Command Window and Help browser **Index** pane. If you use a dark background color for those tools, be sure to use a light or other contrasting color for hyperlinks so that you can see them.

With the **M-Lint autofix highlight** preference selected, code that M-Lint can automatically correct is highlighted in the Editor/Debugger. Use the palette to change the highlight color. For more information, see “M-Lint Automatic Code Analyzer in the Editor/Debugger” on page 6-88.

See Also

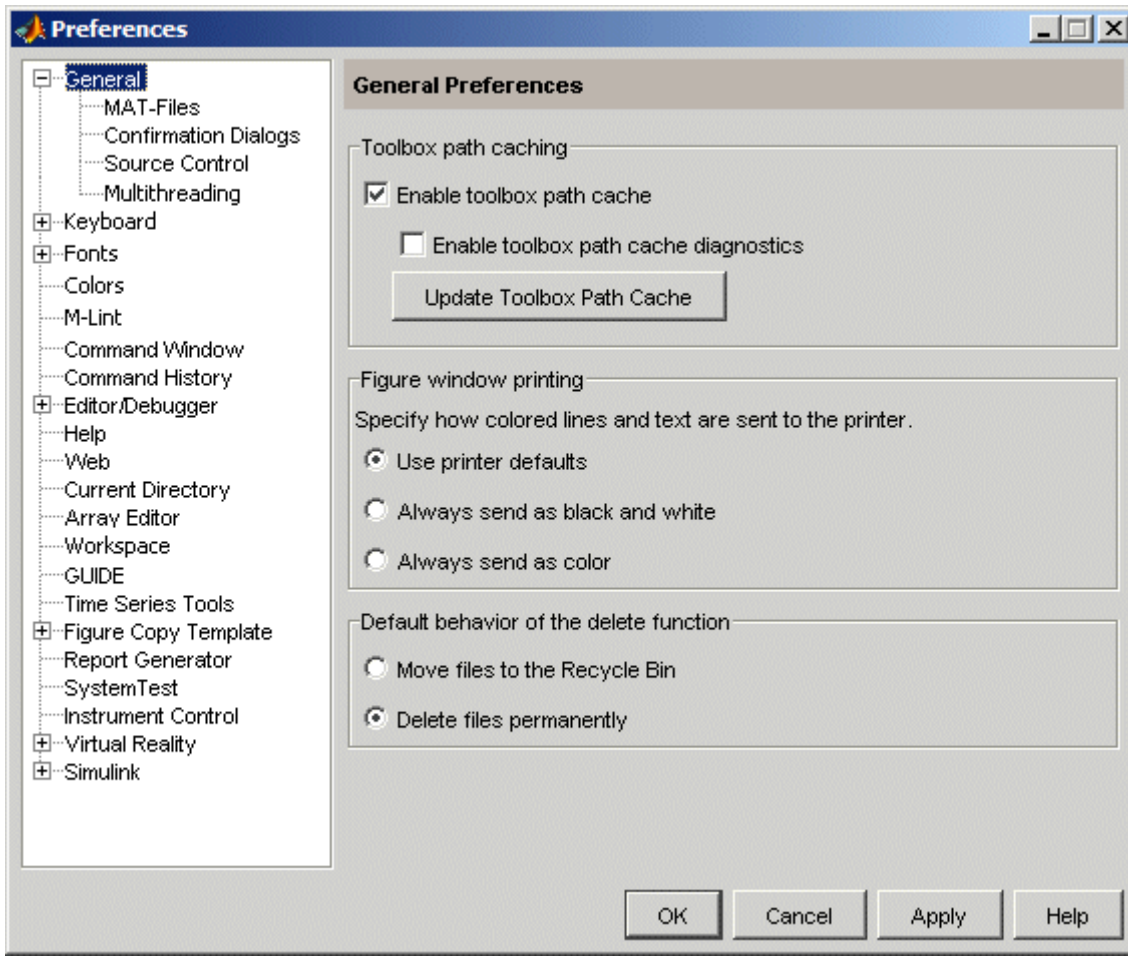
For information about other preferences and how MATLAB stores preferences, see “Preferences” on page 2-59.

General Preferences for MATLAB

In this section...

Setting General Preferences for MATLAB

Select **File > Preferences > General** from any desktop tool to access **General Preferences**.



These preferences apply to all relevant tools in MATLAB.

- Toolbox path caching preference — see “Toolbox Path Caching in MATLAB” on page 1-17
- Figure window printing — see “Printing and Exporting” in MATLAB Graphics documentation
- “Default Behavior of the Delete Function” on page 2-78

- "MAT-Files Preferences" on page 2-79
- "Confirmation Dialogs Preferences" on page 2-81
- Chapter 9, "Source Control Interface"
- "Multithreading Preferences" on page 2-84

Default Behavior of the Delete Function

Files you delete using the `delete` function are permanently removed by default. There is no opportunity to retrieve them.

You can use this preference to instead move deleted files to the Recycle Bin on Windows, to the Trash Can on Macintosh, or to a `tmp` directory on UNIX platforms. Then, you can recover any accidentally deleted files from these locations. Deleted files in these locations are not automatically removed; you must remove them using operating system features, such as **Empty Recycle Bin** on Windows. When you select this preference, `delete` might run slower.

Function Alternative

The MATLAB delete preference actually sets the state of the `recycle` function upon startup and when you change the preference. You can override the behavior of the preference by setting the `recycle` function state. For example, regardless of the preference setting, when you run

```
recycle('off')
delete('thisfile.m')
```

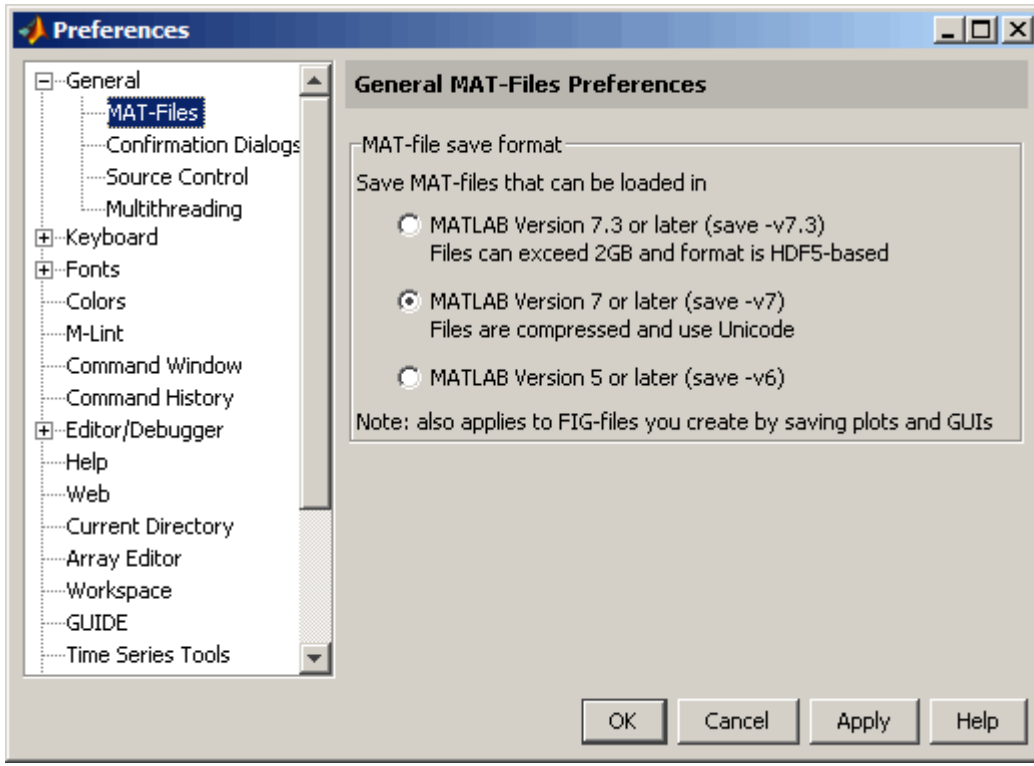
MATLAB permanently removes `thisfile.m` from the current directory. Files you subsequently remove using `delete` are also permanently removed, unless you reapply the preference to recycle or run `recycle('on')`. Regardless of the state of the `recycle` function when you end a session, the next time you start MATLAB, the setting for the preference is honored. For more information, see the `recycle` and `delete` reference pages.

Note that this preference and the `recycle` function do not apply to files you delete using the Current Directory browser. For more information, see "Cutting or Deleting Files and Directories" on page 5-45.

MAT-Files Preferences

The **MAT-file save format** sets the default version compatibility option MATLAB uses when saving MAT-files. Use these options if you use multiple versions of MATLAB or share MAT-files with others who run a different version of MATLAB. The setting applies when you use the `save` function as well as when you use**Save** menu items for MAT-files, such as **File > Save Workspace As** from any desktop tool.

The MAT-file preference also applies to saving FIG-files, which include plots, as well as GUIs you create with GUIDE.



Options are

- **MATLAB Version 7.3 or later (save -v7.3)**—Starting in MATLAB Version 7.3, you can save data that is larger than 2 GB on platforms that

allow it, which is the primary purpose of this option. Using this option is equivalent to running `save -v7.3`. This format of the resulting MAT-file is HDF5-based. You cannot load these MAT-files into any versions prior to MATLAB Version 7.3; in those cases, use one of the other two options.

- **MATLAB Version 7 or later (save -v7)**—Starting in MATLAB Version 7, MATLAB compresses the data when saving a MAT-file, thereby reducing the storage space required. When you load the MAT-file, MATLAB automatically uncompresses the data. In addition, MATLAB uses Unicode character encoding for strings when you save a MAT-file, making the data accessible to other MATLAB users, regardless of the default character encoding scheme used by their systems. MAT-files saved with this option work in all MATLAB 7 versions. Using this option is equivalent to running `save -v7`.
- **MATLAB Version 5 or later (save -v6)**—Releases of MATLAB prior to Version 7 did not save compressed MAT-files. They also did not use Unicode character encoding, which sometimes prevented the exchange of MAT-files among users, particularly when they used localized systems. Specify this option to save MAT-files for use with versions prior to MATLAB Version 7. Using this option is equivalent to running `save -v6`.

Like other preferences, the **MAT-file save format** preference gets its initial value from the preference file for the previous installed version. For example, if the setting in your MATLAB 7.4 preference is `-v6`, when you upgrade from MATLAB Version 7.4 (R2007a) to MATLAB Version 7.5 (R2007b), the initial value in Version 7.5 is `-v6`.

If you upgrade from a version prior to MATLAB Version 7.3, or if you do not have a previous MATLAB version installed, the initial value is `-v7`.

Note For more information about MAT-file save formats, including restrictions, see Version Compatibility Options and Remarks in the `save` reference page.

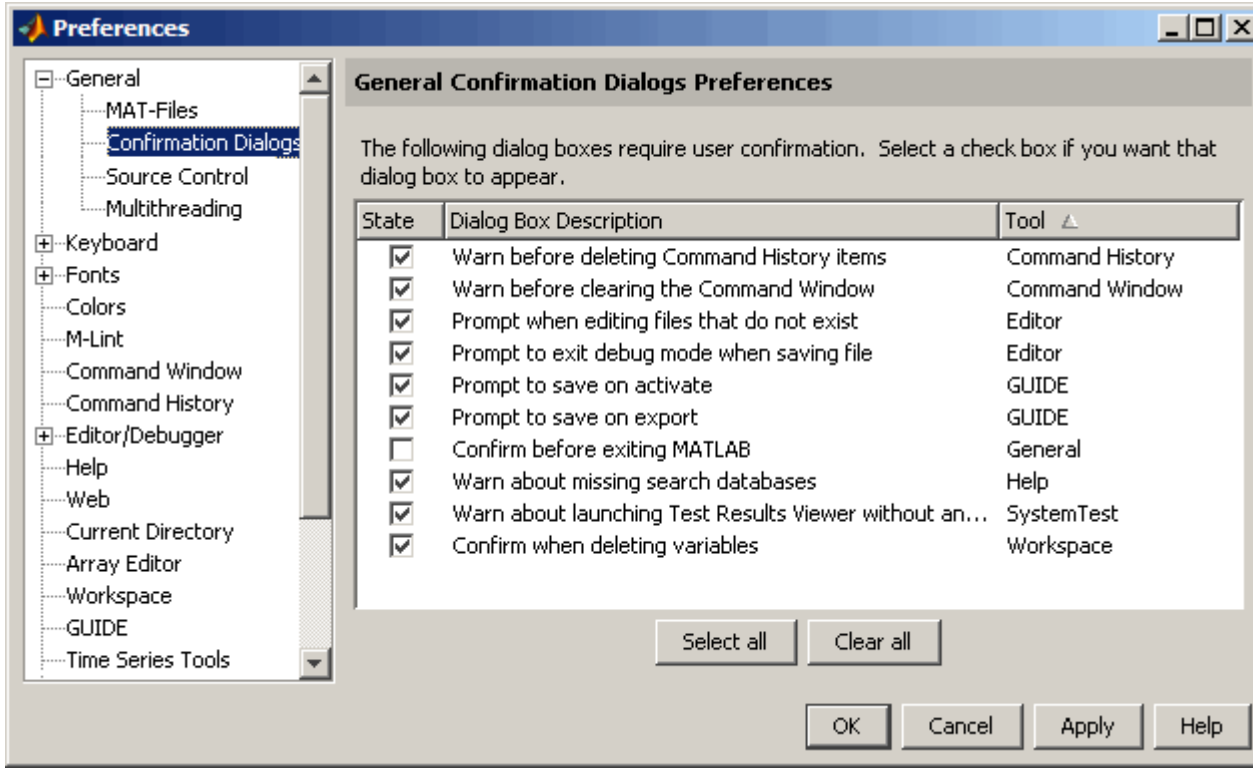
Function Alternative

You can override the **MAT-file save format** preference by using the `save` function with a specified version compatibility option. For occasional use, this

might be more convenient than changing the preference. For example, use `save` with the `-v6` option to ensure compatibility with MATLAB versions prior to Version 7. For more information, see the `save` reference page.

Confirmation Dialogs Preferences

These preferences instruct MATLAB to display or not display specific confirmation dialog boxes.



When the check box for a confirmation dialog is selected and you perform the action it refers to, the confirmation dialog box appears. If you clear that check box, the dialog box does not appear when you perform the action.

When the confirmation dialog box does appear, it includes a **Do not show this prompt again** check box. If you select the check box in the dialog box, it automatically clears the check box for the confirmation preference.

For example, select the check box **Warn before deleting Command History items**. Then select **Edit > Delete Selection** in the Command History, MATLAB displays the following confirmation dialog box.

If you select the **Do not show this prompt again** check box and click **OK**, the confirmation dialog box will not appear the next time you delete items from the Command History window. In addition, the **Warn before deleting Command History items** check box in the **Confirmations Dialogs** preferences pane is cleared.

The following table summarizes the confirmation dialog boxes.

Confirmation Dialogs Check Box Item	About the Confirmation Dialog Box	For More Information
Warn before deleting Command History items	Appears when you delete entries from the Command History window.	"Deleting Entries from the Command History Window" on page 3-57
Warn before clearing the Command Window	Appears when you clear the Command Window content using menu items. Does not appear when you use the `clc` function.	"Clearing the Command Window" on page 3-32

Confirmation Dialogs Check Box Item	About the Confirmation Dialog Box	For More Information
Prompt when editing files that do not exist	Appears when you type `edit filename`, if `filename` does not exist in the current directory or on the MATLAB path.	"Function Alternative" on page 6-9
Prompt to exit debug mode when saving file	Appears when you try to save a modified file while in debug mode.	"Ending Debugging" on page 6-119
Prompt to save on activate	Appears when you have unsaved changes to a figure and M-file, and then activate the GUI, by clicking the **Run** button, for example.	"GUIDE Preferences" in the GUIDE documentation
Prompt to save on export	Appears when you have unsaved changes to a figure and M-file, and then select **File > Export**.	"GUIDE Preferences" in the GUIDE documentation
Confirm before exiting MATLAB	Appears when you quit MATLAB.	Quitting MATLAB
Warn about missing search databases	Appears if you have help files in the Help browser for non-MathWorks products and the search database for those files has not been updated for the version of MATLAB you are running.	Contact the provider of the help files to obtain the correct version of the search database. Without the most current version, you can use the help files in the Help browser, but the Help browser search will not include those files in search results.
Confirm when deleting variables	Appears when you delete variables from the workspace using menu items. Does not appear with the `clear` function.	"Deleting Workspace Variables" on page 5-8

Multithreading Preferences

If you run MATLAB on a multiple-CPU system (multiprocessor or multicore), you can use multithreaded computation, which can improve performance for some operations. For more information, see .

Accessibility

In this section...

Software Accessibility Support

MathWorks products includes a number of modifications to make them more accessible to all users. Software accessibility support for blind and visually impaired users includes

- Support for screen readers and screen magnifiers, as described in "Assistive Technologies" on page 2-87
- Command-line alternatives for most graphical user interface (GUI) options
- Keyboard access to GUI components
- A clear indication of the current cursor focus
- Information available to assistive technologies about user interface elements, including the identity, operation, and state of the element
- Nonreliance on color coding as the sole means of conveying information about working with a GUI
- Noninterference with user-selected contrast and color selections and other individual display attributes, as well as noninterference for other operating system-level accessibility features
- Consistent meaning for bitmapped images used in GUIs
- HTML documentation that is accessible to screen readers

Keyboard access to the user interface includes support for "sticky keys," which allow you to press key combinations (such as **Ctrl+C**) sequentially rather than simultaneously.

Except for scopes and real-time data acquisition, the MathWorks software does not use flashing or blinking text, objects, or other elements having a flash or blink frequency greater than 2 Hz and lower than 55 Hz.

The MathWorks believes that its products do not rely on auditory cues as the sole means of conveying information about working with a GUI. However, if you do encounter any issues in this regard, please report them to the MathWorks Technical Support group.

```
http://www.mathworks.com/contact_TS.html
```

Documentation Accessibility Support

Documentation is available in HTML format for all MathWorks products in this release.

Accessing the Documentation

To access the documentation with a screen reader, go to the documentation area on the MathWorks Web site at

```
http://www.mathworks.com/access/helpdesk/help/helpdesk.html
```

Navigating the Documentation

Note that the first page that opens lists the products. To get the documentation for a specific product, click the link for that product.

The table of contents is in a separate frame. You can use a document's table of contents to navigate through the sections of that document.

Because you will be using a general Web browser, you will not be able to use the search feature included in the MATLAB Help browser. You will have access to an index for the specific document you are using. The cross-product index of the MATLAB Help browser is not available when you are using a general Web browser.

Products

The documentation for all products is in HTML and can be read with a screen reader. However, for most products, most equations and most graphics are not accessible.

The following product documentation has been modified (as described below) to enhance its accessibility for people using a screen reader such as JAWS:

- MATLAB (many sections, but not the function reference pages (however, M-file help is accessible))
- Excel Link
- Optimization Toolbox
- Signal Processing Toolbox
- Statistics Toolbox

Documentation Modifications

Modifications to the documentation include the following:

- Describing illustrations in text (either directly or via links)
- Providing text to describe the content of tables (as necessary)
- Restructuring information in tables to be easily understood when a screen reader is used
- Providing text links in addition to any image mapped links

Equations

Equations that are integrated in paragraphs are generally explained in words. However, most complex equations that are represented as graphics are not currently explained with alternative text.

Assistive Technologies

Note To take advantage of accessibility support features, you must use MathWorks products on a Microsoft Windows platform.

Tested Assistive Technologies

The MathWorks has tested the following assistive technologies:

- JAWS 5.0, 6.0, and 7.0 for Windows (screen reader) from Freedom Scientific
- Built-in accessibility aids from Microsoft, including the Magnifier and "sticky keys"

Use of Other Assistive Technologies

Although The MathWorks has not tested other assistive technologies, such as other screen readers or ZoomText Xtra (screen magnifier) from Ai Squared, The MathWorks believes that most of the accessibility support built into its products should work with most assistive technologies that are generally similar to the ones tested.

If you use other assistive technologies than the ones tested, The MathWorks is very interested in hearing from you about your experiences.

Installation Notes for Accessibility Support

Note If you are not using a screen reader such as JAWS, you can skip this section.

This section describes the installation process for setting up your MATLAB environment to work effectively with JAWS.

Use the regular MATLAB installation script to install the products for which you are licensed. The installation script has been modified to improve its accessibility for all users.

Note Java Access Bridge 2.0 is installed automatically when you install MATLAB.

After you complete the product installation, there are some additional steps you need to perform to ensure JAWS works effectively with MathWorks products.

Setting Up JAWS

Make sure that JAWS is installed on your machine. If it is, there is probably a shortcut to it on the Windows desktop.

Setting up JAWS involves these tasks:

1. Add the Access Bridge to your Windows path (for networked installations only).
2. Create the `accessibility.properties` file.

These tasks are described in more detail below.

(For Networked Installations Only) Add Access Bridge to Your Path.

If you are running MATLAB in a networked installation environment (that is, if the MATLAB Installer was not run on your machine), you need to take the following steps to add Access Bridge to your Windows path.

Note This procedure assumes your Windows **Start** button is set to Classic mode. To set Classic mode, from the **Start** button, select **Settings**. Next select **Task Bar and Menu**. Then select the **Start Menu** tab and make sure the `Classic Start Menu` option is enabled. Click **OK** and you are done.

---

1. From the **Start** button, select **Settings**, next select **Control Panel**. Scroll down and click the **System** icon to display the System Properties dialog box**.**
2. In the **System Properties** dialog box, select the **Advanced** tab.
3. Click **Environment Variables**.
4. Under **System variables**, select the `Path` option.
5. Click the **Edit** button.
6. To the start of the `Path` environment variable, add the directory that contains `matlab.exe`; for example:

   ```
   C:\matlab\bin\win32;
   ```

Be sure to include that semicolon between the end of this directory name and the text that was already there.

7 Click **OK** three times.

8 If JAWS is already running, exit and restart.

Note JAWS must be started with these path changes in effect to work properly with MATLAB.

Create the accessibility.properties File.

1 Create a text file that contains the following two lines:

```
screen_magnifier_present=true
assistive_technologies=com.sun.java.accessibility.AccessBridge
```

2 Use the filename `accessibility.properties`.

3 Move the `accessibility.properties` file into

matlabroot`\sys\java\jre\win32\jre1.5.0_07\lib\`

JAWS Pronunciation Dictionary. As a convenience, The MathWorks provides a pronunciation dictionary for JAWS. This dictionary is in a file called `MATLAB.jdf`.

During installation, the file is copied to your system under the MATLAB root directory at `sys\Jaws\matlab.jdf`.

To use the dictionary, you must copy it to the `\SETTINGS\ENU` folder located beneath the JAWS root installation directory.

You need to restart JAWS and MATLAB for the settings to take effect.

Testing

After you install JAWS and set up your environment as described above, you should test to ensure JAWS is working properly:

1. Start JAWS.
2. Start MATLAB.

JAWS should start talking to you as you select menu items and work with the MATLAB user interface in other ways.

Troubleshooting

This section identifies workarounds for some possible issues you may encounter related to accessibility support in MathWorks products.

JAWS Does Not Detect When the MATLAB Installation Has Started

When you select `setup.exe`, the Windows copying dialog box opens and you are informed. After the files have been copied, the installation splash screen opens, and then the installer starts. However, JAWS does not inform you that the installer has begun: the installer either starts up below other windows or applications or it is minimized. Since the installer is not an active item, nothing is read.

Therefore, check the Windows applications bar for the installer. After you go to the installer, you can use JAWS to perform the installation.

JAWS Stops Speaking

When many desktop components are open, JAWS with MATLAB sometimes stops speaking.

If this happens, close most of the desktop components, exit MATLAB, and restart.

Command Output Not Read

In the MATLAB Command Window, JAWS does not automatically read the results of commands.

To read command output, first select **File** > **Preferences** > **Command Window**, select the option **Use arrow keys for navigation instead of command history recall**, and click **OK**. Then, in the Command Window,

press the arrow keys to move to the command output and use JAWS keystrokes to read the output.

With this preference set, you cannot use arrow keys to recall previous commands. Instead use the following key bindings:

- Windows key bindings:
  - Previous history: **Ctrl+up arrow**
  - Next history: **Ctrl+down arrow**
- Emacs key bindings:
  - Previous history: **Ctrl+p**
  - Next history: **Ctrl+n**

To return to using the up and down arrow keys to recall previous commands, clear the preference.

Some GUI Menus Are Treated as Check Boxes

For some GUIs (for example, the figure window), menus are treated by JAWS as though they are check boxes, whether or not they actually are.

You can choose a menu item for such GUIs by using accelerator keys (e.g., **Ctrl+N** to select **New Figure**), if one is associated with a menu item. You can also use mnemonics for menu navigation (e.g., **Alt+E**).

Note that check boxes that you encounter by tabbing through the elements of a GUI are handled properly.

Text Ignored in Some GUIs

For some dialog boxes, JAWS reads the dialog box title and any buttons, but ignores any text in the dialog box.

Also, in parts of some GUIs, such as some text-entry fields, JAWS ignores the label of the field. However, JAWS will read any text in the text box.

3

Running Functions — Command Window and History

If you have an active Internet connection, you can watch the Working in the Development Environment video demo and the Command History video demo for an overview of the major functionality. The Command Window is where you run (execute) MATLAB statements, while the Command History is a log of the statements you have run.

The Command Window (p. 3-3)	Access the Command Window.
Running Functions and Programs, and Entering Variables (p. 3-7)	Enter statements at the prompt. Run M-files, interrupt programs, run external programs, and examine errors. Evaluate and open selections.
Controlling Input (p. 3-15)	Consider case sensitivity, enter long statements, edit statements, and use syntax highlighting and keyboard shortcuts.
Controlling Output (p. 3-30)	Suppress, page and format output, clear and print contents, and save a session.
Searching in the Command Window (p. 3-34)	Use the Find dialog or incremental search features to find content in the Command Window.

Preferences for the Command Window (p. 3-40)	Specify options for text, display, tab size, accessibility, and indenting for the Command Window and the Editor/Debugger.
Command History Window (p. 3-49)	View session histories. Run statements, copy entries, search, and print the history. Set preferences.
Preferences for Command History (p. 3-59)	Specify how often to automatically save the history file and the types of statements to exclude.

The Command Window

In this section...

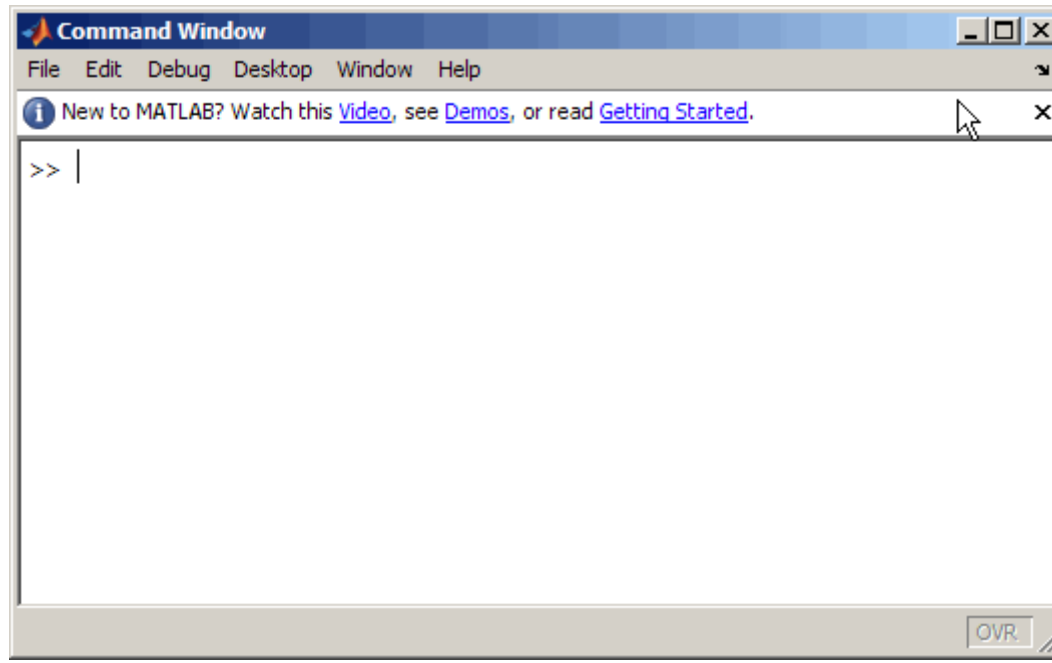
About the Command Window

The Command Window is one of the main tools you use to enter data, run MATLAB functions and other M-files, and display results. If you have an active Internet connection, you can Working in the Development Environment video demo for an overview of the major functionality.

Opening the Command Window

When the Command Window is not open, access it by selecting **Command Window** from the **Desktop** menu. Alternatively, open the Command Window with the `commandwindow` function.

If you prefer a simple command line interface without the other MATLAB desktop tools, select **Desktop > Desktop Layout > Command Window Only**. For more information, see "Arranging the Desktop" on page 2-6.



Command Window Prompt

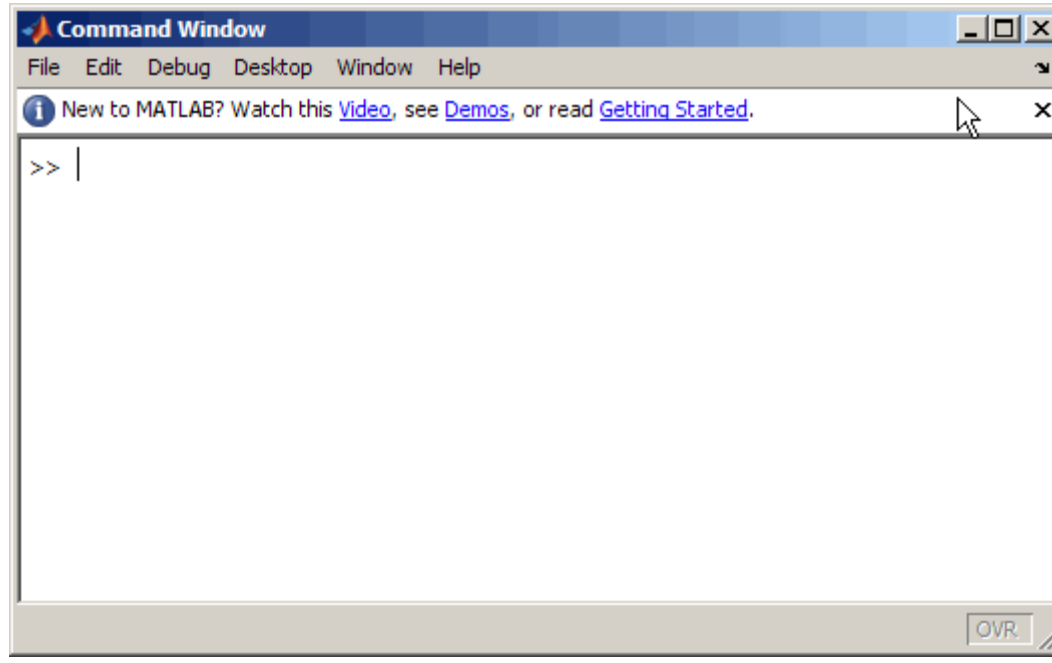
The Command Window prompt, >>, is where you enter statements. For example, you can enter a MATLAB function with arguments, or assign values to variables. The prompt indicates that MATLAB is ready to accept input from you. When you see the prompt, you can enter a variable or run a statement. This prompt is also known as the command line.

When MATLAB displays the `K>>` prompt in the Command Window, MATLAB is in debug mode. Type `dbquit` to return to normal mode. For more information, see Chapter 6, “Editing and Debugging M-Files”

MATLAB displays the `EDU>>` prompt for the MATLAB Student Version.

Getting Started Message Bar in the Command Window

Just below the Command Window menu bar is a message bar that includes links to a video, demos, and information on getting started with MATLAB. If you want to remove the message bar in the Command Window, click the Close box in the right corner of the bar.



If after having closed it, you want to display the information bar again, use “Preferences for the Command Window” on page 3-40.

In addition to the message bar, there are numerous other ways to access the documentation and demos, including using the **Help** menu in most tools. Furthermore, if you place your cursor in a function name, you can right-click and then choose **Help on Selection** from the context menu to see documentation for that function. The reference page for that function opens in a popup window, or if the reference page does not exist, the M-file help appears. For more information help on selection, see “Getting Pop-Up

Help for Functions” on page 4-49—for more general information on help, see Chapter 4, “Help for Using MATLAB”.

Running Functions and Programs, and Entering Variables

In this section...

Running Statements at the Command Line Prompt

Entering Variables and Running Functions

At the prompt, enter data and run functions. For example, to create `A`, a 3-by-3 matrix, type

```
A = [1 2 3; 4 5 6; 7 8 10]
```

When you press the **Enter** or **Return** key after typing the line, MATLAB responds with

```
A =

     1     2     3
     4     5     6
     7     8    10
```

To run a function, type the function including all arguments and press **Enter** or **Return**. MATLAB displays the result. For example, type

```
magic(2)
```

and MATLAB returns

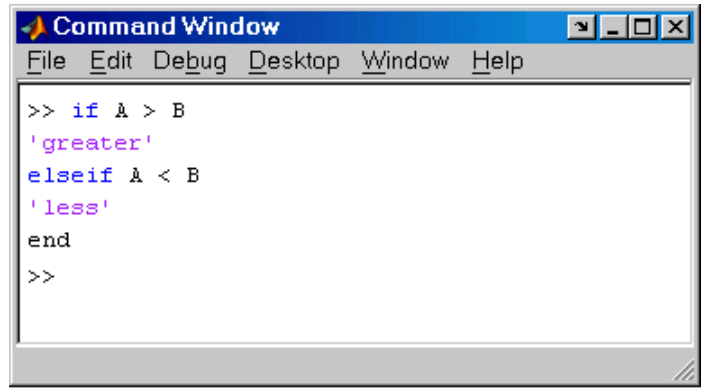
```
ans =
 1     3
 4     2
```

Definition of a Statement. All of the information you type before pressing **Enter** or **Return** is known as a statement. This can include:

- Variable assignments: For example, `a = 3`
- Commands: M-files provided with MATLAB or toolboxes that do not accept input arguments, for example, `clc`, which clears the Command Window.
- Scripts: M-files (MATLAB program files) you write that do not take input arguments or return output arguments, for example, `myfile.m`.
- Functions and their arguments: M-files that can accept input arguments and return output arguments, for example, `magic`.

Some functions support a form that does not require an input argument, thereby operating as commands. For convenience, the term function is used to refer to both functions and commands.

When you enter program control statements, such as `if ... end`, the prompt does not appear until you complete the set of functions. In the following example, you press **Enter** at the end of each line, but the prompt does not appear until you complete the set of statements with `end`.



Running M-Files

Run M-files, files that contain code in the MATLAB language, the same way that you would run any other MATLAB function. Type the name of the M-file in the Command Window and press **Enter** or **Return**. The M-file must be in

the MATLAB current directory or on the MATLAB search path — for details, see “Search Path” on page 5-23. You can also use the `run` function and specify the full pathname to an M-file script.

To determine the name of the M-file currently running, use `mfilename`.

Examining Errors

If an error message appears when you run an M-file, click the underlined portion of the error message, or position the cursor within the filename and press **Ctrl+Enter**. The offending M-file opens in the Editor/Debugger, scrolled to the line containing the error.

Processing Order

In MATLAB, you can only run one process at a time. If MATLAB is busy running one function, any further statements you issue are buffered in a queue. The next statement will run when the previous one finishes.

Interrupting a Running Program

You can stop a running program by pressing **Ctrl+C** or **Ctrl+Break** at any time. On Macintosh platforms, you can also use **Command+.** (the Command key and the period key) to stop the program. For certain operations, stopping the program might generate errors in the Command Window.

For M-files that run a long time, or that call built-ins or MEX-files that run a long time, **Ctrl+C** does not always effectively stop execution. Typically, this happens on Windows rather than UNIX platforms. If you experience this problem, you can help MATLAB break execution by including a `drawnow`, `pause`, or `getframe` function in your M-file, for example, within a large loop. Note that **Ctrl+C** might be less responsive if you started MATLAB with the `-nodesktop` option (an option only for UNIX platforms).

Running External Programs

The exclamation point character, !, sometimes called bang, is a *shell escape* and indicates that the rest of the input line is a command to the operating system. Use it to invoke utilities or call other executable programs without quitting MATLAB. On UNIX, for example,

```
!vi yearlystats.m
```

invokes the vi editor for a file named `yearlystats.m`. After the external program completes or you quit the program, the operating system returns control to MATLAB. Add `&` to the end of the line, such as

```
!dir &
```

on Windows platforms to display the output in a separate window or to run the application in background mode. For example

```
!excel.exe &
```

opens Excel and returns control to the Command Window so you can continue running MATLAB statements.

The maximum length of the argument list provided as input to the bang (!) command is determined by any restrictions maintained within the operating system. If you are running the Windows 2003 Server, for example, the length of the argument list input to the bang command cannot exceed 512 characters.

See the reference pages for the `unix`, `dos`, and `system` functions for details about running external programs that return results and status.

Note To execute operating system commands with specific environment variables, include all commands to the operating system within the `system` call. Separate the commands using `&` (ampersand) for DOS, and `;` (semicolon) for UNIX. This applies to the MATLAB `!` (bang), `dos`, `unix`, and `system` functions. Another approach is to set environment variables before starting MATLAB.

On Macintosh platforms, you cannot run AppleScript directly from MATLAB. However, you can run the Macintosh OS X `osascript` function from the MATLAB `unix` or `!` (bang) function to run AppleScript from MATLAB.

UNIX System Path and Running UNIX Programs from MATLAB

To run a UNIX program from MATLAB if its directory is not on the UNIX system path MATLAB uses, take one of the actions described here.

Change Current Directory in MATLAB. Change the current directory in MATLAB to the directory that contains the program you want to run.

Modify the UNIX System Path MATLAB Uses. Add the directories to the system path from the shell. The exact steps depend on your shell. This is an example using sh:

1. At the system command prompt, type

   ```
   export PATH="$PATH:<mydirectory>"
   ```

   where `<mydirectory>` is the directory that contains the program you want to run.

2. Start MATLAB.

3. In MATLAB, type

   ```
   !echo $PATH
   ```

The directory containing the file is added to the system path that MATLAB uses. This change applies only to the current session of the terminal window.

Automatically Modify System Path at MATLAB Startup. If you want to add a directory to the `PATH` environment variable each time you start MATLAB, perform these steps:

1. In a text editor, open the file `MATLAB/bin/matlab`. This file is used to start MATLAB.

2. Add this line to the beginning of the `matlab` file

   ```
   export PATH="$PATH:<mydirectory>"
   ```

   where `<mydirectory>` is the directory you want to add to the path.

   If you run a tsch shell instead of a bash shell, use `setenv` instead of `export`.

3 Save the file.

The `matlab` file will modify the `PATH` environment variable, and then start MATLAB.

Evaluating or Opening a Selection

Make a selection in the Command Window and press **Enter** or **Return**. The selection is appended to whatever is at the prompt, and MATLAB executes it.

Similarly, you can select a statement from any MATLAB desktop tool, right-click, and select **Evaluate Selection** from the context menu. Alternatively, after making a selection, use the shortcut key, **F9**, or for some tools, press **Enter** or **Return**. For example, you can scroll up in the Command Window, select a statement you entered previously, and then press **Enter** to run it. If you try to evaluate a selection while MATLAB is busy, for example, running an M-file, execution waits until the current operation is done.

You can open a function, file, variable, or Simulink model from the Command Window. Select the name in the Command Window, and then right-click and select **Open Selection** from the context window. This runs the `open` function for the item you selected so that it opens in the appropriate tool:

- M-files and other text files open in the Editor/Debugger.
- Figure files (`.fig`) open in a figure window.
- Variables open in the Array Editor.
- Models open in Simulink.

See the `open` reference page for details about what action occurs if there are name conflicts. If no action exists to work with the selected item, **Open selection** calls `edit`.

Function Alternative

Use `open` or `edit` to open a file in the Editor/Debugger. Use `type` to display the M-file in the Command Window.

Displaying Hyperlinks in the Command Window

You can use MATLAB commands to create hyperlinks in the Command Window. The created hyperlink can:

- Open a Web page in a MATLAB browser using an `href` string.
- Transfer files via the file transfer protocol (FTP).
- Run a MATLAB M-file using the `matlabcolon` (`matlab:`) command.

Hyperlinks to Web Pages

When creating a hyperlink to a Web page, append a full hypertext string on a single line as input to the `disp` or `fprintf` command. For example, the command

```
disp('<a href = "http://www.mathworks.com">The MathWorks Web Site</a>')
```

displays the hyperlink

```
The MathWorks Web Site
```

in the Command Window.

When you click this link, a MATLAB Web browser opens and displays the requested page.

Transferring Files via FTP

To create a link to an FTP site, enter the site address as input to the `disp` command as shown below.

```
disp('<a href = "ftp://ftp.mathworks.com">The MathWorks FTP Site</a>')
```

This command displays

```
The MathWorks FTP Site
```

as a link in the Command Window.

When you click this link, a MATLAB browser opens and displays the requested FTP site.

Running MATLAB Functions by Hyperlink

Use `matlab:` to run a specified statement when you click a hyperlink in the Command Window. For example

```
disp('<a href="matlab:magic(4)">Generate magic square</a>')
```

displays

Generate magic square

When you click the link `Generate magic square`, MATLAB runs `magic(4)`. Alternatively, you can press **Ctrl+Enter** if the cursor is positioned in the link text. You can use the `disp`, `error`, `fprintf`, or `warning` function with this feature. Change the hyperlink color using **Colors Preferences** — see “Colors Preferences for Desktop Tools” on page 2-70. For more information, including examples, see the `matlabcolon (matlab:)` reference page.

Controlling Input

In this section...

Case and Space Sensitivity

Uppercase and Lowercase for Variables

With respect to case, MATLAB requires an exact match for variable names. For example, if you have a variable `a`, you cannot refer to that variable as `A`.

Uppercase and Lowercase for Files and Functions

With respect to functions, filenames, objects, and classes on the search path or in the current directory, MATLAB prefers an exact match with regard to case. MATLAB runs a function if you do not enter the function name using the exact case, but displays a warning the first time you do this.

To avoid ambiguity and warning messages, always match the case exactly. It is a best practice to use lowercase only when running and naming functions. This is especially useful when you use both Windows and UNIX platforms because their file systems behave differently with regard to case.

Note that if you use the `help` function, function names are shown in all uppercase, for example, `PLOT`, solely to distinguish them. Some functions for interfacing to Java do use mixed case and the M-file help and documentation accurately reflect that.

Examples. The directory `first` is at the top of the search path and contains the file `A.m`. If you type `a` instead of `A`, MATLAB runs `A.m` but issues a warning. When you type `a` again during that session, MATLAB runs `A.m` but does not show the warning.

Add the directory `second` after `first` on the search path, with the file `a.m` in `second`. The directory `first` contains `A.m`, while `second` contains `a.m` Type `a`. MATLAB runs `a.m` but displays a warning the first time you do this.

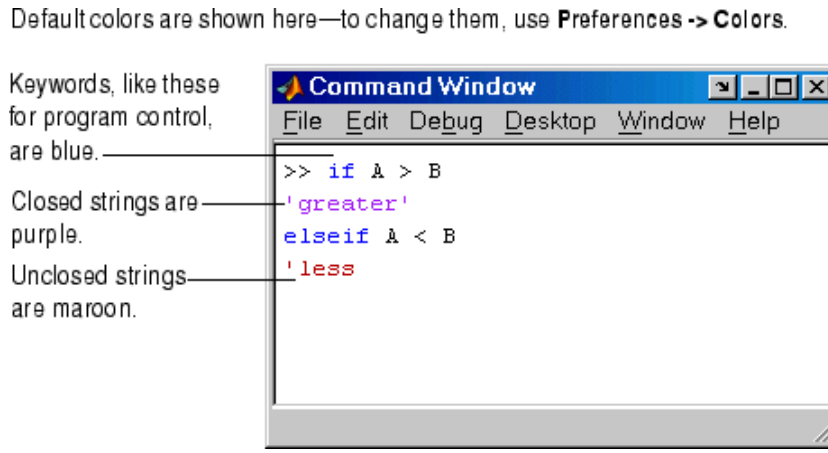
Spaces in Expressions

Blank spaces around operators such as `-`, `:`, and `( )`, are optional, but they can improve readability. For example, MATLAB interprets the following statements the same way.

```
y = sin (3 * pi) / 2
y=sin(3*pi)/2
```

Syntax Highlighting

Some entries appear in different colors to help you better find elements, such as matching `if/else` statements. This is known as syntax highlighting. You can change the colors using preferences. Note that output does not appear with syntax highlighting, except for errors. For more information, see “Colors Preferences for Desktop Tools” on page 2-70.



Matching Delimiters (Parentheses)

You can set a preference for MATLAB to notify you about matched and unmatched delimiters. For example, when you type a parenthesis, bracket, or brace, MATLAB highlights the matched delimiter in the pair. To set these preferences, select **File > Preferences > Keyboard > Delimiter Matching**. This feature is also available in the Editor/Debugger.

For more information, see “Delimiter Matching” on page 3-46.

Cut, Copy, Paste, and Undo Features

Use the **Cut**, **Copy**, **Paste**, **Undo**, and **Redo** features from the **Edit** menu when working in the Command Window. You can also access some of these features in the context menu for the Command Window.

Undo applies to some of the actions listed in **Edit** menu. You can undo multiple times in succession until there are no remaining actions to undo. Select **Edit > Redo** to reverse an undo.

If you use **Enter**, you cannot edit a line after entering it, even though you have not completed the flow. In that event, use **Ctrl+C** to end the flow, and then enter the statements again.

Enter Multiple Lines Without Running Them

To enter multiple lines before running any of them, use **Shift+Enter** or **Shift+Return** after typing a line. This is useful, for example, when entering a set of statements containing keywords, such as `if ... end`. The cursor moves down to the next line, which does not show a prompt, where you can type the next line. Continue for more lines. Then press **Enter** or **Return** to run all of the lines.

This allows you to edit any of the lines you entered before you pressing **Enter** or **Return**.

Entering Multiple Functions in a Line

To enter multiple functions on a single line, separate the functions with a comma (,) or semicolon (;). Using the semicolon instead of the comma will suppress the output for the command preceding it. For example, put three functions on one line to build a table of logarithms by typing

```
format short; x = (1:10)'; logs = [x log10(x)]
```

and then press **Enter** or **Return**. The functions run in left-to-right order.

Entering Long Statements (Line Continuation)

If a statement does not fit on one line, enter three periods (`...`) , also called dots, stops, or an ellipsis, at the end of the line to indicate it continues on the next line. Then press **Enter** or **Return**. Continue typing the statement on the next line. You can repeat the ellipsis to add a line break after each line until you complete the statement. When you finish the statement, press **Enter** or **Return**.

For items in single quotation marks, such as strings, you must complete the string in the line on which it was started. For example, completing a string as shown here

```
headers = ['Author Last Name, Author First Name, ' ...
'Author Middle Initial']
```

results in

```
headers =
Author Last Name, Author First Name, Author Middle Initial
```

MATLAB produces an error when you do not complete the string, as shown here:

```
headers = ['Author Last Name, Author First Name, ...
Author Middle Initial']

??? headers = ['Author Last Name, Author First Name, ...
Error: Missing variable or function.
```

Note that MATLAB ignores anything appearing after the `...` on a line, and continues processing on the next line. This effectively creates a comment out of the text following the `...` on a line. For more information, see "Commenting Out Part of a Statement" on page 6-19.

Recalling Previous Lines

Use the arrow, tab, and control keys on your keyboard to recall, edit, and reuse functions you typed earlier. For example, suppose you mistakenly enter

```
rho = (1+ sqt(5))/2
```

Because you misspelled `sqrt`, MATLAB responds with

```
Undefined function or variable 'sqt'.
```

Instead of retyping the entire line, press the up arrow ↑ key. The previously typed line is redisplayed. Use the left arrow key to move the cursor, add the missing `r`, and press **Enter** or **Return** to run the line. Repeated use of the up arrow key recalls earlier lines, from the current and previous sessions. Using the up arrow key, you can recall any line maintained in the Command History window.

Similarly, specify the first few characters of a line you entered previously and press the up arrow key to recall the previous line. For example, type the letters `plo` and then press the up arrow key. This displays the last line that started with `plo`, as in the most recent `plot` function. Press the up arrow key

again to display the next most recent line that began with `plo`, and so on. Then press **Enter** or **Return** to run the line. This feature is case sensitive.

If the up arrow key moves the cursor up but does not recall previous lines, clear the accessibility preference. For more information, see "Accessibility" on page 3-43.

Another way to view and access commands from the current and previous MATLAB sessions is with the Command History window — see "Command History Window" on page 3-49.

Tab Completion in the Command Window

MATLAB helps you automatically complete the names of these items as you type them in the Command Window:

- Function or model on the search path or in the current directory
- Filename or directory
- Variable, including structures, in the current workspace
- Handle Graphics property for figure in the current workspace

Type the first few characters of the item name and then press the **Tab** key. To use tab completion, you must have the tab completion preference for the Command Window selected. For details, see "Keyboard Preferences" on page 3-43.

Tab completion is also available in the Editor/Debugger, but there are some slight differences in usage. See "Tab Completion in the Editor/Debugger" on page 6-21.

These examples demonstrate how to use tab completion in the Command Window:

• "Tab Completion for Properties" on page 3-25

Basic Example — Unique Completion

This example illustrates a basic use for tab completion. After creating a variable, `costs_march`, type

```
costs
```

and press **Tab**. MATLAB automatically completes the name of the variable, displaying

```
costs_march
```

Then complete the statement, adding any arguments, operators, or options, and press **Return** or **Enter** to run it. In this example, if you just press **Enter**, MATLAB displays the contents of `costs_march`. If MATLAB does not complete the name `costs_march` but instead moves the cursor to the right, you do not have the preference set for tab completion. If MATLAB displays `No Completions Found`, `costs_march` does not exist in the current workspace.

You can use tab completion anywhere in the line, not just at the beginning. For example, if you type

```
a = cost
```

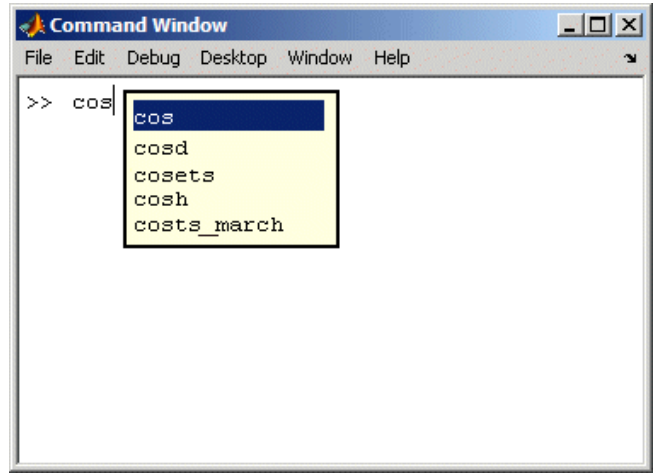
and press **Tab**, MATLAB completes `costs_march`. You can also select `co` or position the cursor after `co` and press **Tab** to complete `costs_march`.

Multiple Possible Completions

If there is more than one name that starts with the characters you typed, when you press the **Tab** key, MATLAB displays a list of all names that start with those characters. For example, type

```
cos
```

and press **Tab**. MATLAB displays

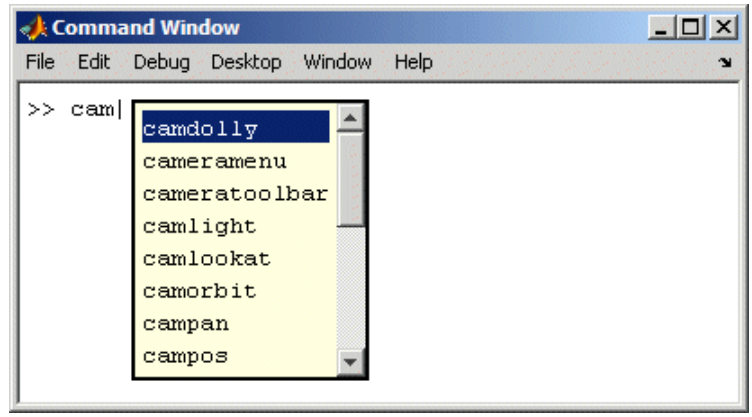


The resulting list of possible completions includes the variable name you created, `costs_march`, but also includes functions that begin with `cos`, including `cosets` from Communications Toolbox, if it is installed on the system and on the MATLAB search path. MATLAB completes variable names in the currently selected workspace, and the names of functions and models on the MATLAB search path or in the current directory.

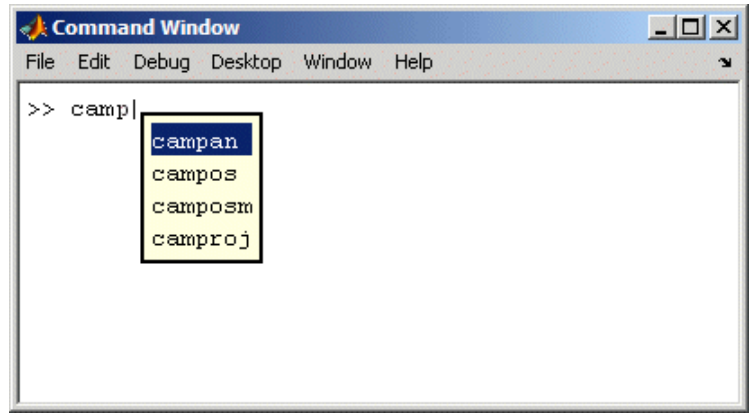
Continue typing to make your entry unique. For example, type the next character, such as `t` in the example. MATLAB selects the first item in the list that matches what you typed, in this case, `costs_march`. Press **Enter** (or **Return**) or **Tab** to select that item, which completes the name at the prompt. In the example, MATLAB displays `costs_march` at the prompt. Add any arguments, and press **Enter** again to run the statement.

You can navigate the list of possible completions using up and down arrow keys, and **Page Up** and **Page Down** keys. You can clear the list without selecting anything by pressing **Escape**. Note that the list of possible completions might include items that are not valid commands, such as private functions.

Narrowing Completions Shown. You can narrow the list of completions shown by typing a character and then pressing **Tab** if the Command Window preference **Tab key narrows completions** is selected. This is particularly useful for large lists. For example, type `cam` and press **Tab** to see the possible completions. There is a scroll bar with the list because there are too many completions to be seen at once.



Type `p` and press **Tab** again. MATLAB narrows the list, showing only all possible `camp` completions.



Continue narrowing the list in the same way. For the above example, type `o` and press **Tab** to further narrow the list. Press **Enter** or **Return** to select an item, which completes the name at the prompt.

Tab Completion for Directories and Filenames

Tab completion works for directories and filenames in MATLAB functions. For example, type

```
edit d:/
```

and press **Tab**.

MATLAB displays the list of directories and files in `d`, from which you can choose one. For example, type

```
mym
```

and press **Tab**.

MATLAB displays

```
edit d:/mymfiles/
```

where `mymfiles` is the only directory on your `d` drive whose name begins with `mym`. Continue using tab completion to display and complete directory names or filenames until you finish the `edit` statement.

Tab completion for directories and filenames is not supported for functions you write.

Tab Completion for Structures

For structures in the current workspace, after the period separator, press **Tab**. For example, type

```
mystruct.
```

and press **Tab** to display all fields of `mystruct`. If you type a structure and include the start of a unique field after the period, pressing **Tab** completes that structure and field entry.

For example, type

```
mystruct.n
```

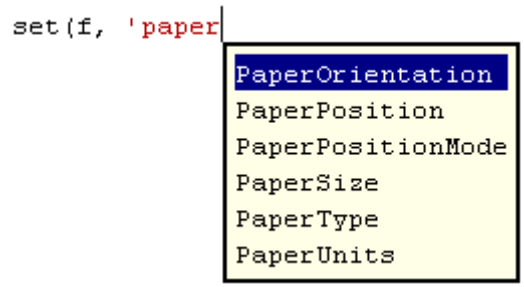
and press **Tab**, which completes the entry `mystruct.name`, where `mystruct` contains no other fields that begin with `n`.

Tab Completion for Properties

Complete property names for figures in the current workspace using tab completion, as in this graphics example. Here, `f` is a figure. Type

```
set(f, 'pap
```

and press **Tab**. MATLAB displays



Select a property from the list. For example, type

```
u
```

and press **Enter**. MATLAB completes the property, including the closing quote.

```
set(f, 'paperunits'
```

Continue adding to the statement, as in this example

```
set(f, 'paperunits', 'c
```

and press **Tab**. MATLAB automatically completes the property

```
set(f, 'paperUnits', 'centimeters'
```

because `centimeters` is the only possible completion.

Keyboard Shortcuts in the Command Window

Following is the list of arrow and control keys that serve as shortcuts for using the Command Window. In addition to these shortcut keys (sometimes called hot keys), you can use shortcuts for menu items, which you can view on the menus, as well as general desktop shortcuts described in "Keyboard Shortcuts" on page 2-40. If you select the Emacs (MATLAB standard) preference for key bindings (see "Command Window Key Bindings" on page 3-44 for an explanation), you can also use the **Ctrl+key** combinations shown in the table.

Key or Mouse Action for Windows Preference	Control Key for MATLAB standard (Emacs) Preference	Key or Mouse Action for Macintosh Preference	Operation
↑	**Ctrl+P**	↑	Recall *p*revious line — for details, see "Recalling Previous Lines" on page 3-19. See also "Command History Window" on page 3-49, which is a log of previously used functions, and "Keeping a Session Log" on page 3-33. With the **Accessibility** preference selected, moves the cursor up a line when it is above the prompt. In that event, use **Ctrl+**↑ to recall previous lines for Windows and Macintosh key bindings.

Key or Mouse Action for Windows Preference	Control Key for MATLAB standard (Emacs) Preference	Key or Mouse Action for Macintosh Preference	Operation
↓	**Ctrl+N**	↓	Recall *n*ext line — for details, see "Recalling Previous Lines" on page 3-19. Works only after using the up arrow or **Ctrl**+**P**. With the **Accessibility** preference selected, moves the cursor down a line when it is above the prompt. In that event, use **Ctrl**+↓ to recall previous lines for Windows and Macintosh key bindings.
Ctrl+Home	None	**Home**	Move to top of Command Window.
Ctrl+End	None	**End**	Move to end of Command Window.
None	None	**Cmd+Home**	Move cursor and scroll to top of Command Window.
None	None	**Cmd+End**	Move cursor and scroll to end of Command Window.
None	None	**Shift+Cmd+Home**	Select to top of Command Window.
None	None	**Shift+Cmd+End**	Select to end of Command Window.
←	**Ctrl+B**	←	Move *b*ack one character.
→	**Ctrl+F**	→	Move *f*orward one character.
Ctrl+←	None	**Option+**←	Move *l*eft one word.
Ctrl+→	None	**Option+**→	Move *r*ight one word.
Home	**Ctrl+A**	**Cmd+**←	Move to beginning of current statement. With Macintosh key bindings, move to beginning of current line.
End	**Ctrl+E**	**Cmd+**→	Move to *e*nd of current statement. With Macintosh key bindings, move to end of current line.

Key or Mouse Action for Windows Preference	Control Key for MATLAB standard (Emacs) Preference	Key or Mouse Action for Macintosh Preference	Operation
Esc	**Ctrl+U**	**Esc**	Clear the command line when cursor is at the command line. Otherwise, move cursor to command line.
Delete	**Ctrl+D**	Forward **Delete**	Delete character after cursor.
Backspace	**Ctrl+H**	**Delete**	Delete character before cursor.
None	**Ctrl+K**	None	Cut contents (*k*ill) from cursor to end of current line.
Insert	None	None	Change to overwrite mode from insert mode, or change to insert mode from overwrite mode. View current mode in the status bar: OVR is gray for insert mode. In overwrite mode, what you type replaces existing text and the cursor is a wide block. (Not supported on Macintosh platforms.)
Double-click	None	Double-click	Select current word. To select additional words, hold mouse after second click and continue dragging left or right.
None	None	**Shift+Option+←**	Select to previous word.
None	None	**Shift+Option+→**	Select to next word.
Triple-click	None	None	Select current line. To select additional lines, hold mouse after second click and continue dragging up or down.
Shift+Home	None	**Shift+Cmd+←**	Select from cursor to beginning of statement. With Macintosh key bindings, select to beginning of line.

Key or Mouse Action for Windows Preference	Control Key for MATLAB standard (Emacs) Preference	Key or Mouse Action for Macintosh Preference	Operation
Shift+End	None	**Shift+Cmd+→**	Select from cursor to end of statement. With Macintosh key bindings, select to end of line.
Enter in selection	None	None	Append selection to statement at command line and execute it.
Ctrl+Enter in hyperlink	None	**Ctrl+Enter** in hyperlink	Open hyperlink displayed in Command Window. For example, in the hyperlink of an error message, opens the file in the Editor/Debugger at that line number.

Navigating Above the Command Line

To look at or copy information in the Command Window that is above the command line (>> prompt), use the mouse and scroll bar, key combinations such as **Ctrl+Home**, and search features. By default, the up and down arrow keys recall statements so you cannot use them to move the cursor when it is above the command line.

To use the up and down arrow keys to move the cursor when it is above the command line, select **File > Preferences > Command Window**, and select the **Accessibility** preference.

Controlling Output

In this section...

Echoing Execution

To display each function within a statement as it executes, run `echo on`. For details, see the `echo` reference page.

Suppressing Output

If you end a statement with a semicolon (`;`) and then press **Enter** or **Return**, MATLAB runs the statement but does not display any output. This is particularly useful when you generate large matrices. For example, running

```
A = magic(100);
```

creates `A` but does not show the resulting matrix in the Command Window.

Paging of Output in the Command Window

If output in the Command Window is lengthy, it might not fit within the screen and display too quickly for you to see it without scrolling back to it. To avoid that problem, use the `more` function to control the paging of output in the Command Window. By default, `more` is `off`.

After you type `more on`, MATLAB displays only a page (a screen full) of output, pauses, and displays

```
--more--
```

indicating there is more output to display. Press one of the following keys.

Key	Action
Enter or **Return**	To advance to the next line
Space Bar	To advance to the next page
q	To stop displaying the output

You can scroll in the Command Window to see input and output that are no longer in view. As an alternative to scrolling, you can use the up and down arrow keys if the Command Window Accessibility preference is selected.

Formatting and Spacing Numeric Output

By default, numeric output in the Command Window is displayed as 5-digit scaled, fixed-point values, called the short format. To change the numeric format of output for the current and future sessions, set the Command Window preference for text display. The text display format affects only how numbers are shown, not how MATLAB computes or saves them.

Function Alternative

Use the `format` function to control the output format of the numeric values displayed in the Command Window. The format you specify applies until you change it or until the end of the session. More advanced alternatives are listed in the “See Also” section of the `format` reference page.

Examples of Formats

Here are a few examples of the various formats and the output produced from the following two-element vector `x`.

```
x = [4/3 1.2345e-6]

format short
   1.3333    0.0000

format short e
```

```
   1.3333e+000  1.2345e-006

format +
++
```

A complete list and description of available formats is in the reference page for `format`. For more control over the output format, use the `sprintf` and `fprintf` functions.

Controlling Spacing

To control spacing in the output, use the Command Window preference for text display or the `format` function. Use

```
format compact
```

to suppress blank lines, allowing you to view more information in the Command Window. To include the blank lines, which can help make output more readable, use

```
format loose
```

Clearing the Command Window

Select **Clear Command Window** from the **Edit** menu or context menu to clear it. This does not clear the workspace, but only clears the view. Afterwards, you still can use the up arrow key to recall previous functions. A confirmation dialog box appears if you select the preference for it; see preferences for “Confirmation Dialogs Preferences” on page 2-81 for more information.

Function Alternative

Use `clc` to clear the Command Window. Similar to `clc` is the `home` function, which moves the prompt to provide a clear screen, but does not clear the text so you can still scroll up to see it.

Printing Command Window Contents

To print the complete contents of the Command Window, select **File > Print**. To print only a selection, first make the selection in the Command Window and then select **File > Print Selection**.

Specify printing options for the Command Window by selecting **File > Page Setup**. For example, you can print with a header. For more information, see "Printing and Page Setup Options for Desktop Tools" on page 2-52.

Keeping a Session Log

The diary Function

The `diary` function creates a copy of your MATLAB session in a disk file, including keyboard input and system responses, but excluding graphics. You can view and edit the resulting text file using any text editor, such as the Editor/Debugger. To create a file on your disk called `sept23.out` that contains all the functions you enter, as well as MATLAB output, enter

```
diary('sept23.out')
```

To stop recording the session, use

```
diary('off')
```

To view the file, run

```
edit('sept23.out')
```

Other Session Logs

There are two other means of viewing session information:

- The Command History window, which contains a log of all functions executed in the current and previous sessions.
- The `logfile` startup option — see "Startup Options" on page 1-12.

Searching in the Command Window

In this section...

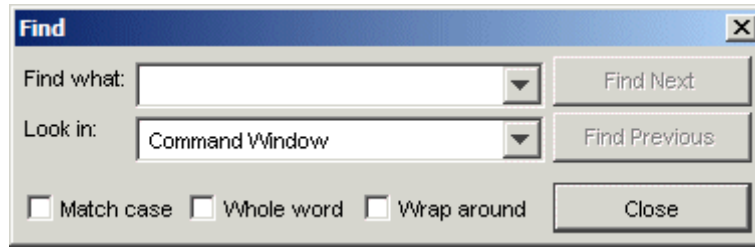
Introduction

You can search for specified text that appears in the Command Window, where the text was either part of input you supplied, or output displayed by MATLAB. After finding the desired text, you can copy and paste it to the prompt in the Command Window to run it, or into an M-file or other file.

See also "Recalling Previous Lines" on page 3-19, "Tab Completion in the Command Window" on page 3-20, and "Keyboard Shortcuts in the Command Window" on page 3-26 for techniques to reuse previous statements and navigate in the Command Window. To find files and text in files, see "Finding Files and Content Within Files" on page 5-49.

Find Dialog Box

Select **Find** from the **Edit** menu to search for specified text in the Command Window using the Find dialog box. Complete the dialog box. The search begins at the current cursor position. MATLAB finds the text you specified and highlights it. Click **Find Next** or **Find Previous** to find another occurrence, or use the keyboard shortcuts **F3** and **Shift+F3**.



MATLAB beeps when a search for **Find Next** reaches the end of the Command Window, or when a search for **Find Previous** reaches the top of the Command Window. If you have **Wrap around** selected, it continues searching after beeping.

Note that you can only search for text currently displayed in the Command Window. To increase the amount of information maintained in the Command Window, increase the setting for the command session scroll buffer size in **Command Window Preferences**, and do not clear the Command Window.

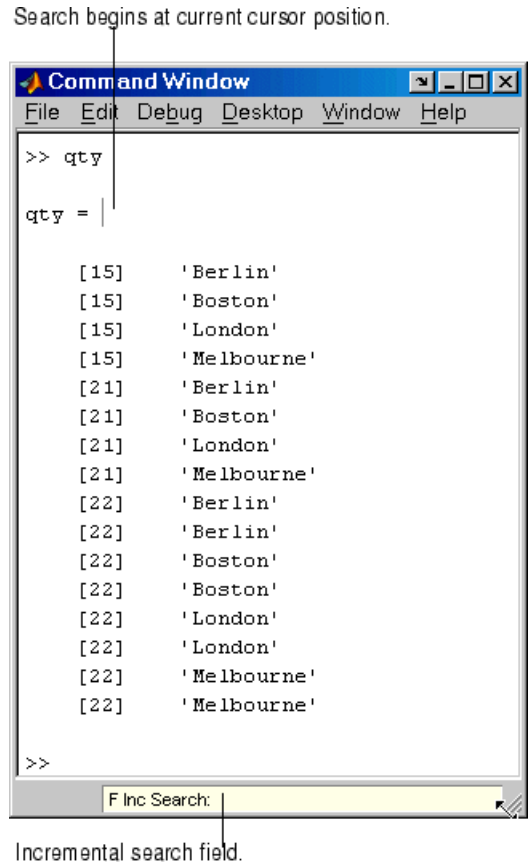
Change the selection in the **Look in** field to search for the specified text in other MATLAB desktop tools.

Incremental Search

With the incremental search feature, the cursor moves to the next or previous occurrence of the specified text in the Command Window. It is similar to the Emacs search feature. To use the incremental search feature in the Command Window,

1. Position the cursor where you want the search to begin.
2. How you begin the incremental search depends on your setting for the Command Window key bindings preference:
   - Press **Ctrl**+**S** for **Emacs**, or
   - Press **Ctrl**+**Shift**+**S** for **Windows**
3. To look for the previous occurrence, press **Ctrl**+**R** or **Ctrl**+**Shift**+**R** instead.

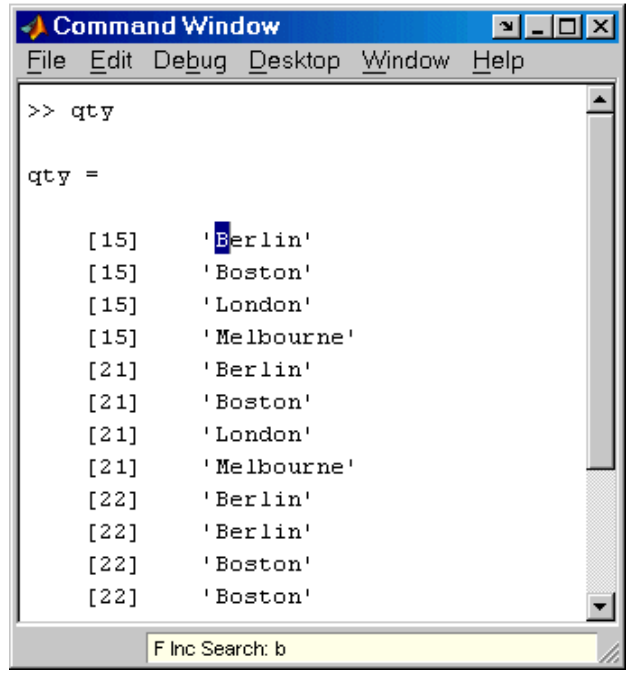
   An incremental search field, **Inc Search**, appears at the bottom of the Command Window and is preceded by **F** for a forward search, or **R** when you are looking for the previous occurrence (reverse search).



4 In the **Inc Search** field, type the text you want to find. For example, look for `Boston`.

As you type the first letter, `b`, the first occurrence of that letter in the Command Window after the current cursor position is highlighted. For the example shown, the first occurrence of `b` is highlighted, the `b` in `Berlin`. Note that incremental search allows for case sensitivity — see “Case Sensitivity in Incremental Search” on page 3-38.

MATLAB finds the next b.



When you type the next letter, the first occurrence of the text becomes highlighted. In the example, when you add the letter `o` to the `b` so that the **Inc Search** field now has `bo`, the `bo` in `Boston` becomes highlighted.

- If you mistype in the **Inc Search** field, use the **Back Space** key to remove the last letters and make corrections.
- After finding the `bo`, you can press **Ctrl+W** to complete that word. In this example, `Boston` appears in the **Inc Search** field.

5 To find the next occurrence of `Boston` in the Command Window, press **Ctrl+S**. To find the previous occurrence of the text, press **Ctrl+R**

6 If MATLAB beeps, it means either that the text was not found, or the search wrapped past the end (or beginning) of the Command Window and continued at the beginning (or end).

- When the text is not found, **Failing** appears in the incremental search field. Modify the search term in the incremental search field and try again. Use **Ctrl+G** to automatically remove characters back to the last successful search. For example, if `plode` fails, **Ctrl+G** removes the `de` from the search term because `plo` does exist in the Command Window.

7 To end the incremental search, press **Esc** or **Enter**, or any other key that is not a character or number.

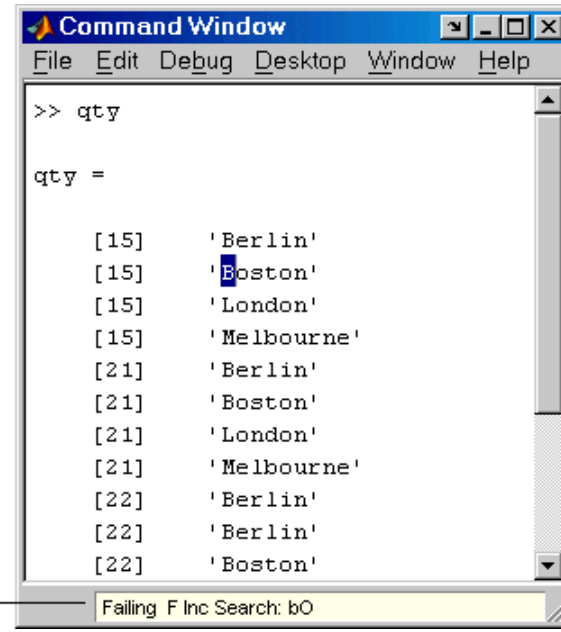
The **Inc Search** field no longer appears. The cursor is at the position where the text was last found, with the search text highlighted.

Incremental search is also available in the Editor/Debugger — see "Incremental Search" on page 6-51.

Case Sensitivity in Incremental Search

When you enter lowercase letters in the **Inc Search** field, for example, `b`, incremental search looks for both lowercase and uppercase instances of the letters, for example `b` and `B`. However, if you enter uppercase letters, for example, `B`, incremental search only looks for instances that match the case you entered.

In the example, enter `b0` in the **Inc Search** field and incremental search does not find any matching text.



Preferences for the Command Window

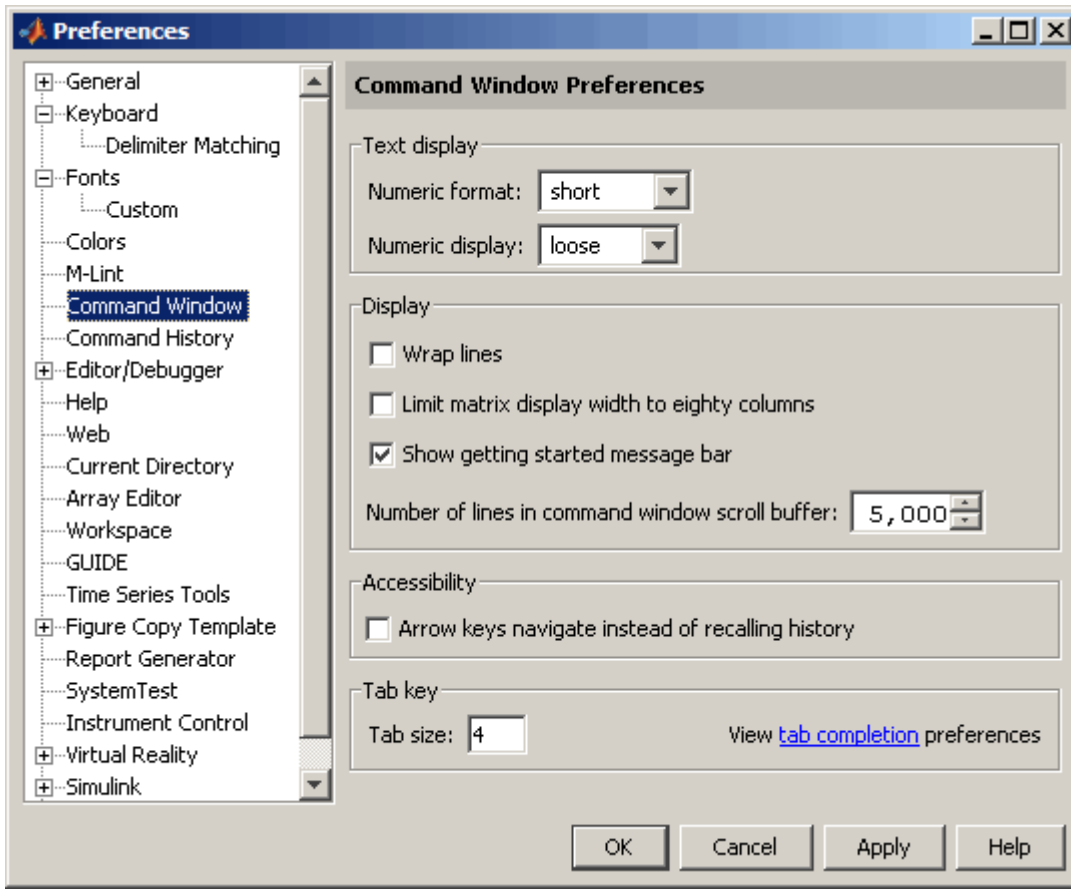
In this section...

See also:

- "Fonts Preferences for Desktop Tools" on page 2-62
- "Confirmation Dialogs Preferences" on page 2-81

Text, Display, Accessibility, and Tab Size Preferences

To set these preferences for the Command Window, select **File > Preferences** and then select **Command Window** in the left pane of the Preferences dialog box.



Text Display

Specify the format, that is, how output appears in the Command Window.

Numeric format. Specify the output format of numeric values displayed in the Command Window. This affects only how numbers are displayed, not how MATLAB computes or saves them. The `format` reference page includes the list of available formats, with examples.

Numeric display. Specify spacing of output in the Command Window. To suppress blank lines, use `compact`. To display blank lines, use `loose`. For more information, see the reference page for `format`.

Display

Wrap lines. Select to make a single line of input or output in the Command Window break into multiple lines in order to fit within the current width of the Command Window. This is useful for console mode. With this option selected, an entire line is visible without scrolling, and the horizontal scroll bar does not appear because it is not needed.

Show getting started message bar. Select to display the getting started message bar in the Command Window. It appears beneath the menu bar and contains links to a video, documentation, and demos. For more information, see “Getting Started Message Bar in the Command Window” on page 3-5

Limit matrix display width to eighty columns. When selected, MATLAB displays only 80 columns of matrix output, regardless of the width of the Command Window. Clear the check box if you make the Command Window wider than 80 columns and want matrix output to fill the width of the Command Window. See also the `display` reference page.

To determine the number of columns and rows that will display in the Command Window, given its current size, use

```
get(0,'CommandWindowSize')
```

With the matrix display width preference cleared, the number of columns is based on the width of the Command Window. With the preference set to 80 columns, the number of columns is always 80.

Number of lines in command window scroll buffer. Set the number of lines maintained in the Command Window, from `1,000` to `25,000`. This is the number of lines you can see when you scroll vertically. A larger buffer means you can view more lines and it provides a larger base for search features, but requires more memory.

This preference setting does not impact the number of lines you can recall when you use the up arrow key in the Command Window. Using the up arrow key, you can recall all lines shown in the Command History window, regardless of how many lines you can see in the Command Window.

Accessibility

Select this option to use the up and down arrow keys to move the cursor when it is above the command line. With this preference selected, use the **Ctrl+** up arrow or down arrow key to recall statements for Windows and Macintosh key bindings, or **Ctrl+P** and **Ctrl+N** for **MATLAB standard (Emacs)** key bindings.

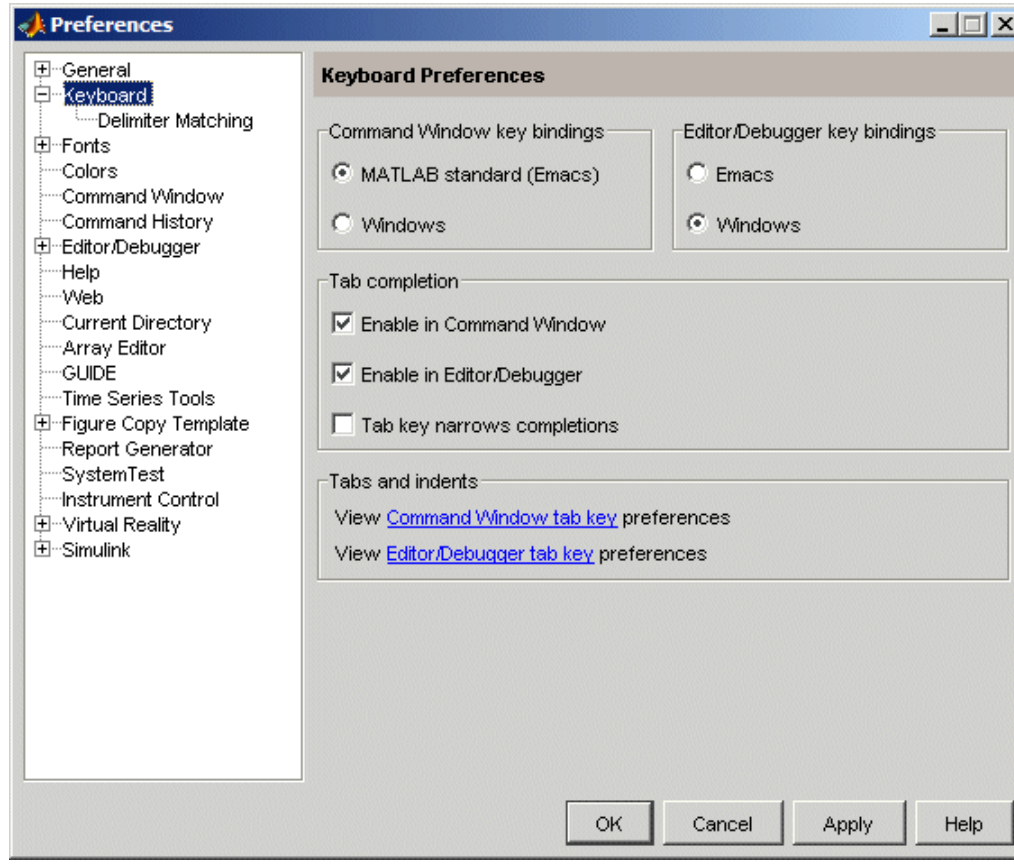
Clear this preference to use the up and down arrow keys to recall statements. Use the mouse and other features to move the cursor when above the command line.

Tab key

Tab size. Number of spaces assigned to a tab stop when displaying output. The default is four spaces, except on UNIX platforms where the default is eight spaces. This does not apply when the tab completion preference is selected.

Keyboard Preferences

To set key binding, tab completion, and delimiter matching preferences for the Command Window and the Editor/Debugger, select **File > Preferences** and then select **Keyboard** in the left pane of the Preferences dialog box.



Command Window Key Bindings

Specify the keyboard shortcuts (key bindings) to be used at the command line.

MATLAB standard (Emacs). Allows you to use the control keys listed in "Keyboard Shortcuts in the Command Window" on page 3-26, which should be familiar to existing MATLAB users and Emacs users. For example, **Ctrl+A** moves the cursor to the beginning of the line.

Windows. Allows you to use standard Windows control keys. For example, **Ctrl+A** is the shortcut for **Edit > Select All**, which selects the entire contents of the Command Window.

Macintosh. This option is available only on Macintosh platforms. It allows you to use Macintosh keys, such as the **Command** key instead of the **Ctrl** key.

Editor/Debugger Key Bindings

Specify the keyboard shortcuts (key bindings) to be used by the Editor/Debugger. The Editor/Debugger key bindings are also used by other tools, for example, the **Callback** field in the Shortcut Editor dialog box.

Select **Windows**, **Emacs**, or **Macintosh** (available only on Macintosh platforms), depending on which convention you want the Editor/Debugger to follow for accelerators and shortcuts. The accelerators on the menus change after you change this option.

For example, when you select Windows key bindings, the shortcut to paste a selection is **Ctrl+V**. When you select Emacs key bindings, the shortcut to paste a selection is **Ctrl+Y**. When you select Macintosh key bindings, the shortcut to paste a selection is **Command+V**. You can see the accelerator on the **Edit** menu for the **Paste** item.

Tab Completion

Enable in Command Window. Select the check box to use tab completion when typing functions in the Command Window. Clear the check box if you do not want to use the tab completion feature. In that event, when you press the **Tab** key, MATLAB moves the cursor to the next tab stop rather than completing a function — see also the preference for "Tab size" on page 3-43.

Enable in Editor/Debugger. Select the check box to use tab completion when typing functions in the Editor/Debugger. Clear the check box if you do not want to use the tab completion feature. In that event, when you press the **Tab** key, MATLAB moves the cursor to the next tab stop rather than completing a function — see also in the online documentation.

Tab key narrows completions. Select this check box to narrow the list of possible completions shown by typing another character and pressing **Tab**. For details, see “Narrowing Completions Shown” on page 3-23.

Tabs and Indents

The links go to the panes where you can view and set preferences for

- **Tab** key size in the Command Window, which is used when the tab completion preference is not set
- **Tab** key size and indenting preferences in the Editor/Debugger

Delimiter Matching

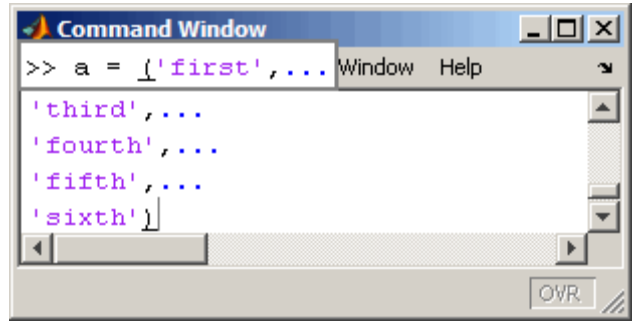
To set these preferences, select **File > Preferences > Keyboard > Delimiter Matching** . These preferences apply to the Command Window and the Editor/Debugger.

With these preferences selected, MATLAB alerts you to matched and unmatched delimiters based on the MATLAB language syntax rules. For example, when you type a parenthesis or another delimiter, MATLAB highlights the matched parenthesis or delimiter in the pair.

Delimiter pairs are parentheses ( ), brackets [ ], and braces { }. For the Editor/Debugger , paired language keywords are also matched. Paired language keywords include `for`, `if`, `while`, `else`, and `end` statements.

In the following illustration, MATLAB underlines the left parenthesis in the pair when you move over the right parenthesis using an arrow key.

If the matching delimiter is not visible on the screen, a pop-up window appears and shows the line containing the matching delimiter. In the Editor/Debugger, the line number is included. Click in the pop-up window to go to that line.



Match while typing. Select the check box if you want to be alerted to matches and mismatches in pairs of delimiters as you type them. Then choose how you want MATLAB to alert you to matches by selecting an entry from **Show match with**. When you type a closing (or opening) delimiter in the Command Window or Editor/Debugger, MATLAB alerts you based on the option you choose:

- `Balance` — The corresponding delimiter is highlighted briefly.
- `Underline` — Both delimiters in the pair are underlined briefly.
- `Highlight` — Both delimiters in the pair are highlighted briefly.

Choose how you want MATLAB to alert you to mismatches using **Show mismatch with**. When you type a closing delimiter that does not have an opening match, MATLAB alerts you based on the option you choose:

- `Beep` — MATLAB beeps.
- `Strikethrough` — The delimiter you typed is briefly crossed out.
- `None` — There is no action.

Match on arrow key. Select the check box if you want to be alerted to matches and mismatches in pairs of delimiters when you use an arrow key to move the cursor over a delimiter. Then choose how you want MATLAB to alert you to matches by selecting an entry from **Show match with**. When you move the arrow over a closing (or opening) delimiter in the Command Window or Editor/Debugger, MATLAB alerts you based on the option you choose:

- `Underline` — Both delimiters in the pair are underlined briefly.
- `Highlight` — Both delimiters in the pair are highlighted briefly.

Choose how you want MATLAB to alert you to mismatches by selecting an entry from **Show mismatch with**. When you move an arrow key over a delimiter that does not have a match, MATLAB alerts you based on the option you choose:

- `Beep` — MATLAB beeps.
- `Strikethrough` — The delimiter is briefly crossed out.
- `None` — There is no alert.

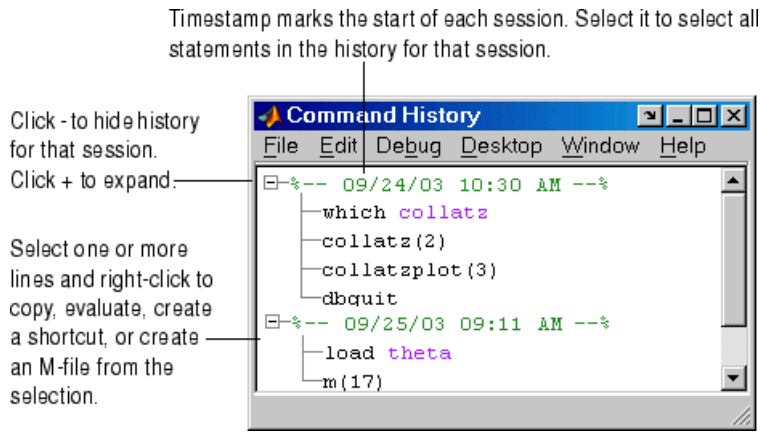
Command History Window

In this section...

Overview

The Command History window displays a log of the statements most recently run in the Command Window. If you have an active Internet connection, you can watch the Command History video demo for an overview of the major functionality.

To show or hide the Command History window, use the **Desktop** menu. Alternatively, use `commandhistory` to open the MATLAB Command History window when it is closed, or to select it when it is open. For details, see "Arranging the Desktop" on page 2-6.



MATLAB provides other options for viewing a history of statements. See also the following sections:

- "Recalling Previous Lines" on page 3-19, which describes using the up arrow in the Command Window
- The `diary` function reference page
- "Startup Options" on page 1-12, which includes the `logfile` startup option

Viewing Statements in the Command History Window

The Command History window lists statements you ran in the current session and in previous sessions. The time and date for each session appear at the top of the history of statements for that session. Use the scroll bar or the up and down arrow keys to move through the Command History window.

Click **-** to hide the history for a session, and click **+** to show it. Select a timestamp to select all entries for that session. With a timestamp selected, you can press the **+** or **-** key on the numeric keypad to show and hide entries.

The Command History window and the Command Window's statement recall feature save to the file `history.m`, which is stored in the same directory as MATLAB preferences. Type `prefdir` in the Command Window to see the location of the file. The `history.m` file is loaded when MATLAB starts, and it stores a maximum of 20,000 bytes, deleting the oldest entries as needed to maintain that size.

MATLAB automatically saves the `history.m` file throughout the session according to the **Saving** preference you specified. You can choose to automatically exclude certain statements from being written to the `history.m` file with the **Settings** preference. For details, see "Preferences for Command History" on page 3-59.

Using Statements from the Command History Window

You can select entries in the Command History window and then perform the following actions for the selected entries.

Action	How to Perform the Action
Run statements in the Command Window	Double-click an entry (entries) in the Command History window to execute the statement(s) in the entries. For example, double-click `edit myfile` to open `myfile.m` in the Editor/Debugger. You can also run the statements in an entry by right-clicking the entry and selecting **Evaluate Selection** from the context menu, or by selecting an entry and pressing **Enter** or **Return**.
Edit and run statements in the Command Window	Select an entry or entries and then select **Copy** from the context menu. Paste the selection into the Command Window. Alternatively, drag the selection to the Command Window. Then in the Command Window, edit the statements, and press **Enter** or **Return** to execute them.
Copy statements to another window	Select an entry or entries and then select **Copy** from the context menu. Paste the selection into an open M-file in the Editor/Debugger or any application. Alternatively, drag the selection from the Command History window to an open M-file or another application.
Create an M-file from statement(s)	Select an entry or entries and then right-click and select **Create M-File** from the context menu. The Editor/Debugger opens a new M-file that contains the statements you selected from the Command History window.
Create a shortcut from statement(s)	Select an entry or entries and then right-click and select **Create Shortcut** from the context menu. Alternatively, drag the selection to the **Shortcuts** toolbar. The Shortcut Editor opens and the selected statements appear in the **Callback** field. For more information, see “Shortcuts for MATLAB — Easily Run a Group of Statements” on page 2-32.

Searching in the Command History Window

There are two types of search in the Command History window:

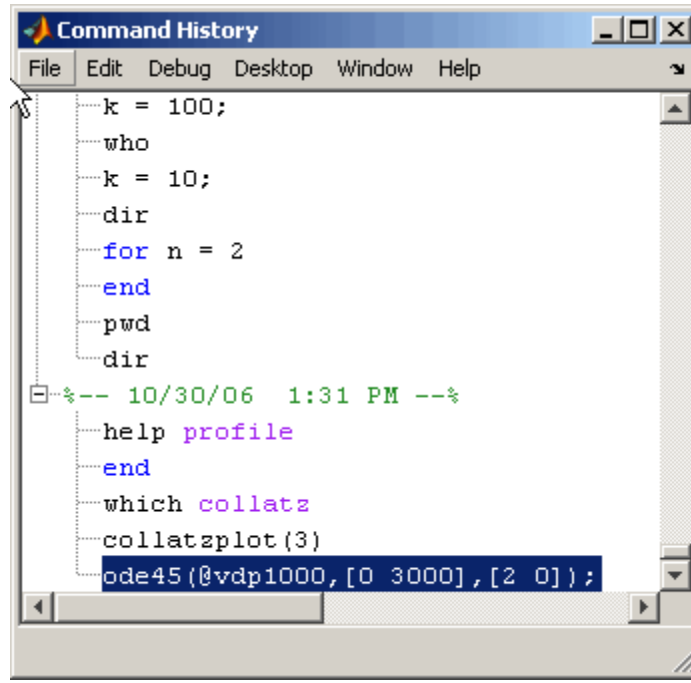
- “Finding Next Entry By Letter” on page 3-52
- “Finding Text” on page 3-56

After finding an entry, you can copy and paste it into an M-file or any file, or you can right-click and select **Evaluate Selection** to run the entry.

Finding Next Entry By Letter

Type a letter in the Command History window. The Command History window searches backwards to find the last previous entry that begins with that letter as illustrated in this example:

1 Position the cursor at anywhere in the Command History window.

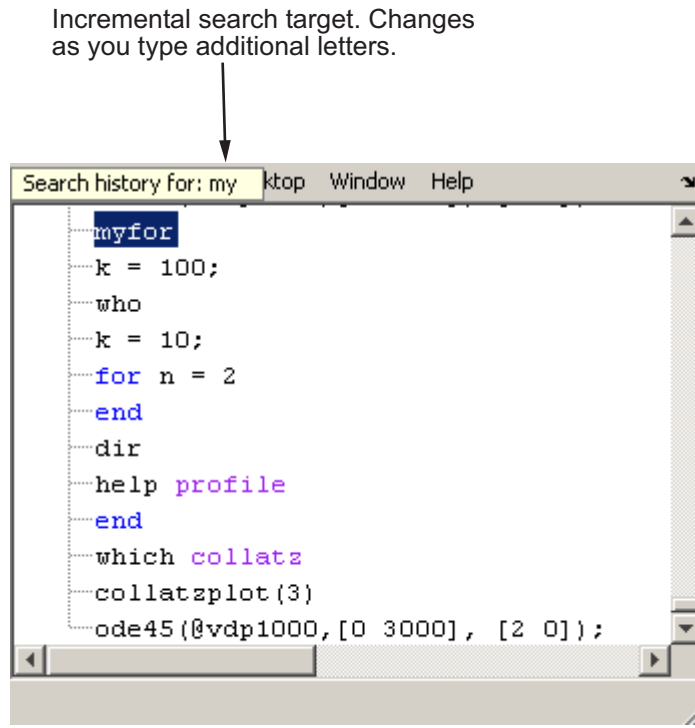


2 Type the first letters of the entry you want to find. For example, type `my`.

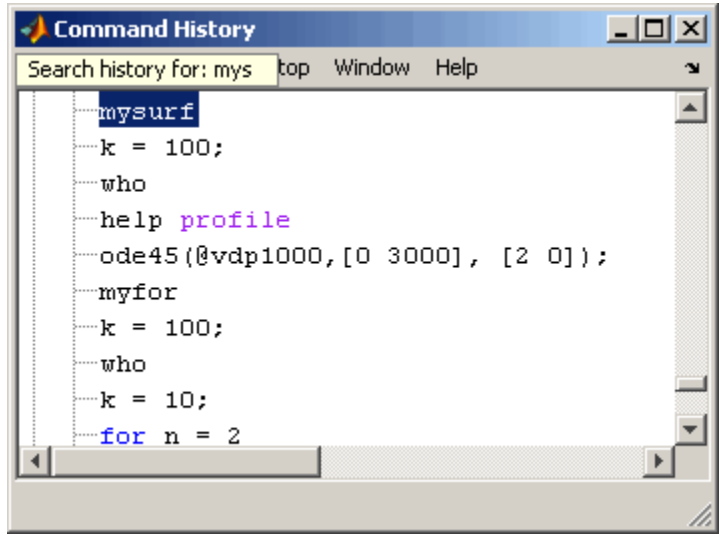
The Command History window searches backwards and selects the previous entry that begins with the letters you typed; in this example, you typed `my`, and the Command History finds `myfor`.

As you begin typing that a small yellow-background pop-up window, `Search history for:`, appears at the top of the Command History window. This window keeps track of your search target as you type additional letters to narrow the focus of your search.

If the search finds a matching entry in a sessions that is collapsed, it expands the session and selects the entry.

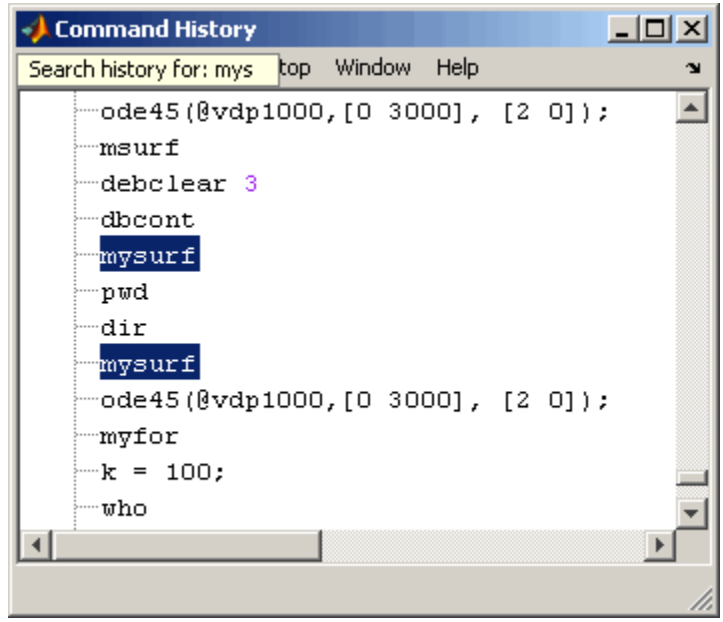


3 Now type an `s` to extend the search to `mys`. The Command History window continues to search backwards, stopping next at the function `mysurf`.

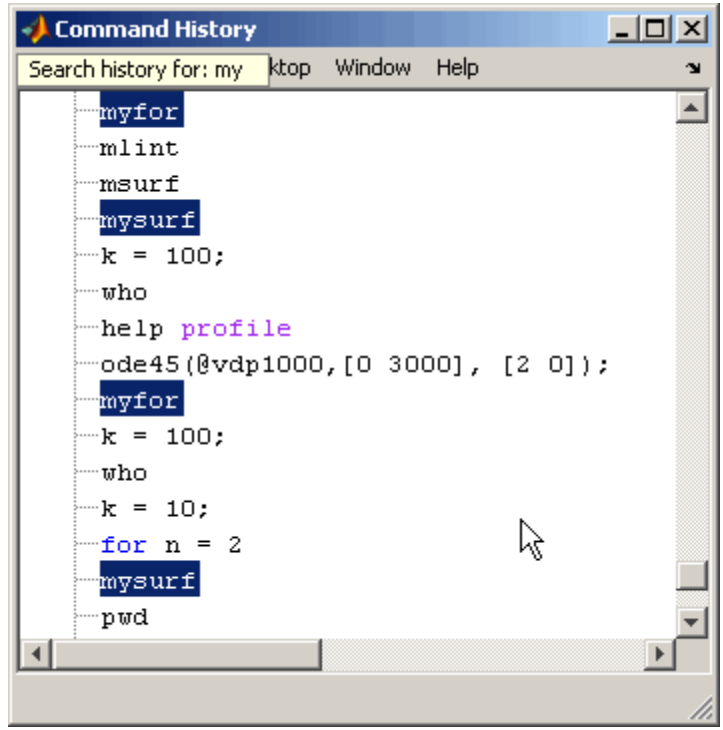


Finding Multiple Occurrences of the Entry. You can use the up and down arrow keys to search for the next or the previous occurrence of the entry you just found.

When you press **Ctrl** and the up or down arrow key, each occurrence of the entry remains highlighted while you search for additional instances.



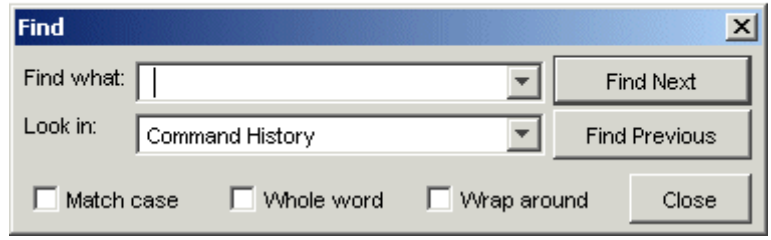
To highlight all instances of the entry, press **Ctrl+A**. In the example below, all instances of entries beginning with `my` are highlighted.



Finding Text

Select **Find** from the **Edit** menu to search for specified text using the Find dialog box. Complete the dialog box. The search begins at the current cursor position. MATLAB finds the text you specified and highlights it. Click **Find Next** or **Find Previous** to find another occurrence, or use the keyboard shortcuts **F3** and **Shift+F3**. Find looks for visible entries only, that is, it does not find entries in collapsed nodes.

Search for specified text in the Command History window.



MATLAB beeps when a search for **Find Next** reaches the end of the Command History window, or when a search for **Find Previous** reaches the top of the Command History window. If you have **Wrap around** selected, it continues searching after beeping.

Change the selection in the **Look in** field to search for the specified text in other MATLAB desktop tools.

Printing the Command History Window

To print the contents of the Command History window, select **File > Print** or **Print Selection**. Specify options for printing by selecting **File > Page Setup**. For example, you can print the history with a header. For more information, see “Printing and Page Setup Options for Desktop Tools” on page 2-52.

The printed version is sized to fit the page. If there is a long statement in the Command History, the reduced page size might be difficult to read. As a workaround, either use **Print Selection**, where the long statement is not part of the selection, or remove any extremely long statements from the Command History before printing it.

Deleting Entries from the Command History Window

Delete entries from the Command History window when you feel there are too many and it becomes inconvenient to find the ones you want. All entries remain until you delete them or until the `history.m` file exceeds its maximum size, when MATLAB automatically deletes the oldest entries—see “Viewing Statements in the Command History Window” on page 3-50.

To delete entries in the Command History window, first select the entries to delete, using one of these methods:

- Select a single entry.
- **Shift**+click or **Ctrl**+click to select multiple entries.
- Select the timestamp for a session to select all entries for that session. Then use **Shift**+click or **Ctrl**+click to select multiple timestamps with all of their entries.

Then right-click and select **Delete selection** from the context menu, or press the **Delete** key. A confirmation dialog box might appear; see preferences for "Confirmation Dialogs Preferences" on page 2-81 for more information.

To delete all entries, select **Edit > Clear Command History**, or select **Clear Entire History** from the context menu.

After deleting entries from the Command History window, you will not be able to recall those statements in the Command Window as described in "Recalling Previous Lines" on page 3-19.

Preferences for Command History

In this section...

Introduction

Using Command History preferences, you can choose to exclude statements from the `history.m` file and specify how often to save it. The `history.m` file is used for both the Command History window and statement recall in the Command Window.

To set preferences for the `history.m` file, select **File > Preferences**, and then select **Command History** in the Preferences dialog box.

Settings

Specify the types of statements to exclude from the `history.m` file. Note that when you exclude statements from the `history.m` file, you cannot recall them in the Command Window as described in "Recalling Previous Lines" on page 3-19, nor can you view them in the Command History window.

Save Exit/Quit Commands

Select the check box to save `exit` and `quit` commands in the `history.m` file.

Save Consecutive Duplicate Commands

Select the check box if you want consecutive executions of the same statement to be saved to the `history.m` file.

For example, with this option selected, run `magic(5)`, and then run `magic(5)` again. The `history.m` file saves two consecutive entries for `magic(5)`. With this option cleared, for the same example, the command history file saves only

one entry for `magic(5)`. If you then run `magic(10)`, the command history file saves both entries, `magic(5)` followed by `magic(10)`.

Saving

Use **Saving** preferences to specify how often to automatically save the `history.m` file during a MATLAB session.

Save History File On Quit

Select this option to save the `history.m` file when you end the MATLAB session. If the session does not end via a normal termination, that is, via the `exit` or `quit` functions, **File > Exit MATLAB**, or the MATLAB desktop Close box, the history file is not saved for that session.

Save After n Commands

Select this option to save the `history.m` file after `n` statements are added to the file. For example, when you select the option and set `n` to `10`, after every 10 statements are added, the history file is automatically saved. Use this option if you don't want to risk losing entries to the saved history because of an abnormal termination, such as a power failure.

Don't Save History File

Select this option if you do not want to save the `history.m` file. This feature is useful when multiple users share the same machine and do not want other users to view the statements they have run.

Note that any entries already in the `history.m` file remain. Prior to setting this preference, you might want to remove any existing entries. Follow the instructions in "Deleting Entries from the Command History Window" on page 3-57.

See Also

Additional preferences that relate to the Command History are

- "Fonts Preferences for Desktop Tools" on page 2-62
- "Confirmation Dialogs Preferences" on page 2-81

4

Help for Using MATLAB

The primary means for getting help is the Help browser, which provides documentation for all your installed products. Other forms of help are available including M-file help and Technical Support solutions. If you have an active Internet connection, you can watch the Help and Documentation video demo for an overview of the major functionality.

Help Functions (p. 4-44)	Use functions to get information, such as `help` and `doc`.
Getting Pop-Up Help for Functions (p. 4-49)	Get pop-up help (help on selection) for functions from within the Editor/Debugger and the Command Window.
Other Forms of Help (p. 4-51)	Use product-specific help features, download M-files, contact Technical Support, see documentation for other MathWorks products, view a list of other books, and participate in a MATLAB newsgroup.

Help Browser Overview

In this section...

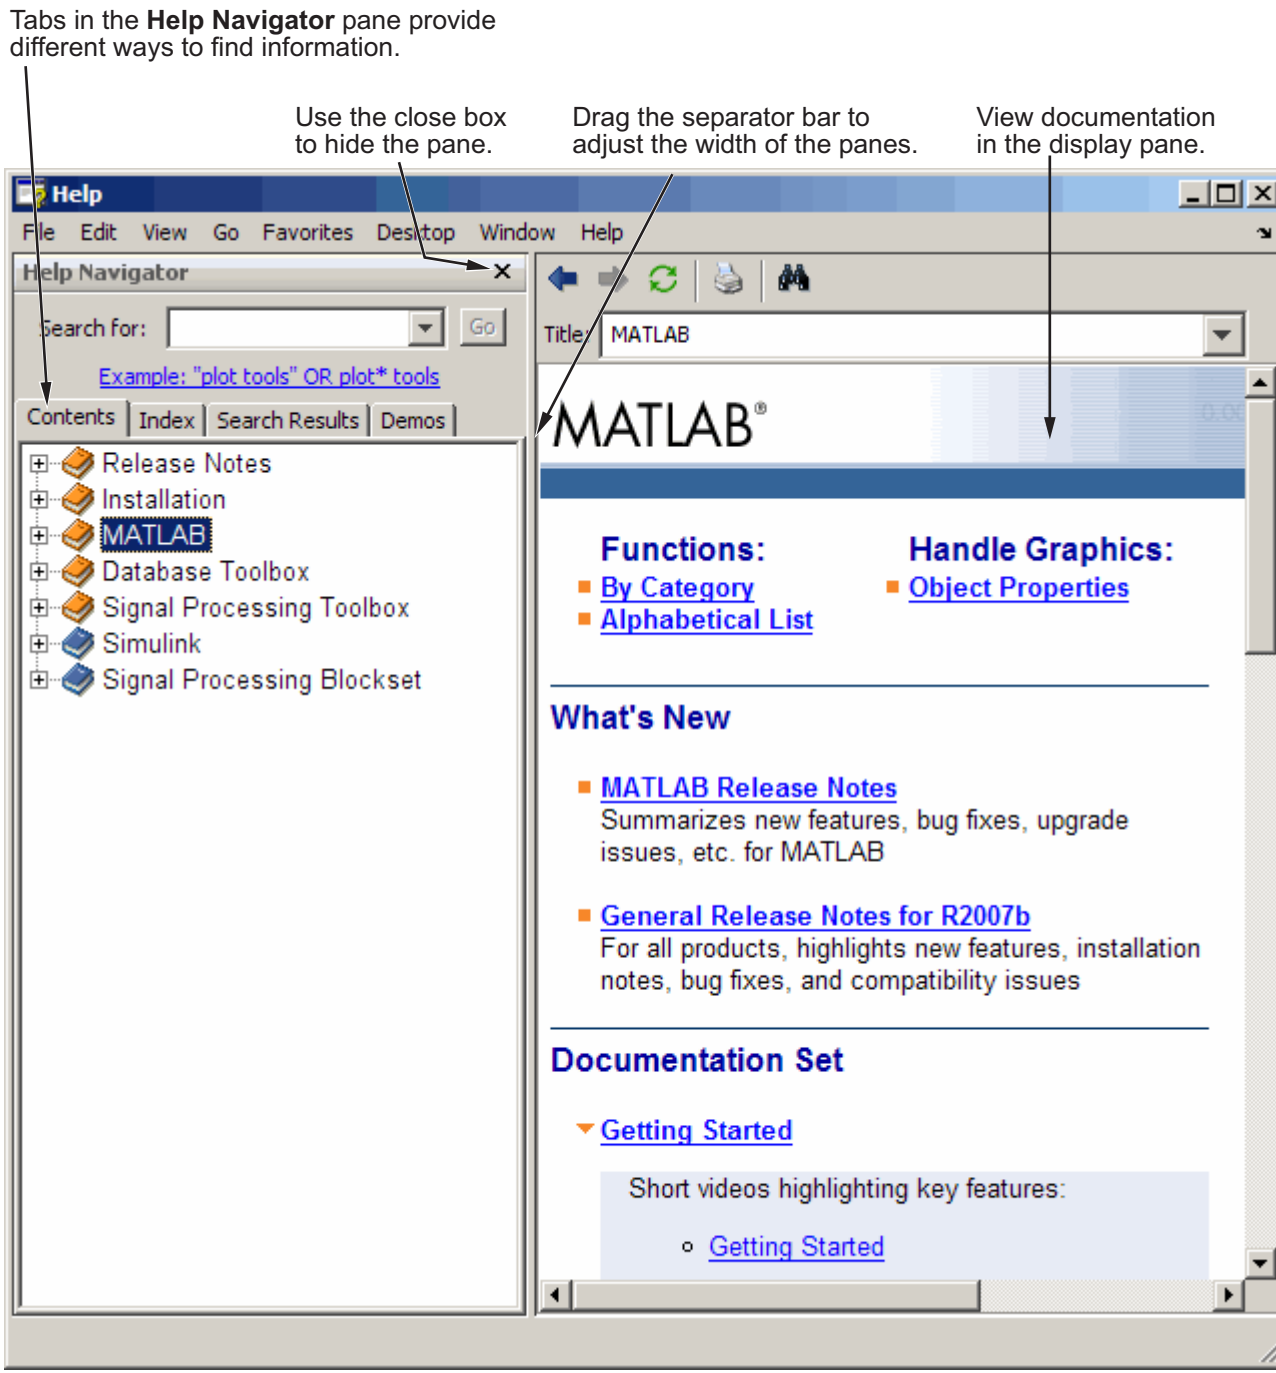
About the Help Browser

The Help browser is an HTML browser integrated with the MATLAB desktop. Use the Help browser to search and view documentation and demonstrations for MATLAB and all other installed MathWorks products. MATLAB automatically installs the documentation and demos for a product when you install that product.

Opening the Help Browser

To open the Help browser, click the Help button  in the desktop toolbar, type `helpbrowser` in the Command Window, or use the **Help** menu in any tool. There are two panes:

- The Help Navigator, on the left, for finding information, includes a **Search for** field, and **Contents**, **Index**, **Search Results**, and **Demos** tabs. For more information, see “Finding Information with the Help Browser” on page 4-10.
- The display pane, on the right, for viewing documentation and demos.



Tabs in the **Help Navigator** pane provide different ways to find information.
Use the close box to hide the pane.
Drag the separator bar to adjust the width of the panes.
View documentation in the display pane.

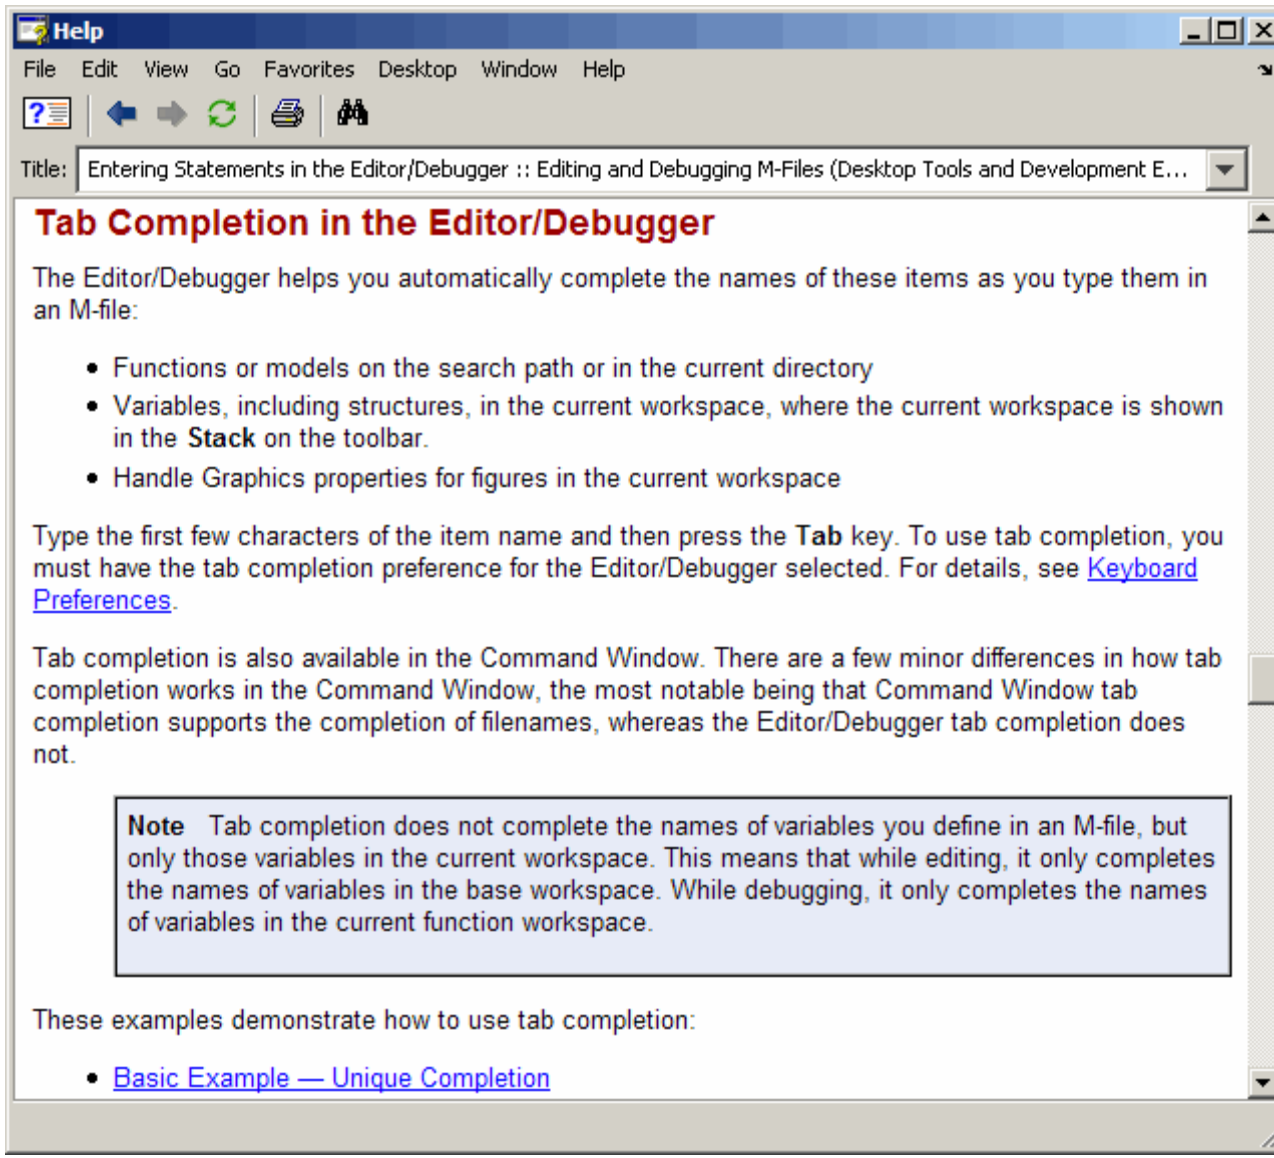
Short videos highlighting key features:
Getting Started

Resizing the Help Browser

To adjust the relative width of the two panes, drag the separator bar between them. You can also change the font in either of the panes — see “Help Fonts and Colors Preferences” on page 4-39.

Once you find the documentation you want, you can close the **Help Navigator** pane so there is more screen space to view the information itself. This is shown in the following figure. To close the **Help Navigator** pane, click the Close box in the pane’s upper right corner. To open the **Help Navigator** pane from the display pane, click the Help Navigator button on the toolbar. Alternatively, use the **View** menu.



Help
File Edit View Go Favorites Desktop Window Help
Title: Entering Statements in the Editor/Debugger :: Editing and Debugging M-Files (Desktop Tools and Development E...
Tab Completion in the Editor/Debugger
The Editor/Debugger helps you automatically complete the names of these items as you type them in an M-file:
Functions or models on the search path or in the current directory
Variables, including structures, in the current workspace, where the current workspace is shown in the Stack on the toolbar.
Handle Graphics properties for figures in the current workspace
Type the first few characters of the item name and then press the Tab key. To use tab completion, you must have the tab completion preference for the Editor/Debugger selected. For details, see Keyboard Preferences.
Tab completion is also available in the Command Window. There are a few minor differences in how tab completion works in the Command Window, the most notable being that Command Window tab completion supports the completion of filenames, whereas the Editor/Debugger tab completion does not.
Note Tab completion does not complete the names of variables you define in an M-file, but only those variables in the current workspace. This means that while editing, it only completes the names of variables in the base workspace. While debugging, it only completes the names of variables in the current function workspace.
These examples demonstrate how to use tab completion:
Basic Example — Unique Completion

Types of Documentation

The Help browser and help functions provide access to the following types of information for all installed MathWorks products. The icons shown here appear in the Help browser contents listing to help you quickly identify documentation by type.

Icon	Type of Documentation	Description and When to Use
	Getting Started	Review Getting Started documentation before you begin using a product or feature for the first time. Then, to learn more, go to the user guides, reference pages, demos, and examples.
 or  or 	Product	MATLAB, toolboxes, and related products use orange book icons  . Simulink, blocksets, and related products use blue book icons  . Link and Target products use green book icons  .
	Index of Examples	Accessible via the Help browser **Contents** listing, this is an index of the major examples included in the Help browser documentation.
	User Guides (blue)	User guide material contains overviews as well as detailed instructions. Consult it after reviewing Getting Started material.
	Reference Pages (orange)	Each function has a reference page that provides the syntax, description, examples, and other information for that function. Each reference page includes links to related functions and additional information. Reference pages are also provided for blocks and properties.
	Release Notes	An overview of new products and features in a release. Release Notes also include upgrade information, links to fixed and known problems, and compatibility considerations. Review the Release Notes for all your products when you first start using a new release. Release Notes for the current version include the release notes for multiple prior versions.

Icon	Type of Documentation	Description and When to Use
	Printable Documentation	Most products provide access to the online documentation in a printable format, PDF. Access PDF files via the Help browser and print them from your PDF reader, such as Adobe Acrobat. Most PDF files reside only on the MathWorks Web site, so you need an Internet connection to view them.
none	Demos	MathWorks products come with demonstrations that run key features of the product. Many of the demos run MATLAB code. Use the Help browser **Demos** pane or **Search Results** to access demos for the products you have installed.
none	M-File Help	Get M-file help in the Command Window to quickly access basic information for a function or model. It provides a brief description of a function and its syntax. It is called M-file help because the text of the help is a series of comments at the top of the M-file for a function.

Accessing Documentation on the Web

You can access all product documentation on the MathWorks Web site at `http://www.mathworks.com/access/helpdesk/help/helpdesk.shtml`. These are some uses for the Web site version of the documentation:

- Access documentation for products you have not installed.
- Access documentation for the most current version. If you do not see the information you are looking for in the Help browser and know you are not running the most current version of MATLAB, the most current version of the documentation, which is on the Web site, might include more information. Note, though, that the documentation on the Web site might refer to features that are not part of your earlier-version product.
- Access documentation for a prior version of some products (Release 13 with Service Pack 2). Note that the release notes on this page include release notes for multiple prior versions. For example, you can find information about MATLAB Version 6.0 (Release 12) new features and changes.

- Access documentation via your system Web browser, such as when you are not running MATLAB or if you prefer your system Web browser.

To determine the URL for a page in the Help browser, see “View the Page Location” on page 4-30

PDF documentation is available only on the Web site.

You cannot read MATLAB documentation files from the MATLAB installation media. You also cannot use a Web browser to read the documentation files installed with MATLAB because the files are compressed JAR files.

Adding Help Files

You can add your own HTML help files so that they appear in the Help browser. For details, see in the online documentation.

Documentation in Other Languages

The MathWorks documentation is available in English. Japanese versions of MATLAB include documentation that has been translated into Japanese. For more information, go to `http://www.cybernet.co.jp/matlab`.

Finding Information with the Help Browser

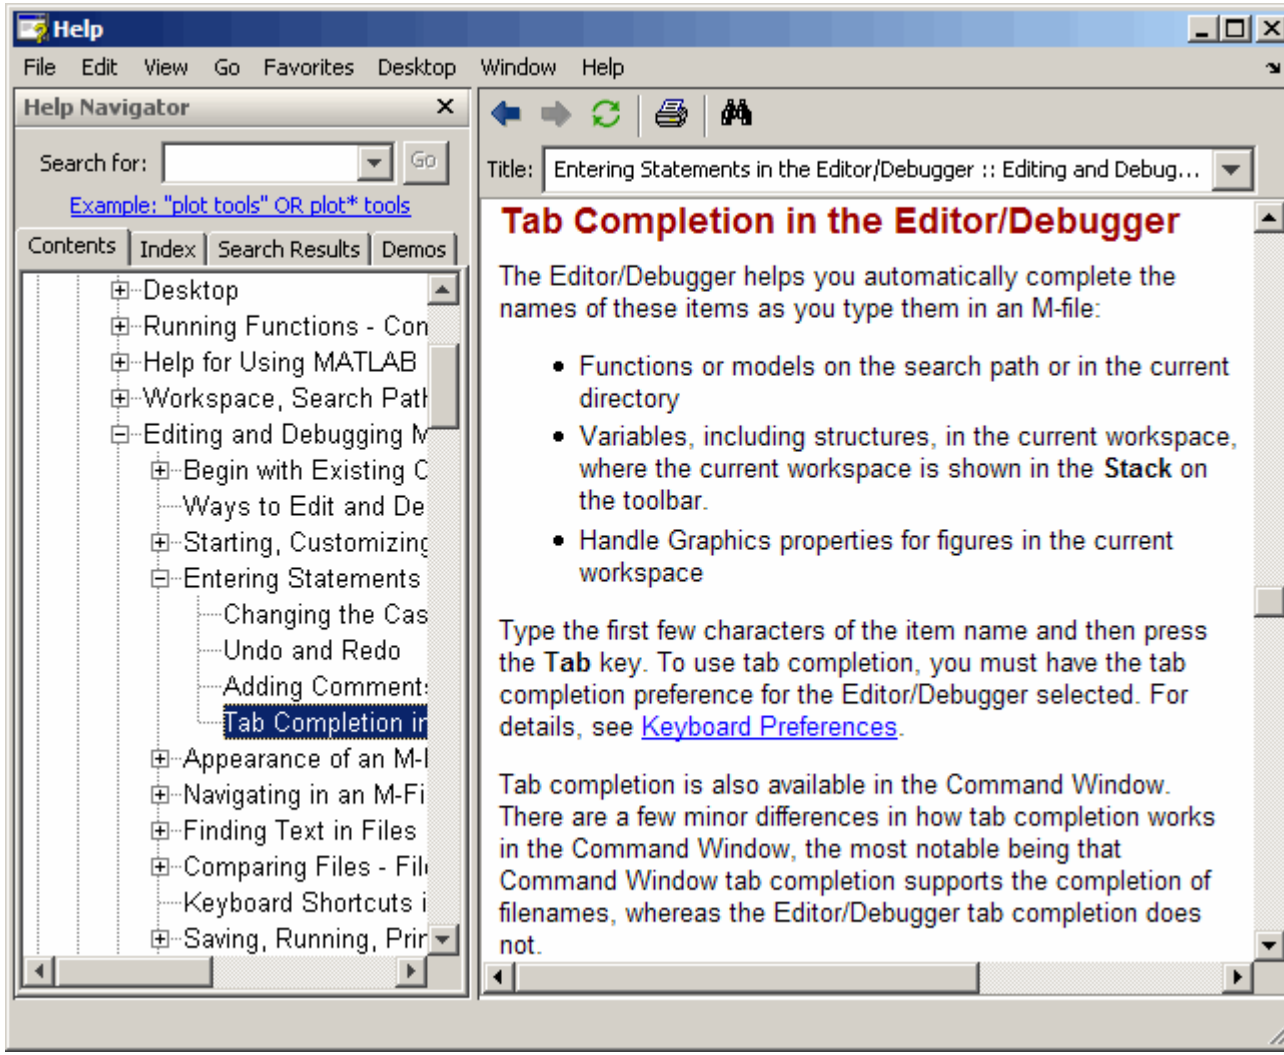
In this section...

Help Navigator

The **Help Navigator** is in the left pane of the Help browser. It provides a table of contents, an index, and a search feature to help you find information.

Contents in the Help Browser

To list the documentation titles and tables of contents for products you installed, click the **Contents** tab in the **Help Navigator** pane. To show documentation for only some of the installed products, use the product filter.



Product Roadmap

When you select a product in the **Contents** pane (any entry with a book icon), such as MATLAB or Communications Toolbox, a *roadmap* of the documentation for that product appears in the display pane. The roadmap includes links to commonly used documentation sections, including

- Function and block references pages
- An index of major examples in the documentation
- The PDF version of the documentation, which is suitable for printing (this is the only direct access from MATLAB to the printable documentation)

Navigate the Contents Listing

In the **Contents** listing, you can

- Click the **+** to the left of an item to show the first page of that document or section in the display pane and expand the listing for that item in the **Help Navigator** pane. You can alternatively: double-click the item, press the right arrow key, or press **+** on the numeric keypad.
- Click the **-** to the left of an item to collapse the listings for that item. You can alternatively: double-click the item, press the left arrow key, or press **-** on the numeric keypad.
- Select an item to show the first page of that document or section in the display pane.
- Press * on the numeric keypad to show all subentries for the selection.
- Use the down and up arrow keys to move through the list of items.

Icons in the Contents Listing

Icons for entries in the top levels of the **Contents** pane listing represent the type of documentation so you can quickly find the kind of information you need for a product. See the table for icons in “Types of Documentation” on page 4-7.

Synchronize the Contents Listing and Demos Listing with the Display Pane

By default, the topic highlighted in the **Contents** pane matches the title of the page appearing in the display pane. The **Contents** pane listing is said to be synchronized with the displayed document. This feature is useful if you access documentation with a method other than the **Contents** pane, for example, using a link in a page in the display pane, or selecting a search result. With synchronization, you know what book and section the displayed page is part of, and where that section fits within the overall book. Note that synchronization

only applies to the major headings in a document. For pages that begin with lower level headings, the **Contents** pane listing does not synchronize.

You can turn off synchronization. To do so, use preferences. See “General — Keep Contents Synchronized” on page 4-38.

Synchronization applies to the **Contents** and **Demos** panes. The page shown in the display pane does not necessarily correspond to the selection in the **Index**, or **Search Results** panes. However, if you return to the **Contents** pane (or **Demos** pane), the displayed page synchronizes with the **Contents** (or **Demos**) pane.

This example illustrates synchronization for after performing a search. When you enter `"interactive plotting"` in the **Search for** field, the **Search Results** pane displays a list of results in the Help Navigator, with the first documentation result selected. The display pane shows the page corresponding to that first result, `Plotting Tools  Interactive Plotting`. When you click the **Contents** tab, the tree automatically expands to show `MATLAB > Graphics > Plots and Plotting Tools` and selects the `Plotting Tools  Interactive Plotting` entry.

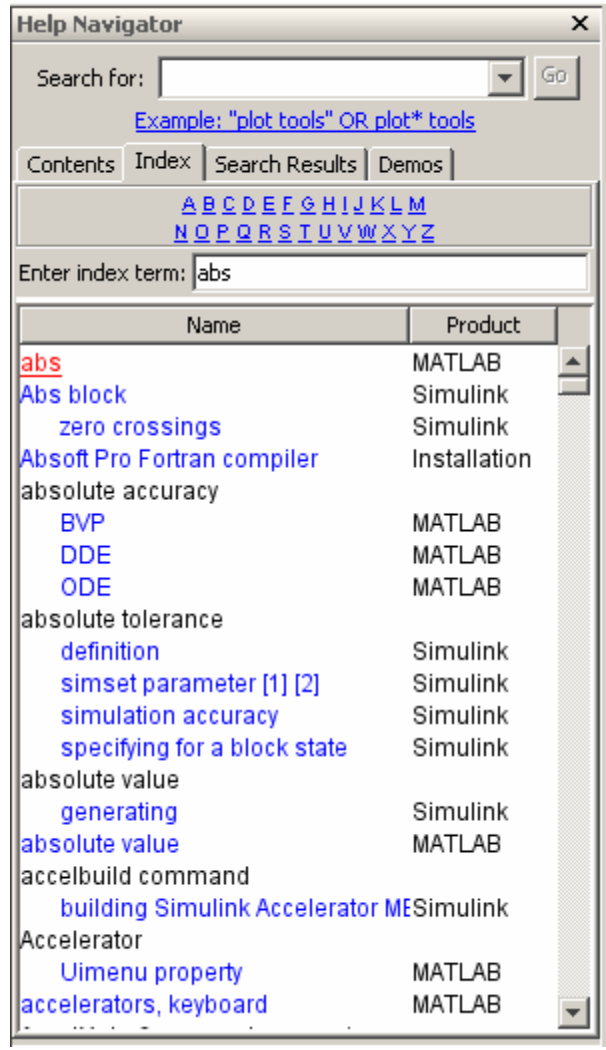
This example illustrates synchronization for demos. When you run

```
demo('matlab', 'graphics')
```

the **Demos** pane appears, with the MATLAB Graphics entry selected.

Index for the Help Browser

To find specific index entries (selected keywords) in the MathWorks documentation for installed products, use the **Index** in the **Help Navigator** pane.



1 Click the **Index** tab.

2 Type a word or words in the **Enter index term** field. As you type, the **Index** pane displays matching entries and their subentries (indented). It might take a moment for the display to appear. The index is not case

sensitive. If there is not a matching entry, it displays the page for the letter that your entry begins with.

The product whose documentation includes the matching index entry is listed next to the index entry, which is useful when there are multiple matching index entries. You might have to make the **Help Navigator** pane wider to see the product.

3 Select a blue index entry from the list (where blue represents a hyperlink) to display the page to which the term refers. Multiple links per entry are denoted by numbers in brackets following the term. (Black index entries are headings and do not link to any page.)

When you select an entry, its color becomes red. The page whose entry you selected appears in the display pane, scrolled to the location that the entry references.

4 To see more matching entries, scroll through the list.

Tips for Using the Index

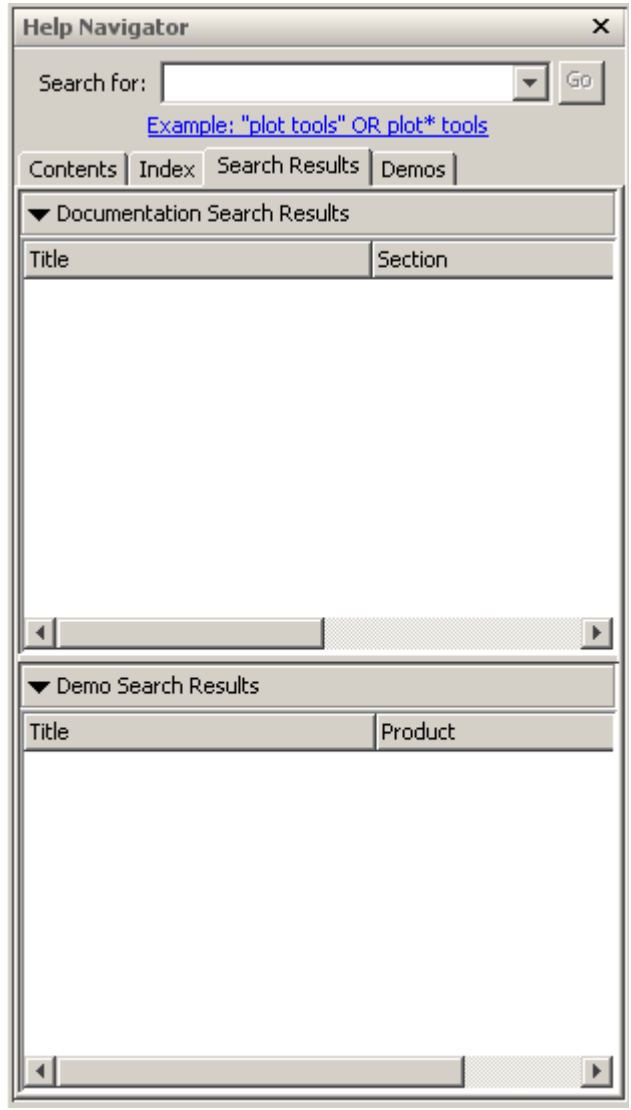
- To see entries for selected products only, select **File > Preferences > Help** and set the product filter.
- To see entries for all installed products, select **File > Preferences > Help**, and clear the **Enable product filter** check box.
- For more or different results, type a different term or reverse the order of the words you type. For example, if you are looking for an entry about tab completion for `Editor/Debugger`, a subentry does not exist. Instead type `tab completion` and there is a subentry `Editor/Debugger`.
- After selecting an entry, search for specified text in the displayed page using the **Find** tool, accessible from the Find button on the display pane toolbar.
- When there are multiple matching entries, refer to the product associated with each entry, which appears in the second column of the **Index** results. You might need to make the pane wider to see it.

- For different but related results, try using the **Search for** field—for instructions, see “Search Documentation and Demos with the Help Browser” on page 4-16.
- See “Specifying Colors for the Help Browser” on page 4-41 for information about changing the color of hyperlinks in the **Index**.

Search Documentation and Demos with the Help Browser

Searching in the Help Browser

To look for a specific word or phrase in the documentation or demos, use the **Search for** field in the **Help Navigator**.



1 To limit (or extend) the products whose documentation and demos are searched, set the product filter.

2 In the **Search for** field, type the word or words you want to find and click **Go** (or press **Enter** or **Return**). Some techniques for honing your search are

- Exact Phrase — Search for an exact phrase by enclosing words in quotation marks, for example, `"plot tools"`. For more information, see "Exact Phrases in Search" on page 4-21.
- Wildcard (Partial Word) — Search for variations of a word, also called partial word searching, by using the wildcard symbol (`*`) in place of letters in a word, for example, `plot* tools`. For more information, see "Wildcards in Search (Partial Word)" on page 4-21.
- Boolean Operators — Add the Boolean operators `AND`, `OR`, and `NOT` between search words to include or exclude words. By default, search assumes an `AND` between all search words and exact phrases. For more information, see "Boolean Operators in Search" on page 4-21.

The documents and demos containing all of the search words are listed in the **Search Results** tab. Two sets of results appear: **Documentation** and **Demo**. The number of results for each appears in parentheses at the top of the listing, and the total number for both sets of results appears in the lower left corner of the Help browser. Both sets of results have additional columns that list the **Product**, and for documentation, another column lists the **Section**. You might need to make the **Help Navigator** pane wider to see all columns.

3 Select an entry from the list of results. By default, the first documentation entry is automatically selected. If there are no documentation results, but there are demo results, the first demo entry is automatically selected.

The selected page appears in the display pane with all occurrences of the search words and exact phrases highlighted, using a different color for each search word or phrase. Highlights remain until you view another page or until you click the Refresh button  in the toolbar.

In the display pane, use the **Find** tool, accessible from the Find button  on the toolbar, to find a specified word in that page.

4 Search results are ordered by relevance. For example, for documentation, reference pages that match the search term appear first, followed by titles

that contain all search words, with pages containing a single instance of each search word appearing last. Change the display of search results to more easily find the most relevant results:

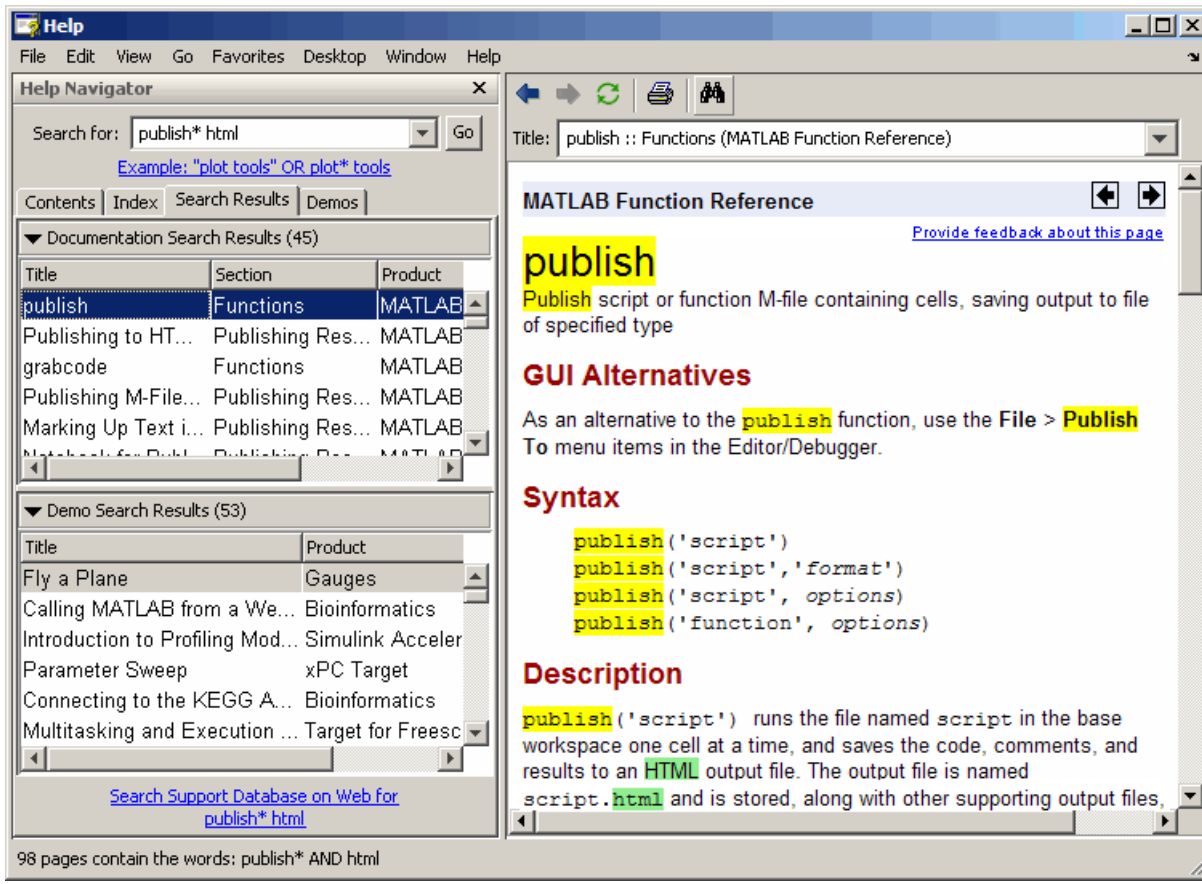
- Sort by column — Change the order of the results by clicking a column heading. For example, click **Product** to group results by product. Click **Title** to sort titles alphabetically. A triangular icon indicates the column on which you most recently sorted. Click the heading again to sort by the column but in the reverse order.

  After changing the order of results, to see results ordered by relevance, click **Go** to rerun the search.

- Reorder columns — Change the location of a column by dragging its heading to a new position. For example, you can drag the **Product** column to the middle for documentation results.

- Resize columns — Make columns wider or narrower by dragging the separator bar between the column headings. Similarly, make the Help Navigator wider or narrower.

5 For more results, you can search for the words in the Technical Support database of bug reports, solutions, and notes on the MathWorks Web site by clicking the link at the bottom of the **Search** results pane.



Function Alternative. From the Command Window, use `docsearch` to open the Help browser to the **Search** pane and search for the specified term. For example

```
docsearch('publish* html')
```

finds all pages that contain the word `publish` or its variations, such as `publishing`, `published`, and so on, and also contains the word `html`.

```
docsearch('"plot tools"')
```

finds all pages containing the exact phrase `plot tools`.

For details, see the `docsearch` reference page.

Wildcards in Search (Partial Word)

You can use the wildcard character (`*`) in place of letters or digits in your search terms. For example, `plot*` finds various forms of the word *plot*, such as *plot*, *plots*, and *plotting*. The search term `p*t` also finds those variations of *plot* as well as variations of *print* and *part*, among others.

You can use multiple wildcards in a word or search term. For example, `plot* tool*` finds *plotting tools*, among other terms. The term `p*t* tool*` finds not only *plotting tools*, but also *pointer tooltip*.

You cannot use a wildcard with just one letter or digit, nor can you include wildcards within an exact phrase. You cannot begin a word in a search term with a wildcard character. For example, these fail: `p*`, `"plot* tools"`, `plot *ool`.

Exact Phrases in Search

To find a phrase, type quotation marks around it. For example, `"plot tools"` finds only pages that include `plot tools` together, but does not find pages that include `plot` in one part of the page and `tools` in another part of the page. Specify an exact phrase to reduce the number of irrelevant results. For example, `"plot tools"` finds about 10 pages in MATLAB documentation, while `plot tools` finds about 100 pages.

You can specify more than one exact phrase, such as `"plot tools" "figure palette"` to find pages that contain both `"plot tools"` and `"figure palette"`. You cannot use a wildcard within an exact phrase.

Boolean Operators in Search

The search automatically performs a Boolean `AND` for multiple words. In the example `publish* html`, it finds all pages that have the word `publish` or its variations, and the word `html`.

You can refine the search by including the Boolean operators `NOT`, `OR`, and `AND` between words. The operators must be in all capital letters and there must be a space before and after each operator. The `NOT`s are evaluated first, followed by the `OR`s, and then the `AND`s.

Example Using Boolean Operators in Search. Type

```
plot* tools NOT time series
```

to find all pages that contain the words `plot` or its variations and `tools`, but not the phrase `time series`.

More About Search

These are the guidelines search uses:

- Insignificant words (a, an, the, of) are ignored.
- Search is not case sensitive.
- Search only finds letters and digits, but not symbols. To find a symbol, look for the word (for example, `plus` instead of +), use the **Index**, or see Operators and Special Characters in the MATLAB Functions — By Category. Another option is to search the PDF documentation, which supports searching for symbols — instructions to access the PDF file are included in "Printing the PDF Version of Documentation" on page 4-42.
- Search find words in comments or code for M-file and Model types demos. It finds comments in the M-file help for M-GUI demos. It does not search video demos.
- If you search for a function that is used in multiple products (called an overloaded function), the reference pages for all those products are listed. Use the **Product** column in **Search Results** to determine the reference page you want.

Get Fewer Results

If there are too many results for the search to be useful, try the following.

Problem	Try These Suggestions
Too many products	Select **File > Preferences > Help** and enable the product filter for specified products. For details, see "Product Filter" on page 4-37. Order results by product — click the **Product** column in **Search Results**. If you cannot see the column, make the pane wider.

Problem	Try These Suggestions
Pages are not about search word, but just mention it	Try the **Index** pane to see more important entries for that search word.
Too many irrelevant results	Type more than one word in the **Search for** field. Look for an exact phrase by enclosing words in quotations marks, such as `"plot tools"`. Use Boolean operators (in all capitals), for example, `printing AND figures NOT exporting`.
Topic is not relevant	Look at the **Section** column in **Search Results**, which provides context for the result. If you cannot see the column, make the pane wider.
Want to look only within part of a product's documentation	For products like MATLAB, you might want to search only part of the documentation. There is no way to do this in the Help browser. However, you might be able to accomplish that via PDF search. For example, you can search the "Getting Started with MATLAB" PDF file, or the "MATLAB External Interfaces" PDF file. Instructions to access the PDF file are included in "Printing the PDF Version of Documentation" on page 4-42.

Get More Results

If you want more results, try the following.

Problem	Try These Suggestions
No results for the product	Be sure the product filter is set correctly. Select **File > Preferences > Help** and disable the product filter, or at least ensure the products of interest are selected. For details, see "Product Filter" on page 4-37.

Problem	Try These Suggestions
No results but you know the word should be there	Try variations of the search word by using a wildcard symbol (`*`). For example, search for `preference*` to find all pages that contain either the word `preference` or the word `preferences`.
Not enough information	Try searching the Technical Support database of bug reports, solutions, and technical notes by clicking the link at the bottom of the **Search** results pane. If you are not running the most current version of MATLAB, try looking at the most current version on the Web site. It might contain additional information. For more information, see "Accessing Documentation on the Web" on page 4-8.

See Also. "Finding Files and Content Within Files" on page 5-49, which describes the Find Files tool you use to look for files and content within files, such as comments in M-files or code fragments.

Favorites

Favorites are bookmarks to pages in the Help browser documentation and M-file type demos.

Add Favorites

To designate the displayed page as a favorite (that is, to bookmark it),

1. Select **Favorites > Add to Favorites**.
2. The **Favorites Editor** dialog box opens. You can accept the defaults and click **Save**, or make changes to the entries:
   a. Use the **Label** provided, or change it to another term.
   b. Do not change the entry for **Callback**.
   c. Maintain the **Category** as `Help Browser Favorites` so you can access them from the **Favorites** menu.
   d. For **Icon**, keep the default `Help icon`, or choose another.

A favorite is implemented as a MATLAB shortcut, so the dialog box is the same as for the **Shortcut Editor**.

Favorites from previous releases are not migrated to a new release.

Go to Favorites

Select the **Favorites** menu to view the list of pages you previously designated as favorites (bookmarks). Select an entry and that page appears in the display pane.

Organize Favorites

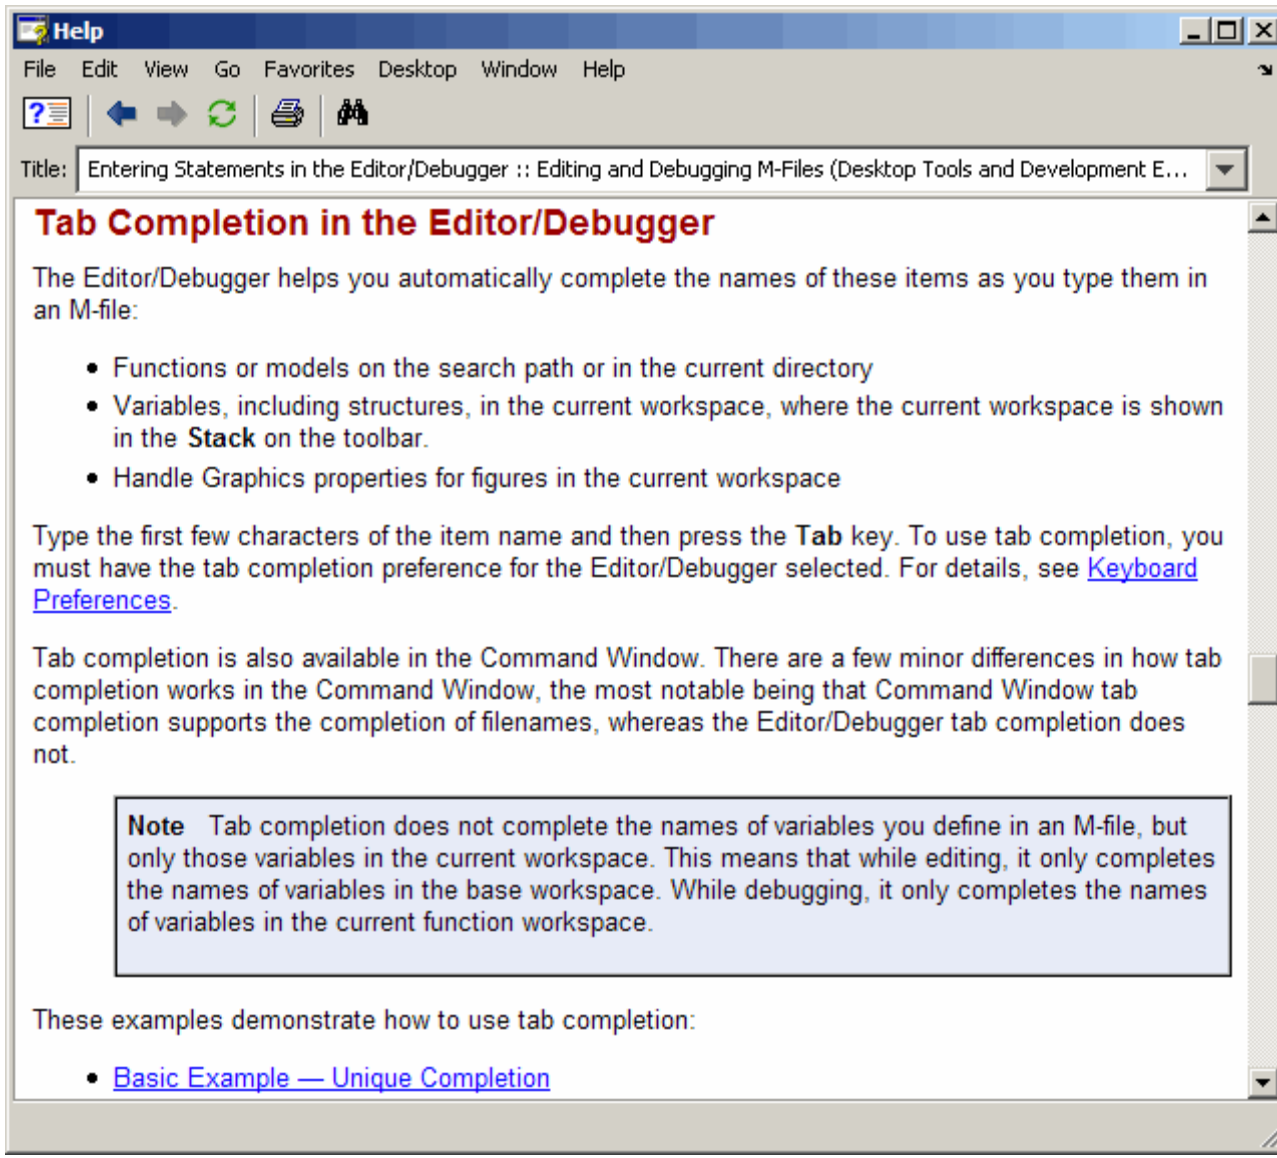
You can rename, remove, and reorder the list of favorites. Select **Favorites > Organize Favorites**. For more information, click **Help** in the **Organize Favorites** dialog box.

Viewing Documentation in the Help Browser

In this section...

About the Display Pane

After finding documentation with the **Help Navigator**, view the documentation in the display pane. The following illustration shows the **Help Navigator** closed to provide a larger area for viewing the information.



Browse to Other Pages

Use the arrow buttons in the page and in the toolbar to go to other pages.

View the next page in a document by clicking the Next page button at the top or bottom of the page. View the previous page in a document by clicking the Previous page button at the top or bottom of the page. These arrows allow you to move forward or backward within a single document. The arrows at the bottom of the page are labeled with the title of the page they go to.

View the page previously shown by clicking the Back button in the display pane toolbar. After using the Back button, view the next page shown by clicking the Forward button in the display pane toolbar. These buttons work like the forward and back buttons of popular Web browsers. You can also go back or forward by right-clicking a page and selecting **Back** or **Forward** from the context menu.

Links

Click links in the displayed page to go to a related topic for more information on the subject. Links appear underlined and in blue, while visited links appear in purple. Links to Web addresses open in the MATLAB Web Browser. Click the middle mouse button to open the linked page in a separate window.

Find Text in Displayed Pages

To find a phrase in the currently displayed page,

1. Click the Find button . In the resulting **Find** dialog box, type the word or phrase you are looking for. You can type a partial word, for example, `preference` to find all occurrences of `preference` and `preferences`. Use the check boxes to specify options. Click **Find Next**.

   The search begins at the current cursor position and the page scrolls to the first occurrence of the phrase in the page and highlights it.

2. To find more occurrences in that page, click **Find Next** or **Find Previous** in the **Find** dialog box, or use the keyboard shortcuts **F3** and **Shift+F3**.

   MATLAB beeps when a search for **Find Next** reaches the end of the page, or when a search for **Find Previous** reaches the top of the page. If you have **Wrap around** selected, it continues searching after beeping.

You can change the selection in the **Look in** field to search for the specified text in other MATLAB desktop tools.

See “Search Documentation and Demos with the Help Browser” on page 4-16 for instructions on looking through all the documentation instead of just one page.

Copy Information

To copy information from the display pane, such as code in an example, first select the information. Then right-click and select **Copy** from the context menu. You can then paste the information into another tool, such as the Command Window or Editor/Debugger, or into another application, such as a word processing application.

Evaluate a Selection

To run code examples that appear in the documentation, select the code in the display pane. Then right-click and select **Evaluate Selection** from the context menu. The statements execute in the Command Window.

Open a Selection

In a page in the display pane, select the name of a file that is provided with MATLAB, such as an M-file. Then right-click and select **Open Selection** from the context menu. The file opens in MATLAB. For example, an M-file opens in the Editor/Debugger.

Help on Selection

In a page in the display pane, select the name of a function that is provided with MATLAB. Then right-click and select **Help on Selection** from the context menu. The reference page for that function opens in Help browser.

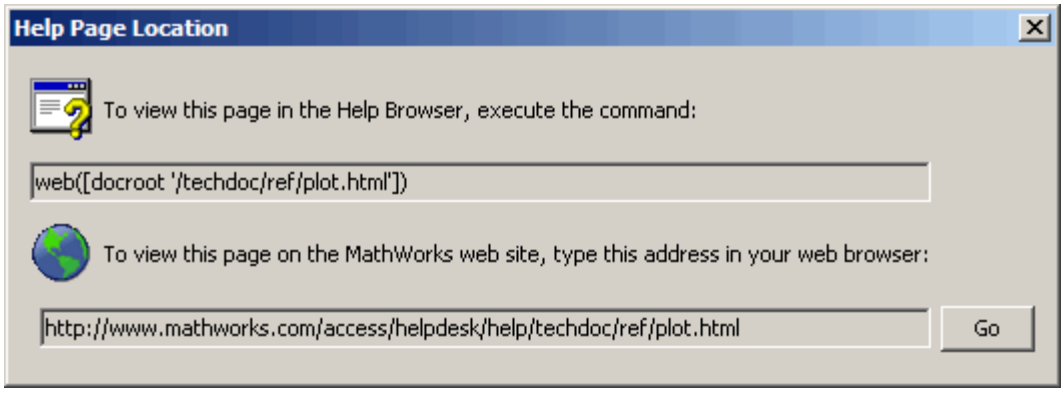
View the Page Source (HTML)

To view the HTML source for the currently displayed page, select **View > Page Source**. A read-only HTML version of the page appears in a separate window. You can copy selections from the HTML source and paste

them into other tools like the Editor/Debugger or Command Window, or into other applications.

View the Page Location

To view the location of the page currently displayed, select **View > Page Location**. The Help Page Location dialog box appears, providing the full path to the documentation file for both your local system and the MathWorks Web site.



You can copy the information from this window into an e-mail message or other tool to facilitate communication with other users or The MathWorks. For example, if you find a page of documentation that you know would be useful to a colleague running MATLAB, send them the link so they can view the page in the Help browser. Note that the `docroot` function used with the `web` function is unsupported, intended only for use by MathWorks products.

Click the **Go** button to view the same documentation page on The MathWorks Web site. This is useful if you do not see the information you are looking for on the page in view and know you are not running the most current version of MATLAB. The documentation for the most current version is on the Web site and might include more information than the documentation for your version. Note, though, that the documentation on the Web site might refer to features that are not part of your earlier-version product. See “Accessing Documentation on the Web” on page 4-8 for more information.

Demos in the Help Browser

In this section...

About Demos

MATLAB and related products include demos that you can access from the Help browser **Demos** pane.

There are four types of demos:

- M-file: Demos that tell a step-by-step story, including source code, commentary, and output. They are published from M-file scripts to HTML output using the Editor/Debugger. The first comment line of the demo M-file begins with two comment symbols (%%), and similarly, two comment symbols (%%) create a cell for each step. The MATLAB Graphics Square Wave from Sine Waves demo is an M-file type demo.
- M-GUI: Stand-alone tools for exploring a feature. An example is the MATLAB Graphics Vibrating Logo demo.
- Model: Simulink block diagrams. An example is the Engine Timing Simulation demo.
- Video: Movies that highlight key features in a tool. They play in your system browser and require the Macromedia Flash Player plug-in. Some also require an Internet connection. An example is the MATLAB Desktop and Command Window demo.

The MATLAB code and Simulink blocks used in the demos (except videos) are available for you to view and copy for use in your own applications.

See also Examples for each product in the **Contents** pane. These examples are similar to demos but are integrated in the documentation.

Using Demos

To access demos for the products you have installed,

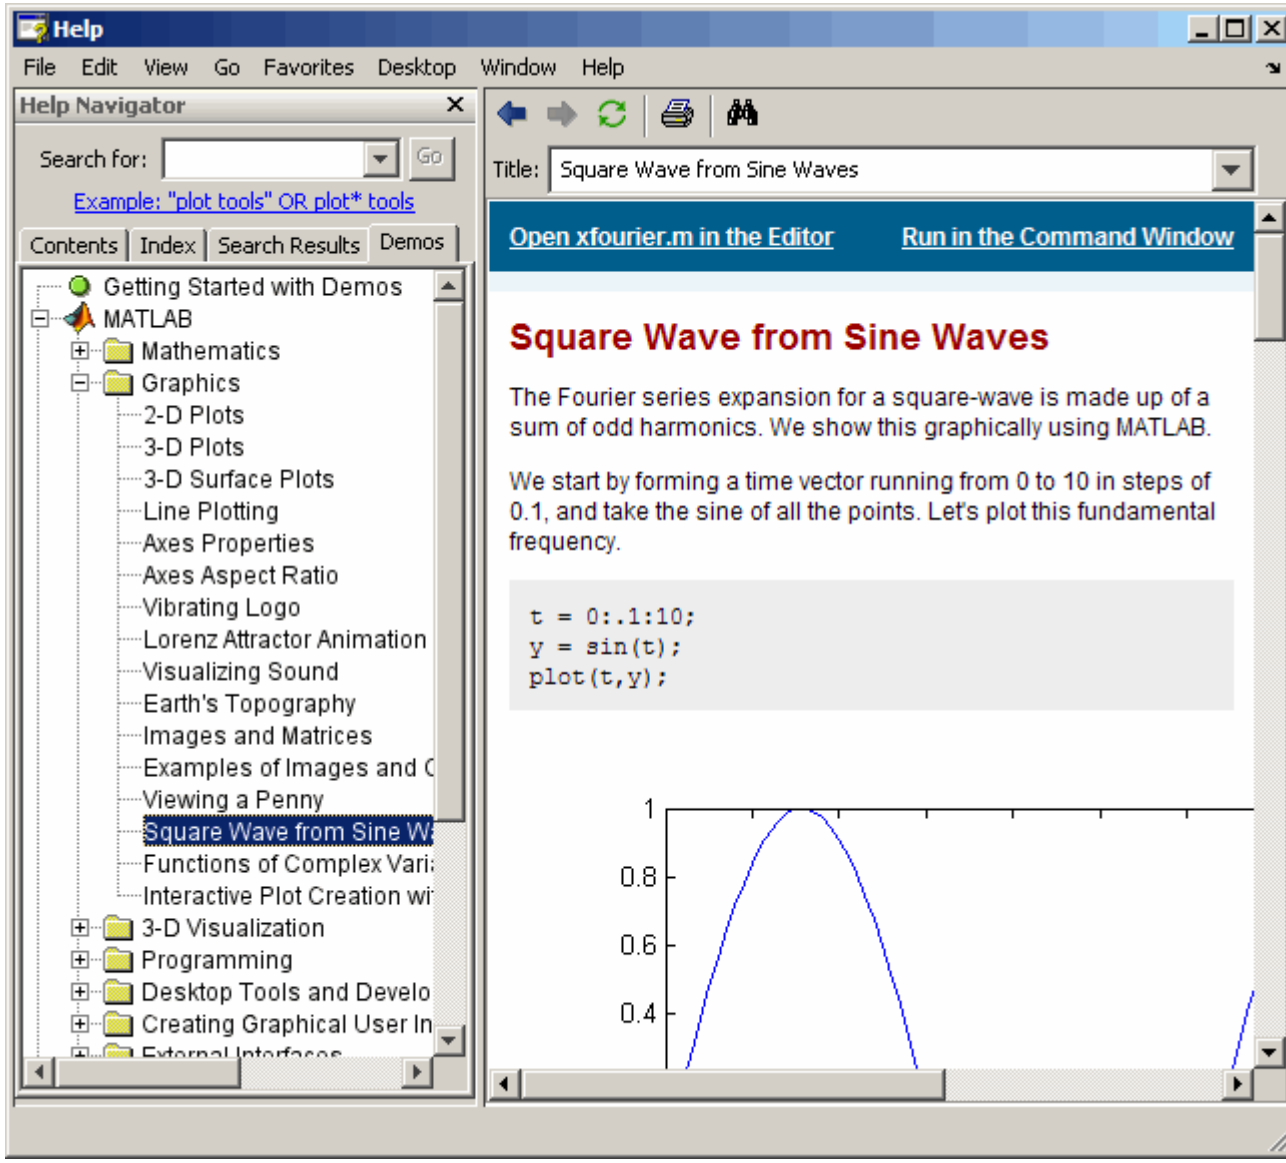
1. Click the **Demos** tab in the **Help Navigator**.

   You can also access demos from the **Start** button, by using the `demo` function, or from the **Help** menu for some tools.

2. Click the **+** for a product area to list the products or categories that have demos. Then click **+** for a product or product category to list its demos.

   All demos for that product or product area are listed in the display pane, and each includes the type of demo along with a thumbnail image that represents output from the demo.

3. Select a specific demo. Information about the demo appears in the display pane.



4 You can then view and run the demo, with specific options depending on the type of demo:

- For M-file demos, click the **Open filename in the Editor** link at the top left. This opens the M-file in the Editor/Debugger. From the Editor/Debugger, run the demo step by step by selecting **Cell > Evaluate Current Cell and Advance**.

  You can also click **Run in the Command Window**, and then follow the instructions that appear in the Command Window. You might need to scroll up to see all of the instructions.

  See also "Running Demos and Base Workspace Variables" on page 4-35.

- For M-GUI demos, click the **Open filename in the Editor** link at the top left. This opens the M-file in the Editor/Debugger.

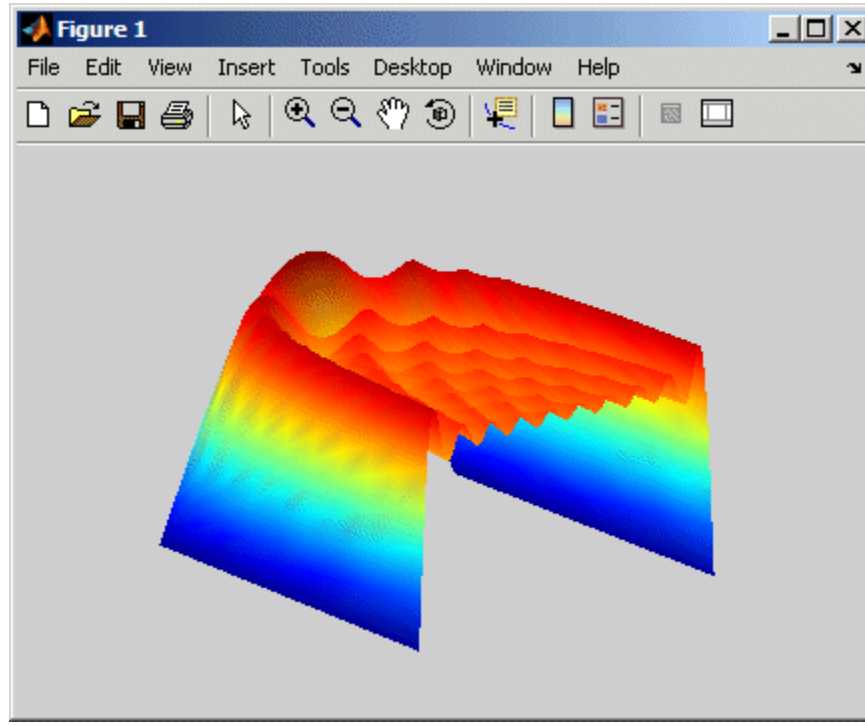
  Click the **Run this demo** link at the top right to start the GUI. Then follow the instructions in the GUI to proceed through the demo.

- For Model demos, click **Open this model** to open the block diagram.

- For Video demos, click the **Run this demo** link in the top right to play the video. These demos run in your system browser and require the Macromedia Flash Player plug-in. Some also require an Internet connection.

When you double-click a demo name in the **Help Navigator** pane, the demo file opens for M-file and Model demos, or runs for M-GUI and Video demos.

The following example shows the results of running the MATLAB Graphics Square Wave from Sine Waves demo (`xfourier`). In it, MATLAB generates a series of plots, culminating in the final one shown here.



Searching for Demos

You can use the Help browser search feature to find demos. Search find words in comments or code for M-file and Model types demos. It finds comments in the M-file help for M-GUI demos. It does not search video demos. For instructions, see “Search Documentation and Demos with the Help Browser” on page 4-16.

Running Demos and Base Workspace Variables

M-file demos run as scripts. Their variables are created in the MATLAB base workspace. If you have variables in the base workspace when you run an M-file demo, and the demo uses an identical variable name, there could be problems due to variable name conflicts. For example, a variable of yours might be overwritten by the demo. The demo’s variables remain in the base workspace until you clear them or quit MATLAB.

Function Alternative

To open the **Demos** pane in the Help browser, type `demo` in the Command Window. You can go directly to the demos for a specific product. For example

```
demo toolbox signal
```

opens the **Demos** listing for Signal Processing Toolbox.

To run an M-GUI demo, type the demo name in the Command Window. For example, type

```
vibes
```

to run the MATLAB Graphics demo showing an animated L-shaped membrane.

To run an M-file demo step by step from the Command Window, type `echodemo` followed by the demo name. For example, run

```
echodemo xfourier
```

Typing the demo name for an M-file demo runs the demo, but not step by step.

Typing the name of a model demo opens the block diagram.

Adding Your Own Demos

You can add your own demos so they appear in the **Demos** pane. For details, see in the online documentation.

Preferences for the Help Browser

In this section...

Product Filter

If you have MathWorks products in addition to MATLAB, such as Simulink, toolboxes, and blocksets, set the product filter to limit the product documentation and demos used:

1. Select **File > Preferences > Help**.
2. Under **Product filter**, select the check box for **Enable product filter**. Click **Select products**.

   The **Help Product Filter** dialog box opens.
3. Select the products whose documentation and demos you want to appear in the **Help Navigator**. Click **OK**.

   The **Help Navigator** updates to include only those products you specified. The product filter settings are saved for your next MATLAB session.
4. When you want to use documentation and demos for all installed products, in **Help Preferences**, clear the check box for **Enable product filter**.

The `Release Notes` entry in the **Help Product Filter** dialog box applies to the Release Notes overview document for a release, for example, all products in R2007b, not to the Release Notes for an individual product, for example, MATLAB Release Notes for R2007b. Release Notes for a product are considered part of the product’s documentation. For example, MATLAB Release Notes are considered part of MATLAB, and Database Toolbox Release Notes are considered part of Database Toolbox when you use the **Help Product Filter**.

Example Using the Product Filter

If you want to perform a search and have many products installed but know the information you are seeking is in MATLAB or Communications Toolbox, in the **Help Product Filter**, click **Clear All** and then select `MATLAB` and `Communications Toolbox`.

The **Contents** only shows MATLAB and Communications Toolbox documentation, the **Index** only shows entries for MATLAB and Communications Toolbox, and the **Search for** feature only looks in and shows results for MATLAB and Communications Toolbox documentation and demos. **Demos** lists only demos for MATLAB and Communications Toolbox.

PDF Reader — Specifying Its Location

If you want to view the PDF version of the documentation, use the link on the roadmap page for that product. To open the PDF file, the Help browser needs to know the location of your PDF reader (for example, Adobe Acrobat).

For Windows systems, MATLAB reads the PDF reader location from the registry, so you do not specify its location.

For UNIX systems, the default PDF reader is Acrobat and MATLAB determines its location. If a different command starts your PDF reader, specify it using preferences. Select **File > Preferences > Help**, and enter the full pathname in the **PDF reader** field or use the Browse for Folder (**...**) button to navigate your file system to select it.

General — Keep Contents Synchronized

By default, the displayed page is synchronized with the **Contents** or **Demos** listings. For more information about this feature, see “Synchronize the Contents Listing and Demos Listing with the Display Pane” on page 4-12.

To turn synchronization off, select **File > Preferences > Help**. Under **General**, clear the check box for **Keep contents tree synchronized with displayed document**. Select the check box to turn synchronization back on.

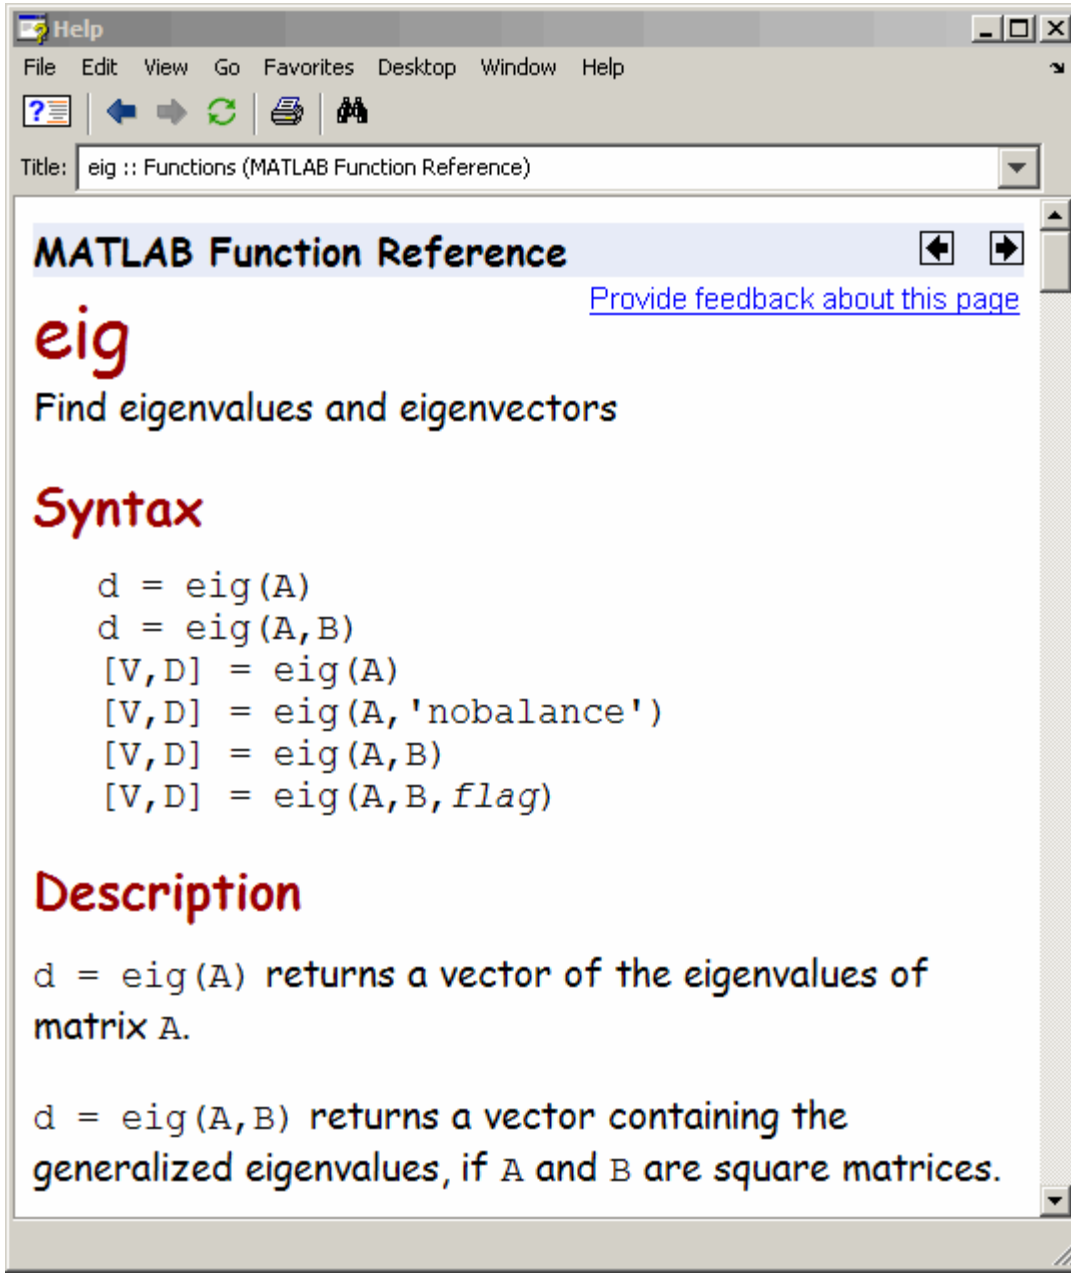
Help Fonts and Colors Preferences

Set fonts and colors for the Help browser the same way you would for other desktop tools. This section describes the process for the Help browser:

Specifying Font Name, Style, and Size

You can specify the font name (also called font type or family), style, and size used in the **Help Navigator**.

For the display pane, you can specify the font name and size for the text font, but changes do not impact the style. For the code font, your changes to size apply, but changes to name and style have no impact. The following example shows the results of specifying Comic Sans MS, bold, 14 point for the text font; note that the bold has no effect.



Help
File Edit View Go Favorites Desktop Window Help
Title: eig :: Functions (MATLAB Function Reference)
MATLAB Function Reference
Provide feedback about this page
eig
Find eigenvalues and eigenvectors
Syntax
d = eig(A)
d = eig(A,B)
[V,D] = eig(A)
[V,D] = eig(A,'nobalance')
[V,D] = eig(A,B)
[V,D] = eig(A,B,flag)
Description
d = eig(A) returns a vector of the eigenvalues of matrix A.
d = eig(A,B) returns a vector containing the generalized eigenvalues, if A and B are square matrices.

Use the same method as you would to specify fonts for any desktop tool — for more information, see “Fonts Preferences for Desktop Tools” on page 2-62. By default, the **Help Navigator** uses the desktop text font. The display pane is considered to be an HTML Proportional Text tool, and by default, uses the desktop text font.

This example changes the display pane font:

1. Select **File > Preferences > Fonts > Custom**.
2. From the **Desktop tools** list, select `HTML Proportional Text`. The Help browser display pane is considered to be an HTML Proportional Text tool, as is the MATLAB Web Browser. Changing the font preference affects both tools.
3. For **Font to Use**, select **Custom**, and then specify the font characteristics:
   - Name, for example, `Comic Sans`
   - Size in points, for example, `14`

   After you make a selection, the **Sample** area shows how the font will look.
4. Click **OK**. The Help display pane fonts use the new settings. The MATLAB Web Browser fonts also use the new settings.

Specifying Colors for the Help Browser

You can specify the background and text color used in the **Help Navigator**. Use the same method as you would to specify the background color for any desktop tool — for more information, see “Colors Preferences for Desktop Tools” on page 2-70.

If the background color preference for your desktop tools is a dark color, you might not be able to see index entries in the **Help Navigator** because they are links, for which the default color is blue. To see the links, change the **Hyperlink** color preference to a light or other contrasting color — for more information, see “Other Colors” on page 2-75.

You cannot specify colors for the Help browser display pane.

Printed Documentation

In this section...

About Printed Manuals

Generally, printed manuals are not provided for most products and tools. The printed manuals typically contain less information, and is also sometimes less current than the online documentation. If you want to purchase printed documentation, see the online store at the MathWorks Web site at `http://www.mathworks.com`.

Printing a Page from the Help Browser

To print the page currently shown in the Help browser, select **File > Print**, or click the Print button in the display pane toolbar. The Print dialog box appears.

Select **All** in the Print dialog box to print the entire page shown in the display pane. Specifying a range of pages, for example, `1 to 3`, prints the first three pages of the page currently shown in the display pane.

Complete the dialog box and click **OK** to print.

Printing the PDF Version of Documentation

If you need to print more than a few pages of documentation, or if you want the pages to appear as if they came from a printed book, print the PDF version of the documentation. PDF documentation is shown and printed using your PDF reader, usually Adobe Acrobat Reader. The PDF documentation reproduces the look and feel of a printed book. In the PDF document, use links from the table of contents, index, or within the document to go directly to the page of interest within that document. Note that some documentation available from the Help browser is not available in PDF format.

Note The Help browser accesses PDF documentation from the MathWorks Web site. Therefore, you need Internet access to view or print PDF documentation.

1. In the Help browser, click the **Contents** tab and select a product, for example, MATLAB.

   The roadmap page opens for that product, providing links to key documentation for that product.

2. Near the end of the roadmap page, listed under **Printing the Documentation Set**, are links for printing the documentation. Select the link for the item you want to print.

   The selected document is accessed from the MathWorks Web site. Your PDF reader opens, displaying the documentation.

   If you are using a UNIX platform and cannot open the PDF documentation, check the Help preferences. See "PDF Reader — Specifying Its Location" on page 4-38 for more information.

3. To print the documentation, select **Print** from the **File** menu in your PDF reader.

Help Functions

In this section...

About Help Functions

There are several help functions that provide forms of help different than the Help browser documentation, or provide alternative ways to access the Help browser information.

Summary Table of Help Functions

Function	Description
`dbtype`	Displays specified M-file with line numbers. If you want to see only the input and output arguments for a function, use `dbtype function 1`, which displays the first line of the M-file.
`demo`	Displays the **Demos** pane in the Help browser, from which you can access demonstrations for the products you have installed. With an argument, runs the specified demo.
`doc`	Displays in the Help browser, the reference page for the specified function, block, or property. Usually more extensive than results for the `help` function, the reference page provides syntax, a description, examples, illustrations, and links to related functions.
`docopt`	On UNIX systems, specifies Web browser information, used when displaying Internet Web pages.
`docsearch`	Run the Help browser search feature for the specified term.
`help`	Displays M-file help (a description and syntax) in the Command Window for the specified function. For MDL-files, displays a description of the model.

Function	Description
`helpbrowser`	Opens the Help browser, the MATLAB interface for accessing documentation.
`helpdesk`	Opens the Help browser. In previous releases, `helpdesk` displayed the Help Desk, which was the precursor to the Help browser. This function will be removed in a future release.
`helpwin`	Displays in the Help browser a list of all functions, and provides access to M-file help for the functions.
`lookfor`	Displays in the Command Window a list and brief description of all functions whose brief description includes the specified keyword.
`web`	Opens the specified URL in the specified browser. Use `web` in your own M-files to display HTML documentation you create for your work.
`whatsnew`	Displays the Release Notes in the Help browser.

View Function Reference Pages — the doc Function

To view the reference page for a function, block, or property in the Help browser, use `doc`. For example, type

```
doc format
```

to view the reference page for the `format` function.

Overloaded Functions with the doc Function

When a function name is used in multiple products, it is said to be an overloaded function. The `doc` function displays the reference page for the first function on the MATLAB search path having that name, and displays a hyperlinked list of the overloaded functions in the Command Window.

For example, using the default search path

```
doc set
```

displays the reference page for the MATLAB `set` function in the Help browser. The Command Window displays a hyperlinked list of the `set` functions located in other directories, such as

```
database/set
```

which is the `set` function for Database Toolbox. Click a link to go to that `set` reference page.

To directly get the reference page for an overloaded function, specify the name of the directory containing the function you want the reference page for, followed by the function name. For example, to display the reference page for the `set` function in Database Toolbox, type

```
doc database/set
```

Some products have more than one function with the same name. For example, MATLAB includes a built-in `get` function in the `graphics` directory and a `get` function in the MATLAB `serial` directory (for serial port functions). Type

```
doc get
```

The reference page for the MATLAB `graphics` built-in `get` function appears, and the Command Window lists overloaded functions in other products. But the list does not include any overloaded functions in the same product. Therefore, `get` in the MATLAB `serial` directory is not listed as an overloaded function. Type

```
doc ('get (serial)')
```

to display the reference page for the `get` function located in the MATLAB `serial` directory.

Getting Help in the Command Window — the help Function

To quickly view a brief description and syntax for a function in the Command Window, use the `help` function. For example, typing

```
help bar
```

displays a description and syntax for the `bar` function in the Command Window. This is called the M-file help. For other arguments you can supply, see the reference page for `help`.

Note M-file help displayed in the Command Window uses all uppercase characters for the function and variable names to distinguish them from the rest of the text. When typing function names, however, use lowercase characters. Some functions for interfacing to Java do use mixed case; the M-file help accurately reflects that, and you should use mixed case when typing them.

If you need more information than the `help` function provides, use the `doc` function, which displays the reference page in the Help browser. It can include color, images, links, and more extensive examples than the M-file help. For example, typing

```
doc bar
```

displays the reference page for the `bar` function in the Help browser.

Overloaded Functions with the help Function

When a function name is used in multiple products, it is said to be an overloaded function. The `help` function displays M-file help for the first function on the MATLAB search path having that name, and displays a hyperlinked list of the overloaded functions at the end.

For example, using the default search path

```
help set
```

displays M-file help for the MATLAB `set` function, and displays a hyperlinked list of the `set` functions residing in other directories, such as

```
database/set
```

which is the `set` function for Database Toolbox. Click a link to display the M-file help for that `set` function.

To directly get help for an overloaded function, specify the name of the directory containing the function you want help for, followed by the function name. For example, to get help for the `set` function in Database Toolbox, type

```
help database/set
```

Creating M-File Help for Your Own M-Files

You can create M-file help for your own M-files and access it using the `help` command. See the `help` reference page for details.

Help in the Current Directory Browser

The Help Report and the Contents Report provide other ways of looking at and managing help for M-files — see “Directory Reports in Current Directory Browser” on page 7-2.

You can also see the help for an M-file in the Current Directory browser if you have its preference for **Show M, MDL, and MAT file contents** selected.

Help for Model Files

Use the `help` function with an MDL filename to display the complete description for the model file. For example, run

```
help f14_dap.mdl
```

and MATLAB displays the description of the Simulink F-14 Digital Autopilot High Angle of Attack Mode, as defined in the **Model > Properties > Description**.

```
Multirate digital pitch loop control for F-14 control design
demonstration.
```

If Simulink is installed, you do not need to include the `.mdl` extension.

You can see the same description in the Current Directory browser if you have its preference for **Show M, MDL, and MAT file contents** selected.

Getting Pop-Up Help for Functions

MATLAB provides pop-up help for MATLAB functions from both the Editor/Debugger and the Command Window. Pop-up help, also referred to as "help on selection," enables you to view documentation for a function without requiring you to interrupt the flow of your work to open the Help browser.

To access pop-up help, follow these steps:

1. Select a function or click the pointer in a function for which you want information.
2. Press **F1** or right-click and select **Help on Selection**.

   Documentation for the function opens in a small pop-up window, similar to that shown in the figure that follows.
3. Move or resize the pop-up window, if desired.
4. Press the **F1** key to toggle focus between the pop-up window and Command Window or the Editor/Debugger.

   When you type in the Command Window or the Editor/Debugger, the pop-up window remains open.
5. With the pop-up window active, press the Escape (**Esc**) key to close the pop-up window.

If you want to get documentation on a different function while the pop-up window is open, there is no need to close it. Repeat steps 1 and 2—the pop-up window refreshes with documentation for the new function.

If you want to open the Help browser from the pop-up window, click the **Open Help Browser** link at the bottom of the pop-up window. The Help browser opens and the pop-up window closes.

Other Forms of Help

In this section...

Documentation for Other Products

The Help browser provides access to documentation for all products installed on your system. To view the online documentation for all MathWorks products, use the MathWorks Web site at `http://www.mathworks.com/access/helpdesk/help/helpdesk.shtml`.

Product-Specific Help Features

In addition to the Help browser and help functions, some products and tools allow other methods for getting help. You will encounter some methods in the course of using a product, such as entries in the **Help** menu, **Help** buttons in dialog boxes, and selecting **Help** from a context menu. These methods all display context-sensitive help. Other methods for getting help, such as pressing the **F1** key, are described in the documentation for the product or tool that uses the method.

User-Contributed M-Files

You can download M-files contributed by users and developers of MATLAB, Simulink, and related products from MATLAB Central. Before you write an M-file yourself, especially if it seems to be a generic utility, check the list of contributed files to see if someone has already written it. These files are freely contributed and can be used without charge by anyone

who downloads them. To view the files available to download, go to the MATLAB Central File Exchange page on the MathWorks Web site, `http://www.mathworks.com/matlabcentral/fileexchange/index.jsp`. You can access this from any desktop component via **Help > Web Resources**.

If you write M-files that you think would be of use to others, consider submitting them to the MATLAB Central File Exchange via the Web page.

Technical Support

Technical Support provides help for problems you have with MathWorks products:

- Find specific Technical Support information using the Help browser **Search** feature. Run a search for a specified term. The end of the results list includes a link that runs the same search on the support database. This database, on the MathWorks Web site, provides the most up-to-date solutions, bug reports, and technical notes for questions posed by users.
- Select **Help > Web Resources > Support** to go to the Support Web page (`http://www.mathworks.com/support`). The page displays in your system's default Web browser. You can find out about other types of information such as third-party books, ask questions, make suggestions, view known bugs and workarounds, and report possible bugs.
- If you cannot access the Web site, e-mail Technical Support using the address `support@mathworks.com`. You must provide your license number to obtain support. It is helpful if you also provide your operating system and MATLAB version number. You can obtain the information by running the `ver` function or by selecting **Help > About**.

Newsgroup for MathWorks Products

The Usenet newsgroup for MATLAB and related products, `comp.soft-sys.matlab`, (also known as `cssm`) is read by thousands of users worldwide. Access the newsgroup to ask for or provide help or advice. You can read and submit postings as well as view and search through a sizable archive of postings using the MATLAB Central Newsgroup Access Web page on the MathWorks Web site, `http://www.mathworks.com/matlabcentral`. You can access this via **Help > Web Resources > MATLAB Newsgroup Access** from any desktop component.

First-time users to the newsgroup should read the newsgroup FAQ, linked to from the MATLAB Central page. It is a good practice to try to solve your own problem using the documentation and Technical Support database before posting a question to the newsgroup. Be sure to post with a meaningful subject that briefly describes the nature of the issue.

Other Resources for MATLAB Information

Following are some additional resources for help with MATLAB and related products:

- Newsletters — The MathWorks publishes News and Notes twice a year, containing feature articles, technical notes, and product information for MATLAB users. More frequently, The MathWorks issues MATLAB Digest, an electronic bulletin consisting of technical notes, solutions, and timely announcements to the user community. Select **Help > Web Resources > MATLAB Newsletters** or see `http://www.mathworks.com/company/newsletters/`.
- Books — There are hundreds of MATLAB based books. For a list with descriptions, see `http://www.mathworks.com/support/books/`.
- Seminars and Training — The MathWorks regularly presents free seminars on special topics conducted in various locations. Webinars on special topics are presented via the Web. The MathWorks offers training classes for MATLAB and other products. For details, see `http://www.mathworks.com/company/events/`.
- `Mathtools.net` — This is a technical computing Web portal with links to many resources for MATLAB users. See `http://www.mathtools.net/`.

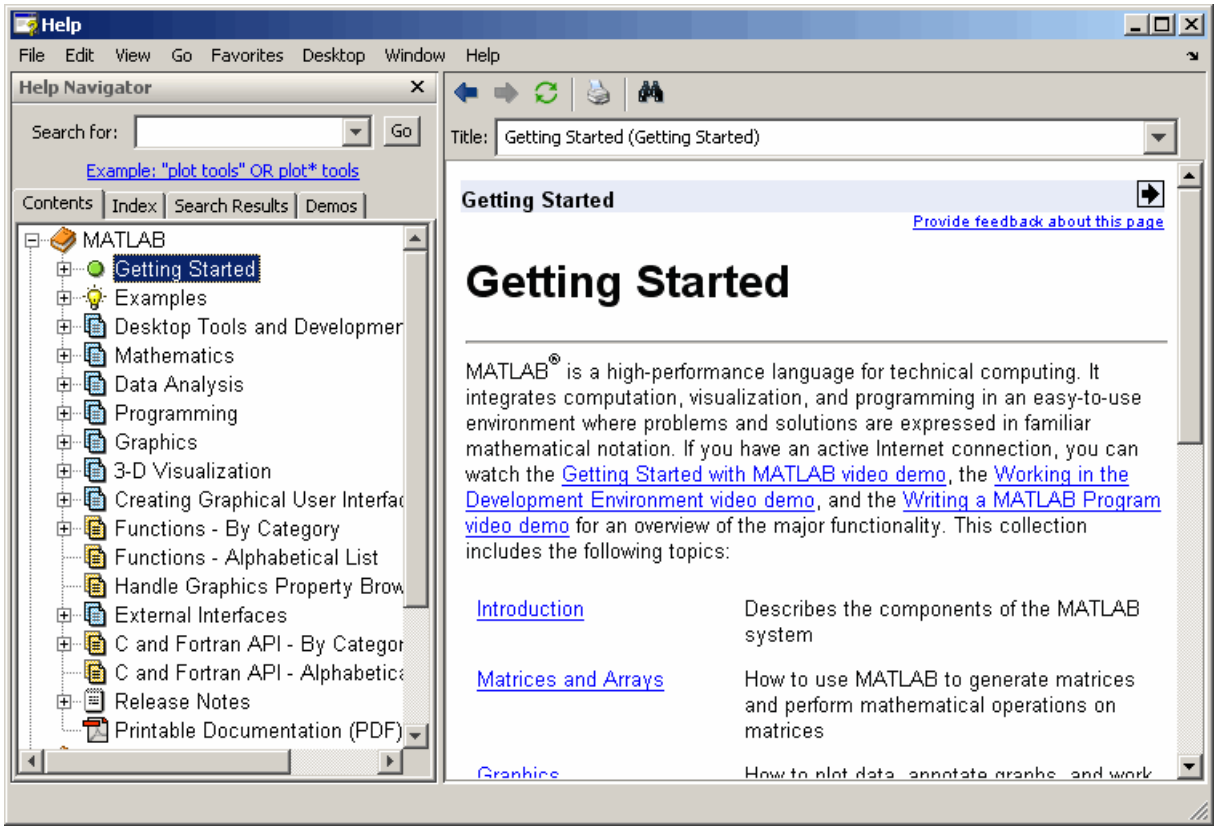
Version and License Information

If you need the version or license information for a product, select **About** from the **Help** menu for that product. The version is displayed in an About dialog box. If the product does not have a **Help** menu, use the `ver` function. To see the license number for MATLAB, type `license` in the Command Window. See also the `ver`, `version`, and `license` reference pages.

You can access information about your passcodes and licenses, as well get trial versions of products, using **Help > Web Resources > MathWorks Account**.

Provide Feedback

To report problems or provide comments or suggestions to The MathWorks about the documentation, help features, or products, use the **Provide feedback on this page** link on the top and bottom of every page in the Help browser.



5

Workspace, Search Path, and File Operations

If you have an active Internet connection, you can watch the Workspace Browser video demo, the Array Editor video demo, and the Current Directory Browser video demo for an overview of the major functionality.

MATLAB Workspace (p. 5-2)	The workspace is the set of variables maintained in memory during a MATLAB session. Use the Workspace browser or equivalent functions to view the workspace.
Viewing and Editing Workspace Variables with the Array Editor (p. 5-12)	View and make changes to variables using the Array Editor.
Search Path (p. 5-23)	MATLAB uses a search path to find M-files and other MATLAB related files. View and change the path using the Set Path dialog box or equivalent functions.
File Management Operations (p. 5-35)	Search for, view, open, and make changes to MATLAB related directories and files, using the Current Directory browser or equivalent functions.

MATLAB Workspace

In this section...

About the MATLAB Workspace

The MATLAB workspace consists of the set of variables (named arrays) built up during a MATLAB session and stored in memory. You add variables to the workspace by using functions, running M-files, and loading saved workspaces. For example, if you type

```
t = 0:pi/4:2*pi;
y = sin(t);
```

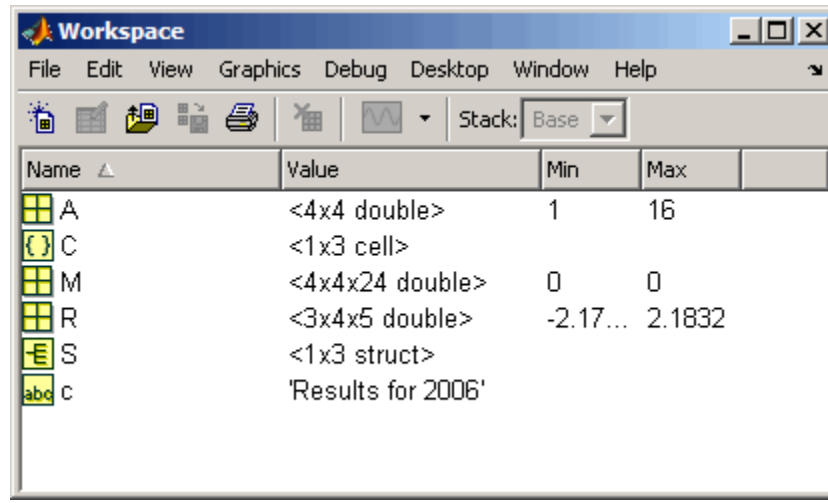
the workspace includes two variables, `y` and `t`, each having nine values.

You can perform workspace operations and related features using the Workspace browser. Equivalent functions are available and are documented with each feature of the Workspace browser. If you have an active Internet connection, you can watch the Workspace browser video demo for an overview of the major functionality:

Opening the Workspace Browser

To open the Workspace browser, select **Workspace** from the **Desktop** menu in the MATLAB desktop, or type `workspace` at the Command Window prompt.

The Workspace browser opens.



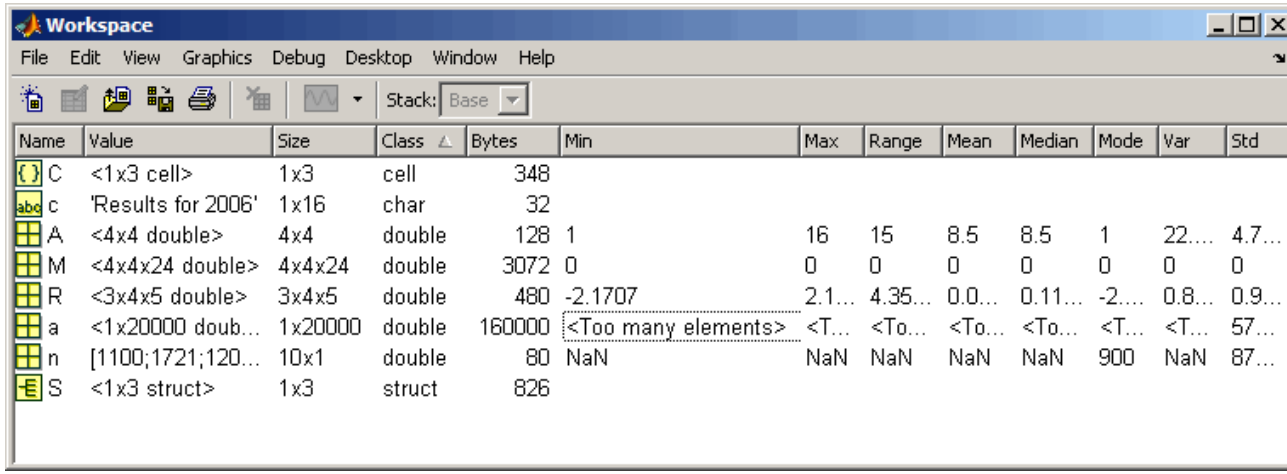
Viewing and Editing Values in the Current Workspace

The Workspace browser shows the name of each variable, its value, and the **Min** and **Max** calculations, which MATLAB computes using the `min` and `max` functions, and updates automatically. The icon for each variable denotes its class.

- You can display additional columns, including size (dimensions), size in bytes, class, and other common statistical calculations such as mode and standard deviation. To show or hide columns, select **View > Choose Columns** or right-click any column heading. To specify the size limit for calculations and how NaNs are considered, use “Preferences for the Workspace Browser” on page 5-10.
- To resize the columns of information, drag the column header borders. To reorder columns, drag a column header to a new position.

- You can select the column on which to sort as well as reverse the sort order of any column. Click a column heading to sort on that column. Click the column heading again to reverse the sort order in that column. For example, to sort on **Name**, click the column heading once. To change from ascending to descending, click the heading again. You cannot sort by the **Value** column in the Workspace browser. Alternatively, select **View > Sort By**
- You can edit variable values directly in the Workspace browser **Value** column. To edit a value, select the row to change in the **Value** column and type the new value.

This illustration shows the Workspace browser with all columns in view, sorted by the **Class** column, as indicated by the triangle in that column heading. Preferences are set to show statistical values only for arrays under `10,000` elements, so results for `a`, `(1 x 20000)`, do not appear. The preference for treatment of NaNs is set to include them in calculations, as seen for `n`. With the preference set to ignore NaNs, values other than `NaN` would appear.



Name	Value	Size	Class	Bytes	Min	Max	Range	Mean	Median	Mode	Var	Std
C	<1x3 cell>	1x3	cell	348								
c	'Results for 2006'	1x16	char	32								
A	<4x4 double>	4x4	double	128	1	16	15	8.5	8.5	1	22....	4.7...
M	<4x4x24 double>	4x4x24	double	3072	0	0	0	0	0	0	0	0
R	<3x4x5 double>	3x4x5	double	480	-2.1707	2.1...	4.35...	0.0...	0.11...	-2....	0.8...	0.9...
a	<1x20000 doub...	1x20000	double	160000	<Too many elements>	<T...	<To...	<To...	<To...	<T...	<T...	57...
n	[1100;1721;120...	10x1	double	80	NaN	NaN	NaN	NaN	NaN	900	NaN	87...
S	<1x3 struct>	1x3	struct	826								

Function Alternative

Use `who` to list the current workspace variables. Use `whos` to list the variables and information about their size and class. For example:

```
>> who
```

```
Your variables are:

A  C  M  R  S  c

>> whos
 Name      Size              Bytes  Class     Attributes

  A         4x4                 128  double
  C         1x3                 348  cell
  M         4x4x24             3072  double
  R         3x4x5               480  double
  S         1x3                 826  struct
  c         1x16                 32  char
```

Use `exist` to see if the specified variable is in the workspace.

Saving the Current Workspace

The workspace is not maintained across MATLAB sessions. When you quit MATLAB, the workspace is cleared. You can save any or all of the variables in the current workspace to a MAT-file, which is a MATLAB specific binary file. You can then load the MAT-file at a later time during the current or another session to reuse the workspace variables. MAT-files use a `.mat` extension.

Note The `.mat` extension is also used by Microsoft Access.

Saving All Variables

To save all of the workspace variables using the Workspace browser,

1. From the **File** menu, select **Save Workspace As**, or click the Save button  in the Workspace browser toolbar.

   The **Save** dialog box opens.

2. Specify the location and **File name**. MATLAB automatically supplies the `.mat` extension.

3. Click **Save**.

The workspace variables are saved under the MAT-file name you specified.

You can also save the workspace variables from the desktop by selecting **Save Workspace As** from the **File** menu.

Saving Selected Variables

To save some but not all of the current workspace variables,

1. Select the variable in the Workspace browser. To select multiple variables, **Shift**+click or **Ctrl**+click.
2. Right-click and from the context menu, select **Save As**.

   The **Save to MAT-File** dialog box opens.
3. Specify the location and **File name**. MATLAB automatically supplies the `.mat` extension.
4. Click **Save**.

   The workspace variables are saved under the MAT-file name you specified.

To specify preferences for saving MAT-files, see "MAT-Files Preferences" on page 2-79.

Function Alternative

To save workspace variables, use the `save` function followed by the filename you want to save to. For example,

```
save('june10')
```

saves all current workspace variables to the file `june10.mat`.

If you don't specify a filename, the workspace is saved to `matlab.mat` in the current working directory. You can specify which variables to save, as well as control the format in which the data is stored, such as ASCII. For these and other forms of the function, see the reference page for `save`. For a related function, see `genvarname`. MATLAB provides additional functions for saving

information — see “Data Import and Export” in the MATLAB Programming documentation.

Loading a Saved Workspace and Importing Data

To load saved variables into the workspace,

1. Click the Import Data button on the toolbar in the Workspace browser.

   The **Open** dialog box opens.

2. Select the MAT-file you want to load and click **Open**.

   The variables and their values, as stored in the MAT-file, are loaded into the current workspace. If any variables being loaded have the same names as variables in the current workspace, the values from the MAT-file replace the values in the current workspace. Any variables in the MAT-file that are not in the workspace are added to the workspace.

Function Alternative

Use `load` to open a saved workspace. For example,

```
load('june10')
```

loads all workspace variables from the file `june10.mat`.

Importing Data

MATLAB provides other methods and functions for loading information. You can use one of these methods, the Import Wizard, from the Workspace browser — select **Edit > Paste to workspace** or use **Ctrl+V** to import data to MATLAB using the Import Wizard. For more information on the Import Wizard and other methods for loading information, see the “Using the Import Wizard”.

Viewing Variables in MAT-Files

Use the Current Directory browser to view the contents of a MAT-file without loading the file into MATLAB. For details, see “Finding Files and Content Within Files” on page 5-49.

Function Alternative. Use `whos` with the `-file` option.

Changing and Copying Variable Names

To rename a variable in the workspace, right-click the variable in the Workspace browser and select **Rename** from the context menu. Type the new variable name over the existing name and press **Enter** or **Return**.

To copy variable names to the clipboard, select the workspace variables and select **Edit > Copy**. You can then paste the names, for example, into the Command Window. Multiple variables are comma separated.

Deleting Workspace Variables

You can delete a variable, which removes it from the workspace. To delete a variable using the Workspace browser,

1. In the Workspace browser, select the variable, or **Shift**+click or **Ctrl**+click to select multiple variables. To select all variables, choose **Select All** from the **Edit** or context menus.
2. Press the **Delete** key on your keyboard or click the Delete button on the Workspace browser toolbar.
3. A confirmation dialog box might appear. If it does, click **OK** to clear the variables.

   The confirmation dialog box appears if you selected that preference. For more information, see “Confirmation Dialogs Preferences” on page 2-81.

To delete all variables, select **Edit > Clear Workspace** from any desktop tool.

Function Alternative

Use the `clear` function to clear variables from the workspace. For example,

```
clear A M
```

clears the variables `A` and `M` from the workspace.

Viewing Base and Function Workspaces Using the Stack

When you run M-files, MATLAB assigns each function its own workspace, called the function workspace, which is separate from the MATLAB base workspace. To access the base and function workspaces when running or debugging M-files, use the **Stack** field in the Workspace browser. The **Stack** field is only available in debug mode and otherwise is grayed out. The **Stack** field is also accessible from the Array Editor and the Editor/Debugger. See "Finding Errors, Debugging, and Correcting M-Files" on page 6-84for more information. See also the `dbstack` and `evalin` functions.

Creating Plots from the Workspace Browser

From the Workspace browser, you can generate a plot of a variable. To create a plot, click the Plot button  on the Workspace browser toolbar and select the plot type. The plot appears in a figure window. The button itself changes to reflect the currently selected style of plot, for example bar or stem.

This feature is only available for variables whose data types can be plotted, such as numeric. Open the variable in the Array Editor for additional plotting options.

In addition, you can right-click the variable you want to plot. From the context menu, choose the type of plot you want to create.

You can also **Shift**+click or **Ctrl**+click to select multiple variables to plot together. When one of the variables is named `time`, `t`, or `T`, MATLAB assumes it is the independent variable.

For more information about creating graphs in MATLAB, see the *MATLAB Graphics* documentation.

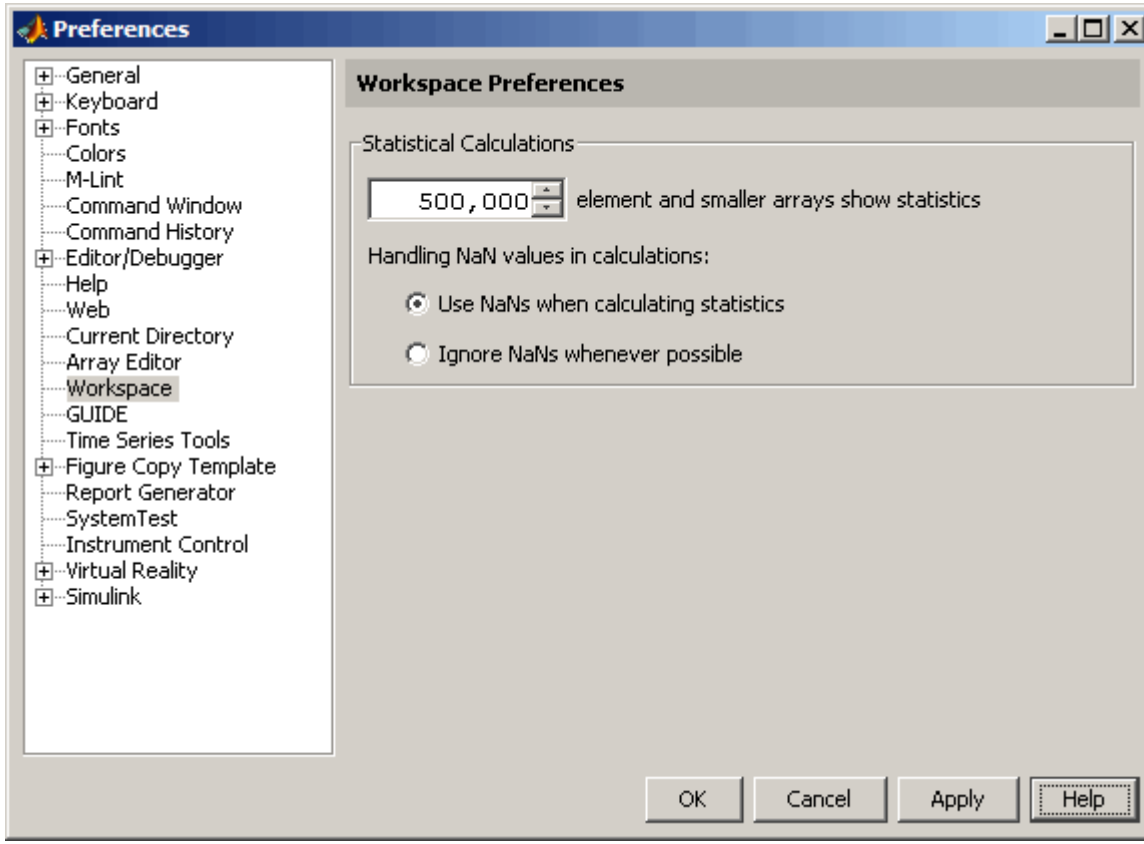
Opening Variables and Objects for Viewing and Editing

In the Workspace browser, double-click a variable and it opens in the Array Editor, where you can view and edit the contents of the variable. See "Viewing and Editing Workspace Variables with the Array Editor" on page 5-12 for more information about opening arrays.

Some toolboxes allow you to double-click an object in the Workspace browser to open a viewer or other tool appropriate for that object. For details, see the toolbox documentation for that object type.

Preferences for the Workspace Browser

The Workspace browser displays statistical calculations for variables. Use preferences to restrict the size of arrays on which calculations are performed and to specify if NaNs are included or ignored in calculations. Select **File > Preferences** to open the dialog box. Make changes and click **OK**.



Specify Maximum Array Size on Which to Compute Statistics

If you show statistical columns in the Workspace browser, and if you work with very large arrays, you might experience performance issues when the data changes as MATLAB updates the statistical results. In that event, show only the columns of interest to you and hide those you do not need.

Another step you can take is specify via a preference that the Workspace browser *not* perform statistical calculations on the largest arrays. Use the arrows to change the value of the maximum array size for which you want the Workspace browser to perform statistical calculations. The default value is `500,000` elements. Any variable exceeding that size reports `<Too many elements>` instead of statistical results.

Handling NaN Values in Calculations

If your data includes NaNs, you can specify that the statistical calculations consider the NaNs, or ignore the NaNs. For example, if a variable includes a `NaN` and the preference is set to **Use NaNs when calculating statistics**, the values for **Min**, **Max**, **Var** and some others will appear as `NaN`, although **Mode**, for example, shows a numeric result. With the preference set to **Ignore NaNs whenever possible**, numeric results appear for most of the statistical columns including **Min** and **Max**, however, **Var** is still reported as `NaN`.

For more information about statistical values in the Workspace browser, see “Viewing and Editing Values in the Current Workspace” on page 5-3.

Viewing and Editing Workspace Variables with the Array Editor

In this section...

About the Array Editor

You use the Array Editor to view and edit a visual representation of one or two-dimensional numeric arrays, strings, cell arrays of strings, and structures. You can also view the contents of multidimensional arrays. If you have an active Internet connection, watch the Array Editor video demo for an overview of the major functionality.

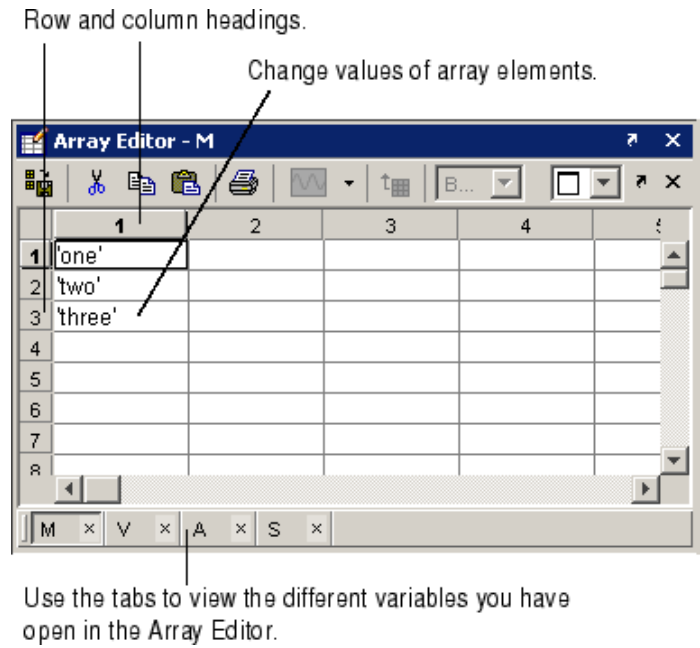
Opening the Array Editor

To open the Array Editor from the Workspace browser,

1 In the Workspace browser, select the variable you want to open. **Shift**+click or **Ctrl**+click to select multiple variables, or use **Ctrl+A** to select all variables to open.

2 Click the Open Selection button on the toolbar. For one variable, you can also open it by double-clicking it.

The Array Editor opens, displaying the values for the selected variable.



Repeat the steps to open additional variables in the Array Editor. Access each variable via its tab at the bottom of the window, or use the **Window** menu.

Changes you make to variables via the Command Window or other operations automatically update the information for those variables in the Array Editor.

Note The maximum array size that you can open in the Array Editor is not limited by MATLAB, but is based on your operating system or the amount of physical memory installed on your system.

Function Alternatives

To open a variable in the Array Editor, use `openvar` with the name of the variable you want to open as the argument. For example, type

```
openvar('M')
```

MATLAB opens `M` in the Array Editor.

To see the contents of a variable in the workspace, just type the variable name at the Command Window prompt. For example, type

```
M
```

and MATLAB returns

```
M =
'one'
'two'
'three'
```

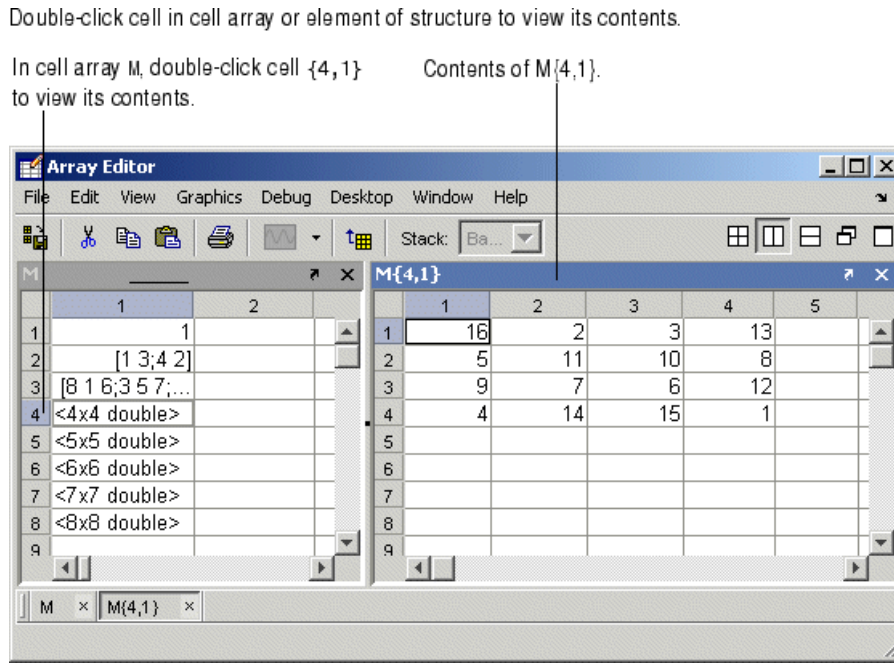
Viewing and Editing Cell Arrays, Structures, and Multidimensional Arrays

Cell Arrays and Structures in the Array Editor

You can view and edit the content of cell arrays and structures in the Array Editor.

In the Array Editor, double-click an element of a structure to open it as its own Array Editor document. You can then view and edit the contents of that element.

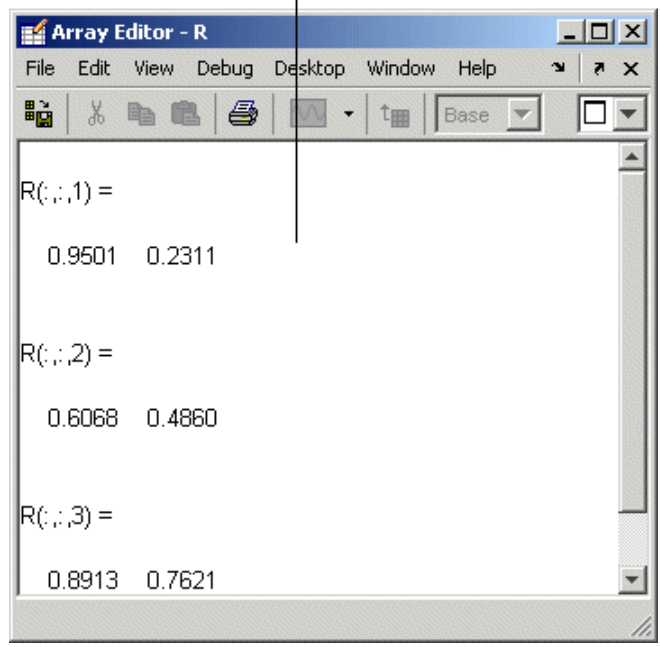
Similarly, double-click a cell in a cell array to view and edit its contents. The following illustration shows an 8-by-1 cell array, `M`, and the contents of `M{4,1}`.



Multidimensional Arrays in the Array Editor

You can view the contents of multidimensional arrays in the Array Editor. When you open a multidimensional array in the Array Editor, it does not have usual grid structure, because multidimensional arrays do not fit that format. You cannot double-click an element in a multidimensional array to edit it. The following illustration shows `R = rand(1,2,3)`.

You can view but cannot edit the contents of a multidimensional array in the Array Editor.



Navigating and Editing Shortcut Keys for the Array Editor

Use the following shortcut keys (sometimes called hot keys) to move among elements in the Array Editor. Navigating in the Array Editor is much like navigating in Microsoft Excel.

Key	Result
Enter	Commit any changes to the element and move to next element, where next element is specified using “Preferences for the Array Editor” on page 5-22 (default is down)

Key	Result
Tab	Move right Within a selection, also moves from the last column to the first column in the next row
Shift+Enter or **Shift+Tab**	Move in opposite direction of **Enter** or **Tab**
Page Up	Move up m rows, where m is the number of visible rows
Page Down	Move down m rows, where m is the number of visible rows
Home	Move to column 1
Ctrl+Home	Move to row 1, column 1
Shift+Home	Select to column 1
End	Move to last column in current row
F2 (**Ctrl+U** on Macintosh)	Edit current element, positioning cursor at the end of the element

Changing Array Size, Content, and Format of Elements in the Array Editor

To increase the size of an array, scroll to the desired location in the array and enter a value. The array will automatically expand to accommodate the new value. Empty cells are filled with zeros, if numeric, or empty arrays, if a cell array. To decrease the size of an array, select the rows or columns that you want to remove by clicking in the row or column header to select the entire row, right-clicking, and selecting **Delete**.

To change the value of an element in the Array Editor, click in that element and type a new value. Press **Enter** or **Return**, or click in another element to make the change take effect. You can specify where the cursor moves to after you press **Enter** — see “Preferences for the Array Editor” on page 5-22.

If you want to change the display format for the Array Editor, select the **View** menu and choose a format. To change the default format for future use, use

the **Preferences** dialog. For more information, see “Preferences for the Array Editor” on page 5-22.

If you opened an existing MAT-file and made changes to it using the Array Editor, save that MAT-file if you want the changes to be saved. For instructions, see “Saving the Current Workspace” on page 5-5.

Cut, Copy, Paste, and Clear Contents in the Array Editor

You can cut or copy selected elements, rows, and columns in an array and paste them to another position in that or another open array. To select a column or row, click in the row or column heading (the element that shows the row or column number). **Shift**+click to choose contiguous elements, rows, or columns in the array, or **Ctrl+A** to select all elements. For the cut, copy, and paste operations, use the **Edit** menu, the context menu, or the toolbar buttons. You can undo the last operation you performed in the Array Editor.

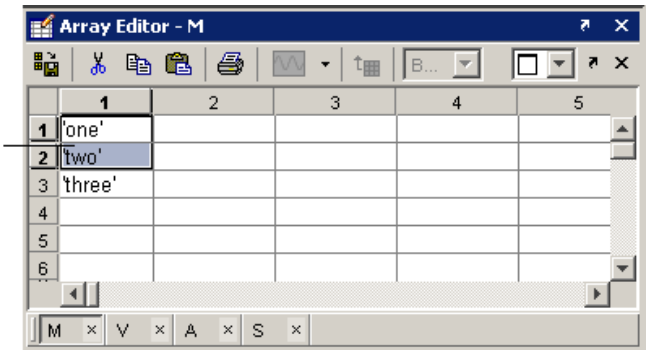
When you cut elements, the value of each element you cut becomes `0` if numeric or `[]` if a cell array. After cutting, select the elements whose value you want to replace with the cut elements and then choose **Paste**. If the shape of the elements you cut differs from the shape of the elements into which you are pasting, the Array Editor pastes all the elements, either by expanding the selection to be pasted into, or by expanding the array size to allow all the elements to be pasted. Pasting copied elements is the same as pasting cut elements, but the elements copied maintain their value rather than becoming `0`.

Select elements, rows, or columns and then select **Edit > Clear Contents**. The value of the selected elements becomes `0`. It differs from a performing a **Cut** because the data from the selected elements does not move to the clipboard; any clipboard content is unaffected by **Clear Contents**.

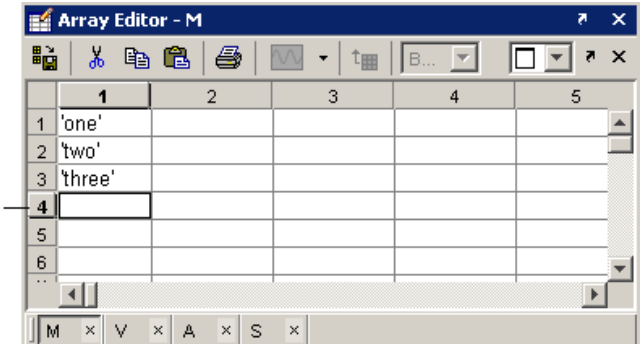
Example Copying and Pasting Array Elements

In this example, two elements are copied but the selected area for pasting is only one element, so the Array Editor expands the selected area for pasting.

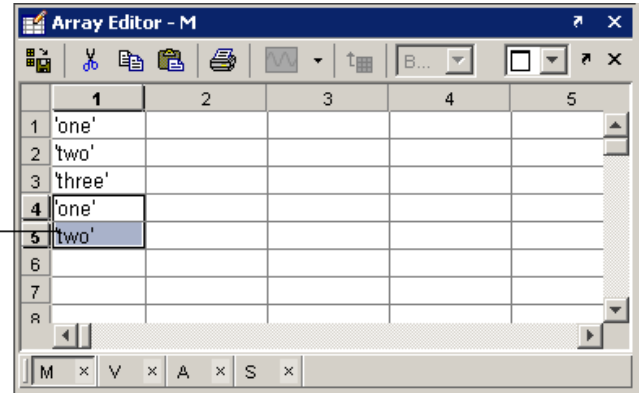
Two elements are selected and copied.



One element is selected as the paste area.

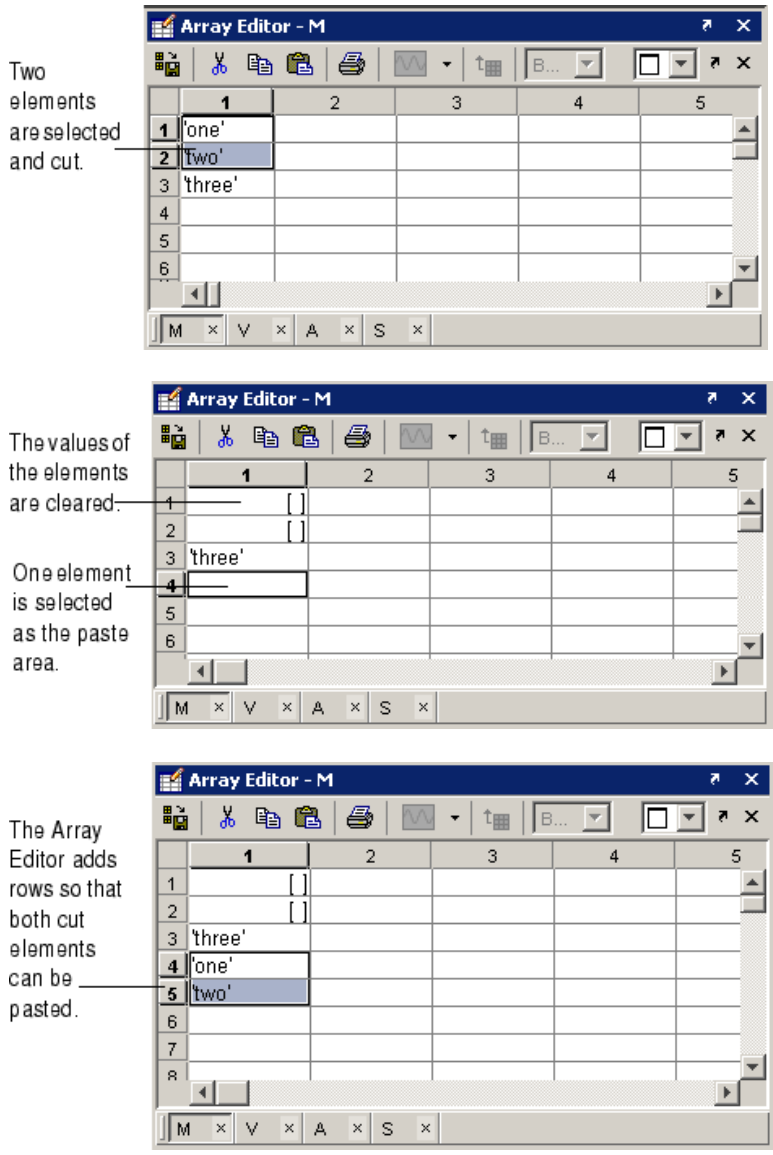


The Array Editor pastes all of the copied elements.



Example Cutting and Pasting Array Elements

In this example, the area selected for pasting requires the Array Editor to expand the array size in order for all cut elements to be pasted.



Insert and Delete in the Array Editor

You can insert and delete elements, rows, and columns in the Array Editor. When you select **Edit > Insert**, or **Edit > Delete**, a dialog box appears in which you specify cells, rows, or columns, and for cells, the direction for shifting.

Undo and Redo in the Array Editor

You can undo the last action you performed in the Array Editor, or redo a change after choosing undo. Select **Edit > Undo** or **Edit > Redo**. The actions supported are a change to a value you make by editing it in the Array Editor, cutting, pasting, inserting, deleting, clearing contents, and pasting Excel data.

Exchanging Data with the Command Window

You can copy data from the Array Editor and paste it into the Command Window. You can also copy a value from the Command Window and paste it into an element in the Array Editor. Be sure the data types are compatible. For example, you cannot paste text from the Command Window into a numeric array in the Array Editor.

Exchanging Data with Excel

You can cut or copy cells from Microsoft Excel and paste them into the Array Editor—use **Edit > Paste from Excel**. You can also cut or copy elements from the Array Editor and paste them into Excel.

Be sure the data types are compatible. For example, you cannot paste text from Excel into a numeric array in the Array Editor.

Creating Graphs and Variables from the Current Selection

You can create graphs and new variables from the Array Editor. To create a graph, select a cell, row, or column, and in the right-click context menu, choose the graph type. MATLAB presents allowable options for the selected data. In some cases, MATLAB makes assumptions, such as using `cell2mat` to convert selected cell array data, which cannot be plotted directly.

To create a new variable, select a cell, row, or column in the Array Editor, right-click, and from the context menu, select **Create Variable from Selection**.

Preferences for the Array Editor

To set preferences for the Array Editor, select **File > Preferences**. The Preferences dialog box opens showing **Array Editor Preferences**.

Format

Specify the default array output format of numeric values displayed in the Array Editor. This affects only how numbers are displayed, not how MATLAB computes or saves them. For more information, see the reference page for `format`.

Editing

You can specify where the cursor moves to after you type in an element and press **Enter**:

- If you want the cursor to remain at the element where you just typed, clear the **Move selection after Enter** check box.
- If you want the cursor to move to another element, select the **Move selection after Enter** check box, and then use **Direction** to specify how you want the cursor to move. For example, if you want the cursor to move right one element after you press **Enter**, select **Right**.

International Number Handling

You can specify how you want decimal numbers to be formatted when you cut or copy cells from the Array Editor and paste them into text files or other applications. The **Decimal separator to use when copying** edit field is by default `"."` (period). If you are working in or providing data to a locale that uses a different character to delimit decimals, type that character in this preference and click **OK** or **Apply**.

Search Path

In this section...

About the Search Path

MATLAB uses a *search path* to find M-files and other MATLAB related files, which are organized in directories on your file system. By default, the files supplied with MATLAB and MathWorks products are included in the search path. This default search path includes many of the directories and files under *`matlabroot`*`/toolbox`, where `matlabroot` is the directory in which MATLAB was installed, as returned by running the `matlabroot` function.

Any file you want to run or debug in MATLAB must reside in a directory that is on the search path, or in the current directory. If you create any MATLAB related files, add the directories containing the files to the MATLAB search path.

If you try to run or debug a file that is in a directory not on the path, the action fails. When this occurs in the Command Window, MATLAB errors. In the Editor/Debugger, a dialog box prompts you to

- **Change Directory** — Makes the directory containing the file you want to run become the current directory
- **Add to Path** — Adds the directory containing the file to the top of the search path

If there is already another file of the same name on the search path, the file you want to run is considered shadowed. You might need to perform some

action so that MATLAB runs the file you want—for more information, see "How the Search Path Determines Which Function to Use" on page 5-24.

The search path is also referred to as the *MATLAB path*. Directories included are considered to be *on the path*. When you include a directory in the search path, you *add it to the path*. Subdirectories must be explicitly added to the path; they are not on the path just because their parent directories are. Adding directories to the path is similar to performing an include or import in some other applications.

For instructions to view the search path and add directories to it, see "Viewing and Setting the Search Path" on page 5-26, including "Caution Against Saving Files in matlabroot/toolbox" on page 5-31.

How the Search Path Determines Which Function to Use

The order of directories on the path is relevant. MATLAB looks for a named element, for example, `foo`, as described here. If you enter `foo` at the MATLAB prompt, MATLAB performs the following actions:

1. Looks for `foo` as a variable.
2. Looks in the current directory for a file named `foo.m`.
3. Searches the directories on the MATLAB search path, in order, for `foo` as a built-in function, followed by `foo.m` which is not built-in.

If there is more than one function with the same name, the order of directories on the path determines which of those functions MATLAB uses. When MATLAB looks for that function, it uses the first one found in the search path:

- To use a function with the same name that is located in a directory further down on the search path, called a *shadowed* function, make its location the current directory. For M-file scripts, you can use `run` with the full pathname for the M-file. For example, use `run d:/mymfiles/foo.m` to ensure that version of `foo` runs. Another option is to move the directory containing the shadowed function to a position in the search path ahead of the directory containing the file of the same name. For example, add it to the top of the search path.

- If you are not sure of the function MATLAB is using, run `which` for a specified function and MATLAB returns the full path to the function.

Although the actual search path rules are more complicated because of the restricted scope of private functions, subfunctions, object-oriented functions, P-files, and MAT-files, this simplified perspective is accurate for the ordinary M-files you usually work with. For more information, see "Determining Which Function Is Called" in the MATLAB Programming documentation.

How MATLAB Finds the Search Path, pathdef.m

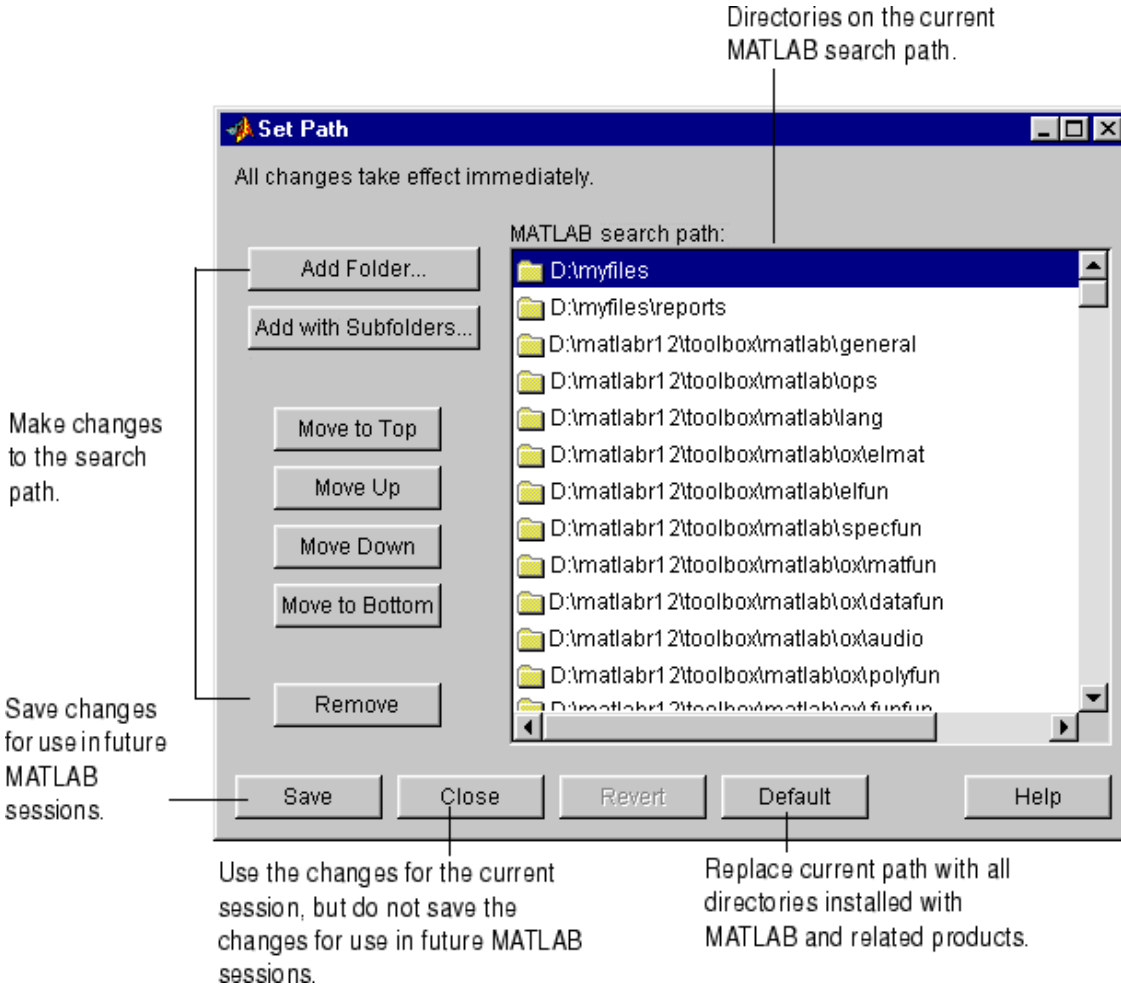
The search path is stored in the file `pathdef.m`, which by default, is located in *`matlabroot`*`/toolbox/local`. You can store it in the MATLAB startup directory, and modify it for the current session or for all future sessions.

When MATLAB starts, it looks for a `pathdef.m` file in its startup directory. If none is found, it uses `pathdef.m` in `matlabroot/toolbox/local`. MATLAB modifies the path based on any path statements in a `startup.m` file. During a session, you can save changes to the path using the **Set Path** dialog box or the `savepath` function, and MATLAB uses the path you saved to for the remainder of the session.

If MATLAB finds a `pathdef.m` in the current directory, it uses that version instead. To avoid problems, do not maintain a `pathdef.m` file in a directory other than the MATLAB startup directory or *`matlabroot`*`/toolbox/local`.

Viewing and Setting the Search Path

Use the **Set Path** dialog box to view and modify the MATLAB search path. Equivalent functions are documented for each feature of the **Set Path** dialog box. Select **Set Path** from the **File** menu, or type `pathtool` at the Command Window prompt. The **Set Path** dialog box opens.



Use the **Set Path** dialog box for the following actions. Equivalent functions are listed as well:

See also

Viewing the Search Path

The **MATLAB search path** field in the **Set Path** dialog box lists all of the directories on the search path. The top of the list is the start of the search path, while the bottom of the list is the end.

Function Alternative. Use the `path` function to view the search path.

Adding Directories to the Search Path

Add directories to the search path when you want to run M-files in those directories.

To add directories to the MATLAB search path using the **Set Path** dialog box,

1. Click **Add Folder** or **Add with Subfolders**.

   - If you want to add only the selected directory but do not want to add all of its subdirectories, click **Add Folder**.
   - If you want to add the selected directory and all of its subdirectories, click **Add with Subfolders**.

The **Browse for Folder** dialog box opens.

2 In the Browse for Folder dialog box, use the view of your file system to select the directory to add, and then click **OK**.

The selected directory, and subdirectories if specified in step 1, are added to the top of the search path.

3 To use the newly modified search path in future sessions, click **Save**. For more information about saving the path, see "Saving Settings to the Path" on page 5-30.

4 Click **Close**. If you did not save the changes in the previous step, the directories you added remain on the search path until you end the current MATLAB session.

You cannot add method directories (directories that start with @) and private directories to the MATLAB search path.

Adding Directories to the Path from the Current Directory Browser. In the Current Directory browser, select a directory, right-click, and select **Add to Path** from the context menu. Then select one of the submenus, for example, **Selected Folder and Subfolders**.

Function Alternative. To add directories to the top or the end of the search path, use `addpath`. The `addpath` function offers an option to get the path as a string and to concatenate multiple strings to form a new path.

You can include `addpath` statements in your `startup` M-file to automatically modify the path when MATLAB starts. For details, see "Modifying the Path in a startup.m File" on page 5-31.

Moving Directories Within the Search Path

The order of files on the search path is relevant — for more information, see "How the Search Path Determines Which Function to Use" on page 5-24.

To modify the order of directories within the search path,

1 Select the directory or directories you want to move.

2 Click one of the **Move** buttons, such as **Move to Top**. The order of the directories changes.

3 To use the newly modified search path in future sessions, click **Save**. For more information about saving the path, see "Saving Settings to the Path" on page 5-30.

4 Click **Close**. If you did not save the changes in the previous step, the new order of files on the search path remains in effect until you end the current MATLAB session.

Function Alternative. While there is not a specific function to move directories, you can edit the `pathdef.m` file with any text editor to change the order of the directories. Use caution when editing the file so that you do not make MATLAB and toolbox functions unusable.

Removing Directories from the Search Path

To remove directories from the MATLAB search path using the **Set Path** dialog box,

1 Select the directories to remove.

2 Click **Remove**. The directories are removed from the path.

3 To use the newly modified search path in future sessions, click **Save**. For more information about saving the path, see "Saving Settings to the Path" on page 5-30.

4 Click **Close**. If you did not save the changes in the previous step, the directories are removed from the search path until you end the current MATLAB session.

Function Alternative. To remove directories from the search path, use `rmpath`.

You can include `rmpath` statements in your `startup` M-file to automatically modify the path when MATLAB starts. For details see "Modifying the Path in a startup.m File" on page 5-31.

Restoring the Default Search Path

To restore the default search path, click **Default** in the **Set Path** dialog box. This changes the search path so that it includes only the directories installed with MATLAB and related products.

Reverting to the Previous Path

To restore the previous path, click **Revert** in the **Set Path** dialog box. This cancels any unsaved changes you have made in the **Set Path** dialog box.

Saving Settings to the Path

When you make changes to the search path, they remain in effect during the current MATLAB session. To keep the changes in effect for subsequent sessions, you need to save them. To save changes using the **Set Path** dialog box, click **Save**.

If you want to automatically use this search path in future sessions, save the path to your MATLAB startup directory, which saves `pathdef.m` to that location. You can save the changes to the default `pathdef.m` file, in *`matlabroot`*`/toolbox/local` if you have write permission for that directory but see the following caution. Alternatively, you can include `addpath` and `rmpath` statements in a `startup.m` file, which avoids some problems you might have with saving the path, for example, using the same path with both Windows and UNIX platforms. For more information, see "Using the Path in Future Sessions" on page 5-31.

Note When MATLAB starts up, it may provide in the Command Window a list of invalid directories. These directories were previously in `pathdef.m` but were subsequently deleted. The directories do not now appear on the search path listing in the **Set Path** dialog box. Click **Save** to overwrite the `pathdef` M-file, thereby eliminating future reporting of these nonexistent directories.

Caution Against Saving Files in matlabroot/toolbox. Save any M-files you create and any MathWorks supplied M-files that you edit in a directory that is not in the *matlabroot*/toolbox directory tree. If you keep your files in *matlabroot*/toolbox directories, they can be overwritten when you install a new version of MATLAB. Also note that locations of files in the *matlabroot*/toolbox directory tree are loaded and cached in memory at the beginning of each MATLAB session to improve performance. If you save files to *matlabroot*/toolbox directories using an external editor or add or remove in from these directories using file system operations, run rehash toolbox before you use the files in the current session. If you make changes to existing files in *matlabroot*/toolbox directories using an external editor, run clear functionname before you use the files in the current session. For more information, see rehash or "Toolbox Path Caching in MATLAB" on page 1-17.

Function Alternative. Use savepath to save the current path to pathdef.m. Locate pathdef.m in your MATLAB startup directory to automatically use it in future sessions. Consider using savepath in your finish.m file. To modify the default path upon startup, include addpath and rmpath functions in your startup.m file. For more information, see "Modifying the Path in a startup.m File" on page 5-31.

Using the Path in Future Sessions

There are three basic ways for MATLAB to automatically use a search path you specify, each with advantages and disadvantages:

- "Modifying the Path in a startup.m File" on page 5-31
- "Saving the Path in the MATLAB Startup Directory" on page 5-32
- "Saving the Path in matlabroot/toolbox/local" on page 5-32

For background information, see "How MATLAB Finds the Search Path, pathdef.m" on page 5-25.

Modifying the Path in a startup.m File

Put addpath and rmpath statements in a startup.m file, and include the startup file in MATLAB's startup directory. When MATLAB starts, it uses the search path defined in pathdef.m in *matlabroot*/toolbox/local and modifies it based on the commands in the startup.m file.

By maintaining an unaltered `pathdef.m` in *`matlabroot`*`/toolbox/local`, you avoid inadvertently removing directories supplied by The MathWorks from the path. This method continues working even when you update to a new version of MATLAB. If you run MATLAB on both Windows and UNIX platforms, this method works well — for example, for each platform, include separate `addpath` sections in the `startup.m` file, with each section preceded by an `ispc` or `isunix` statement.

One disadvantage of this method is that changes you make to the path using the **Set Path** dialog box are not incorporated in the `startup.m` file.

Saving the Path in the MATLAB Startup Directory

Copy `pathdef.m` from *`matlabroot`*`/toolbox/local` to the MATLAB startup directory. Make changes to the path using the **Set Path** dialog box, and with `addpath` and `rmpath` functions — choose whichever suits your needs. You can use this method if you do not have write access to *`matlabroot`*`/toolbox/local`.

There are some disadvantages to this method. You might inadvertently remove directories supplied by The MathWorks from the path. When you update to a new version of MATLAB, you cannot use the `pathdef.m` file in the startup directory, but must delete it and create a new version. If you run MATLAB on both Windows and UNIX platforms, you need to maintain a separate `pathdef.m` file for each.

Saving the Path in matlabroot/toolbox/local

If you have write access to *`matlabroot`*`/toolbox/local`, make and save changes to the path using the **Set Path** dialog box, and with `addpath` and `rmpath` functions — choose whichever suits your needs.

There are some disadvantages to this method. You cannot maintain this file when you update to a new version of MATLAB, but will need to use the new default `pathdef.m` and make changes to it. If you run MATLAB on both Windows and UNIX platforms, you need to maintain a separate `pathdef.m` file for each.

Recovering from Problems with the Search Path

If you get unexpected results that are related to the search path, you can try to correct the path file or restore the default path. You might experience path problems if you save the path on a Windows platform and then try to use the same `pathdef.m` file on a UNIX platform. Similarly, you might experience problems if you edit the `pathdef.m` file directly and make it invalid, or if the file becomes corrupt, renamed, or lost.

For example, if an error message similar to the following appears when you start MATLAB

```
Warning: MATLAB did not appear to successfully set the search
path...
```

it indicates a problem with the search path and you will not be able to use MATLAB successfully.

To recover from problems with the search path, try the following, in order, proceeding to the next step only if needed:

1. View the `pathdef.m` and `startup.m` files, looking for obvious problems. Make changes and save them. If path problems appear to be resolved, start MATLAB again to be sure the problem does not reappear. Depending on the problem, you might not be able to even view the `pathdef.m` file.

2. Use the default path for MathWorks products. In the **Set Path** dialog box, select **Default**, then **Save**, then **Close**. Depending on the problem, you might not be able to even open the dialog box.

3. Run `restoredefaultpath`. This sets the search path to include only installed products from The MathWorks. If that seems to have corrected the problem, run `savepath`. Start MATLAB again to be sure the problem does not reappear.

   Depending on the problem, this might generate a message such as

   ```
   The path may be bad. Please save your work (if desired), and quit.
   ```

   If so, perform step 4.

4. Perform these steps after trying step 3.

a Run

```
restoredefaultpath; matlabrc
```

This might run for a few minutes. It sets the search path to include only installed products from The MathWorks and corrects path problems encountered during startup.

b If there is a `pathdef.m` in your startup directory for MATLAB, it caused the problem. So either remove the bad `pathdef.m` file or replace the with a good `pathdef.m` file, for example, one you can generate at this point with

```
savepath('path_to_your_startup_directory/pathdef.m')
```

c Start MATLAB again to be sure the problem does not reappear.

File Management Operations

In this section...

Note You generally cannot perform operations on files and directories for which you do not have proper permission. For example, you cannot copy a file to a read-only directory using the Current Directory browser, however, you can do so using `movefile` with the appropriate option.

About MATLAB File Operations

MATLAB file operations use the current directory and the MATLAB search path as reference points. Any file you want to run must either be in the current directory or on the search path. The key tools for performing file operations are

Current Directory Field

A quick way to view or change the current directory is by using the current directory field in the desktop toolbar.

To change the current directory from this field, do one of the following:

- In the field, type the path for the new current directory.
- Click the down arrow to view a list of previous working directories, and select an item from the list to make that directory become the MATLAB current working directory. The directories are listed in order, with the most recently used at the top of the list. You can clear the list and set the number of directories saved in the list — see “Preferences for the Current Directory Browser” on page 5-54.
- Click the Browse for Folder button (**...**) to set a new current directory.
- Use the Go Up One Level button to move the current directory up one level.

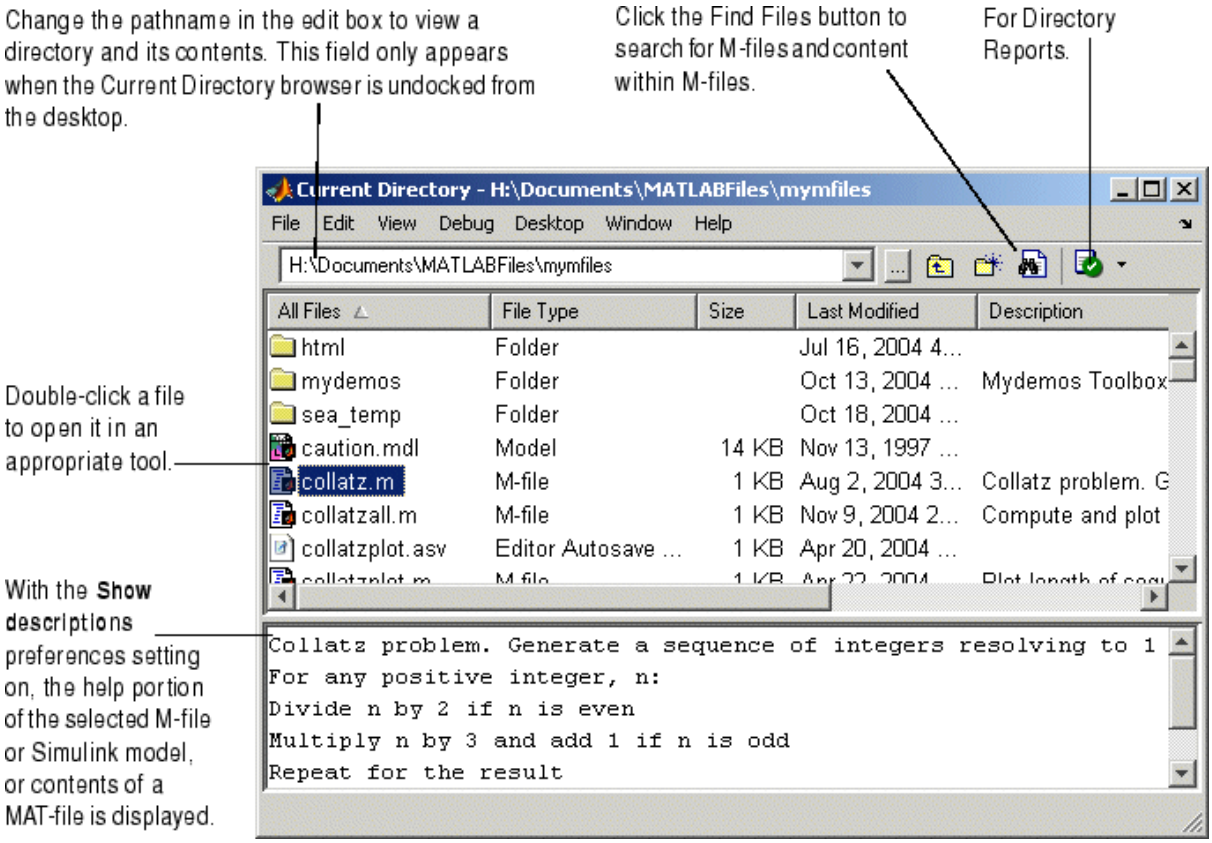
The current directory field in the desktop also appears in the Current Directory browser, when the Current Directory browser is undocked. Consider it to be one tool with two different means of accessing it.

Current Directory Browser

To search for, view, open, find, and make changes to MATLAB related directories and files, use the MATLAB Current Directory browser. Most features of the Current Directory browser have equivalent functions that perform similar actions. If you have an active Internet connection, you can watch the Current Directory Browser video demo for an overview of the major functionality.

In addition to the features described here, the Current Directory browser includes tools to help you manage your M-files — see “Directory Reports in Current Directory Browser” on page 7-2.

To open the Current Directory browser, select **Desktop > Current Directory** from the MATLAB desktop, or type `filebrowser` at the Command Window prompt. The Current Directory browser opens.



The main tasks you perform with the Current Directory browser are

- “Viewing and Making Changes to Directories” on page 5-38
- “Creating, Renaming, Copying, and Removing Directories and Files” on page 5-43
- “Opening and Running Files” on page 5-47
- “Finding Files and Content Within Files” on page 5-49
- “Accessing Source Control Features” on page 5-54
- Setting “Preferences for the Current Directory Browser” on page 5-54

Viewing and Making Changes to Directories

You can change the current directory, view its contents, add directories to the MATLAB search path, and change the way the Current Directory browser presents entries.

Changing the Current Working Directory and Viewing Its Contents

To change the current directory, use the current directory field. The Current Directory browser lists the files and directories in the current directory.

To view the contents of a subdirectory, double-click it, or select the subdirectory and press **Enter** or **Return**.

To move up one level in the directory structure, press the backspace (**<-**) key.

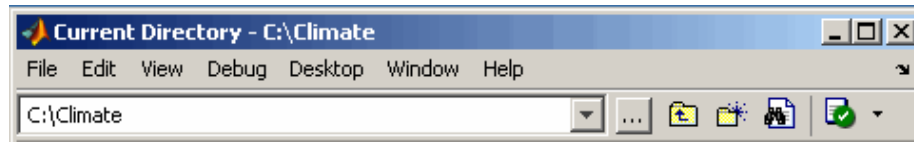
Function Alternative. Use `dir` to view the contents of the current working directory or another specified directory. Use a return argument with `dir` to get a structure containing information including the names of the files in the directory and their last modified date and time.

Use `what` with no arguments to display the MATLAB related files in the current working directory. Use `which` to display the pathname for a specified function. Use `exist` to see if a directory or file exists. Use `fileattrib` to see or set file attributes, much like `attrib` in DOS or `chmod` in UNIX.

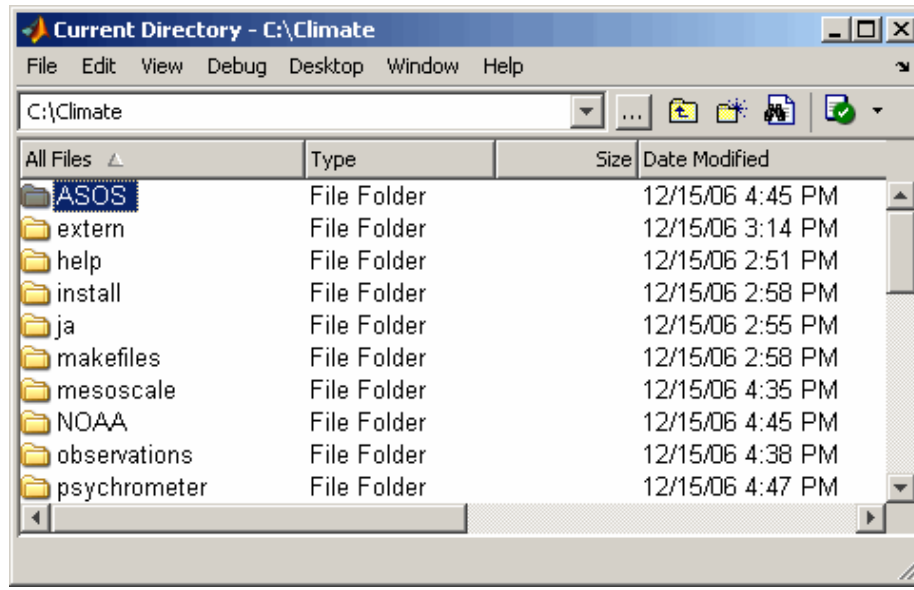
Searching in the Current Directory Browser

You can search the Current Directory browser for files and directories by typing directly in the window. As you type the Current Directory browser searches downward from the top of the window to find an entry that matches what you have typed. For example:

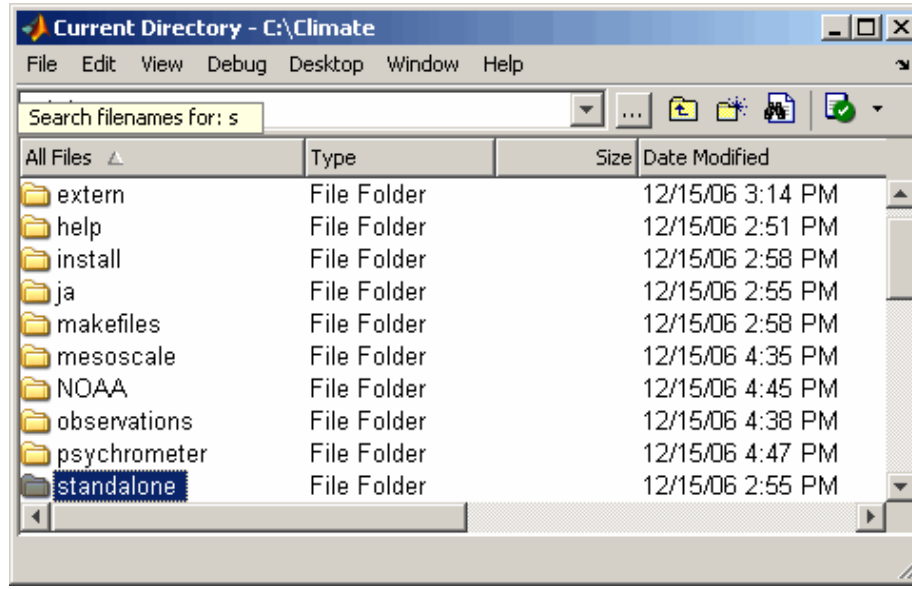
1 Set `C:\Climate` as your current directory.



2 Assume that you want to search the Current Directory for the file named `standard.m`. Begin your search by positioning the cursor anywhere within the Current Directory browser.

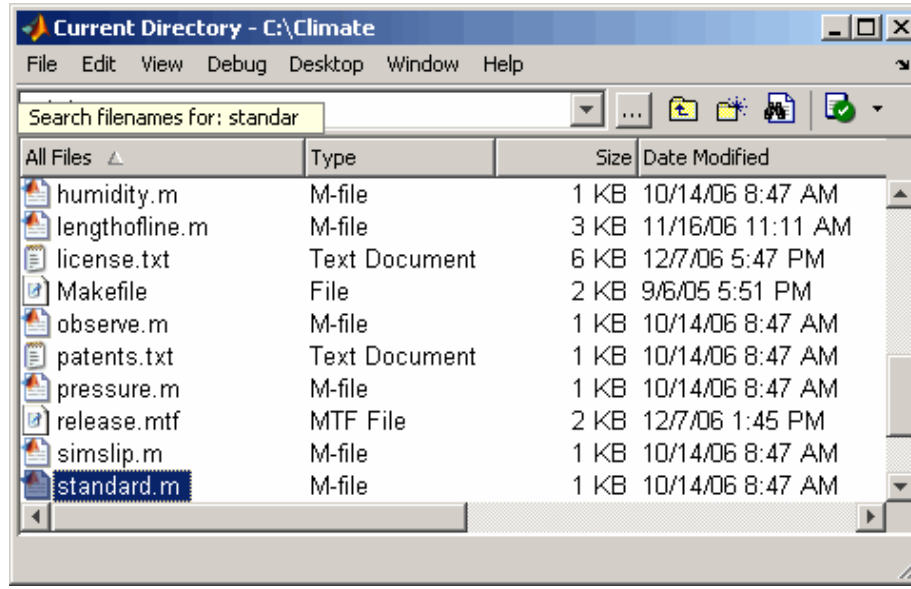


3 Type the letter `s`. The Current Directory browser searches to find the first entry beginning with the letter `s`. In this example it stops at the directory named `standalone`. Note as you begin typing that a small yellow-background `Search filenames for:` dialog box appears at the top of the Current Directory browser window. This dialog box keeps track of your search target as you type additional letters to narrow the focus of your search.



4 Since the `standalone` directory is not your intended search target, continue typing additional letters that identify your search target, eventually entering the letters `standar`.

5 When you have entered the letters `standar`, the search resumes, stopping this time at the `standard.m` file, your intended search target.



Changing the Display

Types of Files. To specify the types of files shown in the Current Directory browser, use the **View** menu. For example, you can show only M-files. If **All Files** is selected and you want to see specific file types, first clear the selection for **All Files** and then select the specific file types.

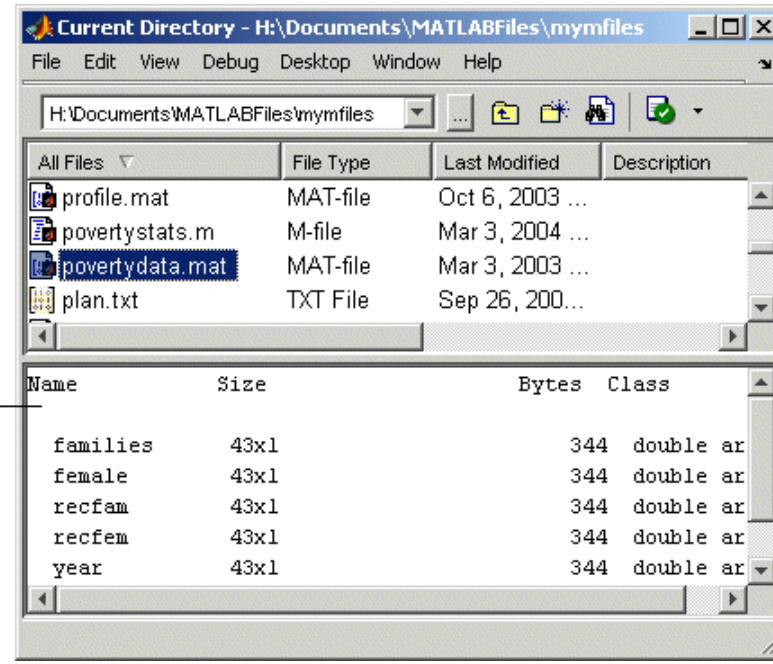
Columns. To show or hide columns, use preferences for the Current Directory browser. Select **File > Preferences > Current Directory** and select or clear the check boxes for **Browser display options**. For more information, see “Browser Display Options” on page 5-55.

You can sort the information shown in the Current Directory browser by column. Click the title of column on which you want to sort. The display is sorted, with the information in that column shown in ascending order, and an up arrow icon indicating the direction. Click a second time on the column title to sort the information in descending order.

Contents. In the Current Directory browser, select a file and then view information about the file in the Current Directory browser's lower pane. To view this, you must first select **File > Preferences > Current Directory** and under **Browser display options**, select the check box **Show M, MDL and MAT file contents**.

For an M-file, it shows the M-file help. For a Simulink model, it shows the complete description, allowing you to view information about a model without having to start Simulink. For a MAT-file, it displays the names of its variables along with their size, bytes, and class, allowing you to view the content of a MAT-file without loading it.

View variables in selected MAT-file without loading the file.



You can view more extensive help for the M-file selected in the Current Directory browser. From the context menu, select **View Help**. The reference page for that function appears in the Help browser.

Adding Directories to the MATLAB Search Path

From the Current Directory browser, you can add directories to the MATLAB search path. Right-click and from the context menu, select **Add to Path**. Then select one of the options:

- **Current Directory** — Adds the current directory to the path.
- **Selected Folders** — Adds the directories selected in the Current Directory browser to the path.
- **Selected Folder and Subfolders** — Adds the directory selected in the Current Directory browser to the path, and adds all of its subdirectories to the path.

Creating, Renaming, Copying, and Removing Directories and Files

General Notes

If you have write permission, you can create, copy, remove, and rename MATLAB related files and directories for the directory shown in the Current Directory browser. If you do not have write permission, you can still copy files and directories to another directory, or you can use equivalent functions, such as `movefile`.

To run functions whose arguments require the use of a pathname or filename, use the function form rather than the unquoted or command form of the syntax when the pathname or filename includes spaces. For example, the command form

```
delete my file.m
```

generates a warning and does not delete `my file.m`. Instead use the function form of the syntax:

```
delete('my file.m')
```

Creating New Files

To create a new file in the current directory,

1. Select **New** from the context menu or **File** menu and then select the type of file to create.

   An icon for that file type, for example, an M-file icon  , with the default name `Untitledn`, appears at the end of the list of files shown in the Current Directory browser.

2. Type over `Untitledn` with the name you want to give to the new file.

3. Press **Enter** or **Return**.

   The file is added.

4. To enter the contents of the new M-file, open the file—see "Opening and Running Files" on page 5-47. If you created the file using the context menu, the new file opens in the Editor/Debugger with a template for writing an M-file function.

Function Alternative. Use the `edit` function to create a new M-file or other type of text file in the Editor/Debugger.

Creating New Directories

To create a new directory in the current directory,

1. Click the New Folder button  in the Current Directory browser toolbar, or select **New > Folder** from the context menu.

   An icon, with the default name `NewFoldern` appears at the end of the list of files shown in the Current Directory browser.

2. Type over `NewFoldern` with the name you want to give to the new directory.

3 Press the **Enter** or **Return** key.

   The directory is added.

Function Alternative. To create a directory, use the `mkdir` function. For example,

```
mkdir newdir
```

creates the directory `newdir` within the current directory.

Renaming Files and Directories

To rename a file or directory, select the item, right-click, and select **Rename** from the context menu. Type over the existing name with the new name for the file or directory, and press **Enter** or **Return**. The file or directory is renamed.

Function Alternative. You can use `movefile` to rename a file or directory. For example,

```
movefile('myfile.m','projectresults.m')
```

renames `myfile.m` to `projectresults.m`.

Cutting or Deleting Files and Directories

To cut or delete files and directories,

1 Select the files and directories to remove. Use **Shift**+click or **Ctrl**+click to select multiple items.

2 Right-click and select **Cut** or **Delete** from the context menu.

   The files and directories are removed.

Files and directories you delete from the Current Directory browser go to the Recycle Bin on Windows (or the Trash Can on Macintosh platforms). If you do not want the selected items to go to the Recycle Bin, press **Shift+Delete**. A confirmation dialog box displays before the items are deleted if you have set that option in your operating system. For example, on Windows, right-click

the Recycle Bin, select **Properties** from the context menu, and then, under the **Global** tab, select the check box to **Display delete confirmation dialog**.

Function Alternative. To delete a file, use the `delete` function. For example,

```
delete('d:/mymfiles/testfun.m')
```

deletes the file `testfun.m`. You can recover deleted files if you use the `recycle` function or the equivalent preference described in "Default Behavior of the Delete Function" on page 2-78.

To delete a directory and optionally its contents, use `rmdir`. For example,

```
rmdir('myfiles')
```

removes the directory `myfiles` from the current directory.

Copying and Pasting Files and Directories

Use the Current Directory browser, to copy (or cut) and paste files and directories:

1. Select the files or directories to copy. Use **Shift**+click or **Ctrl**+click to select multiple items. For a directory, the entire contents are copied, including all subdirectories and files.
2. Right-click and select **Copy** from the context menu.
3. Navigate to the file or directory where you want to paste the items you just copied.
4. Right-click and select **Paste** from the context menu.

You can also copy and paste files and directories to and from tools outside of MATLAB, such as Windows Explorer. You can use Current Directory browser menu items or keyboard shortcuts, or you can drag the items.

Function Alternative. Use `movefile` or `copyfile` to cut and paste or to copy and paste files or directories. For example, to make a copy of the file `myfun.m` in the current directory, assigning it the name `myfun2.m`, type

```
copyfile('myfun.m','myfun2.m')
```

Opening and Running Files

Opening Files

You can open a file from the Current Directory browser and the file opens in the tool associated with that file type.

To open a file, select one or more files and perform one of the following actions:

- Press the **Enter** or **Return** key.
- Right-click and select **Open** from the context menu.
- Double-click the file(s).

The file opens in the appropriate tool, provided that the tool has been installed on your system. For example, the Editor/Debugger opens for M-files, and Simulink opens for model (`.mdl`) files.

To open a file in the Editor/Debugger, no matter what type it is, select **Open as Text** from the context menu. One exception is P-files (`.p`), which you cannot open.

To open a file using an external application, select **Open Outside MATLAB** from the context menu. For example, if you select `myfile.doc`, **Open Outside MATLAB** opens `myfile.doc` in Microsoft Word, assuming you have the `.doc` file association configured to start Word. This is also useful for file types associated with MATLAB that are also associated with an external application in Windows. For example, `.mat` is the extension for MATLAB data files as well as Microsoft Access files. When you double-click a `.mat` file in the Current Directory browser, it loads the MATLAB data file into the workspace. If instead you want to open the `.mat` file in Access, right-click it and select **Open Outside MATLAB**. MATLAB opens the file using the applications you associated with that file type in Windows. For more information, see "Changing File Associations for MATLAB from Windows" on page 1-5.

You can also import data from a file. Select the file, right-click, and select **Import Data** from the context menu. The Import Wizard opens. See the Import Wizard documentation for instructions to import the data.

You can run a Windows shortcut directly from the Current Directory browser. Double-click the shortcut icon in the Current Directory browser to perform the Windows operation.

Function Alternative. Use the `open` function to open a file in the tool appropriate for the file, given its file extension. Default behavior is provided for standard MATLAB file types. You can add other file types and override the default behavior for the standard files. For `name.ext`, `open` performs the following actions.

File Type	Extension	Action
Figure file	`fig`	Opens figure `name.fig` in a figure window.
HTML file	`html`	Opens HTML file `name.html` in the MATLAB Web browser.
M-file	`m`	Opens M-file `name.m` in the Editor/Debugger.
MAT-file	`mat`	Opens MAT-file `name.mat` in the Import Wizard.
Model	`mdl`	Opens model `name.mdl` in Simulink.
PDF file	`pdf`	Opens the PDF file `name.pdf` in the installed PDF reader, for example, Adobe Acrobat.
Project file	`prj`	Opens the project file `name.prj` in the MATLAB Compiler Deployment Tool. If the MATLAB Compiler or Deployment Tool is not installed, opens the project file in a text editor.

File Type	Extension	Action
Variable	none	Opens the numeric or string array `name` in the Array Editor; `open` calls `openvar`.
Other	`custom`	Opens `name.custom` by calling the helper function `opencustom`, where `opencustom` is a user-defined function.

Use `winopen` to open a file using an external application on Windows platforms.

To view the content of an ASCII file, such as an M-file, use the `type` function. For example

```
type('startup')
```

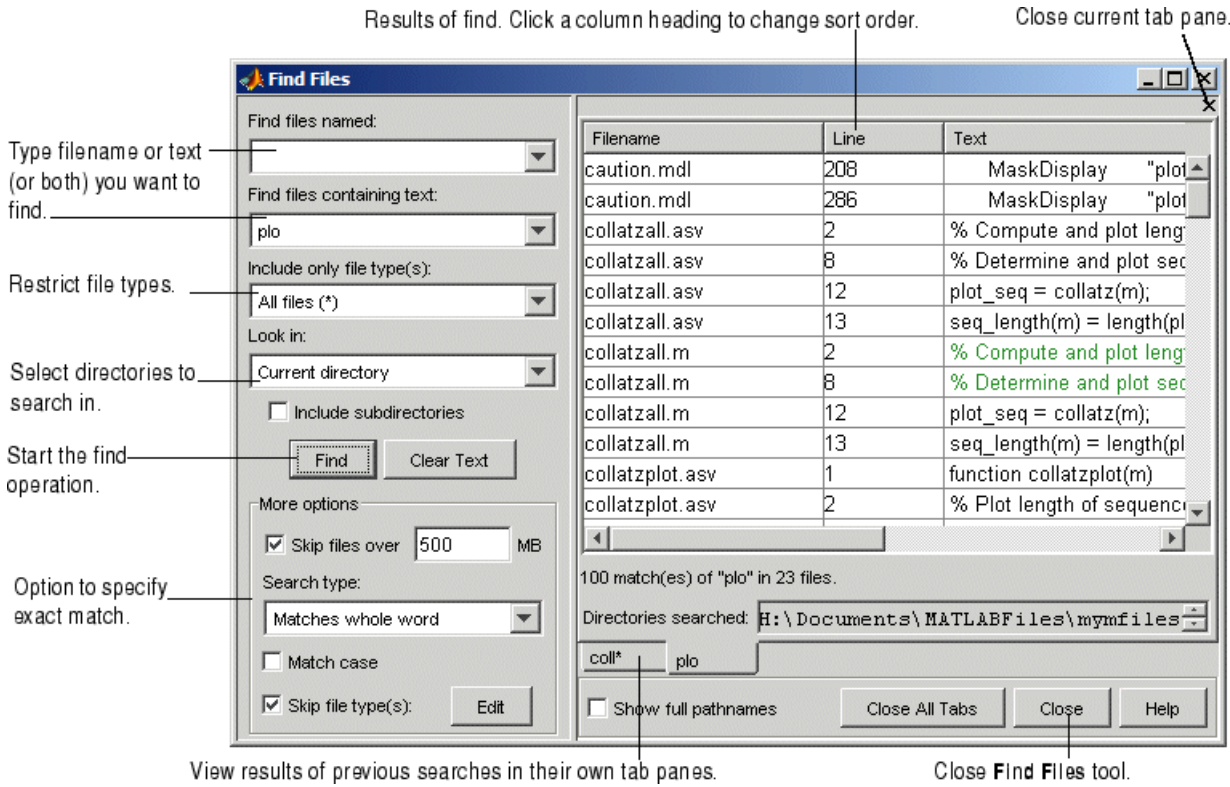
displays the contents of the file `startup.m` in the Command Window.

Running M-Files

To run an M-file from the Current Directory browser, select it, right-click, and select **Run** from the context menu. The results appear in the Command Window.

Finding Files and Content Within Files

Use the Find Files tool to search for files or for specified text within files.



To search for files in one or more directories, or to search for specified text in files, follow these instructions:

1 Open the **Find Files** tool by clicking the Find Files button in the Current Directory browser toolbar, or by selecting **Edit > Find Files** from any desktop tool, such as the Current Directory browser or the Editor/Debugger.

   The **Find Files** dialog box opens.

2 Type the filename and/or text you are searching for:

   - To search for files, type the filename in the **Find files named** field. You can use the wildcard character (`*`) in the filename. For example, type `coll*` to search for filenames that start with `coll`.

- To search for text within files, type the text in the **Find files containing text** field. For example, search for `plot`. Alternatively, you can select text in the Command Window or Editor/Debugger and that text appears in the **Find files containing text** field.

  Under **More options**, use the **Search type** to specify **Matches whole word**, or specify a partial match by selecting **Contains text**.

- To search for text in specified filenames only, type entries in both fields. Use the **Clear Text** button to clear the entries in both fields.

Click the down arrow next to each field to select previous entries from the current MATLAB session.

3 You can restrict the types of files to search by selecting an option in **Include only file type(s)**. For example, select `*.m` to limit the search to M-files only.

With **All files (*)** selected, use **Skip file types** (under **More options**) to ignore files of the specified type. For details, see "Skip File Types in Find Files" on page 5-52.

4 From the **Look in** list box, select the directories to search in. Select the MATLAB current directory or MATLAB search path, or use the `Browse` option to select another directory. You can instead type the full pathname for one or more directories into this field, with each pathname separated by a semicolon (`;`). To include subdirectories in the search, select the **Include subdirectories** check box.

5 Use additional entries under **More options** to further restrict the search:

- **Skip files over** the specified size to ignore large files that might take a long time to search through. This option is only available when you are searching for text within files.
- **Match case** when lower or upper case is relevant.

6 To execute the search, click **Find**. While the search is in progress, the **Find** button label changes to **Stop Find**. To abort a search, click **Stop Find**.

Search results appear in the pane on the right side of the **Find Files** dialog box, with a summary of the results at the bottom of the pane. For text searches, the line number and line of code are shown. To see the full pathnames for the files, select the **Show full pathnames** check box.

7 Click a column heading to sort the results based on that column. Click the column heading again to reverse the sort order for that column. For example, click **Line** to sort results by line number.

Opening Files from Find Files

To open files shown in the results list, do one of the following:

- Double-click the file
- Select the files and press **Enter** or **Return**
- Right-click the selected files and select **Open** from the context menu

The files open in the Editor/Debugger. For text searches, the file opens scrolled to the line number shown in the results section of the **Find Files** dialog box. Once in the Editor/Debugger, you can use the Find & Replace tool to change specified text.

Previous Results of Find Files

To see the results of a previous search, select its tab at the bottom of the results pane. **Find Files** shows up 10 search result tabs while the tool is open, but does not maintain the results after you close the tool.

MATLAB maintains the state for options in the Find Files tool even after you end the session.

Skip File Types in Find Files

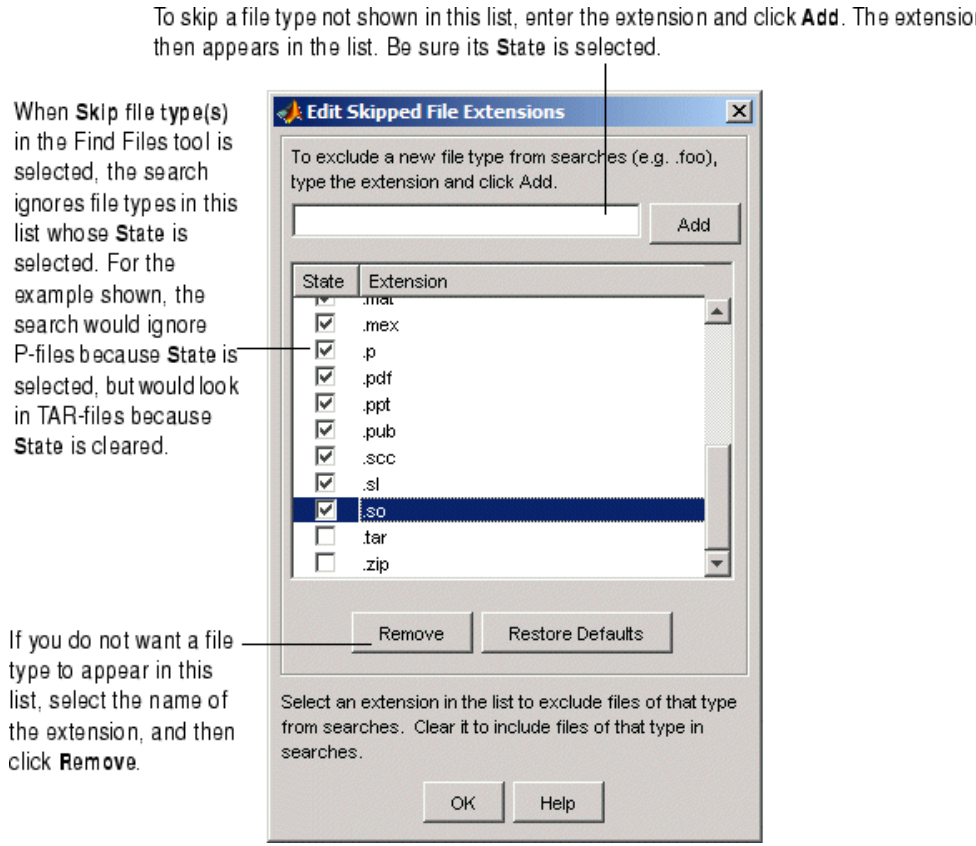
In the Find Files tool, you can restrict the search to look in all file types except those you specify:

1 For **Include only file type(s)**, select **All files (*)**.

2 Select the **Skip file type(s)** check box.

3 Click **Edit** to view or change the list of file types the search ignores.

The **Edit Skipped File Extensions** dialog box opens.



4 Find Files will not look in any file type in the list whose **State** check box is selected. It will look in any file type in the list whose **State** check box is cleared.

   a Clear or select the **State** check box as needed to instruct Find Files about file types to skip.

   b If you want Find Files to skip a file type not shown in the list, enter the file extension in the field at the top of the dialog box and click **Add**. The type appears in the list. Be sure its **State** check box is selected. For the example shown, the `scc` file type was added.

   c You can reduce the size of the list by removing any file extensions. Select the name of the extension and click **Remove**.

5 Click **OK** to accept the changes and close the **Edit Skipped File Extensions** dialog box.

6 When you click **Find** in the Find Files tool, the search ignores the selected file types.

Function Alternative

Use `lookfor` to search for the specified text in the first line of help for all M-files on the search path.

Comparing Files

The MATLAB File Comparison tool highlights the line-by-line differences between two files. Access it by selecting a file in the Current Directory browser, then right-click, and from the context menu, select **Compare Against > Browse** and navigate to the file to compare. Select it and click **Open**.

For two files in the same directory, select the files, right-click, and from the context menu, select **Compare Selected Files**.

For information about using the results and other options, see "Comparing Files — File Comparison Tool" on page 6-54.

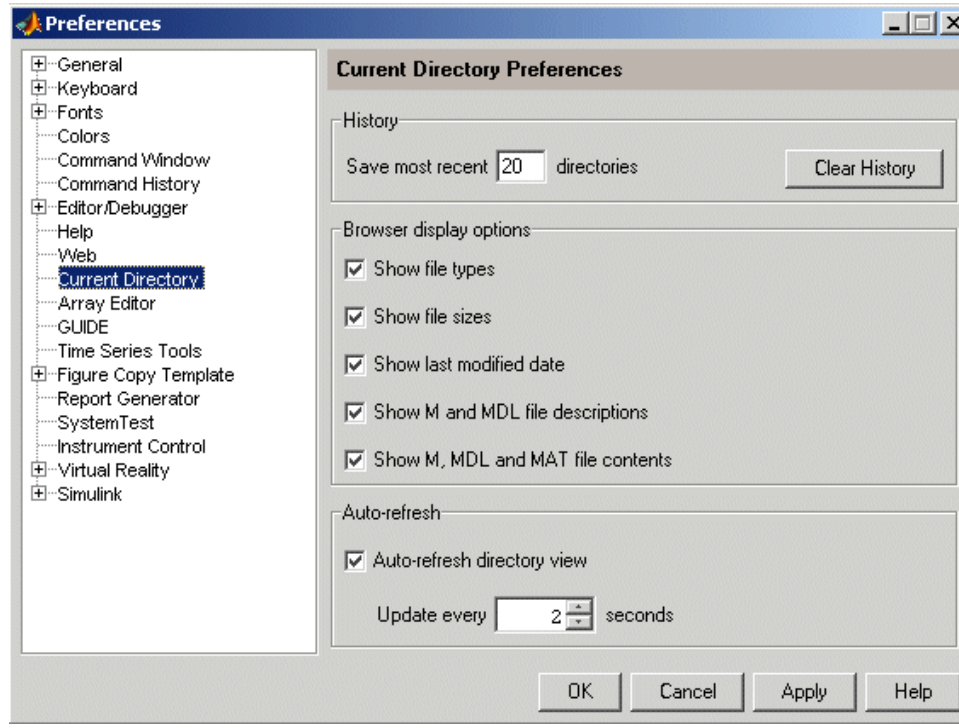
Accessing Source Control Features

Select a file or files in the Current Directory browser and right-click to view the context menu. From there you can access features for Source Control. For details on these features, see Chapter 9, "Source Control Interface".

Preferences for the Current Directory Browser

Using preferences, you can specify the number of recently used current directories to maintain in the history list as well as the type of information to display in the Current Directory browser.

From the Current Directory browser, select **File > Preferences**. The **Current Directory Preferences** pane appears in the Preferences dialog box.



History

The drop-down list in the current directory field shows the history of current directories, that is, the most recently used current directories.

Saving Directories. When the MATLAB session ends, the list of directories will be maintained. Use the **Save most recent directories** field to specify how many directories will appear on the list at the start of the next MATLAB session.

Removing Directories. To remove all entries in the list, click **Clear History**. The list is cleared immediately.

Browser Display Options

In the Current Directory browser, you can view or hide the following information by selecting the appropriate **Browser display options**:

- File type
- File size
- Last modified date
- M-file descriptions (the first comment line in the M-file, also called the H1 line) and the start of MDL file descriptions (approximately the first 128 characters)
- M-file help, MDL complete descriptions, and MAT-file contents

For more information, see “Changing the Display” on page 5-41.

Auto-Refresh

By default, the **Auto-refresh directory view** check box is selected, with an update time of 2 seconds. This means that every 2 seconds, the Current Directory browser checks for and reflects any changes you made to files and directories in the current directory using other applications.

In some cases when the current directory is on a network, MATLAB becomes slow because of the auto-refresh feature in the Current Directory browser. If you experience general slowness in MATLAB and have the Current Directory browser open, try increasing the default update time to alleviate this problem. For extremely slow performance situations, clear the check box to turn auto-refresh off. You can then right-click and select **Refresh** from the context menu to update the Current Directory browser display.

6

Editing and Debugging M-Files

MATLAB provides powerful tools for creating, editing, and debugging files, as detailed here. For information about the MATLAB language and writing M-files, see the MATLAB Programming documentation.

Navigating in an M-File (p. 6-42)	Go to a line number, function, bookmark, back and forward, and open a selection.
Finding Text in Files (p. 6-49)	Find and replace text in the current file or multiple files. Incremental search tool.
Comparing Files — File Comparison Tool (p. 6-54)	View differences between two files.
Keyboard Shortcuts in the Editor/Debugger (p. 6-59)	Use the keyboard to navigate in or perform other common actions in a file.
Saving, Printing, and Closing Files in the Editor/Debugger (p. 6-62)	Save and autosave features, printing and page setup, and closing files.
Running M-Files in the Editor/Debugger (p. 6-66)	Running M-files from the Editor/Debugger, with no input arguments or with input arguments
Finding Errors, Debugging, and Correcting M-Files (p. 6-84)	Automatically analyze code using M-Lint to find errors and make improvements, and use debugging features to isolate run-time problems.
M-Lint Code Analyzer (p. 6-87)	Check your code for problems and get recommendations to maximize performance and maintainability.
Debugging Process and Features (p. 6-103)	Graphical debugging tools and functions for debugging in the Command Window.
Using Cells for Rapid Code Iteration and Publishing Results (p. 6-133)	Define sections of your M-files as cells. Use cells for publishing M-files to formats like HTML. Also use cells to experiment and incrementally modify values in M-files.

Begin with Existing Code

In this section...

Create M-Files from Command Window and History

Before you begin writing MATLAB code in a blank file, consider starting with existing resources for the code, and then use the MATLAB Editor/Debugger to modify the code.

In many cases, you create and run MATLAB statements in the Command Window, modify those statements to your satisfaction, and then create an M-file that includes the statements. To facilitate this process, in the Command History, select the MATLAB statements you want to include in the M-file. Right-click and select **Create M-File**. The Editor/Debugger opens a new file that includes the statements you selected from the Command History. You can also copy the statements from the Command History and paste them into an existing M-file.

Use Existing M-Files and Examples

If you can find existing M-files that accomplish what you want to do, copy and use the code in your own M-file, assuming you have legal permission to do so. Following are some resources you can use.

MATLAB and Toolbox M-Files

You can access and reuse the code in most MATLAB and toolbox functions that have a `.m` file extension. You cannot use MATLAB and toolbox functions that are built-in. They are efficient but their code is not accessible.

If there is a MATLAB function that is similar to what you need to do and it is not built-in, open the file in the Editor/Debugger and use it as a basis for your file. Be sure to save the file using a different name and in a directory that is not in `matlabroot/toolbox`. See “Saving Files” on page 6-62 for details.

Demos and Examples

MATLAB and its toolboxes include demonstration programs. You can view the code in the demos and copy it for use in your own M-files. To see the demos, type `demo`, which opens the Help browser to the **Demos** pane. For more information about demos, see "Demos in the Help Browser" on page 4-31.

There are also code examples in the online documentation. To see a list of examples for a product, type `helpbrowser` to open the Help browser. In the **Contents** pane, click **+** for a product to view the help topics, and then select the **Examples** entry.

File Exchange

The MathWorks Web site features a user-contributed code library, from which you can download free M-files contributed by users and developers of MATLAB, Simulink, and related products. To view the files available to download, go to the MATLAB Central File Exchange page on the MathWorks Web site, `http://www.mathworks.com/matlabcentral/fileexchange/index.jsp`, or access it via the **Help > Web** menu in any desktop component.

Ways to Edit, Evaluate, and Debug M-Files

There are several methods for creating, editing, evaluating, and debugging files with MATLAB.

Creating and Editing Files — Options	Instructions
MATLAB Editor/Debugger	See "Starting, Customizing, and Closing the Editor/Debugger" on page 6-7, and "Saving, Printing, and Closing Files in the Editor/Debugger" on page 6-62. You can create, open, edit and save M-files as well as other file types in the MATLAB Editor/Debugger — see "Creating and Editing Other Text File Types" on page 6-12.
Any text editor, such as Emacs or vi	To specify another editor as the default for use with MATLAB, select **File > Preferences > Editor/Debugger**, and for **Editor**, specify the **Text editor**. Click the **Help** button in the Preferences dialog box for details. Use that editor by default, or use any other editor you open. Regardless of the editor you use, you can debug M-files using the MATLAB Editor/Debugger or debugging functions.

Debugging M-Files – Options	Instructions
General debugging tips	See "Finding Errors, Debugging, and Correcting M-Files" on page 6-84.
MATLAB Editor/Debugger	See • "M-Lint Code Analyzer" on page 6-87 to identify errors and make improvements. • "Debugging Process and Features" on page 6-103 to help you isolate run-time problems.
MATLAB debugging functions (for use in the Command Window)	See function alternatives in "Debugging Process and Features" on page 6-103.

Use preferences for the Editor/Debugger to set up the editing and debugging environment to best meet your needs.

For information about the MATLAB language and writing M-files, see the MATLAB Programming documentation.

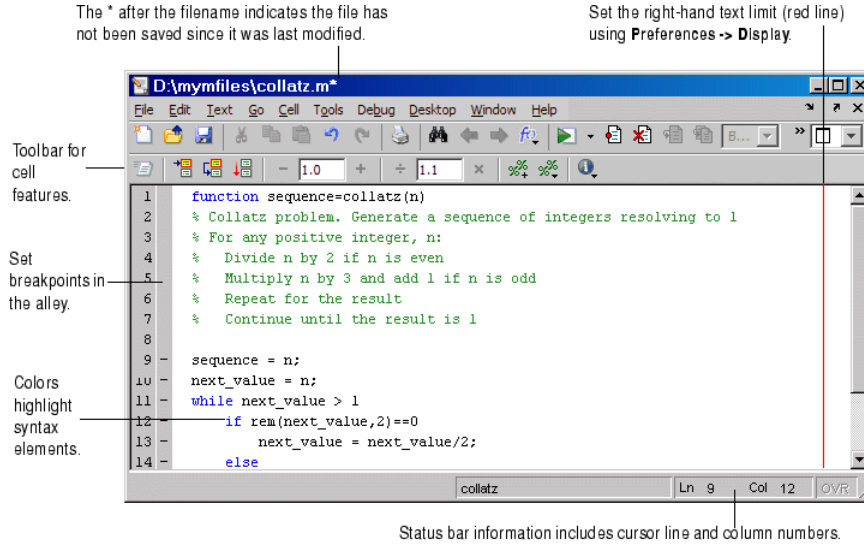
Starting, Customizing, and Closing the Editor/Debugger

In this section...

Starting the Editor/Debugger

The MATLAB Editor/Debugger provides a graphical user interface for basic text editing features for any file type, as well as for M-file debugging. The Editor/Debugger is a single tool that you can use for editing, debugging, or both. There are various ways to start the Editor/Debugger. The Editor/Debugger automatically starts when you open a document or create a new one. Once started, you can customize the Editor/Debugger to suit your needs.

This figure shows an example of the Editor/Debugger outside of the desktop opened to an existing M-file, and calls out some of the tool's useful features.



Creating a New File in the Editor/Debugger

To create a new text file in the Editor/Debugger, either click the New M-file button on the MATLAB desktop toolbar, or select **File > New > M-File** from the MATLAB desktop. The Editor/Debugger opens, if it is not already open, with an untitled file in the MATLAB current directory, in which you can create an M-file or another type of text file.

The location of the new file and the Editor/Debugger are determined by document positioning guidelines. You can rearrange the documents to suit your needs. For details, see “Opening and Arranging Documents” on page 2-8.

If the Editor/Debugger is open, create more new files by using the New M-file button on the toolbar, or select **File > New > M-File**.

Other tools also provide features for creating new M-files. For example, in the Command History, select statements, right-click, and select **Create M-File** from the context menu. Similarly, create a new file from the context menu in the Current Directory browser — see “Creating New Files” on page 5-44.

Function Alternative

Type `edit` in the Command Window to create a new file in the Editor/Debugger.

Type `edit filename.ext` to create the file `filename.ext`. If `filename.ext` already exists in the current directory or on the MATLAB search path, this opens the existing file. If `filename.ext` does not exist in the current directory or on the MATLAB search path, a confirmation dialog box might appear asking if you want to create a new file titled `filename.ext`:

- If you click **Yes**, the Editor/Debugger creates a blank file titled `filename.ext`. If you do not want the dialog to appear in this situation, select that check box in the dialog. Then, the next time you type `edit filename.ext`, the file is created without first prompting you.
- If you click **No**, the Editor/Debugger does not create a new file. If you do not want the dialog to appear in this situation, select that check box in the dialog. In that case, the next time you type `edit filename.ext`, a "`file not found`" message appears.

For more information about the confirmation dialog box, see preferences for "Confirmation Dialogs Preferences" on page 2-81.

Opening Existing Files in the Editor/Debugger

To open an existing file in the Editor/Debugger, click the Open file button on the desktop or Editor/Debugger toolbar, or select **File > Open**.

The **Open** dialog box appears, listing all M-files. You can see different files by changing the selection for **Files of type** in the dialog box. Type or select a filename, and click **Open**. If you access the **Open** dialog box from the desktop, the current directory files are shown, but if you access it from the Editor/Debugger, the files in the directory for the current file are shown.

The Editor/Debugger opens, if it is not already open, with the file displayed. You can have multiple Editor/Debugger files open at once, and the location of the files and the Editor/Debugger are determined by document positioning guidelines. You can rearrange the documents to suit your needs. For details, see "Opening and Arranging Documents" on page 2-8.

To make a document in the Editor/Debugger become the current document, click it, or select it from the **Window** menu or document bar.

M-File Cells

If you open an M-file that contains M-file cells, yellow highlighting and gray horizontal lines might appear in the M-file, along with an information toolbar. Cell mode is used for publishing results and rapid code iteration. An M-file cell is denoted by a %% at the start of a line. MATLAB interprets any M-file that contains %% at the start of a line as including cells and the Editor/Debugger reflect the cell toolbar state and the cell display preferences, such as yellow highlighting of the current cell and gray lines between cells.

The first time you open an M-file that contains cells, an information bar appears below the cell toolbar, providing links for details about cell mode. To dismiss the information bar, click the close box on the right side of the bar. The information bar does not appear again, but you can get the same quick access to the information about M-file cells from the information button on the cell toolbar.

To hide the cell toolbar, right-click in the toolbar and select **Cell Toolbar** from the context menu. If you do not want cell mode enabled, select **Cell > Disable Cell Mode**. Because MATLAB remembers the cell mode between sessions, if cell mode is disabled when you quit MATLAB, it is disabled the next time you start MATLAB, and the converse is true.

Other Methods for Opening Files in the Editor/Debugger

These are other ways to open files in the Editor/Debugger:

- Drag a file from another MATLAB desktop tool or a Windows tool into the Editor/Debugger. For example, drag files from the Current Directory browser, or from Windows Explorer.
- Open files from the Current Directory browser — see “Opening Files” on page 5-47.
- Select a file to open from the most recently used files, which are listed at the bottom of the **File** menu in the Editor/Debugger and all other desktop tools. You can change the number of files appearing on the list — select

File > Preferences > Editor/Debugger and in the **Most recently used file list**, specify the **Number of entries**.

- In the Editor/Debugger or another desktop tool such as the Command Window, select a filename, right-click, and select **Open Selection** from the context menu to open that file. For details, see "Opening a Selection in an M-File" on page 6-48.
- Set a preference that instructs MATLAB, upon startup, to automatically open the files that were open when the previous MATLAB session ended. Select **File > Preferences > Editor/Debugger** and in the **Opening files in editor area**, select the check box for **On restart reopen files from previous MATLAB session**.

Function Alternative for Opening an M-File. Use the `edit` or `open` function to open an existing file in the Editor/Debugger. For example, type

```
edit collatz.m
```

to open the file `collatz.m` in the Editor/Debugger, where `collatz.m` is on the search path or in the current directory. Use the relative or absolute pathname for the file you want to open if it is not on the search path or in the current directory.

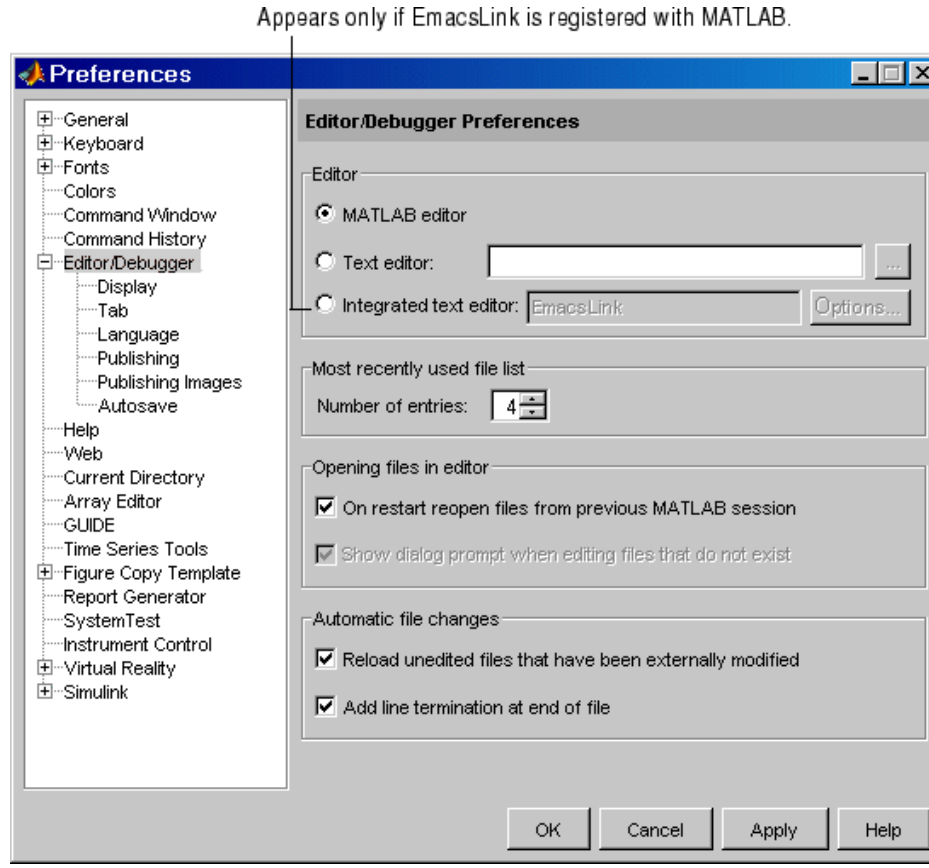
Arranging Editor/Debugger Documents

You can arrange the size and location of M-files and other text documents you open in the Editor/Debugger. Editor/Debugger documents follow the same arrangement practices as other desktop documents. For details, see "Opening and Arranging Documents" on page 2-8.

Preferences for the Editor/Debugger

Using preferences, you can specify the default behavior for various aspects of the Editor/Debugger.

To set preferences for the Editor/Debugger, select **File > Preferences**. The Preferences dialog box opens showing **Editor/Debugger Preferences**.



Click the **+** next to Editor/Debugger in the left pane to view all categories of Editor/Debugger preferences. Select a category and that preference pane displays. Make changes and click **Apply** or **OK**.

Click the **Help** button in the Preferences dialog box for details about Editor/Debugger preferences.

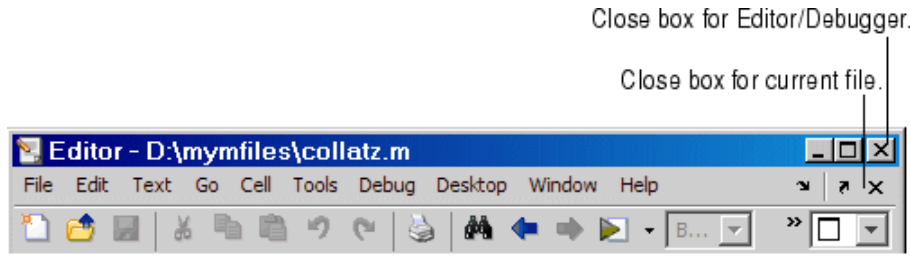
Creating and Editing Other Text File Types

You can edit any type of text file using the MATLAB Editor/Debugger. For example, you can open and edit an HTML file. Note that you can run or debug only M-files from the Editor/Debugger.

When working with files created for C/C++, Java, and HTML, you can specify syntax highlighting and indenting preferences appropriate to those languages. Select **File > Preferences > Editor/Debugger > Language**. See details in the online documentation for Editor/Debugger language preferences, or click the **Help** button in the dialog box.

Closing the Editor/Debugger

To close the Editor/Debugger, click the **Close** box in the title bar of the Editor/Debugger. This is different from the **Close** box in the menu bar of the Editor/Debugger, which closes the current file when multiple files are open in a single window.



If multiple files are open, with each in a separate window, close each window separately. To close all files at once, select **Close All Documents** from the **Window** menu. Note that this will close other desktop documents as well, such as arrays in the Array Editor, and it will close the tools as well, that is, the Editor/Debugger and Array Editor, for example.

When you close the Editor/Debugger and any of the open files have unsaved changes, you are prompted to save the files.

Entering Statements in the Editor/Debugger

In this section...

Use Command Window Features in the Editor/Debugger

After opening an existing file or creating a new file in the Editor/Debugger, enter statements in the file. Follow the same rules you would use for entering statements in the Command Window as described in Chapter 3, "Running Functions — Command Window and History":

- "Case and Space Sensitivity" on page 3-15
- "Matching Delimiters (Parentheses)" on page 3-17
- "Entering Multiple Functions in a Line" on page 3-18
- "Entering Long Statements (Line Continuation)" on page 3-18
- "Suppressing Output" on page 3-30
- "Formatting and Spacing Numeric Output" on page 3-31

In addition, utilize the Editor/Debugger features described in the remaining parts of this section.

Changing the Case of Selected Text

To change the case of text in the Editor/Debugger, select the text and then from the **Text** menu, select one of the following:

- **Change to Upper Case** to change all text to uppercase
- **Change to Lower Case** to change all text to lowercase

- **Reverse Case** to change the case of each letter

This is useful, for example, when copying syntax from help in an M-file, where function and variable names are distinguished by the use of uppercase. But because of that, the code will not run in MATLAB. In this example, the text was copied and pasted from the output of `help get`.

```
V = GET(H, 'Default')
```

Select all of the text. Select **Text > Change to Lower Case**. The text becomes

```
v = get(h, 'default')
```

If instead you select **Reverse Case** for

```
V = GET(H, 'Default')
```

the case changes to

```
v = get(h, 'dEFAULT')
```

Undo and Redo

You can undo many of the Editor/Debugger actions listed in **Edit** and **Text** menus. Select **Edit > Undo**. You can undo multiple times in succession until there are no remaining actions to undo. Select **Edit > Redo** to reverse an undo.

Adding Comments

Comments in an M-file are strings or statements that do not execute. Add comments in an M-file to describe the code or how to use it. Comments determine what text displays when you run `help` for a filename. Use comments when testing your files or looking for errors—temporarily turn lines of code into comments to see how the M-file runs without those lines. These topics provide details:

- “Commenting in M-Files Using the MATLAB Editor/Debugger” on page 6-16

Commenting in M-Files Using the MATLAB Editor/Debugger

You can comment the current line or a selection of lines in an M-file:

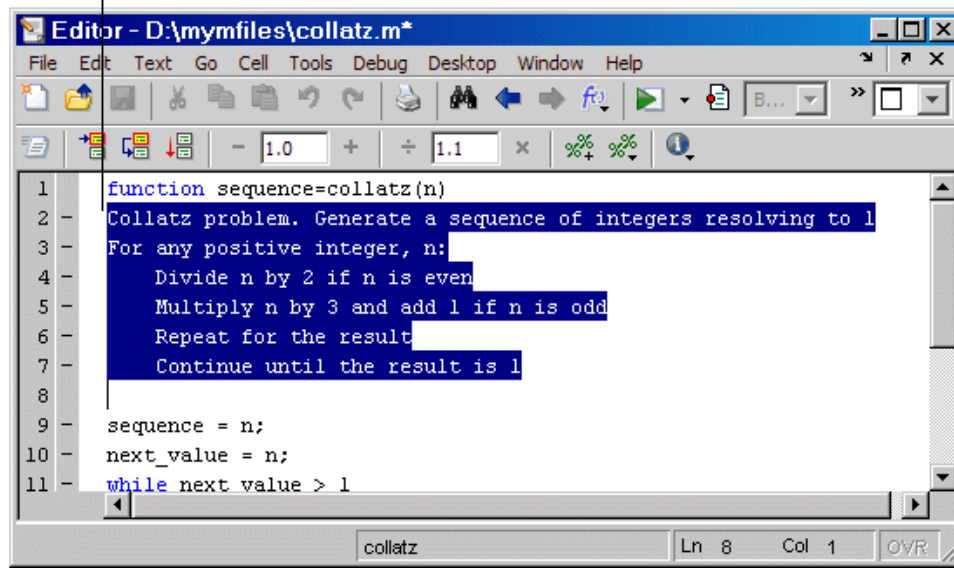
1. For a single line, position the cursor in that line. For multiple lines, click in the line and then drag or **Shift**+click to select multiple lines.
2. Select **Comment** from the **Text** menu, or right-click and select it from the context menu.

A comment symbol, `%`, is added at the start of each selected line, and the color of the text becomes green or the color specified for comments — see "Syntax Highlighting" on page 6-28.

To uncomment the current line or a selected group of lines, select **Uncomment** from the **Text** menu, or right-click and select it from the context menu.

Click in the area to the left of a line to select that line.
To select multiple lines, click+drag or **Sh**ift+click.

Select **Text -> Comment** to make all the selected lines comments.



Commenting in Java and C/C++ Files Using the MATLAB Editor/Debugger

For Java and C/C++ files, selecting **Text > Comment** adds the // symbols at the front of the selected lines. Similarly, **Text > Uncomment** removes the // symbols from the front of selected lines in Java and C/C++ files.

Commenting in M-File Using Any Text Editor

You can make any line in an M-file a comment by typing % at the beginning of the line. To put a comment within a line, type % followed by the comment text; MATLAB treats all the information after the % on a line as a comment.

```
% This is a comment.
```
——MATLAB ignores this comment line when you run the M-file.

```
This is not a comment.
```
——This line produces an error when you run the M-file.

To uncomment any line, delete the comment symbol, %.

To comment a contiguous group of lines, type `%{` before the first line and `%}` after the last line you want to comment. This is referred to as a block comment. The lines that contain `%{` and `%}` can contain spaces, but not contain any other text. After typing the opening block comment symbol, `%{`, all subsequent lines assume the syntax highlighting color for comments until you type the closing block comment symbol, `%}`. Remove the block comment symbols, `%{` and `%}`, to uncomment the lines.

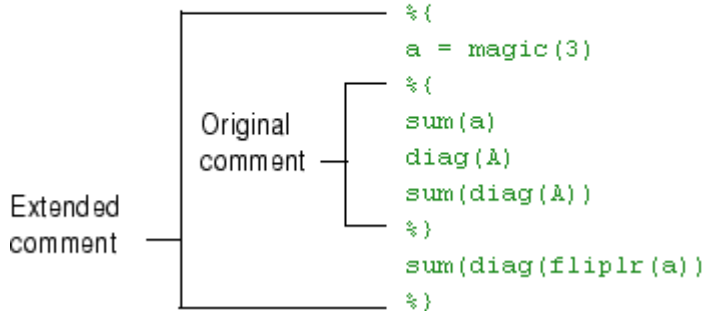
This examples shows some lines of code commented out. When you run the M-file, the commented lines will not execute. This is useful when you want to identify the section of a file that is not working as expected.

Comment a block of code by adding `%{` before the first line and `%}` after the last line.

```
a = magic(3)
%{
sum(a)
diag(A)
sum(diag(a))
%}
sum(diag(fliplr(a)))
```

You can easily extend a block comment without losing the original block comment, that is, create a nested block comment, as shown in the following example.

Create a nested comment, that is, a block comment within a block comment.



Commenting Out Part of a Statement

To comment out the end of a statement in an M-file, put the comment character, `%`, before the comment. When you run the file, MATLAB ignores any text on the line after the `%`.

Any text following a `%` within a line is considered to be a comment.

```
a = zeros(10) % Initialize matrix
```

To comment out text within a multiline statement, use the ellipsis (`...`). MATLAB ignores any text appearing after the `...` on a line and continues processing on the next line. This effectively makes a comment out of anything on the current line that follows the `...`. The following example comments out the `Middle Initial` line.

```
header = ['Last Name, '...
'First Name, '...
... 'Middle Initial, '...
'Title']
```

MATLAB ignores the text following the `...` on the line

```
... 'Middle Initial, '...
```

Note that `Middle Initial` is green, which is the syntax highlighting color for a comment.

MATLAB continues processing the statement with the next line

```
'Title']
```

MATLAB effectively runs

```
headers = ['Last Name, ' ...
'First Name, ' ...
'Title']
```

Formatting Comments in M-Files

To make comment lines in M-files wrap when they reach a certain column,

1. Specify the maximum column number using preferences for the Editor/Debugger. Select **Language > M**. For **Comment formatting**, set the **Max width**.

2. Select contiguous comment lines that you want to limit to the specified maximum width.

3. Select **Text > Wrap Selected Comments**.

   The selected comment lines are reformatted so that no comment line in the selected area is longer than the maximum. Lines that were shorter than the specified maximum are merged to make longer lines if they are at the same level of indentation.

To automatically limit comment lines to the maximum width while you type, select the **Comment formatting** preference to **Autowrap comments**.

For example, assume you select **Autowrap comments** and set the maximum width to be 75 characters, which is the width that will fit on a printed page using the default font for the Editor/Debugger. When typing a comment line,

as you reach the 75th column, the comment automatically continues on the next line.

Tab Completion in the Editor/Debugger

The Editor/Debugger helps you automatically complete the names of these items as you type them in an M-file:

- Functions or models on the search path or in the current directory
- Variables, including structures, in the current workspace, where the current workspace is shown in the **Stack** on the toolbar.
- Handle Graphics properties for figures in the current workspace

Type the first few characters of the item name and then press the **Tab** key. To use tab completion, you must have the tab completion preference for the Editor/Debugger selected. For details, see “Keyboard Preferences” on page 3-43.

Tab completion is also available in the Command Window. There are a few minor differences in how tab completion works in the Command Window, the most notable being that Command Window tab completion supports the completion of filenames, whereas the Editor/Debugger tab completion does not.

Note Tab completion does not complete the names of variables you define in an M-file, but only those variables in the current workspace. This means that while editing, it only completes the names of variables in the base workspace. While debugging, it only completes the names of variables in the current function workspace.

These examples demonstrate how to use tab completion:

- “Basic Example — Unique Completion” on page 6-22
- “Multiple Possible Completions” on page 6-23
- “Narrowing Completions Shown” on page 6-24

Basic Example — Unique Completion

This example illustrates a basic use for tab completion in the Editor/Debugger. In an M-file opened in the Editor/Debugger, type the beginning of a function or model on the MATLAB search path or in the current directory, for example,

```
horz
```

and press **Tab**. The Editor/Debugger automatically completes the name, which for this example displays the function name

```
horzcat
```

Complete the statement, adding any arguments, operators, or options. If the Editor/Debugger does not complete the name `horzcat` but instead moves the cursor to the right, you do not have the preference set for tab completion. The Editor/Debugger also moves the cursor to the right when you try to complete a filename; filename tab completion is not supported in the Editor/Debugger, but is supported in the Command Window.

You can use tab completion anywhere in the line, not just at the beginning. For example, if you type

```
a = horz
```

and press **Tab**, the Editor/Debugger completes `horzcat`.

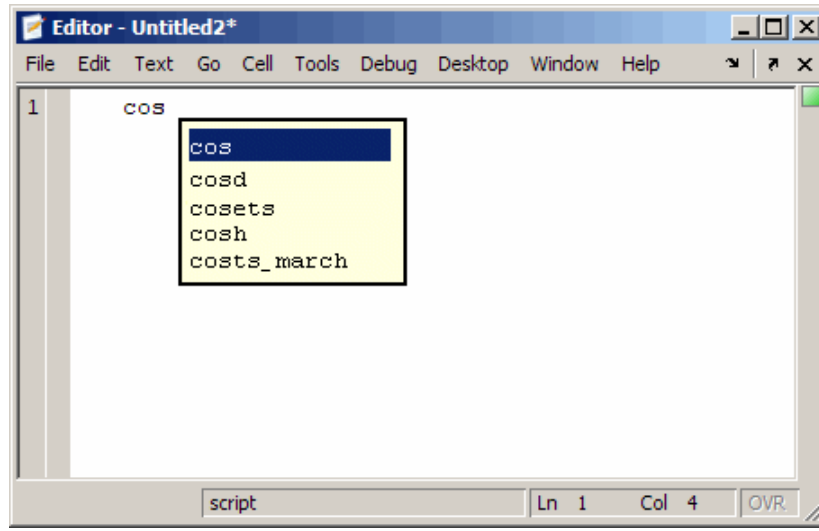
The Editor/Debugger also completes the names of variables in the current workspace. For example, if there is a variable `costs_march` in the currently selected workspace, type `cost` and press **Tab**. The Editor/Debugger completes the variable name `costs_march`. If MATLAB displays `No Completions Found`, `costs_march` does not exist in the current workspace.

Multiple Possible Completions

If there is more than one name that starts with the characters you typed, when you press the **Tab** key, the Editor/Debugger displays a list of all names that start with those characters. For example, assume you had created the variable `costs_march` in the base workspace. In an M-file in the Editor/Debugger, type

```
cos
```

and press **Tab**. The Editor/Debugger displays



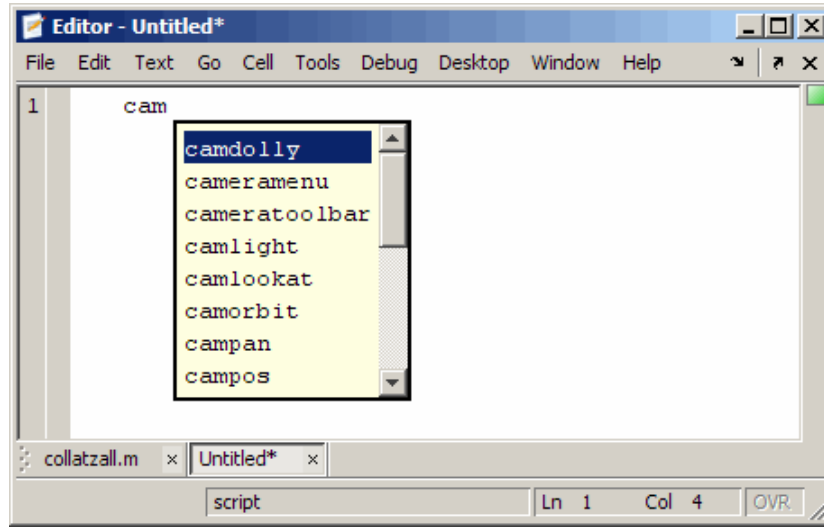
The resulting list of possible completions includes the variable name you created, `costs_march`, but also includes functions and models that begin with `cos`, including `cosets` from Communications Toolbox, if it is installed and on the MATLAB search path.

Continue typing to make your entry unique. For example, type the next character, such as `t` in the example. The Editor/Debugger selects the first item in the list that matches what you typed, in this case, `costs_march`. Press **Enter** (or **Return**) or **Tab** to select that item, which completes the name in the M-file. In the example, MATLAB displays `costs_march` at the prompt.

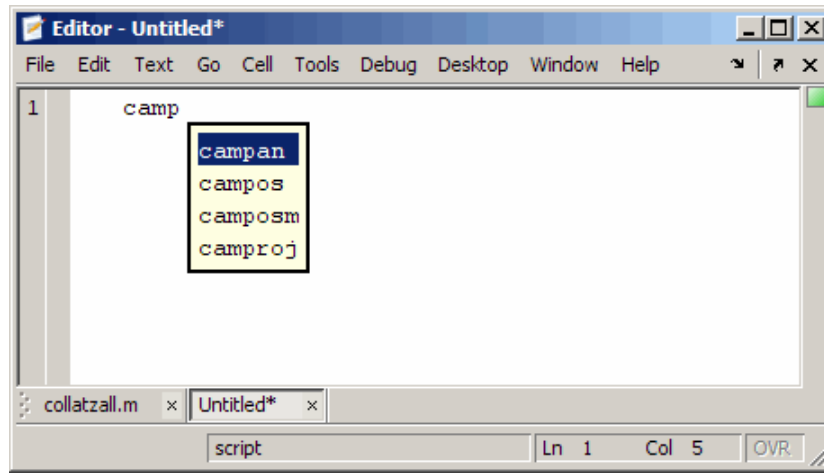
You can navigate the list of possible completions using up and down arrow keys, and **Page Up** and **Page Down** keys. You can clear the list without selecting anything by pressing **Esc**. The list of possible completions might include items that are not valid commands, such as private functions.

Narrowing Completions Shown

You can narrow the list of completions shown by typing a character and then pressing **Tab** if the **Keyboard** preference **Tab key narrows completions** is selected. This is particularly useful for large lists. For example, type `cam` and press **Tab** to see the possible completions. There is a scroll bar with the list because there are too many completions to be seen at once.



Type `p` and press **Tab** again. The Editor/Debugger narrows the list, showing only all possible `camp` completions.



Continue narrowing the list in the same way. For the above example, type `o` and press **Tab** to further narrow the list. Press **Enter** or **Return** to select an item, which completes the name at the prompt.

Tab Completion for Structures

For structures that are in the current workspace, after the period separator, press **Tab**. For example, type

```
mystruct.
```

and press **Tab** to display all fields of `mystruct`. If you type a structure and include the start of a unique field after the period, pressing **Tab** completes that structure and field entry.

For example, type

```
mystruct.n
```

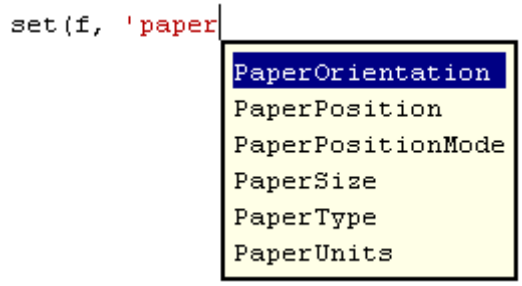
and press **Tab**, which completes the entry `mystruct.name`, where `mystruct` is in the current workspace and contains no other fields that begin with `n`.

Tab Completion for Properties

Complete property names for figures in the current workspace using tab completion, as in this graphics example. Here, `f` is a figure. Type

```
set(f, 'pap
```

and press **Tab**. The Editor/Debugger displays



Select a property from the list. For example, type

```
u
```

and press **Enter**. The Editor/Debugger completes the property, including the closing quote.

```
set(f, 'paperunits'
```

Continue adding to the statement, as in this example,

```
set(f, 'paperunits', 'c
```

and press **Tab**. The Editor/Debugger automatically completes the property

```
set(f, 'paperUnits', 'centimeters'
```

because `centimeters` is the only possible completion.

Using Tab for Spacing

If the preference for tab completion is selected, and you want to also use the **Tab** key to add spacing within your statements, add a space before pressing **Tab**. For example, to create this statement

```
if a=mate     %test input value
```

add a space after `mate` and then press **Tab**. If you do not include the space, the following happens instead:

```
if a=material
```

This is because the tab completion feature automatically causes `mate` to complete as the `material` function.

Alternatively, turn off the tab completion preference to use **Tab** for spacing in the Editor/Debugger.

Appearance of an M-File — Making Files More Readable

In this section...

Note You can specify the default behaviors for some of these features—see "Preferences" on page 2-59.

Syntax Highlighting

Some entries appear in different colors to help you better find matching elements, such as `if/else` statements. Similarly, unterminated strings have a different color than terminated strings. This is called syntax highlighting and is used in the Command Window and History, as well as in the Editor/Debugger. For more information, see the Command Window documentation for "Syntax Highlighting" on page 3-16.

When you paste or drag a selection from the Editor/Debugger to another application, such as Microsoft Word, the pasted text maintains the syntax highlighting colors and font characteristics from the Editor/Debugger. MATLAB pastes the selection to the clipboard in RTF format, which many Windows and Macintosh applications support.

Indenting

Automatic Indenting

You can set an indenting preference so that program control entries are automatically indented to make reading loops, such as `while`/`end` statements, easier. To do so, select **File > Preferences > Editor/Debugger > Language**, and select a **Language**, for example, `M`. For **Indenting for Enter key**, select **Smart indenting** or **Block indent**, and then click **OK**. Use **No indent** instead if you want to indent manually. For more information about indenting preferences, see the in the online documentation. Specify the indenting size and other options using in the online documentation.

Manual Indenting

You can manually apply smart indenting to selected lines — select the lines and then select **Smart Indent** from the **Text** menu, or right-click and select it from the context menu. This feature indents lines that start with keyword functions or that follow lines containing certain keyword functions. Smart indenting can help you to follow the code sequence.

To move the current or selected lines further to the left, select **Decrease Indent** from the **Text** menu. To move the current or selected lines further to the right, select **Increase Indent** from the **Text** menu.

You can also indent a line by pressing the **Tab** key at the start of a line. Or select a line or group or lines and press the **Tab** key. Press **Shift+Tab** to decrease the indent for the selected lines. This works differently if you select the Editor/Debugger **Tab** preference for **Emacs-style Tab key smart indenting** — when you position the cursor in any line or select a group of lines and press **Tab**, the lines indent according to smart indenting practices.

For more information about manual indenting, see in the online documentation.

Function Indenting

If you select the language preference for smart indent, you can select from three indenting options when you enter a subfunction or a nested function

(a function within a function) in the Editor/Debugger. For details, see in the online documentation.

Line and Column Numbers

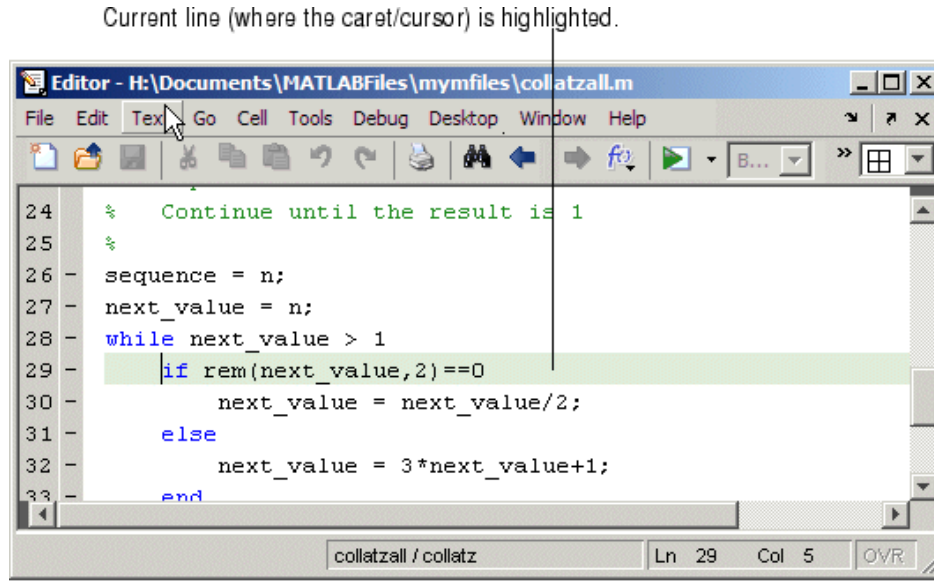
Line numbers are displayed along the left side of the Editor/Debugger window. You can elect not to show the line numbers using preferences — for details, see in the online documentation.

The line and column numbers for the current cursor position are shown in the far right side of the status bar in the Editor/Debugger.

Highlight Current Line

You can set a preference to highlight the current line, that is the line with the caret (also called the cursor). This is useful, for example, to help you see where copied text will be inserted when you paste.

To highlight the current line, select **File > Preferences > Editor/Debugger > Display**, and under **General display options**, select the check box for **Highlight current line**. You can also specify the color used to highlight the line.



Right-Hand Text Limit

By default, a light red vertical line (rule) appears at column 75 in the Editor/Debugger, providing a cue as to when a line becomes wider than desired, which is useful if you plan to print the file, for example. You can hide the line or change the column number at which it appears — see in the online documentation.

View Function or Subfunction

The function or subfunction the cursor is currently at is shown at the right side of the status bar in the Editor/Debugger.

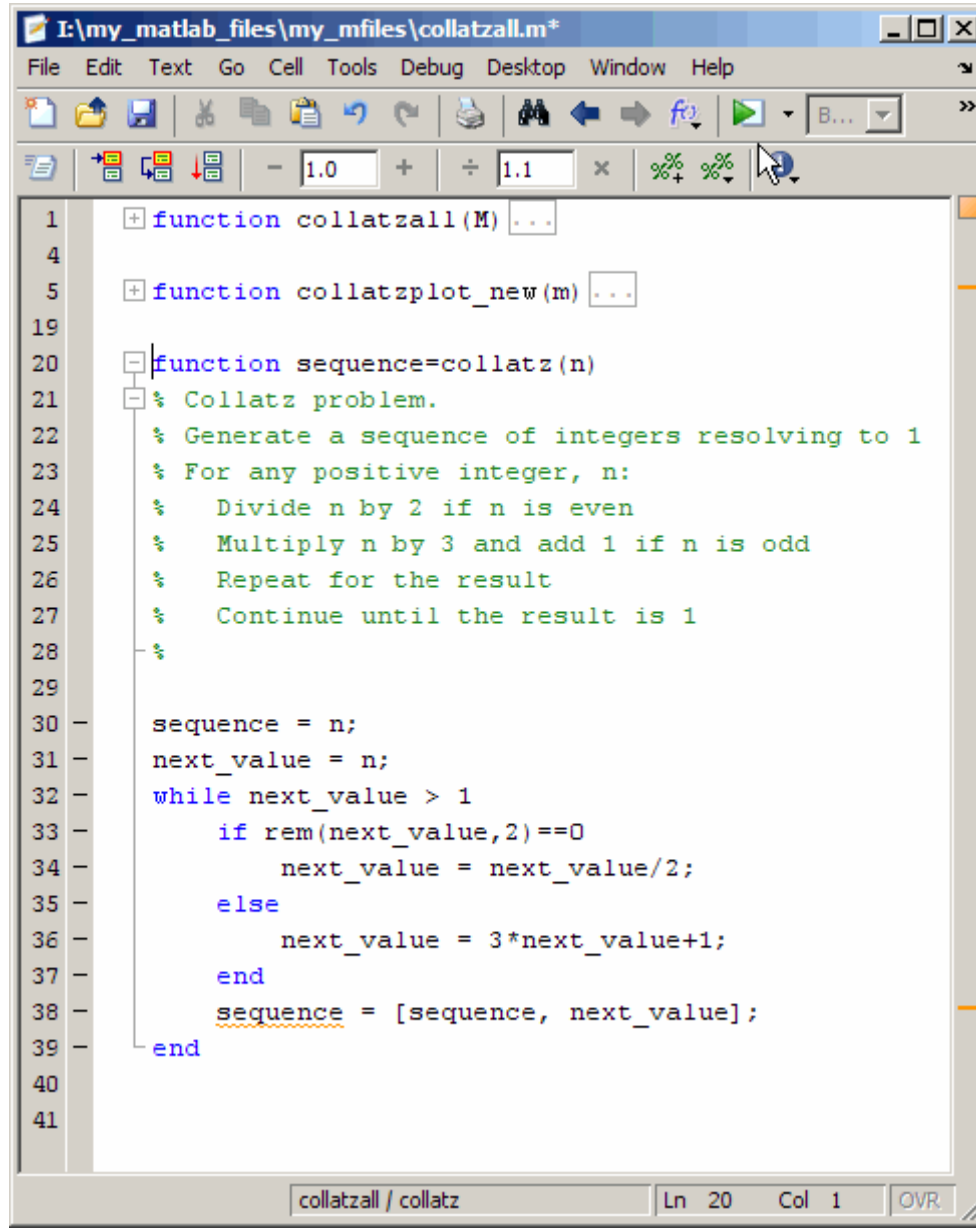
Code Folding—Expanding and Collapsing M-File Constructs

You can enable or disable the ability to expand and collapse M-file programming constructs; this ability is referred to as code folding. Programming constructs include functions and function help.

Code folding is particularly useful for improving readability when an M-file contains numerous subfunctions and you want to hide code on which you are not currently working.

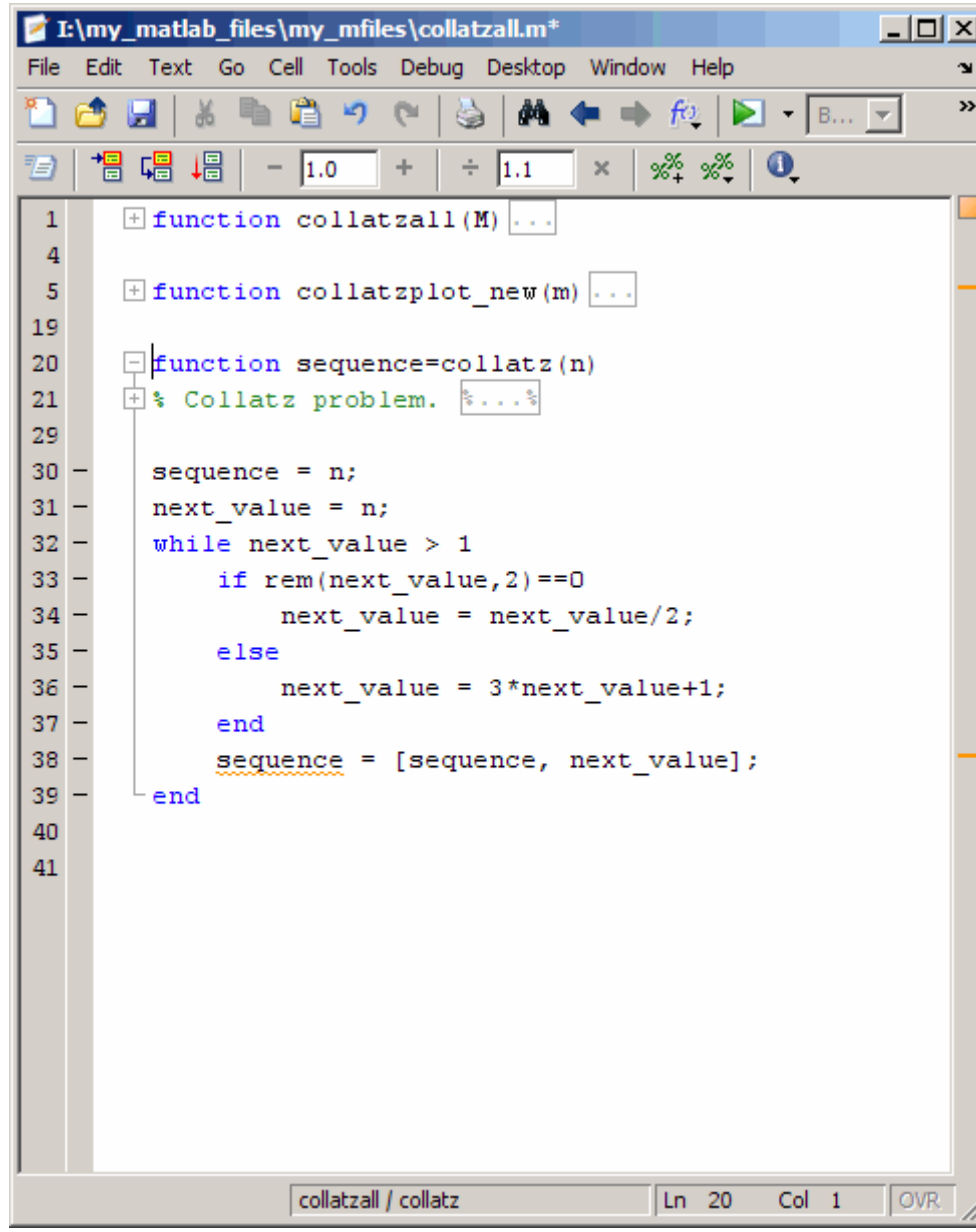
When you fold a function, all the code associated with that function (including any help code) is collapsed such that the Editor/Debugger displays only the function definition line. The function definition line is appended with an ellipsis icon  to indicate there is more function code.

The following image shows the `collatz` function code expanded and the `collatzall` and `collatzplot_new` functions collapsed:



I:\my_matlab_files\my_mfiles\collatzall.m*
File Edit Text Go Cell Tools Debug Desktop Window Help
1.0
1.1
1 function collatzall(M) ...
4
5 function collatzplot_new(m) ...
19
20 function sequence=collatz(n)
21 % Collatz problem.
22 % Generate a sequence of integers resolving to 1
23 % For any positive integer, n:
24 % Divide n by 2 if n is even
25 % Multiply n by 3 and add 1 if n is odd
26 % Repeat for the result
27 % Continue until the result is 1
28 %
29
30 sequence = n;
31 next_value = n;
32 while next_value > 1
33 if rem(next_value,2)==0
34 next_value = next_value/2;
35 else
36 next_value = 3*next_value+1;
37 end
38 sequence = [sequence, next_value];
39 end
40
41
collatzall / collatz
Ln 20 Col 1
OVR

When you expand a function, but collapse its associated help code, the Editor/Debugger displays all the function code and just the H1 line of the help code. The H1 line ends with a commented ellipsis icon  to indicate there is additional help code, as shown in the following image:



I:\my_matlab_files\my_mfiles\collatzall.m*
File Edit Text Go Cell Tools Debug Desktop Window Help
1.0
1.1
1 function collatzall(M) ...
4
5 function collatzplot_new(m) ...
19
20 function sequence=collatz(n)
21 % Collatz problem. %...%
29
30 sequence = n;
31 next_value = n;
32 while next_value > 1
33 if rem(next_value,2)==0
34 next_value = next_value/2;
35 else
36 next_value = 3*next_value+1;
37 end
38 sequence = [sequence, next_value];
39 end
40
41
collatzall / collatz
Ln 20 Col 1
OVR

To expand code for a construct that is currently collapsed, do one of the following:

- Click the plus sign icon ⊞ to the left of the construct that you want to expand.
- Place your cursor in the code that you want to expand, right-click, and then select **Code Folding > Expand** from the context menu.

To collapse code for a construct that is currently expanded, do one of the following:

- Click the minus sign icon ⊟ to the left of the construct that you want to collapse.
- Place your cursor in the code that you want to collapse, right-click, and then select **Code Folding > Collapse** from the context menu.

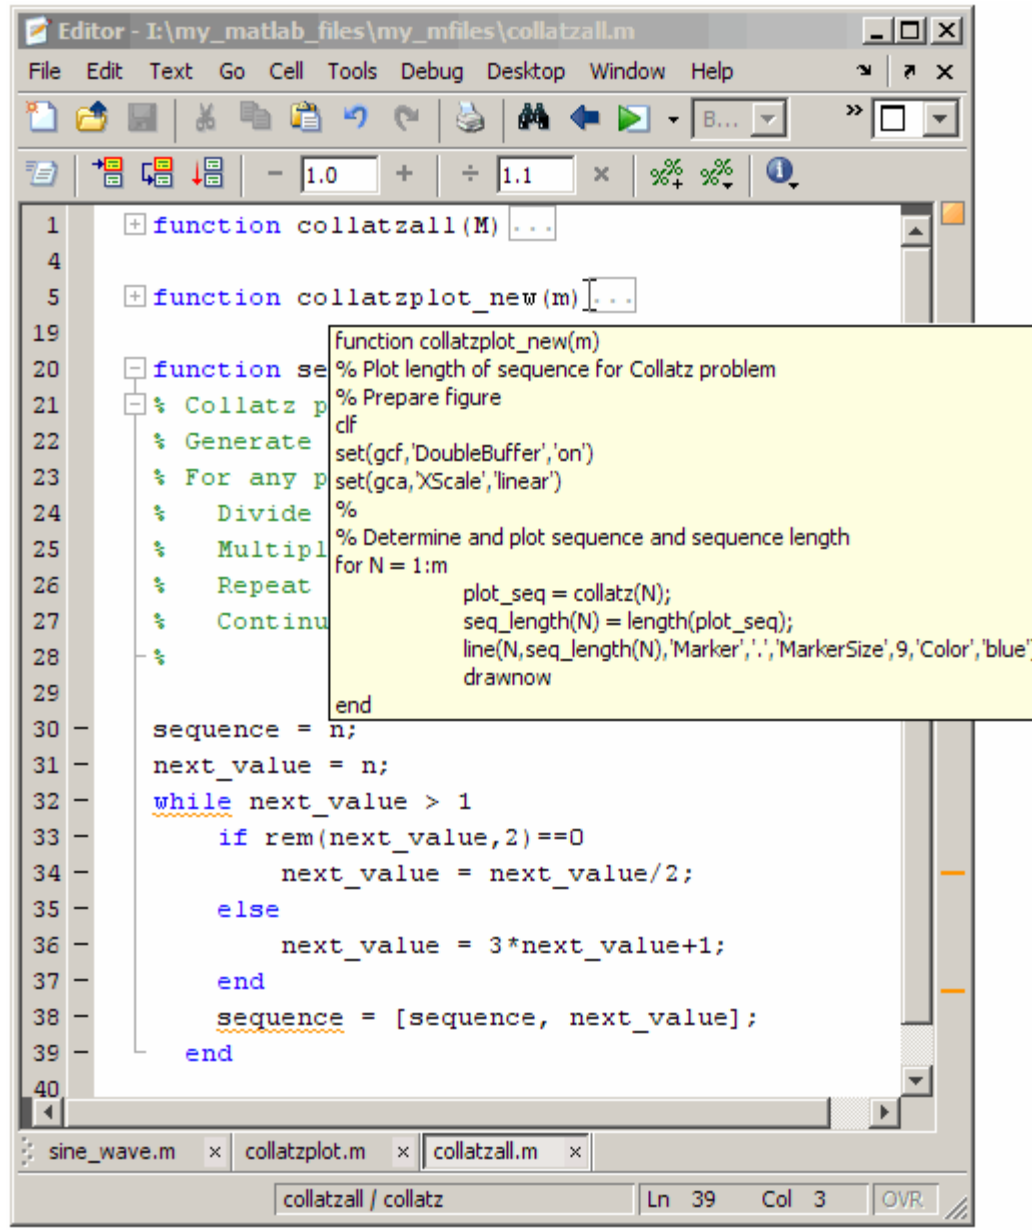
To expand or collapse all of the code in an M-file, place your cursor anywhere within the M-file, right-click, and then select **Code Folding > Expand All** or **Code Folding > Collapse All** from the context menu.

For information on the structure of an M-file, including a description of a function definition line and an H1 line, see Basic Parts of an M-File in the MATLAB Programming documentation

Viewing Folded Code in a Tooltip

You can view code that is currently folded by positioning the pointer over its ellipsis icon ... . The code displays in a tooltip. This enables you to get a quick view of the code without requiring you to unfold it.

The following image shows the tooltip that displays when the pointer is placed over the ellipsis icon on line 5 of collatzall.m when the collatzplot_new function is folded.



Editor - I:\my_matlab_files\my_mfiles\collatzall.m
File Edit Text Go Cell Tools Debug Desktop Window Help
1.0
1.1
function collatzall(M) ...
function collatzplot_new(m) ...
function collatzplot_new(m)
% Plot length of sequence for Collatz problem
% Prepare figure
clf
set(gcf,'DoubleBuffer','on')
set(gca,'XScale','linear')
%
% Determine and plot sequence and sequence length
for N = 1:m
plot_seq = collatz(N);
seq_length(N) = length(plot_seq);
line(N,seq_length(N),'Marker','.','MarkerSize',9,'Color','blue')
drawnow
end
sequence = n;
next_value = n;
while next_value > 1
if rem(next_value,2)==0
next_value = next_value/2;
else
next_value = 3*next_value+1;
end
sequence = [sequence, next_value];
end
sine_wave.m
collatzplot.m
collatzall.m
collatzall / collatz
Ln 39 Col 3
OVR

Code Folding Behavior and Preferences

Be aware of the following:

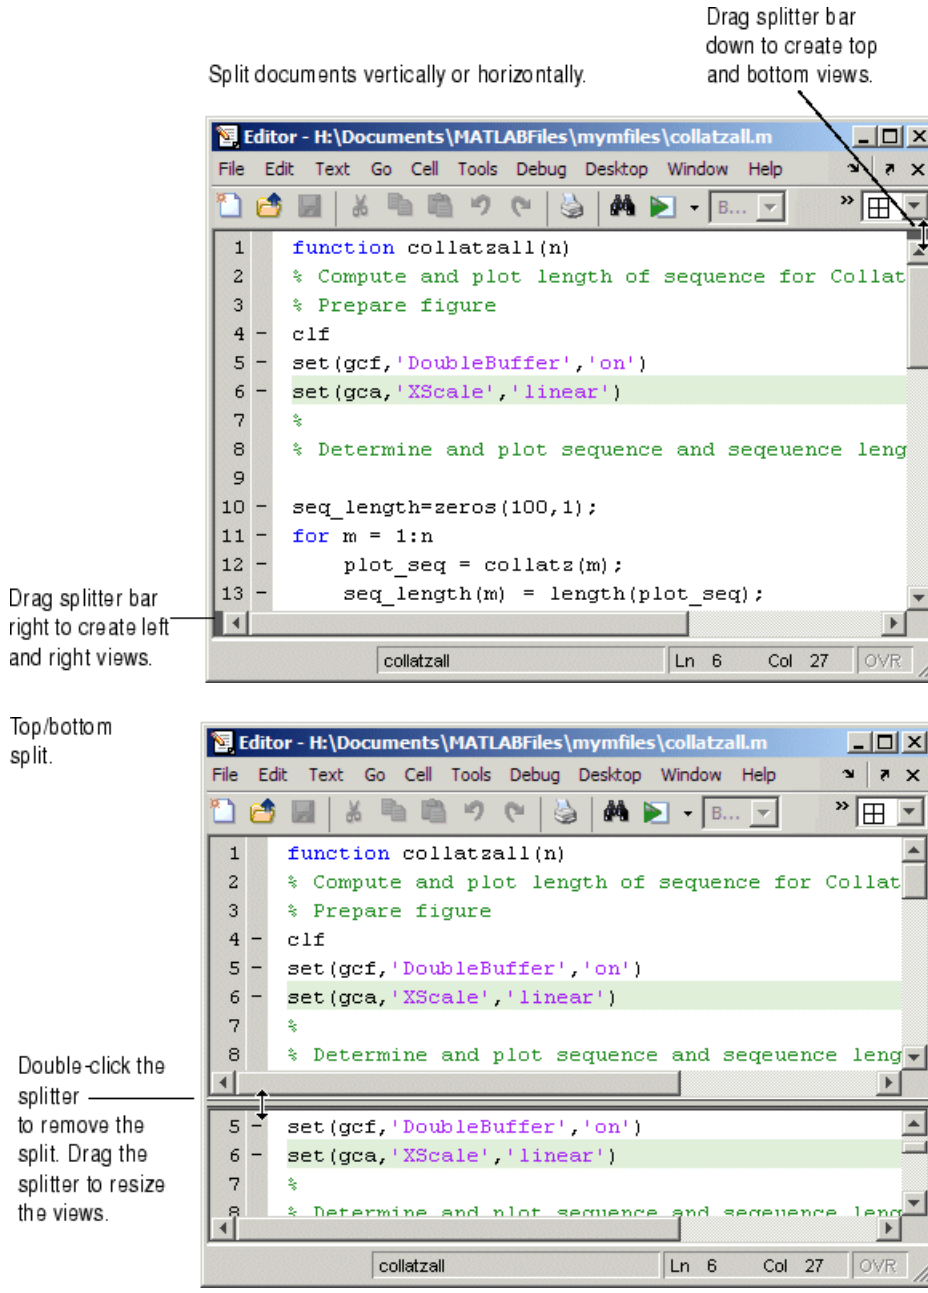
- You can change the current code folding settings, by selecting **File > Preferences > Editor/Debugger > Code Folding** and then clicking **Help** for assistance.
- By default, the first time you open an existing M-file in MATLAB release 7.5 (R2007b), code folding is enabled and all constructs are expanded.
- Constructs that are collapsed when you close an M-file remain collapsed when you reopen the file.
- If you copy a collapsed construct from one region of an M-file and paste it in another region, the construct is expanded in the pasted location.
- If you print a file with one or more collapsed constructs, those constructs are expanded in the printed version of the file.

Split Screen Display

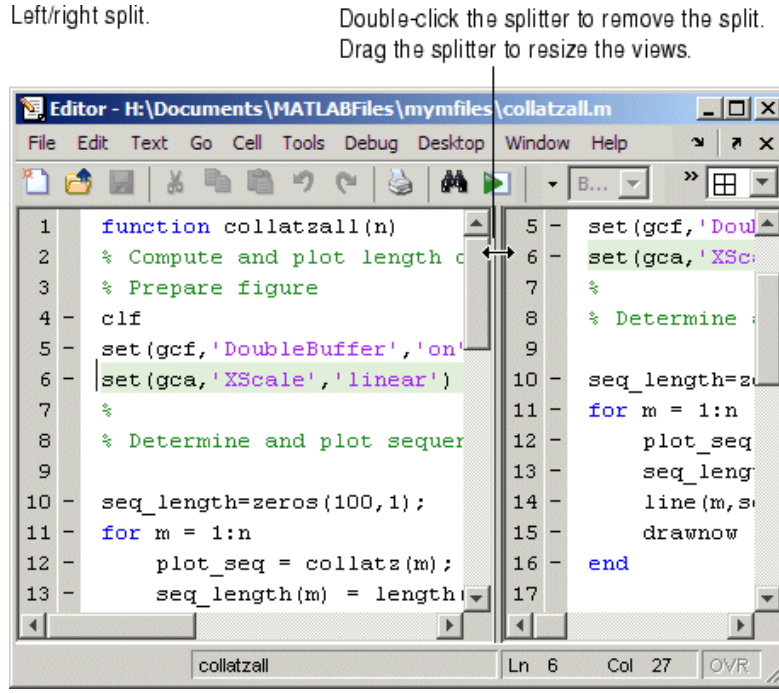
You can simultaneously display two different parts of a file in the Editor/Debugger. This makes it easy to compare different lines in a file or to copy and paste from one part of a file to another.

Split the screen horizontally by selecting **Window > Split Screen > Top/Bottom**. Or to split it vertically, select **Left/Right**.

Alternatively, when there is a scroll bar, split the document into top and bottom views by dragging the splitter bar, (as shown in the following illustration), down from above the vertical scroll bar. Similarly, to split into left and right views, drag the splitter bar from the left of the horizontal scroll bar. The pointer assumes a double-headed arrow shape when it is positioned on the splitter bar.



Split documents vertically or horizontally.
Drag splitter bar down to create top and bottom views.
Drag splitter bar right to create left and right views.
Top/bottom split.
Double-click the splitter to remove the split. Drag the splitter to resize the views.
Editor - H:\Documents\MATLABFiles\mymfiles\collatzall.m
File Edit Text Go Cell Tools Debug Desktop Window Help
function collatzall(n)
% Compute and plot length of sequence for Collat
% Prepare figure
clf
set(gcf,'DoubleBuffer','on')
set(gca,'XScale','linear')
%
% Determine and plot sequence and seqeuence leng
seq_length=zeros(100,1);
for m = 1:n
plot_seq = collatz(m);
seq_length(m) = length(plot_seq);
collatzall
Ln 6 Col 27
OVR



Adjust the size of the views by dragging the splitter. The pointer assumes an arrow shape when it is positioned on the splitter.

Only one view is active at any time, meaning, you will only see the cursor in one of the views. To change the active view use **Window > Split Screen > Switch Focus** or its keyboard equivalent, which is shown with the menu item. The cursor returns to its last position in that view.

Make changes to the document in either view. Both views of the file are always current, so you see the changes in either view.

You split each open document individually, so there can be multiple configurations at once. You can split some documents horizontally, others vertically, and leave others unsplit. When you open a document, it always opens unsplit, regardless of its split status when you last had it open.

You can remove a document split using any of these methods:

- Drag the splitter to an edge of the window.
- Double-click the splitter.
- Select **Window > Split > Screen > Off**.

See also “Summary of Actions for Arranging Documents” on page 2-11 for instructions to display multiple documents simultaneously.

Navigating in an M-File

In this section...

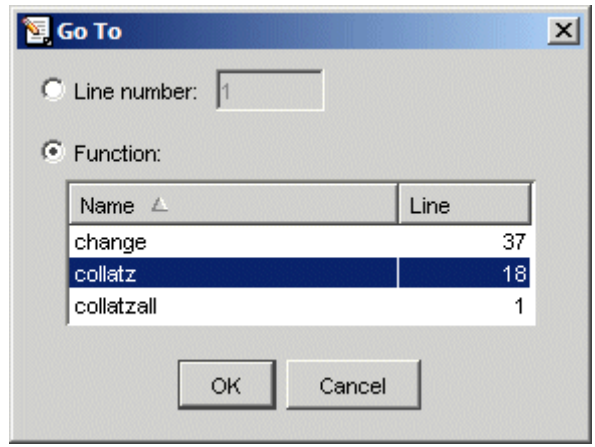
Note See also "Finding Text in Files" on page 6-49.

Going to a Line Number

Select **Go > Go To**. In the resulting **Go To** dialog box, select the **Line number** option, enter a line number, and click **OK**. The cursor moves to that line number in the current M-file.

Going to a Function (Subfunctions and Nested Functions)

To go to a function within an M-file (either a subfunction or a nested function), select **Go > Go To**. In the resulting **Go To** dialog box, select the **Function** option, and then select an entry from the list of subfunctions and nested functions in the file. Click **OK**.



Functions in the list appear alphabetically by name. To order them by their position in the file, click the **Line** column heading. The list does not include functions that are called from the M-file, but only shows lines in the current M-file that begin with a `function` statement.

Alternatively, click the Show Functions button on the toolbar. Then select the subfunction or nested function you want to go to from the list. The functions are listed in order of position in the file.

Note that the status bar shows the function and subfunction the current line is part of.

Going to a Cell

For M-file scripts that contain cells for rapid code iteration or publishing, the **Go To** dialog box lists cell titles.

Going to a Bookmark

You can set a bookmark at a line in a file in the Editor/Debugger so you can quickly go to the bookmarked line. This is particularly useful in long files. For example, while working on a line, if you need to look at another part of the file and then return, set a bookmark at the current line, go to the other part of the file, and then go back to the bookmark.

To set a bookmark, position the cursor anywhere in the line and select **Go > Set/Clear Bookmark**. A bookmark icon appears to the left of the line.

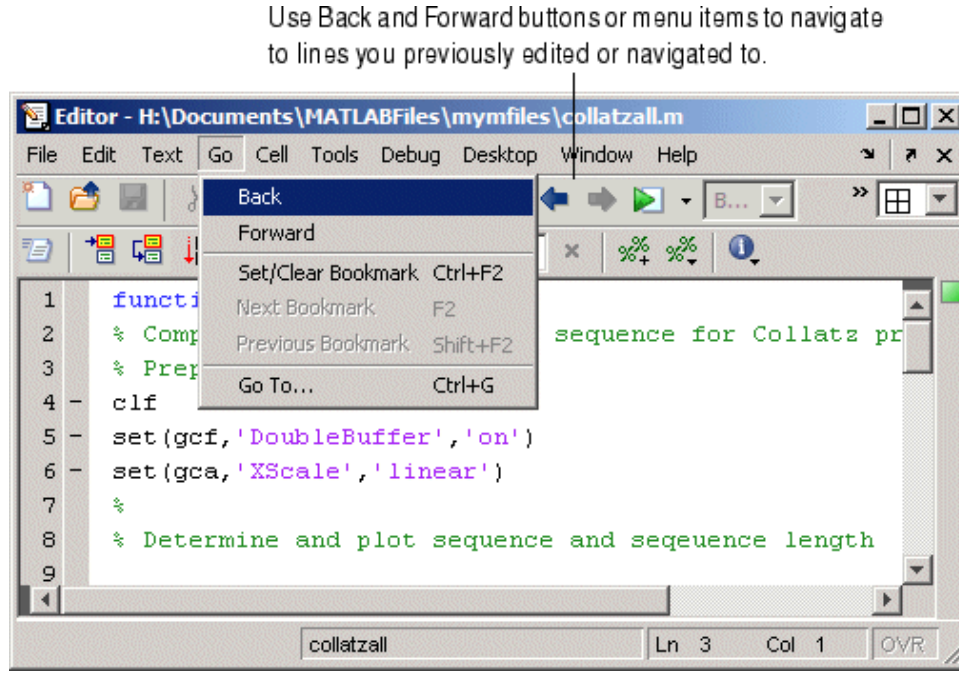
To go to a bookmark, select **Next Bookmark** or **Previous Bookmark** from the **Go** menu.

To clear a bookmark, position the cursor anywhere in the line and select **Go > Select/Clear Bookmark**.

Bookmarks are not maintained after you close a file.

Navigating Back and Forward in Files

Use **Go > Back** (and **Go > Forward**) to go to lines you previously edited or navigated to in a file. The feature goes to the lines in the sequence you accessed them. As an alternative to the menu items, use the Back and Forward buttons on the toolbar.



For example, if you open a file and make changes at lines 3, 9, and 6, use **Go > Back** to return to line 9, then 3, then 1, and then use **Go > Forward** to go from 1 to 3 to 9 to 6, and then return to 3. Detailed instructions to accomplish this are

1. Select **Go > Back** to return from line 6 to line 9.
2. Select **Go > Back** again to return to line 3.
3. Select **Go > Back** again to return to line 1, which is the first line you originally navigate to in a file by virtue of opening it.
4. Use **Go > Forward** to reverse the direction of the feature—select **Go > Forward** to navigate to line 3.
5. Select **Go > Forward** to navigate to line 9.
6. Reverse the direction of the feature again—select **Go > Back** to navigate to line 3.

Lines Navigated to Using Go Back

Use **Go > Back** and **Forward** to go to lines you previously edited or navigated to via these features:

Feature	Examples	Notes
Opening a file (first line in the file)	**File > Open**	None
Changes made using text-editing tools	**Delete** key, or **Text > Increase Indent**	Edits made to a selection of lines are represented by the first line in the selection. Changes made using **Cell > Insert Cell Divider** and **Cell > Insert Text Markup** are not considered as having been previously navigated to.
Changes made using Find and Replace	**Edit > Find and Replace**	Changes made using **Replace All** are not considered as having been previously navigated to.
Find features	**Edit > Find and Replace**, **Find Next**, **Find Previous**, and **Find Selection**	None
Incremental search	**Ctrl+S** and **Ctrl+R**	None
Show Function button		None
Opening a selection	**File > Open Selection**	None
Go to	**Go > Go To** line number, function, or cell title	None
Bookmark navigation	**Go > Next Bookmark** and **Previous Bookmark**	A line at which you **Set/Clear Bookmark** is not considered as having been previously navigated to.
Hyperlink access	From warnings or errors in the Command Window, from **Find Files** results, and from reports like the Profiler	None

Feature	Examples	Notes
Debugging navigation	Lines with breakpoints that were stopped at while running, and lines stepped to	A line at which you set a breakpoint is not considered as having been previously navigated to, unless it was actually stopped at during execution.
Cell mode navigation	**Cell > Next Cell** and **Previous Cell**, and **Cell > Evaluate Current Cell and Advance**	Lines accessed using **Cell > Evaluate Current Cell** are not considered as having been previously navigated to.

Interrupting the Sequence of Go Back and Forward

If you use **Go > Back** and **Go > Forward**, and then edit another line or navigate to another line using the list of features described in the above table, the **Go > Back** or **Go > Forward** feature sequence is interrupted. You can still go to the lines preceding the interruption point in the sequence, but you cannot go to any lines after that point. Any lines you edit or navigate to after interrupting the sequence are added to the sequence after the interruption point.

For example,

1. Open a file and edit lines 2, then 4, and then 6.
2. Use **Go > Back** to move back to line 4, and then back to line 2.
3. You could then **Go > Forward** to lines 4 and 6, or **Go > Back** to line 1.

   Instead, make an edit at line 3. Now you cannot **Go > Forward** to lines 4 and 6 and you can only **Go > Back** to line 2 and then line 1.

Closed Files and Behavior of Go Back and Forward

Go > Back and **Forward** do not go to lines in closed files.

Split Screen and Behavior of Go Back and Forward

When you have a split screen display, **Go > Back** and **Forward** go to the view in which the line was originally navigated to or edited in. If you remove

the split, **Go > Back** and **Forward** do not go to any lines that were visited in the lower (or right) view.

Opening a Selection in an M-File

You can open a subfunction, function, file, variable, or Simulink model from within a file in the Editor/Debugger. Position the cursor in the name and then right-click and select **Open Selection** from the context menu. Based on what the selection is, the Editor/Debugger performs a different action.

Selection	Action
Subfunction	Cursor moves to the subfunction within the current M-file. If no subfunction by that name is found in the current M-file, the Editor/Debugger runs the `open` function on the selection, which opens the selection in the appropriate tool, as shown for the other selection types in this table.
M-file or other text file	Opens in the Editor/Debugger.
Figure file (`.fig`)	Opens in a figure window.
Variable	Opens in the Array Editor.
Model	Opens in Simulink.
Other	If the selection is some other type, **Open selection** looks for a matching file in a private directory in the current directory and performs the appropriate action.

After selecting a name, you can also choose **Help on Selection** from the context menu to see documentation for the item. For example, select a function, right-click and select **Help on Selection**. The reference page for that function opens in a popup window, or if the reference page does not exist, the M-file help appears. For more information, see “Getting Pop-Up Help for Functions” on page 4-49

Finding Text in Files

In this section...

Finding Text in the Current File

Within the current file, select the text you want to find. From the **Edit** menu, select **Find Selection**. The next occurrence of that text is selected. Select **Find Selection** again (or **Find Next**) to continue finding more occurrences of the text.

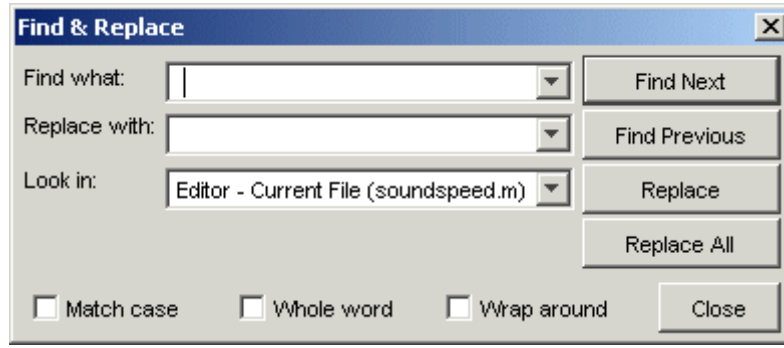
To find the previous occurrence of selected text (find backwards) in the current file, select **Find Previous** from the **Edit** menu. The previous occurrence of the text is selected. Repeat to continue finding the previous occurrences of the text.

Finding and Replacing Text in the Current File

You can search for specified text within multiple files, and then replace the text within a file.

Finding Text

To search for text in files, click the Find button in the Editor/Debugger toolbar, or select **Edit > Find and Replace**. Complete the resulting **Find & Replace** dialog box.



The search begins at the current cursor position. MATLAB finds the text you specified and highlights it. To find another occurrence, click **Find Next** or **Find Previous**, or use the keyboard shortcuts **F3** and **Shift+F3** (or **Command+F3** and **Command+Shift+F3** with Macintosh key bindings).

MATLAB beeps when a search for **Find Next** reaches the end of the file, or when a search for **Find Previous** reaches the top of the file. If you have **Wrap around** selected, it continues searching after beeping.

Use **F3** and **Shift+F3** to continue finding the specified text even after closing the **Find & Replace** dialog box. You can go to another file and find the specified text in it.

Change the selection in the **Look in** field to search for the specified text in other MATLAB desktop tools.

Replacing Text

After finding text using the **Find & Replace** dialog box, you can replace the text in the current file:

1. In the **Replace with** field, type the text that is to replace the found text.
2. Click **Replace** to replace the text currently selected, or click **Replace All** to replace all instances in the current file.

   The text is replaced. For **Replace All**, the number of instances that were replaced appears in the Editor/Debugger status bar.

3 To save the changes to the file, select **Save** from the **File** menu.

You can repeat this for multiple files.

Function Alternative for Finding Text

Use `lookfor` to search for the specified text in the first line of help for all M-files on the search path.

Finding Files or Text in Multiple Files

To find directories and filenames that include specified text, or whose contents contain specified text, use **Edit > Find Files**. For details, see "Finding Files and Content Within Files" on page 5-49.

Incremental Search

With the incremental search feature, the cursor moves to the next or previous occurrence of the specified text in the current file. It is similar to the Emacs search feature. Incremental search is also available in the Command Window — see "Incremental Search" on page 3-35.

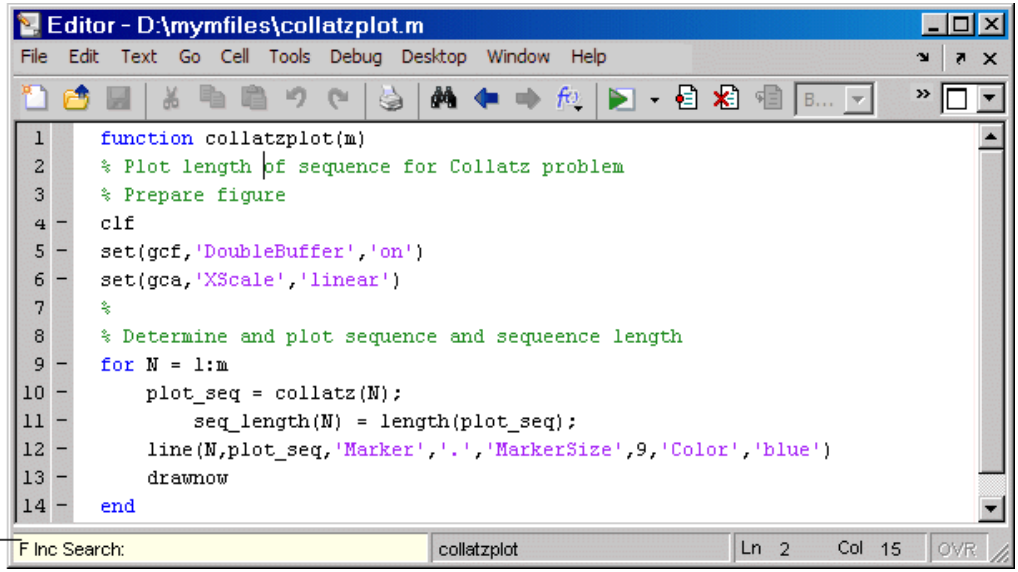
To use the incremental search feature in the Editor/Debugger, follow these steps:

1 Position the cursor where you want the search to begin.

2 How you begin the incremental search depends on your setting for theEditor/Debugger key bindings preference and in which direction you want to search:

- Press **Ctrl+S** to search forward or **Ctrl+R** to search backward for Emacs and Macintosh key bindings.
- Press **Ctrl+Shift+S** to search forward or **Ctrl+Shift+R** to search backward for Windows key bindings.

An incremental search field appears in the left side of the status bar of the current file window. **F Inc Search** means search *F*orward from the cursor. The field label is instead **R Inc Search** when you search backwards.



Incremental search field. **F** means search *Forward* from the cursor.

3 In the incremental search field, type the text you want to find. For example, type `plot`.

As you type the first letter, `p`, the first occurrence of that letter after the cursor is highlighted. In the example shown, the cursor is in the middle of line 2, so the first occurrence of `p`, the `p` in `problem` on line 2, is highlighted.

```
1   function collatzplot(m)
2   % Plot length of sequence for Collatz problem
3   % Prepare figure
```

Incremental search is case sensitive for uppercase letters. In the above example, searching for uppercase `P`, would instead find the `P` in `Prepare` on line 3.

When you type the next letter in the term you are searching for, the first occurrence of the term becomes highlighted. In the example, when you add the letter `l` to the `p` so that the incremental search field now has `pl`, the `pl` in `plot` on line 8 is highlighted. When you add `ot` to the term in the incremental search field, the whole word `plot` in line 8 is highlighted.

- If you mistype in the incremental search field, use the backspace key to remove the last letters and make corrections.
- After finding the `p`, press **Ctrl+W** to highlight the rest of the word found, in this case `plot`, which also puts the complete word in incremental search field.

4. To find the next occurrence of `plot` in the file, press **Ctrl+S**. To find the previous occurrence of the text, press **Ctrl+R**.

5. If MATLAB beeps, it either means the search is at the end or beginning of the file, or it means that the text was not found.

   - When the text is not found, `Failing` appears in the incremental search field. Modify the search term in the incremental search field and try again. Use **Ctrl+G** to automatically remove characters back to the last successful search. For example, if `plode` fails, **Ctrl+G** removes the `de` from the search term because `plo` does exist in the file.
   - When at the end or beginning of the file, press **Ctrl+S** or **Ctrl+R** again to wrap to the beginning (or end) of the file and continue the search. Use **Ctrl+G** after a finding a string to clear the search and return the cursor to the starting point.

6. To end the incremental search, press **Esc** or **Enter**, or any other noncharacter or number key except **Tab** or backspace.

   The incremental search field no longer appears in the status bar. The cursor is now located at the position where the string was last found.

If you press **Ctrl+S** or **Ctrl+R** after displaying the blank incremental search field, the search term from your previous incremental search appears in the field. Then the backspace key deletes the entire previous search term, rather than just the last letter.

Comparing Files — File Comparison Tool

In this section...

What Is the File Comparison Tool?

The File Comparisons tool identifies differences line by line between two files. Some other applications refer to this as a file diff. As an example, you can use this to easily compare an autosaved version of a file to the latest version.

Running the File Comparison Tool

To use the tool, follow these steps:

1. Open one of the files you want to compare in the Editor/Debugger.

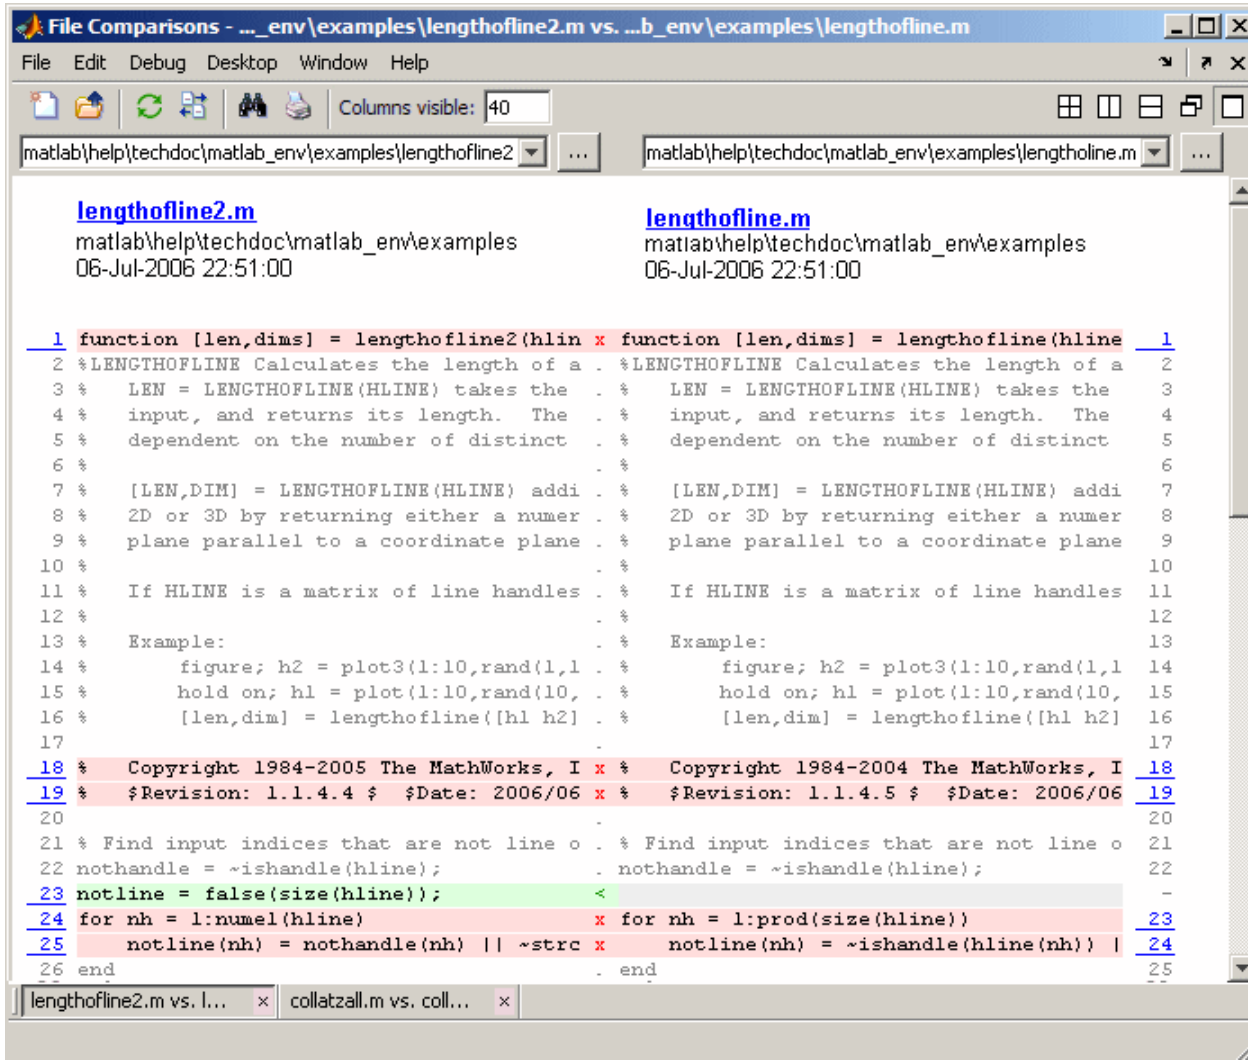
   To open the example file provided, `lengthofline.m`, run

   ```
   open(fullfile(matlabroot,'help','techdoc','matlab_env',...
    'examples','lengthofline.m'))
   ```

2. Select **Tools > Compare Against > Browse**. Navigate to the file you want to compare against, select the file, and click **Open**. To open the example file provided, select `lengthofline2.m`. Other options available are

- **Tools > Compare Against > Autosave Version** to compare the open file to the Editor/Debugger's automatic copy, *filename*.asv. For more information, see "Autosave" on page 6-63.
- **Tools > Compare Against Version on Disk** to compare an open file that has been changed but not saved to the saved version.

3 The File Comparisons tool opens, displaying the files side by side and highlighting lines that do not match. Pink highlighting and an x at the start of a line indicates that the content of the lines differs between the two files. Green highlighting and a > at the start of a line indicates a line that exists in the file presented on the right side of the page but not in the file presented on the left side of the page. Green highlighting and a < at the end of a line indicates a line that exists in the file presented on the left side of the page but not in the file presented on the right side of the page.



4 Use features of the File Comparisons tool to work with the results.

Increase or Decrease Line Lengths Shown

By default, the display is 60 columns wide for each file. To see the full line length for each file, use a high number for **Columns visible**, and drag the

vertical edges of the window to make it wider. With a narrower window size, if there are more columns shown in the left file but fewer in the right file, reduce the number for **Columns visible** to see enough in both sides.

Exchange Positions

To move the file on the left side to the right side and vice-versa, select **File > Swap Sides**, or click the equivalent toolbar button  .

Show Updated Files

After making changes to and saving the files in the Editor/Debugger, update the results in the File Comparisons tool by selecting **File > Refresh** or clicking the equivalent toolbar button  .

Find Text in Files

To find a phrase in the currently displayed files, select **Edit > Find**, or click the equivalent toolbar button. The resulting Find dialog box is the same as the one you use in the Command Window—for more information, see “Find Dialog Box” on page 3-34.

Compare to Other Files

You can replace an existing file in the tool. Drag a different filename from the Current Directory browser or Windows Explorer to the left or right side of the File Comparisons window, replacing the file currently shown there. Alternatively, type the path to a file or browse to find a file using the field below the File Comparisons toolbar. Another option is to use **File > Open**.

Perform New and View Previous Comparisons

You can perform another comparison by selecting **File > New File Comparison**. Supply the files to compare using the techniques described in “Compare to Other Files” on page 6-57. You can see the results of either pair of comparisons by selecting its entry in the document bar (as shown at the bottom of the window in the above example illustration).

Alternative Ways to Access the Tool

These are additional ways you can access the tool:

- From the MATLAB desktop, select **Desktop > File Comparisons**.
- From the Current Directory browser, select a file, right-click, and from the context menu, select **Compare Against**.
- For two files in the same directory, from the Current Directory browser, select the files, right-click, and from the context menu, select **Compare Selected Files**.

Supply the files to compare using the techniques described in “Compare to Other Files” on page 6-57.

Keyboard Shortcuts in the Editor/Debugger

Following is the list of keys that serve as shortcuts for using the Editor/Debugger. This list does not include shortcut keys (sometimes called hot keys) for menu items—you can view those on the menus. If you select the **Emacs** "Editor/Debugger Key Bindings" on page 3-45 preference, you can also use the **Ctrl+key** combinations shown. See also general desktop "Keyboard Shortcuts" on page 2-40.

Key or Mouse Action for Windows Preference	Additional Control Key for Emacs Preference	Key or Mouse Action for Macintosh Preference	Operation
↑	**Ctrl+P**	↑	Move to *p*revious line.
↓	**Ctrl+N**	↓	Move to *n*ext line.
Ctrl+Home	None	**Cmd+Home**	Move to top of file.
Ctrl+End	None	**Cmd+End**	Move to end of file.
Ctrl+↑	None	**Home**	Scroll up without moving cursor position (with cell mode disabled). Move to top of current cell or top of previous cell (with cell mode enabled).
Ctrl+↓	None	**End**	Scroll down without moving cursor position (with cell mode disabled). Move to top of next cell (with cell mode enabled).
Page Down	**Ctrl+V**	**Page Down**	Move down one screen.
Page Up	**Alt+V**	**Page Up**	Move up one screen.
←	**Ctrl+B**	←	Move *b*ack one character.
→	**Ctrl+F**	→	Move *f*orward one character.
Ctrl+←	None	**Option+**←	Move *l*eft one word.
Ctrl+→	None	**Option+**→	Move *r*ight one word.

Key or Mouse Action for Windows Preference	Additional Control Key for Emacs Preference	Key or Mouse Action for Macintosh Preference	Operation
Home	**Ctrl+A**	**Cmd+←**	Move to beginning of line.
End	**Ctrl+E**	**Cmd+→**	Move to *e*nd of line.
Delete	**Ctrl+D**	**Forward Delete**	Delete character after cursor.
Backspace	none	**Delete**	Delete character before cursor.
None	**Ctrl+K**	None	Cut contents (*k*ill) to end of line.
Double-click	None	Double-click	Select current word. To select additional words, hold mouse after second click and continue dragging left or right.
Triple-click	None	Triple-click	Select current line. To select additional lines, hold mouse after second click and continue dragging up or down.
Ctrl+Shift+←	None	**Option+Shift+←**	Select word to the left
Ctrl+Shift+→	None	**Option+Shift+→**	Select word to the right.
Shift+Home	None	**Cmd+Shift+←**	Select to beginning of line.
Shift+End	None	**Cmd+Shift+→**	Select to end of line.
Shift+Page Up	**Ctrl+Shift+V**	**Shift+Page Up**	Select one screen up.
Shift+Page Down	**Alt+Shift+V**	**Shift+Page Down**	Select one screen down.
Ctrl+Shift+Home	None	**Cmd+Shift+Home**	Select to top of file.
Ctrl+Shift+End	None	**Cmd+Shift+End**	Select to end of file.
Shift+Enter	None	**Shift+Enter**	Add a new line that is not indented.

Key or Mouse Action for Windows Preference	Additional Control Key for Emacs Preference	Key or Mouse Action for Macintosh Preference	Operation
Insert	None	None	Change to overwrite mode from insert mode, or change to insert mode from overwrite mode. View current mode in the status bar: OVR is gray for insert mode. In overwrite mode, what you type replaces existing text, and the cursor is a wide block. (Not supported on Macintosh platforms.)
Shift+F5	None	**Shift+F5**	Exit debug mode. Equivalent to typing `dbquit`. The Command Window displays the standard prompt `>>`.

Saving, Printing, and Closing Files in the Editor/Debugger

In this section...

Saving Files

After making changes to an file, you see an asterisk (*) next to the filename in the title bar of the Editor/Debugger. This indicates there are unsaved changes to the file.

To save the changes, use one of the **Save** commands in the **File** menu:

- **Save** — Saves the file using its existing name. If the file is newly created, the **Save file as** dialog box opens, where you assign a name to the file before saving it. Another way to save is by using the Save button on the toolbar. If the file has not been changed, **Save** is grayed out, but you can instead use **Save As** from the **File** menu to save to a different filename.
- **Save As** — The **Save file as** dialog box opens, where you assign a name to the file and save it. By default, if you do not type an extension, MATLAB automatically assigns the `.m` extension to the filename. If you do not want an extension, type a `.` (period) after the filename.
- **Save All** — Saves all named files to their existing filenames. For all newly created files, the **Save file as** dialog box opens, where you assign a name to each untitled file and save it.

You cannot save an M-file while in debug mode. If you try to, MATLAB displays a dialog box asking if you want to exit debug mode and then save the file. While debugging, you can execute sections of an M-file even though there are unsaved changes — see “Running Sections in M-Files That Have Unsaved Changes” on page 6-125.

Note Save any M-files you create and any M-files from The MathWorks that you edit in a directory that is not in the *matlabroot*/toolbox directory tree. If you keep your files in *matlabroot*/toolbox directories, they can be overwritten when you install a new version of MATLAB. Also note that locations of files in the *matlabroot*/toolbox directory tree are loaded and cached in memory at the beginning of each MATLAB session to improve performance. If you save files to *matlabroot*/toolbox directories using an external editor or add or remove files from these directories using file system operations, run `rehash toolbox` before you use the files in the current session. If you make changes to existing files in *matlabroot*/toolbox directories using an external editor, run `clear functionname` before you use the files in the current session. For more information, see `rehash` or "Toolbox Path Caching in MATLAB" on page 1-17.

Autosave

As you make changes to a file in the Editor/Debugger, every five minutes the Editor/Debugger automatically saves a copy of the file to a file of the same name but with an `.asv` extension. The autosave copy is useful if you have system problems and lose changes made to your file. In that event, you can open the autosave version, `filename.asv`, and then save it as `filename.m` to use the last good version of `filename`. For example, if you edit `filename.m` and do not save it for five minutes, MATLAB saves the file including the unsaved changes, to `filename.asv`.

Use autosave preferences to turn the autosave feature off or on, to specify the number of minutes between automatic saves, and to specify the file extension and location for autosave files. For details, see in the online documentation.

If the file you are editing is in a read-only directory and the autosave preference for location is the source file directory, an autosave copy of the file is *not* made.

Deleting Autosave Files. By default, autosave files are not automatically deleted when you delete the source file. To keep autosave to M-file relationships clear and current, it is a good practice when you rename or remove an M-file to delete or rename its corresponding autosave file.

There is a preference to **Automatically delete autosave files**. With this preference selected, when you close an M-file in the Editor/Debugger, MATLAB automatically deletes the corresponding autosave file.

Accessing Your Source Control System

If you use a source control system for M-files, you can access it from within the Editor/Debugger using **File > Source Control**. For more information, see Chapter 9, “Source Control Interface”.

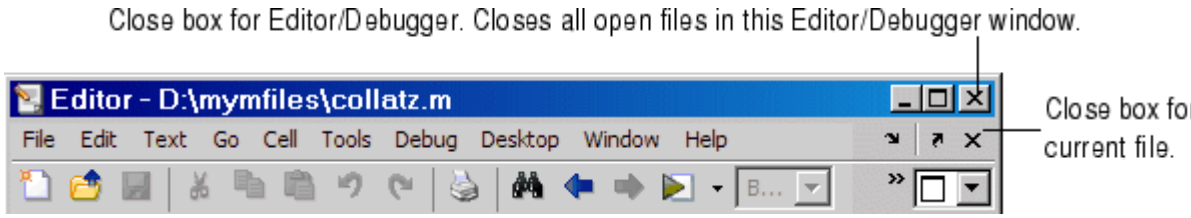
Printing M-Files

To print an entire M-file, select **File > Print**, or click the Print button on the toolbar. To print the current selection, select **File > Print Selection**. Complete the standard print dialog box that appears.

Specify printing options for the Editor/Debugger by selecting **File > Page Setup**. For example, you can specify printing with a header. For more information, see “Printing and Page Setup Options for Desktop Tools” on page 2-52.

Closing M-Files

To close the current M-file, select **Close filename** from the **File** menu, or click the Close box in the Editor/Debugger menu bar. This is different from the Close box in the titlebar of the Editor/Debugger, which closes all open files in that Editor/Debugger window.



To close all files within the Editor/Debugger, select **Window > Close Editor Documents**. This does not close any files undocked from the Editor/Debugger. The Editor/Debugger remains open with no files in it.

If each file is open in a separate window, close all the files at once using the **Close All Documents** item in the **Window** menu. Note that this also closes desktop documents of all types, including Array Editor documents.

When you close a file that has unsaved changes, you are prompted to save the file. If you do not want to be prompted, hold **Ctrl** and click the Close box. The prompt will not appear and the document will close without saving any unsaved changes.

Running M-Files in the Editor/Debugger

In this section...

Running M-Files with No Input Arguments in the Editor/Debugger

In the Editor/Debugger, to run a script M-file, or a function M-file that requires no input arguments, click the Run button  on the toolbar. The button's tooltip includes the name of the file to be run, which is useful when you have more than one file open. Alternatively, select **Debug > Run filename**.

If the file is not in a directory on the search path or in the current directory, a dialog box appears, presenting you with options that allow you to run the file. You can either change the current directory to the directory containing the file, or you can add the directory containing the file to the search path.

If the file has unsaved changes, running it from the Editor/Debugger automatically saves the changes before running. In that event, the menu item is **Save File and Run filename**.

If the M-file is a script, you can view the value of a variable in the file, which is called a *datatip* (like a tooltip for data). You need to set the preference to show datatips in edit mode — select **File > Preferences > Display**, and for

General Display Options, select the check box for **Enable datatips in edit mode**.

Using Configurations — Running M-Files with Input Arguments in the Editor/Debugger

In the Editor/Debugger, you can provide values for a function's input arguments using a configuration, and then run that configuration to use the assigned values. When you are editing a function M-file, use a configuration as an alternative to running the function in the Command Window. You can associate multiple configurations with an M-file, for different input values. MATLAB saves the configurations between sessions.

For example, the function `collatzplot_new.m`, which computes and plots the Collatz sequence for any given positive integer, requires you to specify the integer as an input value. You cannot simply run `collatplot_new.m` in the Editor/Debugger because the input value is not defined. One way to specify the input value is to run the M-file in the Command Window. Configurations allow you to run `collatzplot_new(`*`specific value`*`)` in the Editor/Debugger.

You can also use configurations to provide preparatory or setup information prior to running an M-file, whether it takes input arguments or not.

Create and Run a Configuration for an M-file

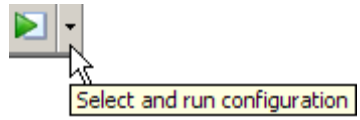
Follow these steps to create and run a configuration for an M-file in the Editor/Debugger. These steps specify Editor/Debugger toolbar buttons, but you can also use equivalent items in the **Debug** menu.

1. Open the file you want to run in the Editor/Debugger. For example, open `collatzplot_new.m` by running

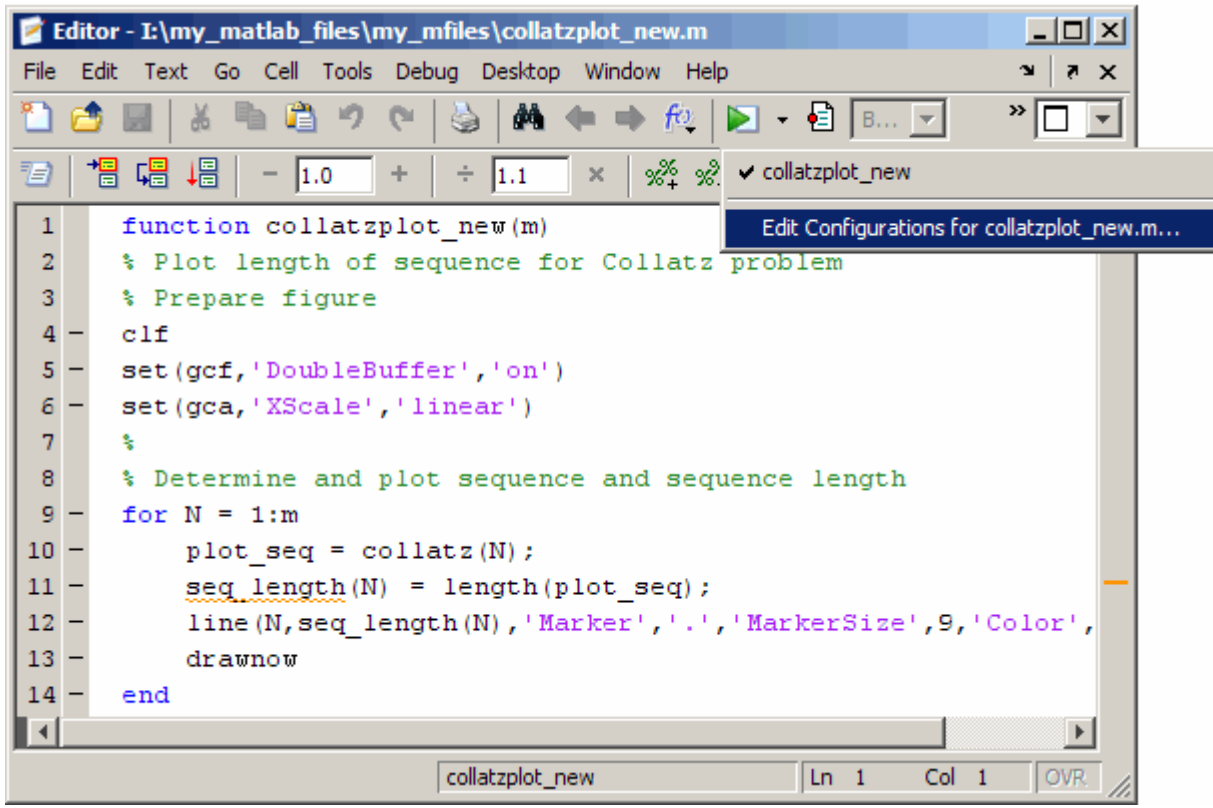
   ```
   cd ([matlabroot '/help/techdoc/matlab_env/examples'])
   edit collatzplot_new.m
   ```

   To work with `collatzplot_new.m` on your system, save the file to a directory for which you have write permission. In the example, the file is saved to `I:\my_matlab_files\my_mfiles\collatzplot_new.m`

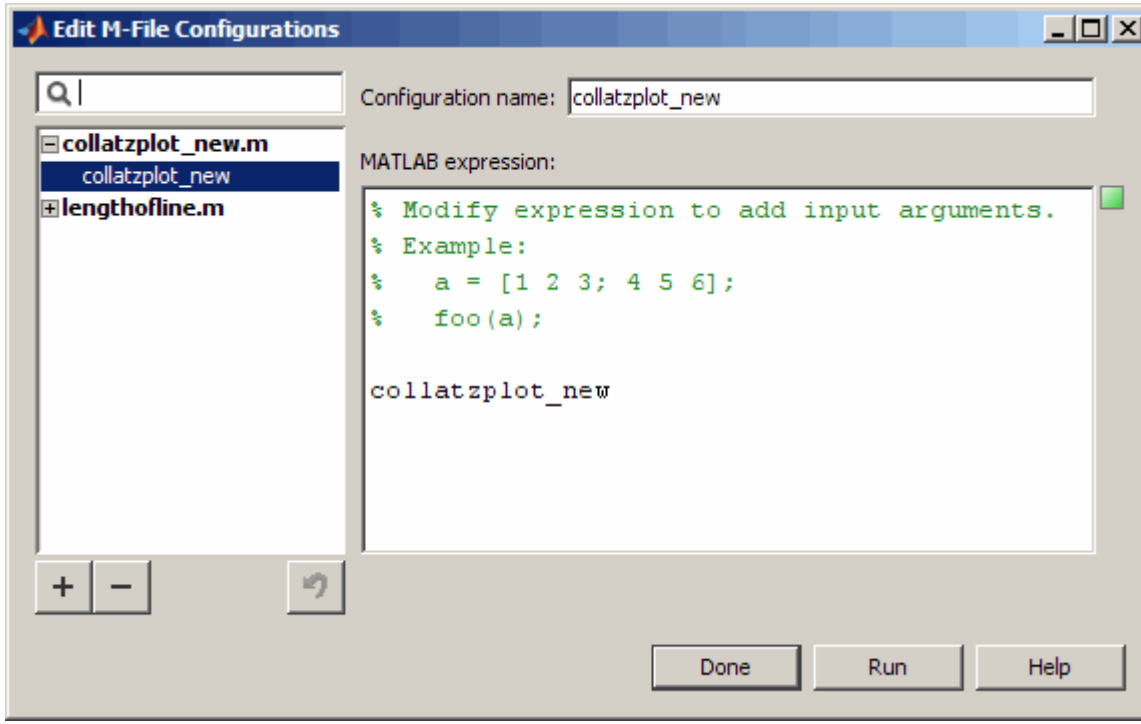
2 Click the down arrow on the Run button in the Editor/Debugger toolbar



and select **Edit Configurations for *filename***, where filename in this example is `collatzplot_new.m`.

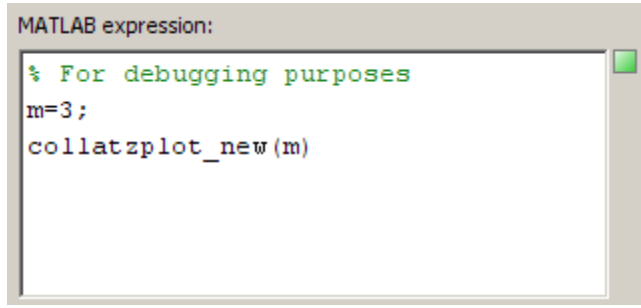


The Edit M-File Configurations dialog box opens, with a default configuration template for `collatzplot_new.m`.



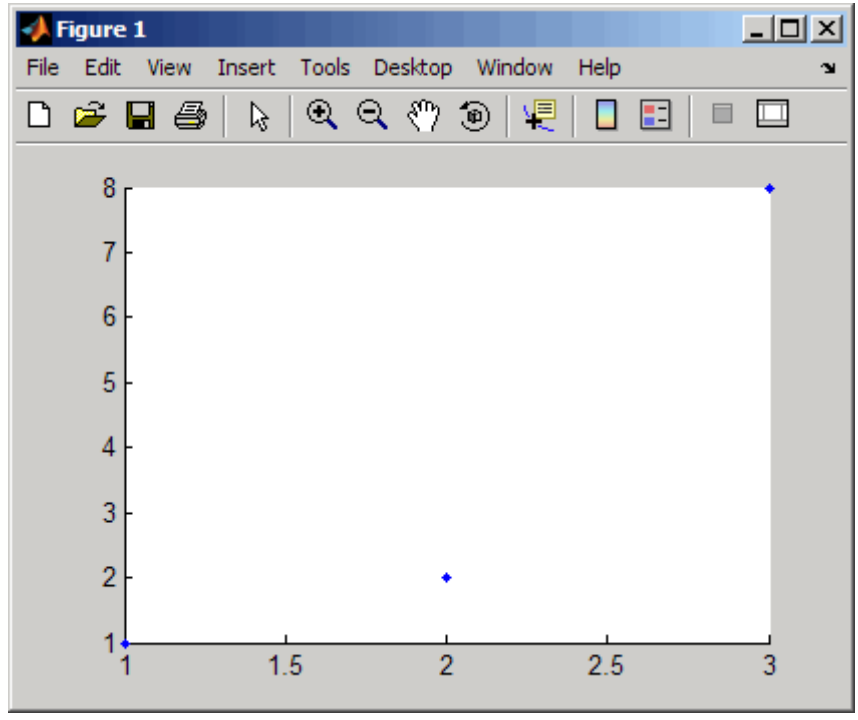
3 In the dialog box, enter MATLAB statements in the **MATLAB expression** area of the dialog box, specifying what you want to run. Delete the existing comments or replace them with comments relevant to your configuration. To undo and redo, use the keyboard shortcuts for your platform, such as **Ctrl+Z** and **Ctrl+Y** for Windows.

In this example, set `m` equal to `3`, a small value useful for debugging purposes. Complete the statement to run `collatzplot_new(m)`.



The MATLAB expression area provides syntax highlighting and shows M-Lint messages, similar to the Editor/Debugger.

4 To ensure your configuration runs as expected, click **Run** to execute the statements in the **MATLAB expression** area of the dialog box. In this example, `collatzplot_new(3)` runs, and a figure window displays the plot.



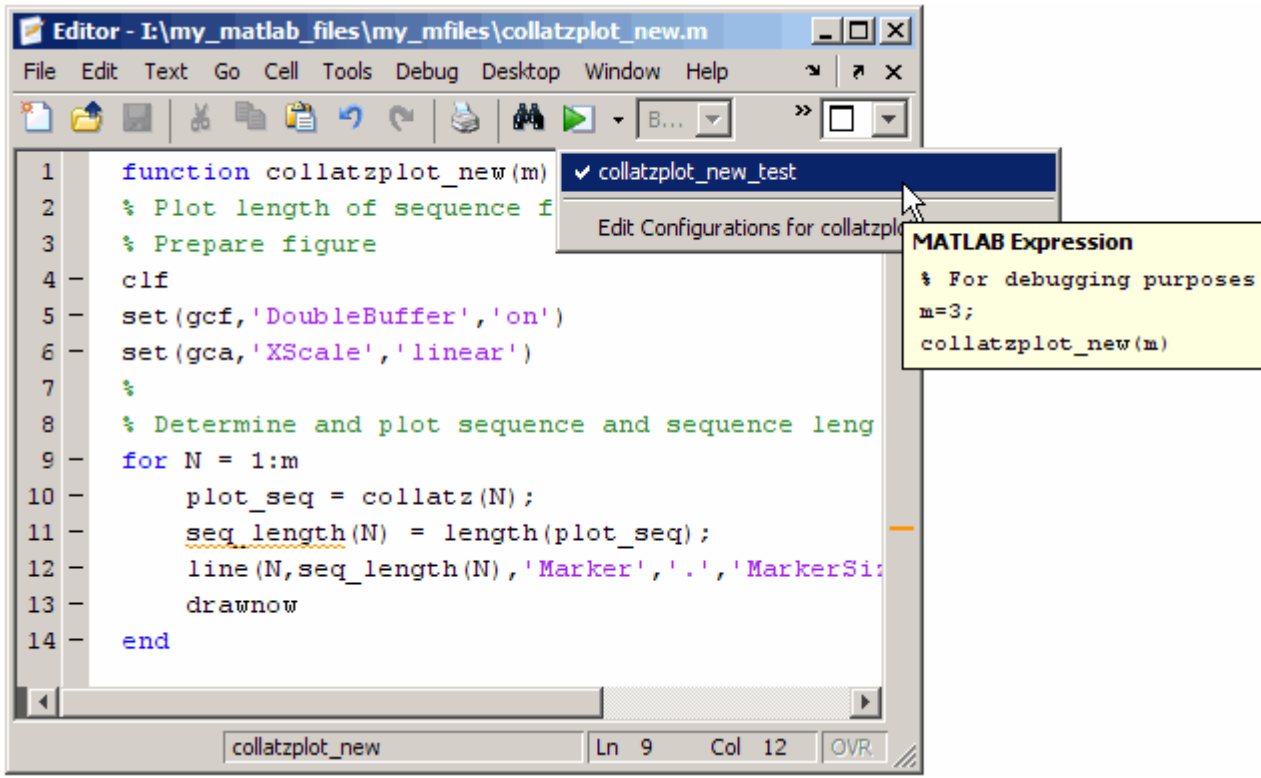
5 You can modify the statements in the **MATLAB expression** area of the dialog box and click **Run** to see the results of the changes. You can also modify the M-file and save the changes while the Edit M-File Configurations dialog box is open, and then click **Run** to see the results of the M-file changes.

6 You can assign a name using **Configuration name** in the Edit M-File Configurations dialog box. By default, the configuration name is the M-file name. If you expect to create multiple configurations for an M-file, assign each a name that helps you identify the configuration. In this example, name the configuration `collatzplot_new_test`.

7 To close the Edit M-File Configurations dialog box, click **Done**. MATLAB saves the configuration and its association with the M-file.

8 After creating a configuration, you can view and run the configuration without opening the Edit M-File Configurations dialog box.

In the Editor/Debugger toolbar, click the down arrow on the Run button  and position the pointer on a configuration name. MATLAB displays a tooltip showing the configuration's expression so you can see what will run.



To run the configuration, select the configuration name. MATLAB runs the expression you specified in the configuration. For example, select `collatzplot_new_test`, and MATLAB runs `collatzplot_new(3)`, as specified in step 3. You can modify the M-file, save it, and run the configuration from the toolbar to see the effects of the M-file changes.

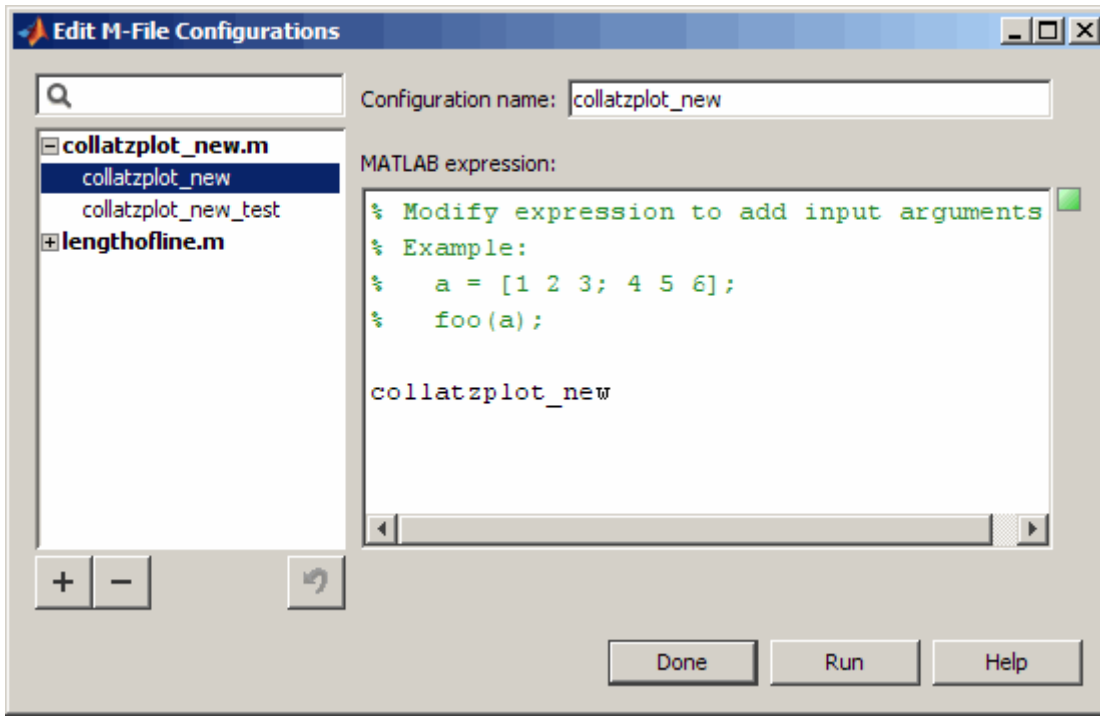
Create and Run Multiple Configurations for an M-File

You can create multiple configurations for a given M-file, allowing you to run with different values for input arguments, each for a different purpose. Create a named configuration for each purpose, all associated with the M-file. Then any time you open the M-file, chose and run the configuration you want. For example, for `collatzplot_new(m)` you might use three values for `m` and have three configurations:

- Small value, e.g., 3, for debugging and testing
- Realistic value, e.g., 200 or more, for a specific project
- Random value to observe changes

1. Open the Edit M-File Configurations dialog box. Select the M-file to which you want to add a configuration, or select a configuration associated with that M-file. Click the Add button  (under the list of M-files and configurations). MATLAB creates a new default configuration template, in this example, `collatzplot_new`.

   The example shows `collatzplot_new` and its default expression, as well as one previously created configuration associated with `collatzplot_new.m`, `collatzplot_new_test`.



2. In the Edit M-File Configurations dialog box, modify, run, and name the new configurations as you did for the initial configuration,

`collatplot_new_test`, described in "Create and Run a Configuration for an M-file" on page 6-67.

For example, rename `collatzplot_new` to `collatzplot_new_largevalue`, and replace the default template expression with

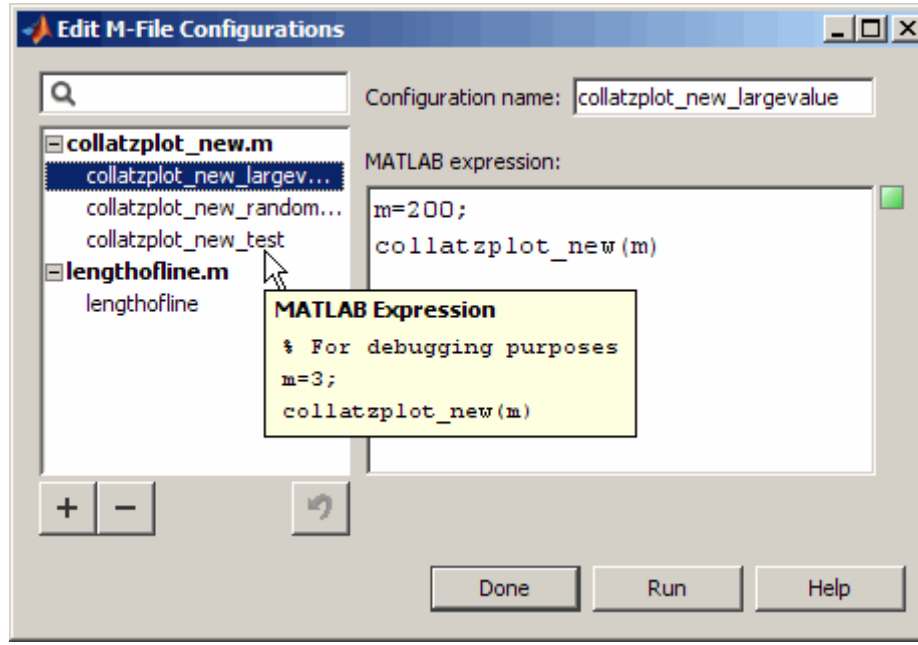
```
m=200;
collatzplot_new(m)
```

To create another configuration, click the Add button  . Rename `collatzplot_new` to `collatzplot_new_random` and replace the default template expression with

```
% Random value
m=int16(rand*50);
collatzplot_new(m)
clear all
```

3. Select a configuration in the listing to see and modify its expression, or to rename the configuration. Click the expander next to an M-file name (**+** and **-** icon on Windows) to see or hide all the configurations associated with that M-file.

4. To get a quick view of the expression in a configuration, position the pointer on the name of a configuration without selecting it. In this example, `collatzplot_new_largevalue` is selected and you can edit its expression or name. The pointer is positioned on `collatzplot_new_test` and you can see the statements in it.



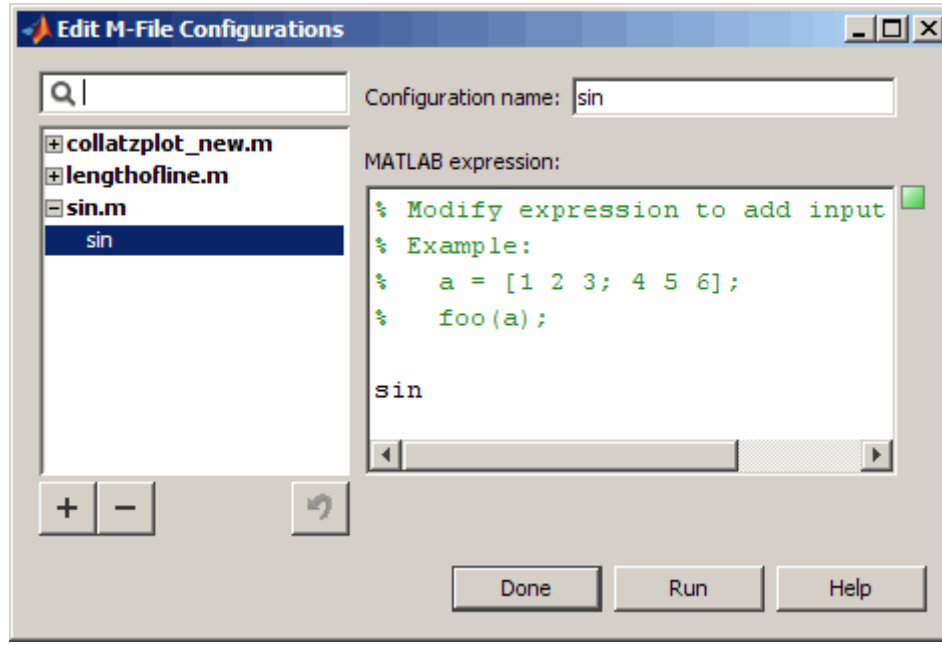
5 Click **Done** to close the Edit M-File Configurations dialog box.

Find Configurations

1 Open any M-file in Editor/Debugger. For example, open the MATLAB function `sin`.

2 Open the Edit M-File Configurations dialog box. MATLAB automatically creates a default configuration for `sin.m`, if none exists.

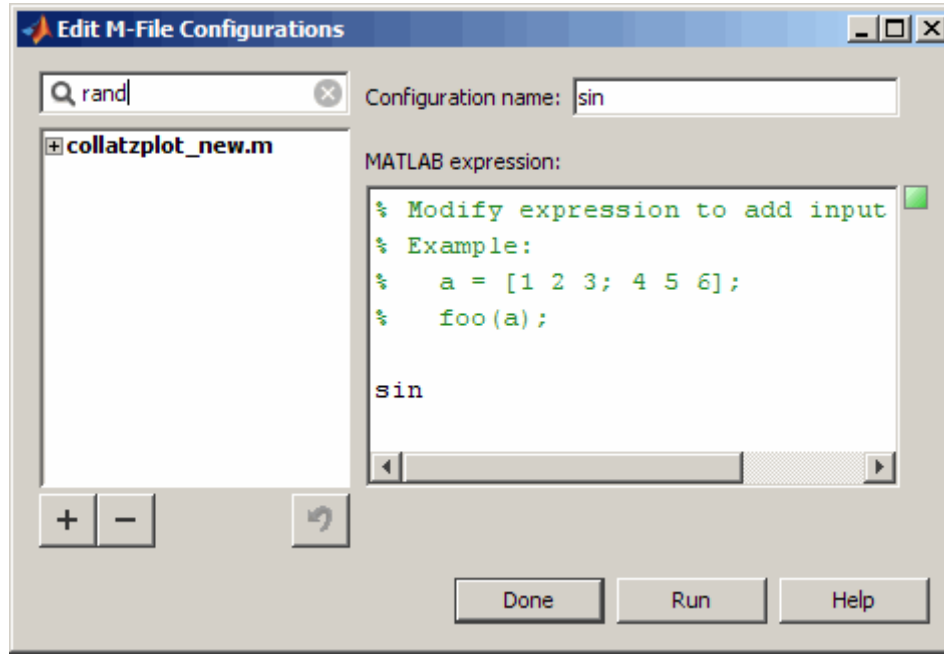
In the left panel, MATLAB displays a list of all M-files containing configurations.



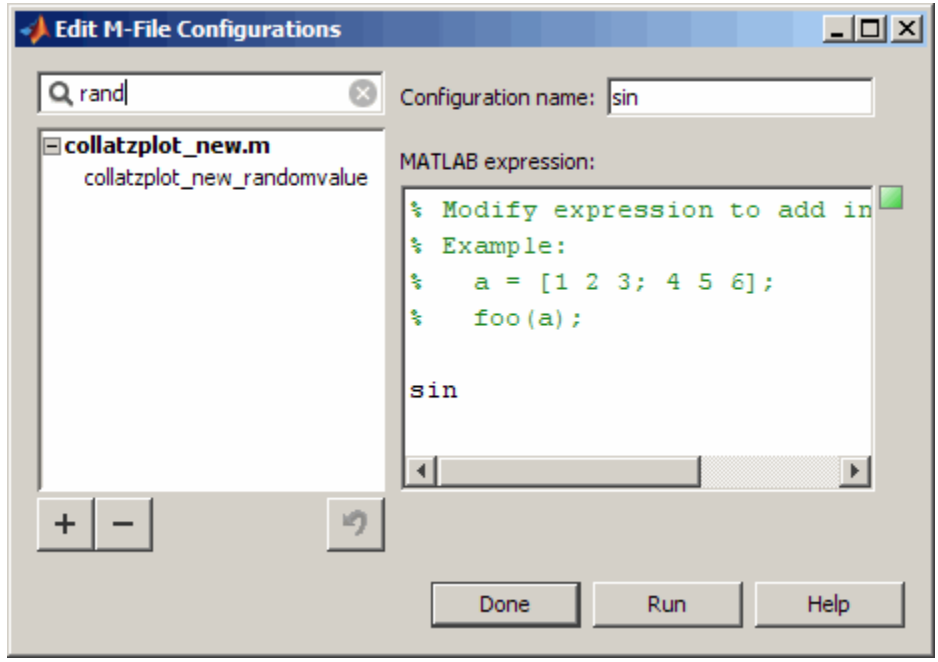
3 Type a term in the filter field  to find an M-file or configuration by name.

MATLAB displays only those M-files whose names contain the term, or whose associated configurations contain the term in their name. As you type, MATLAB filters out files and configurations that do not contain the term.

For example, type `rand`. In this example, only one M-file, `collatzplot_new.m`, has a configuration that contains the term `rand`.



4 Expand the M-file name to see associated configurations whose names contain the term you entered in the filter field. In this example, click the expander (**+** on Windows) for `collatzplot_new.m` to see configurations whose names contain `rand`. If you cannot view the entire name of a configuration, drag the separator bar to the right of the list, making the left panel wider. For the example, there is only one configuration, `collatzplot_new_randomvalue`.



5 To see the expression in that configuration, select the configuration, or position the pointer over the name.

6 As you type additional letters in the filter field, fewer M-files remain in the list of results. Use the backspace key to modify the term. If there are no M-files or configurations containing the term, the list will be empty.

7 To clear the filter and show all M-files with configurations, click the clear button in the filter field.

Remove Configurations

If you no longer need a configuration because you do not use it or because you deleted the M-file with which it is associated, it is a good practice to delete the configuration.

1 Open any M-file in the Editor/Debugger.

2 Open the Edit M-File Configurations dialog box.

3 Select the configuration you want to delete.

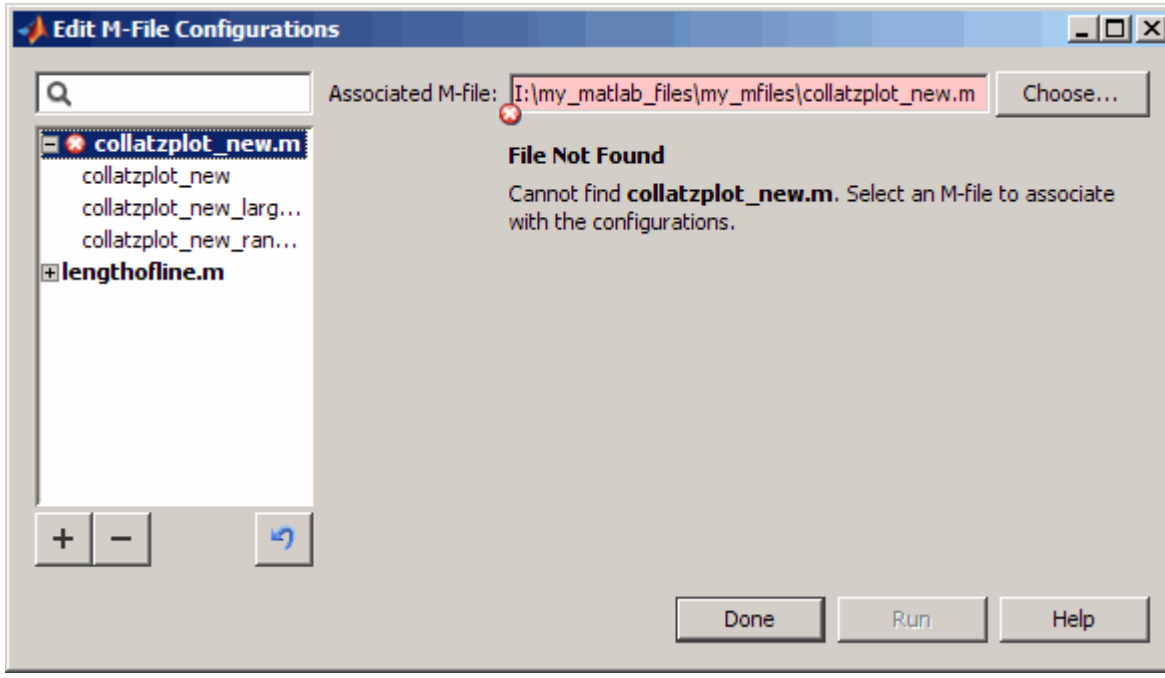
4 Click the Remove button  .

5 To undo the last deletion, click the Undo button  . You cannot undo the last deletion after having closed the Edit M-File Configuration dialog box.

Reassociate and Rename Configurations

Each configuration is associated with a specific M-file. If you move or rename the M-file, you need to redefine the association. If you delete an M-file, you might want to delete the associated configurations, or associate them with a different M-file. You might also need to modify the statements in the configurations so they will run.

When MATLAB cannot associate a configuration with an M-file, the Edit M-File Configurations dialog box displays the M-file name in red, displays a **File Not Found** message, and allows you to find the M-file to which you want to associate the configuration. In this example, MATLAB cannot find the file `collatzplot_new.m`, which has three configurations associated with it. For this example, `collatzplot_new.m` had been renamed to `collatzplot.m`, so the configurations associated with `collatzplot_new.m` need to be reassociated.



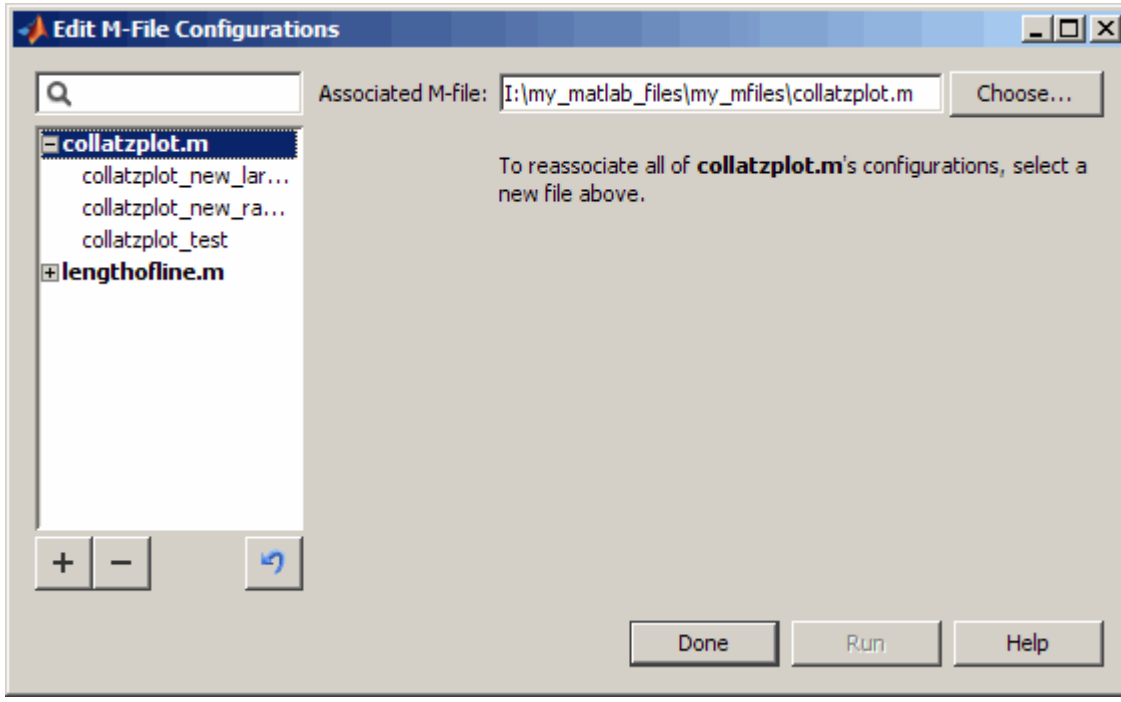
To reassociate configurations

1. In the list of configurations (left pane), select the M-file. The **Associated M-file** displays the full path to the M-file that was associated with the configurations. Click **Choose**.

2. In the resulting Open dialog box, navigate to and select the M-file with which you now want to associate the configurations. Click **Open**

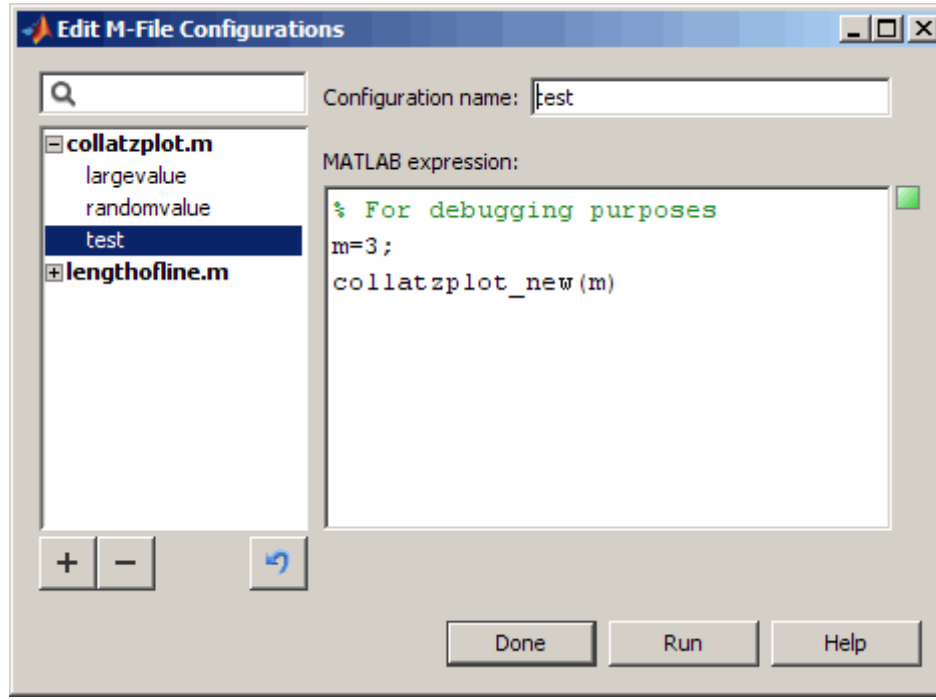
   In this example, you want to associate the configurations with `collatzplot.m`; select `collatzplot.m`.

3. In the Edit M-File Configurations dialog box, the **Associated M-file** value reflects the change you made and the **File Not Found** message no longer appears.

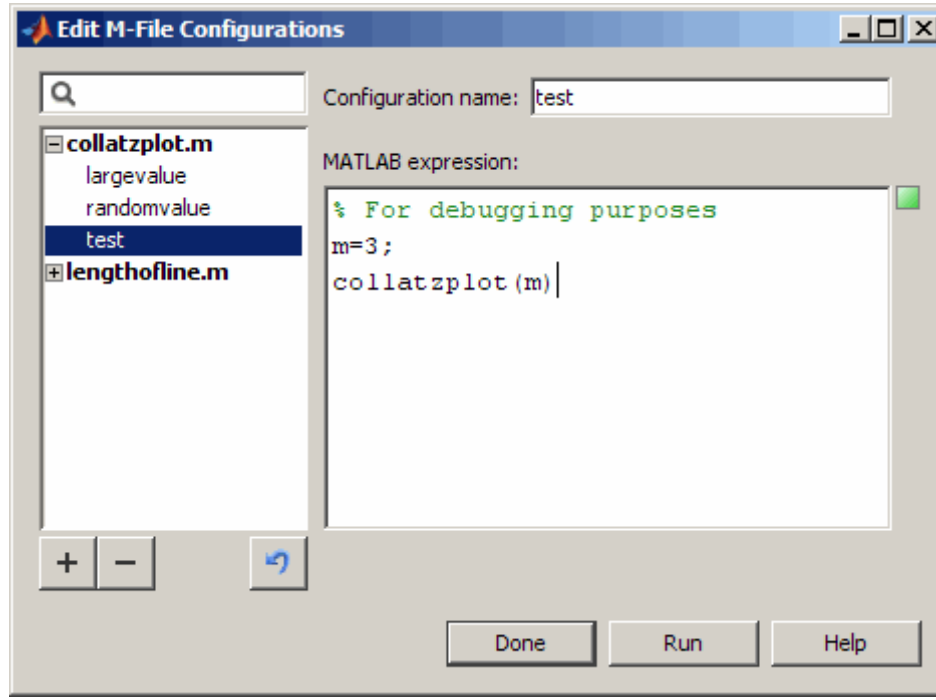


4 You might want to rename the configurations to be consistent with the new M-file name, or at least to not reflect the former M-file name. This is not required, but it is a good practice. To do so, select a configuration from the list in the left pane. In the right pane, edit the value for **Configuration name**. Repeat for all configurations associated with the M-file.

   In this example, remove `collatzplot_new` from the start of each configuration name.



5 For an M-file name change, you might need to modify the configuration statements to run correctly. For this example, modify the `collatzplot_new(m)` statement in each configuration to use `collatzplot(m)`.



See Also — Other Ways to Run M-Files from the Editor/Debugger

- See “Running an M-File with Breakpoints” on page 6-111 for additional information about running M-files while debugging.
- While debugging, you can execute sections of an M-file even though there are unsaved changes—see “Running Sections in M-Files That Have Unsaved Changes” on page 6-125.
- You can execute M-files one section at a time and quickly modify values incrementally using the toolbar—for more information, see “Using Cells for Rapid Code Iteration and Publishing Results” on page 6-133.

Finding Errors, Debugging, and Correcting M-Files

This section introduces general techniques for finding errors and using M-Lint automatic code analyzer to detect possible improvements in M-files. It then illustrates MATLAB debugger features found in the Editor/Debugger, as well equivalent Command Window debugging functions, using a simple example.

There are two kinds of errors:

- Syntax errors — For example, misspelling a function name or omitting a parenthesis.
- Run-time errors — These errors are usually algorithmic in nature. For example, you might modify the wrong variable or code a calculation incorrectly. Run-time errors are usually apparent when an M-file produces unexpected results. Run-time errors are difficult to track down because the function's local workspace is lost when the error forces a return to the MATLAB base workspace. The process of isolating and fixing these run-time problems is referred to as *debugging*.

In addition to finding and fixing problems with your M-files, you might want to improve the performance and make other enhancements using MATLAB tools.

Use the following techniques to isolate the causes of errors and improve your M-files.

Technique or Tool	Description	For More Information
Syntax highlighting and Delimiter matching	Syntax highlighting helps you identify unterminated strings in an M-file before you run the file. Delimiter matching helps you correctly match pairs of parentheses, brackets, braces, and keywords.	"Syntax Highlighting" on page 6-28 "Matching Delimiters (Parentheses)" on page 3-17

Technique or Tool	Description	For More Information
Error Messages	When you run an M-file with a syntax error, MATLAB will most likely detect it and display an error message in the Command Window describing the error and showing its line number in the M-file. Click the underlined portion of the error message, or position the cursor within the message and press **Ctrl+Enter**. The offending M-file opens in the Editor/Debugger, scrolled to the line containing the error. To check for syntax errors in an M-file without running the M-file, use the `pcode` function.	None
M-Lint	Use the M-Lint code analyzer to help you verify the integrity of your code and learn about potential improvements. Access M-Lint messages automatically while you work in a file in the Editor/Debugger, or run an M-Lint report for an existing file. To evaluate the McCabe complexity (also known as the cyclomatic complexity) of an M-File, use the `mlint` function with the `-cyc` option.	"M-Lint Code Analyzer" on page 6-87 and the reference page for the `mlint` function
Editor/ Debugger Graphical Debugger and MATLAB Debugging Functions	The MATLAB Editor/Debugger graphical debugger and MATLAB debugging functions are useful for correcting run-time problems because you can access function workspaces and examine or change the values they contain. You can set and clear *breakpoints*, indicators that temporarily halt execution in an M-file. While stopped at a breakpoint, you can change workspace contexts, view the function call stack, and execute the lines in an M-file one by one.	"Debugging Process and Features" on page 6-103

Technique or Tool	Description	For More Information
Other Debugging Techniques	• Add `keyboard` statements to the M-file — `keyboard` statements stop M-file execution at the point where they appear and allow you to examine and change the function's local workspace. This mode is indicated by a special `K>>`prompt. Resume function execution by typing `return` and pressing the **Enter** key. For more information, see the `keyboard` reference page. • Remove selected semicolons from the statements in your M-file—semicolons disable the display of output in the M-file. By removing the semicolons, you instruct MATLAB to display these results on your screen as the M-file executes. • List dependent functions—use the `depfun` function to see the dependent functions.	Reference pages for `keyboard` and `depfun` function
Cells	In the Editor/Debugger, isolate sections of an M-file, called cells, so you can easily make changes to and run a single section.	"Using Cells for Rapid Code Iteration and Publishing Results" on page 6-133
Profiler	Use the Profiler to help you improve performance and detect problems in your M-files. Access the Profiler from the Editor/Debugger by selecting **Tools > Open Profiler**.	"Profiling for Improving Performance" on page 7-27
Directory Reports	The M-file Directory Reports help you polish and package M-files before providing them to others to use. Access all of these tools from the Current Directory browser. You can access some of these directly from the Editor/Debugger **Tools** menu.	"Directory Reports in Current Directory Browser" on page 7-2

M-Lint Code Analyzer

In this section...

What Is M-Lint?

The M-Lint code analyzer checks your code for problems and recommends modifications to maximize performance and maintainability.

Ways to Use M-Lint

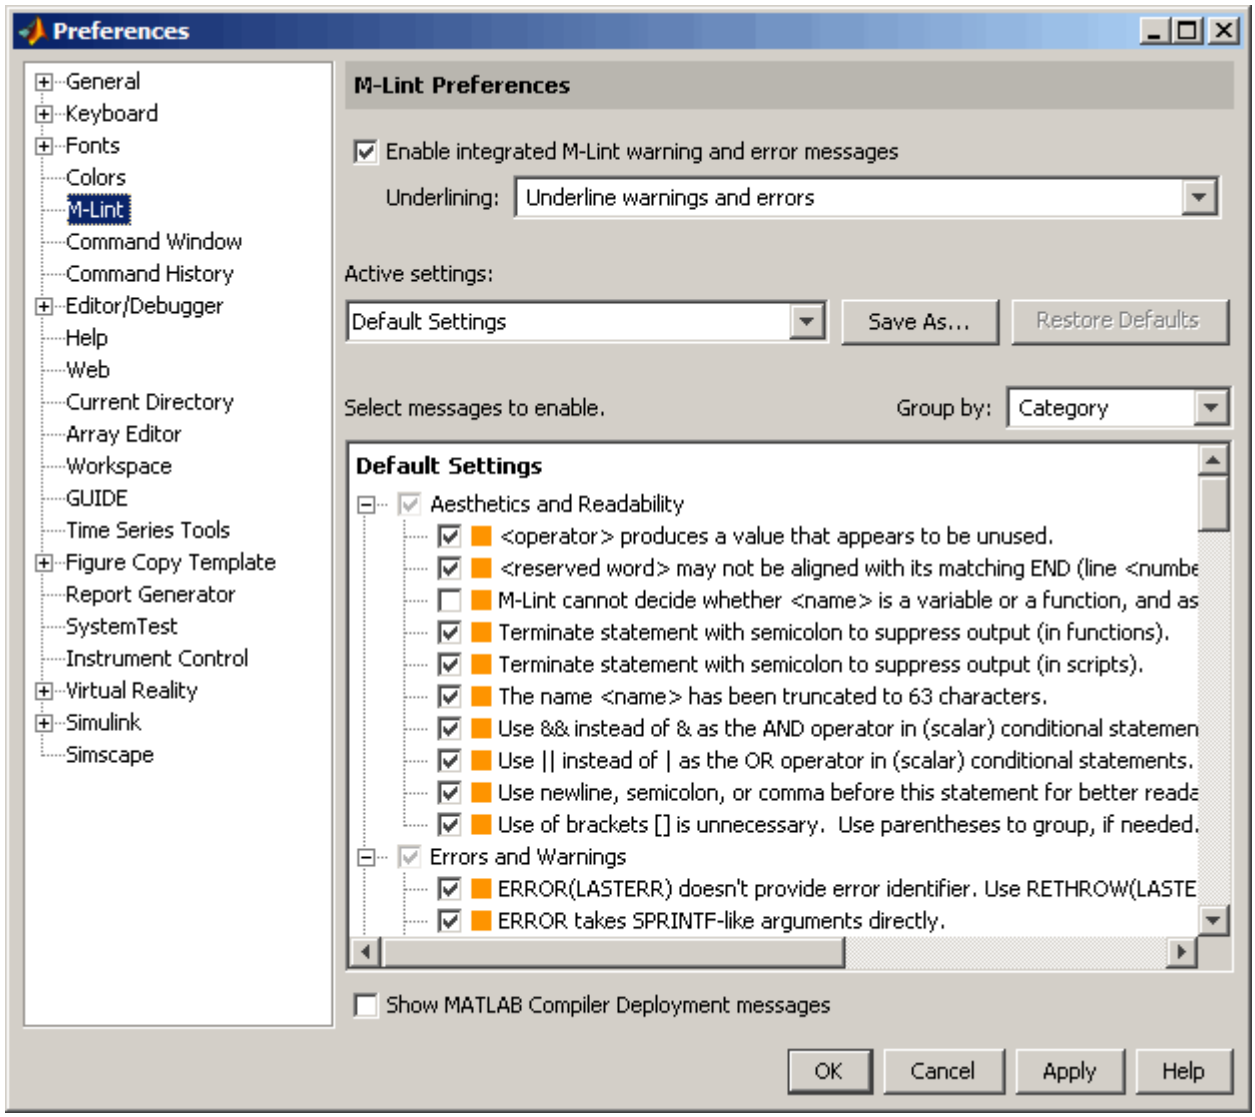
You can use M-Lint in two different ways, both of which report the same information:

- Run a report for an existing M-file or group of M-files. To do so, from an M-file in the Editor/Debugger, select **Tools > M-Lint > Show M-Lint Report**. Make any changes to your file based on the M-Lint messages in the report. After making changes, you must save the file and rerun the report to see if your changes addressed the issues noted in M-Lint messages. To run M-Lint for all files in a directory, access M-Lint from the Current Directory browser — select **View > Directory Reports > M-Lint Code Check Report**. For details, see "M-Lint Code Check Report" on page 7-16.
- Continuously check code in the Editor/Debugger while you work. View M-Lint messages and make changes to your file based on the messages. The code analyzer updates automatically and continuously so you can see if your changes addressed the issues noted in the M-Lint messages. For some messages, M-Lint offers automatic code correction. For details about specific M-Lint messages, see "M-Lint Code Check Report" on page 7-16. Information about using the continuous checking and correction interface in the Editor/Debugger is explained here.

M-Lint Automatic Code Analyzer in the Editor/Debugger

To use the M-Lint continuous code checking in an M-file in the Editor/Debugger, perform the following steps:

1. Ensure the M-Lint messaging preference is enabled: Select **File > Preferences > M-Lint** and select the **Enable integrated M-Lint warning and error messages** check box. To follow these instructions, be sure the **Underlining** option is set to `Underline warnings and errors`. Click **OK**.



2 Open an M-file in the Editor/Debugger. This example uses the sample file `lengthofline.m`:

a Open the example file:

```
open(fullfile(matlabroot,'help','techdoc','matlab_env','examples','lengthofline.m'))
```

b Save the example file to a directory to which you have write access. For the example, `lengthofline.m` is saved to `I:\MATLABFiles\mymfiles`.

3 The M-Lint message indicator at the top right edge of the window conveys the M-Lint messages reported for the file:

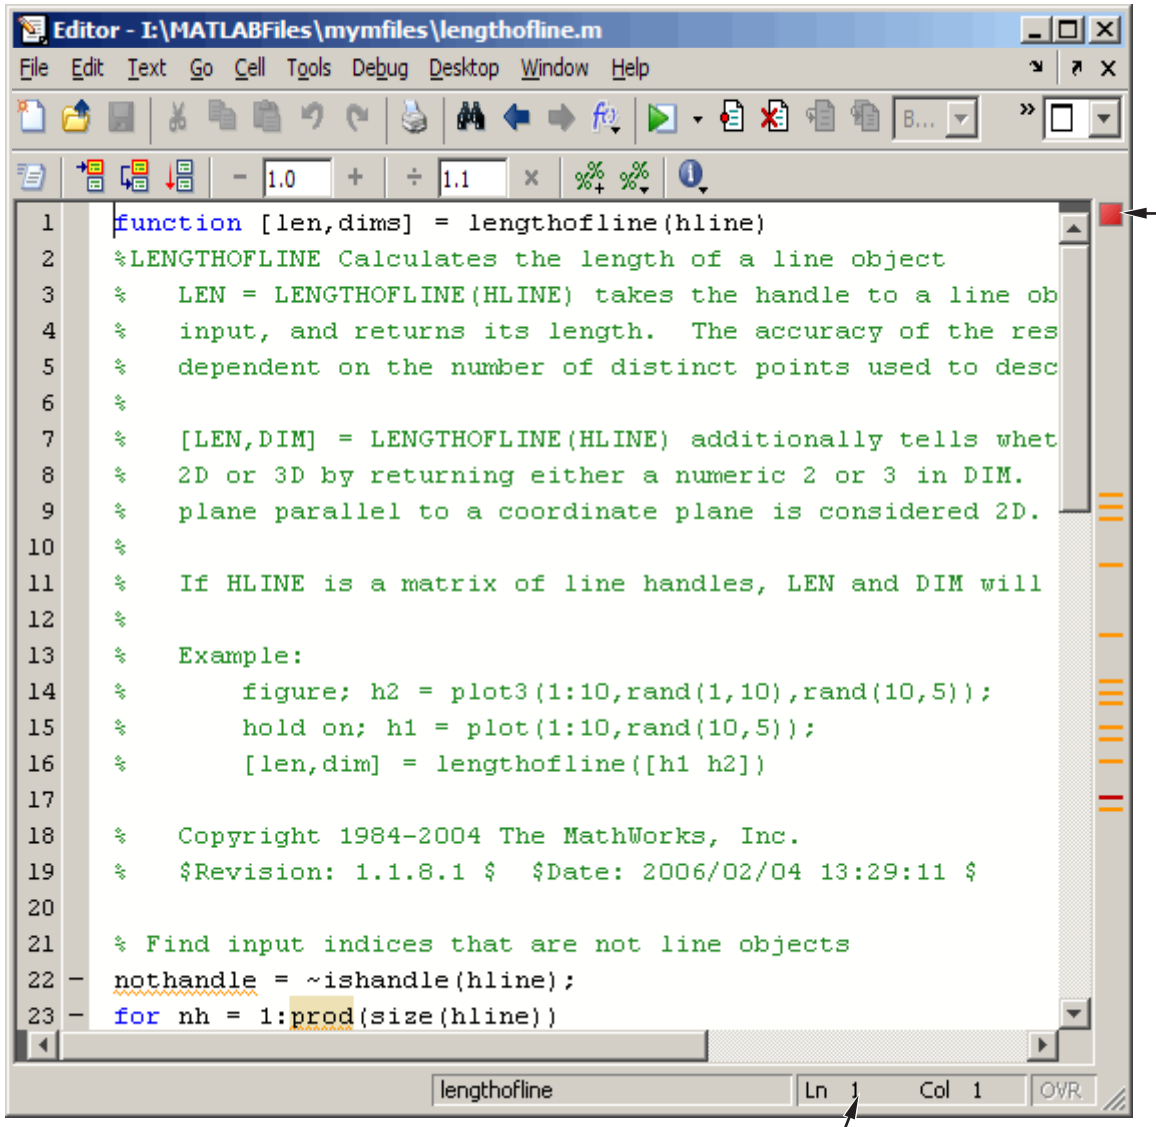
- Red means syntax errors were detected. Another way to detect some of these errors is using syntax highlighting to identify unterminated strings, and delimiter matching to identify unmatched keywords, parentheses, braces, and brackets.
- Orange means warnings or opportunities for improvement were detected, but no errors were detected.
- Green means no errors, warnings, or opportunities for improvement were detected.

For the example, the indicator is red, meaning there is at least one error in the file.

M-Lint message indicator for all messages in entire file:

- Red means errors detected
- Orange means warnings or improvement opportunities detected
- Green means none detected

Click indicator to go to next line that has an associated M-Lint message.



Current cursor position

4 Click the M-Lint message indicator to go to the next code fragment containing an M-Lint message. The next code fragment is relative to the current cursor position, viewable in the status bar.

   In the `lengthofline` example, the first message is at line 22. The cursor moves to the beginning of line 22.

5 The code fragment for which there is an M-Lint message is underlined in either red for errors or orange for warnings and improvement opportunities.

   To view the M-Lint message, move the pointer within the underlined fragment. The message appears with a yellow highlighted background, similar to datatips (see "Viewing Values as Datatips in the Editor/Debugger" on page 6-115).

Position cursor within orange underlined code fragment and Editor/Debugger displays the related M-Lint message.

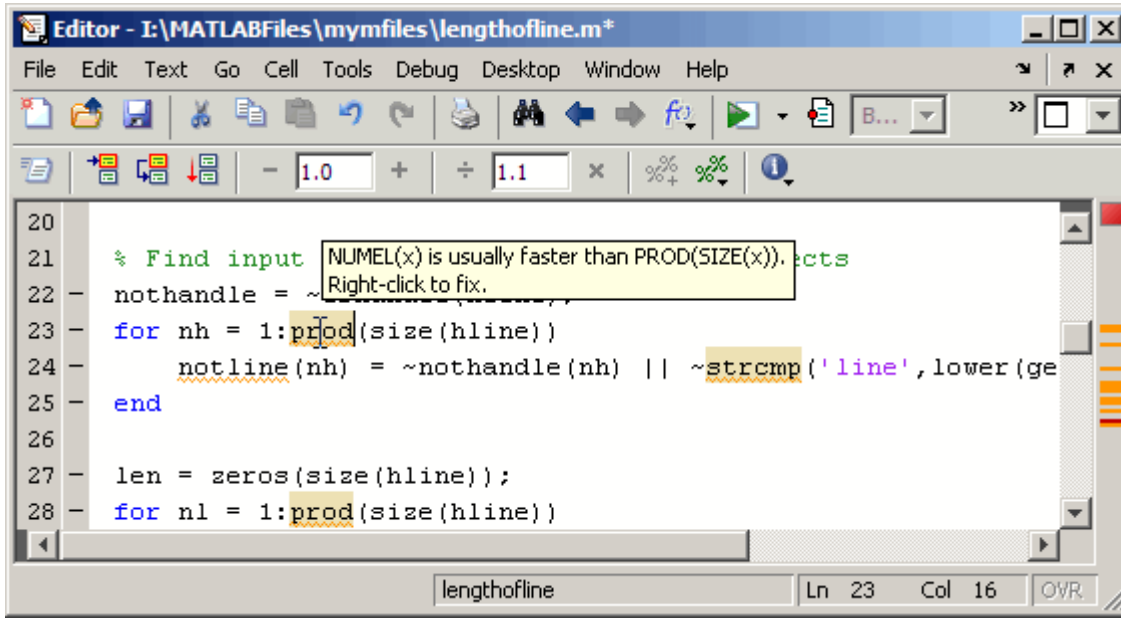
   This message means that in line 22, `nothandle` is assigned a value, but is probably not used anywhere after that in the file. The line might be

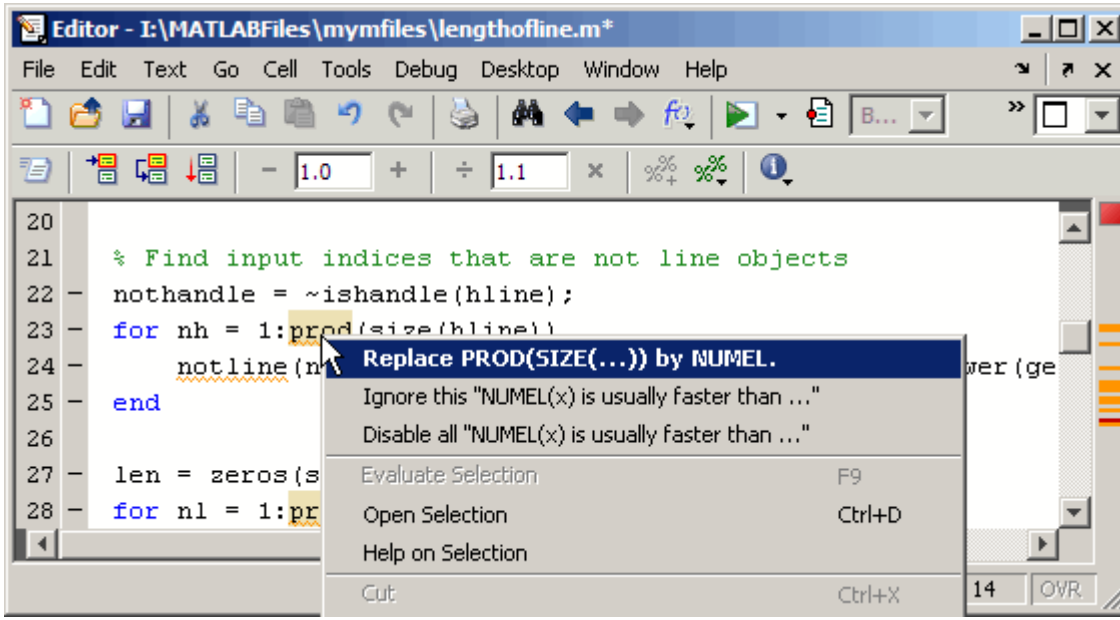
extraneous and you could delete it. But it might be that you actually intended to use the variable, as shown in step 6 of this example.

6 Make changes to your code as needed. The M-Lint indicator and underlining automatically update to reflect the changes you make, even if you do not save the file.

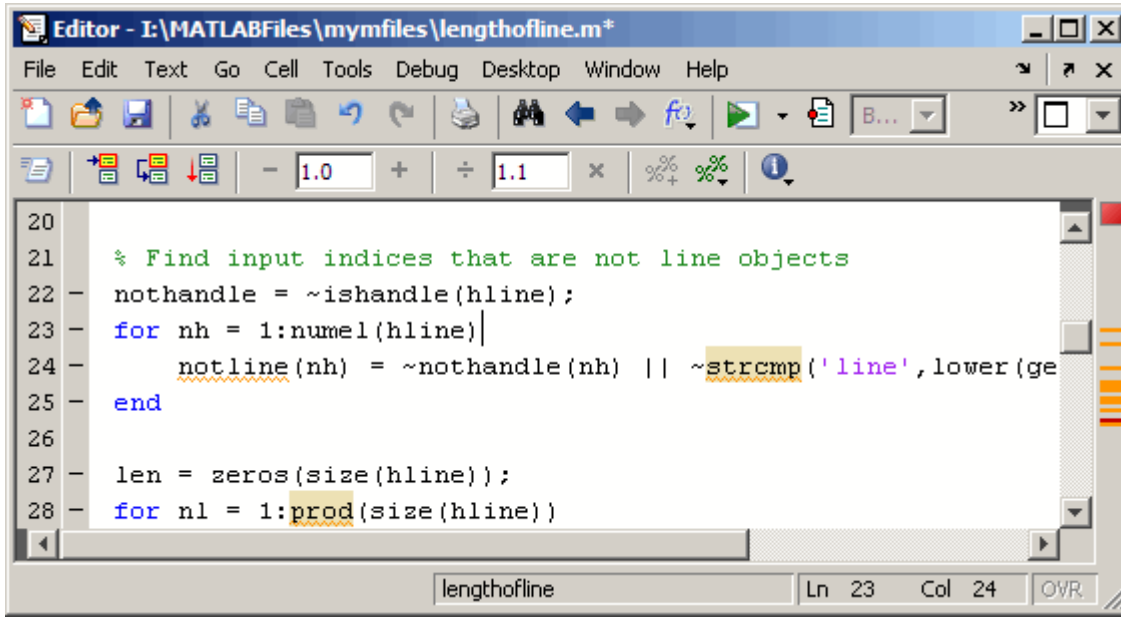
In this example, the intention was to use `nothandle` as a performance improvement by determining the value prior to the loop. Changing `~ishandle(hline(nh))` in line 24 to `nothandle(nh)` means there is no longer an M-Lint message associated with line 22. For more information about what the warning and improvement messages in this example mean and actions you can take to address them, see "Messages and Resulting Changes for the lengthofline Example" on page 7-21.

7 Some errors and warnings are highlighted, indicating M-Lint can automatically fix the code. For example, in `lengthofline`, line 23, `prod` is underlined because there is an M-Lint warning, and it is highlighted because an automatic fix is available. When you view the M-Lint message, it also indicates the auto-fix that is available.





Right-click the highlighted code (for a single-button mouse, use **Ctrl**+click). The first item in the context menu indicates the automatic fix that M-Lint can perform. Select it and M-Lint automatically corrects the code. In this example, M-Lint replaces `prod(size(hline))` with `numel(hline)`.



There is a preference you can set for the color—for more information, see "Other Colors" on page 2-75.

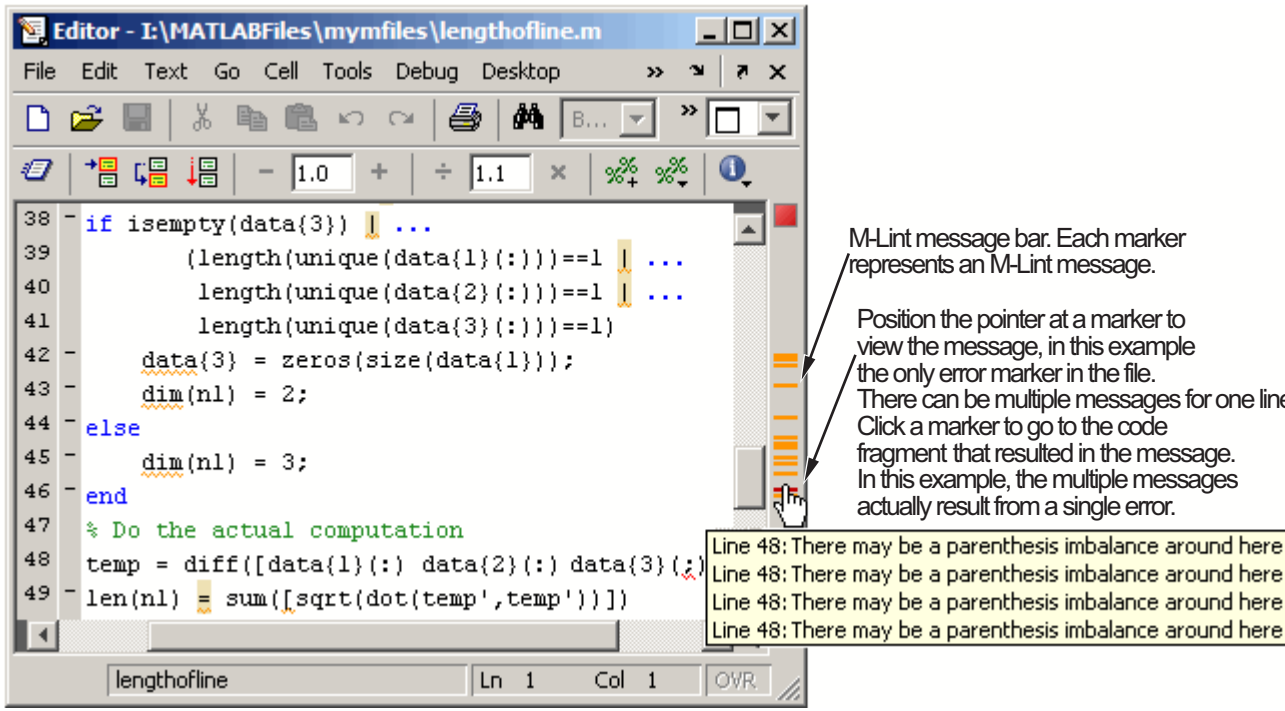
8 You might want to ignore certain M-Lint messages and do not want the messages to display; for more information, see "Suppressing M-Lint Indicators and Messages" on page 6-98.

9 You can click the M-Lint message indicator to go to the next message, or use the other way to view messages, which is the M-Lint message bar. Each marker in the bar represents a line that has associated M-Lint messages. A red marker means there is an error at that line, while an orange marker means there are warnings or suggested improvements, but no errors at that line.

   a Position the pointer at a marker in the message bar to view the message. For example, to see an error in `lengthofline`, position the pointer at a red marker in the message bar. There is only one error in the file and with the pointer positioned over it, the associated M-Lint messages appears. Click the marker to go to the first code fragment in the line that resulted in an M-Lint message. For the example, click the red marker, which takes you to the first suspect code fragment in line 48.

```
temp = diff([data{1}(:) data{2}(:) data{3}(;)]);
```

Multiple messages can represent a single problem or multiple problems. Addressing one might address all of them, or after addressing one, the other messages might change or what you need to do might become clearer.



b Make changes to address the problem noted in the M-Lint message—the M-Lint indicators update automatically.

In the example, the M-Lint message suggest a delimiter imbalance. You can check that by moving the arrow key over each of the delimiters to see if MATLAB indicates a mismatch. This requires that **File > Preferences > Keyboard > Delimiter Matching** has the **Match on arrow key** option selected. There are no mismatched delimiters. The actual problem is the semicolon in parentheses, `data{3}(;)`, is incorrect and should be a colon. In line 48, change `data{3}(;)` to `data{3}(:)`. When you make the change, the underline no longer appears in line 48.

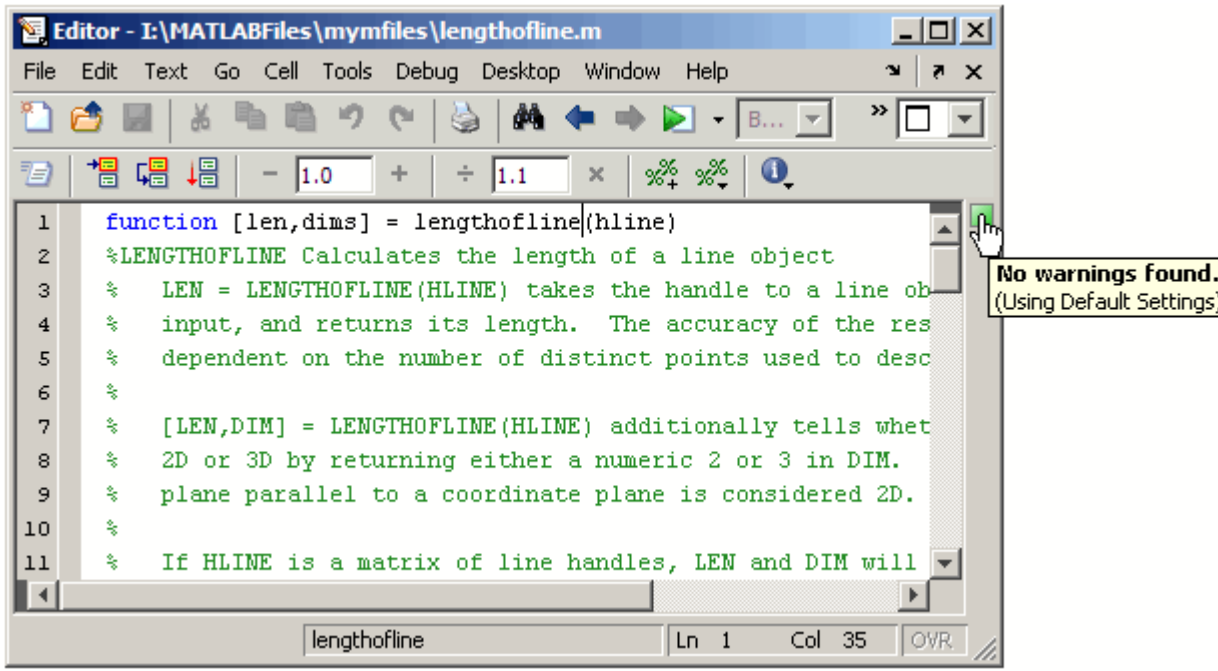
That single change addressed the issues in all of the M-Lint messages for line 48.

Because the change you made removed the only error in the file, the M-Lint message indicator at the top of the bar changes from red to orange, indicating that only warnings and potential improvements remain.

c If there are multiple messages associated with a line, there might be multiple underlined code fragments that are adjacent, as in the above example, making it difficult to display the message of interest. In those cases, it might be easier to view the messages via the marker on the message bar.

10 After making changes to address all M-Lint messages, or disabling designated messages, the M-Lint message indicator becomes green The example file with all M-Lint messages addressed has been saved as `lengthofline2.m`, which you can open by running

```
open(fullfile(matlabroot,'help','techdoc','matlab_env',...
'examples','lengthofline2.m'))
```



Suppressing M-Lint Indicators and Messages

Depending on what stage you are at in completing the M-file, you might want to restrict the underlining, which you can do via the M-Lint preference referred to in step 1, above. For example, when first coding, you might prefer no underlines because they would be distracting. For details, click the **Help** button in the Preferences dialog box.

M-Lint does not provide perfect information about every situation and in some cases, you might not want to make any changes based on an M-Lint message. In the event you do not want to change the code but you also do not want to see the M-Lint indicator and message for that line, instruct M-Lint to suppress them. For the `lengthofline` example, in line 49, the first M-Lint message is `Terminate statement with semicolon to suppress output (in functions)`. Adding a semicolon to the end of a statement suppresses output and is a common practice. M-Lint alerts you to lines that produce output but lack the terminating semicolon. If you want to view output from line 49, do not add the semicolon as M-Lint suggests.

There are a few different ways to suppress the M-Lint indicators and messages:

- "Ignore Only a Specific Instance" on page 6-99
- "Disable All Instances in All Files" on page 6-101
- "Disable Specified Messages or in Selected Files as Needed" on page 6-101

Note that you cannot suppress M-Lint error messages such as syntax errors, and therefore, the following options do not apply.

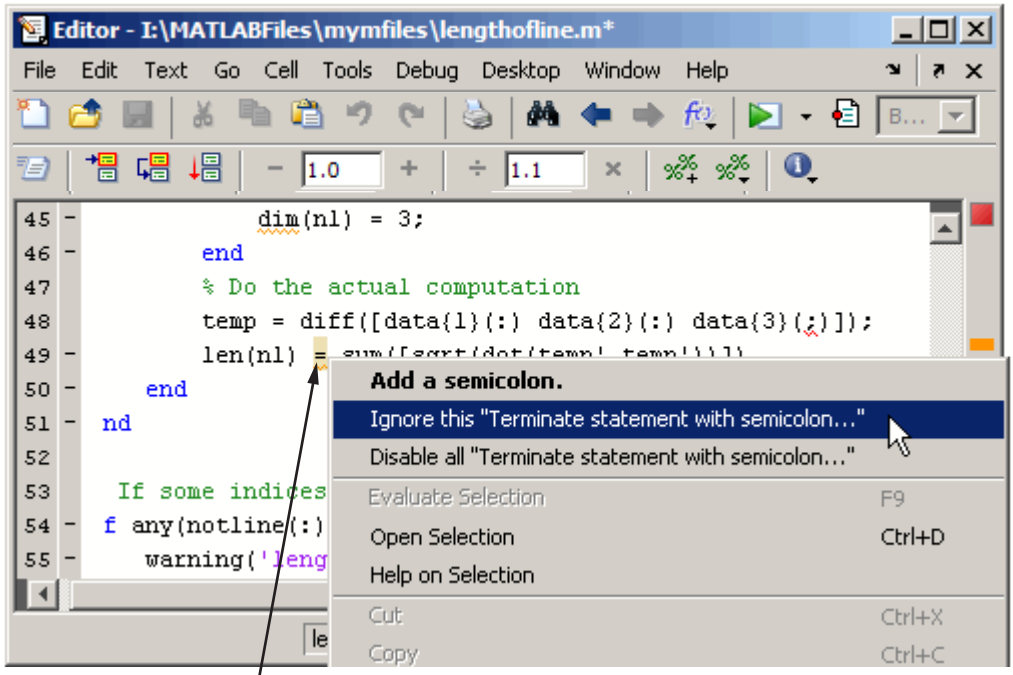
Ignore Only a Specific Instance

Right-click at the M-Lint underline (for a single-button mouse, use **Ctrl**+click). From the context menu, select `Ignore this "Terminate statement with semicolon..."`. M-Lint adds a `%#ok<NOPRT>` to the end of the line, which instructs MATLAB not to check for a terminating semicolon at that line. M-Lint removes the underline and mark in the M-Lint indicator bar for that message.

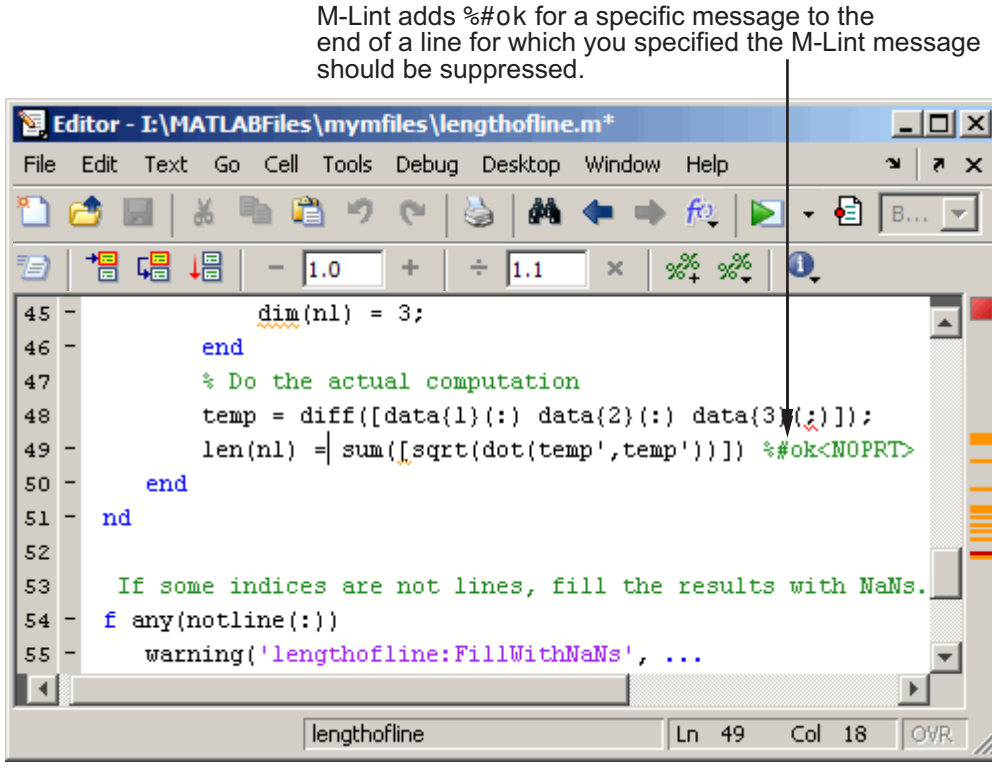
If there are two messages on a line that you do not want M-Lint to display, right-click separately at each underline and select the appropriate entry from the context menu. M-Lint expands the `%#ok` syntax. For the example, ignoring both messages for line 49 would add `%#ok<NBRAK,NOPRT>`.

For more information about `%#ok`, see the `mlint` function reference page.

This method of suppressing the messages changes the M-file. If M-Lint preferences are to set to enable this message, the specific instance of the message suppressed in this way will not appear because the `%#ok` takes precedence over the preference setting. If you later decide you want M-Lint to check for a terminating semicolon at that line, delete the `%#ok<NOPRT>` from the line.



Right-click at an M-Lint underline and select the option instructing M-Lint to ignore only this instance of the message, as shown in this example.



Disable All Instances in All Files

Right-click at the M-Lint underline (for a single-button mouse, use **Ctrl**+click). From the context menu, select `Disable all "Terminate statement with semicolon..."`. Doing so modifies the M-Lint preference setting, which applies to all occurrences in all files, unless a line includes a `%#ok` for that message. For more information about the M-Lint preference, including how to restore MATLAB default settings, select **File > Preferences > M-Lint**, and click **Help**.

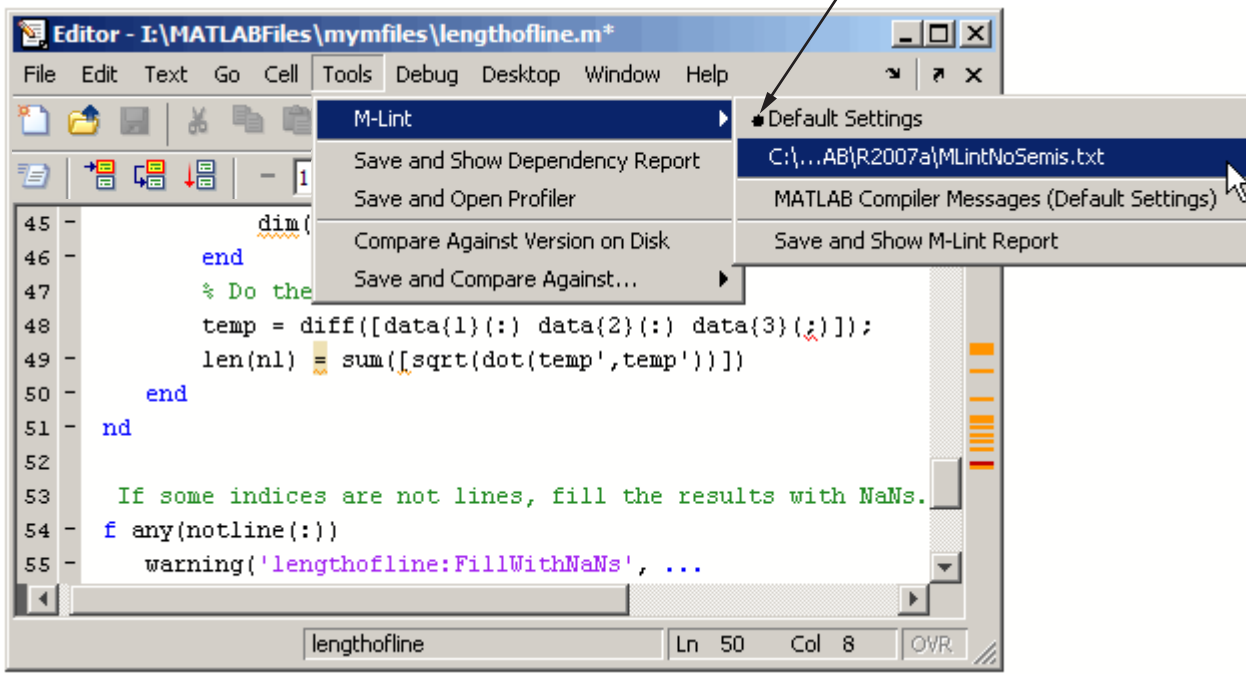
Disable Specified Messages or in Selected Files as Needed

Use M-Lint preferences by selecting **File > Preferences > M-Lint**. Then enable specific messages or categories of messages and save the settings to a

`txt` file. You can reuse the settings for any M-file, or provide the settings file to another user.

To use the saved settings, either select the settings file in M-Lint preferences, or in the Editor/Debugger. In the Editor/Debugger, right-click the M-Lint message bar (for a single-button mouse, use **Ctrl**+click), or select **Tools > M-Lint**. The currently-selected setting choice is shown, preceded by a bullet point. You can choose from any of the settings files, such as the `MLintNoSemis` example, as shown here.

M-Lint default settings are currently selected (as indicated by the bullet point preceding that menu item). Select any `txt` file to use the M-Lint settings specified in that file.



For more about M-Lint settings and preferences, click **Help** in the M-Lint preferences panel.

Debugging Process and Features

In this section...

Ways to Debug M-Files

You can debug the M-files using the Editor/Debugger, which is a graphical user interface, as well as by using debugging functions from the Command Window. You can use both methods interchangeably. These topics and the example describe both methods.

Preparing for Debugging

Do the following to prepare for debugging:

- Open the file — To use the Editor/Debugger for debugging, open it with the file to run.
- Save changes — If you are editing the file, save the changes before you begin debugging. If you try to run a file with unsaved changes from within the Editor/Debugger, the file is automatically saved before it runs. If you run a file with unsaved changes from the Command Window, MATLAB runs the saved version of the file, so you will not see the results of your changes.
- Add the files to a directory on the search path or put them in the current directory — Be sure the file you run and any files it calls are in directories

that are on the search path. If all files to be used are in the same directory, you can instead make that directory be the current directory.

Debugging Example — The Collatz Problem

The debugging process and features are best described via an example. To prepare to use the example, create two M-files, `collatz.m` and `collatzplot.m`, that produce data for the Collatz problem.

For any given positive integer, `n`, the `Collatz` function produces a sequence of numbers that always resolves to 1. If `n` is even, divide it by 2 to get the next integer in the sequence. If `n` is odd, multiply it by 3 and add 1 to get the next integer in the sequence. Repeat the steps until the next integer is 1. The number of integers in the sequence varies, depending on the starting value, `n`.

The Collatz problem is to prove that the Collatz function will resolve to 1 for all positive integers. The M-files for this example are useful for studying the Collatz problem. The file `collatz.m` generates the sequence of integers for any given `n`. The file `collatzplot.m` calculates the number of integers in the sequence for all integers from 1 through `m`, and plots the results. The plot shows patterns that can be further studied.

Following are the results when `n` is 1, 2, or 3.

n	Sequence	Number of Integers in the Sequence
1	1	1
2	2 1	2
3	3 10 5 16 8 4 2 1	8

M-Files for the Collatz Problem. Following are the two M-files you use for the debugging example. To create these files on your system, open two new M-files. Select and copy the following code from the Help browser and paste it into the M-files. Save and name the files `collatz.m` and `collatzplot.m`. Save them to your current directory or add the directory where you save them to the search path. One of the files has an embedded error to illustrate the debugging features.

Code for `collatz.m`.

```
function sequence=collatz(n)
% Collatz problem. Generate a sequence of integers resolving to 1
% For any positive integer, n:
%  Divide n by 2 if n is even
%  Multiply n by 3 and add 1 if n is odd
%  Repeat for the result
%  Continue until the result is 1%

sequence = n;
next_value = n;
while next_value > 1
 if rem(next_value,2)==0
  next_value = next_value/2;
 else
  next_value = 3*next_value+1;
 end
 sequence = [sequence, next_value];
end
```

Code for `collatzplot.m`.

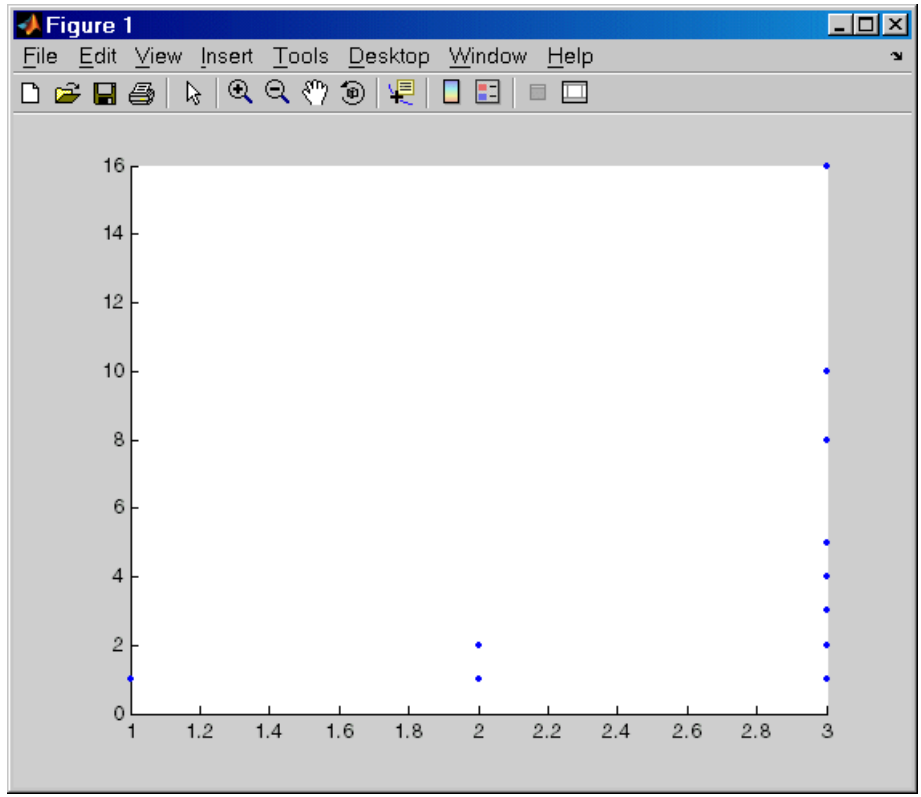
```
function collatzplot(m)
% Plot length of sequence for Collatz problem
% Prepare figure
clf
set(gcf,'DoubleBuffer','on')
set(gca,'XScale','linear')
%
% Determine and plot sequence and sequence length
for N = 1:m
 plot_seq = collatz(N);
 seq_length(N) = length(plot_seq);
 line(N,plot_seq,'Marker','.','MarkerSize',9,'Color','blue')
 drawnow
end
```

Trial Run for Example. Open the file `collatzplot.m`. Make sure the current directory is the directory in which you saved `collatzplot`.

Try out `collatzplot` to see if it works correctly. Use a simple input value, for example, 3, and compare the results to those shown in the preceding table. Typing

```
collatzplot(3)
```

produces the plot shown in the following figure.



The plot for n = 1 appears to be correct—for 1, the Collatz series is 1, and contains one integer. But for n = 2 and n = 3, it is wrong because there should be only one value plotted for each integer, the number of integers in the sequence, which the preceding table shows to be 2 (for n = 2) and 8 (for n = 3). Instead, multiple values are plotted. Use MATLAB debugging features to isolate the problem.

Setting Breakpoints

Set breakpoints to pause execution of the M-file so you can examine values where you think the problem might be. You can set breakpoints in the Editor/Debugger, using functions in the Command Window, or both.

There are three basic types of breakpoints you can set in M-files:

- A standard breakpoint, which stops at a specified line in an M-file. For details, see "Setting Standard Breakpoints" on page 6-108.
- A conditional breakpoint, which stops at a specified line in an M-file only under specified conditions. For details, see "Conditional Breakpoints" on page 6-126.
- An error breakpoint that stops in any M-file when it produces the specified type of warning, error, or `NaN` or infinite value. For details, see "Error Breakpoints" on page 6-129.

You can disable standard and conditional breakpoints so that MATLAB temporarily ignores them, or you can remove them. For details, see "Disabling and Clearing Breakpoints" on page 6-119. Breakpoints are not maintained after you exit the MATLAB session.

You can only set valid standard and conditional breakpoints at executable lines in saved files that are in the current directory or in directories on the search path. When you add or remove a breakpoint in a file that is not in a directory on the search path or in the current directory, a dialog box appears, presenting you with options that allow you to add or remove the breakpoint. You can either change the current directory to the directory containing the file, or you can add the directory containing the file to the search path.

Do not set a breakpoint at a `for` statement if you want to examine values at increments in the loop. For example, in

```
for n = 1:10
    m = n+1;
end
```

MATLAB executes the `for` statement only once, which is efficient. Therefore, when you set a breakpoint at the `for` statement and step through the file, you

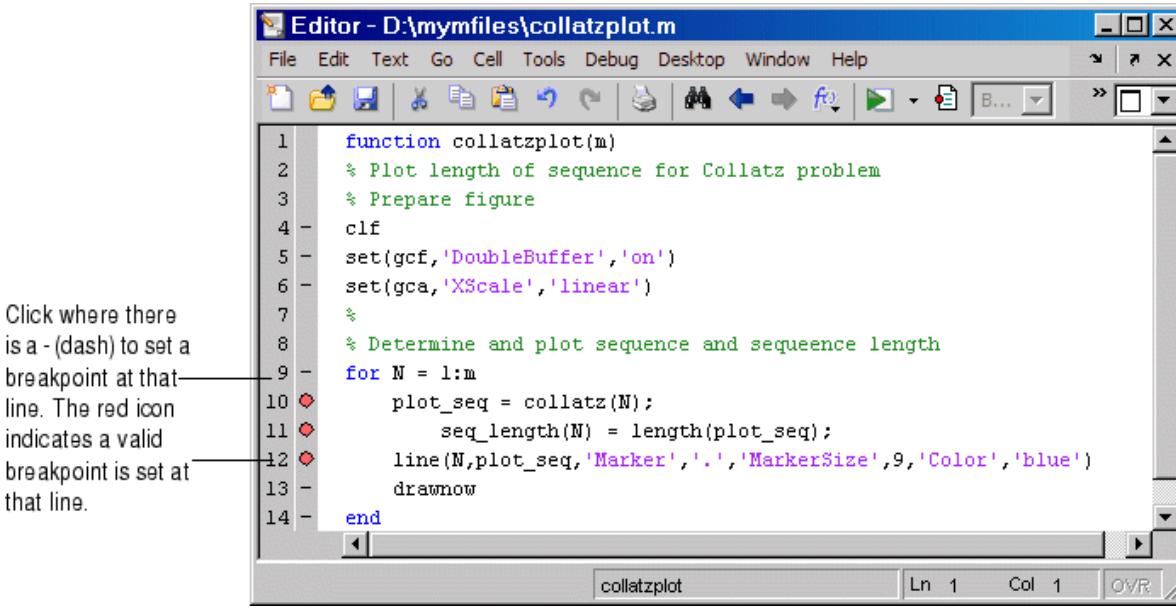
only stop at the `for` statement once. Instead place the breakpoint at the next line, `m=n+1` to stop at each pass through the loop.

You cannot set breakpoints while MATLAB is busy, for example, running an M-file, unless that M-file is paused at a breakpoint.

Setting Standard Breakpoints

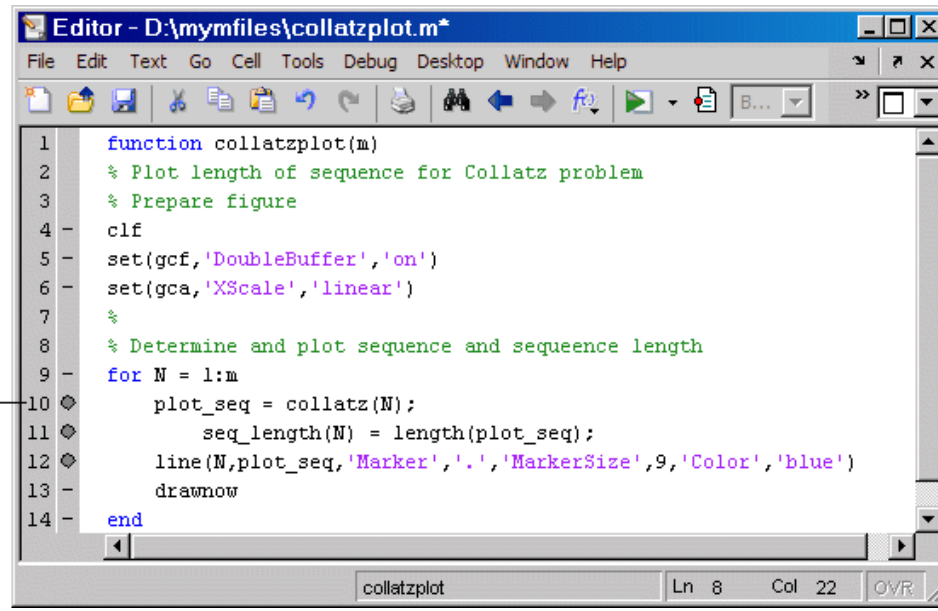
To set a standard breakpoint using the Editor/Debugger, click in the breakpoint alley at the line where you want to set the breakpoint. The breakpoint alley is the narrow column on the left side of the Editor/Debugger, just right of the line number. Set breakpoints at lines that are preceded by a - (dash). Lines not preceded by a dash, such as comments or blank lines, are not executable — if you try to set a breakpoint there, it is actually set at the next executable line. Other ways to set a breakpoint are to position the cursor in the line and then click the Set/Clear Breakpoint button  on the toolbar, or select **Set/Clear Breakpoint** from the **Debug** menu or the context menu. A breakpoint icon appears.

Set Breakpoints for the Example. It is unclear whether the problem in the example is in `collatzplot` or `collatz`. To start, set breakpoints in `collatzplot.m` at lines 10, 11, and 12. The breakpoint at line 10 allows you to step into `collatz` to see if the problem might be there. The breakpoints at lines 11 and 12 stop the program where you can examine the interim results.



Valid (Red) and Invalid (Gray) Breakpoints. Red breakpoints are valid standard breakpoints. If breakpoints are instead gray, they are not valid.

When breakpoints are gray, they are not valid. In this example, it is because the file has not been saved since changes were made to it. Save the file to make the breakpoints valid (red).



Breakpoints are gray for either of these reasons:

- The file has not been saved since changes were made to it. Save the file to make breakpoints valid. The gray breakpoints become red, indicating they are now valid. Any gray breakpoints that were entered at invalid breakpoint lines automatically move to the next valid breakpoint line with the successful file save.
- There is a syntax error in the file. When you set a breakpoint, an error message appears indicating where the syntax error is. Fix the syntax error and save the file to make breakpoints valid.

Function Alternative for Setting Breakpoints

To set a breakpoint using the debugging functions, use `dbstop`. For the example, type

```
dbstop in collatzplot at 10
dbstop in collatzplot at 11
dbstop in collatzplot at 12
```

Some useful related functions are

- `dbtype` — Lists the M-file with line numbers in the Command Window.
- `dbstatus` — Lists breakpoints.

Running an M-File with Breakpoints

After setting breakpoints, run the M-file from the Command Window or the Editor/Debugger.

Running the Example

For the example, run `collatzplot` for the simple input value, 3, by typing in the Command Window

```
collatzplot(3)
```

The example, `collatzplot`, requires an input argument and therefore runs only from the Command Window and not from the Editor/Debugger.

Results of Running an M-File Containing Breakpoints

Running the M-file results in the following:

- The prompt in the Command Window changes to

  ```
  K>>
  ```

  indicating that MATLAB is in debug mode.

- The program pauses at the first breakpoint. This means that line will be executed when you continue. The pause is indicated in the Editor/Debugger by the green arrow just to the right of the breakpoint, which in the example, is line 10 of `collatzplot` as shown here.

  
  If you use debugging functions from the Command Window, the line at which you are paused is displayed in the Command Window. For the example, it would show

  ```
  10   plot_seq = collatz(N);
  ```

- The function displayed in the **Stack** field on the toolbar changes to reflect the current function (sometimes referred to as the caller or calling workspace). The call stack includes subfunctions as well as called functions. If you use debugging functions from the Command Window, use `dbstack` to view the current call stack.
- If the file you are running is not in the current directory or a directory on the search path, you are prompted to either add the directory to the path or change the current directory.

In debug mode, you can set breakpoints, step through programs, examine variables, and run other functions.

Note that MATLAB could become nonresponsive if it stops at a breakpoint while displaying a modal dialog box or figure that your M-file creates. In that event, use **Ctrl+C** to go the MATLAB prompt.

Stepping Through an M-File

While debugging, you can step through an M-file, pausing at points where you want to examine values.

Use the step buttons or the step items in the **Debug** menu of the Editor/Debugger or desktop, or use the equivalent functions.

Toolbar Button	Debug Menu Item	Description	Function Alternative
	**Continue** or **Run** or **Save and Run**	Continue execution of M-file until completion or until another breakpoint is encountered. The menu item says **Run** or **Save and Run** if a file is not already running.	`dbcont`
None	**Go Until Cursor**	Continue execution of M-file until the line where the cursor is positioned. Also available on the context menu.	None

Toolbar Button	Debug Menu Item	Description	Function Alternative
	**Step**	Execute the current line of the M-file.	`dbstep`
	**Step In**	Execute the current line of the M-file and, if the line is a call to another function, step into that function.	`dbstep in`
	**Step Out**	After stepping in, run the rest of the called function or subfunction, leave the called function, and pause.	`dbstep out`

Continue Running in the Example

In the example, `collatzplot` is paused at line 10. Because the problem results are correct for `N/n = 1`, continue running until `N/n = 2`. Press the Continue button three times to move through the breakpoints at lines 10, 11, and 12. Now the program is again paused at the breakpoint at line 10.

Stepping In to Called Function in the Example

Now that `collatzplot` is paused at line 10 during the second iteration, use the Step In button or type `dbstep in` in the Command Window to step into `collatz` and walk through that M-file. Stepping into line 10 of `collatzplot` goes to line 9 of `collatz`. If `collatz` is not open in the Editor/Debugger, it automatically opens if you have selected **Debug > Open M-Files When Debugging**.

The pause indicator at line 10 of `collatzplot` changes to a hollow arrow ⇨, indicating that MATLAB control is now in a subfunction called from the main program. The call stack shows that the current function is now `collatz`.

In the called function, `collatz` in the example, you can do the same things you can do in the main (calling) function—set breakpoints, run, step through, and examine values.

Examining Values

While the program is paused, you can view the value of any variable currently in the workspace. Examine values when you want to see whether a line of code has produced the expected result or not. If the result is as expected, continue running or step to the next line. If the result is not as expected, then that line, or a previous line, contains an error. Use the following methods to examine values:

Many of these methods are used in "Examining Values in the Example" on page 6-117.

Selecting the Workspace

Variables assigned through the Command Window and created using scripts are considered to be in the base workspace. Variables created in a function belong to their own function workspace. To examine a variable, you must first select its workspace. When you run a program, the current workspace is shown in the **Stack** field. To examine values that are part of another workspace for a currently running function or for the base workspace, first select that workspace from the list in the **Stack** field.

If you use debugging functions from the Command Window, use `dbstack` to display the call stack. Use `dbup` and `dbdown` to change to a different workspace. Use `who` or `whos` to list the variables in the current workspace.

Workspace in the Example. At line 10 of `collatzplot`, you stepped in, so the current line is 9 in `collatz`. The **Stack** shows that `collatz` is the current workspace.

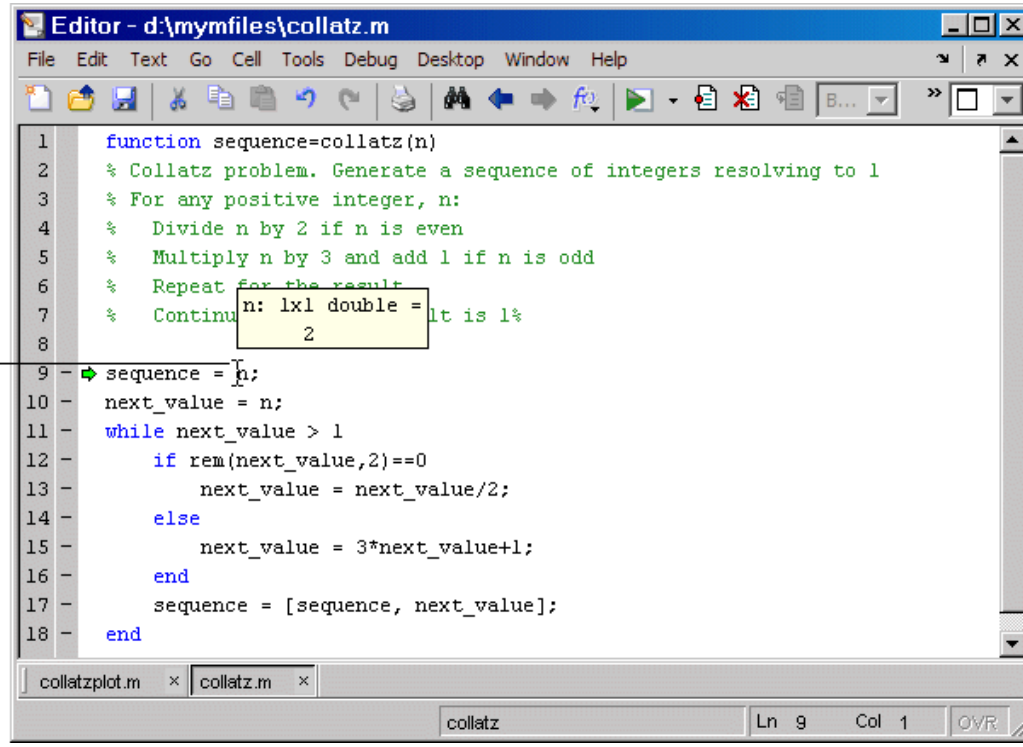
Viewing Values as Datatips in the Editor/Debugger

In the Editor/Debugger, position the pointer to the left of a variable on that line. Its current value appears — this is called a datatip, which is like a tooltip for data. The datatip stays in view until you move the pointer. If you have trouble getting the datatip to appear, click in the line and then move the pointer next to the variable.

A related function is `datatipinfo`.

Datatips in the Example. Position the pointer over `n` in line 9 of `collatz`. The datatip shows that `n = 2`, as expected.

Hold the pointer over a variable. Its current value temporarily displays as a datatip.



```
1   function sequence=collatz(n)
2   % Collatz problem. Generate a sequence of integers resolving to 1
3   % For any positive integer, n:
4   %   Divide n by 2 if n is even
5   %   Multiply n by 3 and add 1 if n is odd
6   %   Repeat for the result
7   %   Continu                    lt is 1%
8
9   sequence = n;
10  next_value = n;
11  while next_value > 1
12      if rem(next_value,2)==0
13          next_value = next_value/2;
14      else
15          next_value = 3*next_value+1;
16      end
17      sequence = [sequence, next_value];
18  end
```

Viewing Values in the Command Window

You can examine values while in debug mode at the `K>>` prompt. To see the variables currently in the workspace, use `who`. Type a variable name in the

Command Window and MATLAB displays its current value. For the example, to see the value of `n`, type

```
n
```

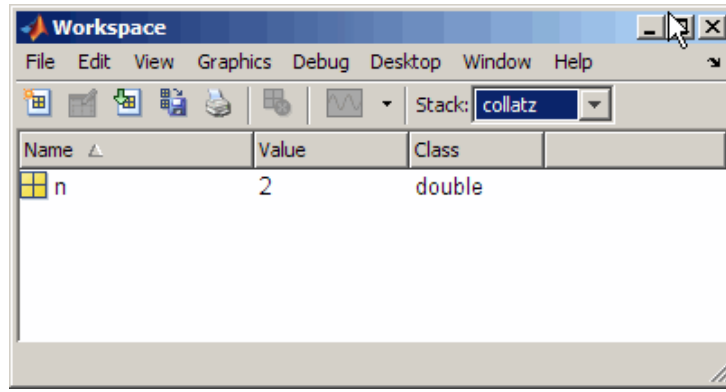
MATLAB returns the expected result

```
n =
 2
```

and displays the debug prompt, `K>>`.

Viewing Values in the Workspace Browser and Array Editor

You can view the value of variables in the **Value** column of the Workspace browser. The Workspace browser displays all variables in the current workspace. Use the **Stack** in the Workspace browser to change to another workspace and view its variables.

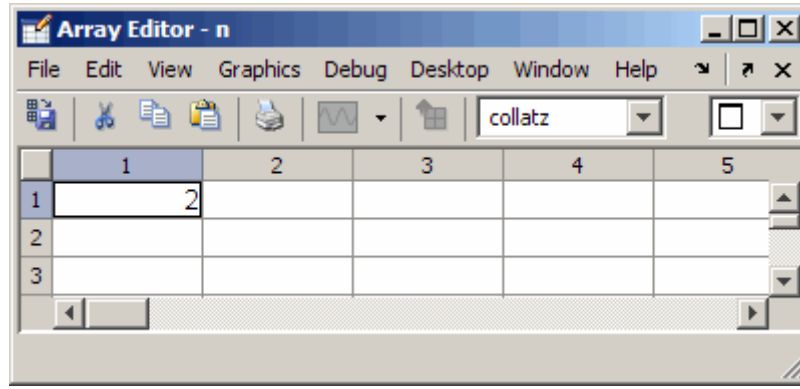


The **Value** column does not show all details for all variables. To see details, double-click a variable in the Workspace browser. The Array Editor opens, displaying the content for that variable. You can open the Array Editor directly for a variable using `openvar`.

To see the value of `n` in the Array Editor for the example, type

```
openvar n
```

and the Array Editor opens, showing that n = 2 as expected.



Evaluating a Selection

Select a variable or equation in an M-file in the Editor/Debugger. Right-click and select **Evaluate Selection** from the context menu (for a single-button mouse, use **Ctrl**+click). MATLAB displays the value of the variable or equation in the Command Window. You cannot evaluate a selection while MATLAB is busy, for example, running an M-file.

Examining Values in the Example

Step from line 9 through line 13 in `collatz`. Step again, and the pause indicator jumps to line 17, just after the `if` loop, as expected. Step again, to line 18, check the value of `sequence` in line 17 and see that the array is

```
2   1
```

as expected for n = 2. Step again, which moves the pause indicator from line 18 to line 11. At line 11, step again. Because `next_value` is now 1, the `while` loop ends. The pause indicator is at line 11 and appears as a green down arrow ⬇. This indicates that processing in the called function is complete and program control will return to the calling program. Step again from line 11 in `collatz` and execution is now paused at line 10 in `collatzplot`.

Note that instead of stepping through `collatz`, the called function, as was just done in this example, you can step out from a called function back to the

calling function, which automatically runs the rest of the called function and returns to the next line in the calling function. To step out, use the Step Out button or type `dbstep out` in the Command Window.

In `collatzplot`, step again to advance to line 11, then line 12. The variable `seq_length` in line 11 is a vector with the elements

```
1   2
```

which is correct.

Finally, step again to advance to line 13. Examining the values in line 12, `N = 2` as expected, but the second variable, `plot_seq`, has two values, where only one value is expected. While the value for `plot_seq` is as expected

```
2   1
```

it is the incorrect variable for plotting. Instead, `seq_length(N)` should be plotted.

Correcting Problems and Ending Debugging

These are some of the ways to correct problems and end the debugging session:

Many of these features are used in "Completing the Example" on page 6-121.

Changing Values and Checking Results

While debugging, you can change the value of a variable in the current workspace to see if the new value produces expected results. While the

program is paused, assign a new value to the variable in the Command Window, Workspace browser, or Array Editor. Then continue running or stepping through the program. If the new value does not produce the expected results, the program has a different problem.

Ending Debugging

After identifying a problem, end the debugging session. You must end a debugging session if you want to change and save an M-file to correct a problem, or if you want to run other functions in MATLAB.

Note It is recommended that you quit debug mode before editing an M-file. If you edit an M-file while in debug mode, you can get unexpected results when you run the file. If you do edit an M-file while in debug mode, breakpoints turn gray, indicating that results might not be reliable. See "Valid (Red) and Invalid (Gray) Breakpoints" on page 6-109 for details.

If you attempt to save an edited M-file while in debug mode, a dialog box appears allowing you to exit debug mode and save the file.

To end debugging, click the Exit Debug Mode button  , or select **Exit Debug Mode** from the **Debug** menu.

You can instead use the function `dbquit` or the **Shift+F5** keyboard shortcut to end debugging.

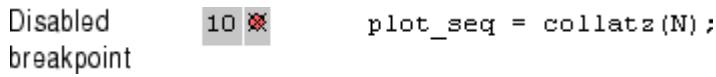
After quitting debugging, pause indicators in the Editor/Debugger display no longer appear, and the normal prompt `>>` appears in the Command Window instead of the debugging prompt, `K>>`. You can no longer access the call stack.

Disabling and Clearing Breakpoints

Disable a breakpoint to temporarily ignore it. Clear a breakpoint to remove it.

Disabling and Enabling Breakpoints. You can disable selected breakpoints so the program temporarily ignores them and runs uninterrupted, for example, after you think you identified and corrected a problem. This is especially useful for conditional breakpoints — see “Conditional Breakpoints” on page 6-126.

To disable a breakpoint, right-click the breakpoint icon and select **Disable Breakpoint** from the context menu, or click anywhere in a line and select **Enable/Disable Breakpoint** from the **Debug** or context menu. You can also disable a conditional breakpoint by clicking the breakpoint icon. This puts an `X` through the breakpoint icon as shown here.



After disabling a breakpoint, you can enable it to make it active again, or clear it. To enable it, right-click the breakpoint icon and select **Enable Breakpoint** from the context menu, or click anywhere in a line and select **Enable/Disable Breakpoint** from the **Breakpoints** or context menu. The `X` no longer appears on the breakpoint icon and program execution will pause at that line.

When you run `dbstatus`, the resulting message for a disabled breakpoint is

```
Breakpoint on line 10 has conditional expression 'false'.
```

Clearing (Removing) Breakpoints. All breakpoints remain in a file until you clear (remove) them or until they are automatically cleared. Clear a breakpoint after determining that a line of code is not causing a problem.

To clear a breakpoint in the Editor/Debugger, click anywhere in a line and select **Set/Clear Breakpoint** from the **Debug** or context menu. The breakpoint for that line is cleared. Another way to clear a breakpoint is to click a standard breakpoint icon, or a disabled conditional breakpoint icon.

To clear all breakpoints in all files, select **Debug > Clear Breakpoints in All Files**, or click its equivalent button on the toolbar.

The function that clears breakpoints is `dbclear`. To clear all breakpoints, use `dbclear all`. For the example, clear all of the breakpoints in `collatzplot` by typing

```
dbclear all in collatzplot
```

Breakpoints are automatically cleared when you

- End the MATLAB session
- Clear the M-file using `clear name` or `clear all`

Note When `clear name` or `clear all` is in a statement in an M-file that you are debugging, it clears the breakpoints.

Saving Breakpoints

You can use the `s=dbstatus` syntax and then save `s` to save the current breakpoints to a MAT-file. At a later time, you can load `s` and restore the breakpoints using `dbstop(s)`. For more information, including an example, see the `dbstatus` reference page.

Correcting an M-File

To correct a problem in an M-file,

1. Quit debugging.

   Do not make changes to an M-file while MATLAB is in debug mode. If you do edit an M-file while in debug mode, breakpoints turn gray, indicating that results might not be reliable. See“Valid (Red) and Invalid (Gray) Breakpoints” on page 6-109 for details.

2. Make changes to the M-file.

3. Save the M-file.

4. Set, disable, or clear breakpoints, as appropriate.

5. Run the M-file again to be sure it produces the expected results.

Completing the Example

To correct the problem in the example, do the following:

1. End the debugging session. One way to do this is to select **Exit Debug Mode** from the **Debug** menu.

2. In `collatzplot.m` line 12, change the string `plot_seq` to `seq_length(N)` and save the file.

3. Clear the breakpoints in `collatzplot.m`. One way to do this is by typing

   ```
   dbclear all in collatzplot
   ```

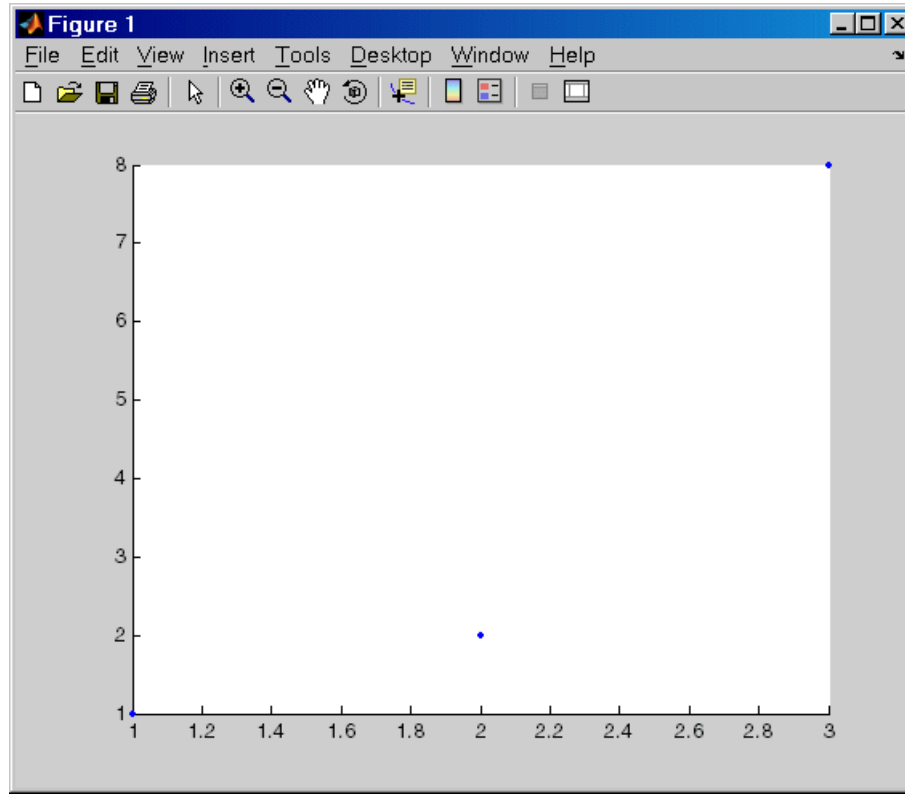
   in the Command Window.

4. Run `collatzplot` for `m` = 3 by typing

   ```
   collatzplot(3)
   ```

   in the Command Window.

5. Verify the result. The figure shows that the length of the Collatz series is 1 when `n` = 1, 2 when `n` = 2, and 8 when `n` = 3, as expected.



6 Test the function for a slightly larger value of `m`, such as 6, to be sure the results are still accurate. To make it easier to verify `collatzplot` for `m = 6` as well as the results for `collatz`, add this line at the end of `collatz.m`

```
sequence
```

which displays the series in the Command Window. The results for when `n = 6` are

```
sequence =

     6     3    10     5    16     8     4     2     1
```

Then run `collatzplot` for `m = 6` by typing

```
collatzplot(6)
```

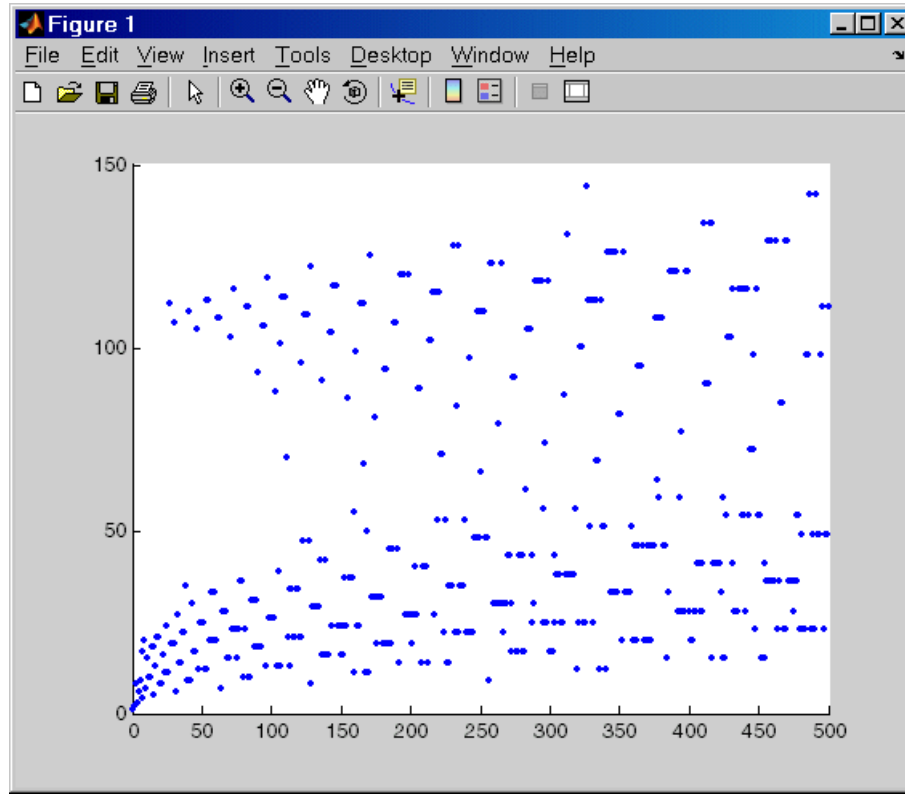
7 To make debugging easier, you ran `collatzplot` for a small value of `m`. Now that you know it works correctly, run `collatzplot` for a larger value to produce more interesting results. Before doing so, you might want to disable output for the line you just added in step 6, line 19 of `collatz.m`, by adding a semicolon to the end of the line so it appears as

```
sequence;
```

Then run

```
collatzplot(500)
```

The following figure shows the lengths of the Collatz series for n = 1 through n = 500.



Running Sections in M-Files That Have Unsaved Changes

It is a good practice to make changes to an M-file after you quit debugging, and to save the changes and then run the file. Otherwise, you might get unexpected results. But there are situations where you might want to experiment during debugging, to make a change to a part of the file that has not yet run, and then run the remainder of the file without saving the change.

To do this, while stopped at a breakpoint, make a change to a part of the file that has not yet run. Breakpoints will turn gray, indicating they are invalid. Then select all of the code after the breakpoint, right-click, and

choose **Evaluate Selection** from the context menu. You can also use cell mode to do this.

Conditional Breakpoints

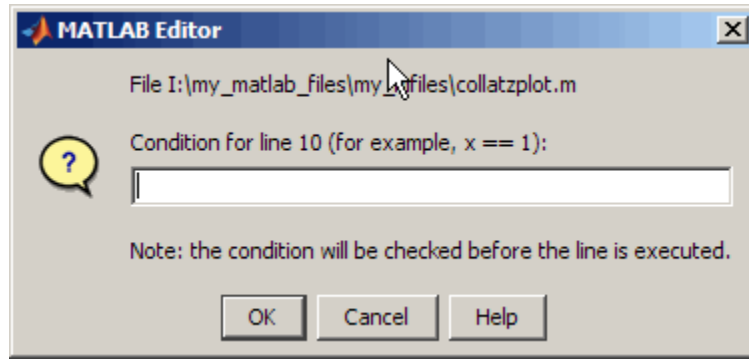
Set conditional breakpoints to cause MATLAB to stop at a specified line in a file only when the specified condition is met. One particularly good use for conditional breakpoints is when you want to examine results after a certain number of iterations in a loop. For example, set a breakpoint at line 10 in `collatzplot`, specifying that MATLAB should stop only if `N` is greater than or equal to `2`. This section covers the following topics:

Setting Conditional Breakpoints

To set a conditional breakpoint, follow these steps:

1. Click in the line where you want to set the conditional breakpoint. Then select **Set/Modify Conditional Breakpoint** from the **Debug** or context menu. If a standard breakpoint already exists at that line, use this same method to make it conditional.

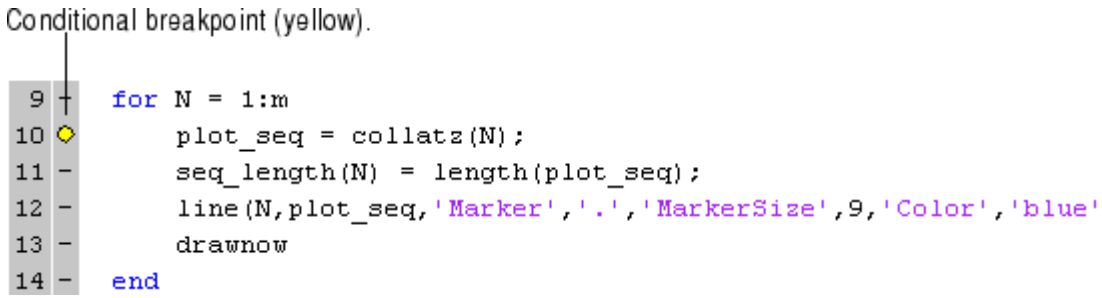
The **MATLAB Editor** conditional breakpoint dialog box opens as shown in this example.



2 Type a condition in the dialog box, where a condition is any legal MATLAB expression that returns a logical scalar value. Click **OK**. As noted in the dialog box, the condition is evaluated before running the line. For the example, at line 10 in `collatzplot`, enter

```
N>=2
```

as the condition. A yellow breakpoint icon (indicating the breakpoint is conditional) appears in the breakpoint alley at that line.



When you run the file, MATLAB enters debug mode and pauses at the line only when the condition is met. In the `collatzplot` example, MATLAB runs through the `for` loop once and pauses on the second iteration at line 10 when `N` is `2`. If you continue executing, MATLAB pauses again at line 10 on the third iteration when `N` is `3`.

Copying, Modifying, Disabling, and Clearing Conditional Breakpoints

To copy a conditional breakpoint, right-click the icon in the breakpoint alley and select **Copy** from the context menu. Then right-click in the breakpoint alley at the line where you want to paste the conditional breakpoint and select **Paste** from the context menu.

Modify the condition for the breakpoint in the current line by selecting **Set/Modify Conditional Breakpoint** from the **Debug** or context menu.

Click a conditional breakpoint icon to disable it. Click a disabled conditional breakpoint to clear it.

Function Alternative for Conditional Breakpoints

Use the `dbstop` function with appropriate arguments to set conditional breakpoints from the Command Window, and use `dbclear` to clear them. Use `dbstatus` to view the breakpoints currently set, including any conditions, which are listed in the `expression` field. If no condition exists, the value in the `expression` field is `[ ]` (empty). For details, see the function reference pages: `dbstop`, `dbclear`, and `dbstatus`.

Breakpoints in Anonymous Functions

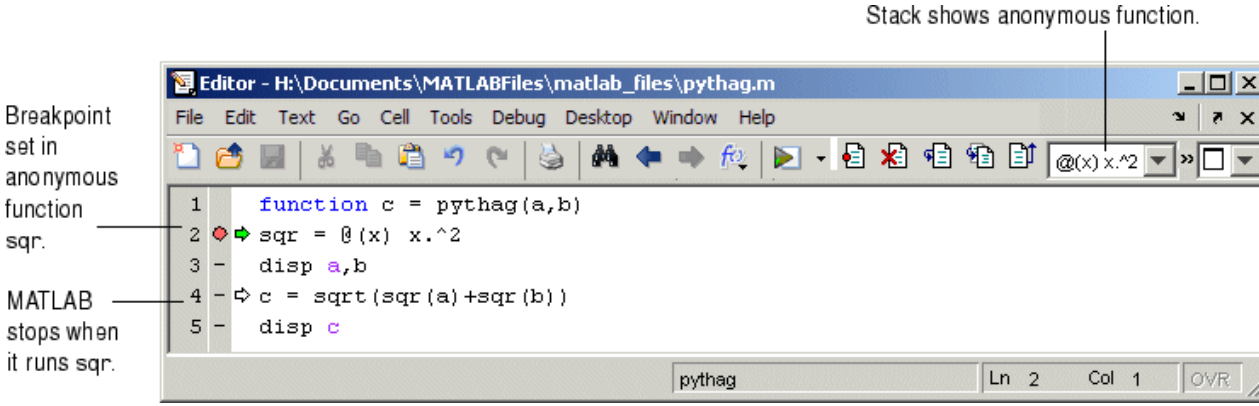
There can be multiple breakpoints in an M-file line that contains anonymous functions. There can be a breakpoint for the line itself (MATLAB stops at the start of the line), as well as a breakpoint for each anonymous function in that line. When you add a breakpoint to a line containing an anonymous function, the Editor/Debugger asks exactly where in the line you want to add the breakpoint. If there is more than one breakpoint in a line, the breakpoint icon is blue .

When there are multiple breakpoints set on a line, the icon is always blue, regardless of the status of any of the breakpoints on the line. Position the mouse on the icon and a tooltip displays information about all breakpoints in that line.

To perform a breakpoint action for a line that can contain multiple breakpoints, such as **Clear Breakpoint**, right-click the breakpoint alley at

that line and select the action. MATLAB prompts you to specify the exact breakpoint on which to act in that line.

When you set a breakpoint in an anonymous function, MATLAB stops when the anonymous function is called. The following illustration shows the Editor/Debugger when you set a breakpoint in the anonymous function `sqr` in line 2, and then run the file. MATLAB stops when it runs `sqr` in line 4. After you continue execution, MATLAB stops again when it runs `sqr` the second time in line 4. Note that the **Stack** display shows the anonymous function.



Error Breakpoints

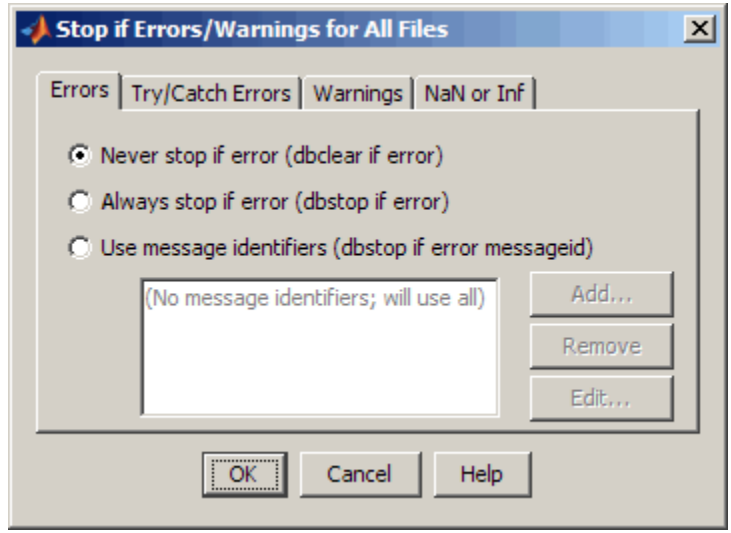
Set error breakpoints to stop program execution and enter debug mode when MATLAB encounters a problem. Unlike standard and conditional breakpoints, you do not set these breakpoints at a specific line in a specific file. Rather, once set, MATLAB stops at any line in any file when the error condition specified via the error breakpoint occurs. MATLAB then enters debug mode and opens the file containing the error, with the pause indicator at the line containing the error. Files open only when the you select **Debug > Open M-Files** . Error breakpoints remain in effect until you clear them or until you end the MATLAB session. You can set error breakpoints from the **Debug** menu in any desktop tool. This section covers the following topics:

- “Setting Error Breakpoints” on page 6-130
- “Error Breakpoint Types and Options” on page 6-130

• "Function Alternative for Error Breakpoints" on page 6-132

Setting Error Breakpoints

To set error breakpoints, select **Debug > Stop if Errors/Warnings**. In the resulting **Stop if Errors/Warnings for All Files** dialog box, specify error breakpoints on all appropriate tabs and click **OK**. To clear error breakpoints, select the **Never stop if ...** option for all appropriate tabs and click **OK**.



For example, to pause execution when a warning occurs, select the **Warnings** tab, and from it select **Always stop if warning**, then click **OK**. When you run an M-file and MATLAB produces a warning, execution pauses, MATLAB enters debug mode, and the file opens in the Editor/Debugger at the line that produced the warning. To remove the warning breakpoint, select **Never stop if warning** in the **Warnings** tab and click **OK**.

Error Breakpoint Types and Options

The four basic types of error breakpoints you can set are **Errors**, **Try/Catch Errors**, **Warnings**, and **NaN or Inf**. Select the **Always stop if ...** option for each tab to set that type of breakpoint. Select the **Use message identifiers ...** option to limit each type of error breakpoint (except NaN or Inf) so that execution stops only for specific errors.

Errors. When an error occurs, execution stops, unless the error is in a `try...catch` block. MATLAB enters debug mode and opens the M-file to the line in the `try` portion of the block that produced the error. You cannot resume execution.

Try/Catch Errors. When an error occurs in a `try...catch` block, execution pauses. MATLAB enters debug mode and opens the M-file to the line that produced the error. You can resume execution or use debugging features.

Warnings. When a warning is produced, MATLAB pauses, enters debug mode, and opens the M-file, paused at the line that produced the warning. You can resume execution or use debugging features.

NaN or Inf. When an operator, function call, or scalar assignment produces a `NaN` (not-a-number) or `Inf` (infinite) value, MATLAB pauses, enters debug mode, and opens the M-file, paused immediately after the line that encountered the value. You can resume execution or use debugging features.

Use Message Identifiers. Execution stops only when MATLAB encounters one of the specified errors. This option is not available for the **NaN or Inf** type of error breakpoint. To use this feature:

1. Select the **Errors**, **Try/Catch Errors,** or **Warnings** tab.
2. Select the **Use Message Identifiers** option.
3. Click **Add**.
4. In the resulting **Add Message Identifier** dialog box, supply the message identifier of the specific error you want to stop for, where the identifier is of the form `component:message`, and click **OK**.
5. The message identifier you added appears in the **Stop If Errors/Warnings for All Files** dialog box, where you click **OK**.

   You can add multiple message identifiers, and edit or remove them.

One way to obtain an error message identifier generated by a MATLAB function for example, is to produce the error, and then run the `lasterror` function. MATLAB returns the error message and identifier. Copy the identifier from the Command Window output and paste it into the **Add**

Message Identifier dialog box. An example of an error message identifier is `MATLAB:UndefinedFunction`. Similarly, to obtain a warning message identifier, produce the warning and then run `[m,id] = lastwarn`; MATLAB returns the last warning identifier to `id`. An example of a warning message identifier is `MATLAB:divideByZero`.

Function Alternative for Error Breakpoints

The function equivalent for each option appears in the **Stop if Errors/Warnings for All Files** dialog box. For example, the function equivalent for **Always stop if error** is `dbstop if error`. Use the `dbstop` function with appropriate arguments to set error breakpoints from the Command Window, and use `dbclear` to clear them. Use `dbstatus` to view the error breakpoints currently set. Error breakpoints are listed in the `cond` field and message identifiers for breakpoints are listed in the `identifier` field of the `dbstatus` output.

Using Cells for Rapid Code Iteration and Publishing Results

In this section...

What Are Cells?

M-files often have a natural structure consisting of multiple sections. Especially for larger files, you typically focus efforts on a single section at a time, working with the code in just that section. Similarly, when conveying information about your M-files to others, often you describe the sections of the code. To facilitate these processes, use M-file *cells*, where *cell* means a section of code. Specifically, MATLAB uses cells for

- Rapid code iteration in the Editor/Debugger — This makes the experimental phase of your work with M-file scripts easier. The next section, "Rapid Code Iteration Overview" on page 6-133, outlines the process, and is followed by details for defining, evaluating, and modifying values in cells.
- Publishing M-files — This allows you to include code and results in a presentation format such as HTML. Publishing using cells requires you to define cells using the same instructions as for rapid code iteration. You can also make use of the cell navigation and evaluation features used for rapid code iteration. See "Publishing to HTML, XML, LaTeX, Word, and PowerPoint Using Cells" on page 8-2 for complete details.

Rapid Code Iteration Overview

When working with MATLAB, you often experiment with your code — modifying it, testing it, and updating it — until you have an M-file that does what you want. Use the MATLAB Editor/Debugger cells features with M-file scripts to facilitate this process. You can also use cell features with function M-files, but there are some restrictions — see "Using Cells in Function M-Files" on page 6-144.

If you have an active Internet connection, you can watch the Rapid Code Iteration Using Cells video demo for an overview of the major functionality.

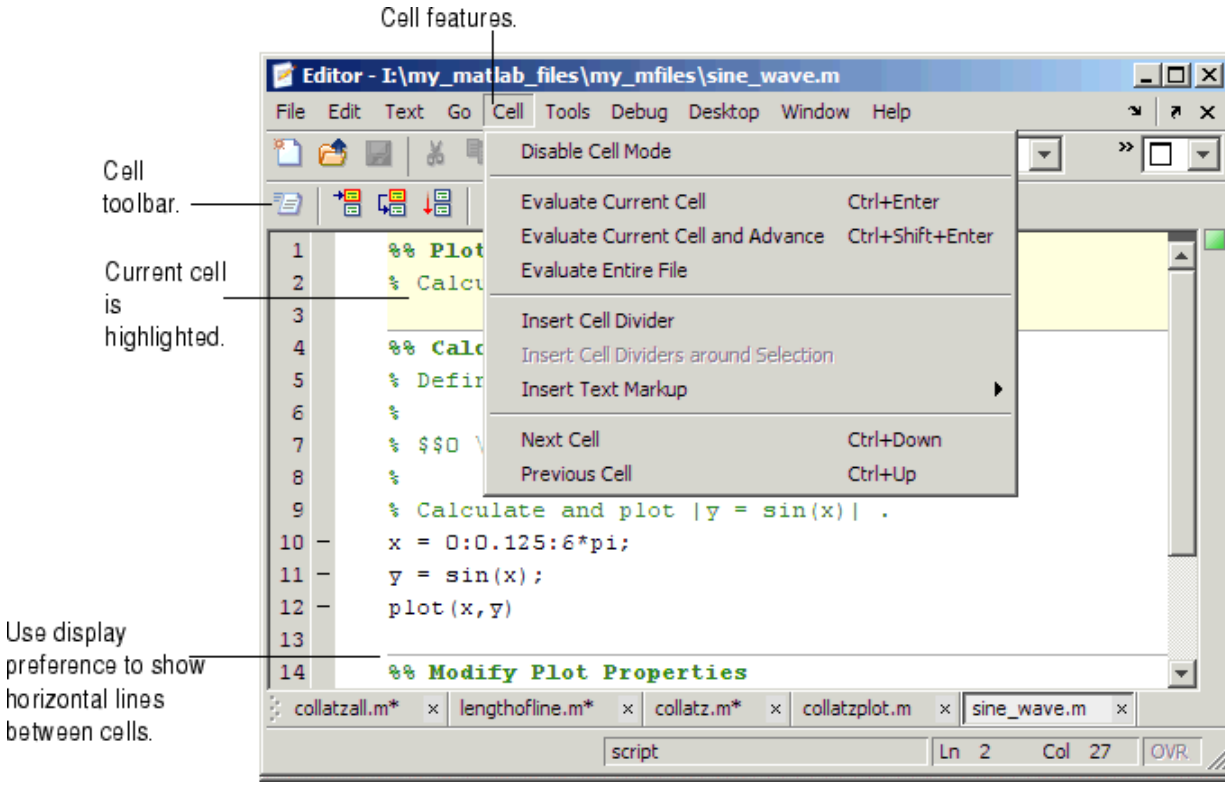
This is the overall process of using cells for rapid code iteration:

1. In the MATLAB Editor/Debugger, enable cell mode by selecting **Cell > Enable Cell Mode**. Items in the **Cell** menu become selectable. The cell toolbar appears, unless you had previously hidden it. With cell mode enabled, hide or show the toolbar by right-clicking in the Editor/Debugger menu bar or toolbars and selecting **Cell Toolbar** from the context menu.

2. Define the boundaries of the cells in an M-file script using cell features. Cells are denoted by a specialized comment syntax, %%. For details, see "Defining Cells" on page 6-135.

3. Once you define the cells, use cell features to navigate quickly from cell to cell in your file, evaluate the code in a cell in the base workspace, and view the results. To facilitate experimentation, use cell features to modify values in cells and then reevaluate them, to see how different values impact the result. For details, see "Navigating and Evaluating with Cells" on page 6-139.

4. Cells also facilitate sharing your code and results via cell publishing to a presentation format. For details, see "Publishing to HTML, XML, LaTeX, Word, and PowerPoint Using Cells" on page 8-2.



Defining Cells

Cell features operate on cells, where a cell is contiguous lines of code you want to evaluate as a whole in an M-file script. To define a cell, first be sure that cell mode is enabled (see step). Position the cursor just before the line at which you want to start the cell and select **Cell > Insert Cell Divider** or click the Insert Cell Divider button . MATLAB inserts a line after the cursor that consists of two percent signs (%%), which is the “start new cell” indicator to MATLAB. A cell consists of the line starting with %% and the lines that follow, up to the start of the next cell, which is identified by %% at the start of a new line.

You can also define a cell by entering two percent signs (%%) at the start of the line where you want to begin the new cell. Alternatively, select the

lines of code you want in a cell and then select **Cell > Insert Cell Dividers Around Selection**.

You can define a cell at the start of a new empty file, enter code for the cell, define the start of the next cell, enter its code, and so on. Redefine cells by defining new cells, removing existing cells, and moving lines of code.

You can set an Editor/Debugger preference to show a faint gray horizontal line (rule) above each cell that helps distinguish the cells. Select **File > Preferences > Editor/Debugger > Display** and in **Cell display options**, use **Show lines between cells**. The horizontal lines do not appear in the M-file when you print it.

MATLAB does not execute the code in lines beginning with `%%`, so be sure to put any executable code for the cell on the following line. For program control statements, such as `if ... end`, a cell must contain both the opening and closing statements, that is, it must contain both the `if` and the `end` statements.

Note that the first cell in a file does not have to begin with `%%`. MATLAB automatically understands any lines above the first `%%` line to be a cell. If there are no cell dividers in an M-file, MATLAB understands the entire file to be a single cell.

Cell Titles and Highlighting

After the `%%`, type a space, followed by a description of the cell. The Editor/Debugger emphasizes the special meaning of the start of a cell by making any text following the percent signs appear bold. The text on the `%%` line is called the *cell title* (like a section title). Including text in cell titles is optional, however, they improve readability of the file and are used for cell publishing features.

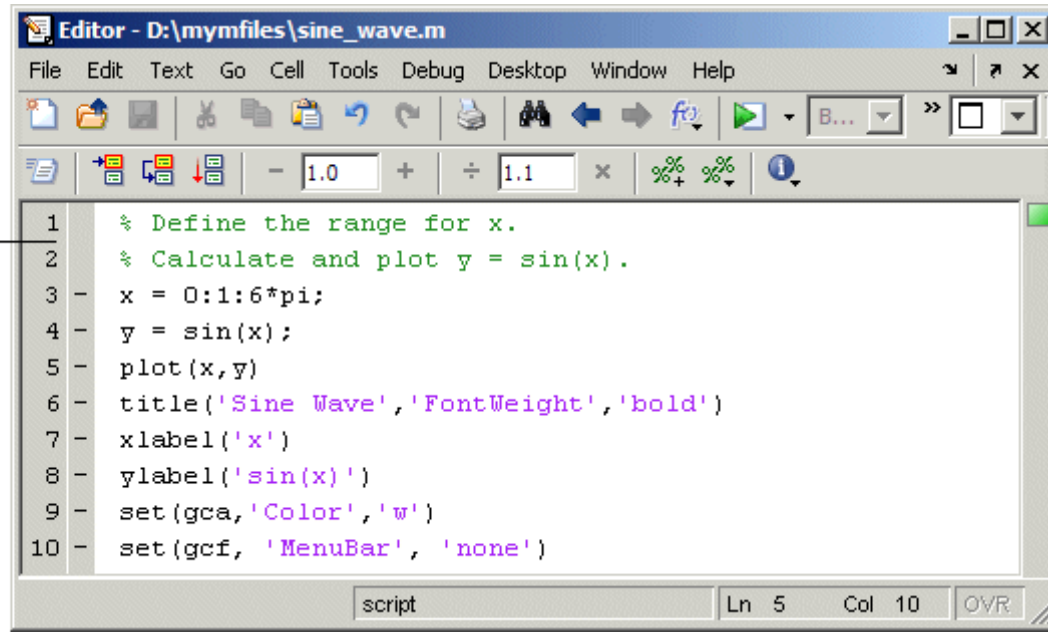
When the cursor is positioned in any line within a cell, the Editor/Debugger highlights the entire cell with a yellow background. This identifies it as the *current cell*. For example, it is used when you select the **Evaluate Current Cell** option on the **Cell** menu. If you do not want yellow highlighting for the current cell, change it using preferences. Select **File > Preferences > Editor/Debugger > Display** and change the appropriate **Cell display options**.

Example — Define Cells

This example defines two cells for a simple M-file called `sine_wave`, shown in the following code and figure. The first cell creates the basic results, while the second label the plot. The two cells in this example allow you to experiment with the plot of the data first, and then when that is final, change the plot properties to affect the style of presentation.

```
% Define the range for x.
% Calculate and plot y = sin(x).
x = 0:1:6*pi;
y = sin(x);
plot(x,y)
title('Sine Wave','FontWeight','bold')
xlabel('x')
ylabel('sin(x)')
set(gca,'Color','w')
set(gcf, 'MenuBar', 'none')
```

M-file before defining cells.



1 Select **Cell > Enable Cell Mode**, if it is not already enabled.

2. Position the cursor at the start of the first line. Select **Cell > Insert Cell Divider**.

   The Editor/Debugger inserts `%%` as the first line and moves the rest of the file down one line. All lines are highlighted in yellow, indicating that the entire file is a single cell, unless you do not have that display preference for cells selected.

3. Enter a cell title following the `%%`. Type a space first, followed by the description.

   ```
   Calculate and Plot Sine Wave
   ```

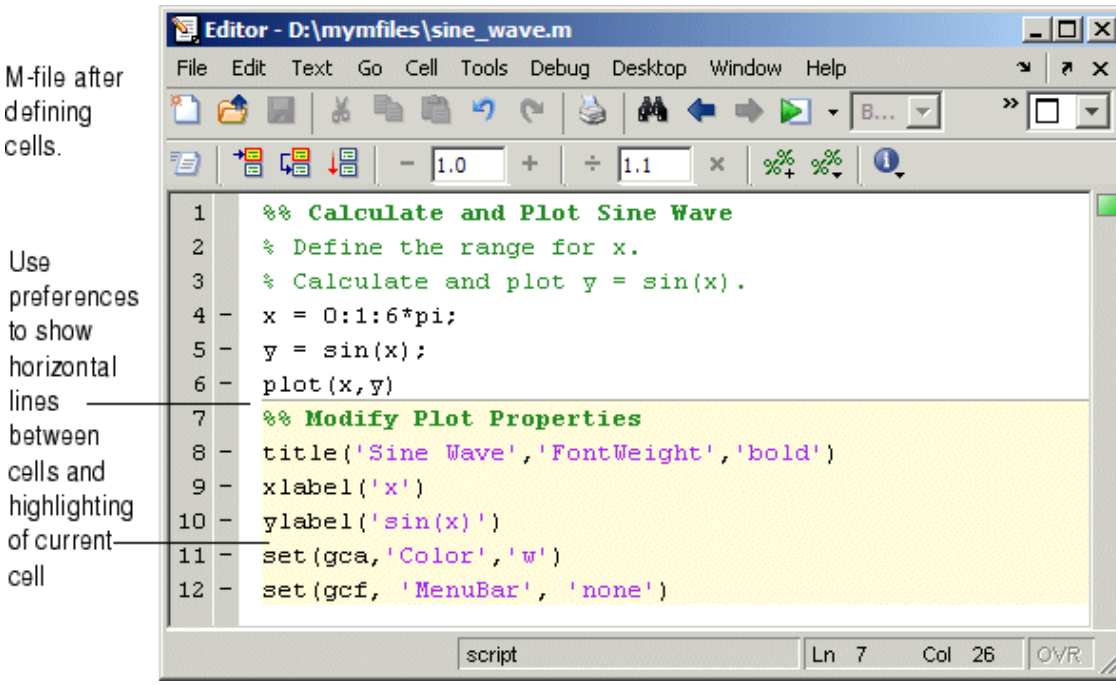
4. Position the cursor at the start of line 7, `title...`. Select **Cell > Insert Cell Divider**.

   The Editor/Debugger inserts a line containing only `%%` at line 7 and moves the remaining lines down by one line. A horizontal line that helps you distinguish the two cells appears above the `%%` line, unless you do not have that display preference for cells selected. Lines 7 through 12 are highlighted in yellow, indicating they comprise the current cell.

5. Enter a cell title for the new cell. On line 7, type a space after the `%%`, followed by the description

   ```
   Modify Plot Properties
   ```

   Save the file. The file appears as shown in this figure.



Removing Cells

To remove a cell, delete one of the percent signs (%) from the line that starts the cell. This changes the line from a cell to a standard comment and merges the cell with the preceding cell. You can also just delete the entire line that contains the %%.

Navigating and Evaluating with Cells

While you develop an M-file, you can use these Editor/Debugger cell features:

Navigating Among Cells in an M-File

To move to the next cell, select **Cell > Next Cell**. To move to the previous cell, select **Cell > Previous Cell**. To move to a specific cell, click the Show Cell Titles button and from it, select the cell title to which you want to move. You can also go to cells by selecting **Edit > Go To**.

Evaluating Cells in an M-File

To evaluate the code in a cell, use the **Cell** menu evaluation items or equivalent buttons in the cell toolbar. When you evaluate a cell, the results display in the Command Window, figure window, or otherwise, depending on the code evaluated.

The cell evaluation features run the code currently shown in the Editor/Debugger, even if the file contains unsaved changes. The file does not have to be on the search path. To evaluate a cell, it must contain all the values it requires, or the values must already exist in the MATLAB workspace.

Note While you can set breakpoints and debug a file containing cells, when you evaluate a file from the **Cell** menu or cell toolbar, breakpoints are ignored. To run the file and stop at breakpoints, use **Run/Continue** in the **Debug** menu. This means you cannot debug while running a single cell.

Evaluate Current Cell. Select **Cell > Evaluate Current Cell** or click the Evaluate Cell button to run the code in the current cell.

Evaluate and Advance. Select **Cell > Evaluate Current Cell and Advance** or click the Evaluate Cell and Advance button to run the code in the current cell and move to the next cell.

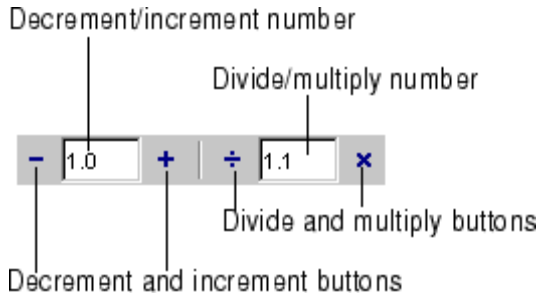
Evaluate File. Select **Cell > Evaluate Entire File** or click the Evaluate Entire File button to run all of the code in the file.

Note A beep means there is an error. See the Command Window for the error message.

Modifying Values in a Cell

You can use cell features to modify numbers in a cell, which also automatically reevaluates the cell. This helps you experiment with and fine-tune your code.

To modify a number in a cell, select the number (or place the cursor near it) and use the value modification tool in the cell toolbar. Using this tool, you can specify a number and press the appropriate math operator to add (increment), subtract (decrement), multiply, or divide the number. The cell then automatically reevaluates.



You can use the numeric keypad operator keys (**-**, **+**, **/**, and *) instead of the operator buttons on the toolbar.

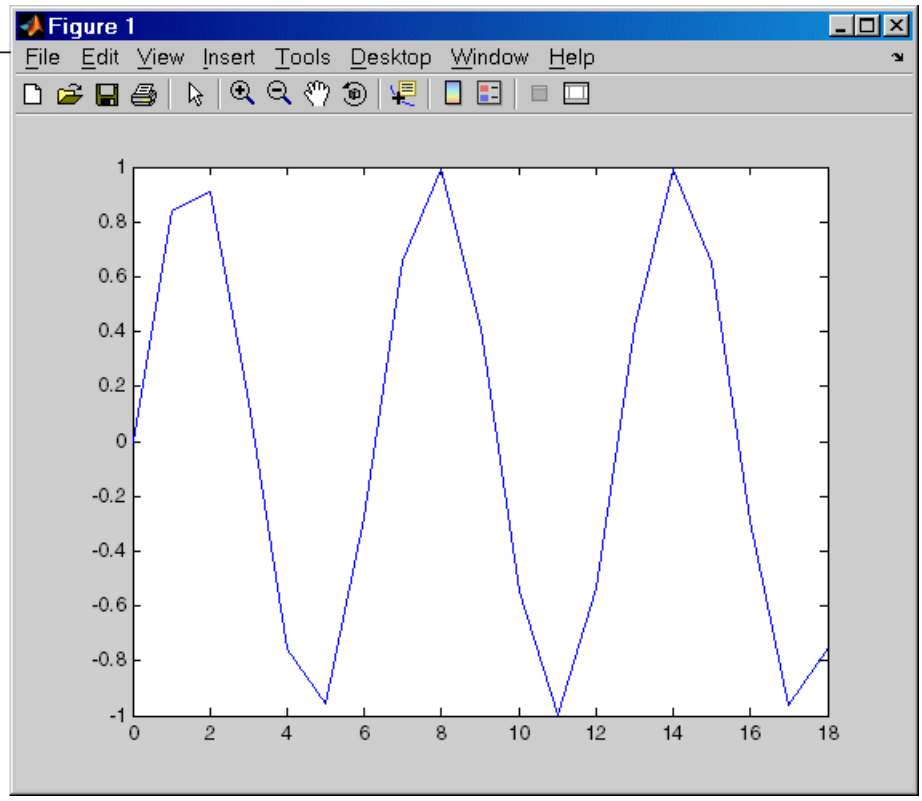
Note MATLAB does not automatically save changes you make to values using the cell toolbar. To save changes, select **File > Save**.

Example — Evaluate Cells

In this example, modify the values for `x` in `sine_wave.m`:

1. Run the first cell in `sine_wav.m`. Click somewhere in the first cell, that is, between lines 1 and 6. Select **Cell > Evaluate Current Cell**. The following figure appears.

Plot generated by running `sine_wave.m`.



2 Assume you want to produce a smoother curve. Use more values for `x` in `0:1:6*pi`. Position the cursor in line 4, next to the `1`. In the cell toolbar, change the `1.1` default multiply/divide by value to `2`. Click the Divide button ÷.

Line 4 becomes

```
4 -   x = 0:0.5:6*pi;
```

and the length of `x` doubles. The plot automatically updates. The curve still has some rough edges.

3 To add more values for `x`, click the Divide button three more times. Line 4 becomes

```
4 -   x = 0:0.0625:6*pi;
```

The curve is smooth, but because there are more values, processing time is slower. It would be better to find a smaller `x` that still produces a smooth curve.

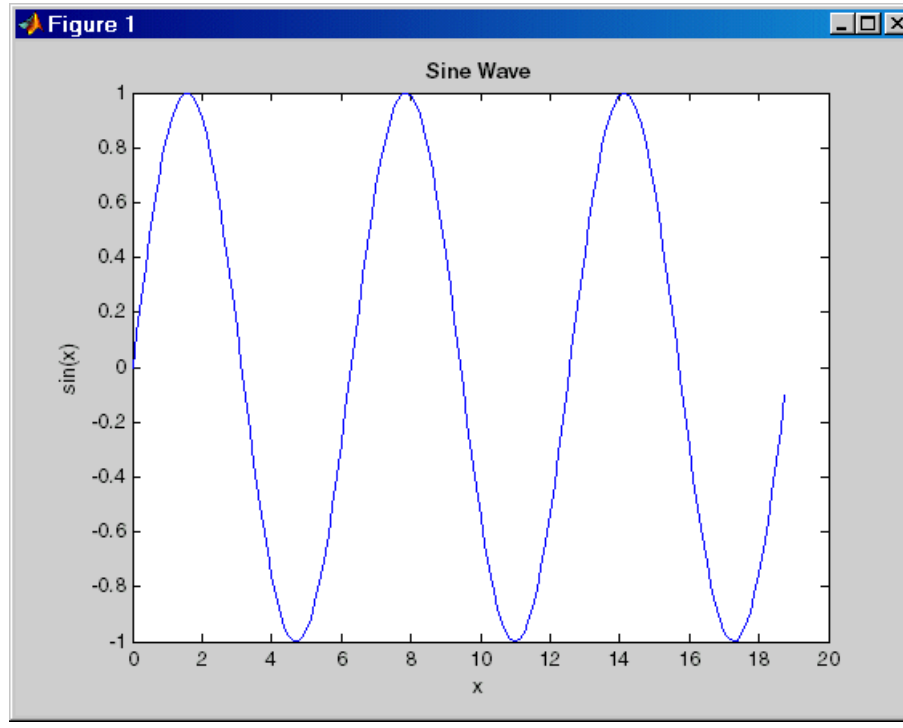
4. In the cell toolbar, click the Multiply button once. The increment for `x` as shown in line 4 changes from `0.0625` to `0.125`.

   The resulting curve is still smooth.

5. Save these changes. Select **File > Save**.

6. Now you can apply the plot properties, defined in the second cell, that is, lines 7 through 12. You do not need to evaluate the entire file to apply the plot properties. Instead, position the cursor in the second cell and use the shortcut **Ctrl+Enter** to evaluate the current cell. (The shortcut appears with the menu item, **Cell > Evaluate Current Cell**.)

MATLAB updates the figure.



Using Cells in Function M-Files

You can define and evaluate cells in function M-files as long as the variables referred to in the cell are in your workspace. For example, this can be useful during debugging. If execution is stopped at a breakpoint, you can define cells and execute them without saving the file. If you are not debugging, add the necessary variables to the base workspace and then execute the cells.

7

Tuning and Managing M-Files

This set of tools provides useful information about the M-files in a directory that can help you refine the files and improve performance. The tools can help you polish M-files before providing them to others to use. If you have an active Internet connection, you can watch the Directory Reports video demo for an overview of the major functionality.

Directory Reports in Current Directory Browser (p. 7-2)	HTML reports about files in the current directory: TODO/FIXME, Help, Contents, Dependency, Coverage (for Profiling), and M-Lint Code Check.
M-Lint Code Check Report (p. 7-16)	Report that identifies potential errors, problems, and opportunities for improvement in your code.
Profiling for Improving Performance (p. 7-27)	Report that identifies where an M-file spends the most time, indicating where to focus when looking for performance improvements.

Directory Reports in Current Directory Browser

In this section...

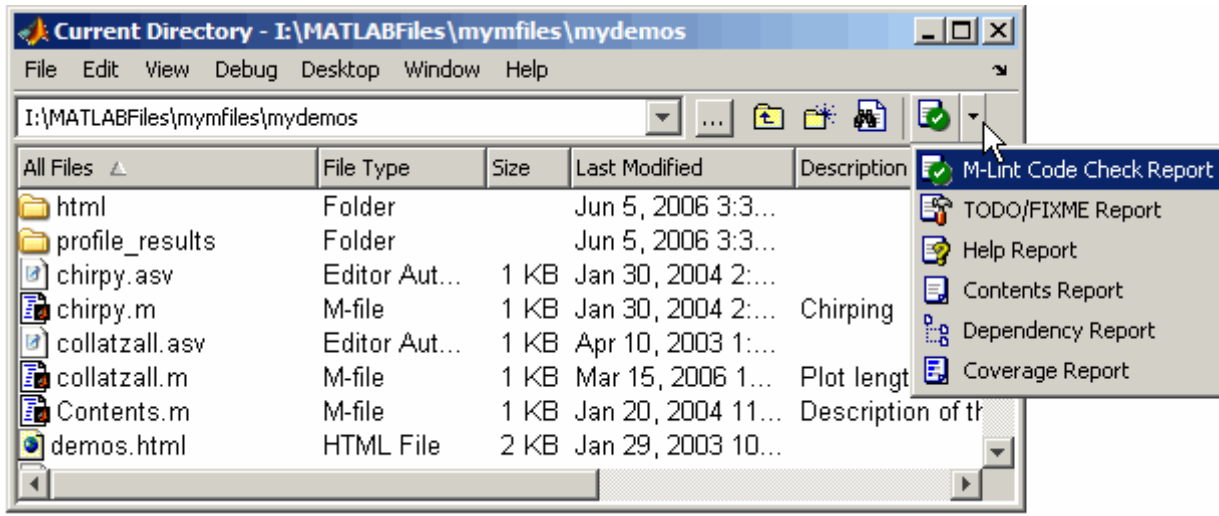
See also another Directory Report, "M-Lint Code Check Report" on page 7-16, and the File Comparisons tool.

Accessing and Using Directory Reports

Directory reports help you refine the M-files in a directory and improve their performance. They are also useful for when you prepare files for use by others, such as for a finished project, to share on MATLAB Central, or for a toolbox to be distributed.

Access directory reports from the MATLAB Current Directory browser. To display the Current Directory browser, select **Desktop > Current Directory**. For more information, see "Current Directory Browser" on page 5-36.

Navigate to the directory whose M-files you want to produce reports about. Then, in the Current Directory browser toolbar, click the down arrow button and select the type of report you want to run for all the M-files in the current directory.



The report you selected appears as an HTML document in the MATLAB Web Browser:

- In a report, click a filename to open that file in the Editor/Debugger, where you can view it or make changes to it. Click a line number to open the file at that line.
- To update a report after making changes to the report options, or after changing any files in the directory, click **Rerun This Report**. Note that this reruns the report for the directory shown in the report, not for the MATLAB current directory.
- While a report is displayed, you can change the MATLAB current directory and then click **Run Report on Current Directory** to generate the same type of report for the new current directory.
- When you run a report, it replaces the report currently displayed. Use the Back and Forward buttons in the toolbar to see a previously run report and then return to the most recent.

You cannot run directory reports when the path is a UNC (Universal Naming Convention) pathname, that is, starts with \\. Instead, use an actual hard drive on your system, or a mapped network drive.

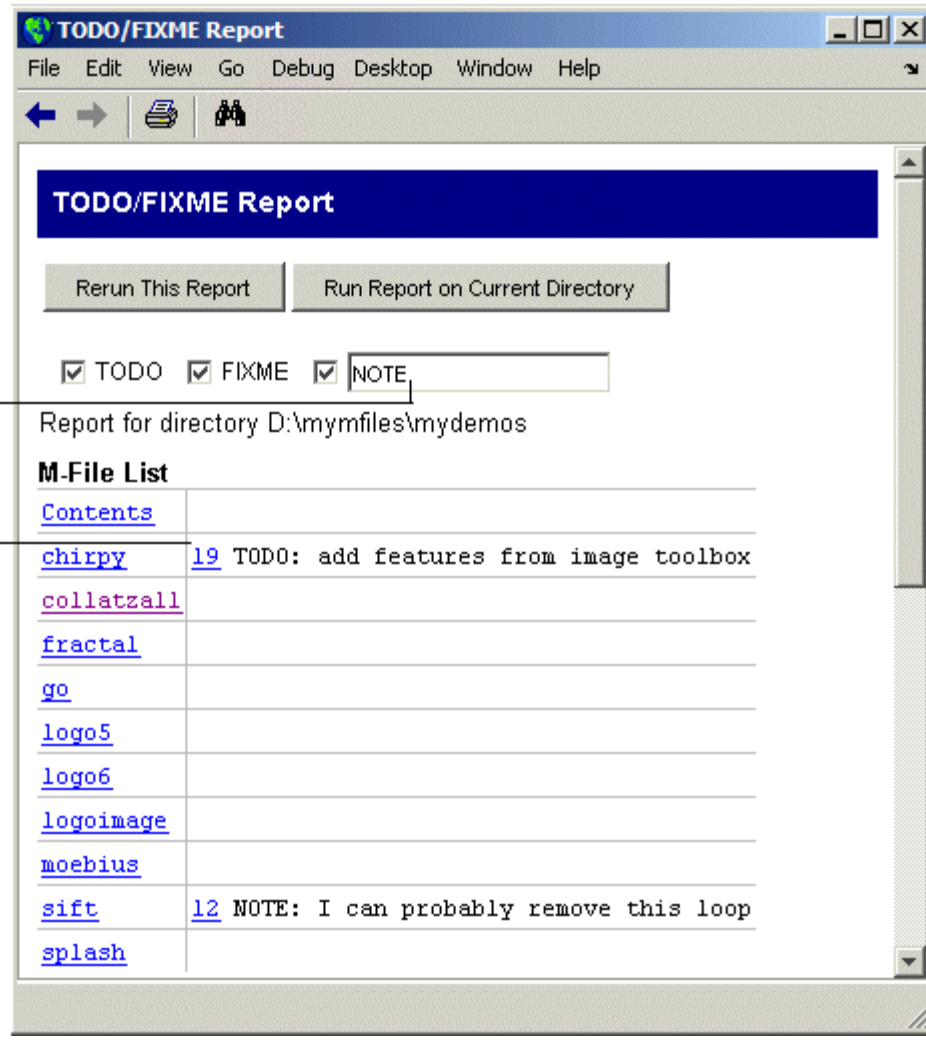
TODO/FIXME Report

The TODO/FIXME Report shows M-files that contain text strings you included as notes to yourself, such as `TODO`. Use this report to easily identify M-files that still require work or some other actions.

To access this report, follow the instructions in “Accessing and Using Directory Reports” on page 7-2.

In the report, select one or more check boxes to display lines containing the specified strings (`TODO` and `FIXME`), and click **Rerun This Report**. You can also select the check box for the text field and enter any text string in the field, such as `NOTE` or `TBD` to identify lines containing that string.

The TODO/FIXME Report identifies lines containing specified text strings, such as TODO and NOTE shown here, so you can easily see reminders you included.



Enter any text string in this field.

Click the line number to open the file at that line in the Editor/Debugger, where you can make changes.

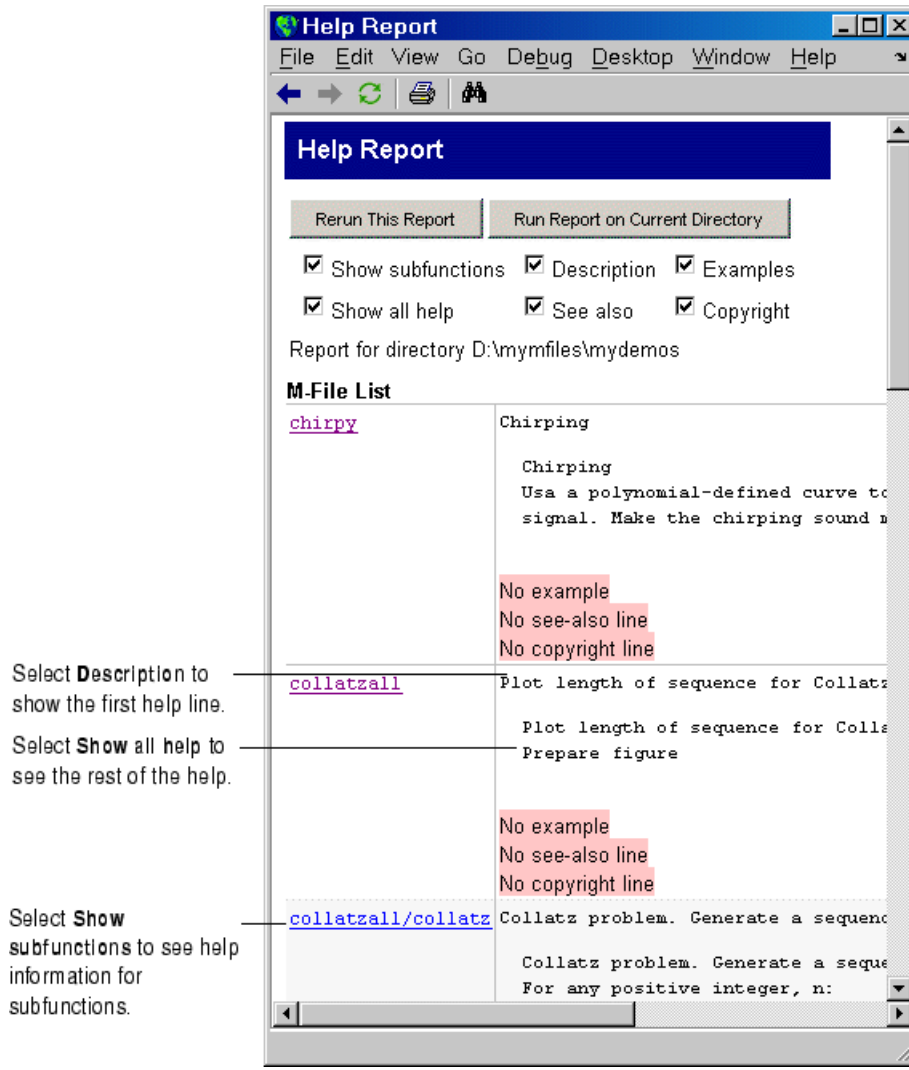
Help Report

The Help Report presents a summary view of the help component of your M-files. In MATLAB, the M-file help component is all contiguous nonexecutable lines (comment lines and blank lines), starting with the second line of a function M-file or the first line of a script M-file. For more information about creating help for your own M-files, see the reference page for the `help` function.

To access this report, follow the instructions in “Accessing and Using Directory Reports” on page 7-2.

Select one or more check boxes to display the specified help information and click **Rerun This Report**.

Use this information to help you identify files of interest or files that lack help information. It is a good practice to provide help for your files not only to help you recall their purpose, but to help others who might use the files.



Show Subfunctions

With **Show subfunctions** selected, the Help Report displays help information for all subfunctions called by each function. Help information for subfunctions is highlighted in gray.

Description

With **Description** selected, the Help Report displays the first line of help in the M-file. If the first comment line is empty, or if there is not a comment before the executable code, **No description line**, highlighted in pink, appears instead.

Examples

With **Examples** selected, the Help Report displays the line number where the examples section of the M-file help begins. The Help Report looks for a line in the M-file help that begins with the string `example` or `Example` and displays any subsequent nonblank comment lines. Select this option to easily locate and go to examples in your M-files.

It is a good practice to include examples in the help for your M-files. If you do not have examples in the help for all your M-files, use this option to identify those without examples. If the report does not find examples in the M-file help, **No example**, highlighted in pink, appears.

Show All Help

With **Show all help** selected, the Help Report displays complete M-file help, which is all contiguous nonexecutable lines (comment lines and blank lines), starting with the second line of a function M-file, or the first line of a script M-file. The M-file help shown also includes overloaded functions and methods, which are not actually part of the M-file help comments, but are automatically generated when `help` runs.

If the comment lines before the executable code are empty, or if there are no comments before the executable code, **No help**, highlighted in pink, appears instead.

See Also

With **See Also** selected, the Help Report displays the line number for the see also line in the M-file help. The see also line in M-file help lists related functions. When MATLAB displays the help for an M-file, any function name listed on the see also line appears as a link you can click to display its help. It is a good practice to include a see also line in the help for your M-files.

The report looks for a line in the M-file help that begins with the string `See also`. If the report does not find a see also line in the M-file help, **No see-also line**, highlighted in pink, appears. This helps you identify those M-files without a see also line, should you want to include one in each M-file.

The report also indicates when an M-file noted in the see also line is not in a directory on the search path. You might want to move that file to a directory that is on the search path. If not, you will not be able to click the link to get help for the file, unless you then add its directory to the path or make its directory become the current directory.

Copyright

With **Copyright** selected, the Help Report displays the line number for the copyright line in the M-file. The report looks for a comment line in the M-file that begins with the string `Copyright` and is followed by `year1-year2` (with no spaces between the years and the hyphen that separates them). It also notes if the end of the date range is not the current year.

It is a good practice to include a copyright line in the help for your M-files, that notes the year you created the file and the current year. For example, for an M-file you created in 2001, include this line

```
% Copyright 2001-2006
```

If the report does not find a copyright line in the M-file help, **No copyright line**, highlighted in pink, appears. This helps you identify those files without a copyright line, should you want to include one in each M-file.

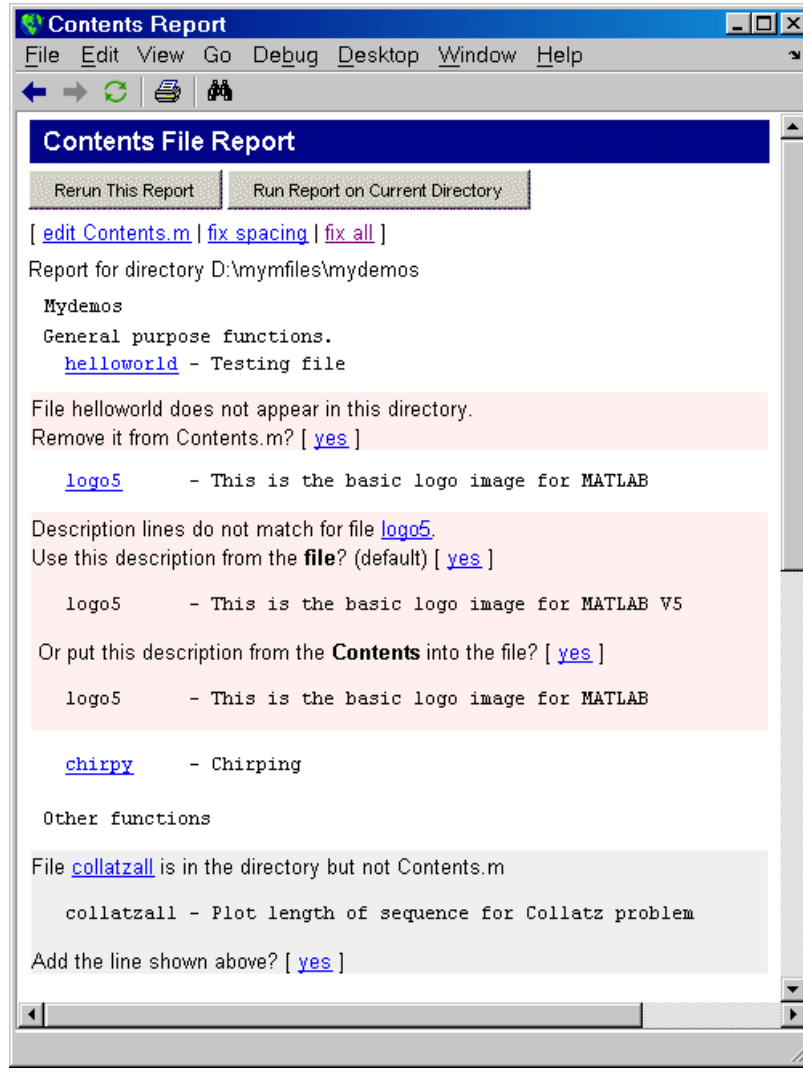
Contents Report

The Contents Report displays information about the integrity of the `Contents.m` file for the directory. A `Contents.m` file includes the filename and a brief description of each M-file in the directory. When you type `help` followed by the directory name, such as `help mydemos`, MATLAB displays the information in the `mydemos/Contents.m` file. For more information, see “Providing Help for Your Program” in the MATLAB Programming documentation.

To access this report, follow the instructions in “Accessing and Using Directory Reports” on page 7-2.

If there is no `Contents.m` file for the directory and you run the Contents Report, the report tells you the `Contents.m` file does not exist and asks if you want to create one. Click **yes** to automatically create the `Contents.m` file. Edit the `Contents.m` file in the Editor/Debugger to include the names of files you plan to create, or to remove files that you do not want to expose when displaying help for the directory, such as files for internal use.

You need to update the `Contents.m` file to reflect changes you make to files in the directory. For example, when you remove a file from a directory, remove its entry from the `Contents.m` file. The Contents Report helps you to maintain the `Contents.m` file. It displays discrepancies between the `Contents.m` file and the M-files in the directory.



Use the links displayed for each line, or edit the `Contents.m` file directly, or edit the M-files to make the changes. To make all of the suggested changes at once, click **fix all**. To automatically align the filenames and descriptions in the `Contents.m` file, click **fix spacing**.

If you always want the `Contents.m` file to reflect all files in the directory, you can automatically generate a new `Contents.m` file rather than changing the file based on the Contents Report. To do this, first delete the existing `Contents.m` file, run the Contents Report, and click `yes` when prompted for MATLAB to automatically create one.

Messages in the Contents File Report

No Contents File. This message appears if there is no `Contents.m` file in the directory. Click **yes** to automatically create a `Contents.m` file, which contains the filenames and descriptions for all M-files in the directory.

```
No Contents.m file. Make one? [ yes ]
```

File Not Found. This message appears when a file included in `Contents.m` is not in the directory. These messages are highlighted in pink. For example, a message such as

```
File helloworld does not appear in this directory.
Remove it from Contents.m? [ yes ]
```

means the `Contents.m` file includes an entry for `helloworld`, but that file is not in the directory. This might be because you removed the file `helloworld`, or you manually added it to `Contents.m` because you planned to create the file but have not as yet, or you renamed `helloworld`.

Description Lines Do Not Match. This message appears when the description line in the M-file help does not match the description provided for the M-file in `Contents.m`. These messages are highlighted in pink. Click **yes** to replace the description in the `Contents.m` file with the description from the M-file. Or select the option to replace the description line in the M-file help using the description for that file in `Contents.m`.

```
Description lines do not match for file logo5.
Use this description from the file? (default) [ yes ]
 logo5      - This is the basic logo image for MATLAB V5
Or put this description from the Contents into the file? [ yes ]
 logo5 - This is the basic logo image for MATLAB
```

Files Not In Contents.m. This message appears when a file in the directory is not in `Contents.m`. These messages are highlighted in gray. Click **yes** to add the filename and its description line from the M-file help to the `Contents.m` file.

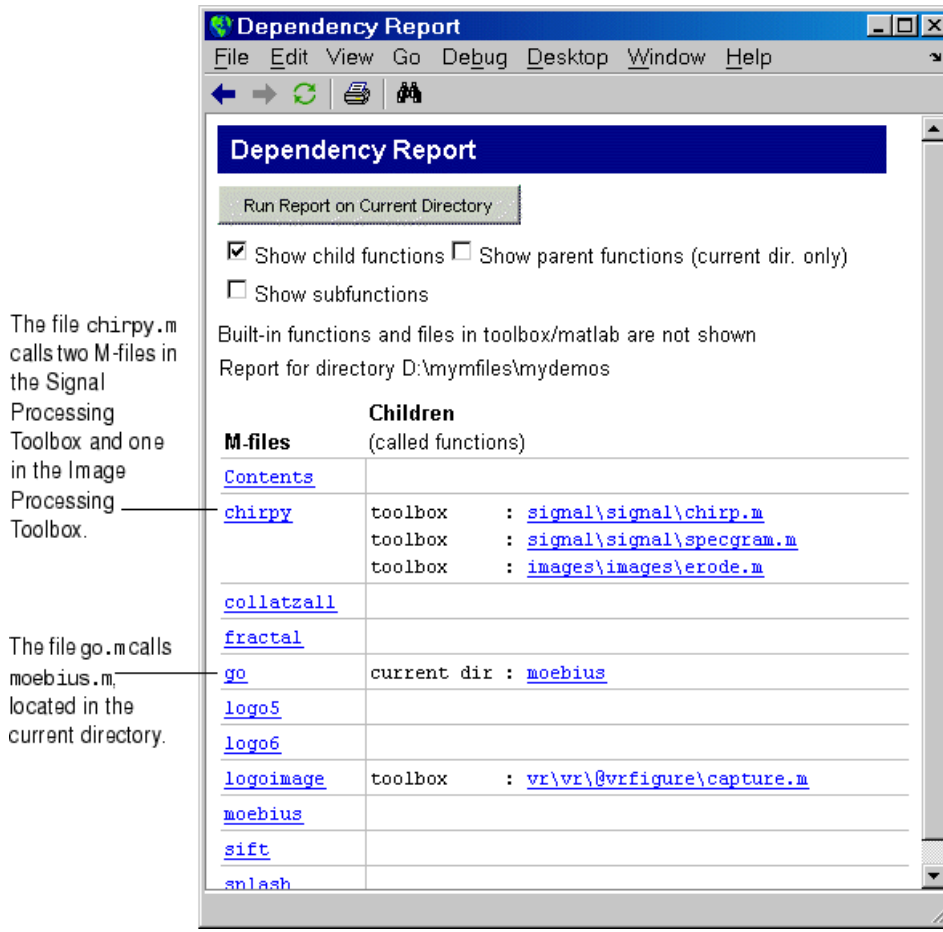
```
collatzall is in the directory but not Contents.m
 collatzall - Plot length of sequence for Collatz problem
Add the line shown above? [ yes ]
```

Dependency Report

The Dependency Report shows dependencies among M-files in a directory. This helps you determine all the M-files you need to provide when you tell someone to run a particular M-file. If you do not provide all the dependent M-files along with the M-file you want them to run, they will not be able run the file. The report does not list as dependencies the M-files in the `toolbox/matlab` directory because every MATLAB user already has those files.

To access this report, follow the instructions in “Accessing and Using Directory Reports” on page 7-2. You can also access the report from the Editor/Debugger **Tools** menu.

Select **Show child functions** to see a list of all M-files (children) called by each M-file in the directory (parent). The report also indicates where each child function resides, for example, in a specified toolbox. If a child function’s location is listed as unknown, it could be because the child function is not on the search path or in the current directory.



The Dependency Report is similar to running the `depfun` function, although the two do not provide the exact same results. For performance purposes, the Dependency Report limits the functions considered.

Select **Show parent functions** to list the M-files that call each M-file. The report limits the parent (calling) functions to those in the current directory. Select **Show subfunctions** to include subfunctions in the report. Subfunctions are listed directly after the main function and are highlighted in gray.

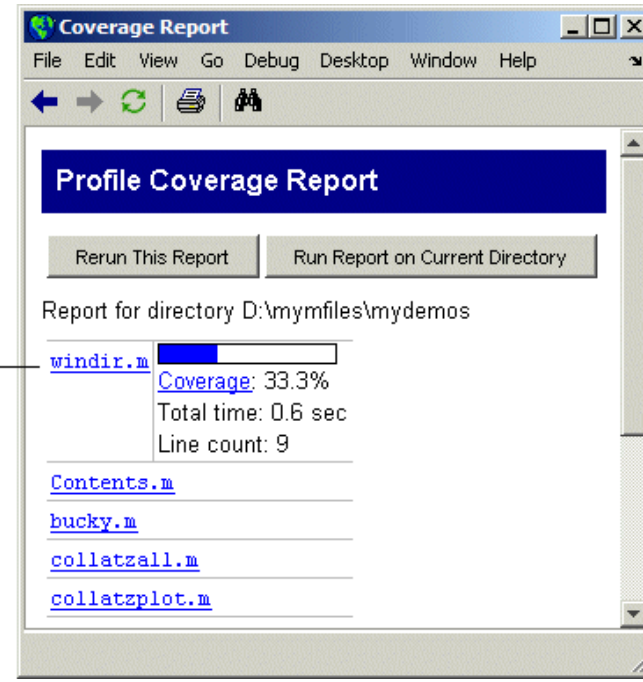
Coverage Report

Run the Coverage Report after you run the Profiler to identify how much of a file ran when it was profiled. For example, when you have an `if` statement in your code, that section might not run during profiling, depending on conditions.

You can run the Coverage Report from the Profiler, or follow these steps:

1. In the MATLAB desktop, select **Desktop > Profiler**. Profile an M-file in the Profiler. For detailed instructions, see "Profiling for Improving Performance" on page 7-27.

2. In the Current Directory browser, select `Coverage Report`. The **Coverage Report** appears, providing a summary of coverage for the M-file you profiled.



The Coverage Report shows the percentage of a file that ran when it was profiled.

3. Click the **Coverage** link to see the Profile Detail Report for the file.

M-Lint Code Check Report

In this section...

Running the M-Lint Code Check Directory Report

The M-Lint Code Check Report displays potential errors and problems, as well as opportunities for improvement in your code. The term "lint" is the name given to similar tools used with other programming languages such as C. In MATLAB, M-Lint produces a message for each line of an M-file that it determines might be improved. For example, a common M-Lint message is that a variable `foo` in line 12 is defined but never used in the M-file.

To run the M-Lint code check directory report, follow these steps:

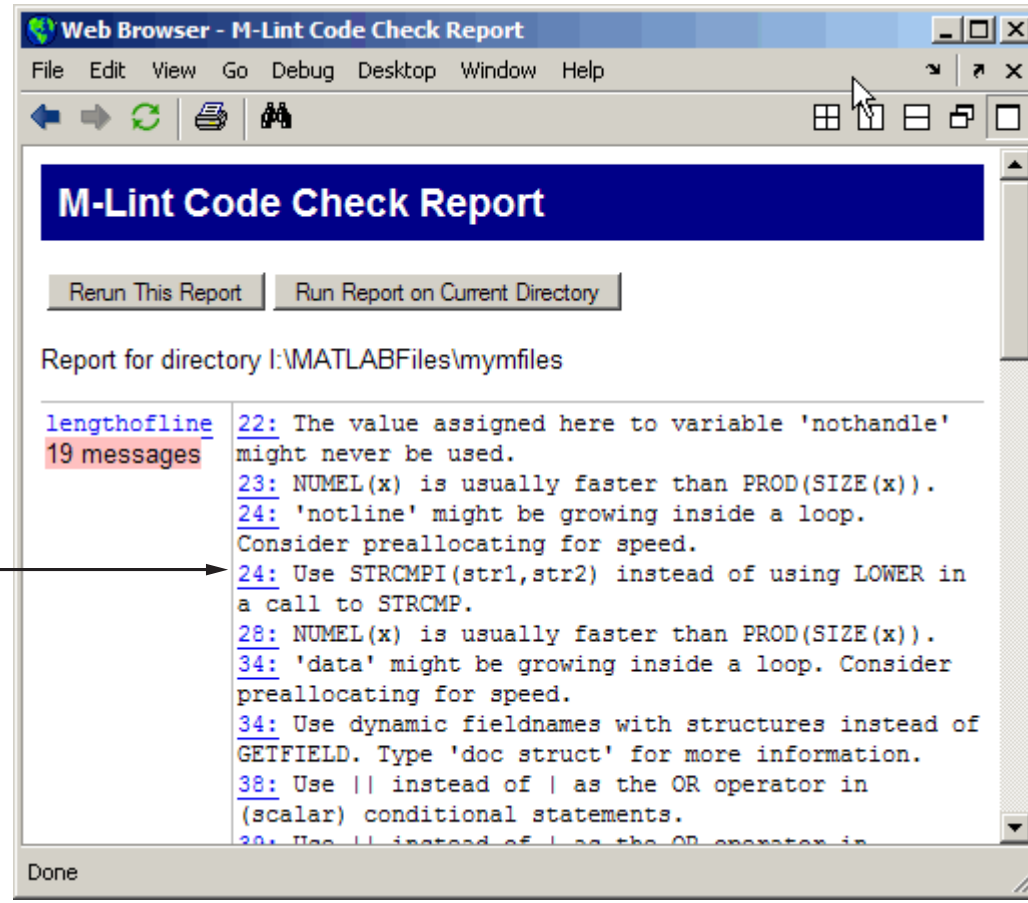
1. In the Current Directory browser, navigate to the directory that contains the M-files you want to check with M-Lint. To use the example shown in this documentation, `lengthofline.m`, you can change the current directory by running

   ```
   cd(fullfile(matlabroot,'help','techdoc','matlab_env','examples'))
   ```

2. If you plan to modify the example, save the file to a directory for which you have write access, and then make that directory the current MATLAB directory. In this example, the file is saved to `I:\MATLABFiles\mymfiles`.

3. In the Current Directory browser toolbar, select the `M-Lint Code Check Report` from the Directory Reports listing—for details, see "Accessing and Using Directory Reports" on page 7-2.

   The M-Lint Code Check Report displays in the MATLAB Web Browser, showing those M-files that M-Lint identified as having potential problems or opportunities for improvement.



Line number and message describing a potential problem or improvement opportunity.

Click a line number to open the M-file in the Editor/Debugger at the line.

4 For each message, review the suggestion and your code, click the line number to open the M-file in the Editor/Debugger at that line, and make changes based on the message. Use the following general advice:

- If you are not sure what a message means or what to change in the code as a result, use the Help browser to look for related topics in the online documentation. For examples of messages and what to do about them, including specific changes to make for the example, `lengthofline.m`, see “Making Changes Based on M-Lint Messages” on page 7-18.

- M-Lint does not provide perfect information about every situation and in some cases, you might not want to make any changes based on the M-Lint message. In the event you do not want to change the code but you also do not want to see the M-Lint message for that line in the M-Lint Report, instruct M-Lint to ignore a line by adding `%#ok` to the end of the line in the M-file. (You can override the `%#ok` by running the `mlint` function with the `'-notok'` tag.)
- If there are certain messages or types of messages you do not want to see, you can set a preference so that M-Lint does not report them. Select **File > Preferences > M-Lint**. In **Select messages to enable**, clear the check box for messages you do not want to see. Review the settings for all messages to ensure you are seeing those pertinent to your file. Click **OK**. For more information, click the **Help** button in the **M-Lint Preferences** pane. The next time you run the report, the messages will not appear. You can use `%#ok` with a specific message ID so that only that type of message is suppressed—for more information, see the reference page for `mlint`.

5. After making changes, save the M-file. Consider saving the file to a different name if you made significant changes that might introduce errors. Then you can refer to the original file if needed to resolve problems with the updated file. Use **Tools > Compare Against** in the Editor/Debugger to help you identify the changes you made to the file. For more information, see “Comparing Files — File Comparison Tool” on page 6-54.

6. Run and debug the file(s) again to be sure you have not introduced any inadvertent errors.

7. If the M-Lint Code Check Report is already displayed, click **Rerun This Report** to update the report based on the changes you made to the file, or run the report from the Current Directory browser toolbar. Ensure the M-Lint messages are gone, based on the changes you made to the M-files.

Making Changes Based on M-Lint Messages

For information on how to correct the potential problems presented by M-Lint, use the following resources:

- Look for relevant topics in the MATLAB Programming and “Programming Tips” documentation.

- Use the Help browser **Search** and **Index** panes to find documentation about terms presented in the M-Lint messages.

Other techniques to help you identify problems in and improve your M-files are in these topics:

- "Syntax Highlighting" on page 6-28 in the Command Window and Editor/Debugger
- "Examining Errors" on page 3-9 generated when you run the M-file
- "Finding Errors, Debugging, and Correcting M-Files" on page 6-84, namely the Editor/Debugger and debugging functions
- "Profiling for Improving Performance" on page 7-27 for improving performance

Example Using M-Lint Messages to Improve Code

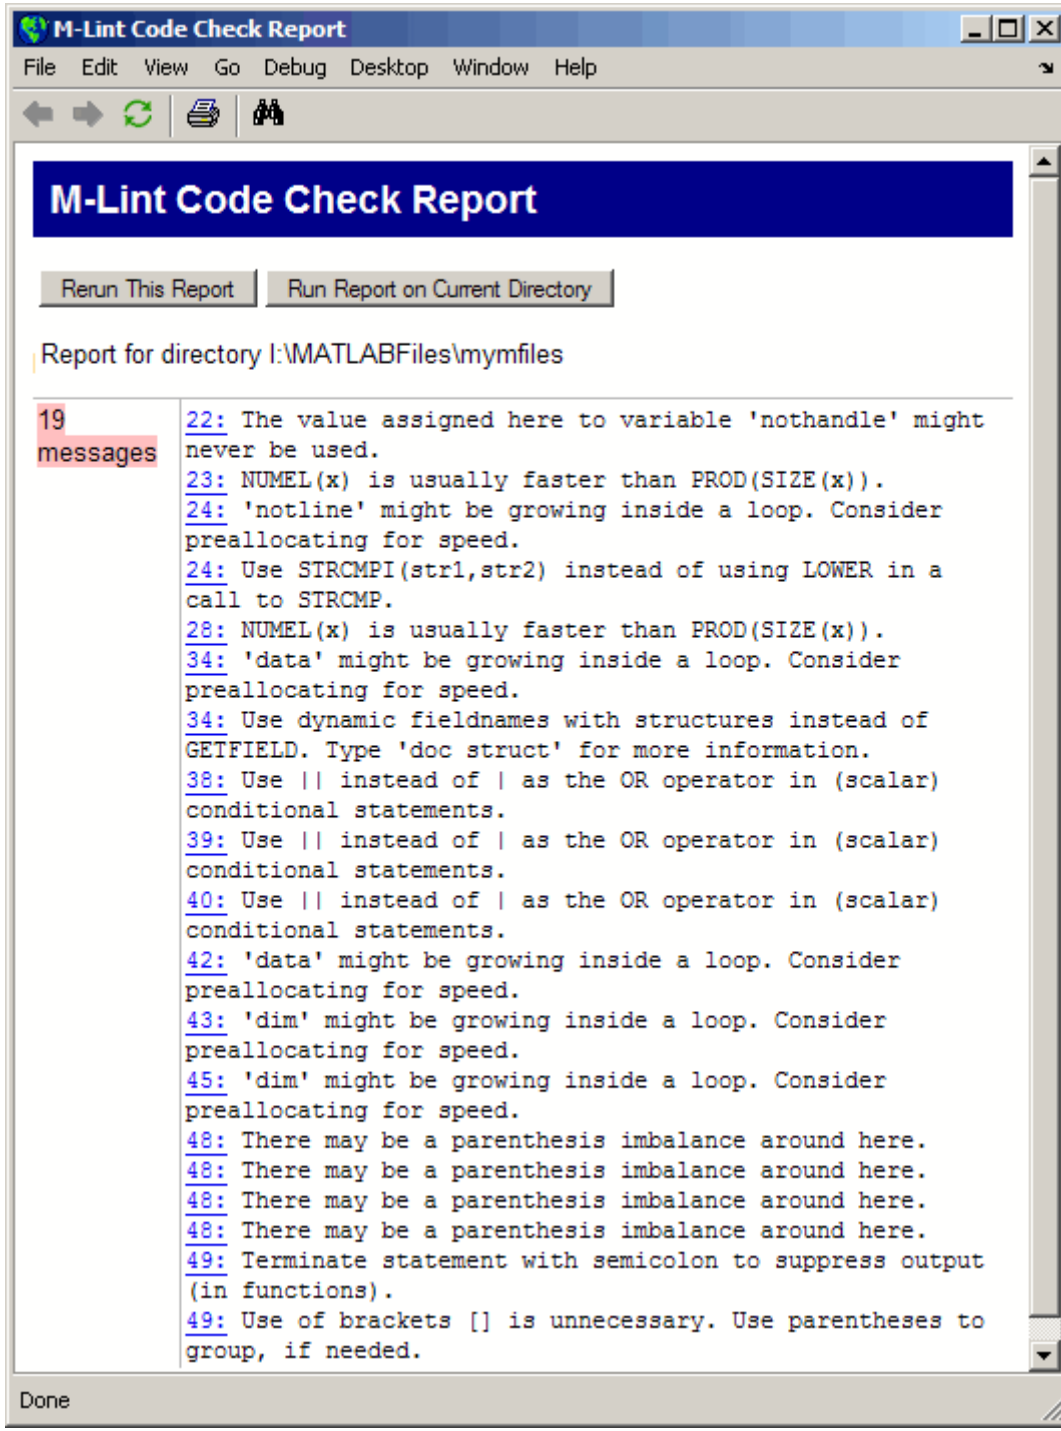
An example file, `lengthofline.m`, is included with MATLAB in *`matlabroot`*`/matlab/help/techdoc/matlab_env/examples`.

To run the M-Lint Code Check Report for `lengthofline.m`, change the current directory to its location by running

```
cd(fullfile(matlabroot,'help','techdoc','matlab_env','examples'))
```

In the Current Directory browser, select the **M-Lint Code Check Report** from the list of directory reports on the toolbar.

The M-Lint Code Check Report appears, with its list of messages suggesting improvements you can make to `lengthofline.m` and any other files in the directory.



M-Lint Code Check Report
File Edit View Go Debug Desktop Window Help
M-Lint Code Check Report
Rerun This Report
Run Report on Current Directory
Report for directory I:\MATLABFiles\mymfiles
19 messages
22: The value assigned here to variable 'nothandle' might never be used.
23: NUMEL(x) is usually faster than PROD(SIZE(x)).
24: 'notline' might be growing inside a loop. Consider preallocating for speed.
24: Use STRCMPI(str1,str2) instead of using LOWER in a call to STRCMP.
28: NUMEL(x) is usually faster than PROD(SIZE(x)).
34: 'data' might be growing inside a loop. Consider preallocating for speed.
34: Use dynamic fieldnames with structures instead of GETFIELD. Type 'doc struct' for more information.
38: Use || instead of | as the OR operator in (scalar) conditional statements.
39: Use || instead of | as the OR operator in (scalar) conditional statements.
40: Use || instead of | as the OR operator in (scalar) conditional statements.
42: 'data' might be growing inside a loop. Consider preallocating for speed.

45: 'dim' might be growing inside a loop. Consider preallocating for speed.
48: There may be a parenthesis imbalance around here.
48: There may be a parenthesis imbalance around here.
48: There may be a parenthesis imbalance around here.
48: There may be a parenthesis imbalance around here.
49: Terminate statement with semicolon to suppress output (in functions).
49: Use of brackets [] is unnecessary. Use parentheses to group, if needed.
Done

Messages and Resulting Changes for the lengthofline Example. The following table describes each message and demonstrates a way to change the file, based on the message.

Message — Code (Original Line Numbers)	Explanation and Updated Code (New Line Numbers)

`22:  The value assigned here to variable 'nothandle' might never be used.`
`— — — — — — — — — — — — — — — — — — — —`
`22 nothandle = ~ishandle(hline);`
`23 for nh = 1:prod(size(hline))`
`24 notline(nh) = ~ishandle(hline(nh))`
`...`
	In line 22, `nothandle` is assigned a value, but `nothandle` is probably not used anywhere after that in the file. The line might be extraneous and you could delete it. But it might be that you actually intended to use the variable, which is the case for the `lengthofline` example. Update line 24 to use `nothandle`, which is faster than computing `~ishandle` for each iteration of the loop, as shown here.
	`22 nothandle = ~ishandle(hline);`
	`23 for nh = 1:numel(hline)`
	`24 notline(nh) = nothandle(nh) ...`

`23:  NUMEL(x) is usually faster than PROD(SIZE(x)).`
`— — — — — — — — — — — — — — — — — — — —`
`23 for nh = 1:prod(size(hline))`
	While `prod(size(x))` returns the number of elements in a matrix, the `numel` function was designed to do just that, and therefore is usually more efficient. Type `doc numel` to see the `numel` reference page. Change the line to
	`23 for nh = 1:numel(hline)`

Message — Code (Original Line Numbers)	Explanation and Updated Code (New Line Numbers)

`24: 'notline' might be growing inside a loop. Consider preallocating for speed.`
`— — — — — — — — — — — — — — — — — — —`
`22 nothandle = ~ishandle(hline);`
`23 for nh = 1:numel(hline)`
`24 notline(nh) = ~ishandle(hline(nh))`
`...`
	When you increase the size of an array within a loop, it is inefficient. Before the loop, preallocate the array to its maximum size to improve performance. For more information, see "Preallocating Memory" in the MATLAB Programming documentation. In the example, add a new line to preallocate `notline` before the loop.
	`23 notline = false(size(hline));`
	`24 for nh = 1:numel(hline)`
	`25 notline(nh) = nothandle(nh) ...`

`24: Use STRCMPI(str1,str2) instead of using LOWER in a call to STRCMP.`
`— — — — — — — — — — — — — — — — — — —`
`24 notline(nh)=~ishandle(hline(nh)) || ~strcmp('line',lower(get(hline(nh), 'type')));`
	While
	`strcmp ('line',lower(get(hline(nh)'type'))`
	converts the result of the `get` function to a lowercase string before doing the comparison, the `strcmpi` function ignores the case while performing the comparison, with advantages that include more efficiency. Change line 25 to
	`notline(nh) = nothandle(nh) || ~strcmpi('line',get(hline(nh),'type'));`

`28: NUMEL(x) is usually faster than PROD(SIZE(x)).`
`— — — — — — — — — — — — — — — — — — —`
`28 for nl = 1:prod(size(hline))`
	See the same message and explanation reported for line 23. Change the line 29 to
	`for nl = 1:numel(hline)`

Message — Code (Original Line Numbers)	Explanation and Updated Code (New Line Numbers)

`34: 'data' might be growing inside a loop. Consider preallocating for speed.`
`— — — — — — — — — — — — — — — — — — —`
`33 for nd = 1:length(fdata)`
`34 data{nd} = getfield(flds,fdata{nd});`
	See the same message and explanation reported for line 24. Add this line, 34, before the loop
	`data = cell(size(fdata));`

`34: Use dynamic fieldnames with structures instead of GETFIELD. Type 'doc struct' for more information.`
`— — — — — — — — — — — — — — — — — — —`
`34 data{nd} = getfield(flds,fdata{nd});`
	You can access a field in a structure as a variable expression that MATLAB evaluates at run-time. This is more efficient than using `getfield`. For more information, type `doc struct` to see the reference page for structures, or see "Using Dynamic Field Names" in the MATLAB Programming documentation. Change line 37 to
	`data{nd} = flds.(fdata{nd});`

`38: Use || instead of | as the OR operator in (scalar) conditional statements.`
`39: Use || instead of | as the OR operator in (scalar) conditional statements.`
`40: Use || instead of | as the OR operator in (scalar) conditional statements.`
`— — — — — — — — — — — — — — — — — — —`
`38 if isempty(data{3}) | ...`
`39 (length(unique(data{1}(:)))==1 | ...`
`40 length(unique(data{2}(:)))==1 | ...`
`41 length(unique(data{3}(:)))==1)`
	While `|` (the element-wise logical `OR` operator) performs the comparison correctly, use the `||` (short circuit `OR` operator) for efficiency. For details, see "Logical Operators" in the MATLAB Programming documentation. Change lines 40, 41, and 42 to
	`if isempty(data{3}) || ...`
	`(length(unique(data{1}(:)))==1 || ...`
	`length(unique(data{2}(:)))==1 || ...`

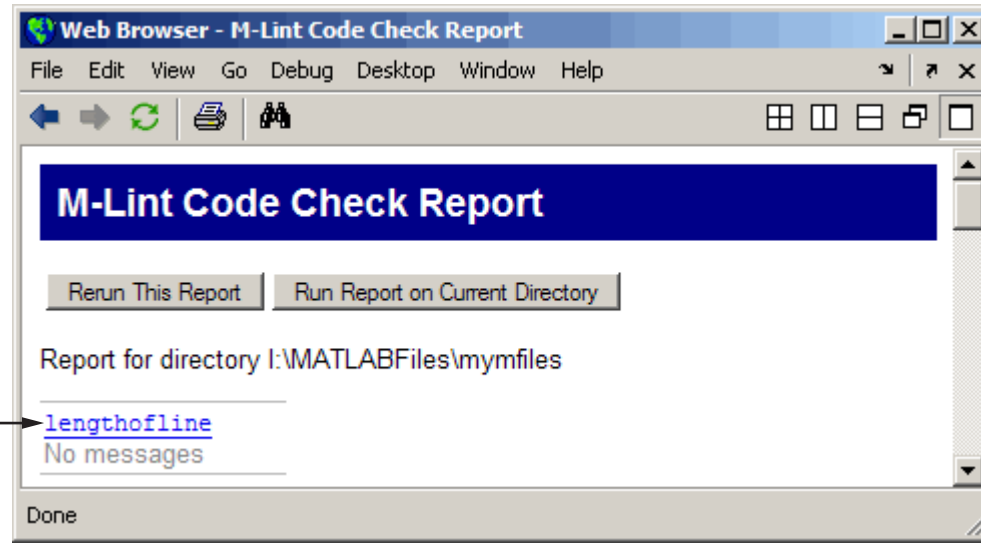
Message — Code (Original Line Numbers)	Explanation and Updated Code (New Line Numbers)

`42: 'data' might be growing inside a loop. Consider preallocating for speed.`
— — — — — — — — — — — — — — — — — —
`42 data{3} = zeros(size(data{1}));`
	This message no longer appears due to the change made to line 34 `data{nd} = getfield(flds,fdata{nd});`. Sometimes fixing code in one line automatically clears a message for another line. If the reason for a message or the action to take for a message is not obvious at first, it could be because another line is causing the message. Address the issues that are easy to fix first and rerun the report. Do not make any changes to line 44.

`43: 'dim' might be growing inside a loop. Consider preallocating for speed.` `43 dim(nl) = 2;`	See the same message and explanation reported for line 24. Add this line before the first line of the loop `dim = len;`
`48: There may be a parenthesis imbalance around here.` `48: There may be a parenthesis imbalance around here.` `48: There may be a parenthesis imbalance around here.` `48: There may be a parenthesis imbalance around here.`	There is an error in this line, which you would see by running `lengthofline`. M-Lint suggests that it might be due to a parenthesis imbalance. You can check that by moving the arrow key over each of the delimiters, to see if MATLAB indicates a mismatch. This requires that **File > Preferences > Keyboard > Delimiter Matching** has the **Match on arrow key** option selected. There are no mismatched delimiters. The actual problem is the semicolon in parentheses, `data{3}(:)` is incorrect and should be a colon. In line 51, change `data{3}(;)` to `data{3}(:)`. That single change addressed the issues in all the messages for that line.

Message — Code (Original Line Numbers)	Explanation and Updated Code (New Line Numbers)
`49:  Terminate statement with semicolon to suppress output (in functions).`	Adding a semicolon to the end of a statement suppresses output and is a common practice. M-Lint alerts you to lines that produce output but lack the terminating semicolon. If you want to view output from this line, do not add the semicolon. You can instruct M-Lint to ignore all messages on this line so that the messages on it will not appear by adding `%#ok` to the end of the line. However, because there is currently another message on the line, do not add `%#ok` until you have addressed the other message. Alternatively, you can add `%#ok` with the message ID for the specific message you want to suppress. To determine the message ID, run `mlint('lengthofline.m', '-id')`, which indicates the ID is `NOPRT`—for more information, see the `mlint` function reference page. For this example, assume you want to display the output and suppress the M-Lint message. To do so, add `%#ok<NOPRT>` to the end of the line. Note that there is a similar message for M-file scripts. This is so you can suppress the message for M-files that are cell-mode scripts, because they are often intended as demos and the display of output is intentional.

`49:  Use of brackets [] is unnecessary. Use parentheses to group, if needed.`
 	
`— — — — — — — — — — — — — — — — — — —`
 	
`49 len(nl) =`
`sum([sqrt(dot(temp',temp'))])`
	For more information about the use of brackets and parentheses, see the Special Characters reference page. In this example, remove the brackets because they are not needed. They add processing time because MATLAB concatenates unnecessarily. Change line 52 to
	
	`len(nl) = sum(sqrt(dot(temp',temp'))) %#ok`



Updated M-Lint Code Check Report after making changes to the lenghtofline file based on M-Lint messages. Now, no messages are reported.

The M-file that includes all of the changes suggested by M-Lint is `lengthofline2.m`. To view it, run

```
edit(fullfile(matlabroot,'help','techdoc','matlab_env',...
'examples','lengthofline2.m')).
```

Other Ways to Access M-Lint

You can get M-Lint messages using any of the following methods. Each provides the same M-Lint messages, but in a different format:

- Access the M-Lint Code Check report for an M-file from the Editor/Debugger Tools menu or from the Profiler detail report.
- Run the `mlint` function, which analyzes the specified file and displays messages in the Command Window, or `mlintrpt`, which runs `mlint` and displays the messages in the Web Browser.
- Use automatic M-Lint analysis and code correction while you work on a file in the Editor/Debugger — see “M-Lint Code Analyzer” on page 6-87.

Profiling for Improving Performance

In this section...

What Is Profiling?

Profiling is a way to measure where a program spends time. To assist you in profiling, MATLAB provides a graphical user interface, called the Profiler, which is based on the results returned by the `profile` function. Once you identify which functions are consuming the most time, you can determine why you are calling them and look for ways to minimize their use and thus improve performance. It is often helpful to decide whether the number of times a particular function is called is reasonable. Because programs often have several layers, your code may not explicitly call the most time-consuming functions. Rather, functions within your code might be calling other time-consuming functions that can be several layers down in the code. In this case it is important to determine which of your functions are responsible for such calls.

Profiling helps to uncover performance problems that you can solve by

- Avoiding unnecessary computation, which can arise from oversight
- Changing your algorithm to avoid costly functions
- Avoiding recomputation by storing results for future use

When you reach the point where most of the time is spent on calls to a small number of built-in functions, you have probably optimized the code as much as you can expect.

Profiling Process and Guidelines

Here is a general process you can follow to use the Profiler to improve performance in your M-files. This section also describes how you can use profiling as a debugging tool and as a way to understand complex M-files.

Note Premature optimization can increase code complexity unnecessarily without providing a real gain in performance. Your first implementation should be as simple as possible. Then, if speed is an issue, use profiling to identify bottlenecks.

---

1. In the summary report produced by the Profiler, look for functions that used a significant amount of time or were called most frequently. See "Profile Summary Report" on page 7-33 for more information.

2. View the detail report produced by the Profiler for those functions and look for the lines that use the most time or are called most often. See "Profile Detail Report" on page 7-35 for more information.

   You might want to keep a copy of your first detail report to use as a reference to compare with after you make changes, and then profile again.

3. Determine whether there are changes you can make to the lines most called or the most time-consuming lines to improve performance.

   For example, if you have a `load` statement within a loop, `load` is called every time the loop is called. You might be able to save time by moving the `load` statement so it is before the loop and therefore is only called once.

4. Click the links to the files and make the changes you identified for potential performance improvement. Save the files and run `clear all`. Run the Profiler again and compare the results to the original report. Note that there are inherent time fluctuations that are not dependent on your code. If you profile the exact same code twice, you can get slightly different results each time.

5. Repeat this process to continue improving the performance.

Using Profiling as a Debugging Tool

The Profiler is a useful tool for isolating problems in your M-files.

For example, if a particular section of the file did not run, you can look at the detail reports to see what lines did run, which might point you to the problem.

You can also view the lines that did not run to help you develop test cases that exercise that code.

If you get an error in the M-file when profiling, the Profiler provides partial results in the reports. You can see what ran and what did not to help you isolate the problem. Similarly, you can do this if you stop the execution using **Ctrl+C**, which might be useful when a file is taking much more time to run than expected.

Using Profiling for Understanding an M-File

For lengthy M-files that you did not create or that you have not used for awhile and are unfamiliar with, you can use the Profiler to see how the M-file actually worked. Use the Profiler detail reports to see the lines actually called.

If there is an existing GUI tool (or M-file) similar to one that you want to create, start profiling, use the tool, then stop profiling. Look through the Profiler detail reports to see what functions and lines ran. This helps you determine the lines of code in the file that are most like the code you want to create.

Using the Profiler

Use the Profiler to help you determine where you can modify your code to make performance improvements. The Profiler is a tool that shows you where an M-file is spending its time. This section covers

For information about the reports generated by the Profiler, see “Profile Summary Report” on page 7-33 and “Profile Detail Report” on page 7-35.

Opening the Profiler

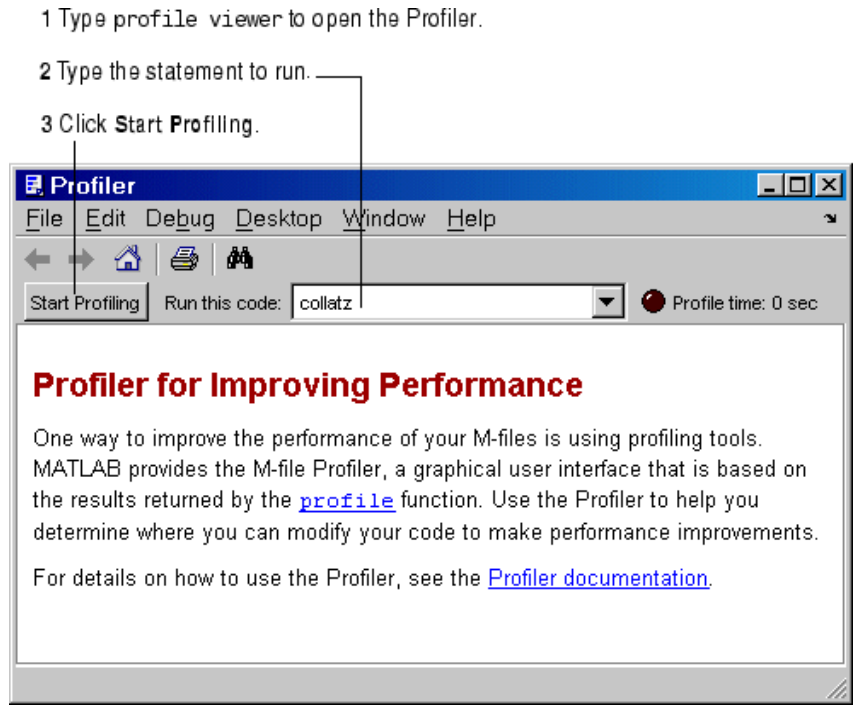
You can use any of the following methods to open the Profiler:

- Select **Desktop > Profiler** from the MATLAB desktop.
- Click the Profiler button in the MATLAB desktop toolbar.
- With a file open in the MATLAB Editor/Debugger, select **Tools > Open Profiler**.
- Select one or more statements in the Command History window, right-click to view the context menu, and choose **Profile Code**.
- Enter the following function in the Command Window:

```
profile viewer
```

Running the Profiler

The following illustration summarizes the steps for profiling.



To profile an M-file or a line of code, follow these steps:

1 In the **Run this code** field in the Profiler, type the statement you want to run.

   You can run this example

   ```
   [t,y] = ode23('lotka',[0 2],[20;20])
   ```

   as the code is provided with MATLAB demos. It runs the Lotka-Volterra predator-prey population model. For more information about this model, type `lotkademo`, which runs the demonstration.

   To run a statement you previously profiled in the current MATLAB session, select the statement from the list box — MATLAB automatically starts profiling the code, so skip to step 3.

2 Click **Start Profiling** (or press **Enter** after typing the statement).

While the Profiler is running, the **Profile time** indicator (at the top right of the Profiler window) is green and the number of seconds it reports increases.

When the profiling is finished, the **Profile time** indicator becomes black and shows the length of time the Profiler ran. The statements you profiled are shown as having been executed in the Command Window.

This is not the actual time that your statements took to run; it is the wall clock (or `tic/toc`) time elapsed from when you clicked **Start Profiling** until profiling stops. If the time reported is much different from what you expected (for example, hundreds of seconds for a simple statement), you might have had profiling on longer than you realized. This also does not match the time reported in Profiler statistics, which is based on `cpu` time by default, not wall clock time.

3 When profiling is complete, the Profile Summary report appears in the Profiler window. For more information about this report, see “Profile Summary Report” on page 7-33.

Profiling a Graphical User Interface

You can run the Profiler for a graphical user interface, such as the Filter Design and Analysis tool included with Signal Processing Toolbox. You can also run the Profiler for an interface you created, such as one built using GUIDE.

To profile a graphical user interface, follow these steps:

1 In the Profiler, click **Start Profiling**. Make sure that no code appears in the **Run this code** field.

2 Start the graphical user interface. (If you do not want to include its startup process in the profile, do not click **Start Profiling**, step 1, until after you have started the graphical interface.)

3 Use the graphical interface. When you are finished, click **Stop Profiling** in the Profiler.

The Profile Summary report appears in the Profiler.

Profiling Statements from the Command Window

To profile more than one statement, follow these steps:

1 In the Profiler, clear the **Run this code** field and click **Start Profiling**.

2 In the Command Window, enter and run the statements you want to profile.

3 After running all the statements, click **Stop Profiling** in the Profiler.

The Profile Summary report appears in the Profiler.

Changing Fonts for the Profiler

To change the fonts used in the Profiler, follow these steps:

1 Select **File > Preferences > Fonts** to open the **Font** Preferences dialog box.

2 In the Font Preferences dialog box, select the code or text font that you want to use in the Profiler. The Profiler is an HTML Proportional Text tool. For more information, click the **Help** button in the dialog box.

3 Click **Apply** or **OK**. The Profiler font reflects the changes.

Profile Summary Report

The Profile Summary report presents statistics about the overall execution of the function and provides summary statistics for each function called. The report formats these values in four columns.

- **Function Name** — A list of all the functions and subfunctions called by the profiled function. When first displayed, the functions are listed in

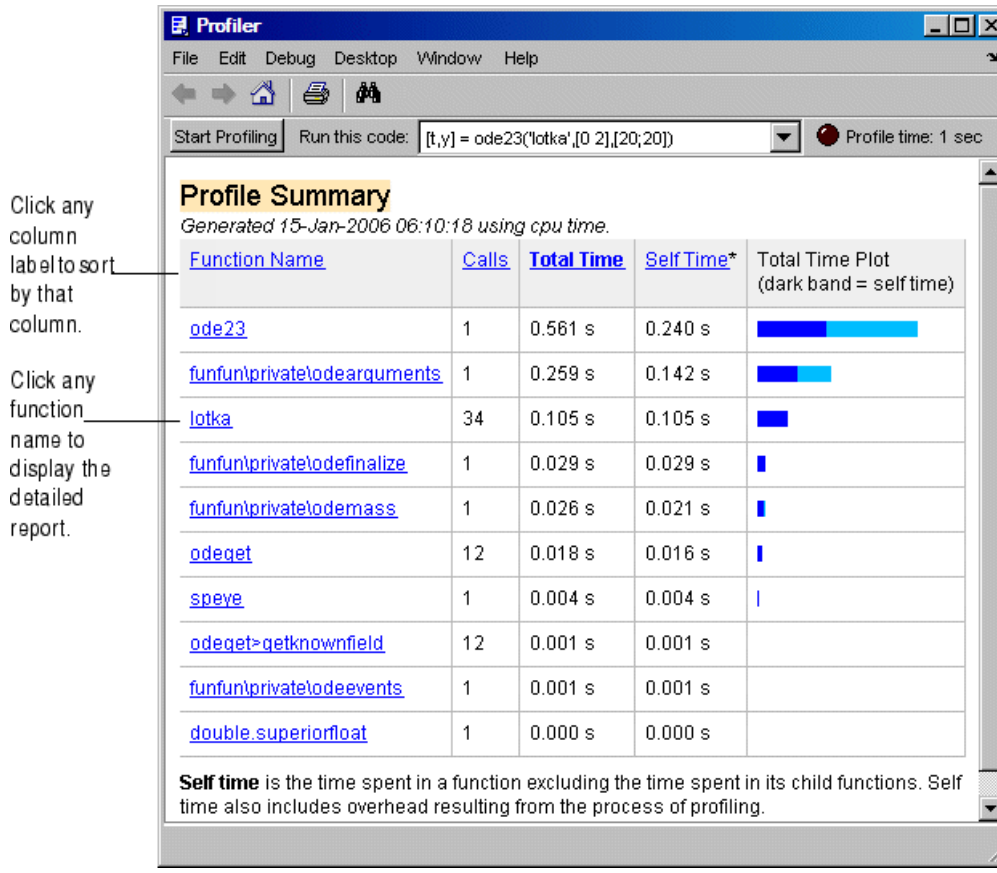
order by the amount of time they took to process. To sort the functions alphabetically, click the **Function Name** link at the top of the column.

- **Calls** — The number of times the function was called while profiling was on. To sort the report by the number of times functions were called, click the **Calls** link at the top of the column.
- **Total Time** — The total time spent in a function, including all child functions called, in seconds. The time for a function includes time spent on child functions. To sort the functions by the amount of time they consumed, click the **Total Time** link at the top of the column. By default, the summary report displays profiling information sorted by **Total Time**. Note that the Profiler itself uses some time, which is included in the results. Also note that total time can be zero for files whose running time was inconsequential.
- **Self Time** — The total time spent in a function, *not* including time for any child functions called, in seconds. To sort the functions by this time value, click the **Self Time** link at the top of the column.
- **Total Time Plot** — Graphic display showing self time compared to total time.

Following is the summary report for the Lotka-Volterra model described in “Example: Using the profile Function” on page 7-43.

To print a summary report, click the Print button  .

To get more detailed information about a particular function, click its name in the **Function Name** column. See “Profile Detail Report” on page 7-35 for more information.



Profile Detail Report

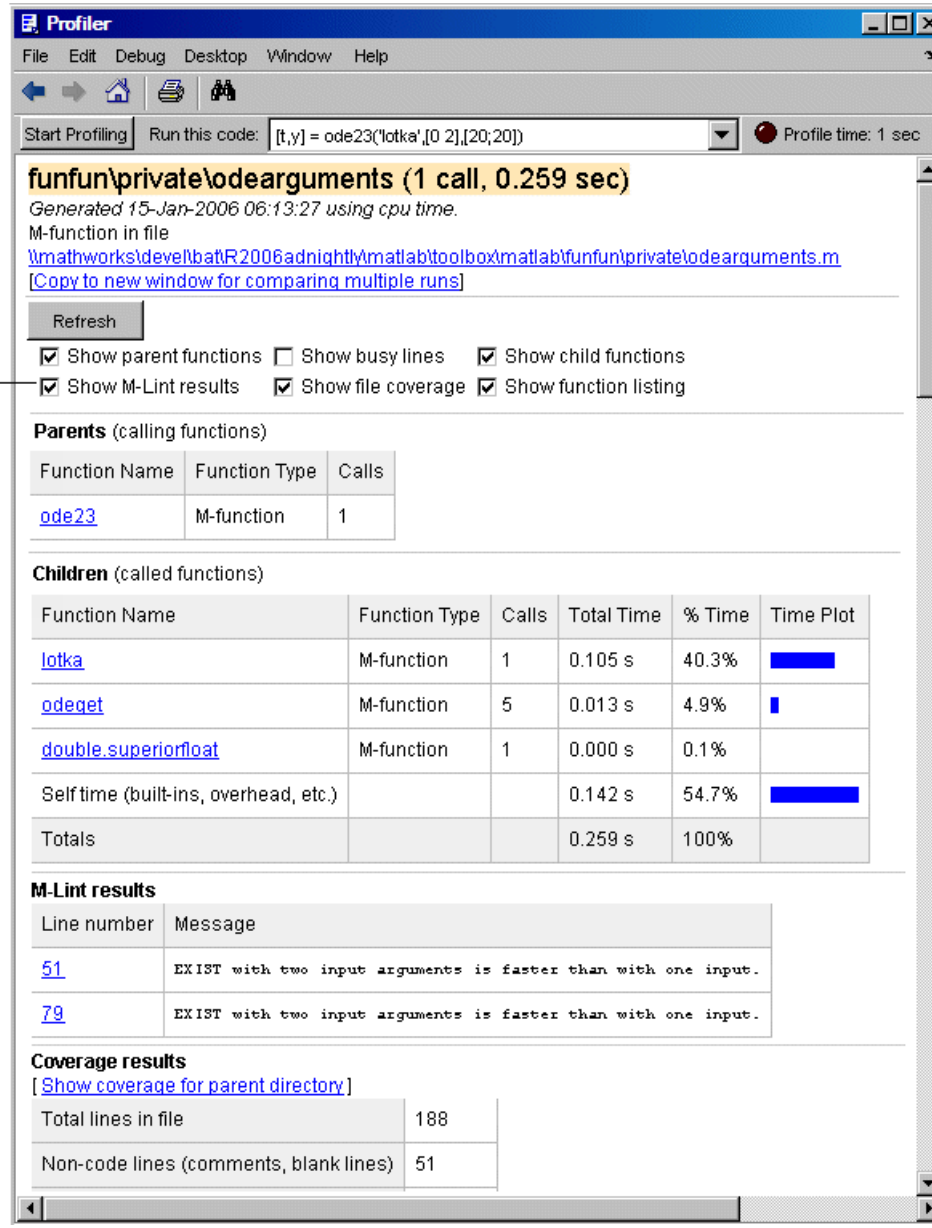
The Profile Detail report shows profiling results for a selected function that was called during profiling. A Profile Detail report is made up of seven sections, summarized below. By default, the Profile Detail report includes all seven sections, although, depending on the function, not every section contains data. To return to the Profile Summary report from the Profile Detail report, click the Home button in the toolbar. The following sections provide more detail:

Controlling the Contents of the Detail Report Display (p. 7-36)	Customize display to include only sections you are interested in.
Profile Detail Report Header (p. 7-38)	Provides general information about the function.
Parent Functions (p. 7-38)	Provides information about the parent function.
Busy Lines (p. 7-38)	Lists the lines in the function that used the greatest amount of processing time.
Child Functions (p. 7-39)	
M-Lint Results (p. 7-40)	Lists the lines in the functions that M-Lint highlighted.
File Coverage (p. 7-40)	Provides statistics about the lines of code in the function that executed while profiling was on.
Function Listing (p. 7-41)	Includes the source code for the function, if it is an M-file.

Controlling the Contents of the Detail Report Display

You can determine which sections are included in the display by selecting them and then clicking the **Refresh** button. The following sections provide more detail about each section of this report.

Select report options to display, and then click **Refresh**.

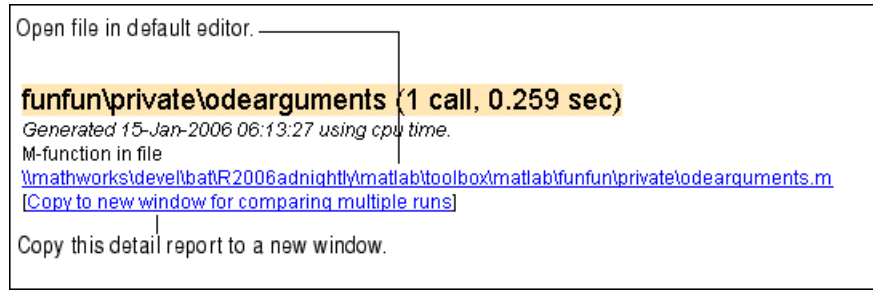


Profile Detail Report Header

The detail report header includes the name of the function that was profiled, the number of times it was called in the parent function, and the amount of time it used.

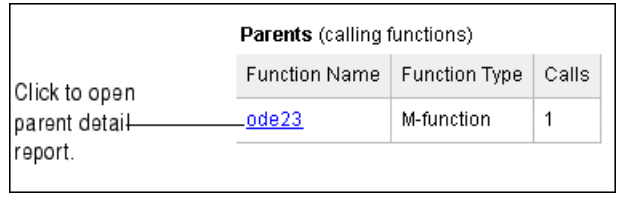
The header includes a link that opens the function in your default text editor.

The header also includes a link that copies the report to a separate window. Creating a copy of the report can be helpful when you make changes to the file, run the Profiler for the updated file, and compare the Profile Detail reports for the two runs. Do not make changes to M-files provided with MathWorks products, that is, files in *`matlabroot`*`/toolbox` directories.



Parent Functions

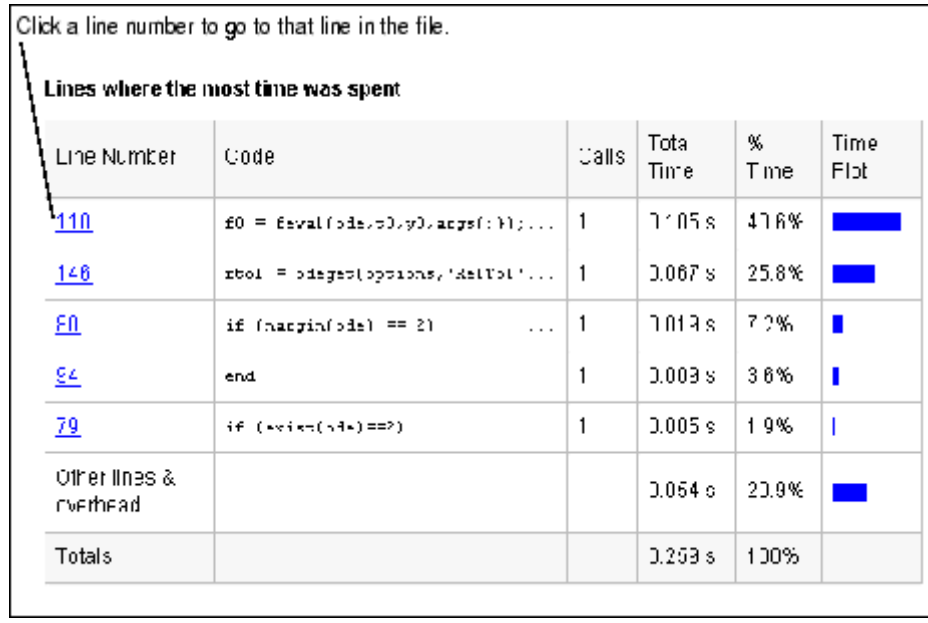
To include the **Parents** section in the detail report, select the **Show parent functions** check box. This section of the report provides information about the parent functions, with links to their detail reports.



Busy Lines

To include information about the lines of code that used the most amount of processing time in the detail report, select the **Show busy lines** check box.

Note that this was not selected in the example. Click a line number to view that line of code in the source listing.



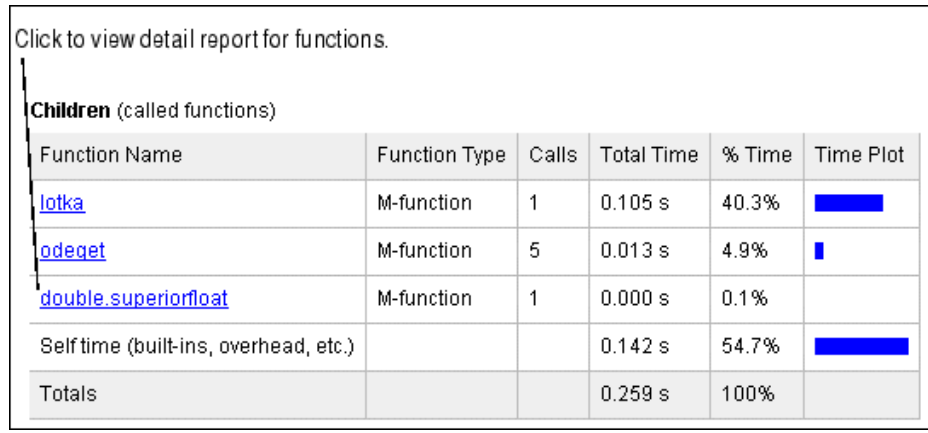
Click a line number to go to that line in the file.

Lines where the most time was spent

Line Number	Code	Calls	Tota Time	% Time	Time Plot
110	f0 = feval(p1s,p3),y),args{:});...	1	1.105 s	47.6%	
146	xbol = p1sgns(options,'dellol'...	1	0.067 s	25.8%	
50	if (nargin(p1s) == 2) ...	1	0.013 s	7.2%	
82	end	1	0.009 s	3.6%	
79	if (exist(p1s)==2)	1	0.005 s	1.9%	
Other lines & overhead			0.054 s	20.9%	
Totals			0.259 s	100%	

Child Functions

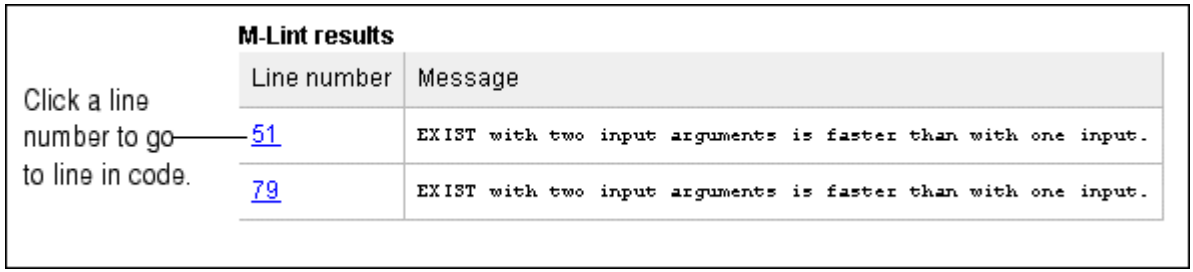
To include the **Children** section of the detail report, select the **Show child functions** check box. This section of the report lists all the functions called by the profiled function. If the called function is an M-file, you can view the source code for the function by clicking its name.



Function Name	Function Type	Calls	Total Time	% Time	Time Plot
lotka	M-function	1	0.105 s	40.3%	
odeget	M-function	5	0.013 s	4.9%	
double.superiorfloat	M-function	1	0.000 s	0.1%	
Self time (built-ins, overhead, etc.)			0.142 s	54.7%	
Totals			0.259 s	100%	

M-Lint Results

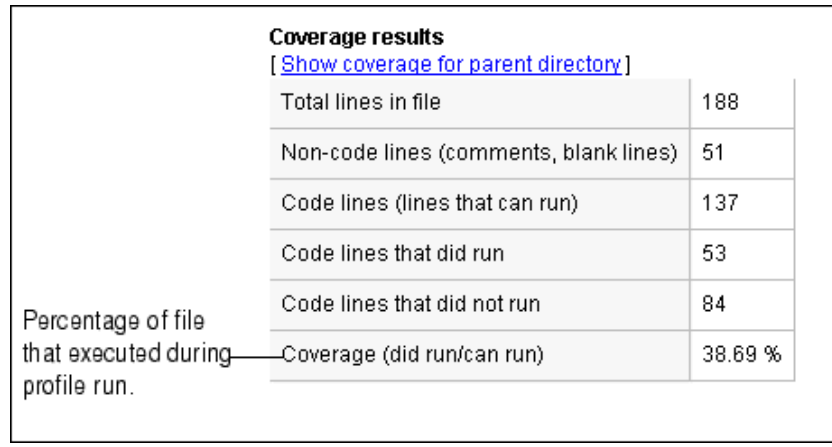
To include the **M-Lint results** section in the detail report display, select the **Show M-Lint results** check box. This section of the report provides information about problems and potential improvements, generated by M-Lint about the function. For more information about M-Lint, see "M-Lint Code Check Report" on page 7-16.



Line number	Message
51	EXIST with two input arguments is faster than with one input.
79	EXIST with two input arguments is faster than with one input.

File Coverage

To include the **Coverage results** section in the detail report display, select the **Show file coverage** check box. This section of the report provides statistical information about the number of lines in the code that executed during the profile run.

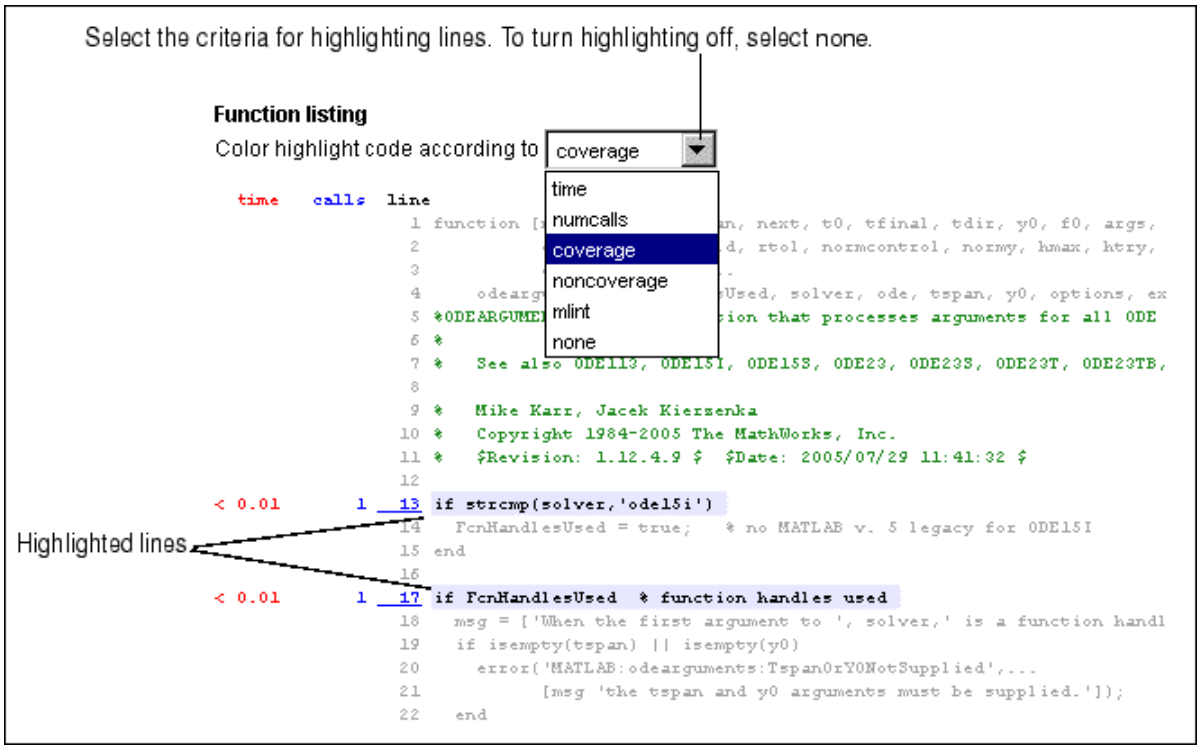


Function Listing

To include the **Function listing** section in the detail report display, select the **Show function listing** check box. If the file is an M-file, the Profile Detail report includes a column listing the execution time for each line, a column listing the number of times the line was called, and the source code for the function.

In the function listing, comment lines appear in green, lines of code that executed appear in black, and lines of code that did not execute appear in gray. If you click a function name in the listing, you can view its detail report.

By default, the Profile Detail report uses the color red to highlight the lines of code with the longest execution time. The darker the shade of red, the longer the line of code took to execute. Using the menu in this section of the detail report you can change this default and choose to highlight lines of code based on other criteria such as the lines called the most, lines called out by M-Lint, or lines of code that were (or were not) executed. Using this menu, you can also turn off highlighting completely.



The profile Function

The Profiler is based on the results returned by the `profile` function. This section describes

profile Function Syntax Summary

Here is a summary of some of the main forms of `profile`. For details about these and other options, type `doc profile`. Some people use `profile` simply to see the child functions; see also `depfun` for that purpose.

Syntax	Description
`profile on`	Starts `profile`, clearing previously recorded statistics.
`profile on -detail level`	Specifies the level of function to be profiled, where *`level`* can be either: `'mmex'` — M-functions, M-subfunctions, and MEX-functions `'builtin'` — M-functions, M-subfunctions, MEX-functions, and built-ins
`profile on -history`	Specifies that the exact sequence of function calls is to be recorded.
`profile off`	Suspends `profile`.
`profile resume`	Restarts `profile` without clearing previously recorded statistics.
`profile clear`	Clears the statistics recorded by `profile`.
`profile viewer`	Opens the Profiler, a graphical user interface and displays the information gathered as an HTML-formatted report. Note: If you run the obsoleted syntax `profile report`, the `profile` function calls this syntax.
`s = profile('status')`	Displays a structure containing the current `profile` status.
`stats = profile('info')`	Suspends `profile` and displays a structure containing `profile` results.

Example: Using the profile Function

This example demonstrates how to run `profile`:

1 To start `profile`, type in the Command Window

```
profile on
```

2 Execute an M-file. This example runs the Lotka-Volterra predator-prey population model. For more information about this model, type `lotkademo`, which runs a demonstration.

```
[t,y] = ode23('lotka',[0 2],[20;20]);
```

3 Generate the profile report and display it in the Profiler window. This suspends `profile`.

```
profile viewer
```

4 Restart `profile`, without clearing the existing statistics.

```
profile resume
```

The `profile` function is now ready to continue gathering statistics for any more M-files you run. It will add these new statistics to those generated in the previous steps.

5 Stop `profile` when you finish gathering statistics.

```
profile off
```

6 To view the profile data, call `profile` specifying the `'info'` argument. The profile function returns data in a structure.

```
p = profile('info')

p =
      FunctionTable: [10x1 struct]
    FunctionHistory: [2x0 double]
     ClockPrecision: 3.3333e-010
         ClockSpeed: 3.0000e+009
               Name: 'MATLAB'
```

The `FunctionTable` indicates that statistics were gathered for 10 functions.

7 To save the profile report, use the `profsave` function. This function stores the profile information in separate HTML files, for each function listed in `FunctionTable` of `p`.

```
profsave(p)
```

By default, `profsave` puts these HTML files in a subdirectory of the current directory named `profile_results`, and displays the summary report in your system browser. You can specify another directory name as an optional second argument to `profsave`.

Accessing Profiler Results

The `profile` function returns results in a structure. This example illustrates how you can access these results:

1 To start `profile`, specifying the `detail` and `history` options, type in the Command Window.

```
profile on -detail builtin -history
```

The detail option specifies that built-ins should be included in the profile data. The history option specifies that the report include information about the sequence of functions as they are entered and exited during profiling.

2 Execute an M-file. This example runs the Lotka-Volterra predator-prey population model. For more information about this model, type `lotkademo`, which runs a demonstration.

```
[t,y] = ode23('lotka',[0 2],[20;20]);
```

3 Stop profiling.

```
profile off
```

4 Get the structure containing profile results.

```
stats = profile('info')
stats =
      FunctionTable: [43x1 struct]
    FunctionHistory: [2x754 double]
     ClockPrecision: 3.3333e-010
```

```
          ClockSpeed: 3.0000e+009
                Name: 'MATLAB'
```

5 The `FunctionTable` field is an array of structures, where each structure represents an M-function, M-subfunction, MEX-function, or, because the `builtin` option is specified, a MATLAB built-in function.

```
stats.FunctionTable

ans =

41x1 struct array with fields:
    CompleteName
    FunctionName
    FileName
    Type
    NumCalls
    TotalTime
    TotalRecursiveTime
    Children
    Parents
    ExecutedLines
    IsRecursive
    PartialData
```

6 View the second structure in `FunctionTable`.

```
stats.FunctionTable(2)

ans =
           CompleteName: [1x79 char]
           FunctionName: 'ode23'
               FileName: [1x73 char]
                   Type: 'M-function'
               NumCalls: 1
              TotalTime: 0.3902
    TotalRecursiveTime: 0
               Children: [20x1 struct]
                Parents: [0x1 struct]
          ExecutedLines: [139x3 double]
```

```
    IsRecursive: 0
    PartialData: 0
```

7 To view the history data generated by `profile`, view the `FunctionHistory`, for example, `stats.FunctionHistory`. The history data is a 2-by-n array. The first row contains Boolean values, where `0` (zero) means entrance into a function and `1` means exit from a function. The second row identifies the function being entered or exited by its index in the `FunctionTable` field. To see how to create a formatted display of history data, see the example on the `profile` reference page.

Saving Profile Reports

To save the profile report, use the `profsave` function.

This function stores the profile information in separate HTML files, for each function listed in the `FunctionTable` field of the structure, `stats`.

```
profsave(stats)
```

By default, `profsave` puts these HTML files in a subdirectory of the current directory named `profile_results`. You can specify another directory name as an optional second argument to `profsave`.

```
profsave(stats,'mydir')
```

8

Publishing Results

MATLAB provides two different approaches for publishing: using cells and with the Notebook features for Microsoft Word.

Publishing to HTML, XML, LaTeX, Word, and PowerPoint Using Cells

In this section...

About Publishing M-Files

When you have completed writing and debugging an M-file, use the M-file cell features in the Editor/Debugger to quickly publish the M-file and its results in any of several presentation formats: HTML, XML, LaTeX, or, when the applications are installed, Microsoft Word or PowerPoint. This allows you to share your work with others, presenting not only the code, but also commentary on the code and results from running the file.

Publishing features evaluate M-files cell-by-cell and display the contents of a cell in a presentation quality document. For M-file scripts, publishing also displays the results. For example, published documents include bold headings for each section of the file. For M-file scripts, published documents include output to the Command Window and figures. The cells in the Editor/Debugger that you use for publishing are the same ones you might already have used for rapid code iteration—see "Using Cells for Rapid Code Iteration and Publishing Results" on page 6-133.

If you have an active Internet connection, you can watch the Publishing M Code from the Editor/Debugger video demo for an overview of the major functionality.

This is the overall process to publish an M-file using cell features in the Editor/Debugger:

1. Enable cell mode and define cells as described in steps 1 through 3 in "Using Cells for Rapid Code Iteration and Publishing Results" on page 6-133. When you publish the file without adding any text markup, comments at

the start of a cell appear as plain text. Comments appearing after code in a cell appear as unformatted M-file comments in the published document.

2. Use **Cell > Insert Text Markup** to insert markup symbols in the M-file comments to stylize the text for the output, for example, to display specified text as bold or monospaced. For details, see "Marking Up Text in Cells for Publishing" on page 8-11.

3. When publishing an M-file function, select **File > Preferences > Editor/Debugger > Publishing**, and clear the **Evaluate code** option.

4. Select **File > Publish To**, and select the format in which you want to publish the M-file: HTML, XML, LaTeX, Word, or PowerPoint. For details, see "Publishing M-Files Using Cells" on page 8-24.

5. Change the **Editor/Debugger Publishing** and **Publishing Images** preferences to adjust the output. For example, you can choose to include or exclude the code from the output. For details, see "Modifying Published Output Using Preferences" on page 8-26.

MATLAB publishes the M-file by writing the cell titles, comment text, and code to a file using the specified format. For M-file scripts, MATLAB also evaluates the cells and writes the results of the evaluation to the output file. Any figures created or modified during the evaluation are saved as graphics files, and are shown with the results.

Publishing Scripts and Functions—Differences

When you publish M-file scripts, MATLAB runs the code and the published output includes the results.

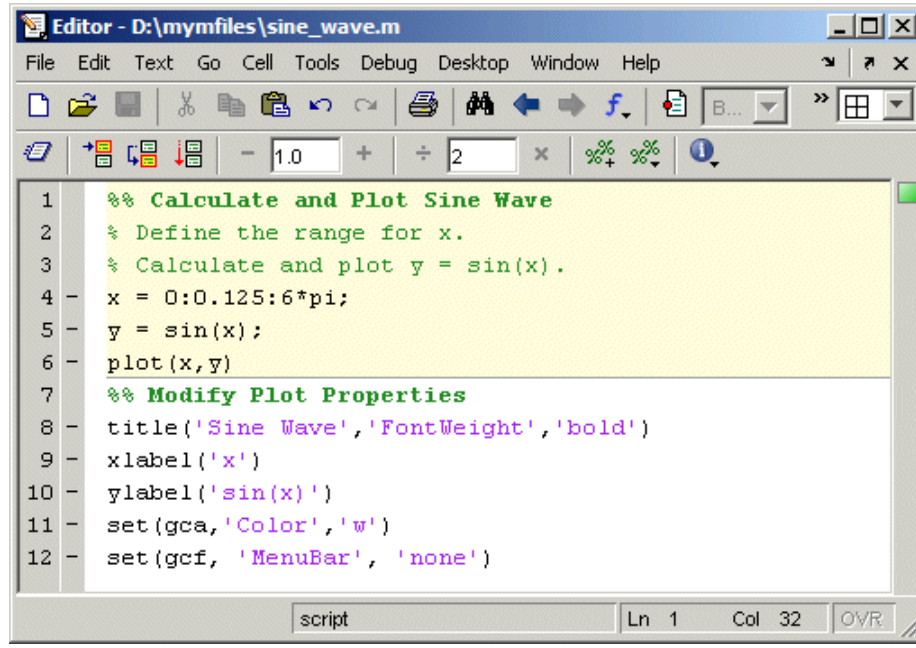
When you publish M-file functions, MATLAB does not run the code, so the published output does not include results. Publishing an M-file function allows you to effectively save the M-file code along with formatted M-file comments. The instructions for publishing M-files apply to M-file functions, with the exception of steps that involve evaluating code and displaying results from running the file.

If you want to publish an M-file function that includes results, change the M-file function to a script. Remove the function declaration statement and

within the M-file script, supply any input values that you had passed when you ran the function.

Example of Publishing Without Text Markup

This is based on the M-file script used in “Example — Evaluate Cells” on page 6-141, as shown here. Instructions for preparing and publishing the file follow.



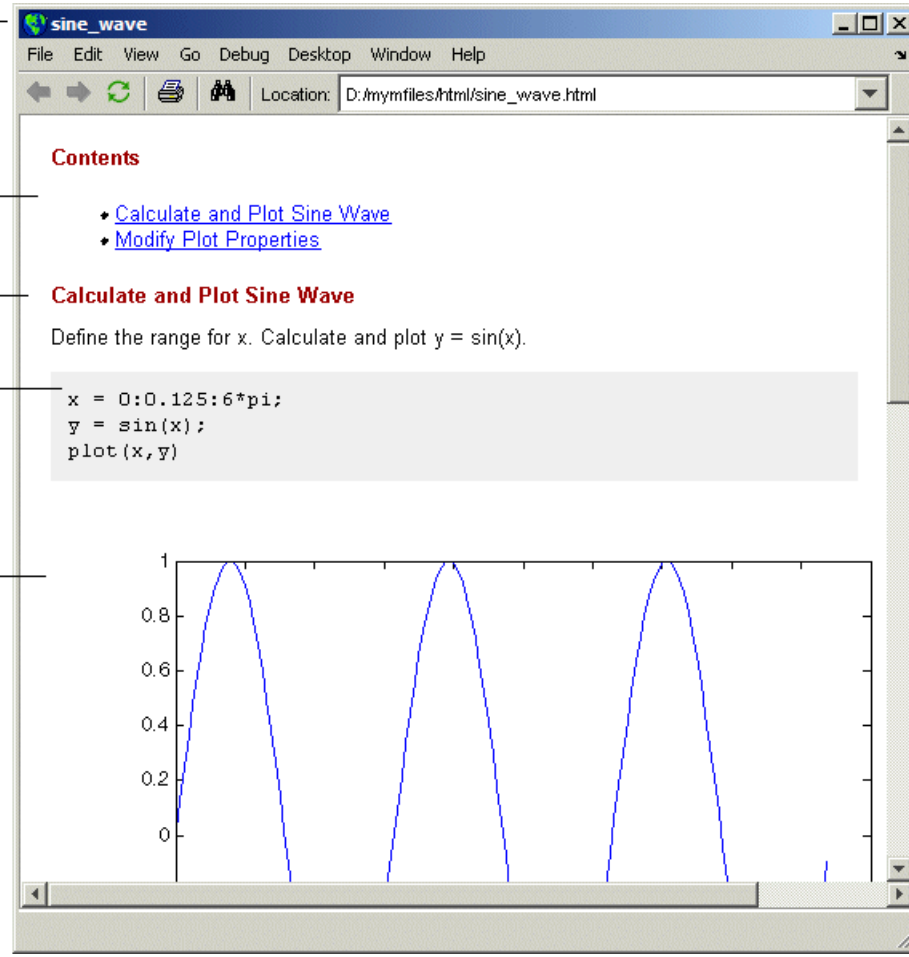
Select **File > Publish to HTML** to produce the following result.

M-file published to HTML format.

Publishing automatically generates a cell contents listing with links to all cell (section) titles.

Automatic formatting makes cell titles bold and shows code in a monospace font. Executable code appears with a gray background.

Results from running the M-file are included in the published document.



Example of Publishing with Text Markup

This simple example adds text markup to the `sine_wave.m` file used in “Example of Publishing Without Text Markup” on page 8-4 to produce the following published HTML document.

Published file after applying text markup.

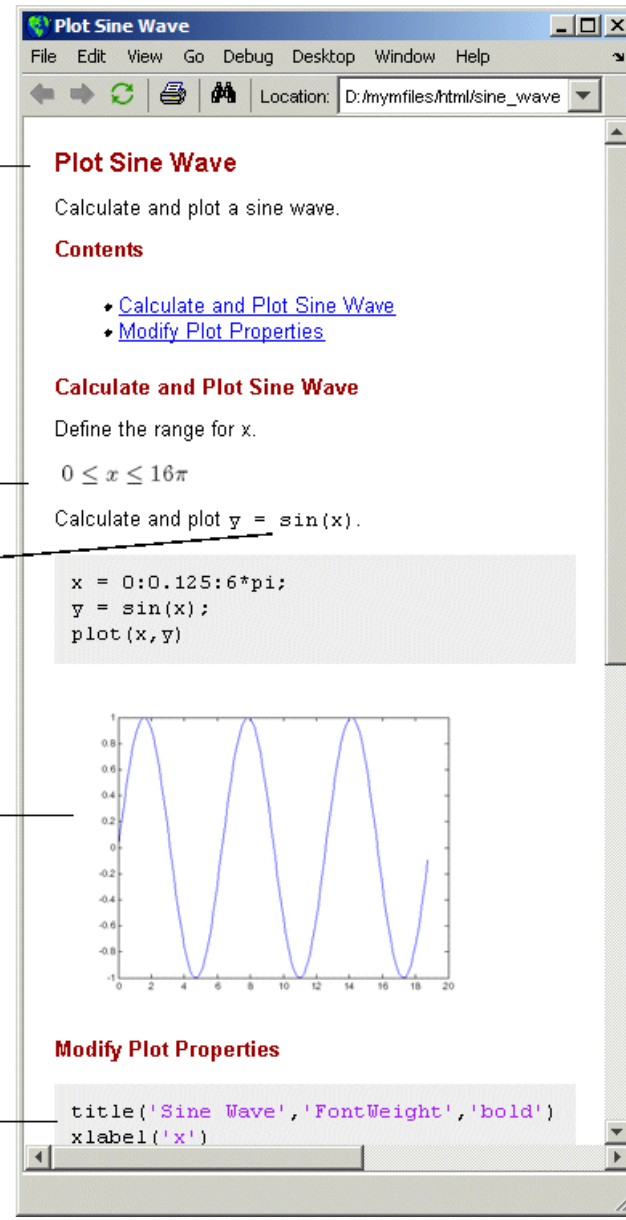
Add a title for the document.

Display comment lines using TeX format.

Make selected comment text appear in monospace.

Reduce the size of the figure output in the document using **Preferences for Publishing Images**.

MATLAB code appears with gray background to distinguish it from results.



1. Add an overall title and introduction for the published document

   a. Select **Cell > Insert Text Markup > > Document Title and Introduction**. MATLAB adds the following at the top of the file.

   ```
   %% DOCUMENT TITLE
   % INTRODUCTORY TEXT
   ```

   The two percent signs (`%%`) indicate the start of a new cell, where a cell is a section of an M-file. A single percent sign indicates a comment line.

   b. Replace **`DOCUMENT TITLE`** with **`Plot Sine Wave`**.

   c. On line 2, after the single percent sign, replace `INTRODUCTORY TEXT` with a comment about the overall file. For example, `Calculate and plot a sine wave`.

   d. On line 3, insert a blank line for better readability.

   You can add any overall comments about the file in the lines following the title. You cannot add executable code between document title and before the next cell (a line starting with `%%`) if you want the document title to appear as the overall document title.

2. Display equations in comments with symbols and Greek characters using the TeX format. For a list of symbols you can display and the character sequence to create them, see the `String` property on the MATLAB reference page for graphics `Text Properties`. In this example, to create a comment containing the following equation in the published document: $0 \le x \le 6\pi$, use text markup as follows:

   a. Position the cursor at the end of line 5, where the text`Define the range for x` appears.

   b. Select **Cell > Insert Text Markup > TeX Equation**.

   MATLAB inserts the following lines:

   ```
   %
   % $$e^{\pi i} + 1 = 0$$
   %
   ```

   The sample equation, which is the text between the set of two dollar signs (`$$`), is highlighted.

c Replace the sample equation with the following TeX equation:

```
0 \leq x \leq 6\pi
```

The three lines that display the TeX equation in the published document now appear as follows in the M-file.

```
%
% $$0 \leq x \leq 6\pi$$
%
```

3 Display a selected comment text in a monospace font, as follows:

a Position the cursor in the following comment, which appears in line 9.

```
% Calculate and plot y = sin(x).
```

b To make the equation `y = sin(x)` appear in monospace font in the published document, select the equation and then select **Cell> Insert Text Markup> Monospaced Text**. Line 9 should appear as follows:

```
% Calculate and plot |y = sin(x)|.
```

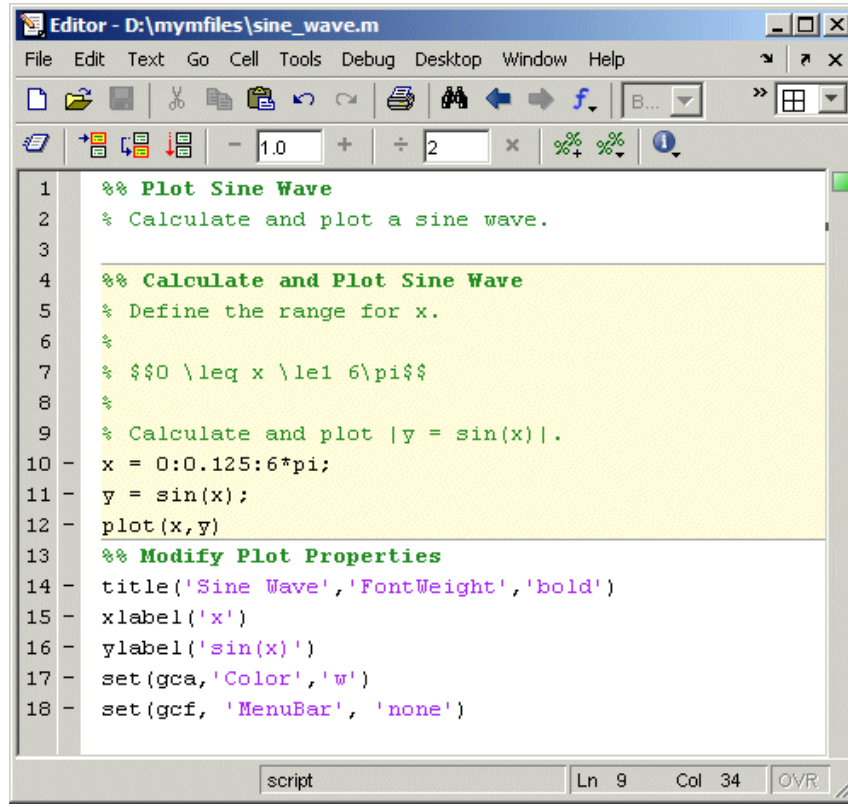
4 To reduce the size of the published figure, select **File > Preferences > Editor/Debugger > Publishing Images**. In the **Preferences** dialog box, for **Resize image**, select **Restrict height to** and enter `200`. Click **OK** to close the dialog box.

5 Select **File > Save and Publish to HTML**.

The HTML file displays in the MATLAB Web Browser, as shown at the start of this example, “Example of Publishing with Text Markup” on page 8-6.

6 By default, MATLAB stores the HTML document, `sine_wave.html`, and the associated image files in `d:/mymfiles/html` for this example.

The file `sine_wave.m` now appears as shown in the following illustration.



Editor - D:\mymfiles\sine_wave.m
File Edit Text Go Cell Tools Debug Desktop Window Help
1.0
2
%% Plot Sine Wave
% Calculate and plot a sine wave.
%% Calculate and Plot Sine Wave
% Define the range for x.
%
% $$0 \leq x \le1 6\pi$$
%
% Calculate and plot |y = sin(x)|.
x = 0:0.125:6*pi;
y = sin(x);
plot(x,y)
%% Modify Plot Properties
title('Sine Wave','FontWeight','bold')
xlabel('x')
ylabel('sin(x)')
set(gca,'Color','w')
set(gcf, 'MenuBar', 'none')
script

Marking Up Text in Cells for Publishing

In this section...

Overview of Text Markup

When you publish an M-file and results, you can mark up the file using cell features—this adds and formats comments in the published file. You can include the markup as you write the basic code, mark up the file after you've written the code, or do both. The markup applies to any of the available publishing options: HTML, XML, LaTeX, Word, and PowerPoint.

Any cell features you use for evaluating and improving your code are used for publishing purposes as well. The "Example of Publishing Without Text Markup" on page 8-4 shows how the cells used for improving an M-file appear when the M-file is published. You might want to change the existing cells for publishing purposes, but note that this changes the cells for evaluation purposes as well. For example, to have text markup and formatted comments in the output document, the comments must appear at the start of a cell, before any code.

Mark up comment text in one of two ways:

- Use **Cell > Insert Text Markup** menu items to format the code, which automatically inserts the markup symbols for you. This is not available for all markup options.

- Type the markup symbols directly in the code. Note that what you type is the same as the code that results if you instead use the equivalent menu item.

The following tables describe each markup option and how to use it. The tables refer to “Example of Publishing with Text Markup” on page 8-6:

Text Markup for Cell Breaks, Headings, and Formatted Comments

Cell breaks, headings, and formatted comments are the structural elements that control the overall output format of the published document.

Format	How to Produce Format	Resulting Code	Published Results
Overall document heading and introductory text	**1** Position the cursor anywhere in the editor. **2** Select **Cell > Insert Text Markup > Document Title and Introduction.** **3** Replace **`DOCUMENT TITLE`** in the resulting code with your desired cell heading. **4** Replace `INTRODUCTORY TEXT` in the resulting code with text that introduces the M-file. See step in the example.	**`%% DOCUMENT TITLE`** `% INTRODUCTORY TEXT` In the example, the overall heading is **`%% Plot Sine Wave`**	Document title is formatted as a top-level heading (`h1` in HTML), using a large size, bold font. Introductory text appears as formatted text.
Section title, formatted comments, and a cell break	**1** Position the cursor where you want to insert a new cell. **2** Select **Cell > Insert Text Markup > Section Title with Cell Break.** **3** Replace **`SECTION TITLE`** with your desired title. **4** Replace `DESCRIPTIVE TEXT` with text that describes the cell.	`%%` **`SECTION TITLE`** `% DESCRIPTIVE TEXT` In the example, the section titles are **`%% Calculate and Plot Sine Wave`** **`%% Modify Plot Properties`** Note that descriptive text must appear before the first line of executable code in a cell.	Formatted as a heading (`h2` in HTML), using a medium size, bold font. Descriptive text appears as formatted text in the published output.

Text Markup for Indented Text, Lists, and Graphics

Indented text, lists, and graphics are types of block styles. Block styles control the appearance of large sections of text within the final published document. A block is a series of comment lines within a cell's descriptive text that starts and ends with a blank comment line, or the beginning or end of the descriptive text.

Format	How to Produce Format	Resulting Code and Explanation	Published Results

Indented text	**1** Position the cursor before the line where you want to add indented text.
	
	2 Select **Cell > Insert Text Markup > Preformatted Text**.
	
	3 Replace the resulting code with your desired text, including tabs and spaces. Be careful, however, to keep the percent signs (%) at the beginning of each line.
		`%  PREFORMATTED`
		`% TEXT`
		
		More than one space at the start of a block distinguishes it as preformatted.
			The indents, spacing, and line breaks in the M-file are preserved in the output:
			`  PREFORMATTED`
			`TEXT`

Format	How to Produce Format	Resulting Code and Explanation	Published Results
Image	**1** Position the cursor before the line where you want to add a graphic. **2** Select **Cell > Insert Text Markup > Image**. **3** Replace the sample text inserted, `FILENAME.PNG`, with filename of the graphic you want to insert. Keep the percent sign (%) and angle brackets (<< >>) . The image file must be in the same directory as the output file, or you must specify a relative path to the image file, from the output file.	`% <<FILENAME.PNG>>`	If you replace `FILENAME.PNG` with `surfpeaks.jpg`, the published results appear as follows: 
Format	How to Produce Format	Resulting Code and Explanation	Published Results

Bulleted list	**1** Position the cursor before the line where you want to add a bulleted list.
	2 Select **Cell > Insert Text Markup > Bulleted List**.
	3 Replace the sample text inserted, `ITEM 1` and `ITEM 2`, with your desired text. Be careful, however, to keep the percent signs (%) and asterisk (*) at the beginning of each line.
		`% * ITEM1`
		`% * ITEM2`
		The asterisk (`*`) at the start of a line indicates it is a bulleted list item.
			• `ITEM1`
			• `ITEM2`

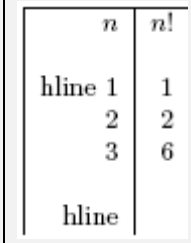
Numbered list	**1** Position the cursor before the line where you want to add a numbered list.
	2 Select **Cell > Insert Text Markup > Numbered List**.
	3 Replace the inserted text , `ITEM 1` and `ITEM 2`, with your desired text. Do not, however, replace the percent sign (%) and number sign (#) that appear at the beginning of each line.
		`% # ITEM1`
		`% # ITEM2`
		The number sign (#) at the start of a line indicates it is a numbered list item.
			1 `ITEM1`
			2 `ITEM2`

Text Markup for HTML, LaTeX, and TeX Equation Output Types

You can specify the output type for a published M-file as HTML, LaTeX or TeX equation. When you publish the M-file, use the **File > Publish to** menu options accordingly. For details, see “Publishing M-Files Using Cells” on page 8-24.

Note When you markup text for the HTML or LaTex output type, that text is published only when the specified output type matches the markup type. For example, if you add HTML markup, but then select **File > Publish To > LaTeX**, the text enclosed within the HTML markup is not published. Similarly, if you add LaTeX markup, but then select **File > Publish To > HTML** or click the Publish to HTML button (), the text enclosed within the LaTeX markup is not published.

Format	How to Produce Format	Resulting Code	Published Results
HTML markup	1 Position the cursor before the line where you want to add HTML markup. 2 Select **Cell > Insert Text Markup > HTML Markup**. 3 Replace the inserted HTML markup (as shown in the next column) with your desired text. Be careful, however, to keep the percent signs (%) at the beginning of each line.	`% <table border=1><tr> <td>one</td><td>two </td></tr></table>% </html>`	
Format	How to Produce Format	Resulting Code	Published Results

LaTeX markup	**1** Position the cursor before the line where you want to add LaTeX markup.
	2 Select **Cell > Insert Text Markup > LaTeX Markup**.
	3 Replace the inserted LaTeX markup (as shown in the next column) with your desired text. Be careful, however, to keep the percent signs (%) at the beginning of each line.
		`% <latex>`
		`%`
		`\begin{tabular}{|r|r}`
		`% \hline $n$&$n!$\\`
		`\\hline 1&1\\ 2&2\\`
		`3&6\\ \\hline`
		`% \end{tabular}`
		`% </latex>`
			


TeX Equations and symbols	**1** Position the cursor before the line where you want to add an equation or symbols.
	2 Select **Cell > Insert Text Markup > TeX Equation**.
	3 Replace the inserted text inserted, `e^{\pi i} + 1 = 0`, with your desired TeX equation. See step in the example.
		`% $$e^{\pi i} + 1 = 0$$`
		`%`
		The `$$` at the start and end of a block description distinguish the TeX equation.
		For a list of symbols you can display and the character sequence to create them, see the `String` property on MATLAB graphics reference page for `Text Properties`.
		In the example, line 7 includes a TeX equation:
		`% $$0\leq 6\pi$$`
			$e^{\pi i} + 1 = 0$

Text Markup for Bold, Italic, and Monospaced Text Formats

You can mark up selected strings in the M-file comments so that they appear in bold, italic or monospaced text formats when you publish the M-file.

Format	How to Produce Format	Resulting Code	Published Results
Bold text	Follow these steps to bold existing text: **1** Within a comment, select text that you want to be bold. **2** Select **Cell > Insert Text Markup > Bold Text**. To insert sample text, that you will replace with your desired text, follow these steps: **1** Select **Cell > Insert Text Markup > Bold Text**. **2** Replace the inserted text with the text that you want to be bold.	`% *BOLD TEXT*`	**BOLD TEXT**

Format	How to Produce Format	Resulting Code	Published Results
Italic text	Follow these steps to bold existing text: **1** Within a comment, select text that you want to be italic. **2** Select **Cell > Insert Text Markup > Italic Text**. To insert sample text, that you will replace with your desired text, follow these steps: **1** Select **Cell > Insert Text Markup > Italic Text**. **2** Replace the inserted text with the text you want to be italic.	`% _ITALIC TEXT_`	*ITALIC TEXT*

Monospaced text	Follow these steps to bold existing text:
	1 Within a comment, select text that you want to be monospaced.
	2 Select **Cell > Insert Text Markup > Monospaced Text**.
	To insert sample text, that you will replace with your desired text, follow these steps:
	1 Select **Cell > Insert Text Markup > Monospaced Text**.
	2 Replace the inserted text with the text you want to be monospaced.
		`% |MONOSPACED TEXT|`
		In the example, monospaced text is added in line 9:
		`% Calculate and plot |y=sin(x)|.`
			`MONOSPACED TEXT`

Text Markup for Inline Links

When you specify hypertext links within an M-file, when you publish the document the hypertext links become active links to a URL on the web.

Format	How to Produce Format	Resulting Code	Published Results
URL as hyperlinked text	**1** Within a comment, position the cursor where you want to insert the hypertext link. **2** Select **Cell > Insert Text Markup > Hyperlinked Text**. The Editor/Debugger inserts the following code: `<http://www.mathworks .com The MathWorks>` **3** Replace www.mathworks.com with your desired URL. **4** Delete the string, The MathWorks.	`% <http: //www.mathworks .com>>`	http://www.mathworks.com
Hyperlinked text without a printed URL	**1** Within a comment, position the cursor where you want to insert the hypertext link. **2** Select **Cell > Insert Text Markup > Hyperlinked Text**. The Editor/Debugger inserts the following code: <http://www.mathworks .com The MathWorks> **3** Replace www.mathworks.com with your desired URL. **4** Replace The MathWorks with the text that you want to appear as the hyperlinked text.	`% <http: //www.mathworks .com The MathWorks>>`	The MathWorks

Publishing M-Files Using Cells

In this section...

How to Publish an M-File

When you publish an M-file that contains cells and text markup, MATLAB produces an output document consisting of the M-file code, comments, and results.

1. When you publish an M-file function, MATLAB does not run the code or include results from running the code in the output document—for M-file functions, clear the **Evaluate code** preference prior to publishing.

2. After adding cells and text markup to an M-file, select **File > Publish To** and select an output format from those listed in the menu: **HTML**, **XML**, **LaTeX**, **Word**, or **PowerPoint**. If the M-file contains unsaved changes, the menu item becomes **Save and Publish To**.

   You can also publish to the default output format specified in **Preferences** using the Publish button in the Editor/Debugger toolbar.

MATLAB displays the published document in the appropriate tool for the selected output format:

- HTML displays in the MATLAB Web Browser.
- XML displays in the MATLAB Editor/Debugger.
- LaTeX displays in the MATLAB Editor/Debugger.
- Word displays in Microsoft Word.
- PowerPoint displays in Microsoft PowerPoint.

Note Publishing to Microsoft Word and to PowerPoint features are available only on Windows systems that have the applications installed. Supported Word and PowerPoint versions are 2000, 2002, 2003, and 2007.

The published file contains the formatted comments, code with syntax highlighting and a gray background to distinguish it from results, and results for each cell. It also contains a **Contents** heading at the top of the file with a bulleted list of links to the named cells in the rest of the document.

When code in a cell creates or modifies a figure, the published file includes an image of the figure. If the code in a given cell modifies a figure more than once, the published file includes only one image of the figure, that being the last version of the figure.

When publishing to HTML, the M-file code is included at the end of published HTML file as comments. Use the `grabcode` function to extract the code from the HTML file.

Function Alternative

From the Command Window, run the `publish` function to run the M-file and publish the results. See the `publish` function reference page for options you can set.

About Published M-Files

Published Filenames and Locations

MATLAB names the published file the same as the M-file that produced it, adding the relevant extension for the selected output format: `.html`, `.xml`, `.tex`, `.doc`, or `.ppt`. MATLAB stores this output file, along with supporting files such as images of figure windows, in the `html` subdirectory under the directory containing the M-file you published.

For example, when you publish `d:/mymfiles/sine_wave.m` to HTML, MATLAB creates a directory `d:/mymfiles/html` that includes the published document `sine_wave.html`. Any figure windows produced by running the M-file appear as image files in the directory, for example, `sine_wave_img.png`.

TeX equations are image files as well; in the example, the equation file is `sine_wave_eq_eq####.png`. MATLAB creates a thumbnail file for the document, `sine_wave_img_thumbnail.png` in the example, if that preference is selected — see in the online documentation.

Publishing Code that Displays Hyperlinks in Command Window

If the M-file you publish contains statements that display hyperlinks in the MATLAB Command Window, the published document shows the code rather than the hyperlinks.

For example

```
disp('<a href="http://www.mathworks.com">Link to MathWorks</a>')
```

displays

Link to MathWorks

in the Command Window. You can click the link to go to the MathWorks Web site. When that `disp` statement is in an M-file you publish, the hyperlink tag and the text between it, that is,

```
<a href="http://www.mathworks.com">Link to MathWorks</a>
```

rather than the link, appears in the published document.

Similar results occur if you include

```
help matlab_functioname
```

in an M-file.

Modifying Published Output Using Preferences

Use preferences to control execution, output, and options related to images created during publishing. For details about these preferences, click the **Help** button in the **Preferences** dialog box for those panes.

Notebook for Publishing to Word

In this section...

Note Notebook is available only on Windows systems that have Microsoft Word installed. For supported versions of Word, see "Configuring Notebook" on page 8-53.

Using Notebook to Create an M-book

Notebook enables you to access the numeric computation and visualization software of MATLAB from within the word processing environment, Microsoft Word. Using Notebook, you can create a document, called an *M-book*, that contains text, MATLAB commands, and the output from MATLAB commands.

You can think of an M-book as a record of an interactive MATLAB session annotated with text, or as a document embedded with live MATLAB commands and output. Notebook is useful for creating electronic or printed records of MATLAB sessions, class notes, textbooks or technical reports.

See Also Publishing Using Cells

As an alternative to Notebook, consider publishing using cells. For more information, see "Publishing to HTML, XML, LaTeX, Word, and PowerPoint Using Cells" on page 8-2.

Creating or Opening an M-Book

Creating an M-Book from MATLAB

To create a new M-book from within MATLAB, type

```
notebook
```

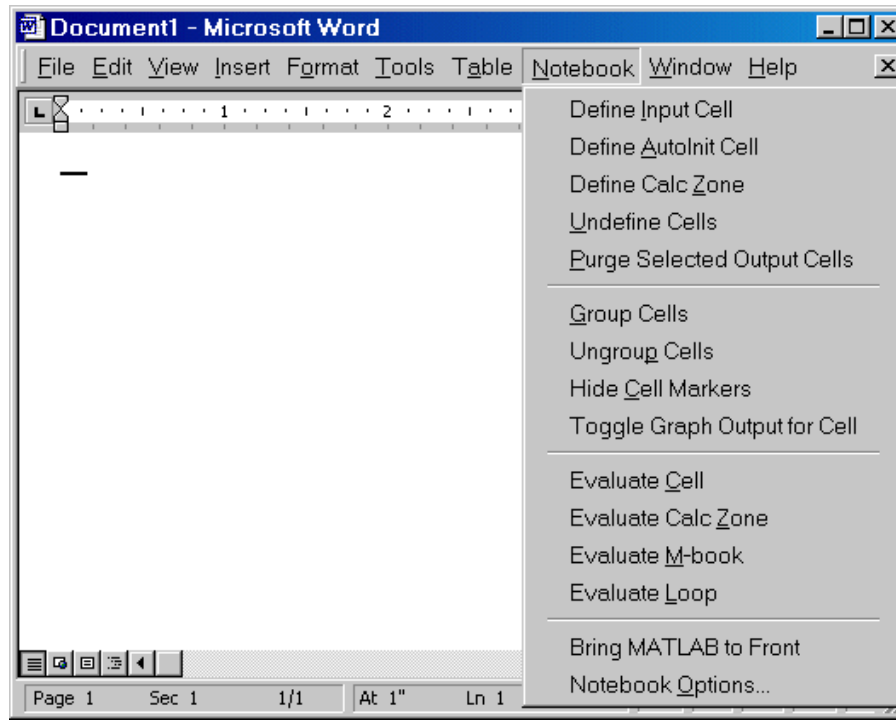
in the Command Window. If you are running Notebook for the first time, you might need to configure it. See “Configuring Notebook” on page 8-53 for more information.

Notebook starts Microsoft Word on your system and creates a new M-book, called `Document1`.

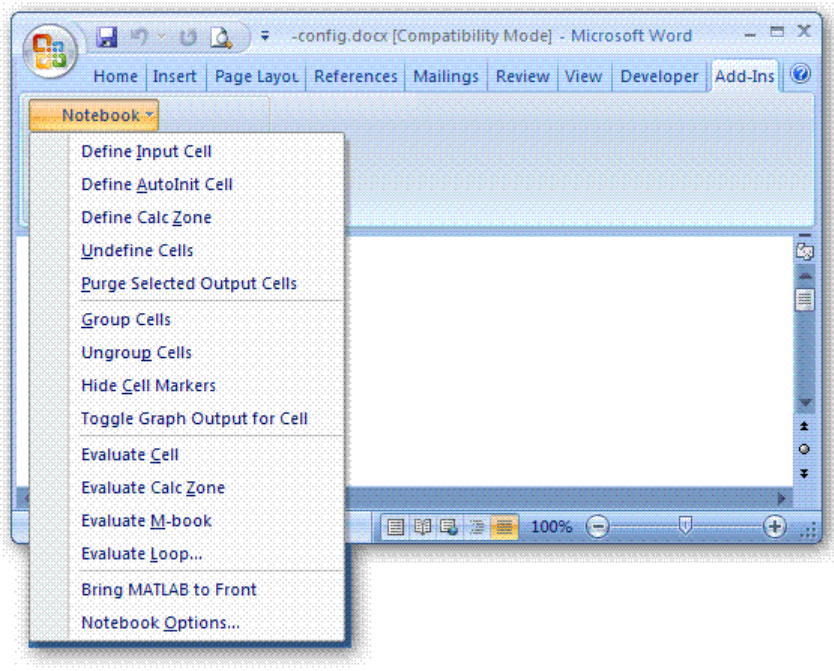
When Word is opening, if a dialog box appears asking you to enable or disable macros, choose to enable macros. Notebook defines Microsoft Word macros that enable MATLAB to interpret the different types of cells that hold MATLAB commands and their output. For more information on macro security, see “Configuring Notebook” on page 8-53.

Depending on the version of Word you are using, one of the following occurs:

- In Word 2000, 2002, and 2003, Notebook adds the **Notebook** menu to the Word menu bar, as shown in the following illustration. Use this menu to access Notebook features.



- In Word 2007, Notebook adds the **Notebook** menu to the Word **Add-Ins** tab, as shown in the following illustration. Use this menu to access Notebook features.

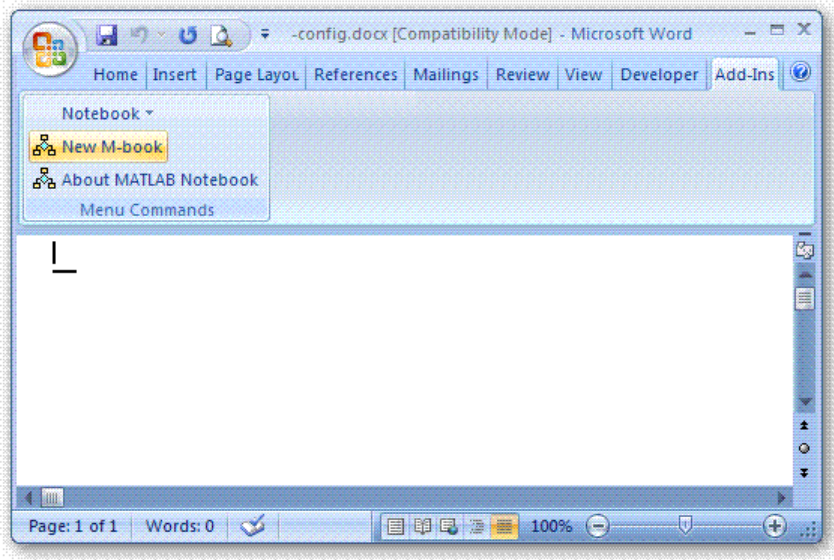


Microsoft product screen shot reprinted with permission from Microsoft Corporation.

Creating an M-Book While Running Notebook

With Notebook running, you can create a new M-book as follows:

- In Word 2000, 2002, and 2003, select **File > New M-book**
- In Word 2007, select **Add-Ins > New M-book**, as shown in the following figure:



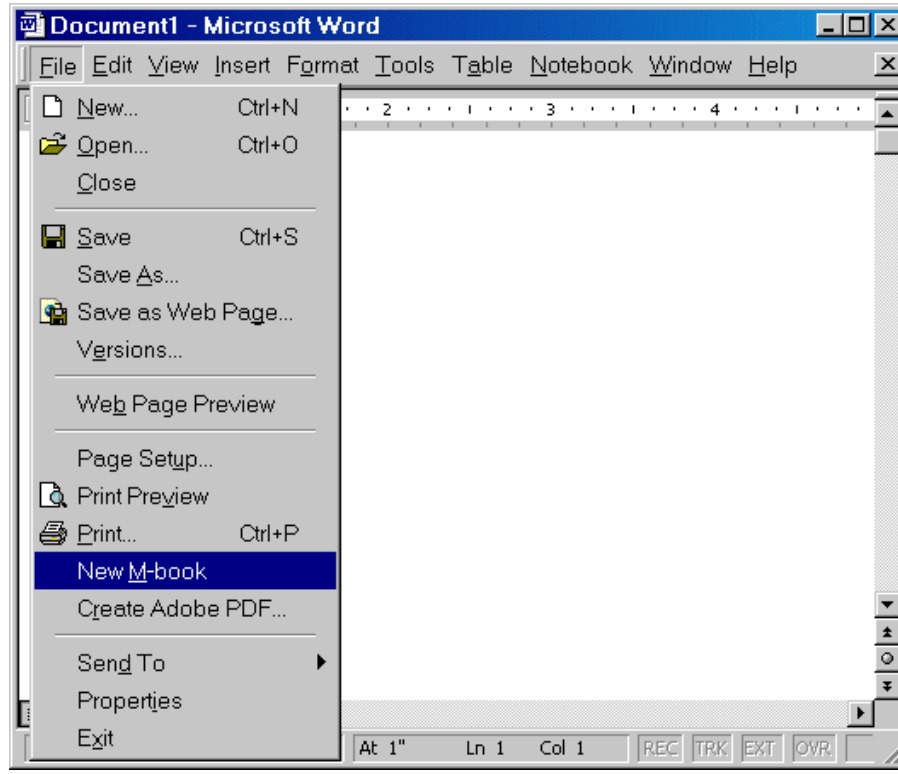
Microsoft product screen shot reprinted with permission from Microsoft Corporation.

Opening an Existing M-Book

You can use the `notebook` command to open an existing M-book

```
notebook filename
```

where `filename` is the M-book you want to open. Or you can double-click an M-book file in a Windows file management tool, such as Explorer.



When you double-click on an M-book, Microsoft Word opens the M-book and starts MATLAB if it is not already running. Notebook adds the **Notebook** menu to the Word menu bar and adds **New M-book** to the **File** menu.

Converting a Word Document to an M-Book

To convert a Word document to an M-book, follow these steps, depending on the version of Word you are using:

- Microsoft Word 2000, 2002, or 2003:

  1 Create a new M-book.

  2 From the **Insert** menu, select **File**.

3 Select the file you want to convert.

4 Click **OK**.

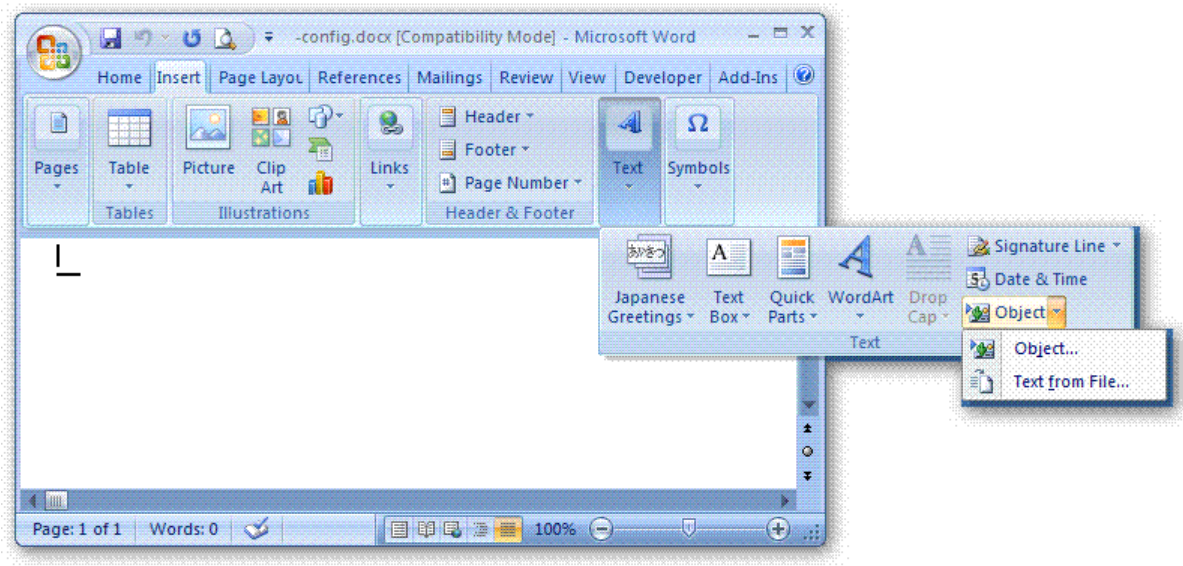
- Microsoft Word 2007:

1 Create a new M-book.

2 From the **Insert** tab, in the **Text** group, click the arrow next to **Object** and then click **Text from File**, as shown in the image that follows.

The Insert File dialog box opens.

3 In the Insert File dialog box, select the file that you want to convert, and then click **OK**.



Microsoft product screen shot reprinted with permission from Microsoft Corporation.

Entering MATLAB Commands in an M-Book

Note A good way to learn how to use Notebook is to open the sample M-book, `Readme.doc`, and try out the various techniques described in this section. You can find this file in the *`matlabroot`*`/notebook/pc` directory.

You enter MATLAB commands in an M-book the same way you enter text in any other Word document. For example, you can enter the following text in a Word document. The example uses text in Courier Font but you can use any font:

```
Here is a sample M-book.

a = magic(3)
```

To execute the MATLAB `magic` command in this document, you must

- Define the command as an input cell
- Evaluate the input cell

MATLAB displays the output of the command in the Word document in an output cell.

Protecting the Integrity of Your Workspace in M-Books

When you work on more than one M-book in a single word processing session, note that:

- Each M-book uses the same “copy” of MATLAB.
- All M-books share the same workspace.

If you use the same variable names in more than one M-book, data used in one M-book can be affected by another M-book. You can protect the integrity of your workspace by specifying the `clear` command as the first autoinit cell in the M-book.

Ensuring Data Consistency in M-Books

An M-book can be thought of as a sequential record of a MATLAB session. When executed in order, from the first MATLAB command to the last, the M-book accurately reflects the relationships among these commands.

If, however, you change an input cell or output cell as you refine your M-book, Notebook does not automatically recalculate input cells that depend on either the contents or the results of the changed cells. As a result, the M-book may contain inconsistent data.

When working on an M-book, you might find it useful to select **Evaluate M-book** periodically to ensure that your M-book data is consistent. You could also use calc zones to isolate related commands in a section of the M-book. You can then use **Evaluate Calc Zone** to execute only those input cells contained in the calc zone.

Debugging and Notebook

Do not use debugging functions or use the Editor/Debugger while evaluating cells with Notebook. Instead debug M-files from within MATLAB, and then after completing debugging, clear all the breakpoints and access the M-file via Notebook. If you debug while evaluating from Notebook, you might experience problems with MATLAB.

Defining MATLAB Commands as Input Cells for Notebook

In this section...

For information about evaluating the input cells you define, see "Evaluating MATLAB Commands with Notebook" on page 8-41.

Defining Commands as Input Cells for Notebook

To define a MATLAB command in a Word document as an input cell,

1. Type the command into the M-book as text. For example,

```
This is a sample M-book.

a = magic(3)
```

2. Position the cursor anywhere in the command and select **Notebook > Define Input Cell** or press **Alt+D**. If the command is embedded in a line of text, use the mouse to select it. Notebook defines the MATLAB command as an input cell:

```
This is a sample M-book.

[a = magic(3)]
```

Note how Notebook changes the character font of the text in the input cell to a bold, dark green color and encloses it within *cell markers*. Cell markers are bold, gray brackets. They differ from the brackets used to enclose matrices by their size and weight. For information about changing these default formats, see "Modifying Styles in the M-Book Template" on page 8-47.

Defining Cell Groups for Notebook

You can collect several input cells into a single input cell. This is called a *cell group*. Because all the output from a cell group appears in a single output cell that Notebook places immediately after the group, cell groups are useful when several MATLAB commands are needed, such as, to fully define a graphic.

For example, if you define all the MATLAB commands that produce a graphic as a cell group and then evaluate the cell group, Notebook generates a single graphic that includes all the graphic components defined in the commands. If instead you define all the MATLAB commands that generate the graphic as separate input cells, evaluating the cells generates multiple graphic output cells.

See “Evaluating Cell Groups with Notebook” on page 8-42 for information about evaluating a cell group. For information about ungrouping a cell group, see “Ungroup Cells” on page 8-61.

Creating a Cell Group for Notebook

To create a cell group,

1. Use the mouse to select the input cells that are to make up the group.
2. Select **Notebook > Group Cells** or press **Alt+G**.

Notebook converts the selected cells into a cell group and replaces cell markers with a single pair that surrounds the group:

```
This is a sample cell group.

[date
a = magic(3) ]
```

Note the following:

- A cell group cannot contain output cells. If the selection includes output cells, Notebook deletes them.
- A cell group cannot contain text. If the selection includes text, Notebook places the text after the cell group. However, if the text precedes the first input cell in the selection, Notebook leaves it where it is.

- If you select part or all of an output cell but not its input cell, Notebook includes the input cell in the cell group.

When you create a cell group, Notebook defines it as an input cell unless its first line is an autoinit cell, in which case Notebook defines the group as an autoinit cell.

Defining Autoinit Input Cells for Notebook

You can use *autoinit cells* to specify MATLAB commands to be automatically evaluated each time an M-book is opened. This is a quick and easy way to initialize the workspace. *Autoinit cells* are simply input cells with the following additional characteristics:

- Notebook evaluates the autoinit cells when it opens the M-book.
- Notebook displays the commands in autoinit cells using dark blue characters.

Autoinit cells are otherwise identical to input cells.

Creating an Autoinit Cell for Notebook

You can create an autoinit cell in two ways:

- Enter the MATLAB command as text, then convert the command to an autoinit cell by selecting **Notebook > Define AutoInit Cell**.
- If you already entered the MATLAB command as an input cell, you can convert the input cell to an autoinit cell. Either select the input cell or position the cursor in the cell, then select **Notebook > Define AutoInit Cell**.

See “Evaluating MATLAB Commands with Notebook” on page 8-41 for information about evaluating autoinit cells.

Defining Calc Zones for Notebook

You can partition an M-book into self-contained sections, called *calc zones*. A calc zone is a contiguous block of text, input cells, and output cells. Notebook inserts Microsoft Word section breaks before and after the section to define

the calc zone. The section break indicators include bold, gray brackets to distinguish them from standard Word section breaks.

You can use calc zones to prepare problem sets, making each problem a separate calc zone that can be created and tested on its own. An M-book can contain any number of calc zones.

Note Using calc zones does not affect the scope of the variables in an M-book. Variables used in one calc zone are accessible to all calc zones.

Creating a Calc Zone

After you create the text and cells you want to include in the calc zone, you define the calc zone by following these steps:

1. Select the input cells and text to be included in the calc zone.
2. Select **Notebook > Define Calc Zone**.

Note You must select an input cell and its output cell in their entirety to include them in the calc zone.

See “Evaluating a Calc Zone with Notebook” on page 8-44 for information about evaluating a calc zone.

Converting an Input Cell to Text with Notebook

To convert an input cell (or an autoinit cell or a cell group) to text,

1. Select the input cell with the mouse or position the cursor in the input cell.
2. Select **Notebook > Undefine Cells** or press **Alt+U**.

When Notebook converts the cell to text, it reformats the cell contents according to the Microsoft Word Normal style. For more information about M-book styles, see “Modifying Styles in the M-Book Template” on page

8-47. When you convert an input cell to text, Notebook also converts the corresponding output cell to text.

Evaluating MATLAB Commands with Notebook

In this section...

Evaluating Input Commands with Notebook

After you define a MATLAB command as an input cell, or as an autoinit cell, you can evaluate it in your M-book. Use the following steps to define and evaluate a MATLAB command:

1. Type the command into the M-book as text. For example:

   ```
   This is a sample M-book

   a = magic(3)
   ```

2. Position the cursor anywhere in the command. If the command is embedded in a line of text, use the mouse to select it. Then select **Notebook > Define Input Cell** or press **Alt+D**.

   Notebook defines the MATLAB command as an input cell. For example:

   ```
   This is a sample M-book

   [a = magic(3)]
   ```

3 Specify the input cell to be evaluated by selecting it with the mouse or by placing the cursor in it. Then select **Notebook > Evaluate Cell** or press **Ctrl+Enter**.

   Notebook evaluates the input cell and displays the results in a output cell immediately following the input cell. If there is already an output cell, Notebook replaces its contents, wherever it is in the M-book. For example:

```
This is a sample M-book.

[a = magic(3) ]

[a =
     8     1     6
     3     5     7
     4     9     2  ]
```

The text in the output cell is blue and is enclosed within cell markers. Cell markers are bold, gray brackets. They differ from the brackets used to enclose matrices by their size and weight. Error messages appear in red. For information about changing these default formats, see “Modifying Styles in the M-Book Template” on page 8-47.

Evaluating Cell Groups with Notebook

You evaluate a cell group the same way you evaluate an input cell (because a cell group is an input cell):

1 Position the cursor anywhere in the cell or in its output cell.

2 Select **Notebook > Evaluate Cell** or press **Ctrl+Enter**.

For information about creating a cell group, see “Defining Cell Groups for Notebook” on page 8-37.

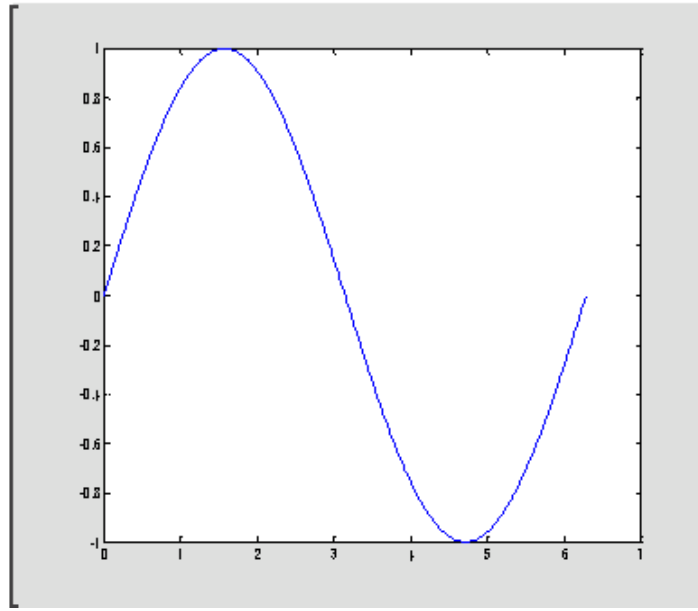
When MATLAB evaluates a cell group, the output for all commands in the group appears in a single output cell. By default, Notebook places the output cell immediately after the cell group the first time the cell group is evaluated. If you evaluate a cell group with an existing output cell, Notebook places the results in the output cell wherever it is located in the M-book.

Note Text or numeric output always comes first, regardless of the order of the commands in the group.

The illustration shows a cell group and the figure created when you evaluate the cell group.

This is a sample M-book with a cell group.

```
t = 0:pi/100:2*pi;
y = sin(t);
plot(t,y)
```



Evaluating a Range of Input Cells with Notebook

To evaluate more than one MATLAB command contained in different but contiguous input cells,

1 Select the range of cells that includes the input cells you want to evaluate. You can include text that surrounds input cells in your selection.

2 Select **Notebook > Evaluate Cell** or press **Ctrl+Enter**.

Notebook evaluates each input cell in the selection, inserting new output cells or replacing existing ones.

Evaluating a Calc Zone with Notebook

To evaluate a calc zone,

1 Position the cursor anywhere in the calc zone.

2 Select **Notebook > Evaluate Calc Zone** or press **Alt+Enter**.

For information about creating a calc zone, see "Defining Calc Zones for Notebook" on page 8-38.

By default, Notebook places the output cell immediately after the calc zone the first time the calc zone is evaluated. If you evaluate a calc zone with an existing output cell, Notebook places the results in the output cell wherever it is located in the M-book.

Evaluating an Entire M-Book

To evaluate the entire M-book, either select **Notebook > Evaluate M-book** or press **Alt+R**.

Notebook begins at the top of the M-book regardless of the cursor position and evaluates each input cell in the M-book. As it evaluates the M-book, Notebook inserts new output cells or replaces existing output cells.

Controlling Execution of Multiple Commands

When you evaluate an entire M-book, and an error occurs, evaluation continues. If you want to stop evaluation if an error occurs, follow this procedure:

1 Select **Notebook > Notebook Options**.

The **Notebook Options** dialog box opens.

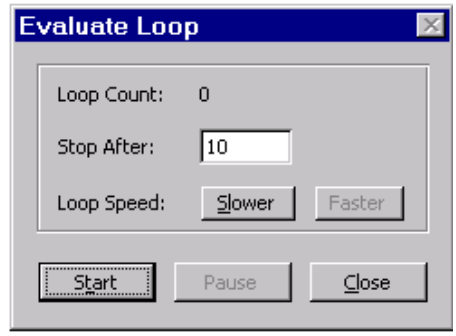
2 Select the **Stop evaluating on error** check box and click **OK**.

Using a Loop to Evaluate Input Cells Repeatedly with Notebook

To evaluate a sequence of MATLAB commands repeatedly,

1 Use the mouse to select the input cells, including any text or output cells located between them.

2 Select **Notebook > Evaluate Loop** or press **Alt+L**. Notebook displays the **Evaluate Loop** dialog box.



3 Enter the number of times you want MATLAB to evaluate the selected commands in the **Stop After** field, then click **Start**. The button changes to **Stop**. Notebook begins evaluating the commands and indicates the number of completed iterations in the **Loop Count** field.

You can increase or decrease the delay at the end of each iteration by clicking **Slower** or **Faster**. Slower increases the delay. Faster decreases the delay.

To suspend evaluation of the commands, click **Pause**. The button changes to **Resume**. Click **Resume** to continue evaluation.

To stop processing the commands, click **Stop**. To close the **Evaluate Loop** dialog box, click **Close**.

Converting Output Cells to Text with Notebook

You can convert an output cell to text by undefining cells. If the output is numeric or textual, Notebook removes the cell markers and converts the cell contents to text according to the Microsoft Word Normal style. If the output is graphical, Notebook removes the cell markers and dissociates the graphic from its input cell, but does not alter its contents.

Note Undefining an output cell does not affect the associated input cell.

To undefine an output cell,

1. Select the output cell you want to undefine.
2. Select **Notebook > Undefine Cells** or press **Alt+U**.

Deleting Output Cells with Notebook

To delete output cells,

1. Select an output cell, using the mouse, or place the cursor in the output cell.
2. Select **Notebook > Purge Selected Output Cells** or press **Alt+P**.

If you select a range of cells, Notebook deletes all the output cells in the selected range, but any associate input cells remain intact.

Printing and Formatting an M-Book

In this section...

Printing an M-Book

You can print all or part of an M-book by doing one of the following, depending on the version of Microsoft Word you are using:

- In Microsoft Word 2000, 2002, 2003 — Select **File > Print**.
- In Microsoft Word 2007 — Select **Microsoft Office Button > Print**

Word follows these rules when printing M-book cells and graphics:

- Cell markers are not printed.
- Input cells, autoinit cells, and output cells (including error messages) are printed according to their defined styles. If you prefer to print these cells using black type instead of colors or shades of gray, you can modify the styles.

Modifying Styles in the M-Book Template

You can control the appearance of the text in your M-book by modifying the predefined styles stored in the M-book template, `m-book.dot`. These styles control the appearance of text and cells. By default, M-books use the Word Normal style for all other text.

For example, if you print an M-book on a color printer, input cells appear dark green, output and autoinit cells appear dark blue, and error messages appear red. If you print the M-book on a grayscale printer, these cells appear as

shades of gray. To print these cells using black type, you need to modify the color of the Input, Output, AutoInit, and Error styles in the M-book template.

The table below describes the default styles used by Notebook. If you modify styles, you can use the information in the tables below to help you return the styles to their original settings. For general information about using styles in Word documents, see the Word documentation.

Style	Font	Size	Weight	Color
Normal	Times New Roman	10 points	N/A	Black
AutoInit	Courier New	10 points	Bold	Dark blue
Error	Courier New	10 points	Bold	Red
Input	Courier New	10 points	Bold	Dark green
Output	Courier New	10 points	N/A	Blue

When you change a style, Word applies the change to all characters in the M-book that use that style and gives you the option to change the template. Be cautious about making changes to the template. If you choose to apply the changes to the template, you will affect all new M-books you create using the template. See the Word documentation for more information.

Choosing Loose or Compact Format for Notebook

You can specify whether a blank line appears between the input and output cells by selecting the loose or compact format:

1. Select **Notebook > Notebook Options**.
2. In the **Notebook Options** dialog box, select either **Loose** or **Compact**. Loose format adds an empty line. Compact format does not.
3. Click **OK**.

Note Changes you make using the **Notebook Options** dialog box take effect for output generated *after* you click **OK**. To affect existing input or output cells, you must reevaluate the cells.

Controlling Numeric Output Format for Notebook

To change how Notebook displays numeric output,

1. Select **Notebook > Notebook Options**.
2. In the **Notebook Options** dialog box, select a format from the **Numeric Format** list. These settings correspond to the choices available with the MATLAB `format` command.
3. Click **OK**.

Note Changes you make using the **Notebook Options** dialog box take effect for output generated *after* you click **OK**. To affect existing input or output cells, you must reevaluate the cells.

Controlling Graphic Output for Notebook

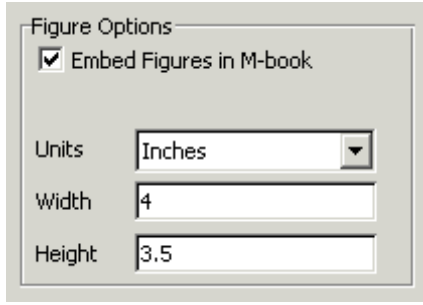
This section describes how to control several aspects of the graphic output produced by MATLAB commands in an M-book, including

Embedding Graphic Output in the M-Book

By default, graphic output is embedded in an M-book. To display graphic output in a separate figure window,

1 Select **Notebook > Notebook Options**.

2 In the **Notebook Options** dialog box, clear the **Embed Figures in M-book** check box.



3 Click **OK**.

Note Embedded figures do not include Handle Graphics objects generated by the `uicontrol` and `uimenu` functions.

Notebook determines whether to embed a figure in the M-book by examining the value of the figure object's `Visible` property. If the value of the property is `off`, Notebook embeds the figure. If the value of this property is `on`, all graphic output is directed to the current figure window.

Suppressing Graphic Output for Individual Input Cells in Notebook

If an input or autoinit cell generates figure output that you want to suppress,

1 Place the cursor in the input cell.

2 Select **Notebook > Toggle Graph Output for Cell**.

Notebook suppresses graphic output from the cell, inserting the string `(no graph)` after the input cell.

To allow graphic output for a cell, repeat the procedure. Notebook removes the `(no graph)` marker and allows graphic output from the cell.

Note **Toggle Graph Output for Cell** overrides the **Embed Figures in M-book** option, if that option is set.

Sizing Graphic Output in Notebook

To set the default size of embedded graphics in an M-book,

1. Select **Notebook > Notebook Options**.
2. In the **Notebook Options** dialog box, use the **Units**, **Width** and **Height** fields to set the size of graphics generated by the M-book.
3. Click **OK**.

Note Changes you make using the **Notebook Options** dialog box take effect for graphic output generated *after* you click **OK**. To affect existing input or output cells, you must reevaluate the cells.

You change the size of an existing embedded figure by selecting the figure, clicking the left mouse button anywhere in the figure, and dragging the resize handles of the figure. If you resize an embedded figure using its resize handles and then regenerate the figure, its size reverts to its original size.

Cropping Graphic Output in Notebook

To crop an embedded figure to cut off areas you do not want to show,

1. Select the graphic by clicking the left mouse button anywhere in the figure.
2. Hold down the **Shift** key.
3. Drag a sizing handle toward the center of the graphic.

Adding White Space Around Graphic Output in Notebook

You can add white space around an embedded figure by moving the boundaries of a graphic outward. Select the graphic, then hold down the **Shift** key and drag a sizing handle away from the graphic.

Configuring Notebook

After you install Notebook but before you begin using it, you must configure it. (Notebook is installed as part of the MATLAB installation process on Windows platforms. For more information, see the MATLAB installation documentation for your platform.)

Before configuring Notebook, you must specify that Word can use the Notebook macros.

- In Word 2000, 2002, and 2003 do either of the following:
  - Set the macro security level to medium: in Word, select **Tools > Macros > Security**, and in the resulting dialog box, choose **Medium**.
  - After starting Notebook, when Word first opens, a security warning dialog box appears. In the dialog box, select **Always trust macros from this source**. This allows you to use Notebook, but still maintain a high security level for other macros you use in Word.
- In Word 2007, follow the Word help instructions in the topic entitled "Enable or disable macros in Office documents."

To configure Notebook, type the following in the MATLAB Command Window:

```
notebook ('-setup')
```

MATLAB accesses the Windows system registry to locate Microsoft Word and the Word templates directory, and to identify the version of Word. MATLAB then copies Notebook's `m-book.dot` template to the Word templates directory. MATLAB Notebook supports Word versions 2000, 2002, 2003, and 2007.

When Notebook setup successfully finishes, MATLAB displays the message

```
Setup complete
```

Notebook Feature Reference

In this section...

This section provides reference information about each of the Notebook features, listed alphabetically. To use these features, select them from the **Notebook** menu in Microsoft Word. (In Word 2007, the **Notebook** menu is on the **Add-Ins** tab.)

Bring MATLAB to Front

Bring MATLAB to Front brings the MATLAB Command Window to the foreground.

Define Autoinit Cell

Define AutoInit Cell creates an autoinit cell by converting the current paragraph, selected text, or input cell. An autoinit cell is an input cell that is automatically evaluated whenever you open an M-book.

Result

If you select this feature while the cursor is in a paragraph of text, Notebook converts the entire paragraph to an autoinit cell. If you select this feature while text is selected, Notebook converts the text to an autoinit cell. If you select this feature while the cursor is in an input cell, Notebook converts the input cell to an autoinit cell.

Format

Notebook formats the autoinit cell using the AutoInit style, defined as bold, dark blue, 10-point Courier New.

See Also

For more information about autoinit cells, see “Defining Autoinit Input Cells for Notebook” on page 8-38.

Define Calc Zone

Define Calc Zone defines the selected text, input cells, and output cells as a calc zone. A calc zone is a contiguous block of related text, input cells, and output cells that describes a specific operation or problem.

Result

Notebook defines a calc zone as a Word document section, placing section breaks before and after the calc zone. However, Word does not display section breaks at the beginning or end of a document.

See Also

For information about evaluating calc zones, see “Evaluating a Calc Zone with Notebook” on page 8-44. For more information about document sections, see the Microsoft Word documentation.

Define Input Cell

Define Input Cell creates an input cell by converting the current paragraph, selected text, or autoinit cell. An input cell contains a MATLAB command.

Result

If you select this feature while the cursor is in a paragraph of text, Notebook converts the entire paragraph to an input cell. If you select this feature while text is selected, Notebook converts the text to an input cell. If you select this feature while the cursor is in an autoinit cell, Notebook converts the autoinit cell to an input cell.

Format

Notebook encloses the text in cell markers and formats the cell using the Input style, defined as bold, dark green, 10-point Courier New.

See Also

For more information about creating input cells, see “Defining MATLAB Commands as Input Cells for Notebook” on page 8-36. For information about evaluating input cells, see “Evaluating MATLAB Commands with Notebook” on page 8-41.

Evaluate Calc Zone

Evaluate Calc Zone sends the input cells in the current calc zone to MATLAB to be evaluated. The current calc zone is the Word section that contains the cursor.

Result

As Notebook evaluates each input cell, it generates an output cell. When you evaluate an input cell for which there is no output cell, Notebook places the output cell immediately after the input cell that generated it. If you evaluate an input cell for which there is an output cell, Notebook replaces the results in the output cell wherever it is in the M-book.

See Also

For more information, see “Evaluating a Calc Zone with Notebook” on page 8-44.

Evaluate Cell

Evaluate Cell sends the current input cell or cell group to MATLAB to be evaluated. An input cell contains a MATLAB command. A cell group is a single, multiline input cell that contains more than one MATLAB command. Notebook displays the output or an error message in an output cell.

Result

If you evaluate an input cell for which there is no output cell, Notebook places the output cell immediately after the input cell that generated it. If you evaluate an input cell for which there is an output cell, Notebook replaces the results in the output cell wherever it is in the M-book. If you evaluate a cell group, all output for the cell appears in a single output cell.

An input cell or cell group is the current input cell or cell group if

- The cursor is in the input cell or cell group.
- The cursor is at the end of the line that contains the closing cell marker for the input cell or cell group.
- The cursor is in the output cell for the input cell or cell group.
- The input cell or cell group is selected.

Note Evaluating a cell that involves a lengthy operation may cause a time-out. If this happens, Word displays a time-out message and asks whether you want to continue waiting for a response or terminate the request. If you choose to continue, Word resets the time-out value and continues waiting for a response. Word sets the time-out value; you cannot change it.

See Also

For more information, see “Evaluating MATLAB Commands with Notebook” on page 8-41. For information about evaluating the entire M-book, see “Evaluating an Entire M-Book” on page 8-44.

Evaluate Loop

Evaluate Loop evaluates the selected input cells repeatedly.

For more information, see “Using a Loop to Evaluate Input Cells Repeatedly with Notebook” on page 8-45.

Evaluate M-Book

Evaluate M-book evaluates the entire M-book, sending all input cells to MATLAB to be evaluated. Notebook begins at the top of the M-book regardless of the cursor position.

Result

As Notebook evaluates each input cell, it generates an output cell. When you evaluate an input cell for which there is no output cell, Notebook places the output cell immediately after the input cell that generated it. If you evaluate an input cell for which there is an output cell, Notebook replaces the results in the output cell wherever it is in the M-book.

See Also

For more information, see “Evaluating an Entire M-Book” on page 8-44.

Group Cells

Group Cells converts the input cells in the selection into a single multiline input cell called a cell group. You evaluate a cell group using **Evaluate Cell**. When you evaluate a cell group, all of its output follows the group and appears in a single output cell.

Result

If you include text in the selection, Notebook moves it after the cell group. However, if text precedes the first input cell in the group, the text will remain before the group.

If you include output cells in the selection, Notebook deletes them. If you select all or part of an output cell before selecting this feature, Notebook includes its input cell in the cell group.

If the first line in the cell group is an autoinit cell, the entire group acts as a sequence of autoinit cells. Otherwise, the group acts as a sequence of input cells. You can convert an entire cell group to an autoinit cell by using **Define AutoInit Cell**.

See Also

For more information, see "Defining Cell Groups for Notebook" on page 8-37. For information about converting a cell group to individual input cells, see the description of the "Ungroup Cells" on page 8-61.

Hide Cell Markers

Hide Cell Markers hides cell markers in the M-book.

When you select this feature, it changes to **Show Cell Markers**.

Note Notebook does not print cell markers whether you choose to hide them or show them on the screen.

Notebook Options

Notebook Options allows you to examine and modify display options for numeric and graphic output.

See Also

See "Printing and Formatting an M-Book" on page 8-47 for more information.

Purge Selected Output Cells

Purge Selected Output Cells deletes all output cells from the current selection.

See Also

For more information, see “Deleting Output Cells with Notebook” on page 8-46.

Toggle Graph Output for Cell

Toggle Graph Output for Cell suppresses or allows graphic output from an input cell.

If an input or autoinit cell generates figure output that you want to suppress, place the cursor in the input cell and choose this feature. The string `(no graph)` will be placed after the input cell to indicate that graph output for that cell will be suppressed.

To allow graphic output for that cell, place the cursor inside the input cell and choose **Toggle Graph Output for Cell** again. The `(no graph)` marker will be removed. This feature overrides the **Embed Figures in M-book** option, if that option is set in the **Notebook Options** dialog box.

See Also

See “Embedding Graphic Output in the M-Book” on page 8-49 and “Suppressing Graphic Output for Individual Input Cells in Notebook” on page 8-50 for more information.

Undefine Cells

Undefine Cells converts the selected cells to text. If no cells are selected but the cursor is in a cell, Notebook undefines that cell. Notebook removes the cell markers and reformats the cell according to the Normal style.

If you undefine an input cell, Notebook automatically undefines its output cell. However, if you undefine an output cell, Notebook does not undefine its input cell. If you undefine an output cell containing an embedded graphic, the graphic remains in the M-book but is no longer associated with an input cell.

See Also

For information about the Normal style, see “Modifying Styles in the M-Book Template” on page 8-47. For information about deleting output cells, see the description of the “Purge Selected Output Cells” on page 8-60.

Ungroup Cells

Ungroup Cells converts the current cell group into a sequence of individual input cells or autoinit cells. If the cell group is an input cell, Notebook converts the cell group to input cells. If the cell group is an autoinit cell, Notebook converts the cell group to autoinit cells. Notebook deletes the output cell for the cell group.

A cell group is the current cell group if

- The cursor is in the cell group.
- The cursor is at the end of a line that contains the closing cell marker for the cell group.
- The cursor is in the output cell for the cell group.
- The cell group is selected.

See Also

For information about creating cell groups, see the description of the “Defining Cell Groups for Notebook” on page 8-37.

Source Control Interface

The source control interface provides access to your source control system from MATLAB. Source control systems, also known as version control, revision control, configuration management, and file management systems, are platform dependent — the topics for the Windows platforms appear first, followed by the topics for the UNIX platforms.

Troubleshooting Source Control Problems on Windows (p. 9-24)	Solutions to some common source control problems.
Source Control Interface on UNIX (p. 9-26)	Overview of the ways you can use the source control interface on UNIX platforms.
Specifying the Source Control System on UNIX (p. 9-27)	Specify the source control system using MATLAB, list the currently selected source control system using the `cmopts` function, set a view and check out a directory with ClearCase.
Checking Files Into the Source Control System on UNIX (p. 9-30)	Check in files using the Current Directory browser, the Editor/Debugger, Simulink, Stateflow, or the `checkin` function.
Checking Files Out of the Source Control System on UNIX (p. 9-33)	Check files out using the Current Directory browser, the Editor/Debugger, Simulink, Stateflow, or the `checkout` function.
Undoing the Checkout on UNIX (p. 9-36)	Undoing a checkout using the Current Directory browser, the Editor/Debugger, Simulink, Stateflow, or the `undocheckout` function

Source Control Interface on Windows

If you use source control systems to manage your files, you can interface with the systems to perform source control actions from within MATLAB, Simulink, and Stateflow®. Use menu items in MATLAB, Simulink, or Stateflow, or run functions in the MATLAB Command Window to interface with your source control systems.

The source control interface on Windows works with any source control system that conforms to the Microsoft Common Source Control standard, Version 1.1. If your source control system does not conform to the standard, use a Microsoft Source Code Control API wrapper product for your source control system so that you can interface with it from MATLAB, Simulink, and Stateflow.

Perform most source control interface actions from the Current Directory browser. You can also perform many of these actions for a single file from the MATLAB Editor/Debugger, a Simulink model window, or a Stateflow chart window — for more information, see “Performing Source Control Actions from the Editor/Debugger, Simulink, or Stateflow on Windows” on page 9-23. Another way to access many of the source control actions is with the `verctrl` function.

Setting Up the Source Control Interface on Windows

In this section...

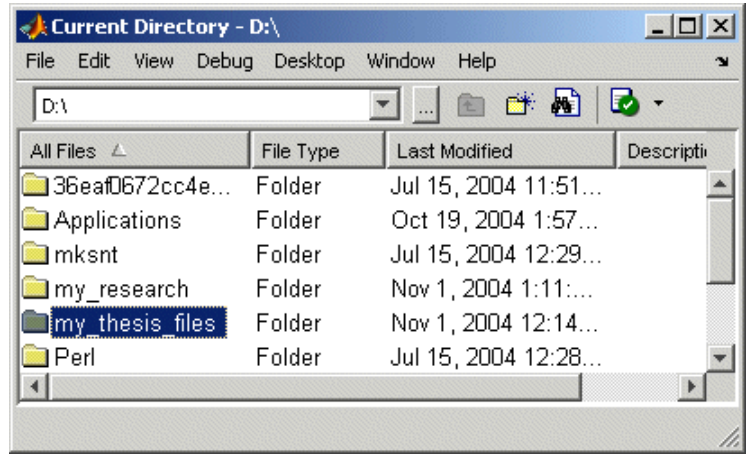
Create Projects in Source Control System

In your source control system, create the projects that your directories and files will be associated with.

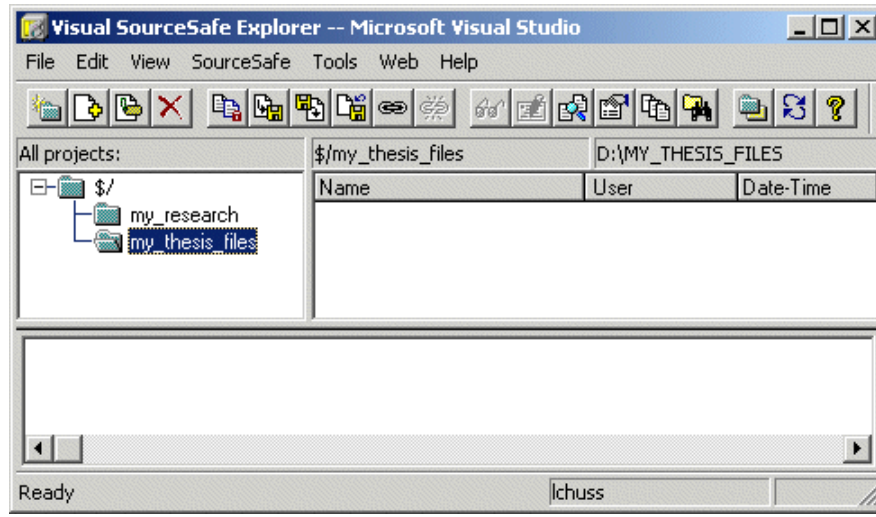
All files in a directory must belong to the same source control project. Be sure the working directory for the project in the source control system specifies the correct pathname to the directory on disk.

Example of Creating Source Control Project

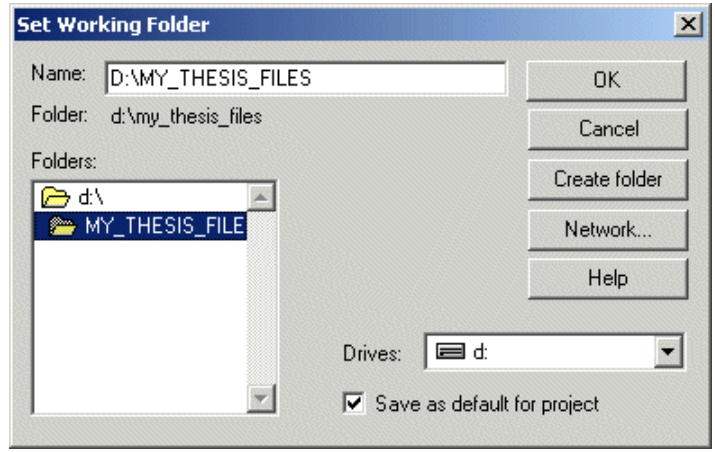
This example uses the project `my_thesis_files` in Microsoft Visual SourceSafe. This illustration of the Current Directory browser shows the pathname to the directory on disk, `D:\my_thesis_files`.



The following illustration shows the example project in the source control system.



To set the working directory in Microsoft Visual SourceSafe for this example, select `my_thesis_files`, right-click, select **Set Working Folder** from the context menu, and specify `D:\my_thesis_files` in the resulting dialog box.

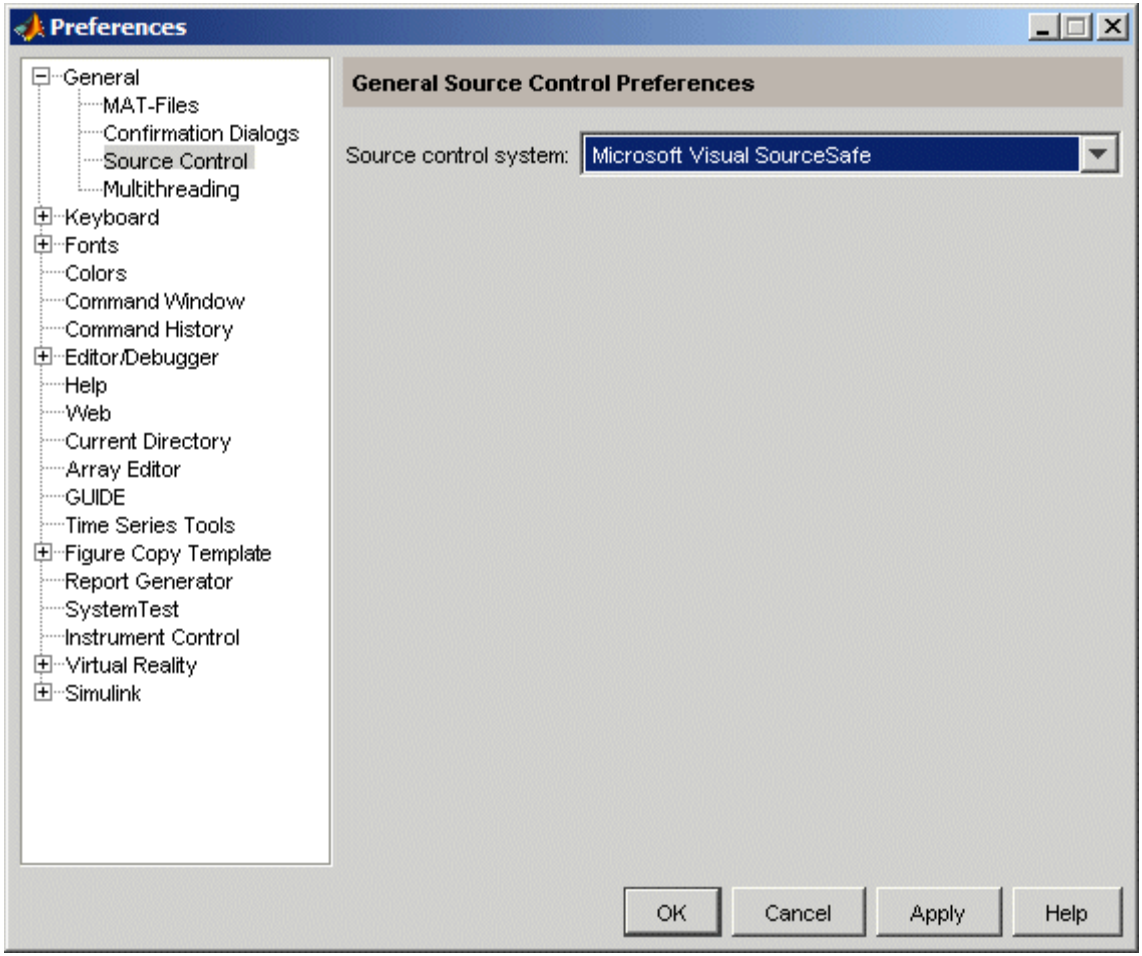


Specify Source Control System in MATLAB

In MATLAB, specify the source control system you want to access. Select **File > Preferences > General > Source Control**.

The currently selected system is shown in the Preferences dialog box. The list includes all installed source control systems that support the Microsoft Common Source Control standard.

Select the source control system you want to interface with and click **OK**.



MATLAB remembers preferences between sessions, so you only need to perform this action again when you want to access a different source control system.

Function Alternative

A function alternative to select a source control system is not available, but you can list all available source control systems using `verctrl` with the `all_systems` argument. Use `cmopts` to display the name of the currently selected source control system.

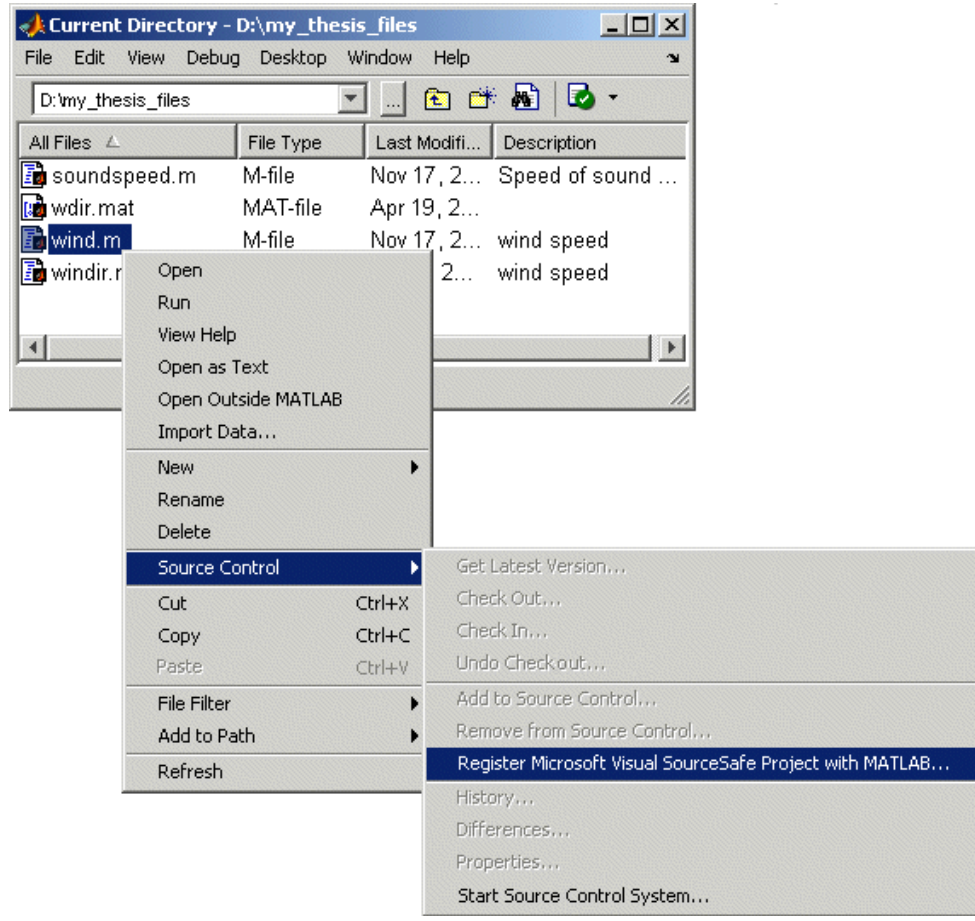
Register Source Control Project with MATLAB

Register a source control system project with a directory in MATLAB, that is, associate a source control system project with a directory and all files in that directory. Do this only one time for any file in the directory, which registers all files in that directory:

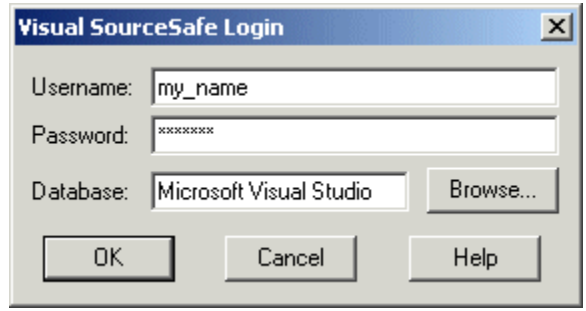
1. In the MATLAB Current Directory browser, select a file that is in the directory you want to associate with a project in your source control system. For example, select `D:\my_thesis_files\wind.m`. This will associate all files in the `my_thesis_files` directory.

2. Right-click, and from the context menu, select **Source Control > Register Name_of_Source_Control_System Project with MATLAB**. The **Name_of_Source_Control_System** is the source control system you selected using preferences as described in “Specify Source Control System in MATLAB” on page 9-6.

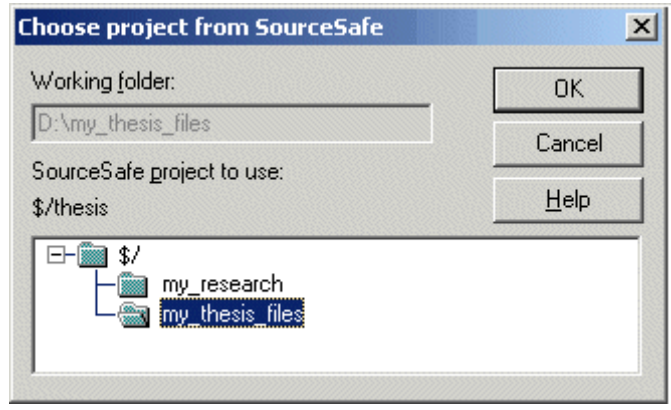
The following example shows Microsoft Visual SourceSafe.



3 In the resulting **Name_of_Source_Control_System Login** dialog box, provide the username and password you use to access your source control system, and click **OK**.



4 In the resulting **Choose project from Name_of_Source_Control_System** dialog box, select the source control system project to associate with the directory and click **OK**. This example shows `my_thesis_files`.



The selected file, its directory, and all files in the directory, are associated with the source control system project you selected. For the example, MATLAB associates all files in `D:\my_thesis_files` with the source control project `my_thesis_files`.

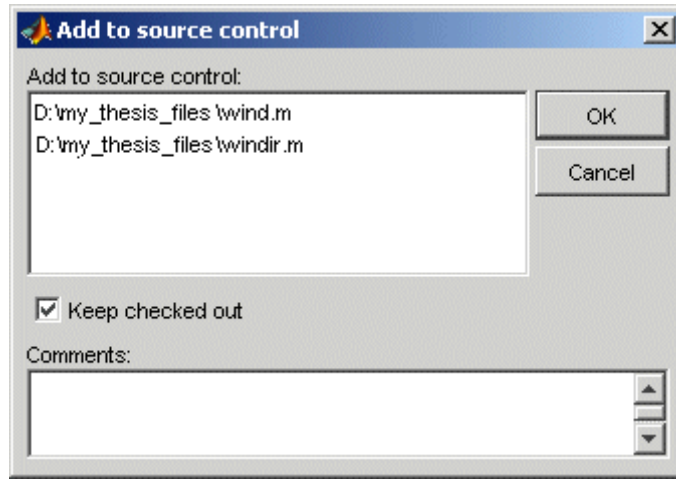
Add Files to Source Control

Add files to the source control system. Do this only once for each file:

1 In the Current Directory browser, select files you want to add to the source control system.

2 Right-click, and from the context menu, select **Source Control > Add to Source Control**.

3 The resulting **Add to source control** dialog box lists files you selected to add. You can add text in the **Comments** field. If you expect to use the files soon, select the **Keep checked out** check box (which is selected by default). Click **OK**.



If you try to add an unsaved file, the file is automatically saved upon adding.

Function Alternative

The function alternative is `verctrl` with the `add` argument.

Checking Files Into and Out of Source Control from MATLAB on Windows

In this section...

Before checking files into and out of your source control system from MATLAB, be sure to set up your system for use with MATLAB as described in “Setting Up the Source Control Interface on Windows” on page 9-4.

Check Files Into Source Control

After creating or modifying files in MATLAB or related products, check the files into the source control system by performing these steps:

1. In the Current Directory browser, select the files to check in. A file can be open or closed when you check it in, but it must be saved, that is, it cannot contain unsaved changes.
2. Right-click, and from the context menu, select **Source Control > Check In**.
3. In the resulting **Check in file(s)** dialog box, you can add text in the **Comments** field. If you want to continue working on the files, select the check box **Keep checked out**. Click **OK**.

If a file contains unsaved changes when you try to check it in, you will be prompted to save the changes to complete the checkin. If you did not keep the file checked out and you keep the file open, note that it is a read-only version.

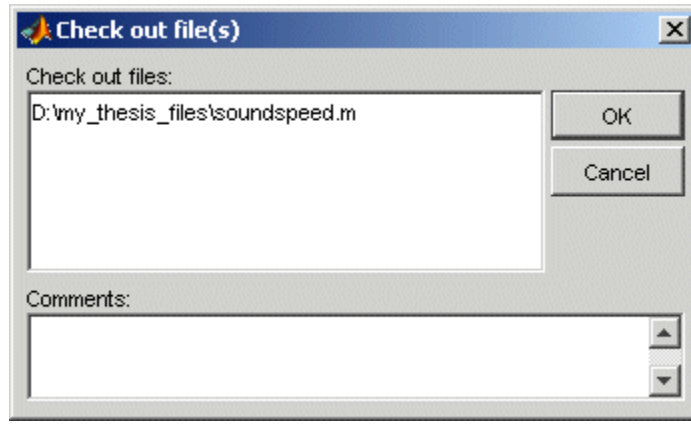
Function Alternative

The function alternative is `verctrl` with the `checkin` argument.

Check Files Out of Source Control

From MATLAB, to check out the files you want to modify, perform these steps:

1. In the Current Directory browser, select the files to check out.
2. Right-click, and from the context menu, select **Source Control > Check Out**.
3. The resulting **Check out file(s)** dialog box lists files you selected to check out. Enter comment text in the **Comments** field, which appears if your source control system supports comments on checkout. Click **OK**.



After checking out a file, make changes to it in MATLAB or another product, and save the file. For example, edit an M-file in the Editor/Debugger.

If you try to change a file without first having checked it out, the file is read-only, as seen in the title bar, and you will not be able to save any changes. This protects you from accidentally overwriting the source control version of the file.

If you end the MATLAB session, the file remains checked out. You can check in the file from within MATLAB during a later session, or directly from your source control system.

Function Alternative

The function alternative is `verctrl` with the `checkout` argument.

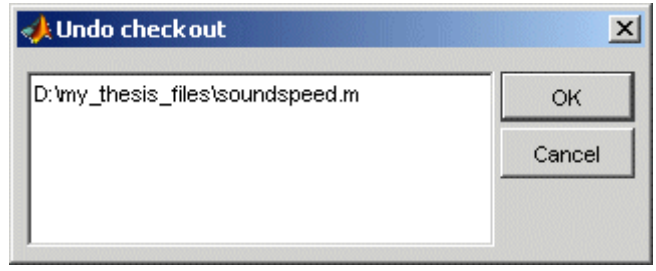
Undoing the Checkout

You can undo the checkout for files. The files remain checked in, and do not have any of the changes you made since you last checked them out. To save any changes you have made since checking out a particular file select **File > Save As**, and supply a different filename before you undo the checkout.

To undo a checkout, follow these steps:

1. In the MATLAB **Current Directory** browser, select the files for which you want to undo the checkout.
2. Right-click, and from the context menu, select **Source Control > Undo Checkout**.

   The MATLAB **Undo checkout** dialog box opens, listing the files you selected.



3. Click **OK**.

Function Alternative

The function alternative is `verctrl` with the `undocheckout` argument.

Additional Source Control Actions on Windows

In this section...

Getting the Latest Version of Files for Viewing or Compiling

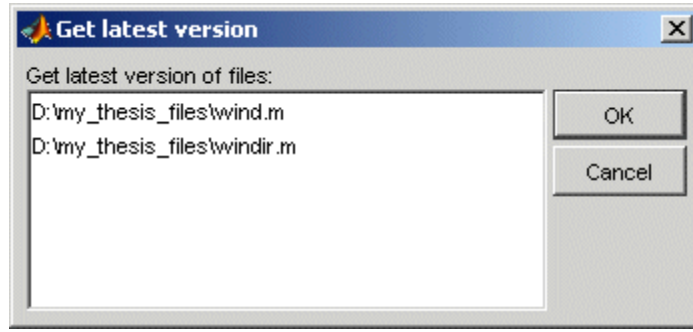
You can get the latest version of a file from the source control system for viewing or running. Getting a file differs from checking it out. When you get a file, it is write protected so you cannot edit it, but when you check out a file, you can edit it.

To get the latest version, follow these steps:

1 In the MATLAB **Current Directory** browser, select the directories or files that you want to get. If you select files, you cannot also select directories.

2 Right-click, and from the context menu, select **Source Control > Get Latest Version**.

The MATLAB **Get latest version** dialog box opens, listing the files or directories you selected.



3 Click **OK**.

You can now open the file to view it, run the file, or check out the file for editing.

Function Alternative

The function alternative is `verctrl` with the `get` argument.

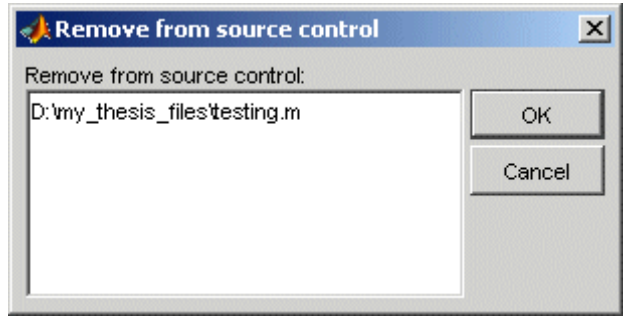
Removing Files from the Source Control System

To remove files from the source control system, follow these steps:

1 In the MATLAB **Current Directory** browser, select the files you want to remove.

2 Right-click, and from the context menu, select **Source Control > Remove from Source Control**.

The MATLAB **Remove from source control** dialog box opens, listing the files you selected.



3 Click **OK**.

Function Alternative

The function alternative is `verctrl` with the `remove` argument.

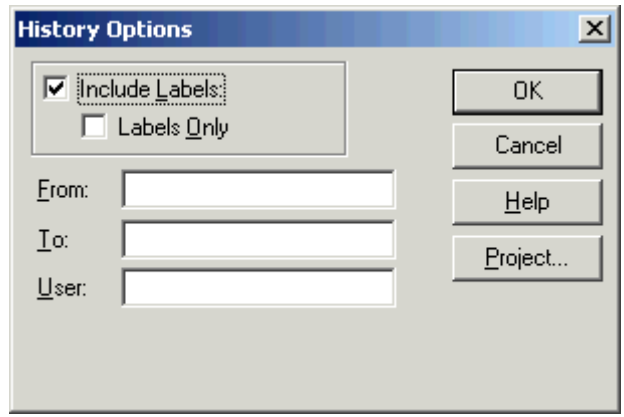
Showing File History

To show the history of a file in the source control system, follow these steps:

1 In the MATLAB **Current Directory** browser, select the file for which you want to view the history.

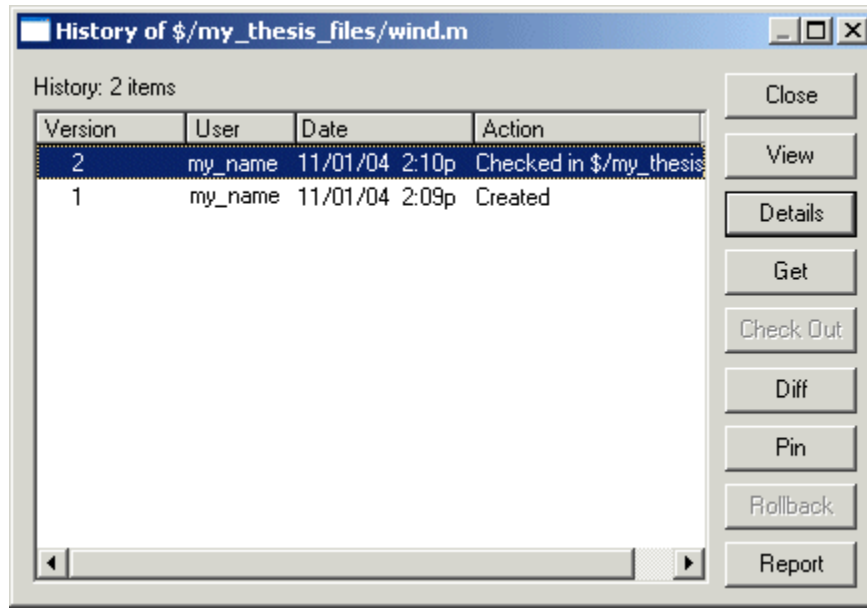
2 Right-click, and from the context menu, select **Source Control > History**.

A dialog box, which is specific to your source control system, opens. For Microsoft Visual SourceSafe, the **History Options** dialog box opens, as shown in the following example illustration.



3 Complete the dialog box to specify the range of history you want for the selected file and click **OK**. For example, enter `my_name` for **User**.

The history presented depends on your source control system. For Microsoft Visual SourceSafe, the **History** dialog box opens for that file, showing the file's history in the source control system.



Function Alternative

The function alternative is `verctrl` with the `history` argument.

Comparing the Working Copy of a File to the Latest Version in Source Control

You can compare the current working copy of a file with the latest checked-in version of the file in the source control system. This highlights the differences between the two files, showing the changes you made since you checked out the file.

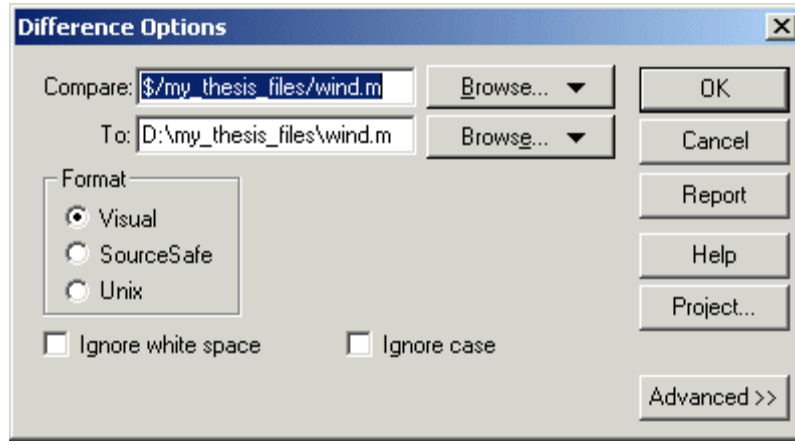
To view the differences, follow these steps:

1. In the MATLAB **Current Directory** browser, select the file for which you want to view differences. This is a file that has been checked out and edited.

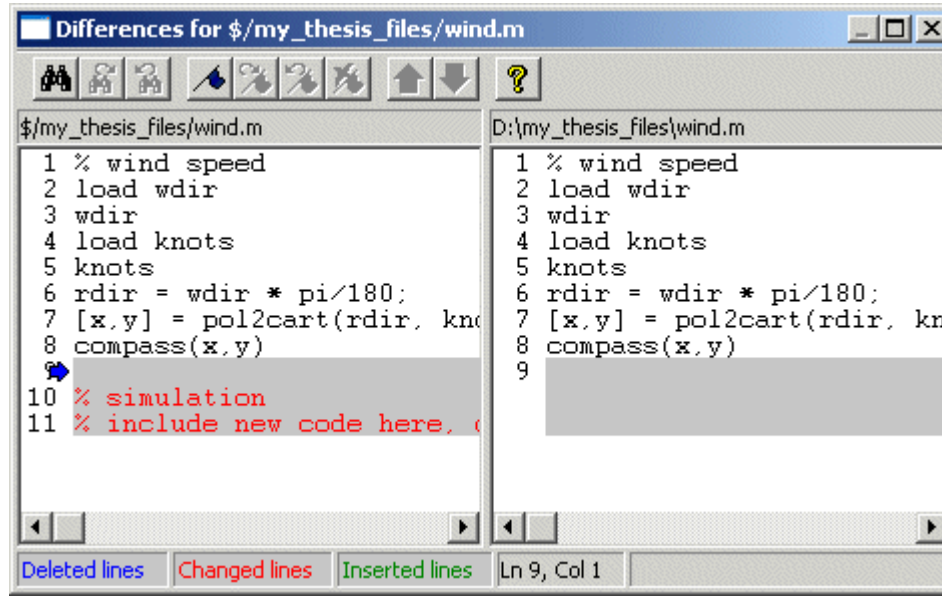
2 Right-click, and from the context menu, select **Source Control > Differences**.

A dialog box, which is specific to your source control system, opens. For Microsoft Visual SourceSafe, the **Difference Options** dialog box opens.

3 Review the default entries in the dialog box, make any needed changes, and click **OK**. The following example is for Microsoft Visual Source Safe.



The method of presenting differences depends on your source control system. For Microsoft Visual SourceSafe, the **Differences for** dialog box opens. This highlights the differences between the working copy of the file and the latest checked-in version of the file.



Function Alternative

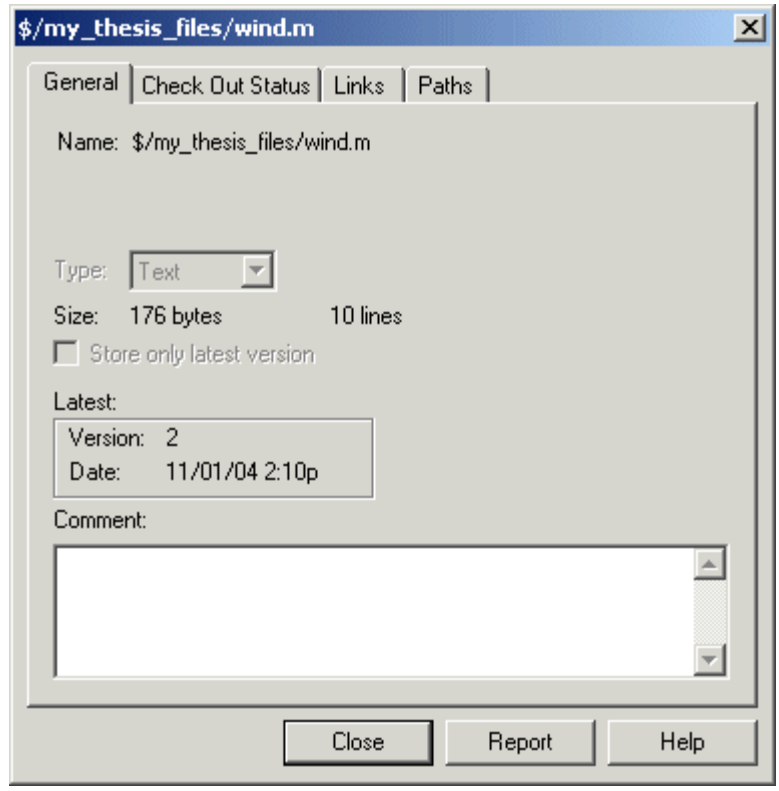
The function alternative is `verctrl` with the `showdiff` or `isdiff` argument.

Viewing Source Control Properties of a File

To view the source control properties of a file, follow these steps:

1. In the MATLAB **Current Directory** browser, select the file for which you want to view properties.
2. Right-click, and from the context menu, select **Source Control > Properties**.

A dialog box, which is specific to your source control system, opens. The following example shows the Microsoft Visual SourceSafe properties dialog box.



Function Alternative

The function alternative is `verctrl` with the `properties` argument.

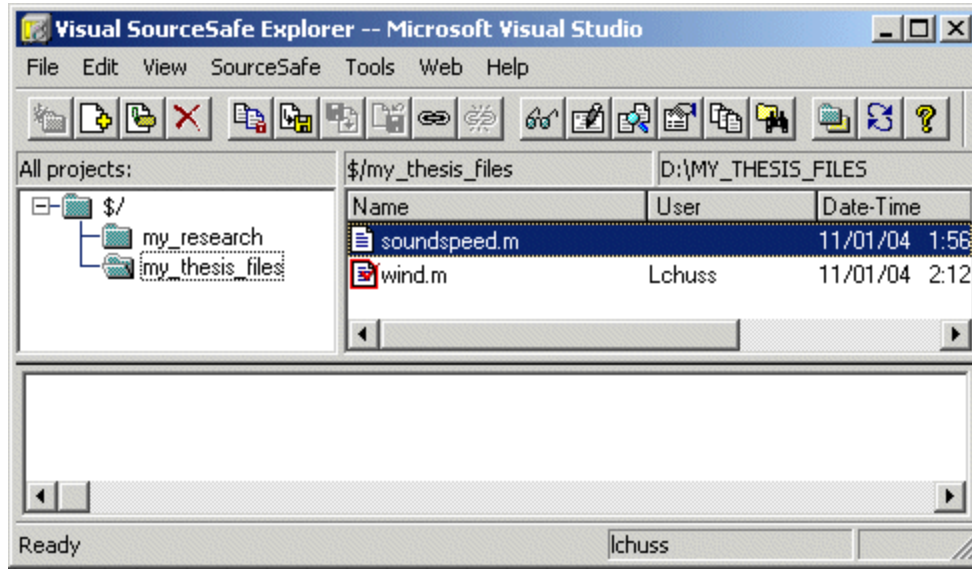
Starting the Source Control System

All the MATLAB source control actions automatically start the source control system to perform the action, if the source control system is not already open. If you want to start the source control system from MATLAB without performing a specific action source control action,

1 Right-click any directory or file in the MATLAB Current Directory browser

2 From the context menu, select **Source Control > Start Source Control System**.

The interface to your source control system opens, showing the source control project associated with the current directory in MATLAB. The following example shows the Microsoft **Visual SourceSafe Explorer** interface.



Function Alternative

The function alternative is `verctrl` with the `runscc` argument.

Performing Source Control Actions from the Editor/Debugger, Simulink, or Stateflow on Windows

You can create or open a file in the Editor/Debugger, Simulink, or Stateflow and perform most source control actions from their **File > Source Control** menus, rather than from the Current Directory browser as described in previous sections. Following are some differences in the source control interface process when you use the Editor/Debugger, Simulink, or Stateflow:

- You can perform actions on only one file at time.
- Some of the dialog boxes have a different icon in the title bar. For example, the **Check out file(s)** dialog box uses an M-file Editor/Debugger document icon instead of the MATLAB icon.
- You cannot add a new (`Untitled`) file, but must instead first save the file.
- You cannot register projects from Simulink or Stateflow. Instead, register a project using the Current Directory browser, as described in “Register Source Control Project with MATLAB” on page 9-7.

Troubleshooting Source Control Problems on Windows

In this section...

Source Control Error: Provider Not Present or Not Installed Properly

In some cases, MATLAB recognizes your source control system but you cannot use source control features for MATLAB. Specifically, when you select **File > Preferences > General > Source Control**, or run `cmopts`, MATLAB lists your source control system, but you cannot perform any source control actions. Only the **File > Source Control > Start Source Control System** menu item is available, and when you select it, MATLAB displays this error:

```
Source control provider is not present or not installed properly.
```

Often, this error occurs because a registry key that MATLAB requires from the source control application is not present. Make sure this registry key is present:

```
HKEY_LOCAL_MACHINE\SOFTWARE\SourceCodeControlProvider\
InstalledSCCProviders
```

The registry key refers to another registry key that is similar to

```
HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\SourceSafe\SccServerPath
```

This registry key has a path to a DLL-file in the file system. Make sure the DLL-file exists in that location. If you are not familiar with registry keys, ask your system administrator for help.

If this does not solve the problem and you use Microsoft Visual SourceSafe, try running a client setup for your source control application. When SourceSafe is

installed on a server for a group to use, each machine client can run a setup but is not required to do so. However, some applications that interface with SourceSafe, including MATLAB, require you to run the client setup. Run the client setup, which should resolve the problem.

If the problem persists, access source control outside of MATLAB.

Restriction Against @ Character

Some source control systems, such as Perforce and Synergy, reserve the `@` character. Perforce, for example, uses it as a revision specifier. Therefore, you might experience problems if you use these source control systems with MATLAB files and directories that include the `@` character in the directory or filename.

You might be able to work around this restriction by quoting nonstandard characters in filenames, such as with an escape sequence, which some source control systems allow. Consult your source control system documentation or technical support resources for a workaround.

Add to Source Control Is the Only Action Available

To use source control features for a file in Simulink or Stateflow, the file's source control project must first be registered with MATLAB. When a file's source control project is *not* registered with MATLAB, all **File > Source Control** menu items are disabled except **Add to Source Control**. You can select **Add to Source**, which registers the project with MATLAB, or you can register the project using the Current Directory browser, as described in "Register Source Control Project with MATLAB" on page 9-7. You can then perform source control actions for all files in that project (directory).

More Solutions for Source Control Problems

The latest solutions for problems interfacing MATLAB with a source control system appear on the MathWorks Web page for support at `http://www.mathworks.com/support/`. Search Solutions and Technical Notes for "source control."

Source Control Interface on UNIX

If you use a source control system to manage your files, you can check M-files and Simulink models, and Stateflow charts into and out of the source control system from within MATLAB, Simulink, and Stateflow.

The source control interface supports four popular source control systems, as well as a custom option:

- ClearCase from IBM Rational
- Concurrent Version System (CVS)
- ChangeMan from Serena (also used for PVCS from Merant)
- Revision Control System (RCS)
- Custom option — Allows you to build your own interface if you use a different source control system. For details, see the reference page for `customverctrl`.

Perform source control interface actions for a single file using menu items in the MATLAB Editor/Debugger, a Simulink model window, or a Stateflow chart window. To perform source control actions on multiple files, use the Current Directory browser. Alternatively, run source control functions in the Command Window, which provide some options not supported with the menu items.

Specifying the Source Control System on UNIX

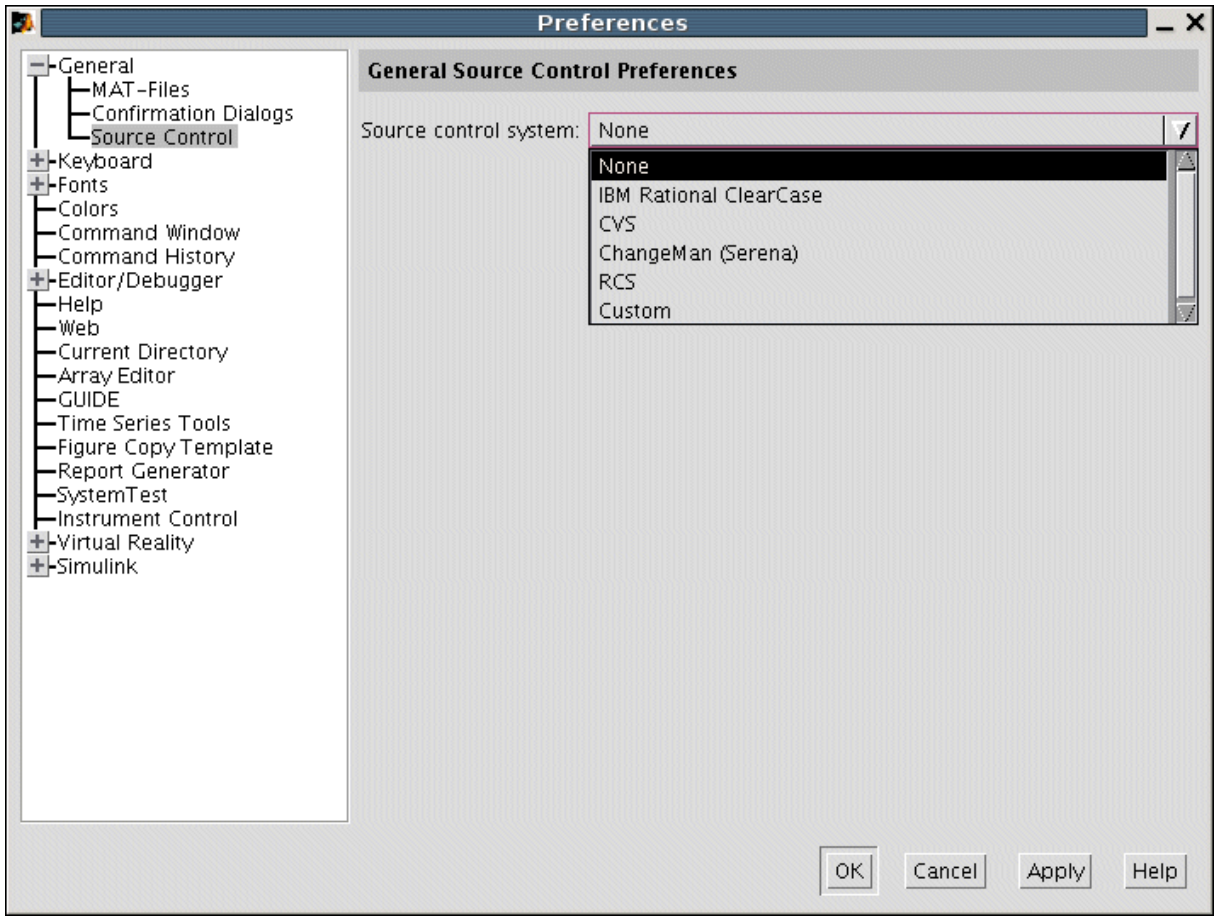
In this section...

MATLAB Alternative

In MATLAB, specify the source control system you want to access. Select **File > Preferences > General > Source Control**.

The currently selected system is shown in the Preferences dialog box. The default selection is `None`.

Select the source control system you want to interface with and click **OK**.



MATLAB remembers preferences between sessions, so you only need to perform this action when you want to access a different source control system.

Function Alternative

A function alternative to select a source control system is not available, but you can list the currently selected source control system by running `cmopts`.

Setting a View and Checking Out a Directory with ClearCase on UNIX

If you use ClearCase on a UNIX platform, perform the following from ClearCase:

1. Set a view.
2. Check out the directory that contains files you want to save, check in, or check out.

You can now use the MATLAB, Simulink, or Stateflow source control interfaces to ClearCase.

Checking Files Into the Source Control System on UNIX

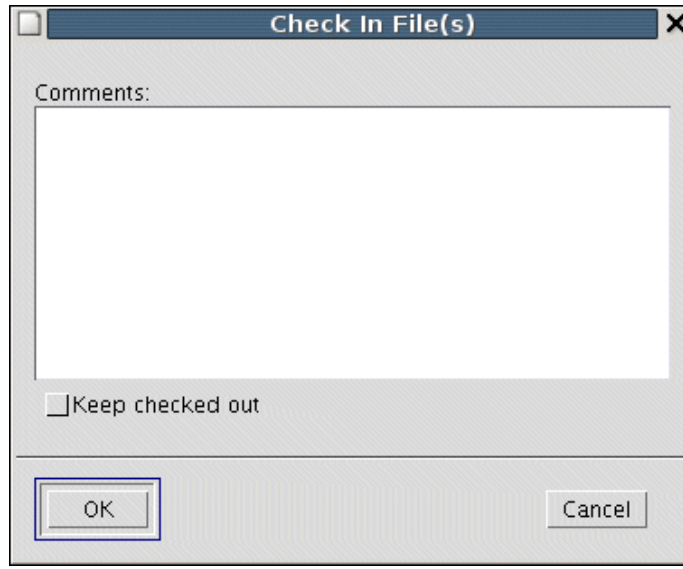
In this section...

Checking In One or More Files Using the Current Directory Browser

1. From the Current Directory browser, select the file or files to check in. A file can be open or closed when you check it in, but it must be saved, that is, it cannot contain unsaved changes.

2. Right-click, and from the context menu, select **Source Control > Check In**.

3. In the resulting **Check in file(s)** dialog box, you can add text in the **Comments** field. If you want to continue working on the files, select the check box **Keep checked out**. Click **OK**.



The files are checked into the source control system. If any file contains unsaved changes when you try to check it in, you will be prompted to and must then save the changes to complete the checkin.

An error appears in the Command Window if a file is already checked in.

If you did not keep a file checked out and you keep that file open, note that it is a read-only version.

Checking In One File Using the Editor/Debugger, Simulink, or Stateflow

1. From the Editor/Debugger, Simulink, or Stateflow, with the file open and saved, select **File > Source Control > Check In**.

2. In the resulting **Check in file(s)** dialog box, you can add text in the **Comments** field. If you want to continue working on the files, select the check box **Keep checked out**. Click **OK**.

Function Alternative

Use `checkin` to check files into the source control system. The files can be open or closed when you use `checkin`. The `checkin` function takes this form:

```
checkin({'file1','file2', ...},'comments','comment_text',...
'option','value')
```

For `filen`, use the complete path and include the file extension. You must supply the `comments` argument and a comments string with `checkin`.

Use the `option` argument to

- Check in a file and keep it checked out — set the `lock` option value to `on`.
- Check in a file even though it has not changed since the previous check in — set the `force` option value to `on`.

The `comments` argument and the `lock` and `force` options apply to all files checked in.

Example Using checkin Function

To check in the file `clock.m` with the comment `Adjustment for leap year`, type

```
checkin('\myserver\mymfiles\clock.m','comments', ...
'Adjustment for leap year')
```

For other examples, see the reference page for `checkin`.

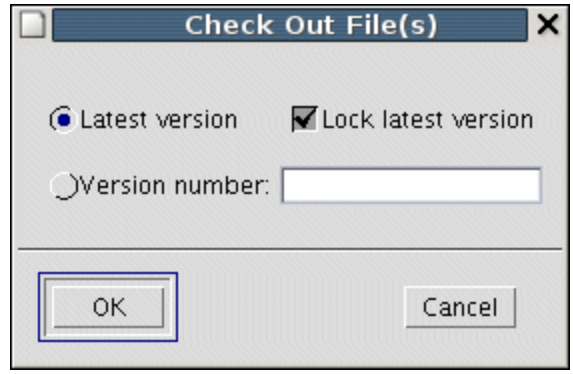
Checking Files Out of the Source Control System on UNIX

In this section...

Checking Out One or More Files Using the Current Directory Browser

1 In the Current Directory browser, select the file or files to check out.

2 Right-click, and from the context menu, select **Source Control > Check Out**. The **Check out file(s)** dialog box opens.



3 Complete the dialog box:

a To check out the versions that were most recently checked in, select the **Latest version** option.

b To check out a specific version of the files, select the **Version number** option and type the version number in the field.

c To prevent others from checking out the files while you have them checked out, select **Lock latest version**. To check out read-only versions of the file, clear **Lock latest version**.

4 Click **OK**.

An error appears in the Command Window if a file is already checked out.

After checking out files, make changes to them in MATLAB or another product, and save the files. For example, edit an M-file in the Editor/Debugger.

If you try to change a file without first having checked it out, the file is read-only, as seen in the title bar, and you will not be able to save any changes. This protects you from accidentally overwriting the source control version of the file.

If you end the MATLAB session, the file or files remain checked out. You can check in files from within MATLAB during a later session, or directly from your source control system.

Checking Out a Single File Using the Editor/Debugger, Simulink, or Stateflow

1 Open the M-file, Simulink model, or Stateflow chart you want to check out. The title bar indicates the file is read-only.

2 Select **File > Source Control > Check Out**. The **Check out file(s)** dialog box opens.

3 Complete the dialog box as described in step of "Checking Out One or More Files Using the Current Directory Browser" on page 9-33, and click **OK**.

Function Alternative

Use `checkout` to check out a file from the source control system. You can check out multiple files at once and specify checkout options. The `checkout` function takes this form:

```
checkout({'file1','file2', ...},'option','value')
```

For `filen`, use the complete path and include the file extension.

Use the `option` argument to

- Check out a read-only version of the file — set the `lock` option value to `off`.
- Check out the file even if you already have it checked out — set the `force` option value to `on`.
- Check out a specific version of the file — use the `revision` option, and assign the version number to the `value` argument.

The options apply to all files being checked out. The files can be open or closed when you use `checkout`.

Example Using checkout Function—Check Out a Specific Version of a File

To check out the 1.1 version of the file `clock.m`, type

```
checkout('\myserver\mymfiles\clock.m','revision','1.1')
```

For other examples, see the reference page for `checkout`.

Undoing the Checkout on UNIX

In this section...

Impact of Undoing a File Checkout

When you undo the checkout for a file, the file remains checked in, and does not have any of the changes you made since you checked it out. To save any changes you have made since checking out a file, select **File > Save As**, and supply a different filename before you undo the checkout. Undo the checkout using the Current Directory browser for one or more files. For only one file, you can also use the Editor/Debugger, Simulink, or Stateflow.

Undoing the Checkout for One or More Files Using the Current Directory Browser

1. In the MATLAB **Current Directory** browser, select the file or files for which you want to undo the checkout.
2. Right-click, and from the context menu, select **Source Control > Undo Checkout**. MATLAB undoes the checkout.

An error appears in the Command Window if the file is not checked out.

Undoing the Checkout for a Single File Using the Editor/Debugger, Simulink, or Stateflow

1. Open the M-file, Simulink model, or Stateflow chart for which you want to undo the checkout.

2 Select **File > Source Control > Undo Checkout**. MATLAB undoes the checkout.

Function Alternative

The `undocheckout` function takes this form:

```
undocheckout({'file1','file2', ...})
```

Use the complete path for `filen` and include the file extension. For example, to undo the checkout for the files `clock.m` and `calendar.m`, type

```
undocheckout({'\myserver\mymfiles\clock.m',...
'\myserver\mymfiles\calendar.m'})
```

Importing and Exporting Data

Using MAT-Files

In this section...

Introduction

MAT-files, the data file format MATLAB uses for saving data to your disk, provide a convenient mechanism for moving MATLAB data between platforms and for importing and exporting data to stand-alone MATLAB applications.

To simplify your use of MAT-files in applications outside of MATLAB, we have developed a library of access routines with a `mat` prefix that you can use in your own C or Fortran programs to read and write MAT-files. Programs that access MAT-files also use the `mx` prefixed API (application program interface) routines discussed in Chapter 4, "Creating C Language MEX-Files" and Chapter 5, "Creating Fortran MEX-Files".

Importing Data to MATLAB

The best method for importing data into MATLAB depends on how much data there is, whether the data is already in machine-readable form, and what format the data is in. Here are some choices; select the one that best meets your needs.

- **Enter the data at the MATLAB command prompt.**

  For small amounts of data, less than 10-15 elements, type the data directly into MATLAB using brackets [ ]. This method is awkward for large amounts of data because you can't edit your input.

- **Create data in an M-file.**

  With a text editor, create an M-file to enter data as an explicit list of elements. This method is useful when the data isn't already in computer-readable format and must be typed in. Use the editor to change the data or correct mistakes, then rerun the M-file to reenter the data.

- **Load data from an ASCII flat file.**

  A *flat file* stores data in ASCII format, with fixed-length rows terminated by new lines (carriage returns) and with spaces separating the numbers. Edit ASCII flat files using a text editor and use the `load` command to read them directly into MATLAB. MATLAB creates a variable with the same name as the filename.

- **Read data using MATLAB I/O functions.**

  Use `fopen`, `fread`, and other low-level MATLAB I/O functions to read data. This method allows you to load data files from applications that have their own file formats.

- **Write a MEX-file to read the data.**

  This is the method of choice if subroutines are available for reading data files from other applications. See the section, "Introducing MEX-Files" on page 3-2, for more information.

- **Write a program to translate your data.**

  Write programs in C or Fortran to translate your data into MAT-file format. Use the `load` command to read the MAT-file into MATLAB. Refer to the section, "Reading and Writing MAT-Files" on page 1-5, for more information.

Exporting Data from MATLAB

There are several methods for exporting MATLAB data.

- **Create a diary file.**

  For small matrices, use the `diary` command to create a diary file, a log of keyboard input and the resulting text output. You can use a text editor to modify the file. The diary file displays the variables and includes the MATLAB commands used during the session, which can be used in documents and reports.

- **Use the save command.**

  Save data in ASCII format using the `save` command with the `-ascii` option. For example,

  ```
  A = rand(4,3);
  save temp.dat A -ascii
  ```

  creates an ASCII file called `temp.dat`, which may look something like this:

  ```
  1.3889088e-001  2.7218792e-001  4.4509643e-001
  2.0276522e-001  1.9881427e-001  9.3181458e-001
  1.9872174e-001  1.5273927e-002  4.6599434e-001
  6.0379248e-001  7.4678568e-001  4.1864947e-001
  ```

  The `-ascii` option supports two-dimensional double and character arrays only. Multidimensional arrays, cell arrays, and structures are not supported.

- **Use MATLAB I/O functions.**

  Write the data in a special format using `fopen`, `fwrite`, and other low-level file I/O functions. This method is useful for writing data files in file formats required by other applications. See the section, "Using Low-Level File I/O Functions", for more information.

- **Create a MEX-file to write the data.**

  This is the method of choice if subroutines are available for writing data files in the form needed by other applications. See the section, "Introducing MEX-Files" on page 3-2, for more information.

- **Translate data from a MAT-file.**

  Write data into a MAT-file using the `save` command, then write a program in C or Fortran to translate the MAT-file into your own special format. See the section, "Reading and Writing MAT-Files" on page 1-5, for more information.

Exchanging Data Files Between Platforms

You can work with MATLAB on different computer systems and send MATLAB applications to users on other systems. MATLAB applications consist of M-files containing functions and scripts, and MAT-files containing binary data.

Both types of files can be transported directly between machines: M-files because they are platform independent and MAT-files because they contain a machine signature in the file header. MATLAB checks the signature when it loads a file and, if a signature indicates that a file is foreign, performs the necessary conversion.

Using MATLAB across different machine architectures requires a facility for exchanging both binary and ASCII data between the machines. Examples of this type of facility include FTP, NFS, and Kermit. When using these programs, be careful to transmit MAT-files in *binary file mode* and M-files in *ASCII file mode*. Failure to set these modes correctly corrupts the data.

Reading and Writing MAT-Files

Use the MATLAB `save` command to save MATLAB arrays currently in memory to a binary file called a MAT-file. MAT-files have the extension `.mat`. The `load` command reads MATLAB arrays from a MAT-file on disk back into the MATLAB workspace.

A MAT-file contains one or more of the data types supported in MATLAB 5 or later, including strings, matrices, multidimensional arrays, structures, and cell arrays. MATLAB writes the data sequentially onto disk in a continuous byte stream.

MAT-File Interface Library

The MAT-file interface library contains routines for reading and writing MAT-files. You can call these routines from your own C and Fortran programs. Use these routines, rather than attempt to write your own code, to perform these operations, since using the library insulates your applications from future changes to the MAT-file structure.

Functions in the MAT-file library begin with the three-letter prefix `mat`. These tables list and describe the MAT-functions.

C MAT-File Routines

MAT-Function	Purpose
`matOpen`	Open a MAT-file.
`matClose`	Close a MAT-file.
`matGetDir`	Get a list of MATLAB arrays from a MAT-file.
`matGetFp`	Get an ANSI C file pointer to a MAT-file.
`matGetVariable`	Read a MATLAB array from a MAT-file.
`matPutVariable`	Write a MATLAB array to a MAT-file.
`matGetNextVariable`	Read the next MATLAB array from a MAT-file.
`matDeleteVariable`	Remove a MATLAB array from a MAT-file.
`matPutVariableAsGlobal`	Put a MATLAB array into a MAT-file such that the `load` command places it into the global workspace.
`matGetVariableInfo`	Load a MATLAB array header from a MAT-file (no data).
`matGetNextVariableInfo`	Load the next MATLAB array header from a MAT-file (no data).

Fortran MAT-File Routines

MAT-Function	Purpose
`matOpen`	Open a MAT-file.
`matClose`	Close a MAT-file.
`matGetDir`	Get a list of MATLAB arrays from a MAT-file.
`matGetVariable`	Get a named MATLAB array from a MAT-file.
`matGetVariableInfo`	Get header for named MATLAB array from a MAT-file.

Fortran MAT-File Routines (Continued)

MAT-Function	Purpose
`matPutVariable`	Put a MATLAB array into a MAT-file.
`matPutVariableAsGlobal`	Put a MATLAB array into a MAT-file.
`matGetNextVariable`	Get the next sequential MATLAB array from a MAT-file.
`matGetNextVariableInfo`	Get header for next sequential MATLAB array from a MAT-file.
`matDeleteVariable`	Remove a MATLAB array from a MAT-file.

Writing Character Data

By default, MATLAB writes character data to MAT-files using Unicode character encoding. To override this setting and use your system's default encoding instead, do one of the following:

- From the MATLAB command line or a MATLAB function, save your data to the MAT-file using the command `save -nounicode`.
- From a C mex file, open the MAT-file you will write the data to using the command `matOpen -wL`.

See the individual reference pages for these functions for more information.

You can also set a save preference for all MATLAB sessions. See MAT-Files Preferences in the "General Preferences for MATLAB" section of the Desktop Tools and Development Environment documentation for more information.

ASCII Data Formats

When writing character data using Unicode character encoding (the default), MATLAB checks if the data is 7-bit ASCII. If it is, MATLAB writes the 7-bit ASCII character data to the MAT-file using 8 bits per character (UTF-8 format), thus minimizing the size of the resulting file. Any character data that is not 7-bit ASCII is written in 16-bit Unicode form (UTF-16). This algorithm operates on a per-string basis.

Note Level 4 MAT-files support only ASCII character data. If you have non-ASCII character data, writing a Level 4 MAT-file is not supported. In the event that a Level 4 MAT-file is created with such character data, it is unlikely that the original representation of the characters will be preserved.

Converting Character Data

Writing character data to MAT-files using Unicode character encoding enables you to share data with users that have systems with a different default system character encoding scheme, without character data loss or corruption. Although conversion between Unicode and other encoding forms is often lossless, there are scenarios in which round-trip conversions can result in loss of data. The following guidelines may reduce your chances of data loss or corruption.

In order to prevent loss or corruption of character data, all users sharing the data must have at least one of the following in common:

- They exchange Unicode-based MAT-files, and use a version of MATLAB that supports these files.
- Their computer systems all use the same default encoding, and all character data in the MAT-file was written using the `-nounicode` option

For example, if one user on a Japanese language operating system writes ASCII data having more than 7 bits per character to a MAT-file, another user running MATLAB version 6.5 on an English language operating system will be unable to read the data accurately. However, if both have MATLAB version 7, the information can be shared without corruption or loss of data.

Finding Associated Files

A collection of files associated with reading and writing MAT-files is located on your disk. The following table, MAT-Function Subdirectories, lists the path to the required subdirectories for importing and exporting data using MAT-functions. The term *`matlabroot`* refers to the root directory of your MATLAB installation.

MAT-Function Subdirectories

Platform	Contents	Directories
Windows	Include files	*matlabroot*\extern\include
	Libraries	*matlabroot*\bin\win32 or *matlabroot*\bin\win64
	Examples	*matlabroot*\extern\examples\eng_mat
UNIX	Include files	*matlabroot*/extern/include
	Libraries	*matlabroot*/bin/$arch
	Examples	*matlabroot*/extern/examples/eng_mat

Include Files

The `include` subdirectory holds header files containing function declarations with prototypes for the routines that you can access in the API Library. These files are the same for both Windows and UNIX. Included in the subdirectory are

- The `matrix.h` header file that defines MATLAB array access and creation methods
- The `mat.h` header file that defines MAT-file access and creation methods

Libraries

The libraries subdirectory, that contains shared (dynamically linkable) libraries for linking your programs, is platform dependent.

Shared Libraries on Windows. The `bin` subdirectory contains the shared libraries for linking your programs:

- The `libmat.dll` library of MAT-file routines (C and Fortran)
- The `libmx.dll` library of array access and creation routines

Shared Libraries on UNIX. The `bin/$arch` subdirectory, where `$arch` is your machine's architecture, contains the shared libraries for linking your programs. For example, on Solaris, the subdirectory is `bin/sol64`:

- The `libmat.so` library of MAT-file routines (C and Fortran)
- The `libmx.so` library of array access and creation routines

Example Files

The `examples/eng_mat` subdirectory contains C and Fortran source code for a number of example files that demonstrate how to use the MAT-file routines. The source code files are the same for both Windows and UNIX.

C and Fortran Examples

Library	Description
`matcreat.c`	C program that demonstrates how to use the library routines to create a MAT-file that can be loaded into MATLAB
`matdgns.c`	C program that demonstrates how to use the library routines to read and diagnose a MAT-file
`matdemo1.F`	Fortran program that demonstrates how to call the MATLAB MAT-file functions from a Fortran program
`matdemo2.F`	Fortran program that demonstrates how to use the library routines to read the MAT-file created by `matdemo1.F` and describe its contents

For more information about MATLAB API files and directories, see "Additional Information" on page 3-43.

Examples of MAT-Files

In this section...

Creating a MAT-File in C

This program, `matcreat.c`, illustrates how to use the library routines to create a MAT-file that can be loaded into MATLAB. The program also demonstrates how to check the return values of MAT-function calls for read or write failures. To see the code, you can open the file in MATLAB Editor.

To produce an executable version of this program, compile the file and link it with the appropriate library. Details of how to compile and link MAT-file programs on various platforms are discussed in the section, "Compiling and Linking MAT-File Programs" on page 1-15.

Once you have compiled and linked your MAT-file program, you can run the stand-alone application you have just produced. This program creates `mattest.mat`, a MAT-file that can be loaded into MATLAB. To run the application, depending on your platform, either double-click its icon or enter `matcreat` at the system prompt:

```
matcreat
Creating file mattest.mat...
```

To verify the MAT-file was created, at the MATLAB prompt type

```
whos -file mattest.mat
  Name               Size         Bytes  Class

  GlobalDouble       3x3             72  double array (global)
  LocalDouble        3x3             72  double array
  LocalString        1x43            86  char array
```

```
Grand total is 61 elements using 230 bytes
```

Reading a MAT-File in C

This program, `matdgns.c`, illustrates how to use the library routines to read and diagnose a MAT-file. To see the code, you can open the file in MATLAB Editor.

After compiling and linking this program, you can view its results:

```
matdgns mattest.mat
Reading file mattest.mat...

Directory of mattest.mat:
GlobalDouble
LocalString
LocalDouble

Examining the header for each variable:
According to its header, array GlobalDouble has 2 dimensions
  and was a global variable when saved
According to its header, array LocalString has 2 dimensions
  and was a local variable when saved
According to its header, array LocalDouble has 2 dimensions
  and was a local variable when saved

Reading in the actual array contents:
According to its contents, array GlobalDouble has 2 dimensions
  and was a global variable when saved
According to its contents, array LocalString has 2 dimensions
  and was a local variable when saved
According to its contents, array LocalDouble has 2 dimensions
  and was a local variable when saved
Done
```

Creating a MAT-File in Fortran

This program, `matdemo1.F`, creates the MAT-file, `matdemo.mat`. To see the code, you can open the file in MATLAB Editor.

Once you have compiled and linked your MAT-file program, you can run the stand-alone application you have just produced. This program creates a MAT-file, `matdemo.mat`, that can be loaded into MATLAB. To run the application, depending on your platform, either double-click its icon or enter `matdemo1` at the system prompt:

```
matdemo1
Creating MAT-file matdemo.mat ...
Done creating MAT-file
```

To verify that the MAT-file has been created, at the MATLAB prompt enter

```
whos -file matdemo.mat
Name          Size         Bytes  Class

Numeric       3x3             72  double array
String        1x33            66  char array

Grand total is 42 elements using 138 bytes
```

Note For an example of a Windows stand-alone program (not MAT-file specific), see `engwindemo.c` in the *`matlabroot`*`\extern\examples\eng_mat` directory.

Reading a MAT-File in Fortran

This program, `matdemo2.F`, illustrates how to use the library routines to read the MAT-file created by `matdemo1.F` and describe its contents. To see the code, you can open the file in MATLAB Editor.

After compiling and linking this program, you can view its results:

```
matdemo2
Directory of Mat-file:
String
Numeric
Getting full array contents:
  1
Retrieved String
```

```
  With size   1-by-  33
  3
Retrieved Numeric
  With size   3-by-  3
```

Compiling and Linking MAT-File Programs

In this section...

Masking Floating Point Exceptions

Certain mathematical operations can result in nonfinite values. For example, division by zero results in the nonfinite IEEE value, `inf`. A floating-point exception occurs when such an operation is performed. Because MATLAB uses an IEEE model that supports nonfinite values such as `inf` and `NaN`, MATLAB disables, or *masks*, floating-point exceptions.

Some compilers do not mask floating-point exceptions by default. This causes MAT-file applications built with such compilers to terminate when a floating-point exception occurs. Consequently, you need to take special precautions when using these compilers to mask floating-point exceptions so that your MAT-file application performs properly.

Note MATLAB-based applications should never get floating-point exceptions. If you do get a floating-point exception, verify that any third-party libraries that you link against do not enable floating-point exception handling.

The only compiler and platform on which you need to mask floating-point exceptions is the Borland C++ compiler on Windows.

Borland C++ Compiler on Windows

To mask floating-point exceptions when using the Borland C++ compiler on the Windows platform include the following at the beginning of your `main()` or `WinMain()` function, before calling any MATLAB API functions:

```
#include <float.h>
   .
   .
   .
_control87(MCW_EM,MCW_EM);
   .
   .
   .
```

Compiling and Linking on UNIX

Under UNIX at run-time, you must tell the system where the API shared libraries reside. These sections provide the necessary UNIX commands, depending on your shell and system architecture.

Setting Run-Time Library Path

Set the library path as follows for the C and Bourne shells. Replace the terms *envvar* and *pathspec* with the appropriate values from the table below.

In the C shell, set the library path using the command

```
setenv envvar pathspec
```

In the Bourne shell, use

```
envvar = pathspec:envvar
export envvar
```

Operating System	*envvar*	*pathspec*
Linux	LD_LIBRARY_PATH	*matlabroot*/bin/glnx86: *matlabroot*/sys/os/glnx86
64-bit Linux	LD_LIBRARY_PATH	*matlabroot*/bin/glnxa64: *matlabroot*/sys/os/glnxa64
64-bit Solaris SPARC	LD_LIBRARY_PATH	*matlabroot*/bin/sol64: *matlabroot*/sys/os/sol64

Operating System	*envvar*	*pathspec*
Macintosh (PPC)	DYLD_LIBRARY_PATH	*matlabroot*/bin/mac: *matlabroot*/sys/os/mac
Macintosh (Intel)	DYLD_LIBRARY_PATH	*matlabroot*/bin/maci: *matlabroot*/sys/os/maci

For example, for the C shell on a Solaris system use:

```
setenv LD_LIBRARY_PATH
matlabroot/bin/sol64:matlabroot/sys/os/sol64
```

and for the Bourne shell:

```
LD_LIBRARY_PATH=matlabroot/bin/sol64:matlabroot/sys/os/sol64:$LD_LIBRARY_PATH
export LD_LIBRARY_PATH
```

You can place these commands in a startup script such as `~/.cshrc` for C shell or `~/.profile` for Bourne shell.

Using the Options File

MATLAB provides an options file, `matopts.sh`, that lets you use the `mex` script to easily compile and link MAT-file applications. For example, to compile and link the `matcreat.c` example, first copy the file

```
matlabroot/extern/examples/eng_mat/matcreat.c
```

(where *matlabroot* is the MATLAB root directory) to a writable directory, then use the following command to build it:

```
mex -f matlabroot/bin/matopts.sh matcreat.c
```

If you need to modify the options file for your particular compiler or platform, use the `-v` switch to view the current compiler and linker settings and then make the appropriate changes in a local copy of the `matopts.sh` file.

Compiling and Linking on Windows

To compile and link Fortran or C MAT-file programs, use the `mex` script with a MAT options file. The MAT options files reside in *`matlabroot`*`\bin\win32\mexopts` or *`matlabroot`*`\bin\win64\mexopts` and are named `*engmatopts.bat`, where `*` represents the compiler type and version.

For example, to compile and link the stand-alone MAT application `matcreat.c` using MSVC Version 7.1 on Windows, first copy the file

```
matlabroot\extern\examples\eng_mat\matcreat.c
```

(where *`matlabroot`* is the MATLAB root directory) to a directory that is writable, and then use the following command to build it:

```
mex -f matlabroot\bin\win32\mexopts\msvc71engmatopts.bat matcreat.c
```

If you need to modify the options file for your particular compiler, use the `-v` switch to view the current compiler and linker settings and then make the appropriate changes in a local copy of the options file.

Required Files from Third-Party Sources

MATLAB requires the following data and library files for building any MAT-file application. You must also distribute these files along with any MAT-file application that you deploy to another system.

Third-Party Data Files

When building a MAT-file application on your system or deploying a MAT-file application to some other system, make sure that the appropriate Unicode data file is installed in the *`matlabroot`*`/bin/$ARCH` directory. MATLAB uses this file to support Unicode.

For systems that order bytes in a big-endian manner, use `icudt32b.dat`.

For systems that order bytes in a little-endian manner, use `icudt32l.dat`.

Third-Party Libraries

When building a MAT-file application on your system or deploying a MAT-file application to some other system, make sure that the appropriate libraries are installed in the *matlabroot*/bin/$ARCH directory:

On Windows	On UNIX	On Intel-based Macintosh
libmat.dll	libmat.so	libmat.dylib
libmx.dll	libmx.so	libmx.dylib

In addition to these libraries, you must also have all third-party library files that libmat depends on. MATLAB uses these additional libraries to support Unicode character encoding and data compression in MAT-files. These library files must reside in the same directory as libmx.

You can determine what most of these libraries are using the platform-specific methods described below.

On Linux or Solaris Systems

Type the following command:

```
ldd -d libmat.so
```

On Macintosh Systems

Type the following command:

```
otool -L libmat.dylib
```

On Windows Systems

Download the Dependency Walker utility from the following Web site:

```
http://www.dependencywalker.com/
```

and then drag and drop the file *matlabroot*/bin/win32/libmat.dll or *matlabroot*/bin/win64/libmat.dll into Depends window. (*matlabroot* represents the MATLAB root directory).

Working Directly with Unicode

If you need to manipulate Unicode text directly in your application, the latest version of International Components for Unicode (ICU) is freely available online from the IBM Corporation Web site at

```
http://icu.sourceforge.net/download
```

2

MATLAB Interface to Generic DLLs

A shared library is a collection of functions that are available for use by one or more applications running on a system. MATLAB supports dynamic linking of external libraries on 32-bit MS-Windows systems and on 32-bit Linux systems.

You precompile the library into a dynamic link library file (`.dll`) on Windows, a shared object file (`.so`) on UNIX and Linux, or a dynamic shared library (`.dylib`) on Intel-based Macintosh. At run-time, the library is loaded into memory and made accessible to all applications. The MATLAB Interface to Generic DLLs enables you to interact with functions in dynamic link libraries directly from MATLAB.

This chapter covers the following topics:

Overview (p. 2-3)	Describes how to call functions in external, shared libraries (`.dll`, `.so`, and `.dylib` files) from MATLAB.
Loading and Unloading the Library (p. 2-4)	Describes functions to use in loading the library into MATLAB memory and later releasing that memory.
Getting Information About the Library (p. 2-6)	Shows several ways of obtaining information about the functions contained in a library.
Invoking Library Functions (p. 2-9)	Tells you how to make a call to any function in the library.

Passing Arguments (p. 2-10)	Explains how to construct MATLAB arguments that are compatible with the argument types found in the library functions.
Data Conversion (p. 2-15)	Describes how to convert MATLAB data to C data types when you need to do the conversion manually.

Overview

C programs built into external, shared libraries are accessed by MATLAB through a command-line interface. This interface gives you the ability to load an external library into MATLAB memory space and then access any of the functions defined therein. Although data types differ between the two language environments, in most cases you can pass MATLAB types to the C functions without having to do the work of conversion. MATLAB does this for you.

Note The MATLAB Generic Shared Library interface does not support library functions that have function pointer inputs because there is no way to write a MATLAB function that is compatible with a C function pointer.

This interface also supports libraries containing functions programmed in languages other than C, provided that the functions have a C interface. For example, it is possible to call a Visual Basic 6.0 DLL using `loadlibrary`; however, you must create a C header file for the library. The ActiveX interface might be simpler to use for this reason. See “Introducing MATLAB COM Integration” on page 8-3 for more information on ActiveX.

Loading and Unloading the Library

In this section...

Using a Shared Library

To give MATLAB access to external functions in a shared library, you must first load the library into memory. Once loaded, you can request information about any of the functions in the library and call them directly from MATLAB. When the library is no longer needed, unload it from memory to conserve memory usage.

Loading the Library

To load a shared library into MATLAB, use the `loadlibrary` function. The syntax for `loadlibrary` is

```
loadlibrary('shrlib', 'hfile')
```

where `shrlib` is the filename for the shared library file, and `hfile` is the filename for the header file that contains the function prototypes. See the reference page for `loadlibrary` for variations in the syntax that you can use and information on library file extensions.

Note The header file provides signatures for the functions in the library and is a required argument for `loadlibrary`.

As an example, you can use `loadlibrary` to load the `libmx` library that defines the MATLAB `mx` routines. The first statement below forms the directory specification for the `matrix.h` header file for the `mx` routines. The second loads the library from `libmx` (note the file extension is platform dependent), also specifying the header file:

```
hfile = [matlabroot '\extern\include\matrix.h'];
loadlibrary('libmx', hfile)
```

There are also several optional arguments that you can use with `loadlibrary`. See the `loadlibrary` reference page for more information.

Unloading the Library

To unload the library and free up the memory that it occupied, use the `unloadlibrary` function. For example:

```
unloadlibrary libmx
```

Getting Information About the Library

In this section...

Introduction

You can use these functions to get information on the functions available in a library that you have loaded:

```
libfunctions('libname')
libfunctionsview('libname')
```

The main difference is that `libfunctions` displays the information in the MATLAB Command Window (and you can assign its output to a variable), and `libfunctionsview` displays the information as a graphical display in a new window.

Listing Functions

To see what functions are available in the `libmx` library, use `libfunctions`, specifying the library filename as the only argument. Note that you can use the MATLAB command syntax (with no parentheses or quotes required) when specifying no output variables:

```
libfunctions libmx

Functions in library libmx:

mxAddField               mxGetFieldNumber  mxIsLogicalScalarTrue
mxArrayToString          mxGetImagData     mxIsNaN
mxCalcSingleSubscript    mxGetInf          mxIsNumeric
mxCalloc                 mxGetIr           mxIsObject
mxClearScalarDoubleFlag  mxGetJc           mxIsOpaque
mxCreateCellArray        mxGetLogicals     mxIsScalarDoubleFlagSet
       .                        .                 .
```

```
        .                   .                   .
        .                   .                   .
```

To list the functions along with their signatures, use the `-full` switch with `libfunctions`. This shows the MATLAB syntax for calling functions written in C. The data types used in the argument lists and return values match MATLAB types, not C types. See the section "Data Conversion" on page 2-15 for more information on these data types.

```
libfunctions libmx -full

Functions in library libmx:

[int32, MATLAB array, cstring] mxAddField(MATLAB array, cstring)
[cstring, MATLAB array] mxArrayToString(MATLAB array)
[int32, MATLAB array, int32Ptr] mxCalcSingleSubscript(MATLAB array, int32, int32Ptr)
lib.pointer mxCalloc(uint32, uint32)
MATLAB array mxClearScalarDoubleFlag(MATLAB array)
[MATLAB array, int32Ptr] mxCreateCellArray(int32, int32Ptr)
MATLAB array mxCreateCellMatrix(int32, int32)
        .
        .
        .
```

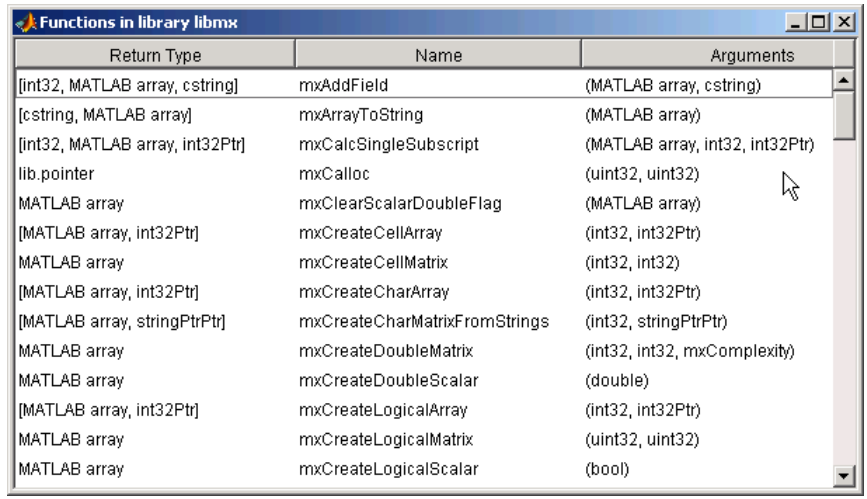
Viewing Functions in a GUI Interface

The `libfunctionsview` function creates a new window that displays all of the functions defined in a specific library. For each method, the following information is shown.

Heading	Description
Return Type	Data types that the method returns
Name	Function name
Arguments	Valid data types for input arguments
Inherited From	Not relevant for shared library functions

The following command opens the window shown below for the `libmx` library:

```
libfunctionsview libmx
```



As was true for the `libfunctions` function, the data types displayed here are MATLAB types. See the section “Data Conversion” on page 2-15 for more information on these data types.

Invoking Library Functions

Once a shared library has been loaded into MATLAB, use the `calllib` function to call any of the functions from that library. Specify the library name, function name, and any arguments that get passed to the function:

```
calllib('libname', 'funcname', arg1, ..., argN)
```

This example calls functions from the `libmx` library to test the value stored in `y`.

```
hfile = [matlabroot '\extern\include\matrix.h'];
loadlibrary('libmx', hfile)

y = rand(4, 7, 2);

calllib('libmx', 'mxGetNumberOfElements', y)
ans =
    56

calllib('libmx', 'mxGetClassID', y)
ans =
   mxDOUBLE_CLASS
```

See the section “Passing Arguments” on page 2-10 for information on how to define the argument types.

Passing Arguments

In this section...

Displaying MATLAB Syntax for Library Functions

A sample external library called `shrlibsample` is supplied with MATLAB. The library file for the `shrlibsample` library resides in the directory `extern\examples\shrlib`. MATLAB selects the appropriate version for your platform. The `mexext` function returns the file extension that is used on your platform. See the `mex` function for a list of all extensions used by MATLAB.

To use the `shrlibsample` library, you first need to either add this directory to your MATLAB path with the command

```
addpath([matlabroot '\extern\examples\shrlib'])
```

or make this your current working directory with the command,

```
cd([matlabroot '\extern\examples\shrlib'])
```

The following example loads the `shrlibsample` library and displays the MATLAB syntax for calling functions that come with the library:

```
loadlibrary shrlibsample shrlibsample.h
libfunctions shrlibsample -full

Functions in library shrlibsample:

[double, doublePtr] addDoubleRef(double, doublePtr, double)
double addMixedTypes(int16, int32, double)
[double, c_structPtr] addStructByRef(c_structPtr)
double addStructFields(c_struct)
```

```
c_structPtrPtr allocateStruct(c_structPtrPtr)
voidPtr deallocateStruct(voidPtr)
doublePtr multDoubleArray(doublePtr, int32)
[lib.pointer, doublePtr] multDoubleRef(doublePtr)
int16Ptr multiplyShort(int16Ptr, int32)
cstring readEnum(Enum1)
[cstring, cstring] stringToUpper(cstring)
```

While these functions are all written in C, `libfunctions` with the `full` option displays the MATLAB syntax for calling the C functions.

See "Primitive Types" on page 2-15 for a table of extended MATLAB data types (e.g., `doublePtr`).

General Rules for Passing Arguments

There are some important things to note about the input and output arguments shown in the function listing of the previous section:

- Many of the arguments (like `int32`, `double`) are very similar to their C counterparts. In these cases, you need only to pass in the MATLAB data types shown for these arguments.
- Some arguments in C (like `**double`, or predefined structures), are quite different from standard MATLAB data types. In these cases, you usually have the option of either passing a standard MATLAB type and letting MATLAB convert it for you, or converting the data yourself using MATLAB functions like `libstruct` and `libpointer`. See the next section on "Data Conversion" on page 2-15.
- C input arguments are often passed by reference. Although MATLAB does not support passing by reference, you can create MATLAB arguments that are compatible with C references. In the listing shown above, these are the arguments with names ending in `Ptr` and `PtrPtr`. See "Creating References" on page 2-26.
- C functions often return data in input arguments passed by reference. MATLAB creates additional output arguments to return these values. Note that in the listing in the previous section, all input arguments ending in `Ptr` or `PtrPtr` are also listed as outputs.

General Guidelines for Passing Arguments

- Nonscalar arguments must be declared as passed by reference in the library functions.
- If the library function uses single subscript indexing to reference a two-dimensional matrix, keep in mind that C programs process matrices row by row while MATLAB processes matrices by column. To get C behavior from the function, transpose the input matrix before calling the function, and then transpose the function output.
- When passing an array having more than two dimensions, the shape of the array might be altered by MATLAB. To ensure that the array retains its shape, store the size of the array before making the call, and then use this same size to reshape the output array to the correct dimensions:

```
vs = size(vin)              % Store the original dimensions
vs =
     2     5     2

vout = calllib('shrlibsample','multDoubleArray', vin, 20);

size(vout)                  % Dimensions have been altered
ans =
     2    10

vout = reshape(vout, vs);   % Restore the array to 2-by-5-by-2

size(vout)
ans =
     2     5     2
```

- Use an empty array, `[]`, to pass a `NULL` parameter to a library function that supports optional input arguments. This is valid only when the argument is declared as a `Ptr` or `PtrPtr` as shown by `libfunctions` or `libfunctionsview`.

Passing References

Many functions in external libraries use arguments that are passed by reference. To enable you to interact with these functions, MATLAB passes what is called a *pointer object* to these arguments. This should not be confused

with “passing by reference” in the typical sense of the term. See “Creating References” on page 2-26 for more information.

Passing a NULL Pointer

You can create a `NULL` pointer to pass to library functions in the following ways:

- Pass a `0` as the argument.
- Use the `libpointer` function:

```
p = libpointer; % no arguments

p = libpointer('string') % string argument

p = libpointer('stringPtr') % pointer to a string argument
```

- Use the `libstruct` function:

```
p = libstruct; % no arguments
```

Using C++ Libraries

The `loadlibrary` function cannot load C++ libraries unless you define the function prototypes as `extern "C"` in the library header file. For example, the following function prototype from the file `mex.h` shows the syntax to use for each function:

```
#ifdef __cplusplus
extern "C" {
#endif
void mexFunction(
    int           nlhs,
    mxArray       *plhs[],
    int           nrhs,
    const mxArray *prhs[]
);
#ifdef __cplusplus
}
#endif
```

Another approach to using C++ libraries is to generate a prototype M-file that contain aliases for the mangled C++ function names. Use the original (premangled) function names as the aliases for the C++ functions. Generate the M-file with the `mfilename` option of the `loadlibrary` function and then determine which functions in the library you want to make available by defining aliases for these functions.

Data Conversion

In this section...

When to Convert Manually

Under most conditions, data passed to and from external library functions is automatically converted by MATLAB to the data type expected by the external function. However, you may choose, at times, to convert some of your argument data manually. Circumstances under which you might find this advantageous are

- When you pass the same piece of data to a series of library functions, it probably makes more sense to convert it once manually at the start rather than having MATLAB convert it automatically on every call. This saves time on unnecessary copy and conversion operations.
- When you pass large structures, you can save memory by creating MATLAB structures that match the shape of the C structures used in the external function instead of using generic MATLAB structures. The `libstruct` function creates a MATLAB structure modeled from a C structure taken from the library. See "Structures" on page 2-20 for more information.
- When an argument to an external function uses more than one level of referencing (e.g., `double **`), you must pass a reference that you have constructed using the `libpointer` function rather than relying on MATLAB to convert the data type automatically.

Primitive Types

All standard scalar C data types are supported by the shared library interface. These are shown in the two tables below along with their equivalent MATLAB

types. MATLAB uses the type from the right column for arguments having the C type shown in the left column.

The second table shows *extended* MATLAB types in the right column. These are instances of the MATLAB `lib.pointer` class rather than standard MATLAB data types. See "Creating References" on page 2-26 for information on the `lib.pointer` class.

MATLAB Primitive Types

C Type (on a 32-bit computer)	Equivalent MATLAB Type
`char`, `byte`	`int8`
`unsigned char`, `byte`	`uint8`
`short`	`int16`
`unsigned short`	`uint16`
`int`, `long`	`int32`
`unsigned int`, `unsigned long`	`uint32`
`float`	`single`
`double`	`double`
`char *`	`cstring (1xn char array)`
`*char[]`	cell array of strings

MATLAB Extended Types

C Type (on a 32-bit computer)	Equivalent MATLAB Type
`integer pointer types (int *)`	`(u)int(`*`size`*`)Ptr`
Null-terminated string passed by value	`cstring`
Null-terminated string passed by reference (from a `libpointer` only)	`stringPtr`
Array of pointers to strings (or one `**char`)	`stringPtrPtr`

MATLAB Extended Types (Continued)

C Type (on a 32-bit computer)	Equivalent MATLAB Type
Matrix of signed bytes	`int8Ptr`
`float *`	`singlePtr`
`double *`	`doublePtr`
`mxArray *`	`MATLAB array`
`void *`	`voidPtr`
`void **`	`voidPtrPtr`
`type` `**`	Same as *`type`*`Ptr` with an added `Ptr` (e.g., `double **` is `doublePtrPtr`)

Converting to Other Primitive Types

For primitive types, MATLAB automatically converts any argument to the data type expected by the external function. This means that you can pass a `double` to a function that expects to receive a `byte` (8-bit integer) and MATLAB does the conversion for you.

For example, the C function shown here takes arguments that are of types `short`, `int`, and `double`:

```
double addMixedTypes(short x, int y, double z)
{
   return (x + y + z);
}
```

You can simply pass all of the arguments as type `double` from MATLAB. MATLAB determines what type of data is expected for each argument and performs the appropriate conversions:

```
calllib('shrlibsample', 'addMixedTypes', 127, 33000, pi)
ans =
  3.3130e+004
```

Converting to a Reference

MATLAB also automatically converts an argument passed by value into an argument passed by reference when the external function prototype defines the argument as a reference. So a MATLAB `double` argument passed to a function that expects `double *` is converted to a `double` reference by MATLAB.

`addDoubleRef` is a C function that takes an argument of type `double *`:

```
double addDoubleRef(double x, double *y, double z)
{
    return (x + *y + z);
}
```

Call the function with three arguments of type `double`, and MATLAB handles the conversion:

```
calllib('shrlibsample', 'addDoubleRef', 1.78, 5.42, 13.3)
ans =
   20.5000
```

Strings

For arguments that require `char *`, you can pass a MATLAB string (i.e., character array).

For example, the following C function takes a `char *` input argument:

```
char* stringToUpper(char *input) {
   char *p = input;

   if (p != NULL)
      while (*p!=0)
         *p++ = toupper(*p);
   return input;
}
```

`libfunctions` shows that you can use a MATLAB `cstring` for this input.

```
libfunctions shrlibsample -full
          .
```

```
        .
    [cstring, cstring] stringToUpper(cstring)
```

Create a MATLAB character array, `str`, and pass it as the input argument:

```
str = 'This was a Mixed Case string';
calllib('shrlibsample', 'stringToUpper', str)
ans =
   THIS WAS A MIXED CASE STRING
```

Note Although the input argument that MATLAB passes to `stringToUpper` resembles a reference to type `char`, it is not a true reference data type. That is, it does not contain the address of the MATLAB character array, `str`. So, when the function executes, it returns the correct result but does not modify the value in `str`. If you now examine `str`, you find that its original value is unchanged:

```
str

str =

  This was a Mixed Case string
```

Enumerated Types

For arguments defined as C enumerated types, you can pass either the enumeration string or its integer equivalent.

The `readEnum` function from the `shrlibsample` library returns the enumeration string that matches the argument passed in. Here is the `Enum1` definition and the `readEnum` function in C:

```
enum Enum1 {en1 = 1, en2, en4 = 4} TEnum1;

char* readEnum(TEnum1 val) {
   switch (val) {
   case 1 :return "You chose en1";
   case 2: return "You chose en2";
   case 4: return "You chose en4";
   default : return "enum not defined";
   }
}
```

In MATLAB, you can express an enumerated type as either the enumeration string or its equivalent numeric value. The `TEnum1` definition above declares enumeration `en4` to be equal to `4`. Call `readEnum` first with a string:

```
calllib('shrlibsample', 'readEnum', 'en4')
ans =
   You chose en4
```

Now call it with the equivalent numeric argument, `4`:

```
calllib('shrlibsample', 'readEnum', 4)
ans =
   You chose en4
```

Structures

For library functions that take structure arguments, you need to pass structures that have field names that are the same as those in the structure definitions in the library. To determine the names and also the data types of structure fields, you can:

- Consult the documentation that was provided with the library.
- Look for the structure definition in the header file that you used to load the library into MATLAB.

When you create and initialize the structure, you do not necessarily have to match the data types of numeric fields. MATLAB converts to the correct numeric type for you when you make the call using the `calllib` function.

Finding Field Names From MATLAB

You can also determine the field names of an externally defined structure from within MATLAB using the following procedure:

1. Use `libfunctionsview` to display the signatures for all functions in the library. `libfunctionsview` shows the names of the structures used by each function. For example, when you type

   ```
   libfunctionsview shrlibsample
   ```

   MATLAB opens a new window displaying function signatures for the `shrlibsample` library. The line showing the `addStructFields` function reads:

   ```
   double addStructFields (c_struct)
   ```

2. If the function you are using takes a structure argument, get the structure type from the `libfunctionsview` display, and invoke the `libstruct` function on that type. `libstruct` returns an object that is modeled on the structure as defined in the library:

   ```
   s = libstruct('c_struct');
   ```

3. Get the names of the structure fields from the object returned by `libstruct`:

   ```
   get(s)
       p1: 0
       p2: 0
       p3: 0
   ```

4. Initialize the fields to the values you want to pass to the library function and make the call using `calllib`:

   ```
   s.p1 = 476;   s.p2 = -299;   s.p3 = 1000;
   calllib('shrlibsample','addStructFields',s);
   ```

Specifying Structure Field Names

Here are a few general guidelines that apply to structures passed to external library functions:

- These structures can contain fewer fields than defined in the library structure. MATLAB sets any undefined or uninitialized fields to zero.
- Any structure field name that you use must match a field name in the structure definition. Structure names are case sensitive.
- Structures cannot contain additional fields that are not in the library structure definition.

Passing a MATLAB Structure

As with other data types, when an external function takes a structure argument (such as a C structure), you can pass a MATLAB structure to the function in its place. Structure field names must match field names defined in the library, but data types for numeric fields do not have to match. MATLAB converts each numeric field of the MATLAB structure to the correct data type.

Example of Passing a MATLAB Structure. The sample shared library, `shrlibsample`, defines the following C structure and function:

```
struct c_struct {
    double p1;
    short p2;
    long  p3;
};

double addStructFields(struct c_struct st)
{
    double t = st.p1 + st.p2 + st.p3;
    return t;
}
```

The following code passes a MATLAB structure, `sm`, with three `double` fields to `addStructFields`. MATLAB converts the fields to the `double`, `short`, and `long` data types defined in the C structure, `c_struct`.

```
sm.p1 = 476;   sm.p2 = -299;   sm.p3 = 1000;

calllib('shrlibsample', 'addStructFields', sm)
ans =
        1177
```

Passing a libstruct Object

When you pass a structure to an external function, MATLAB makes sure that the structure being passed matches the library's definition for that structure type. It must contain all the necessary fields defined for that type and each field must be of the expected data type. For any fields that are missing in the structure being passed, MATLAB creates an empty field of that name and initializes its value to zero. For any fields that have a data type that doesn't match the structure definition, MATLAB converts the field to the expected type.

When working with small structures, it is efficient enough to have MATLAB do this work for you. You can pass the original MATLAB structure with `calllib` and let MATLAB handle the conversions automatically. However, when working with repeated calls that pass one or more large structures, it may be to your advantage to convert the structure manually before making any calls to external functions. In this way, you save processing time by converting the structure data only once at the start rather than at each function call. You can also save memory if the fields of the converted structure take up less space than the original MATLAB structure.

Preconverting a MATLAB Struct with libstruct. You can convert a MATLAB structure to a C-like structure derived from a specific type definition in the library in one step. Call the `libstruct` function, passing in the name of the structure type from the library, and the original structure from MATLAB. The syntax for `libstruct` is

```
s = libstruct('structtype', mlstruct)
```

The value `s` returned by this function is called a *libstruct object*. Although it is truly a MATLAB object, it handles much like a MATLAB structure. The fields of this new "structure" are derived from the external structure type specified by `structtype` in the syntax above.

For example, to convert a MATLAB structure, `sm`, to a `libstruct` object, `sc`, that is derived from the `c_struct` structure type, use

```
sm.p1 = 476;   sm.p2 = -299;   sm.p3 = 1000;
sc = libstruct('c_struct', sm);
```

The original structure, `sm`, has fields that are all of type `double`. The object, `sc`, returned from the `libstruct` call has fields that match the `c_struct` structure type. These fields are `double`, `short`, and `long`.

Note You can only use `libstruct` on scalar structures.

Creating an Empty libstruct Object. You can also create an empty libstruct object by calling `libstruct` with only the `structtype` argument. This constructs an object with all the required fields and with each field initialized to zero.

```
s = libstruct('structtype')
```

libstruct Requirements for Structures. When converting a MATLAB structure to a libstruct object, the structure to be converted must adhere to the same guidelines that were documented for MATLAB structures passed directly to external functions. See “Specifying Structure Field Names” on page 2-21.

Using the Structure as an Object

The value returned by `libstruct` is not a true MATLAB structure. It is actually an instance of a class called `lib.c_struct`, as seen by examining the output of `whos`:

```
whos sc
  Name      Size                    Bytes  Class

sc         1x1                           lib.c_struct
sm         1x1                       396  struct array

Grand total is 7 elements using 396 bytes
```

Determining the Size of a lib.c_struct Object. You can use the `lib.c_struct` class method `structsize` to obtain the size of a `lib.c_struct` object:

```
sc.structsize
ans =
  16
```

Accessing lib.c_struct Fields. The fields of this structure are implemented as properties of the `lib.c_struct` class. You can read and modify any of these fields using the MATLAB object-oriented functions, `set` and `get`:

```
sc = libstruct('c_struct');

set(sc, 'p1', 100, 'p2', 150, 'p3', 200);

get(sc)
    p1: 100
    p2: 150
    p3: 200
```

You can also read and modify the fields by simply treating them like any other MATLAB structure fields:

```
sc.p1 = 23;

sc.p1
ans =
   23
```

Example of Passing a libstruct Object

Repeat the `addStructFields` example, this time converting the structure to one of type `c_struct` before calling the function:

```
sm.p1 = 476;   sm.p2 = -299;   sm.p3 = 1000;
sc = libstruct('c_struct', sm);

get(sc)
    p1: 476
    p2: -299
```

```
    p3: 1000
```

Now call the function, passing the structure `sc`:

```
calllib('shrlibsample', 'addStructFields', sc)
ans =
    1177
```

Note When passing manually converted structures, the structure passed must be of the same type as that used by the external function. For example, you cannot pass a structure of type `records` to a function that expects type `c_struct`.

Creating References

You can pass most arguments to an external function by value, even when the prototype for that function declares the argument to be a reference. The `calllib` function uses the header file to determine how to convert the function arguments.

There are times, however, when it is useful to pass MATLAB arguments that are the equivalent of C references:

- You want to modify the data in the input arguments.
- You are passing large amounts of data, and you don't want MATLAB to make copies of the data.
- The library is going to store and use the pointer for a period of time so it is better to give the M-code control over the lifetime of the pointer object.

In the cases above, you should use `libpointer` to construct a pointer object of a specified type (for structures use `libstruct`).

Constructing a Reference with the libpointer Function

To construct a reference, use the function `libpointer` with this syntax:

```
p = libpointer('type', 'value')
```

To give an example, create a pointer `pv` to an `int16` value. In the first argument to `libpointer`, enter the `type` of pointer you are creating. The type is always the data type (`int16`, in this case) suffixed by the letters `Ptr`:

```
v = int16(485);
pv = libpointer('int16Ptr', v);
```

The value returned, `pv`, is actually an instance of a MATLAB class called `lib.pointer`. The `lib.pointer` class has the properties `Value` and `DataType`. You can read and modify these properties with the MATLAB `get` and `set` functions:

```
get(pv)
       Value: 485
    DataType: 'int16Ptr'
```

The `lib.pointer` class also has two methods, `setdatatype` and `reshape`, that are described in the next section, "Obtaining the Function's Return Values" on page 2-28:

```
methods(pv)

Methods for class lib.pointer:
   disp plus reshape setdatatype
```

Creating a Reference to a Primitive Type

Here is a simple example that illustrates how to construct and pass a pointer to type `double`, and how to interpret the output data. The function `multDoubleRef` takes one input that is a reference to a `double` and returns the same.

Here is the C function:

```
double *multDoubleRef(double *x)
{
     *x *= 5;
     return x;
}
```

Construct a reference, xp, to input data, x, and verify its contents:

```
x = 15;
xp = libpointer('doublePtr', x);

get(xp)
       Value: 15
    DataType: 'doublePtr'
```

Now call the function and check the results:

```
calllib('shrlibsample', 'multDoubleRef', xp);

get(xp, 'Value')
ans =
   75
```

Note It is important to note that reference xp is not a true pointer as it would be in a language like C. That is, even though it was constructed as a reference to x, it does not contain the address of x. So, when the function executes, it modifies the Value property of xp, but it does not modify the value in x. If you now examine x, you find that its original value is unchanged:

```
x

x =

     15
```

Obtaining the Function's Return Values. In the last example, the result of the function called from MATLAB could be obtained by examining the modified input reference. But this function also returns data in its output arguments that may be useful.

The MATLAB prototype for this function (returned by `libfunctions -full`) indicates that MATLAB returns two outputs. The first is an object of class `lib.pointer`; the second is the `Value` property of the `doublePtr` input argument:

```
libfunctions shrlibsample -full
   [lib.pointer, doublePtr] multDoubleRef(doublePtr)
```

Run the example once more, but this time check the output values returned:

```
x = 15;
xp = libpointer('doublePtr', x);

[xobj, xval] = calllib('shrlibsample', 'multDoubleRef', xp)
xobj =
   lib.pointer
xval =
    75
```

Like the input reference argument, the first output, `xobj`, is an object of class `lib.pointer`. You can examine this output, but first you need to initialize its data type and size as these factors are undefined when returned by the function. Use the `setdatatype` method defined by class `lib.pointer` to set the data type to `doublePtr` and the size to `1`-by-`1`. Once initialized, you can examine outputs.

The first output is `xobj`:

```
setdatatype(xobj, 'doublePtr', 1, 1)

get(xobj)
ans =
       Value: 75
    DataType: 'doublePtr'
```

The second output, `xval`, is a `double` copied from the `Value` of input `xp`.

Creating a Reference by Offsetting from an Existing libpointer. You can use the plus operator (`+`) to create a new pointer that is offset from an existing pointer by a scalar numeric value. Note that this operation applies only to pointer of numeric data types. For example, suppose you create a `libpointer` to the vector `x`:

```
x = 1:10;
xp = libpointer('doublePtr',x);
xp.Value
ans =

     1     2     3     4     5     6     7     8     9    10
```

You can now use the plus operator to create a new `libpointer` that is offset from the `xp`:

```
xp2 = xp+4;
xp2.Value

ans =

     5     6     7     8     9    10
```

Note that the new pointer (`xp2` in this example) is valid only as long as the original pointer exists.

Creating a Structure Reference

Creating a reference argument to a structure is not much different than using a reference to a primitive type. The function shown here takes a reference to a structure of type `c_struct` as its only input. It returns an output argument that is the sum of all fields in the structure. It also modifies the fields of the input argument:

```
double addStructByRef(struct c_struct *st)
{
    double t = st->p1 + st->p2 + st->p3;
    st->p1 = 5.5;
    st->p2 = 1234;
    st->p3 = 12345678;
    return t;
 }
```

Passing the Structure Itself. Although this function expects to receive a structure reference input, it is easier to pass the structure itself and let MATLAB do the conversion to a reference. This example passes a MATLAB structure, `sm`, to the function `addStructByRef`. MATLAB returns the correct value in the output, `x`, but does not modify the contents of the input, `sm`, since `sm` is not a reference:

```
sm.p1 = 476;   sm.p2 = -299;   sm.p3 = 1000;

x = calllib('shrlibsample', 'addStructByRef', sm)
x =
        1177
```

Passing a Structure Reference. The second part of this example passes the structure by reference. This time, the function receives a pointer to the structure and is then able to modify the structure fields.

```
sp = libpointer('c_struct', sm);
calllib('shrlibsample', 'addStructByRef', sp)
ans =
        1177

get(sp, 'Value')
ans =
    p1: 5.5000
    p2: 1234
    p3: 12345678
```

Passing a Pointer to the First Element of an Array

In cases where a function defines an input argument that is a pointer to the first element of a data array, the `calllib` function automatically passes an argument that is a pointer of the correct type to the first element of data in the MATLAB vector or matrix. For example, the following C function `sum` requires an argument that is a pointer to the first element of an array of shorts (`int16`).

Suppose you have the following variables defined in MATLAB:

```
Data = 1:100;
lp = libpointer(('int16Ptr',Data);
shortData = int16(Data);
```

The signature of the C function `sum` is:

```
int sum(int size, short* data);
```

All of the following statements work correctly and give the same answer:

```
summed_data = calllib('libname','sum',100,Data);
summed_data = calllib('libname','sum',100,shortData);
summed_data = calllib('libname','sum',100,lp);
```

Note that the `size` and `data` arguments must match. That is, length of the data vector must be equal to the specified size. For example:

```
% sum last 50 elements
summed_data = calllib('libname','sum',50,Data(50:100));
```

Creating a Void Pointer to a String

Suppose you want to create a `voidPtr` that points to a string as an input argument. In C, characters are represented as unsigned eight-bit integers. Therefore, you must first cast the string to this MATLAB type before creating a variable of type `voidPtr`.

You can create a variable of the correct type and value using `libpointer` as follows:

```
str = 'string variable';
vp = libpointer('voidPtr',[uint8(str) 0]);
```

To obtain the character string from the pointer, use

```
char(vp.Value)
ans =
string variable
```

Confirm the type of the pointer by accessing its `DataType` property:

```
vp.DataType
ans =
voidPtr
```

You can call a function that takes a `voidPtr` to a string as an input argument using the following syntax because MATLAB automatically converts an argument passed by value into an argument passed by reference when the external function prototype defines the argument as a reference:

```
func_name(uint8(str))
```

Note that while MATLAB converts the argument from a value to a reference, it must be of the correct type.

Memory Allocation for an External Library

In general, a valid memory address is passed each time you pass a MATLAB variable to a library function. You need to explicitly allocate memory only if the library provides a memory allocation function that you are required to use.

When to Use libpointer. You should use a `libpointer` object in cases where the library is going to store the pointer and access the buffer over a period of time. In these cases, you need to ensure that MATLAB has control over the lifetime of the buffer and to prevent copies of the data from being made. The following pseudo code is an example of asynchronous data acquisition that shows how to use `libpointer` in this type of situation.

Suppose an external library has the following functions:

```
AcquireData(int points, short *buffer)
IsAquistionDone(void)
```

First, create a pointer to a buffer of 1024 points:

```
BufferSize = 1024;
pBuffer = libpointer('int16Ptr',1:BufferSize);
```

Then, begin acquiring data and wait in a loop until it is done:

```
calllib('lib_name','AcquireData,BufferSize,pbuffer);
while (~calllib('lib_name','IsAcquisitionDone')
 pause(0.1)
end
```

The following statement reads the data in the buffer:

```
result = pBuffer.Value;
```

When the library is done with the buffer, `clear` the MATLAB variable:

```
clear pBuffer
```

Reference Pointers

Arguments that have more than one level of referencing (e.g., `uint16 **`) are referred to here as reference pointers. In MATLAB, these argument types are named with the suffix `PtrPtr` (for example, `uint16PtrPtr`). See the output of `libfunctionsview` or `methods -full` for examples of this type.

When calling a function that takes a reference pointer argument, you can use a reference argument instead and MATLAB converts it to the reference pointer. For example, the external `allocateStruct` function expects a `c_structPtrPtr` argument:

```
libfunctions shrlibsample -full
   c_structPtrPtr allocateStruct(c_structPtrPtr)
```

Here is the C function:

```
void allocateStruct(struct c_struct **val)
{
    *val=(struct c_struct*) malloc(sizeof(struct c_struct));
    (*val)->p1 = 12.4;
    (*val)->p2 = 222;
    (*val)->p3 = 333333;
}
```

Although the prototype says that a `c_structPtrPtr` is required, you can use a `c_structPtr` and let MATLAB do the second level of conversion. Create a reference to an empty structure argument and pass it to `allocateStruct`:

```
sp = libpointer('c_structPtr');
calllib('shrlibsample', 'allocateStruct', sp)

get(sp)
ans =
       Value: [1x1 struct]
    DataType: 'c_structPtr'

get(sp, 'Value')
ans =
    p1: 12.4000
    p2: 222
    p3: 333333
```

When you are done, return the memory that you had allocated:

```
calllib('shrlibsample', 'deallocateStruct', sp)
```

3

Calling C and Fortran Programs from MATLAB

Although MATLAB is a complete, self-contained environment for programming and manipulating data, it is often useful to interact with data and programs external to the MATLAB environment. MATLAB provides an interface to external programs written in the C and Fortran languages.

Introducing MEX-Files

In this section...

What are MEX-Files

You can call your own C or Fortran subroutines from MATLAB as if they were built-in functions. MATLAB callable C and Fortran programs are referred to as MEX-files. MEX-files are dynamically linked subroutines that the MATLAB interpreter can automatically load and execute.

MEX-files have several applications:

- Large pre-existing C and Fortran programs can be called from MATLAB without having to be rewritten as M-files.
- Bottleneck computations that do not run fast enough in MATLAB can be recoded in C or Fortran for efficiency.

MEX-files are not appropriate for all applications. MATLAB is a high-productivity system whose specialty is eliminating time-consuming, low-level programming in compiled languages like Fortran or C. In general, most programming should be done in MATLAB. Don't use the MEX facility unless your application requires it.

MATLAB supports MEX-files created in C++, with some limitations. For more information, see "Creating C++ MEX-Files" on page 4-9.

Using MEX-Files

MEX-files are subroutines produced from C, C++, or Fortran source code. They behave just like M-files and built-in functions. While M-files have a platform-independent extension, `.m`, MATLAB identifies MEX-files by

platform-specific extensions. This table lists the platform-specific extensions for MEX-files.

MEX-File Extensions

Platform	MEX-File Extension
Linux (32-bit)	`mexglx`
Linux x86-64	`mexa64`
Macintosh (PPC)	`mexmac`
Macintosh (Intel)	`mexmaci`
64-bit Solaris SPARC	`mexs64`
Windows (32-bit)	`mexw32`
Windows x64	`mexw64`

You call MEX-files exactly as you call any M-function. For example, on a Windows platform, there is a MEX-file called `histc.mexw32` in one of the MATLAB toolbox directories (*`matlabroot`*`\toolbox\matlab\datafun`) that performs a histogram count. The file `histc.m` contains the help text documentation. When you call `histc` from MATLAB, the dispatcher looks through the list of directories on the MATLAB search path. It scans each directory looking for the first occurrence of a file named `histc` with either the corresponding filename extension from the table or `.m`. When it finds one, it loads the file and executes it. MEX-files take precedence over M-files when like-named files exist in the same directory. However, help text documentation still reads from the `.m` file.

You cannot use a MEX-file on a platform if it was compiled on a different platform. You must recompile the source code on the platform for which you wish to use the MEX-file.

MEX-File Placement

For MATLAB to be able to execute your C or Fortran functions, you must either put the compiled MEX-files containing those functions in a directory on the MATLAB path, or run MATLAB in the directory in which they reside.

Functions in the current working directory are found before functions on the MATLAB path.

Type `path` to see what directories are currently included in your path. You can add new directories to the path either by using the `addpath` function, or by selecting **File > SetPath** to edit the path.

If you are using a Windows operating system and any of your MEX-files are on a network drive, be aware that file servers do not always report directory and file changes correctly. If you change any MEX-files that are on a network drive and you find that MATLAB is not using your latest changes, you can force MATLAB to look for the correct version of the file by changing directories away from and then back to the directory in which the files reside.

The Distinction Between mx and mex Prefixes

Routines in the API that are prefixed with `mx` allow you to create, access, manipulate, and destroy `mxArrays`. Routines prefixed with `mex` perform operations back in the MATLAB environment.

mx Routines

The array access and creation library provides a set of array access and creation routines for manipulating MATLAB arrays. These subroutines, which are fully documented in the online API reference pages, always start with the prefix `mx`. For example, `mxGetPi` retrieves the pointer to the imaginary data inside the array.

Although most of the routines in the array access and creation library let you manipulate the MATLAB array, there are two exceptions—the IEEE routines and memory management routines. For example, `mxGetNaN` returns a `double`, not an `mxArray`.

mex Routines

Routines that begin with the `mex` prefix perform operations back in the MATLAB environment. For example, the `mexEvalString` routine evaluates a string in the MATLAB workspace.

Note `mex` routines are only available in MEX-functions.

MATLAB Data

In this section...

The MATLAB Array

The MATLAB language works with only a single object type: the MATLAB array. All MATLAB variables, including scalars, vectors, matrices, strings, cell arrays, structures, and objects, are stored as MATLAB arrays. In C, the MATLAB array is declared to be of type `mxArray`. The `mxArray` structure contains, among other things:

- Its type
- Its dimensions
- The data associated with this array
- If numeric, whether the variable is real or complex
- If sparse, its indices and nonzero maximum elements
- If a structure or object, the number of fields and field names

Data Storage

All MATLAB data is stored columnwise, which is how Fortran stores matrices. MATLAB uses this convention because it was originally written in Fortran. For example, given the matrix

```
a=['house'; 'floor'; 'porch']
a =
   house
   floor
   porch
```

its dimensions are

```
size(a)
ans =
     3     5
```

and its data is stored as

Data Types in MATLAB

Complex Double-Precision Matrices

The most common data type in MATLAB is the complex double-precision, nonsparse matrix. These matrices are of type `double` and have dimensions `m`-by-`n`, where `m` is the number of rows and `n` is the number of columns. The data is stored as two vectors of double-precision numbers—one contains the real data and one contains the imaginary data. The pointers to this data are referred to as `pr` (pointer to real data) and `pi` (pointer to imaginary data), respectively. A real-only, double-precision matrix is one whose `pi` is `NULL`.

Numeric Matrices

MATLAB also supports other types of numeric matrices. These are single-precision floating-point and 8-, 16-, and 32-bit integers, both signed and unsigned. The data is stored in two vectors in the same manner as double-precision matrices.

Logical Matrices

The logical data type represents a logical `true` or `false` state using the numbers `1` and `0`, respectively. Certain MATLAB functions and operators return logical `1` or logical `0` to indicate whether a certain condition was found to be true or not. For example, the statement `(5 * 10) > 40` returns a logical 1 value.

MATLAB Strings

MATLAB strings are of type `char` and are stored the same way as unsigned 16-bit integers except there is no imaginary data component. Unlike C, MATLAB strings are not null terminated.

Cell Arrays

Cell arrays are a collection of MATLAB arrays where each `mxArray` is referred to as a cell. This allows MATLAB arrays of different types to be stored together. Cell arrays are stored in a similar manner to numeric matrices, except the data portion contains a single vector of pointers to `mxArrays`. Members of this vector are called cells. Each cell can be of any supported data type, even another cell array.

Structures

A 1-by-1 structure is stored in the same manner as a 1-by-`n` cell array where `n` is the number of fields in the structure. Members of the data vector are called fields. Each field is associated with a name stored in the `mxArray`.

Objects

Objects are stored and accessed the same way as structures. In MATLAB, objects are named structures with registered methods. Outside MATLAB, an object is a structure that contains storage for an additional classname that identifies the name of the object.

Multidimensional Arrays

MATLAB arrays of any type can be multidimensional. A vector of integers is stored where each element is the size of the corresponding dimension. The storage of the data is the same as matrices.

Empty Arrays

MATLAB arrays of any type can be empty. An empty `mxArray` is one with at least one dimension equal to zero. For example, a double-precision `mxArray` of type `double`, where `m` and `n` equal 0 and `pr` is `NULL`, is an empty array.

Sparse Matrices

Sparse matrices have a different storage convention from that of full matrices in MATLAB. The parameters `pr` and `pi` are still arrays of double-precision numbers, but these arrays contain only nonzero data elements. There are three additional parameters: `nzmax`, `ir`, and `jc`.

- `nzmax` is an integer that contains the length of `ir`, `pr`, and, if it exists, `pi`. It is the maximum possible number of nonzero elements in the sparse matrix.
- `ir` points to an integer array of length `nzmax` containing the row indices of the corresponding elements in `pr` and `pi`.
- `jc` points to an integer array of length `n+1`, where `n` is the number of columns in the sparse matrix. The `jc` array contains column index information. If the `j`th column of the sparse matrix has any nonzero elements, `jc[j]` is the index in `ir` and `pr` (and `pi` if it exists) of the first nonzero element in the `j`th column, and `jc[j+1] - 1` is the index of the last nonzero element in that column. For the `j`th column of the sparse matrix, `jc[j]` is the total number of nonzero elements in all preceding columns. The last element of the `jc` array, `jc[n]`, is equal to `nnz`, the number of nonzero elements in the entire sparse matrix. If `nnz` is less than `nzmax`, more nonzero entries can be inserted into the array without allocating additional storage.

Using Data Types

You can write MEX-files, MAT-file applications, and engine applications in C that accept any data type supported by MATLAB. In Fortran, only the creation of double-precision n-by-m arrays and strings are supported. You can treat C and Fortran MEX-files, once compiled, exactly like M-functions.

Caution MATLAB does not check the validity of MATLAB data structures created in C or Fortran using one of the `mx` functions (e.g., `mxCreateStructArray`). Using invalid syntax to create a MATLAB data structure can result in unexpected behavior in your C or Fortran program.

The explore Example

There is an example MEX-file included with MATLAB, called `explore`, that identifies the data type of an input variable. The source file for this example is in the *`matlabroot`*`/extern/examples/mex` directory, where *`matlabroot`* represents the top-level directory where MATLAB is installed on your system.

Note In platform-independent discussions that refer to directory paths, this book uses the UNIX convention. For example, a general reference to the `mex` directory is *`matlabroot`*`/extern/examples/mex`.

For example, typing

```
cd([matlabroot '/extern/examples/mex']);
x = 2;
explore(x);
```

produces this result

```
------------------------------------------------
Name: prhs[0]
Dimensions: 1x1
Class Name: double
------------------------------------------------
 (1,1) = 2
```

`explore` accepts any data type. Try using `explore` with these examples.

```
explore([1 2 3 4 5])
explore 1 2 3 4 5
explore({1 2 3 4 5})
explore(int8([1 2 3 4 5]))
explore {1 2 3 4 5}
explore(sparse(eye(5)))
explore(struct('name', 'Joe Jones', 'ext', 7332))
explore(1, 2, 3, 4, 5)
```

Building MEX-Files

In this section...

Compiler Requirements

Your installed version of MATLAB contains all the tools you need to work with the API. MATLAB includes a C compiler for the PC called Lcc, but does not include a Fortran compiler. If you choose to use your own C compiler, it must be an ANSI C compiler. Also, if you are working on a Microsoft Windows platform, your compiler must be able to create 32-bit windows dynamically linked libraries (DLL files).

MATLAB supports many compilers and provides preconfigured files, called options files, designed specifically for these compilers. The purpose of supporting this large collection of compilers is to provide you with the flexibility to use the tool of your choice. However, in many cases, you simply can use the provided Lcc compiler with your C code to produce your applications.

The MathWorks maintains a list of compilers supported by MATLAB at the following location on the Web:

```
http://www.mathworks.com/support/tech-notes/1600/1601.shtml
```

Note The MathWorks provides an option called `-setup` for the `mex` script that lets you easily choose or switch your compiler.

The following sections contain configuration information for creating MEX-files on UNIX and Windows systems. More detailed information about the `mex` script is provided in "Custom Building MEX-Files" on page 3-19.

In addition, there is a section on "Troubleshooting" on page 3-32, if you are having difficulties creating MEX-files.

Testing Your Configuration on UNIX

The quickest way to check if your system is set up properly to create MEX-files is by trying the actual process. There is C source code for an example, `yprime.c`, and its Fortran counterpart, `yprimef.F` and `yprimefg.F`, included in the *`matlabroot`*`/extern/examples/mex` directory, where *`matlabroot`* represents the top-level directory where MATLAB is installed on your system.

To compile and link the example source files, `yprime.c` or `yprimef.F` and `yprimefg.F`, on UNIX, you must first copy the file(s) to a local directory, and then change directory (`cd`) to that local directory.

At the MATLAB prompt, type

```
mex yprime.c
```

This uses the system compiler to create the MEX-file called `yprime` with the appropriate extension for your system.

You can now call `yprime` as if it were an M-function:

```
yprime(1,1:4)
ans =
     2.0000   8.9685   4.0000    -1.0947
```

To try the Fortran version of the sample program with your Fortran compiler, at the MATLAB prompt, type

```
mex yprimef.F yprimefg.F
```

In addition to running the `mex` script from the MATLAB prompt, you can also run the script from the system prompt.

Selecting a Compiler

To change your default compiler, you select a different options file. You can do this anytime by using the command

```
mex -setup
```

```
    Using the 'mex -setup' command selects an options file that is
    placed in ~/matlab and used by default for 'mex'. An options
    file in the current working directory or specified on the
    command line overrides the default options file in ~/matlab.

    Options files control which compiler to use, the compiler and
    link command options, and the runtime libraries to link
    against.

    To override the default options file, use the 'mex -f' command
    (see 'mex -help' for more information).

The options files available for mex are:

  1: matlabroot/bin/gccopts.sh :
         Template Options file for building gcc MEXfiles

  2: matlabroot/bin/mexopts.sh :
         Template Options file for building MEXfiles using the
          system ANSI compiler

Enter the number of the options file to use as your default
options file:
```

Select the proper options file for your system by entering its number and pressing **Enter**. If an options file doesn't exist in your MATLAB directory, the system displays a message stating that the options file is being copied to your user-specific `matlab` directory. If an options file already exists in your `matlab` directory, the system prompts you to overwrite it.

Note The `-setup` option creates a user-specific `matlab` directory in your individual home directory and copies the appropriate options file to the directory. (If the directory already exists, a new one is not created.) This `matlab` directory is used for your individual options files only; each user can have his or her own default options files (other MATLAB products may place options files in this directory). Do not confuse these user-specific `matlab` directories with the system `matlab` directory, where MATLAB is installed. To see the name of this directory on your machine, use the MATLAB command `prefdir`.

Using the setup option resets your default compiler so that the new compiler is used every time you use the `mex` script.

Testing Your Configuration on Windows

Before you can create MEX-files on the Windows platform, you must configure the default options file, `mexopts.bat`, for your compiler. The `-setup` option provides an easy way for you to configure the default options file. To configure or change the options file at anytime, run

```
mex -setup
```

from either the MATLAB or DOS command prompt.

Lcc Compiler

MATLAB includes a C compiler called Lcc that you can use to create C MEX-files. Help on using the Lcc compiler is available in a help file that ships with MATLAB. To view this file, type in the MATLAB command window

```
!matlabroot\sys\lcc\bin\wedit.hlp
```

replacing the term *`matlabroot`* with the path to the directory in which MATLAB is installed on your system. (Type `matlabroot` in the Command Window to get the path for this directory.)

Selecting a Compiler

The `mex` script uses the Lcc compiler by default if you do not have a C or C++ compiler of your own already installed on your system and you try to compile a C MEX-file. If you need to compile Fortran programs, you must supply your own supported Fortran compiler.

The `mex` script uses the filename extension to determine the type of compiler to use for creating your MEX-files. For example,

```
mex test1.F
```

uses your Fortran compiler and

```
mex test2.c
```

uses your C compiler.

On Systems without a Compiler. If you do not have your own C or C++ compiler on your system, the `mex` script automatically configures itself for the included Lcc compiler. So, to create a C MEX-file on these systems, you can simply enter

```
mex filename.c
```

This simple method of creating MEX-files works for the majority of users.

If using the included Lcc compiler satisfies your needs, you can skip ahead in this section to "Building the MEX-File on Windows" on page 3-16.

On Systems with a Compiler. On systems where there is a C, C++, or Fortran compiler, you can select which compiler you want to use. Once you choose your compiler, that compiler becomes your default compiler and you no longer have to select one when you compile MEX-files. To select a compiler or change to existing default compiler, use `mex -setup`.

This example shows the process of setting your default compiler to the Microsoft Visual C++ Version 6.0 compiler:

```
mex -setup

Please choose your compiler for building external interface (MEX)
```

```
files.

Would you like mex to locate installed compilers [y]/n? n

Select a compiler:
[1] Compaq Visual Fortran version 6.6
[2] Lcc C version 2.4
[3] Microsoft Visual C/C++ version 6.0

[0] None

Compiler: 3

Your machine has a Microsoft Visual C/C++ compiler located at
D:\Applications\Microsoft Visual Studio. Do you want to use this
compiler [y]/n? y

Please verify your choices:

Compiler: Microsoft Visual C/C++ 6.0
Location: C:\Program Files\Microsoft Visual Studio

Are these correct?([y]/n): y

The default options file:
"C:\WINNT\Profiles\username\ApplicationData\MathWorks\MATLAB\R1
3\mexopts.bat" is being updated from ...
```

If the specified compiler cannot be located, you are given the message:

```
The default location for compiler-name is directory-name,
but that directory does not exist on this machine.
Use directory-name anyway [y]/n?
```

Using the `setup` option sets your default compiler so that the new compiler is used every time you use the `mex` script.

Building the MEX-File on Windows

There is example C source code, `yprime.c`, and its Fortran counterpart, `yprimef.F` and `yprimefg.F`, included in the

matlabroot\extern\examples\mex directory, where *matlabroot* represents the top-level directory where MATLAB is installed on your system.

To compile and link the example source file on Windows, at the MATLAB prompt, type

```
cd([matlabroot '\extern\examples\mex'])
mex yprime.c
```

This should create the MEX-file called `yprime` with the `.mexw32` extension, which corresponds to the 32-bit Windows platform.

You can now call `yprime` as if it were an M-function:

```
yprime(1,1:4)
ans =
     2.0000    8.9685    4.0000    -1.0947
```

To try the Fortran version of the sample program with your Fortran compiler, switch to your Fortran compiler using `mex -setup`. Then, at the MATLAB prompt, type

```
cd([matlabroot '\extern\examples\mex'])
mex yprimef.F yprimefg.F
```

In addition to running the `mex` script from the MATLAB prompt, you can also run the script from the system prompt.

Specifying an Options File

You can use the `-f` option to specify an options file on either UNIX or Windows. To use the `-f` option, at the MATLAB prompt type

```
mex filename -f <optionsfile>
```

and specify the name of the options file along with its pathname.

There are several situations when it may be necessary to specify an options file every time you use the `mex` script. These include

- *(Windows and UNIX)* You want to use a different compiler (and not use the `-setup` option), or you want to compile MAT or engine stand-alone programs.
- *(UNIX)* You do not want to use the system C compiler.

Preconfigured Options Files

MATLAB includes some preconfigured options files that you can use with particular compilers. The options files are located in the directory *`matlabroot`*`\bin\win32\mexopts` on Windows, *`matlabroot`*`\bin\win64\mexopts` on Windows x64, and *`matlabroot`*`/bin` on UNIX, where *`matlabroot`* stands for the MATLAB root directory as returned by the `matlabroot` command. On Windows and Windows x64, the options files are named `*.bat`, where `*` stands for the compiler type and version. On UNIX, the options file is named `*opts.sh`, where `*` stands for `mex` or a specific compiler.

For a list of all the compilers supported by MATLAB, see the following location on the Web:

```
http://www.mathworks.com/support/tech-notes/1600/1601.shtml
```

Note The next section, "Custom Building MEX-Files" on page 3-19, contains specific information on how to modify options files for particular systems.

Custom Building MEX-Files

In this section...

Who Should Read this Chapter

In general, the defaults that come with MATLAB should be sufficient for building most MEX-files. Following are reasons that you might need more detailed information:

- You want to use an Integrated Development Environment (IDE), rather than the provided script, to build MEX-files.
- You want to create a new options file, for example, to use a compiler that is not directly supported.
- You want to exercise more control over the build process than the script uses.

The script, in general, uses two stages (or three, for Microsoft Windows) to build MEX-files. These are the compile stage and the link stage. In between these two stages, Windows compilers must perform some additional steps to prepare for linking (the prelink stage).

MEX Script Switches

The `mex` script has a set of switches (also called **options**) that you can use to modify the link and compile stages. The MEX Script Switches table lists the available switches and their uses. Each switch is available on both UNIX and Windows unless otherwise noted.

For customizing the build process, you should modify the options file, which contains the compiler-specific flags corresponding to the general compile, prelink, and link steps required on your system. The options file consists of a series of variable assignments; each variable represents a different logical piece of the build process.

MEX Script Switches

Switch	Function
`@<rsp_file>`	(Windows only) Include the contents of the text file `<rsp_file>` as command-line arguments to `mex`.
`-<arch>`	Build an output file for architecture `<arch>`. To determine the value for `<arch>`, type `computer('arch')` at the MATLAB Command Prompt on the target machine. Valid values for `<arch>` depend on the architecture of the build platform.
`-ada <sfcn.ads>`	Use this option to compile a Simulink® S-function written in Ada, where `<sfcn.ads>` is the Package Specification for the S-function. When this option is specified, only the `-v` (verbose) and `-g` (debug) options are relevant. All other options are ignored. For examples and information on supported compilers and other requirements, see `README` in the `simulink/ada/examples` directory.
`-argcheck`	(C functions only) Add argument checking. This adds code so arguments passed incorrectly to MATLAB API functions cause assertion failures.
`-c`	Compile only. Creates an object file, but not a MEX-file.
`-compatibleArrayDims`	Build a MEX-file using the MATLAB Version 7.2 array-handling API, which limits arrays to 2^31-1 elements. This option is the default. (See also the `-largeArrayDims` option.)

MEX Script Switches (Continued)

Switch	Function
`-cxx`	(UNIX only) Use the C++ linker to link the MEX-file if the first source file is in C and there are one or more C++ source or object files. This option overrides the assumption that the first source file in the list determines which linker to use.
`-D<name>`	Define a symbol name to the C preprocessor. Equivalent to a `#define <name>` directive in the source.
`-D<name>=<value>`	Define a symbol name and value to the C preprocessor. Equivalent to a `#define <name> <value>` directive in the source.
`-f <optionsfile>`	Specify location and name of options file to use. Overrides the `mex` default-options-file search mechanism.
`-fortran`	(UNIX only) Specify that the gateway routine is in Fortran. This option overrides the assumption that the first source file in the list determines which linker to use.
`-g`	Create a MEX-file containing additional symbolic information for use in debugging. This option disables the `mex` default behavior of optimizing built object code (see the `-O` option).
`-h[elp]`	Print help for `mex`.
`-I<pathname>`	Add `<pathname>` to the list of directories to search for `#include` files.
`-inline`	Inline matrix accessor functions (`mx*`). The generated MEX-function may not be compatible with future versions of MATLAB.
`-l<name>`	Link with object library. On Windows, `<name>` expands to `<name>.lib` or `lib<name>.lib` and on UNIX to `lib<name>.so` or `lib<name>.dylib`.

MEX Script Switches (Continued)

Switch	Function
`-L<directory>`	Add `<directory>` to the list of directories to search for libraries specified with the `-l` option. On UNIX systems, you must also set the run-time library path, as explained in "Setting Run-Time Library Path" on page 1-16.
`-largeArrayDims`	Build a MEX-file using the MATLAB large-array-handling API. This API can handle arrays with more than 2^31–1 elements when compiled on 64-bit platforms. (See also the `-compatibleArrayDims` option.)
`-n`	No execute mode. Print any commands that `mex` would otherwise have executed, but do not actually execute any of them.
`-O`	Optimize the object code. Optimization is enabled by default and by including this option on the command line. If the `-g` option appears without the `-O` option, optimization is disabled.
`-outdir <dirname>`	Place all output files in directory `<dirname>`.
`-output <resultname>`	Create MEX-file named `<resultname>`. The appropriate MEX-file extension is automatically appended. Overrides the default MEX-file naming mechanism.
`-setup`	Interactively specify the compiler options file to use as the default for future invocations of `mex` by placing it in the user profile directory (returned by the `prefdir` command). When this option is specified, no other command-line input is accepted.
`-U<name>`	Remove any initial definition of the C preprocessor symbol `<name>`. (Inverse of the `-D` option.)

MEX Script Switches (Continued)

Switch	Function
`-v`	Verbose mode. Print the values for important internal variables after the options file is processed and all command-line arguments are considered. Prints each compile step and final link step fully evaluated.
`<name>=<value>`	Supplement or override an options file variable for variable `<name>`. This option is processed after the options file is processed and all command line arguments are considered.

Default Options File on UNIX

The default MEX options file provided with MATLAB is located in *`matlabroot`*`/bin`. The `mex` script searches for an options file called `mexopts.sh` in the following order:

- The current directory
- The directory specified by *`matlabroot`*`/bin`
- The directory returned by the `prefdir` function

`mex` uses the first occurrence of the options file it finds. If no options file is found, `mex` displays an error message. You can directly specify the name of the options file using the `-f` switch.

On UNIX, the options file is written in the Bourne shell script language.

For specific information on the default settings for the MATLAB supported compilers, you can examine the options file in `fullfile(`*`matlabroot`*`, 'bin', 'mexopts.sh')`, or you can invoke the `mex` script in verbose mode (`-v`). Verbose mode prints the exact compiler options, prelink commands (if appropriate), and linker options used in the build process for each compiler. “Custom Building on UNIX” on page 3-24 gives an overview of the high-level build process.

Default Options File on Windows

The default MEX options file is placed in your `user profile` directory after you configure your system by running `mex -setup`. The `mex` script searches for an options file called `mexopts.bat` in the following order:

- The current directory
- The user profile directory (returned by the `prefdir` function)

`mex` uses the first occurrence of the options file it finds. If no options file is found, `mex` searches your machine for a supported C compiler and automatically configures itself to use that compiler. Also, during the configuration process, it copies the compiler's default options file to the `user profile` directory. If multiple compilers are found, you are prompted to select one.

On Windows, the options file is written in the Perl script language.

For specific information on the default settings for the MATLAB supported compilers, you can examine the options file, `mexopts.bat`, or you can invoke the `mex` script in verbose mode (`-v`). Verbose mode prints the exact compiler options, prelink commands, if appropriate, and linker options used in the build process for each compiler. "Custom Building on Windows" on page 3-27 gives an overview of the high-level build process.

The User Profile Directory

The Windows `user profile` directory is a directory that contains user-specific information such as desktop appearance, recently used files, and **Start** menu items. The `mex` and `mbuild` utilities store their respective options files, `mexopts.bat` and `compopts.bat`, which are created during the `-setup` process, in a subdirectory of your `user profile` directory, named `Application Data\MathWorks\MATLAB`.

Custom Building on UNIX

On UNIX systems, there are two stages in MEX-file building: compiling and linking.

Compile Stage

The compile stage must

- Add *matlabroot*/extern/include to the list of directories in which to find header files (-I*matlabroot*/extern/include).
- Define the preprocessor macro MATLAB_MEX_FILE (-DMATLAB_MEX_FILE).
- (C MEX-files only) Compile the source file, which contains version information for the MEX-file, *matlabroot*/extern/src/mexversion.c.

Link Stage

The link stage must

- Instruct the linker to build a shared library.
- If you link with your own libraries, set the run-time library path, which is explained in "Setting Run-Time Library Path" on page 1-16.
- Link all objects from compiled source files (including mexversion.c).
- (Fortran MEX-files only) Link in the precompiled versioning source file, *matlabroot*/extern/lib/$Arch/version4.o.
- Export the symbols mexFunction and mexVersion (these symbols represent functions called by MATLAB).

For Fortran MEX-files, the symbols are all lowercase and may have appended underscores. For specific information, invoke the mex script in verbose mode and examine the output.

Build Options

For customizing the build process, you should modify the options file. The options file contains the compiler-specific flags corresponding to the general steps outlined above. The options file consists of a series of variable assignments. Each variable represents a different logical piece of the build process. The options files provided with MATLAB are located in *matlabroot*/bin. The section "Default Options File on UNIX" on page 3-23, describes how the mex script looks for an options file.

To aid in providing flexibility, there are two sets of options in the options file that you can turn on and off with switches to the `mex` script. These sets of options correspond to building in *debug mode* and building in *optimization mode*. They are represented by the variables `DEBUGFLAGS` and `OPTIMFLAGS`, respectively, one pair for each *driver* that is invoked (`CDEBUGFLAGS` for the C compiler, `FDEBUGFLAGS` for the Fortran compiler, and `LDDEBUGFLAGS` for the linker; similarly for the `OPTIMFLAGS`):

- If you build in optimization mode (the default), the `mex` script includes the `OPTIMFLAGS` options in the compile and link stages.
- If you build in debug mode, the `mex` script includes the `DEBUGFLAGS` options in the compile and link stages. It does not include the `OPTIMFLAGS` options.
- You can include both sets of options by specifying both the optimization and debugging flags to the `mex` script (`-O` and `-g`, respectively).

Aside from these special variables, the `mex` options file defines the executable invoked for each of the three modes (C compile, Fortran compile, link) and the flags for each stage. You also can provide explicit lists of libraries that must be linked in to all MEX-files containing source files of each language.

The variable summary follows.

Variable	C Compiler	Fortran Compiler	Linker
Executable	`CC`	`FC`	`LD`
Flags	`CFLAGS`	`FFLAGS`	`LDFLAGS`
Optimization	`COPTIMFLAGS`	`FOPTIMFLAGS`	`LDOPTIMFLAGS`
Debugging	`CDEBUGFLAGS`	`FDEBUGFLAGS`	`LDDEBUGFLAGS`
Additional libraries	`CLIBS`	`FLIBS`	(none)

For specifics on the default settings for these variables, you can

- Examine the options file in *`matlabroot`*`/bin/mexopts.sh` (or the options file you are using), or

- Invoke the mex script in verbose mode.

Custom Building on Windows

There are three stages to MEX-file building for both C and Fortran on Windows: compiling, prelinking, and linking.

Compile Stage

For the compile stage, a mex options file must

- Set up paths to the compiler using the COMPILER (e.g., Watcom), PATH, INCLUDE, and LIB environment variables. If your compiler always has the environment variables set (e.g., in AUTOEXEC.BAT), you can comment them out in the options file.
- Define the name of the compiler, using the COMPILER environment variable, if needed.
- Define the compiler switches in the COMPFLAGS environment variable:
  - The switch to create a DLL is required for MEX-files.
  - For stand-alone programs, the switch to create an exe is required.
  - The -c switch (compile only; do not link) is recommended.
  - The switch to specify 8-byte alignment.
  - You can use any other switch specific to the environment.
- Define preprocessor macro, with -D, MATLAB_MEX_FILE is required.
- Set up optimizer switches and/or debug switches using OPTIMFLAGS and DEBUGFLAGS.
  - If you build in optimization mode (the default), the mex script includes the OPTIMFLAGS option in the compile stage.
  - If you build in debug mode, the mex script includes the DEBUGFLAGS options in the compile stage. It does not include the OPTIMFLAGS option.
  - You can include both sets of options by specifying both the optimization and debugging flags to the mex script (OPTIMFLAGS and DEBUGFLAGS, respectively).

Prelink Stage

The prelink stage dynamically creates import libraries to import the required function into the MEX, MAT, or engine file:

- All MEX-files link against `libmex.dll` (MEX library).
- MAT stand-alone programs link against `libmx.dll` (array access library) and `libmat.dll` (MAT-functions).
- Engine stand-alone programs link against `libmx.dll` (array access library) and `libeng.dll` for engine functions.

MATLAB and each DLL have corresponding `.def` files of the same names located in the *`matlabroot`*`\extern\include` directory.

Link Stage

For the link stage, a `mex` options file must

- Define the name of the linker in the `LINKER` environment variable.
- Define the `LINKFLAGS` environment variable that must contain
  - The switch to create a DLL for MEX-files, or the switch to create an `exe` for stand-alone programs.
  - Export of the entry point to the MEX-file as `mexFunction` for C or `MEXFUNCTION@16` for Fortran.
  - The import library (or libraries) created in the `PRELINK_CMDS` stage.
  - You can use any other link switch specific to the compiler.
- Set up the linking optimization and debugging switches `LINKOPTIMFLAGS` and `LINKDEBUGFLAGS`. Use the same conditions described in the “Compile Stage” on page 3-27.
- Define the link-file identifier in the `LINK_FILE` environment variable, if necessary. For example, Watcom uses `file` to identify that the name following is a file and not a command.
- Define the link-library identifier in the `LINK_LIB` environment variable, if necessary. For example, Watcom uses `library` to identify the name following is a library and not a command.

- Optionally, set up an output identifier and name with the output switch in the `NAME_OUTPUT` environment variable. The environment variable `MEX_NAME` contains the name of the first program in the command line. This must be set for `-output` to work. If this environment is not set, the compiler default is to use the name of the first program in the command line. Even if this is set, you can override it by specifying the `mex -output` switch.

Linking DLL Files to MEX-Files

To link a DLL to a MEX-file, list the DLL's `.lib` file on the command line.

Versioning MEX-Files

The `mex` script can build your MEX-file with a resource file that contains versioning and other essential information. The resource file is called `mexversion.rc` and resides in the `extern\include` directory. To support versioning, there are two new commands in the options files, `RC_COMPILER` and `RC_LINKER`, to provide the resource compiler and linker commands. It is assumed that

- If a compiler command is given, the compiled resource links to the MEX-file using the standard link command.
- If a linker command is given, the resource file links to the MEX-file after it is built using that command.

Compiling MEX-Files with the Microsoft Visual C++ IDE

Note This section provides information on how to compile MEX-files in the Microsoft Visual C++ (MSVC) IDE. It is not totally inclusive. This section assumes that you know how to use the IDE. If you need more information on using the MSVC IDE, refer to the corresponding Microsoft documentation.

To build MEX-files with the Microsoft Visual C++ integrated development environment:

1. Create a project and insert your MEX source files.

2. Add `mexversion.rc` from the MATLAB `include` directory, `matlab\extern\include`, to the project.

3. Create a `.def` file to export the MEX entry point. On the **Project** menu, click **Add New Item** and select **Module-Definition File (.def)**. For example:

```
LIBRARY MYFILE
EXPORTS mexFunction          <-- for a C MEX-file
   or
EXPORTS _MEXFUNCTION@16       <-- for a Fortran MEX-file
```

4. On the **Project** menu, click **Properties** for the project to open the property pages.

5. Under C/C++ General properties, add the MATLAB `include` directory, `matlab\extern\include`, as an additional include directory.

6. Under C/C++ Preprocessor properties, add `MATLAB_MEX_FILE` as a preprocessor definition.

7. Under Linker General properties, change the output file extension to `.mexw32` if you are building for a 32–bit platform or `.mexw64` if you are building for a 64–bit platform.

8. Locate the `.lib` files for the compiler you are using under *`matlabroot`*`\extern\lib\win32\microsoft` or *`matlabroot`*`\extern\lib\win64\microsoft`. Under Linker Input properties, add `libmx.lib`, `libmex.lib`, and `libmat.lib` as additional dependencies.

9. Under **Linker Input properties**, add the module definition (`.def`) file you created.

10. Under **Linker Debugging properties**, if you intend to debug the MEX-file using the IDE, specify that the build should generate debugging information. For more information about debugging, see “Debugging on Windows” on page 4-46.

If you are using a compiler other than the Microsoft Visual C/C++ compiler, the process for building MEX files is similar to that described above. In

step 4, locate the `.lib` files for the compiler you are using in a subdirectory of *`matlabroot`*`\extern\lib\win32` or *`matlabroot`*`\extern\lib\win64`. For example, if you are using the Borland C/C++ compiler, look in *`matlabroot`*`\extern\lib\win32\borland`.

Troubleshooting

In this section...

Configuration Issues

This section focuses on common problems that might occur when creating MEX-files.

Search Path Problem on Windows

Under Windows, if you move the MATLAB executable without reinstalling MATLAB, you may need to modify `mex.bat` to point to the new MATLAB location.

MATLAB Path Names Containing Spaces on Windows

If you have problems building MEX-files on Windows and there is a space in any of the directory names within the MATLAB path, either reinstall MATLAB into a path name that contains no spaces or rename the directory that contains the space. For example, if you install MATLAB under the `Program Files` directory, you may have difficulty building MEX-files with certain C compilers.

DLL Files Not on Path on Windows

MATLAB fails to load MEX-files if it cannot find all `.dll` files referenced by the MEX-file; the `.dll` files must be on the DOS path or in the same directory as the MEX-file. This is also true for third-party `.dll` files.

When this happens, MATLAB displays an error message of the following form:

```
??? Invalid MEX-file <mexfilename>:
The specified module could not be found.
```

On Windows, the third-party product Dependency Walker can be used to diagnose this problem. Dependency Walker is a free utility that scans any 32-bit or 64-bit Windows module and builds a hierarchical tree diagram of all dependent modules. For each module found, it lists all the functions that are exported by that module, and which of those functions are actually being called by other modules. You can download the Dependency Walker utility from the following Web site:

```
http://www.dependencywalker.com/
```

See the Technical Support solution 1-2RQL4L for information on using the Dependency Walker:

```
http://www.mathworks.com/support/solutions/data/1-2RQL4L.html
```

Internal Error When Using mex -setup (PC)

Some antivirus software packages may conflict with the `mex -setup` process or other `mex` commands. If you get an error message of the following form in response to a mex command,

```
mex.bat: internal error in sub get_compiler_info(): don't
recognize <string>
```

then you need to disable your antivirus software temporarily and reenter the command. After you have successfully run the `mex` script, you can reenable your antivirus software.

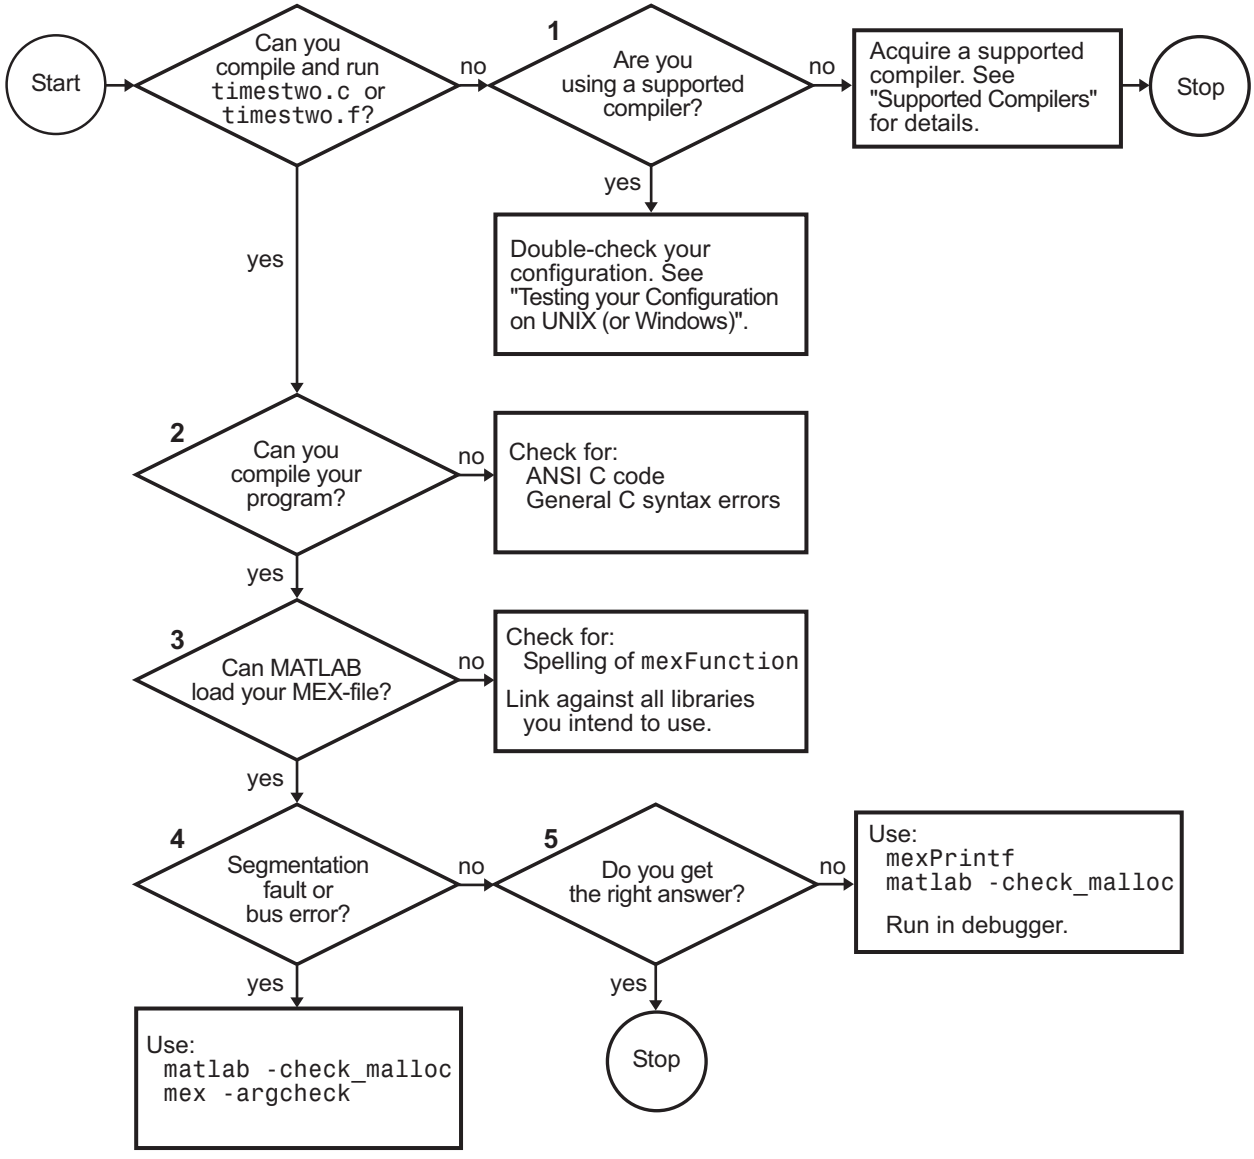
Alternatively, you can open a separate MS-DOS window and enter the `mex` command from that window.

General Configuration Problem

Make sure you followed the configuration steps for your platform described in this chapter. Also, refer to “Custom Building MEX-Files” on page 3-19 for additional information.

Understanding MEX-File Problems

This section contains information regarding common problems that occur when creating MEX-files. Use the following figure to help isolate these problems.



Troubleshooting MEX-File Creation Problems

Problems 1 through 5 refer to the corresponding numbered sections of the previous flowchart. For additional suggestions on resolving MEX-file build problems, access The MathWorks Technical Support Web site at:

```
http://www.mathworks.com/support
```

Problem 1 — Compiling a MathWorks Program Fails

The most common configuration problem in creating C MEX-files on UNIX involves using a non-ANSI C compiler, or failing to pass to the compiler a flag that tells it to compile ANSI C code.

A reliable way of knowing if you have this type of configuration problem is if the header files supplied by The MathWorks generate a string of syntax errors when you try to compile your code. See “Building MEX-Files” on page 3-11 for information on selecting the appropriate options file or, if necessary, obtain an ANSI C compiler.

Problem 2 — Compiling Your Own Program Fails

Mixing ANSI and non-ANSI C code can generate a string of syntax errors. The MathWorks provides header and source files that are ANSI C compliant. Therefore, your C code must also be ANSI compliant.

Other common problems that can occur in any C program are neglecting to include all necessary header files, or neglecting to link against all required libraries.

Make sure you are using a MATLAB supported compiler. See “Compiler Requirements” on page 3-11 for this information. Additional information can be found in “Compiler and Platform-Specific Issues” on page 3-37.

Problem 3 — MEX-File Load Errors

If you receive an error of the form

```
Unable to load mex file:
??? Invalid MEX-file
```

MATLAB does not recognize your MEX-file.

MATLAB loads MEX-files by looking for the gateway routine, `mexFunction`. If you misspell the function name, MATLAB cannot load your MEX-file and generates an error message. On Windows, check that you are exporting `mexFunction` correctly.

On some platforms, if you fail to link against required libraries, you may get an error when MATLAB loads your MEX-file rather than when you compile your MEX-file. In such cases, a system error message referring to *unresolved symbols* or *unresolved references* appears. Be sure to link against the library that defines the function in question.

On Windows, MATLAB fails to load MEX-files if it cannot find all `.dll` files referenced by the MEX-file; the `.dll` files must be on the path or in the same directory as the MEX-file. This is also true for third-party `.dll` files. See "DLL Files Not on Path on Windows" on page 3-32 for information to diagnose this problem.

Problem 4 — Segmentation Fault or Bus Error

If your MEX-file causes a segmentation violation or bus error, it means the MEX-file has attempted to access protected, read-only, or unallocated memory. Since this is such a general category of programming errors, such problems are sometimes difficult to track down.

Segmentation violations do not always occur at the same point as the logical errors that cause them. If a program writes data to an unintended section of memory, an error may not occur until the program reads and interprets the corrupted data. Consequently, a segmentation violation or bus error can occur after the MEX-file finishes executing.

MATLAB provides three features to help you troubleshoot problems of this nature. Listed in order of simplicity, they are as follows:

- Recompile your MEX-file with argument checking (C MEX-files only). You can add a layer of error checking to your MEX-file by recompiling with the `mex` script flag `-argcheck`. This warns you about invalid arguments to both MATLAB MEX-file (`mex`) and matrix access (`mx`) API functions.

  Although your MEX-file will not run as efficiently as it can, this switch detects errors such as passing `null` pointers to API functions.

- Run MATLAB with the `-check_malloc` option. The MATLAB startup flag, `-check_malloc`, indicates that MATLAB should maintain additional memory-checking information. When memory is freed, MATLAB checks to make sure that memory just before and just after this memory remains unwritten and that the memory has not been previously freed.

  If an error occurs, MATLAB reports the size of the allocated memory block. Using this information, you can track down where in your code this memory was allocated, and proceed accordingly.

  Although using this flag prevents MATLAB from running as efficiently as it can, it detects errors such as writing past the end of a dimensioned array, or freeing previously freed memory.

- Run MATLAB within a debugging environment. This process is already described in the chapters on creating C and Fortran MEX-files, respectively.

Problem 5 - Program Generates Incorrect Results

If your program generates the wrong answer(s), there are several possible causes. First, there could be an error in the computational logic. Second, the program could be reading from an uninitialized section of memory. For example, reading the 11th element of a 10-element vector yields unpredictable results.

Another cause of generating a wrong answer could be overwriting valid data due to memory mishandling. For example, writing to the 15th element of a 10-element vector might overwrite data in the adjacent variable in memory. This case can be handled in a similar manner as segmentation violations, as described in Problem 4.

In all of these cases, you can use `mexPrintf` to examine data values at intermediate stages or run MATLAB within a debugger to exploit all the tools the debugger provides.

Compiler and Platform-Specific Issues

This section describes situations specific to particular compilers and platforms.

Using MEX-Files from Other Sources

If you obtain a MEX-file from another source, be sure the file was compiled for the same platform on which you want to run it. See “What are MEX-Files” on page 3-2 for platform-specific information.

When you try to run a MEX-file from a version of MATLAB that is different from the version that created the MEX-file, MATLAB displays an error message of the following form:

```
??? Invalid MEX-file <mexfilename>:
The specified module could not be found.
```

Linux gcc Compiler Version Error

For information concerning a gcc compiler version error on Linux, see the Technical Support solution 1-2H64MF at:

```
http://www.mathworks.com/support/solutions/data/1-2H64MF.html
```

Fortran MEX-Files Compiler Errors

When you try to compile a Fortran MEX-file using a free source form format, MATLAB displays an error message of the following form:

```
Illegal character in statement label field
```

`mex` supports the fixed source form. The difference between free and fixed source forms is explained in the Fortran Language Reference Manual Source Forms topic. The URL for this topic is:

```
http://h21007.www2.hp.com/portal/download/files/unprot/Fortran/
docs/lrm/lrm0015.htm#source_formatmenu?&Record=383697&STASH=7
```

The URL for the Fortran Language Reference Manual is:

```
http://h21007.www2.hp.com/portal/download/files/unprot/Fortran/
docs/lrm/dflrm.htm
```

MEX-Files Created in Watcom IDE

If you use the Watcom IDE to create MEX-files and get unresolved references to API functions when linking against our libraries, check the argument-passing convention. The Watcom IDE uses a default switch that passes parameters in registers. MATLAB requires that you pass parameters on the stack.

Memory Management Compatibility Issues

MATLAB implicitly calls `mxDestroyArray`, the `mxArray` destructor, at the end of a MEX-file's execution on any `mxArrays` that are not returned in the left-hand side list (`plhs[]`). We recommend you review code in your MEX-files to avoid using these functions in the following situations. For additional information, see "Memory Management" on page 4-29 in Creating C Language MEX-Files.

Improperly Destroying an mxArray

You cannot use `mxFree` to destroy an `mxArray`.

Example. In the following example, `mxFree` does not destroy the array object. This operation frees the structure header associated with the array, but MATLAB stills operates as if the array object needs to be destroyed. Thus MATLAB tries to destroy the array object, and in the process, attempts to free its structure header again:

```
mxArray *temp = mxCreateDoubleMatrix(1,1,mxREAL);
      ...
mxFree(temp);  /* INCORRECT */
```

Solution. Call `mxDestroyArray` instead:

```
mxDestroyArray(temp);  /* CORRECT */
```

Incorrectly Constructing a Cell or Structure mxArray

You cannot call `mxSetCell` or `mxSetField` variants with `prhs[]` as the member array.

Example. In the following example, when the MEX-file returns, MATLAB destroys the entire cell array. Since this includes the members of the cell, this implicitly destroys the MEX-file's input arguments. This can cause several strange results, generally having to do with the corruption of the caller's workspace, if the right-hand side argument used is a temporary array (i.e., a literal or the result of an expression):

```
myfunction('hello')
/* myfunction is the name of your MEX-file and your code */
/* contains the following:    */

    mxArray *temp = mxCreateCellMatrix(1,1);
      ...
    mxSetCell(temp, 0, prhs[0]);  /* INCORRECT */
```

Solution. Make a copy of the right-hand side argument with `mxDuplicateArray` and use that copy as the argument to `mxSetCell` (or `mxSetField` variants). For example:

```
mxSetCell(temp, 0, mxDuplicateArray(prhs[0]));  /* CORRECT */
```

Creating a Temporary mxArray with Improper Data

You cannot call `mxDestroyArray` on an `mxArray` whose data was not allocated by an API routine.

Example. If you call `mxSetPr`, `mxSetPi`, `mxSetData`, or `mxSetImagData`, specifying memory that was not allocated by `mxCalloc`, `mxMalloc`, or `mxRealloc` as the intended data block (second argument), then when the MEX-file returns, MATLAB attempts to free the pointers to real data and imaginary data (if any). Thus MATLAB attempts to free memory, in this example, from the program stack.

```
mxArray *temp = mxCreateDoubleMatrix(0,0,mxREAL);
double data[5] = {1,2,3,4,5};
      ...
mxSetM(temp,1); mxSetN(temp,5); mxSetPr(temp, data);
/* INCORRECT */
```

Solution. Rather than use `mxSetPr` to set the data pointer, instead, create the `mxArray` with the right size and use `memcpy` to copy the stack data into the buffer returned by `mxGetPr`:

```
mxArray *temp = mxCreateDoubleMatrix(1,5,mxREAL);
double data[5] = {1,2,3,4,5};
      ...
memcpy(mxGetPr(temp), data, 5*sizeof(double)); /* CORRECT */
```

Potential Memory Leaks

Prior to Version 5.2, if you created an `mxArray` using one of the API creation routines and then you overwrote the pointer to the data using `mxSetPr`, MATLAB still freed the original memory. This is no longer the case.

For example,

```
pr = mxCalloc(5*5, sizeof(double));
... <load data into pr>
plhs[0] = mxCreateDoubleMatrix(5,5,mxREAL);
mxSetPr(plhs[0], pr);  /* INCORRECT */
```

will now leak 5*5*8 bytes of memory, where 8 bytes is the size of a `double`.

You can avoid that memory leak by changing the code

```
plhs[0] = mxCreateDoubleMatrix(5,5,mxREAL);
pr = mxGetPr(plhs[0]);
... <load data into pr>
```

or alternatively

```
pr = mxCalloc(5*5, sizeof(double));
... <load data into pr>
plhs[0] = mxCreateDoubleMatrix(5,5,mxREAL);
mxFree(mxGetPr(plhs[0]));
mxSetPr(plhs[0], pr);
```

Note that the first solution is more efficient.

Similar memory leaks can also occur when using `mxSetPi`, `mxSetData`, `mxSetImagData`, `mxSetIr`, or `mxSetJc`. You can avoid memory leaks by changing the code as described in this section.

MEX-Files Should Destroy Their Own Temporary Arrays

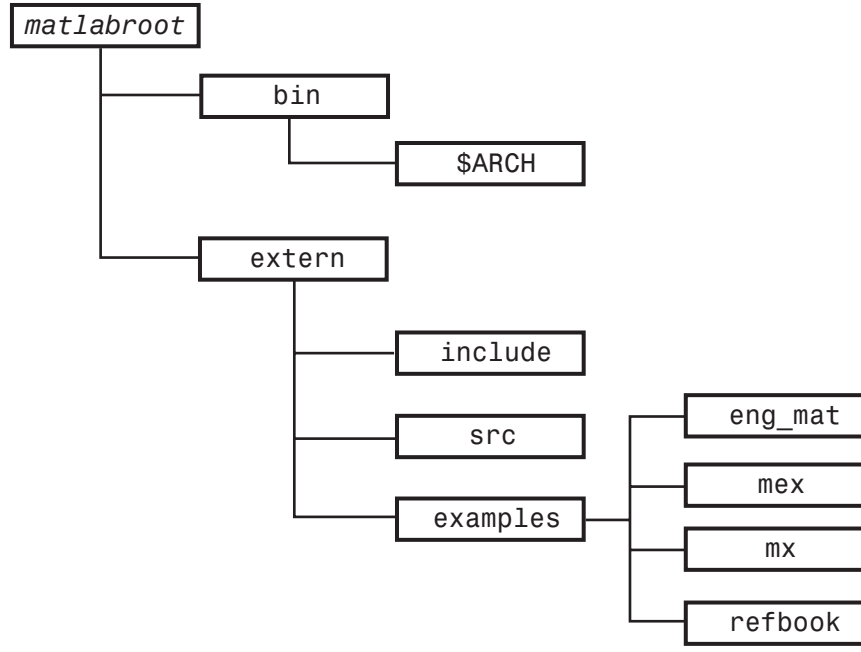
In general, we recommend that MEX-files destroy their own temporary arrays and clean up their own temporary memory. All `mxArrays` except those returned in the left-hand side list and those returned by `mexGetVariablePtr` may be safely destroyed. This approach is consistent with other MATLAB API applications (i.e., MAT-file applications, engine applications, and MATLAB Compiler generated applications, which do not have any automatic cleanup mechanism.)

Additional Information

In this section...

Files and Directories - UNIX Systems

This section describes the directory organization and purpose of the files associated with the MATLAB API on UNIX systems.



matlabroot/bin

The *matlabroot*/bin directory contains two files that are relevant for the MATLAB API:

mex
: UNIX shell script that creates MEX-files from C or Fortran MEX-file source code.

matlab
: UNIX shell script that initializes your environment and then invokes the MATLAB interpreter.

This directory also contains the preconfigured options files that the mex script uses with particular compilers. See "Preconfigured Options Files" on page 3-18 for more information.

matlabroot/bin/$ARCH

The *matlabroot*/bin/*$ARCH* directory contains libraries, where *$ARCH* specifies a particular UNIX platform. On some UNIX platforms, this directory contains two versions of this library. Library filenames ending with .so or .dylib are shared libraries.

matlabroot/extern/include

The *matlabroot*/extern/include directory contains the header files for developing C and C++ applications that interface with MATLAB.

The relevant header files for the MATLAB API are

engine.h
: Header file for MATLAB engine programs. Contains function prototypes for engine routines.

mat.h
: Header file for programs accessing MAT-files. Contains function prototypes for mat routines.

matrix.h
: Header file containing a definition of the mxArray structure and function prototypes for matrix access routines.

`mex.h`
: Header file for building MEX-files. Contains function prototypes for `mex` routines.

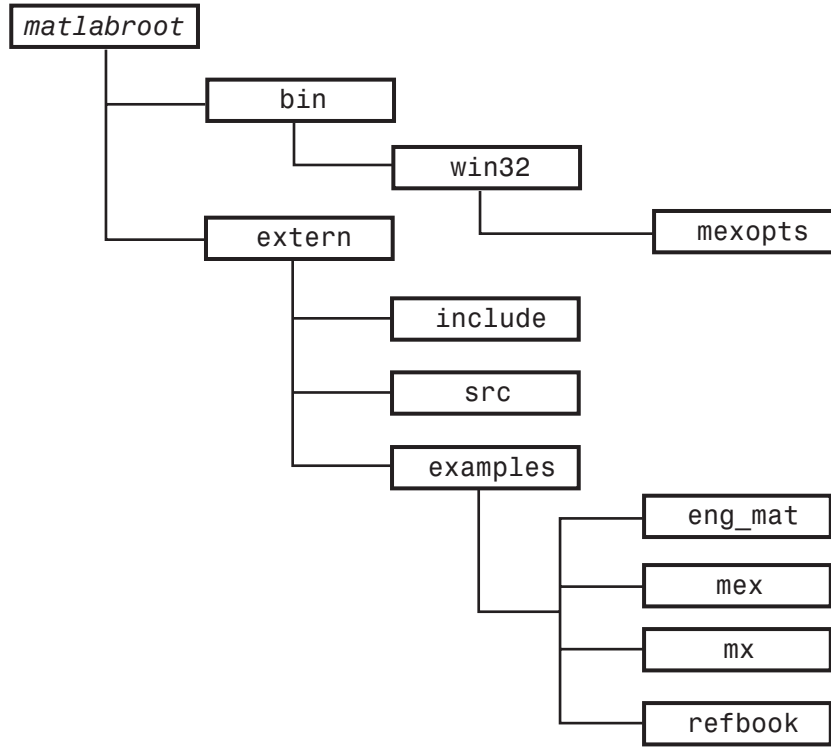
matlabroot/extern/src

The *`matlabroot`*`/extern/src` directory contains those C source files that are necessary to support certain MEX-file features such as argument checking and versioning.

Files and Directories — Windows Systems

This section describes the directory organization and purpose of the files associated with the MATLAB API on Microsoft Windows systems.

The following figure illustrates the directories in which the MATLAB API files are located. In the illustration, *matlabroot* symbolizes the top-level directory where MATLAB is installed on your system.



matlabroot\bin

The *matlabroot*\bin directory contains the mex.bat batch file that builds C and Fortran files into MEX-files. Also, this directory contains mex.pl, which is a Perl script used by mex.bat.

matlabroot\bin\win32\mexopts or matlabroot\bin\win64\mexopts

The *matlabroot*\bin\win32\mexopts or *matlabroot*\bin\win64\mexopts directory contains the preconfigured options files that the mex script uses

with particular compilers. See “Preconfigured Options Files” on page 3-18 for more information.

matlabroot\extern\include

The *matlabroot*\extern\include directory contains the header files for developing C and C++ applications that interface with MATLAB.

The relevant header files for the MATLAB API (MEX-files, engine, and MAT-files) are

`engine.h`
: Header file for MATLAB engine programs. Contains function prototypes for engine routines.

`mat.h`
: Header file for programs accessing MAT-files. Contains function prototypes for `mat` routines.

`matrix.h`
: Header file containing a definition of the `mxArray` structure and function prototypes for matrix access routines.

`mex.h`
: Header file for building MEX-files. Contains function prototypes for `mex` routines.

`_*.def`
: Files used by Borland compiler.

`*.def`
: Files used by MSVC and Microsoft Fortran compilers.

`mexversion.rc`
: Resource file for inserting versioning information into MEX-files.

matlabroot\extern\src

The *matlabroot*\extern\src directory contains files that are used for debugging MEX-files.

Examples

This book uses many examples to show how to write C and Fortran MEX-files.

Examples from the Text

The `refbook` subdirectory in the `extern/examples` directory contains the MEX-file examples (C and Fortran) that are used in this topic.

MEX Reference Examples

The `mex` subdirectory of `/extern/examples` directory contains MEX-file examples. It includes the examples described in the online C and Fortran API Reference for "MEX-Files" (the functions beginning with the `mex` prefix).

MX Examples

The `mx` subdirectory of `extern/examples` contains examples for using the array access functions. Although you can use these functions in stand-alone programs, most of these are MEX-file examples. The exception is `mxSetAllocFcns.c`, since this function is available only to stand-alone programs.

Engine and MAT Examples

The `eng_mat` subdirectory in the `extern/examples` directory contains the MEX-file examples (C and Fortran) for using the MATLAB engine facility, as well as examples for reading and writing MATLAB data files (MAT-files). These examples are all stand-alone programs.

Technical Support

The MathWorks provides additional Technical Support through its Web site. A few of the services provided are as follows:

- Solution Search Engine

This knowledge base on our Web site includes thousands of solutions and links to Technical Notes and is updated several times each week.

```
http://www.mathworks.com/support/
```

- Technical Notes

Technical notes are written by our Technical Support staff to address commonly asked questions.

```
http://www.mathworks.com/support/tech-notes/list_all.shtml
```

4

Creating C Language MEX-Files

This chapter describes how to write MEX-files in the C programming language. It discusses the MEX-file itself, how these C language files interact with MATLAB, how to pass and manipulate arguments of different data types, how to debug your MEX-file programs, and several other, more advanced topics.

C MEX-Files

In this section...

The Components of a C MEX-File

MEX-files are built by using the `mex` function. `mex` compiles and links source files into a shared library called a MEX-file, which you can run in MATLAB. Once compiled, you treat MEX-files exactly like MATLAB M-files and built-in functions.

The MEX-file consists of:

- A "Gateway Routine" on page 4-2 that interfaces C and MATLAB data.
- A "Computational Routine" on page 4-4 written in C that performs the computations you want implemented in the MEX-file.
- "Preprocessor Macros" on page 4-5 for building platform-independent code.

Gateway Routine

The *gateway routine* is the entry point to the MEX-file shared library. It is through this routine that MATLAB accesses the rest of the routines in your MEX-files. Use the following guideline to create a gateway routine:

- "Naming the Gateway Routine" on page 4-3
- "Required Parameters" on page 4-3
- "Creating and Using Source Files" on page 4-4
- "Using MATLAB Libraries" on page 4-4

A C MEX-file gateway routine looks like this:

```
void mexFunction(
    int nlhs, mxArray *plhs[],
    int nrhs, const mxArray *prhs[])
{
   /* more C code ... */
}
```

Naming the Gateway Routine

The name of the gateway routine must be `mexFunction`.

Required Parameters

A gateway routine must contain the parameters `prhs`, `nrhs`, `plhs`, and `nlhs` which are described in the following table.

Parameter	Description
`prhs`	An array of right-hand input arguments.
`plhs`	An array of left-hand output arguments.
`nrhs`	The number of right-hand arguments, or the size of the `prhs` array.
`nlhs`	The number of left-hand arguments, or the size of the `plhs` array.

Both `prhs` and `plhs` are declared as type `mxArray *`, which means they point to MATLAB arrays. They are vectors that contain pointers to the arguments of the MEX-file.

You can think of the name `prhs` as representing the "parameters, right-hand side," that is, the input parameters. Likewise, `plhs` represents the "parameters, left-hand side," or output parameters.

Creating and Using Source Files

It is good practice to write the gateway routine to call a "Computational Routine" on page 4-4; however, this is not required. The computational code can be part of the gateway routine. If you use both gateway and computational routines, they can be combined in one source file or in separate files. If you use separate files, the gateway routine must be the first source file listed in the `mex` command.

The name of the file containing your gateway routine is important, as explained in "Naming the MEX-File" on page 4-4.

Using MATLAB Libraries

The MATLAB C and Fortran API Reference describes functions you can use in your gateway and computational routines that interact with MATLAB programs and the data in the MATLAB workspace. The `mx` prefixed functions provide access methods for manipulating MATLAB arrays. The `mex` prefixed functions perform operations in the MATLAB environment.

Required Header Files

To use the functions in the C and Fortran Reference library you must include the `mex` header, which declares the entry point and interface routines. Put this statement in your source file:

```
#include "mex.h"
```

Naming the MEX-File

The MEX-file name, and hence the name of the function you use in MATLAB, is the name of the source file containing your gateway routine.

The file extension of the MEX-file is platform-dependent. The `mexext` function returns the extension for the current machine.

Computational Routine

The *computational routine* contains the code for performing the computations you want implemented in the MEX-file. Computations can be numerical computations as well as inputting and outputting data. The gateway calls the computational routine as a subroutine.

The programming requirements described in "Creating and Using Source Files" on page 4-4, "Using MATLAB Libraries" on page 4-4, and "Required Header Files" on page 4-4 may also apply to your computational routine.

Preprocessor Macros

The MATLAB *preprocessor macros* `mwSize` and `mwIndex` are used in the `mx` and `mex` functions for cross-platform flexibility. `mwSize` represents size values, such as array dimensions and number of elements. `mwIndex` represents index values, such as indices into arrays.

Data Flow in MEX-Files

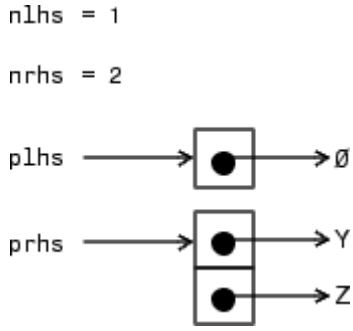
The following examples illustrate data flow in MEX-files:

Showing Data Input and Output

Suppose your MEX-file `myFunction` has 2 input arguments and 1 output argument. The MATLAB syntax is `[X] = myFunction(Y, Z)`. To call `myFunction` from MATLAB, type:

```
X = myFunction(Y, Z);
```

The MATLAB interpreter calls `mexFunction`, the gateway routine to `myFunction`, with the following arguments:



Your input is `prhs`, a 2-element C array (`nrhs = 2`). The first element is a pointer to an `mxArray` named `Y` and the second element is a pointer to an `mxArray` named `Z`.

Your output is `plhs`, a 1-element C array (`nlhs = 1`) where the single element is a `null` pointer. The parameter `plhs` points at nothing because the output `X` is not created until the subroutine executes.

The gateway routine creates the output array and sets a pointer to it in `plhs[0]`. If `plhs[0]` is left unassigned and you assign an output value to the function when you call it, MATLAB generates an error stating that no output was assigned.

Note It is possible to return an output value even if `nlhs = 0`. This corresponds to returning the result in the `ans` variable.

Gateway Routine Data Flow Diagram

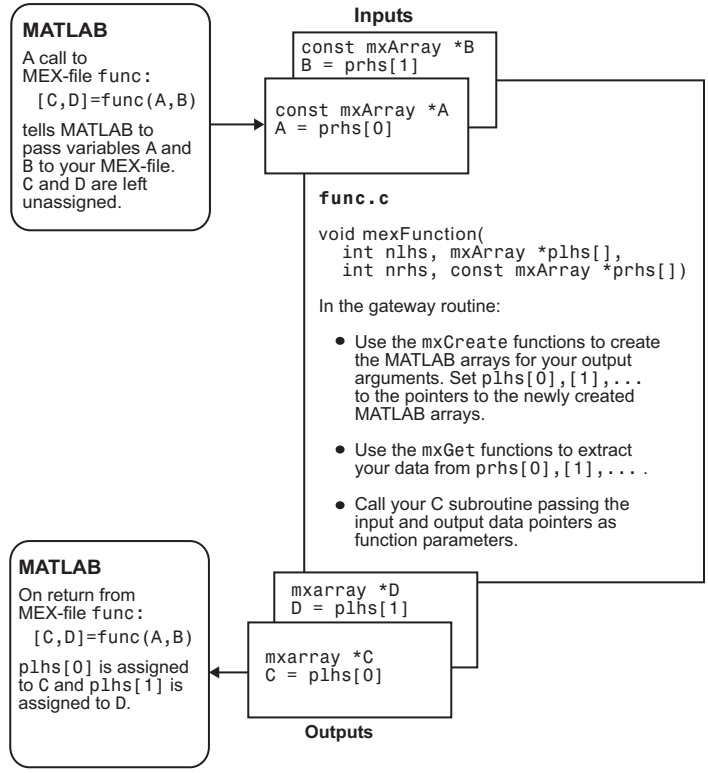
The following MEX Cycle diagram shows how inputs enter a MEX-file, what functions the gateway routine performs, and how outputs return to MATLAB.

In this example, the syntax of the MEX-file `func` is `[C, D] = func(A,B)`. In the figure, a call to `func` tells MATLAB to pass variables `A` and `B` to your MEX-file. `C` and `D` are left unassigned.

The gateway routine `func.c` uses the `mxCreate*` functions to create the MATLAB arrays for your output arguments. It sets `plhs[0]` and `plhs[1]`

to the pointers to the newly created MATLAB arrays. It uses the `mxGet*` functions to extract your data from your input arguments `prhs[0]` and `prhs[0]`. Finally, it calls your computational routine, passing the input and output data pointers as function parameters.

On return to MATLAB, `plhs[0]` is assigned to `C` and `plhs[1]` is assigned to `D`.



C MEX Cycle

MATLAB Example yprime.c

Let's look at an example, `yprime.c`, found in your *`matlabroot`*`/extern/examples/mex/` directory. ("Building MEX-Files" on page 3-11 explains how to create the MEX-file.) It's calling syntax is `[YP] = YPRIME(T,Y)`, where `T` is an integer and `Y` is a vector with 4 elements. For `T=1` and `Y=1:4`, when you type

```
yprime(T,Y)
```

MATLAB displays:

```
ans =
     2.0000    8.9685    4.0000    -1.0947
```

The gateway routine should validate the input arguments. This step includes checking the number, type, and size of the input arrays as well as examining the number of output arrays. If the inputs are not valid, call `mexErrMsgTxt`. For example,

`mexErrMsgTxt`

```
/* Check for proper number of arguments */
if (nrhs != 2) {
 mexErrMsgTxt("Two input arguments required.");
} else if (nlhs > 1) {
 mexErrMsgTxt("Too many output arguments.");
}

/* Check the dimensions of Y.  Y can be 4 X 1 or 1 X 4. */
m = mxGetM(Y_IN);
n = mxGetN(Y_IN);
if (!mxIsDouble(Y_IN) || mxIsComplex(Y_IN) ||
   (MAX(m,n) != 4) || (MIN(m,n) != 1)) {
 mexErrMsgTxt("YPRIME requires that Y be a 4 x 1 vector.");
}
```

To create MATLAB arrays, call any of the `mxCreate*` functions, like `mxCreateDoubleMatrix`, `mxCreateSparse`, or `mxCreateString`. If it needs them, the gateway routine can call `mxCalloc` to allocate temporary work arrays for the computational routine. In this example,

```
/* Create a matrix for the return argument */
plhs[0] = mxCreateDoubleMatrix(m, n, mxREAL);
```

In the gateway routine, you access the data in `mxArray` and manipulate it in your computational subroutine. For example, the expression `mxGetPr(prhs[0])` returns a pointer of type `double *` to the real data in the

mxArray pointed to by prhs[0]. You can then use this pointer like any other pointer of type double * in C. For example,

```
/* Assign pointers to the various parameters */
yp = mxGetPr(plhs[0]);
```

In this example, a computational routine, yprime, performs the calculations:

```
/* Do the actual computations in a subroutine */
yprime(yp,t,y);
```

After calling your computational routine from the gateway, you can set a pointer of type mxArray to the data it returns. MATLAB recognizes the output from your computational routine as the output from the MEX-file.

When a MEX-file completes its task, it returns control to MATLAB. Any MATLAB arrays that are created by the MEX-file but are not returned to MATLAB through the left-hand side arguments are automatically destroyed.

Creating C++ MEX-Files

All C++ language standards are supported in MEX-files.

This section discusses specific C++ language issues to consider when creating and using MEX-files.

Creating Your C++ Source File

The C++ source code for the examples provided by MATLAB use the .cpp file extension. The extension .cpp is unambiguous and generally recognized by C++ compilers. Other possible extensions include .C, .cc, and .cxx.

For information on using C++ features, see Technical Note 1605, MEX-files Guide, at http://www.mathworks.com/support/tech-notes/1600/1605.html. Look for the sections under the “C++ Mex-files” heading.

Compiling and Linking

You can run a C++ MEX-file only on systems with the same version of MATLAB that the file was compiled on.

Use `mex setup` to select a C++ compiler, then type

```
mex filename.cpp
```

You can use command-line options, as shown in the “MEX Script Switches” on page 3-19 table.

Your link command must have all of the necessary DLL files that the MEX-function is dependent upon. To help you check for dependent files, see the Troubleshooting topic “DLL Files Not on Path on Windows” on page 3-32.

Examples

The examples “Using C++ Features in MEX-Files” on page 4-21 and “File Handling with C++” on page 4-22 illustrate the use of C++ by walking through source code examples available in your MATLAB directory.

Examples of C MEX-Files

In this section...

Introduction

The MATLAB API provides a full set of routines that handle the various data types supported by MATLAB. For each data type there is a specific set of functions that you can use for data manipulation. The first example discusses the simple case of doubling a scalar. After that, the examples discuss how to pass in, manipulate, and pass back various data types, and how to handle multiple inputs and outputs. Finally, the sections discuss passing and manipulating various MATLAB data types.

Note Source code for most examples in this chapter is available in the *matlabroot*`/extern/examples/refbook` directory of your MATLAB installation. *matlabroot* is your MATLAB root directory, the value returned by the `matlabroot` function.

A First Example — Passing a Scalar

Let's look at a simple example of C code and its MEX-file equivalent. Here is a C computational function that takes a scalar and doubles it.

```
#include <math.h>
void timestwo(double y[], double x[])
{
  y[0] = 2.0*x[0];
  return;
}
```

To see the same function written in the MEX-file format (`timestwo.c`), open the file in MATLAB Editor.

In C, function argument checking is done at compile time. In MATLAB, you can pass any number or type of arguments to your M-function, which is responsible for argument checking. This is also true for MEX-files. Your program must safely handle any number of input or output arguments of any supported type.

To compile and link this example source file at the MATLAB prompt, type

```
mex timestwo.c
```

This carries out the necessary steps to create the MEX-file called `timestwo` with an extension corresponding to the platform on which you're running. You can now call `timestwo` as if it were an M-function.

```
x = 2;
y = timestwo(x)
y =
     4
```

You can create and compile MEX-files in MATLAB or at your operating system's prompt. MATLAB uses `mex.m`, an M-file version of the `mex` script, and your operating system uses `mex.bat` on Windows and `mex.sh` on UNIX. In either case, typing

```
mex filename
```

at the prompt produces a compiled version of your MEX-file.

In the above example, scalars are viewed as 1-by-1 matrices. Alternatively, you can use a special API function called `mxGetScalar` that returns the values of scalars instead of pointers to copies of scalar variables (`timestwoalt.c`). To see the alternative code (error checking has been omitted for brevity), open the file in MATLAB Editor.

This example passes the input scalar `x` by value into the `timestwo_alt` subroutine, but passes the output scalar `y` by reference.

Passing Strings

Any MATLAB data type can be passed to and from MEX-files. The example `revord.c` accepts a string and returns the characters in reverse order. To see the example, open the file in MATLAB Editor.

In this example, the API function `mxCalloc` replaces `calloc`, the standard C function for dynamic memory allocation. `mxCalloc` allocates dynamic memory using the MATLAB memory manager and initializes it to zero. You must use `mxCalloc` in any situation where C would require the use of `calloc`. The same is true for `mxMalloc` and `mxRealloc`; use `mxMalloc` in any situation where C would require the use of `malloc` and use `mxRealloc` where C would require `realloc`.

Note MATLAB automatically frees up memory allocated with the `mx` allocation routines (`mxCalloc`, `mxMalloc`, `mxRealloc`) upon exiting your MEX-file. If you don't want this to happen, use the API function `mexMakeMemoryPersistent`.

The gateway routine `mexFunction` allocates memory for the input and output strings. Since these are C strings, they need to be one greater than the number of elements in the MATLAB string. Next the MATLAB string is copied to the input string. Both the input and output strings are passed to the computational subroutine (`revord`), which loads the output in reverse order. Note that the output buffer is a valid null-terminated C string because `mxCalloc` initializes the memory to 0. The API function `mxCreateString` then creates a MATLAB string from the C string, `output_buf`. Finally, `plhs[0]`, the left-hand side return argument to MATLAB, is set to the MATLAB array you just created.

By isolating variables of type `mxArray` from the computational subroutine, you can avoid having to make significant changes to your original C code.

In this example, typing

```
x = 'hello world';
y = revord(x)
```

produces

```
The string to convert is 'hello world'.
y =
dlrow olleh
```

Passing Two or More Inputs or Outputs

The `plhs[]` and `prhs[]` parameters are vectors that contain pointers to each left-hand side (output) variable and each right-hand side (input) variable, respectively. Accordingly, `plhs[0]` contains a pointer to the first left-hand side argument, `plhs[1]` contains a pointer to the second left-hand side argument, and so on. Likewise, `prhs[0]` contains a pointer to the first right-hand side argument, `prhs[1]` points to the second, and so on.

This example, `xtimesy`, multiplies an input scalar by an input scalar or matrix and outputs a matrix. For example, using `xtimesy` with two scalars gives

```
x = 7;
y = 7;
z = xtimesy(x,y)

z =
     49
```

Using `xtimesy` with a scalar and a matrix gives

```
x = 9;
y = ones(3);
z = xtimesy(x,y)

z =
     9     9     9
     9     9     9
     9     9     9
```

To see the corresponding MEX-file C code `xtimesy.c`, open the file in MATLAB Editor.

As this example shows, creating MEX-file gateways that handle multiple inputs and outputs is straightforward. All you need to do is keep track of which indices of the vectors `prhs` and `plhs` correspond to the input and output arguments of your function. In the example above, the input variable `x` corresponds to `prhs[0]` and the input variable `y` to `prhs[1]`.

Note that `mxGetScalar` returns the value of `x` rather than a pointer to `x`. This is just an alternative way of handling scalars. You could treat `x` as a 1-by-1 matrix and use `mxGetPr` to return a pointer to `x`.

Passing Structures and Cell Arrays

Passing structures and cell arrays into MEX-files is just like passing any other data types, except the data itself is of type `mxArray`. In practice, this means that `mxGetField` (for structures) and `mxGetCell` (for cell arrays) return pointers of type `mxArray`. You can then treat the pointers like any other pointers of type `mxArray`, but if you want to pass the data contained in the `mxArray` to a C routine, you must use an API function such as `mxGetData` to access it.

This example takes an m-by-n structure matrix as input and returns a new 1-by-1 structure that contains these fields:

- String input generates an m-by-n cell array

- Numeric input (noncomplex, scalar values) generates an m-by-n vector of numbers with the same class ID as the input, for example, `int`, `double`, and so on.

To see the program `phonebook.c`, open the file in MATLAB Editor.

To see how this program works, enter this structure.

```
friends(1).name = 'Jordan Robert';
friends(1).phone = 3386;
friends(2).name = 'Mary Smith';
friends(2).phone = 3912;
friends(3).name = 'Stacy Flora';
friends(3).phone = 3238;
friends(4).name = 'Harry Alpert';
friends(4).phone = 3077;
```

The results of this input are

```
phonebook(friends)

ans =
     name: {1x4 cell  }
    phone: [3386 3912 3238 3077]
```

Prompting User for Input

Because MATLAB does not use `stdin` and `stdout`, C functions like `scanf` and `printf` cannot be used to prompt users for input. The following example shows how to use `mexCallMATLAB` with the `input` function to get a number from the user.

```
#include "mex.h"
#include "string.h"
void mexFunction( int nlhs, mxArray *plhs[],
                  int nrhs, const mxArray *prhs[] )
{
  mxArray   *new_number, *str;
  double out;

  str = mxCreateString("Enter extension:  ");
```

```
  mexCallMATLAB(1,&new_number,1,&str,"input");
  out = mxGetScalar(new_number);
  mexPrintf("You entered: %.0f ", out);
  mxFree(new_number);
  mxFree(str);
  return;
 }
```

Handling Complex Data

Complex data from MATLAB is separated into real and imaginary parts. The MATLAB API provides two functions, `mxGetPr` and `mxGetPi`, that return pointers (of type `double *`) to the real and imaginary parts of your data.

This example, `convec.c`, takes two complex row vectors and convolves them. To see the example, open the file in MATLAB Editor.

Entering these numbers at the MATLAB prompt

```
x = [3.000 - 1.000i, 4.000 + 2.000i, 7.000 - 3.000i];
y = [8.000 - 6.000i, 12.000 + 16.000i, 40.000 - 42.000i];
```

and invoking the new MEX-file

```
z = convec(x,y)
```

results in

```
z =
   1.0e+02 *

Columns 1 through 4

0.1800 - 0.2600i 0.9600 + 0.2800i 1.3200 - 1.4400i 3.7600 - 0.1200i

Column 5

1.5400 - 4.1400i
```

which agrees with the results that the built-in MATLAB function `conv.m` produces.

Handling 8-,16-, and 32-Bit Data

You can create and manipulate signed and unsigned 8-, 16-, and 32-bit data from within your MEX-files. The MATLAB API provides a set of functions that support these data types. The API function `mxCreateNumericArray` constructs an unpopulated N-dimensional numeric array with a specified data size. Refer to the entry for `mxClassID` in the online reference pages for a discussion of how the MATLAB API represents these data types.

Once you have created an unpopulated MATLAB array of a specified data type, you can access the data using `mxGetData` and `mxGetImagData`. These two functions return pointers to the real and imaginary data. You can perform arithmetic on data of 8-, 16- or 32-bit precision in MEX-files and return the result to MATLAB, which will recognize the correct data class.

The example, `doubleelement.c`, constructs a 2-by-2 matrix with unsigned 16-bit integers, doubles each element, and returns both matrices to MATLAB. To see the example, open the file in MATLAB Editor.

At the MATLAB prompt, entering

```
doubleelement
```

produces

```
ans =
     2     6
     4     8
```

The output of this function is a 2-by-2 matrix populated with unsigned 16-bit integers.

Manipulating Multidimensional Numerical Arrays

You can manipulate multidimensional numerical arrays by using `mxGetData` and `mxGetImagData` to return pointers to the real and imaginary parts of the data stored in the original multidimensional array. The example, `findnz.c`, takes an N-dimensional array of doubles and returns the indices for the nonzero elements in the array. To see the example, open the file in MATLAB Editor.

Entering a sample matrix at the MATLAB prompt gives

```
matrix = [ 3 0 9 0; 0 8 2 4; 0 9 2 4; 3 0 9 3; 9 9 2 0]
matrix =
     3     0     9     0
     0     8     2     4
     0     9     2     4
     3     0     9     3
     9     9     2     0
```

This example determines the position of all nonzero elements in the matrix. Running the MEX-file on this matrix produces

```
nz = findnz(matrix)
nz =
     1     1
     4     1
     5     1
     2     2
     3     2
     5     2
     1     3
     2     3
     3     3
     4     3
     5     3
     2     4
     3     4
     4     4
```

Handling Sparse Arrays

The MATLAB API provides a set of functions that allow you to create and manipulate sparse arrays from within your MEX-files. These API routines access and manipulate `ir` and `jc`, two of the parameters associated with sparse arrays. For more information on how MATLAB stores sparse arrays, see “The MATLAB Array” on page 3-6.

The example, `fulltosparse.c`, illustrates how to populate a sparse matrix. To see the example, open the file in MATLAB Editor.

At the MATLAB prompt, entering

```
full = eye(5)
full =
     1     0     0     0     0
     0     1     0     0     0
     0     0     1     0     0
     0     0     0     1     0
     0     0     0     0     1
```

creates a full, 5-by-5 identity matrix. Using `fulltosparse` on the full matrix produces the corresponding sparse matrix.

```
spar = fulltosparse(full)
spar =
   (1,1)        1
   (2,2)        1
   (3,3)        1
   (4,4)        1
   (5,5)        1
```

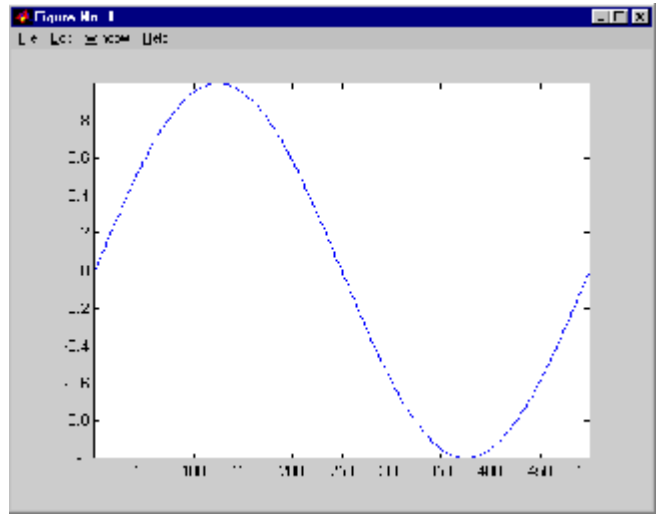
Calling Functions from C MEX-Files

It is possible to call MATLAB functions, operators, M-files, and other MEX-files from within your C source code by using the API function `mexCallMATLAB`. The example, `sincall.c`, creates an `mxArray`, passes various pointers to a subfunction to acquire data, and calls `mexCallMATLAB` to calculate the `sine` function and plot the results. To see the example, open the file in MATLAB Editor.

Running this example

```
sincall
```

displays the results



Note It is possible to generate an object of type `mxUNKNOWN_CLASS` using `mexCallMATLAB`. See the example below.

The following example creates an M-file that returns two variables but only assigns one of them a value.

```
function [a,b] = foo[c]
a = 2*c;
```

MATLAB displays the following warning message.

```
Warning: One or more output arguments not assigned during call to
'foo'.
```

If you then call `foo` using `mexCallMATLAB`, the unassigned output variable is now type `mxUNKNOWN_CLASS`.

Using C++ Features in MEX-Files

This example, `mexcpp.cpp`, illustrates how to use C++ code with your C language MEX-file. It makes use of member functions, constructors,

destructors, and the `iostream` include file. To see the example, open the file in MATLAB Editor.

The calling syntax is `mexcpp(num1, num2)`.

The routine defines a class, `MyData`, with member functions `display` and `set_data`, and variables `v1` and `v2`. It constructs an object `d` of class `MyData` and displays the initialized values of `v1` and `v2`. It then sets `v1` and `v2` to your input, `num1` and `num2`, and displays the new values. Finally, cleanup of the object is done using the `delete` operator.

File Handling with C++

This example, `mexatexit.cpp`, illustrates C++ file handling features. To see the C++ code, open the C++ file in MATLAB Editor. To compare it with a C code example `mexatexit.c`, open the C file in MATLAB Editor.

C Example

The C code example registers the `mexAtExit` function to perform cleanup tasks (close the data file) when the MEX-file clears. This example prints a message on the screen (using `mexPrintf`) when performing file operations `fopen`, `fprintf`, and `fclose`.

To build the `mexatexit.c` MEX-file, type:

```
mex mexatexit.c
```

If you type

```
x = 'my input string';
mexatexit(x)
```

MATLAB displays

```
Opening file matlab.data.
Writing data to file.
```

To clear the MEX-file, type

```
clear mexatexit
```

MATLAB displays

```
Closing file matlab.data.
```

You can see the contents of `matlab.data` by typing

```
type matlab.data
```

MATLAB displays

```
my input string
```

C++ Example

The C++ example does not use the `mexAtExit` function. The file open and close functions are handled in a `fileresource` class. The destructor for this class (which closes the data file) is automatically called when the MEX-file clears. This example also prints a message on the screen when performing operations on the data file. However, in this case, the only C file operation performed is the write operation, `fprintf`.

To build the `mexatexit.cpp` MEX-file, make sure you have selected a C++ compiler, then type:

```
mex mexatexit.cpp
```

If you type

```
z = 'for the C++ MEX-file';
mexatexit(x)
mexatexit(z)
clear mexatexit
```

MATLAB displays

```
Writing data to file.
Writing data to file.
```

To see the contents of `matlab.data`, type

```
type matlab.data
```

MATLAB displays

```
my input string
for the C++ MEX-file
```

Advanced Topics

In this section...

Help Files

Because the MATLAB interpreter chooses the MEX-file when both an M-file and a MEX-file with the same name are encountered in the same directory, it is possible to use M-files for documenting the behavior of your MEX-files. The MATLAB `help` command automatically finds and displays the appropriate M-file when help is requested and the interpreter finds and executes the corresponding MEX-file when the function is invoked.

Linking Multiple Files

It is possible to combine several object files and to use object file libraries when building MEX-files. To do so, simply list the additional files with their full extension, separated by spaces. For example, on the PC

```
mex circle.c square.obj rectangle.c shapes.lib
```

is a legal command that operates on the `.c`, `.obj`, and `.lib` files to create a MEX-file called `circle.mexw32`, where `mexw32` is the extension corresponding to the MEX-file type on 32-bit Windows. The name of the resulting MEX-file is taken from the first file in the list.

You may find it useful to use a software development tool like `MAKE` to manage MEX-file projects involving multiple source files. Simply create a `MAKEFILE` that contains a rule for producing object files from each of your source files

and then invoke `mex` to combine your object files into a MEX-file. This way you can ensure that your source files are recompiled only when necessary.

Workspace for MEX-File Functions

Unlike M-file functions, MEX-file functions do not have their own variable workspace. MEX-file functions operate in the caller's workspace.

`mexEvalString` evaluates the string in the caller's workspace. In addition, you can use the `mexGetVariable` and `mexPutVariable` routines to get and put variables into the caller's workspace.

Handling Large mxArrays

MEX-files built on 64-bit platforms can handle 64-bit mxArrays. These large data arrays can have up to 2^{48}–1 elements. The maximum number of elements a sparse mxArray can have is 2^{48}-2.

Using the following instructions creates platform-independent MEX-files as well.

Your system configuration can impact the performance of MATLAB. The 64-bit processor requirement enables you to create the mxArray and access data in it. However, your system's memory, in particular the size of RAM and virtual memory, determine the speed at which MATLAB processes the mxArray. The more memory available, the faster the processing.

The amount of RAM also limits the amount of data you can process at one time in MATLAB. For guidance on memory issues, see "Memory Allocation in MATLAB". Memory management within MEX-files can have special considerations, as described in "Memory Management" on page 4-29.

Using the 64-Bit API

To work with 64-bit mxArrays, your source code must comply with the 64-bit API, which consists of the functions in the following table.

`mxCalcSingleSubscript`	`mxCreateCellMatrix`
`mxCalloc`	`mxCreateCharArray`

mxCopyCharacterToPtr	mxCreateCharMatrixFromStrings
mxCopyComplex16ToPtr	mxCreateDoubleMatrix
mxCopyComplex8ToPtr	mxCreateLogicalArray
mxCopyInteger1ToPtr	mxCreateLogicalMatrix
mxCopyInteger2ToPtr	mxCreateNumericArray
mxCopyInteger4ToPtr	mxCreateNumericMatrix
mxCopyPtrToCharacter	mxCreateSparse
mxCopyPtrToComplex16	mxCreateSparseLogicalMatrix
mxCopyPtrToComplex8	mxCreateSparseLogicalMatrix
mxCopyPtrToInteger1	mxCreateStructMatrix
mxCopyPtrToInteger2	mxGetCell
mxCopyPtrToInteger4	mxGetElementSize
mxCopyPtrToPtrArray	mxGetField
mxCopyPtrToReal4	mxGetFieldByNumber
mxCopyPtrToReal8	mxGetIr
mxCopyReal4ToPtr	mxGetJc
mxCopyReal8ToPtr	mxGetM
mxCopyReal8ToPtr	mxGetN
mxCopyReal4ToPtr	mxGetNumberOfDimensions
mxCreateCellArray	mxGetNumberOfElements

Functions in this API use the `mwIndex` and `mwSize` types. For information about using these macros, see "Required Header Files" on page 4-4.

Building the MEX-File

Use the `mex` command option, `-largeArrayDims`, with the 64-bit API.

Example

The example, `arraySize.c` in *`matlabroot`*`/extern/examples/mex`, illustrates memory requirements of large mxArrays. To see the example, open the file in MATLAB Editor.

This function requires one positive scalar numeric input, which it uses to create a square matrix. It checks the size of the input to make sure your system can theoretically create a matrix of this size. If the input is valid, it displays the size of the mxArray in kilobytes.

To build this MEX-file, type:

```
mex -largeArrayDims arraySize.c
```

To run the MEX-file, type:

```
arraySize(2^10)
```

If your system has enough available memory, MATLAB displays:

```
Dimensions: 1024 x 1024
Size of array in kilobytes: 1024
```

If your system does not have enough memory to create the array, MATLAB displays an `Out of memory` error.

You can experiment with this function to test the performance and limits of handling large arrays on your system.

Caution Using Negative Values

When using the 64-bit API, `mwSize` and `mwIndex` are equivalent to `size_t` in C or `INTEGER*8` in Fortran. These types are unsigned, unlike `int` and `INTEGER*4`, which are the types used in the 32-bit API. Be careful not to pass any negative values to functions that take `mwSize` or `mwIndex` arguments. Do not cast negative `int` or `INTEGER*4` values to `mwSize` or `mwIndex`; the returned value can not be predicted. Instead, change your code to avoid using negative values.

Building Cross-Platform Applications

If you develop cross-platform applications (programs that can run on both 32- and 64-bit architectures), you must pay attention to the upper limit of values you use for `mwSize` and `mwIndex`. The 32-bit application reads these values and assigns them to variables declared as `int` in C or `INTEGER*4` in Fortran. Be careful to avoid assigning a large `mwSize` or `mwIndex` value to an `int`, `INTEGER*4`, or other variable that might be too small.

Memory Management

Memory management within MEX-files is not unlike memory management for regular C or Fortran applications. However, there are special considerations because the MEX-file must exist within the context of a larger application, i.e., MATLAB itself.

Automatic Cleanup of Temporary Arrays

When a MEX-file returns to MATLAB, it gives to MATLAB the results of its computations in the form of the left-hand side arguments — the `mxArrays` contained within the `plhs[]` list. Any `mxArrays` created by the MEX-file that are not in this list are automatically destroyed. In addition, any memory allocated with `mxCalloc`, `mxMalloc`, or `mxRealloc` during the MEX-file's execution is automatically freed.

In general, we recommend that MEX-files destroy their own temporary arrays and free their own dynamically allocated memory. It is more efficient for the MEX-file to perform this cleanup than to rely on the automatic mechanism. However, there are several circumstances in which the MEX-file does not reach its normal return statement.

The normal return is not reached if:

- A call to `mexErrMsgTxt` occurs.
- A call to `mexCallMATLAB` occurs and the function being called creates an error. (A MEX-file can trap such errors by using `mexSetTrapFlag`, but not all MEX-files necessarily need to trap errors.)
- The user interrupts the MEX-file's execution using **Ctrl+C**.

- The MEX-file runs out of memory. When this happens, the MATLAB out-of-memory handler immediately terminates the MEX-file.

A careful MEX-file programmer can ensure safe cleanup of all temporary arrays and memory before returning in the first two cases, but not in the last two cases. In the last two cases, the automatic cleanup mechanism is necessary to prevent memory leaks.

Persistent Arrays

You can exempt an array, or a piece of memory, from the MATLAB automatic cleanup by calling `mexMakeArrayPersistent` or `mexMakeMemoryPersistent`. However, if a MEX-file creates such persistent objects, there is a danger that a memory leak could occur if the MEX-file is cleared before the persistent object is properly destroyed. In order to prevent this from happening, a MEX-file that creates persistent objects should register a function, using `mexAtExit`, which disposes of the objects. (You can use a `mexAtExit` function to dispose of other resources as well; for example, you can use `mexAtExit` to close an open file.)

For example, here is a simple MEX-file that creates a persistent array and properly disposes of it.

```
#include "mex.h"

static int initialized = 0;
static mxArray *persistent_array_ptr = NULL;

void cleanup(void) {
    mexPrintf("MEX-file is terminating, destroying array\n");
    mxDestroyArray(persistent_array_ptr);
}

void mexFunction(int nlhs,
    mxArray *plhs[],
    int nrhs,
    const mxArray *prhs[])
{
  if (!initialized) {
    mexPrintf("MEX-file initializing, creating array\n");
```

```
    /* Create persistent array and register its cleanup. */
    persistent_array_ptr = mxCreateDoubleMatrix(1, 1, mxREAL);
    mexMakeArrayPersistent(persistent_array_ptr);
    mexAtExit(cleanup);
    initialized = 1;

    /* Set the data of the array to some interesting value. */
    *mxGetPr(persistent_array_ptr) = 1.0;
  } else {
    mexPrintf("MEX-file executing; value of first array
        element is %g\n", *mxGetPr(persistent_array_ptr));
  }
}
```

Hybrid Arrays

Functions such as `mxSetPr`, `mxSetData`, and `mxSetCell` allow the direct placement of memory pieces into an `mxArray`. `mxDestroyArray` destroys these pieces along with the entire array. Because of this, it is possible to create an array that cannot be destroyed, i.e., an array on which it is not safe to call `mxDestroyArray`. Such an array is called a *hybrid* array, because it contains both destroyable and nondestroyable components.

For example, it is not legal to call `mxFree` (or the ANSI `free()` function, for that matter) on automatic variables. Therefore, in the following code fragment, `pArray` is a hybrid array.

```
mxArray *pArray = mxCreateDoubleMatrix(0, 0, mxREAL);
double data[10];

mxSetPr(pArray, data);
mxSetM(pArray, 1);
mxSetN(pArray, 10);
```

Another example of a hybrid array is a cell array or structure, one of whose children is a read-only array (an array with the `const` qualifier, such as one of the inputs to the MEX-file). The array cannot be destroyed because the input to the MEX-file would also be destroyed.

Because hybrid arrays cannot be destroyed, they cannot be cleaned up by the automatic mechanism outlined in “Automatic Cleanup of Temporary Arrays” on page 4-29. As described in that section, the automatic cleanup mechanism is the only way to destroy temporary arrays in case of a user interrupt. Therefore, *temporary hybrid arrays are illegal* and can cause your MEX-file to crash. Although persistent hybrid arrays are viable, it is best to avoid using them whenever possible.

Large File I/O

MATLAB supports the use of 64-bit file I/O operations in your MEX-file programs. This enables you to read and write data to files that are up to and greater than 2 GB (2^{31-1} bytes) in size. Note that some operating systems or compilers might not support files larger than 2 GB.

This section covers the following topics on large file I/O:

Prerequisites to Using 64-Bit I/O

This section describes the components you need to use 64-bit file I/O in your MEX-file programs:

Header File. Header file `io64.h` defines many of the types and functions required for 64-bit file I/O. The statement to include this file must be the *first* `#include` statement in your source file and must also precede any system header include statements:

```
#include "io64.h"
#include "mex.h"
        .
        .
        .
```

Type Declarations. Use the following types to declare variables used in 64-bit file I/O.

MEX Type	Description	POSIX
`fpos_T`	Declares a 64-bit `int` type for `setFilePos()` and `getFilePos()`. Defined in `io64.h`.	`fpos_t`
`int64_T, uint64_T`	Declares 64-bit signed and unsigned integer types. Defined in `tmwtypes.h`.	`long, long`
`structStat`	Declares a structure to hold the size of a file. Defined in `io64.h`.	`struct stat`
`FMT64`	Used in `mexPrintf` to specify length within a format specifier such as `%d`. See example in the section "Printing Formatted Messages" on page 4-36. `FMT64` is defined in `tmwtypes.h`.	`%lld`
`LL, LLU`	Suffixes for literal `int` constant 64-bit values (C Standard ISO/IEC 9899:1999(E) Section 6.4.4.1). Used only on UNIX.	`LL, LLU`

Functions. Here are the functions you need for 64-bit file I/O. All are defined in the header file `io64.h`.

Function	Description	POSIX
`fileno()`	Gets a file descriptor from a file pointer	`fileno()`
`fopen()`	Opens the file and obtains the file pointer	`fopen()`
`getFileFstat()`	Gets the file size of a given file pointer	`fstat()`
`getFilePos()`	Gets the file position for the next I/O	`fgetpos()`
`getFileStat()`	Gets the file size of a given filename	`stat()`
`setFilePos()`	Sets the file position for the next I/O	`fsetpos()`

Specifying Constant Literal Values

To assign signed and unsigned 64-bit integer literal values, use type definitions `int64_T` and `uint64_T`.

On UNIX, to assign a literal value to an integer variable where the value to be assigned is greater than $2^{31}-1$ signed, you must suffix the value with `LL`. If the value is greater than $2^{32}-1$ unsigned, then use `LLU` as the suffix. These suffixes apply only to UNIX systems and are considered invalid on Windows systems.

Note The `LL` and `LLU` suffixes are not required for hardcoded (literal) values less than `2 G (2 `^{31}`-1)`, even if they are assigned to a 64-bit `int` type.

The following example declares a 64-bit integer variable initialized with a large literal `int` value, and two 64-bit integer variables:

```
void mexFunction(int nlhs, mxArray *plhs[], int nrhs,
```

```
                  const mxArray *prhs[])
{
#if defined(_MSC_VER) || defined(__BORLANDC__)     /* Windows */
   int64_T large_offset_example = 9000222000;
#else                                              /* UNIX    */
   int64_T large_offset_example = 9000222000LL;
#endif

int64_T offset   = 0;
int64_T position = 0;
```

Opening a File

To open a file for reading or writing, use the C `fopen` function as you normally would. As long as you have included `io64.h` at the start of your program, `fopen` works correctly for large files. No changes at all are required for `fread`, `fwrite`, `fprintf`, `fscanf`, and `fclose`.

To open an existing file for read and update in binary mode,

```
fp = fopen(filename, "r+b");
if (NULL == fp)
   {
   /* File does not exist. Create new file for writing
    * in binary mode.
    */
   fp = fopen(filename, "wb");
   if (NULL == fp)
      {
      sprintf(str, "Failed to open/create test file '%s'",
              filename);
      mexErrMsgTxt(str);
      return;
      }
   else
      {
      mexPrintf("New test file '%s' created\n",filename);
      }
   }
else mexPrintf("Existing test file '%s' opened\n",filename);
```

Printing Formatted Messages

You cannot print 64-bit integers using the `%d` conversion specifier. Instead, use `FMT64` to specify the appropriate format for your platform. `FMT64` is defined in the header file `tmwtypes.h`. The following example shows how to print a message showing the size of a large file:

```
int64_T large_offset_example = 9000222000LL;

mexPrintf("Example large file size: %" FMT64 "d bytes.\n",
           large_offset_example);
```

Replacing fseek and ftell with 64-Bit Functions

The ANSI C `fseek` and `ftell` functions are not 64-bit file I/O capable on most platforms. The functions `setFilePos` and `getFilePos`, however, are defined as the corresponding POSIX `fsetpos` and `fgetpos`, (or `fsetpos64` and `fgetpos64`), as required by your platform/OS. These functions are 64-bit file I/O capable on all platforms.

The following example shows how to use `setFilePos` instead of `fseek`, and `getFilePos` instead of `ftell`. It uses `getFileFstat` to find the size of the file, and then uses `setFilePos` to seek to the end of the file to prepare for adding data at the end of the file.

Note Although the `offset` parameter to `setFilePos` and `getFilePos` is really a pointer to a signed 64-bit integer, `int64_T`, it must be cast to an `fpos_T*`. The `fpos_T` type is defined in `io64.h` as the appropriate `fpos64_t` or `fpos_t`, as required by your platform/OS.

```
getFileFstat(fileno(fp), &statbuf);
fileSize = statbuf.st_size;
offset = fileSize;

setFilePos(fp, (fpos_T*) &offset);
getFilePos(fp, (fpos_T*) &position );
```

Unlike `fseek`, `setFilePos` supports only absolute seeking relative to the beginning of the file. If you want to do a relative seek, first call `getFileFstat`

to obtain the file size, and then convert the relative offset to an absolute offset that you can pass to `setFilePos`.

Determining the Size of an Open File

Getting the size of an open file involves two steps:

1. Refresh the record of the file size stored in memory using `getFilePos` and `setFilePos`.
2. Retrieve the size of the file using `getFileFstat`.

Refreshing the File Size Record. Before attempting to retrieve the size of an open file, you should first refresh the record of the file size residing in memory. If you skip this step on a file that is opened for writing, the file size returned might be incorrect or 0.

To refresh the file size record, seek to any offset in the file using `setFilePos`. If you do not want to change the position of the file pointer, you can seek to the current position in the file. This example obtains the current offset from the start of the file and then seeks to the current position to update the file size without moving the file pointer:

```
getFilePos( fp, (fpos_T*) &position);
setFilePos( fp, (fpos_T*) &position);
```

Getting the File Size. The `getFileFstat` function takes a file descriptor input argument (that you can obtain from the file pointer of the open file using `fileno`), and returns the size of that file in bytes in the `st_size` field of a `structStat` structure:

```
structStat statbuf;
int64_T fileSize = 0;

if (0 == getFileFstat(fileno(fp), &statbuf))
   {
   fileSize = statbuf.st_size;
   mexPrintf("File size is %" FMT64 "d bytes\n", fileSize);
   }
```

Determining the Size of a Closed File

The `getFileStat` function takes the filename of a closed file as an input argument, and returns the size of the file in bytes in the `st_size` field of a `structStat` structure:

```
structStat statbuf;
int64_T fileSize = 0;

if (0 == getFileStat(filename, &statbuf))
   {
   fileSize = statbuf.st_size;
   mexPrintf("File size is %" FMT64 "d bytes\n", fileSize);
   }
```

Using LAPACK and BLAS Functions

LAPACK is a large, multiauthor Fortran subroutine library that MATLAB uses for numerical linear algebra. BLAS, which stands for Basic Linear Algebra Subroutines, is used by MATLAB to speed up matrix multiplication and the LAPACK routines themselves. The functions provided by LAPACK and BLAS can also be called directly from within your C MEX-files.

This section explains how to write and build MEX-files that call LAPACK and BLAS functions. It provides information on

Specifying the Function Name

When calling an LAPACK or BLAS function, some platforms require an underscore character following the function name in the call statement.

On the PC platform use the function name alone, with no trailing underscore. For example, to call the LAPACK `dgemm` function, use

```
dgemm(arg1, arg2, ..., argn);
```

On the LINUX, Solaris, and Macintosh platforms, add the underscore after the function name. For example, to call `dgemm` on any of these platforms, use

```
dgemm_(arg1, arg2, ..., argn);
```

Calling LAPACK and BLAS Functions from C

Since the LAPACK and BLAS functions are written in Fortran, arguments passed to and from these functions must be passed by reference. The following example calls `dgemm`, passing all arguments by reference. An ampersand (&) precedes each argument unless that argument is already a reference.

```
#include "mex.h"

void mexFunction(int nlhs, mxArray *plhs[],
                 int nrhs, const mxArray *prhs[])
{
  double *A, *B, *C, one = 1.0, zero = 0.0;
  int m,n,p;
  char *chn = "N";

  A = mxGetPr(prhs[0]);
  B = mxGetPr(prhs[1]);
  m = mxGetM(prhs[0]);
  p = mxGetN(prhs[0]);
  n = mxGetN(prhs[1]);

  if (p != mxGetM(prhs[1])) {mexErrMsgTxt
    ("Inner dimensions of matrix multiply do not match");
  }

  plhs[0] = mxCreateDoubleMatrix(m, n, mxREAL);
```

```
  C = mxGetPr(plhs[0]);

  /* Pass all arguments to Fortran by reference */
  dgemm(chn, chn, &m, &n, &p, &one, A, &m, B, &p, &zero, C, &m);
}
```

Handling Complex Numbers

MATLAB stores complex numbers differently than Fortran. MATLAB stores the real and imaginary parts of a complex number in separate, equal length vectors, `pr` and `pi`. Fortran stores the same number in one location with the real and imaginary parts interleaved.

As a result, complex variables exchanged between MATLAB and the Fortran functions in LAPACK and BLAS are incompatible. MATLAB provides conversion routines that change the storage format of complex numbers to address this incompatibility.

Input Arguments. For all complex variables passed as input arguments to a Fortran function, you need to convert the storage of the MATLAB variable to be compatible with the Fortran function. Use the `mat2fort` function for this. See the example that follows.

Output Arguments. For all complex variables passed as output arguments to a Fortran function, you need to do the following:

1. When allocating storage for the complex variable, allocate a real variable with twice as much space as you would for a MATLAB variable of the same size. You need to do this because the returned variable uses the Fortran format, which takes twice the space. See the allocation of `zout` in the example that follows.

2. Once the variable is returned to MATLAB, convert its storage so that it is compatible with MATLAB. Use the `fort2mat` function for this.

Example — Passing Complex Variables. The example below shows how to call an LAPACK function from MATLAB, passing complex `prhs[0]` as input and receiving complex `plhs[0]` as output. Temporary variables `zin` and `zout` are used to hold `prhs[0]` and `plhs[0]` in Fortran format.

```
#include "mex.h"
```

```
#include "fort.h"      /* defines mat2fort and fort2mat */

void mexFunction(int nlhs, mxArray *plhs[], int nrhs, mxArray
*prhs[])
{
  int lda, n;
  double *zin, *zout;
  lda = mxGetM(prhs[0]);
  n = mxGetN(prhs[0]);

  /* Convert input to Fortran format */
  zin = mat2fort(prhs[0], lda, n);

  /* Allocate a real, complex, lda-by-n variable to store output
*/
  zout = mxCalloc(2*lda*n, sizeof(double));

  /* Call complex LAPACK function */
  zlapack_function(zin, &lda, &n, zout);

  /* Convert output to MATLAB format */
  plhs[0] = fort2mat(zout, lda, lda, n);

  /* Free intermediate Fortran format arrays */
  mxFree(zin);
  mxFree(zout);
}
```

Preserving Input Values from Modification

Many LAPACK and BLAS functions modify the values of arguments passed in to them. It is advisable to make a copy of arguments that can be modified prior to passing them to the function. For complex inputs, this point is moot since the `mat2fort` version of the input is a new piece of memory, but for real data this is not the case.

The following example calls an LAPACK function that modifies the first input argument. The code in this example makes a copy of `prhs[0]`, and then passes the copy to the LAPACK function to preserve the contents of `prhs[0]`.

```
/* lapack_function modifies A so make a copy of the input */
m = mxGetM(prhs[0]);
n = mxGetN(prhs[0]);
A = mxCalloc(m*n, sizeof(double));

/* Copy mxGetPr(prhs[0]) into A */
temp = mxGetPr(prhs[0]);
for (k = 0; k < m*n; k++) {
   A[k] = temp[k];
   }

/* lapack_function does not modify B
/* so it is OK to use the input
directly */
B = mxGetPr(prhs[1]);
lapack_function(A, B);       /* modifies A but not B */

/* Free A when you are done with it */
mxFree(A);
```

Building the C MEX-File

The examples in this section show how to compile and link a C MEX file, `myCmexFile.c`, on the platforms supported by MATLAB.

Building on the PC. If you build your C MEX-file on a PC platform, you need to explicitly specify a library file to link with.

On the PC, use this command if you are using the Lcc compiler that ships with MATLAB:

```
mex myCmexFile.c
matlabroot\extern\lib\win32\lcc\libmwlapack.lib
matlabroot\extern\lib\win32\lcc\libmwblas.lib
```

Or, use this command if you are using Microsoft Visual C++ as your C compiler:

```
mex myCmexFile.c
matlabroot\extern\lib\win32\microsoft\libmwlapack.lib
matlabroot\extern\lib\win32\microsoft\libmwblas.lib
```

or

```
mex myCmexFile.c
matlabroot\extern\lib\win64\microsoft\libmwlapack.lib
matlabroot\extern\lib\win64\microsoft\libmwblas.lib
```

Building on Other Platforms. On all other platforms, you can build your MEX-file as you would any other C MEX-file. For example,

```
mex myCmexFile.c
```

MEX-Files That Perform Complex Number Conversion. MATLAB supplies the files `fort.c` and `fort.h`, which provide routines for conversion between MATLAB and FORTRAN complex data structures. These files define the `mat2fort` and `fort2mat` routines mentioned previously under "Handling Complex Numbers" on page 4-40.

If your program uses these routines, you need to:

1. Include the `fort.h` file in your program using `#include "fort.h"`. See "Example — Passing Complex Variables" on page 4-40.
2. Build the `fort.c` file with your program. Specify the path, *`matlabroot`*`/extern/examples/refbook` for both `fort.c` and `fort.h` in the build command.

On the PC, use either one of the following:

1.

```
mex myCmexFile.c matlabroot/extern/examples/refbook/fort.c
-Imatlabroot/extern/examples/refbook
matlabroot/extern/lib/win32/microsoft/libmwlapack.lib
matlabroot/extern/lib/win32/microsoft/libmwblas.lib
```

2.

```
mex myCmexFile.c matlabroot/extern/examples/refbook/fort.c
-Imatlabroot/extern/examples/refbook
matlabroot/extern/lib/win32/lcc/libmwlapack.lib
matlabroot/extern/lib/win32/lcc/libmwblas.lib
```

For all other platforms, use

```
mex myCmexFile.c matlabroot/extern/examples/refbook/fort.c
-Imatlabroot/extern/examples/refbook
```

Example — Symmetric Indefinite Factorization Using LAPACK

The directory *matlabroot*/extern/examples/refbook contains an example C MEX-file that calls two LAPACK functions. There are two versions of this file:

- utdu_slv.c - calls functions zhesvx and dsysvx, and thus is compatible with the PC platform.
- utdu_slv_.c - calls functions zhesvx_ and dsysvx_, and thus is compatible with the LINUX, Solaris, and Macintosh platforms.

Calling LAPACK and BLAS Functions from Fortran

You can make calls to the LAPACK and BLAS functions used by MATLAB from your Fortran MEX files. The following is an example program that takes two matrices and multiplies them by calling the LAPACK routine, dgemm:

```
subroutine mexFunction(nlhs, plhs, nrhs, prhs)
integer plhs(*), prhs(*)
integer nlhs, nrhs
integer mxcreatedoublematrix, mxgetpr
integer mxgetm, mxgetn
integer m, n, p
integer A, B, C
double precision one, zero, ar, br
character ch1, ch2

ch1 = 'N'
ch2 = 'N'
one = 1.0
zero = 0.0

A = mxgetpr(prhs(1))
B = mxgetpr(prhs(2))
m = mxgetm(prhs(1))
p = mxgetn(prhs(1))
```

```
      n = mxgetn(prhs(2))

      plhs(1) = mxcreatedoublematrix(m, n, 0.0)
      C = mxgetpr(plhs(1))
      call mxcopyptrtoreal8(A, ar, 1)
      call mxcopyptrtoreal8(B, br, 1)

      call dgemm(ch1, ch2, m, n, p, one, %val(A), m,
     +           %val(B), p, zero, %val(C), m)

      return
      end
```

Building the Fortran MEX-File

The examples in this section show how to compile and link a Fortran MEX file, `myFortranmexFile.F`, on the platforms supported by MATLAB.

Building on the PC. On the PC, using Visual Fortran, link against the libraries `libdflapack.lib` and `libdfblas.lib`:

```
mex -v myFortranMexFile.F
matlabroot/extern/lib/win32/microsoft/libdflapack.lib
matlabroot/extern/lib/win32/microsoft/libdfblas.lib
```

Building on Other UNIX Platforms. On the UNIX platforms, create the MEX file as follows:

```
mex -v myFortranMexFile.F
```

Debugging C Language MEX-Files

In this section...

Notes on Debugging

The examples show how to debug `yprime.c`, found in your *`matlabroot`*`/extern/examples/mex/` directory.

MEX-files built with the `-g` option do not execute on other computers because they rely on files that are not distributed with MATLAB. Refer to the "Calling C and Fortran Programs from MATLAB" topic "Troubleshooting" on page 3-32 for additional information on isolating problems with MEX-files.

Debugging on Windows

The Microsoft Visual Studio development environment provides complete source code debugging, including the ability to set breakpoints, examine variables, and step through the source code line-by-line.

For information on debugging MEX-files compiled with other MATLAB supported compilers, see Technical Note 1605, MEX-files Guide, at `http://www.mathworks.com/support/tech-notes/1600/1605.html`.

Microsoft Visual Studio 2005

This section describes how to debug using the default compiler, that is, the compiler used to build MATLAB.

1 Select the Microsoft Visual C++ 2005 compiler. At the MATLAB prompt, type

```
mex -setup
```

Type `y` to locate installed compilers, and then type the number corresponding to this compiler.

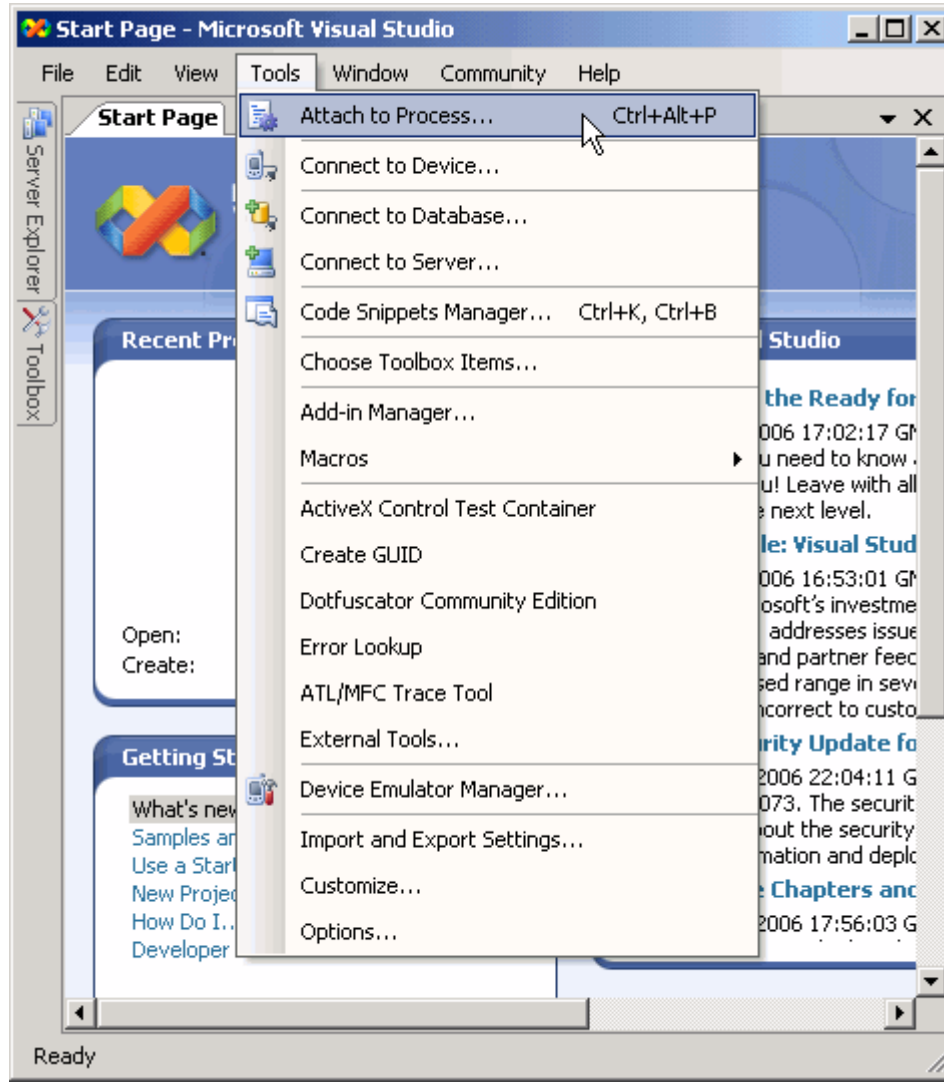
2 Next, compile the MEX-file with the `-g` option, which builds the file with debugging symbols included. For example

```
mex -g yprime.c
```

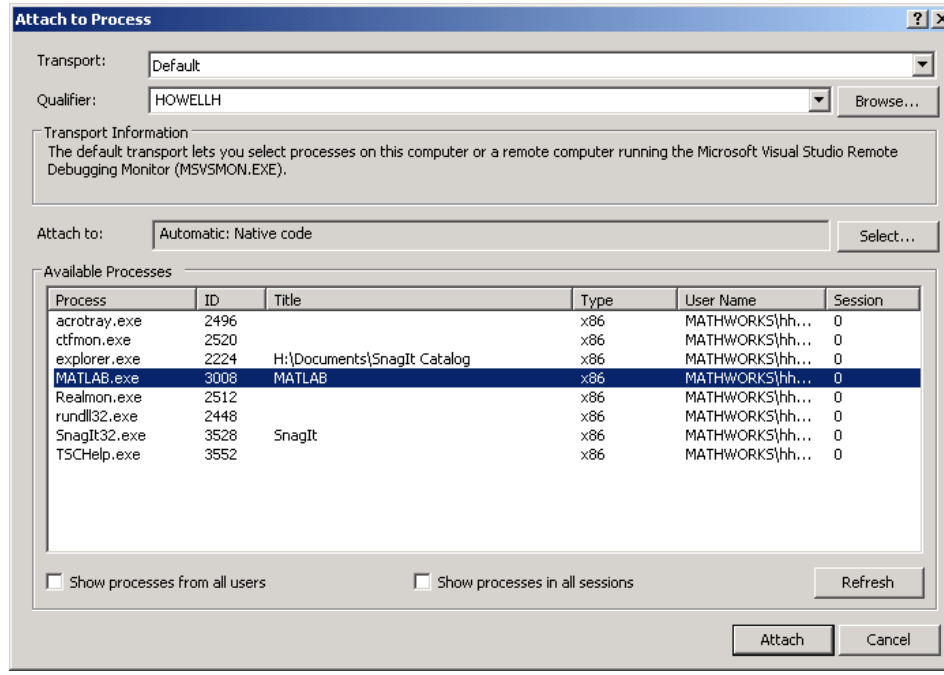
On a 32–bit platform, this command creates the executable file `yprime.mexw32`.

3 Start Visual Studio. Do not exit your MATLAB session.

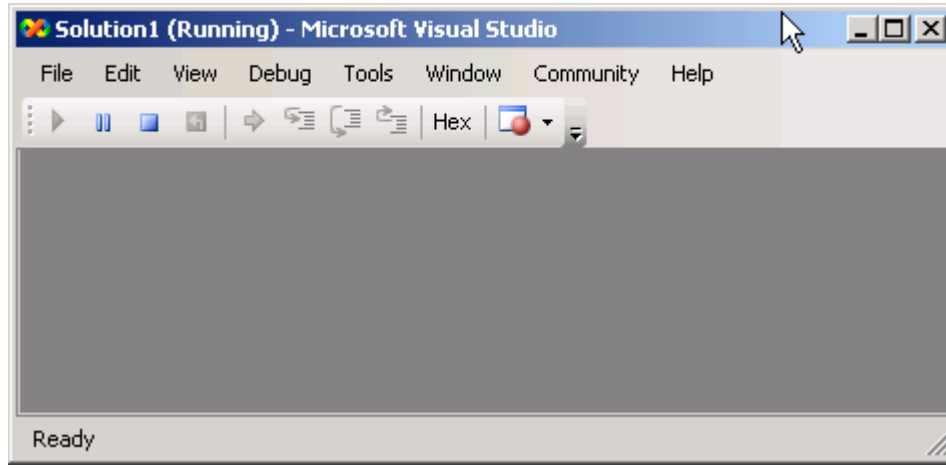
4 From the Visual Studio **Tools** menu, select **Attach to Process...**



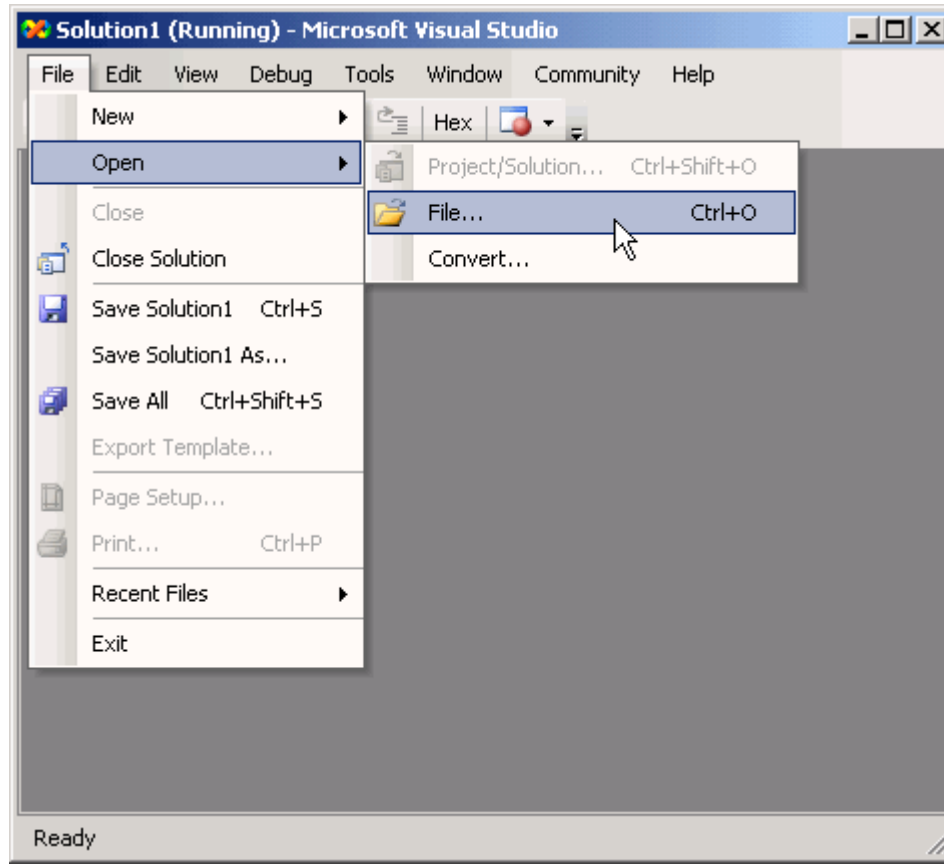
5 In the Attach to Process dialog box, select the MATLAB process and click **Attach**.



Visual Studio loads data then displays an empty code pane.



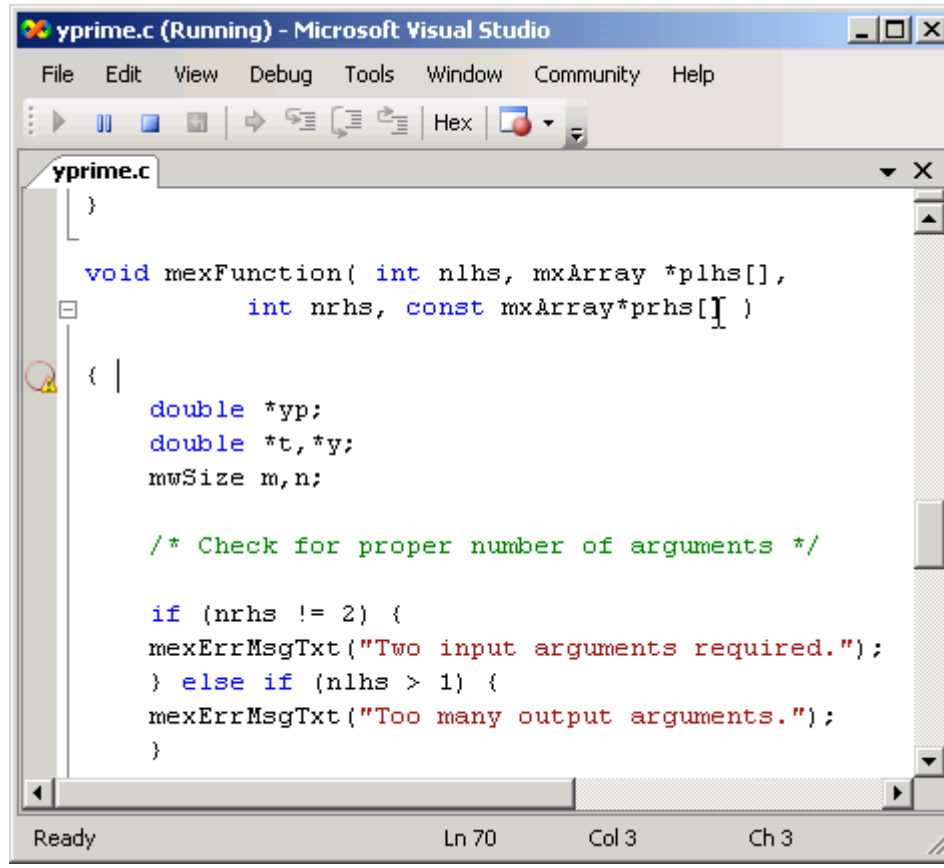
6 Open the source file `yprime.c` by selecting **File > Open > File**. `yprime.c` is found in the *`matlabroot`*`/extern/examples/mex/` directory.



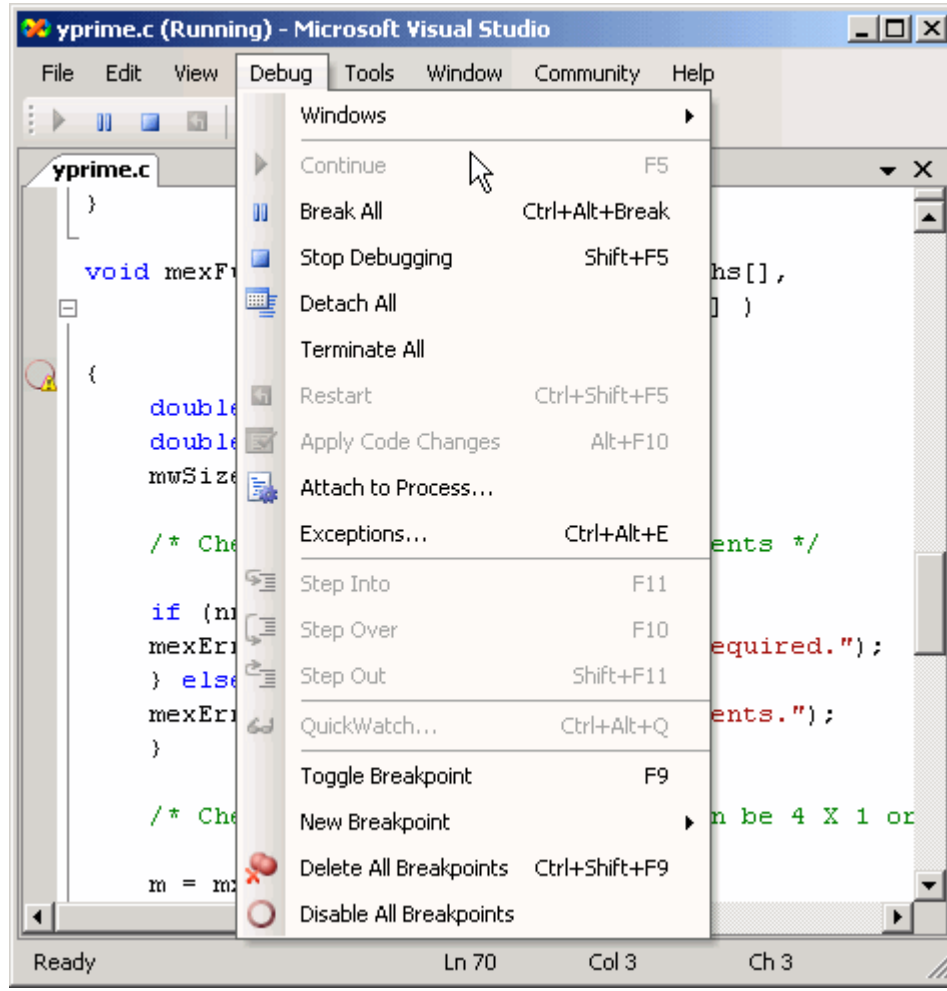
7 Set a breakpoint by right-clicking the desired line of code and following **Breakpoint > Insert Breakpoint** on the context menu. It is often

convenient to set a breakpoint at `mexFunction` in order to stop at the beginning of the gateway routine.

If you have not yet run the executable file, ignore any "`!`" icon that appears with the breakpoint next to the line of code.



Once you hit one of your breakpoints, you can make full use of any commands the debugger provides to examine variables, display memory, or inspect registers.



8 Run the MEX-file in MATLAB. After typing

```
yprime(1,1:4)
```

`yprime.c` is opened in the Visual Studio debugger at the first breakpoint.

9 If you select **Debug > Continue**, MATLAB displays

```
ans =

    2.0000    8.9685    4.0000   -1.0947
```

For more information on how to debug in the Visual Studio environment, see the Microsoft documentation.

Debugging on Linux

The GNU Debugger gdb, available on Linux, provides complete source code debugging, including the ability to set breakpoints, examine variables, and step through the source code line-by-line.

For information on debugging MEX-files compiled with other MATLAB supported compilers, see Technical Note 1605, MEX-files Guide, at `http://www.mathworks.com/support/tech-notes/1600/1605.html`.

GNU Debugger gdb

In this procedure, the MATLAB command prompt >> is shown in front of MATLAB commands, and `linux>` represents a Linux prompt; your system may show a different prompt. The debugger prompt is `<gdb>`.

To debug with gdb,

1 Compile the MEX-file with the `-g` option, which builds the file with debugging symbols included. For this example, at the Linux prompt, type

```
linux> mex -g yprime.c
```

On a Linux 32–bit platform, this command creates the executable file `yprime.mexglx`.

2 At the Linux prompt, start the gdb debugger using the `matlab` function `-D` option:

```
linux> matlab -Dgdb
```

3 Start MATLAB without the Java virtual machine (JVM) by using the `-nojvm` startup flag:

```
<gdb> run -nojvm
```

4 In MATLAB, enable debugging with the `dbmex` function and run your MEX-file:

```
>> dbmex on
>> yprime(1,1:4)
```

5 At this point, you are ready to start debugging.

It is often convenient to set a breakpoint at `mexFunction` so you stop at the beginning of the gateway routine.

```
<gdb> break mexFunction
<gdb> continue
```

6 Once you hit one of your breakpoints, you can make full use of any commands the debugger provides to examine variables, display memory, or inspect registers.

To proceed from a breakpoint, type

```
<gdb> continue
```

7 After stopping at the last breakpoint, type

```
<gdb> continue
```

`yprime` finishes and MATLAB displays

```
ans =

    2.0000    8.9685    4.0000   -1.0947
```

8 From the MATLAB prompt you can return control to the debugger by typing

```
>> dbmex stop
```

Or, if you are finished running MATLAB, type

```
>> quit
```

9 When you are finished with the debugger, type

```
<gdb> quit
```

You return to the Linux prompt.

Refer to the documentation provided with your debugger for more information on its use.

5

Creating Fortran MEX-Files

Fortran MEX-Files

In this section...

The Components of a Fortran MEX-File

MEX-files are built by using the `mex` function. `mex` compiles and links source files into a shared library called a MEX-file, which you can run in MATLAB. Once compiled, you treat MEX-files exactly like MATLAB M-files and built-in functions.

The MEX-file consists of:

- A "Gateway Routine" on page 5-2 that interfaces Fortran and MATLAB data.
- A "Computational Routine" on page 5-5 that performs the computations you want implemented in the MEX-file.
- "Preprocessor Macros" on page 5-5 for building platform-independent code.

Gateway Routine

The *gateway routine* is the entry point to the MEX-file shared library. It is through this routine that MATLAB accesses the rest of the routines in your MEX-files. Use the following guideline to create a gateway routine:

- "Naming the Gateway Routine" on page 5-3
- "Required Parameters" on page 5-3
- "Creating and Using Source Files" on page 5-4

A Fortran MEX-file gateway routine looks like this:

```
C     The gateway routine.
      subroutine mexFunction(nlhs, plhs, nrhs, prhs)
      integer nlhs, nrhs
      mwpointer plhs(*), prhs(*)
```

Note Fortran is not case sensitive. This document uses mixed-case function names for ease of reading.

Naming the Gateway Routine

The name of the gateway routine must be `mexFunction`.

Required Parameters

A gateway routine must contain the parameters `prhs`, `nrhs`, `plhs`, and `nlhs` which are described in the following table.

Parameter	Description
`prhs`	An array of right-hand input arguments.
`plhs`	An array of left-hand output arguments.
`nrhs`	The number of right-hand arguments, or the size of the `prhs` array.
`nlhs`	The number of left-hand arguments, or the size of the `plhs` array.

Both `prhs` and `plhs` are declared as type `mxArray *`, which means they point to MATLAB arrays. They are vectors that contain pointers to the arguments of the MEX-file.

You can think of the name `prhs` as representing the "parameters, right-hand side," that is, the input parameters. Likewise, `plhs` represents the "parameters, left-hand side," or output parameters.

Creating and Using Source Files

It is good practice to write the gateway routine to call a "Computational Routine" on page 4-4; however, this is not required. The computational code can be part of the gateway routine. If you use both gateway and computational routines, they can be combined in one source file or in separate files. If you use separate files, the gateway routine must be the first source file listed in the `mex` command.

The name of the file containing your gateway routine is important, as explained in "Naming the MEX-File" on page 5-5.

Name your Fortran source file with an uppercase `.F` file extension.

The Difference Between .f and .F Files. Fortran compilers assume source files using a lowercase `.f` file extension have been preprocessed. On most platforms, `mex` makes sure the file is preprocessed regardless of the file extension. However, on Macintosh systems, `mex` cannot force preprocessing. Use an uppercase `.F` file extension to ensure your Fortran MEX-file is platform independent.

Using MATLAB Libraries

The MATLAB C and Fortran API Reference describes functions you can use in your gateway and computational routines that interact with MATLAB programs and the data in the MATLAB workspace. The `mx` prefixed functions provide access methods for manipulating MATLAB arrays. The `mex` prefixed functions perform operations in the MATLAB environment.

Required Header Files

To use the functions in the C and Fortran Reference library you must include the `mex` header, which declares the entry point and interface routines. Put this statement in your source file:

```
#include "mex.h"
```

In addition, Fortran MEX-files require the `fintrf.h` header file, which is used by the `mwPointer` preprocessor macro. Put this statement in your Fortran source file:

```
#include "fintrf.h"
```

Naming the MEX-File

The MEX-file name, and hence the name of the function you use in MATLAB, is the name of the source file containing your gateway routine.

The file extension of the MEX-file is platform-dependent. The `mexext` function returns the extension for the current machine.

Computational Routine

The *computational routine* contains the code for performing the computations you want implemented in the MEX-file. Computations can be numerical computations as well as inputting and outputting data. The gateway calls the computational routine as a subroutine.

The programming requirements described in "Creating and Using Source Files" on page 4-4, "Using MATLAB Libraries" on page 4-4, and "Required Header Files" on page 4-4 may also apply to your computational routine.

Preprocessor Macros

The MATLAB *preprocessor macros* `mwSize` and `mwIndex` are used in the `mx` and `mex` functions for cross-platform flexibility. `mwSize` represents size values, such as array dimensions and number of elements. `mwIndex` represents index values, such as indices into arrays.

MATLAB has an additional preprocessor macro for Fortran files, `mwPointer`. MATLAB uses a unique data type, the `mxArray`. Because there is no way to create a new data type in Fortran, MATLAB passes a special identifier, created by the `mwPointer` preprocessor macro, to a Fortran program. This is how you get information about an `mxArray` in a native Fortran data type. For example, you can find out the size of the `mxArray`, determine whether or not it is a string, and look at the contents of the array. Use `mwPointer` to build platform-independent code.

The Fortran preprocessor converts `mwPointer` to `integer*4` when building MEX-files on 32-bit platforms and to `integer*8` when building on 64-bit platforms.

Note Declaring a pointer to be the incorrect size may cause your program to crash.

Using the Fortran %val Construct

The Fortran `%val(arg)` construct specifies that an argument, *arg*, is to be passed by value, instead of by reference. The `%val` construct is supported by most, but not all, Fortran compilers. Compaq Visual Fortran *does* support the construct.

If your compiler does not support the `%val` construct, you must copy the array values into a temporary true Fortran array using the `mxCopy*` routines (e.g., `mxCopyPtrToReal8`).

A %val Construct Example

If your compiler supports the `%val` construct, you can use routines that point directly to the data (i.e., the pointer returned by `mxGetPr` or `mxGetPi`). You can use `%val` to pass this pointer's contents to a subroutine, where it is declared as a Fortran double-precision matrix.

For example, consider a gateway routine that calls its computational routine, `yprime`, by

```
call yprime(%val(yp), %val(t), %val(y))
```

If your Fortran compiler does not support the `%val` construct, you would replace the call to the computational subroutine with

```
C Copy array pointers to local arrays.
       call mxCopyPtrToReal8(t, tr, 1)
       call mxCopyPtrToReal8(y, yr, 4)
C
C Call the computational subroutine.
       call yprime(ypr, tr, yr)
```

```
C
C Copy local array to output array pointer.
       call mxCopyReal8ToPtr(ypr, yp, 4)
```

You must also add the following declaration line to the top of the gateway routine:

```
real*8 ypr(4), tr, yr(4)
```

Note that if you use `mxCopyPtrToReal8` or any of the other `mxCopy*` routines, the size of the arrays declared in the Fortran gateway routine must be greater than or equal to the size of the inputs to the MEX-file coming in from MATLAB. Otherwise, `mxCopyPtrToReal8` does not work correctly.

Data Flow in MEX-Files

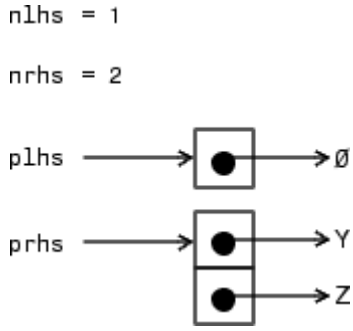
The following examples illustrate data flow in MEX-files:

Showing Data Input and Output

Suppose your MEX-file `myFunction` has 2 input arguments and 1 output argument. The MATLAB syntax is `[X] = myFunction(Y, Z)`. To call `myFunction` from MATLAB, type:

```
X = myFunction(Y, Z);
```

The MATLAB interpreter calls `mexFunction`, the gateway routine to `myFunction`, with the following arguments:



Your input is `prhs`, a 2-element C array (`nrhs = 2`). The first element is a pointer to an `mxArray` named `Y` and the second element is a pointer to an `mxArray` named `Z`.

Your output is `plhs`, a 1-element C array (`nlhs = 1`) where the single element is a `null` pointer. The parameter `plhs` points at nothing because the output `X` is not created until the subroutine executes.

The gateway routine creates the output array and sets a pointer to it in `plhs[0]`. If `plhs[0]` is left unassigned and you assign an output value to the function when you call it, MATLAB generates an error stating that no output was assigned.

Note It is possible to return an output value even if `nlhs = 0`. This corresponds to returning the result in the `ans` variable.

Gateway Routine Data Flow Diagram

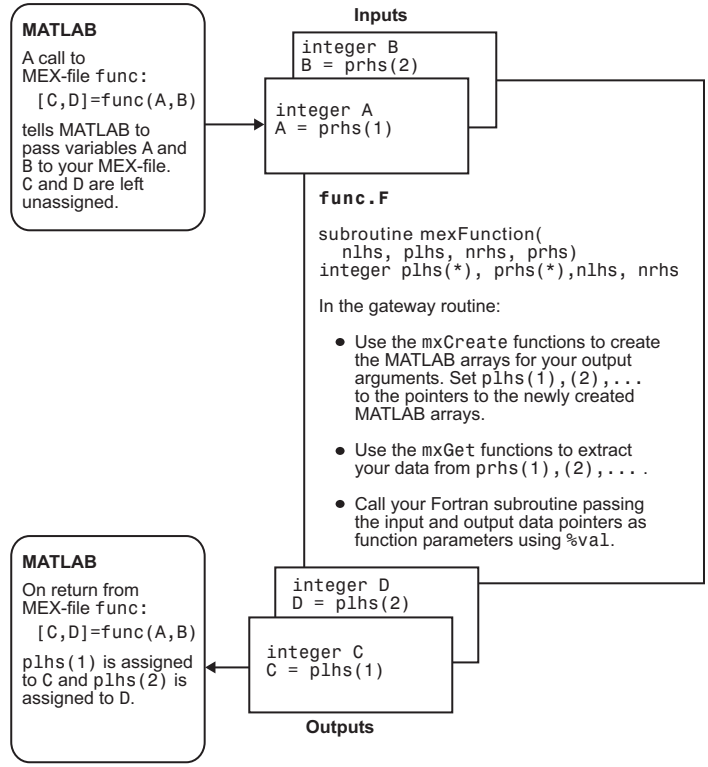
The following MEX Cycle diagram shows how inputs enter a MEX-file, what functions the gateway routine performs, and how outputs return to MATLAB.

In this example, the syntax of the MEX-file `func` is `[C, D] = func(A,B)`. In the figure, a call to `func` tells MATLAB to pass variables `A` and `B` to your MEX-file. `C` and `D` are left unassigned.

The gateway routine `func.F` uses the `mxCreate*` functions to create the MATLAB arrays for your output arguments. It sets `plhs[0]` and `plhs[1]`

to the pointers to the newly created MATLAB arrays. It uses the `mxGet*` functions to extract your data from your input arguments `prhs[0]` and `prhs[0]`. Finally, it calls your computational routine, passing the input and output data pointers as function parameters.

On return to MATLAB, `plhs[0]` is assigned to `C` and `plhs[1]` is assigned to `D`.



Fortran MEX Cycle

MATLAB Example yprime.F

Let's look at an example, `yprime.F`, found in your *matlabroot*`/extern/examples/mex/` directory. ("Building MEX-Files" on page 3-11 explains how to create the MEX-file.) It's calling syntax is `[YP] = YPRIME(T,Y)`, where `T` is an integer and `Y` is a vector with 4 elements. For `T=1` and `Y=1:4`, when you type

```
yprime(T,Y)
```

MATLAB displays:

```
ans =
     2.0000    8.9685    4.0000    -1.0947
```

The gateway routine should validate the input arguments. This step includes checking the number, type, and size of the input arrays as well as examining the number of output arrays. If the inputs are not valid, call `mexErrMsgTxt`. For example,

```
C
C CHECK FOR PROPER NUMBER OF ARGUMENTS
C
      IF (NRHS .NE. 2) THEN
        CALL MEXERRMSGTXT('YPRIME requires two input arguments')
      ELSEIF (NLHS .GT. 1) THEN
        CALL MEXERRMSGTXT('YPRIME requires one output argument')
      ENDIF
C
C CHECK THE DIMENSIONS OF Y.  IT CAN BE 4 X 1 OR 1 X 4.
C
      M = MXGETM(PRHS(2))
      N = MXGETN(PRHS(2))
C
      IF ((MAX(M,N) .NE. 4) .OR. (MIN(M,N) .NE. 1)) THEN
        CALL MEXERRMSGTXT('YPRIME requires that Y be a 4 x 1 vector')
      ENDIF
```

To create MATLAB arrays, call any of the `mxCreate*` functions, like `mxCreateDoubleMatrix`, `mxCreateSparse`, or `mxCreateString`. If it needs them, the gateway routine can call `mxCalloc` to allocate temporary work arrays for the computational routine. In this example,

```
C
C CREATE A MATRIX FOR RETURN ARGUMENT
C
       PLHS(1) = MXCREATEDOUBLEMATRIX(M,N,0)
```

In the gateway routine, you access the data in `mxArray` and manipulate it in your computational subroutine. For example, the expression `mxGetPr(prhs[0])` returns a pointer of type `double *` to the real data in the `mxArray` pointed to by `prhs[0]`. You can then use this pointer like any other pointer of type `double *` in Fortran. For example,

```
C
C ASSIGN POINTERS TO THE VARIOUS PARAMETERS
C
      YPP = MXGETPR(PLHS(1))
C
      TP = MXGETPR(PRHS(1))
      YP = MXGETPR(PRHS(2))
C
C COPY RIGHT HAND ARGUMENTS TO LOCAL ARRAYS OR VARIABLES
      NEL = 1
      CALL MXCOPYPTRTOREAL8(TP, RTP, NEL)
      NEL = 4
      CALL MXCOPYPTRTOREAL8(YP, RYP, NEL)
```

In this example, a computational routine, `yprime`, performs the calculations:

```
C
C DO THE ACTUAL COMPUTATIONS IN A SUBROUTINE
C       CREATED ARRAYS.
C
      CALL YPRIME(RYPP,RTP,RYP)
```

After calling your computational routine from the gateway, you can set a pointer of type `mxArray` to the data it returns. MATLAB recognizes the output from your computational routine as the output from the MEX-file.

```
C
C COPY OUTPUT WHICH IS STORED IN LOCAL ARRAY TO MATRIX OUTPUT
      NEL = 4
      CALL MXCOPYREAL8TOPTR(RYPP, YPP, NEL)
```

When a MEX-file completes its task, it returns control to MATLAB. Any MATLAB arrays that are created by the MEX-file but are not returned to MATLAB through the left-hand side arguments are automatically destroyed.

Examples of Fortran MEX-Files

In this section...

Introduction

The MATLAB API provides a set of Fortran routines that handle double-precision data and strings in MATLAB. For each data type, there is a specific set of functions that you can use for data manipulation.

Note Source code for the examples in this chapter are located in the *matlabroot*/extern/examples/refbook directory of your MATLAB installation.

A First Example — Passing a Scalar

Let's look at a simple example of Fortran code and its MEX-file equivalent. Here is a Fortran computational routine that takes a scalar and doubles it:

```
      subroutine timestwo(y, x)
      real*8 x, y
C
      y = 2.0 * x
```

```
      return
      end
```

To see the same function written in the MEX-file format (`timestwo.F`), open the file in MATLAB Editor.

To compile and link this example, at the MATLAB prompt type

```
mex timestwo.F
```

This command creates the MEX-file called `timestwo` with an extension corresponding to the machine type on which you're running. You can now call `timestwo` as if it were an M-function:

```
x = 2;
y = timestwo(x)
y =
     4
```

Passing Strings

Passing strings from MATLAB to a Fortran MEX-file is straightforward. The program `revord.F` accepts a string and returns the characters in reverse order. To see the example `revord.F`, open the file in MATLAB Editor.

After checking for the correct number of inputs, the gateway routine `mexFunction` verifies that the input was a row vector string. It then finds the size of the string and places the string into a Fortran character array. Note that in the case of character strings, it is not necessary to copy the data into a Fortran character array using `mxCopyPtrToCharacter`. In fact, `mxCopyPtrToCharacter` works only with MAT-files. For more information, see "Using MAT-Files" on page 1-2.

For an input string

```
x = 'hello world';
```

typing

```
y = revord(x)
```

produces

```
y =

dlrow olleh
```

Passing Arrays of Strings

Passing arrays of strings adds a complication to the example “Passing Strings” on page 5-13. Because MATLAB stores elements of a matrix by column instead of by row, the size of the string array must be correctly defined in the Fortran MEX-file. The key point is that the row and column sizes as defined in MATLAB must be reversed in the Fortran MEX-file. Consequently, when returning to MATLAB, the output matrix must be transposed.

This example places a string array/character matrix into MATLAB as output arguments rather than placing it directly into the workspace. At the MATLAB prompt, type

```
passstr;
```

which creates the 5-by-15 `mystring` matrix. You need to do some further manipulation. The original string matrix is 5-by-15. Because of the way MATLAB reads and orients elements in matrices, the size of the matrix must be defined as `M=15` and `N=5` in the MEX-file. After the matrix is put into MATLAB, the matrix must be transposed. The program `passstr.F` illustrates how to pass a character matrix. To see the code `passstr.F`, open the file in MATLAB Editor.

Typing

```
passstr
```

at the MATLAB prompt produces this result:

```
ans =

MATLAB
The Scientific
Computing
Environment
   by TMW, Inc.
```

Passing Matrices

In MATLAB, you can pass matrices into and out of MEX-files written in Fortran. You can manipulate the MATLAB arrays by using `mxGetPr` and `mxGetPi` to assign pointers to the real and imaginary parts of the data stored in the MATLAB arrays. You can create new MATLAB arrays from within your MEX-file by using `mxCreateDoubleMatrix`.

The example `matsq.F` takes a real 2-by-3 matrix and squares each element. To see the source code, open the file in MATLAB Editor.

After performing error checking to ensure that the correct number of inputs and outputs was assigned to the gateway subroutine and to verify the input was in fact a numeric matrix, `matsq.F` creates a matrix. The matrix is copied to a Fortran matrix using `mxCopyPtrToReal8`. Now the computational subroutine can be called, and the return argument is placed into `y_pr`, the pointer to the output, using `mxCopyReal8ToPtr`.

For a 2-by-3 real matrix

```
x = [1 2 3; 4 5 6];
```

typing

```
y = matsq(x)
```

produces this result:

```
y =
     1     4     9
    16    25    36
```

Passing Two or More Inputs or Outputs

The `plhs` and `prhs` parameters (see "The Components of a Fortran MEX-File" on page 5-2) are vectors containing pointers to the left-hand side (output) variables and right-hand side (input) variables. `plhs(1)` contains a pointer to the first left-hand side argument, `plhs(2)` contains a pointer to the second left-hand side argument, and so on. Likewise, `prhs(1)` contains a pointer to the first right-hand side argument, `prhs(2)` points to the second, and so on.

The example `xtimesy.F` multiplies an input scalar times an input scalar or matrix. To see the source code, open the file in MATLAB Editor.

As this example shows, creating MEX-file gateways that handle multiple inputs and outputs is straightforward. All you need to do is keep track of which indices of the vectors `prhs` and `plhs` correspond to which input and output arguments of your function. In this example, the input variable `x` corresponds to `prhs(1)` and the input variable `y` to `prhs(2)`.

For an input scalar `x` and a real 3-by-3 matrix,

```
x = 3; y = ones(3);
```

typing

```
z = xtimesy(x, y)
```

yields this result:

```
z =
     3     3     3
     3     3     3
     3     3     3
```

Handling Complex Data

MATLAB stores complex double-precision data as two vectors of numbers—one vector contains the real data and the other contains the imaginary data. The functions `mxCopyPtrToComplex16` and `mxCopyComplex16ToPtr` copy MATLAB data to a native `complex*16` Fortran array.

The example `convec.F` takes two complex vectors (of length 3) and convolves them. To see the source code, open the file in MATLAB Editor.

Entering the following at the MATLAB prompt

```
x = [3 - 1i, 4 + 2i, 7 - 3i]

x =

   3.0000 - 1.0000i   4.0000 + 2.0000i   7.0000 - 3.0000i
y = [8 - 6i, 12 + 16i, 40 - 42i]

y =

   8.0000 - 6.0000i  12.0000 +16.0000i  40.0000 -42.0000i
```

and calling the new MEX-file

```
z = convec(x, y)
```

results in

```
z =

   1.0e+02 *

  Columns 1 through 4

   0.1800 - 0.2600i   0.9600 + 0.2800i   1.3200 - 1.4400i
   3.7600 - 0.1200i

  Column 5

   1.5400 - 4.1400i
```

which agrees with the results the built-in MATLAB function `conv.m` produces.

Dynamically Allocating Memory

To allocate memory dynamically in a Fortran MEX-file, use `%val`. (See "Using the Fortran %val Construct" on page 5-6.) The example `dblmat.F` takes an input matrix of real data and doubles each of its elements. To see the source code, open the file in MATLAB Editor.

`compute.F` is the subroutine `dblmat` calls to double the input matrix. (Open the file in MATLAB Editor.)

For the 2-by-3 matrix

```
x = [1 2 3; 4 5 6];
```

typing

```
y = dblmat(x)
```

yields

```
y =
     2     4     6
     8    10    12
```

Note The `dblmat.F` example, as well as `fulltosparse.F` and `sincall.F`, are split into two parts, the gateway and the computational subroutine, because of restrictions in some compilers.

Handling Sparse Matrices

MATLAB provides a set of functions that allow you to create and manipulate sparse matrices. There are special parameters associated with sparse matrices, namely `ir`, `jc`, and `nzmax`. For information on how to use these parameters and how MATLAB stores sparse matrices in general, see “Sparse Matrices” on page 3-9.

Note Sparse array indexing is zero-based, not one-based.

The `fulltosparse.F` example illustrates how to populate a sparse matrix. To see the source code, open the file in MATLAB Editor.

`loadsparse.F` is the subroutine `fulltosparse` calls to fill the `mxArray` with the sparse data. (Open the file in MATLAB Editor.)

At the MATLAB prompt, typing

```
full = eye(5)
full =
     1     0     0     0     0
     0     1     0     0     0
     0     0     1     0     0
     0     0     0     1     0
     0     0     0     0     1
```

creates a full, 5-by-5 identity matrix. Using `fulltosparse` on the full matrix produces the corresponding sparse matrix:

```
spar = fulltosparse(full)
spar =
   (1,1)        1
   (2,2)        1
   (3,3)        1
   (4,4)        1
   (5,5)        1
```

Calling Functions from Fortran MEX-Files

You can call MATLAB functions, operators, M-files, and even other MEX-files from within your Fortran source code by using the API function `mexCallMATLAB`. The `sincall.F` example creates an `mxArray`, passes various pointers to a subfunction to acquire data, and calls `mexCallMATLAB` to calculate the sine function and plot the results. To see the source code, open the file in MATLAB Editor.

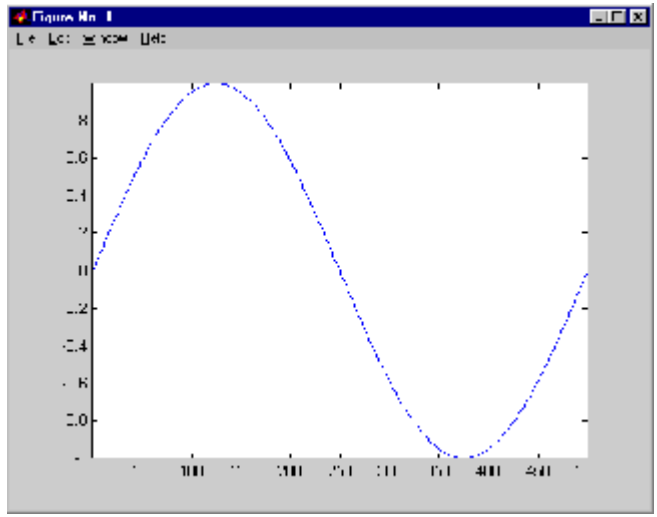
`fill.F` is the subroutine `sincall` calls to fill the `mxArray` with data. (Open the file in MATLAB Editor.)

It is possible to use `mexCallMATLAB` (or any other API routine) from within your computational Fortran subroutine. Note that you can only call most MATLAB functions with double-precision data. M-functions that perform computations, such as `eig`, do not work correctly with data that is not double precision.

Running this example

```
sincall
```

displays the results



Note You can generate an object of type `mxUNKNOWN_CLASS` using `mexCallMATLAB`. See the following example.

This example creates an M-file that returns two variables but only assigns one of them a value:

```
function [a,b]=foo[c]
a=2*c;
```

MATLAB displays the following warning:

```
Warning: One or more output arguments not assigned during call to
'foo'.
```

If you then call `foo` using `mexCallMATLAB`, the unassigned output variable is now of type `mxUNKNOWN_CLASS`.

Advanced Topics

In this section...

Help Files

Because the MATLAB interpreter chooses the MEX-file when both an M-file and a MEX-file with the same name are encountered in the same directory, it is possible to use M-files for documenting the behavior of your MEX-files. The MATLAB `help` command automatically finds and displays the appropriate M-file when help is requested and the interpreter finds and executes the corresponding MEX-file when the function is actually invoked.

Linking Multiple Files

You can combine several source files when building MEX-files. For example,

```
mex circle.F square.o rectangle.F shapes.o
```

is a legal command that operates on the `.F` and `.o` files to create a MEX-file called `circle.`*`ext`*, where *`ext`* is the extension corresponding to the MEX-file type. The name of the resulting MEX-file is taken from the first file in the list.

You may find it useful to use a software development tool like `MAKE` to manage MEX-file projects involving multiple source files. Simply create a `MAKEFILE` that contains a rule for producing object files from each of your source files and then invoke `mex` to combine your object files into a MEX-file. This way you can ensure that your source files are recompiled only when necessary.

Note On Linux, you must use the `-fortran` switch to the `mex` script if you are linking Fortran objects.

Workspace for MEX-File Functions

Unlike M-file functions, MEX-file functions do not have their own variable workspace. `mexEvalString` evaluates the string in the caller's workspace. In addition, you can use the `mexGetVariable` and `mexPutVariable` routines to get and put variables into the caller's workspace.

Handling Large mxArrays

MEX-files built on 64-bit platforms can handle 64-bit mxArrays. These large data arrays can have up to 2^{48}–1 elements. The maximum number of elements a sparse mxArray can have is 2^{48}-2.

Using the following instructions creates platform-independent MEX-files as well.

Your system configuration can impact the performance of MATLAB. The 64-bit processor requirement enables you to create the mxArray and access data in it. However, your system's memory, in particular the size of RAM and virtual memory, determine the speed at which MATLAB processes the mxArray. The more memory available, the faster the processing.

The amount of RAM also limits the amount of data you can process at one time in MATLAB. For guidance on memory issues, see "Memory Allocation in MATLAB". Memory management within MEX-files can have special considerations, as described in "Memory Management" on page 4-29.

Using the 64-Bit API

To work with 64-bit mxArrays, your source code must comply with the 64-bit API, which consists of the functions in the following table.

`mxCalcSingleSubscript`	`mxCreateCellMatrix`
`mxCalloc`	`mxCreateCharArray`

mxCopyCharacterToPtr	mxCreateCharMatrixFromStrings
mxCopyComplex16ToPtr	mxCreateDoubleMatrix
mxCopyComplex8ToPtr	mxCreateLogicalArray
mxCopyInteger1ToPtr	mxCreateLogicalMatrix
mxCopyInteger2ToPtr	mxCreateNumericArray
mxCopyInteger4ToPtr	mxCreateNumericMatrix
mxCopyPtrToCharacter	mxCreateSparse
mxCopyPtrToComplex16	mxCreateSparseLogicalMatrix
mxCopyPtrToComplex8	mxCreateSparseLogicalMatrix
mxCopyPtrToInteger1	mxCreateStructMatrix
mxCopyPtrToInteger2	mxGetCell
mxCopyPtrToInteger4	mxGetElementSize
mxCopyPtrToPtrArray	mxGetField
mxCopyPtrToReal4	mxGetFieldByNumber
mxCopyPtrToReal8	mxGetIr
mxCopyReal4ToPtr	mxGetJc
mxCopyReal8ToPtr	mxGetM
mxCopyReal8ToPtr	mxGetN
mxCopyReal4ToPtr	mxGetNumberOfDimensions
mxCreateCellArray	mxGetNumberOfElements

Functions in this API use the `mwIndex`, `mwSize`, and `mwPointer` preprocessor macros. For information about using these macros, see "Required Header Files" on page 5-4.

Building the MEX-File

Use the `mex` command option, `-largeArrayDims`, with the 64-bit API.

Caution Using Negative Values

When using the 64-bit API, `mwSize` and `mwIndex` are equivalent to `size_t` in C or `INTEGER*8` in Fortran. These types are unsigned, unlike `int` and `INTEGER*4`, which are the types used in the 32-bit API. Be careful not to pass any negative values to functions that take `mwSize` or `mwIndex` arguments. Do not cast negative `int` or `INTEGER*4` values to `mwSize` or `mwIndex`; the returned value can not be predicted. Instead, change your code to avoid using negative values.

Building Cross-Platform Applications

If you develop cross-platform applications (programs that can run on both 32- and 64-bit architectures), you must pay attention to the upper limit of values you use for `mwSize` and `mwIndex`. The 32-bit application reads these values and assigns them to variables declared as `int` in C or `INTEGER*4` in Fortran. Be careful to avoid assigning a large `mwSize` or `mwIndex` value to an `int`, `INTEGER*4`, or other variable that might be too small.

Memory Management

MATLAB now implicitly destroys (by calling `mxDestroyArray`) any arrays created by a MEX-file that are not returned in the left-hand side list (`plhs()`). Consequently, any misconstructed arrays left over at the end of a MEX-file's execution have the potential to cause memory errors.

In general, we recommend that MEX-files destroy their own temporary arrays and clean up their own temporary memory. For additional information on memory management techniques, see the sections "Memory Management" on page 4-29 and "Memory Management Compatibility Issues" on page 3-39.

Debugging Fortran Language MEX-Files

In this section...

Notes on Debugging

The examples show how to debug `timestwo.F`, found in your *`matlabroot`*`/extern/examples/refbook/` directory.

MEX-files built with the `-g` option do not execute on other computers because they rely on files that are not distributed with MATLAB. Refer to the "Calling C and Fortran Programs from MATLAB" topic "Troubleshooting" on page 3-32 for additional information on isolating problems with MEX-files.

Debugging on Windows

For MEX-files compiled with any version of the Intel Visual Fortran compiler, you can use the debugging tools found in your version of Microsoft Visual Studio. Refer to the "Creating C Language MEX-Files" topic "Debugging on Windows" on page 4-46 for instructions on using this debugger.

For information on debugging MEX-files compiled with other MATLAB supported compilers, see Technical Note 1605, MEX-files Guide, at http://www.mathworks.com/support/tech-notes/1600/1605.html.

Debugging on Linux

The MATLAB supported Fortran compiler g95 has a `-g` option for building MEX-files with debug information. Such files can be used with gdb, the GNU Debugger. This section describes using gdb.

For information on debugging MEX-files compiled with other MATLAB supported compilers, see Technical Note 1605, MEX-files Guide, at http://www.mathworks.com/support/tech-notes/1600/1605.html.

GNU Debugger gdb

In this example, the MATLAB command prompt >> is shown in front of MATLAB commands, and `linux>` represents a Linux prompt; your system may show a different prompt. The debugger prompt is `<gdb>`.

1. To compile the MEX-file, type

   ```
   linux> mex -g timestwo.F
   ```

   On a Linux 32–bit platform, this command creates the executable file `timestwo.mexglx`.

2. At the Linux prompt, start the gdb debugger using the `matlab -D` option:

   ```
   linux> matlab -Dgdb
   ```

3. Start MATLAB without the Java virtual machine (JVM) by using the `-nojvm` startup flag:

   ```
   <gdb> run -nojvm
   ```

4. In MATLAB, enable debugging with the `dbmex` function and run your MEX-file:

   ```
   >> dbmex on
   >> y = timestwo(4)
   ```

5. At this point, you are ready to start debugging.

   It is often convenient to set a breakpoint at `mexFunction` so you stop at the beginning of the gateway routine.

Note The function name may be slightly altered by the compiler (e.g., it may have an underscore appended). To determine how this symbol appears in a given MEX-file, use the Linux command `nm`. For example,

```
linux> nm timestwo.mexglx | grep -i mexfunction
```

Linux responds with something like

```
0000091c T mexfunction_
```

Use `mexfunction_` in the breakpoint statement. Be sure to use the correct case.

```
<gdb> break mexfunction_
<gdb> continue
```

6 Once you hit one of your breakpoints, you can make full use of any commands the debugger provides to examine variables, display memory, or inspect registers.

To proceed from a breakpoint, type `continue`.

```
<gdb> continue
```

7 After stopping at the last breakpoint, type

```
<gdb> continue
```

`timestwo` finishes and MATLAB displays

```
y =

     8
```

8 From the MATLAB prompt you can return control to the debugger by typing

```
>> dbmex stop
```

Or, if you are finished running MATLAB, type

```
>> quit
```

9 When you are finished with the debugger, type

```
<gdb> quit
```

You return to the Linux prompt.

Refer to the documentation provided with your debugger for more information on its use.

6

Calling MATLAB from C and Fortran Programs

The MATLAB engine library is a set of routines that allows you to call MATLAB from your own programs, thereby employing MATLAB as a computation engine. MATLAB engine programs are C or Fortran programs that communicate with a separate MATLAB process via pipes, on UNIX, and through a Component Object Model (COM) interface, on Windows. There is a library of functions provided with MATLAB that allows you to start and end the MATLAB process, send data to and from MATLAB, and send commands to be processed in MATLAB.

Using the MATLAB Engine

In this section...

Introduction

Some of the things you can do with the MATLAB engine are

- Call a math routine, for example, to invert an array or to compute an FFT from your own program. When employed in this manner, MATLAB is a powerful and programmable mathematical subroutine library.
- Build an entire system for a specific task, for example, radar signature analysis or gas chromatography, where the front end (GUI) is programmed in C and the back end (analysis) is programmed in MATLAB, thereby shortening development time.

The MATLAB engine operates by running in the background as a separate process from your own program. This offers several advantages:

- On UNIX, the MATLAB engine can run on your machine, or on any other UNIX machine on your network, including machines of a different architecture. This allows you to implement a user interface on your workstation and perform the computations on a faster machine located elsewhere on your network. The description of the `engOpen` function offers further information.
- Instead of requiring that all of MATLAB be linked to your program (a substantial amount of code), only a small engine communication library is needed.

Note To run MATLAB engine on the UNIX platform, you must have the C shell `csh` installed at `/bin/csh`.

The Engine Library

The engine library contains the following routines for controlling the MATLAB computation engine. Their names all begin with the three-letter prefix `eng`. These tables list all the available engine functions and their purposes.

C Engine Routines

Function	Purpose
`engOpen`	Start up MATLAB engine
`engClose`	Shut down MATLAB engine
`engGetVariable`	Get a MATLAB array from the MATLAB engine
`engPutVariable`	Send a MATLAB array to the MATLAB engine
`engEvalString`	Execute a MATLAB command
`engOutputBuffer`	Create a buffer to store MATLAB text output
`engOpenSingleUse`	Start a MATLAB engine session for single, nonshared use
`engGetVisible`	Determine visibility of MATLAB engine session
`engSetVisible`	Show or hide MATLAB engine session

Fortran Engine Routines

Function	Purpose
`engOpen`	Start up MATLAB engine
`engClose`	Shut down MATLAB engine
`engGetVariable`	Get a MATLAB array from the MATLAB engine
`engPutVariable`	Send a MATLAB array to the MATLAB engine

Fortran Engine Routines (Continued)

Function	Purpose
`engEvalString`	Execute a MATLAB command
`engOutputBuffer`	Create a buffer to store MATLAB text output

The MATLAB engine also uses the `mx`–prefixed API routines discussed in Chapter 4, “Creating C Language MEX-Files” and Chapter 5, “Creating Fortran MEX-Files”.

Communicating with MATLAB

On UNIX, the engine library communicates with the MATLAB engine using pipes, and, if needed, `rsh` for remote execution. On Microsoft Windows, the engine library communicates with MATLAB using a Component Object Model (COM) interface. Chapter 8, “COM Support in MATLAB (Windows Only)” contains a detailed description of COM.

GUI-Intensive Applications

If you have graphical user interface (GUI) intensive applications that execute a lot of callbacks through the MATLAB engine, you should force these callbacks to be evaluated in the context of the base workspace. Use `evalin` to specify that the base workspace be used in evaluating the callback expression, as follows:

```
engEvalString(ep, "evalin('base', expression)")
```

Specifying the base workspace in this manner ensures MATLAB processes the callback correctly and returns results for that call.

This does not apply to computational applications that do not execute callbacks.

Examples of Calling Engine Functions

In this section...

Overview

It is important to understand the sequence of steps you must follow when using the engine functions. For example, before using `engPutVariable`, you must create the matrix and populate it.

After reviewing these examples, follow the instructions in "Compiling and Linking MATLAB Engine Programs" on page 6-10 to build the application and test it. By building and running the application, you ensure that your system is properly configured for engine applications.

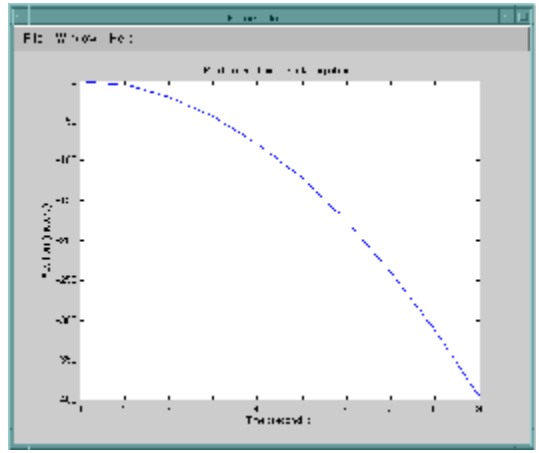
Calling MATLAB from a C Application

This program, `engdemo.c`, illustrates how to call the engine functions from a stand-alone C program. For the Windows version of this program, see `engwindemo.c` in the *`matlabroot`*`\extern\examples\eng_mat` directory. *`matlabroot`* is the MATLAB root directory. engine examples, like the MAT-file examples, are located in the `eng_mat` directory:

To see `engdemo.c`, open the file in MATLAB Editor.

To see the Windows version `engwindemo.c`, open the file.

The first part of this program launches MATLAB and sends it data. MATLAB then analyzes the data and plots the results.



The program then continues with

```
Press Return to continue
```

Pressing **Return** continues the program:

```
Done for Part I.
Enter a MATLAB command to evaluate.  This command should
create a variable X.  This program will then determine
what kind of variable you created.
For example: X = 1:5
```

Entering `X = 17.5` continues the program execution.

```
X = 17.5

X =

   17.5000

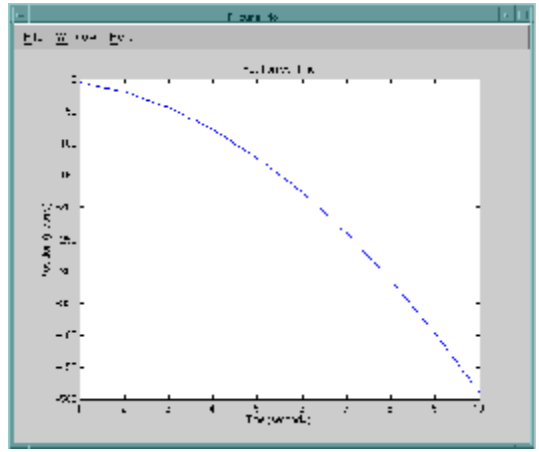
Retrieving X...
X is class double
Done!
```

Finally, the program frees memory, closes the MATLAB engine, and exits.

Calling MATLAB from a Fortran Application

The program, `fengdemo.F`, illustrates how to call the engine functions from a stand-alone Fortran program. To see the code, open the file in MATLAB Editor.

Executing this program launches MATLAB, sends it data, and plots the results.



The program continues with

```
Type 0 <return> to Exit
Type 1 <return> to continue
```

Entering `1` at the prompt continues the program execution:

```
1
 MATLAB computed the following distances:
   time(s)  distance(m)
   1.00     -4.90
   2.00     -19.6
   3.00     -44.1
   4.00     -78.4
   5.00     -123.
   6.00     -176.
   7.00     -240.
```

```
8.00     -314.
9.00     -397.
10.0     -490.
```

Finally, the program frees memory, closes the MATLAB engine, and exits.

Attaching to an Existing MATLAB Session

You can make a MATLAB engine program attach to a MATLAB session that is already running by starting the MATLAB session with `/Automation` in the command line. When you make a call to `engOpen`, it then connects to this existing session. You should only call `engOpen` once, because any `engOpen` calls now connect to this one MATLAB session.

The `/Automation` option also causes the command window to be minimized. You must open it manually.

Note For more information on the `/Automation` command-line argument, see "Additional Automation Server Information" on page 8-122. For information about the Component Object Model interfaces used by MATLAB, see "Introducing MATLAB COM Integration" on page 8-3.

For example,

1. Shut down any MATLAB sessions.
2. From the **Start** button on the Windows menu bar, click **Run**.
3. In the **Open** field, type

   ```
   d:\matlab\bin\win32\matlab.exe /Automation
   ```

   or

   ```
   d:\matlab\bin\win64\matlab.exe /Automation
   ```

   where `d:\matlab\bin\win32` or `d:\matlab\bin\win64` represents the path to the MATLAB executable.

4 Click **OK**. This starts MATLAB.

5 In MATLAB, change directories to *matlabroot*`/extern/examples/eng_mat`.

6 Compile the `engwindemo.c` example.

7 Run the `engwindemo` program by typing at the MATLAB prompt

```
!engwindemo
```

This does not start another MATLAB session, but rather uses the MATLAB session that is already open.

Note On the UNIX platform, you cannot make a MATLAB engine program use a MATLAB session that is already running.

Compiling and Linking MATLAB Engine Programs

In this section...

Step 1 — Write Your Application

Write your application in C or Fortran using any of the MATLAB engine routines to perform computations in MATLAB. See "Using the MATLAB Engine" on page 6-2 and "Examples of Calling Engine Functions" on page 6-5 for help.

Note If you plan to build with the Borland C++ compiler on Windows, read "Masking Floating-Point Exceptions" on page 6-18 for information on floating-point exceptions.

Step 2 — Check Required Libraries and Files

MATLAB requires the following files for building any engine application:

- "Third-Party Libraries" on page 6-11
- "Library Files Required by libeng" on page 6-11
- "Unicode Data Files" on page 6-12

Third-Party Libraries

Verify that the required libraries are installed. Use the following table to identify the path and library filename. Replace *`libfile`* with each of these filenames:

```
libeng
libmx
```

Operating System	Library Path and Filename
Linux	*`matlabroot`*`/bin/glnx86/`*`libfile`*`.so`
64-bit Linux	*`matlabroot`*`/bin/glnxa64/`*`libfile`*`.so`
64-bit Solaris SPARC	*`matlabroot`*`/bin/sol64/`*`libfile`*`.so`
Macintosh (PPC)	*`matlabroot`*`/bin/mac/`*`libfile`*`.dylib`
Macintosh (Intel)	*`matlabroot`*`/bin/maci/`*`libfile`*`.dylib`
Windows	*`matlabroot`*`\bin\win32\`*`libfile`*`.dll`
Windows x64	*`matlabroot`*`\bin\win64\`*`libfile`*`.dll`

Library Files Required by libeng

The `libeng` library requires additional third-party library files. MATLAB uses these libraries to support Unicode character encoding and data compression in MAT-files.

These library files must reside in the same directory as `libmx`. You can determine what most of these libraries are using the platform-specific commands shown here.

Operating System	Library Path and Filename
All Linux, Solaris	`ldd -d libeng.so`
All Macintosh	`otool -L libeng.dylib`
Windows	See instructions below.

On Windows, download the Dependency Walker utility from the following Web site:

```
http://www.dependencywalker.com/
```

Drag and drop the `libeng.dll` file into the Depends window.

Unicode Data Files

Verify that the appropriate Unicode data file is installed. Systems that order bytes in a big-endian manner use `icudt32b.dat`, and those that have little-endian ordering use `icudt32l.dat`.

Operating System	Unicode File Path and Filename
Linux	*matlabroot*`/bin/glnx86/icudt32l.dat`
64-bit Linux	*matlabroot*`/bin/glnxa64/icudt32l.dat`
64-bit Solaris SPARC	*matlabroot*`/bin/sol64/icudt32b.dat`
Macintosh (PPC)	*matlabroot*`/bin/mac/icudt32b.dat`
Macintosh (Intel)	*matlabroot*`/bin/maci/icudt32b.dat`
Windows	*matlabroot*`\bin\win32\icudt32l.dat`
Windows x64	*matlabroot*`\bin\win64\icudt32l.dat`

Note If you need to manipulate Unicode text directly in your application, the latest version of International Components for Unicode (ICU) is available online from the IBM Corporation Web site at `http://icu.sourceforge.net/download`.

Step 3 — Build the Application

Use the `mex` script to compile and link engine programs. `mex` has a set of switches you can use to modify the compile and link stages. The table MEX Script Switches on page 3-20 lists the available switches and their uses.

MEX Options File

MATLAB supplies an options file to facilitate building MEX applications. This file contains compiler-specific flags that correspond to the general compile, prelink, and link steps required on your system. If you want to customize the build process, you can modify this file.

Different options files are provided for UNIX and Windows.

Operating System	Default Options File
UNIX	*matlabroot*/bin/engopts.sh
Windows	*matlabroot*\bin\win32\mexopts*engmatopts.bat
Windows x64	*matlabroot*\bin\win64\mexopts*engmatopts.bat

On Windows systems, the options file depends on which compiler you use. The name of the options file is prefixed with a string representing the compiler and compiler version it is used with.

For example, to locate the options file on a Windows 32-bit system, type:

```
dir([matlabroot '\bin\win32\mexopts\*engmatopts.bat'])
```

If you need to modify the options file for your particular compiler, use the `mex` command with the `-v` switch to view the current compiler and linker settings, and then make the appropriate changes in the options file.

Build the Application

To build your engine application, use the `mex` script with the options filename and the name of your MEX-file.

On UNIX Systems. Enter the following command, where *`mexfilename`* is the name of your C or Fortran program. Enclose *`mexfilename`* in single quotation marks.

```
mex('-f', [matlabroot '/bin/engopts.sh'], mexfilename);
```

Alternatively, copy the options file to your current working directory, and then enter the following command:

```
mex -f engopts.sh mexfilename
```

On Windows Systems. Enter the following command, where *mexfilename* is the name of your C or Fortran program. Enclose *mexfilename* in single quotation marks. This example uses the Lcc compiler. Be sure to use the appropriate options file for your compiler.

```
mex('-f', [matlabroot ...
   '\bin\win32\mexopts\lccengmatopts.bat'], mexfilename);
```

Alternatively, copy the options file to your current working directory, and then enter the following command:

```
mex -f lccengmatopts.bat mexfilename
```

Step 4 — Set Run-Time Library Path

At run-time, you need to tell the system where the API shared libraries reside.

On UNIX Systems

Set the library path as follows for the C and Bourne shells. In the commands shown, replace the terms *envvar* and *pathspec* with the appropriate values from the table that follows.

In the C shell, the command to set the library path is

```
setenv envvar pathspec
```

In the Bourne shell, use

```
envvar = pathspec:envvar export envvar
```

Operating System	*envvar*	*pathspec*
Linux	LD_LIBRARY_PATH	*matlabroot*/bin/glnx86: *matlabroot*/sys/os/glnx86
64-bit Linux	LD_LIBRARY_PATH	*matlabroot*/bin/glnxa64: *matlabroot*/sys/os/glnxa64
64-bit Solaris SPARC	LD_LIBRARY_PATH	*matlabroot*/bin/sol64: *matlabroot*/sys/os/sol64
Macintosh (PPC)	DYLD_LIBRARY_PATH	*matlabroot*/bin/mac: *matlabroot*/sys/os/mac
Macintosh (Intel)	DYLD_LIBRARY_PATH	*matlabroot*/bin/maci: *matlabroot*/sys/os/maci

Here is an example for a Solaris system for the C shell:

```
setenv LD_LIBRARY_PATH matlabroot/bin/sol64:matlabroot/sys/os/sol64
```

and for the Bourne shell:

```
LD_LIBRARY_PATH=matlabroot/bin/sol64:matlabroot/sys/os/sol64:$LD_LIBRARY_PATH
export LD_LIBRARY_PATH
```

Place these commands in a startup script such as `~/.cshrc` for the C shell or `~/.profile` for the Bourne shell.

On Windows Systems

Set the `Path` environment variable to the path string returned by MATLAB in response to the following expression:

```
[matlabroot '\bin\win32']
```

or

```
[matlabroot '\bin\win64']
```

To set an environment variable in Windows, select **Start > Settings > Control Panel > System**. Windows opens the System

Properties dialog box. Click the **Advanced** tab, and then the **Environment Variables** button.

In the **System variables** panel scroll down until you find the `Path` variable. Click this variable to highlight it, and then click the **Edit** button to open the Edit System Variable dialog box. At the end of the path string, enter a semicolon and then the path string returned by evaluating the expression shown above in MATLAB. Click **OK** in the Edit System Variable dialog box, and in all remaining dialog boxes.

Step 5 — (Windows Only) Register MATLAB as a COM Server

To run this program on Windows, you need to have MATLAB registered as a COM server on your system. This registration is part of the MATLAB installation and should have already been done for you as part of the installation. If, for some reason, the registration was not done or did not complete successfully, you may see the following error displayed when you try to run this example:

```
Can't start MATLAB engine
```

If you see this error, manually register MATLAB as a server by entering the following commands in a DOS command window:

```
cd matlabroot\bin\win32
matlab /regserver
```

or

```
cd matlabroot\bin\win64
matlab /regserver
```

Step 6 — Test the Program

Test your application in MATLAB by typing

```
!engwindemo
```

Example — Building an Engine Application on Windows

MATLAB provides a demonstration program written in C that you can use to verify the build process on your computer. The demo file for Windows systems is `engwindemo.c`.

Copy the C language MEX-file `engwindemo.c` to your current working directory:

```
demofile = [matlabroot '\extern\examples\eng_mat\engwindemo.c'];
copyfile(demofile, '.');
```

Look in the `\bin\win32\mexopts` directory for the appropriate options file for the Lcc compiler. Use the following commands to build the executable file using this compiler:

```
optsfile = [matlabroot '\bin\win32\mexopts\lccengmatopts.bat'];
mex('-f', optsfile, 'engwindemo.c');
```

Verify that the build worked by looking in your current working directory for the file `engwindemo.exe`:

```
dir engwindemo.exe
```

To run the demo from MATLAB, make sure your current working directory is set to the one in which you built the executable file, and then type

```
!engwindemo
```

Borland Compilers on Windows

When using a Borland compiler to build a Windows application such as `engwindemo`, you must modify the appropriate `bcc*engmatopts.bat` options file. For information about making these changes, see *`matlabroot`*`\bin\win32\mexopts\README.borland`.

Example — Building an Engine Application on UNIX

MATLAB provides a demonstration program written in C that you can use to verify the build process on your computer. The demo file for UNIX systems is called `engdemo.c`.

Copy the C language MEX-file `engdemo.c` to your current working directory:

```
demofile = [matlabroot '/extern/examples/eng_mat/engdemo.c'];
copyfile(demofile, '.');
```

Build the executable file using the ANSI compiler for engine stand-alone programs and the options file `engopts.sh`:

```
optsfile = [matlabroot '/bin/engopts.sh'];
mex('-f', optsfile, 'engdemo.c');
```

Verify that the build worked by looking in your current working directory for the file `engdemo`:

```
dir engdemo
```

To run the demo in MATLAB, make sure your current working directory is set to the one in which you built the executable file, and then type

```
!engdemo
```

Masking Floating-Point Exceptions

Read this section if you plan to build with the Borland C++ compiler on Windows. It explains how to avoid program termination when a floating-point exception occurs.

Certain mathematical operations can result in nonfinite values. For example, division by zero results in the nonfinite IEEE value `inf`. A floating-point exception occurs when such an operation is performed. Because MATLAB uses an IEEE model that supports nonfinite values such as `inf` and `NaN`, MATLAB disables, or *masks*, floating-point exceptions.

Some compilers do not mask floating-point exceptions by default. This causes engine programs built with such compilers to terminate when a floating-point exception occurs. Take special precautions when using these compilers to mask floating-point exceptions so that your engine application performs properly.

Note MATLAB based applications should never get floating-point exceptions. If you do get a floating-point exception, verify that any third-party libraries that you link against do not enable floating-point exception handling.

The only compiler and platform on which you need to mask floating-point exceptions is the Borland C++ compiler on Windows.

Borland C++ Compiler on Windows

To mask floating-point exceptions when using the Borland C++ compiler on the Windows platform, you must add some code to your program. Include the following at the beginning of your `main()` or `WinMain()` function, before any calls to MATLAB API functions.

```
#include <float.h>
 .
 .
 .
_control87(MCW_EM,MCW_EM);
 .
 .
 .
```

7

Calling Java from MATLAB

Example — Communicating Through a Serial Port (p. 7-76)	Create a SerialPort object and configure the port using methods provided by that class
Example — Creating and Using a Phone Book (p. 7-82)	Create a phone book using a data dictionary that operates using key/value pairs in a hash table

Using Java from MATLAB: An Overview

In this section...

Java Interface Is Integral to MATLAB

Every installation of MATLAB includes a Java Virtual Machine (JVM), so that you can use the Java interpreter via MATLAB commands, and you can create and run programs that create and access Java objects. For information on MATLAB installation, see the MATLAB installation documentation for your platform.

Benefits of the MATLAB Java Interface

The MATLAB Java interface enables you to:

- Access Java API (application programming interface) class packages that support essential activities such as I/O and networking. For example, the `URL` class provides convenient access to resources on the Internet.
- Access third-party Java classes
- Easily construct Java objects in MATLAB
- Call Java object methods, using either Java or MATLAB syntax
- Pass data between MATLAB variables and Java objects

Who Should Use the MATLAB Java Interface

The MATLAB Java interface is intended for all MATLAB users who want to take advantage of the special capabilities of the Java programming language.

For example:

- You need to access, from MATLAB, the capabilities of available Java classes.
- You are familiar with object-oriented programming in Java or in another language, such as C++.
- You are familiar with MATLAB object-oriented classes, or with MATLAB MEX-files.

To Learn More About Java Programming

For a complete description of the Java language and for guidance in object-oriented software design and programming, you'll need to consult outside resources. For example, these recently published books may be helpful:

- *Java in a Nutshell* (Fourth Edition), by David Flanagan
- *Teach Yourself Java in 21 Days*, by Lemay and Perkins

Another place to find information is the JavaSoft Web site.

```
http://www.javasoft.com
```

For other suggestions on object-oriented programming resources, see:

- *Object-Oriented Software Construction*, by Bertrand Meyer
- *Object-Oriented Analysis and Design with Applications*, by Grady Booch, Robert A. Maksimchuk, Michael W. Engel, and Alan Brown

Platform Support for the Java Virtual Machine

To find out which version of the Java Virtual Machine (JVM) is being used by MATLAB on your platform, type the following at the MATLAB prompt.

```
version -java
```

Using a Different Version of the Java JVM

MATLAB ships with one specific version of the Java Virtual Machine (JVM) and uses this version by default with the MATLAB interface to Java. This section describes how to download and select a version other than the default.

Note MATLAB is only fully supported on the JVM that it ships with. Some components might not work properly under a different version of the JVM. For example, calling functions in a dynamically linked library that was created with a different JVM than that used by MATLAB might cause a segmentation violation error.

To change the JVM version that MATLAB uses, follow these steps:

1. "Download the JVM Version You Want to Use" on page 7-5.
2. "Locate the Root of the Run-time Path for this Version" on page 7-5.
3. "Set the MATLAB_JAVA Environment Variable to this Path" on page 7-6.

When you have enabled a different version of the JVM, you can verify that MATLAB is using this version by entering the `version -java` command documented in the previous section.

Download the JVM Version You Want to Use

You can download the Java Virtual Machine from the Web site `http://java.sun.com/j2se/downloads.html`.

If you are using Linux, go to the Web site `http://www.blackdown.org/java-linux/mirrors.html`, and choose the version required by your processor.

Locate the Root of the Run-time Path for this Version

To get MATLAB to use the version you have just downloaded, you must first find the root of the run-time path for this JVM, and then set the `MATLAB_JAVA` environment variable to that path. To locate the JVM run-time path, find the directory in the Java installation tree that is one level up from the directory containing the file `rt.jar`. This may be a subdirectory of the main JDK install directory. (If you cannot find `rt.jar`, look for the file `classes.zip`.)

For example, if the JDK is installed in `D:\jdk1.2.1` on Windows and the `rt.jar` file is in `D:\jdk1.2.1\jre\lib`, set `MATLAB_JAVA` to the directory one level up from that: `D:\jdk1.2.1\jre`.

On UNIX, if the JDE is installed in `/usr/openv/java/jre/lib` and the `rt.jar` is in `/usr/openv/java/jre/lib`, set `MATLAB_JAVA` to the path `/usr/openv/java/jre`.

Set the MATLAB_JAVA Environment Variable to this Path

The way you set or modify the value of the `MATLAB_JAVA` variable depends on which platform you are running MATLAB on.

Windows 2000/XP. To set `MATLAB_JAVA` on Windows 2000 or Windows XP:

1. Click **Settings** in the **Start** Menu.
2. Choose **Control Panel**.
3. Click **System**.
4. Choose the **Advanced** tab and then click the **Environment Variables** button.
5. You now can set (or add) the `MATLAB_JAVA` system environment variable to the path of your JVM.

UNIX/Linux. To set `MATLAB_JAVA` on UNIX or Linux systems, use the `setenv` command, as shown here:

```
setenv MATLAB_JAVA <path to JVM>
```

Bringing Java Classes and Methods into MATLAB

In this section...

Introduction

You can draw from an extensive collection of existing Java classes or create your own class definitions to use with MATLAB. This section explains how to go about finding the class definitions that you need or how to create classes of your own design. Once you have the classes you need, defined in either individual `.class` files, packages, or Java Archive files, you can make them available in the MATLAB environment. This section also describes how to specify the native method libraries used by Java.

Sources of Java Classes

Following are the three main Java class sources that you can use in MATLAB:

- Java built-in classes — general-purpose class packages, such as `java.awt`, included in the Java language. See your Java language documentation for descriptions of these packages.
- Third-party classes — packages of special-purpose Java classes.
- User-defined classes — Java classes or subclasses of existing classes that you define. You need to use a Java development environment to do this, as explained in the following section.

Defining New Java Classes

To define new Java classes and subclasses of existing classes, you must use a Java development environment external to MATLAB. See Technical Note 1601 `http://www.mathworks.com/support/tech-notes/1600/1601.html` for information on supported versions of the JDK. You can download the development kit from the Sun Microsystems Web site, (`http://java.sun.com/j2se/`). The Sun site also provides documentation for the Java language and classes that you need for development.

After you create class definitions in `.java` files, use your Java compiler to produce `.class` files from them. The next step is to make the class definitions in those `.class` files available for you to use in MATLAB.

The Java Class Path

MATLAB loads Java class definitions from files that are on the *Java class path*. The class path is a series of file and directory specifications that MATLAB uses to locate class definitions. When loading a particular Java class, MATLAB searches files and directories in the order they occur on the class path until a file is found that contains that class definition. The first definition that is found ends the search.

The Java class path consists of two segments: the *static path* and *dynamic path*. The static path is loaded at the start of each MATLAB session and cannot be changed without restarting MATLAB. The dynamic path can be loaded and modified at any time during a session using MATLAB functions. MATLAB always searches the static path before the dynamic path.

Note Java classes on the static path should not have dependencies on classes on the dynamic path.

You can view these two path segments using the `javaclasspath` function:

```
javaclasspath

       STATIC JAVA PATH

   D:\SysO\Java\util.jar
   D:\SysO\Java\widgets.jar
   D:\SysO\Java\beans.jar
              .
              .

       DYNAMIC JAVA PATH

   C:\Work\Java\ClassFiles
   C:\Work\Java\mywidgets.jar
              .
              .
```

You probably want to use both the static and dynamic paths:

- Put the Java class definitions that are more stable on the static class path. Classes defined on the static path load somewhat faster than those on the dynamic path.
- Put the Java class definitions that you are likely to modify on the dynamic class path. You can make changes to the class definitions on this path without restarting MATLAB.

The Static Path

MATLAB loads the static Java class path from the file `classpath.txt` at the start of each session. The static path offers better Java class loading performance than the dynamic path. However, to modify the static path you need to edit the file `classpath.txt` and then restart MATLAB.

Finding and Editing classpath.txt. The default `classpath.txt` file resides in the `toolbox\local` subdirectory of your MATLAB root directory:

```
[matlabroot '\toolbox\local\classpath.txt']
ans =
   \\sys07\matlab\toolbox\local\classpath.txt
```

To make changes in the static path that affect all users who share this same MATLAB root directory, edit this file in `toolbox\local`. If you want to make changes that do not affect anyone else, copy `classpath.txt` to your own startup directory and edit the file there. When MATLAB starts up, it looks for `classpath.txt` first in your startup directory, and then in the default location. It uses the file it finds first.

To see which `classpath.txt` file is currently being used by your MATLAB environment, use the `which` function:

```
which classpath.txt
```

To edit either the default file or the copy in your own directory, enter the following command in MATLAB:

```
edit classpath.txt
```

Note MATLAB reads `classpath.txt` only upon startup. If you edit `classpath.txt` or change your `.class` files while MATLAB is running, you must restart MATLAB to put those changes into effect.

Special Symbols in classpath.txt. You can designate special tokens or macros in the `classpath.txt` file using a leading dollar sign, (e.g., `$matlabroot` or `$jre_home`). However, this can cause problems if you use this sign in any of your class directory paths. For example, the following path string does not correctly represent the path to a directory named `hello$world`:

```
d:\applications\hello$world
```

You must use two consecutive dollar signs in `classpath.txt` to represent a single `$` character. So, to correctly specify the directory path shown above, you need to use the following text:

```
d:\applications\hello$$world
```

The Dynamic Path

The dynamic Java class path can be loaded at any time during a MATLAB session using the `javaclasspath` function. You can define the dynamic path (using `javaclasspath`), modify the path (using `javaaddpath` and `javarmpath`), and refresh the Java class definitions for all classes on the dynamic path (using `clear` with the `java` keyword) without restarting MATLAB. See the Java function reference pages for more information on how to use these functions.

Although the dynamic path offers more flexibility in changing the path, Java classes on the dynamic path may load more slowly than those on the static path.

Making Java Classes Available to MATLAB

To make your third-party and user-defined Java classes available in MATLAB, place them on either the static or dynamic Java class path, as described in the previous section, "The Java Class Path" on page 7-8.

- For classes you want on the static path, edit the `classpath.txt` file.
- For classes you want on the dynamic path, use either the `javaclasspath` or `javaaddpath` function.

Making Individual (Unpackaged) Classes Available

To make individual classes (classes that are not part of a package) available in MATLAB, specify the full path to the directory you want to use for the `.class` file(s).

For example, to make available your compiled Java classes in the file `d:\work\javaclasses\test.class`, add the following entry to the static or dynamic class path:

```
d:\work\javaclasses
```

To put this directory on the static class path, add the above line to the default copy (in `toolbox\local`) or your own local copy of `classpath.txt`. See "Finding and Editing classpath.txt" on page 7-9.

To put this on the dynamic class path, use the following command:

```
javaaddpath d:\work\javaclasses
```

Making Entire Packages Available

To access one or more classes belonging to a package, you need to make the entire package available to MATLAB. To do this, specify the full path to the *parent directory of the highest level directory* of the package path. This directory is the first component in the package name.

For example, if your Java class package `com.mw.tbx.ini` has its classes in directory `d:\work\com\mw\tbx\ini`, add the following directory to your static or dynamic class path:

```
d:\work
```

Making Classes in a JAR File Available

You can use the `jar` (Java Archive) tool to create a JAR file, containing multiple Java classes and packages in a compressed ZIP format. For information on `jar` and JAR files, consult your Java development documentation or the JavaSoft Web site http://www.javasoft.com. See also "To Learn More About Java Programming" on page 7-4.

To make the contents of a JAR file available for use in MATLAB, specify the full path, *including full filename*, for the JAR file.

Note The `classpath.txt` requirement for JAR files is different than that for `.class` files and packages, for which you do not specify any filename.

For example, to make available the JAR file `e:\java\classes\utilpkg.jar`, add the following file specification to your static or dynamic class path:

```
e:\java\classes\utilpkg.jar
```

Loading Java Class Definitions

Normally, MATLAB loads a Java class automatically when your code first uses it, (for example, when you call its constructor). However, there is one exception you should be aware of.

When you use the `which` function on methods defined by Java classes, the function only acts on the classes currently loaded into the MATLAB working environment. In contrast, `which` always operates on MATLAB classes, whether or not they are loaded.

Determining Which Classes Are Loaded

At any time during a MATLAB session, you can obtain a listing of all the Java classes that are currently loaded. To do so, use the `inmem` function as follows:

```
[M,X,J] = inmem
```

This function returns the list of Java classes in the output argument `J`. (It also returns in `M` the names of all currently loaded M-files, and in `X` the names of all currently loaded MEX-files.)

Here's a sample of output from the `inmem` function:

```
[m,x,j] = inmem;
j =
 'java.awt.Frame'
 'com.mathworks.ide.desktop.MLDesktop'
```

Simplifying Java Class Names

Your MATLAB commands can refer to any Java class by its fully qualified name, which includes its package name. For example, the following are fully qualified names:

- `java.lang.String`
- `java.util.Enumeration`

A fully qualified name can be rather long, making commands and functions, such as constructors, cumbersome to edit and to read. You can refer to classes by the class name alone (without a package name) if you first import the fully qualified name into MATLAB.

The `import` command has the following forms:

```
import pkg_name.*               % Import all classes in package
import pkg_name1.* pkg_name2.*  % Import multiple packages
import class_name               % Import one class
import                          % Display current import list
L = import                      % Return current import list
```

MATLAB adds all classes that you import to a list called the *import list*. You can see what classes are on that list by typing `import`, without any arguments. Your code can refer to any class on the list by class name alone.

When called from a function, `import` adds the specified classes to the import list in effect for that function. When invoked at the command prompt, `import` uses the base import list for your MATLAB environment.

For example, suppose a function contains the following statements:

```
import java.lang.String
import java.util.* java.awt.*
import java.util.Enumeration
```

Code that follows the `import` statements above can now refer to the `String`, `Frame`, and `Enumeration` classes without using the package names.

```
str = String('hello');     % Create java.lang.String object
frm = Frame;               % Create java.awt.Frame object
methods Enumeration        % List java.util.Enumeration methods
```

To `clear` the list of imported Java classes, invoke the command

```
clear import
```

Locating Native Method Libraries

Java classes can dynamically load native methods using the Java method `java.lang.System.loadLibrary("LibFile")`. In order for the JVM to locate the specified library file, the directory containing it must be on the Java Library Path. This path is established when MATLAB launches the JVM at startup, and is based on the contents of the file

```
matlabroot/toolbox/local/librarypath.txt
```

(where *matlabroot* is the MATLAB root directory returned by the MATLAB command `matlabroot`).

You can augment the search path for native method libraries by editing the `librarypath.txt` file. Follow these guidelines when editing this file:

- Specify each new directory on a line by itself.
- Specify only the directory names, not the names of the DLL files. The `loadLibrary` call does this for you.
- To simplify the specification of directories in cross-platform environments, use any of these macros: `$matlabroot`, `$arch`, and `$jre_home`.

Java Classes Contained in a JAR File

You can access Java classes that are contained in a JAR file once you have added the JAR file to either the static or dynamic Java class path. See "The Java Class Path" on page 7-8 for more information on how MATLAB uses the Java class path.

For example, suppose you have a file, `myArchive.jar` in a directory called `work` in your MATLAB root directory. You can construct the path to this file using the `matlabroot` command:

```
[matlabroot '/work/myArchive.jar']
```

Add the JAR file to your dynamic Java class path using the `javaaddpath` function (`fullfile` adds the platform-correct directory separators):

```
javaaddpath(fullfile(matlabroot,'work','myArchive.jar'))
```

You can now call the public methods in the JAR file.

Creating and Using Java Objects

In this section...

Overview

In MATLAB, you create a Java object by calling one of the constructors of that class. You then use commands and programming statements to perform operations on these objects. You can also save your Java objects to a MAT-file and, in subsequent sessions, reload them into MATLAB.

Constructing Java Objects

You construct Java objects in MATLAB by calling the Java class constructor, which has the same name as the class. For example, the following constructor creates a `Frame` object with the title `'Frame A'` and the other properties with their default values.

```
frame = java.awt.Frame('Frame A');
```

Displaying the new object `frame` shows the following.

```
frame =
java.awt.Frame[frame0,0,0,0x0,invalid,hidden,layout=
java.awt.BorderLayout,title=Frame A,resizable,normal]
```

All of the programming examples in this chapter contain Java object constructors. For example, the code in the Example — Reading a URL creates a `java.net.URL` object with the constructor

```
url = java.net.URL(...
     'http://archive.ncsa.uiuc.edu/demoweb/')
```

Using the javaObject Function

Under certain circumstances, you may need to use the `javaObject` function to construct a Java object. The following syntax invokes the Java constructor for class, `class_name`, with the argument list that matches `x1,...,xn`, and returns a new object, `J`.

```
J = javaObject('class_name',x1,...,xn);
```

For example, to construct and return a Java object of class `java.lang.String`, you use

```
strObj = javaObject('java.lang.String','hello');
```

Using the `javaObject` function enables you to:

- Use classes that have names that exceed the maximum length of a MATLAB identifier. (Call the `namelengthmax` function to obtain the maximum identifier length.)
- Specify the class for an object at run-time, for example, as input from an application user

The default MATLAB constructor syntax requires that no segment of the input class name be longer than `namelengthmax` characters. (A *class name segment* is any portion of the class name before, between, or after a dot. For example, there are three segments in class, `java.lang.String`.) Any class name segment that exceeds `namelengthmax` characters is truncated by MATLAB. In the rare case where you need to use a class name of this length, you must use `javaObject` to instantiate the class.

The `javaObject` function also allows you to specify the Java class for the object being constructed at run-time. In this situation, you call `javaObject` with a string variable in place of the class name argument.

```
class  = 'java.lang.String';
text = 'hello';
strObj = javaObject(class, text);
```

In the usual case, when the class to instantiate is known at development time, it is more convenient to use the MATLAB constructor syntax. For example, to create a `java.lang.String` object, you would use

```
strObj = java.lang.String('hello');
```

Note Typically, you do not need to use `javaObject`. The default MATLAB syntax for instantiating a Java class is somewhat simpler and is preferable for most applications. Use `javaObject` primarily for the two cases described above.

Java Objects Are References in MATLAB

In MATLAB, Java objects are *references* and do not adhere to MATLAB copy-on-assignment and pass-by-value rules. For example,

```
origFrame = java.awt.Frame;
setSize(origFrame, 800, 400);
newFrameRef = origFrame;
```

In the third statement above, the variable `newFrameRef` is a second reference to `origFrame`, not a copy of the object. In any code following the example above, any change to the object at `newFrameRef` also changes the object at `origFrame`. This effect occurs whether the object is changed by MATLAB code, or by Java code.

The following example shows that `origFrame` and `newFrameRef` are both references to the same entity. When the size of the frame is changed via one reference (`newFrameRef`), the change is reflected through the other reference (`origFrame`), as well.

```
setSize(newFrameRef, 1000, 800);

getSize(origFrame)
ans =
java.awt.Dimension[width=1000,height=800]
```

Concatenating Java Objects

You can concatenate Java objects in the same way that you concatenate native MATLAB data types. You use either the `cat` function or the [ ] operators to tell MATLAB to assemble the enclosed objects into a single object.

Concatenating Objects of the Same Class

If all of the objects being operated on are of the same Java class, the concatenation of those objects produces an array of objects from the same class.

In the following example, the `cat` function concatenates two objects of the class `java.awt.Point`. The class of the result is also `java.awt.Point`.

```
point1 = java.awt.Point(24,127);
point2 = java.awt.Point(114,29);

cat(1, point1, point2)
ans =
java.awt.Point[]:
    [1x1 java.awt.Point]
    [1x1 java.awt.Point]
```

Concatenating Objects of Unlike Classes

When you concatenate objects of unlike classes, MATLAB finds one class from which all of the input objects inherit, and makes the output an instance of this class. MATLAB selects the lowest common parent in the Java class hierarchy as the output class.

For example, concatenating objects of `java.lang.Byte`, `java.lang.Integer`, and `java.lang.Double` yields an object of `java.lang.Number`, since this is the common parent to the three input classes.

```
byte = java.lang.Byte(127);
integer = java.lang.Integer(52);
double = java.lang.Double(7.8);

[byte; integer; double]

ans =
java.lang.Number[]:
```

```
    [   127]
    [    52]
    [7.8000]
```

If there is no common, lower level parent, then the resultant class is `java.lang.Object`, which is the root of the entire Java class hierarchy.

```
byte = java.lang.Byte(127);
point = java.awt.Point(24,127);

[byte; point]

ans =
java.lang.Object[]:
    [               127]
    [1x1 java.awt.Point]
```

Saving and Loading Java Objects to MAT-Files

Use the MATLAB `save` function to save a Java object to a MAT-file. Use the `load` function to load it back into MATLAB from that MAT-file. To save a Java object to a MAT-file, and to load the object from the MAT-file, make sure that the object and its class meet all of the following criteria:

- The class implements the Serializable interface (part of the Java API), either directly or by inheriting it from a parent class. Any embedded or otherwise referenced objects must also implement Serializable.
- The definition of the class is not changed between saving and loading the object. Any change to the data fields or methods of a class prevents the loading (deserialization) of an object that was constructed with the old class definition.
- Either the class does not have any transient data fields, or the values in transient data fields of the object to be saved are not significant. Values in transient data fields are never saved with the object.

If you define your own Java classes, or subclasses of existing classes, you can follow the criteria above to enable objects of the class to be saved and loaded in MATLAB. For details on defining classes to support serialization, consult your Java development documentation. (See also “To Learn More About Java Programming” on page 7-4.)

Finding the Public Data Fields of an Object

To list the public fields that belong to a Java object, use the `fieldnames` function, which takes either of these forms.

```
names = fieldnames(obj)
names = fieldnames(obj,'-full')
```

Calling `fieldnames` without `'-full'` returns the names of all the data fields (including inherited) on the object. With the `'-full'` qualifier, `fieldnames` returns the full description of the data fields defined for the object, including type, attributes, and inheritance information.

Suppose, for example, that you constructed a `Frame` object with:

```
frame = java.awt.Frame;
```

To obtain the full description of the data fields on `frame`, you could use the command

```
fieldnames(frame,'-full')
```

Sample output from this command follows:

```
ans =
'static final int WIDTH
    % Inherited from java.awt.image.ImageObserver'
'static final int HEIGHT
    % Inherited from java.awt.image.ImageObserver'
[1x74 char]
'static final int SOMEBITS
    % Inherited from java.awt.image.ImageObserver'
'static final int FRAMEBITS
    % Inherited from java.awt.image.ImageObserver'
'static final int ALLBITS
    % Inherited from java.awt.image.ImageObserver'
'static final int ERROR
    % Inherited from java.awt.image.ImageObserver'
'static final int ABORT
    % Inherited from java.awt.image.ImageObserver'
'static final float TOP_ALIGNMENT
    % Inherited from java.awt.Component'
```

```
'static final float CENTER_ALIGNMENT
    % Inherited from java.awt.Component'
'static final float BOTTOM_ALIGNMENT
    % Inherited from java.awt.Component'
'static final float LEFT_ALIGNMENT
    % Inherited from java.awt.Component'
'static final float RIGHT_ALIGNMENT
    % Inherited from java.awt.Component'
.
.
.
```

Accessing Private and Public Data

Java API classes provide accessor methods you can use to read from and, where allowed, to modify *private* data fields. These are sometimes referred to as *get* and *set* methods, respectively.

Some Java classes have *public* data fields, which your code can read or modify directly. To access these fields, use the syntax `object.field`.

Examples

The `java.awt.Frame` class provides an example of access to both private and public data fields. This class has the read accessor method `getSize`, which returns a `java.awt.Dimension` object. The `Dimension` object has data fields `height` and `width`, which are public and therefore directly accessible. The following example shows MATLAB commands accessing this data.

```
frame = java.awt.Frame;
frameDim = getSize(frame);
height = frameDim.height;
frameDim.width = 42;
```

The programming examples in this chapter also contain calls to data field accessors. For instance, the sample code for “Example — Finding an Internet Protocol Address” on page 7-74 uses calls to accessors on a `java.net.InetAddress` object.

```
hostname = address.getHostName;
ipaddress = address.getHostAddress;
```

Accessing Data from a Static Field

In Java, a static data field is a field that applies to an entire class of objects. Static fields are most commonly accessed in relation to the class name itself in Java. For example, the code below accesses the `WIDTH` field of the `Frame` class by referring to it in relation to the package and class names, `java.awt.Frame`, rather than an object instance.

```
width = java.awt.Frame.WIDTH;
```

In MATLAB, you can use that same syntax. Or you can refer to the `WIDTH` field in relation to an instance of the class. The following example creates an instance of `java.awt.Frame` called `frameObj`, and then accesses the `WIDTH` field using the name `frameObj` rather than the package and class names.

```
frame = java.awt.Frame('Frame A');

width = frame.WIDTH
width =
    1
```

Assigning to a Static Field

You can assign values to static Java fields by using a static `set` method of the class, or by making the assignment in reference to an instance of the class. For more information, see the previous section, “Accessing Data from a Static Field” on page 7-23. You can assign `value` to the field `staticFieldName` in the example below by referring to this field in reference to an instance of the class.

```
objectName = java.className;
objectName.staticFieldName = value;
```

Note MATLAB does not allow assignment to static fields using the class name itself.

Determining the Class of an Object

To find the class of a Java object, use the query form of the MATLAB function, `class`. After execution of the following example, `frameClass` contains the name of the package and class that Java object `frame` instantiates.

```
frameClass = class(frame)
frameClass =
java.awt.Frame
```

Because this form of `class` also works on MATLAB objects, it does not, in itself, tell you whether it is a Java class. To determine the type of class, use the `isjava` function, which has the form

```
x = isjava(obj)
```

`isjava` returns `1` if `obj` is Java, and `0` if it is not.

```
isjava(frame)
ans =
    1
```

To find out whether or not an object is an instance of a specified class, use the `isa` function, which has the form

```
x = isa(obj, 'class_name')
```

`isa` returns `1` if `obj` is an instance of the class named `'class_name'`, and `0` if it is not. Note that `'class_name'` can be a MATLAB built-in or user-defined class, as well as a Java class.

```
isa(frame, 'java.awt.Frame')
ans =
    1
```

Invoking Methods on Java Objects

In this section...

Using Java and MATLAB Calling Syntax

To call methods on Java objects, you can use the Java syntax

```
object.method(arg1,...,argn)
```

In the following example, `frame` is the `java.awt.Frame` object created above, and `getTitle` and `setTitle` are methods of that object.

```
frame.setTitle('Sample Frame')

title = frame.getTitle
title =
Sample Frame
```

Alternatively, you can call Java object (nonstatic) methods with the MATLAB syntax

```
method(object, arg1,...,argn)
```

With MATLAB syntax, the `java.awt.Frame` example above becomes

```
setTitle(frame, 'Sample Frame')

title = getTitle(frame)
title =
Sample Frame
```

All of the programming examples in this chapter contain invocations of Java object methods. For example, the code for "Example — Reading a URL" on page 7-71 contains a call, using MATLAB syntax, to the `openStream` method on a `java.net.URL` object, `url`.

```
is = openStream(url)
```

In another example, the code for "Example — Creating and Using a Phone Book" on page 7-82 contains a call, using Java syntax, to the `load` method on a `java.utils.Properties` object, `pb_htable`.

```
pb_htable.load(FIS);
```

Using the javaMethod Function on Nonstatic Methods

Under certain circumstances, you may need to use the `javaMethod` function to call a Java method. The following syntax invokes the method, `method_name`, on Java object `J` with the argument list that matches `x1,...,xn`. This returns the value `X`.

```
X = javaMethod('method_name',J,x1,...,xn);
```

For example, to call the `startsWith` method on a `java.lang.String` object passing one argument, use

```
gAddress = java.lang.String('Four score and seven years ago');
str = java.lang.String('Four score');

javaMethod('startsWith', gAddress, str)
ans =
     1
```

Using the `javaMethod` function enables you to

- Use methods that have names that exceed the maximum length of a MATLAB identifier. (Call the `namelengthmax` function to obtain the maximum identifier length.)
- Specify the method you want to invoke at run time, for example, as input from an application user.

The only way to invoke a method whose name is longer than `namelengthmax` characters is to use `javaMethod`. The Java and MATLAB calling syntax does not accept method names of this length.

With `javaMethod`, you can also specify the method to be invoked at run time. In this situation, your code calls `javaMethod` with a string variable in place of the `method_name` argument. When you use `javaMethod` to invoke a static method, you can also use a string variable in place of the class name argument.

Note Typically, you do not need to use `javaMethod`. The default MATLAB syntax for invoking a Java method is somewhat simpler and is preferable for most applications. Use `javaMethod` primarily for the two cases described above.

Invoking Static Methods on Java Classes

To invoke a `static` method on a Java class, use the Java invocation syntax

```
class.method(arg1,...,argn)
```

For example, call the `isNaN` static method on the `java.lang.Double` class.

```
java.lang.Double.isNaN(2.2)
```

Alternatively, you can apply static method names to instances of a class. In this example, the `isNaN` static method is referenced in relation to the `dblObject` instance of the `java.lang.Double` class.

```
dblObject = java.lang.Double(2.2);

dblObject.isNaN
ans =
     0
```

Several of the programming examples in this chapter contain examples of static method invocation. For example, the code in the Example — Communicating Through a Serial Port contains a call to static method `getPortIdentifier` on Java class `javax.comm.CommPortIdentifier`.

```
commPort =
javax.comm.CommPortIdentifier.getPortIdentifier('COM1');
```

Using the javaMethod Function on Static Methods

The `javaMethod` function was introduced in section "Using the javaMethod Function on Nonstatic Methods" on page 7-26. You can also use this function to call static methods.

The following syntax invokes the static method, `method_name`, in class, `class_name`, with the argument list that matches `x1,...,xn`. This returns the value `X`.

```
X = javaMethod('method_name','class_name',x1,...,xn);
```

For example, to call the static `isNaN` method of the `java.lang.Double` class on a double value of 2.2, you use

```
javaMethod('isNaN','java.lang.Double',2.2);
```

Using the `javaMethod` function to call static methods enables you to:

- Use methods that have names that exceed the maximum length of a MATLAB identifier. (Call the `namelengthmax` function to obtain the maximum identifier length.)
- Specify method and class names at run-time, for example, as input from an application user.

Obtaining Information About Methods

MATLAB offers several functions to help obtain information related to the Java methods you are working with. You can request a list of all of the methods that are implemented by any class. The list may be accompanied by other method information such as argument types and exceptions. You can also request a listing of every Java class that you loaded into MATLAB that implements a specified method.

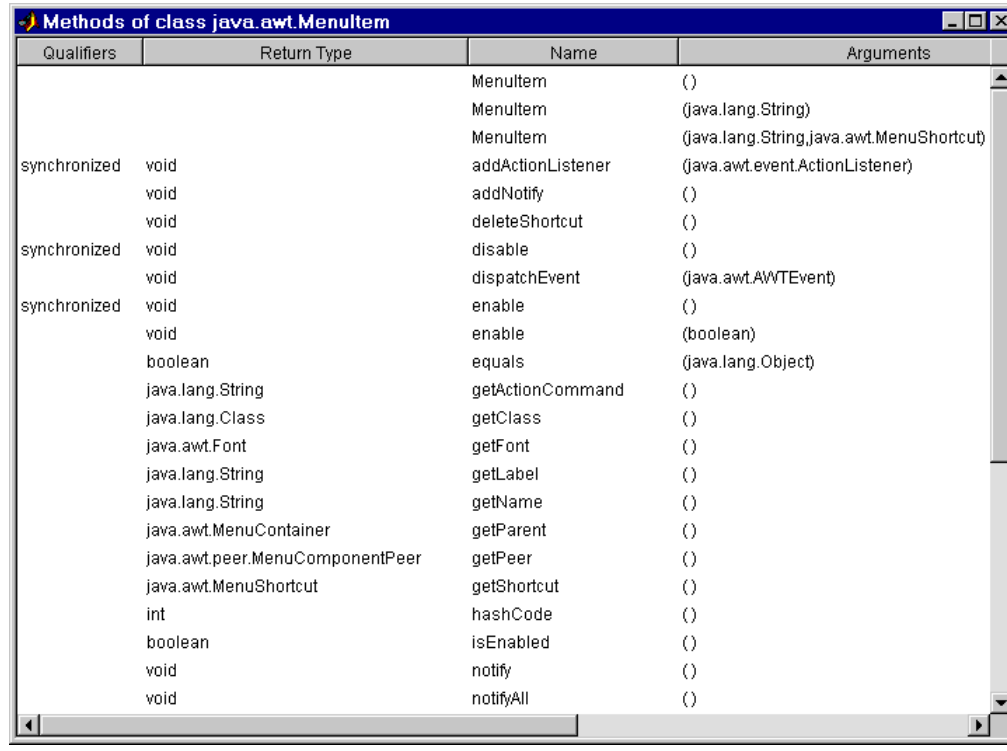
Methodsview: Displaying a Listing of Java Methods

If you want to know what methods are implemented by a particular Java (or MATLAB) class, use the `methodsview` function in MATLAB. Specify the class name (along with its package name, for Java classes) in the command line. If you have imported the package that defines this class, then the class name alone suffices.

The following command lists information on all methods in the `java.awt.MenuItem` class.

```
methodsview java.awt.MenuItem
```

A new window appears, listing one row of information for each method in the class. This is what the `methodsview` display looks like. The field names shown at the top of the window are described following the figure.



Each row in the window displays up to six fields of information describing the method. The table below lists the fields displayed in the `methodsview` window along with a description and examples of each field type.

Fields Displayed in the Methodsview Window

Field Name	Description	Examples
Qualifiers	Method type qualifiers	abstract, synchronized
Return Type	Data type returned by the method	`void`, `java.lang.String`
Name	Method name	`addActionListener`, `dispatchEvent`
Arguments	Arguments passed to method	`boolean`, `java.lang.Object`
Other	Other relevant information	throws `java.io.IOException`
Parent	Parent of the specified class	`java.awt.MenuComponent`

Using the Methods Function on Java Classes

In addition to `methodsview`, the MATLAB `methods` function, which returns information on methods of MATLAB classes, also works on Java classes. You can use any of the following forms of this command.

```
methods class_name
methods class_name -full
n = methods('class_name')
n = methods('class_name','-full')
```

Use `methods` without the `'-full'` qualifier to return the names of all the methods (including inherited methods) of the class. Names of overloaded methods are listed only once.

With the `'-full'` qualifier, `methods` returns a listing of the method names (including inherited methods) along with attributes, argument lists, and inheritance information on each. Each overloaded method is listed separately.

For example, display a full description of all methods of the `java.awt.Dimension` object.

```
methods java.awt.Dimension -full

Methods for class java.awt.Dimension:
Dimension()
Dimension(java.awt.Dimension)
Dimension(int,int)
java.lang.Class getClass()  % Inherited from java.lang.Object
int hashCode()  % Inherited from java.lang.Object
boolean equals(java.lang.Object)
java.lang.String toString()
void notify()  % Inherited from java.lang.Object
void notifyAll()  % Inherited from java.lang.Object
void wait(long) throws java.lang.InterruptedException
   % Inherited from java.lang.Object
void wait(long,int) throws java.lang.InterruptedException
   % Inherited from java.lang.Object
void wait() throws java.lang.InterruptedException
   % Inherited from java.lang.Object
java.awt.Dimension getSize()
void setSize(java.awt.Dimension)
void setSize(int,int)
```

Determining What Classes Define a Method

You can use the `which` function to display the fully qualified name (package and class name) of a method implemented by a *loaded* Java class. With the `-all` qualifier, the `which` function finds all classes with a method of the name specified.

Suppose, for example, that you want to find the package and class name for the `concat` method, with the `String` class currently loaded. Use the command

```
which concat
java.lang.String.concat  % String method
```

If the `java.lang.String` class has not been loaded, the same `which` command would give the output

```
which concat
concat not found.
```

If you use `which -all` for the method `equals`, with the `String` and `java.awt.Frame` classes loaded, you see the following display.

```
which -all equals
java.lang.String.equals                      % String method
java.awt.Frame.equals                        % Frame method
com.mathworks.ide.desktop.MLDesktop.equals   % MLDesktop method
```

The `which` function operates differently on Java classes than it does on MATLAB classes. MATLAB classes are always displayed by `which`, whether or not they are loaded. This is not true for Java classes. You can find out which Java classes are currently loaded by using the command `[m,x,j]=inmem`, described in "Determining Which Classes Are Loaded" on page 7-13.

For a description of how Java classes are loaded, see "Making Java Classes Available to MATLAB" on page 7-11.

Java Methods That Affect MATLAB Commands

MATLAB commands that operate on Java objects and arrays make use of the methods that are implemented within, or inherited by, these objects' classes. There are some MATLAB commands that you can alter somewhat in behavior by changing the Java methods that they rely on.

Changing the Effect of disp and display

You can use the `disp` function to display the value of a variable or an expression in MATLAB. Terminating a command line without a semicolon also calls the `disp` function. You can also use `disp` to display a Java object in MATLAB.

When `disp` operates on a Java object, MATLAB formats the output using the `toString` method of the class to which the object belongs. If the class does not implement this method, then an inherited `toString` method is used. If no intermediate ancestor classes define this method, it uses the `toString` method defined by the `java.lang.Object` class. You can override inherited `toString` methods in classes that you create by implementing such a method

within your class definition. In this way, you can change the way MATLAB displays information regarding the objects of the class.

Changing the Effect of isequal

The MATLAB `isequal` function compares two or more arrays for equality in type, size, and contents. This function can also be used to test Java objects for equality.

When you compare two Java objects using `isequal`, MATLAB performs the comparison using the Java method, `equals`. MATLAB first determines the class of the objects specified in the command, and then uses the `equals` method implemented by that class. If it is not implemented in this class, then an inherited `equals` method is used. This is the `equals` method defined by the `java.lang.Object` class if no intermediate ancestor classes define this method.

You can override inherited `equals` methods in classes that you create by implementing such a method within your class definition. In this way, you can change the way MATLAB performs comparison of the members of this class.

Changing the Effect of double and char

You can also define your own Java methods `toDouble` and `toChar` to change the output of the MATLAB `double` and `char` functions. For more information, see the sections entitled “Converting to the MATLAB double Data Type” on page 7-66 and “Converting to the MATLAB char Data Type” on page 7-67.

How MATLAB Handles Undefined Methods

If your MATLAB command invokes a nonexistent method on a Java object, MATLAB looks for a function with the same name. If MATLAB finds a function of that name, it attempts to invoke it. If MATLAB does not find a function with that name, it displays a message stating that it cannot find a method by that name for the class.

For example, MATLAB has a function named `size`, and the Java API `java.awt.Frame` class also has a `size` method. If you call `size` on a `Frame` object, the `size` method defined by `java.awt.Frame` is executed. However,

if you call `size` on an object of `java.lang.String`, MATLAB does not find a `size` method for this class. It executes the MATLAB `size` function instead.

```
string = java.lang.String('hello');

size(string)
ans =
     1     1
```

Note When you define a Java class for use in MATLAB, avoid giving any of its methods the same name as a MATLAB function.

How MATLAB Handles Java Exceptions

If invoking a Java method or constructor throws an exception, MATLAB catches the exception and transforms it into a MATLAB error. MATLAB puts the text of the Java error message into its own error message. Receiving an error from a Java method or constructor has the same appearance as receiving an error from an M-file.

Method Execution in MATLAB

When calling a `main` method from MATLAB, the method returns as soon as it executes its last statement, even if the method creates a thread that is still executing. In other environments, the `main` method does not return until the thread completes execution.

You, therefore, need to be cautious when calling `main` methods from MATLAB, particularly `main` methods that launch GUIs. `main` methods are usually written assuming they are the entry point to application code. When called from MATLAB this is not the case, and the fact that other Java GUI code might be already running can lead to problems.

Working with Java Arrays

In this section...

Introduction

You can pass singular Java objects to and from methods or you may pass them in an array, providing the method expects them in that form. This array must either be a Java array (returned from another method call or created within MATLAB) or, under certain circumstances, a MATLAB cell array. This section describes how to create and manipulate Java arrays in MATLAB. Later sections will describe how to use MATLAB cell arrays in calls to Java methods.

Note The term *dimension* here refers more to the number of subscripts required to address the elements of an array than to its length, width, and height characteristics. For example, a 5-by-1 array is referred to as being one-dimensional, as its individual elements can be indexed into using only one array subscript.

How MATLAB Represents the Java Array

The term *java array* refers to any array of Java objects returned from a call to a Java class constructor or method. You may also construct a Java array within MATLAB using the `javaArray` function. The structure of a Java array is significantly different from that of a MATLAB matrix or array. MATLAB *hides* these differences whenever possible, allowing you to operate on the

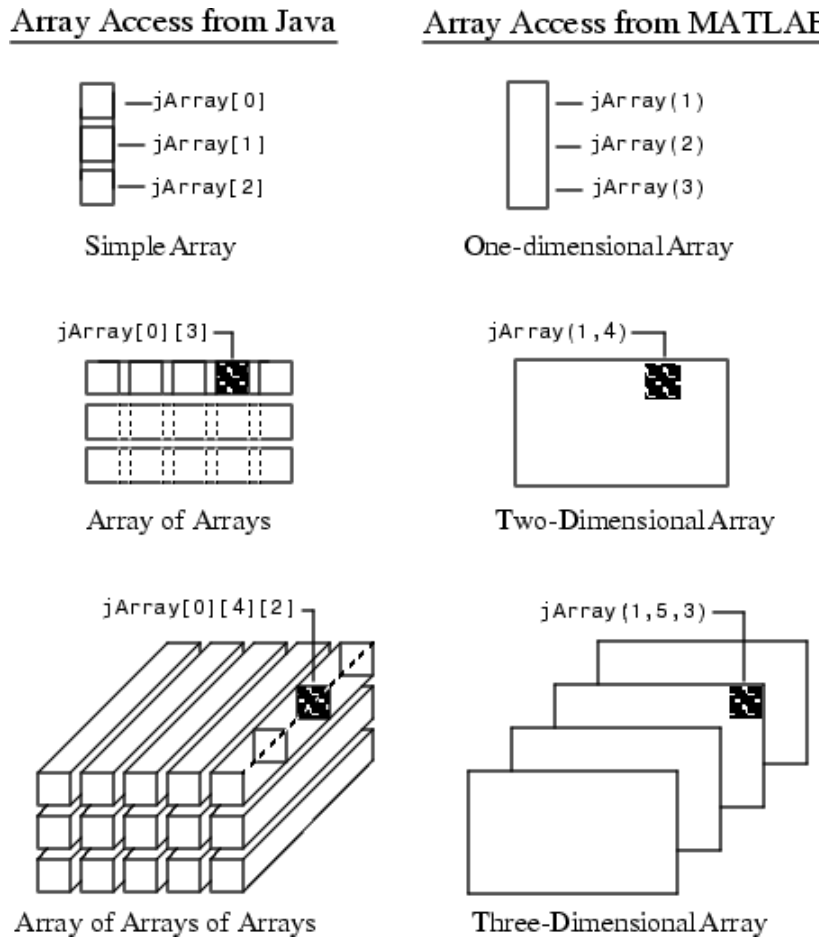
arrays using the usual MATLAB command syntax. Just the same, it may be helpful to keep the following differences in mind as you work with Java arrays.

Representing More Than One Dimension

An array in the Java language is strictly a one-dimensional structure because it is measured only in length. If you want to work with a two-dimensional array, you can create an equivalent structure using an array of arrays. To add further dimensions, you add more levels to the array, making it an array of arrays of arrays, and so on. You may want to use such multilevel arrays when working in MATLAB as it is a matrix and array-based programming language.

MATLAB makes it easy for you to work with multilevel Java arrays by treating them like the matrices and multidimensional arrays that are a part of the language itself. You access elements of an array of arrays using the same MATLAB syntax that you use if you are handling a matrix. If you add more levels to the array, MATLAB can access and operate on the structure as if it is a multidimensional MATLAB array.

The left side of the following figure shows Java arrays of one, two, and three dimensions. To the right of each is the way the same array is represented to you in MATLAB. Note that single-dimension arrays are represented as a column vector.



Array Indexing

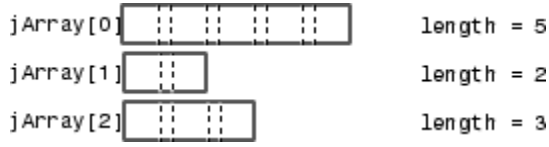
Java array indexing is different than MATLAB array indexing. Java array indices are zero-based, MATLAB array indices are one-based. In Java programming, you access the elements of array `y` of length `N` using `y[0]`

through `y[N-1]`. When working with this array in MATLAB, you access these same elements using the MATLAB indexing style of `y(1)` through `y(N)`. Thus, if you have a Java array of 10 elements, the seventh element is obtained using `y(7)`, and not `y[6]` as you use when writing a program in Java.

The Shape of the Java Array

A Java array can be different from a MATLAB array in its overall *shape*. A two-dimensional MATLAB array maintains a rectangular shape, as each row is of equal length and each column of equal height. The Java counterpart of this, an array of arrays, does not necessarily hold to this rectangular form. Each individual lower level array may have a different length.

Such an array structure is pictured below. This is an array of three underlying arrays of different lengths. The term *ragged* is commonly used to describe this arrangement of array elements as the array ends do not match up evenly. When a Java method returns an array with this type of structure, it is stored in a cell array by MATLAB.

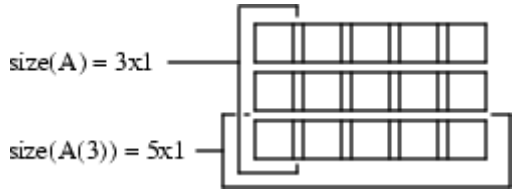


Interpreting the Size of a Java Array

When the MATLAB `size` function is applied to a simple Java array, the number of rows returned is the length of the Java array and the number of columns is always 1.

Determining the size of a Java array of arrays is not so simple. The potentially ragged shape of an array returned from Java makes it impossible to size the array in the same way as for a rectangular matrix. In a ragged Java array, there is no one value that represents the size of the lower level arrays.

When the `size` function is applied to a Java array of arrays, the resulting value describes the top level of the specified array. For the Java array



`size(A)` returns the dimensions of the highest array level of A. The highest level of the array has a size of 3-by-1.

```
size(A)
ans =
     3     1
```

To find the size of a lower level array, say the five-element array in row 3, refer to the row explicitly.

```
size(A(3))
ans =
     5     1
```

You can specify a dimension in the `size` command using the following syntax. However, you will probably find this useful only for sizing the first dimension, `dim=1`, as this will be the only non-unary dimension.

```
m = size(X,dim)

size(A, 1)
ans =
     3
```

Interpreting the Number of Dimensions of a Java Arrays

For Java arrays, whether they are simple one-level arrays or multilevel, the MATLAB `ndims` function always returns a value of 2 to indicate the number of dimensions in the array. This is a measure of the number of dimensions in the top-level array, which always equals 2.

Creating an Array of Objects Within MATLAB

To call a Java method that has one or more arguments defined as an array of Java objects, you must, under most circumstances, pass your objects in a Java array. You can construct an array of objects in a call to a Java method or constructor. Or you can create the array within MATLAB.

The MATLAB `javaArray` function lets you create a Java array structure that can be handled in MATLAB as a single multidimensional array. You specify the number and size of the array dimensions along with the class of objects you intend to store in it. Using the one-dimensional Java array as its primary building block, MATLAB then builds an array structure that satisfies the dimensions requested in the `javaArray` command.

Using the javaArray Function

To create a Java object array, use the MATLAB `javaArray` function, which has the following syntax:

```
A = javaArray('element_class', m, n, p, ...)
```

The first argument is the `'element_class'` string, which names the class of the elements in the array. You must specify the fully qualified name (package and class name). The remaining arguments (`m, n, p, ...`) are the number of elements in each dimension of the array.

An array that you create with `javaArray` is equivalent to the array that you create with the Java code.

```
A = new element_class[m][n][p]...;
```

The following command builds a Java array of four lower level arrays, each capable of holding five objects of the `java.lang.Double` class. (You are more likely to use primitive types of `double` than instances of the `java.lang.Double` class, but in this context, it affords us a simple example.)

```
dblArray = javaArray('java.lang.Double', 4, 5);
```

The `javaArray` function does not deposit any values into the array elements that it creates. You must do this separately. The following MATLAB code stores objects of the `java.lang.Double` type in the Java array `dblArray` that was just created.

```
for m = 1:4
    for n = 1:5
    dblArray(m,n) = java.lang.Double((m*10) + n);
    end
end

dblArray
dblArray =
java.lang.Double[][]:
    [11]    [12]    [13]    [14]    [15]
    [21]    [22]    [23]    [24]    [25]
    [31]    [32]    [33]    [34]    [35]
    [41]    [42]    [43]    [44]    [45]
```

Another Way to Create a Java Array

You can also create an array of Java objects using syntax that is more typical to MATLAB. For example, the following syntax creates a 4-by-5 MATLAB array of type double and assigns zero to each element of the array.

```
matlabArray(4,5) = 0;
```

You use similar syntax to create a Java array in MATLAB, except that you must specify the Java class name. The value being assigned, `0` in this example, is stored in the final element of the array, javaArray`(4,5)`. All other elements of the array receive the empty matrix.

```
javaArray(4,5) = java.lang.Double(0)
javaArray =
java.lang.Double[][]:
     []     []     []     []     []
     []     []     []     []     []
     []     []     []     []     []
     []     []     []     []    [0]
```

Note You cannot change the dimensions of an existing Java array as you can with a MATLAB array. The same restriction exists when working with Java arrays in the Java language. See the example below.

This example first creates a scalar MATLAB array, and then successfully modifies it to be two-dimensional.

```
matlabArray = 0;
matlabArray(4,5) = 0

matlabArray =

     0     0     0     0     0
     0     0     0     0     0
     0     0     0     0     0
     0     0     0     0     0
```

When you try this with a Java array, you get an error. Similarly, you cannot create an array of Java arrays from a Java array, and so forth.

```
javaArray = java.lang.Double(0);
javaArray(4,5) = java.lang.Double(0);
??? Index exceeds Java array dimensions.
```

Accessing Elements of a Java Array

You can access elements of a Java object array by using the MATLAB array indexing syntax, `A(row,col)`. For example, to access the element of array `dblArray` located at row 3, column 4, use

```
row3_col4 = dblArray(3,4)
row3_col4 =
34.0
```

In Java, this is `dblArray[2][3]`.

You can also use MATLAB array indexing syntax to access an element in an object's data field. Suppose that `myMenuObj` is an instance of a window menu class. This user-supplied class has a data field, `menuItemArray`, which is a Java array of `java.awt.menuItem`. To get element `3` of this array, use the following command.

```
currentItem = myMenuObj.menuItemArray(3)
```

Using Single Subscript Indexing to Access Arrays

Elements of a MATLAB matrix are most commonly referenced using both row and column subscripts. For example, you use `x(3,4)` to reference the array element at the intersection of row 3 and column 4. Sometimes it is more advantageous to use just a single subscript. MATLAB provides this capability (see the section on "Linear Indexing" in MATLAB Programming).

Indexing into a MATLAB matrix using a single subscript references one element of the matrix. Using the MATLAB matrix shown here, `matlabArray(3)` returns a single element of the matrix.

```
matlabArray = [11 12 13 14 15; 21 22 23 24 25; ...
               31 32 33 34 35; 41 42 43 44 45]
matlabArray =
    11    12    13    14    15
    21    22    23    24    25
    31    32    33    34    35
    41    42    43    44    45

matlabArray(3)
ans =
    31
```

Indexing this way into a Java array of arrays references an entire subarray of the overall structure. Using the `dblArray` Java array, that looks the same as `matlabArray` shown above, `dblArray(3)` returns the 5-by-1 array that makes up the entire third row.

```
row3 = dblArray(3)
row3 =
java.lang.Double[]:
    [31]
    [32]
    [33]
    [34]
    [35]
```

This is a useful feature of MATLAB because it allows you to specify an entire array from a larger array structure, and then manipulate it as an object.

Using the Colon Operator

Use of the MATLAB `colon` operator (`:`) is supported in subscripting Java array references. This operator works just the same as when referencing the contents of a MATLAB array. Using the Java array of `java.lang.Double` objects shown here, the statement `dblArray(2,2:4)` refers to a portion of the lower level array, `dblArray(2)`. A new array, `row2Array`, is created from the elements in columns 2 through 4.

```
dblArray
dblArray =
java.lang.Double[][]:
    [11]    [12]    [13]    [14]    [15]
    [21]    [22]    [23]    [24]    [25]
    [31]    [32]    [33]    [34]    [35]
    [41]    [42]    [43]    [44]    [45]

row2Array = dblArray(2,2:4)
row2Array =
java.lang.Double[]:
    [22]
    [23]
    [24]
```

You also can use the colon operator in single-subscript indexing, as covered in “Using Single Subscript Indexing to Access Arrays” on page 7-43. By making your subscript a colon rather than a number, you can convert an array of arrays into one linear array. The following example converts the 4-by-5 array `dblArray` into a 20-by-1 linear array.

```
linearArray = dblArray(:)
linearArray =
java.lang.Double[]:
    [11]
    [12]
    [13]
    [14]
    [15]
    [21]
    [22]
     .
     .
     .
```

This works the same way on an N-dimensional Java array structure. Using the colon operator as a single subscripted index into the array produces a linear array composed of all of the elements of the original array.

Note Java and MATLAB arrays are stored differently in memory. This is reflected in the order they are given in a linear array. Java array elements are stored in an order that matches the *rows* of the matrix, (`11`, `12`, `13`, `...` in the array shown above). MATLAB array elements are stored in an order that matches the *columns*, (`11`, `21`, `31`, `...`).

Using END in a Subscript

You can use the `end` keyword in the first subscript of an access statement. The first subscript references the top-level array in a multilevel Java array structure.

Note Using `end` on lower level arrays is not valid due to the potentially ragged nature of these arrays (see “The Shape of the Java Array” on page 7-38). In this case, there is no consistent end value to be derived.

The following example displays data from the third to the last row of Java array `dblArray`.

```
last2rows = dblArray(3:end, :)
last2rows =
java.lang.Double[][]:
    [31]    [32]    [33]    [34]    [35]
    [41]    [42]    [43]    [44]    [45]
```

Assigning to a Java Array

You assign values to objects in a Java array in essentially the same way as you do in a MATLAB array. Although Java and MATLAB arrays are structured quite differently, you use the same command syntax to specify which elements you want to assign to. See "Introduction" on page 7-35 for more information on Java and MATLAB array differences.

The following example deposits the value `300` in the `dblArray` element at row 3, column 2. In Java, this is `dblArray[2][1]`.

```
dblArray(3,2) = java.lang.Double(300)
dblArray =
java.lang.Double[][]:
    [11]    [ 12]    [13]    [14]    [15]
    [21]    [ 22]    [23]    [24]    [25]
    [31]    [300]    [33]    [34]    [35]
    [41]    [ 42]    [43]    [44]    [45]
```

You use the same syntax to assign to an element in an object's data field. Continuing with the `myMenuObj` example shown in "Accessing Elements of a Java Array" on page 7-42, you assign to the third menu item in `menuItemArray` as follows.

```
myMenuObj.menuItemArray(3) = java.lang.String('Save As...');
```

Using Single Subscript Indexing for Array Assignment

You can use a single-array subscript to index into a Java array structure that has more than one dimension. Refer to "Using Single Subscript Indexing to Access Arrays" on page 7-43 for a description of this feature as used with Java arrays.

You can use single-subscript indexing to assign values to an array as well. The example below assigns a one-dimensional Java array, `onedimArray`, to a row of a two-dimensional Java array, `dblArray`. Start out by creating the one-dimensional array.

```
onedimArray = javaArray('java.lang.Double', 5);
for k = 1:5
    onedimArray(k) = java.lang.Double(100 * k);
    end
```

Since `dblArray(3)` refers to the 5-by-1 array displayed in the third row of `dblArray`, you can assign the entire, similarly dimensioned, 5-by-1 `onedimArray` to it.

```
dblArray(3) = onedimArray
dblArray =
java.lang.Double[][]:
    [ 11]    [ 12]    [ 13]    [ 14]    [ 15]
    [ 21]    [ 22]    [ 23]    [ 24]    [ 25]
    [100]    [200]    [300]    [400]    [500]
    [ 41]    [ 42]    [ 43]    [ 44]    [ 45]
```

Assigning to a Linear Array

You can assign a value to *every* element of a multidimensional Java array by treating the array structure as if it were a single linear array. This entails replacing the single, numerical subscript with the MATLAB colon operator. If you start with the `dblArray` array, you can initialize the contents of every object in the two-dimensional array with the following statement.

```
dblArray(:) = java.lang.Double(0)
dblArray =
java.lang.Double[][]:
    [0]    [0]    [0]    [0]    [0]
    [0]    [0]    [0]    [0]    [0]
    [0]    [0]    [0]    [0]    [0]
    [0]    [0]    [0]    [0]    [0]
```

You can use the MATLAB colon operator as you would when working with MATLAB arrays. The statements below assign given values to each of the four rows in the Java array, `dblArray`. Remember that each row actually represents a separate Java array in itself.

```
dblArray(1,:) = java.lang.Double(125);
dblArray(2,:) = java.lang.Double(250);
dblArray(3,:) = java.lang.Double(375);
dblArray(4,:) = java.lang.Double(500)
dblArray =
java.lang.Double[][]:
    [125]    [125]    [125]    [125]    [125]
    [250]    [250]    [250]    [250]    [250]
    [375]    [375]    [375]    [375]    [375]
    [500]    [500]    [500]    [500]    [500]
```

Assigning the Empty Matrix

When working with MATLAB arrays, you can assign the empty matrix, (i.e., the 0-by-0 array denoted by []) to an element of the array. For Java arrays, you can also assign [] to array elements. This stores the `NULL` value, rather than a 0-by-0 array, in the Java array element.

Subscripted Deletion

When you assign the empty matrix value to an entire row or column of a MATLAB array, you find that MATLAB actually removes the affected row or column from the array. In the example below, the empty matrix is assigned to all elements of the fourth column in the MATLAB matrix, `matlabArray`. Thus, the fourth column is completely eliminated from the matrix. This changes its dimensions from 4-by-5 to 4-by-4.

```
matlabArray = [11 12 13 14 15; 21 22 23 24 25; ...
               31 32 33 34 35; 41 42 43 44 45]
matlabArray =
    11    12    13    14    15
    21    22    23    24    25
    31    32    33    34    35
    41    42    43    44    45

matlabArray(:,4) = []
matlabArray =
    11    12    13    15
    21    22    23    25
    31    32    33    35
    41    42    43    45
```

You can assign the empty matrix to a Java array, but the effect is different. The next example shows that, when the same operation is performed on a Java array, the structure is not collapsed; it maintains its 4-by-5 dimensions.

```
dblArray(:,4) = []
dblArray =
java.lang.Double[][]:
    [125]    [125]    [125]     []    [125]
    [250]    [250]    [250]     []    [250]
    [375]    [375]    [375]     []    [375]
    [500]    [500]    [500]     []    [500]
```

The `dblArray` data structure is actually an array of five-element arrays of `java.lang.Double` objects. The empty array assignment placed the `NULL` value in the fourth element of each of the lower level arrays.

Concatenating Java Arrays

You can concatenate arrays of Java objects in the same way as arrays of other data types. Java objects, however, can only be catenated along the first or second axis. To understand how scalar Java objects are concatenated in MATLAB, see “Concatenating Java Objects” on page 7-19.

Use either the `cat` function or the square bracket (`[]`) operators. This example horizontally concatenates two Java arrays: `d1` and `d2`.

```
% Construct a 2-by-3 array of java.lang.Double.
d1 = javaArray('java.lang.Double',2,3);
for m = 1:3     for n = 1:3
d1(m,n) = java.lang.Double(n*2 + m-1);
end;            end;

d1
d1 =
java.lang.Double[][]:
    [2]    [4]    [6]
    [3]    [5]    [7]
    [4]    [6]    [8]

% Construct a 2-by-2 array of java.lang.Double.
d2 = javaArray('java.lang.Double',2,2);
for m = 1:3     for n = 1:2
d2(m,n) = java.lang.Double((n+3)*2 + m-1);
end;            end;

d2
d2 =
java.lang.Double[][]:
    [ 8]    [10]
    [ 9]    [11]
    [10]    [12]

% Concatenate the two along the second dimension.
d3 = cat(2,d1,d2)
d3 =
java.lang.Double[][]:
    [2]    [4]    [6]    [ 8]    [10]
    [3]    [5]    [7]    [ 9]    [11]
    [4]    [6]    [8]    [10]    [12]
```

Creating a New Array Reference

Because Java arrays in MATLAB are *references*, assigning an array variable to another variable results in a second reference to the array.

Consider the following example where two separate array variables reference a common array. The original array, `origArray`, is created and initialized.

The statement `newArrayRef = origArray` creates a copy of this array variable. Changes made to the array referred to by `newArrayRef` also show up in the original array.

```
origArray = javaArray('java.lang.Double', 3, 4);
for m = 1:3
   for n = 1:4
      origArray(m,n) = java.lang.Double((m * 10) + n);
   end
end

origArray
origArray =
java.lang.Double[][]:
    [11]    [12]    [13]    [14]
    [21]    [22]    [23]    [24]
    [31]    [32]    [33]    [34]

%  ----- Make a copy of the array reference -----
newArrayRef = origArray;
newArrayRef(3,:) = java.lang.Double(0);

origArray
origArray =
java.lang.Double[][]:
    [11]    [12]    [13]    [14]
    [21]    [22]    [23]    [24]
    [ 0]    [ 0]    [ 0]    [ 0]
```

Creating a Copy of a Java Array

You can create an entirely new array from an existing Java array by indexing into the array to describe a block of elements, (or subarray), and assigning this subarray to a variable. The assignment copies the values in the original array to the corresponding cells of the new array.

As with the example in section “Creating a New Array Reference” on page 7-50, an original array is created and initialized. But, this time, a copy is made of the array contents rather than copying the array reference. Changes made using the reference to the new array do not affect the original.

```
origArray = javaArray('java.lang.Double', 3, 4);
for m = 1:3
   for n = 1:4
      origArray(m,n) = java.lang.Double((m * 10) + n);
   end
end

origArray
origArray =
java.lang.Double[][]:
    [11]    [12]    [13]    [14]
    [21]    [22]    [23]    [24]
    [31]    [32]    [33]    [34]

%  ----- Make a copy of the array contents -----
newArray = origArray(:,:);
newArray(3,:) = java.lang.Double(0);

origArray
origArray =
java.lang.Double[][]:
    [11]    [12]    [13]    [14]
    [21]    [22]    [23]    [24]
    [31]    [32]    [33]    [34]
```

Passing Data to a Java Method

In this section...

Introduction

When you make a call from MATLAB to Java code, any MATLAB data types you pass in the call are converted to data types native to the Java language. MATLAB performs this conversion on each argument that is passed, except for those arguments that are already Java objects. This section describes the conversion that is performed on specific MATLAB data types and, at the end, also takes a look at how argument types affect calls made to overloaded methods.

If data is to be returned by the method being called, MATLAB receives this data and converts it to the appropriate MATLAB format wherever necessary. This process is covered in "Handling Data Returned from a Java Method" on page 7-64.

Conversion of MATLAB Argument Data

MATLAB data, passed as arguments to Java methods, are converted by MATLAB into data types that best represent the data to the Java language. The table below shows all of the MATLAB base types for passed arguments and the Java base types defined for input arguments. Each row shows a MATLAB type followed by the possible Java argument matches, from left to right in order of closeness of the match. The MATLAB types (except cell arrays) can all be scalar (1-by-1) arrays or matrices. All of the Java types can be scalar values or arrays.

Conversion of MATLAB Types to Java Types

MATLAB Argument	Closest Type (7)	Java Input Argument (Scalar or Array)					Least Close Type (1)
logical	boolean	byte	short	int	long	float	double
double	double	float	long	int	short	byte	boolean
single	float	double	N/A	N/A	N/A	N/A	N/A
char	String	char	N/A	N/A	N/A	N/A	N/A
uint8	byte	short	int	long	float	double	N/A
uint16	short	int	long	float	double	N/A	N/A
uint32	int	long	float	double	N/A	N/A	N/A
int8	byte	short	int	long	float	double	N/A
int16	short	int	long	float	double	N/A	N/A
int32	int	long	float	double	N/A	N/A	N/A
cell array of strings	array of String	N/A	N/A	N/A	N/A	N/A	N/A
Java object	Object	N/A	N/A	N/A	N/A	N/A	N/A
cell array of object	array of Object	N/A	N/A	N/A	N/A	N/A	N/A
MATLAB object	N/A	N/A	N/A	N/A	N/A	N/A	N/A

Data type conversion of arguments passed to Java code are discussed in the following three categories. MATLAB handles each category differently.

- "Passing Built-In Data Types" on page 7-55
- "Passing String Arguments" on page 7-56
- "Passing Java Objects" on page 7-57

Passing Built-In Data Types

Java has eight data types that are intrinsic to the language and are not represented as Java objects. These are often referred to as *built-in*, or *elemental*, data types and they include `boolean`, `byte`, `short`, `long`, `int`, `double`, `float`, and `char`. MATLAB converts its own data types to these Java built-in types according to the table, Conversion of MATLAB Types to Java Types on page 7-54. Built-in types are in the first 10 rows of the table.

When a Java method you are calling expects one of these data types, you can pass it the type of MATLAB argument shown in the left-most column of the table. If the method takes an array of one of these types, you can pass a MATLAB array of the data type. MATLAB converts the data type of the argument to the type assigned in the method declaration.

The MATLAB code shown below creates a top-level window frame and sets its dimensions. The call to `setBounds` passes four MATLAB scalars of the `double` type to the inherited Java Frame method, `setBounds`, that takes four arguments of the `int` type. MATLAB converts each 64-bit double data type to a 32-bit integer prior to making the call. Shown here is the `setBounds` method declaration followed by the MATLAB code that calls the method.

```
public void setBounds(int x, int y, int width, int height)

frame=java.awt.Frame;
frame.setBounds(200,200,800,400);
frame.setVisible(1);
```

Passing Built-In Types in an Array

To call a Java method with an argument defined as an *array* of a built-in type, you can create and pass a MATLAB matrix with a compatible base type. The following code defines a polygon by sending four `x` and `y` coordinates to the Polygon constructor. Two 1-by-4 MATLAB arrays of `double` are passed to `java.awt.Polygon`, which expects `integer` arrays in the first two arguments. Shown here is the Java method declaration followed by MATLAB code that calls the method, and then verifies the set coordinates.

```
public Polygon(int xpoints[], int ypoints[], int npoints)

poly = java.awt.Polygon([14 42 98 124], [55 12 -2 62], 4);
[poly.xpoints poly.ypoints]       % Verify the coordinates
ans =
14     55
42     12
98    -2
124    62
```

MATLAB Arrays Are Passed by Value

Since MATLAB arrays are passed by value, any changes that a Java method makes to them are not visible to your MATLAB code. If you need to access changes that a Java method makes to an array, then, rather than passing a MATLAB array, you should create and pass a Java array, which is a reference. For a description of using Java arrays in MATLAB, see "Working with Java Arrays" on page 7-35.

Note Generally, it is preferable to have methods return data that has been modified using the return argument mechanism as opposed to passing a reference to that data in an argument list.

Passing String Arguments

To call a Java method that has an argument defined as an object of class `java.lang.String`, you can pass either a `String` object that was returned from an earlier Java call or a MATLAB 1-by-n character array. If you pass the character array, MATLAB converts the array to a Java object of `java.lang.String` for you.

For a programming example, see "Example — Reading a URL" on page 7-71. This shows a MATLAB character array that holds a URL being passed to the Java `URL` class constructor. The constructor, shown below, expects a Java `String` argument.

```
public URL(String spec) throws MalformedURLException
```

In the MATLAB call to this constructor, a character array specifying the URL is passed. MATLAB converts this array to a Java String object prior to calling the constructor.

```
url = java.net.URL(...
     'http://archive.ncsa.uiuc.edu/demoweb/')
```

Passing Strings in an Array

When the method you are calling expects an argument of an array of type `String`, you can create such an array by packaging the strings together in a MATLAB cell array. The strings can be of varying lengths since you are storing them in different cells of the array. As part of the method call, MATLAB converts the cell array to a Java array of `String` objects.

In the following example, the `echoPrompts` method of a user-written class accepts a string array argument that MATLAB converted from its original format as a cell array of strings. The parameter list in the Java method appears as follows:

```
public String[] echoPrompts(String s[])
```

You create the input argument by storing both strings in a MATLAB cell array. MATLAB converts this structure to a Java array of `String`.

```
myaccount.echoPrompts({'Username: ','Password: '})
ans =
'Username: '
'Password: '
```

Passing Java Objects

When calling a method that has an argument belonging to a particular Java class, you must pass an object that is an instance of that class. In the example below, the `add` method belonging to the `java.awt.Menu` class requires, as an argument, an object of the `java.awt.MenuItem` class. The method declaration for this is

```
public MenuItem add(MenuItem mi)
```

The example operates on the frame created in the previous example in “Passing Built-In Data Types” on page 7-55. The second, third, and fourth

lines of code shown here add items to a menu to be attached to the existing window frame. In each of these calls to `menu1.add`, an object that is an instance of the `java.awt.MenuItem` Java class is passed.

```
menu1 = java.awt.Menu('File Options');
menu1.add(java.awt.MenuItem('New'));
menu1.add(java.awt.MenuItem('Open'));
menu1.add(java.awt.MenuItem('Save'));

menuBar=java.awt.MenuBar;
menuBar.add(menu1);
frame.setMenuBar(menuBar);
```

Handling Objects of Class java.lang.Object

A special case exists when the method being called takes an argument of the `java.lang.Object` class. Since this class is the root of the Java class hierarchy, you can pass objects of any class in the argument. The following hash table example passes objects belonging to different classes to a common method, `put`, which expects an argument of `java.lang.Object`. The method declaration for `put` is

```
public synchronized Object put(Object key, Object value)
```

The following MATLAB code passes objects of different types (`boolean`, `float`, and `string`) to the `put` method.

```
hTable = java.util.Hashtable;
hTable.put(0, java.lang.Boolean('TRUE'));
hTable.put(1, java.lang.Float(41.287));
hTable.put(2, java.lang.String('test string'));

hTable                  % Verify hash table contents
hTable =
{1.0=41.287, 2.0=test string, 0.0=true}
```

When passing arguments to a method that takes `java.lang.Object`, it is not necessary to specify the class name for objects of a built-in data type. Line 3, in the example above, specifies that `41.287` is an instance of class `java.lang.Float`. You can omit this and simply say, `41.287`, as shown in the

following example. Thus, MATLAB creates each object for you, choosing the closest matching Java object representation for each argument.

The three calls to `put` from the preceding example can be rewritten as

```
hTable.put(0, 1);
hTable.put(1, 41.287);
hTable.put(2, 'test string');
```

Passing Objects in an Array

The only types of object arrays that you can pass to Java methods are Java arrays and MATLAB cell arrays. MATLAB automatically converts the cell array elements to `java.lang.Object` class objects. Note that in order for a cell array to be passed from MATLAB, the corresponding argument in the Java method signature must specify `java.lang.Object` or an array of `java.lang.Object`.

If the objects are already in a Java array, either an array returned from a Java constructor or constructed in MATLAB by the `javaArray` function, then you simply pass it as the argument to the method being called. No conversion is done by MATLAB, because the argument is already a Java array.

The following example shows the `mapPoints` method of a user-written class accepting an array of `java.awt.Point` objects. The declaration for this method is

```
public Object mapPoints(java.awt.Point p[])
```

The MATLAB code shown below creates a 4-by-1 array containing four Java Point objects. When the array is passed to the `mapPoints` method, no conversion is necessary because the `javaArray` function created a Java array of `java.awt.Point` objects.

```
pointObj = javaArray('java.awt.Point',4);
pointObj(1) = java.awt.Point(25,143);
pointObj(2) = java.awt.Point(31,147);
pointObj(3) = java.awt.Point(49,151);
pointObj(4) = java.awt.Point(52,176);

testData.mapPoints(pointObj);
```

Handling a Cell Array of Java Objects

You create a cell array of Java objects by using the MATLAB syntax `{a1,a2,...}`. You index into a cell array of Java objects in the usual way, with the syntax `a{m,n,...}`.

The following example creates a cell array of two `Frame` objects, `frame1` and `frame2`, and assigns it to variable `frameArray`.

```
frame1 = java.awt.Frame('Frame A');
frame2 = java.awt.Frame('Frame B');

frameArray = {frame1, frame2}
frameArray =
[1x1 java.awt.Frame]    [1x1 java.awt.Frame]
```

The next statement assigns element `{1,2}` of the cell array `frameArray` to variable `f`.

```
f = frameArray {1,2}
f =
java.awt.Frame[frame2,0,0,0x0,invalid,hidden,layout =
java.awt.BorderLayout,resizable,title=Frame B]
```

Other Data Conversion Topics

There are several remaining items of interest regarding the way MATLAB converts its data to a compatible Java type. This includes how MATLAB matches array dimensions, and how it handles empty matrices and empty strings.

How Array Dimensions Affect Conversion

The term *dimension*, as used in this section, refers more to the number of subscripts required to address the elements of an array than to its length, width, and height characteristics. For example, a 5-by-1 array is referred to as having one dimension, because its individual elements can be indexed into using only one array subscript.

In converting MATLAB to Java arrays, MATLAB handles dimension in a special manner. For a MATLAB array, dimension can be considered as the number of nonsingleton dimensions in the array. For example, a 10-by-1 array

has dimension 1, and a 1-by-1 array has dimension 0. In Java, dimension is determined solely by the number of nested arrays. For example, `double[][]` has dimension 2, and `double` has dimension 0.

If the Java array's number of dimensions exactly matches the MATLAB array's number of dimensions `n`, the conversion results in a Java array with `n` dimensions. If the Java array has fewer than `n` dimensions, the conversion drops singleton dimensions, starting with the first one, until the number of remaining dimensions matches the number of dimensions in the Java array.

Empty Matrices and Nulls

The empty matrix is compatible with any method argument for which `NULL` is a legal value in Java. The empty string (`''`) in MATLAB translates into an empty (not `NULL`) `String` object in Java.

Passing Data to Overloaded Methods

When you invoke an overloaded method on a Java object, MATLAB determines which method to invoke by comparing the arguments your call passes to the arguments defined for the methods. Note that in this discussion, the term *method* includes constructors. When it determines the method to call, MATLAB converts the calling arguments to Java method types according to Java conversion rules, except for conversions involving objects or cell arrays. See "Passing Objects in an Array" on page 7-59.

How MATLAB Determines the Method to Call

When your MATLAB function calls a Java method, MATLAB

1. Checks to make sure that the object (or class, for a static method) has a method by that name.
2. Determines whether the invocation passes the same number of arguments of at least one method with that name.
3. Makes sure that each passed argument can be converted to the Java type defined for the method.

If all of the preceding conditions are satisfied, MATLAB calls the method.

In a call to an overloaded method, if there is more than one candidate, MATLAB selects the one with arguments that best fit the calling arguments. First, MATLAB rejects all methods that have any argument types that are incompatible with the passed arguments (for example, if the method has a `double` argument and the passed argument is a `char`).

Among the remaining methods, MATLAB selects the one with the highest fitness value, which is the sum of the fitness values of all its arguments. The fitness value for each argument is the fitness of the base type minus the difference between the MATLAB array dimension and the Java array dimension. (Array dimensionality is explained in "How Array Dimensions Affect Conversion" on page 7-60.) If two methods have the same fitness, the first one defined in the Java class is chosen.

Example — Calling an Overloaded Method

Suppose a function constructs a `java.io.OutputStreamWriter` object, `osw`, and then invokes a method on the object.

```
osw.write('Test data', 0, 9);
```

MATLAB finds that the class `java.io.OutputStreamWriter` defines three `write` methods.

```
public void write(int c);
public void write(char[] cbuf, int off, int len);
public void write(String str, int off, int len);
```

MATLAB rejects the first `write` method, because it takes only one argument. Then, MATLAB assesses the fitness of the remaining two `write` methods. These differ only in their first argument, as explained below.

In the first of these two `write` methods, the first argument is defined with base type, `char`. The table, Conversion of MATLAB Types to Java Types on page 7-54, shows that for the type of the calling argument (MATLAB `char`), Java type, `char`, has a value of 6. There is no difference between the dimension of the calling argument and the Java argument. So the fitness value for the first argument is 6.

In the other `write` method, the first argument has Java type `String`, which has a fitness value of 7. The dimension of the Java argument is 0, so the

difference between it and the calling argument dimension is 1. Therefore, the fitness value for the first argument is 6.

Because the fitness value of those two `write` methods is equal, MATLAB calls the one listed first in the class definition, with `char[]` first argument.

Handling Data Returned from a Java Method

In this section...

Introduction

In many cases, data returned from Java is incompatible with the data types operated on within MATLAB. When this is the case, MATLAB converts the returned value to a data type native to the MATLAB language. This section describes the conversion performed on the various data types that can be returned from a call to a Java method.

Conversion of Java Return Data

The following table lists Java return types and the resulting MATLAB types. For some Java base return types, MATLAB treats scalar and array returns differently, as described following the table.

Conversion of Java Types to MATLAB Types

Java Return Type	If Scalar Return, Resulting MATLAB Type	If Array Return, Resulting MATLAB Type
`boolean`	`logical`	`logical`
`byte`	`double`	`int8`
`short`	`double`	`int16`
`int`	`double`	`int32`
`long`	`double`	`double`
`float`	`double`	`single`

Conversion of Java Types to MATLAB Types (Continued)

Java Return Type	If Scalar Return, Resulting MATLAB Type	If Array Return, Resulting MATLAB Type
`double`	`double`	`double`
`char`	`char`	`char`

Built-In Data Types

Java *built-in* data types are described in "Passing Built-In Data Types" on page 7-55. This data type includes `boolean`, `byte`, `short`, `long`, `int`, `double`, `float`, and `char`. When the value returned from a method call is one of these types, MATLAB converts it according to the table Conversion of Java Types to MATLAB Types on page 7-64.

A single numeric or `boolean` value converts to a 1-by-1 matrix of `double`, which is convenient for use in MATLAB. An array of a numeric or `boolean` return values converts to an array of the closest base type to minimize the required storage space. Array conversions are listed in the right-hand column of the table.

A return value of Java type `char` converts to a 1-by-1 matrix of `char`. An array of Java `char` converts to a MATLAB array of that type.

Java Objects

When a method call returns Java objects, MATLAB leaves them in their original form. They remain as Java objects so you can continue to use them to interact with other Java methods.

The only exception to this is when the method returns data of type `java.lang.Object`. This class is the root of the Java class hierarchy and is frequently used as a catchall for objects and arrays of various types. When the method being called returns a value of the `Object` class, MATLAB converts its value according to the table Conversion of Java Types to MATLAB Types on page 7-64. That is, numeric and `boolean` objects such as `java.lang.Integer` or `java.lang.Boolean` convert to a 1-by-1 MATLAB matrix of `double`.

Object arrays of these types convert to the MATLAB data types listed in the right-hand column of the table. Other object types are not converted.

Converting Objects to MATLAB Data Types

With the exception of objects of class `Object`, MATLAB does not convert Java objects returned from method calls to a native MATLAB data type. If you want to convert Java object data to a form more readily usable in MATLAB, there are a few MATLAB functions that enable you to do this. These are described in the following sections.

Converting to the MATLAB double Data Type

Using the `double` function in MATLAB, you can convert any Java object or array of objects to the MATLAB `double` data type. The action taken by the `double` function depends on the class of the object you specify:

- If the object is an instance of a numeric class (`java.lang.Number` or one of the classes that inherit from that class), MATLAB uses a preset conversion algorithm to convert the object to a MATLAB `double`.
- If the object is not an instance of a numeric class, MATLAB checks the class definition to see if it implements a method called `toDouble`. MATLAB uses `toDouble` to perform its conversion of Java objects to the MATLAB `double` data type. If such a method is implemented for this class, MATLAB executes it to perform the conversion.
- If you are using a class of your own design, you can write your own `toDouble` method to perform conversions on objects of that class to a MATLAB `double`. This enables you to specify your own means of data type conversion for objects belonging to your own classes.

Note If the class of the specified object is not `java.lang.Number`, does not inherit from that `java.lang.Number`, and does not implement a `toDouble` method, then an attempt to convert the object using the `double` function results in a MATLAB error.

The syntax for the `double` command is as follows, where `object` is a Java object or Java array of objects:

```
double(object);
```

Converting to the MATLAB char Data Type

With the MATLAB `char` function, you can convert `java.lang.String` objects and arrays to MATLAB data types. A single `java.lang.String` object converts to a MATLAB character array. An array of `java.lang.String` objects converts to a MATLAB cell array, with each cell holding a character array.

If the object specified in the `char` command is not an instance of the `java.lang.String` class, MATLAB checks its class to see if it implements a method named `toChar`. If this is the case, MATLAB executes the `toChar` method of the class to perform the conversion. If you write your own class definitions, you can make use of this feature by writing a `toChar` method that performs the conversion according to your own needs.

Note If the class of the specified object is not `java.lang.String` and it does not implement a `toChar` method, an attempt to convert the object using the `char` function results in a MATLAB error.

The syntax for the `char` command is as follows, where `object` is a Java object or Java array of objects:

```
char(object);
```

Converting to a MATLAB Structure

Java objects are similar to the MATLAB `structure` in that many of an object's characteristics are accessible via field names defined within the object. You may want to convert a Java object into a MATLAB `structure` to facilitate the handling of its data in MATLAB. Use the MATLAB `struct` function to do this.

The syntax for the `struct` command is as follows, where `object` is a Java object or a Java array of objects:

```
struct(object);
```

The following example converts a `java.awt.Polygon` object into a MATLAB `structure`. You can access the fields of the object directly using MATLAB `structure` operations. The last line indexes into the array, `pstruct.xpoints`, to deposit a new value into the third array element.

```
polygon = java.awt.Polygon([14 42 98 124], [55 12 -2 62], 4);

pstruct = struct(polygon)
pstruct =
    npoints: 4
    xpoints: [4x1 int32]
    ypoints: [4x1 int32]

pstruct.xpoints
ans =
    14
    42
    98
   124

pstruct.xpoints(3) = 101;
```

Converting to a MATLAB Cell Array

Use the `cell` function to convert a Java array or Java object into a MATLAB cell array. Elements of the resulting cell array are of the MATLAB type (if any) closest to the Java array elements or Java object.

The syntax for the `cell` command is as follows, where `object` is a Java object or a Java array of objects.

```
cell(object);
```

The code in the following example creates a MATLAB cell array in which each cell holds an array of a different data type. The `cell` command used in the first line converts each type of object array into a cell array.

```
import java.lang.* java.awt.*;

% Create a Java array of double
dblArray = javaArray('java.lang.Double', 1, 10);
```

```
for m = 1:10
   dblArray(1, m) = Double(m * 7);
end

% Create a Java array of points
ptArray = javaArray('java.awt.Point', 3);
ptArray(1) = Point(7.1, 22);
ptArray(2) = Point(5.2, 35);
ptArray(3) = Point(3.1, 49);

% Create a Java array of strings
strArray = javaArray('java.lang.String', 2, 2);
strArray(1,1) = String('one');    strArray(1,2) = String('two');
strArray(2,1) = String('three');  strArray(2,2) = String('four');

% Convert each to cell arrays
cellArray = {cell(dblArray), cell(ptArray), cell(strArray)}
cellArray =
    {1x10 cell}    {3x1 cell}    {2x2 cell}

cellArray{1,1}       % Array of type double
ans =

   [7]   [14]   [21]   [28]   [35]   [42]   [49]   [56]   [63]   [70]

cellArray{1,2}       % Array of type Java.awt.Point

ans =
F
    [1x1 java.awt.Point]
    [1x1 java.awt.Point]
    [1x1 java.awt.Point]

cellArray{1,3}       % Array of type char array

ans =
    'one'      'two'
    'three'    'four'
```

Introduction to Programming Examples

Each example contains the following sections:

- Overview — Describes what the example does and how it uses the Java interface to accomplish it. Highlighted are the most important Java objects that are constructed and used in the example code.
- Description — provides a detailed description of all code in the example. For longer functions, the description is divided into functional sections that focus on a few statements.
- Running the Example — Shows a sample of the output from execution of the example code.

The example descriptions concentrate on the Java-related functions. For information on other MATLAB programming constructs, operators, and functions used in the examples, see the applicable sections in the MATLAB documentation.

Example — Reading a URL

In this section...

Overview

This program, `URLdemo`, opens a connection to a Web site specified by a URL (Uniform Resource Locator) for the purpose of reading text from a file at that site.

`URLdemo` constructs an object of the Java API class, `java.net.URL`, which enables convenient handling of URLs. Then, it calls a method on the URL object, to open a connection.

To read and display the lines of text at the site, `URLdemo` uses classes from the Java I/O package `java.io`. It creates an `InputStreamReader` object, and then uses that object to construct a `BufferedReader` object. Finally, it calls a method on the `BufferedReader` object to read the specified number of lines from the site.

Description of URLdemo

The major tasks performed by `URLdemo` are:

1. Construct a URL object.

   The example first calls a constructor on `java.net.URL` and assigns the resulting object to variable `url`. The `URL` constructor takes a single argument, the name of the URL to be accessed, as a string. The constructor checks whether the input URL has a valid form.

   ```
   url = java.net.URL(...
   'http://www.mathworks.com/support/tech-notes/1100/1109.shtml')
   ```

2. Open a connection to the URL.

The second statement of the example calls the method, `openStream`, on the `URL` object `url`, to establish a connection with the Web site named by the object. The method returns an `InputStream` object to variable, `is`, for reading bytes from the site.

```
is = openStream(url);
```

3 Set up a buffered stream reader.

The next two lines create a buffered stream reader for characters. The `java.io.InputStreamReader` constructor is called with the input stream `is`, to return to variable `isr` an object that can read characters. Then, the `java.io.BufferedReader` constructor is called with `isr`, to return a `BufferedReader` object to variable `br`. A buffered reader provides for efficient reading of characters, arrays, and lines.

```
isr = java.io.InputStreamReader(is);
br = java.io.BufferedReader(isr);
```

4 Read and display lines of text.

The final statements read the initial lines of HTML text from the site, displaying only the first 4 lines that contain meaningful text. Within the MATLAB `for` statements, the `BufferedReader` method `readLine` reads each line of text (terminated by a `return` and/or line feed character) from the site.

```
for k = 1:288           % Skip initial HTML formatting lines
   s = readLine(br);
end

for k = 1:4             % Read the first 4 lines of text
   s = readLine(br);
   disp(s)
end
```

Running the Example

When you run this example, you see output similar to the following. (Note that the line breaks were changed to fit the output in the documentation).

```
<p>This technical note provides an introduction to vectorization techniques.
```

```
In order to understand some of the possible techniques, an introduction to MATLAB
referencing is provided. Then several vectorization examples are discussed.</p>
<p>This technical note examines how to identify situations where vectorized techniques
would yield a quicker or cleaner algorithm. Vectorization is ofen a smooth process;
however, in many application-specific cases, it can be difficult to construct a vectorized
routine. Understanding the tools and
```

Example — Finding an Internet Protocol Address

In this section...

Overview

The `resolveip` function returns either the name or address of an IP (internet protocol) host. If you pass `resolveip` a host name, it returns the IP address. If you pass `resolveip` an IP address, it returns the host name. The function uses the Java API class `java.net.InetAddress`, which enables you to find an IP address for a host name, or the host name for a given IP address, without making DNS calls.

`resolveip` calls a `static` method on the `InetAddress` class to obtain an `InetAddress` object. Then, it calls accessor methods on the `InetAddress` object to get the host name and IP address for the input argument. It displays either the host name or the IP address, depending on the program input argument.

Description of resolveip

The major tasks performed by `resolveip` are:

1. Create an InetAddress object.

   Instead of constructors, the `java.net.InetAddress` class has `static` methods that return an instance of the class. The `try` statement calls one of those methods, `getByName`, passing the `input` argument that the user has passed to `resolveip`. The input argument can be either a host name or an IP address. If `getByName` fails, the `catch` statement displays an `error` message.

```
function resolveip(input)
try
 address = java.net.InetAddress.getByName(input);
```

```
catch
 error(sprintf('Unknown host %s.', input));
end
```

2 Retrieve the host name and IP address.

The example uses calls to the `getHostName` and `getHostAddress` accessor functions on the `java.net.InetAddress` object, to obtain the host name and IP address, respectively. These two functions return objects of class `java.lang.String`; use the `char` function to convert them to character arrays.

```
hostname = char(address.getHostName);
ipaddress = char(address.getHostAddress);
```

3 Display the host name or IP address.

The example uses the MATLAB `strcmp` function to compare the `input` argument to the resolved IP address. If it matches, MATLAB displays the host name for the Internet address. If the input does not match, MATLAB displays the IP address.

```
if strcmp(input,ipaddress)
 disp(sprintf('Host name of %s is %s', input, hostname));
else
 disp(sprintf('IP address of %s is %s', input, ipaddress));
end;
```

Running the Example

Here is an example of calling the `resolveip` function with a host name.

```
resolveip ('www.mathworks.com')
IP address of www.mathworks.com is 144.212.100.10
```

Here is a call to the function with an IP address.

```
resolveip ('144.212.100.10')
Host name of 144.212.100.10 is www.mathworks.com
```

Example — Communicating Through a Serial Port

In this section...

Overview

The `serialexample` program uses classes of the Java API `javax.comm` package, which support access to communications ports.

After defining port configuration variables, `serialexample` constructs a `javax.comm.CommPortIdentifier` object to manage the serial communications port. The program calls the `open` method on that object to return an object of the `javax.comm.SerialPort` class, which describes the low-level interface to the `COM1` serial port, assumed to be connected to a Tektronix oscilloscope. (The example can be run without an oscilloscope.) The `serialexample` program then calls several methods on the `SerialPort` object to configure the serial port.

The `serialexample` program uses the I/O package `java.io` to write to and read from the serial port. It calls a `static` method to return an `OutputStream` object for the serial port. It then passes that object to the constructor for `java.io.OutputStreamWriter`. It calls the `write` method on the `OutputStreamWriter` object to write a command to the serial port, which sets the contrast on the oscilloscope. It calls `write` again to write a command that checks the contrast. It then constructs an object of the `java.io.InputStreamWriter` class to read from the serial port.

It calls another `static` method on the SerialPort object to return an `OutputStream` object for the serial port. It calls a method on that object to get the number of bytes to read from the port. It passes the InputStream object to the constructor for `java.io.OutputStreamWriter`. Then, if there is data to read, it calls the `read` method on the `OutputStreamWriter` object to read the contrast data returned by the oscilloscope.

Note MATLAB also provides built-in serial port support, described in Chapter 10, “Serial Port I/O”.

Setting Up the Java Environment

Before beginning to run this example, follow the procedure described here to set up your Java environment:

1. Download the Java class `javax.comm` to a local directory. You can download this class from

   ```
   http://java.sun.com/products/javacomm/downloads/index.html
   ```

2. Add the Java class to your Java class path in MATLAB. See “Finding and Editing classpath.txt” on page 7-9.

   For example, if you downloaded the package to *`matlabroot`*`/work/javax`, where *`matlabroot`* is your MATLAB root directory, you need to add the following entry to `classpath.txt`:

   ```
   $matlabroot/work/javax/commapi/comm.jar
   ```

3. Copy the file `win32com.dll` from the `commapi` directory into

   `matlabroot``\sys\java\jre\win32\jre1.5.0\bin`

4. Copy the file `comm.jar` from the `commapi` directory into

   `matlabroot``\sys\java\jre\win32\jre1.5.0\lib\ext`

5. Copy the file `javax.comm.properties` from the `commapi` directory into

   `matlabroot``\sys\java\jre\win32\jre1.5.0\lib`

6. Exit, then restart MATLAB.

Description of Serial Example

The major tasks performed by `serialexample` are:

1 Define variables for serial port configuration and output.

   The first five statements define variables for configuring the serial port. The first statement defines the baud rate to be 9600, the second defines number of data bits to be 8, and the third defines the number of stop bits to be 1. The fourth statement defines parity to be off, and the fifth statement defines flow control (handshaking) to be off.

2 Create a CommPortIdentifier object.

   Instead of constructors, the `javax.comm.CommPortIdentifier` class has `static` methods that return an instance of the class. The example calls one of these, `getPortIdentifier`, to return a `CommPortIdentifier` object for port `COM1`.

```
commPort = ...
javax.comm.CommPortIdentifier.getPortIdentifier('COM1');
```

3 Open the serial port.

   The example opens the serial port by calling `open` on the `CommPortIdentifier` object `commPort`. The `open` call returns a `SerialPort` object, assigning it to `serialPort`. The first argument to `open` is the name (owner) for the port, the second argument is the name for the port, and the third argument is the number of milliseconds to wait for the open.

```
serialPort = open(commPort, 'serial', 1000);
```

4 Configure the serial port.

   The next three statements call configuration methods on the `SerialPort` object `serialPort`. The first statement calls `setSerialPortParams` to set the baud rate, data bits, stop bits, and parity. The next two statements call `setFlowControlMode` to set the flow control, and then `enableReceiveTimeout` to set the timeout for receiving data.

```
setSerialPortParams(serialPort, SerialPort_BAUD_9600,...
SerialPort_DATABITS_8, SerialPort_STOPBITS_1,...
SerialPort_PARITY_NONE);
setFlowControlMode(serialPort, SerialPort_FLOWCTRL_NONE);
enableReceiveTimeout(serialPort, 1000);
```

5 Set up an output stream writer.

The example then calls a constructor to create and open a `java.io.OutputStreamWriter` object. The constructor call passes the `java.io.OutputStream` object, returned by a call to the `getOutputStream` method `serialPort`, and assigns the `OutputStreamWriter` object to `out`.

```
out = java.io.OutputStreamWriter(getOutputStream(serialPort));
```

6 Write data to serial port and close output stream.

The example writes a string to the serial port, by calling `write` on the object `out`. The string is formed by concatenating (with MATLAB [ ] syntax) a command to set the oscilloscope's contrast to 45, with the command terminator that is required by the instrument. The next statement calls `flush` on `out` to flush the output stream.

```
write(out, ['Display:Contrast 45' terminator]);
flush(out);
```

Then, the example again calls `write` on `out` to send another string to the serial port. This string is a query command, to determine the oscilloscope's contrast setting, concatenated with the command terminator. The example then calls `close` on the output stream.

```
write(out, ['Display:Contrast?' terminator]);
close(out);
```

7 Open an input stream and determine number of bytes to read.

To read the data expected from the oscilloscope in response to the contrast query, the example opens an input stream by calling the `static` method, `InputStream.getInputStream`, to obtain an `InputStream` object for the serial port. Then, the example calls the method `available` on the `InputStream` object, `in`, and assigns the returned number of bytes to `numAvail`.

```
in = getInputStream(serialPort);
numAvail = available(in);
```

8 Create an input stream reader for the serial port.

The example then calls a `java.io.InputStreamReader` constructor, with the `InputStream` object, `in`, and assigns the new object to `reader`.

```
reader = java.io.InputStreamReader(in);
```

9 Read data from serial port and close reader.

The example reads from the serial port, by calling the `read` method on the `InputStreamReader` object reader for each available byte. The `read` statement uses MATLAB array concatenation to add each newly read byte to the array of bytes already read. After reading the data, the example calls `close` on `reader` to close the input stream reader.

```
result = [];
for k = 1:numAvail
 result = [result read(reader)];
end
close(reader);
```

10 Close the serial port.

The example closes the serial port, by calling `close` on the `serialPort` object.

```
close(serialPort);
```

11 Convert input argument to a MATLAB character array.

The last statement of the example uses the MATLAB function, `char`, to convert the array input bytes (integers) to an array of characters:

```
result = char(result);
```

Running the serialexample Program

The value of `result` depends upon whether your system's COM1 port is cabled to an oscilloscope. If you have run the example with an oscilloscope, you see the result of reading the serial port.

```
result =
45
```

If you run the example without an oscilloscope attached, there is no data to read. In that case, you see an empty character array.

```
result =
''
```

Example — Creating and Using a Phone Book

In this section...

Overview

The example's main function, `phonebook`, can be called either with no arguments, or with one argument, which is the key of an entry that exists in the phone book. The function first determines the directory to use for the phone book file.

If no phone book file exists, it creates one by constructing a `java.io.FileOutputStream` object, and then closing the output stream. Next, it creates a data dictionary by constructing an object of the Java API class, `java.util.Properties`, which is a subclass of `java.util.Hashtable` for storing key/value pairs in a hash table. For the `phonebook` program, the key is a name, and the value is one or more telephone numbers.

The `phonebook` function creates and opens an input stream for reading by constructing a `java.io.FileInputStream` object. It calls `load` on that object to load the hash table contents, if it exists. If the user passed the key to an entry to look up, it looks up the entry by calling `pb_lookup`, which finds and displays it. Then, the `phonebook` function returns.

If phonebook was called without the name argument, it then displays a textual menu of the available phone book actions:

- Look up an entry
- Add an entry
- Remove an entry
- Change the phone number(s) in an entry
- List all entries

The menu also has a selection to exit the program. The function uses MATLAB functions to display the menu and to input the user selection.

The phonebook function iterates accepting user selections and performing the requested phone book action until the user selects the menu entry to exit. The phonebook function then opens an output stream for the file by constructing a java.io.FileOutputStream object. It calls save on the object to write the current data dictionary to the phone book file. It finally closes the output stream and returns.

Description of Function phonebook

The major tasks performed by phonebook are:

1. Determine the data directory and full filename.

   The first statement assigns the phone book filename, 'myphonebook', to the variable pbname. If the phonebook program is running on a PC, it calls the java.lang.System static method getProperty to find the directory to use for the data dictionary. This is set to the user's current working directory. Otherwise, it uses MATLAB function getenv to determine the directory, using the system variable HOME, which you can define beforehand to anything you like. It then assigns to pbname the full pathname, consisting of the data directory and filename 'myphonebook'.

```
function phonebook(varargin)
pbname = 'myphonebook'; % name of data dictionary
if ispc
   datadir = char(java.lang.System.getProperty('user.dir'));
```

```
else
   datadir = getenv('HOME');
end;
pbname = fullfile(datadir, pbname);
```

2 If needed, create a file output stream.

If the `phonebook` file does not already exist, `phonebook` asks the user whether to create a new one. If the user answers `y`, `phonebook` creates a new phone book by constructing a `FileOutputStream` object. In the `try` clause of a `try-catch` block, the argument `pbname` passed to the `FileOutputStream` constructor is the full name of the file that the constructor creates and opens. The next statement closes the file by calling `close` on the `FileOutputStream` object `FOS`. If the output stream constructor fails, the `catch` statement prints a message and terminates the program.

```
if ~exist(pbname)
   disp(sprintf('Data file %s does not exist.', pbname));
   r = input('Create a new phone book (y/n)?','s');
   if r == 'y',
      try
         FOS = java.io.FileOutputStream(pbname);
         FOS.close
      catch
         error(sprintf('Failed to create %s', pbname));
      end;
   else
      return;
   end;
end;
```

3 Create a hash table.

The example constructs a `java.util.Properties` object to serve as the hash table for the data dictionary.

```
pb_htable = java.util.Properties;
```

4 Create a file input stream.

In a `try` block, the example invokes a `FileInputStream` constructor with the name of the phone book file, assigning the object to `FIS`. If the call fails, the `catch` statement displays an `error` message and terminates the program.

```
try
   FIS = java.io.FileInputStream(pbname);
catch
   error(sprintf('Failed to open %s for reading.', pbname));
   end;
```

5 Load the phone book keys and close the file input stream.

The example calls `load` on the `FileInputStream` object `FIS`, to load the phone book keys and their values (if any) into the hash table. It then closes the file input stream.

```
pb_htable.load(FIS);
FIS.close;
```

6 Display the Action menu and get the user's selection.

Within a `while` loop, several `disp` statements display a menu of actions that the user can perform on the phone book. Then, an `input` statement requests the user's typed selection.

```
while 1
   disp ' '
   disp ' Phonebook Menu:'
   disp ' '
   disp ' 1. Look up a phone number'
   disp ' 2. Add an entry to the phone book'
   disp ' 3. Remove an entry from the phone book'
   disp ' 4. Change the contents of an entry in the phone book'
   disp ' 5. Display entire contents of the phone book'
   disp ' 6. Exit this program'
   disp ' '
   s = input('Please type the number for a menu selection: ','s');
```

7 Invoke the function to perform a phone book action

Still within the `while` loop, a `switch` statement provides a case to handle each user selection. Each of the first five cases invokes the function to perform a phone book action.

Case 1 prompts for a name that is a key to an entry. It calls `isempty` to determine whether the user has entered a name. If a name has not been entered, it calls `disp` to display an error message. If a name has been input, it passes it to `pb_lookup`. The `pb_lookup` routine looks up the entry and, if it finds it, displays the entry contents.

```
switch s
   case '1',
      name = input('Enter the name to look up: ','s');
      if isempty(name)
         disp 'No name entered'
      else
         pb_lookup(pb_htable, name);
      end;
```

Case 2 calls `pb_add`, which prompts the user for a new entry and then adds it to the phone book.

```
    case '2',
       pb_add(pb_htable);
```

Case 3 uses `input` to prompt for the name of an entry to remove. If a name has not been entered, it calls `disp` to display an error message. If a name has been entered, it passes it to `pb_remove`.

```
    case '3',
       name=input('Enter the name of the entry to remove: ', 's');
       if isempty(name)
          disp 'No name entered'
       else
          pb_remove(pb_htable, name);
       end;
```

Case 4 uses `input` to prompt for the name of an entry to change. If a name has not been entered, it calls `disp` to display an error message. If a name has been entered, it passes it to `pb_change`.

```
    case '4',
```

```
        name=input('Enter the name of the entry to change: ', 's');
        if isempty(name)
           disp 'No name entered'
        else
           pb_change(pb_htable, name);
        end;
```

Case 5 calls `pb_listall` to display all entries.

```
     case '5',
        pb_listall(pb_htable);
```

8 Exit by creating an output stream and saving the phone book.

If the user has selected case `6` to exit the program, a `try` statement calls the constructor for a `FileOuputStream` object, passing it the name of the phone book. If the constructor fails, the `catch` statement displays an error message.

If the object is created, the next statement saves the phone book data by calling `save` on the `Properties` object `pb_htable`, passing the `FileOutputStream` object `FOS` and a descriptive header string. It then calls `close` on the `FileOutputStream` object, and returns.

```
     case '6',
        try
           FOS = java.io.FileOutputStream(pbname);
        catch
           error(sprintf('Failed to open %s for writing.',...
                         pbname));
        end;
        pb_htable.save(FOS,'Data file for phonebook program');
        FOS.close;
        return;
     otherwise
        disp 'That selection is not on the menu.'
     end;
  end;
```

Description of Function pb_lookup

Arguments passed to `pb_lookup` are the `Properties` object `pb_htable` and the `name` key for the requested entry. The `pb_lookup` function first calls `get` on `pb_htable` with the `name` key, on which support function `pb_keyfilter` is called to change spaces to underscores. The `get` method returns the entry (or null, if the entry is not found) to variable `entry`. Note that `get` takes an argument of type `java.lang.Object` and also returns an argument of that type. In this invocation, the key passed to `get` and the entry returned from it are actually character arrays.

`pb_lookup` then calls `isempty` to determine whether `entry` is `null`. If it is, it uses `disp` to display an message stating that the name was not found. If `entry` is not `null`, it calls `pb_display` to display the entry.

```
function pb_lookup(pb_htable,name)
entry = pb_htable.get(pb_keyfilter(name));
if isempty(entry),
   disp(sprintf('The name %s is not in the phone book',name));
else
   pb_display(entry);
end
```

Description of Function pb_add

1 Input the entry to add.

The `pb_add` function takes one argument, the `Properties` object `pb_htable`. `pb_add` uses `disp` to prompt for an entry. Using the up arrow (`^`) character as a line delimiter, `input` inputs a name to the variable `entry`. Then, within a while loop, it uses input to get another line of the entry into variable `line`. If the line is empty, indicating that the user has finished the entry, the code breaks out of the while loop. If the line is not empty, the `else` statement appends line to entry and then appends the line delimiter. At the end, the `strcmp` checks the possibility that no input was entered and, if that is the case, returns.

```
function pb_add(pb_htable)
disp 'Type the name for the new entry, followed by Enter.'
disp 'Then, type the phone number(s), one per line.'
disp 'To complete the entry, type an extra Enter.'
```

```
name = input(':: ','s');
entry=[name '^'];
while 1
   line = input(':: ','s');
   if isempty(line)
      break;
   else
      entry=[entry line '^'];
   end;
end;

if strcmp(entry, '^')
   disp 'No name entered'
   return;
end;
```

2 Add the entry to the phone book.

After the input has completed, `pb_add` calls `put` on `pb_htable` with the hash key `name` (on which `pb_keyfilter` is called to change spaces to underscores) and `entry`. It then displays a message that the entry has been added.

```
pb_htable.put(pb_keyfilter(name),entry);
disp ' '
disp(sprintf('%s has been added to the phone book.', name));
```

Description of Function pb_remove

1 Look for the key in the phone book.

Arguments passed to `pb_remove` are the `Properties` object `pb_htable` and the `name` key for the entry to remove. The `pb_remove` function calls `containsKey` on `pb_htable` with the `name` key, on which support function `pb_keyfilter` is called to change spaces to underscores. If `name` is not in the phone book, `disp` displays a message and the function returns.

```
function pb_remove(pb_htable,name)
if ~pb_htable.containsKey(pb_keyfilter(name))
   disp(sprintf('The name %s is not in the phone book',name))
   return
end;
```

2 Ask for confirmation and if given, remove the key.

If the key is in the hash table, pb_remove asks for user confirmation. If the user confirms the removal by entering y, pb_remove calls remove on pb_htable with the (filtered) name key, and displays a message that the entry has been removed. If the user enters n, the removal is not performed and disp displays a message that the removal has not been performed.

```
r = input(sprintf('Remove entry %s (y/n)? ',name), 's');
if r == 'y'
   pb_htable.remove(pb_keyfilter(name));
   disp(sprintf('%s has been removed from the phone book',name))
else
   disp(sprintf('%s has not been removed',name))
end;
```

Description of Function pb_change

1 Find the entry to change, and confirm.

Arguments passed to pb_change are the Properties object pb_htable and the name key for the requested entry. The pb_change function calls get on pb_htable with the name key, on which pb_keyfilter is called to change spaces to underscores. The get method returns the entry (or null, if the entry is not found) to variable entry. pb_change calls isempty to determine whether the entry is empty. If the entry is empty, pb_change displays a message that the name is added to the phone book, and allows the user to enter the phone number(s) for the entry.

If the entry is found, in the else clause, pb_change calls pb_display to display the entry. It then uses input to ask the user to confirm the replacement. If the user enters anything other than y, the function returns.

```
function pb_change(pb_htable,name)
entry = pb_htable.get(pb_keyfilter(name));
if isempty(entry)
   disp(sprintf('The name %s is not in the phone book', name));
   return;
else
   pb_display(entry);
   r = input('Replace phone numbers in this entry (y/n)? ','s');
```

```
    if r ~= 'y'
       return;
    end;
end;
```

2 Input new phone number(s) and change the phone book entry.

`pb_change` uses `disp` to display a prompt for new phone number(s). Then, `pb_change` inputs data into variable `entry`, with the same statements described in "Description of Function pb_lookup" on page 7-88.

Then, to replace the existing entry with the new one, `pb_change` calls `put` on `pb_htable` with the (filtered) key `name` and the new entry. It then displays a message that the entry has been changed.

```
disp 'Type in the new phone number(s), one per line.'
disp 'To complete the entry, type an extra Enter.'
disp(sprintf(':: %s', name));
entry=[name '^'];
while 1
   line = input(':: ','s');
   if isempty(line)
      break;
   else
      entry=[entry line '^'];
   end;
end;
pb_htable.put(pb_keyfilter(name),entry);
disp ' '
disp(sprintf('The entry for %s has been changed', name));
```

Description of Function pb_listall

The `pb_listall` function takes one argument, the `Properties` object `pb_htable`. The function calls `propertyNames` on the `pb_htable` object to return to `enum` a `java.util.Enumeration` object, which supports convenient enumeration of all the keys. In a `while` loop, `pb_listall` calls `hasMoreElements` on `enum`, and if it returns true, `pb_listall` calls `nextElement` on `enum` to return the next key. It then calls `pb_display` to display the key and entry, which it retrieves by calling `get` on `pb_htable` with the key.

```
function pb_listall(pb_htable)
enum = pb_htable.propertyNames;
while enum.hasMoreElements
   key = enum.nextElement;
   pb_display(pb_htable.get(key));
end;
```

Description of Function pb_display

The `pb_display` function takes an argument `entry`, which is a phone book entry. After displaying a horizontal line, `pb_display` calls MATLAB function `strtok` to extract the first line of the entry, up to the line delimiter (`^`), into `t` and the remainder into `r`. Then, within a `while` loop that terminates when `t` is empty, it displays the current line in `t`. Then it calls `strtok` to extract the next line from `r`, into `t`. When all lines have been displayed, `pb_display` indicates the end of the entry by displaying another horizontal line.

```
function pb_display(entry)
disp ' '
disp '-------------------------'
[t,r] = strtok(entry,'^');
while ~isempty(t)
   disp(sprintf(' %s',t));
   [t,r] = strtok(r,'^');
end;
disp '-------------------------'
```

Description of Function pb_keyfilter

The `pb_keyfilter` function takes an argument `key`, which is a name used as a key in the hash table, and either filters it for storage or unfilters it for display. The filter, which replaces each space in the key with an underscore (_), makes the key usable with the methods of `java.util.Properties`.

```
function out = pb_keyfilter(key)
if ~isempty(findstr(key,' '))
   out = strrep(key,' ','_');
else
   out = strrep(key,'_',' ');
end;
```

Running the phonebook Program

In this sample run, a user invokes `phonebook` with no arguments. The user selects menu action `5`, which displays the two entries currently in the phone book (all entries are fictitious). Then, the user selects `2`, to add an entry. After adding the entry, the user again selects `5`, which displays the new entry along with the other two entries.

```
Phonebook Menu:

     1. Look up a phone number
     2. Add an entry to the phone book
     3. Remove an entry from the phone book
     4. Change the contents of an entry in the phone book
     5. Display entire contents of the phone book
     6. Exit this program

Please type the number for a menu selection: 5

COM Support in MATLAB (Windows Only)

The Microsoft Component Object Model, or COM, is a set of object-oriented technologies and tools that enable software developers to integrate application-specific components from different vendors into their own application solution.

With COM, MATLAB can include ActiveX controls or OLE server processes, or you can configure MATLAB as a computational server controlled by your client application programs.

COM support in MATLAB is available only on the Microsoft Windows platform.

MATLAB Automation Server Functions and Properties (p. 8-116)	How to use properties and methods in a MATLAB Automation server
Additional Automation Server Information (p. 8-122)	Starting the MATLAB server, shared and dedicated servers, using MATLAB as a DCOM server
Examples of a MATLAB Automation Server (p. 8-125)	Examples that show how to access a MATLAB Automation server from Visual Basic .NET and C#

Introducing MATLAB COM Integration

In this section...

What is COM?

The *Component Object Model* (*COM*) provides a framework for integrating reusable, binary software components into an application. Because components are implemented with compiled code, the source code can be written in any of the many programming languages that support COM. Upgrades to applications are simplified, as components can simply be swapped without the need to recompile the entire application. In addition, a component's location is transparent to the application, so components can be relocated to a separate process or even a remote system without having to modify the application.

Using COM, developers and end users can select application-specific components produced by different vendors and integrate them into a complete application solution. For example, a single application might require database access, mathematical analysis, and presentation-quality business graphs. Using COM, a developer can choose a database-access component by one vendor, a business graph component by another, and integrate these into a mathematical analysis package produced by yet a third.

MATLAB supports COM integration on the Microsoft Windows platform.

Concepts and Terminology

While the ideas behind COM technology are straightforward, the terminology is not. The meaning of COM terms has changed over time and few concise definitions exit. Here are some terms that you should be familiar with before

reading this chapter. These are not comprehensive definitions. For a complete description of COM, you'll need to consult outside resources.

COM Objects, Clients, and Servers

A COM *object* is a software component that conforms to Microsoft's Component Object Model. COM enforces encapsulation of the object, preventing direct access of its data and implementation. COM objects expose "Interfaces" on page 8-4, which consist of properties, methods and events.

A COM *client* is a program that makes use of COM objects. COM objects that expose functionality for use are called COM *servers*. COM servers can be in-process or out-of-process. An example of an out-of-process server is Microsoft Excel. These configurations are described in "In-Process and Out-of-Process Servers" on page 8-5.

An *ActiveX control* is a type of in-process COM server that requires a control container. ActiveX controls typically have a user interface. An example is the Microsoft Calendar control. A control container is an application capable of hosting ActiveX controls. A MATLAB figure window or a Simulink model are examples of control containers.

MATLAB can be used as either a COM client or COM server.

Interfaces

The functionality of a component is defined by one or more interfaces. To use a COM component, you must learn about its interfaces, and the methods, properties, and events implemented by the component. The component vendor provides this information.

There are two standard COM interfaces:

- `IUnknown` — An interface required by all COM components. All other COM interfaces are derived from `IUnknown`.
- `IDispatch` — An interface that exposes objects, methods and properties to applications that support Automation.

COM Server Types

There are three types of COM servers:

- Automation — A server that supports the OLE Automation standard. Automation servers are based on the `IDispatch` interface. Automation servers can be accessed by clients of all types, including scripting clients.
- Custom — A server that implements an interface directly derived from `IUnknown`. Custom servers are preferred when faster client access is critical.
- Dual — A server that implements a combination of Automation and Custom interfaces.

Programmatic Identifiers

To create an instance of a COM object, you use its programmatic identifier, or *ProgID*. The ProgID is a unique string defined by the component vendor to identify the COM object. You obtain a ProgID from the vendor's documentation.

MATLAB's ProgIDs are

- `Matlab.Application` — Starts a command window Automation server with the version of MATLAB that was most recently used as an Automation server (might not be the latest installed version of MATLAB).
- `Matlab.Autoserver` — Starts a command window Automation server using the most recent version of MATLAB.
- `Matlab.Desktop.Application` — Starts the full desktop MATLAB as an Automation server using the most recent version of MATLAB.

In-Process and Out-of-Process Servers

You can configure a server three ways. MATLAB supports all of these configurations.

In-Process Server. An in-process server is a component implemented as a dynamic link library (DLL) or ActiveX control that runs in the same process as the client application, sharing the same address space. Communication between client and server is relatively fast and simple.

Local Out-of-Process Server. A local out-of-process server is a component implemented as an executable (`EXE`) file that runs in a separate process from the client application. The client and server processes are on the same computer system. This configuration is somewhat slower due to the overhead required when transferring data across process boundaries.

Remote Out-of Process Server. This is a type of out-of-process server; however, the client and server processes are on different systems and communicate over a network. Network communications, in addition to the overhead required for data transfer, can make this configuration slower than the local out-of-process configuration. This configuration runs only on systems that support the *Distributed Component Object Model* (*DCOM*).

The MATLAB COM Client

Using MATLAB as a COM client provides two techniques for developing programs in MATLAB:

- You can include COM components in your MATLAB application (for example, a spreadsheet).
- You can access existing applications that expose objects via Automation.

In a typical scenario, MATLAB creates ActiveX controls in figure windows, which are manipulated by MATLAB through the controls' properties, methods, and events. This is useful because there exists a wide variety of graphical user interface components implemented as ActiveX controls. For example, Internet Explorer exposes objects that you can include in a figure to display an HTML file. There also are treeviews, spreadsheets, and calendars available from a variety of sources.

MATLAB COM clients can access applications that support Automation, such as Excel. In this case, MATLAB creates an Automation server in which to run the application and returns a handle to the primary interface for the object created.

Information about creating and using COM controls and server objects in MATLAB can be found in "MATLAB COM Client Support" on page 8-38.

The MATLAB COM Automation Server

Automation provides an infrastructure whereby applications called automation controllers can access and manipulate (i.e. set properties of or call methods on) shared automation objects that are exported by other applications, called Automation servers. Any Windows program that can be configured as an Automation controller can control MATLAB.

For example, using Visual Basic, you can run a MATLAB demo in a Microsoft PowerPoint presentation. In this case, PowerPoint is the controller and MATLAB is the server.

Information for creating and connecting to a MATLAB Automation server running MATLAB can be found in "MATLAB COM Automation Server Support" on page 8-112.

Registering Controls and Servers

Before using COM objects, you must register their controls and servers. Most are registered by default. However, if you get a new `.ocx`, `.dll`, or other object file for the control or server, you must register the file manually in the Windows registry.

Use the DOS `regsvr32` command to register your file. From the DOS prompt, use the `cd` function to go to the directory where the object file is located. If your object file is an `.ocx` file, type

```
regsvr32 filename.ocx
```

For example, to register the MATLAB control `mwsamp2.ocx`, type

```
cd matlabroot\toolbox\matlab\winfun\win32
regsvr32 mwsamp2.ocx
```

If you encounter problems with this procedure, please consult a Windows manual or contact your local system administrator.

Verifying the Registration

Here are several ways to verify that a control or server is registered. These examples use the MATLAB `mwsamp` control. Refer to your Microsoft product documentation for information about using Microsoft Visual Studio or the Registry Editor.

- Go to the Microsoft Visual Studio .NET 2003 Tools menu and execute the ActiveX control test container. Click **Edit**, insert a new control, and select `MwSamp Control`. If you are able to insert the control without any problems, the control is successfully registered. Note that this method only works on controls.
- Open the Registry Editor by typing `regedit` at the DOS prompt. Search for your control or server object by selecting **Find** from the **Edit** menu. It will likely be in the following structure:

  ```
  HKEY_CLASSES_ROOT/progid
  ```

- Open OLEViewer from the Microsoft Visual Studio .NET 2003 Tools menu. Look in the following structure for your `Control` object:

  ```
  Object Classes : Grouped by Component Category : Control :
  Your_Control_Object_Name (i.e. Object Classes : Grouped by
  Component Category : Control : Mwsamp Control)
  ```

Getting Started with COM

In this section...

Introduction

A COM client is a program that manipulates COM objects. These objects can run in the MATLAB application or can be part of another application that exposes its objects as a programmatic interface to the application.

This section provides examples that show how to use MATLAB as a COM client.

Note You can also access MATLAB as an Automation server from other applications, such as Visual Basic. For information on this technique, see "MATLAB COM Automation Server Support" on page 8-112.

Basic COM Functions

To start using COM objects, you need to create the object and get information about it. This section covers the following topics:

- "Creating an Instance of a COM Object" on page 8-10
- "Getting Information About a Particular COM Control" on page 8-10
- "Getting an Object's ProgID" on page 8-11
- "Registering a Custom Control" on page 8-11

Creating an Instance of a COM Object

Two MATLAB functions enable you to create COM objects:

- `actxcontrol` — Creates an instance of a control in a MATLAB figure.
- `actxserver` — Creates and manipulates objects from MATLAB that are exposed in an application that supports Automation.

Each function returns a *handle* to the object's main interface, which you use to access the object's methods, properties, and events, and any other interfaces it provides.

Getting Information About a Particular COM Control

In general, you can determine what you can do with an object using the `methods`, `get`, and `events` functions.

Information about Methods. To list the methods supported by the object *`handle`*, type

```
handle.methods
```

Information about Properties. To list the properties of the object *`handle`*, type

```
get(handle)
```

To see the value of the property *`PropertyName`*, type

```
get(handle,'PropertyName')
```

Use `set` to change a property value.

Information about Events. To list the events supported by the object *`handle`*, type

```
handle.events
```

For more information on calling syntax, see "Getting Interfaces to the Object" on page 8-50 and "Invoking Commands on a COM Object" on page 8-53. For more information on events, see "Control and Server Events" on page 8-75.

Getting an Object's ProgID

To get the programmatic identifier (`ProgID`) of a COM control that is already registered on your computer, use the `actxcontrollist` command. You can also use the ActiveX Control Selector, displayed with the command `actxcontrolselect`. This interface lets you see instances of the controls installed on your computer.

For more information on using these commands, see "Creating an ActiveX Control" on page 8-39.

Registering a Custom Control

If your MATLAB program uses a custom control (e.g., one that you have created especially for your application), you must register it with the Windows operating system before you can use it. You can do this from your MATLAB program by issuing an operating system command:

```
!regsvr32 /s filename.ocx
```

where *`filename`* is the name of the file containing the control. Using this command in your program enables you to provide custom-made controls that you make available to other users by registering the control on their computer when they run your MATLAB program. You might also want to supply versions of a Microsoft ActiveX control to ensure that all users have the same version.

For more information about registration, see "Registering Controls and Servers" on page 8-7.

Overview of MATLAB COM Client Examples

The following examples illustrate various techniques for using MATLAB as an COM client. Some of the examples use ActiveX controls, which is a specific type of COM object. For a description, see "COM Objects, Clients, and Servers" on page 8-4.

- "Example — Using Internet Explorer in a MATLAB Figure" on page 8-12 — This example uses the ActiveX control exposed by Internet Explorer to add an HTML viewer to a MATLAB Figure, which also contains an axes object for plotting. As the user clicks various graphics objects that are

displayed in the figure (including the figure itself), the documentation of the object's properties is displayed in the viewer.

- "Example — Grid ActiveX Control in a Figure" on page 8-17 — This example puts a spreadsheet-like grid control in a figure and uses the control's mouse-down event to trigger the acquisition of data from the grid and plot the data in the axes.
- "Example — Reading Data from Excel" on page 8-24 — This MATLAB GUI reads data programmatically from an Excel spreadsheet. By running an Automation server, MATLAB can access the objects exposed by Excel, which provides a variety of interfaces to the application.

Example — Using Internet Explorer in a MATLAB Figure

This example uses the ActiveX control `Shell.Explorer`, which is exposed by Microsoft's Internet Explore application, to include an HTML viewer in a MATLAB figure. The figure's window button down function is then used to select a graphics object when the user clicks the graph and load the object's property documentation into the HTML viewer.

Techniques Demonstrated

- Using Internet Explore from a MATLAB ActiveX client program.
- Defining a window button down function that displays HTML property documentation for whatever object the user clicks.
- Defining a resize function for the figure that also resizes the ActiveX object container.

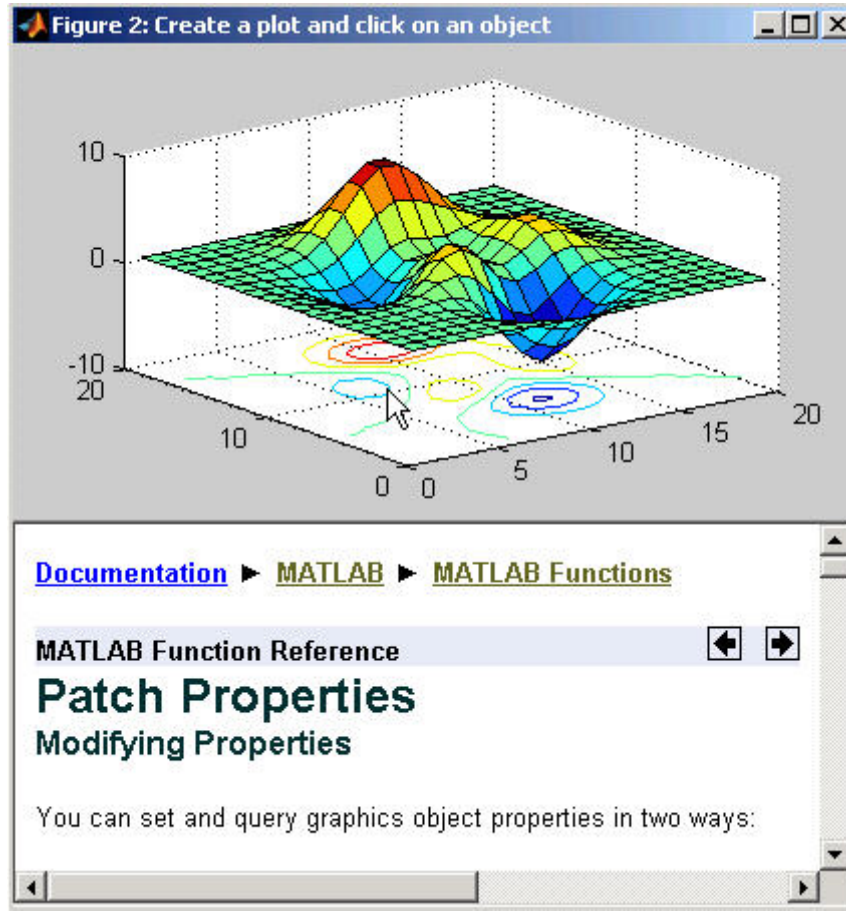
Using the Figure to Access Properties

This example creates a larger than normal figure window that contains an axes object and an HTML viewer on the lower part of the figure window. By default, the viewer displays the URL `http://www.mathworks.com`. When you issue a plotting command, such as

```
surfc(peaks(20))
```

the graph displays in the axes.

Click anywhere in the graph to see the property documentation for the selected object.



Complete Code Listing

You can open the M-file that implements this example in the MATLAB editor or you can run this example with the following links:

- Open M-file in editor
- Run this example

Creating the Figure

This example defines the figure size based on the default figure size and adds space for the ActiveX control. Here is the code to define the figure:

```
dfpos = get(0,'DefaultFigurePosition');
hfig = figure('Position',dfpos([1 2 3 4]).*[.8 .2 1 1.65],...
   'Menu','none','Name','Create a plot and click on an object',...
   'ResizeFcn',@reSize,...
   'WindowButtonDownFcn',@wbdf,...
   'Renderer','Opengl',...
   'DeleteFcn',@figDelete);
```

Note that the figure also defines a resize function and a window button down function by assigning function handles to the `ResizeFcn` and `WindowButtonDownFcn` properties. The callback functions `reSize` and `wbdf` are defined as nested functions in the same M-file.

The figure's `delete` function (called when the figure is closed) provides a mechanism to delete the control.

Calculating the ActiveX Object Container Size

The MATLAB `actxcontrol` function creates the ActiveX control inside the specified figure and returns the control's handle. You need to supply the following information:

- Control's programmatic identifier (use `actxcontrollist` to find it)
- Location and size of the control container in the figure (pixels) [left bottom width height]
- Handle of the figure that contains the control

```
conSize = calcSize;                                % Calculate the container size
hExp = actxcontrol('Shell.Explorer.2',conSize,hfig);  % Create the control
Navigate(hExp,'http://www.mathworks.com/');          % Specify content of html viewer
```

The nested function, `calcSize` calculates the size of the object container based on the current size of the figure. `calcSize` is also used by the figure `resize` function, which is described in the next section.

```
function conSize = calcSize
fp = get(hfig,'Position');              % Get current figure size
conSize = [0 0 1 .45].*fp([3 4 3 4]);   % Calculate container size
end % calcSize
```

Automatic Resize

In MATLAB, you can change the size of a figure and the axes automatically resize to fit the new size. This example implements similar resizing behavior for the ActiveX object container within the figure using the object's `move` method. This method enables you to change both size and location of the ActiveX object container (i.e., it is equivalent to setting the figure `Position` property).

When you resize the figure window, MATLAB automatically calls the function assigned to the figure's `ResizeFcn` property. This example implements the nested function `reSize` for the figure `resize` function.

ResizeFcn at Figure Creation. The `resize` function first determines if the ActiveX object exists because MATLAB calls the figure resize function when the figure is first created. Since the ActiveX object has not been created at this point, the `resize` function simply returns.

When the Figure Is Resized. When you change the size of the figure, the `resize` function executes and does the following:

- Calls the `calcSize` function to calculate a new size for the control container based on the new figure size.
- Calls the control's `move` method to apply the new size to the control.

Figure ResizeFcn.

```
function reSize(src,evnt)
if ~exist('hExp','var')
   return
end
conSize = calcSize;
move(hExp,conSize);
end % reSize
```

Selecting Graphics Objects

This example uses the figure `WindowButtonDownFcn` property to define a callback function that handles mouse click events within the figure. When you click the left mouse button while the cursor is over the figure, MATLAB executes the `WindowButtonDownFcn` callback on the mouse down event.

The callback determines which object was clicked by querying the figure `CurrentObject` property, which contains the handle of the graphics object most recently clicked. Once you have the object's handle, you can determine its type and then load the appropriate HTML page into the `Shell.Explorer` control.

The nested function `wbdf` implements the callback. Once it determines the type of the selected object, it uses the control `Navigate` method to display the documentation for the object type.

Figure WindowButtonDownFcn.

```
function wbdf(src,evnt)
cobj = get(hfig,'CurrentObject');
if isempty(cobj)
   disp('Click somewhere else')
   return
end
pth = 'http://www.mathworks.com/access/helpdesk/help/techdoc/ref/';
typ = get(cobj,'Type');
switch typ
   case ('figure')
      Navigate(hExp,[pth,'figure_props.html']);
   case ('axes')
      Navigate(hExp,[pth,'axes_props.html']);
   case ('line')
      Navigate(hExp,[pth,'line_props.html']);
   case ('image')
      Navigate(hExp,[pth,'image_props.html']);
   case ('patch')
      Navigate(hExp,[pth,'patch_props.html']);
   case ('surface')
      Navigate(hExp,[pth,'surface_props.html']);
   case ('text')
```

```
      Navigate(hExp,[pth,'text_props.html']);
   case ('hggroup')
      Navigate(hExp,[pth,'hggroupproperties.html']);
   otherwise % Display property browser
      Navigate(hExp,[pth(1:end-4),'infotool/hgprop/doc_frame.html']);
end
end % wbdf
```

Closing the Figure

This example uses the figure `delete` function (`DeleteFcn` property) to delete the ActiveX object before closing the figure. MATLAB calls the figure `delete` function before deleting the figure, which enables the function to perform any clean up needed before closing the figure. The figure `delete` function calls the control's `delete` method.

```
function figDelete(src,evnt)
   hExp.delete;
end
```

Example — Grid ActiveX Control in a Figure

This example adds a simple spreadsheet ActiveX control to a figure, which also contains an axes object for plotting the data displayed by the control. Clicking a column in the spreadsheet causes the data in that column to be plotted. Clicking down and dragging the mouse across multiple columns plots all columns touched.

Techniques Demonstrated

- Registering a control for use on your system.
- Writing a handler for one of the control's events and using the event to execute MATLAB plotting commands.
- Writing a `resize` function for the figure that manages the control's size as users resize the figure.

Using the Control

This example assumes that your data samples are organized in columns and that the first cell in each column is a title, which is used by the legend. See

"Complete Code Listing" on page 8-19 for an example of how to load data into the control.

Once the data is loaded, click the column to plot the data. The following picture shows a graph of the results of `Test2` and `Test3` created by selecting column `B` and dragging and releasing on column `C`.

	A	B	C	D	E	F
1	Test1	Test2	Test3	Test4	Test5	Test6
2	1.3807825	-0.42092154	1.537409	0.6793866	-0.071617644	0.24678572
3	1.3198429	0.22913337	0.14007153	0.55475763	-2.4145909	-1.4357729
4	-0.90942924	-0.95949703	-1.8627667	1.0016304	-0.69434901	0.14857313
5	-2.3056051	-0.14604259	-0.4541931	1.2593651	-1.391389	-1.6930726

Complete Code Listing

You can open the M-file used to implement this example in the MATLAB editor:

- Open M-file in editor.

Preparing to Use the Control

The ActiveX control used in this example is typical of those downloadable from the Internet. Once you have downloaded the files you need, register the control on your system using the DOS command `regsvr32`. In a command prompt, enter a command of the following form:

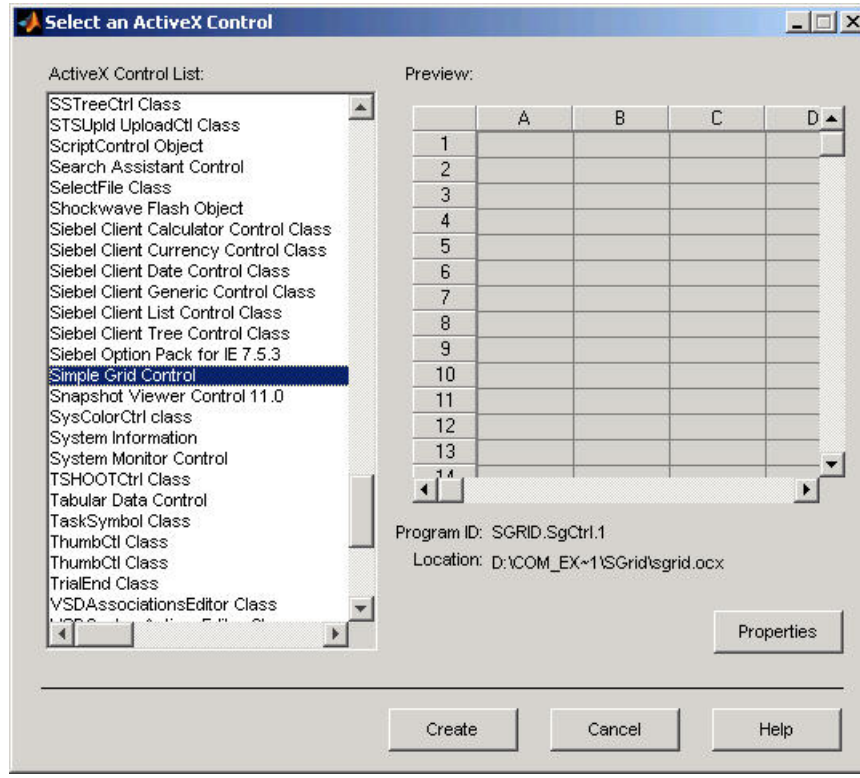
```
regsvr32 sgrid.ocx
```

From MATLAB, use the following command:

```
system 'regsvr32 sgrid.ocx'
```

See the section “Registering Controls and Servers” on page 8-7 for more information.

Finding the Control's ProgID. Once you have installed and registered the control, you can obtain its programmatic identifier using the ActiveX Control Selector dialog. To display this dialog box, use the MATLAB `actxcontrolselect` command. Locate the control in the list and the selector displays the control and the ProgID.



Creating a Figure to Contain the Control

This example creates a figure that contains an axes object and the grid control. The first step is to determine the size of the figure and then create the figure and axes. This example uses the default figure and axes size (obtained from the respective `Position` properties) to calculate a new size and location for each object.

```
dfpos = get(0,'DefaultFigurePosition');
dapos = get(0,'DefaultAxesPosition');
hfig = figure('Position',dfpos([1 2 3 4]).*[1 .8 1 1.25],...
   'Name','Select the columns to plot',...
   'Renderer','ZBuffer',...
   'ResizeFcn',{@reSize dfpos(3)});
hax = axes('Position',dapos([1 2 3 4]).*[1 4 1 .65]);
```

The above code moves the figure down from the top of the screen (multiply second element in position vector by `.8`) and increases the height of the figure (multiply fourth element in position vector by `1.25`). Axes are created and sized in a similar way.

Creating an Instance of the Control

Use the MATLAB `actxcontrol` function to create an instance of the control in a figure window. This function creates a container for the control and enables you to specify the size of this container, which usually defines the size of the control. See “Managing Figure Resize” on page 8-23 for a specific example.

Specifying the Size and Location. The control size and location in the figure is calculated by a nested function `calcSize`. This function is used to calculate both the initial size of the control container and the size resulting from resize of the figure. It gets the figure's current position (i.e., size and location) and scales the four-element vector so that the control container is

- Positioned at the lower-left corner of the figure.
- Equal to the figure in width.
- Has a height that is `.35` times the figure's height.

The value returned is of the correct form to be passed to the `actxcontrol` function and the control's `move` method.

```
function conSize = calcSize
   fp = get(hfig,'Position');
   conSize = fp([3 4 3 4]).*[0 0 1 .35];
end % conSize
```

Creating the Control. Creating the control entails the following steps:

- Calculating the container size
- Instantiating the control in the figure
- Setting the number of rows and columns to match the size of the data array
- Specifying the width of the columns

```
conSize = calcSize;
hgrid = actxcontrol('SGRID.SgCtrl.1',conSize,hfig);
hgrid.NRows = size(dat,1);
hgrid.NColumns = size(dat,2);
colwth = 4350; hdwth = hgrid.HdrWidth;
SetColWidth(hgrid,0,sz(2)-1,colwth,1)
```

Using Mouse-Click Event to Plot Data

This example uses the control's `Click` event to implement interactive plotting. When a user clicks the control, MATLAB executes a function that plots the data in the column where the mouse click occurred. Users can also select multiple columns by clicking down and dragging the cursor over more than one column.

Registering the Event. You need to register events with MATLAB so that when the event occurs (a mouse click in this case), MATLAB responds by executing the event handler function. Register the event with the `registerevent` method:

```
hgrid.registerevent({'Click',@click_event});
```

Pass the event name (`Click`) and a function handle for the event handler function inside a cell array.

Defining the Event Handler. The event handler function `click_event` uses the control's `GetSelection` method to determine what columns and rows have been selected by the mouse click. This function plots the data in the selected columns as lines, one line per column.

It is possible to click down on a column and drag the mouse to select multiple columns before releasing the mouse. In this case, each column is plotted because the event is not fired until the mouse button is released (which reflects the way the author chose to implement the control). The MATLAB

`legend` uses the column number stored in the variable `cols` to label the individual plotted lines. You must add one to `cols` because the control counts the columns starting from zero.

Note that you implement event handlers to accept a variable number of arguments (`varargin`) .

```
function click_event(varargin)
[row1,col1,row2,col2] = hgrid.GetSelection(1,1,1,1,1);
ncols = (col2-col1)+1;
cols = [col1:col2];
   for n = 1:ncols
      hgrid.Col = cols(n);
      for ii = 1:sz(1)
         hgrid.Row = ii;
         plot_data(ii,n) = hgrid.Number;
      end
   end
hgrid.SetSelection(row1,col1,row2,col2);
plot(plot_data)
legend(labels(cols+1))
end % click_event
```

Managing Figure Resize

The size and location of a MATLAB axes object is defined in units that are normalized to the figure that contains it. Therefore, when you resize the figure, the axes automatically resize proportionally. When a figure contains objects that are not contained in axes, you are responsible for defining a function that manages the resize process.

The figure `ResizeFcn` property references a function that executes whenever the figure is resized and also when the figure is first created. This example creates a resize function that manages resizing grid control by doing the following:

- Disables control updates while changes are being made to improve performance (use the `hDisplay` property).
- Calculates a new size for the control container based on the new figure size (`calcSize` function).

- Applies the new size to the control container using its `move` method.
- Scales the column widths of the grid proportional to the change in width of the figure (`SetColWidth` method).
- Refreshes the display of the control, showing the new size.

```
function reSize(src,evnt,dfp)
% Return if control does not exist (figure creation)
if ~exist('hgrid','var')
   return
end
% Resize container
hgrid.bDisplay = 0;
conSize = calcSize;
move(hgrid,conSize);
% Resize columns
scl = conSize(3)/dfp;
ncolwth = scl*colwth;
nhdrwth = hdwth*(scl);
hgrid.HdrWidth = nhdrwth;
SetColWidth(hgrid,0,sz(2)-1,ncolwth,2)
hgrid.Refresh;
end % reSize
```

Closing the Figure

This example uses the figure delete function (`DeleteFcn` property) to delete the ActiveX object before closing the figure. MATLAB calls the figure delete function before deleting the figure, which enables the function to perform any clean up needed before closing the figure. The figure delete function calls the control's `delete` method.

```
function figDelete(src,evnt)
   hgrid.delete;
end
```

Example — Reading Data from Excel

This example creates a graphical interface to access the data in a Microsoft Excel file. To enable the communication between MATLAB and Excel, this example creates an ActiveX object in an Automation server running Excel.

MATLAB then accesses the data in the Excel file through the interfaces provided by the Excel Automation server.

Techniques Demonstrated

This example shows how to use the following techniques:

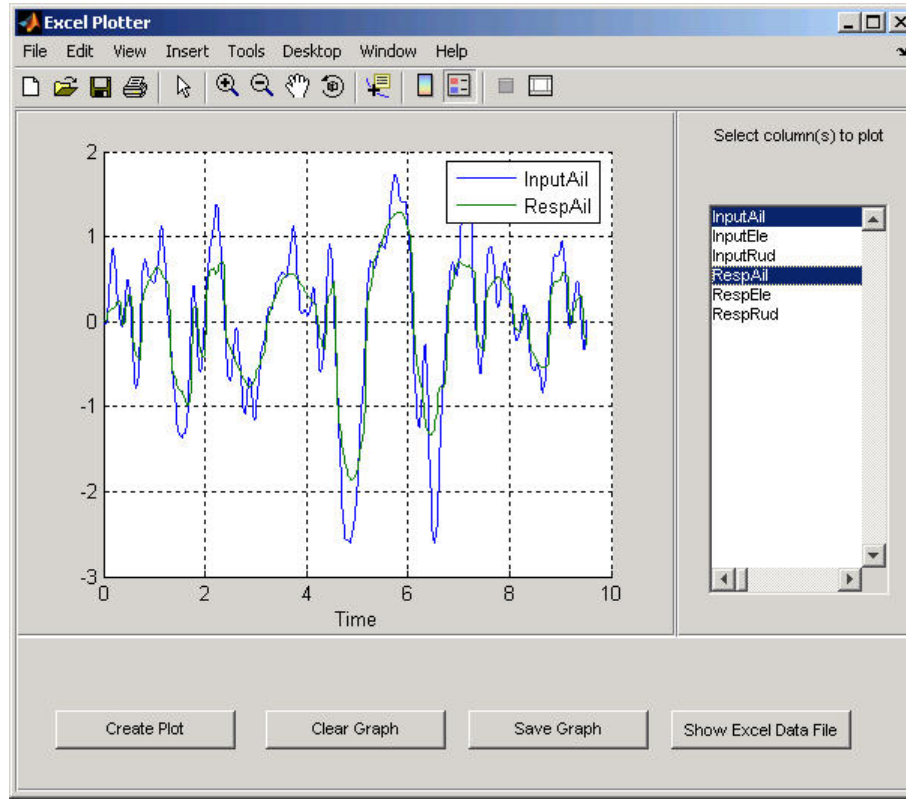
- Use of an Automation server to access another application from MATLAB
- Ways to manipulate Excel data into types used in the GUI and plotting.
- Implementing a GUI that enables plotting of selected columns of the Excel spreadsheet.
- Inserting a MATLAB figure into an Excel file.

Using the GUI

To use the GUI, select any items in the list box and click the **Create Plot** button. The sample data provided with this example contain three input and three associated response data sets, all of which are plotted vs. the first column in the Excel file, which is the time data.

You can view the Excel data file by clicking the **Show Excel Data File** button, and you can save an image of the graph in a different Excel file by clicking **Save Graph** button. Note that the **Save Graph** option creates a temporary PNG file in your working directory.

The following picture shows the GUI with an input/response pair selected in the list box and plotted in the axes.



Complete Code Listing

You can open the M-file used to implement this example in the MATLAB editor or run this example:

- Open M-file in editor.
- Run this example.

Excel Spreadsheet Format

This example assumes a particular organization of the Excel spreadsheet, as shown in the following picture.

	A	B	C	D	E	F	G
1	Time	InputAil	InputEle	InputRud	RespAil	RespEle	RespRud
2	0	0.00E+00	2.8827	-0.0004868	0	0	0
3	0	0.00E+00	2.8827	-0.0004868	0	0	0
4	0	0.00E+00	2.8827	-0.0004868	0	0	0
5	0.00E+00	0.00E+00	2.8827	-0.0004868	0	0.00E+00	0.00E+00
6	0.00E+00	0.00E+00	2.8827	-0.0004868	0.00E+00	0.00E+00	0.00E+00
7	0.00E+00	0.00E+00	2.8828	-0.0004868	0.00E+00	0.00E+00	0.00E+00
8	0.00E+00	0.00E+00	2.8832	-0.0004868	0.00E+00	0.00E+00	0.00E+00
9	0.00E+00	0.00E+00	2.8853	-0.0004873	0.00E+00	0.00E+00	0.00E+00
10	0.000141	0.00E+00	2.8955	-0.0004995	0.00E+00	0.00E+00	0.00E+00
11	0.000358	0	2.9154	-0.0005692	0.00E+00	0.00035612	0.00E+00
12	0.000358	0	2.9154	-0.0005692	0.00E+00	0.00035612	0.00E+00
13	0.000358	0	2.9154	-0.0005692	0.00E+00	0.00035612	0.00E+00
14	0.000876	0.00E+00	2.9628	-0.0009769	0	0.0021199	0.00E+00
15	0.000876	0.00E+00	2.9628	-0.0009769	0	0.0021199	0.00E+00
16	0.000876	0.00E+00	2.9628	-0.0009769	0	0.0021199	0.00E+00
17	0.000876	0.00E+00	2.9628	-0.0009769	0	0.0021199	0.00E+00
18	0.000876	0.00E+00	2.9628	-0.0009769	0	0.0021199	0.00E+00

The format of the Excel file is as follows:

- The first element in each column is a text string that identifies the data contain in the column. These strings are extracted and used to populate the list box.
- The first column (Time) is used for the *x*-axis of all plots of the remaining data.
- All rows in each column are read into MATLAB.

Excel Automation Server

The first step in accessing Excel from MATLAB is to run the Excel application in an Automation server process using the `actxserver` function and the Excel program ID, `excel.application`.

```
exl = actxserver('excel.application');
```

The ActiveX object that is returned provides access to a number of interfaces supported by Excel. Use the workbook interface to open the Excel file containing the data.

```
exlWkbk = exl.Workbooks;
exlFile = exlWkbk.Open([docroot '/techdoc/matlab_external/examples/input_resp_data.xls']);
```

Use the workbook's sheet interface to access the data from a range object, which stores a reference to a range of data from the specified sheet. This example accesses all the data in column `A`, first cell to column `G`, last cell:

```
exlSheet1 = exlFile.Sheets.Item('Sheet1');
robj = exlSheet1.Columns.End(4);       % Find the end of the column
numrows = robj.row;                    % And determine what row it is
dat_range = ['A1:G' num2str(numrows)]; % Read to the last row
rngObj = exlSheet1.Range(dat_range);
```

At this point, the entire data set from the Excel file's `sheet1` is accessed via the range object interface. This object returns the data in a MATLAB cell array, which can contain both numeric and character data:

```
exlData = rngObj.Value;
```

Manipulating the Data in MATLAB

Now that the data is in a cell array, you can use MATLAB functions to extract and reshape parts of the data into the forms needed to use in the GUI and pass to the plot function.

The following code performs two operations:

- Extracts numeric data from the cell array (indexing with curly braces), concatenates the individual doubles returned by the indexing operation (square brackets), and reshapes it into an array that arranges the data in columns.
- Extracts the string in the first cell in each column of Excel sheet and stores them in a cell array, which is used to generate the items in the list box.

```
for ii = 1:size(exlData,2)
   matData(:,ii) = reshape([exlData{2:end,ii}],size(exlData(2:end,ii)));
   lBoxList{ii} = [exlData{1,ii}];
end
```

The Plotter GUI

This example uses a GUI that enables you to select from a list of input and response data from a list box. All data is plotted as a function of time (which is, therefore, not a choice in the list box) and you can continue to add more data to the graph. Each data plot added to the graph causes the legend to expand.

Additional implementation details include:

- A legend that updates as you add data to a graph
- A clear button that enables you to clear all graphs from the axes
- A save button that saves the graph as a PNG file and adds it to another Excel file
- A toggle button that shows or hides the Excel file being accessed
- The figure delete function (`DeleteFcn` property), which MATLAB calls when the figure is closed, is used to terminate the Automation server process.

Selecting and Plotting Data. When you click the **Create Plot** button, its callback function queries the list box to determine what items are selected and plots each data vs. time. The legend is updated to display any new data while maintaining the legend for the existing data.

```
function plotButtonCallback(src,evnt)
iSelected = get(listBox,'Value');
grid(a,'on');hold all
for p = 1:length(iSelected)
   switch iSelected(p)
      case 1
         plot(a,tme,matData(:,2))
      case 2
         plot(a,tme,matData(:,3))
      case 3
```

```
            plot(a,tme,matData(:,4))
         case 4
            plot(a,tme,matData(:,5))
         case 5
            plot(a,tme,matData(:,6))
         case 6
            plot(a,tme,matData(:,7))
         otherwise
            disp('Select data to plot')
      end
   end
   [b,c,g,lbs] = legend([lbs lBoxList(iSelected+1)]);
   end % plotButtonCallback
```

Clearing the Axes. The plotter is designed to continually add graphs as the user selects data from the list box. The **Clear Graph** button clears and resets the axes and clears the variable used to store the labels of the plot data (used by legend).

```
%% Callback for clear button
function clearButtonCallback(src,evt)
   cla(a,'reset')
   lbs = '';
end % clearButtonCallback
```

Display or Hide Excel File. The MATLAB program has access to the properties of the Excel application running in the Automation server. By setting the `Visible` property to `1` or `0`, this callback controls the visibility of the Excel file.

```
%% Display or hide Excel file
function dispButtonCallback(src,evt)
   exl.visible = get(src,'Value');
end % dispButtonCallback
```

Close Figure and Terminate Excel Automation Process. Since the Excel Automation server runs in a separate process from MATLAB, you must terminate this process explicitly. There is no reason to keep this process running after the GUI has been closed, so this example uses the figure's delete function to terminate the Excel process with the `Quit` method. Also, terminate the second Excel process used for saving the graph. See "Inserting MATLAB Graphs Into Excel" on page 8-31 for information on this second process.

```
%% Terminate Excel processes
function deleteFig(src,evt)
   exlWkbk.Close
   exlWkbk2.Close
   exl.Quit
   exl2.Quit
end % deleteFig
```

Inserting MATLAB Graphs Into Excel

You can save the graph created with this GUI in an Excel file. (This example uses a separate Excel Automation server process for this purpose.) The callback for the **Save Graph** push button creates the image and adds it to an Excel file:

- Both the axes and legend are copied to an invisible figure configured to print the graph as you see it on the screen (figure `PaperPositionMode` property is set to `auto`).
- The `print` command creates the PNG image.
- Use the `Shapes` interface to insert the image in the Excel workbook.

The server and interfaces are instanced during GUI initialization phase:

```
exl2 = actxserver('excel.application');
exlWkbk2 = exl2.Workbooks;
wb = invoke(exlWkbk2,'Add');
graphSheet = invoke(wb.Sheets,'Add');
Shapes = graphSheet.Shapes;
```

The following code implements the **Save Graph** button callback:

```
function saveButtonCallback(src,evt)
   tempfig = figure('Visible','off','PaperPositionMode','auto');
   tempfigfile = [tempname '.png'];
   ah = findobj(f,'type','axes');
   copyobj(ah,tempfig) % Copy both graph axes and legend axes
   print(tempfig,'-dpng',tempfigfile);
   Shapes.AddPicture(tempfigfile,0,1,50,18,300,235);
   exl2.visible = 1;
end
```

Supported Client/Server Configurations

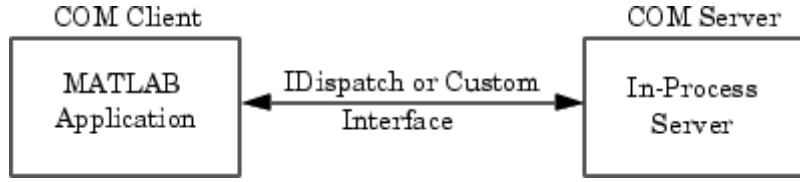
In this section...

Introduction

You can configure MATLAB to either control or be controlled by other COM components. When MATLAB controls another component, MATLAB is the client, and the other component is the server. When another component controls MATLAB, MATLAB is the server.

MATLAB Client and In-Process Server

The following diagram shows how the MATLAB client interacts with an "In-Process Server" on page 8-6.



The server exposes its properties and methods through the IDispatch (Automation) interface or a Custom interface, depending on which interfaces the component implements. For information on accessing interfaces, see "Getting Interfaces to the Object" on page 8-50 .

ActiveX Controls

An ActiveX control is an object with some type of graphical user interface (GUI). When MATLAB constructs an ActiveX control, it places the control's GUI in a MATLAB figure window. Click the various options available in the user interface (e.g., making a particular menu selection) to trigger *events* that get communicated from the control in the server to the client MATLAB application. The client decides what to do about each event and responds accordingly.

MATLAB comes with a sample ActiveX control called `mwsamp`. This control draws a circle on the screen and displays some text. You can use this control to try out MATLAB COM features. For more information, see "MATLAB Sample Control" on page 8-105.

DLL Servers

Any COM component that has been implemented as a dynamic link library (DLL) is also instantiated in an in-process server. That is, it is created in the same process as the MATLAB client application. When MATLAB uses a DLL server, it runs in a separate window rather than a MATLAB figure window.

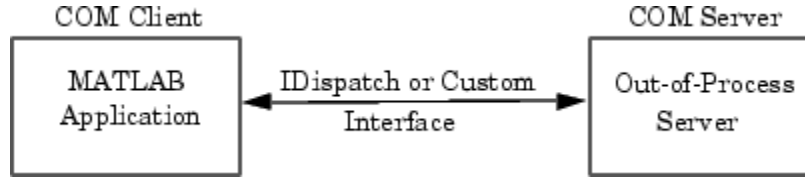
MATLAB responds to events generated by a DLL server in the same way as events from an ActiveX control.

For More Information

To learn more about working with MATLAB as a client, see "MATLAB COM Client Support" on page 8-38 and "Additional COM Client Information" on page 8-110.

MATLAB Client and Out-of-Process Server

In this configuration, a MATLAB client application interacts with a component that has been implemented as a "Local Out-of-Process Server" on page 8-6. Examples of out-of-process servers are Microsoft Excel and Microsoft Word.



As with in-process servers, this server exposes its properties and methods through the IDispatch (Automation) interface or a Custom interface, depending on which interfaces the component implements. For information on accessing interfaces, see “Getting Interfaces to the Object” on page 8-50.

Since the client and server run in separate processes, you have the option of creating the server on any system on the same network as the client.

If the component provides a user interface, its window is separate from the client application.

MATLAB responds to events generated by an out-of-process server in the same way as events from an ActiveX control.

For More Information

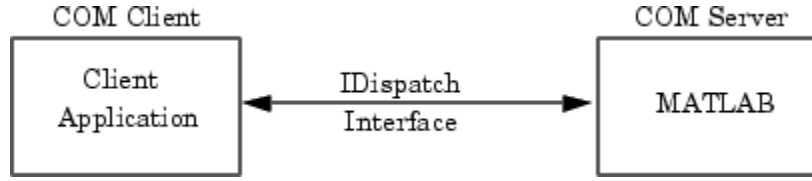
To learn more about working with MATLAB as a client, see “MATLAB COM Client Support” on page 8-38 and “Additional COM Client Information” on page 8-110.

COM Implementations Supported by MATLAB

MATLAB only supports COM implementations that are compatible with the Microsoft Active Template Library (ATL) API. In general, your COM object should be able to be contained in an ATL host window in order to work with MATLAB.

Client Application and MATLAB Automation Server

MATLAB operates as the Automation server in this configuration. It can be created and controlled by any Windows program that can be an *Automation controller*. Some examples of Automation controllers are Microsoft Excel, Microsoft Access, Microsoft Project, and many Visual Basic and Visual C++ programs.



MATLAB Automation server capabilities include the ability to execute commands in the MATLAB workspace, and to get and put matrices directly from and into the workspace. You can start a MATLAB server to run in either a shared or dedicated mode. You also have the option of running it on a local or remote system.

To create the MATLAB server from an external application program, use the appropriate function from that language to instantiate the server. (For example, use the `CreateObject` function in Visual Basic.) For the programmatic identifier, specify `matlab.application`. To run MATLAB as a dedicated server, use the `matlab.application.single` programmatic identifier. See “Shared and Dedicated Servers” on page 8-113 for more information.

The function that creates the MATLAB server also returns a handle to the properties and methods available in the server through the IDispatch interface. See “MATLAB Automation Server Functions and Properties” on page 8-116 for descriptions of these methods.

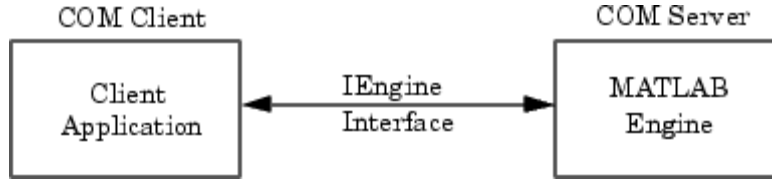
Note Because VBScript client programs require an Automation interface to communicate with servers, this is the only configuration that supports a VBScript client.

For More Information

To learn more about working with MATLAB Automation servers, see “MATLAB COM Automation Server Support” on page 8-112 and “Additional Automation Server Information” on page 8-122.

Client Application and MATLAB Engine Server

MATLAB provides a faster custom interface called IEngine for client applications written in C, C++, or Fortran. MATLAB uses IEngine to communicate between the client application and the MATLAB engine running as a COM server.



MATLAB provides a library of functions that let you to start and end the server process, and to send commands to be processed by MATLAB. See "MATLAB Engine" in the C and Fortran API Reference for more information.

For More Information

To learn more about the MATLAB engine and the functions provided in its C and Fortran libraries, see Chapter 6, "Calling MATLAB from C and Fortran Programs".

MATLAB COM Client Support

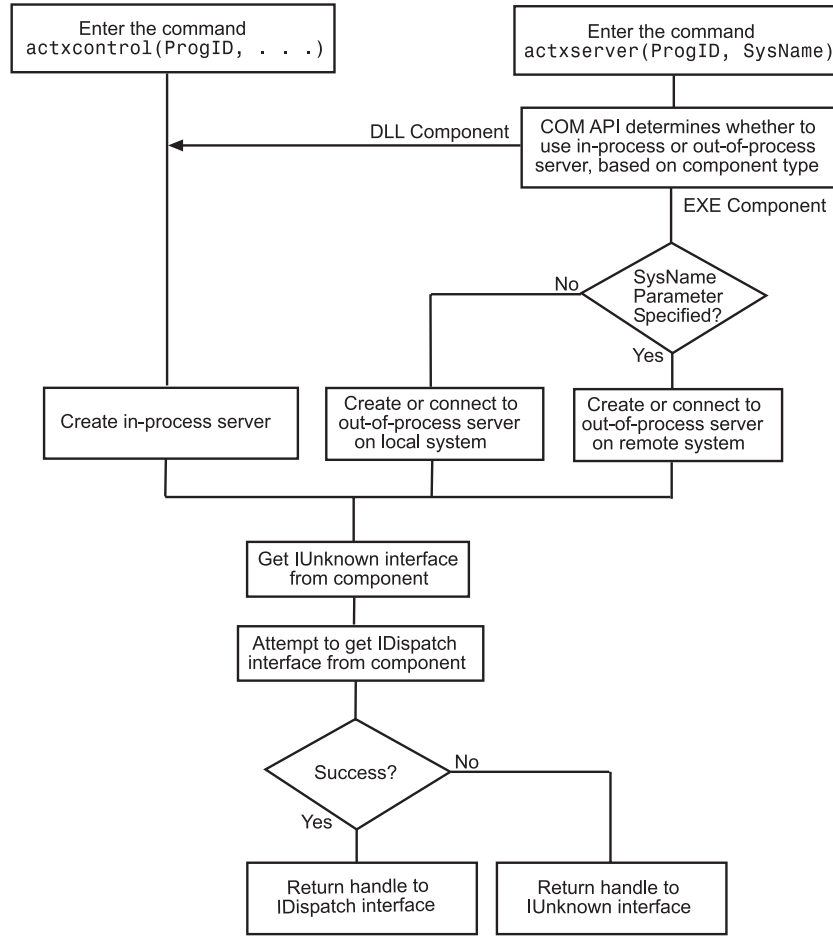
In this section...

Creating the Server Process — An Overview

MATLAB provides two functions to create a COM object:

- `actxcontrol` — Creates an ActiveX control in a MATLAB figure window.
- `actxserver` — Creates an in-process server for a dynamic link library (DLL) component or an out-of-process server for an executable (EXE) component.

The diagram below shows the basic steps in creating the server process. For more information on how MATLAB establishes interfaces to the resultant COM object, see “Getting Interfaces to the Object” on page 8-50.



Creating an ActiveX Control

You can create an ActiveX control from the MATLAB client using either a graphical user interface or the `actxcontrol` function directly from the command line. Either of these methods creates an instance of the control in

the MATLAB client process and returns a handle to the primary interface to the COM object. Through this interface, you can access the object's public properties or methods . You can also establish additional interfaces to the object, including interfaces that use IDispatch, and any custom interfaces that may exist.

This section describes how to create the control and how to position its physical representation in the MATLAB figure window:

Finding Out What Controls Are Installed

The `actxcontrollist` function shows you what COM controls are currently installed on your system. Type

```
list = actxcontrollist
```

and MATLAB returns a cell array listing each control, including its name, programmatic identifier (ProgID), and filename.

This example shows information that might be returned for several controls (your results might be different):

```
list = actxcontrollist;
s=sprintf(' Name = %s\n ProgID = %s\n File = %s\n', list{114:115,:})
```

MATLAB displays:

```
s =
 Name = OleInstall Class
 ProgID = Outlook Express Mime Editor
 File = OlePrn.OleInstall.1
 Name = OutlookExpress.MimeEdit.1
```

```
ProgID = C:\WINNT\System32\oleprn.dll
File = C:\WINNT\System32\inetcomm.dll
```

Finding a Particular Control

If you know the name of a control, you can find it in the list and display its ProgID and the path of the directory containing it using a few MATLAB commands. For example the `Mwsamp2` control is used in some of the examples in this manual. You can find it with the following code:

```
list = actxcontrollist;
for ii = 1:length(list)
   if ~isempty(findstr('Mwsamp2',[list{ii,:}]))
      s = sprintf(' Name = %s\n ProgID = %s\n File = %s\n', ...
             list{ii,:})
   end
end
```

The formatted output contained in `s` is displayed:

```
s =
   Name = Mwsamp2 Control
   ProgID = MWSAMP.MwsampCtrl.2
   File =
   D:\Apps\MATLAB\R2006a\toolbox\matlab\winfun\win32\mwsamp2.ocx
```

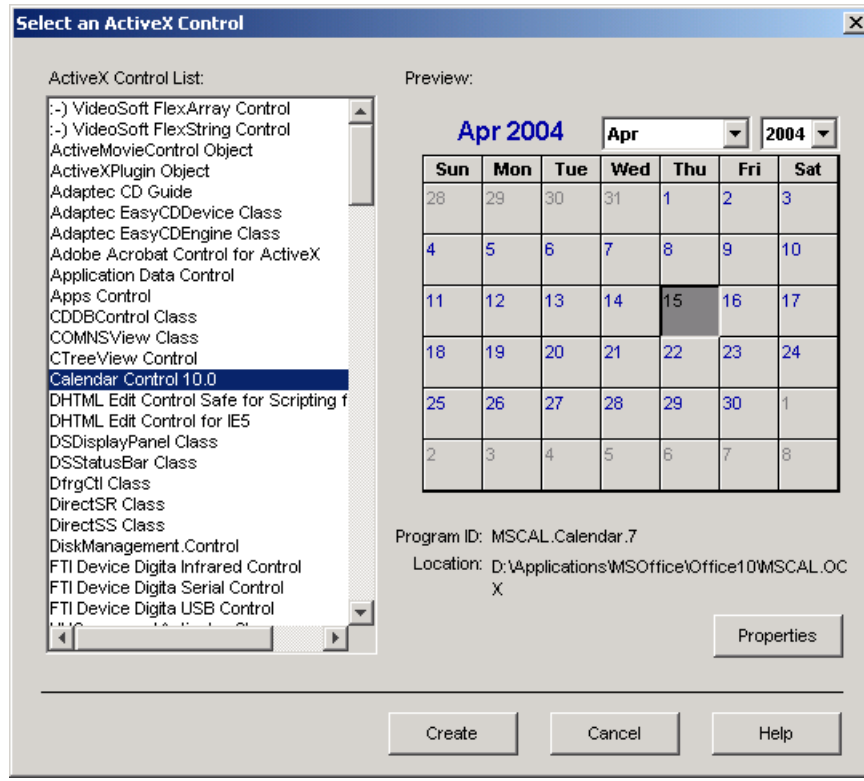
The location of this file might be different on your system.

Creating Control Objects Using a Graphical Interface

The simplest way to create a control object is to use the `actxcontrolselect` function. This function displays a graphical user interface (GUI) listing all controls installed on your system. When you select an item from the list and click the **Create** button, MATLAB creates the control and returns a handle to it. Type

```
h = actxcontrolselect
```

MATLAB displays:



The interface has a selection panel on the left and a preview panel on the right. Click one of the control names in the selection panel to see a preview of the control. (For controls that do not have a preview, the preview panel

is blank.) If MATLAB cannot create the control, an error message appears in the preview panel.

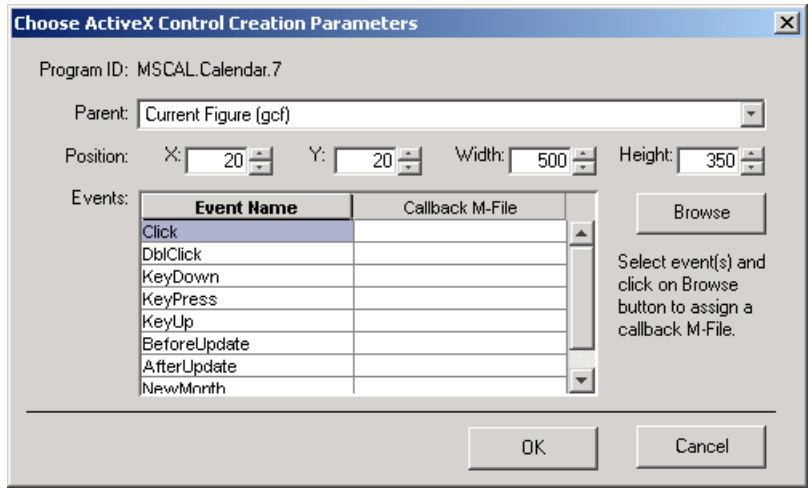
Setting Properties with actxcontrolselect. Click the **Properties** button on the `actxcontrolselect` window to change property values when creating the control. You can select which figure window to put the control in (**Parent** field), where to position it in the window (**X** and **Y** fields), and what size to make the control (**Width** and **Height**).

You can register events you want the control to respond to in this window. (See "Control and Server Events" on page 8-75 for an explanation of event registration.) Register an event and the callback routine to handle that event by entering the name of the routine to the right of the event under **Callback M-File**.

You can select callback routines by browsing for their M-files. Click a name in the **Event Names** column and then click the **Browse** button. To assign a callback routine to more than one event, first press the **Ctrl** key and click individual event names, or drag the mouse over consecutive event names, then click **Browse** to select the callback routine.

MATLAB only responds to registered events, so if you do not specify a **Callback M-File**, the event is ignored.

For example, at the `actxcontrolselect` window, select **Calendar Control 10.0** and click **Properties** to see the window shown below. Enter a **Width** of `500` and a **Height** of `350` to change the default size for the control. Click **OK** in this window, and click **Create** in the `actxcontrolselect` window to create the Calendar control.



You can also set control parameters using the `actxcontrol` function. One parameter you can set with `actxcontrol` but not with `actxcontrolselect` is the name of an initialization file. When you specify this filename, MATLAB sets the initial state of the control to that of a previously saved control.

Information Returned by actxcontrolselect. `actxcontrolselect` creates an object that is an instance of the MATLAB COM class. The function returns up to two arguments: a handle for the object `h`, and a 1-by-3 cell array `info` containing information about the control.

```
[h, info] = actxcontrolselect;
```

The cell array `info` shows the name, ProgID, and filename for the control.

If you select Calendar Control 9.0 and then click **Create**, MATLAB displays:

```
h =
   COM.mscal.calendar.7
```

```
info =
    [1x20 char]    'MSCAL.Calendar.7'    [1x41 char]
```

Expand the `info` cell array to show the control name, ProgID, and filename.

```
info{:}
ans =
   Calendar Control 9.0
ans =
   MSCAL.Calendar.7
ans =
   D:\Applications\MSOffice\Office\MSCAL.OCX
```

Creating Control Objects from the Command Line

If you already know which control you want and you know its ProgID, you can bypass the GUI by using the `actxcontrol` function to create it.

The only required input when calling the function is the ProgID. However, as with `actxcontrolselect`, you can supply additional inputs that enable you to select which figure window to put the control in, where to position it in the window, and what size to make it. You can also register any events you want the control to respond to, or set the initial state of the control by reading that state from a file. See the reference page on `actxcontrol` for a full explanation of its input arguments.

`actxcontrol` returns a handle to the primary interface to the object. Use this handle to reference the object in other COM function calls. You can also use the handle to obtain additional interfaces to the object. For more information on using interfaces, see “Getting Interfaces to the Object” on page 8-50.

This example creates a control to run a Microsoft Calendar application. Position the control in figure window `fig3`, at a `[0 0] x-y` offset from the bottom left of the window, and make it `300` by `400` pixels in size:

```
fig3 = figure('position', [50 50 600 500]);
h = actxcontrol('mscal.calendar', [0 0 300 400], fig3)
```

MATLAB displays:

```
h =
    COM.mscal.calendar
```

Repositioning the Control in a Figure Window

Once a control has been created, you can change its shape and position in the window with the `move` function.

Observe what happens to the object created in the last section when you specify new origin coordinates (`70`, `120`) and new width and height dimensions of `400` and `350`:

```
h.move([70 120 400 350]);
```

Using Microsoft Forms 2.0 Controls

You may encounter problems when creating or using Microsoft Forms 2.0 controls in MATLAB. Forms 2.0 controls are designed for use with applications enabled by Visual Basic for Applications (VBA). Microsoft Office is one such application.

To work around these problems, use the replacement controls listed below, or consult article 236458 in the Microsoft Knowledge Base for further information:

```
http://support.microsoft.com/default.aspx?kbid=236458
```

Affected Controls. You may see this behavior with any of the following Forms 2.0 controls:

- `Forms.TextBox.1`
- `Forms.CheckBox.1`

- `Forms.CommandButton.1`
- `Forms.Image.1`
- `Forms.OptionButton.1`
- `Forms.ScrollBar.1`
- `Forms.SpinButton.1`
- `Forms.TabStrip.1`
- `Forms.ToggleButton.1`

Replacement Controls. The following replacements are recommended by Microsoft:

Old	New
`Forms.TextBox.1`	`RICHTEXT.RichtextCtrl.1`
`Forms.CheckBox.1`	`vidtc3.Checkbox`
`Forms.CommandButton.1`	`MSComCtl2.FlatScrollBar.2`
`Forms.TabStrip.1`	`COMCTL.TabStrip.1`

Deploying ActiveX Controls Requiring Run-Time Licenses

When you deploy an ActiveX control that requires a run-time license, you must include a license key, which the control reads at run-time. If the key matches the control's own version of the license key, an instance of the control is created. Use the following procedure to deploy a run-time-licensed control with MATLAB.

Create an M-File to Build the Control

First, create an M-file to build the control. This M-file must contain two elements:

- The pragma `%#function actxlicense`. This pragma causes MATLAB Compiler to embed a function named `actxlicense` into the stand-alone executable file you build.

- A call to `actxcontrol` to create the control.

Place this M-file in a directory that is not part of the MATLAB code tree.

Here is an example M-file.

```
function buildcontrol
%#function actxlicense
h=actxcontrol('MFCCONTROL2.MFCControl2Ctrl.1',[10 10 200 200]);
```

Build the Control and the License M-File

Change to the directory where you placed the M-file you created to build the control. Call the function you defined in the M-file. When it executes this function, MATLAB determines whether the control requires a run-time license. If it does, MATLAB creates another M-file, named `actxlicense.m`, in the current working directory. The `actxlicense` function defined in this file provides the license key to MATLAB at run-time.

Build the Executable

Next, call MATLAB Compiler to create the stand-alone executable from the file you created to build the control. The executable contains both the function that builds the control and the `actxlicense` function.

```
mcc -m buildcontrol
```

Deploy the Files

Finally, distribute `buildcontrol.exe`, `buildcontrol.ctf`, and the control (`.ocx` or `.dll`).

Instantiating a DLL Component

To create a server for a component implemented as a dynamic link library (DLL), use the `actxserver` function. MATLAB creates an instance of the component in the same process that contains the client application.

The syntax for `actxserver`, when used with a DLL component, is

```
actxserver(ProgID)
```

where `ProgID` is the programmatic identifier for the component.

`actxserver` returns a handle to the primary interface to the object. Use this handle to reference the object in other COM function calls. You can also use the handle to obtain additional interfaces to the object. For more information on using interfaces, see “Getting Interfaces to the Object” on page 8-50.

Unlike ActiveX controls, any user interface displayed by the server appears in a separate window.

Instantiating an EXE Component

You can use the `actxserver` function to create a server for a component implemented as an executable (EXE). In this case, MATLAB instantiates the component in an out-of-process server.

The syntax for `actxserver` is

```
actxserver(ProgID, sysname)
```

where `ProgID` is the programmatic identifier for the component, and `sysname` is an optional argument used in configuring a distributed COM (DCOM) system.

`actxserver` returns a handle to the primary interface to the COM object. Use this handle to reference the object in other COM function calls. You can also use the handle to obtain additional interfaces to the object. For more information on using interfaces, see “Getting Interfaces to the Object” on page 8-50.

Any user interface displayed by the server appears in a separate window.

This example creates a COM server application running Excel. The handle is assigned to `h`:

```
h = actxserver('excel.application')
```

MATLAB displays:

```
h =
    COM.excel.application
```

MATLAB can programmatically connect to an instance of a COM Automation server application that is already running on your computer. Use the `actxGetRunningServer` function to get a reference to such an application.

The syntax for `actxGetRunningServer` is

```
actxGetRunningServer(ProgID)
```

where `ProgID` is the programmatic identifier for the component.

This example gets a reference to Excel, which must already be running on your system. The returned handle is assigned to `h`:

```
h = actxGetRunningServer('excel.application')
```

MATLAB displays:

```
h =
    COM.excel.application
```

Getting Interfaces to the Object

The COM component you are working with can provide different types of interfaces for accessing the object's public properties and methods:

- The IUnknown and IDispatch interfaces
- One or more custom interfaces

IUnknown and IDispatch

When you invoke the `actxserver` or `actxcontrol` function, MATLAB creates the server and returns a handle to the server interface as a means of accessing its properties and methods. MATLAB uses the following process to determine which handle to return:

1. MATLAB first gets a handle to the IUnknown interface from the component. All COM components are required to implement this interface.
2. MATLAB then attempts to get the IDispatch interface. If IDispatch is implemented, MATLAB returns a handle to this interface. If IDispatch is not implemented, MATLAB returns the handle to IUnknown.

Additional Interfaces. Components often provide additional interfaces, based on IDispatch, that are implemented as properties. Like any other property, you obtain these interfaces using the MATLAB `get` function.

For example, a Microsoft Excel component contains numerous interfaces. To list these interfaces, along with other Excel properties, use the MATLAB `get` function without any arguments. For example, type:

```
h = actxserver('excel.application');
h.get
```

MATLAB displays information similar to:

```
    Application: [1x1 Interface.Microsoft_Excel_9.0_
Object_Library._Application]
        Creator: 'xlCreatorCode'
         Parent: [1x1 Interface.Microsoft_Excel_9.0_
Object_Library._Application]
     ActiveCell: []
    ActiveChart: [1x50 char]
                .
                .
```

In the following example, `h` is a handle to a specific interface and `Workbooks` is the name of the interface. Type

```
w = h.Workbooks
```

MATLAB displays:

```
w =
   Interface.Microsoft_Excel_9.0_Object_Library.Workbooks
```

The information displayed depends on the version of Excel you have on your system.

Custom Interfaces

The following two client/server configurations support a component's custom interface:

- "Introduction" on page 8-33

• "MATLAB Client and Out-of-Process Server" on page 8-34

Once you have created the server, you can query the server component to see if any custom interfaces are implemented. Use the `interfaces` function to return a list of all available custom interfaces. This list is returned in a cell array of strings.

For example, for a component with the ProgID `mytestenv.calculator`, type

```
h = actxserver('mytestenv.calculator')
```

MATLAB displays:

```
h =
   COM.mytestenv.calculator
```

Type

```
customlist = h.interfaces
```

MATLAB displays:

```
customlist =
   ICalc1
   ICalc2
   ICalc3
```

To get a handle to a particular custom interface, use the `invoke` function, specifying the handle returned by `actxcontrol` or `actxserver`, and also the name of the custom interface:

```
c1 = h.invoke('ICalc1')
c1 =
   Interface.Calc_1.0_Type_Library.ICalc_Interface
```

Use this handle with the COM client functions to access the properties and methods of the object through the selected custom interface.

For example, to list the properties available through the `ICalc1` interface, use

```
c1.get
     background: 'Blue'
         height: 10
          width: 0
```

To list the methods, use

```
c1.invoke
   Add = double Add(handle, double, double)
   Divide = double Divide(handle, double, double)
   Multiply = double Multiply(handle, double, double)
   Subtract = double Subtract(handle, double, double)
```

Add and multiply numbers using the `Add` and `Multiply` methods of the custom object `c1`:

```
sum = c1.Add(4, 7)
sum =
    11

prod = c1.Multiply(4, 7)
prod =
    28
```

Invoking Commands on a COM Object

This section covers the following topics:

Dot Syntax

When invoking either MATLAB COM functions or methods belonging to COM objects, the simplest syntax to use is *dot syntax*. Specify the object name, the

dot (.), and the name of the function or method you are calling. Enclose any input arguments in parentheses after the function name. Specify output arguments to the left of the equal sign:

```
outputvalue = object.function(arg1, arg2, ...)
```

An Example of Calling Syntax

To work with the example that follows, first create an ActiveX control called mwsamp. (The mwsamp control is built into MATLAB to enable you to work with the examples shown in the COM documentation. The control displays a circle and text label that you can manipulate from MATLAB.)

Call actxcontrol to create the mwsamp control. This function returns a handle h that you need to work further with the control.

```
h = actxcontrol('mwsamp.mwsampctrl.2', [200 120 200 200]);
```

Once you have a handle to an object, you can invoke MATLAB functions on the object by referencing it through the handle.

For example, you can create a custom property, called Position, using the addproperty function. See “Custom Properties” on page 8-74.

```
h.addproperty('Position');
```

An alternative syntax for the same operation is

```
addproperty(h, 'Position');
```

Specifying Property, Method, and Event Names

You can specify the names of properties and methods using the simple notation

```
handle.propertyname
handle.methodname
```

For example, the mwsamp object has a property called Radius that represents the radius of the circle it draws, and a method called Redraw that redraws the circle. You can get the circle's radius by typing

```
h.Radius
```

You can redraw the circle with

```
h.Redraw
```

More information is provided on this in the sections "Implicit Syntax for Calling get, set, and invoke" on page 8-55 and "Exceptions to Using Implicit Syntax" on page 8-56. Here are a few specific rules regarding how to express property, method, and event names.

Property Names. You can abbreviate the names of properties, as long as you include enough characters in the name to distinguish it from another property. Property names are also case insensitive.

These two statements produce the same result:

```
x = h.Radius
x = h.r
```

Method Names. Method names cannot be abbreviated and are case sensitive.

Event Names. Event names are always specified as quoted strings in arguments to a function. Event names cannot be abbreviated and they are not case sensitive.

These statements produce the same result:

```
h.registerevent({'MouseDown' 'mymoused'});
h.registerevent({'MOUSEdown' 'myMOUSEd'});
```

Implicit Syntax for Calling get, set, and invoke

When calling `get`, `set`, or `invoke` on a COM object, MATLAB provides a simpler syntax that doesn't require an explicit function call. You can use this shortened syntax in all but a few cases (see "Exceptions to Using Implicit Syntax" on page 8-56).

Continue with the `mwsamp` control created in the last section and represented by handle `h`. To get the value of `Radius` property and assign it to variable `x`, use the syntax shown here. MATLAB still makes the call to `get`, but this shortened syntax is somewhat easier to enter:

```
x = h.Radius
x =
    20
```

The same shortened syntax applies when calling the `set` and `invoke` functions. Compare these two ways of setting a new radius value for the circle and invoking the `Redraw` method of `mwsamp` to display the circle in its enlarged size. The commands on the left call `set` and `invoke` explicitly. The commands on the right make implicit calls:

```
h.set('Radius', 40);              h.Radius = 40;
h.invoke('Redraw');               h.Redraw;
```

Exceptions to Using Implicit Syntax

There are some conditions under which you must explicitly call `get`, `set`, and `invoke`:

- When the property or method is not public
- When accessing a property that takes arguments
- When operating on a vector of objects

Nonpublic properties and methods. If the property or method you want to access is not provided as a public property or method of the object class, or if it is not in the type library for the control or server, you must call `get`, `set`, or `invoke` explicitly. For example, the `Visible` property of an Internet Explorer application is not public and must be accessed using `get` and `set`:

```
h = actxserver('internetexplorer.application');

% This syntax is invalid because 'Visible' is not public.
v = h.Visible
??? No appropriate method or public field Visible for class
   COM.internetexplorer.application.

% You must call the get function explicitly.
v = h.get('Visible')
v =
     1
```

```
% The same holds true when setting nonpublic properties.
h.set('Visible', 1);
```

Public properties and methods are those that are listed in response to the following commands on COM object `h`:

```
publicproperties = h.get
publicmethods = h.invoke
```

Accessing Properties That Take Arguments. Some COM objects have properties that behave somewhat like methods in that they accept input arguments. This is explained fully in the section "Properties That Take Arguments" on page 8-68. In order to get or set the value of such a property, you must make an explicit call to the `get` or `set` function, as shown here. In this example, `A1` and `B2` are arguments that specify which `Range` interface to return on the `get` operation:

```
eActivesheetRange = e.Activesheet.get('Range', 'A1', 'B2')
eActivesheetRange =
   Interface.Microsoft_Excel_5.0_Object_Library.Range
```

Operating on a Vector of Objects. If you operate on a vector of objects, (see "Get and Set on a Vector of Objects" on page 8-69), you must call `get` and `set` explicitly to access properties.

This example creates a vector of handles to two Microsoft Calendar objects. It then modifies the `Day` property of both objects in one operation by invoking `set` on the vector. Explicit calls to `get` and `set` are required:

```
h1 = actxcontrol('mscal.calendar', [0 200 250 200]);
h2 = actxcontrol('mscal.calendar', [250 200 250 200]);
H = [h1 h2];

H.set('Day', 23)
H.get('Day')
ans =
    [23]
    [23]
```

This applies only to `get` and `set`. You cannot invoke a method on more than one COM object at a time, even if you call `invoke` explicitly.

Identifying Objects and Interfaces

You can get some additional information about a control or server using the following functions.

Function	Description
`class`	Return the class of an object
`isa`	Determine if an object is of a given MATLAB class
`iscom`	Determine if the input is a COM or ActiveX object
`isinterface`	Determine if the input is a COM interface

This example creates a COM object in an Automation server running Excel, giving it the handle `h`, and a `Workbooks` interface to the object, with handle `w`.

```
h = actxserver('excel.application');
w = h.Workbooks;
```

Use the `iscom` function to see if variable `h` is a handle to a COM or ActiveX object:

```
h.iscom
ans =
     1
```

Use the `isa` function to test variable `h` against a known class name:

```
h.isa('COM.excel.application')
ans =
     1
```

Use `isinterface` to see if variable `w` is a handle to a COM interface:

```
w.isinterface
ans =
     1
```

Use the `class` function to find out the class of variable `w`:

```
w.class
ans =
```

```
Interface.Microsoft_Excel_9.0_Object_Library.Workbooks
```

Invoking Methods

This section covers the following topics:

Functions for Working with Methods

Use the following MATLAB functions to find out what methods a COM object has and to invoke any of these methods on the object.

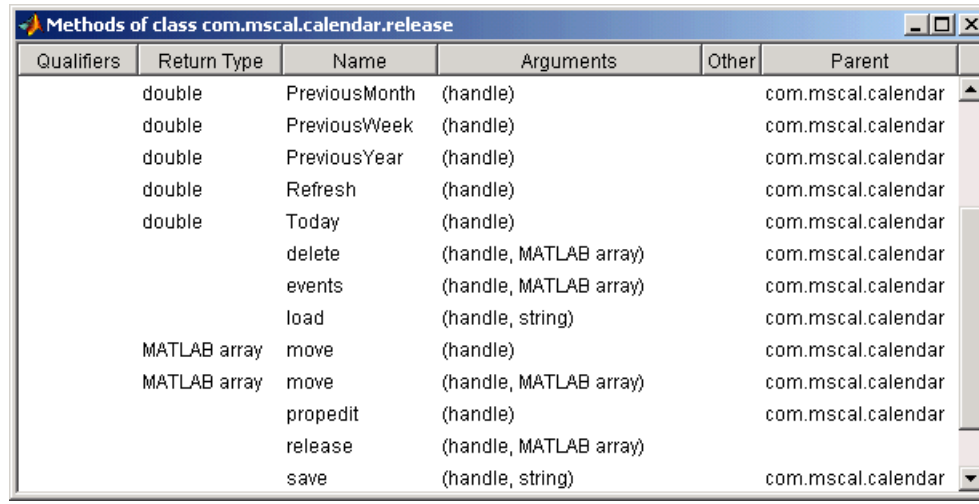
Function	Description
`invoke`	Invoke a method or display a list of methods and types
`ismethod`	Determine if an item is a method of a COM object
`methods`	List all method names for the control or server
`methodsview`	GUI interface to list information on all methods and types

Listing the Methods of a Class or Object

You can see what methods are supported by a control or server object either in a graphical display using the `methodsview` function, or in a returned cell array using the `methods` function.

Using methodsview. The `methodsview` function opens a new window with an easy-to-read display of all methods supported by the specified control or server object along with several related fields of information. Type the following to bring up a window such as the one shown below:

```
cal = actxcontrol('mscal.calendar', [0 0 400 400]);
cal.methodsview
```



Qualifiers	Return Type	Name	Arguments	Other	Parent
	double	PreviousMonth	(handle)		com.mscal.calendar
	double	PreviousWeek	(handle)		com.mscal.calendar
	double	PreviousYear	(handle)		com.mscal.calendar
	double	Refresh	(handle)		com.mscal.calendar
	double	Today	(handle)		com.mscal.calendar
		delete	(handle, MATLAB array)		com.mscal.calendar
		events	(handle, MATLAB array)		com.mscal.calendar
		load	(handle, string)		com.mscal.calendar
	MATLAB array	move	(handle)		com.mscal.calendar
	MATLAB array	move	(handle, MATLAB array)		com.mscal.calendar
		propedit	(handle)		com.mscal.calendar
		release	(handle, MATLAB array)		
		save	(handle, string)		com.mscal.calendar

Methods that return `void` show no **Return Type** in the display.

Using methods. The `methods` function returns in a cell array the names of all methods supported by the specified control or server object. This includes MATLAB COM functions that you can use on the object.

When you include the `-full` switch in the command, MATLAB also specifies the input and output arguments for each method:

```
cal.methods('-full')

Methods for class COM.mscal.calendar:

release(handle, MATLAB array)
delete(handle, MATLAB array)
MATLAB array events(handle, MATLAB array)
```

```
          .
          .
HRESULT Refresh(handle)
HRESULT Today(handle)
HRESULT AboutBox(handle)
```

The `invoke` function, when called with only a handle argument, returns a similar output.

Invoking Methods on an Object

To execute, or *invoke*, any method on an object, use either the MATLAB `invoke` function, or the somewhat simpler method name syntax.

Using invoke. The `invoke` function executes the specified method on an object. You can use either of the following syntaxes with `invoke`:

```
v = invoke(handle, 'methodname', 'arg1', 'arg2', ...);
v = handle.invoke('methodname', 'arg1', 'arg2', ...);
```

See the output of `methodsview` for a method to see what data types to use for input and output arguments.

The following example reads today's date and then advances it by five years by invoking the `NextYear` method in a loop.

To get today's date, type

```
cal = actxcontrol('mscal.calendar', [0 0 400 400]);
cal.Value
ans =
   11/5/2001
```

Call the NextYear method to advance the date, and verify the results:

```
for k = 1:5
   cal.invoke('NextYear');
end

cal.Value
ans =
   11/5/2006
```

Using the Method Name. Instead of using invoke, you can just use the name of the method to call it. The syntax for calling by method name is

```
v = handle.methodname('arg1', 'arg2', ...);
```

or

```
v = methodname(handle, 'arg1', 'arg2', ...);
```

Continuing the example shown in the last section, return to the original data by going back five years.

```
for k = 1:5
   cal.PreviousYear;
end

cal.Value
ans =
   11/5/2001
```

Specifying Enumerated Parameters

Enumeration is a way of representing a somewhat cryptic symbolic value by using a more descriptive name that makes it clear what the value stands for. For example, a program that takes atomic numbers of elements as input is easier to work with if the program accepts element names as input rather than requiring you to recall and pass atomic numbers for each element. You can pass the word 'arsenic' as an enumeration for the value 33.

MATLAB supports enumeration for parameters passed to methods under the condition that the type library in use reports the parameter as ENUM, and only as ENUM.

Note MATLAB does not support enumeration for any parameter that the type library reports as both `ENUM` and `Optional`.

The last line of this example passes an enumerated value (`'xlLocationAsObject'`) to the `Location` method of a Microsoft Excel `Chart` object. You have the choice of passing the enumeration or its numeric equivalent:

```
e = actxserver('Excel.Application');

% Insert a new workbook.
Workbook = e.Workbooks.Add;
e.Visible = 1;
Sheets = e.ActiveWorkBook.Sheets;

% Get a handle to the active sheet.
Activesheet = e.Activesheet;

%Add a Chart
Charts = Workbook.Charts;
Chart = Charts.Add;

% Set chart type to be a line plot.
Chart.ChartType = 'xlXYScatterLines'
C1 = Chart.Location('xlLocationAsObject', 'Sheet1');
```

When you are dealing with only three numeric values, it is not that difficult to remember the meaning of each. But with programs that require a large number of such values, enumeration becomes more important.

Optional Input Arguments

When calling a method that takes optional input arguments, you can skip any optional argument by specifying an empty array (`[]`) in its place. The syntax for calling a method with second argument (`arg2`) not specified is as follows:

```
handle.methodname(arg1, [], arg3);
```

The example below invokes the `Add` method of an Excel object. This method adds new sheets to an Excel workbook. The `Add` method takes up to four optional input arguments:

- `Before` — The sheet before which to add the new sheet
- `After` — The sheet after which to add the new sheet
- `Count` — The total number of sheets to add
- `Type` — The type of sheet to add

The following code creates a workbook with the default number of worksheets, and inserts an additional sheet after Sheet 1. To do this, you invoke `Add` specifying only the second argument, `After`. You can omit the first argument, `Before`, by using `[]` in its place. This is done on the last line:

```
% Open an Excel Server.
e = actxserver('excel.application');

% Insert a new workbook.
e.Workbooks.Add;
e.Visible = 1;

% Get the Active Workbook with three sheets.
eSheets = e.ActiveWorkbook.Sheets;

% Add a new sheet after eSheet1.
eSheet1 = eSheets.Item(1);
eNewSheet = eSheets.Add([], eSheet1);
```

Returning Multiple Output Arguments

If you know that a server function supports multiple outputs, you can return any or all of those outputs to a MATLAB client. Specify the output arguments within brackets on the left side of the equation. This gives the MATLAB client code access to any values returned by the server function.

The syntax shown here shows a server function being called by the MATLAB client. The function's return value is shown as `retval`. The function's output arguments (`out1`, `out2`, `...`) follow this:

```
[retval out1 out2 ...] = handle.functionname(in1, in2, ...);
```

MATLAB makes use of the pass-by-reference capabilities in COM to implement this feature. Note that pass by reference is a COM feature. It is not available in MATLAB at this time.

Argument Callouts in Error Messages

When a MATLAB client sends a command with an invalid argument to a COM server application, the server sends back an error message similar to that shown here, identifying the invalid argument. Be careful when interpreting the argument callout in this type of message:

```
PutFullMatrix(handle, 'a', 'base', 7, [5 8]);
??? Error: Type mismatch, argument 3.
```

In the `PutFullMatrix` command shown above, the fourth argument, `7`, is invalid. (It is scalar and not the expected array data type.) However, the error message identifies the failing argument as `argument 3`.

This is because the COM server receives only the last four of the arguments shown in the MATLAB code. (The `handle` argument merely identifies the server. It does not get passed to the server). So the server sees `'a'` as the first argument, and the invalid argument, `7`, as the third.

As another example, submitting the same command with the `invoke` function makes the invalid argument fifth in the MATLAB client code. Yet the server still identifies it as `argument 3` because neither of the first two arguments is seen by the server:

```
invoke(handle, 'PutFullMatrix', 'a', 'base', 7, [5 8]);
??? Error: Type mismatch, argument 3.
```

Object Properties

This section covers the following topics describing how to set and get the value of a property, and how to create custom properties:

Functions for Working with Object Properties

Use these MATLAB functions to get, set, and modify the properties of a COM object or interface, or to add your own custom properties.

Function	Description
`addproperty`	Add a custom property to a COM object
`deleteproperty`	Remove a custom property from a COM object
`get`	List one or more properties and their values
`inspect`	Display graphical interface to list and modify property values
`isprop`	Determine if an item is a property of a COM object
`propedit`	Display the control's built-in property page
`set`	Set a property on an interface

Getting the Value of a Property

The `get` function returns information on one or more properties belonging to a COM object or interface. Use `get` with only the handle argument, and MATLAB returns a list of all properties for the object, and their values:

```
h = actxserver('excel.application');

h.get
    Application: [1x1 Interface.Microsoft_Excel_9.0_
Object_Library._Application]
        Creator: 'xlCreatorCode'
         Parent: [1x1 Interface.Microsoft_Excel_9.0_
Object_Library._Application]
```

```
      ActiveCell: []
     ActiveChart: [1x50 char]
                 .
                 .
```

To return the value of just one property, specify the object handle and property name using dot syntax:

```
company = h.OrganizationName
company =
   The MathWorks, Inc.
```

Property names are not case sensitive and may also be abbreviated, as long as you include enough letters in the name to make it unambiguous. You can use `'org'` in place of the full `'OrganizationName'` property name used above:

```
company = h.org
company =
   The MathWorks, Inc.
```

You can also use the `get` function, without dot syntax, for this same purpose:

```
filepath = h.get('DefaultFilePath')
filepath =
   H:\Documents
```

Getting Multiple Property Values. To get more than one property with just one command, you must use the `get` function, specifying the property names in a cell array of strings. This returns a cell array containing a column for each property value:

```
C = h.get({'prop1', 'prop2', ...});
```

For example, to get the `DefaultFilePath` and `UserName` property values for COM object `h`, use

```
h = actxserver('excel.application');

C = h.get({'DefaultFilePath', 'UserName'});
C{:}
ans =
   H:\Documents
```

```
ans =
   C. Coolidge
```

Setting the Value of a Property

The simplest way to set or modify the value of a property is to use an assignment statement like that shown in the second line below. This sets the value of the `DefaultFilePath` property for object `h` to '`C:\ExcelWork`':

```
h = actxserver('excel.application');
h.DefaultFilePath = 'C:\ExcelWork';
```

You can also use the `set` function, without dot syntax, for this same purpose. Specify both the property name and new value as input arguments to `set`:

```
h.set('DefaultFilePath', 'C:\ExcelWork');
```

Setting Multiple Property Values. To change more than one property with one command, you must use the `set` function:

```
h.set('prop1', 'value1', 'prop2', 'value2', ...);
```

For example, to set the `DefaultFilePath` and `UserName` fields of COM object `h`, use

```
h = actxserver('excel.application');
h.set('DefaultFilePath', 'C:\ExcelWork', ...
   'UserName', 'H. Hoover');
```

Properties That Take Arguments

Some COM objects have properties that behave somewhat like methods in that they accept input arguments. On a `get` or `set` operation, the value they end up getting or setting depends on the arguments you pass in.

The `Activesheet` interface of a Microsoft Excel application running as a COM server is one example. This interface has a property called `Range`, which is actually another interface. In order to `get` the correct `Range` interface, you must pass in specific range coordinates.

The first line of code shown here (taken from the example in "Using MATLAB as an Automation Client" on page 8-105) returns a specific `Range` interface.

Arguments `A1` and `B2` specify which rectangular region of the spreadsheet to get the interface for:

```
eActivesheetRange = e.Activesheet.get('Range', 'A1', 'B2')
eActivesheetRange =
   Interface.Microsoft_Excel_5.0_Object_Library.Range
```

To get or set this type of property, use the `get` or `set` function as shown above for the `Range` property. Enter the input arguments in the parentheses following the property name:

```
handle.get(propertyname, arg1, arg2, ...);
```

In some ways, MATLAB handles these properties internally as though they were actually methods. The most important difference is that you need to use `invoke`, not `get`, to view the property:

```
e.Activesheet.invoke
            :
   Range = handle Range(handle, Variant, Variant(Optional))
            :
```

Get and Set on a Vector of Objects

You can use the `get` and `set` functions on more than one object at a time by putting the object handles into a vector and then operating on the vector.

This example creates a vector of handles to four Microsoft Calendar objects. It then modifies the `Day` property of all the objects in one operation by invoking `set` on the vector:

```
h1 = actxcontrol('mscal.calendar', [0 200 250 200]);
h2 = actxcontrol('mscal.calendar', [250 200 250 200]);
h3 = actxcontrol('mscal.calendar', [0 0 250 200]);
h4 = actxcontrol('mscal.calendar', [250 0 250 200]);
H = [h1 h2 h3 h4];

H.set('Day', 23)
H.get('Day')
ans =
    [23]
    [23]
    [23]
    [23]
```

Note To get or set values for multiple objects, you must use the `get` and `set` functions explicitly. Syntax like `H.Day` is only supported for scalar objects.

Using Enumerated Values for Properties

Enumeration makes examining and changing properties easier because each possible value for the property is given a string to represent it. For example, one of the values for the `DefaultSaveFormat` property in an Excel application is `xlUnicodeText`. This is easier to remember than a numeric value like 57.

Finding All Enumerated Properties. The MATLAB COM `get` and `set` functions support enumerated values for properties for those applications that provide them. To see which properties use enumerated types, use the `set` function with the object handle argument:

```
h = actxserver('excel.application');

h.set
ans =
                    Creator: {'xlCreatorCode'}
        ConstrainNumeric: {}
    CopyObjectsWithCells: {}
                  Cursor: {4x1 cell}
            CutCopyMode: {2x1 cell}
                    .
                    .
```

MATLAB displays the properties that accept enumerated types as nonempty cell arrays. Properties for which there is a choice of settings are displayed as a multirow cell array, with one row per setting (see `Cursor` in the example above). Properties for which there is only one possible setting are displayed as a one row cell array (see `Creator`, above).

To display the current values of these properties, use `get` with just the object handle argument:

```
h.get
                    Creator: 'xlCreatorCode'
        ConstrainNumeric: 0
    CopyObjectsWithCells: 1
                  Cursor: 'xlDefault'
            CutCopyMode: ''
                    .
                    .
```

Setting an Enumerated Value. To list all possible enumerated values for a specific property, use `set` with the property name argument. The output is a cell array of strings, one string for each possible setting of the specified property:

```
h.set('Cursor')
ans =
    'xlIBeam'
    'xlDefault'
    'xlNorthwestArrow'
    'xlWait'
```

To set the value of a property, assign the enumerated value to the property name:

```
handle.property = 'enumeratedvalue';
```

You can also use the `set` function with the property name and enumerated value:

```
handle.set('property', 'enumeratedvalue');
```

You have a choice of using the enumeration or its equivalent numeric value. You can abbreviate the enumeration string, as in the third line below, as long as you use enough letters in the string to make it unambiguous. Enumeration strings are also case insensitive.

Make the Excel spreadsheet window visible and then change the cursor from the MATLAB client. To see how the cursor has changed, you need to click the spreadsheet window. Either of the following assignments to `h.Cursor` sets the cursor to the `Wait` (hourglass) type:

```
h.Visible = 1;

h.Cursor = 'xlWait'
h.Cursor = 'xlw'           % Abbreviated form of xlWait
```

Read the value of the `Cursor` property you have just set:

```
h.Cursor
ans =
   xlWait
```

Using the Property Inspector

MATLAB provides a GUI to display and modify properties. Open the Property Inspector using either of these two methods:

- Call the `inspect` function from the MATLAB command line.
- Double-click the object in the MATLAB Workspace browser.

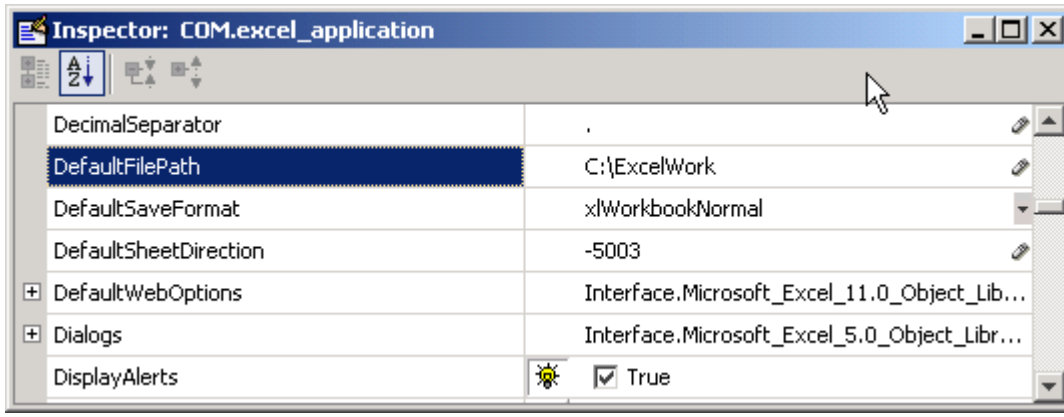
For example, create a server object running Microsoft Excel, then set the object's `DefaultFilePath` property to '`C:\ExcelWork`':

```
h = actxserver('excel.application');
h.DefaultFilePath = 'C:\ExcelWork';
```

Next call the `inspect` function to display a new window showing the server object's properties:

```
h.inspect
```

Scroll down until you see the `DefaultFilePath` property that you just changed. It should read `C:\ExcelWork`.



Using the Property Inspector, change `DefaultFilePath` once more, this time to `C:\MyWorkDirectory`. To do this, select the value at the right and type the new value.

Now go back to the MATLAB Command Window and confirm that the `DefaultFilePath` property has changed as expected.

```
h.DefaultFilePath
```

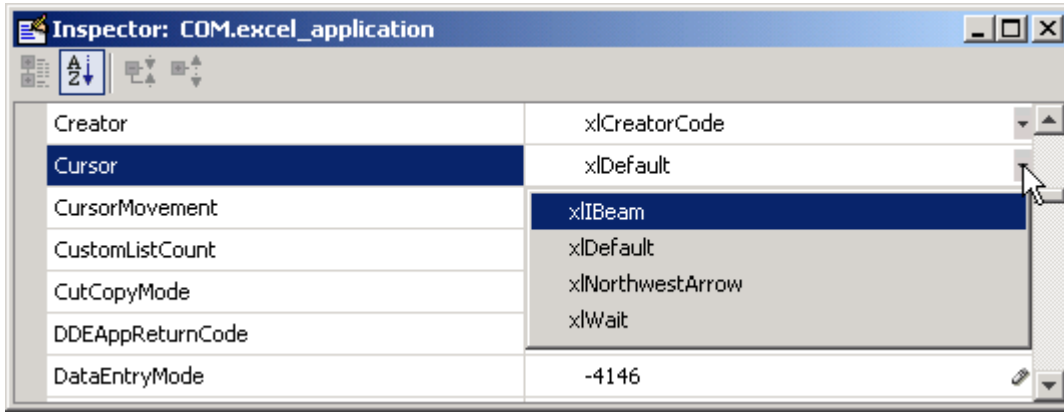
MATLAB displays:

```
ans =

C:\MyWorkDirectory
```

Note If you modify properties at the MATLAB command line, you must refresh the Property Inspector window to see the change reflected there. Refresh the Property Inspector window by reinvoking `inspect` on the object.

Using the Property Inspector on Enumerated Values. A drop-down list button next to a property value indicates the property accepts enumerated values. Click anywhere in the field on the right to see the values. The following figure displays four enumerated values for the `Cursor` property. The current value is displayed in the field next to the property name.



To change a property's value using the Property Inspector, use the drop-down list to display the options for that property, and then click the desired value.

Custom Properties

You can attach your own properties to a control using the `addproperty` function. The syntax shown here creates a custom property for control, `h`:

```
h.addproperty('propertyName')
```

This example creates the `mwsamp2` control, adds a new property called `Position` to it, and assigns the value `[200 120]` to that property:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [200 120 200 200]);
h.addproperty('Position');
h.Position = [200 120];
```

Use `get` to list all properties of control, `h`. You see that the new `Position` property has been added:

```
h.get
ans =
     Label: 'Label'
    Radius: 20
  Position: [200 120]

h.Position
ans =
   200   120
```

To remove custom properties from a control, use `deleteproperty` with the following syntax:

```
h.deleteproperty('propertyName')
```

For example, delete the `Position` property that you just created, and use `get` to show that it no longer exists:

```
h.deleteproperty('Position');

h.get
     Label: 'Label'
    Radius: 20
```

Control and Server Events

An *event* is typically a user-initiated action that takes place in a server application which often requires a reaction from the client. For example, a user clicking the mouse at a particular location in a server interface window might require the client take some action in response. When an event is *fired*, the server communicates this occurrence to the client. If the client is *listening* for this particular type of event, it responds by executing a routine called an event handler.

The MATLAB COM client can subscribe to and handle the events fired by an ActiveX control or a COM server. Select which events you want the client to listen to by registering each event you want active along with the event handler to be used in responding to the event. When any registered event takes place in the control or server, the client is notified and responds by executing the appropriate handler routine. Event handlers in MATLAB are often implemented using M-files.

This section covers the following topics on registering and responding to events fired from an ActiveX control or a COM server:

Note MATLAB does not support interface events from a Custom server.

Functions for Working with Events

Use these MATLAB functions to register and unregister events, to list all events, or to list just registered events for a control or server.

Function	Description
`actxcontrol`	Create a COM control and optionally register those events you want the client to listen to
`eventlisteners`	Return a list of events attached to listeners
`events`	List all events, both registered and unregistered, a control or server can generate
`isevent`	Determine if an item is an event of a COM object

Function	Description
`registerevent`	Register an event handler with a control or server event
`unregisterallevents`	Unregister all events for a control or server
`unregisterevent`	Unregister an event handler with a control or server event

When using these functions, enter event names and event handler names as strings or in a cell array of strings. These names are case insensitive, but cannot be abbreviated.

Examples of Event Handlers

The following examples have implementations of event handlers:

- "Example — Grid ActiveX Control in a Figure" on page 8-17
- "Example — Reading Data from Excel" on page 8-24

Responding to Events from a COM Server

This section describes the basic steps you need to take in handling events fired by a COM control or server.

- "Identifying All Events" on page 8-77
- "Registering Those Events You Want to Respond To" on page 8-78
- "Identifying Registered Events" on page 8-78
- "Responding to Events As They Occur" on page 8-79
- "Unregistering Events You No Longer Want to Listen To" on page 8-79

Identifying All Events. Use the `events` function to list all events the control or server is capable of responding to. This function returns a structure array, where each field of the structure is the name of an event handler and the value of that field contains the signature for the handler routine. To invoke `events` on an object with handle `h`, type

```
S = h.events
```

Registering Those Events You Want to Respond To. Use the `registerevent` function to register those server events you want the client to respond to. There are two ways you can register events:

- If you have one function to handle all server events, you can register this common event handler using the syntax

```
h.registerevent('handler');
```

- If you have a separate event handler function for different events, use the syntax

```
h.registerevent({'event1' 'handler1'; 'event2' 'handler2';
...});
```

For ActiveX controls, you can register events at the time you create the control using the `actxcontrol` function.

- To register a common event handler function to respond to all events, use

```
h = actxcontrol('progid', position, figure, 'handler');
```

- To register a separate function to handle each type of event, use

```
h = actxcontrol('progid', position, figure, ...
   {'event1' 'handler1'; 'event2' 'handler2'; ...});
```

The MATLAB client responds only to events you have registered.

Identifying Registered Events. The `eventlisteners` function lists only those events that are currently registered. This function returns a cell array, with each row representing a registered event and the name of its event handler. For example, to invoke `eventlisteners` on an object with handle `h`, type

```
C = h.eventlisteners
```

Responding to Events As They Occur. Whenever a control or server fires an event that the client is listening to, the client responds to the event by invoking one or more event handlers that have been registered for that event. You can implement these routines in M-file programs that you write to handle events. Read more about event handlers in the section on "Writing Event Handlers" on page 8-87.

Unregistering Events You No Longer Want to Listen To. If you have registered events that you now want the client to ignore, you can unregister them at any time using the functions `unregisterevent` and `unregisterallevents` as follows:

- For a server with handle `h`, to unregister all events registered with a common event handling function `handler`, use

  ```
  h.unregisterevent('handler');
  ```

- To unregister individual events `eventN`, each registered with its own event handling function `handlerN`, use

  ```
  h.unregisterevent({'event1' 'handler1'; 'eventN' 'handlerN'});
  ```

- To unregister all events from the server regardless of which event handling function they are registered with, use

  ```
  h.unregisterallevents;
  ```

Responding to Events from an ActiveX Control

This section describes how to handle events fired by an ActiveX control. It uses a control called `mwsamp2` that ships with MATLAB. The event handler routines for `mwsamp2` are defined when you install MATLAB.

Tasks described in this section are

Creating a Control and Registering Events. The `actxcontrol` function not only creates the control object, but can be used to register specific events as well. The code shown here registers two events (`Click` and `MouseDown`) and two respective handler routines (`myclick` and `mymoused`) with the `mwsamp2` control.

```
f = figure('position', [100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], f, ...
    {'Click' 'myclick'; 'MouseDown' 'mymoused'});
```

If, at some later time, you want to register additional events, use the `registerevent` function:

```
h.registerevent({'DblClick' 'my2click'});
```

You can view the event handler code written for the `mwsamp2` control in the section "Sample Event Handlers" on page 8-90.

Unregister the `DblClick` event before continuing with the example:

```
h.unregisterevent({'DblClick' 'my2click'});
```

Listing Control Events. At this point, only the `Click` and `MouseDown` events should be registered. To see all events that the control can fire, use the `events` function. This function returns a structure array, where each field of the structure is the name of an event handler and the value of that field contains the signature for the handler routine.

To list all events, whether registered or not, use

```
S = h.events
S =
         Click: 'void Click()'
      DblClick: 'void DblClick()'
     MouseDown: 'void MouseDown(int16 Button, int16 Shift,
                 Variant x, Variant y)'
    Event_Args: [1x101 char]

S.Event_Args
ans =
   void Event_Args(int16 typeshort, int32 typelong,
        double typedouble, string typestring, bool typebool)
```

To list only those events that are currently registered with the control, use the `eventlisteners` function. This function returns a cell array, with each row representing a registered event and the name of its event handler.

Use `eventlisteners` to list registered event names and their handler routines:

```
h.eventlisteners
ans =
    'click'        'myclick'
    'mousedown'    'mymoused'
```

Responding to Control Events. When MATLAB creates the `mwsamp2` control, it also displays a figure window showing a label and circle at the center. If you click on different positions in this window, you see a report in the MATLAB Command Window of the `X` and `Y` position of the mouse.

Each time you press the mouse button, the `MouseDown` event fires, calling the `mymoused` function. This function prints the position values for that event to the MATLAB Command Window:

```
The X position is:
ans =
    [122]
The Y position is:
ans =
```

```
    [63]
```

You also see the following line reported in response to the `Click` event:

```
Single click function
```

Double-clicking the mouse does nothing different, since the `DblClick` event has been unregistered.

Unregistering Control Events. When you unregister an event, the client discontinues listening for occurrences of that event. When the event fires, the client does not respond. If you unregister the `MouseDown` event, MATLAB no longer reports the `X` and `Y` position when you click in the window:

```
h.unregisterevent({'MouseDown' 'mymoused'});
```

Now, register the `DblClick` event, connecting it with handler function `my2click`:

```
h.registerevent({'DblClick', 'my2click'});
```

If you call `eventlisteners` again, the registered events are now `Click` and `DblClick`:

```
h.eventlisteners
ans =
    'click'       'myclick'
    'dblclick'    'my2click'
```

When you double-click the mouse button, MATLAB responds to both the `Click` and `DblClick` events by displaying the following in the MATLAB Command Window:

```
Single click function
Double click function
```

An easy way to unregister all events for a control is to use the `unregisterallevents` function. When there are no events registered, `eventlisteners` returns an empty cell array:

```
h.unregisterallevents
```

```
h.eventlisteners
ans =
     {}
```

Clicking the mouse in the control window now does nothing since there are no active events.

If you have events that are registered with a common event handling routine, such as `sampev.m` used in the example below, you can use `unregisterevent` to unregister all of these events in one operation. The example that follows first registers all events from the server with a common handling routine `sampev`. MATLAB now handles any type of event from this server by executing `sampev`:

```
h.registerevent('sampev');
```

Verify the registration by listing all event listeners for that server:

```
h.eventlisteners
ans =
    'click'        'sampev'
    'dblclick'     'sampev'
    'mousedown'    'sampev'
```

Now unregister all events for the server that use the `sampev` event handling routine:

```
h.unregisterevent('sampev');
h.eventlisteners
ans =
     {}
```

Responding to Events from an Automation Server

The next section shows how to handle events fired by an Automation server. The example creates a server running Internet Explorer, registers a common handler for all events, and then has you fire events by browsing to Web sites using the Internet Explorer application.

Tasks described in this section are

- "Creating an Event Handler" on page 8-84

Creating an Event Handler. This example registers all events with the same handler routine, `serverevents`. Since this example does not ship with MATLAB, you have to create the event handler routine yourself.

Create the file `serverevents.m`, inserting the following code. Make sure the file is in your current directory.

```
function serverevents(varargin)

% Display incoming event name
eventname = varargin{end}

% Display incoming event args
eventargs = varargin{end-1}
```

Creating a Server. Next, in your MATLAB session, use the following commands to create your Automation server application.

```
% Create a server running Internet Explorer.
h = actxserver('internetexplorer.application');

% Make the server application visible.
h.set('Visible', 1);
```

Listing Server Events. Use the `events` function to list all events the control or server is capable of responding to, and `eventlisteners` to list only those events that are currently registered.

```
h.events
```

MATLAB displays event information similar to:

```
        :
StatusTextChange = void StatusTextChange(string Text)
ProgressChange = void ProgressChange(int32 Progress,int32 ProgressMax)
CommandStateChange = void CommandStateChange(int32 Command,bool Enable)
        :
```

No events are registered at this time, so `eventlisteners` returns an empty cell array.

```
h.eventlisteners
```

MATLAB displays:

```
ans =
      {}
```

Registering Server Events. Now use your event handler `serverevents`.

```
h.registerevent('serverevents');
h.eventlisteners
```

MATLAB displays:

```
ans =
              :                    :
    'statustextchange'      'serverevents'
    'progresschange'        'serverevents'
    'commandstatechange'    'serverevents'
              :                    :
```

Responding to Server Events. At this point, all events have been registered. If any event fires, the common handler routine defined in `serverevents.m` executes to handle that event. Use the Internet Explorer application to browse your favorite Web site, or enter the following command in the MATLAB Command Window:

```
h.Navigate2('http://www.mathworks.com');
```

You should see a long series of events displayed in your client window.

Unregistering Server Events. Use the `unregisterevent` function to remove specific events from the registry. If the events were registered with a common handler, as in this example, specify the name of the common routine with each event that you want removed from the event registry for that object:

```
h.unregisterevent({'event1', 'commonhandler'; ...
   'event2', 'commonhandler', ...});
```

Continuing with this example, unregister the `progresschange` and `commandstatechange` events:

```
h.unregisterevent({'progresschange', 'serverevents'; ...
   'commandstatechange', 'serverevents'});
```

To unregister all events for an object, use `unregisterallevents`. The following commands unregister all the events that had been registered for the Internet Explorer application and then register a single event:

```
h.unregisterallevents;
h.registerevent({'TitleChange', 'serverevents'});
```

If you now browse with Internet Explorer, MATLAB only responds to the `TitleChange` event.

Closing the Application. It is always advisable to close a server application when you no longer intend to use it. To unregister all events and close the application, type:

```
h.unregisterallevents;
h.Quit;
h.delete;
```

Responding to Interface Events from an Automation Server

This example, demonstrating how to handle a COM interface event, shows how to set up an event in a Microsoft Excel's Workbook object and how to handle its `BeforeClose` event.

To create the event handler `OnBeforeCloseWorkbook`, create the file `OnBeforeCloseWorkbook.m`, inserting the following code. Make sure the file is in your current directory.

```
% Event handler for Excel workbook BeforeClose event
function OnBeforeCloseWorkbook(varargin)
    disp('BeforeClose event occured');
```

When you run the following commands

```
% Create Excel automation server instance
xl = actxserver('Excel.Application');
% Make it visible
xl.Visible = 1;

% Get collection of workbooks and add a new workbook
hWbks = xl.Workbooks;
hWorkbook = hWbks.Add;

% Register OnClose event
hWorkbook.registerevent({'BeforeClose' @OnBeforeCloseWorkbook});

%% Close the workbook. This will fire Close event and call OnClose handler
hWorkbook.Close
```

MATLAB displays:

```
BeforeClose event occured
```

Writing Event Handlers

This section covers the following topics on writing handler routines to respond to events fired from an ActiveX control or Automation server:

Overview of Event Handling

An event is fired when a control or server wants to notify its client that something of interest has occurred. For example, many controls trigger an event when the user clicks somewhere in the interface window of a control. In MATLAB, you can create and register your own M-file functions to respond to events when they occur. These functions serve as event handlers. You can create one handler function to handle all events or a separate handler for each type of event.

For controls, you can register handler functions either at the time you create the control (using `actxcontrol`), or at any time afterwards (using `registerevent`).

Both `actxcontrol` and `registerevent` use an event handler argument. The event handler argument can be either the name of a single callback routine or a cell array that associates specific events with their respective event handlers. Strings used in the event handler argument are not case sensitive.

For servers, you must use `registerevent` to register those events you want the client to listen to. For example, to register the `Click` and `DblClick` events, use

```
h.registerevent({'click' 'myclick'; 'dblclick' 'my2click'});
```

Use `events` to list all the events a COM object recognizes. For example, to list all events for the `mwsamp2` control, use

```
f = figure ('position', [100 200 200 200]);
h = actxcontrol ('mwsamp.mwsampctrl.2', [0 0 200 200], f);

h.events
   Click = void Click()
   DblClick = void DblClick()
   MouseDown = void MouseDown(int16 Button, int16 Shift,
      Variant x, Variant y)
```

Arguments Passed to Event Handlers

When a registered event is triggered, MATLAB passes information from the event to its handler function, as shown in this table.

Arguments Passed by MATLAB

Arg. No.	Contents	Format
1	Object name	MATLAB COM class
2	Event ID	double
3	Start of Event Argument List	As passed by the control
end-2	End of Event Argument List (Argument N)	As passed by the control
end-1	Event Structure	structure
end	Event Name	char array

When writing an event handler function, use the Event Name argument to identify the source of the event. Get the arguments passed by the control from the Event Argument List (arguments 3 through end-2). All event handlers must accept a variable number of arguments:

```
function event (varargin)
if (varargin{end}) == 'MouseDown')      % Check the event name
    x_pos = varargin{5};              % Read 5th Event Argument
    y_pos = varargin{6};              % Read 6th Event Argument
end
```

Note The values passed vary with the particular event and control being used.

Event Structure

The second to last argument passed by MATLAB is the Event Structure, which has the following fields.

Fields of the Event Structure

Field Name	Description	Format
`Type`	Event Name	`char array`
`Source`	Control Name	MATLAB `COM` class
`EventID`	Event Identifier	`double`
`Event Arg Name 1`	Event Arg Value 1	As passed by the control
`Event Arg Name 2`	Event Arg Value 2	As passed by the control
etc.	Event Arg N	As passed by the control

For example, when the `MouseDown` event of the `mwsamp2` control is triggered, MATLAB passes this Event Structure to the registered event handler:

```
    Type: 'MouseDown'
  Source: [1x1 COM.mwsamp.mwsampctrl.2]
 EventID: -605
  Button: 1
   Shift: 0
       x: 27
       y: 24
```

Sample Event Handlers

Specify a single callback, `sampev`:

```
f = figure('position', [100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], ...
    gcf, 'sampev')
h =
    COM.mwsamp.mwsampctrl.2
```

Or specify several events using the cell array format:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], f, ...
    {'Click' 'myclick'; 'DblClick' 'my2click'; ...
    'MouseDown' 'mymoused'});
```

The event handlers, `myclick.m`, `my2click.m`, and `mymoused.m`, are

```
function myclick(varargin)
disp('Single click function')

function my2click(varargin)
disp('Double click function')

function mymoused(varargin)
disp('You have reached the mouse down function')
disp('The X position is: ')
double(varargin{5})
disp('The Y position is: ')
double(varargin{6})
```

Alternatively, you can use the same event handler for all the events you want to monitor using the cell array pairs. Response time is better than using the callback style.

For example:

```
f = figure('position', [100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2', ...
[0 0 200 200], f, {'Click' 'allevents'; ...
'DblClick' 'allevents'; 'MouseDown' 'allevents'})
```

where `allevents.m` is

```
function allevents(varargin)
if (strcmp(varargin{end-1}.Type, 'Click'))
   disp ('Single Click Event Fired')
elseif (strcmp(varargin{end-1}.Type, 'DblClick'))
   disp ('Double Click Event Fired')
elseif (strcmp(varargin{end-1}.Type, 'MouseDown'))
   disp ('Mousedown Event Fired')
end
```

Writing Event Handlers Using M-File Subfunctions

Instead of having to maintain a separate M-file for every event handler routine you write, you can consolidate some or all of these routines into a single M-file using M-file subfunctions.

This example shows three event handler routines, (`myclick`, `my2click`, and `mymoused`) implemented as subfunctions in the file `mycallbacks.m`. The call to `str2func` converts the input string to a function handle:

```
function a = mycallbacks(str)
a = str2func(str);

function myclick(varargin)
disp('Single click function')

function my2click(varargin)
disp('Double click function')

function mymoused(varargin)
disp('You have reached the mouse down function')
disp('The X position is: ')
double(varargin{5})
disp('The Y position is: ')
double(varargin{6})
```

To register one of these events, call `mycallbacks`, passing the name of the event handler:

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], ...
    gcf, 'sampev')
h.registerevent({'Click', mycallbacks('myclick')});
```

Saving Your Work

Use these MATLAB functions to save and restore the state of a COM control object.

Function	Description
`load`	Load and initialize a COM control object from a file
`save`	Write and serialize a COM control object to a file

Save the current state of a COM control to a file using the `save` function. The following example creates an `mwsamp2` control and saves its original state to the file `mwsample`:

```
f = figure('position', [100 200 200 200]);
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 200 200], f);
h.save('mwsample')
```

Now, alter the figure by changing its label and the radius of the circle:

```
h.Label = 'Circle';
h.Radius = 50;
h.Redraw;
```

Using the `load` function, you can restore the control to its original state:

```
h.load('mwsample');
h.get
ans =
     Label: 'Label'
    Radius: 20
```

Note The COM `save` and `load` functions are only supported for controls at this time.

Releasing COM Interfaces and Objects

Use these MATLAB functions to release or delete a COM object or interface.

Function	Description
`delete`	Delete a COM object or interface
`release`	Release a COM object or interface

When each interface is no longer needed, use the `release` function to release the interface and reclaim the memory used by it. When the entire control or server is no longer needed, use the `delete` function to delete it. Alternatively, you can use the `delete` function on any valid interface. All interfaces for that object are automatically released and the server or control itself is deleted.

Note In versions of MATLAB earlier than 6.5, failure to explicitly release interface handles or delete the control or server often results in a memory leak. This is true even if the variable representing the interface or COM object has been reassigned. In MATLAB 6.5 and later, the control or server, along with all interfaces to it, is destroyed on reassignment of the variable or when the variable representing a COM object or interface goes out of scope.

MATLAB automatically releases all interfaces for a control when the figure window that contains that control is deleted or closed. MATLAB also automatically releases all handles for an Automation server when MATLAB is shut down.

Identifying Objects

Use these MATLAB functions to get information about a COM object.

Function	Description
`class`	Return the class of a COM object
`isa`	Detect a COM object of a given class
`isevent`	Determine if an item is an event of a COM object
`ismethod`	Determine if an item is a method of a COM object
`isprop`	Determine if an item is a property of a COM object

Create a COM object, `h`, in an Automation server running Excel, and also a `Workbooks` interface, `w`, to the object:

```
h = actxserver('excel.application');
w = h.Workbooks;
```

To find out the class of variable `w`, use the `class` function:

```
w.class
ans =
   Interface.Microsoft_Excel_9.0_Object_Library.Workbooks
```

To test a variable against a known class name, use `isa`:

```
h.isa('COM.excel.application')
ans =
     1
```

To see if `UsableWidth` is a property of object `h`, use `isprop`:

```
h.isprop('UsableWidth')
ans =
     1
```

To see if `SaveWorkspace` is a method of object `h`, use `ismethod`. Method names are case sensitive and cannot be abbreviated:

```
h.ismethod('SaveWorkspace')
ans =
     1
```

Create the sample `mwsamp2` control that comes with MATLAB, and use `isevent` to see if `DblClick` is one of the events that this control recognizes:

```
f = figure ('position', [100 200 200 200]);
h = actxcontrol ('mwsamp.mwsampctrl.2', [0 0 200 200], f);

h.isevent('DblClick')
ans =
     1
```

Handling COM Data in MATLAB

This section covers the following topics:

• "Displaying MATLAB Syntax for COM Objects" on page 8-102

Passing Data to a COM Object

When you call a COM object from MATLAB, the MATLAB data types you pass in the call are converted to data types native to the COM object. MATLAB performs this conversion on each argument that is passed. This section describes the conversion.

MATLAB arguments are converted by MATLAB into data types that best represent the data to the COM object. The following table shows all of the MATLAB base types for passed arguments and the COM types defined for input arguments. Each row shows a MATLAB type followed by the possible COM argument matches.

MATLAB Argument	Closest Type	Allowed Types
handle	VT_DISPATCH VT_UNKNOWN	VT_DISPATCH VT_UNKNOWN
string	VT_BSTR	VT_LPWSTR VT_LPSTR VT_BSTR VT_FILETIME VT_ERROR VT_DECIMAL VT_CLSID VT_DATE
int16	VT_I2	VT_UINT VT_I2 VT_UI2
int32	VT_I4	VT_I4 VT_UI4 VT_INT
single	VT_R4	VT_R4
double	VT_R8	VT_R8 VT_CY (currency)

MATLAB Argument	Closest Type	Allowed Types
bool	VT_BOOL	VT_BOOL
char	VT_I1	VT_I1 VT_UI1

Variant Data. variant is any data type except a structure or a sparse array. (Refer to the Data Type Summary table in the MATLAB Programming documentation.)

When used as an input argument, MATLAB treats variant and variant(pointer) the same way.

MATLAB Argument	Closest Type	Allowed Types
variant	VT_VARIANT	VT_VARIANT VT_USERDEFINED VT_ARRAY
variant(pointer)	VT_VARIANT	VT_VARIANT | VT_BYREF

SAFEARRAY Data. When a COM method identifies a SAFEARRAY or SAFEARRAY(pointer), the MATLAB equivalent is a matrix.

MATLAB Argument	Closest Type	Allowed Types
SAFEARRAY	VT_SAFEARRAY	VT_SAFEARRAY
SAFEARRAY(pointer)	VT_SAFEARRAY	VT_SAFEARRAY | VT_BYREF

Handling Data from a COM Object

Data returned from a COM object is often incompatible with MATLAB data types. When this occurs, MATLAB converts the returned value to a data type native to the MATLAB language. This section describes the conversion performed on the various data types that can be returned from COM objects.

This table shows how MATLAB converts data from a COM object into MATLAB variables.

COM Return Type	MATLAB Representation
VT_DISPATCH VT_UNKNOWN	handle
VT_LPWSTR VT_LPSTR VT_BSTR VT_FILETIME VT_ERROR VT_DECIMAL VT_CLSID VT_DATE	string
VT_UINT VT_I2 VT_UI2	int16
VT_I4 VT_UI4 VT_INT	int32
VT_R4	single
VT_R8 VT_CY (currency)	double
VT_BOOL	bool
VT_I1 VT_UI1	char
VT_VARIANT VT_USERDEFINED VT_ARRAY	variant
VT_VARIANT | VT_BYREF	variant(pointer)
VT_SAFEARRAY	SAFEARRAY
VT_SAFEARRAY | VT_BYREF	SAFEARRAY(pointer)

Unsupported Data Types

The following data types are not supported in the MATLAB COM interface:

- VT_I8
- VT_UI8
- Structure
- Sparse array
- Unsigned integer
- Multidimensional SAFEARRAYs
- Write-only properties
- Enumerated types

Passing Data from MATLAB to ActiveX Objects

The tables also show the mapping of MATLAB data types to COM data types that you must use to pass data from MATLAB to an ActiveX object. Note that all other types result in the following warning:

```
"ActiveX - invalid argument type or value".
```

Passing SAFEARRAY from MATLAB to COM Object

The SAFEARRAY data type is a standard way to pass arrays between COM objects. This section explains how MATLAB passes SAFEARRAY data to a COM object.

- “Default Behavior in MATLAB” on page 8-99
- “Examples” on page 8-99
- “How to Pass a Single-Dimension SAFEARRAY” on page 8-101
- “Passing SAFEARRAY By Reference” on page 8-101

Default Behavior in MATLAB. MATLAB represents an m-by-n matrix as a two-dimensional SAFEARRAY, where the first dimension has m elements and the second dimension has n elements. MATLAB passes the SAFEARRAY by value.

Examples. The following examples use a COM object that expects a SAFEARRAY input parameter.

When MATLAB passes a 1-by-3 array

```
B = [2 3 4]
B =
     2     3     4
```

the object reads

```
No. of dimensions: 2
Dim: 1,   No. of elements: 1
Dim: 2,   No. of elements: 3
    Elements:
    2.0
    3.0
    4.0
```

When MATLAB passes a 3-by-1 array

```
C = [1;2;3]
C =
     1
     2
     3
```

the object reads

```
No. of dimensions: 2
Dim: 1,   No. of elements: 3
Dim: 2,   No. of elements: 1
Elements:
    1.0
    2.0
    3.0
```

When MATLAB passes a 2-by-4 array

```
D = [2 3 4 5;5 6 7 8]

D =
     2     3     4     5
     5     6     7     8
```

the object reads

```
No. of dimensions: 2
Dim: 1,   No. of elements: 2
Dim: 2,   No. of elements: 4
Elements:
    2.0
    3.0
    4.0
    5.0
    5.0
    6.0
    7.0
    8.0
```

How to Pass a Single-Dimension SAFEARRAY. For information about passing arguments as one-dimensional arrays to a COM object, see the Technical Support solution 1-SKYP9 at `http://www.mathworks.com/support/solutions/data/1-SKYP9.html?solution=1-SKY`

Passing SAFEARRAY By Reference. For information about passing arguments by reference to a COM object, see the Technical Support solution 1-SKYPY at `http://www.mathworks.com/support/solutions/data/1-SKYPY.html?solution=1-SKY`

Reading SAFEARRAY from a COM Object in MATLAB

This section explains how MATLAB reads `SAFEARRAY` data from a COM object.

A one-dimensional `SAFEARRAY` with `n` elements from a COM object is rendered as a 1-by-`n` matrix. For example, using methods from the MATLAB sample control `mwsamp`,

```
h=actxcontrol('mwsamp.mwsampctrl.1')
a = h.GetI4Vector
```

MATLAB displays:

```
a =
           1           2           3
```

A two-dimensional SAFEARRAY with n elements is rendered by MATLAB as a 2-by-n matrix, for example:

```
a = h.GetR8Array
```

MATLAB displays:

```
a =
     1     2     3
     4     5     6
```

A three-dimensional SAFEARRAY with 2 elements is rendered as a 2-by-2-by-2 cell array, for example:

```
a = h.GetBSTRArray
```

MATLAB displays:

```
a(:,:,1) =

    '1 1 1'    '1 2 1'
    '2 1 1'    '2 2 1'

a(:,:,2) =

    '1 1 2'    '1 2 2'
    '2 1 2'    '2 2 2'
```

Displaying MATLAB Syntax for COM Objects

To determine which MATLAB data types to use when passing arguments to COM objects, use the invoke or methodsview functions. These functions list all of the methods found in an object, along with a specification of the data types required for each argument.

In the following example, a server called MyApp has a method TestMeth1 with the following syntax:

```
HRESULT TestMeth1 ([out, retval] double* dret);
```

This method has no input argument, and it returns a variable of type `double`. To display the MATLAB syntax for calling the method, type

```
h = actxserver('MyApp');
h.invoke
```

MATLAB displays:

```
ans =
   TestMeth1 = double TestMeth1 (handle)
```

The signature of `TestMeth1` is

```
double TestMeth1(handle)
```

MATLAB requires you to use an object handle as an input argument for every method, in addition to any input arguments required by the method itself.

Using the variable `var`, which is of type `double`, type

```
var = h.TestMeth1;
```

or

```
var = TestMeth1(h);
```

While the following syntax is correct, its use is discouraged:

```
var = invoke(h,'TestMeth1');
```

Now consider the server called `MyApp1` with the following methods:

```
HRESULT TestMeth1 ([out, retval] double* dret);
HRESULT TestMeth2 ([in] double* d, [out, retval] double* dret);
HRESULT TestMeth3 ([out] BSTR* sout,
                   [in, out] double* dinout,
                   [in, out] BSTR* sinout,
                   [in] short sh,
                   [out] long* ln,
                   [in, out] float* b1,
                   [out, retval] double* dret);
```

Type the commands:

```
h = actxserver('MyApp1');
h.invoke
```

MATLAB displays the list of methods

```
ans =
   TestMeth1 = double TestMeth1 (handle)
   TestMeth2 = double TestMeth1 (handle, double)
   TestMeth3 = [double, string, double, string, int32, single] ...
               TestMeth3(handle, double, string, int16, single)
```

`TestMeth2` requires an input argument `d` of type `double`, as well as returning a variable `dret` of type `double`. Some examples of calling `TestMeth2` are

```
var = h.TestMeth2(5);
```

or

```
var = TestMeth2(h, 5);
```

`TestMeth3` requires multiple input arguments, as indicated within the parentheses on the right side of the equals sign, and returns multiple output arguments, as indicated within the brackets on the left side of the equals sign.

```
[double, string, double, string, int32, single]  %output arguments
TestMeth3(handle, double, string, int16, single) %input arguments
```

The first input argument is the required `handle`, followed by four input arguments.

```
TestMeth3(handle, in1, in2, in3, in4)
```

The first output argument is the return value `retval`, followed by five output arguments.

```
[retval, out1, out2, out3, out4, out5]
```

This is how the arguments map into a MATLAB command:

```
[dret, sout, dinout, sinout, ln, b1] = TestMeth3(handle, ...
```

```
                                                    dinout, sinout, sh, b1)
```

where `dret` is `double`, `sout` is `string`, `dinout` is `double` and is both an input and an output argument, `sinout` is `string` (input and output argument), `ln` is `int32`, `b1` is `single` (input and output argument), `handle` is the handle to the object, and `sh` is `int16`.

Examples of MATLAB as an Automation Client

This section provides examples of using MATLAB as an Automation client with controls and servers:

MATLAB Sample Control

MATLAB ships with a simple example COM control that draws a circle on the screen, displays some text, and fires events when the user single- or double-clicks on the control. Create the control by running the `mwsamp.m` file in the directory, `winfun\comcli`, or type

```
h = actxcontrol('mwsamp.mwsampctrl.2', [0 0 300 300]);
```

This control is stored in the MATLAB `bin`, or executable, directory along with the control's *type library*. The type library is a binary file used by COM tools to decipher the control's capabilities. See the section "Writing Event Handlers" on page 8-87 for other examples that use the `mwsamp2` control.

Using MATLAB as an Automation Client

This example uses MATLAB as an Automation client and Microsoft Excel as the server. It provides a good overview of typical functions. In addition, it is a good example of using the Automation interface of another application:

```
% MATLAB Automation client example
%
```

```
% Open Excel, add workbook, change active worksheet,
% get/put array, save.

% First, open an Excel Server.
e = actxserver('excel.application');

% Insert a new workbook.
eWorkbook = e.Workbooks.Add;
e.Visible = 1;

% Make the first sheet active.
eSheets = e.ActiveWorkbook.Sheets;

eSheet1 = eSheets.get('Item', 1);
eSheet1.Activate;

% Put a MATLAB array into Excel.
A = [1 2; 3 4];
eActivesheetRange = e.Activesheet.get('Range', 'A1:B2');
eActivesheetRange.Value = A;

% Get back a range.
% It will be a cell array, since the cell range
% can contain different types of data.
eRange = e.Activesheet.get('Range', 'A1:B2');
B = eRange.Value;

% Convert to a double matrix. The cell array must contain only
% scalars.
B = reshape([B{:}], size(B));

% Now, save the workbook.
eWorkbook.SaveAs('myfile.xls');

% Avoid saving the workbook and being prompted to do so
eWorkbook.Saved = 1;
eWorkbook.Close;

% Quit Excel and delete the server.
e.Quit;
```

```
e.delete;
```

Note Make sure that you always close any workbooks that you add in Excel. This can prevent potential memory leaks.

Connecting to an Existing Excel Application

You can give MATLAB access to a file that is open by another application by creating a new COM server from the MATLAB client, and then opening the file through this server. This example shows how to do this for an Excel application that has a file `weekly_log.xls` open:

```
excelapp = actxserver('Excel.Application');
wkbk = excelapp.Workbooks;
wdata = wkbk.Open('d:\weatherlog\weekly_log.xls');
```

To see what methods are available, type

```
wdata.methods
   Methods for class Interface.Microsoft_Excel_10.0_
      Object_Library._Workbook:

   AcceptAllChanges     LinkInfo        ReloadAs
   Activate             LinkSources     RemoveUser
      :                    :               :
      :                    :               :
```

Access data from the spreadsheet by selecting a particular sheet (called `'Week 12'` in the example), selecting the range of values (the rectangular area defined by `D1` and `F6` here), and then reading from this range:

```
sheets = wdata.Sheets;
sheet12 = sheets.Item('Week 12');
range = sheet12.get('Range', 'D1', 'F6');
range.value

ans =
    'Temp.'      'Heat Index'    'Wind Chill'
    [78.4200]    [        32]    [        37]
```

```
    [69.7300]    [        27]    [        30]
    [77.6500]    [        17]    [        16]
    [74.2500]    [        -5]    [         0]
    [68.1900]    [        22]    [        35]

wkbk.Close;
excelapp.Quit;
```

Running a Macro in an Excel Server Application

In the example below, MATLAB runs Microsoft Excel in a COM server and invokes a macro that has been defined within the active Excel spreadsheet file. The macro, `init_last`, takes no input parameters and is called from the MATLAB client using the statement

```
handle.ExecuteExcel4Macro('!macroname()');
```

Start the example by opening the spreadsheet file and recording a macro. The macro used here simply sets all items in the last column to zero. Save your changes to the spreadsheet.

Next, in MATLAB, create a COM server running an Excel application, and open the spreadsheet:

```
h = actxserver('Excel.Application');
wkbk = h.Workbooks;
file = wkbk.Open('d:\weatherlog\weekly.xls');
```

Open the sheet that you want to change, and retrieve the current values in the range of interest:

```
sheets = file.Sheets;
sheet12 = sheets.Item('Week 12');
range = sheet12.get('Range', 'D1', 'F5');
range.Value
ans =
    [     78]    [        32]    [        37]
    [     69]    [        27]    [        30]
    [     77]    [        17]    [        16]
    [     74]    [        -5]    [        -1]
    [     68]    [        22]    [        35]
```

Now execute the macro, and verify that the values have changed as expected:

```
h.ExecuteExcel4Macro('!init_last()');
range.Value
ans =
    [     78]    [         32]    [          0]
    [     69]    [         27]    [          0]
    [     77]    [         17]    [          0]
    [     74]    [         -5]    [          0]
    [     68]    [         22]    [          0]
```

MATLAB COM Client Demo

MATLAB includes a demo illustrating the use of the COM Client with MATLAB. To run the demo, click the **Demos** tab in the MATLAB Help browser. Click to expand the folder called `External Interfaces` and select `Programming with COM`.

Additional COM Client Information

In this section...

Using COM Collections

COM *collections* are a way to support groups of related COM objects that can be iterated over. A collection is itself a special interface with a `Count` property (read only), which contains the number of items in the collection, and an `Item` method, which allows you to retrieve a single item from the collection.

The `Item` method is indexed, which means that it requires an argument that specifies which item in the collection is being requested. The data type of the index can be any data type that is appropriate for the particular collection and is specific to the control or server that supports the collection. Although integer indices are common, the index could just as easily be a string value. Often, the return value from the `Item` method is itself an interface. Like all interfaces, this interface should be released when you are finished with it.

This example iterates through the members of a collection. Each member of the collection is itself an interface (called `Plot` and represented by a MATLAB COM object called `hPlot`.) In particular, this example iterates through a collection of `Plot` interfaces, invokes the `Redraw` method for each interface, and then releases each interface:

```
hCollection = hControl.Plots;
for i = 1:hCollection.Count
   hPlot = hCollection.invoke('Item', i);
   hPlot.Redraw;
   hPlot.release;
end;
hCollection.release;
```

Using MATLAB as a DCOM Client

Distributed Component Object Model (DCOM) is a protocol that allows clients to use remote COM objects over a network. Additionally, MATLAB can be used as a DCOM client with remote Automation servers if the operating system on which MATLAB is running is DCOM enabled.

Note If you use MATLAB as a remote DCOM server, all MATLAB windows appears on the remote machine.

MATLAB COM Support Limitations

The following is a list of limitations of MATLAB COM support:

- MATLAB only supports indexed collections.
- COM controls are not printed with figure windows.
- “Unsupported Data Types” on page 8-98

MATLAB COM Automation Server Support

In this section...

Introduction

Automation is a COM protocol that allows one application (the *controller*) to control objects exported by another application (the *server*). MATLAB on Microsoft Windows supports COM Automation server capabilities. Any Windows program that can be configured as an Automation controller can control MATLAB. Some examples of applications that can be Automation controllers are Microsoft Excel, Microsoft Access, Microsoft Project, and many Visual Basic and Visual C++ programs.

Note If you plan to build your client application using C, C++, or Fortran, we recommend you use MATLAB Engine instead of an Automation server.

Creating the MATLAB Server

A controller needs a programmatic identifier (ProgID) to identify the server. MATLAB's ProgID is `matlab.application`.

Exactly how you create an Automation server depends on the controller you are using. Consult your controller's documentation for this information.

If your controller is a MATLAB application, you can create the Automation server using `actxserver`:

```
h = actxserver('matlab.application')
h =
   COM.matlab.application
```

This command automatically creates the Automation server. You can also create the server manually. See “Creating the Server Manually” on page 8-122.

Shared and Dedicated Servers

The MATLAB Automation server has two modes:

- Shared — One or more client applications connect to the same MATLAB server. The server is shared between all clients.
- Dedicated — Each client application creates its own dedicated MATLAB server.

If you use `matlab.application` as your ProgID, MATLAB creates a shared server. See “Specifying a Shared or Dedicated Server” on page 8-123.

Startup Directory

The Automation server starts up in the *`matlabroot`*`\bin\win32` directory. If this is not the startup directory, the newly created server does not run the MATLAB startup file (`startup.m`) and does not have access to files in that directory.

To access files in the startup directory, do one of the following:

- Set the server’s working directory to the startup directory (using `cd`) and add the startup directory to the server’s MATLAB path (using `addpath`).
- Include the path name to the startup directory when referencing those files.

Get the Status of a MATLAB Automation Server

Using the `enableservice` function you can learn the current state of a MATLAB Automation server. The function returns a logical value, where logical `1` (`true`) means MATLAB is an Automation server and logical `0` (`false`) means MATLAB is not an Automation server.

For example, if you type

```
enableservice('AutomationServer')
```

and MATLAB displays:

```
ans =

     1
```

then MATLAB is currently an Automation server.

Creating a MATLAB Automation Server from Visual Basic .NET

If you are using a Visual Basic client application to access a MATLAB Automation server, you can start the server using one of the following two methods:

- `New MLApp.MLApp`
- `CreateObject`

The first method requires you to reference the MATLAB *type library* in your Visual Basic project. By using the Object Browser of your Visual Basic client application you can see what methods are available from a MATLAB Automation server. Use the following procedure to reference the MATLAB Application Type Library:

1. Select the **Project** menu.
2. Select **Reference** from the subsequent menu.
3. Check the box next to the **MATLAB Application Type Library**.
4. Click **OK**.

Start the server with the following code:

```
Matlab = New MLApp.MLApp
```

View MATLAB automation methods from the Visual Basic Object Browser under the Library called `MLAPP`.

Alternatively, use the following code to start the server:

```
MatLab = CreateObject("Matlab.Application")
```

Connecting to an Existing MATLAB Server

It is not always necessary to create a new instance of a MATLAB server whenever your application needs some task done in MATLAB. Clients can connect to an existing MATLAB Automation server using the `actxGetRunningServer` function or by using a command similar to the Visual Basic .NET `GetObject` command.

Using Visual Basic .NET

The Visual Basic .NET command shown here returns a handle `h` to the MATLAB server application:

```
h = GetObject(, "matlab.application")
```

Note It is important to use the syntax shown above to connect to an existing MATLAB Automation server. Omit the first argument, and make sure the second argument is as shown.

The following Visual Basic .NET example connects to an existing MATLAB server, then executes a plot command in the server. If you do not already have a MATLAB server running, create one following the instructions in “Creating a MATLAB Automation Server from Visual Basic .NET” on page 8-114.

```
Dim h As Object
h = GetObject(, "matlab.application")

' Handle h should be valid now. Test it by calling Execute.
h.Execute ("plot([0 18], [7 23])")
```

MATLAB Automation Server Functions and Properties

In this section...

Introduction

As an Automation server, MATLAB provides functions and properties to enable an Automation controller to manipulate data in the MATLAB workspace. MATLAB can be both a controller and a server. The examples in this section use a MATLAB M-file as the client application. "Examples of a MATLAB Automation Server" on page 8-125 shows you how to access MATLAB from other applications.

This section explains how to call functions in the MATLAB Automation server and how to use properties that affect the server. These are shown in the following tables and are described in individual function reference pages.

For a complete list of these functions, see "Component Object Model and ActiveX" in the MATLAB Function Reference documentation.

Executing Commands in the MATLAB Server

The client program can execute commands in the MATLAB server using these functions.

Function	Description
Execute	Execute MATLAB command in server
Feval	Evaluate MATLAB command in server

Using Execute

Use Execute when you want the MATLAB server to execute a command that can be expressed in a single string:

```
h = actxserver('matlab.application');

h.PutWorkspaceData('A', 'base', rand(6))
h.Execute('A(4:6,:) = [];'); % remove rows 4-6
B = h.GetWorkspaceData('A', 'base')
B =
    0.6208    0.2344    0.6273    0.3716    0.7764    0.7036
    0.7313    0.5488    0.6991    0.4253    0.4893    0.4850
    0.1939    0.9316    0.3972    0.5947    0.1859    0.1146
```

Using Feval

Use Feval when you want the server to execute commands that you cannot express in a single string. The following example uses variables defined in the client, rows and cols, to modify the server.

This is a continuation of the example above:

```
rows = 6;   cols = 3;
h.Feval('reshape', 0, 'A=', rows, cols);
```

MATLAB interprets A in the expression 'A=' as a server variable name.

The reshape operation in the statement above does not make an assignment to the server variable A; it is equivalent to the following MATLAB statement:

```
reshape(A,6,3)
```

which returns a result, but does not assign the new array. If you get the variable A from the server, it is unchanged:

```
B = h.GetWorkspaceData('A', 'base')
B =
    0.6208    0.2344    0.6273    0.3716    0.7764    0.7036
    0.7313    0.5488    0.6991    0.4253    0.4893    0.4850
    0.1939    0.9316    0.3972    0.5947    0.1859    0.1146
```

Use the `Feval` method returned value to get the result of this type of operation. For example, the following statement reshapes the server-side array `A` and returns the result of this MATLAB operation in the client-side variable `a`.

```
a = h.Feval('reshape', 1, 'A=', rows, cols);
```

The `Feval` method returns a cell array:

```
a{:}
ans =
    0.6208    0.6273    0.7764
    0.7313    0.6991    0.4893
    0.1939    0.3972    0.1859
    0.2344    0.3716    0.7036
    0.5488    0.4253    0.4850
    0.9316    0.5947    0.1146
```

Date Data Type

When you need to pass a `VT_DATE` type input to a Visual Basic program or an ActiveX control method, you can use the MATLAB class `COM.date`. For example:

```
d = COM.date(2005,12,21,15,30,05);
get(d)
     Value: 7.3267e+005
    String: '12/21/2005 3:30:05 PM'
```

You can use `now` to set the `Value` property to a date number:

```
d.Value = now;
```

Exchanging Data with the Server

MATLAB provides functions to read and write data to any workspace of a MATLAB server. In these commands, pass the name of the variable to read or write, and the name of the workspace holding that data.

Function	Description
`GetCharArray`	Get character array from server
`GetFullMatrix`	Get matrix from server
`GetWorkspaceData`	Get any type of data from server
`PutCharArray`	Store character array in server
`PutFullMatrix`	Store matrix in server
`PutWorkspaceData`	Store any type of data in server

The `Get/PutCharArray` functions read and write string values to the MATLAB server.

The `Get/PutFullMatrix` functions pass data as a `SAFEARRAY` data type. You can use these functions with any client that supports the `SAFEARRAY` type. This includes MATLAB and Visual Basic clients.

The `Get/PutWorkspaceData` functions pass data as a `variant` data type. Use these functions with any client that supports the `variant` type. These functions are especially useful for VBScript clients because VBScript does not support the `SAFEARRAY` data type.

In this example, write a string to variable `str` in the base workspace of the MATLAB server and read it back to the client:

```
h = actxserver('matlab.application');
h.PutCharArray('str', 'base', ...
   'He jests at scars that never felt a wound.');

S = h.GetCharArray('str', 'base')
S =
  He jests at scars that never felt a wound.
```

Controlling the Server Window

These functions enable you to make the server window visible or to minimize it.

Function	Description
`MaximizeCommandWindow`	Display server window on Windows desktop
`MinimizeCommandWindow`	Minimize size of server window

In this example, create a COM server running MATLAB and minimize it:

```
h = actxserver('matlab.application');
h.MinimizeCommandWindow;
```

Terminating the Server Process

When you are finished with the MATLAB server, use these functions to quit the MATLAB session and terminate the server process.

Function	Description
`Quit`	Quit the MATLAB session
`delete`	Terminate MATLAB server process

To quit MATLAB, type

```
h.Quit;
```

To terminate the server process, type

```
h.delete;
```

Client-Specific Information

This section provides information specific to MATLAB and Visual Basic .NET clients only.

For MATLAB Clients

To see a summary of all functions along with the required syntax, use the `invoke` function as follows:

```
handle = actxserver('matlab.application');
handle.invoke
```

For Visual Basic .NET Clients

Data types for the arguments and return values of the server functions are expressed as Automation data types, which are language-independent types defined by the Automation protocol.

For example, `BSTR` is a wide-character string type defined as an Automation type, and is the same data format used by Visual Basic to store strings. Any COM-compliant controller should support these data types, although the details of how you declare and manipulate these are controller specific.

Using the Visible Property

You have the option of making MATLAB visible or not by setting the `Visible` property. When visible, MATLAB appears on the desktop, enabling the user to interact with it. This might be useful for such purposes as debugging. When not visible, the MATLAB window does not appear, thus perhaps making for a cleaner interface and also preventing any interaction with the application.

By default, the `Visible` property is enabled, or set to `1`:

```
h = actxserver('matlab.application');
h.Visible
ans =
     1
```

You can change the `Visible` property by setting it to `0` (invisible) or `1` (visible). The following command removes the server application window from the desktop:

```
h.Visible = 0;
h.Visible
ans =
     0
```

Additional Automation Server Information

In this section...

Creating the Server Manually

An Automation server is created automatically by Windows when a controller application first establishes a server connection. Alternatively, you may choose to create the server manually, prior to starting any of the client processes.

To manually create a MATLAB server, use the `/Automation` switch in the MATLAB startup command. You can do this from the DOS command line by typing

```
matlab /Automation
```

Alternatively, you can add this switch every time you run MATLAB, as follows:

1. Right-click the MATLAB shortcut icon

   and select **Properties** from the context menu. The Properties dialog box for `matlab.exe` opens to the **Shortcut** tab.

2. In the **Target** field, add `/Automation` to the end of the target path for `matlab.exe`. Be sure to include a space between the file name and the symbol `/`. For example:

   ```
   "C:\Program Files\MATLAB\R2006a\bin\win32\MATLAB.exe /Automation"
   ```

Note When Windows automatically creates a MATLAB server, it too uses the `/Automation` switch. In this way, MATLAB servers are differentiated from other MATLAB sessions. This protects controllers from interfering with any interactive MATLAB sessions that may be running.

Specifying a Shared or Dedicated Server

You can start the MATLAB Automation server in one of two modes – shared or dedicated. A dedicated server is dedicated to a single client; a shared server is shared by multiple clients. The mode is determined by the programmatic identifier (ProgID) used by the client to start MATLAB.

Starting a Shared Server

The ProgID, `matlab.application`, specifies the default mode, which is shared. You can also use the version-specific ProgID, `matlab.application.N.M`, where `N` is the major version and `M` is the minor version of your MATLAB. For example, use `N = 7` and `M = 4` for MATLAB 7.4.

Once MATLAB is started as a shared server, all clients that request a connection to MATLAB using the shared server ProgID connect to the already running instance of MATLAB. In other words, there is never more than one instance of a shared server running, since it is shared by all clients that use the shared server ProgID.

Starting a Dedicated Server

To specify a dedicated server, use the ProgID, `matlab.application.single`, (or the version-specific ProgID, `matlab.application.single.N.M`).

Each client that requests a connection to MATLAB using a dedicated ProgID creates a separate instance of MATLAB; it also requests the server not be shared with any other client. Therefore, there can be several instances of a dedicated server running simultaneously, since the dedicated server is not shared by multiple clients.

Using MATLAB as a DCOM Server

Distributed Component Object Model (DCOM) is a protocol that allows COM connections to be established over a network. If you are using a version of Windows that supports DCOM and a controller that supports DCOM, you can use the controller to start a MATLAB server on a remote machine.

To do this, DCOM must be configured properly, and MATLAB must be installed on each machine that is used as a client or server. (Even though the client machine may not be running MATLAB in such a configuration, the

client machine must have a MATLAB installation because certain MATLAB components are required to establish the remote connection.) Consult the DCOM documentation for how to configure DCOM for your environment.

Examples of a MATLAB Automation Server

In this section...

Example — Running an M-File from Visual Basic .NET

This example calls a user-defined M-file function named `solve_bvp` from a Visual Basic client application through a COM interface. It also plots a graph in a new MATLAB window and performs a simple computation:

```
Dim MatLab As Object
Dim Result As String
Dim MReal(1, 3) As Double
Dim MImag(1, 3) As Double

MatLab = CreateObject("Matlab.Application")

'Calling m-file from VB
'Assuming solve_bvp exists at specified location
Result = MatLab.Execute("cd d:\matlab\work\bvp")
Result = MatLab.Execute("solve_bvp")

'Executing other MATLAB commands
Result = MatLab.Execute("surf(peaks)")
Result = MatLab.Execute("a = [1 2 3 4; 5 6 7 8]")
Result = MatLab.Execute("b = a + a ")
'Bring matrix b into VB program
MatLab.GetFullMatrix("b", "base", MReal, MImag)
```

Example — Viewing Methods from a Visual Basic .NET Client

You can find out what methods are available from a MATLAB Automation server using the Object Browser of your Visual Basic client application. To do this, follow this procedure in the client application to reference the MATLAB Application Type Library:

1. Select the **Project** menu.
2. Select **Reference** from the subsequent menu.
3. Check the box next to the **MATLAB Application Type Library**.
4. Click **OK**.

This enables you to view MATLAB Automation methods from the Visual Basic Object Browser under the Library called `MLAPP`. You can also see a list of MATLAB Automation methods when you use the term `Matlab` followed by a period. For example:

```
Dim Matlab As MLApp.MLApp
Private Sub View_Methods()
Matlab = New MLApp.MLApp
'The next line shows a list of MATLAB Automation methods
Matlab.
End Sub
```

Example — Calling MATLAB from a Web Application

This example shows you how to create a Web page that uses MATLAB as an Automation server. For another example using ASP.NET, see Technical Support solution 1–3JJZWN at `http://www.mathworks.com/support/solutions/data/1-3JJZWN.html?solution=1-3J`

You can invoke MATLAB as an Automation server from any language that supports COM, so for Web applications, you can use VBScript and JavaScript. While this example is simple, it illustrates techniques for passing commands to MATLAB and writing data to and retrieving data from the MATLAB workspace. See “Exchanging Data with the Server” on page 8-119 for related functions.

VBScript and HTML forms are combined in this example to create an interface that enables the user to select a MATLAB plot type from a pull-down menu, click a button, and create the plot in a MATLAB figure window. To accomplish this, the HTML file contains code that:

- Starts MATLAB as an Automation server via a VBScript.
- When users click a button on the HTML page, a VBScript executes that:
  - **a** Determines the type of plot selected.
  - **b** Forms a command string to create the type of plot selected.
  - **c** Forms a string describing the type of plot selected, which passes to the MATLAB base workspace in a variable.
  - **d** Executes the MATLAB command.
  - **e** Retrieves the descriptive string from the MATLAB workspace.
  - **f** Updates the text box on the HTML page.

Here is the HTML used to create this example:

```
<HTML>
<HEAD>
<TITLE>Example of calling MATLAB from VBScript</TITLE>
</HEAD>
<BODY>
<FONT FACE = "Arial, Helvetica, Geneva" SIZE = "+1" COLOR = "maroon">
Example of calling MATLAB from VBScript
</FONT>
<FONT FACE = "Arial, Helvetica, Geneva" SIZE = "-1">

<!-- %%%%%%%%%%%%%%%%%%%% BEGIN SCRIPT %%%%%%%%%%%%%%%%%%%% -->
<SCRIPT LANGUAGE="VBScript">
<!-- Invoke MATLAB as a COM Automation server upon loading page
' Initialize global variables
Dim MatLab 'COM Automation server variable
Dim MLcmd 'string to send to MATLAB for execution
' Invoke COM Automation server
Set MatLab = CreateObject("Matlab.Application")
' End initialization script -->
</SCRIPT>
```

```
<!-- %%%%%%%%%%%%%%%%%%%% END SCRIPT %%%%%%%%%%%%%%%%%%%% -->
<!-- Create form to contain controls -->
<FORM NAME="Form">
<!-- Create pulldown menu to select which plot to view -->
<P>Select type of plot:
<SELECT NAME=plot_choice>
 <OPTION SELECTED VALUE=first>Line</OPTION>
 <OPTION VALUE=second>Peaks</OPTION>
 <OPTION VALUE=third>Logo</OPTION>
</SELECT>
<!-- Create button to create plot and fill text area -->
<P>Create figure:
<INPUT TYPE="button" NAME="plot_but" VALUE="Plot">

<!-- %%%%%%%%%%%%%%%%%%%% BEGIN SCRIPT %%%%%%%%%%%%%%%%%%%% -->
<SCRIPT FOR="plot_but" EVENT="onClick" LANGUAGE="VBScript">
<!-- Start script
Dim plot_choice
Dim text_str   'string to display in text area
Dim form_var 'form object variable
Set form_var = Document.Form
plot_choice = form_var.plot_choice.value
' Condition MATLAB command to execute based on plot choice
If plot_choice = "first" Then
   MLcmd = "figure; plot(1:10);"
   text_str = "Simple line plot of 1 to 10"
   Call MatLab.PutCharArray("text","base",text_str)
Elseif plot_choice = "second" Then
   MLcmd = "figure; mesh(peaks);"
   text_str = "Mesh plot of peaks"
   Call MatLab.PutCharArray("text","base",text_str)
Elseif plot_choice = "third" Then
   MLcmd = "figure; logo;"
   text_str = "MATLAB logo"
   Call MatLab.PutCharArray("text","base",text_str)
End If
' Execute command in MATLAB
MatLab.execute(MLcmd)
' Get variable from MATLAB into VBScript
```

```
Call MatLab.GetWorkspaceData("text","base","text_str")
' Update text area
form_var.plottext.value = text_str
' End script -->
</SCRIPT>

<!-- %%%%%%%%%%%%%%%%%%%% END SCRIPT %%%%%%%%%%%%%%%%%%%% -->
<!-- Create text area to show text -->
<P><TEXTAREA NAME="plottext" ROWS="1" COLS="50"
CONTENTEDITABLE="false"></TEXTAREA>
</FONT>
</FORM>
</BODY>
</HTML>
```

Example — Calling MATLAB from a C# Client

This example creates data in the client C# program and passes it to MATLAB. The matrix (containing complex data) is then passed back to the C# program.

The reference to the MATLAB Type Library for C# is:

```
MLApp.MLAppClass matlab = new MLApp.MLAppClass();
```

Here is the complete example:

```
using System;
namespace ConsoleApplication4
{
class Class1
{
[STAThread]
static void Main(string[] args)
{
MLApp.MLAppClass matlab = new MLApp.MLAppClass();

System.Array pr = new double[4];
pr.SetValue(11,0);
pr.SetValue(12,1);
pr.SetValue(13,2);
pr.SetValue(14,3);
```

```
System.Array pi = new double[4];
pi.SetValue(1,0);
pi.SetValue(2,1);
pi.SetValue(3,2);
pi.SetValue(4,3);

matlab.PutFullMatrix("a", "base", pr, pi);

System.Array prresult = new double[4];
System.Array piresult = new double[4];

matlab.GetFullMatrix("a", "base", ref prresult, ref piresult);
}
}
}
```

9

Web Services in MATLAB

What Are Web Services in MATLAB?

In this section...

Introduction

The term *Web service* encompasses a set of XML-based technologies for making remote procedure calls over a network. The network can be a local intranet within an organization or a remote server on the other side of the globe. In short, Web services let applications running on disparate operating systems and development platforms communicate with each other.

MATLAB acts as a Web service client by sending requests to a server and handling the responses. MATLAB implements the following Web service technologies:

- Simple Object Access Protocol (SOAP)
- Web Services Description Language (WSDL)

SOAP defines a standard for making XML-based exchanges between clients and servers. The client initiates the client/server interaction, which usually takes place over HTTP. When the server receives the request, which includes the operation to be performed and any necessary parameters, it sends back a response.

Web Service Examples

The following example shows a simple HTTP-based SOAP request for retrieving the local temperature by zip code:

```
<?xml version="1.0" encoding="UTF-8"?>
<soapenv:Envelope
    xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
```

```
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema">
  <soapenv:Body>
    <ns1:getTemp
        xmlns:ns1="urn:xmethods-Temperature-Demo"
        soapenv:encodingStyle=
          "http://schemas.xmlsoap.org/soap/encoding/">
      <zipcode xsi:type="xsd:string">94041</zipcode>
    </ns1:getTemp>
  </soapenv:Body>
</soapenv:Envelope>
```

The SOAP protocol defines an envelope, and inside the envelope, defines a message body. Also, inside the message body, the SOAP method `getTempRequest` is specified, as well as the `zipcode` parameter.

In the response sent by the server, notice that the SOAP message structure is similar:

```
<?xml version="1.0" encoding="UTF-8"?>
<soapenv:Envelope
    xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema">
  <soapenv:Body>
    <ns1:getTempResponse
        xmlns:ns1="urn:xmethods-Temperature-Demo"
        soapenv:encodingStyle=
          "http://schemas.xmlsoap.org/soap/encoding/">
      <return xsi:type="xsd:float">68.0</return>
    </ns1:getTempResponse>
  </soapenv:Body>
</soapenv:Envelope>
```

In the code, SOAP defines the envelope and message body as well as the response (`return`).

Most SOAP implementations use WSDL, an XML-based language, to describe and locate available services. The following example shows the message and

service definitions of the WSDL file for the temperature service from the previous examples:

```
<?xml version="1.0" encoding="UTF-8"?>
<definitions name="TemperatureService"
    targetNamespace=
      "http://www.xmethods.net/sd/TemperatureService.wsdl"
    xmlns:tns=
      "http://www.xmethods.net/sd/TemperatureService.wsdl"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
    xmlns="http://schemas.xmlsoap.org/wsdl/">
  <message name="getTempRequest">
   <part name="zipcode" type="xsd:string"/>
  </message>
  <message name="getTempResponse">
    <part name="return" type="xsd:float"/>
  </message>
  <portType name="TemperaturePortType">
    <operation name="getTemp">
      <input message="tns:getTempRequest"/>
      <output message="tns:getTempResponse"/>
    </operation>
  </portType>
  <binding name="TemperatureBinding"
      type="tns:TemperaturePortType">
    <soap:binding style="rpc"
        transport="http://schemas.xmlsoap.org/soap/http"/>
    <operation name="getTemp">
      <soap:operation soapAction=""/>
      <input>
        <soap:body use="encoded"
            namespace="urn:xmethods-Temperature-Demo"
            encodingStyle=
              "http://schemas.xmlsoap.org/soap/encoding/"/>
      </input>
      <output>
        <soap:body use="encoded"
            namespace="urn:xmethods-Temperature-Demo"
            encodingStyle=
```

```
            "http://schemas.xmlsoap.org/soap/encoding/"/>
        </output>
      </operation>
    </binding>
    <service name="TemperatureService">
      <documentation>Returns current temperature in a given U.S.
        zipcode</documentation>
      <port name="TemperaturePort"
          binding="tns:TemperatureBinding">
        <soap:address
          location=
          "http://services.xmethods.net:80/soap/servlet/rpcrouter"/>
      </port>
    </service>
  </definitions>
```

The code defines the request and response message actions (`getTempRequest` and `getTempResponse`) and the service name (`TemperatureService`).

Understanding Data Type Conversions

Using SOAP data types, MATLAB automatically converts XML data types to native MATLAB data types and vice versa. The following table contains the XML data type with the corresponding MATLAB data type.

XML Data Type	MATLAB Data Type
`string`	`char` array
`boolean`	`logical` scalar
`decimal`	`double` scalar
`float`	`double` scalar
`double`	`double` scalar
`duration`	`double` scalar
`time`	`double` scalar
`date`	`double` scalar
`gYearMonth`	`char` array

XML Data Type	MATLAB Data Type
gYear	char array
gMonthDay	char array
hexbinary	double array
base64Binary	double array
anyURI	char array
QName	char array

Finding More Information About Web Services

To learn more about SOAP, see the following resources:

- World Wide Web Consortium (W3C) SOAP specification
- Apache Axis Web Services
- W3 Schools SOAP Tutorial

To learn more about WSDL, see the following resources:

- W3C WSDL specification
- WSDL4J Project
- W3 Schools WSDL Tutorial

To find publicly available Web services and for more information about popular development platforms for Web services, see the following resources:

- XMethods
- Java Web Services
- Microsoft Developer Network—Web Services

Using Web Services in MATLAB

In this section...

Getting Started

In MATLAB, use the `createClassFromWsdl` function to call Web service methods. The function creates a MATLAB class based on the methods of the Web service application program interface (API).

Here is an example of the `createClassFromWsdl` function using a URL:

```
createClassFromWsdl('http://example.com/service.wsdl')
```

The example passes a URL to a WSDL file to the function. The following example uses a file path instead of a URL:

```
createClassFromWsdl('\myservicedirectory\service.wsdl')
```

The example passes a relative file path to the function. Keep in mind that the target file must contain WSDL.

Note To call remote Web services with MATLAB, you must have a working Internet connection.

Building a Simple Web Service

The following procedure walks you through the necessary steps to build a simple Web service. To begin, the procedure shows you how to find the Currency Exchange Rate Web service:

1. In a Web browser, go to the XMethods Web site at `http://www.xmethods.net/`.

2 In **XMethods Demo Services**, click the **Currency Exchange Rate** link near the bottom of the page.

3 On the Currency Exchange Rate Web page, find the WSDL URL, as well as links to analyze the WSDL. Click the **View RPC Profile** link.

In the RPC Profile page, find the available methods. In this case, the available method is `getRate`.

In addition to the method name, notice the input and output parameters and their data types. The output parameter returns a `float` data type. In "Understanding Data Type Conversions" on page 9-5, note that MATLAB converts `float` to a `double` scalar.

4 Enter the following code at the MATLAB command line to pass the WSDL URL to the function`createClassFromWsdl`, creating the `CurrencyExchangeService` class:

```
createClassFromWsdl(['http://www.xmethods.net/sd/2001' ...
                     '/CurrencyExchangeService.wsdl']);
ans =
    CurrencyExchangeService
```

Use the MATLAB `methods` function to view the methods associated with the `CurrencyExchangeService` class:

```
methods(CurrencyExchangeService)

   Methods for class CurrencyExchangeService:

   CurrencyExchangeService    getRate    display
```

5 In the current MATLAB directory, find the `@CurrencyExchangeService` folder. In the folder, you see the following files:

- `CurrencyExchangeService.m` — Contains the M-code for MATLAB object constructor
- `display.m` — Contains the M-code for a generic display method
- `getRate.m` — Contains the M-code for the `getRate` method

The `createClassFromWsdl` function automatically creates a file for each Web service method, a file for a generic display method, and a file for the Web service MATLAB object.

You can use the MATLAB `help` function to see the method signature, such as

```
help CurrencyExchangeService/getRate

getRate(obj,country1,country2)

      Input:
        country1 = (string)
        country2 = (string)

      Output:
        Result = (float)
```

6 Call the `getRate` method to obtain the exchange rate between two countries.

```
ces = CurrencyExchangeService;

getRate(ces, 'USA', 'France')
ans =
    5.1127

getRate(ces, 'Argentina', 'Chile')
ans =
    172.3052
```

To review, the `createClassFromWsdl` function performs the following actions:

- Fetches and parses the WSDL to determine the Web service API
- Creates a folder, such as `@CurrencyExchangeService`, in the current MATLAB directory
- Creates the necessary M files in the directory, such as `getRate.m`, `display.m`, and `CurrencyExchangeService.m`, based on the service API

For more information about object-oriented programming in MATLAB, see the MATLAB Programming documentation.

Building MATLAB Applications with Web Services

In this section...

Understanding Web Service Limitations

At the time of this writing, Web service technologies continue to evolve and change. The following list contains possible limitations to consider before building MATLAB applications with Web services:

- The majority of Web services are made available via HTTP. Like the Internet itself, quality of service cannot be guaranteed. Therefore, your application performance might suffer or might appear unreliable.
- Web services and the related technologies like WSDL and SOAP are relatively new. As with any new technology, established procedures and best practices are still being written.
- If you plan to call remote Web services, make sure you validate their accuracy and reliability. Also, Web services that are free today might not remain free in the future.

Programming with Web Services

Because the Internet is inherently unpredictable, make sure to take proper precautions in programming with Web services. One way to minimize the risk is to use common program control and error-handling routines.

Common programming techniques you might use include

- Try - Catch statements can catch errors that result from method calls as well as creating the MATLAB class from the WSDL. The following example shows a method call in a `try - catch` statement:

```
try
 r = getRate(CurrencyExchangeService, 'USA', 'France');
catch
 r = Nan;
 disp(lasterr);
end
```

- If statements can check that expressions or statements are true or false. The following example uses an `if` statement to cache the WSDL locally:

```
% Note: Code contains line breaks for formatting
wsdlUrl = ['http://www.xmethods.net/sd/2001' ...
           '/CurrencyExchangeService.wsdl'];
wsdlFile = 'CurrencyExchangeService.wsdl';
if ~(exist(wsdlFile,'file') == 2)
    urlwrite(wsdlUrl,wsdlFile);
end
```

- Error functions can be used to throw specific errors. The following example shows an `error` function used in an `try - catch` statement:

```
try
 r = getRate(CurrencyExchangeService, 'USA', 'France');
catch
 error('Could not return exchange rate');
end
```

For more information about program control and error-handling statements, see the MATLAB Programming documentation.

Simple M-File Example

The following M-file example provides a simple demonstration of programming with Web services. The script takes an array of country name strings and uses the Currency Exchange Rate Web service to return the rates of exchange between each pair of countries. It then runs the `max`, and `min` functions on the exchange rates:

```
% Note: Code contains line breaks for formatting
% Create a cell array with the country names:
```

```
C = { ...
   'USA', 'France'; ...
   'Argentina', 'Chile'; ...
   'Morocco', 'Portugal'; ...
   'Germany', 'Denmark'};

% Create empty array to contain exchange rate output
rates = {};

wsdlUrl = ['http://www.xmethods.net/sd/2001' ...
           '/CurrencyExchangeService.wsdl'];
wsdlFile = 'CurrencyExchangeService.wsdl';
if ~(exist(wsdlFile, 'file') == 2)
    urlwrite(wsdlUrl, wsdlFile);
end

% Catch errors during class creation
try
    % Create class from WSDL
    createClassFromWsdl(wsdlFile);
catch
    % Throw error
    error('Unable to create WSDL class');
end

ces = CurrencyExchangeService;

% Iterate through the country array
count = length(C);
for x = 1:count
    try
        % Call the getRate method
        r = getRate(ces, C{x,:});
    catch
        % Throw error
        r = NaN;
        warning(lasterr);
    end
    % Concatenate exchange rates to array
    rates = horzcat(rates, r);
```

```
end

for x = 1:count
   disp(['Exchange rate for ' C{x,1} ' and ' C{x,2} ':'])
   disp(rates{x})
end
disp(' ')

% Display highest rate
disp('Highest exchange rate:');
disp(max([rates{:}]));
disp(' ')

% Display lowest rate
disp('Lowest exchange rate:');
disp(min([rates{:}]));
```

Serial Port I/O

Disconnecting and Cleaning Up (p. 10-74)	Disconnect the serial port object from the device, and remove the object from memory and from the workspace

Introduction

In this section...

What Is the MATLAB Serial Port Interface?

The MATLAB serial port interface provides direct access to peripheral devices such as modems, printers, and scientific instruments that you connect to your computer's serial port. This interface is established through a serial port object. The serial port object supports functions and properties that allow you to

- Configure serial port communications
- Use serial port control pins
- Write and read data
- Use events and callbacks
- Record information to disk

Additional serial port functionality is available by using Instrument Control Toolbox. In addition to command-line access, Instrument Control Toolbox provides a graphical tool called the Test & Measurement Tool, which allows you to communicate with, configure, and transfer data with your serial device without writing code. The Test & Measurement Tool generates MATLAB code for your serial device that you can later reuse to communicate with your device or to develop GUI-based applications. Instrument Control Toolbox also includes additional serial I/O utility functions that facilitate object creation and configuration, instrument communication, and so on. Instrument Control Toolbox also lets you communicate with GPIB- or VISA-compatible instruments.

If you want to communicate with PC-compatible data acquisition hardware such as multifunction I/O boards, you need Data Acquisition Toolbox.

For more information about these products, visit the MathWorks Web site at `http://www.mathworks.com/products`.

Supported Serial Port Interface Standards

Over the years, several serial port interface standards have been developed. These standards include RS-232, RS-422, and RS-485 - all of which are supported by the MATLAB serial port object. Of these, the most widely used interface standard for connecting computers to peripheral devices is RS-232.

This guide assume you are using the RS-232 standard, which is discussed in "Overview of the Serial Port" on page 10-5. Refer to your computer and device documentation to see which interface standard you can use.

Supported Platforms

The MATLAB serial port interface is supported on Microsoft Windows 32-bit, Linux 32-bit, and Sun Solaris 64-bit platforms.

Using the Examples with Your Device

Many of the examples in this section reflect specific peripheral devices connected to a PC serial port — in particular a Tektronix TDS 210 two-channel oscilloscope connected to the COM1 port. Therefore, many of the string commands are specific to this instrument.

If your peripheral device is connected to a different serial port, or if it accepts different commands, modify the examples accordingly.

Overview of the Serial Port

In this section...

Introduction

For many serial port applications, you can communicate with your device without detailed knowledge of how the serial port works. If your application is straightforward, or if you are already familiar with the topics mentioned above, you might want to begin with "The Serial Port Session" on page 10-19 to see how to use your serial port device with MATLAB.

What Is Serial Communication?

Serial communication is the most common low-level protocol for communicating between two or more devices. Normally, one device is a computer, while the other device can be a modem, a printer, another computer, or a scientific instrument such as an oscilloscope or a function generator.

As the name suggests, the serial port sends and receives bytes of information in a serial fashion — one bit at a time. These bytes are transmitted using either a binary (numerical) format or a text format.

The Serial Port Interface Standard

The serial port interface for connecting two devices is specified by the TIA/EIA-232C standard published by the Telecommunications Industry Association.

The original serial port interface standard was given by RS-232, which stands for Recommended Standard number 232. The term *RS-232* is still in popular use, and is used in this guide when referring to a serial communication port that follows the TIA/EIA-232 standard. RS-232 defines these serial port characteristics:

- The maximum bit transfer rate and cable length
- The names, electrical characteristics, and functions of signals
- The mechanical connections and pin assignments

Primary communication is accomplished using three pins: the Transmit Data pin, the Receive Data pin, and the Ground pin. Other pins are available for data flow control, but are not required.

Other standards such as RS-485 define additional functionality such as higher bit transfer rates, longer cable lengths, and connections to as many as 256 devices.

Connecting Two Devices with a Serial Cable

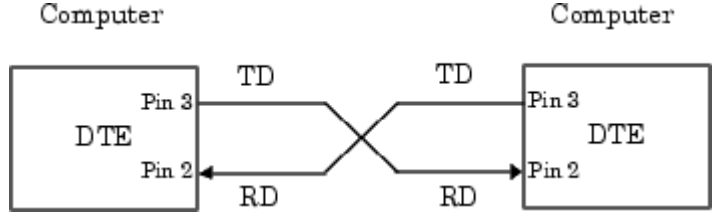
The RS-232 standard defines the two devices connected with a serial cable as the Data Terminal Equipment (DTE) and Data Circuit-Terminating Equipment (DCE). This terminology reflects the RS-232 origin as a standard for communication between a computer terminal and a modem.

Throughout this guide, your computer is considered a DTE, while peripheral devices such as modems and printers are considered DCE's. Many scientific instruments function as DTEs.

Because RS-232 mainly involves connecting a DTE to a DCE, the pin assignments are defined such that straight-through cabling is used, where pin 1 is connected to pin 1, pin 2 is connected to pin 2, and so on. A DTE to DCE serial connection using the transmit data (TD) pin and the receive data (RD) pin is shown below.

Refer to “Serial Port Signals and Pin Assignments” on page 10-7 for more information about serial port pins.

If you connect two DTEs or two DCEs using a straight serial cable, the TD pins on each device are connected to each other, and the RD pins on each device are connected to each other. Therefore, to connect two like devices, you must use a *null modem* cable. As shown below, null modem cables cross the transmit and receive lines in the cable.

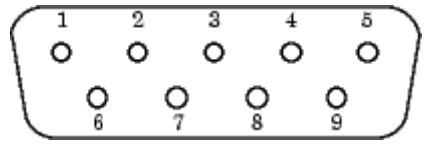


Note You can connect multiple RS-422 or RS-485 devices to a serial port. If you have an RS-232/RS-485 adaptor, you can use the MATLAB serial port object with these devices.

Serial Port Signals and Pin Assignments

Serial ports consist of two signal types: data signals and control signals. To support these signal types, as well as the signal ground, the RS-232 standard defines a 25-pin connection. However, most PCs and UNIX platforms use a 9-pin connection. In fact, only three pins are required for serial port communications: one for receiving data, one for transmitting data, and one for the signal ground.

The pin assignment scheme for a 9-pin male connector on a DTE is shown below.



The pins and signals associated with the 9-pin connector are described below. Refer to the RS-232 standard for a description of the signals and pin assignments used for a 25-pin connector.

Serial Port Pin and Signal Assignments

Pin	Label	Signal Name	Signal Type
1	CD	Carrier Detect	Control
2	RD	Received Data	Data
3	TD	Transmitted Data	Data
4	DTR	Data Terminal Ready	Control
5	GND	Signal Ground	Ground
6	DSR	Data Set Ready	Control
7	RTS	Request to Send	Control
8	CTS	Clear to Send	Control
9	RI	Ring Indicator	Control

The term *data set* is synonymous with *modem* or *device*, while the term *data terminal* is synonymous with *computer*.

Note The serial port pin and signal assignments are with respect to the DTE. For example, data is transmitted from the TD pin of the DTE to the RD pin of the DCE.

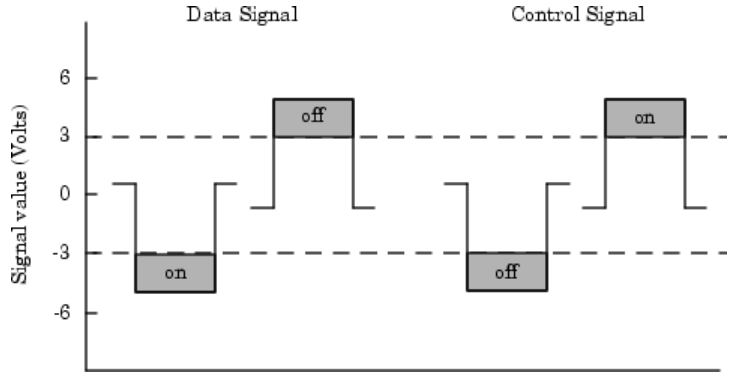
Signal States

Signals can be in either an *active* state or an *inactive* state. An active state corresponds to the binary value 1, while an inactive state corresponds to the binary value 0. An active signal state is often described as *logic 1*, *on*, *true*, or a *mark*. An inactive signal state is often described as *logic 0*, *off*, *false*, or a *space*.

For data signals, the *on* state occurs when the received signal voltage is more negative than -3 volts, while the *off* state occurs for voltages more positive than 3 volts. For control signals, the *on* state occurs when the received signal voltage is more positive than 3 volts, while the *off* state occurs for voltages more negative than -3 volts. The voltage between -3 volts and +3 volts is considered a transition region, and the signal state is undefined.

To bring the signal to the *on* state, the controlling device *unasserts* (or *lowers*) the value for data pins and *asserts* (or *raises*) the value for control pins. Conversely, to bring the signal to the *off* state, the controlling device asserts the value for data pins and unasserts the value for control pins.

The *on* and *off* states for a data signal and for a control signal are shown below.



The Data Pins

Most serial port devices support *full-duplex* communication meaning that they can send and receive data at the same time. Therefore, separate pins are used for transmitting and receiving data. For these devices, the TD, RD, and GND pins are used. However, some types of serial port devices support

only one-way or *half-duplex* communications. For these devices, only the TD and GND pins are used. This guide assumes that a full-duplex serial port is connected to your device.

The TD pin carries data transmitted by a DTE to a DCE. The RD pin carries data that is received by a DTE from a DCE.

The Control Pins

The control pins of a 9-pin serial port are used to determine the presence of connected devices and control the flow of data. The control pins include

- "The RTS and CTS Pins" on page 10-10
- "The DTR and DSR Pins" on page 10-10
- "The CD and RI Pins" on page 10-11

The RTS and CTS Pins. The RTS and CTS pins are used to signal whether the devices are ready to send or receive data. This type of data flow control—called *hardware handshaking*—is used to prevent data loss during transmission. When enabled for both the DTE and DCE, hardware handshaking using RTS and CTS follows these steps:

1. The DTE asserts the RTS pin to instruct the DCE that it is ready to receive data.
2. The DCE asserts the CTS pin indicating that it is clear to send data over the TD pin. If data can no longer be sent, the CTS pin is unasserted.
3. The data is transmitted to the DTE over the TD pin. If data can no longer be accepted, the RTS pin is unasserted by the DTE and the data transmission is stopped.

To enable hardware handshaking in MATLAB, refer to "Controlling the Flow of Data: Handshaking" on page 10-63.

The DTR and DSR Pins. Many devices use the DSR and DTR pins to signal if they are connected and powered. Signaling the presence of connected devices using DTR and DSR follows these steps:

1. The DTE asserts the DTR pin to request that the DCE connect to the communication line.
2. The DCE asserts the DSR pin to indicate it is connected.
3. DCE unasserts the DSR pin when it is disconnected from the communication line.

The DTR and DSR pins were originally designed to provide an alternative method of hardware handshaking. However, the RTS and CTS pins are usually used in this way, and not the DSR and DTR pins. Refer to your device documentation to determine its specific pin behavior.

The CD and RI Pins. The CD and RI pins are typically used to indicate the presence of certain signals during modem-modem connections.

CD is used by a modem to signal that it has made a connection with another modem, or has detected a carrier tone. CD is asserted when the DCE is receiving a signal of a suitable frequency. CD is unasserted if the DCE is not receiving a suitable signal.

RI is used to indicate the presence of an audible ringing signal. RI is asserted when the DCE is receiving a ringing signal. RI is unasserted when the DCE is not receiving a ringing signal (e.g., it is between rings).

Serial Data Format

The serial data format includes one start bit, between five and eight data bits, and one stop bit. A parity bit and an additional stop bit might be included in the format as well. The diagram below illustrates the serial data format.

The format for serial port data is often expressed using the following notation

number of data bits - parity type - number of stop bits

For example, 8-N-1 is interpreted as eight data bits, no parity bit, and one stop bit, while 7-E-2 is interpreted as seven data bits, even parity, and two stop bits.

The data bits are often referred to as a *character* because these bits usually represent an ASCII character. The remaining bits are called *framing bits* because they frame the data bits.

Bytes Versus Values

The collection of bits that comprise the serial data format is called a *byte*. At first, this term might seem inaccurate because a byte is 8 bits and the serial data format can range between 7 bits and 12 bits. However, when serial data is stored on your computer, the framing bits are stripped away, and only the data bits are retained. Moreover, eight data bits are always used regardless of the number of data bits specified for transmission, with the unused bits assigned a value of 0.

When reading or writing data, you might need to specify a *value*, which can consist of one or more bytes. For example, if you read one value from a device using the `int32` format, that value consists of four bytes. For more information about reading and writing values, refer to "Writing and Reading Data" on page 10-32.

Synchronous and Asynchronous Communication

The RS-232 standard supports two types of communication protocols: synchronous and asynchronous.

Using the synchronous protocol, all transmitted bits are synchronized to a common clock signal. The two devices initially synchronize themselves to each other, and continually send characters to stay synchronized. Even when actual data is not really being sent, a constant flow of bits allows each device to know where the other is at any given time. That is, each bit that is sent is either actual data or an idle character. Synchronous communications allows faster data transfer rates than asynchronous methods, because additional bits to mark the beginning and end of each data byte are not required.

Using the asynchronous protocol, each device uses its own internal clock, resulting in bytes that are transferred at arbitrary times. So, instead of using time as a way to synchronize the bits, the data format is used.

In particular, the data transmission is synchronized using the start bit of the word, while one or more stop bits indicate the end of the word. The requirement to send these additional bits causes asynchronous communications to be slightly slower than synchronous. However, it has the advantage that the processor does not have to deal with the additional idle characters. Most serial ports operate asynchronously.

Note When used in this guide, the terms *synchronous* and *asynchronous* refer to whether read or write operations block access to the MATLAB command line. Refer to "Controlling Access to the MATLAB Command Line" on page 10-33 for more information.

How Are the Bits Transmitted?

By definition, serial data is transmitted one bit at a time. The order in which the bits are transmitted is as follows

1. The start bit is transmitted with a value of 0.
2. The data bits are transmitted. The first data bit corresponds to the least significant bit (LSB), while the last data bit corresponds to the most significant bit (MSB).
3. The parity bit (if defined) is transmitted.
4. One or two stop bits are transmitted, each with a value of 1.

The number of bits transferred per second is given by the *baud rate*. The transferred bits include the start bit, the data bits, the parity bit (if defined), and the stop bits.

Start and Stop Bits

As described in "Synchronous and Asynchronous Communication" on page 10-12, most serial ports operate asynchronously. This means that the transmitted byte must be identified by start and stop bits. The start bit indicates when the data byte is about to begin; the stop bit(s) indicate(s) when the data byte has been transferred. The process of identifying bytes with the serial data format follows these steps:

1. When a serial port pin is idle (not transmitting data), it is in an *on* state.
2. When data is about to be transmitted, the serial port pin switches to an *off* state due to the start bit.
3. The serial port pin switches back to an *on* state due to the stop bit(s). This indicates the end of the byte.

Data Bits

The data bits transferred through a serial port might represent device commands, sensor readings, error messages, and so on. The data can be transferred as either binary data or ASCII data.

Most serial ports use between five and eight data bits. Binary data is typically transmitted as eight bits. Text-based data is transmitted as either seven bits or eight bits. If the data is based on the ASCII character set, a minimum of seven bits is required because there are 2^7 or 128 distinct characters. If an eighth bit is used, it must have a value of 0. If the data is based on the extended ASCII character set, eight bits must be used because there are 2^8 or 256 distinct characters.

The Parity Bit

The parity bit provides simple error (parity) checking for the transmitted data. The types of parity checking are shown below.

Parity Types

Parity Type	Description
Even	The data bits plus the parity bit result in an even number of 1s.
Mark	The parity bit is always 1.

Parity Types (Continued)

Parity Type	Description
Odd	The data bits plus the parity bit result in an odd number of 1s.
Space	The parity bit is always 0.

Mark and space parity checking are seldom used because they offer minimal error detection. You might choose to not use parity checking at all.

The parity checking process follows these steps:

1. The transmitting device sets the parity bit to 0 or to 1, depending on the data bit values and the type of parity-checking selected.
2. The receiving device checks if the parity bit is consistent with the transmitted data. If it is, the data bits are accepted. If it is not, an error is returned.

Note Parity checking can detect only 1-bit errors. Multiple-bit errors can appear as valid data.

For example, suppose the data bits 01110001 are transmitted to your computer. If even parity is selected, the parity bit is set to 0 by the transmitting device to produce an even number of 1s. If odd parity is selected, the parity bit is set to 1 by the transmitting device to produce an odd number of 1s.

Finding Serial Port Information for Your Platform

This section describes the ways to find serial port information for Windows and UNIX platforms.

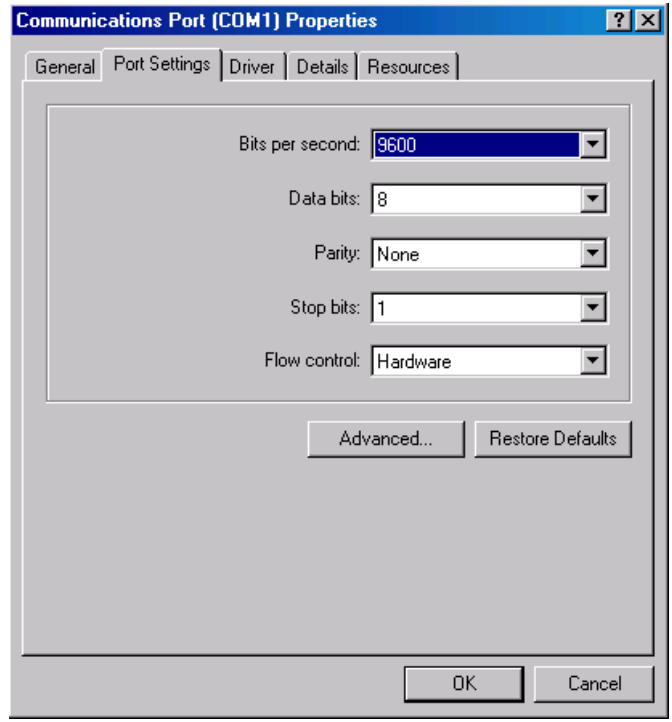
Note Your operating system provides default values for all serial port settings. However, these settings are overridden by your MATLAB code, and will have no effect on your serial port application.

Windows Platform

You can access serial port information through the **System Properties** dialog. To access this in Windows XP,

1. Right-click **My Computer** on the desktop, and select **Properties**.
2. In the **System Properties** dialog, click the **Hardware** tab.
3. Click **Device Manager**.
4. In the **Device Manager** dialog, expand the Ports node.
5. Double-click the `Communications Port (COM1)` node.
6. Select the **Port Settings** tab.

The resulting Ports dialog box is shown below.



UNIX Platform

To find serial port information for UNIX platforms, you need to know the serial port names. These names might vary between different operating systems.

On Linux, serial port devices are typically named `ttyS0`, `ttyS1`, etc. Use the `setserial` command to display or configure serial port information. For example, to display which ports are available

```
setserial -bg /dev/ttyS*
/dev/ttyS0 at 0x03f8 (irq = 4) is a 16550A
/dev/ttyS1 at 0x02f8 (irq = 3) is a 16550A
```

To display detailed information about `ttyS0`

```
setserial -ag /dev/ttyS0
/dev/ttyS0, Line 0, UART: 16550A, Port: 0x03f8, IRQ: 4
        Baud_base: 115200, close_delay: 50, divisor: 0
        closing_wait: 3000, closing_wait2: infinte
        Flags: spd_normal skip_test session_lockout
```

Note If the `setserial -ag` command does not work, make sure that you have read and write permission for the port.

For all supported UNIX platforms, use the `stty` command to display or configure serial port information. For example, to display serial port properties for `ttyS0`, enter

```
stty -a < /dev/ttyS0
```

To configure the baud rate to 4800 bits per second, enter

```
stty speed 4800 < /dev/ttyS0 > /dev/ttyS0
```

Getting Started with Serial I/O

In this section...

Example: Getting Started

This example illustrates some basic serial port commands.

If you have a device connected to the serial port COM1 and configured for a baud rate of 4800, execute the following example.

```
s = serial('COM1');
set(s,'BaudRate',4800);
fopen(s);
fprintf(s,'*IDN?')
out = fscanf(s);
fclose(s)
delete(s)
clear s
```

The `*IDN?` command queries the device for identification information, which is returned to `out`. If your device does not support this command, or if it is connected to a different serial port, modify the above example accordingly.

Note `*IDN?` is one of the commands supported by the Standard Commands for Programmable Instruments (SCPI) language, which is used by many modern devices. Refer to your device documentation to see if it supports the SCPI language.

The Serial Port Session

This example describes the steps you use to perform any serial port task from beginning to end.

The serial port *session* comprises all the steps you are likely to take when communicating with a device connected to a serial port. These steps are:

1. Create a serial port object — Create a serial port object for a specific serial port using the `serial` creation function.

   Configure properties during object creation if necessary. In particular, you might want to configure properties associated with serial port communications such as the baud rate, the number of data bits, and so on.

2. Connect to the device — Connect the serial port object to the device using the `fopen` function.

   After the object is connected, alter the necessary device settings by configuring property values, read data, and write data.

3. Configure properties — To establish the desired serial port object behavior, assign values to properties using the `set` function or dot notation.

   In practice, you can configure many of the properties at any time including during, or just after, object creation. Conversely, depending on your device settings and the requirements of your serial port application, you might be able to accept the default property values and skip this step.

4. Write and read data — Write data to the device using the `fprintf` or `fwrite` function, and read data from the device using the `fgetl`, `fgets`, `fread`, `fscanf`, or `readasync` function.

   The serial port object behaves according to the previously configured or default property values.

5. Disconnect and clean up — When you no longer need the serial port object, disconnect it from the device using the `fclose` function, remove it from memory using the `delete` function, and remove it from the MATLAB workspace using the `clear` command.

The serial port session is reinforced in many of the serial port documentation examples. Refer to “Example: Getting Started” on page 10-19 to see a basic example that uses the steps shown above.

Configuring and Returning Properties

This example describes how you display serial port property names and property values, and how you assign values to properties.

You establish the desired serial port object behavior by configuring property values. You can display or configure property values using the `set` function, the `get` function, or dot notation.

Displaying Property Names and Property Values

Once the serial port object is created, use the `set` function to display all the configurable properties to the command line. Additionally, if a property has a finite set of string values, `set` also displays these values.

```
s = serial('COM1');
set(s)
    ByteOrder: [ {littleEndian} | bigEndian ]
    BytesAvailableFcn
    BytesAvailableFcnCount
    BytesAvailableFcnMode: [ {terminator} | byte ]
    ErrorFcn
    InputBufferSize
    Name
    OutputBufferSize
    OutputEmptyFcn
    RecordDetail: [ {compact} | verbose ]
    RecordMode: [ {overwrite} | append | index ]
    RecordName
    Tag
    Timeout
    TimerFcn
    TimerPeriod
    UserData

    SERIAL specific properties:
    BaudRate
    BreakInterruptFcn
    DataBits
    DataTerminalReady: [ {on} | off ]
    FlowControl: [ {none} | hardware | software ]
```

```
    Parity: [ {none} | odd | even | mark | space ]
    PinStatusFcn
    Port
    ReadAsyncMode: [ {continuous} | manual ]
    RequestToSend: [ {on} | off ]
    StopBits
    Terminator
```

Use the `get` function to display one or more properties and their current values to the command line. To display all properties and their current values

```
get(s)
    ByteOrder = littleEndian
    BytesAvailable = 0
    BytesAvailableFcn =
    BytesAvailableFcnCount = 48
    BytesAvailableFcnMode = terminator
    BytesToOutput = 0
    ErrorFcn =
    InputBufferSize = 512
    Name = Serial-COM1
    OutputBufferSize = 512
    OutputEmptyFcn =
    RecordDetail = compact
    RecordMode = overwrite
    RecordName = record.txt
    RecordStatus = off
    Status = closed
    Tag =
    Timeout = 10
    TimerFcn =
    TimerPeriod = 1
    TransferStatus = idle
    Type = serial
    UserData = []
    ValuesReceived = 0
    ValuesSent = 0

    SERIAL specific properties:
    BaudRate = 9600
```

```
    BreakInterruptFcn =
    DataBits = 8
    DataTerminalReady = on
    FlowControl = none
    Parity = none
    PinStatus = [1x1 struct]
    PinStatusFcn =
    Port = COM1
    ReadAsyncMode = continuous
    RequestToSend = on
    StopBits = 1
    Terminator = LF
```

To display the current value for one property, supply the property name to `get`.

```
get(s,'OutputBufferSize')
ans =
   512
```

To display the current values for multiple properties, include the property names as elements of a cell array.

```
get(s,{'Parity','TransferStatus'})
ans =
    'none'    'idle'
```

Use the dot notation to display a single property value.

```
s.Parity
ans =
none
```

Configuring Property Values

You can configure property values using the `set` function

```
set(s,'BaudRate',4800);
```

or the dot notation

```
s.BaudRate = 4800;
```

To configure values for multiple properties, supply multiple property name/property value pairs to `set`.

```
set(s,'DataBits',7,'Name','Test1-serial')
```

Note that you can configure only one property value at a time using the dot notation.

In practice, you can configure many of the properties at any time while the serial port object exists — including during object creation. However, some properties are not configurable while the object is connected to the device or when recording information to disk. Refer to “Property Reference” on page 10-76 for information about when a property is configurable.

Specifying Property Names

Serial port property names are presented using mixed case. While this makes property names easier to read, use any case you want when specifying property names. Additionally, you need use only enough letters to identify the property name uniquely, so you can abbreviate most property names. For example, you can configure the `BaudRate` property any of these ways:

```
set(s,'BaudRate',4800)
set(s,'baudrate',4800)
set(s,'BAUD',4800)
```

When you include property names in an M-file, you should use the full property name. This practice can prevent problems with future releases of MATLAB if a shortened name is no longer unique because of the addition of new properties.

Default Property Values

Whenever you do not explicitly define a value for a property, the default value is used. All configurable properties have default values.

Note Your operating system provides default values for all serial port settings such as the baud rate. However, these settings are overridden by your MATLAB code and have no effect on your serial port application.

If a property has a finite set of string values, the default value is enclosed by `{}`. For example, the default value for the `Parity` property is `none`.

```
set(s,'Parity')
[ {none} | odd | even | mark | space ]
```

You can find the default value for any property in the property reference pages.

Creating a Serial Port Object

In this section...

Overview of a Serial Port Object

The `serial` function requires the name of the serial port connected to your device as an input argument. Additionally, you can configure property values during object creation. For example, to create a serial port object associated with the serial port COM1, enter

```
s = serial('COM1');
```

The serial port object `s` now exists in the MATLAB workspace. You can display the class of `s` with the `whos` command.

```
whos s
  Name      Size         Bytes  Class

  s         1x1            512  serial object

Grand total is 11 elements using 512 bytes
```

Once the serial port object is created, the properties listed below are automatically assigned values. These general-purpose properties provide descriptive information about the serial port object based on the object type and the serial port.

Descriptive General Purpose Properties

Property Name	Description
`Name`	Specify a descriptive name for the serial port object

Descriptive General Purpose Properties (Continued)

Property Name	Description
Port	Indicate the platform-specific serial port name
Type	Indicate the object type

Display the values of these properties for s with the get function.

```
get(s,{'Name','Port','Type'})
ans =
    'Serial-COM1'    'COM1'    'serial'
```

Configuring Properties During Object Creation

You can configure serial port properties during object creation. serial accepts property names and property values in the same format as the set function. For example, you can specify property name/property value pairs.

```
s = serial('COM1','BaudRate',4800,'Parity','even');
```

If you specify an invalid property name, the object is not created. However, if you specify an invalid value for some properties (for example, BaudRate is set to 50), the object might be created but you are not informed of the invalid value until you connect the object to the device with the fopen function.

The Serial Port Object Display

The serial port object provides you with a convenient display that summarizes important configuration and state information. You can invoke the display summary these three ways:

- Type the serial port object variable name at the command line.
- Exclude the semicolon when creating a serial port object.
- Exclude the semicolon when configuring properties using the dot notation.

The display summary for the serial port object s is as follows:

```
Serial Port Object : Serial-COM1
```

```
Communication Settings
   Port:               COM1
   BaudRate:           9600
   Terminator:         'LF'

Communication State
   Status:             closed
   RecordStatus:       off

Read/Write State
   TransferStatus:     idle
   BytesAvailable:     0
   ValuesReceived:     0
   ValuesSent:         0
```

Creating an Array of Serial Port Objects

In MATLAB, you can create an array from existing variables by concatenating those variables together. The same is true for serial port objects. For example, suppose you create the serial port objects `s1` and `s2`.

```
s1 = serial('COM1');
s2 = serial('COM2');
```

You can now create a serial port object array consisting of `s1` and `s2` using the usual MATLAB syntax. To create the row array `x`, enter

```
x = [s1 s2]

Instrument Object Array

   Index:   Type:        Status:      Name:
   1        serial       closed       Serial-COM1
   2        serial       closed       Serial-COM2
```

To create the column array `y`, enter

```
y = [s1;s2];
```

Note that you cannot create a matrix of serial port objects. For example, you cannot create the matrix

```
z = [s1 s2;s1 s2];
??? Error using ==> serial/vertcat
Only a row or column vector of instrument objects can be created.
```

Depending on your application, you might want to pass an array of serial port objects to a function. For example, to configure the baud rate and parity for `s1` and `s2` using one call to `set`:

```
set(x,'BaudRate',19200,'Parity','even')
```

Refer to the Serial Port Devices functional reference to see which functions accept a serial port object array as an input.

Connecting to the Device

Before you can use the serial port object to write or read data, you must connect it to your device via the serial port specified in the `serial` function. You connect a serial port object to the device with the `fopen` function.

```
fopen(s)
```

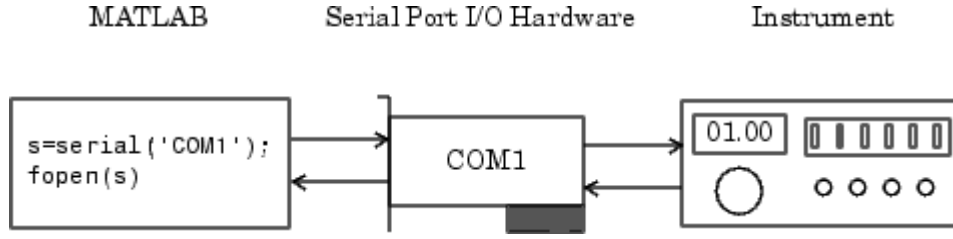
Some properties are read only while the serial port object is connected and must be configured before using `fopen`. Examples include the `InputBufferSize` and the `OutputBufferSize` properties. Refer to "Property Reference" on page 10-76 to determine when you can configure a property.

Note You can create any number of serial port objects, but you can connect only one serial port object per MATLAB session to a given serial port at a time. However, the serial port is not locked by MATLAB, so other applications or other instances of MATLAB can access the same serial port, which could result in a conflict, with unpredictable results.

You can examine the `Status` property to verify that the serial port object is connected to the device.

```
s.Status
ans =
open
```

As illustrated below, the connection between the serial port object and the device is complete; data is readable and writable.



Configuring Communication Settings

Before you can write or read data, both the serial port object and the device must have identical communication settings. Configuring serial port communications involves specifying values for properties that control the baud rate and the serial data format. The properties described below.

Communication Properties

Property Name	Description
`BaudRate`	Specify the rate at which bits are transmitted
`DataBits`	Specify the number of data bits to transmit
`Parity`	Specify the type of parity checking
`StopBits`	Specify the number of bits used to indicate the end of a byte
`Terminator`	Specify the terminator character

Note If the serial port object and the device communication settings are not identical, data is not readable or writable.

Refer to the device documentation for an explanation of its supported communication settings.

Writing and Reading Data

In this section...

Before You Begin

For many serial port applications, there are three important questions that you should consider when writing or reading data:

- Will the read or write function block access to the MATLAB command line?
- Is the data to be transferred binary (numerical) or text?
- Under what conditions will the read or write operation complete?

For write operations, these questions are answered in "Writing Data" on page 10-34. For read operations, these questions are answered in "Reading Data" on page 10-39.

Example — Introduction to Writing and Reading Data

Suppose you want to return identification information for a Tektronix TDS 210 two-channel oscilloscope connected to the serial port COM1. This requires writing the `*IDN?` command to the instrument using the `fprintf` function, and reading back the result of that command using the `fscanf` function.

```
s = serial('COM1');
fopen(s)
fprintf(s,'*IDN?')
```

```
out = fscanf(s)
```

The resulting identification information is as follows.

```
out =
TEKTRONIX,TDS 210,0,CF:91.1CT FV:v1.16 TDS2CM:CMV:v1.04
```

End the serial port session.

```
fclose(s)
delete(s)
clear s
```

Controlling Access to the MATLAB Command Line

You control access to the MATLAB command line by specifying whether a read or write operation is *synchronous* or *asynchronous*.

A synchronous operation blocks access to the command line until the read or write function completes execution. An asynchronous operation does not block access to the command line, and you can issue additional commands while the read or write function executes in the background.

The terms *synchronous* and *asynchronous* are often used to describe how the serial port operates at the hardware level. The RS-232 standard supports an asynchronous communication protocol. Using this protocol, each device uses its own internal clock. The data transmission is synchronized using the start bit of the bytes, while one or more stop bits indicate the end of the byte. Refer to “Serial Data Format” on page 10-11 for more information on start bits and stop bits. The RS-232 standard also supports a synchronous mode where all transmitted bits are synchronized to a common clock signal.

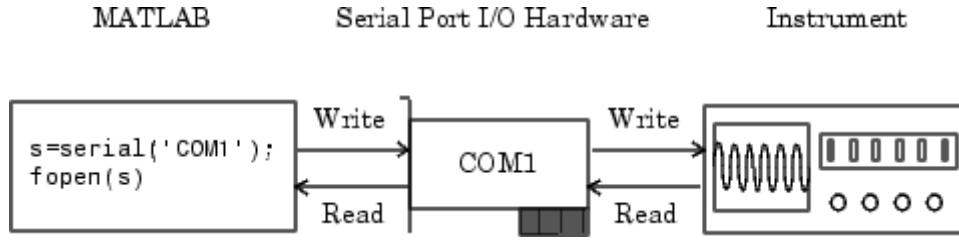
At the hardware level, most serial ports operate asynchronously. However, using the default behavior for many of the read and write functions, you can mimic the operation of a synchronous serial port.

Note When used in this guide, the terms *synchronous* and *asynchronous* refer to whether read or write operations block access to the MATLAB command-line. In other words, these terms describe how the software behaves, and not how the hardware behaves.

The two main advantages of writing or reading data asynchronously are:

- You can issue another command while the write or read function is executing.
- You can use all supported callback properties (see "Events and Callbacks" on page 10-51).

For example, because serial ports have separate read and write pins, you can simultaneously read and write data. This is illustrated below.



Writing Data

This section describes writing data to your serial port device in three parts:

- "The Output Buffer and Data Flow" on page 10-35 describes the flow of data from MATLAB to the device.
- "Writing Text Data" on page 10-37 describes how to write text data (string commands) to the device.
- "Writing Binary Data" on page 10-39 describes how to write binary (numerical) data to the device.

The functions associated with writing data are shown below.

Functions Associated with Writing Data

Function Name	Description
`fprintf`	Write text to the device
`fwrite`	Write binary data to the device
`stopasync`	Stop asynchronous read and write operations

The properties associated with writing data are shown below.

Properties Associated with Writing Data

Property Name	Description
`BytesToOutput`	Indicate the number of bytes currently in the output buffer
`OutputBufferSize`	Specify the size of the output buffer in bytes
`Timeout`	Specify the waiting time to complete a read or write operation
`TransferStatus`	Indicate if an asynchronous read or write operation is in progress
`ValuesSent`	Indicate the total number of values written to the device

The Output Buffer and Data Flow

The output buffer is computer memory allocated by the serial port object to store data that is to be written to the device. When writing data to your device, the data flow follows these two steps:

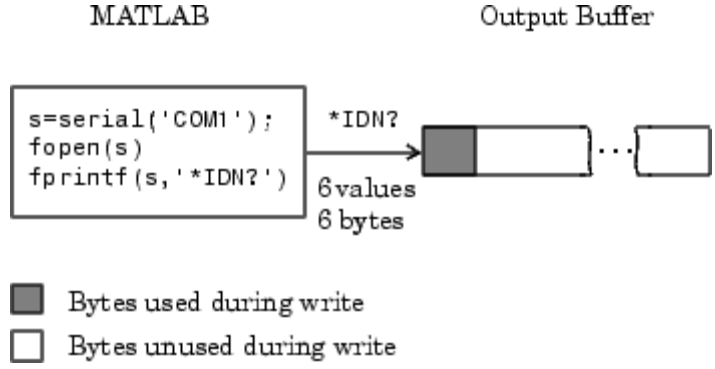
1. The data specified by the write function is sent to the output buffer.
2. The data in the output buffer is sent to the device.

The `OutputBufferSize` property specifies the maximum number of bytes that you can store in the output buffer. The `BytesToOutput` property indicates the number of bytes currently in the output buffer. The default values for these properties are shown below.

```
s = serial('COM1');
get(s,{'OutputBufferSize','BytesToOutput'})
ans =
    [512]    [0]
```

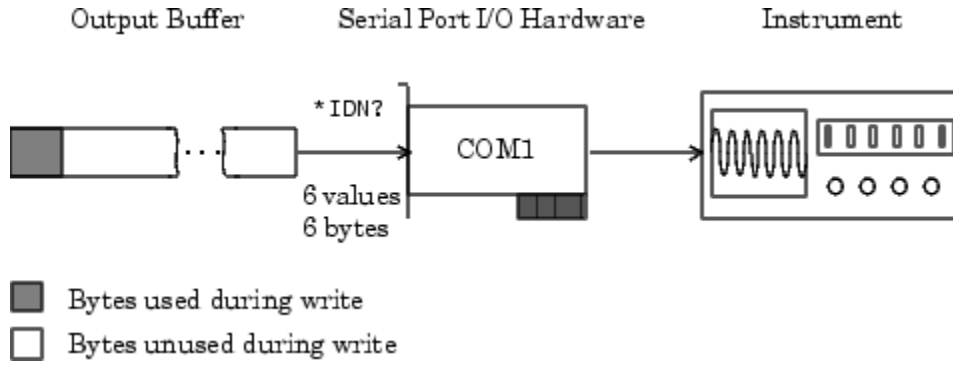
If you attempt to write more data than can fit in the output buffer, an error is returned and no data is written.

For example, suppose you write the string command `*IDN?` to the TDS 210 oscilloscope using the `fprintf` function. As shown below, the string is first written to the output buffer as six values.



The `*IDN?` command consists of six values because the terminator is automatically written. Moreover, the default data format for the `fprintf` function specifies that one value corresponds to one byte. For more information about bytes and values, refer to “Bytes Versus Values” on page 10-12. `fprintf` and the terminator are discussed in “Writing Text Data” on page 10-37.

As shown below, after the string is written to the output buffer, it is then written to the device via the serial port.



Writing Text Data

You use the `fprintf` function to write text data to the device. For many devices, writing text data means writing string commands that change device settings, prepare the device to return data or status information, and so on.

For example, the `Display:Contrast` command changes the display contrast of the oscilloscope.

```
s = serial('COM1');
fopen(s)
fprintf(s,'Display:Contrast 45')
```

By default, `fprintf` writes data using the `%s\n` format because many serial port devices accept only text-based commands. However, you can specify many other formats, as described in the `fprintf` reference pages.

You can verify the number of values sent to the device with the `ValuesSent` property.

```
s.ValuesSent
ans =
    20
```

Note that the `ValuesSent` property value includes the terminator because each occurrence of `\n` in the command sent to the device is replaced with the `Terminator` property value.

```
s.Terminator
```

```
ans =
LF
```

The default value of `Terminator` is the linefeed character. The terminator required by your device will be described in its documentation.

Synchronous Versus Asynchronous Write Operations. By default, `fprintf` operates synchronously and blocks the MATLAB command line until execution completes. To write text data asynchronously to the device, you must specify `async` as the last input argument to `fprintf`.

```
fprintf(s,'Display:Contrast 45','async')
```

Asynchronous operations do not block access to the MATLAB command line. Additionally, while an asynchronous write operation is in progress, you can:

- Execute an asynchronous read operation because serial ports have separate pins for reading and writing
- Make use of all supported callback properties

You can determine which asynchronous operations are in progress with the `TransferStatus` property. If no asynchronous operations are in progress, `TransferStatus` is `idle`.

```
s.TransferStatus
ans =
idle
```

Rules for Completing a Write Operation with fprintf. A synchronous or asynchronous write operation using `fprintf` completes when:

- The specified data is written.
- The time specified by the `Timeout` property passes.

Additionally, you can stop an asynchronous write operation with the `stopasync` function.

Writing Binary Data

You use the `fwrite` function to write binary data to the device. Writing binary data means writing numerical values. A typical application for writing binary data involves writing calibration data to an instrument such as an arbitrary waveform generator.

Note Some serial port devices accept only text-based commands. These commands might use the SCPI language or some other vendor-specific language. Therefore, you might need to use the `fprintf` function for all write operations.

By default, `fwrite` translates values using the `uchar` precision. However, you can specify many other precisions as described in the reference pages for this function.

By default, `fwrite` operates synchronously. To write binary data asynchronously to the device, you must specify `async` as the last input argument to `fwrite`. For more information about synchronous and asynchronous write operations, refer to the “Writing Text Data” on page 10-37. For a description of the rules used by `fwrite` to complete a write operation, refer to its reference pages.

Reading Data

This section describes reading data from your serial port device in three parts:

- “The Input Buffer and Data Flow” on page 10-40 describes the flow of data from the device to MATLAB.
- “Reading Text Data” on page 10-42 describes how to read from the device, and format the data as text.
- “Reading Binary Data” on page 10-44 describes how to read binary (numerical) data from the device.

The functions associated with reading data are shown below.

Functions Associated with Reading Data

Function Name	Description
`fgetl`	Read one line of text from the device and discard the terminator
`fgets`	Read one line of text from the device and include the terminator
`fread`	Read binary data from the device
`fscanf`	Read data from the device and format as text
`readasync`	Read data asynchronously from the device
`stopasync`	Stop asynchronous read and write operations

The properties associated with reading data are shown below.

Properties Associated with Reading Data

Property Name	Description
`BytesAvailable`	Indicate the number of bytes available in the input buffer
`InputBufferSize`	Specify the size of the input buffer in bytes
`ReadAsyncMode`	Specify whether an asynchronous read operation is continuous or manual
`Timeout`	Specify the waiting time to complete a read or write operation
`TransferStatus`	Indicate if an asynchronous read or write operation is in progress
`ValuesReceived`	Indicate the total number of values read from the device

The Input Buffer and Data Flow

The input buffer is computer memory allocated by the serial port object to store data that is to be read from the device. When reading data from your device, the data flow follows these two steps:

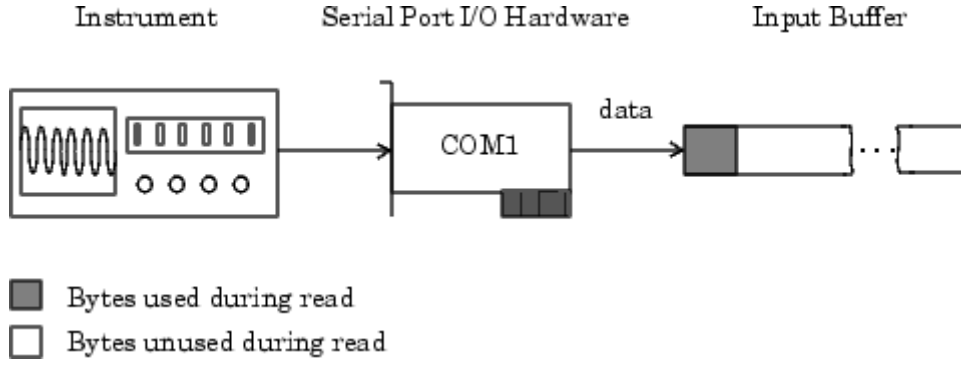
1. The data read from the device is stored in the input buffer.
2. The data in the input buffer is returned to the MATLAB variable specified by the read function.

The `InputBufferSize` property specifies the maximum number of bytes that you can store in the input buffer. The `BytesAvailable` property indicates the number of bytes currently available to be read from the input buffer. The default values for these properties are shown below.

```
s = serial('COM1');
get(s,{'InputBufferSize','BytesAvailable'})
ans =
    [512]    [0]
```

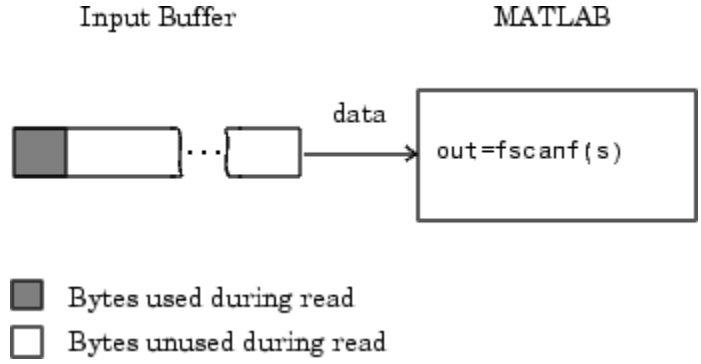
If you attempt to read more data than can fit in the input buffer, an error is returned and no data is read.

For example, suppose you use the `fscanf` function to read the text-based response of the `*IDN?` command previously written to the TDS 210 oscilloscope. As shown below, the text data is first read into to the input buffer via the serial port.



Note that for a given read operation, you might not know the number of bytes returned by the device. Therefore, you might need to preset the `InputBufferSize` property to a sufficiently large value before connecting the serial port object.

As shown below, after the data is stored in the input buffer, it is then transferred to the output variable specified by `fscanf`.



Reading Text Data

You use the `fgetl`, `fgets`, and `fscanf` functions to read data from the device, and format the data as text.

For example, suppose you want to return identification information for the oscilloscope. This requires writing the `*IDN?` command to the instrument, and then reading back the result of that command.

```
s = serial('COM1');
fopen(s)
fprintf(s,'*IDN?')
out = fscanf(s)
out =
TEKTRONIX,TDS 210,0,CF:91.1CT FV:v1.16 TDS2CM:CMV:v1.04
```

By default, `fscanf` reads data using the `%c` format because the data returned by many serial port devices is text based. However, you can specify many other formats as described in the `fscanf` reference pages.

You can verify the number of values read from the device - including the terminator — with the `ValuesReceived` property.

```
s.ValuesReceived
ans =
    56
```

Synchronous Versus Asynchronous Read Operations. You specify whether read operations are synchronous or asynchronous with the `ReadAsyncMode` property. You can configure `ReadAsyncMode` to `continuous` or `manual`.

If `ReadAsyncMode` is `continuous` (the default value), the serial port object continuously queries the device to determine if data is available to be read. If data is available, it is asynchronously stored in the input buffer. To transfer the data from the input buffer to MATLAB, use one of the synchronous (blocking) read functions such as `fgetl` or `fscanf`. If data is available in the input buffer, these functions return quickly.

```
s.ReadAsyncMode = 'continuous';
fprintf(s,'*IDN?')
s.BytesAvailable
ans =
    56
out = fscanf(s);
```

If `ReadAsyncMode` is `manual`, the serial port object does not continuously query the device to determine if data is available to be read. To read data asynchronously, use the `readasync` function. Then use one of the synchronous read functions to transfer data from the input buffer to MATLAB.

```
s.ReadAsyncMode = 'manual';
fprintf(s,'*IDN?')
s.BytesAvailable
ans =
    0
readasync(s)
s.BytesAvailable
ans =
    56
out = fscanf(s);
```

Asynchronous operations do not block access to the MATLAB command line. Additionally, while an asynchronous read operation is in progress, you can

- Execute an asynchronous write operation because serial ports have separate pins for reading and writing

- Make use of all supported callback properties

You can determine which asynchronous operations are in progress with the `TransferStatus` property. If no asynchronous operations are in progress, then `TransferStatus` is `idle`.

```
s.TransferStatus
ans =
idle
```

Rules for Completing a Read Operation with fscanf. A read operation with `fscanf` blocks access to the MATLAB command line until:

- The terminator specified by the `Terminator` property is read.
- The time specified by the `Timeout` property passes.
- The specified number of values specified is read.
- The input buffer is filled.

Reading Binary Data

You use the `fread` function to read binary data from the device. Reading binary data means that you return numerical values to MATLAB.

For example, suppose you want to return the cursor and display settings for the oscilloscope. This requires writing the `CURSOR?` and `DISPLAY?` commands to the instrument, and then reading back the results of those commands.

```
s = serial('COM1');
fopen(s)
fprintf(s,'CURSOR?')
fprintf(s,'DISPLAY?')
```

Because the default value for the `ReadAsyncMode` property is `continuous`, data is asynchronously returned to the input buffer as soon as it is available from the device. You can verify the number of values read with the `BytesAvailable` property.

```
s.BytesAvailable
ans =
    69
```

You can return the data to MATLAB using any of the synchronous read functions. However, if you use `fgetl`, `fgets`, or `fscanf`, you must issue the function twice because there are two terminators stored in the input buffer. If you use `fread`, you can return all the data to MATLAB in one function call.

```
out = fread(s,69);
```

By default, `fread` returns numerical values in double precision arrays. However, you can specify many other precisions as described in the `fread` reference pages. You can convert the numerical data to text using the MATLAB `char` function.

```
val = char(out)'
val =
HBARS;CH1;SECONDS;-1.0E-3;1.0E-3;VOLTS;-6.56E-1;6.24E-1
YT;DOTS;0;45
```

For more information about synchronous and asynchronous read operations, refer to "Reading Text Data" on page 10-42. For a description of the rules used by `fread` to complete a read operation, refer to its reference pages.

Example — Writing and Reading Text Data

This example illustrates how to communicate with a serial port instrument by writing and reading text data.

The instrument is a Tektronix TDS 210 two-channel oscilloscope connected to the COM1 port. Therefore, many of the commands shown below are specific to this instrument. A sine wave is input into channel 2 of the oscilloscope, and your job is to measure the peak-to-peak voltage of the input signal.

1. Create a serial port object — Create the serial port object `s` associated with serial port COM1.

   ```
   s = serial('COM1');
   ```

2. Connect to the device — Connect `s` to the oscilloscope. Because the default value for the `ReadAsyncMode` property is `continuous`, data is asynchronously returned to the input buffer as soon as it is available from the instrument.

```
fopen(s)
```

3 Write and read data — Write the `*IDN?` command to the instrument using `fprintf`, and then read back the result of the command using `fscanf`.

```
fprintf(s,'*IDN?')
idn = fscanf(s)
idn =
TEKTRONIX,TDS 210,0,CF:91.1CT FV:v1.16 TDS2CM:CMV:v1.04
```

You need to determine the measurement source. Possible measurement sources include channel 1 and channel 2 of the oscilloscope.

```
fprintf(s,'MEASUREMENT:IMMED:SOURCE?')
source = fscanf(s)
source =
CH1
```

The scope is configured to return a measurement from channel 1. Because the input signal is connected to channel 2, you must configure the instrument to return a measurement from this channel.

```
fprintf(s,'MEASUREMENT:IMMED:SOURCE CH2')
fprintf(s,'MEASUREMENT:IMMED:SOURCE?')
source = fscanf(s)
source =
CH2
```

You can now configure the scope to return the peak-to-peak voltage, and then request the value of this measurement.

```
fprintf(s,'MEASUREMENT:MEAS1:TYPE PK2PK')
fprintf(s,'MEASUREMENT:MEAS1:VALUE?')
```

Transfer data from the input buffer to MATLAB using `fscanf`.

```
ptop = fscanf(s,'%g')
ptop =
2.0199999809E0
```

4 Disconnect and clean up — When you no longer need s disconnect it from the instrument and remove it from memory and from the MATLAB workspace.

```
fclose(s)
delete(s)
clear s
```

Example — Parsing Input Data Using strread

This example illustrates how to use the `strread` function to parse and format data that you read from a device. `strread` is particularly useful when you want to parse a string into one or more variables, where each variable has its own specified format.

The instrument is a Tektronix TDS 210 two-channel oscilloscope connected to the serial port COM1.

1 Create a serial port object — Create the serial port object `s` associated with serial port COM1.

```
s = serial('COM1');
```

2 Connect to the device — Connect `s` to the oscilloscope. Because the default value for the `ReadAsyncMode` property is `continuous`, data is asynchronously returned to the input buffer as soon as it is available from the instrument.

```
fopen(s)
```

3 Write and read data — Write the `RS232?` command to the instrument using `fprintf`, and then read back the result of the command using `fscanf`. `RS232?` queries the RS-232 settings and returns the baud rate, the software flow control setting, the hardware flow control setting, the parity type, and the terminator.

```
fprintf(s,'RS232?')
data = fscanf(s)
data =
9600;0;0;NONE;LF
```

Use the `strread` function to parse and format the `data` variable into five new variables.

```
[br,sfc,hfc,par,tm] = strread(data,'%d%d%d%s%s','delimiter',';')

br =
        9600
sfc =
     0
hfc =
     0
par =
    'NONE'
tm =
    'LF'
```

4 Disconnect and clean up — When you no longer need `s`, you should disconnect it from the instrument, and remove it from memory and from the MATLAB workspace.

```
fclose(s)
delete(s)
clear s
```

Example — Reading Binary Data

This example illustrates how you can download the TDS 210 oscilloscope screen display to MATLAB. The screen display data is transferred and saved to disk using the Windows bitmap format. This data provides a permanent record of your work, and is an easy way to document important signal and scope parameters.

Because the amount of data transferred is expected to be fairly large, it is asynchronously returned to the input buffer as soon as it is available from the instrument. This allows you to perform other tasks as the transfer progresses. Additionally, the scope is configured to its highest baud rate of 19,200.

1 Create a serial port object — Create the serial port object `s` associated with serial port COM1.

```
s = serial('COM1');
```

2 Configure property values — Configure the input buffer to accept a reasonably large number of bytes, and configure the baud rate to the highest value supported by the scope.

```
s.InputBufferSize = 50000;
s.BaudRate = 19200;
```

3 Connect to the device — Connect `s` to the oscilloscope. Because the default value for the `ReadAsyncMode` property is `continuous`, data is asynchronously returned to the input buffer as soon as it is available from the instrument.

```
fopen(s)
```

4 Write and read data — Configure the scope to transfer the screen display as a bitmap.

```
fprintf(s,'HARDCOPY:PORT RS232')
fprintf(s,'HARDCOPY:FORMAT BMP')
fprintf(s,'HARDCOPY START')
```

Wait until all the data is sent to the input buffer, and then transfer the data to the MATLAB workspace as unsigned 8-bit integers.

```
out = fread(s,s.BytesAvailable,'uint8');
```

5 Disconnect and clean up — When you no longer need `s`, disconnect it from the instrument and remove it from memory and from the MATLAB workspace.

```
fclose(s)
delete(s)
clear s
```

Viewing the Bitmap Data

To view the bitmap data, follow these steps:

1 Open a disk file.

2 Write the data to the disk file.

3 Close the disk file.

4 Read the data into MATLAB using the `imread` function.

5 Scale and display the data using the `imagesc` function.

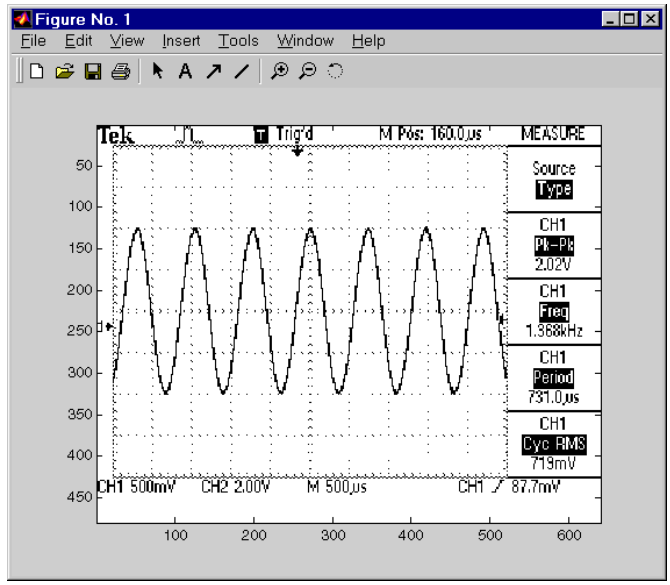
Note that the file I/O versions of the `fopen`, `fwrite`, and `fclose` functions are used.

```
fid = fopen('test1.bmp','w');
fwrite(fid,out,'uint8');
fclose(fid)
a = imread('test1.bmp','bmp');
imagesc(a)
```

Because the scope returns the screen display data using only two colors, an appropriate colormap is selected.

```
mymap = [0 0 0; 1 1 1];
colormap(mymap)
```

The resulting bitmap image is shown below.



Events and Callbacks

In this section...

Introduction

You can enhance the power and flexibility of your serial port application by using *events*. An event occurs after a condition is met and might result in one or more callbacks.

While the serial port object is connected to the device, you can use events to display a message, display data, analyze data, and so on. Callbacks are controlled through *callback properties* and *callback functions*. All event types have an associated callback property. Callback functions are M-file functions that you construct to suit your specific application needs.

You execute a callback when a particular event occurs by specifying the name of the M-file callback function as the value for the associated callback property.

Example — Introduction to Events and Callbacks

This example uses the M-file callback function `instrcallback` to display a message to the command line when a bytes-available event occurs. The event is generated when the terminator is read.

```
s = serial('COM1');
fopen(s)
s.BytesAvailableFcnMode = 'terminator';
s.BytesAvailableFcn = @instrcallback;
```

```
fprintf(s,'*IDN?')
out = fscanf(s);
```

The resulting display from `instrcallback` is shown below.

```
BytesAvailable event occurred at 17:01:29 for the object:
Serial-COM1.
```

End the serial port session.

```
fclose(s)
delete(s)
clear s
```

You can use the `type` command to display `instrcallback` at the command line.

Event Types and Callback Properties

The serial port event types and callback properties are described below.

This table consists of two columns and nine rows. In the first column (event type), the second item (bytes available) applies to rows 2 through 4. Also, in the first column the last item (timer) applies to rows 8 and 9.

Event Types and Callback Properties

Event Type	Associated Properties
Break interrupt	`BreakInterruptFcn`
Bytes available	`BytesAvailableFcn`
	`BytesAvailableFcnCount`
	`BytesAvailableFcnMode`
Error	`ErrorFcn`
Output empty	`OutputEmptyFcn`
Pin status	`PinStatusFcn`

Event Types and Callback Properties (Continued)

Event Type	Associated Properties
Timer	`TimerFcn`
	`TimerPeriod`

Break-Interrupt Event

A break-interrupt event is generated immediately after a break interrupt is generated by the serial port. The serial port generates a break interrupt when the received data has been in an inactive state longer than the transmission time for one character.

This event executes the callback function specified for the `BreakInterruptFcn` property. It can be generated for both synchronous and asynchronous read and write operations.

Bytes-Available Event

A bytes-available event is generated immediately after a predetermined number of bytes are available in the input buffer or a terminator is read, as determined by the `BytesAvailableFcnMode` property.

If `BytesAvailableFcnMode` is `byte`, the bytes-available event executes the callback function specified for the `BytesAvailableFcn` property every time the number of bytes specified by `BytesAvailableFcnCount` is stored in the input buffer. If `BytesAvailableFcnMode` is `terminator`, the callback function executes every time the character specified by the `Terminator` property is read.

This event can be generated only during an asynchronous read operation.

Error Event

An error event is generated immediately after an error occurs.

This event executes the callback function specified for the `ErrorFcn` property. It can be generated only during an asynchronous read or write operation.

An error event is generated when a time-out occurs. A time-out occurs if a read or write operation does not successfully complete within the time specified by the `Timeout` property. An error event is not generated for configuration errors such as setting an invalid property value.

Output-Empty Event

An output-empty event is generated immediately after the output buffer is empty.

This event executes the callback function specified for the `OutputEmptyFcn` property. It can be generated only during an asynchronous write operation.

Pin Status Event

A pin status event is generated immediately after the state (pin value) changes for the CD, CTS, DSR, or RI pins. Refer to "Serial Port Signals and Pin Assignments" on page 10-7 for a description of these pins.

This event executes the callback function specified for the `PinStatusFcn` property. It can be generated for both synchronous and asynchronous read and write operations.

Timer Event

A timer event is generated when the time specified by the `TimerPeriod` property passes. Time is measured relative to when the serial port object is connected to the device.

This event executes the callback function specified for the `TimerFcn` property. Note that some timer events might not be processed if your system is significantly slowed or if the `TimerPeriod` value is too small.

Storing Event Information

You can store event information in a callback function or in a record file. Event information is stored in a callback function using two fields: `Type` and `Data`. The `Type` field contains the event type, while the `Data` field contains event-specific information. As described in "Creating and Executing Callback Functions" on page 10-57, these two fields are associated with a structure that you define in the callback function header. Refer to "Debugging: Recording

Information to Disk" on page 10-66 to learn about recording data and event information to a record file.

The event types and the values for the `Type` and `Data` fields are shown below.

The table consists of three columns and 15 rows. Items in the first column (event type) span several rows, as follows:

Break interrupt: rows 1 and 2

Bytes available: rows 3 and 4

Error: rows 5 through 7

Output empty: rows 8 and 9

Pin status: rows 10 through 13

Timer: rows 14 and 15

Event Information

Event Type	Field	Field Value
Break interrupt	`Type`	`BreakInterrupt`
	`Data.AbsTime`	day-month-year hour:minute:second
Bytes available	`Type`	`BytesAvailable`
	`Data.AbsTime`	day-month-year hour:minute:second
Error	`Type`	`Error`
	`Data.AbsTime`	day-month-year hour:minute:second
	`Data.Message`	An error string

Event Information (Continued)

Event Type	Field	Field Value
Output empty	`Type`	`OutputEmpty`
	`Data.AbsTime`	day-month-year hour:minute:second
Pin status	`Type`	`PinStatus`
	`Data.AbsTime`	day-month-year hour:minute:second
	`Data.Pin`	`CarrierDetect`, `ClearToSend`, `DataSetReady`, or `RingIndicator`
	`Data.PinValue`	`on` or `off`
Timer	`Type`	`Timer`
	`Data.AbsTime`	day-month-year hour:minute:second

The `Data` field values are described below.

The AbsTime Field

`AbsTime` is defined for all events, and indicates the absolute time the event occurred. The absolute time is returned using the `clock` format: day-month-year hour:minute:second

The Pin Field

`Pin` is used by the pin status event to indicate if the CD, CTS, DSR, or RI pins changed state. Refer to “Serial Port Signals and Pin Assignments” on page 10-7 for a description of these pins.

The PinValue Field

`PinValue` is used by the pin status event to indicate the state of the CD, CTS, DSR, or RI pins. Possible values are `on` or `off`.

The Message Field

`Message` is used by the error event to store the descriptive message that is generated when an error occurs.

Creating and Executing Callback Functions

You can specify the callback function to be executed when a specific event type occurs by including the name of the M-file as the value for the associated callback property. You can specify the callback function as a function handle or as a string cell array element. Function handles are described in the `function_handle` reference pages.

For example, to execute the callback function `mycallback` every time the terminator is read from your device

```
s.BytesAvailableFcnMode = 'terminator';
s.BytesAvailableFcn = @mycallback;
```

Alternatively, you can specify the callback function as a cell array.

```
s.BytesAvailableFcn = {'mycallback'};
```

M-file callback functions require at least two input arguments. The first argument is the serial port object. The second argument is a variable that captures the event information shown in the table, Event Information on page 10-55. This event information pertains only to the event that caused the callback function to execute. The function header for `mycallback` is shown below.

```
function mycallback(obj,event)
```

You pass additional parameters to the callback function by including both the callback function and the parameters as elements of a cell array. For example, to pass the MATLAB variable `time` to `mycallback`

```
time = datestr(now,0);
s.BytesAvailableFcnMode = 'terminator';
s.BytesAvailableFcn = {@mycallback,time};
```

Alternatively, you can specify the callback function as a string in the cell array.

```
s.BytesAvailableFcn = {'mycallback',time};
```

The corresponding function header is

```
function mycallback(obj,event,time)
```

If you pass additional parameters to the callback function, they must be included in the function header after the two required arguments.

Note You can also specify the callback function as a string. In this case, the callback is evaluated in the MATLAB workspace and no requirements are made on the input arguments of the callback function.

Enabling Callback Functions After They Error

If an error occurs while a callback function is executing the following occurs:

- The callback function is automatically disabled.
- A warning is displayed at the command line, indicating that the callback function is disabled.

If you want to enable the same callback function, set the callback property to the same value or disconnect the object with the `fclose` function. If you want to use a different callback function, the callback is enabled when you configure the callback property to the new value.

Example — Using Events and Callbacks

This example uses the M-file callback function `instrcallback` to display event-related information to the command line when a bytes-available event or an output-empty event occurs.

1. Create a serial port object — Create the serial port object `s` associated with serial port COM1.

   ```
   s = serial('COM1');
   ```

2. Connect to the device — Connect `s` to the Tektronix TDS 210 oscilloscope. Because the default value for the `ReadAsyncMode` property is `continuous`, data is asynchronously returned to the input buffer as soon as it is available from the instrument.

```
fopen(s)
```

3 Configure properties — Configure `s` to execute the callback function `instrcallback` when a bytes-available event or an output-empty event occurs. Because `instrcallback` requires the serial port object and event information to be passed as input arguments, the callback function is specified as a function handle.

```
s.BytesAvailableFcnMode = 'terminator';
s.BytesAvailableFcn = @instrcallback;
s.OutputEmptyFcn = @instrcallback;
```

4 Write and read data — Write the `RS232?` command asynchronously to the oscilloscope. This command queries the RS-232 settings and returns the baud rate, the software flow control setting, the hardware flow control setting, the parity type, and the terminator.

```
fprintf(s,'RS232?','async')
```

`instrcallback` is called after the `RS232?` command is sent, and when the terminator is read. The resulting displays are shown below.

```
OutputEmpty event occurred at 17:37:21 for the object:
Serial-COM1.

BytesAvailable event occurred at 17:37:21 for the object:
Serial-COM1.
```

Read the data from the input buffer.

```
out = fscanf(s)
out =
9600;0;0;NONE;LF
```

5 Disconnect and clean up — When you no longer need `s`, disconnect it from the instrument and remove it from memory and from the MATLAB workspace.

```
fclose(s)
delete(s)
clear s
```

Using Control Pins

In this section...

Properties of Serial Port Control Pins

As described in "Serial Port Signals and Pin Assignments" on page 10-7, 9-pin serial ports include six control pins. The properties associated with the serial port control pins are shown below.

Control Pin Properties

Property Name	Description
`DataTerminalReady`	Specify the state of the DTR pin
`FlowControl`	Specify the data flow control method to use
`PinStatus`	Indicate the state of the CD, CTS, DSR, and RI pins
`RequestToSend`	Specify the state of the RTS pin

Signaling the Presence of Connected Devices

DTEs and DCEs often use the CD, DSR, RI, and DTR pins to indicate whether a connection is established between serial port devices. Once the connection is established, you can begin to write or read data.

You can monitor the state of the CD, DSR, and RI pins with the `PinStatus` property. You can specify or monitor the state of the DTR pin with the `DataTerminalReady` property.

The following example illustrates how these pins are used when two modems are connected to each other.

Example — Connecting Two Modems

This example connects two modems to each other via the same computer, and illustrates how you can monitor the communication status for the computer-modem connections, and for the modem-modem connection. The first modem is connected to COM1, while the second modem is connected to COM2.

1. Create the serial port objects — After the modems are powered on, the serial port object `s1` is created for the first modem, and the serial port object `s2` is created for the second modem.

   ```
   s1 = serial('COM1');
   s2 = serial('COM2');
   ```

2. Connect to the devices — `s1` and `s2` are connected to the modems. Because the default value for the `ReadAsyncMode` property is `continuous`, data is asynchronously returned to the input buffers as soon as it is available from the modems.

   ```
   fopen(s1)
   fopen(s2)
   ```

   Because the default `DataTerminalReady` property value is `on`, the computer (data terminal) is now ready to exchange data with the modems. You can verify that the modems (data sets) can communicate with the computer by examining the value of the Data Set Ready pin with the `PinStatus` property.

   ```
   s1.Pinstatus
   ans =
       CarrierDetect: 'off'
         ClearToSend: 'on'
        DataSetReady: 'on'
       RingIndicator: 'off'
   ```

   The value of the `DataSetReady` field is `on` because both modems were powered on before they were connected to the objects.

3. Configure properties — Both modems are configured for a baud rate of 2400 bits per second and a carriage return (CR) terminator.

```
s1.BaudRate = 2400;
s1.Terminator = 'CR';
s2.BaudRate = 2400;
s2.Terminator = 'CR';
```

4 Write and read data — Write the `atd` command to the first modem. This command puts the modem "off the hook," which is equivalent to manually lifting a phone receiver.

```
fprintf(s1,'atd')
```

Write the `ata` command to the second modem. This command puts the modem in "answer mode," which forces it to connect to the first modem.

```
fprintf(s2,'ata')
```

After the two modems negotiate their connection, verify the connection status by examining the value of the Carrier Detect pin using the `PinStatus` property.

```
s1.PinStatus
ans =
    CarrierDetect: 'on'
      ClearToSend: 'on'
     DataSetReady: 'on'
    RingIndicator: 'off'
```

Verify the modem-modem connection by reading the descriptive message returned by the second modem.

```
s2.BytesAvailable
ans =
    25
out = fread(s2,25);
char(out)'
ans =
ata
CONNECT 2400/NONE
```

Now break the connection between the two modems by configuring the `DataTerminalReady` property to `off`. You can verify that the modems are disconnected by examining the Carrier Detect pin value.

```
s1.DataTerminalReady = 'off';
s1.PinStatus
ans =
    CarrierDetect: 'off'
      ClearToSend: 'on'
     DataSetReady: 'on'
    RingIndicator: 'off'
```

5 Disconnect and clean up — Disconnect the objects from the modems and remove the objects from memory and from the MATLAB workspace.

```
fclose([s1 s2])
delete([s1 s2])
clear s1 s2
```

Controlling the Flow of Data: Handshaking

Data flow control or *handshaking* is a method used for communicating between a DCE and a DTE to prevent data loss during transmission. For example, suppose your computer can receive only a limited amount of data before it must be processed. As this limit is reached, a handshaking signal is transmitted to the DCE to stop sending data. When the computer can accept more data, another handshaking signal is transmitted to the DCE to resume sending data.

If supported by your device, you can control data flow using one of these methods:

- Hardware handshaking
- Software handshaking

Note Although you might be able to configure your device for both hardware handshaking and software handshaking at the same time, MATLAB does not support this behavior.

You can specify the data flow control method with the `FlowControl` property. If `FlowControl` is `hardware`, hardware handshaking is used to control data

flow. If `FlowControl` is `software`, software handshaking is used to control data flow. If `FlowControl` is `none`, no handshaking is used.

Hardware Handshaking

Hardware handshaking uses specific serial port pins to control data flow. In most cases, these are the RTS and CTS pins. Hardware handshaking using these pins is described in "The RTS and CTS Pins" on page 10-10.

If `FlowControl` is `hardware`, the RTS and CTS pins are automatically managed by the DTE and DCE. You can return the CTS pin value with the `PinStatus` property. Configure or return the RTS pin value with the `RequestToSend` property.

Note Some devices also use the DTR and DSR pins for handshaking. However, these pins are typically used to indicate that the system is ready for communication, and are not used to control data transmission. In MATLAB, hardware handshaking always uses the RTS and CTS pins.

If your device does not use hardware handshaking in the standard way, then you might need to manually configure the `RequestToSend` property. In this case, you should configure `FlowControl` to `none`. If `FlowControl` is `hardware`, then the `RequestToSend` value that you specify might not be honored. Refer to the device documentation to determine its specific pin behavior.

Software Handshaking

Software handshaking uses specific ASCII characters to control data flow. These characters, known as Xon and Xoff (or XON and XOFF), are described below.

Software Handshaking Characters

Character	Integer Value	Description
Xon	17	Resume data transmission
Xoff	19	Pause data transmission

When using software handshaking, the control characters are sent over the transmission line the same way as regular data. Therefore, only the TD, RD, and GND pins are needed.

The main disadvantage of software handshaking is that Xon or Xoff characters are not writable while numerical data is being written to the device. This is because numerical data might contain a 17 or 19, which makes it impossible to distinguish between the control characters and the data. However, you can write Xon or Xoff while data is being asynchronously read from the device because you are using both the TD and RD pins.

Example: Using Software Handshaking

Suppose you want to use software flow control with the example described in “Example — Reading Binary Data” on page 10-48. To do this, you must configure the oscilloscope and serial port object for software flow control.

```
fprintf(s,'RS232:SOFTF ON')
s.FlowControl = 'software';
```

To pause data transfer, write the numerical value `19` to the device.

```
fwrite(s,19)
```

To resume data transfer, write the numerical value `17` to the device.

```
fwrite(s,17)
```

Debugging: Recording Information to Disk

In this section...

Introduction

Recording information to disk provides a permanent record of your serial port session, and is an easy way to debug your application. While the serial port object is connected to the device, you can record the following information to a disk file:

- The number of values written to the device, the number of values read from the device, and the data type of the values
- Data written to the device, and data read from the device
- Event information

Recording Properties

You record information to a disk file with the `record` function. The following table shows the properties associated with recording information to disk.

Recording Properties

Property Name	Description
`RecordDetail`	Specify the amount of information saved to a record file
`RecordMode`	Specify whether data and event information is saved to one record file or to multiple record files

Recording Properties (Continued)

Property Name	Description
RecordName	Specify the name of the record file
RecordStatus	Indicate if data and event information are saved to a record file

Example: Introduction to Recording Information

This example records the number of values written to and read from the device, and stores the information to the file myfile.txt.

```
s = serial('COM1');
fopen(s)
s.RecordName = 'myfile.txt';
record(s)
fprintf(s,'*IDN?')
idn = fscanf(s);
fprintf(s,'RS232?')
rs232 = fscanf(s);
```

End the serial port session.

```
fclose(s)
delete(s)
clear s
```

You can use the type command to display myfile.txt at the command line.

Creating Multiple Record Files

When you initiate recording with the record function, the RecordMode property determines if a new record file is created or if new information is appended to an existing record file.

You can configure RecordMode to overwrite, append, or index. If RecordMode is overwrite, the record file is overwritten each time recording is initiated. If RecordMode is append, the new information is appended to the file specified by RecordName. If RecordMode is index, a different disk file is created each

time recording is initiated. The rules for specifying a record filename are discussed in the next section.

Specifying a Filename

You specify the name of the record file with the `RecordName` property. You can specify any value for `RecordName` — including a directory path — provided the filename is supported by your operating system. Additionally, if `RecordMode` is `index`, the filename follows these rules:

- Indexed filenames are identified by a number. This number precedes the filename extension and is increased by 1 for successive record files.
- If no number is specified as part of the initial filename, the first record file does not have a number associated with it. For example, if `RecordName` is `myfile.txt`, `myfile.txt` is the name of the first record file, `myfile01.txt` is the name of the second record file, and so on.
- `RecordName` is updated after the record file is closed.
- If the specified filename already exists, the existing file is overwritten.

The Record File Format

The record file is an ASCII file that contains a record of one or more serial port sessions. You specify the amount of information saved to a record file with the `RecordDetail` property.

`RecordDetail` can be `compact` or `verbose`. A compact record file contains the number of values written to the device, the number of values read from the device, the data type of the values, and event information. A verbose record file contains the preceding information as well as the data transferred to and from the device.

Binary data with precision given by `uchar`, `schar`, `(u)int8`, `(u)int16`, or `(u)int32` is recorded using hexadecimal format. For example, if the integer value 255 is read from the instrument as a 16-bit integer, the hexadecimal value 00FF is saved in the record file. Single- and double-precision floating-point numbers are recorded as decimal values using the `%g` format, and as hexadecimal values using the format specified by the IEEE Standard 754-1985 for Binary Floating-Point Arithmetic.

The IEEE floating-point format includes three components: the sign bit, the exponent field, and the significant field. Single-precision floating-point values consist of 32 bits. The value is given by

$$value = (-1)^{sign}(2^{exp-127})(1.significand)$$

Double-precision floating-point values consist of 64 bits. The value is given by

$$value = (-1)^{sign}(2^{exp-1023})(1.significand)$$

The floating-point format component, and the associated single-precision and double-precision bits are shown below.

Component	Single-Precision Bits	Double-Precision Bits
`sign`	1	1
`exp`	2–9	2–12
`significand`	10–32	13–64

Bit 1 is the left-most bit as stored in the record file.

Example: Recording Information to Disk

This example illustrates how to record information transferred between a serial port object and a Tektronix TDS 210 oscilloscope. Additionally, the structure of the resulting record file is presented.

1. Create the serial port object — Create the serial port object `s` associated with the serial port COM1.

```
s = serial('COM1');
```

2. Connect to the device — Connect `s` to the oscilloscope. Because the default value for the `ReadAsyncMode` property is `continuous`, data is asynchronously returned the input buffer as soon as it is available from the instrument.

```
fopen(s)
```

3 Configure property values — Configure `s` to record information to multiple disk files using the verbose format. Recording is then initiated with the first disk file defined as `WaveForm1.txt`.

```
s.RecordMode = 'index';
s.RecordDetail = 'verbose';
s.RecordName = 'WaveForm1.txt';
record(s)
```

4 Write and read data — The commands written to the instrument, and the data read from the instrument are recorded in the record file. Refer to "Example — Writing and Reading Text Data" on page 10-45 for an explanation of the oscilloscope commands.

```
fprintf(s,'*IDN?')
idn = fscanf(s);
fprintf(s,'MEASUREMENT:IMMED:SOURCE CH2')
fprintf(s,'MEASUREMENT:IMMED:SOURCE?')
source = fscanf(s);
```

Read the peak-to-peak voltage with the `fread` function. Note that the data returned by `fread` is recorded using hex format.

```
fprintf(s,'MEASUREMENT:MEAS1:TYPE PK2PK')
fprintf(s,'MEASUREMENT:MEAS1:VALUE?')
ptop = fread(s,s.BytesAvailable);
```

Convert the peak-to-peak voltage to a character array.

```
char(ptop)'
ans =
2.0199999809E0
```

The recording state is toggled from `on` to `off`. Because the `RecordMode` value is `index`, the record filename is automatically updated.

```
record(s)
s.RecordStatus
ans =
off
s.RecordName
ans =
```

```
WaveForm2.txt
```

5 Disconnect and clean up — When you no longer need s, disconnect it from the instrument, and remove it from memory and from the MATLAB workspace.

```
fclose(s)
delete(s)
clear s
```

The Record File Contents

The contents of the `WaveForm1.txt` record file are shown below. Because the `RecordDetail` property was `verbose`, the number of values, commands, and data were recorded. Note that data returned by the `fread` function is in hex format.

```
type WaveForm1.txt

Legend:
  * - An event occurred.
  > - A write operation occurred.
  < - A read operation occurred.
1      Recording on 22-Jan-2000 at 11:21:21.575. Binary data in...
2    > 6 ascii values.
       *IDN?
3    < 56 ascii values.
       TEKTRONIX,TDS 210,0,CF:91.1CT FV:v1.16 TDS2CM:CMV:v1.04
4    > 29 ascii values.
       MEASUREMENT:IMMED:SOURCE CH2
5    > 26 ascii values.
       MEASUREMENT:IMMED:SOURCE?
6    < 4 ascii values.
       CH2
7    > 27 ascii values.
       MEASUREMENT:MEAS1:TYPE PK2PK
8    > 25 ascii values.
       MEASUREMENT:MEAS1:VALUE?
9    < 15 uchar values.

10     Recording off.
```

Saving and Loading

In this section...

Using save and load

You can save serial port objects to a MAT-file just as you would any workspace variable - using the `save` command. For example, suppose you create the serial port object `s` associated with the serial port COM1, configure several property values, and perform a write and read operation.

```
s = serial('COM1');
s.BaudRate = 19200;
s.Tag = 'My serial object';
fopen(s)
fprintf(s, '*IDN?')
out = fscanf(s);
```

To save the serial port object and the data read from the device to the MAT-file `myserial.mat`

```
save myserial s out
```

Note You can save data and event information as text to a disk file with the `record` function.

You can recreate `s` and `out` in the workspace using the `load` command.

```
load myserial
```

Values for read only properties are restored to their default values upon loading. For example, the `Status` property is restored to `closed`. Therefore, to use `s`, you must connect it to the device with the `fopen` function. To determine if a property is read only, examine its reference pages.

Using Serial Port Objects on Different Platforms

If you save a serial port object from one platform, and then load that object on a different platform having different serial port names, you need to modify the `Port` property value. For example, suppose you create the serial port object `s` associated with the serial port COM1 on a Windows platform. If you want to save `s` for eventual use on a Linux platform, configure `Port` to an appropriate value such as `ttyS0` after the object is loaded.

Disconnecting and Cleaning Up

In this section...

Disconnecting a Serial Port Object

When you no longer need to communicate with the device, disconnect it from the serial port object with the `fclose` function.

```
fclose(s)
```

Examine the `Status` property to verify that the serial port object and the device are disconnected.

```
s.Status
ans =
closed
```

After `fclose` is issued, the serial port associated with `s` is available. Now connect another serial port object to it using `fopen`.

Cleaning Up the MATLAB Environment

When the serial port object is no longer needed, remove it from memory with the `delete` function.

```
delete(s)
```

Before using `delete`, disconnect the serial port object from the device with the `fclose` function.

A deleted serial port object is *invalid*, which means that you cannot connect it to the device. In this case, remove the object from the MATLAB workspace. To remove serial port objects and other variables from the MATLAB workspace, use the `clear` command.

```
clear s
```

Use `clear` on a serial port object that is still connected to a device to remove the object from the workspace but leave it connected to the device. Restore cleared objects to MATLAB with the `instrfind` function.

Property Reference

In this section...

The Property Reference Page Format

Each serial port property description contains some or all of this information:

- The property name
- A description of the property
- The property characteristics, including:
  - Read only — The condition under which the property is read only

    A property can be read-only always, never, while the serial port object is open, or while the serial port object is recording. You can configure a property value using the `set` function or dot notation. You can return the current property value using the `get` function or dot notation.
  - Data type — the property data type

    This is the data type you use when specifying a property value.
- Valid property values including the default value

  When property values are given by a predefined list, the default value is usually indicated by `{}`.
- An example using the property
- Related properties and functions

Serial Port Object Properties

The serial port object properties are briefly described below, and organized into categories based on how they are used. Following this section the properties are listed alphabetically and described in detail.

Communications Properties	
BaudRate	Specify the rate at which bits are transmitted
DataBits	Specify the number of data bits to transmit
Parity	Specify the type of parity checking
StopBits	Specify the number of bits used to indicate the end of a byte
Terminator	Specify the terminator character

Write Properties	
BytesToOutput	Indicate the number of bytes currently in the output buffer
OutputBufferSize	Specify the size of the output buffer in bytes
Timeout	Specify the waiting time to complete a read or write operation
TransferStatus	Indicate if an asynchronous read or write operation is in progress
ValuesSent	Indicate the total number of values written to the device

Read Properties	
BytesAvailable	Indicate the number of bytes available in the input buffer
InputBufferSize	Specify the size of the input buffer in bytes
ReadAsyncMode	Specify whether an asynchronous read operation is continuous or manual
Timeout	Specify the waiting time to complete a read or write operation

Read Properties	
TransferStatus	Indicate if an asynchronous read or write operation is in progress
ValuesReceived	Indicate the total number of values read from the device

Callback Properties	
BreakInterruptFcn	Specify the M-file callback function to execute when a break-interrupt event occurs
BytesAvailableFcn	Specify the M-file callback function to execute when a specified number of bytes is available in the input buffer, or a terminator is read
BytesAvailableFcnCount	Specify the number of bytes that must be available in the input buffer to generate a bytes-available event
BytesAvailableFcnMode	Specify if the bytes-available event is generated after a specified number of bytes is available in the input buffer, or after a terminator is read
ErrorFcn	Specify the M-file callback function to execute when an error event occurs
OutputEmptyFcn	Specify the M-file callback function to execute when the output buffer is empty
PinStatusFcn	Specify the M-file callback function to execute when the CD, CTS, DSR, or RI pins change state
TimerFcn	Specify the M-file callback function to execute when a predefined period of time passes
TimerPeriod	Specify the period of time between timer events

Control Pin Properties	
DataTerminalReady	Specify the state of the DTR pin
FlowControl	Specify the data flow control method to use
PinStatus	Indicate the state of the CD, CTS, DSR, and RI pins
RequestToSend	Specify the state of the RTS pin

Recording Properties	
RecordDetail	Specify the amount of information saved to a record file
RecordMode	Specify whether data and event information are saved to one record file or to multiple record files
RecordName	Specify the name of the record file
RecordStatus	Indicate if data and event information are saved to a record file

General Purpose Properties	
ByteOrder	Specify the order in which the device stores bytes
Name	Specify a descriptive name for the serial port object
Port	Indicate the platform-specific serial port name
Status	Indicate if the serial port object is connected to the device
Tag	Specify a label to associate with a serial port object
Type	Indicate the object type
UserData	Specify data that you want to associate with a serial port object

Properties — Alphabetical List

Purpose

Specify the rate at which bits are transmitted

Description

You configure `BaudRate` as bits per second. The transferred bits include the start bit, the data bits, the parity bit (if used), and the stop bits. However, only the data bits are stored.

The baud rate is the rate at which information is transferred in a communication channel. In the serial port context, "9600 baud" means that the serial port is capable of transferring a maximum of 9600 bits per second. If the information unit is one baud (one bit), the bit rate and the baud rate are identical. If one baud is given as 10 bits, (for example, eight data bits plus two framing bits), the bit rate is still 9600 but the baud rate is 9600/10, or 960. You always configure `BaudRate` as bits per second. Therefore, in the above example, set `BaudRate` to 9600.

Note Both the computer and the peripheral device must be configured to the same baud rate before you can successfully read or write data.

Standard baud rates include 110, 300, 600, 1200, 2400, 4800, 9600, 14400, 19200, 38400, 57600, 115200, 128000 and 256000 bits per second. To display the supported baud rates for the serial ports on your platform, refer to "Finding Serial Port Information for Your Platform" on page 10-16.

Characteristics

Read only	Never
Data type	Double

Values

The default value is `9600`.

See Also

Properties

`DataBits`, `Parity`, `StopBits`

BreakInterruptFcn

Purpose

Specify the M-file callback function to execute when a break-interrupt event occurs

Description

You configure `BreakInterruptFcn` to execute an M-file callback function when a break-interrupt event occurs. A break-interrupt event is generated by the serial port when the received data is in an off (space) state longer than the transmission time for one byte.

Note A break-interrupt event can be generated at any time during the serial port session.

If the `RecordStatus` property value is `on`, and a break-interrupt event occurs, the record file records this information:

- The event type as `BreakInterrupt`
- The time the event occurred using the format day-month-year hour:minute:second:millisecond

Refer to "Creating and Executing Callback Functions" on page 10-57 to learn how to create a callback function.

Characteristics

Read only	Never
Data type	Callback function

Values

The default value is an empty string.

See Also

Functions

`record`

Properties

`RecordStatus`

Purpose

Specify the byte order of the device

Description

You configure `ByteOrder` to be `littleEndian` or `bigEndian`. If `ByteOrder` is `littleEndian`, the device stores the first byte in the first memory address. If `ByteOrder` is `bigEndian`, the device stores the last byte in the first memory address.

For example, suppose the hexadecimal value 4F52 is to be stored in device memory. Because this value consists of two bytes, 4F and 52, two memory locations are used. Using big-endian format, 4F is stored first in the lower storage address. Using little-endian format, 52 is stored first in the lower storage address.

Note You should configure `ByteOrder` to the appropriate value for your device before performing a read or write operation. Refer to your device documentation for information about the order in which it stores bytes.

Characteristics

Read only	Never
Data type	String

Values

`{littleEndian}`	The byte order of the device is little-endian.
`bigEndian`	The byte order of the device is big-endian.

See Also

Properties

`Status`

BytesAvailable

Purpose

Indicate the number of bytes available in the input buffer

Description

`BytesAvailable` indicates the number of bytes currently available to be read from the input buffer. The property value is continuously updated as the input buffer is filled, and is set to `0` after the `fopen` function is issued.

You can make use of `BytesAvailable` only when reading data asynchronously. This is because when reading data synchronously, control is returned to the MATLAB command line only after the input buffer is empty. Therefore, the `BytesAvailable` value is always 0. Refer to "Reading Text Data" on page 10-42 to learn how to read data asynchronously.

The `BytesAvailable` value can range from zero to the size of the input buffer. Use the `InputBufferSize` property to specify the size of the input buffer. Use the `ValuesReceived` property to return the total number of values read.

Characteristics

Read only	Always
Data type	Double

Values

The default value is `0`.

See Also

Functions

`fopen`

Properties

`InputBufferSize`, `TransferStatus`, `ValuesReceived`

Purpose

Specify the M-file callback function to execute when a specified number of bytes is available in the input buffer, or a terminator is read

Description

You configure `BytesAvailableFcn` to execute an M-file callback function when a bytes-available event occurs. A bytes-available event occurs when the number of bytes specified by the `BytesAvailableFcnCount` property is available in the input buffer, or after a terminator is read, as determined by the `BytesAvailableFcnMode` property.

Note A bytes-available event can be generated only for asynchronous read operations.

If the `RecordStatus` property value is `on`, and a bytes-available event occurs, the record file records this information:

- The event type as `BytesAvailable`
- The time the event occurred using the format day-month-year hour:minute:second:millisecond

Refer to "Creating and Executing Callback Functions" on page 10-57 to learn how to create a callback function.

Characteristics

Read only	Never
Data type	Callback function

Values

The default value is an empty string.

Example

Create the serial port object `s` for a Tektronix TDS 210 two-channel oscilloscope connected to the serial port COM1.

```
s = serial('COM1');
```

Configure s to execute the M-file callback function instrcallback when 40 bytes are available in the input buffer.

```
s.BytesAvailableFcnCount = 40;
s.BytesAvailableFcnMode = 'byte';
s.BytesAvailableFcn = @instrcallback;
```

Connect s to the oscilloscope.

```
fopen(s)
```

Write the *IDN? command, which instructs the scope to return identification information. Because the default value for the ReadAsyncMode property is continuous, data is read as soon as it is available from the instrument.

```
fprintf(s,'*IDN?')
```

The resulting output from instrcallback is shown below.

```
BytesAvailable event occurred at 18:33:35 for the object:
Serial-COM1.
```

56 bytes are read and instrcallback is called once. The resulting display is shown above.

```
s.BytesAvailable
ans =
    56
```

Suppose you remove 25 bytes from the input buffer and then issue the MEASUREMENT? command, which instructs the scope to return its measurement settings.

```
out = fscanf(s,'%c',25);
fprintf(s,'MEASUREMENT?')
```

The resulting output from instrcallback is shown below.

```
BytesAvailable event occurred at 18:33:48 for the object:
```

```
Serial-COM1.

BytesAvailable event occurred at 18:33:48 for the object:
Serial-COM1.
```

There are now 102 bytes in the input buffer, 31 of which are left over from the `*IDN?` command. `instrcallback` is called twice—once when 40 bytes are available and once when 80 bytes are available.

```
s.BytesAvailable
ans =
   102
```

See Also

Functions

`record`

Properties

`BytesAvailableFcnCount`, `BytesAvailableFcnMode`, `RecordStatus`, `Terminator`, `TransferStatus`

BytesAvailableFcnCount

Purpose

Specify the number of bytes that must be available in the input buffer to generate a bytes-available event

Description

You configure `BytesAvailableFcnCount` to the number of bytes that must be available in the input buffer before a bytes-available event is generated.

Use the `BytesAvailableFcnMode` property to specify whether the bytes-available event occurs after a certain number of bytes are available or after a terminator is read.

The bytes-available event executes the M-file callback function specified for the `BytesAvailableFcn` property.

You can configure `BytesAvailableFcnCount` only when the object is disconnected from the device. You disconnect an object with the `fclose` function. A disconnected object has a `Status` property value of `closed`.

Characteristics

Read only	While open
Data type	Double

Values

The default value is `48`.

See Also

Functions

`fclose`

Properties

`BytesAvailableFcn`, `BytesAvailableFcnMode`, `Status`

Purpose

Specify if the bytes-available event is generated after a specified number of bytes is available in the input buffer, or after a terminator is read

Description

You can configure `BytesAvailableFcnMode` to be `terminator` or `byte`. If `BytesAvailableFcnMode` is `terminator`, a bytes-available event occurs when the terminator specified by the `Terminator` property is reached. If `BytesAvailableFcnMode` is `byte`, a bytes-available event occurs when the number of bytes specified by the `BytesAvailableFcnCount` property is available.

The bytes-available event executes the M-file callback function specified for the `BytesAvailableFcn` property.

You can configure `BytesAvailableFcnMode` only when the object is disconnected from the device. You disconnect an object with the `fclose` function. A disconnected object has a `Status` property value of `closed`.

Characteristics

Read only	While open
Data type	String

Values

`{terminator}`	A bytes-available event is generated when the terminator is read.
`byte`	A bytes-available event is generated when the specified number of bytes are available.

See Also

Functions

`fclose`

Properties

`BytesAvailableFcn`, `BytesAvailableFcnCount`, `Status`, `Terminator`

BytesToOutput

Purpose

Indicate the number of bytes currently in the output buffer

Description

`BytesToOutput` indicates the number of bytes currently in the output buffer waiting to be written to the device. The property value is continuously updated as the output buffer is filled and emptied, and is set to `0` after the `fopen` function is issued.

You can make use of `BytesToOutput` only when writing data asynchronously. This is because when writing data synchronously, control is returned to the MATLAB command line only after the output buffer is empty. Therefore, the `BytesToOutput` value is always `0`. Refer to "Writing Text Data" on page 10-37 to learn how to write data asynchronously.

Use the `ValuesSent` property to return the total number of values written to the device.

Note If you attempt to write out more data than can fit in the output buffer, an error is returned and `BytesToOutput` is `0`. Specify the size of the output buffer with the `OutputBufferSize` property.

Characteristics

Read only	Always
Data type	Double

Values

The default value is `0`.

See Also

Functions

`fopen`

Properties

`OutputBufferSize`, `TransferStatus`, `ValuesSent`

Purpose

Specify the number of data bits to transmit

Description

You can configure `DataBits` to be `5`, `6`, `7`, or `8`. Data is transmitted as a series of five, six, seven, or eight bits with the least significant bit sent first. At least seven data bits are required to transmit ASCII characters. Eight bits are required to transmit binary data. Five and six bit data formats are used for specialized communications equipment.

Note Both the computer and the peripheral device must be configured to transmit the same number of data bits.

In addition to the data bits, the serial data format consists of a start bit, one or two stop bits, and possibly a parity bit. You specify the number of stop bits with the `StopBits` property, and the type of parity checking with the `Parity` property.

To display the supported number of data bits for the serial ports on your platform, refer to "Finding Serial Port Information for Your Platform" on page 10-16.

Characteristics

Read only	Never
Data type	Double

Values

`DataBits` can be `5`, `6`, `7`, or `8`. The default value is `8`.

See Also

Properties

`Parity`, `StopBits`

DataTerminalReady

Purpose

Specify the state of the DTR pin

Description

You can configure `DataTerminalReady` to be `on` or `off`. If `DataTerminalReady` is `on`, the Data Terminal Ready (DTR) pin is asserted. If `DataTerminalReady` is `off`, the DTR pin is unasserted.

In normal usage, the DTR and Data Set Ready (DSR) pins work together, and are used to signal if devices are connected and powered. However, there is nothing in the RS-232 standard that states the DTR pin must be used in any specific way. For example, DTR and DSR might be used for handshaking. You should refer to your device documentation to determine its specific pin behavior.

You can return the value of the DSR pin with the `PinStatus` property. Handshaking is described in "Controlling the Flow of Data: Handshaking" on page 10-63.

Characteristics

Read only	Never
Data type	String

Values

`{on}`	The DTR pin is asserted.
`off`	The DTR pin is unasserted.

See Also

Properties

`FlowControl`, `PinStatus`

Purpose

Specify the M-file callback function to execute when an error event occurs

Description

You configure `ErrorFcn` to execute an M-file callback function when an error event occurs.

Note An error event is generated only for asynchronous read and write operations.

An error event is generated when a time-out occurs. A time-out occurs if a read or write operation does not successfully complete within the time specified by the `Timeout` property. An error event is not generated for configuration errors such as setting an invalid property value.

If the `RecordStatus` property value is `on`, and an error event occurs, the record file records this information:

- The event type as `Error`
- The error message
- The time the event occurred using the format day-month-year hour:minute:second:millisecond

Refer to "Creating and Executing Callback Functions" on page 10-57 to learn how to create a callback function.

Characteristics

Read only	Never
Data type	Callback function

Values

The default value is an empty string.

See Also

Functions

`record`

Properties

`RecordStatus`, `Timeout`

Purpose

Specify the data flow control method to use

Description

You can configure `FlowControl` to be `none`, `hardware`, or `software`. If `FlowControl` is `none`, data flow control (handshaking) is not used. If `FlowControl` is `hardware`, hardware handshaking is used to control data flow. If `FlowControl` is `software`, software handshaking is used to control data flow.

Hardware handshaking typically utilizes the Request to Send (RTS) and Clear to Send (CTS) pins to control data flow. Software handshaking uses control characters (Xon and Xoff) to control data flow. Refer to "Controlling the Flow of Data: Handshaking" on page 10-63 for more information about handshaking.

You can return the value of the CTS pin with the `PinStatus` property. You can specify the value of the RTS pin with the `RequestToSend` property. However, if `FlowControl` is `hardware`, and you specify a value for `RequestToSend`, that value might not be honored.

Note Although you might be able to configure your device for both hardware handshaking and software handshaking at the same time, MATLAB does not support this behavior.

Characteristics

Read only	Never
Data type	String

Values

`{none}`	No flow control is used.
`hardware`	Hardware flow control is used.
`software`	Software flow control is used.

See Also

Properties

`PinStatus`, `RequestToSend`

Purpose

Specify the size of the input buffer in bytes

Description

You configure `InputBufferSize` as the total number of bytes that can be stored in the input buffer during a read operation.

A read operation is terminated if the amount of data stored in the input buffer equals the `InputBufferSize` value. You can read text data with the `fgetl`, `fgets`, or `fscanf` functions. You can read binary data with the `fread` function.

You can configure `InputBufferSize` only when the serial port object is disconnected from the device. You disconnect an object with the `fclose` function. A disconnected object has a `Status` property value of `closed`.

If you configure `InputBufferSize` while there is data in the input buffer, that data is flushed.

Characteristics

Read only	While open
Data type	Double

Values

The default value is `512`.

See Also

Functions

`fclose`, `fgetl`, `fgets`, `fopen`, `fread`, `fscanf`

Properties

`Status`

Name

Purpose

Specify a descriptive name for the serial port object

Description

You configure `Name` to be a descriptive name for the serial port object.

When you create a serial port object, a descriptive name is automatically generated and stored in `Name`. This name is given by concatenating the word “Serial” with the serial port specified in the `serial` function. However, you can change the value of `Name` at any time.

The serial port is given by the `Port` property. If you modify this property value, then `Name` is automatically updated to reflect that change.

Characteristics

Read only	Never
Data type	String

Values

`Name` is automatically defined when the serial port object is created.

Example

Suppose you create a serial port object associated with the serial port COM1.

```
s = serial('COM1');
```

`s` is automatically assigned a descriptive name.

```
s.Name
ans =
Serial-COM1
```

See Also

Functions

`serial`

Purpose

Control access to serial port object

Description

The `ObjectVisibility` property provides a way for application developers to prevent end-user access to the serial port objects created by their applications. When an object's `ObjectVisibility` property is set to `off`, `instrfind` does not return or delete that object.

Objects that are not visible are still valid. If you have access to the object (for example, from within the M-file that creates it), you can set and get its properties and pass it to any function that operates on serial port objects.

Characteristics

Usage	Any serial port object
Read only	Never
Data type	String

Values

`{on}`	Object is visible to `instrfind`.
`off`	Object is not visible from the command line (except by `instrfindall`).

Examples

The following statement creates a serial port object with its `ObjectVisibility` property set to `off`:

```
s = serial('COM1','ObjectVisibility','off');
instrfind
ans =
     []
```

However, because the hidden object is in the workspace (`s`), you can access it.

```
get(s,'ObjectVisibility')
ans =
 off
```

See Also

Functions

`instrfind`, `instrfindall`

Purpose

Specify the size of the output buffer in bytes

Description

You configure `OutputBufferSize` as the total number of bytes that can be stored in the output buffer during a write operation.

An error occurs if the output buffer cannot hold all the data to be written. You write text data with the `fprintf` function. You write binary data with the `fwrite` function.

You can configure `OutputBufferSize` only when the serial port object is disconnected from the device. You disconnect an object with the `fclose` function. A disconnected object has a `Status` property value of `closed`.

Characteristics

Read only	While open
Data type	Double

Values

The default value is `512`.

See Also

Functions

`fprintf`, `fwrite`

Properties

`Status`

OutputEmptyFcn

Purpose

Specify the M-file callback function to execute when the output buffer is empty

Description

You configure `OutputEmptyFcn` to execute an M-file callback function when an output-empty event occurs. An output-empty event is generated when the last byte is sent from the output buffer to the device.

Note An output-empty event can be generated only for asynchronous write operations.

If the `RecordStatus` property value is `on`, and an output-empty event occurs, the record file records this information:

- The event type as `OutputEmpty`
- The time the event occurred using the format day-month-year hour:minute:second:millisecond

Refer to "Creating and Executing Callback Functions" on page 10-57 to learn how to create a callback function.

Characteristics

Read only	Never
Data type	Callback function

Values

The default value is an empty string.

See Also

Functions

`record`

Properties

`RecordStatus`

Purpose

Specify the type of parity checking

Description

You can configure `Parity` to be `none`, `odd`, `even`, `mark`, or `space`. If `Parity` is `none`, parity checking is not performed and the parity bit is not transmitted. If `Parity` is `odd`, the number of mark bits (1s) in the data is counted, and the parity bit is asserted or unasserted to obtain an odd number of mark bits. If `Parity` is `even`, the number of mark bits in the data is counted, and the parity bit is asserted or unasserted to obtain an even number of mark bits. If `Parity` is `mark`, the parity bit is asserted. If `Parity` is `space`, the parity bit is unasserted.

Parity checking can detect errors of one bit only. An error in two bits might cause the data to have a seemingly valid parity, when in fact it is incorrect. Refer to "The Parity Bit" on page 10-14 for more information about parity checking.

In addition to the parity bit, the serial data format consists of a start bit, between five and eight data bits, and one or two stop bits. You specify the number of data bits with the `DataBits` property, and the number of stop bits with the `StopBits` property.

Characteristics

Read only	Never
Data type	String

Values

`{none}`	No parity checking
`odd`	Odd parity checking
`even`	Even parity checking
`mark`	Mark parity checking
`space`	Space parity checking

See Also

Properties

`DataBits`, `StopBits`

PinStatus

Purpose

Indicate the state of the CD, CTS, DSR, and RI pins

Description

`PinStatus` is a structure array that contains the fields `CarrierDetect`, `ClearToSend`, `DataSetReady` and `RingIndicator`. These fields indicate the state of the Carrier Detect (CD), Clear to Send (CTS), Data Set Ready (DSR) and Ring Indicator (RI) pins, respectively. Refer to "Serial Port Signals and Pin Assignments" on page 10-7 for more information about these pins.

`PinStatus` can be `on` or `off` for any of these fields. A value of `on` indicates the associated pin is asserted. A value of `off` indicates the associated pin is unasserted. A pin status event occurs when any of these pins changes its state. A pin status event executes the M-file specified by `PinStatusFcn`.

In normal usage, the Data Terminal Ready (DTR) and DSR pins work together, while the Request to Send (RTS) and CTS pins work together. You can specify the state of the DTR pin with the `DataTerminalReady` property. You can specify the state of the RTS pin with the `RequestToSend` property.

Refer to "Example — Connecting Two Modems" on page 10-61 for an example that uses `PinStatus`.

Characteristics

Read only	Always
Data type	Structure

Values

`off`	The associated pin is asserted.
`on`	The associated pin is asserted.

The default value is device dependent.

See Also

Properties

`DataTerminalReady`, `PinStatusFcn`, `RequestToSend`

Purpose

Specify the M-file callback function to execute when the CD, CTS, DSR, or RI pins change state

Description

You configure `PinStatusFcn` to execute an M-file callback function when a pin status event occurs. A pin status event occurs when the Carrier Detect (CD), Clear to Send (CTS), Data Set Ready (DSR) or Ring Indicator (RI) pin changes state. A serial port pin changes state when it is asserted or unasserted. Information about the state of these pins is recorded in the `PinStatus` property.

Note A pin status event can be generated at any time during the serial port session.

If the `RecordStatus` property value is `on`, and a pin status event occurs, the record file records this information:

- The event type as `PinStatus`
- The pin that changed its state, and the pin state as either `on` or `off`
- The time the event occurred using the format day-month-year hour:minute:second:millisecond

Refer to “Creating and Executing Callback Functions” on page 10-57 to learn how to create a callback function.

Characteristics

Read only	Never
Data type	Callback function

Values

The default value is an empty string.

See Also

Functions

`record`

Properties

PinStatus, RecordStatus

Purpose

Specify the platform-specific serial port name

Description

You configure `Port` to be the name of a serial port on your platform. `Port` specifies the physical port associated with the object and the device.

When you create a serial port object, `Port` is automatically assigned the port name specified for the `serial` function.

You can configure `Port` only when the object is disconnected from the device. You disconnect an object with the `fclose` function. A disconnected object has a `Status` property value of `closed`.

Characteristics

Read only	While open
Data type	String

Values

The `Port` value is determined when the serial port object is created.

Example

Suppose you create a serial port object associated with serial port COM1.

```
s = serial('COM1');
```

The value of the `Port` property is `COM1`.

```
s.Port
ans =
COM1
```

See Also

Functions

`fclose`, `serial`

Properties

`Name`, `Status`

ReadAsyncMode

Purpose

Specify whether an asynchronous read operation is continuous or manual

Description

You can configure `ReadAsyncMode` to be `continuous` or `manual`. If `ReadAsyncMode` is `continuous`, the serial port object continuously queries the device to determine if data is available to be read. If data is available, it is automatically read and stored in the input buffer. If issued, the `readasync` function is ignored.

If `ReadAsyncMode` is `manual`, the object does not query the device to determine if data is available to be read. Instead, you must manually issue the `readasync` function to perform an asynchronous read operation. Because `readasync` checks for the terminator, this function can be slow. To increase speed, configure `ReadAsyncMode` to `continuous`.

Note If the device is ready to transmit data, it will do so regardless of the `ReadAsyncMode` value. Therefore, if `ReadAsyncMode` is `manual` and a read operation is not in progress, data might be lost. To guarantee that all transmitted data is stored in the input buffer, you should configure `ReadAsyncMode` to `continuous`.

You can determine the amount of data available in the input buffer with the `BytesAvailable` property. For either `ReadAsyncMode` value, you can bring data into the MATLAB workspace with one of the synchronous read functions such as `fscanf`, `fgetl`, `fgets`, or `fread`.

Characteristics

Read only	Never
Data type	String

Values

`{continuous}`	Continuously query the device to determine if data is available to be read.
`manual`	Manually read data from the device using the `readasync` function.

See Also

Functions

`fgetl`, `fgets`, `fread`, `fscanf`, `readasync`

Properties

`BytesAvailable`, `InputBufferSize`

RecordDetail

Purpose

Specify the amount of information saved to a record file

Description

You can configure `RecordDetail` to be `compact` or `verbose`. If `RecordDetail` is `compact`, the number of values written to the device, the number of values read from the device, the data type of the values, and event information are saved to the record file. If `RecordDetail` is `verbose`, the data written to the device, and the data read from the device are also saved to the record file.

The event information saved to a record file is shown in the table, Event Information on page 10-55. The verbose record file structure is shown in “Example: Recording Information to Disk” on page 10-69.

Characteristics

Read only	Never
Data type	String

Values

`{compact}`	The number of values written to the device, the number of values read from the device, the data type of the values, and event information are saved to the record file.
`verbose`	The data written to the device, and the data read from the device are also saved to the record file.

See Also

Functions

`record`

Properties

`RecordMode`, `RecordName`, `RecordStatus`

Purpose

Specify whether data and event information are saved to one record file or to multiple record files

Description

You can configure `RecordMode` to be `overwrite`, `append`, or `index`. If `RecordMode` is `overwrite`, the record file is overwritten each time recording is initiated. If `RecordMode` is `append`, data is appended to the record file each time recording is initiated. If `RecordMode` is `index`, a different record file is created each time recording is initiated, each with an indexed filename.

You can configure `RecordMode` only when the object is not recording. You terminate recording with the `record` function. A object that is not recording has a `RecordStatus` property value of `off`.

You specify the record filename with the `RecordName` property. The indexed filename follows a prescribed set of rules. Refer to "Specifying a Filename" on page 10-68 for a description of these rules.

Characteristics

Read only	While recording
Data type	String

Values

`{overwrite}`	The record file is overwritten.
`append`	Data is appended to an existing record file.
`index`	A different record file is created, each with an indexed filename.

Example

Suppose you create the serial port object `s` associated with the serial port COM1.

```
s = serial('COM1');
fopen(s)
```

Specify the record filename with the `RecordName` property, configure `RecordMode` to `index`, and initiate recording.

```
s.RecordName = 'MyRecord.txt';
s.RecordMode = 'index';
record(s)
```

The record filename is automatically updated with an indexed filename after recording is turned off.

```
record(s,'off')
s.RecordName
ans =
MyRecord01.txt
```

Disconnect s from the peripheral device, remove s from memory, and remove s from the MATLAB workspace.

```
fclose(s)
delete(s)
clear s
```

See Also

Functions

`record`

Properties

`RecordDetail`, `RecordName`, `RecordStatus`

Purpose

Specify the name of the record file

Description

You configure `RecordName` to be the name of the record file. You can specify any value for `RecordName` - including a directory path - provided the filename is supported by your operating system.

MATLAB supports any filename supported by your operating system. However, if you access the file through MATLAB, you might need to specify the filename using single quotes. For example, suppose you name the record file `My Record.txt`. To type this file at the MATLAB command line, you must include the name in quotes.

```
type('My Record.txt')
```

You can specify whether data and event information are saved to one disk file or to multiple disk files with the `RecordMode` property. If `RecordMode` is `index`, the filename follows a prescribed set of rules. Refer to “Specifying a Filename” on page 10-68 for a description of these rules.

You can configure `RecordName` only when the object is not recording. You terminate recording with the `record` function. An object that is not recording has a `RecordStatus` property value of `off`.

Characteristics

Read only	While recording
Data type	String

Values

The default record filename is `record.txt`.

See Also

Functions

`record`

Properties

`RecordDetail`, `RecordMode`, `RecordStatus`

RecordStatus

Purpose

Indicate if data and event information are saved to a record file

Description

You can configure `RecordStatus` to be `off` or `on` with the `record` function. If `RecordStatus` is `off`, then data and event information are not saved to a record file. If `RecordStatus` is `on`, then data and event information are saved to the record file specified by `RecordName`.

Use the `record` function to initiate or complete recording. `RecordStatus` is automatically configured to reflect the recording state.

For more information about recording to a disk file, refer to "Debugging: Recording Information to Disk" on page 10-66.

Characteristics

Read only	Always
Data type	String

Values

`{off}`	Data and event information are not written to a record file.
`on`	Data and event information are written to a record file.

See Also

Functions

`record`

Properties

`RecordDetail`, `RecordMode`, `RecordName`

Purpose

Specify the state of the RTS pin

Description

You can configure `RequestToSend` to be `on` or `off`. If `RequestToSend` is `on`, the Request to Send (RTS) pin is asserted. If `RequestToSend` is `off`, the RTS pin is unasserted.

In normal usage, the RTS and Clear to Send (CTS) pins work together, and are used as standard handshaking pins for data transfer. In this case, RTS and CTS are automatically managed by the DTE and DCE. However, there is nothing in the RS-232 standard that requires the RTS pin must be used in any specific way. Therefore, if you manually configure the `RequestToSend` value, it is probably for nonstandard operations.

If your device does not use hardware handshaking in the standard way, and you need to manually configure `RequestToSend`, configure the `FlowControl` property to `none`. Otherwise, the `RequestToSend` value that you specify might not be honored. Refer to your device documentation to determine its specific pin behavior.

You can return the value of the CTS pin with the `PinStatus` property. Handshaking is described in "Controlling the Flow of Data: Handshaking" on page 10-63.

Characteristics

Read only	Never
Data type	String

Values

`{on}`	The RTS pin is asserted.
`off`	The RTS pin is unasserted.

See Also

Properties

`FlowControl`, `PinStatus`

Status

Purpose

Indicate if the serial port object is connected to the device

Description

`Status` can be `open` or `closed`. If `Status` is `closed`, the serial port object is not connected to the device. If `Status` is `open`, the serial port object is connected to the device.

Before you can write or read data, you must connect the serial port object to the device with the `fopen` function. Use the `fclose` function to disconnect a serial port object from the device.

Characteristics

Read only	Always
Data type	String

Values

`{closed}`	The serial port object is not connected to the device.
`open`	The serial port object is connected to the device.

See Also

Functions

`fclose`, `fopen`

Purpose

Specify the number of bits used to indicate the end of a byte

Description

You can configure `StopBits` to be `1`, `1.5`, or `2`. If `StopBits` is `1`, one stop bit is used to indicate the end of data transmission. If `StopBits` is `2`, two stop bits are used to indicate the end of data transmission. If `StopBits` is `1.5`, the stop bit is transferred for 150% of the normal time used to transfer one bit.

Note Both the computer and the peripheral device must be configured to transmit the same number of stop bits.

In addition to the stop bits, the serial data format consists of a start bit, between five and eight data bits, and possibly a parity bit. You specify the number of data bits with the `DataBits` property, and the type of parity checking with the `Parity` property.

Characteristics

Read only	Never
Data type	Double

Values

`{1}`	One stop bit is transmitted to indicate the end of a byte.
`1.5`	The stop bit is transferred for 150% of the normal time used to transfer one bit.
`2`	Two stop bits are transmitted to indicate the end of a byte.

See Also

Properties

`DataBits`, `Parity`

Tag

Purpose

Specify a label to associate with a serial port object

Description

You configure `Tag` to be a string value that uniquely identifies a serial port object.

`Tag` is particularly useful when constructing programs that would otherwise need to define the serial port object as a global variable, or pass the object as an argument between callback routines.

You can return the serial port object with the `instrfind` function by specifying the `Tag` property value.

Characteristics

Read only	Never
Data type	String

Values

The default value is an empty string.

Example

Suppose you create a serial port object associated with the serial port COM1.

```
s = serial('COM1');
fopen(s)
```

You can assign `s` a unique label using `Tag`.

```
set(s,'Tag','MySerialObj')
```

You can access `s` in the MATLAB workspace or in an M-file using the `instrfind` function and the `Tag` property value.

```
s1 = instrfind('Tag','MySerialObj');
```

See Also

Functions

`instrfind`

Purpose

Specify the terminator character

Description

You can configure `Terminator` to an integer value ranging from 0 to 127, which represents the ASCII code for the character, or you can configure `Terminator` to the ASCII character. For example, to configure `Terminator` to a carriage return, specify the value to be `CR` or `13`. To configure `Terminator` to a linefeed, specify the value to be `LF` or `10`. You can also set `Terminator` to `CR/LF` or `LF/CR`. If `Terminator` is `CR/LF`, the terminator is a carriage return followed by a line feed. If Terminator is `LF/CR`, the terminator is a linefeed followed by a carriage return. Note that there are no integer equivalents for these two values. Additionally, you can set `Terminator` to a 1-by-2 cell array. The first element of the cell is the read terminator and the second element of the cell array is the write terminator.

When performing a write operation using the `fprintf` function, all occurrences of `\n` are replaced with the `Terminator` property value. Note that `%s\n` is the default format for `fprintf`. A read operation with `fgetl`, `fgets`, or `fscanf` completes when the `Terminator` value is read. The terminator is ignored for binary operations.

You can also use the terminator to generate a bytes-available event when the `BytesAvailableFcnMode` is set to `terminator`.

Characteristics

Read only	Never
Data type	String

Values

An integer value ranging from 0 to 127, or the equivalent ASCII character. `CR/LF` and `LF/CR` are also accepted values. You specify different read and write terminators as a 1-by-2 cell array.

See Also

Functions

`fgetl`, `fgets`, `fprintf`, `fscanf`

Properties

`BytesAvailableFcnMode`

Purpose

Specify the waiting time to complete a read or write operation

Description

You configure `Timeout` to be the maximum time (in seconds) to wait to complete a read or write operation.

If a time-out occurs, the read or write operation aborts. Additionally, if a time-out occurs during an asynchronous read or write operation, then:

- An error event is generated.
- The M-file callback function specified for `ErrorFcn` is executed.

Characteristics

Read only	Never
Data type	Double

Values

The default value is `10` seconds.

See Also

Properties

`ErrorFcn`

TimerFcn

Purpose

Specify the M-file callback function to execute when a predefined period of time passes.

Description

You configure `TimerFcn` to execute an M-file callback function when a timer event occurs. A timer event occurs when the time specified by the `TimerPeriod` property passes. Time is measured relative to when the serial port object is connected to the device with `fopen`.

Note A timer event can be generated at any time during the serial port session.

If the `RecordStatus` property value is `on`, and a timer event occurs, the record file records this information:

- The event type as `Timer`
- The time the event occurred using the format day-month-year hour:minute:second:millisecond

Some timer events might not be processed if your system is significantly slowed or if the `TimerPeriod` value is too small.

Refer to "Creating and Executing Callback Functions" on page 10-57 to learn how to create a callback function.

Characteristics

Read only	Never
Data type	Callback function

Values

The default value is an empty string.

See Also

Functions

`fopen`, `record`

Properties

RecordStatus, TimerPeriod

TimerPeriod

Purpose

Specify the period of time between timer events

Description

`TimerPeriod` specifies the time, in seconds, that must pass before the callback function specified for `TimerFcn` is called. Time is measured relative to when the serial port object is connected to the device with `fopen`.

Some timer events might not be processed if your system is significantly slowed or if the `TimerPeriod` value is too small.

Characteristics

Read only	Never
Data type	Callback function

Values

The default value is 1 second. The minimum value is 0.01 second.

See Also

Functions

`fopen`

Properties

`TimerFcn`

Purpose

Indicate if an asynchronous read or write operation is in progress

Description

`TransferStatus` can be `idle`, `read`, `write`, or `read&write`. If `TransferStatus` is `idle`, no asynchronous read or write operations are in progress. If `TransferStatus` is `read`, an asynchronous read operation is in progress. If `TransferStatus` is `write`, an asynchronous write operation is in progress. If `TransferStatus` is `read&write`, both an asynchronous read and an asynchronous write operation are in progress.

You can write data asynchronously using the `fprintf` or `fwrite` functions. You can read data asynchronously using the `readasync` function, or by configuring the `ReadAsyncMode` property to `continuous`. While `readasync` is executing, `TransferStatus` might indicate that data is being read even though data is not filling the input buffer. If `ReadAsyncMode` is `continuous`, `TransferStatus` indicates that data is being read only when data is actually filling the input buffer.

You can execute an asynchronous read and an asynchronous write operation simultaneously because serial ports have separate read and write pins. Refer to "Writing and Reading Data" on page 10-32 for more information about synchronous and asynchronous read and write operations.

Characteristics

Read only	Always
Data type	String

Values

`{idle}`	No asynchronous operations are in progress.
`read`	An asynchronous read operation is in progress.
`write`	An asynchronous write operation is in progress.
`read&write`	Asynchronous read and write operations are in progress.

See Also

Functions

`fprintf`, `fwrite`, `readasync`

Properties

`ReadAsyncMode`

Purpose

Indicate the object type

Description

`Type` indicates the type of the object. `Type` is automatically defined after the serial port object is created with the `serial` function. The `Type` value is always `serial`.

Characteristics

Read only	Always
Data type	String

Values

`Type` is always `serial`. This value is automatically defined when the serial port object is created.

Example

Suppose you create a serial port object associated with the serial port COM1.

```
s = serial('COM1');
```

The value of the `Type` property is `serial`, which is the object class.

```
s.Type
ans =
serial
```

You can also display the object class with the `whos` command.

```
Name      Size          Bytes  Class

  s         1x1             644  serial object

Grand total is 18 elements using 644 bytes
```

See Also

Functions

`serial`

UserData

Purpose

Specify data that you want to associate with a serial port object

Description

You configure `UserData` to store data that you want to associate with a serial port object. The object does not use this data directly, but you can access it using the `get` function or the dot notation.

Characteristics

Read only	Never
Data type	Any type

Values

The default value is an empty vector.

Example

Suppose you create the serial port object associated with the serial port COM1.

```
s = serial('COM1');
```

You can associate data with `s` by storing it in `UserData`.

```
coeff.a = 1.0;
coeff.b = -1.25;
s.UserData = coeff;
```

Purpose

Indicate the total number of values read from the device

Description

`ValuesReceived` indicates the total number of values read from the device. The value is updated after each successful read operation, and is set to `0` after the `fopen` function is issued. If the terminator is read from the device, then this value is reflected by `ValuesReceived`.

If you are reading data asynchronously, use the `BytesAvailable` property to return the number of bytes currently available in the input buffer.

When performing a read operation, the received data is represented by values rather than bytes. A value consists of one or more bytes. For example, one `uint32` value consists of four bytes. Refer to "Bytes Versus Values" on page 10-12 for more information about bytes and values.

Characteristics

Read only	Always
Data type	Double

Values

The default value is `0`.

Example

Suppose you create a serial port object associated with the serial port COM1.

```
s = serial('COM1');
fopen(s)
```

If you write the `RS232?` command, and read back the response using `fscanf`, `ValuesReceived` is `17` because the instrument is configured to send the `LF` terminator.

```
fprintf(s,'RS232?')
out = fscanf(s)
out =
9600;0;0;NONE;LF
s.ValuesReceived
```

```
ans =
    17
```

See Also

Functions

`fopen`

Properties

`BytesAvailable`

Purpose

Indicate the total number of values written to the device

Description

`ValuesSent` indicates the total number of values written to the device. The value is updated after each successful write operation, and is set to `0` after the `fopen` function is issued. If you are writing the terminator, `ValuesSent` reflects this value.

If you are writing data asynchronously, use the `BytesToOutput` property to return the number of bytes currently in the output buffer.

When performing a write operation, the transmitted data is represented by values rather than bytes. A value consists of one or more bytes. For example, one `uint32` value consists of four bytes. Refer to "Bytes Versus Values" on page 10-12 for more information about bytes and values.

Characteristics

Read only	Always
Data type	Double

Values

The default value is `0`.

Example

Suppose you create a serial port object associated with the serial port COM1.

```
s = serial('COM1');
fopen(s)
```

If you write the `*IDN?` command using the `fprintf` function, `ValuesSent` is `6` because the default data format is `%s\n`, and the terminator was written.

```
fprintf(s,'*IDN?')
s.ValuesSent
ans =
    6
```

Figures, Plots, and Graphs

In this section...

Graphing In MATLAB

MATLAB® offers you a variety of data plotting functions plus a set of GUI tools to create, and modify graphic displays. The GUI tools afford most of the control over graphic properties and options that typed commands such as `annotate`, `get`, and `set` provide.

A *figure* is a MATLAB window that contains graphic displays (usually data plots) and UI components. You create figures explicitly with the `figure` function, and implicitly whenever you plot graphics and no figure is active. By default, figure windows are resizable and include pull-down menus and toolbars.

A *plot* is any graphic display you can create within a figure window. Plots can display tabular data, geometric objects, surface and image objects, and annotations such as titles, legends, and colorbars. Figures can contain any number of plots. Each plot is created within a 2-D or a 3-D data space called an *axes*. You can explicitly create axes with the `axes` or `subplot` functions.

A *graph* is a plot of *data* within a 2-D or 3-D axes. Most plots made with MATLAB are therefore graphs. When you graph a one-dimensional variable (e.g., `rand(100,1)`), MATLAB assigns the indices of the data vector (in this case `1:100`) as *x*-values, and plots the data vector as *y*-values. Some types of graphs can display more than one variable at a time, others cannot.

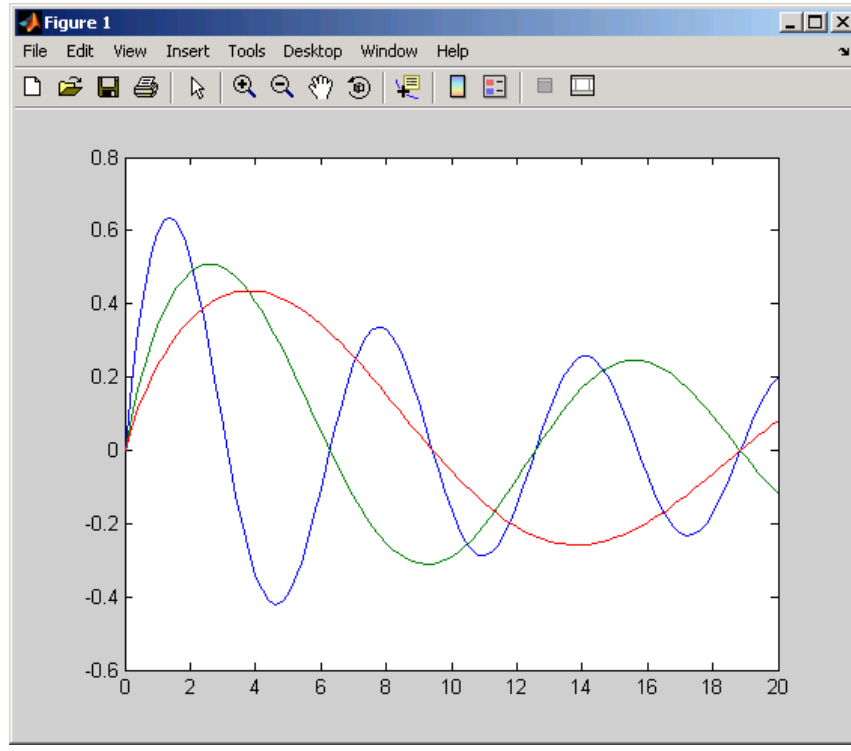
The contents and varieties of figures, plots and graphs that MATLAB can make are explained in the following sections.

Anatomy of a Graph

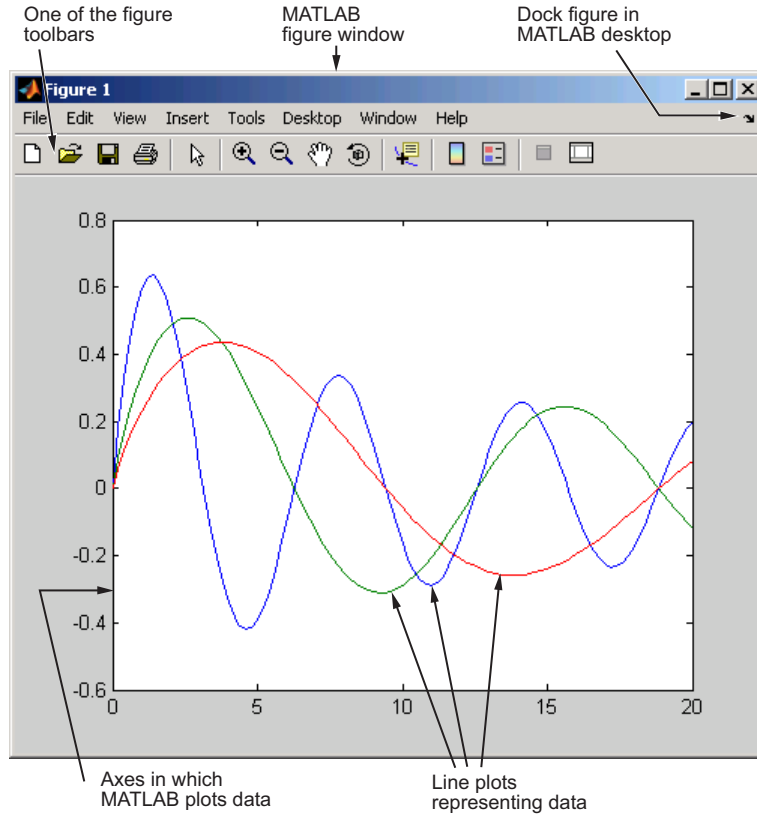
MATLAB plotting functions and tools direct their output to a figure window. Each figure is a separate window that you can dock in the desktop, and collect together with other plots in a *Figure Group*. To illustrate the basic components of a graph, execute the following M-code to create a plot of a family of sine curves:

```
x = [0:.2:20];
y = sin(x)./sqrt(x+1);
y(2,:) = sin(x/2)./sqrt(x+1);
y(3,:) = sin(x/3)./sqrt(x+1);
plot(x,y)
```

The resulting figure contains a 2-D set of axes and looks like this:



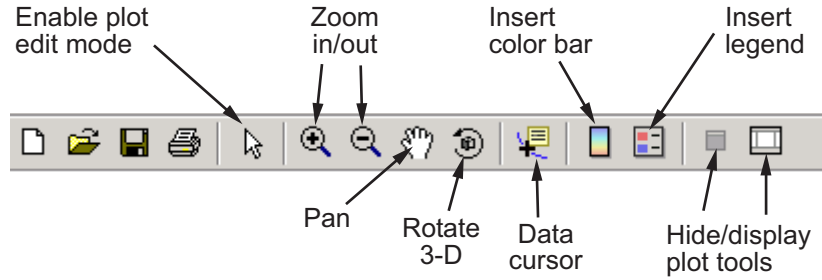
Some of the components and tools of figure windows are called out below:



MATLAB uses a default line style and color to distinguish the data sets plotted in the graph. You can change the appearance of these graphic components or add annotations to the graph to present your data in a particular way.

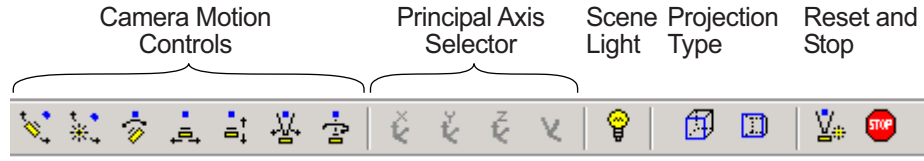
Figure Toolbars

Figure toolbars provide shortcuts to access commonly used features. These include operations such as saving and printing, plus tools for interactive zooming, panning, rotating, querying, and editing plots. The following picture shows the features available from this toolbar.

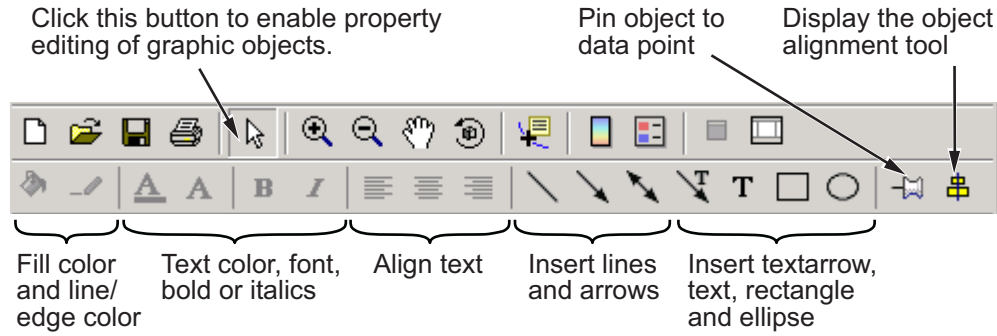


Note that you can enable two other toolbars from the **View** menu:

- Camera Toolbar — Use for manipulating 3-D views. See “View Control with the Camera Toolbar” in the MATLAB 3-D Visualization documentation for more information.



- Plot Edit Toolbar — Use for annotation and setting object properties. See “Annotation Tools on the Plot Edit Toolbar” on page 3-3 for more information.



Types of Plots Available in MATLAB

MATLAB can construct a wide variety of 2-D and 3-D plots without any programming required on your part. The following two tables classify and illustrate most of the kinds of plots you can create. They include line, bar, area, direction and vector field, radial, and scatter graphs. They also include 2-D and 3-D functions that generate and plot geometric shapes and objects. Most 2-D plots have 3-D analogs, and there are a variety of volumetric displays for 3-D solids and vector fields. Plot types that begin with "ez" (such as `exsurf`) are convenience functions that can plot arguments given as functions.

Two-Dimensional Plotting Functions

The table below shows 2-D plot functions available in MATLAB. If you are reading this online, you can click any icon to see the documentation for that function. Techniques for using many of the functions are also discussed in later sections of this document.

Line Graphs	Bar Graphs	Area Graphs	Direction Graphs	Radial Graphs	Scatter Graphs
`plot` 	`bar` (grouped) 	`area` 	`feather` 	`polar` 	`scatter` 
Line Graphs	Bar Graphs	Area Graphs	Direction Graphs	Radial Graphs	Scatter Graphs
plotyy 	barh (grouped) 	pie 	quiver 	rose 	spy loglog 	bar (stacked) 	fill 	comet 	compass 	plotmatrix semilogx 	barh (stacked) 	contourf 		ezpolar 	
semilogy 	hist 	image 			
stairs 	pareto 	pcolor 			
contour 	errorbar 	ezcontourf 			

Line Graphs	Bar Graphs	Area Graphs	Direction Graphs	Radial Graphs	Scatter Graphs
ezplot 	stem 				
ezcontour 					

Three-Dimensional Plotting Functions

The table below shows 3-D plot functions available in MATLAB. It includes functions that generate 3-D data (`cylinder`, `ellipsoid`, `sphere`), but most plot either arrays of data or functions. If you are reading this online, you can click any picture in the table to see the documentation for that function. For information about and examples of using 3-D plotting functions, see "Creating 3-D Graphs" in the 3-D Visualization documentation.

Line Graphs	Mesh Graphs and Bar Graphs	Area Graphs and Constructive Objects	Surface Graphs	Direction Graphs	Volumetric Graphs
plot3 	mesh 	pie3 	surf 	quiver3 	scatter3 contour3 	meshc 	fill3 	surfl 	comet3 	coneplot contourslice 	meshz 	patch 	surfc 	streamslice 	streamline 
Line Graphs	Mesh Graphs and Bar Graphs	Area Graphs and Constructive Objects	Surface Graphs	Direction Graphs	Volumetric Graphs
ezplot3 	ezmesh 	cylinder 	ezsurf 		streamribbon waterfall 	stem3 	ellipsoid 	ezsurfc 		streamtube 	bar3 	sphere 			
	bar3h 				

Choosing a Plot Type with the Plot Catalog

Most of the plotting functions shown in the previous tables are accessible through the **Figure Palette**, one of the Plot Tools you can access via the figure window **View** menu. When the Figure Palette is active and you select one, two or more variables listed within it, you can generate a plot of any appropriate type by right-clicking and selecting a plot type from the context menu that appears. The lowest item on that menu is **More Plots**. When you select **More Plots**, the *Plot Catalog* opens for you to browse through all plot types and generate one of them, either to display the variables you selected in the Figure Palette or a MATLAB expression you can specify in the Plot Catalog window. For more information, see “The Figure Palette” on page 1-18.

Plotting Tools — Interactive Plotting

In this section...

What Are Plotting Tools?

The modular, interactive plotting environment of MATLAB called *plotting tools* enables you to

- Create various type of graphs
- Select variables to plot directly from a workspace browser
- Easily create and manipulate subplots in the figure
- Add annotations such as arrows, lines, and text
- Set properties on graphics objects

You can open and configure plotting tools in many ways. To create a figure with the plotting tools attached, use the `plottools` command. You can also start the plotting tools from the figure toolbar by clicking the **Show Plot Tools** icon  .

Remove the plotting tools from a figure using the Hide Plot Tools icon  .

You can display the three basic plotting tools from the **View** menu by selecting **Figure Palette**, **Plot Browser**, or **Property Editor** .

The next section describes the individual components making up the plotting tools.

Plotting Tools Interface Overview

The Plotting Tools interface includes three panels that are associated with a figure.

- Figure Palette — Use to create and arrange subplot axes, view and plot workspace variables, and add annotations. Display the Figure Palette using the `figurepalette` command.
- Plot Browser — Use to select and control the visibility of the axes or graphic objects plotted in the figure. You can also add data to any selected axes by clicking the **Add Data** button. Display the Plot Browser using the `plotbrowser` command.
- Property Editor — Use to set common properties of the selected object. You can also open the Property Editor using the `propertyeditor` command. In the Property Editor you can click the **More Properties** button to display the Property Inspector, a GUI that displays most object properties and allows you to change any property's value (unless it is read-only). See "Accessing Object Properties with the Property Inspector" on page 1-29 for details.

Activating Plotting Tools

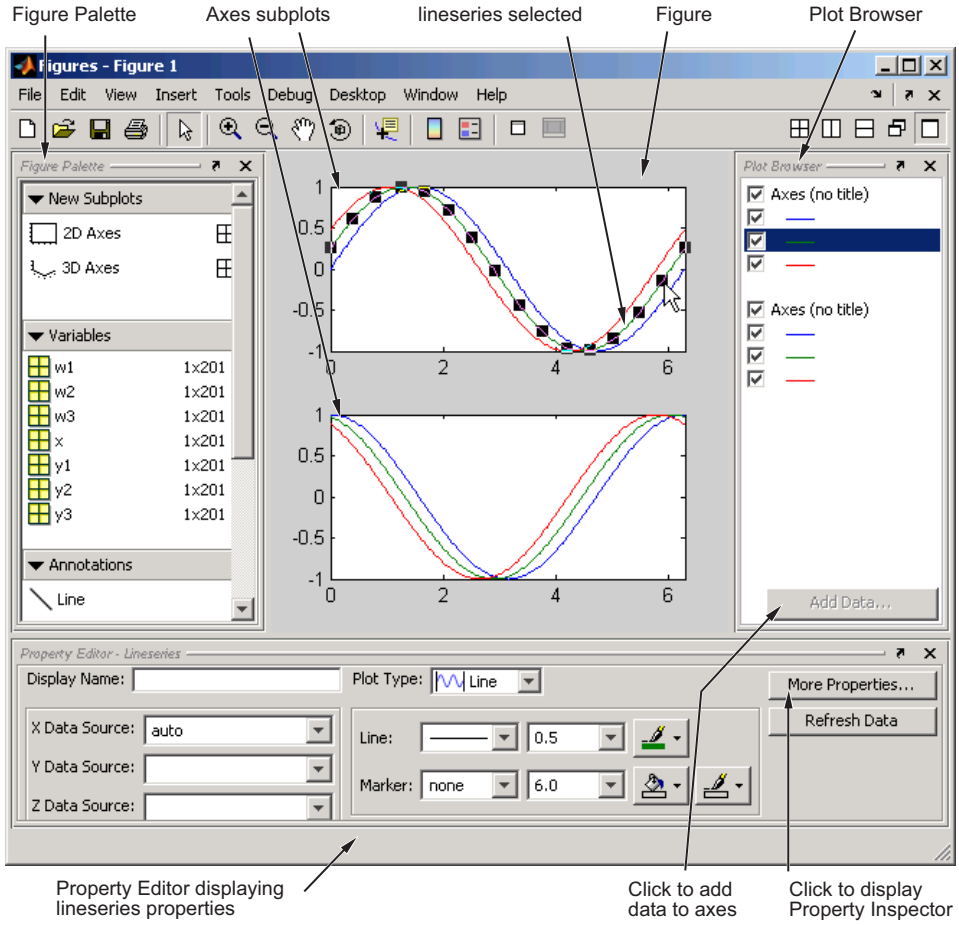
The example illustrated below shows the plotting tools attached to a figure containing two subplots of lineseries data. The code to produce the graphs is

```
x = 0:pi/100:2*pi;
y1 = sin(x);
y2 = sin(x+.25);
y3 = sin(x+.5);
subplot(2,1,1);
plot(x,y1,x,y2,x,y3);
axis tight;
w1 = cos(x);
w2 = cos(x+.25);
w3 = cos(x+.5);
subplot(2,1,2);
plot(x,w1,x,w2,x,w3);
axis tight;
```

You summon the plotting tools, either by selecting **Figure Palette**, **Plot Browser**, and **Property Editor** from the figure's **View** menu, or by typing

```
plottools
```

in the Command Window. Typing `plottools` or `plottools on` restores the configuration of tools the last time you were using them; use the View menu to show the ones you need and hide the ones you do not, and the mouse to dock and undock them. The default configuration of plotting tools is shown below. Note that MATLAB remembers the current arrangement of plot tools — whether they are visible or not — each time you exit; if you want to revert to the default configuration you need to restore the arrangement shown below manually.



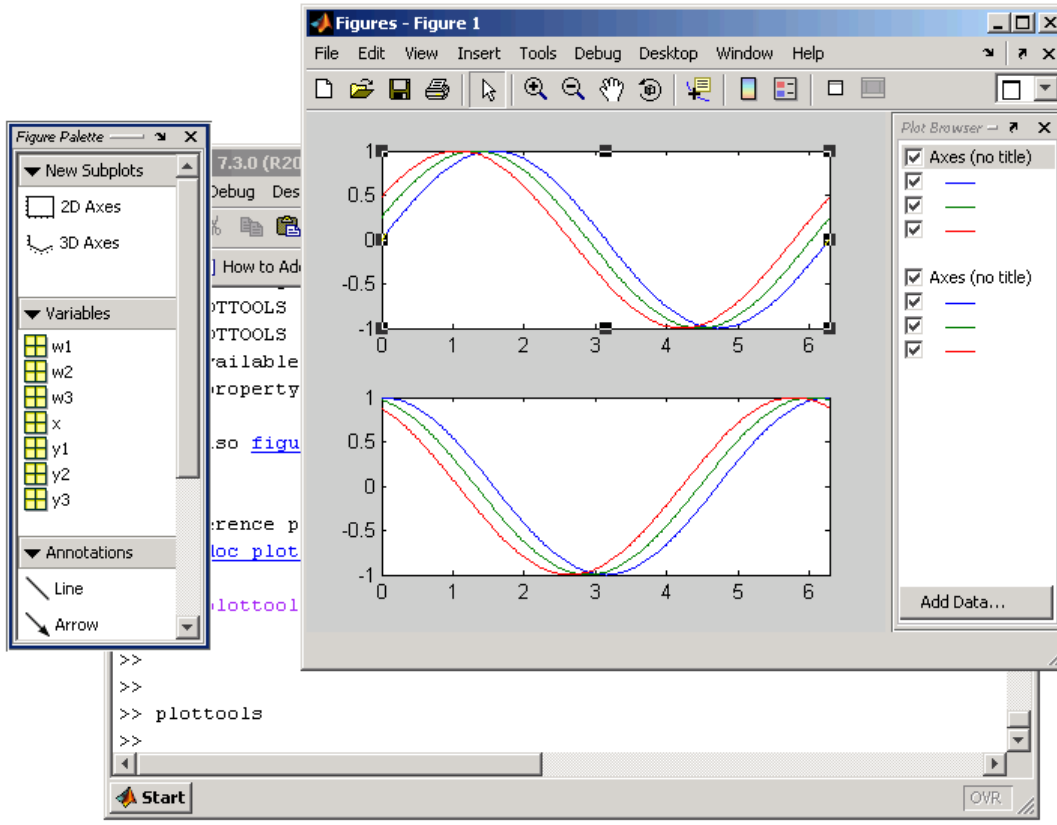
Managing Plotting Tools

Each of the plotting tools shown above can be docked or undocked from its figure, or dismissed by clicking the **x** at the right end of its titlebar. If you dismiss a tool and want it back again, you can raise it from the View menu or by typing one of several commands. For instance, if you had undocked, and then dismissed the figure palette, you could type either

```
plottools( 'on', 'figurepalette') or
```

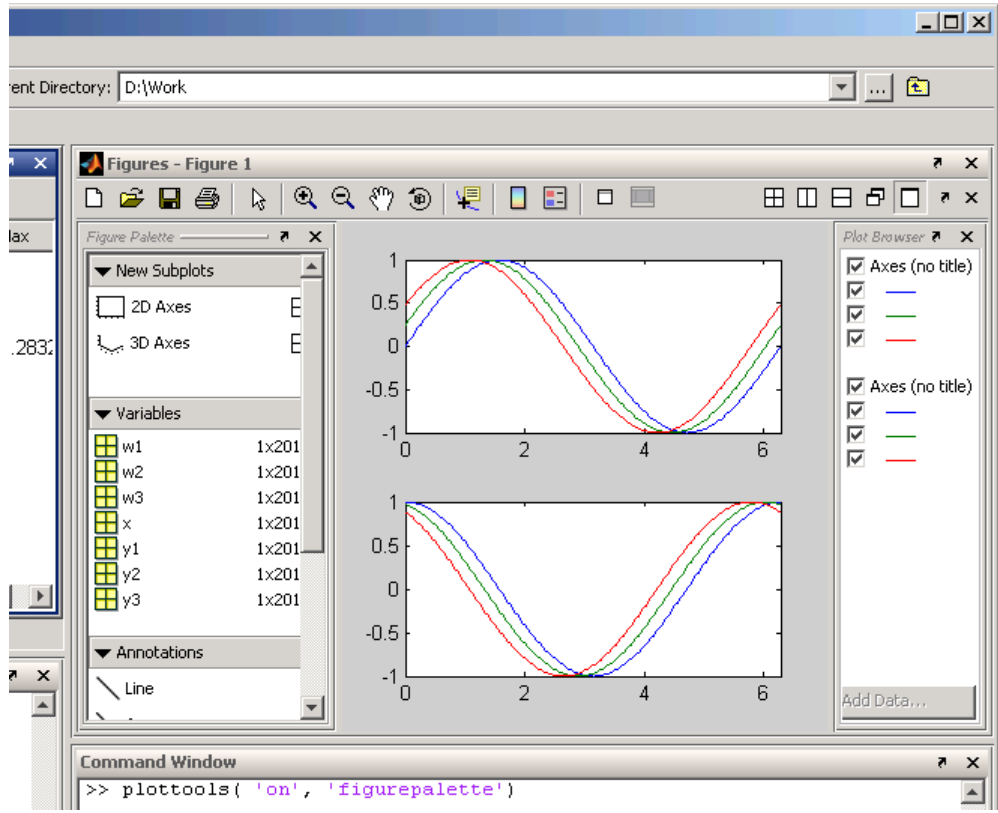
```
figurepalette
```

Your desktop configuration might then look like this:



Figures Groups. When you activate any plot tool for a figure (or dock the figure in the desktop), the figure becomes part of a Figures group. Figures groups are desktop containers that you can dock s in your desktop. Individual figures are not dockable except within the Figures group container. If you create subsequent figures, they will also dock in the Figures group, where they can be panelled or overlapped for viewing. A row of tabs appears along the bottom, one for each figure in the group.

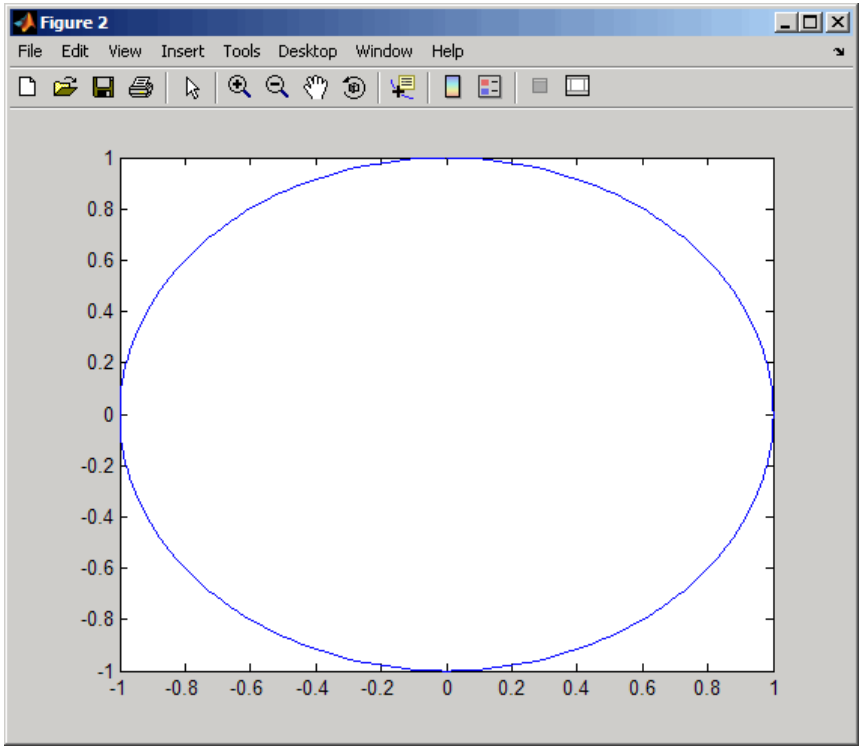
When you dock a plot tool in a figure group and then dock the figure group in the desktop, the tool is included in that section of the desktop as well, as the following illustration shows:



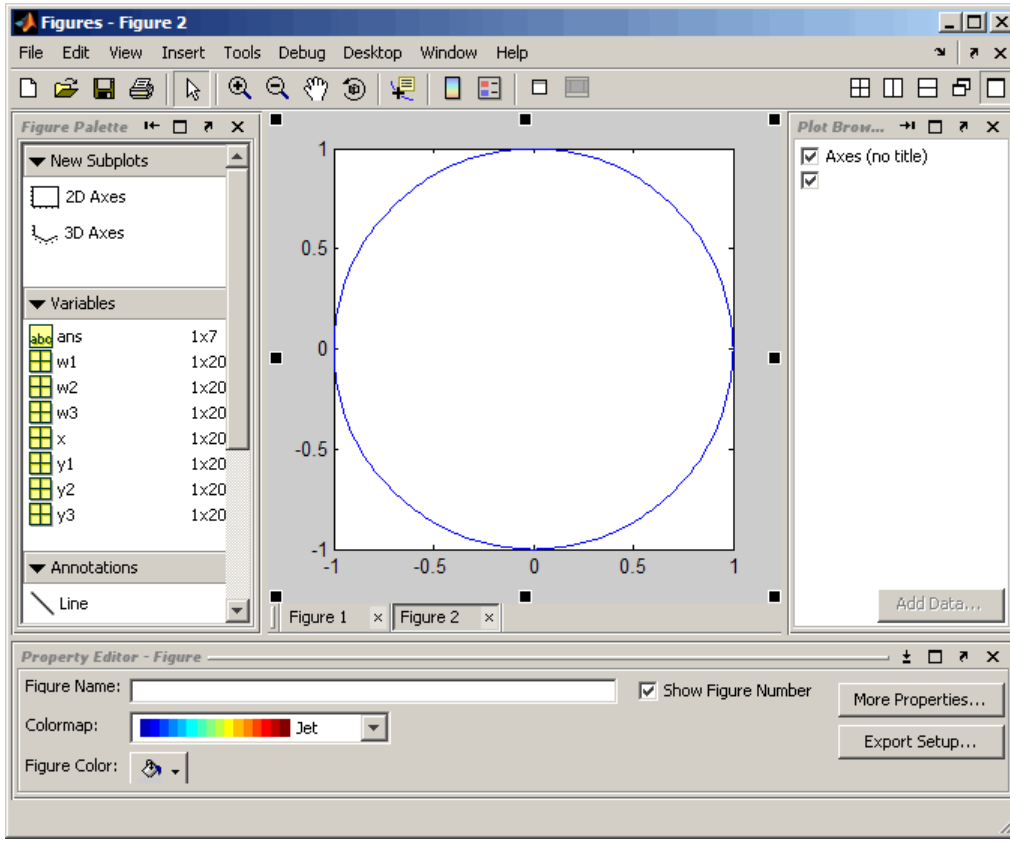
Working with Multiple Figures. When you create a new figure and plot into it, It is created without plotting tools enabled, even if another figure already has them open:

```
figure
plot(y1,w1)
```

This generates a freestanding plot, like this:

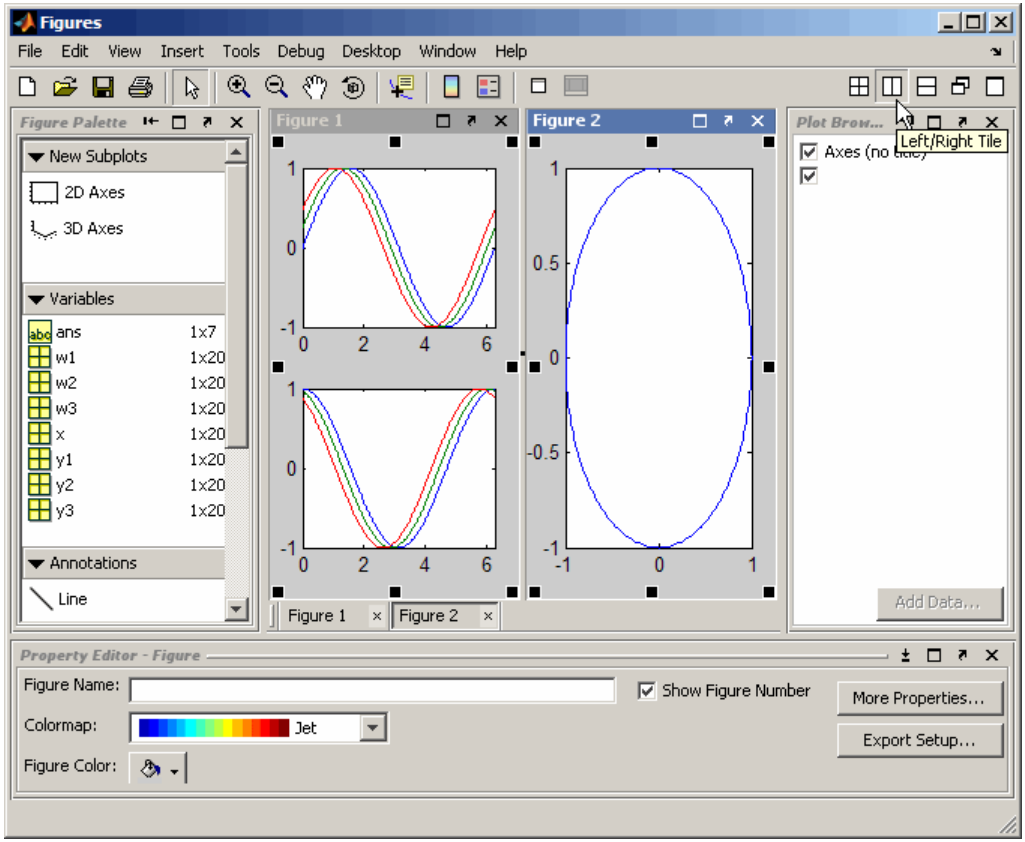


If you then open the plotting tools for the figure by clicking the Open Plotting Tools icon  , the figure docks in the figure window:



The new figure might seem to disappear if the Figures window is hidden, but it will overlay the existing plot within that window (it does not replace it). You can switch between the two figures by clicking the tabs at the bottom of the figure area. Be aware that clicking the x on the right side of a figure's tab deletes that figure entirely, without asking for confirmation.

If you want to see both figures at once, use the Tiling Palette  at the upper right corner of the Figures window to arrange the figures. For example, clicking the Left/Right tiling tool lays out the two figures side by side:



As the above illustrations shows, plot objects can be selected in both figures, but only one figure has focus at a time.

The Figure Palette

The Figure Palette contains three panels. Select the panel you want to view by clicking the respective button, which twists down the panel and exposes its contents.

The Figure Palette enables you to perform the following tasks with these panels:

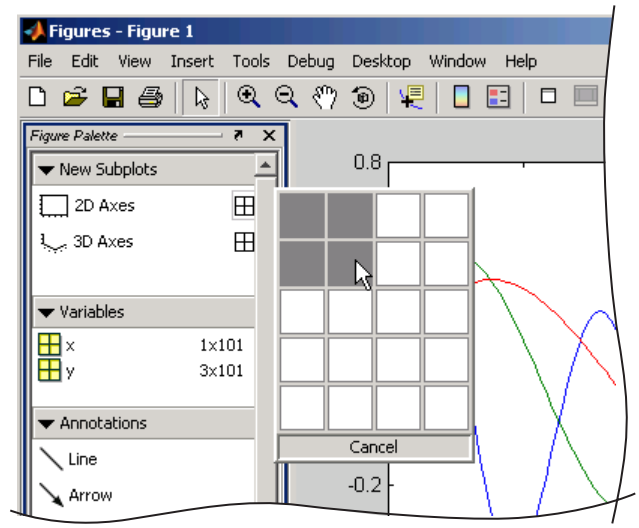
- **New Subplots** — Add 2-D or 3-D axes to the figure.

- **Variables** — Browse and plot workspace variables.
- **Annotations** — Add annotations to graphs.

Adding Subplot Axes

The **New Subplots** panel enables you to create a grid of either 2-D or 3-D axes. To display the selector, click the grid icon next to the axes type. MATLAB displays the selector grid.

As you move the cursor, squares darken to indicate the layout of axes that will be created if you release the mouse button. Click **Cancel** at the bottom of the grid to leave the figure unchanged.



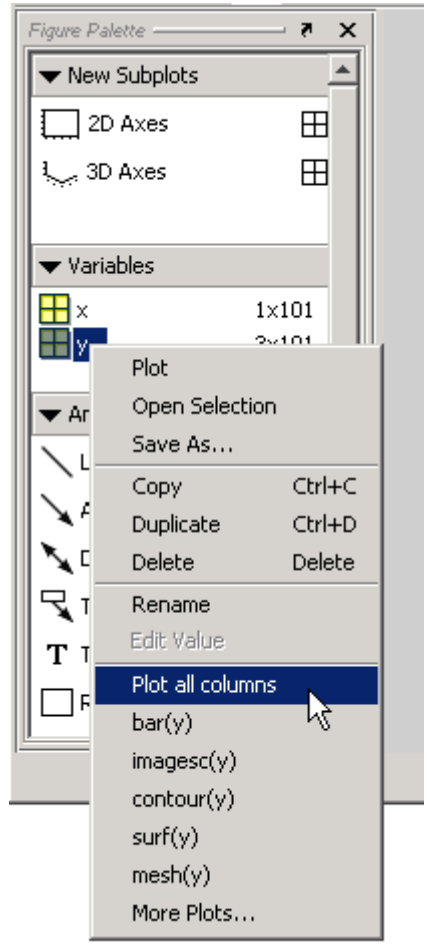
The picture above shows the **New Subplots** panel selected to display four equally sized axes in the figure. Existing axes resize as required to accommodate the new layout.

Plotting Workspace Variables

The **Variables** panel displays current workspace variables. Double-clicking a variable in this panel opens that variable in the Array Editor. If you select a

variable and right-click to display the context menu, you can select a graphics function to plot the variable.

For example, the following picture illustrates how to plot the columns of variable `Z`. This is equivalent to passing a matrix to the `plot` function.



The context menu contains a list of possible plot types based on the variable you select and also enables you to perform certain operation on the variable, such as opening it in the Array Editor, saving, copying, and so on.

Note that the context menu items may change when you select different variables because a particular variable might be incompatible some of the plot types.

Drag and Drop Plotting

You can also drag the variable directly into an axes, in which case MATLAB selects the first appropriate plot type for that variable. If there are multiple axes, you must first select the one you want to plot in and then drag the variable to that axes.

In the previous example, the variable `Z` would be plotted using the `plot` function if you were to drag it into an axes.

If the desired plotting function is not available from the context menu, you can select **More Plots** to display the Plot Catalog tool.

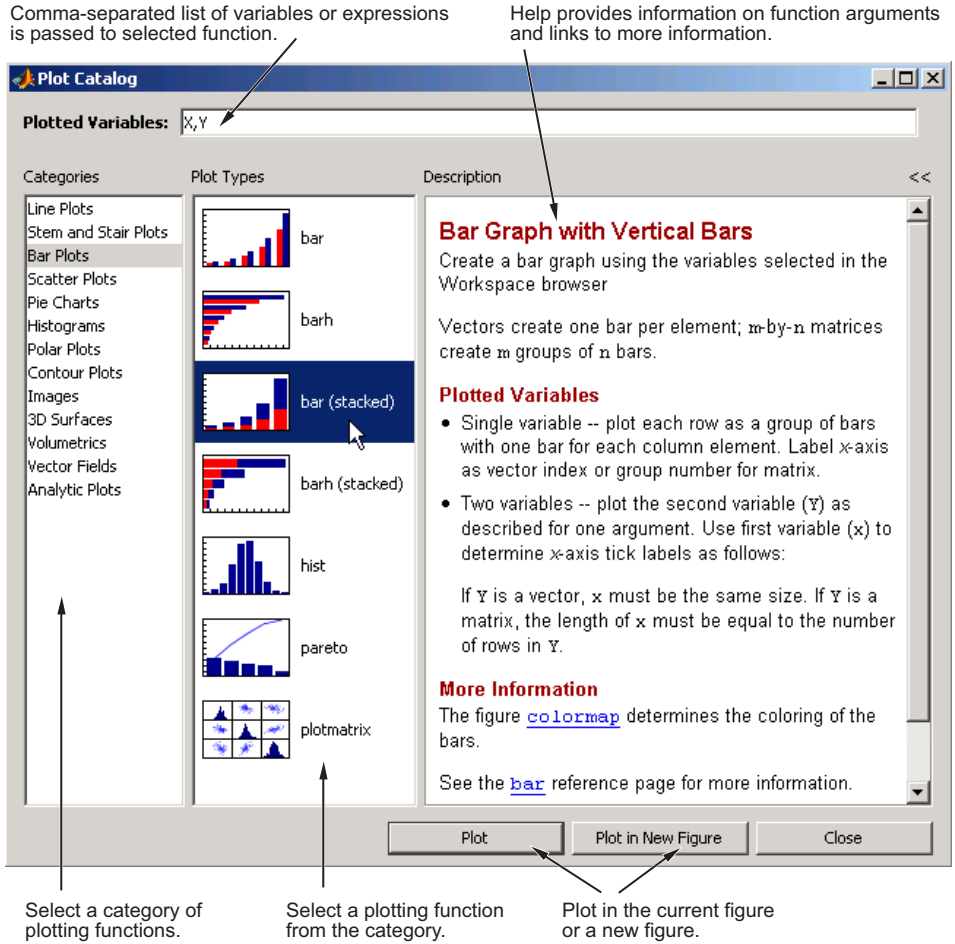
The Plot Catalog Tool

The Plot Catalog tool provides access to most of the MATLAB plotting functions. You can type any workspace variables or MATLAB expressions in the **Plotted Variables** field, which are then passed to the selected plotting function as arguments. Separate variables with a comma.

You can also enter function handles to pass to one of the “ez...” family of plotting functions from the Analytic Plots category.

Note The Plot Catalog does not prevent you from passing inappropriate or insufficient data to a plotting function; if the plot appears to be incorrect or if a plot fails to draw after you press **Plot** or **Plot in New Figure**, you should check the Command Window for warning and error messages.

The following picture shows the Plot Catalog tool and describes its components.



Adding Annotations to Graphs

The **Annotations** panel enables you to insert annotation objects into a plot. To add an object, first select the object you want to add, and then click and drag the mouse to position and size the object.

See “How to Annotate Graphs” on page 3-2 for more information about the various types of annotation objects.

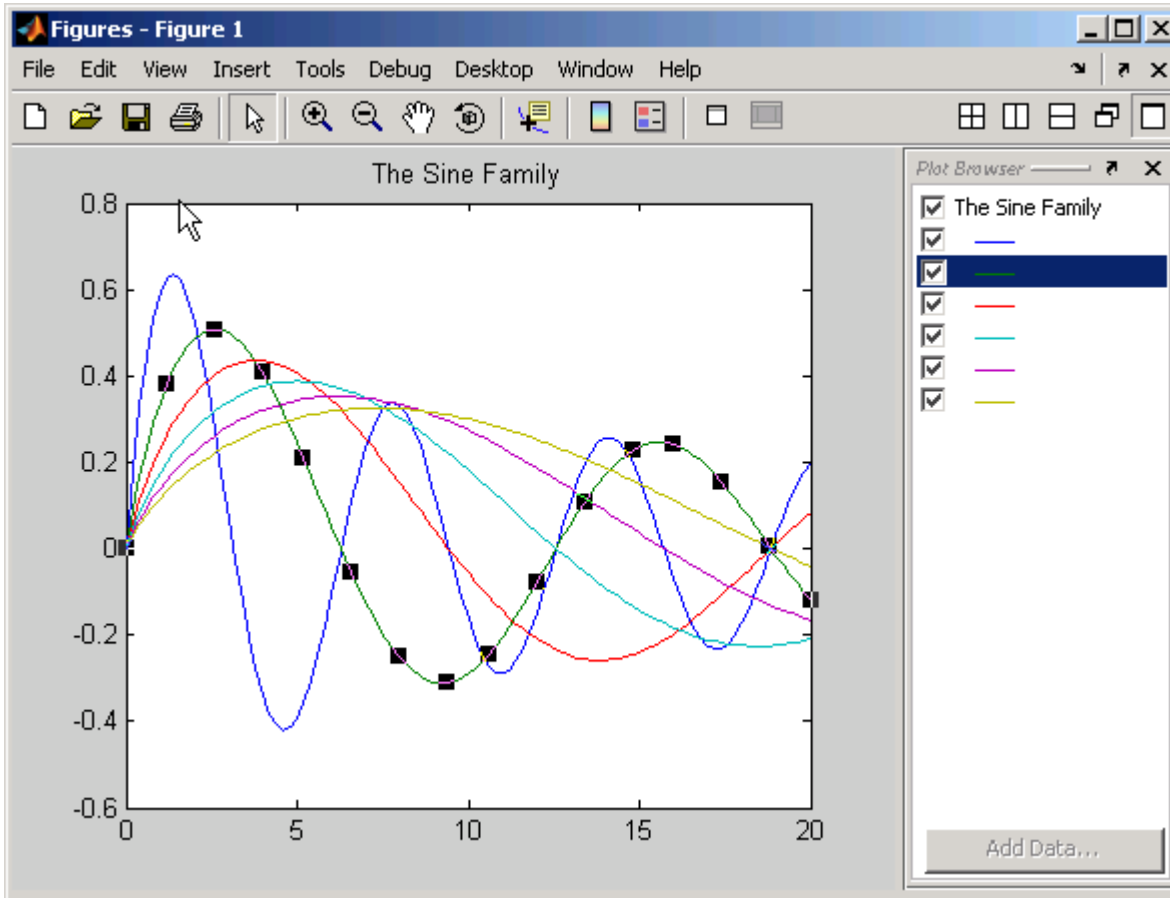
The Plot Browser

The Plot Browser provides a legend of all the graphs in the figure. It lists each axes and the objects (lines, surfaces, etc.) used to create the graph.

For example, suppose you plot an 11-by-11 matrix `z`. The `plot` function creates one line for each column in `z`.

```
plot(z,'DisplayName','z')
```

When you set the `DisplayName` property, the Plot Browser indicates which line corresponds to which column.

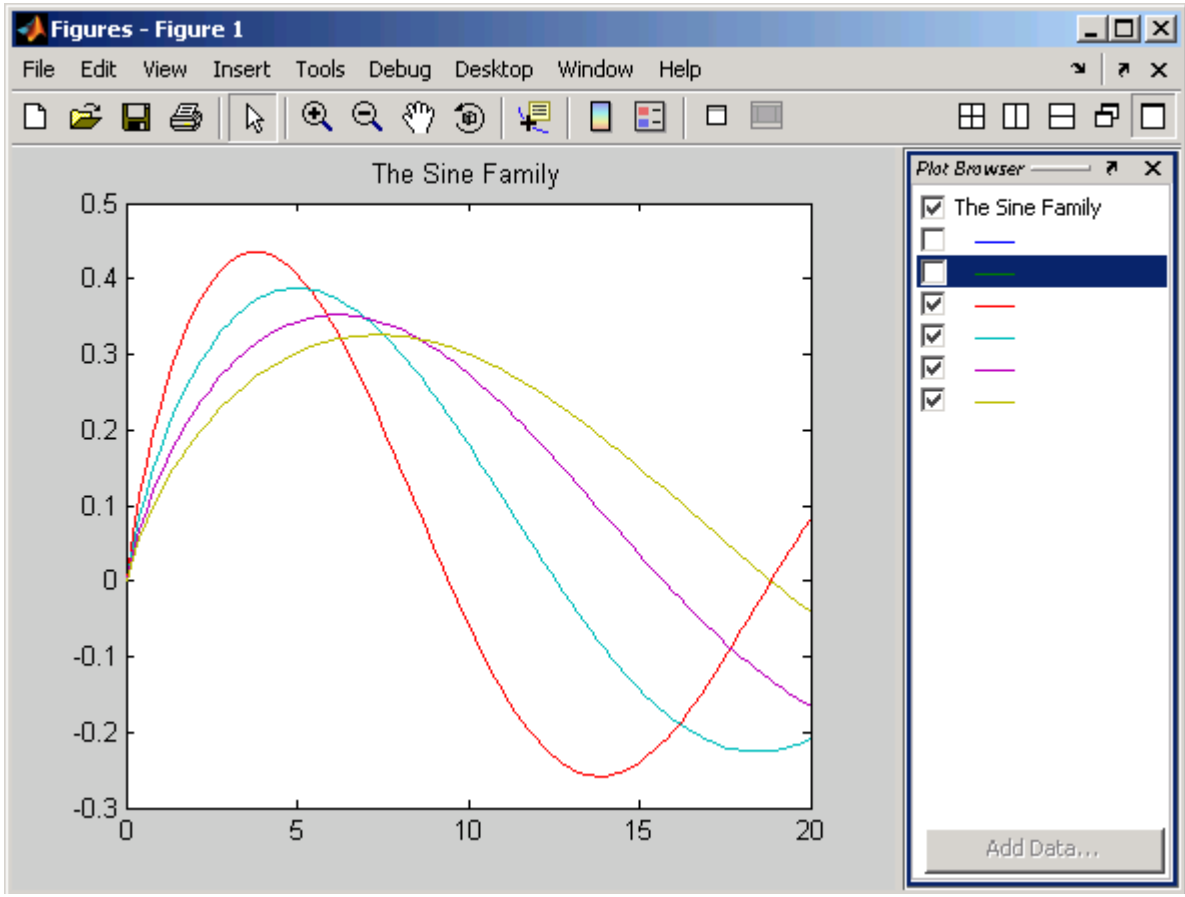


If you want to set the properties of an individual line, double-click on the line in the Plot Browser. Its properties are displayed in the Property Editor, which opens on the bottom of the figure.

You can select a line in the graph, and the corresponding entry in the Plot Browser is highlighted, enabling you to see which column in the variable produced the line.

Controlling Object Visibility

The check box next to each item in the Plot Browser controls the object's visibility. For example, suppose you want to plot only certain columns of data in z, perhaps the positive values. You can deselect the columns you do not want to display. The graph updates as you deselect each box and rescales the axes as required.



Deleting Objects

You can delete any selected item in the Plot Browser by selecting **Delete** from the right-click context menu.

Adding Data to Axes

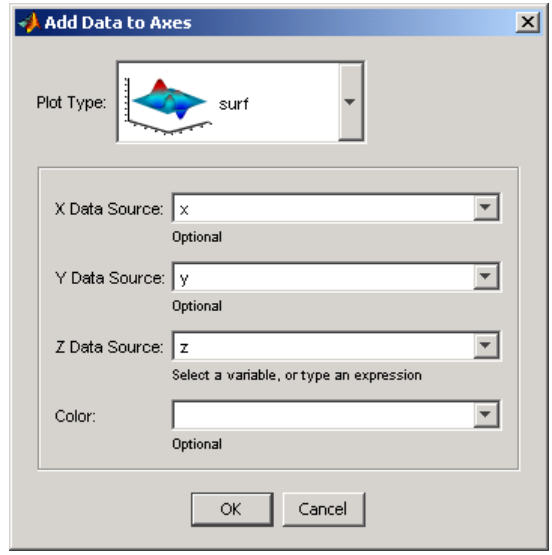
The Plot Browser provides the mechanism by which you add data to axes. The procedure is as follows:

1. Select a 2-D or 3-D axes from the **New Subplots** subpanel.
2. After creating the axes, select it in the Plot Browser panel to enable the **Add Data** button at the bottom of the panel.
3. Click the **Add Data** button to display the Add Data to Axes dialog.

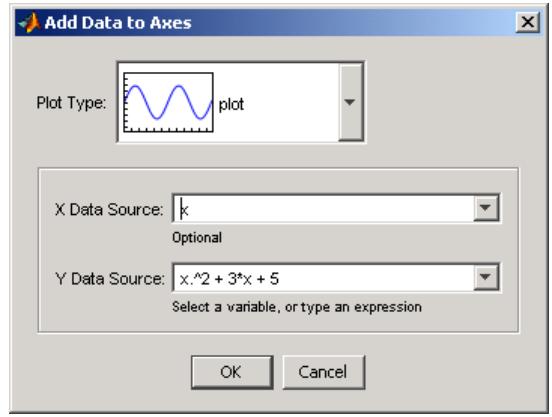
The Add Data to Axes dialog enables you to select a plot type and specify the workspace variables to pass to the plotting function. You can also specify a MATLAB expression, which is evaluated to produce the data to plot.

Selecting Workspace Variables to Create a Graph. Suppose you want to create a surface graph from three workspace variables defining the `XData`, `YData`, and `ZData` (see the `surf` function for more information on this type of graph).

In the workspace you have defined three variables, `x`, `y`, and `z`. To create the graph, configure the Add Data to Axes dialog as shown in the following picture.



Using a MATLAB Expression to Create a Graph. The following picture shows the Add Data to Axes dialog specifying a workspace variable `x` for the plot's x data and a MATLAB expression (`x.^2 + 3*x + 5`) for the y data.



You can use the default **X Data** value of `index` if you do not want to specify x data. In this case, MATLAB plots the y data versus the index of the y data value, which is equivalent to calling the `plot` command with only one argument.

The Property Editor

The Property Editor enables you to access a subset of the selected object's properties. When no object is selected, the Property Editor displays the figure's properties.

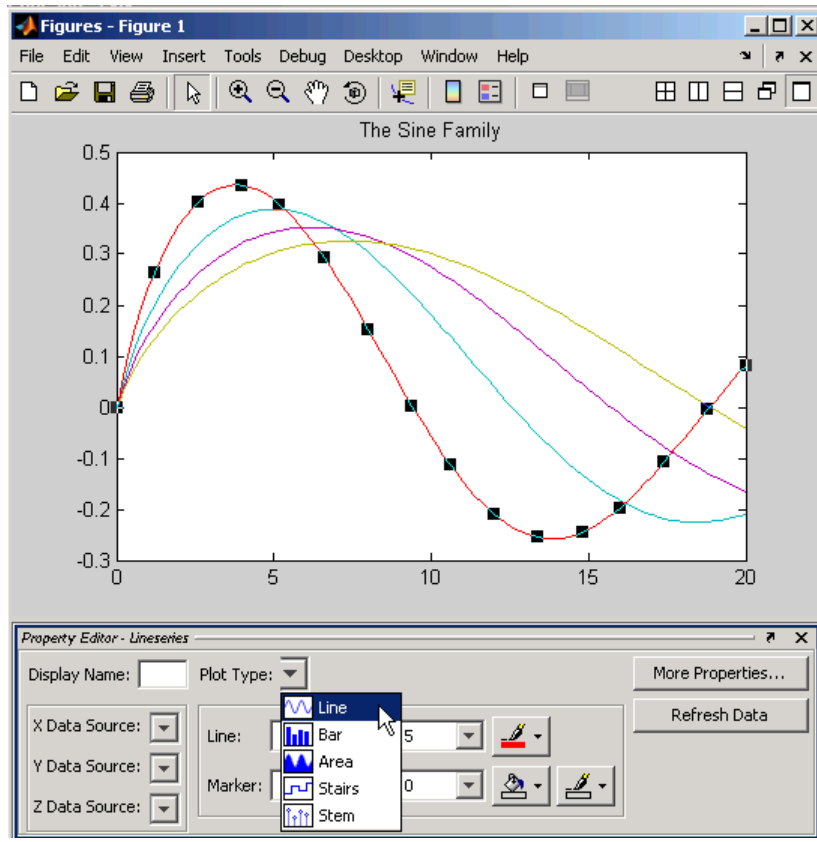
Ways to Display the Property Editor

There are a variety of ways to display the Property Editor:

- Double-click an object when plot edit mode is enabled.
- Select an object and right-click to display its context menu, then select **Properties.**
- Select **Property Editor** from the **View** menu.
- Use the `propertyeditor` command.

Changing Plot Types

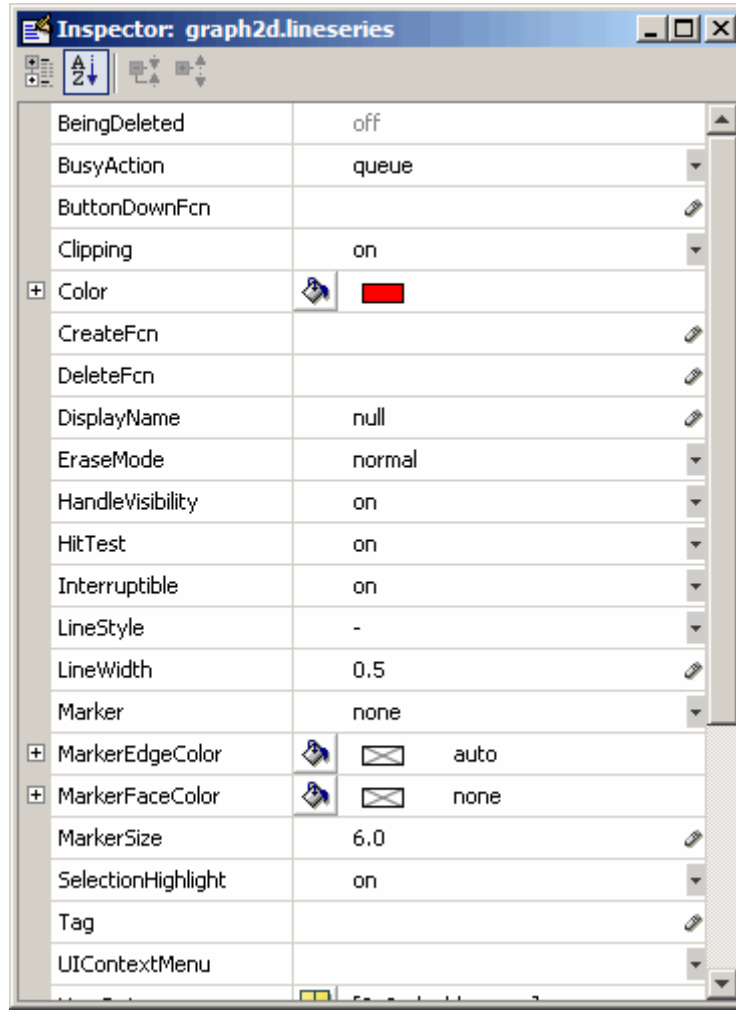
You can use the property editor to change the type of plot used to display data. For example, you can change the following line graph to a stem, stairs, area, or bar graph by changing the **Plot Type** field.



Accessing Object Properties with the Property Inspector

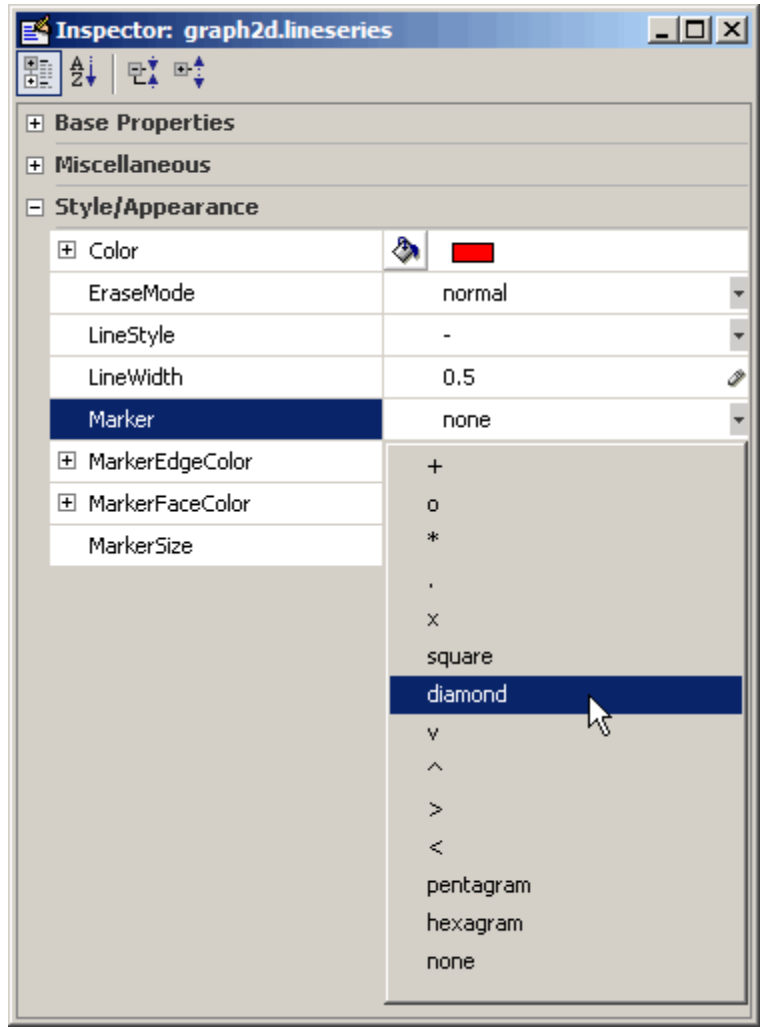
The Property Editor enables you to change the most commonly used object properties. To access more object properties, use the Property Inspector. Open the Property Inspector by clicking the **More Properties** button on the Property Editor or by typing `inspect` in the Command Window. The following

picture shows the Property Inspector displaying the properties of the same lineseries object as that in the previous picture.



The default view of properties is an alphabetic list; you can change to a tree view by clicking the icon in the upper left corner containing plus marks. Click the “AZ” icon to its right to return to an alphabetized list view. Properties that contain fields, such as RGB color components, have a plus mark to

their left you can click to expose the individual values. You can change properties that have enumerated values, such as `Marker`, via drop-down lists (downward-pointing triangles on the right edge of the inspector window). The following figure shows the `Marker` property being set to `diamond` using the Property Inspector (note the tree view in which other groups of properties have been collapsed):



There are a few properties of objects that the Property Inspector does not show, for example `Parent` and `Children`. For complete descriptions of the properties of graphics objects, use the Handle Graphics Property Browser.

Getting Help for Object Properties

If you are not sure what a property does or what values it can take on, you can get a description of it from the Property Inspector. To do so, right-click on the name or values of a property and select **What's This** from the popup menu; a Help window opens displaying the property reference page for the current object, scrolled to the property you clicked. The following picture shows how this works:

Accessing Objects You Cannot Click

If you want to access the properties of light or uicontextmenus objects, you need to get the handle using MATLAB commands, because you cannot click on these objects.

For example, to get the handles of all light objects in the current axes, use `findobj`.

```
h = findobj(gca,'Type','light');
```

Then use the `inspect` command to display the Property Inspector.

```
inspect(h)    % Inspect all light objects
inspect(h(1)) % Inspect the first light object in list
```

Example — Working with Plotting Tools

In this section...

Identifying Workspace Data to Plot

This example illustrates how to use the plotting tools to graph a workspace variable versus an expression typed into the **Add Data to Axes** dialog.

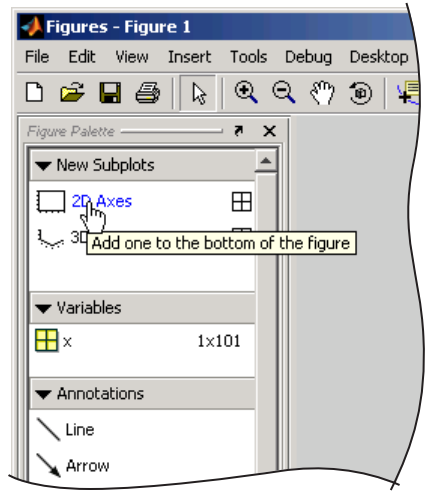
Create a variable in the workspace,

```
x = -2*pi:pi/25:2*pi;
```

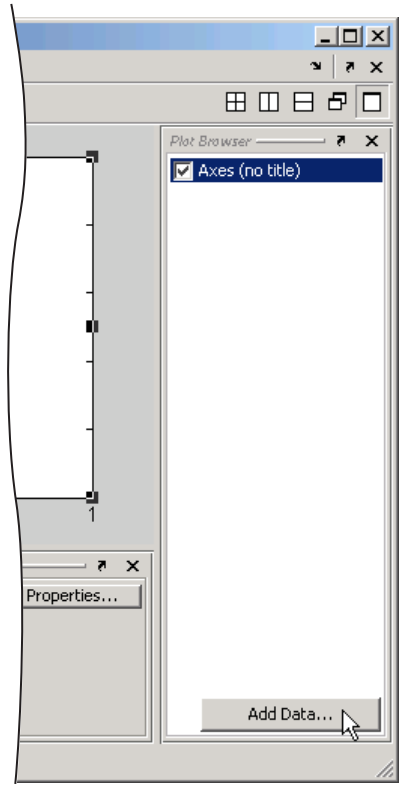
Use the `plottools` command to create a figure group with the plotting tools attached.

```
plottools
```

Click **2D Axes** in the **New Subplot** panel of the Figure Palette.

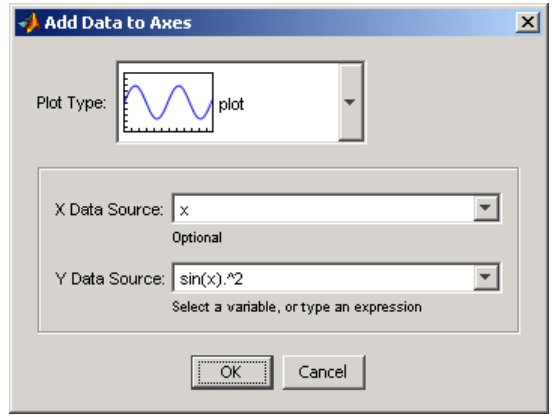


Once the axes appears, the **Add Data** button on the Plot Browser is activated.



Click this button to display the Add Data to Axes dialog. When the Add Data to Axes dialog is displayed, enter the following values:

- Select plot as the **Plot Type**.
- Set **X Data Source** to `x`.
- Set **Y Data Source** to `sin(x).^2`.
- Click **OK** to plot this data.

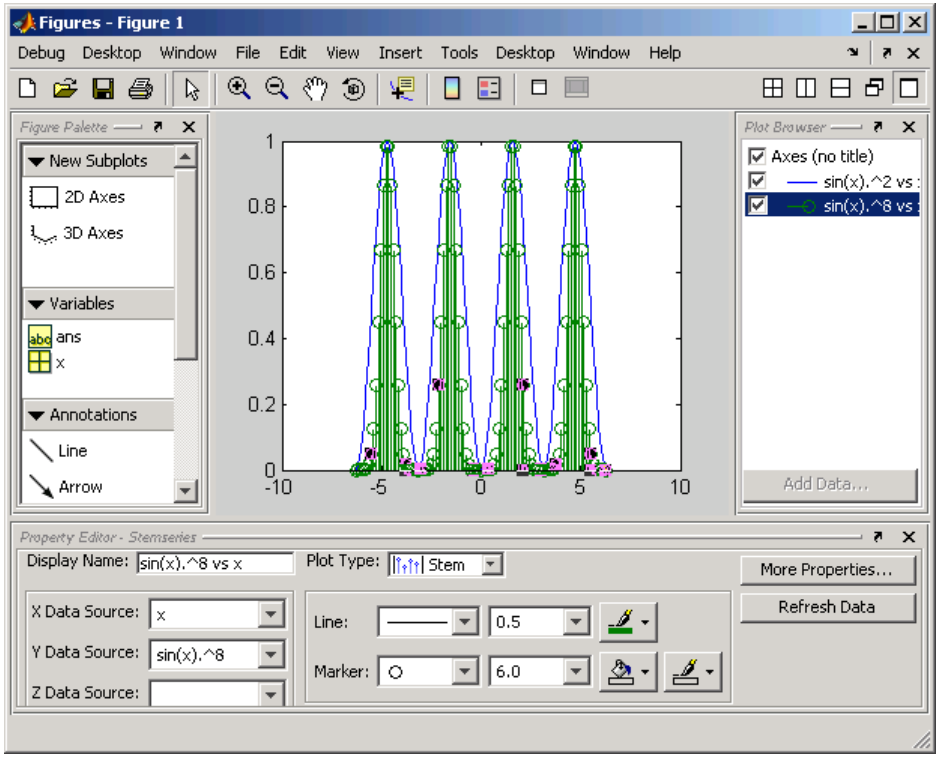


MATLAB draws a plot of `sin(x).^2` versus `x`.

Now add another plot to the same axes. Click **Add Data** again and specify the data to plot:

- Set **X Data Source** to `x`.
- Set **Y Data Source** set to `sin(x).^8`.
- Click **OK** to plot this data.

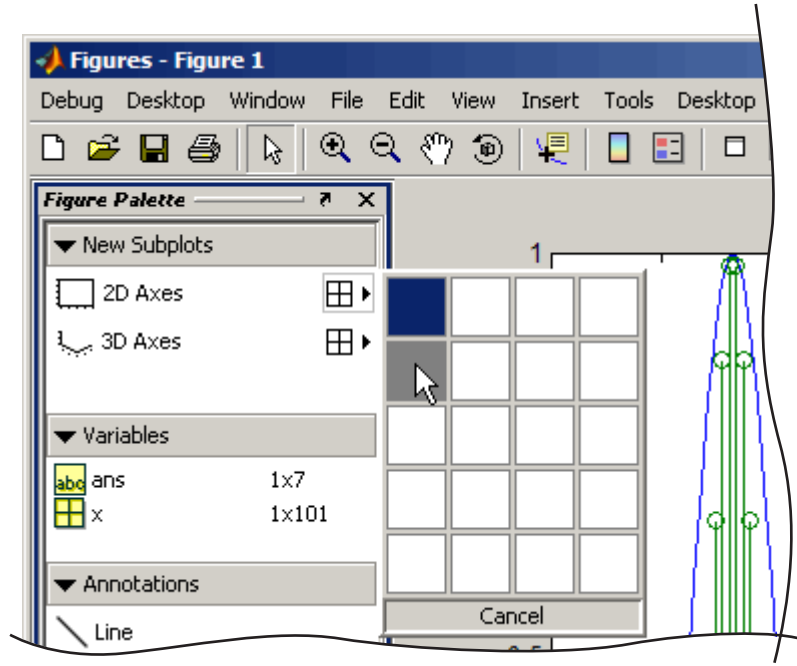
Select the last plot (the green line) and set the `Plot Type` in the Property Editor to `Stem`. The plot should now look like the following picture.



Adding a Subplot

Add a second axes below the current axes using the **New Subplots** panel. Click the right-facing arrowhead next to **2D Axes** and move the mouse to darken two squares, one on top of the other.

This creates a subplot axes below the existing axes. MATLAB resizes the existing axes so both fit in the figure.



Once MATLAB inserts the new axes, select its entry in the Plot Browser and then click **Add Data**.

When the Add Data to Axes dialog is displayed, enter the following values:

- Set **X Data Source** to `x`.
- Set **Y Data Source** to `sin(x).^3`.
- Click **OK** to plot this data.

Now add another plot overlaid on the first by clicking **Add Data** again and specify the data to plot:

- Set **X Data Source** to `x`.

- Set **Y Data Source** to `sin(x).^9`.
- Click **OK** to plot this data.

Select the plot labeled `sin(x).^9` under the second axes in the Plot Browser. Set the `Plot Type` in the Property Editor to `Area`.

Setting Axis Limits

Adjust the *x*-axis in both axes using the Property Editor.

- Select the first axes in the Plot Browser.
- Change **X Limits** to -7 and 7.

Repeat these steps for the second axes.

Adding Titles and Labels

Select the first axes in the Plot Browser and set the following properties in the Property Editor:

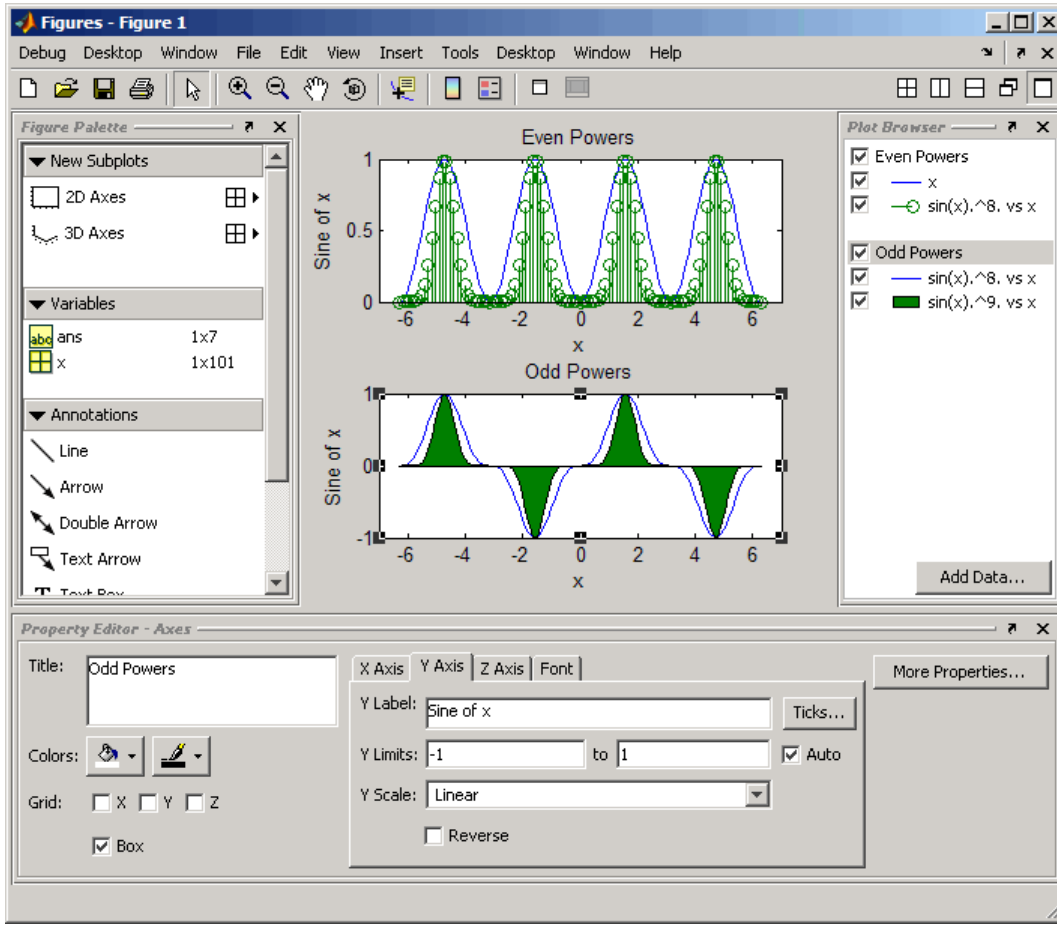
- Set **Title** to `Even Powers`.
- Set **X Label** to `X`.
- Click the **Y Axis** tab and set **Y Label** to `Sine of X`.

Select the second axes in the Plot Browser and set the following properties in the properties panel:

- Set **Title** to `Odd Powers`.
- Set **Axis label** to `Sine of X`.
- On the **Y Axis** tab, set **Axis label** to `Sine of X`.

Note that the Plot Browser reflects the new axes names.

The following picture shows the result of these steps.

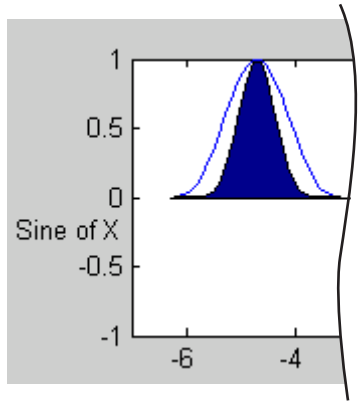


Select the text of the *y*-axis label on the first axes (now labeled `Even Powers` in the Plot Browser) and click the **More Properties** button on the Property Editor. Set the `Rotation` property to `0` and reposition the text by hand.

To make more space for the *y*-axis label, which is now in a horizontal position, select the axes and move it to the right with the mouse.

Repeat this process for the second axes (labeled `Odd Powers` in the Plot Browser).

The repositioned text label now looks like the following picture.



Note You can always undo your last change to the graph by selecting **Undo** from the **Edit** menu.

Example — Plotting from the Figure Palette

In this section...

Using the Plot Catalog

This example shows how to use the Figure Palette to select variables to plot. Suppose you have three variables in your workspace (`x`, `y`, `z`) created by the following statements:

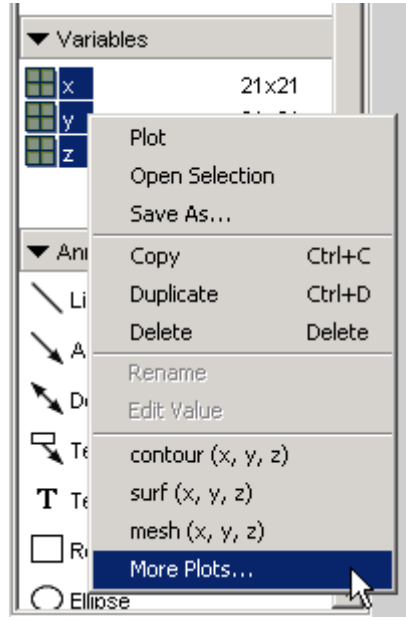
```
[x,y] = meshgrid([-2:.2:2]);
z = x.*exp(-x.^2-y.^2);
```

You decide to visualize this data as a surface/contour plot (as produced by the `surfc` function).

The first step is to display a figure with the Figure Palette tool attached. You can do this with the `figurepalette` command.

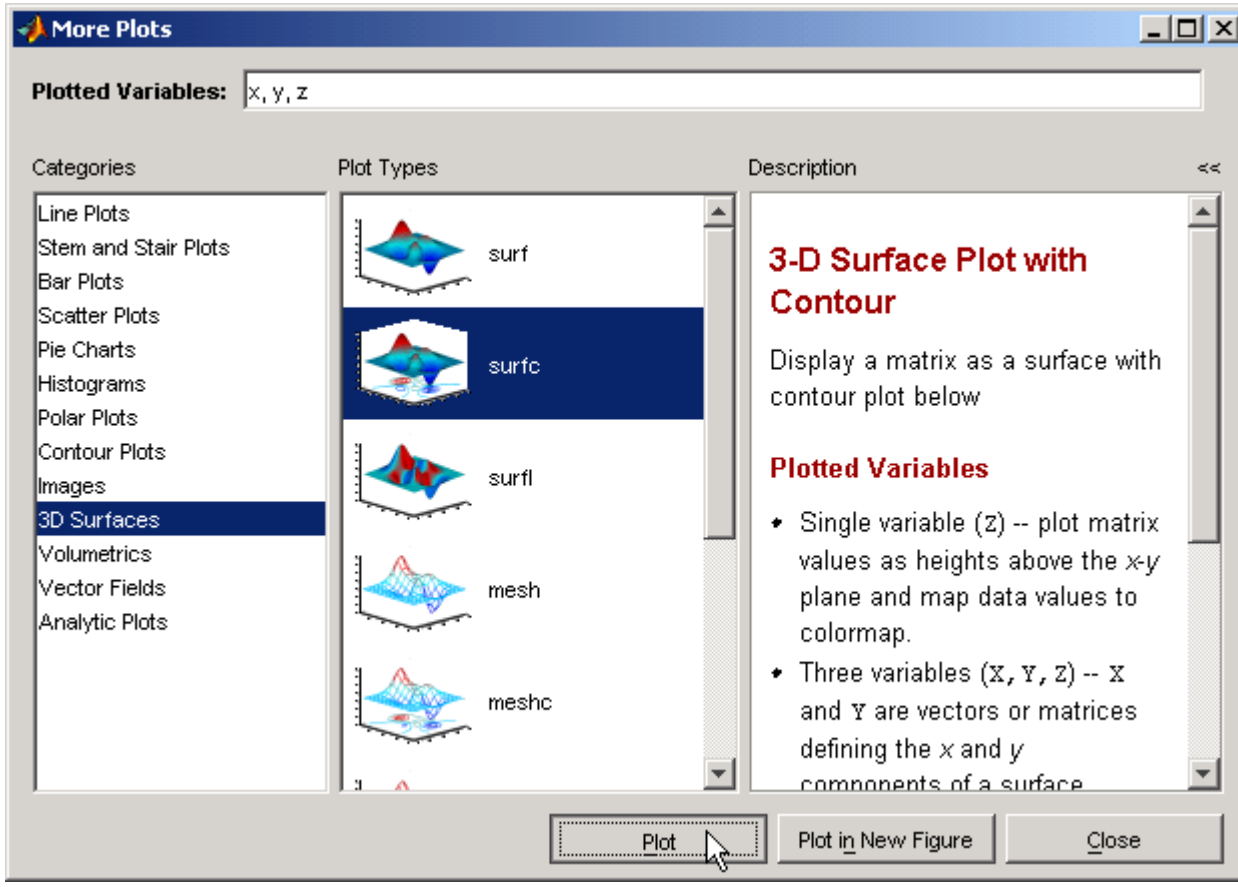
```
figurepalette
```

Expand the **Variables** panel and **shift-click** (for multiple selection) on the three variables you want to pass the plotting function. Since `surfc` is not in the list, select **More Plots**.

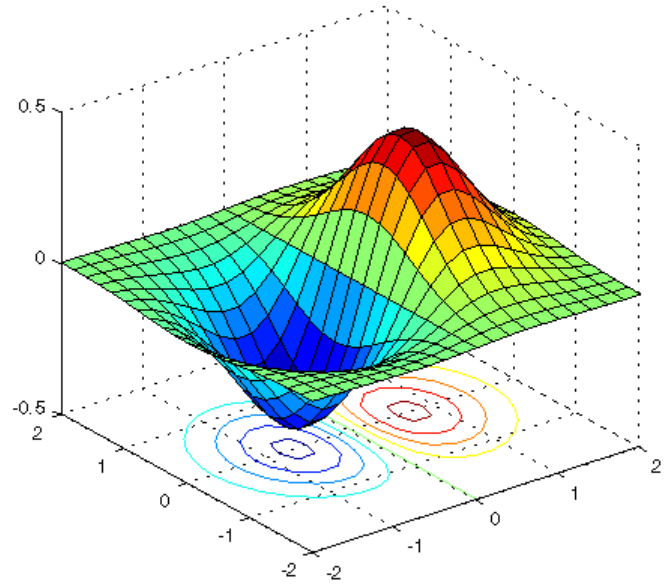


Variables
x
21x21
y
z
Plot
Open Selection
Save As...
Copy Ctrl+C
Duplicate Ctrl+D
Delete Delete
Rename
Edit Value
contour (x, y, z)
surf (x, y, z)
mesh (x, y, z)
More Plots...
Ellipse

From the Plot Catalog tool, select the **3D Surfaces** in the **Categories** column and **surfc** as the **Plot Type**, as shown in the following picture. To create the plot, click the **Plot** button.



MATLAB creates the following graph.



Plotting Expressions

You can enter MATLAB expressions in the Plot Catalog tool, as well as variables. For example, suppose you have created the following variables in the workspace.

```
t = 0:.01:20;
alpha =.055;
```

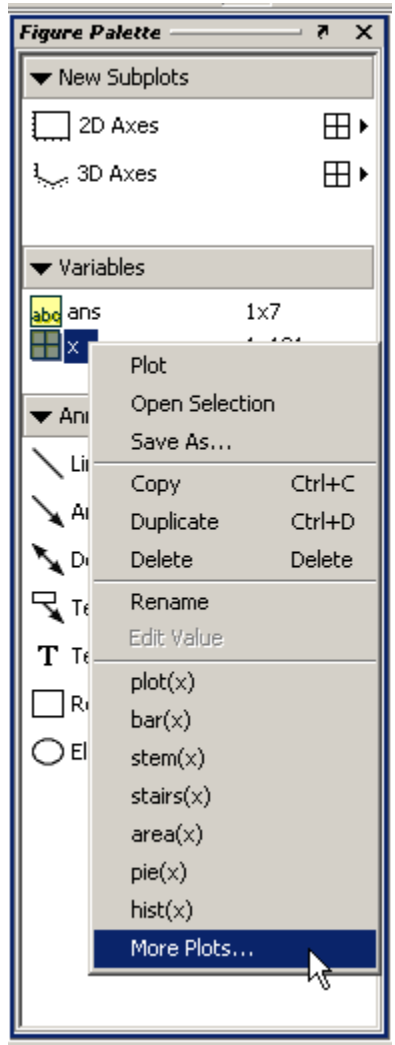
and you want to plot `t` versus this expression:

```
exp(-alpha*t).*sin(.5*t)
```

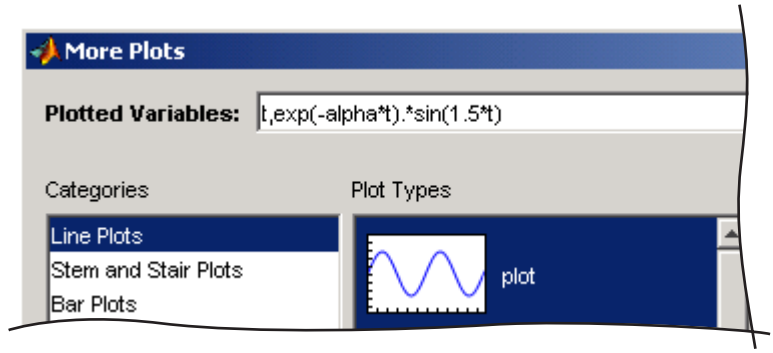
The first step is to display a figure with the Figure Palette tool attached. You can do this with the `figurepalette` command.

```
figurepalette
```

First select the variable `t` and right-click to display the context menu. Select **More Plots**.



When the Plot Catalog tool is displayed, add the expression to the **Plotted Variables** text field. Note that you can reference the variable `alpha` because you created it in the base workspace. See MATLAB Workspace for information about variables in the MATLAB workspace.



Click the **Plot** button to create the graph. Note that the previous step is the equivalent of issuing the following command:

```
plot(t,exp(-alpha*t).*sin(.5*t))
```

Example — Specifying a Data Source

In this section...

Creating the Graph

First define two variables by issuing these statements in the command window.

```
t = 0:.01:20;
alpha =.055;
```

Next plot `t` versus the expression `exp(-alpha*t).*sin(.5*t)` using the `plot` function or the plot tools.

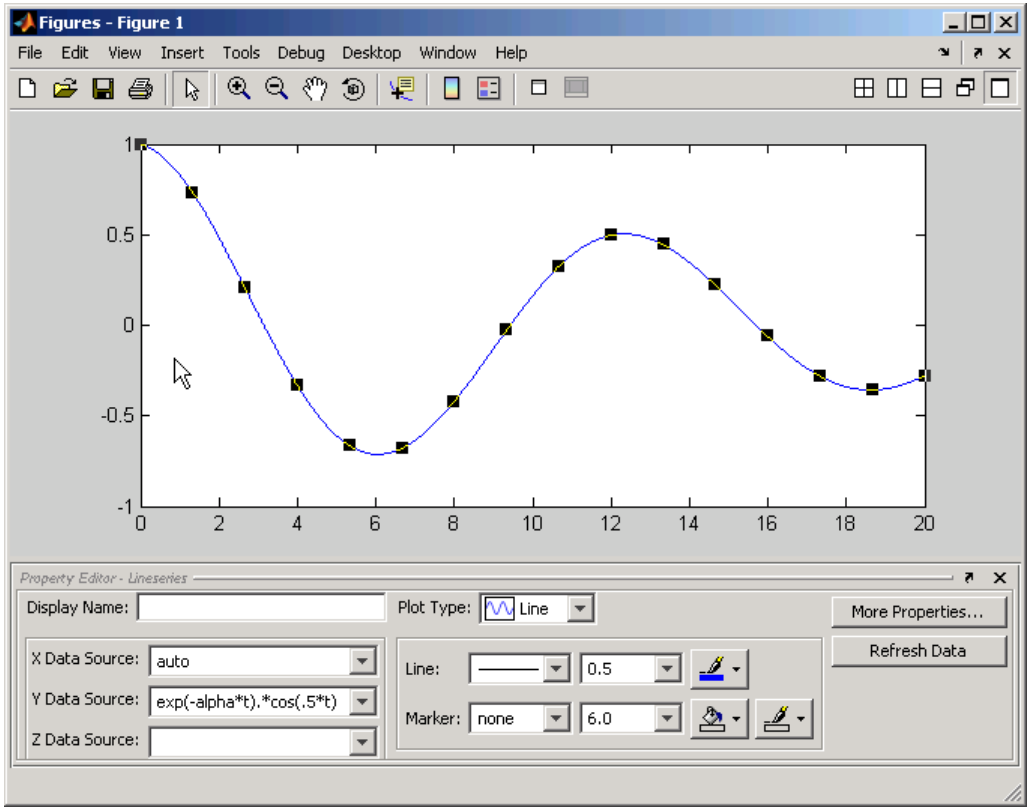
```
plot(t,exp(-alpha*t).*sin(.5*t))
```

Varying the Data Source

Plot objects have properties that enable you to specify the source of the data that defines the object. For example, you can specify a workspace variable name or a MATLAB expression as the value of the `XDataSource`, `YDataSource`, or `ZDataSource` property for a line in a plot (i.e., a lineseries object). You can then use the Property Editor to change the variable name or alter the expression, and the plot is updated to reflect the change.

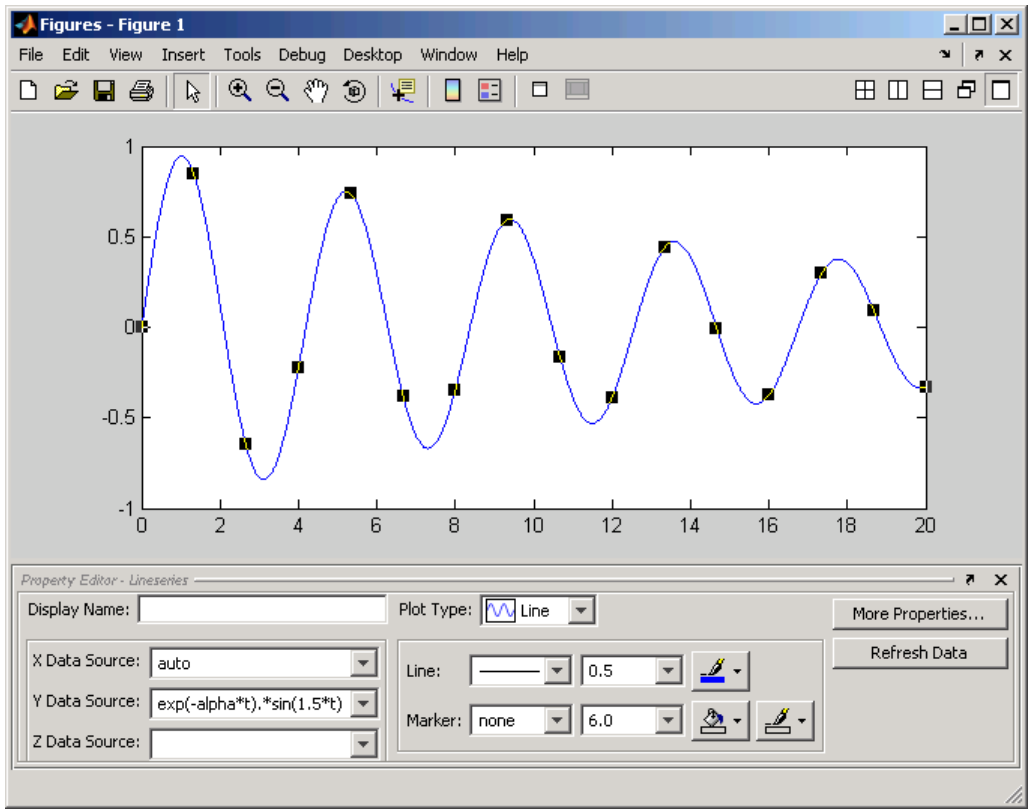
After creating the graph, you can use the Property Editor to couple the plotted line to the MATLAB expression.

1. Double-click on the plotted line to display its property panel.
2. Enter the MATLAB expression `exp(-alpha*t).*cos(.5*t)` in the **Y Data Source** text field.



You can now modify the expression in the **Y Data Source** text field and observe how the graph changes. After changing the text, click the **Refresh Data** button to update the data.

In the following picture, `alpha` is no longer negated, so the function grows instead of decays. Also the period has been shortened by changing `sin(.5*t)` to `sin(1.5*t)`.



Data Sources for Multiobject Graphs

Suppose you create a line graph from matrix data. For example,

```
z = peaks;
h = plot(z,'YDataSource','z');
```

Because MATLAB creates one lineseries object for each column of `z`, the following is true.

The data source for `h(1)` is `z(:,1)`.

The data source for `h(2)` is `z(:,2)`.

...

The data source for `h(n)` is `z(:,n)`.

Example — Generating M-Code to Reproduce a Graph

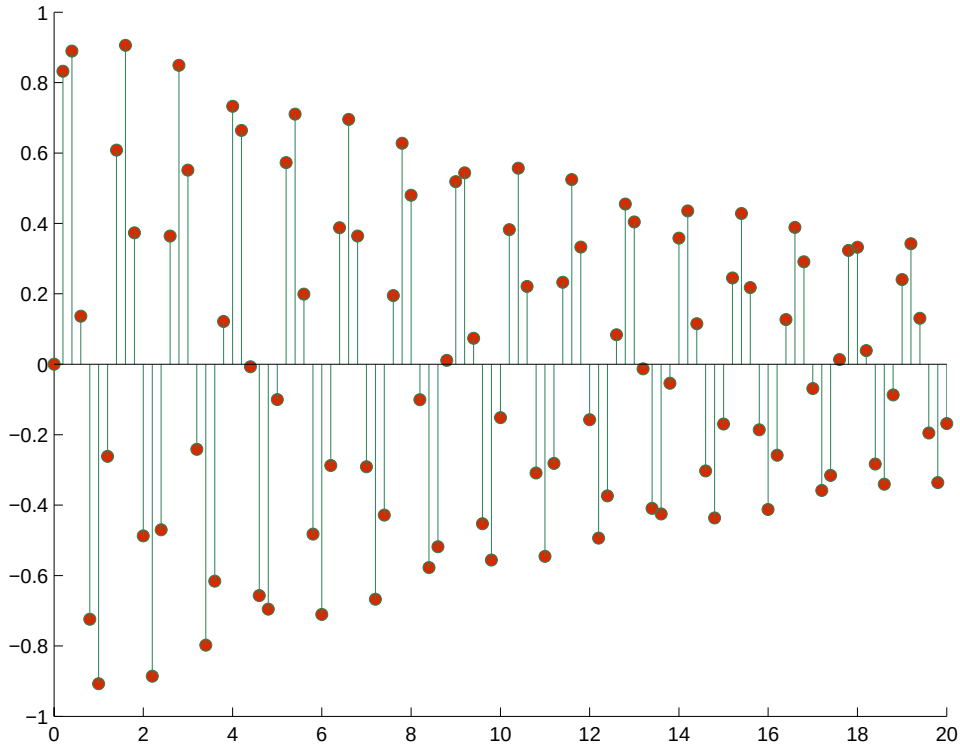
In this section...

Create a Stem Plot and Generate Code for It

Suppose you have created the following graph.

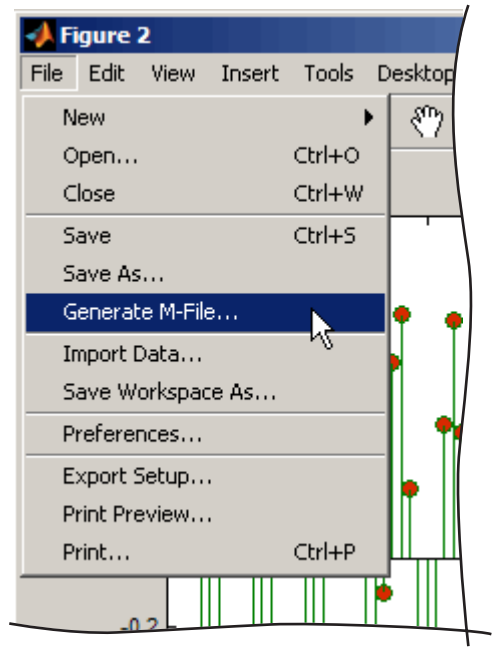
```
t = 0:.2:20;
alpha =.055;
stem(t,exp(-alpha*t).*sin(5*t))
```

Use the Property Editor to modify the graph. Select the stemseries and change the marker fill color to dark red, and marker edge color and line color to dark green. Remove the axes box, and change the font size for the axes labels to 8 to look like the following picture:



You can generate code to reproduce this graph by selecting **Generate M-File** from the **Figure** menu. MATLAB creates a function that recreates the graph and opens the generated M-File in the editor.

This feature is particularly useful for capturing property settings and other modifications you make using the plot tools GUI.



The M-file appears in an editor window and consists of the following code:

```
function createfigure(X1, Y1)
%CREATEFIGURE(X1,Y1)
%  X1:  stem x
%  Y1:  stem y

%  Auto-generated by MATLAB on 24-May-2006 14:23:45

% Create figure
figure1 = figure('Color',[1 1 1]);

% Create axes
axes('Parent',figure1,'FontSize',8);
hold('all');

% Create stem
stem(X1,Y1,'MarkerFaceColor',[0.8471 0.1608 0],...
    'MarkerEdgeColor',[0.1686 0.5059 0.3373],...
```

```
    'Color',[0 0.498 0]);
```

You must save the M-file before exiting MATLAB if you want to use it in future sessions.

Data Arguments

Generated functions do not store the data necessary to recreate the graph. You must supply the data arguments `t` as `X1` and `exp(-alpha*t).*sin(5*t)` as `Y1` to the function to recreate your graph. Of course, you can call the generated function with other argument pairs too.

Limitations

Attempting to generate code for graphics objects containing a large number of graphics objects (e.g., greater than 20 plotted lines) might be impractical.

Editing Plots

In this section...

Why Edit Plots?

MATLAB formats a graph to provide readability, setting the scale of axes, including tick marks on the axes, and using color and line style to distinguish the plots in the graph. However, if you are creating presentation graphics, you might want to change this default formatting or add descriptive labels, titles, legends, and other annotations to help explain your data.

MATLAB supports two ways to edit the plots you create:

- Using the mouse to select and edit objects interactively
- Using MATLAB functions at the command line or in an M-file

Interactive Plot Editing

If you enable plot editing mode in the MATLAB figure window, you can perform point-and-click editing of your graph. In this mode, you can modify the appearance of a graphics object by double-clicking on the object and changing the values of its properties. You access the properties through a graphical user interface called the Property Editor.

For more information about interactive editing, see "Working in Plot Edit Mode" on page 1-59.

For information about editing object properties in plot editing mode, see "The Property Editor" on page 1-28.

Using Functions to Edit Graphs

If you prefer to work from the MATLAB command line or if you are creating an M-file, you can use MATLAB commands to edit the graphs you create.

Taking advantage of the MATLAB Handle Graphics® system, you can use the `set` and `get` commands to change the properties of the objects in a graph.

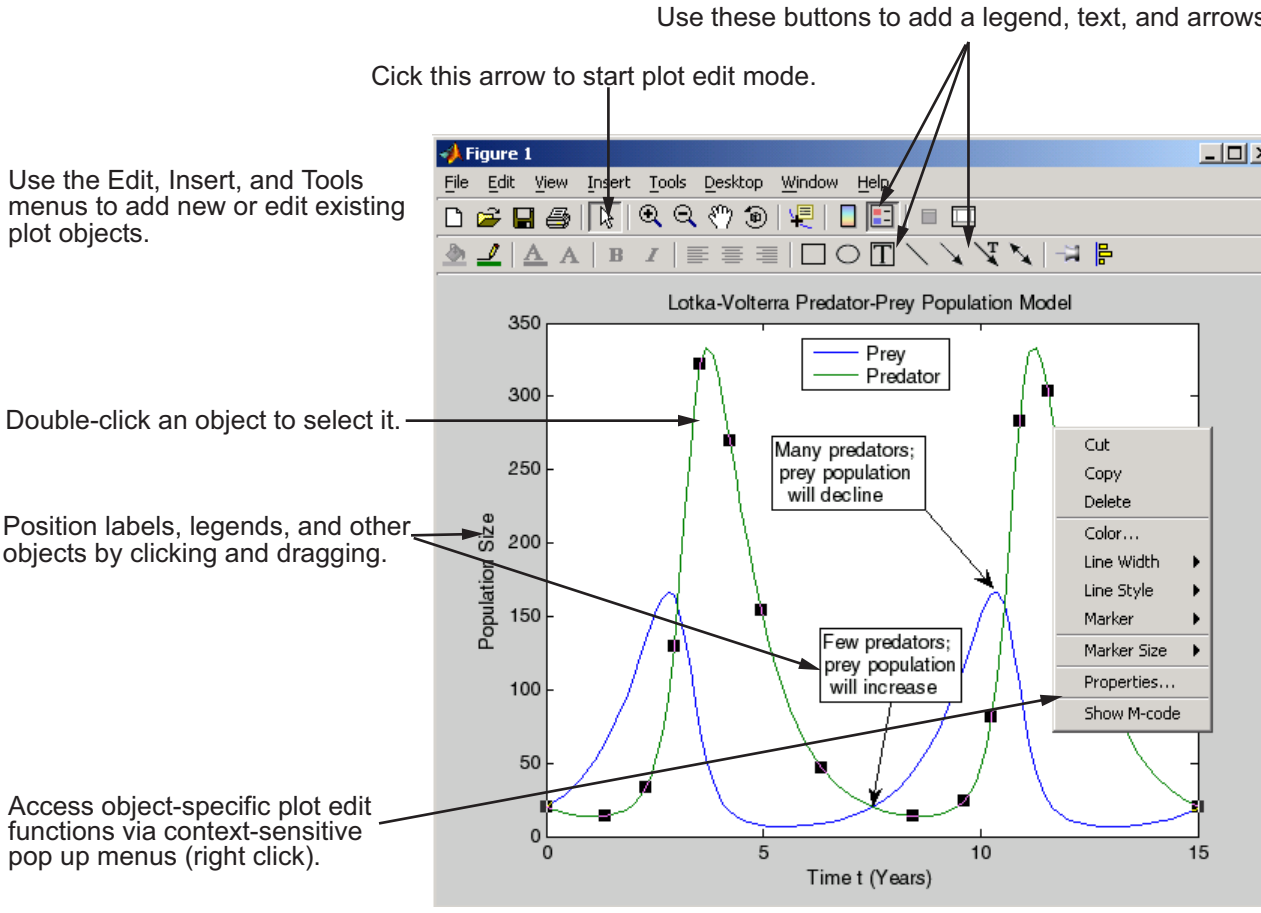
Note Plot editing mode provides an alternative way to access the properties of MATLAB graphic objects. However, you can only access a subset of object properties through this mechanism. You might need to use a combination of interactive editing and command-line editing to achieve the effect you desire.

Working in Plot Edit Mode

In this section...

Figure Windows in Plot Edit Mode

The MATLAB figure window supports a point-and-click editing mode that you can use to customize the appearance of your graph. This section describes how to enter plot edit mode and perform basic editing tasks, including selecting, cutting, copying, pasting, moving, and resizing objects and modifying other plot properties. The following figure illustrates some capabilities of plot edit mode.



Starting Plot Edit Mode

Before you can select objects in a figure by clicking on them, you must activate plot editing mode. There are several ways to activate plot edit mode:

- Choose the **Edit Plot** option on the figure window **Tools** menu.
- Click the selection button in the figure window toolbar.

- Choose an option from the **Edit** or **Insert** menu. For example, if you choose the **Axes Properties** option on the **Edit** menu, MATLAB activates plot edit mode and the axes appear selected.
- Run the `plotedit` command in the MATLAB Command Window.
- Start the plotting tools with the `plottools` command.

When a figure window is in plot edit mode, the **Edit Plot** option on the **Tools** menu is checked and the selection button in the toolbar is depressed.

Exiting Plot Edit Mode

To exit plot edit mode, click the selection button or click the **Edit Plot** option on the **Tools** menu. When plot edit mode is turned off, the selection button is no longer depressed.

Selecting Objects in a Graph

To select an object in a graph,

1. Start plot edit mode.
2. Move the cursor over the object and click it.

   Selection handles appear on the selected object.

Note When you manually select an object, its `Selected` property is set to `on`. Handles appear regardless of the setting of its `SelectionHighlight` property (which when `off` prevents handles from appearing outside of plot edit mode). Plot edit mode does not consider objects selected with `set` (as in `set(h,'Selected','on')`) to be selected, even if they have selection handles. Programmatically selected objects therefore do not respond to actions such as typing **Delete**. They can be dragged, however, because doing so selects them manually.

Selecting Multiple Objects

To select multiple objects at the same time,

1. Start plot edit mode.
2. Move the cursor over an object and **Shift**+click to select it. Repeat for each object you want to select.

You can perform actions on all the selected objects. For example, to remove a textbox annotation and an arrow annotation from a graph, select the objects and then select **Delete** or **Cut** from the **Edit** menu (**Cut** keeps a copy on the clipboard, **Delete** does not).

Deselecting Objects

To deselect an object, move the cursor off the object onto the figure window background and click the left mouse button (this deselects all selected objects and selects the one you clicked). You can also **Shift**+click on a selected object to deselect it (doing this will not deselect any other object).

Cutting, Copying, and Pasting Plot Objects

To cut an object from a graph, or copy and paste an object in a graph, perform these steps:

1. Start plot edit mode.
2. Select the object.
3. Select the **Cut**, **Copy**, or **Paste** option from the **Edit** menu or use standard shortcut keys for your platform.

Alternatively, with plot edit mode enabled, you can right-click on an object and then select an editing command from the context menu associated with the object.

Copying and Pasting Multiple Objects

When you cut or copy axes and plot objects such as lineseries or barseries from a figure and paste them there or elsewhere, the results depend on what you select and the type of container into which you paste the objects.

Copy and Paste Axes. The following semantics apply to copying and pasting axes into the same or different figure:

Select, Copy, and Paste Axes	Result of Pasting Axes
Select axes Ax1 from figure Fig1, copy and paste it into Fig2, which has no axes.	New axes Ax2 is created in Fig2. Ax2 inherits all properties of Ax1, including all children. Ax1 will be selected in Fig1; Ax2 will be selected in Fig2.
Select axes Ax1 from figure Fig1, copy and paste (from Edit Menu) into Fig2, that contains axis Ax2 which is not selected.	New axes Ax3 is created in Fig2. All children of Ax1 are copied to Ax3. All the selected objects in Fig2 are deselected, and the pasted axes Ax3 is selected. The selections in Fig1 are unchanged.
Select axes Ax1 from figure Fig1, copy and paste into Ax2 in the same or different figure.	New axis Ax3 is created having the same properties (including position) and children as Ax1; any selected objects in Ax2 are deselected, and axes Ax3 is selected. When pasting to a new figure, selections in Fig1 will be unchanged.
Select axes Ax1 from figure Fig1, copy and paste into same or different axes in Fig1.	New axes Ax2 is added to Fig1, offset from Ax1, and is the only selected object.

Note When an axis is pasted into an existing axes, the pasted axes becomes a peer of the existing axes and is offset slightly to visually indicate that the paste operation was successful.

Copy and Paste Plot Objects. The following semantics apply to copying and pasting plot objects (lines are used as examples) from one axes into the same or different figure:

Select, Copy, and Paste Objects	Result of Pasting Objects
Select and copy one or more lines from axes Ax1 and paste into selected axes Ax2 in the same or different figure.	The lines are added to Ax2; the pasted lines are the only selected objects in the destination figure.
Select and copy lines from axes Ax1 in Fig1 and paste into figure Fig2, which contains no axes or has no axes selected.	New axes Ax2 is created in Fig2 containing the lines, which are selected in it; Ax2 has default axes properties.
Select and copy lines from axes Ax1 and paste into selected axes Ax2 and Ax3.	Lines are pasted into both Ax2 and Ax3; all the pasted lines are selected.
Select and copy lines from axes Ax1 and paste into selected axes Ax1.	Nothing is pasted, as the extra content would be redundant.

Copy and Paste Plot Objects from Multiple Axes. The following semantics apply to copying and pasting plot objects (lines are used as examples) from one or more axes into the same or different figure:

Select, Copy, and Paste Objects	Result of Pasting Objects
Select and copy Line1 from axes Ax1 and Line2 from axes Ax2 and paste into axes Ax3.	Two lines are pasted into axes Ax3 and are the only selected objects there.
Select and copy lines from axes Ax1 and axes Ax2 and paste into figure Fig2, which contains no axes or has no axes selected.	New axes Ax3 is created in Fig2, into which all the lines are pasted; Ax3 has default axes properties.
Select and copy multiple lines from Axes Ax1 and axes Ax2 and paste into Ax1, Ax2, or some other axes.	Only those lines that did not originate in an axes are pasted into it, and the pasted lines are the only selected objects.

Copy and Paste Multiple Axes and Plot Objects. The following semantics apply to copying and pasting several axes and selected plot objects (lines are used as examples) from one or more axes into the same or different figure:

Select, Copy, and Paste Objects	Result of Pasting Objects
Select Line1 from axes Ax1, select axes Ax2, and paste into figure Fig2, which contains no axes or has no axes selected.	Ax2 and its contents is pasted as new axes Ax3; another new axis Ax4 is created into which the line is pasted
Select Line1 from axes Ax1, select axes Ax2, and paste into axes Ax3.	Line1 is pasted into axes Ax3 and axes Ax2 is pasted as new axis Ax4.
Select axes Ax1 and Line1 from Ax1, and paste into Ax1.	New axes Ax2 is created having all the properties of Ax1 but containing Line1 as its only child.
Select axes Ax1 and Line1 from Ax1 in Fig1 and paste into figure Fig2, which contains no axes or has no axes selected.	Line1 is pasted in new axes Ax2, and Ax1 and its children (including Line1) is pasted as new axis Ax3.
Select axes Ax1 and Line1 from Ax1, and paste into axes Ax2.	New axes Ax3 is created having all the properties of Ax1 but containing Line1 as its only child.

Copying and Pasting Annotation Objects

In plot edit mode you can copy and paste annotations such as textboxes, textarrows, rectangles, and ellipses, in various combinations. If any such objects happen to be pinned to their axes (see “Pinning — Attaching to a Point in the Graph” on page 3-23), their copies are pasted unpinned. As annotation objects are children of figures, they never create new axes when you paste them.

Moving and Resizing Objects

To move or resize an object in a graph, perform these steps:

1. Start plot edit mode.
2. Select the object. Selection handles appear on the object When the cursor is over the object, it turns into crossed arrows; outside the selection it reverts to a pointer.

To move the object, drag it to the new location. You can also nudge it one pixel up, down, left, or right with the appropriate arrow key on your keyboard. If you have selected **Snap to Layout Grid** from the **Tools** menu, each keypress makes objects move to the next grid position.

To resize the object, drag a selection handle.

You can shift-click to select multiple objects and move them as a group. Arrow keys work well for this. However, when you resize one of several selected objects, only that object changes size.

Note You can move text objects, but you cannot resize them (annotation text boxes can be resized, however). You can resize axes objects, but you can only move them by dragging their edges (or via their selection handles, one at a time).

Setting Object Properties

In MATLAB, every object in a graph supports a set of properties that control the graph's appearance and behavior. For example, line objects have properties that control thickness, color, and line style.

Double-clicking on an object displays the Property Editor. To edit the properties of the axes or figure, double-click on a region that does not contain other objects.

See "The Property Editor" on page 1-28 for more information.

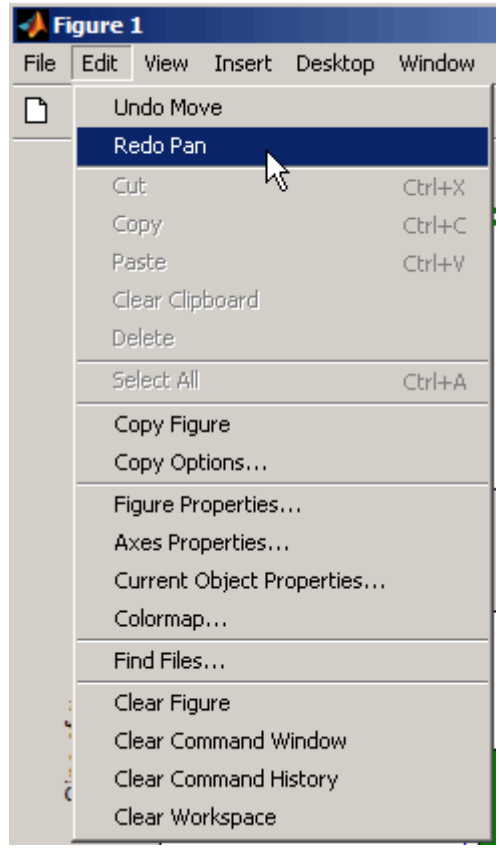
Undo/Redo — Eliminating Mistakes

The figure **Edit** menu contains two items that enable you to undo recent operation.

Undo — Remove the effect of the last operation.

Redo — Perform again the last operation that you removed by selecting **Undo**.

For example, if you create a plot, zoom in, pan the view, and then undo the pan operation, the menu looks as follows:



You could now undo the previous zoom operation or redo the pan operation you just undid.

Saving Your Work

In this section...

Saving a Graph in MAT-File Format

Note To save a figure in a format that is compatible with MATLAB versions before MATLAB 7, refer to "Plot Objects and Backward Compatibility" on page 8-22 for more information.

MATLAB supports a binary format in which you can save figures so that they can be opened in subsequent MATLAB sessions. MATLAB assigns these files the `.fig` filename extension.

To save a graph in a figure file,

1. Select **Save** from the figure window **File** menu or click the **Save** button on the toolbar. If this is the first time you are saving the file, the **Save As** dialog box appears.
2. Make sure that the `Save as type` is **MATLAB Figure (*.fig)**.
3. Specify the name you want assigned to the figure file.
4. Click **OK**.

The graph is saved as a figure file (`.fig`), which is a binary file format used to store figures.

You can also use the `saveas` command.

Use the `hgsave` command to create backward compatible FIG-files.

If you want to save the figure in a format that can be used by another application, see “Saving to a Different Format — Exporting Figures” on page 1-69.

Opening a Figure File

To open a figure file, perform these steps:

1. Select **Open** from the **File** menu or click the **Open** button on the toolbar.
2. Select the figure file you want to open and click **OK**.

   The figure file appears in a new figure window.

You can also use the `open` command.

Saving to a Different Format — Exporting Figures

To save a figure in a format that can be used by another application, such as the standard graphics file formats TIFF or EPS, perform these steps:

1. Select **Export Setup** from the **File** menu. This dialog provides options you can specify for the output file, such as the figure size, fonts, line size and style, and output format.
2. Select **Export** from the Export Setup dialog. A standard Save As dialog appears.
3. Select the format from the list of formats in the `Save as type` drop-down menu. This selects the format of the exported file and adds the standard filename extension given to files of that type.
4. Enter the name you want to give the file, less the extension.
5. Click **Save**.

Copying a Figure to the Clipboard

On Windows systems, you can also copy a figure to the clipboard and then paste it into another application:

1. Select **Copy Options** from the **Edit** menu. The **Copying Options** page of the **Preferences** dialog box appears.
2. Complete the fields on the **Copying Options** page and click **OK**.
3. Select **Copy Figure** from the **Edit** menu.

   The figure is copied to the Windows clipboard. You can then paste the figure from the Windows clipboard into a file in another application.

Printing Figures

Before printing a figure,

1. Select **Print Preview** from the **File** menu to set printing options, including plot size and position, and paper size and orientation.

   The **Print Preview** dialog box opens.
2. Make changes in the dialog box. Changes you can make are arranged by tabs on the left-hand pane. If you want the printed output to match the annotated plot you see on the screen exactly,
   a. On the **Layout** tab, click **Auto (Actual Size, Centered)**.
   b. On the **Advanced** tab, click **Keep screen limits and ticks**.

   For information about other options for print preview, click the **Help** button in the dialog box.

To print a figure, select **Print** from the figure window **File** menu and complete the **Print** dialog box that appears.

You can also use the `print` command.

Generating an M-File to Recreate a Graph

You can generate an M-file from a graph, which you can then use to regenerate the graph. This approach is a useful way to generate M-code for work you have performed with the plotting tools. To use this option,

1. Select **Generate M-file** from the **File** menu.

MATLAB displays the generated code in the MATLAB Editor.

2 Save the M-file using **Save As** from the Editor **File** menu.

Running the Saved M-File

Most of the generated M-files require you to pass in data as arguments. The M-file assumes you are using the same data originally used to create the graph.

Comments at the beginning of the M-file state the type of data expected. For example, the following statements illustrate a case where three input vectors are required.

```
function createplot(X1, Y1, Y2)
%CREATEPLOT(X1,Y1,Y2)
%  X1:  vector of x data
%  Y1:  vector of y data
%  Y2:  vector of y data
```

See “Example — Generating M-Code to Reproduce a Graph” on page 1-53 for another example.

2

Data Exploration Tools

Ways to Explore Graphical Data

In this section...

Introduction

After determining what type of graph best represents your data, you can further enhance the visual display of information using the tools discussed in this section. These tools enable you to explore data interactively, eliminating the need to set the plethora of graphics properties required to achieve the same results using MATLAB commands.

Once you have achieved the desired results, you can then generate the MATLAB code necessary to reproduce the graph you created interactively. See "Example — Generating M-Code to Reproduce a Graph" on page 1-53 for more information.

Types of Tools

See the following sections for information on specific tools.

- "Data Cursor — Displaying Data Values Interactively" on page 2-4
- "Enlarging the View" on page 2-19
- "Panning — Shifting Your View of the Graph" on page 2-23
- "Rotate 3D — Interactive Rotation of 3-D Views" on page 2-25
- Camera Toolbar — Interacting with 3-D Views

You can perform data analysis directly on graphs with curve fitting and time series tools; see

- "Linear Regression Analysis"
- "Interactive Fitting"
- "Time Series Tools"

These and other topics are covered in the “Preparing Data for Analysis” section of the Data Analysis documentation. You can also use `cftool` if you have Curve Fitting Toolbox.

Data Cursor — Displaying Data Values Interactively

In this section...

What Is a Data Cursor?

Data cursors enable you to read data directly from a graph by displaying the values of points you select on plotted lines, surfaces, images, and so on. You can place multiple datatips in a plot and move them interactively. If you save the figure, the datatips in it are saved, along with any other annotations present.

When data cursor mode is enabled, you can

- Click on any graphics object defined by data values and display the x, y, and z (if 3-D) values of the nearest data point.
- Interpolate the values of points between data points.
- Display multiple data tips on graphs.
- Display the data values in a cursor window that you can locate anywhere in the figure window or as a data tip (small text box) located next to the data point.
- Export data values as workspace variables.
- Print or export the graph with data tip or cursor window displayed for annotation purposes.
- Edit the data tip display function to customize what information is displayed and how it is presented
- Select a different data tip display function

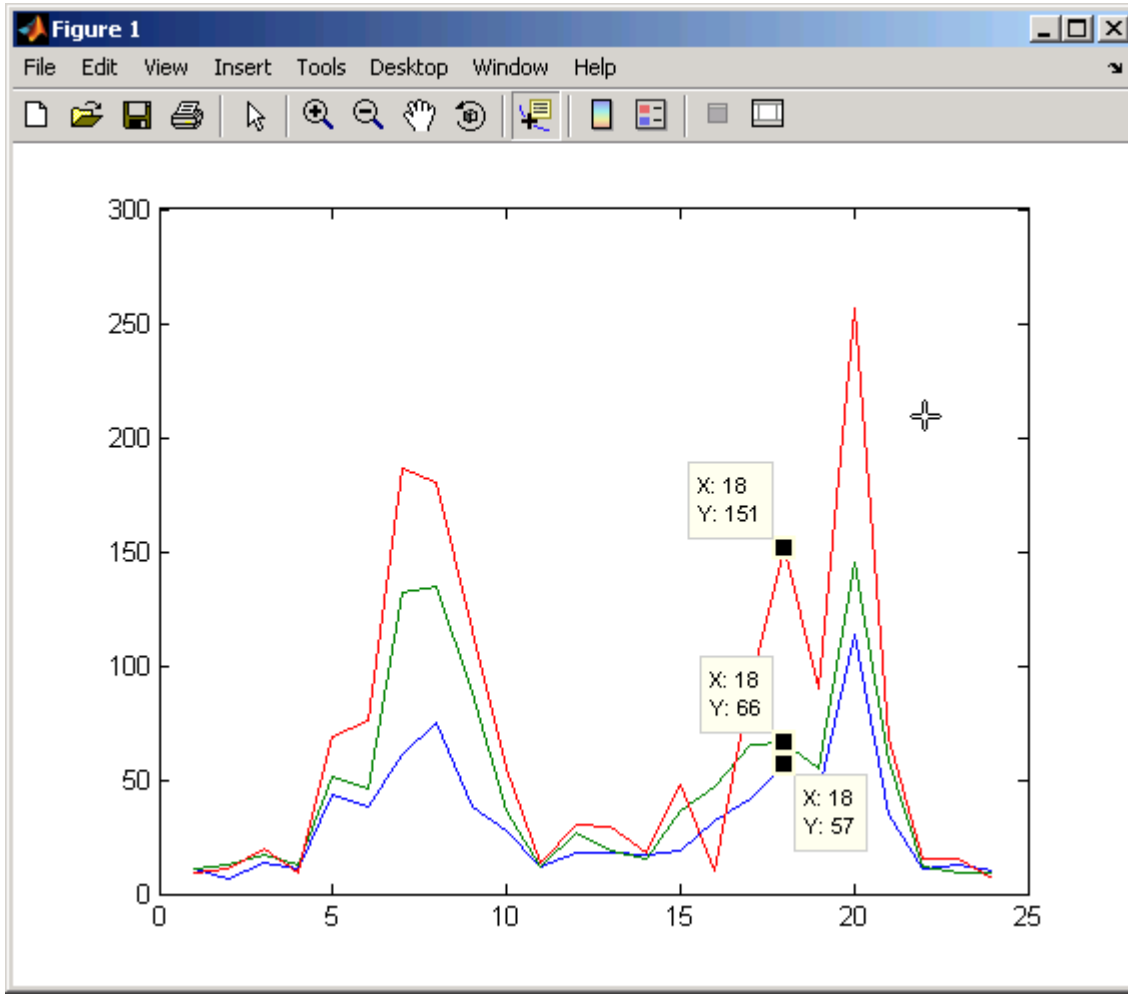
Enabling Data Cursor Mode

Select the data cursor icon in the figure toolbar  or select the **Data Cursor** item in the **Tools** menu.

Once you have enabled data cursor mode, clicking the mouse on a line or other graph object displays data values of the point clicked. Clicking elsewhere does not create or update data tips. To place additional data tips, as the picture below shows, see “Creating Multiple Data Tips” on page 2-11, below. In the picture, the black squares are located at points selected by the Data Cursor tool, and the data tips next to them display the x and y-values of those points.

The illustrations below use traffic count data stored in `count.dat`:

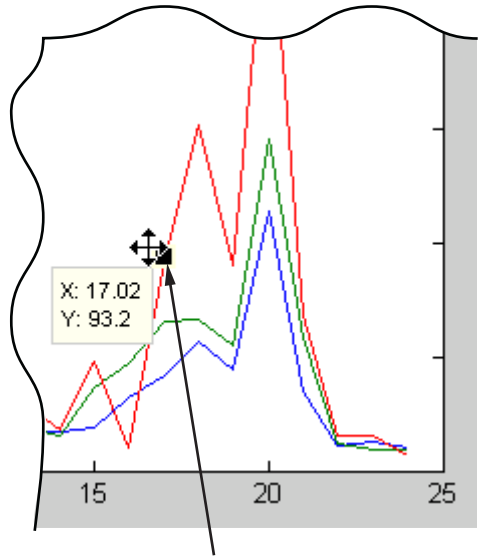
```
load count.dat
plot(count)
```



Moving the Marker

You can move the marker using the arrow keys and the mouse. The up and right arrows move the marker to data points having greater index values in the data arrays. The down and left arrow keys move the marker to data points having lesser index values. When you set **Selection Style** to **Mouse Position** using the tool's context menu, you can drag markers and position them anywhere along a line. However, you cannot drag markers between different

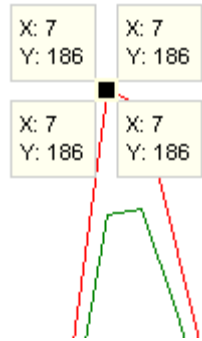
line or other series on a plot. The cursor changes to crossed arrows when it comes close enough to a marker for you to drag the datatip, as shown below:



Positioning the Datatip Text Box

You can position the data tip text box in any one of four positions with respect to the data point: upper right (the default), upper left, lower left, and lower right.

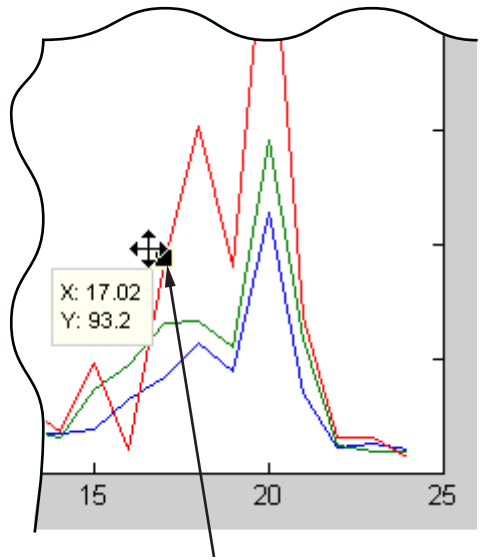
To position the datatip, press, but do not release the mouse button while over the datatip text box and drag it to one of the four positions, as shown below:



You can reposition a datatip, but not its text box, using the arrow keys as well.

Dragging the Datatip to Different Locations

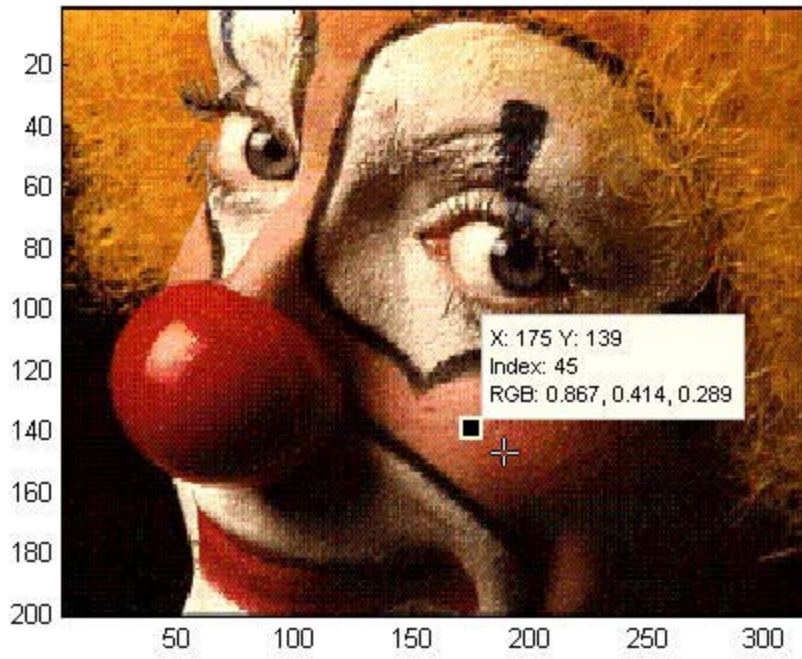
You can drag the datatip to different locations on the graph object by clicking down on the datatip and dragging the mouse. You can also use the arrow keys to move the datatip.



Note Surface plots and 3-D bar graphs can contain `NaN` values. If you drag a datatip to a location coded as `NaN`, the datatip will disappear (because its coordinates become `(NaN,NaN,NaN)`). You can continue to drag it invisibly, however, and it will reappear when it is over a non-`NaN` location. However, if you create a new datatip while the previous current one is invisible, the previous one cannot be retrieved.

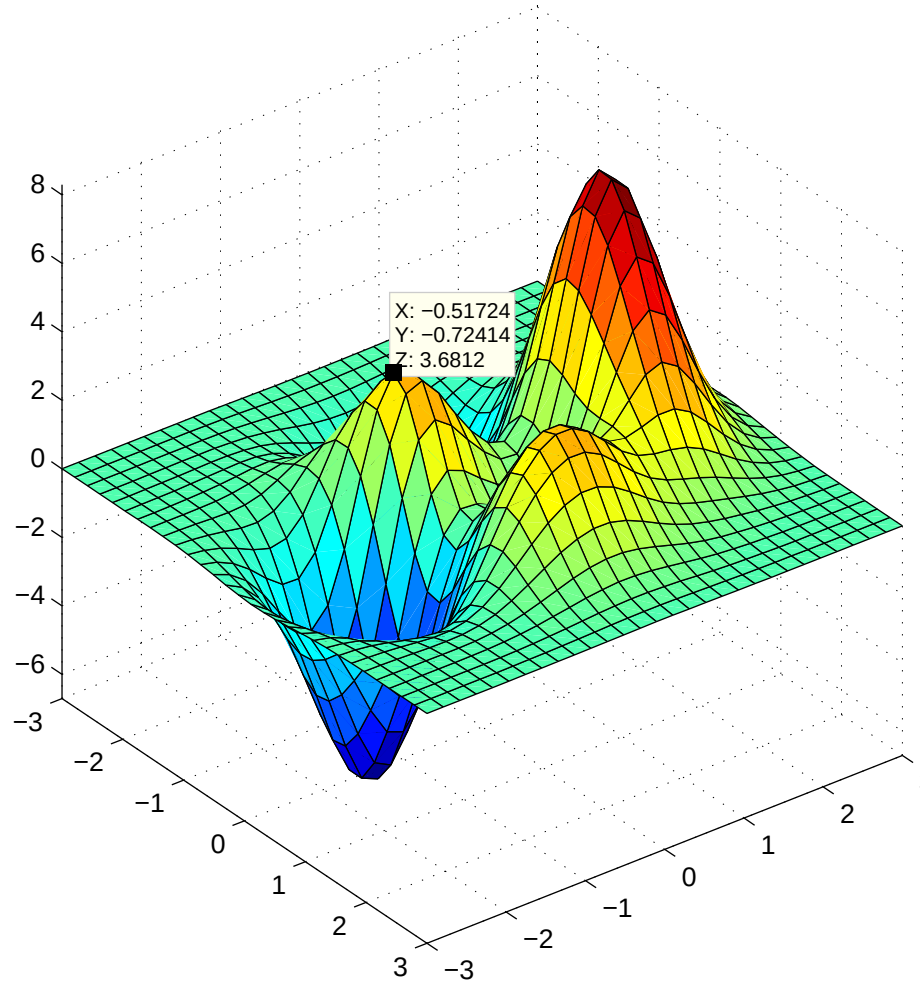
Datatips on Image Objects

Datatips on images display the *x*- and *y*-coordinates as well as the RGB values and a color index (for indexed images), as show below:



Datatips on 3-D Objects

You can use datatips to read data points on 3-D graphs as well. In 3-D views, data tips display the *x*-, *y*- and *z*-coordinates.



X: −0.51724
Y: −0.72414
Z: 3.6812
8

3

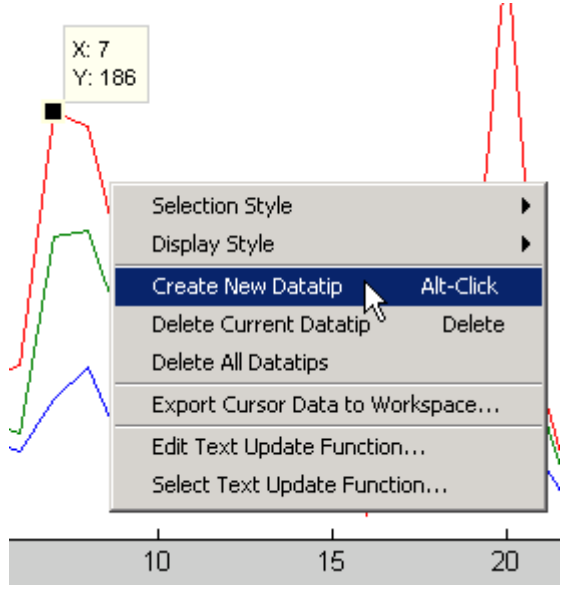
Creating Multiple Data Tips

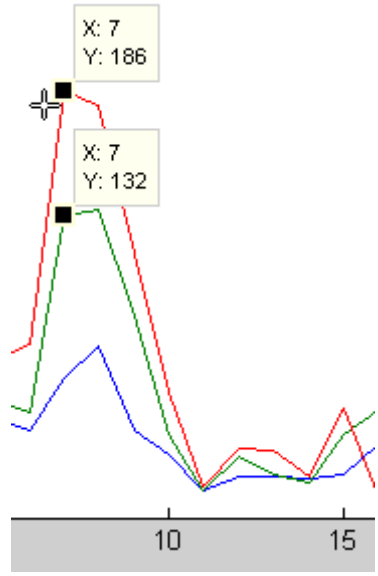
Normally, there is only one datatip displayed at one time. However, you can display multiple datatips simultaneously on a graph. This is a simple way to annotate a number of points on a graph.

Use the following procedure to create multiple datatips.

1. Enable data cursor mode from the figure toolbar. The cursor changes to a cross.
2. Click on the graph to insert a datatip.
3. Right-click to display the context menu. Select **Create New Datatip**.

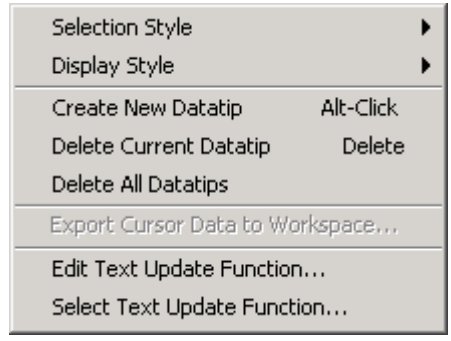


4. Click on the graph to place the second datatip.



Customizing Data Cursor Text

You can customize the text displayed by the data cursor using the `datacursormode` function. Use the last two items in the Data Cursor context menu to for this purpose:



- **Edit Text Update Function** — Opens an editor window to let you modify the function currently being used to place text in datatips

- **Select Text Update Function** — Opens an input file dialog for you to navigate to and select an M-file to use to format text in datatips you subsequently create

When you select **Edit Text Update Function** for the first time, an editor window opens with the default text update callback, which consists of the following code:

```
function output_txt = myfunction(obj,event_obj)
% Display the position of the data cursor
% obj          Currently not used (empty)
% event_obj    Handle to event object
% output_txt   Data cursor text string (string or cell array of strings).

pos = get(event_obj,'Position');
output_txt = {['X: ',num2str(pos(1),4)],...
    ['Y: ',num2str(pos(2),4)]};

% If there is a Z-coordinate in the position, display it as well
if length(pos) > 2
    output_txt{end+1} = ['Z: ',num2str(pos(3),4)];
end
```

You can modify this code to display properties of the graphics object other than position. If you want to do so, you should first save this code to an M-file before changing it, and select that file if you want to revert to default datatip displays during the same session.

If for example you save it as `def_datatip_cb.m`, and then modify the code and save it to another M-file, you can then choose between the default behavior and customized behavior by choosing **Select Text Update Function** from the context menu and selecting one of the callbacks you saved.

See the Examples section of the `datacursormode` reference page for more information on using data cursor objects and update functions.

Deleting Datatips

You can remove the most recently added datatip or all datatips. When in data cursor mode, right-click to display the context menu.

- Select **Delete Current Datatip** or press the **Delete** key to remove the last datatip that you added.
- Select **Delete All Datatips** to remove all datatips.

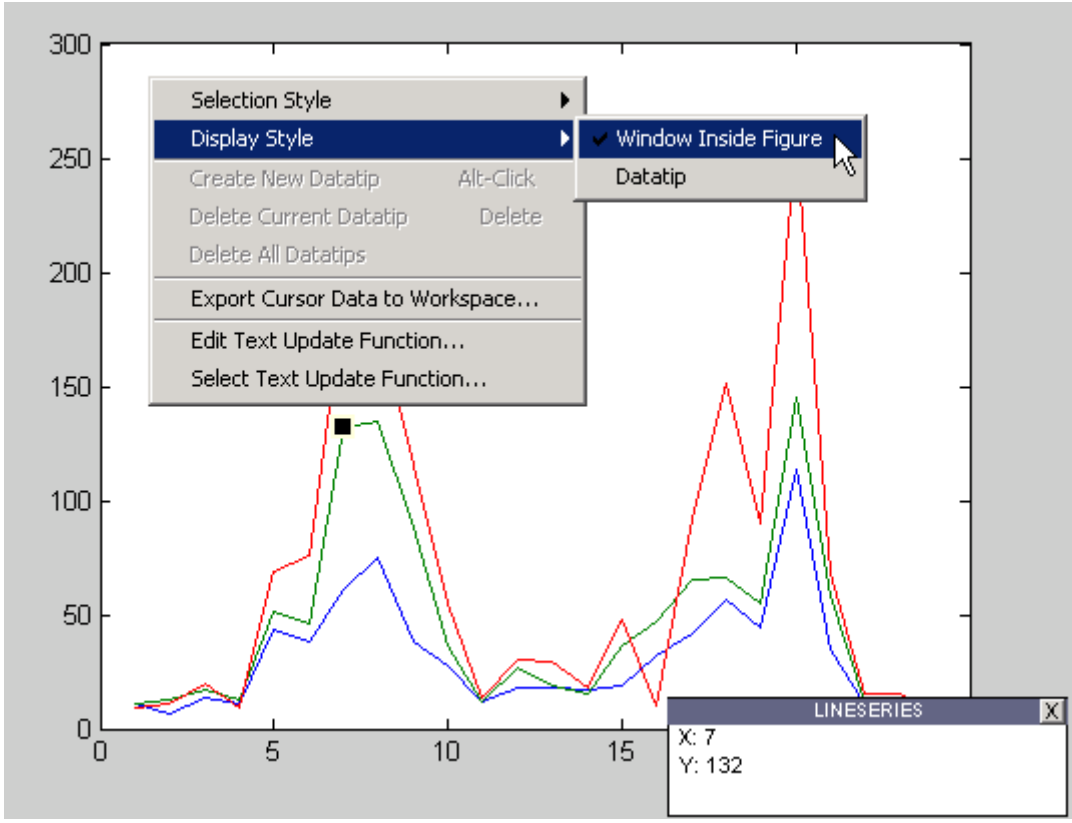
Display Style — Datatip or Cursor Window

By default, the data cursor displays values as a datatip (small text box located next to the data point). You can also display a single data value in a cursor window that is anchored within the figure window. You can place multiple datatips on a graph, which makes this display style useful for annotations.

The cursor window style is particularly useful when you want to drag the data cursor to explore image and surface data; numeric information in the window updates without obscuring the any of the figure's symbology.

To use the cursor window, change the display style as follows:

1. While in data cursor mode, right-click to display the context menu.
2. Mouse over the **Display Style** item.
3. Select **Window Inside Figure**.



Note If you change the data cursor **Display Style** from **Datatip** to **Window Inside Figure** with the context menu, only the most recent data tip is displayed; all other existing data tips are removed because the window can display only one datatip at a time.

Selection Style — Select Data Points or Interpolate Points on Graph

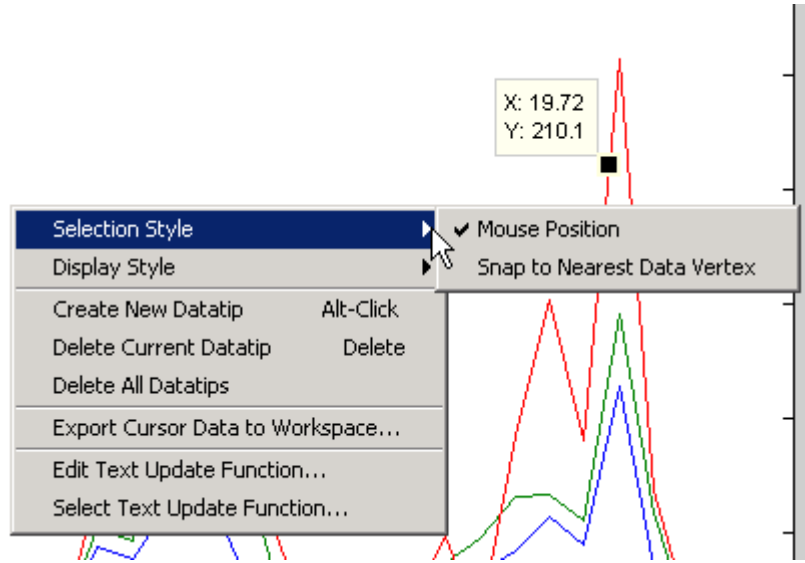
By default, the data cursor displays the values of the data point nearest to the point you click with the mouse, and the data marker snaps to this point. The data cursor can also determine the values of points that lie in between

the data defining the graph, by linearly interpolating between the two data points closest to the location you click the mouse.

Enabling Interpolation Mode

If you want to be able to select any point along a graph and display its value, use the following procedure:

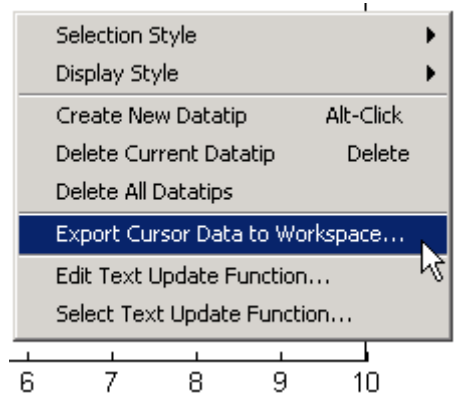
1. While in data cursor mode, right-click to display the context menu.
2. Mouse over the **Selection Style** item.
3. Select **Mouse Position**.



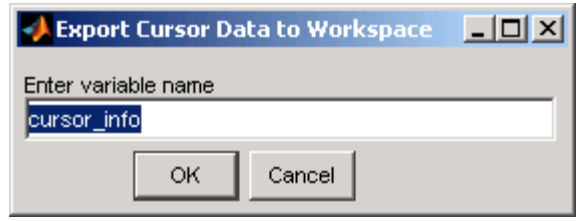
Note that interpolation mode is not honored when you are using the arrow keys to move a datatip to a new location.

Exporting Data Value to Workspace Variable

You can export the values displayed with the data cursor to MATLAB workspace variables. To do this, display the right-click context menu while in data cursor mode and select **Export Cursor Data to Workspace**.



MATLAB then displays a dialog that enables you to name the workspace variable.



When you click **OK**, MATLAB creates a structure with the specified name in your base workspace, containing the following fields:

- `Target` — Handle of the graphics object containing the data point
- `Position` — *x*- and *y*- (and *z*-) coordinates of the data cursor location in axes data units

Line and lineseries objects have an additional field:

- `DataIndex` — A scalar index into the data arrays that correspond to the nearest data point. The value is the same for each array.

For example, if you saved the workspace variable as `cursor_info`, then you would access the position data by referencing the `Position` field.

```
cursor_info.Position
ans =
    0.4189  0.1746  0
```

Enlarging the View

In this section...

Zooming in 2-D and 3-D

Zooming changes the magnification of a graph without changing the size of the figure or axes. Zooming is useful to see greater detail in a small area. As explained below, zooming behaves differently depending on whether it is applied to a 2-D or 3-D view.

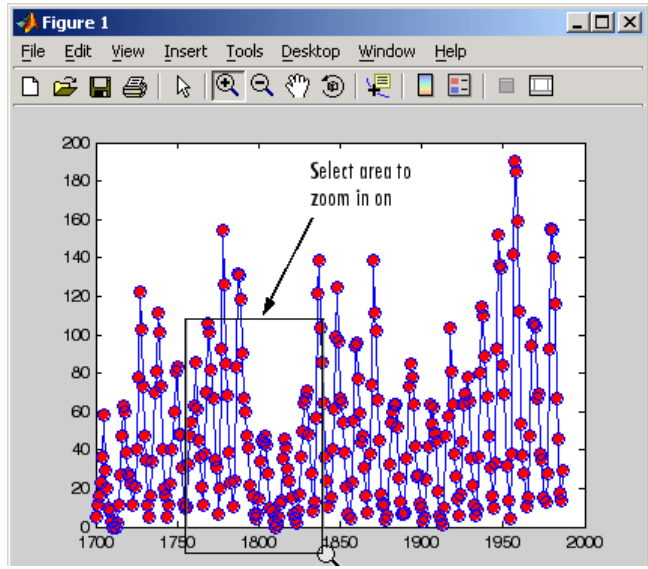
Enable zooming by clicking one of the zoom icons  . Select **+** to zoom in and **–** to zoom out.

Note, when in zoom in mode, you can use **Shift**+click to zoom out (i.e., press and hold down the **Shift** key while clicking the mouse). You can also right-click and zoom out or restore the plot to its original view using the context menu.

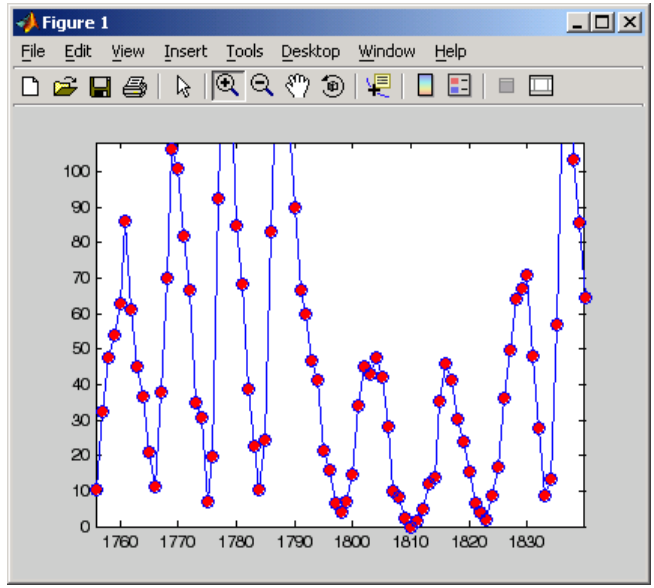
Zooming in 2-D Views

In 2-D views, click the area of the axes where you want to zoom in, or drag the cursor to draw a box around the area you want to zoom in on. MATLAB redraws the axes, changing the limits to display the specified area.

For example, selecting the region of the following plot,



results in a rescaling of the axes to display only that region.

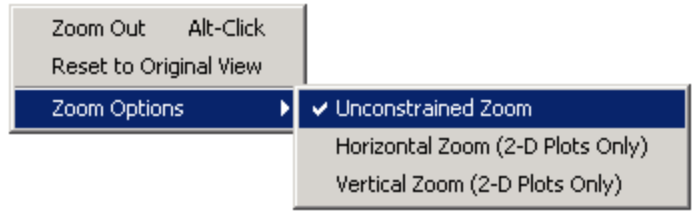


Undoing Zoom Actions

If you want to reset the graph to its original view, right-click to display the context menu and select **Reset to Original View**. You can also use the **Undo** item on the **Edit** menu to undo each operation you performed on your graph.

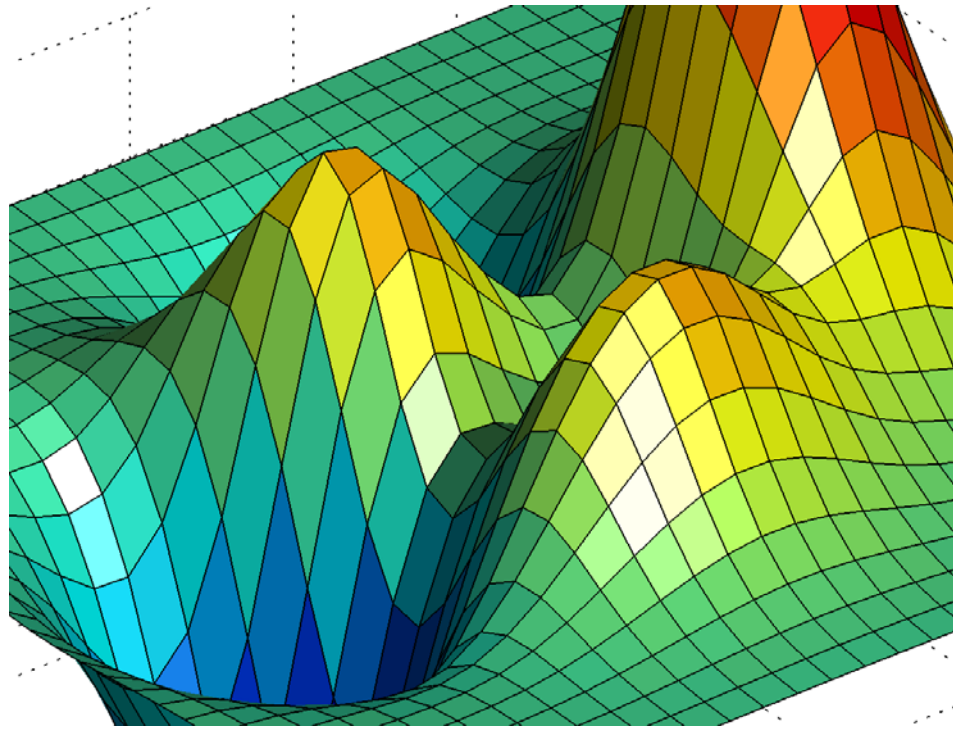
Zoom Constrained to Horizontal or Vertical

In 2-D views, you can constrain zoom to operate in either the horizontal or vertical direction. To do this, right-click to display the context menu while in zoom mode and select the desired zoom option.



Zooming in 3-D Views

In 3-D views, moving the cursor up or to the right zooms in, while moving the cursor down or to the left zooms out. Both toolbar icons enable the same behavior. 3-D zooming does not change the axes limits, as in 2-D zooming. Instead it changes the view (specifically, the axes `CameraViewAngle` property) as if you were looking through a camera with a zoom lens.

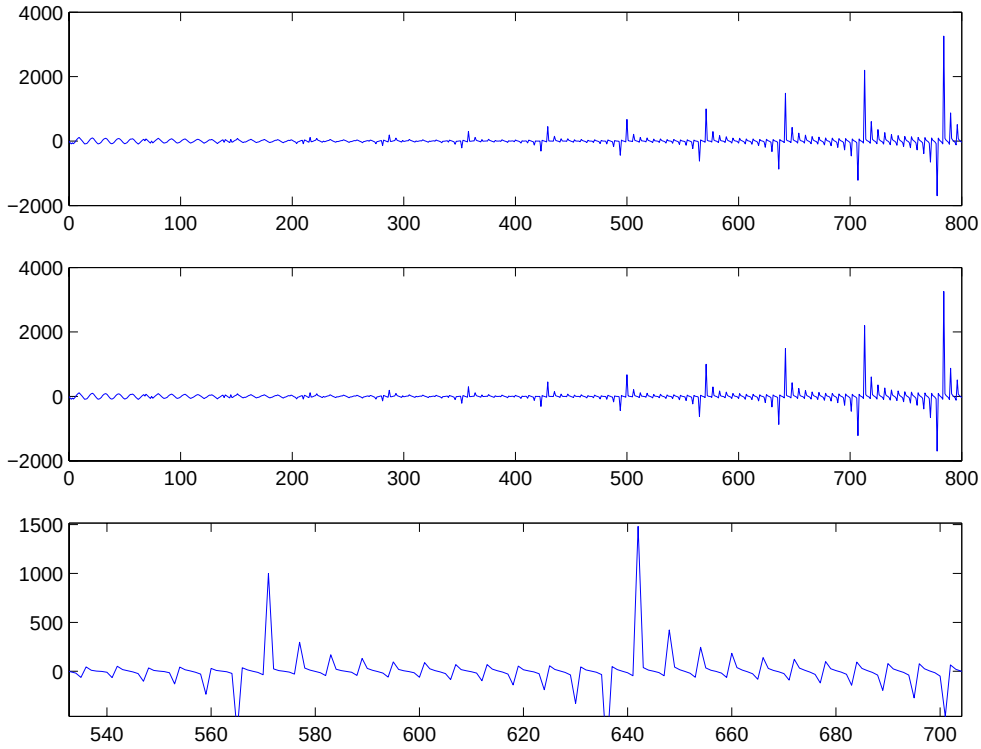


Panning — Shifting Your View of the Graph

You can move your view of a graph up and down as well as left and right with the pan tool. Panning is useful when you have zoomed in on a graph and want to translate the plot to view different portions.

Click this icon on the figure toolbar to enable panning  . In pan mode you can freely move up, down, left or right, or you can constrain movement to be vertical or horizontal only by right-clicking and selecting one of the **Pan Options** from the pan tool's context menu.

You can pan across both 2-D and 3-D views. 2-D panning has the effect of changing the axis limits that you are viewing, but it does not change the actual limits of the plot. For example, suppose you have a time-series waveform that you want to zoom in on to view detail, but you also want to be able to scan the entire plot.



3-D panning moves the axes with the object, because the 3-D view is not aligned to the *x*-, *y*-, or *z*-axis. The axes limits do not change as in 2-D panning.

Rotate 3D — Interactive Rotation of 3-D Views

In this section...

Enabling 3-D Rotation

MATLAB enables you to rotate graphs to any orientation with the mouse. Rotation involves the reorientation of the axes and all the graphics objects it contains. Therefore none of the data defining the graphics objects is affected by rotation; instead the orientation of the *x*-, *y*-, and *z*-axes changes with respect to the viewer.

There are three ways to enable Rotate 3D mode:

- Select **Rotate 3D** from the **Tools** menu.
- Click the Rotate 3D icon in the figure toolbar  .
- Execute the `rotate3d` command.

Once the mode is enabled, you press and hold the mouse button while moving the cursor to rotate the graph.

Selecting Predefined Views

When Rotate 3D mode is enabled, you can control various rotation options from the right-click context menu.

You can rotate to predefined views on the right-click context menu:

- **Reset to Original View** — Reset to the default MATLAB view (azimuth -37.5°, elevation 30°).
- **Go to X-Y View** — View graph along the *z*-axis (azimuth 0°, elevation 90°).

- **Go to X-Z View** — View graph along the *y*-axis (azimuth 0°, elevation 0°).
- **Go to Y-Z View** — View graph along the *x*-axis (azimuth 90°, elevation 0°).

Rotation Style for Complex Graphs

You can select from two rotation styles on the right-click context menu's **Rotation Options** submenu:

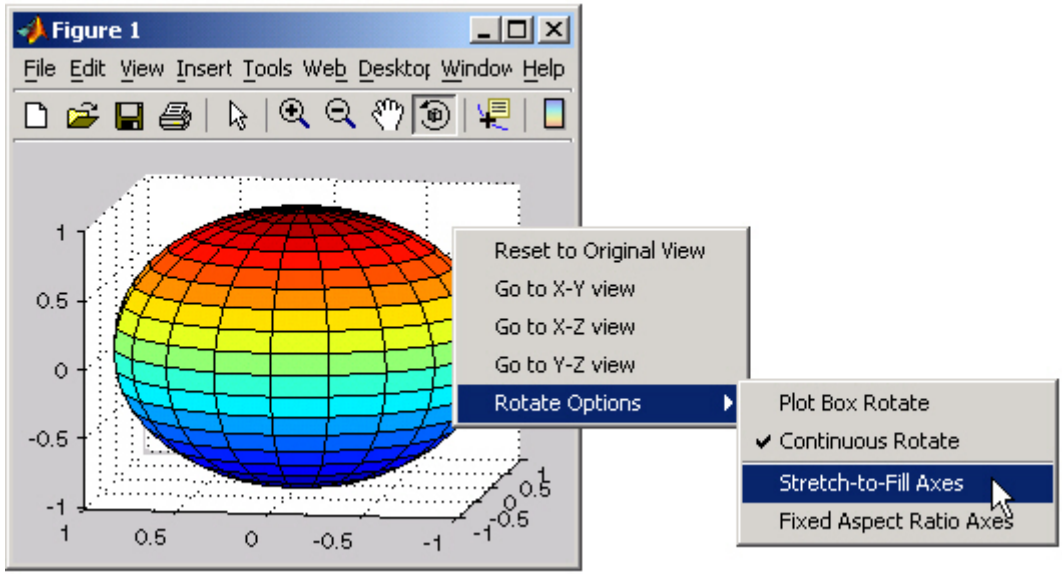
- **Plot Box Rotate** — Display only the axes bounding box for faster rotation of complex objects. Use this option if the default **Continuous Rotate** style is unacceptably slow.
- **Continuous Rotate** — Display all graphics during rotation.

Axes Behavior During Rotation

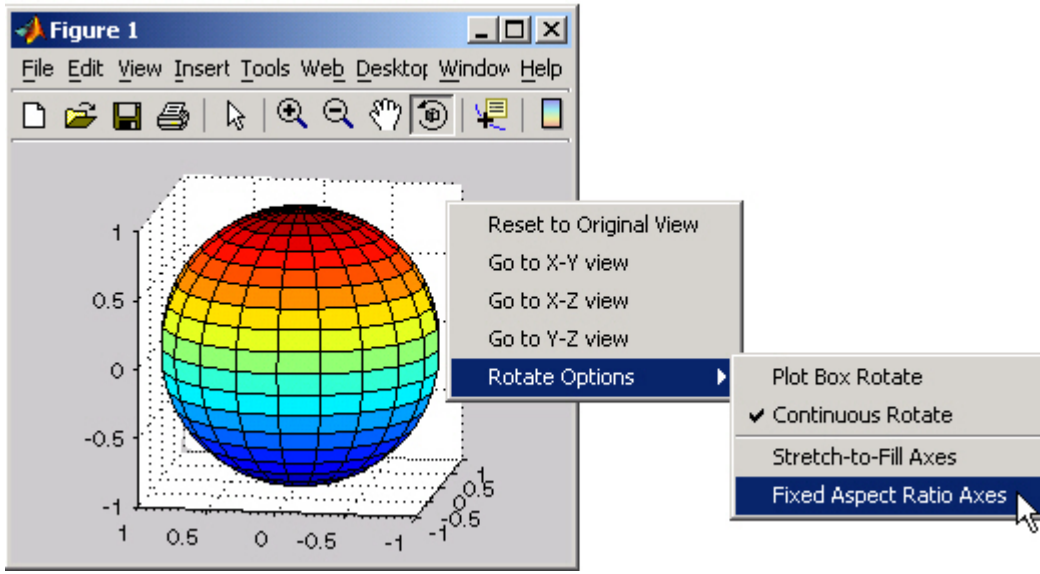
You can select two types of behavior with respect to the aspect ratio of axes during rotation:

- **Stretch-to-Fill Axes** – Default axes behavior is optimized for 2-D plots. Graphs fit the rectangular shape of the figure.
- **Fixed Aspect Ratio Axes** – Maintains a fixed shape of objects in the axes as they are rotated. Use this setting when rotating 3-D plots.

The following pictures illustrate a sphere as it is rotated with **Stretch-to-Fill Axes** selected. Note that the sphere is not round.



The next picture shows how the **Fixed Aspect Ratio Axes** option results in a sphere that maintains its proper shape as it is rotated.



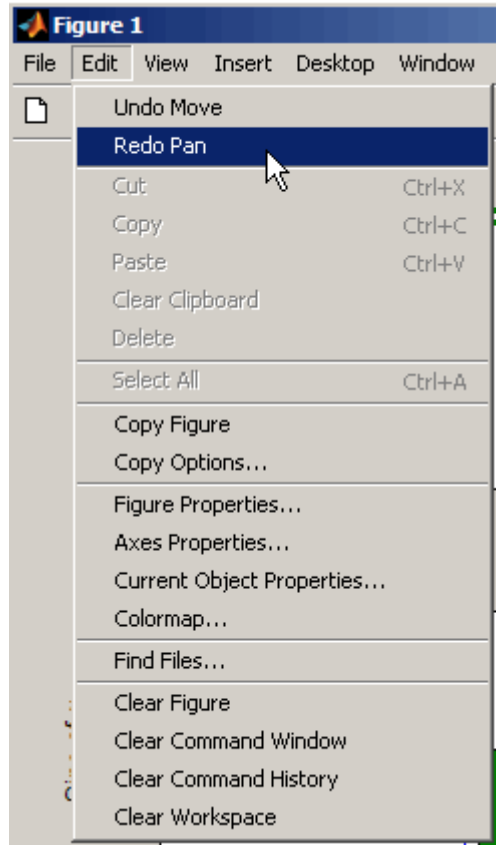
Undo/Redo — Eliminating Mistakes

The figure **Edit** menu contains two items that enable you to undo any zoom, pan, or rotate operation.

Undo — Remove the effect of the last operation.

Redo — Perform again the last operation that you removed by selecting **Undo**.

For example, if you create a plot, zoom in, pan the view, and then undo the pan operation, the menu looks as follows:



You could now undo the previous zoom operation or redo the pan operation you just undid.

3

Annotating Graphs

How to Annotate Graphs

In this section...

Graph Annotation Features

Annotating graphs with text and other explanatory material can improve the graph's ability to convey information. MATLAB provides a variety of features for annotating graphs, including those that

- Add text, lines and arrows, rectangles, ellipses, and other annotation objects anywhere on the figure
- Anchor annotations to locations in data space
- Add a legend and colorbar
- Add axis labels and titles
- Edit the properties of graphics objects

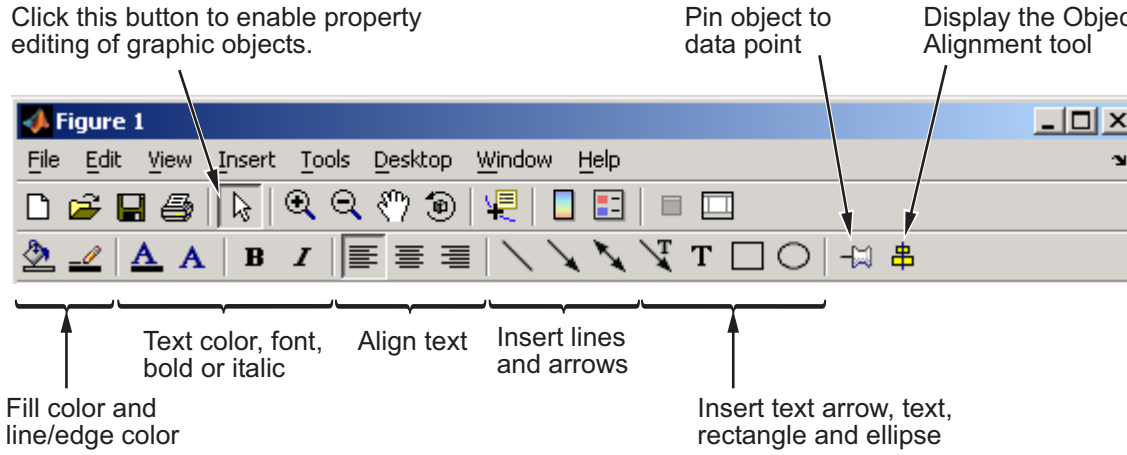
The following sections provide more information.

- "Enclosing Regions of a Graph in a Rectangle or an Ellipse" on page 3-6
- "Textbox Annotations" on page 3-8
- "Annotation Lines and Arrows" on page 3-13
- "Adding a Colorbar to a Graph" on page 3-16
- "Adding a Legend to a Graph" on page 3-20

- "Pinning — Attaching to a Point in the Graph" on page 3-23

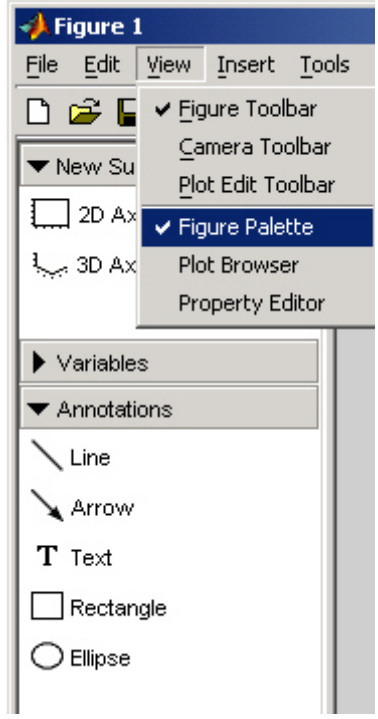
Annotation Tools on the Plot Edit Toolbar

Select **Plot Edit Toolbar** from the **View** menu to display the toolbar.



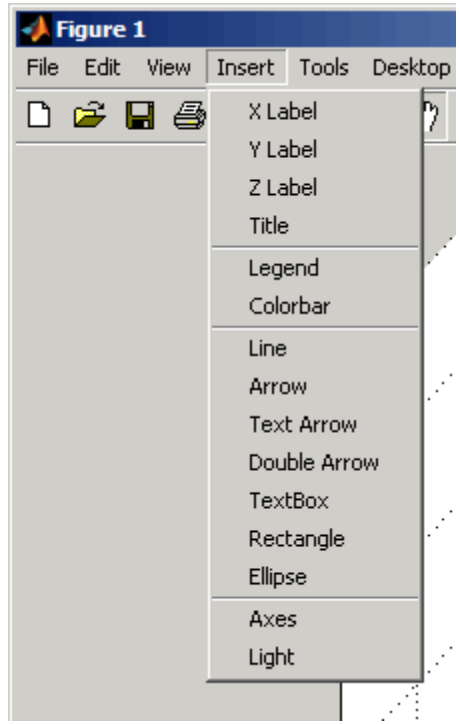
Annotation Tools on the Figure Palette

Basic annotation tools are available from the figure palette. Select **Figure Palette** from the **View** menu to display the figure palette.



Adding Annotations from the Insert Menu

Annotation features are available from the **Insert** menu.



Command Interface

You can add annotations using MATLAB commands. The following table lists the functions used to create annotations.

MATLAB Functions for Creating Annotations

Function	Purpose
`annotation`	Create annotations including lines, arrows, text arrows, double arrows, text boxes, rectangles, and ellipses
`xlabel`, `ylabel`, `zlabel`	Add a text label to the respective axis
`title`	Add a title to a graph

MATLAB Functions for Creating Annotations (Continued)

Function	Purpose
`colorbar`	Add a colorbar to a graph
`legend`	Add a legend to a graph

Removing Annotations

You can delete any annotation manually, and (if it has an explicit handle) programmatically. See “Deleting Annotations” in the MATLAB function reference documentation for details.

Enclosing Regions of a Graph in a Rectangle or an Ellipse

You can add a rectangle or an ellipse to draw attention to a specific region of a graph. While either object is selected, you can move and resize it as well as display a right-click context menu that enables you to modify behavior and appearance.

Insert the rectangle or ellipse by clicking the corresponding button in the plot edit toolbar

or by selecting **Rectangle** or **Ellipse** from the **Insert** menu. MATLAB changes the cursor to a cross indicating you can click down, drag, and release the left mouse button to define the size and shape of the object.

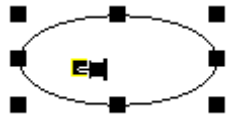
Pinning Rectangles and Ellipses

You can attach the rectangle to a particular point in the figure by pinning it to that point. There are three ways to pin the rectangle:

- Right-click the rectangle to display its context menu. Select **Pin to axes** to set a pin in the default location.

- Select the pin button in the figure toolbar (see “Pinning — Attaching to a Point in the Graph” on page 3-23).
- Select **Pin to axes** from the **Tools** menu. The cursor changes to a pin; click anywhere within the object to set a pin at that location.

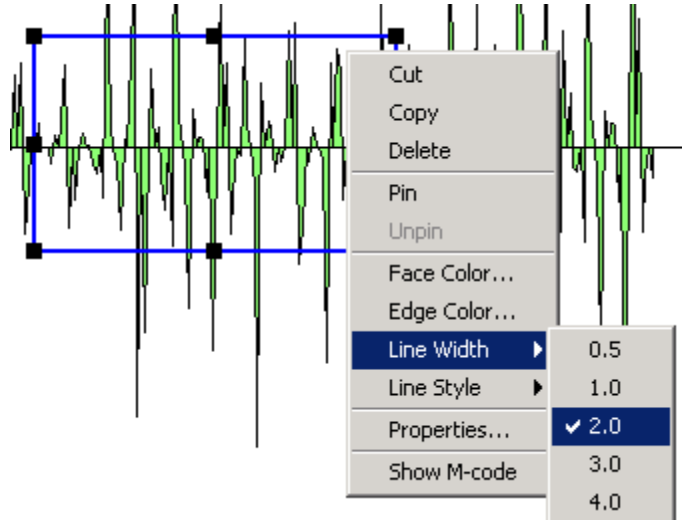
By default (using the first of the options described above), pinning attaches the lower left corner of the rectangle or ellipse to its current location in the axes data units. You can move the point of attachment by clicking the corner and dragging the anchor to another point. The cursor changes to a pin while you are dragging.



Note that you cannot drag or resize a rectangle or an ellipse when it is pinned.

Modifying the Rectangle or Ellipse from the Context Menu

Right-click the rectangle or ellipse to display its context menu.



The menu contains the following options:

- **Cut**, **Copy**, **Delete** — Cut to clipboard, copy to clipboard, or delete the selected object.
- **Pin to axes** — Pin the lower left corner to the current location (you can move the point of attachment by clicking and dragging the point while in plot edit mode).
- **Unpin** — Detach the rectangle from the attachment point.
- **Face Color** — Fill color for the rectangle or ellipse
- **Edge Color** — Color of the line used to draw the rectangle or ellipse
- **Line Width** — Width of the line used to draw the rectangle or ellipse
- **Line Style** — Type of line used to draw the rectangle or ellipse
- **Properties** — Display the Property Editor with textbox properties.
- **Show M-code** — Create M-code that recreates the graph.

Setting Rectangle and Ellipse Properties

You can use the Property Editor to set rectangle and ellipse properties by selecting **Properties** from the context menu. The Property Editor displays the same properties that are described above in the context menu section.

You can click the **More Properties** button on the Property Editor to display the Property Inspector. The Property Inspector displays all properties for the selected annotation object. However, you should not change some of these properties because doing so can affect the proper functioning of the annotation object. See the following sections for descriptions of the properties you can change on the respective objects.

- Annotation Rectangle Properties
- Annotation Ellipse Properties

Textbox Annotations

A textbox is a rectangle that can contain multiline text. You can attach the textbox to any point in the figure.

Insert a textbox by clicking the textbox button in the figure toolbar  , then click where you want to place the text string. The default behavior for textboxes is for them to resize to accommodate the amount of text you enter into them. You can also resize the textbox after typing or click and drag the box to a certain size when you create it (when you do this, the textbox stays that size no matter how much text you place within it).

You can also select **TextBox** from the **Insert** menu.

Selecting Textbox Objects

The selection behavior of the textbox object differs from other annotation objects.

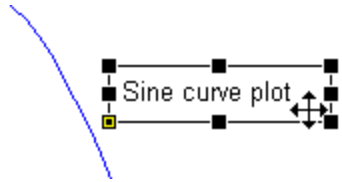
- To move a textbox, click the text once to select it.
- To edit the a textbox, double-click within the box.
- To display the Property Editor with textbox properties, right-click to display the context menu and select **Properties**.

Pinning the Textbox

You can attach the textbox to a particular point in the figure by pinning it to that point. There are three ways to pin the textbox:

- Right-click within the textbox to display its context menu and select **Pin to Axes**.
- Select the pin button in the figure toolbar and click a handle of the textbox (See “Pinning — Attaching to a Point in the Graph” on page 3-23).
- Select **Pin Object** from the **Edit** menu.

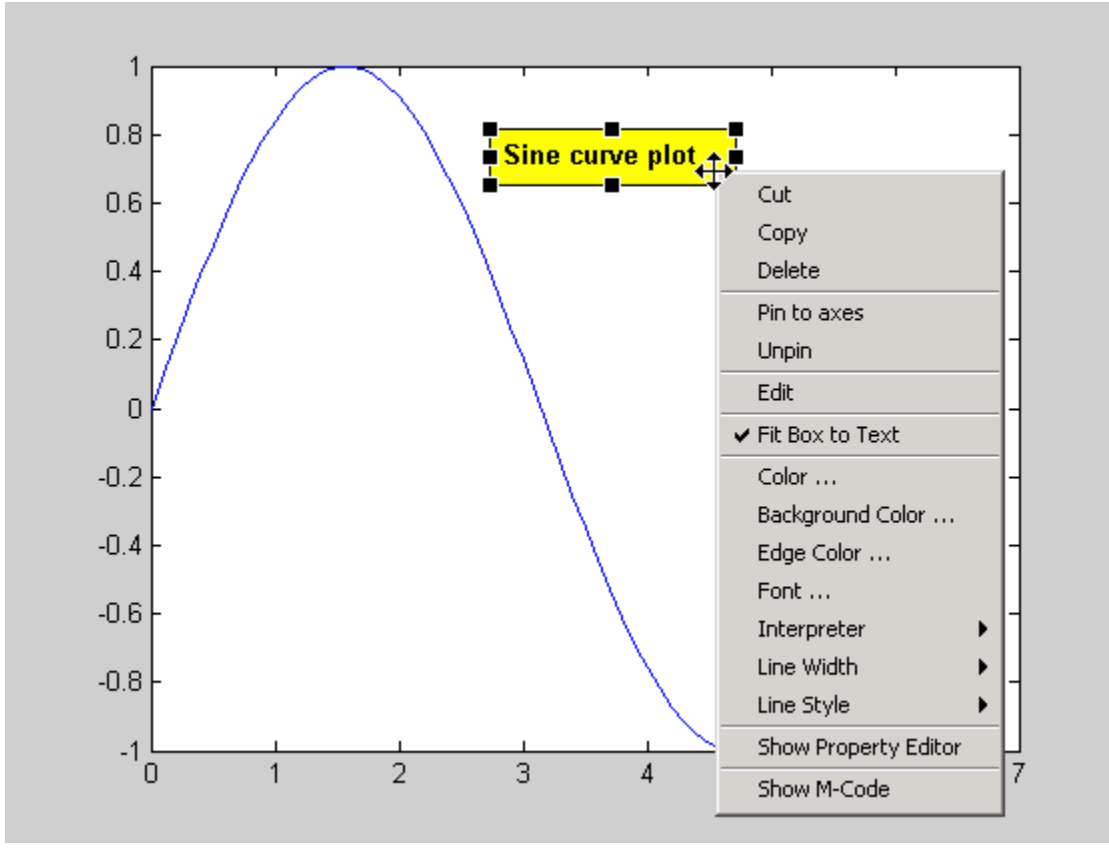
By default, pinning attaches the lower left corner of the textbox to its location in the axes data space. You can move the point of attachment by clicking on the corner and dragging the anchor to another point.



Note that you cannot drag the textbox when it is pinned.

Modifying the Textbox from the Context Menu

Right-clicking in a textbox displays its context menu, which enables you to perform a number of operations on the textbox. In the following picture, the textbox **Background Color** has been set to yellow and its **Font** has been set to bold using the context menu. The textbox has its default resizing behavior, as indicated by the checked item **Fit Box to Text**:



When you create a textbox without dragging it to have a specific size, **Fit Box to Text** is enabled, and the box will grow or shrink as you type or edit its text. If you drag when creating a textbox, or change its size by dragging any of its handles in plot edit mode, **Fit Box to Text** is disabled, but you can re-enable it using the context menu.

The menu contains the following options:

- **Cut**, **Copy**, **Delete** — Cut to clipboard, copy to clipboard, or delete the textbox.

- **Pin to axes** — Pin the textbox to the current location (you can move the point of attachment by clicking and dragging the textbox while in plot edit mode).
- **Unpin** — Detach the textbox from the attachment point.
- **Edit** — Enable edit mode to change the text. You can also double-click the textbox with the left mouse button to enable edit mode.
- **Fit Box to Text** — Resize textbox to accommodate text extents (or not)
- **Text Color** — Color of the text characters
- **Background Color** — Fill color of the rectangle enclosing the text
- **Edge Color** — Color of the textbox edge line (you must set **Line Style** to a value other than **none** to display edges)
- **Font** — Type of font used for the text
- **Interpreter** — Interpret characters as T_EX (`latex` or `tex`) or as literal characters (`none`).
- **Line Width** — Width of the textbox edge line
- **Line Style** — Style of line used for the textbox edge
- **Properties** — Display the Property Editor with textbox properties.
- **Show M-code** — Create M-code that recreates the graph.

Setting Textbox Properties

You can use the Property Editor to set textbox properties by selecting **Show Property Editor** from the textbox context menu. It displays the same properties that are described above in the context menu section.

You can click the **More Properties** button on the Property Editor to display the Property Inspector. The Property Inspector displays all textbox properties. However, you should not change some of these properties because doing so can affect the proper functioning of the textbox.

See Textbox Properties in the reference documentation for a description of the properties you can change.

Annotation Lines and Arrows

You can add lines and three types of arrows to a graph and attach them to any point in the figure. The three types of arrows include

- Single-headed arrow
- Arrow with attached text box
- Double-headed arrow

Insert a line or arrow by clicking the appropriate button in the figure toolbar  , then click down, drag the line or arrow to the desired point, and release the mouse. The arrowhead appears at the terminal end.

With the line or arrow selected, right-click to display the context menu, which provides access to a number of options.

Inserting a Text Arrow

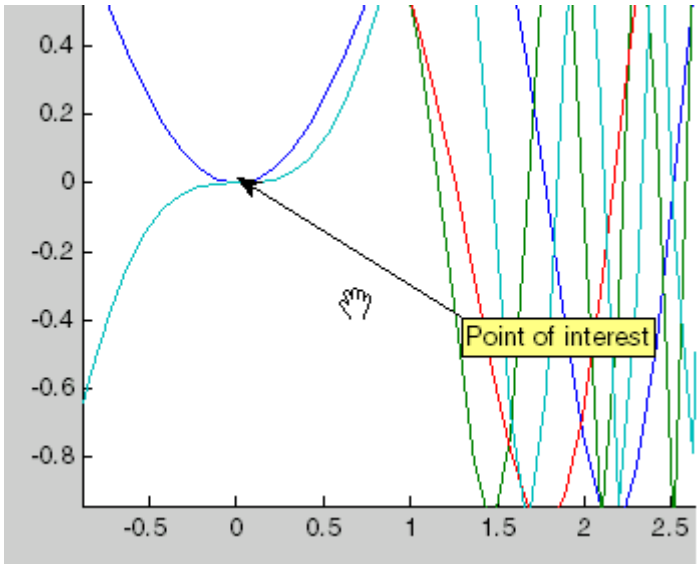
A text arrow combines a textbox with an arrow. It is useful for labeling points on a graph. Add a text arrow to a graph by selecting the arrow button that has a T above the arrow. Insert the text arrow and type text in the box.

Pinning the Arrowhead End

You can attach the arrowhead end to the point of interest on the graph while letting the text box automatically reposition itself as you zoom or pan the graph.

There are three ways to pin annotations:

- Right-click the object to display its context menu and select **Pin**.
- Select the **pin** button in the plot edit toolbar (See “Pinning — Attaching to a Point in the Graph” on page 3-23).
- Select **Pin Object** from the **Edit** menu.



You can pin the arrowhead and then pan the graph to get the desired view.

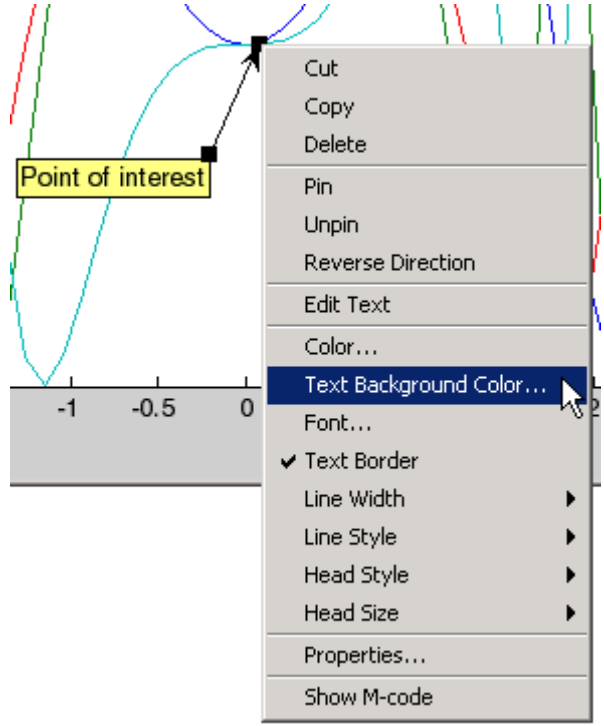
Modifying the Text Arrow from the Context Menu

Right-clicking on a text arrow displays its context menu, which enables you to perform a number of operations on the text arrow. The context menus for lines, arrows, and double arrows contain similar items:

- **Cut**, **Copy**, **Delete** — Cut to clipboard, copy to clipboard, or delete the textbox.
- **Pin to axes** — Pin the textbox to the current location (you can move the point of attachment by clicking and dragging the point while in plot edit mode).
- **Unpin** — Detach the textbox from the attachment point.
- **Reverse Direction** — Swap the arrow head and the textbox or move the arrowhead to the other end of a plain arrow.
- **Edit Text** — Enable edit mode to change the text characters.
- **Color** — Color of the text characters, textbox edge, and arrow
- **Text Background Color** — Color of the rectangle enclosing the text
- **Font** — Type of font used for the text

- **Line Width** — Width of the textbox edge line
- **Line Style** — Style of line used for the textbox edge
- **Head Style** — Type of arrowhead to use
- **Head Size** — Size of the arrowhead in points
- **Properties** — Display the Property Editor with textbox properties.
- **Show M-code** — Create M-code that recreates the graph.

For example, the following illustration shows the text border enabled and the text background color set to yellow.



Setting Line and Arrow Properties

You can use the Property Editor to set line and arrow properties by selecting **Properties** from the context menu. The Property Editor displays the same properties that are described above in the context menu section.

You can click the **More Properties** button on the Property Editor to display the Property Inspector. The Property Inspector displays all properties for the selected annotation object. However, you should not change some of these properties, because doing so can affect the proper functioning of the annotation. See the following sections in the reference documentation for descriptions of the properties you can change on the respective objects.

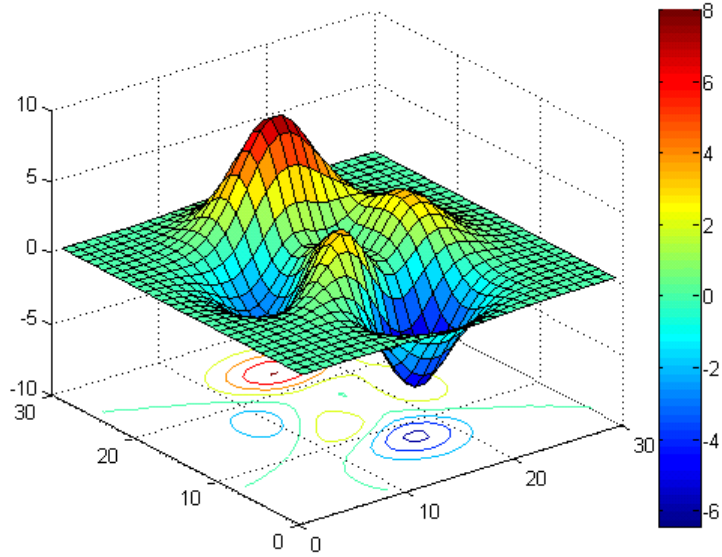
- Annotation Line Properties
- Annotation Arrow Properties
- Annotation Textarrow Properties
- Annotation Doublearrow Properties

Adding a Colorbar to a Graph

Colorbars display the current colormap and indicate the mapping from data values to colors. The following picture shows a surface plot with 2-D contour lines below. Note how the colorbar at the right indicates how the *z*-axis data values correspond to colors in both the surface and contour graphs.

Add a colorbar by clicking the colorbar button in the toolbar  or by selecting **Colorbar** from the **Insert** menu. When plot editing is enabled, you can select and then move and resize the colorbar. The following commands will also create this plot:

```
surfc(peaks(30))
colorbar
```



You can also use the `colorbar` function to add a colorbar to a 2-D graph.

Positioning Options for Colorbars

There are a variety of ways to reposition a colorbar in the figure.

- Enable plot edit mode, then select and drag the colorbar to the desired location.
- Right-click over the colorbar to display its context menu. Mouse over **Locations** and select one of the predefined locations for the colorbar.
- Right-click over the colorbar to display its context menu and select **Properties**. This displays the Property Editor, which provides a graphical positioning device for the colorbar.

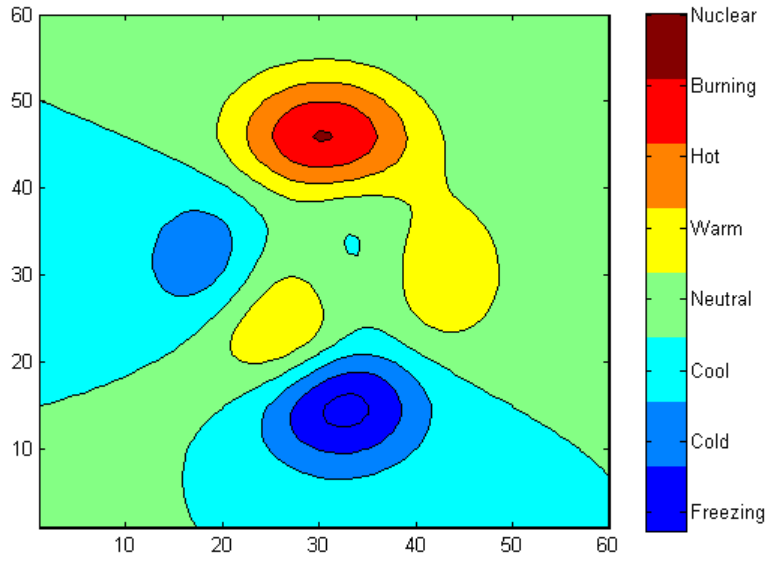
Labeling Colorbar Ticks

The default colorbar labels ticks with numeric values, which are placed at intervals specified by the colorbar's `YTick` parameter (for vertical colorbars) or its `XTick` parameter (for horizontal colorbars), within upper and lower limits specified by `CData`. You can override these limits by using the `caxis` function.

You can specify strings in place of the numeric labels on colorbars. This is useful for display of data on nominal or ordinal scales and for when you want to interpret the meaning of entries in the colormap for the viewer. To substitute strings for numbers along a colorbar, you define a label for each tick location. You do this by specifying a cell array of strings for `YTicklabel` (vertical colorbars) or `XTickLabel` (horizontal colorbars), as the examples below show.

Example 1: Default Vertical Colorbar with YTickLabels

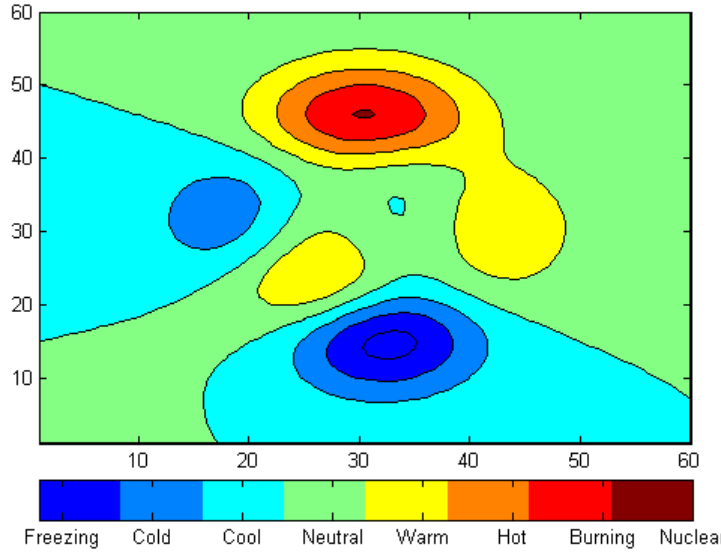
```
contourf(peaks(60));
colormap(jet(8));
hcb = colorbar('YTickLabel',...
{'Freezing','Cold','Cool','Neutral',...
'Warm','Hot','Burning','Nuclear'});
set(hcb,'YTickMode','manual')
```



Example 2: Horizontal Colorbar with XTickLabels

```
figure
contourf(peaks(60));
```

```
colormap(jet(8));
hcb = colorbar('Location','SouthOutside','XTickLabel',...
{'Freezing','Cold','Cool','Neutral',...
'Warm','Hot','Burning','Nuclear'});
set(hcb,'XTickMode','manual')
```



In these examples, the number of colors and the number of labels were set to be the same (8). This is typical for nominal (categorical) data, but not necessary if you do not object to having a range of colors associated with each label.

Note that if ticks change, for instance if `YTick` (`XTick`) values change or the plot is rescaled while `YTickMode` (`XTickMode`) or `YTickLabelMode` (`XTickLabelMode`) is `auto`, too few or too many colorbar labels may be displayed, and can sit next to colors they do not represent. When there are fewer labels than ticks, the labels will cycle, with the lowest one following the highest one, etc., to give each tick a label. This is probably not what you want, so you need to reset `YTick` (`XTick`) values in such cases. Finding the correct values can take some experimentation. The `set` functions in the above examples prevent MATLAB from changing the number of ticks when you resize figures.

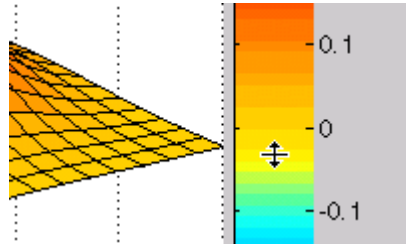
Selecting a Different Colormap

If you change the figure colormap, the colorbar updates automatically. Use one of the following methods to change the colormap.

- Right-click over the colorbar to display its context menu. Mouse over **Standard Colormaps** and select from the displayed list.
- Right-click over the colorbar to display its context menu and select **Properties**. Click the figure background to load the figure properties into the Property Editor. Select the colormap from the pull-down list.
- Use the `colormap` function.

Modifying the Colormap

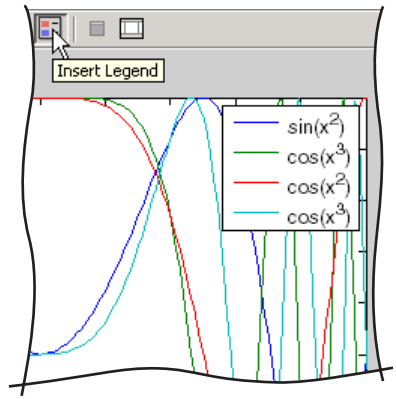
You can use a colorbar to modify the current colormap. To do this, select **Interactive Colormap Shift** from the right-click context menu. In this mode, you can left-click down on any color in the colorbar and, by dragging the mouse, shift the color-to-data mapping.



To perform more sophisticated operations on the colormap, launch the colormap editor by selecting **Launch Colormap Editor** from the colorbar's context menu. See the `colormapeditor` reference page for more information.

Adding a Legend to a Graph

Legends provide a key to the various data plotted on a graph. The following picture shows the legend for a graph of four functions of a variable plotted with lines of different colors. A graph can have only one legend, which applies to and will symbolize all data series contained by an axes, according to their form (e.g., lines, bars, pies, etc.). Note how you can assign an appropriate string to each line in the legend.



Add a legend by clicking the legend button in the toolbar  or by selecting **Legend** from the **Insert** menu. When plot editing is enabled, you can select and then move and resize the legend.

You can also use the `legend` function to add a legend to a graph, which gives additional controls over appearance. You must use this command in order to display a legend with more than 20 entries, as the legend toolbar button is limited to displaying legends for 20 elements (columns) of a lineseries only.

Specifying the Text

By default, the legend labels each plotted object (line, surface, etc.) with the strings `data1`, `data2`, etc. You can change this text by double-clicking on the text to enable edit mode. In edit mode, you can retype the text string.

You can use T_EX characters in the text strings to produce symbols. You can disable interpretation of characters as T_EX sequences by selecting **none** from the **Interpreter** submenu of the legend's right-click context menu.

See the Table of TEX symbols in the Text Properties reference documentation for more information.

Positioning the Legend

There are a number of ways to position the legend.

- Enable plot edit mode, select the legend, and drag it to the desired location.
- Right-click the legend to display its context menu, mouse over **Location,** and select one of the predefined locations from the submenu.
- Right-click the legend to display its context menu and select **Properties** to display the Property Editor, which provides a graphical device for positioning the legend.

You can also select a vertical or horizontal orientation for the legend. Use the **Orientation** item in the context menu to make this selection.

Changing the Appearance of the Legend

You can specify the following legend characteristics from the context menu:

- **Color** — Set the background color of the legend. In addition, you can specify the `Color` property as `'none'` to make the legend background be transparent.
- **EdgeColor** — Set the color of the line enclosing the legend box.
- **TextColor** — Set the color of the legend text.

  You can use a colorspec or an RGB color triplet to set the above three properties.
- **LineWidth** — Set the width of the edge line.
- **Font** — Set the font, font style, and font size of the text used in the legend.
- **Interpreter** — Set the text `Interpreter` property to use T_EX or plain text.
- **Orientation** — Orient the legend entries side by side (horizontal) or on top of each other.
- **Properties** — Display the Property Editor with legend properties.
- **Show M-code** — Generates M-code for recreating the legend.

Controlling the Appearance of Grouped Objects on a Legend

When you create a legend for groups of graphic objects such as lineseries, barseries, or stemseries, the default legend will show an individual legend entry for each of the graphics objects. Sometimes you might want only certain objects to appear in a legend, to show one legend entry for the entire series,

or to show the individual children of a series (however, not all series have children; you can use the Handle Graphics Property Browser to determine this). You can control how groups appear in the legend by setting values for their `Annotation` property via M-code. For information on how to customize legends in this manner, see “Controlling Legends” on page 8-99.

You can view the values of an object's `Annotation` property in the Property Inspector, but you can not set them there; you need to use M-code.

Pinning — Attaching to a Point in the Graph

Pinning is the attachment of an object to a particular point in the figure. Pinning enables you to pan or resize the figure while keeping annotations associated with the same point. For example, the following picture shows regions in two different graphs associated by pinning both ends of a double arrow.

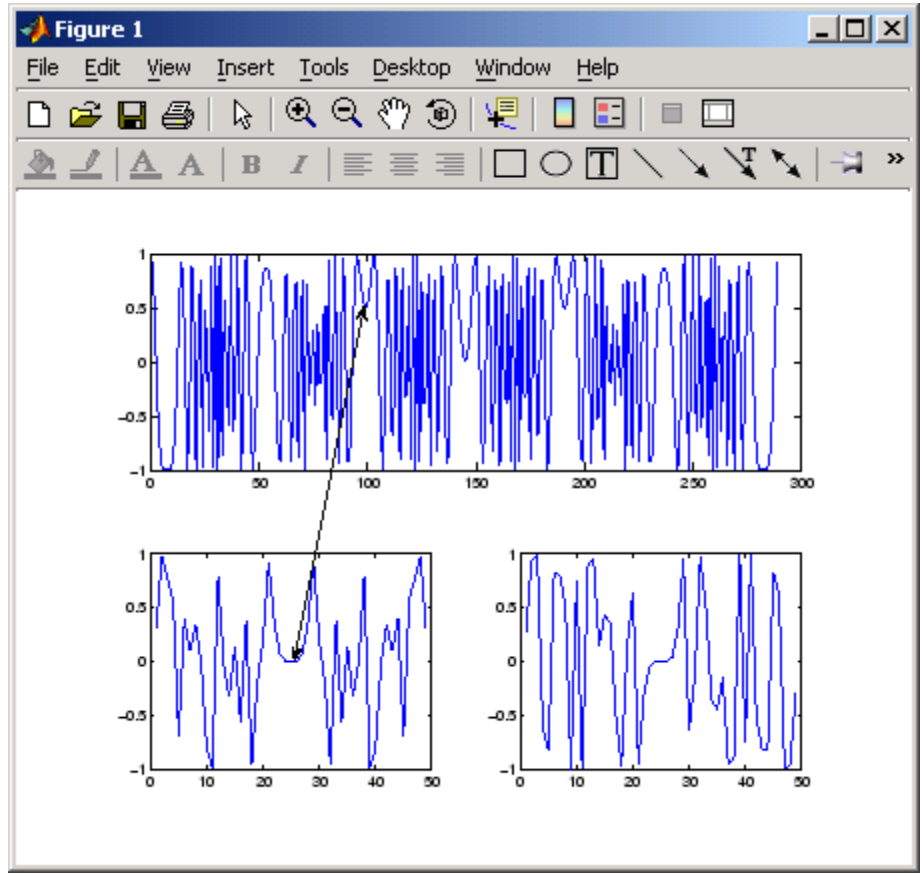


Figure 1
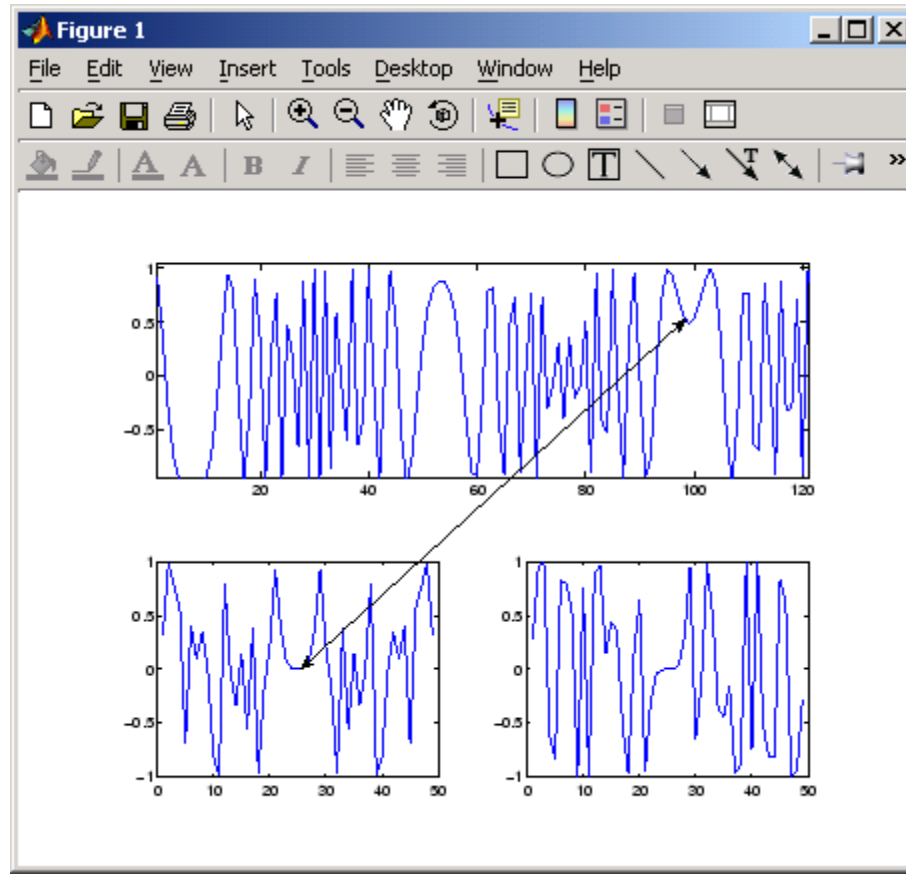
File Edit View Insert Tools Desktop Window Help

If you perform a horizontal zoom on the top axes (select **Horizontal Zoom** from the **Options** submenu of the **Tools** menu) and then pan the graph to show the first 120 seconds of the data, the double arrow continues to point to the same locations on the graph.



Pinning Objects

To pin an object, first enable pinning mode by clicking the **pin object** button  in the plot edit toolbar or selecting **Pin Object** from the **Edit** menu. Then click the point you want to pin.

To unpin an object, right-click to display the context menu and select **Unpin**.

You can pin annotation lines, arrows, rectangles, ellipses, and text boxes.

When this mode is enabled, axes, rectangle, arrows, and lines automatically align their upper left corners to the grid. As you move or resize one of these objects, the size or position snaps to the next grid location.

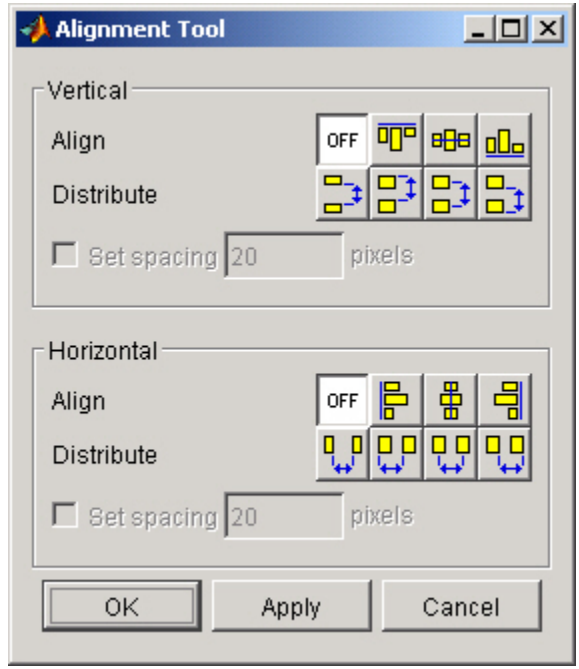
Alignment Tool — Aligning and Distributing Objects

In this section...

Alignment Tool Functionality

The Alignment Tool enables you to position objects with respect to each other and to adjust the spacing between selected objects. The specified align/distribute operations apply to all components that are selected when you click the **Apply** or **OK** buttons.

Display the Alignment Tool by clicking the Align/Distribute button  or by selecting **Align Distribute Tool** from the **Tools** menu.



The Alignment Tool provides two types of positioning operations:

- **Align** — Align all selected objects to a single reference line.
- **Distribute** — Space all selected objects uniformly with respect to each other.

You can align and distribute objects in the vertical and horizontal directions. The following sections provide more information.

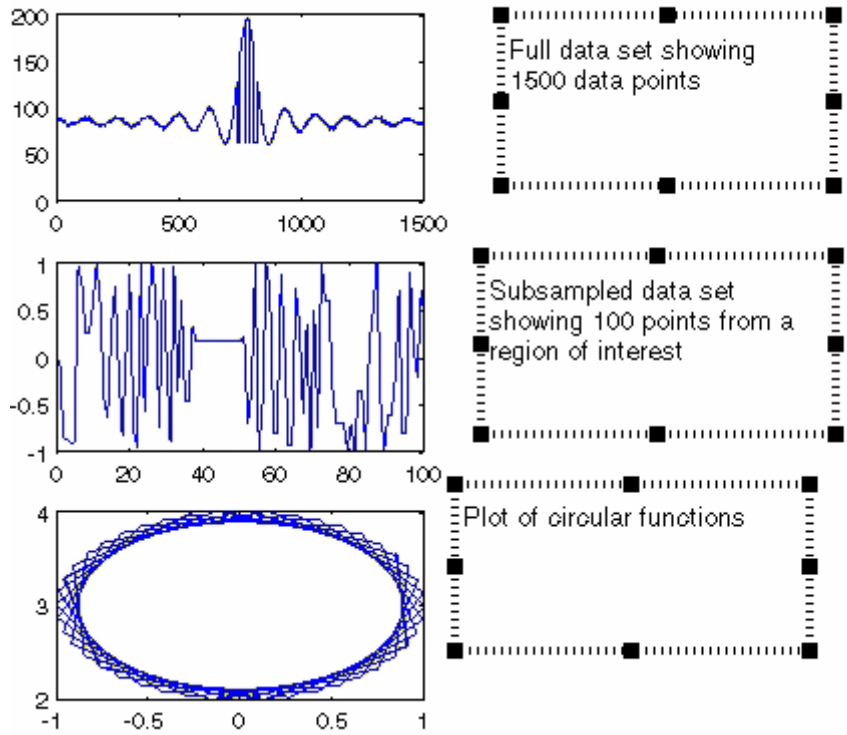
- "Example — Vertical Distribute, Horizontal Align" on page 3-28
- "Align/Distribute Menu Options" on page 3-31
- "Snap to Grid — Aligning Objects on a Grid" on page 3-33

Example — Vertical Distribute, Horizontal Align

This example illustrates how to align three textboxes with three corresponding axes. In this example, the text boxes were just plunked down close to the

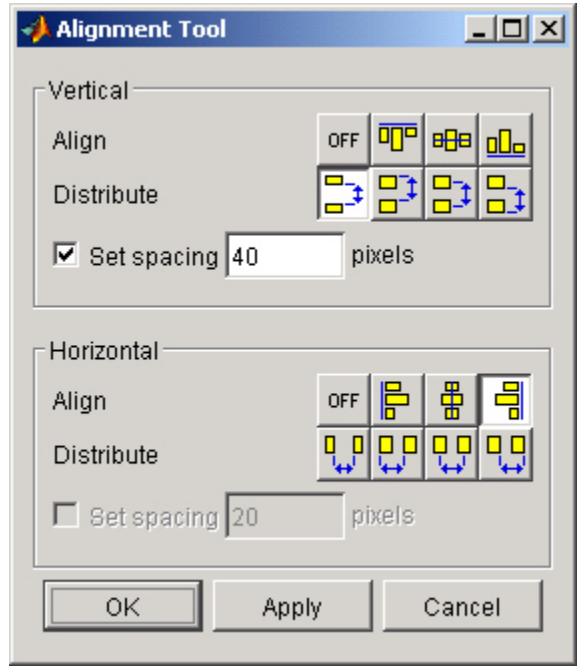
desired position and then right aligned and distributed to have 40 pixels between them.

The following picture shows the initial layout.



Use **Shift**+click to select all three textboxes and then configure the Alignment Tool as shown in the following picture.

- Set vertical distribution to 40 pixels.
- Set horizontal alignment to right-aligned.
- Click **Apply.**



Alignment Tool
Vertical

Distribute
Set spacing
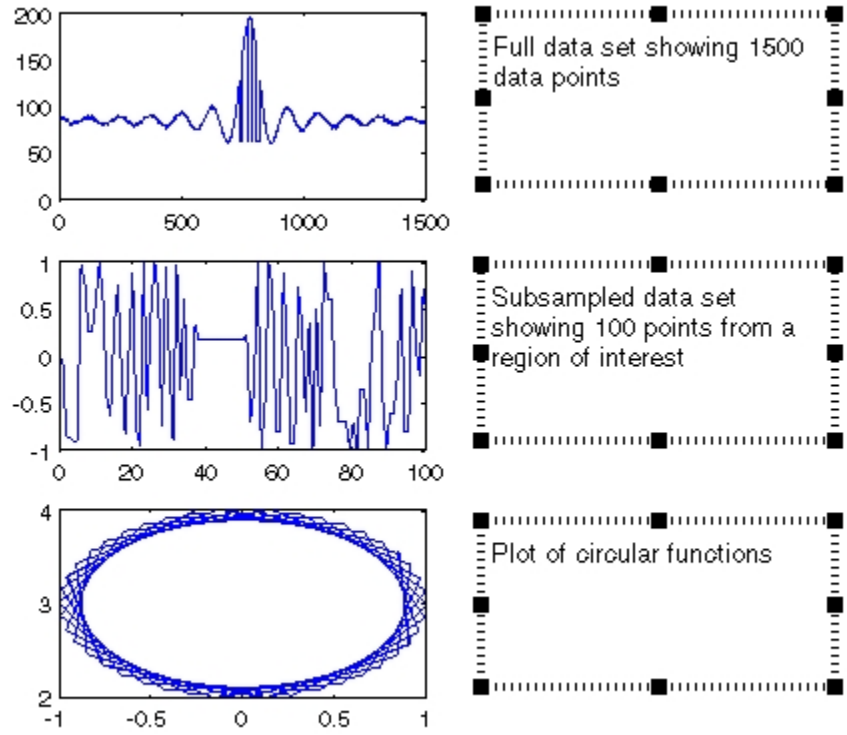
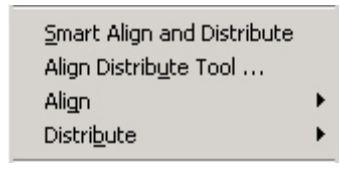
20
pixels
OK
Apply
Cancel

The following picture shows the result.



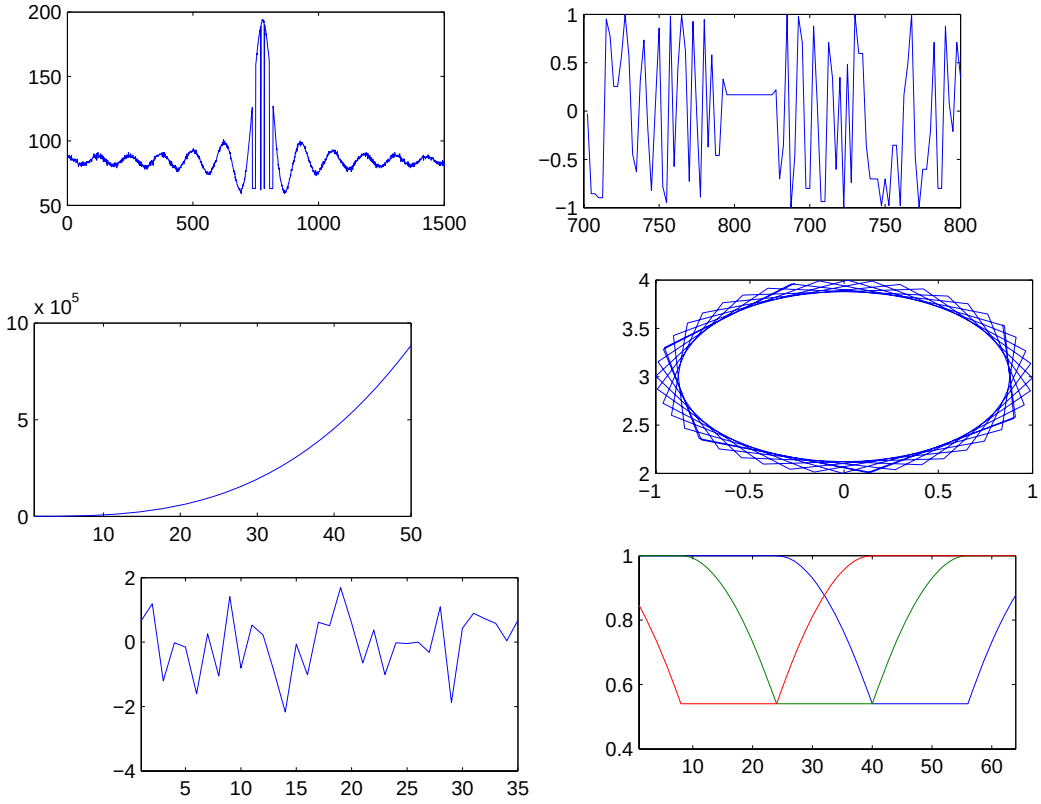
Align/Distribute Menu Options

The **Tools** menu contains the alignment and distribution options that are available via the Alignment Tool.



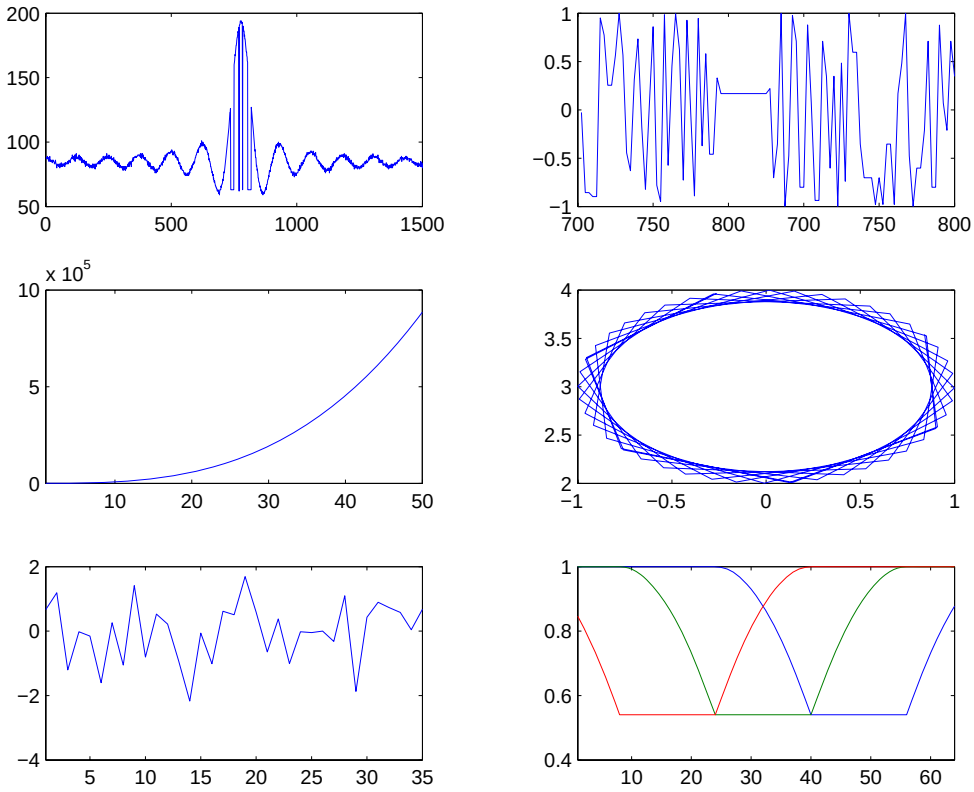
The **Smart Align and Distribute** option aligns objects into rows and columns with equal spacing between each object. It is useful when you have a number of objects to align that can be positioned in an m-by-n grid.

For example, the following figure contains six axes that have been placed approximately into two columns in the figure.



To align all axes in a grid, select each axes (**Shift**+click each one), then select **Smart Align and Distribute** from the **Tools** menu.

The resulting alignment and distribution of the axes are shown below.



Snap to Grid — Aligning Objects on a Grid

Figures have a layout grid that can aid the hand layout of objects displayed in the figure. You can also enable a snap-to-grid feature that forces objects to align with the grid increments when moved.

To display the grid on the figure background, select **View Layout Grid** from the **Tools** menu.

To force objects to align with the grid, select **Snap To Layout Grid** from the **Tools** menu.

To move objects in the figure, enable Plot Edit mode by selecting **Edit Plot** from the **Tools** menu. Click to select an object and then drag it to the desired location.

The following picture illustrates a figure with four subplots. You can select any of the four axes and move them. Note that all axis labels and the title move with the axes. Annotation objects move independently of the plot axes.

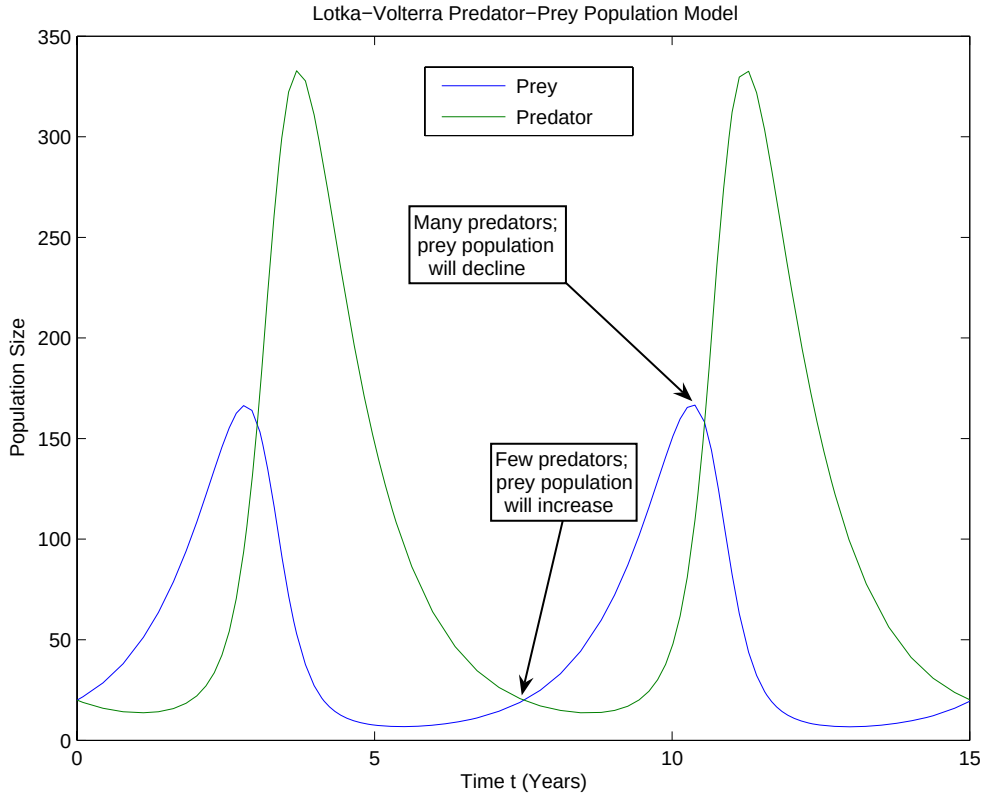
Adding Titles to Graphs

In this section...

What Is a Title?

In MATLAB, a title is a text string at the top of an axes. It appears in the figure border, not within the axes it describes. Titles typically define the subject of the graph. The following figure shows a title, centered at its top.



Note While you can use text annotations to create a title for your graph, it is not recommended. Titles are anchored to the top of the axes they describe; text annotations are not. If you move or resize your axes, the title remains at the top. Additionally, if you cut a title and then paste it back into a figure, the title is no longer anchored to the axes.

You can add a title to a graph in several ways, described in the following sections.

Using the Title Option on the Insert Menu

To add a title to a graph using the **Insert** menu,

1. Click the **Insert** menu in the figure menu bar and choose **Title**. MATLAB opens a text entry box at the top of the axes.

   Note When you select the **Title** option, MATLAB enables plot editing mode automatically.

2. Enter the text of the label.

3. When you are finished entering text, click anywhere in the figure background to close the text entry box around the title. If you click on another object in the figure, such as an axes or line, you close the title text entry box and also automatically select the object you clicked.

To change the font used in the title to bold, you must edit the title. You can edit the title as you would any other text object in a graph.

Using the Property Editor to Add a Title

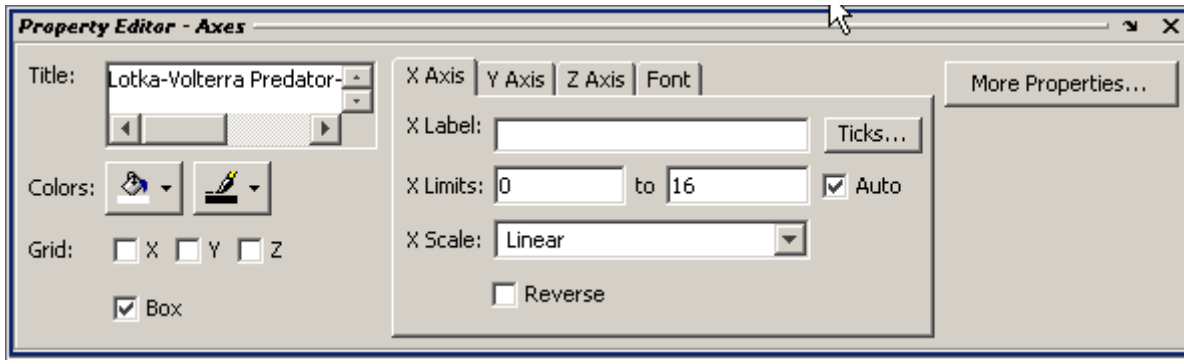
To add a title to a graph using the Property Editor,

1. Start plot editing mode by selecting **Edit Plot** from the figure **Tools** menu.

2. Double-click an empty region of the axes in the graph. This starts the Property Editor. You can also start the Property Editor by right-clicking on the axes and selecting **Show Property Editor** from the context menu or by selecting **Property Editor** from the **View** menu.

   The Property Editor displays a property panel specific to axes objects. Titles are a property of axes objects.

3. Type the text of your title in the **Title** text entry box.



You can change the font, font style, position, and many other aspects of the title format.

- To move the title, select the text and drag it to the desired position.
- To edit the text, double-click the title and type new characters.
- To change the font and other text properties, select the title and right-click to display the context menu.

Using the title Function

To add a title to a graph at the MATLAB command prompt or from an M-file, use the `title` function.

For example, the following code adds a title to the current axes and sets the value of the `FontWeight` property to bold.

```
title('Lotka-Volterra Predator-Prey Population Model',...
  'FontWeight','bold')
```

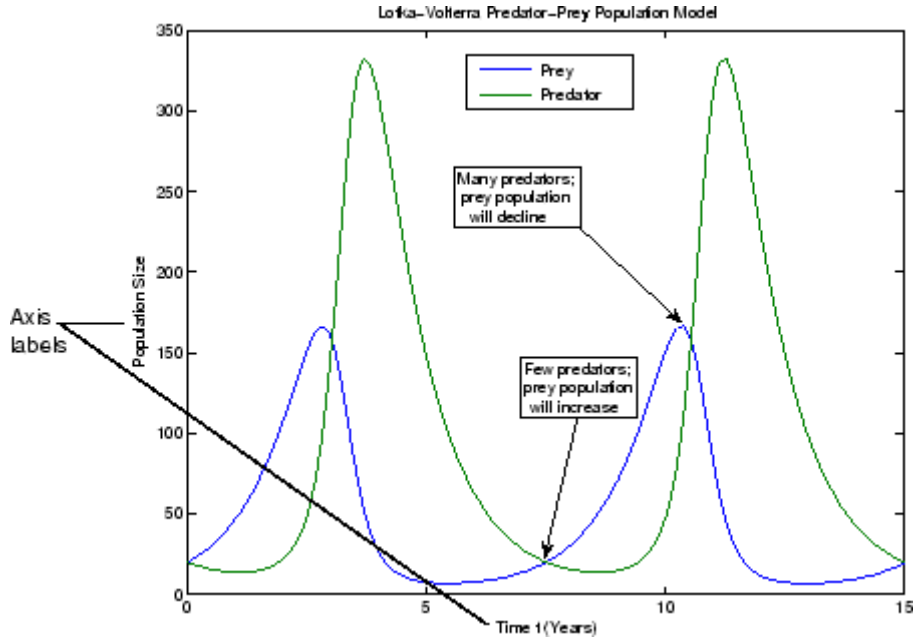
To edit a title from the MATLAB command prompt or from an M-file, use the `set` function.

Adding Axis Labels to Graphs

In this section...

What Are Axis Labels?

In MATLAB, an axis label is a text string aligned with the *x*-, y-, or *z*-axis in a graph. Axis labels can help explain the meaning of the units that each axis represents.



Note While you can use free-form text annotations to create axes labels, it is not recommended. Axis labels are anchored to the axes they describe; text annotations are not. If you move or resize your axes, the labels automatically move with the axes. Additionally, if you cut a label and then paste it back into a figure, the label is no longer anchored to the axes.

You can add axis labels to a graph in several ways, described in the following sections.

Using the Label Options on the Insert Menu

1. Click the **Insert** menu and choose the label option that corresponds to the axis you want to label: **X Label**, **Y Label**, or **Z Label**. MATLAB opens a text entry box along the axis or around an existing axis label.

   Note MATLAB opens up a horizontal text editing box for the *y*- and *z*-axis labels and automatically rotates the label into alignment with the axis when you finish entering text.

2. Enter the text of the label, or edit the text of an existing label.

3. Click anywhere else in the figure background to close the text entry box around the label. If you click on another object in the figure, such as an axes or line, you close the label text entry box but also automatically select the object you clicked.

Note After you use the **Insert** menu to add an axis label, plot edit mode is enabled in the figure, if it was not already enabled.

Using the Property Editor to Add Axis Labels

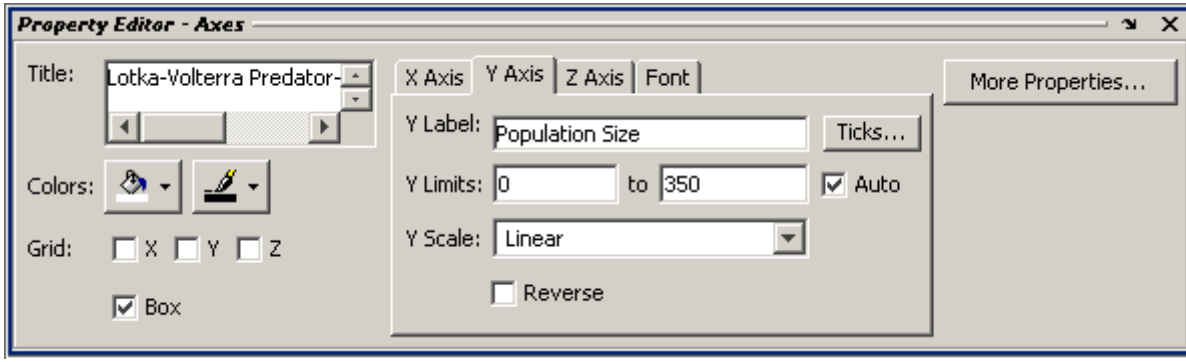
To add labels to a graph using the Property Editor,

1. Start plot editing mode by selecting **Edit Plot** from the figure **Tools** menu.

2 Start the Property Editor by double-clicking on the axes in the graph. You can also start the Property Editor by right-clicking on the axes and selecting **Properties** from the context menu or by selecting **Property Editor** from the **View** menu.

   The Property Editor displays the set of property panels specific to axes objects.

3 Select the **X Axis**, **Y Axis**, or **Z Axis** tab, depending on which axis label you want to add. Enter the label text in the text entry box.



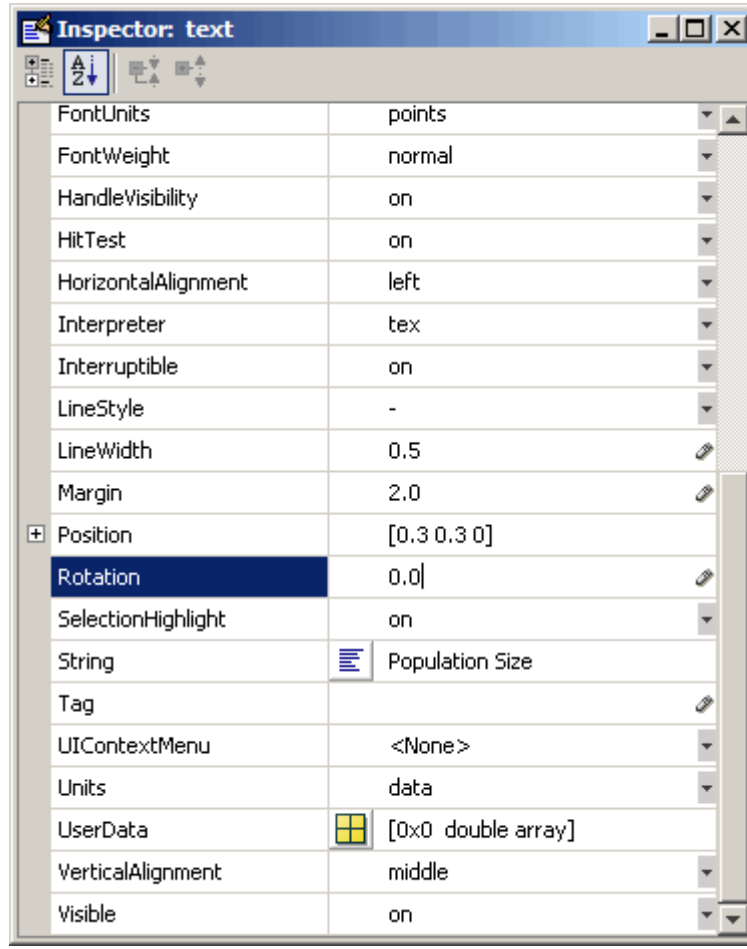
Rotating Axis Labels

You can rotate axis labels using the Property Editor:

1 Start plot editing mode by selecting **Edit Plot** from the figure **Tools** menu.

2 Display the Property Editor by selecting (left-clicking) the axis label you want to rotate. Right-click over the selected text, then choose **Properties** from the context menu.

3 Click the **More Properties** button to display the Property Inspector.



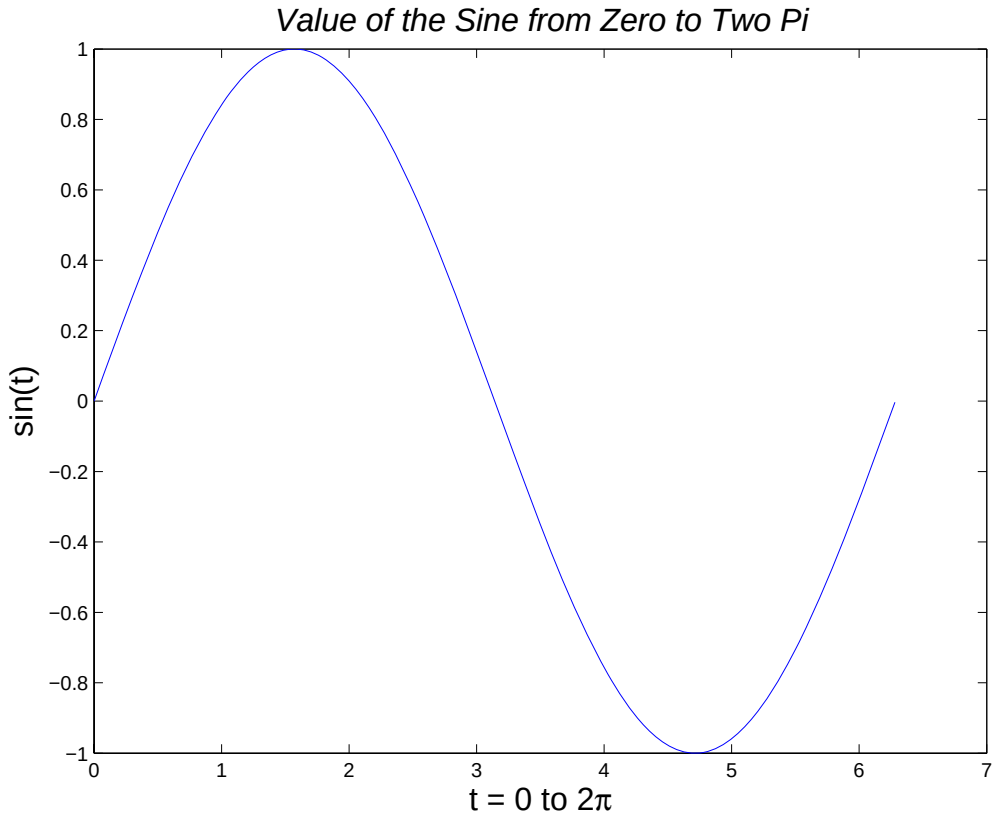
4 Select the **Rotation** property text field. A value of 0 degrees orients the label in the horizontal position.

5 With the left mouse button down on the selected label, drag the text to the desired location and release.

Using Axis-Label Commands

You can add *x*-, *y*-, and *z*-axis labels using the `xlabel`, `ylabel`, and `zlabel` functions. For example, these statements label the axes and add a title.

```
xlabel('t = 0 to 2\pi','FontSize',16)
ylabel('sin(t)','FontSize',16)
title('\it{Value of the Sine from Zero to Two Pi}','FontSize',16)
```



The labeling commands automatically position the text string appropriately. MATLAB interprets the characters immediately following the backslash (`\`) as TeX commands. These commands draw symbols such as Greek letters and arrows.

See the text `String` property for a list of TeX character sequences. See also the `texlabel` function for converting MATLAB expressions to TeX symbols.

Rotating Axis Labels Using Commands

Axis labels are text objects that you can rotate by specifying a value for the object's `Rotation` property. The handles of the *x*-, *y*-, and *z*-axis labels are stored in the axes `XLabel`, `YLabel`, and `ZLabel` properties respectively.

Therefore, to rotate the *y*-axis label so that the text is horizontal:

1. Get the handle of the text object using the axes `YLabel` property.
2. Set the `Rotation` property to 0.0 degrees.

For example, this statement rotates the text of the *y*-axis label on the current axes:

```
set(get(gca,'YLabel'),'Rotation',0.0)
```

Repositioning Axis Labels

You can reposition an axis label by dragging the text.

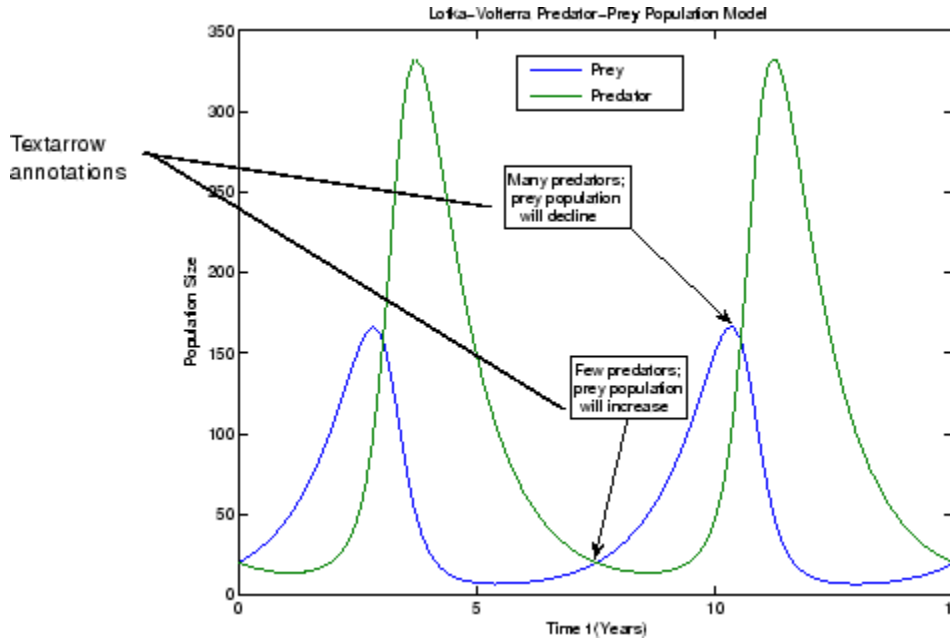
1. Start plot editing mode by selecting **Edit Plot** from the figure **Tools** menu.
2. Select the text of the label you want to reposition (handles appear around the text object).
3. With the left mouse button down on the selected label, drag the text to the desired location and release.

Adding Text Annotations to Graphs

In this section...

What Are Text Annotations?

Text annotations are boxes containing text strings that you compose. The box can have a border and a background, or be invisible. The text can be in any installed text font, and can include TeX or LaTeX markup. You can add free-form text annotations anywhere in a MATLAB figure to help explain your data or bring attention to specific points in your data sets.



If you enable plot editing mode, you can create text annotations by clicking in an area of the graph or the figure background and entering text. You can also add text annotations from the command line, using the `text` or `gtext` function.

Using plot editing mode or `gtext` makes it easy to place a text annotation anywhere in a graph. Use the `text` function when you want to position a text annotation at a specific point in a data set.

Note Text annotations created using the `text` or `gtext` function are anchored to the axes. Text annotations created in plot edit mode are not. If you move or resize your axes, you will have to reposition your text annotations. For more information, see “Positioning Annotations in Data Space” on page 3-67.

Creating Text Annotations with the text or gtext Function

To create a text annotation using the `text` function, you must specify the text and its location in the graph, using *x*- and *y*-coordinates. You specify the coordinates in the units of the graph.

Use the `gtext` function when you want to position a text annotation at a specific point in the data space with the mouse.

For example, the following code creates text annotations at specific points in the Lotka-Volterra Predator-Prey Population Model graph.

```
str1(1) = {'Many Predators;'};
str1(2) = {'Prey Population'};
str1(3) = {'Will Decline'};
text(7,220,str1)

str2(1) = {'Few Predators;'};
str2(2) = {'Prey Population'};
str2(3) = {'Will Increase'};
text(5.5,125,str2)
```

This example also illustrates how to create multiline text annotations with cell arrays.

Calculating the Positions of Text Annotations

You can also calculate the positions of text annotations in a graph. The following code adds annotations at three data points on a graph.

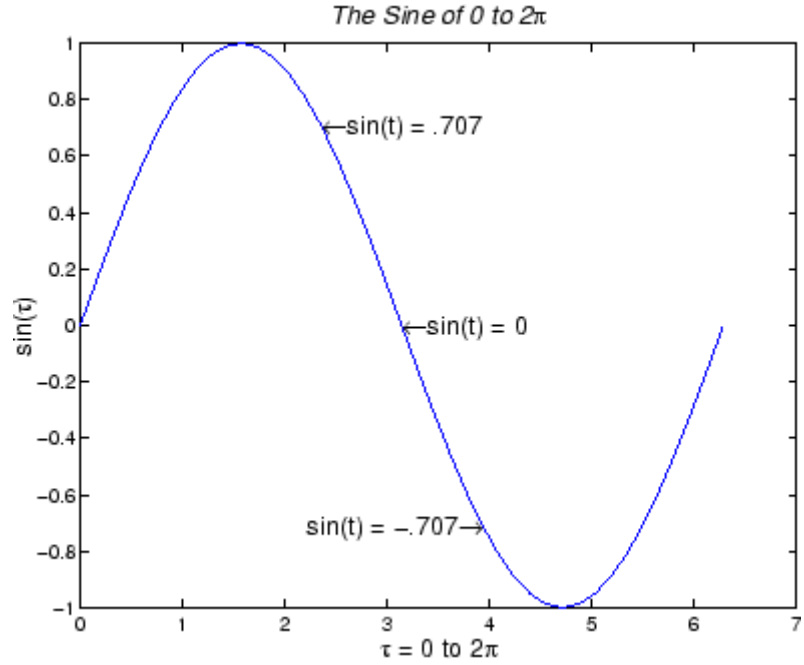
```
text(3*pi/4,sin(3*pi/4),...
     '\leftarrowsin(t) = .707',...
     'FontSize',16)

text(pi,sin(pi),'\leftarrowsin(t) = 0',...
     'FontSize',16)

text(5*pi/4,sin(5*pi/4),'sin(t) = -.707\rightarrow',...
     'HorizontalAlignment','right',...
     'FontSize',16)
```

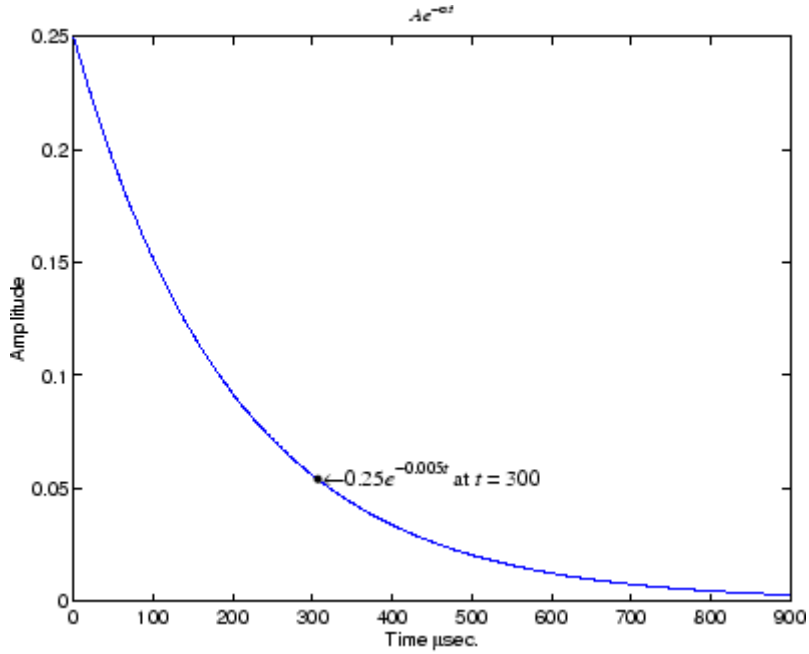
The `HorizontalAlignment` of the text string `'sin(t) = -.707 \rightarrow'` is set to `right` to place it on the left side of the point `[5*pi/4,sin(5*pi/4)]` on the graph. For more information about aligning text annotations, see "Text Alignment" on page 3-51.

Defining Symbols. For information on using symbols in text strings, see "Mathematical Symbols, Greek Letters, and TEX Characters" on page 3-54.



You can use text objects to annotate axes at arbitrary locations. MATLAB locates text in the data units of the axes. For example, suppose you plot the function $y = Ae^{-\alpha t}$ with A = 0.25, α = 0.005, and t = 0 to 900.

```
t = 0:900;
plot(t,0.25*exp(-0.005*t))
```



To annotate the point where the value of t = 300, calculate the text coordinates using the function you are plotting.

```
text(300,.25*exp(-0.005*300),...
'\bullet\leftarrow\fontname{times}0.25{\ite}^{-0.005{\itt}} at {\itt} =
300',...
'FontSize',14)
```

This statement defines the text `Position` property as

x = 300, $y = 0.25e^{-0.005 \times 300}$

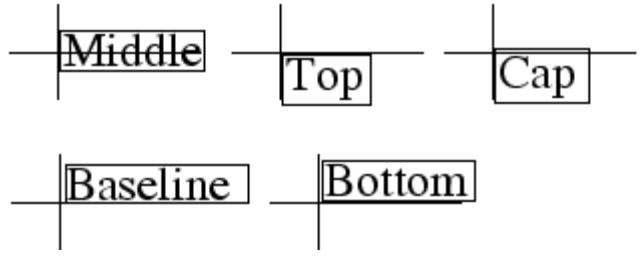
The default text alignment places this point to the left of the string and centered vertically with the rectangle defined by the text `Extent` property. The following section provides more information about changing the default text alignment.

Text Alignment

The `HorizontalAlignment` and the `VerticalAlignment` properties control the placement of the text characters with respect to the specified *x*-, *y*-, and z-coordinates. The following diagram illustrates the options for each property and the corresponding placement of the text.

Text `HorizontalAlignment` property viewed with the `VerticalAlignment` property set to `middle` (the default).

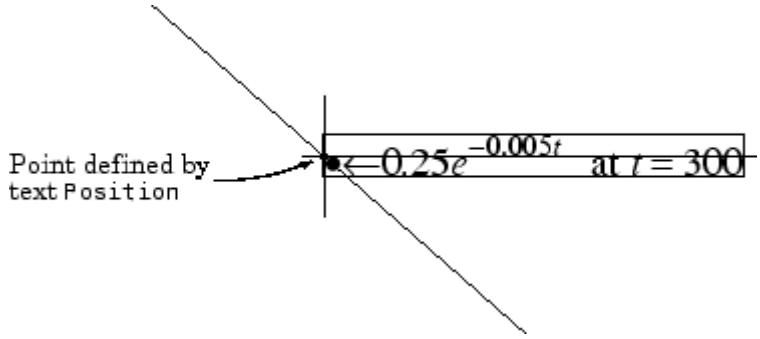
Text `VerticalAlignment` property viewed with the `HorizontalAlignment` property set to `left` (the default).



The default alignment is

- `HorizontalAlignment = left`
- `VerticalAlignment = middle`

MATLAB does not place the text `String` exactly on the specified `Position`. For example, the previous section showed a plot with a point annotated with text. Zooming in on the plot enables you to see the actual positioning of the text.



The small dot is the point specified by the text `Position` property. The larger dot is the bullet defined as the first character in the text `String` property.

Example — Aligning Text

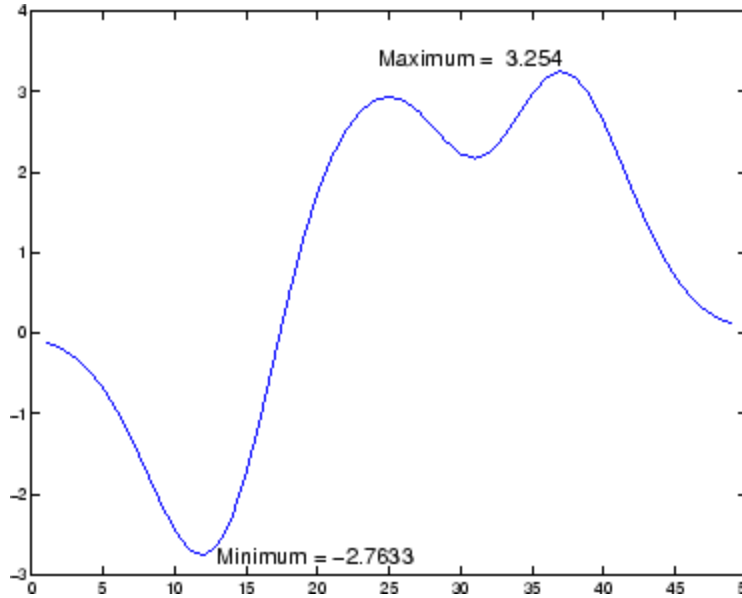
Suppose you want to label the minimum and maximum values in a plot with text that is anchored to these points and that displays the actual values. This example uses the plotted data to determine the location of the text and the values to display on the graph. One column from the `peaks` matrix generates the data to plot.

```
Z = peaks;
h = plot(Z(:,33));
```

The first step is to find the indices of the minimum and maximum values to determine the coordinates needed to position the text at these points (`get`, `find`). Then create the string by concatenating the values with a description of what the values are.

```
x = get(h,'XData');   % Get the plotted data
y = get(h,'YData');
imin = find(min(y) == y);  % Find the index of the min and max
imax = find(max(y) == y);
text(x(imin),y(imin),[' Minimum = ',num2str(y(imin))],...
 'VerticalAlignment','middle',...
 'HorizontalAlignment','left',...
 'FontSize',14)
text(x(imax),y(imax),['Maximum =  ',num2str(y(imax))],...
 'VerticalAlignment','bottom',...
```

```
'HorizontalAlignment','right',...
'FontSize',14)
```



The `text` function positions the string relative to the point specified by the coordinates, in accordance with the settings of the alignment properties. For the minimum value, the string appears to the right of the text position point; for the maximum value the string appears above and to the left of the text position point. The text always remains in the plane of the computer screen, regardless of the view.

Editing Text Objects

You can edit any of the text labels or annotations in a graph:

1. Start plot edit mode.
2. Double-click the string, or right-click the string and select **Edit** from the context menu.

   An editing bar (|) appears next to the text.

3 Make any changes to the text.

4 Click anywhere outside the text edit box to end text editing.

Note To create special characters in text, such as Greek letters or mathematical symbols, use T_EX sequences. See the text `string` property for a table of characters you can use. If you create special characters by using the **Font** dialog box (available via text objects' context menus, and also found in the Property Editor) and selecting the Symbol font family, you cannot edit that text object using MATLAB commands.

Mathematical Symbols, Greek Letters, and TEX Characters

You can include mathematical symbols and Greek letters in text using T_EX-style character sequences. This section describes how to construct a T_EX character sequence.

Two Levels of TEX Support

MATLAB provides two levels of T_EX support, controlled by the text `Interpreter` property:

- `tex` — Support for a subset of T_EX markup
- `latex` — Support for T_EX and LaT_EX markup

If you do not want the characters interpreted as T_EX markup, then set the `interpreter` property to `none`.

Available Symbols and Greek Letters

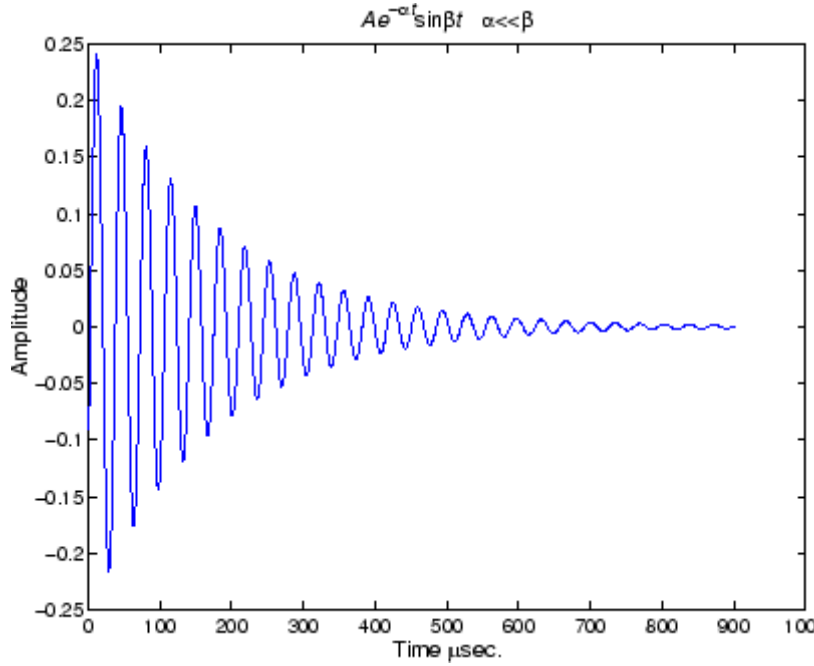
For a list of symbols and the character sequences used to define them, see the table of available T_EX characters in the Text Properties reference page.

In general, you can define text that includes symbols and Greek letters using the `text` function, assigning the character sequence to the `String` property of text objects. You can also include these character sequences in the string arguments of the `title`, `xlabel`, `ylabel`, and `zlabel` functions.

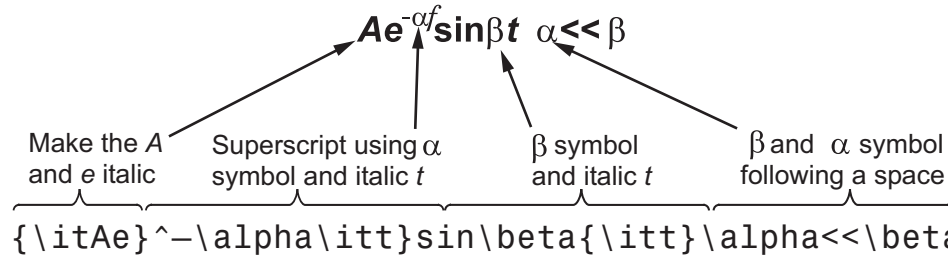
Example — Using a Mathematical Expression to Title a Graph

This example uses T_EX character sequences to create graph labels. The following statements add a title and x- and y-axis labels to an existing graph.

```
title('{\itAe}^{-\alpha\itt}sin\beta{\itt} \alpha<<\beta')
xlabel('Time \musec.')
ylabel('Amplitude')
```



The backslash character (\) precedes all T_EX character sequences. Looking at the string defining the title illustrates how to use these characters.



Controlling the Interpretation of TEX Characters

The text `Interpreter` property controls the interpretation of T_EX characters. If you set this property to `none`, MATLAB interprets the special characters literally.

Using Character and Numeric Variables in Text

Any string variable is a valid specification for the text `String` property. This section illustrates how to use matrix, cell array, and numeric variables as arguments to the `text` function.

Character Variables

For example, each row of the matrix `PersonalData` contains specific information about a person (note that all but the longest row are padded with a space so that each has the same number of columns).

```
PersonalData = ['Jack Straw ';'489 Main St.';'Wichita KN '];
```

To display the data, index into the desired row.

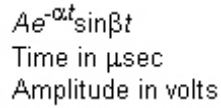
```
text(x1,y1,['Name: ',PersonalData(1,:)])
text(x2,y2,['Address: ',PersonalData(2,:)])
text(x3,y3,['City and State: ',PersonalData(3,:)])
```

Cell Arrays

Using a cell array enables you to create multiline text with a single text object. Each cell does not need to be the same number of characters. For example, the following statements,

```
key(1)={'{\itAe}^{-\alpha\itt}sin\beta{\itt}'};
key(2)={'Time in \musec'};
key(3)={'Amplitude in volts'};
text(x,y,key)
```

produce this output.



Numeric Variables

You can specify numeric variables in text strings using the `num2str` (number to string) function. For example, if you type on the command line

```
x = 21;
['Today is the ',num2str(x),'st day.']
```

MATLAB concatenates the three separate strings into one.

```
Today is the 21st day.
```

Since the result is a valid string, you can specify it as a value for the text `String` property.

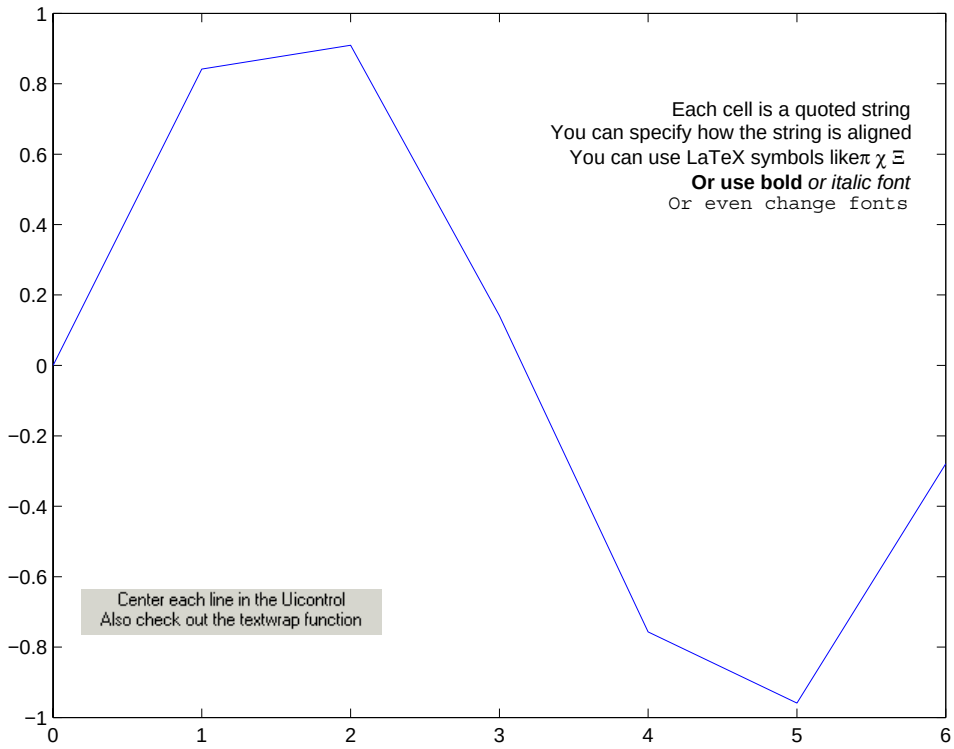
```
text(xcoord,ycoord,['Today is the ',num2str(x),'st day.'])
```

Example — Multiline Text

MATLAB supports multiline text strings using cell arrays. Simply define a string variable as a cell array with one line per cell. This example defines two cell arrays, one used for a `uicontrol` and the other as `text`.

```
str1(1) = {'Center each line in the Uicontrol'};
str1(2) = {'Also check out the textwrap function'};
str2(1) = {'Each cell is a quoted string'};
str2(2) = {'You can specify how the string is aligned'};
str2(3) = {'You can use LaTeX symbols like \pi \chi \Xi'};
str2(4) = {'\bfOr use bold \rm\itor italic font\rm'};
str2(5) = {'\fontname{courier}Or even change fonts'};
```

```
plot(0:6,sin(0:6))
uicontrol('Style','text','Position',[80 80 200 30],...
          'String',str1);
text(5.75,sin(2.5),str2,'HorizontalAlignment','right')
```



Example — Using LaTeX to Format Math Equations

The LaT$_e$X markup language evolved from T$_E$X, and has a superset of its capabilities. LaT$_e$X gives you more elaborate control over specifying and styling mathematical symbols.

The following example illustrates some LaTeX typesetting capabilities when used with the `text` function. Because the default interpreter is for TEX, you need to specify the parameter-value pair `'interpreter','latex'` when typesetting equations such as are contained in the following script:

```
%% LaTeX Examples--Some well known equations rendered in LaTeX
%
figure('color','white','units','inches','position',[2 2 4 6.5]);
axis off

%% A matrix; LaTeX code is
% \hbox {magic(3) is } \left( {\matrix{ 8 & 1 & 6 \cr
% 3 & 5 & 7 \cr 4 & 9 & 2 } } \right)
h(1) = text('units','inch', 'position',[.2 5], ...
    'fontsize',14, 'interpreter','latex', 'string',...
    ['$$\hbox {magic(3) is } \left( {\matrix{ 8 & 1 & 6 \cr'...
    '3 & 5 & 7 \cr 4 & 9 & 2 } } \right)$$']);

%% A 2-D rotation transform; LaTeX code is
%  \left[ {\matrix{\cos(\phi) & -\sin(\phi) \cr
%  \sin(\phi) & \cos(\phi) \cr}}
%  \right] \left[ \matrix{x \cr y} \right]
%
%  $$ \left[ {\matrix{\cos(\phi)
%  & -\sin(\phi) \cr \sin(\phi) & \cos(\phi)  % \cr}}
%  \right] \left[ \matrix{x \cr y} \right] $$
%
h(2) = text('units','inch', 'position',[.2 4], ...
    'fontsize',14, 'interpreter','latex', 'string',...
    ['$$\left[ {\matrix{\cos(\phi) & -\sin(\phi) \cr'...
    '\sin(\phi) & \cos(\phi) \cr}} \right]'...
    '\left[ \matrix{x \cr y} \right]$$']);

%% The Laplace transform; LaTeX code is
%  L\{f(t)\}  \equiv  F(s) = \int_0^\infty\!\!{e^{-st}f(t)dt}
%  $$ L\{f(t)\} \equiv  F(s) = \int_0^\infty\!\!{e^{-st}f(t)dt} $$
%  The Initial Value Theorem for the Laplace transform:
%  \lim_{s \rightarrow \infty} sF(s) = \lim_{t \rightarrow 0} f(t)
%  $$ \lim_{s \rightarrow \infty} sF(s) = \lim_{t \rightarrow 0}
%  f(t) $$
```

```
%
h(3) = text('units','inch', 'position',[.2 3], ...
    'fontsize',14, 'interpreter','latex', 'string',...
    ['$$L\{f(t)\}  \equiv  F(s) = \int_0^\infty\!\!{e^{-st}'...
    'f(t)dt}$$']);

%% The definition of e; LaTeX code is
%  e = \sum_{k=0}^\infty {1 \over {k!} }
%  $$ e = \sum_{k=0}^\infty {1 \over {k!} } $$
%
h(4) = text('units','inch', 'position',[.2 2], ...
    'fontsize',14, 'interpreter','latex', 'string',...
    '$$e = \sum_{k=0}^\infty {1 \over {k!} } $$');

%% Differential equation
% The equation for motion of a falling body with air resistance
% LaTeX code is
%  m \ddot y = -m g + C_D \cdot {1 \over 2} \rho {\dot y}^2 \cdot A
%  $$ m \ddot y = -m g + C_D \cdot {1 \over 2} \rho {\dot y}^2
%  \cdot A  $$
%
h(5) = text('units','inch', 'position',[.2 1], ...
    'fontsize',14, 'interpreter','latex', 'string',...
    ['$$m \ddot y = -m g + C_D \cdot {1 \over 2}'...
    '\rho {\dot y}^2 \cdot A$$']);

%% Integral Equation; LaTeX code is
%  \int_{0}^{\infty} x^2 e^{-x^2} dx = \frac{\sqrt{\pi}}{4}
%  $$ \int_{0}^{\infty} x^2 e^{-x^2} dx = \frac{\sqrt{\pi}}{4} $$
%
h(6) = text('units','inch', 'position',[.2 0], ...
    'fontsize',14, 'interpreter','latex', 'string',...
    '$$\int_{0}^{\infty} x^2 e^{-x^2} dx = \frac{\sqrt{\pi}}{4}$$');
```

$$\text{magic}(3) \text{ is } \begin{pmatrix} 8 & 1 & 6 \\ 3 & 5 & 7 \\ 4 & 9 & 2 \end{pmatrix}$$

$$\begin{bmatrix} \cos(\phi) & -\sin(\phi) \\ \sin(\phi) & \cos(\phi) \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

$$L\{f(t)\} \equiv F(s) = \int_0^\infty e^{-st} f(t) dt$$

$$e = \sum_{k=0}^{\infty} \frac{1}{k!}$$

$$m\ddot{y} = -mg + C_D \cdot \frac{1}{2} \rho \dot{y}^2 \cdot A$$

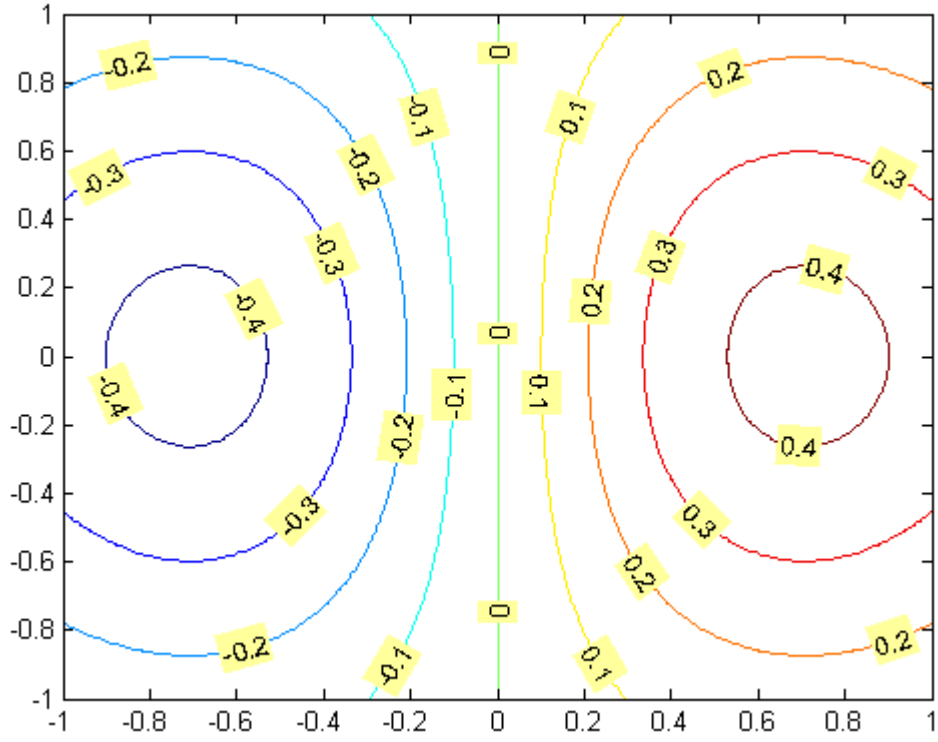
$$\int_0^\infty x^2 e^{-x^2} dx = \frac{\sqrt{\pi}}{4}$$

You can find out more about the LaTeX system at The LaTeX Project Web site, http://www.latex-project.org/.

Drawing Text in a Box

When you use the `text` function to display a character string, the string's position is defined by a rectangle called the `Extent` of the text. You can display this rectangle either as a box or a filled area. For example, you can highlight contour labels to make the text easier to read.

```
[x,y] = meshgrid(-1:.01:1);
z = x.*exp(-x.^2-y.^2);
[c,h]=contour(x,y,z);
h = clabel(c,h);
set(h,'BackgroundColor',[1 1 .6])
```



For additional features, see the following text properties:

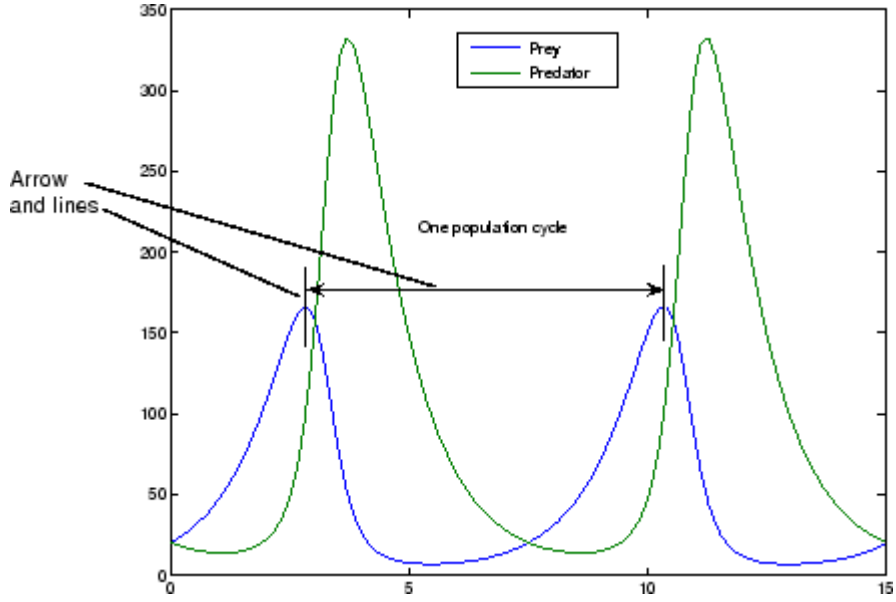
- `BackgroundColor` — Color of the rectangle's interior (none by default)
- `EdgeColor` — Color of the rectangle's edge (none by default)
- `LineStyle` — Style of the rectangle's edge line (first set `EdgeColor`)
- `LineWidth` — Width of the rectangle's edge line (first set `EdgeColor`)
- `Margin` — Increase the size of the rectangle by adding a margin to the text extent.

Adding Arrows and Lines to Graphs

In this section...

Creating Arrows and Lines in Plot Editing Mode

With plot editing mode enabled, you can add arrows and lines anywhere in a figure window.



You can also use arrow characters (TeX characters) to create arrows using the `text` function. However, arrows created this way can only point to the left or right, horizontally. See “Calculating the Positions of Text Annotations” on page 3-48 for an example.

To add an arrow or line annotation to a graph,

1 Click the **Insert** menu and choose the **Arrow** or **Line** option, or click the **Arrow** or **Line** button in the Plot Edit toolbar.

   MATLAB changes the cursor to a cross-hair.

2 Position the cursor in the figure where you want to start the line or arrow and press either mouse button. Hold the button down and move the mouse to define the length and direction of the line or arrow.

3 Release the mouse button.

Note After you add an arrow or line, plot edit mode is enabled in the figure, if it was not already enabled.

Editing Arrows and Line Annotations

You can edit the appearance of arrow and line annotations using the context menu.

With plot editing mode enabled, right-click the arrow or line annotation to display its context menu.

You can select an annotation and then choose **Show M-code** to obtain a code snippet that you can insert in a function or script to reproduce the annotation.

For more options, select **Properties** to display the Property Editor.

Positioning Annotations in Data Space

Example — Pinning Textarrows and Ellipses

Some annotation object types (arrow, doublearrow, textarrow, and ellipse) are attached to figures rather than to axes. This makes it difficult to programmatically place them precisely on an axes, especially if the axes changes its position. You can, however, still locate figure-based annotations in data space by applying a transformation to their coordinates. The following example shows how to do this using a function called `dsxy2figxy` that transforms figure coordinates to axes coordinates for the four types of annotations listed above.

Before following the steps given below, copy the code for `dsxy2figxy` and save in your current directory or elsewhere on the MATLAB path.

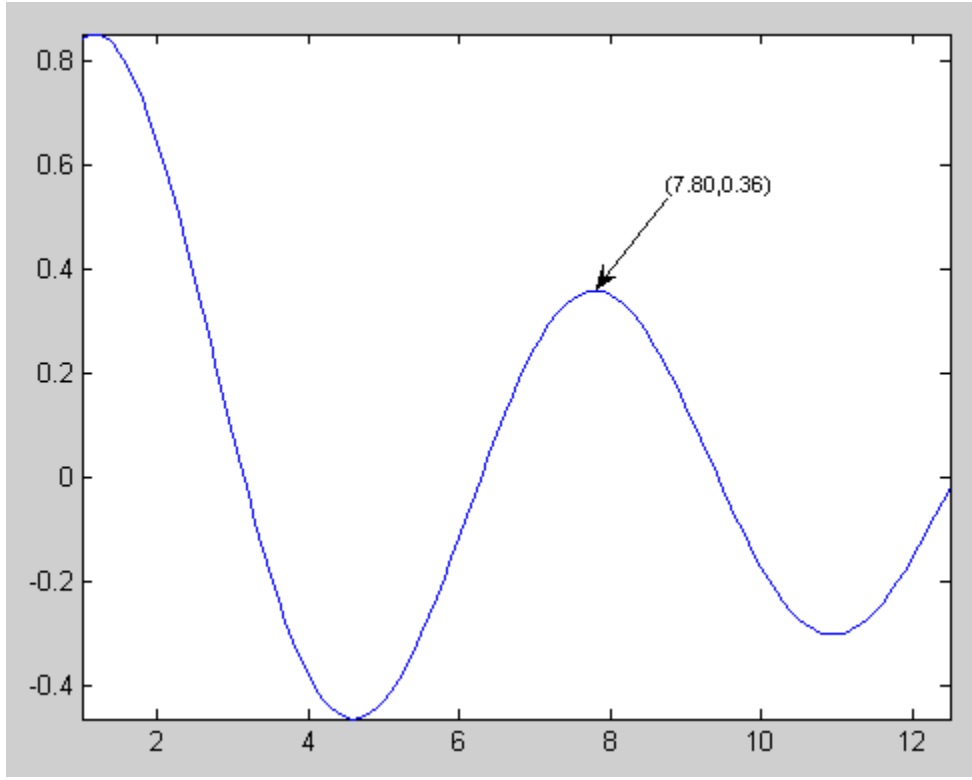
1 Create sine function data and make a line plot of it:

```
x1 = 1:.1:4*pi;
y1 = sin(x1)./sqrt(x1);
figure
plot(x1,y1)
axis tight
```

2 Interactively place a textarrow on the graph

Using `ginput`, interactively locate a textarrow annotation. Two clicks are required by `ginput`:

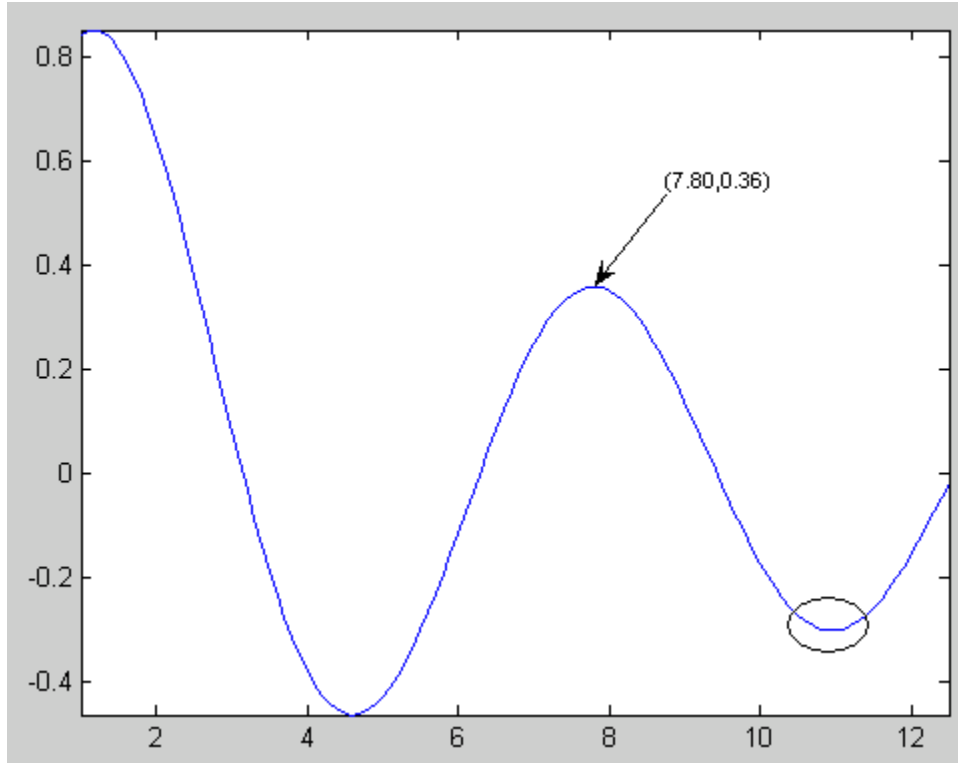
```
disp('Click graph to place arrow; first tail, then head:')
[axx axy] = ginput(2);      % Returns list of x, list of y in data space
% Get coords in figure space; gca will be correct even for subplots
% Transform from data space to fig space
[arrowx,arrowy] = dsxy2figxy(gca, axx, axy);
har = annotation('textarrow',arrowx,arrowy);
content = sprintf('(%4.2f,%4.2f)',axx(2), axy(2));
% Plot anno text centered at the tail of the arrow
set(har,'String',content,'Fontsize',8)
```



3 Place an ellipse on the axes

To place ellipses, a coordinate box (position rectangle) is needed instead of two *x*-*y* tuples. The function `dsxy2figxy` computes and returns a position rectangle if it is called with one:

```
disp('Click in the axes to define the bounding box of an ellipse:')
[axx axy] = ginput(2);      % Returns list of x, list of y in data space
abox(1) = min(axx); abox(2) = min(axy);     % Get least x and y coords
abox(3) = abs(axx(1)-axx(2));               % Get box width
abox(4) = abs(axy(1)-axy(2));               % Get box height
% Get coords in figure space; gca will be correct even for subplots
[bbox] = dsxy2figxy(gca, abox);    % Xform from axes to fig space
annotation('ellipse',bbox);
```



Here is the code for `dsxy2figxy` ; copy it to an M-file that can be called when you execute the example above:

```
function varargout = dsxy2figxy(varargin)
% dsxy2figxy -- Transform point or position from axis to figure coords
% Transforms [axx axy] or [xypos] from axes hAx (data) coords into coords
% wrt GCF for placing annotation objects that use figure coords into data
% space. The annotation objects this can be used for are
%    arrow, doublearrow, textarrow
%    ellipses (coordinates must be transformed to [x, y, width, height])
% Note that line, text, and rectangle anno objects already are placed
% on a plot using axes coordinates and must be located within an axes.
% Usage: Compute a position and apply to an annotation, e.g.,
%   [axx axy] = ginput(2);
%   [figx figy] = getaxannopos(gca, axx, axy);
```

```
%   har = annotation('textarrow',figx,figy);
%   set(har,'String',['(' num2str(axx(2)) ',' num2str(axy(2)) ')'])

%% Obtain arguments (only limited argument checking is performed).
% Determine if axes handle is specified
if length(varargin{1})== 1 && ishandle(varargin{1}) && ...
  strcmp(get(varargin{1},'type'),'axes')
 hAx = varargin{1};
 varargin = varargin(2:end);
else
 hAx = gca;
end;
% Parse either a position vector or two 2-D point tuples
if length(varargin)==1 % Must be a 4-element POS vector
 pos = varargin{1};
else
 [x,y] = deal(varargin{:});  % Two tuples (start & end points)
end
%% Get limits
axun = get(hAx,'Units');
set(hAx,'Units','normalized');  % Need normaized units to do the xform
axpos = get(hAx,'Position');
axlim = axis(hAx);              % Get the axis limits [xlim ylim (zlim)]
axwidth = diff(axlim(1:2));
axheight = diff(axlim(3:4));
%% Transform data from figure space to data space
if exist('x','var')     % Transform a and return pair of points
 varargout{1} = (x-axlim(1))*axpos(3)/axwidth + axpos(1);
 varargout{2} = (y-axlim(3))*axpos(4)/axheight + axpos(2);
else                    % Transform and return a position rectangle
 pos(1) = (pos(1)-axlim(1))/axwidth*axpos(3) + axpos(1);
 pos(2) = (pos(2)-axlim(3))/axheight*axpos(4) + axpos(2);
 pos(3) = pos(3)*axpos(3)/axwidth;
 pos(4) = pos(4)*axpos(4)/axheight;
 varargout{1} = pos;
end
%% Restore axes units
set(hAx,'Units',axun)
```

4

Basic Plotting Commands

Setting Up Figures

In this section...

Creating Figure Windows

MATLAB directs graphics output to a window that is separate from the Command Window. In MATLAB this window is referred to as a *figure*. The characteristics of this window are controlled by your computer's windowing system and MATLAB figure properties (see a description of each property). See Chapter 9, "Figure Properties" for some examples illustrating how to use figure properties.

Graphics functions automatically create new figure windows if none currently exist. If a figure already exists, MATLAB uses that window. If multiple figures exist, one is designated as the *current figure* and is used by MATLAB (this is generally the last figure used or the last figure you clicked the mouse in).

The `figure` function creates figure windows. For example,

```
figure
```

creates a new window and makes it the current figure. You can make an existing figure current by clicking it with the mouse or by passing its handle (the number indicated in the window title bar), as an argument to `figure`.

```
figure(h)
```

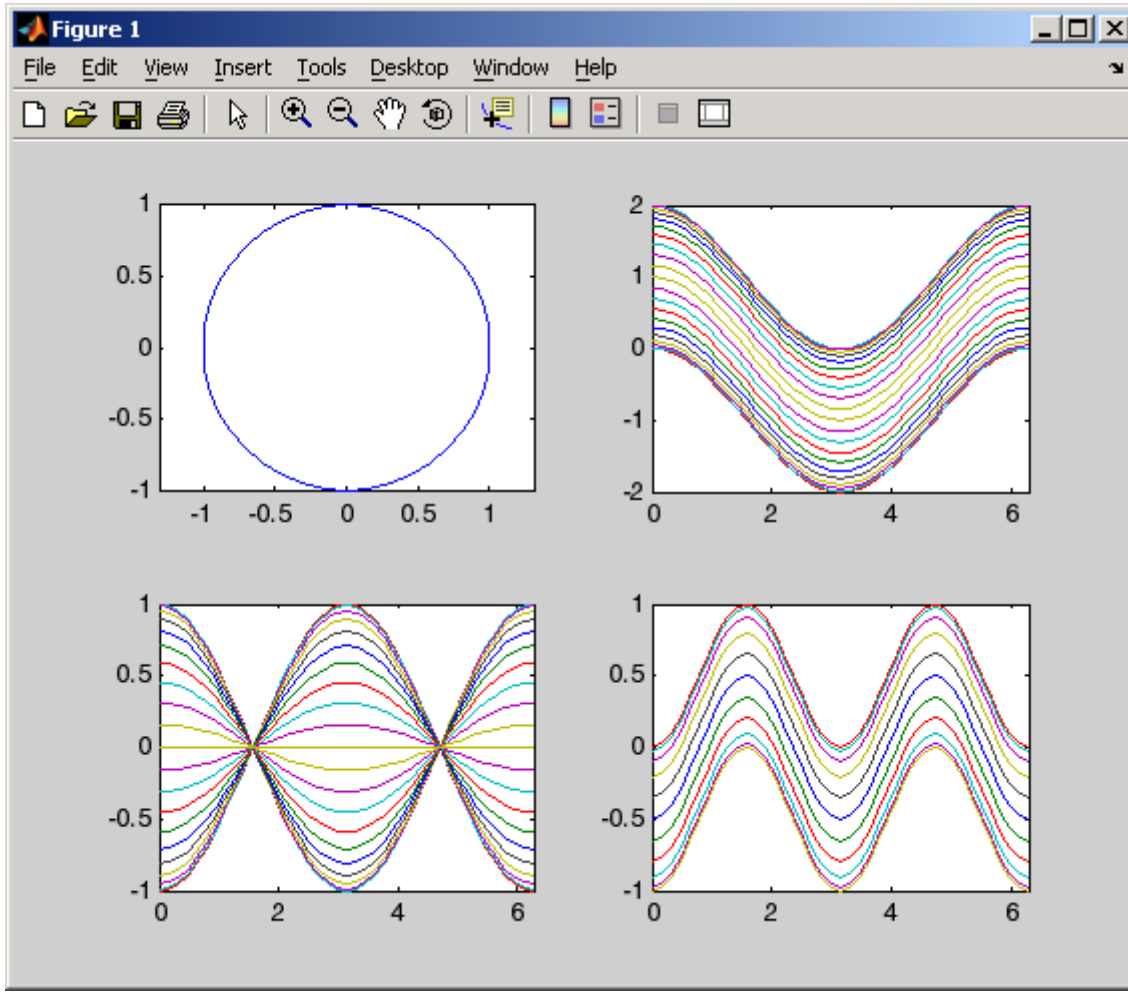
Displaying Multiple Plots per Figure

You can display multiple plots in the same figure window and print them on the same piece of paper with the `subplot` function.

`subplot(m,n,i)` breaks the figure window into an *m*-by-*n* matrix of small subplots and selects the `i`the subplot for the current plot. The plots are numbered along the top row of the figure window, then the second row, and so forth.

For example, the following statements plot data in four different subregions of the figure window.

```
t = 0:pi/20:2*pi;
[x,y] = meshgrid(t);
subplot(2,2,1)
plot(sin(t),cos(t))
axis equal
subplot(2,2,2)
z = sin(x)+cos(y);
plot(t,z)
axis([0 2*pi -2 2])
subplot(2,2,3)
z = sin(x).*cos(y);
plot(t,z)
axis([0 2*pi -1 1])
subplot(2,2,4)
z = (sin(x).^2)-(cos(y).^2);
plot(t,z)
axis([0 2*pi -1 1])
```



Each subregion contains its own axes with characteristics you can control independently of the other subregions. This example uses the `axis` function to set limits and change the shape of the subplots.

See the `axes`, `axis`, and `subplot` functions for more information.

Specifying the Target Axes

The current axes is the last one defined by `subplot`. If you want to access a previously defined subplot, for example to add a title, you must first make that axes current.

You can make an axes current in three ways:

- Click on the subplot with the mouse.
- Call `subplot` the `m`, `n`, `i` specifiers.
- Call `subplot` with the handle (identifier) of the axes.

For example,

```
subplot(2,2,2)
title('Top Right Plot')
```

adds a title to the plot in the upper right side of the figure.

You can obtain the handles of all the subplot axes with the statement

```
h = get(gcf,'Children');
```

MATLAB returns the handles of all the axes, with the most recently created one first. That is, `h(1)` is subplot 224, `h(2)` is subplot 223, `h(3)` is subplot 222, and `h(4)` is subplot 221. For example, to replace subplot 222 with a new plot, first make it the current axes with

```
subplot(h(3))
```

Default Color Scheme

The default figure color scheme produces good contrast and visibility for the various graphics functions. This scheme defines colors for the window background, the axis background, the axis lines and labels, the colors of the lines used for plotting and surface edges, and other properties that affect appearance.

The `colordef` function enables you to select from predefined color schemes and to modify colors individually. `colordef` predefines three color schemes:

- `colordef white` — Sets the axis background color to white, the window background color to gray, the colormap to `jet`, surface edge colors to black, and defines appropriate values for the plotting color order and other properties.
- `colordef black` — Sets the axis background color to black, the window background color to dark gray, the colormap to `jet`, surface edge colors to black, and defines appropriate values for the plotting color order and other properties.
- `colordef none` — Set the colors to match that of MATLAB 4. This is basically a black background with white axis lines and no grid. MATLAB programs that are based on the MATLAB 4 color scheme may need to call `colordef` with the `none` option to produce the expected results.

You can examine the `colordef.m` M-file to determine what properties it sets (enter `type colordef` at the MATLAB prompt).

Using High-Level Plotting Functions

In this section...

Functions for Plotting Line Graphs

MATLAB provides a variety of functions for displaying vector data as line plots, as well as functions for annotating and printing these graphs. The following table summarizes the functions that produce basic line plots. These functions differ in the way they scale the plot's axes. Each accepts input in the form of vectors or matrices and automatically scales the axes to accommodate the data.

Function	Description
`plot`	Graph 2-D data with linear scales for both axes
`plot3`	Graph 3-D data with linear scales for both axes
`loglog`	Graph with logarithmic scales for both axes
`semilogx`	Graph with a logarithmic scale for the *x*-axis and a linear scale for the *y*-axis

Function	Description
`semilogy`	Graph with a logarithmic scale for the *y*-axis and a linear scale for the *x*-axis
`plotyy`	Graph with *y*-tick labels on the left and right side

For a synopsis of all the high level plot functions with links to their reference pages, see "Types of Plots Available in MATLAB" on page 1-6.

Programmatic Plotting

The process of constructing a basic graph to meet your presentation graphics requirements is outlined in the following table. The table shows seven typical steps and some example code for each.

If you are performing analysis only, you may want to view various graphs just to explore your data. In this case, steps 1 and 3 may be all you need. If you are creating presentation graphics, you may want to fine-tune your graph by positioning it on the page, setting line styles and colors, adding annotations, and making other such improvements.

Step	Typical Code

1 Prepare your data	`x = 0:0.2:12;`
	`y1 = bessel(1,x);`
	`y2 = bessel(2,x);`
	`y3 = bessel(3,x);`

2 Select a window and position a plot region within the window	`figure(1)` `subplot(2,2,1)`
3 Call elementary plotting function	`h = plot(x,y1,x,y2,x,y3);`

4 Select line and marker characteristics	`set(h,'LineWidth',2,{'LineStyle'},`
	`{'--';':';'-.'})`
	`set(h,{'Color'},{'r';'g';'b'})`

Step	Typical Code
5 Set axis limits, tick marks, and grid lines	`axis([0 12 -0.5 1])` `grid on`

6 Annotate the graph with axis labels, legend, and text	`xlabel('Time')`
	`ylabel('Amplitude')`
	`legend(h,'First','Second','Third')`
	`title('Bessel Functions')`
	`[y,ix] = min(y1);`
	`text(x(ix),y,'First Min \rightarrow',...`
	`'HorizontalAlignment','right')`

7 Export graph	`print -depsc -tiff -r200 myplot`

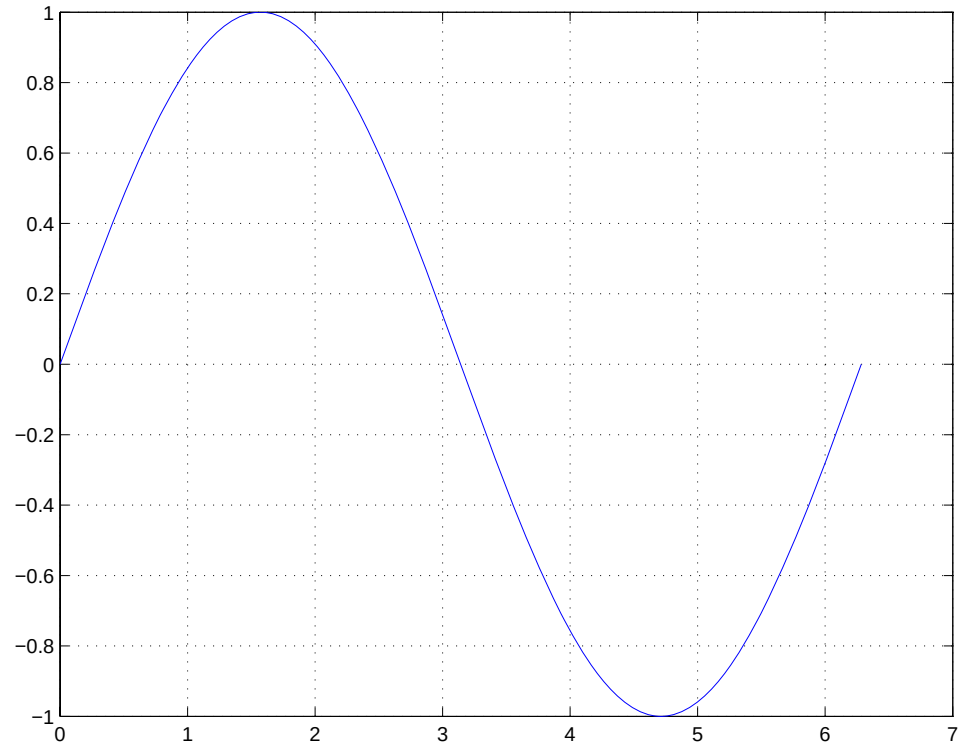
Creating Line Plots

The `plot` function has different forms depending on the input arguments. For example, if `y` is a vector, `plot(y)` produces a linear graph of the elements of `y` versus the index of the elements of `y`. If you specify two vectors as arguments, `plot(x,y)` produces a graph of `y` versus `x`.

For example, the following statements create a vector of values in the range [0, 2π] in increments of π/100 and then use this vector to evaluate the sine function over that range. MATLAB plots the vector on the *x*-axis and the value of the sine function on the *y*-axis.

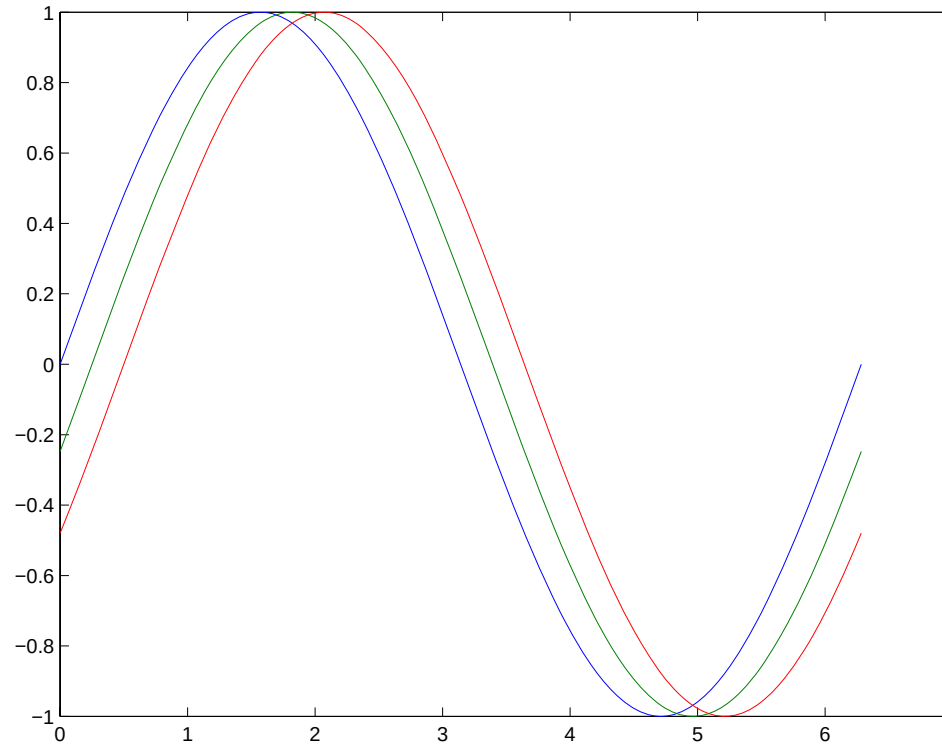
```
t = 0:pi/100:2*pi;
y = sin(t);
plot(t,y)
grid on % Turn on grid lines for this plot
```

MATLAB automatically selects appropriate axis ranges and tick mark locations.



You can plot multiple graphs in one call to `plot` using *x-y* pairs. MATLAB automatically cycles through a predefined list of colors (determined by the axes `ColorOrder` property) to allow discrimination between sets of data. Plotting three curves as a function of `t` produces

```
y = sin(t);
y2 = sin(t-0.25);
y3 = sin(t-0.5);
plot(t,y,t,y2,t,y3)
```

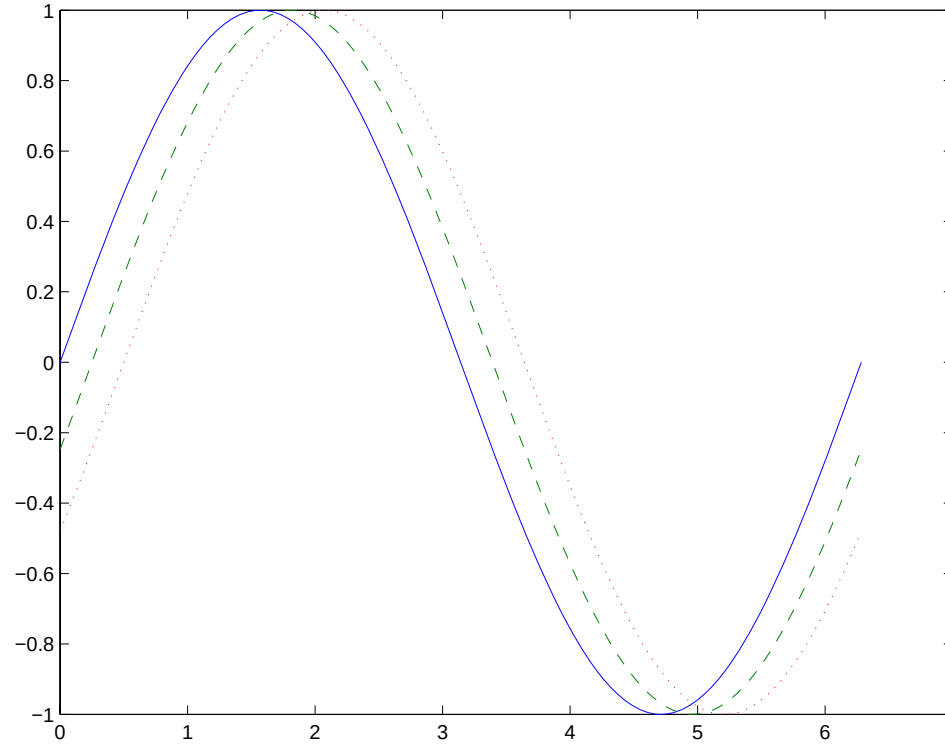


Specifying Line Style

You can assign different line styles to each data set by passing line style identifier strings to `plot`. For example,

```
t = 0:pi/100:2*pi;
y = sin(t);
y2 = sin(t-0.25);
y3 = sin(t-0.5);
plot(t,y,'-',t,y2,'--',t,y3,':')
```

The graph shows three lines of different colors and lines styles representing the value of the sine function with a small phase shift between each line, as defined by `y`, `y2`, and `y3`. The lines are blue solid, green dashed, and red dotted.



Colors, Line Styles, and Markers

The basic plotting functions accepts character-string arguments that specify various line styles, marker symbols, and colors for each vector plotted. In the general form,

```
plot(x,y,'linestyle_marker_color')
```

`linestyle_marker_color` is a character string (delineated by single quotation marks) constructed from

- A line style (e.g., dashed, dotted, etc.)
- A marker type (e.g., `x`, `*`, `o`, etc.)
- A predefined color specifier (`c`, `m`, `y`, `k`, `r`, `g`, `b`, `w`)

For example,

```
plot(x,y,':squarey')
```

plots a yellow dotted line and places square markers at each data point. If you specify a marker type, but not a line style, MATLAB draws only the marker.

The specification can consist of one or none of each specifier in any order. For example, the string

```
'go--'
```

defines a dashed line with circular markers, both colored green.

You can also specify the size of the marker and, for markers that are closed shapes, you can specify separately the colors of the edges and the face.

See the `LineSpec` discussion for more information.

Specifying the Color and Size of Lines

You can control a number of line style characteristics by specifying values for line properties:

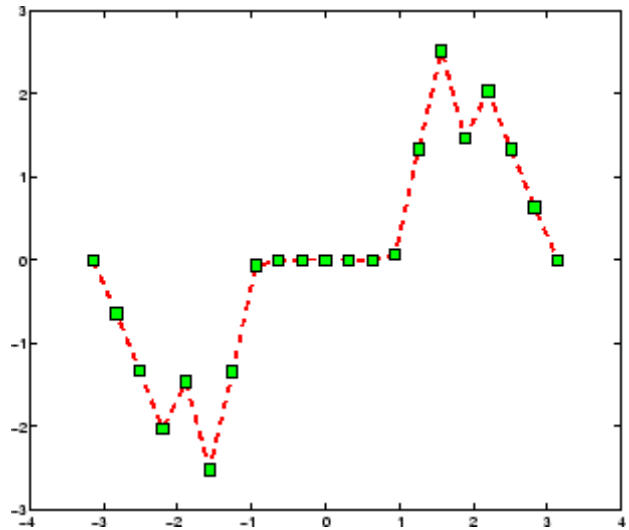
- `LineWidth` — Width of the line in units of points
- `MarkerEdgeColor` — Color of the marker or the edge color for filled markers (circle, square, diamond, pentagram, hexagram, and the four triangles)
- `MarkerFaceColor` — Color of the face of filled markers
- `MarkerSize` — Size of the marker in units of points

For example, these statements,

```
x = -pi:pi/10:pi;
y = tan(sin(x)) - sin(tan(x));
plot(x,y,'--rs','LineWidth',2,...
                'MarkerEdgeColor','k',...
                'MarkerFaceColor','g',...
                'MarkerSize',10)
```

produce a graph with

- A red dashed line with square markers
- A line width of two points
- The edge of the marker colored black
- The face of the marker colored green
- The size of the marker set to 10 points



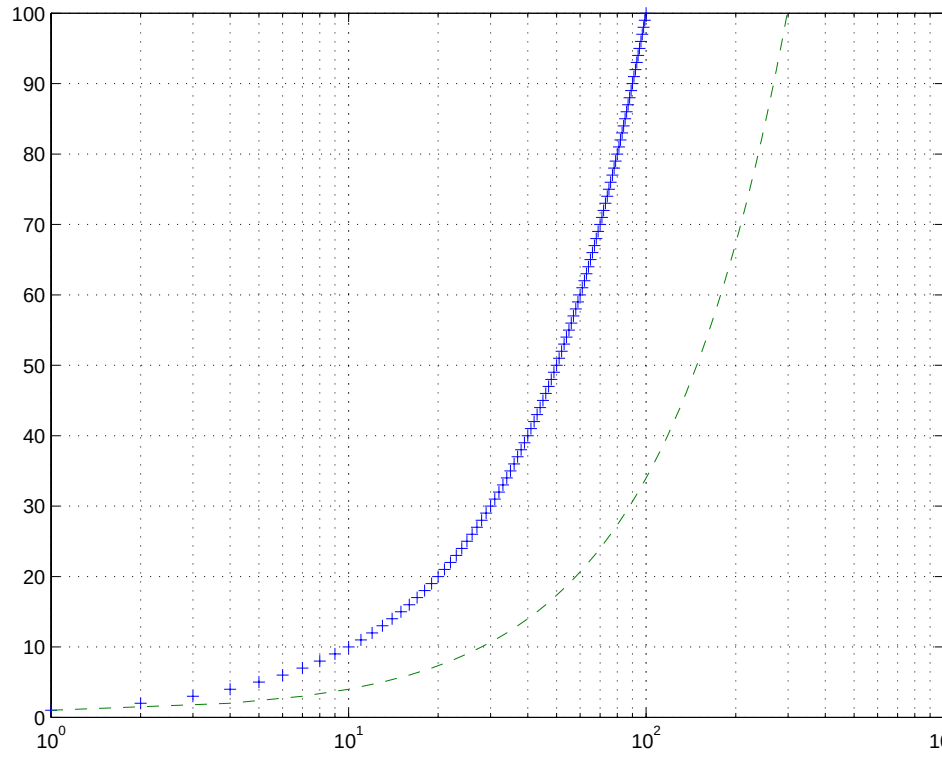
Adding Plots to an Existing Graph

You can add plots to an existing graph using the `hold` command. When you set `hold` to `on`, MATLAB does not remove the existing graph; it adds the new data to the current graph, rescaling if the new data falls outside the range of the previous axis limits.

For example, these statements first create a semilogarithmic plot, then add a linear plot.

```
semilogx(1:100,'+')
hold all % hold plot and cycle line colors
plot(1:3:300,1:100,'--')
hold off
grid on % Turn on grid lines for this plot
```

While MATLAB resets the *x*-axis limits to accommodate the new data, it does not change the scaling from logarithmic to linear.



Plotting Only the Data Points

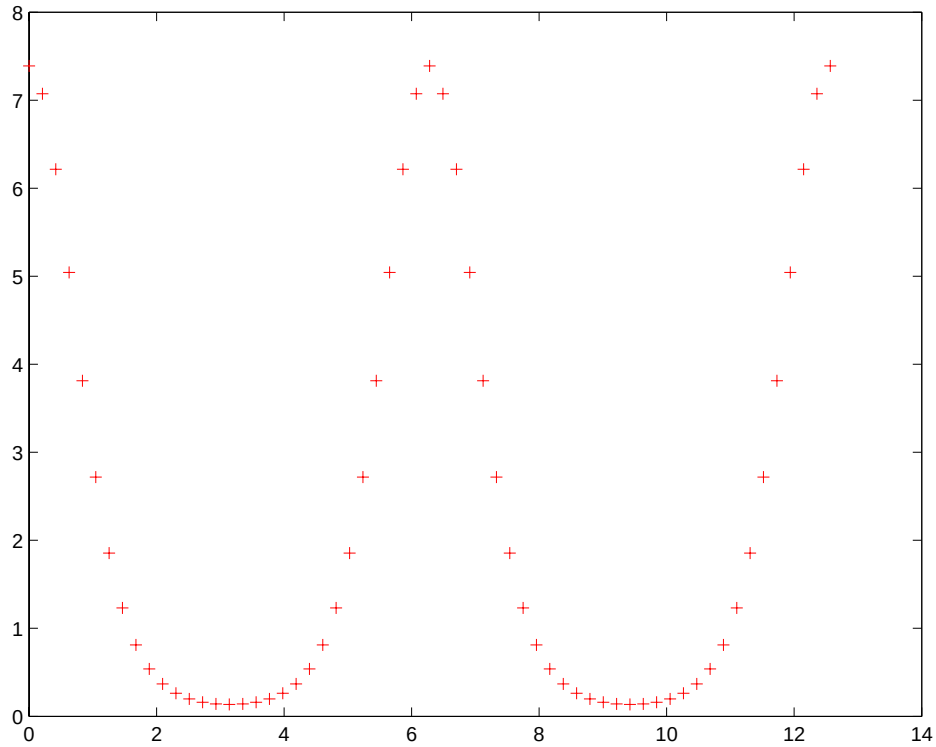
To plot a marker at each data point without connecting the markers with lines, use a specification that does not contain a line style. For example, given two vectors,

```
x = 0:pi/15:4*pi;
y = exp(2*cos(x));
```

calling `plot` with only a color and marker specifier

```
plot(x,y,'r+')
```

plots a red plus sign at each data point.

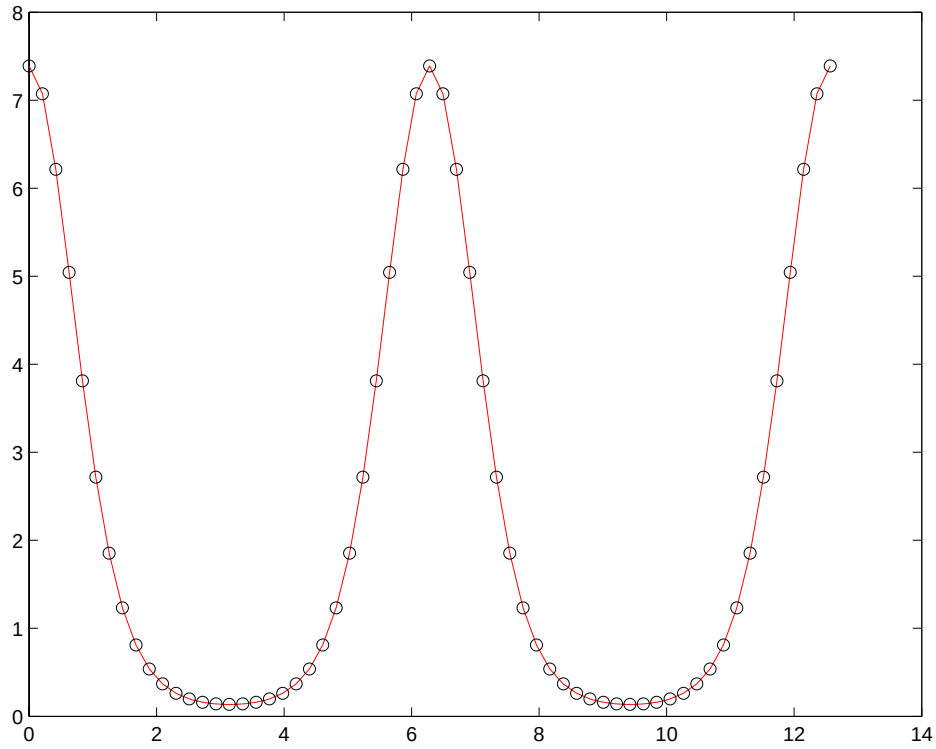


See `LineSpec` for a list of available line styles, markers, and colors.

Plotting Markers and Lines

To plot both markers and the lines that connect them, specify a line style and a marker type. For example, the following code plots the data as a red, solid line and then adds circular markers with black edges at each data point.

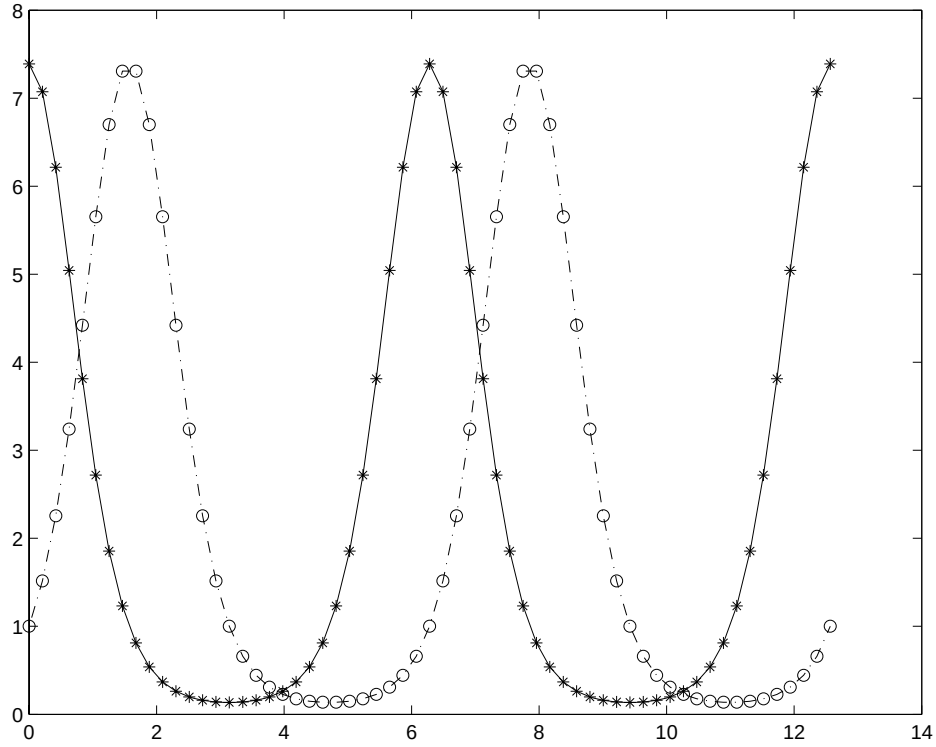
```
x = 0:pi/15:4*pi;
y = exp(2*cos(x));
plot(x,y,'-r',x,y,'ok')
```



Line Styles for Black and White Output

Line styles and markers enable you to discriminate different plots on the same graph when color is not available. For example, the following statements create a graph using a solid (`'-*k'`) line with asterisk markers colored black and a dash-dot (`'-.ok'`) line with circular markers colored black.

```
x = 0:pi/15:4*pi;
y1 = exp(2*cos(x));
y2 = exp(2*sin(x));
plot(x,y1,'-*k',x,y2,'-.ok')
```



Setting Default Line Styles

You can configure MATLAB to use line styles instead of colors for multiline plots by setting a default value for the axes `LineStyleOrder` property. For example, the command

```
set(0,'DefaultAxesLineStyleOrder',{'-o',':s','--+'})
```

defines three line styles and makes them the default for all plots.

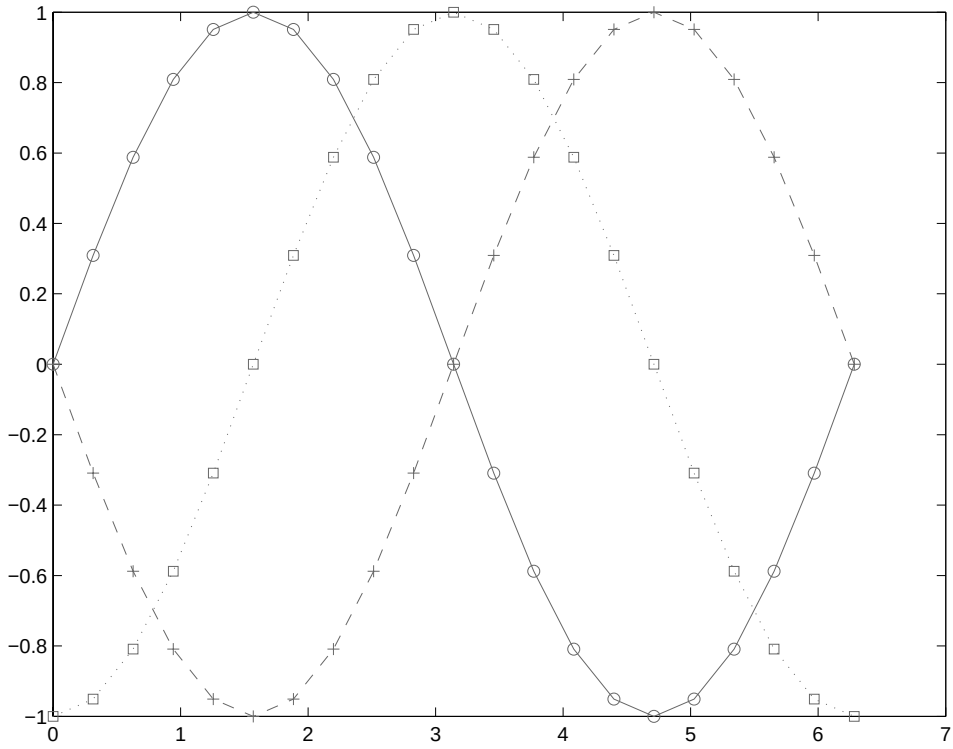
To set the default line color to dark gray, use the statement

```
set(0,'DefaultAxesColorOrder',[0.4,0.4,0.4])
```

See `ColorSpec` for information on how to specify color as a three-element vector of RGB values.

Now the plot function uses the line styles and colors you have defined as defaults. For example, these statements create a multiline plot.

```
x = 0:pi/10:2*pi;
y1 = sin(x);
y2 = sin(x-pi/2);
y3 = sin(x-pi);
plot(x,y1,x,y2,x,y3)
```



The default values persist until you quit MATLAB. To remove default values during your MATLAB session, use the reserved word `remove`.

```
set(0,'DefaultAxesLineStyleOrder','remove')
set(0,'DefaultAxesColorOrder','remove')
```

See “Setting Default Property Values” on page 8-51 for more information.

Line Plots of Matrix Data

When you call the `plot` function with a single matrix argument

```
plot(Y)
```

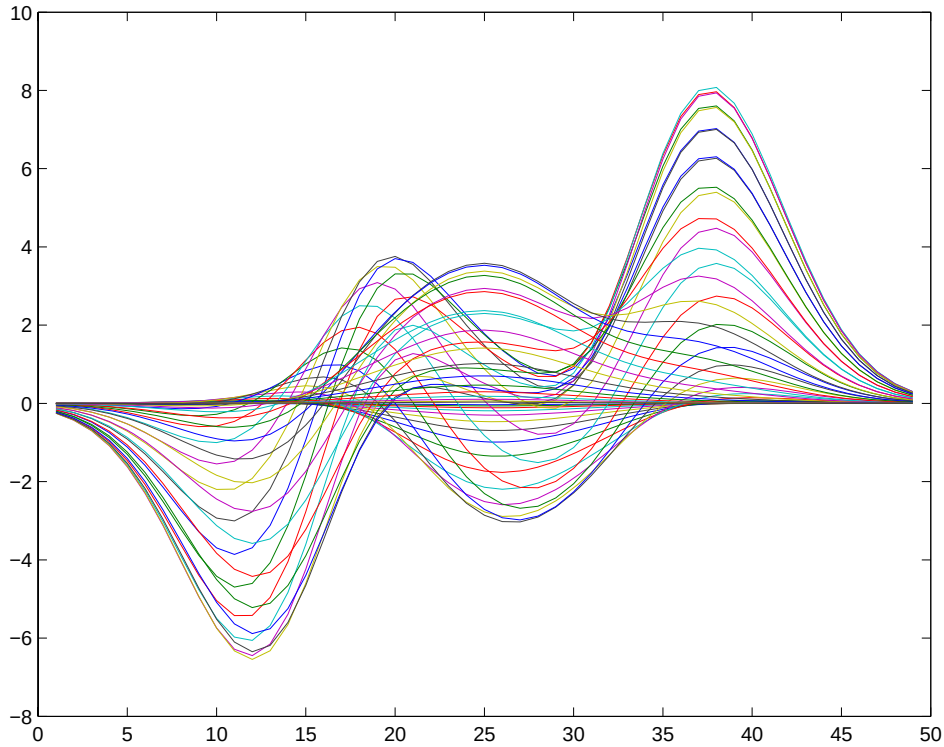
MATLAB draws one line for each column of the matrix. The *x*-axis is labeled with the row index vector `1:m`, where `m` is the number of rows in `Y`. For example,

```
Z = peaks;
```

returns a 49-by-49 matrix obtained by evaluating a function of two variables. Plotting this matrix

```
plot(Z)
```

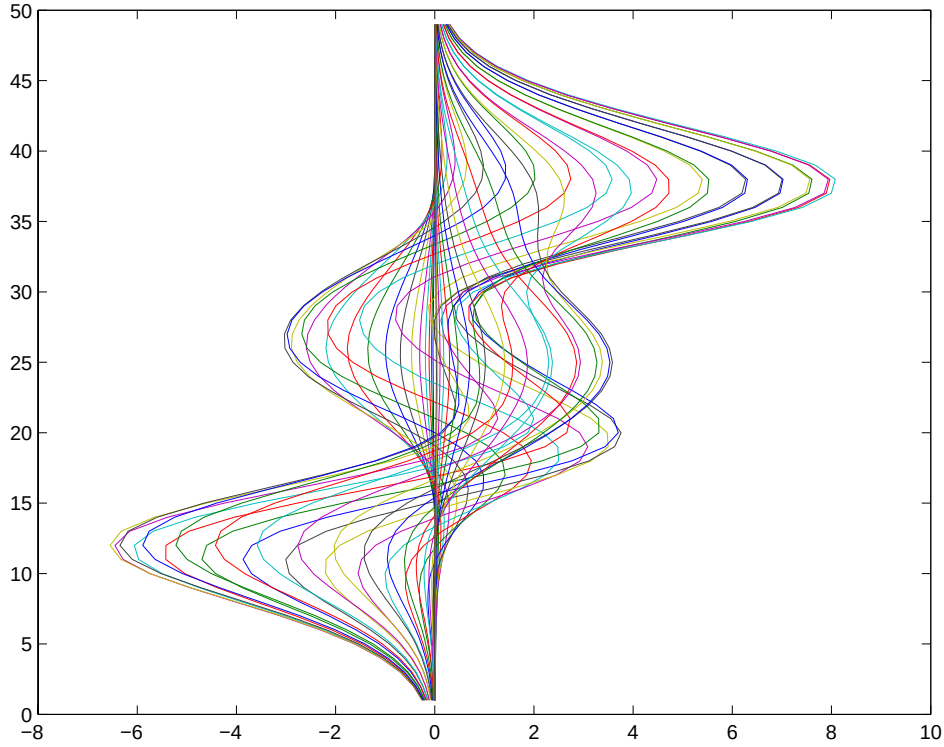
produces a graph with 49 lines.



In general, if `plot` is used with two arguments and if either `X` or `Y` has more than one row or column, then

- If `Y` is a matrix, and `x` is a vector, `plot(x,Y)` successively plots the rows or columns of `Y` versus vector `x`, using different colors or line types for each. The row or column orientation varies depending on whether the number of elements in `x` matches the number of rows in `Y` or the number of columns. If `Y` is square, its columns are used.
- If `X` is a matrix and `y` is a vector, `plot(X,y)` plots each row or column of `X` versus vector `y`. For example, plotting the `peaks` matrix versus the vector `1:length(peaks)` rotates the previous plot.

```
y = 1:length(peaks);
plot(peaks,y)
```



- If `X` and `Y` are both matrices of the same size, `plot(X,Y)` plots the columns of `X` versus the columns of `Y`.

You can also use the `plot` function with multiple pairs of matrix arguments.

```
plot(X1,Y1,X2,Y2,...)
```

This statement graphs each `X-Y` pair, generating multiple lines. The different pairs can be of different dimensions.

Plotting Imaginary and Complex Data

When the arguments to `plot` are complex (i.e., the imaginary part is nonzero), MATLAB ignores the imaginary part *except* when `plot` is given a single complex data argument. For this special case, the command is a shortcut for a plot of the real part versus the imaginary part. Therefore,

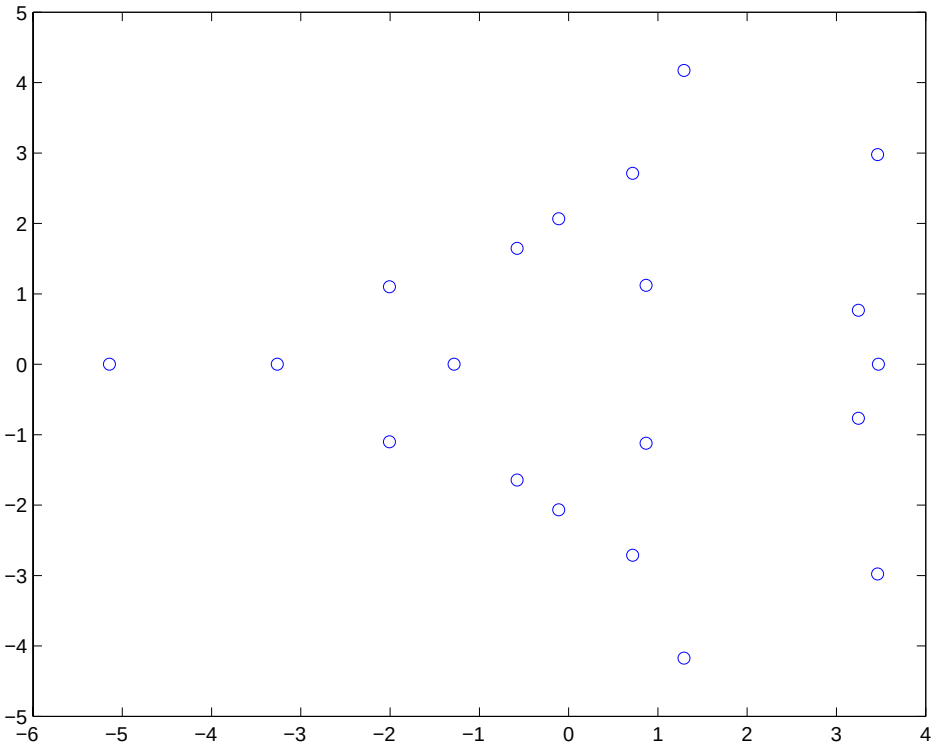
```
plot(Z)
```

where `Z` is a complex vector or matrix, is equivalent to

```
plot(real(Z),imag(Z))
```

For example, this statement plots the distribution of the eigenvalues of a random matrix using circular markers to indicate the data points.

```
plot(eig(randn(20,20)),'o','MarkerSize',6)
```



To plot more than one complex matrix, there is no shortcut; the real and imaginary parts must be taken explicitly.

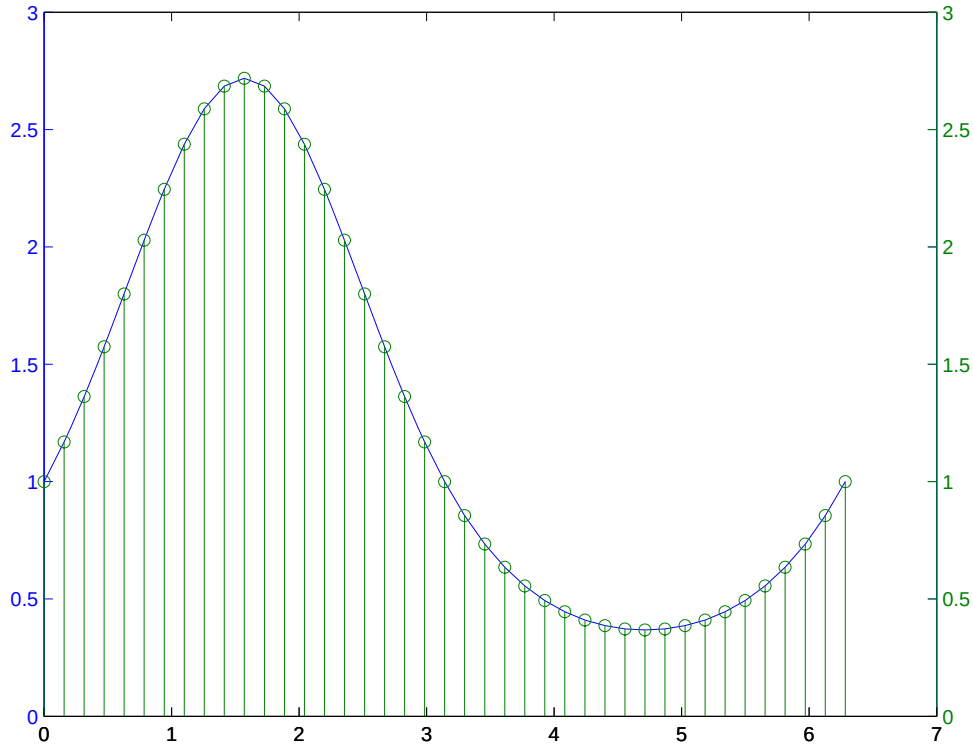
Plotting with Two Y-Axes

In this section...

Introduction

The `plotyy` function enables you to create plots of two data sets and use both left and right side *y*-axes. You can also apply different plotting functions to each data set. For example, you can combine a line plot with a stem plot of the same data.

```
t = 0:pi/20:2*pi;
y = exp(sin(t));
plotyy(t,y,t,y,'plot','stem')
```



Combining Linear and Logarithmic Axes

You can use `plotyy` to apply linear and logarithmic scaling to compare two data sets having different ranges of values.

```
t = 0:900; A = 1000; a = 0.005; b = 0.005;
z1 = A*exp(-a*t);
z2 = sin(b*t);
[haxes,hline1,hline2] = plotyy(t,z1,t,z2,'semilogy','plot');
```

This example saves the handles of the lines and axes created to adjust and label the graph. First, label the axes whose *y* value ranges from 10 to 1000.

This is the first handle in `haxes` because it was specified first in the call to `plotyy`. Use the `axes` function to make `haxes(1)` the current axes, which is then the target for the `ylabel` function.

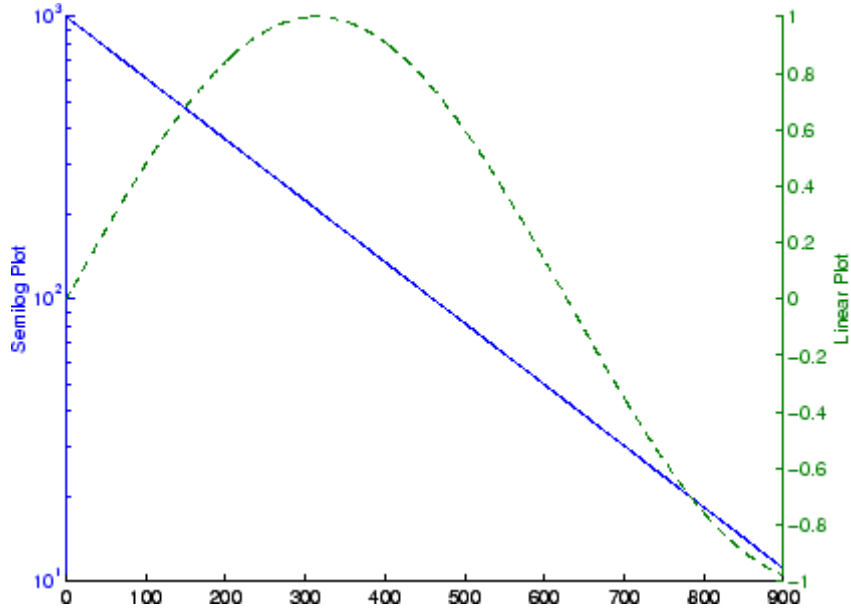
```
axes(haxes(1))
ylabel('Semilog Plot')
```

Now make the second axes current and call `ylabel` again.

```
axes(haxes(2))
ylabel('Linear Plot')
```

You can modify the characteristics of the plotted lines in a similar way. For example, to change the line style of the second line plotted to a dashed line, use the statement

```
set(hline2,'LineStyle','--')
```



See “Using Multiple X- and Y-Axes” on page 10-25 for an example that employs double *x*- and *y*-axes.

See `LineSpec` for additional line properties.

Setting Axis Parameters

In this section...

Axis Scaling and Ticks

When you create a graph, MATLAB automatically selects the axis limits and tick-mark spacing based on the data plotted. However, you can also specify your own values for axis limits and tick marks with the following functions:

- `axis` — Sets values that affect the current axes object (the most recently created or the last clicked on).
- `axes` — (Not axis) creates a new axes object with the specified characteristics.
- `get` and `set` — Enable you to query and set a wide variety of properties of existing axes.
- `gca` — Returns the handle (identifier) of the current axes. If there are multiple axes in the figure window, the current axes is the last graph created or the last graph you clicked on with the mouse. The following two sections provide more information and examples:

See “Defining the View” in the 3-D Visualization documentation for more extensive information on manipulating 3-D views.

Axis Limits and Ticks

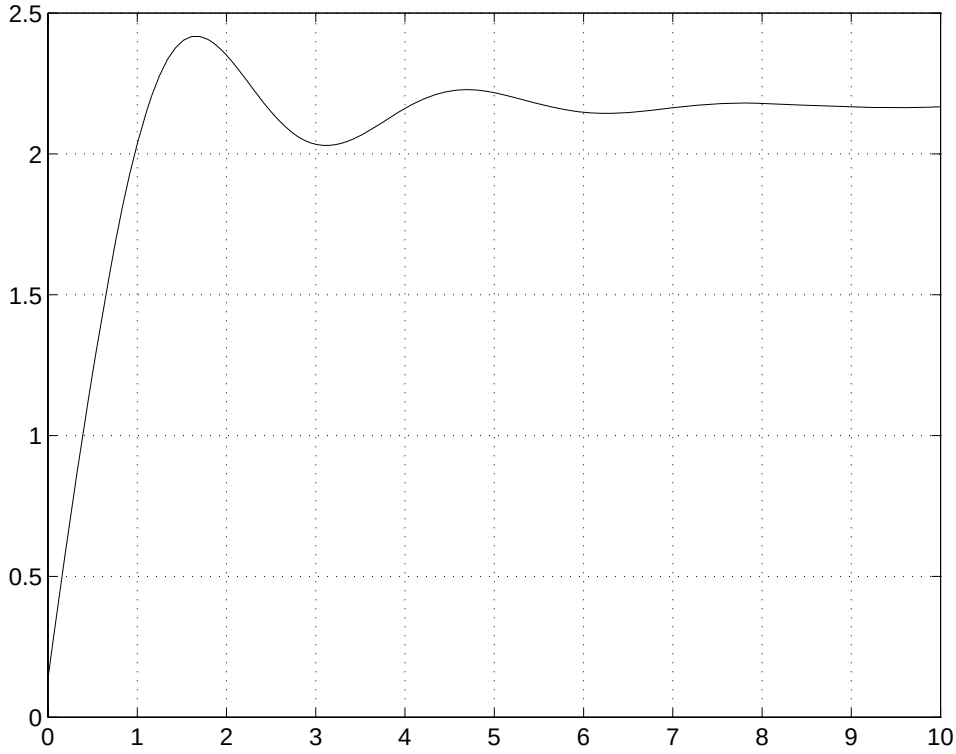
MATLAB selects axis limits based on the range of the plotted data. You can specify the limits manually using the `axis` function. Call `axis` with the new limits defined as a four-element vector.

```
axis([xmin,xmax,ymin,ymax])
```

Note that the minimum values must be less than the maximum values.

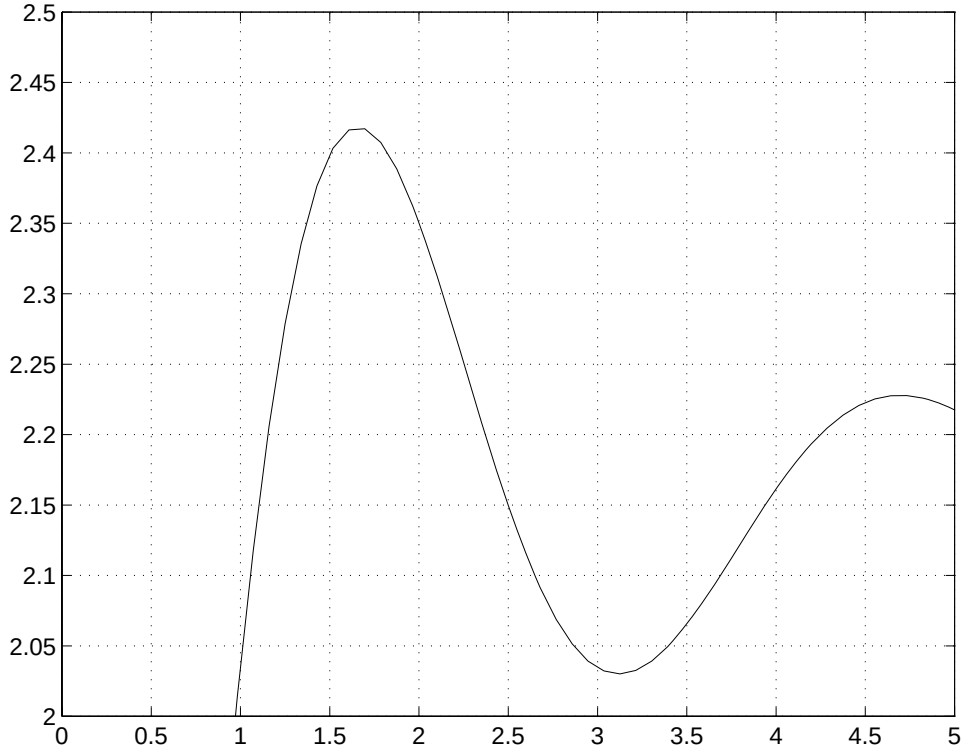
Semiautomatic Limits

If you want MATLAB to autoscale only one of a min/max set of axis limits, but you want to specify the other, use the MATLAB variable `Inf` or `-Inf` for the autoscaled limit. For example, this graph uses default scaling.



Compare the default limits to the following graph, which sets the maximum limit of the *x*-axis, but autoscales the minimum limit.

```
axis([-Inf 5 2 2.5])
```



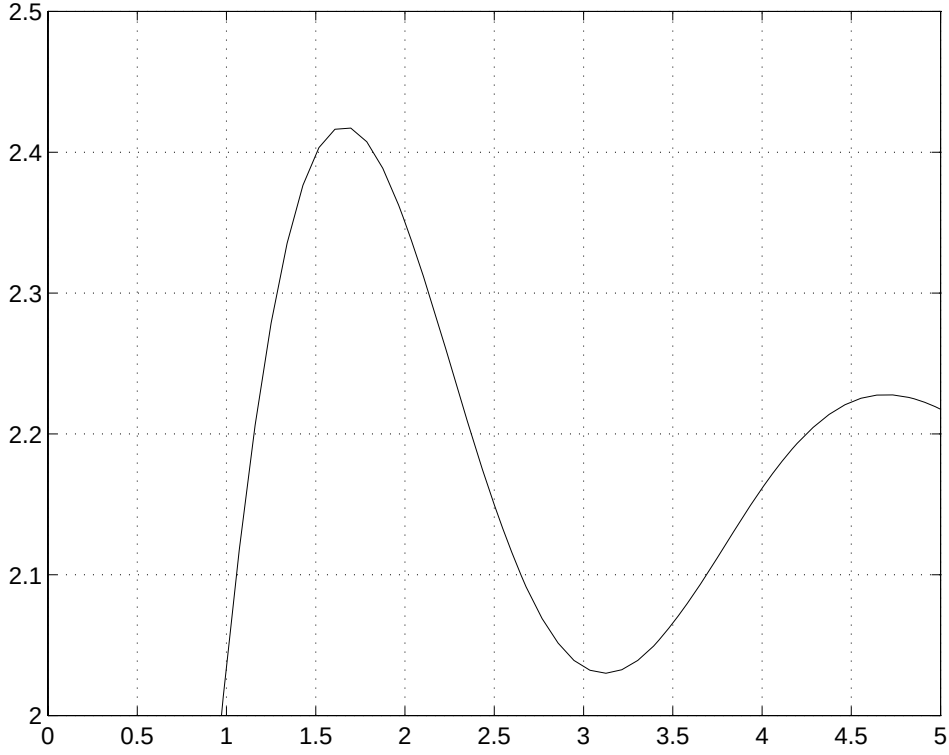
Axis Tick Marks

MATLAB selects the tick-mark locations based on the range of data so as to produce equally spaced ticks (for linear graphs). You can specify different tick marks by setting the axes `XTick` and `YTick` properties. Define tick marks as a vector of increasing values. The values do not need to be equally spaced.

For example, setting the *y*-axis tick marks for the graph from the preceding example,

```
set(gca,'ytick',[2 2.1 2.2 2.3 2.4 2.5])
```

produces a graph with only the specified ticks on the *y*-axis.



Note that if you specify tick-mark values that are outside the axis limits, MATLAB does not display them (that is, specifying tick marks cannot cause axis limits to change).

Example — Specifying Ticks and Tick Labels

You can adjust the axis tick-mark locations and the labels appearing at each tick mark. For example, this plot of the sine function relabels the *x*-axis with more meaningful values.

```
x = -pi:.1:pi;
y = sin(x);
plot(x,y)
set(gca,'XTick',-pi:pi/2:pi)
set(gca,'XTickLabel',{'-pi','-pi/2','0','pi/2','pi'})
```

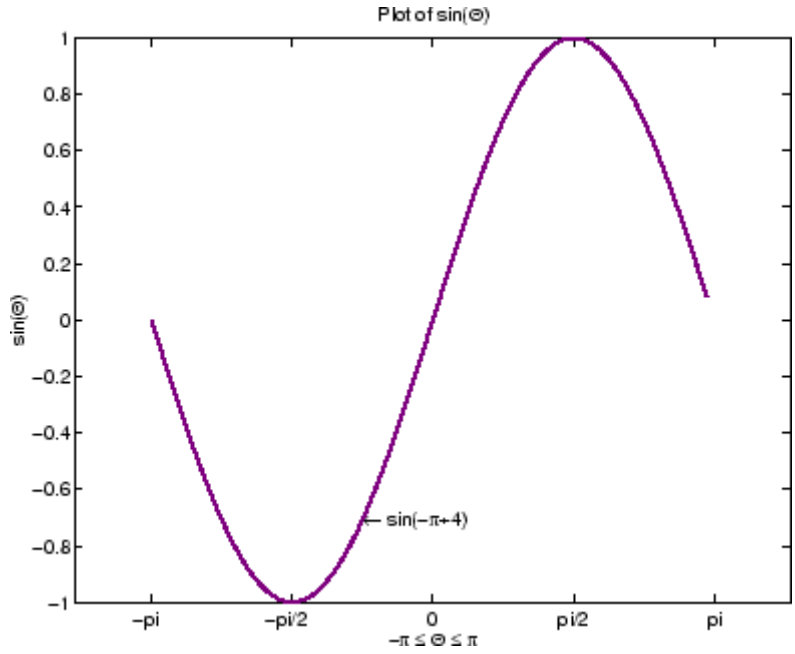
These functions (`xlabel`, `ylabel`, `title`, `text`) add axis labels and draw an arrow that points to the location on the graph where y = sin(-pi/4).

```
xlabel('-\pi \leq \Theta \leq \pi')
ylabel('sin(\Theta)')
title('Plot of sin(\Theta)')
text(-pi/4,sin(-pi/4),'\leftarrow sin(-\pi\div4)',...
     'HorizontalAlignment','left')
```

Setting Line Properties on an Existing Plot

Change the line color to purple by first finding the handle of the line object created by `plot` and then setting its `Color` property. Use `findobj` and the fact that MATLAB creates a blue line (RGB value [0 0 1]) by default. In the same statement, set the `LineWidth` property to 2 points.

```
set(findobj(gca,'Type','line','Color',[0 0 1]),...
    'Color',[0.5,0,0.5],'LineWidth',2)
```



The Greek symbols are created using TeX character sequences.

Setting Aspect Ratio

By default, MATLAB displays graphs in a rectangular axes that has the same aspect ratio as the figure window. This makes optimum use of space available for plotting. MATLAB provides control over the aspect ratio with the `axis` function.

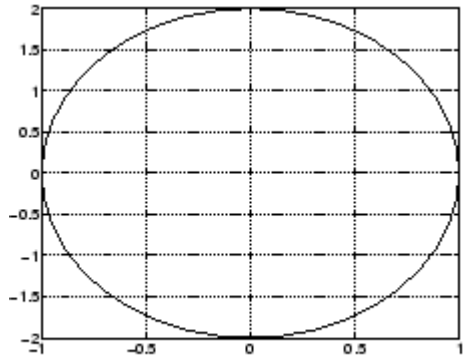
For example,

```
t = 0:pi/20:2*pi;
plot(sin(t),2*cos(t))
grid on
```

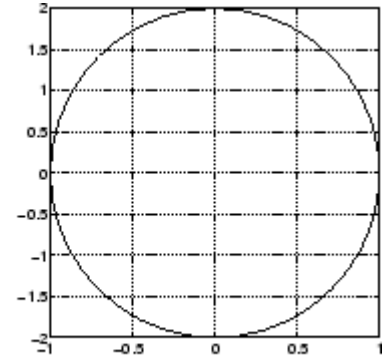
produces a graph with the default aspect ratio. The command

```
axis square
```

makes the *x*- and *y*-axes equal in length.



axis normal

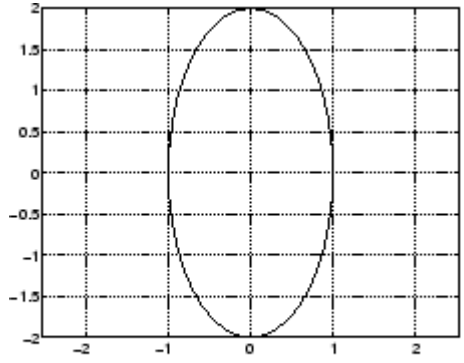


axis square

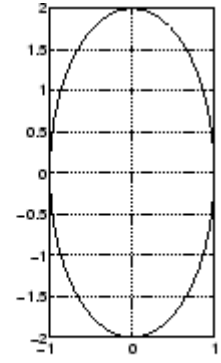
The square axes has one data unit in *x* to equal two data units in *y*. If you want the *x*- and *y*-data units to be equal, use the command

```
axis equal
```

This produces an axes that is rectangular in shape, but has equal scaling along each axis.



axis equal



axis equal tight

If you want the axes shape to conform to the plotted data, use the `tight` option in conjunction with `equal`.

```
axis equal tight
```

Note In order to format aspect ratio using `axis`, axes must exist and contain a plot. That is, you cannot pre-format an axes that has no actual *x*-, *y*-, or *z*-limits. To overcome this, you can preformat the axes with `axis` and issue the `hold on` command before plotting data.

5

Creating Specialized Plots

Bar and Area Graphs

In this section...

Types of Bar Graphs

Bar and area graphs display vector or matrix data. These types of graphs are useful for viewing results over a period of time, comparing results from different data sets, and showing how individual elements contribute to an aggregate amount. Bar graphs are suitable for displaying discrete data, whereas area graphs—like line graphs—are more suitable for displaying continuous data. The functions that plot bar and area graphs are listed below:

Function	Description
`bar`	Displays columns of *m*-by-*n* matrix as *m* groups of *n* vertical bars
`barh`	Displays columns of *m*-by-*n* matrix as *m* groups of *n* horizontal bars
`bar3`	Displays columns of *m*-by-*n* matrix as *m* groups of *n* vertical 3–D bars
`bar3h`	Displays columns of *m*-by-*n* matrix as *m* groups of *n* horizontal 3–D bars
`area`	Displays vector data as stacked area plots

Four of these five functions display bar graphs (there is only one type of area graph; see “Area Graphs” on page 5-19). Bar graphs differ according to whether they plot in 2-D or 3-D and create vertical or horizontal bars, as follows:

Orientation	Two–Dimensional	Three–Dimensional
Vertical	`bar`	`bar3`
Horizontal	`barh`	`bar3h`

Grouped Bar Graph
