Acknowledgments and Permissions

The authors would like to thank the following people:

Joe Hicklin of MathWorks for getting Howard into neural network research years ago at the University of Idaho, for encouraging Howard and Mark to write the toolbox, for providing crucial help in getting the first toolbox Version 1.0 out the door, for continuing to help with the toolbox in many ways, and for being such a good friend.

Roy Lurie of MathWorks for his continued enthusiasm for the possibilities for Neural Network Toolbox™ software.

Mary Ann Freeman of MathWorks for general support and for her leadership of a great team of people we enjoy working with.

Rakesh Kumar of MathWorks for cheerfully providing technical and practical help, encouragement, ideas and always going the extra mile for us.

Alan LaFleur of MathWorks for facilitating our documentation work.

Stephen Vanreusel of MathWorks for help with testing.

Dan Doherty of MathWorks for marketing support and ideas.

Orlando De Jesús of Oklahoma State University for his excellent work in developing and programming the dynamic training algorithms described in “Dynamic Networks” and in programming the neural network controllers described in “Control Systems” in the *Neural Network Toolbox User’s Guide*.

Martin T. Hagan, Howard B. Demuth, and Mark Hudson Beale for permission to include various problems, demonstrations, and other material from *Neural Network Design*, January, 1996.

Product Overview

Neural Network Toolbox™ provides tools for designing, implementing, visualizing, and simulating neural networks. Neural networks are used for applications where formal analysis is difficult or impossible, such as pattern recognition and nonlinear system identification and control. The toolbox supports feedforward networks, radial basis networks, dynamic networks, self-organizing maps, and other proven network paradigms.

Neural networks are composed of simple elements operating in parallel. These elements are inspired by biological nervous systems. As in nature, the connections between elements largely determine the network function. You can train a neural network to perform a particular function by adjusting the values of the connections (weights) between elements.

Typically, neural networks are adjusted, or trained, so that a particular input leads to a specific target output. The next figure illustrates such a situation. There, the network is adjusted, based on a comparison of the output and the target, until the network output matches the target. Typically, many such input/target pairs are needed to train a network.

Neural networks have been trained to perform complex functions in various fields, including pattern recognition, identification, classification, speech, vision, and control systems.

Neural networks can also be trained to solve problems that are difficult for conventional computers or human beings. The toolbox emphasizes the use of neural network paradigms that build up to—or are themselves used in—engineering, financial, and other practical applications.

This chapter explains how to use four graphical tools for training neural networks to solve problems in function fitting, pattern recognition, clustering, and time series. Using these four tools will give you an excellent introduction to the use of the Neural Network Toolbox software.

Using the Toolbox and Its Documentation

There are four ways you can use the Neural Network Toolbox software. The first way is through the four graphical user interfaces (GUIs) that are described in this chapter. (You can open these GUIs from a master GUI, which you can open with the command `nnstart`.) These provide a quick and easy way to access the power of the toolbox for the following tasks:

- Function fitting
- Pattern recognition
- Data clustering
- Time series analysis

The second way to use the toolbox is through basic command-line operations. The command-line operations offer more flexibility than the GUIs, but with some added complexity. This chapter introduces some of the command-line functions, while the *Neural Network Toolbox User's Guide* covers command-line operations in more detail, including these two chapters, which are important to understanding the use of the command line, and the fundamentals of training neural networks. You should read them before advancing to later topics in the *User's Guide*.

- “Network Objects, Data and Training Styles” presents the fundamentals of **the neuron model and the architectures of neural networks**. It also describes the network object, which is used by the Neural Network Toolbox software to store all of the information that defines a neural network. It is important to understand the structure of the network object, especially when using command-line operations. This chapter also describes how data is stored and used in the toolbox, and how networks are trained.
- “Multilayer Networks and Backpropagation Training” explains the basic steps involved in designing the multilayer network. This network is the workhorse of the toolbox, and it can be used for both function fitting and pattern recognition. Most of the design steps for this network can be applied to the design of any other network in the toolbox.

If this is your first experience with the toolbox, the GUIs provide the best introduction. In addition, the GUIs can generate scripts of documented MATLAB® code to provide you with templates for creating your own

customized command-line functions. The process of using the GUIs first, and then generating and modifying MATLAB scripts, is an excellent way to learn about the functionality of the toolbox.

The third way to use the toolbox is through customization. This advanced capability allows you to create your own custom neural networks, while still having access to the full functionality of the toolbox. You can create networks with arbitrary connections, and you will still be able to train them using existing toolbox training functions (as long as the network components are differentiable). Customizing the toolbox is described in “Advanced Topics”. An example of creating and training a customized network is given in “Training Custom Networks”.

The fourth way to use the toolbox is through the ability to modify any of the functions contained in the toolbox. Every computational component is written in MATLAB code and is fully accessible.

These four levels of toolbox usage span the novice to the expert - simple wizards guide the new user through specific applications, and network customization allows researchers to try novel architectures with minimal effort. Whatever your level of neural network and MATLAB knowledge, there are toolbox features to suit your needs.

Automatic Script Generation

The GUIs described in this chapter form an important part of the documentation for the Neural Network Toolbox software. The GUIs guide you through the process of designing neural networks to solve problems in four important application areas, without requiring any background in neural networks or sophistication in using MATLAB. In addition, the GUIs can automatically generate both simple and advanced MATLAB scripts that can reproduce the steps performed by the GUI, but with the option to override default settings. These scripts can provide you with a template for creating customized code, and they can aid you in becoming familiar with the command-line functionality of the toolbox. It is highly recommended that you use the automatic script generation facility of the GUIs.

Neural Network Toolbox Applications

It would be impossible to cover the total range of applications for which neural networks have provided outstanding solutions. The remaining sections of this chapter will demonstrate only a few of the applications in function fitting, pattern recognition, clustering, and time series analysis. The following table provides an idea of the diversity of applications for which neural networks provide state-of-the-art solutions.

| Industry | Business Applications |
|---------------|---|
| Aerospace | High-performance aircraft autopilot, flight path simulation, aircraft control systems, autopilot enhancements, aircraft component simulation, and aircraft component fault detection |
| Automotive | Automobile automatic guidance system, and warranty activity analysis |
| Banking | Check and other document reading and credit application evaluation |
| Defense | Weapon steering, target tracking, object discrimination, facial recognition, new kinds of sensors, sonar, radar and image signal processing including data compression, feature extraction and noise suppression, and signal/image identification |
| Electronics | Code sequence prediction, integrated circuit chip layout, process control, chip failure analysis, machine vision, voice synthesis, and nonlinear modeling |
| Entertainment | Animation, special effects, and market forecasting |
| Financial | Real estate appraisal, loan advising, mortgage screening, corporate bond rating, credit-line use analysis, credit card activity tracking, portfolio trading program, corporate financial analysis, and currency price prediction |
| Industrial | Prediction of industrial processes, such as the output gases of furnaces, replacing complex and costly equipment used for this purpose in the past |

| Industry | Business Applications |
|--------------------|---|
| Insurance | Policy application evaluation and product optimization |
| Manufacturing | Manufacturing process control, product design and analysis, process and machine diagnosis, real-time particle identification, visual quality inspection systems, beer testing, welding quality analysis, paper quality prediction, computer-chip quality analysis, analysis of grinding operations, chemical product design analysis, machine maintenance analysis, project bidding, planning and management, and dynamic modeling of chemical process system |
| Medical | Breast cancer cell analysis, EEG and ECG analysis, prosthesis design, optimization of transplant times, hospital expense reduction, hospital quality improvement, and emergency-room test advisement |
| Oil and gas | Exploration |
| Robotics | Trajectory control, forklift robot, manipulator controllers, and vision systems |
| Securities | Market analysis, automatic bond rating, and stock trading advisory systems |
| Speech | Speech recognition, speech compression, vowel classification, and text-to-speech synthesis |
| Telecommunications | Image and data compression, automated information services, real-time translation of spoken language, and customer payment processing systems |
| Transportation | Truck brake diagnosis systems, vehicle scheduling, and routing systems |

Neural Network Design Steps

In the remaining sections of this chapter, you will follow the standard steps for designing neural networks to solve problems in four application areas: function fitting, pattern recognition, clustering, and time series analysis. The work flow for any of these problems has seven primary steps. (Data collection in step 1, while important, generally occurs outside the MATLAB environment.)

- 1** Collect data
- 2** Create the network
- 3** Configure the network
- 4** Initialize the weights and biases
- 5** Train the network
- 6** Validate the network
- 7** Use the network

You will follow these steps using both the GUI tools and command-line operations in the next four sections. More details of the design steps are discussed in “Network Objects, Data and Training Styles” and “Multilayer Networks and Backpropagation Training” in the User’s Guide.

Fitting a Function

Neural networks are good at fitting functions. In fact, there is proof that a fairly simple neural network can fit any practical function.

Suppose, for instance, that you have data from a housing application [HaRu78]. You want to design a network that can predict the value of a house (in \$1000s), given 13 pieces of geographical and real estate information. You have a total of 506 example homes for which you have those 13 items of data and their associated market values.

You can solve this problem in two ways:

- Use a graphical user interface, `nftool`, as described in “Using the Neural Network Fitting Tool” on page 1-11.
- Use command-line functions, as described in “Using Command-Line Functions” on page 1-21.

It is generally best to start with the GUI, and then to use the GUI to automatically generate command-line scripts. Before using either method, first define the problem by selecting a data set. Each GUI has access to many sample data sets that you can use to experiment with the toolbox (see “Sample Data Sets” on page 1-91). If you have a specific problem that you want to solve, you can load your own data into the workspace. The next section describes the data format.

Defining a Problem

To define a fitting problem for the toolbox, arrange a set of Q input vectors as columns in a matrix. Then, arrange another set of Q target vectors (the correct output vectors for each of the input vectors) into a second matrix (see “Data Structures” in the User’s Guide for a detailed description of data formatting for static and time series data). For example, you can define the fitting problem for a Boolean AND gate with four sets of two-element input vectors and one-element targets as follows:

```
inputs = [0 1 0 1; 0 0 1 1];  
targets = [0 0 0 1];
```

The next section demonstrates how to train a network to fit a data set, using the neural network fitting tool GUI, `nftool`. This example uses the housing data set provided with the toolbox.

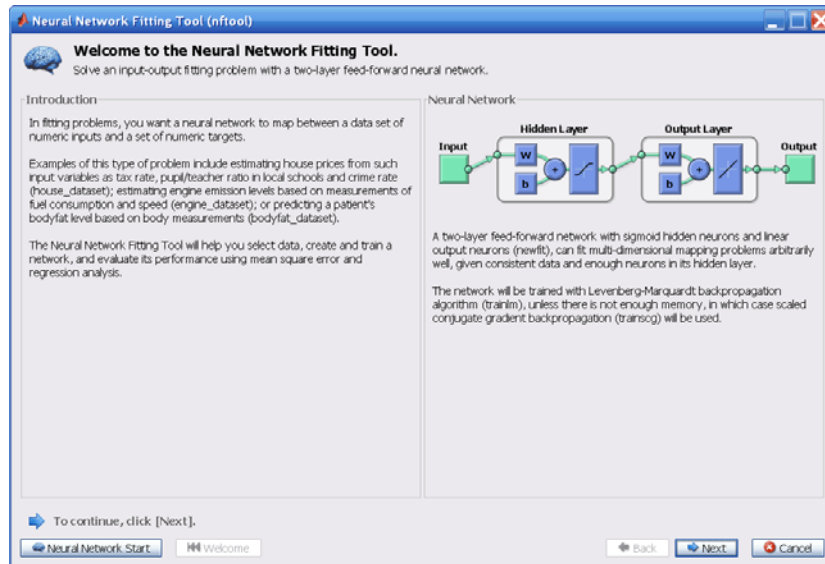

Using the Neural Network Fitting Tool

- 1 Open the Neural Network Start GUI with this command:

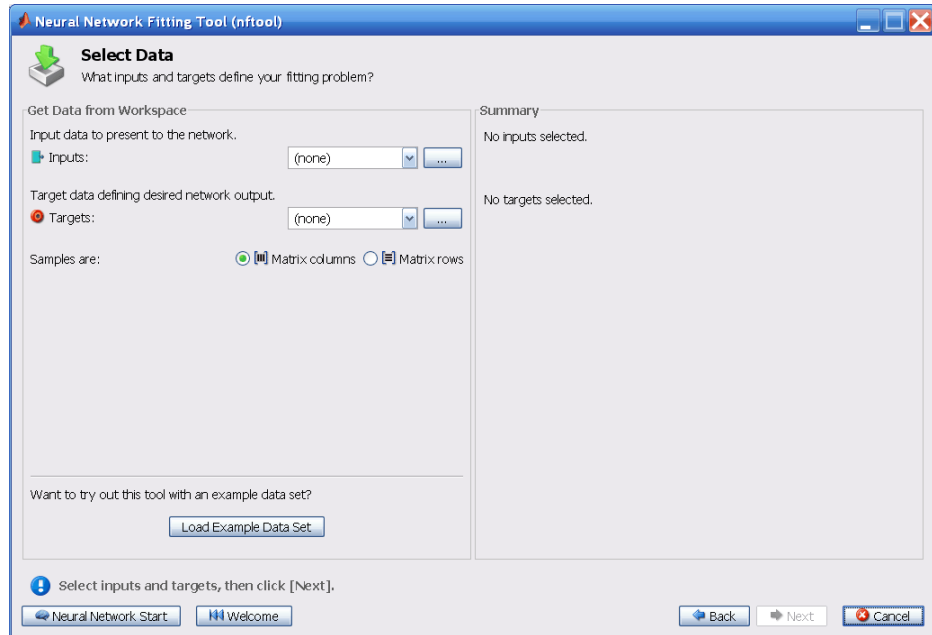

```
nstart
```

- 2 Click **Fitting Tool** to open the Neural Network Fitting Tool. (You can also use the command `nftool`.)

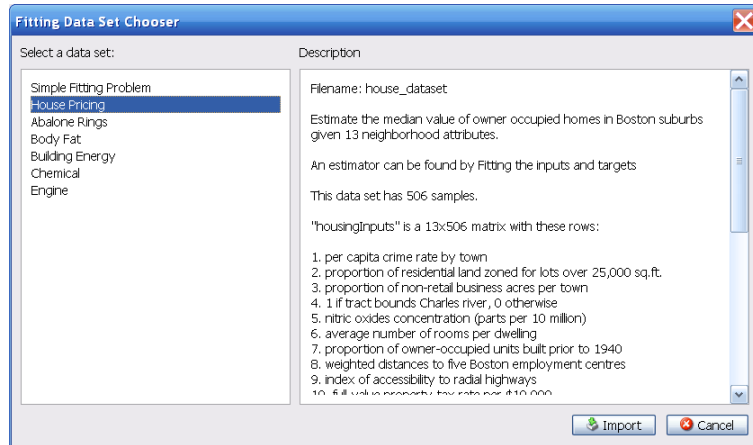

3 Click **Next** to proceed.

4 Click **Load Example Data Set** in the Select Data window. The Fitting Data Set Chooser window opens.

Note Use the **Inputs** and **Targets** options in the Select Data window when you need to load data from the MATLAB workspace.

5 Select **House Pricing**, and click **Import**. This returns you to the Select Data window.

6 Click **Next** to display the Validation and Test Data window, shown in the following figure.

The validation and test data sets are each set to 15% of the original data.

With these settings, the input vectors and target vectors will be randomly divided into three sets as follows:

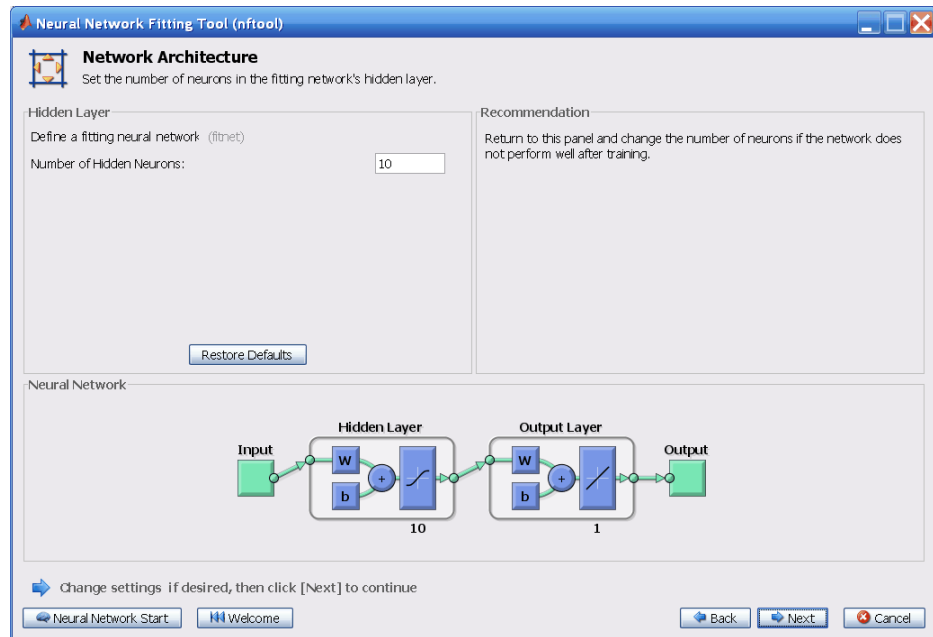

- 70% will be used for training.
- 15% will be used to validate that the network is generalizing and to stop training before overfitting.
- The last 15% will be used as a completely independent test of network generalization.

(See “Dividing the Data” in the User’s Guide for more discussion of the data division process.)

7 Click Next.

The standard network that is used for function fitting is a two-layer feedforward network, with a sigmoid transfer function in the hidden layer and a linear transfer function in the output layer. (This network is discussed in more detail in “Multilayer Networks and Backpropagation Training” and in Chapters 11-12 of [HDB96].) The default number of

hidden neurons is set to 10. You might want to increase this number later, if the network training performance is poor.

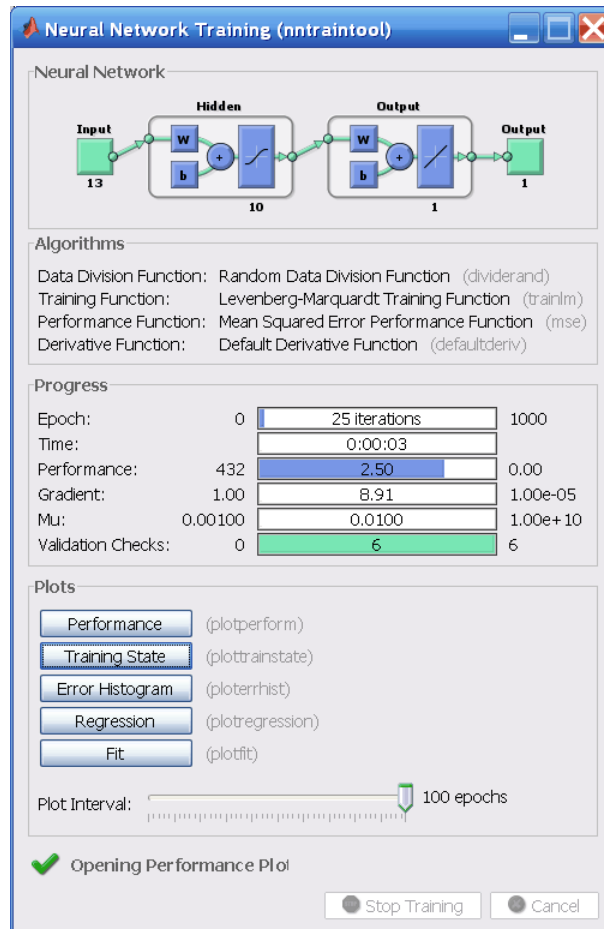

8 Click **Next**.

9 Click **Train**.

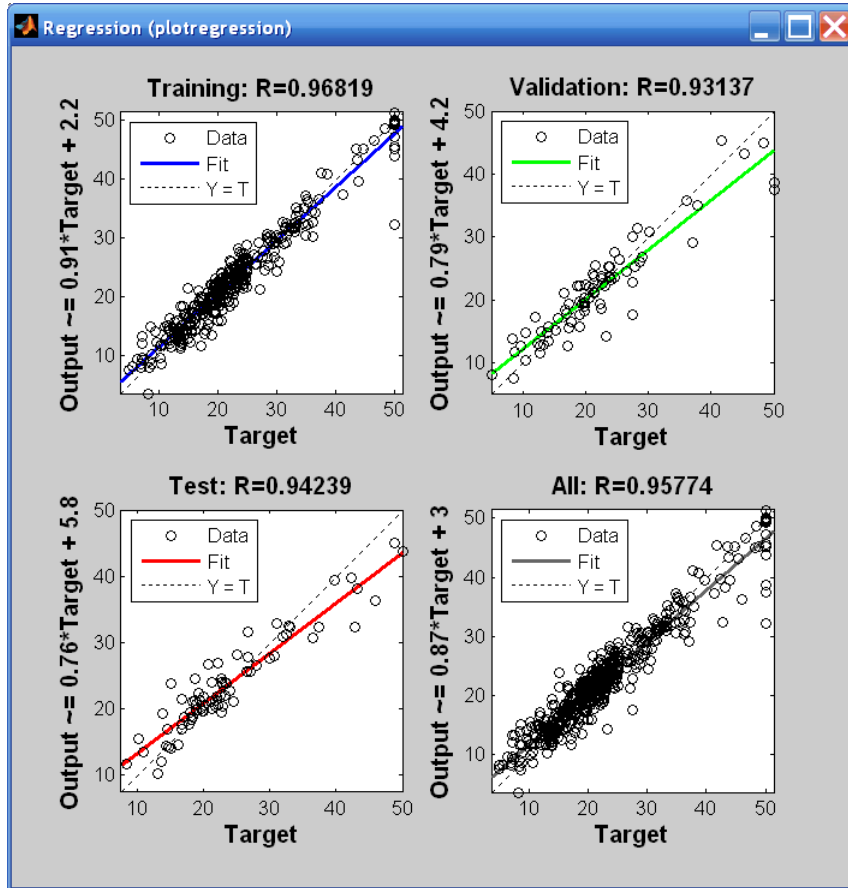

The training continued until the validation error failed to decrease for six iterations (validation stop).

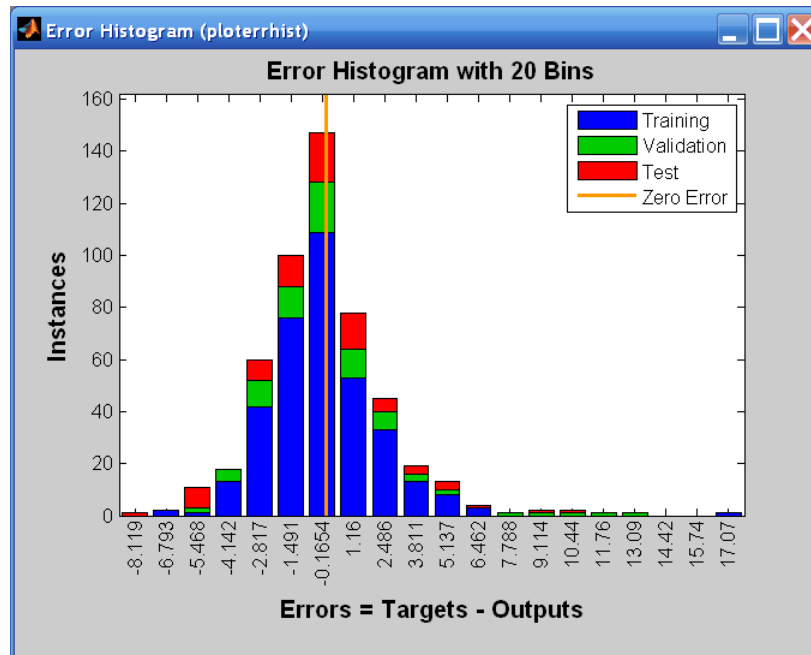

- 10** Under **Plots**, click **Regression**. This is used to validate the network performance.

The following regression plots display the network outputs with respect to targets for training, validation, and test sets. For a perfect fit, the data should fall along a 45 degree line, where the network outputs are equal to the targets. For this problem, the fit is reasonably good for all data sets, with R values in each case of 0.93 or above. If even more accurate results were required, you could retrain the network by clicking **Retrain** in `nftool`. This will change the initial weights and biases of the network,

and may produce an improved network after retraining. Other options are provided on the following pane.

- 11 View the error histogram to obtain additional verification of network performance. Under the **Plots** pane, click **Error Histogram**.

The blue bars represent training data, the green bars represent validation data, and the red bars represent testing data. The histogram can give you an indication of outliers, which are data points where the fit is significantly worse than the majority of data. In this case, you can see that while most errors fall between -5 and 5, there is a training point with an error of 17 and validation points with errors of 12 and 13. These outliers are also visible on the testing regression plot. The first corresponds to the point with a target of 50 and output near 33. It is a good idea to check the outliers to determine if the data is bad, or if those data points are different than the rest of the data set. If the outliers are valid data points, but are unlike the rest of the data, then the network is extrapolating for these points. You should collect more data that looks like the outlier points, and retrain the network.

12 Click **Next** in the Neural Network Fitting Tool to evaluate the network.

At this point, you can test the network against new data.

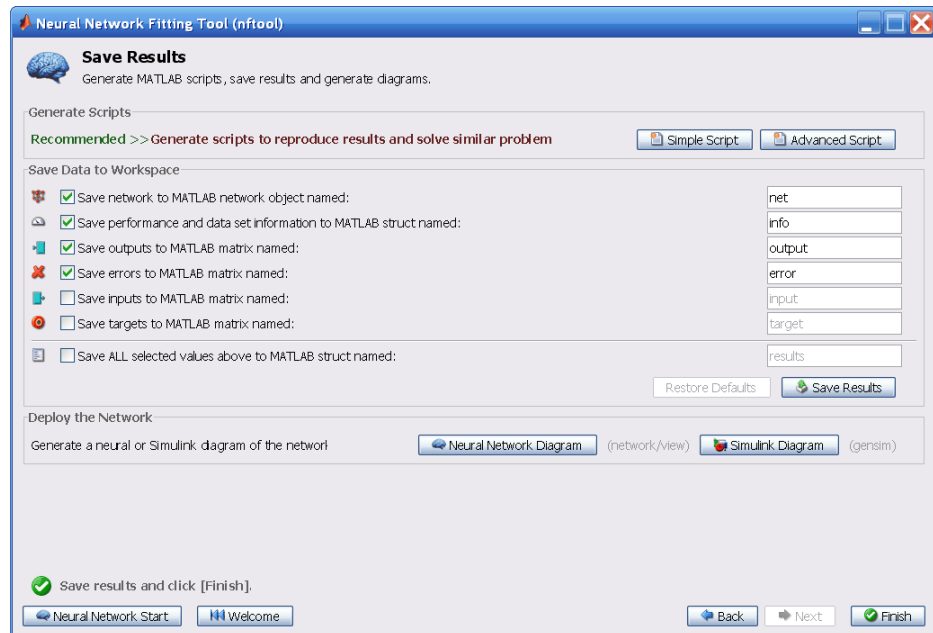

If you are dissatisfied with the network's performance on the original or new data, you can do one of the following:

- Train it again.
- Increase the number of neurons.
- Get a larger training data set.

If the performance on the training set is good, but the test set performance is significantly worse, which could indicate overfitting, then reducing the number of neurons can improve your results. If training performance is poor, then you may want to increase the number of neurons.

13 If you are satisfied with the network performance, click **Next**.

14 Use the buttons on this screen to generate scripts or to save your results.

- You can click **Simple Script** or **Advanced Script** to create MATLAB code that can be used to reproduce all of the previous steps from the command line. Creating MATLAB code can be helpful if you want to learn how to use the command-line functionality of the toolbox to customize the training process. In “Using Command-Line Functions” on page 1-21, you will investigate the generated scripts in more detail.
- You can also have the network saved as `net` in the workspace. You can perform additional tests on it or put it to work on new inputs.

15 When you have created the MATLAB code and saved your results, click **Finish**.

Using Command-Line Functions

The easiest way to learn how to use the command-line functionality of the toolbox is to generate scripts from the GUIs, and then modify them to customize the network training. As an example, look at the simple script that was created at step 14 of the previous section.

```
% Solve an Input-Output Fitting problem with a Neural Network
```

```
% Script generated by NFTOOL
%
% This script assumes these variables are defined:
%
%   houseInputs - input data.
%   houseTargets - target data.

inputs = houseInputs;
targets = houseTargets;

% Create a Fitting Network
hiddenLayerSize = 10;
net = fitnet(hiddenLayerSize);

% Set up Division of Data for Training, Validation, Testing
net.divideParam.trainRatio = 70/100;
net.divideParam.valRatio = 15/100;
net.divideParam.testRatio = 15/100;

% Train the Network
[net,tr] = train(net,inputs,targets);

% Test the Network
outputs = net(inputs);
errors = gsubtract(outputs,targets);
performance = perform(net,targets,outputs)

% View the Network
view(net)

% Plots
% Uncomment these lines to enable various plots.
%figure, plotperform(tr)
%figure, plottrainstate(tr)
%figure, plotfit(targets,outputs)
%figure, plotregression(targets,outputs)
%figure, ploterrhist(errors)
```

You can save the script, and then run it from the command line to reproduce the results of the previous GUI session. You can also edit the script to customize the training process. In this case, follow each step in the script.

- 1 The script assumes that the input vectors and target vectors are already loaded into the workspace. If the data are not loaded, you can load them as follows:

```
load house_dataset
inputs = houseInputs;
targets = houseTargets;
```

This data set is one of the sample data sets that is part of the toolbox (see “Sample Data Sets” on page 1-91). You can see a list of all available data sets by entering the command `help nndatasets`. The `load` command also allows you to load the variables from any of these data sets using your own variable names. For example, the command

```
[inputs,targets] = house_dataset;
```

will load the housing inputs into the array `inputs` and the housing targets into the array `targets`.

- 2 Create a network. The default network for function fitting (or regression) problems, `fitnet`, is a feedforward network with the default tan-sigmoid transfer function in the hidden layer and linear transfer function in the output layer. You assigned ten neurons (somewhat arbitrary) to the one hidden layer in the previous section. The network has one output neuron, because there is only one target value associated with each input vector.

```
hiddenLayerSize = 10;
net = fitnet(hiddenLayerSize);
```

Note More neurons require more computation, and they have a tendency to overfit the data when the number is set too high, but they allow the network to solve more complicated problems. More layers require more computation, but their use might result in the network solving complex problems more efficiently. To use more than one hidden layer, enter the hidden layer sizes as elements of an array in the `fitnet` command.

3 Set up the division of data.

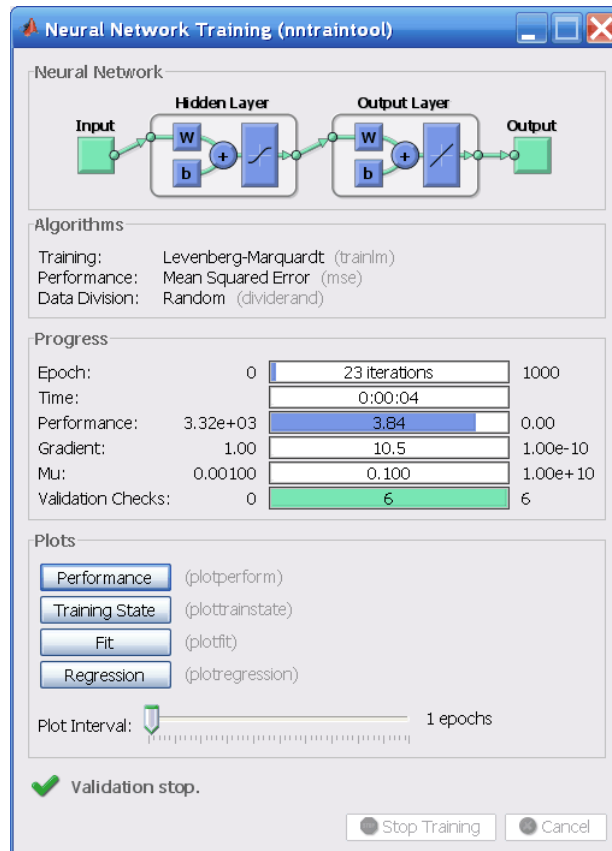

```
net.divideParam.trainRatio = 70/100;  
net.divideParam.valRatio = 15/100;  
net.divideParam.testRatio = 15/100;
```

With these settings, the input vectors and target vectors will be randomly divided, with 70% used for training, 15% for validation and 15% for testing. (See “Dividing the Data” in the User’s Guide for more discussion of the data division process.)

4 Train the network. The network uses the default Levenberg-Marquardt algorithm for training (`trainlm`). To train the network, enter:

```
[net,tr] = train(net,inputs,targets);
```

During training, the following training window opens. This window displays training progress and allows you to interrupt training at any point by clicking **Stop Training**.

This training stopped when the validation error increased for six iterations, which occurred at iteration 23. If you click **Performance** in the training window, a plot of the training errors, validation errors, and test errors appears, as shown in the following figure. In this example, the result is reasonable because of the following considerations:

- The final mean-square error is small.
- The test set error and the validation set error have similar characteristics.
- No significant overfitting has occurred by iteration 17 (where the best validation performance occurs).

- 5 Test the network. After the network has been trained, you can use it to compute the network outputs. The following code calculates the network outputs, errors and overall performance.

```
outputs = net(inputs);
errors = gsubtract(targets, outputs);
performance = perform(net, targets, outputs)
```

It is also possible to calculate the network performance only on the test set, by using the testing indices, which are located in the training record. (See Post-Training Analysis (Network Validation) in the User's Guide for a full description of the training record.)

```
tInd = tr.testInd;
tstOutputs = net(inputs(tInd));
tstPerform = perform(net, targets(tInd), tstOutputs)
```

- 6 Perform some analysis of the network response. If you click **Regression** in the training window, you can perform a linear regression between the network outputs and the corresponding targets.

The following figure shows the results.

The output tracks the targets very well for training, testing, and validation, and the R-value is over 0.95 for the total response. If even more accurate results were required, you could try any of these approaches:

- Reset the initial network weights and biases to new values with `init` and train again (see “Initializing Weights” (`init`)) in the User’s Guide.

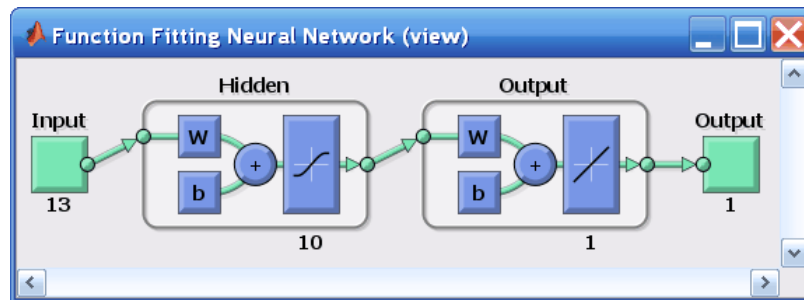

- Increase the number of hidden neurons.
- Increase the number of training vectors.
- Increase the number of input values, if more relevant information is available.
- Try a different training algorithm (see “Training Algorithms”) in the User’s Guide.

In this case, the network response is satisfactory, and you can now put the network to use on new inputs.

7 View the network diagram.

```
view(net)
```

This creates the following diagram of the network.

To get more experience in command-line operations, try some of these tasks:

- During training, open a plot window (such as the regression plot), and watch it animate.
- Plot from the command line with functions such as `plotfit`, `plotregression`, `plottrainstate` and `plotperform`. (For more information on using these functions, see their reference pages.)

Also, see the advanced script for more options, when training from the command line.

Recognizing Patterns

In addition to function fitting, neural networks are also good at recognizing patterns.

For example, suppose you want to classify a tumor as benign or malignant, based on uniformity of cell size, clump thickness, mitosis, etc. [MuAh94]. You have 699 example cases for which you have 9 items of data and the correct classification as benign or malignant.

As with function fitting, there are two ways to solve this problem:

- Use the `nprtool` GUI, as described in “Using the Neural Network Pattern Recognition Tool” on page 1-31.
- Use a command-line solution, as described in “Using Command-Line Functions” on page 1-60.

It is generally best to start with the GUI, and then to use the GUI to automatically generate command-line scripts. Before using either method, the first step is to define the problem by selecting a data set. The next section describes the data format.

Defining a Problem

To define a pattern recognition problem, arrange a set of Q input vectors as columns in a matrix. Then arrange another set of Q target vectors so that they indicate the classes to which the input vectors are assigned (see “Data Structures” for a detailed description of data formatting for static and time series data). There are two approaches to creating the target vectors.

One approach can be used when there are only two classes; you set each scalar target value to either 1 or 0, indicating which class the corresponding input belongs to. For instance, you can define the exclusive-or classification problem as follows:

```
inputs = [0 1 0 1; 0 0 1 1];  
targets = [0 1 0 1];
```

Alternately, target vectors can have N elements, where for each target vector, one element is 1 and the others are 0. This defines a problem where inputs are to be classified into N different classes. For example, the following lines show how to define a classification problem that divides the corners of a 5-by-5-by-5 cube into three classes:

- The origin (the first input vector) in one class
- The corner farthest from the origin (the last input vector) in a second class
- All other points in a third class

```
inputs = [0 0 0 0 5 5 5 5; 0 0 5 5 0 0 5 5; 0 5 0 5 0 5 0 5];  
targets = [1 0 0 0 0 0 0 0; 0 1 1 1 1 1 1 0; 0 0 0 0 0 0 0 1];
```

Classification problems involving only two classes can be represented using either format. The targets can consist of either scalar 1/0 elements or two-element vectors, with one element being 1 and the other element being 0.

The next section demonstrates how to train a network to recognize patterns, using the neural network pattern recognition tool GUI, `nprtool`. This example uses the cancer data set provided with the toolbox. This data set consists of 699 nine-element input vectors and two-element target vectors. There are two elements in each target vector, because there are two categories (benign or malignant) associated with each input vector.

Using the Neural Network Pattern Recognition Tool

- 1 If needed, open the Neural Network Start GUI with this command:

```
nnstart
```

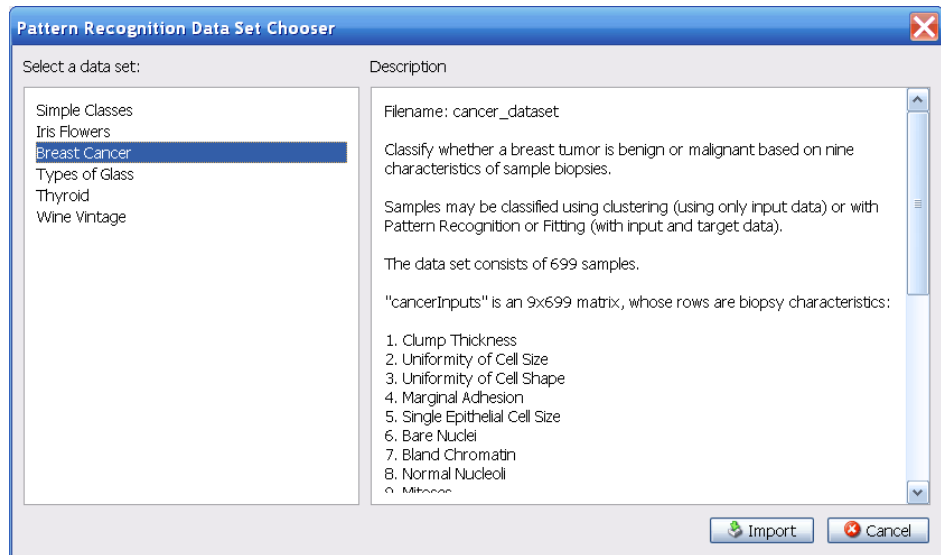

- 2 Click **Pattern Recognition Tool** to open the Neural Network Pattern Recognition Tool. (You can also use the command `nprtool`.)

3 Click **Next** to proceed. The Select Data window opens.

4 Click **Load Example Data Set**. The Pattern Recognition Data Set Chooser window opens.

5 Select **Breast Cancer** and click **Import**. You return to the Select Data window.

6 Click **Next** to continue to the Validation and Test Data window.

Validation and test data sets are each set to 15% of the original data. With these settings, the input vectors and target vectors will be randomly divided into three sets as follows:

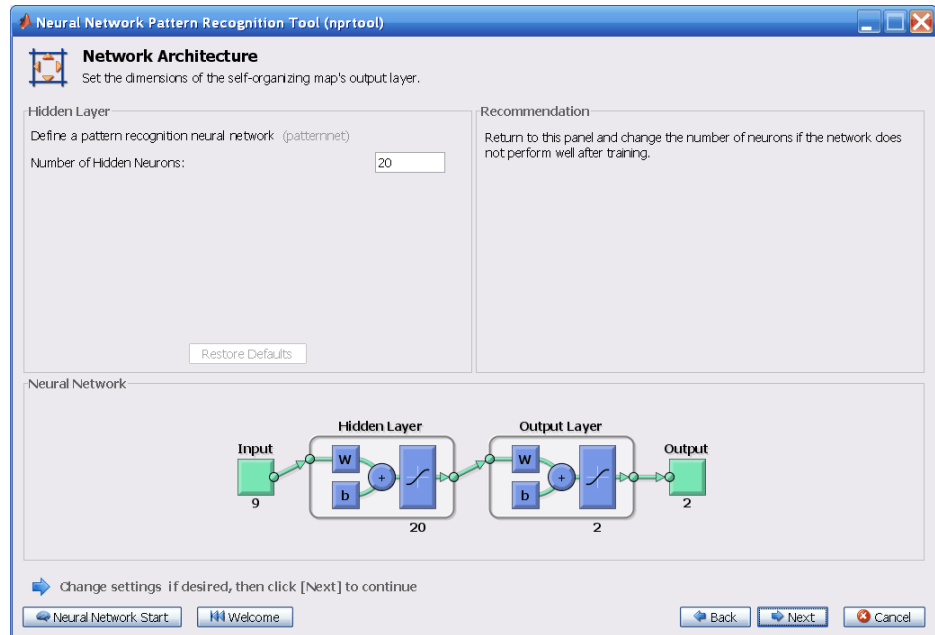

- 70% are used for training.
- 15% are used to validate that the network is generalizing and to stop training before overfitting.
- The last 15% are used as a completely independent test of network generalization.

(See “Dividing the Data” in the User’s Guide for more discussion of the data division process.)

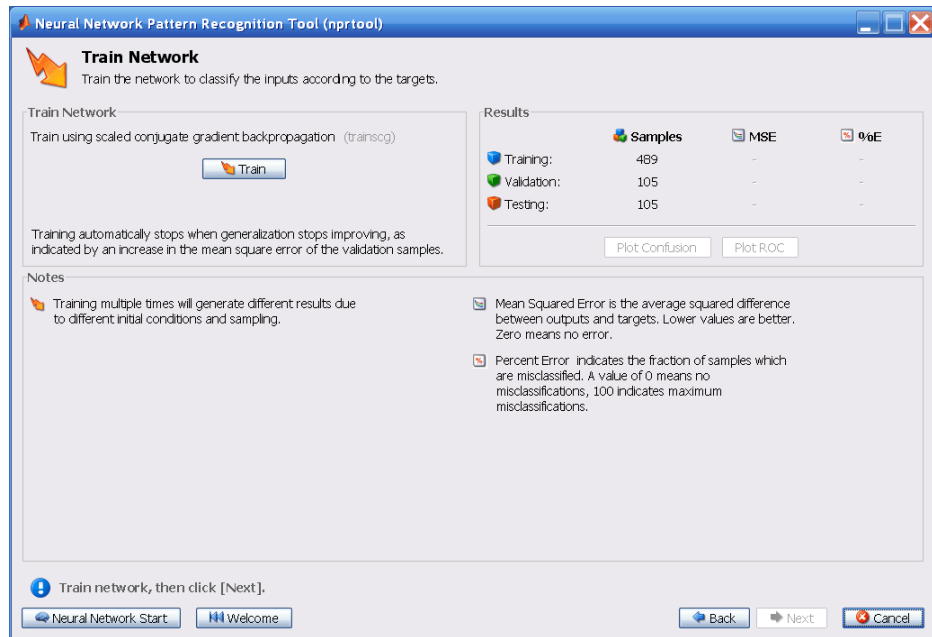

7 Click Next.

The standard network that is used for pattern recognition is a two-layer feedforward network, with sigmoid transfer functions in both the hidden layer and the output layer. This network architecture is discussed in more detail in “Network Objects, Data and Training Styles”, “Multilayer

Networks and Backpropagation Training” in the User’s Guide, and in Chapters 11-12 of [HDB96]. The default number of hidden neurons is set to 10. You might want to come back and increase this number if the network does not perform as well as you expect. The number of output neurons is set to 2, which is equal to the number of elements in the target vector (the number of categories).

8 Click **Next**.

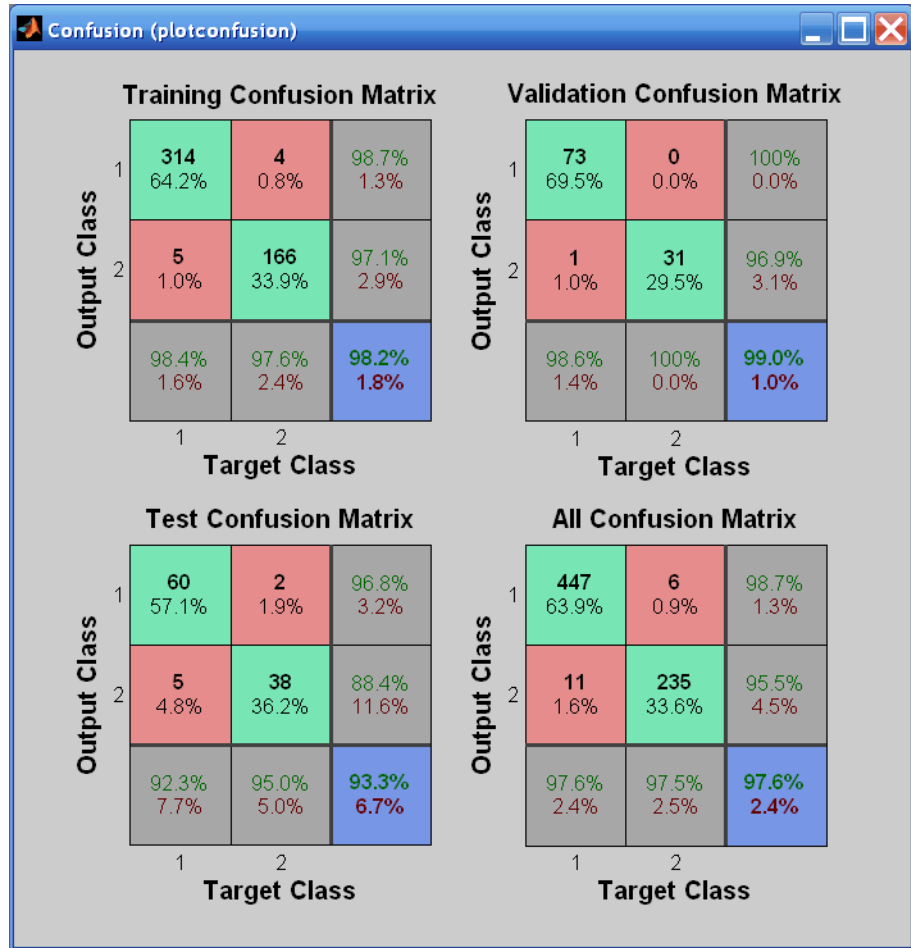

9 Click **Train**.

The training continues for 55 iterations.

- 10 Under the **Plots** pane, click **Confusion** in the Neural Network Pattern Recognition Tool.

The next figure shows the confusion matrices for training, testing, and validation, and the three kinds of data combined. The network outputs are very accurate, as you can see by the high numbers of correct responses in the green squares and the low numbers of incorrect responses in the red squares. The lower right blue squares illustrate the overall accuracies.

- Plot the Receiver Operating Characteristic (ROC) curve. Under the **Plots** pane, click **Receiver Operating Characteristic** in the Neural Network Pattern Recognition Tool.

The colored lines in each axis represent the ROC curves. The *ROC curve* is a plot of the true positive rate (sensitivity) versus the false positive rate (1 - specificity) as the threshold is varied. A perfect test would show points in the upper-left corner, with 100% sensitivity and 100% specificity. For this problem, the network performs very well.

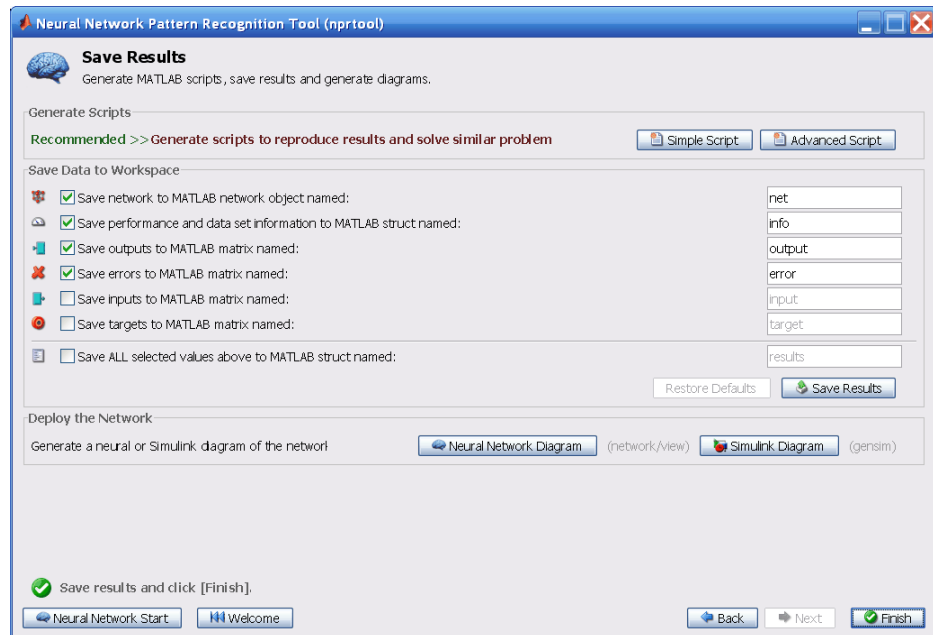

- 12** In the Neural Network Pattern Recognition Tool, click **Next** to evaluate the network.

At this point, you can test the network against new data.

If you are dissatisfied with the network's performance on the original or new data, you can train it again, increase the number of neurons, or perhaps get a larger training data set. If the performance on the training set is good, but the test set performance is significantly worse, which could indicate overfitting, then reducing the number of neurons can improve your results.

13 When you are satisfied with the network performance, click **Next**.

14 Use the buttons on this screen to save your results.

- You can click **Simple Script** or **Advanced Script** to create MATLAB code that can be used to reproduce all of the previous steps from the command line. Creating MATLAB code can be helpful if you want to learn how to use the command-line functionality of the toolbox to customize the training process. In “Using Command-Line Functions” on page 1-41, you will investigate the generated scripts in more detail.
- You can also save the network as `net` in the workspace. You can perform additional tests on it or put it to work on new inputs.

15 When you have saved your results, click **Finish**.

Using Command-Line Functions

The easiest way to learn how to use the command-line functionality of the toolbox is to generate scripts from the GUIs, and then modify them to customize the network training. As an example, let’s look at the simple script that was created at step 14 of the previous section.

```
% Solve a Pattern Recognition Problem with a Neural Network
% Script generated by NPRTOOL
%
% This script assumes these variables are defined:
%
%   cancerInputs - input data.
%   cancerTargets - target data.

inputs = cancerInputs;
inputs = cancerTargets;

% Create a Pattern Recognition Network
hiddenLayerSize = 10;
net = patternnet(hiddenLayerSize);

% Set up Division of Data for Training, Validation, Testing
net.divideParam.trainRatio = 70/100;
net.divideParam.valRatio = 15/100;
net.divideParam.testRatio = 15/100;

% Train the Network
[net,tr] = train(net,inputs,targets);

% Test the Network
outputs = net(inputs);
errors = gsubtract(targets,outputs);
performance = perform(net,targets,outputs)

% View the Network
view(net)

% Plots
% Uncomment these lines to enable various plots.
%figure, plotperform(tr)
%figure, plottrainstate(tr)
%figure, plotconfusion(targets,outputs)
%figure, ploterrhist(errors)
```

You can save the script, and then run it from the command line to reproduce the results of the previous GUI session. You can also edit the script to customize the training process. In this case, follow each step in the script.

- 1 The script assumes that the input vectors and target vectors are already loaded into the workspace. If the data are not loaded, you can load them as follows:

```
load cancer_dataset
inputs = cancerInputs;
targets = cancerTargets;
```

- 2 Create the network. The default network for function fitting (or regression) problems, `patternnet`, is a feedforward network with the default tan-sigmoid transfer functions in both the hidden and output layers. You assigned ten neurons (somewhat arbitrary) to the one hidden layer in the previous section.
 - The network has two output neurons, because there are two target values (categories) associated with each input vector.
 - Each output neuron represents a category.
 - When an input vector of the appropriate category is applied to the network, the corresponding neuron should produce a 1, and the other neurons should output a 0.

To create the network, enter these commands:

```
hiddenLayerSize = 10;
net = patternnet(hiddenLayerSize);
```

Note The choice of network architecture for pattern recognition problems follows similar guidelines to function fitting problems. More neurons require more computation, and they have a tendency to overfit the data when the number is set too high, but they allow the network to solve more complicated problems. More layers require more computation, but their use might result in the network solving complex problems more efficiently. To use more than one hidden layer, enter the hidden layer sizes as elements of an array in the `patternnet` command.

3 Set up the division of data.

```
net.divideParam.trainRatio = 70/100;  
net.divideParam.valRatio = 15/100;  
net.divideParam.testRatio = 15/100;
```

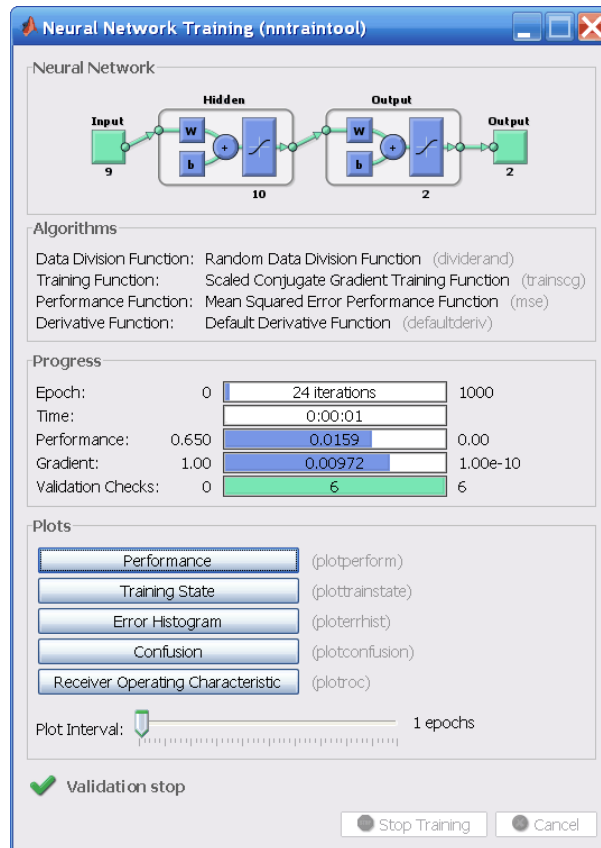

With these settings, the input vectors and target vectors will be randomly divided, with 70% used for training, 15% for validation and 15% for testing.

(See “Dividing the Data” in the User’s Guide for more discussion of the data division process.)

4 Train the network. The pattern recognition network uses the default Scaled Conjugate Gradient (`trainscg`) algorithm for training. To train the network, enter this command:

```
[net,tr] = train(net,inputs,targets);
```

During training, as in function fitting, the training window opens. This window displays training progress. To interrupt training at any point, click **Stop Training**.

This training stopped when the validation error increased for six iterations, which occurred at iteration 24.

- 5 Test the network. After the network has been trained, you can use it to compute the network outputs. The following code calculates the network outputs, errors and overall performance.

```
outputs = net(inputs);
errors = gsubtract(targets,outputs);
performance = perform(net,targets,outputs)
```

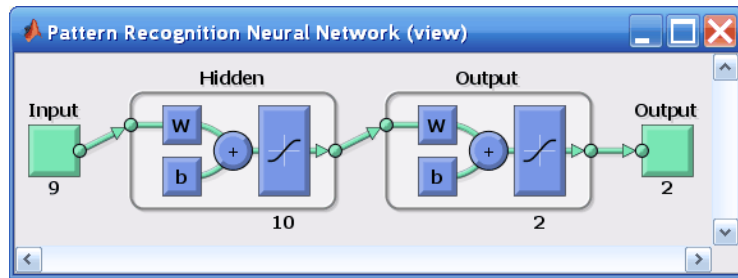

It is also possible to calculate the network performance only on the test set, by using the testing indices, which are located in the training record.

```
tInd = tr.testInd;  
tstOutputs = net(inputs(tInd));  
tstPerform = perform(net,targets(tInd),tstOutputs)
```

- 6 View the network diagram.

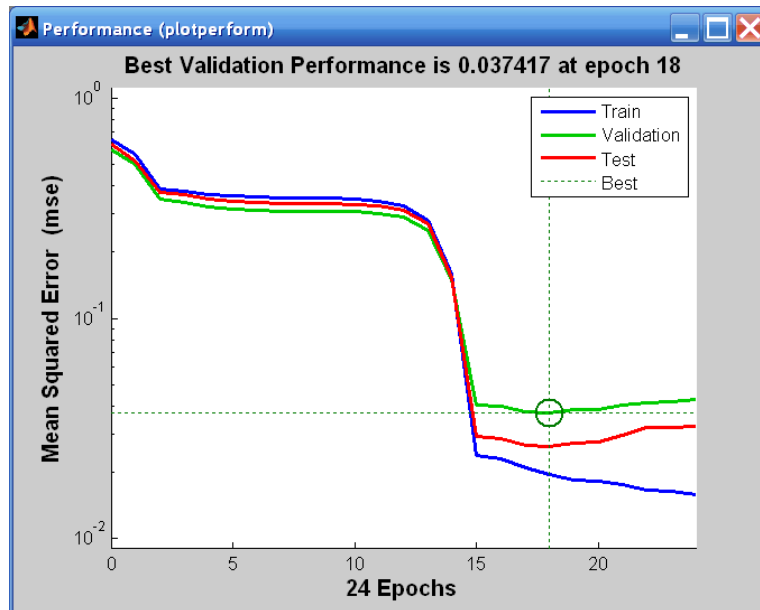

```
view(net)
```

This creates the following diagram of the network.

- 7 Plot the training, validation, and test performance.

```
figure, plotperform(tr)
```

- 8 Use the `plotconfusion` function to plot the confusion matrix. It shows the various types of errors that occurred for the final trained network.

```
figure, plotconfusion(targets, outputs)
```

The next figure shows the results.

The diagonal cells show the number of cases that were correctly classified, and the off-diagonal cells show the misclassified cases. The blue cell in the bottom right shows the total percent of correctly classified cases (in green) and the total percent of misclassified cases (in red). The results show very good recognition. If you needed even more accurate results, you could try any of the following approaches:

- Reset the initial network weights and biases to new values with `init` and train again.
- Increase the number of hidden neurons.
- Increase the number of training vectors.
- Increase the number of input values, if more relevant information is available.
- Try a different training algorithm (see “Training Algorithms” in the User’s Guide).

In this case, the network response is satisfactory, and you can now put the network to use on new inputs.

To get more experience in command-line operations, here are some tasks you can try:

- During training, open a plot window (such as the confusion plot), and watch it animate.
- Plot from the command line with functions such as `plotroc` and `plottrainstate`.

Also, see the advanced script for more options, when training from the command line.

Clustering Data

Clustering data is another excellent application for neural networks. This process involves grouping data by similarity. For example, you might perform:

- Market segmentation by grouping people according to their buying patterns
- Data mining by partitioning data into related subsets
- Bioinformatic analysis by grouping genes with related expression patterns

Suppose that you want to cluster flower types according to petal length, petal width, sepal length, and sepal width [MuAh94]. You have 150 example cases for which you have these four measurements.

As with function fitting and pattern recognition, there are two ways to solve this problem:

- Use the `nctool` GUI, as described in “Using the Neural Network Clustering Tool” on page 1-51.
- Use a command-line solution, as described in “Using Command-Line Functions” on page 1-60.

Defining a Problem

To define a clustering problem, simply arrange Q input vectors to be clustered as columns in an input matrix (see “Data Structures” in the User’s Guide for a detailed description of data formatting for static and time series data). For instance, you might want to cluster this set of 10 two-element vectors:

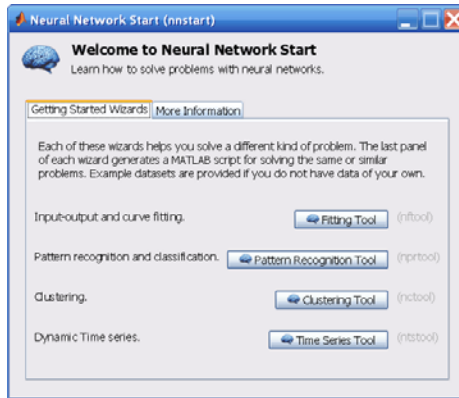

```
inputs = [7 0 6 2 6 5 6 1 0 1; 6 2 5 0 7 5 5 1 2 2]
```

The next section demonstrates how to train a network using the `nctool` GUI.

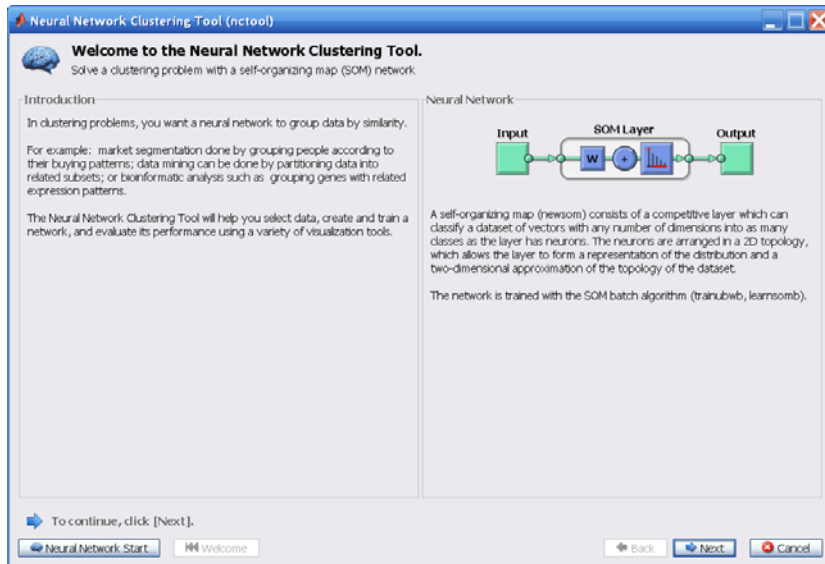

Using the Neural Network Clustering Tool

- 1 If needed, open the Neural Network Start GUI with this command:

```
nnstart
```

- 2 Click **Clustering Tool** to open the Neural Network Clustering Tool. (You can also use the command `nctool`.)

3 Click **Next**. The Select Data window appears.

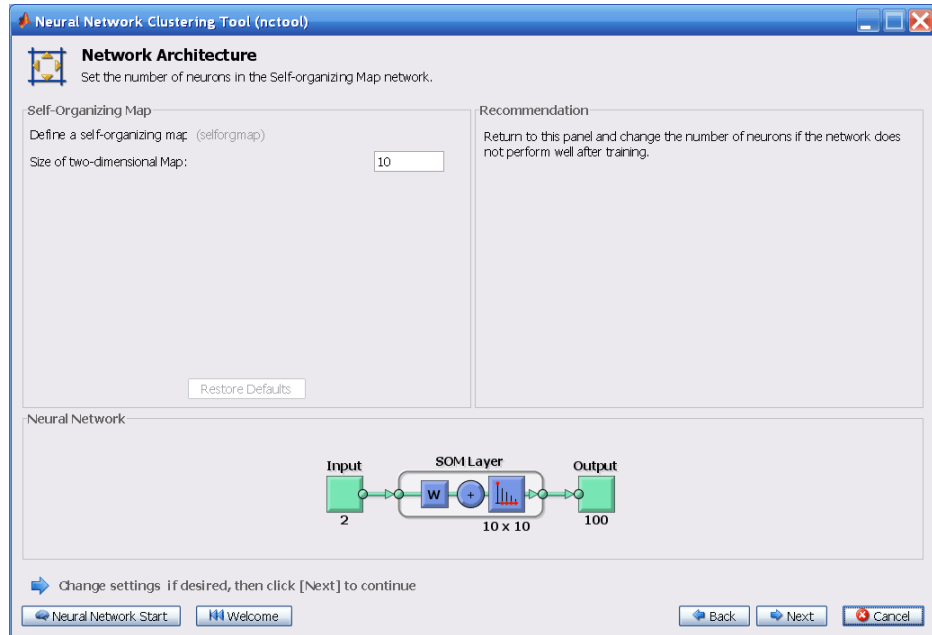

4 Click **Load Example Data Set**. The Clustering Data Set Chooser window appears.

- 5 In this window, select **Simple Clusters**, and click **Import**. You return to the Select Data window.
- 6 Click **Next** to continue to the Network Size window, shown in the following figure.

For clustering problems, the self-organizing feature map (SOM) is the most commonly used network, because after the network has been trained, there are many visualization tools that can be used to analyze the resulting clusters. This network has one layer, with neurons organized in a grid. (For more information on the SOM, see “Self-Organizing Feature Maps” in the User’s Guide and Chapter 14 of [HDB96].) When creating the network, you specify the numbers of rows and columns in the grid. Here, the number of rows and columns is set to 10. The total number of neurons is 100. You can change this number in another run if you want.

7 Click **Next**. The Train Network window appears.

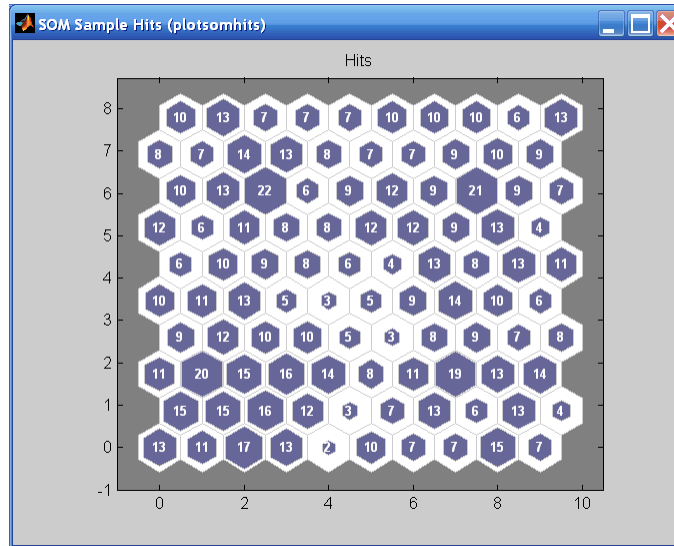

8 Click **Train**.

The training runs for the maximum number of epochs, which is 200.

- 9 For SOM training, the weight vector associated with each neuron moves to become the center of a cluster of input vectors. In addition, neurons that are adjacent to each other in the topology should also move close to each other in the input space, therefore it is possible to visualize a high-dimensional inputs space in the two dimensions of the network topology. Investigate some of the visualization tools for the SOM. Under the **Plots** pane, click **SOM Sample Hits**.

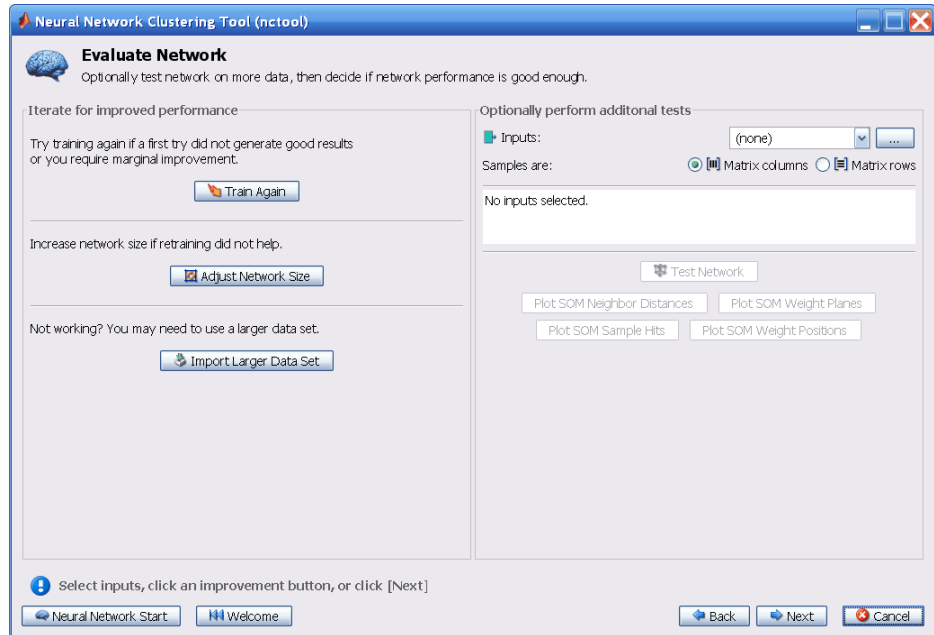

The default topology of the SOM is hexagonal. This figure shows the neuron locations in the topology, and indicates how many of the training data are associated with each of the neurons (cluster centers). The topology is a 10-by-10 grid, so there are 100 neurons. The maximum number of hits associated with any neuron is 22. Thus, there are 22 input vectors in that cluster.

- 10** You can also visualize the SOM by displaying weight planes (also referred to as *component planes*). Click **SOM Weight Planes** in the Neural Network Clustering Tool.

This figure shows a weight plane for each element of the input vector (two, in this case). They are visualizations of the weights that connect each input to each of the neurons. (Darker colors represent larger weights.) If the connection patterns of two inputs were very similar, you can assume that the inputs are highly correlated. In this case, input 1 has connections that are very different than those of input 2.

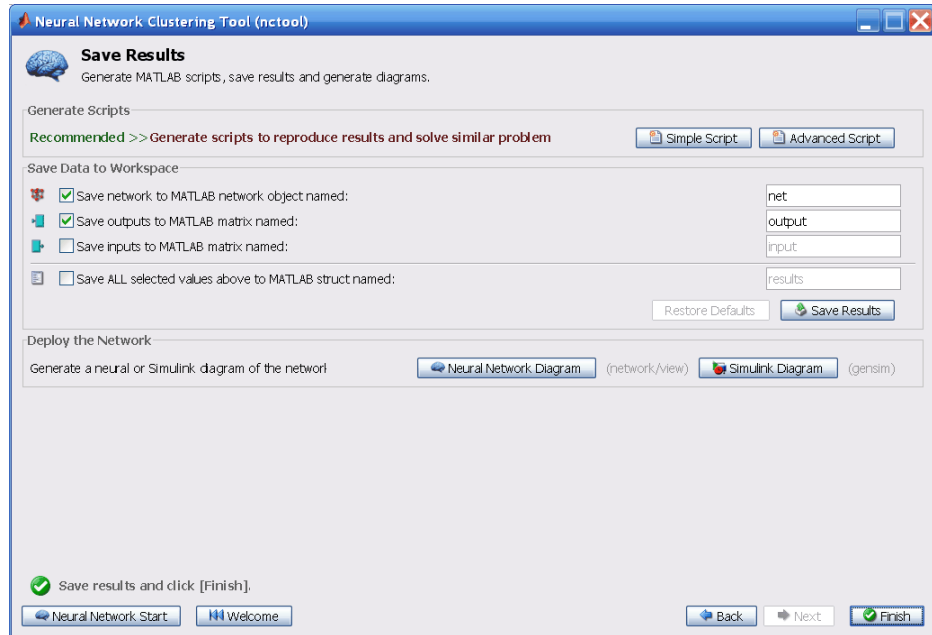

- 11 In the Neural Network Clustering Tool, click **Next** to evaluate the network.

At this point you can test the network against new data.

If you are dissatisfied with the network's performance on the original or new data, you can increase the number of neurons, or perhaps get a larger training data set.

- 12** When you are satisfied with the network performance, click **Next**.
- 13** Use the buttons on this screen to save your results.

- You can click **Simple Script** or **Advanced Script** to create MATLAB code that can be used to reproduce all of the previous steps from the command line. Creating MATLAB code can be helpful if you want to learn how to use the command-line functionality of the toolbox to customize the training process. In “Using Command-Line Functions” on page 1-60, you will investigate the generated scripts in more detail.
- You can also save the network as `net` in the workspace. You can perform additional tests on it or put it to work on new inputs.

14 When you have generated scripts and saved your results, click **Finish**.

Using Command-Line Functions

The easiest way to learn how to use the command-line functionality of the toolbox is to generate scripts from the GUIs, and then modify them to customize the network training. As an example, look at the simple script that was created in step 14 of the previous section.

```
% Solve a Clustering Problem with a Self-Organizing Map
% Script generated by NCTOOL
```

```
%  
% This script assumes these variables are defined:  
%  
% simpleclusterInputs - input data.  
  
inputs = simpleclusterInputs;  
  
% Create a Self-Organizing Map  
dimension1 = 10;  
dimension2 = 10;  
net = selforgmap([dimension1 dimension2]);  
  
% Train the Network  
[net,tr] = train(net,inputs);  
  
% Test the Network  
outputs = net(inputs);  
  
% View the Network  
view(net)  
  
% Plots  
% Uncomment these lines to enable various plots.  
%figure, plotsomtop(net)  
%figure, plotsomnc(net)  
%figure, plotsomnd(net)  
%figure, plotsomplanes(net)  
%figure, plotsomhits(net,inputs)  
%figure, plotsompos(net,inputs)
```

You can save the script, and then run it from the command line to reproduce the results of the previous GUI session. You can also edit the script to customize the training process. In this case, let's follow each of the steps in the script.

- 1 The script assumes that the input vectors are already loaded into the workspace. To demonstrate the command-line operations, you can use a different data set than you used for the GUI operation. Use the flower data set as an example. The iris data set consists of 150 four-element input vectors.

```
load iris_dataset
inputs = irisInputs;
```

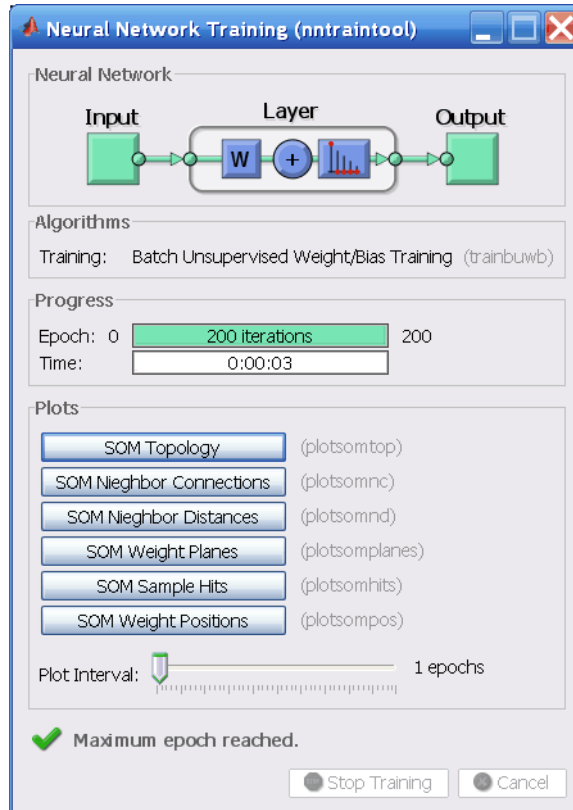

- 2** Create a network. For this example, you use a self-organizing map (SOM). This network has one layer, with the neurons organized in a grid. (For more information, see “Self-Organizing Feature Maps” in the User’s Guide and Chapter 14 of [HDB96].) When creating the network with `selforgmap`, you specify the number of rows and columns in the grid:

```
dimension1 = 10;
dimension2 = 10;
net = selforgmap([dimension1 dimension2]);
```

- 3** Train the network. The SOM network uses the default batch SOM algorithm for training.

```
[net,tr] = train(net,inputs);
```

- 4** During training, the training window opens and displays the training progress. To interrupt training at any point, click **Stop Training**.

- 5** Test the network. After the network has been trained, you can use it to compute the network outputs.

```
outputs = net(inputs);
```

- 6** View the network diagram.

```
view(net)
```

This creates the following diagram of the network.

- 7 For SOM training, the weight vector associated with each neuron moves to become the center of a cluster of input vectors. In addition, neurons that are adjacent to each other in the topology should also move close to each other in the input space, therefore it is possible to visualize a high-dimensional inputs space in the two dimensions of the network topology. The default SOM topology is hexagonal; to view it, enter the following commands.

```
figure, plotsomtop(net)
```

In this figure, each of the hexagons represents a neuron. The grid is 10-by-10, so there are a total of 100 neurons in this network. There are four elements in each input vector, so the input space is four-dimensional. The weight vectors (cluster centers) fall within this space.

Because this SOM has a two-dimensional topology, you can visualize in two dimensions the relationships among the four-dimensional cluster centers. One visualization tool for the SOM is the *weight distance matrix* (also called the *U-matrix*).

- 8 To view the U-matrix, click **SOM Neighbor Distances** in the training window.

In this figure, the blue hexagons represent the neurons. The red lines connect neighboring neurons. The colors in the regions containing the red lines indicate the distances between neurons. The darker colors represent larger distances, and the lighter colors represent smaller distances. A band of dark segments crosses from the lower-center region to the upper-right region. The SOM network appears to have clustered the flowers into two distinct groups.

To get more experience in command-line operations, try some of these tasks:

- During training, open a plot window (such as the SOM weight position plot) and watch it animate.
- Plot from the command line with functions such as `plotsomhits`, `plotsomnc`, `plotsomnd`, `plotsomplanes`, `plotsompos`, and `plotsomtop`. (For more information on using these functions, see their reference pages.)

Also, see the advanced script for more options, when training from the command line.

Time Series Prediction

Dynamic neural networks, such as those described in “Dynamic Networks” in the User’s Guide are good at time series prediction.

Suppose, for instance, that you have data from a pH neutralization process [McHs72]. You want to design a network that can predict the pH of a solution in a tank from past values of the pH and past values of the acid and base flow rate into the tank. You have a total of 2001 time steps for which you have those series.

You can solve this problem in two ways:

- Use a graphical user interface, `ntstool`, as described in “Using the Neural Network Time Series Tool” on page 1-69.
- Use command-line functions, as described in “Using Command-Line Functions” on page 1-81.

It is generally best to start with the GUI, and then to use the GUI to automatically generate command-line scripts. Before using either method, the first step is to define the problem by selecting a data set. Each GUI has access to many sample data sets that you can use to experiment with the toolbox. If you have a specific problem that you want to solve, you can load your own data into the workspace. The next section describes the data format.

Defining a Problem

To define a time series problem for the toolbox, arrange a set of TS input vectors as columns in a cell array. Then, arrange another set of TS target vectors (the correct output vectors for each of the input vectors) into a second cell array (see “Data Structures” in the User’s Guide for a detailed description of data formatting for static and time series data). However, there are cases in which you only need to have a target data set. For example, you can define the following time series problem, in which you want to use previous values of a series to predict the next value:

```
targets = {1 2 3 4 5};
```

The next section demonstrates how to train a network to fit a time series data set, using the neural network time series tool GUI, `ntstool`. This example uses the pH neutralization data set provided with the toolbox.

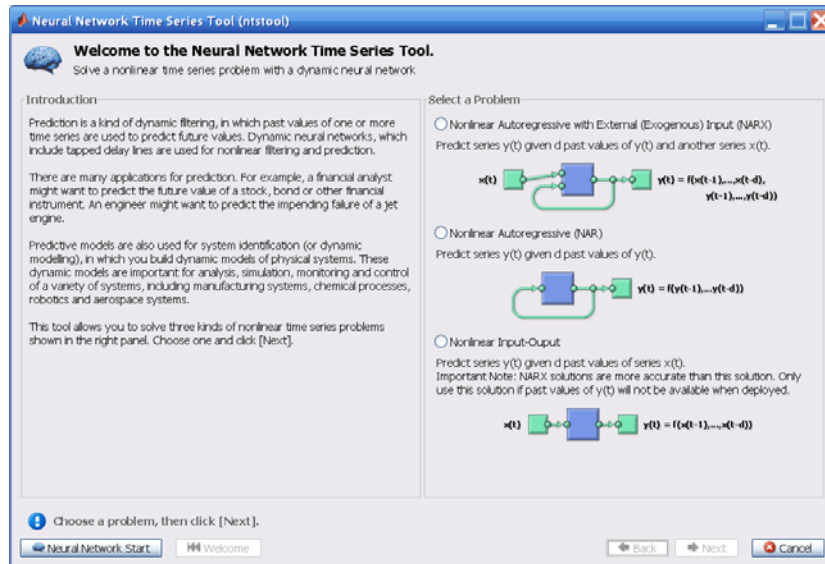

Using the Neural Network Time Series Tool

- 1 If needed, open the Neural Network Start GUI with this command:

```
nnstart
```

- 2 Click **Time Series Tool** to open the Neural Network Time Series Tool. (You can also use the command `ntstool`.)

Notice that this opening pane is different than the opening panes for the other GUIs. This is because `ntstool` can be used to solve three different kinds of time series problems.

- In the first type of time series problem, you would like to predict future values of a time series $y(t)$ from past values of that time series and past values of a second time series $x(t)$. This form of prediction is called nonlinear autoregressive with exogenous (external) input, or NARX (see “NARX Network” (`narxnet`, `closeloop`) in the User’s Guide), and can be written as follows:

$$y(t) = f(y(t-1), \dots, y(t-d), x(t-1), \dots, (t-d))$$

This model could be used to predict future values of a stock or bond, based on such economic variables as unemployment rates, GDP, etc. It could also be used for system identification, in which models are developed to represent dynamic systems, such as chemical processes, manufacturing systems, robotics, aerospace vehicles, etc.

- In the second type of time series problem, there is only one series involved. The future values of a time series $y(t)$ are predicted only from past values of that series. This form of prediction is called nonlinear autoregressive, or NAR, and can be written as follows:

$$y(t) = f(y(t-1), \dots, y(t-d))$$

This model could also be used to predict financial instruments, but without the use of a companion series.

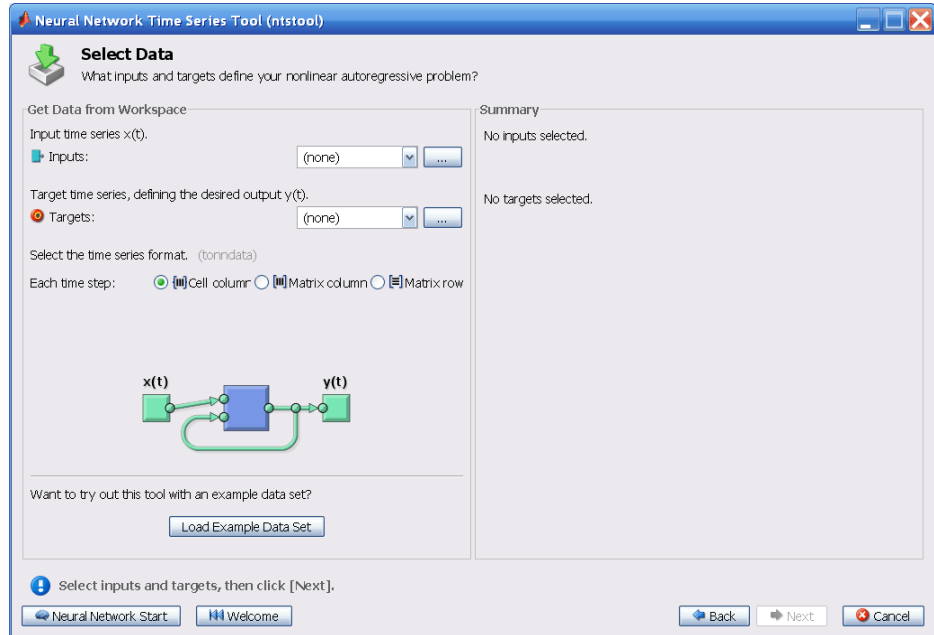

- The third time series problem is similar to the first type, in that two series are involved, an input series $x(t)$ and an output/target series $y(t)$. Here you want to predict values of $y(t)$ from previous values of $x(t)$, but without knowledge of previous values of $y(t)$. This input/output model can be written as follows:

$$y(t) = f(x(t-1), \dots, x(t-d))$$

The NARX model will provide better predictions than this input-output model, because it uses the additional information contained in the previous values of $y(t)$. However, there may be some applications in which the previous values of $y(t)$ would not be available. Those are the

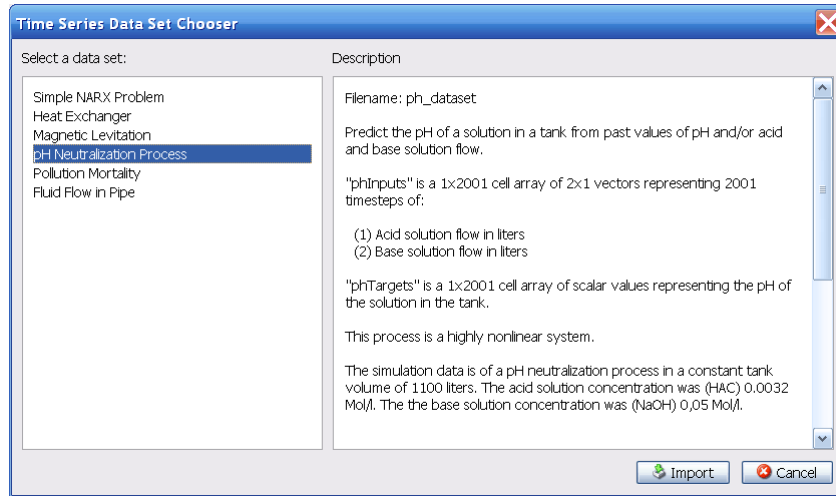

only cases where you would want to use the input-output model instead of the NARX model.

- 3 For this demonstration, select the NARX model and click **Next** to proceed.

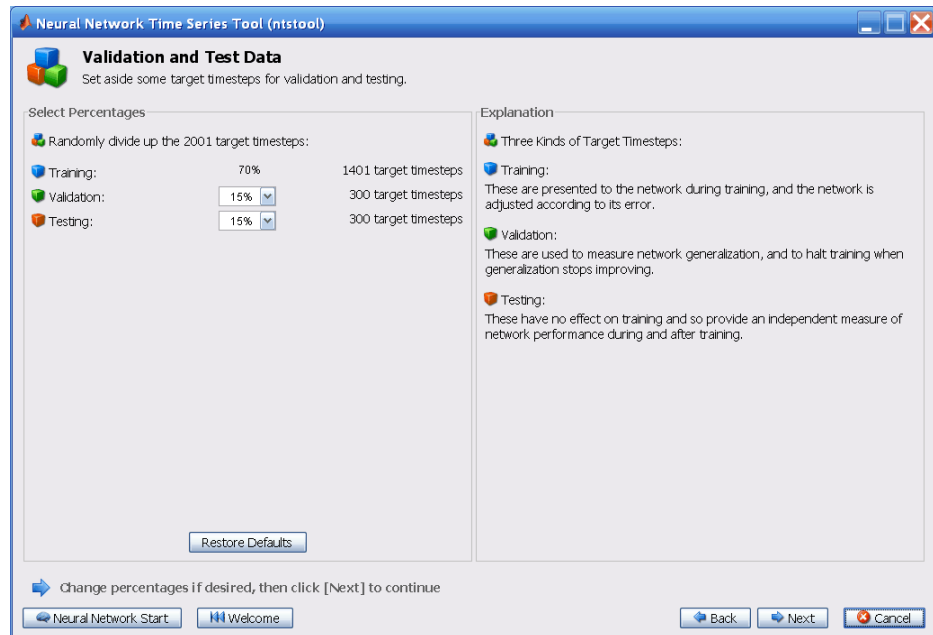

- 4 Click **Load Example Data Set** in the Select Data window. The Time Series Data Set Chooser window opens.

Note Use the **Inputs** and **Targets** options in the Select Data window when you need to load data from the MATLAB workspace.

- 5 Select **pH Neutralization Process**, and click **Import**. This returns you to the Select Data window.
- 6 Click **Next** to open the Validation and Test Data window, shown in the following figure.

The validation and test data sets are each set to 15% of the original data.

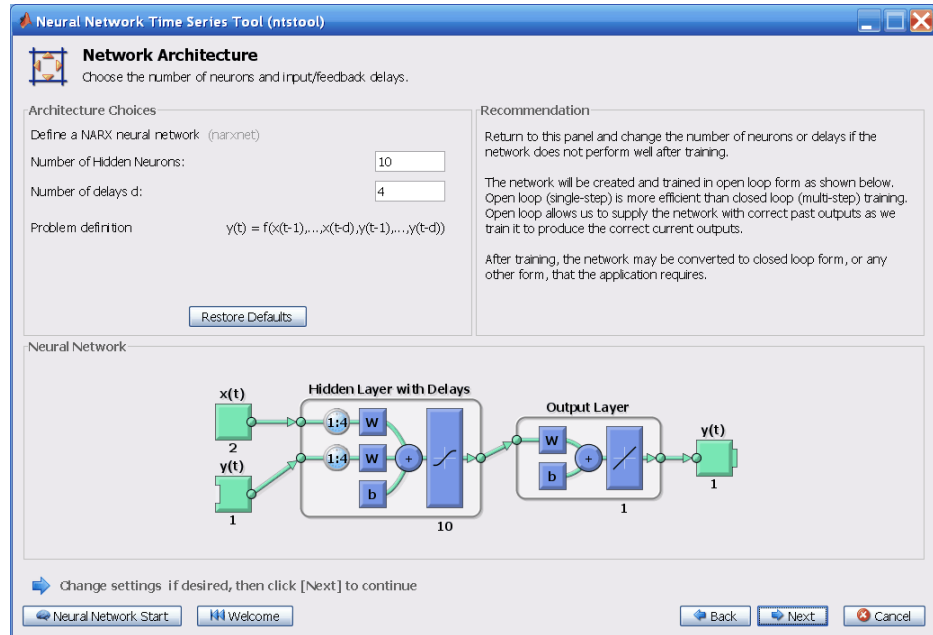

With these settings, the input vectors and target vectors will be randomly divided into three sets as follows:

- 70% will be used for training.
- 15% will be used to validate that the network is generalizing and to stop training before overfitting.
- The last 15% will be used as a completely independent test of network generalization.

(See “Dividing the Data” in the User’s Guide for more discussion of the data division process.)

7 Click **Next**.

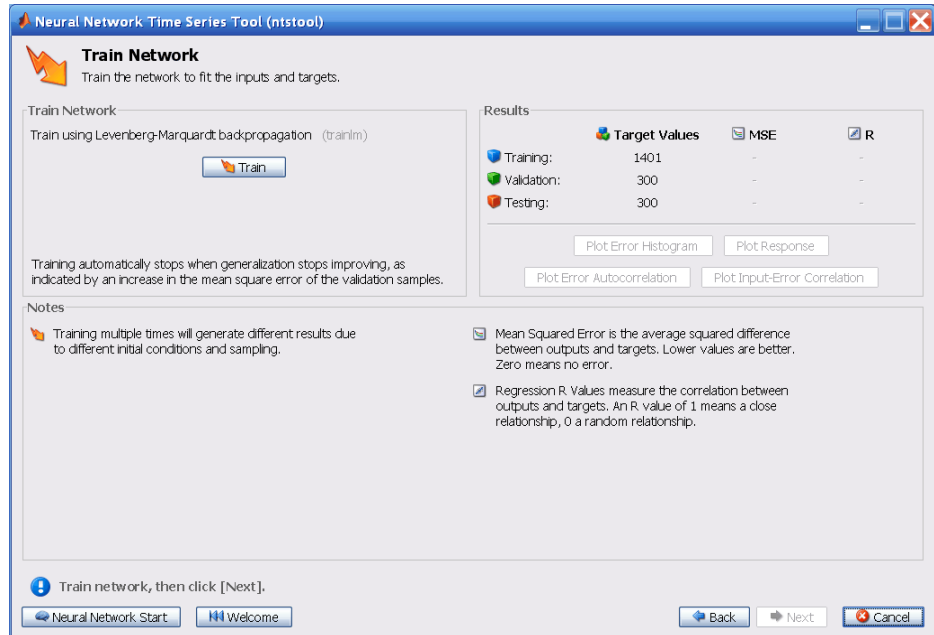

The standard NARX network is a two-layer feedforward network, with a sigmoid transfer function in the hidden layer and a linear transfer function in the output layer. This network also uses tapped delay lines to store previous values of the $x(t)$ and $y(t)$ sequences. Note that the output of the NARX network, $y(t)$, is fed back to the input of the network (through delays), since $y(t)$ is a function of $y(t-1)$, $y(t-2)$, ..., $y(t-d)$. However, for efficient training this feedback loop can be opened.

Because the true output is available during the training of the network, you can use the open-loop architecture shown above, in which the true output is used instead of feeding back the estimated output. This has two advantages. The first is that the input to the feedforward network is more accurate. The second is that the resulting network has a purely feedforward architecture, and therefore a more efficient algorithm can be used for training. This network is discussed in more detail in “NARX Network” (narxnet, closeloop) in the User’s Guide.

The default number of hidden neurons is set to 10. The default number of delays is 2. Change this value to 4. You might want to adjust these numbers if the network training performance is poor.

8 Click **Next**.

9 Click **Train**.

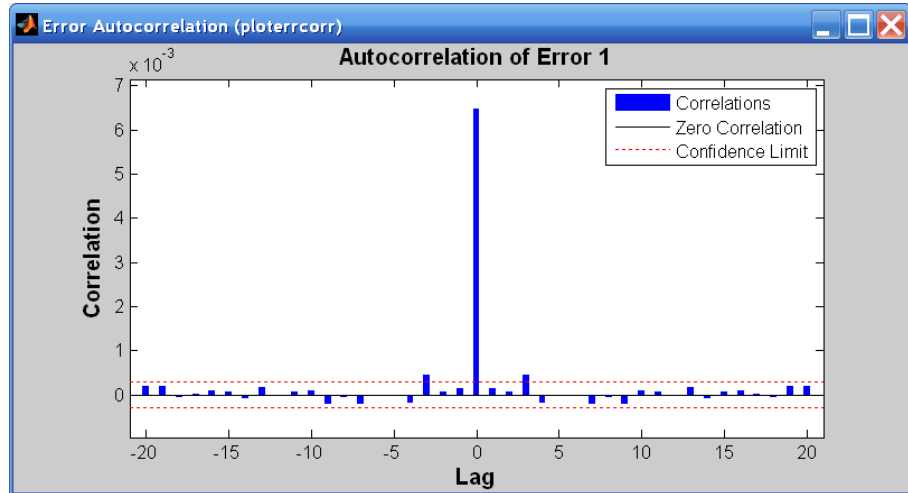

The training continued until the validation error failed to decrease for six iterations (validation stop).

10 Under **Plots**, click **Error Autocorrelation**. This is used to validate the network performance.

The following plot displays the error autocorrelation function. It describes how the prediction errors are related in time. For a perfect prediction model, there should only be one nonzero value of the autocorrelation function, and it should occur at zero lag. (This is the mean square error.) This would mean that the prediction errors were completely uncorrelated with each other (white noise). If there was significant correlation in the prediction errors, then it should be possible to improve the prediction - perhaps by increasing the number of delays in the tapped delay lines. In this case, the correlations, except for the one at zero lag, fall approximately

within the 95% confidence limits around zero, so the model seems to be adequate. If even more accurate results were required, you could retrain the network by clicking **Retrain** in `ntstool`. This will change the initial weights and biases of the network, and may produce an improved network after retraining.

- 11 View the input-error cross-correlation function to obtain additional verification of network performance. Under the **Plots** pane, click **Input-Error Cross-correlation**.

This input-error cross-correlation function illustrates how the errors are correlated with the input sequence $x(t)$. For a perfect prediction model, all of the correlations should be zero. If the input is correlated with the error, then it should be possible to improve the prediction, perhaps by increasing the number of delays in the tapped delay lines. In this case, all of the correlations fall within the confidence bounds around zero.

- 12** Under **Plots**, click **Time Series Response**. This displays the inputs, targets and errors versus time. It also indicates which time points were selected for training, testing and validation.

13 Click **Next** in the Neural Network Time Series Tool to evaluate the network.

At this point, you can test the network against new data.

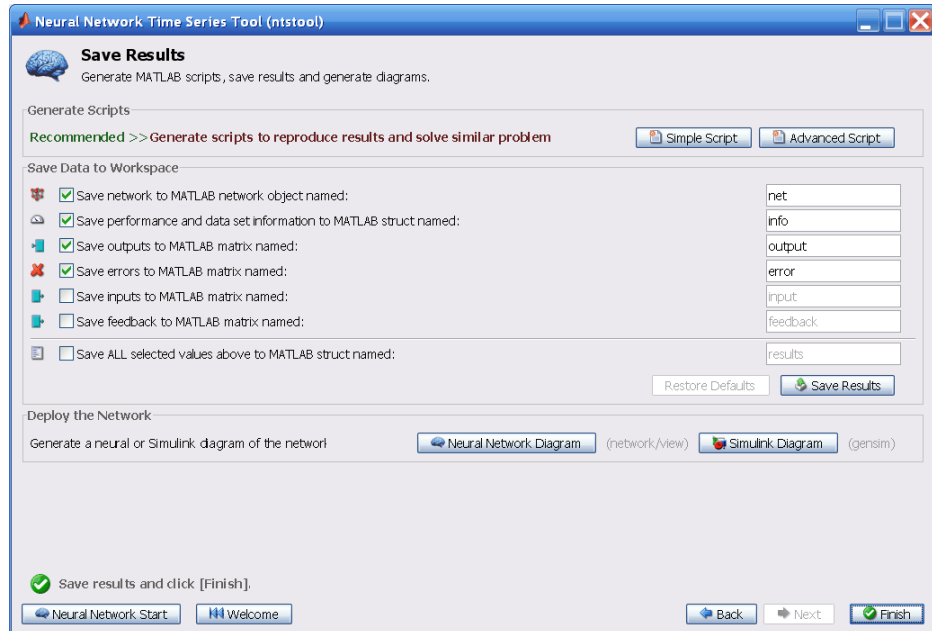

If you are dissatisfied with the network's performance on the original or new data, you can do any of the following:

- Train it again.
- Increase the number of neurons and/or the number of delays.
- Get a larger training data set.

If the performance on the training set is good, but the test set performance is significantly worse, which could indicate overfitting, then reducing the number of neurons can improve your results.

14 If you are satisfied with the network performance, click **Next**.

15 Use the buttons on this screen to generate scripts or to save your results.

- You can click **Simple Script** or **Advanced Script** to create MATLAB code that can be used to reproduce all of the previous steps from the command line. Creating MATLAB code can be helpful if you want to learn how to use the command-line functionality of the toolbox to customize the training process. In “Using Command-Line Functions” on page 1-81, you will investigate the generated scripts in more detail.
- You can also have the network saved as `net` in the workspace. You can perform additional tests on it or put it to work on new inputs.

16 After creating MATLAB code and saving your results, click **Finish**.

Using Command-Line Functions

The easiest way to learn how to use the command-line functionality of the toolbox is to generate scripts from the GUIs, and then modify them to customize the network training. As an example, look at the simple script that was created at step 15 of the previous section.

```
% Solve an Autoregression Problem with External
% Input with a NARX Neural Network
```

```
% Script generated by NTSTOOL
%
% This script assumes the variables on the right of
% these equalities are defined:
%
%   phInputs - input time series.
%   phTargets - feedback time series.

inputSeries = phInputs;
targetSeries = phTargets;

% Create a Nonlinear Autoregressive Network with External Input
inputDelays = 1:4;
feedbackDelays = 1:4;
hiddenLayerSize = 10;
net = narxnet(inputDelays,feedbackDelays,hiddenLayerSize);

% Prepare the Data for Training and Simulation
% The function PREPARETS prepares time series data
% for a particular network, shifting time by the minimum
% amount to fill input states and layer states.
% Using PREPARETS allows you to keep your original
% time series data unchanged, while easily customizing it
% for networks with differing numbers of delays, with
% open loop or closed loop feedback modes.
[inputs,inputStates,layerStates,targets] = ...
    preparets(net,inputSeries,{},targetSeries);

% Set up Division of Data for Training, Validation, Testing
net.divideParam.trainRatio = 70/100;
net.divideParam.valRatio = 15/100;
net.divideParam.testRatio = 15/100;

% Train the Network
[net,tr] = train(net,inputs,targets,inputStates,layerStates);

% Test the Network
outputs = net(inputs,inputStates,layerStates);
errors = gsubtract(targets,outputs);
performance = perform(net,targets,outputs)
```

```
% View the Network
view(net)

% Plots
% Uncomment these lines to enable various plots.
%figure, plotperform(tr)
%figure, plottrainstate(tr)
%figure, plotregression(targets,outputs)
%figure, plotresponse(targets,outputs)
%figure, ploterrcorr(errors)
%figure, plotinerrcorr(inputs,errors)

% Closed Loop Network
% Use this network to do multi-step prediction.
% The function CLOSELOOP replaces the feedback input with a direct
% connection from the outout layer.
netc = closeloop(net);
netc.name = [net.name ' - Closed Loop'];
view(netc)
[xc,xic,aic,tc] = preparets(netc,inputSeries,{},targetSeries);
yc = netc(xc,xic,aic);
closedLoopPerformance = perform(netc,tc,yc)

% Early Prediction Network
% For some applications it helps to get the prediction a
% timestep early.
% The original network returns predicted  $y(t+1)$  at the same
% time it is given  $y(t+1)$ .
% For some applications such as decision making, it would
% help to have predicted  $y(t+1)$  once  $y(t)$  is available, but
% before the actual  $y(t+1)$  occurs.
% The network can be made to return its output a timestep early
% by removing one delay so that its minimal tap delay is now
% 0 instead of 1. The new network returns the same outputs as
% the original network, but outputs are shifted left one timestep.
nets = removedelay(net);
nets.name = [net.name ' - Predict One Step Ahead'];
view(nets)
[xs,xis,ais,ts] = preparets(nets,inputSeries,{},targetSeries);
```

```
ys = nets(xs,xis,ais);  
earlyPredictPerformance = perform(nets,ts,ys)
```

You can save the script, and then run it from the command line to reproduce the results of the previous GUI session. You can also edit the script to customize the training process. In this case, follow each of the steps in the script.

- 1** The script assumes that the input vectors and target vectors are already loaded into the workspace. If the data are not loaded, you can load them as follows:

```
load pH_dataset  
X = pHInputs;  
T = pHTargets;
```

- 2** Create a network. The NARX network, `narxnet`, is a feedforward network with the default tan-sigmoid transfer function in the hidden layer and linear transfer function in the output layer. This network has two inputs. One is an external input, and the other is a feedback connection from the network output. (After the network has been trained, this feedback connection can be closed, as you will see at a later step.) For each of these inputs, there is a tapped delay line to store previous values. To assign the network architecture for a NARX network, you must select the delays associated with each tapped delay line, and also the number of hidden layer neurons. In the following steps, you assign the input delays and the feedback delays to range from 1 to 4 and the number of hidden neurons to be 10.

```
inputDelays = 1:4;  
feedbackDelays = 1:4;  
hiddenLayerSize = 10;  
net = narxnet(inputDelays,feedbackDelays,hiddenLayerSize);
```

Note Increasing the number of neurons and the number of delays requires more computation, and this has a tendency to overfit the data when the numbers are set too high, but it allows the network to solve more complicated problems. More layers require more computation, but their use might result in the network solving complex problems more efficiently. To use more than one hidden layer, enter the hidden layer sizes as elements of an array in the `fitnet` command.

- 3** Prepare the data for training. When training a network containing tapped delay lines, it is necessary to fill the delays with initial values of the inputs and outputs of the network. There is a toolbox command that facilitates this process - `preparets`. This function has three input arguments: the network, the input sequence and the target sequence. The function returns the initial conditions that are needed to fill the tapped delay lines in the network, and modified input and target sequences, where the initial conditions have been removed. You can call the function as follows:

```
[inputs,inputStates,layerStates,targets] = ...  
    preparets(net,inputSeries,{},targetSeries);
```

- 4** Set up the division of data.

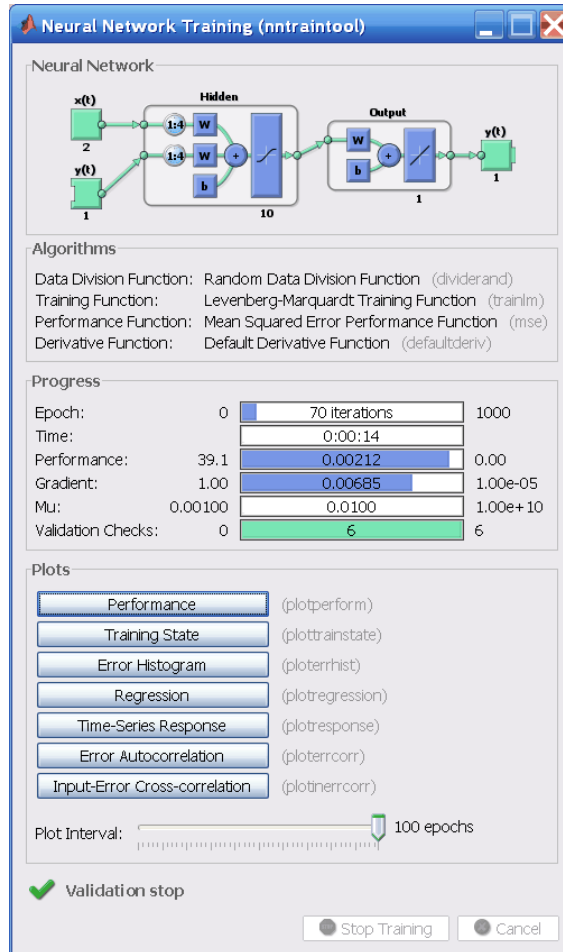

```
net.divideParam.trainRatio = 70/100;  
net.divideParam.valRatio = 15/100;  
net.divideParam.testRatio = 15/100;
```

With these settings, the input vectors and target vectors will be randomly divided, with 70% used for training, 15% for validation and 15% for testing.

- 5** Train the network. The network uses the default Levenberg-Marquardt algorithm (`trainlm`) for training. To train the network, enter:

```
[net,tr] = train(net,inputs,targets,inputStates,layerStates);
```

During training, the following training window opens. This window displays training progress and allows you to interrupt training at any point by clicking **Stop Training**.

This training stopped when the validation error increased for six iterations, which occurred at iteration 70.

- 6 Test the network. After the network has been trained, you can use it to compute the network outputs. The following code calculates the network outputs, errors and overall performance. Note that to simulate a network with tapped delay lines, you need to assign the initial values for these delayed signals. This is done with `inputStates` and `layerStates` provided by `prepares` at an earlier stage.

```

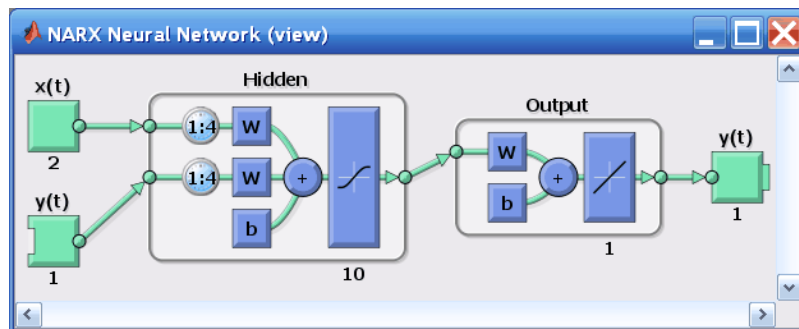

outputs = net(inputs,inputStates,layerStates);
errors = gsubtract(targets,errors);
performance = perform(net,targets,outputs)

```

7 View the network diagram.

```
view(net)
```

This creates the following diagram of the network.

8 Plot the performance training record to check for potential overfitting.

```
figure, plotperform(tr)
```

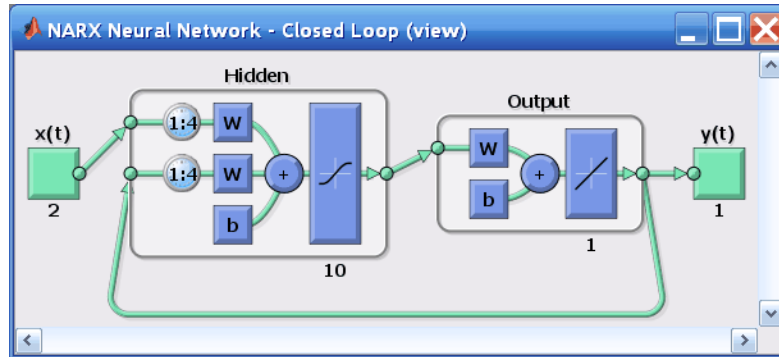

This creates the following figure, which demonstrates that training, validation and testing errors all decreased until iteration 64. It does not appear that any overfitting has occurred, since neither testing or validation error increased before iteration 64.

- 9 Close the loop on the NARX network. When the feedback loop is open on the NARX network, it is performing a one-step-ahead prediction. It is predicting the next value of $y(t)$ from previous values of $y(t)$ and $x(t)$. With the feedback loop closed, it can be used to perform multi-step-ahead predictions. This is because predictions of $y(t)$ will be used in place of actual future values of $y(t)$. The following commands can be used to close the loop and calculate closed-loop performance

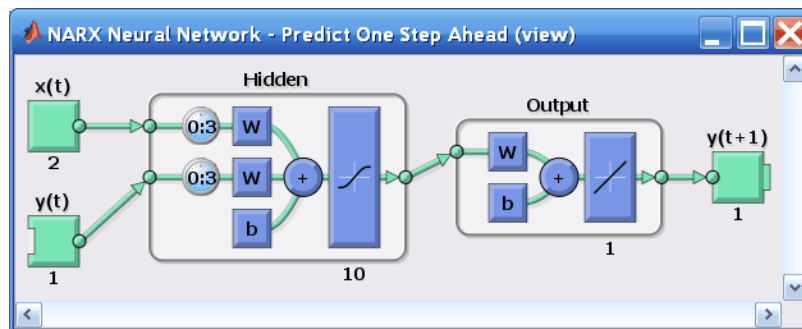

```
netc = closeloop(net);
netc.name = [net.name ' - Closed Loop'];
view(netc)
[xc,xic,aic,tc] = preparets(netc,inputSeries,{},targetSeries);
yc = netc(xc,xic,aic);
perfc = perform(netc,tc,yc)
```

The following figure shows the closed loop network.

10 Remove a delay from the network, to get the prediction one time step early.

```
nets = removedelay(net);
nets.name = [net.name ' - Predict One Step Ahead'];
view(nets)
[xs,xis,ais,ts] = preparets(nets,inputSeries,{},targetSeries);
ys = nets(xs,xis,ais);
earlyPredictPerformance = perform(nets,ts,ys)
```

From this figure, you can see that the network is identical to the previous open-loop network, except that one delay has been removed from each of the tapped delay lines. The output of the network is then $y(t + 1)$ instead of $y(t)$. This may sometimes be helpful when a network is deployed for certain applications.

If the network performance is not satisfactory, you could try any of these approaches:

- Reset the initial network weights and biases to new values with `init` and train again (see “Initializing Weights” (`init`)) in the User’s Guide.
- Increase the number of hidden neurons or the number of delays.
- Increase the number of training vectors.
- Increase the number of input values, if more relevant information is available.
- Try a different training algorithm (see “Training Algorithms” in the User’s Guide).

To get more experience in command-line operations, try some of these tasks:

- During training, open a plot window (such as the error correlation plot), and watch it animate.
- Plot from the command line with functions such as `plotresponse`, `ploterrcorr` and `plotperform`. (For more information on using these functions, see their reference pages.)

Also, see the advanced script for more options, when training from the command line.

Sample Data Sets

The Neural Network Toolbox software contains a number of sample data sets that you can use to experiment with the functionality of the toolbox. To view the data sets that are available, use the following command:

```
help nndatasets
```

```
Neural Network Datasets
```

```
-----
```

```
Function Fitting, Function approximation and Curve fitting.
```

```
Function fitting is the process of training a neural network on a set of inputs in order to produce an associated set of target outputs. Once the neural network has fit the data, it forms a generalization of the input-output relationship and can be used to generate outputs for inputs it was not trained on.
```

```
simplefit_dataset      - Simple fitting dataset.  
abalone_dataset      - Abalone shell rings dataset.  
bodyfat_dataset      - Body fat percentage dataset.  
building_dataset     - Building energy dataset.  
chemical_dataset     - Chemical sensor dataset.  
cho_dataset          - Cholesterol dataset.  
engine_dataset       - Engine behavior dataset.  
house_dataset        - House value dataset
```

```
-----
```

```
Pattern Recognition and Classification
```

```
Pattern recognition is the process of training a neural network to assign the correct target classes to a set of input patterns. Once trained the network can be used to classify patterns it has not seen before.
```

```
simpleclass_dataset   - Simple pattern recognition dataset.  
cancer_dataset       - Breast cancer dataset.  
crab_dataset         - Crab gender dataset.
```

| | |
|-----------------|-----------------------------|
| glass_dataset | - Glass chemical dataset. |
| iris_dataset | - Iris flower dataset. |
| thyroid_dataset | - Thyroid function dataset. |
| wine_dataset | - Italian wines dataset. |

Clustering, Feature extraction and Data dimension reduction

Clustering is the process of training a neural network on patterns so that the network comes up with its own classifications according to pattern similarity and relative topology. This is useful for gaining insight into data, or simplifying it before further processing.

simplecluster_dataset - Simple clustering dataset.

The inputs of fitting or pattern recognition datasets may also be clustered.

Input-Output Time-Series Prediction, Forecasting, Dynamic modelling, Nonlinear autoregression, System identification and Filtering

Input-output time series problems consist of predicting the next value of one time-series given another time-series. Past values of both series (for best accuracy), or only one of the series (for a simpler system) may be used to predict the target series.

| | |
|----------------------|--|
| simpleseries_dataset | - Simple time-series prediction dataset. |
| simplenarx_dataset | - Simple time-series prediction dataset. |
| exchanger_dataset | - Heat exchanger dataset. |
| maglev_dataset | - Magnetic levitation dataset. |
| ph_dataset | - Solution PH dataset. |
| pollution_dataset | - Pollution mortality dataset. |
| valve_dataset | - Valve fluid flow dataset. |

Single Time-Series Prediction, Forecasting, Dynamic modelling, Nonlinear autoregression, System identification, and Filtering

Single time-series prediction involves predicting the next value of a time-series given its past values.

| | |
|--------------------|--|
| simplenar_dataset | - Simple single series prediction dataset. |
| chickenpox_dataset | - Monthly chickenpox instances dataset. |
| ice_dataset | - Global ice volume dataset. |
| laser_dataset | - Chaotic far-infrared laser dataset. |
| oil_dataset | - Monthly oil price dataset. |
| river_dataset | - River flow dataset. |
| solar_dataset | - Sunspot activity dataset |

See also `nndemos`, `nntextdemos`, `nntextbook`.

Notice that all of the data sets have file names of the form `name_dataset`. Inside these files will be the arrays `nameInputs` and `nameTargets`. You can load a data set into the workspace with a command such as

```
load simplefit_dataset
```

This will load `simplefitInputs` and `simplefitTargets` into the workspace. If you want to load the input and target arrays into different names, you can use a command such as

```
[x,t] = simplefit_datasets;
```

This will load the inputs and targets into the arrays `x` and `t`. You can get a description of a data set with a command such as

```
help maglev_dataset
```

ADALINE

Acronym for a linear neuron: ADaptive LINear Element.

adaption

Training method that proceeds through the specified sequence of inputs, calculating the output, error, and network adjustment for each input vector in the sequence as the inputs are presented.

adaptive filter

Network that contains delays and whose weights are adjusted after each new input vector is presented. The network adapts to changes in the input signal properties if such occur. This kind of filter is used in long distance telephone lines to cancel echoes.

adaptive learning rate

Learning rate that is adjusted according to an algorithm during training to minimize training time.

architecture

Description of the number of the layers in a neural network, each layer's transfer function, the number of neurons per layer, and the connections between layers.

backpropagation learning rule

Learning rule in which weights and biases are adjusted by error-derivative (delta) vectors backpropagated through the network. Backpropagation is commonly applied to feedforward multilayer networks. Sometimes this rule is called the *generalized delta rule*.

backtracking search

Linear search routine that begins with a step multiplier of 1 and then backtracks until an acceptable reduction in performance is obtained.

batch

Matrix of input (or target) vectors applied to the network simultaneously. Changes to the network weights and biases are made just once for the entire set of vectors in the input matrix. (The term *batch* is being replaced by the more descriptive expression "concurrent vectors.")

batching

Process of presenting a set of input vectors for simultaneous calculation of a matrix of output vectors and/or new weights and biases.

Bayesian framework

Assumes that the weights and biases of the network are random variables with specified distributions.

BFGS quasi-Newton algorithm

Variation of Newton's optimization algorithm, in which an approximation of the Hessian matrix is obtained from gradients computed at each iteration of the algorithm.

bias

Neuron parameter that is summed with the neuron's weighted inputs and passed through the neuron's transfer function to generate the neuron's output.

bias vector

Column vector of bias values for a layer of neurons.

Brent's search

Linear search that is a hybrid of the golden section search and a quadratic interpolation.

cascade-forward network

Layered network in which each layer only receives inputs from previous layers.

Charalambous' search

Hybrid line search that uses a cubic interpolation together with a type of sectioning.

classification

Association of an input vector with a particular target vector.

competitive layer

Layer of neurons in which only the neuron with maximum net input has an output of 1 and all other neurons have an output of 0. Neurons compete with each other for the right to respond to a given input vector.

competitive learning

Unsupervised training of a competitive layer with the instar rule or Kohonen rule. Individual neurons learn to become feature detectors. After training, the layer categorizes input vectors among its neurons.

competitive transfer function

Accepts a net input vector for a layer and returns neuron outputs of 0 for all neurons except for the winner, the neuron associated with the most positive element of the net input \mathbf{n} .

concurrent input vectors

Name given to a matrix of input vectors that are to be presented to a network simultaneously. All the vectors in the matrix are used in making just one set of changes in the weights and biases.

conjugate gradient algorithm

In the conjugate gradient algorithms, a search is performed along conjugate directions, which produces generally faster convergence than a search along the steepest descent directions.

connection

One-way link between neurons in a network.

connection strength

Strength of a link between two neurons in a network. The strength, often called weight, determines the effect that one neuron has on another.

cycle

Single presentation of an input vector, calculation of output, and new weights and biases.

dead neuron

Competitive layer neuron that never won any competition during training and so has not become a useful feature detector. Dead neurons do not respond to any of the training vectors.

decision boundary

Line, determined by the weight and bias vectors, for which the net input n is zero.

delta rule

See **Widrow-Hoff learning rule**.

delta vector

The delta vector for a layer is the derivative of a network's output error with respect to that layer's net input vector.

distance

Distance between neurons, calculated from their positions with a distance function.

distance function

Particular way of calculating distance, such as the Euclidean distance between two vectors.

early stopping

Technique based on dividing the data into three subsets. The first subset is the training set, used for computing the gradient and updating the network weights and biases. The second subset is the validation set. When the validation error increases for a specified number of iterations, the training is stopped, and the weights and biases at the minimum of the validation error are returned. The third subset is the test set. It is used to verify the network design.

epoch

Presentation of the set of training (input and/or target) vectors to a network and the calculation of new weights and biases. Note that training vectors can be presented one at a time or all together in a batch.

error jumping

Sudden increase in a network's sum-squared error during training. This is often due to too large a learning rate.

error ratio

Training parameter used with adaptive learning rate and momentum training of backpropagation networks.

error vector

Difference between a network's output vector in response to an input vector and an associated target output vector.

feedback network

Network with connections from a layer's output to that layer's input. The feedback connection can be direct or pass through several layers.

feedforward network

Layered network in which each layer only receives inputs from previous layers.

Fletcher-Reeves update

Method for computing a set of conjugate directions. These directions are used as search directions as part of a conjugate gradient optimization procedure.

function approximation

Task performed by a network trained to respond to inputs with an approximation of a desired function.

generalization

Attribute of a network whose output for a new input vector tends to be close to outputs for similar input vectors in its training set.

generalized regression network

Approximates a continuous function to an arbitrary accuracy, given a sufficient number of hidden neurons.

global minimum

Lowest value of a function over the entire range of its input parameters. Gradient descent methods adjust weights and biases in order to find the global minimum of error for a network.

golden section search

Linear search that does not require the calculation of the slope. The interval containing the minimum of the performance is subdivided at each iteration of the search, and one subdivision is eliminated at each iteration.

gradient descent

Process of making changes to weights and biases, where the changes are proportional to the derivatives of network error with respect to those weights and biases. This is done to minimize network error.

hard-limit transfer function

Transfer function that maps inputs greater than or equal to 0 to 1, and all other values to 0.

Hebb learning rule

Historically the first proposed learning rule for neurons. Weights are adjusted proportional to the product of the outputs of pre- and postweight neurons.

hidden layer

Layer of a network that is not connected to the network output (for instance, the first layer of a two-layer feedforward network).

home neuron

Neuron at the center of a neighborhood.

hybrid bisection-cubic search

Line search that combines bisection and cubic interpolation.

initialization

Process of setting the network weights and biases to their original values.

input layer

Layer of neurons receiving inputs directly from outside the network.

input space

Range of all possible input vectors.

input vector

Vector presented to the network.

input weight vector

Row vector of weights going to a neuron.

input weights

Weights connecting network inputs to layers.

Jacobian matrix

Contains the first derivatives of the network errors with respect to the weights and biases.

Kohonen learning rule

Learning rule that trains a selected neuron's weight vectors to take on the values of the current input vector.

layer

Group of neurons having connections to the same inputs and sending outputs to the same destinations.

layer diagram

Network architecture figure showing the layers and the weight matrices connecting them. Each layer's transfer function is indicated with a symbol. Sizes of input, output, bias, and weight matrices are shown. Individual neurons and connections are not shown. (See Network Objects, Data and Training Styles in the *Neural Network Toolbox User's Guide*.)

layer weights

Weights connecting layers to other layers. Such weights need to have nonzero delays if they form a recurrent connection (i.e., a loop).

learning

Process by which weights and biases are adjusted to achieve some desired network behavior.

learning rate

Training parameter that controls the size of weight and bias changes during learning.

learning rule

Method of deriving the next changes that might be made in a network or a procedure for modifying the weights and biases of a network.

Levenberg-Marquardt

Algorithm that trains a neural network 10 to 100 times faster than the usual gradient descent backpropagation method. It always computes the approximate Hessian matrix, which has dimensions n -by- n .

line search function

Procedure for searching along a given search direction (line) to locate the minimum of the network performance.

linear transfer function

Transfer function that produces its input as its output.

link distance

Number of links, or steps, that must be taken to get to the neuron under consideration.

local minimum

Minimum of a function over a limited range of input values. A local minimum might not be the global minimum.

log-sigmoid transfer function

Squashing function of the form shown below that maps the input to the interval (0,1). (The toolbox function is `logsig`.)

$$f(n) = \frac{1}{1 + e^{-n}}$$

Manhattan distance

The Manhattan distance between two vectors \mathbf{x} and \mathbf{y} is calculated as

$$D = \text{sum}(\text{abs}(\mathbf{x} - \mathbf{y}))$$

maximum performance increase

Maximum amount by which the performance is allowed to increase in one iteration of the variable learning rate training algorithm.

maximum step size

Maximum step size allowed during a linear search. The magnitude of the weight vector is not allowed to increase by more than this maximum step size in one iteration of a training algorithm.

mean square error function

Performance function that calculates the average squared error between the network outputs \mathbf{a} and the target outputs \mathbf{t} .

momentum

Technique often used to make it less likely for a backpropagation network to get caught in a shallow minimum.

momentum constant

Training parameter that controls how much momentum is used.

mu parameter

Initial value for the scalar μ .

neighborhood

Group of neurons within a specified distance of a particular neuron. The neighborhood is specified by the indices for all the neurons that lie within a radius d of the winning neuron i^* :

$$N_i(d) = \{j, d_{ij} \leq d\}$$

net input vector

Combination, in a layer, of all the layer's weighted input vectors with its bias.

neuron

Basic processing element of a neural network. Includes weights and bias, a summing junction, and an output transfer function. Artificial neurons, such as those simulated and trained with this toolbox, are abstractions of biological neurons.

neuron diagram

Network architecture figure showing the neurons and the weights connecting them. Each neuron's transfer function is indicated with a symbol.

ordering phase

Period of training during which neuron weights are expected to order themselves in the input space consistent with the associated neuron positions.

output layer

Layer whose output is passed to the world outside the network.

output vector

Output of a neural network. Each element of the output vector is the output of a neuron.

output weight vector

Column vector of weights coming from a neuron or input. (See also **outstar learning rule**.)

outstar learning rule

Learning rule that trains a neuron's (or input's) output weight vector to take on the values of the current output vector of the postweight layer. Changes in the weights are proportional to the neuron's output.

overfitting

Case in which the error on the training set is driven to a very small value, but when new data is presented to the network, the error is large.

pass

Each traverse through all the training input and target vectors.

pattern

A vector.

pattern association

Task performed by a network trained to respond with the correct output vector for each input vector presented.

pattern recognition

Task performed by a network trained to respond when an input vector close to a learned vector is presented. The network "recognizes" the input as one of the original target vectors.

perceptron

Single-layer network with a hard-limit transfer function. This network is often trained with the perceptron learning rule.

perceptron learning rule

Learning rule for training single-layer hard-limit networks. It is guaranteed to result in a perfectly functioning network in finite time, given that the network is capable of doing so.

performance

Behavior of a network.

performance function

Commonly the mean squared error of the network outputs. However, the toolbox also considers other performance functions. Type `nnets` and look under performance functions.

Polak-Ribière update

Method for computing a set of conjugate directions. These directions are used as search directions as part of a conjugate gradient optimization procedure.

positive linear transfer function

Transfer function that produces an output of zero for negative inputs and an output equal to the input for positive inputs.

postprocessing

Converts normalized outputs back into the same units that were used for the original targets.

Powell-Beale restarts

Method for computing a set of conjugate directions. These directions are used as search directions as part of a conjugate gradient optimization procedure. This procedure also periodically resets the search direction to the negative of the gradient.

preprocessing

Transformation of the input or target data before it is presented to the neural network.

principal component analysis

Orthogonalize the components of network input vectors. This procedure can also reduce the dimension of the input vectors by eliminating redundant components.

quasi-Newton algorithm

Class of optimization algorithm based on Newton's method. An approximate Hessian matrix is computed at each iteration of the algorithm based on the gradients.

radial basis networks

Neural network that can be designed directly by fitting special response elements where they will do the most good.

radial basis transfer function

The transfer function for a radial basis neuron is

$$radbas(n) = e^{-n^2}$$

regularization

Modification of the performance function, which is normally chosen to be the sum of squares of the network errors on the training set, by adding some fraction of the squares of the network weights.

resilient backpropagation

Training algorithm that eliminates the harmful effect of having a small slope at the extreme ends of the sigmoid squashing transfer functions.

saturating linear transfer function

Function that is linear in the interval (-1,+1) and saturates outside this interval to -1 or +1. (The toolbox function is `satlin`.)

scaled conjugate gradient algorithm

Avoids the time-consuming line search of the standard conjugate gradient algorithm.

sequential input vectors

Set of vectors that are to be presented to a network one after the other. The network weights and biases are adjusted on the presentation of each input vector.

sigma parameter

Determines the change in weight for the calculation of the approximate Hessian matrix in the scaled conjugate gradient algorithm.

sigmoid

Monotonic S-shaped function that maps numbers in the interval $(-\infty, \infty)$ to a finite interval such as (-1,+1) or (0,1).

simulation

Takes the network input \mathbf{p} , and the network object `net`, and returns the network outputs \mathbf{a} .

spread constant

Distance an input vector must be from a neuron's weight vector to produce an output of 0.5.

squashing function

Monotonically increasing function that takes input values between $-\infty$ and $+\infty$ and returns values in a finite interval.

star learning rule

Learning rule that trains a neuron's weight vector to take on the values of the current input vector. Changes in the weights are proportional to the neuron's output.

sum-squared error

Sum of squared differences between the network targets and actual outputs for a given input vector or set of vectors.

supervised learning

Learning process in which changes in a network's weights and biases are due to the intervention of any external teacher. The teacher typically provides output targets.

symmetric hard-limit transfer function

Transfer that maps inputs greater than or equal to 0 to +1, and all other values to -1.

symmetric saturating linear transfer function

Produces the input as its output as long as the input is in the range -1 to 1. Outside that range the output is -1 and +1, respectively.

tan-sigmoid transfer function

Squashing function of the form shown below that maps the input to the interval (-1,1). (The toolbox function is `tansig`.)

$$f(n) = \frac{1}{1 + e^{-n}}$$

tapped delay line

Sequential set of delays with outputs available at each delay output.

target vector

Desired output vector for a given input vector.

test vectors

Set of input vectors (not used directly in training) that is used to test the trained network.

topology functions

Ways to arrange the neurons in a grid, box, hexagonal, or random topology.

training

Procedure whereby a network is adjusted to do a particular job. Commonly viewed as an offline job, as opposed to an adjustment made during each time interval, as is done in adaptive training.

training vector

Input and/or target vector used to train a network.

transfer function

Function that maps a neuron's (or layer's) net output **n** to its actual output.

tuning phase

Period of SOFM training during which weights are expected to spread out relatively evenly over the input space while retaining their topological order found during the ordering phase.

underdetermined system

System that has more variables than constraints.

unsupervised learning

Learning process in which changes in a network's weights and biases are not due to the intervention of any external teacher. Commonly changes are a function of the current network input vectors, output vectors, and previous weights and biases.

update

Make a change in weights and biases. The update can occur after presentation of a single input vector or after accumulating changes over several input vectors.

validation vectors

Set of input vectors (not used directly in training) that is used to monitor training progress so as to keep the network from overfitting.

weight function

Weight functions apply weights to an input to get weighted inputs, as specified by a particular function.

weight matrix

Matrix containing connection strengths from a layer's inputs to its neurons. The element $w_{i,j}$ of a weight matrix W refers to the connection strength from input j to neuron i .

weighted input vector

Result of applying a weight to a layer's input, whether it is a network input or the output of another layer.

Widrow-Hoff learning rule

Learning rule used to train single-layer linear networks. This rule is the predecessor of the backpropagation rule and is sometimes referred to as the delta rule.

P

- pattern recognition 1-29
- pattern recognition problems
 - defining 1-29

R

regression plots 1-17

ROC curve 1-38

S

sample hits plot 1-56

self-organizing feature map (SOFM)

networks 1-53

neighbor distances plot 1-65

sample hits plot 1-56

SOM topology 1-64

weight planes plot 1-57

SOM topology 1-64

T

time series 1-67

time series problems

defining 1-67

solving with command-line functions 1-84

solving with ntstool 1-69

W

weight planes plot 1-57
