# **About Phased Array System Toolbox Software**

#### In this section...

"Product Overview" on page 1-2

"Required Products" on page 1-3

"MATLAB® Compiler Support" on page 1-3

#### **Product Overview**

Phased Array System Toolbox<sup>TM</sup> provides algorithms and tools for the design, simulation, and analysis of phased array signal processing systems. These capabilities are provided as MATLAB® functions and MATLAB System objects. The system toolbox includes algorithms for waveform generation, beamforming, direction of arrival estimation, target detection, and space-time adaptive processing. The system toolbox lets you build monostatic, bistatic, and multistatic architectures for a variety of array geometries. You can model these architectures on stationary or moving platforms. Array analysis and visualization tools help you evaluate spatial, spectral, and temporal performance. The system toolbox lets you model an end-to-end phased array system or use individual algorithms to process acquired data.

Key features of this product include:

- Algorithms available as MATLAB functions and MATLAB System objects
- Monostatic, bistatic, and multistatic phased array system modeling
- Array analysis and 3D visualization; physical array modeling for uniform linear arrays, uniform rectangular arrays, and arbitrary conformal arrays on platforms with motion
- Broadband and narrowband digital beamforming functions, including MVDR/Capon, LCMV, time delay, Frost, time delay LCMV, and subband phase shift
- Space-time adaptive processing algorithms, including displaced phase center array (DPCA), adaptive DPCA, sample matrix inversion (SMI) beamforming, and angle-Doppler response visualization

- Direction of arrival algorithms, including MVDR, ESPRIT, Beamscan, Root MUSIC, and monopulse tracking
- Waveform synthesis functions for pulsed CW, linear FM, stepped FM, and staggered PRF signals, and waveform visualization tools for ambiguity function and matched filter response
- Algorithms for TVG, pulse compression, coherent and non-coherent integration, CFAR processing, plotting ROC curves, and estimating range and Doppler

#### **Required Products**

The Phased Array System Toolbox product requires both the Signal Processing Toolbox<sup>TM</sup> and the DSP System Toolbox<sup>TM</sup> software. You must install these products to use the Phased Array System Toolbox software.

## **MATLAB Compiler Support**

Phased Array System Toolbox software does not support the MATLAB® Compiler™. You cannot compile any functionality in the toolbox.

#### **Standards and Conventions**

#### In this section...

"Scope of Standards and Conventions" on page 1-4

"Complex-Valued Baseband Signals" on page 1-4

"Data Organization of Baseband Signals" on page 1-5

"Spatial Coordinates" on page 1-5

"Physical Quantities" on page 1-5

"Supported Data Types" on page 1-5

#### **Scope of Standards and Conventions**

Phased Array System Toolbox software uses consistent conventions with respect to units of measure, data representations, and coordinate systems. You must understand these conventions to use the toolbox.

#### **Complex-Valued Baseband Signals**

In phased array signal processing, it is common to shift the frequency content of a waveform to support effective radiation and propagation in the medium. You accomplish this task by modulating a baseband signal with nonzero spectral magnitudes in the vicinity of zero frequency to create a bandpass signal with nonzero spectral magnitudes centered around a carrier frequency. Typically, the bandwidth of the baseband signal is small compared to the carrier frequency resulting in a narrowband signal. To process returned signals, the receiver demodulates the bandpass signal to the baseband. The demodulation involves local oscillators both in phase and 90 degrees out of phase with the modulating carrier frequency. This demodulation results in in-phase (I) and quadrature (Q) baseband signals, or channels. For processing, it is convenient to create a complex-valued baseband signal by assigning the I channel to be the real part and the Q channel to be the imaginary part, I+jQ.

This software uses the complex-valued baseband representation to represent both transmitted and received signals. Actual phased array systems transmit real-valued signals and create complex-valued baseband signals only at the receiver. However, you can use a complex-valued representation at all stages. Doing so enables you to accurately model the effect of system gains, losses, and interference on the received signal samples.

#### **Data Organization of Baseband Signals**

You can use this software to efficiently implement space-time processing of complex-valued baseband samples by organizing the data in a three-dimensional matrix. See Radar Data Cube for an explanation of how the software organizes space-time data.

#### **Spatial Coordinates**

Representation of position in three dimensions is a fundamental aspect of array signal processing. This software specifies rectangular and spherical coordinates as column vectors with respect to both global and local origins. See "Coordinate Systems and Motion Modeling" for a detailed explanation of the conventions.

## **Physical Quantities**

This software uses the International System of Units (SI) almost exclusively for measurement. In addition, there are physical constants declared and used in calculations. See "Units of Measure and Physical Constants" on page 3-7 for a detailed explanation of the conventions.

#### **Supported Data Types**

This software supports only double-precision data types. Inputting a data type that is not double precision can produce an error or incorrect results.

# Phased Array Systems

# **System Overviews**

#### In this section...

"Phased Array System Overview" on page 2-2

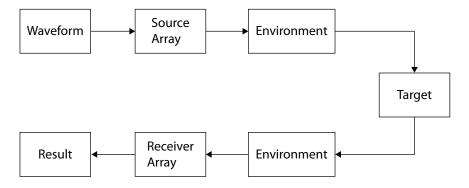

"Radar Phased Array Overview" on page 2-4

#### **Phased Array System Overview**

Phased array systems use the spatial and temporal characteristics of propagating space-time wavefields to extract information about any sources of the wavefields. By processing data collected over a spatiotemporal aperture using an array of sensors, you can significantly improve performance over a single sensor in a number of areas. These areas include, but are not limited to:

- Signal detectability
- Spatial selectivity
- Source identification and localization

The following figure shows a high-level overview of a phased array system.

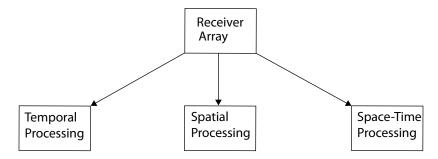

Phased array systems in diverse applications, such as radar, sonar, medical ultrasonography, medical imaging, and cellular phone communication share many common elements including:

Source Array — The source array transmits a waveform through an
environment. The waveform often consists of repeating pulses modulated

by a carrier frequency. Depending on the application, the wave may be an acoustic (mechanical), or electromagnetic wave. The source array is often electronically or mechanically steered to transmit in preferred directions.

- **Environment** The medium in which the waveform travels to and from the target affects a number of system parameters including propagation speed, absorption loss, and wave dispersion.
- **Target** The target reflects a portion of the incident waveform energy from the source array. Some percentage of the reflected energy is backscattered in the direction of the receiver array. In some applications, the target is the source of the waveform energy.
- **Receiver Array** The receiver array collects energy from the target representing the *signal* along with external and internal sources of *noise*. The receiver implements algorithms to improve the signal-to-noise ratio and extract space-time information from the signal.

At the receiver, phased array systems implement algorithms to extract temporal and spatial information about the source, or sources of energy. The following figure shows a high-level overview of array signal processing algorithms common to a significant number of phased array systems.

Brief descriptions of the three categories are:

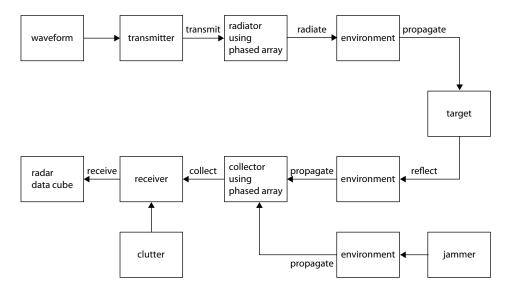

• **Temporal Processing** — Phased arrays often operate in poor signal-to-noise (SNR) ratios. Employing temporal integration and matched filtering improves the SNR. Knowing the propagation speed of the transmitted waveform and measuring the time it takes for a pulse to travel to and from a target allows phased array systems to estimate range.

Performing Fourier analysis on a time series of pulses enables the phased array to extract Doppler information from moving targets.

- Spatial Processing Combining weighted information across multiple sensor elements with a known geometry enables phased array systems to spatially filter incoming waveforms. Phased arrays can also estimate the direction of arrival and the number of source waveforms incident on the array.
- Space-Time Processing Simultaneously analyzing both spatial and temporal information enables phased array systems to produce joint angle-Doppler measurements of incident waveforms. Space-time processing enables phased array systems to distinguish moving targets from stationary targets when the phased array is in motion.

## Radar Phased Array Overview

The following figure presents an overview of a radar phased array system. The figure expands on the high-level overview shown in "Phased Array System Overview" on page 2-2.

To exploit the advantages of array processing, you must first understand how to model and optimize the performance of each component and operation in a phased array system. This software provides models for all the components of the phased array system illustrated in the preceding figure from signal synthesis to signal analysis.

The software supports models in which the transmitter and receiver are collocated or spatially separated. The software also supports models in which both the targets and phased array are in motion.

#### **Waveform Synthesis**

Phased Array System Toolbox software supports the design of rectangular, linear frequency-modulated, and linear stepped-frequency pulsed waveforms. To create such waveforms, you use phased.RectangularWaveform, phased.LinearFMWaveform, and phased.SteppedFMWaveform.

#### **Physical Components and Environment Modeling**

The software enables you to simulate the physical components of a phased array system, including:

- **Transmitter** You can specify the transmitter peak power, gain, and loss factor. See phased. Transmitter for details.
- Antenna elements You can create antenna elements with isotropic response patterns or antenna elements with user-specified response patterns. These response patterns can encompass the entire range of azimuth ([-180,180] degrees) and elevation ([-90,90] degrees) angles. See phased.IsotropicAntennaElement, phased.CosineAntennaElement, and phased.CustomAntennaElement for details.
- Microphone elements For acoustic applications, you can model an omnidirectional or custom microphone with phased.OmnidirectionalMicrophoneElement or phased.CustomMicrophoneElement.

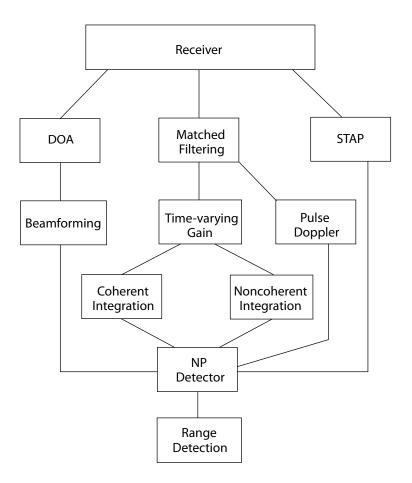

**Phased arrays** — There are System objects for three phased array geometries:

Uniform linear array (ULA) — phased.ULA enables you to model a
uniform linear array consisting of sensor elements with isotropic or
custom radiation patterns. You can specify the number of elements and
element spacing.

- Uniform rectangular array phased.URA enables you to model a uniform rectangular array of sensor elements with isotropic or custom radiation patterns. You can specify the number of elements, element spacing along two orthogonal axes, and lattice geometry.
- Conformal array phased.ConformalArray enables you to model a conformal array of sensor elements with isotropic or custom radiation patterns. To do so, specify the antenna element positions and normal directions.
- **Radiator** You can model waveform radiation through an antenna element, microphone, or array with the phased.Radiator object.
- **Environment** You can model the propagation of an electromagnetic (EM) wave in free space with phased.FreeSpace. You can simulate one-way or two-way propagation of a narrowband EM signal by applying range-dependent attenuation and time delays, or phase shifts.
- Target You can simulate a target with a specified radar cross section (RCS) using phased.RadarTarget. phased.RadarTarget supports both nonfluctuating and fluctuating (random) models of the RCS. The toolbox supports a family of random models based on the chi-square distribution known as *Swerling target models*.
- **Interference** You can simulate wideband interference with a user-specified radiated power, using phased.BarrageJammer.
- Clutter You can simulate surface clutter using phased.ConstantGammaClutter.
- Signal collection You can simulate far-field or near-field narrowband and wideband signal reception from specified directions using phased.Collector and phased.WidebandCollector.
- **Receiver** phased.ReceiverPreamp enables you to simulate the gain, loss factor, and internal noise characteristics of your receiver.

#### **Array Signal Processing**

For the processing of received data, Phased Array System Toolbox software supports a wide-range of array signal processing algorithms. The following figure presents a more detailed view of the general concepts discussed in "Phased Array System Overview" on page 2-2.

The preceding figure only presents an overview of the array signal processing operations supported by the software rather than predetermined orders of operation. For example, direction of arrival (DOA) estimation, beamforming, and space-time adaptive processing (STAP) often follow operations that improve the signal-to-noise ratio such as matched filtering. You can implement the supported algorithms in the manner best-suited to your application.

• **Matched Filtering** — You can perform matched filtering on your data with phased.MatchedFilter. See "Matched Filtering" for examples.

- Time-varying gain You can equalize the power level of the incident waveform across samples from different ranges using phased.TimeVaryingGain. This object compensates for signal power loss due to range.
- Beamforming and direction-of-arrival (DOA) estimation The Phased Array System Toolbox provides a number of algorithms for beamforming and direction of arrival estimation. See "Beamformers" and "Direction of Arrival (DOA)" for a list of supported beamforming and DOA algorithms. You can find example workflows for each in "Beamforming" and Direction of Arrival (DOA) Estimation.
- **Detection** A number of utility functions implement and evaluate Neyman-Pearson detectors using both coherent and noncoherent pulse integration.

The toolbox also provides routines for evaluating detector performance through the construction of receiver operating characteristic curves.

To model fluctuating noise characteristics, phased.CFARDetector object adaptively estimates the noise characteristics from the data to maintain a constant false-alarm rate.

You can find example workflows in the "Detection" section of the User's Guide.

• Pulse Doppler — The Phased Array System Toolbox has utility functions for estimating Doppler shift based on speed (speed2dop) and to estimate speed based on the Doppler shift (dop2speed. You can implement pulse-Doppler processing by using the spectrum estimation algorithms in the Signal Processing Toolbox product on the slow-time data. See "Radar Data Cube" on page 3-2 for an explanation of the slow-time data.

See "Doppler Shift and Pulse-Doppler Processing" for examples of Doppler processing.

To calculate the joint angle-Doppler response of the input data, use phased.AngleDopplerResponse.

Example workflows for computing the angle-Doppler response can be found in "Angle-Doppler Response".

 Space-time adaptive processing — You can implement displaced phase center antenna techniques with phased.DPCACanceller and phased.ADPCACanceller. phased.STAPSMIBeamformer implements an adaptive beamformer by calculating the beamformer weights using the estimated space-time interference covariance matrix.

See "Space-Time Adaptive Processing (STAP)" for examples.

#### Radar Data Cube

#### In this section...

"Radar Data Cube Concept" on page 3-2

"Fast Time Samples" on page 3-3

"Slow Time Samples" on page 3-4

"Spatial Sampling" on page 3-4

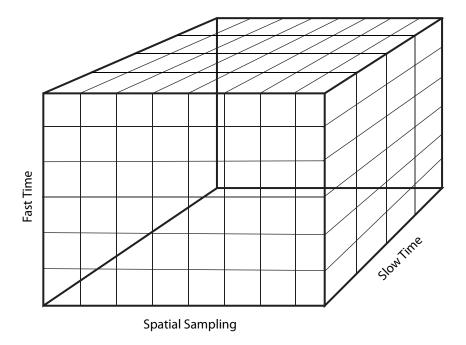

"Space-Time Processing" on page 3-5

"Organizing Data in the Radar Data Cube" on page 3-5

#### Radar Data Cube Concept

The radar data cube is a convenient way to conceptually represent space-time processing. To construct the radar data cube, assume that preprocessing converts the RF signals received from multiple pulses across multiple array elements to complex-valued baseband samples. Arrange the complex-valued baseband samples in a three-dimensional array of size *M*-by-*N*-by-*L*. Many radar signal processing operations in Phased Array System Toolbox software correspond to processing lower-dimensional subsets of the radar data cube. The subset could be a one-dimensional subvector or a two-dimensional submatrix.

The following figure shows the organization of the radar data cube in this software. Subsequent sections explain each of the dimensions and which aspect of space-time processing they represent.

# **Fast Time Samples**

Consider each *M*-by-1 subvector of the radar data cube. Each of these *M*-by-1 column vectors represent complex-valued baseband samples from one pulse at one array element. Because pulse bandwidths can be on the order of a few hundred kHz, you require high sampling rates to avoid aliasing. Such high sampling rates lead to the designation *fast time*.

The fast time dimension is also referred to as the *range* dimension. If the two-way range to a target from the phased array is 2R, the difference in range,  $\Delta R$ , represented by two samples acquired with sampling interval, T is:

$$\Delta R = \frac{cT}{2}$$

Each sample in the fast time dimension represents an incremental change in range of  $\Delta R$  in range. For this reason, fast time samples are also referred to as *range bins*, or *range gates*.

Pulse compression is an example of a signal processing operation performed on the fast time samples.

## **Slow Time Samples**

Consider each M-by-L submatrix of the radar data cube. In the submatrix there are M row vectors with dimension 1-by-L. Each of these row vectors contains complex-valued baseband samples from L different pulses corresponding to the same range bin. There is a M-by-L matrix for each of the N array elements. The sampling interval between the L samples is the pulse repetition interval (PRI). Typical PRIs are much longer than the fast-time sampling interval. Because of the long sampling intervals, samples taken across multiple pulses are referred to as  $slow\ time$ .

Processing data in the slow time dimension allows you to estimate the Doppler spectrum at a given range bin.

The Nyquist criterion applies equally to the slow-time dimension. The reciprocal of the PRI is the *pulse repetition frequency* (PRF). The PRF gives the width of the unambiguous Doppler spectrum.

#### **Spatial Sampling**

Phased arrays consist of multiple array elements. Consider each M-by-N submatrix of the radar data cube. Each column vector consists of M fast-time samples for a single pulse received at a single array element. The N column vectors represent the same pulse sampled across N array elements. The sampled data in the N column vectors is a spatial sampling of the incident waveform. Analysis of the data across the array elements allows you to examine the spatial frequency content of each received pulse.

It is also possible to spatially sample a wavefield by mechanically steering a single antenna, but the more common scenario is to sample the wavefield by multiple array elements. The Nyquist criterion for spatial sampling dictates that array elements must not be separated by more than one-half the wavelength of the carrier frequency.

Beamforming is a spatial filtering operation that combines data across the array elements to selectively enhance and suppress wavefields incident on the array from particular directions.

## **Space-Time Processing**

Space-time adaptive processing operates on the two-dimensional angle-Doppler data for each range bin. Consider the M-by-N-by-L radar data cube. Each of the M samples is data from the same range. This range is sampled across N array elements, and L PRIs. Collapsing the three-dimensional matrix at each range bin into N-by-L submatrices allows the simultaneous two-dimensional analysis of angle of arrival and Doppler frequency.

#### Organizing Data in the Radar Data Cube

If you have M complex-valued baseband data samples collected from L pulses received at N sensors, you can organize your data in a format compatible with the Phased Array System Toolbox conventions using permute. After processing your data, you can convert back to your original data cube format with ipermute.

#### **Reordering the Data Cube**

Assume you have a data set consisting of 200 samples per pulse for ten pulses collected at 6 sensor elements. Assume that your data are organized as a 6-by-10-by-200 matrix. Simulate this data structure using complex-valued white Gaussian noise samples.

```
OrigData = randn(6,10,200)+1j*randn(6,10,200);
```

The first dimension of OrigData is the number of sensors (spatial sampling), the second dimension is the number of pulses (slow-time), and the third dimension contains the fast-time samples. This format is not compatible with the radar data cube conventions of the Phased Array System Toolbox.

The Phased Array System Toolbox expects the first dimension to contain the fast-time samples, the second dimension to represent individual sensors in the array, and the third dimension to contain the slow-time samples.

To reorganize OrigData in a format compatible with the toolbox conventions, enter:

```
NewData = permute(OrigData,[3 1 2]);
```

The preceding line of code moves the third dimension of OrigData to be the first dimension of NewData. The first dimension of OrigData becomes the second dimension of NewData and the second dimension of OrigData becomes the third dimension of NewData. This results in NewData being organized as fast-time samples-by-sensors-by-slow-time samples. You can now process NewData with the Phased Array System Toolbox software.

After you process your data, you can use ipermute to return your data format to the original structure.

```
Data = ipermute(NewData,[3 1 2]);
% Data is equal to OrigData
```

# **Units of Measure and Physical Constants**

#### In this section...

"Units of Measure" on page 3-7

"Physical Constants" on page 3-7

#### **Units of Measure**

Phased Array System Toolbox software almost exclusively uses SI base and derived units to measure physical quantities. The software does not provide any utilities for converting SI base or derived units to other systems of measurement.

#### **Angles**

Angles are an exception to the use of SI base and derived units. All angles in Phased Array System Toolbox software are specified in degrees. See "Rectangular and Spherical Coordinates" for an explanation of the angles used in the software. There are two utility functions for converting angles from radians to degrees and degrees to radians: radtodeg and degtorad.

#### **Decibels**

To accurately model and simulate phased array systems, it is necessary to account for gains and losses in power incurred at various stages of processing. In Phased Array System Toolbox software, these gains and losses are specified in decibels (dB). Signal to noise ratios (SNRs) and the receiver noise figure are also expressed in dB. A power of *P* watts in dB is:

$$10\log_{10}(P)$$

There are two utility functions for converting between dB and power: db2pow and pow2db, and two utility functions for converting between magnitude and dB: db2mag and mag2db.

#### **Physical Constants**

Modeling and simulating phased array systems requires that you specify values for a number of physical constants. For example, the distribution of thermal noise power per unit bandwidth depends on the Boltzmann constant. To measure Doppler shift and range in radar, you have to specify a value for the speed of light. The following table summarizes the three physical constants specified in the toolbox. See physconst for additional information.

Description	Value
The speed of light in a vacuum	299,792,458 meters/second. Most commonly denoted by $c$ .
The Boltzmann constant relating energy to temperature.	$1.38 \mathrm{x} 10^{-23}$ joules/degree kelvin. Most commonly denoted by $k$ .
Mean radius of the Earth	6,137,000 meters

# System Objects in the Phased Array System Toolbox

- "System Objects" on page 4-2
- "Processing Data with System Objects" on page 4-6

# **System Objects**

#### In this section...

"What Are System Objects?" on page 4-2

"Creating a System Object" on page 4-2

"Changing System Object Properties" on page 4-2

"Modes" on page 4-4

"Changing Properties While Running System Objects" on page 4-5

## What Are System Objects?

System objects are MATLAB object-oriented implementations of algorithms. They extend MATLAB by enabling you to model dynamic systems represented by time-varying algorithms. System objects are well integrated into the MATLAB language, regardless of whether you are writing simple functions, working interactively in the command window, or creating large applications.

In contrast to MATLAB functions, System objects automatically manage state information, data indexing, and buffering. You can use this capability for iterative computations or stream data processing to efficiently process long data sets.

## **Creating a System Object**

To use a System object, you must first create the object. For example, to create a phased.LinearFMWaveform object, enter:

HLFMwav = phased.LinearFMWaveform;

The variable HLFMwav is an object handle. System objects are handle class objects. For more detailed information on handle class objects, see "Comparing Handle and Value Classes".

#### **Changing System Object Properties**

Each System object has one or more properties that determine how the object operates. To view the property names and their current values, enter the

object handle at the command prompt without a semicolon (;). The object property names and values are also displayed in the command window when you create a System object without a terminating semicolon.

```
hURA = phased.URA('Size',[2 2], 'ElementSpacing',0.5)
```

When you create an object using ObjectHandle = phased. ObjectName, the properties are assigned their default values. If a property is not read-only, you can modify the property value. To modify property values, you can either:

- Change the property values after construction using the *ObjectHandle.Property* syntax.
- Assign the property values at construction using name-value pairs. You can enter name-value pairs in any order.
- Assign the property values using value-only arguments at construction in the specified order. The reference page for each object describes which value-only arguments, if any, the object supports.

The following examples create phased.LinearFMWaveform objects with the same property values.

Change property values after construction.

```
HLFMwav1 = phased.LinearFMWaveform;
% Change the value of the SweepBandwidth property
HLFMwav1.SweepBandwidth = 2e5;
% Change the value of the SweepDirection property
HLFMwav1.SweepDirection = 'down';
```

Use name-value pairs at construction.

```
HLFMwav2 = phased.LinearFMWaveform('SweepBandwidth',2e5,...
'SweepDirection','down');
```

The following code creates phased. URA objects with the same property values.

Change property values after construction.

```
hURA1 = phased.URA;
hURA1.Size = [2 3];
```

```
hURA1.ElementSpacing = 0.25;
```

Use name-value pairs at construction.

```
hURA2 = phased.URA('Size',[2 3],'ElementSpacing',0.25);
% equivalent to
% hURA = phased.URA('ElementSpacing', 0.25, 'Size', [2 3]);
```

Use value-only arguments in a supported order. See phased. URA for a description of the value-only syntax.

```
hURA3 = phased.URA([2 3], 0.25);
```

To obtain command-line help on an object property, enter help phased. Object Name / Property Name at the MATLAB command prompt. For example:

```
help phased.LinearFMWaveform/SweepBandwidth
```

System object properties are also documented on the class reference page in the help documentation. See phased.LinearFMWaveform for an example.

#### Modes

System objects can be in one of two modes: unlocked or locked. After you create an instance of an object and until it starts processing data, that object is in unlocked mode. You can change any of its properties as desired.

When the object begins processing data, that object initializes and becomes locked. The typical way in which an object becomes locked is when the step method is called on that object. To determine if an object is locked, use the isLocked method. When the object is locked, you cannot change the number of inputs, the number of outputs, or the value of any property unless the property is tunable. These restrictions allow the object to maintain states and allocate memory appropriately. See "Changing Properties While Running System Objects" on page 4-5 for information on tunable and nontunable properties.

# **Changing Properties While Running System Objects**

When an object is in locked mode, that object is processing data and you can only change the values of properties that are *tunable*. To determine if a particular System object property is tunable, see the corresponding object reference page. For information on locked and unlocked modes, see "Modes" on page 4-4.

Changing the data type or dimension of a nontunable property value is not allowed without first calling the release method.

# **Processing Data with System Objects**

#### In this section...

"What Are System Object Methods?" on page 4-6

"The Step Method" on page 4-6

"Step Method Examples" on page 4-6

"Common System Object Methods" on page 4-8

"Custom System Object Methods" on page 4-9

## What Are System Object Methods?

After you create a System object and assign property values, you use object methods to process data or obtain information from or about the object. All methods that are applicable to an object are described in the reference pages for that object. System object method names begin with a lowercase letter and class and property names begin with an uppercase letter. The syntax for using methods is methodname(ObjectHandle, ...), such as step(H,...) where the ellipsis denotes a place holder for additional input arguments. For example, see the reference page for the plotResponse method of the uniform linear array, phased.ULA.

#### The Step Method

The step method is the key System object method. You use step to process data using the algorithm defined by the object. The step method performs other important tasks related to data processing, such as initialization and handling object states. Every System object has a customized step method, which is described in detail on the step reference page for that object. For more information about the step method and other available methods, see the descriptions in "Common System Object Methods" on page 4-8.

# **Step Method Examples**

This section presents examples of using the step method. The action of the step method differs for each object. See the object reference page for a detailed description.

#### Calculate the Steering Vector for a Uniform Linear Array

Construct a uniform linear array (ULA) consisting of 8 elements spaced 0.5 meters apart.

```
hULA = phased.ULA(8,0.5);
```

Construct the steering vector for the specified ULA. First construct the steering vector object with the ULA as the value of the SensorArray property.

```
hSV = phased.SteeringVector('SensorArray',hULA,...
'PropagationSpeed',physconst('lightspeed'));
```

Calculate the steering vector assuming an operating frequency of 1 GHz and azimuth and elevation angles of 45 degrees.

```
SteerVec = step(hSV, 1e9, [45 45]);
```

#### Calculate the Effect of Propagating a Signal in Free Space

This example uses two different step methods. The first step method is associated with the phased.LinearFMWaveform object and the second step method is associated with the phased.Freespace object.

Construct a linear FM waveform with a pulse duration of 50 microseconds, a sweep bandwidth of 100 kHz, an increasing instantaneous frequency, and a pulse repetition frequency (PRF) of 10 kHz..

```
hFM = phased.LinearFMWaveform('SampleRate',1e6,...
    'PulseWidth',5e-5,'PRF',1e4,...
    'SweepBandwidth',1e5,'SweepDirection','Up',...
    'OutputFormat','Pulses','NumPulses',1);
```

Obtain the waveform using the step method. Note that the input to the step method is a handle to a phased.LinearFMWaveform object.

```
Sig = step(hFM);
```

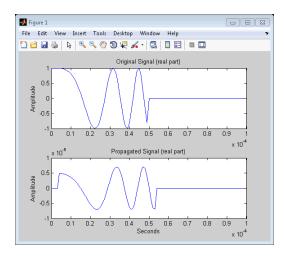

Construct a free space object with a propagation speed equal to the speed of light, an operating frequency of 3 GHz, and a sample rate of 1 MHz. The free space object is constructed to model one way propagation.

```
hFS = phased.FreeSpace(...
```

```
'PropagationSpeed',physconst('lightspeed'),...
'OperatingFrequency', 3e9, 'TwoWayPropagation', false,...
'SampleRate',1e6);
```

Calculate the effect on the waveform of one-way propagation in free space from coordinates [0;0;0] to [500; 1e3; 20] and plot the results for comparison.

```
PropSig = step(hFS,Sig,[0; 0; 0],[500; 1e3; 20]);
% compare the original signal to the propagated waveform
t = unigrid(0,1/hFS.SampleRate,length(Sig)*1/hFS.SampleRate,'[)');
subplot(211)
plot(t,real(Sig)); title('Original Signal (real part)');
ylabel('Amplitude');
subplot(212)
plot(t,real(PropSig)); title('Propagated Signal (real part)');
xlabel('Seconds'); ylabel('Amplitude');
```

## **Common System Object Methods**

All Phased Array System Toolbox System objects have the following methods, each of which is described in a method reference page associated with each specific object.

Method	Description
step	Processes data using the algorithm defined by the object. As part of this processing, this method initializes needed resources, returns outputs, and updates the object states. After you call the step method, you cannot change any input specifications (i.e., dimensions, data type, complexity). During execution, you can change only tunable properties. The step method returns regular MATLAB variables.
	Example: Y = step(H,X)
release	release releases any special resources allocated by the object, such as file handles and device drivers, and unlocks the object. See "Modes" on page 4-4.
clone	Creates another object with the same property values.
isLocked	Returns a logical value indicating whether the object is locked. See "Modes" on page 4-4.
getNumInputs	Returns the number of inputs expected by the step method. This number varies for an object depending on whether any properties enable additional inputs.
getNumOutputs	Returns the number of outputs expected from the step method. This number varies for an object depending on whether any properties enable additional outputs.

Additionally, select System objects have a reset method. For example, both phased.Platform and phased.RadarTarget have reset methods.

## **Custom System Object Methods**

In addition to common System object methods, each System object in Phased Array System Toolbox software may have one or more methods specific to that object's functionality. You can find these methods listed on the object reference page with links to the method reference page. Examples include:

• The plotResponse method for phased.URA.

hURA = phased.URA([4,4],0.5); %Construct URA

```
plotResponse(hURA,3e8,physconst('lightspeed'));
```

• The collectPlaneWave method for phased.ULA.

```
hULA = phased.ULA(8,0.5); %Construct ULA
Fc = 3e8; % Carrier Frequency 300 MHz
t = (0:1e-3:1)';
Sig = cos(2*pi*200*t); %Incident signal
% Obtain the plane wave response at the 8 array elements
RecSig = collectPlaneWave(hULA,Sig,[10;25],Fc);
```

• The bandwidth and plot methods for phased.LinearFMWaveform

```
HLFMwav = phased.LinearFMWaveform('SampleRate',50e6,...
    'PulseWidth',1e-6,'SweepBandwidth',100e5);
BWidth = bandwidth(HLFMwav);
plot(HLFMwav)
```

# Basic Radar Workflow

- "Overview of Basic Workflow" on page 5-2
- "Building The Basic Radar Workflow Model" on page 5-3

## **Overview of Basic Workflow**

The scenario and code examples contained in "Building The Basic Radar Workflow Model" on page 5-3 are intended as an introduction to the fundamental workflow used in the Phased Array System Toolbox. The example is intentionally simplified in order to familiarize you with the basic theme that extends throughout the toolbox. You will find the core elements of this workflow in all the demos and documentation examples.

The basic workflow consists of:

- Constructing objects that represent the physical components and algorithms of your model. The objects have modifiable properties that enable you to parameterize your model. For information about the object properties, see the object reference page.
- Using the object's step method to perform the action of your parameterized object on inputs. The action of step is specific to each algorithm. For example, the step method for the linear FM waveform, phased.LinearFMWaveform, performs a different action than the step method for the steering vector, phased.SteeringVector. The specific action and syntax of each step method are documented on the reference page. You can access the documentation for an object's step method by entering:

doc phased.ObjectName/step

at the MATLAB command prompt, or via the hyperlink in the Methods section of the object's reference page.

## **Building The Basic Radar Workflow Model**

"Implementing the Basic Radar Model" on page 5-7

#### **Basic Radar Workflow Scenario**

The basic toolbox workflow is illustrated with the following scenario: Assume you have a single isotropic antenna operating at 4 GHz. Assume the antenna is located at the origin of your global coordinate system. There is a target with a nonfluctuating radar cross section of 0.5 square meters initially located at [7000; 5000; 0]. The target moves with a constant velocity vector of [-15;-10;0]. Your antenna transmits ten rectangular pulses with a duration of 1 microsecond at a pulse repetition frequency (PRF) of 5 kHz. The pulses propagate to the target, reflect off the target, propagate back to the antenna, and are collected by the antenna. The antenna operates in a monostatic mode, receiving only when the transmitter is inactive.

#### Waveform

To build the waveform described in "Basic Radar Workflow Scenario" on page 5-3, use phased.RectangularWaveform and set the properties to the desired values.

```
hwav = phased.RectangularWaveform('PulseWidth',1e-6,...
'PRF',5e3,'OutputFormat','Pulses','NumPulses',1);
```

See "Rectangular Pulse Waveforms" for more detailed examples on building waveform models.

#### Antenna

To model the antenna described in "Basic Radar Workflow Scenario" on page 5-3, use phased. IsotropicAntennaElement. Set the operating frequency range of the antenna to [1,10] GHz. The isotropic antenna radiates equal energy for azimuth angles from -180 to 180 degees and elevation angles from -90 to 90 degrees.

```
hant = phased.IsotropicAntennaElement('FrequencyRange',...
    [1e9 10e9]);
```

## Target Model

To model the target described in "Basic Radar Workflow Scenario" on page 5-3, use phased.RadarTarget. The target has a nonfluctuating RCS of 0.5 square meters and the waveform incident on the target has a carrier frequency of 4 GHz. The waveform reflecting off the target propagates at the speed of light. Parameterize this information in defining your target.

```
htgt = phased.RadarTarget('Model', 'Nonfluctuating',...
    'MeanRCS', 0.5, 'PropagationSpeed', physconst('lightspeed'),...
    'OperatingFrequency',4e9);
```

## **Antenna and Target Platforms**

To model the location and movement of the antenna and target in "Basic Radar Workflow Scenario" on page 5-3, use phased.Platform.

The antenna is stationary in this scenario and is located at the origin of the global coordinate system. The target is initially located at [7000; 5000; 0] and moves with a constant velocity vector of [-15;-10;0].

```
htxplat = phased.Platform('InitialPosition',[0;0;0],...
    'Velocity',[0;0;0],'OrientationAxes',[1 0 0;0 1 0;0 0 1]);
htgtplat = phased.Platform('InitialPosition',[7000; 5000; 0],...
    'Velocity',[-15;-10;0]);
```

For definitions and conventions regarding global and local coordinates, see "Global and Local Coordinate Systems".

Use rangeangle to determine the range and angle between the antenna and the target.

```
[tgtrng,tgtang] = rangeangle(htgtplat.InitialPosition,...
htxplat.InitialPosition);
```

See "Motion Modeling in Phased Array Systems" for more details on modeling motion.

## **Modeling the Transmitter**

To model the transmitter specifications, use phased.Transmitter. A key parameter in modeling a transmitter is the peak transmit power. To determine the peak transmit power, assume that the desired probability of detection is 0.9 and the maximum tolerable false-alarm probability is  $10^{-6}$ . Assume that the ten rectangular pulses are noncoherently integrated at the receiver. You can use albersheim to determine the required signal-to-noise ratio (SNR).

```
Pd = 0.9;
Pfa = 1e-6;
numpulses = 10;
SNR = albersheim(Pd,Pfa,10);
```

The required SNR is approximately 5 dB. Assume you want to set the peak transmit power in order to achieve the required SNR for your target at a range of up to 15 kM. Assume that the transmitter has a 20 dB gain. You can use radaregpow to determine the required peak transmit power.

```
maxrange = 1.5e4;
lambda = physconst('lightspeed')/4e9;
tau = hwav.PulseWidth;
Pt = radareqpow(lambda,maxrange,SNR,tau,'RCS',0.5,'Gain',20);
```

The required peak transmit power is approximately 45 kilowatts. To be conservative, use a peak power of 50 kilowatts in modeling your transmitter. To maintain a constant phase in the pulse waveforms, set the CoherentOnTransmit property to true. Because you are operating the transmitter in a monostatic (transmit-receive) mode, set the InUseOutputPort property to true to keep a record of the transmitter status.

```
htx = phased.Transmitter('PeakPower',50e3,'Gain',20,...
    'LossFactor',0,'InUseOutputPort',true,...
    'CoherentOnTransmit', true);
```

See "Transmitter" for more examples on modeling transmitters and "Radar Equation" for examples involving the radar equation.

## **Modeling Waveform Radiation and Collection**

To model waveform radiation from the array, use phased.Radiator. To model narrowband signal collection at the array, use phased.Collector. For wideband signal collection, use phased.WidebandCollector.

In this example, the pulse satisfies the narrowband assumption around the carrier frequency of 4 GHz. For the value of the Sensor property, use the handle for the isotropic antenna. In phased.Collector, setting the Wavefront property to 'Plane' assumes the waveform incident on the antenna is a plane wave.

```
hrad = phased.Radiator('Sensor',hant,...
    'PropagationSpeed', physconst('lightspeed'),...
    'OperatingFrequency', 4e9);
hcol = phased.Collector('Sensor',hant,...
    'PropagationSpeed',physconst('lightspeed'),...
    'Wavefront', 'Plane', 'OperatingFrequency', 4e9);
```

## Modeling the Receiver

To model the receiver in "Basic Radar Workflow Scenario" on page 5-3, use phased.ReceiverPreamp. In the receiver, you specify the noise figure and reference temperature, which are key contributors to the internal noise of your system. In this example, set the noise figure to 2 dB and the reference temperature to 290 degrees kelvin. Seed the random number generator for reproducible results.

```
hrec = phased.ReceiverPreamp('Gain',20,'NoiseFigure',2,...
    'ReferenceTemperature',290, 'SampleRate',1e6,...
    'EnableInputPort',true,'SeedSource','Property','Seed',1e3);
```

See "Receiver Preamp" for more details.

## **Modeling the Propagation Environment**

To model the propagation environment in "Basic Radar Workflow Scenario" on page 5-3, use phased.FreeSpace. You can model one-way and two-propagation by setting the TwoWayPropagation property. In this example, set this property to false to model one-way propagation.

```
hspace = phased.FreeSpace(...
    'PropagationSpeed',physconst('lightspeed'),...
    'OperatingFrequency',4e9,'TwoWayPropagation',false,...
'SampleRate',1e6);
```

See "Free Space Path Loss" for more details.

## Implementing the Basic Radar Model

Having parameterized all the necessary components for the model outlined in "Basic Radar Workflow Scenario" on page 5-3, you are ready to generate the pulses, propagate the pulses to and from the target, and collect the echoes.

The following code prepares for the main simulation loop.

```
% Time step between pulses
T = 1/hwav.PRF;
% Get antenna position
txpos = htxplat.InitialPosition;
% Allocate array for received echoes
rxsig = zeros(hwav.SampleRate*T,numpulses);
```

You can execute the main simulation loop with the following code:

```
for n = 1:numpulses
    % Update the target position
    tgtpos = step(htgtplat,T);
    % Get the range and angle to the target
    [tgtrng,tgtang] = rangeangle(tgtpos,txpos);
    % Generate the pulse
    sig = step(hwav);
    % Transmit the pulse. Output transmitter status
    [sig,txstatus] = step(htx,sig);
    % Radiate the pulse toward the target
    sig = step(hrad,sig,tgtang);
```

```
% Propagate the pulse to the target in free space
    sig = step(hspace,sig,txpos,tgtpos);
    % Reflect the pulse off the target
    sig = step(htgt,sig);
    % Propagate the echo to the antenna in free space
    sig = step(hspace,sig,tgtpos,txpos);
    % Collect the echo from the incident angle at the antenna
    sig = step(hcol,sig,tgtang);
    % Receive the echo at the antenna when not transmitting
    rxsig(:,n) = step(hrec,sig,~txstatus);
end
```

Noncoherently integrate the received echoes, create a vector of range gates, and plot the result. The red vertical line on the plot marks the range of the target.

```
rxsig = pulsint(rxsig, 'noncoherent');
t = unigrid(0,1/hrec.SampleRate,T,'[)');
rangegates = (physconst('lightspeed')*t)/2;
plot(rangegates,rxsig); hold on;
xlabel('Meters'); ylabel('Power');
ylim = get(gca, 'YLim');
plot([tgtrng,tgtrng],[0 ylim(2)],'r');
```
