## **Product Description**

#### Model and simulate aircraft, spacecraft, and propulsion systems

Aerospace Blockset<sup>™</sup> software extends Simulink<sup>®</sup> with blocks for modeling and simulating aircraft, spacecraft, rocket, and propulsion systems, as well as unmanned airborne vehicles. It also includes blocks that implement mathematical representations from aerospace standards, common references, and first principles. Blocks for modeling equations of motion and for navigation, gain scheduling, visualization, unit conversion, and other key operations are also provided.

## **Key Features**

- Simulates aerospace vehicle components, including propulsion systems, control systems, mass properties, and actuators
- Models flight dynamics, including three- and six-degrees-of-freedom equations of motion with fixed or variable mass
- Provides options for visualizing vehicle dynamics in a three-dimensional environment, including an interface to FlightGear flight simulator
- Includes standards-based environmental models for atmosphere, gravity, wind, geoid height, and magnetic field
- Implements predefined utilities for converting units, transforming coordinate systems and spatial representations, and performing common aerospace math operations

## **Code Generation Support**

Use the Aerospace Blockset software with the Simulink Coder<sup>TM</sup> software to automatically generate code for real-time execution in rapid prototyping and for hardware-in-the-loop systems.

1

## **Support for Aerospace Toolbox Quaternion Functions**

The Aerospace Blockset product supports the following Aerospace Toolbox quaternion functions in the MATLAB Function block:

quatconj quatinv quatmod quatmultiply quatdivide quatnorm quatnormalize

For further information on using the MATLAB Function block, see:

- "What Is a MATLAB Function Block?"
- asbQuatEML example, which illustrates quaternions and models the equations

## Introduction

This section introduces a NASA HL-20 lifting body airframe model that uses blocks from the Aerospace Blockset software to simulate the airframe of a NASA HL-20 lifting body, in conjunction with other Simulink blocks.

The model simulates the NASA HL-20 lifting body airframe approach and landing flight phases using an automatic-landing controller.

For more information on this model, see "NASA HL-20 Lifting Body Airframe" on page 3-20.

## What This Example Illustrates

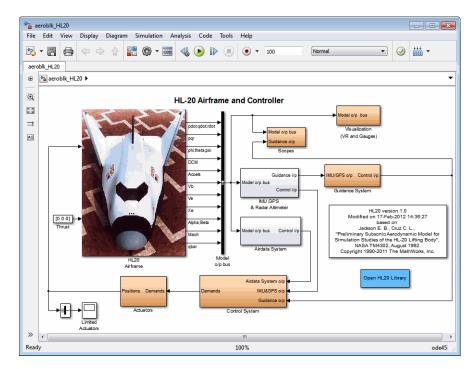

The NASA HL-20 lifting body airframe example illustrates the following features of the blockset:

- Representing bodies and degrees of freedom with the Equations of Motion library blocks
- Using the Aerospace Blockset blocks with other Simulink blocks
- Feeding in and feeding out Simulink signals to and from Aerospace Blockset blocks with Actuator and Sensor blocks
- Encapsulating groups of blocks into subsystems

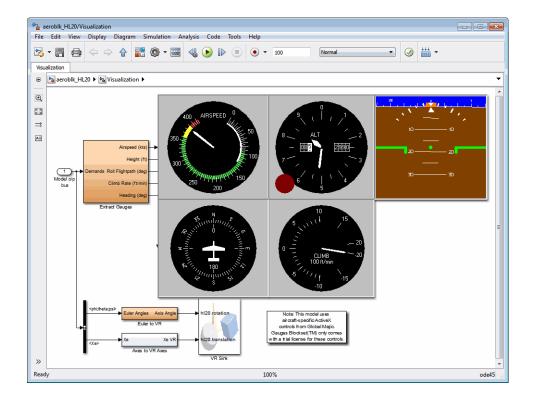

• Visualizing an aircraft with Simulink 3D Animation<sup>™</sup> and Gauges Blockset<sup>™</sup> library blocks.

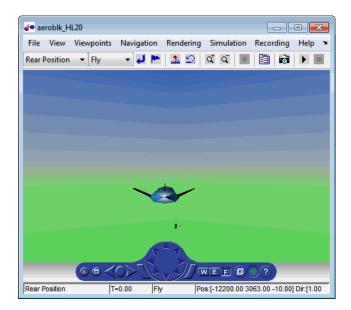

## **Open the Model**

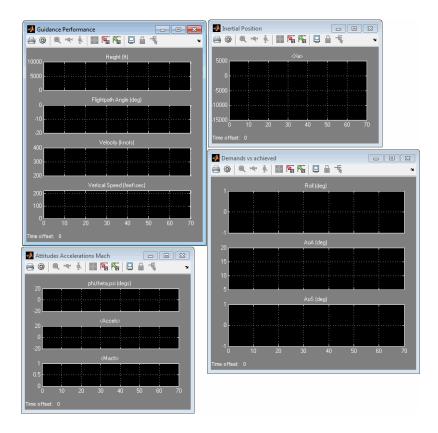

To open the NASA HL-20 airframe example, type the example name, aeroblk\_HL20, at the MATLAB command line. The model opens.

The visualization subsystem, four scopes, and a Simulink 3D Animation viewer for the airframe also appear.

## **Key Subsystems**

The model implements the airframe using the following subsystems:

- The 6DoF (Euler Angles) subsystem implements the 6DoF (Euler Angles) block along with other Simulink blocks.
- The Environment Models subsystem implements the WGS84 Gravity Model and COESA Atmosphere Model blocks. It also contains a Wind Models subsystem that implements a number of wind blocks.
- The Alpha, Beta, Mach subsystem implements the Incidence, Sideslip & Airspeed, Mach Number, and Dynamic Pressure blocks. These blocks calculate aerodynamic coefficient values and lookup functionality.

- The Forces and Moments subsystem implements the Aerodynamic Forces and Moments block. This subsystem calculates body forces and body moments.
- The Aerodynamic Coefficients subsystem implements several subsystems to calculate six aerodynamic coefficients.

## NASA HL-20 Example

Running an example lets you observe the model simulation in real time. After you run the example, you can examine the resulting data in plots, graphs, and other visualization tools. To run this model, follow these steps:

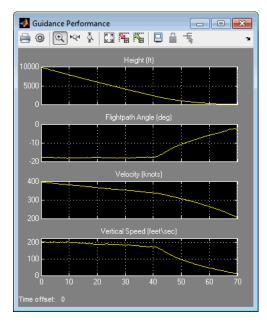

- 1 If it is not already open, open the aeroblk\_HL20 example.
- 2 From the Simulation menu, select Run. On Microsoft<sup>®</sup> Windows<sup>®</sup> systems, you can also click the Run button in the model window toolbar.

The simulation proceeds until the aircraft lands:

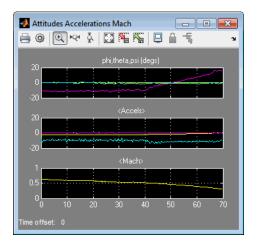

View of the landed airframe

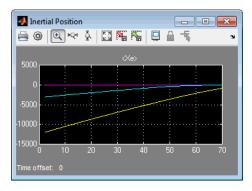

1

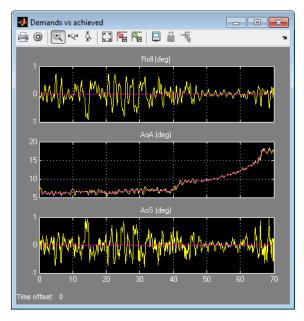

**Plot that Measures Guidance Performance** 

Plot that Measures Altitude Accelerations Mach

**Plot that Measures Inertial Position** 

Plot that Measures Demand Data Against Achieved Data

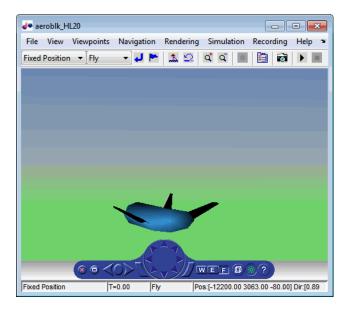

## Modify the Model

You can adjust the airframe model settings and examine the effects on simulation performance. Here is one modification that you can try. It changes the camera point of view for the landing animation.

#### **Change the Animation Point of View**

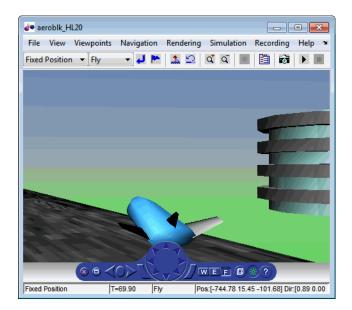

By default, the airframe animation viewpoint is Rear position, which means the view tracks with the airframe flight path from the rear. You can change the animation point of view by selecting another viewpoint from the Simulink 3D Animation viewer:

- 1 Open the aeroblk\_HL20 model, and click the Simulink 3D Animation viewer.
- **2** From the list of existing viewpoints, change the viewpoint to Fixed Position.

The airframe view changes to a fixed position.

**3** Start the model again. Notice the different airframe viewpoint when the airframe lands.

You can experiment with different viewpoints to watch the animation from different perspectives.

1

## **Open Aerospace Examples**

To open an Aerospace Blockset example from Help Browser:

- 1 Open the MATLAB Command Window.
- **2** Click the question mark.
- **3** Navigate to Aerospace Blockset and click **Examples** in the top right-hand corner.

The Aerospace Blockset Examples page is displayed.

Alternatively, you can open the **Examples** window by entering demos at the MATLAB command line.

For in-depth case studies of the following examples, see:

- "Ideal Airspeed Correction" on page 3-2
- "1903 Wright Flyer" on page 3-10
- "NASA HL-20 Lifting Body Airframe" on page 3-20

## **Create Aerospace Models**

## **Basic Steps**

Regardless of the model's complexity, you use the same essential steps for creating an aerospace model as you would for creating any other Simulink model.

1 Open the Aerospace Blockset Library.

Type simulink to open Simulink Library Browser in the MATLAB

Command Window or click the button. The left pane contains a list of all the blocksets that you currently have installed.

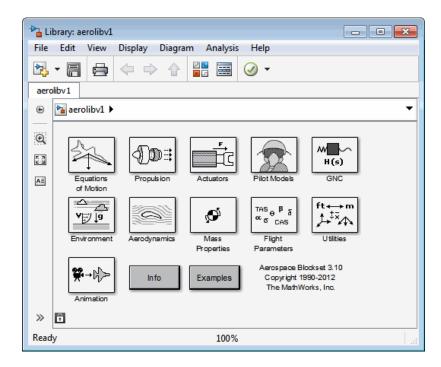

Navigate to the Aerospace Blockset node and expand the hierarchical list to display that blockset's libraries within the browser.

Alternatively, to open the Aerospace Blockset window from the MATLAB command line, enter

#### aerolib

Double-click any library in the window to display its contents. The following figure shows the Aerospace Blockset library window.

- **2** Select and position the blocks. You must first select the blocks that you need to build your model, and then position the blocks in the model window. For the majority of Simulink models, you select one or more blocks from each of the following categories:
  - **a** Source blocks generate or import signals into the model, such as a sine wave, a clock, or limited-band white noise.
  - **b** Simulation blocks can consist of almost any type of block that performs an action in the simulation. A simulation block represents a part of the model functionality to be simulated, such as an actuator block, a mathematical operation, a block from the Aerospace Blockset library, and so on.
  - Signal Routing blocks route signals from one point in a model to another. If you need to combine or redirect two or more signals in your model, you will probably use a Simulink Signal Routing block, such as Mux and Demux.

As an alternative to the Mux block, you can use the Vector option of the Concatenate block **Mode** parameter (also known as the Vector Concatenate block). This block provides a more general way for you to route signals from one point in the a model to another. The Vector mode takes as input a vector of signals of the same data type and creates a contiguous output signal. Depending on the input, this block outputs a row or column vector if any of the inputs are row or column vectors, respectively.

- **d** Sink blocks display, write, or save model output. To see the results of the simulation, you must use a Sink block.
- **3** *Configure the blocks.* Most blocks feature configuration options that let you customize block functionality to specific simulation parameters. For example, the ISA Atmosphere Model block provides configuration options for setting the height of the troposphere, tropopause, and air density at sea level.
- **4** *Connect the blocks.* To create signal pathways between blocks, you connect the blocks to each other. You can do this manually by clicking and dragging, or you can connect blocks automatically.
- **5** *Encapsulate subsystems*. Systems made with Aerospace Blockset blocks can function as subsystems of larger, more complex models, like subsystems in any Simulink model.

## **Build a Simple Actuator System**

#### In this section ...

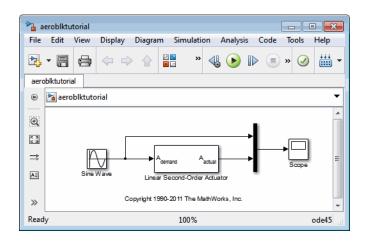

"Build the Model" on page 2-5

"Run the Simulation" on page 2-10

## **Build the Model**

The Simulink product is a software environment for modeling, simulating, and analyzing dynamic systems. Try building a simple model that drives an actuator with a sine wave and displays the actuator's position superimposed on the sine wave.

**Note** If you prefer to open the complete model shown below instead of building it, enter aeroblktutorial at the MATLAB command line.

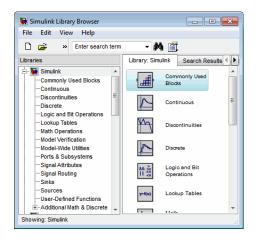

The following section ("Create a Model" on page 2-6) explains how to build a model on Windows platforms. You can use this same procedure to build a model on UNIX<sup>®</sup> platforms.

The section describes how to build the model. It does not describe how to set the configuration parameters for the model. See "Configure Simulation". That topic describes setting configuration parameters for models. If you do not set any configuration parameters, simulating models might cause warnings like:

Warning: Using a default value of 0.2 for maximum step size. The simulation step size will be equal to or less than this value. You can disable this diagnostic by setting 'Automatic solver parameter selection' diagnostic to 'none' in the Diagnostics page of the configuration parameters dialog

#### Create a Model

1 Click the button in the MATLAB Toolstrip or enter simulink at the MATLAB command line. The Simulink library browser appears.

- 2 Select New > Model from the File menu in the Library Browser. A new model window appears on your screen.
- **3** Add a Sine Wave block to the model.
  - **a** Click **Sources** in the Library Browser to view the blocks in the Simulink Sources library.
  - **b** Drag the Sine Wave block from the Sources library into the new model window.

- 4 Add a Linear Second-Order Actuator block to the model.
  - a Click the symbol next to Aerospace Blockset in the Library Browser to expand the hierarchical list of the aerospace blocks.
  - **b** In the expanded list, click **Actuators** to view the blocks in the Actuator library.
  - c Drag the Linear Second-Order Actuator block into the model window.
- **5** Add a Mux block to the model.
  - **a** Click **Signal Routing** in the Library Browser to view the blocks in the Simulink Signals & Systems library.
  - **b** Drag the Mux block from the Signal Routing library into the model window.
- **6** Add a Scope block to the model.
  - **a** Click **Sinks** in the Library Browser to view the blocks in the Simulink Sinks library.
  - **b** Drag the Scope block from the Sinks library into the model window.
- 7 Resize the Mux block in the model.
  - a Click the Mux block to select the block.
  - **b** Hold down the mouse button and drag a corner of the Mux block to change the size of the block.
- 8 Connect the blocks.
  - **a** Position the pointer near the output port of the Sine Wave block. Hold down the mouse button and drag the line that appears until it touches the input port of the Linear Second-Order Actuator block. Release the mouse button.
  - **b** Using the same technique, connect the output of the Linear Second-Order Actuator block to the second input port of the Mux block.
  - Using the same technique, connect the output of the Mux block to the input port of the Scope block.
  - **d** Position the pointer near the first input port of the Mux block. Hold down the mouse button and drag the line that appears over the line

from the output port of the Sine Wave block until double crosshairs appear. Release the mouse button. The lines are connected when a knot is present at their intersection.

- **9** Set the block parameters.
  - **a** Double-click the Sine Wave block. The dialog box that appears allows you to set the block's parameters.

For this example, configure the block to generate a 10 rad/s sine wave by entering 10 for the **Frequency** parameter. The sinusoid has the default amplitude of 1 and phase of 0 specified by the **Amplitude** and **Phase offset** parameters.

**b** Click **OK**.

Source Block Parameters: Sine Wave
Sine Wave
Output a sine wave:
O(t) = Amp*Sin(Freq*t+Phase) + Bias
Sine type determines the computational technique used. The parameters in the two types are related through:
Samples per period = $2*pi$ / (Frequency * Sample time)
Number of offset samples = Phase * Samples per period / $(2*pi)$
Use the sample-based sine type if numerical problems due to running for large times (e.g. overflow in absolute time) occur.
Parameters

c Double-click the Linear Second-Order Actuator block.

In this example, the actuator has the default natural frequency of 150 rad/s, a damping ratio of 0.7, and an initial position of 0 radians specified by the **Natural frequency**, **Damping ratio**, and **Initial position** parameters.

d Click OK.

## **Run the Simulation**

You can now run the model that you built to see how the system behaves in time:

- **1** Double-click the Scope block if the Scope window is not already open on your screen. The Scope window appears.
- **2** Select **Run** from the **Simulation** menu in the model window. The signal containing the 10 rad/s sinusoid and the signal containing the actuator position are plotted on the scope.
- **3** Adjust the Scope block's display. While the simulation is running, right-click the *y*-axis of the scope and select **Autoscale**. The vertical range of the scope is adjusted to better fit the signal.
- 4 Vary the Sine Wave block parameters.
  - **a** While the simulation is running, double-click the Sine Wave block to open its parameter dialog box.
  - b You can then change the frequency of the sinusoid. Try entering 1 or
    20 in the Frequency field. Close the Sine Wave dialog box to enter your change. You can then observe the changes on the scope.

5 Select Stop from the Simulation menu to stop the simulation.

Many parameters *cannot* be changed while a simulation is running. This is usually the case for parameters that directly or indirectly alter a signal's dimensions or sample rate. However, there are some parameters, like the Sine Wave **Frequency** parameter, that you can *tune* without stopping the simulation.

#### Run a Simulation from a Script

You can also modify and run a Simulink simulation from a script. By doing this, you can automate the variation of model parameters to explore a large number of simulation conditions rapidly and efficiently. For information on how to do this, see "About Programmatic Simulation".

## **About Aerospace Coordinate Systems**

#### In this section ...

"Fundamental Coordinate System Concepts" on page 2-12

"Coordinate Systems for Modeling" on page 2-14

"Coordinate Systems for Navigation" on page 2-16

"Coordinate Systems for Display" on page 2-19

"References" on page 2-20

## **Fundamental Coordinate System Concepts**

Coordinate systems allow you to keep track of an aircraft or spacecraft's position and orientation in space. The Aerospace Blockset coordinate systems are based on these underlying concepts from geodesy, astronomy, and physics.

#### Definitions

The blockset uses *right-handed* (RH) *Cartesian* coordinate systems. The *right-hand rule* establishes the *x-y-z* sequence of coordinate axes.

An *inertial frame* is a nonaccelerating motion reference frame. In an inertial frame, Newton's second law holds: force = mass × acceleration. Loosely speaking, acceleration is defined with respect to the distant cosmos, and an inertial frame is often said to be nonaccelerated with respect to the "fixed stars." Because the Earth and stars move so slowly with respect to one another, this assumption is a very accurate approximation.

Strictly defined, an inertial frame is a member of the set of all frames not accelerating relative to one another. A *noninertial frame* is any frame accelerating relative to an inertial frame. Its acceleration, in general, includes both translational and rotational components, resulting in *pseudoforces* (*pseudogravity*, as well as *Coriolis* and *centrifugal forces*).

The blockset models the Earth's shape (the *geoid*) as an oblate spheroid, a special type of ellipsoid with two longer axes equal (defining the *equatorial plane*) and a third, slightly shorter (*geopolar*) axis of symmetry. The equator is the intersection of the equatorial plane and the Earth's surface. The

geographic poles are the intersection of the Earth's surface and the geopolar axis. In general, the Earth's geopolar and rotation axes are not identical.

Latitudes parallel the equator. Longitudes parallel the geopolar axis. The *zero longitude* or *prime meridian* passes through Greenwich, England.

#### **Approximations**

The blockset makes three standard approximations in defining coordinate systems relative to the Earth.

- The Earth's surface or geoid is an oblate spheroid, defined by its longer equatorial and shorter geopolar axes. In reality, the Earth is slightly deformed with respect to the standard geoid.
- The Earth's rotation axis and equatorial plane are perpendicular, so that the rotation and geopolar axes are identical. In reality, these axes are slightly misaligned, and the equatorial plane wobbles as the Earth rotates. This effect is negligible in most applications.
- The only noninertial effect in Earth-fixed coordinates is due to the Earth's rotation about its axis. This is a *rotating*, *geocentric* system. The blockset ignores the Earth's acceleration around the Sun, the Sun's acceleration in the Galaxy, and the Galaxy's acceleration through the cosmos. In most applications, only the Earth's rotation matters.

This approximation must be changed for spacecraft sent into deep space, i.e., outside the Earth-Moon system, and a heliocentric system is preferred.

#### **Motion with Respect to Other Planets**

The blockset uses the standard WGS-84 geoid to model the Earth. You can change the equatorial axis length, the flattening, and the rotation rate.

You can represent the motion of spacecraft with respect to any celestial body that is well approximated by an oblate spheroid by changing the spheroid size, flattening, and rotation rate. If the celestial body is rotating westward (retrogradely), make the rotation rate negative.

## **Coordinate Systems for Modeling**

Modeling aircraft and spacecraft is simplest if you use a coordinate system fixed in the body itself. In the case of aircraft, the forward direction is modified by the presence of wind, and the craft's motion through the air is not the same as its motion relative to the ground.

See "Equations of Motion" for further details on how the Aerospace Blockset product implements body and wind coordinates.

#### **Body Coordinates**

The noninertial body coordinate system is fixed in both origin and orientation to the moving craft. The craft is assumed to be rigid.

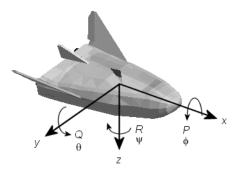

The orientation of the body coordinate axes is fixed in the shape of body.

- The *x*-axis points through the nose of the craft.
- The *y*-axis points to the right of the *x*-axis (facing in the pilot's direction of view), perpendicular to the *x*-axis.
- The *z*-axis points down through the bottom the craft, perpendicular to the *xy* plane and satisfying the RH rule.

**Translational Degrees of Freedom.** Translations are defined by moving along these axes by distances x, y, and z from the origin.

**Rotational Degrees of Freedom.** Rotations are defined by the Euler angles *P*, *Q*, *R* or  $\Phi$ ,  $\Theta$ ,  $\Psi$ . They are:

$P  ext{ or } \Phi$	Roll about the <i>x</i> -axis
$Q  ext{ or } \Theta$	Pitch about the <i>y</i> -axis
$R  ext{ or } \Psi$	Yaw about the <i>z</i> -axis

#### Wind Coordinates

The noninertial wind coordinate system has its origin fixed in the rigid aircraft. The coordinate system orientation is defined relative to the craft's velocity V.

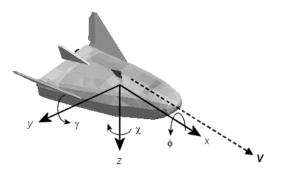

The orientation of the wind coordinate axes is fixed by the velocity V.

- The *x*-axis points in the direction of *V*.
- The y-axis points to the right of the x-axis (facing in the direction of V), perpendicular to the x-axis.
- The *z*-axis points perpendicular to the *xy* plane in whatever way needed to satisfy the RH rule with respect to the *x* and *y*axes.

**Translational Degrees of Freedom.** Translations are defined by moving along these axes by distances x, y, and z from the origin.

**Rotational Degrees of Freedom.** Rotations are defined by the Euler angles  $\Phi$ ,  $\gamma$ ,  $\chi$ . They are:

$\Phi$	Bank angle about the <i>x</i> -axis
Y	Flight path about the y-axis
Х	Heading angle about the $z$ -axis

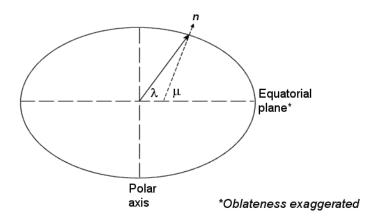

## **Coordinate Systems for Navigation**

Modeling aerospace trajectories requires positioning and orienting the aircraft or spacecraft with respect to the rotating Earth. Navigation coordinates are defined with respect to the center and surface of the Earth.

#### **Geocentric and Geodetic Latitudes**

The geocentric latitude  $\lambda$  on the Earth's surface is defined by the angle subtended by the radius vector from the Earth's center to the surface point with the equatorial plane.

The *geodetic latitude*  $\mu$  on the Earth's surface is defined by the angle subtended by the surface normal vector n and the equatorial plane.

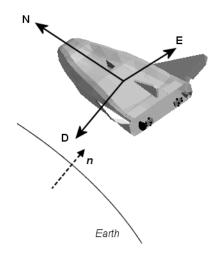

#### **NED Coordinates**

The north-east-down (NED) system is a noninertial system with its origin fixed at the aircraft or spacecraft's center of gravity. Its axes are oriented along the geodetic directions defined by the Earth's surface.

- The *x*-axis points north parallel to the geoid surface, in the polar direction.
- The *y*-axis points east parallel to the geoid surface, along a latitude curve.
- The z-axis points downward, toward the Earth's surface, antiparallel to the surface's outward normal n.

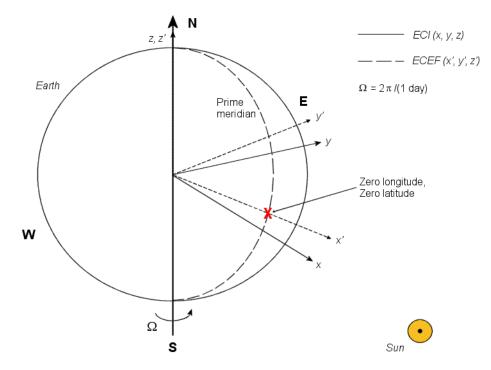

Flying at a constant altitude means flying at a constant z above the Earth's surface.

#### **ECI Coordinates**

The Earth-centered inertial (ECI) system is a mixed inertial system. It is oriented with respect to the Sun. Its origin is fixed at the center of the Earth. (See figure following.)

- The *z*-axis points northward along the Earth's rotation axis.
- The *x*-axis points outward in the Earth's equatorial plane exactly at the Sun. (This rule ignores the Sun's oblique angle to the equator, which varies with season. The actual Sun always remains in the *xz* plane.)

• The *y*-axis points into the eastward quadrant, perpendicular to the *xz* plane so as to satisfy the RH rule.

#### **Earth-Centered Coordinates**

#### **ECEF Coordinates**

The Earth-center, Earth-fixed (ECEF) system is a noninertial system that rotates with the Earth. Its origin is fixed at the center of the Earth. (See figure preceding.)

- The z'-axis points northward along the Earth's rotation axis.
- The *x*'-axis points outward along the intersection of the Earth's equatorial plane and prime meridian.
- The *y*'-axis points into the eastward quadrant, perpendicular to the *x*-*z* plane so as to satisfy the RH rule.

## **Coordinate Systems for Display**

Several display tools are available for use with the Aerospace Blockset product. Each has a specific coordinate system for rendering motion.

#### **MATLAB Graphics Coordinates**

See the "Coordinate System" for more information about the MATLAB Graphics coordinate axes.

MATLAB Graphics uses this default coordinate axis orientation:

- The *x*-axis points out of the screen.
- The *y*-axis points to the right.
- The z-axis points up.

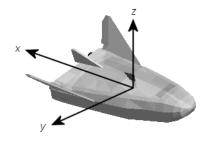

#### **FlightGear Coordinates**

FlightGear is an open-source, third-party flight simulator with an interface supported by the blockset.

- "Work with the Flight Simulator Interface" on page 2-28 discusses the blockset interface to FlightGear.
- See the FlightGear documentation at www.flightgear.org for complete information about this flight simulator.

The FlightGear coordinates form a special body-fixed system, rotated from the standard body coordinate system about the *y*-axis by -180 degrees:

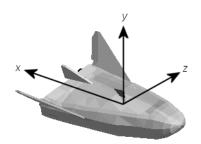

- The *x*-axis is positive toward the back of the vehicle.
- The *y*-axis is positive toward the right of the vehicle.
- The *z*-axis is positive upward, e.g., wheels typically have the lowest *z* values.

#### **AC3D Coordinates**

AC3D is a low-cost, widely used, geometry editor available from www.ac3d.org. Its body-fixed coordinates are formed by inverting the three standard body coordinate axes:

- The *x*-axis is positive toward the back of the vehicle.
- The *y*-axis is positive upward, e.g., wheels typically have the lowest *y* values.
- The *z*-axis is positive to the left of the vehicle.

## **Flight Simulator Interface**

#### In this section ...

"About the FlightGear Interface" on page 2-22

"Obtain FlightGear" on page 2-22

"Configure Your Computer for FlightGear" on page 2-23

"Install and Start FlightGear" on page 2-26

## About the FlightGear Interface

The Aerospace Blockset product supports an interface to the third-party FlightGear flight simulator, an open source software package available through a GNU General Public License (GPL). The FlightGear flight simulator interface included with the blockset is a unidirectional transmission link from the Simulink interface to FlightGear using FlightGear's published net\_fdm binary data exchange protocol. Data is transmitted via UDP network packets to a running instance of FlightGear. The blockset supports multiple standard binary distributions of FlightGear. See "Run FlightGear with the Simulink Models" on page 2-34 for interface details.

FlightGear is a separate software entity neither created, owned, nor maintained by MathWorks.

- To report bugs in or request enhancements to the Aerospace Blockset FlightGear interface, use this form http://www.mathworks.com/contact\_TS.html.
- To report bugs or request enhancements to FlightGear itself, visit www.flightgear.org and use the contact page.

## **Obtain FlightGear**

You can obtain FlightGear from www.flightgear.org in the download area or by ordering CDs from FlightGear. The download area contains extensive documentation for installation and configuration. Because FlightGear is an open source project, source downloads are also available for customization and porting to custom environments.

## **Configure Your Computer for FlightGear**

You must have a high performance graphics card with stable drivers to use FlightGear. For more information, see the FlightGear CD distribution or the hardware requirements and documentation areas of the FlightGear Web site, www.flightgear.org.

MathWorks tests of FlightGear performance and stability indicate significant sensitivity to computer video cards, driver versions, and driver settings. You need OpenGL<sup>®</sup> support with hardware acceleration activated. The OpenGL settings are particularly important. Without proper setup, performance can drop from about a 30 frames-per-second (fps) update rate to less than 1 fps. If your system allows you to update OpenGL settings, modify them to improve performance.

#### **Graphics Recommendations for Windows**

MathWorks recommends the following for Windows users:

- Choose a graphics card with good OpenGL performance.
- Always use the latest tested and stable driver release for your video card. Test the driver thoroughly on a few computers before deploying to others.

For Microsoft Windows XP systems running on x86 (32-bit) or AMD-64/EM64T chip architectures, the graphics card operates in the unprotected kernel space known as Ring Zero. This means that glitches in the driver can cause Windows to lock or crash. Before buying a large number of computers for 3-D applications, test, with your vendor, one or two computers to find a combination of hardware, operating system, drivers, and settings that are stable for your applications.

#### Set Up OpenGL Graphics on Windows

For complete information on OpenGL settings, refer to the documentation at the OpenGL Web site: www.opengl.org.

If your system allows you to modify OpenGL, perform steps like the following to optimize your video card settings. Your driver's panes might look different.

1 Ensure that you have activated the OpenGL hardware acceleration on your video card. On Windows, access this configuration through Start > **Settings > Control Panel > Display**, which opens the following dialog box. Select the **Settings** tab.

Display Properties	<u>? ×</u>
Background Screen Saver Appearance	
Colors	Screen area Less More 1280 by 1024 pixels
	Troubleshoot Advanced
OK	Cancel Apply

2 Click the **Advanced** button in the lower right of the dialog box, which brings up the graphics card's custom configuration dialog box, and go to the **OpenGL** tab. For an ATI Mobility Radeon 9000 video card, the **OpenGL** pane looks like this:

POWERPLA neral Adapter Monitor			n Screen Display nt   🏧 Displays   🏧   🏧 Overla	
Main Settings			OpenGL.	
<- Performance	Optimal Qua Performance	lity→ ⊑ <u>Q</u> ut	stom Settings	
Custom Settings Anisotropic Filtering				
Application Prefere	nce Sampl		K 8X 16X	
Anti-aliasing		es: C Perform	ance 🕫 Quality	
Application Prefere	nce			
		<- Perfo	rmance   Quality ->	
Texture Preference:	Performance	e .	- <del>)</del>	
Mipmap Detail Level:	Performance	e .	·	
Wait for Vertical Sync:	Always Off	C Appli	cation Preference	
	[	Compatibility Settin	igs	

- **3** For best performance, move the **Main Settings** slider near the top of the dialog box to the **Performance** end of the slider.
- **4** If stability is a problem, try other screen resolutions, other color depths in the **Displays** pane, and other OpenGL acceleration modes.

Many cards perform much better at 16 bits-per-pixel color depth (also known as 65536 color mode, 16-bit color). For example, on an ATI Mobility Radeon 9000 running a given model, 30 fps are achieved in 16-bit color mode, while 2 fps are achieved in 32-bit color mode.

#### Setup on Linux, Macintosh, and Other Platforms

FlightGear distributions are available for Linux<sup>®</sup>, Macintosh, and other UNIX platforms from the FlightGear Web site, www.flightgear.org. Installation on these platforms, like Windows, requires careful configuration of graphics cards and drivers. Consult the documentation and hardware requirements sections at the FlightGear Web site.

# Use MATLAB Graphics Controls to Configure Your OpenGL Settings

You can also control your OpenGL rendering from the MATLAB command line with the MATLAB Graphics opengl command. Consult the opengl command reference for more information.

## Install and Start FlightGear

The extensive FlightGear documentation guides you through the installation in detail. Consult the following:

- Documentation section of the FlightGear Web site for installation instructions: http://mapserver.flightgear.org/getstart/ located at www.flightgear.org.
- MATLAB system requirements.

Keep the following points in mind:

- Configure your computer's graphics card before you install FlightGear. See the preceding section, "Configure Your Computer for FlightGear" on page 2-23.
- Shut down all running applications (including the MATLAB interface) before installing FlightGear.
- MathWorks tests indicate that the operational stability of FlightGear is especially sensitive during startup. It is best to not move, resize, mouse over, overlap, or cover up the FlightGear window until the initial simulation scene appears after the startup splash screen fades out.

Aerospace Blockset supports FlightGear on a number of platforms (http://www.mathworks.com/products/aeroblks/requirements.html). The following table lists the properties you should be aware of before you start to use FlightGear.

FlightGear Property	Folder Description	Platforms	Typical Location
FlightGearBase- Directory	FlightGear installation folder.	Windows 64-bit	C:\Program Files\FlightGear (default)
		Windows 32-bit	C:\Program Files (x86)\- FlightGear (default)
		Solaris™ or Linux	Folder into which you installed FlightGear
		Mac	/Applications (directory to which you dragged the FlightGear icon)
-	Model geometry folder	Windows 64-bit	C:\Program Files\- FlightGear\data\- Aircraft\HL20 (default)
		Windows 32-bit	C:\Program Files (x86)\- FlightGear\data\- Aircraft\HL20 (default)
		Solaris or Linux	<pre>\$FlightGearBaseDirectory/- data/Aircraft/HL20</pre>
		Mac	<pre>\$FlightGearBaseDirectory/- FlightGear.app/Contents/- Resources/data/Aircraft/HL20</pre>

## Work with the Flight Simulator Interface

#### In this section...

"Introduction" on page 2-28

"About Aircraft Geometry Models" on page 2-29

"Work with Aircraft Geometry Models" on page 2-31

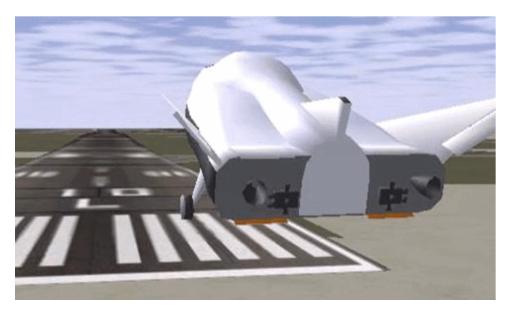

"Run FlightGear with the Simulink Models" on page 2-34

"Send and Receive Data" on page 2-45

## Introduction

Use this section to learn how to use the FlightGear flight simulator and the Aerospace Blockset software to visualize your Simulink aircraft models. If you have not yet installed FlightGear, see "Flight Simulator Interface" on page 2-22 first.

Simulink<sup>®</sup> Driven HL-20 Model in a Landing Flare at KSFC

## **About Aircraft Geometry Models**

Before you can visualize your aircraft's dynamics, you need to create or obtain an aircraft model file compatible with FlightGear. This section explains how to do this.

#### **Aircraft Geometry Editors and Formats**

You have a competitive choice of over twelve 3-D geometry file formats supported by FlightGear.

Currently, the most popular 3-D geometry file format is the AC3D format, which has the suffix \*.ac. AC3D is a low-cost geometry editor available from www.ac3d.org. Another popular 3-D editor for aircraft models is Flight Sim Design Studio, distributed by Abacus Publications at www.abacuspub.com.

#### **Aircraft Model Structure and Requirements**

Aircraft models are contained in the *FlightGearRoot*/data/Aircraft/ folder and subfolders. A complete aircraft model must contain a folder linked through the required aircraft master file named *model*-set.xml.

All other model elements are optional. This is a partial list of the optional elements you can put in an aircraft data folder:

- Vehicle objects and their shapes and colors
- Vehicle objects' surface bitmaps
- Variable geometry descriptions
- Cockpit instrument 3-D models
- Vehicle sounds to tie to events (e.g., engine, gear, wind noise)
- Flight dynamics model
- Simulator views
- Submodels (independently movable items) associated with the vehicle

Model behavior reverts to defaults when these elements are not used. For example,

• Default sound: no vehicle-related sounds are emitted.

• Default instrument panel: no instruments are shown.

Models can contain some, all, or even none of the above elements. If you always run FlightGear from the cockpit view, the aircraft geometry is often secondary to the instrument geometries.

A how-to document for including optional elements is included in the FlightGear documentation at:

http://www.flightgear.org/Docs/fgfs-model-howto.html

#### **Required Flight Dynamics Model Specification**

The flight dynamics model (FDM) specification is a required element for an aircraft model. To set the Simulink software as the source of the flight dynamics model data stream for a given geometry model, you put this line in data/Aircraft/model.model.set.xml:

<flight-model>network</flight-model>

#### **Obtain and Modify Existing Aircraft Models**

You can quickly build models from scratch by referencing instruments, sounds, and other optional elements from existing FlightGear models. Such models provide examples of geometry, dynamics, instruments, views, and sounds. It is simple to copy an aircraft folder to a new name, rename the *model*-set.xml file, modify it for network flight dynamics, and then run FlightGear with the aircraft flag set to the name in *model*-set.xml.

Many existing 3-D aircraft geometry models are available for use with FlightGear. Visit the download area of www.flightgear.org to see some of the aircraft models available. Additional models can be obtained via Web search. Search key words such as "flight gear aircraft model" are a good starting point. Be sure to comply with copyrights when distributing these files.

#### Hardware Requirements for Aircraft Geometry Rendering

When creating your own geometry files, keep in mind that your graphics card can efficiently render a limited number of surfaces. Some cards can efficiently render fewer than 1000 surfaces with bitmaps and specular reflections at

2-30

the nominal rate of 30 frames per second. Other cards can easily render on the order of 10,000 surfaces.

If your performance slows while using a particular geometry, gauge the effect of geometric complexity on graphics performance by varying the number of aircraft model surfaces. An easy way to check this is to replace the full aircraft geometry file with a simple shape, such as a single triangle, then test FlightGear with this simpler geometry. If a geometry file is too complex for smooth display, use a 3-D geometry editor to simplify your model by reducing the number of surfaces in the geometry.

## Work with Aircraft Geometry Models

Once you have obtained, modified, or created an aircraft data file, you need to put it in the correct folder for FlightGear to access it.

#### Import Aircraft Models into FlightGear

To install a compatible model into FlightGear, use one of the following procedures. Choose the one appropriate for your platform. This section assumes that you have read "Install and Start FlightGear" on page 2-26.

If your platform is Windows:

- 1 Go to your installed FlightGear folder. Open the data folder, then the Aircraft folder: \FlightGear\data\Aircraft\.
- 2 Make a subfolder *model* here for your aircraft data.
- 3 Put model-set.xml in that subfolder, plus any other files needed.

It is common practice to make subdirectories for the vehicle geometry files (\model\), instruments (\instruments\), and sounds (\sounds\).

If your platform is UNIX or Linux:

- 1 Go to your installed FlightGear directory. Open the data directory, then the Aircraft directory: *\$FlightGearBaseDirectory*/data/Aircraft/.
- 2 Make a subdirectory model/ here for your aircraft data.

3 Put model-set.xml in that subdirectory, plus any other files needed.

It is common practice to make subdirectories for the vehicle geometry files (/model/), instruments (/instruments/), and sounds (/sounds/).

If your platform is Mac:

- 1 Open a terminal.
- **2** Go to your installed FlightGear folder. Open the data folder, then the Aircraft folder:

\$FlightGearBaseDirectory/FlightGear.app/Contents/Resources/data/Aircraft/

- 3 Make a subfolder model/ here for your aircraft data.
- 4 Put model-set.xml in that subfolder, plus any other files needed.

It is common practice to make subdirectories for the vehicle geometry files (/model/), instruments (/instruments/), and sounds (/sounds/).

#### **Example: Animate Vehicle Geometries**

This example illustrates how to prepare hinge line definitions for animated elements such as vehicle control surfaces and landing gear. To enable animation, each element must be a named entity in a geometry file. The resulting code forms part of the HL20 lifting body model presented in "Run the NASA HL-20 Example with FlightGear" on page 2-42.

- 1 The standard body coordinates used in FlightGear geometry models form a right-handed system, rotated from the standard body coordinate system in Y by -180 degrees:
  - *X* = positive toward the back of the vehicle
  - *Y* = positive toward the right of the vehicle
  - *Z* = positive is up, e.g., wheels typically have the lowest *Z* values.

See "About Aerospace Coordinate Systems" on page 2-12 for more details.

**2** Find two points that lie on the desired named-object hinge line in body coordinates and write them down as *XYZ* triplets or put them into a MATLAB calculation like this:

a = [2.98, 1.89, 0.53]; b = [3.54, 2.75, 1.46];

**3** Calculate the difference between the points:

pdiff = b - a pdiff = 0.5600 0.8600 0.9300

**4** The hinge point is either of the points in step 2 (or the midpoint as shown here):

mid = a + pdiff/2 mid = 3.2600 2.3200 0.9950

5 Put the hinge point into the animation scope in *model*-set.xml:

```
<center>
<x-m>3.26</x-m>
<y-m>2.32</y-m>
<z-m>1.00</z-m>
</center>
```

**6** Use the difference from step 3 to define the relative motion vector in the animation axis:

```
<axis>
<x>0.56</x>
<y>0.86</y>
<z>0.93</z>
</axis>
```

7 Put these steps together to obtain the complete hinge line animation used in the HL20 example model:

<animation>

```
<type>rotate</type>
<object-name>RightAileron</object-name>
<property>/surface-positions/right-aileron-pos-norm</property>
<factor>30</factor>
<offset-deg>0</offset-deg>
<center>
 <x-m>3.26</x-m>
 <v-m>2.32</v-m>
 <z-m>1.00</z-m>
</center>
<axis>
 <x>0.56</x>
 <v>0.86</v>
 <z>0.93</z>
</axis>
</animation>
```

## **Run FlightGear with the Simulink Models**

To run a Simulink model of your aircraft and simultaneously animate it in FlightGear with an aircraft data file *model*-set.xml, you need to configure the aircraft data file and modify your Simulink model with some new blocks.

These are the main steps to connecting and using FlightGear with the Simulink software:

- "Set the Flight Dynamics Model to Network in the Aircraft Data File" on page 2-35 explains how to create the network connection you need.
- "Obtain the Destination IP Address" on page 2-35 starts by determining the IP address of the computer running FlightGear.
- "Send Simulink Data to FlightGear" on page 2-45 shows how to add and connect interface and pace blocks to your Simulink model.
- "Create a FlightGear Run Script" on page 2-36 shows how to write a FlightGear run script compatible with your Simulink model.
- "Start FlightGear" on page 2-39 guides you through the final steps to making the Simulink software work with FlightGear.
- "Improve Performance" on page 2-40 helps you speed your model up.

• "Run FlightGear and Simulink Software on Different Computers" on page 2-41 explains how to connect a simulation from the Simulink software running on one computer to FlightGear running on another computer.

# Set the Flight Dynamics Model to Network in the Aircraft Data File

Be sure to:

- Remove any pre-existing flight dynamics model (FDM) data from the aircraft data file.
- Indicate in the aircraft data file that its FDM is streaming from the network by adding this line:

<flight-model>network</flight-model>

#### **Obtain the Destination IP Address**

You need the destination IP address for your Simulink model to stream its flight data to FlightGear.

• If you know your computer's name, enter at the MATLAB command line:

```
java.net.InetAddress.getByName('www.mathworks.com')
```

• If you are running FlightGear and the Simulink software on the same computer, get your computer's name by entering at the MATLAB command line:

java.net.InetAddress.getLocalHost

• If you are working in Windows, get your computer's IP address by entering at the DOS prompt:

ipconfig /all

Examine the IP address entry in the resulting output. There is one entry per Ethernet device.

#### Create a FlightGear Run Script

To start FlightGear with the desired initial conditions (location, date, time, weather, operating modes), it is best to create a run script by "Use the Generate Run Script Block" on page 2-36 or "Use the Interface Provided with FlightGear" on page 2-39.

If you make separate run scripts for each model you intend to link to FlightGear and place them in separate directories, run the appropriate script from the MATLAB interface just before starting your Simulink model.

**Use the Generate Run Script Block.** The easiest way to create a run script is by using the Generate Run Script block. Use the following procedure:

- 1 Open the Flight Simulator Interfaces sublibrary.
- 2 Create a new Simulink model or open an existing model.
- 3 Drag a Generate Run Script block into the Simulink diagram.
- **4** Double-click the Generate Run Script block. Its dialog opens. Observe the three panes, **FlightGear**, **Network**, and **File**.

눰 Block Parameters: Generate Ru	ın Script	
Generate FlightGear Run Scrip	ot	
Generate a custom FlightGear run script file on the current platform. To generate the run script, fill in the information then press Generate Script. Items marked with an asterisk (*) are evaluated as MATLAB expressions, the rest of the fields are literal text.		
Parameters		
Select target architecture:	Default	
Select FlightGear data flow:	Send 👻	
Generate Script		
Generate Script		
FlightGear Network File		
FlightGear geometry model nar	-	
HL20		
Airport ID:

Initial heading (deg)*:		
113		
Offset distance (miles)*:		
4.72		
Offset azimuth (deg)*:		
0		
ОК	Cancel Help Apply	

**5** In the **File > Output file name** field, type the name of the output file. This name should be the name of the command you want to use to start FlightGear with these initial parameters. Use the appropriate file extension:

Platform	Extension
Windows	.bat
Linux and Mac OS	.sh

For example, if your file name is runfg.bat, use the runfg command to execute the run script and start FlightGear.

- **6** In the **File > FlightGear base directory** field, specify the name of your FlightGear installation folder.
- 7 In the File > FlightGear geometry model name field, specify the name of the subfolder, in the FlightGear/data/Aircraft folder, containing the desired model geometry.
- 8 Specify the initial conditions as needed.
- 9 Click the Generate Script button at the top of the Parameters area.

The Aerospace Blockset software generates the run script, and saves it in your MATLAB working folder under the file name that you specified in the **File > Output file name** field.

- 10 Repeat steps 5 through 9 to generate other run scripts, if needed.
- 11 Click **OK** to close the dialog box. You do not need to save the Generate Run Script block with the Simulink model.

The Generate Run Script block saves the run script as a text file in your working folder. This is an example of the contents of a run script file:

```
>> cd D:\Applications\FlightGear-2.6
>> SET FG_ROOT=D:\Applications\FlightGear-2.6\data
>> cd \bin\Win32\
>> fgfs --aircraft=HL20 --fdm=network,localhost,5501,5502,5503
--fog-fastest --disable-clouds --start-date-lat=2004:06:01:09:00:00
--disable-sound --in-air --enable-freeze --airport=KSF0 --runway=10L
--altitude=7224 --heading=113 --offset-distance=4.72 --offset-azimuth=0
```

**Use the Interface Provided with FlightGear.** The FlightGear launcher GUI (part of FlightGear, not the Aerospace Blockset product) lets you build simple and advanced options into a visible FlightGear run command.

#### Start FlightGear

If your computer has enough computational power to run both the Simulink software and FlightGear at the same time, a simple way to start FlightGear on a Windows system is to create a MATLAB desktop button containing the following command to execute a run script like the one created above:

system('runfg &')

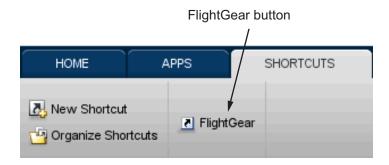

To create a desktop button:

- 1 In the MATLAB Command Window, select the **Shortcuts** and click **New Shortcut**. The **Shortcut Editor** dialog opens.
- **2** Set the **Label**, **Callback**, **Category**, and **Icon** fields as shown in the following figure.

📣 Shortci	ut Editor
Label:	FlightGear
Callback:	<pre>dos('runfg &amp;');</pre>
Category:	Toolbar Shortcuts 🗸
Icon:	I Standard icon
	ortcut to Start button. Selecting "Toolbar Shortcuts" category also Shortcuts toolbar.
	Save Cancel Help

3 Click Save.

The **FlightGear** button appears in your MATLAB desktop. If you click it, the output file, for example runfg.bat, runs in the current folder.

Once you have completed the setup, start FlightGear and run your model:

- 1 Make sure your model is in a writable folder. Open the model, and update the diagram. This step ensures that any referenced block code is compiled and that the block diagram is compiled before running. Once you start FlightGear, it uses all available processor power while it is running.
- 2 Click the FlightGear button or run the FlightGear run script manually.
- **3** When FlightGear starts, it displays the initial view at the initial coordinates specified in the run script. If you are running the Simulink software and FlightGear on different computers, arrange to view the two displays at the same time.
- **4** Now begin the simulation and view the animation in FlightGear.

#### **Improve Performance**

If your Simulink model is complex and cannot run at the aggregate rate needed for the visualization, you might need to

- Use the Accelerator mode in Simulink ("Perform Acceleration".)
- Free up processor power by running the Simulink model on one computer and FlightGear on another computer. Use the **Destination IP Address** parameter of the Send net\_fdm Packet to FlightGear block to specify the network address of the computer where FlightGear is running.
- Simulate the Simulink model first, then save the resulting translations (*x*-axis, *y*-axis, *z*-axis) and positions (latitude, longitude, altitude), and use

the FlightGear Animation object in Aerospace Toolbox to visualize this data.

#### **Run FlightGear and Simulink Software on Different Computers**

It is possible to simulate an aerospace system in the Simulink environment on one computer (the source) and use its simulation output to animate FlightGear on another computer (the target). The steps are similar to those already explained, with certain modifications.

- 1 Obtain the IP address of the computer running FlightGear. See "Obtain the Destination IP Address" on page 2-35.
- 2 Enter this target computer's IP address in the Send net\_fdm Packet to FlightGear block. See "Send Simulink Data to FlightGear" on page 2-45.
- **3** Update the Generate Run Script block in your model with the target computer's FlightGear base folder. Regenerate the run script to reflect the target computer's separate identity.

See "Create a FlightGear Run Script" on page 2-36.

- **4** Copy the generated run script to the target computer. Start FlightGear there. See "Start FlightGear" on page 2-39.
- **5** If you want to also receive data from FlightGear, use the Receive net\_ctrl Packet from FlightGear block. Enter the IP address of the computer running FlightGear in the **Origin IP address** parameter.
- **6** Update the run script for the receive data. Use the Generate Run Script block to regenerate the run script.
- **7** Start your Simulink model on the source computer. FlightGear running on the target displays the simulation motion.

#### Install Additional FlightGear Scenery

When you install the FlightGear software, the installation provides a basic level of scenery files. The FlightGear documentation guides you through installing scenery as part the general FlightGear installation. If you need to install more FlightGear scenery files, see the instructions at http://www.flightgear.org. The instructions describe how to install the additional scenery in a default location. MathWorks recommends that you follow those instructions.

If you must install additional scenery in a nonstandard location, try setting the FG\_SCENERY environment variable in the script output from the Generate Run Script block. See the documentation at http://www.flightgear.org for a description of the FG\_SCENERY variable.

**Note** Each time that you click the **Generate Script** button, the Generate Run Script block creates a new script and overwrites any edits that you have added.

### Run the NASA HL-20 Example with FlightGear

The Aerospace Blockset software contains an example model of the NASA HL-20 lifting body that uses the FlightGear interface.

Before attempting to simulate this model, you must have FlightGear installed and configured. See "Flight Simulator Interface" on page 2-22. Also, before attempting to simulate this model, read "Install and Start FlightGear" on page 2-26. Before you start, perform the following actions, depending on your platform.

#### Windows

Copy the HL20 folder from *matlabroot*\toolbox\aeroblks\aerodemos\ folder to *FlightGear*\data\Aircraft\ folder. This folder contains the preconfigured geometries for the HL-20 simulation and HL20-set.xml. The file *matlabroot*\toolbox\aeroblks\aerodemos\HL20\models\HL20.xml defines the geometry.

For more information, see "Import Aircraft Models into FlightGear" on page 2-31.

#### UNIX/Linux

Copy the HL20 directory from matlabroot/toolbox/aeroblks/aerodemos/ directory to

\$FlightGearBaseDirectory/data/Aircraft/ directory.
This directory contains the preconfigured geometries
for the HL-20 simulation and HL20-set.xml. The file
matlabroot/toolbox/aeroblks/aerodemos/HL20/models/HL20.xml
defines the geometry.

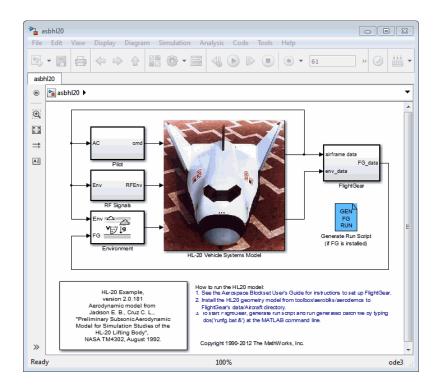

For more about this step, see "Import Aircraft Models into FlightGear" on page 2-31.

Mac

Copy the HL20 folder from matlabroot/toolbox/aeroblks/aerodemos/ folder to \$FlightGearBaseDirectory/FlightGear.app/Contents/Resources/data/Aircraft/ folder. This folder contains the preconfigured geometries for the HL-20 simulation and HL20-set.xml. The file matlabroot\toolbox\aeroblks\aerodemos\HL20\models\HL20.xml defines the geometry.

For more about this step, see "Import Aircraft Models into FlightGear" on page 2-31.

1 Start the MATLAB interface. Open the example either by entering asbh120 in the MATLAB Command Window or by finding the example entry (NASA HL-20 with FlightGear Interface) in the Aerospace Blockset Examples page. The model opens.

- **2** If this is your first time running FlightGear for this model, double-click the Generate Run Script block to create a run script. Make sure to specify your FlightGear installation folder in the **File > FlightGear base directory** field. For more information, see "Create a FlightGear Run Script" on page 2-36.
- **3** Execute the script you just created manually by entering the following at the MATLAB command line:

```
system('runfg &')
```

If you created a **FlightGear** desktop button, you can click it instead to start the run script and start FlightGear. For more information, see "Start FlightGear" on page 2-39.

4 Now start the simulation and view the animation in FlightGear.

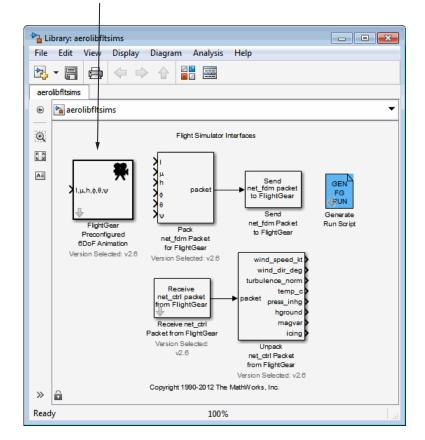

**Note** With the FlightGear window in focus, press the V key to alternate between the different aircraft views: cockpit view, helicopter view, chase view, and so on.

## Send and Receive Data

You can send and receive data between a Simulink model and a running FlightGear Flight Simulator.

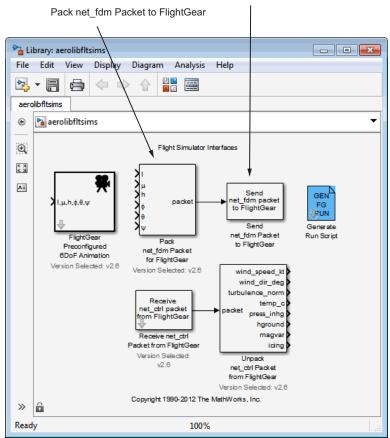

#### Send Simulink Data to FlightGear

The easiest way to connect your model to FlightGear with the blockset is to use the FlightGear Preconfigured 6DoF Animation block:

FlightGear Preconfigured 6DoF Animation Block

The FlightGear Preconfigured 6DoF Animation block is a subsystem containing the Pack net\_fdm Packet for FlightGear and Send net\_fdm Packet to FlightGear blocks:

Send net\_fdm Packet to FlightGear

These blocks transmit data from a model to a FlightGear session. The blocks are separate for maximum flexibility and compatibility.

• The Pack net\_fdm Packet for FlightGear block formats a binary structure compatible with FlightGear from model inputs. In the default configuration, the block displays only the 6DoF ports, but you can configure the full FlightGear interface supporting more than 50 distinct signals from the block dialog box:

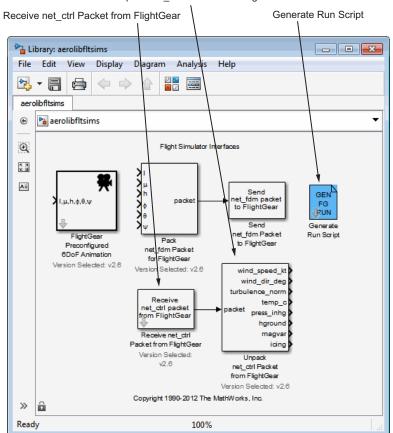

dė/dt dw/dt v climb\_rate east and body port wind booy east AV plut AV plut AV plut still deg elevator elevator tright\_flap left\_flap right\_sileron rudder nose\_wheel speedbrake spoilers wind body east packet spoilers num\_engines eng\_state pm uel\_flow fuel\_px egt np\_osi oil\_temp oil\_px num\_tanks fuel quantity num\_wheels wow gear\_pos gear\_steer gear\_compression agl cur\_time varp visibility Pack net\_fdm Packet for FlightGear Version Selected: v2.6

- The Send net\_fdm Packet to FlightGear block transmits this packet via UDP to the specified IP address and port where a FlightGear session awaits an incoming datastream. Use the IP address you found in "Obtain the Destination IP Address" on page 2-35.
- The Simulation Pace block slows the simulation so that its aggregate run rate is 1 second of simulation time per second of clock time. You can also use it to specify other ratios of simulation time to clock time.

#### Send FlightGear Data to Model

To increase the accuracy of your model simulation, you might want to send FlightGear environment variables to the Simulink model. Use the following blocks:

Unpack net\_ctrl Packet from FlightGear

- Receive net\_ctrl Packet from FlightGear Receives a network control and environment data packet net\_ctrl from either the simulation of a Simulink model in the FlightGear simulator, or from a FlightGear session.
- Unpack net\_ctrl Packet from FlightGear Unpacks net\_ctrl variable packets received from FlightGear and makes them available for the Simulink environment.
- Generate Run Script Generates a customized FlightGear run script on the current platform.

For an example of how to use these blocks to send data to a Simulink model, see NASA HL-20 with FlightGear Interface.

These blocks use UDP to transfer data from FlightGear to the Simulink environment. Note the following:

- When a host and target are Windows or Linux platforms, you can use any combination of Windows or Linux platforms for the host and target.
- When a host or target is a Mac platform, use only Mac platforms for both the host and target.

#### **Macintosh Platform and FlightGear 2.6**

On a Macintosh system with FlightGear 2.6, you might see unexpected results (for example, very large or very small data values) if your model uses the following blocks:

- Receive net\_ctrl Packet from FlightGear
- Unpack net\_ctrl Packet from FlightGear

To work around this issue:

- **1** In the model, change the **FlightGear version** parameter to v2.4 for both blocks.
- **2** Save and rerun the model.

The results should now be as expected.

## Introduction

This case study simulates indicated and true airspeed. It constitutes a fragment of a complete aerodynamics problem, including only measurement and calibration.

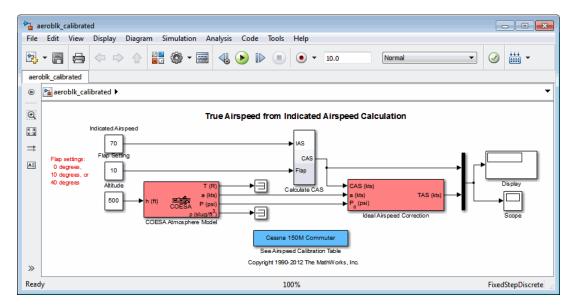

## **Airspeed Correction Models**

To view the airspeed correction models, enter the following at the MATLAB command line:

aeroblk\_indicated
aeroblk\_calibrated

#### aeroblk\_indicated Model

aeroblk\_calibrated Model

### **Measure Airspeed**

To measure airspeed, most light aircraft designs implement pitot-static airspeed indicators based on Bernoulli's principle. Pitot-static airspeed indicators measure airspeed by an expandable capsule that expands and contracts with increasing and decreasing dynamic pressure. This is known as *calibrated airspeed* (CAS). It is what a pilot sees in the cockpit of an aircraft.

To compensate for measurement errors, it helps to distinguish three types of airspeed. These types are explained more completely in the following.

Airspeed Type	Description
Calibrated	Indicated airspeed corrected for calibration error
Equivalent	Calibrated airspeed corrected for compressibility error
True	Equivalent airspeed corrected for density error

#### **Calibration Error**

An airspeed sensor features a static vent to maintain its internal pressure equal to atmospheric pressure. Position and placement of the static vent with respect to the angle of attack and velocity of the aircraft determines the pressure inside the airspeed sensor and therefore the calibration error. Thus, a calibration error is specific to an aircraft's design.

An airspeed calibration table, which is usually included in the pilot operating handbook or other aircraft documentation, helps pilots convert the indicated airspeed to the calibrated airspeed.

#### **Compressibility Error**

The density of air is not constant, and the compressibility of air increases with altitude and airspeed, or when contained in a restricted volume. A pitot-static airspeed sensor contains a restricted volume of air. At high altitudes and high airspeeds, calibrated airspeed is always higher than equivalent airspeed. Equivalent airspeed can be derived by adjusting the calibrated airspeed for compressibility error.

#### **Density Error**

At high altitudes, airspeed indicators read lower than true airspeed because the air density is lower. True airspeed represents the compensation of equivalent airspeed for the density error, the difference in air density at altitude from the air density at sea level, in a standard atmosphere.

# **Model Airspeed Correction**

The aeroblk\_indicated and aeroblk\_calibrated models show how to take true airspeed and correct it to indicated airspeed for instrument display in a Cessna 150M Commuter light aircraft. The aeroblk\_indicated model implements a conversion to indicated airspeed. The aeroblk\_calibrated model implements a conversion to true airspeed.

Each model consists of two main components:

- "COESA Atmosphere Model Block" on page 3-5 calculates the change in atmospheric conditions with changing altitude.
- "Ideal Airspeed Correction Block" on page 3-5 transforms true airspeed to calibrated airspeed and vice versa.

#### **COESA Atmosphere Model Block**

The COESA Atmosphere Model block is a mathematical representation of the U.S. 1976 COESA (Committee on Extension to the Standard Atmosphere) standard lower atmospheric values for absolute temperature, pressure, density, and speed of sound for input geopotential altitude. Below 32,000 meters (104,987 feet), the U.S. Standard Atmosphere is identical with the Standard Atmosphere of the ICAO (International Civil Aviation Organization).

The aeroblk\_indicated and aeroblk\_calibrated models use the COESA Atmosphere Model block to supply the speed of sound and air pressure inputs for the Ideal Airspeed Correction block in each model.

#### **Ideal Airspeed Correction Block**

The Ideal Airspeed Correction block compensates for airspeed measurement errors to convert airspeed from one type to another type. The following table contains the Ideal Airspeed Correction block's inputs and outputs.

Airspeed Input	Airspeed Output
True Airspeed	Equivalent airspeed
	Calibrated airspeed
Equivalent Airspeed	True airspeed
	Calibrated airspeed
Calibrated Airspeed	True airspeed
	Equivalent airspeed

In the aeroblk\_indicated model, the Ideal Airspeed Correction block transforms true to calibrated airspeed. In the aeroblk\_calibrated model, the Ideal Airspeed Correction block transforms calibrated to true airspeed.

The following sections explain how the Ideal Airspeed Correction block mathematically represents airspeed transformations:

- "True Airspeed Implementation" on page 3-6
- "Calibrated Airspeed Implementation" on page 3-7
- "Equivalent Airspeed Implementation" on page 3-7

**True Airspeed Implementation.** True airspeed (TAS) is implemented as an input and as a function of equivalent airspeed (EAS), expressible as

$$TAS = \frac{EAS \times a}{a_0 \sqrt{\delta}}$$

where

- $\alpha$  Speed of sound at altitude in m/s
- δ Relative pressure ratio at altitude
- $a_0$  Speed of sound at mean sea level in m/s

**Calibrated Airspeed Implementation.** Calibrated airspeed (CAS), derived using the compressible form of Bernoulli's equation and assuming isentropic conditions, can be expressed as

$$CAS = \sqrt{\frac{2\gamma P_0}{(\gamma - 1)\rho_0} \left[ \left(\frac{q}{P_0} + 1\right)^{(\gamma - 1)/\gamma} - 1 \right]}$$

where

$\rho_0$	Air density at mean sea level in kg/m <sup>3</sup>
$P_0$	Static pressure at mean sea level in N/m <sup>2</sup>
γ	Ratio of specific heats
q	Dynamic pressure at mean sea level in $N\!/m^2$

**Equivalent Airspeed Implementation.** Equivalent airspeed (EAS) is the same as CAS, except static pressure at sea level is replaced by static pressure at altitude.

$$EAS = \sqrt{\frac{2\gamma P}{(\gamma - 1)\rho_0} \left[ \left(\frac{q}{P} + 1\right)^{(\gamma - 1)/\gamma} - 1 \right]}$$

The symbols are defined as follows:

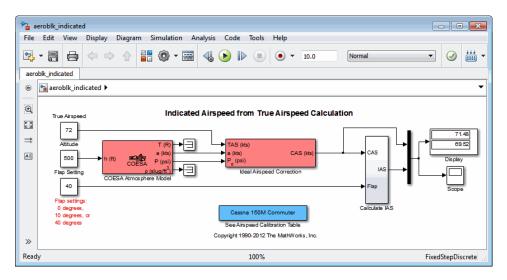

$ ho_0$	Air density at mean sea level in kg/m <sup>3</sup>
Р	Static pressure at altitude in N/m <sup>2</sup>
γ	Ratio of specific heats
q	Dynamic pressure at mean sea level in $N/m^2$

### **Simulate Airspeed Correction**

In the aeroblk\_indicated model, the aircraft is defined to be traveling at a constant speed of 72 knots (true airspeed) and altitude of 500 feet. The flaps are set to 40 degrees. The COESA Atmosphere Model block takes the

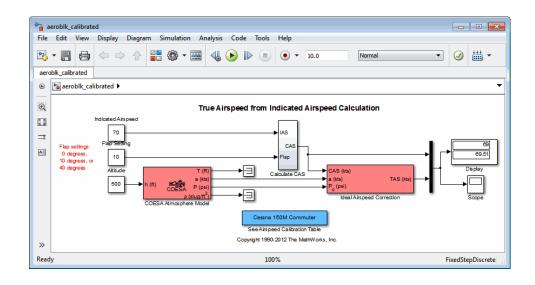

altitude as input and outputs the speed of sound and air pressure. Taking the speed of sound, air pressure, and airspeed as inputs, the Ideal Airspeed Correction block converts true airspeed to calibrated airspeed. Finally, the Calculate IAS subsystem uses the flap setting and calibrated airspeed to calculate indicated airspeed.

The model's Display block shows both indicated and calibrated airspeeds.

In the aeroblk\_calibrated model, the aircraft is defined to be traveling at a constant speed of 70 knots (indicated airspeed) and altitude of 500 feet. The flaps are set to 10 degrees. The COESA Atmosphere Model block takes the altitude as input and outputs the speed of sound and air pressure. The Calculate CAS subsystem uses the flap setting and indicated airspeed to calculate the calibrated airspeed. Finally, using the speed of sound, air pressure, and true calibrated airspeed as inputs, the Ideal Airspeed Correction block converts calibrated airspeed back to true airspeed.

The model's Display block shows both calibrated and true airspeeds.

# Introduction

**Note** The final section of this study requires the Simulink 3D Animation software.

This case study describes a model of the 1903 Wright Flyer. Built by Orville and Wilbur Wright, the Wright Flyer took to the skies in December 1903 and opened the age of controlled flight. The Wright brothers' flying machine achieved the following goals:

- Left the ground under its own power
- Moved forward and maintained its speed
- Landed at an elevation no lower than where it started

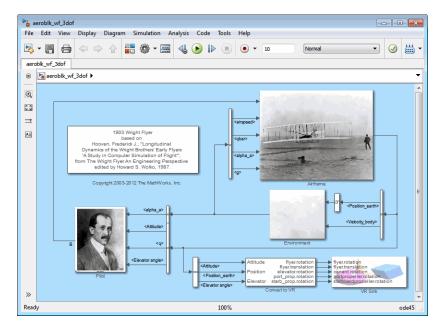

This model is based on an earlier simulation [1] that explored the longitudinal stability of the Wright Flyer and therefore modeled only forward and vertical motion along with the pitch angle. The Wright Flyer suffered from numerous engineering challenges, including dynamic and static instability. Laterally, the Flyer tended to overturn in crosswinds and gusts, and longitudinally, its pitch angle would undulate [2].

Under these constraints, the model recreates the longitudinal flight dynamics that pilots of the Wright Flyer would have experienced. Because they were able to control lateral motion, Orville and Wilbur Wright were able to maintain a relatively straight flight path.

Note, running this model generates assertion messages in the MATLAB Command Window. This is because the model illustrates the use of the Assertion block to indicate that the flyer is hitting the ground when landing.

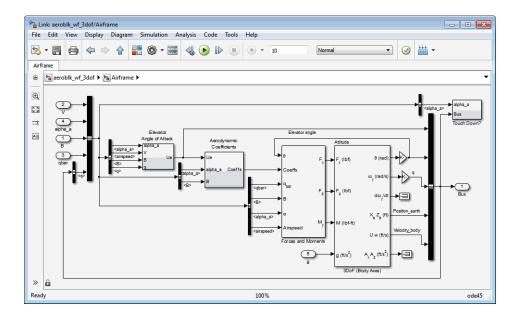

# Wright Flyer Model

Open the Wright Flyer model by entering <code>aeroblk\_wf\_3dof</code> at the MATLAB command line.

# **Airframe Subsystem**

The Airframe subsystem simulates the rigid body dynamics of the Wright Flyer airframe, including elevator angle of attack, aerodynamic coefficients, forces and moments, and three-degrees-of-freedom equations of motion.

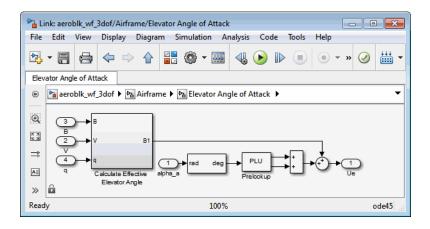

The Airframe subsystem consists of the following parts:

- "Elevator Angle of Attack Subsystem" on page 3-12
- "Aerodynamic Coefficients Subsystem" on page 3-13
- "Forces and Moments Subsystem" on page 3-14
- "3DoF (Body Axes) Block" on page 3-14

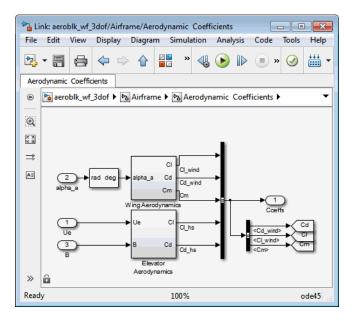

#### **Elevator Angle of Attack Subsystem**

The Elevator Angle of Attack subsystem calculates the effective elevator angle for the Wright Flyer airframe and feeds its output to the Pilot subsystem.

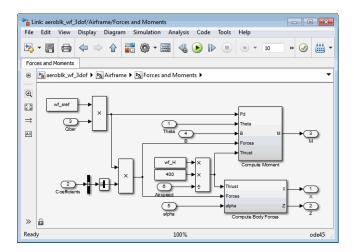

#### Aerodynamic Coefficients Subsystem

The Aerodynamic Coefficients subsystem contains aerodynamic data and equations for calculating the aerodynamic coefficients, which are summed and passed to the Forces and Moments subsystem. Stored in data sets, the aerodynamic coefficients are determined by interpolation using Prelookup blocks.

#### **Forces and Moments Subsystem**

The aerodynamic forces and moments acting on the airframe are generated from aerodynamic coefficients. The Forces and Moments subsystem calculates the body forces and body moments acting on the airframe about the center of gravity. These forces and moments depend on the aerodynamic coefficients, thrust, dynamic pressure, and reference airframe parameters.

#### **3DoF (Body Axes) Block**

The 3DoF (Body Axes) block use equations of motion to define the linear and angular motion of the Wright Flyer airframe. It also performs conversions from the original model's axis system and the body axes.

# **Environment Subsystem**

The first and final flights of the Wright Flyer occurred on December 17, 1903. Orville and Wilbur Wright chose an area near Kitty Hawk, North Carolina, situated near the Atlantic coast. Wind gusts of more than 25 miles per hour were recorded that day. After the final flight on that blustery December day, a wind gust caught and overturned the Wright Flyer, damaging it beyond repair.

The Environment subsystem of the Wright Flyer model contains a variety of blocks from the Environment sublibrary of the Aerospace Blockset software, including wind, atmosphere, and gravity, and calculates airspeed and dynamic pressure. The Discrete Wind Gust Model block provides wind gusts to the simulated environment. The other blocks are

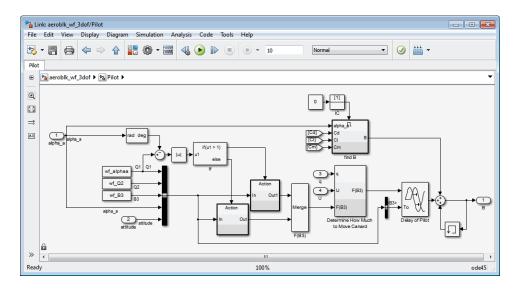

- The Incidence & Airspeed block calculates the angle of attack and airspeed.
- The COESA Atmosphere Model block calculates the air density.
- The Dynamic Pressure block computes the dynamic pressure from the air density and velocity.
- The WGS84 Gravity Model block produces the gravity at the Wright Flyer's latitude, longitude, and height.

# **Pilot Subsystem**

The Pilot subsystem controls the aircraft by responding to both pitch angle (attitude) and angle of attack. If the angle of attack differs from the set angle of attack by more than one degree, the Pilot subsystem responds with a correction of the elevator (canard) angle. When the angular velocity exceeds +/- 0.02 rad/s, angular velocity and angular acceleration are also taken into consideration with additional corrections to the elevator angle.

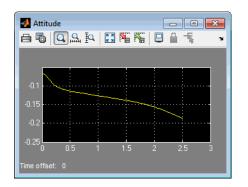

Pilot reaction time largely determined the success of the flights [1]. Without an automatic controller, a reaction time of 0.06 seconds is optimal for

successful flight. The Delay of Pilot (Variable Time Delay) block recreates this effect by producing a delay of no more than 0.08 second.

# **Run the Simulation**

The default values for this simulation allow the Wright Flyer model to take off and land successfully. The pilot reaction time (wf\_B3) is set to 0.06 seconds, the desired angle of attack (wf\_alphaa) is constant, and the altitude attained is low. The Wright Flyer model reacts similarly to the actual Wright Flyer. It leaves the ground, moves forward, and lands on a point as high as that from which it started. This model exhibits the longitudinal undulation in attitude of the original aircraft.

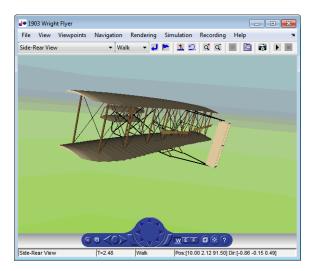

Attitude Scope (Measured in Radians)

A pilot with quick reaction times and ideal flight conditions makes it possible to fly the Wright Flyer successfully. The Wright Flyer model confirms that controlling its longitudinal motion was a serious challenge. The longest recorded flight on that day lasted a mere 59 seconds and covered 852 feet.

#### Virtual Reality Visualization of the Wright Flyer

Note This section requires the Simulink 3D Animation.

The Wright Flyer model also provides a virtual world visualization, coded in Virtual Reality Modeling Language (VRML) [3]. The VR Sink block in the main model allows you to view the flight motion in three dimensions.

# NASA HL-20 Lifting Body Airframe

#### In this section ...

"Introduction" on page 3-20

"NASA HL-20 Lifting Body" on page 3-20

"The HL-20 Airframe and Controller Model" on page 3-21

"References" on page 3-34

# Introduction

This case study models the airframe of a NASA HL-20 lifting body, a low-cost complement to the Space Shuttle orbiter. The HL-20 is unpowered, but the model includes both airframe and controller.

For most flight control designs, the airframe, or plant model, needs to be modeled, simulated, and analyzed. Ideally, this airframe should be modeled quickly, reusing blocks or model structure to reduce validation time and leave more time available for control design. In this study, the Aerospace Blockset software efficiently models portions of the HL-20 airframe. The remaining portions, including calculation of the aerodynamic coefficients, are modeled with the Simulink software. This case study examines the HL-20 airframe model and touches on how the aerodynamic data are used in the model.

# NASA HL-20 Lifting Body

The HL-20, also known as the Personnel Launch System (PLS), is a lifting body reentry vehicle designed to complement the Space Shuttle orbiter. It was developed originally as a low-cost solution for getting to and from low Earth orbit. It can carry up to 10 people and a limited cargo [1].

The HL-20 lifting body can be placed in orbit either by launching it vertically with booster rockets or by transporting it in the payload bay of the Space Shuttle orbiter. The HL-20 lifting body deorbits using a small onboard propulsion system. Its reentry profile is nose first, horizontal, and unpowered.

#### Top-Front View of the HL-20 Lifting Body (Photo: NASA Langley)

The HL-20 design has a number of benefits:

- Rapid turnaround between landing and launch reduces operating costs.
- The HL-20 has exceptional flight safety.
- It can land conventionally on aircraft runways.

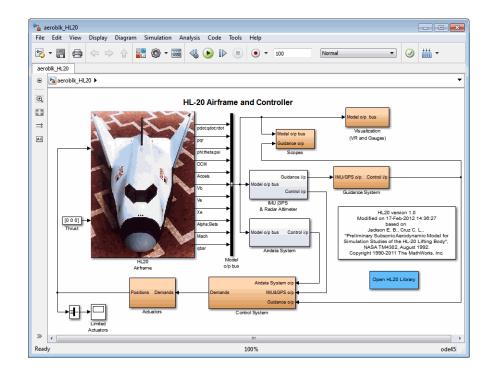

Potential uses for the HL-20 include

- Orbital rescue of stranded astronauts
- International Space Station crew exchanges
- Observation missions
- Satellite servicing missions

Although the HL-20 program is not currently active, the aerodynamic data from HL-20 tests are being used in current NASA projects [2].

# The HL-20 Airframe and Controller Model

You can open the HL-20 airframe and controller model by entering aeroblk\_HL20 at the MATLAB command line.

#### **Modeling Assumptions and Limitations**

Preliminary aerodynamic data for the HL-20 lifting body are taken from NASA document TM4302 [1].

The airframe model incorporates several key assumptions and limitations:

- The airframe is assumed to be rigid and have constant mass, center of gravity, and inertia, since the model represents only the unpowered reentry portion of a mission.
- HL-20 is assumed to be a laterally symmetric vehicle.
- Compressibility (Mach) effects are assumed to be negligible.
- Control effectiveness is assumed to vary nonlinearly with angle of attack and linearly with angle of deflection. Control effectiveness is not dependent on sideslip angle.

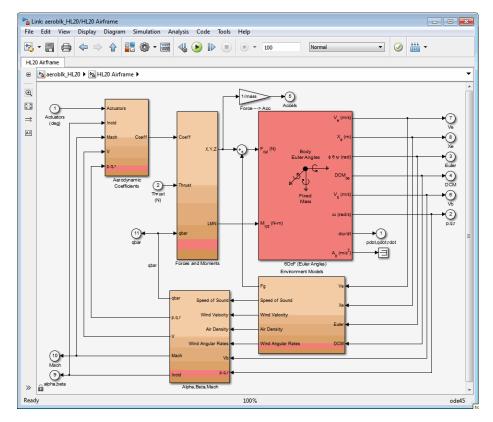

• The nonlinear six-degrees-of-freedom aerodynamic model is a representation of an early version of the HL-20. Therefore, the model is not intended for realistic performance simulation of later versions of the HL-20.

The typical airframe model consists of a number of components, such as

- Equations of motion
- Environmental models
- Calculation of aerodynamic coefficients, forces, and moments

The airframe subsystem of the HL-20 model contains five subsystems, which model the typical airframe components:

- "6DoF (Euler Angles) Subsystem" on page 3-24
- "Environmental Models Subsystem" on page 3-25
- "Alpha, Beta, Mach Subsystem" on page 3-27
- "Aerodynamic Coefficients Subsystem" on page 3-28
- "Forces and Moments Subsystem" on page 3-33

**HL-20 Airframe Subsystem** 

#### 6DoF (Euler Angles) Subsystem

The 6DoF (Euler Angles) subsystem contains the six-degrees-of-freedom equations of motion for the airframe. In the 6DoF (Euler Angles) subsystem, the body attitude is propagated in time using an Euler angle representation. This subsystem is one of the equations of motion blocks from the Aerospace Blockset library. A quaternion representation is also available. See the 6DoF (Euler Angles) and 6DoF (Quaternion) block reference pages for more information on these blocks.

#### **Environmental Models Subsystem**

The Environmental Models subsystem contains the following subsystems and blocks:

• The WGS84 Gravity Model block implements the mathematical representation of the geocentric equipotential ellipsoid of the World Geodetic System (WGS84).

See the WGS84 Gravity Model block reference page for more information on this block.

• The COESA Atmosphere Model block implements the mathematical representation of the 1976 Committee on Extension to the Standard Atmosphere (COESA) standard lower atmospheric values for absolute temperature, pressure, density, and speed of sound, given the input geopotential altitude.

See the COESA Atmosphere Model block reference page for more information on this block.

- The Wind Models subsystem contains the following blocks:
  - The Wind Shear Model block adds wind shear to the model.

See the Wind Shear Model block reference page for more information on this block.

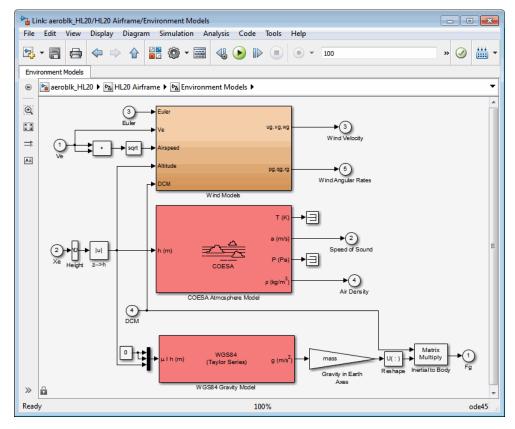

• The Discrete Wind Gust Model block implements a wind gust of the standard "1 - cosine" shape.

See the Discrete Wind Gust Model block reference page for more information on this block.

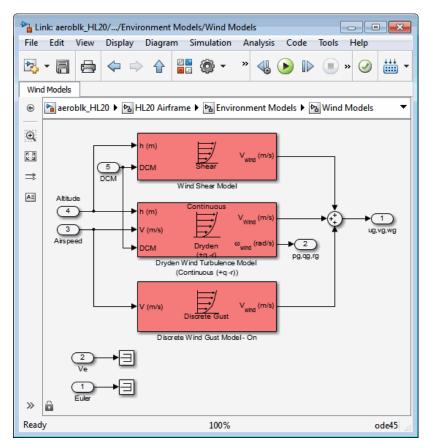

• The Dryden Wind Turbulence Model (Continuous) block uses the Dryden spectral representation to add turbulence to the aerospace model by passing band-limited white noise through appropriate forming filters.

See the Dryden Wind Turbulence Model (Continuous) block reference page for more information on this block.

The environmental models implement mathematical representations within standard references, such as U.S. Standard Atmosphere, 1976.

**Environmental Models in HL-20 Airframe Model** 

Wind Models in HL-20 Airframe Model

#### Alpha, Beta, Mach Subsystem

The Alpha, Beta, Mach subsystem calculates additional parameters needed for the aerodynamic coefficient computation and lookup. These additional parameters include

- Mach number
- Incidence angles  $(\alpha, \beta)$
- Airspeed
- Dynamic pressure

Link: aeroblk\_HL20/HL20 Airframe/Alpha,Beta,Mach - C X File Edit View Display Diagram Simulation Analysis Code Tools Help ..... ▶ » 🥑 Alpha,Beta,Mach 🎦 aeroblk\_HL20 🕨 ங HL20 Airframe 🕨 陆 Alpha,Beta,Mach ۲ Ð Incidence, Sideslip & Airspeed К 7 Ц У Alpha Beta ⇒ AΞ 2 Wind Velocit d of Sound 3 Air Density 2 Wind Angula Rates >> ô Ready 100% ode45

The Alpha, Beta, Mach subsystem corrects the body velocity for wind velocity and corrects the body rates for wind angular acceleration.

# Additional Computed Parameters for HL-20 Airframe Model (Alpha, Beta, Mach Subsystem)

#### **Aerodynamic Coefficients Subsystem**

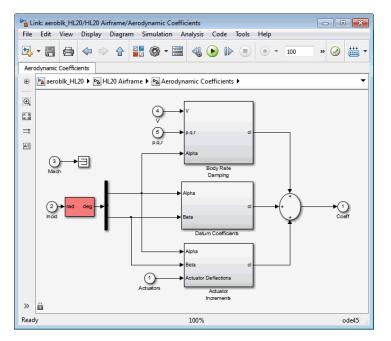

The Aerodynamic Coefficients subsystem contains aerodynamic data and equations for calculating the six aerodynamic coefficients, which are implemented as in reference [1]. The six aerodynamic coefficients follow.

- $C_{\rm x}$  Axial-force coefficient
- C<sub>y</sub> Side-force coefficient
- C<sub>z</sub> Normal-force coefficient
- C<sub>1</sub> Rolling-moment coefficient

$C_{\mathrm{m}}$	Pitching-moment coefficient
$C_{\rm n}$	Yawing-moment coefficient

Ground and landing gear effects are not included in this model.

The contribution of each of these coefficients is calculated in the subsystems (body rate, actuator increment, and datum), and then summed and passed to the Forces and Moments subsystem.

Aerodynamic Coefficients in HL-20 Airframe Model

The aerodynamic data was gathered from wind tunnel tests, mainly on scaled models of a preliminary subsonic aerodynamic model of the HL-20. The data was curve fitted, and most of the aerodynamic coefficients are described by polynomial functions of angle of attack and sideslip angle. In-depth details about the aerodynamic data and the data reduction can be found in reference [1].

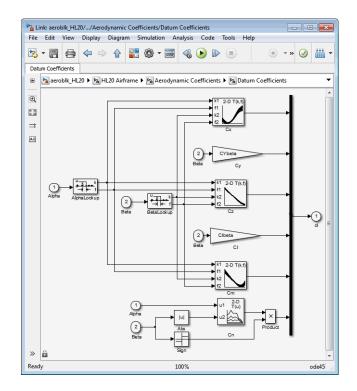

The polynomial functions contained in the aeroblk\_init\_hl20.m file are used to calculate lookup tables used by the model's preload function. Lookup tables substitute for polynomial functions. Depending on the order and implementation of the function, using lookup tables can be more efficient than recalculating values at each time step with functions. To further improve efficiency, most tables are implemented as PreLook-up Index Search and Interpolation (n-D) using PreLook-up blocks. These blocks improve performance most when the model has a number of tables with identical breakpoints. These blocks reduce the number of times the model has to search for a breakpoint in a given time step. Once the tables are populated by the preload function, the aerodynamic coefficient can be computed.

The equations for calculating the six aerodynamic coefficients are divided among three subsystems:

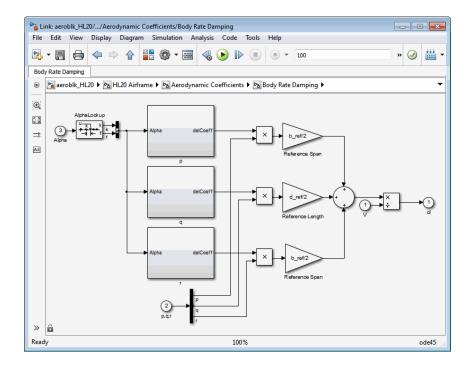

- "Datum Coefficients Subsystem" on page 3-30
- "Body Rate Damping Subsystem" on page 3-31
- "Actuator Increment Subsystem" on page 3-32

Summing the Datum Coefficients, Body Rate Damping, and Actuator Increments subsystem outputs generates the six aerodynamic coefficients used to calculate the airframe forces and moments [1].

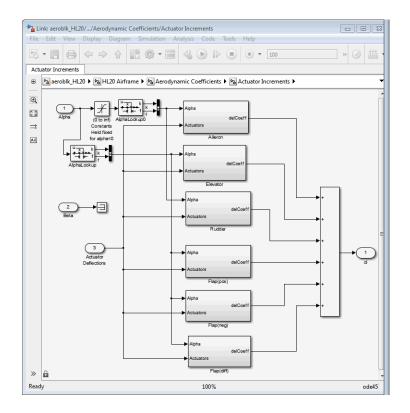

**Datum Coefficients Subsystem.** The Datum Coefficients subsystem calculates coefficients for the basic configuration without control surface deflection. These datum coefficients depend only on the incidence angles of the body.

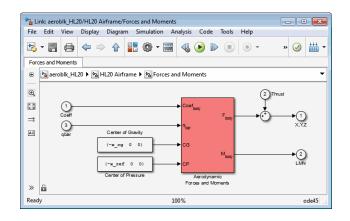

**Body Rate Damping Subsystem.** Dynamic motion derivatives are computed in the Body Rate Damping subsystem.

**Actuator Increment Subsystem.** Lookup tables determine the incremental changes to the coefficients due to the control surface deflections in the Actuator Increment subsystem. Available control surfaces include symmetric wing flaps (elevator), differential wing flaps (ailerons), positive body flaps, negative body flaps, differential body flaps, and an all-movable rudder.

**Forces and Moments Subsystem.** The Forces and Moments subsystem calculates the body forces and body moments acting on the airframe about the center of gravity. These forces and moments depend on the aerodynamic coefficients, thrust, dynamic pressure, and reference airframe parameters.

#### **Complete the Model**

These subsystems that you have examined complete the HL-20 airframe. The next step in the flight control design process is to analyze, trim, and linearize the HL-20 airframe so that a flight control system can be designed for it. You can see an example of an auto-land flight control for the HL-20 airframe in the aeroblk\_HL20 example.

MATLAB-Based Animation (p. 4-4)	Display aerospace motion with MATLAB Graphics
Flight Simulator Interfaces (p. 4-4)	Display aerospace motion with flight simulators
Animation Support Utilities (p. 4-5)	Additional animation support

### **MATLAB-Based Animation**

3DoF Animation	Create 3-D MATLAB Graphics animation of three-degrees-of-freedom object
6DoF Animation	Create 3-D MATLAB Graphics animation of six-degrees-of-freedom object
MATLAB Animation	Create six-degrees-of-freedom multibody custom geometry block

## **Flight Simulator Interfaces**

FlightGear Preconfigured 6DoF Animation	Connect model to FlightGear flight simulator
Generate Run Script	Generate FlightGear run script on current platform
Pack net_fdm Packet for FlightGear	Generate net_fdm packet for FlightGear
Receive net_ctrl Packet from FlightGear	Receive net_ctrl packet from FlightGear

Send net_fdm Packet to FlightGear	Transmit net_fdm packet to destination IP address and port for FlightGear session
Unpack net_ctrl Packet from FlightGear	Unpack net_ctrl variable packet received from FlightGear

# **Animation Support Utilities**

Pilot Joystick	Provide joystick interface on Windows platform
Pilot Joystick All	Provide joystick interface in All Outputs configuration on Windows platform
Simulation Pace	Set simulation rate for improved animation viewing

# Environment

Atmosphere (p. 4-6)	Atmospheric profiles
Gravity & Magnetism (p. 4-7)	Gravity and magnetic fields
Wind (p. 4-8)	Atmospheric winds

## Atmosphere

CIRA-86 Atmosphere Model	Implement mathematical representation of 1986 CIRA atmosphere
COESA Atmosphere Model	Implement 1976 COESA lower atmosphere
ISA Atmosphere Model	Implement International Standard Atmosphere (ISA)
Lapse Rate Model	Implement lapse rate model for atmosphere
Non-Standard Day 210C	Implement MIL-STD-210C climatic data
Non-Standard Day 310	Implement MIL-HDBK-310 climatic data
NRLMSISE-00 Atmosphere Model	Implement mathematical representation of 2001 United States Naval Research Laboratory Mass Spectrometer and Incoherent Scatter Radar Exosphere
Pressure Altitude	Calculate pressure altitude based on ambient pressure

## Gravity & Magnetism

Centrifugal Effect Model	Implement mathematical representation of centrifugal effect for planetary gravity
EGM96 Geoid	Calculate geoid height as determined from EGM96 Geopotential Model
Geoid Height	Calculate undulations/height
International Geomagnetic Reference Field 11	Calculate Earth's magnetic field and secular variation using 11th generation of International Geomagnetic Reference Field
Spherical Harmonic Gravity Model	Implement spherical harmonic representation of planetary gravity
WGS84 Gravity Model	Implement 1984 World Geodetic System (WGS84) representation of Earth's gravity
World Magnetic Model 2000	Calculate Earth's magnetic field at specific location and time using World Magnetic Model 2000 (WMM2000)
World Magnetic Model 2005	Calculate Earth's magnetic field at specific location and time using World Magnetic Model 2005 (WMM2005)
World Magnetic Model 2010	Calculate Earth's magnetic field at specific location and time using World Magnetic Model 2010 (WMM2010)
Zonal Harmonic Gravity Model	Calculate zonal harmonic representation of planetary gravity

### Wind

Discrete Wind Gust Model	Generate discrete wind gust
Dryden Wind Turbulence Model (Continuous)	Generate continuous wind turbulence with Dryden velocity spectra
Dryden Wind Turbulence Model (Discrete)	Generate discrete wind turbulence with Dryden velocity spectra
Horizontal Wind Model	Transform horizontal wind into body-axes coordinates
Von Karman Wind Turbulence Model (Continuous)	Generate continuous wind turbulence with Von Kármán velocity spectra
Wind Shear Model	Calculate wind shear conditions

# **Flight Parameters**

Dynamic Pressure	Compute dynamic pressure using velocity and air density
Ideal Airspeed Correction	Calculate equivalent airspeed (EAS), calibrated airspeed (CAS), or true airspeed (TAS) from each other
Incidence & Airspeed	Calculate incidence and airspeed
Incidence, Sideslip & Airspeed	Calculate incidence, sideslip, and airspeed
Mach Number	Compute Mach number using velocity and speed of sound
Radius at Geocentric Latitude	Estimate radius of ellipsoid planet at geocentric latitude
Relative Ratio	Calculate relative atmospheric ratios
Wind Angular Rates	Calculate wind angular rates from body angular rates, angle of attack, sideslip angle, rate of change of angle of attack, and rate of change of sideslip

# **Equations of Motion**

Three DoFs (p. 4-10)	Dynamics with one rotation and two translation axes
Six DoFs (p. 4-11)	Dynamics with three rotation and three translation axes
Point Masses (p. 4-13)	Dynamics of point masses

### Three DoFs

3DoF (Body Axes)	Implement three-degrees-of-freedom equations of motion with respect to body axes
3DoF (Wind Axes)	Implement three-degrees-of-freedom equations of motion with respect to wind axes
Custom Variable Mass 3DoF (Body Axes)	Implement three-degrees-of-freedom equations of motion of custom variable mass with respect to body axes
Custom Variable Mass 3DoF (Wind Axes)	Implement three-degrees-of-freedom equations of motion of custom variable mass with respect to wind axes
Simple Variable Mass 3DoF (Body Axes)	Implement three-degrees-of-freedom equations of motion of simple variable mass with respect to body axes
Simple Variable Mass 3DoF (Wind Axes)	Implement three-degrees-of-freedom equations of motion of simple variable mass with respect to wind axes

### Six DoFs

6DoF (Euler Angles)	Implement Euler angle representation of six-degrees-of-freedom equations of motion
6DoF (Quaternion)	Implement quaternion representation of six-degrees-of-freedom equations of motion with respect to body axes
6DoF ECEF (Quaternion)	Implement quaternion representation of six-degrees-of-freedom equations of motion in Earth-centered Earth-fixed (ECEF) coordinates
6DoF Wind (Quaternion)	Implement quaternion representation of six-degrees-of-freedom equations of motion with respect to wind axes
6DoF Wind (Wind Angles)	Implement wind angle representation of six-degrees-of-freedom equations of motion
Custom Variable Mass 6DoF (Euler Angles)	Implement Euler angle representation of six-degrees-of-freedom equations of motion of custom variable mass
Custom Variable Mass 6DoF (Quaternion)	Implement quaternion representation of six-degrees-of-freedom equations of motion of custom variable mass with respect to body axes

Custom Variable Mass 6DoF ECEF (Quaternion)	Implement quaternion representation of six-degrees-of-freedom equations of motion of custom variable mass in Earth-centered Earth-fixed (ECEF) coordinates
Custom Variable Mass 6DoF Wind (Quaternion)	Implement quaternion representation of six-degrees-of-freedom equations of motion of custom variable mass with respect to wind axes
Custom Variable Mass 6DoF Wind (Wind Angles)	Implement wind angle representation of six-degrees-of-freedom equations of motion of custom variable mass
Simple Variable Mass 6DoF (Euler Angles)	Implement Euler angle representation of six-degrees-of-freedom equations of motion of simple variable mass
Simple Variable Mass 6DoF (Quaternion)	Implement quaternion representation of six-degrees-of-freedom equations of motion of simple variable mass with respect to body axes
Simple Variable Mass 6DoF ECEF (Quaternion)	Implement quaternion representation of six-degrees-of-freedom equations of motion of simple variable mass in Earth-centered Earth-fixed (ECEF) coordinates

Simple Variable Mass 6DoF Wind (Quaternion)	Implement quaternion representation of six-degrees-of-freedom equations of motion of simple variable mass with respect to wind axes
Simple Variable Mass 6DoF Wind (Wind Angles)	Implement wind angle representation of six-degrees-of-freedom equations of motion of simple variable mass

### **Point Masses**

4th Order Point Mass (Longitudinal)	Calculate fourth-order point mass
4th Order Point Mass Forces (Longitudinal)	Calculate forces used by fourth-order point mass
6th Order Point Mass (Coordinated Flight)	Calculate sixth-order point mass in coordinated flight
6th Order Point Mass Forces (Coordinated Flight)	Calculate forces used by sixth-order point mass in coordinated flight

# Guidance, Navigation, and Control

Control (p. 4-14)	Controlling vehicles
Guidance (p. 4-15)	Guiding motion
Navigation (p. 4-15)	Navigating in space

### Control

1D Controller Blend u=(1-L).K1.y+L.K2.y	Implement 1-D vector of state-space controllers by linear interpolation of their outputs
1D Controller [A(v),B(v),C(v),D(v)]	Implement gain-scheduled state-space controller depending on one scheduling parameter
1D Observer Form [A(v),B(v),C(v),F(v),H(v)]	Implement gain-scheduled state-space controller in observer form depending on one scheduling parameter
2D Controller Blend	Implement 2-D vector of state-space controllers by linear interpolation of their outputs
2D Controller [A(v),B(v),C(v),D(v)]	Implement gain-scheduled state-space controller depending on two scheduling parameters
2D Observer Form [A(v),B(v),C(v),F(v),H(v)]	Implement gain-scheduled state-space controller in observer form depending on two scheduling parameters
2D Self-Conditioned $[A(v),B(v),C(v),D(v)]$	Implement gain-scheduled state-space controller in self-conditioned form depending on two scheduling parameters

3D Controller [A(v),B(v),C(v),D(v)]	Implement gain-scheduled state-space controller depending on three scheduling parameters
3D Observer Form [A(v),B(v),C(v),F(v),H(v)]	Implement gain-scheduled state-space controller in observer form depending on three scheduling parameters
3D Self-Conditioned [A(v),B(v),C(v),D(v)]	Implement gain-scheduled state-space controller in self-conditioned form depending on two scheduling parameters
Gain Scheduled Lead-Lag	Implement first-order lead-lag with gain-scheduled coefficients
Interpolate Matrix(x)	Return interpolated matrix for given input
Interpolate Matrix(x,y)	Return interpolated matrix for given inputs
Interpolate Matrix(x,y,z)	Return interpolated matrix for given inputs
Self-Conditioned [A,B,C,D]	Implement state-space controller in self-conditioned form

### Guidance

Calculate Range Calculate range between two crafts given their respective positions

### Navigation

Three-Axis Accelerometer	Implement three-axis accelerometer
Three-Axis Gyroscope	Implement three-axis gyroscope
Three-Axis Inertial Measurement Unit	Implement three-axis inertial measurement unit (IMU)

# **Mass Properties**

Estimate Center of Gravity	Calculate center of gravity location
Estimate Inertia Tensor	Calculate inertia tensor
Moments About CG Due to Forces	Compute moments about center of gravity due to forces applied at a point, not center of gravity
Symmetric Inertia Tensor	Create inertia tensor from moments and products of inertia

### **Pilot Models**

Crossover Pilot Model Precision Pilot Model Tustin Pilot Model Represent crossover pilot model Represent precision pilot model Represent Tustin pilot model

# Propulsion

Turbofan Engine System

Implement first-order representation of turbofan engine with controller

# Utilities

Axes Transformations (p. 4-19)	Geometric and kinematic transformations
Math Operations (p. 4-21)	Additional mathematical functions
Unit Conversions (p. 4-21)	Changing units
Axes Transformations	
Besselian Epoch to Julian Epoch	Transform position and velocity components from discontinued Standard Besselian Epoch (B1950) to Standard Julian Epoch (J2000)
Direction Cosine Matrix Body to Wind	Convert angle of attack and sideslip angle to direction cosine matrix
Direction Cosine Matrix Body to Wind to Alpha and Beta	Convert direction cosine matrix to angle of attack and sideslip angle
Direction Cosine Matrix ECEF to NED	Convert geodetic latitude and longitude to direction cosine matrix
Direction Cosine Matrix ECEF to NED to Latitude and Longitude	Convert direction cosine matrix to geodetic latitude and longitude
Direction Cosine Matrix to Quaternions	Convert direction cosine matrix to quaternion vector
Direction Cosine Matrix to Rotation Angles	Convert direction cosine matrix to rotation angles
Direction Cosine Matrix to Wind Angles	Convert direction cosine matrix to wind angles
ECEF Position to LLA	Calculate geodetic latitude, longitude, and altitude above planetary ellipsoid from Earth-centered Earth-fixed (ECEF) position

Flat Earth to LLA	Estimate geodetic latitude, longitude, and altitude from flat Earth position
Geocentric to Geodetic Latitude	Convert geocentric latitude to geodetic latitude
Geodetic to Geocentric Latitude	Convert geodetic latitude to geocentric latitude
Julian Epoch to Besselian Epoch	Transform position and velocity components from Standard Julian Epoch (J2000) to discontinued Standard Besselian Epoch (B1950)
LLA to ECEF Position	Calculate Earth-centered Earth-fixed (ECEF) position from geodetic latitude, longitude, and altitude above planetary ellipsoid
LLA to Flat Earth	Estimate flat Earth position from geodetic latitude, longitude, and altitude
Quaternions to Direction Cosine Matrix	Convert quaternion vector to direction cosine matrix
Quaternions to Rotation Angles	Determine rotation vector from quaternion
Rotation Angles to Direction Cosine Matrix	Convert rotation angles to direction cosine matrix
Rotation Angles to Quaternions	Calculate quaternion from rotation angles
Wind Angles to Direction Cosine Matrix	Convert wind angles to direction cosine matrix

### **Math Operations**

3x3 Cross Product

Adjoint of 3x3 Matrix Create 3x3 Matrix

Determinant of 3x3 Matrix Invert 3x3 Matrix Quaternion Conjugate Quaternion Division

Quaternion Inverse Quaternion Modulus Quaternion Multiplication Quaternion Norm Quaternion Normalize Quaternion Rotation SinCos Calculate cross product of two 3-by-1 vectors

# Blocks — Alphabetical List

# 1D Controller [A(v),B(v),C(v),D(v)]

Purpose	Implement gain-scheduled state-space controller depending on one scheduling parameter			
Library	GNC/Control			
Description	The 1D Controller $[A(v),B(v),C(v),D(v)]$ block implements a gain-scheduled state-space controller as defined by the equations $\dot{x} = A(v)x + B(v)y$ u = C(v)x + D(v)y where v is a parameter over which A, B, C, and D are defined. This			

where v is a parameter over which A, B, C, and D are defined. This type of controller scheduling assumes that the matrices A, B, C, and D vary smoothly as a function of v, which is often the case in aerospace applications.

Dialog	Function Block Parameters: 1D Controller [A(v),B(v),C(v),D(v)]
Box	StateSpaceABCD-1D (mask) (link)

#### A-matrix(v)

A-matrix of the state-space implementation. In the case of 1-D scheduling, the A-matrix should have three dimensions, the last one corresponding to the scheduling variable v. Hence, for example, if the A-matrix corresponding to the first entry of v is the identity matrix, then  $A(:,:,1) = [1 \ 0; 0 \ 1];$ .

#### B-matrix(v)

*B*-matrix of the state-space implementation. In the case of 1-D scheduling, the *B*-matrix should have three dimensions, the last one corresponding to the scheduling variable v. Hence, for

example, if the *B*-matrix corresponding to the first entry of v is the identity matrix, then  $B(:,:,1) = [1 \ 0; 0 \ 1];$ .

#### C-matrix(v)

*C*-matrix of the state-space implementation. In the case of 1-D scheduling, the *C*-matrix should have three dimensions, the last one corresponding to the scheduling variable v. Hence, for example, if the *C*-matrix corresponding to the first entry of v is the identity matrix, then  $C(:,:,1) = [1 \ 0; 0 \ 1];$ .

#### D-matrix(v)

*D*-matrix of the state-space implementation. In the case of 1-D scheduling, the *D*-matrix should have three dimensions, the last one corresponding to the scheduling variable v. Hence, for example, if the *D*-matrix corresponding to the first entry of v is the identity matrix, then  $D(:,:,1) = [1 \ 0; 0 \ 1];$ .

#### Scheduling variable breakpoints

Vector of the breakpoints for the scheduling variable. The length of v should be same as the size of the third dimension of A, B, C, and D.

#### Initial state, x\_initial

Any

First

Vector of initial states for the controller, i.e., initial values for the state vector, x. It should have length equal to the size of the first dimension of A.

Contains the actuator demands.

ınd	Input	<b>Dimension Type</b>	Description	
S	First	Any	Contains the measurements.	
	Second		Contains the scheduling variable conforming to the dimensions of the state-space matrices.	
	Output	Dimension Type	Description	

#### Inputs and Outputs

Assumptions and Limitations	If the scheduling parameter inputs to the block go out of range, then they are clipped; i.e., the state-space matrices are not interpolated out of range.
Examples	See H-Infinity Controller (1 Dimensional Scheduling) in aeroblk_lib_HL20 for an example of this block.
See Also	1D Controller Blend u=(1-L).K1.y+L.K2.y
	1D Observer Form $[A(v),B(v),C(v),F(v),H(v)]$
	1D Self-Conditioned [A(v),B(v),C(v),D(v)]
	2D Controller $[A(v),B(v),C(v),D(v)]$
	3D Controller $[A(v),B(v),C(v),D(v)]$

# 1D Controller Blend u=(1-L).K1.y+L.K2.y

Purpose	Implement 1-D vector of state-space controllers by linear interpolation of their outputs
Library	GNC/Control
Description	The 1D Controller Blend u=(1-L).K1.y+L.K2.y block implements an array of state-space controller designs. The controllers are run in parallel, and their outputs interpolated according to the current flight condition or operating point. The advantage of this implementation approach is that the state-space matrices $A$ , $B$ , $C$ , and $D$ for the individual controller designs do not need to vary smoothly from one

For example, suppose two controllers are designed at two operating points  $v=v_{\min}$  and  $v=v_{\max}$ . The 1D Controller Blend block implements

$$\begin{split} \dot{x}_1 &= A_1 x_1 + B_1 y \\ u_1 &= C_1 x_1 + D_1 y \\ \dot{x}_2 &= A_2 x_2 + B_2 y \\ u_2 &= C_2 x_2 + D_2 y \\ u &= (1 - \lambda) u_1 + \lambda u_2 \end{split}$$

design point to the next.

 $\lambda = \begin{cases} 0 & v < v_{\min} \\ \frac{v - v_{\min}}{v_{\max} - v_{\min}} & v_{\min} \le v \le v_{\max} \\ 1 & v > v_{\max} \end{cases}$ 

For longer arrays of design points, the blocks only implement nearest neighbor designs. For the 1D Controller Blend block, at any given instant in time, three controller designs are being updated. This reduces computational requirements.

As the value of the scheduling parameter varies and the index of the controllers that need to be run changes, the states of the oncoming

controller are initialized by using the self-conditioned form as defined for the Self-Conditioned [A,B,C,D] block.

#### A-matrix(v)

A-matrix of the state-space implementation. In the case of 1-D blending, the A-matrix should have three dimensions, the last one corresponding to scheduling variable v. Hence, for example, if

the A-matrix corresponding to the first entry of v is the identity matrix, then  $A(:,:,1) = [1 \ 0; 0 \ 1];$ .

#### B-matrix(v)

B-matrix of the state-space implementation.

#### C-matrix(v)

C-matrix of the state-space implementation.

#### D-matrix(v)

D-matrix of the state-space implementation.

#### Scheduling variable breakpoints

Vector of the breakpoints for the scheduling variable. The length of v should be same as the size of the third dimension of A, B, C, and D.

#### Initial state, x\_initial

Vector of initial states for the controller, i.e., initial values for the state vector, x. It should have length equal to the size of the first dimension of A.

#### Poles of A(v)-H(v)\*C(v)

For oncoming controllers, an observer-like structure is used to ensure that the controller output tracks the current block output, *u*. The poles of the observer are defined in this dialog box as a vector, the number of poles being equal to the dimension of the A-matrix. Poles that are too fast result in sensor noise propagation, and poles that are too slow result in the failure of the controller output to track *u*.

# 1D Observer Form [A(v),B(v),C(v),F(v),H(v)]

# **Purpose** Implement gain-scheduled state-space controller in observer form depending on one scheduling parameter

#### Library GNC/Control

### Description

yy-y_dem		
×v k	u_dem	Þ
>u_meas		

The 1D Observer Form [A(v),B(v),C(v),F(v),H(v)] block implements a gain-scheduled state-space controller defined in the following observer form:

$$\begin{split} \dot{x} &= (A(v) + H(v)C(v))x + B(v)u_{meas} + H(v)(y - y_{dem}) \\ u_{dem} &= F(v)x \end{split}$$

The main application of this block is to implement a controller designed using H-infinity loop-shaping, one of the design methods supported by Robust Control Toolbox.

#### Dialog Box

#### A-matrix(v)

A-matrix of the state-space implementation. The A-matrix should have three dimensions, the last one corresponding to the scheduling variable v. Hence, for example, if the A-matrix corresponding to the first entry of v is the identity matrix, then  $A(:,:,1) = [1 \ 0; 0 \ 1];$ .

#### B-matrix(v)

*B*-matrix of the state-space implementation. The *B*-matrix should have three dimensions, the last one corresponding to the scheduling variable v. Hence, for example, if the *B*-matrix corresponding to the first entry of v is the identity matrix, then  $B(:,:,1) = [1 \ 0; 0 \ 1];$ .

#### C-matrix(v)

*C*-matrix of the state-space implementation. The *C*-matrix should have three dimensions, the last one corresponding to the scheduling variable v. Hence, for example, if the *C*-matrix corresponding to the first entry of v is the identity matrix, then  $C(:,:,1) = [1 \ 0; 0 \ 1];$ .

#### F-matrix(v)

State-feedback matrix. The *F*-matrix should have three dimensions, the last one corresponding to the scheduling variable v. Hence, for example, if the *F*-matrix corresponding to the first entry of v is the identity matrix, then  $F(:,:,1) = [1 \ 0; 0 \ 1];$ .

#### H-matrix(v)

Observer (output injection) matrix. The *H*-matrix should have three dimensions, the last one corresponding to the scheduling variable v. Hence, for example, if the *H*-matrix corresponding to the first entry of v is the identity matrix, then  $H(:,:,1) = [1 \ 0; 0 \ 1];$ .

#### Scheduling variable breakpoints

Vector of the breakpoints for the scheduling variable. The length of v should be same as the size of the third dimension of A, B, C, F, and H.

#### Initial state, x\_initial

Vector of initial states for the controller, i.e., initial values for the state vector, x. It should have length equal to the size of the first dimension of A.

## 1D Self-Conditioned [A(v),B(v),C(v),D(v)]

# **Purpose** Implement gain-scheduled state-space controller in self-conditioned form depending on one scheduling parameter

## Library GNC/Control

Description

u\_meas

u\_dem

The 1D Self-Conditioned [A(v),B(v),C(v),D(v)] block implements a gain-scheduled state-space controller as defined by the equations

 $\dot{x} = A(v)x + B(v)y$ u = C(v)x + D(v)y

in the self-conditioned form

$$\begin{split} \dot{z} &= (A(v) - H(v)C(v))z + (B(v) - H(v)D(V))e + H(v)u_{meas} \\ u_{dem} &= C(v)z + D(v)e \end{split}$$

For the rationale behind this self-conditioned implementation, refer to the Self-Conditioned [A,B,C,D] block reference. This block implements a gain-scheduled version of the Self-Conditioned [A,B,C,D] block, v being the parameter over which A, B, C, and D are defined. This type of controller scheduling assumes that the matrices A, B, C, and D vary smoothly as a function of v, which is often the case in aerospace applications.

## Dialog Box

Function Block Parameters: 1D Self-Conditioned [A(v),B(v),C(v),D(v)]
StateSpaceSelfCond-1D (mask) (link)
Implement a state-space controller $[A(v),B(v),C(v),D(v)]$ in a self- conditioned form. If u_meas = u_dem, then the implemented controller is $[A,B,C,D]$ . If u_meas is limited, e.g., rate limiting, then the poles of the controller become those defined in the mask dialog box. Uses call to Control Systems Toolbox function place.m when initializing. A, B, C, and D should be 3-D matrices, the last dimension corresponding to the scheduling parameter, and the first two corresponding to the matrix for a given set of scheduling parameter values.
Parameters

## A-matrix(v)

A-matrix of the state-space implementation. The A-matrix should have three dimensions, the last one corresponding to

the scheduling variable v. Hence, for example, if the A-matrix corresponding to the first entry of v is the identity matrix, then  $A(:,:,1) = [1 \ 0; 0 \ 1];$ .

#### B-matrix(v)

*B*-matrix of the state-space implementation. The *B*-matrix should have three dimensions, the last one corresponding to the scheduling variable v. Hence, for example, if the *B*-matrix corresponding to the first entry of v is the identity matrix, then  $B(:,:,1) = [1 \ 0; 0 \ 1];$ .

### C-matrix(v)

*C*-matrix of the state-space implementation. The *C*-matrix should have three dimensions, the last one corresponding to the scheduling variable v. Hence, for example, if the *C*-matrix corresponding to the first entry of v is the identity matrix, then  $C(:,:,1) = [1 \ 0; 0 \ 1];$ .

### D-matrix(v)

*D*-matrix of the state-space implementation. The *D*-matrix should have three dimensions, the last one corresponding to the scheduling variable v. Hence, for example, if the *D*-matrix corresponding to the first entry of v is the identity matrix, then  $D(:,:,1) = [1 \ 0; 0 \ 1];$ .

#### Scheduling variable breakpoints

Vector of the breakpoints for the first scheduling variable. The length of v should be same as the size of the third dimension of A, B, C, and D.

## Initial state, x\_initial

Vector of initial states for the controller, i.e., initial values for the state vector, x. It should have length equal to the size of the first dimension of A.

## Poles of A(v)-H(v)\*C(v)

Vector of the desired poles of A-HC. Note that the poles are assigned to the same locations for all values of the scheduling parameter v. Hence the number of pole locations defined should be equal to the length of the first dimension of the A-matrix.

## **2D Controller Blend**

## **Purpose** Implement 2-D vector of state-space controllers by linear interpolation of their outputs

## Library GNC/Control

## Description

>y >v1 >v2	us
>ν1 >ν2	

The 2D Controller Blend block implements an array of state-space controller designs. The controllers are run in parallel, and their outputs interpolated according to the current flight condition or operating point. The advantage of this implementation approach is that the state-space matrices A, B, C, and D for the individual controller designs do not need to vary smoothly from one design point to the next.

For the 2D Controller Blend block, at any given instant in time, nine controller designs are updated.

As the value of the scheduling parameter varies and the index of the controllers that need to be run changes, the states of the oncoming controller are initialized by using the self-conditioned form as defined for the Self-Conditioned [A,B,C,D] block.

#### C-matrix(v1,v2)

*C*-matrix of the state-space implementation.

#### D-matrix(v1,v2)

*D*-matrix of the state-space implementation.

#### First scheduling variable (v1) breakpoints

Vector of the breakpoints for the first scheduling variable. The length of v1 should be same as the size of the third dimension of *A*, *B*, *C*, and *D*.

#### Second scheduling variable (v2) breakpoints

Vector of the breakpoints for the second scheduling variable. The length of v2 should be same as the size of the fourth dimension of *A*, *B*, *C*, and *D*.

#### Initial state, x\_initial

Vector of initial states for the controller, i.e., initial values for the state vector, x. It should have length equal to the size of the first dimension of A.

#### Poles of A(v)-H(v)\*C(v)

For oncoming controllers, an observer-like structure is used to ensure that the controller output tracks the current block output, u. The poles of the observer are defined in this dialog box as a vector, the number of poles being equal to the dimension of the *A*-matrix. Poles that are too fast result in sensor noise propagation, and poles that are too slow result in the failure of the controller output to track u.

## 2D Observer Form [A(v),B(v),C(v),F(v),H(v)]

## **Purpose** Implement gain-scheduled state-space controller in observer form depending on two scheduling parameters

## Library GNC/Control

## Description

>y-y_dem >v1	u_dem	
>v2 >u_meas	u_aem	P

The 2D Observer Form [A(v),B(v),C(v),F(v),H(v)] block implements a gain-scheduled state-space controller defined in the following observer form:

$$\begin{split} \dot{x} &= (A(v) + H(v)C(v))x + B(v)u_{meas} + H(v)\big(y - y_{dem}\big) \\ u_{dem} &= F(v)x \end{split}$$

The main application of these blocks is to implement a controller designed using H-infinity loop-shaping, one of the design methods supported by Robust Control Toolbox.

## A-matrix(v1,v2)

A-matrix of the state-space implementation. In the case of 2-D scheduling, the A-matrix should have four dimensions, the last two corresponding to scheduling variables v1 and v2. Hence, for example, if the A-matrix corresponding to the first entry of

v1 and first entry of v2 is the identity matrix, then A(:,:,1,1)
= [1 0;0 1];.

### B-matrix(v1,v2)

*B*-matrix of the state-space implementation. In the case of 2-D scheduling, the *B*-matrix should have four dimensions, the last two corresponding to scheduling variables v1 and v2. Hence, for example, if the *B*-matrix corresponding to the first entry of v1 and first entry of v2 is the identity matrix, then  $B(:,:,1,1) = [1 \ 0; 0 \ 1];$ .

### C-matrix(v1,v2)

*C*-matrix of the state-space implementation. In the case of 2-D scheduling, the *C*-matrix should have four dimensions, the last two corresponding to scheduling variables v1 and v2. Hence, for example, if the *C*-matrix corresponding to the first entry of v1 and first entry of v2 is the identity matrix, then  $C(:,:,1,1) = [1 \ 0; 0 \ 1];$ .

### F-matrix(v1,v2)

State-feedback matrix. In the case of 2-D scheduling, the *F*-matrix should have four dimensions, the last two corresponding to scheduling variables v1 and v2. Hence, for example, if the *F*-matrix corresponding to the first entry of v1 and first entry of v2 is the identity matrix, then  $F(:,:,1,1) = [1 \ 0; 0 \ 1];$ .

## H-matrix(v1,v2)

Observer (output injection) matrix. In the case of 2-D scheduling, the *H*-matrix should have four dimensions, the last two corresponding to scheduling variables v1 and v2. Hence, for example, if the *H*-matrix corresponding to the first entry of v1 and first entry of v2 is the identity matrix, then  $H(:,:,1,1) = [1 \ 0; 0 \ 1];$ .

#### First scheduling variable (v1) breakpoints

Vector of the breakpoints for the first scheduling variable. The length of v1 should be same as the size of the third dimension of *A*, *B*, *C*, *F*, and *H*.

## Second scheduling variable (v2) breakpoints

Vector of the breakpoints for the second scheduling variable. The length of v2 should be same as the size of the fourth dimension of A, B, C, F, and H.

## Initial state, x\_initial

Vector of initial states for the controller, i.e., initial values for the state vector, x. It should have length equal to the size of the first dimension of A.

Inputs and	Input	Dimension Type	Description
Outputs	First		Contains the set-point error.
	Second		Contains the scheduling variable, conforming to the dimensions of the state-space matrices.
	Third		Contains the scheduling variable, conforming to the dimensions of the state-space matrices.
	Fourth		Contains the measured actuator position.
	Output	Dimension Type	Description
	First		Contains the actuator demands.
Assumptions and Limitations	If the scheduling parameter inputs to the block go out of range, then they are clipped; i.e., the state-space matrices are not interpolated out of range.		
Examples		nity Controller (Two ib_HL20 for an exam	Dimensional Scheduling) in ple of this block.

# 2D Observer Form [A(v),B(v),C(v),F(v),H(v)]

	3D Observer Form [A(v),B(v),C(v),F(v),H(v)]

## **Purpose** Implement gain-scheduled state-space controller in self-conditioned form depending on two scheduling parameters

GNC/Control

**Description** 

Library

The 2D Self-Conditioned [A(v),B(v),C(v),D(v)] block implements a gain-scheduled state-space controller as defined by the equations

 $\dot{x} = A(v)x + B(v)y$ u = C(v)x + D(v)y

in the self-conditioned form

$$\begin{split} \dot{z} &= \big(A(v) - H(v)C(v)\big)z + \big(B(v) - H(v)D(v)\big)e + H(v)u_{meas} \\ u_{dem} &= C(v)z + D(v)e \end{split}$$

For the rationale behind this self-conditioned implementation, refer to the Self-Conditioned [A,B,C,D] block reference. This block implements a gain-scheduled version of the Self-Conditioned [A,B,C,D] block, v being the vector of parameters over which A, B, C, and D are defined. This type of controller scheduling assumes that the matrices A, B, C, and D vary smoothly as a function of v, which is often the case in aerospace applications.

# 2D Self-Conditioned [A(v),B(v),C(v),D(v)]

Dialog Box

Punction Block Parameters: 2D Self-Conditioned [A(v),B(v),C(v),D(v)]
StateSpaceSelfCond-2D (mask) (link)
Implement a state-space controller [A(v1,v2),B(v1,v2),C(v1,v2),D(v1,v2)] in a self-conditioned form. If $u_meas = u_dem$ , then the implemented controller is $[A,B,C,D]$ . If $u_meas$ is limited, e.g., rate limiting, then the poles of the controller become those defined in the mask dialog box. Uses call to Control Systems Toolbox function place.m when initializing. A, B, C, and D should be 4-D matrices, the last two dimensions corresponding to the scheduling parameters, and the first two corresponding to the matrix for a given set of scheduling parameter values.

## A-matrix(v1,v2,v3)

A-matrix of the state-space implementation. In the case of 3-D scheduling, the A-matrix should have five dimensions, the last three corresponding to scheduling variables v1, v2, and v3. Hence, for example, if the A-matrix corresponding to the first entry of v1, the first entry of v2, and the first entry of v3 is the identity matrix, then  $A(:,:,1,1,1) = [1 \ 0; 0 \ 1];$ .

## B-matrix(v1,v2,v3)

*B*-matrix of the state-space implementation. In the case of 3-D scheduling, the *B*-matrix should have five dimensions, the last three corresponding to scheduling variables v1, v2, and v3. Hence, for example, if the *B*-matrix corresponding to the first entry of v1, the first entry of v2, and the first entry of v3 is the identity matrix, then  $B(:,:,1,1,1) = [1 \ 0; 0 \ 1];$ .

### C-matrix(v1,v2,v3)

*C*-matrix of the state-space implementation. In the case of 3-D scheduling, the *C*-matrix should have five dimensions, the last three corresponding to scheduling variables v1, v2, and v3. Hence, for example, if the *C*-matrix corresponding to the first entry of v1, the first entry of v2, and the first entry of v3 is the identity matrix, then  $C(:,:,1,1,1) = [1 \ 0; 0 \ 1];$ .

### D-matrix(v1,v2,v3)

*D*-matrix of the state-space implementation. In the case of 3-D scheduling, the *D*-matrix should have five dimensions, the last three corresponding to scheduling variables v1, v2, and v3. Hence, for example, if the *D*-matrix corresponding to the first entry of v1, the first entry of v2, and the first entry of v3 is the identity matrix, then  $D(:,:,1,1,1) = [1 \ 0; 0 \ 1];$ .

#### First scheduling variable (v1) breakpoints

Vector of the breakpoints for the first scheduling variable. The length of v1 should be same as the size of the third dimension of *A*, *B*, *C*, and *D*.

#### Second scheduling variable (v2) breakpoints

Vector of the breakpoints for the second scheduling variable. The length of v2 should be same as the size of the fourth dimension of *A*, *B*, *C*, and *D*.

#### Third scheduling variable (v3) breakpoints

Vector of the breakpoints for the third scheduling variable. The length of v3 should be same as the size of the fifth dimension of *A*, *B*, *C*, and *D*.

## Initial state, x\_initial

Vector of initial states for the controller, i.e., initial values for the state vector, x. It should have length equal to the size of the first dimension of A.

Inputs and	Input	Dimension Type	Description
Outputs	First		Contains the measurements.
	Second		Contains the scheduling variable, ordered conforming to the dimensions of the state-space matrices.
	Third		Contains the scheduling variable, ordered conforming to the dimensions of the state-space matrices.
	Fourth		Contains the scheduling variable, ordered conforming to the dimensions of the state-space matrices.
	Output	Dimension Type	Description
	First		Contains the actuator demands.

## Library GNC/Control

## Description

×	y-y_dem		
×	v1		
×	v2	u_dem	þ
×	vЗ		
×	u_meas		

The 3D Observer Form [A(v),B(v),C(v),F(v),H(v)] block implements a gain-scheduled state-space controller defined in the following observer form:

$$\dot{x} = (A(v) + H(v)C(v))x + B(v)u_{meas} + H(v)(y - y_{dem})$$
$$u_{dem} = F(v)x$$

The main application of this block is to implement a controller designed using H-infinity loop-shaping, one of the design methods supported by Robust Control Toolbox.

## A-matrix(v1,v2,v3)

A-matrix of the state-space implementation. In the case of 3-D scheduling, the A-matrix should have five dimensions, the last three corresponding to scheduling variables v1, v2, and v3. Hence, for example, if the A-matrix corresponding to the first entry of v1, the first entry of v2, and the first entry of v3 is the identity matrix, then  $A(:,:,1,1,1) = [1 \ 0; 0 \ 1];$ .

#### B-matrix(v1,v2,v3)

*B*-matrix of the state-space implementation. In the case of 3-D scheduling, the *B*-matrix should have five dimensions, the last three corresponding to scheduling variables v1, v2, and v3. Hence, for example, if the *B*-matrix corresponding to the first entry of v1, the first entry of v2, and the first entry of v3 is the identity matrix, then  $B(:,:,1,1,1) = [1 \ 0; 0 \ 1];$ .

#### C-matrix(v1,v2,v3)

*C*-matrix of the state-space implementation. In the case of 3-D scheduling, the *C*-matrix should have five dimensions, the last three corresponding to scheduling variables v1, v2, and v3. Hence, for example, if the *C*-matrix corresponding to the first entry of v1, the first entry of v2, and the first entry of v3 is the identity matrix, then  $C(:,:,1,1,1) = [1 \ 0; 0 \ 1];$ .

#### F-matrix(v1,v2,v3)

State-feedback matrix. In the case of 3-D scheduling, the *F*-matrix should have five dimensions, the last three corresponding to scheduling variables v1, v2, and v3. Hence, for example, if the *F*-matrix corresponding to the first entry of v1, the first entry of v2, and the first entry of v3 is the identity matrix, then  $F(:,:,1,1,1) = [1 \ 0; 0 \ 1];$ .

#### H-matrix(v1,v2,v3)

Observer (output injection) matrix. In the case of 3-D scheduling, the *H*-matrix should have five dimensions, the last three corresponding to scheduling variables v1, v2, and v3. Hence, for example, if the *H*-matrix corresponding to the first entry of v1, the first entry of v2, and the first entry of v3 is the identity matrix, then  $H(:,:,1,1,1) = [1 \ 0; 0 \ 1];$ .

## First scheduling variable (v1) breakpoints

Vector of the breakpoints for the first scheduling variable. The length of v1 should be same as the size of the third dimension of A, B, C, F, and H.

### Second scheduling variable (v2) breakpoints

Vector of the breakpoints for the second scheduling variable. The length of v2 should be same as the size of the fourth dimension of A, B, C, F, and H.

### Third scheduling variable (v3) breakpoints

Vector of the breakpoints for the third scheduling variable. The length of v3 should be same as the size of the fifth dimension of A, B, C, F, and H.

### Initial state, x\_initial

Vector of initial states for the controller, i.e., initial values for the state vector, x. It should have length equal to the size of the first dimension of A.

Inputs and	Input	Dimension Type	Description
Outputs	First		Contains the set-point error.
	Second		Contains the scheduling variable, ordered conforming to the dimensions of the state-space matrices.
	Third		Contains the scheduling variable, ordered conforming to the dimensions of the state-space matrices.
	Fourth		Contains the scheduling variable, ordered conforming to the dimensions of the state-space matrices.
	Fifth		Contains the measured actuator position.

# **Purpose** Implement gain-scheduled state-space controller in self-conditioned form depending on two scheduling parameters

GNC/Control

**Description** 

Library

The 3D Self-Conditioned [A(v),B(v),C(v),D(v)] block implements a gain-scheduled state-space controller as defined by the equations

 $\dot{x} = A(v)x + B(v)y$ u = C(v)x + D(v)y

in the self-conditioned form

$$\begin{split} \dot{z} &= \big(A(v) - H(v)C(v)\big)z + \big(B(v) - H(v)D(v)\big)e + H(v)u_{meas} \\ u_{dem} &= C(v)z + D(v)e \end{split}$$

For the rationale behind this self-conditioned implementation, refer to the Self-Conditioned [A,B,C,D] block reference. These blocks implement a gain-scheduled version of the Self-Conditioned [A,B,C,D] block, v being the vector of parameters over which A, B, C, and D are defined. This type of controller scheduling assumes that the matrices A, B, C, and D vary smoothly as a function of v, which is often the case in aerospace applications.

## A-matrix(v1,v2,v3)

A-matrix of the state-space implementation. In the case of 3-D scheduling, the A-matrix should have five dimensions, the last three corresponding to scheduling variables v1, v2, and v3. Hence, for example, if the A-matrix corresponding to the first entry of v1, the first entry of v2, and the first entry of v3 is the identity matrix, then A(:,:,1,1,1) = [1 0;0 1];.

## B-matrix(v1,v2,v3)

*B*-matrix of the state-space implementation. In the case of 3-D scheduling, the *B*-matrix should have five dimensions, the last three corresponding to scheduling variables v1, v2, and v3. Hence, for example, if the *B*-matrix corresponding to the first entry of v1, the first entry of v2, and the first entry of v3 is the identity matrix, then  $B(:,:,1,1,1) = [1 \ 0; 0 \ 1];$ .

## C-matrix(v1,v2,v3)

*C*-matrix of the state-space implementation. In the case of 3-D scheduling, the *C*-matrix should have five dimensions, the last three corresponding to scheduling variables v1, v2, and v3. Hence, for example, if the *C*-matrix corresponding to the first entry of v1, the first entry of v2, and the first entry of v3 is the identity matrix, then  $C(:,:,1,1,1) = [1 \ 0; 0 \ 1];$ .

## D-matrix(v1,v2,v3)

*D*-matrix of the state-space implementation. In the case of 3-D scheduling, the *D*-matrix should have five dimensions, the last three corresponding to scheduling variables v1, v2, and v3. Hence, for example, if the *D*-matrix corresponding to the first entry of v1, the first entry of v2, and the first entry of v3 is the identity matrix, then  $D(:,:,1,1,1) = [1 \ 0; 0 \ 1];$ .

## First scheduling variable (v1) breakpoints

Vector of the breakpoints for the first scheduling variable. The length of v1 should be same as the size of the third dimension of *A*, *B*, *C*, and *D*.

## Second scheduling variable (v2) breakpoints

Vector of the breakpoints for the second scheduling variable. The length of v2 should be same as the size of the fourth dimension of *A*, *B*, *C*, and *D*.

#### Third scheduling variable (v3) breakpoints

Vector of the breakpoints for the third scheduling variable. The length of v3 should be same as the size of the fifth dimension of A, B, C, and D.

#### Initial state, x\_initial

Vector of initial states for the controller, i.e., initial values for the state vector, x. It should have length equal to the size of the first dimension of A.

#### Poles of A(v)-H(v)\*C(v)

Vector of the desired poles of A-HC. Note that the poles are assigned to the same locations for all values of the scheduling parameter v. Hence the number of pole locations defined should be equal to the length of the first dimension of the A-matrix.

### Axes limits [xmin xmax ymin ymax zmin zmax]

Specifies the three-dimensional space to be viewed.

### Time interval between updates

Specifies the time interval at which the animation is redrawn.

### Size of craft displayed

Scale factor to adjust the size of the craft and target.

### **Enter view**

Selects preset MATLAB Graphics parameters **CameraTarget** and **CameraUpVector** for the figure axes. The dialog parameters **Position of camera** and **View angle** are used to customize the position and field of view for the selected view. Possible views are

- Fixed position
- Cockpit
- Fly alongside

### Position of camera [xc yc zc]

Specifies the MATLAB Graphics parameter CameraPosition for the figure axes. Used in all cases except for the Cockpit view.

#### View angle

Specifies the MATLAB Graphics parameter CameraViewAngle for the figure axes in degrees.

### **Enable animation**

When selected, the animation is displayed during the simulation. If not selected, the animation is not displayed.

Inputs	Input	Dimension Type	Description		
	First	Vector	Contains the altitude and the downrange position of the target in Earth coordinates.		
	Second	Vector	Contains the altitude and the downrange position of the craft in Earth coordinates.		
	Third		Contains the attitude of the craft.

## **3DoF (Body Axes)**

# **Purpose** Implement three-degrees-of-freedom equations of motion with respect to body axes

### Library Equations of Motion/3DoF

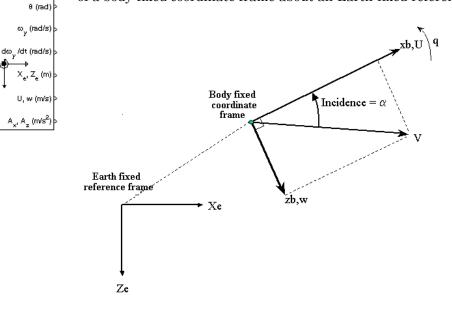

### Description

F\_ (N)

F\_ (N)

> M (N-m)

The 3DoF (Body Axes) block considers the rotation in the vertical plane of a body-fixed coordinate frame about an Earth-fixed reference frame.

The equations of motion are

$$\dot{u} = \frac{F_x}{m} - qw - g\sin\theta$$
$$\dot{w} = \frac{F_z}{m} + qu + g\cos\theta$$
$$\dot{q} = \frac{M}{I_{yy}}$$
$$\dot{\theta} = q$$

where the applied forces are assumed to act at the center of gravity of the body.

### Mass Type

Select the type of mass to use:

Fixed	Mass is constant throughout the simulation.
Simple Variable	Mass and inertia vary linearly as a function of mass rate.
Custom Variable	Mass and inertia variations are customizable.

The Fixed selection conforms to the previously described equations of motion.

### **Initial velocity**

A scalar value for the initial velocity of the body,  $(V_0)$ .

### Initial body attitude

A scalar value for the initial pitch attitude of the body,  $(\theta_0)$ .

### **Initial incidence**

A scalar value for the initial angle between the velocity vector and the body,  $(a_0)$ .

#### Initial body rotation rate

A scalar value for the initial body rotation rate,  $(q_0)$ .

### Initial position (x,z)

A two-element vector containing the initial location of the body in the Earth-fixed reference frame.

### **Initial Mass**

A scalar value for the mass of the body.

#### Inertia

A scalar value for the inertia of the body.

### **Gravity Source**

Specify source of gravity:

External	Variable gravity input to block
Internal	Constant gravity specified in mask

#### Acceleration due to gravity

A scalar value for the acceleration due to gravity used if internal gravity source is selected. If gravity is to be neglected in the simulation, this value can be set to 0.

Inputs and	
Outputs	

Input	<b>Dimension Type</b>	Description
First		Contains the force acting along the body <i>x</i> -axis, $(F_x)$ .
Second		Contains the force acting along the body <i>z</i> -axis, $(F_z)$ .
Third		Contains the applied pitch moment, $(M)$ .
Fourth (Optional)		Contains the block is gravity in the selected units.

Output	Dimension Type	Description
First		Contains the pitch attitude, in radians $(\theta)$ .
Second		Contains the pitch angular rate, in radians per second $(q)$ .
Third		Contains the pitch angular acceleration, in radians per second
		squared $(\dot{q})$ .
Fourth	Two-element vector	Contains the location of the body, in the Earth-fixed reference frame, ( <i>Xe</i> , <i>Ze</i> ).
Fifth	Two-element vector	Contains the velocity of the body resolved into the body-fixed coordinate frame, $(u, w)$ .
Sixth	Two-element vector	Contains the acceleration of the body resolved into the body-fixed coordinate frame, $(Ax, Az)$ .

### Purpose Calculate cross product of two 3-by-1 vectors

Library

Utilities/Math Operations

### **Description**

The 3x3 Cross Product block computes cross (or vector) product of two vectors, A and B, by generating a third vector, C, in a direction normal to the plane containing A and B, and with magnitude equal to the product of the lengths of A and B multiplied by the sine of the angle between them. The direction of C is that in which a right-handed screw would move in turning from A to B.

$$A = a_1 \mathbf{i} + a_2 \mathbf{j} + a_3 \mathbf{k}$$
  

$$B = b_1 \mathbf{i} + b_2 \mathbf{j} + b_3 \mathbf{k}$$
  

$$C = A \times B = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ a_1 & a_2 & a_3 \\ b_1 & b_2 & b_3 \end{vmatrix}$$
  

$$= (a_2 b_3 - a_3 b_2) \mathbf{i} + (a_3 b_1 - a_1 b_3) \mathbf{j} + (a_1 b_2 - a_2 b_1) \mathbf{k}$$

Equations of Motion/Point Mass

### Description

	E (N)	4th Order	y(rad)>
> F <sub>*</sub> (N)	Point Mass	V (m/s)>	
>	F <sub>2</sub> (N)	Longitudinal	× <sub>East</sub> (m) >
	-		X <sub>Up</sub> (m) >

The 4th Order Point Mass (Longitudinal) block performs the calculations for the translational motion of a single point mass or multiple point masses.

The translational motions of the point mass  $[X_{\text{East}} X_{\text{Up}}]^{\text{T}}$  are functions of airspeed (V) and flight path angle ( $\gamma$ ),

$$F_{x} = m\dot{V}$$

$$F_{z} = mV\dot{\gamma}$$

$$\dot{X}_{East} = V\cos\gamma$$

$$\dot{X}_{Up} = V\sin\gamma$$

where the applied forces  $[F_x F_z]^T$  are in a system defined as follows: x-axis is in the direction of vehicle velocity relative to air, z-axis is upward, and y-axis completes the right-handed frame. The mass of the body m is assumed constant.

Library

X	Lift		
>	Drag	F,	
>	Weight	×	ſ
>	Thrust		
>	y		
>	њ	۶z	Þ
>	a		

The 4th Order Point Mass Forces (Longitudinal) block calculates the applied forces for a single point mass or multiple point masses.

The applied forces  $[F_x F_z]^T$  are in a system defined as follows: *x*-axis is in the direction of vehicle velocity relative to air, *z*-axis is upward, and *y*-axis completes the right-handed frame. They are functions of lift (*L*), drag (*D*), thrust (*T*), weight (*W*), flight path angle (*y*), angle of attack (*a*), and bank angle ( $\mu$ ).

$$F_{z} = (L + T \sin \alpha) \cos \mu - W \cos \gamma$$
$$F_{x} = T \cos \alpha - D - W \sin \gamma$$

## **6DoF** Animation

Purpose	Create 3-D MATLAB Graphics animation of six-degrees-of-freedom object
Library	Animation
Description	The 6DoF Animation block displays a 3-D animated view of a six-degrees-of-freedom (6DoF) craft, its trajectory, and its target using MATLAB Graphics.
	The 6DoF Animation block uses the input values and the dialog parameters to create and display the animation.
	This block does not produce deployable code, but can be used with Simulink Coder external mode as a SimViewingDevice.

### Dialog Box

Sink Block Parameters: 6DoF Animation				
6DoF_Animation (mask) (link)				
Create a 3-D animated view of a six-degrees-of-freedom craft, where X, Y, and Z craft position (Position) and craft Euler angles (Euler) are inputs.				
Display parameters are in the same units of length as the input parameters.				
Parameters				
Axes limits [xmin xmax ymin ymax zmin zmax]:				
[0 4000 -2000 2000 -5000 -3000]				
Time interval between updates:

### Axes limits [xmin xmax ymin ymax zmin zmax]

Specifies the three-dimensional space to be viewed.

### Time interval between updates

Specifies the time interval at which the animation is redrawn.

#### Size of craft displayed

Scale factor to adjust the size of the craft and target.

#### Static object position

Specifies the altitude, the crossrange position, and the downrange position of the target.

#### Enter view

Selects preset MATLAB Graphics parameters **CameraTarget** and **CameraUpVector** for the figure axes. The dialog parameters **Position of camera** and **View angle** are used to customize the position and field of view for the selected view. Possible views are

- Fixed position
- Cockpit
- Fly alongside

### Position of camera [xc yc zc]

Specifies the MATLAB Graphics parameter CameraPosition for the figure axes. Used in all cases except for the Cockpit view.

#### View angle

Specifies the MATLAB Graphics parameter CameraViewAngle for the figure axes in degrees.

#### **Enable animation**

When selected, the animation is displayed during the simulation. If not selected, the animation is not displayed.

Input	<b>Dimension Type</b>	Description
First	Vector	Contains the altitude, the crossrange position, and the downrange position of the craft in Earth coordinates.
Second	Vector	Contains the Euler angles of the craft.

## **6DoF** (Euler Angles)

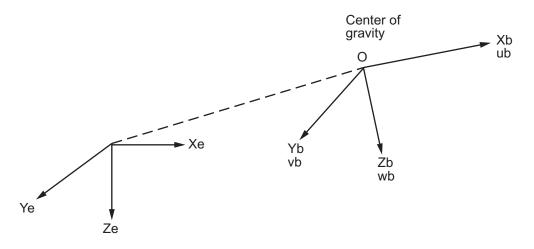

# **Purpose** Implement Euler angle representation of six-degrees-of-freedom equations of motion

### Library Equations of Motion/6DoF

### Description

The 6DoF (Euler Angles) block considers the rotation of a body-fixed coordinate frame  $(X_b, Y_b, Z_b)$  about a flat Earth reference frame  $(X_e, Y_e, Z_e)$ . The origin of the body-fixed coordinate frame is the center of gravity of the body, and the body is assumed to be rigid, an assumption that eliminates the need to consider the forces acting between individual elements of mass. The flat Earth reference frame is considered inertial, an excellent approximation that allows the forces due to the Earth's motion relative to the "fixed stars" to be neglected.

Flat Earth reference frame

The translational motion of the body-fixed coordinate frame is given below, where the applied forces  $[F_x F_y F_z]^T$  are in the body-fixed frame, and the mass of the body *m* is assumed constant.

$$\begin{split} \bar{F}_{b} &= \begin{bmatrix} F_{x} \\ F_{y} \\ F_{z} \end{bmatrix} = m \left( \dot{\bar{V}}_{b} + \bar{\omega} \times \bar{V}_{b} \right) \\ \bar{V}_{b} &= \begin{bmatrix} u_{b} \\ v_{b} \\ w_{b} \end{bmatrix}, \bar{\omega} = \begin{bmatrix} p \\ q \\ r \end{bmatrix} \end{split}$$

The rotational dynamics of the body-fixed frame are given below, where the applied moments are  $[L M N]^{T}$ , and the inertia tensor I is with respect to the origin O.

$$\bar{M}_B = \begin{bmatrix} L \\ M \\ N \end{bmatrix} = I\bar{\varpi} + \bar{\varpi} \times (I\bar{\varpi})$$
$$I = \begin{bmatrix} I_{xx} & -I_{xy} & -I_{xz} \\ -I_{yx} & I_{yy} & -I_{yz} \\ -I_{zx} & -I_{zy} & I_{zz} \end{bmatrix}$$

The relationship between the body-fixed angular velocity vector,  $[p \ q \ r]^{\mathrm{T}}$ ,

and the rate of change of the Euler angles,  $[\dot{\phi} \ \dot{\theta} \ \dot{\psi}]^{T}$ , can be determined by resolving the Euler rates into the body-fixed coordinate frame.

$$\begin{bmatrix} p \\ q \\ r \end{bmatrix} = \begin{bmatrix} \dot{\phi} \\ 0 \\ 0 \end{bmatrix} + \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\phi & \sin\phi \\ 0 & -\sin\phi & \cos\phi \end{bmatrix} \begin{bmatrix} 0 \\ \dot{\theta} \\ 0 \end{bmatrix} + \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\phi & \sin\phi \\ 0 & -\sin\phi & \cos\phi \end{bmatrix} \begin{bmatrix} \cos\theta & 0 & -\sin\theta \\ 0 & 1 & 0 \\ \sin\theta & 0 & \cos\theta \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ \psi \end{bmatrix} \equiv J^{-1} \begin{bmatrix} \dot{\phi} \\ \dot{\theta} \\ \psi \end{bmatrix}$$

Inverting  ${\cal J}$  then gives the required relationship to determine the Euler rate vector.

<b>F</b> . 7			_	Γ		-	
$\phi$		p		1	$(\sin\phi\tan\theta)$	$(\cos\phi\tan\theta)$	p
$\dot{\theta}$	=J	q	=	0	$\cos\phi$	$-\sin\phi$	q
ψ		r		0	$\sin\phi$	$\cos\phi$	$\lfloor r \rfloor$
				Ľ	$\cos  heta$	$\cos \theta$

### Units

Specifies the input and output units:

Units	Forces	Moment	Acceleration	Velocity	Position	Mass	Inertia
Metric (MKS)	Newton	Newton meter	Meters per second squared	Meters per second	Meters	Kilogram	Kilogram meter squared
English (Velocity in ft/s)	Pound	Foot pound	Feet per second squared	Feet per second	Feet	Slug	Slug foot squared
English (Velocity in kts)	Pound	Foot pound	Feet per second squared	Knots	Feet	Slug	Slug foot squared

### Mass Type

Select the type of mass to use:

Fixed	${\it Mass}$ is constant throughout the simulation.
Simple Variable	Mass and inertia vary linearly as a function of mass rate.
Custom Variable	Mass and inertia variations are customizable.

The Fixed selection conforms to the previously described equations of motion.

### Representation

Select the representation to use:

Euler	Use Euler angles within equations of motion.
Angles	
Quaternion	Use quaternions within equations of motion.

The Euler Angles selection conforms to the previously described equations of motion.

#### Initial position in inertial axes

The three-element vector for the initial location of the body in the flat Earth reference frame.

### Initial velocity in body axes

The three-element vector for the initial velocity in the body-fixed coordinate frame.

#### **Initial Euler rotation**

The three-element vector for the initial Euler rotation angles [roll, pitch, yaw], in radians.

### Initial body rotation rates

The three-element vector for the initial body-fixed angular rates, in radians per second.

### **Initial Mass**

The mass of the rigid body.

#### Inertia

The 3-by-3 inertia tensor matrix *I*.

Inputs and Outputs	Input	Dimension Type	Description
	First	Vector	Contains the three applied forces in body-fixed coordinate frame.
	Second	Vector	Contains the three applied moments in body-fixed coordinate frame.
	Output	<b>Dimension Type</b>	Description
	First	Three-element vector	Contains the velocity in the flat Earth reference frame.
	Second	Three-element vector	Contains the position in the flat Earth reference frame.

Output	<b>Dimension Type</b>	Description
Third	Three-element vector	Contains the Euler rotation angles [roll, pitch, yaw], in radians.
Fourth	3-by-3 matrix	Contains the coordinate transformation from flat Earth axes to body-fixed axes.
Fifth	Three-element vector	Contains the velocity in the body-fixed frame.
Sixth	Three-element vector	Contains the angular rates in body-fixed axes, in radians per second.
Seventh	Three-element vector	Contains the angular accelerations in body-fixed axes, in radians per second squared.
Eighth	Three-element vector	Contains the accelerations in body-fixed axes.

Assumptions and Limitations	The block assumes that the applied forces are acting at the center of gravity of the body, and that the mass and inertia are constant.	
Examples	See the aeroblk_six_dof airframe in aeroblk_HL20 and asbh120 for examples of this block.

Library

Equations of Motion/6DoF

# Description

 $\label{eq:rescaled_$ 

For a description of the coordinate system and the translational dynamics, see the block description for the 6DoF (Euler Angles) block.

The integration of the rate of change of the quaternion vector is given below. The gain K drives the norm of the quaternion state vector to 1.0 should  $\varepsilon$  become nonzero. You must choose the value of this gain with care, because a large value improves the decay rate of the error in the norm, but also slows the simulation because fast dynamics are introduced. An error in the magnitude in one element of the quaternion vector is spread equally among all the elements, potentially increasing the error in the state vector.

$$\begin{bmatrix} \dot{q}_0 \\ \dot{q}_1 \\ \dot{q}_2 \\ \dot{q}_3 \end{bmatrix} = \frac{1}{2} \begin{bmatrix} 0 & -p & -q & -r \\ p & 0 & r & -q \\ q & -r & 0 & p \\ r & q & -p & 0 \end{bmatrix} \begin{bmatrix} q_0 \\ q_1 \\ q_2 \\ q_3 \end{bmatrix} + K\varepsilon \begin{bmatrix} q_0 \\ q_1 \\ q_2 \\ q_3 \end{bmatrix}$$

$$\varepsilon = 1 - ({q_0}^2 + {q_1}^2 + {q_2}^2 + {q_3}^2)$$

# Purpose

Implement quaternion representation of six-degrees-of-freedom equations of motion in Earth-centered Earth-fixed (ECEF) coordinates

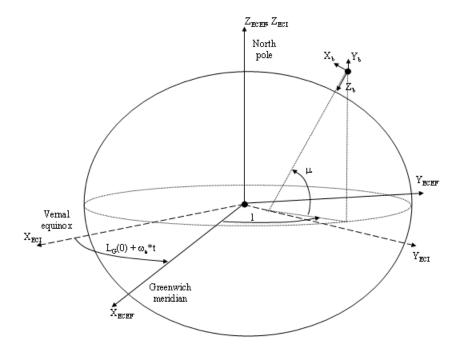

# Library

Equations of Motion/6DoF

# Description

The 6DoF ECEF (Quaternion) block considers the rotation of a Earth-centered Earth-fixed (ECEF) coordinate frame ( $X_{ECEF}$ ,  $Y_{ECEF}$ ,  $Z_{ECEF}$ ) about an Earth-centered inertial (ECI) reference frame ( $X_{ECI}$ ,  $Y_{ECI}$ ,  $Z_{ECI}$ ). The origin of the ECEF coordinate frame is the center of the Earth, additionally the body of interest is assumed to be rigid, an assumption that eliminates the need to consider the forces acting between individual elements of mass. The representation of the rotation of ECEF frame from ECI frame is simplified to consider only the constant rotation of the ellipsoid Earth ( $\omega_e$ ) including an initial celestial longitude ( $L_G(0)$ ). This excellent approximation allows the forces due to the Earth's complex motion relative to the "fixed stars" to be neglected.

The translational motion of the ECEF coordinate frame is given below, where the applied forces  $[F_x F_y F_z]^T$  are in the body frame, and the mass of the body *m* is assumed constant.

$$\bar{F}_{b} = \begin{bmatrix} F_{x} \\ F_{y} \\ F_{z} \end{bmatrix} = m(\bar{\bar{V}}_{b} + \bar{\omega}_{b} \times \bar{V}_{b} + DCM_{bf}\bar{\omega}_{e} \times \bar{V}_{b}) + DCM_{bf}(\bar{\omega}_{e} \times (\bar{\omega}_{e} \times \bar{X}_{f}))$$

where the change of position in ECEF  $\dot{\bar{x}}_{f}$  is calculated by

$$\dot{\bar{x}}_f = DCM_{fb}\overline{V}_b$$

\_

and the velocity of the body with respect to ECEF frame, expressed in body frame  $(\bar{V}_b)$ , angular rates of the body with respect to ECI frame,

expressed in body frame  $(\bar{\omega}_b)$ . Earth rotation rate  $(\bar{\omega}_e)$ , and relative angular rates of the body with respect to north-east-down (NED) frame, expressed in body frame  $(\bar{\omega}_{rel})$  are defined as

$$\begin{split} \bar{V}_{b} &= \begin{bmatrix} u \\ v \\ w \end{bmatrix}, \bar{\varpi}_{rel} = \begin{bmatrix} p \\ q \\ r \end{bmatrix}, \bar{\varpi}_{e} = \begin{bmatrix} 0 \\ 0 \\ \omega_{e} \end{bmatrix}, \bar{\varpi}_{b} = \bar{\varpi}_{rel} + DCM_{bf}\bar{\varpi}_{e} + DCM_{be}\bar{\varpi}_{ned} \\ \bar{\varpi}_{ned} &= \begin{bmatrix} i \cos \mu \\ -\dot{\mu} \\ -\dot{l} \sin \mu \end{bmatrix} = \begin{bmatrix} V_{E}/(N+h) \\ -V_{N}/(M+h) \\ V_{E} \bullet \tan \mu/(N+h) \end{bmatrix} \end{split}$$

The rotational dynamics of the body defined in body-fixed frame are given below, where the applied moments are  $[L M N]^{T}$ , and the inertia tensor I is with respect to the origin O.

$$\bar{M}_{b} = \begin{bmatrix} L \\ M \\ N \end{bmatrix} = I \dot{\bar{\varpi}}_{b} + \bar{\varpi}_{b} \times (I \bar{\varpi}_{b})$$

$$I = \begin{bmatrix} I_{xx} & -I_{xy} & -I_{xz} \\ -I_{yx} & I_{yy} & -I_{yz} \\ -I_{zx} & -I_{zy} & I_{zz} \end{bmatrix}$$

The integration of the rate of change of the quaternion vector is given below.

$$\begin{bmatrix} \dot{q}_0 \\ \dot{q}_1 \\ \dot{q}_2 \\ \dot{q}_3 \end{bmatrix} = -\frac{1/2} \begin{bmatrix} 0 & \omega_b (1) & \omega_b (2) & \omega_b (3) \\ -\omega_b (1) & 0 & -\omega_b (3) & \omega_b (2) \\ -\omega_b (2) & \omega_b (3) & 0 & -\omega_b (1) \\ -\omega_b (3) & -\omega_b (2) & \omega_b (1) & 0 \end{bmatrix} \begin{bmatrix} q_0 \\ q_1 \\ q_2 \\ q_3 \end{bmatrix}$$

### Mass type

Select the type of mass to use:

Fixed	Mass is constant throughout the simulation.
Simple Variable	Mass and inertia vary linearly as a function of mass rate (see Simple Variable Mass 6DoF ECEF (Quaternion)).
Custom Variable	Mass and inertia variations are customizable (see Simple Variable Mass 6DoF (Quaternion)).

The Fixed selection conforms to the previously described equations of motion.

# **Initial position in geodetic latitude, longitude and altitude** The three-element vector for the initial location of the body in the geodetic reference frame, in degrees.

# Initial velocity in body axes

The three-element vector containing the initial velocity of the body with respect to ECEF frame, expressed in body frame..

# **Initial Euler orientation**

The three-element vector containing the initial Euler rotation angles [roll, pitch, yaw], in radians. Euler rotation angles are those between the body and north-east-down (NED) coordinate systems.

### Initial body rotation rates

The three-element vector for the initial angular rates of the body with respect to NED frame, expressed in body frame, in radians per second.

### **Initial mass**

The mass of the rigid body.

### Inertia

The 3-by-3 inertia tensor matrix I, in body-fixed axes.

## Planet model

Specifies the planet model to use: Custom or Earth (WGS84).

## Flattening

Specifies the flattening of the planet. This option is only available when **Planet model** is set to Custom.

## Equatorial radius of planet

Specifies the radius of the planet at its equator. The units of the equatorial radius parameter should be the same as the units for ECEF position. This option is only available when **Planet model** is set to **Custom**.

## **Rotational rate**

Specifies the scalar rotational rate of the planet in rad/s. This option is only available when **Planet model** is set to **Custom**.

## Celestial longitude of Greenwich source

Specifies the source of Greenwich meridian's initial celestial longitude:

Internal	Use celestial longitude value from mask dialog.
External	Use external input for celestial longitude value.

# **Celestial longitude of Greenwich**

The initial angle between Greenwich meridian and the *x*-axis of the ECI frame.

Input	Dimension Type	Description
First	Vector	Contains the three applied forces in body-fixed axes.
Second	Vector	Contains the three applied moments in body-fixed axes.

Output	Dimension Type	Description
First	Vector	Contains the velocity of the body with respect to ECEF frame, expressed in ECEF frame.
Second	Three-element vector	Contains the position in ECEF reference frame.
Third	Three-element vector	Contains the position in geodetic latitude, longitude and altitude, in degrees, degrees and selected units of length respectively.

# Inputs and Outputs

Output	Dimension Type	Description
Fourth	Three-element vector	Contains the body rotation angles [roll, pitch, yaw], in radians. Euler rotation angles are those between the body and north-east-down (NED) coordinate systems.
Fifth	3-by-3 matrix	Applies to the coordinate transformation from ECI axes to body-fixed axes
Sixth	3-by-3 matrix	Applies to the coordinate transformation from NED axes to body-fixed axes.
Seventh	3-by-3 matrix	Applies to the coordinate transformation from ECEF axes to NED axes.
Eighth	Three-element vector	Contains the velocity of the body with respect to ECEF frame, expressed in the body frame.
Ninth	Three-element vector	Contains the relative angular rates of the body with respect to NED frame, expressed in the body frame, in radians per second.
Tenth	Three-element vector	Contains the angular rates of the body with respect to the ECI frame, expressed in body frame, in radians per second.
Eleventh	Three-element vector	Contains the angular accelerations of the body with respect to ECI frame, expressed in the body frame, in radians per second squared.
Twelfth	Three-element vector	Contains the accelerations in body-fixed axes.

Assumptions and Limitations	<ul> <li>This implementation assumes that the applied forces are acting at the center of gravity of the body, and that the mass and inertia are constant.</li> <li>This implementation generates a geodetic latitude that lies between ±90 degrees, and longitude that lies between ±180 degrees. Additionally, the MSL altitude is approximate.</li> <li>The Earth is assumed to be ellipsoidal. By setting flattening to 0.0, a spherical planet can be achieved. The Earth's precession, nutation, and polar motion are neglected. The celestial longitude of Greenwich is Greenwich Mean Sidereal Time (GMST) and provides a rough approximation to the sidereal time.</li> <li>The implementation of the ECEF coordinate system assumes that the origin is at the center of the planet, the x-axis intersects the Greenwich</li> </ul>
	meridian and the equator, the <i>z</i> -axis is the mean spin axis of the planet, positive to the north, and the <i>y</i> -axis completes the right-handed system. The implementation of the ECI coordinate system assumes that the origin is at the center of the planet, the <i>x</i> -axis is the continuation of the line from the center of the Earth through the center of the Sun toward the vernal equinox, the <i>z</i> -axis points in the direction of the mean equatorial plane's north pole, positive to the north, and the <i>y</i> -axis completes the right-handed system.

# **6DoF Wind (Quaternion)**

# **Purpose** Implement quaternion representation of six-degrees-of-freedom equations of motion with respect to wind axes

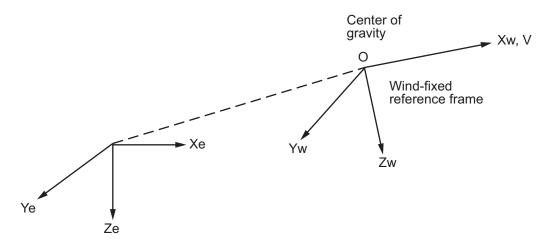

Equations of Motion/6DoF

# Description

Library

The 6DoF Wind (Quaternion) block considers the rotation of a wind-fixed coordinate frame  $(X_w, Y_w, Z_w)$  about an flat Earth reference frame  $(X_e, Y_e, Z_e)$ . The origin of the wind-fixed coordinate frame is the center of gravity of the body, and the body is assumed to be rigid, an assumption that eliminates the need to consider the forces acting between individual elements of mass. The flat Earth reference frame is considered inertial, an excellent approximation that allows the forces due to the Earth's motion relative to the "fixed stars" to be neglected.

Flat Earth reference frame

The translational motion of the wind-fixed coordinate frame is given below, where the applied forces  $[F_x F_y F_z]^T$  are in the wind-fixed frame, and the mass of the body *m* is assumed constant.

$$\begin{split} \vec{F}_w &= \begin{bmatrix} F_x \\ F_y \\ F_z \end{bmatrix} = m(\dot{\vec{V}}_w + \vec{\omega}_w \times \vec{V}_w) \\ \vec{V}_w &= \begin{bmatrix} V \\ 0 \\ 0 \end{bmatrix}, \vec{\omega}_w = \begin{bmatrix} p_w \\ q_w \\ r_w \end{bmatrix} = DMC_{wb} \begin{bmatrix} p_b - \dot{\beta} \sin \alpha \\ q_b - \dot{\alpha} \\ r_b + \dot{\beta} \cos \alpha \end{bmatrix}, \vec{\omega}_b = \begin{bmatrix} p_b \\ q_b \\ r_b \end{bmatrix} \end{split}$$

The rotational dynamics of the body-fixed frame are given below, where the applied moments are  $[L \ M \ N]^T$ , and the inertia tensor I is with respect to the origin O. Inertia tensor I is much easier to define in body-fixed frame.

$$\bar{M}_{b} = \begin{bmatrix} L \\ M \\ N \end{bmatrix} = I \dot{\bar{\varpi}}_{b} + \bar{\varpi}_{b} \times (I \bar{\varpi}_{b})$$

$$I = \begin{bmatrix} I_{xx} & -I_{xy} & -I_{xz} \\ -I_{yx} & I_{yy} & -I_{yz} \\ -I_{zx} & -I_{zy} & I_{zz} \end{bmatrix}$$

The integration of the rate of change of the quaternion vector is given below.

$$\begin{bmatrix} \dot{q}_0 \\ \dot{q}_1 \\ \dot{q}_2 \\ \dot{q}_3 \end{bmatrix} = -\frac{1}{2} \begin{bmatrix} 0 & p & q & r \\ -p & 0 & -r & q \\ -q & r & 0 & -p \\ -r & -q & p & 0 \end{bmatrix} \begin{bmatrix} q_0 \\ q_1 \\ q_2 \\ q_3 \end{bmatrix}$$

Metric (MKS)	Newton	Newton meter	Meters per second squared	Meters per second	Meters	Kilogram	Kilogram meter squared
English (Velocity in ft/s)	Pound /	Foot pound	Feet per second squared	Feet per second	Feet	Slug	Slug foot squared
English (Velocity in kts)	Pound /	Foot pound	Feet per second squared	Knots	Feet	Slug	Slug foot squared

# Mass Type

Select the type of mass to use:

Fixed	Mass is constant throughout the simulation.
Simple Variable	Mass and inertia vary linearly as a function of mass rate.
Custom Variable	Mass and inertia variations are customizable.

The  $\ensuremath{\texttt{Fixed}}$  selection conforms to the previously described equations of motion.

# Representation

Select the representation to use:

Wind Angles	Use wind angles within equations of motion.
Quaternion	Use quaternions within equations of motion.

The Quaternion selection conforms to the previously described equations of motion.

### Initial position in inertial axes

The three-element vector for the initial location of the body in the flat Earth reference frame.

## Initial airspeed, angle of attack, and sideslip angle

The three-element vector containing the initial airspeed, initial angle of attack and initial sideslip angle.

#### Initial wind orientation

The three-element vector containing the initial wind angles [bank, flight path, and heading], in radians.

### Initial body rotation rates

The three-element vector for the initial body-fixed angular rates, in radians per second.

### **Initial mass**

The mass of the rigid body.

### Inertia matrix

The 3-by-3 inertia tensor matrix *I*, in body-fixed axes.

Inputs and	Input	Dimension Type	Description
Outputs	First	Vector	Contains the three applied forces in wind-fixed axes.
	Second	Vector	Contains the three applied moments in body-fixed axes.
	Output	<b>Dimension Type</b>	Description
	First	Three-element vector	Contains the velocity in the flat Earth reference frame.
	Second	Three-element vector	Contains the position in the flat Earth reference frame.

Output	<b>Dimension Type</b>	Description
Third	Three-element vector	Contains the wind rotation angles [bank, flight path, heading], in radians.
Fourth	3-by-3 matrix	Contains the coordinate transformation from flat Earth axes to wind-fixed axes.
Fifth	Three-element vector	Contains the velocity in the wind-fixed frame.
Sixth	Two-element vector	Contains the angle of attack and sideslip angle, in radians.
Seventh	Two-element vector	Contains the rate of change of angle of attack and rate of change of sideslip angle, in radians per second
Eight	Three-element vector	Contains the angular rates in body-fixed axes, in radians per second.
Ninth	Three-element vector	Contains the angular accelerations in body-fixed axes, in radians per second squared.
Tenth	Three-element vector	Contains the accelerations in body-fixed axes.

Equations of Motion/6DoF

# Description

< m

y 7 (rad) DOM

∝β (nad) /dt dβ/dt

(rad/s)

do/dt Aູ (m/s) For a description of the coordinate system employed and the translational dynamics, see the block description for the 6DoF Wind (Quaternion) block.

The relationship between the wind angles,  $[\mu \gamma \chi]^{T}$ , can be determined by resolving the wind rates into the wind-fixed coordinate frame.

$\begin{bmatrix} p_w \end{bmatrix}$	]	Γµ¯		1	0	0	[0]	[1	0	0 ]	$\cos \gamma$	0	$-\sin\gamma$	0	]	[µ]	
$q_w$	=	0	+	0	$0 \\ \cos \mu \\ -\sin \mu$	$\sin \mu$	γ  +	0	$\cos \mu$	$\sin \mu$	0	1	0	0	$\equiv J^{-1}$	Ϋ́	
$r_w$		0		0	$-\sin\mu$	$\cos \mu$	[0]	0	$-\sin\mu$	$\cos \mu$	$\sin \gamma$	0	$\cos \gamma$	Ż		χ	

Inverting J then gives the required relationship to determine the wind rate vector.

$$\begin{bmatrix} \dot{\mu} \\ \dot{\gamma} \\ \dot{\chi} \end{bmatrix} = J \begin{bmatrix} p_w \\ q_w \\ r_w \end{bmatrix} = \begin{bmatrix} 1 & (\sin\mu\tan\gamma) & (\cos\mu\tan\gamma) \\ 0 & \cos\mu & -\sin\mu \\ 0 & \frac{\sin\mu}{\cos\gamma} & \frac{\cos\mu}{\cos\gamma} \end{bmatrix} \begin{bmatrix} p_w \\ q_w \\ r_w \end{bmatrix}$$

The body-fixed angular rates are related to the wind-fixed angular rate by the following equation.

$$\begin{bmatrix} p_w \\ q_w \\ r_w \end{bmatrix} = DMC_{wb} \begin{bmatrix} p_b - \dot{\beta} \sin \alpha \\ q_b - \dot{\alpha} \\ r_b + \dot{\beta} \cos \alpha \end{bmatrix}$$

Using this relationship in the wind rate vector equations, gives the relationship between the wind rate vector and the body-fixed angular rates.

$$\begin{bmatrix} \dot{\mu} \\ \dot{\gamma} \\ \dot{\chi} \end{bmatrix} = J \begin{bmatrix} p_w \\ q_w \\ r_w \end{bmatrix} = \begin{bmatrix} 1 & (\sin\mu\tan\gamma) & (\cos\mu\tan\gamma) \\ 0 & \cos\mu & -\sin\mu \\ 0 & \frac{\sin\mu}{\cos\gamma} & \frac{\cos\mu}{\cos\gamma} \end{bmatrix} DMC_{wb} \begin{bmatrix} p_b - \dot{\beta}\sin\alpha \\ q_b - \dot{\alpha} \\ r_b + \dot{\beta}\cos\alpha \end{bmatrix}$$

# **Purpose** Compute aerodynamic forces and moments using aerodynamic coefficients, dynamic pressure, center of gravity, center of pressure, and velocity

#### Library Aerodynamics

#### Description

The Aerodynamic Forces and Moments block computes the aerodynamic forces and moments about the center of gravity. By default, the inputs and outputs are represented in the body axes.

Let  $\alpha$  be the angle of attack and  $\beta$  the sideslip. The rotation from body to stability axes:

$$C_{s \leftarrow b} = \begin{bmatrix} \cos(\alpha) & 0 & \sin(\alpha) \\ 0 & 1 & 0 \\ -\sin(\alpha) & 0 & \cos(\alpha) \end{bmatrix}$$

can be combined with the rotation from stability to wind axes:

$$C_{w \leftarrow s} = \begin{bmatrix} \cos(\beta) & \sin(\beta) & 0\\ -\sin(\beta) & \cos(\beta) & 0\\ 0 & 0 & 1 \end{bmatrix}$$

to yield the net rotation from body to wind axes:

$$C_{w \leftarrow b} = \begin{bmatrix} \cos(\alpha)\cos(\beta) & \sin(\beta) & \sin(\alpha)\cos(\beta) \\ -\cos(\alpha)\sin(\beta) & \cos(\beta) & -\sin(\alpha)\sin(\beta) \\ -\sin(\alpha) & 0 & \cos(\alpha) \end{bmatrix}$$

Moment coefficients have the same notation in all systems. Force coefficients are given below. Note there are no specific symbols for stability-axes force components. However, the stability axes have two components that are unchanged from the other axes.

×	Coef <sub>stab</sub>	_
ł	9 <sub>bar</sub>	Fbody
ł	CG	
X	CP	M <sub>body</sub>
ł	V <sub>b</sub>	r

$$\mathbf{F}_{A}^{w} \equiv \begin{bmatrix} -D \\ -C \\ -L \end{bmatrix} = C_{w \leftarrow b} \cdot \begin{bmatrix} X_{A} \\ Y_{A} \\ Z_{A} \end{bmatrix} \equiv C_{w \leftarrow b} \cdot \mathbf{F}_{A}^{b}$$

Components/Axes	x	у	z
Wind	$C_D$	$C_{C}$	$C_{L}$
Stability	_	$C_Y$	$C_L$
Body	$C_X$	$C_Y$	$C_Z (-C_N)$

Given these definitions, to account for the standard definitions of D, C, Y (where Y = -C), and L, force coefficients in the wind axes are multiplied by the negative identity diag(-1, -1, -1). Forces coefficients in the stability axes are multiplied by diag(-1, 1, -1).  $C_{\rm N}$  and  $C_{\rm X}$  are, respectively, the normal and axial force coefficients ( $C_{\rm N} = -C_{\rm Z}$ ).

#### **Input Axes**

Specifies coordinate system for input coefficients: Body (default), Stability, or Wind.

#### **Force Axes**

Specifies coordinate system for aerodynamic force: Body (default), Stability, or Wind.

#### Moment Axes

Specifies coordinate system for aerodynamic moment: Body (default), Stability, or Wind.

#### **Reference** area

Specifies the reference area for calculating aerodynamic forces and moments.

#### **Reference span**

Specifies the reference span for calculating aerodynamic moments in *x*-axes and *z*-axes.

#### **Reference length**

Specifies the reference length for calculating aerodynamic moment in the *y*-axes.

#### Inputs and Outputs

The first input consists of aerodynamic coefficients (in the chosen input axes) for forces and moments. These coefficients are ordered into a vector depending on the choice of axes:

Input Axes	Input Vector
Body	(axial force $C_{\rm x}$ , side force $C_{\rm y}$ , normal force $C_{\rm z}$ , rolling moment $C_{\rm l}$ , pitching moment $C_{\rm m}$ , yawing moment $C_{\rm n}$ )
Stability	(drag force $C_{D(B=0)}$ , side force $C_y$ , lift force $C_L$ , rolling moment $C_l$ , pitching moment $C_m$ , yawing moment $C_n$ )
Wind	(drag force $C_{\rm D}$ , cross-wind force $C_{\rm c}$ , lift force $C_{\rm L}$ , rolling moment $C_{\rm l}$ , pitching moment $C_{\rm m}$ , yawing moment $C_{\rm n}$ )

Input	Dimension Type	Description
Second		Contains the dynamic pressure.
Third		Contains the center of gravity.
Fourth		Contains the center of pressure. This can also be taken as any general moment reference point as long as the rest of the model reflects the use of the moment reference point.
Fifth (For inputs or outputs in stability or wind axes)	vector	Contains the velocity in the body axes.

Output Dimension Type	Description
First	Contains the aerodynamic forces (in the chosen output axes) at the center of gravity in <i>x</i> -, <i>y</i> -, and <i>z</i> -axes.
Second	Contains the aerodynamic moments (in the chosen output axes) at the center of gravity in <i>x</i> -, <i>y</i> -, and <i>z</i> -axes.

Assumptions and	The default state of the block hides the $V_{\rm b}$ input port and assumes that the transformation is body-body.
Limitations	The center of gravity and the center of pressure are assumed to be in body axes.

	While this block has the ability to output forces and/or moments in the stability axes, the blocks in the Equations of Motion library are currently designed to accept forces and moments in either the body or wind axes only.
Examples	See Airframe in aeroblk_HL20 for an example of this block.

# **Centrifugal Effect Model**

**Purpose** Implement mathematical representation of centrifugal effect for planetary gravity

Library Environment/Gravity

#### Description

>X<sub>ecef</sub> Centrifugal Effect g<sub>ecef</sub> >

Centrifugal Effect Model

The Centrifugal Effect Model block implements the mathematical representation of centrifugal effect for planetary gravity. The gravity centrifugal effect is the acceleration portion of centrifugal force effects due to the rotation of a planet. This block implements this representation using planetary rotation rates. You use centrifugal force values in rotating or non-inertial coordinate systems.

Dialog Box	Function Block Parameters: Centrifugal Effect Model     Centrifugal Effect Model (mask) (link)     Implements the mathematical representation of centrifugal effect for     planetary gravity based on planetary rotation rate.     Parameters		
	Planet model: Earth		

#### **Planet model**

Specify the planetary model. From the list, select Mercury, Venus, Earth, Moon, Mars, Jupiter, Saturn, Uranus, Neptune, or Custom.

	The block uses the rotation of the selected planet to implement the mathematical representation of the centrifugal effect.
	Selecting Custom enables you to specify your own planetary model. This option enables the <b>Planetary rotational rate</b> (rad/sec) and <b>Input planetary rotation rate</b> parameters.
	<b>Planetary rotational rate (rad/sec)</b> Specify the planetary rotational rate in radians per second.
	If you want to specify the planetary rotational rate as an input to the block, see the <b>Input planetary rotation rate</b> parameter.
	Selecting the <b>Input planetary rotation rate</b> check box disables the <b>Planetary rotational rate (rad/sec)</b> parameter.
	<b>Input planetary rotation rate</b> Select this check box to enable a block input. You can then input a planetary rotation rate as a block input. When you select this check box, the block mask updates to display an input port for the rotation rate.
	Selecting the <b>Input planetary rotation rate</b> check box disables the <b>Planetary rotational rate (rad/sec)</b> parameter.

# **CIRA-86 Atmosphere Model**

#### **Purpose** Implement mathematical representation of 1986 CIRA atmosphere

Library

Environment/Atmosphere

#### Description

The CIRA-86 Atmosphere Model block implements the mathematical representation of the 1986 Committee on Space Research (COSPAR) International Reference Atmosphere (CIRA). The block provides values for absolute temperature, pressure, density, and speed of sound for the input geopotential altitude.

The CIRA-86 Atmosphere Model block icon displays the input and output units selected from the **Units** list.

Dialog Box	<ul> <li>Function Block Parameters: CIRA-86 Atmosphere Model</li> <li>CIRA-86 Model (mask) (link)</li> <li>Calculate COSPAR International Reference Atmosphere 1986. This block implements the mathematical representation of the Committee on Space Research (COSPAR) International Reference Atmosphere (CIRA) from 1986.</li> <li>The CIRA 1986 model provides a mean climatology of temperature, zonal wind, and geopotential height or pressure with nearly pole-topole coverage (80 degrees S-80 degrees N) for 0 to 120 kilometers, encompassing the troposphere, middle atmosphere, and lower thermosphere.</li> </ul>
	Parameters   Units:   Metric (MKS)   Coordinate type:   GPHeight   Mean value type:   Monthly   Month:   January   Action for out of range input:   Warning   OK   Cancel   Help   Apply

#### Units

Specifies the input and output units:

Units	Height	Temperature	Speed of Sound	Air Pressure	Air Density
Metric (MKS)	Meters	Kelvin	Meters per second	Pascal	Kilograms per cubic meter
English (Velocity in ft/s)	Feet	Degrees Rankine	Feet per second	Pound-force per square inch	Slug per cubic foot
English (Velocity in kts)	Feet	Degrees Rankine	Knots	Pound-force per square inch	Slug per cubic foot

#### **Coordinate type**

Specify the representation of the coordinate type. The default is GPHeight.

• Pressure

Indicates pressure in pascal.

• GPHeight

Indicates geopotential height in meters.

#### Mean value type

Specify mean value types. The default is Monthly.

• Monthly

Indicates monthly values. If you select Monthly, you must also set the **Month** parameter.

• Annual

Indicates annual values. Valid when **Coordinate type** has a value of Pressure.

#### Month

Indicates the month in which the mean values are taken. From the list, select the desired month. This parameter applies only when **Mean value type** has a value of Monthly.

#### Action for out or range input

Specify if out-of-range input invokes a warning, error, or no action.

Inputs a	Ind
Outputs	5

Input	Dimension Type	Description
First	Array	Contains the latitude in degrees (limited to +/-80 degrees).
Second	Array	Contains an m array of either:
		<ul> <li>Geopotential heights in selected length units (Coordinate type is GPHeight)</li> </ul>
		<ul> <li>Pressures in selected pressure units (Coordinate type is Pressure)</li> </ul>

Output	Dimension Type	Description
First	Array	Contains mean temperature in selected units.
Second	Array	Contains geopotential heights in selected units.
Third	Array	Contains mean zonal windows in selected units.

Assumptions and	This function uses a corrected version of the CIRA data files provided by J. Barnett in July 1990 in ASCII format.		
Limitations	This function has the limitations of the CIRA 1986 model. The values for the CIRA 1986 model are limited to the regions of 80 degrees S		

	to 80 degrees N on the Earth and geopotential heights of 0 to 120 kilometers. In each monthly mean data set, values at 80 degrees S for 101,300 pascal or 0 meters were omitted because these levels are within the Antarctic land mass. For zonal mean pressure in constant altitude coordinates, pressure data is not available below 20 kilometers. Therefore, this is the bottom level of the CIRA climatology.

#### Purpose Implement 1976 COESA lower atmosphere

Library

Environment/Atmosphere

#### Description

The COESA Atmosphere Model block implements the mathematical representation of the 1976 Committee on Extension to the Standard Atmosphere (COESA) United States standard lower atmospheric values for absolute temperature, pressure, density, and speed of sound for the input geopotential altitude.

Below 32,000 meters (approximately 104,987 feet), the U.S. Standard Atmosphere is identical with the Standard Atmosphere of the International Civil Aviation Organization (ICAO).

The COESA Atmosphere Model block icon displays the input and output units selected from the **Units** list.

# **COESA Atmosphere Model**

Dialog Box

Pa Function Block Parameters: COESA Atmosphere Model			
Atmosphere Model (mask) (link)			
Calculate various atmosphere models including 1976 COESA-extended U.S. Standard Atmosphere, MIL-HDBK-310, and MIL-STD-210C. Given geopotential altitude, calculate absolute temperature, pressure and density using standard interpolation formulas.			
The COESA model extrapolates temperature linearly and pressure/density logarithmically beyond the range			
0 <= altitude <= 84852 meters (geopotential)			
The MIL specifications are not extrapolated beyond their defined altitudes which are typically			
0 <= altitude <= 80000 meters (geometric)			
Depending on the given information either density or pressure is calculated using a perfect gas relationship.			
The unit system selected applies to both input and outputs.

#### Purpose Represent crossover pilot model

#### Library

Pilot Models

#### Description

The Crossover Pilot Model block represents the pilot model described in *Mathematical Models of Human Pilot Behavior*. (For more information, see [1]). This pilot model is a single input, single output (SISO) model that represents some aspects of human behavior when controlling aircraft. When modeling human pilot models, use this block for more accuracy than that provided by the Tustin Pilot Model block. This block is also less accurate than the Precision Pilot Model block.

The Crossover Model takes into account the combined dynamics of the human pilot and the aircraft, using the following form around the crossover frequency:

$$Y_p Y_c = \frac{\omega_c e^{-\tau s}}{s}.$$

In this equation:

Variable	Description
$Y_p$	Pilot transfer function.
$Y_c$	Aircraft transfer function.
$\omega_c$	Crossover frequency.
τ	Transport delay time caused by the pilot neuromuscular system.

If the dynamics of the aircraft  $(Y_c)$  change,  $Y_p$  changes correspondingly. From the options provided in the **Type of control** parameter, specify the dynamics of the aircraft. The preceding table lists the possible types of control that you can select for the aircraft. **Note** This block is valid only around the crossover frequency. It is not valid for discrete inputs such as a step.

This block has non-linear behavior. If you want to linearize the block (for example, with one of the Simulink linmod functions), you might need to change the Pade approximation order. The Crossover Pilot Model block implementation incorporates the Simulink Transport Delay block with the **Pade order (for linearization)** parameter set to 2 by default. To change this value, use the set\_param function, for example:

set\_param(gcb, 'pade', '3')

## Dialog Box

📔 Function Block Parameters: Crossover Pilot Model 🧮
CrossoverPilotModel (mask) (link)
Implement a human pilot model for a single-input, single-output system, based on the crossover model proposed by D. T. McRuer.
(*) Indicates that the pilot model includes a derivative block, for which additional care must be taken so the input is "smooth".

## Type of control

From the list, select one of the following options to specify the type of dynamics control that you want the pilot to have over for the aircraft.

Option (Controlled Element Transfer Function)	Transfer Function of Controlled Element $(Y_c)$	Transfer Function of Pilot $(Y_p)$	Υ <sub>c</sub> Υ <sub>p</sub>	Notes
Proportion- al	K <sub>c</sub>	$\frac{K_p e^{-\tau s}}{s}$	$\frac{K_c K_p e^{-\tau s}}{s}$	
Rate or velocity	$\frac{K_c}{s}$	$K_p e^{-\tau s}$	$\frac{K_c K_p e^{-\tau s}}{s}$	
Spiral divergence	$\frac{K_c}{T_I s - 1}$	$K_p e^{-\tau s}$	$\frac{K_c K_p e^{-\tau s}}{(T_I s - 1)}$	
Second order - Short period	$\frac{K_c \omega_n^2}{s^2 + 2\zeta \omega_n s + \omega_n^2}$	$\frac{K_p e^{-\tau s}}{T_I s + 1}$	$\frac{K_c \omega_n^2}{s^2 + 2\zeta \omega_n s + \omega_n^2} \times \frac{K_p e^{-\tau s}}{T_I s + 1}$	Short period, with $\omega_n > 1/\tau$
Accelera- tion (*)	$rac{K_c}{s^2}$	$K_p se^{-\tau s}$	$\frac{K_c K_p e^{-\tau s}}{s}$	
Roll attitude (*)	$\frac{K_c}{s(T_Is+1)}$	$K_p(T_Ls+1)e^{-\tau s}$	$\frac{K_c K_p e^{-\tau s}}{s}$	With $T_L \approx T_I$

Option (Controlled Element Transfer Function)	Transfer Function of Controlled Element $(\Upsilon_c)$	Transfer Function of Pilot $(\Upsilon_p)$	Υ <sub>c</sub> Υ <sub>p</sub>	Notes
Unstable short period(*)	$\frac{K_c}{(T_{I1}s+1)(T_{I2}s-1)}$	$K_p(T_Ls+1)e^{-\tau s}$	$\frac{K_c K_p e^{-\tau s}}{(T_{I2} s - 1)}$	With $T_L \approx T_{I1}$
Second order - Phugoid(*)	$\frac{K_c \omega_n^2}{s^2 + 2\zeta \omega_n s + \omega_n^2}$	$K_p(T_Ls+1)e^{-\tau s}$	$\frac{K_c K_p \omega_n^2 e^{-\tau s}}{s}$	Phugoid, with $\omega_n \Box 1/\tau$ , $1/T_L \approx \zeta \omega_n$

\* Indicates that the pilot model includes a Derivative block, which produces a numerical derivative. For this reason, do not send discontinuous (such as a step) or noisy input to the Crossover Pilot Model block. Such inputs can cause large outputs that might render the system unstable.

Variable	Description
K <sub>c</sub>	Aircraft gain.
K <sub>p</sub>	Pilot gain.
τ	Pilot time delay.
T <sub>I</sub>	Lag constant.

Variable	Description
$T_{L}$	Lead constant.
ζ	Damping ratio for the aircraft.
ω <sub>n</sub>	Natural frequency of the aircraft.

### **Calculated** value

From the list, select one of the following options to specify which value the block is to calculate:

- Crossover frequency The block calculates the crossover frequency value. Selecting this option disables the **Crossover frequency (rad/s)** parameter.
- Pilot gain The block calculates the pilot gain value. Selecting this option disables the **Pilot gain** parameter.

### **Controlled element gain**

Specifies the gain of the aircraft controlled dynamics.

### Pilot gain

Specifies the pilot gain.

### **Crossover frequency (rad/s)**

Specifies a crossover frequency value, rad/s. This value ranges from 1 to 10 rad/s.

### Pilot time delay(s)

Specifies the total pilot time delay, in seconds. This value typically ranges from 0.1 s to 0.2 s.

Inputs and Outputs	Input	Dimension Type	Description
	First	1-by-1	Contains the command for the signal that the pilot model controls.
	Second	1-by-1	Contains the signal that the pilot model controls.
	Output	Dimension Type	Description
	First	1-by-1	Contains the command for the aircraft.

The Custom Variable Mass 3DoF (Body Axes) block considers the rotation in the vertical plane of a body-fixed coordinate frame about an Earth-fixed reference frame.

The equations of motion are

$$\begin{split} \dot{u} &= \frac{F_x}{m} - \frac{\dot{m}U}{m} - qw - g\sin\theta \\ \dot{w} &= \frac{F_z}{m} - \frac{\dot{m}w}{m} + qu + g\cos\theta \\ \dot{q} &= \frac{M - \dot{I}_{yy}q}{I_{yy}} \\ \dot{\theta} &= q \end{split}$$

where the applied forces are assumed to act at the center of gravity of the body.

## Purpose

Implement Euler angle representation of six-degrees-of-freedom equations of motion of custom variable mass

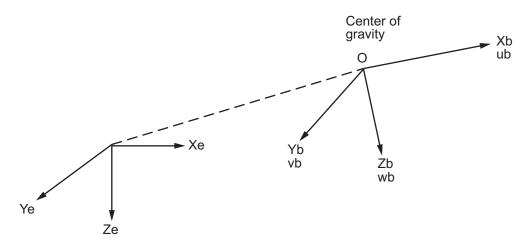

# Library

Equations of Motion/6DoF

# Description

The Custom Variable Mass 6DoF (Euler Angles) block considers the rotation of a body-fixed coordinate frame  $(X_b, Y_b, Z_b)$  about a flat Earth reference frame  $(X_e, Y_e, Z_e)$ . The origin of the body-fixed coordinate frame is the center of gravity of the body, and the body is assumed to be rigid, an assumption that eliminates the need to consider the forces acting between individual elements of mass. The flat Earth reference frame is considered inertial, an excellent approximation that allows the forces due to the Earth's motion relative to the "fixed stars" to be neglected.

Flat Earth reference frame

The translational motion of the body-fixed coordinate frame is given below, where the applied forces  $[F_x F_y F_z]^T$  are in the body-fixed frame.

$$\begin{split} \vec{F}_{b} &= \begin{bmatrix} F_{x} \\ F_{y} \\ F_{z} \end{bmatrix} = m(\dot{\vec{V}}_{b} + \vec{\omega} \times \vec{V}_{b}) + \dot{m}\vec{V}_{b} \\ \vec{V}_{b} &= \begin{bmatrix} u_{b} \\ v_{b} \\ w_{b} \end{bmatrix}, \vec{\omega} = \begin{bmatrix} p \\ q \\ r \end{bmatrix} \end{split}$$

The rotational dynamics of the body-fixed frame are given below, where the applied moments are  $[L M N]^{T}$ , and the inertia tensor I is with respect to the origin O.

$$\bar{M}_{B} = \begin{bmatrix} L \\ M \\ N \end{bmatrix} = I\bar{\varpi} + \bar{\varpi} \times (I\bar{\varpi}) + \bar{I}\bar{\varpi}$$

$$I = \begin{bmatrix} I_{xx} & -I_{xy} & -I_{xz} \\ -I_{yx} & I_{yy} & -I_{yz} \\ -I_{zx} & -I_{zy} & I_{zz} \end{bmatrix}$$

$$\dot{I} = \begin{bmatrix} I_{xx} & -I_{xy} & -I_{xz} \\ -\dot{I}_{yx} & \dot{I}_{yy} & -\dot{I}_{yz} \\ -\dot{I}_{zx} & -\dot{I}_{zy} & \dot{I}_{zz} \end{bmatrix}$$

The relationship between the body-fixed angular velocity vector,  $[p \ q \ r]^{T}$ ,

and the rate of change of the Euler angles,  $[\dot{\phi} \dot{\theta} \dot{\psi}]^{T}$ , can be determined by resolving the Euler rates into the body-fixed coordinate frame.

$$\begin{bmatrix} p \\ q \\ r \end{bmatrix} = \begin{bmatrix} \dot{\phi} \\ 0 \\ 0 \end{bmatrix} + \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\phi & \sin\phi \\ 0 & -\sin\phi & \cos\phi \end{bmatrix} \begin{bmatrix} 0 \\ \dot{\theta} \\ 0 \end{bmatrix} + \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\phi & \sin\phi \\ 0 & -\sin\phi & \cos\phi \end{bmatrix} \begin{bmatrix} \cos\theta & 0 & -\sin\theta \\ 0 & 1 & 0 \\ \sin\theta & 0 & \cos\theta \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ \psi \end{bmatrix} = J^{-1} \begin{bmatrix} \dot{\phi} \\ \dot{\theta} \\ \psi \end{bmatrix}$$

Inverting  ${\cal J}$  then gives the required relationship to determine the Euler rate vector.

$$\begin{bmatrix} \dot{\phi} \\ \dot{\theta} \\ \dot{\psi} \end{bmatrix} = J \begin{bmatrix} p \\ q \\ r \end{bmatrix} = \begin{bmatrix} 1 & (\sin\phi\tan\theta) & (\cos\phi\tan\theta) \\ 0 & \cos\phi & -\sin\phi \\ 0 & \frac{\sin\phi}{\cos\theta} & \frac{\cos\phi}{\cos\theta} \end{bmatrix} \begin{bmatrix} p \\ q \\ r \end{bmatrix}$$

## **Description**

For a description of the coordinate system and the translational dynamics, see the block description for the Custom Variable Mass 6DoF (Euler Angles) block.

The integration of the rate of change of the quaternion vector is given below. The gain K drives the norm of the quaternion state vector to 1.0 should  $\varepsilon$  become nonzero. You must choose the value of this gain with care, because a large value improves the decay rate of the error in the norm, but also slows the simulation because fast dynamics are introduced. An error in the magnitude in one element of the quaternion vector is spread equally among all the elements, potentially increasing the error in the state vector.

$$\begin{bmatrix} \dot{q}_{0} \\ \dot{q}_{1} \\ \dot{q}_{2} \\ \dot{q}_{3} \end{bmatrix} = \frac{1}{2} \begin{bmatrix} 0 & -p & -q & -r \\ p & 0 & r & -q \\ q & -r & 0 & p \\ r & q & -p & 0 \end{bmatrix} \begin{bmatrix} q_{0} \\ q_{1} \\ q_{2} \\ q_{3} \end{bmatrix} + K\varepsilon \begin{bmatrix} q_{0} \\ q_{1} \\ q_{2} \\ q_{3} \end{bmatrix}$$
$$\varepsilon = 1 - (q_{0}^{2} + q_{1}^{2} + q_{2}^{2} + q_{3}^{2})$$

## Purpose

Library

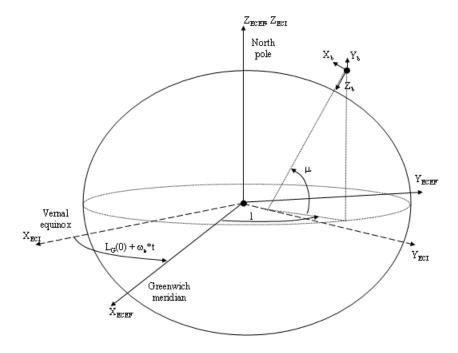

Implement quaternion representation of six-degrees-of-freedom equations of motion of custom variable mass in Earth-centered Earth-fixed (ECEF) coordinates

Equations of Motion/6DoF

# Description

The Custom Variable Mass 6DoF ECEF (Quaternion) block considers the rotation of a Earth-centered Earth-fixed (ECEF) coordinate frame ( $X_{ECEF}$ ,  $Y_{ECEF}$ ,  $Z_{ECEF}$ ) about an Earth-centered inertial (ECI) reference frame ( $X_{ECI}$ ,  $Y_{ECI}$ ,  $Z_{ECI}$ ). The origin of the ECEF coordinate frame is the center of the Earth, additionally the body of interest is assumed to be rigid, an assumption that eliminates the need to consider the forces acting between individual elements of mass. The representation of the rotation of ECEF frame from ECI frame is simplified to consider only the constant rotation of the ellipsoid Earth ( $\omega_e$ ) including an initial celestial longitude ( $L_G(0)$ ). This excellent approximation allows the forces due to the Earth's complex motion relative to the "fixed stars" to be neglected.

The translational motion of the ECEF coordinate frame is given below, where the applied forces  $[F_x\,F_y\,F_z]^{\rm T}$  are in the body frame.

$$\begin{split} \bar{F}_{b} = & \begin{bmatrix} F_{x} \\ F_{y} \\ F_{z} \end{bmatrix} = m \Big( \dot{\bar{V}}_{b} + \bar{\omega}_{b} \times \bar{V}_{b} + DCM_{bf} \bar{\omega}_{e} \times \bar{V}_{b} \Big) + DCM_{bf} \left( \bar{\omega}_{e} \times (\bar{\omega}_{e} \times \bar{X}_{f}) \right) \\ + \dot{m} \Big( \bar{V}_{b} + DCM_{bf} (\bar{\omega}_{e} \times \bar{X}_{f}) \Big) \end{split}$$

where the change of position in ECEF  $\dot{\bar{x}}_{f}$  is calculated by

$$\dot{\bar{x}}_f = DCM_{fb}\bar{V}_b$$

and the velocity of the body with respect to ECEF frame, expressed in body frame  $(\bar{V}_b)$ , angular rates of the body with respect to ECI frame, expressed in body frame  $(\bar{\omega}_b)$ . Earth rotation rate  $(\bar{\omega}_e)$ , and relative angular rates of the body with respect to north-east-down (NED) frame, expressed in body frame  $(\bar{\omega}_{rel})$  are defined as

$$\begin{split} \bar{V}_{b} &= \begin{bmatrix} u \\ v \\ w \end{bmatrix}, \bar{\omega}_{rel} = \begin{bmatrix} p \\ q \\ r \end{bmatrix}, \bar{\omega}_{e} = \begin{bmatrix} 0 \\ 0 \\ \omega_{e} \end{bmatrix}, \bar{\omega}_{b} = \bar{\omega}_{rel} + DCM_{bf}\bar{\omega}_{e} + DCM_{be}\bar{\omega}_{ned} \\ \bar{\omega}_{ned} &= \begin{bmatrix} \dot{l}\cos\mu \\ -\dot{\mu} \\ -\dot{l}\sin\mu \end{bmatrix} = \begin{bmatrix} V_{E}/(N+h) \\ -V_{N}/(M+h) \\ V_{E} \bullet \tan\mu/(N+h) \end{bmatrix} \end{split}$$

The rotational dynamics of the body defined in body-fixed frame are given below, where the applied moments are  $[L M N]^{T}$ , and the inertia tensor I is with respect to the origin O.

$$\bar{M}_{b} = \begin{bmatrix} L \\ M \\ N \end{bmatrix} = \bar{I}\dot{\bar{\omega}}_{b} + \bar{\omega}_{b} \times (\bar{I}\bar{\omega}_{b}) + \dot{I}\bar{\omega}_{b}$$

$$I = \begin{bmatrix} I_{xx} & -I_{xy} & -I_{xz} \\ -I_{yx} & I_{yy} & -I_{yz} \\ -I_{zx} & -I_{zy} & I_{zz} \end{bmatrix}$$

The rate of change of the inertia tensor is defined by the following equation.

# Custom Variable Mass 6DoF ECEF (Quaternion)

$$\dot{I} = \begin{bmatrix} \dot{I}_{xx} & -\dot{I}_{xy} & -\dot{I}_{xz} \\ -\dot{I}_{yx} & \dot{I}_{yy} & -\dot{I}_{yz} \\ -\dot{I}_{zx} & -\dot{I}_{zy} & \dot{I}_{zz} \end{bmatrix}$$

The integration of the rate of change of the quaternion vector is given below.

$\left[\dot{q}_{0}\right]$		0	$egin{aligned} & \omega_b\left(1 ight) \ & 0 \ & \omega_b\left(3 ight) \ & -\omega_b\left(2 ight) \end{aligned}$	$\omega_{b}\left(2 ight)$	$egin{aligned} & \omega_b\left(3 ight) \ & \omega_b\left(2 ight) \ & -\omega_b\left(1 ight) \end{aligned}$	$\left[q_{0}\right]$
$\dot{q}_1$	1/	$-\omega_{b}(1)$	0	$-\omega_{b}(3)$	$\omega_{b}(2)$	$ q_1 $
$\dot{q}_2$	$ ^{-}/2$	$-\omega_{b}(2)$	$\omega_{b}(3)$	0	$-\omega_{b}\left(1 ight)$	$q_2$
$\dot{q}_3$		$-\omega_{b}(3)$	$-\omega_{\!b}(2)$	$\omega_{b}\left(1 ight)$	0	$\left\lfloor q_3 \right\rfloor$

## Units

Specifies the input and output units:

# **Custom Variable Mass 6DoF ECEF (Quaternion)**

Units	Forces	Moment	Acceleration	Velocity	Position	Mass	Inertia
Metric (MKS)	Newton	Newton meter	Meters per second squared	Meters per second	Meters	Kilogram	Kilogram meter squared
English (Velocity in ft/s)	Pound y	Foot pound	Feet per second squared	Feet per second	Feet	Slug	Slug foot squared
English (Velocity in kts)	Pound y	Foot pound	Feet per second squared	Knots	Feet	Slug	Slug foot squared

#### Mass type

Select the type of mass to use:

Fixed	Mass is constant throughout the simulation (see 6DoF ECEF (Quaternion)).
Simple Variable	Mass and inertia vary linearly as a function of mass rate (see Simple Variable Mass 6DoF ECEF (Quaternion)).
Custom Variable	Mass and inertia variations are customizable.

The Simple Variable selection conforms to the previously described equations of motion.

## Initial position in geodetic latitude, longitude and altitude

The three-element vector for the initial location of the body in the geodetic reference frame.

#### Initial velocity in body-axis

The three-element vector containing the initial velocity of the body with respect to ECEF frame, expressed in body frame.

### **Initial Euler orientation**

The three-element vector containing the initial Euler rotation angles [roll, pitch, yaw], in radians. Euler rotation angles are those between the body and north-east-down (NED) coordinate systems.

### Initial body rotation rates

The three-element vector for the initial angular rates of the body with respect to NED frame, expressed in body frame, in radians per second.

### **Planet model**

Specifies the planet model to use, Custom or Earth (WGS84).

### Flattening

Specifies the flattening of the planet. This option is only available when **Planet model** is set to Custom.

### Equatorial radius of planet

Specifies the radius of the planet at its equator. The units of the equatorial radius parameter should be the same as the units for ECEF position. This option is only available when **Planet model** is set to Custom.

### **Rotational rate**

Specifies the scalar rotational rate of the planet in rad/s. This option is only available when **Planet model** is set to **Custom**.

### Celestial longitude of Greenwich source

Specifies the source of Greenwich meridian's initial celestial longitude:

Internal	Use celestial longitude value from mask dialog.
External	Use external input for celestial longitude value.

### **Celestial longitude of Greenwich**

The initial angle between Greenwich meridian and the *x*-axis of the ECI frame.

Inputs and	Input	<b>Dimension Type</b>	Description
Outputs	First	Vector	Contains the three applied forces in body-fixed axes.
	Second	Vector	Contains the three applied moments in body-fixed axes.
	Third	Scalar	Contains the rate of change of mass.
	Fourth	Scalar	Contains the mass.
	Fifth	3-by-3 matrix	Applies to the rate of change of inertia tensor matrix.
	Sixth	3-by-3 matrix	Applies to the inertia tensor matrix.
	Output	Dimension Type	Description
	First	Three-element vector	Contains the velocity of the body with respect to ECEF frame, expressed in ECEF frame.
	Second	Three-element vector	Contains the position in the ECEF reference frame.
	Third	Three-element vector	Contains the position in geodetic latitude, longitude and altitude, in degrees, degrees and selected units of length respectively.
	Fourth	Three-element vector	Contains the body rotation angles [roll, pitch, yaw], in radians. Euler rotation angles are those between the body and NED coordinate systems.

Output	Dimension Type	Description
Fifth	3-by-3 matrix	Applies to the coordinate transformation from ECI axes to body-fixed axes.
Sixth	3-by-3 matrix	Applies to the coordinate transformation from NED axes to body-fixed axes.
Seventh	3-by-3 matrix	Applies to the coordinate transformation from ECEF axes to NED axes.
Eighth	Three-element vector	Contains the velocity of the body with respect to ECEF frame, expressed in body frame.
Ninth	Three-element vector	Contains the relative angular rates of the body with respect to NED frame, expressed in body frame, in radians per second.
Tenth	Three-element vector	Contains the angular rates of the body with respect to ECI frame, expressed in body frame, in radians per second.
Eleventh	Three-element vector	Contains the angular accelerations of the body with respect to ECI frame, expressed in body frame, in radians per second squared.
Twelfth	Three-element vector	Contains the accelerations in body-fixed axes.

# Custom Variable Mass 6DoF ECEF (Quaternion)

Assumptions and Limitations	<ul> <li>This implementation assumes that the applied forces are acting at the center of gravity of the body.</li> <li>This implementation generates a geodetic latitude that lies between ±90 degrees, and longitude that lies between ±180 degrees. Additionally, the MSL altitude is approximate.</li> <li>The Earth is assumed to be ellipsoidal. By setting flattening to 0.0, a</li> </ul>
	spherical planet can be achieved. The Earth's precession, nutation, and polar motion are neglected. The celestial longitude of Greenwich is Greenwich Mean Sidereal Time (GMST) and provides a rough approximation to the sidereal time.
	The implementation of the ECEF coordinate system assumes that the origin is at the center of the planet, the <i>x</i> -axis intersects the Greenwich meridian and the equator, the <i>z</i> -axis is the mean spin axis of the planet, positive to the north, and the <i>y</i> -axis completes the right-handed system.
	The implementation of the ECI coordinate system assumes that the origin is at the center of the planet, the <i>x</i> -axis is the continuation of the line from the center of the Earth through the center of the Sun toward the vernal equinox, the <i>z</i> -axis points in the direction of the mean equatorial plane's north pole, positive to the north, and the <i>y</i> -axis completes the right-handed system.

## Description

F <sub>xyz</sub> (N)     Wind     Quaterrian     dm/dt (kg/s)     w (kg)     Custom Variable     dd/dt (kg/s)     Mass	V_ (m/s) X_ (m) μy π (rad) DOM <sub>w</sub> V <sub>w</sub> (m/s) α <sub>β</sub> (rad) de/dt dβ/dt ≥ ∞ (rad/s)
Mass dl/dt (kg-m <sup>2</sup> /s)	o (nacus)o do/dto
>l≬kg-nf)	A <sub>b</sub> (m/s <sup>2</sup> ) ⊳

The Custom Variable Mass 6DoF Wind (Quaternion) block considers the rotation of a wind-fixed coordinate frame  $(X_w, Y_w, Z_w)$  about an flat Earth reference frame  $(X_e, Y_e, Z_e)$ . The origin of the wind-fixed coordinate frame is the center of gravity of the body, and the body is assumed to be rigid, an assumption that eliminates the need to consider the forces acting between individual elements of mass. The flat Earth reference frame is considered inertial, an excellent approximation that allows the forces due to the Earth's motion relative to the "fixed stars" to be neglected.

Flat Earth reference frame

The translational motion of the wind-fixed coordinate frame is given below, where the applied forces  $[F_x, F_y, F_z]^T$  are in the wind-fixed frame.

$$\bar{F}_{w} = \begin{bmatrix} F_{x} \\ F_{y} \\ F_{z} \end{bmatrix} = m(\bar{V}_{w} + \bar{\omega}_{w} \times \bar{V}_{w}) + \dot{m}\bar{V}_{w}$$

$$\begin{bmatrix} V \\ F_{z} \end{bmatrix} = \begin{bmatrix} n \\ 0 \end{bmatrix} \begin{bmatrix} n \\ 0 \end{bmatrix} \begin{bmatrix} n \\ 0 \end{bmatrix} \begin{bmatrix} n \\ 0 \end{bmatrix}$$

$$\bar{V}_w = \begin{bmatrix} v \\ 0 \\ 0 \end{bmatrix}, \bar{\omega}_w = \begin{bmatrix} p_w \\ q_w \\ r_w \end{bmatrix} = DMC_{wb} \begin{bmatrix} p_b - \beta \sin \alpha \\ q_b - \dot{\alpha} \\ r_b + \dot{\beta} \cos \alpha \end{bmatrix}, \bar{w}_b = \begin{bmatrix} p_b \\ q_b \\ r_b \end{bmatrix}$$

The rotational dynamics of the body-fixed frame are given below, where the applied moments are  $[L \ M \ N]^T$ , and the inertia tensor I is with respect to the origin O. Inertia tensor I is much easier to define in body-fixed frame.

$$\bar{M}_{b} = \begin{bmatrix} L \\ M \\ N \end{bmatrix} = I \dot{\bar{\omega}}_{b} + \bar{\omega}_{b} \times (I \bar{\omega}_{b}) + \dot{I} \bar{\omega}_{b}$$

$$I = \begin{bmatrix} I_{xx} & -I_{xy} & -I_{xz} \\ -I_{yx} & I_{yy} & -I_{yz} \\ -I_{zx} & -I_{zy} & I_{zz} \end{bmatrix}$$

The integration of the rate of change of the quaternion vector is given below.

$$\begin{bmatrix} \dot{q}_0 \\ \dot{q}_1 \\ \dot{q}_2 \\ \dot{q}_3 \end{bmatrix} = -\frac{1}{2} \begin{bmatrix} 0 & p & q & r \\ -p & 0 & -r & q \\ -q & r & 0 & -p \\ -r & -q & p & 0 \end{bmatrix} \begin{bmatrix} q_0 \\ q_1 \\ q_2 \\ q_3 \end{bmatrix}$$

## **Description**

>	F <sub>xyx</sub> (N)	V <sub>o</sub> (m/s)⊳
>	M <sub>xyz</sub> (N-m) Wind Wind Angles	<(m) Х < (ben), хүщ
>	am/at (kg/s)	→ DOM <sub>we</sub> > V <sub>w</sub> (m/s) >
>	m (kg) 🖌 🖓 Custom Variable	∝β(nad)> ed∞/dtdβ/dt>
>	Mass dl/dt (kg-nĥ/s)	o (nadv/s)> do/dt>
>	l (kg-nf)	A <sub>b</sub> (m/s <sup>2</sup> ) ⊳

For a description of the coordinate system employed and the translational dynamics, see the block description for the Custom Variable Mass 6DoF Wind (Quaternion) block.

The relationship between the wind angles,  $[\mu \gamma \chi]^T$ , can be determined by resolving the wind rates into the wind-fixed coordinate frame.

$$\begin{bmatrix} p_w \\ q_w \\ r_w \end{bmatrix} = \begin{bmatrix} \dot{\mu} \\ 0 \\ 0 \end{bmatrix} + \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos \mu & \sin \mu \\ 0 & -\sin \mu & \cos \mu \end{bmatrix} \begin{bmatrix} 0 \\ \dot{\gamma} \\ 0 \end{bmatrix} + \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos \mu & \sin \mu \\ 0 & -\sin \mu & \cos \mu \end{bmatrix} \begin{bmatrix} \cos \gamma & 0 & -\sin \gamma \\ 0 & 1 & 0 \\ \sin \gamma & 0 & \cos \gamma \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ \dot{\chi} \end{bmatrix} \equiv J^{-1} \begin{bmatrix} \dot{\mu} \\ \dot{\gamma} \\ \dot{\chi} \end{bmatrix}$$

Inverting  ${\cal J}$  then gives the required relationship to determine the wind rate vector.

$$\begin{bmatrix} \dot{\mu} \\ \dot{\gamma} \\ \dot{\chi} \end{bmatrix} = J \begin{bmatrix} p_w \\ q_w \\ r_w \end{bmatrix} = \begin{bmatrix} 1 & (\sin \mu \tan \gamma) & (\cos \mu \tan \gamma) \\ 0 & \cos \mu & -\sin \mu \\ 0 & \frac{\sin \mu}{\cos \gamma} & \frac{\cos \mu}{\cos \gamma} \end{bmatrix} \begin{bmatrix} p_w \\ q_w \\ r_w \end{bmatrix}$$

The body-fixed angular rates are related to the wind-fixed angular rate by the following equation.

$$\begin{bmatrix} p_w \\ q_w \\ r_w \end{bmatrix} = DMC_{wb} \begin{bmatrix} p_b - \dot{\beta} \sin \alpha \\ q_b - \dot{\alpha} \\ r_b + \dot{\beta} \cos \alpha \end{bmatrix}$$

Using this relationship in the wind rate vector equations, gives the relationship between the wind rate vector and the body-fixed angular rates.

### Mass Type

Select the type of mass to use:

Fixed	Mass is constant throughout the simulation.
Simple Variable	Mass and inertia vary linearly as a function of mass rate.
Custom Variable	Mass and inertia variations are customizable.

The Custom Variable selection conforms to the previously described equations of motion.

### Representation

Select the representation to use:

Wind Angles	Use wind angles within equations of motion.
Quaternion	Use quaternions within equations of motion.

# **Custom Variable Mass 6DoF Wind (Wind Angles)**

The Wind Angles selection conforms to the previously described equations of motion.

#### Initial position in inertial axes

The three-element vector for the initial location of the body in the flat Earth reference frame.

#### Initial airspeed, sideslip angle, and angle of attack

The three-element vector containing the initial airspeed, initial sideslip angle and initial angle of attack.

### Initial wind orientation

The three-element vector containing the initial wind angles [bank, flight path, and heading], in radians.

#### Initial body rotation rates

The three-element vector for the initial body-fixed angular rates, in radians per second.

Inputs and	Input	Dimension Type	Description
Outputs	First	Vector	Contains the three applied forces in wind-fixed axes.
	Second	Vector	Contains the three applied moments in body-fixed axes.
	Third	Scalar	Contains the rate of change of mass.
	Fourth	Scalar	Contains the mass.
	Fifth	3-by-3 matrix	Applies to the rate of change of inertia tensor matrix in body-fixed axes.
	Sixth	3-by-3 matrix	Applies to the inertia tensor matrix in body-fixed axes.

Output	Dimension Type	Description
First	Three-element vector	Contains the velocity in the flat Earth reference frame.
Second	Three-element vector	Contains the position in the flat Earth reference frame.
Third	Three-element vector	Contains the wind rotation angles [bank, flight path, heading], in radians.
Fourth	3-by-3 matrix	Applies to the coordinate transformation from flat Earth axes to wind-fixed axes.
Fifth	Three-element vector	Contains the velocity in the wind-fixed frame.
Sixth	Two-element vector	Contains the angle of attack and sideslip angle, in radians.
Seventh	Two-element vector	Contains the rate of change of angle of attack and rate of change of sideslip angle, in radians per second.
Eighth	Three-element vector	Contains the angular rates in body-fixed axes, in radians per second.
Ninth	Three-element vector	Contains the angular accelerations in body-fixed axes, in radians per second squared.
Tenth	Three-element vector	Contains the accelerations in body-fixed axes.

## Assumptions and Limitations

The block assumes that the applied forces are acting at the center of gravity of the body.

- **Purpose** Compute determinant of matrix
- Library Utilities/Math Operations

Description

The Determinant of 3x3 Matrix block computes the determinant for the input matrix.

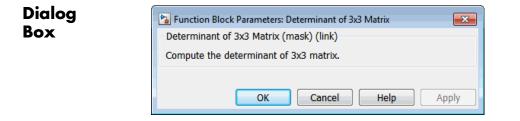

>det(A) (3x3)

The input matrix has the form of

$$A = \begin{bmatrix} A_{11} & A_{12} & A_{13} \\ A_{21} & A_{22} & A_{23} \\ A_{31} & A_{32} & A_{33} \end{bmatrix}$$

The determinant of the matrix has the form of

$$det(A) = A_{11}(A_{22}A_{33} - A_{23}A_{32}) - A_{12}(A_{21}A_{33} - A_{23}A_{31}) + A_{13}(A_{21}A_{32} - A_{22}A_{31})$$

# **Purpose** Compute aerodynamic forces and moments using Digital DATCOM static and dynamic stability derivatives

### **Library** Aerodynamics

### **Description**

_			
>α (I			
>p ()	ad)	F <sub>body</sub> (N)	>
>Ма			
> h ()	m)		
	r(Pa)	M <sub>body</sub> (N-m)	>
$ V_{bc} $	dy <sup>(m/s)</sup>		

The Digital DATCOM Forces and Moments block computes the aerodynamic forces and moments about the center of gravity using aerodynamic coefficients from Digital DATCOM.

Algorithms for calculating forces and moments build up the overall aerodynamic forces and moments (F and M) from data contained in the **Digital DATCOM structure** parameter:

$$F = F_{\text{static}} + F_{\text{dyn}}$$
  
 $M = M_{\text{static}} + M_{\text{dyn}}$ 

 $F_{\rm static}$  and  $M_{\rm static}$  are the static contribution, and  $F_{\rm dyn}$  and  $M_{\rm dyn}$  the dynamic contribution, to the aerodynamic coefficients. If the dynamic characteristics are not contained in the **Digital DATCOM structure** parameter, their contribution is set to zero.

## **Static Stability Characteristics**

Static stability characteristics include the following.

### **Coefficient Meaning**

C <sub>D</sub>	Matrix of drag coefficients. These coefficients are defined positive for an aft-acting load.
$C_{ m L}$	Matrix of lift coefficients. These coefficients are defined positive for an up-acting load.
$C_{\rm m}$	Matrix of pitching-moment coefficients. These coefficients are defined positive for a nose-up rotation.
$C_{ m YB}$	Matrix of derivatives of side-force coefficients with respect to sideslip angle

### **Coefficient Meaning**

$C_{\mathrm{nB}}$	Matrix of derivatives of yawing-moment coefficients with respect to sideslip angle
$C_{16}$	Matrix of derivatives of rolling-moment coefficients with respect to sideslip angle

These are the static contributions to the aerodynamic coefficients in stability axes.

$$C_{\rm D \ static} = C_{\rm D}$$

$$C_{\rm y \ static} = C_{\rm Y6} \beta$$

$$C_{\rm L \ static} = C_{\rm L}$$

$$C_{\rm l \ static} = C_{\rm l6} \beta$$

$$C_{\rm m \ static} = C_{\rm M}$$

$$C_{\rm n \ static} = C_{\rm n6} \beta$$

## **Dynamic Stability Characteristics**

Dynamic stability characteristics include the following.

### **Coefficient** Meaning

$C_{ m lq}$	Matrix of rolling-moment derivatives due to pitch rate
$C_{\mathrm{mq}}$	Matrix of pitching-moment derivatives due to pitch rate
$C_{ m Ld\alpha/dt}$	Matrix of lift force derivatives due to rate of angle of attack
$C_{ m mda/dt}$	Matrix of pitching-moment derivatives due to rate of angle of attack
$C_{ m lp}$	Matrix of rolling-moment derivatives due to roll rate

Coefficient	Meaning
$C_{ m Yp}$	Matrix of lateral force derivatives due to roll rate
$C_{ m np}$	Matrix of yawing-moment derivatives due to roll rate
$C_{ m nr}$	Matrix of yawing-moment derivatives due to yaw rate
$C_{ m lr}$	Matrix of rolling-moment derivatives due to yaw rate

These are the dynamic contributions to the aerodynamic coefficients in stability axes.

### Units

Specifies the input and output units:

Units	Force	Moment	Length	Velocity	Pressure
Metric (MKS)	Newton	Newton- meter	Meters	Meters per second	Pascal
English (Velocity in ft/s)	Pound	Foot-pound	Feet	Feet per second	Pound per square inch
English (Velocity in kts)	Pound	Foot-pound	Feet	Knots	Pound per square inch

### **Digital DATCOM structure**

Specifies the MATLAB structure containing the digital DATCOM data. This structure is generated by the Aerospace Toolbox function datcomimport.

#### Force axes

Inputs and Outputs Specifies coordinate system for aerodynamic force: Body or Wind.

### Interpolation method

None (flat) or Linear

### **Extrapolation method**

None (clip) or Linear

### Process out of range input

Specifies how to handle out-of-range input: Linear Extrapolation or Clip to Range.

### Action for out of range input

Specifies if out-of-range input invokes a warning, an error, or no action.

Input	Dimension Type	Description
First	3-by-3 matrix	Contains the angle of attack.
Second		Contains the sideslip angle, in radians.
Third		Contains the Mach number.
Fourth		Contains the altitude, in selected length units.
Fifth		Contains the dynamic pressure, in selected pressure units.
Sixth		Contains the velocity, selected velocity units and selected force axes.
Seventh (Optional)		Contains the angle of attack rate, in radians per second.

	Input	Dimension Type	Description
	Eight (Optional)		Contains the body angular rates, in radians per second.
	Ninth (Optional)		Contains the ground height, in select units of length
	Tenth (Optional)		Contains the control surface deflections, radians.
	Output	Dimension Type	Description
	First		Contains the aerodynamic forces at the center of gravity in selected coordinate system: Body ( $F_x$ , $F_y$ , and $F_z$ ), or Wind ( $F_D$ , $F_y$ , and $F_L$ ).
	Second		Contains the aerodynamic moments at the center of gravity in body coordinates $(M_x, M_y, \text{ and } M_z)$ .
Assumptions and Limitations	The operational limitations of Digital DATCOM apply to the data contained in the <b>Digital DATCOM structure</b> parameter. For more information on Digital DATCOM limitations, see Section 2.4.5 of reference [1].		
	The <b>Digital DATCOM structure</b> parameters alpha, mach, alt, grndht, and delta must be strictly monotonically increasing to be used with the Digital DATCOM Forces and Moments block.		
	The <b>Digital DATCOM structure</b> coefficients must correspond to the dimensions of the breakpoints (alpha, mach, alt, grndht, and delta) to be used with the Digital DATCOM Forces and Moments block.

# **Direction Cosine Matrix Body to Wind**

**Purpose** Convert angle of attack and sideslip angle to direction cosine matrix

**Utilities/Axes Transformations** 

## Description

Library

The Direction Cosine Matrix Body to Wind block converts angle of attack and sideslip angle into a 3-by-3 direction cosine matrix (DCM). The DCM matrix performs the coordinate transformation of a vector in body axes  $(ox_0, oy_0, oz_0)$  into a vector in wind axes  $(ox_2, oy_2, oz_2)$ . The order of the axis rotations required to bring this about is:

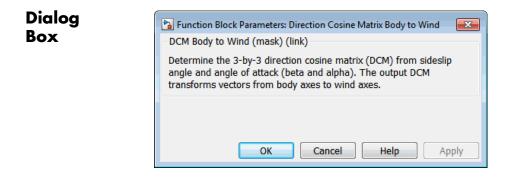

- **1** A rotation about  $oy_0$  through the angle of attack (*a*) to axes ( $ox_1$ ,  $oy_1$ ,  $oz_1$ )
- **2** A rotation about  $oz_1$  through the sideslip angle ( $\beta$ ) to axes ( $ox_2$ ,  $oy_2$ ,  $oz_2$ )

$$\begin{bmatrix} ox_2 \\ oy_2 \\ oz_2 \end{bmatrix} = DCM_{wb} \begin{bmatrix} ox_0 \\ oy_0 \\ oz_0 \end{bmatrix}$$

$$\begin{bmatrix} ox_2 \\ oy_2 \\ oz_2 \end{bmatrix} = \begin{bmatrix} \cos\beta & \sin\beta & 0 \\ -\sin\beta & \cos\beta & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} \cos\alpha & 0 & \sin\alpha \\ 0 & 1 & 0 \\ -\sin\alpha & 0 & \cos\alpha \end{bmatrix} \begin{bmatrix} ox_0 \\ oy_0 \\ oz_0 \end{bmatrix}$$

Combining the two axis transformation matrices defines the following DCM.

$$DCM_{wb} = \begin{bmatrix} \cos\alpha\cos\beta & \sin\beta & \sin\alpha\cos\beta \\ -\cos\alpha\sin\beta & \cos\beta & -\sin\alpha\sin\beta \\ -\sin\alpha & 0 & \cos\alpha \end{bmatrix}$$

Inputs and	Input	Dimension Type	Description
Outputs	First	2-by-1 vector	Contains the angle of attack and sideslip angle, in radians.

### **Purpose** Convert direction cosine matrix to angle of attack and sideslip angle

Library Utilities/Axes Transformations

## Description

The Direction Cosine Matrix Body to Wind to Alpha and Beta block converts a 3-by-3 direction cosine matrix (DCM) into angle of attack and sideslip angle. The DCM matrix performs the coordinate transformation of a vector in body axes  $(ox_0, oy_0, oz_0)$  into a vector in wind axes  $(ox_2, oy_2, oz_2)$ . The order of the axis rotations required to bring this about is:

- **1** A rotation about  $oy_0$  through the angle of attack (*a*) to axes  $(ox_1, oy_1, oz_1)$
- **2** A rotation about  $oz_1$  through the sideslip angle ( $\beta$ ) to axes ( $ox_2$ ,  $oy_2$ ,  $oz_2$ )

$$\begin{bmatrix} ox_2 \\ oy_2 \\ oz_2 \end{bmatrix} = DCM_{wb} \begin{bmatrix} ox_0 \\ oy_0 \\ oz_0 \end{bmatrix}$$

$$\begin{bmatrix} ox_2 \\ oy_2 \\ oz_2 \end{bmatrix} = \begin{bmatrix} \cos\beta & \sin\beta & 0 \\ -\sin\beta & \cos\beta & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} \cos\alpha & 0 & \sin\alpha \\ 0 & 1 & 0 \\ -\sin\alpha & 0 & \cos\alpha \end{bmatrix} \begin{bmatrix} ox_0 \\ oy_0 \\ oz_0 \end{bmatrix}$$

Combining the two axis transformation matrices defines the following DCM.

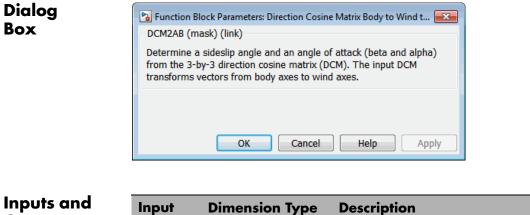

$$DCM_{wb} = \begin{bmatrix} \cos\alpha\cos\beta & \sin\beta & \sin\alpha\cos\beta \\ -\cos\alpha\sin\beta & \cos\beta & -\sin\alpha\sin\beta \\ -\sin\alpha & 0 & \cos\alpha \end{bmatrix}$$

To determine angles from the DCM, the following equations are used:

# Direction Cosine Matrix Body to Wind to Alpha and Beta

 $\alpha = \operatorname{asin}(-DCM(3,1))$ 

 $\beta = \operatorname{asin}(DCM(1,2))$ 

	Input	Dimension Type	Description
Outputs	First	3-by-3 direction cosine matrix	Transforms body-fixed vectors to wind-fixed vectors.
	Output	<b>Dimension Type</b>	Description
	First	2-by-1 vector	Contains angle of attack and sideslip angle, in radians.
Assumptions and Limitations	This implementation generates angles that lie between ±90 degrees.

Direction Cosine Matrix to Wind Angles Rotation Angles to Direction Cosine Matrix Wind Angles to Direction Cosine Matrix **Purpose** Convert geodetic latitude and longitude to direction cosine matrix

Library

Utilities/Axes Transformations

## **Description**

The Direction Cosine Matrix ECEF to NED block converts geodetic latitude and longitude into a 3-by-3 direction cosine matrix (DCM). The DCM matrix performs the coordinate transformation of a vector in Earth-centered Earth-fixed (ECEF) axes  $(ox_0, oy_0, oz_0)$  into a vector in north-east-down (NED) axes  $(ox_2, oy_2, oz_2)$ . The order of the axis rotations required to bring this about is:

- **1** A rotation about  $oz_0$  through the longitude (*i*) to axes ( $ox_1, oy_1, oz_1$ )
- ${\bf 2}$  A rotation about  $oy_1$  through the geodetic latitude  $(\mu)$  to axes  $(ox_2, oy_2, oz_2)$

$$\begin{bmatrix} ox_2 \\ oy_2 \\ oz_2 \end{bmatrix} = DCM_{ef} \begin{bmatrix} ox_0 \\ oy_0 \\ oz_0 \end{bmatrix}$$

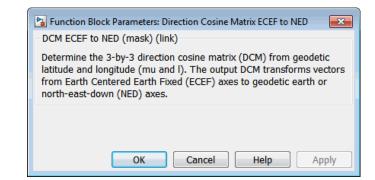

$$\begin{bmatrix} ox_2 \\ oy_2 \\ oz_2 \end{bmatrix} = \begin{bmatrix} -\sin\mu & 0 & \cos\mu \\ 0 & 1 & 0 \\ -\cos\mu & 0 & -\sin\mu \end{bmatrix} \begin{bmatrix} \cos\iota & \sin\iota & 0 \\ -\sin\iota & \cos\iota & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} ox_0 \\ oy_0 \\ oz_0 \end{bmatrix}$$

Combining the two axis transformation matrices defines the following DCM.

$$DCM_{ef} = \begin{bmatrix} -\sin\mu\cos\iota & -\sin\mu\sin\iota & \cos\mu\\ -\sin\iota & \cos\iota & 0\\ -\cos\mu\cos\iota & -\cos\mu\sin\iota & -\sin\mu \end{bmatrix}$$

#### **Purpose** Convert direction cosine matrix to geodetic latitude and longitude

Library Utilities/Axes Transformations

#### Description

The Direction Cosine Matrix ECEF to NED to Latitude and Longitude block converts a 3-by-3 direction cosine matrix (DCM) into geodetic latitude and longitude. The DCM matrix performs the coordinate transformation of a vector in Earth-centered Earth-fixed (ECEF) axes  $(ox_0, oy_0, oz_0)$  into a vector in north-east-down (NED) axes  $(ox_2, oy_2, oz_2)$ . The order of the axis rotations required to bring this about is:

- **1** A rotation about  $oz_0$  through the longitude (*i*) to axes ( $ox_1, oy_1, oz_1$ )
- **2** A rotation about  $oy_1$  through the geodetic latitude ( $\mu$ ) to axes ( $ox_2$ ,  $oy_2$ ,  $oz_2$ )

 $\begin{bmatrix} ox_2 \\ oy_2 \\ oz_2 \end{bmatrix} = DCM_{ef} \begin{bmatrix} ox_0 \\ oy_0 \\ oz_0 \end{bmatrix}$ 

$ox_2$		$-\sin\mu$	0	$\cos \mu$	$\cos \iota$	$\sin \iota$	0]	$\left[ox_0\right]$
$oy_2$	=	0	1	0	$-\sin\iota$	$\cos\iota$	0	oy <sub>0</sub>
$oz_2$		$-\cos\mu$	0	$-\sin\mu$	0	0	1]	$\left\lfloor oz_0 \right\rfloor$

Combining the two axis transformation matrices defines the following DCM.

$$DCM_{ef} = \begin{bmatrix} -\sin\mu\cos\iota & -\sin\mu\sin\iota & \cos\mu\\ -\sin\iota & \cos\iota & 0\\ -\cos\mu\cos\iota & -\cos\mu\sin\iota & -\sin\mu \end{bmatrix}$$

To determine geodetic latitude and longitude from the DCM, the following equations are used:

### Direction Cosine Matrix ECEF to NED to Latitude and Longitude

 $\mu = \operatorname{asin}(-DCM(3,3))$ 

$$\iota = \operatorname{atan}\left(\frac{-DCM(2,1)}{DCM(2,2)}\right)$$

Dialog Box	Function Block Parameters: Direction Cosine Matrix ECEF to NED to DCM to LATLON (mask) (link) Determine a geodetic latitude and longitude (mu and l) from the 3- by-3 direction cosine matrix (DCM). #### **Purpose** Convert direction cosine matrix to quaternion vector

Utilities/Axes Transformations

Description

Library

DCM2Quat p

The Direction Cosine Matrix to Quaternions block transforms a 3-by-3 direction cosine matrix (DCM) into a four-element unit quaternion vector  $(q_0, q_1, q_2, q_3)$ . The DCM performs the coordinate transformation of a vector in inertial axes to a vector in body axes.

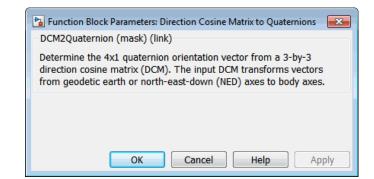

The DCM is defined as a function of a unit quaternion vector by the following:

$$DCM = \begin{bmatrix} (q_0^2 + q_1^2 - q_2^2 - q_3^2) & 2(q_1q_2 + q_0q_3) & 2(q_1q_3 - q_0q_2) \\ 2(q_1q_2 - q_0q_3) & (q_0^2 - q_1^2 + q_2^2 - q_3^2) & 2(q_2q_3 + q_0q_1) \\ 2(q_1q_3 + q_0q_2) & 2(q_2q_3 - q_0q_1) & (q_0^2 - q_1^2 - q_2^2 + q_3^2) \end{bmatrix}$$

Using this representation of the DCM, there are a number of calculations to arrive at the correct quaternion. The first of these is to calculate the trace of the DCM to determine which algorithms are used. If the trace is greater that zero, the quaternion can be automatically calculated. When the trace is less than or equal to zero, the major diagonal element of the DCM with the greatest value must be identified to determine the final algorithm used to calculate the quaternion. Once the major diagonal element is identified, the quaternion is calculated. For a detailed view of these algorithms, look under the mask of this block.

Utilities/Axes Transformations

Description

>DCM<sub>be</sub> [R<sub>1</sub>,R<sub>2</sub>,R<sub>3</sub>]

The Direction Cosine Matrix to Rotation Angles block converts a 3-by-3 direction cosine matrix (DCM) into three rotation angles R1, R2, and R3, respectively the first, second, and third rotation angles. The DCM matrix performs the coordinate transformation of a vector in inertial axes into a vector in body axes. The block **Rotation Order** parameter specifies the order of the block output rotations. For example, if **Rotation Order** has a value of ZYX, the block outputs are in the rotation order z - y - x (psi theta phi).

### **Direction Cosine Matrix to Wind Angles**

**Purpose** Convert direction cosine matrix to wind angles

Library

Utilities/Axes Transformations

#### Description

The Direction Cosine Matrix to Wind Angles block converts a 3-by-3 direction cosine matrix (DCM) into three wind rotation angles. The DCM matrix performs the coordinate transformation of a vector in earth axes  $(ox_0, oy_0, oz_0)$  into a vector in wind axes  $(ox_3, oy_3, oz_3)$ . The order of the axis rotations required to bring this about is:

- ${\bf 1}$  A rotation about  $oz_0$  through the heading angle  $(\chi)$  to axes  $(ox_1,\,oy_1,\,oz_1)$
- **2** A rotation about  $oy_1$  through the flight path angle (y) to axes  $(ox_2, oy_2, oz_2)$
- **3** A rotation about  $ox_2$  through the bank angle ( $\mu$ ) to axes ( $ox_3$ ,  $oy_3$ ,  $oz_3$ )

$$\begin{bmatrix} ox_3 \\ oy_3 \\ oz_3 \end{bmatrix} = DCM_{we} \begin{bmatrix} ox_0 \\ oy_0 \\ oz_0 \end{bmatrix}$$

 $\begin{bmatrix} ox_3\\ oy_3\\ oz_3 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0\\ 0 & \cos\mu & \sin\mu\\ 0 & -\sin\mu & \cos\mu \end{bmatrix} \begin{bmatrix} \cos\gamma & 0 & -\sin\gamma\\ 0 & 1 & 0\\ \sin\gamma & 0 & \cos\gamma \end{bmatrix} \begin{bmatrix} \cos\chi & \sin\chi & 0\\ -\sin\chi & \cos\chi & 0\\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} ox_0\\ oy_0\\ oz_0 \end{bmatrix}$ 

Combining the three axis transformation matrices defines the following DCM.

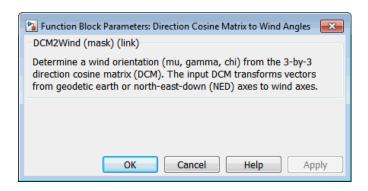

$$DCM_{we} = \begin{bmatrix} \cos\gamma\cos\chi & \cos\gamma\sin\chi & -\sin\gamma\\ (\sin\mu\sin\gamma\cos\chi - \cos\mu\sin\chi) & (\sin\mu\sin\gamma\sin\chi + \cos\mu\cos\chi) & \sin\mu\cos\gamma\\ (\cos\mu\sin\gamma\cos\chi + \sin\mu\sin\chi) & (\cos\mu\sin\gamma\sin\chi - \sin\mu\cos\chi) & \cos\mu\cos\gamma \end{bmatrix}$$

To determine wind angles from the DCM, the following equations are used:

$$\mu = \operatorname{atan}\left(\frac{DCM(2,3)}{DCM(3,3)}\right)$$
$$\gamma = \operatorname{asin}\left(-DCM(1,3)\right)$$
$$\chi = \operatorname{atan}\left(\frac{DCM(1,2)}{DCM(1,1)}\right)$$

Library Environment/Wind

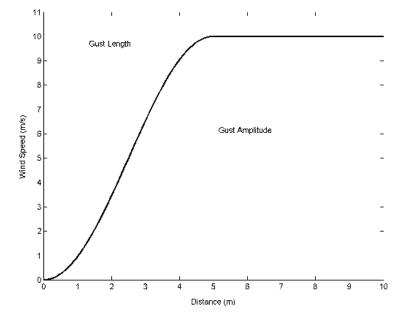

#### Description

The Discrete Wind Gust Model block implements a wind gust of the standard "1-cosine" shape. This block implements the mathematical representation in the Military Specification MIL-F-8785C [1]. The gust is applied to each axis individually, or to all three axes at once. You specify the gust amplitude (the increase in wind speed generated by the gust), the gust length (length, in meters, over which the gust builds up) and the gust start time.

The Discrete Wind Gust Model block can represent the wind speed in units of feet per second, meters per second, or knots.

The following figure shows the shape of the gust with a start time of zero. The parameters that govern the gust shape are indicated on the diagram.

The discrete gust can be used singly or in multiples to assess airplane response to large wind disturbances.

The mathematical representation of the discrete gust is

$$V_{wind} = \begin{cases} 0 & x < 0 \\ \frac{V_m}{2} \left( 1 - \cos\left(\frac{\pi x}{d_m}\right) \right) & 0 \le x \le d_m \\ V_m & x > d_m \end{cases}$$

where  $V_{\rm m}$  is the gust amplitude,  $d_{\rm m}$  is the gust length, x is the distance traveled, and  $V_{\rm wind}$  is the resultant wind velocity in the body axis frame.

The Dryden Wind Turbulence Model (Continuous) block uses the Dryden spectral representation to add turbulence to the aerospace model by passing band-limited white noise through appropriate forming filters. This block implements the mathematical representation in the Military Specification MIL-F-8785C and Military Handbook MIL-HDBK-1797.

According to the military references, turbulence is a stochastic process defined by velocity spectra. For an aircraft flying at a speed V through a frozen turbulence field with a spatial frequency of  $\Omega$  radians per meter, the circular frequency  $\omega$  is calculated by multiplying V by  $\Omega$ . The following table displays the component spectra functions:

	MIL-F-8785C	MIL-HDBK-1797
Longitudinal		
$\Phi_u(\omega)$	$\frac{2\sigma_u^2 L_u}{\pi V} \cdot \frac{1}{1 + \left(L_u \frac{\omega}{V}\right)^2}$	$\frac{2\sigma_u^2 L_u}{\pi V} \cdot \frac{1}{1 + \left(L_u \frac{\omega}{V}\right)^2}$
$\Phi_{p_g}(\omega)$	$\frac{\sigma_w^2}{VL_w} \cdot \frac{0.8 \left(\frac{\pi L_w}{4b}\right)^{1/3}}{1 + \left(\frac{4b\omega}{\pi V}\right)^2}$	$\frac{\sigma_w^2}{2VL_w} \cdot \frac{0.8 \left(\frac{2\pi L_w}{4b}\right)^{1/3}}{1 + \left(\frac{4b\omega}{\pi V}\right)^2}$
Lateral		

	MIL-F-8785C	MIL-HDBK-1797
$\Phi_{v}\left(\omega ight)$	$\frac{\sigma_v^2 L_v}{\pi V} \cdot \frac{1 + 3\left(L_v \frac{\omega}{V}\right)^2}{\left[1 + \left(L_v \frac{\omega}{V}\right)^2\right]^2}$	$\frac{2\sigma_v^2 L_v}{\pi V} \cdot \frac{1 + 12 \left(L_v \frac{\omega}{V}\right)^2}{\left[1 + 4 \left(L_v \frac{\omega}{V}\right)^2\right]^2}$
$\Phi_r(\omega)$	$\frac{\mp \left(\frac{\omega}{V}\right)^{2}}{1 + \left(\frac{3b\omega}{\pi V}\right)^{2}} \cdot \Phi_{v}\left(\omega\right)$	$\frac{\mp \left(\frac{\omega}{V}\right)^{2}}{1 + \left(\frac{3b\omega}{\pi V}\right)^{2}} \cdot \Phi_{v}\left(\omega\right)$
Vertical	-	
$\Phi_w(\omega)$	$\frac{\sigma_w^2 L_w}{\pi V} \cdot \frac{1 + 3 \left(L_w \frac{\omega}{V}\right)^2}{\left[1 + \left(L_w \frac{\omega}{V}\right)^2\right]^2}$	$\frac{2\sigma_w^2 L_w}{\pi V} \cdot \frac{1 + 12 \left(L_w \frac{\omega}{V}\right)^2}{\left[1 + 4 \left(L_w \frac{\omega}{V}\right)^2\right]^2}$
$\Phi_q(\omega)$	$\frac{\pm \left(\frac{\omega}{V}\right)^{2}}{1 + \left(\frac{4b\omega}{\pi V}\right)^{2}} \cdot \Phi_{w}\left(\omega\right)$	$\frac{\pm \left(\frac{\omega}{V}\right)^{2}}{1 + \left(\frac{4b\omega}{\pi V}\right)^{2}} \cdot \Phi_{w}\left(\omega\right)$

The variable b represents the aircraft wingspan. The variables  $L_u$ ,  $L_v$ ,  $L_w$  represent the turbulence scale lengths. The variables  $\sigma_u$ ,  $\sigma_v$ ,  $\sigma_w$  represent the turbulence intensities.

The spectral density definitions of turbulence angular rates are defined in the specifications as three variations, which are displayed in the following table:

$$p_{g} = \frac{\partial w_{g}}{\partial y} \qquad q_{g} = \frac{\partial w_{g}}{\partial x} \qquad r_{g} = -\frac{\partial v_{g}}{\partial x}$$
$$p_{g} = \frac{\partial w_{g}}{\partial y} \qquad q_{g} = \frac{\partial w_{g}}{\partial x} \qquad r_{g} = \frac{\partial v_{g}}{\partial x}$$
$$p_{g} = -\frac{\partial w_{g}}{\partial y} \qquad q_{g} = -\frac{\partial w_{g}}{\partial x} \qquad r_{g} = \frac{\partial v_{g}}{\partial x}$$

The variations affect only the vertical  $(\boldsymbol{q}_{g})$  and lateral  $(r_{g})$  turbulence angular rates.

Keep in mind that the longitudinal turbulence angular rate spectrum

$$\Phi_{p_g}(\omega)$$

is a rational function. The rational function is derived from curve-fitting a complex algebraic function, not the vertical turbulence velocity spectrum,  $\Phi_w(\omega)$ , multiplied by a scale factor. Because the turbulence angular rate spectra contribute less to the aircraft gust response than the turbulence velocity spectra, it may explain the variations in their definitions.

The variations lead to the following combinations of vertical and lateral turbulence angular rate spectra:

Vertical	Lateral	
$\Phi_q(\omega)$	$-\Phi_r(\omega)$	
$\Phi_q(\omega)$	$\Phi_r(\omega)$	
$-\Phi_q(\omega)$	$\Phi_r(\omega)$	

To generate a signal with the correct characteristics, a unit variance, band-limited white noise signal is passed through forming filters. The forming filters are derived from the spectral square roots of the spectrum equations.

The following table displays the transfer functions:

	MIL-F-8785C	MIL-HDBK-1797
Longitudin	al	
$H_u(s)$	$\sigma_u \sqrt{\frac{2L_u}{\pi V}} \cdot \frac{1}{1 + \frac{L_u}{V}s}$	$\sigma_u \sqrt{\frac{2L_u}{\pi V}} \cdot \frac{1}{1 + \frac{L_u}{V}s}$
$H_p(s)$	$\sigma_w \sqrt{\frac{0.8}{V}} \cdot \frac{\left(\frac{\pi}{4b}\right)^{1/6}}{L_w^{1/3} \left(1 + \left(\frac{4b}{\pi V}\right)s\right)}$	$\sigma_w \sqrt{\frac{0.8}{V}} \cdot \frac{\left(\frac{\pi}{4b}\right)^{1/6}}{\left(2L_w\right)^{1/3} \left(1 + \left(\frac{4b}{\pi V}\right)s\right)}$
Lateral		

	MIL-F-8785C	MIL-HDBK-1797
$H_v(s)$	$\sigma_v \sqrt{rac{L_v}{\pi V}} \cdot rac{1 + rac{\sqrt{3}L_v}{V}s}{\left(1 + rac{L_v}{V}s ight)^2}$	$\sigma_v \sqrt{rac{2L_v}{\pi V}} \cdot rac{1 + rac{2\sqrt{3}L_v}{V}s}{\left(1 + rac{2L_v}{V}s ight)^2}$
$H_r(s)$	$\frac{\mp \frac{s}{V}}{\left(1 + \left(\frac{3b}{\pi V}\right)s\right)} \cdot H_v(s)$	$\frac{\mp \frac{s}{V}}{\left(1 + \left(\frac{3b}{\pi V}\right)s\right)} \cdot H_v(s)$
Vertical	-	
$H_w(s)$	$\sigma_w \sqrt{rac{L_w}{\pi V}} \cdot rac{1 + rac{\sqrt{3}L_w}{V}s}{\left(1 + rac{L_w}{V}s ight)^2}$	$\sigma_w \sqrt{\frac{2L_w}{\pi V}} \cdot \frac{1 + \frac{2\sqrt{3}L_w}{V}s}{\left(1 + \frac{2L_w}{V}s\right)^2}$
$H_q(s)$	$\frac{\pm \frac{s}{V}}{\left(1 + \left(\frac{4b}{\pi V}\right)s\right)} \cdot H_w(s)$	$\frac{\pm \frac{s}{V}}{\left(1 + \left(\frac{4b}{\pi V}\right)s\right)} \cdot H_w(s)$

Divided into two distinct regions, the turbulence scale lengths and intensities are functions of altitude.

**Note** The military specifications result in the same transfer function after evaluating the turbulence scale lengths. The differences in turbulence scale lengths and turbulence transfer functions balance offset.

#### Low-Altitude Model (Altitude < 1000 feet)

According to the military references, the turbulence scale lengths at low altitudes, where h is the altitude in feet, are represented in the following table:

MIL-F-8785C	MIL-HDBK-1797
$L_w = h$	$2L_w = h$
$L_u = L_v = \frac{h}{(0.177 + 0.000823h)^{1.2}}$	$L_u = 2L_v = \frac{h}{(0.177 + 0.000823h)^{1.2}}$

The turbulence intensities are given below, where  $W_{20}$  is the wind speed at 20 feet (6 m). Typically for light turbulence, the wind speed at 20 feet is 15 knots; for moderate turbulence, the wind speed is 30 knots; and for severe turbulence, the wind speed is 45 knots.

$$\sigma_{w} = 0.1 W_{20}$$
  
$$\frac{\sigma_{u}}{\sigma_{w}} = \frac{\sigma_{u}}{\sigma_{w}} = \frac{1}{(0.177 + 0.000823h)^{0.4}}$$

The turbulence axes orientation in this region is defined as follows:

- Longitudinal turbulence velocity,  $\boldsymbol{u}_{g},$  aligned along the horizontal relative mean wind vector
- Vertical turbulence velocity,  $w_g$ , aligned with vertical

At this altitude range, the output of the block is transformed into body coordinates.

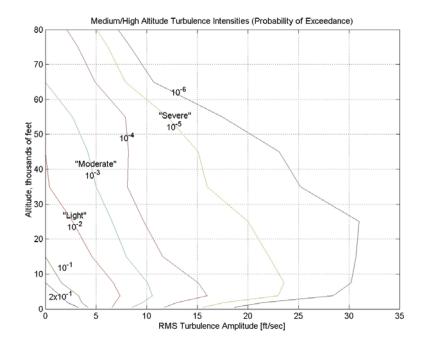

#### Medium/High Altitudes (Altitude > 2000 feet)

For medium to high altitudes the turbulence scale lengths and intensities are based on the assumption that the turbulence is isotropic. In the military references, the scale lengths are represented by the following equations:

MIL-F-8785C	MIL-HDBK-1797
$L_u = L_v = L_w = 1750 \text{ ft}$	$L_u$ = $2L_v$ = $2L_w$ = 1750 ft

The turbulence intensities are determined from a lookup table that provides the turbulence intensity as a function of altitude and the probability of the turbulence intensity being exceeded. The relationship of the turbulence intensities is represented in the following equation:  $\sigma_u = \sigma_v = \sigma_w$ .

The turbulence axes orientation in this region is defined as being aligned with the body coordinates.

## Between Low and Medium/High Altitudes (1000 feet < Altitude < 2000 feet)

At altitudes between 1000 feet and 2000 feet, the turbulence velocities and turbulence angular rates are determined by linearly interpolating between the value from the low altitude model at 1000 feet transformed from mean horizontal wind coordinates to body coordinates and the value from the high altitude model at 2000 feet in body coordinates.

#### Units

Define the units of wind speed due to the turbulence.

Units	Wind Velocity	Altitude	Airspeed
Metric (MKS)	Meters/second	Meters	Meters/second
English (Velocity in ft/s)	Feet/second	Feet	Feet/second
English (Velocity in kts)	Knots	Feet	Knots

#### Specification

Define which military reference to use. This affects the application of turbulence scale lengths in the lateral and vertical directions.

#### Model type

Select the wind turbulence model to use.

Continuous Von Karman (+q -r)	Use continuous representation of Von Kármán velocity spectra with positive vertical and negative lateral angular rates spectra.
Continuous Von Karman (+q +r)	Use continuous representation of Von Kármán velocity spectra with positive vertical and lateral angular rates spectra.
Continuous Von Karman (-q +r)	Use continuous representation of Von Kármán velocity spectra with negative vertical and positive lateral angular rates spectra.
Continuous Dryden (+q -r)	Use continuous representation of Dryden velocity spectra with positive vertical and negative lateral angular rates spectra.
Continuous Dryden (+q +r)	Use continuous representation of Dryden velocity spectra with positive vertical and lateral angular rates spectra.
Continuous Dryden (-q +r)	Use continuous representation of Dryden velocity spectra with negative vertical and positive lateral angular rates spectra.

Discrete Dryden (+q -r)	Use discrete representation of Dryden velocity spectra with positive vertical and negative lateral angular rates spectra.
Discrete Dryden (+q +r)	Use discrete representation of Dryden velocity spectra with positive vertical and lateral angular rates spectra.
Discrete Dryden (-q +r)	Use discrete representation of Dryden velocity spectra with negative vertical and positive lateral angular rates spectra.

The Continuous Dryden selections conform to the transfer function descriptions.

#### Wind speed at 6 m defines the low altitude intensity

The measured wind speed at a height of 6 meters (20 feet) provides the intensity for the low-altitude turbulence model.

#### Wind direction at 6 m (degrees clockwise from north)

The measured wind direction at a height of 6 meters (20 feet) is an angle to aid in transforming the low-altitude turbulence model into a body coordinates.

#### Probability of exceedance of high-altitude intensity

Above 2000 feet, the turbulence intensity is determined from a lookup table that gives the turbulence intensity as a function of altitude and the probability of the turbulence intensity's being exceeded.

#### Scale length at medium/high altitudes (m)

The turbulence scale length above 2000 feet is assumed constant, and from the military references, a figure of 1750 feet is recommended for the longitudinal turbulence scale length of the Dryden spectra. **Note** An alternate scale length value changes the power spectral density asymptote and gust load.

#### Wingspan

The wingspan is required in the calculation of the turbulence on the angular rates.

#### **Band-limited noise sample time (sec)**

The sample time at which the unit variance white noise signal is generated.

#### Noise seeds

There are four random numbers required to generate the turbulence signals, one for each of the three velocity components and one for the roll rate. The turbulences on the pitch and yaw angular rates are based on further shaping of the outputs from the shaping filters for the vertical and lateral velocities.

#### **Turbulence** on

Selecting the check box generates the turbulence signals.

Inputs and Outputs	Input	Dimension Type	Description
	First		Contains the altitude, in units selected.
	Second		Contains the aircraft speed, in units selected.
	Third		Contains the direction cosine matrix.
	Output	<b>Dimension Type</b>	Description
	First	Three-element signal	Contains the turbulence velocities, in the selected units.
	Second	Three-element signal	Contains the turbulence angular rates, in radians per second.

## Dryden Wind Turbulence Model (Continuous)

Assumptions and Limitations	The frozen turbulence field assumption is valid for the cases of mean-wind velocity and the root-mean-square turbulence velocity, or intensity, is small relative to the aircraft's ground speed.		
	The turbulence model describes an average of all conditions for clear air turbulence because the following factors are not incorporated into the model:		
	• Terrain roughness		
	• Lapse rate		
	• Wind shears		
	• Mean wind magnitude		
	Other meteorological factions (except altitude)		
Examples	See Airframe/Environment Models/Wind Models in aeroblk_HL20 for an example of this block.

### **Dryden Wind Turbulence Model (Discrete)**

Purpose	Generate discrete wind turbulence with Dryden velocity spectra
Library	Environment/Wind

#### Description

>h (m)	Discrete	V <sub>Wind</sub> (m/s)
>V (m/s) >DGM	Dryden (+q +r)	ω <sub>vind</sub> (rad/s);

The Dryden Wind Turbulence Model (Discrete) block uses the Dryden spectral representation to add turbulence to the aerospace model by using band-limited white noise with appropriate digital filter finite difference equations. This block implements the mathematical representation in the Military Specification MIL-F-8785C and Military Handbook MIL-HDBK-1797.

According to the military references, turbulence is a stochastic process defined by velocity spectra. For an aircraft flying at a speed V through a frozen turbulence field with a spatial frequency of  $\Omega$  radians per meter, the circular frequency  $\omega$  is calculated by multiplying V by  $\Omega$ . The following table displays the component spectra functions:

	MIL-F-8785C	MIL-HDBK-1797
Longitudinal		
$\Phi_{u}\left(\omega ight)$	$\frac{2\sigma_u^2 L_u}{\pi V} \cdot \frac{1}{1 + \left(L_u \frac{\omega}{V}\right)^2}$	$\frac{2\sigma_u^2 L_u}{\pi V} \cdot \frac{1}{1 + \left(L_u \frac{\omega}{V}\right)^2}$
$\Phi_p(\omega)$	$\frac{\sigma_w^2}{VL_w} \cdot \frac{0.8 \left(\frac{\pi L_w}{4b}\right)^{\!$	$\frac{\sigma_w^2}{2VL_w} \cdot \frac{0.8 \left(\frac{2\pi L_w}{4b}\right)^{1/3}}{1 + \left(\frac{4b\omega}{\pi V}\right)^2}$

	MIL-F-8785C	MIL-HDBK-1797
Lateral	-	
$\Phi_v(\omega)$	$\frac{\sigma_v^2 L_v}{\pi V} \cdot \frac{1 + 3 \left(L_v \frac{\omega}{V}\right)^2}{\left[1 + \left(L_v \frac{\omega}{V}\right)^2\right]^2}$	$\frac{2\sigma_v^2 L_v}{\pi V} \cdot \frac{1 + 12 \left(L_v \frac{\omega}{V}\right)^2}{\left[1 + 4 \left(L_v \frac{\omega}{V}\right)^2\right]^2}$
$\Phi_r(\omega)$	$\frac{\mp \left(\frac{\omega}{V}\right)^{2}}{1 + \left(\frac{3b\omega}{\pi V}\right)^{2}} \cdot \Phi_{v}\left(\omega\right)$	$\frac{\mp \left(\frac{\omega}{V}\right)^{2}}{1 + \left(\frac{3b\omega}{\pi V}\right)^{2}} \cdot \Phi_{v}\left(\omega\right)$
Vertical		
$\Phi_w(\omega)$	$\frac{\sigma_w^2 L_w}{\pi V} \cdot \frac{1 + 3 \left(L_w \frac{\omega}{V}\right)^2}{\left[1 + \left(L_w \frac{\omega}{V}\right)^2\right]^2}$	$\frac{2\sigma_w^2 L_w}{\pi V} \cdot \frac{1 + 12 \left(L_w \frac{\omega}{V}\right)^2}{\left[1 + 4 \left(L_w \frac{\omega}{V}\right)^2\right]^2}$
$\Phi_q(\omega)$	$\frac{\pm \left(\frac{\omega}{V}\right)^{2}}{1 + \left(\frac{4b\omega}{\pi V}\right)^{2}} \cdot \Phi_{w}\left(\omega\right)$	$\frac{\pm \left(\frac{\omega}{V}\right)^{2}}{1 + \left(\frac{4b\omega}{\pi V}\right)^{2}} \cdot \Phi_{w}\left(\omega\right)$

The variable b represents the aircraft wingspan. The variables  $L_u$ ,  $L_v$ ,  $L_w$  represent the turbulence scale lengths. The variables  $\sigma_u$ ,  $\sigma_v$ ,  $\sigma_w$  represent the turbulence intensities.

The spectral density definitions of turbulence angular rates are defined in the references as three variations, which are displayed in the following table:

 $p_{g} = \frac{\partial w_{g}}{\partial y} \qquad q_{g} = \frac{\partial w_{g}}{\partial x} \qquad r_{g} = -\frac{\partial v_{g}}{\partial x}$  $p_{g} = \frac{\partial w_{g}}{\partial y} \qquad q_{g} = \frac{\partial w_{g}}{\partial x} \qquad r_{g} = \frac{\partial v_{g}}{\partial x}$  $p_{g} = -\frac{\partial w_{g}}{\partial y} \qquad q_{g} = -\frac{\partial w_{g}}{\partial x} \qquad r_{g} = \frac{\partial v_{g}}{\partial x}$ 

The variations affect only the vertical  $(\boldsymbol{q}_{g})$  and lateral  $(r_{g})$  turbulence angular rates.

Keep in mind that the longitudinal turbulence angular rate spectrum,  $\Phi_p(\omega)$ , is a rational function. The rational function is derived from curve-fitting a complex algebraic function, not the vertical turbulence velocity spectrum,  $\Phi_w(\omega)$ , multiplied by a scale factor. Because the turbulence angular rate spectra contribute less to the aircraft gust response than the turbulence velocity spectra, it may explain the variations in their definitions.

The variations lead to the following combinations of vertical and lateral turbulence angular rate spectra:

Vertical	Lateral
$\Phi_q(\omega)$	$-\Phi_r(\omega)$
$\Phi_q(\omega)$	$\Phi_r(\omega)$
$-\Phi_q(\omega)$	$\Phi_r(\omega)$

To generate a signal with the correct characteristics, a unit variance, band-limited white noise signal is used in the digital filter finite difference equations.

The following table displays the digital filter finite difference equations:

	MIL-F-8785C	MIL-HDBK-1797
Longitud	inal	
u <sub>g</sub>	$\left(1 - \frac{V}{L_u}T\right) u_g + \sqrt{2\frac{V}{L_u}T}\frac{\sigma_u}{\sigma_\eta}\eta_1$	$\left(1 - \frac{V}{L_u}T\right) u_g + \sqrt{2\frac{V}{L_u}T} \frac{\sigma_u}{\sigma_\eta} \eta_1$
$p_g$	$egin{pmatrix} 1 - rac{2.6}{\sqrt{L_w b}} T \end{pmatrix} p_g + \end{split}$	$\left(1\!-\!rac{2.6}{\sqrt{2L_wb}}T ight)\!p_g$ +

r <sub>g</sub>	$\left(1-rac{\pi V}{3b}T ight)r_{g}\mprac{\pi}{3b}\left(v_{g}-v_{g_{past}} ight)$	$\left(1 - \frac{\pi V}{3b}T\right) r_g \mp \frac{\pi}{3b} \left(v_g - v_{g_{past}}\right)$
Vertical		
w <sub>g</sub>	$\left(1-\frac{V}{L_u}T\right)w_g + \sqrt{2rac{V}{L_u}T}rac{\sigma_w}{\sigma_\eta}\eta_3$	$\left(1 - \frac{V}{L_u}T\right) w_g + \sqrt{2\frac{V}{L_u}T} \frac{\sigma_w}{\sigma_\eta} \eta_3$
$q_g$	$\left(1-rac{\pi V}{4b}T ight)q_g\pmrac{\pi}{4b}\left(w_g-w_{g_{past}} ight)$	$\left(1-rac{\pi V}{4b}T ight)q_g\pmrac{\pi}{4b}\left(w_g-w_{g_{past}} ight)$

Divided into two distinct regions, the turbulence scale lengths and intensities are functions of altitude.

#### Low-Altitude Model (Altitude < 1000 feet)

According to the military references, the turbulence scale lengths at low altitudes, where h is the altitude in feet, are represented in the following table:

MIL-F-8785C	MIL-HDBK-1797
$L_w = h$	$2L_w = h$
$L_u = L_v = \frac{h}{(0.177 + 0.000823h)^{1.2}}$	$L_u = 2L_v = \frac{h}{(0.177 + 0.000823h)^{1.2}}$

The turbulence intensities are given below, where  $W_{20}$  is the wind speed at 20 feet (6 m). Typically for light turbulence, the wind speed at 20 feet is 15 knots; for moderate turbulence, the wind speed is 30 knots, and for severe turbulence, the wind speed is 45 knots.

$$\sigma_w = 0.1 W_{20}$$

$$\frac{\sigma_u}{\sigma_w} = \frac{\sigma_v}{\sigma_w} = \frac{1}{(0.177 + 0.000823h)^{0.4}}$$

The turbulence axes orientation in this region is defined as follows:

- Longitudinal turbulence velocity,  $\boldsymbol{u}_{g},$  aligned along the horizontal relative mean wind vector
- Vertical turbulence velocity,  $w_{g}$ , aligned with vertical.

At this altitude range, the output of the block is transformed into body coordinates.

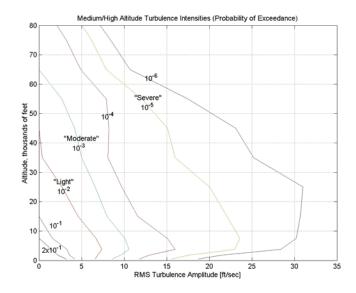

### Medium/High Altitudes (Altitude > 2000 feet)

For medium to high altitudes the turbulence scale lengths and intensities are based on the assumption that the turbulence is isotropic. In the military references, the scale lengths are represented by the following equations:

MIL-F-8785C	MIL-HDBK-1797
$L_u = L_v = L_w = 1750 \text{ ft}$	$L_u = 2L_v = 2L_w = 1750 \text{ ft}$

The turbulence intensities are determined from a lookup table that provides the turbulence intensity as a function of altitude and the probability of the turbulence intensity being exceeded. The relationship of the turbulence intensities is represented in the following equation:  $\sigma_u = \sigma_v = \sigma_w$ .

The turbulence axes orientation in this region is defined as being aligned with the body coordinates.

# Between Low and Medium/High Altitudes (1000 feet < Altitude < 2000 feet)

At altitudes between 1000 feet and 2000 feet, the turbulence velocities and turbulence angular rates are determined by linearly interpolating between the value from the low altitude model at 1000 feet transformed from mean horizontal wind coordinates to body coordinates and the value from the high altitude model at 2000 feet in body coordinates.

#### Units

Define the units of wind speed due to the turbulence.

# Dryden Wind Turbulence Model (Discrete)

Units	Wind Velocity	Altitude	Airspeed
Metric (MKS)	Meters/second	Meters	Meters/second
English (Velocity in ft/s)	Feet/second	Feet	Feet/second
English (Velocity in kts)	Knots	Feet	Knots

#### Specification

Define which military reference to use. This affects the application of turbulence scale lengths in the lateral and vertical directions

### Model type

Select the wind turbulence model to use:

Continuous Von Karman (+q -r)	Use continuous representation of Von Kármán velocity spectra with positive vertical and negative lateral angular rates spectra.
Continuous Von Karman (+q +r)	Use continuous representation of Von Kármán velocity spectra with positive vertical and lateral angular rates spectra.
Continuous Von Karman (-q +r)	Use continuous representation of Von Kármán velocity spectra with negative vertical and positive lateral angular rates spectra.
Continuous Dryden (+q -r)	Use continuous representation of Dryden velocity spectra with positive vertical and negative lateral angular rates spectra.

Continuous Dryden (+q +r)	Use continuous representation of Dryden velocity spectra with positive vertical and lateral angular rates spectra.
Continuous Dryden (-q +r)	Use continuous representation of Dryden velocity spectra with negative vertical and positive lateral angular rates spectra.
Discrete Dryden (+q -r)	Use discrete representation of Dryden velocity spectra with positive vertical and negative lateral angular rates spectra.
Discrete Dryden (+q +r)	Use discrete representation of Dryden velocity spectra with positive vertical and lateral angular rates spectra.
Discrete Dryden (-q +r)	Use discrete representation of Dryden velocity spectra with negative vertical and positive lateral angular rates spectra.

The Discrete Dryden selections conform to the transfer function descriptions.

#### Wind speed at 6 m defines the low altitude intensity

The measured wind speed at a height of 6 meters (20 feet) provides the intensity for the low-altitude turbulence model.

#### Wind direction at 6 m (degrees clockwise from north)

The measured wind direction at a height of 6 meters (20 feet) is an angle to aid in transforming the low-altitude turbulence model into a body coordinates.

#### Probability of exceedance of high-altitude intensity

Above 2000 feet, the turbulence intensity is determined from a lookup table that gives the turbulence intensity as a function of

altitude and the probability of the turbulence intensity's being exceeded.

#### Scale length at medium/high altitudes

The turbulence scale length above 2000 feet is assumed constant, and from the military references, a figure of 1750 feet is recommended for the longitudinal turbulence scale length of the Dryden spectra.

**Note** An alternate scale length value changes the power spectral density asymptote and gust load.

#### Wingspan

The wingspan is required in the calculation of the turbulence on the angular rates.

#### Band-limited noise and discrete filter sample time (sec)

The sample time at which the unit variance white noise signal is generated and at which the discrete filters are updated.

#### Noise seeds

There are four random numbers required to generate the turbulence signals, one for each of the three velocity components and one for the roll rate. The turbulences on the pitch and yaw angular rates are based on further shaping of the outputs from the shaping filters for the vertical and lateral velocities.

#### **Turbulence** on

Selecting the check box generates the turbulence signals.

Inputs and	Input	Dimension Type	Description
Outputs	First		Contains the altitude, in units selected.
	Second		Contains the aircraft speed, in units selected.
	Third		Contains the NED direction cosine matrix.
	Outrout	Dimension Trans	Description
	Output	Dimension Type	Description
	First	Three-element signal	Contains the turbulence velocities, in the selected units.
	Second	Three-element signal	Contains the turbulence angular rates, in radians per second.
Assumptions and Limitations	The "frozen turbulence field" assumption is valid for the cases of mean-wind velocity and the root-mean-square turbulence velocity, or intensity, is small relative to the aircraft's ground speed.		
	The turbulence model describes an average of all conditions for clear air turbulence because the following factors are not incorporated into the model:		
	• Terrain	roughness	
	Lapse rate		
	• Wind shears		
	• Mean wind magnitude		
	• Other m	eteorological factions	(except altitude)

# **ECEF** Position to LLA

**Purpose**Calculate geodetic latitude, longitude, and altitude above planetary<br/>ellipsoid from Earth-centered Earth-fixed (ECEF) position

**Utilities/Axes Transformations** 

Description

×<sub>f</sub> h≥

Library

The ECEF Position to LLA block converts a 3-by-1 vector of ECEF position  $(\bar{p})$  into geodetic latitude  $(\bar{\mu})$ , longitude  $(\bar{\tau})$ , and altitude

 $(\bar{h})$  above the planetary ellipsoid.

The ECEF position is defined as

$$\overline{p} = \begin{bmatrix} \overline{p}_x \\ \overline{p}_y \\ \overline{p}_z \end{bmatrix}$$

Longitude is calculated from the ECEF position by

$$\iota = \operatorname{atan}\left(\frac{p_y}{p_x}\right)$$

Geodetic latitude  $(\bar{\mu})$  is calculated from the ECEF position using Bowring's method, which typically converges after two or three iterations. The method begins with an initial guess for geodetic latitude

 $(\bar{\mu})$  and reduced latitude  $(\bar{\beta})$ . An initial guess takes the form:

$$\begin{split} \overline{\beta} &= \operatorname{atan}\!\left(\frac{p_z}{(1-f)s}\right) \\ \overline{\mu} &= \operatorname{atan}\!\left(\frac{p_z + \frac{e^2(1-f)}{(1-e^2)}R(\sin\beta)^3}{s - e^2R(\cos\beta)^3} \end{split}$$

where *R* is the equatorial radius, *f* the flattening of the planet,  $e^2 = 1-(1-f)^2$ , the square of first eccentricity, and

$$s = \sqrt{p_x^2 + p_y^2}$$

After the initial guesses are calculated, the reduced latitude  $\left(\bar{\beta}\right)$  is recalculated using

$$\beta = \operatorname{atan}\left(\frac{(1-f)\sin\mu}{\cos\mu}\right)$$

and geodetic latitude  $(\bar{\mu})$  is reevaluated. This last step is repeated until  $\bar{\mu}$  converges.

The altitude  $\left(ar{h}
ight)$  above the planetary ellipsoid is calculated with

$$h = s\cos\mu + \left(p_z + e^2N\sin\mu\right)\sin\mu - N$$

where the radius of curvature in the vertical prime  $\left(ar{N}
ight)$  is given by

$$N = \frac{R}{\sqrt{1 - e^2 (\sin \mu)^2}}$$

Specifies the radius of the planet at its equator. The equatorial radius units should be the same as the desired units for ECEF position.

This option is available only with Planet model set to Custom.

Inputs	and
Output	S

Input	Dimension Type	Description
First	3-by-1 vector	Contains the position in ECEF frame.

Output	Dimension Type	Description
First	2-by-1 vector	Contains the geodetic latitude and longitude, in degrees.
Second	Scalar	Contains the altitude above the planetary ellipsoid, in the same units as the ECEF position.

Assumptions and Limitations	This implementation generates a geodetic latitude that lies between $\pm 90$ degrees, and longitude that lies between $\pm 180$ degrees. The planet is assumed to be ellipsoidal. By setting the flattening to 0, you model a spherical planet.
	The implementation of the ECEF coordinate system assumes that its origin lies at the center of the planet, the <i>x</i> -axis intersects the prime (Greenwich) meridian and the equator, the <i>z</i> -axis is the mean spin axis of the planet (positive to the north), and the <i>y</i> -axis completes the right-handed system.

Environment/Gravity

# Description

>	λ(deg)	N (m)	
>	l (deg)	N (m)	ĺ

Dialog Box The EGM96 Geoid block calculates the geoid height as determined from the EGM96 Geopotential Model. The block interpolates the geoid heights from a 15 minute grid of point values in the tide-free system. It uses the EGM96 Geopotential Model to degree and order 360. The geoid undulations are with respect to the WGS84 ellipsoid.

The interpolation scheme wraps over the poles to allow for geoid height calculations at and near these locations.

# Flat Earth to LLA

- **Purpose** Estimate geodetic latitude, longitude, and altitude from flat Earth position
- Library Utilities/Axes Transformations

**Description** The Flat Earth to LLA block converts a 3-by-1 vector of Flat Earth

>Х<sub>е</sub> µI> >h<sub>ref</sub> h> position  $(\bar{p})$  into geodetic latitude  $(\bar{\mu})$ , longitude  $(\bar{\iota})$ , and altitude (h). The flat Earth coordinate system assumes the *z*-axis is downward positive. The estimation begins by transforming the flat Earth *x* and *y* coordinates to North and East coordinates. The transformation has the form of

$$\begin{bmatrix} N \\ E \end{bmatrix} = \begin{bmatrix} \cos\psi & -\sin\psi \\ \sin\psi & \cos\psi \end{bmatrix} \begin{bmatrix} p_x \\ p_y \end{bmatrix}$$

where  $(\bar{\psi})$  is the angle in degrees clockwise between the *x*-axis and north.

To convert the North and East coordinates to geodetic latitude and longitude, the radius of curvature in the prime vertical  $(R_N)$  and the radius of curvature in the meridian  $(R_M)$  are used.  $(R_N)$  and  $(R_M)$  are defined by the following relationships:

$$R_N = \frac{R}{\sqrt{1 - (2f - f^2)\sin^2 \mu_0}}$$
$$R_M = R_N \frac{1 - (2f - f^2)}{1 - (2f - f^2)\sin^2 \mu_0}$$

where (R) is the equatorial radius of the planet and  $(\overline{f})$  is the flattening of the planet.

Small changes in the in latitude and longitude are approximated from small changes in the North and East positions by

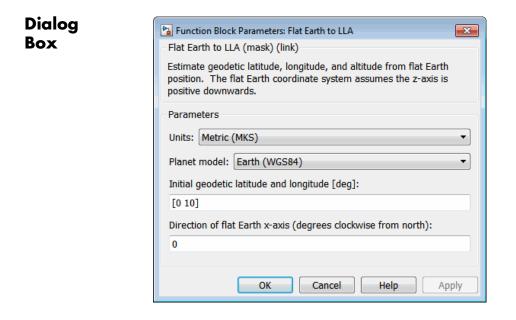

$$d\mu = \operatorname{atan}\left(\frac{1}{R_M}\right) dN$$
$$d\iota = \operatorname{atan}\left(\frac{1}{R_N \cos \mu}\right) dE$$

The output latitude and longitude are simply the initial latitude and longitude plus the small changes in latitude and longitude.

$$\mu = \mu_0 + d\mu$$
$$\iota = \iota_0 + d\iota$$

The altitude is the negative flat Earth z-axis value minus the reference height  $(h_{ref})$ .

$$h = -p_z - h_{ref}$$

Second	Scalar	Contains the altitude above the input reference altitude, in same units as flat Earth position.

### Inputs and Outputs

# Flat Earth to LLA

Assumptions and	This estimation method assumes the flight path and bank angle are zero.			
Limitations	This estimation method assumes the flat Earth <i>z</i> -axis is normal to the Earth at the initial geodetic latitude and longitude only. This method has higher accuracy over small distances from the initial geodetic latitude and longitude, and nearer to the equator. The longitude will have higher accuracy the smaller the variations in latitude. Additionally, longitude is singular at the poles.

# Animation/Flight Simulator Interfaces

### Description

The FlightGear Preconfigured 6DoF Animation block lets you drive position and attitude values to a FlightGear flight simulator vehicle given double-precision values for longitude (1), latitude ( $\mu$ ), altitude (h), roll ( $\phi$ ), pitch ( $\theta$ ), and yaw ( $\psi$ ), respectively.

The block is a masked subsystem containing principally a Pack net\_fdm Packet for FlightGear block set for 6DoF inputs, a Send net\_fdm Packet to FlightGear block, and a Simulation Pace block. To access the full capabilities of these blocks, use the individual corresponding blocks from the Aerospace Blockset library.

The block is additionally configured as a SimViewingDevice, so that if you generate code for your model using the Simulink Coder product and connect to the running target code using theSimulink Coder External Mode available from the model toolbar, then the Simulink software can obtain the data from the target on the fly and transmit position and attitude data to FlightGear. For more information, see "Sim Viewing Devices in External Mode".

This block does not produce deployable code, but it can be used with Simulink Coder external mode as a SimViewingDevice.

# Select target architecture

From the list, select the target platform on which you want to execute the run script. This platform can differ from the platform on which you create the run script. Select Default if you want to generate a run script to run on the platform from which you create the run script.

• Win32

- Win64
- Linux
- Mac

#### Select FlightGear data flow

From the list, select the direction of the data flow:

• Send

Creates the run script to set up the sending of the net\_fdm control model from Simulink to FlightGear.

• Receive

Creates the run script to set up the receiving of the net\_ctrl control model from FlightGear to Simulink.

Send-Receive

Creates the run script to set up FlightGear to receive and broadcast data to and from Simulink.

**Note** Selecting this option does not mean that you receive the same data that you sent (for example, with the Send-Receive option, you might not see control surface position data). With this option, you see primarily user input (such as joystick) and environmental data.

#### FlightGear geometry model name

Specify the name of the folder containing the model geometry that you want in the *FlightGear*\data\Aircraft folder.

#### Airport ID

Specify the airport ID. The list of supported airports is available in the FlightGear interface, under **Location**.

#### Runway ID

Specify the runway ID.

# Initial altitude (ft)\*

Specify the initial altitude of the aircraft, in feet. The block evaluates the value as a MATLAB expression.

## Initial heading (deg)\*

Specify the initial heading of the aircraft, in degrees. The block evaluates the value as a MATLAB expression.

#### Offset distance (miles)\*

Specify the offset distance of the aircraft from the airport, in miles. The block evaluates the value as a MATLAB expression.

## **Offset azimuth (deg)\***

Specify the offset azimuth of the aircraft, in degrees. The block evaluates the value as a MATLAB expression.

## **Destination/Origin IP address**

Specify the network IP address of the machine on which the FlightGear software runs.

## **Destination port**

Specify your network flight dynamics model (fdm) port. For more information, see the Send net\_fdm Packet to FlightGear block reference.

# **Origin port**

Specify your network control (ctrl) port. For more information, see the Receive net\_ctrl Packet from FlightGear block.

#### **Network IP address**

Specify the network IP address of the machine on which the MATLAB software runs.

# Output file name

Specify the name of the output file. The file name is the name of the command that you use to start FlightGear with these initial parameters. Use these file extensions:

Platform	Extension
Windows	.bat
Linux and Mac OS	.sh

## FlightGear base directory

Specify the name of your FlightGear installation folder.

#### **Generate Script**

Enter the correct information in the dialog box fields, then click **Generate Script** to generate a run script for FlightGear. Do not click this button until you have entered the correct information in the dialog box fields.

**Examples** See the asbh120 example.

Receive net\_ctrl Packet from FlightGear

Unpack net\_ctrl Packet from FlightGear

Purpose Convert geocentric latitude to geodetic latitude

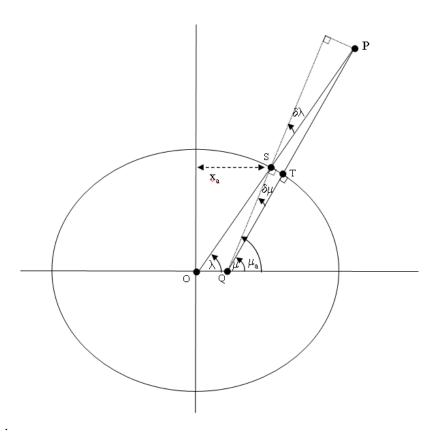

Library

Utilities/Axes Transformations

# Description

The Geocentric to Geodetic Latitude block converts a geocentric latitude  $(\lambda)$  into geodetic latitude  $(\mu)$ . There are a number of geometric relationships that are used to calculate the geodetic latitude in this noniterative method. A number of angles and points are involved in the calculation, which are shown in following figure.

Given geocentric latitude  $(\lambda)$  and the radius (r) from the center of the planet (O) to the center of gravity (P), this noniterative method starts by computing values for the point of r that intercepts the surface of the planet (S). By rearranging the equation for an ellipse, the horizontal coordinate,  $(x_a)$  is determined. When equatorial radius (R), polar radius ((1-f)R) and  $x_a \tan \lambda$ , are substituted for semi-major axis, semi-minor axis and vertical coordinate  $(y_a)$ , the resulting equation for  $x_a$  has the following form:

$$x_a = \frac{(1-f)R}{\sqrt{\tan^2 \lambda + (1-f)^2}}$$

To determine the geodetic latitude at S  $\mu_a$ , the equation for an ellipse with equatorial radius (*R*), polar radius ((1-f)R) is used again. This time it is used to define  $y_a$  in terms of  $x_a$ .

$$y_a=\sqrt{R^2-x_a^2}(1-f)$$

Additionally, the relationship between geocentric latitude at the planet's surface and geodetic latitude is used.

$$\mu_a = \operatorname{atan}\!\left(\frac{\tan\lambda}{(1-f)^2}\right)$$

Using the relationship  $\tan \lambda = y_a / x_a$  and the two equations above, the resulting equation for  $\mu_a$  is obtained.

$$\mu_a = \operatorname{atan}\left(\frac{\sqrt{R^2 - {x_a}^2}}{(1-f)x_a}\right)$$

The correct sign of  $\mu_a$  is determined by testing  $\lambda$  and if  $\lambda$  is less than zero  $\mu_a$  changes sign accordingly.

In order to calculate the geodetic latitude of P, a number of geometric relationships are required to be calculated. These calculations follow.

The radius  $(r_a)$  from the center of the planet (O) to the surface of the planet (S) is calculated by using trigonometric relationship.

$$r_a = \frac{x_a}{\cos \lambda}$$

The distance from S to P is defined by:

 $l = r - r_a$ 

The angular difference between geocentric latitude and geodetic latitude at  $S(\delta\lambda)$  is defined by:

$$\delta \lambda = \mu_a - \lambda$$

Using l and  $\delta\lambda$ , the segment TP or the mean sea-level altitude (*h*) is estimated.

 $h = l\cos\delta\lambda$ 

The equation for the radius of curvature in the Meridian  $(\rho_a)$  at  $\mu_a$  is

$$\rho_a = \frac{R(1-f)^2}{\left(1 - (2f - f^2)\sin^2\mu_a\right)^{3/2}}$$

Using l,  $\delta\lambda$ , h, and  $\rho_a$ , the angular difference between geodetic latitude at S ( $\mu$ ) and geodetic latitude at P ( $\mu_a$ ) is defined as:

$$\delta\mu = \operatorname{atan}\left(\frac{l\sin\delta\lambda}{\rho_a + h}\right)$$

Subtracting  $\delta \mu$  from  $\mu_a$  then gives  $\mu$ .

$$\mu = \mu_a - \delta \mu$$

Purpose	Calculate undulations/height
---------	------------------------------

Library Environment/Gravity

# Description

The Geoid Height block calculates the geoid height using the **Geopotential model** parameter. The block interpolates the geoid heights from a grid of point values in the tide-free system. It uses the specified geopotential model to degree and order 360. The geoid undulations are relative to the WGS84 ellipsoid.

The interpolation scheme wraps over the poles to allow for geoid height calculations at and near these locations.

# Purpose Transform horizontal wind into body-axes coordinates

Library

Environment/Wind

# Description

The Horizontal Wind Model block computes the wind velocity in body-axes coordinates.

The wind is specified by wind speed and wind direction in Earth axes. The speed and direction can be constant or variable over time. The direction of the wind is in degrees clockwise from the direction of the Earth *x*-axis (north). The wind direction is defined as the direction from which the wind is coming. Using the direction cosine matrix (DCM), the wind velocities are transformed into body-axes coordinates.

# **Ideal Airspeed Correction**

# **Purpose**Calculate equivalent airspeed (EAS), calibrated airspeed (CAS), or true<br/>airspeed (TAS) from each other

# Library Flight Parameters

# Description

The Ideal Airspeed Correction block calculates one of the following airspeeds: equivalent airspeed (EAS), calibrated airspeed (CAS), or true airspeed (TAS), from one of the other two airspeeds.

Three equations are used to implement the Ideal Airspeed Correction block. The first equation shows TAS as a function of EAS, relative pressure ratio at altitude ( $\delta$ ), and speed of sound at altitude (a).

$$TAS = \frac{EAS \times a}{a_0 \sqrt{\delta}}$$

Using the compressible form of Bernoulli's equation and assuming isentropic conditions, the last two equations for EAS and CAS are derived.

$$EAS = \sqrt{\frac{2\gamma P}{(\gamma - 1)\rho_0} \left( \left(\frac{q}{P} + 1\right)^{(\gamma - 1)/\gamma} - 1 \right)}$$

$$CAS = \sqrt{\frac{2\gamma P_0}{(\gamma - 1)\rho_0}} \left( \left(\frac{q}{P_0} + 1\right)^{(\gamma - 1)/\gamma} - 1 \right)$$

In order to generate a correction table and its approximate inverse, these two equations were solved for dynamic pressure (q). Having values of q by a function of *EAS* and ambient pressure at altitude (*P*) or by a function of *CAS*, allows the two equations to be solved using the other's solution for q, thus creating a solution for *EAS* that depends on *P* and *CAS* and a solution for *CAS* that depends on *P* and *EAS*.

English

Feet

### Input decimal year

When selected, the decimal year is an input for the International Geomagnetic Reference Field 11 block. Otherwise, specify a date using the dialog parameters **Month**, **Day**, and **Year**.

#### Month

Specifies the month to calculate decimal year.

### Day

Specifies the day to calculate decimal year.

#### Year

Specifies the year to calculate decimal year. In the list, select from 1900 to 2015.

### Action for out of range input

Specifies whether out-of-range input invokes a warning, error, or no action.

#### **Output secular variance**

Select this check box to enable the output of secular variances (annual rate of change) with nonsecular variances:

Secular Variance	Description
Magnetic Field	Magnetic field vector, in nanotesla (nT). <i>Z</i> is the vertical component (+ve down).
Horizontal Intensity	Horizontal intensity, in nanotesla (nT).
Declination	Declination, in degrees (+ve east).
Inclination	Inclination, in degrees (+ve down).
Total Intensity	Total intensity, in nanotesla (nT).

Secular Variance	Description
SV Magnetic Field	Secular variation of magnetic field.
SV Horizontal Intensity	Secular variation of horizontal intensity.
SV Declination	Secular variation of declination, the angle between true north and the magnetic field vector (positive eastward).
SV Inclination	Secular variation of inclination, the angle between the horizontal plane and the magnetic field vector (positive downward).
SV Total Intensity	Secular variation of total intensity.

Clear this check box to enable just the nonsecular variances:

- Magnetic Field
- Horizontal Intensity
- Declination
- Inclination
- Total Intensity

Inputs and Outputs

Input	Dimension Type	Description
First	Scalar	Contains the height, in selected units.
Second	Scalar	Contains the latitude, in degrees.

# International Geomagnetic Reference Field 11

Input	Dimension Type	Description
Third	Scalar	Contains the longitude, in degrees.
Fourth (Optional)	Scalar	Contains the desired year in a decimal format to include any fraction of the year that has already passed. The value is the current year plus the number of days that have passed in this year divided by 365.The following code illustrates how to calculate the decimal year, dyear, for March 21, 2005: ***BEGIN CODE*** dyear=decyear('21-March-2005','dd-mmm-yyyy')
		STATING CODESSS

Dimension Type	Description
	Contains the magnetic field vector, in selected units.
	Contains the horizontal intensity, in selected units.
	Contains the declination, in degrees.
	Contains the inclination, in degrees.
	Contains the total intensity, in selected units.
	Contains the secular variation of magnetic field vector, in selected units per years.
	Contains the secular variation of horizontal intensity, in selected units per year.
	Dimension Type

	Output	Dimension Type	Description			
	Eight (Optional)		Contains the secular variation of declination, in minutes per year.			
	Ninth (Optional)		Contains the secular variation of inclination, in minutes per year.			
	Tenth (Optional)		Contains the secular variation of total intensity, in selected units per year.			
Limitations	This block is valid between the heights of -1000 m and 600000 m. This block is valid between the years of 1900 and 2015.

# Interpolate Matrix(x)

Purpose	Return	interpolated	matrix for	given	input

Library GNC/Controls

# Description

x\_k x\_f Matrix(x) The Interpolate Matrix(x) block interpolates a one-dimensional array of matrices.

This one-dimensional case assumes a matrix M is defined at a discrete number of values of an independent variable

$$x = [x_1 x_2 x_3 \dots x_i x_{i+1} \dots x_n].$$

Then for  $x_i < x < x_{i+1}$ , the block output is given by

 $(1-\lambda)M(x_i) + \lambda M(x_{i+1})$ 

where the interpolation fraction is defined as

 $\lambda = (x - x_i) / (x_{i+1} - x_i)$ 

The matrix to be interpolated should be three dimensional, the first two dimensions corresponding to the matrix at each value of x. For example, if you have three matrices A, B, and C defined at x = 0, x = 0.5, and x = 1.0, then the input matrix is given by

matrix(:,:,1) = A; matrix(:,:,2) = B; matrix(:,:,3) = C;

### Dialog Box

#### Matrix to interpolate

Matrix to be interpolated, with three indices and the third index labeling the interpolating values of x.

Inputs and	Input	Dimension Type	Description
Outputs	First	<i>.</i>	Contains the interpolation index $i$ .
	Second		Contains the interpolation fraction $\lambda$ .
	Output	Dimension Type	Description
	First		Contains the interpolated matrix.
Assumptions and Limitations	This block must be driven from the Simulink Prelookup block.		
Examples	See the following block reference pages: 1D Controller [A(v),B(v),C(v),D(v)], 1D Observer Form [A(v),B(v),C(v),F(v),H(v)], and 1D Self-Conditioned [A(v),B(v),C(v),D(v)].		
See Also	Interpolate Matrix(x,y)		

Interpolate Matrix(x,y,z)

### Purpose Return interpolated matrix for given inputs

GNC/Controls

Description

Library

 $x_k$   $x_f$  Matrix(x,y)  $y_k$  $y_f$  The Interpolate Matrix(x,y) block interpolates a two-dimensional array of matrices.

This two-dimensional case assumes the matrix is defined as a function of two independent variables,  $\mathbf{x} = [x_1 x_2 x_3 \dots x_i x_{i+1} \dots x_n]$  and  $\mathbf{y} = [y_1 y_2 y_3 \dots y_j y_{j+1} \dots y_m]$ . For given values of x and y, four matrices are interpolated. Then for  $x_i < x < x_{i+1}$  and  $y_j < y < y_{j+1}$ , the output matrix is given by

$$\begin{aligned} &(1-\lambda_y)[(1-\lambda_x)M(x_i,y_j)+\lambda_xM(x_{i+1},y_j)]+\\ &\lambda_y[(1-\lambda_x)M(x_i,y_{j+1})+\lambda_xM(x_{i+1},y_{j+1})] \end{aligned}$$

where the two interpolation fractions are denoted by

$$\lambda_x = (x - x_i) / (x_{i+1} - x_i)$$

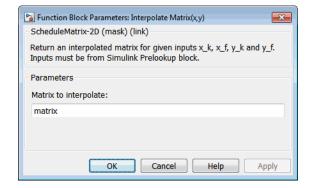

and

$$\lambda_y = (y - y_j) / (y_{j+1} - y_j)$$

In the two-dimensional case, the interpolation is carried out first on x and then y.

The matrix to be interpolated should be four dimensional, the first two dimensions corresponding to the matrix at each value of x and y. For example, if you have four matrices A, B, C, and D defined at (x = 0.0, y = 1.0), (x = 0.0, y = 3.0), (x = 1.0, y = 1.0) and (x = 1.0, y = 3.0), then the input matrix is given by

matrix(:,:,1,1) = A; matrix(:,:,1,2) = B; matrix(:,:,2,1) = C; matrix(:,:,2,2) = D; Dialog Box

#### Matrix to interpolate

Matrix to be interpolated, with four indices and the third and fourth indices labeling the interpolating values of *x* and *y*.

Inputs and Outputs	Input	Dimension Type	Description
	First		Contains the first interpolation index $i$ .
	Second		Contains the first interpolation fraction $\lambda_{\mathbf{x}}$ .
	Third		Contains the second interpolation index $j$ .
	Fourth		Contains the second interpolation fraction $\lambda_{\rm y}.$

Output	<b>Dimension Type</b>	Description	
First		Contains the interpolated matrix.	

This block must be driven from the Simulink Prelookup block.

### Assumptions and Limitations

Examples	See the following block reference pages: 2D Controller $[A(v),B(v),C(v),D(v)]$ , 2D Observer Form $[A(v),B(v),C(v),F(v),H(v)]$ , and 2D Self-Conditioned $[A(v),B(v),C(v),D(v)]$ .	
See Also	Interpolate Matrix(x)	

Interpolate Matrix(x,y,z)

## Interpolate Matrix(x,y,z)

**Purpose** Return interpolated matrix for given inputs

Library GNC/Controls

### Description

x\_k x\_f y\_k Matrix(x,y,z) z\_k z\_f The Interpolate Matrix(x,y,z) block interpolates a three-dimensional array of matrices.

This three-dimensional case assumes the matrix is defined as a function of three independent variables:

$$x = [x_1 \ x_2 \ x_3 \ \dots \ x_i \ x_{i+1} \ \dots \ x_n]$$
$$y = [y_1 \ y_2 \ y_3 \ \dots \ y_j \ y_{j+1} \ \dots \ y_m]$$
$$z = [z_1 \ z_2 \ z_3 \ \dots \ z_k \ z_{k+1} \ \dots \ z_p]$$

For given values of x, y, and z, eight matrices are interpolated. Then for

$$x_{i} < x < x_{i+1}$$
  
 $y_{j} < y < y_{j+1}$   
 $z_{k} < z < z_{k+1}$ 

the output matrix is given by

$$\begin{split} (1-\lambda_z)\Big\{& \big(1-\lambda_y\big)\Big[\big(1-\lambda_x\big)M\big(x_i,y_j,z_k\big)+\lambda_xM\big(x_{i+1},y_j,z_k\big)\Big]\\ & +\lambda_y\Big[\big(1-\lambda_x\big)M\big(x_i,y_{j+1},z_k\big)+\lambda_xM\big(x_{i+1},y_{j+1},z_k\big)\Big]\Big\}\\ & +\lambda_z\Big\{& \big(1-\lambda_y\big)\Big[\big(1-\lambda_x\big)M\big(x_i,y_j,z_{k+1}\big)+\lambda_xM\big(x_{i+1},y_j,z_{k+1}\big)\Big]\\ & +\lambda_y\Big[\big(1-\lambda_x\big)M\big(x_i,y_{j+1},z_{k+1}\big)+\lambda_xM\big(x_{i+1},y_{j+1},z_{k+1}\big)\Big]\Big\}\end{split}$$

where the three interpolation fractions are denoted by

$$\lambda_{x} = (x - x_{i}) / (x_{i+1} - x_{i})$$
  

$$i_{y} = (y - y_{j}) / (y_{j+1} - y_{j})$$
  

$$\lambda_{z} = (z - z_{k}) / (z_{k+1} - z_{k})$$

In the three-dimensional case, the interpolation is carried out first on x, then y, and finally z.

The matrix to be interpolated should be five dimensional, the first two dimensions corresponding to the matrix at each value of x, y, and z. For example, if you have eight matrices A, B, C, D, E, F, G, and H defined at the following values of x, y, and z, then the corresponding input matrix is given by

(x = 0.0, y = 1.0, z = 0.1)	matrix(:,:,1,1,1) = A;
(x = 0.0, y = 1.0, z = 0.5)	matrix(:,:,1,1,2) = B;
(x = 0.0, y = 3.0, z = 0.1)	matrix(:,:,1,2,1) = C;
(x = 0.0, y = 3.0, z = 0.5)	matrix(:,:,1,2,2) = D;
(x = 1.0, y = 1.0, z = 0.1)	matrix(:,:,2,1,1) = E;
(x = 1.0, y = 1.0, z = 0.5)	matrix(:,:,2,1,2) = F;
(x = 1.0, y = 3.0, z = 0.1)	matrix(:,:,2,2,1) = G;
(x = 1.0, y = 3.0, z = 0.5)	matrix(:,:,2,2,2) = H;

## Lapse Rate Model

**Purpose** Implement lapse rate model for atmosphere

Library

Environment/Atmosphere

Description

The Lapse Rate Model block implements the mathematical representation of the lapse rate atmospheric equations for ambient temperature, pressure, density, and speed of sound for the input geopotential altitude. You can customize this atmospheric model, described below, by specifying atmospheric properties in the block dialog.

The following equations define the troposphere

$$T = T_0 - Lh$$
$$P = P_0 \left(\frac{T}{T_0}\right)^{\frac{g}{LR}}$$
$$\rho = \rho_0 \left(\frac{T}{T_0}\right)^{\frac{g}{LR}-1}$$
$$a = \sqrt{\gamma RT}$$

The following equations define the tropopause (lower stratosphere)

$$\begin{split} T &= T_0 - Lhts \\ P &= P_0 \bigg( \frac{T}{T_0} \bigg)^{\frac{g}{LR}} e^{\frac{g}{RT}(hts - h)} \\ \rho &= \rho_0 \bigg( \frac{T}{T_0} \bigg)^{\frac{g}{LR} - 1} e^{\frac{g}{RT}(hts - h)} \\ a &= \sqrt{\gamma RT} \end{split}$$

where:

$T_0$	Absolute temperature at mean sea level in kelvin (K)
$ ho_0$	Air density at mean sea level in kg/m <sup>3</sup>
$P_{0}$	Static pressure at mean sea level in N/m <sup>2</sup>
h	Altitude in m
hts	Height of the troposphere in m
T	Absolute temperature at altitude $h$ in kelvin (K)
ρ	Air density at altitude $h$ in kg/m <sup>3</sup>
Р	Static pressure at altitude $h$ in N/m <sup>2</sup>
a	Speed of sound at altitude $h$ in m/s $^2$
L	Lapse rate in K/m
R	Characteristic gas constant J/kg-K
γ	Specific heat ratio
g	Acceleration due to gravity in m/s <sup>2</sup>

The Lapse Rate Model block icon displays the input and output metric units.

# Purpose Calculate Earth-centered Earth-fixed (ECEF) position from geodetic latitude, longitude, and altitude above planetary ellipsoid

Utilities/Axes Transformations

**Description** 

×µu ×<sub>f</sub>⊳

Library

The LLA to ECEF Position block converts geodetic latitude  $(\bar{\mu})$ ,

longitude  $(\bar{\iota})$ , and altitude  $(\bar{h})$  above the planetary ellipsoid into a 3-by-1 vector of ECEF position  $(\bar{p})$ . The ECEF position is calculated from geocentric latitude at mean sea-level  $(\lambda_{i})$  and longitude using:

$$\overline{p} = \begin{bmatrix} \overline{p}_x \\ \overline{p}_y \\ \overline{p}_z \end{bmatrix} = \begin{bmatrix} r_s \cos \lambda_s \cos \iota + h \cos \mu \cos \iota \\ r_s \cos \lambda_s \sin \iota + h \cos \mu \sin \iota \\ r_s \sin \lambda_s + h \sin \mu \end{bmatrix}$$

where geocentric latitude at mean sea-level and the radius at a surface

point  $(r_s)$  are defined by flattening  $(\bar{f})$ , and equatorial radius  $(\bar{R})$  in the following relationships.

$$\lambda_s = \operatorname{atan}((1-f)^2 \tan \mu)$$

$$r_{s} = \sqrt{\frac{R^{2}}{1 + (1 / (1 - f)^{2} - 1) \sin^{2} \lambda_{s}}}$$

This option is only available when **Planet model** is set to Earth (WGS84).

#### **Planet model**

Specifies the planet model to use: Custom or Earth (WGS84).

#### Flattening

Specifies the flattening of the planet. This option is only available with **Planet model** set to Custom.

#### Equatorial radius of planet

Specifies the radius of the planet at its equator. The units of the equatorial radius parameter should be the same as the units for altitude. This option is only available with **Planet model** set to Custom.

Inputs and	
Outputs	

Input	<b>Dimension Type</b>	Description
First	2-by-1 vector	Contains the geodetic latitude and longitude, in degrees.
Second	Scalar	Contains the altitude above the planetary ellipsoid.
Output	Dimension Type	Description

Assumptions and	The planet is assumed to be ellipsoidal. To use a spherical planet, set the <b>Flattening</b> parameter to zero.			
Limitations	The implementation of the ECEF coordinate system assumes that the origin is at the center of the planet, the <i>x</i> -axis intersects the Greenwich meridian and the equator, the <i>z</i> -axis being the mean spin axis of the planet, positive to the north, and the <i>y</i> -axis completes the right-handed system.

LLA to Flat Earth

The LLA to Flat Earth block converts a geodetic latitude  $(\bar{\mu})$ , longitude

 $(\bar{\iota})$ , and altitude (h) into a 3-by-1 vector of Flat Earth position  $(\bar{p})$ . The flat Earth coordinate system assumes the *z*-axis is downward positive. The estimation begins by finding the small changes in latitude and longitude from the output latitude and longitude minus the initial latitude and longitude.

$$d\mu = \mu - \mu_0$$
$$d_1 = i - i_0$$

To convert geodetic latitude and longitude to the North and East coordinates, the estimation uses the radius of curvature in the prime vertical  $(R_N)$  and the radius of curvature in the meridian  $(R_M)$ .  $R_N$  and  $R_M$  are defined by the following relationships:

$$\begin{split} R_N &= \frac{R}{\sqrt{1 - (2f - f^2)\sin^2\mu_0}} \\ R_M &= R_N \, \frac{1 - (2f - f^2)}{1 - (2f - f^2)\sin^2\mu_0} \end{split}$$

where (R) is the equatorial radius of the planet and f is the flattening of the planet.

Small changes in the North (dN) and East (dE) positions are approximated from small changes in the North and East positions by

$$dN = \frac{d\mu}{\operatorname{atan}\left(\frac{1}{R_M}\right)}$$
$$dE = \frac{d\iota}{\operatorname{atan}\left(\frac{1}{R_N \cos \mu_0}\right)}$$

With the conversion of the North and East coordinates to the flat Earth x and y coordinates, the transformation has the form of

$$\begin{bmatrix} p_x \\ p_y \end{bmatrix} = \begin{bmatrix} \cos\psi & \sin\psi \\ -\sin\psi & \cos\psi \end{bmatrix} \begin{bmatrix} N \\ E \end{bmatrix}$$

where

 $(\psi)$ 

is the angle in degrees clockwise between the *x*-axis and north.

The flat Earth z-axis value is the negative altitude minus the reference height  $(h_{ref})$ .

$$p_z = -h - h_{ref}$$

#### Units

Specifies the parameter and output units:

Units	Position	Equatorial Radius	Altitude
Metric (MKS)	Meters	Meters	Meters
English	Feet	Feet	Feet

This option is available only when Planet model is set to Earth (WGS84).

#### **Planet model**

Specifies the planet model to use: Custom or Earth (WGS84).

#### Flattening

Specifies the flattening of the planet. This option is available only with **Planet model Custom**.

#### Equatorial radius of planet

Specifies the radius of the planet at its equator. The units of the equatorial radius parameter should be the same as the units for flat Earth position. This option is available only with **Planet model Custom**.

#### Initial geodetic latitude and longitude

Specifies the reference location, in degrees of latitude and longitude, for the origin of the estimation and the origin of the flat Earth coordinate system.

#### **Direction of flat Earth x-axis**

Specifies angle for converting flat Earth x and y coordinates to North and East coordinates.

Output	Dimension Type	Description
First	2-by-1 vector	Contains the geodetic latitude and longitude, in degrees.
Second	Scalar	Contains the altitude above the input reference altitude, in same units as flat Earth position.
Third	Scalar	Contains the reference height from the surface of the Earth to the flat Earth frame, in same units as flat Earth position. The reference height is estimated with regard to Earth frame.
Input	<b>Dimension Type</b>	Description
First	3-by-1 vector	Contains the position in flat Earth frame.

### Inputs and Outputs

## LLA to Flat Earth

Assumptions and	<b>15</b> This estimation method assumes the flight path and bank angle zero.				
Limitations	This estimation method assumes the flat Earth <i>z</i> -axis is normal to the Earth at the initial geodetic latitude and longitude only. This method has higher accuracy over small distances from the initial geodetic latitude and longitude, and nearer to the equator. The longitude has higher accuracy with smaller variations in latitude. Additionally, longitude is singular at the poles.

## Purpose Create six-degrees-of-freedom multibody custom geometry block

Animation/MATLAB-Based Animation

Library

Description

The MATLAB Animation block creates a six-degrees-of-freedom multibody custom geometry block based on the Aero.Animation object. This block animates one or more vehicle geometries with x - y - z position and Euler angles through the specified bounding box, camera offset, and field of view. This block expects the rotation order z - y - x (psi, theta, phi).

To update the camera parameters in the animation, first set the parameters then close and double-click the block to reopen the MATLAB Animation window.

To access the dialog box for this block, right-click the block, then select **Mask Parameters**. Alternatively, double-click the block to display the MATLAB Animation window, then click the **Block Parameters** icon.

**Note** The underlying graphics system stores values in single precision. As a result, you might notice that motion at coordinate positions greater than approximately 1e6 appear unstable. This is because a single-precision number has approximately six digits of precision. The instability is due to quantization at the local value of the eps MATLAB function. To visualize more stable motion for coordinates beyond 1e6, either offset the input data to a local zero, or scale down the coordinate values feeding the visualization.

# **MATLAB** Animation

Dialog Box

Sink Block Parameters: MATLAB Animation		
AeroMATLABAnimation (mask) (link)		
AcromATLABANIMATION (mask) (tink) Animate one or more vehicle geometries with XYZ position and euler angles through the specified bounding box, camera offset, and field of view. By default, the camera aim point is the position of the first body lagged dynamically to indicate motion. The camera offset represents the distance from the camera aim point to the camera itself. To update the camera parameters in the animation, first set the parameters then close and reopen the animation window. Vehicle geometries can be specified using a variable name, a cell array of variable names, a filename string with quotes 'mygeom.mat', or a mixed cell array of variable names and strings, e.g., {'file1.mat', 'file2.mat', 'file3.ac', geomVar }. Currently, geometries specified in variables must exist in the MATLAB workspace and file names must exist in the current directory or be on the MATLAB path.		
Parameters		
Vehicles: 1		
Geometries (use 'quotes' on filenames):		
'astredwedge.mat'		
Bounding box coordinates:		
[-50,50,-50,50,50]		
Camera offset:		
[-150,-50,0]		
Camera view angle:		
3		
Sample time:		
0.2

#### Vehicles

Specifies the vehicle to animate. From the list, select from 1 to 10. The block mask inputs change to reflect the number of vehicles you select. Each vehicle has its own set of inputs, denoted by the number at the beginning of the input label.

#### Geometries

Specifies the vehicle geometries. You can specify these geometries using one of the following:

- Variable name, for example geomVar
- Cell array of variable names, for example {geomVar, AltGeomVar}
- String with single quotes, for example, 'astredwedge.mat'
- Mixed cell array of variable names and strings, for example {'file1.mat', 'file2.mat', 'file3.ac', geomVar}

**Note** All specified geometries specified must exist in the MATLAB workspace and file names must exist in the current folder or be on the MATLAB path.

## **Bounding box coordinates**

Specifies the boundary coordinates for the vehicle.

This parameter is not tunable during simulation. A change to this parameter takes effect after simulation stops.

#### **Camera** offset

Specifies the distance from the camera aim point to the camera itself.

This parameter is not tunable during simulation. A change to this parameter takes effect after simulation stops.

#### Camera view angle

Specifies the camera view angle. By default, the camera aim point is the position of the first body lagged dynamically to indicate motion.

This parameter is not tunable during simulation. A change to this parameter takes effect after simulation stops.

#### Sample time

Specify the sample time (-1 for inherited).

nputs and	Input	Dimension Type	Description
Outputs	First	Vector	Contains the altitude, the crossrange position, and the downrange position of the vehicle in Earth coordinates.
	Output	Dimension Type	Description
	First	Vectors	Contains the Euler angles (roll, pitch, and yaw) of the vehicle.

English (Velocity in kts)	Feet	Degrees Rankine	Knots	Pound force per square inch	Slug per cubic foot

#### Specification

Specify the atmosphere model type from one of the following atmosphere models. The default is MIL-STD-210C.

1976 COESA-extended U.S. Standard Atmosphere

This selection is linked to the COESA Atmosphere Model block. See the block reference for more information.

#### MIL-HDBK-310

This selection is linked to the Non-Standard Day 310 block. See the block reference for more information.

#### MIL-STD-210C

This selection is linked to the Non-Standard Day 210C block. See the block reference for more information.

#### Atmospheric model type

Select the representation of the atmospheric data.

Profile	Realistic atmospheric profiles associated with extremes at specified altitudes. Recommended for simulation of vehicles vertically traversing the atmosphere or when the total influence of the atmosphere is needed.
Envelope	Uses extreme atmospheric values at each altitude.

Recommended for vehicles only horizontally traversing the atmosphere without much change in altitude.

## Extreme parameter

Select the atmospheric parameter that is the extreme value.

High temperature	Option always available
Low temperature	Option always available
High density	Option always available
Low density	Option always available
High pressure	This option is available only when Envelope is selected for <b>Atmospheric</b> model type
Low pressure	This option is available only when Envelope is selected for Atmospheric model type

#### Frequency of occurrence

Select percent of time the values would occur.

Extreme values	This option is available only when Envelope is selected for <b>Atmospheric model type</b> .
1%	Option always available
5%	This option is available only when Envelope is selected for <b>Atmospheric model type</b> .

10%	Option always available
20%	This option is available only when Envelope is selected for <b>Atmospheric model type</b> .

#### Altitude of extreme value

Select geometric altitude at which the extreme values occur. Applies to the profile atmospheric model only.

5 km (16404 ft) 10 km (32808 ft) 20 km (65617 ft) 30 km (98425 ft) 40 km (131234 ft)

#### Action for out of range input

Specify if out-of-range input invokes a warning, error, or no action.

feet) and above the geometric altitude of 30,000 meters (approximately

Inputs and	Input	Dimension Type	Description
Outputs	First		Contains the geopotential height.
	Output	Dimension Type	Description
	First		Contains the temperature.
	Second		Contains the speed of sound.
	Third		Contains the air pressure.
	Fourth		Contains the air density.
Assumptions and Limitations	All values are held below the geometric altitude of 0 m (0 feet) and above the geometric altitude of 80,000 meters (approximately 262,000 feet). The envelope atmospheric model has a few exceptions where values are held below the geometric altitude of 1 kilometer (approximately 3,281		

98,425 feet). These exceptions arise from lack of data in MIL-STD-210C for these conditions.

In general, temperature values are interpolated linearly, and density values are interpolated logarithmically. Pressure and speed of sound are calculated using a perfect gas law. The envelope atmospheric model has a few exceptions where the extreme value is the only value provided as an output. Pressure in these cases is interpolated logarithmically. These envelope atmospheric model exceptions apply to all cases of high and low pressure, high and low temperature, and high and low density, excluding the extreme values and 1% frequency of occurrence. These exceptions arise from lack of data in MIL-STD-210C for these conditions.

Another limitation is that climatic data for the region south of 60°S latitude is excluded from consideration in MIL-STD-210C.

This block uses the metric version of data from the MIL-STD-210C specifications. Certain data within the envelope are inconsistent between metric and English versions for low density, low temperature, high temperature, low pressure, and high pressure. The most significant differences occur in the following values:

- For low density envelope data with 5% frequency, the density values in metric units are inconsistent at 4 km and 18 km and the density values in English units are inconsistent at 14 km.
- For low density envelope data with 10% frequency,
  - The density values in metric units are inconsistent at 18 km.
  - The density values in English units are inconsistent at 14 km.
- For low density envelope data with 20% frequency, the density values in English units are inconsistent at 14 km.
- For low temperature envelope data with 20% frequency, the temperature values at 20 km are inconsistent.
- For high pressure envelope data with 10% frequency, the pressure values in metric units at 8 km are inconsistent.

Dialog Box

A dem and

#### Natural frequency

The natural frequency of the actuator. The units of natural frequency are radians per second.

#### **Damping** ratio

The damping ratio of the actuator. A dimensionless parameter.

#### **Maximum deflection**

The largest actuator position allowable. The units of maximum deflection must be the same as the units of demanded actuator position.

#### **Minimum deflection**

The smallest actuator position allowable. The units of minimum deflection must be the same as the units of demanded actuator position.

#### **Rate limit**

The fastest speed allowable for actuator motion. The units of maximum rate must be the units of demanded actuator position per second.

#### **Initial position**

The initial position of the actuator. The units of initial position must be the same as the units of demanded actuator position.

If the specified value is less than the value of **Minimum deflection**, the block sets the value of **Minimum deflection** as the initial position value. If the specified value is greater than the value of **Maximum deflection**, the block sets the value of **Maximum deflection** as the initial position value.

#### **Initial velocity**

The initial velocity of the actuator. The units of initial velocity must be the same as the units of demanded actuator position per second.

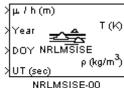

If the absolute value of the specified value is greater than the absolute value of **Rate Limit**, this block sets the value of **Rate Limit** as the initial velocity value.

# Library Environment/Atmosphere

# Description

Atmosphere Model

The NRLMSISE-00 Atmosphere Model block implements the mathematical representation of the 2001 United States Naval Research Laboratory Mass Spectrometer and Incoherent Scatter Radar Exosphere (NRLMSISE-00). This block calculates the neutral atmosphere empirical model from the surface to lower exosphere (0 to 1,000,000 meters). When configuring the block for this calculation, you can also take into account the anomalous oxygen, which can affect the satellite drag above 500,000 meters.

**Note** This block is valid only for altitudes between 0 and 1,000,000 meters (1,000 kilometers).

# Dialog Box

🔁 Function Block Parameters: NRLMSISE-00 Atmosphere Model 📃 🗾			
NRLMSISE-00 Model (mask) (link)			
Implement the mathematical representation of the 2001 United States Naval Research Laboratory Mass Spectrometer and Incoherent Scatter Radar Exosphere (NRLMSISE-00). NRLMSISE-00 calculates the neutral atmosphere empirical model from the surface to lower exosphere (0 to 1,000,000 meters) with the option of including contributions from anomalous oxygen which can affect satellite drag above 500,000 meters.			
Parameters			
Units: Metric (MKS)			
Input local apparent solar time			
Input flux and magnetic index information			
Source for flags: Internal			
Flags:			
ones(1,23)			
🗐 Include anomalous oxygen number density in total mass density			
Action for out of range input: Warning			
OK Cancel Help Apply			

# Units

Specifies the input and output units:

Units	Temperature	Height	Density
Metric (MKS)	Kelvin	Meters	kg/m <sup>3</sup> , some density outputs 1/m <sup>3</sup>
English	Rankine	Feet	lbm/ft <sup>3</sup> , some density outputs 1/ft <sup>3</sup>

#### Input local apparent solar time

Select this check box to input the local apparent solar time, in hours. Otherwise, the block inputs the default value.

#### Input flux and magnetic index information

Select this check box to input the 81-day average of F10.7, the daily F10.7 flux for the previous day, and the array of 7 magnetic index information (see the aph argument in the Aerospace Toolbox atmosnrlmsise00 function). Otherwise, the block inputs the default value.

#### Source for flags

Specify the variation flag source. If you specify External, you must enter the variation flag as an array of 23. If you specify Internal, the flag source is internal to the block.

#### Flags

Specify the variation flag as an array of 23. This parameter applies only when **Source for flags** has a value of Internal. You can specify one of the following values for a field. The default value for each field is 1.

• 0.0

Removes that value's effect on the output.

• 1.0

Applies the main and the cross-term effects of that value on the output.

• 2.0

Applies only the cross-term effect of that value on the output. The array has the following fields.

Field	Description	
Flags(1)	F10.7 effect on mean	
Flags(2)	Independent of time	

Field	Description
Flags(3)	Symmetrical annual
Flags(4)	Symmetrical semiannual
Flags(5)	Asymmetrical annual
Flags(6)	Asymmetrical semiannual
Flags(7)	Diurnal
Flags(8)	Semidiurnal
Flags(9)	Daily AP. If you set this field to -1, the block uses the entire matrix of magnetic index information (APH) instead of APH(:,1)
Flags(10)	All UT, longitudinal effects
Flags(11)	Longitudinal
Flags(12)	UT and mixed UT, longitudinal
Flags(13)	Mixed AP, UT, longitudinal
Flags(14)	Terdiurnal
Flags(15)	Departures from diffusive equilibrium
Flags(16)	All exospheric temperature variations
Flags(17)	All variations from 120,000 meter temperature (TLB)
Flags(18)	All lower thermosphere (TN1) temperature variations
Flags(19)	All 120,000 meter gradient (S) variations
Flags(20)	All upper stratosphere (TN2) temperature variations
Flags(21)	All variations from 120,000 meter values (ZLB)

Field	Description
Flags(22)	All lower mesosphere temperature (TN3) variations
Flags(23)	Turbopause scale height variations

**Include anomalous oxygen number density in total mass density** Select this check box to take into account the anomalous oxygen when calculating the neutral atmosphere empirical model from the surface to lower exosphere (0 to 1,000,000 meters). Taking into account this number can affect the satellite drag above 500,000 meters.

#### Action for out of range input

Specify if out-of-range input invokes a warning, error, or no action.

Inputs and Outputs	Input	Dimension Type	Description
	First	Three-element matrix	Contains latitudes, in degrees, longitude, in degrees, and altitude, in selected length units.
	Second	Array	Contains N years.
	Third	Array	Contains N days of a year (1 to 365 (or 366)).
	Fourth	Array	Contains N seconds in a day, in universal time (UT).
	Fifth (Optional)	Array	Contains N local apparent solar time, in hours.
	Sixth (Optional)	Array	Contains N 81-day average of F10.7 flux, centered on day of year (doy).
	Seventh (Optional)	Array	Contains N daily F10.7 flux for previous day.

Input	Dimension Type	Description
Eight (Optional)	N-by-7 array	Contains N-by-7 of magnetic index information.
Ninth (Optional)	Array of 23	Contains flags to enable or disable particular variations for the outputs. See following table.

These flags, associated with the ninth input, enable or disable particular variations for the outputs.

Field	Description
Flags(1)	F10.7 effect on mean
Flags(2)	Independent of time
Flags(3)	Symmetrical annual
Flags(4)	Symmetrical semiannual
Flags(5)	Asymmetrical annual
Flags(6)	Asymmetrical semiannual
Flags(7)	Diurnal
Flags(8)	Semidiurnal
Flags(9)	Daily AP. If you set this field to -1, the block uses the entire matrix of magnetic index information (APH) instead of APH(:,1)
Flags(10)	All UT, longitudinal effects
Flags(11)	Longitudinal
Flags(12)	UT and mixed UT, longitudinal
Flags(13)	Mixed AP, UT, longitudinal
Flags(14)	Terdiurnal

Field	Description
Flags(15)	Departures from diffusive equilibrium
Flags(16)	All exospheric temperature variations
Flags(17)	All variations from 120,000 meter temperature (TLB)
Flags(18)	All lower thermosphere (TN1) temperature variations
Flags(19)	All 120,000 meter gradient (S) variations
Flags(20)	All upper stratosphere (TN2) temperature variations
Flags(21)	All variations from 120,000 meter values (ZLB)
Flags(22)	All lower mesosphere temperature (TN3) variations
Flags(23)	Turbopause scale height variations

The outputs are:

Output	Dimension Type	Description
First	Array	Contains N-by-2 values of temperature, in selected temperature units. The first column is exospheric temperature, the second column is temperature at altitude.
Second	Array	Contains N-by-9 values of densities in selected density units. See the following table:

These densities are associated with the second output.

Density	Description
Density(1)	Density of He
Density(2)	Density of O
Density(3)	Density of N2

Density	Description
Density(4)	Density of O2
Density(5)	Density of Ar
Density(6)	Total mass density
	Density(6), total mass density, is defined as the sum of the mass densities of He, O, N2, O2, Ar, H, and N. Optionally, Density(6) can include the mass density of anomalous oxygen making Density(6), the effective total mass density for drag.
Density(7)	Density of H
Density(8)	Density of N
Density(9)	Anomalous oxygen number density

# Assumptions and Limitations

The F107 and F107A values that are used to generate the model correspond to the 10.7 cm radio flux at the actual distance of the Earth from the Sun rather than the radio flux at 1 AU. The following site provides both classes of values:

ftp://ftp.ngdc.noaa.gov/STP/SOLAR\_DATA/SOLAR\_RADIO/FLUX/

# Pack net\_fdm Packet for FlightGear

<b>Purpose</b> Generate net_fdm packet for FlightGear
---

Library Animation/Flight Simulator Interfaces

# Description

>I >µ >h >ф Р >⊕ >Ψ	acket
------------------------------------	-------

The Pack net\_fdm Packet for FlightGear block creates, from separate inputs, a FlightGear net\_fdm data packet compatible with a particular version of FlightGear flight simulator. All the signals supported by the FlightGear net\_fdm data packet are supported by this block. The signals are arranged into six groups. Any group can be turned on or off. Zeros are inserted for packet values that are part of inactive signal groups.

See "Inputs and Outputs" on page 5-408 for details on signals and signal groups.

Supported FlightGear versions: v0.9.3, v0.9.8/0.9.8a, v0.9.9, v0.9.10, v1.0, v1.9.1, v2.0, v2.4, v2.6.

	O	I		

### **Output Signal**

The output signal is the FlightGear net\_fdm data packet.

**Examples** See asbh120 for an example of this block.

See Also FlightGear Preconfigured 6DoF Animation Generate Run Script Send net\_fdm Packet to FlightGear

Purpose	Provide joystick interface on Windows platform
Library	Animation/Animation Support Utilities
Description	The Pilot Joystick block provides a pilot joystick interface for a Windows platform. Roll, pitch, yaw, and throttle are mapped to the joystick $X$ , $Y$ , $R$ , and $Z$ channels respectively.
yaw > throttle >	You can also configure the block to output all channels by setting the <b>Output configuration</b> parameter to AllOutputs.

This block does not produce deployable code.

## **Pilot Joystick**

Dialog
Box

Source Block Parameters: Pilot Joystick					
PilotJoystick (mask) (link)					
Joystick interface for Windows platform. Outputs values are [-1,1] for centered values, [0,1] for non-centered values, and uint32 for the buttons in All Outputs mode. Output sense is positive for right-hand rule rotations on centered values (roll, pitch, and yaw).					
Roll, pitch, yaw, and throttle are mapped to the joystick X, Y, R, and Z channels resepectively. If the joystick does not support an R (a.k.a. rudder or "twist") channel, yaw output is set to zero. Outputs are of type double except for the buttons output in All Outputs mode. On non-windows platforms, this block currently outputs zeros. Note: pitch value has the opposite sense as that delivered by FlightGear's joystick interface.					
In the AllOutputs configuration, 6 analog channels are output from the first port, buttons are output from the second port as an unsigned 32-bit flag word, and the POV (point of view) indication is output from the third port in degrees as a scalar double. Different joystick devices can map individual channels in different ways. Buttons can be mapped differently as well. While the POV is being pressed, the output values range from 0 to 315 in increments of 45 degrees (360 is the same a 0). When the POV button is NOT being pressed, the operating system typically returns 655.35 degrees, so plan your logic accordingly.

## All Outputs Mode (All Values Double Precision, Except for Buttons) (Continued)

Purpose	Represent precision pilot model
---------	---------------------------------

## Library

Pilot Models

## Description

The Precision Pilot Model block represents the pilot model described in *Mathematical Models of Human Pilot Behavior*. (For more information, see [1]). This pilot model is a single input, single output (SISO) model that represents some aspects of human behavior when controlling aircraft. When modeling human pilot models, use this block for the most accuracy, compared to that provided by the Tustin Pilot Model and Crossover Pilot Model blocks.

This block is an extension of the Crossover Pilot Model block. When calculating the model, this block also takes into account the neuromuscular dynamics of the pilot. This block implements the following equation:

$$Y_p = K_p e^{-\tau s} \left( \frac{T_L s + 1}{T_I s + 1} \right) \left[ \frac{1}{\left( T_{N1} s + 1 \right) \left( \frac{s^2}{\omega_N^2} + \frac{2\zeta_N}{\omega_N} s + 1 \right)} \right]$$

In this equation:

Variable	Description
$K_p$	Pilot gain.
τ	Pilot delay time.
$T_L$	Time lead constant for the equalizer term.
$T_{I}$	Time lag constant.
$T_{NI}$	Time constant for the neuromuscular system.

Variable	Description
$\omega_N$	Undamped frequency for the neuromuscular system.
$\zeta_{\rm N}$	Damping ratio for the neuromuscular system.

A sample value for the natural frequency and the damping ratio of a human is 20 rad/s and 0.7, respectively. The term containing the lead-lag term is the equalizer form. This form changes depending on the characteristics of the controlled system. A consistent behavior of the model can occur at different frequency ranges other than the crossover frequency.

This block has non-linear behavior. If you want to linearize the block (for example, with one of the Simulink linmod functions), you might need to change the Pade approximation order. The Precision Pilot Model block implementation incorporates the Simulink Transport Delay block with the **Pade order (for linearization)** parameter set to 2 by default. To change this value, use the set\_param function, for example:

```
set_param(gcb, 'pade', '3')
```

# **Quaternions to Direction Cosine Matrix**

**Purpose** Convert quaternion vector to direction cosine matrix

Library Utilities/Axes Transformations

### Description

> Quat2DCM >

The Quaternions to Direction Cosine Matrix block transforms the four-element unit quaternion vector  $(q_0, q_1, q_2, q_3)$  into a 3-by-3 direction cosine matrix (DCM). The outputted DCM performs the coordinate transformation of a vector in inertial axes to a vector in body axes.

Using quaternion algebra, if a point P is subject to the rotation described by a quaternion q, it changes to P' given by the following relationship:

$$P' = qPq^{c}$$

$$q = q_{0} + iq_{1} + jq_{2} + kq_{3}$$

$$q^{c} = q_{0} - iq_{1} - jq_{2} - kq_{3}$$

$$P = 0 + ix + jy + kz$$

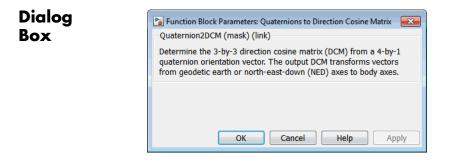

Expanding P' and collecting terms in x, y, and z gives the following for P' in terms of P in the vector quaternion format:

$$P' = \begin{bmatrix} 0\\ x'\\ y'\\ z' \end{bmatrix} = \begin{bmatrix} 0\\ (q_0^2 + q_1^2 - q_2^2 - q_3^2)x + 2(q_1q_2 - q_0q_3)y + 2(q_1q_3 + q_0q_2)z\\ 2(q_0q_3 + q_1q_2)x + (q_0^2 - q_1^2 + q_2^2 - q_3^2)y + 2(q_2q_3 - q_0q_1)z\\ 2(q_1q_3 - q_0q_2)x + 2(q_0q_1 + q_2q_3)y + (q_0^2 - q_1^2 - q_2^2 + q_3^2)z \end{bmatrix}$$

Since individual terms in P' are linear combinations of terms in x, y, and z, a matrix relationship to rotate the vector (x, y, z) to (x', y', z') can be extracted from the preceding. This matrix rotates a vector in inertial axes, and hence is transposed to generate the DCM that performs the coordinate transformation of a vector in inertial axes into body axes.

# **Quaternions to Direction Cosine Matrix**

$$DCM = \begin{bmatrix} (q_0^2 + q_1^2 - q_2^2 - q_3^2) & 2(q_1q_2 + q_0q_3) & 2(q_1q_3 - q_0q_2) \\ 2(q_1q_2 - q_0q_3) & (q_0^2 - q_1^2 + q_2^2 - q_3^2) & 2(q_2q_3 + q_0q_1) \\ 2(q_1q_3 + q_0q_2) & 2(q_2q_3 - q_0q_1) & (q_0^2 - q_1^2 - q_2^2 + q_3^2) \end{bmatrix}$$

Description

>q [R<sub>1</sub>.R<sub>2</sub>.R<sub>3</sub>] >

The Quaternions to Rotation Angles block converts the four-element quaternion vector  $(q_0, q_1, q_2, q_3)$  into the rotation described by the three rotation angles (R1, R2, R3). The block generates the conversion by comparing elements in the direction cosine matrix (DCM) as a function of the rotation angles. The elements in the DCM are functions of a unit quaternion vector. For example, for the rotation order z - y - x, the DCM is defined as:

$$DCM = \begin{bmatrix} \cos\theta \cos\psi & -\sin\theta \\ (\sin\phi \sin\theta \cos\psi - \cos\phi \sin\psi) & (\sin\phi \sin\theta \sin\psi + \cos\phi \cos\psi) & \sin\phi \cos\theta \\ (\cos\phi \sin\theta \cos\psi + \sin\phi \sin\psi) & (\cos\phi \sin\theta \sin\psi - \sin\phi \cos\psi) & \cos\phi \cos\theta \end{bmatrix}$$

The DCM defined by a unit quaternion vector is:

$$DCM = \begin{bmatrix} (q_0^2 + q_1^2 - q_2^2 - q_3^2) & 2(q_1q_2 + q_0q_3) & 2(q_1q_3 - q_0q_2) \\ 2(q_1q_2 - q_0q_3) & (q_0^2 - q_1^2 + q_2^2 - q_3^2) & 2(q_2q_3 + q_0q_1) \\ 2(q_1q_3 + q_0q_2) & 2(q_2q_3 - q_0q_1) & (q_0^2 - q_1^2 - q_2^2 + q_3^2) \end{bmatrix}$$

From the preceding equation, you can derive the following relationships between DCM elements and individual rotation angles for a ZYX rotation order:

$$\begin{split} \phi &= \operatorname{atan}(DCM(2,3), DCM(3,3)) \\ &= \operatorname{atan}(2(q_2q_3 + q_0q_1), (q_0^2 - q_1^2 - q_2^2 + q_3^2)) \\ \theta &= \operatorname{asin}(-DCM(1,3)) \\ &= \operatorname{asin}(-2(q_1q_3 - q_0q_2)) \\ \psi &= \operatorname{atan}(DCM(1,2), DCM(1,1)) \\ &= \operatorname{atan}(2(q_1q_2 + q_0q_3), (q_0^2 + q_1^2 - q_2^2 - q_3^2)) \end{split}$$

where  $\Psi$  is R1,  $\Theta$  is R2, and  $\Phi$  is R3.

**Purpose** Estimate radius of ellipsoid planet at geocentric latitude

Library Flight Parameters

Description

> <sup>A</sup>s r<sub>s</sub> >

The Radius at Geocentric Latitude block estimates the radius  $(r_s)$  of an ellipsoid planet at a particular geocentric latitude  $(\lambda_s)$ .

The following equation estimates the ellipsoid radius  $(r_s)$  using flattening  $(\overline{f})$ , geocentric latitude  $(\overline{\lambda}_s)$ , and equatorial radius  $(\overline{R})$ .

$$r_{s} = \sqrt{\frac{R^{2}}{1 + \left[1 / (1 - f)^{2} - 1\right] \sin^{2} \lambda_{s}}}$$

### Purpose Receive net\_ctrl packet from FlightGear

Animation/Flight Simulator Interfaces

Library

# Description

Receive net\_ctrl packet from FlightGear The Receive net\_ctrl Packet from FlightGear block receives a network control and environment data packet, net\_ctrl, from the simulation of a Simulink model in the FlightGear simulator, or from a FlightGear session. This data packet is compatible with a particular version of FlightGear flight simulator. All the signals supported by the FlightGear net\_ctrl data packet are supported by this block. The signals are arranged into multiple groups. Any group can be turned on or off. Zeros are inserted for packet values that are part of inactive signal groups.

In Rapid Accelerator mode, if you run a model that contains this block , the block produces zeroes (0s). It does not produce deployable code. In Accelerator mode, the block works as expected.

For details on signals and signal groups, see "Inputs and Outputs" on page 5-408.

Supported FlightGear versions are:

- v0.9.3
- v0.9.8/0.9.8a
- v0.9.9
- v0.9.10
- v1.0
- v1.9.1
- v2.0
- v2.4
- v2.6

Determining the Source	To determine the source IP address, you can use one of several techniques, such as:				
IP Address	• Use 127.0.0.1 for the local computer (localhost).				
	• Ping another computer from a Windows cmd.exe (or UNIX shell) prompt:				
	C:\> ping andyspc				
	Pinging andyspc [144.213.175.92] with 32 bytes of data:

#### **FlightGear version**

Select your FlightGear software version.

Supported FlightGear versions are: v0.9.3, v0.9.8/0.9.8a, v0.9.9, v0.9.10, v1.0, v1.9.1, v2.0, v2.4, v2.6.

#### **Origin IP address**

Enter a valid IP address as a dot-decimal string. This IP address must be the address of the PC from which FlightGear is run.

For example, 10.10.10.3. You can also use a MATLAB expression that returns a valid IP address as a string. If FlightGear is run on the local PC, leave the default value of 127.0.0.1 (localhost).

#### **Origin port**

UDP port that the block accepts data from. The sender sends data to the port specified in this parameter. This value must match the **Origin port** parameter of the Generate Run Script block. It must be a unique port number that no other application on the PC uses. The site, http://en.wikipedia.org/wiki/List\_of\_TCP\_and\_UDP\_port\_numbers, lists commonly known UDP port numbers. To identify UDP port numbers already in use on your PC, type:

netstat -a -p UDP

#### Sample time

Specify the sample time (-1 for inherited).

The Relative Ratio block computes the relative atmospheric ratios, including relative temperature ratio ( $\theta$ ),  $\sqrt{\theta}$ , relative pressure ratio ( $\delta$ ), and relative density ratio ( $\sigma$ ).

 $\theta$  represents the ratio of the air stream temperature at a chosen reference station relative to sea level standard atmospheric conditions.

$$\theta = \frac{T}{T_0}$$

 $\delta$  represents the ratio of the air stream pressure at a chosen reference station relative to sea level standard atmospheric conditions.

$$\delta = \frac{P}{P_0}$$

 $\sigma$  represents the ratio of the air stream density at a chosen reference station relative to sea level standard atmospheric conditions.

$$\sigma = \frac{\rho}{\rho_0}$$

The Relative Ratio block icon displays the input units selected from the **Units** list.

**Purpose** Calculate quaternion from rotation angles

Utilities/Axes Transformations

### **Description**

Library

>[R<sub>1</sub>.R<sub>2</sub>.R<sub>3</sub>] q>

The Rotation Angles to Quaternions block converts the rotation described by the three rotation angles (R1, R2, R3) into the four-element quaternion vector ( $q_0$ ,  $q_1$ ,  $q_2$ ,  $q_3$ ). A quaternion vector represents a

rotation about a unit vector  $(\mu_x, \mu_y, \mu_z)$  through an angle  $\theta$ . A unit quaternion itself has unit magnitude, and can be written in the following vector format.

$$q = \begin{bmatrix} q_0 \\ q_1 \\ q_2 \\ q_3 \end{bmatrix} = \begin{bmatrix} \cos(\theta / 2) \\ \sin(\theta / 2) \mu_x \\ \sin(\theta / 2) \mu_y \\ \sin(\theta / 2) \mu_z \end{bmatrix}$$

An alternative representation of a quaternion is as a complex number,

$$q = q_0 + \boldsymbol{i}q_1 + \boldsymbol{j}q_2 + \boldsymbol{k}q_3$$

where, for the purposes of multiplication,

$$i^{2} = j^{2} = k^{2} = -1$$
$$ij = -ji = k$$
$$jk = -kj = i$$
$$ki = -ik = j$$

The benefit of representing the quaternion in this way is the ease with which the quaternion product can represent the resulting transformation after two or more rotations. Dialog Box

## Assumptions and Limitations

The limitations for the 'ZYX', 'ZXY', 'YXZ', 'YZX', 'XYZ', and 'XZY' implementations generate an R2 angle that is between  $\pm 90$  degrees, and R1 and R3 angles that are between  $\pm 180$  degrees.

The limitations for the 'ZYZ', 'ZXZ', 'YXY', 'YZY', 'XYX', and 'XZX' implementations generate an R2 angle that is between 0 and 180 degrees, and R1 and R3 angles that are between  $\pm 180$  degrees.

# Self-Conditioned [A,B,C,D]

Purpose	Implement state-space	controller in	self-conditioned form
	imprement state space	controller m	

Library GNC/Controls

Description

≻e ≻u\_meas u\_dem: The Self-Conditioned [A,B,C,D] block can be used to implement the state-space controller defined by

 $\begin{bmatrix} \dot{x} = Ax + Be \\ u = Cx + De \end{bmatrix}$ 

in the self-conditioned form

$$\dot{z} = (A - HC)z + (B - HD)e + Hu_{meas}$$
$$u_{dem} = Cz + De$$

The input  $u_{meas}$  is a vector of the achieved actuator positions, and the output  $u_{dem}$  is the vector of controller actuator demands. In the case that the actuators are not limited, then  $u_{meas} = u_{dem}$  and substituting the output equation into the state equation returns the nominal controller. In the case that they are not equal, the dynamics of the controller are set by the poles of *A*-*HC*.

Hence H must be chosen to make the poles sufficiently fast to track

 $u_{meas}$  but at the same time not so fast that noise on e is propagated to

 $u_{dem}$ . The matrix H is designed by a callback to the Control System Toolbox command place to place the poles at defined locations.

### Dialog Box

Function Block Parameters: Self-Conditioned [A,B,C,D]
Self-Conditioned (mask) (link)
Implement a state-space controller [A,B,C,D] in a self-conditioned form. If u_meas = u_dem, then the implemented controller is [A,B,C,D]. If u_meas is limited, e.g., rate limiting, then the poles of the controller become those defined in the mask dialog box. Uses call to Control Systems Toolbox function place.m when initializing.
Parameters

OK Cancel Help Apply

#### A-matrix

A-matrix of the state-space implementation.

#### **B-matrix**

B-matrix of the state-space implementation.

#### **C-matrix**

C-matrix of the state-space implementation.

#### **D-matrix**

D-matrix of the state-space implementation.

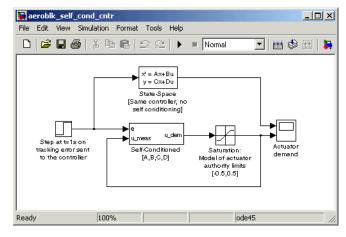

#### Initial state, x\_initial

This is a vector of initial states for the controller, i.e., initial values for the state vector, z. It should have length equal to the size of the first dimension of A.

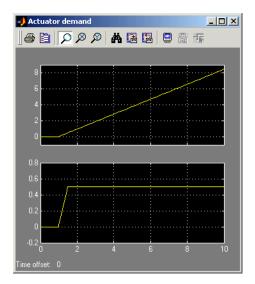

#### Poles of A-H\*C

This is a vector of the desired poles of A- $H^*C$ . Hence the number of pole locations defined should be equal to the dimension of the A-matrix.

Inputs and	Input	Dimension Type	Description
Outputs	First		Contains the control error.
	Second		Contains the measured actuator position.
	• • •		<b>-</b>
	Output	Dimension Type	Description
	First		Contains the actuator demands.
Assumptions and Limitations	Note This	block requires the Co	ontrol System Toolbox product.
Examples	This Simulink model shows a state-space controller implemented in both self-conditioned and standard state-space forms. The actuator authority limits of $\pm 0.5$ units are modeled by the saturation block.		

The top trace shows the conventional state-space implementation. The output of the controller winds up well past the actuator upper authority limit of +0.5. The lower trace shows that the self-conditioned form

results in an actuator demand that tracks the upper authority limit, which means that when the sign of the control error, e, is reversed, the actuator demand responds immediately.

# **Purpose** Transmit net\_fdm packet to destination IP address and port for FlightGear session

Animation/Flight Simulator Interfaces

**Description** 

Library

Send net\_fdm packet to Flight Gear The Send net\_fdm Packet to FlightGear block transmits the net\_fdm packet to FlightGear on the current computer, or a remote computer on the network. The packet is constructed using the Pack net\_fdm Packet for FlightGear block. The destination port should be an unused port that you can use when you launch FlightGear with the FlightGear command line flag:

--fdm=network,localhost,5501,5502,5503

The second port in the list, 5502, is the network flight dynamics model (fdm) port.

This block does not produce deployable code.

#### **Determining the Destination IP Address**

You can use one of several techniques to determine the destination IP address, such as:

- Use 127.0.0.1 for "this" computer
- Ping another computer from a Windows cmd.exe (or UNIX shell) prompt:

C:\> ping andyspc

Pinging andyspc [144.213.175.92] with 32 bytes of data:

The Simple Variable Mass 3DoF (Body Axes) block considers the rotation in the vertical plane of a body-fixed coordinate frame about an Earth-fixed reference frame.

The equations of motion are

$$\dot{u} = \frac{F_x}{m} - \frac{\dot{m}U}{m} - qw - g\sin\theta$$
$$\dot{w} = \frac{F_z}{m} - \frac{\dot{m}w}{m} + qu + g\cos\theta$$
$$\dot{q} = \frac{M - \dot{I}_{yy}q}{I_{yy}}$$
$$\dot{\theta} = q$$
$$\dot{I}_{yy} = \frac{I_{yyfull} - I_{yyempty}}{m_{full} - m_{empty}} \dot{m}$$

where the applied forces are assumed to act at the center of gravity of the body.

#### Units

Specifies the input and output units:

Units	Forces	Moment	Acceleration	Velocity	Position	Mass	Inertia
Metric (MKS)	Newton	Newton meter	Meters per second squared	Meters per second	Meters	Kilogram	Kilogram meter squared
English (Velocity in ft/s)	Pound /	Foot pound	Feet per second squared	Feet per second	Feet	Slug	Slug foot squared
English (Velocity in kts)	Pound /	Foot pound	Feet per second squared	Knots	Feet	Slug	Slug foot squared

#### Mass Type

Select the type of mass to use:

Fixed	Mass is constant throughout the simulation.
Simple Variable	Mass and inertia vary linearly as a function of mass rate.
Custom Variable	Mass and inertia variations are customizable.

The Simple Variable selection conforms to the previously described equations of motion.

#### **Initial velocity**

A scalar value for the initial velocity of the body,  $(V_0)$ .

#### Initial body attitude

A scalar value for the initial pitch attitude of the body,  $(\theta_0)$ .

#### Initial incidence

A scalar value for the initial angle between the velocity vector and the body,  $(\alpha_0)$ .

#### Initial body rotation rate

A scalar value for the initial body rotation rate,  $(q_0)$ .

#### Initial position (x,z)

A two-element vector containing the initial location of the body in the Earth-fixed reference frame.

#### **Initial mass**

A scalar value for the initial mass of the body.

#### **Empty mass**

A scalar value for the empty mass of the body.

#### Full mass

A scalar value for the full mass of the body.

#### **Empty inertia**

A scalar value for the empty inertia of the body.

#### Full inertia

A scalar value for the full inertia of the body.

#### **Gravity source**

Specify source of gravity:

External	Variable gravity input to block
Internal	Constant gravity specified in mask

#### Acceleration due to gravity

A scalar value for the acceleration due to gravity used if internal gravity source is selected. If gravity is to be neglected in the simulation, this value can be set to 0.

## Inputs and Outputs

Input	<b>Dimension Type</b>	Description
First		Contains the force acting along the body x-axis, $(F_x)$ .
Second		Contains the force acting along the body <i>z</i> -axis, $(F_z)$ .
Third		Contains the applied pitch moment, $(M)$ .
Fourth		Contains the rate of change of mass, $(\dot{m})$ .
Fifth (Optional	)	Contains the gravity in the selected units.

Output	<b>Dimension Type</b>	Description
First		Contains the pitch attitude, in radians $(\theta)$ .
Second		Contains the pitch angular rate, in radians per second $(q)$ .
Third		Contains the pitch angular acceleration, in radians per second squared $(\dot{q})$ .
Fourth	Two-element vector	Contains the location of the body, in the Earth-fixed reference frame, ( $Xe$ , $Ze$ ).
Fifth	Two-element vector	Contains the velocity of the body resolved into the body-fixed coordinate frame, $(u, w)$ .

Output	<b>Dimension Type</b>	Description
Sixth	Two-element vector	Contains the acceleration of the body resolved into the body-fixed coordinate frame, $(Ax,Az)$ .
Seventh	Scalar element	Contains a flag for fuel tank status, ( <i>Fuel</i> ):
		• 1 indicates that the tank is full.
		• 0 indicates that the integral is neither full nor empty.
		• -1 indicates that the tank is empty.

> anvat (kg/s) > g (m/s <sup>2</sup> )	Mass × z. α.(rad)> Fuel>

The Simple Variable Mass 3DoF (Wind Axes) block considers the rotation in the vertical plane of a wind-fixed coordinate frame about an Earth-fixed reference frame.

The equations of motion are

$$\begin{split} \dot{V} &= \frac{F_{x_{wind}}}{m} - \frac{\dot{m}V}{m} - g\sin\gamma \\ \dot{\alpha} &= \frac{F_{z_{wind}}}{mV} + q + \frac{g}{V}\cos\gamma \\ \dot{q} &= \dot{\theta} = \frac{M_{y_{body}} - \dot{I}_{yy}q}{I_{yy}} \\ \dot{\gamma} &= q - \dot{\alpha} \\ \dot{I}_{yy} &= \frac{I_{yyfull} - I_{yyempty}}{m_{full} - m_{empty}} \dot{m} \end{split}$$

where the applied forces are assumed to act at the center of gravity of the body.

## Simple Variable Mass 6DoF (Euler Angles)

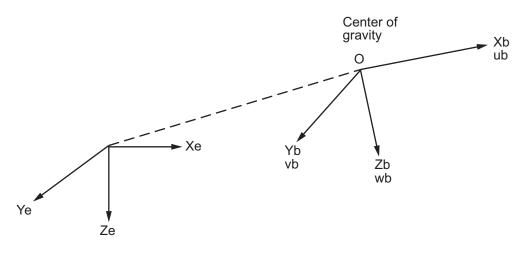

# **Purpose** Implement Euler angle representation of six-degrees-of-freedom equations of motion of simple variable mass

#### Library Equations of Motion/6DoF

### Description

F <sub>xyz</sub> (N)		V <sub>e</sub> (m/s) > X <sub>e</sub> (m) > φθψ (rad) >
> M <sub>xyz</sub> (N-m	Euler Angles	DCM > V <sub>b</sub> (m/s) > ω (rad/s) >
>dm/dt (kg	Mass	dco/dt> A <sub>b</sub> (m/s <sup>2</sup> )> Fuel>

The Simple Variable Mass 6DoF (Euler Angles) block considers the rotation of a body-fixed coordinate frame  $(X_b, Y_b, Z_b)$  about a flat Earth reference frame  $(X_e, Y_e, Z_e)$ . The origin of the body-fixed coordinate frame is the center of gravity of the body, and the body is assumed to be rigid, an assumption that eliminates the need to consider the forces acting between individual elements of mass. The flat Earth reference frame is considered inertial, an excellent approximation that allows the forces due to the Earth's motion relative to the "fixed stars" to be neglected.

Flat Earth reference frame

The translational motion of the body-fixed coordinate frame is given below, where the applied forces  $[F_x F_y F_z]^T$  are in the body-fixed frame.

$$\begin{split} \bar{F}_{b} &= \begin{bmatrix} F_{x} \\ F_{y} \\ F_{z} \end{bmatrix} = m(\dot{\bar{V}_{b}} + \bar{\omega} \times \bar{V}_{b}) + \dot{m}\bar{V}_{b} \\ \bar{V}_{b} &= \begin{bmatrix} u_{b} \\ v_{b} \\ w_{b} \end{bmatrix}, \bar{\omega} = \begin{bmatrix} p \\ q \\ r \end{bmatrix} \end{split}$$

The rotational dynamics of the body-fixed frame are given below, where the applied moments are  $[L M N]^T$ , and the inertia tensor *I* is with respect to the origin O.

$$\begin{split} \bar{M}_B &= \begin{bmatrix} L \\ M \\ N \end{bmatrix} = I\dot{\overline{\omega}} + \bar{\omega} \times (I\bar{\omega}) + \dot{I}\bar{\omega} \\ I &= \begin{bmatrix} I_{xx} & -I_{xy} & -I_{xz} \\ -I_{yx} & I_{yy} & -I_{yz} \\ -I_{zx} & -I_{zy} & I_{zz} \end{bmatrix} \end{split}$$

The inertia tensor is determined using a table lookup which linearly interpolates between  $I_{full}$  and  $I_{empty}$  based on mass (*m*). While the rate of change of the inertia tensor is estimated by the following equation.

$$\dot{I} = \frac{I_{full} - I_{empty}}{m_{full} - m_{empty}} \dot{m}$$

The relationship between the body-fixed angular velocity vector, [p q r]<sup>T</sup>,

and the rate of change of the Euler angles,  $[\dot{\phi}\dot{\theta}\dot{\psi}]^{T}$ , can be determined by resolving the Euler rates into the body-fixed coordinate frame.

$$\begin{bmatrix} p \\ q \\ r \end{bmatrix} = \begin{bmatrix} \dot{\phi} \\ 0 \\ 0 \end{bmatrix} + \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\phi & \sin\phi \\ 0 & -\sin\phi & \cos\phi \end{bmatrix} \begin{bmatrix} 0 \\ \dot{\theta} \\ 0 \end{bmatrix} + \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos\phi & \sin\phi \\ 0 & -\sin\phi & \cos\phi \end{bmatrix} \begin{bmatrix} \cos\theta & 0 & -\sin\theta \\ 0 & 1 & 0 \\ \sin\theta & 0 & \cos\theta \end{bmatrix} \begin{bmatrix} 0 \\ 0 \\ \psi \end{bmatrix} \equiv J^{-1} \begin{bmatrix} \dot{\phi} \\ \dot{\theta} \\ \psi \end{bmatrix}$$

Inverting  ${\cal J}$  then gives the required relationship to determine the Euler rate vector.

$$\begin{bmatrix} \dot{\phi} \\ \dot{\theta} \\ \psi \end{bmatrix} = J \begin{bmatrix} p \\ q \\ r \end{bmatrix} = \begin{bmatrix} 1 & (\sin\phi \tan\theta) & (\cos\phi \tan\theta) \\ 0 & \cos\phi & -\sin\phi \\ 0 & \frac{\sin\phi}{\cos\theta} & \frac{\cos\phi}{\cos\theta} \end{bmatrix} \begin{bmatrix} p \\ q \\ r \end{bmatrix}$$

Equations of Motion/6DoF

## **Description**

For a description of the coordinate system and the translational dynamics, see the block description for the Simple Variable Mass 6DoF (Euler Angles) block.

The integration of the rate of change of the quaternion vector is given below. The gain K drives the norm of the quaternion state vector to 1.0 should  $\varepsilon$  become nonzero. You must choose the value of this gain with care, because a large value improves the decay rate of the error in the norm, but also slows the simulation because fast dynamics are introduced. An error in the magnitude in one element of the quaternion vector is spread equally among all the elements, potentially increasing the error in the state vector.

$$\begin{bmatrix} \dot{q}_{0} \\ \dot{q}_{1} \\ \dot{q}_{2} \\ \dot{q}_{3} \end{bmatrix} = \frac{1}{2} \begin{bmatrix} 0 & -p & -q & -r \\ p & 0 & r & -q \\ q & -r & 0 & p \\ r & q & -p & 0 \end{bmatrix} \begin{bmatrix} q_{0} \\ q_{1} \\ q_{2} \\ q_{3} \end{bmatrix} + K\varepsilon \begin{bmatrix} q_{0} \\ q_{1} \\ q_{2} \\ q_{3} \end{bmatrix}$$

$$\varepsilon = 1 - \left( q_{0}^{2} + q_{1}^{2} + q_{3}^{2} + q_{4}^{2} \right)$$

## Simple Variable Mass 6DoF ECEF (Quaternion)

### Purpose

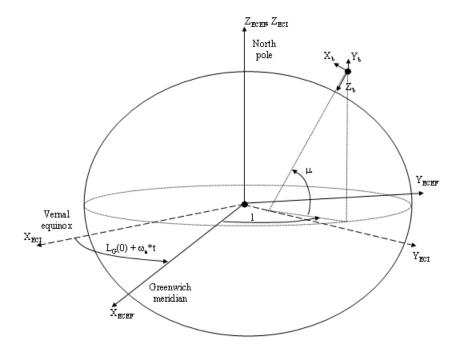

Implement quaternion representation of six-degrees-of-freedom equations of motion of simple variable mass in Earth-centered Earth-fixed (ECEF) coordinates

### Library Equations of Motion/6DoF

### Description

The Simple Variable Mass 6DoF ECEF (Quaternion) block considers the rotation of a Earth-centered Earth-fixed (ECEF) coordinate frame  $(X_{ECEF}, Y_{ECEF}, Z_{ECEF})$  about an Earth-centered inertial (ECI) reference frame  $(X_{ECF}, Y_{ECF}, Z_{ECI})$ . The origin of the ECEF coordinate frame is the center of the Earth, additionally the body of interest is assumed to be rigid, an assumption that eliminates the need to consider the forces acting between individual elements of mass. The representation of the rotation of ECEF frame from ECI frame is simplified to consider only the constant rotation of the ellipsoid Earth ( $\omega_e$ ) including an initial celestial longitude ( $L_G(0)$ ). This excellent approximation allows the forces due to the Earth's complex motion relative to the "fixed stars" to be neglected.

The translational motion of the ECEF coordinate frame is given below, where the applied forces  $[F_x F_y F_z]^T$  are in the body frame.

$$\begin{split} \bar{F}_{b} = \begin{bmatrix} F_{x} \\ F_{y} \\ F_{z} \end{bmatrix} = m \Big( \dot{\bar{V}}_{b} + \bar{\omega}_{b} \times \bar{V}_{b} + DCM_{bf} \bar{\omega}_{e} \times \bar{V}_{b} \Big) + DCM_{bf} \left( \bar{\omega}_{e} \times (\bar{\omega}_{e} \times \bar{X}_{f}) \right) \\ + \dot{m} \big( \bar{V}_{b} + DCM_{bf} (\bar{\omega}_{e} \times \bar{X}_{f}) \big) \end{split}$$

where the change of position in ECEF  $\dot{ar{x}}_f(\dot{ar{x}}_i)$  is calculated by

$$\dot{\bar{x}}_f = DCM_{fb}\bar{V}_b$$

and the velocity of the body with respect to ECEF frame, expressed in body frame  $(\bar{V}_b)$  , angular rates of the body with respect to ECI frame,

expressed in body frame  $(\bar{\omega}_b)$ . Earth rotation rate  $(\bar{\omega}_e)$ , and relative angular rates of the body with respect to north-east-down (NED) frame, expressed in body frame  $(\bar{\omega}_{rel})$  are defined as

$$\bar{V}_{b} = \begin{bmatrix} u \\ v \\ w \end{bmatrix} \bar{\varpi}_{rel} = \begin{bmatrix} p \\ q \\ r \end{bmatrix} \bar{\varpi}_{e} = \begin{bmatrix} 0 \\ 0 \\ \omega_{e} \end{bmatrix}$$

$$\overline{\omega}_{b} = \overline{\omega}_{rel} + DCM_{bf}\overline{\omega}_{e} + DCM_{be}\overline{\omega}_{ned}$$

$$\overline{\omega}_{ned} = \begin{bmatrix} \dot{l}\cos\mu \\ -\dot{\mu} \\ -\dot{l}\sin\mu \end{bmatrix} = \begin{bmatrix} V_E/(N+h) \\ -V_N/(M+h) \\ V_E\tan\mu/(N+h) \end{bmatrix}$$

The rotational dynamics of the body defined in body-fixed frame are given below, where the applied moments are  $[L M N]^{T}$ , and the inertia tensor I is with respect to the origin O.

$$\bar{M}_{b} = \begin{bmatrix} L \\ M \\ N \end{bmatrix} = \bar{I}\dot{\bar{\omega}}_{b} + \bar{\omega}_{b} \times (\bar{I}\bar{\omega}_{b}) + \dot{I}\bar{\omega}_{b}$$

$$I = \begin{bmatrix} I_{xx} & -I_{xy} & -I_{xz} \\ -I_{yx} & I_{yy} & -I_{yz} \\ -I_{zx} & -I_{zy} & I_{zz} \end{bmatrix}$$

The inertia tensor is determined using a table lookup which linearly interpolates between  $I_{\text{full}}$  and  $I_{\text{empty}}$  based on mass (*m*). The rate of change of the inertia tensor is estimated by the following equation.

$$\dot{I} = \frac{I_{full} - I_{empty}}{m_{full} - m_{empty}} \dot{m}$$

The integration of the rate of change of the quaternion vector is given below.

$$\begin{bmatrix} \dot{q}_{0} \\ \dot{q}_{1} \\ \dot{q}_{2} \\ \dot{q}_{3} \end{bmatrix} = -\frac{1}{2} \begin{bmatrix} 0 & \omega_{b}(1) & \omega_{b}(2) & \omega_{b}(3) \\ -\omega_{b}(1) & 0 & -\omega_{b}(3) & \omega_{b}(2) \\ -\omega_{b}(2) & \omega_{b}(3) & 0 & -\omega_{b}(1) \\ -\omega_{b}(3) & -\omega_{b}(2) & \omega_{b}(1) & 0 \end{bmatrix} \begin{bmatrix} q_{0} \\ q_{1} \\ q_{2} \\ q_{3} \end{bmatrix}$$

### Units

Specifies the input and output units:

## Simple Variable Mass 6DoF ECEF (Quaternion)

Units	Forces	Moment	Acceleration	Velocity	Position	Mass	Inertia
Metric (MKS)	Newton	Newton meter	Meters per second squared	Meters per second	Meters	Kilogram	Kilogram meter squared
English (Velocity in ft/s)	Pound y	Foot pound	Feet per second squared	Feet per second	Feet	Slug	Slug foot squared
English (Velocity in kts)	Pound y	Foot pound	Feet per second squared	Knots	Feet	Slug	Slug foot squared

#### Mass type

Select the type of mass to use:

Fixed	Mass is constant throughout the simulation (see 6DoF ECEF (Quaternion)).
Simple Variable	Mass and inertia vary linearly as a function of mass rate.
Custom Variable	Mass and inertia variations are customizable (see Custom Variable Mass 6DoF ECEF (Quaternion)).

The Simple Variable selection conforms to the previously described equations of motion.

#### Initial position in geodetic latitude, longitude and altitude

The three-element vector for the initial location of the body in the geodetic reference frame.

#### Initial velocity in body axes

The three-element vector containing the initial velocity of the body with respect to the ECEF frame, expressed in the body frame.

#### **Initial Euler orientation**

The three-element vector containing the initial Euler rotation angles [roll, pitch, yaw], in radians. Euler rotation angles are those between the body and NED coordinate systems.

#### Initial body rotation rates

The three-element vector for the initial angular rates of the body with respect to the NED frame, expressed the body frame, in radians per second.

#### **Initial mass**

The mass of the rigid body.

#### **Empty mass**

A scalar value for the empty mass of the body.

#### Full mass

A scalar value for the full mass of the body.

#### Empty inertia matrix

A 3-by-3 inertia tensor matrix for the empty inertia of the body.

#### Full inertia matrix

A 3-by-3 inertia tensor matrix for the full inertia of the body.

#### **Planet model**

Specifies the planet model to use: Custom or Earth (WGS84).

#### Flattening

Specifies the flattening of the planet. This option is only available when **Planet model** is set to Custom.

#### Equatorial radius of planet

Specifies the radius of the planet at its equator. The units of the equatorial radius parameter should be the same as the units for ECEF position. This option is only available when **Planet model** is set to **Custom**.

#### **Rotational rate**

Specifies the scalar rotational rate of the planet in rad/s. This option is only available when **Planet model** is set to Custom.

## Simple Variable Mass 6DoF ECEF (Quaternion)

#### Celestial longitude of Greenwich source

Specifies the source of Greenwich meridian's initial celestial longitude:

Internal	Use celestial longitude value from mask dialog.
External	Use external input for celestial longitude value.

#### **Celestial longitude of Greenwich**

The initial angle between Greenwich meridian and the *x*-axis of the ECI frame.

Input	Dimension Type	Description
First	Vector	Contains the three applied forces in body-fixed axes.
Second	Vector	Contains the three applied moments in body-fixed axes.
Third	Scalar	Contains the rate of change of mass.
Output	Dimension Type	Description
First	Three-element vector	Contains the velocity of body respect to ECEF frame, expressed in ECEF frame.
Second	Three-element vector	Contains the position in the ECEF reference frame.
Third	Three-element vector	Contains the position in geodetic latitude, longitude and altitude, in degrees, degrees and selected units of length respectively.
	First Second Third Output First Second	First Vector Second Vector Third Scalar Output Dimension Type First Three-element vector Second Three-element vector Third Three-element

Output	Dimension Type	Description
Fourth	Three-element vector	Contains the body rotation angles [roll, pitch, yaw], in radians. Euler rotation angles are those between body and NED coordinate systems.
Fifth	3-by-3 matrix	Applies to the coordinate transformation from ECI axes to body-fixed axes.
Sixth	3-by-3 matrix	Applies to the coordinate transformation from NED axes to body-fixed axes.
Seventh	3-by-3 matrix	Applies to the coordinate transformation from ECEF axes to NED axes.
Eighth	Three-element vector	Contains the velocity of body with respect to ECEF frame, expressed in body frame.
Ninth	Three-element vector	Contains the relative angular rates of body with respect to NED frame, expressed in body frame, in radians per second.
Tenth	Three-element vector	Contains the angular rates of the body with respect to ECI frame, expressed in body frame, in radians per second.
Eleventh	Three-element vector	Contains the angular accelerations of the body with respect to ECI frame, expressed in body frame, in radians per second squared.

Output	Dimension Type	Description
Twelfth	Three-element vector	Contains the accelerations in body-fixed axes.
Thirteenth	Scalar	Is an element containing a flag for fuel tank status:
		• 1 indicates that the tank is full.
		• 0 indicates that the integral is neither full nor empty.
		• -1 indicates that the tank is empty.

**Assumptions** This implementation assumes that the applied forces are acting at the center of gravity of the body.

Limitations

This implementation generates a geodetic latitude that lies between  $\pm 90$  degrees, and longitude that lies between  $\pm 180$  degrees. Additionally, the MSL altitude is approximate.

The Earth is assumed to be ellipsoidal. By setting flattening to 0.0, a spherical planet can be achieved. The Earth's precession, nutation, and polar motion are neglected. The celestial longitude of Greenwich is Greenwich Mean Sidereal Time (GMST) and provides a rough approximation to the sidereal time.

The implementation of the ECEF coordinate system assumes that the origin is at the center of the planet, the *x*-axis intersects the Greenwich meridian and the equator, the *z*-axis is the mean spin axis of the planet, positive to the north, and the *y*-axis completes the right-hand system.

The implementation of the ECI coordinate system assumes that the origin is at the center of the planet, the *x*-axis is the continuation of the line from the center of the Earth through the center of the Sun toward the vernal equinox, the *z*-axis points in the direction of the mean equatorial plane's north pole, positive to the north, and the *y*-axis completes the right-hand system.

## Simple Variable Mass 6DoF Wind (Quaternion)

### Purpose

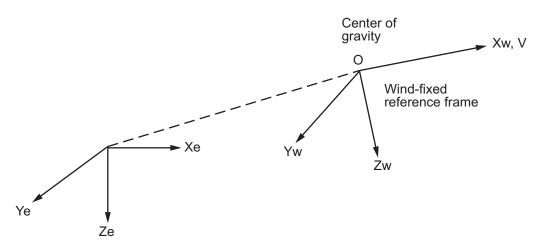

Implement quaternion representation of six-degrees-of-freedom equations of motion of simple variable mass with respect to wind axes

#### Library Equations of Motion/6DoF

### Description

The Simple Variable Mass 6DoF Wind (Quaternion) block considers the rotation of a wind-fixed coordinate frame  $(X_w, Y_w, Z_w)$  about an flat Earth reference frame  $(X_e, Y_e, Z_e)$ . The origin of the wind-fixed coordinate frame is the center of gravity of the body, and the body is assumed to be rigid, an assumption that eliminates the need to consider the forces acting between individual elements of mass. The flat Earth reference frame is considered inertial, an excellent approximation that allows the forces due to the Earth's motion relative to the "fixed stars" to be neglected.

Flat Earth reference frame

The translational motion of the wind-fixed coordinate frame is given below, where the applied forces  $[F_x F_v F_z]^T$  are in the wind-fixed frame.

$$\begin{split} \bar{F}_{w} &= \begin{bmatrix} F_{x} \\ F_{y} \\ F_{z} \end{bmatrix} = m(\dot{\bar{V}}_{w} + \bar{\omega}_{w} \times \bar{V}_{w}) + \dot{m}\bar{V}_{w} \\ \bar{V}_{w} &= \begin{bmatrix} V \\ 0 \\ 0 \end{bmatrix}, \bar{\omega}_{w} = \begin{bmatrix} p_{w} \\ q_{w} \\ r_{w} \end{bmatrix} = DMC_{wb} \begin{bmatrix} p_{b} - \dot{\beta}\sin\alpha \\ q_{b} - \dot{\alpha} \\ r_{b} + \dot{\beta}\cos\alpha \end{bmatrix}, \bar{w}_{b} \begin{bmatrix} p_{b} \\ q_{b} \\ r_{b} \end{bmatrix} \end{split}$$

The rotational dynamics of the body-fixed frame are given below, where the applied moments are  $[L M N]^T$ , and the inertia tensor *I* is with respect to the origin O. Inertia tensor *I* is much easier to define in body-fixed frame.

$$\begin{split} \bar{M}_b &= \begin{bmatrix} L \\ M \\ N \end{bmatrix} = I \dot{\bar{\omega}}_b + \bar{\omega}_b \times (I \bar{\omega}_b) + \dot{I} \bar{\omega}_b \\ I &= \begin{bmatrix} I_{xx} & -I_{xy} & -I_{xz} \\ -I_{yx} & I_{yy} & -I_{yz} \\ -I_{zx} & -I_{zy} & I_{zz} \end{bmatrix} \end{split}$$

The inertia tensor is determined using a table lookup which linearly interpolates between  $I_{full}$  and  $I_{empty}$  based on mass (*m*). While the rate of change of the inertia tensor is estimated by the following equation.

$$\dot{I} = \frac{I_{full} - I_{empty}}{m_{full} - m_{empty}} \dot{m}$$

The integration of the rate of change of the quaternion vector is given below.

$$\begin{bmatrix} \dot{q}_0 \\ \dot{q}_1 \\ \dot{q}_2 \\ \dot{q}_3 \end{bmatrix} = -1/2 \begin{bmatrix} 0 & p & q & r \\ -p & 0 & -r & q \\ -q & r & 0 & -p \\ -r & -q & p & 0 \end{bmatrix} \begin{bmatrix} q_0 \\ q_1 \\ q_2 \\ q_3 \end{bmatrix}$$

### Description

 
 F<sub>xyz</sub> (N)
 V (m/s), V (m/s), V (nd)

 Wind Angles
 μyz (nd), DOM, V (m/s), V ( For a description of the coordinate system employed and the translational dynamics, see the block description for the Simple Variable Mass 6DoF (Quaternion) block.

The relationship between the wind angles,  $[\mu\gamma\chi]^T$ , can be determined by resolving the wind rates into the wind-fixed coordinate frame.

$[p_w]$		μ		1	0	0	0		[1	0	0 ]	$\int \cos \gamma$	$0 - \sin \gamma$	][0]		Γµ̀]	
$q_w$	=	0	+	0	$\cos \mu$	$\sin \mu$	γ̈́	+	0	$\cos \mu$	$\sin \mu$	0	$\begin{array}{c} 0 & -\sin\gamma \\ 1 & 0 \\ 0 & \cos\gamma \end{array}$	0	$\equiv J^{-1}$	γ̈́	
$r_w$		0		0	$-\sin\mu$	$\cos \mu$	0		0	$-\sin\mu$	$\cos \mu$	$sin \gamma$	$0 \cos \gamma$	][ ż		χ	

Inverting  ${\cal J}$  then gives the required relationship to determine the wind rate vector.

$$\begin{bmatrix} \dot{\mu} \\ \dot{\gamma} \\ \dot{\chi} \end{bmatrix} = J \begin{bmatrix} p_w \\ q_w \\ r_w \end{bmatrix} = \begin{bmatrix} 1 & (\sin \mu \tan \gamma) & (\cos \mu \tan \gamma) \\ 0 & \cos \mu & -\sin \mu \\ 0 & \frac{\sin \mu}{\cos \gamma} & \frac{\cos \mu}{\cos \gamma} \end{bmatrix} \begin{bmatrix} p_w \\ q_w \\ r_w \end{bmatrix}$$

The body-fixed angular rates are related to the wind-fixed angular rate by the following equation.

$$\begin{bmatrix} p_w \\ q_w \\ r_w \end{bmatrix} = DMC_{wb} \begin{bmatrix} p_b - \dot{\beta} \sin \alpha \\ q_b - \dot{\alpha} \\ r_b + \dot{\beta} \cos \alpha \end{bmatrix}$$

Using this relationship in the wind rate vector equations, gives the relationship between the wind rate vector and the body-fixed angular rates.

$$\begin{bmatrix} \dot{\mu} \\ \dot{\gamma} \\ \dot{\chi} \end{bmatrix} = J \begin{bmatrix} p_w \\ q_w \\ r_w \end{bmatrix} = \begin{bmatrix} 1 & (\sin \mu \tan \gamma) & (\cos \mu \tan \gamma) \\ 0 & \cos \mu & -\sin \mu \\ 0 & \frac{\sin \mu}{\cos \gamma} & \frac{\cos \mu}{\cos \gamma} \end{bmatrix} DMC_{wb} \begin{bmatrix} p_b - \dot{\beta} \sin \alpha \\ q_b - \dot{\alpha} \\ r_b + \dot{\beta} \cos \alpha \end{bmatrix}$$

Purpose	Set simulation rate for improved animation viewing
Library	Animation/Animation Support Utilities
Description	The Simulation Pace block lets you run the simulation at the specified pace so that connected animations appear aesthetically pleasing.
Set Pace	This block does not produce deployable code.
	Use the <b>Sample time</b> parameter to set how often the Simulink interface synchronizes with the wall clock.

The sample time of this block should be considered for human interaction with visualizations. The default is 1/30th of a second, chosen to correspond to a 30 frames-per-second visualization rate (typical for desktop computers).

#### Caution

Choose as slow of a sample time as needed for smooth animation, since oversampling has little benefit and undersampling can cause animation "jumpiness" and potentially block the MATLAB main thread on your computer.

## **Simulation Pace**

Dialog Box

🔁 Block Parameters: Simulation Pace
Simulation Pace (mask) (link)
Run the simulation at the specified pace so that connected animations appear aesthetically pleasing.
The pace is the ratio: simulation seconds / clock seconds, such as 1 sim second per clock second, 86400 sec/sec, 0.001 sec/sec, etc. You can optionally output the "pace error" value from the block (simulationTime - ClockTime), in seconds. This means that the pace error is positive if the simulation is running faster than the specified pace and negative if slower than the specified pace. When Simulink is ahead of the pace, this block puts all MATLAB/Simulink computations to sleep so that other processes on the computer can run. NOTE: This block does NOT make the simulation run in real-time, it merely attempts to make the aggregate simulation pace match the specified clock pace.
Parameters
Simulation pace (sim sec per clock sec):
Sleep mode: MATLAB Thread
Output pace error (sec)
Sample time (-1 for inherited):
1/30
OK Cancel Help Apply

#### Simulation pace

Specifies the ratio of simulation time to clock time. The default is 1 second of simulation time per second of clock time.

#### Sleep mode

Setting the **Sleep mode** parameter to **off** lets you disable the pace functionality and run as fast as possible.

#### **Output pace error**

If you select this check box, the block outputs the "pace error" value (simulationTime minus ClockTime), in seconds. The pace

	error is positive if the simulation is running faster than the specified pace and negative if slower than the specified pace.
	Sample time Specify the sample time (-1 for inherited). Larger sample times result in more efficient simulations, but less smooth in output pace when there are multiple Simulink time steps between pacer block samples. If the <b>Sample time</b> is too large, the MATLAB interface may become less responsive as MATLAB and Simulink calculations are blocked from running when the block puts the MATLAB interface to sleep.
Inputs and Outputs	The block optionally outputs the "pace error" value (simulationTime minus ClockTime), in seconds. The pace error is positive if the simulation is running faster than the specified pace and negative if slower than the specified pace.
	Outputting the pace error from the block lets you record the overall pace achieved during the simulation or routing the signal to other blocks to make decisions about the simulation if the simulation is too slow to keep up with the specified pace.
Assumptions and Limitations	The simulation pace is implemented by putting the entire MATLAB thread to sleep until it needs to run again to keep up the pace. The Simulink software is single threaded and runs on the one MATLAB thread, so only one Simulation Pace block can be active at a time.
Examples	See asbh120 for an example of this block.

## SinCos

Purpose	Compute sine and cosine of angle
	<b>Note</b> SinCos will be removed in a future release. Use the Simulink Trigonometric Function block instead.
Library	Utilities/Math Operations
Description	The SinCos block computes the sine and cosine of the input angle, theta.
>sin(u) >cos(u)>	
Dialog Box	Block Parameters: SinCos     Image: SinCos (mask) (link)       Compute the sine and cosine of input, u. u is in radians.       OK     Cancel       Help     Apply
Inputs and Outputs	The first input is an angle, in radians. The first output is the sine of the input angle. The second output is the cosine of the input angle.

**Purpose** Implement spherical harmonic representation of planetary gravity

Library Environment/Gravity

### **Description**

The Spherical Harmonic Gravity Model block implements the mathematical representation of spherical harmonic planetary gravity based on planetary gravitational potential. It provides a convenient way to describe a planet gravitational field outside of its surface in spherical harmonic expansion.

You can use spherical harmonics to modify the magnitude and direction of spherical gravity (- $GM/r^2$ ). The most significant or largest spherical harmonic term is the second degree zonal harmonic, J2, which accounts for oblateness of a planet.

Use this block if you want more accurate gravity values than spherical gravity models. For example, nonatmospheric flight applications might require higher accuracy.

# Spherical Harmonic Gravity Model

# Units

Specifies the parameter and output units:

Units	Height
Metric (MKS)	Meters
English	Feet

## Degree

Specify the degree of harmonic model. Recommended degrees are:

Planet Model	Degree
EGM2008	120
EGM96	70
LP100K	60
LP165P	60
GMM2B	60
EIGENGL04C	70

# Action for out of range input

Specify if out-of-range input invokes a warning, error, or no action.

# Planet model

Specify the planetary model. From the list, select:

Planet Model	Notes	
EGM2008	Earth — Is the latest Earth spherical harmonic gravitational model from National Geospatial-Intelligence Agency (NGA). This block provides the WGS-84 version of this gravitational model. You can use the EGM96 planetary model if you need to use the older standard for Earth.	
EGM96	Earth	
LP100K	Moon — Is best for lunar orbit determination based upon computational time required to compute orbits. This planet model was created in approximately the same year as LP165P with similar data.	

Planet Model	Notes	
LP165P	Moon — Is best for extended lunar mission orbit accuracy. This planet model was created in approximately the same year as LP165P with similar data.	
GMM2B	Mars	
Custom	Enables you to specify your own planetary model. This option enables the <b>Planet</b> <b>mat-file</b> parameter.	
EIGENGL04C	Earth — Supports the gravity field model, EIGEN-GL04C (http://icgem.gfz-potsdam.de/ICGEM/). This model is an upgrade to EIGEN-CG03C.	

When defining your own planetary model, the **Degree** parameter is limited to the maximum value for int16. When inputting a large degree, you might receive an out-of-memory error. For more information about avoiding out-of-memory errors in the MATLAB environment, see "Memory Usage".

### **Planet mat-file**

Specify a MAT-file that contains definitions for a custom planetary model. The aerogmm2b.mat file in the Aerospace Toolbox is the default MAT-file for a custom planetary model.

This file must contain:

Variable	Description
Re	Scalar of planet equatorial radius in meters (m).
GM	Scalar of planetary gravitational parameter in meters cubed per second squared $(m^{3}/s^{2})$
degree	Scalar of maximum degree.

Variable	Description
С	( <i>degree</i> +1)-by-( <i>degree</i> +1) matrix containing normalized spherical harmonic coefficients matrix, <i>C</i> .
S	( <i>degree</i> +1)-by-( <i>degree</i> +1) matrix containing normalized spherical harmonic coefficients matrix, <i>S</i> .

When using a large value for **Degree**, you might receive an out-of-memory error. For more information about avoiding out-of-memory errors in the MATLAB environment, see "Memory Usage".

# Symmetric Inertia Tensor

# **Purpose** Create inertia tensor from moments and products of inertia

Library

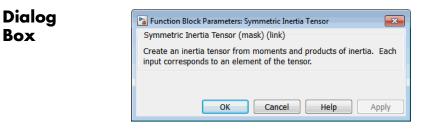

**Mass Properties** 

Description

The Symmetric Inertia Tensor block creates an inertia tensor from moments and products of inertia. Each input corresponds to an element of the tensor.

The inertia tensor has the form of

$$Inertia = \begin{bmatrix} I_{xx} & -I_{xy} & -I_{yz} \\ -I_{xy} & I_{yy} & -I_{xz} \\ -I_{yz} & -I_{xz} & I_{zz} \end{bmatrix}$$

Inputs and **Dimension Type** Input **Description** Outputs Contains the moment of inertia First about the *x*-axis. Second Contains the product of inertia in the *xy* plane. Third Contains the product of inertia in the *xz* plane. Fourth Contains the moment of inertia about the y-axis.

Input	<b>Dimension Type</b>	Description
Fifth		Contains the product of inertia in the $yz$ plane.
Sixth		Contains the moment of inertia about the <i>z</i> -axis.

Output	<b>Dimension Type</b>	Description
First		Contains a symmetric 3-by-3 inertia tensor.

# **Three-Axis Accelerometer**

# Library GNC/Navigation

# Description

| A<sub>b</sub> (m/s<sup>2</sup>) > ∞ (rad/s) > d∞/dt A<sub>m ess</sub> (m/s<sup>2</sup>) > CG (m) > g (m/s<sup>2</sup>) The Three-Axis Accelerometer block implements an accelerometer on

each of the three axes. The ideal measured accelerations  $(\bar{A}_{imeas})$ 

include the acceleration in body axes at the center of gravity ( $\bar{A}_b$ ), lever arm effects due to the accelerometer not being at the center of gravity, and, optionally, gravity in body axes can be removed.

$$\bar{A}_{imeas} = \bar{A}_b + \bar{\omega}_b \times (\bar{\omega}_b \times \bar{d}) + \dot{\bar{\omega}}_b \times \bar{d} - \bar{g}$$

where  $\bar{\omega}_b$  are body-fixed angular rates,  $\dot{\bar{\omega}}_b$  are body-fixed angular accelerations and  $\bar{d}$  is the lever arm. The lever arm ( $\bar{d}$ ) is defined as the distances that the accelerometer group is forward, right and below the center of gravity.

$$\overline{d} = \begin{bmatrix} d_x \\ d_y \\ d_z \end{bmatrix} = \begin{bmatrix} -(x_{acc} - x_{CG}) \\ y_{acc} - y_{CG} \\ -(z_{acc} - z_{CG}) \end{bmatrix}$$

The orientation of the axes used to determine the location of the accelerometer group  $(x_{acc}, y_{acc}, z_{acc})$  and center of gravity  $(x_{CG}, y_{CG}, z_{CG})$  is from the zero datum (typically the nose) to aft, to the right of the vertical centerline and above the horizontal centerline. The x-axis and z-axis of this measurement axes are opposite the body-fixed axes producing the negative signs in the lever arms for x-axis and z-axis.

Measured accelerations ( $\bar{A}_{meas}$ ) output by this block contain error sources and are defined as

$$\overline{A}_{meas} = \overline{A}_{imeas} \times \overline{A}_{SFCC} + \overline{A}_{bias} + noise$$

where  $\bar{A}_{SFCC}$  is a 3-by-3 matrix of scaling factors on the diagonal and

misalignment terms in the nondiagonal, and  $\bar{A}_{bias}$  are the biases.

Optionally discretizations can be applied to the block inputs and dynamics along with nonlinearizations of the measured accelerations via a Saturation block.

# Accelerometer location

The location of the accelerometer group is measured from the zero datum (typically the nose) to aft, to the right of the vertical

centerline and above the horizontal centerline. This measurement reference is the same for the center of gravity input. The units are in selected length units.

## Subtract gravity

Select to subtract gravity from acceleration readings.

## Second order dynamics

Select to apply second-order dynamics to acceleration readings.

## Natural frequency (rad/sec)

The natural frequency of the accelerometer. The units of natural frequency are radians per second.

# **Damping ratio**

The damping ratio of the accelerometer. A dimensionless parameter.

## Scale factors and cross-coupling

The 3-by-3 matrix used to skew the accelerometer from body axes and to scale accelerations along body axes.

# **Measurement bias**

The three-element vector containing long-term biases along the accelerometer axes. The units are in selected acceleration units.

# Update rate (sec)

Specify the update rate of the accelerometer. An update rate of 0 will create a continuous accelerometer. If noise is selected and the update rate is 0, then the noise will be updated at the rate of 0.1. The units of update rate are seconds.

## Noise on

Select to apply white noise to acceleration readings.

### Noise seeds

The scalar seeds for the Gaussian noise generator for each axis of the accelerometer.

### Noise power

The height of the PSD of the white noise for each axis of the accelerometer.

## Lower and upper output limits

The six-element vector containing three minimum values and three maximum values of acceleration in each of the accelerometer axes. The units are in selected acceleration units.

Inputs and	Input	Dimension Type	Description

	First	Three-element vector	Contains the measured accelerations from the accelerometer, in selected units.		
	Second	Three-element vector	Contains the measured angular rates from the gyroscope, in radians per second.		
Assumptions and Limitations	Vibropendulous error, hysteresis affects, anisoelastic bias and anisoinertial bias are not accounted for in this block. Additionally, this block is not intended to model the internal dynamics of different forms of the instrument.				
	<b>Note</b> This block requires the Control System Toolbox product for discrete operation (nonzero sample time).				
Examples	See asbh120 for an example of this block.

# Purpose Implement first-order representation of turbofan engine with controller

# **Library** Propulsion

# **Description**

> Throttle positi	' <sup>n</sup> Thrust (N) ;	spo
> Mach		m
> Altitude (m)	Fuel flow (kg/s)	T.

The Turbofan Engine System block computes the thrust and the weight of fuel flow of a turbofan engine and controller at a specific throttle position, Mach number, and altitude.

This system is represented by a first-order system with unitless heuristic lookup tables for thrust, thrust specific fuel consumption (TSFC), and engine time constant. For the lookup table data, thrust is a function of throttle position and Mach number, TSFC is a function of thrust and Mach number, and engine time constant is a function of thrust. The unitless lookup table outputs are corrected for altitude using the relative pressure ratio  $\delta$  and relative temperature ratio  $\theta$ , and scaled by maximum sea level static thrust, fastest engine time constant at sea level static, sea level static thrust specific fuel consumption, and ratio of installed thrust to uninstalled thrust.

The Turbofan Engine System block icon displays the input and output units selected from the **Units** list.

# Turbofan Engine System

Dialog Box

Pa Function Block Parameters: Turbofan Engine System
Turbofan Engine System (mask) (link)
Implement a turbofan engine system. The turbofan engine system includes both engine and controller.
Throttle position can vary from zero to one, corresponding to no and full throttle. Altitude, initial thrust, and maximum thrust are entered in the same unit system as selected from the block for thrust and fuel flow output.
Parameters
Units: Metric (MKS)
Initial thrust source: Internal
Initial thrust:
0
Maximum sea-level static thrust:
45000
Fastest engine time constant at sea-level static (sec):
1
Sea-level static thrust specific fuel consumption:
0.35
Ratio of installed thrust to uninstalled thrust:
0.9
OK Cancel Help Apply

# Units

Specifies the input and output units:

Units	Altitude	Thrust	Fuel Flow
Metric (MKS)	Meters	Newtons	Kilograms per second
English	Feet	Pound force	Pound mass per second

#### Initial thrust source

Specifies the source of initial thrust:

Internal	Use initial thrust value from mask dialog.
External	Use external input for initial thrust value.

#### **Initial thrust**

Initial value for thrust.

# Maximum sea-level static thrust

Maximum thrust at sea-level and at Mach = 0.

#### Fastest engine time constant at sea-level static Fastest engine time at sea level.

#### Sea-level static thrust specific fuel consumption

Thrust specific fuel consumption at sea level, at Mach = 0, and at maximum thrust, in specified mass units per hour per specified thrust units.

## Ratio of installed thrust to uninstalled thrust

Coefficient representing the loss in thrust due to engine installation.

Inputs and	Input	Dimension Type	Description
Outputs	First		Contains the throttle position, which can vary from zero to one, corresponding to no and full throttle.
	Second		Contains the Mach number.
	Third		Contains the altitude in specified length units.

	Output	Dimension Type	Description		
	First		Contains the thrust in specified force units.		
	Second		Contains the fuel flow in specified mass units per second.		
Assumptions	The atmosphere is at standard day conditions and an ideal gas.				
and Limitations	The Mach number is limited to less than 1.0.				
	This engine system is for indication purposes only. It is not meant to be used as a reference model.				
	This engine system is assumed to have a high bypass ratio.

# Purpose Represent Tustin pilot model

# Library

Pilot Models

# Description

The Tustin Pilot Model block represents the pilot model that A. Tustin describes in *The Nature of the Operator's Response in Manual Control, and its Implications for Controller Design*. (For more information, see [1].) When modeling human pilot models, use this block for the least accuracy, compared to that provided by the Crossover Pilot Model and Precision Pilot Model blocks. This block requires less input than those blocks, and provides better performance. However, the results might be less accurate.

This pilot model is a single input, single output (SISO) model that represents human behavior, based on the transfer function:

$$\frac{u(s)}{e(s)} = \frac{K_p(1+Ts)}{s}e^{-\tau s}$$

In this equation:

Variable	Description	
$K_p$	Pilot gain.	
T	Lead constant.	
τ	Transport delay time caused by the pilot neuromuscular system.	
<i>u(s)</i>	Input to the aircraft model and output to the pilot model.	
<i>e(s)</i>	Error between the desired pilot value and the actual value.	

This block has non-linear behavior. If you want to linearize the block (for example, with one of the Simulink linmod functions), you might need to change the Pade approximation order. The Tustin Pilot Model block implementation incorporates the Simulink Transport Delay block

# **Tustin Pilot Model**

with the **Pade order (for linearization)** parameter set to **2** by default. To change this value, use the **set\_param** function, for example:

set\_param(gcb, 'pade', '3')

Animation/Flight Simulator Interfaces

# Description

wind speed kt wind dir deg turbulence norm temp c packet press inhg hground magvar icing The Unpack net\_ctrl Packet from FlightGear block unpacks net\_ctrl variable packets received from FlightGear and makes them available for the Simulink environment.

Supported FlightGear versions:

- v0.9.3
- v0.9.8/0.9.8a
- v0.9.9
- v0.9.10
- v1.0
- v1.9.1
- v2.0
- v2.4
- v2.6

Dialog Box	Function Block Parameters: Unpack net_ctrl Packet from FlightGear
	FlightGearUnpackNetCtrl (mask) (link)
	Unpack a FlightGear net_ctrl data packet compatible with a particular version of FlightGear Flight Simulator.
	Press the help button for details on signals and signal groups.
	Parameters
	FlightGear version: v2.6
	Show control surface position outputs
	Show engine / fuel outputs
	Show landing gear outputs
	Show avionic outputs
	Show environment outputs
	Sample time (-1 for inherited):

#### FlightGear version

Select your FlightGear software version.

Supported FlightGear versions: v0.9.3, v0.9.8/0.9.8a, v0.9.9, v0.9.10, v1.0, v1.9.1, v2.0, v2.4, v2.6.

#### Show control surface position outputs

Select this check box to include the control surface position outputs (signal group 1) from the FlightGear net\_ctrl data packet.

#### Show engine/fuel outputs

Select this check box to include the engine and fuel outputs (signal group 2) from the FlightGear net\_ctrl data packet.

#### Show landing gear outputs

Select this check box to include the landing gear outputs (signal group 3) from the FlightGear net\_ctrl data packet.

#### Show avionic outputs

Select this check box to include the avionic outputs (signal group 4) from the FlightGear net\_ctrl data packet.

#### Show environment outputs

Select this check box to include the environment outputs (signal group 5) from the FlightGear net\_ctrl data packet.

#### Sample time

Specify the sample time (-1 for inherited).

# Inputs and<br/>OutputsOutput Signals Supported for FlightGear<br/>0.9.10/1.0/1.9.1/2.0/2.4/2.6

This table lists all the output signals supported for Versions 0.9.10, 1.0, 1.9.1, 2.0, 2.4, and 2.6:

Name	Units	Туре	Width	Description
aileron	geometry specific units [-1,1]	double	1	Aileron position.
elevator	geometry specific units [-1,1]	double	1	Elevator position.
rudder	geometry specific units [-1,1]	double	1	Rudder position.
aileron_trim	geometry specific units [-1,1]	double	1	Aileron trim position.

#### Signal Group 1: Control surface position outputs

Name	Units	Туре	Width	Description
elevator_trim	geometry specific units [-1,1]	double	1	Elevator trim position.
rudder_trim	geometry specific units [0,1]	double	1	Rudder trim position.
flaps	geometry specific units	double	1	Flaps position.
spoilers	geometry specific units	double	1	Spoilers position.
flaps_power	_	single	1	Power administered to the flaps (1 = power available).
flap_motor_ok	_	single	1	Shows whether or not the flap motor is working properly.

# Signal Group 1: Control surface position outputs (Continued)

# Signal Group 2: Engine/fuel outputs

Name	Units	Туре	Width	Description
num_engines	_	single	1	Number of valid engines.
master_bat	_	single	1	Master battery switch position.
master_alt	_	single	1	Master alternator switch position.
magnetos	_	single	1	Magnetos switch position.

Name	Units	Туре	Width	Description
starter_power	geometry specific units [0,1]	single	1	Starter power switch position (1 = starter power).
throttle	geometry specific units [0,1]	double	1	Throttle position.
mixture	geometry specific units [0,1]	double	1	Fuel mixture lever position.
condition	—	double	1	Condition lever position.
fuel_pump_power	_	single	1	Fuel pump power switch position (1 = on).
prop_advance	—	double	1	Propeller blade advance ratio.
feed_tank_to	—	single	1	Tank feed switch position.
reverse	_	single	1	Reverse switch position.
engine_ok	_	single	1	Indicates whether the engine is okay or not.
mag_left_ok	_	single	1	Indicates whether the left magneto is okay or not.

# Signal Group 2: Engine/fuel outputs (Continued)

Name	Units	Туре	Width	Description
mag_right_ok	_	single	1	Indicates whether the right magneto is okay or not.
spark_plugs_ok	_	single		Indicates whether the spark plugs are fouled or not (0 = fouled plugs).
oil_press_status	_	single		Oil pressure status indicator (0 = normal, 1 = low, 2 = full failure).
fuel_pump_ok	_	single		Indicates fuel pump status.
num_tanks	_	single		Number of valid tanks.
fuel_selector	_	single		Fuel selector switch position. There is one per each fuel tank. (0 = off, 1 = on).
xfer_pump	_	single		Specifies transfer from array value to tank specified by an integer value.
cross_feed	—	single		Cross feed fuel pump switch indicator (0 = off, 1 = on).

# Signal Group 2: Engine/fuel outputs (Continued)

Name	Units	Туре	Width	Description
brake_left	geometry- specific units	double	1	Left brake position for the pilot.
brake_right	geometry- specific units	double	1	Right brake position for the pilot.
copilot_brake_left	geometry- specific units	double	1	Left brake position for the copilot.
copilot_brake_right	geometry- specific units	double	1	Right brake position for the copilot.
brake_parking	geometry- specific units	double	1	Parking brake position.
gear_handle	—	single	1	Landing gear handle position (0 = gear handle up).

# Signal Group 3: Landing gear outputs

#### Signal Group 4: Avionics outputs

Name	Units	Туре	Width	Description
master_avionics	_	single	1	Master avionics switch.
comm_1	Hz	double	1	Communications primary frequency.

#### Purpose Generate continuous wind turbulence with Von Kármán velocity spectra

#### Library

Environment/Wind

# Description

>h (m)	Continuous
>V (m/s) >DGM	Von Karman <sub>ovind</sub> (rad/s) >

The Von Kármán Wind Turbulence Model (Continuous) block uses the Von Kármán spectral representation to add turbulence to the aerospace model by passing band-limited white noise through appropriate forming filters. This block implements the mathematical representation in the Military Specification MIL-F-8785C and Military Handbook MIL-HDBK-1797.

According to the military references, turbulence is a stochastic process defined by velocity spectra. For an aircraft flying at a speed V through a frozen turbulence field with a spatial frequency of  $\Omega$  radians per meter, the circular frequency  $\omega$  is calculated by multiplying V by  $\Omega$ . The following table displays the component spectra functions:

	MIL-F-8785C	MIL-HDBK-1797
Longitudinal		
$\Phi_u(\omega)$	$\frac{2\sigma_u^2 L_u}{\pi V} \cdot \frac{1}{\left[1 + \left(1.339 L_u \frac{\omega}{V}\right)^2\right]^{5/6}}$	$\frac{2\sigma_u^2 L_u}{\pi V} \cdot \frac{1}{\left[1 + \left(1.339 L_u \frac{\omega}{V}\right)^2\right]^{5/6}}$
$\Phi_p(\omega)$	$\frac{\sigma_w^2}{VL_w} \cdot \frac{0.8 \left(\frac{\pi L_w}{4b}\right)^{1/3}}{1 + \left(\frac{4b\omega}{\pi V}\right)^2}$	$\frac{\sigma_w^2}{2VL_w} \cdot \frac{0.8 \left(\frac{2\pi L_w}{4b}\right)^{1/3}}{1 + \left(\frac{4b\omega}{\pi V}\right)^2}$
Lateral		

	MIL-F-8785C	MIL-HDBK-1797

Vertical		
$\Phi_w(\omega)$	$\frac{\sigma_w^2 L_w}{\pi V} \cdot \frac{1 + \frac{8}{3} \left(1.339 L_w \frac{\omega}{V}\right)^2}{\left[1 + \left(1.339 L_w \frac{\omega}{V}\right)^2\right]^{\frac{11}{6}}}$	$\frac{2\sigma_w^2 L_w}{\pi V} \cdot \frac{1 + \frac{8}{3} \left(2.678 L_w \frac{\omega}{V}\right)^2}{\left[1 + \left(2.678 L_w \frac{\omega}{V}\right)^2\right]^{\frac{11}{6}}}$
$\Phi_q(\omega)$	$\frac{\pm \left(\frac{\omega}{V}\right)^2}{1 + \left(\frac{4b\omega}{\pi V}\right)^2} \cdot \Phi_w(\omega)$	$\frac{\pm \left(\frac{\omega}{V}\right)^{2}}{1 + \left(\frac{4b\omega}{\pi V}\right)^{2}} \cdot \Phi_{w}\left(\omega\right)$

The variable b represents the aircraft wingspan. The variables  $L_u$ ,  $L_v$ ,  $L_w$  represent the turbulence scale lengths. The variables  $\sigma_u$ ,  $\sigma_v$ ,  $\sigma_w$  represent the turbulence intensities:

The spectral density definitions of turbulence angular rates are defined in the references as three variations, which are displayed in the following table:

$$p_{g} = \frac{\partial w_{g}}{\partial y} \qquad q_{g} = \frac{\partial w_{g}}{\partial x} \qquad r_{g} = -\frac{\partial v_{g}}{\partial x}$$
$$p_{g} = \frac{\partial w_{g}}{\partial y} \qquad q_{g} = \frac{\partial w_{g}}{\partial x} \qquad r_{g} = \frac{\partial v_{g}}{\partial x}$$

$$p_g = -\frac{\partial w_g}{\partial y}$$
  $q_g = -\frac{\partial w_g}{\partial x}$   $r_g = \frac{\partial v_g}{\partial x}$ 

The variations affect only the vertical  $(\boldsymbol{q}_{g})$  and lateral  $(\boldsymbol{r}_{g})$  turbulence angular rates.

Keep in mind that the longitudinal turbulence angular rate spectrum,  $\Phi_p(\omega)$ , is a rational function. The rational function is derived from curve-fitting a complex algebraic function, not the vertical turbulence velocity spectrum,  $\Phi_w(\omega)$ , multiplied by a scale factor. Because the turbulence angular rate spectra contribute less to the aircraft gust response than the turbulence velocity spectra, it may explain the variations in their definitions.

The variations lead to the following combinations of vertical and lateral turbulence angular rate spectra.

Vertical	Lateral
$\Phi_q(\omega)$	$-\Phi_r(\omega)$
$\Phi_q(\omega)$	$\Phi_r(\omega)$
$-\Phi_q(\omega)$	$\Phi_r(\omega)$

# Von Karman Wind Turbulence Model (Continuous)

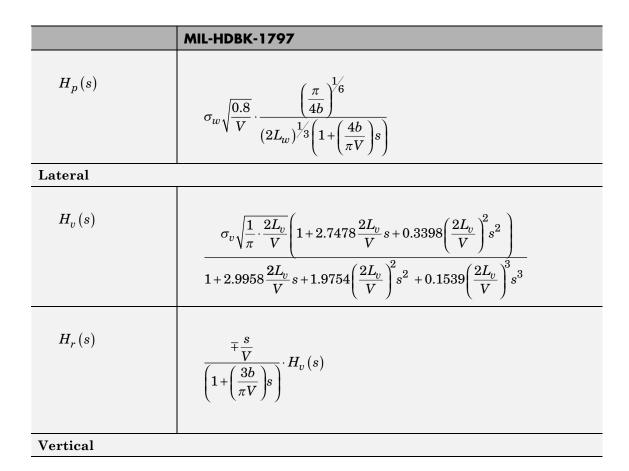

To generate a signal with the correct characteristics, a unit variance, band-limited white noise signal is passed through forming filters. The forming filters are approximations of the Von Kármán velocity spectra which are valid in a range of normalized frequencies of less than 50 radians. These filters can be found in both the Military Handbook MIL-HDBK-1797 and the reference by Ly and Chan.

 $\begin{array}{c|c} \hline \textbf{MIL-F-8785C} \\ \hline \textbf{Longitudinal} \\ \hline H_u(s) & \hline \\ & \frac{\sigma_u \sqrt{\frac{2}{\pi} \cdot \frac{L_u}{V}} \left(1 + 0.25 \frac{L_u}{V} s\right)}{1 + 1.357 \frac{L_u}{V} s + 0.1987 \left(\frac{L_u}{V}\right)^2 s^2} \\ \hline \\ & H_p(s) & \hline \\ & \sigma_w \sqrt{\frac{0.8}{V}} \cdot \frac{\left(\frac{\pi}{4b}\right)^{1/6}}{L_w^{1/3} \left(1 + \left(\frac{4b}{\pi V}\right)s\right)} \\ \hline \\ \hline \\ \textbf{Lateral} \\ \hline \\ & H_v(s) & \hline \\ & \frac{\sigma_v \sqrt{\frac{1}{\pi} \cdot \frac{L_v}{V}} \left(1 + 2.7478 \frac{L_v}{V} s + 0.3398 \left(\frac{L_v}{V}\right)^2 s^2\right)}{1 + 2.9958 \frac{L_v}{V} s + 1.9754 \left(\frac{L_v}{V}\right)^2 s^2 + 0.1539 \left(\frac{L_v}{V}\right)^3 s^3} \end{array}$ 

The following two tables display the transfer functions.

	MIL-F-8785C
$H_r(s)$	$\frac{\mp \frac{s}{V}}{\left(1\!+\!\left(\frac{3b}{\pi V}\right)\!s\right)}\!\cdot H_{v}\left(s\right)$

	MIL-HDBK-1797

	MIL-HDBK-1797
Longitudinal	
$H_{u}\left(s ight)$	$\frac{\sigma_u \sqrt{\frac{2}{\pi} \cdot \frac{L_u}{V}} \left(1 + 0.25 \frac{L_u}{V} s\right)}{1 + 1.357 \frac{L_u}{V} s + 0.1987 \left(\frac{L_u}{V}\right)^2 s^2}$

	MIL-HDBK-1797
$H_w(s)$	$\frac{\sigma_w \sqrt{\frac{1}{\pi} \cdot \frac{2L_w}{V}} \left(1 + 2.7478 \frac{2L_w}{V} s + 0.3398 \left(\frac{2L_w}{V}\right)^2 s^2\right)}{1 + 2.9958 \frac{2L_w}{V} s + 1.9754 \left(\frac{2L_w}{V}\right)^2 s^2 + 0.1539 \left(\frac{2L_w}{V}\right)^3 s^3}$
$H_q(s)$	$\frac{\pm \frac{s}{V}}{\left(1\!+\!\left(\frac{4b}{\pi V}\right)\!s\right)}\!\cdot H_{w}\left(s\right)$

Divided into two distinct regions, the turbulence scale lengths and intensities are functions of altitude.

**Note** The same transfer functions result after evaluating the turbulence scale lengths. The differences in turbulence scale lengths and turbulence transfer functions balance offset.

# Low-Altitude Model (Altitude < 1000 feet)

According to the military references, the turbulence scale lengths at low altitudes, where h is the altitude in feet, are represented in the following table:

MIL-F-8785C	MIL-HDBK-1797
$L_{w} = h$	$2L_w = h$
$L_{u} = L_{v} = \frac{h}{(0.177 + 0.000823h)^{1.2}}$	$L_u = 2L_v = \frac{h}{(0.177 + 0.000823h)^{1.2}}$

The turbulence intensities are given below, where  $W_{20}$  is the wind speed at 20 feet (6 m). Typically for light turbulence, the wind speed at 20 feet is 15 knots; for moderate turbulence, the wind speed is 30 knots; and for severe turbulence, the wind speed is 45 knots.

 $\sigma_{w} = 0.1W_{20}$   $\frac{\sigma_{u}}{\sigma_{w}} = \frac{\sigma_{v}}{\sigma_{w}} = \frac{1}{(0.177 + 0.000823h)^{0.4}}$ 

The turbulence axes orientation in this region is defined as follows:

- Longitudinal turbulence velocity,  $\boldsymbol{u}_{g},$  aligned along the horizontal relative mean wind vector
- Vertical turbulence velocity,  $w_{g}$ , aligned with vertical.

At this altitude range, the output of the block is transformed into body coordinates.

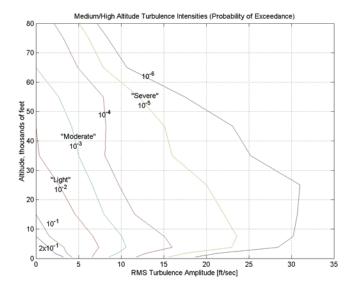

#### Medium/High Altitudes (Altitude > 2000 feet)

For medium to high altitudes the turbulence scale lengths and intensities are based on the assumption that the turbulence is isotropic. In the military references, the scale lengths are represented by the following equations:

MIL-F-8785C	MIL-HDBK-1797
$L_u = L_v = L_w = 2500 \text{ ft}$	$L_u=2L_v=2L_w=2500~{\rm ft}$

The turbulence intensities are determined from a lookup table that provides the turbulence intensity as a function of altitude and the probability of the turbulence intensity being exceeded. The relationship of the turbulence intensities is represented in the following equation:  $\sigma_u = \sigma_v = \sigma_w$ .

The turbulence axes orientation in this region is defined as being aligned with the body coordinates:

# Between Low and Medium/High Altitudes (1000 feet < Altitude < 2000 feet)

At altitudes between 1000 feet and 2000 feet, the turbulence velocities and turbulence angular rates are determined by linearly interpolating between the value from the low altitude model at 1000 feet transformed from mean horizontal wind coordinates to body coordinates and the value from the high altitude model at 2000 feet in body coordinates.

#### Units

Define the units of wind speed due to the turbulence.

Units	Wind Velocity	Altitude	e Air Speed
Metric (MKS)	Meters/second	Meters	Meters/second
English (Velocity in ft/s)	Feet/second	Feet	Feet/second
English (Velocity in kts)	Knots	Feet	Knots

#### Specification

Define which military reference to use. This affects the application of turbulence scale lengths in the lateral and vertical directions

#### Model type

Select the wind turbulence model to use:

Continuous -r)	Von	Karman	(+q	Use continuous representation of Von Kármán velocity spectra with positive vertical and negative lateral angular rates spectra.
Continuous +r)	Von	Karman	(+q	Use continuous representation of Von Kármán velocity spectra with positive vertical and lateral angular rates spectra.
Continuous +r)	Von	Karman	( - q	Use continuous representation of Von Kármán velocity spectra with negative vertical and positive lateral angular rates spectra.

# Von Karman Wind Turbulence Model (Continuous)

Continuous Dryden (+q -r)	Use continuous representation of Dryden velocity spectra with positive vertical and negative lateral angular rates spectra.
Continuous Dryden (+q +r)	Use continuous representation of Dryden velocity spectra with positive vertical and lateral angular rates spectra.
Continuous Dryden (-q +r)	Use continuous representation of Dryden velocity spectra with negative vertical and positive lateral angular rates spectra.
Discrete Dryden (+q -r)	Use discrete representation of Dryden velocity spectra with positive vertical and negative lateral angular rates spectra.
Discrete Dryden (+q +r)	Use discrete representation of Dryden velocity spectra with positive vertical and lateral angular rates spectra.
Discrete Dryden (-q +r)	Use discrete representation of Dryden velocity spectra with negative vertical and positive lateral angular rates spectra.

The Continuous Von Kármán selections conform to the transfer function descriptions.

#### Wind speed at 6 m defines the low altitude intensity

The measured wind speed at a height of 20 feet (6 meters) provides the intensity for the low-altitude turbulence model.

#### Wind direction at 6 m (degrees clockwise from north)

The measured wind direction at a height of 20 feet (6 meters) is an angle to aid in transforming the low-altitude turbulence model into a body coordinates.

#### Probability of exceedance of high-altitude intensity

Above 2000 feet, the turbulence intensity is determined from a lookup table that gives the turbulence intensity as a function of altitude and the probability of the turbulence intensity's being exceeded.

#### Scale length at medium/high altitudes

The turbulence scale length above 2000 feet is assumed constant, and from the military references, a figure of 1750 feet is recommended for the longitudinal turbulence scale length of the Dryden spectra.

**Note** An alternate scale length value changes the power spectral density asymptote and gust load.

#### Wingspan

The wingspan is required in the calculation of the turbulence on the angular rates.

#### Band-limited noise sample time (seconds)

The sample time at which the unit variance white noise signal is generated.

#### Noise seeds

There are four random numbers required to generate the turbulence signals, one for each of the three velocity components and one for the roll rate. The turbulences on the pitch and yaw angular rates are based on further shaping of the outputs from the shaping filters for the vertical and lateral velocities.

#### **Turbulence** on

Selecting the check box generates the turbulence signals.

# Von Karman Wind Turbulence Model (Continuous)

Inputs and	Input	Dimension Type	Description			
Outputs	First		Contains the altitude in units selected.			
	Second		Contains the aircraft speed in units selected.			
	Third		Contains a direction cosine matrix.			
	Output	<b>Dimension Type</b>	Description			
	First	Three-element signal	Contains the turbulence velocities, in the selected units.			
	Second	Three-element signal	Contains the turbulence angular rates, in radians per second.			
Assumptions and Limitations	The frozen turbulence field assumption is valid for the cases of mean-wind velocity and the root-mean-square turbulence velocity, or intensity, are small relative to the aircraft's ground speed.					
	The turbulence model describes an average of all conditions for clear air turbulence because the following factors are not incorporated into the model:					
	• Terrain roughness					
	• Lapse rate					
• Other meteorological factions (except altitude)

## WGS84 Gravity Model

## **Purpose** Implement 1984 World Geodetic System (WGS84) representation of Earth's gravity

### Library Environment/Gravity

### Description

The WGS84 Gravity Model block implements the mathematical representation of the geocentric equipotential ellipsoid of the World Geodetic System (WGS84). The block output is the Earth's gravity at a specific location. Gravity precision is controlled via the **Type of gravity model** parameter.

The WGS84 Gravity Model block icon displays the input and output units selected from the **Units** list.

### Dialog Box

Function Block Parameters: WGS84 Gravity Model				
WGS84 Gravity Model 3D (mask) (link)				
Calculate Earth's gravity at a specific location using World Geodetic System (WGS 84).				
The WGS 84 model is defined as a geocentric equipotential ellipsoid. This model can be found in NIMA TR8350.2, "Department of Defense World Geodetic System 1984, Its Definition and Relationship with Local Geodetic Systems."				
Height is entered in the same unit system as selected for gravity. Geodetic latitude and longitude are entered in degrees.				
Parameters				
Type of gravity model: WGS84 Taylor Series				
Units: Metric (MKS)				
Action for out of range input: Warning				
OK Cancel Help Apply				

### Type of gravity model

Specifies the method to calculate gravity:

- WGS84 Taylor Series
- WGS84 Close Approximation
- WGS84 Exact

### Units

Specifies the input and output units:

Units	Height	Gravity
Metric (MKS)	Meters	Meters per second squared
English	Feet	Feet per second squared

### **Exclude Earth's atmosphere**

Select for the value for the Earth's gravitational field to exclude the mass of the atmosphere.

Clear for the value for the Earth's gravitational field to include the mass of the atmosphere.

This option is available only with **Type of gravity model** WGS84 Close Approximation or WGS84 Exact.

#### **Precessing reference frame**

When selected, the angular velocity of the Earth is calculated using the International Astronomical Union (IAU) value of the Earth's angular velocity and the precession rate in right ascension. To obtain the precession rate in right ascension, Julian centuries from Epoch J2000.0 is calculated using the dialog parameters of **Month**, **Day**, and **Year**.

If cleared, the angular velocity of the Earth used is the value of the standard Earth rotating at a constant angular velocity.

### This option is available only with **Type of gravity model** WGS84 Close Approximation or WGS84 Exact.

### Input Julian date

When selected, another input port, JD, appears on the block mask. Select this check box if you want to manually specify the Julian date for the block. Otherwise, the block calculates the Julian date given the values of **Month**, **Day**, and **Year**. Selecting this block disables the **Month**, **Day**, and **Year** parameters.

#### Month

Specifies the month used to calculate Julian centuries from Epoch J2000.0.

This option is available only with **Type of gravity model WGS84 Close Approximation** or **WGS84 Exact** and only when **Precessing reference frame** is selected. It is disabled if you select **Input Julian Date**.

### Day

Specifies the day used to calculate Julian centuries from Epoch J2000.0.

This option is available only with **Type of gravity model WGS84 Close Approximation** or **WGS84 Exact** and only when **Precessing reference frame** is selected. It is disabled if you select **Input Julian Date**.

### Year

Specifies the year used to calculate Julian centuries from Epoch J2000.0. The year must be 2000 or greater.

This option is available only with **Type of gravity model WGS84 Close Approximation** or **WGS84 Exact** and only when **Precessing reference frame** is selected. It is disabled if you select **Input Julian Date**.

### No centrifugal effects

When selected, calculated gravity is based on pure attraction resulting from the normal gravitational potential.

If cleared, calculated gravity includes the centrifugal force resulting from the Earth's angular velocity.

This option is available only with **Type of gravity model** WGS84 Close Approximation or WGS84 Exact.

#### Action for out of range input

Inputs and Outputs Specify if out-of-range input invokes a warning, error, or no action.

Input	Dimension Type	Description
First	Three-element vector	Contains the position in geodetic latitude, longitude and altitude, with units in degrees, degrees, and selected units of length respectively.
Second (Option		Contains the Julian centuries that you specified.
Output	Dimension Type	Description
Output	Vector	Applies to gravity in the north-east-down (NED) coordinate system. The Exact method should output both normal and tangent gravity (down and north in the NED

Assumptions and Limitations	The WGS84 gravity calculations are based on the assumption of a geocentric equipotential ellipsoid of revolution. Since the gravity potential is assumed to be the same everywhere on the ellipsoid, there must be a specific theoretical gravity potential that can be uniquely determined from the four independent constants defining the ellipsoid.
	Use of the WGS84 Taylor Series model should be limited to low geodetic heights. It is sufficient near the surface when submicrogal precision is not necessary. At medium and high geodetic heights, it is less accurate.
	Use of the WGS84 Close Approximation model should be limited to a geodetic height of 20,000.0 m (approximately 65,620.0 feet). Below this height, it gives results with submicrogal precision.
	To predict and determine a satellite orbit with high accuracy, use the EGM96 through degree and order 70.
Examples	See the Environment Models subsystem in the Airframe subsystem of the aeroblk_HL20 model for an example of this block.
Reference	[1] NIMA TR8350.2: "Department of Defense World Geodetic System 1984, Its Definition and Relationship with Local Geodetic Systems."

### **Purpose** Convert wind angles to direction cosine matrix

### Library Util:

Utilities/Axes Transformations

### Description

The Wind Angles to Direction Cosine Matrix block converts three wind rotation angles into a 3-by-3 direction cosine matrix (DCM). The DCM matrix performs the coordinate transformation of a vector in earth axes  $(ox_0, oy_0, oz_0)$  into a vector in wind axes  $(ox_3, oy_3, oz_3)$ . The order of the axis rotations required to bring this about is:

- **1** A rotation about  $oz_0$  through the heading angle ( $\chi$ ) to axes ( $ox_1$ ,  $oy_1$ ,  $oz_1$ )
- **2** A rotation about  $oy_1$  through the flight path angle (y) to axes  $(ox_2, oy_2, oz_2)$
- **3** A rotation about  $ox_2$  through the bank angle ( $\mu$ ) to axes ( $ox_3$ ,  $oy_3$ ,  $oz_3$ )

$$\begin{bmatrix} ox_3 \\ oy_3 \\ oz_3 \end{bmatrix} = DCM_{we} \begin{bmatrix} ox_0 \\ oy_0 \\ oz_0 \end{bmatrix}$$

$\left[ ox_{3} \right]$		[1	0	0 ]	$\cos \gamma$	0	$-\sin\gamma$	$\cos \chi$	$\sin \chi$	$ \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix} \begin{bmatrix} ox_0 \\ oy_0 \\ oz_0 \end{bmatrix} $
oy <sub>3</sub>	=	0	$\cos \mu$	$\sin \mu$	0	1	0	$-\sin \chi$	$\cos \chi$	$0 \mid oy_0 \mid$
$\lfloor oz_3 \rfloor$		0	$-\sin\mu$	$\cos \mu$	$\sin \gamma$	0	$\cos \gamma$	0	0	$1 \left[ oz_0 \right]$

Combining the three axis transformation matrices defines the following DCM.

$$DCM_{we} = \begin{bmatrix} \cos\gamma\cos\chi & \cos\gamma\sin\chi & -\sin\gamma \\ (\sin\mu\sin\gamma\cos\chi - \cos\mu\sin\chi) & (\sin\mu\sin\gamma\sin\chi + \cos\mu\cos\chi) & \sin\mu\cos\gamma \\ (\cos\mu\sin\gamma\cos\chi + \sin\mu\sin\chi) & (\cos\mu\sin\gamma\sin\chi - \sin\mu\cos\chi & \cos\mu\cos\gamma \end{bmatrix}$$

# **Purpose** Calculate wind angular rates from body angular rates, angle of attack, sideslip angle, rate of change of angle of attack, and rate of change of sideslip

### Library Flight Parameters

### Description

The Wind Angular Rates block supports the equations of motion in wind-fixed frame models by calculating the wind-fixed angular rates

 $(p_w, q_w, r_w)$ . The body-fixed angular rates  $(p_b, q_b, r_b)$ , angle of attack  $(\alpha)$ , sideslip angle  $(\beta)$ , rate of change of angle of attack  $(\dot{\alpha})$ , and rate of

change of sideslip  $(\dot{\beta})$  are related to the wind-fixed angular rate by the following equation.

$$\begin{bmatrix} p_w \\ q_w \\ r_w \end{bmatrix} = \begin{bmatrix} \cos\alpha\cos\beta & \sin\beta & \sin\alpha\cos\beta \\ -\cos\alpha\sin\beta & \cos\beta & -\sin\alpha\sin\beta \\ -\sin\alpha & 0 & \cos\alpha \end{bmatrix} \begin{bmatrix} p_b - \dot{\beta}\sin\alpha \\ q_b - \dot{\alpha} \\ r_b + \dot{\beta}\cos\alpha \end{bmatrix}$$

Purpose Calculate wind shear conditions

Library Environment/Wind

### Description

>h (m) >DCM Shear V<sub>vind</sub> (m/s) >

> The Wind Shear Model block adds wind shear to the aerospace model. This implementation is based on the mathematical representation in the Military Specification MIL-F-8785C [1]. The magnitude of the wind shear is given by the following equation for the mean wind profile as a function of altitude and the measured wind speed at 20 feet (6 m) above the ground.

$$u_w = W_{20} \frac{\ln\left(\frac{h}{z_0}\right)}{\ln\left(\frac{20}{z_0}\right)}, \ 3ft < h < 1000ft$$

where  $u_w$  is the mean wind speed,  $W_{20}$  is the measured wind speed at an altitude of 20 feet, h is the altitude, and  $z_0$  is a constant equal to 0.15 feet for Category C flight phases and 2.0 feet for all other flight phases. Category C flight phases are defined in reference [1] to be terminal flight phases, which include takeoff, approach, and landing.

The resultant mean wind speed in the flat Earth axis frame is changed to body-fixed axis coordinates by multiplying by the direction cosine matrix (DCM) input to the block. The block output is the mean wind speed in the body-fixed axis.

## Wind Shear Model

Dialog Box

Pa Function Block Parameters: Wind Shear Model
Wind Shear Model (mask) (link)
Calculate the wind shear from conditions measured at a height of 6 meters (20 feet) above the ground.

### Wind speed at 6 m (20 feet) altitude (m/s, f/s, or knots)

The measured wind speed at an altitude of 20 feet (6 m) above the ground.

## Wind direction at 6 m (20 feet) altitude (degrees clockwise from north)

The direction of the wind at an altitude of 20 feet (6 m), measured in degrees clockwise from the direction of the Earth *x*-axis (north). The wind direction is defined as the direction from which the wind is coming.

Inputs and	Input	Dimension Type	Description	
Outputs	First		Contains the altitude in units selected.

English	Feet	Nanogauss	Nanogauss	Nanogauss

### Input decimal year

When selected, the decimal year is an input for the World Magnetic Model 2000 block. Otherwise, a date must be specified using the dialog parameters of **Month**, **Day**, and **Year**.

### Month

Specifies the month used to calculate decimal year.

### Day

Specifies the day used to calculate decimal year.

### Year

Specifies the year used to calculate decimal year.

### Action for out of range input

Specify if out-of-range input invokes a warning, error or no action.

### **Output horizontal intensity**

When selected, the horizontal intensity is output.

### **Output declination**

When selected, the declination, the angle between true north and the magnetic field vector (positive eastwards), is output.

### **Output** inclination

When selected, the inclination, the angle between the horizontal plane and the magnetic field vector (positive downwards), is output.

### **Output total intensity**

When selected, the total intensity is output.

Inputs and	Input	Dimension Type	Description
Outputs	First		Contains the height, in selected units.
	Second		Contains the latitude in degrees.

Dimension Type	Description
	Contains the longitude in degrees.
	Contains the desired year in a decimal format to include any fraction of the year that has already passed. The value is the current year plus the number of days that have passed in this year divided by 365.The following code illustrates how to calculate the decimal year, dyear, for March 21, 2005:
	%%%BEGIN CODE%%%
	dyear=decyear('21-March-2005','dd-mmm-yyyy') %%%END CODE%%%
	Dimension Type

Output	Dimension Type	Description
First		Contains the magnetic field vector in selected units.
Second (Optional)		Contains the horizontal intensity in selected units.
Third (Optional)		Contains the declination in degrees.
Fourth (Optional)		Contains the inclination in degrees.
Fifth (Optional)		Contains the total intensity in selected units.

## **Limitations** The WMM2000 specification produces data that is reliable five years after the epoch of the model, which is January 1, 2000.

The internal calculation of decimal year does not take into account local time or leap seconds.

The WMM2000 specification describes only the long-wavelength spatial<br/>magnetic fluctuations due to the Earth's core. Intermediate and<br/>short-wavelength fluctuations, contributed from the crustal field (the<br/>mantle and crust), are not included. Also, the substantial fluctuations<br/>of the geomagnetic field, which occur constantly during magnetic<br/>storms and almost constantly in the disturbance field (auroral zones),<br/>are not included.**Reference**Macmillian, S. and J. M. Quinn, 2000. Purpose Calculate zonal harmonic representation of planetary gravity

Library Environment/Gravity

### Description

>X<sub>ecer</sub> (m) g<sub>ecer</sub> (m/s<sup>2</sup>) :

The Zonal Harmonic Gravity Model block calculates the zonal harmonic representation of planetary gravity at a specific location based on planetary gravitational potential. This block provides a convenient way to describe the gravitational field of a planet outside its surface.

By default, the block uses the fourth order zonal coefficient for Earth to calculate the zonal harmonic gravity. It also allows you to specify the second or third zonal coefficient.

gravityzonal is implemented using the following planetary parameter values for each planet:

Planet	Equatorial Radius (Re) in Meters	Gravitational Parameter (GM) in m <sup>3</sup> /s <sup>2</sup>	Zonal Harmonic Coefficients (J Values)
Earth	6378.1363e3	3.986004415e14	[ 0.0010826269 -0.0000025323 -0.0000016204 ]
Jupiter	71492.e3	1.268e17	[0.01475 0 -0.00058]
Mars	3397.2e3	4.305e13	[ 0.001964 0.000036 ]
Mercury	2439.0e3	2.2032e13	0.00006
Moon	1738.0e3	4902.799e9	0.0002027
Neptune	24764e3	6.809e15	0.004
Saturn	60268.e3	3.794e16	[0.01645 0 -0.001]

Planet	Equatorial Radius (Re) in Meters	Gravitational Parameter (GM) in m <sup>3</sup> /s <sup>2</sup>	Zonal Harmonic Coefficients (J Values)
Uranus	25559.e3	5.794e15	0.012
Venus	6052.0e3	3.257e14	0.000027

Dialog Box

Punction Block Parameters: Zonal Harmonic Gravity Model		
Zonal Harmonic Gravity Model (mask) (link)		
Calculate a zonal harmonic representation of planetary gravity at a specific location based on planetary gravitational potential.		
The zonal harmonic gravity is calculated for planet using fourth order zonal coefficients by default.		
Position is entered in length units of selected unit system.		
Main Planet		
Units: Metric (MKS)

### Units

Specify the input units:

Units	Position	Equatorial Radius	Gravitational Parameter
Metric (MKS)	Meters	Meters	Meters cubed per second squared
English	Feet	Feet	Feet cubed per second squared

### Degree

Specify the degree of harmonic model.

• 2 — Second degree, J2. Most significant or largest spherical harmonic term, which accounts for the oblateness of a planet.

- 3 Third degree, J3.
- 4 Fourth degree, J4 (default).

#### Action for out of range input

Specify if out-of-range input invokes a warning, error, or no action.

#### **Planet model**

Specify the planetary model. From the list, select Mercury, Venus, Earth, Moon, Mars, Jupiter, Saturn, Uranus, Neptune, or Custom.

Selecting Custom enables you to specify your own planetary model. This option enables the Equatorial radius, Gravitational parameter, and J values parameters.

Selecting Mercury, Venus, Moon, Uranus, or Neptune limits the degree to 2.

Selecting Mars limits the degree to 3.

### **Equatorial radius**

Specify the planetary equatorial radius in the length units that the **Units** parameter defines.

#### Gravitational parameter

Specify the planetary gravitational parameter in the length units cubed per second squared that the **Units** parameter defines.

### J values

Specify a 3-element array that defines the zonal harmonic coefficients.

Inputs	and
Output	ts

This block accepts only scalar inputs (m=1).

Input	Dimensio Type	Dimension Description Type		
First	m-by-3 matrix	Contains planet-centered planet-fixed coordinates from the center of the planet in the selected length units. If <b>Planet</b> <b>model</b> has a value of Earth, this matrix contains Earth-centered Earth-fixed (ECEF) coordinates.		
Output	Dimension Description Type			
First	m-by-3 array	Contains gravity values in the <i>x</i> -axis, <i>y</i> -axis and <i>z</i> -axis of the planet-centered planet-fixed coordinates in the selected length units per second squared.

Horizontal Wind Model block 5-319

### 

Ideal Airspeed Correction block 5-322 Incidence & Airspeed block 5-326 Incidence, Sideslip & Airspeed block 5-328 Interpolate Matrix(x) block 5-336 Interpolate Matrix(x,y) block 5-339 Interpolate Matrix(x,y,z) block 5-342 Invert 3x3 Matrix block 5-346 ISA Atmosphere Model block 5-347

### J

Julian Epoch to Besselian Epoch block 5-349

### L

Lapse Rate Model block 5-352 latitude 2-16 Length Conversion block 5-357 lifting body (HL-20) 3-20 LLA to ECEF Position block 5-361 LLA to Flat Earth block 5-365

### M

Mach Number block 5-371 Mass Conversion block 5-373 MATLAB opening examples using the command line 1-16 MATLAB files running simulations from 2-11 Moments about CG due to Forces block 5-379

### Ν

NED coordinates 2-17 Non-Standard Day 210C block 5-381 Non-Standard Day 310 block 5-388 NRLMSISE-00 Model block 5-398

### Ρ

Pack net\_fdm Packet for FlightGear block 5-406 parameters tuning 2-10 Pilot Joystick All block 5-429 Pilot Joystick block 5-425 Precision Pilot Model 5-433 Pressure Altitude block 5-438 Pressure Conversion block 5-440

### Q

Quaternion Conjugate block 5-442 Quaternion Division block 5-444 Quaternion Inverse block 5-446 Quaternion Modulus block 5-448 Quaternion Multiplication block 5-450 Quaternion Norm block 5-452 Quaternion Normalize block 5-454 Quaternion Rotation block 5-456 Quaternions to Direction Cosine Matrix block 5-458 Quaternions to Rotation Angles block 5-460

### R

Radius at Geocentric Latitude block 5-463
Receive net\_ctrl Packet from FlightGear block 5-467
Relative Ratio block 5-472
Rotation Angles to Direction Cosine Matrix block 5-475

### S

Second Order Linear Actuator block 5-359 Second Order Nonlinear Actuator block 5-395 Self-Conditioned [A,B,C,D] block 5-480 Send net\_fdm Packet to FlightGear block 5-485 Simple Variable Mass 3DoF (Body Axes) block 5-488 Simple Variable Mass 3DoF (Wind Axes) block 5-495 Simple Variable Mass 6DoF (Euler Angles) block 5-502 Simple Variable Mass 6DoF (Quaternion) block 5-511 Simple Variable Mass 6DoF ECEF (Quaternion) block 5-518 Simple Variable Mass 6DoF Wind (Quaternion) block 5-530

Simple Variable Mass 6DoF Wind (Wind Angles) block 5-539 Simulation Pace block 5-547 simulations running from MATLAB file 2-11 Simulink modifying models 1-13 opening examples using the Help browser 1-16 using the Help browser 1-16 running examples 1-11 using the Simulink Library Browser 2-2 SinCos block 5-550 Symmetric Inertia Tensor block 5-558

### Т

Temperature Conversion block 5-560 Three-Axis Accelerometer block 5-562 Three-axis Gyroscope block 5-568 Three-Axis Inertial Measurement Unit block 5-573 tuning parameters 2-10 Turbofan Engine System block 5-581 Tustin Pilot Model 5-585

### U

Unpack net\_ctrl Packet from FlightGear block 5-588

### V

Velocity Conversion block 5-609 Von K\x87 rm\x87 n Wind Turbulence Model (Continuous) block 5-611

### W

WGS84 Gravity Model block 5-626
Wind Angles to Direction Cosine Matrix block 5-631
Wind Angular Rates block 5-633
wind coordinates 2-15
Wind Shear Model block 5-635
World Magnetic Model 2000 block 5-638
World Magnetic Model 2005 block 5-643
World Magnetic Model 2010 block 5-648
Wright Flyer 3-10
