API Reference

MAT-File Library (p. 1-2)	Incorporate and use MATLAB® data in C/C++ and Fortran programs
MX Matrix Library (p. 1-3)	Create and manipulate MATLAB arrays from C/C++ and Fortran MEX and engine routines
MEX Library (p. 1-10)	Perform operations in MATLAB environment from C/C++ and Fortran MEX-files
Engine Library (p. 1-12)	Call MATLAB software from C/C++ and Fortran programs

See also C/C++ and Fortran API Reference in the MATLAB Function Reference for interfaces to shared libraries, the SunTM JavaTM programming language, Microsoft[®] .NET, Component Object Model (COM), and ActiveX[®] technologies, Web services, and serial port devices.

MAT-File Library

matClose (C and Fortran) Close MAT-file matDeleteVariable (C and Delete array from MAT-file Fortran) MATFile (C and Fortran) Type for MAT-file matGetDir (C and Fortran) List of variables in MAT-file matGetFp (C) File pointer to MAT-file matGetNextVariable (C and Next array in MAT-file Fortran) matGetNextVariableInfo (C and Array header information only Fortran) matGetVariable (C and Fortran) Array from MAT-file matGetVariableInfo (C and Array header information only Fortran) matOpen (C and Fortran) Open MAT-file matPutVariable (C and Fortran) Array to MAT-file Array to MAT-file as originating matPutVariableAsGlobal (C and Fortran) from global workspace

MX Matrix Library

mwIndex (C and Fortran) Type for index values mwPointer (Fortran) Platform-independent pointer type mwSignedIndex (C and Fortran) Signed integer type for size values mwSize (C and Fortran) Type for size values mxAddField (C and Fortran) Add field to structure array mxArray (C) Type for MATLAB array mxArrayToString (C) rray to string mxAssert (C) Check assertion value for debugging purposes mxAssertS (C) Check assertion value without printing assertion text mxCalcSingleSubscript (C and Offset from first element to desired Fortran) element mxCalloc (C and Fortran) Allocate dynamic memory for array using MATLAB memory manager mxChar (C) Type for string array mxClassID (C) Enumerated value identifying class of array mxClassIDFromClassName Identifier corresponding to class (Fortran) mxComplexity (C) Flag specifying whether array has imaginary components mxCopyCharacterToPtr (Fortran) CHARACTER values from Fortran array to pointer array mxCopyComplex16ToPtr (Fortran) COMPLEX*16 values from Fortran array to pointer array mxCopyComplex8ToPtr (Fortran) COMPLEX*8 values from Fortran array to pointer array

mxCopyInteger1ToPtr (Fortran)	INTEGER*1 values from Fortran array to pointer array
mxCopyInteger2ToPtr (Fortran)	INTEGER*2 values from Fortran array to pointer array
mxCopyInteger4ToPtr (Fortran)	INTEGER*4 values from Fortran array to pointer array
mxCopyPtrToCharacter (Fortran)	CHARACTER values from pointer array to Fortran array
mxCopyPtrToComplex16 (Fortran)	COMPLEX*16 values from pointer array to Fortran array
mxCopyPtrToComplex8 (Fortran)	COMPLEX*8 values from pointer array to Fortran array
mxCopyPtrToInteger1 (Fortran)	INTEGER*1 values from pointer array to Fortran array
mxCopyPtrToInteger2 (Fortran)	INTEGER*2 values from pointer array to Fortran array
mxCopyPtrToInteger4 (Fortran)	INTEGER*4 values from pointer array to Fortran array
mxCopyPtrToPtrArray (Fortran)	Pointer values from pointer array to Fortran array
mxCopyPtrToReal4 (Fortran)	REAL*4 values from pointer array to Fortran array
mxCopyPtrToReal8 (Fortran)	REAL*8 values from pointer array to Fortran array
mxCopyReal4ToPtr (Fortran)	REAL*4 values from Fortran array to pointer array
mxCopyReal8ToPtr (Fortran)	REAL*8 values from Fortran array to pointer array
mxCreateCellArray (C and Fortran)	N-D cell array
mxCreateCellMatrix (C and Fortran)	2-D cell array

mxCreateCharArray (C and Fortran)	N-D string array
<pre>mxCreateCharMatrixFromStrings (C and Fortran)</pre>	2-D string array initialized to specified value
mxCreateDoubleMatrix (C and Fortran)	2-D, double-precision, floating-point array
mxCreateDoubleScalar (C and Fortran)	Scalar, double-precision array initialized to specified value
mxCreateLogicalArray (C)	N-D logical array
mxCreateLogicalMatrix (C)	2-D logical array
mxCreateLogicalScalar (C)	Scalar, logical array
mxCreateNumericArray (C and Fortran)	N-D numeric array
mxCreateNumericMatrix (C and Fortran)	2-D numeric matrix
mxCreateSparse (C and Fortran)	2-D sparse array
<pre>mxCreateSparseLogicalMatrix (C)</pre>	2-D, sparse, logical array
mxCreateString (C and Fortran)	1-N array initialized to specified string
mxCreateStructArray (C and Fortran)	N-D structure array
<pre>mxCreateStructMatrix (C and Fortran)</pre>	2-D structure array
mxDestroyArray (C and Fortran)	Free dynamic memory allocated by MXCREATE* functions
mxDuplicateArray (C and Fortran)	Make deep copy of array
mxFree (C and Fortran)	Free dynamic memory allocated by MXCALLOC, MXMALLOC, or MXREALLOC functions
mxGetCell (C and Fortran)	Contents of array cell

mxGetChars (C) Pointer to character array data mxGetClassID (C and Fortran) Class of array mxGetClassName (C and Fortran) Class of array as string mxGetData (C and Fortran) Pointer to real data mxGetDimensions (C and Pointer to dimensions array Fortran) mxGetElementSize (C and Number of bytes required to store Fortran) each data element mxGetEps (C and Fortran) Value of EPS mxGetField (C and Fortran) Field value, given field name and index, into structure array mxGetFieldByNumber (C and Field value, given field number and Fortran) index, into structure array mxGetFieldNameByNumber (C and Field name, given field number, in Fortran) structure array mxGetFieldNumber (C and Field number, given field name, in Fortran) structure array mxGetImagData (C and Fortran) Pointer to imaginary data of array mxGetInf (C and Fortran) Value of infinity mxGetIr (C and Fortran) Sparse matrix IR array mxGetJc (C and Fortran) Sparse matrix JC array mxGetLogicals (C) Pointer to logical array data mxGetM (C and Fortran) Number of rows in array mxGetN (C and Fortran) Number of columns in array mxGetNaN (C and Fortran) Value of NaN (Not-a-Number) mxGetNumberOfDimensions (C and Number of dimensions in array Fortran) mxGetNumberOfElements (C and Number of elements in array Fortran)

mxGetNumberOfFields (C and Fortran)	Number of fields in structure array
mxGetNzmax (C and Fortran)	Number of elements in IR, PR, and PI arrays
mxGetPi (C and Fortran)	Imaginary data elements in array of type DOUBLE
mxGetPr (C and Fortran)	Real data elements in array of type DOUBLE
mxGetProperty (C and Fortran)	Value of public property of MATLAB object
mxGetScalar (C and Fortran)	Real component of first data element in array
mxGetString (C and Fortran)	String array to C-style string
mxIsCell (C and Fortran)	Determine whether input is cell array
mxIsChar (C and Fortran)	Determine whether input is string array
mxIsClass (C and Fortran)	Determine whether array is member of specified class
mxIsComplex (C and Fortran)	Determine whether data is complex
mxIsDouble (C and Fortran)	Determine whether mxArray represents data as double-precision, floating-point numbers
mxIsEmpty (C and Fortran)	Determine whether array is empty
mxIsFinite (C and Fortran)	Determine whether input is finite
mxIsFromGlobalWS (C and Fortran)	Determine whether array was copied from MATLAB global workspace
mxIsInf (C and Fortran)	Determine whether input is infinite
mxIsInt16 (C and Fortran)	Determine whether array represents data as signed 16-bit integers
mxIsInt32 (C and Fortran)	Determine whether array represents data as signed 32-bit integers

mxIsInt64 (C and Fortran)	Determine whether array represents data as signed 64-bit integers
mxIsInt8 (C and Fortran)	Determine whether array represents data as signed 8-bit integers
mxIsLogical (C and Fortran)	Determine whether array is of type mxLogical
mxIsLogicalScalar (C)	Determine whether scalar array is of type mxLogical
mxIsLogicalScalarTrue (C)	Determine whether scalar array of type mxLogical is true
mxIsNaN (C and Fortran)	Determine whether input is NaN (Not-a-Number)
mxIsNumeric (C and Fortran)	Determine whether array is numeric
mxIsSingle (C and Fortran)	Determine whether array represents data as single-precision, floating-point numbers
mxIsSparse (C and Fortran)	Determine whether input is sparse array
mxIsStruct (C and Fortran)	Determine whether input is structure array
mxIsUint16 (C and Fortran)	Determine whether array represents data as unsigned 16-bit integers
mxIsUint32 (C and Fortran)	Determine whether array represents data as unsigned 32-bit integers
mxIsUint64 (C and Fortran)	Determine whether array represents data as unsigned 64-bit integers
mxIsUint8 (C and Fortran)	Determine whether array represents data as unsigned 8-bit integers
mxLogical (C)	Type for logical array
mxMalloc (C and Fortran)	Allocate dynamic memory using MATLAB memory manager

Reallocate dynamic memory using MATLAB memory manager mxRemoveField (C and Fortran) Remove field from structure array mxSetCell (C and Fortran) Value of one cell of array mxSetClassName (C) Structure array to MATLAB object array mxSetData (C and Fortran) Set pointer to data mxSetDimensions (C and Modify number of dimensions and Fortran) size of each dimension mxSetField (C and Fortran) Set structure array field, given structure field name and array index mxSetFieldByNumber (C and Set structure array field, given field Fortran) number and index mxSetImagData (C and Fortran) Imaginary data pointer for array mxSetIr (C and Fortran) IR array of sparse array mxSetJc (C and Fortran) JC array of sparse array mxSetM (C and Fortran) Number of rows in array mxSetN (C and Fortran) Set number of columns in array

mxRealloc (C and Fortran)

mxSetNzmax (C and Fortran)

mxSetPi (C and Fortran)

mxSetPr (C and Fortran)

mxSetProperty (C and Fortran)

Set new real data for array Set value of public property of MATLAB object

Set new imaginary data for array

Set storage space for nonzero

elements

MEX Library

mexAtExit (C and Fortran)	Register function to call when MEX-function cleared or MATLAB software terminates
mexCallMATLAB (C and Fortran)	Call MATLAB function, user-defined function, or MEX-file
mexCallMATLABWithTrap (C and Fortran)	Call MATLAB function, user-defined function, or MEX-file and capture error information
<pre>mexErrMsgIdAndTxt (C and Fortran)</pre>	Display error message with identifier and return to MATLAB prompt
mexErrMsgTxt (C and Fortran)	Display error message and return to MATLAB prompt
mexEvalString (C and Fortran)	Execute MATLAB command in caller workspace
mexEvalStringWithTrap (C and Fortran)	Execute MATLAB command in caller workspace and capture error information
mexFunction (C and Fortran)	Entry point to C/C++ or Fortran MEX-file
mexFunctionName (C and Fortran)	Name of current MEX-function
mexGet (C)	Value of specified Handle Graphics® property
mexGetVariable (C and Fortran)	Copy of variable from specified workspace
mexGetVariablePtr (C and Fortran)	Read-only pointer to variable from another workspace
mexIsGlobal (C and Fortran)	Determine whether variable has global scope
mexIsLocked (C and Fortran)	Determine whether MEX-file is locked

mexLock (C and Fortran) Prevent clearing MEX-file from memory mexMakeArrayPersistent (C and Make array persist after MEX-file Fortran) completes mexMakeMemoryPersistent (C and Make memory allocated by MATLAB Fortran) software persist after MEX-function completes mexPrintf (C and Fortran) ANSI® C PRINTF-style output routine mexPutVariable (C and Fortran) Array from MEX-function into specified workspace mexSet (C) Set value of specified Handle Graphics property mexSetTrapFlag (C and Fortran) Control response of MEXCALLMATLAB to errors Allow clearing MEX-file from mexUnlock (C and Fortran) memory mexWarnMsgIdAndTxt (C and Warning message with identifier Fortran) mexWarnMsgTxt (C and Fortran) Warning message

Engine Library

engClose (C and Fortran) Quit MATLAB engine session engEvalString (C and Fortran) Evaluate expression in string engGetVariable (C and Fortran) Copy variable from MATLAB engine workspace engGetVisible (C) Determine visibility of MATLAB engine session Engine (C) Type for MATLAB engine engOpen (C and Fortran) Start MATLAB engine session engOpenSingleUse (C) Start MATLAB engine session for single, nonshared use engOutputBuffer (C and Specify buffer for MATLAB output Fortran) engPutVariable (C and Fortran) Put variable into MATLAB engine workspace engSetVisible (C) Show or hide MATLAB engine session

API Reference

engClose (C and Fortran)

Purpose Quit MATLAB engine session

C Syntax #include "engine.h"

int engClose(Engine *ep);

Fortran

integer*4 engClose(ep)

Syntax mwPointer ep

Arguments ep

Engine pointer

Returns 0 on success, and 1 otherwise. Possible failure includes attempting to

terminate an already-terminated MATLAB engine session.

Description This routine sends a quit command to the MATLAB engine session

and closes the connection.

Examples See the following examples in matlabroot/extern/examples/eng_mat.

 \bullet engdemo.c for a C example on $UNIX^{\circledR}$ operating systems.

• engwindemo.c for a C example on Microsoft Windows® operating systems.

• fengdemo.F for a Fortran example.

See Also engOpen

engEvalString (C and Fortran)

Purpose Evaluate expression in string

C Syntax #include "engine.h"

int engEvalString(Engine *ep, const char *string);

Fortran Syntax

integer*4 engEvalString(ep, string)

mwPointer ep

character*(*) string

Arguments

ер

Engine pointer

string

String to execute

Returns

1 if the engine session is no longer running or the engine pointer is invalid or NULL. Otherwise, returns 0 even if the MATLAB engine session cannot evaluate the command.

Description

engEvalString evaluates the expression contained in string for the MATLAB engine session, ep, previously started by engOpen.

UNIX Operating Systems

On UNIX systems, engEvalString sends commands to the MATLAB workspace by writing down a pipe connected to the MATLAB stdin process. MATLAB reads back from stdout any output resulting from the command that ordinarily appears on the screen, into the buffer defined by engOutputBuffer.

To turn off output buffering in C, use:

```
engOutputBuffer(ep, NULL, 0);
```

To turn off output buffering in Fortran, use:

```
engOutputBuffer(ep, '')
```

engEvalString (C and Fortran)

Microsoft Windows Operating Systems

On a Windows system, engEvalString communicates with MATLAB software using a Component Object Model (COM) interface.

Examples

See the following examples in matlabroot/extern/examples/eng mat.

- engdemo.c for a C example on UNIX operating systems.
- engwindemo.c for a C example on Microsoft Windows operating systems.
- fengdemo.F for a Fortran example.

See Also

engOpen, engOutputBuffer

engGetVariable (C and Fortran)

Purpose Copy variable from MATLAB engine workspace

C Syntax #include "engine.h"

mxArray *engGetVariable(Engine *ep, const char *name);

Fortran mwPointer engGetVariable(ep, name)
Svntax mwPointer ep

Syntax mwPointer ep character*(*) name

Arguments ep

Arguments ep Engine pointer

name

Name of mxArray to get from MATLAB workspace

Returns Pointer to a newly allocated mxArray structure, or NULL if the attempt

fails. engGetVariable fails if the named variable does not exist.

Description engGetVariable reads the named mxArray from the MATLAB engine

session associated with ep.

Use mxDestroyArray to destroy the mxArray created by this routine

when you are finished with it.

Examples See the following examples in *matlabroot*/extern/examples/eng_mat.

• engdemo.c for a C example on UNIX operating systems.

• engwindemo.c for a C example on Microsoft Windows operating

systems.

See Also engPutVariable, mxDestroyArray

engGetVisible (C)

Purpose Determine visibility of MATLAB engine session

C Syntax #include "engine.h"

int engGetVisible(Engine *ep, bool *value);

Arguments ep

Engine pointer

value

Pointer to value returned from engGetVisible

Returns Microsoft Windows Operating Systems Only

0 on success, and 1 otherwise.

Description engGetVisible returns the current visibility setting for MATLAB

engine session, ep. A *visible* engine session runs in a window on the Windows desktop, thus making the engine available for user interaction. MATLAB removes an invisible session from the desktop.

Examples The following code opens engine session ep and disables its visibility.

Engine *ep;
bool vis;

ep = engOpen(NULL);
engSetVisible(ep, 0);

To determine the current visibility setting, use:

engGetVisible(ep, &vis);

See Also engSetVisible

Purpose

Type for MATLAB engine

Description

A handle to a MATLAB engine object.

Engine is a C language opaque type.

You can call MATLAB software as a computational engine by writing C and Fortran programs that use the MATLAB engine library. Engine is the link between your program and the separate MATLAB engine process.

The header file containing this type is:

#include "engine.h"

Examples

See the following examples in matlabroot/extern/examples/eng mat.

- engdemo.c shows how to call the MATLAB engine functions from a C program.
- engwindemo.c show how to call the MATLAB engine functions from a C program for Windows systems.
- fengdemo.F shows how to call the MATLAB engine functions from a Fortran program.

See Also

eng0pen

engOpen (C and Fortran)

Purpose Start MATLAB engine session

C Syntax #include "engine.h"

Engine *engOpen(const char *startcmd);

Fortran mwPointer engOpen(startcmd)
Syntax character*(*) startcmd

Arguments startcmd

String to start the MATLAB process. On Windows systems, the

startcmd string must be NULL.

Returns Pointer to an engine handle, or NULL if the open fails.

Description This routine allows you to start a MATLAB process for using MATLAB as a computational engine.

engOpen starts a MATLAB process using the command specified in the string startcmd, establishes a connection, and returns an engine pointer.

On UNIX systems, if startcmd is NULL or the empty string, engopen starts a MATLAB process on the current host using the command matlab. If startcmd is a hostname, engopen starts a MATLAB process on the designated host by embedding the specified hostname string into the larger string:

```
"rsh hostname \"/bin/csh -c 'setenv DISPLAY\
hostname:0; matlab'\""
```

If startcmd is any other string (has white space in it, or nonalphanumeric characters), MATLAB executes the string literally.

On UNIX systems, engOpen performs the following steps:

1 Creates two pipes.

engOpen (C and Fortran)

- **2** Forks a new process. Sets up the pipes to pass *stdin* and *stdout* from MATLAB (parent) software to two file descriptors in the engine program (child).
- **3** Executes a command to run MATLAB software (rsh for remote execution).

On Windows systems, engOpen opens a COM channel to MATLAB. The MATLAB software you registered during installation starts. If you did not register during installation, on the command line you can enter the command:

!matlab /regserver

See "MATLAB COM Integration" for additional details.

Examples

See the following examples in matlabroot/extern/examples/eng_mat.

- engdemo.c for a C example on UNIX operating systems.
- engwindemo.c for a C example on Microsoft Windows operating systems.
- fengdemo.F for a Fortran example.

engOpenSingleUse (C)

Purpose

Start MATLAB engine session for single, nonshared use

C Syntax

#include "engine.h"

Engine *engOpenSingleUse(const char *startcmd, void *dcom,

int *retstatus);

Arguments

startcmd

String to start MATLAB process. On Microsoft Windows systems,

the startcmd string must be NULL.

dcom

Reserved for future use; must be NULL.

retstatus

Return status; possible cause of failure.

Returns

Microsoft Windows Operating Systems Only

Pointer to an engine handle, or NULL if the open fails.

UNIX Operating Systems

Not supported on UNIX systems.

Description

This routine allows you to start multiple MATLAB processes using MATLAB as a computational engine.

engOpenSingleUse starts a MATLAB process, establishes a connection, and returns a unique engine identifier, or NULL if the open fails. Each call to engOpenSingleUse starts a new MATLAB process.

engOpenSingleUse opens a COM channel to MATLAB. This starts the MATLAB software you registered during installation. If you did not register during installation, on the command line you can enter the command:

!matlab /regserver

engOpenSingleUse (C)

engOpenSingleUse allows single-use instances of an engine server. engOpenSingleUse differs from engOpen, which allows multiple applications to use the same engine server.

See "MATLAB COM Integration" for additional details.

engOutputBuffer (C and Fortran)

```
Purpose
                   Specify buffer for MATLAB output
C Syntax
                   #include "engine.h"
                   int engOutputBuffer(Engine *ep, char *p, int n);
Fortran
                   integer*4 engOutputBuffer(ep, p)
                   mwPointer ep
Syntax
                   character*n p
Arguments
                   ер
                         Engine pointer
                   р
                         Pointer to character buffer
                   n
                         Length of buffer p
Returns
                   1 if you pass it a NULL engine pointer. Otherwise, returns 0.
Description
                   engOutputBuffer defines a character buffer for engEvalString to
                   return any output that ordinarily appears on the screen.
                   The default behavior of engEvalString is to discard any standard output
                   caused by the command it is executing. A call to engOutputBuffer with
                   a buffer of nonzero length tells any subsequent calls to engEvalString
                   to save output in the character buffer pointed to by p.
                   To turn off output buffering in C, use:
                   engOutputBuffer(ep, NULL, 0);
                   To turn off output buffering in Fortran, use:
                   engOutputBuffer(ep, '')
```

engOutputBuffer (C and Fortran)

Note The buffer returned by engEvalString is not NULL terminated.

Examples

See the following examples in matlabroot/extern/examples/eng mat.

- engdemo.c for a C example on UNIX operating systems.
- engwindemo.c for a C example on Microsoft Windows operating systems.
- fengdemo.F for a Fortran example.

See Also

engOpen, engEvalString

engPutVariable (C and Fortran)

Purpose Put variable into MATLAB engine workspace

C Syntax #include "engine.h"

int engPutVariable(Engine *ep, const char *name, const mxArray

*pm);

Fortran Syntax

integer*4 engPutVariable(ep, name, pm)

mwPointer ep, pm
character*(*) name

Arguments

ер

Engine pointer

name

Name of mxArray in the engine workspace

pm

mxArray pointer

Returns

0 if successful and 1 if an error occurs.

Description

engPutVariable writes mxArray pm to the engine ep, giving it the variable name name.

If the mxArray does not exist in the workspace, the function creates it. If an mxArray with the same name exists in the workspace, the function replaces the existing mxArray with the new mxArray.

Do not use MATLAB function names for variable names. Common variable names that conflict with function names include i, j, mode, char, size, or path. To determine whether a particular name is associated with a MATLAB function, use the which function.

The engine application owns the original mxArray and is responsible for freeing its memory. Although the engPutVariable function sends a copy of the mxArray to the MATLAB workspace, the engine application does not need to account for or free memory for the copy.

engPutVariable (C and Fortran)

Examples

See the following examples in matlabroot/extern/examples/eng_mat.

- engdemo.c for a C example on UNIX operating systems.
- engwindemo.c for a C example on Microsoft Windows operating systems.

See Also

engGetVariable

engSetVisible (C)

Purpose Show or hide MATLAB engine session

C Syntax #include "engine.h"

int engSetVisible(Engine *ep, bool value);

Arguments ep

Engine pointer

value

Value to set the Visible property to. Set value to 1 to make the

engine window visible, or to 0 to make it invisible.

Returns Microsoft Windows Operating Systems Only

0 on success, and 1 otherwise.

Description engSetVisible makes the window for the MATLAB engine session,

ep, either visible or invisible on the Windows desktop. You can use this function to enable or disable user interaction with the MATLAB

engine session.

Examples The following code opens engine session ep and disables its visibility.

Engine *ep;
bool vis;

ep = engOpen(NULL);
engSetVisible(ep, 0);

To determine the current visibility setting, use:

engGetVisible(ep, &vis);

See Also engGetVisible

matClose (C and Fortran)

Purpose Close MAT-file

C Syntax #include "mat.h"

int matClose(MATFile *mfp);

Fortran integer*4 matClose(mfp)

Syntax mwPointer mfp

Arguments mfp

Pointer to MAT-file information

Returns EOF in C (-1 in Fortran) for a write error, and 0 if successful.

Description matClose closes the MAT-file associated with mfp.

Examples See the following examples in matlabroot/extern/examples/eng_mat.

• matcreat.c

• matdgns.c

• matdemo1.F

• matdemo2.F

See Also matOpen

matDeleteVariable (C and Fortran)

Purpose Delete array from MAT-file

C Syntax #include "mat.h"

int matDeleteVariable(MATFile *mfp, const char *name);

Syntax mwPointer mfp

character*(*) name

Arguments mfp

Pointer to MAT-file information

name

Name of mxArray to delete

Returns 0 if successful, and nonzero otherwise.

Description matDeleteVariable deletes the named mxArray from the MAT-file

pointed to by mfp.

MATFile (C and Fortran)

Purpose Type for MAT-file

Description A handle to a MAT-file object. A MAT-file is the data file format

MATLAB software uses for saving data to your disk.

MATFile is a C language opaque type.

The MAT-file interface library contains routines for reading and writing MAT-files. Call these routines from your own C/C++ and Fortran

programs, using MATFile to access your data file.

The header file containing this type is:

#include "mat.h"

Examples See the following examples in matlabroot/extern/examples/eng_mat.

• matcreat.c

• matdgns.c

• matdemo1.F

• matdemo2.F

See Also matOpen, matClose, matPutVariable, matGetVariable,

mxDestroyArray

matGetDir (C and Fortran)

Purpose List of variables in MAT-file

C Syntax #include "mat.h"

char **matGetDir(MATFile *mfp, int *num);

Fortran Syntax mwPointer matGetDir(mfp, num)

mwPointer mfp integer*4 num

Arguments

Pointer to MAT-file information

num

mfp

Pointer to the variable containing the number of mxArrays in the

MAT-file

Returns

Pointer to an internal array containing pointers to the names of the mxArrays in the MAT-file pointed to by mfp. In C, each name is a NULL-terminated string. The num output argument is the length of the internal array (number of mxArrays in the MAT-file). If num is zero, mfp contains no arrays.

 ${\tt matGetDir}$ returns NULL in C (0 in Fortran). If ${\tt matGetDir}$ fails, sets num to a negative number.

Description

This routine provides you with a list of the names of the mxArrays contained within a MAT-file.

matGetDir allocates memory for the internal array of strings using a mxCalloc. You must free the memory using mxFree when you are finished with the array.

MATLAB variable names can be up to length mxMAXNAM, defined in the C header file matrix.h.

Examples

See the following examples in matlabroot/extern/examples/eng mat.

• matcreat.c

matGetDir (C and Fortran)

- matdgns.c
- matdemo2.F

matGetFp (C)

Purpose File pointer to MAT-file

C Syntax #include "mat.h"

FILE *matGetFp(MATFile *mfp);

Arguments mfp

Pointer to MAT-file information

Returns C file handle to the MAT-file with handle mfp. Returns NULL if mfp is a

handle to a MAT-file in HDF5-based format.

Description Use matGetFp to obtain a C file handle to a MAT-file. Standard C library

routines, like ferror and feof, use file handle to investigate errors.

matGetNextVariable (C and Fortran)

Purpose Next array in MAT-file

C Syntax #include "mat.h"

mxArray *matGetNextVariable(MATFile *mfp, const char **name);

Fortran Syntax

mwPointer matGetNextVariable(mfp, name)

mwPointer mfp

character*(*) name

Arguments

mfp

Pointer to MAT-file information

name

Pointer to the variable containing the mxArray name

Returns

Pointer to a newly allocated mxArray structure representing the next mxArray from the MAT-file pointed to by mfp. The function returns the name of the mxArray in name.

matGetNextVariable returns NULL in C (0 in Fortran) for end-of-file or if there is an error condition. In C, use feof and ferror from the Standard C Library to determine status.

Description

matGetNextVariable allows you to step sequentially through a MAT-file and read all the mxArrays in a single pass. The function reads and returns the next mxArray from the MAT-file pointed to by mfp.

Use matGetNextVariable immediately after opening the MAT-file with matOpen and not with other MAT-file routines. Otherwise, the concept of the *next* mxArray is undefined.

Use mxDestroyArray to destroy the mxArray created by this routine when you are finished with it.

The order of variables returned from successive calls to matGetNextVariable is not guaranteed to be the same order in which the variables were written.

matGetNextVariable (C and Fortran)

Examples See the following examples in matlabroot/extern/examples/eng_mat.

• matdgns.c

See Also matGetNextVariableInfo, matGetVariable, mxDestroyArray

matGetNextVariableInfo (C and Fortran)

Purpose Array header information only

C Syntax #include "mat.h"

mxArray *matGetNextVariableInfo(MATFile *mfp, const char **name);

Fortran Syntax mwPointer matGetNextVariableInfo(mfp, name)

mwPointer mfp

character*(*) name

Arguments

mfp

Pointer to MAT-file information

name

Pointer to the variable containing the mxArray name

Returns

Pointer to a newly allocated mxArray structure representing header information for the next mxArray from the MAT-file pointed to by mfp. The function returns the name of the mxArray in name.

matGetNextVariableInfo returns NULL in C (0 in Fortran) when the end-of-file is reached or if there is an error condition. In C, use feof and ferror from the Standard C Library to determine status.

Description

matGetNextVariableInfo loads only the array header information, including everything except pr, pi, ir, and jc, from the current file offset.

If pr, pi, ir, and jc are nonzero values when loaded with matGetVariable, matGetNextVariableInfo sets them to -1 instead. These headers are for informational use only. *Never* pass this data back to the MATLAB workspace or save it to MAT-files.

Use mxDestroyArray to destroy the mxArray created by this routine when you are finished with it.

The order of variables returned from successive calls to matGetNextVariableInfo is not guaranteed to be the same order in which the variables were written.

matGetNextVariableInfo (C and Fortran)

Examples See the following examples in matlabroot/extern/examples/eng_mat.

• matdgns.c

See Also matGetNextVariable, matGetVariableInfo

matGetVariable (C and Fortran)

Purpose Array from MAT-file

C Syntax #include "mat.h"

mxArray *matGetVariable(MATFile *mfp, const char *name);

Fortran mwPointer matGetVariable(mfp, name)

Syntax mwPointer mfp

character*(*) name

Arguments mfp

Pointer to MAT-file information

name

Name of mxArray to get from MAT-file

Returns Pointer to a newly allocated mxArray structure representing the

mxArray named by name from the MAT-file pointed to by mfp.

matGetVariable returns NULL in C (0 in Fortran) if the attempt to

return the mxArray named by name fails.

Description This routine allows you to copy an mxArray out of a MAT-file.

Use mxDestroyArray to destroy the mxArray created by this routine

when you are finished with it.

Examples See the following examples in matlabroot/extern/examples/eng_mat.

• matcreat.c

See Also matPutVariable, mxDestroyArray

matGetVariableInfo (C and Fortran)

Purpose Array header information only

C Syntax #include "mat.h"

mxArray *matGetVariableInfo(MATFile *mfp, const char *name);

Fortran Syntax mwPointer matGetVariableInfo(mfp, name)

mwPointer mfp

character*(*) name

Arguments

mfp

Pointer to MAT-file information

name

Name of mxArray to get from MAT-file

Returns

Pointer to a newly allocated mxArray structure representing header information for the mxArray named by name from the MAT-file pointed to by mfp.

matGetVariableInfo returns NULL in C (0 in Fortran) if the attempt to return header information for the mxArray named by name fails.

Description

matGetVariableInfo loads only the array header information, including everything except pr, pi, ir, and jc. It recursively creates the cells and structures through their leaf elements, but does not include pr, pi, ir, and jc.

If pr, pi, ir, and jc are nonzero values when loaded with matGetVariable, matGetVariableInfo sets them to -1 instead. These headers are for informational use only. *Never* pass this data back to the MATLAB workspace or save it to MAT-files.

Use mxDestroyArray to destroy the mxArray created by this routine when you are finished with it.

See Also matGetVariable

matOpen (C and Fortran)

Purpose Open MAT-file

C Syntax #include "mat.h"

MATFile *matOpen(const char *filename, const char *mode);

Fortran mwPointer matOpen(filename, mode)
Syntax character*(*) filename, mode

Arguments filename

Name of file to open

mode

File opening mode. The following table lists valid values for mode.

r	Opens file for reading only; determines the current version of the MAT-file by inspecting the files and preserves the current version.
u	Opens file for update, both reading and writing. If the file does not exist, does not create a file (equivalent to the r+ mode of fopen). Determines the current version of the MAT-file by inspecting the files and preserves the current version.
W	Opens file for writing only; deletes previous contents, if any.
w4	Creates a MAT-file compatible with MATLAB Versions 4 software and earlier.
wL	Opens file for writing character data using the default character set for your system. Use MATLAB Version 6 or 6.5 software to read the resulting MAT-file.
	If you do not use the wL mode switch, MATLAB writes character data to the MAT-file using Unicode® character encoding by default.

matOpen (C and Fortran)

WZ	Opens file for writing compressed data. By default, the MATLAB save function compresses workspace variables as they are saved to a MAT-file. To use the same compression ratio when creating a MAT-file with the matOpen function, use the wz option.
w7.3	Creates a MAT-file in an HDF5-based format that can store objects that occupy more than 2 GB.

Returns File handle, or NULL in C (0 in Fortran) if the open fails.

Description This routine opens a MAT-file for reading and writing.

Examples See the following examples in matlabroot/extern/examples/eng_mat.

• matcreat.c

• matdgns.c

• matdemo1.F

• matdemo2.F

See Also matClose

matPutVariable (C and Fortran)

Purpose Array to MAT-file

C Syntax #include "mat.h"

int matPutVariable(MATFile *mfp, const char *name, const mxArray

*pm);

Fortran Syntax integer*4 matPutVariable(mfp, name, pm)

mwPointer mfp, pm
character*(*) name

Arguments

mfp

Pointer to MAT-file information

name

Name of mxArray to put into MAT-file

pm

mxArray pointer

Returns

0 if successful and nonzero if an error occurs. In C, use feof and ferror from the Standard C Library along with matGetFp to determine status.

Description

This routine puts an mxArray into a MAT-file.

matPutVariable writes mxArray pm to the MAT-file mfp. If the mxArray does not exist in the MAT-file, the function appends it to the end. If an mxArray with the same name exists in the file, the function replaces the existing mxArray with the new mxArray by rewriting the file.

Do not use MATLAB function names for variable names. Common variable names that conflict with function names include i, j, mode, char, size, or path. To determine whether a particular name is associated with a MATLAB function, use the which function.

The size of the new mxArray can be different from the existing mxArray.

matPutVariable (C and Fortran)

Examples See the following examples in *matlabroot*/extern/examples/eng_mat.

• matcreat.c

See Also matGetVariable, matGetFp

matPutVariableAsGlobal (C and Fortran)

Purpose

Array to MAT-file as originating from global workspace

C Syntax

```
#include "mat.h"
```

int matPutVariableAsGlobal(MATFile *mfp, const char *name, const
 mxArray *pm);

Fortran Syntax

integer*4 matPutVariableAsGlobal(mfp, name, pm)

mwPointer mfp, pm
character*(*) name

Arguments

mfp

Pointer to MAT-file information

name

Name of mxArray to put into MAT-file

pm

mxArray pointer

Returns

O if successful and nonzero if an error occurs. In C, use feof and ferror from the Standard C Library with matGetFp to determine status.

Description

This routine puts an mxArray into a MAT-file. matPutVariableAsGlobal is like matPutVariable, except that MATLAB software loads the array into the global workspace and sets a reference to it in the local workspace. If you write to a MATLAB 4 format file, matPutVariableAsGlobal does not load it as global and has the same effect as matPutVariable.

matPutVariableAsGlobal writes mxArray pm to the MAT-file mfp. If the mxArray does not exist in the MAT-file, the function appends it to the end. If an mxArray with the same name exists in the file, the function replaces the existing mxArray with the new mxArray by rewriting the file.

Do not use MATLAB function names for variable names. Common variable names that conflict with function names include i, j, mode,

matPutVariableAsGlobal (C and Fortran)

char, size, or path. To determine whether a particular name is associated with a MATLAB function, use the which function.

The size of the new mxArray can be different from the existing mxArray.

Examples

See the following examples in matlabroot/extern/examples/eng_mat.

• matcreat.c

See Also

matPutVariable, matGetFp

mexAtExit (C and Fortran)

Purpose Register function to call when MEX-function cleared or MATLAB

software terminates

C Syntax #include "mex.h"

int mexAtExit(void (*ExitFcn)(void));

Fortran integer*4 mexAtExit(ExitFcn)

Syntax subroutine ExitFcn()

Arguments ExitFcn

Pointer to function you want to run on exit

Returns Always returns 0.

Description Use mexAtExit to register a function to call just before clearing

the MEX-function or terminating MATLAB. mexAtExit gives your MEX-function a chance to perform tasks such as freeing persistent memory and closing files. Other typical tasks include closing streams

or sockets.

Each MEX-function can register only one active exit function at a time. If you call mexAtExit more than once, MATLAB uses the ExitFon from

the more recent mexAtExit call as the exit function.

If a MEX-function is locked, you cannot clear the MEX-file.

Consequently, if you attempt to clear a locked MEX-file, MATLAB does

not call the ExitFcn.

In Fortran, declare the ExitFon as external in the Fortran routine

that calls mexAtExit if it is not within the scope of the file.

Examples See the following examples in *matlabroot*/extern/examples/mex.

• mexatexit.c

See Also mexLock, mexUnlock

mexCallMATLAB (C and Fortran)

Purpose

Call MATLAB function, user-defined function, or MEX-file

C Syntax

#include "mex.h"

int mexCallMATLAB(int nlhs, mxArray *plhs[], int nrhs,
 mxArray *prhs[], const char *functionName);

Fortran Syntax

integer*4 mexCallMATLAB(nlhs, plhs, nrhs, prhs, functionName)

integer*4 nlhs, nrhs

mwPointer plhs(*), prhs(*)
character*(*) functionName

Arguments

nlhs

Number of output arguments

plhs

Array of pointers to output arguments

nrhs

Number of input arguments

prhs

Array of pointers to input arguments

functionName

Character string containing name of the MATLAB built-in function, operator, user-defined function, or MEX-file you are calling

Returns

0 if successful, and a nonzero value if unsuccessful.

Description

Call mexCallMATLAB to invoke internal MATLAB numeric functions, MATLAB operators, user-defined functions, or other MEX-files. Both mexCallMATLAB and mexEvalString execute MATLAB commands. Use mexCallMATLAB for returning results (left-hand side arguments) back to the MEX-file. The mexEvalString function cannot return values to the MEX-file.

For a complete description of the input and output arguments passed to functionName, see mexFunction. When calling the mexCallMATLAB

mexCallMATLAB (C and Fortran)

function, the number of output arguments nlhs and input arguments nrhs must be less than or equal to 50.

MATLAB allocates dynamic memory to store the mxArrays in plhs. MATLAB automatically deallocates the dynamic memory when you clear the MEX-file. However, if heap space is at a premium, call mxDestroyArray when you are finished with the mxArrays plhs points to.

If functionName is an operator, place the operator inside a pair of single quotes, for example, '+'.

Note It is possible to generate an object of type mxUNKNOWN_CLASS using mexCallMATLAB.

This function returns two variables but only assigns one of them a value:

```
function [a,b] = foo[c]
a = 2*c;
```

If you then call foo using mexCallMATLAB, the unassigned output variable is now type mxUNKNOWN_CLASS.

Error Handling

If functionName detects an error, MATLAB terminates the MEX-file and returns control to the MATLAB prompt. If you want to trap errors, use the mexCallMATLABWithTrap function.

Examples

See the following examples in matlabroot/extern/examples/mex.

- mexcallmatlab.c
- mexevalstring.c
- mexcallmatlabwithtrap.c

See the following examples in matlabroot/extern/examples/refbook.

mexCallMATLAB (C and Fortran)

- sincall.c
- sincall.F

See the following examples in matlabroot/extern/examples/mx.

- mxcreatecellmatrix.c
- mxcreatecellmatrixf.F
- mxisclass.c

See Also

mexFunction, mexCallMATLABWithTrap, mexEvalString,
mxDestroyArray

mexCallMATLABWithTrap (C and Fortran)

Purpose Call MATLAB function, user-defined function, or MEX-file and capture

error information

C Syntax #include "mex.h"

mxArray *mexCallMATLABWithTrap(int nlhs, mxArray *plhs[], int nrhs,

mxArray *prhs[], const char *functionName);

Fortran Syntax mwPointer mexCallMATLABWithTrap(nlhs, plhs, nrhs, prhs, functionName)

integer*4 nlhs, nrhs

mwPointer plhs(*), prhs(*)
character*(*) functionName

Arguments

For more information about arguments, see mexCallMATLAB.

nlhs

Number of desired output arguments.

plhs

Array of pointers to output arguments.

nrhs

Number of input arguments.

prhs

Array of pointers to input arguments.

functionName

Character string containing the name of the MATLAB built-in function, operator, function, or MEX-file that you are calling.

Returns

 $\ensuremath{\mathsf{NULL}}$ if no error occurred; otherwise, a pointer to an $\ensuremath{\mathsf{mxArray}}$ of class

MException.

Description

The mexCallMATLABWithTrap function performs the same function as mexCallMATLAB. However, if MATLAB detects an error when executing functionName, MATLAB returns control to the line in the MEX-file immediately following the call to mexCallMATLABWithTrap. For information about MException, see "Respond to an Exception"

mexCallMATLABWithTrap (C and Fortran)

See Also

mexCallMATLAB, MException

mexErrMsgldAndTxt (C and Fortran)

Purpose

Display error message with identifier and return to MATLAB prompt

C Syntax

```
#include "mex.h"
```

void mexErrMsgIdAndTxt(const char *errorid,

const char *errormsg, ...);

Fortran Syntax

subroutine mexErrMsgIdAndTxt(errorid, errormsg)

character*(*) errorid, errormsg

Arguments

errorid

String containing a MATLAB message identifier. For information on creating identifiers, see "Message Identifiers".

errormsg

String to display. In C, the string can include conversion specifications, used by the ANSI C printf function.

. . .

In C, any arguments used in the message. Each argument must have a corresponding conversion specification.

Description

The mexErrMsgIdAndTxt function writes an error message to the MATLAB window. For more information, see the error function syntax statement using a message identifier. After the error message prints, MATLAB terminates the MEX-file and returns control to the MATLAB prompt.

Calling mexErrMsgIdAndTxt does not clear the MEX-file from memory. Consequently, mexErrMsgIdAndTxt does not invoke the function registered through mexAtExit.

If your application called mxCalloc or one of the mxCreate* routines to allocate memory, mexErrMsgIdAndTxt automatically frees the allocated memory.

mexErrMsgldAndTxt (C and Fortran)

Note If you get warnings when using mexErrMsgIdAndTxt, you might have a memory management compatibility problem. For more information, see "Memory Management Issues" in the External Interfaces documentation.

Remarks

In addition to the errorid and errormsg, the mexerrmsgtxt function determines where the error occurred, and displays the following information. For example, in the function foo, mexerrmsgtxt displays:

Error using foo

Examples

See the following examples in matlabroot/extern/examples/refbook.

- arrayFillGetPr.c
- matrixDivide.c
- timestwo.F
- xtimesy.F

See Also

mexErrMsgTxt, mexWarnMsgIdAndTxt, mexWarnMsgTxt

mexErrMsgTxt (C and Fortran)

Purpose Display error message and return to MATLAB prompt

C Syntax #include "mex.h"

void mexErrMsgTxt(const char *errormsg);

Fortran subroutine mexErrMsgTxt(errormsg) character*(*) errormsg

Syntax

Arguments errormsg

String containing the error message to display

Description

Call mexErrMsgTxt to write an error message to the MATLAB window. After the error message prints, MATLAB terminates the MEX-file and returns control to the MATLAB prompt.

Calling mexErrMsgTxt does not clear the MEX-file from memory. Consequently, mexErrMsgTxt does not invoke the function registered through mexAtExit.

If your application called mxCalloc or one of the mxCreate* routines to allocate memory, mexErrMsgTxt automatically frees the allocated memory.

Note If you get warnings when using mexErrMsqTxt, you might have a memory management compatibility problem. For more information, see "Memory Management Issues".

Remarks

In addition to the errormsq, the mexerrmsqtxt function determines where the error occurred, and displays the following information. If an error labeled Print my error message occurs in the function foo, mexerrmsgtxt displays:

Error using foo Print my error message

mexErrMsgTxt (C and Fortran)

Examples

See the following examples in matlabroot/extern/examples/refbook.

- xtimesy.c
- convec.c
- findnz.c
- fulltosparse.c
- phonebook.c
- revord.c
- timestwo.c

mexErrMsgIdAndTxt, mexWarnMsgIdAndTxt, mexWarnMsgTxt

mexEvalString (C and Fortran)

Purpose Execute MATLAB command in caller workspace

C Syntax #include "mex.h"

int mexEvalString(const char *command);

Fortran integer*4 mexEvalString(command)

Syntax character*(*) command

Arguments command

String containing MATLAB command to execute

Returns 0 if successful, and 1 if an error occurs.

Description Call mexEvalString to invoke a MATLAB command in the workspace

of the caller.

mexEvalString and mexCallMATLAB both execute MATLAB commands. Use mexCallMATLAB for returning results (left-hand side arguments) back to the MEX-file. The mexEvalString function cannot return

values to the MEX-file.

All arguments that appear to the right of an equal sign in the command

string must be current variables of the caller workspace.

Do not use MATLAB function names for variable names. Common variable names that conflict with function names include i, j, mode, char, size, or path. To determine whether a particular name is associated with a MATLAB function, use the which function. For more

information, see "Variable Names".

Error Handling If command detects an error, MATLAB returns control to the MEX-file and mexEvalString returns 1. If you want to trap errors, use the

 ${\tt mexEvalStringWithTrap\ function}.$

Examples See the following examples in *matlabroot*/extern/examples/mex.

• mexevalstring.c

mexEvalString (C and Fortran)

See Also

mexCallMATLAB, mexEvalStringWithTrap

mexEvalStringWithTrap (C and Fortran)

Purpose Execute MATLAB command in caller workspace and capture error

information

C Syntax #include "mex.h"

mxArray *mexEvalStringWithTrap(const char *command);

Fortran mwPointer mexEvalStringWithTrap(command)

Syntax character*(*) command

Arguments command

String containing the MATLAB command to execute

Returns Object ME of class MException

Description The mexEvalStringWithTrap function performs the same function

as ${\tt mexEvalString}.$ However, if MATLAB detects an error when

executing command, MATLAB returns control to the line in the MEX-file

immediately following the call to mexEvalStringWithTrap.

See Also mexEvalString, MException, mexCallMATLAB

mexFunction (C and Fortran)

Purpose

Entry point to C/C++ or Fortran MEX-file

C Syntax

#include "mex.h"

void mexFunction(int nlhs, mxArray *plhs[], int nrhs,

const mxArray *prhs[])

Fortran Syntax

subroutine mexFunction(nlhs, plhs, nrhs, prhs)

integer*4 nlhs, nrhs

mwPointer plhs(*), prhs(*)

Arguments

nlhs

Number of expected output mxArrays

plhs

Array of pointers to the expected output mxArrays

nrhs

Number of input mxArrays

prhs

Array of pointers to the input mxArrays. Do not modify any prhs values in your MEX-file. Changing the data in these read-only mxArrays can produce undesired side effects.

Description

mexFunction is not a routine you call. Rather, mexFunction is the name of the gateway function in C (subroutine in Fortran) which every MEX-file requires. When you invoke a MEX-function, MATLAB software finds and loads the corresponding MEX-file of the same name. MATLAB then searches for a symbol named mexFunction within the MEX-file. If it finds one, it calls the MEX-function using the address of the mexFunction symbol. MATLAB displays an error message if it cannot find a routine named mexFunction inside the MEX-file.

When you invoke a MEX-file, MATLAB automatically seeds nlhs, plhs, nrhs, and prhs with the caller's information. In the syntax of the MATLAB language, functions have the general form:

$$[a,b,c,...] = fun(d,e,f,...)$$

mexFunction (C and Fortran)

where the ... denotes more items of the same format. The a,b,c... are left-hand side arguments, and the d,e,f... are right-hand side arguments. The arguments nlhs and nrhs contain the number of left-hand side and right-hand side arguments, respectively. prhs is an array of mxArray pointers whose length is nrhs. plhs is an array whose length is nlhs, where your function must set pointers for the returned left-hand side mxArrays.

Examples

See the following examples in *matlabroot*/extern/examples/mex.

• mexfunction.c

mexFunctionName (C and Fortran)

Purpose Name of current MEX-function

C Syntax #include "mex.h"

const char *mexFunctionName(void);

Fortran Syntax

character*(*) mexFunctionName()

Returns Name of the current MEX-function.

Description mexFunctionName returns the name of the current MEX-function.

Examples See the following examples in *matlabroot*/extern/examples/mex.

• mexgetarray.c

Purpose Value of specified Handle Graphics property

C Syntax #include "mex.h"

const mxArray *mexGet(double handle, const char *property);

Arguments handle

Handle to a particular graphics object

property

Handle Graphics property

Returns Value of the specified property in the specified graphics object on

success. Returns NULL on failure. Do not modify the return argument from mexGet. Changing the data in a const (read-only) mxArray can

produce undesired side effects.

Description Call mexGet to get the value of the property of a certain graphics object.

mexGet is the API equivalent of the MATLAB get function. To set a

graphics property value, call mexSet.

Examples See the following examples in *matlabroot*/extern/examples/mex.

• mexget.c

See Also mexSet

mexGetVariable (C and Fortran)

Purpose Copy of variable from specified workspace

C Syntax #include "mex.h"

mxArray *mexGetVariable(const char *workspace, const char

*varname);

Fortran Syntax

mwPointer mexGetVariable(workspace, varname)

character*(*) workspace, varname

Arguments

workspace

Specifies where mexGetVariable searches for array varname. The

possible values are:

base Search for the variable in the base workspace.

caller Search for the variable in the caller workspace.

global Search for the variable in the global workspace.

varname

Name of the variable to copy

Returns

Copy of the variable on success. Returns NULL in C (0 on Fortran) on failure. A common cause of failure is specifying a variable that is not currently in the workspace. Perhaps the variable was in the workspace

at one time but has since been cleared.

Description

Call mexGetVariable to get a copy of the specified variable. The returned mxArray contains a copy of all the data and characteristics that the variable had in the other workspace. Modifications to the returned mxArray do not affect the variable in the workspace unless you

write the copy back to the workspace with mexPutVariable.

Use mxDestroyArray to destroy the mxArray created by this routine

when you are finished with it.

mexGetVariable (C and Fortran)

Examples See the following examples in *matlabroot*/extern/examples/mex.

• mexgetarray.c

See Also mexGetVariablePtr, mexPutVariable, mxDestroyArray

mexGetVariablePtr (C and Fortran)

Purpose Read-only pointer to variable from another workspace

C Syntax #include "mex.h"

const mxArray *mexGetVariablePtr(const char *workspace,

const char *varname);

Fortran Syntax

mwPointer mexGetVariablePtr(workspace, varname)

character*(*) workspace, varname

Arguments

workspace

Specifies which workspace you want mexGetVariablePtr to

search. The possible values are

base Search for the variable in the base workspace.

caller Search for the variable in the caller workspace.

global Search for the variable in the global workspace.

varname

Name of a variable in another workspace. This is a variable name,

not an mxArray pointer.

Returns

Read-only pointer to the mxArray on success. Returns NULL in C (0 in

Fortran) on failure.

Description

Call mexGetVariablePtr to get a read-only pointer to the specified variable, varname, into your MEX-file workspace. This command is

useful for examining an mxArray's data and characteristics. If you want to change data or characteristics, use mexGetVariable (along with

mexPutVariable) instead of mexGetVariablePtr.

If you simply want to examine data or characteristics,

mexGetVariablePtr offers superior performance because the caller

wants to pass only a pointer to the array.

mexGetVariablePtr (C and Fortran)

Examples See the following examples in *matlabroot*/extern/examples/mx.

• mxislogical.c

See Also mexGetVariable

mexIsGlobal (C and Fortran)

Purpose Determine whether variable has global scope

C Syntax #include "matrix.h"

bool mexIsGlobal(const mxArray *pm);

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Logical 1 (true) if the mxArray has global scope, and logical 0 (false)

otherwise.

Description Use mexIsGlobal to determine whether the specified mxArray has

global scope.

Examples See the following examples in *matlabroot*/extern/examples/mx.

 $\bullet \ {\tt mxislogical.c}$

See Also mexGetVariable, mexGetVariablePtr, mexPutVariable, global

mexisLocked (C and Fortran)

Purpose Determine whether MEX-file is locked

C Syntax #include "mex.h"

bool mexIsLocked(void);

Fortran Syntax

integer*4 mexIsLocked()

Returns Logical 1 (true) if the MEX-file is locked; logical 0 (false) if the file

is unlocked.

Description Call mexIsLocked to determine whether the MEX-file is locked. By

default, MEX-files are unlocked, meaning you can clear the MEX-file

at any time.

To unlock a MEX-file, call mexUnlock.

Examples See the following examples in *matlabroot*/extern/examples/mex.

• mexlock.c

• mexlockf.F

See Also mexLock, mexMakeArrayPersistent, mexMakeMemoryPersistent,

mexUnlock, clear

mexLock (C and Fortran)

Purpose Prevent clearing MEX-file from memory

C Syntax #include "mex.h"

void mexLock(void);

Fortran Syntax

subroutine mexLock()

Description

By default, MEX-files are unlocked, meaning you can clear them at any

time. Call mexLock to prohibit clearing a MEX-file.

To unlock a MEX-file, you must call mexUnlock. Do not use the munlock

function.

mexLock increments a lock count. If you call mexLock n times, call

mexUnlock n times to unlock your MEX-file.

Examples

See the following examples in matlabroot/extern/examples/mex.

• mexlock.c

• mexlockf.F

See Also

mexIsLocked, mexMakeArrayPersistent, mexMakeMemoryPersistent,

mexUnlock, clear

mexMakeArrayPersistent (C and Fortran)

Purpose Make array persist after MEX-file completes

C Syntax #include "mex.h"

void mexMakeArrayPersistent(mxArray *pm);

Fortran Syntax

 $subroutine\ mexMakeArrayPersistent(pm)$

mwPointer pm

Arguments pm

Pointer to an mxArray created by an mxCreate* function

Description

By default, an mxArray allocated by an mxCreate* function is not persistent. The MATLAB memory management facility automatically frees a nonpersistent mxArray when the MEX-function finishes. If you want the mxArray to persist through multiple invocations of the MEX-function, you must call the mexMakeArrayPersistent function.

Note If you create a persistent mxArray, you are responsible for destroying it using mxDestroyArray when the MEX-file is cleared. If you do not destroy a persistent mxArray, MATLAB leaks memory. See mexAtExit to see how to register a function that gets called when the MEX-file is cleared. See mexLock to see how to lock your MEX-file so that it is never cleared.

See Also

mexAtExit, mxDestroyArray, mexLock, mexMakeMemoryPersistent,
and the mxCreate* functions

mexMakeMemoryPersistent (C and Fortran)

Purpose Make memory allocated by MATLAB software persist after

MEX-function completes

C Syntax #include "mex.h"

void mexMakeMemoryPersistent(void *ptr);

Fortran Syntax

subroutine mexMakeMemoryPersistent(ptr)

mwPointer ptr

Arguments ptr

Pointer to the beginning of memory allocated by one of the

MATLAB memory allocation routines

Description

By default, memory allocated by MATLAB software is nonpersistent, so it is freed automatically when the MEX-function finishes. If you want the memory to persist, you must call mexMakeMemoryPersistent.

Note If you create persistent memory, you are responsible for freeing it when the MEX-function is cleared. If you do not free the memory, MATLAB leaks memory. To free memory, use mxFree. See mexAtExit to see how to register a function that gets called when the MEX-function is cleared. See mexLock to see how to lock your MEX-function so that it is never cleared.

See Also

 $\label{eq:mexatexit} \mbox{mexLock, mexMakeArrayPersistent, mxCalloc, mxFree,} \\ \mbox{mxMalloc, mxRealloc}$

mexPrintf (C and Fortran)

Purpose

ANSI C PRINTF-style output routine

C Syntax

#include "mex.h"
int mexPrintf(const char *message, ...);

Fortran Syntax

integer*4 mexPrintf(message)
character*(*) message

Arguments

message

String to display. In C, the string can include conversion specifications, used by the ANSI C printf function.

. . .

In C, any arguments used in the message. Each argument must have a corresponding conversion specification.

Returns

Number of characters printed including characters specified with backslash codes, such as \n and \b.

Description

This routine prints a string on the screen and in the diary (if the diary is in use). It provides a callback to the standard C printf routine already linked inside MATLAB software, which avoids linking the entire stdio library into your MEX-file.

In a C MEX-file, you must call mexPrintf instead of printf to display a string.

Note If you want the literal % in your message, use %% in the message string since % has special meaning to printf. Failing to do so causes unpredictable results.

Examples

See the following examples in *matlabroot*/extern/examples/mex.

• mexfunction.c

mexPrintf (C and Fortran)

See the following examples in matlabroot/extern/examples/refbook.

• phonebook.c

See Also

 $\label{lem:mexerrMsgIdAndTxt} \mbox{mexErrMsgTxt, mexWarnMsgIdAndTxt}, \\ \mbox{mexWarnMsgTxt}$

mexPutVariable (C and Fortran)

Purpose Array from MEX-function into specified workspace

C Syntax #include "mex.h"

int mexPutVariable(const char *workspace, const char *varname,

const mxArray *pm);

Fortran Syntax

integer*4 mexPutVariable(workspace, varname, pm)

character*(*) workspace, varname

mwPointer pm

Arguments

workspace

Specifies scope of the array you are copying. Values for workspace

are:

base Copy mxArray to the base workspace.

caller Copy mxArray to the caller workspace.

global Copy mxArray to the list of global variables.

varname

Name of mxArray in the workspace

pm

Pointer to the mxArray

Returns

 $\boldsymbol{0}$ on success; $\boldsymbol{1}$ on failure. A possible cause of failure is that pm is NULL

in C (0 in Fortran).

Description

Call mexPutVariable to copy the mxArray, at pointer pm, from your MEX-function into the specified workspace. MATLAB software gives the name, varname, to the copied mxArray in the receiving workspace.

mexPutVariable makes the array accessible to other entities, such as MATLAB, user-defined functions, or other MEX-functions.

If a variable of the same name exists in the specified workspace, mexPutVariable overwrites the previous contents of the variable with

mexPutVariable (C and Fortran)

the contents of the new mxArray. For example, suppose the MATLAB workspace defines variable Peaches as:

Peaches

1 2

3 4

and you call mexPutVariable to copy Peaches into the same workspace:

mexPutVariable("base", "Peaches", pm)

The value passed by mexPutVariable replaces the old value of Peaches.

Do not use MATLAB function names for variable names. Common variable names that conflict with function names include i, j, mode, char, size, or path. To determine whether a particular name is associated with a MATLAB function, use the which function.

Examples

See the following examples in matlabroot/extern/examples/mex.

• mexgetarray.c

See Also

mexGetVariable

Purpose

Set value of specified Handle Graphics property

C Syntax

#include "mex.h"
int mexSet(double handle, const char *property,
 mxArray *value);

Arguments

handle

Handle to a particular graphics object

property

String naming a Handle Graphics property

value

Pointer to an mxArray holding the new value to assign to the property

Returns

0 on success; 1 on failure. Possible causes of failure include:

- Specifying a nonexistent property.
- Specifying an illegal value for that property, for example, specifying a string value for a numerical property.

Description

Call mexSet to set the value of the property of a certain graphics object. mexSet is the API equivalent of the MATLAB set function. To get the value of a graphics property, call mexGet.

Examples

See the following examples in the *matlabroot*/extern/examples/mex folder.

- mexcallmatlab.c
- mexget.c
- mexgetarray.c

See Also

mexGet

mexSetTrapFlag (C and Fortran)

Purpose

Control response of MEXCALLMATLAB to errors

C Syntax

#include "mex.h"

void mexSetTrapFlag(int trapflag);

Note mexSetTrapFlag will be removed in a future version. Use mexCallMATLABWithTrap instead.

Fortran Syntax

subroutine mexSetTrapFlag(trapflag)
integer*4 trapflag

Arguments

trapflag

Control flag. Possible values are:

On error, control returns to the MATLAB prompt.

1 On error, control returns to your MEX-file.

Description

Call ${\tt mexSetTrapFlag}$ to control the MATLAB response to errors in ${\tt mexCallMATLAB}$.

If you do not call mexSetTrapFlag, then whenever MATLAB detects an error in a call to mexCallMATLAB, MATLAB automatically terminates the MEX-file and returns control to the MATLAB prompt. Calling mexSetTrapFlag with trapflag set to 0 is equivalent to not calling mexSetTrapFlag at all.

If you call mexSetTrapFlag and set the trapflag to 1, then whenever MATLAB detects an error in a call to mexCallMATLAB, MATLAB does not automatically terminate the MEX-file. Rather, MATLAB returns control to the line in the MEX-file immediately following the call to mexCallMATLAB. The MEX-file is then responsible for taking an appropriate response to the error.

If you call mexSetTrapFlag, the value of the trapflag you set remains in effect until the next call to mexSetTrapFlag within that MEX-file or,

mexSetTrapFlag (C and Fortran)

if there are no more calls to mexSetTrapFlag, until the MEX-file exits. If a routine defined in a MEX-file calls another MEX-file, MATLAB:

- 1 Saves the current value of the trapflag in the first MEX-file.
- **2** Calls the second MEX-file with the trapflag initialized to 0 within that file.
- **3** Restores the saved value of trapflag in the first MEX-file when the second MEX-file exits.

See Also

mexCallMATLAB, mexCallMATLABWithTrap, mexAtExit, mexErrMsgTxt

mexUnlock (C and Fortran)

Purpose Allow clearing MEX-file from memory

C Syntax #include "mex.h"

void mexUnlock(void);

Fortran Syntax

subroutine mexUnlock()

Description

By default, MEX-files are unlocked, meaning you can clear them at any time. Calling mexLock locks a MEX-file so that you cannot clear it from

memory. Call mexUnlock to remove the lock.

mexLock increments a lock count. If you called mexLock n times, call

mexUnlock n times to unlock your MEX-file.

Examples

See the following examples in matlabroot/extern/examples/mex.

• mexlock.c

• mexlockf.F

See Also

mexIsLocked, mexLock, mexMakeArrayPersistent,

mexMakeMemoryPersistent, clear

mexWarnMsgldAndTxt (C and Fortran)

Purpose Warning message with identifier

C Syntax #include "mex.h"

void mexWarnMsgIdAndTxt(const char *warningid,

const char *warningmsg, ...);

Fortran Syntax

subroutine mexWarnMsgIdAndTxt(warningid, warningmsg)

character*(*) warningid, warningmsg

Arguments warningid

String containing a MATLAB message identifier. For information

on creating identifiers, see "Message Identifiers".

warningmsg

String to display. In C, the string can include conversion

specifications, used by the ANSI C printf function.

. . .

In C, any arguments used in the message. Each argument must

have a corresponding conversion specification.

Description The mexWarnMsgIdAndTxt function writes a warning message to the

MATLAB window. For more information, see the warning function

syntax statement using a message identifier.

Unlike mexErrMsgIdAndTxt, calling mexWarnMsgIdAndTxt does not

terminate the MEX-file.

See Also mexErrMsgTxt, mexErrMsgIdAndTxt, mexWarnMsgTxt

mexWarnMsgTxt (C and Fortran)

Purpose Warning message

C Syntax #include "mex.h"

void mexWarnMsgTxt(const char *warningmsg);

Fortran subroutine mexWarnMsgTxt(warningmsg)

Syntax character*(*) warningmsg

Arguments warningmsg

String containing the warning message to display

Description mexWarnMsgTxt causes MATLAB software to display the contents of

warningmsg.

Unlike mexErrMsgTxt, mexWarnMsgTxt does not terminate the MEX-file.

Examples See the following examples in matlabroot/extern/examples/mex.

• yprime.c

• explore.c

See the following examples in ${\it matlabroot/extern/examples/refbook}$.

mwIndex (C and Fortran)

Purpose

Type for index values

Description

mwIndex is a type that represents index values, such as indices into arrays. Use this function for cross-platform flexibility. By default, mwIndex is equivalent to int in C. When using the mex -largeArrayDims switch, mwIndex is equivalent to size_t in C. In Fortran, mwIndex is similarly equivalent to INTEGER*4 or INTEGER*8, based on platform and compilation flags.

The C header file containing this type is:

#include "matrix.h"

In Fortran, mwIndex is a preprocessor macro. The Fortran header file containing this type is:

#include "fintrf.h"

See Also

mex, mwSize, mwSignedIndex

mwPointer (Fortran)

Purpose

Platform-independent pointer type

Description

mwPointer is a preprocessor macro that declares the appropriate Fortran type representing a pointer to an mxArray or to other data that is not of a native Fortran type, such as memory allocated by mxMalloc. On 32-bit platforms, the Fortran type that represents a pointer is INTEGER*4; on 64-bit platforms, it is INTEGER*8. The Fortran preprocessor translates mwPointer to the Fortran declaration that is appropriate for the platform on which you compile your file.

If your Fortran compiler supports preprocessing, you can use mwPointer to declare functions, arguments, and variables that represent pointers. If you cannot use mwPointer, you must ensure that your declarations have the correct size for the platform on which you are compiling Fortran code.

The Fortran header file containing this type is:

#include "fintrf.h"

Examples

This example declares the arguments for mexFunction in a Fortran MEX-file:

subroutine mexFunction(nlhs, plhs, nrhs, prhs)
mwPointer plhs(*), prhs(*)
integer nlhs, nrhs

For additional examples, see the Fortran files with names ending in .F in the *matlabroot*/extern/examples folder.

mwSignedIndex (C and Fortran)

Purpose Signed integer type for size values

Description mwSignedIndex is a signed integer type that represents size values, such

as array dimensions. Use this function for cross-platform flexibility. By default, mwSignedIndex is equivalent to ptrdiff_t in C++. In Fortran, mwSignedIndex is similarly equivalent to INTEGER*4 or INTEGER*8,

based on platform and compilation flags.

The C header file containing this type is:

#include "matrix.h"

The Fortran header file containing this type is:

#include "fintrf.h"

See Also mwSize

mwSize (C and Fortran)

Purpose

Type for size values

Description

mwSize is a type that represents size values, such as array dimensions. Use this function for cross-platform flexibility. By default, mwSize is equivalent to int in C. When using the mex -largeArrayDims switch, mwSize is equivalent to size_t in C. In Fortran, mwSize is similarly equivalent to INTEGER*4 or INTEGER*8, based on platform and compilation flags.

The C header file containing this type is:

#include "matrix.h"

In Fortran, mwSize is a preprocessor macro. The Fortran header file containing this type is:

#include "fintrf.h"

See Also

mex, mwIndex, mwSignedIndex

mxAddField (C and Fortran)

Purpose Add field to structure array

C Syntax #include "matrix.h"

extern int mxAddField(mxArray *pm, const char *fieldname);

Fortran integer*4 mxAddField(pm, fieldname)

Syntax mwPointer pm

character*(*) fieldname

Arguments pm

Pointer to a structure mxArray

fieldname

Name of the field you want to add

Returns Field number on success, or -1 if inputs are invalid or an out-of-memory

condition occurs.

Description Call mxAddField to add a field to a structure array. Create the values

with the mxCreate* functions and use mxSetFieldByNumber to set the

individual values for the field.

See Also mxRemoveField, mxSetFieldByNumber

mxArray (C)

Purpose

Type for MATLAB array

Description

The fundamental type underlying MATLAB data. For information on how the MATLAB array works with MATLAB-supported variables, see "MATLAB Data".

mxArray is a C language opaque type.

All C MEX-files start with a gateway routine, called mexFunction, which requires mxArray for both input and output parameters. For information about the C MEX-file gateway routine, see "C/C++ Source MEX-Files".

Once you have MATLAB data in your MEX-file, use functions in the MX Matrix Library to manipulate the data, and functions in the MEX Library to perform operations in the MATLAB environment. You use mxArray to pass data to and from these functions.

Use any of the mxCreate* functions to create data, and the corresponding mxDestroyArray function to free memory.

The header file containing this type is:

#include "matrix.h"

Example

See the following examples in matlabroot/extern/examples/mx.

• mxcreatecharmatrixfromstr.c

See Also

mexFunction, mxClassID, mxCreateDoubleMatrix,
mxCreateNumericArray, mxCreateString, mxDestroyArray,
mxGetData, mxSetData

Purpose Array to string

C Syntax #include "matrix.h"

char *mxArrayToString(const mxArray *array ptr);

Arguments array_ptr

Pointer to a string mxArray; that is, a pointer to an mxArray

having the mxCHAR_CLASS class.

Returns C-style string. Returns NULL on failure. Possible reasons for failure

include out of memory and specifying an mxArray that is not a string

mxArray.

Description Call mxArrayToString to copy the character data of a string mxArray into a C-style string. The C-style string is always terminated with a

NULL character.

If the string array contains several rows, they are copied, one column at a time, into one long string array. This function is similar to

mxGetString, except that

• It does not require the length of the string as an input.

• It supports multibyte encoded characters.

mxArrayToString does not free the dynamic memory that the char pointer points to. Consequently, you should typically free the string (using mxFree) immediately after you have finished using it.

Examples

See the following examples in matlabroot/extern/examples/mex.

• mexatexit.c

See the following examples in matlabroot/extern/examples/mx.

• mxcreatecharmatrixfromstr.c

mxArrayToString (C)

• mxislogical.c

See Also

mxCreateCharArray, mxCreateCharMatrixFromStrings,
mxCreateString, mxGetString

Purpose

Check assertion value for debugging purposes

C Syntax

#include "matrix.h"

void mxAssert(int expr, char *error message);

Arguments

expr

Value of assertion

error message

Description of why assertion failed

Description

Like the ANSI C assert macro, mxAssert checks the value of an assertion, and continues execution only if the assertion holds. If expr evaluates to logical 1 (true), mxAssert does nothing. If expr evaluates to logical 0 (false), mxAssert terminates the MEX-file and prints an error to the MATLAB command window. The error contains the failed assertion's expression, the file name and line number where the failed assertion occurred, and the error_message string. The error_message string allows you to specify a better description of why the assertion failed. Use an empty string if you do not want a description to follow the failed assertion message.

The mex script turns off these assertions when building optimized MEX-functions, so use this for debugging purposes only. Build the MEX-file using the syntax mex -g filename in order to use mxAssert.

Assertions are a way of maintaining internal consistency of logic. Use them to keep yourself from misusing your own code and to prevent logical errors from propagating before they are caught; do not use assertions to prevent users of your code from misusing it.

Assertions can be taken out of your code by the C preprocessor. You can use these checks during development and then remove them when the code works properly, letting you use them for troubleshooting during development without slowing down the final product.

See Also

mxAssertS, mexErrMsgIdAndTxt

mxAssertS (C)

Purpose Check assertion value without printing assertion text

C Syntax #include "matrix.h"

void mxAssertS(int expr, char *error_message);

Arguments expr

Value of assertion

error_message

Description of why assertion failed

Description mxAssertS is like mxAssert, except mxAssertS does not print the text of

the failed assertion.

See Also mxAssert

mxCalcSingleSubscript (C and Fortran)

Purpose Offset from first element to desired element

C Syntax #include "matrix.h"

mwIndex mxCalcSingleSubscript(const mxArray *pm, mwSize nsubs,

mwIndex *subs);

Fortran Syntax mwIndex mxCalcSingleSubscript(pm, nsubs, subs)

mwPointer pm
mwSize nsubs

mwSize nsubs mwIndex subs

Arguments

pm

Pointer to an mxArray

nsubs

Number of elements in the subs array. Typically, you set nsubs equal to the number of dimensions in the mxArray that pm points to.

subs

An array of integers. Each value in the array specifies that dimension's subscript. In C syntax, the value in subs[0] specifies the row subscript, and the value in subs[1] specifies the column subscript. Use zero-based indexing for subscripts. For example, to express the starting element of a two-dimensional mxArray in subs, set subs[0] to 0 and subs[1] to 0.

In Fortran syntax, the value in subs(1) specifies the row subscript, and the value in subs(2) specifies the column subscript. Use 1-based indexing for subscripts. For example, to express the starting element of a two-dimensional mxArray in subs, set subs(1) to 1 and subs(2) to 1.

Returns

The number of elements, or *index*, between the start of the mxArray and the specified subscript. This is the linear index equivalent of

mxCalcSingleSubscript (C and Fortran)

the subscripts. Many MX Matrix Library routines (for example, mxGetField) require an index as an argument.

If subs describes the starting element of an mxArray, mxCalcSingleSubscript returns 0. If subs describes the final element of an mxArray, mxCalcSingleSubscript returns N-1 (where N is the total number of elements).

Description

Call mxCalcSingleSubscript to determine how many elements there are between the beginning of the mxArray and a given element of that mxArray. The function converts subscripts to linear indices.

For example, given a subscript like (5,7), mxCalcSingleSubscript returns the distance from the first element of the array to the (5,7) element. Remember that the mxArray data type internally represents all data elements in a one-dimensional array no matter how many dimensions the MATLAB mxArray appears to have. For examples showing the internal representation, see "Data Storage".

Avoid using mxCalcSingleSubscript to traverse the elements of an array. In C, it is more efficient to do this by finding the array's starting address and then using pointer autoincrementing to access successive elements. For example, to find the starting address of a numerical array, call mxGetPr or mxGetPi.

Examples

See the following examples in matlabroot/extern/examples/mx.

• mxcalcsinglesubscript.c

See Also

mxGetCell, mxSetCell

mxCalloc (C and Fortran)

Purpose

Allocate dynamic memory for array using MATLAB memory manager

C Syntax

```
#include "matrix.h"
#include <stdlib.h>
```

void *mxCalloc(mwSize n, mwSize size);

Fortran Syntax

mwPointer mxCalloc(n, size)
mwSize n, size

Arguments

n

Number of elements to allocate. This must be a nonnegative number.

size

Number of bytes per element. (The C sizeof operator calculates the number of bytes per element.)

Returns

Pointer to the start of the allocated dynamic memory, if successful. If unsuccessful in a MAT or engine standalone application, mxCalloc returns NULL in C (0 in Fortran). If unsuccessful in a MEX-file, the MEX-file terminates and control returns to the MATLAB prompt.

mxCalloc is unsuccessful when there is insufficient free heap space.

Description

mxCalloc allocates contiguous heap space sufficient to hold n elements of size bytes each, and initializes this newly allocated memory to 0. Use mxCalloc instead of the ANSI C calloc function to allocate memory in MATLAB applications.

In MEX-files, but not MAT or engine applications, mxCalloc registers the allocated memory with the MATLAB memory manager. When control returns to the MATLAB prompt, the memory manager then automatically frees, or *deallocates*, this memory.

How you manage the memory created by this function depends on the purpose of the data assigned to it. If you assign it to an output argument in plhs[] using the mxSetPr function, MATLAB is responsible for freeing the memory.

mxCalloc (C and Fortran)

If you use the data internally, the MATLAB memory manager maintains a list of all memory allocated by the function and automatically frees (deallocates) the memory when control returns to the MATLAB prompt. In general, we recommend that MEX-file functions destroy their own temporary arrays and free their own dynamically allocated memory. It is more efficient to perform this cleanup in the source MEX-file than to rely on the automatic mechanism. Therefore, when you finish using the memory allocated by this function, call mxFree to deallocate the memory.

If you do not assign this data to an output argument, and you want it to persist after the MEX-file completes, call mexMakeMemoryPersistent after calling this function. If you write a MEX-file with persistent memory, be sure to register a mexAtExit function to free allocated memory in the event your MEX-file is cleared.

Examples

See the following examples in matlabroot/extern/examples/mex.

• explore.c

See the following examples in matlabroot/extern/examples/refbook.

See Also

 $\label{lem:mexatexit} mexMakeArrayPersistent, mexMakeMemoryPersistent, \\ mxDestroyArray, mxFree, mxMalloc, mxRealloc$

Purpose Type for string array

Description A string mxArray stores its data elements as mxChar rather than as

char. MATLAB stores characters as 2-byte Unicode characters on

machines with multi-byte character sets.

The header file containing this type is:

#include "matrix.h"

Examples See the following examples in *matlabroot*/extern/examples/mx.

• mxmalloc.c

• mxcreatecharmatrixfromstr.c

See the following examples in matlabroot/extern/examples/mex.

• explore.c

See Also mxCreateCharArray

Purpose

Enumerated value identifying class of array

C Syntax

```
typedef enum {
        mxUNKNOWN CLASS,
        mxCELL CLASS,
        mxSTRUCT CLASS,
        mxLOGICAL CLASS,
        mxCHAR CLASS,
        mxVOID CLASS,
        mxDOUBLE CLASS,
        mxSINGLE CLASS,
        mxINT8 CLASS,
        mxUINT8 CLASS,
        mxINT16 CLASS,
        mxUINT16 CLASS,
        mxINT32 CLASS,
        mxUINT32 CLASS,
        mxINT64 CLASS,
        mxUINT64 CLASS,
        mxFUNCTION CLASS
} mxClassID;
```

Constants

mxUNKNOWN CLASS

Undetermined class. You cannot specify this category for an mxArray; however, if mxGetClassID cannot identify the class, it returns this value.

mxCELL CLASS

Identifies a cell mxArray.

mxSTRUCT CLASS

Identifies a structure mxArray.

mxLOGICAL CLASS

Identifies a logical mxArray, an mxArray of mxLogical data.

mxCHAR CLASS

Identifies a string mxArray, an mxArray whose data is represented as mxChar.

mxVOID CLASS

Reserved.

mxDOUBLE CLASS

Identifies a numeric mxArray whose data is stored as the type specified in the MATLAB Primitive Types table.

mxSINGLE CLASS

Identifies a numeric mxArray whose data is stored as the type specified in the MATLAB Primitive Types table.

mxINT8 CLASS

Identifies a numeric mxArray whose data is stored as the type specified in the MATLAB Primitive Types table.

mxUINT8_CLASS

Identifies a numeric mxArray whose data is stored as the type specified in the MATLAB Primitive Types table.

mxINT16 CLASS

Identifies a numeric mxArray whose data is stored as the type specified in the MATLAB Primitive Types table.

mxUINT16 CLASS

Identifies a numeric mxArray whose data is stored as the type specified in the MATLAB Primitive Types table.

mxINT32 CLASS

Identifies a numeric mxArray whose data is stored as the type specified in the MATLAB Primitive Types table.

mxUINT32 CLASS

Identifies a numeric mxArray whose data is stored as the type specified in the MATLAB Primitive Types table.

mxINT64 CLASS

Identifies a numeric mxArray whose data is stored as the type specified in the MATLAB Primitive Types table.

mxUINT64 CLASS

Identifies a numeric mxArray whose data is stored as the type specified in the MATLAB Primitive Types table.

mxClassID (C)

mxFUNCTION_CLASS

Identifies a function handle mxArray.

Description

Various MX Matrix Library functions require or return an mxClassID argument. mxClassID identifies the way in which the mxArray represents its data elements.

The following table shows MATLAB types with their equivalent C types. Use the type from the right-most column for reading mxArrays with the mxClassID value shown in the left column.

MATLAB Primitive Types

mxClassID Value	MATLAB Type	MEX Type	C Primitive Type
mxINT8_CLAS	Sint8	int8_T	char, byte
mxUINT8_CLA	S£nt8	uint8_T	unsigned char, byte
mxINT16_CLA	∖SiSnt16	int16_T	short
mxUINT16_CL	ASSnt16	uint16_T	unsigned short
mxINT32_CLA	∖SiSnt32	int32_T	int
mxUINT32_CL	ASSnt32	uint32_T	unsigned int
mxINT64_CLA	∖SiSnt64	int64_T	long long
mxUINT64_CL	ASSnt64	uint64_T	unsigned long long
mxSINGLE_CL	AsSiSngle	float	float
mxDOUBLE_CL	AdStrible	double	double

mxGetClassID , mxCreateNumericArray

mxClassIDFromClassName (Fortran)

Purpose Identifier corresponding to class

Fortran integer*4 mxClassIDFromClassName(classname)

Syntax character*(*) classname

Arguments classname

character array specifying a MATLAB class name. For a list of valid classname choices, see the mxIsClass reference page.

valid classifalle choices, see the lixisciass reference page.

Returns Numeric identifier used internally by MATLAB software to represent

the MATLAB class, classname. Returns unknown if classname is not a

recognized MATLAB class.

Description Use mxClassIDFromClassName to obtain an identifier for any MATLAB

class. This function is most commonly used to provide a classid argument to mxCreateNumericArray and mxCreateNumericMatrix.

Examples See the following examples in *matlabroot*/extern/examples/refbook.

• matsqint8.F

See Also mxGetClassName, mxCreateNumericArray, mxCreateNumericMatrix,

mxIsClass

mxComplexity (C)

Purpose Flag specifying whether array has imaginary components

C Syntax typedef enum mxComplexity {mxREAL=0, mxCOMPLEX};

Constants mxREAL

Identifies an mxArray with no imaginary components.

mxCOMPLEX

Identifies an mxArray with imaginary components.

Description Various MX Matrix Library functions require an mxComplexity

argument. You can set an mxComplex argument to either mxREAL or

mxCOMPLEX.

Examples See the following examples in *matlabroot*/extern/examples/mx.

• mxcalcsinglesubscript.c

See Also mxCreateNumericArray, mxCreateDoubleMatrix, mxCreateSparse

mxCopyCharacterToPtr (Fortran)

Purpose CHARACTER values from Fortran array to pointer array

Fortran Syntax subroutine mxCopyCharacterToPtr(y, px, n)
character*(*) y

mwPointer px

mwSize n

Arguments

character Fortran array

рх

У

Pointer to character or name array

n

Number of elements to copy

Description

mxCopyCharacterToPtr copies n character values from the Fortran character array y into the MATLAB string array pointed to by px. This subroutine is essential for copying character data between MATLAB pointer arrays and ordinary Fortran character arrays.

See Also

mxCopyPtrToCharacter, mxCreateCharArray, mxCreateString,

mxCreateCharMatrixFromStrings

mxCopyComplex16ToPtr (Fortran)

Purpose COMPLEX*16 values from Fortran array to pointer array Fortran subroutine mxCopyComplex16ToPtr(y, pr, pi, n) **Syntax** complex*16 y(n)mwPointer pr, pi mwSize n **Arguments** У COMPLEX*16 Fortran array pr Pointer to the real data of a double-precision MATLAB array рi Pointer to the imaginary data of a double-precision MATLAB array n Number of elements to copy **Description** mxCopyComplex16ToPtr copies n COMPLEX*16 values from the Fortran COMPLEX*16 array v into the MATLAB arrays pointed to by pr and pi. Sets up standard Fortran arrays for passing as arguments to or from the computation routine of a MEX-file. Use this subroutine with Fortran compilers that do not support the %VAL construct. **Examples** See the following examples in matlabroot/extern/examples/refbook. • convec.F See Also mxCopyPtrToComplex16, mxCreateNumericArray,

mxCopyPtrToReal8, mxCreateNumericArray, mxCreateNumericMatrix, mxGetData, mxGetImagData

mxCreateCellArray (C and Fortran)

Purpose

N-D cell array

C Syntax

```
#include "matrix.h"
```

mxArray *mxCreateCellArray(mwSize ndim, const mwSize *dims);

Fortran Syntax

mwPointer mxCreateCellArray(ndim, dims)

mwSize ndim, dims

Arguments

ndim

Number of dimensions in the created cell. For example, to create a three-dimensional cell mxArray, set ndim to 3.

dims

Dimensions array. Each element in the dimensions array contains the size of the mxArray in that dimension. For example, in C, setting dims[0] to 5 and dims[1] to 7 establishes a 5-by-7 mxArray. In Fortran, setting dims(1) to 5 and dims(2) to 7 establishes a 5-by-7 mxArray. In most cases, there should be ndim elements in the dims array.

Returns

Pointer to the created mxArray, if successful. If unsuccessful in a standalone (non-MEX-file) application, returns NULL in C (0 in Fortran). If unsuccessful in a MEX-file, the MEX-file terminates and returns control to the MATLAB prompt. The function is unsuccessful when there is not enough free heap space to create the mxArray.

Description

Use mxCreateCellArray to create a cell mxArray with size defined by ndim and dims. For example, in C, to establish a three-dimensional cell mxArray having dimensions 4-by-8-by-7, set:

```
ndim = 3;
dims[0] = 4; dims[1] = 8; dims[2] = 7;
```

In Fortran, to establish a three-dimensional cell mxArray having dimensions 4-by-8-by-7, set:

```
ndim = 3;
```

mxCreateCellArray (C and Fortran)

```
dims(1) = 4; dims(2) = 8; dims(3) = 7;
```

The created cell mxArray is unpopulated; mxCreateCellArray initializes each cell to NULL. To put data into a cell, call mxSetCell.

MATLAB automatically removes any trailing singleton dimensions specified in the dims argument. For example, if ndim equals 5 and dims equals [4 1 7 1 1], the resulting array has the dimensions 4-by-1-by-7.

Examples

See the following examples in matlabroot/extern/examples/refbook.

• phonebook.c

See Also

mxCreateCellMatrix, mxGetCell, mxSetCell, mxIsCell

mxCreateCellMatrix (C and Fortran)

Purpose 2-D cell array

C Syntax #include "matrix.h"

mxArray *mxCreateCellMatrix(mwSize m, mwSize n);

Fortran Syntax

mwPointer mxCreateCellMatrix(m, n)

mwSize m, n

Arguments

Number of rows

n

m

Number of columns

Returns

Pointer to the created mxArray, if successful. If unsuccessful in a standalone (non-MEX-file) application, returns NULL in C (0 in Fortran). If unsuccessful in a MEX-file, the MEX-file terminates and returns control to the MATLAB prompt. The function is unsuccessful when there is not enough free heap space to create the mxArray.

Description

Use mxCreateCellMatrix to create an m-by-n two-dimensional cell mxArray. The created cell mxArray is unpopulated; mxCreateCellMatrix initializes each cell to NULL in C (0 in Fortran). To put data into cells, call mxSetCell.

mxCreateCellMatrix is identical to mxCreateCellArray except that mxCreateCellMatrix can create two-dimensional mxArrays only, but mxCreateCellArray can create mxArrays having any number of dimensions greater than 1.

Examples

See the following examples in matlabroot/extern/examples/mx.

- mxcreatecellmatrix.c
- mxcreatecellmatrixf.F

See Also mxCreateCellArray

mxCreateCharArray (C and Fortran)

Purpose N-D string array

C Syntax #include "matrix.h"

mxArray *mxCreateCharArray(mwSize ndim, const mwSize *dims);

Fortran Syntax

mwPointer mxCreateCharArray(ndim, dims)

mwSize ndim, dims

Arguments ndim

Number of dimensions in the string mxArray. You must specify a positive number. If you specify 0, 1, or 2, mxCreateCharArray

creates a two-dimensional mxArray.

dims

Dimensions array. Each element in the dimensions array contains the size of the array in that dimension. For example, in C, setting dims[0] to 5 and dims[1] to 7 establishes a 5-by-7 mxArray. In Fortran, setting dims(1) to 5 and dims(2) to 7 establishes a 5-by-7 character mxArray. The dims array must have at least

ndim elements.

Returns Pointer to the created mxArray, if successful. If unsuccessful in a

standalone (non-MEX-file) application, returns NULL in C (0 in Fortran). If unsuccessful in a MEX-file, the MEX-file terminates and returns control to the MATLAB prompt. The function is unsuccessful when

there is not enough free heap space to create the mxArray.

Description Call mxCreateCharArray to create an N-dimensional string mxArray.

The created mxArray is unpopulated; that is, mxCreateCharArray

initializes each cell to NULL in C (0 in Fortran).

MATLAB automatically removes any trailing singleton dimensions specified in the dims argument. For example, if ndim equals 5 and dims equals [4 1 7 1 1], the resulting array has the dimensions

4-by-1-by-7.

See Also mxCreateCharMatrixFromStrings, mxCreateString

mxCreateCharMatrixFromStrings (C and Fortran)

Purpose

2-D string array initialized to specified value

C Syntax

#include "matrix.h"

mxArray *mxCreateCharMatrixFromStrings(mwSize m, const char **str);

Fortran Syntax mwPointer mxCreateCharMatrixFromStrings(m, str)

mwSize m

character*(*) str(m)

Arguments

m

Number of rows in the created string mxArray. The value you

specify for m is the number of strings in str.

str

In C, an array of strings containing at least m strings. In Fortran, a character*n array of size m, where each element of the array

is n bytes.

Returns

Pointer to the created mxArray, if successful. If unsuccessful in a standalone (non-MEX-file) application, returns NULL in C (0 in Fortran). If unsuccessful in a MEX-file, the MEX-file terminates and returns control to the MATLAB prompt. The function is unsuccessful when there is not enough free heap space to create the mxArray. Another

possible reason for failure is that str contains fewer than m strings.

Description

Use mxCreateCharMatrixFromStrings to create a two-dimensional string mxArray, where each row is initialized to a string from str. In C, the created mxArray has dimensions m-by-max, where max is the length of the longest string in str. In Fortran, the created mxArray has dimensions m-by-n, where n is the number of characters in str(i).

String mxArrays represent their data elements as mxChar rather than

as C char.

Examples

See the following examples in *matlabroot*/extern/examples/mx.

• mxcreatecharmatrixfromstr.c

mxCreateCharMatrixFromStrings (C and Fortran)

See Also

mxCreateCharArray, mxCreateString, mxGetString

mxCreateDoubleMatrix (C and Fortran)

Purpose

2-D, double-precision, floating-point array

C Syntax

#include "matrix.h"
mxArray *mxCreateDoubleMatrix(mwSize m, mwSize n,

mxComplexity ComplexFlag);

Fortran Syntax

mwPointer mxCreateDoubleMatrix(m, n, ComplexFlag)

mwSize m, n

integer*4 ComplexFlag

Arguments

m

Number of rows

n

Number of columns

ComplexFlag

If the mxArray you are creating is to contain imaginary data, set ComplexFlag to mxCOMPLEX in C (1 in Fortran). Otherwise, set ComplexFlag to mxREAL in C (0 in Fortran).

Returns

Pointer to the created mxArray, if successful. If unsuccessful in a standalone (non-MEX-file) application, returns NULL in C (0 in Fortran). If unsuccessful in a MEX-file, the MEX-file terminates and returns control to the MATLAB prompt. The function is unsuccessful when there is not enough free heap space to create the mxArray.

Description

Use mxCreateDoubleMatrix to create an m-by-n mxArray. mxCreateDoubleMatrix initializes each element in the pr array to 0. If you set ComplexFlag to mxCOMPLEX in C (1 in Fortran), mxCreateDoubleMatrix also initializes each element in the pi array to 0.

If you set ComplexFlag to mxREAL in C (0 in Fortran), mxCreateDoubleMatrix allocates enough memory to hold m-by-n real elements. If you set ComplexFlag to mxCOMPLEX in C (1 in Fortran), mxCreateDoubleMatrix allocates enough memory to hold m-by-n real elements and m-by-n imaginary elements.

mxCreateDoubleMatrix (C and Fortran)

Call mxDestroyArray when you finish using the mxArray. mxDestroyArray deallocates the mxArray and its associated real and complex elements.

Examples

See the following examples in matlabroot/extern/examples/refbook.

- convec.c
- findnz.c
- matrixDivide.c
- sincall.c
- timestwo.c
- timestwoalt.c
- xtimesy.c

- xtimesy.F

See Also

mxCreateNumericArray

mxCreateDoubleScalar (C and Fortran)

Purpose Scalar, double-precision array initialized to specified value

C Syntax #include "matrix.h"

mxArray *mxCreateDoubleScalar(double value);

Fortran mwPointer mxCreateDoubleScalar(value)

Syntax real*8 value

Arguments value

Value to which you want to initialize the array

Returns Pointer to the created mxArray, if successful. If unsuccessful in a

standalone (non-MEX-file) application, returns NULL in C (0 in Fortran). If unsuccessful in a MEX-file, the MEX-file terminates and returns control to the MATLAB prompt. The function is unsuccessful when

there is not enough free heap space to create the mxArray.

Description Call mxCreateDoubleScalar to create a scalar double mxArray. When

you finish using the ${\tt mxArray},$ call ${\tt mxDestroyArray}$ to destroy it.

Alternatives C Language

In C, you can replace the statements:

```
pa = mxCreateDoubleMatrix(1, 1, mxREAL);
*mxGetPr(pa) = value;
```

with a call to mxCreateDoubleScalar:

pa = mxCreateDoubleScalar(value);

Fortran Language

In Fortran, you can replace the statements:

```
pm = mxCreateDoubleMatrix(1, 1, 0)
mxCopyReal8ToPtr(value, mxGetPr(pm), 1)
```

mxCreateDoubleScalar (C and Fortran)

with a call to mxCreateDoubleScalar:

pm = mxCreateDoubleScalar(value)

See Also mxGetPr, mxCreateDoubleMatrix

mxCreateLogicalArray (C)

Purpose N-D logical array

C Syntax #include "matrix.h"

mxArray *mxCreateLogicalArray(mwSize ndim, const mwSize *dims);

Arguments ndim

> Number of dimensions. If you specify a value for ndim that is less than 2, mxCreateLogicalArray automatically sets the number of dimensions to 2.

dims

Dimensions array. Each element in the dimensions array contains the size of the array in that dimension. For example, setting dims[0] to 5 and dims[1] to 7 establishes a 5-by-7 mxArray. There are ndim elements in the dims array.

Returns Pointer to the created mxArray, if successful. If unsuccessful in a

standalone (non-MEX-file) application, returns NULL in C (0 in Fortran). If unsuccessful in a MEX-file, the MEX-file terminates and returns control to the MATLAB prompt. The function is unsuccessful when there is not enough free heap space to create the mxArray.

Description Call mxCreateLogicalArray to create an N-dimensional mxArray of mxLogical elements. After creating the mxArray, mxCreateLogicalArray initializes all its elements to logical 0. mxCreateLogicalArray differs from mxCreateLogicalMatrix in that the latter can create two-dimensional arrays only.

> mxCreateLogicalArray allocates dynamic memory to store the created mxArray. When you finish with the created mxArray, call mxDestroyArray to deallocate its memory.

MATLAB automatically removes any trailing singleton dimensions specified in the dims argument. For example, if ndim equals 5 and dims equals [4 1 7 1 1], the resulting array has the dimensions 4-by-1-by-7.

mxCreateLogicalArray (C)

See Also

 $\label{logical} \mbox{\tt mxCreateLogicalMatrix, mxCreateSparseLogicalMatrix,} \\ \mbox{\tt mxCreateLogicalScalar}$

mxCreateLogicalMatrix (C)

Purpose 2-D logical array

C Syntax #include "matrix.h"

mxArray *mxCreateLogicalMatrix(mwSize m, mwSize n);

Arguments m

Number of rows

n

Number of columns

Returns Pointer to the created mxArray, if successful. If unsuccessful in a

standalone (non-MEX-file) application, returns NULL in C (0 in Fortran). If unsuccessful in a MEX-file, the MEX-file terminates and returns control to the MATLAB prompt. The function is unsuccessful when

there is not enough free heap space to create the mxArray.

Description Use mxCreateLogicalMatrix to create an m-by-n mxArray of mxLogical

elements. mxCreateLogicalMatrix initializes each element in the

array to logical 0.

Call mxDestroyArray when you finish using the mxArray.

mxDestroyArray deallocates the mxArray.

Examples See the following examples in *matlabroot*/extern/examples/mx.

• mxislogical.c

See Also mxCreateLogicalArray, mxCreateSparseLogicalMatrix,

mxCreateLogicalScalar

mxCreateLogicalScalar (C)

Purpose Scalar, logical array

C Syntax #include "matrix.h"

mxArray *mxCreateLogicalScalar(mxLogical value);

Arguments value

Logical value to which you want to initialize the array

Returns Pointer to the created mxArray, if successful. If unsuccessful in a

standalone (non-MEX-file) application, returns NULL in C (0 in Fortran). If unsuccessful in a MEX-file, the MEX-file terminates and returns control to the MATLAB prompt. The function is unsuccessful when

there is not enough free heap space to create the mxArray.

Description Call mxCreateLogicalScalar to create a scalar logical mxArray.

mxCreateLogicalScalar is a convenience function that replaces the

following code:

pa = mxCreateLogicalMatrix(1, 1); *mxGetLogicals(pa) = value;

When you finish using the mxArray, call mxDestroyArray to destroy it.

See Also mxCreateLogicalArray, mxCreateLogicalMatrix,

mxIsLogicalScalar, mxIsLogicalScalarTrue, mxGetLogicals,

mxDestroyArray

mxCreateNumericArray (C and Fortran)

Purpose N-D numeric array

C Syntax #include "matrix.h"

mxArray *mxCreateNumericArray(mwSize ndim, const mwSize *dims,

mxClassID classid, mxComplexity ComplexFlag);

Fortran Syntax

mwPointer mxCreateNumericArray(ndim, dims, classid,

ComplexFlag)
mwSize ndim, dims

integer*4 classid, ComplexFlag

Arguments

ndim

Number of dimensions. If you specify a value for ndim that is less than 2, mxCreateNumericArray automatically sets the number of dimensions to 2.

dims

Dimensions array. Each element in the dimensions array contains the size of the array in that dimension. For example, in C, setting dims[0] to 5 and dims[1] to 7 establishes a 5-by-7 mxArray. In Fortran, setting dims(1) to 5 and dims(2) to 7 establishes a 5-by-7 mxArray. In most cases, there are ndim elements in the dims array.

classid

Identifier for the class of the array, which determines the way the numerical data is represented in memory. For example, specifying mxINT16_CLASS in C causes each piece of numerical data in the mxArray to be represented as a 16-bit signed integer. In Fortran, use the function mxClassIDFromClassName to derive the classid value from a MATLAB class name. See the Description section for more information.

ComplexFlag

If the mxArray you are creating is to contain imaginary data, set ComplexFlag to mxCOMPLEX in C (1 in Fortran). Otherwise, set ComplexFlag to mxREAL in C (0 in Fortran).

mxCreateNumericArray (C and Fortran)

Returns

Pointer to the created mxArray, if successful. If unsuccessful in a standalone (non-MEX-file) application, returns NULL in C (0 in Fortran). If unsuccessful in a MEX-file, the MEX-file terminates and returns control to the MATLAB prompt. The function is unsuccessful when there is not enough free heap space to create the mxArray.

Description

Call mxCreateNumericArray to create an N-dimensional mxArray in which all data elements have the numeric data type specified by classid. After creating the mxArray, mxCreateNumericArray initializes all its real data elements to 0. If ComplexFlag equals mxCOMPLEX in C (1 in Fortran), mxCreateNumericArray also initializes all its imaginary data elements to 0. mxCreateNumericArray differs from mxCreateDoubleMatrix as follows:

- All data elements in mxCreateDoubleMatrix are double-precision, floating-point numbers. The data elements in mxCreateNumericArray can be any numerical type, including different integer precisions.
- mxCreateDoubleMatrix can create two-dimensional arrays only; mxCreateNumericArray can create arrays of two or more dimensions.

mxCreateNumericArray allocates dynamic memory to store the created mxArray. When you finish with the created mxArray, call mxDestroyArray to deallocate its memory.

MATLAB automatically removes any trailing singleton dimensions specified in the dims argument. For example, if ndim equals 5 and dims equals [4 1 7 1 1], the resulting array has the dimensions 4-by-1-by-7.

The following table shows the C classid values and the Fortran data types that are equivalent to MATLAB classes.

MATLAB Class Name	C classid Value	Fortran Type
int8	mxINT8_CLASS	BYTE
uint8	mxUINT8_CLASS	

mxCreateNumericArray (C and Fortran)

MATLAB Class Name	C classid Value	Fortran Type
int16	mxINT16_CLASS	INTEGER*2
uint16	mxUINT16_CLASS	
int32	mxINT32_CLASS	INTEGER*4
uint32	mxUINT32_CLASS	
int64	mxINT64_CLASS	INTEGER*8
uint64	mxUINT64_CLASS	
single	mxSINGLE_CLASS	REAL*4
double	mxDOUBLE_CLASS	REAL*8
single, with imaginary components	mxSINGLE_CLASS	COMPLEX*8
double, with imaginary components	mxDOUBLE_CLASS	COMPLEX*16

Examples

See the following examples in matlabroot/extern/examples/refbook.

- phonebook.c
- doubleelement.c
- matrixDivide.c
- matsqint8.F

See the following examples in matlabroot/extern/examples/mx.

• mxisfinite.c

mxCreateNumericMatrix (C and Fortran)

Purpose 2-D numeric matrix

C Syntax #include "matrix.h"

mxArray *mxCreateNumericMatrix(mwSize m, mwSize n,
 mxClassID classid, mxComplexity ComplexFlag);

Fortran Syntax

mwPointer mxCreateNumericMatrix(m, n, classid,

ComplexFlag)
mwSize m, n

integer*4 classid, ComplexFlag

Arguments

Number of rows

n

m

Number of columns

classid

Identifier for the class of the array, which determines the way the numerical data is represented in memory. For example, specifying mxINT16_CLASS in C causes each piece of numerical data in the mxArray to be represented as a 16-bit signed integer. In Fortran, use the function mxClassIDFromClassName to derive the classid value from a MATLAB class name.

ComplexFlag

If the mxArray you are creating is to contain imaginary data, set ComplexFlag to mxCOMPLEX in C (1 in Fortran). Otherwise, set ComplexFlag to mxREAL in C (0 in Fortran).

Returns

Pointer to the created mxArray, if successful. If unsuccessful in a standalone (non-MEX-file) application, returns NULL in C (0 in Fortran). If unsuccessful in a MEX-file, the MEX-file terminates and returns control to the MATLAB prompt. The function is unsuccessful when there is not enough free heap space to create the mxArray.

Description

Call mxCreateNumericMatrix to create a 2-D mxArray in which all data elements have the numeric data type specified by classid. After

mxCreateNumericMatrix (C and Fortran)

creating the mxArray, mxCreateNumericMatrix initializes all its real data elements to 0. If ComplexFlag equals mxCOMPLEX in C (1 in Fortran), mxCreateNumericMatrix also initializes all its imaginary data elements to 0. mxCreateNumericMatrix allocates dynamic memory to store the created mxArray. When you finish using the mxArray, call mxDestroyArray to destroy it.

The following table shows the C classid values and the Fortran data types that are equivalent to MATLAB classes.

MATLAB Class Name	C classid Value	Fortran Type
int8	mxINT8_CLASS	BYTE
uint8	mxUINT8_CLASS	
int16	mxINT16_CLASS	INTEGER*2
uint16	mxUINT16_CLASS	
int32	mxINT32_CLASS	INTEGER*4
uint32	mxUINT32_CLASS	
int64	mxINT64_CLASS	INTEGER*8
uint64	mxUINT64_CLASS	
single	mxSINGLE_CLASS	REAL*4
double	mxDOUBLE_CLASS	REAL*8
single, with imaginary components	mxSINGLE_CLASS	COMPLEX*8
double, with imaginary components	mxD0UBLE_CLASS	COMPLEX*16

Examples

See the following examples in matlabroot/extern/examples/refbook.

• arrayFillGetPr.c

mxCreateNumericMatrix (C and Fortran)

The following Fortran statements create a 4-by-3 matrix of REAL*4 elements having no imaginary components:

See Also

 $\label{lem:mxClassIdFromClassName, mxComplexity,} \\ \text{mxCreateNumericArray}$

mxCreateSparse (C and Fortran)

Purpose

2-D sparse array

C Syntax

#include "matrix.h"

 $\verb|mxArray| *mxCreateSparse(mwSize m, mwSize n, mwSize nzmax,$

mxComplexity ComplexFlag);

Fortran Syntax

mwPointer mxCreateSparse(m, n, nzmax, ComplexFlag)

mwSize m, n, nzmax
integer*4 ComplexFlag

Arguments

m

Number of rows

n

Number of columns

nzmax

Number of elements that mxCreateSparse should allocate to hold the pr, ir, and, if ComplexFlag is mxCOMPLEX in C (1 in Fortran), pi arrays. Set the value of nzmax to be greater than or equal to the number of nonzero elements you plan to put into the mxArray, but make sure that nzmax is less than or equal to m*n.

ComplexFlag

If the mxArray you are creating is to contain imaginary data, set ComplexFlag to mxCOMPLEX in C (1 in Fortran). Otherwise, set ComplexFlag to mxREAL in C (0 in Fortran).

Returns

Pointer to the created mxArray, if successful. If unsuccessful in a standalone (non-MEX-file) application, returns NULL in C (0 in Fortran). If unsuccessful in a MEX-file, the MEX-file terminates and returns control to the MATLAB prompt. The function is unsuccessful when there is not enough free heap space to create the mxArray. In that case, try reducing nzmax, m, or n.

Description

Call mxCreateSparse to create an unpopulated sparse double mxArray. The returned sparse mxArray contains no sparse information and cannot be passed as an argument to any MATLAB sparse functions. To

mxCreateSparse (C and Fortran)

make the returned sparse mxArray useful, you must initialize the pr, ir, jc, and (if it exists) pi arrays.

mxCreateSparse allocates space for:

- A pr array of length nzmax.
- A pi array of length nzmax, but only if ComplexFlag is mxCOMPLEX in C (1 in Fortran).
- An ir array of length nzmax.
- A jc array of length n+1.

When you finish using the sparse mxArray, call mxDestroyArray to reclaim all its heap space.

Examples

See the following examples in matlabroot/extern/examples/refbook.

- fulltosparse.c
- fulltosparse.F

mxCreateSparseLogicalMatrix (C)

Purpose

2-D, sparse, logical array

C Syntax

#include "matrix.h"

mxArray *mxCreateSparseLogicalMatrix(mwSize m, mwSize n,

mwSize nzmax);

Arguments

m

Number of rows

n

Number of columns

nzmax

Number of elements that mxCreateSparseLogicalMatrix should allocate to hold the data. Set the value of nzmax to be greater than or equal to the number of nonzero elements you plan to put into the mxArray, but make sure that nzmax is less than or equal to m*n.

Returns

Pointer to the created mxArray, if successful. If unsuccessful in a standalone (non-MEX-file) application, returns NULL in C (0 in Fortran). If unsuccessful in a MEX-file, the MEX-file terminates and returns control to the MATLAB prompt. The function is unsuccessful when there is not enough free heap space to create the mxArray.

Description

Use mxCreateSparseLogicalMatrix to create an m-by-n mxArray of mxLogical elements. mxCreateSparseLogicalMatrix initializes each element in the array to logical 0.

Call mxDestroyArray when you finish using the mxArray. mxDestroyArray deallocates the mxArray and its elements.

See Also

 $\label{logical} {\tt mxCreateLogicalArray,\ mxCreateLogicalMatrix,} \\ {\tt mxCreateLogicalScalar,\ mxCreateSparse,\ mxIsLogical} \\$

mxCreateString (C and Fortran)

Purpose 1-N array initialized to specified string

C Syntax #include "matrix.h"

mxArray *mxCreateString(const char *str);

Fortran mwPointer mxCreateString(str)

Syntax character*(*) str

Arguments str

String that is to serve as the mxArray's initial data

Returns Pointer to the created mxArray, if successful. If unsuccessful in a

standalone (non-MEX-file) application, returns NULL in C (0 in Fortran). If unsuccessful in a MEX-file, the MEX-file terminates and returns control to the MATLAB prompt. The function is unsuccessful when

there is not enough free heap space to create the mxArray.

Description Use mxCreateString to create a string mxArray initialized to str.

Many MATLAB functions (for example, strcmp and upper) require

string array inputs.

Free the string mxArray when you are finished using it. To free a string

mxArray, call mxDestroyArray.

Examples See the following examples in *matlabroot*/extern/examples/refbook.

• revord.c

revord.F

mxCreateString (C and Fortran)

• matdemo1.F

See Also

 $\verb|mxCreateCharMatrixFromStrings|, \verb|mxCreateCharArray||$

mxCreateStructArray (C and Fortran)

Purpose N-D structure array

C Syntax #include "matrix.h"

mxArray *mxCreateStructArray(mwSize ndim, const mwSize *dims,

int nfields, const char **fieldnames);

Fortran Syntax

mwPointer mxCreateStructArray(ndim, dims, nfields,

fieldnames)

mwSize ndim, dims
integer*4 nfields

character*(*) fieldnames(nfields)

Arguments

ndim

Number of dimensions. If you set ndim to be less than 2, mxCreateStructArray creates a two-dimensional mxArray.

dims

Dimensions array. Each element in the dimensions array contains the size of the array in that dimension. For example, in C, setting dims[0] to 5 and dims[1] to 7 establishes a 5-by-7 mxArray. In Fortran, setting dims(1) to 5 and dims(2) to 7 establishes a 5-by-7 mxArray. Typically, the dims array should have ndim elements.

nfields

Number of fields in each element

fieldnames

List of field names

Each structure field name must begin with a letter and is case sensitive. The rest of the name may contain letters, numerals, and underscore characters. Use the namelengthmax function to determine the maximum length of a field name.

Returns

Pointer to the created mxArray, if successful. If unsuccessful in a standalone (non-MEX-file) application, returns NULL in C (0 in Fortran).

mxCreateStructArray (C and Fortran)

If unsuccessful in a MEX-file, the MEX-file terminates and returns control to the MATLAB prompt. The function is unsuccessful when there is not enough free heap space to create the mxArray.

Description

Call mxCreateStructArray to create an unpopulated structure mxArray. Each element of a structure mxArray contains the same number of fields (specified in nfields). Each field has a name; the list of names is specified in fieldnames. A MATLAB structure mxArray is conceptually identical to an array of structs in the C language.

Each field holds one mxArray pointer. mxCreateStructArray initializes each field to NULL in C (0 in Fortran). Call mxSetField or mxSetFieldByNumber to place a non-NULL mxArray pointer in a field.

When you finish using the returned structure mxArray, call mxDestroyArray to reclaim its space.

Any trailing singleton dimensions specified in the dims argument are automatically removed from the resulting array. For example, if ndim equals 5 and dims equals [4 1 7 1 1], the resulting array is given the dimensions 4-by-1-by-7.

Examples

See the following examples in matlabroot/extern/examples/mx.

• mxcreatestructarray.c

mxDestroyArray, mxAddField, mxRemoveField, mxSetField,
mxSetFieldByNumber

mxCreateStructMatrix (C and Fortran)

Purpose 2-D structure array

C Syntax #include "matrix.h"

mxArray *mxCreateStructMatrix(mwSize m, mwSize n, int nfields,

const char **fieldnames);

Fortran Syntax

mwPointer mxCreateStructMatrix(m, n, nfields, fieldnames)

mwSize m, n

integer*4 nfields

character*(*) fieldnames(nfields)

Arguments

Number of rows. This must be a positive integer.

n

m

Number of columns. This must be a positive integer.

nfields

Number of fields in each element.

fieldnames

List of field names.

Each structure field name must begin with a letter and is case sensitive. The rest of the name may contain letters, numerals, and underscore characters. Use the namelengthmax function to determine the maximum length of a field name.

the maximum length of a field har

Returns

Pointer to the created mxArray, if successful. If unsuccessful in a standalone (non-MEX-file) application, returns NULL in C (0 in Fortran). If unsuccessful in a MEX-file, the MEX-file terminates and returns control to the MATLAB prompt. The function is unsuccessful when there is not enough free heap space to create the mxArray.

Description

mxCreateStructMatrix and mxCreateStructArray are almost identical. The only difference is that mxCreateStructMatrix can create only two-dimensional mxArrays, while mxCreateStructArray can create mxArrays having two or more dimensions.

mxCreateStructMatrix (C and Fortran)

C

See the following examples in matlabroot/extern/examples/refbook.

Examples

• phonebook.c

See Also

mxCreateStructArray

mxDestroyArray (C and Fortran)

Purpose Free dynamic memory allocated by MXCREATE* functions

C Syntax #include "matrix.h"

void mxDestroyArray(mxArray *pm);

Fortran Syntax

subroutine mxDestroyArray(pm)

mwPointer pm

Arguments pm

Pointer to the mxArray you want to free

Description

mxDestroyArray deallocates the memory occupied by the specified mxArray. mxDestroyArray not only deallocates the memory occupied by the mxArray's characteristics fields (such as m and n), but also deallocates all the mxArray's associated data arrays, such as pr and pi for complex arrays, ir and jc for sparse arrays, fields of structure arrays, and cells of cell arrays. Do not call mxDestroyArray on an mxArray you are returning on the left-hand side.

Examples

See the following examples in matlabroot/extern/examples/refbook.

mxDuplicateArray (C and Fortran)

Purpose Make deep copy of array

C Syntax #include "matrix.h"

mxArray *mxDuplicateArray(const mxArray *in);

Fortran mwPointer mxDuplicateArray(in)

Syntax mwPointer in

Arguments in

Pointer to the mxArray you want to copy

Returns Pointer to the created mxArray, if successful. If unsuccessful in a

standalone (non-MEX-file) application, returns NULL in C (0 in Fortran). If unsuccessful in a MEX-file, the MEX-file terminates and returns control to the MATLAB prompt. The function is unsuccessful when

there is not enough free heap space to create the mxArray.

Description mxDuplicateArray makes a deep copy of an array, and returns a

pointer to the copy. A deep copy refers to a copy in which all levels of data are copied. For example, a deep copy of a cell array copies each cell

and the contents of each cell (if any), and so on.

Examples See the following examples in *matlabroot*/extern/examples/mex.

mxFree (C and Fortran)

Purpose Free dynamic memory allocated by MXCALLOC, MXMALLOC, or

MXREALLOC functions

C Syntax #include "matrix.h"

void mxFree(void *ptr);

Fortran subroutine mxFree(ptr)

Syntax mwPointer ptr

Arguments ptr

Pointer to the beginning of any memory parcel allocated by

mxCalloc, mxMalloc, or mxRealloc.

Description

mxFree deallocates heap space using the MATLAB memory management facility. This ensures correct memory management in error and abort (Ctrl+C) conditions.

To deallocate heap space, MATLAB applications in C should always call mxFree rather than the ANSI C free function.

In MEX-files, but excluding MAT or engine standalone applications, the MATLAB memory management facility maintains a list of all memory allocated by mxCalloc, mxMalloc, and mxRealloc. The memory management facility automatically deallocates all of a MEX-file's managed parcels when the MEX-file completes and control returns to the MATLAB prompt. mxFree also removes the memory parcel from the memory management facility's list of memory parcels.

When mxFree appears in a MAT or engine standalone MATLAB application, it simply deallocates the contiguous heap space that begins at address ptr.

In MEX-files, your use of mxFree depends on whether the specified memory parcel is persistent or nonpersistent. By default, memory parcels created by mxCalloc, mxMalloc, and mxRealloc are nonpersistent. The memory management facility automatically frees all nonpersistent memory whenever a MEX-file completes. Thus, even if you do not call mxFree, MATLAB takes care of freeing the memory

mxFree (C and Fortran)

for you. Nevertheless, it is good programming practice to deallocate memory as soon as you are through using it. Doing so generally makes the entire system run more efficiently.

If an application calls mexMakeMemoryPersistent, the specified memory parcel becomes persistent. When a MEX-file completes, the memory management facility does not free persistent memory parcels. Therefore, the only way to free a persistent memory parcel is to call mxFree. Typically, MEX-files call mexAtExit to register a cleanup handler. The cleanup handler calls mxFree.

Examples

See the following examples in matlabroot/extern/examples/mx.

- mxcalcsinglesubscript.c

mexAtExit, mexMakeArrayPersistent, mexMakeMemoryPersistent,
mxCalloc, mxDestroyArray, mxMalloc, mxRealloc

mxGetCell (C and Fortran)

Purpose

Contents of array cell

C Syntax

#include "matrix.h"

mxArray *mxGetCell(const mxArray *pm, mwIndex index);

Fortran Syntax

mwPointer mxGetCell(pm, index)

mwPointer pm
mwIndex index

Arguments

рm

Pointer to a cell mxArray

index

Number of elements in the cell mxArray between the first element and the desired one. See mxCalcSingleSubscript for details on calculating an index in a multidimensional cell array.

Returns

Pointer to the ith cell mxArray if successful, and NULL in C (0 in Fortran) otherwise. Causes of failure include

- Specifying the index of a cell array element that has not been populated.
- Specifying a pm that does not point to a cell mxArray.
- Specifying an index greater than the number of elements in the cell.
- Insufficient free heap space to hold the returned cell mxArray.

Description

Call mxGetCell to get a pointer to the mxArray held in the indexed element of the cell mxArray.

Note Inputs to a MEX-file are constant read-only mxArrays. Do not modify the inputs. Using mxSetCell* or mxSetField* functions to modify the cells or fields of a MATLAB argument causes unpredictable results.

mxGetCell (C and Fortran)

Examples See the following examples in *matlabroot*/extern/examples/mex.

• explore.c

See Also mxCreateCellArray, mxIsCell, mxSetCell

mxGetChars (C)

Purpose Pointer to character array data

C Syntax #include "matrix.h"

mxChar *mxGetChars(const mxArray *array_ptr);

Arguments array ptr

Pointer to an mxArray

Returns Pointer to the first character in the mxArray. Returns NULL if the

specified array is not a character array.

Description Call mxGetChars to access the first character in the mxArray that

array ptr points to. Once you have the starting address, you can

access any other element in the mxArray.

See Also mxGetString

mxGetClassID (C and Fortran)

Purpose Class of array

C Syntax #include "matrix.h"

mxClassID mxGetClassID(const mxArray *pm);

Fortran integer*4 mxGetClassID(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Numeric identifier of the class (category) of the mxArray that pm

points to. For a list of C-language class identifiers, see the mxClassID

reference page.

Description Use mxGetClassId to determine the class of an mxArray. The class

of an mxArray identifies the kind of data the mxArray is holding. For example, if pm points to a logical mxArray, then mxGetClassId returns

mxLOGICAL_CLASS (in C).

mxGetClassId is like mxGetClassName, except that the former returns the class as an integer identifier and the latter returns the class as a

string.

Examples See the following examples in *matlabroot*/extern/examples/mex.

• explore.c

See the following examples in matlabroot/extern/examples/refbook.

• phonebook.c

See Also mxClassID, mxGetClassName

mxGetClassName (C and Fortran)

Purpose Class of array as string

C Syntax #include "matrix.h"

const char *mxGetClassName(const mxArray *pm);

Fortran character*(*) mxGetClassName(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Class (as a string) of the mxArray pointed to by pm.

Description Call mxGetClassName to determine the class of an mxArray. The class

of an mxArray identifies the kind of data the mxArray is holding. For example, if pm points to a logical mxArray, mxGetClassName returns

logical.

mxGetClassID is like mxGetClassName, except that the former returns the class as an integer identifier, as listed in the mxClassID reference page, and the latter returns the class as a string, as listed in the

mxIsClass reference page.

Examples See the following examples in *matlabroot*/extern/examples/mex.

• mexfunction.c

See the following examples in *matlabroot*/extern/examples/mx.

• mxisclass.c

See Also mxGetClassID, mxIsClass

mxGetData (C and Fortran)

Purpose Pointer to real data

C Syntax #include "matrix.h"

pm

void *mxGetData(const mxArray *pm);

Fortran Syntax

mwPointer mxGetData(pm)

mwPointer pm

Arguments

Pointer to an mxArray

Returns

Pointer to the first element of the real data. Returns NULL in C (0 in Fortran) if there is no real data.

Description

In C, mxGetData returns a void pointer (void *). Since void pointers point to a value that has no type, you must cast the return value to the pointer type that matches the type specified by pm. To see how MATLAB types map to their equivalent C types, see the table on the mxClassID reference page.

In Fortran, to copy values from the returned pointer, use one of the mxCopyPtrTo* functions in the following manner:

Examples

See the following examples in matlabroot/extern/examples/mex.

• explore.c

See the following examples in matlabroot/extern/examples/refbook.

- matrixDivide.c
- matrixDivideComplex.c
- phonebook.c

mxGetData (C and Fortran)

See the following examples in matlabroot/extern/examples/mx.

- mxcreatecharmatrixfromstr.c
- mxisfinite.c

See Also

mxGetImagData, mxGetPr, mxClassID

mxGetDimensions (C and Fortran)

Purpose

Pointer to dimensions array

C Syntax

#include "matrix.h"

const mwSize *mxGetDimensions(const mxArray *pm);

Fortran Syntax

mwPointer mxGetDimensions(pm)

mwPointer pm

Arguments

Pointer to an mxArray.

Returns

Pointer to the first element in the dimensions array. Each integer in the dimensions array represents the number of elements in a particular dimension. The array is not NULL terminated.

Description

Use mxGetDimensions to determine how many elements are in each dimension of the mxArray that pm points to. Call mxGetNumberOfDimensions to get the number of dimensions in the mxArray.

To copy the values to Fortran, use mxCopyPtrToInteger4 in the following manner:

Examples

See the following examples in matlabroot/extern/examples/mx.

- mxcalcsinglesubscript.c
- mxgeteps.c
- mxisfinite.c

See the following examples in matlabroot/extern/examples/refbook.

• findnz.c

mxGetDimensions (C and Fortran)

• phonebook.c

See the following examples in ${\it matlabroot/extern/examples/mex}$.

• explore.c

See Also mxGetNumberOfDimensions

mxGetElementSize (C and Fortran)

Purpose Number of bytes required to store each data element

C Syntax #include "matrix.h"

size t mxGetElementSize(const mxArray *pm);

Fortran mwPointer mxGetElementSize(pm)

Syntax mwPointer pm

Arguments ma

Pointer to an mxArray

Returns Number of bytes required to store one element of the specified mxArray,

if successful. Returns 0 on failure. The primary reason for failure is that pm points to an mxArray having an unrecognized class. If pm points to a cell mxArray or a structure mxArray, mxGetElementSize returns the size of a pointer (not the size of all the elements in each cell or

structure field).

Description Call mxGetElementSize to determine the number of bytes in each data

element of the mxArray. For example, if the MATLAB class of an mxArray is int16, the mxArray stores each data element as a 16-bit

(2-byte) signed integer. Thus, mxGetElementSize returns 2.

mxGetElementSize is helpful when using a non-MATLAB routine to manipulate data elements. For example, the C function memcpy requires

(for its third argument) the size of the elements you intend to copy.

Note Fortran does not have an equivalent of size t. mwPointer is a preprocessor macro that provides the appropriate Fortran type. The value returned by this function, however, is not a pointer.

Examples See the following examples in matlabroot/extern/examples/refbook.

• doubleelement.c

mxGetElementSize (C and Fortran)

• phonebook.c

mxGetEps (C and Fortran)

Purpose Value of EPS

C Syntax #include "matrix.h"

double mxGetEps(void);

Fortran Syntax

real*8 mxGetEps

Returns Value of the MATLAB eps variable

Description Call mxGetEps to return the value of the MATLAB eps variable. This

variable holds the distance from 1.0 to the next largest floating-point number. As such, it is a measure of floating-point accuracy. The MATLAB pinv and rank functions use eps as a default tolerance.

Examples See the following examples in *matlabroot*/extern/examples/mx.

• mxgeteps.c

• mxgetepsf.F

See Also mxGetInf, mxGetNan

mxGetField (C and Fortran)

Purpose

Field value, given field name and index, into structure array

C Syntax

```
#include "matrix.h"
```

Fortran Syntax

mwPointer mxGetField(pm, index, fieldname)

mwPointer pm
mwIndex index

character*(*) fieldname

Arguments

pm

Pointer to a structure mxArray

index

Index of the desired element.

In C, the first element of an mxArray has an index of 0. The index of the last element is N-1, where N is the number of elements in the array. In Fortran, the first element of an mxArray has an index of 1. The index of the last element is N, where N is the number of elements in the array.

fieldname

Name of the field whose value you want to extract.

Returns

Pointer to the mxArray in the specified field at the specified fieldname, on success. Returns NULL in C (0 in Fortran) if passed an invalid argument or if there is no value assigned to the specified field. Common causes of failure include:

- Specifying an array pointer pm that does not point to a structure mxArray. To determine whether pm points to a structure mxArray, call mxIsStruct.
- Specifying an index to an element outside the bounds of the mxArray. For example, given a structure mxArray that contains ten elements, you cannot specify an index greater than 9 in C (10 in Fortran).

mxGetField (C and Fortran)

- Specifying a nonexistent fieldname. Call mxGetFieldNameByNumber or mxGetFieldNumber to get existing field names.
- Insufficient heap space to hold the returned mxArray.

Description

Call mxGetField to get the value held in the specified element of the specified field. In pseudo-C terminology, mxGetField returns the value at:

```
pm[index].fieldname
```

mxGetFieldByNumber is like mxGetField. Both functions return the same value. The only difference is in the way you specify the field. mxGetFieldByNumber takes a field number as its third argument, and mxGetField takes a field name as its third argument.

Note Inputs to a MEX-file are constant read-only mxArrays. Do not modify the inputs. Using mxSetCell* or mxSetField* functions to modify the cells or fields of a MATLAB argument causes unpredictable results.

```
In C, calling:
mxGetField(pa, index, "field_name");
is equivalent to calling:
field_num = mxGetFieldNumber(pa, "field_name");
mxGetFieldByNumber(pa, index, field_num);
where index is 0 if you have a 1-by-1 structure.
In Fortran, calling:
mxGetField(pm, index, 'fieldname')
is equivalent to calling:
```

mxGetField (C and Fortran)

fieldnum = mxGetFieldNumber(pm, 'fieldname')
mxGetFieldByNumber(pm, index, fieldnum)

where index is 1 if you have a 1-by-1 structure.

See Also

mxGetFieldByNumber, mxGetFieldNameByNumber, mxGetFieldNumber,
mxGetNumberOfFields, mxIsStruct, mxSetField, mxSetFieldByNumber

mxGetFieldByNumber (C and Fortran)

Purpose Field value, given field number and index, into structure array

C Syntax #include "matrix.h"

mxArray *mxGetFieldByNumber(const mxArray *pm, mwIndex index,

int fieldnumber);

Fortran Syntax

mwPointer mxGetFieldByNumber(pm, index, fieldnumber)

mwPointer pm
mwIndex index

integer*4 fieldnumber

Arguments

pm

Pointer to a structure mxArray

index

Index of the desired element.

In C, the first element of an mxArray has an index of 0. The index of the last element is N-1, where N is the number of elements in the array. In Fortran, the first element of an mxArray has an index of 1. The index of the last element is N, where N is the number of elements in the array.

See mxCalcSingleSubscript for more details on calculating an index.

fieldnumber

Position of the field whose value you want to extract

In C, the first field within each element has a field number of 0, the second field has a field number of 1, and so on. The last field has a field number of N-1, where N is the number of fields.

In Fortran, the first field within each element has a field number of 1, the second field has a field number of 2, and so on. The last field has a field number of N, where N is the number of fields.

mxGetFieldByNumber (C and Fortran)

Returns

Pointer to the mxArray in the specified field for the desired element, on success. Returns NULL in C (0 in Fortran) if passed an invalid argument or if there is no value assigned to the specified field. Common causes of failure include:

- Specifying an array pointer pm that does not point to a structure mxArray. Call mxIsStruct to determine whether pm points to a structure mxArray.
- Specifying an index to an element outside the bounds of the mxArray. For example, given a structure mxArray that contains ten elements, you cannot specify an index greater than 9 in C (10 in Fortran).
- Specifying a nonexistent field number. Call mxGetFieldNumber to determine the field number that corresponds to a given field name.

Description

Call mxGetFieldByNumber to get the value held in the specified fieldnumber at the indexed element.

Note Inputs to a MEX-file are constant read-only mxArrays. Do not modify the inputs. Using mxSetCell* or mxSetField* functions to modify the cells or fields of a MATLAB argument causes unpredictable results.

```
In C, calling:
mxGetField(pa, index, "field_name");
is equivalent to calling:
field_num = mxGetFieldNumber(pa, "field_name");
mxGetFieldByNumber(pa, index, field_num);
where index is 0 if you have a 1-by-1 structure.
In Fortran, calling:
```

mxGetFieldByNumber (C and Fortran)

```
mxGetField(pm, index, 'fieldname')
is equivalent to calling:
fieldnum = mxGetFieldNumber(pm, 'fieldname')
mxGetFieldByNumber(pm, index, fieldnum)
where index is 1 if you have a 1-by-1 structure.
```

Examples

See the following examples in matlabroot/extern/examples/refbook.

• phonebook.c

See the following examples in matlabroot/extern/examples/mx.

• mxisclass.c

See the following examples in matlabroot/extern/examples/mex.

• explore.c

 $\label{lem:mxGetFieldNumber} mx GetFieldNumber, \ mx GetFieldNumber, \ mx GetNumber Of Fields, \ mx Is Struct, \ mx SetField, \ mx SetFieldBy Number Of GetField SetField Se$

mxGetFieldNameByNumber (C and Fortran)

Purpose

Field name, given field number, in structure array

C Syntax

#include "matrix.h"

Fortran Syntax

 $\verb|character*(*)| mxGetFieldNameByNumber(pm, fieldnumber)|$

mwPointer pm

integer*4 fieldnumber

Arguments

pm

Pointer to a structure mxArray

fieldnumber

Position of the desired field. For instance, in C, to get the name of the first field, set fieldnumber to 0; to get the name of the second field, set fieldnumber to 1; and so on. In Fortran, to get the name of the first field, set fieldnumber to 1; to get the name of the second field, set fieldnumber to 2; and so on.

Returns

Pointer to the nth field name, on success. Returns NULL in C (0 in Fortran) on failure. Common causes of failure include

- Specifying an array pointer pm that does not point to a structure mxArray. Call mxIsStruct to determine whether pm points to a structure mxArray.
- Specifying a value of fieldnumber outside the bounds of the number of fields in the structure mxArray. In C, fieldnumber 0 represents the first field, and fieldnumber N-1 represents the last field, where N is the number of fields in the structure mxArray. In Fortran, fieldnumber 1 represents the first field, and fieldnumber N represents the last field.

Description

Call mxGetFieldNameByNumber to get the name of a field in the given structure mxArray. A typical use of mxGetFieldNameByNumber is to call

mxGetFieldNameByNumber (C and Fortran)

it inside a loop in order to get the names of all the fields in a given mxArray.

Consider a MATLAB structure initialized to:

```
patient.name = 'John Doe';
patient.billing = 127.00;
patient.test = [79 75 73; 180 178 177.5; 220 210 205];
```

In C, the field number 0 represents the field name; field number 1 represents field billing; field number 2 represents field test. A field number other than 0, 1, or 2 causes mxGetFieldNameByNumber to return NULL.

In Fortran, the field number 1 represents the field name; field number 2 represents field billing; field number 3 represents field test. A field number other than 1, 2, or 3 causes mxGetFieldNameByNumber to return 0.

Examples

See the following examples in matlabroot/extern/examples/refbook.

• phonebook.c

See the following examples in matlabroot/extern/examples/mx.

• mxisclass.c

See the following examples in *matlabroot*/extern/examples/mex.

• explore.c

See Also

 $\label{lem:mxGetFieldNumber} {\tt mxGetFieldNumber}, \ {\tt mxGetFieldNumber}, \\ {\tt mxGetNumberOfFields}, \ {\tt mxIsStruct}, \ {\tt mxSetField}, \ {\tt mxSetFieldByNumber}$

mxGetFieldNumber (C and Fortran)

Purpose

Field number, given field name, in structure array

C Syntax

Fortran Syntax

```
integer*4 mxGetFieldNumber(pm, fieldname)
mwPointer pm
character*(*) fieldname
```

Arguments

pm

Pointer to a structure mxArray

fieldname

Name of a field in the structure mxArray

Returns

Field number of the specified fieldname, on success. In C, the first field has a field number of 0, the second field has a field number of 1, and so on. In Fortran, the first field has a field number of 1, the second field has a field number of 2, and so on. Returns -1 in C (0 in Fortran) on failure. Common causes of failure include

- Specifying an array pointer pm that does not point to a structure mxArray. Call mxIsStruct to determine whether pm points to a structure mxArray.
- Specifying the fieldname of a nonexistent field.

Description

If you know the name of a field but do not know its field number, call mxGetFieldNumber. Conversely, if you know the field number but do not know its field name, call mxGetFieldNameByNumber.

For example, consider a MATLAB structure initialized to:

```
patient.name = 'John Doe';
patient.billing = 127.00;
patient.test = [79 75 73; 180 178 177.5; 220 210 205];
```

mxGetFieldNumber (C and Fortran)

In C, the field name has a field number of 0; the field billing has a field number of 1; and the field test has a field number of 2. If you call mxGetFieldNumber and specify a field name of anything other than name, billing, or test, mxGetFieldNumber returns -1.

Calling:

```
mxGetField(pa, index, "field_name");
is equivalent to calling:
field_num = mxGetFieldNumber(pa, "field_name");
mxGetFieldByNumber(pa, index, field_num);
```

where index is 0 if you have a 1-by-1 structure.

In Fortran, the field name has a field number of 1; the field billing has a field number of 2; and the field test has a field number of 3. If you call mxGetFieldNumber and specify a field name of anything other than name, billing, or test, mxGetFieldNumber returns 0.

Calling:

```
mxGetField(pm, index, 'fieldname');
is equivalent to calling:
fieldnum = mxGetFieldNumber(pm, 'fieldname');
mxGetFieldByNumber(pm, index, fieldnum);
where index is 1 if you have a 1-by-1 structure.
```

mxGetImagData (C and Fortran)

Purpose Pointer to imaginary data of array

C Syntax #include "matrix.h"

void *mxGetImagData(const mxArray *pm);

Fortran mwPointer mxGetImagData(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Pointer to the first element of the imaginary data. Returns NULL in C (0

in Fortran) if there is no imaginary data or if there is an error.

Description This function is like mxGetPi, except that in C it returns a void *. For

more information, see the description for the mxGetData function.

Examples See the following examples in matlabroot/extern/examples/mex.

• explore.c

See the following examples in matlabroot/extern/examples/mx.

• mxisfinite.c

See Also mxGetData, mxGetPi

mxGetInf (C and Fortran)

Purpose Value of infinity

C Syntax #include "matrix.h"

double mxGetInf(void);

Fortran Syntax

real*8 mxGetInf

Returns Value of infinity on your system.

Description Call mxGetInf to return the value of the MATLAB internal inf variable.

inf is a permanent variable representing IEEE® arithmetic positive infinity. Your system specifies the value of inf; you cannot modify it.

Operations that return infinity include:

• Division by 0. For example, 5/0 returns infinity.

• Operations resulting in overflow. For example, exp(10000) returns infinity because the result is too large to be represented on your

machine.

Examples See the following examples in *matlabroot*/extern/examples/mx.

• mxgetinf.c

See Also mxGetEps, mxGetNaN

mxGetIr (C and Fortran)

Purpose Sparse matrix IR array

C Syntax #include "matrix.h"

mwIndex *mxGetIr(const mxArray *pm);

Fortran Syntax mwPointer mxGetIr(pm)

mwPointer pm

Arguments

pm

Pointer to a sparse mxArray

Returns

Pointer to the first element in the ir array, if successful, and NULL in C (0 in Fortran) otherwise. Possible causes of failure include:

- Specifying a full (nonsparse) mxArray.
- Specifying a value for pm that is NULL in C (0 in Fortran). This usually means that an earlier call to mxCreateSparse failed.

Description

Use mxGetIr to obtain the starting address of the ir array. The ir array is an array of integers. The length of ir is nzmax, the storage allocated for the sparse array, or nnz, the number of nonzero matrix elements. For example, if nzmax equals 100, the ir array contains 100 integers.

Each value in an ir array indicates a row (offset by 1) at which a nonzero element can be found. (The jc array is an index that indirectly specifies a column where nonzero elements can be found.)

For details on the ir and jc arrays, see mxSetIr and mxSetJc.

Examples

See the following examples in matlabroot/extern/examples/refbook.

- fulltosparse.c
- fulltosparse.F

See the following examples in matlabroot/extern/examples/mx.

mxGetIr (C and Fortran)

- mxsetdimensions.c
- mxsetnzmax.c

• explore.c

See Also

 $\verb|mxGetJc|, \verb|mxGetNzmax|, \verb|mxSetIr|, \verb|mxSetJc|, \verb|mxSetNzmax|, \verb|nzmax|, \verb|nnz|$

mxGetJc (C and Fortran)

Purpose

Sparse matrix JC array

C Syntax

#include "matrix.h"

mwIndex *mxGetJc(const mxArray *pm);

Fortran Syntax

mwPointer mxGetJc(pm)

mwPointer pm

Arguments

pm

Pointer to a sparse mxArray

Returns

Pointer to the first element in the jc array, if successful, and NULL in C (0 in Fortran) otherwise. Possible causes of failure include

- Specifying a full (nonsparse) mxArray.
- Specifying a value for pm that is NULL in C (0 in Fortran). This usually means that an earlier call to mxCreateSparse failed.

Description

Use mxGetJc to obtain the starting address of the jc array. The jc array is an integer array having n+1 elements, where n is the number of columns in the sparse mxArray. The values in the jc array indirectly indicate columns containing nonzero elements. For a detailed explanation of the jc array, see mxSetJc.

Examples

See the following examples in matlabroot/extern/examples/refbook.

- fulltosparse.c
- fulltosparse.F

See the following examples in matlabroot/extern/examples/mx.

- mxgetnzmax.c
- mxsetdimensions.c
- mxsetnzmax.c

mxGetJc (C and Fortran)

See the following examples in matlabroot/extern/examples/mex.

• explore.c

See Also

mxGetIr, mxGetNzmax, mxSetIr, mxSetJc, mxSetNzmax

mxGetLogicals (C)

Purpose Pointer to logical array data

C Syntax #include "matrix.h"

mxLogical *mxGetLogicals(const mxArray *array_ptr);

Arguments array ptr

Pointer to an mxArray

Returns Pointer to the first logical element in the mxArray. The result is

unspecified if the mxArray is not a logical array.

Description Call mxGetLogicals to access the first logical element in the mxArray

that array ptr points to. Once you have the starting address, you can

access any other element in the mxArray.

Examples See the following examples in *matlabroot*/extern/examples/mx.

• mxislogical.c

See Also mxCreateLogicalArray, mxCreateLogicalMatrix,

mxCreateLogicalScalar, mxIsLogical, mxIsLogicalScalar,

mxIsLogicalScalarTrue

mxGetM (C and Fortran)

Purpose Number of rows in array

C Syntax #include "matrix.h"

size t mxGetM(const mxArray *pm);

Fortran mwPointer mxGetM(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Number of rows in the mxArray to which pm points.

Description mxGetM returns the number of rows in the specified array. The term

rows always means the first dimension of the array, no matter how many dimensions the array has. For example, if pm points to a four-dimensional array having dimensions 8-by-9-by-5-by-3, mxGetM

returns 8.

Note Fortran does not have an equivalent of size_t. mwPointer is a preprocessor macro that provides the appropriate Fortran type. The value returned by this function, however, is not a pointer.

Examples See the following examples in *matlabroot*/extern/examples/refbook.

- convec.c
- fulltosparse.c
- matrixDivide.c
- matrixDivideComplex.c
- revord.c
- timestwo.c

mxGetM (C and Fortran)

• matdemo2.F

See Also mxGetN, mxSetM, mxSetN

mxGetN (C and Fortran)

Purpose Number of columns in array

C Syntax #include "matrix.h"

size t mxGetN(const mxArray *pm);

Fortran mwPointer mxGetN(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Number of columns in the mxArray.

Description Call mxGetN to determine the number of columns in the specified mxArray.

If pm is an N-dimensional mxArray, mxGetN is the product of dimensions 2 through N. For example, if pm points to a four-dimensional mxArray having dimensions 13-by-5-by-4-by-6, mxGetN returns the value 120 (5 \times 4 \times 6). If the specified mxArray has more than two dimensions and you need to know exactly how many elements are in each dimension, call mxGetDimensions.

If pm points to a sparse mxArray, mxGetN still returns the number of columns, not the number of occupied columns.

Note Fortran does not have an equivalent of size_t. mwPointer is a preprocessor macro that provides the appropriate Fortran type. The value returned by this function, however, is not a pointer.

Examples

See the following examples in matlabroot/extern/examples/refbook.

- convec.c
- fulltosparse.c

mxGetN (C and Fortran)

- revord.c

mxGetNaN (C and Fortran)

Purpose Value of NaN (Not-a-Number)

C Syntax #include "matrix.h"

double mxGetNaN(void);

Fortran Syntax

real*8 mxGetNaN

Returns Value of NaN (Not-a-Number) on your system

Description Call mxGetNaN to return the value of NaN for your system. NaN is

the IEEE arithmetic representation for Not-a-Number. Certain mathematical operations return NaN as a result, for example,

• 0.0/0.0

• Inf-Inf

Your system specifies the value of Not-a-Number. You cannot modify it.

C Examples

See the following examples in matlabroot/extern/examples/mx.

mxgetinf.c

See Also mxGetEps, mxGetInf

mxGetNumberOfDimensions (C and Fortran)

Purpose Number of dimensions in array

C Syntax #include "matrix.h"

mwSize mxGetNumberOfDimensions(const mxArray *pm);

Fortran mwSize mxGetNumberOfDimensions(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Number of dimensions in the specified mxArray. The returned value is

always 2 or greater.

Description Use mxGetNumberOfDimensions to determine how many dimensions are

in the specified array. To determine how many elements are in each

dimension, call mxGetDimensions.

Examples See the following examples in matlabroot/extern/examples/mex.

• explore.c

See the following examples in matlabroot/extern/examples/refbook.

• findnz.c

mxSetM, mxSetN, mxGetDimensions

mxGetNumberOfElements (C and Fortran)

Purpose Number of elements in array

C Syntax #include "matrix.h"

size t mxGetNumberOfElements(const mxArray *pm);

Fortran Syntax mwPointer mxGetNumberOfElements(pm)

mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Number of elements in the specified mxArray

Description

mxGetNumberOfElements tells you how many elements an array has. For example, if the dimensions of an array are 3-by-5-by-10, mxGetNumberOfElements returns the number 150.

Note Fortran does not have an equivalent of size_t. mwPointer is a preprocessor macro that provides the appropriate Fortran type. The value returned by this function, however, is not a pointer.

Examples

See the following examples in matlabroot/extern/examples/refbook.

- findnz.c
- phonebook.c

See the following examples in matlabroot/extern/examples/mx.

- mxcalcsinglesubscript.c

mxGetNumberOfFields (C and Fortran)

Purpose Number of fields in structure array

C Syntax #include "matrix.h"

int mxGetNumberOfFields(const mxArray *pm);

Fortran Syntax

integer*4 mxGetNumberOfFields(pm)

x mwPointer pm

Arguments pm

Pointer to a structure mxArray

Returns Number of fields, on success. Returns 0 on failure. The most common

cause of failure is that pm is not a structure mxArray. Call mxIsStruct

to determine whether pm is a structure.

Description Call mxGetNumberOfFields to determine how many fields are in the

specified structure mxArray.

Once you know the number of fields in a structure, you can loop through

every field in order to set or to get field values.

Examples See the following examples in matlabroot/extern/examples/refbook.

• phonebook.c

See the following examples in matlabroot/extern/examples/mx.

• mxisclass.c

See the following examples in matlabroot/extern/examples/mex.

• explore.c

See Also mxGetField, mxIsStruct, mxSetField

mxGetNzmax (C and Fortran)

Purpose Number of elements in IR, PR, and PI arrays

C Syntax #include "matrix.h"

mwSize mxGetNzmax(const mxArray *pm);

Fortran mwSize mxGetNzmax(pm)

Syntax mwPointer pm

Arguments pm

Pointer to a sparse mxArray

Returns Number of elements allocated to hold nonzero entries in the specified

sparse mxArray, on success. Returns an indeterminate value on error. The most likely cause of failure is that pm points to a full (nonsparse)

mxArray.

Description Use mxGetNzmax to get the value of the nzmax field. The nzmax field

holds an integer value that signifies the number of elements in the ir, pr, and, if it exists, the pi arrays. The value of nzmax is always greater than or equal to the number of nonzero elements in a sparse mxArray. In addition, the value of nzmax is always less than or equal to

the number of rows times the number of columns.

As you adjust the number of nonzero elements in a sparse mxArray, MATLAB software often adjusts the value of the nzmax field. MATLAB adjusts nzmax in order to reduce the number of costly reallocations and

in order to optimize its use of heap space.

Examples See the following examples in *matlabroot*/extern/examples/mx.

• mxgetnzmax.c

mxsetnzmax.c

See Also mxSetNzmax

mxGetPi (C and Fortran)

Purpose Imaginary data elements in array of type DOUBLE

C Syntax #include "matrix.h"

double *mxGetPi(const mxArray *pm);

Fortran mwPointer mxGetPi(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray of type double

Returns Pointer to the imaginary data elements of the specified mxArray, on

success. Returns NULL in C (0 in Fortran) if there is no imaginary data

or if there is an error.

Description Use mxGetPi on arrays of type double only. Use mxIsDouble to validate

the mxArray type. For other mxArray types, use mxGetImagData.

The pi field points to an array containing the imaginary data of the mxArray. Call mxGetPi to get the contents of the pi field, that is, to get

the starting address of this imaginary data.

The best way to determine whether an mxArray is purely real is to call

mxIsComplex.

If any of the input matrices to a function are complex, MATLAB

allocates the imaginary parts of all input matrices.

Examples See the following examples in matlabroot/extern/examples/refbook.

mxGetPr (C and Fortran)

Purpose Real data elements in array of type DOUBLE

C Syntax #include "matrix.h"

double *mxGetPr(const mxArray *pm);

Fortran mwPointer mxGetPr(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray of type double

Returns Pointer to the first element of the real data. Returns NULL in C (0 in

Fortran) if there is no real data.

Description Use mxGetPr on arrays of type double only. Use mxIsDouble to validate

the mxArray type. For other mxArray types, use mxGetData.

Call mxGetPr to access the real data in the mxArray that pm points to. Once you have the starting address, you can access any other element

in the mxArray.

mxGetPi, mxSetPi, mxSetPr, mxGetData, mxIsDouble

mxGetProperty (C and Fortran)

Purpose

Value of public property of MATLAB object

C Syntax

#include "matrix.h"

Fortran Syntax

mwPointer mxGetProperty(pa, index, propname)

mwPointer pa
mwIndex index

character*(*) propname

Arguments

pa

Pointer to an mxArray which is an object.

index

Index of the desired element of the object array.

In C, the first element of an mxArray has an index of 0. The index of the last element is N-1, where N is the number of elements in the array. In Fortran, the first element of an mxArray has an index of 1. The index of the last element is N, where N is the number of elements in the array.

propname

Name of the property whose value you want to extract.

Returns

Pointer to the mxArray of the specified propname on success. Returns NULL in C (0 in Fortran) if unsuccessful. Common causes of failure include:

- Specifying a nonexistent propname.
- Specifying a nonpublic propname.
- Specifying an index to an element outside the bounds of the mxArray.
 Use mxGetNumberOfElements or mxGetM and mxGetN to test the index value.
- Insufficient memory (in the heap) to hold the returned mxArray.

mxGetProperty (C and Fortran)

Description Call mxGetProperty to get the value held in the specified element. In

pseudo-C terminology, mxGetProperty returns the value at:

pa[index].propname

See Also mxSetProperty, mxGetNumberOfElements, mxGetM, mxGetN

mxGetScalar (C and Fortran)

Purpose Real component of first data element in array

C Syntax #include "matrix.h"

double mxGetScalar(const mxArray *pm);

Fortran Syntax

real*8 mxGetScalar(pm)

mwPointer pm

Arguments pm

Pointer to an mxArray; cannot be a cell mxArray, a structure

mxArray, or an empty mxArray.

Returns

Pointer to the value of the first real (nonimaginary) element of the

mxArray.

In C, mxGetScalar returns a double. If real elements in the mxArray are of a type other than double, mxGetScalar automatically converts the scalar value into a double. To preserve the original data representation

of the scalar, cast the return value to the desired data type. $\,$

If pm points to a sparse mxArray, mxGetScalar returns the value of the first nonzero real element in the mxArray. If there are no nonzero elements, mxGetScalar returns 0.

Description

Call mxGetScalar to get the value of the first real (nonimaginary) element of the mxArray.

In most cases, you call mxGetScalar when pm points to an mxArray containing only one element (a scalar). However, pm can point to an mxArray containing many elements. If pm points to an mxArray containing multiple elements, mxGetScalar returns the value of the first real element. For example, if pm points to a two-dimensional mxArray, mxGetScalar returns the value of the (1,1) element. If pm points to a three-dimensional mxArray, mxGetScalar returns the value of the (1,1,1) element; and so on.

Use mxGetScalar only on a 32-bit, nonempty, numeric, logical, or char mxArray. Use MX Matrix Library functions such as mxIsEmpty,

mxGetScalar (C and Fortran)

 ${\tt mxIsLogical}, {\tt mxIsNumeric}, {\tt or} {\tt mxIsChar}$ to test for this condition before calling ${\tt mxGetScalar}.$

Examples

See the following examples in matlabroot/extern/examples/refbook.

- timestwoalt.c
- xtimesy.c

mxGetM, mxGetN

mxGetString (C and Fortran)

Purpose

String array to C-style string

C Syntax

#include "matrix.h"

int mxGetString(const mxArray *pm, char *str, mwSize strlen);

Fortran Syntax

integer*4 mxGetString(pm, str, strlen)

mwPointer pm
character*(*) str
mwSize strlen

Arguments

pm

Pointer to a string mxArray; that is, a pointer to an mxArray having the mxCHAR CLASS class.

str

Starting location for the string. mxGetString writes the character data into str and then, in C, terminates the string with a NULL character (in the manner of C strings). str can point to either dynamic or static memory.

strlen

Size in bytes of destination buffer pointed to by str. Typically, in C, you set strlen to 1 plus the number of elements in the string mxArray to which pm points. See the mxGetM and mxGetN reference pages to find out how to get the number of elements.

Do not use with "Multibyte Encoded Characters" on page 2-192.

Returns

0 on success or if strlen == 0, and 1 on failure. Possible reasons for failure include

- mxArray is not a string array.
- strlen is not large enough to store the entire mxArray. If so, the function returns 1 and truncates the string.

Description

Call mxGetString to copy the character data of a string mxArray into a C-style string in C or a character array in Fortran. The copied string

mxGetString (C and Fortran)

starts at str and contains no more than strlen-1 characters in C (no more than strlen characters in Fortran). In C, the C-style string is always terminated with a NULL character.

If the string array contains several rows, the function copies them into one long string array, one column at a time.

Multibyte Encoded Characters

Use this function only with strings represented in single-byte encoding schemes. For strings represented in multibyte encoding schemes, use the C function mxArrayToString. Fortran users must allocate sufficient space for the return string to avoid possible truncation.

Examples

See the following examples in matlabroot/extern/examples/mx.

• mxmalloc.c

See the following examples in matlabroot/extern/examples/mex.

• explore.c

See the following examples in matlabroot/extern/examples/refbook.

• revord.F

mxIsCell (C and Fortran)

Purpose Determine whether input is cell array

C Syntax #include "matrix.h"

bool mxIsCell(const mxArray *pm);

Fortran integer*4 mxIsCell(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Logical 1 (true) if pm points to an array having the class mxCELL CLASS,

and logical O (false) otherwise.

Description Use mxIsCell to determine whether the specified array is a cell array.

In C, calling mxIsCell is equivalent to calling:

mxGetClassID(pm) == mxCELL CLASS

In Fortran, calling mxIsCell is equivalent to calling:

mxGetClassName(pm) .eq. 'cell'

Note mxIsCell does not answer the question "Is this mxArray a cell of a cell array?" An individual cell of a cell array can be of any type.

See Also mxIsClass

Arguments pm

Pointer to an mxArray

Returns Logical 1 (true) if pm points to an array having the class mxCHAR_CLASS,

and logical O (false) otherwise.

Description Use mxIsChar to determine whether pm points to string mxArray.

In C, calling mxIsChar is equivalent to calling:

mxGetClassID(pm) == mxCHAR CLASS

In Fortran, calling mxIsChar is equivalent to calling:

mxGetClassName(pm) .eq. 'char'

Examples See the following examples in *matlabroot*/extern/examples/refbook.

• phonebook.c

• revord.c

See the following examples in ${\it matlabroot/extern/examples/mx}$.

- mxcreatecharmatrixfromstr.c
- mxislogical.c
- mxmalloc.c

mxlsChar (C and Fortran)

See Also mxIsClass, mxGetClassID

mxIsClass (C and Fortran)

Purpose Determine whether array is member of specified class

C Syntax #include "matrix.h"

bool mxIsClass(const mxArray *pm, const char *classname);

Fortran Syntax

integer*4 mxIsClass(pm, classname)

mwPointer pm

character*(*) classname

Arguments

рm

Pointer to an mxArray

classname

Array category you are testing. Specify classname as a string (not as an integer identifier). You can specify any one of the following predefined constants:

Value of classname	Corresponding Class
cell	mxCELL_CLASS
char	mxCHAR_CLASS
double	mxDOUBLE_CLASS
function_handle	mxFUNCTION_CLASS
int8	mxINT8_CLASS
int16	mxINT16_CLASS
int32	mxINT32_CLASS
int64	mxINT64_CLASS
logical	mxLOGICAL_CLASS
single	mxSINGLE_CLASS
struct	mxSTRUCT_CLASS
uint8	mxUINT8_CLASS

Value of classname	Corresponding Class
uint16	mxUINT16_CLASS
uint32	mxUINT32_CLASS
uint64	mxUINT64_CLASS
<class_name></class_name>	<class_id></class_id>
unknown	mxUNKNOWN_CLASS

In the table, <class_name> represents the name of a specific MATLAB custom object. You can also specify one of your own class names.

Returns

Logical 1 (true) if pm points to an array having category classname, and logical 0 (false) otherwise.

Description

Each mxArray is tagged as being a certain type. Call mxIsClass to determine whether the specified mxArray has this type.

In C:

```
mxIsClass(pm, "double");
is equivalent to calling either of these forms:
mxIsDouble(pm);
strcmp(mxGetClassName(pm), "double");
In Fortran:
mxIsClass(pm, 'double')
is equivalent to calling either one of the following:
mxIsDouble(pm)
mxGetClassName(pm) .eq. 'double'
```

mxIsClass (C and Fortran)

It is most efficient to use the mxIsDouble form.

Examples

See the following examples in matlabroot/extern/examples/mx.

• mxisclass.c

See Also

mxClassID, mxGetClassID, mxIsEmpty, mxGetClassName

mxIsComplex (C and Fortran)

Purpose Determine whether data is complex

C Syntax #include "matrix.h"

bool mxIsComplex(const mxArray *pm);

Fortran integer*4 mxIsComplex(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Logical 1 (true) if pm is a numeric array containing complex data, and

logical O (false) otherwise. If pm points to a cell array or a structure

array, mxIsComplex returns false.

Description Use mxIsComplex to determine whether an imaginary part is allocated

for an mxArray. The imaginary pointer pi is NULL in C (0 in Fortran) if an mxArray is purely real and does not have any imaginary data. If an

mxArray is complex, pi points to an array of numbers.

Examples See the following examples in *matlabroot*/extern/examples/mx.

mxIsNumeric

mxIsDouble (C and Fortran)

Purpose Determine whether mxArray represents data as double-precision,

floating-point numbers

C Syntax #include "matrix.h"

bool mxIsDouble(const mxArray *pm);

Fortran integer*4 mxIsDouble(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Logical 1 (true) if the mxArray stores its data as double-precision,

floating-point numbers, and logical O (false) otherwise.

Description Call mxIsDouble to determine whether the specified mxArray represents

its real and imaginary data as double-precision, floating-point numbers.

Older versions of MATLAB software store all mxArray data as double-precision, floating-point numbers. However, starting with MATLAB Version 5 software, MATLAB can store real and imaginary

data in various numerical formats.

In C, calling mxIsDouble is equivalent to calling:

mxGetClassID(pm) == mxDOUBLE_CLASS

In Fortran, calling ${\tt mxIsDouble}$ is equivalent to calling:

mxGetClassName(pm) .eq. 'double'

Examples See the following examples in matlabroot/extern/examples/refbook.

fulltosparse.c

• fulltosparse.F

See the following examples in matlabroot/extern/examples/mx.

mxIsDouble (C and Fortran)

- mxgeteps.c

• mexget.c

See Also

mxIsClass, mxGetClassID

mxIsEmpty (C and Fortran)

Purpose Determine whether array is empty

C Syntax #include "matrix.h"

bool mxIsEmpty(const mxArray *pm);

Fortran integer*4 mxIsEmpty(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Logical 1 (true) if the mxArray is empty, and logical 0 (false) otherwise.

Description Use mxIsEmpty to determine whether an mxArray contains no data. An

mxArray is empty if the size of any of its dimensions is 0.

Examples See the following examples in matlabroot/extern/examples/mx.

• mxisfinite.c

See Also mxIsClass

mxlsFinite (C and Fortran)

Purpose Determine whether input is finite

C Syntax #include "matrix.h"

bool mxIsFinite(double value);

Syntax real*8 value

Arguments value

Double-precision, floating-point number you are testing

Returns Logical 1 (true) if value is finite, and logical 0 (false) otherwise.

Description Call mxIsFinite to determine whether value is finite. A number is

finite if it is greater than -Inf and less than Inf.

Examples See the following examples in *matlabroot*/extern/examples/mx.

• mxisfinite.c

See Also mxIsInf, mxIsNan

mxIsFromGlobalWS (C and Fortran)

Purpose Determine whether array was copied from MATLAB global workspace

C Syntax #include "matrix.h"

bool mxIsFromGlobalWS(const mxArray *pm);

Fortran integer*4 mxIsFromGlobalWS(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Logical 1 (true) if the array was copied out of the global workspace,

and logical O (false) otherwise.

Description mxIsFromGlobalWS is useful for standalone MAT-file programs.

mexIsGlobal tells you whether the pointer you pass actually points

into the global workspace.

Examples See the following examples in matlabroot/extern/examples/eng_mat.

• matcreat.c

• matdgns.c

See Also mexIsGlobal

mxIsInf (C and Fortran)

Purpose Determine whether input is infinite

C Syntax #include "matrix.h"

bool mxIsInf(double value);

Fortran Syntax integer*4 mxIsInf(value)

real*8 value

Arguments value

Double-precision, floating-point number you are testing

Returns Logical 1 (true) if value is infinite, and logical 0 (false) otherwise.

Description Call mxIsInf to determine whether value is equal to infinity or minus

infinity. MATLAB software stores the value of infinity in a permanent variable named Inf, which represents IEEE arithmetic positive infinity. The value of the variable Inf is built into the system; you

cannot modify it.

Operations that return infinity include

• Division by 0. For example, 5/0 returns infinity.

• Operations resulting in overflow. For example, exp(10000) returns infinity because the result is too large to be represented on your

machine.

If value equals NaN (Not-a-Number), ${\tt mxIsInf}$ returns false. In other

words, NaN is not equal to infinity.

Examples See the following examples in *matlabroot*/extern/examples/mx.

• mxisfinite.c

See Also mxIsFinite, mxIsNaN

mxlsInt16 (C and Fortran)

Purpose Determine whether array represents data as signed 16-bit integers

C Syntax #include "matrix.h"

bool mxIsInt16(const mxArray *pm);

Fortran integer*4 mxIsInt16(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Logical 1 (true) if the array stores its data as signed 16-bit integers,

and logical O (false) otherwise.

Description Use mxIsInt16 to determine whether the specified array represents its

real and imaginary data as 16-bit signed integers.

In C, calling mxIsInt16 is equivalent to calling:

 $mxGetClassID(pm) == mxINT16_CLASS$

In Fortran, calling mxIsInt16 is equivalent to calling:

mxGetClassName(pm) == 'int16'

See Also mxIsClass, mxGetClassID, mxIsInt8, mxIsInt32, mxIsInt64,

mxlsInt32 (C and Fortran)

Purpose Determine whether array represents data as signed 32-bit integers

C Syntax #include "matrix.h"

bool mxIsInt32(const mxArray *pm);

Fortran in

integer*4 mxIsInt32(pm)

Syntax

mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Logical 1 (true) if the array stores its data as signed 32-bit integers,

and logical O (false) otherwise.

Description Use mxIsInt32 to determine whether the specified array represents its

real and imaginary data as 32-bit signed integers.

In C, calling mxIsInt32 is equivalent to calling:

mxGetClassID(pm) == mxINT32 CLASS

In Fortran, calling ${\tt mxIsInt32}$ is equivalent to calling:

mxGetClassName(pm) == 'int32'

See Also mxIsClass, mxGetClassID, mxIsInt8, mxIsInt16, mxIsInt64,

mxlsInt64 (C and Fortran)

Purpose Determine whether array represents data as signed 64-bit integers

C Syntax #include "matrix.h"

bool mxIsInt64(const mxArray *pm);

Fortran integer*4 mxIsInt64(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Logical 1 (true) if the array stores its data as signed 64-bit integers,

and logical O (false) otherwise.

Description Use mxIsInt64 to determine whether the specified array represents its

real and imaginary data as 64-bit signed integers.

In C, calling mxIsInt64 is equivalent to calling:

 $mxGetClassID(pm) == mxINT64_CLASS$

In Fortran, calling mxIsInt64 is equivalent to calling:

mxGetClassName(pm) == 'int64'

See Also mxIsClass, mxGetClassID, mxIsInt8, mxIsInt16, mxIsInt32,

mxIsInt8 (C and Fortran)

Purpose Determine whether array represents data as signed 8-bit integers

C Syntax #include "matrix.h"

bool mxIsInt8(const mxArray *pm);

Fortran integer*4 mxIsInt8(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Logical 1 (true) if the array stores its data as signed 8-bit integers,

and logical O (false) otherwise.

Description Use mxIsInt8 to determine whether the specified array represents its

real and imaginary data as 8-bit signed integers.

In C, calling mxIsInt8 is equivalent to calling:

 $mxGetClassID(pm) == mxINT8_CLASS$

In Fortran, calling mxIsInt8 is equivalent to calling:

mxGetClassName(pm) .eq. 'int8'

See Also mxIsClass, mxGetClassID, mxIsInt16, mxIsInt32, mxIsInt64,

mxlsLogical (C and Fortran)

Purpose Determine whether array is of type mxLogical

C Syntax #include "matrix.h"

bool mxIsLogical(const mxArray *pm);

Fortran integer*4 mxIsLogical(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Logical 1 (true) if pm points to a logical mxArray, and logical 0 (false)

otherwise.

Description Use mxIsLogical to determine whether MATLAB software treats the

data in the mxArray as Boolean (logical). If an mxArray is logical, MATLAB treats all zeros as meaning false and all nonzero values as meaning true. For additional information on the use of logical variables in MATLAB software, type help logical at the MATLAB prompt.

Examples See the following examples in *matlabroot*/extern/examples/mx.

• mxislogical.c

See Also mxIsClass

mxIsLogicalScalar (C)

Purpose Determine whether scalar array is of type mxLogical

C Syntax #include "matrix.h"

bool mxIsLogicalScalar(const mxArray *array ptr);

Arguments array_ptr

Pointer to an mxArray

Returns Logical 1 (true) if the mxArray is of class mxLogical and has 1-by-1

dimensions, and logical O (false) otherwise.

Description Use mxIsLogicalScalar to determine whether MATLAB software

treats the scalar data in the mxArray as logical or numerical. For additional information on the use of logical variables in MATLAB

software, type help logical at the MATLAB prompt.

See Also mxIsLogical, mxIsLogicalScalarTrue, mxGetLogicals, mxGetScalar

mxlsLogicalScalarTrue (C)

Purpose Determine whether scalar array of type mxLogical is true

C Syntax #include "matrix.h"

bool mxIsLogicalScalarTrue(const mxArray *array_ptr);

Arguments array ptr

Pointer to an mxArray

Returns Logical 1 (true) if the value of the mxArray's logical, scalar element is

true, and logical O (false) otherwise.

Description Use mxIsLogicalScalarTrue to determine whether the value of a

scalar mxArray is true or false. For additional information on the use of logical variables in MATLAB software, type help logical at the

MATLAB prompt.

See Also mxIsLogical, mxIsLogicalScalar, mxGetLogicals, mxGetScalar

mxIsNaN (C and Fortran)

Purpose Determine whether input is NaN (Not-a-Number)

C Syntax #include "matrix.h"

bool mxIsNaN(double value);

Fortran i

integer*4 mxIsNaN(value)

Syntax real*8 value

Arguments value

Double-precision, floating-point number you are testing

Returns Logical 1 (true) if value is NaN (Not-a-Number), and logical 0 (false)

otherwise.

Description Call mxIsNaN to determine whether value is NaN. NaN is the IEEE arithmetic representation for Not-a-Number. A NaN is obtained as a

result of mathematically undefined operations such as

• 0.0/0.0

• Inf-Inf

The system understands a family of bit patterns as representing NaN. In other words, NaN is not a single value; rather, it is a family of numbers that MATLAB software (and other IEEE-compliant applications) uses to represent an error condition or missing data.

Examples

See the following examples in matlabroot/extern/examples/mx.

• mxisfinite.c

See the following examples in matlabroot/extern/examples/refbook.

• findnz.c

• fulltosparse.c

mxIsNaN (C and Fortran)

See Also mxIsFinite, mxIsInf

mxIsNumeric (C and Fortran)

Purpose Determine whether array is numeric

C Syntax #include "matrix.h"

ma

bool mxIsNumeric(const mxArray *pm);

Fortran Syntax

integer*4 mxIsNumeric(pm)

mwPointer pm

Arguments

Pointer to an mxArray

Returns

Logical 1 (true) if the array can contain numeric data. The following class IDs represent storage types for arrays that can contain numeric data:

- mxDOUBLE CLASS
- mxSINGLE CLASS
- mxINT8_CLASS
- mxUINT8_CLASS
- mxINT16_CLASS
- mxUINT16_CLASS
- mxINT32 CLASS
- mxUINT32_CLASS
- mxINT64_CLASS
- mxUINT64_CLASS

Logical O (false) if the array cannot contain numeric data.

Description

Call mxIsNumeric to determine whether the specified array contains numeric data. If the specified array has a storage type that represents

mxIsNumeric (C and Fortran)

numeric data, mxIsNumeric returns logical 1 (true). Otherwise, mxIsNumeric returns logical 0 (false).

Call mxGetClassID to determine the exact storage type.

Examples

See the following examples in matlabroot/extern/examples/refbook.

• phonebook.c

See the following examples in matlabroot/extern/examples/eng mat.

• matdemo1.F

mxGetClassID

mxIsSingle (C and Fortran)

Purpose Determine whether array represents data as single-precision,

floating-point numbers

C Syntax #include "matrix.h"

bool mxIsSingle(const mxArray *pm);

Fortran integer*4 mxIsSingle(pm)

Syntax mwPointer pm

Arguments pm Pointer to an mxArray

Returns Logical 1 (true) if the array stores its data as single-precision,

floating-point numbers, and logical O (false) otherwise.

Description Use mxIsSingle to determine whether the specified array represents

its real and imaginary data as single-precision, floating-point numbers.

In C, calling mxIsSingle is equivalent to calling:

mxGetClassID(pm) == mxSINGLE_CLASS

In Fortran, calling mxIsSingle is equivalent to calling:

mxGetClassName(pm) .eq. 'single'

See Also mxIsClass, mxGetClassID

mxlsSparse (C and Fortran)

Purpose Determine whether input is sparse array

C Syntax #include "matrix.h"

bool mxIsSparse(const mxArray *pm);

Fortran integer*4 mxIsSparse(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Logical 1 (true) if pm points to a sparse mxArray, and logical 0 (false)

otherwise. A false return value means that pm points to a full mxArray

or that pm does not point to a legal mxArray.

Description Use mxIsSparse to determine whether pm points to a sparse mxArray.

Many routines (for example, mxGetIr and mxGetJc) require a sparse

mxArray as input.

Examples See the following examples in *matlabroot*/extern/examples/refbook.

• phonebook.c

See the following examples in matlabroot/extern/examples/mx.

• mxgetnzmax.c

• mxsetdimensions.c

• mxsetdimensionsf.F

mxsetnzmax.c

mxlsStruct (C and Fortran)

Purpose Determine whether input is structure array

C Syntax #include "matrix.h"

bool mxIsStruct(const mxArray *pm);

Fortran integer*4 mxIsStruct(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Logical 1 (true) if pm points to a structure mxArray, and logical 0

(false) otherwise.

Description Use mxIsStruct to determine whether pm points to a structure

mxArray. Many routines (for example, mxGetFieldNameByNumber and

mxSetField) require a structure mxArray as an argument.

Examples See the following examples in *matlabroot*/extern/examples/refbook.

• phonebook.c

See Also mxCreateStructArray, mxCreateStructMatrix,

mxGetFieldNameByNumber, mxGetField, mxSetField

mxlsUint16 (C and Fortran)

Purpose Determine whether array represents data as unsigned 16-bit integers

C Syntax #include "matrix.h"

bool mxIsUint16(const mxArray *pm);

Fortran integer*4 mxIsUint16(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Logical 1 (true) if the mxArray stores its data as unsigned 16-bit

integers, and logical O (false) otherwise.

Description Use mxIsUint16 to determine whether the specified mxArray represents

its real and imaginary data as 16-bit unsigned integers.

In C, calling mxIsUint16 is equivalent to calling:

mxGetClassID(pm) == mxUINT16 CLASS

In Fortran, calling mxIsUint16 is equivalent to calling:

mxGetClassName(pm) .eq. 'uint16'

See Also mxIsClass, mxGetClassID, mxIsInt8, mxIsInt16, mxIsInt32,

mxIsInt64, mxIsUint8, mxIsUint32, mxIsUint64

mxIsUint32 (C and Fortran)

Purpose Determine whether array represents data as unsigned 32-bit integers

C Syntax #include "matrix.h"

bool mxIsUint32(const mxArray *pm);

Fortran

integer*4 mxIsUint32(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Logical 1 (true) if the mxArray stores its data as unsigned 32-bit

integers, and logical O (false) otherwise.

Description Use mxIsUint32 to determine whether the specified mxArray represents

its real and imaginary data as 32-bit unsigned integers.

In C, calling mxIsUint32 is equivalent to calling:

mxGetClassID(pm) == mxUINT32 CLASS

In Fortran, calling mxIsUint32 is equivalent to calling:

mxGetClassName(pm) .eq. 'uint32'

See Also mxIsClass, mxGetClassID, mxIsInt8, mxIsInt16, mxIsInt32,

mxIsInt64, mxIsUint8, mxIsUint16, mxIsUint64

mxlsUint64 (C and Fortran)

Purpose Determine whether array represents data as unsigned 64-bit integers

C Syntax #include "matrix.h"

bool mxIsUint64(const mxArray *pm);

Fortran integer*4 mxIsUint64(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Logical 1 (true) if the mxArray stores its data as unsigned 64-bit

integers, and logical O (false) otherwise.

Description Use mxIsUint64 to determine whether the specified mxArray represents

its real and imaginary data as 64-bit unsigned integers.

In C, calling mxIsUint64 is equivalent to calling:

mxGetClassID(pm) == mxUINT64 CLASS

In Fortran, calling mxIsUint64 is equivalent to calling:

mxGetClassName(pm) .eq. 'uint64'

See Also mxIsClass, mxGetClassID, mxIsInt8, mxIsInt16, mxIsInt32,

mxIsInt64, mxIsUint8, mxIsUint16, mxIsUint32

mxIsUint8 (C and Fortran)

Purpose Determine whether array represents data as unsigned 8-bit integers

C Syntax #include "matrix.h"

bool mxIsUint8(const mxArray *pm);

Fortran integer*4 mxIsUint8(pm)

Syntax mwPointer pm

Arguments pm

Pointer to an mxArray

Returns Logical 1 (true) if the mxArray stores its data as unsigned 8-bit integers,

and logical O (false) otherwise.

Description Use mxIsUint8 to determine whether the specified mxArray represents

its real and imaginary data as 8-bit unsigned integers.

In C, calling mxIsUint8 is equivalent to calling:

mxGetClassID(pm) == mxUINT8 CLASS

In Fortran, calling mxIsUint8 is equivalent to calling:

mxGetClassName(pm) .eq. 'uint8'

See Also mxIsClass, mxGetClassID, mxIsInt8, mxIsInt16, mxIsInt32,

Purpose Type for logical array

Description All logical mxArrays store their data elements as mxLogical rather

than as bool.

The header file containing this type is:

#include "matrix.h"

Examples See the following examples in *matlabroot*/extern/examples/mx.

• mxislogical.c

See Also mxCreateLogicalArray

mxMalloc (C and Fortran)

Purpose Allocate dynamic memory using MATLAB memory manager

C Syntax #include "matrix.h"

#include <stdlib.h>

void *mxMalloc(mwSize n);

Fortran mwPointer mxMalloc(n)

Syntax mwSize n

Arguments n

Number of bytes to allocate

Returns Pointer to the start of the allocated dynamic memory, if successful. If

unsuccessful in a MAT or engine standalone application, mxMalloc returns NULL in C (0 in Fortran). If unsuccessful in a MEX-file, the MEX-file terminates and control returns to the MATLAB prompt.

mxMalloc is unsuccessful when there is insufficient free heap space.

Description mxMalloc allocates contiguous heap space sufficient to hold n bytes. Use mxMalloc instead of the ANSI C malloc function to allocate memory

in MATLAB applications.

In MEX-files, but not MAT or engine applications, mxMalloc registers the allocated memory with the MATLAB memory manager. When control returns to the MATLAB prompt, the memory manager then automatically frees, or *deallocates*, this memory.

How you manage the memory created by this function depends on the purpose of the data assigned to it. If you assign it to an output argument in plhs[] using the mxSetPr function, MATLAB is responsible for freeing the memory.

If you use the data internally, the MATLAB memory manager maintains a list of all memory allocated by the function and automatically frees (deallocates) the memory when control returns to the MATLAB prompt. In general, we recommend that MEX-file functions destroy their own temporary arrays and free their own dynamically allocated memory. It

mxMalloc (C and Fortran)

is more efficient to perform this cleanup in the source MEX-file than to rely on the automatic mechanism. Therefore, when you finish using the memory allocated by this function, call mxFree to deallocate the memory.

If you do not assign this data to an output argument, and you want it to persist after the MEX-file completes, call mexMakeMemoryPersistent after calling this function. If you write a MEX-file with persistent memory, be sure to register a mexAtExit function to free allocated memory in the event your MEX-file is cleared.

Examples

See the following examples in matlabroot/extern/examples/mx.

- mxmalloc.c
- mxsetdimensions.c

See the following examples in matlabroot/extern/examples/refbook.

• arrayFillSetPr.c

mxCalloc, mxDestroyArray, mxFree, mxRealloc

mxRealloc (C and Fortran)

Purpose

Reallocate dynamic memory using MATLAB memory manager

C Syntax

#include "matrix.h"
#include <stdlib.h>

void *mxRealloc(void *ptr, mwSize size);

Fortran

mwPointer mxRealloc(ptr, size)

Syntax

mwPointer ptr mwSize size

Arguments

ptr

Pointer to a block of memory allocated by mxCalloc, mxMalloc, or mxRealloc.

size

New size of allocated memory, in bytes.

Returns

Pointer to the start of the reallocated block of memory, if successful. If unsuccessful in a MAT or engine standalone application, mxRealloc returns NULL in C (0 in Fortran) and leaves the original memory block unchanged. (You must use mxFree to free the original memory block). If unsuccessful in a MEX-file, the MEX-file terminates and control returns to the MATLAB prompt.

mxRealloc is unsuccessful when there is insufficient free heap space.

Description

mxRealloc changes the size of a memory block that has been allocated with mxCalloc, mxMalloc, or mxRealloc. Use mxRealloc instead of the ANSI C realloc function to allocate memory in MATLAB applications.

mxRealloc changes the size of the memory block pointed to by ptr to size bytes. The contents of the reallocated memory are unchanged up to the smaller of the new and old sizes. The reallocated memory might be in a different location from the original memory, so the returned pointer can be different from ptr. If the memory location changes, mxRealloc frees the original memory block pointed to by ptr.

mxRealloc (C and Fortran)

If size is greater than 0 and ptr is NULL in C (0 in Fortran), mxRealloc behaves like mxMalloc, allocating a new block of memory of size bytes and returning a pointer to the new block.

If size is 0 and ptr is not NULL in C (0 in Fortran), mxRealloc frees the memory pointed to by ptr and returns NULL in C (0 in Fortran).

In MEX-files, but not MAT or engine applications, mxRealloc registers the allocated memory with the MATLAB memory manager. When control returns to the MATLAB prompt, the memory manager then automatically frees, or *deallocates*, this memory.

How you manage the memory created by this function depends on the purpose of the data assigned to it. If you assign it to an output argument in plhs[] using the mxSetPr function, MATLAB is responsible for freeing the memory.

If you use the data internally, the MATLAB memory manager maintains a list of all memory allocated by the function and automatically frees (deallocates) the memory when control returns to the MATLAB prompt. In general, we recommend that MEX-file functions destroy their own temporary arrays and free their own dynamically allocated memory. It is more efficient to perform this cleanup in the source MEX-file than to rely on the automatic mechanism. Therefore, when you finish using the memory allocated by this function, call mxFree to deallocate the memory.

If you do not assign this data to an output argument, and you want it to persist after the MEX-file completes, call mexMakeMemoryPersistent after calling this function. If you write a MEX-file with persistent memory, be sure to register a mexAtExit function to free allocated memory in the event your MEX-file is cleared.

Examples

See the following examples in matlabroot/extern/examples/mx.

mxsetnzmax.c

mexAtExit, mexMakeArrayPersistent, mexMakeMemoryPersistent,
mxCalloc, mxDestroyArray, mxFree, mxMalloc

mxRemoveField (C and Fortran)

Purpose Remove field from structure array

C Syntax #include "matrix.h"

void mxRemoveField(mxArray *pm, int fieldnumber);

Fortran Syntax

subroutine mxRemoveField(pm, fieldnumber)

mwPointer pm

integer*4 fieldnumber

Arguments

pm

Pointer to a structure mxArray

fieldnumber

Number of the field you want to remove. In C, to remove the first field, set fieldnumber to 0; to remove the second field, set fieldnumber to 1; and so on. In Fortran, to remove the first field, set fieldnumber to 1; to remove the second field, set fieldnumber to 2; and so on.

Description

Call mxRemoveField to remove a field from a structure array. If the field does not exist, nothing happens. This function does not destroy the field values. Use mxDestroyArray to destroy the actual field values.

Consider a MATLAB structure initialized to:

```
patient.name = 'John Doe';
patient.billing = 127.00;
patient.test = [79 75 73; 180 178 177.5; 220 210 205];
```

In C, the field number 0 represents the field name; field number 1 represents field billing; field number 2 represents field test. In Fortran, the field number 1 represents the field name; field number 2 represents field billing; field number 3 represents field test.

See Also

mxAddField, mxDestroyArray, mxGetFieldByNumber

mxSetCell (C and Fortran)

Purpose Value of one cell of array

C Syntax #include "matrix.h"

void mxSetCell(mxArray *pm, mwIndex index, mxArray *value);

Fortran Syntax

subroutine mxSetCell(pm, index, value)

mwPointer pm, value

mwIndex index

Arguments

pm

Pointer to a cell mxArray

index

Index from the beginning of the mxArray. Specify the number of elements between the first cell of the mxArray and the cell you want to set. The easiest way to calculate index in a multidimensional cell array is to call mxCalcSingleSubscript.

value

Pointer to new value for the cell. You can put an mxArray of any type into a cell. You can even put another cell mxArray into a cell.

Description

Call mxSetCell to put the designated value into a particular cell of a cell mxArray.

Note Inputs to a MEX-file are constant read-only mxArrays. Do not modify the inputs. Using mxSetCell* or mxSetField* functions to modify the cells or fields of a MATLAB argument causes unpredictable results.

This function does not free any memory allocated for existing data that it displaces. To free existing memory, call mxDestroyArray on the pointer returned by mxGetCell before you call mxSetCell.

mxSetCell (C and Fortran)

Examples

See the following examples in matlabroot/extern/examples/refbook.

• phonebook.c

See the following examples in matlabroot/extern/examples/mx.

- mxcreatecellmatrix.c
- mxcreatecellmatrixf.F

See Also

mxCreateCellArray, mxCreateCellMatrix, mxGetCell, mxIsCell,
mxDestroyArray

Purpose Structure array to MATLAB object array

C Syntax #include "matrix.h"

int mxSetClassName(mxArray *array_ptr, const char *classname);

Arguments array_ptr

Pointer to an mxArray of class mxSTRUCT_CLASS

classname

Object class to which to convert array_ptr

Returns 0 if successful, and nonzero otherwise. One cause of failure is that

array ptr is not a structure mxArray. Call mxIsStruct to determine

whether array_ptr is a structure.

Description mxSetClassName converts a structure array to an object array, to be

saved subsequently to a MAT-file. The object is not registered or validated by MATLAB software until it is loaded via the LOAD command. If the specified classname is an undefined class within MATLAB, LOAD

converts the object back to a simple structure array.

See Also mxIsClass, mxGetClassID

mxSetData (C and Fortran)

Purpose Set pointer to data

C Syntax #include "matrix.h"

void mxSetData(mxArray *pm, void *pr);

Fortran subroutine mxSetData(pm, pr)
Syntax mwPointer pm, pr

Arguments pm

Pointer to an mxArray

pr

Pointer to an array. Each element in the array contains the real component of a value. The array must be in dynamic memory; call mxCalloc to allocate this memory. Do not use the ANSI C calloc function, which can cause memory alignment issues leading to

program termination.

Description mxSetData is like mxSetPr, except that in C, its second argument is a

void *. Use this function on numeric arrays with contents other than

double.

This function does not free any memory allocated for existing data that it displaces. To free existing memory, call mxFree on the pointer

returned by ${\tt mxGetData}$ before you call ${\tt mxSetData}$.

Examples See the following examples in matlabroot/extern/examples/refbook.

• arrayFillSetData.c

See Also mxCalloc, mxFree, mxGetData, mxSetPr

mxSetDimensions (C and Fortran)

Purpose

Modify number of dimensions and size of each dimension

C Syntax

```
#include "matrix.h"
```

int mxSetDimensions(mxArray *pm, const mwSize *dims,

mwSize ndim);

Fortran Syntax

integer*4 mxSetDimensions(pm, dims, ndim)

mwPointer pm

mwSize dims, ndim

Arguments

pm

Pointer to an mxArray

dims

Dimensions array. Each element in the dimensions array contains the size of the array in that dimension. For example, in C, setting dims[0] to 5 and dims[1] to 7 establishes a 5-by-7 mxArray. In Fortran, setting dims(1) to 5 and dims(2) to 7 establishes a 5-by-7 mxArray. In most cases, there are ndim elements in the dims array.

ndim

Number of dimensions

Returns

O on success, and 1 on failure. mxSetDimensions allocates heap space to hold the input size array. So it is possible (though unlikely) that increasing the number of dimensions can cause the system to run out of heap space.

Description

Call mxSetDimensions to reshape an existing mxArray.
mxSetDimensions is like mxSetM and mxSetN; however,
mxSetDimensions provides greater control for reshaping mxArrays that
have more than two dimensions.

mxSetDimensions does not allocate or deallocate any space for the pr or pi arrays. Consequently, if your call to mxSetDimensions increases the number of elements in the mxArray, enlarge the pr (and pi, if it exists) arrays accordingly.

mxSetDimensions (C and Fortran)

If your call to mxSetDimensions reduces the number of elements in the mxArray, you can optionally reduce the size of the pr and pi arrays using mxRealloc.

MATLAB automatically removes any trailing singleton dimensions specified in the dims argument. For example, if ndim equals 5 and dims equals [4 1 7 1 1], the resulting array has the dimensions 4-by-1-by-7.

Examples

See the following examples in ${\it matlabroot/extern/examples/mx}$.

- mxsetdimensions.c
- mxsetdimensionsf.F

See Also

mxGetNumberOfDimensions, mxSetM, mxSetN, mxRealloc

mxSetField (C and Fortran)

Purpose

Set structure array field, given structure field name and array index

C Syntax

#include "matrix.h"

void mxSetField(mxArray *pm, mwIndex index, const char *fieldname, mxArray *pvalue);

Fortran Syntax

subroutine mxSetField(pm, index, fieldname, pvalue)

mwPointer pm, pvalue

mwIndex index

character*(*) fieldname

Arguments

pm

Pointer to a structure mxArray. Call mxIsStruct to determine whether pm points to a structure mxArray.

index

Index of an element in the array.

In C, the first element of an mxArray has an index of 0. The index of the last element is N-1, where N is the number of elements in the array. In Fortran, the first element of an mxArray has an index of 1. The index of the last element is N, where N is the number of elements in the array.

See mxCalcSingleSubscript for details on calculating an index.

fieldname

Name of a field in the structure. The field must exist in the structure. Call mxGetFieldNameByNumber or mxGetFieldNumber to determine existing field names.

pvalue

Pointer to an mxArray containing the data you want to assign to fieldname.

Description

Use mxSetField to assign the contents of pvalue to the field fieldname of element index.

mxSetField (C and Fortran)

If you want to replace the contents of fieldname, you must first free the memory of the existing data. Use the mxGetField function to get a pointer to the field, call mxDestroyArray on the pointer, then call mxSetField to assign the new value.

You cannot assign pvalue to more than one field in a structure or to more than one element in the mxArray. If you want to assign the contents of pvalue to multiple fields, use the mxDuplicateArray function to make copies of the data then call mxSetField on each copy.

To free memory for structures created using this function, call mxDestroyArray only on the structure array. Do not call mxDestroyArray on the array pvalue points to. If you do, MATLAB attempts to free the same memory twice, which can corrupt memory.

Note Inputs to a MEX-file are constant read-only mxArrays. Do not modify the inputs. Using mxSetCell* or mxSetField* functions to modify the cells or fields of a MATLAB argument causes unpredictable results.

Alternatives

C Language

In C, you can replace the statements:

```
field_num = mxGetFieldNumber(pa, "fieldname");
mxSetFieldByNumber(pa, index, field_num, new_value_pa);
with a call to mxSetField:
mxSetField(pa, index, "fieldname", new value pa);
```

Fortran Language

In Fortran, you can replace the statements:

```
fieldnum = mxGetFieldNumber(pm, 'fieldname')
mxSetFieldByNumber(pm, index, fieldnum, newvalue)
```

mxSetField (C and Fortran)

with a call to mxSetField:

mxSetField(pm, index, 'fieldname', newvalue)

Examples

See the following examples in matlabroot/extern/examples/mx.

• mxcreatestructarray.c

See Also

mxCreateStructArray, mxCreateStructMatrix, mxGetField,
mxGetFieldNameByNumber, mxGetFieldNumber, mxGetNumberOfFields,
mxIsStruct, mxSetFieldByNumber, mxDestroyArray,
mxCalcSingleSubscript

mxSetFieldByNumber (C and Fortran)

Purpose

Set structure array field, given field number and index

C Syntax

#include "matrix.h"

 $\verb"void mxSetFieldByNumber(mxArray *pm, mwIndex index",$

int fieldnumber, mxArray *pvalue);

Fortran Syntax

 $subroutine \ mxSetFieldByNumber(pm, index, fieldnumber, pvalue)\\$

mwPointer pm, pvalue

mwIndex index

integer*4 fieldnumber

Arguments

pm

Pointer to a structure mxArray. Call mxIsStruct to determine whether pm points to a structure mxArray.

index

Index of the desired element.

In C, the first element of an mxArray has an index of 0. The index of the last element is N-1, where N is the number of elements in the array. In Fortran, the first element of an mxArray has an index of 1. The index of the last element is N, where N is the number of elements in the array.

See mxCalcSingleSubscript for details on calculating an index.

fieldnumber

Position of the field in the structure. The field must exist in the structure.

In C, the first field within each element has a fieldnumber of 0. The fieldnumber of the last is N-1, where N is the number of fields.

In Fortran, the first field within each element has a fieldnumber of 1. The fieldnumber of the last is N, where N is the number of fields.

mxSetFieldByNumber (C and Fortran)

pvalue

Pointer to the mxArray containing the data you want to assign.

Description

Use mxSetFieldByNumber to assign the contents of pvalue to the field specified by fieldnumber of element index. mxSetFieldByNumber is like mxSetField; however, the function identifies the field by position number, not by name.

If you want to replace the contents at fieldnumber, you must first free the memory of the existing data. Use the mxGetFieldByNumber function to get a pointer to the field, call mxDestroyArray on the pointer, then call mxSetFieldByNumber to assign the new value.

You cannot assign pvalue to more than one field in a structure or to more than one element in the mxArray. If you want to assign the contents of pvalue to multiple fields, use the mxDuplicateArray function to make copies of the data then call mxSetFieldByNumber on each copy.

To free memory for structures created using this function, call mxDestroyArray only on the structure array. Do not call mxDestroyArray on the array pvalue points to. If you do, MATLAB attempts to free the same memory twice, which can corrupt memory.

Note Inputs to a MEX-file are constant read-only mxArrays. Do not modify the inputs. Using mxSetCell* or mxSetField* functions to modify the cells or fields of a MATLAB argument causes unpredictable results.

Alternatives

C Language

In C, calling:

mxSetField(pa, index, "field name", new value pa);

is equivalent to calling:

mxSetFieldByNumber (C and Fortran)

```
field_num = mxGetFieldNumber(pa, "field_name");
mxSetFieldByNumber(pa, index, field_num, new_value_pa);
```

Fortran Language

```
In Fortran, calling:
mxSetField(pm, index, 'fieldname', newvalue)
is equivalent to calling:
fieldnum = mxGetFieldNumber(pm, 'fieldname')
mxSetFieldByNumber(pm, index, fieldnum, newvalue)
```

Examples

See the following examples in matlabroot/extern/examples/mx.

• mxcreatestructarray.c

See Also

mxCreateStructArray, mxCreateStructMatrix, mxGetFieldByNumber, mxGetFieldNameByNumber, mxGetFieldNumber, mxGetNumberOfFields, mxIsStruct, mxSetField, mxDestroyArray, mxCalcSingleSubscript

mxSetImagData (C and Fortran)

Purpose Imaginary data pointer for array

C Syntax #include "matrix.h"

void mxSetImagData(mxArray *pm, void *pi);

Fortran su Syntax mw

subroutine mxSetImagData(pm, pi)

mwPointer pm, pi

Arguments pm

Pointer to an mxArray

рi

Pointer to the first element of an array. Each element in the array contains the imaginary component of a value. The array must be in dynamic memory; call mxCalloc to allocate this memory. Do not use the ANSI C calloc function, which can cause memory alignment issues leading to program termination. If pi points to static memory, memory errors will result when the array is destroyed.

Description

mxSetImagData is like mxSetPi, except that in C, its pi argument is a void *. Use this function on numeric arrays with contents other than double.

This function does not free any memory allocated for existing data that it displaces. To free existing memory, call mxFree on the pointer returned by mxGetImagData before you call mxSetImagData.

Examples

See the following examples in matlabroot/extern/examples/mx.

• mxisfinite.c

See Also

mxCalloc, mxFree, mxGetImagData, mxSetPi

mxSetIr (C and Fortran)

```
Purpose
                  IR array of sparse array
C Syntax
                  #include "matrix.h"
                   void mxSetIr(mxArray *pm, mwIndex *ir);
Fortran
                   subroutine mxSetIr(pm, ir)
Syntax
                   mwPointer pm, ir
Arguments
                   mg
                        Pointer to a sparse mxArray
                   ir
                        Pointer to the ir array. The ir array must be sorted in
                        column-major order.
Description
                   Use mxSetIr to specify the ir array of a sparse mxArray. The ir array
                   is an array of integers; the length of the ir array equals the value of
                   nzmax.
```

Each element in the ir array indicates a row (offset by 1) at which a nonzero element can be found. (The jc array is an index that indirectly specifies a column where nonzero elements can be found. See mxSetJc for more details on jc.)

For example, suppose you create a 7-by-3 sparse mxArray named Sparrow containing six nonzero elements by typing:

```
Sparrow = zeros(7,3);
Sparrow(2,1) = 1;
Sparrow(5,1) = 1;
Sparrow(3,2) = 1;
Sparrow(2,3) = 2;
Sparrow(5,3) = 1;
Sparrow(6,3) = 1;
Sparrow = sparse(Sparrow);
```

The pr array holds the real data for the sparse matrix, which in Sparrow is the five 1s and the one 2. If there is any nonzero imaginary data, it is in a pi array.

Subscript	ir	pr	jc	Comments
(2,1)	1	1	0	Column 1; ir is 1 because row is 2.
(5,1)	4	1	2	Column 1; ir is 4 because row is 5.
(3,2)	2	1	3	Column 2; ir is 2 because row is 3.
(2,3)	1	2	6	Column 3; ir is 1 because row is 2.
(5,3)	4	1		Column 3; ir is 4 because row is 5.
(6,3)	5	1		Column 3; ir is 5 because row is 6.

Notice how each element of the ir array is always 1 less than the row of the corresponding nonzero element. For instance, the first nonzero element is in row 2; therefore, the first element in ir is 1 (that is, 2-1). The second nonzero element is in row 5; therefore, the second element in ir is 4(5-1).

The ir array must be in column-major order. That means that the ir array must define the row positions in column 1 (if any) first, then the row positions in column 2 (if any) second, and so on, through column N. Within each column, row position 1 must appear before row position 2, and so on.

mxSetIr does not sort the ir array for you; you must specify an ir array that is already sorted.

This function does not free any memory allocated for existing data that it displaces. To free existing memory, call mxFree on the pointer returned by mxGetIr before you call mxSetIr.

Examples

See the following examples in matlabroot/extern/examples/mx.

• mxsetnzmax.c

See the following examples in matlabroot/extern/examples/mex.

mxSetIr (C and Fortran)

• explore.c

See Also

mxCreateSparse, mxGetIr, mxGetJc, mxSetJc, mxFree

Purpose JC array of sparse array

C Syntax #include "matrix.h"

void mxSetJc(mxArray *pm, mwIndex *jc);

Fortran Syntax

subroutine mxSetJc(pm, jc)
mwPointer pm, jc

Arguments

pm
Pointer to a sparse mxArray

įС

Pointer to the jc array

Description

Use mxSetJc to specify a new jc array for a sparse mxArray. The jc array is an integer array having n+1 elements, where n is the number of columns in the sparse mxArray.

If the jth column of the sparse mxArray has any nonzero elements:

- jc[j] is the index in ir, pr, and pi (if it exists) of the first nonzero element in the jth column.
- jc[j+1]-1 is the index of the last nonzero element in the jth column.
- For the jth column of the sparse matrix, jc[j] is the total number of nonzero elements in all preceding columns.

The number of nonzero elements in the jth column of the sparse mxArray is:

```
jc[j+1] - jc[j];
```

For the jth column of the sparse mxArray, jc[j] is the total number of nonzero elements in all preceding columns. The last element of the jc array, jc[number of columns], is equal to nnz, which is the number of nonzero elements in the entire sparse mxArray.

mxSetJc (C and Fortran)

For example, consider a 7-by-3 sparse mxArray named Sparrow containing six nonzero elements, created by typing:

```
Sparrow = zeros(7,3);
Sparrow(2,1) = 1;
Sparrow(5,1) = 1;
Sparrow(3,2) = 1;
Sparrow(2,3) = 2;
Sparrow(5,3) = 1;
Sparrow(6,3) = 1;
Sparrow = sparse(Sparrow);
```

The following table lists the contents of the ir, jc, and pr arrays.

Subscript	ir	pr	jc	Comment
(2,1)	1	1	0	Column 1 contains two nonzero elements, with rows designated by ir[0] and ir[1]
(5,1)	4	1	2	Column 2 contains one nonzero element, with row designated by ir[2]
(3,2)	2	1	3	Column 3 contains three nonzero elements, with rows designated by ir[3],ir[4], and ir[5]
(2,3)	1	2	6	There are six nonzero elements in all.
(5,3)	4	1		
(6,3)	5	1		

As an example of a much sparser mxArray, consider a 1000-by-8 sparse mxArray named Spacious containing only three nonzero elements. The ir, pr, and jc arrays contain the values listed in this table.

mxSetJc (C and Fortran)

Subscript	ir	pr	jc	Comment
(73,2)	72	1	0	Column 1 contains no nonzero elements.
(50,3)	49	1	0	Column 2 contains one nonzero element, with row designated by ir[0].
(64,5)	63	1	1	Column 3 contains one nonzero element, with row designated by ir[1].
			2	Column 4 contains no nonzero elements.
			2	Column 5 contains one nonzero element, with row designated by ir[2].
			3	Column 6 contains no nonzero elements.
			3	Column 7 contains no nonzero elements.
			3	Column 8 contains no nonzero elements.
			3	There are three nonzero elements in all.

This function does not free any memory allocated for existing data that it displaces. To free existing memory, call mxFree on the pointer returned by mxGetJc before you call mxSetJc.

Examples

See the following examples in matlabroot/extern/examples/mx.

• mxsetdimensions.c

mxSetJc (C and Fortran)

• explore.c

See Also

mxCreateSparse, mxGetIr, mxGetJc, mxSetIr, mxFree

mxSetM (C and Fortran)

Purpose Number of rows in array

C Syntax #include "matrix.h"

void mxSetM(mxArray *pm, mwSize m);

Fortran subroutine mxSetM(pm, m) **Syntax**

mwPointer pm mwSize m

Arguments pm

Pointer to an mxArray

m

Number of rows

Description

Call mxSetM to set the number of rows in the specified mxArray. The term rows means the first dimension of an mxArray, regardless of the number of dimensions. Call mxSetN to set the number of columns.

You typically use mxSetM to change the shape of an existing mxArray. The mxSetM function does not allocate or deallocate any space for the pr, pi, ir, or jc arrays. Consequently, if your calls to mxSetM and mxSetN increase the number of elements in the mxArray, enlarge the pr, pi, ir, and/or jc arrays. Call mxRealloc to enlarge them.

If your calls to mxSetM and mxSetN end up reducing the number of elements in the mxArray, you might want to reduce the sizes of the pr, pi, ir, and/or jc arrays in order to use heap space more efficiently. However, reducing the size is not mandatory.

Examples

See the following examples in matlabroot/extern/examples/mx.

mxGetM, mxGetN, mxSetN

mxSetN (C and Fortran)

Purpose Set number of columns in array

C Syntax #include "matrix.h"

void mxSetN(mxArray *pm, mwSize n);

Fortran Syntax subroutine mxSetN(pm, n)

mwPointer pm mwSize n

Arguments

pm
Pointer to an mxArray

n

Number of columns

Description

Call mxSetN to set the number of columns in the specified mxArray. The term *columns* always means the second dimension of a matrix. Calling mxSetN forces an mxArray to have two dimensions. For example, if pm points to an mxArray having three dimensions, calling mxSetN reduces the mxArray to two dimensions.

You typically use mxSetN to change the shape of an existing mxArray. The mxSetN function does not allocate or deallocate any space for the pr, pi, ir, or jc arrays. Consequently, if your calls to mxSetN and mxSetM increase the number of elements in the mxArray, enlarge the pr, pi, ir, and/or jc arrays.

If your calls to mxSetM and mxSetN end up reducing the number of elements in the mxArray, you might want to reduce the sizes of the pr, pi, ir, and/or jc arrays in order to use heap space more efficiently. However, reducing the size is not mandatory.

Examples

See the following examples in matlabroot/extern/examples/mx.

mxGetM, mxGetN, mxSetM

mxSetNzmax (C and Fortran)

Purpose Set storage space for nonzero elements

C Syntax #include "matrix.h"

void mxSetNzmax(mxArray *pm, mwSize nzmax);

Fortran Syntax

subroutine mxSetNzmax(pm, nzmax)

mwPointer pm
mwSize nzmax

Arguments

pm

Pointer to a sparse mxArray.

nzmax

Number of elements mxCreateSparse should allocate to hold the arrays pointed to by ir, pr, and pi (if it exists). Set nzmax greater than or equal to the number of nonzero elements in the mxArray, but set it to be less than or equal to the number of rows times the number of columns. If you specify an nzmax value of 0, mxSetNzmax sets the value of nzmax to 1.

Description

Use mxSetNzmax to assign a new value to the nzmax field of the specified sparse mxArray. The nzmax field holds the maximum number of nonzero elements in the sparse mxArray.

The number of elements in the ir, pr, and pi (if it exists) arrays must be equal to nzmax. Therefore, after calling mxSetNzmax, you must change the size of the ir, pr, and pi arrays. To change the size of one of these arrays:

- 1 Call mxRealloc with a pointer to the array, setting the size to the new value of nzmax
- **2** Call the appropriate mxSet routine (mxSetIr, mxSetPr, or mxSetPi) to establish the new memory area as the current one.

Ways to determine how large to make nzmax are:

mxSetNzmax (C and Fortran)

- Set nzmax equal to or slightly greater than the number of nonzero elements in a sparse mxArray. This approach conserves precious heap space.
- Make nzmax equal to the total number of elements in an mxArray. This approach eliminates (or, at least reduces) expensive reallocations.

Examples

See the following examples in matlabroot/extern/examples/mx.

• mxsetnzmax.c

See Also

mxGetNzmax, mxRealloc

mxSetPi (C and Fortran)

Purpose Set new imaginary data for array

C Syntax #include "matrix.h"

void mxSetPi(mxArray *pm, double *pi);

Fortran Syntax

subroutine mxSetPi(pm, pi)

mwPointer pm, pi

Arguments

pm
Pointer to a full (nonsparse) mxArray

рi

Pointer to the first element of an array. Each element in the array contains the imaginary component of a value. The array must be in dynamic memory; call mxCalloc to allocate this memory. Do not use the ANSI C calloc function, which can cause memory alignment issues leading to program termination. If pi points to static memory, memory leaks and other memory errors might result.

Description

Use mxSetPi to set the imaginary data of the specified mxArray.

Most mxCreate* functions optionally allocate heap space to hold imaginary data. If you tell an mxCreate* function to allocate heap space—for example, by setting the ComplexFlag to mxCOMPLEX in C (1 in Fortran) or by setting pi to a non-NULL value in C (a nonzero value in Fortran)—you do not ordinarily use mxSetPi to initialize the created mxArray's imaginary elements. Rather, you call mxSetPi to replace the initial imaginary values with new ones.

This function does not free any memory allocated for existing data that it displaces. To free existing memory, call mxFree on the pointer returned by mxGetPi before you call mxSetPi.

Examples

See the following examples in matlabroot/extern/examples/mx.

• mxisfinite.c

mxSetPi (C and Fortran)

• mxsetnzmax.c

mxGetPi, mxGetPr, mxSetImagData, mxSetPr, mxFree

Purpose Set new real data for array

C Syntax #include "matrix.h"

void mxSetPr(mxArray *pm, double *pr);

Fortran Syntax

subroutine mxSetPr(pm, pr)

mwPointer pm, pr

Arguments

pm

Pointer to a full (nonsparse) mxArray

pr

Pointer to the first element of an array. Each element in the array contains the real component of a value. The array must be in dynamic memory; call mxCalloc to allocate this memory. Do not use the ANSI C calloc function, which can cause memory alignment issues leading to program termination. If pr points to static memory, memory leaks and other memory errors can result.

Description

Use mxSetPr to set the real data of the specified mxArray.

All mxCreate* calls allocate heap space to hold real data. Therefore, you do not ordinarily use mxSetPr to initialize the real elements of a freshly created mxArray. Rather, you call mxSetPr to replace the initial real values with new ones.

This function does not free any memory allocated for existing data that it displaces. To free existing memory, call mxFree on the pointer returned by mxGetPr before you call mxSetPr.

Examples

See the following examples in ${\it matlabroot/extern/examples/refbook}$.

• arrayFillSetPr.c

mxsetnzmax.c

mxSetPr (C and Fortran)

See Also

mxGetPi, mxGetPr, mxSetData, mxSetPi, mxFree

mxSetProperty (C and Fortran)

Purpose

Set value of public property of MATLAB object

C Syntax

#include "matrix.h"

void mxSetProperty(mxArray *pa, mwIndex index, const char *propname, const mxArray *value);

Fortran Syntax

subroutine mxSetProperty(pa, index, propname, value)

mwPointer pa, value

mwIndex index

character*(*) propname

Arguments

pa

Pointer to an mxArray which is an object.

index

Index of the desired element of the object array.

In C, the first element of an mxArray has an index of 0. The index of the last element is N-1, where N is the number of elements in the array. In Fortran, the first element of an mxArray has an index of 1. The index of the last element is N, where N is the number of elements in the array.

propname

Name of the property whose value you are assigning.

value

Pointer to the mxArray you are assigning.

Description

Use mxSetProperty to assign a value to the specified property. In pseudo-C terminology, mxSetProperty performs the assignment:

```
pa[index].propname = value;
```

mxSetProperty makes a copy of the value before assigning it as the new property value. This might be a concern if the property uses a large amount of memory.
